One or more image versions within the plan **Windows Server 2016 Datacenter** from the publisher, **Microsoft**, have been scheduled for deprecation. As of March 28, 2022, you have workloads that are running on these images These workloads will continue to run and will not be impacted. However, additional instances cannot be deployed after the deprecation date, as explained below.

Impact

- Following the scheduled deprecation date, you won't be able to deploy any additional virtual machine (VM) or virtual machine scale set (VMSS) instances using any images within these respective plans.
- Your active VM instances **won't be affected** following the deprecation date.
- Your existing VMSS deployments will continue to be operational but can't be scaled out following deprecation.

Image versions scheduled for deprecation

Publisher	Offer	Version	Deprecation date (UTC)	Recommended alternative
Microsoft	WindowsServer	1.0.0	October 27, 2021	WithinCurrentOffer
Microsoft	WindowsServer	1.0.0	October 27, 2021	WithinCurrentOffer
Microsoft	WindowsServer	1.0.0	October 27, 2021	WithinCurrentOffer

Deprecation levels

Deprecation occurs at three levels:

- **Image version deprecation**: A specific VM image version.
- **Plan/SKU deprecation**: An entire plan or SKU and all image versions within it.
- **Offer deprecation**: The entire VM offer, including all plans and image versions.

What is the deprecation timeline and how does it affect my workloads?

Notice period (90 days before enforcement)

The publisher sets an enforcement date when deprecating an image. You typically have at least 90 days between the deprecation announcement and the enforcement date. The exact enforcement date is included in your email notification and Azure Advisor recommendation.

During the notice period:

- You receive email notifications and Azure Advisor recommendations about the upcoming deprecation.
- Existing VMs and virtual machine scale set instances continue to run normally.
- You can deploy new instances by using Azure CLI, PowerShell, or APIs.
- Deprecation warnings appear in the Azure portal, Azure CLI, and APIs.
- You can migrate or update your deployments until the enforcement date.

After enforcement date (soft delete)

After the enforcement date, the image enters a "soft delete" state. The image is no longer available for new deployments, but existing resources aren't deleted or modified.

Images without a purchase plan (for example, Windows Server, Canonical Ubuntu, Red Hat, SUSE):

- Existing VMs and virtual machine scale set instances continue to run without disruption.
- Start, stop, restart, deallocate, and redeploy continue to work.
- VM backup and restore operations continue to work, including restoring a backup to create a new VM.
- Azure Site Recovery and disaster recovery operations continue to work.
- New VM creation from the deprecated image is blocked.
- Reimage is blocked because it requires recreating the OS disk from the source image.
- Virtual machine scale set scale-out is blocked if new instances must be created from the deprecated version. Scale-out with automatic OS upgrade or "latest" version continues to work.

Images with a purchase plan (third-party Marketplace images such as CIS, F5, Cisco):

- Existing VMs and virtual machine scale set instances continue to run without disruption.
- Start, stop, restart, deallocate, and redeploy continue to work.
- New VM creation from the deprecated image is blocked.
- Backup restore operations that require Marketplace purchase validation might fail.
- Reimage is blocked because purchase plan eligibility checks fail after deprecation.
- Virtual machine scale set scale-out is blocked because it requires creating new instances from the deprecated image.

For more details, see Which operations are affected by image deprecation?.

Required actions

The actions you need to take depend on whether your image requires a purchase plan. For help determining this, see How do I check if my image has a purchase plan?. For detailed migration guidance, see When should I migrate?.

Images without a purchase plan:

- If you use automatic OS upgrades, no action is needed. Automatic OS upgrade handles migration across publisher, offer, SKU, and version changes automatically.
- If you need your virtual machine scale set to scale out after deprecation, migrate to a supported image before the enforcement date.
- To avoid future dependency on Marketplace image availability, consider capturing your workload as a custom image in Azure Compute Gallery. Custom images aren't subject to Marketplace deprecation.

Images with a purchase plan:

- Automatic OS upgrade handles only individual version deprecation. For plan, SKU, or offer deprecation, you must migrate manually.
- Migrate your virtual machine scale set to a supported image before the enforcement date to avoid disruption to scale-out, reimage, and backup restore operations.

Which operations are affected by image deprecation?

The impact of deprecation depends on whether the image requires a Marketplace purchase plan.

Operations that continue to work after deprecation (no migration required)

These behaviors apply to images that don't require a purchase plan (for example, Windows Server, Canonical Ubuntu, Red Hat, SUSE):

Expand table

Operation	Status after enforcement	Explanation
Running VMs	Continue operating normally	After creation, VMs boot from their OS disk—not from the Marketplace image—and no purchase plan validation is required.
Start / Stop / Restart / Redeploy	Continue working	These operations don't require the source image.
VM backup and restore	Continue working	Restoring a backup, including restoring to create a new VM, continues to work.
Azure Site Recovery and disaster recovery	Continue working	Recovery operations continue to work for Microsoft-endorsed images.
VMSS existing instances	Continue running	Existing instances aren't affected by deprecation.
VMSS scale-out	Blocked only if new instances must be created from the deprecated version	Scale-out with automatic OS upgrade or "latest" version continues to work.

Operations that are blocked after deprecation

Expand table

Operation	Applies to	Status after enforcement	Explanation
Creating new VMs	All images	Blocked	New VM creation from the deprecated image is blocked regardless of purchase plan status.
Reimage	All images	Blocked	Reimage fails because it requires recreating the OS disk from the deprecated source image.

Operation	Applies to	Status after enforcement	Explanation
Restoring backups	Images with a purchase plan	Might fail	Backup restore operations that require Marketplace purchase validation might fail. Restore continues to work for images without a purchase plan.
VMSS scale-out	Images with a purchase plan	Blocked	Scale-out is blocked for images with a purchase plan. For images without a purchase plan, scale-out with automatic OS upgrade or "latest" version continues to work.

> **Note**
>
> The VM's image reference property might disappear from the Azure portal, but this doesn't affect VM operation. The OS disk is authoritative for boot.

How do I check if my image has a purchase plan?

The deprecation impact depends on whether your image requires a Marketplace purchase plan. Use one of the following methods to check.

Option 1: Use Azure CLI

Check the Marketplace image directly:

Azure CLI

```
az vm image show --location eastus --urn <publisher>:<offer>:<sku>:<version> --query plan
```

Or check an existing VM:

Azure CLI

```
az vm show --resource-group <resource-group> --name <vm-name> --query plan
```

Option 2: Use PowerShell

Check from an existing VM:

```PowerShell
(Get-AzVM -ResourceGroupName <resource-group> -Name <vm-name>).Plan
```

Check from a Marketplace image:

```PowerShell
Get-AzVMImage -Location "eastus" -PublisherName <publisher> -Offer <offer> -Skus
<sku> -Version <version> | Select-Object -ExpandProperty PurchasePlan
```

Interpreting the results

- If the command returns `null` or empty output, the image doesn't have a purchase plan. Deprecation has minimal impact on your workloads.
- If the command returns `name`, `publisher`, and `product` values, the image has a purchase plan. You should migrate to a supported image before the enforcement date.

For more information, see Supply Azure Marketplace purchase plan information when creating images.

Can I restore a VM from backup after my image is deprecated?

Yes—if your image doesn't require a purchase plan.

- For Microsoft first-party and endorsed Linux images (for example, Windows Server, Canonical Ubuntu, Red Hat, SUSE), restoring a backup—even to create a new VM—is supported after deprecation. This is expected behavior.
- For third-party images that require a purchase plan, restore behavior might be blocked after deprecation because of Marketplace enforcement checks.

If you're using an image that requires a purchase plan, migrate to a supported image before the enforcement date. For more information, see purchase plan information.

When should I migrate my VMs or virtual machine scale sets to a different image?

Migration isn't always required. Review the following scenarios to determine whether you need to take action.

Migration is not required if:

- Your image doesn't require a purchase plan, even if it's deprecated.
- You're using automatic OS image upgrades for VMSS and only the image version is deprecated.
- You aren't performing reimage or scale-out operations that require the original Marketplace image.

Migration is required if:

- Your image requires a purchase plan.
- You need to scale out, reimage, or create new workloads after the enforcement date.
- The entire offer or SKU is deprecated, your image requires a purchase plan, and automatic OS image upgrade can't handle the migration.

Recommended actions

Images without a purchase plan:

- Don't panic when you receive a deprecation notice. Deprecation doesn't imply immediate disruption for first-party images.
- Existing workloads, backup restore, and disaster recovery scenarios continue to work after deprecation. No migration is required for these operations.
- To avoid future dependency on Marketplace image availability, consider capturing your workload as a custom image in Azure Compute Gallery. Custom images aren't subject to Marketplace deprecation.

Images with a purchase plan:

- Coordinate migration with the publisher before the enforcement date. Backup restore, reimage, and scale-out operations might fail after deprecation.
- Custom images that include purchase plan information are still subject to Marketplace enforcement checks. Migrate to a newer, non-deprecated image to avoid disruption.

All images:

- Review which VMs and virtual machine scale sets use the deprecated image. See How do I find VMs using deprecated images? and How do I find virtual machine scale sets using deprecated images?.

How do I find VMs using deprecated images?

Option 1: Use automated script (recommended)

Run Get-AzVMImageDeprecationStatus.ps1 to list all VMs in a subscription that were created from deprecated or soon-to-be-deprecated images.

Option 2: Use Azure Resource Graph

Run the following query in Azure Resource Graph to list all VMs and their image details:

Kusto

```
resources
| where type == "microsoft.compute/virtualmachines"
//| where properties.storageProfile.imageReference.publisher =~
'MicrosoftWindowsServer' //Optional: Filter by publisher
//| where properties.storageProfile.imageReference.sku =~ '2016-Datacenter'
//Optional: Filter by SKU (Plan)
//| where properties.storageProfile.imageReference.version == '14393.4467.2106061537'
//Optional: Filter by version
| project name, subscriptionId, resourceGroup,
ImagePublisher=properties.storageProfile.imageReference.publisher,
ImageOffer=properties.storageProfile.imageReference.offer,
imageSku=properties.storageProfile.imageReference.sku,
imageVersion=properties.storageProfile.imageReference.exactVersion
```

Option 3: Use Azure CLI

To list all VMs using a specific SKU (replace `2016-Datacenter` with your deprecated SKU):

Azure CLI

```
az vm list --query "[?storageProfile.imageReference.sku=='2016-Datacenter'].{VM:id,
imageOffer:storageProfile.imageReference.offer,
imagePublisher:StorageProfile.imageReference.publisher, imageSku:
storageProfile.imageReference.sku,
imageVersion:storageProfile.imageReference.version}"
```

To list all VMs using a specific image version (replace with your deprecated version):

Azure CLI

```
az vm list --query "[?storageProfile.imageReference.version=='14393.4402.2105052108'].
{VM:id, imageOffer:storageProfile.imageReference.offer,
imagePublisher:StorageProfile.imageReference.publisher, imageSku:
storageProfile.imageReference.sku,
imageVersion:storageProfile.imageReference.version}"
```

Option 4: Use PowerShell

To list all VMs using a specific SKU (replace `2016-Datacenter` with your deprecated SKU):

PowerShell

```
Get-AzVM | Where-Object {$_.StorageProfile.ImageReference.Sku -eq '2016-Datacenter'}
| Select-Object -Property ResourceGroupName, Name, @{label='imageOffer'; expression=
{$_.StorageProfile.ImageReference.Offer}}, @{label='imagePublisher'; expression=
{$_.StorageProfile.ImageReference.Publisher}}, @{label='imageSKU'; expression=
{$_.StorageProfile.ImageReference.Sku}}, @{label='imageVersion'; expression=
{$_.StorageProfile.ImageReference.ExactVersion}}
```

To list all VMs using a specific image version (replace with your deprecated version):

PowerShell

```
Get-AzVM | Where-Object {$_.StorageProfile.ImageReference.ExactVersion -eq
'14393.4402.2105052108'} | Select-Object -Property ResourceGroupName, Name,
@{label='imageOffer'; expression={$_.StorageProfile.ImageReference.Offer}},
@{label='imagePublisher'; expression={$_.StorageProfile.ImageReference.Publisher}},
@{label='imageSKU'; expression={$_.StorageProfile.ImageReference.Sku}},
@{label='imageVersion'; expression={$_.StorageProfile.ImageReference.ExactVersion}}
```

How do I find virtual machine scale sets using deprecated images?

Option 1: Use automated script (recommended)

Run Get-AzVMImageDeprecationStatus.ps1 to list all virtual machine scale sets in a subscription that were created from deprecated or soon-to-be-deprecated images.

Option 2: Use Azure Resource Graph

Run the following query in Azure Resource Graph to list all virtual machine scale sets and their image details:

Kusto

```
resources
| where type == "microsoft.compute/virtualmachinescalesets"
//| where properties.virtualMachineProfile.storageProfile.imageReference.publisher =~
'MicrosoftWindowsServer' //Optional: Filter by publisher
//| where properties.virtualMachineProfile.storageProfile.imageReference.sku =~ '2016-
Datacenter' //Optional: Filter by SKU (Plan)
//| where properties.virtualMachineProfile.storageProfile.imageReference.version ==
'14393.4467.2106061537' //Optional: Filter by version
//| where properties.virtualMachineProfile.storageProfile.imageReference.version !=
"latest" //Optional: Exclude scale sets using "latest"
| project name, subscriptionId, resourceGroup,
ImagePublisher=properties.virtualMachineProfile.storageProfile.imageReference.publishe
r, ImageOffer=properties.virtualMachineProfile.storageProfile.imageReference.offer,
imageSku=properties.virtualMachineProfile.storageProfile.imageReference.sku,
imageVersion=properties.virtualMachineProfile.storageProfile.imageReference.version
```

Option 3: Use Azure CLI

To list all virtual machine scale sets using a specific SKU (replace `2016-Datacenter` with your deprecated SKU):

Azure CLI

```
az vmss list --query "[?
virtualMachineProfile.storageProfile.imageReference.sku=='2016-Datacenter'].{VMSS:id,
imageOffer:virtualMachineProfile.storageProfile.imageReference.offer,
imagePublisher:virtualMachineProfile.storageProfile.imageReference.publisher,
imageSku:virtualMachineProfile.storageProfile.imageReference.sku,
imageVersion:virtualMachineProfile.storageProfile.imageReference.version}"
```

To list all virtual machine scale sets using a specific image version (replace with your deprecated version):

Azure CLI

```
az vmss list --query "[?
virtualMachineProfile.storageProfile.imageReference.version=='14393.4402.2105052108'].
{VMSS:id, imageOffer:virtualMachineProfile.storageProfile.imageReference.offer,
imagePublisher:virtualMachineProfile.storageProfile.imageReference.publisher,
imageSku:virtualMachineProfile.storageProfile.imageReference.sku,
imageVersion:virtualMachineProfile.storageProfile.imageReference.version}"
```

Option 4: Use PowerShell

To find virtual machine scale sets using a specific SKU (replace `2016-Datacenter` with your deprecated SKU):

PowerShell

```
$vmsslist = Get-AzVmss
$vmsslist | Where-Object {$_.virtualMachineProfile.storageProfile.imageReference.Sku -
eq '2016-Datacenter'} | Select-Object -Property ResourceGroupName, Name,
@{label='imageOffer'; expression=
{$_.virtualMachineProfile.storageProfile.imageReference.Offer}},
@{label='imagePublisher'; expression=
{$_.virtualMachineProfile.storageProfile.imageReference.Publisher}},
@{label='imageSKU'; expression=
{$_.virtualMachineProfile.storageProfile.imageReference.Sku}}, @{label='imageVersion';
expression={$_.virtualMachineProfile.storageProfile.imageReference.Version}}
```

To find virtual machine scale sets using a specific image version (replace with your deprecated version):

PowerShell

```
$vmsslist = Get-AzVmss
$vmsslist | Where-Object
{$_.virtualMachineProfile.storageProfile.imageReference.Version -eq
'14393.4402.2105052108'} | Select-Object -Property ResourceGroupName, Name,
@{label='imageOffer'; expression=
{$_.virtualMachineProfile.storageProfile.imageReference.Offer}},
@{label='imagePublisher'; expression=
{$_.virtualMachineProfile.storageProfile.imageReference.Publisher}},
@{label='imageSKU'; expression=
{$_.virtualMachineProfile.storageProfile.imageReference.Sku}}, @{label='imageVersion';
expression={$_.virtualMachineProfile.storageProfile.imageReference.Version}}
```

How do I migrate a VM to a different image?

Azure VMs don't support in-place OS upgrades. Create a new VM with a supported image, migrate your data, and decommission the old VM.

> **Important**
>
> For deprecated images that require a Marketplace purchase plan, you can't create new VMs or perform backup restore operations after the enforcement date. Migrate before the enforcement date.

Part 1: Create a new VM

1. **Identify the replacement image**: Check your deprecation email for the recommended replacement. For more information, see Find and use images using the Azure CLI or Find

and use images using Azure PowerShell.

2. **Configure the new VM**: Match the region and networking settings of your existing VM for the simplest migration. You can change VM size or region if needed.

3. **Deploy and test**: Confirm the VM starts correctly and your application dependencies are present.

Part 2: Migrate data

Method A: Detach and attach data disks (recommended)

If your workload data is stored on data disks (not the OS disk):

1. Stop and deallocate the old VM.
2. Detach the data disks from the old VM. For more information, see Detach a data disk from a Linux VM or Detach a data disk from a Windows VM.
3. Attach the data disks to the new VM. For more information, see Attach a data disk to a Linux VM or Attach a data disk to a Windows VM.
4. Start the new VM and verify data accessibility.

> ⓘ **Note**
>
> Data on the OS disk isn't preserved with this method. Only data on attached data disks is migrated.

Method B: Use snapshots (for OS disk data or backup requirements)

If you need to preserve OS disk data or create a backup before migration:

1. Create a snapshot of the data disks.
2. Create managed disks from the snapshots.
3. Attach the disks to the new VM. For more information, see Attach a data disk to a Linux VM or Attach a data disk to a Windows VM.

Method C: Use file-based transfer

Use OS transfer tools for selective data migration:

- **Windows**: Robocopy or SMB share
- **Linux**: rsync, scp, or sftp

- **Cross-OS**: AzCopy with Azure Storage as an intermediate location

Part 3: Switch over

1. **Validate**: Verify network connectivity, application functionality, firewall rules, and extensions.
2. **Update references**: Point DNS names, load balancers, or API endpoints to the new VM.
3. **Decommission**: Keep the old VM briefly for rollback, then deallocate and delete it.

How do I migrate a virtual machine scale set to a different image?

The migration approach depends on whether an image version, plan/SKU, or entire offer is deprecated.

> **Note**
>
> If your image doesn't have a purchase plan and you have automatic OS image upgrade enabled, automatic OS upgrade handles migration automatically for all deprecation levels (version, plan/SKU, and offer), including changes to publisher, offer, SKU, and version. The manual steps in each section below apply only to images with a purchase plan or scale sets without automatic OS upgrade enabled.

Version deprecation

If only a specific image version is deprecated:

- **Using "latest" version**: No action required for new instances. Azure resolves to the newest available version at deployment time. Existing instances remain on their original version.
- **Using automatic OS upgrades**: No action required. Azure upgrades existing instances to the latest version automatically, regardless of whether your image reference uses "latest" or a pinned version. This applies to all images, including those with a purchase plan.
- **Using a pinned version without automatic OS upgrades**: Update the image reference to a supported version. See Modify an Azure virtual machine scale set. After updating the model, upgrade existing instances using one of these methods:
  - **Manual upgrade**: Use `az vmss update-instances` (CLI) or `Update-AzVmssInstance` (PowerShell) to upgrade specific instances.
  - **Rolling upgrade policy**: Configure the upgrade policy to "Rolling" so instances automatically upgrade when the model changes.

> **Tip**
>
> Enable automatic OS image upgrade to avoid manual intervention for future deprecations.

Plan/SKU deprecation

If an entire plan or SKU is deprecated:

- **Images without a purchase plan and automatic OS upgrade enabled**: No action required. Automatic OS upgrade migrates your scale set to the replacement SKU automatically.
- **Images with a purchase plan, or automatic OS upgrade not enabled**: Update to a different SKU from the same offer using a scale-out/scale-in approach:

1. Find an alternative SKU from your deprecation email. For more information, see Find and use images using the Azure CLI or Find and use images using Azure PowerShell.

2. Update the VMSS model to use the new SKU:

   Azure CLI

   ```
   az vmss update --resource-group <resource-group> --name <vmss-name> \
     --set virtualMachineProfile.storageProfile.imageReference.sku=<new-sku> \
     --set virtualMachineProfile.storageProfile.imageReference.version=latest
   ```

3. Scale out to create new instances using the updated image, then scale in to remove old instances. Or delete specific old instances and let the scale set replace them with new ones.

> **Important**
>
> Upgrading or reimaging existing instances replaces their OS disks. Use scale-out/scale-in to avoid data loss on OS disks.

Offer deprecation

If an entire offer is deprecated:

- **Images without a purchase plan and automatic OS upgrade enabled**: No action required. Automatic OS upgrade migrates your scale set to the replacement offer automatically, even if the publisher, offer, or SKU changes.

- **Images with a purchase plan, or automatic OS upgrade not enabled**: Create a new virtual machine scale set with a supported image:

1. Find a replacement offer from your deprecation email or search in the Azure Marketplace.
2. Create a new virtual machine scale set using the replacement image. Match your existing configuration (networking, extensions, scaling rules).
3. Test application compatibility thoroughly. A different publisher or offer may have significant OS or configuration differences.
4. Migrate traffic to the new scale set, then delete the old one.

> **Note**
>
> We recommend that you create a new VMSS instead of doing in-place updates when you change publishers or offers, because the differences between images are typically significant.

How do I receive email notifications about image deprecation?

Azure notifies you about image deprecation through two channels:

- **Email notifications**: Sent directly to subscription administrators with the **Owner** or **Account Admin** role on the subscription.
- **Azure Advisor recommendations**: Deprecation recommendations appear in Azure Advisor.

Notify additional recipients

To notify team members who don't have Owner or Account Admin roles on the subscription, create an Advisor alert with an action group. Use action groups to specify email addresses, SMS numbers, or webhooks that receive notifications when new deprecation recommendations are published.

How do I check if a specific image is deprecated or scheduled for deprecation?

Option 1: Use Azure CLI

Azure CLI

```
az vm image show --location eastus --urn MicrosoftWindowsServer:WindowsServer:2016-Datacenter:14393.4169.2101090332 --query [imageDeprecationStatus]
```

Option 2: Use PowerShell

To check a single image version:

PowerShell

```
Get-AzVMImage -Location "eastus" -PublisherName "MicrosoftWindowsServer" -Offer "WindowsServer" -Skus "2016-Datacenter" -Version "14393.4169.2101090332" | Select-Object -ExpandProperty "ImageDeprecationStatus"
```

To check all versions of a SKU with deprecation details:

PowerShell

```
Get-AzVMImage -Location "westus" `
  -PublisherName "center-for-internet-security-inc" `
  -Offer "cis-rocky" `
  -Skus "cis-rockylinux-9-l1-gen2-azure-observability" `
  -Expand "properties/imageDeprecationStatus" |
  Select-Object Version, @{
    Name = "DeprecationDetails"
    Expression = { $_.ImageDeprecationStatus | Out-String }
  } | Format-Table -Wrap -AutoSize
```

Option 3: Use REST API

Use the Virtual Machine Images - Get API. If the image is deprecated, you receive a response like:

JSON

```
{
  "error": {
    "code": "ImageVersionDeprecated",
    "message": "VM Image from publisher: MicrosoftWindowsServer with - Offer: WindowsServer, Sku: 2016-Datacenter, Version: 14393.4169.2101090332 is deprecated."
  }
}
```

Option 4: Use automated script

Run Get-AzVMImageDeprecationStatus.ps1 in Cloud Shell or locally to check all VMs and virtual machine scale sets in a subscription for deprecated images.

How do I list active (non-deprecated) image versions for a specific SKU?

Active images are images that aren't scheduled for deprecation or already deprecated.

Option 1: Use Azure CLI

Azure CLI

```
az vm image list --location eastus --publisher "MicrosoftWindowsServer" --offer
"WindowsServer" --sku "2022-Datacenter" --all --query "[?
imageDeprecationStatus.imageState=='Active']"
```

Option 2: Use PowerShell

PowerShell

```
Get-AzVMImage -Location "westus" `
  -PublisherName "center-for-internet-security-inc" `
  -Offer "cis-rocky" `
  -Skus "cis-rockylinux-9-l1-gen2-azure-observability" `
  -Expand "properties/imageDeprecationStatus" |
  Where-Object { $_.ImageDeprecationStatus.ImageState -eq "Active" } |
  Select-Object Version
```

What happens to SQL Server if a SQL Server Azure Marketplace image is deprecated?

Your SQL Server remains unaffected when a SQL Server Azure Marketplace image is deprecated:

- Your Azure VM continues to run without interruption.
- Your SQL Server instance continues to function normally.
- You can't deploy new VMs using the deprecated SQL Server image.

Existing deployments require no action.

VM Applications overview

Summarize this article for me

VM Applications are a resource type in Azure Compute Gallery that simplifies application management for your virtual machines (VMs) and Virtual Machine Scale Sets. You package your applications once, store them in your gallery, and deploy them to any VM in your organization.

With VM Applications, you decouple application deployment from your base VM images. This separation enables you to update applications independently without rebuilding images, reducing maintenance overhead, accelerating deployment cycles, and effectively handle critical vulnerabilities and disaster recovery.

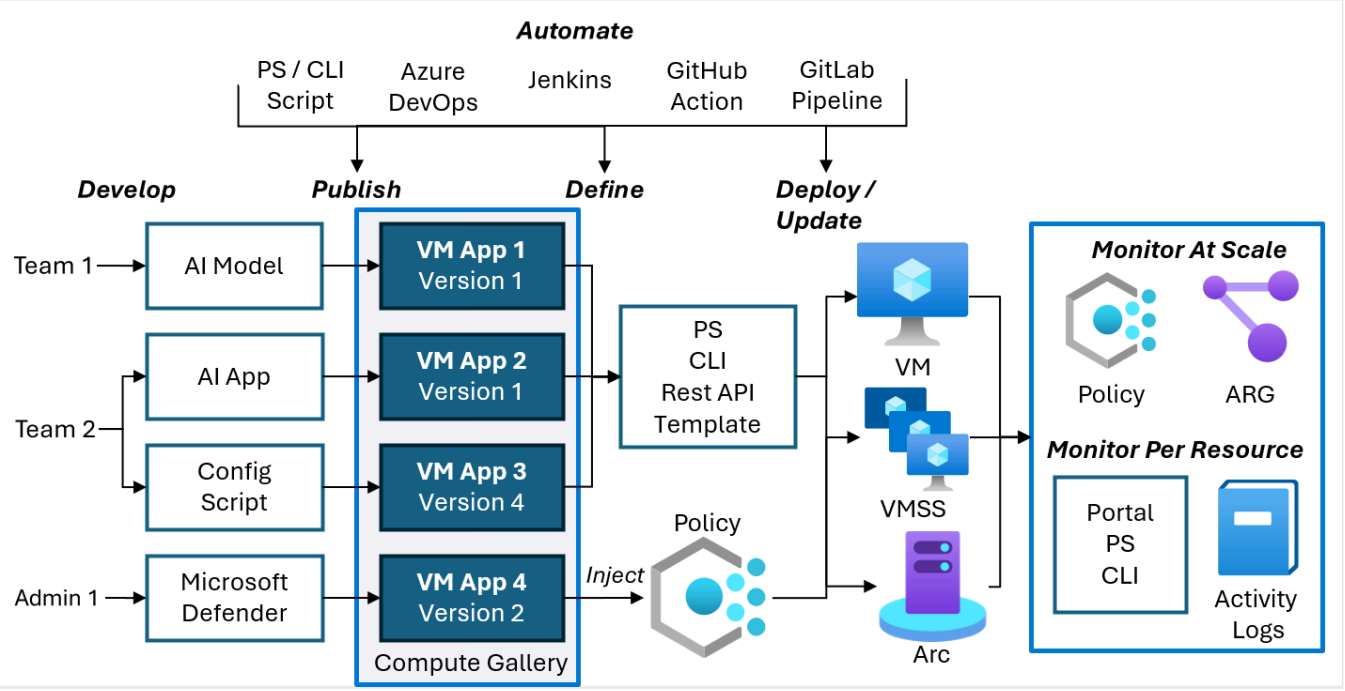
When to use VM Applications

VM Applications are the recommended approach when you need to publish, deploy, and manage software across Azure VMs. Consider VM Applications when you want to:

- Deploy applications across large VM fleets with consistent configuration.
- Update applications frequently without rebuilding VM images.
- Manage application versions and roll back when issues arise.
- Respond to zero-day vulnerabilities by publishing new versions quickly and updating your fleet centrally with Azure Policy.
- Enforce application presence and configuration using Azure Policy.
- Reduce deployment latency for high-scale and time-sensitive workloads like AI inferencing and gaming.
- Gain visibility into deployed applications with post-deployment inventory and monitoring.
- Modularize applications and scripts for reusability and operational efficiency.
- Consolidate application management into a single Azure-managed solution.

How VM Applications work

VM Applications integrate with your existing development workflows and Azure infrastructure to provide end-to-end application lifecycle management.



- **Develop and publish**: Different teams develop applications, scripts, and configurations independently. Each team publishes their packages as Azure VM Application to Azure Compute Gallery, which serves as a personal app repository.
- **Deploy or update**: Deploy published applications to VMs and Virtual Machine Scale Sets using Azure portal, PowerShell, CLI, REST API, or ARM/Bicep templates.
- **Enforce**: Use Azure Policy to automatically inject required applications across your fleet.
- **Automate**: Automate publishing, deployment and updates using CI/CD pipelines like Azure DevOps, GitHub Actions, GitLab pipelines, Jenkins, and scripts.
- **Monitor**: View application inventory & state across your infrastructure. Use Azure Policy and Azure Resource Graph for fleet-wide compliance monitoring, or view per-resource details in the Azure portal, PowerShell, CLI, and activity logs.

Key capabilities

Private application store for your organization

- Store and manage all application packages in Azure Compute Gallery.
- Package applications, scripts, configurations, and files in any format: `.zip`, `.msi`, `.exe`, `.tar.gz`, `.deb`, `.rpm`, `.sh`, or others.
- Maintain multiple versions of each application and deploy `latest` or specific version.
- Deploy test versions without being considered as `latest`.

Access control and sharing

- Control who can publish applications to gallery and access published app to deploy using Azure role-based access control (RBAC).
- Share gallery across subscriptions, Microsoft tenant or publicly.

Security

- Download packages from Azure-managed infrastructure instead of external URLs eliminating need to keep VM internet facing.
- Use Managed Identity assigned to Azure Compute Gallery for securely publishing VM applications.
- Handle critical security vulnerabilities by quickly publishing new version and updating your fleet using Azure Policy or Scripts.
- Use Azure Policy to enforce specific applications, security components, or application configuration across the infrastructure.

Flexible deployment options

- Deploy to individual VMs, flexible, or uniform Virtual Machine Scale Sets.
- Install, update, or remove applications independently without rebuilding VM images.
- Define custom install, update, and remove commands for each application.
- Specify deployment order when installing multiple applications.
- Configure reboot handling using the `scriptBehaviorAfterReboot` property.
- Use `treatFailureAsDeploymentFailure` to mark VM deployment as failed when an application fails to install.

Failure resiliency and high-scale performance

- Automatically replicate application packages across Azure regions and availability zones providing resiliency to region, zone, or content delivery network (CDN) failure.
- Create up to 10 replicas per region to distribute load during high-scale deployments.
- Deploy 25 packages up to 2 GB each, 50 GB total per VM.
- Use block blobs for chunked uploads and background streaming of large packages.

Governance and compliance

- Use Azure Policy to audit and enforce application presence and configuration across your fleet.
- Monitor application inventory and state using Azure portal, Azure Policy, and Azure Resource Graph.
- Monitor and apply pending updates across your infrastructure.

Cost

There's no extra charge for using VM Application Packages, but you're charged for the following resources:

- Storage costs of storing each package and any replicas.
- Network egress charges for replication of the first version from the source region to the replicated regions. Subsequent replicas are handled within the region, so there are no extra charges.

For more information on network egress, see Bandwidth pricing.

Publish application as Azure VM Application

To deploy VM applications, first the application needs to be published to Azure Compute Gallery. To publish Azure VM Application

1. First, create a **VM Application Resource** which is a logical resource containing metadata about the application.
2. Then create a **VM Application Version Resource** within the VM Application resource containing the application package and instructions on how to install, update, delete and replicate the VM application.

Azure resources required to publish Azure VM Application

Expand table

Resource	ARM Resource Type	Description
Azure Compute Gallery	Microsoft.Compute/galleries	A gallery is a repository for managing and sharing application packages. Users can share the gallery resource and all the child resources are shared automatically. The gallery name must be unique per subscription. For example, you may have one gallery to store all your OS images and another gallery to store all your VM applications.
VM Application	Microsoft.Compute/galleries/applications	The definition of your VM application. This logical resource stores the common metadata for all its versions, including the name, description, supported OS type, and end-of-life

Resource	ARM Resource Type	Description
		information. Think of it as a container that holds all versions of a single application. For example, you might have a VM Application called *Apache Tomcat* that contains version 9.0.0, 9.0.1, and 10.0.0.
VM Application Version	Microsoft.Compute/galleries/applications/versions	The deployable resource that contains your actual application package and version-specific configuration. Each version points to the application binary or script in your storage account and defines the install, update, and remove commands. You can replicate versions to multiple Azure regions to improve deployment reliability and reduce latency. Before you deploy an application to a VM, the version must be replicated to the VM's region.
Storage Account	Microsoft.Storage/storageAccounts	Application packages are first uploaded to your storage account. Azure Compute Gallery then downloads the application package from this storage account using SAS URLs and stores it within the VM Application version. Azure Compute Gallery also replicates this package across regions & regional replicas per the VM Application version definition. The application package in the storage account can be deleted after VM application version is created in Azure Compute Gallery.

Properties in VM Application Resource

The VM Application resource defines follows properties:

Expand table

Property	Description	Updatable	Limitations
name	Name of the application	Yes	Max length of 117 characters. Allowed characters are uppercase or lowercase

Property	Description	Updatable	Limitations
			letters, digits, hyphen(-), period (.), underscore (_). Names not allowed to end with period(.).
location	Location of the resource	No	
supportedOSType	Define the supported OS type	No	"Linux" or "Windows"
endOfLifeDate	Optional. A future end of life date for the application. The date is for reference only and isn't enforced.	Yes	
description	Optional. A description of the VM application	Yes	
eula	Optional. Reference to End User License Agreement (EULA)	Yes	
privacyStatementUri	Optional. Reference to privacy statement for the application.	Yes	
releaseNoteUri	Optional. Reference to release notes for the application.	Yes	

Properties in VM Application Version Resource

VM application versions are the deployable resources within the VM Application resource. Versions are defined with the following properties:

Expand table

Property	Description	Updatable	Limitations
location	Source location for the VM Application version.	No	Valid Azure Region
source/mediaLink	Link to the application package file in a storage account	Partially.	Valid and existing storage url. Only SASToken within the

Property	Description	Updatable	Limitations
			SASURL can be changed.
source/defaultConfigurationLink	Optional. A link to the configuration file for the VM application. It can be overridden at deployment time.	Partially	Valid and existing storage url. Only SASToken within the SASURL can be changed.
manageActions/install	Install script as string to properly install the application	No	Valid command for the given OS in string format.
manageActions/remove	Remove script as string to properly remove the application	No	Valid command for the given OS in string format
manageActions/update	Optional. Update script as string to properly update the VM application to a newer version.	No	Valid command for the given OS in string format
targetRegions/name	Name of target regions to which to replicate. Improves resiliency to region failure and create latency.	Yes	Valid Azure region
targetRegions/regionalReplicaCount	Optional. The number of replicas to create in the region. Improves load handling and create latency. Defaults to 1.	Yes	Integer between 1 and 3 inclusive
replicaCount	Optional. Defines the number of replicas across each region. Takes effect if regionalReplicaCount isn't defined. Improves resiliency to region or	Yes	Integer between 1 and 3 inclusive.

Property	Description	Updatable	Limitations
	cluster failure and create latency during high scale.		
endOfLifeDate	Optional. A future end of life date for the application version. This property is for customer reference only and isn't enforced.	Yes	Valid future date
excludeFromLatest	Optional. Exclude version from being used as the latest version of the application when 'latest' keyword is used in applicationProfile.	Yes	Defaults to false.
storageAccountType	Optional. Type of storage account to use in each region for storing application package. Defaults to Standard_LRS.	No	
safetyProfile/allowDeletionOfReplicatedLocations	Optional. Indicates whether or not removing this Gallery Image Version from replicated regions is allowed.	Yes	
settings/packageFileName	Optional. Package file name to use when the package is downloaded to the VM.	No	Character limit is of 4,096 characters.
settings/configFileName	Optional. Configuration file name to be use when the configuration is downloaded to the VM.	No	Character limit is of 4,096 characters.
settings/scriptBehaviorAfterReboot	Optional. The action to be taken for installing, updating, or removing gallery application after the VM is rebooted.	No	

Deploy Azure VM Applications

After the VM Application version is published to Azure Compute Gallery, you can deploy the version across Azure Virtual Machines (VM) and Azure Virtual Machine Scale Sets. This deployment is done by referencing the ARM ID of the VM application in the `applicationProfile` of the Azure Virtual Machine and Virtual Machine Scale Sets.

Properties in applicationProfile of VM and Virtual Machine Scale Sets

The `applicationProfile` in Azure VM and Virtual Machine Scale Sets defines the following properties:

Expand table

Property	Description	Limitations
galleryApplications	Gallery Applications to deploy	
packageReferenceId	Reference to application version to deploy	Valid application version reference
configurationReference	Optional. The full url of a storage blob containing the configuration for this deployment. This overrides any value provided for defaultConfiguration earlier.	Valid storage blob reference
order	Optional. Order in which to deploy applications. When not set, the application is installed last after all ordered applications are installed.	Valid integer
treatFailureAsDeploymentFailure	Optional. Mark application failure as VM deployment failure for failure handling	True or False

The order field may be used to specify dependencies between applications. The rules for order are as follows:

Expand table

Case	Install Meaning	Failure Meaning
No order specified	Unordered applications are installed after ordered applications. There's no guarantee of	Installation failures of other applications, be it ordered or unordered doesn't affect the installation of unordered applications.

Case	Install Meaning	Failure Meaning
	installation order among the unordered applications.	
Duplicate order values	Application is installed in any order compared to other applications with the same order. All applications of the same order are installed after the ones with lower orders and before the ones with higher orders.	If a previous application with a lower order failed to install, no applications with this order install. If any application with this order fails to install, no applications with a higher order install.
Increasing orders	Application will be installed after the ones with lower orders and before the ones with higher orders.	If a previous application with a lower order failed to install, this application doesn't install. If this application fails to install, no application with a higher order installs.

Technical Details for VM Applications

Considerations and Current Limits for VM Applications

- **Up to 10 replicas per region**: When you're creating a VM Application version, the maximum number of replicas per region is 10 for both page blob and block blob.
- **Up to 300 versions per region**: When creating a VM Application version, you can have up to 300 application versions per region across all applications.
- **Manual retry for failed installations**: Currently, the only way to retry a failed installation is to remove the application from the profile, then add it back.
- **Up to 25 applications per VM**: A maximum of 25 applications can be deployed to a single virtual machine.
- **2 GB application size**: The maximum file size of an application version `mediaLink` is 2 GB. The maximum file size for `defaultConfigurationLink` is 1 GB.
- **Requires a VM Agent**: The VM agent must exist on the VM and be able to receive goal states.
- **Single version of the application per VM**: Only one version of a given application can be deployed to a VM.
- **Move operations currently not supported**: Moving VMs with associated VM Applications across resource groups is currently not supported.

> ⓘ Note
>
> For Azure Compute Gallery and VM Applications, Storage SAS can be deleted after replication. However, any subsequent update operation requires a valid SAS.

Download directory within the VM

The download location of the application package and the configuration files are:

- Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>`
- Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.9\Downloads\<application name>\<application version>`

The install/update/remove commands should be written assuming the application package and the configuration file are in the current directory.

File naming for deployed VM application

When the application file gets downloaded to the VM, Azure uses VM Application name as the file name without any file extension. For example, if VM Application name is "TestPythonApp", the python.exe file uploaded in the VM Application gets downloaded as TestPythonApp. Azure is unable to retain the original file name and file extension.

Similarly, if configuration file is passes via `defaultConfigurationLink` in `publishingProfile` or via `configurationReference` in `applicationProfile`, Azure downloads the file with < `vm application name` >-config. For example, if the configuration file name is `config.json' and VM Application name is "TestPythonApp", the downloaded file is named TestPythonApp-config.

VM Applications provide `packageFileName` and `configFileName` properties in the `publishingProfile\settings` to override the default file names and allow customers to set custom file names. For example, if `packageFileName="pythonApp.exe"` and `configFileName="pythonConfig.json`, Azure downloads the files with respective names.

Alternatively, include a command for renaming the files before execution in the `installScript`.

Command interpreter used by VM application

The default command interpreters are:

- Linux: `/bin/bash`
- Windows: `cmd.exe`

It's possible to use a different interpreter like Chocolatey or PowerShell, as long as it's installed on the machine, by calling the executable and passing the command to it. For example, to have your command run in PowerShell on Windows instead of cmd, you can pass `powershell.exe -Command '<powershell commmand>'`

How VM Application updates are handled

When you update an application version on a VM or Virtual Machine Scale Sets, the update command you provided during deployment is used. If the updated version doesn't have an update command, then the current version is removed and the new version is installed.

Update commands should be written with the expectation that it could be updating from any older version of the VM Application.

Treat VM Application failure as deployment failure

By default, if an application fails to install, update, or remove, the VM Application extension still reports its status as *success*. The extension only reports a failure on its own when there's a problem with the extension itself or the underlying infrastructure, not with your application scripts.

To change this behavior, set the `treatFailureAsDeploymentFailure` property to `true` on the application in the VM's `applicationProfile`. When you enable this setting, any application installation, update, or removal failure causes the VMAppExtension provisioning status to report failure. This failure also causes the VM provisioning status to report as failed.

Error messages

These are the error messages that you might encounter when publishing and deploying your VM applications.

Expand table

Message	Description
Current VM Application Version {name} was deprecated at {date}.	You tried to deploy a VM Application version that was deprecated. Try using `latest` instead of

Message	Description
	specifying a specific version.
Current VM Application Version {name} supports OS {OS}, while current OSDisk's OS is {OS}.	You tried to deploy a Linux application to Windows instance or vice versa.
The maximum number of VM applications (max=5, current={count}) has been exceeded. Use fewer applications and retry the request.	We currently only support five VM applications per VM or Virtual Machine Scale Sets.
More than one VM Application was specified with the same packageReferenceId.	The same application was specified more than once.
Subscription not authorized to access this image.	The subscription doesn't have access to this application version.
Storage account in the arguments doesn't exist.	There are no applications for this subscription.
The platform image {image} isn't available. Verify that all fields in the storage profile are correct. For more information about storage profile, see https://aka.ms/storageprofile .	The application doesn't exist.
The gallery image {image} isn't available in {region} region. Contact image owner to replicate to this region, or change your requested region.	The gallery application version exists, but it wasn't replicated to this region.
The SAS isn't valid for source uri {uri}.	A `Forbidden` error was received from storage when attempting to retrieve information about the url (either mediaLink or defaultConfigurationLink).
The blob referenced by source uri {uri} doesn't exist.	The blob provided for the mediaLink or defaultConfigurationLink properties doesn't exist.
The gallery application version url {url} can't be accessed due to the following error: remote name not found. Ensure that the blob exists and that it's either publicly accessible or is a SAS url with read privileges.	The most likely case is that a SAS uri with read privileges wasn't provided.

Message	Description
The gallery application version url {url} can't be accessed due to the following error: {error description}. Ensure that the blob exists and that it's either publicly accessible or is a SAS url with read privileges.	There was an issue with the storage blob provided. The error description provides more information.
Operation {operationName} isn't allowed on {application} since it's marked for deletion. You can only retry the delete operation (or wait for an ongoing one to complete).	Attempt to update an application that's currently being deleted.
The value {value} of parameter 'galleryApplicationVersion.properties.publishingProfile.replicaCount' is out of range. The value must be between one and three, inclusive.	Only between one and three replicas are allowed for VM Application versions.
Changing property 'galleryApplicationVersion.properties.publishingProfile.manageActions.install' isn't allowed. (Or update, delete)	It isn't possible to change any of the manage actions on an existing VmApplication. A new VmApplication version must be created.
Changing property ' galleryApplicationVersion.properties.publishingProfile.settings.packageFileName ' isn't allowed. (Or configFileName)	It isn't possible to change any of the settings, such as the package file name or config file name. A new VmApplication version must be created.
The blob referenced by source uri {uri} is too large: size = {size}. The maximum blob size allowed is '1 GB'.	The maximum size for a blob referred to by mediaLink or defaultConfigurationLink is currently 1 GB.
The blob referenced by source uri {uri} is empty.	An empty blob was referenced.
{type} blob type isn't supported for {operation} operation. Only page blobs and block blobs are supported.	VmApplications only supports page blobs and block blobs.
The SAS isn't valid for source uri {uri}.	The SAS uri supplied for mediaLink or defaultConfigurationLink isn't a valid SAS uri.
Can't specify {region} in target regions because the subscription is missing required feature {featureName}. Either register your subscription with the	To use VmApplications in certain restricted regions,

Message	Description
required feature or remove the region from the target region list.	one must have the feature flag registered for that subscription.
Gallery image version publishing profile regions {regions} must contain the location of image version {location}.	The list of regions for replication must contain the location where the application version is.
Duplicate regions aren't allowed in target publishing regions.	The publishing regions may not have duplicates.
Gallery application version resources currently don't support encryption.	The encryption property for target regions isn't supported for VM Applications
Entity name doesn't match the name in the request URL.	The gallery application version specified in the request url doesn't match the one specified in the request body.
The gallery application version name is invalid. The application version name should follow Major(int32). Minor(int32). Patch(int32) format, where `int` is between 0 and 2,147,483,647 (inclusive). For example, 1.0.0, 2018.12.1 etc.	The gallery application version must follow the format specified.

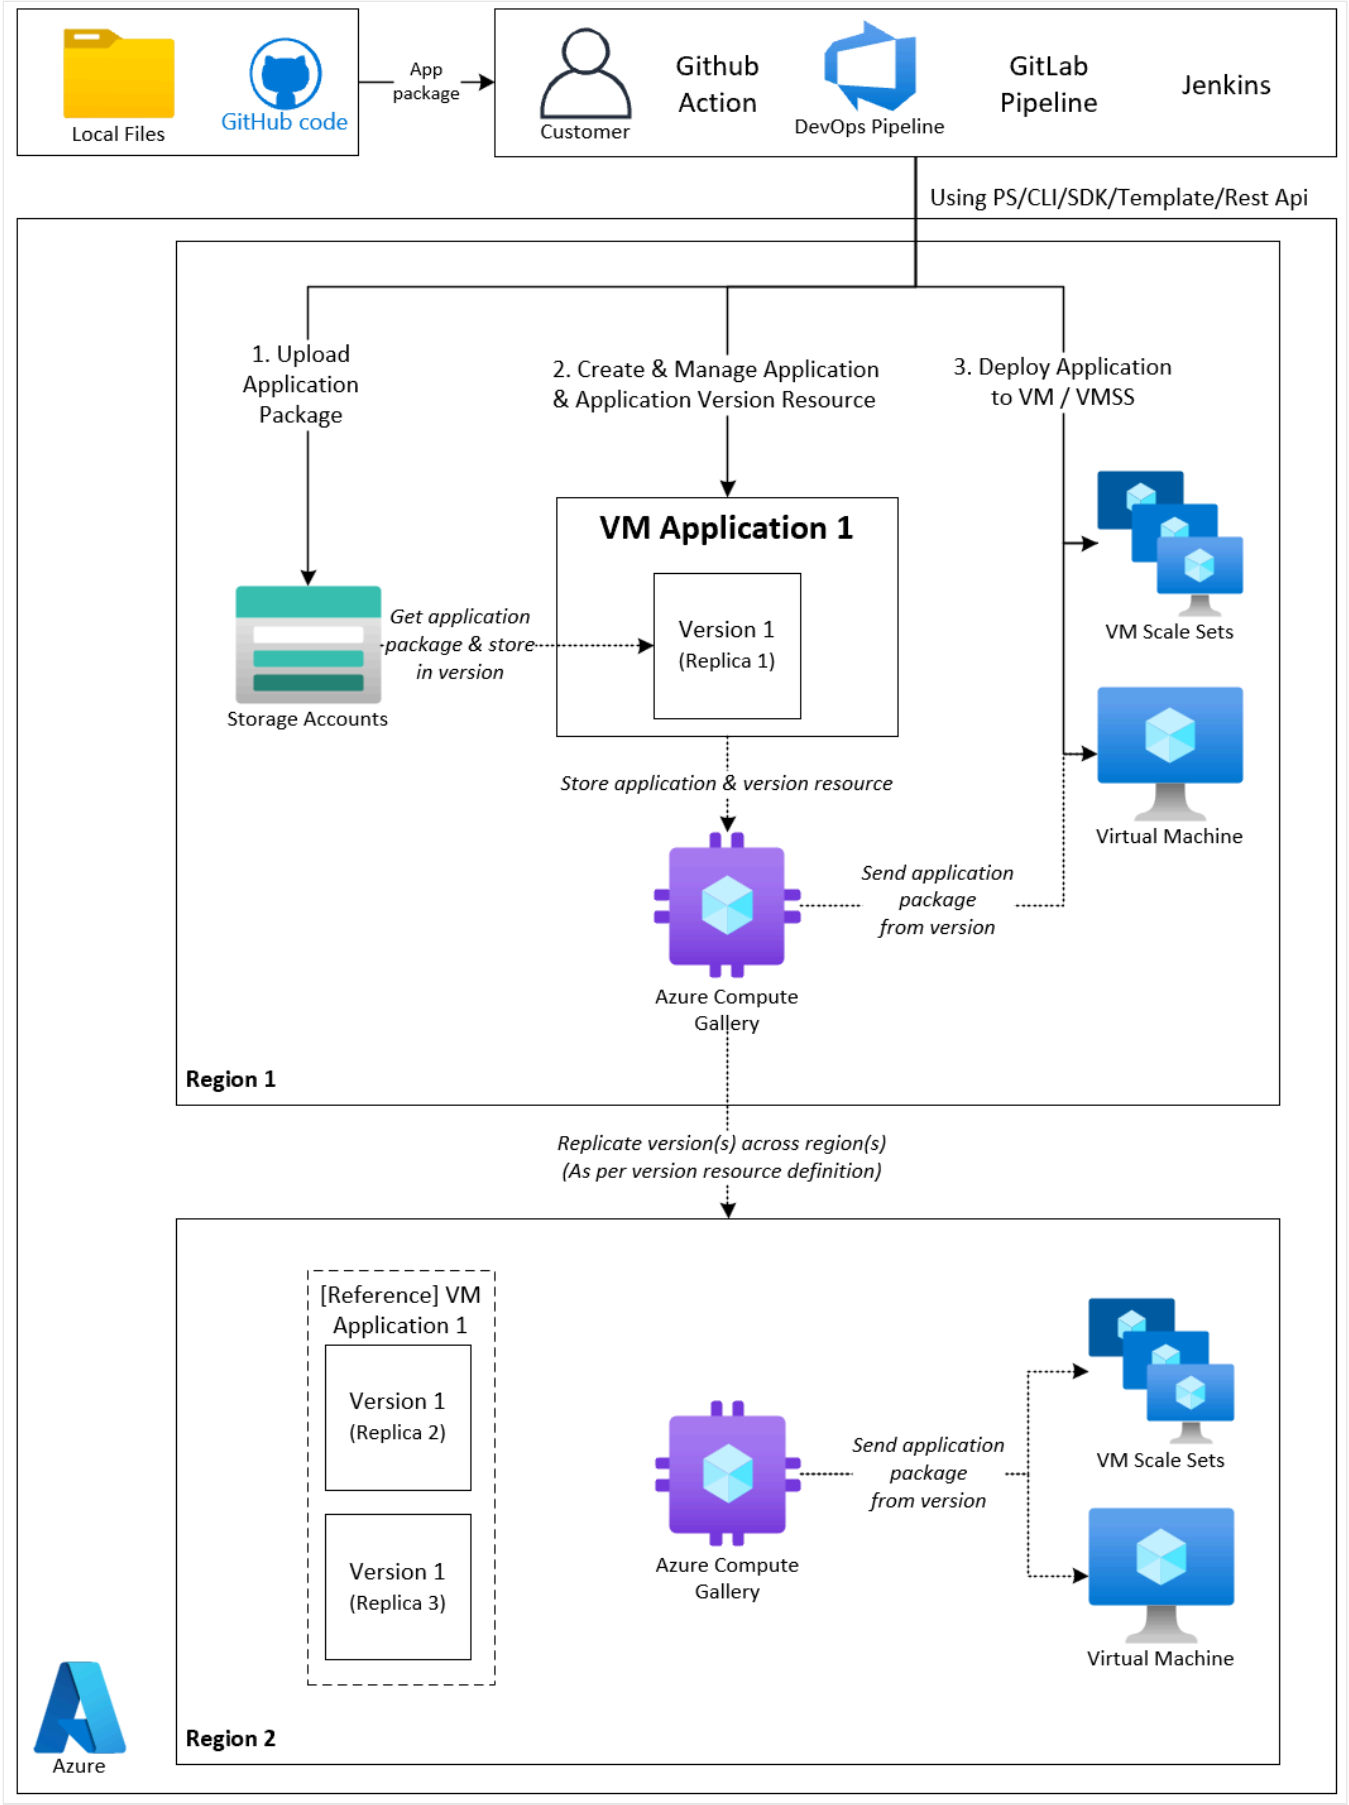
Create and deploy VM Application

Summarize this article for me

VM Application is a resource type in Azure Compute Gallery that simplifies publishing, deployment, management, sharing, and global distribution of applications and scripts for your virtual machines. VM Applications support a wide range of scenarios, including high-scale deployments, low-latency requirements, failure resiliency, secure trusted rollouts, fleet-wide consistency, microservice architectures, and post-deployment management. Learn more about VM Applications.

To create and deploy applications on Azure VM, first package and upload your application to Azure Storage Account as a storage blob. Then create `Azure VM application` resource and `VM application version` resource referencing these storage blobs. Azure stores and replicates these blobs in regional managed storage accounts. Finally, deploy the application on any VM or Virtual Machine Scale Sets by passing application reference in `applicationProfile`.



Prerequisites

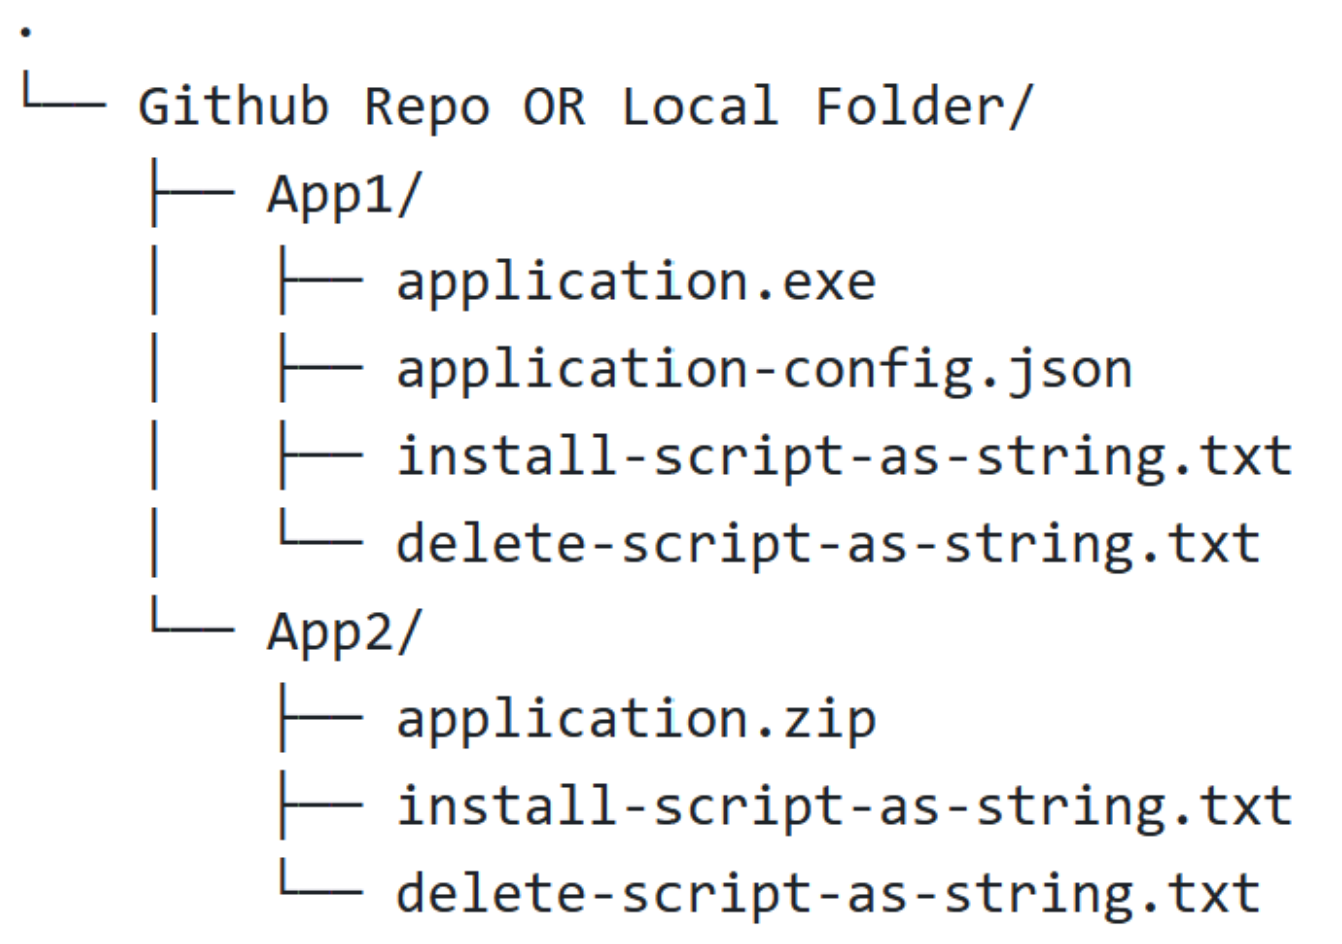
1. Create Azure storage account and storage container. This container is used to upload your application files.

2. Create Azure Compute Gallery for storing and sharing application resources.
3. Create user-assigned managed identity and assign to Azure Compute Gallery

> ⓘ Note
>
> Create your storage account with anonymous access disabled for improved security. Use a managed identity assigned to Azure Compute Gallery to publish your VM Applications securely without requiring SAS tokens.

Package the application

Before publishing the VM Application resource in Azure Compute Gallery, package your application files for upload to Azure Storage Account. The following diagram shows possible folder structures for organizing your application files:



1. Package the application files

VM Application requires a single file as the application package.

- If your application installation requires a single executable file (.exe, .msi, .sh, .ps, etc.) then you can use it as the application package.
- If your application requires multiple files (executables, dependencies, scripts, metadata, etc.), archive them into a single file (`.zip`, `.tar`, `.tar.gz`) and use this file as the application package.
- For microservice application, you can package and publish each microservice as a separate Azure VM Application. This modularization facilitates application reusability, cross-team development, and sequential installation of microservices using `order` property in the applicationProfile.

Learn more about creating application packages for Azure VM Applications.

2. (Optional) Package the application configuration file

- You can provide the configuration file separately using `defaultConfigurationLink` in the `publishingProfile` of the VM Application. This reduces the overhead of archiving and unarchiving application packages.
- Configuration files can also be passed during app deployment using `configurationReference` property in the `applicationProfile` of the VM enabling customized installation per VM.
- If both properties are set, `configurationReference` overrides the configuration passed using `defaultConfigurationLink`.

3. Create the install script

After the application and configuration blob is downloaded on the VM, Azure executes the provided install script to install the application. **The install script is provided as a string** and has a maximum character limit of 4,096 chars. The install commands should be written assuming the application package and the configuration file are in the current directory.

There may be few operations required to be performed in the install script

- **(Optional) Use the right command interpreter** The default command interpreter used by Azure are `/bin/bash` on Linux OS and `cmd.exe` on Windows OS. It's possible to use a different interpreter like Chocolatey or PowerShell, if its installed on the machine. Call the executable and pass the commands to it. For example, `powershell.exe -command '<powershell command>'`. If you're using PowerShell, you need to be using version 3.11.0 of the Az.Storage module.

- **(Optional) Rename application blob and configuration blob** Azure can't retain the original blob name and the file extensions. Azure downloads the application file with the

name of the VM application resource published on Azure Compute Gallery. So if name of VM App is "VMApp1", the file downloaded on VM has the name "VMApp1" without an extension. The configuration file has a default name as "VMApp1-config" without a file extension.

You can rename the file with the file extension using the install script or you can also pass the names in `packageFileName` and `configFileName` properties of the publishingProfile of VM Application version resource. Azure uses these names instead of default names while downloading the files.

- **Unarchive application blob** For archived application packages, it needs to be unarchived before installing the application. Use .zip or .tar since most OS has built-in support for unarchiving these formats. For other formats, make sure the Guest OS provides support.

- **Convert the script to string** The install script is passed as a string for the `install` property in the `publishingProfile` of Azure VM Application version resource.

- **Install quietly and synchronously** Install applications quietly or silently without any user interface prompts. Since the installation runs on a VM where customer input isn't available, you must use silent or unattended installation flags. Additionally, if the application installer spawns background or child processes or runs asynchronously, the parent script might return before the installation completes. To ensure the full installation finishes before Azure marks the operation as successful, use wait flags or blocking commands. This approach helps when installation involves multiple steps that run asynchronously or you need to verify installation completes before the subsequent application in the `order` sequence begins.

  Common examples include:
  - **Windows .msi**: `start /wait msiexec /i app.msi /quiet /qn`
  - **Windows .exe**: `start /wait app.exe /silent` or `start /wait app.exe /quiet` or `start /wait app.exe /S`
  - **PowerShell**: `Start-Process -FilePath '.\app.exe' -ArgumentList '/quiet' -Wait`
  - **Linux .sh**: `./install.sh --silent` (shell scripts run synchronously by default)
  - **Linux .deb**: `sudo DEBIAN_FRONTEND=noninteractive dpkg -i app.deb` (runs synchronously by default)
  - **Linux .rpm**: `sudo rpm -ivh app.rpm` (runs synchronously by default)

- **(Optional) Set right execution policy and permissions** After unarchiving, file permissions could be reset. It's a good practice to set the right permissions before executing the files.

- **(Optional) Set verbose execution and logging** VM Applications automatically captures any output from the install script and stores it in a stdout file on the VM. Use this

capability to log installation progress, debug failures, and verify successful deployments.
    - **Enable verbose mode** to capture application installer logs. Bash: `set -x`, PowerShell: `$VerbosePreference='Continue'`, Cmd: `@echo on`.
    - **Add custom messages** to track script progress. Bash: `echo "Install started"`, PowerShell: `Write-Output "Install started"`, Cmd: `echo Install started`

    You can retrieve these logs using Run Command or by connecting to the VM. The `stdout` and `stderr` files are located at the following path
    - Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>/`
    - Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.9\Downloads\<application name>\<application version>/`

- **(Optional) Move application and configuration blob to appropriate location** Azure downloads the application blob and configuration blob to following locations. The install script must move the files to appropriate locations when necessary.

    Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>`

    Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.16\Downloads\<application name>\<application version>`

Here are few sample install scripts based on the file extension of the application blob. If `packageFileName` & `configFileName` properties are provided in the `publishingProfile` with file name and extension, remove the code for renaming files in following scripts.

.TAR

Replace `VMApp1` with your VM App name in application package (VMApp1) and configuration file (VMApp1-config). Replace `app.tar` with desired app name. Replace `config.yaml` with your desired config name.

Install using bash without config file:

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && bash ./install.sh
```

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && sudo
DEBIAN_FRONTEND=noninteractive dpkg -i ./app.deb
```

Install using bash with config file:

Bash

```
mv VMApp1 app.tar && mv VMApp1-config config.yaml && tar -xf app.tar && chmod -
R +xr . && bash ./install.sh --config config.yaml
```

If config file is packaged within the tar file

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && sudo debconf-set-
selections < config.cfg && sudo DEBIAN_FRONTEND=noninteractive dpkg -i
./app.deb
```

4. Create the remove script

The `remove` script enables you to define the operations for removing the application. The `remove` script is provided as a string and has a maximum character limit of 4,096 characters. Write the commands assuming the application package and the configuration file are in the current directory. During uninstall operation, Azure runs the uninstall script and then deletes all files from the repository.

There are few operations that the `remove` script must perform.

- **Uninstall application:** Properly uninstall the application from the VM. For example:

CMD

CMD on Windows:

cli

```
start /wait uninstall.exe /quiet
```

cli

```
start /wait python.exe /uninstall /quiet
```

cli

```
start /wait msiexec /x app.msi /quiet /qn
```

- **Remove residual files:** If the application installation creates files in other parts of the file system, remove those files.

Upload the application files to Azure storage account

> ⓘ **Important**
>
> Before uploading files or generating SAS URLs, assign roles to the user, service principal, or managed identity that performs these operations on the target Storage account or container:
>
> - Storage Blob Data Contributor or Storage Blob Data Owner: required to upload, modify, or delete blobs.
> - For generating SAS with Azure AD (for example, using `--auth-mode` login in CLI/PowerShell), also assign Storage Blob Delegator at the storage account scope.

1. Upload your application and configuration files to a container in your Azure storage account.

Upload your packaged application and optional configuration file as blobs. Block blobs work for most scenarios.

Optionally, if you need to use page blobs, byte-align your files before uploading using one of the following scripts:

CLI

Azure CLI

```
inputFile="<the file you want to pad>"

# Get the file size
fileSize=$(stat -c %s "$inputFile")

# Calculate the remainder when divided by 512
```

```
remainder=$((fileSize % 512))

if [ "$remainder" -ne 0 ]; then
  # Calculate how many bytes to pad
  difference=$((512 - remainder))

  # Create padding (empty bytes)
  dd if=/dev/zero bs=1 count=$difference >> "$inputFile"
fi
```

2. Generate SAS or Blob URL for the application package and the configuration file

Once the application and configuration files are uploaded to the storage account, you need to generate a Blob URL or SAS URL with read privilege for these blobs. These URLs are then provided as reference while creating the VM Application version resource.

> ⓘ **Note**
>
> Use of blob URL with managed identity is strongly recommended for improved security and privacy.

Use blob URL:

- If managed identity is assigned to Azure Compute Gallery.
- If storage account is enabled for anonymous access. Use this method only for testing since its insecure.

Use SAS URL:

- If storage account is disabled for anonymous access and managed identity isn't assigned to Azure Compute Gallery.

Blob URL = https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${BLOB_NAME}
SAS URL = https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${BLOB_NAME}?${SAS_TOKEN}

CLI using Blob URL

Use the following script if managed identity is assigned to Azure Compute Gallery. This approach uses blob URLs without SAS tokens.

Azure CLI

```
#!/bin/bash
set -euo pipefail

# === CONFIGURATION ===
STORAGE_ACCOUNT="your-storage-account-name"
CONTAINER_NAME="your-container-name"
APP_FILE="./path/to/your-app-file"           # Path to your application payload
file
CONFIG_FILE="./path/to/your-config-file"     # Path to your configuration file
(optional)

# === LOGIN (if not already logged in) ===
az login --only-show-errors

# === CREATE CONTAINER IF NOT EXISTS ===
az storage container create \
  --name "$CONTAINER_NAME" \
  --account-name "$STORAGE_ACCOUNT" \
  --auth-mode login \
  --only-show-errors

# === UPLOAD APPLICATION FILE ===
APP_BLOB_NAME=$(basename "$APP_FILE")
az storage blob upload \
  --account-name "$STORAGE_ACCOUNT" \
  --container-name "$CONTAINER_NAME" \
  --name "$APP_BLOB_NAME" \
  --file "$APP_FILE" \
  --auth-mode login \
  --overwrite \
  --only-show-errors

# === UPLOAD CONFIG FILE (optional) ===
if [ -n "$CONFIG_FILE" ] && [ -f "$CONFIG_FILE" ]; then
  CONFIG_BLOB_NAME=$(basename "$CONFIG_FILE")
  az storage blob upload \
    --account-name "$STORAGE_ACCOUNT" \
    --container-name "$CONTAINER_NAME" \
    --name "$CONFIG_BLOB_NAME" \
    --file "$CONFIG_FILE" \
    --auth-mode login \
    --overwrite \
    --only-show-errors
fi

# === GENERATE BLOB URLs ===
echo "Generating Blob URLs..."

APP_BLOB_URL="https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME
}/${APP_BLOB_NAME}"
echo "Application file: $APP_BLOB_URL"
```

```
if [ -n "$CONFIG_FILE" ] && [ -f "$CONFIG_FILE" ]; then

CONFIG_BLOB_URL="https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${CONFIG_BLOB_NAME}"
  echo "Configuration file: $CONFIG_BLOB_URL"
fi
```

Create the VM Application

To create the VM Application, first create the **VM Application** resource, which describes the application. Then create **VM Application Version** resource within it, which contains the VM application payload and scripts to install, update, and delete the application. Payload is supplied using Blob URL or SAS URL to the blob container in Azure Storage Account.

Refer schema for VM Application and VM Application version resource to learn more about each property.

Template

Use the following ARM template to create an Azure Compute Gallery, VM Application, and VM Application version. This template demonstrates the key properties and configuration options for publishing your application package.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2020-06-01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",

```

Deploy the VM Apps

One or more VM Applications can now be referenced in the `applicationProfile` of Azure VM or Azure Virtual Machine Scale Sets. Azure then pulls the payload of the VM Application and installs it on each VM using the provided install script. The `order` property defines the sequential order in which the VM Applications are installed on the VM.

Refer schema of applicationProfile of the VM / Virtual Machine Scale Sets to learn more about each property.

Template

Use the following ARM template to deploy VM Application on Azure VM or Azure Virtual Machine Scale Sets. This template demonstrates the key properties and configuration options for deploying your VM application.

Manage Azure VM Applications

Summarize this article for me

This article talks about how to view, update, and delete published VM Application in Azure Compute Gallery. It then talks about how to view, monitor, update, and delete deployed VM application resource on Azure Virtual Machine (VM) or Virtual Machine Scale Sets.

Managed VM Application published in Azure Compute Gallery

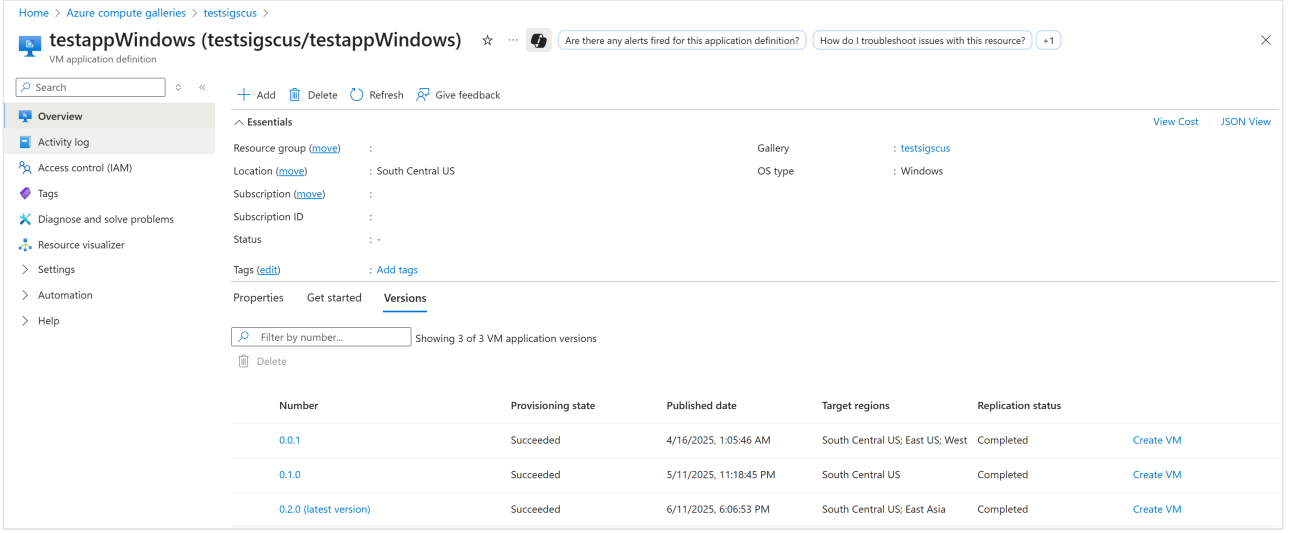
This section explains about how to view, update, and delete **published VM Applications** in Azure Compute Gallery.

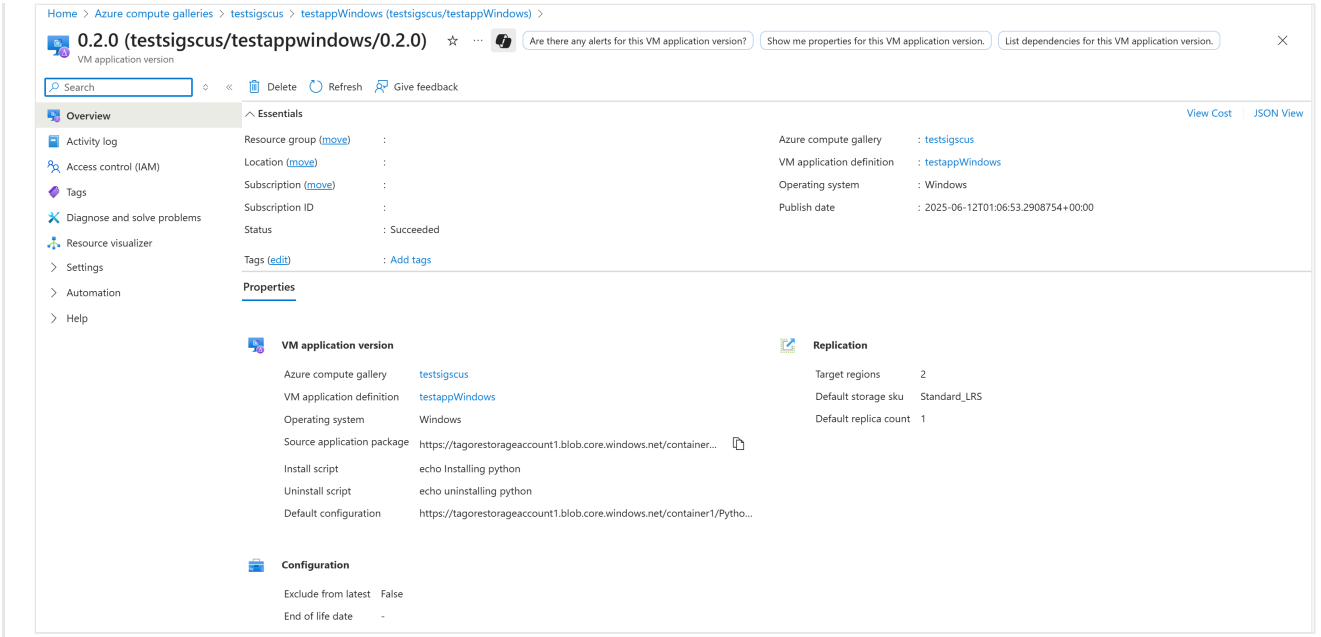
View published VM Applications

Portal

To view the properties of a published VM Application in the Azure portal:

1. Sign in to the Azure portal.
2. Search for **Azure Compute Gallery**.
3. Select the gallery that contains your VM Application.
4. Click the **VM Application Name** you want to view.
5. The **Overview/Properties** blade displays information about the VM Application.
6. The **Overview/Versions** blade displays all published versions and its basic properties like Target Regions, Provisioning state, and Replication state.
7. Select a **specific version** to view all its details.





View published VM applications using Azure Resource Graph

Azure resource graph query can be used to view all published VM applications and their properties across all compute galleries. It provides a programmatic way to view application inventory, and their properties at high scale. Use this method for integrating with dashboards and custom reports.

View list of all compute galleries

Kusto

```
resources
| where type == "microsoft.compute/galleries"
| where subscriptionId == "85236c53-92ad-4e66-97a4-8253a5246b99"
| extend provisioningState = properties["provisioningState"]
| extend permissions = properties["sharingProfile"]["permissions"]
| extend communityGalleryInfo = properties["sharingProfile"]
["communityGalleryInfo"]
| project subscriptionId, resourceGroup, location, name, provisioningState,
permissions, communityGalleryInfo
```

View list of all published VM Applications across all galleries

Kusto

```
resources
| where subscriptionId == "85236c53-92ad-4e66-97a4-8253a5246b99"
| where type == "microsoft.compute/galleries/applications"
| extend OSType = properties["supportedOSType"]
```

```
| extend description = properties["description"]
| extend endOfLifeDate = properties["endOfLifeDate"]
| parse id with  "/subscriptions/" SubId "/resourceGroups/" rgName
"/providers/Microsoft.Compute/galleries/" gallaryName "/applications/" appName
| project subscriptionId, resourceGroup, location, gallaryName, name, OSType,
description
```

View list of all published VM Application Versions across all applications and galleries

Kusto

```
resources
| where type == "microsoft.compute/galleries/applications/versions"
| project subscriptionId, resourceGroup, id, location, properties
| parse id with  "/subscriptions/" SubId "/resourceGroups/" rgName
"/providers/Microsoft.Compute/galleries/" gallaryName "/applications/" appName
"/versions/" versionNumber
| extend provisioningState = properties["provisioningState"]
| extend publishingProfile = properties["publishingProfile"]
| extend storageAccountType = publishingProfile["storageAccountType"]
| extend scriptBehaviorAfterReboot = publishingProfile["settings"]
["scriptBehaviorAfterReboot"]
| extend packageFileName = publishingProfile["settings"]["packageFileName"]
| extend configFileName = publishingProfile["settings"]["configFileName"]
| extend mediaLink = publishingProfile["source"]["mediaLink"]
| extend defaultConfigurationLink = publishingProfile["source"]
["defaultConfigurationLink"]
| extend excludeFromLatest = publishingProfile["excludeFromLatest"]
| extend targetRegions = publishingProfile["targetRegions"]
| extend replicaCount = publishingProfile["replicaCount"]
| extend publishedDate = publishingProfile["publishedDate"]
| extend installScript = publishingProfile["manageActions"]["install"]
| extend removeScript = publishingProfile["manageActions"]["remove"]
| extend safetyProfile = properties["safetyProfile"]
| extend allowDeletionOfReplicatedLocations =
safetyProfile["allowDeletionOfReplicatedLocations"]
| project-away safetyProfile, publishingProfile, SubId, rgName, id, properties
```

Update published VM Application

> **Note**
>
> Not all properties of a published VM Application or VM Application version can be updated. For a complete list of updatable properties, refer to the VM Application resource and VM Application version resource schema.

REST

Update VM Application resource:

rest

```
PATCH
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/galleries/{galleryName}/applications/{galleryApplicationName}?api-version=2024-03-03

Body
{
    "properties": {
        "description": "Updated description",
        "endOfLifeDate": "2026-12-31T00:00:00Z",
        "eula": "Updated EULA text",
        "privacyStatementUri": "https://contoso.com/privacy",
        "releaseNoteUri": "https://contoso.com/release-notes"
    }
}
```

Update VM Application version resource:

rest

```
PATCH
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/galleries/{galleryName}/applications/{galleryApplicationName}/versions/{galleryApplicationVersionName}?api-version=2024-03-03

Body
{
    "properties": {
        "publishingProfile": {
            "targetRegions": [
                {
                    "name": "eastus",
                    "regionalReplicaCount": 2,
                    "storageAccountType": "Standard_LRS"
                },
                {
                    "name": "westus",
                    "regionalReplicaCount": 1,
                    "storageAccountType": "Standard_LRS"
                }
            ],
            "excludeFromLatest": false
        }
```

```
    }
}
```

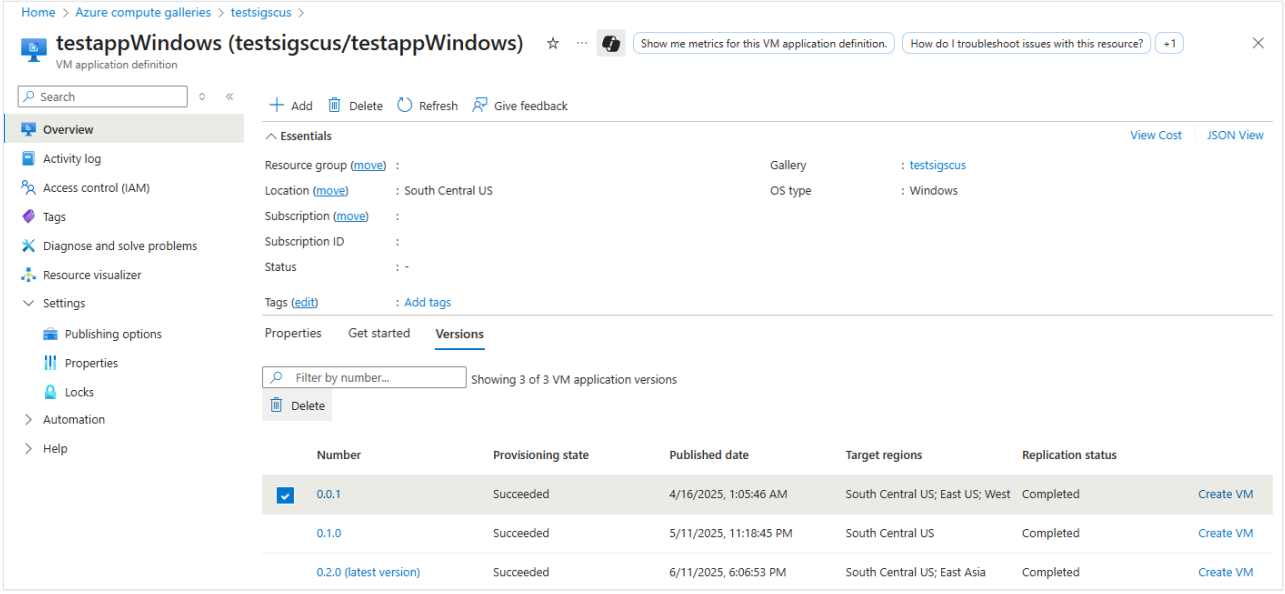
Delete published VM Application from Azure Compute Gallery

To delete the VM Application resource, you need to first delete all its versions. Deleting the application version causes deletion of the application version resource from Azure Compute Gallery and all its replicas. The application blob in Storage Account used to create the application version is unaffected.

> ⚠ **Warning**
>
> - Deleting the application version causes subsequent PUT operations on VMs using that version to fail. To prevent this failure, use `latest` keyword as the version number in the `applicationProfile` instead of hard coding the version number .
> - Deleting the VM application that is deployed on any VM or Virtual Machine Scale Sets causes subsequent PUT operations on these resources to fail (for example, update, scale, or reimage). Before deleting, ensure all VMs/Virtual Machine Scale Sets instances stop using the application by removing it from their applicationProfile.
> - To prevent accidental deletion, set `safetyProfile/allowDeletionOfReplicatedLocations` to `false` while publishing the version and apply an Azure Resource Manager lock (CanNotDelete or ReadOnly) on the VM application resource.

Portal

1. Sign in to the Azure portal.
2. Search for Azure Compute Gallery and open the target gallery.
3. Select the VM application you want to remove.
4. Select one or more versions, which you want to delete.
5. To delete the VM application, first delete all the versions. Then click delete (on top of the blade).
6. Monitor Notifications for completion. If deletion is blocked, remove any locks and ensure no VM or Virtual Machine Scale Sets references the application.



Manage deployed VM Application on Azure VM and Virtual Machine Scale Sets

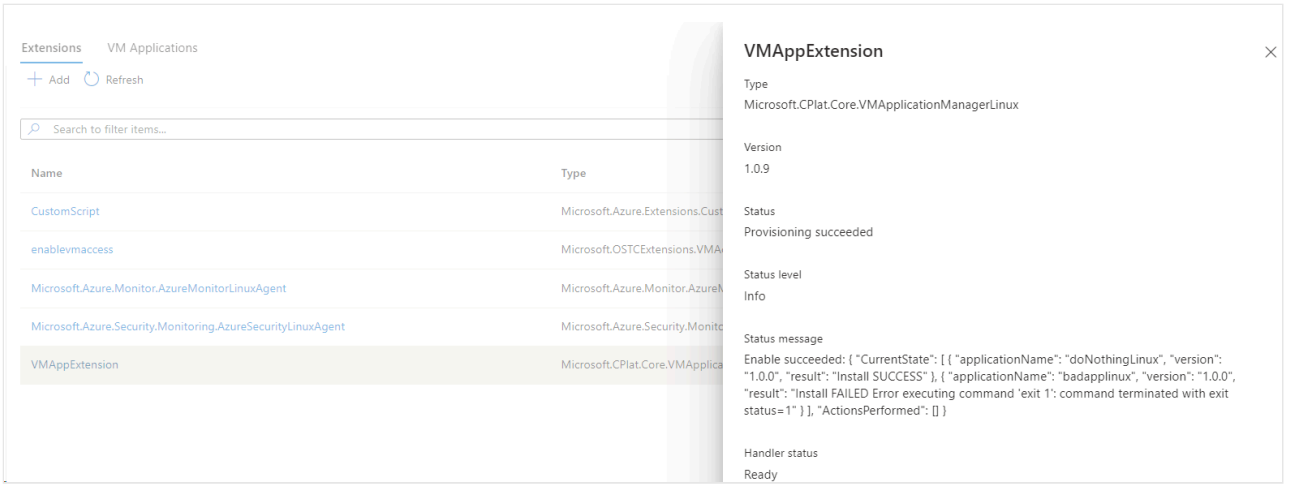
This section explains how to view deployed application details and monitor deployed applications across infrastructure. It also talks about how to update and delete **deployed VM Applications** on Azure VMs and Virtual Machine Scale Sets.

View deployed VM Applications & their state

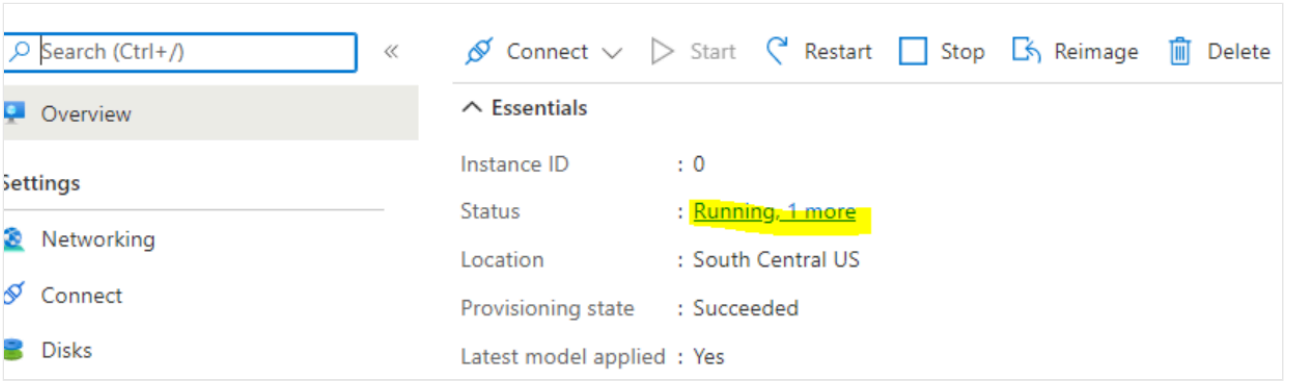
Azure uses VMAppExtension to deploy, monitor, and manage VM Applications on the VM. Therefore, provisioning state of the deployed VM Application is described in the status of the VMAppExtension.

Portal

To show the VM application status, go to the **Extensions + applications** tab under settings and check the status of the VMAppExtension:



To show the VM application status for a Virtual Machine Scale Sets, go to the Azure portal Virtual Machine Scale Sets page. In the Instances section, select one of the instances. Then go to **Extensions + Applications** tab under settings and check the status of the **VMAppExtension**:



View logs of application installation using Run command

When Azure VM Applications downloads and installs the application on Azure VM or Virtual Machine Scale Sets, it pipes all stdout results to `stdout` file within the application repository. Customers can enable verbose logging for the application installation and write custom logs using the `installScript`. Customers can then manually check the `stdout` and `stderr` file or use Runcommand to get the file content.

Use the following PowerShell script in your managed run command. Update the `appName` and `appVersion` variables for your application

Windows

azure-powershell

```
$appName = "vm-application-name"        # VM Application definition name
$appVersion = "1.0.0"                   # VM Application version name

$VMAppManagerVersion = "1.0.16"         # Version of the
VMApplicationManagerWindows extension on the VM
$StdoutFilePath =
"C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\$VMAppMan
agerVersion\Downloads\$appName\$appVersion\stdout"
$StderrFilePath =
"C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\$VMAppMan
agerVersion\Downloads\$appName\$appVersion\stderr"

Write-Host "`n=== Contents of stdout ==="
Get-Content -Path $StdoutFilePath

Write-Host "`n=== Contents of stderr ==="
Get-Content -Path $StderrFilePath
```

Execute the run command using the scripts and get the application install logs.

Portal

1. Open the Azure portal and navigate to your VM.
2. Under **Operations**, select **Run command**.
3. Choose **RunPowerShellScript** from the list.
4. Enter your PowerShell script in the editor.
5. Select **Run** to execute the script.
6. View the output in the **Output** section. If the script fails, check the **Error** section for details.

For more information, see Run PowerShell scripts in your Windows VM by using Run Command.

View all deployed VM applications using Azure Resource Graph

Azure resource graph query can be used to view all deployed VM applications and their properties across all VMs and Virtual Machine Scale Sets. It provides a programmatic way to view application inventory, state, and deployed versions at high scale. Use this method for integrating with dashboards and custom reports.

Kusto

```
resources
| where type == "microsoft.compute/virtualmachines" or type ==
"microsoft.compute/virtualmachinescalesets"
| where properties has "applicationProfile"
| extend resourceType = iff(type == "microsoft.compute/virtualmachines", "VM",
"VMSS")
| extend applications = iff(resourceType == "VM",
parse_json(properties["applicationProfile"]["galleryApplications"]),
parse_json(properties["virtualMachineProfile"]["applicationProfile"]
["galleryApplications"]))
| mv-expand applications
| extend enableAutomaticUpgrade = applications["enableAutomaticUpgrade"]
| extend packageReferenceId = applications["packageReferenceId"]
| extend treatFailureAsDeploymentFailure =
applications["treatFailureAsDeploymentFailure"]
| parse packageReferenceId with "/subscriptions/" publisherSubcriptionId

galleryName "/applications/" appName "/versions/" version
| project tenantId, subscriptionId, resourceGroup, resourceName = name, type,
location, appName, version, enableAutomaticUpgrade,
treatFailureAsDeploymentFailure, galleryName, publisherSubcriptionId,
publisherResourceGroup, properties
```

Audit required VM Application using Azure Policy

Azure Policy helps enforce governance by auditing whether required VM applications are deployed across your VMs and Virtual Machine Scale Sets. You can create and assign custom policies to check compliance and ensure that specific applications are present on your infrastructure.

For step-by-step instructions on how to audit VM application deployment using Azure Policy, see Audit required VM applications using Azure Policy.

Update the deployed VM Application

To update a deployed VM application, modify the `applicationProfile` to reference a newer version or change deployment settings such as `treatFailureAsDeploymentFailure` or `order`.

REST

Update the VM application version or settings on a single VM:

rest

```
PATCH
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{res
```

```
ourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}?api-
version=2024-03-03

Body
{
    "properties": {
        "applicationProfile": {
            "galleryApplications": [
                {

        "virtualMachineProfile": {
            "applicationProfile": {
                "galleryApplications": [
                    {
                        "packageReferenceId":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/M
icrosoft.Compute/galleries/{galleryName}/applications/{applicationName}/version
s/{newVersion | latest}",
                        "treatFailureAsDeploymentFailure": true,
                        "order": 2
                    }
                ]
            }
        }
    }
}
```

Apply the change to existing Virtual Machine Scale Sets instances (required when upgradePolicy.mode is Manual):

rest

```
POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{res
ourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{vmssName}/
updateInstances?api-version=2024-03-03

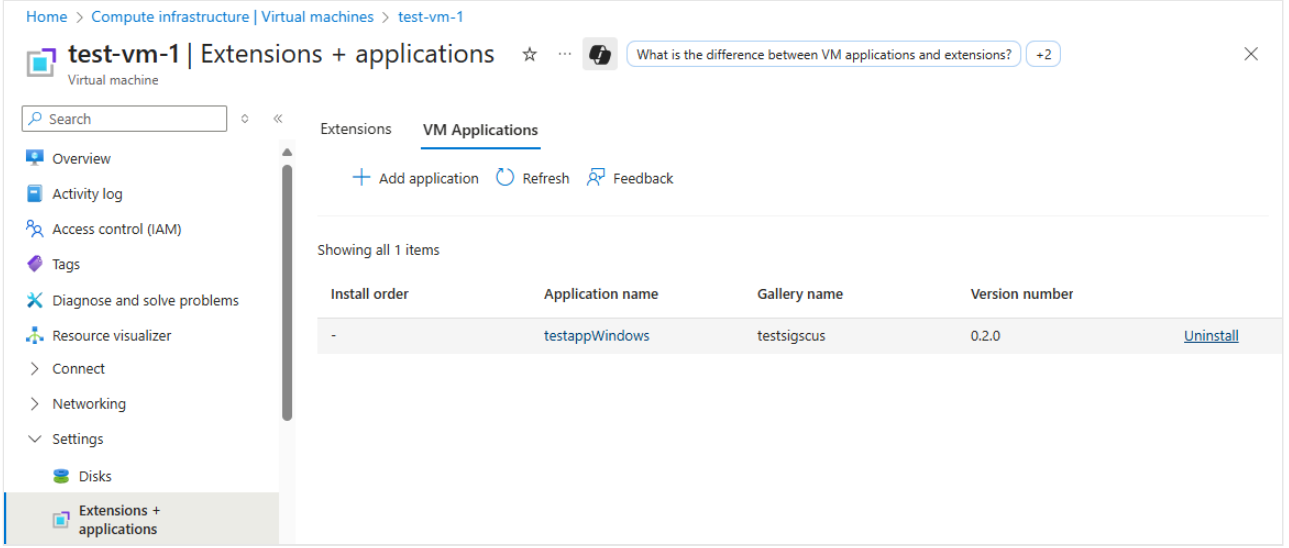
Body
{
    "instanceIds": ["*"]
}
```

> **Tip**
>
> Use `latest` as the version identifier in `packageReferenceId` to automatically deploy the newest published version without manually updating deployments.

Remove the VM Application from Azure VM or Virtual Machine Scale Sets

Portal

1. Open the Azure portal and go to the target virtual machine (VM) or Virtual Machine Scale Sets.
2. In Settings, select **Extensions + applications**, then select the **VM Applications** tab.
3. Click uninstall button on the VM Application and Save.
4. Track progress in Notifications or check Instance view for the VMAppExtension status.



Next steps

- Learn more about Azure VM Applications.
- Learn to create Azure VM applications.

Create packages for VM applications

Summarize this article for me

To create a VM Application, you need application package and scripts to properly install, update, and delete the application. This article explains how to create packages and scripts for different operating systems and formats that you can use as VM application payloads.

Package and Install VM Applications on Linux

Third party applications for Linux can be packaged in a few ways. Let's explore how to handle creating the install commands for some of the most common.

.tar and .gz files

These files are compressed archives and can be extracted to a desired location. Check the installation instructions for the original package in case they need to be extracted to a specific location. If .tar.gz file contains source code, see the instructions for the package for how to install from source.

Example to install command to install `golang` on a Linux machine:

Bash

```
sudo tar -C /usr/local -xzf go_linux
```

Example remove command:

Bash

```
sudo rm -rf /usr/local/go
```

Creating application packages using `.deb`, `.rpm`, and other platform specific packages for VMs with restricted internet access

You can download individual packages for platform specific package managers, but they usually don't contain all the dependencies. For these files, you must also include all dependencies in the application package, or have the system package manager download the dependencies through the repositories that are available to the VM. If you're working with a VM with restricted internet access, you must package all the dependencies yourself.

Figuring out the dependencies can be a bit tricky. There are third party tools that can show you the entire dependency tree.

Following process shows how to identify application dependencies, download them and package them together for different linux OS flavors.

Ubuntu

In Ubuntu, you can run `sudo apt show <package_name> | grep Depends` to show all the packages that are installed when executing the `sudo apt-get install <packge_name>` command. Then you can use that output to download all `.deb` files to create an archive that can be used as the application package.

To create a VM Application package for installing PowerShell on Ubuntu, perform the following steps:

1. Run the following commands to enable the repository to download PowerShell and to identify package dependencies on a new Ubuntu VM

Bash

```
# Download the Microsoft repository GPG keys
wget -q "https://packages.microsoft.com/config/ubuntu/$(lsb_release -
rs)/packages-microsoft-prod.deb"
# Register the Microsoft repository GPG keys
sudo dpkg -i packages-microsoft-prod.deb
sudo rm -rf packages-microsoft-prod.deb
sudo apt update
sudo apt show powershell | grep Depends
```

2. Check the output of the line **Depends** which lists the following packages:

Output

```
Depends: libc6, lib32gcc-s1, libgssapi-krb5-2, libstdc++6, zlib1g,
libicu72|libicu71|libicu70|libicu69|libicu68|libicu67|libicu66|libicu65|libicu6
3|libicu60|libicu57|libicu55|libicu52, libssl3|libssl1.1|libssl1.0.2|libssl1.
```

3. Download each of these files using `sudo apt-get download <package_name>` and create a tar compressed archive with all files.

- Ubuntu 18.04:

Bash

```
mkdir /tmp/powershell
cd /tmp/powershell
sudo apt-get download libc6
sudo apt-get download lib32gcc
sudo apt-get download libgssapi-krb5-2
sudo apt-get download libstdc++6
sudo apt-get download zlib1g
sudo apt-get download libssl1.1
sudo apt-get download libicu60
sudo apt-get download powershell
sudo tar -cvzf powershell.tar.gz *.deb
```

- Ubuntu 20.04:

Bash

```
mkdir /tmp/powershell
cd /tmp/powershell
sudo apt-get download libc6
sudo apt-get download lib32gcc-s1
sudo apt-get download libgssapi-krb5-2
sudo apt-get download libstdc++6
sudo apt-get download zlib1g
sudo apt-get download libssl1.1
sudo apt-get download libicu66
sudo apt-get download powershell
sudo tar -cvzf powershell.tar.gz *.deb
```

- Ubuntu 22.04:

Bash

```
mkdir /tmp/powershell
cd /tmp/powershell
sudo apt-get download libc6
sudo apt-get download lib32gcc-s1
sudo apt-get download libgssapi-krb5-2
sudo apt-get download libstdc++6
sudo apt-get download zlib1g
sudo apt-get download libssl3
sudo apt-get download libicu70
sudo apt-get download powershell
sudo tar -cvzf powershell.tar.gz *.deb
```

- Ubuntu 24.04:

Bash

```
mkdir /tmp/powershell
cd /tmp/powershell
```

```
sudo apt-get download libc6
sudo apt-get download lib32gcc-s1
sudo apt-get download libgssapi-krb5-2
sudo apt-get download libstdc++6
sudo apt-get download zlib1g
sudo apt-get download libssl3t64
sudo apt-get download libicu74
sudo apt-get download powershell
sudo tar -cvzf powershell.tar.gz *.deb
```

4. This tar archive is the application package file.

- The install command in this case is:

Bash

```
sudo tar -xvzf powershell.tar.gz && sudo dpkg -i *.deb
```

- And the remove command is:

Bash

```
sudo apt remove powershell
```

Use `sudo apt autoremove` instead of explicitly trying to remove all the dependencies. You may have installed other applications with overlapping dependencies, and in that case, an explicit remove command would fail.

In case you don't want to resolve the dependencies yourself, and `apt` is able to connect to the repositories, you can install an application with just one `.deb` file and let `apt` handle the dependencies.

Example install command:

Bash

```
dpkg -i <package_name> || apt --fix-broken install -y
```

Creating VM Applications on Windows

Most third party applications in Windows are available as .exe or .msi installers. Some are also available as extract and run zip files. Let us look at the best practices for each of them.

.exe installer

Installer executables typically launch a user interface (UI) and require someone to select through the UI. If the installer supports a silent mode parameter, it should be included in your installation string.

Cmd.exe also expects executable files to have the extension `.exe`, so you need to rename the file to have the `.exe` extension.

If I want to create a VM Application package for `myApp.exe`, which ships as an executable, my VM Application is called 'myApp', so I write the command assuming the application package is in the current directory:

terminal

```
"move .\\myApp .\\myApp.exe & myApp.exe /S -config myApp_config"
```

If the installer executable file doesn't support an uninstall parameter, you can sometimes look up the registry on a test machine to know where the uninstaller is located.

In the registry, the uninstall string is stored in `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\<installed application name>\UninstallString` so I would use the contents as my remove command:

terminal

```
'\"C:\\Program Files\\myApp\\uninstall\\helper.exe\" /S'
```

.msi installer

For command line execution of `.msi` installers, the commands to install or remove an application should use `msiexec`. Typically, `msiexec` runs as its own separate process and `cmd` doesn't wait for it to complete, which can lead to problems when installing more than one VM application. The `start` command can be used with `msiexec` to ensure that the installation completes before the command returns. For example:

terminal

```
start /wait %windir%\\system32\\msiexec.exe /i myapp /quiet /forcerestart /log
myapp_install.log
```

Example remove command:

```
terminal
start /wait %windir%\\system32\\msiexec.exe /x myapp /quiet /forcerestart /log
myapp_uninstall.log
```

Typically, the `start` command would be called within a batch script. If used with the `/wait` parameter, the calling script is paused until the called process terminates. Once complete, the batch script would check for the `errorlevel` variable set by the `start` command and exit as follows:

```
batch
start /wait %windir%\\system32\\msiexec.exe /i myapp /quiet /forcerestart /log
myapp_install.log
if %errorlevel% neq 0 exit /b %errorlevel%
...
```

Zipped files

For .zip or other zipped files, rename and unzip the contents of the application package to the desired destination.

Example install command:

```
terminal
rename myapp myapp.zip && mkdir C:\myapp && powershell.exe -Command "Expand-Archive
-path myapp.zip -destinationpath C:\myapp"
```

Example remove command:

```
terminal
rmdir /S /Q C:\\myapp
```

Publish Azure VM applications using managed identity

Summarize this article for me

This article explains how to use managed identity with Azure Compute Gallery to securely publish Azure VM applications using blob URLs, eliminating the need for SAS URLs or publicly accessible storage accounts.

Overview

Deploying applications through Azure VM applications requires you to upload the application package to a storage account and provide a URL to the blob. Azure Compute Gallery uses this URL to access the blob and publish it as a VM application version.

Without managed identity, you have two options to provide blob access:

- **Blob URL** - Requires the storage account to enable anonymous access.
- **SAS URL** - The SAS token is stored as plain text in the application version resource, and you must manage token expiration and regeneration.

Both approaches are insecure as blob URLs expose your storage account to the public internet, and SAS URLs, which are secrets must be stored in plain text.

Managed identity for Azure Compute Gallery

A managed identity is a security feature that lets an Azure service prove its identity to other Azure services without storing passwords, keys, or tokens in your code or configuration. Instead of you managing credentials, Microsoft Entra ID handles authentication automatically.

By attaching a user-assigned managed identity to your Azure Compute Gallery, you give the gallery permission to access blobs in your storage account on your behalf. The gallery presents this identity when it needs to read your application package, and Microsoft Entra ID verifies the identity and grants access. Because Azure Compute Gallery is a trusted Microsoft service, this access works even when the storage account is behind a virtual network.

This approach enables you to:

- Restrict storage account access to specific virtual networks.
- Disable shared key access on the storage account and use plain blob URLs.
- Ensure access credentials like SAS URLs aren't stored as plain text.

How it works

At a high level, the authentication and access flow work as follows:

1. You upload your application package to a blob in your storage account.
2. You create a user-assigned managed identity and grant it the **Storage Blob Data Contributor** role on the storage account.
3. You attach the managed identity to your Azure Compute Gallery.
4. When you publish a VM application version, you provide a plain blob URL instead of a SAS URL.
5. Azure Compute Gallery attempts to access the blob using the blob URL directly.
6. Microsoft Entra ID verifies the identity and grants the gallery access to the blob.

Prerequisites

- An Azure Compute Gallery
- A storage account with your VM application package uploaded to a blob container.

Step 1: Create a user-assigned managed identity

Create a user-assigned managed identity that Azure Compute Gallery uses to authenticate with your storage account.

For detailed steps, see Create a user-assigned managed identity.

Step 2: Assign storage access permission to the identity

Assign the **Storage Blob Data Contributor** role to the managed identity so it can access the application package in your storage account.

For detailed steps, see Assign Azure roles using the Azure portal. When assigning the role:

1. Select **Storage Blob Data Contributor** as the role.
2. Assign access to **Managed identity**.
3. Select the user-assigned managed identity you created in the previous step.

Step 3: Attach managed identity to Azure Compute Gallery

Update your Azure Compute Gallery to use the user-assigned managed identity. Portal experience isn't currently available for this step.

Using REST API

Use the Galleries - Create Or Update API to attach the managed identity to your gallery.

HTTP

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/galleries/{galleryName}?api-version=2025-04-01

{
    "location": "<location>",
    "identity": {
        "type": "UserAssigned",
        "userAssignedIdentities": {
            "/subscriptions/<subscription-id>/resourceGroups/<resource-group>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<identity-name>": {}
        }
    }
}
```

Step 4: Get the blob URL for your application package

Retrieve the blob URL for the application package stored in your storage account. The URL format is:

```
https://<storage-account-name>.blob.core.windows.net/<container-name>/<blob-name>
```

Step 5: Publish a VM application version using the blob URL

Use the blob URL in the `mediaLink` property of the publishing profile when creating or updating your VM application version. Azure Compute Gallery uses the attached managed identity to authenticate and access the blob.

For detailed steps on creating a VM application version, see Create a VM application version.

Technical details

- **Authentication flow** - Azure Compute Gallery first attempts to access the blob using the provided URL. If direct access fails due to insufficient permissions, the gallery falls back to the attached managed identity for authentication.
- **Trusted service access** - Azure Compute Gallery is a trusted Microsoft service. The managed identity provides trusted access that bypasses storage account virtual network restrictions, so the gallery doesn't need to be inside a virtual network to reach a network-restricted storage account.

Limitations

- Managed identity access is supported only when **publishing** a VM application version to Azure Compute Gallery. It can't be used when deploying a VM application to a VM or Virtual Machine Scale Sets.
- Portal experience for attaching managed identity to the gallery isn't currently available. Use the REST API, Azure CLI, or Azure PowerShell.

Govern and enforce compliance for Azure VM Applications using Azure Policy

Summarize this article for me

Azure VM Applications let you package, version, and deliver software to Azure Virtual Machines (VMs) and Virtual Machine Scale Sets from an Azure Compute Gallery.

Using Azure Policy with VM Applications enables customers and admin teams to:

- Monitor presence of required VM Applications across Virtual Machines & Virtual Machines Scale Sets.
- Inject required VM Applications across all Virtual Machines & Virtual Machine Scale Sets.
- Enforce consistent configuration and best practices across all Virtual Machines and Virtual Machine Scale Sets for improved reliability and security.

This guide shows how to:

- Govern required VM application for compliance monitoring.
- Enforce required VM Application for driving consistency and security.

Prerequisites

- An Azure Compute Gallery with the published VM Application and versions to enforce. See create and manage VM Applications.
  - Ensure the version is replicated to all regions where the application presence is required.
  - Ensure the gallery is shared to all subscriptions requiring access to the VM Application.
- Permissions:
  - Policy Contributor to create/assign policies. See policy definition structure and assignments.

Set up compliance monitor to govern required VM applications

Azure Policy with `audit` effect can be used to monitor presence of specific VM Applications across Azure Virtual Machine and Virtual Machine Scale Sets. Admin teams can use this policy to

- Setup compliance monitors for VM Applications (view compliant vs noncompliant Virtual Machines and Virtual Machine Scale Sets)
- Measuring rollout progress of software packaged as a VM Application.

1. Create a custom policy definition

Create a new custom policy using the following definition. This policy checks whether specific VM Applications are present on Virtual Machines and Virtual Machine Scale Sets, and reports compliance status.

Policy

This policy monitors compliance of all Virtual Machines, Virtual Machines Scale Sets across linux and windows. Linux apps on windows VMs and windows apps on linux VMs are considered as compliant resources.

JSON

```
{
    "mode": "Indexed",
    "policyRule": {
        "if": {
            "anyOf": [
                {
                    "allOf": [
                        { "field": "type", "equals":
"Microsoft.Compute/virtualMachines" },
                        {"field":
"Microsoft.Compute/virtualMachines/storageProfile.osDisk.osType", "equals": "
[parameters('osType')]" },
                        {
                            "count": {
                                "field":
"Microsoft.Compute/virtualMachines/applicationProfile.galleryApplications[*]",
                                "where": {
                                    "allOf": [
                                        {
                                            "field":
"Microsoft.Compute/virtualMachines/applicationProfile.galleryApplications[*].pa
ckageReferenceId",
                                            "contains": "[concat('/galleries/',
parameters('galleryName'), '/applications/', parameters('applicationName'),
'/')]"
                                        }
                                    ]
                                }
                            },
                            "equals": 0
                        }
```

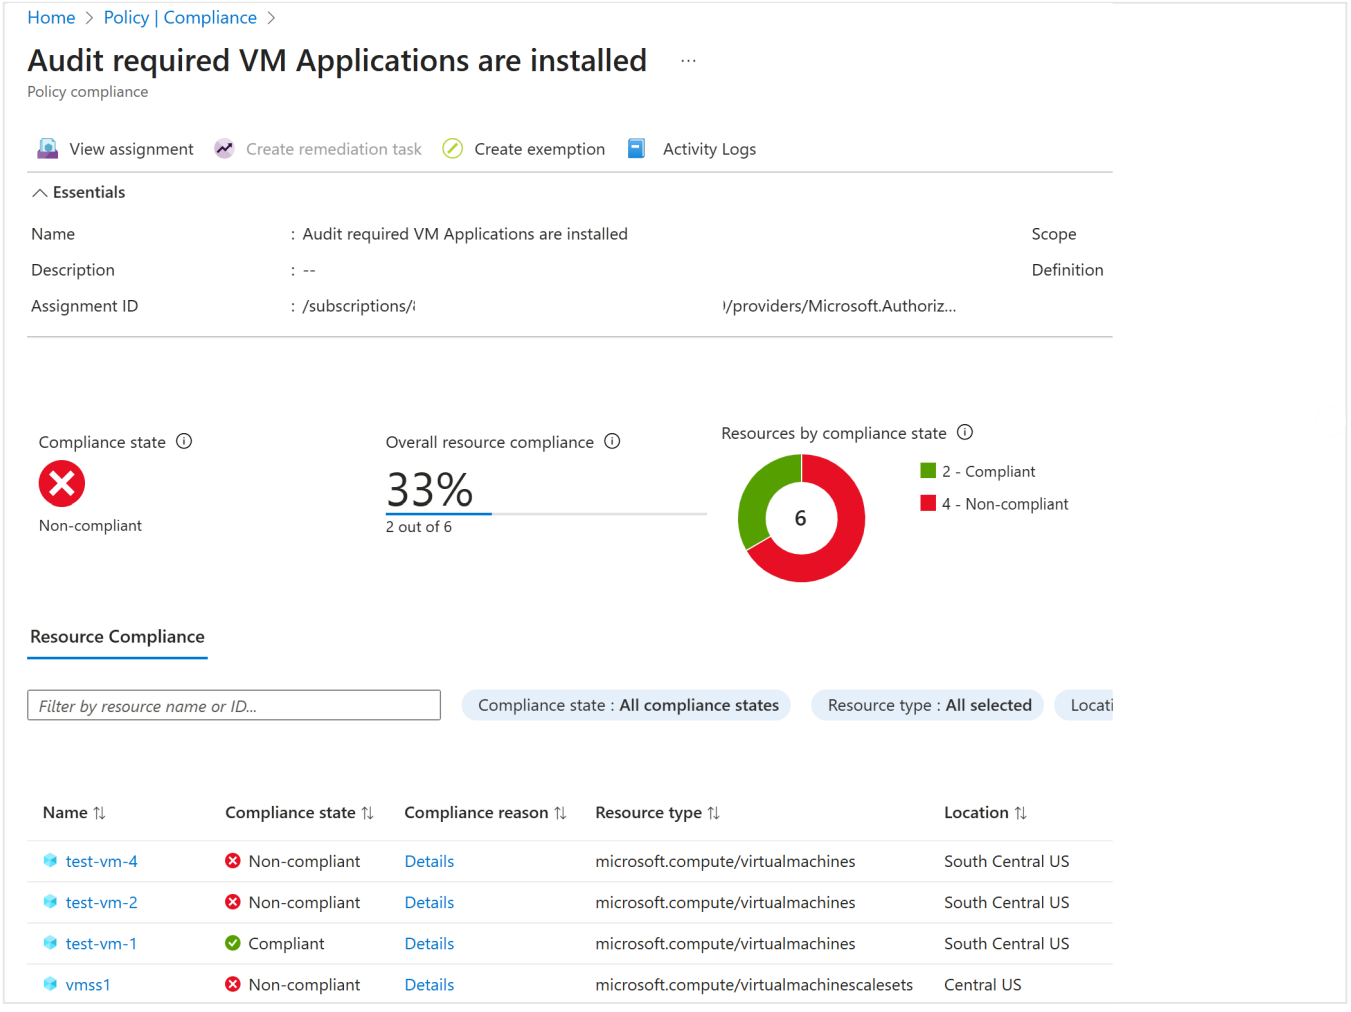
```
                    ]
                },
                {
                    "allOf": [
                        { "field": "type", "equals":
"Microsoft.Compute/virtualMachineScaleSets" },
                        {"field":
"Microsoft.Compute/virtualMachineScaleSets/virtualMachineProfile.storageProfile
.osDisk.osType", "equals": "[parameters('osType')]" },
                        {
                            "count": {
                                "field":
"Microsoft.Compute/virtualMachineScaleSets/virtualMachineProfile.applicationPro
file.galleryApplications[*]",
                                "where": {
                                    "allOf": [
                                        {
                                            "field":
"Microsoft.Compute/virtualMachineScaleSets/virtualMachineProfile.applicationPro
file.galleryApplications[*].packageReferenceId",
                                            "contains": "[concat('/galleries/',
parameters('galleryName'), '/applications/', parameters('applicationName'),
'/')]"
                                        }
                                    ]
                                }
                            },
                            "equals": 0
                        }
                    ]
                }
            ]
        },
        "then": { "effect": "audit" }
    },
    "parameters": {
        "galleryName": {
            "type": "String",
            "metadata": { "description": "Name of the Azure Compute Gallery
containing the VM Application." }
        },
        "applicationName": {
            "type": "String",
            "metadata": { "description": "Name of the VM Application to audit
for presence." }
        },
        "osType": {
            "type": "String",
            "allowedValues": [ "Windows", "Linux" ],
            "metadata": { "description": "OS type of the VM Application
(Windows or Linux)." }
        }
    }
}
```

2. Assign the policy and view compliance

Assign the newly created policy to start monitoring the VM application and generate compliance score. All Virtual Machines and Virtual Machine Scale Sets within the assigned scope are monitored for compliance.

Create separate assignments per VM application for granular and accurate monitoring.

Once the policy is assigned, all existing resources are evaluated and displayed on compliance monitor. Noncompliant resources are missing the VM Application defined in the policy. Resources without `applicationProfile` are also counted as noncompliant. Newly created or updated resources may take a few minutes to appear in evaluation cycles.



Common adjustments

- **Audit multiple required applications**: Create a separate policy (one per application) or update the policy by adding other applications under `allOf` parameter.

- **Block creation of Virtual Machines without the required applications**: Change effect to `deny` to prevent noncompliant creations.
- **Limit policy scope to Virtual Machines or Virtual Machine Scale Sets**: Remove the unused branch from `anyOf` within `policyRule`.
- **Limit policy scope by OS type**: Check `osType` of `storageProfile` within `policyRule` to filter based on Window / Linux OS:

  JSON

  ```
  { "field": "Microsoft.Compute/virtualMachines/storageProfile.osDisk.osType",
  "equals": "[parameters('osType')]" }
  ```

- **Limit policy scope by OS Image**: Check `offer` and `sku` within `policyRule` to filter based on image:

  JSON

  ```
  { "field":
  "Microsoft.Compute/virtualMachines/storageProfile.imageReference.offer",
  "equals": "[parameters('imageOffer')]" },
  { "field":
  "Microsoft.Compute/virtualMachines/storageProfile.imageReference.sku",
  "equals": "[parameters('imageSku')]" }
  ```

Inject VM Applications on Virtual Machine and Virtual Machine Scale Sets

Azure Policy with `modify` effect injects VM applications while creating new Virtual Machine and Virtual Machine Scale Sets. Remediation tasks can be used to modify existing resources and inject the VM Application.

Pre-requisite

- Managed identity on the policy assignment with **Virtual Machine Contributor** role, so remediation can modify resources. See remediation identity requirements.

1. Create a custom policy definition

Create a new custom policy using the policy definition. This policy checks for the presence of VM applications while creating Virtual Machines or Virtual Machine Scale Sets and appends the VM application if it doesn't exist. To modify multiple resource types (Virtual Machine and Virtual Machine Scale Sets), it's recommended to create different policies per resource type.

VM

JSON

```
{
    "displayName": "Inject VM Application into single instance VMs",
    "policyType": "Custom",
    "mode": "Indexed",
    "description": "Appends a VM Application reference to applicationProfile
for single instance VMs if the application is not already present. Filters by
OS type to prevent cross-platform injection.",
    "parameters": {
      "subscriptionId": {
        "type": "String",
        "metadata": {
          "description": "Subscription ID where the Compute Gallery resides."
        }
      },
      "resourceGroup": {
        "type": "String",
        "metadata": {
          "description": "Resource group of the Compute Gallery."
        }
      },
      "galleryName": {
        "type": "String",
        "metadata": {
          "description": "Name of the Compute Gallery."
        }
      },
      "applicationName": {
        "type": "String",
        "metadata": {
          "description": "VM Application name."
        }
      },
      "applicationVersion": {
        "type": "String",
        "defaultValue": "latest",
        "metadata": {
          "description": "VM Application version. Defaults to latest."
        }
      },
      "osType": {
        "type": "String",
        "allowedValues": [
```

```
          "Windows",
          "Linux"
        ],
        "metadata": {
          "description": "Target OS type. Ensures the application is only
injected onto VMs with a matching OS."
        }
      }
    },
    "policyRule": {
      "if": {
        "allOf": [
          {
            "field": "type",
            "equals": "Microsoft.Compute/virtualMachines"
          },
          {
            "field":
"Microsoft.Compute/virtualMachines/storageProfile.osDisk.osType",
            "equals": "[parameters('osType')]"
          },
          {
            "count": {
              "field":
"Microsoft.Compute/virtualMachines/applicationProfile.galleryApplications[*]",
              "where": {
                "field":
"Microsoft.Compute/virtualMachines/applicationProfile.galleryApplications[*].pa
ckageReferenceId",
                "contains": "[concat('/galleries/', parameters('galleryName'),
'/applications/', parameters('applicationName'), '/')]"
              }
            },
            "equals": 0
          }
        ]
      },
      "then": {
        "effect": "modify",
        "details": {

4d73-94e8-173b1dc7cf3c"
          ],
          "operations": [
            {
              "operation": "add",
              "field":
"Microsoft.Compute/virtualMachines/applicationProfile.galleryApplications",
              "value": {
                "packageReferenceId": "[concat('/subscriptions/',
parameters('subscriptionId'), '/resourceGroups/', parameters('resourceGroup'),
'/providers/Microsoft.Compute/galleries/', parameters('galleryName'),
'/applications/', parameters('applicationName'), '/versions/',
parameters('applicationVersion'))]",
```

```
                "order": 1,
                "treatFailureAsDeploymentFailure": true
              }
            }
          ]
        }
      }
    }
}
```

2. Assign the policy

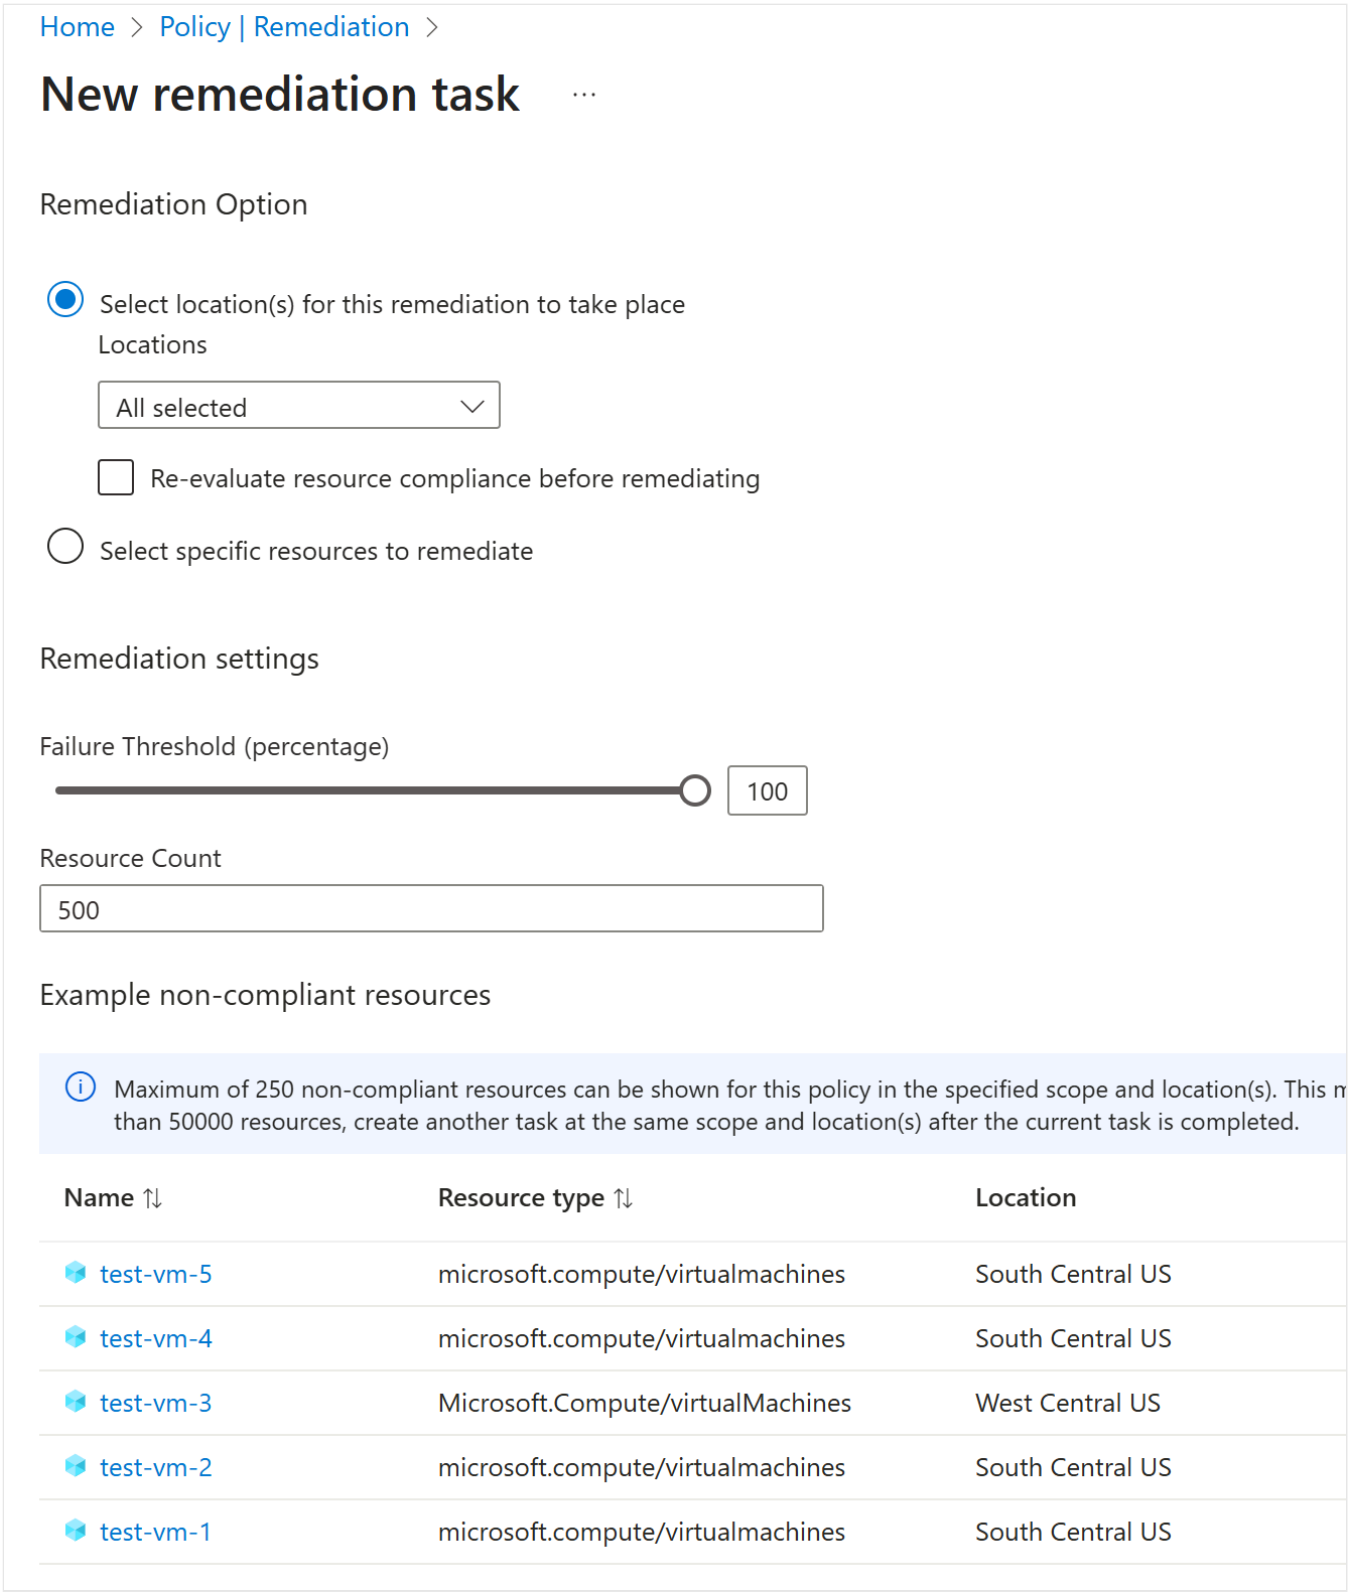
Assign the newly created policy to start generating compliance score. All Virtual Machines and Virtual Machine Scale Sets within the assigned scope are monitored for compliance. Once the policy is assigned, all existing resources are evaluated and displayed on compliance monitor.

Creating new Virtual Machines and Virtual Machine Scale Sets resource triggers this policy and modifies the applicationProfile of the resource to inject the application.

3. Create Remediation Task and modify existing resources

To modify existing resources, create a new Remediation tasks.

> **Note**
>
> Gradually remediate noncompliant resources for higher availability and failure resiliency. Create multiple remediation tasks, each scoped to one or more regions.



Common adjustments

The following examples show more conditions you can add to the `allOf` block within `policyRule` to narrow the policy scope.

- **Limit policy scope by OS image**: Filter based on a specific image offer and SKU:

  JSON

```
{ "field":
"Microsoft.Compute/virtualMachines/storageProfile.imageReference.offer",
"equals": "[parameters('imageOffer')]" },
{ "field":
"Microsoft.Compute/virtualMachines/storageProfile.imageReference.sku",
"equals": "[parameters('imageSku')]" }
```

- **Limit policy scope by region**: Target specific Azure regions:

  JSON

  ```
  { "field": "location", "in": "[parameters('allowedLocations')]" }
  ```

- **Limit policy scope by resource group or subscription**: To reduce the scope for remediation, assign the policy to a specific resource group or subscription. Use the assignment scope when assigning the policy rather than modifying the policy definition. For more granular control, use exclusions to omit specific resource groups from the assignment.

Find Azure Marketplace image information using the Azure CLI

Article • 08/22/2024

> **⊗ Caution**
>
> This article references CentOS, a Linux distribution that is End Of Life (EOL) status. Please consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This topic describes how to use the Azure CLI to find VM images in the Azure Marketplace. Use this information to specify a Marketplace image when you create a VM programmatically with the CLI, Resource Manager templates, or other tools.

You can also browse available images and offers using the Azure Marketplace or Azure PowerShell.

Terminology

A Marketplace image in Azure has the following attributes:

- **Publisher**: The organization that created the image. Examples: Canonical, RedHat, SUSE.
- **Offer**: The name of a group of related images created by a publisher. Examples: 0001-com-ubuntu-server-jammy, RHEL, sles-15-sp3.
- **SKU**: An instance of an offer, such as a major release of a distribution. Examples: 22_04-lts-gen2, 8-lvm-gen2, gen2.
- **Version**: The version number of an image SKU.

These values can be passed individually or as an image *URN*, combining the values separated by the colon (:). For example: *Publisher*:*Offer*:*Sku*:*Version*. You can replace the version number in the URN with `latest` to use the latest version of the image.

If the image publisher provides extra license and purchase terms, then you must accept those terms before you can use the image. For more information, see Check the purchase plan information.

List popular images

You can run the az vm image list --all to see all of the images available to you, but it can take several minutes to produce the entire list. A faster option is the use `az vm image list`, without the `--all` option, to see a list of popular VM images in the Azure Marketplace. For example, run the following command to display a cached list of popular images in table format:

Azure CLI

```
az vm image list --output table
```

The output includes the image URN. If you omit the `--all` option, you can see the *UrnAlias* for each image, if available. *UrnAlias* is a shortened version created for popular images like *Ubuntu2204*. The Linux image alias names and their details outputted by this command are:

Output

```
Architecture    Offer                         Publisher              Sku

Datacenter:latest                    Win2012Datacenter         latest
```

Find specific images

You can filter the list of images by `--publisher` or another parameter to limit the results.

For example, the following command displays all Debian offers:

Azure CLI

```
az vm image list --offer Debian --all --output table
```

You can limit your results to a single architecture by adding the `--architecture` parameter. For example, to display all Arm64 images available from Canonical:

Azure CLI

```
az vm image list --architecture Arm64 --publisher Canonical --all --output
table
```

Look at all available images

Another way to find an image in a location is to run the az vm image list-publishers, az vm image list-offers, and az vm image list-skus commands in sequence. With these commands, you determine these values:

1. List the image publishers for a location. In this example, we're looking at the *West US* region.

   Azure CLI

   ```
   az vm image list-publishers --location westus --output table
   ```

2. For a given publisher, list their offers. In this example, we add *RedHat* as the publisher.

   Azure CLI

   ```
   az vm image list-offers --location westus --publisher RedHat --output
   table
   ```

3. For a given offer, list their SKUs. In this example, we add *RHEL* as the offer.

   Azure CLI

   ```
   az vm image list-skus --location westus --publisher RedHat --offer RHEL
   --output table
   ```

> **Note**
>
> Canonical has changed the **Offer** names they use for the most recent versions. Before Ubuntu 20.04, the **Offer** name is UbuntuServer. For Ubuntu 20.04 the **Offer** name is `0001-com-ubuntu-server-focal` and for Ubuntu 22.04 it's `0001-com-ubuntu-server-jammy`.

1. For a given publisher, offer, and SKU, show all of the versions of the image. In this example, we add *9_1* as the SKU.

   Azure CLI

   ```
   az vm image list \
       --location westus \
       --publisher RedHat \
   ```

```
    --offer RHEL \
    --sku 9_1 \
    --all --output table
```

Pass this value of the URN column with the `--image` parameter when you create a VM with the az vm create command. You can also replace the version number in the URN with "latest", to use the latest version of the image.

If you deploy a VM with a Resource Manager template, you set the image parameters individually in the `imageReference` properties. See the template reference.

Check the purchase plan information

Some VM images in the Azure Marketplace have extra license and purchase terms that you must accept before you can deploy them programmatically.

To deploy a VM from such an image, you'll need to accept the image's terms the first time you use it, once per subscription. You'll also need to specify *purchase plan* parameters to deploy a VM from that image

To view an image's purchase plan information, run the az vm image show command with the URN of the image. If the `plan` property in the output isn't `null`, the image has terms you need to accept before programmatic deployment.

For example, the Canonical Ubuntu Server 18.04 LTS image doesn't have extra terms, because the `plan` information is `null`:

Azure CLI

```
az vm image show --location westus --urn Canonical:UbuntuServer:18.04-
LTS:latest
```

Output:

Output

```
{
  "dataDiskImages": [],
  "id": "/Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/Canonic
al/ArtifactTypes/VMImage/Offers/UbuntuServer/Skus/18.04-
LTS/Versions/18.04.201901220",
  "location": "westus",
  "name": "18.04.201901220",
  "osDiskImage": {
    "operatingSystem": "Linux"
```

```
  },
  "plan": null,
  "tags": null
}
```

Running a similar command for the RabbitMQ Certified by Bitnami image shows the following `plan` properties: `name`, `product`, and `publisher`. (Some images also have a `promotion code` property.)

Azure CLI

```
az vm image show --location westus --urn bitnami:rabbitmq:rabbitmq:latest
```

Output:

Output

```
{
  "dataDiskImages": [],
  "id": "/Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/bitnami
/ArtifactTypes/VMImage/Offers/rabbitmq/Skus/rabbitmq/Versions/3.7.1901151016
",
  "location": "westus",
  "name": "3.7.1901151016",
  "osDiskImage": {
    "operatingSystem": "Linux"
  },
  "plan": {
    "name": "rabbitmq",
    "product": "rabbitmq",
    "publisher": "bitnami"
  },
  "tags": null
}
```

To deploy this image, you need to accept the terms and provide the purchase plan parameters when you deploy a VM using that image.

Accept the terms

To view and accept the license terms, use the az vm image terms command. When you accept the terms, you enable programmatic deployment in your subscription. You only need to accept terms once per subscription for the image. For example:

Azure CLI

```
az vm image terms show --urn bitnami:rabbitmq:rabbitmq:latest
```

The output includes a `licenseTextLink` to the license terms, and indicates that the value of `accepted` is `true`:

Output

```
{
  "accepted": true,
  "additionalProperties": {},
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/providers/Microsoft.MarketplaceOrdering/offertypes/bitnami/offe
rs/rabbitmq/plans/rabbitmq",
  "licenseTextLink":
"https://storelegalterms.blob.core.windows.net/legalterms/3E5ED_legalterms_B
ITNAMI%253a24RABBITMQ%253a24RABBITMQ%253a24IGRT7HHPIFOBV3IQYJHEN2O2FGUVXXZ3W
UYIMEIVF3KCUNJ7GTVXNNM23I567GBMNDWRFOY4WXJPN5PUYXNKB2QLAKCHP4IE5GO3B2I.txt",
  "name": "rabbitmq",
  "plan": "rabbitmq",
  "privacyPolicyLink": "https://bitnami.com/privacy",
  "product": "rabbitmq",
  "publisher": "bitnami",
  "retrieveDatetime": "2019-01-25T20:37:49.937096Z",
  "signature":
"XXXXXXLAZIK7ZL2YRV5JYQXONPV76NQJW3FKMKDZYCRGXZYVDGX6BVY45JO3BXVMNA2COBOEYG2
NO76ONORU7ITTRHGZDYNJNXXXXXX",
  "type": "Microsoft.MarketplaceOrdering/offertypes"
}
```

To accept the terms, type:

Azure CLI

```
az vm image terms accept --urn bitnami:rabbitmq:rabbitmq:latest
```

Deploy a new VM using the image parameters

With information about the image, you can deploy it using the `az vm create` command.

To deploy an image that doesn't have plan information, like the latest Ubuntu Server 18.04 image from Canonical, pass the URN for `--image`:

Azure CLI

```
az group create --name myURNVM --location westus
az vm create \
```

```
    --resource-group myURNVM \
    --name myVM \
    --admin-username azureuser \
    --generate-ssh-keys \
    --image Canonical:UbuntuServer:18.04-LTS:latest
```

For an image with purchase plan parameters, like the RabbitMQ Certified by Bitnami image, you pass the URN for `--image` and also provide the purchase plan parameters:

Azure CLI

```
az group create --name myPurchasePlanRG --location westus

az vm create \
   --resource-group myPurchasePlanRG \
   --name myVM \
   --admin-username azureuser \
   --generate-ssh-keys \
   --image bitnami:rabbitmq:rabbitmq:latest \
   --plan-name rabbitmq \
   --plan-product rabbitmq \
   --plan-publisher bitnami
```

If you get a message about accepting the terms of the image, review section Accept the terms. Make sure the output of `az vm image accept-terms` returns the value `"accepted": true,` showing that you've accepted the terms of the image.

Using an existing VHD with purchase plan information

If you have an existing VHD from a VM that was created using a paid Azure Marketplace image, you might need to give the purchase plan information when creating a new VM from that VHD.

If you still have the original VM, or another VM created using the same marketplace image, you can get the plan name, publisher, and product information from it using az vm get-instance-view. This example gets a VM named *myVM* in the *myResourceGroup* resource group and then displays the purchase plan information.

Azure CLI

```
az vm get-instance-view -g myResourceGroup -n myVM --query plan
```

If you didn't get the plan information before the original VM was deleted, you can file a support request. They'll need the VM name, subscription ID and the time stamp of the delete operation.

Once you have the plan information, you can create the new VM using the `--attach-os-disk` parameter to specify the VHD.

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name myNewVM \
  --nics myNic \
  --size Standard_DS1_v2 --os-type Linux \
  --attach-os-disk myVHD \
  --plan-name planName \
  --plan-publisher planPublisher \
  --plan-product planProduct
```

Next steps

To create a virtual machine quickly by using the image information, see Create and Manage Linux VMs with the Azure CLI.

Find and use Azure Marketplace VM images with Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article describes how to use Azure PowerShell to find VM images in the Azure Marketplace. You can then specify a Marketplace image and plan information when you create a VM.

You can also browse available images and offers using the Azure Marketplace or the Azure CLI.

Terminology

A Marketplace image in Azure has the following attributes:

- **Publisher**: The organization that created the image. Examples: Canonical, MicrosoftWindowsServer
- **Offer**: The name of a group of related images created by a publisher. Examples: UbuntuServer, WindowsServer
- **SKU**: An instance of an offer, such as a major release of a distribution. Examples: 18.04-LTS, 2019-Datacenter
- **Version**: The version number of an image SKU.

These values can be passed individually or as an image *URN*, combining the values separated by the colon (:). For example: *Publisher*:*Offer*:*Sku*:*Version*. You can replace the version number in the URN with `latest` to use the latest version of the image.

If the image publisher provides other license and purchase terms, then you must accept those before you can use the image. For more information, see Accept purchase plan terms.

Default Images

Powershell offers several pre-defined image aliases to make the resource creation process easier. There are different images for resources with either a Windows or Linux operating system. Several Powershell cmdlets, such as `New-AzVM` and `New-AzVmss`, allow you to input the alias name as a parameter. For example:

PowerShell

```
$rgname = <Resource Group Name>
$location = <Azure Region>
$vmName = "v" + $rgname
$domainNameLabel = "d" + $rgname
$securePassword = <Password> | ConvertTo-SecureString -AsPlainText -Force
$username = <Username>
$credential = New-Object System.Management.Automation.PSCredential
($username, $securePassword)
New-AzVM -ResourceGroupName $rgname -Location $location -Name $vmName -image
Ubuntu2204 -Credential $credential -DomainNameLabel $domainNameLabel
```

The Linux image alias names and their details are:

Output

```
Alias                     Architecture    Offer
Publisher               Sku                                 Urn

```

List images

You can use PowerShell to narrow down a list of images if you want to use a specific image that is not provided by default. Replace the values of the below variables to meet your needs.

1. List the image publishers using Get-AzVMImagePublisher.

   PowerShell

   ```powershell
   $locName="<location>"
   Get-AzVMImagePublisher -Location $locName | Select PublisherName
   ```

2. For a given publisher, list their offers using Get-AzVMImageOffer.

   PowerShell

   ```powershell
   $pubName="<publisher>"
   Get-AzVMImageOffer -Location $locName -PublisherName $pubName | Select
   ```

```
Offer
```

3. For a given publisher and offer, list the SKUs available using Get-AzVMImageSku.

```PowerShell
$offerName="<offer>"
Get-AzVMImageSku -Location $locName -PublisherName $pubName -Offer
$offerName | Select Skus
```

4. For a SKU, list the versions of the image using Get-AzVMImage.

```PowerShell
$skuName="<SKU>"
Get-AzVMImage -Location $locName -PublisherName $pubName -Offer
$offerName -Sku $skuName | Select Version
```

   You can also use `latest` if you want to use the latest image and not a specific older version.

Now you can combine the selected publisher, offer, SKU, and version into a URN (values separated by :). Pass this URN with the `-Image` parameter when you create a VM with the New-AzVM cmdlet. You can also replace the version number in the URN with `latest` to get the latest version of the image.

If you deploy a VM with a Resource Manager template, then you must set the image parameters individually in the `imageReference` properties. See the template reference.

View purchase plan properties

Some VM images in the Azure Marketplace have other license and purchase terms that you must accept before you can deploy them programmatically. You need to accept the image's terms once per subscription.

To view an image's purchase plan information, run the `Get-AzVMImage` cmdlet. If the `PurchasePlan` property in the output is not `null`, the image has terms you need to accept before programmatic deployment.

For example, the *Windows Server 2016 Datacenter* image doesn't have additional terms, so the `PurchasePlan` information is `null`:

```PowerShell
```

```
$version = "2016.127.20170406"
Get-AzVMImage -Location $locName -PublisherName $pubName -Offer $offerName -
Skus $skuName -Version $version
```

The output looks similar to the following output:

Output

```
Id                : /Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/Microso
ftWindowsServer/ArtifactTypes/VMImage/Offers/WindowsServer/Skus/2016-
Datacenter/Versions/2019.0.20190115
Location          : westus
PublisherName     : MicrosoftWindowsServer
Offer             : WindowsServer
Skus              : 2019-Datacenter
Version           : 2019.0.20190115
FilterExpression  :
Name              : 2019.0.20190115
OSDiskImage       : {
                      "operatingSystem": "Windows"
                    }
PurchasePlan      : null
DataDiskImages    : []
```

The example below shows a similar command for the *Data Science Virtual Machine - Windows 2016* image, which has the following `PurchasePlan` properties: `name`, `product`, and `publisher`. Some images also have a `promotion code` property. To deploy this image, see the following sections to accept the terms and to enable programmatic deployment.

PowerShell

```
Get-AzVMImage -Location "westus" -PublisherName "microsoft-ads" -Offer
"windows-data-science-vm" -Skus "windows2016" -Version "0.2.02"
```

The output looks similar to the following output:

```
Id                : /Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/microso
ft-ads/ArtifactTypes/VMImage/Offers/windows-data-science-
vm/Skus/windows2016/Versions/19.01.14
Location          : westus
PublisherName     : microsoft-ads
Offer             : windows-data-science-vm
```

```
Skus             : windows2016
Version          : 19.01.14
FilterExpression :
Name             : 19.01.14
OSDiskImage      : {
                     "operatingSystem": "Windows"
                   }
PurchasePlan     : {
                     "publisher": "microsoft-ads",
                     "name": "windows2016",
                     "product": "windows-data-science-vm"
                   }
DataDiskImages   : []
```

To view the license terms, use the Get-AzMarketplaceterms cmdlet and pass in the purchase plan parameters. The output provides a link to the terms for the Marketplace image and shows whether you previously accepted the terms. Be sure to use all lowercase letters in the parameter values.

PowerShell

```
Get-AzMarketplaceterms -Publisher "microsoft-ads" -Product "windows-data-
science-vm" -Name "windows2016"
```

The output will look similar to the following:

Output

```
Publisher         : microsoft-ads
Product           : windows-data-science-vm
Plan              : windows2016
LicenseTextLink   :

Accepted          : False
Signdate          : 1/25/2019 7:43:00 PM
```

Accept purchase plan terms

Use the Set-AzMarketplaceterms cmdlet to accept or reject the terms. You only need to accept terms once per subscription for the image. Be sure to use all lowercase letters in the parameter values.

PowerShell

```
$agreementTerms=Get-AzMarketplaceterms -Publisher "microsoft-ads" -Product
"windows-data-science-vm" -Name "windows2016"

Set-AzMarketplaceTerms -Publisher "microsoft-ads" -Product "windows-data-
science-vm" -Name "windows2016" -Terms $agreementTerms -Accept
```

Output

```
Publisher         : microsoft-ads
Product           : windows-data-science-vm
Plan              : windows2016
LicenseTextLink   :

Create a new VM from a marketplace image

If you already have the information about what image you want to use, you can pass that information into Set-AzVMSourceImage cmdlet to add image information to the VM configuration. See the next sections for searching and listing the images available in the marketplace.

Some paid images also require that you provide purchase plan information using the Set-AzVMPlan.

PowerShell

```
...

$vmConfig = New-AzVMConfig -VMName "myVM" -VMSize Standard_D1
```

```
# Set the Marketplace image
$offerName = "windows-data-science-vm"
$skuName = "windows2016"
$version = "19.01.14"
$vmConfig = Set-AzVMSourceImage -VM $vmConfig -PublisherName $publisherName
-Offer $offerName -Skus $skuName -Version $version

# Set the Marketplace plan information, if needed
$publisherName = "microsoft-ads"
$productName = "windows-data-science-vm"
$planName = "windows2016"
$vmConfig = Set-AzVMPlan -VM $vmConfig -Publisher $publisherName -Product
$productName -Name $planName

...
```

You'll then pass the VM configuration along with the other configuration objects to the `New-AzVM` cmdlet. For a detailed example of using a VM configuration with PowerShell, see this script.

If you get a message about accepting the terms of the image, see the earlier section Accept purchase plan terms.

Create a new VM from a VHD with purchase plan information

If you have an existing VHD that was created using an Azure Marketplace image, you might need to supply the purchase plan information when you create a new VM from that VHD.

If you still have the original VM, or another VM created from the same image, you can get the plan name, publisher, and product information from it using Get-AzVM. This example gets a VM named *myVM* in the *myResourceGroup* resource group and then displays the purchase plan information.

Azure PowerShell

```
$vm = Get-azvm `
   -ResourceGroupName myResourceGroup `
   -Name myVM
$vm.Plan
```

If you didn't get the plan information before the original VM was deleted, you can file a support request. The support request needs at minimum the VM name, subscription ID and the time stamp of the delete operation.

To create a VM using a VHD, refer to this article Create a VM from a specialized VHD and add in a line to add the plan information to the VM configuration using Set-AzVMPlan similar to the following:

Azure PowerShell

```
$vmConfig = Set-AzVMPlan `
    -VM $vmConfig `
    -Publisher "publisherName" `
    -Product "productName" `
    -Name "planName"
```

Next steps

To create a virtual machine quickly with the `New-AzVM` cmdlet by using basic image information, see Create a Windows virtual machine with PowerShell.

For more information on using Azure Marketplace images to create custom images in an Azure Compute Gallery (formerly known as Shared Image Gallery), see Supply Azure Marketplace purchase plan information when creating images.

Use Windows client in Azure for dev/test scenarios

05/22/2025

Applies to: ✔ Windows VMs

You can use Windows 10 Enterprise (x64) or Windows 11 Enterprise (x64) in Azure for dev/test scenarios provided you have an appropriate Visual Studio (formerly MSDN) subscription.

To run Windows 10 or 11 in a production environment see, How to deploy Windows 10 or 11 on Azure with Multitenant Hosting Rights.

Subscription eligibility

Active Visual Studio subscribers (people who have acquired a Visual Studio subscription license) can use Windows client images for development and testing purposes. Windows client images can be used on your own hardware or on Azure virtual machines.

Certain Windows client images are available from the Azure Marketplace. Visual Studio subscribers within any type of offer can also prepare and create 64-bit Windows 10 or 11 images and then upload to Azure.

Eligible offers and client images

The following table details the offer IDs that are eligible to deploy Windows client images through the Azure Marketplace. The Windows client images are only visible to the following offers.

> **Note**
>
> Image offers are under **Windows Client** in the Azure Marketplace. Use **Windows Client** when searching for client images available to Visual Studio subscribers. If you need to purchase a Visual Studio subscription, see the various options at Buy Visual Studio

Expand table

Offer Name	Offer Number	Available client images
Pay-As-You-Go Dev/Test	0023P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)

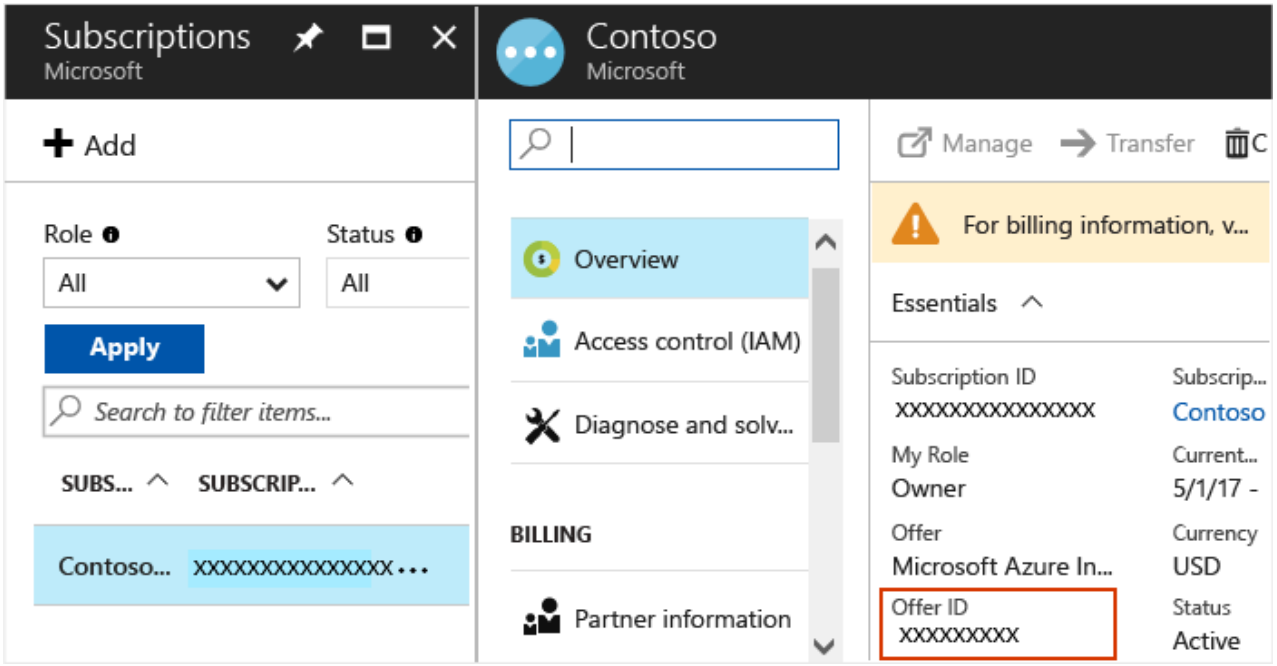
Offer Name	Offer Number	Available client images
Visual Studio Enterprise (MPN) subscribers	0029P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)
Visual Studio Professional subscribers	0059P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)
Visual Studio Test Professional subscribers	0060P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)
Visual Studio Enterprise subscribers	0063P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)
Visual Studio Enterprise (BizSpark) subscribers	0064P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)
Enterprise Dev/Test	0148P	Windows 10 Enterprise N (x64) Windows 11 Enterprise (x64)

For more information, see Understand Microsoft offer types

Check your Azure subscription

If you do not know your offer ID, you can obtain it through the Azure portal.

- On the *Subscriptions* window:



- Or, click **Billing** and then click your subscription ID. The offer ID appears in the *Billing* window.

Next steps

You can now deploy your VMs using PowerShell, Resource Manager templates, or Visual Studio.

How to deploy Windows 11 on Azure

05/22/2025

Applies to: ✔ Windows VMs ✔ Flexible scale sets

For customers with Windows 11 Enterprise E3/E5 per user or Azure Virtual Desktop Access per user (User Subscription Licenses or Add-on User Subscription Licenses), Multitenant Hosting Rights for Windows 11 allows you to bring your Windows 11 Licenses to the cloud and run Windows 11 Virtual Machines on Azure without paying for another license.

For more information, see Multitenant Hosting for Windows 11.

> **Note**
>
> - To use Windows 10 or 11 images for development or testing see Windows client in Azure for dev/test scenarios
> - Student & Free Trial accounts are enabled to deploy Windows 11 images for development or testing purposes.
> - For Windows Server licensing benefits, please refer to Azure Hybrid use benefits for Windows Server images.
> - When selecting a VM size, ensure the size meets the Windows 11 hardware minimum requirements

Subscription Licenses that qualify for Multitenant Hosting Rights

For more details about subscription licenses that qualify to run Windows 11 on Azure, download the Windows 11 licensing brief for Virtual Desktops

> **Important**
>
> Users **must** have one of the below subscription licenses in order to use Windows 11 images in Azure for any production workload. If you do not have one of these subscription licenses, they can be purchased through your Cloud Service Partner or directly through Microsoft.

Operating systems and licenses

You have a choice of operating systems that you can use for session hosts to provide virtual desktops and remote apps. You can use different operating systems with different host pools to provide flexibility to your users. Supported dates are inline with the Microsoft Lifecycle Policy. We support the following 64-bit versions of these operating systems:

Operating system licenses

- Windows 11 Enterprise multi-session
- Windows 11 Enterprise
- Windows 10 Enterprise, version 1909 and later (For Windows 10 deployments)

License entitlement

- Microsoft 365 E3, E5, A3, A5, F3, Business Premium, Student Use Benefit
- Windows Enterprise E3, E5
- Windows VDA E3, E5
- Windows Education A3, A5

External users can use per-user access pricing instead of license entitlement.

Deploying Windows 11 Image from Azure Marketplace

For PowerShell, CLI and Azure Resource Manager template deployments, Windows 11 images can be found using the `PublisherName: MicrosoftWindowsDesktop` and `Offer: Windows-11`.

PowerShell

```
Get-AzVmImageSku -Location 'West US' -PublisherName 'MicrosoftWindowsDesktop' -
Offer 'Windows-11'

Skus                Offer      PublisherName           Location
----                -----      -------------           --------
win11-21h2-avd      Windows-11 MicrosoftWindowsDesktop westus
win11-21h2-ent      Windows-11 MicrosoftWindowsDesktop westus
win11-21h2-entn     Windows-11 MicrosoftWindowsDesktop westus
win11-21h2-pro      Windows-11 MicrosoftWindowsDesktop westus
win11-21h2-pron     Windows-11 MicrosoftWindowsDesktop westus
win11-22h2-avd      Windows-11 MicrosoftWindowsDesktop westus
win11-22h2-ent      Windows-11 MicrosoftWindowsDesktop westus
win11-22h2-entn     Windows-11 MicrosoftWindowsDesktop westus
win11-22h2-pro      Windows-11 MicrosoftWindowsDesktop westus
win11-22h2-pron     Windows-11 MicrosoftWindowsDesktop westus
```

For more information on available images, see Find and use Azure Marketplace VM images with Azure PowerShell

> **Note**
>
> If you are upgrading to a newer version of Windows 11 with Trusted launch enabled and you are currently on a Windows 11 version without Trusted Launch enabled, the VM needs to be deallocated before proceeding with the upgrade. For more information, see Enabling Trusted Launch on existing Azure VMs

Uploading Windows 11 VHD to Azure

If you're uploading a generalized Windows 11 VHD, note Windows 11 doesn't have built-in administrator account enabled by default. To enable the built-in administrator account, include the following command as part of the Custom Script extension.

PowerShell

```
Net user <username> /active:yes
```

The following PowerShell snippet is to mark all administrator accounts as active, including the built-in administrator. This example is useful if the built-in administrator username is unknown.

PowerShell

```
$adminAccount = Get-WmiObject Win32_UserAccount -filter "LocalAccount=True" | ?
{$_.SID -Like "S-1-5-21-*-500"}
if($adminAccount.Disabled)
{
    $adminAccount.Disabled = $false
    $adminAccount.Put()
}
```

For more information:

- How to upload VHD to Azure
- How to prepare a Windows VHD to upload to Azure

Deploying Windows 11 with Multitenant Hosting Rights

Make sure you've installed and configured the latest Azure PowerShell. Once you've prepared your VHD, upload the VHD to your Azure Storage account using the `Add-AzVhd` cmdlet as follows:

PowerShell

```
Add-AzVhd -ResourceGroupName "myResourceGroup" -LocalFilePath
"C:\Path\To\myvhd.vhd" `
    -Destination "https://mystorageaccount.blob.core.windows.net/vhds/myvhd.vhd"
```

Deploy using Azure Resource Manager Template Deployment Within your Resource Manager templates, an additional parameter for `licenseType` can be specified. You can read more about authoring Azure Resource Manager templates. Once you've your VHD uploaded to Azure, edit your Resource Manager template to include the license type as part of the compute provider and deploy your template as normal:

JSON

```
"properties": {
    "licenseType": "Windows_Client",
    "hardwareProfile": {
        "vmSize": "[variables('vmSize')]"
    }
```

Deploy via PowerShell When deploying your Windows Server VM via PowerShell, you need to add another parameter for `-LicenseType`. Once you have your VHD uploaded to Azure, you can create a VM using `New-AzVM` and specify the licensing type as follows:

PowerShell

```
New-AzVM -ResourceGroupName "myResourceGroup" -Location "West US" -VM $vm -
LicenseType "Windows_Client"
```

Verify your VM is utilizing the licensing benefit

Once you've deployed your VM through either the PowerShell or Resource Manager deployment method, verify the license type with `Get-AzVM`:

PowerShell

```
Get-AzVM -ResourceGroup "myResourceGroup" -Name "myVM"
```

The output is similar to the following example for Windows 10 with correct license type:

PowerShell

```
Type                    : Microsoft.Compute/virtualMachines
Location                : westus
LicenseType             : Windows_Client
```

This output contrasts with the following VM deployed without Azure Hybrid Use Benefit licensing, such as a VM deployed straight from the Azure Gallery:

PowerShell

```
Type                    : Microsoft.Compute/virtualMachines
Location                : westus
LicenseType             :
```

Additional Information about joining Microsoft Entra ID

Azure provisions all Windows VMs with built-in administrator account, which can't be used to join Microsoft Entra ID. For example, *Settings* > *Account* > *Access Work or School* > + *Connect* won't work. You must create and log on as a second administrator account to join Microsoft Entra ID manually. You can also configure Microsoft Entra ID using a provisioning package, use the link in the *Next Steps* section to learn more.

- Learn more about Multitenant Hosting for Windows 11

Remove machine specific information by deprovisioning or generalizing a VM before creating an image

Summarize this article for me

Generalizing removes machine specific information so the image can be used to create multiple VMs. Once the VM has been generalized or deprovisioned, you need to let the platform know so that the boot sequence can be set correctly.

Generalizing or deprovisioning a VM isn't necessary for creating an image in an Azure Compute Gallery unless you want to create an image that has no machine specific information, like user accounts. Azure Compute Gallery supports *specialized* images that retain machine specific information. For more information, see Generalized and specialized images.

Generalizing is still required when creating a legacy image outside of a gallery.

> **Important**
>
> Once you mark a VM as `generalized` in Azure, you can't restart the VM.

Deprovisioning a Linux VM before creating an image

Use the Azure Linux Agent (waagent) to remove machine-specific information from a Linux VM to prepare it for imaging. Waagent deletes the Azure VM agent's provisioning data, machine-specific files, and the last provisioned user account, making the VM ready to be captured as a reusable image template.

Prerequisites for Linux VMs

Before creating a deprovisioning a VM to create an image, we recommend you follow the distro specific instructions for production workloads. Distribution specific instructions for preparing Linux images for Azure are available here:

- Generic steps
- CentOS
- Debian
- Flatcar

- FreeBSD
- Oracle Linux
- OpenBSD
- Red Hat
- SUSE
- Ubuntu

Deprovision a Linux VM

First you deprovision the VM using the Azure Linux Agent (waagent) to delete machine-specific files and data. Use the `waagent` command with the `-deprovision+user` parameter on your source Linux VM. For more information, see the Azure Linux Agent user guide. This process can't be reversed.

1. Connect to your Linux VM with an SSH client.
2. In the SSH window, enter the following command:

   Bash

   ```
   sudo waagent -deprovision+user
   ```

   > ⓘ **Note**
   >
   > Only run this command on a VM that you'll capture as an image. This command doesn't guarantee that the image is cleared of all sensitive information or is suitable for redistribution. The `+user` parameter also removes the last provisioned user account. To keep user account credentials in the VM, use only `-deprovision`.

3. Type **y** to continue. You can add the `-force` parameter to avoid this confirmation step.
4. After the command completes, type **exit** to close the SSH client. The VM will still be running at this point.

   Deallocate the VM that you deprovisioned with `az vm deallocate` so that it can be generalized.

   Azure CLI

   ```
   az vm deallocate \
      --resource-group myResourceGroup \
      --name myVM
   ```

Then mark the VM as generalized on the platform.

Azure CLI

```
az vm generalize \
   --resource-group myResourceGroup \
   --name myVM
```

Generalizing a Windows VM before creating an image

Sysprep removes all your personal account and security information, and then prepares the machine to be used as an image. For information about Sysprep, see Sysprep overview.

> **Important**
>
> After you have run Sysprep on a VM, that VM is considered *generalized* and can't be restarted. The process of generalizing a VM isn't reversible. If you need to keep the original VM functioning, you should create a snapshot of the OS disk, create a VM from the snapshot, and then generalize that copy of the VM.
>
> Custom answer files aren't supported in the sysprep step, so you can't use the `/unattend:_answerfile_` switch with your sysprep command.

Prerequisites for Windows VMs

- Verify the CD/DVD-ROM is enabled. If it is disabled, the Windows VM will be stuck at out-of-box experience (OOBE). At a command prompt running as an administrator, run the following command:

  Windows Command Prompt

  ```
  REM Enable CD/DVD-ROM
  reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\cdrom /v start /t
  REG_DWORD /d 1 /f
  ```

  The Azure platform mounts an ISO file to the DVD-ROM when a Windows VM is created from a generalized image. For this reason, the **DVD-ROM must be enabled in the OS in the generalized image**. If it is disabled, the Windows VM will be stuck at out-of-box experience (OOBE).

- Verify there are no policies applied restricting removable storage access. For example: Computer configuration\Administrative Templates\System\Removable Storage Access\All Removable Storage classes: Deny all access
- Make sure the server roles running on the machine are supported by Sysprep. For more information, see Sysprep support for server roles and Unsupported scenarios.
- Disable encryption. Sysprep requires the drives to be fully decrypted. If encryption is enabled on your VM, disable encryption before you run Sysprep.
- If you plan to run Sysprep on a local machine before uploading your virtual hard disk (VHD) to Azure for the first time, make sure you have prepared your VM before starting.
- Before generalizing a Windows virtual machine, ensure that all installed applications support Sysprep (preinstalled in an OS image). Some applications (Security related, Store applications, Virtualization agents, etc.) either do not support Sysprep or require a specific preparation process to function correctly in a generalized image. Always review and follow the application's official documentation to confirm the required steps before including it in a reusable image.
- For more information about using Sysprep with SQL, see Install SQL Server with SysPrep.
- For information about using creating images with Microsoft Defender for Endpoint (MDE), see MDE for Non-Persistent VDI — Implementation Guide & Best Practices.

Generalize a Windows VM

To generalize your Windows VM, follow these steps:

1. Sign in to your Windows VM.
2. Open a Command Prompt window as an administrator.
3. Delete the panther directory (C:\Windows\Panther) if it exists. This directory contains logs from previous Sysprep operations that can cause Sysprep to fail.

   Windows Command Prompt

   ```
   rd /s /q C:\Windows\Panther
   ```

4. Change to the %windir%\system32\sysprep directory, and then run:

   Windows Command Prompt

```
sysprep.exe /generalize /shutdown
```

5. The VM will shut down when Sysprep is finished generalizing the VM. Do not restart the VM.

   Once Sysprep has finished, set the status of the virtual machine to **Generalized**.

   Azure PowerShell

   ```
   Set-AzVm -ResourceGroupName $rgName -Name $vmName -Generalized
   ```

Bringing and creating Linux images in Azure

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

This overview covers the basic concepts around imaging and how to successfully build and use Linux images in Azure. Before you bring a custom image to Azure, you need to be aware of the types and options available to you.

This article talks through the image decision points and requirements as well as explain key concepts so that you can follow this and be able to create your own custom images to your specification.

VM scale set lets you deploy and manage a group of identical (or similar) VMs automatically. Azure handles:

- Scaling up/down (adding/removing VMs)
- Load balancing
- Health monitoring
- Zone/region distribution

There are two main types of scale sets:

- Uniform scale set: Use when you want simplicity and speed. All VMs are identical — same size, image, and configuration.
- Flexible scale set: Use when you want flexibility and high availability. VMs can be different sizes or configurations, and you can mix Spot + Regular VMs.

Difference between managed disks and images

Azure allows you to bring a VHD to the platform to use as a Managed Disk or as a source for an image.

An Azure managed disk is a single VHD. You can either take an existing VHD and create a managed disk from it, or create an empty managed disk from scratch. You can create VMs from managed disks by attaching the disk to the VM, but you can only use a VHD with one VM. You won't be able to modify any OS properties as Azure will just try to turn on the VM and start up using that disk.

Azure images can be made up of multiple OS disks and data disks. When you use a managed image to create a VM, the platform makes a copy of the image and uses that to create the VM. This allows managed images to support reusing the same image for multiple VMs. Azure also

provides advanced management capabilities for images, like global replication and versioning through Azure Compute Gallery (formerly known as Shared Image Gallery).

Generalized and specialized

Azure offers two main image types, generalized and specialized. The terms generalized and specialized are originally Windows terms which migrated in to Azure. These types define how the platform handles the VM when it turns it on. Both types have advantages, disadvantages, and prerequisites. Before you get started, you need to know what image type you need. Below summarizes the scenarios and type you would need to choose:

Expand table

Scenario	Image type	Storage options
Create an image that can be configured for use by multiple VMs. You can set the hostname, add an admin user, and perform other tasks during first boot.	Generalized	Azure Compute Gallery or stand-alone managed images
Create an image from a VM snapshot or a backup.	Specialized	Azure Compute Gallery or a managed disk
Quickly create an image that doesn't need any configuration for creating multiple VMs.	Specialized	Azure Compute Gallery

Generalized images

A generalized image is an image that requires setup to be completed on first boot. For example, on first boot you set the hostname, admin user, and other VM-specific configurations. This is useful when you want the image to be reused multiple times and when you want to pass in parameters during creation. If the generalized image contains the Azure agent, the agent processes the parameters and signal back to the platform that the initial configuration has completed. This process is called provisioning.

Provisioning requires that a provisioner is included in the image. There are two provisioners:

- Azure Linux Agent
- cloud-init

These are prerequisites for creating an image.

Specialized images

These are images that are completely configured and don't require VM or special parameters. The platform will just turn on the VM, and you need to handle uniqueness within the VM, like setting a hostname, to avoid DNS conflicts on the same VNET.

Provisioning agents aren't required for these images, however you may want to have extension handling capabilities. You can install the Linux Agent but disable the provisioning option. Even though you don't need a provisioning agent, the image must fulfill prerequisites for Azure Images.

Image storage options

When bringing your Linux image you have two options:

- Managed images for simple VM creation in a development and test environment.
- Azure Compute Gallery for creating and sharing images at-scale.

Managed images

Managed images can be used to create multiple VMs, but they have many limitations. Managed images can only be created from a generalized source (VM or VHD). They can only be used to create VMs in the same region and they can't be shared across subscriptions and tenants.

Managed images can be used for development and test environments, where you need a couple of simple generalized images to use within single region and subscription.

Azure Compute Gallery

Azure Compute Gallery (formerly known as Shared Image Gallery) is recommended for creating, managing, and sharing images at scale. Azure Compute Gallery helps you build structure and organization around your images.

- Support for both generalized and specialized images.
- Support for image both generation 1 and 2 images.
- Global replication of images.
- Versioning and grouping of images for easier management.
- Highly available images with Zone Redundant Storage (ZRS) in regions that support Availability Zones. ZRS offers better resilience against zonal failures.
- Sharing across subscriptions and even between Active Directory (AD) tenants using Azure RBAC.
- Scaling your deployments with image replicas in each region.

At a high level, you create a gallery and it is made up of:

- Image Definitions - These are containers that hold groups of images.
- Image Versions - These are the actual images.

Hyper-V generation

Azure supports Hyper-V Generation 1 (Gen1) and Generation 2 (Gen2). Gen2 is the latest generation and offers additional functionality over Gen1. For example: increased memory, Intel Software Guard Extensions (Intel SGX), and virtualized persistent memory (vPMEM). Generation 2 VMs running on-premises have some features that aren't supported in Azure yet. For more information, see the Features and capabilities section in this article. Create Gen2 images if you require the additional functionality.

If you still need to create your own image, ensure it meets the image prerequisites and upload to Azure. Distribution specific requirements:

- Debian Linux
- Flatcar Container Linux
- FreeBSD
- Oracle Linux
- OpenBSD
- Red Hat Enterprise Linux
- SLES & openSUSE
- Ubuntu

Azure Linux VM provisioning

09/02/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When you create a VM from a generalized image (Azure Compute Gallery or Managed Image), the control plane will allow you to create a VM, and pass parameters and settings to the VM. This is called VM *provisioning*. During provisioning, the platform makes required VM Create parameter values (hostname, username, password, SSH keys, customData) available to the VM as it boots.

A provisioning agent baked inside the image will interface with the platform, connecting up to multiple independent provisioning interfaces), set the properties and signal to the platform it has completed.

The provisioning agents can be the Azure Linux Agent, or cloud-init. These are prerequisites of creating generalized images.

The provisioning agents, provide support for all endorsed Azure Linux distributions, and you will find the endorsed distro images in many cases will ship with both cloud-init and the Linux Agent. This gives you the option to have cloud-init to handle the provisioning, then the Linux Agent will provide support to handle Azure Extensions. Providing support for extensions means the VM will then be eligible to support additional Azure services, such as VM Password Reset, Azure Monitoring, Azure Backup, Azure Disk encryption etc.

After provisioning completes, cloud-init will run on each boot. Cloud-init will monitor for changes to the VM, like networking changes, mounting, and formatting the ephemeral disk, and starting the Linux Agent. The Linux Agent continually runs on the server, seeking a 'goal state' (new configuration) from the Azure platform, so whenever you install extensions, the agent will be able to process them.

Whilst there are currently two provisioning agents, cloud-init should be the provisioning agent you choose, and the Linux Agent should be installed for extension support. This allows you to take advantage of platform optimizations, and allows you to disable/remove the Linux Agent, for more details on how to create images without the agent, and how to remove it, please review this documentation.

If you have a Linux kernel that cannot support running either agent, but wish to set some of the VM Create properties, such as hostname, customData, userName, password, ssh keys, then in this document discusses how you can create generalized images without an agent, and meet platform requirements.

Provisioning agent responsibilities

Image provisioning

- Creation of a user account
- Configuring SSH authentication types
- Deployment of SSH public keys and key pairs
- Setting the host name
- Publishing the host name to the platform DNS
- Reporting SSH host key fingerprint to the platform
- Resource Disk Management
- Formatting and mounting the resource disk
- Consuming and processing `customData`

Networking

- Manages routes to improve compatibility with platform DHCP servers
- Ensures the stability of the network interface name

Kernel

- Configures virtual NUMA (disable for kernel < `2.6.37`)
- Consumes Hyper-V entropy for `/dev/random`
- Configures SCSI timeouts for the root device (which could be remote)

Diagnostics

- Console redirection to the serial port

Communication

The information flow from the platform to the agent occurs via two channels:

- A boot-time attached DVD for IaaS deployments. The DVD includes an OVF-compliant configuration file that includes all provisioning information, other than the actual SSH key pairs.
- A TCP endpoint exposing a REST API used to obtain deployment, and topology configuration.

Azure provisioning agent requirements

The Linux Agent, and cloud-init, depend on some system packages in order to function properly:

- Python 2.6+
- OpenSSL 1.0+
- OpenSSH 5.3+
- Filesystem utilities: `sfdisk`, `fdisk`, `mkfs`, `parted`
- Password tools: chpasswd, sudo
- Text processing tools: sed, grep
- Network tools: ip-route
- Kernel support for mounting UDF filesystems.

Next steps

If you need to, you can disable provisioning and remove the Linux agent.

Endorsed Linux distributions on Azure

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

In this article, we'll cover the following:

- Types of Images
- Partners
- Image Update Cadence
- Azure-tuned Kernels

There are several different sources of Linux Virtual Machine (VM) images for Azure. Each source provides a different expectation for quality, utility, and support. This document summarizes each source (marketplace images, platform images, custom images, and community gallery images) and gives you more details about platform images, which are images provided in partnership between Microsoft and several mainstream Linux publishers such as Red Hat, Canonical, and SUSE.

Microsoft's Linux distribution partners provide a multitude of Linux images in the Azure Marketplace. For distributions that aren't available from the Marketplace, you can always provide a custom built Linux image by following the guidelines found in Create and upload a virtual hard disk that contains the Linux operating system. For older versions, see Linux Kernel Requirements.

The Azure Linux Agent is already preinstalled on Azure Marketplace images and is typically available from the distribution package repository. Source code can be found on GitHub.

For more information on support by distribution, see Support for Linux images in Microsoft Azure.

For more information about running Azure workloads on Linux, see the following video:

https://www.youtube-nocookie.com/embed/K3ybTXorG5I?si=Bedb40scj_A0oD3U

Types of Images

Azure Linux images can be grouped into three categories:

Marketplace Images

Images published and maintained by either Microsoft or partners. There are a large variety of images from multiple publishers for various use cases (security hardened, full database / application stack, etc.), and can be available free, pay-as-you-go, or BYOL (bring your own license/subscription).

Platform Images are a type of Marketplace images for which Microsoft has partnered with several mainstream publishers (see table below about Partners) to create a set of "platform images" that undergo additional testing and receive predictable updates (see section below on Image Update Cadence). These platform images can be used for building your own custom images and solution stacks. These images are published by the endorsed Linux distribution partners such as Canonical (Ubuntu), Red Hat (RHEL), CIQ (Rocky) and Credativ (Debian).

Microsoft provides commercially reasonable customer support for these images. Additionally, Red Hat, Canonical, and SUSE offer integrated vendor support capabilities for their platform images.

Custom Images

These images are created and maintained by the customer, often based on platform images. These images can also be created from scratch and uploaded to Azure - learn how to create custom images. Customers can host these images in Azure Compute Gallery and they can share these images with others in their organization.

Microsoft provides commercially reasonable customer support for custom images.

Community Gallery Images

These images are created and provided by open source projects, communities, and teams. These images are provided using licensing terms set out by the publisher, often under an open source license. They don't appear as traditional marketplace listings, however, they do appear in the portal and via command line tools. More information on community galleries can be found here: Azure Compute Gallery.

Microsoft provides commercially reasonable support for Community Gallery images.

Platform Image Partners

Linux Publisher / Distribution	Images (Offers)	Microsoft Support Policy	Description
AlmaLinux	AlmaLinux OS (x86_64/AMD64) AlmaLinux OS (AArch64/ARM64) AlmaLinux OS (x86_64/AMD64) HPC	Microsoft CSS provides commercially reasonable support for these images.	AlmaLinux OS is a 100% community owned and governed, open source and forever free enterprise-grade Linux distribution. With long-term stability and providing a robust production-grade platform, AlmaLinux OS is 1:1 compatible with RHEL/CentOS.
Canonical / Ubuntu	Ubuntu 22.04 LTS (including Pro) Ubuntu 24.04 LTS (including Pro)	Microsoft CSS provides commercially reasonable support for these images.	Canonical produces official Ubuntu images for Microsoft Azure and continuously tracks and delivers updates to these, ensuring security and stability are built from the moment your virtual machines launch. Canonical works closely with Microsoft to optimize Ubuntu images on Azure and ensure Ubuntu supports the latest cloud features as they're released. Ubuntu powers more mission-critical workloads on Azure than any other operating system. https://ubuntu.com/azure
Credativ / Debian	Debian 11 "Bullseye" Debian 12 "Bookworm"	Microsoft CSS provides support for these images.	Credativ is an independent consulting and services company that specializes in the development and implementation of professional solutions by using free software. As leading open-source specialists, Credativ has international recognition with many IT departments that use their support. In conjunction with Microsoft, Credativ is preparing Debian images. The images are specially designed to run on Azure and can be easily managed via the platform. credativ will also support the long-term maintenance and updating of the Debian images for Azure through its Open Source Support Centers. https://www.credativ.de/portfolio/support/open-source-support-center
Kinvolk / Flatcar	Flatcar Container Linux Flatcar Container Linux (BYOL)	Microsoft CSS provides commercially reasonable support	Flatcar Container Linux is a minimal, immutable, and auto-updating operating system for containerized applications. Originally developed by Kinvolk, it's now 100% community governed as a Cloud Native Computing Foundation (CNCF) project. Flatcar is a minimal distro, containing just those packages

Linux Publisher / Distribution	Images (Offers)	Microsoft Support Policy	Description
	Flatcar Container Linux ARM64	these images.	required for deploying containers. Its immutable file system guarantees consistency and security, while its auto-update capabilities enable you to be always up-to-date with the latest security fixes. Kinvolk was acquired by Microsoft in April 2021 and, post-acquisition, continues its mission within Microsoft to support the Flatcar community. https://www.flatcar.org
Oracle Linux	Oracle Linux	Microsoft CSS provides commercially reasonable support these images.	Oracle's strategy is to offer a broad portfolio of solutions for public and private clouds. The strategy gives customers choice and flexibility in how they deploy Oracle software in Oracle clouds and other clouds. Oracle's partnership with Microsoft enables customers to deploy Oracle software to Microsoft public and private clouds with the confidence of certification and support from Oracle. Oracle's commitment and investment in Oracle public and private cloud solutions is unchanged. https://www.oracle.com/cloud/azure
Red Hat / Red Hat Enterprise Linux (RHEL)	Red Hat Enterprise Linux Red Hat Enterprise Linux RAW Red Hat Enterprise Linux ARM64 Red Hat Enterprise Linux for SAP Apps Red Hat Enterprise Linux for SAP, HA, Updated Services Red Hat Enterprise Linux with HA add-on	Microsoft CSS provides commercially reasonable support these images.	The world's leading provider of open-source solutions, Red Hat helps more than 90% of Fortune 500 companies solve business challenges, align their IT and business strategies, and prepare for the future of technology. Red Hat achieves this by providing secure solutions through an open business model and an affordable, predictable subscription model. https://www.redhat.com/partners/microsoft

Linux Publisher / Distribution	Images (Offers)	Microsoft Support Policy	Description
CIQ / Rocky Linux	Rocky Linux from CIQ	Microsoft CSS provides commercially reasonable support for these images.	Rocky Linux, developed by the Rocky Enterprise Software Foundation (RESF), is an open-source Enterprise Linux operating system designed for the community. As the founding sponsor of RESF, CIQ enhances and supports Rocky Linux on Microsoft Azure, delivering a secure, compliant, high-performance, and user-friendly platform for both development and production workloads. https://ciq.com/partners/cloud/azure/
SUSE / SUSE Linux Enterprise Server (SLES)	SUSE Linux Enterprise Server 12 SP5 SUSE Linux Enterprise Server 15 SP5 SUSE Linux Enterprise Server 15 SP6 SUSE Linux Enterprise Server 15 SP7 SUSE Linux Enterprise Server 16	Microsoft CSS provides commercially reasonable support for these images.	SUSE Linux Enterprise Server on Azure is a proven platform that provides superior reliability and security for cloud computing. SUSE's versatile Linux platform seamlessly integrates with Azure cloud services to deliver an easily manageable cloud environment. With more than 9,200 certified applications from more than 1,800 independent software vendors for SUSE Linux Enterprise Server, SUSE ensures that workloads running supported in the data center can be confidently deployed on Azure. Each Marketplace page provides access to all supported service packs and variants, including: • +24x7 Support • Patching-only • BYOS (Bring Your Own Subscription) • SLES for SAP Applications • Arm64 • Hardened images https://www.suse.com/partners/alliance/microsoft

Image Update Cadence

Azure requires that the publishers of the endorsed Linux distributions regularly update their platform images in Azure Marketplace with the latest patches and security fixes, at a quarterly or faster cadence. Updated images in the Marketplace are available automatically to customers as new versions of an image SKU. More information about how to find Linux images: Find Azure Marketplace image information using the Azure CLI.

Azure-tuned Kernels

Azure works closely with various endorsed Linux distributions to optimize the images that they published to Azure Marketplace. One aspect of this collaboration is the development of "tuned" Linux kernels that are optimized for the Azure platform and delivered as fully supported components of the Linux distribution. The Azure-Tuned kernels incorporate new features and performance improvements, and at a faster (typically quarterly) cadence compared to the default or generic kernels that are available from the distribution.

In most cases, you'll find these kernels preinstalled on the default images in Azure Marketplace so customers will immediately get the benefit of these optimized kernels. More information about these Azure-Tuned kernels can be found in the following links:

- CentOS Azure-Tuned Kernel - Available via the CentOS Virtualization SIG
- Debian Cloud Kernel - Available with the Debian 10 and Debian 9 "backports" image on Azure
- SLES Azure-Tuned Kernel
- Ubuntu Azure-Tuned Kernel
- Flatcar Container Linux

Prepare Linux for imaging in Azure

Article • 10/08/2024

> **⊗ Caution**
>
> This article references CentOS, a Linux distribution that is End Of Life (EOL) status. Please consider your use and plan accordingly. For more information, see the **CentOS End Of Life guidance**.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The Azure platform service-level agreement (SLA) applies to virtual machines (VMs) running the Linux operating system only when you're using one of the endorsed distributions. For endorsed distributions, Azure Marketplace provides preconfigured Linux images. For more information, see:

- Endorsed Linux distributions on Azure
- Support for Linux and open-source technology in Azure

All other distributions running on Azure, including community-supported and non-endorsed distributions, have some prerequisites.

This article focuses on general guidance for running your Linux distribution on Azure. This article can't be comprehensive, because every distribution is different. Even if you meet all the criteria that this article describes, you might need to significantly tweak your Linux system for it to run properly.

General Linux installation notes

- Azure doesn't support the Hyper-V virtual hard disk (VHDX) format. Azure supports only *fixed VHD*. You can convert the disk to VHD format by using Hyper-V Manager or the Convert-VHD cmdlet. If you're using VirtualBox, select **Fixed size** rather than the default (**Dynamically allocated**) when you're creating the disk.
- Azure supports Gen1 (BIOS boot) and Gen2 (UEFI boot) virtual machines.
- The virtual file allocation table (VFAT) kernel module must be enabled in the kernel.
- The maximum size allowed for the VHD is 1,023 GB.
- When you're installing the Linux system, we recommend that you use standard partitions rather than Logical Volume Manager (LVM). LVM is the default for many

installations.

Using standard partitions will avoid LVM name conflicts with cloned VMs, particularly if an OS disk is ever attached to another identical VM for troubleshooting. You can use LVM or RAID on data disks.

- Kernel support for mounting user-defined function (UDF) file systems is necessary. At first boot on Azure, the provisioning configuration is passed to the Linux VM via UDF-formatted media that are attached to the guest. The Azure Linux agent must mount the UDF file system to read its configuration and provision the VM.

- Linux kernel versions earlier than 2.6.37 don't support Non-Uniform Memory Access (NUMA) on Hyper-V with larger VM sizes. This issue primarily affects older distributions that use the upstream Red Hat 2.6.32 kernel. It was fixed in Red Hat Enterprise Linux (RHEL) 6.6 (kernel-2.6.32-504).

  Systems running custom kernels older than 2.6.37, or RHEL-based kernels older than 2.6.32-504, must set the boot parameter `numa=off` on the kernel command line in *grub.conf*. For more information, see Red Hat KB 436883.

- Don't configure a swap partition on the OS disk. You can configure the Linux agent to create a swap file on the temporary resource disk, as described later in this article.

- All VHDs on Azure must have a virtual size aligned to 1 MB (1024 x 1024 bytes). When you're converting from a raw disk to VHD, ensure that the raw disk size is a multiple of 1 MB before conversion, as described later in this article.

- Use the most up-to-date distribution version, packages, and software.

- Remove users and system accounts, public keys, sensitive data, unnecessary software, and applications.

> **Note**
>
> Cloud-init version 21.2 or later removes the UDF requirement. But without the `udf` module enabled, the CD-ROM won't mount during provisioning, which prevents the custom data from being applied. A workaround is to apply user data. However, unlike custom data, user data isn't encrypted. For more information, see User data formats in the cloud-init documentation.

Install kernel modules without Hyper-V

Azure runs on the Hyper-V hypervisor, so Linux requires certain kernel modules to run in Azure. If you have a VM that was created outside Hyper-V, the Linux installers might not include the drivers for Hyper-V in the initial RAM disk (initrd or initramfs), unless the VM detects that it's running in a Hyper-V environment.

When you're using a different virtualization system (such as VirtualBox or KVM) to prepare your Linux image, you might need to rebuild initrd so that at least the `hv_vmbus` and `hv_storvsc` kernel modules are available on the initial RAM disk. This known issue is for systems based on the upstream Red Hat distribution, and possibly others.

The mechanism for rebuilding the initrd or initramfs image can vary, depending on the distribution. Consult your distribution's documentation or support for the proper procedure. Here's one example for rebuilding initrd by using the `mkinitrd` utility:

1. Back up the existing initrd image:

   Bash

   ```
   cd /boot
   sudo cp initrd-`uname -r`.img  initrd-`uname -r`.img.bak
   ```

2. Rebuild initrd by using the `hv_vmbus` and `hv_storvsc` kernel modules:

   Bash

   ```
   sudo mkinitrd --preload=hv_storvsc --preload=hv_vmbus -v -f initrd-
   `uname -r`.img `uname -r`
   ```

Resize VHDs

VHD images on Azure must have a virtual size aligned to 1 MB. Typically, VHDs created through Hyper-V are aligned correctly. If the VHD isn't aligned correctly, you might get an error message similar to the following example when you try to create an image from your VHD:

config

```
The VHD http://<mystorageaccount>.blob.core.windows.net/vhds/MyLinuxVM.vhd
has an unsupported virtual size of 21475270656 bytes. The size must be a
whole number (in MBs).
```

In this case, resize the VM by using either the Hyper-V Manager console or the Resize-VHD PowerShell cmdlet. If you aren't running in a Windows environment, we

recommend using `qemu-img` to convert (if needed) and resize the VHD.

> **Note**
>
> There's a known bug in qemu-img for QEMU version 2.2.1 and some later versions that results in an improperly formatted VHD. The issue was fixed in QEMU 2.6. We recommend using version 2.2.0 or earlier, or using version 2.6 or later.

1. Resizing the VHD directly by using tools such as `qemu-img` or `vbox-manage` might result in an unbootable VHD. We recommend first converting the VHD to a raw disk image by using the following code.

   If the VM image was created as a raw disk image, you can skip this step. Creating the VM image as a raw disk image is the default in some hypervisors, such as KVM.

   Bash

   ```
   sudo qemu-img convert -f vpc -O raw MyLinuxVM.vhd MyLinuxVM.raw
   ```

2. Calculate the required size of the disk image so that the virtual size is aligned to 1 MB. The following Bash shell script uses `qemu-img info` to determine the virtual size of the disk image, and then calculates the size to the next 1 MB:

   Bash

   ```
   rawdisk="MyLinuxVM.raw"
   vhddisk="MyLinuxVM.vhd"

   MB=$((1024*1024))
   size=$(qemu-img info -f raw --output json "$rawdisk" | \
   gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')

   rounded_size=$((($size+$MB-1)/$MB)*$MB))

   echo "Rounded Size = $rounded_size"
   ```

3. Resize the raw disk by using `$rounded_size`:

   Bash

   ```
   sudo qemu-img resize MyLinuxVM.raw $rounded_size
   ```

4. Convert the raw disk back to a fixed-size VHD:

Bash

```
sudo qemu-img convert -f raw -o subformat=fixed,force_size -O vpc
MyLinuxVM.raw MyLinuxVM.vhd
```

Or, with QEMU versions before 2.6, remove the `force_size` option:

Bash

```
sudo qemu-img convert -f raw -o subformat=fixed -O vpc MyLinuxVM.raw
MyLinuxVM.vhd
```

Linux kernel requirements

The Linux Integration Services (LIS) drivers for Hyper-V and Azure are contributed directly to the upstream Linux kernel. Many distributions that include a recent Linux kernel version (such as 3.x) have these drivers available already, or otherwise provide backported versions of these drivers with their kernels.

LIS drivers are constantly being updated in the upstream kernel with new fixes and features. When possible, we recommend running an endorsed distribution that includes these fixes and updates.

If you're running a variant of RHEL versions 6.0 to 6.3, you need to install the latest LIS drivers for Hyper-V. Beginning with RHEL 6.4+ (and derivatives), the LIS drivers are already included with the kernel, so you don't need additional installation packages.

If a custom kernel is required, we recommend a recent kernel version (such as 3.8+). For distributions or vendors that maintain their own kernel, you need to regularly backport the LIS drivers from the upstream kernel to your custom kernel.

Even if you're already running a relatively recent kernel version, we highly recommend keeping track of any upstream fixes in the LIS drivers and backporting them as needed. The locations of the LIS driver source files are specified in the MAINTAINERS file in the Linux kernel source tree:

config

```
F:    arch/x86/include/asm/mshyperv.h
F:    arch/x86/include/uapi/asm/hyperv.h
F:    arch/x86/kernel/cpu/mshyperv.c
F:    drivers/hid/hid-hyperv.c
F:    drivers/hv/
F:    drivers/input/serio/hyperv-keyboard.c
F:    drivers/net/hyperv/
```

```
F:    drivers/scsi/storvsc_drv.c
F:    drivers/video/fbdev/hyperv_fb.c
F:    include/linux/hyperv.h
F:    tools/hv/
```

The VM's active kernel must include the following patches. This list can't be complete for all distributions.

- ata_piix: defer disks to the Hyper-V drivers by default
- storvsc: Account for in-transit packets in the RESET path
- storvsc: avoid usage of WRITE_SAME
- storvsc: Disable WRITE SAME for RAID and virtual host adapter drivers
- storvsc: NULL pointer dereference fix
- storvsc: ring buffer failures may result in I/O freeze
- scsi_sysfs: protect against double execution of __scsi_remove_device

Azure Linux Agent

The Azure Linux Agent (`waagent`) provisions a Linux virtual machine in Azure. You can get the latest version, report problems, or submit pull requests at the Linux Agent GitHub repo.

Here are some considerations for using the Azure Linux Agent:

- The Linux agent is released under the Apache 2.0 license. Many distributions already provide .rpm or .deb packages for the agent. You can easily install and update these packages.
- The Azure Linux Agent requires Python v2.6+.
- The agent also requires the `python-pyasn1` module. Most distributions provide this module as a separate package to be installed.
- In some cases, the Azure Linux Agent might not be compatible with NetworkManager. Many of the packages (.rpm or .deb) provided by distributions configure NetworkManager as a conflict to the `waagent` package. In these cases, the agent will uninstall NetworkManager when you install the Linux agent package.
- The Azure Linux Agent must be at or above the minimum supported version.

> **Note**
>
> Make sure the `udf` and `vfat` modules are enabled. Disabling the `udf` module will cause a provisioning failure. Disabling the `vfat` module will cause both provisioning and boot failures. Cloud-init version 21.2 or later can provision VMs without requiring UDF if both of these conditions exist:

- You created the VM by using SSH public keys and not passwords.
- You didn't provide any custom data.

General Linux system requirements

1. Modify the kernel boot line in GRUB or GRUB2 to include the following parameters, so that all console messages are sent to the first serial port. These messages can assist Azure support with debugging any issues.

   ```config
   GRUB_CMDLINE_LINUX="rootdelay=300 console=ttyS0 earlyprintk=ttyS0
   net.ifnames=0"
   ```

   We also recommend *removing* the following parameters if they exist:

   ```config
   rhgb quiet crashkernel=auto
   ```

   Graphical and quiet boot aren't useful in a cloud environment, where you want all logs sent to the serial port. You can leave the `crashkernel` option configured if needed, but this parameter reduces the amount of available memory in the VM by at least 128 MB. Reducing available memory might be problematic for smaller VM sizes.

2. After you finish editing */etc/default/grub*, run the following command to rebuild the GRUB configuration:

   ```Bash
   sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

3. Add the Hyper-V module for initramfs by using `dracut`:

   ```Bash
   cd /boot
   sudo cp initramfs-<kernel-version>.img <kernel-version>.img.bak
   sudo dracut -f -v initramfs-<kernel-version>.img <kernel-version> --
   add-drivers "hv_vmbus hv_netvsc hv_storvsc"
   ```

```
sudo grub-mkconfig -o /boot/grub/grub.cfg
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

Add the Hyper-V module for initrd by using `mkinitramfs`:

```
Bash

cd /boot
sudo cp initrd.img-<kernel-version>  initrd.img-<kernel-version>.bak
sudo mkinitramfs -o initrd.img-<kernel-version> <kernel-version>  --
with=hv_vmbus,hv_netvsc,hv_storvsc
sudo update-grub
```

4. Ensure that the SSH server is installed and configured to start at boot time. This configuration is usually the default.

5. Install the Azure Linux Agent.

   The Azure Linux Agent is required for provisioning a Linux image on Azure. Many distributions provide the agent as an .rpm or .deb package. The package is typically called `WALinuxAgent` or `walinuxagent`. You can also install the agent manually by following the steps in the Azure Linux Agent guide.

   > **Note**
   >
   > Make sure the `udf` and `vfat` modules are enabled. Removing or disabling them will cause a provisioning or boot failure. Cloud-init version 21.2 or later removes the UDF requirement.

   Install the Azure Linux Agent, cloud-init, and other necessary utilities by running one of the following commands.

   Use this command for Red Hat or CentOS:

   ```
   Bash

   sudo yum install -y WALinuxAgent cloud-init cloud-utils-growpart gdisk
   hyperv-daemons
   ```

   Use this command for Ubuntu/Debian:

   ```
   Bash
   ```

```
sudo apt install walinuxagent cloud-init cloud-utils-growpart gdisk
hyperv-daemons
```

Use this command for SUSE:

```Bash
sudo zypper install python-azure-agent cloud-init cloud-utils-growpart
gdisk hyperv-daemons
```

Then enable the agent and cloud-init on all distributions:

```Bash
sudo systemctl enable waagent.service
sudo systemctl enable cloud-init.service
```

6. Don't create swap space on the OS disk.

   You can use the Azure Linux Agent or cloud-init to configure swap space via the local resource disk. This resource disk is attached to the VM after provisioning on Azure. The local resource disk is a temporary disk and might be emptied when the VM is deprovisioned. The following blocks show how to configure this swap.

   If you choose Azure Linux Agent, modify the following parameters in */etc/waagent.conf*:

```config
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.EnableSwap=y
ResourceDisk.SwapSizeMB=2048    ## NOTE: Set this to your desired size.
```

   If you choose cloud-init, configure cloud-init to handle the provisioning:

```Bash
sudo sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=cloud-init/g'
/etc/waagent.conf
sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g'
/etc/waagent.conf
sudo sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
/etc/waagent.conf
```

To configure cloud-init to format and create swap space, you have two options:

- Pass in a cloud-init configuration every time you create a VM through `customdata`. We recommend this method.
- Use a cloud-init directive in the image to configure swap space every time the VM is created.

Create a .cfg file to configure swap space by using cloud-init:

Bash

```
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' | sudo tee -a /etc/systemd/system.conf
cat << EOF | sudo tee /etc/cloud/cloud.cfg.d/00-azure-swap.cfg
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt/resource"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-systemd.device-timeout=2", "0", "0"]
EOF
```

7. Configure cloud-init to handle the provisioning:

   a. Configure `waagent` for cloud-init:

   Bash

   ```
   sudo sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=cloud-init/g' /etc/waagent.conf
   sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
   sudo sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf
   ```

   If you're migrating a specific virtual machine and don't want to create a generalized image, set `Provisioning.Agent=disabled` in the */etc/waagent.conf*

configuration.

b. Configure mounts:

```
Bash

echo "Adding mounts and disk_setup to init stage"
sudo sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sudo sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - disk_setup'
/etc/cloud/cloud.cfg
```

c. Configure the Azure data source:

```
Bash

echo "Allow only Azure datasource, disable fetching network setting
via IMDS"
cat << EOF | sudo tee /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg
datasource_list: [ Azure ]
datasource:
   Azure:
     apply_network_config: False
EOF
```

d. Remove the existing swap file if you configured one:

```
Bash

if [[ -f /mnt/resource/swapfile ]]; then
echo "Removing swapfile" #RHEL uses a swap file by default
swapoff /mnt/resource/swapfile
rm /mnt/resource/swapfile -f
fi
```

e. Configure cloud-init logging:

```
Bash

echo "Add console log file"
cat << EOF | sudo tee -a /etc/cloud/cloud.cfg.d/05_logging.cfg

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
```

```
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

8. Run the following commands to deprovision the virtual machine.

   > **⊗ Caution**
   >
   > If you're migrating a specific virtual machine and don't want to create a generalized image, skip the deprovisioning step. Running the command `waagent -force -deprovision+user` will render the source machine unusable. This step is intended only to create a generalized image.

   Bash

   ```
   sudo rm -f /var/log/waagent.log
   sudo cloud-init clean
   sudo waagent -force -deprovision+user
   sudo rm -f ~/.bash_history
   sudo export HISTSIZE=0
   ```

   On VirtualBox, you might see an error message after you run `waagent -force -deprovision` that says `[Errno 5] Input/output error`. This error message is not critical, and you can ignore it.

9. Shut down the virtual machine and upload the VHD to Azure.

Prepare a CentOS-based virtual machine for Azure

Article • 08/22/2024

> **⊗ Caution**
>
> This article references CentOS, a Linux distribution that's nearing end-of-life (EOL) status. Consider your use and plan accordingly. For more information, see the CentOS end-of-life guidance.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Learn to create and upload an Azure virtual hard disk (VHD) that contains a CentOS-based Linux operating system (OS). For more information, see:

- Prepare a CentOS 6.x virtual machine (VM) for Azure
- Prepare a CentOS 7.0+ VM for Azure

Prerequisites

This article assumes that you've already installed a CentOS (or similar derivative) Linux OS to a VHD. Multiple tools exist to create .vhd files. An example is a virtualization solution such as Hyper-V. For instructions, see Install the Hyper-V role and configure a VM.

CentOS installation notes

- For more tips on preparing Linux for Azure, see General Linux installation notes.
- The VHDX format isn't supported in Azure, only *fixed VHD*. You can convert the disk to VHD format by using Hyper-V Manager or the `convert-vhd` cmdlet. If you're using VirtualBox, you select **Fixed size** as opposed to the default that's dynamically allocated when you create the disk.
- The vfat kernel module must be enabled in the kernel.
- When you install the Linux system, we recommend that you use standard partitions rather than Logical Volume Manager (LVM), which is often the default for many installations. Using partitions avoids LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another identical VM for troubleshooting. LVM or RAID can also be used on data disks.

- Kernel support for mounting user-defined functions (UDF) file systems is necessary. At first boot on Azure, the provisioning configuration is passed to the Linux VM by using UDF-formatted media that's attached to the guest. The Azure Linux agent or `cloud-init` must mount the UDF file system to read its configuration and provision the VM.
- Linux kernel versions below 2.6.37 don't support NUMA on Hyper-V with larger VM sizes. This issue primarily affects older distributions using the upstream Centos 2.6.32 kernel and was fixed in Centos 6.6 (kernel-2.6.32-504). Systems running custom kernels older than 2.6.37 or Red Hat Enterprise Linux (RHEL)-based kernels older than 2.6.32-504 must set the boot parameter `numa=off` on the kernel command line in *grub.conf*. For more information, see Red Hat KB 436883.
- Don't configure a swap partition on the OS disk.
- All VHDs on Azure must have a virtual size aligned to 1 MB. When you convert from a raw disk to VHD, you must ensure that the raw disk size is a multiple of 1 MB before conversion. For more information, see Linux installation notes.

> **Note**
>
> *Cloud-init >= 21.2 removes the UDF requirement*. But without the UDF module enabled, the CD-ROM won't mount during provisioning, which prevents custom data from being applied. A workaround for this situation is to apply custom data by using user data. Unlike custom data, user data isn't encrypted. For more information, see User data formats.

CentOS 6.x

> **Important**
>
> CentOS 6 has reached its EOL and is no longer supported by the CentOS community. No further updates or security patches will be released for this version, leaving it vulnerable to potential security risks. We strongly recommend that you upgrade to a more recent version of CentOS to ensure the safety and stability of your system. For further assistance, consult with your IT department or system administrator.

1. In Hyper-V Manager, select the VM.
2. Select **Connect** to open a console window for the VM.

3. In CentOS 6, `NetworkManager` can interfere with the Azure Linux agent. Uninstall this package:

```
Bash

sudo rpm -e --nodeps NetworkManager
```

4. Create or edit the file `/etc/sysconfig/network` and add the following text:

```
config

NETWORKING=yes
HOSTNAME=localhost.localdomain
```

5. Create or edit the file `/etc/sysconfig/network-scripts/ifcfg-eth0` and add the following text:

```
config

DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
```

6. Modify udev rules to avoid generating static rules for the Ethernet interfaces. These rules can cause problems when you clone a VM in Azure or Hyper-V:

```
Bash

sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-
generator.rules
sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

7. Ensure that the network service starts at boot time:

```
Bash

sudo chkconfig network on
```

8. If you want to use the OpenLogic mirrors that are hosted within the Azure datacenters, replace the `/etc/yum.repos.d/CentOS-Base.repo` file with the following

repositories. This action also adds the [openlogic] repository that includes extra packages, such as the Azure Linux agent:

config

```
[openlogic]
name=CentOS-$releasever - openlogic packages for $basearch
baseurl=http://olcentgbl.trafficmanager.net/openlogic/$releasever/openl
ogic/$basearch/
enabled=1
gpgcheck=0

[base]
name=CentOS-$releasever - Base
#mirrorlist=http://mirrorlist.centos.org/?
release=$releasever&arch=$basearch&repo=os&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/os/$base
arch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#released updates
[updates]
name=CentOS-$releasever - Updates
#mirrorlist=http://mirrorlist.centos.org/?
release=$releasever&arch=$basearch&repo=updates&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/updates/
$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#additional packages that might be useful
[extras]
name=CentOS-$releasever - Extras
#mirrorlist=http://mirrorlist.centos.org/?
release=$releasever&arch=$basearch&repo=extras&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/extras/$
basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#additional packages that extend functionality of existing packages
[centosplus]
name=CentOS-$releasever - Plus
#mirrorlist=http://mirrorlist.centos.org/?
release=$releasever&arch=$basearch&repo=centosplus&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/centospl
us/$basearch/
gpgcheck=1
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#contrib - packages by Centos Users
[contrib]
```

```
name=CentOS-$releasever - Contrib
#mirrorlist=http://mirrorlist.centos.org/?
release=$releasever&arch=$basearch&repo=contrib&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/contrib/
$basearch/
gpgcheck=1
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6
```

> **Note**
>
> The rest of this article assumes that you're using at least the `[openlogic]` repo, which is used to install the Azure Linux agent.

9. Add the following line to `/etc/yum.conf`:

```config
http_caching=packages
```

10. Clear the current yum metadata and update the system with the latest packages:

```Bash
sudo yum clean all
```

Unless you're creating an image for an older version of CentOS, we recommend that you update all the packages to the latest:

```Bash
sudo yum -y update
```

A reboot might be required after you run this command.

11. Optional: Install the drivers for the Linux Integration Services (LIS).

> **Important**
>
> The step is *required* for CentOS 6.3 and earlier and is optional for later releases.

```Bash
```

```
sudo rpm -e hypervkvpd  ## (might return an error if not installed,
that's OK)
sudo yum install microsoft-hyper-v
```

Alternatively, you can follow the manual installation instructions on the LIS download page to install the RPM onto your VM.

12. Install the Azure Linux agent and dependencies. Start and enable the `waagent` service:

    ```
    Bash

    sudo yum install python-pyasn1 WALinuxAgent
    sudo service waagent start
    sudo chkconfig waagent on
    ```

    The WALinuxAgent package removes the `NetworkManager` and `NetworkManager-gnome` packages if they weren't already removed, as described in step 3.

13. Modify the kernel boot line in your grub configuration to include other kernel parameters for Azure. To do this step, open `/boot/grub/menu.lst` in a text editor and ensure that the default kernel includes the following parameters:

    ```
    config

    console=ttyS0 earlyprintk=ttyS0 rootdelay=300
    ```

    This modification also ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

    We also recommend that you *remove* the following parameters:

    ```
    config

    rhgb quiet crashkernel=auto
    ```

    Graphical and quiet boot aren't useful in a cloud environment where you want all the logs to be sent to the serial port. The `crashkernel` option can be left configured if you want. But this parameter reduces the amount of available memory in the VM by 128 MB or more, which might be a problem for smaller VM sizes.

> **Important**
>
> CentOS 6.5 and earlier must also set the kernel parameter `numa=off`. For more information, see Red Hat KB 436883.

14. Ensure that the Secure Shell server is installed and configured to start at boot time. This setting is usually the default.

15. Don't create swap space on the OS disk.

    The Azure Linux agent can automatically configure swap space by using the local resource disk that's attached to the VM after the VM is provisioned on Azure. The local resource disk is a *temporary* disk and might be emptied when the VM is deprovisioned. After you install the Azure Linux agent (see the previous step), modify the following parameters in `/etc/waagent.conf` appropriately:

    ```config
    ResourceDisk.Format=y
    ResourceDisk.Filesystem=ext4
    ResourceDisk.MountPoint=/mnt/resource
    ResourceDisk.EnableSwap=y
    ResourceDisk.SwapSizeMB=2048 ## NOTE: set this to whatever you need it
    to be.
    ```

16. Deprovision the VM and prepare it for provisioning on Azure:

    ```Bash
    sudo waagent -force -deprovision+user
    sudo export HISTSIZE=0
    ```

    > **Note**
    >
    > If you're migrating a specific VM and don't want to create a generalized image, skip the deprovision step.

17. Select **Action** > **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be uploaded to Azure.

CentOS 7.0+

Follow the steps in the next sections if you're using CentOS 7.0+.

Changes in CentOS 7 (and similar derivatives)

Preparing a CentOS 7 VM for Azure is similar to CentOS 6. Several significant differences are worth noting:

- The `NetworkManager` package no longer conflicts with the Azure Linux agent. This package is installed by default and we recommend that you don't remove it.
- GRUB2 is now used as the default bootloader, so the procedure for editing kernel parameters has changed. (See the "Configuration steps" section.)
- XFS is now the default file system. The ext4 file system can still be used if you want.
- Because CentOS 8 Stream and newer no longer include `network.service` by default, you need to install it manually:

  Bash

  ```
  sudo yum install network-scripts
  sudo systemctl enable network.service
  ```

Configuration steps

1. In Hyper-V Manager, select the VM.
2. Select **Connect** to open a console window for the VM.
3. Create or edit the file `/etc/sysconfig/network` and add the following text:

   config

   ```
   NETWORKING=yes
   HOSTNAME=localhost.localdomain
   ```

4. Create or edit the file `/etc/sysconfig/network-scripts/ifcfg-eth0` and add the following text:

   config

   ```
   DEVICE=eth0
   ONBOOT=yes
   BOOTPROTO=dhcp
   TYPE=Ethernet
   ```

```
USERCTL=no
PEERDNS=yes
IPV6INIT=no
NM_CONTROLLED=no
```

5. Modify udev rules to avoid generating static rules for the Ethernet interfaces. These rules can cause problems when you clone a VM in Azure or Hyper-V:

```Bash
sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules
```

6. If you want to use the `OpenLogic` mirrors that are hosted within the Azure datacenters, replace the */etc/yum.repos.d/CentOS-Base.repo* file with the following repositories. This action also adds the [openlogic] repository that includes packages for the Azure Linux agent:

```confg
[openlogic]
name=CentOS-$releasever - openlogic packages for $basearch
baseurl=http://olcentgbl.trafficmanager.net/openlogic/$releasever/openlogic/$basearch/
enabled=1
gpgcheck=0

[base]
name=CentOS-$releasever - Base
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/os/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

#released updates
[updates]
name=CentOS-$releasever - Updates
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=updates&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/updates/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

#additional packages that might be useful
[extras]
name=CentOS-$releasever - Extras
#mirrorlist=http://mirrorlist.centos.org/?
```

```
release=$releasever&arch=$basearch&repo=extras&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/extras/$
basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

#additional packages that extend functionality of existing packages
[centosplus]
name=CentOS-$releasever - Plus
#mirrorlist=http://mirrorlist.centos.org/?
release=$releasever&arch=$basearch&repo=centosplus&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/centospl
us/$basearch/
gpgcheck=1
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7
```

> **Note**
>
> The rest of this article assumes that you're using at least the `[openlogic]` repo, which is used to install the Azure Linux agent.

7. Clear the current yum metadata and install any updates:

   Bash

   ```
   sudo yum clean all
   ```

   Unless you're creating an image for an older version of CentOS, we recommend that you update all the packages to the latest:

   Bash

   ```
   sudo yum -y update
   ```

   A reboot might be required after you run this command.

8. Modify the kernel boot line in your grub configuration to include other kernel parameters for Azure. To do this step, open `/etc/default/grub` in a text editor and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

   config

   ```
   GRUB_CMDLINE_LINUX="rootdelay=300 console=ttyS0 earlyprintk=ttyS0
   net.ifnames=0"
   ```

This modification also ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues. It also turns off the new CentOS 7 naming conventions for network interface cards. We also recommend that you *remove* the following parameters:

```config
rhgb quiet crashkernel=auto
```

Graphical and quiet boot aren't useful in a cloud environment where you want all the logs to be sent to the serial port. The `crashkernel` option can be left configured if you want. But this parameter reduces the amount of available memory in the VM by 128 MB or more, which might be a problem for smaller VM sizes.

9. After you're finished editing `/etc/default/grub`, rebuild the grub configuration:

```Bash
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

> **Note**
>
> If you're uploading a UEFI-enabled VM, the command to update grub is `grub2-mkconfig -o /boot/efi/EFI/centos/grub.cfg`. Also, the vfat kernel module must be enabled in the kernel. Otherwise, provisioning fails.
>
> Make sure the udf module is enabled. Removing or disabling it will cause a provisioning or boot failure. *(_Cloud-init >= 21.2 removes the udf requirement. For more information, read the top of the document.)*

10. If you're building the image from VMware, VirtualBox, or KVM, ensure that the Hyper-V drivers are included in the initramfs:

    a. Edit `/etc/dracut.conf` and add content:

```config
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

    b. Rebuild the initramfs:

Bash

```
sudo dracut -f -v
```

11. Install the Azure Linux agent and dependencies for Azure VM extensions:

Bash

```
sudo yum install python-pyasn1 WALinuxAgent
sudo systemctl enable waagent
```

12. Install `cloud-init` to handle the provisioning:

Bash

```
sudo yum install -y cloud-init cloud-utils-growpart gdisk hyperv-
daemons
```

- Configure `waagent` for `cloud-init`:

Bash

```
sudo sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=auto/g'
/etc/waagent.conf
sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g'
/etc/waagent.conf
sudo sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
/etc/waagent.conf
```

Bash

```
sudo echo "Adding mounts and disk_setup to init stage"
sudo sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sudo sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
```

Bash

```
sudo echo "Allow only Azure datasource, disable fetching network
setting via IMDS"
sudo cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
datasource_list: [ Azure ]
datasource:
    Azure:
        apply_network_config: False
EOF
```

```
if [[ -f /mnt/swapfile ]]; then
echo Removing swapfile - RHEL uses a swapfile by default
swapoff /mnt/swapfile
rm /mnt/swapfile -f
fi

echo "Add console log file"
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

13. Swap configuration:

    a. Don't create swap space on the OS disk.

    Previously, the Azure Linux agent was used to automatically configure swap space by using the local resource disk that's attached to the VM after the VM is provisioned on Azure. However, `cloud-init` now handles this step. You *must not* use the Linux agent to format the resource disk to create the swap file. Modify the following parameters in `/etc/waagent.conf` appropriately:

    Bash

    ```
    sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g'
    /etc/waagent.conf
    sudo sed -i
    's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
    /etc/waagent.conf
    ```

    b. If you want to mount, format, and create the swap file, you can either:

    - Pass this command in as a `cloud-init` configuration every time you create a VM.
    - Use a `cloud-init` directive baked into the image to do this step every time the VM is created:

      Bash

      ```
      sudo echo
      'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-
      swap.cfg"' >> /etc/systemd/system.conf
      sudo cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
      ```

```
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-
systemd.requires=cloud-init.service,x-systemd.device-
timeout=2", "0", "0"]
EOF
```

14. Run the following commands to deprovision the VM and prepare it for provisioning on Azure.

    > **Note**
    >
    > If you're migrating a specific VM and don't want to create a generalized image, skip the deprovision step.

    Bash

    ```
    sudo rm -f /var/log/waagent.log
    sudo cloud-init clean
    sudo waagent -force -deprovision+user
    sudo rm -f ~/.bash_history
    sudo export HISTSIZE=0
    ```

15. Select **Action** > **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be uploaded to Azure.

Related content

You're now ready to use your CentOS Linux VHD to create new VMs in Azure. If this is the first time that you're uploading the .vhd file to Azure, see Create a Linux VM from a custom disk.

Prepare a Debian VHD for Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Prerequisites

This section assumes that you've already installed a Debian Linux operating system from an .iso file downloaded from the Debian website to a virtual hard disk (VHD). Multiple tools exist to create .vhd files. Hyper-V is only one example. For instructions on using Hyper-V, see Install the Hyper-V role and configure a virtual machine (VM).

Installation notes

- For more tips on preparing Linux for Azure, see General Linux installation notes.
- The newer VHDX format isn't supported in Azure. You can convert the disk to VHD format by using Hyper-V Manager or the `convert-vhd` cmdlet.
- When you install the Linux system, we recommend that you use standard partitions rather than Logical Volume Manager (LVM), which is often the default for many installations. Using partitions avoids LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. LVM or RAID can also be used on data disks.
- Don't configure a swap partition on the OS disk. The Azure Linux agent can be configured to create a swap file on the temporary resource disk. More information is available in the following steps.
- All VHDs on Azure must have a virtual size aligned to 1 MB. When you convert from a raw disk to VHD, you must ensure that the raw disk size is a multiple of 1 MB before conversion. For more information, see Linux installation notes.

Prepare a Debian image for Azure

You can create the base Azure Debian cloud image with the fully automatic installation (FAI) cloud image builder. To prepare an image without FAI, check out the generic steps article.

The following git clone and apt installation commands were pulled from the Debian cloud images repo. Start by cloning the repo and installing dependencies:

```
```

```
$ git clone https://salsa.debian.org/cloud-team/debian-cloud-images.git
$ sudo apt install --no-install-recommends ca-certificates debsums
dosfstools \
    fai-server fai-setup-storage make python3 python3-libcloud python3-
marshmallow \
    python3-pytest python3-yaml qemu-utils udev
$ cd ./debian-cloud-images
```

Optional: Customize the build by adding scripts (for example, shell scripts) to `./config_space/scripts/AZURE`.

Script example to customize the image

```
$ mkdir -p ./config_space/scripts/AZURE
$ cat > ./config_space/scripts/AZURE/10-custom <<EOF
#!/bin/bash

\$ROOTCMD bash -c "echo test > /usr/local/share/testing"
EOF
$ sudo chmod 755 ./config_space/scripts/AZURE/10-custom
```

Prefix any commands you want to have customizing the image with `$ROOTCMD`. It's aliased as `chroot $target`.

Build the Azure Debian image

```
$ make image_[release]_azure_amd64
```

This command outputs a handful of files in the current directory, most notably the `image_[release]_azure_amd64.raw` image file.

Convert the raw image to VHD for Azure:

```
rawdisk="image_[release]_azure_amd64.raw"
vhddisk="image_[release]_azure_amd64.vhd"

MB=$((1024*1024))
size=$(qemu-img info -f raw --output json "$rawdisk" | \
```

```
gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')

rounded_size=$((($size+$MB-1)/$MB)*$MB))
rounded_size_adjusted=$(($rounded_size + 512))

echo "Rounded Size Adjusted = $rounded_size_adjusted"

sudo qemu-img resize "$rawdisk" $rounded_size
qemu-img convert -f raw -o subformat=fixed,force_size -O vpc "$rawdisk"
"$vhddisk"
```

This process creates a VHD `image_[release]_azure_amd64.vhd` with a rounded size so that it can be copied successfully to an Azure disk.

> ⓘ **Note**
>
> Rather than cloning the salsa repository and building images locally, current stable images can be built and downloaded from **FAI**.

After you create a stable Debian VHD image and before you upload, verify that the following packages are installed:

- apt-get install hyperv-daemons
- apt-get install waagent # *(Optional but recommended for password resets and the use of extensions)*
- apt-get install cloud-init

Then perform a full upgrade:

- apt-get full-upgrade

Now the Azure resources must be created for this image. This example uses the `$rounded_size_adjusted` variable, so it should be from within the same shell process from the preceding step.

```
az group create -l $LOCATION -n $RG

az disk create \
    -n $DISK \
    -g $RG \
    -l $LOCATION \
    --for-upload --upload-size-bytes "$rounded_size_adjusted" \
    --sku standard_lrs --hyper-v-generation V1

ACCESS=$(az disk grant-access \
```

```
    -n $DISK -g $RG \
    --access-level write \
    --duration-in-seconds 86400 \
    --query accessSas -o tsv)

azcopy copy "$vhddisk" "$ACCESS" --blob-type PageBlob

az disk revoke-access -n $DISK -g $RG
az image create \
    -g $RG \
    -n $IMAGE \
    --os-type linux \
    --source $(az disk show \
        -g $RG \
        -n $DISK \
        --query id -o tsv)
az vm create \
    -g $RG \
    -n $VM \
    --ssh-key-value $SSH_KEY_VALUE \
    --public-ip-address-dns-name $VM \
    --image $(az image show \
        -g $RG \
        -n $IMAGE \
        --query id -o tsv)
```

If the bandwidth from your local machine to the Azure disk is causing a long time to process the upload with `azcopy`, you can use an Azure VM jumpbox to speed up the process. Here's how this process can be done:

1. Create a tarball of the VHD on your local machine: `tar -czvf ./image_buster_azure_amd64.vhd.tar.gz ./image_[release]_azure_amd64.vhd`.
2. Create an Azure Linux VM (distribution of your choice). Make sure that you create it with a large-enough disk to hold the extracted VHD.
3. Download the `azcopy` utility to the Azure Linux VM. You can retrieve it from Get started with AzCopy.
4. Copy the tarball to the VM: `scp ./image_buster_azure_amd64.vhd.tar.gz <vm>:~`.
5. On the VM, extract the VHD: `tar -xf ./image_buster_azure_amd64.vhd.tar.gz`. This step takes a bit of time based on the size of the file.
6. Finally, on the VM, copy the VHD to the Azure disk with `azcopy` (the preceding command).

Related content

You're now ready to use your Debian Linux VHD to create new VMs in Azure. If this is the first time that you're uploading the .vhd file to Azure, see Create a Linux VM from a

custom disk.

Using a prebuilt Flatcar image for Azure

Applies to: ✔ Linux VMs ✔ Flexible scale sets

You can download prebuilt Azure virtual hard disk images of Flatcar Container Linux for each of the Flatcar supported channels:

- stable
- beta
- alpha
- LTS

This image is already fully set up and optimized to run on Azure. You only need to decompress it.

Building your own Flatcar-based virtual machine for Azure

Alternatively, you can choose to build your own Flatcar Container Linux image.

On any linux based machine, follow the instructions detailed in the Flatcar Container Linux developer SDK guide. When running the `image_to_vm.sh` script, make sure you pass `--format=azure` to create an Azure virtual hard disk.

Next steps

Once you have the .vhd file, you can use the resulting file to create new virtual machines in Azure. If this is the first time that you're uploading a .vhd file to Azure, see Create a Linux VM from a custom disk.

Last updated on 01/22/2026

Introduction to FreeBSD on Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article provides an overview of running a FreeBSD virtual machine (VM) in Azure.

Overview

FreeBSD for Azure is an advanced computer operating system used to power modern servers, desktops, and embedded platforms.

Microsoft is making images of FreeBSD available on Azure with the Azure VM Guest Agent preconfigured. Currently, the following FreeBSD versions are offered as images by Microsoft:

- FreeBSD 10.4 in Azure Marketplace
- FreeBSD 11.2 in Azure Marketplace
- FreeBSD 11.3 in Azure Marketplace
- FreeBSD 12.0 in Azure Marketplace

The following FreeBSD versions also include the Azure VM Guest Agent. They're offered as images by the FreeBSD Foundation:

- FreeBSD 11.4 in Azure Marketplace
- FreeBSD 12.2 in Azure Marketplace
- FreeBSD 13.0 in Azure Marketplace

The agent is responsible for communication between the FreeBSD VM and the Azure fabric for operations such as provisioning the VM on first use (user name, password or SSH key, and host name) and enabling functionality for selective VM extensions.

As for future versions of FreeBSD, the strategy is to stay current and make the latest releases available shortly after they're published by the FreeBSD release engineering team.

Create a FreeBSD VM through the Azure CLI on FreeBSD

First, you need to install the Azure CLI through the following command on a FreeBSD machine:

```
bash
```

```
curl -L https://aka.ms/InstallAzureCli | bash
```

If bash isn't installed on your FreeBSD machine, run the following command before the installation:

Bash

```
sudo pkg install bash
```

If Python isn't installed on your FreeBSD machine, run the following commands before the installation:

Bash

```
sudo pkg install python38
cd /usr/local/bin
sudo rm /usr/local/bin/python
sudo ln -s /usr/local/bin/python3.8 /usr/local/bin/python
```

During the installation, you're asked to `Modify profile to update your $PATH and enable shell/tab completion now? (Y/n)`. If you answer `y` and enter `/etc/rc.conf` as `a path to an rc file to update`, you might see `ERROR: [Errno 13] Permission denied`. To resolve this problem, you should grant the write permission to the current user against the file `etc/rc.conf`.

Now you can sign in to Azure and create your FreeBSD VM. The following example shows how to create a FreeBSD 11.0 VM. You can also add the parameter `--public-ip-address-dns-name` with a globally unique DNS name for a newly created public IP.

Azure CLI

```
az login
az group create --name myResourceGroup --location eastus
az vm create --name myFreeBSD11 \
    --resource-group myResourceGroup \
    --image MicrosoftOSTC:FreeBSD:11.0:latest \
    --admin-username azureuser \
    --generate-ssh-keys
```

Then you can sign in to your FreeBSD VM through the IP address that printed in the output of the preceding deployment.

Bash

```
ssh azureuser@xx.xx.xx.xx -i /etc/ssh/ssh_host_rsa_key
```

VM extensions for FreeBSD

The following VM extensions are supported in FreeBSD.

VMAccess

The VMAccess extension can:

- Reset the password of the original sudo user.
- Create a new sudo user with the password specified.
- Set the public host key with the key given.
- Reset the public host key provided during VM provisioning if the host key isn't provided.
- Open the SSH port (22) and restore the `sshd_config` if `reset_ssh` is set to `true`.
- Remove the existing user.
- Check disks.
- Repair an added disk.

CustomScript

The CustomScript extension can:

- If provided, download the customized scripts from Azure Storage or external public storage (for example, GitHub).
- Run the entry point script.
- Support inline commands.
- Convert Windows-style newline in shell and Python scripts automatically.
- Remove BOM in shell and Python scripts automatically.
- Protect sensitive data in `CommandToExecute`.

> **Note**
>
> FreeBSD VM only supports CustomScript version 1.x by now.

Authentication: User names, passwords, and SSH keys

When you're creating a FreeBSD VM by using the Azure portal, you must provide a user name, password, or SSH public key.

User names for deploying a FreeBSD VM on Azure must not match the names of system accounts (UID <100) already present in the VM ("root," for example).

Currently, only the RSA SSH key is supported. A multiline SSH key must begin with `---- BEGIN SSH2 PUBLIC KEY ----` and end with `---- END SSH2 PUBLIC KEY ----`.

Obtain superuser privileges

The user account that's specified during VM instance deployment on Azure is a privileged account. The package of sudo was installed in the published FreeBSD image.

After you're logged in through this user account, you can run commands as root by using the command syntax.

```
$ sudo <COMMAND>
```

You can optionally obtain a root shell by using `sudo -s`.

Known issues

The Azure VM Guest Agent version 2.2.2 has a known issue that causes the provision failure for FreeBSD VM on Azure. The fix was captured by Azure VM Guest Agent version 2.2.3 and later releases.

Prepare an Oracle Linux virtual machine for Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article assumes that you've already installed an Oracle Linux operating system (OS) to a virtual hard disk (VHD). Multiple tools exist to create .vhd files. An example is a virtualization solution such as Hyper-V. For instructions, see Install the Hyper-V role and configure a virtual machine (VM).

Oracle Linux installation notes

- For more tips on preparing Linux for Azure, see General Linux installation notes.
- Hyper-V and Azure support Oracle Linux with either the Unbreakable Enterprise Kernel (UEK) or the Red Hat Compatible Kernel.
- Oracle's UEK2 isn't supported on Hyper-V and Azure because it doesn't include the required drivers.
- The VHDX format isn't supported in Azure, only *fixed VHD*. You can convert the disk to VHD format by using Hyper-V Manager or the `convert-vhd` cmdlet.
- *Kernel support for mounting user-defined functions (UDF) file systems is required.* At first boot on Azure, the provisioning configuration is passed to the Linux VM via UDF-formatted media that's attached to the guest. The Azure Linux agent must be able to mount the UDF file system to read its configuration and provision the VM.
- When you install the Linux system, we recommend that you use standard partitions rather than Logical Volume Manager (LVM), which is often the default for many installations. These standard partitions avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. LVM or RAID can also be used on data disks.
- Linux kernel versions earlier than 2.6.37 don't support NUMA on Hyper-V with larger VM sizes. This issue primarily affects older distributions that use the upstream Red Hat 2.6.32 kernel and was fixed in Oracle Linux 6.6 and later.
- Don't configure a swap partition on the OS disk.
- All VHDs on Azure must have a virtual size aligned to 1 MB. When you convert from a raw disk to VHD, you must ensure that the raw disk size is a multiple of 1 MB before conversion. For more information, see Linux installation notes.
- Make sure that the `Addons` repository is enabled. Edit the file `/etc/yum.repos.d/public-yum-ol6.repo` (Oracle Linux 6) or

`/etc/yum.repos.d/public-yum-ol7.repo` (Oracle Linux 7). Change the line `enabled=0` to `enabled=1` under [ol6_addons] or [ol7_addons] in this file.

Oracle Linux 6.X

> **ⓘ Important**
>
> Remember that Oracle Linux 6.x is already at end of life. Oracle Linux version 6.10 has available Extended Lifecycle Support, which ends July 2024.

You must complete specific configuration steps in the OS for the VM to run in Azure.

1. In the center pane of Hyper-V Manager, select the VM.
2. Select **Connect** to open the window for the VM.
3. Uninstall `NetworkManager`:

   ```
   Bash

   sudo rpm -e --nodeps NetworkManager
   ```

   > **ⓘ Note**
   >
   > If the package isn't already installed, this command fails with an error message. This message is expected.

4. Create a file named **network** in the `/etc/sysconfig/` directory that contains the following text:

   ```
   config

   NETWORKING=yes
   HOSTNAME=localhost.localdomain
   ```

5. Create a file named **ifcfg-eth0** in the `/etc/sysconfig/network-scripts/` directory that contains the following text:

   ```
   config

   DEVICE=eth0
   ONBOOT=yes
   ```

```
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
```

6. Modify udev rules to avoid generating static rules for the Ethernet interfaces. These rules can cause problems when you clone a VM in Azure or Hyper-V:

```Bash
sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-
generator.rules
sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

7. Ensure that the network service starts at boot time:

```Bash
sudo chkconfig network on
```

8. Install `python-pyasn1`:

```Bash
sudo yum install python-pyasn1
```

9. Modify the kernel boot line in your grub configuration to include more kernel parameters for Azure. To do this step, open `/boot/grub/menu.lst` in a text editor and ensure that the kernel includes the following parameters:

```config-grub
console=ttyS0 earlyprintk=ttyS0
```

   This setting ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

   In addition to the preceding steps, we recommend that you *remove* the following parameters:

```config-grub
rhgb quiet crashkernel=auto
```

Graphical and quiet boot aren't useful in a cloud environment where you want all the logs to be sent to the serial port.

The `crashkernel` option can be left configured if you want. This parameter reduces the amount of available memory in the VM by 128 MB or more, which might be a problem for smaller VM sizes.

10. Ensure that the SSH server is installed and configured to start at boot time. This setting is usually the default.

11. Install the Azure Linux agent by running the following command. The latest version is 2.0.15.

```Bash
sudo yum install WALinuxAgent
```

Installing the `WALinuxAgent` package removes the `NetworkManager` and `NetworkManager-gnome` packages if they weren't already removed, as described in step 2.

12. Don't create swap space on the OS disk.

The Azure Linux agent can automatically configure swap space by using the local resource disk that's attached to the VM after provisioning on Azure. The local resource disk is a *temporary* disk and might be emptied when the VM is deprovisioned. After you install the Azure Linux agent (see the previous step), modify the following parameters in `/etc/waagent.conf` appropriately:

```config-conf
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt
ResourceDisk.EnableSwap=y
ResourceDisk.SwapSizeMB=2048    ## NOTE: set this to whatever you need
it to be.
```

13. Deprovision the VM and prepare it for provisioning on Azure:

```Bash
sudo waagent -force -deprovision
sudo export HISTSIZE=0
sudo logout
```

14. Select **Action** > **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be uploaded to Azure.

Oracle Linux 7.0 and later

Follow the steps in the next sections if you're using Oracle Linux 7.0 or later.

Changes in Oracle Linux 7

Preparing an Oracle Linux 7 VM for Azure is similar to Oracle Linux 6, but several differences are worth noting:

- Azure supports Oracle Linux with either the Unbreakable Enterprise Kernel (UEK) or the Red Hat Compatible Kernel. We recommend that you use Oracle Linux with UEK.
- The `NetworkManager` package no longer conflicts with the Azure Linux agent. This package is installed by default, and we recommend that you don't remove it.
- GRUB2 is now used as the default bootloader, so the procedure for editing kernel parameters has changed. (See the "Configuration steps" section.)
- XFS is now the default file system. The ext4 file system can still be used if you want.

Configuration steps

1. In Hyper-V Manager, select the VM.
2. Select **Connect** to open a console window for the VM.
3. Create a file named **network** in the `/etc/sysconfig/` directory that contains the following text:

   ```
   config

   NETWORKING=yes
   HOSTNAME=localhost.localdomain
   ```

4. Create a file named **ifcfg-eth0** in the `/etc/sysconfig/network-scripts/` directory that contains the following text:

   ```
   config

   DEVICE=eth0
   ONBOOT=yes
   ```

```
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
```

5. Modify udev rules to avoid generating static rules for the Ethernet interfaces. These rules can cause problems when you clone a VM in Azure or Hyper-V:

```
Bash

sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-
generator.rules
```

6. Ensure that the network service starts at boot time:

```
Bash

sudo chkconfig network on
```

7. Install the `python-pyasn1` package:

```
Bash

sudo yum install python3-pyasn1
```

8. Clear the current yum metadata and install any updates:

```
Bash

sudo yum clean all
sudo yum -y update
```

9. Modify the kernel boot line in your grub configuration to include more kernel parameters for Azure. To do this step, open `/etc/default/grub` in a text editor and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

```
config-grub

GRUB_CMDLINE_LINUX="console=ttyS0 earlyprintk=ttyS0 net.ifnames=0"
```

   This modification also ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues. It also turns off the

naming conventions for network interface cards in Oracle Linux 7 with the UEK. We also recommend that you *remove* the following parameters:

config-grub

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot aren't useful in a cloud environment where you want all the logs to be sent to the serial port.

The `crashkernel` option can be left configured if you want. This parameter reduces the amount of available memory in the VM by 128 MB or more, which might be a problem for smaller VM sizes.

10. After you're finished editing `/etc/default/grub`, rebuild the grub configuration:

    Bash

    ```
    sudo grub2-mkconfig -o /boot/grub2/grub.cfg
    ```

11. Ensure that the SSH server is installed and configured to start at boot time. This setting is usually the default.

12. Install the Azure Linux agent and dependencies:

    Bash

    ```
    sudo yum install WALinuxAgent
    sudo systemctl enable waagent
    ```

13. Install `cloud-init` to handle the provisioning:

    Bash

    ```
    sudo yum install -y cloud-init cloud-utils-growpart gdisk hyperv-
    daemons
    ```

14. Configure `waagent` for `cloud-init`:

    Bash

    ```
    sudo sed -i
    's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=y/g'
    /etc/waagent.conf
    ```

```
sudo sed -i 's/Provisioning.Enabled=y/Provisioning.Enabled=n/g'
/etc/waagent.conf
```

Bash

```
sudo echo "Adding mounts and disk_setup to init stage"
sudo sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sudo sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
```

Bash

```
echo "Allow only Azure datasource, disable fetching network setting via
IMDS"
```

Bash

```
sudo cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
datasource_list: [ Azure ]
datasource:
    Azure:
        apply_network_config: False
EOF

if [[ -f /mnt/resource/swapfile ]]; then
echo Removing swapfile - Oracle Linux uses a swapfile by default
swapoff /mnt/swapfile
rm /mnt/swapfile -f
fi

echo "Add console log file"
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

15. Swap configuration:

    a. Don't create swap space on the operating system disk.

    Previously, the Azure Linux agent was used automatically to configure swap space by using the local resource disk that's attached to the VM after the VM is provisioned on Azure. However, `cloud-init` now handles this step. You *must not*

use the Linux agent to format the resource disk to create the swap file. Modify the following parameters in `/etc/waagent.conf` appropriately:

Bash

```
sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g'
/etc/waagent.conf
sudo sed -i
's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
/etc/waagent.conf
```

b. If you want to mount, format, and create the swap, you can either:

- Pass this code in as a `cloud-init` configuration every time you create a VM.
- Use a `cloud-init` directive baked into the image to do this step every time the VM is created:

Bash

```
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-
swap.cfg"' >> /etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt/resource"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-
systemd.requires=cloud-init.service,x-systemd.device-timeout=2",
"0", "0"]
EOF
```

16. Deprovision the VM and prepare it for provisioning on Azure:

Bash

```
sudo cloud-init clean
sudo rm -f /var/log/waagent.log
sudo waagent -force -deprovision
```

```
sudo rm -f ~/.bash_history
sudo export HISTSIZE=0
```

> **Note**
>
> If you're migrating a specific VM and don't want to create a generalized image, skip the deprovision step.

17. Select **Action** > **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be uploaded to Azure.

Related content

You're now ready to use your Oracle Linux .vhd to create new VMs in Azure. If this is the first time that you're uploading the .vhd file to Azure, see Create a Linux VM from a custom disk.

Create and upload an OpenBSD disk image to Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to create and upload a virtual hard disk (VHD) that contains the OpenBSD operating system. After you upload it, you can use it as your own image to create a virtual machine (VM) in Azure through the Azure CLI.

Prerequisites

This article assumes that you have the following items:

- **An Azure subscription**: If you don't have an account, you can create one in a couple of minutes. If you have an MSDN subscription, see Monthly Azure credit for Visual Studio subscribers. Otherwise, learn how to create a free trial account.
- **Azure CLI**: Make sure you have the latest Azure CLI installed and logged in to your Azure account with az login.
- **OpenBSD operating system installed in a .vhd file**: A supported OpenBSD operating system (6.6 version AMD64) must be installed to a VHD. Multiple tools exist to create .vhd files. For example, you can use a virtualization solution such as Hyper-V to create the .vhd file and install the operating system. For instructions about how to install and use Hyper-V, see Install Hyper-V and create a VM.

Prepare an OpenBSD image for Azure

On the VM where you installed the OpenBSD operating system 6.1, which added Hyper-V support, complete the following procedures:

1. If DHCP isn't enabled during installation, enable the service:

   ```sh
   doas echo dhcp > /etc/hostname.hvn0
   ```

2. Set up a serial console:

   ```sh
   ```

```
doas echo "stty com0 115200" >> /etc/boot.conf
doas echo "set tty com0" >> /etc/boot.conf
```

3. Configure package installation:

```sh
doas echo "https://ftp.openbsd.org/pub/OpenBSD" > /etc/installurl
```

4. By default, the `root` user is disabled on VMs in Azure. Users can run commands with elevated privileges by using the `doas` command on OpenBSD VM. Doas is enabled by default.

5. Install and configure prerequisites for the Azure agent:

```sh
doas pkg_add py-setuptools openssl git
doas ln -sf /usr/local/bin/python2.7 /usr/local/bin/python
doas ln -sf /usr/local/bin/python2.7-2to3 /usr/local/bin/2to3
doas ln -sf /usr/local/bin/python2.7-config /usr/local/bin/python-
config
doas ln -sf /usr/local/bin/pydoc2.7  /usr/local/bin/pydoc
```

6. You can find the latest release of the Azure agent on GitHub. Install the agent:

```sh
doas git clone https://github.com/Azure/WALinuxAgent
doas cd WALinuxAgent
doas python setup.py install
doas waagent -register-service
```

> **Important**
>
> After you install the Azure agent, it's a good idea to verify that it's running:
>
> ```sh
> doas ps auxw | grep waagent
> root     79309  0.0  1.5  9184 15356 p1  S      4:11PM    0:00.46
> python /usr/local/sbin/waagent -daemon (python2.7)
> doas cat /var/log/waagent.log
> ```

7. Deprovision the system to clean it and make it suitable for deprovisioning. The following command also deletes the last provisioned user account and the associated data:

```sh
doas waagent -deprovision+user -force
```

> **Note**
>
> If you're migrating a specific VM and don't want to create a generalized image, skip the deprovision step.

Now you can shut down your VM.

Prepare the VHD

The VHDX format isn't supported in Azure, only *fixed VHD*. You can convert the disk to fixed VHD format by using Hyper-V Manager or the PowerShell convert-vhd cmdlet. Here's an example:

```PowerShell
Convert-VHD OpenBSD61.vhdx OpenBSD61.vhd -VHDType Fixed
```

Create storage resources and upload

First, create a resource group with az group create. The following example creates a resource group named `myResourceGroup` in the `eastus` location:

```Azure CLI
az group create --name myResourceGroup --location eastus
```

To upload your VHD, create a storage account with az storage account create. Storage account names must be unique, so provide your own name. The following example creates a storage account named `mystorageaccount`:

Azure CLI

```
az storage account create --resource-group myResourceGroup \
    --name mystorageaccount \
    --location eastus \
    --sku Premium_LRS
```

To control access to the storage account, obtain the storage key with the az storage account keys list:

Azure CLI

```
STORAGE_KEY=$(az storage account keys list \
    --resource-group myResourceGroup \
    --account-name mystorageaccount \
    --query "[?keyName=='key1']  | [0].value" -o tsv)
```

To logically separate the VHDs you upload, create a container within the storage account with az storage container create:

Azure CLI

```
az storage container create \
    --name vhds \
    --account-name mystorageaccount \
    --account-key ${STORAGE_KEY}
```

Finally, upload your VHD with az storage blob upload:

Azure CLI

```
az storage blob upload \
    --container-name vhds \
    --file ./OpenBSD61.vhd \
    --name OpenBSD61.vhd \
    --account-name mystorageaccount \
    --account-key ${STORAGE_KEY}
```

Create a VM from your VHD

You can create a VM with a sample script or directly with az vm create. To specify the OpenBSD VHD you uploaded, use the `--image` parameter:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
```

```
    --name myOpenBSD61 \
    --image
"https://mystorageaccount.blob.core.windows.net/vhds/OpenBSD61.vhd" \
    --os-type linux \
    --admin-username azureuser \
    --ssh-key-value ~/.ssh/id_rsa.pub
```

Obtain the IP address for your OpenBSD VM with az vm list-ip-addresses:

Azure CLI

```
az vm list-ip-addresses --resource-group myResourceGroup --name myOpenBSD61
```

Now you can SSH to your OpenBSD VM as normal:

Bash

```
ssh azureuser@<ip address>
```

Prepare a Red Hat-based virtual machine for Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

In this article, you learn how to prepare a Red Hat Enterprise Linux (RHEL) virtual machine (VM) for use in Azure. The versions of RHEL that are covered in this article are 7.x, 8.X., 9.x. The hypervisors for preparation that are covered in this article are Hyper-V, kernel-based VM (KVM), VMware, and Kickstart.

For more information about eligibility requirements for participating in Red Hat's Cloud Access program, see the Red Hat Cloud Access website and Running RHEL on Azure. For ways to automate building RHEL images, see Azure Image Builder.

Prerequisites

> **Note**
>
> This document assumes you already deployed RHEL7 and have it fully licensed. Uploaded images that are at or beyond EOL are supported on a reasonable business-effort basis. For more information, see the Red Hat Product Life Cycles.

RHEL installation notes

- Azure doesn't support the VHDX format. Azure supports only *fixed VHD*. You can use Hyper-V Manager to convert the disk to VHD format, or you can use the `convert-vhd` cmdlet. If you use VirtualBox, select **Fixed size** as opposed to the default dynamically allocated option when you create the disk.
- Azure supports Gen1 (BIOS boot) and Gen2 (UEFI boot) VMs.
- The maximum allowed size for the VHD is 1,023 GB.
- The vfat kernel module must be enabled in the kernel.
- Logical Volume Manager (LVM) is supported and can be used on the OS disk or data disks in Azure VMs. In general, we recommend that you use standard partitions on the OS disk rather than LVM. This practice avoids LVM name conflicts with cloned VMs, particularly if you ever need to attach an operating system disk to another identical VM for troubleshooting. For more information, see the LVM and RAID documentation.
- *Kernel support for mounting Universal Disk Format (UDF) file systems is required*. At first boot on Azure, the attached UDF-formatted media passes the provisioning configuration

to the Linux VM. The Azure Linux agent must be able to mount the UDF file system to read its configuration and provision the VM. Without this step, provisioning fails.

- Don't configure a swap partition on the operating system disk. For more information, read the following steps.
- All VHDs on Azure must have a virtual size aligned to 1 MB. When you convert from a raw disk to VHD, you must ensure that the raw disk size is a multiple of 1 MB before conversion. For more information, read the following steps. See also Linux installation notes.

> **Note**
>
> *Cloud-init >= 21.2 removes the UDF requirement*. However, without the UDF module enabled, the provided CD-ROM fails to mount, preventing custom data from being applied. A workaround is to apply custom data by using user data. Unlike custom data, user data isn't encrypted. For more information, see User data formats.

RHEL 7 using Hyper-V Manager

1. In Hyper-V Manager, select the VM.
2. Select **Connect** to open a console window for the VM.
3. Create or edit the `/etc/sysconfig/network` file, and add the following text:

   ```config
   NETWORKING=yes
   HOSTNAME=localhost.localdomain
   ```

4. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

   ```config
   DEVICE=eth0
   ONBOOT=yes
   BOOTPROTO=dhcp
   TYPE=Ethernet
   USERCTL=no
   PEERDNS=yes
   IPV6INIT=no
   PERSISTENT_DHCLIENT=yes
   NM_CONTROLLED=yes
   ```

> **Note**
>
> When you use Accelerated Networking, the provisioned synthetic interface must be configured to be unmanaged by using a udev rule. This action prevents `NetworkManager` from assigning the same IP to it as the primary interface.

To apply it:

Bash

```
sudo tee <<EOF /etc/udev/rules.d/68-azure-sriov-nm-unmanaged.rules >
/dev/null
# Accelerated Networking on Azure exposes a new SRIOV interface to the VM.
# This interface is transparently bonded to the synthetic interface,
# so NetworkManager should just ignore any SRIOV interfaces.
SUBSYSTEM=="net", DRIVERS=="hv_pci", ACTION!="remove",
ENV{NM_UNMANAGED}="1"
EOF
```

5. Ensure that the network service starts at boot time:

Bash

```
sudo systemctl enable network
```

6. Register your Red Hat subscription to enable the installation of packages from the RHEL repository:

Bash

```
sudo subscription-manager register --auto-attach --username=XXX --
password=XXX
```

7. Modify the kernel boot line in your grub configuration to include more kernel parameters for Azure. To do this modification, open `/etc/default/grub` in a text editor and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

config-grub

```
GRUB_TIMEOUT=10
GRUB_CMDLINE_LINUX="console=tty1 console=ttyS0,115200n8 earlyprintk=ttyS0
net.ifnames=0 nvme_core.io_timeout=240"
GRUB_TERMINAL="serial console"
GRUB_SERIAL_COMMAND="serial --speed=115200 --unit=0 --word=8 --parity=no -
-stop=1"
```

These modifications turn off the new naming convention for NICs, ensure all console messages are sent to the first serial port, and enable interaction with the console, which can assist Aure support with debugging issues.

```config
rhgb quiet crashkernel=auto
```

Graphical and quiet boots aren't useful in a cloud environment where you want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if you want. This parameter reduces the amount of available memory in the VM by 128 MB or more, which might be a problem for smaller VM sizes.

8. After you're finished editing `/etc/default/grub`, run the following command to rebuild the grub configuration:

```Bash
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

> **Note**
>
> If you're uploading a UEFI-enabled VM, the command to update grub is `grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg`.

9. Ensure that the SSH server is installed and configured to start at boot time, which is usually the default. Modify `/etc/ssh/sshd_config` to include the following line:

```config
ClientAliveInterval 180
```

10. The WALinuxAgent package, `WALinuxAgent-<version>`, is available from the Extras repository.

```Bash
sudo subscription-manager repos --enable=rhel-7-server-extras-rpms
```

11. Install the Azure Linux agent, `cloud-init`, and other necessary utilities:

```Bash
```

```
sudo yum install -y WALinuxAgent cloud-init cloud-utils-growpart gdisk
hyperv-daemons
sudo systemctl enable waagent.service
sudo systemctl enable cloud-init.service
```

12. Configure `cloud-init` to handle the provisioning:

    a. Configure `waagent` for `cloud-init`:

    Bash

    ```
    sudo sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=auto/g'
    /etc/waagent.conf
    sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g'
    /etc/waagent.conf
    sudo sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
    /etc/waagent.conf
    ```

    > **Note**
    >
    > If you're migrating a specific VM and don't want to create a generalized image, set `Provisioning.Agent=disabled` on the `/etc/waagent.conf` configuration.

    b. Configure mounts:

    Bash

    ```
    sudo echo "Adding mounts and disk_setup to init stage"
    sudo sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
    sudo sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
    sudo sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
    sudo sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
    ```

    c. Configure the Azure data source:

    Bash

    ```
    sudo echo "Allow only Azure datasource, disable fetching network setting
    via IMDS"
    sudo tee /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
    datasource_list: [ Azure ]
    datasource:
        Azure:
            apply_network_config: False
    EOF
    ```

d. If configured, remove the existing swap file:

```bash
if [[ -f /mnt/resource/swapfile ]]; then
echo "Removing swapfile" #RHEL uses a swapfile by default
swapoff /mnt/resource/swapfile
rm /mnt/resource/swapfile -f
fi
```

e. Configure `cloud-init` logging:

```bash
sudo echo "Add console log file"
sudo tee <<EOF /etc/cloud/cloud.cfg.d/05_logging.cfg > /dev/null

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

13. Swap configuration:

- Don't create swap space on the operating system disk.

  Previously, the Azure Linux agent was used to automatically configure swap space on the local resource disk attached to the VM after the VM is provisioned on Azure, `cloud-init` handles now this action. You *must not* use the Linux agent to format the resource disk to create the swap file. Modify the following parameters in `/etc/waagent.conf` appropriately:

  ```config
  ResourceDisk.Format=n
  ResourceDisk.EnableSwap=n
  ```

- If you want to mount, format, and create the swap, you can either:
  - Pass this code in as a `cloud-init` configuration every time you create a VM through custom data. We recommend this method.
  - Use a `cloud-init` directive baked into the image that does this step every time the VM is created.

Bash

```
sudo echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >> /etc/systemd/system.conf
sudo tee /etc/cloud/cloud.cfg.d/00-azure-swap.cfg <<EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt/resource"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-systemd.device-timeout=2", "0", "0"]
EOF
```

14. Configure `cloud-init` telemetry to assist with troubleshooting for provisioning issues:

    Bash

    ```
    sudo tee -a /etc/cloud/cloud.cfg.d/10-azure-kvp.cfg <<EOF
    # This config enables cloud-init to report provisioning telemetry to aid with troubleshooting
    Reporting:
      logging:
        type: log
      telemetry:
        type: hyperv
    EOF
    ```

15. If you want to unregister the subscription, run the following command:

    Bash

    ```
    sudo subscription-manager unregister
    ```

16. Deprovision the VM and prepare it for provisioning on Azure:

    ⊗ Caution

If you're migrating a specific VM and don't want to create a generalized image, skip the deprovision step. Running the command `waagent -force -deprovision+user` renders the source machine unusable. This step is intended only to create a generalized image.

Bash

```
sudo rm -f /var/log/waagent.log
sudo cloud-init clean --logs --seed
sudo waagent -force -deprovision+user
sudo rm -f ~/.bash_history
sudo export HISTSIZE=0
```

17. Select **Action** > **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be uploaded to Azure.

Last updated on 02/11/2026

Prepare a SLES or openSUSE Leap virtual machine for Azure

09/02/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets **Applies to:** ✔ Uniform scale sets

In some cases, you might want to use customized SUSE Linux Enterprise Server (SLES) or openSUSE Leap Linux virtual machines (VMs) in your Azure environment and be able to build these types of VMs through automation. This article demonstrates how to create and upload a custom Azure virtual hard disk (VHD) that contains a SUSE Linux operating system.

Prerequisites

This article assumes that you already installed a SLES or openSUSE Leap Linux operating system on a virtual hard disk. Multiple tools exist to create .vhd files. For example, you can use a virtualization solution such as Hyper-V. For instructions, see Install Hyper-V and create a virtual machine.

SLES/openSUSE Leap installation notes

- For more tips on preparing Linux images for Azure, see General Linux installation notes.
- Azure doesn't support Windows Hard Disk Image (.vhdx) files. Only VHD (.vhd) files are supported outside virtual machines. You can convert the disk to VHD format by using Hyper-V Manager or the `Convert-VHD` cmdlet.
- Azure supports Gen1 (BIOS boot) and Gen2 (UEFI boot) virtual machines.
- The virtual file allocation table (VFAT) kernel module must be enabled in the kernel.
- Don't configure a swap partition on the OS disk. You can configure the Linux agent to create a swap file on the temporary resource disk. Steps later in this article give more information about configuring swap space.
- All VHDs on Azure must have a virtual size aligned to 1 MB. When you're converting from a raw disk to VHD, ensure that the raw disk size is a multiple of 1 MB before conversion. For more information, see General Linux installation notes.

> **Note**
>
> Cloud-init version 21.2 or later removes the user-defined function (UDF) requirement. But without the `udf` module enabled, the CD-ROM won't mount during provisioning, which prevents the custom data from being applied. A workaround is to apply user data.

However, unlike custom data, user data isn't encrypted. For more information, see User data formats in the cloud-init documentation.

Use SUSE Studio

SUSE Studio can easily create and manage your SLES and openSUSE Leap images for Azure and Hyper-V. SUSE Studio is the recommended approach for customizing your own SLES and openSUSE Leap images.

As an alternative to building your own VHD, SUSE also publishes BYOS (bring your own subscription) images for SLES at VM Depot.

Prepare SLES for Azure

1. Configure the Azure and Hyper-V modules if required.

   If your software hypervisor is not Hyper-V, other modules need to be added into the initial RAM disk (initramfs) to successfully boot in Azure.

   Edit the */etc/dracut.conf* file and add the following line to the file:

   ```config
   add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
   ```

   Run the `dracut` command to rebuild the initramfs file:

   ```Bash
   sudo dracut --verbose --force
   ```

2. Set up the serial console.

   To successfully work with the serial console, you must set up several variables in the */etc/defaults/grub* file and re-create GRUB on the server:

   ```config
   # Add console=ttyS0 and earlyprintk=ttS0 to the variable.
   # Remove "splash=silent" and "quiet" options.
   GRUB_CMDLINE_LINUX_DEFAULT="audit=1 no-scroll fbcon=scrollback:0
   mitigations=auto security=apparmor crashkernel=228M,high crashkernel=72M,low
   console=ttyS0 earlyprintk=ttyS0"
   ```

```
# Add "console serial" to GRUB_TERMINAL.
GRUB_TERMINAL="console serial"

# Set the GRUB_SERIAL_COMMAND variable.

GRUB_SERIAL_COMMAND="serial --speed=115200 --unit=0 --word=8 --parity=no --
stop=1"
```

shell

```
/usr/sbin/grub2-mkconfig -o /boot/grub2/grub.cfg
```

3. Register your SUSE Linux Enterprise system to allow it to download updates and install packages.

4. Update the system with the latest patches:

Bash

```
sudo zypper update
```

5. Install the Azure Linux VM Agent (`waagent`) and cloud-init:

Bash

```
sudo SUSEConnect -p sle-module-public-cloud/15.2/x86_64  (SLES 15 SP2)
sudo zypper refresh
sudo zypper install python-azure-agent
sudo zypper install cloud-init
```

6. Enable `waagent` and cloud-init to start on boot:

Bash

```
sudo systemctl enable  waagent
sudo systemctl enable cloud-init-local.service
sudo systemctl enable cloud-init.service
sudo systemctl enable cloud-config.service
sudo systemctl enable cloud-final.service
sudo systemctl daemon-reload
sudo cloud-init clean
```

7. Update the cloud-init configuration:

Bash

```
cat <<EOF | sudo tee /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg
datasource_list: [ Azure ]
datasource:
    Azure:
        apply_network_config: False

EOF
```

Bash

```
sudo cat <<EOF | sudo tee  /etc/cloud/cloud.cfg.d/05_logging.cfg
# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF

# Make sure mounts and disk_setup are in the init stage:
echo "Adding mounts and disk_setup to init stage"
sudo sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sudo sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sudo sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
```

8. If you want to mount, format, and create a swap partition, one option is to pass in a cloud-init configuration every time you create a VM.

   Another option is to use a cloud-init directive in the image to configure swap space every time the VM is created:

Bash

```
cat  <<EOF | sudo tee -a /etc/systemd/system.conf
'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"'
EOF

cat <<EOF | sudo tee /etc/cloud/cloud.cfg.d/00-azure-swap.cfg
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
```

```
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-
init.service,x-systemd.device-timeout=2", "0", "0"]
EOF
```

9. Previously, the Azure Linux Agent was used to automatically configure swap space by using the local resource disk that's attached to the virtual machine after the virtual machine is provisioned on Azure. Because cloud-init now handles this step, you *must not* use the Azure Linux Agent to format the resource disk or create the swap file. Use these commands to modify */etc/waagent.conf* appropriately:

   Bash

   ```
   sudo sed -i 's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=auto/g'
   /etc/waagent.conf
   sudo sed -i 's/Provisioning.Enabled=y/Provisioning.Enabled=n/g'
   /etc/waagent.conf
   sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g'
   /etc/waagent.conf
   sudo sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
   /etc/waagent.conf
   ```

   > **Note**
   >
   > If you're using a cloud-init version earlier than 21.2, make sure the `udf` module is enabled. Removing or disabling it will cause a provisioning or boot failure. Cloud-init version 21.2 or later removes the UDF requirement.

10. Ensure that the */etc/fstab* file references the disk by using its UUID (`by-uuid`).

11. Remove udev rules and network adapter configuration files to avoid generating static rules for the Ethernet interfaces. These rules can cause problems when you're cloning a virtual machine in Microsoft Azure or Hyper-V.

    Bash

    ```
    sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
    sudo rm -f /etc/udev/rules.d/85-persistent-net-cloud-init.rules
    sudo rm -f /etc/sysconfig/network/ifcfg-eth*
    ```

12. We recommend that you edit the */etc/sysconfig/network/dhcp* file and change the `DHCLIENT_SET_HOSTNAME` parameter to the following:

    config

```
DHCLIENT_SET_HOSTNAME="no"
```

13. In the */etc/sudoers* file, comment out or remove the following lines if they exist:

```
Output

Defaults targetpw   # Ask for the password of the target user i.e. root
ALL    ALL=(ALL) ALL   # WARNING! Only use this setting together with
'Defaults targetpw'!
```

14. Ensure that the Secure Shell (SSH) server is installed and configured to start at boot time:

```
Bash

sudo systemctl enable sshd
```

15. Clean the cloud-init stage:

```
Bash

sudo cloud-init clean --seed --logs
```

16. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure.

    If you're migrating a specific virtual machine and don't want to create a generalized image, skip the deprovisioning step.

```
Bash

sudo rm -f /var/log/waagent.log
sudo waagent -force -deprovision+user
sudo export HISTSIZE=0
sudo rm -f ~/.bash_history
```

Prepare openSUSE 15.4+

1. On the center pane of Hyper-V Manager, select the virtual machine.
2. Select **Connect** to open the window for the virtual machine.
3. In a terminal, run the command `zypper lr`. If this command returns output similar to the following example, the repositories are configured as expected and no adjustments are

necessary. (Version numbers might vary.)

Expand table

#	Alias	Name	Enabled	GPG Check	Refresh
1	Cloud:Tools_15.4	Cloud:Tools->	Yes	(r) Yes	Yes
2	openSUSE_stable_OSS	openSUSE_st->	Yes	(r) Yes	Yes
3	openSUSE_stable_Updates	openSUSE_st->	Yes	(r) Yes	Yes

If the the message "***No repositories defined***" appears from the `zypper lr` the repositories must be added manually.

Below are examples of commands for adding these repositories (versions and links may vary):

Bash

```
sudo zypper ar -f https://download.opensuse.org/update/openSUSE-stable
openSUSE_stable_Updates
sudo zypper ar -f
https://download.opensuse.org/repositories/Cloud:/Tools/15.4 Cloud:Tools_15.4
sudo zypper ar -f https://download.opensuse.org/distribution/openSUSE-
stable/repo/oss openSUSE_stable_OSS
```

You can then verify that the repositories have been added by running the command `zypper lr` again. If one of the relevant update repositories isn't enabled, enable it by using the following command:

Bash

```
sudo zypper mr -e [NUMBER OF REPOSITORY]
```

4. Update the kernel to the latest available version:

Bash

```
sudo zypper up kernel-default
```

Or update the operating system with all the latest patches:

Bash

```
sudo zypper update
```

5. Install the Azure Linux Agent:

```Bash
sudo zypper install WALinuxAgent
```

6. Modify the kernel boot line in your GRUB configuration to include other kernel parameters for Azure. To do this, open */boot/grub/menu.lst* in a text editor and ensure that the default kernel includes the following parameters:

```config-grub
console=ttyS0 earlyprintk=ttyS0
```

   This option ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues. In addition, remove the following parameters from the kernel boot line if they exist:

```config-grub
 libata.atapi_enabled=0 reserve=0x1f0,0x8
```

7. We recommend that you edit the */etc/sysconfig/network/dhcp* file and change the `DHCLIENT_SET_HOSTNAME` parameter to the following setting:

```config
 DHCLIENT_SET_HOSTNAME="no"
```

8. In the */etc/sudoers* file, comment out or remove the following lines if they exist. This is an important step.

```Output
Defaults targetpw   # ask for the password of the target user i.e. root
ALL    ALL=(ALL) ALL   # WARNING! Only use this together with 'Defaults
targetpw'!
```

9. Ensure that the SSH server is installed and configured to start at boot time.

10. Don't create swap space on the OS disk.

The Azure Linux Agent can automatically configure swap space by using the local resource disk that's attached to the VM after provisioning on Azure. The local resource disk is a *temporary* disk and will be emptied when the VM is deprovisioned.

After you install the Azure Linux Agent, modify the parameters in */etc/waagent.conf* as follows:

```config-conf
ResourceDisk.Format=n
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.EnableSwap=n
ResourceDisk.SwapSizeMB=2048    ## NOTE: set the size to whatever you need it
to be.
```

11. Ensure that the Azure Linux Agent runs at startup:

```Bash
sudo systemctl enable waagent.service
```

12. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure.

    If you're migrating a specific virtual machine and don't want to create a generalized image, skip the deprovisioning step.

```Bash
sudo rm -f ~/.bash_history # Remove current user history
sudo rm -rf /var/lib/waagent/
sudo rm -f /var/log/waagent.log
sudo waagent -force -deprovision+user
sudo rm -f ~/.bash_history # Remove root user history
sudo export HISTSIZE=0
```

13. Select **Action** > **Shut Down** in Hyper-V Manager.

Next steps

You're now ready to use your SUSE Linux VHD to create new virtual machines in Azure. If this is the first time that you're uploading the .vhd file to Azure, see Create a Linux VM from a custom disk.

Prepare an Ubuntu virtual machine for Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Ubuntu provides official Azure-ready cloud images (cloudimg) that include all components required for successful provisioning on Azure, such as *cloud-init*, Azure-optimized kernels, Azure guest agent compatibility, and performance-tuned defaults for virtualized environments. These images are the recommended starting point when creating a custom VHD because they align with Azure VM provisioning requirements and reduce the manual configuration steps required.

Ubuntu publishes these images in multiple formats, including ready-to-use Azure virtual hard disks (VHDs), on the https://cloud-images.ubuntu.com/ website. If you need to build a specialized Ubuntu image for Azure, you can start with these validated VHD builds and customize them as needed. The latest image releases are available at the following locations:

- Ubuntu 20.04/Focal: focal-server-cloudimg-amd64-azure.vhd.tar.gz
- Ubuntu 22.04/Jammy: jammy-server-cloudimg-amd64-azure.vhd.tar.gz
- Ubuntu 24.04/Noble: noble-server-cloudimg-amd64-azure.vhd.tar.gz

Prerequisites

This article assumes that you've already installed an Ubuntu Linux operating system (OS) to a VHD. Multiple tools exist to create .vhd files. An example is a virtualization solution such as Hyper-V. For instructions, see Install the Hyper-V role and configure a virtual machine (VM).

Ubuntu installation notes

- For more tips on preparing Linux for Azure, see General Linux installation notes.
- The VHDX format isn't supported in Azure, only *fixed VHD*. You can convert the disk to VHD format by using Hyper-V Manager or the `Convert-VHD` cmdlet.
- When you install the Linux system, we recommend that you use standard partitions rather than Logical Volume Manager (LVM), which is often the default for many installations. These standard partitions avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. LVM or RAID can also be used on data disks.
- Don't configure a swap partition or swap file on the OS disk. You can configure the `cloud-init` provisioning agent to create a swap file or a swap partition on the temporary

resource disk. For more information about this process, see Create a SWAP partition for an Azure Linux VM.

- All VHDs on Azure must have a virtual size aligned to 1 MB. When you convert from a raw disk to VHD, you must ensure that the raw disk size is a multiple of 1 MB before conversion. For more information, see Linux installation notes.

You can upload a prebuilt Ubuntu image directly to Azure and use the resulting VHD to create new virtual machines. If this is your first time uploading a `.vhd` file, see Create a Linux VM from a custom disk.

Manual steps

> **Note**
>
> Before you attempt to create your own custom Ubuntu image for Azure, consider using the prebuilt and tested images from the Ubuntu Cloud Images webpage instead.

> If you are using Windows to Extract the prebuilt it image , please use Windows WSL and run the following command

Bash

```
sudo tar --sparse -xvzf <image name>-azure.vhd.tar.gz
```

1. In the center pane of Hyper-V Manager, select the VM.
2. Select **Connect** to open the window for the VM.
3. Replace the current repositories in the image to use Ubuntu's Azure repository.

   Before you edit `/etc/apt/sources.list` `/etc/apt/sources.list.d/ubuntu.sources`, we recommend that you make a backup:

   For Ubuntu 22.04 and earlier

   Bash

   ```
   sudo cp /etc/apt/sources.list /etc/apt/sources.list.bak
   ```

   For Ubuntu 24.04 and later

Bash

```
sudo cp /etc/apt/sources.list.d/ubuntu.sources
/etc/apt/sources.list.d/ubuntu.sources.bak
```

For Ubuntu 22.04 and earlier

Bash

```
sudo sed -i
's#http://archive\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubuntu
#g' /etc/apt/sources.list
sudo sed -i 's#http://[a-z][a-
z]\.archive\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubuntu#g'
/etc/apt/sources.list
sudo sed -i
's#http://security\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubunt
u#g' /etc/apt/sources.list
sudo sed -i 's#http://[a-z][a-
z]\.security\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubuntu#g'
/etc/apt/sources.list
sudo apt update
```

For Ubuntu 24.04 and later

Bash

```
sudo sed -i
's#http://archive\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubuntu
#g' /etc/apt/sources.list.d/ubuntu.sources
sudo sed -i 's#http://[a-z][a-
z]\.archive\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubuntu#g'
/etc/apt/sources.list.d/ubuntu.sources
sudo sed -i
's#http://security\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubunt
u#g' /etc/apt/sources.list.d/ubuntu.sources
sudo sed -i 's#http://[a-z][a-
z]\.security\.ubuntu\.com/ubuntu#http://azure\.archive\.ubuntu\.com/ubuntu#g'
/etc/apt/sources.list.d/ubuntu.sources
sudo apt update
```

4. The Ubuntu Azure images use Azure-Tailored Kernels Azure-tailored kernel. Update the OS to the latest Azure-tailored kernel and install Azure Linux tools (including Hyper-V dependencies):

Bash

```
sudo apt update
sudo apt install linux-azure linux-image-azure linux-headers-azure linux-tools-
```

```
common linux-cloud-tools-common linux-tools-azure linux-cloud-tools-azure
sudo apt full-upgrade
sudo reboot
```

5. Modify the kernel boot line for GRUB to include extra kernel parameters for Azure. To do this step, open `/etc/default/grub` in a text editor, find the variable called `GRUB_CMDLINE_LINUX_DEFAULT` (or add it if needed), and edit it to include the following parameters:

config

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0,115200n8
earlyprintk=ttyS0,115200 rootdelay=300 quiet splash"
```

6. Save and close this file, and then run `sudo update-grub`. This step ensures that all console messages are sent to the first serial port, which can assist Azure technical support with debugging issues.

7. Ensure that the SSH server is installed and configured to start at boot time. This setting is usually the default.

8. Install `cloud-init` (the provisioning agent) and the Azure Linux agent (the guest extensions handler). `Cloud-init` uses `netplan` to configure the system network configuration (during provisioning and each subsequent boot) and `gdisk` to partition resource disks.

Bash

```
sudo apt update
sudo apt install cloud-init gdisk netplan.io walinuxagent && systemctl stop
walinuxagent
```

> ⓘ **Note**
>
> The `walinuxagent` package might remove the `NetworkManager` and `NetworkManager-gnome` packages, if they're installed.

9. Remove `cloud-init` default configurations and leftover `netplan` artifacts that might conflict with `cloud-init` provisioning on Azure: For Ubuntu 22.04 and earlier

Bash

```
sudo rm -f /etc/cloud/cloud.cfg.d/50-curtin-networking.cfg
/etc/cloud/cloud.cfg.d/curtin-preserve-sources.cfg /etc/cloud/cloud.cfg.d/99-
```

```
installer.cfg /etc/cloud/cloud.cfg.d/subiquity-disable-cloudinit-networking.cfg
sudo rm -f /etc/cloud/ds-identify.cfg
sudo rm -f /etc/netplan/*.yaml
```

For Ubuntu 24.04 and later

Bash

```
sudo rm -f /etc/cloud/cloud.cfg.d/curtin-preserve-sources.cfg
/etc/cloud/cloud.cfg.d/99-installer.cfg /etc/cloud/cloud.cfg.d/subiquity-
disable-cloudinit-networking.cfg
sudo rm -f /etc/cloud/ds-identify.cfg
sudo rm -f /etc/netplan/*.yaml
```

10. Configure `cloud-init` to provision the system by using the Azure data source:

Bash

```
sudo tee /etc/cloud/cloud.cfg.d/90_dpkg.cfg <<EOF
datasource_list: [ Azure ]
EOF

sudo tee /etc/cloud/cloud.cfg.d/90-azure.cfg <<EOF
system_info:
   package_mirrors:
     - arches: [i386, amd64]
       failsafe:
         primary: http://archive.ubuntu.com/ubuntu
         security: http://security.ubuntu.com/ubuntu
       search:
         primary:
           - http://azure.archive.ubuntu.com/ubuntu/
         security: []
     - arches: [armhf, armel, default]
       failsafe:
         primary: http://ports.ubuntu.com/ubuntu-ports
         security: http://ports.ubuntu.com/ubuntu-ports
EOF

sudo tee /etc/cloud/cloud.cfg.d/10-azure-kvp.cfg <<EOF
reporting:
  logging:
    type: log
  telemetry:
    type: hyperv
EOF
```

11. Configure the Azure Linux agent to rely on `cloud-init` to perform provisioning. For more information on these options, look at the WALinuxAgent project.

Bash

```
sudo sed -i 's/Provisioning.Enabled=y/Provisioning.Enabled=n/g'
/etc/waagent.conf
sudo sed -i 's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=y/g'
/etc/waagent.conf
sudo sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
sudo sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g'
/etc/waagent.conf
```

Bash

```
sudo tee -a /etc/waagent.conf <<EOF
# For Azure Linux agent version >= 2.2.45, this is the option to configure,
# enable, or disable the provisioning behavior of the Linux agent.
# Accepted values are auto (default), waagent, cloud-init, or disabled.
# A value of auto means that the agent will rely on cloud-init to handle
# provisioning if it is installed and enabled, which in this case it will.
Provisioning.Agent=auto
EOF
```

12. Clean `cloud-init` and Azure Linux agent runtime artifacts and logs:

Bash

```
sudo cloud-init clean --logs --seed
sudo rm -rf /var/lib/cloud/
sudo systemctl stop walinuxagent.service
sudo rm -rf /var/lib/waagent/
sudo rm -f /var/log/waagent.log
```

13. Deprovision the VM and prepare it for provisioning on Azure.

> ⓘ **Note**
>
> The `sudo waagent -force -deprovision+user` command generalizes the image by attempting to clean the system and make it suitable for reprovisioning. The `+user` option deletes the last provisioned user account and associated data.

Bash

```
sudo waagent -force -deprovision+user
sudo rm -f ~/.bash_history
```

> ⚠ **Warning**

> Deprovisioning by using the preceding command doesn't guarantee that the image is cleared of all sensitive information and is suitable for redistribution.

14. Select **Action** > **Shut Down** in Hyper-V Manager.

15. Azure only accepts fixed-size VHDs. If the VM's OS disk isn't a fixed-size VHD, use the `Convert-VHD` PowerShell cmdlet and specify the `-VHDType Fixed` option. For more information, look at the docs for `Convert-VHD` at Convert-VHD.

16. To bring a Generation 2 VM on Azure, follow these steps:

    a. Change the directory to the `boot EFI` directory:

    ```
    Bash
    cd /boot/efi/EFI
    ```

    b. Copy the `ubuntu` directory to a new directory named `boot`:

    ```
    Bash
    sudo cp -r ubuntu/ boot
    ```

    c. Change the directory to the newly created boot directory:

    ```
    Bash
    cd boot
    ```

    d. Rename the `shimx64.efi` file:

    ```
    Bash
    sudo mv shimx64.efi bootx64.efi
    ```

    e. Rename the `grub.cfg` file to `bootx64.cfg`:

    ```
    Bash
    sudo mv grub.cfg bootx64.cfg
    ```

cloud-init support for virtual machines in Azure

Article • 03/20/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article explains the support that exists for cloud-init to configure a virtual machine (VM) or Virtual Machine Scale Sets at provisioning time in Azure. These cloud-init configurations are run on first boot once the resources have been provisioned by Azure.

VM Provisioning is the process where Azure passes down your VM Create parameter values, such as hostname, username, and password, and make them available to the VM as it boots up. A 'provisioning agent' will consume those values, configure the VM, and report back when completed.

Azure supports two provisioning agents cloud-init, and the Azure Linux Agent (WALA).

cloud-init overview

cloud-init is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. Because cloud-init is called during the initial boot process, there are no additional steps or required agents to apply your configuration. For more information on how to properly format your `#cloud-config` files or other inputs, see the cloud-init documentation site. `#cloud-config` files are text files encoded in base64.

cloud-init also works across distributions. For example, you don't use **apt-get install** or **yum install** to install a package. Instead you can define a list of packages to install. cloud-init automatically uses the native package management tool for the distro you select.

We're actively working with our endorsed Linux distro partners in order to have cloud-init enabled images available in the Azure Marketplace. These images will make your cloud-init deployments and configurations work seamlessly with VMs and virtual machine scale sets. Initially we collaborate with the endorsed Linux distro partners and upstream to ensure cloud-init functions with the OS on Azure, then the packages are updated and made publicly available in the distro package repositories.

There are two stages to making cloud-init available to the supported Linux distributions on Azure, package support, and then image support:

- 'cloud-init package support on Azure' documents, which cloud-init packages onwards are supported or in preview, so you can use these packages with the OS in a custom image.
- 'image cloud-init ready' documents if the image is already configured to use cloud-init.

Canonical

Currently, Azure Stack supports the provisioning of cloud-init enabled images.

What is the difference between cloud-init and the Linux Agent (WALA)?

WALA is an Azure platform-specific agent used to provision and configure VMs, and handle Azure extensions.

We're enhancing the task of configuring VMs to use cloud-init instead of the Linux Agent in order to allow existing cloud-init customers to use their current cloud-init scripts, or new customers to take advantage of the rich cloud-init configuration functionality. If you have existing investments in cloud-init scripts for configuring Linux systems, there are **no additional settings required** to enable cloud-init process them.

cloud-init can't process Azure extensions, so WALA is still required in the image to process extensions but needs to have its provisioning code disabled. For endorsed Linux distros images that are being converted to provision by cloud-init, they have WALA installed, and setup correctly.

When creating a VM, if you don't include the Azure CLI `--custom-data` switch at provisioning time, cloud-init or WALA takes the minimal VM provisioning parameters required to provision the VM and complete the deployment with the defaults. If you reference the cloud-init configuration with the `--custom-data` switch, whatever is contained in your custom data will be available to cloud-init when the VM boots.

cloud-init configurations applied to VMs don't have time constraints and won't cause a deployment to fail by timing out. This isn't true for WALA, if you change the WALA defaults to process custom-data, it can't exceed the total VM provisioning time allowance of 40 minutes, if so, the VM Create will fail.

cloud-init VM provisioning without a UDF driver

Beginning with cloud-init 21.2, you can use cloud-init to provision a VM in Azure without a UDF driver. If a UDF driver isn't available in the image, cloud-init uses the metadata that's available in the Azure Instance Metadata Service to provision the VM. This option works only for SSH key and user data. To pass in a password or custom data to a VM during provisioning, you must use a UDF driver.

Deploying a cloud-init enabled Virtual Machine

Deploying a cloud-init enabled virtual machine is as simple as referencing a cloud-init enabled distribution during deployment. Linux distribution maintainers have to choose to enable and integrate cloud-init into their base Azure published images. Once you confirm the image you want to deploy is cloud-init enabled, you can use the Azure CLI to deploy the image.

The first step in deploying this image is to create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed.

The following example creates a resource group named *myResourceGroup* in the *eastus* location.

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

The next step is to create a file in your current shell, named *cloud-init.txt* and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor of your choice. Enter sensible-editor cloud-init.txt to create the file and see a list of available editors. Use the editor of your choice. Some typical choices are nano, vim, or ed. Make sure that the whole cloud-init file is copied correctly, especially the first line:

Expand table

SLES	Ubuntu	RHEL
`# cloud-config` `package_upgrade: true`	`# cloud-config` `package_upgrade: true`	`# cloud-config` `package_upgrade: true`

SLES	Ubuntu	RHEL
`packages:` `- apache2`	`packages:` `- httpd`	`packages:` `- httpd`

> **Note**
>
> cloud-init has multiple input types, cloud-init will use first line of the customData/userData to indicate how it should process the input, for example `#cloud-config` indicates that the content should be processed as a cloud-init config.

Exit the file and save the file according to the editor. Verify file name on exit.

The final step is to create a VM with the az vm create command.

The following example creates a VM named `ubuntu2204` and creates SSH keys if they don't already exist in a default key location. To use a specific set of keys, use the `--ssh-key-value` option. Use the `--custom-data` parameter to pass in your cloud-init config file. Provide the full path to the *cloud-init.txt* config if you saved the file outside of your present working directory.

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name ubuntu2204 \
  --image Canonical:UbuntuServer:22_04-lts:latest \
  --custom-data cloud-init.txt \
  --generate-ssh-keys
```

When the VM is created, the Azure CLI shows information specific to your deployment. Take note of the `publicIpAddress`. This address is used to access the VM. It takes some time for the VM to be created, the packages to install, and the app to start. There are background tasks that continue to run after the Azure CLI returns you to the prompt. You can SSH into the VM and use the steps outlined in the Troubleshooting section to view the cloud-init logs.

You can also deploy a cloud-init enabled VM by passing the parameters in ARM template.

Troubleshooting cloud-init

Once the VM has been provisioned, cloud-init runs through all the modules and script defined in `--custom-data` in order to configure the VM. If you need to troubleshoot any errors or omissions from the configuration, you need to search for the module name (`disk_setup` or `runcmd` for example) in the cloud-init log - located in **/var/log/cloud-init.log**.

> **Note**
>
> Not every module failure results in a fatal cloud-init overall configuration failure. For example, using the `runcmd` module, if the script fails, cloud-init will still report provisioning succeeded because the runcmd module executed.

For more information of cloud-init logging, see the cloud-init documentation

Telemetry

cloud-init collects usage data and sends it to Microsoft to help improve our products and services. Telemetry is only collected during the provisioning process (first boot of the VM). The data collected helps us investigate provisioning failures and monitor performance and reliability. Data collected doesn't include any identifiers (personal identifiers). Read our privacy statement to learn more. Some examples of telemetry being collected are (this isn't an exhaustive list): OS-related information (cloud-init version, distro version, kernel version), performance metrics of essential VM provisioning actions (time to obtain DHCP lease, time to retrieve metadata necessary to configure the VM, etc.), cloud-init log, and dmesg log.

Telemetry collection is currently enabled for most of our marketplace images that use cloud-init. It's enabled by specifying KVP telemetry reporter for cloud-init. In most Azure Marketplace images, this configuration can be found in the file /etc/cloud/cloud.cfg.d/10-azure-kvp.cfg. Removing this file during image preparation disables telemetry collection for any VM created from this image.

Sample content of 10-azure-kvp.cfg

```
reporting:
  logging:
    type: log
  telemetry:
    type: hyperv
```

Next steps

Troubleshoot issues with cloud-init.

For cloud-init examples of configuration changes, see the following documents:

- Add an additional Linux user to a VM
- Run a package manager to update existing packages on first boot
- Change VM local hostname
- Install an application package, update configuration files and inject keys

Diving deeper into cloud-init

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

To learn more about cloud-init or troubleshoot it at a deeper level, you need to understand how it works. This document highlights the important parts, and explains the Azure specifics.

When cloud-init is included in a generalized image and a VM is created from that image, it processes configurations and runs through five stages during the initial boot. These stages show you at what point cloud-init applies its configurations.

Understand Cloud-Init configuration

Configuring a VM to run on a platform uses cloud-init to apply multiple configurations. The main configurations you interact with is `User data` (customData), which supports multiple formats. For more information, see User-Data Formats & cloud-init 21.2 documentation. You also have the ability to add and run scripts (/var/lib/cloud/scripts) for other configuration.

Preconfigured Azure Marketplace images

Some configurations are already baked into Azure Marketplace images that come with cloud-init.

- **Cloud data source** - cloud-init contains code that can interact with cloud platforms, these codes are called 'datasources'. When a VM is created from a cloud-init image in Azure, cloud-init loads the Azure datasource, which interacts with the Azure metadata endpoints to get the VM specific configuration.
- **Runtime config** (/run/cloud-init).
- **Image config** (/etc/cloud), like `/etc/cloud/cloud.cfg`, `/etc/cloud/cloud.cfg.d/*.cfg`. An example of where this configuration is used in Azure, it's common for the Linux OS images with cloud-init to have an Azure datasource directive that tells cloud-init what datasource it should use, this configuration saves cloud-init time:

  ```
  Bash
  ```

```
sudo cat /etc/cloud/cloud.cfg.d/90_dpkg.cfg
```

Output

```
# to update this file, run dpkg-reconfigure cloud-init
datasource_list: [ Azure ]
```

Cloud-init boot stages (processing configuration)

When you're provisioning VMs with cloud-init, there are five configuration boot stages. The output from these stages is visible in the logs.

1. Generator Stage: The cloud-init systemd generator starts, and determines that cloud-init should be included in the boot goals, and if so, it enables cloud-init.

2. Cloud-init Local Stage: Here, cloud-init looks for the local "Azure" datasource, which enables cloud-init to interface with Azure, and apply a networking configuration, including fallback.

3. Cloud-init init Stage (Network): Networking should be online, and the NIC and route table information should be generated. At this stage, the modules listed in `cloud_init_modules` in `/etc/cloud/cloud.cfg` are run. The VM in Azure is mounted, the ephemeral disk is formatted, the hostname is set, along with other tasks.

   The following are some of the `cloud_init_modules`:

   config

   ```
   - migrator
   - seed_random
   - bootcmd
   - write-files
   - growpart
   - resizefs
   - disk_setup
   - mounts
   - set_hostname
   - update_hostname
   - ssh
   ```

   After this stage, cloud-init sends a signal to the Azure platform that the VM has been provisioned successfully. Some modules may have failed, however not all

module failures automatically result in a provisioning failure.

4. Cloud-init Config Stage : At this stage, the modules in `cloud_config_modules` defined and listed in `/etc/cloud/cloud`.cfg runs.

5. Cloud-init Final Stage : At this final stage, the modules in `cloud_final_modules`, listed in `/etc/cloud/cloud.cfg`, runs. Here modules that need to be run late in the boot process run, such as package installations and run scripts etc.

    - During this stage, you can run scripts by placing them in the directories under `/var/lib/cloud/scripts`:
        - `per-boot` - scripts within this directory, run on every reboot
        - `per-instance` - scripts within this directory run when a new instance is first booted
        - `per-once` - scripts within this directory run only once

Troubleshooting VM provisioning with cloud-init

Applies to: ✔ Linux VMs ✔ Flexible scale sets

If you create generalized custom images and use cloud-init for provisioning, the VM might not build correctly. In that case, troubleshoot the image to find the issue.

Some examples, of issues with provisioning:

- The Compute Resource Provider API returns an error, and cloud-init reports the resulting failure.
- VM gets stuck at 'creating' for 40 minutes, and the VM creation is marked as failed.
- Custom data or User data doesn't get processed.
- The ephemeral disk fails to mount (for VM skus that come with SCSI resource disks).
- Users don't get created, or there are user access issues.
- Networking isn't set up correctly.
- Swap file or partition failures.

This article steps you through how to troubleshoot cloud-init. For more in-depth details, see cloud-init deep dive.

> **⊗ Caution**
>
> This article references CentOS, a Linux distribution that is End Of Support (EOS) status. Consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Troubleshooting failures reported by cloud-init and logged as error

Cloud-init emits structured errors when reporting failure to Azure during provisioning. These error messages include a reason and supporting data (such as timestamp, VM identifier, documentation URL, etc.) to help investigate the failure.

Expand table

Reason	Description	Action
failure to find DHCP interface	No network interface was found.	Delete and re-create VM. If issue persists, ensure networking drivers or Azure-specific kernel is

Reason	Description	Action
		installed and check boot diagnostics to verify eth0 is enumerated.
failure to obtain DHCP lease	DHCP service fails to respond due to transient platform issue.	Redeploy the VM (delete + recreate) due to a transient Azure DHCP platform issue.
failure to find primary DHCP interface	Primary DHCP interface wasn't found.	Check boot diagnostics to ensure primary network interface is named `eth0` and it isn't renamed.
connection timeout querying IMDS	Connections to IMDS may timeout due to transient platform issue, NSG, or OS firewall configuration.	Delete and re-create VM. If issue persists, validate that NSG or OS firewall isn't preventing access to IMDS.
read timeout querying IMDS	Connections to IMDS may timeout due to transient platform issue or OS firewall configuration.	Delete and re-create VM. If issue persists, validate OS firewall isn't preventing access to IMDS.
unexpected metadata parsing ovf-env.xml	Malformed VM metadata in `ovf-env.xml`.	Submit the issue to the cloud-init tracker.
error waiting for host shutdown	Failure during host shutdown handling.	Submit the issue to the cloud-init tracker.
Azure-proxy-agent not found	The `azure-proxy-agent` binary is missing.	Ensure Azure proxy agent is installed in the image. For more troubleshooting, check out MSP troubleshooting guide.
Azure-proxy-agent status failure	Proxy agent reported a status error.	Review proxy agent logs and update if needed. For more troubleshooting, check out MSP troubleshooting guide.
unhandled exception	An unexpected error occurred inside cloud-init.	Submit the issue to the cloud-init tracker.

For help with enabling and checking boot diagnostics, see Boot Diagnostics.

If any of these issues persist on subsequent attempts at provisioning, it's due to a misconfiguration in the image. If there's reason to believe there's a cloud-init issue, report it to cloud-init GitHub issue tracker.

Troubleshooting other failures unreported by cloud-init

Depending on the failure, consider these steps.

Step 1: Test the deployment without `customData`

Cloud-init can accept `customData` that is passed to it, when the VM is created. First, you should ensure this configuration isn't causing any issues with deployments. Some common issues can include:

- The YAML is malformed
- Scripts inside customData fail or hang
- Override something cloud-init relies on (for example, disk setup or networking)
- The data contains unsupported characters or encoding problems Try to provisioning the VM without passing in any configuration. If the VM fails to provision, follow the recommended troubleshooting steps. If the configuration isn't applied, refer to step 4.

Step 2: Review image requirements

The primary cause of VM provisioning failure is the OS image doesn't satisfy the prerequisites for running on Azure. Make sure your images are properly prepared before attempting to provision them in Azure.

The following articles illustrate the steps to prepare various linux distributions that are supported in Azure:

- CentOS-based Distributions
- Debian Linux
- Flatcar Container Linux
- Oracle Linux
- Red Hat Enterprise Linux
- SLES & openSUSE
- Ubuntu
- Others: Non-Endorsed Distributions

For the supported Azure cloud-init images, the Linux distributions already have all the required packages and configurations in place to correctly provision the image in Azure. If you find your VM is failing to create from your own curated image, try a supported Azure Marketplace image that already is configured for cloud-init, with your optional `customData`. If the `customData` works correctly with an Azure Marketplace image, then there's probably an issue with your curated image.

Step 3: Collect & review VM logs

When the VM fails to provision, Azure shows 'creating' status, for 20 minutes, and then reboot the VM, and wait another 20 minutes before finally marking the VM deployment as failed, before finally marking it with an `OSProvisioningTimedOut` error.

While the VM is running, you need the logs from the VM to understand why provisioning failed. To understand why VM provisioning failed, don't stop the VM. Keep the VM running. You need to keep the failed VM in a running state in order to collect logs. To collect the logs, use one of the following methods:

- Enable Boot Diagnostics before creating the VM and then View them during the boot.
- Serial Console
- Run AZ VM Repair to attach and mount the OS disk (*lvm*, *no lvm*), which will allow you to collect and examine these logs:

```bash
/rescue/var/log/waagent*
/rescue/var/log/syslog*
/rescue/var/log/rsyslog*
/rescue/var/log/messages*
/rescue/var/log/kern*
/rescue/var/log/dmesg*
/rescue/var/log/boot*
/rescue/ /var/log/cloud-init.log
/rescue//var/log/cloud-init-output.log
```

> **Note**
>
> Alternatively, you can create a rescue VM manually by using the Azure portal. For more information, see Troubleshoot a Linux VM by attaching the OS disk to a recovery VM using the Azure portal. To start initial troubleshooting, begin with the serial logs and cloud-init logs to understand where the failure occurred. Then use the other logs for a deeper dive to help provide additional insights.

- /var/log/cloud-init.log
- /var/log/cloud-init-output.log
- Serial/boot logs

In all logs, start searching for "Failed," "WARNING," "WARN," "err," "error," and "ERROR." Setting configuration to ignore case-sensitive searches is recommended.

Alternatively, use command `cloud-init collect-logs` to collect all necessary logs. Azure's latest cloud-init versions (≥ 18.2) include the collect-logs command, which:

Gathers essential logs: /var/log/cloud-init*.log, instance metadata, system info.

Packages everything into a timestamped .tar.gz archive.

Saves the archive locally (for example, `/tmp/cloud-init-logs-timestamp.tar.gz`).

> **Tip**
>
> If you're troubleshooting a custom image, you should consider adding a user during the image. If the provisioning fails to set the admin user, you can still log in to the OS.

Analyzing the logs

Here are more details about what to look for in each cloud-init log.

/var/log/cloud-init.log

By default, all cloud-init events with a priority of debug or higher, are written to `/var/log/cloud-init.log`. This log provides verbose logs of every event that occurred during cloud-init initialization.

For example:

Console

```
2019-10-10 04:51:25,321 - util.py[DEBUG]: Failed mount of '/dev/sr0' as 'auto':
Unexpected error while running command.
Command: ['mount', '-o', 'ro,sync', '-t', 'auto', u'/dev/sr0', '/run/cloud-
init/tmp/tmpLIrklc']
Exit code: 32
Reason: -
Stdout:
Stderr: mount: unknown filesystem type 'udf'
2020-01-31 00:21:53,352 - DataSourceAzure.py[WARNING]: /dev/sr0 was not mountable
```

When you find an error or warning, read backwards in the cloud-init log to understand what cloud-init was attempting before it hit the error or warning. In many cases, cloud-init runs OS commands or performs provisioning steps before the error occurs. These actions can help explain why the error appears in the logs. The following example shows that cloud-init attempted to mount a device right before it encountered the issue.

Output

```
2019-10-10 04:51:24,010 - util.py[DEBUG]: Running command ['mount', '-o', 'ro,sync',
'-t', 'auto', u'/dev/sr0', '/run/cloud-init/tmp/tmpXXXXX'] with allowed return codes
[0] (shell=False, capture=True)
```

If you have access to the Serial Console, you can try to rerun the command that cloud-init was trying to run.

The logging for `/var/log/cloud-init.log` can also be reconfigured within /etc/cloud/cloud.cfg.d/05_logging.cfg. For more information of cloud-init logging, see the cloud-init documentation.

/var/log/cloud-init-output.log

You can get information from the `stdout` and `stderr` during the stages of cloud-init. This data normally involves routing table information, networking information, ssh host key verification information, `stdout,` and `stderr` for each stage of cloud-init, along with the timestamps. If desired, `stderr` and `stdout` logging can be reconfigured from `/etc/cloud/cloud.cfg.d/05_logging.cfg`.

Serial/boot logs

Cloud-init has multiple dependencies. These dependencies are documented in the required prerequisites for images on Azure, such as networking, storage, the ability to mount an ISO, and to mount and format the temporary disk. Any of these dependencies may throw errors and cause cloud-init to fail. For example, If the VM can't get a DHCP lease, cloud-init fails.

If you still can't isolate why cloud-init failed to provision then you need to understand what cloud-init stages, and when modules run. For more information, see Diving deeper into cloud-init.

Step 4: Investigate why the configuration isn't being applied

Not every failure in cloud-init results in a fatal provisioning failure. For example, if you use the `runcmd` module in a cloud-init config, a nonzero exit code from the command causes the VM provisioning to fail. This behavior occurs because the module runs after the core provisioning steps in the first three stages of cloud-init. To troubleshoot why the configuration didn't apply, review the logs in Step 3, and cloud-init modules manually. For example:

- `runcmd` - do the scripts run without errors? To ensure they run as expected, run the configuration manually from the terminal.
- Installing packages - does the VM have access to package repositories?

- Check the `customData` configuration that was provided to the VM. This file is located in `/var/lib/cloud/instances/<unique-instance-identifier>/user-data.txt`.

Next steps

If cloud-init skips the configuration, examine each cloud-init stage and the timing of module execution to identify the cause. For more information, see Diving deeper into cloud-init configuration.

Use cloud-init to set hostname for a Linux VM in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to use cloud-init to configure a specific hostname on a virtual machine (VM) or virtual machine scale sets (VMSS) at provisioning time in Azure. These cloud-init scripts run on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see cloud-init overview

Set the hostname with cloud-init

By default, the hostname is the same as the VM name when you create a new virtual machine in Azure. To run a cloud-init script to change this default hostname when you create a VM in Azure with az vm create, specify the cloud-init file with the `--custom-data` switch.

To see upgrade process in action, create a file in your current shell named *cloud_init_hostname.txt* and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Make sure that the whole cloud-init file is copied correctly, especially the first line.

YAML

```yaml
#cloud-config
fqdn: myhostname
```

Before deploying this image, you need to create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location.

Azure CLI

```azurecli
az group create --name myResourceGroup --location eastus
```

Now, create a VM with az vm create and specify the cloud-init file with `--custom-data cloud_init_hostname.txt` as follows:

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name vmName \
  --image imageCIURN \
  --custom-data cloud_init_hostname.txt \
  --generate-ssh-keys
```

> **Note**
>
> Replace **myResourceGroup**, **vmName**, and **imageCIURN** values accordingly. Make sure an image with Cloud-init is chosen.

Once created, the Azure CLI shows information about the VM. Use the `publicIpAddress` to SSH to your VM. Enter your own address as follows:

Bash

```
ssh <user>@<publicIpAddress>
```

To see the VM name, use the `hostname` command as follows:

Bash

```
sudo hostname
```

The VM should report the hostname as that value set in the cloud-init file, as shown in the following example output:

Output

```
myhostname
```

Next steps

For additional cloud-init examples of configuration changes, see the following:

- Add an additional Linux user to a VM
- Run a package manager to update existing packages on first boot
- Change VM local hostname
- Install an application package, update configuration files and inject keys

Use cloud-init to update and install packages in a Linux VM in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to use cloud-init to update packages on a Linux virtual machine (VM) or virtual machine scale sets at provisioning time in Azure. These cloud-init scripts run on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see cloud-init overview

Update a VM with cloud-init

For security purposes, you may want to configure a VM to apply the latest updates on first boot. As cloud-init works across different Linux distros, there's no need to specify `apt`, `zypper` or `yum` for the package manager. Instead, you define `package_upgrade` and let the cloud-init process determine the appropriate mechanism for the distro in use.

For this example, we use the Azure Cloud Shell. To see the upgrade process in action, create a file named *cloud_init_upgrade.txt* and paste the following configuration. You can use any editor you wish. Make sure that the whole cloud-init file is copied correctly, especially the first line.

Copy the text below and paste it into the `cloud_init_upgrade.txt` file. Make sure that the whole cloud-init file is copied correctly, especially the first line.

YAML

```yaml
#cloud-config
package_upgrade: true
packages:
- httpd
```

Before deploying, you need to create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location.

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with az vm create and specify the cloud-init file with the `--custom-data` parameter as follows:

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name vmName \
  --image imageCIURN \
  --custom-data cloud_init_upgrade.txt \
  --admin-username azureuser \
  --generate-ssh-keys
```

> **Note**
>
> Replace **myResourceGroup**, **vmName**, and **imageCIURN** values accordingly. Make sure an image with Cloud-init is chosen.

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own **user** and **publicIpAddress** as follows:

Bash

```
ssh <user>@<publicIpAddress>
```

Run the package management tool and check for updates:

RHEL/Oracle Linux

- Execute the following command to confirm there are no pending updates

Bash

```
sudo yum check-update
```

As cloud-init checked for and installed updates on boot, there should be no additional updates to apply.

- You can see the update process, number of altered packages, and the installation of `httpd` by running the following command and review the

output.

Bash

```
sudo yum history
```

Output

```
ID     | Command line                                  | Date and time
| Action(s)      | Altered
-------------------------------------------------------------------------------
--------------------------
     3 | -y install httpd                              | 2022-02-18 18:30
| Install        |    7
     2 | -y upgrade                                    | 2022-02-18 18:23
| I, O, U        |  321 EE
     1 |                                               | 2021-02-04 19:20
| Install        |  496 EE
```

Next steps

For additional cloud-init examples of configuration changes, see the following:

- Add an additional Linux user to a VM
- Run a package manager to update existing packages on first boot
- Change VM local hostname
- Install an application package, update configuration files and inject keys

Feedback

Was this page helpful? Yes No

Provide product feedback | Get help at Microsoft Q&A

Use cloud-init to add a user to a Linux VM in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to use cloud-init to add a user on a virtual machine (VM) or virtual machine scale sets (VMSS) at provisioning time in Azure. This cloud-init script runs on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see cloud-init overview.

Add a user to a VM with cloud-init

One of the first tasks on any new Linux VM is to add an additional user for yourself to avoid the use of *root*. SSH keys are best practice for security and usability. Keys are added to the *~/.ssh/authorized_keys* file with this cloud-init script.

To add a user to a Linux VM, create a file in your current shell named *cloud_init_add_user.txt* and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Make sure that the whole cloud-init file is copied correctly, especially the first line. You need to provide your own public key (such as the contents of *~/.ssh/id_rsa.pub*) for the value of `ssh-authorized-keys:` - it has been shortened here to simplify the example.

YAML

```yaml
#cloud-config
users:
  - default
  - name: myadminuser
    groups: sudo
    shell: /bin/bash
    sudo: ['ALL=(ALL) NOPASSWD:ALL']
    ssh-authorized-keys:
      - ssh-rsa AAAAB3<snip>
```

> **Note**
>
> The #cloud-config file includes the `- default` parameter included. This will append the user, to the existing admin user created during provisioning. If you create a user

without the `- default` parameter - the auto generated admin user created by the Azure platform would be overwritten.

Before deploying this image, you need to create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location.

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with az vm create and specify the cloud-init file with `--custom-data cloud_init_add_user.txt` as follows:

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name vmName \
  --image imageCIURN \
  --custom-data cloud_init_add_user.txt \
  --generate-ssh-keys
```

> **Note**
>
> Replace **myResourceGroup**, **vmName**, and **imageCIURN** values accordingly. Make sure an image with Cloud-init is chosen.

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own **user** and **publicIpAddress** as follows:

Bash

```
ssh <user>@<publicIpAddress>
```

To confirm your user was added to the VM and the specified groups, view the contents of the */etc/group* file as follows:

Bash

```
sudo cat /etc/group
```

The following example output shows the user from the *cloud_init_add_user.txt* file has been added to the VM and the appropriate group:

Output

```
root:x:0:
<snip />
sudo:x:27:myadminuser
<snip />
myadminuser:x:1000:
```

Next steps

For additional cloud-init examples of configuration changes, see the following:

- Add an additional Linux user to a VM
- Run a package manager to update existing packages on first boot
- Change VM local hostname
- Install an application package, update configuration files and inject keys

Use cloud-init to configure a swap partition on a Linux VM

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to use cloud-init to configure the swap partition on various Linux distributions. The swap partition was traditionally configured by the Linux Agent (WALA) based on which distributions required one. This document outlines the process for building the swap partition on demand during provisioning time using cloud-init. For more information about how cloud-init works natively in Azure and the supported Linux distros, see cloud-init overview

Create swap partition for Ubuntu based images

By default on Azure, Ubuntu gallery images don't create swap partitions. To enable swap partition configuration during VM provisioning time using cloud-init - please see the AzureSwapPartitions document on the Ubuntu wiki.

Create swap partition for RHEL based images

Create a file in your current shell named *cloud_init_swappart.txt* and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Make sure that the whole cloud-init file is copied correctly, especially the first line.

YAML

```yaml
#cloud-config
disk_setup:
  ephemeral0:
    table_type: gpt
    layout: [66, [33,82]]
    overwrite: true
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
```

```
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-
init.service", "0", "0"]
```

The mount is created with the `nofail` option to ensure that the boot process continues even if the mount isn't completed successfully.

Before deploying this image, you need to create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location.

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with az vm create and specify the cloud-init file with `--custom-data cloud_init_swappart.txt` as follows:

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name vmName \
  --image imageCIURN \
  --custom-data cloud_init_swappart.txt \
  --generate-ssh-keys
```

> **Note**
>
> Replace **myResourceGroup**, **vmName**, and **imageCIURN** values accordingly. Make sure an image with Cloud-init is chosen.

Modify an already running machine

If you already provisioned your server and wish to modify the mount point of the ephemeral storage and want to configure a part of the disk as swap space, use the following steps.

Create cloud-init configuration file named `00-azure-swap.cfg` in the `/etc/cloud/cloud.cfg.d` directory with the following content:

YAML

```
#cloud-config
disk_setup:
  ephemeral0:
    table_type: gpt
    layout: [66, [33,82]]
    overwrite: true
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-
init.service", "0", "0"]
```

Next, append a line to the `/etc/systemd/system.conf` file with following content:

config

```
DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"
```

> ⓘ **Note**
>
> The name of the file is totally arbitrary, it can be replaced with any particular name of your preference, it just needs the .cfg suffix and make sure to reflect the changes in the CLOUD_CFG parameter line as well.

After the changes are done, the machine needs to be deallocated or redeployed for the changes to take effect.

Verify swap partition was created

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own **user** and **publicIpAddress** as follows:

Bash

```
ssh <user>@<publicIpAddress>
```

Once you have SSH'ed into the vm, check if the swap partition was created

Bash

```
sudo swapon -s
```

The output from this command should look like this:

Output

```
Filename                Type        Size    Used    Priority
/dev/sdb2  partition   2494440 0   -1
```

> **Note**
>
> If you have an existing Azure image that has a swap partition configured and you want to change the swap partition configuration for new images, you should remove the existing swap partition. Please see Customize Images to provision by cloud-init document for more details.

Next steps

For more cloud-init examples of configuration changes, see the following:

- Add an additional Linux user to a VM
- Run a package manager to update existing packages on first boot
- Change VM local hostname
- Install an application package, update configuration files and inject keys

Use cloud-init to run a bash script in a Linux VM in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to use cloud-init to run an existing bash script on a Linux virtual machine (VM) or virtual machine scale sets (VMSS) at provisioning time in Azure. These cloud-init scripts run on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see cloud-init overview

Run a bash script with cloud-init

With cloud-init you do not need to convert your existing scripts into a cloud-config, cloud-init accepts multiple input types, one of which is a bash script.

If you have been using the Linux Custom Script Azure Extension to run your scripts, you can migrate them to use cloud-init. However, Azure Extensions have integrated reporting to alert to script failures, a cloud-init image deployment will NOT fail if the script fails.

To see this functionality in action, create a simple bash script for testing. Like the cloud-init `#cloud-config` file, this script must be local to where you will be running the AzureCLI commands to provision your virtual machine. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Make sure that the whole cloud-init file is copied correctly, especially the first line.

Bash

```
#!/bin/sh
echo "this has been written via cloud-init" + $(date) >> /tmp/myScript.txt
```

Before deploying this image, you need to create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location.

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with az vm create and specify the bash script file with `--custom-data simple_bash.sh` as follows:

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name vmName \
  --image imageCIURN \
  --custom-data simple_bash.sh \
  --generate-ssh-keys
```

> ⓘ Note
>
> Replace **myResourceGroup**, **vmName**, and **imageCIURN** values accordingly. Make sure an image with Cloud-init is chosen.

Verify bash script has run

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own **user** and **publicIpAddress** as follows:

Bash

```
ssh <user>@<publicIpAddress>
```

Verify that `/tmp/myScript.txt` file exists and has the appropriate text inside of it.

Bash

```
sudo cat /tmp/myScript
```

If it does not, you can check the `/var/log/cloud-init.log` for more details. Search for the following entry:

Bash

```
sudo cat /var/log/cloud-init.log
```

Output

```
Running config-scripts-user using lock Running command
['/var/lib/cloud/instance/scripts/part-001']
```

Next steps

For additional cloud-init examples of configuration changes, see the following:

- Add an additional Linux user to a VM
- Run a package manager to update existing packages on first boot
- Change VM local hostname
- Install an application package, update configuration files and inject keys

Creating generalized images without a provisioning agent

09/02/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Microsoft Azure provides provisioning agents for Linux VMs in the form of the walinuxagent or cloud-init (recommended). But there could be a scenario when you don't want to use either of these applications for your provisioning agent, such as:

- Your Linux distro/version doesn't support cloud-init/Linux Agent.
- You require specific VM properties to be set, such as hostname.

> **Note**
>
> If you do not require any properties to be set or any form of provisioning to happen you should consider creating a specialized image.

This article shows how you can set up your VM image to satisfy the Azure platform requirements and set the hostname, without installing a provisioning agent.

Networking and reporting ready

In order to have your Linux VM communicate with Azure components, a DHCP client is required. The client is used to retrieve a host IP, DNS resolution, and route management from the virtual network. Most distros ship with these utilities out-of-the-box. Tools that are tested on Azure by Linux distro vendors include `dhclient`, `network-manager`, `systemd-networkd` and others.

> **Note**
>
> Currently creating generalized images without a provisioning agent only supports DHCP-enabled VMs.

After networking has been set up and configured, select "report ready". This tells Azure that the VM has been successfully provisioned.

> **Important**

Failing to report ready to Azure will result in your VM being rebooted!

Demo/sample

An existing Marketplace image (in this case, a Debian Buster VM) with the Linux Agent (walinuxagent) removed and a custom python script added is the easiest way to tell Azure that the VM is "ready".

Create the resource group and base VM:

Azure CLI

```
$ az group create --location eastus --name demo1
```

Create the base VM:

Azure CLI

```
$ az vm create \
    --resource-group demo1 \
    --name demo1 \
    --location eastus \
    --ssh-key-value <ssh_pub_key_path> \
    --public-ip-address-dns-name demo1 \
    --image "debian:debian-10:10:latest"
```

Remove the image provisioning Agent

Once the VM is provisioning, you can connect to it via SSH and remove the Linux Agent:

Bash

```
$ sudo apt purge -y waagent
$ sudo rm -rf /var/lib/waagent /etc/waagent.conf /var/log/waagent.log
```

Add required code to the VM

Also inside the VM, because we've removed the Azure Linux Agent we need to provide a mechanism to report ready.

Python script

Python

```python
import http.client
import sys
from xml.etree import ElementTree

wireserver_ip = '168.63.129.16'
wireserver_conn = http.client.HTTPConnection(wireserver_ip)

print('Retrieving goal state from the Wireserver')
wireserver_conn.request(
    'GET',
    '/machine?comp=goalstate',
    headers={'x-ms-version': '2012-11-30'}
)

resp = wireserver_conn.getresponse()

if resp.status != 200:
    print('Unable to connect with wireserver')
    sys.exit(1)

wireserver_goalstate = resp.read().decode('utf-8')

xml_el = ElementTree.fromstring(wireserver_goalstate)

container_id = xml_el.findtext('Container/ContainerId')
instance_id =
xml_el.findtext('Container/RoleInstanceList/RoleInstance/InstanceId')
incarnation = xml_el.findtext('Incarnation')
print(f'ContainerId: {container_id}')
print(f'InstanceId: {instance_id}')
print(f'Incarnation: {incarnation}')

# Construct the XML response we need to send to Wireserver to report ready.
health = ElementTree.Element('Health')
goalstate_incarnation = ElementTree.SubElement(health, 'GoalStateIncarnation')
goalstate_incarnation.text = incarnation
container = ElementTree.SubElement(health, 'Container')
container_id_el = ElementTree.SubElement(container, 'ContainerId')
container_id_el.text = container_id
role_instance_list = ElementTree.SubElement(container, 'RoleInstanceList')
role = ElementTree.SubElement(role_instance_list, 'Role')
instance_id_el = ElementTree.SubElement(role, 'InstanceId')
instance_id_el.text = instance_id
health_second = ElementTree.SubElement(role, 'Health')
state = ElementTree.SubElement(health_second, 'State')
state.text = 'Ready'

out_xml = ElementTree.tostring(
    health,
    encoding='unicode',
    method='xml'
)
```

```
print('Sending the following data to Wireserver:')
print(out_xml)

wireserver_conn.request(
    'POST',
    '/machine?comp=health',
    headers={
        'x-ms-version': '2012-11-30',
        'Content-Type': 'text/xml;charset=utf-8',
        'x-ms-agent-name': 'custom-provisioning'
    },
    body=out_xml
)

resp = wireserver_conn.getresponse()
print(f'Response: {resp.status} {resp.reason}')

wireserver_conn.close()
```

Bash script

```
#!/bin/bash

attempts=1
until [ "$attempts" -gt 5 ]
do
    echo "obtaining goal state - attempt $attempts"
    goalstate=$(curl --fail -v -X 'GET' -H "x-ms-agent-name: azure-vm-register" \
                                        -H "Content-Type: text/xml;charset=utf-8"
\
                                        -H "x-ms-version: 2012-11-30" \
                                           "http://168.63.129.16/machine/?
comp=goalstate")
    if [ $? -eq 0 ]
    then
       echo "successfully retrieved goal state"
       retrieved_goal_state=true
       break
    fi
    sleep 5
    attempts=$((attempts+1))
done

if [ "$retrieved_goal_state" != "true" ]
then
    echo "failed to obtain goal state - cannot register this VM"
    exit 1
fi

container_id=$(grep ContainerId <<< "$goalstate" | sed 's/\s*<\/*ContainerId>//g'
```

```
| sed 's/\r$//')
instance_id=$(grep InstanceId <<< "$goalstate" | sed 's/\s*<\/*InstanceId>//g' |
sed 's/\r$//')

ready_doc=$(cat << EOF
<?xml version="1.0" encoding="utf-8"?>
<Health xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <GoalStateIncarnation>1</GoalStateIncarnation>
  <Container>
    <ContainerId>$container_id</ContainerId>
    <RoleInstanceList>
      <Role>
        <InstanceId>$instance_id</InstanceId>
        <Health>
          <State>Ready</State>
        </Health>
      </Role>
    </RoleInstanceList>
  </Container>
</Health>
EOF
)

attempts=1
until [ "$attempts" -gt 5 ]
do
    echo "registering with Azure - attempt $attempts"
    curl --fail -v -X 'POST' -H "x-ms-agent-name: azure-vm-register" \
                             -H "Content-Type: text/xml;charset=utf-8" \
                             -H "x-ms-version: 2012-11-30" \
                             -d "$ready_doc" \
                             "http://168.63.129.16/machine?comp=health"
    if [ $? -eq 0 ]
    then
       echo "successfully register with Azure"
       break
    fi
    sleep 5 # sleep to prevent throttling from wire server
done
```

Generic steps (if not using Python or Bash)

If your VM doesn't have Python installed or available, you can programmatically reproduce this above script logic with the following steps:

1. Retrieve the `ContainerId`, `InstanceId`, and `Incarnation` by parsing the response from the WireServer: `curl -X GET -H 'x-ms-version: 2012-11-30' http://168.63.129.16/machine?comp=goalstate`.

2. Construct the following XML data, injecting the parsed `ContainerId`, `InstanceId`, and `Incarnation` from the above step:

```xml
<Health>
  <GoalStateIncarnation>INCARNATION</GoalStateIncarnation>
  <Container>
    <ContainerId>CONTAINER_ID</ContainerId>
    <RoleInstanceList>
      <Role>
        <InstanceId>INSTANCE_ID</InstanceId>
        <Health>
          <State>Ready</State>
        </Health>
      </Role>
    </RoleInstanceList>
  </Container>
</Health>
```

3. Post this data to WireServer: `curl -X POST -H 'x-ms-version: 2012-11-30' -H "x-ms-agent-name: WALinuxAgent" -H "Content-Type: text/xml;charset=utf-8" -d "$REPORT_READY_XML" http://168.63.129.16/machine?comp=health`

Automating running the code at first boot

This demo uses systemd, which is the most common init system in modern Linux distros. So the easiest and most native way to ensure this report ready mechanism runs at the right time is to create a systemd service unit. You can add the following unit file to `/etc/systemd/system` (this example names the unit file `azure-provisioning.service`):

```bash
[Unit]
Description=Azure Provisioning

[Service]
Type=oneshot
ExecStart=/usr/bin/python3 /usr/local/azure-provisioning.py
ExecStart=/bin/bash -c "hostnamectl set-hostname $(curl \
    -H 'metadata: true' \
    'http://169.254.169.254/metadata/instance/compute/name?api-version=2019-06-01&format=text')"
ExecStart=/usr/bin/systemctl disable azure-provisioning.service

[Install]
WantedBy=multi-user.target
```

This systemd service does three things for basic provisioning:

1. Reports ready to Azure (to indicate that it came up successfully).
2. Renames the VM based off of the user-supplied VM name by pulling this data from Azure Instance Metadata Service (IMDS). **Note** IMDS also provides other instance metadata, such as SSH Public Keys, so you can set more than the hostname.
3. Disables itself so that it only runs on first boot and not on subsequent reboots.

With the unit on the filesystem, run the following to enable it:

Bash

```
$ sudo systemctl enable azure-provisioning.service
```

Now the VM is ready to be generalized and have an image created from it.

Completing the preparation of the image

Back on your development machine, run the following to prepare for image creation from the base VM:

Azure CLI

```
$ az vm deallocate --resource-group demo1 --name demo1
$ az vm generalize --resource-group demo1 --name demo1
```

And create the image from this VM:

Azure CLI

```
$ az image create \
    --resource-group demo1 \
    --source demo1 \
    --location eastus \
    --name demo1img
```

Now we're ready to create a new VM from the image. This can also be used to create multiple VMs:

Azure CLI

```
$ IMAGE_ID=$(az image show -g demo1 -n demo1img --query id -o tsv)
$ az vm create \
    --resource-group demo12 \
    --name demo12 \
```

```
    --location eastus \
    --ssh-key-value <ssh_pub_key_path> \
    --public-ip-address-dns-name demo12 \
    --image "$IMAGE_ID"
    --enable-agent false
```

> **Note**
>
> It is important to set `--enable-agent` to `false` because walinuxagent doesn't exist on this VM that is going to be created from the image.

The VM should be provisioned successfully. After Logging into the newly provisioning VM, you should be able to see the output of the report ready systemd service:

Bash

```
$ sudo journalctl -u azure-provisioning.service
-- Logs begin at Thu 2020-06-11 20:28:45 UTC, end at Thu 2020-06-11 20:31:24 UTC.

```

Support

If you implement your own provisioning code/agent, then you own the support of this code, Microsoft support will only investigate issues relating to the provisioning interfaces not being available. We're continually making improvements and changes in this area, so you must monitor for changes in cloud-init and Azure Linux Agent for provisioning API changes.

Next steps

For more information, see Linux provisioning.

Disable or remove the Linux Agent from VMs and images

09/17/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Before removing the Linux Agent, you must understand of what VM will not be able to do after the Linux Agent is removed.

Azure virtual machine (VM) extensions are small applications that provide post-deployment configuration and automation tasks on Azure VMs, extensions are installed and managed by the Azure control plane. It is the job of the Azure Linux Agent to process the platform extension commands and ensure the correct state of the extension inside the VM.

The Azure platform hosts many extensions that range from VM configuration, monitoring, security, and utility applications. There is a large choice of first and third-party extensions, examples of key scenarios that extensions are used for:

- Supporting first party Azure services, such as Azure Backup, Monitoring, Disk Encryption, Security, Site Replication and others.
- SSH / Password resets
- VM configuration - Running custom scripts, installing Chef, Puppet agents etc..
- Third-party products, such as AV products, VM vulnerability tools, VM and App monitoring tooling.
- Extensions can be bundled with a new VM deployment. For example, they can be part of a larger deployment, configuring applications on VM provision, or run against any supported extension operated systems post deployment.

Disabling extension processing

There are several ways to disable extension processing, depending on your needs, but before you continue, you **MUST** remove all extensions deployed to the VM, for example using the Azure CLI, you can list and delete:

Azure CLI

```
az vm extension delete -g MyResourceGroup --vm-name MyVm -n extension_name
```

> ⓘ Note

If you do not do the above, the platform will try to send the extension configuration and timeout after 40min.

Disable at the control plane

If you are not sure whether you will need extensions in the future, you can leave the Linux Agent installed on the VM, then disable extension processing capability from the platform. This is option is available in `Microsoft.Compute` api version `2018-06-01` or higher, and does not have a dependency on the Linux Agent version installed.

Azure CLI

```
az vm update -g <resourceGroup> -n <vmName> --set
osProfile.allowExtensionOperations=false
```

You can easily reenable this extension processing from the platform, with the above command, but set it to 'true'.

Remove the Linux Agent from a running VM

Ensure you have **removed** all existing extensions from the VM before, as per above.

Step 1: Remove the Azure Linux Agent

If you just remove the Linux Agent, and not the associated configuration artifacts, you can reinstall at a later date. Run one of the following, as root, to remove the Azure Linux Agent:

Ubuntu

Bash

```
#For Ubuntu 18.04+:
sudo apt -y remove walinuxagent
```

Step 2: (Optional) Remove the Azure Linux Agent artifacts

ⓘ **Important**

You can remove all associated artifacts of the Linux Agent, but this will mean you cannot reinstall it at a later date. Therefore, it is strongly recommended you consider disabling the Linux Agent first, removing the Linux Agent using the above only.

If you know you will not ever reinstall the Linux Agent again, then you can run the following:

Ubuntu

Bash

```
#For Ubuntu 18.04+:
sudo apt -y purge walinuxagent
sudo cp -rp /var/lib/waagent /var/lib/waagent.bkp
sudo rm -rf /var/lib/waagent
sudo rm -f /var/log/waagent.log
```

Preparing an image without the Linux Agent

If you have an image that already contains cloud-init, and you want to remove the Linux agent, but still provision using cloud-init, run the steps in Step 2 (and optionally Step 3) as root to remove the Azure Linux Agent and then the following will remove the cloud-init configuration and cached data, and prepare the VM to create a custom image.

Bash

```
sudo cloud-init clean --logs --seed
```

Deprovision and create an image

The Linux Agent has the ability to clean up some of the existing image metadata, with the step "waagent -deprovision+user", however, after it has been removed, you will need to perform actions such as the below, and remove any other sensitive data from it.

- Remove all existing ssh host keys

  Bash

  ```
  sudo rm /etc/ssh/ssh_host_*key*
  ```

- Delete the admin account

Bash

```
sudo touch /var/run/utmp
sudo userdel -f -r <admin_user_account>
```

- Delete the root password

Bash

```
sudo passwd -d root
```

Once you have completed the above, you can create the custom image using the Azure CLI.

Create a regular managed image

Azure CLI

```
az vm deallocate -g <resource_group> -n <vm_name>
az vm generalize -g <resource_group> -n <vm_name>
az image create -g <resource_group> -n <image_name> --source <vm_name>
```

Create an image version in a Azure Compute Gallery

Azure CLI

```
az sig image-version create \
    -g $sigResourceGroup
    --gallery-name $sigName
    --gallery-image-definition $imageDefName
    --gallery-image-version 1.0.0
    --managed-image /subscriptions/00000000-0000-0000-0000-
00000000xxxx/resourceGroups/imageGroups/providers/images/MyManagedImage
```

Creating a VM from an image that does not contain a Linux Agent

When you create the VM from the image with no Linux Agent, you need to ensure the VM deployment configuration indicates extensions are not supported on this VM.

> ⓘ **Note**

If you do not do the above, the platform will try to send the extension configuration and timeout after 40min.

To deploy the VM with extensions disabled, you can use the Azure CLI with --enable-agent.

Azure CLI

```
az vm create \
    --resource-group $resourceGroup \
    --name $prodVmName \
    --image RedHat:RHEL:8.1-ci:latest \
    --admin-username azadmin \
    --ssh-key-value "$sshPubkeyPath" \
    --enable-agent false
```

Alternatively, you can do this using Azure Resource Manager (ARM) templates, by setting `"provisionVMAgent": false,`.

JSON

```
"osProfile": {
    "computerName": "[parameters('virtualMachineName')]",
    "adminUsername": "[parameters('adminUsername')]",
    "linuxConfiguration": {
        "disablePasswordAuthentication": "true",
        "provisionVMAgent": false,
        "ssh": {
            "publicKeys": [
                {
                    "path": "[concat('/home/', parameters('adminUsername'),
'/.ssh/authorized_keys')]",
                    "keyData": "[parameters('adminPublicKey')]"
```

Next steps

For more information, see Provisioning Linux.

Prepare a Windows VHD or VHDX to upload to Azure

Article • 08/22/2024

Applies to: ✔ Windows VMs

Before you upload a Windows virtual machine (VM) from on-premises to Azure, you must prepare the virtual hard disk (VHD or VHDX). Azure supports both generation 1 and generation 2 VMs that are in VHD file format and that have a fixed-size disk. The maximum size allowed for the OS VHD on a generation 1 VM is 2 TB. You can validate your VHD or VHDX file by refering to this documentation.

You can convert a VHDX file to VHD, convert a dynamically expanding disk to a fixed-size disk, but you can't change a VM's generation. For more information, see Should I create a generation 1 or 2 VM in Hyper-V? and Support for generation 2 VMs on Azure.

For information about the support policy for Azure VMs, see Microsoft server software support for Azure VMs.

> **Note**
>
> The instructions in this article apply to:
>
> - The 64-bit version of Windows Server 2008 R2 and later Windows Server operating systems. For information about running a 32-bit operating system in Azure, see Support for 32-bit operating systems in Azure VMs.
> - If any Disaster Recovery tool will be used to migrate the workload, like Azure Site Recovery or Azure Migrate, this process is still required on the Guest OS to prepare the image before the migration.

System File Checker

Run Windows System File Checker utility before generalization of OS image

The System File Checker (SFC) is used to verify and replace Windows system files.

> **Important**
>
> Use an elevated PowerShell session to run the examples in this article.

Run the SFC command:

PowerShell

```
sfc.exe /scannow
```

Output

```
Beginning system scan.  This process will take some time.

Beginning verification phase of system scan.
Verification 100% complete.

Windows Resource Protection did not find any integrity violations.
```

After the SFC scan completes, install Windows Updates and restart the computer.

Set Windows configurations for Azure

> **Note**
>
> Azure platform mounts an ISO file to the DVD-ROM when a Windows VM is created from a generalized image. For this reason, the DVD-ROM must be enabled in the OS in the generalized image. If it is disabled, the Windows VM will be stuck at out-of-box experience (OOBE).

1. Remove any static persistent routes in the routing table:

   - To view the routing table, run `route.exe print`.
   - Check the **Persistence Routes** section. If there's a persistent route, use the `route.exe delete` command to remove it.

2. Remove the WinHTTP proxy:

   PowerShell

   ```
   netsh.exe winhttp reset proxy
   ```

   If the VM needs to work with a specific proxy, add a proxy exception for the Azure IP address (168.63.129.16) so the VM can connect to Azure:

   ```
   $proxyAddress='<your proxy server>'
   $proxyBypassList='<your list of bypasses>;168.63.129.16'
   netsh.exe winhttp set proxy $proxyAddress $proxyBypassList
   ```

3. Open DiskPart:

   PowerShell

   ```
   diskpart.exe
   ```

   Set the disk SAN policy to Onlineall:

   DiskPart

   ```
   DISKPART> san policy=onlineall
   DISKPART> exit
   ```

4. Set Coordinated Universal Time (UTC) time for Windows. Also, set the startup type of the Windows time service **w32time** to **Automatic**:

   PowerShell

   ```
   Set-ItemProperty -Path HKLM:\SYSTEM\CurrentControlSet\Control\TimeZoneInformation -Name
   RealTimeIsUniversal -Value 1 -Type DWord -Force
   Set-Service -Name w32time -StartupType Automatic
   ```

5. Set the power profile to high performance:

   PowerShell

   ```
   powercfg.exe /setactive SCHEME_MIN
   powercfg /setacvalueindex SCHEME_CURRENT SUB_VIDEO VIDEOIDLE 0
   ```

6. Make sure the environmental variables **TEMP** and **TMP** are set to their default values:

PowerShell

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Session Manager\Environment' -Name TEMP -
Value "%SystemRoot%\TEMP" -Type ExpandString -Force
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Session Manager\Environment' -Name TMP -
Value "%SystemRoot%\TEMP" -Type ExpandString -Force
```

7. For VMs with legacy operating systems (Windows Server 2012 R2 or Windows 8.1 and below), make sure the latest Hyper-V Integration Component Services are installed. For more information, see Hyper-V integration components update for Windows VM.

> **Note**
>
> In a scenario where VMs are to be set up with a disaster recovery solution between the on-premises VMware server and Azure, the Hyper-V Integration Component Services can't be used. If that's the case, please contact the VMware support to migrate the VM to Azure and make it co-reside in VMware server.

Check the Windows services

Make sure that each of the following Windows services is set to the Windows default value. These services are the minimum that must be configured to ensure VM connectivity. To set the startup settings, run the following example:

PowerShell

```
Get-Service -Name BFE, Dhcp, Dnscache, IKEEXT, iphlpsvc, nsi, mpssvc, RemoteRegistry |
  Where-Object StartType -ne Automatic |
    Set-Service -StartupType Automatic

Get-Service -Name Netlogon, Netman, TermService |
  Where-Object StartType -ne Manual |
    Set-Service -StartupType Manual
```

Update remote desktop registry settings

Make sure the following settings are configured correctly for remote access:

> **Note**
>
> If you receive an error message when running `Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name <string> -Value <object>`, you can safely ignore it. It means the domain isn't setting that configuration through a Group Policy Object.

1. Remote Desktop Protocol (RDP) is enabled:

   PowerShell

   ```
   Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server' -Name fDenyTSConnections -
   Value 0 -Type DWord -Force
   Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name
   fDenyTSConnections -Value 0 -Type DWord -Force
   ```

2. The RDP port is set up correctly using the default port of 3389:

   PowerShell

   ```
   Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name
   PortNumber -Value 3389 -Type DWord -Force
   ```

When you deploy a VM, the default rules are created for port 3389. To change the port number, do that after the VM is deployed in Azure.

3. The listener is listening on every network interface:

```
PowerShell

Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name
LanAdapter -Value 0 -Type DWord -Force
```

4. Configure network-level authentication (NLA) mode for the RDP connections:

```
PowerShell

Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\WinStations\RDP-Tcp' -Name
UserAuthentication -Value 1 -Type DWord -Force
```

5. Set the keep-alive value:

```
PowerShell

Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name
KeepAliveEnable -Value 1  -Type DWord -Force
Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name
KeepAliveInterval -Value 1  -Type DWord -Force
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name
KeepAliveTimeout -Value 1 -Type DWord -Force
```

6. Set the reconnect options:

```
PowerShell

Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name
fDisableAutoReconnect -Value 0 -Type DWord -Force
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name
fInheritReconnectSame -Value 1 -Type DWord -Force
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name
fReconnectSame -Value 0 -Type DWord -Force
```

7. Limit the number of concurrent connections:

```
PowerShell

Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name
MaxInstanceCount -Value 4294967295 -Type DWord -Force
```

8. Remove any self-signed certificates tied to the RDP listener:

```
PowerShell

if ((Get-Item -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\WinStations\RDP-Tcp').Property
-contains 'SSLCertificateSHA1Hash')
{
    Remove-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\WinStations\RDP-Tcp'
-Name SSLCertificateSHA1Hash -Force
}
```

This code ensures that you can connect when you deploy the VM. You can also review these settings after the VM is deployed in Azure.

9. If the VM is part of a domain, check the following policies to make sure the previous settings aren't reverted.

Expand table

Goal	Policy	Value
RDP is enabled	Computer Configuration\Policies\Windows Settings\Administrative Templates\Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Allow users to connect remotely by using Remote Desktop
NLA group policy	Settings\Administrative Templates\Components\Remote Desktop Services\Remote Desktop Session Host\Security	Require user authentication for remote access by using NLA
Keep-alive settings	Computer Configuration\Policies\Windows Settings\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Configure keep-alive connection interval
Reconnect settings	Computer Configuration\Policies\Windows Settings\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Reconnect automatically
Limited number of connection settings	Computer Configuration\Policies\Windows Settings\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Limit number of connections

Configure Windows Firewall rules

1. Turn on Windows Firewall on the three profiles (domain, standard, and public):

```
PowerShell

Set-NetFirewallProfile -Profile Domain, Public, Private -Enabled True
```

2. Run the following example to allow WinRM through the three firewall profiles (domain, private, and public), and enable the PowerShell remote service:

```
PowerShell

Enable-PSRemoting -Force
```

> **Note**
>
> When this command runs, it enables the appropriate firewall rules automatically.

1. Enable the following firewall rules to allow the RDP traffic:

```
PowerShell

Get-NetFirewallRule -DisplayGroup 'Remote Desktop' | Set-NetFirewallRule -Enabled True
```

2. Enable the rule for file and printer sharing so the VM can respond to ping requests inside the virtual network:

```
PowerShell

Set-NetFirewallRule -Name FPS-ICMP4-ERQ-In -Enabled True
```

3. Create a rule for the Azure platform network:

```
PowerShell

New-NetFirewallRule -DisplayName AzurePlatform -Direction Inbound -RemoteAddress 168.63.129.16 -Profile
Any -Action Allow -EdgeTraversalPolicy Allow
New-NetFirewallRule -DisplayName AzurePlatform -Direction Outbound -RemoteAddress 168.63.129.16 -Profile
Any -Action Allow
```

> **Important**
>
> 168.63.129.16 is a special public IP address that is owned by Microsoft for Azure. For more information, see What is IP address 168.63.129.16.

1. If the VM is part of a domain, check the following Microsoft Entra policies to make sure the previous settings aren't reverted.

Expand table

Goal	Policy	Value
Enable the Windows Firewall profiles	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Domain Profile\Windows Firewall	Protect all network connections
Enable RDP	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Domain Profile\Windows Firewall	Allow inbound Remote Desktop exceptions
	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Standard Profile\Windows Firewall	Allow inbound Remote Desktop exceptions
Enable ICMP-V4	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Domain Profile\Windows Firewall	Allow ICMP exceptions
	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Standard Profile\Windows Firewall	Allow ICMP exceptions

Verify the VM

Make sure the VM is healthy, secure, and RDP accessible:

1. To make sure the disk is healthy and consistent, check the disk at the next VM restart:

```
PowerShell

chkdsk.exe /f
```

   Make sure the report shows a clean and healthy disk.

2. Set the Boot Configuration Data (BCD) settings.

```
PowerShell

cmd

bcdedit.exe /set "{bootmgr}" integrityservices enable
bcdedit.exe /set "{default}" device partition=C:
bcdedit.exe /set "{default}" integrityservices enable
bcdedit.exe /set "{default}" recoveryenabled Off
bcdedit.exe /set "{default}" osdevice partition=C:
bcdedit.exe /set "{default}" bootstatuspolicy IgnoreAllFailures

#Enable Serial Console Feature
bcdedit.exe /set "{bootmgr}" displaybootmenu yes
bcdedit.exe /set "{bootmgr}" timeout 5
bcdedit.exe /set "{bootmgr}" bootems yes
bcdedit.exe /ems "{current}" ON
bcdedit.exe /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

```
exit
```

3. The dump log can be helpful in troubleshooting Windows crash issues. Enable the dump log collection:

```PowerShell
# Set up the guest OS to collect a kernel dump on an OS crash event
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\CrashControl' -Name CrashDumpEnabled -Type
DWord -Force -Value 2
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\CrashControl' -Name DumpFile -Type
ExpandString -Force -Value "%SystemRoot%\MEMORY.DMP"
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\CrashControl' -Name NMICrashDump -Type
DWord -Force -Value 1

# Set up the guest OS to collect user mode dumps on a service crash event
$key = 'HKLM:\SOFTWARE\Microsoft\Windows\Windows Error Reporting\LocalDumps'
if ((Test-Path -Path $key) -eq $false) {(New-Item -Path 'HKLM:\SOFTWARE\Microsoft\Windows\Windows Error
Reporting' -Name LocalDumps)}
New-ItemProperty -Path $key -Name DumpFolder -Type ExpandString -Force -Value 'C:\CrashDumps'
New-ItemProperty -Path $key -Name CrashCount -Type DWord -Force -Value 10
New-ItemProperty -Path $key -Name DumpType -Type DWord -Force -Value 2
Set-Service -Name WerSvc -StartupType Manual
```

4. Verify that the Windows Management Instrumentation (WMI) repository is consistent:

```PowerShell
winmgmt.exe /verifyrepository
```

   If the repository is corrupted, see WMI: Repository corruption or not.

5. Make sure no other applications than TermService are using port 3389. This port is used for the RDP service in Azure. To see which ports are used on the VM, run `netstat.exe -anob`:

```PowerShell
netstat.exe -anob
```

   The following is an example.

```PowerShell
netstat.exe -anob | findstr 3389
TCP    0.0.0.0:3389           0.0.0.0:0              LISTENING       4056
TCP    [::]:3389              [::]:0                 LISTENING       4056
UDP    0.0.0.0:3389           *:*                                    4056
UDP    [::]:3389              *:*                                    4056

tasklist /svc | findstr 4056
svchost.exe                  4056 TermService
```

6. To upload a Windows VHD that's a domain controller:

   - Follow these extra steps to prepare the disk.
   - Make sure you know the Directory Services Restore Mode (DSRM) password in case you ever have to start the VM in DSRM. For more information, see Set a DSRM password.

7. Make sure you know the built-in administrator account and password. You might want to reset the current local administrator password and make sure you can use this account to sign in to Windows through the RDP connection. This access permission is controlled by the "Allow log on through Remote Desktop Services" Group Policy Object. View this object in the Local Group Policy Editor:

   - `Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment`

8. Check the following Microsoft Entra policies to make sure they're not blocking RDP access:

   - `Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\Deny access to this computer from the network`
   - `Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\Deny log on through Remote Desktop Services`

9. Check the following Microsoft Entra policy to make sure they're not removing any of the required access accounts:

   - `Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\Access this computer from the network`

   The policy should list the following groups:

   - Administrators
   - Backup Operators
   - Everyone
   - Users

10. Restart the VM to make sure that Windows is still healthy and can be reached through the RDP connection. At this point, consider creating a VM on your local Hyper-V server to make sure the VM starts completely. Then test to make sure you can reach the VM through RDP.
11. Remove any extra Transport Driver Interface (TDI) filters. For example, remove software that analyzes TCP packets or extra firewalls.
12. Uninstall any other third-party software or driver that's related to physical components or any other virtualization technology.

Install Windows updates

> **Note**
>
> To avoid an accidental reboot during the VM provisioning, we recommend completing all Windows update installations and to make sure there's no pending restart. One way to do this is to install all Windows updates and to reboot the VM before performing the migration to Azure.
>
> If you also need to do a generalization of the OS (sysprep), you must update Windows and restart the VM before running the Sysprep command.

Ideally, you should keep the machine updated to the *patch level*, if this isn't possible, make sure the following updates are installed. To get the latest updates, see the Windows update history pages: Windows 10, and Windows Server 2019, Windows 8.1, and Windows Server 2012 R2 and Windows 7 SP1, and Windows Server 2008 R2 SP1.

> **Note**
>
> To avoid an accidental reboot during VM provisioning, we recommend ensuring that all Windows Update installations are finished and that no updates are pending. One way to do this is to install all possible Windows updates and reboot once before you run the `sysprep.exe` command.

Determine when to use Sysprep

System Preparation Tool (`sysprep.exe`) is a process you can run to reset a Windows installation. Sysprep provides an "out of the box" experience by removing all personal data and resetting several components.

You typically run `sysprep.exe` to create a template from which you can deploy several other VMs that have a specific configuration. The template is called a *generalized image*.

To create only one VM from one disk, you don't have to use Sysprep. Instead, you can create the VM from a *specialized image*. For information about how to create a VM from a specialized disk, see:

- Create a VM from a specialized disk
- Create a VM from a specialized VHD disk

To create a generalized image, you need to run Sysprep. For more information, see How to use Sysprep: An introduction.

Not every role or application that's installed on a Windows-based computer supports generalized images. Before you use this procedure, make sure Sysprep supports the role of the computer. For more information, see Sysprep support for server roles.

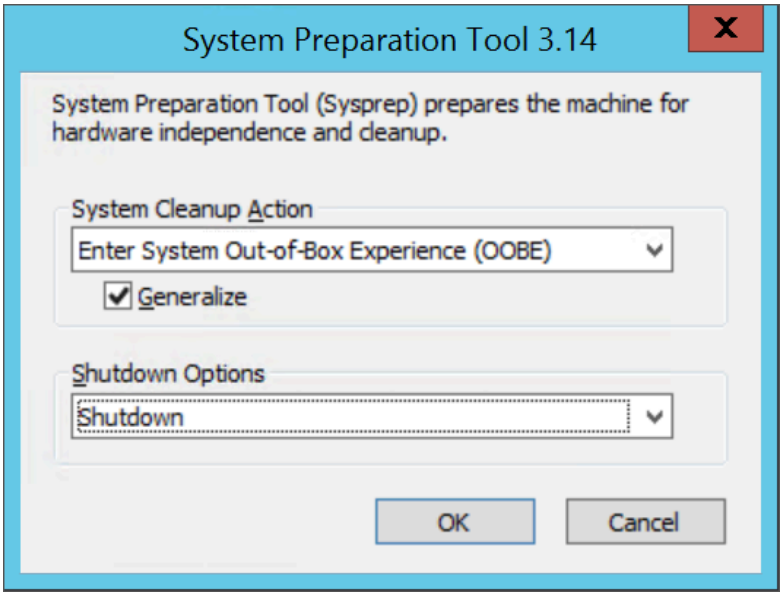
In particular, Sysprep requires the drives to be fully decrypted before execution. If you have enabled encryption on your VM, disable it before running Sysprep.

Generalize a VHD

> **Note**
>
> If you're creating a generalized image from an existing Azure VM, we recommend to remove the VM extensions before running the sysprep.

> **Note**
>
> After you run `sysprep.exe` in the following steps, turn off the VM. Don't turn it back on until you create an image from it in Azure.

1. Sign in to the Windows VM.
2. Run a PowerShell session as an administrator.
3. Delete the panther directory (C:\Windows\Panther).
4. Change the directory to `%windir%\system32\sysprep`. Then run `sysprep.exe`.
5. In the **System Preparation Tool** dialog box, select **Enter System Out-of-Box Experience (OOBE)**, and make sure the **Generalize** checkbox is selected.



6. In **Shutdown Options**, select **Shutdown**.
7. Select **OK**.
8. When Sysprep finishes, shut down the VM. Don't use **Restart** to shut down the VM.

Now the VHD is ready to be uploaded. For more information about how to create a VM from a generalized disk, see Upload a generalized VHD and use it to create a new VM in Azure.

> ⓘ Note
>
> A custom *unattend.xml* file is not supported. Although we do support the **additionalUnattendContent** property, that provides only limited support for adding microsoft-windows-shell-setup options into the *unattend.xml* file that the Azure provisioning agent uses. You can use, for example, additionalUnattendContent to add FirstLogonCommands and LogonCommands. For more information, see additionalUnattendContent FirstLogonCommands example.

Convert the virtual disk to a fixed size VHD

> ⓘ Note
>
> If you're going to use Azure PowerShell to upload your disk to Azure and you have Hyper-V enabled, this step is optional. Add-AzVHD will perform it for you.

Use one of the methods in this section to convert and resize your virtual disk to the required format for Azure:

1. Back up the VM before you run the virtual disk conversion or resize process.
2. Make sure that the Windows VHD works correctly on the local server. Resolve any errors within the VM itself before you try to convert or upload it to Azure.
3. Convert the virtual disk to type fixed.
4. Resize the virtual disk to meet Azure requirements:

   a. Disks in Azure must have a virtual size aligned to 1 MiB. If your VHD is a fraction of 1 MiB, you'll need to resize the disk to a multiple of 1 MiB. Disks that are fractions of a MiB cause errors when creating images from the uploaded VHD. To verify the size you can use the PowerShell Get-VHD cmdlet to show "Size", which must be a multiple of 1 MiB in Azure, and "FileSize", which will be equal to "Size" plus 512 bytes for the VHD footer.

   ```
   PowerShell
   ```

   ```
   $vhd = Get-VHD -Path C:\test\MyNewVM.vhd
   $vhd.Size % 1MB
   0
   $vhd.FileSize - $vhd.Size
   512
   ```

   b. The maximum size allowed for the OS VHD with a generation 1 VM is 2,048 GiB (2 TiB),

   c. The maximum size for a data disk is 32,767 GiB (32 TiB).

> ⓘ Note
>
> - If you are preparing a Windows OS disk after you convert to a fixed disk and resize if needed, create a VM that uses the disk. Start and sign in to the VM and continue with the sections in this article to finish preparing it for uploading.
> - If you are preparing a data disk you may stop with this section and proceed to uploading your disk.

Use Hyper-V Manager to convert the disk

1. Open Hyper-V Manager and select your local computer on the left. In the menu above the computer list, select **Action** > **Edit Disk**.
2. On the **Locate Virtual Hard Disk** page, select your virtual disk.
3. On the **Choose Action** page, select **Convert** > **Next**.

4. To convert from VHDX, select **VHD** > **Next**.
5. To convert from a dynamically expanding disk, select **Fixed size** > **Next**.
6. Locate and select a path to save the new VHD file.
7. Select **Finish**.

Use PowerShell to convert the disk

You can convert a virtual disk using the Convert-VHD cmdlet in PowerShell. If you need information about installing this cmdlet see Install the Hyper-V role.

> ⓘ **Note**
>
> If you're going to use Azure PowerShell to upload your disk to Azure and you have Hyper-V enabled, this step is optional. Add-AzVHD will perform it for you.

The following example converts the disk from VHDX to VHD. It also converts the disk from a dynamically expanding disk to a fixed-size disk.

```
PowerShell

Convert-VHD -Path C:\test\MyVM.vhdx -DestinationPath C:\test\MyNewVM.vhd -VHDType Fixed
```

In this example, replace the value for **Path** with the path to the virtual hard disk that you want to convert. Replace the value for **DestinationPath** with the new path and name of the converted disk.

Use Hyper-V Manager to resize the disk

> ⓘ **Note**
>
> If you're going to use Azure PowerShell to upload your disk to Azure and you have Hyper-V enabled, this step is optional. Add-AzVHD will perform it for you.

1. Open Hyper-V Manager and select your local computer on the left. In the menu above the computer list, select **Action** > **Edit Disk**.
2. On the **Locate Virtual Hard Disk** page, select your virtual disk.
3. On the **Choose Action** page, select **Expand** > **Next**.
4. On the **Locate Virtual Hard Disk** page, enter the new size in GiB > **Next**.
5. Select **Finish**.

Use PowerShell to resize the disk

> ⓘ **Note**
>
> If you're going to use Azure PowerShell to upload your disk to Azure and you have Hyper-V enabled, this step is optional. Add-AzVHD will perform it for you.

You can resize a virtual disk using the Resize-VHD cmdlet in PowerShell. If you need information about installing this cmdlet see Install the Hyper-V role.

The following example resizes the disk from 100.5 MiB to 101 MiB to meet the Azure alignment requirement.

```
PowerShell

Resize-VHD -Path C:\test\MyNewVM.vhd -SizeBytes 105906176
```

In this example, replace the value for **Path** with the path to the virtual hard disk that you want to resize. Replace the value for **SizeBytes** with the new size in bytes for the disk.

Convert from VMware VMDK disk format

If you have a Windows VM image in the VMDK file format, then you can use Azure Migrate to convert the VMDK and upload it to Azure.

Complete the recommended configurations

The following settings don't affect VHD uploading. However, we strongly recommend that you configured them.

- Install the Azure Virtual Machine Agent. Then you can enable VM extensions. The VM extensions implement most of the critical functionality that you might want to use with your VMs. You'll need the extensions, for example, to reset passwords or configure RDP. For more information, see the Azure Virtual Machine Agent overview.
- After you create the VM in Azure, we recommend that you put the page file on the *temporal drive volume* to improve performance. You can set up the file placement as follows:

  PowerShell

  ```
  Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management' -Name
  PagingFiles -Value 'D:\pagefile.sys' -Type MultiString -Force
  ```

  If a data disk is attached to the VM, the temporal drive volume's letter is typically *D*. This designation could be different, depending on your settings and the number of available drives.
  - We recommend disabling script blockers that might be provided by antivirus software. They might interfere and block the Windows Provisioning Agent scripts executed when you deploy a new VM from your image.

> **Tip**
>
> **Optional** Use DISM to optimize your image and reduce your VM's first boot time.
>
> To optimize your image, mount your VHD by double-clicking on it in Windows explorer, and then run DISM with the `/optimize-image` parameter.
>
> Windows Command Prompt
>
> ```
> DISM /image:D:\ /optimize-image /boot
> ```
>
> Where D: is the mounted VHD's path.
>
> Running `DISM /optimize-image` should be the last modification you make to your VHD. If you make any changes to your VHD prior to deployment, you'll have to run `DISM /optimize-image` again.

Visual Studio images on Azure

Using Visual Studio in a preconfigured Azure virtual machine (VM) is a quick, easy way to go from nothing to an up-and-running development environment. System images with different Visual Studio configurations are available in the Azure Marketplace.

New to Azure? Create a free Azure account.

What configurations and versions are available?

Images for the latest major versions, Visual Studio 2022, Visual Studio 2019, and Visual Studio 2017 are available in the Azure Marketplace. These images are updated at least once a month to include the latest Visual Studio and Windows updates. Although the image names remain unchanged, each image's description includes the installed product version and the date it reflects

Expand table

Release version	Editions	Product version
Visual Studio 2022 (Microsoft Dev Box compatible)	Enterprise, Professional, Community	Version 17.12
Visual Studio 2019 (Microsoft Dev Box compatible)	Enterprise, Professional	Version 16.11
Visual Studio 2017: Latest (Version 15.9)	Enterprise, Community	Version 15.9
Visual Studio on Windows Server	Enterprise, Professional, Community	VS 2022 and VS 2019 on Windows Server 2025

The Azure VM image offers help you create and test applications more quickly and easily on both Azure VMs and the Microsoft Dev Box service. For updates on newly added or deprecated images, see the DevBlog post Giving our Azure marketplace images a makeover. To learn more, visit the Visual Studio Servicing Policy.

Windows client for developers (Microsoft Dev Box compatible), a Windows 11 Enterprise image is meant to be used as a starting point for creating custom Dev Box images, and contains additional tools and settings to optimize the developer experience. This image doesn't include Visual Studio. For Visual Studio developers, we recommend using our Visual Studio 2022 or Visual Studio 2019 Dev Box compatible images as a starting point.

What features are installed?

Each image contains the recommended feature set for that Visual Studio edition. Generally, the installation includes:

- All available workloads, including each workload's recommended optional components. Learn more about workloads, components, and SDKs included Visual Studio.
- .NET 4.6.2, .NET 4.7, and .NET 4.8 SDKs, Targeting Packs, and Developer Tools
- Visual F#
- GitHub Extension for Visual Studio
- LINQ to SQL Tools

We use the following command line to install Visual Studio when building the images:

shell

```
vs_enterprise.exe --allWorkloads --includeRecommended --passive ^
   --add Microsoft.Net.Component.4.8.SDK ^
   --add Microsoft.Net.Component.4.7.2.SDK ^
   --add Microsoft.Net.Component.4.7.2.TargetingPack ^
   --add Microsoft.Net.Component.4.6.2.SDK ^
   --add Microsoft.Net.Component.4.6.2.TargetingPack ^
   --add Microsoft.Net.ComponentGroup.4.8.DeveloperTools ^
   --add Microsoft.Net.ComponentGroup.4.7.2.DeveloperTools ^
   --add Microsoft.VisualStudio.Component.FSharp ^
   --add Component.GitHub.VisualStudio ^
   --add Microsoft.VisualStudio.Component.LinqToSql
```

If the images don't include a Visual Studio feature that you require, please provide feedback through the feedback tool in the upper-right corner of the page.

What size VM should I choose?

Azure offers a full range of virtual machine sizes. Because Visual Studio is a powerful, multi-threaded application, you want a VM size that includes at least two processors and 7 GB of memory. We recommend the following VM sizes for the Visual Studio images:

- Standard_D2_v3
- Standard_D2s_v3
- Standard_D4_v3
- Standard_D4s_v3
- Standard_D2_v2
- Standard_D2S_v2

- Standard_D3_v2

For more information on the latest machine sizes, see Sizes for Windows virtual machines in Azure.

With Azure, you can rebalance your initial choice by resizing the VM. You can either provision a new VM with a more appropriate size, or resize your existing VM to different underlying hardware. For more information, see Resize a Windows VM.

After the VM is running, what's next?

Visual Studio follows the “bring your own license” model in Azure. As with an installation on proprietary hardware, one of the first steps is licensing your Visual Studio installation. To unlock Visual Studio, either:

- Sign in with a Microsoft account that’s associated with a Visual Studio subscription
- Unlock Visual Studio with the product key that came with your initial purchase

For more information, see Sign in to Visual Studio and How to unlock Visual Studio.

How do I save the development VM for future or team use?

The spectrum of development environments is huge, and there’s real cost associated with building out the more complex environments. Regardless of your environment’s configuration, you can save, or capture, your configured VM as a "base image" for future use or for other members of your team. Then, when booting a new VM, you provision it from the base image rather than the Azure Marketplace image.

A quick summary: Use the System Preparation tool (Sysprep) and shut down the running VM, and then capture *(Figure 1)* the VM as an image through the UI in the Azure portal. Azure saves the `.vhd` file that contains the image in the storage account of your choosing. The new image then shows up as an Image resource in your subscription’s list of resources.

(Figure 1) Capture an image through the Azure portal’s UI.

For more information, see Create a managed image of a generalized VM in Azure.

> **Important**
>
> Don’t forget to use Sysprep to prepare the VM. If you miss that step, Azure can't provision a VM from the image.

> **Note**
>
> You still incur some cost for storage of the images, but that incremental cost can be insignificant compared to the overhead costs to rebuild the VM from scratch for each team member who needs one. For instance, it costs a few dollars to create and store a 127-GB image for a month that's reusable by your entire team. However, these costs are insignificant compared to hours each employee invests to build out and validate a properly configured dev box for their individual use.

Additionally, your development tasks or technologies might need more scale, like varieties of development configurations and multiple machine configurations. You can use Azure DevTest Labs to create *recipes* that automate construction of your "golden image." You can also use DevTest Labs to manage policies for your team’s running VMs. Using Azure DevTest Labs for developers is the best source for more information on DevTest Labs.

Azure VM Image Builder overview

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

By using standardized virtual machine (VM) images, your organization can more easily migrate to the cloud and help ensure consistency in your deployments. Images ordinarily include predefined security, configuration settings, and any necessary software. Setting up your own imaging pipeline requires time, infrastructure, and many other details. With Azure VM Image Builder, you need only create a configuration that describes your image and submit it to the service, where the image is built and then distributed.

With VM Image Builder, you can migrate your existing image customization pipeline to Azure as you continue to use existing scripts, commands, and processes. You can integrate your core applications into a VM image, so that your VMs can take on workloads after the images are created. You can even add configurations to build images for Azure Virtual Desktop, as virtual hard disks (VHDs) for use in Azure Stack, or for ease of exporting.

VM Image Builder lets you start with Windows or Linux images either from Azure Marketplace or as existing custom images, and then add your own customizations. You can also specify where you want your resulting images to be hosted in Azure Compute Gallery (formerly Shared Image Gallery), as managed images or as VHDs.

Features

Although it's possible to create custom VM images by hand or by other tools, the process can be cumbersome and unreliable. VM Image Builder, which is built on HashiCorp Packer, gives you the benefits of a managed service.

Simplicity

To reduce the complexity of creating VM images, VM Image Builder:

- Removes the need to use complex tooling, processes, and manual steps to create a VM image. VM Image Builder abstracts out all these details and hides Azure-specific requirements, such as the need to generalize the image (Sysprep). And it gives more advanced users the ability to override such requirements.

- Can be integrated with existing image build pipelines for a click-and-go experience. To do so, you can either call VM Image Builder from your pipeline or use an Azure VM Image Builder service DevOps task (preview).
- Can fetch customization data from various sources, which removes the need to collect them all from one place.
- Can be integrated with Compute Gallery, which creates an image management system with which to distribute, replicate, version, and scale images globally. Additionally, you can distribute the same resulting image as a VHD or as one or more managed images, without having to rebuild them from scratch.

Infrastructure as code

With VM Image Builder, there's no need to manage your long-term infrastructure (for example, storage accounts that hold customization data) or transient infrastructure (for example, temporary VMs for building images).

VM Image Builder stores your VM image build artifacts as Azure resources. This feature removes both the need to maintain offline definitions and the risk of environment drifts that are caused by accidental deletions or updates.

Security

To help keep your images secure, VM Image Builder:

- Enables you to create baseline images (that is, your minimum security and corporate configurations) and allows other departments to customize them further. You can help keep these images secure and compliant by using VM Image Builder to quickly rebuild a golden image that uses the latest patched version of a source image. VM Image Builder also makes it easier for you to build images that meet the Azure Windows security baseline. For more information, see VM Image Builder - Windows baseline template.
- Enables you to fetch your customization artifacts without having to make them publicly accessible. VM Image Builder can use your Azure Managed Identity to fetch these resources, and you can restrict the privileges of this identity as tightly as required by using Azure role-based access control (Azure RBAC). You can both keep your artifacts secret and prevent tampering by unauthorized actors.
- Securely stores copies of customization artifacts, transient compute and storage resources, and their resulting images within your subscription, because access is controlled by Azure RBAC. This level of security, which also applies to the build VM

that's used to create the customized image, helps prevent your customization scripts and files from being copied to an unknown VM in an unknown subscription. And you can achieve a high degree of separation from other customers' workloads by using Isolated VM offerings for the build VM.

- Enables you to connect VM Image Builder to your existing virtual networks, so that you can communicate with existing configuration servers, such as DSC (desired state configuration pull server), Chef, and Puppet, file shares, or any other routable servers and services.

- Can be configured to assign your user-assigned identities to the VM Image Builder build VM (that is, the VM that the VM Image Builder service creates in your subscription and uses to build and customize the image). You can then use these identities at customization time to access Azure resources, including secrets, in your subscription. There's no need to assign VM Image Builder direct access to those resources.

Regions

The VM Image Builder service is available in the following regions:

> **Note**
>
> You can still distribute images outside these regions.

- East US
- East US 2
- West Central US
- West US
- West US 2
- West US 3
- South Central US
- North Europe
- West Europe
- South East Asia
- Australia Southeast
- Australia East
- UK South
- UK West
- Brazil South
- Canada Central

- Central India
- Central US
- France Central
- Germany West Central
- Japan East
- North Central US
- Norway East
- Switzerland North
- Jio India West
- UAE North
- East Asia
- Korea Central
- South Africa North
- Qatar Central
- USGov Arizona (public preview)
- USGov Virginia (public preview)
- China North 3 (public preview)
- Sweden Central
- Poland Central
- Italy North
- Israel Central

To access the Azure VM Image Builder public preview in the Fairfax regions (USGov Arizona and USGov Virginia), you must register the *Microsoft.VirtualMachineImages/FairfaxPublicPreview* feature. To do so, run the following command in either PowerShell or Azure CLI:

Azure PowerShell

Azure PowerShell

```
Register-AzProviderPreviewFeature -ProviderNamespace
Microsoft.VirtualMachineImages -Name FairfaxPublicPreview
```

To access the Azure VM Image Builder public preview in the China North 3 region, you must register the *Microsoft.VirtualMachineImages/MooncakePublicPreview* feature. To do so, run the following command in either PowerShell or Azure CLI:

Azure PowerShell

Azure PowerShell

```
Register-AzProviderPreviewFeature -ProviderNamespace
Microsoft.VirtualMachineImages -Name MooncakePublicPreview
```

OS support

VM Image Builder is designed to work with all Azure Marketplace base operating system images.

> **Note**
>
> You can now use the Azure Image Builder service inside the portal as of March 2023. Get started with building and validating custom images inside the portal.

Confidential VM and Trusted Launch Support

VM Image Builder has extended support for TrustedLaunchSupported and ConfidentialVMSupported images, with certain constraints. Below is the list of constraints:

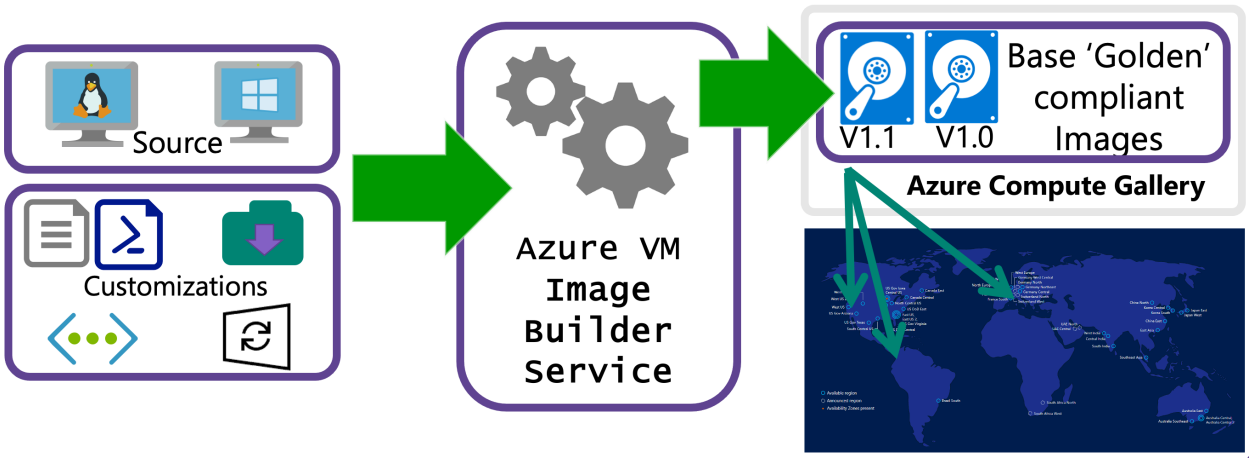
Expand table

SecurityType	Support status
TrustedLaunchSupported	Support as a source image for image builds
ConfidentialVMSupported	Support as a source image for image builds
TrustedLaunch	Not supported as a source image
ConfidentialVM	Not supported as a source image

> **Note**
>
> When using TrustedLaunchSupported images, it's important that the source and distribute must both be TrustedLaunchSupported for it to be supported. If the source is normal and the distribute is TrustedLaunchSupported, or if the source is TrustedLaunchSupported and the distribute is normal Gen2, it's not supported.

How it works

VM Image Builder is a fully managed Azure service that's accessible to Azure resource providers. Resource providers configure it by specifying a source image, a customization to perform, and where the new image is to be distributed. A high-level workflow is illustrated in the following diagram:



You can pass template configurations by using Azure PowerShell, the Azure CLI, or Azure Resource Manager templates, or by using a VM Image Builder DevOps task. When you submit the configuration to the service, Azure creates an *image template resource*. When the image template resource is created, a *staging resource group* is created in your subscription, in the following format: `IT_\<DestinationResourceGroup>_\<TemplateName>_\(GUID)`. The staging resource group contains files and scripts, which are referenced in the File, Shell, and PowerShell customization in the ScriptURI property.

To run the build, you invoke `Run` on the VM Image Builder template resource. The service then deploys additional resources for the build, such as a VM, network, disk, and network adapter.

If you build an image without using an existing virtual network, VM Image Builder also deploys a public IP and network security group, and it connects to the build VM by using Secure Shell (SSH) or Windows Remote Management (WinRM) protocol.

If you select an existing virtual network, the service is deployed via Azure Private Link, and a public IP address isn't required. For more information, see VM Image Builder networking overview.

When the build finishes, all resources are deleted, except for the staging resource group and the storage account. You can remove them by deleting the image template resource, or you can leave them in place to run the build again.

For multiple examples, step-by-step guides, configuration templates, and solutions, go to the VM Image Builder GitHub repository.

Move support

The image template resource is immutable, and it contains links to resources and the staging resource group. Therefore, this resource type doesn't support being moved.

If you want to move the image template resource, either make sure that you have a copy of the configuration template or, if you don't have a copy, extract the existing configuration from the resource. Then, create a new image template resource in the new resource group with a new name, and delete the previous image template resource.

Permissions

When you register for the VM Image Builder service, you're granting the service permission to create, manage, and delete a staging resource group, which is prefixed with `IT_*`. And you have rights to add to it any resources that are required for the image build. This happens because a VM Image Builder service principal name is made available in your subscription after you've registered successfully.

To allow VM Image Builder to distribute images to either the managed images or Compute Gallery, you need to create an Azure user-assigned identity that has permissions to read and write images. If you're accessing Azure Storage, you'll need permissions to read private and public containers.

In API version 2021-10-01 and later, VM Image Builder supports adding Azure user-assigned identities to the build VM to enable scenarios where you need to authenticate with services such as Azure Key Vault in your subscription.

For more information about permissions, see

- Configure VM Image Builder permissions by using PowerShell
- Configure VM Image Builder permissions by using the Azure CLI
- Create a VM Image Builder template

Costs

You'll incur some compute, networking, and storage costs when you create, build, and store images by using VM Image Builder. These costs are similar to those that you incur when you create custom images manually. Your resources are charged at your Azure rates.

> ⓘ **Note**

The Azure Image Builder service currently does not support Azure Hybrid Benefit for Windows Server at this time.

During the image-creation process, files are downloaded and stored in the `IT_<DestinationResourceGroup>_<TemplateName>` resource group, which incurs a small storage cost. If you don't want to keep these files, delete the image template after you've built the image.

VM Image Builder creates a VM by using the default Standard_D1_v2 VM size for Gen1 images and Standard_D2ds_v4 for Gen2 images, along with the storage and networking that's needed for the VM. These resources last for the duration of the build process and are deleted after VM Image Builder has finished creating the image.

VM Image Builder distributes the image to your chosen regions, which might incur network egress charges.

Hyper-V generation

VM Image Builder currently supports creating Hyper-V Gen1 and Gen2 images in a Compute Gallery and as managed images or VHDs. Keep in mind that the distributed image is always in the same generation as the provided image.

For Gen2 images, ensure that you're using the correct SKU. For example, the SKU for an Ubuntu Server 18.04 Gen2 image would be 18_04-lts-gen2. The SKU for an Ubuntu Server 18.04 Gen1 image would be 18.04-lts.

Here's how to find SKUs that are based on the image publisher:

Azure CLI

```
# Find all Gen2 SKUs published by Microsoft Windows Desktop
az vm image list --publisher MicrosoftWindowsDesktop --sku g2 --output table
--all

# Find all Gen2 SKUs published by Canonical
az vm image list --publisher Canonical --sku gen2 --output table --all
```

For more information about Azure VM images that support Gen2, see Gen2 VM images in Azure Marketplace.

Next steps

To try out VM Image Builder, see the articles about building Linux or Windows images.

Feedback

Was this page helpful? Yes No

Provide product feedback | Get help at Microsoft Q&A

Create a Linux image and distribute it to an Azure Compute Gallery by using the Azure CLI

Applies to: ✔ Linux VMs ✔ Flexible scale sets

In this article, you learn how to use Azure VM Image Builder and the Azure CLI to create an image version in an Azure Compute Gallery (formerly Shared Image Gallery) and then distribute the image globally. You can also create an image version by using Azure PowerShell.

This article uses a sample JSON template to configure the image. The JSON file is at helloImageTemplateforSIG.json.

To distribute the image to an Azure Compute Gallery, the template uses sharedImage as the value for the `distribute` section of the template.

Register the providers

To use VM Image Builder, you need to register the providers. Check your registration by running the following commands:

Azure CLI

```
az provider show -n Microsoft.VirtualMachineImages -o json | grep registrationState
az provider show -n Microsoft.KeyVault -o json | grep registrationState
az provider show -n Microsoft.Compute -o json | grep registrationState
az provider show -n Microsoft.Storage -o json | grep registrationState
az provider show -n Microsoft.Network -o json | grep registrationState
az provider show -n Microsoft.ContainerInstance -o json | grep registrationState
```

If the output doesn't say *registered*, run the following commands:

Azure CLI

```
az provider register -n Microsoft.VirtualMachineImages
az provider register -n Microsoft.Compute
az provider register -n Microsoft.KeyVault
az provider register -n Microsoft.Storage
az provider register -n Microsoft.Network
az provider register -n Microsoft.ContainerInstance
```

Set variables and permissions

Because you'll be using some pieces of information repeatedly, create some variables to store that information.

VM Image Builder supports creating custom images only in the same resource group as the source-managed image. In the following example, update the resource group name to be the same resource group as your source-managed image.

Azure CLI

```
# Resource group name - ibLinuxGalleryRG in this example
sigResourceGroup=ibLinuxGalleryRG
# Datacenter location - West US 2 in this example
location=westus2
# Additional region to replicate the image to - East US in this example
additionalregion=eastus
# Name of the Azure Compute Gallery - myGallery in this example
sigName=myIbGallery
# Name of the image definition to be created - myImageDef in this example
imageDefName=myIbImageDef
# Reference name in the image distribution metadata
runOutputName=aibLinuxSIG
```

Create a variable for your subscription ID:

Azure CLI

```
subscriptionID=$(az account show --query id --output tsv)
```

Create the resource group:

Azure CLI

```
az group create -n $sigResourceGroup -l $location
```

Create a user-assigned identity and set permissions on the resource group

VM Image Builder uses the provided user-identity to inject the image into an Azure Compute Gallery. In this example, you create an Azure role definition with specific actions for distributing the image. The role definition is then assigned to the user identity.

The success of the following command relies on RBAC propagation, which can take up to ~30 minutes in some cases. Wait about 5 minutes before running the command and retry after a delay if an error occurs.

Azure CLI

```
# Create user-assigned identity for VM Image Builder to access the storage account
where the script is stored
identityName=aibBuiUserId$(date +'%s')
az identity create -g $sigResourceGroup -n $identityName

# Get the identity ID
imgBuilderCliId=$(az identity show -g $sigResourceGroup -n $identityName --query
clientId -o tsv)

# Get the user identity URI that's needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$sigResourceGroup/provid
ers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# Download an Azure role-definition template, and update the template with the
parameters that were specified earlier
curl
https://raw.githubusercontent.com/Azure/azvmimagebuilder/master/solutions/12_Creati
ng_AIB_Security_Roles/aibRoleImageCreation.json -o aibRoleImageCreation.json

imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# Update the definition
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$sigResourceGroup/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation Role/$imageRoleDefName/g"
aibRoleImageCreation.json

# Create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# Grant a role definition to the user-assigned identity. The success of the
following command relies on RBAC propagation, which can take up to ~30 minutes.
Wait about 5 minutes before running the command and wait a few more minutes before
retrying if you get an error.

az role assignment create \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup
```

Create an image definition and gallery

To use VM Image Builder with Azure Compute Gallery, you need to have an existing gallery and image definition. VM Image Builder doesn't create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them.

First, create a gallery:

Azure CLI

```
az sig create \
    -g $sigResourceGroup \
    --gallery-name $sigName
```

Then, create an image definition:

Azure CLI

```
az sig image-definition create \
   -g $sigResourceGroup \
   --gallery-name $sigName \
   --gallery-image-definition $imageDefName \
   --publisher myIbPublisher \
   --offer myOffer \
   --sku 20_04-lts-gen2 \
   --os-type Linux \
   --hyper-v-generation V2 \
   --features SecurityType=TrustedLaunchSupported
```

Download and configure the JSON file

Download the JSON template and configure it with your variables:

Azure CLI

```
curl
https://raw.githubusercontent.com/Azure/azvmimagebuilder/master/quickquickstarts/1_
Creating_a_Custom_Linux_Shared_Image_Gallery_Image/helloImageTemplateforSIG.json -o
helloImageTemplateforSIG.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateforSIG.json
sed -i -e "s/<rgName>/$sigResourceGroup/g" helloImageTemplateforSIG.json
sed -i -e "s/<imageDefName>/$imageDefName/g" helloImageTemplateforSIG.json
sed -i -e "s/<sharedImageGalName>/$sigName/g" helloImageTemplateforSIG.json
sed -i -e "s/<region1>/$location/g" helloImageTemplateforSIG.json
sed -i -e "s/<region2>/$additionalregion/g" helloImageTemplateforSIG.json
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateforSIG.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateforSIG.json
sed -i -e "s/sudo mkdir/sleep 300;sudo mkdir/g" helloImageTemplateforSIG.json
```

Create the image version

In this section you create the image version in the gallery.

Submit the image configuration to the Azure VM Image Builder service:

Azure CLI

```
az resource create \
    --resource-group $sigResourceGroup \
    --properties @helloImageTemplateforSIG.json \
    --is-full-object \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateforSIG01
```

Start the image build:

Azure CLI

```
az resource invoke-action \
     --resource-group $sigResourceGroup \
     --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
     -n helloImageTemplateforSIG01 \
     --action Run
```

It can take a few moments to create the image and replicate it to both regions. Wait until this part is finished before you move on to create a VM.

Create the VM

Create the VM from the image version that was created by VM Image Builder.

Azure CLI

```
az vm create \
  --resource-group $sigResourceGroup \
  --name myAibGalleryVM \
  --admin-username aibuser \
  --location $location \
  --image
"/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsof
t.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \
  --security-type TrustedLaunch \
  --generate-ssh-keys
```

Connect to the VM via Secure Shell (SSH):

Azure CLI

```
ssh aibuser@<publicIpAddress>
```

As soon as your SSH connection is established, you should see that the image was customized with a *Message of the Day*:

Console

```
**************************************************
**            This VM was built from the:       **
**      !! AZURE VM IMAGE BUILDER Custom Image !!  **
**         You have just been Customized :-)      **
**************************************************
```

Clean up your resources

> **Note**
>
> If you now want to try to recustomize the image version to create a new version of the same image, *skip the step outlined here* and go to Use VM Image Builder to create another image version.

If you no longer need the resources that were created as you followed the process in this article, you can delete them by doing the following.

This process deletes both the image that you created and all the other resource files. Make sure that you've finished this deployment before you delete the resources.

When you're deleting gallery resources, you need delete all the image versions before you can delete the image definition that was used to create them. To delete a gallery, you first need to have deleted all the image definitions in the gallery.

1. Delete the VM Image Builder template.

   Azure CLI

   ```azurecli
   az resource delete \
       --resource-group $sigResourceGroup \
       --resource-type Microsoft.VirtualMachineImages/imageTemplates \
       -n helloImageTemplateforSIG01
   ```

2. Delete permissions assignments, roles, and identity.

   Azure CLI

   ```azurecli
   az role assignment delete \
       --assignee $imgBuilderCliId \
       --role "$imageRoleDefName" \
       --scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup

   az role definition delete --name "$imageRoleDefName"
   ```

```
az identity delete --ids $imgBuilderId
```

3. Get the image version that was created by VM Image Builder (it always starts with `0.`), and then delete it.

Azure CLI

```
sigDefImgVersion=$(az sig image-version list \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID --query [].'name' -o json | grep 0. | tr -d
'"')
az sig image-version delete \
-g $sigResourceGroup \
--gallery-image-version $sigDefImgVersion \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID
```

4. Delete the image definition.

Azure CLI

```
az sig image-definition delete \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID
```

5. Delete the gallery.

Azure CLI

```
az sig delete -r $sigName -g $sigResourceGroup
```

6. Delete the resource group.

Azure CLI

```
az group delete -n $sigResourceGroup -y
```

Create a Windows VM by using Azure VM Image Builder

Article • 10/28/2024

Applies to: ✔ Windows VMs

In this article, you learn how to create a customized Windows image by using Azure VM Image Builder. The example in this article uses customizers for customizing the image:

- PowerShell (ScriptUri): Download and run a PowerShell script.
- Windows Restart: Restarts the VM.
- PowerShell (inline): Runs a specific command. In this example, it creates a directory on the VM by using `mkdir c:\\buildActions`.
- File: Copies a file from GitHub to the VM. This example copies index.md to `c:\buildArtifacts\index.html` on the VM.
- `buildTimeoutInMinutes`: Specifies a build time, in minutes. The default is 240 minutes, which you can increase to allow for longer-running builds. The minimum allowed value is 6 minutes. Values shorter than 6 minutes will cause errors.
- `vmProfile`: Specifies a `vmSize` and network properties.
- `osDiskSizeGB`: Can be used to increase the size of an image.
- `identity`. Provides an identity for VM Image Builder to use during the build.

Use the following sample JSON template to configure the image: helloImageTemplateWin.json.

> **Note**
>
> Windows users can run the following Azure CLI examples on Azure Cloud Shell by using Bash.

Register the providers

To use VM Image Builder, you need to register the feature. Check your registration by running the following commands:

Azure CLI

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState
az provider show -n Microsoft.KeyVault | grep registrationState
az provider show -n Microsoft.Compute | grep registrationState
```

```
az provider show -n Microsoft.Storage | grep registrationState
az provider show -n Microsoft.Network | grep registrationState
az provider show -n Microsoft.ContainerInstance -o json | grep
registrationState
```

If the output doesn't say *registered*, run the following commands:

Azure CLI

```
az provider register -n Microsoft.VirtualMachineImages
az provider register -n Microsoft.Compute
az provider register -n Microsoft.KeyVault
az provider register -n Microsoft.Storage
az provider register -n Microsoft.Network
az provider register -n Microsoft.ContainerInstance
```

Set variables

Because you'll be using some pieces of information repeatedly, create some variables to store that information:

Azure CLI

```
# Resource group name - we're using myImageBuilderRG in this example
imageResourceGroup='myWinImgBuilderRG'
# Region location
location='WestUS2'
# Run output name
runOutputName='aibWindows'
# The name of the image to be created
imageName='aibWinImage'
```

Create a variable for your subscription ID:

Azure CLI

```
subscriptionID=$(az account show --query id --output tsv)
```

Create the resource group

To store the image configuration template artifact and the image, use the following resource group:

Azure CLI

```
az group create -n $imageResourceGroup -l $location
```

Create a user-assigned identity and set permissions on the resource group

VM Image Builder uses the provided user-identity to inject the image into the resource group. In this example, you create an Azure role definition with specific permissions for distributing the image. The role definition is then assigned to the user identity.

Create a user-assigned managed identity and grant permissions

Create a user-assigned identity so that VM Image Builder can access the storage account where the script is stored.

Azure CLI

```
identityName=aibBuiUserId$(date +'%s')
az identity create -g $imageResourceGroup -n $identityName

# Get the identity ID
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName -
-query clientId -o tsv)

# Get the user identity URI that's needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$imageResourceGro
up/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# Download the preconfigured role definition example
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12
_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o
aibRoleImageCreation.json

imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# Update the definition
sed -i -e "s%<subscriptionID>%$subscriptionID%g" aibRoleImageCreation.json
sed -i -e "s%<rgName>%$imageResourceGroup%g" aibRoleImageCreation.json
sed -i -e "s%Azure Image Builder Service Image Creation
Role%$imageRoleDefName%g" aibRoleImageCreation.json

# Create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# Grant a role definition to the user-assigned identity
```

```
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup
```

Download the image configuration template

We've created a parameterized image configuration template for you to try. Download the example JSON file, and then configure it with the variables that you set earlier.

Azure CLI

```
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickquickstarts/0_Creating_a_Custom_Windows_Managed_Image/helloImageTemplateWin.json -o
helloImageTemplateWin.json

sed -i -e "s%<subscriptionID>%$subscriptionID%g" helloImageTemplateWin.json
sed -i -e "s%<rgName>%$imageResourceGroup%g" helloImageTemplateWin.json
sed -i -e "s%<region>%$location%g" helloImageTemplateWin.json
sed -i -e "s%<imageName>%$imageName%g" helloImageTemplateWin.json
sed -i -e "s%<runOutputName>%$runOutputName%g" helloImageTemplateWin.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateWin.json
```

You can modify this example in the terminal by using a text editor such as `vi`.

Azure CLI

```
vi helloImageTemplateWin.json
```

> **Note**
>
> For the source image, always specify a version. You can't specify `latest` as the version.
>
> If you add or change the resource group that the image is distributed to, make sure that the permissions are set on the resource group.

Create the image

Submit the image configuration to the VM Image Builder service by running the following commands:

Azure CLI

```
az resource create \
    --resource-group $imageResourceGroup \
    --properties @helloImageTemplateWin.json \
    --is-full-object \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateWin01
```

When you're done, a success message is returned to the console, and a VM Image Builder configuration template is created in the `$imageResourceGroup`.

In the background, VM Image Builder also creates a staging resource group in your subscription. This resource group is used to build the image in the following format: `IT_<DestinationResourceGroup>_<TemplateName>`.

> **Note**
>
> If deletion is required, don't delete the staging resource group directly. First, delete the image template artifact, which subsequently will delete the staging resource group. Otherwise, the image template may enter a failed state.

If the service reports a failure when you submit the image configuration template, do the following:

- See Troubleshoot the Azure VM Image Builder service.
- Before you try to resubmit the template, delete it by running the following commands:

Azure CLI

```
az resource delete \
    --resource-group $imageResourceGroup \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateWin01
```

Start the image build

Start the image-building process by using az resource invoke-action.

Azure CLI

```
az resource invoke-action \
     --resource-group $imageResourceGroup \
```

```
    --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateWin01 \
    --action Run
```

Wait until the build is complete.

If you encounter any errors, see Troubleshoot the Azure VM Image Builder service.

Create the VM

Create the VM by using the image that you built. In the following code, replace *<password>* with your own password for the *aibuser* on the VM.

Azure CLI

```
az vm create \
  --resource-group $imageResourceGroup \
  --name aibImgWinVm00 \
  --admin-username aibuser \
  --admin-password <password> \
  --image $imageName \
  --location $location
```

Verify the customization

Create a Remote Desktop connection to the VM by using the username and password that you set when you created the VM. In the VM, open a Command Prompt window, and then type:

Console

```
dir c:\
```

The following two directories are created during the image customization:

- buildActions
- buildArtifacts

Clean up your resources

When you're done, delete the resources you've created.

1. Delete the VM Image Builder template.

Azure CLI

```
az resource delete \
    --resource-group $imageResourceGroup \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateWin01
```

2. Delete the role assignment, role definition, and user identity.

Azure CLI

```
az role assignment delete \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

az role definition delete --name "$imageRoleDefName"

az identity delete --ids $imgBuilderId
```

3. Delete the image resource group.

Azure CLI

```
az group delete -n $imageResourceGroup
```

Next steps

To learn more about the components of the JSON file that this article uses, see the VM Image Builder template reference.

Create a Windows VM with VM Image Builder by using PowerShell

Article • 08/22/2024

Applies to: ✔ Windows VMs

This article demonstrates how to create a customized Windows VM image by using the Azure VM Image Builder PowerShell module.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

If you choose to use PowerShell locally, this article requires that you install the Azure PowerShell module and connect to your Azure account by using the Connect-AzAccount cmdlet. For more information, see Install Azure PowerShell.

Some of the steps require cmdlets from the Az.ImageBuilder module. Install separately by using the following command.

Azure PowerShell

```
Install-Module -Name Az.ImageBuilder
```

Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

Expand table

Option	Example/Link
Select **Try It** in the upper-right corner of a code or command block. Selecting **Try It** doesn't automatically copy the code or command to Cloud Shell.	

Option	Example/Link
Go to https://shell.azure.com, or select the **Launch Cloud Shell** button to open Cloud Shell in your browser.	
Select the **Cloud Shell** button on the menu bar at the upper right in the Azure portal.	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl**+**Shift**+**V** on Windows and Linux, or by selecting **Cmd**+**Shift**+**V** on macOS.
4. Select **Enter** to run the code or command.

If you have multiple Azure subscriptions, choose the appropriate subscription in which the resources should be billed. Select a specific subscription by using the Set-AzContext cmdlet.

Azure PowerShell

```
Set-AzContext -SubscriptionId 00000000-0000-0000-0000-000000000000
```

Register providers

If you haven't already done so, register the following resource providers to use with your Azure subscription:

- Microsoft.Compute
- Microsoft.KeyVault
- Microsoft.Storage
- Microsoft.Network
- Microsoft.VirtualMachineImages
- Microsoft.ManagedIdentity
- Microsoft.ContainerInstance

Azure PowerShell

```
Get-AzResourceProvider -ProviderNamespace Microsoft.Compute,
Microsoft.KeyVault, Microsoft.Storage, Microsoft.VirtualMachineImages,
```

```
Microsoft.Network, Microsoft.ManagedIdentity |
  Where-Object RegistrationState -ne Registered |
    Register-AzResourceProvider
```

Define variables

Because you'll be using some pieces of information repeatedly, create some variables to store that information:

Azure PowerShell

```
# Destination image resource group name
$imageResourceGroup = 'myWinImgBuilderRG'

# Azure region
$location = 'WestUS2'

# Name of the image to be created
$imageTemplateName = 'myWinImage'

# Distribution properties of the managed image upon completion
$runOutputName = 'myDistResults'
```

Create a variable for your Azure subscription ID. To confirm that the `subscriptionID` variable contains your subscription ID, you can run the second line in the following example:

Azure PowerShell

```
# Your Azure Subscription ID
$subscriptionID = (Get-AzContext).Subscription.Id
Write-Output $subscriptionID
```

Create a resource group

Create an Azure resource group by using the New-AzResourceGroup cmdlet. A resource group is a logical container in which Azure resources are deployed and managed as a group.

The following example creates a resource group that's based on the name in the `$imageResourceGroup` variable in the region that you've specified in the `$location` variable. This resource group is used to store the image configuration template artifact and the image.

Azure PowerShell

```
New-AzResourceGroup -Name $imageResourceGroup -Location $location
```

Create a user identity and set role permissions

Grant Azure image builder permissions to create images in the specified resource group by using the following example. Without this permission, the image build process won't finish successfully.

1. Create variables for the role definition and identity names. These values must be unique.

   Azure PowerShell

   ```
   [int]$timeInt = $(Get-Date -UFormat '%s')
   $imageRoleDefName = "Azure Image Builder Image Def $timeInt"
   $identityName = "myIdentity$timeInt"
   ```

2. Create a user identity.

   Azure PowerShell

   ```
   New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
   $identityName -Location $location
   ```

3. Store the identity resource and principal IDs in variables.

   Azure PowerShell

   ```
   $identityNameResourceId = (Get-AzUserAssignedIdentity -
   ResourceGroupName $imageResourceGroup -Name $identityName).Id
   $identityNamePrincipalId = (Get-AzUserAssignedIdentity -
   ResourceGroupName $imageResourceGroup -Name $identityName).PrincipalId
   ```

Assign permissions for the identity to distribute the images

1. Download the JSON configuration file, and then modify it based on the settings that are defined in this article.

   Azure PowerShell

```
$myRoleImageCreationUrl =
'https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json'
$myRoleImageCreationPath = "myRoleImageCreation.json"

Invoke-WebRequest -Uri $myRoleImageCreationUrl -OutFile
$myRoleImageCreationPath -UseBasicParsing

$Content = Get-Content -Path $myRoleImageCreationPath -Raw
$Content = $Content -replace '<subscriptionID>', $subscriptionID
$Content = $Content -replace '<rgName>', $imageResourceGroup
$Content = $Content -replace 'Azure Image Builder Service Image
Creation Role', $imageRoleDefName
$Content | Out-File -FilePath $myRoleImageCreationPath -Force
```

2. Create the role definition.

Azure PowerShell

```
New-AzRoleDefinition -InputFile $myRoleImageCreationPath
```

3. Grant the role definition to the VM Image Builder service principal.

Azure PowerShell

```
$RoleAssignParams = @{
  ObjectId = $identityNamePrincipalId
  RoleDefinitionName = $imageRoleDefName
  Scope =
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
}
New-AzRoleAssignment @RoleAssignParams
```

> **Note**
>
> If you receive the error "New-AzRoleDefinition: Role definition limit exceeded. No more role definitions can be created," see Troubleshoot Azure RBAC (role-based access control).

Create an Azure Compute Gallery

1. Create the gallery.

Azure PowerShell

```
$myGalleryName = 'myImageGallery'
$imageDefName = 'winSvrImages'

New-AzGallery -GalleryName $myGalleryName -ResourceGroupName
$imageResourceGroup -Location $location
```

2. Create a gallery definition.

Azure PowerShell

```
$GalleryParams = @{
  GalleryName = $myGalleryName
  ResourceGroupName = $imageResourceGroup
  Location = $location
  Name = $imageDefName
  OsState = 'generalized'
  OsType = 'Windows'
  Publisher = 'myCo'
  Offer = 'Windows'
  Sku = 'Win2019'
}
New-AzGalleryImageDefinition @GalleryParams
```

Create an image

1. Create a VM Image Builder source object. For valid parameter values, see Find Windows VM images in Azure Marketplace with Azure PowerShell.

Azure PowerShell

```
$SrcObjParams = @{
  PlatformImageSource = $true
  Publisher = 'MicrosoftWindowsServer'
  Offer = 'WindowsServer'
  Sku = '2019-Datacenter'
  Version = 'latest'
}
$srcPlatform = New-AzImageBuilderTemplateSourceObject @SrcObjParams
```

2. Create a VM Image Builder distributor object.

Azure PowerShell

```
$disObjParams = @{
  SharedImageDistributor = $true
  ArtifactTag = @{tag='dis-share'}
  GalleryImageId =
```

```
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup/prov
iders/Microsoft.Compute/galleries/$myGalleryName/images/$imageDefName"
  ReplicationRegion = $location
  RunOutputName = $runOutputName
  ExcludeFromLatest = $false
}
$disSharedImg = New-AzImageBuilderTemplateDistributorObject
@disObjParams
```

3. Create a VM Image Builder customization object.

Azure PowerShell

```
$ImgCustomParams01 = @{
  PowerShellCustomizer = $true
  Name = 'settingUpMgmtAgtPath'
  RunElevated = $false
  Inline = @("mkdir c:\\buildActions", "mkdir c:\\buildArtifacts",
"echo Azure-Image-Builder-Was-Here  >
c:\\buildActions\\buildActionsOutput.txt")
}
$Customizer01 = New-AzImageBuilderTemplateCustomizerObject
@ImgCustomParams01
```

4. Create a second VM Image Builder customization object.

Azure PowerShell

```
$ImgCustomParams02 = @{
  FileCustomizer = $true
  Name = 'downloadBuildArtifacts'
  Destination = 'c:\\buildArtifacts\\index.html'
  SourceUri =
'https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickq
uickstarts/exampleArtifacts/buildArtifacts/index.html'
}
$Customizer02 = New-AzImageBuilderTemplateCustomizerObject
@ImgCustomParams02
```

5. Create a VM Image Builder template.

Azure PowerShell

```
$ImgTemplateParams = @{
  ImageTemplateName = $imageTemplateName
  ResourceGroupName = $imageResourceGroup
  Source = $srcPlatform
  Distribute = $disSharedImg
  Customize = $Customizer01, $Customizer02
  Location = $location
```

```
  UserAssignedIdentityId = $identityNameResourceId
}
New-AzImageBuilderTemplate @ImgTemplateParams
```

When the template has been created, a message is returned, and a VM Image Builder configuration template is created in `$imageResourceGroup`.

To determine whether the template creation process was successful, use the following example:

Azure PowerShell

```
Get-AzImageBuilderTemplate -ImageTemplateName $imageTemplateName -
ResourceGroupName $imageResourceGroup |
  Select-Object -Property Name, LastRunStatusRunState, LastRunStatusMessage,
ProvisioningState
```

In the background, VM Image Builder also creates a staging resource group in your subscription. This resource group is used for the image build. It's in the format `IT_<DestinationResourceGroup>_<TemplateName>`.

> ⚠ **Warning**
>
> Don't delete the staging resource group directly. To cause the staging resource group to be deleted, delete the image template artifact.

If the service reports a failure when the image configuration template is submitted, do the following:

- See Troubleshoot Azure VM Image Builder failures.
- Before you retry submitting the template, delete it by following this example:

  Azure PowerShell

  ```
  Remove-AzImageBuilderTemplate -ImageTemplateName $imageTemplateName -
  ResourceGroupName $imageResourceGroup
  ```

Start the image build

Submit the image configuration to the VM Image Builder service by running the following command:

Azure PowerShell

```
Start-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name
$imageTemplateName
```

Wait for the image building process to finish, which could take up to an hour.

If you encounter errors, review Troubleshoot Azure VM Image Builder failures.

Create a VM

1. Store the VM login credentials in a variable. The password must be complex.

   Azure PowerShell

   ```
   $Cred = Get-Credential
   ```

2. Create the VM by using the image you created.

   Azure PowerShell

   ```
   $ArtifactId = (Get-AzImageBuilderTemplateRunOutput -ImageTemplateName
   $imageTemplateName -ResourceGroupName $imageResourceGroup).ArtifactId

   New-AzVM -ResourceGroupName $imageResourceGroup -Image $ArtifactId -
   Name myWinVM01 -Credential $Cred
   ```

Verify the customizations

1. Create a Remote Desktop connection to the VM by using the username and password that you set when you created the VM.

2. Inside the VM, open PowerShell and run `Get-Content`, as shown in the following example:

   Azure PowerShell

   ```
   Get-Content -Path C:\buildActions\buildActionsOutput.txt
   ```

   The output is based on the contents of the file that you created during the image customization process.

   Output

```
Azure-Image-Builder-Was-Here
```

3. From the same PowerShell session, verify that the second customization finished successfully by checking for the presence of `c:\buildArtifacts\index.html`, as shown in the following example:

Azure PowerShell

```
Get-ChildItem c:\buildArtifacts\
```

The result should be a directory listing showing that the file was downloaded during the image customization process.

Output

```
    Directory: C:\buildArtifacts

Mode                 LastWriteTime         Length Name
----                 -------------         ------ ----
-a---          29/01/2021    10:04            276 index.html
```

Clean up your resources

If you no longer need the resources that were created during this process, you can delete them by doing the following:

1. Delete the VM Image Builder template.

Azure PowerShell

```
Remove-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -
Name $imageTemplateName
```

2. Delete the image resource group.

> **⊗ Caution**
>
> The following example deletes the specified resource group and all the resources that it contains. If any resources outside the scope of this article exist in the resource group, they'll also be deleted.

```
```

Azure PowerShell

```
Remove-AzResourceGroup -Name $imageResourceGroup
```

Next steps

Create an Azure Virtual Desktop image by using VM Image Builder and PowerShell

Article • 08/22/2024

Applies to: ✔ Windows VMs

In this article, you learn how to create an Azure Virtual Desktop image with these customizations:

- FSLogix setup
- Azure Virtual Desktop optimization
- Microsoft Teams installation
- Windows Restart customizer
- Windows Update customizer

The article discusses how to automate the customizations by using Azure VM Image Builder. You can then distribute the image to an Azure Compute Gallery (formerly Shared Image Gallery), where you can replicate it to other regions, control the scale, and share the image within and beyond your organization.

To simplify deploying a VM Image Builder configuration, our example uses an Azure Resource Manager template with the VM Image Builder template nested within it. This approach gives you a few more benefits, such as variables and parameter inputs. You can also pass parameters from the command line.

This article is intended as a copy-and-paste exercise.

> **Note**
>
> You'll find the scripts for installing the apps on GitHub. They're for illustration and testing purposes only. Do not use them for production workloads.

Tips for building Windows images

- VM size: For Windows, use `Standard_D2_v2` or greater. The default size is `Standard_D1_v2`, which isn't suitable for Windows.

- This article uses PowerShell customizer scripts. Use the following settings, or the build will stop responding:

  ```JSON
    "runElevated": true,
    "runAsSystem": true,
  ```

  For example:

  ```JSON
    {
        "type": "PowerShell",
        "name": "installFSLogix",
        "runElevated": true,
        "runAsSystem": true,
        "scriptUri":
  "https://raw.githubusercontent.com/azure/azvmimagebuilder/main/solution
  s/14_Building_Images_WVD/0_installConfFsLogix.ps1"
  ```

- Comment your code: The VM Image Builder build log, *customization.log*, is verbose. If you comment your scripts by using 'write-host', they'll be sent to the logs, which should make troubleshooting easier.

  ```PowerShell
  write-host 'AIB Customization: Starting OS Optimizations script'
  ```

- Exit codes: VM Image Builder expects all scripts to return a `0` exit code. If you use a non-zero exit code, VM Image Builder fails the customization and stops the build. If you have complex scripts, add instrumentation and emit exit codes, which will be shown in the *customization.log* file.

  ```PowerShell
  Write-Host "Exit code: " $LASTEXITCODE
  ```

- Test: Test and retest your code on a standalone VM. Ensure that there are no user prompts, that you're using the correct privileges, and so on.

- Networking: `Set-NetAdapterAdvancedProperty` is set in the optimization script but fails the VM Image Builder build. Because it disconnects the network, it's commented out. We're investigating this issue.

Prerequisites

You must have the latest Azure PowerShell cmdlets installed. For more information, see Overview of Azure PowerShell.

PowerShell

```
# Check to ensure that you're registered for the providers and
RegistrationState is set to 'Registered'
Get-AzResourceProvider -ProviderNamespace Microsoft.VirtualMachineImages
Get-AzResourceProvider -ProviderNamespace Microsoft.Storage
Get-AzResourceProvider -ProviderNamespace Microsoft.Compute
Get-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
Get-AzResourceProvider -ProviderNamespace Microsoft.ContainerInstance

# If they don't show as 'Registered', run the following commented-out code

## Register-AzResourceProvider -ProviderNamespace
Microsoft.VirtualMachineImages
## Register-AzResourceProvider -ProviderNamespace Microsoft.Storage
## Register-AzResourceProvider -ProviderNamespace Microsoft.Compute
## Register-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
## Register-AzResourceProvider -ProviderNamespace
Microsoft.ContainerInstance
```

Set up the environment and variables

Azure PowerShell

```
# Step 1: Import module
Import-Module Az.Accounts

# Step 2: get existing context
$currentAzContext = Get-AzContext

# Destination image resource group
$imageResourceGroup="avdImageDemoRg"

# Location (see possible locations in the main docs)
$location="westus2"

# Your subscription. This command gets your current subscription
$subscriptionID=$currentAzContext.Subscription.Id

# Image template name
$imageTemplateName="avd10ImageTemplate01"

# Distribution properties object name (runOutput). Gives you the properties
of the managed image on completion
$runOutputName="sigOutput"
```

```
# Create resource group
New-AzResourceGroup -Name $imageResourceGroup -Location $location
```

Permissions, user identity, and role

1. Create a user identity.

   Azure PowerShell

   ```
   # setup role def names, these need to be unique
   $timeInt=$(get-date -UFormat "%s")
   $imageRoleDefName="Azure Image Builder Image Def"+$timeInt
   $identityName="aibIdentity"+$timeInt

   ## Add Azure PowerShell modules to support AzUserAssignedIdentity and
   Azure VM Image Builder
   'Az.ImageBuilder', 'Az.ManagedServiceIdentity' | ForEach-Object
   {Install-Module -Name $_ -AllowPrerelease}

   # Create the identity
   New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
   $identityName -Location $location

   $identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName
   $imageResourceGroup -Name $identityName).Id
   $identityNamePrincipalId=$(Get-AzUserAssignedIdentity -
   ResourceGroupName $imageResourceGroup -Name $identityName).PrincipalId
   ```

2. Assign permissions to the identity to distribute images. The following commands download and update the template with the previously specified parameters.

   Azure PowerShell

   ```
   $aibRoleImageCreationUrl="https://raw.githubusercontent.com/azure/azvmi
   magebuilder/main/solutions/12_Creating_AIB_Security_Roles/aibRoleImageC
   reation.json"
   $aibRoleImageCreationPath = "aibRoleImageCreation.json"

   # Download the config
   Invoke-WebRequest -Uri $aibRoleImageCreationUrl -OutFile
   $aibRoleImageCreationPath -UseBasicParsing

   ((Get-Content -path $aibRoleImageCreationPath -Raw) -replace
   '<subscriptionID>',$subscriptionID) | Set-Content -Path
   $aibRoleImageCreationPath
   ((Get-Content -path $aibRoleImageCreationPath -Raw) -replace
   '<rgName>', $imageResourceGroup) | Set-Content -Path
   $aibRoleImageCreationPath
   ```

```
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace 'Azure
Image Builder Service Image Creation Role', $imageRoleDefName) | Set-
Content -Path $aibRoleImageCreationPath

# Create a role definition
New-AzRoleDefinition -InputFile  ./aibRoleImageCreation.json

# Grant the role definition to the VM Image Builder service principal
New-AzRoleAssignment -ObjectId $identityNamePrincipalId -
RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
```

> ⓘ **Note**
>
> If you receive the error "New-AzRoleDefinition: Role definition limit exceeded. No more role definitions can be created," see Troubleshoot Azure RBAC (role-based access control).

Create an Azure Compute Gallery

If you don't already have an Azure Compute Gallery, you need to create one.

Azure PowerShell

```
$sigGalleryName= "myaibsig01"
$imageDefName ="win10avd"

# Create the gallery
New-AzGallery -GalleryName $sigGalleryName -ResourceGroupName
$imageResourceGroup  -Location $location

# Create the gallery definition
New-AzGalleryImageDefinition -GalleryName $sigGalleryName -ResourceGroupName
$imageResourceGroup -Location $location -Name $imageDefName -OsState
generalized -OsType Windows -Publisher 'myCo' -Offer 'Windows' -Sku '10avd'
```

Configure the VM Image Builder template

For this example, we've prepared a template that downloads and updates the VM Image Builder template with the parameters that were specified earlier. The template installs FSLogix, operating system optimizations, and Microsoft Teams, and it runs Windows Update at the end.

If you open the template, you can see in the source property the image that's being used. In this example, it uses a Windows 10 multi-session image.

Windows 10 images

You should be aware of two key types of images: multi-session and single-session.

Multi-session images are intended for pooled usage. Here's an example of the image details in Azure:

JSON

```
"publisher": "MicrosoftWindowsDesktop",
"offer": "Windows-10",
"sku": "20h2-avd",
"version": "latest"
```

Single-session images are intended for individual usage. Here's an example of the image details in Azure:

JSON

```
"publisher": "MicrosoftWindowsDesktop",
"offer": "Windows-10",
"sku": "19h2-ent",
"version": "latest"
```

You can also change which Windows 10 images are available:

Azure PowerShell

```
Get-AzVMImageSku -Location westus2 -PublisherName MicrosoftWindowsDesktop -
Offer windows-10
```

Download and configure the template

Now, download the template and configure it for your own use.

Azure PowerShell

```
$templateUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/main/
solutions/14_Building_Images_WVD/armTemplateWVD.json"
$templateFilePath = "armTemplateWVD.json"

Invoke-WebRequest -Uri $templateUrl -OutFile $templateFilePath -
```

```
UseBasicParsing

((Get-Content -path $templateFilePath -Raw) -replace
'<subscriptionID>',$subscriptionID) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace
'<rgName>',$imageResourceGroup) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<region>',$location) |
Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace
'<runOutputName>',$runOutputName) | Set-Content -Path $templateFilePath

((Get-Content -path $templateFilePath -Raw) -replace
'<imageDefName>',$imageDefName) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace
'<sharedImageGalName>',$sigGalleryName) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<region1>',$location)
| Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace
'<imgBuilderId>',$identityNameResourceId) | Set-Content -Path
$templateFilePath
```

Feel free to view the template. All the code is viewable.

Submit the template

Your template must be submitted to the service. Doing so downloads any dependent artifacts, such as scripts, and validates, checks permissions, and stores them in the staging resource group, which is prefixed with *IT_*.

Azure PowerShell

```
New-AzResourceGroupDeployment -ResourceGroupName $imageResourceGroup -
TemplateFile $templateFilePath -TemplateParameterObject @{"api-Version" =
"2020-02-14"; "imageTemplateName" = $imageTemplateName; "svclocation" =
$location}

# Optional - if you have any errors running the preceding command, run:
$getStatus=$(Get-AzImageBuilderTemplate -ResourceGroupName
$imageResourceGroup -Name $imageTemplateName)
$getStatus.ProvisioningErrorCode
$getStatus.ProvisioningErrorMessage
```

Build the image

Azure PowerShell

```
Start-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name
$imageTemplateName -NoWait
```

> **Note**
>
> The command doesn't wait for the VM Image Builder service to complete the image build, so you can query the status as shown here.

Azure PowerShell

```
$getStatus=$(Get-AzImageBuilderTemplate -ResourceGroupName
$imageResourceGroup -Name $imageTemplateName)

# Shows all the properties
$getStatus | Format-List -Property *

# Shows the status of the build
$getStatus.LastRunStatusRunState
$getStatus.LastRunStatusMessage
$getStatus.LastRunStatusRunSubState
```

Create a VM

Now that the image is built, you can build a VM from it. Use the examples from New-AzVM (Az PowerShell module.Compute).

Clean up your resources

If you no longer need the resources that were created during this process, you can delete them by doing the following:

> **Important**
>
> Delete the resource group template first. If you delete only the resource group, the staging resource group (*IT_*) that's used by VM Image Builder won't be cleaned up.

1. Remove the VM Image Builder template.

   Azure PowerShell

```
Remove-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -
Name vd10ImageTemplate
```

2. Delete the role assignment.

Azure PowerShell

```
Remove-AzRoleAssignment -ObjectId $identityNamePrincipalId -
RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"

## Remove the definitions
Remove-AzRoleDefinition -Name "$identityNamePrincipalId" -Force -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"

## Delete the identity
Remove-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -
Name $identityName -Force
```

3. Delete the resource group.

Azure PowerShell

```
Remove-AzResourceGroup $imageResourceGroup -Force
```

Isolated Image Builds for Azure VM Image Builder

Isolated Image Builds is a feature of Azure VM Image Builder (AIB). It transitions the core process of VM image customization/validation from shared platform infrastructure to dedicated Azure Container Instances (ACI) resources in your subscription, providing compute and network isolation.

Advantages of Isolated Image Builds

Isolated Image Builds enables defense-in-depth by limiting network access of your build VM to your subscription. Isolated Image Builds also provides more transparency by allowing you to inspect processing performed by AIB to customize and validate your VM image. Further, Isolated Image Builds simplifies viewing live build logs. Specifically:

1. **Compute Isolation:** Isolated Image Builds performs a major portion of image-building processing in ACI resources in your subscription instead of on AIB's shared platform resources. ACI provides hypervisor isolation for each container group to ensure containers run in isolation without sharing a kernel.

2. **Network Isolation:** Isolated Image Builds removes all direct network WinRM/SSH communication between your build VM and backend components of the AIB service.

    - If you're provisioning an AIB template without your own subnet for build VM, then a Public IP Address resource is no longer provisioned in your staging resource group at image build time.
    - If you're provisioning an AIB template with an existing subnet for build VM, then a Private Link-based communication channel is no longer set up between your build VM and AIB's backend platform resources. Instead, the communication channel is set up between the ACI and the build VM resources, both of which reside in the staging resource group in your subscription.
    - Starting with API version 2024-02-01, you can specify a second subnet for deploying the ACI in addition to the subnet for the build VM. If specified, AIB deploys the ACI on this subnet, and there is no need for AIB to set up the Private Link-based communication channel between the ACI and the build VM.

3. **Transparency:** AIB is built on HashiCorp Packer. Isolated Image Builds executes Packer in the ACI in your subscription, which allows you to inspect the ACI resource and its containers. Similarly, having the entire network communication pipeline in your subscription allows you to inspect all the network resources, their settings, and their allowances.

4. **Better viewing of live logs:** AIB writes customization logs to a storage account in the staging resource group in your subscription. Isolated Image Builds provides another way to follow the same logs directly in the Azure portal by navigating to AIB's container in the ACI resource.

> **Note**
>
> To access the live logs during the image build or the customization and validation log files after the build is complete, please refer to the troubleshooting guide.

For more information about networking topologies and connectivity behavior, see Azure VM Image Builder networking options.

Backward compatibility

Isolated Image Builds is a platform-level change and doesn't affect AIB's interfaces. So, your existing Image Template and Trigger resources continue to function and there's no change in the way you deploy new resources of these types. You need to create new templates or update existing templates if you want to use the network topology that allows you to bring your own ACI subnet.

Your image builds are automatically migrated to Isolated Image Builds and you need to take no action to opt in. Also, customization logs continue to be available in the storage account.

Depending on the network topology specified in the Image Template, you might observe a few new resources temporarily appear in the staging resource group (for example, ACI, Virtual Network, Network Security Group, and Private Endpoint), while some other resources no longer appear (for example, Public IP Address). As before, these temporary resources exist only during the build and AIB deletes them thereafter.

> **Important**
>
> Make sure your subscription is registered for `Microsoft.ContainerInstance provider`:
>
> - Azure CLI: `az provider register -n Microsoft.ContainerInstance`
> - PowerShell: `Register-AzResourceProvider -ProviderNamespace Microsoft.ContainerInstance`
>
> After successfully registering your subscription, make sure there are no Azure Policies in your subscription that deny deployment of ACI resources. Policies allowing only a restricted set of resource types not including ACI would cause Isolated Image Builds to fail.

Ensure that your subscription also has a sufficient quota of resources required for deployment of ACI resources.

> **Important**
>
> Depending on the network topology specified in the Image Template, AIB may need to deploy temporary networking-related resources in the staging resource group in your subscription. Ensure that no Azure Policies deny the deployment of such resources (Virtual Network with Subnets, Network Security Group, Private Endpoint) in the resource group.
>
> If you have Azure Policies applying DDoS protection plans to any newly created Virtual Network, either relax the Policy for the resource group or ensure that the Template Managed Identity has permissions to join the plan. Alternatively, you can use the network topology that does not require deployment of a new Virtual Network by AIB.

> **Important**
>
> Make sure you follow all best practices while using AIB.

> **Note**
>
> AIB is in the process of rolling this change out to all locations and customers. Some of these details (especially around deployment of new networking-related resources) might change as the process is fine-tuned based on service telemetry and feedback. For any errors, please refer to the troubleshooting guide.

Azure Policy Regulatory Compliance controls for Azure VM Image Builder

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Regulatory Compliance in Azure Policy provides initiative definitions, known as *built-ins*, for the compliance domains and security controls related to different compliance standards. Microsoft creates and manages these built-ins.

In this article, you can refer to a list of the compliance domains and security controls for Azure VM Image Builder. You can assign the built-ins for a security control individually, to help make your Azure resources compliant with the specific standard.

The title of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Policy Version** column to view the source on the Azure Policy GitHub repo.

> **Important**
>
> Each control is associated with one or more **Azure Policy** definitions. These policies might help you **assess compliance** with the control. However, there often isn't a one-to-one or complete match between a control and one or more policies. As such, **Compliant** in Azure Policy refers only to the policies themselves. This doesn't ensure that you're fully compliant with all requirements of a control. In addition, the compliance standard includes controls that aren't addressed by any Azure Policy definitions at this time. Therefore, compliance in Azure Policy is only a partial view of your overall compliance status. The associations between controls and Azure Policy Regulatory Compliance definitions for these compliance standards can change over time.

Use Azure VM Image Builder for Linux VMs to access an existing Azure virtual network

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to use Azure VM Image Builder to create a basic, customized Linux image that has access to existing resources on a virtual network. The build virtual machine (VM) you create is deployed to a new or existing virtual network that you specify in your subscription. When you use an existing Azure virtual network, VM Image Builder doesn't require public network connectivity.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Set variables and permissions

For this task, you use some pieces of information repeatedly. Create some variables to store that information.

Azure CLI

```
# set your environment variables here!!!!

# destination image resource group
imageResourceGroup=aibImageRG01

# location (see possible locations in main docs)
location=WestUS2

# your subscription
# get the current subID : 'az account show | grep id'
subscriptionID=$(az account show --query id --output tsv)

# name of the image to be created
imageName=aibCustomLinuxImg01

# image distribution metadata reference name
runOutputName=aibCustLinManImg01ro

# VNET properties (update to match your existing VNET, or leave as-is for
demo)
# VNET name
vnetName=myexistingvnet01
# subnet name
subnetName=subnet01
# VNET resource group name
# NOTE! The VNET must always be in the same region as the Azure Image
Builder service region.
vnetRgName=existingVnetRG
# Existing Subnet NSG Name or the demo will create it
nsgName=aibdemoNsg
```

Create the resource group.

Azure CLI

```
az group create -n $imageResourceGroup -l $location
```

Configure networking

If you don't have an existing virtual network, subnet, or network security group (NSG), use the following script to create one.

Azure CLI

```

# Create a resource group

az group create -n $vnetRgName -l $location
```

```
# Create VNET

az network vnet create \
    --resource-group $vnetRgName \
    --name $vnetName --address-prefix 10.0.0.0/16 \
    --subnet-name $subnetName --subnet-prefix 10.0.0.0/24

# Create base NSG to simulate an existing NSG

az network nsg create -g $vnetRgName -n $nsgName

az network vnet subnet update \
    --resource-group $vnetRgName \
    --vnet-name $vnetName \
    --name $subnetName \
    --network-security-group $nsgName

#  NOTE! The virtual network must always be in the same region as the Azure
Image Builder service region.
```

Add an NSG rule

This rule allows connectivity from the VM Image Builder load balancer to the proxy VM. Port 60001 is for Linux, and port 60000 is for Windows. The proxy VM connects to the build VM by using port 22 for Linux, or port 5986 for Windows.

Azure CLI

```
az network nsg rule create \
    --resource-group $vnetRgName \
    --nsg-name $nsgName \
    -n AzureImageBuilderNsgRule \
    --priority 400 \
    --source-address-prefixes AzureLoadBalancer \
    --destination-address-prefixes VirtualNetwork \
    --destination-port-ranges 60000-60001 --direction inbound \
    --access Allow --protocol Tcp \
    --description "Allow Image Builder Private Link Access to Proxy VM"
```

Disable private service policy on the subnet

Here's how:

Azure CLI

```
az network vnet subnet update \
  --name $subnetName \
```

```
  --resource-group $vnetRgName \
  --vnet-name $vnetName \
  --disable-private-link-service-network-policies true
```

For more information, see Azure VM Image Builder networking options.

Modify the example template and create role

After you configure networking, you can modify the example template and create a role. Here's how:

Bash

```
# download the example and configure it with your vars

curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickquickstarts/1a_Creating_a_Custom_Linux_Image_on_Existing_VNET/existingVNETLinux.json -o existingVNETLinux.json
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleNetworking.json -o
aibRoleNetworking.json
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o
aibRoleImageCreation.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" existingVNETLinux.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" existingVNETLinux.json
sed -i -e "s/<region>/$location/g" existingVNETLinux.json
sed -i -e "s/<imageName>/$imageName/g" existingVNETLinux.json
sed -i -e "s/<runOutputName>/$runOutputName/g" existingVNETLinux.json

sed -i -e "s/<vnetName>/$vnetName/g" existingVNETLinux.json
sed -i -e "s/<subnetName>/$subnetName/g" existingVNETLinux.json
sed -i -e "s/<vnetRgName>/$vnetRgName/g" existingVNETLinux.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleNetworking.json
sed -i -e "s/<vnetRgName>/$vnetRgName/g" aibRoleNetworking.json
```

Set permissions on the resource group

VM Image Builder uses the user identity provided to inject the image into Azure Compute Gallery. In this example, you create an Azure role definition that can distribute the image to the gallery. The role definition is then assigned to the user identity.

Azure CLI

```
# create user assigned identity for image builder
identityName=aibBuiUserId$(date +'%s')
az identity create -g $imageResourceGroup -n $identityName

# get identity id
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName -
-query clientId -o tsv)

# get the user identity URI, needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$imageResourceGro
up/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# update the template
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" existingVNETLinux.json

# make role name unique, to avoid clashes in the same Azure Active Directory
domain
imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')
netRoleDefName="Azure Image Builder Network Def"$(date +'%s')

# update the definitions
sed -i -e "s/Azure Image Builder Service Image Creation
Role/$imageRoleDefName/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Networking Role/$netRoleDefName/g"
aibRoleNetworking.json
```

Instead of granting VM Image Builder lower granularity and increased privilege, you can create two roles. One role gives the builder permissions to create an image, and the other allows it to connect the build VM and load balancer to your virtual network.

Azure CLI

```
# create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json
az role definition create --role-definition ./aibRoleNetworking.json

# grant role definition to the user assigned identity
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

az role assignment create \
    --assignee $imgBuilderCliId \
```

```
    --role "$netRoleDefName" \
    --scope /subscriptions/$subscriptionID/resourceGroups/$vnetRgName
```

For more information, see Configure Azure VM Image Builder permissions by using the Azure CLI or Configure Azure VM Image Builder permissions by using PowerShell.

Create the image

Submit the image configuration to VM Image Builder.

Azure CLI

```
az resource create \
    --resource-group $imageResourceGroup \
    --properties @existingVNETLinux.json \
    --is-full-object \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n existingVNETLinuxTemplate01

# Wait approximately 1-3 mins (validation, permissions etc.)
```

Start the image build.

Azure CLI

```
az resource invoke-action \
     --resource-group $imageResourceGroup \
     --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
     -n existingVNETLinuxTemplate01 \
     --action Run

# Wait approximately 15 mins
```

It can take a while to create the image and replicate it to both regions. Wait until this part is finished before moving on to creating a VM.

Create a VM

Create a VM from the image version that was created by VM Image Builder.

Azure CLI

```
az vm create \
  --resource-group $imageResourceGroup \
  --name aibImgVm0001 \
  --admin-username aibuser \
```

```
  --image $imageName \
  --location $location \
  --generate-ssh-keys
```

Use Secure Shell (SSH) to get into the VM.

Bash

```
ssh aibuser@<publicIpAddress>
```

You should see the image was customized with a *Message of the Day* as soon as your SSH connection is established!

Console

```
*******************************************************
**            This VM was built from the:            **
**      !! AZURE VM IMAGE BUILDER Custom Image !!     **
**         You have just been Customized :-)         **
*******************************************************
```

Clean up resources

If you want to recustomize the image version to create a new version of the same image, skip the next steps and go on to Use Azure VM Image Builder to create another image version.

The following deletes the image that was created, along with all of the other resource files. Make sure you are finished with this deployment before deleting the resources.

When you delete gallery resources, you need to delete all of the image versions before you can delete the image definition used to create them. To delete a gallery, you first need to have deleted all of the image definitions in the gallery.

Delete the VM Image Builder template:

Azure CLI

```
az resource delete \
    --resource-group $imageResourceGroup \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n existingVNETLinuxTemplate01
```

Delete permissions assignments, roles, and identity:

Azure CLI

```
az role assignment delete \
    --assignee $imgBuilderCliId \
    --role $imageRoleDefName \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

az role assignment delete \
    --assignee $imgBuilderCliId \
    --role $netRoleDefName \
    --scope /subscriptions/$subscriptionID/resourceGroups/$vnetRgName

az role definition delete --name "$imageRoleDefName"
az role definition delete --name "$netRoleDefName"

az identity delete --ids $imgBuilderId
```

Delete the resource group:

Azure CLI

```
az group delete -n $imageResourceGroup
```

If you created a virtual network for this quickstart, you can delete the virtual network if it's no longer being used.

Use Azure VM Image Builder to access an existing Azure virtual network

Article • 08/22/2024

Applies to: ✔ Windows VMs

This article shows you how to use Azure VM Image Builder to create a basic, customized Windows image that has access to existing resources on a virtual network. The build virtual machine (VM) you create is deployed to a new or existing virtual network that you specify in your subscription. When you use an existing Azure virtual network, VM Image Builder doesn't require public network connectivity.

Set variables and permissions

For this task, you use some pieces of information repeatedly. Create some variables to store that information.

PowerShell

```
# Step 1: Import module
Import-Module Az.Accounts

# Step 2: get existing context
$currentAzContext = Get-AzContext

# destination image resource group
$imageResourceGroup="aibImageRG"

# location (see possible locations in main docs)
$location="westus2"

## if you need to change your subscription: Get-AzSubscription / Select-
AzSubscription -SubscriptionName

# get subscription, this will get your current subscription
$subscriptionID=$currentAzContext.Subscription.Id

# name of the image to be created
$imageName="win2019image01"

# image distribution metadata reference name
$runOutputName="win2019ManImg02ro"

# image template name
$imageTemplateName="window2019VnetTemplate03"

# distribution properties object name (runOutput), i.e. this gives you the
```

```
properties of the managed image on completion
$runOutputName="winSvrSigR01"

# VNET properties (update to match your existing virtual network, or leave
as-is for demo)
# VNET name
$vnetName="myexistingvnet01"
# subnet name
$subnetName="subnet01"
# VNET resource group name
$vnetRgName="existingVnetRG"
# Existing Subnet NSG Name or the demo will create it
$nsgName="aibdemoNsg"
# NOTE! The virtual network must always be in the same region as the VM
Image Builder service region.
```

Create the resource group.

PowerShell

```
New-AzResourceGroup -Name $imageResourceGroup -Location $location
```

Configure networking

If you don't have an existing virtual network, subnet, or network security group (NSG), use the following script to create one.

PowerShell

```
New-AzResourceGroup -Name $vnetRgName -Location $location

## Create base NSG to simulate an existing NSG
New-AzNetworkSecurityGroup -Name $nsgName -ResourceGroupName $vnetRgName -
location $location

$nsg = Get-AzNetworkSecurityGroup -Name $nsgName -ResourceGroupName
$vnetRgName

$subnet = New-AzVirtualNetworkSubnetConfig -Name $subnetName -AddressPrefix
"10.0.1.0/24" -PrivateLinkServiceNetworkPoliciesFlag "Disabled" -
NetworkSecurityGroup $nsg

New-AzVirtualNetwork -Name $vnetName -ResourceGroupName $vnetRgName -
Location $location -AddressPrefix "10.0.0.0/16" -Subnet $subnet

## NOTE! The virtual network must always be in the same region as the VM
Image Builder service region.
```

Add an NSG rule

This rule allows connectivity from the VM Image Builder load balancer to the proxy VM. Port 60001 is for Linux, and port 60000 is for Windows. The proxy VM connects to the build VM by using port 22 for Linux, or port 5986 for Windows.

PowerShell

```
Get-AzNetworkSecurityGroup -Name $nsgName -ResourceGroupName $vnetRgName  |
Add-AzNetworkSecurityRuleConfig -Name AzureImageBuilderAccess -Description
"Allow Image Builder Private Link Access to Proxy VM" -Access Allow -
Protocol Tcp -Direction Inbound -Priority 400 -SourceAddressPrefix
AzureLoadBalancer -SourcePortRange * -DestinationAddressPrefix
VirtualNetwork -DestinationPortRange 60000-60001 | Set-
AzNetworkSecurityGroup
```

Disable private service policy on the subnet

Here's how:

PowerShell

```
$virtualNetwork= Get-AzVirtualNetwork -Name $vnetName -ResourceGroupName
$vnetRgName

($virtualNetwork | Select -ExpandProperty subnets | Where-Object  {$_.Name -
eq $subnetName} ).privateLinkServiceNetworkPolicies = "Disabled"

$virtualNetwork | Set-AzVirtualNetwork
```

For more information, see Azure VM Image Builder networking options.

Modify the example template and create role

After you configure networking, you can modify the example template and create a role. Here's how:

PowerShell

```
$templateUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/maste
r/quickquickstarts/1a_Creating_a_Custom_Win_Image_on_Existing_VNET/existingV
NETWindows.json"
$templateFilePath = "existingVNETWindows.json"

$aibRoleNetworkingUrl="https://raw.githubusercontent.com/azure/azvmimagebuil
der/master/solutions/12_Creating_AIB_Security_Roles/aibRoleNetworking.json"
```

```
$aibRoleNetworkingPath = "aibRoleNetworking.json"

$aibRoleImageCreationUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json"
$aibRoleImageCreationPath = "aibRoleImageCreation.json"

# download configs
Invoke-WebRequest -Uri $templateUrl -OutFile $templateFilePath -UseBasicParsing

Invoke-WebRequest -Uri $aibRoleNetworkingUrl -OutFile $aibRoleNetworkingPath -UseBasicParsing

Invoke-WebRequest -Uri $aibRoleImageCreationUrl -OutFile $aibRoleImageCreationPath -UseBasicParsing

# update AIB image config template
((Get-Content -path $templateFilePath -Raw) -replace '<subscriptionID>',$subscriptionID) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<rgName>',$imageResourceGroup) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<region>',$location) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<runOutputName>',$runOutputName) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<imageName>',$imageName) | Set-Content -Path $templateFilePath

((Get-Content -path $templateFilePath -Raw) -replace '<vnetName>',$vnetName) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<subnetName>',$subnetName) | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<vnetRgName>',$vnetRgName) | Set-Content -Path $templateFilePath
```

Create a user-assigned identity and set permissions

Next, you create a user-assigned identity and set permissions. Here's how:

PowerShell

```
# setup role def names, these need to be unique
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt
$networkRoleDefName="Azure Image Builder Network Def"+$timeInt
$idenityName="aibIdentity"+$timeInt

# create user identity
## Add AZ PS module to support AzUserAssignedIdentity
```

```powershell
Install-Module -Name Az.ManagedServiceIdentity

# create identity
New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$idenityName

$idenityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $idenityName).Id
$idenityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $idenityName).PrincipalId

# update template with identity
((Get-Content -path $templateFilePath -Raw) -replace
'<imgBuilderId>',$idenityNameResourceId) | Set-Content -Path
$templateFilePath

# update the role defintion names
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace 'Azure Image
Builder Service Image Creation Role',$imageRoleDefName) | Set-Content -Path
$aibRoleImageCreationPath
((Get-Content -path $aibRoleNetworkingPath -Raw) -replace 'Azure Image
Builder Service Networking Role',$networkRoleDefName) | Set-Content -Path
$aibRoleNetworkingPath

# update role definitions
((Get-Content -path $aibRoleNetworkingPath -Raw) -replace
'<subscriptionID>',$subscriptionID) | Set-Content -Path
$aibRoleNetworkingPath
((Get-Content -path $aibRoleNetworkingPath -Raw) -replace
'<vnetRgName>',$vnetRgName) | Set-Content -Path $aibRoleNetworkingPath

((Get-Content -path $aibRoleImageCreationPath -Raw) -replace
'<subscriptionID>',$subscriptionID) | Set-Content -Path
$aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<rgName>',
$imageResourceGroup) | Set-Content -Path $aibRoleImageCreationPath

# create role definitions from role configurations examples, this avoids
granting contributor to the SPN
New-AzRoleDefinition -InputFile  ./aibRoleImageCreation.json
New-AzRoleDefinition -InputFile  ./aibRoleNetworking.json

# grant role definition to image builder user identity
New-AzRoleAssignment -ObjectId $idenityNamePrincipalId -RoleDefinitionName
$imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
New-AzRoleAssignment -ObjectId $idenityNamePrincipalId -RoleDefinitionName
$networkRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$vnetRgName"
```

For more information, see Configure Azure VM Image Builder permissions by using the Azure CLI or Configure Azure VM Image Builder permissions by using PowerShell.

Create the image

Submit the image configuration to Azure VM Image Builder.

PowerShell

```
New-AzResourceGroupDeployment -ResourceGroupName $imageResourceGroup -
TemplateFile $templateFilePath -api-version "2020-02-14" -imageTemplateName
$imageTemplateName -svclocation $location
```

> **Note**
>
> This will take a minute, as validation is run in regards to security, dependenciec, etc.

Start the image build.

PowerShell

```
Invoke-AzResourceAction -ResourceName $imageTemplateName -ResourceGroupName
$imageResourceGroup -ResourceType
Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2020-02-14" -
Action Run -Force
```

Get build status and properties

First, you query the image template for current or last run status, and for image template settings.

powerShell

```
$managementEp = $currentAzureContext.Environment.ResourceManagerUrl

$urlBuildStatus = [System.String]::Format("
{0}subscriptions/{1}/resourceGroups/$imageResourceGroup/providers/Microsoft.
VirtualMachineImages/imageTemplates/{2}?api-version=2020-02-14",
$managementEp, $currentAzureContext.Subscription.Id,$imageTemplateName)

$buildStatusResult = Invoke-WebRequest -Method GET  -Uri $urlBuildStatus -
UseBasicParsing -Headers  @{"Authorization"= ("Bearer " + $accessToken)} -
ContentType application/json
$buildJsonStatus =$buildStatusResult.Content
$buildJsonStatus
```

The image build for this example takes approximately 50 minutes (including multiple reboots and Windows updates). When you query the status, look for `lastRunStatus`. The following code shows that the build is still running. If it had completed successfully, it would show `succeeded`.

text

```
  "lastRunStatus": {
   "startTime": "2019-08-21T00:39:40.61322415Z",
   "endTime": "0001-01-01T00:00:00Z",
   "runState": "Running",
   "runSubState": "Building",
   "message": ""
  },
```

Query the distribution properties

If you're distributing to a VHD location, need managed image location properties, or Azure Compute Gallery replications status, you need to query `runOutput`. Every time you have a distribution target, you will have a unique `runOutput`, to describe properties of the distribution type.

powerShell

```
$managementEp = $currentAzureContext.Environment.ResourceManagerUrl
$urlRunOutputStatus = [System.String]::Format("
{0}subscriptions/{1}/resourceGroups/$imageResourceGroup/providers/Microsoft.
VirtualMachineImages/imageTemplates/$imageTemplateName/runOutputs/{2}?api-
version=2020-02-14", $managementEp, $currentAzureContext.Subscription.Id,
$runOutputName)

$runOutStatusResult = Invoke-WebRequest -Method GET  -Uri
$urlRunOutputStatus -UseBasicParsing -Headers  @{"Authorization"= ("Bearer "
+ $accessToken)} -ContentType application/json
$runOutJsonStatus =$runOutStatusResult.Content
$runOutJsonStatus
```

Create a VM

Now that the build is finished, you can build a VM from the image. Use the examples from the PowerShell New-AzVM documentation.

Clean up tasks

You can now delete the image template artifact, the role assignment, and the resource groups if you want to.

Here's how to delete the image template artifact:

powerShell

```
# Get ResourceID of the Image Template
$resTemplateId = Get-AzResource -ResourceName $imageTemplateName -
ResourceGroupName $imageResourceGroup -ResourceType
Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2020-02-14"

### Delete Image Template Artifact
Remove-AzResource -ResourceId $resTemplateId.ResourceId -Force
```

Here's how to delete the role assignment:

powerShell

```
## remove role assignments
Remove-AzRoleAssignment -ObjectId $idenityNamePrincipalId  -
RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
Remove-AzRoleAssignment -ObjectId $idenityNamePrincipalId -
RoleDefinitionName $networkRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$vnetRgName"

## remove definitions
Remove-AzRoleDefinition -Id $imageRoleDefObjId -Force
Remove-AzRoleDefinition -Id $networkRoleObjId -Force

## delete identity
Remove-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$idenityName -Force
```

Here's how to delete resource groups:

powerShell

```
Remove-AzResourceGroup $imageResourceGroup -Force

# delete VNET created
# BEWARE! In this example, you have either used an existing virtual network
or created one for this example. Do not delete your existing virtual
network. If you want to delete the virtual network resource group used in
this example '$vnetRgName', modify the preceding code.
```

Azure VM Image Builder networking options

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure VM Image Builder (AIB) deploys an Azure Container Instance (ACI) in the staging resource group in your subscription. The ACI must be associated with a subnet in an Azure virtual network (VNet). The AIB service code running in the ACI deploys a build virtual machine (build VM) in the staging resource group to customize your image, and the build VM must be placed on a separate subnet. To customize and validate your image, the ACI must have network connectivity to the build VM. Based on your networking requirements and organizational policies, you can configure AIB to use different network topologies. You can choose to bring both subnets, one subnet, or none. For recommendations, see Best practices for Azure VM Image Builder.

Network topologies

Don't bring your own Build VM subnet or the ACI subnet

- You can select this topology by not specifying the `vnetConfig` field in the Image Template or by specifying the field but without `subnetId` and `containerInstanceSubnetId` subfields.
- If you don't specify any subnets, AIB deploys an Azure virtual network (VNet) in the staging resource group with two subnets: one for the Azure Container Instance and one for the build VM. Both subnets are associated with a network security group (NSG) that includes default rules, while still allowing direct line-of-sight connectivity required for customization. The build VM is also deployed with a network interface resource (and other resources not directly related to networking, like Managed Disk). After the build completes, the build VM and networking resources are deleted.

Bring your own Build VM subnet and bring your own ACI subnet

- You can select this topology by specifying the `vnetConfig` field with the `subnetId` and `containerInstanceSubnetId` subfields in the image template. This option, including the `containerInstanceSubnetId` subfield, is available starting with API version 2024-02-01. You can also update existing templates to use this topology.
- In this topology, AIB deploys the build VM to the specified build VM subnet and the ACI to the specified ACI subnet. Because the subnets are already provided, AIB does not deploy a virtual network, subnets, or a network security group. This topology is useful

when quota restrictions or policies prevent deployment of these resources. The build VM can access resources that are reachable from your virtual network, and you can also create a siloed virtual network that is not connected to any other virtual network. The ACI subnet must satisfy the prerequisites for isolated image builds. For details about these fields, see the template reference.

- This topology is the recommended option for most scenarios because it gives you full control over both subnets, simplifies setup and network configuration, can reduce overall deployment costs, and helps align networking with your organization's security and governance requirements.

Bring your own build VM subnet but not your own ACI subnet

- You can select this topology by specifying the `vnetConfig` field with the `subnetId` subfield while omitting the `containerInstanceSubnetId` subfield in the image template.
- In this topology, AIB deploys a temporary virtual network in the staging resource group with two subnets, each associated with a network security group (NSG). One subnet hosts the ACI, and the other hosts the private endpoint resource. The build VM is deployed in your specified subnet. To enable communication between the ACI subnet and your build VM subnet, AIB also deploys a Private Link-based communication path in the staging resource group that includes a private endpoint, Private Link Service, Azure Load Balancer, network interfaces, and a proxy virtual machine. The exact resources and configurations vary slightly depending on whether you are customizing a Windows image or a Linux image.
- This topology is generally not recommended for most scenarios because it can increase deployment costs, require more setup and operational configuration, and introduce additional components that can make the end-to-end pipeline more sensitive to failures.

For examples of this topology, see the following articles:

- Use Azure VM Image Builder for Windows VMs allowing access to an existing Azure virtual network
- Use Azure VM Image Builder for Linux VMs allowing access to an existing Azure virtual network

What is Azure Private Link?

Azure Private Link provides private connectivity from a virtual network to Azure platform as a service (PaaS), or to customer-owned or Microsoft partner services. It simplifies network architecture and secures connectivity between Azure endpoints by eliminating data exposure to the public internet. Private Link requires an IP address from the specified virtual network and subnet. Azure currently does not support network policies on these IP addresses, so you must

disable network policies on the subnet. For more information, see the Private Link documentation.

Why deploy a proxy VM?

When a VM without a public IP is behind an internal load balancer, it does not have internet access. The load balancer used for the virtual network is internal. The proxy VM allows internet access for the build VM during builds, and AIB uses the proxy VM to send commands between the service and the build VM. You can use the associated network security groups to restrict build VM access. Traffic from the ACI goes across the private link to the load balancer. The load balancer communicates with the proxy VM on port 60001 for Linux, or port 60000 for Windows. The proxy forwards commands to the build VM on port 22 for Linux, or port 5986 for Windows. By default, the deployed proxy VM size is *Standard A1_v2*, but you can change the size. For details, see the template reference.

Checklist for using your virtual network

1. Allow Azure Load Balancer to communicate with the proxy VM in a network security group.
    - Azure CLI example
    - PowerShell example
2. Disable the private service policy on the subnet.
    - Azure CLI example
    - PowerShell example
3. Allow VM Image Builder to create a load balancer, and add VMs to the virtual network.
    - Azure CLI example
    - PowerShell example
4. Allow VM Image Builder to read and write source images, and create images.
    - Azure CLI example
    - PowerShell example
5. Ensure that you're using a virtual network in the same region as the VM Image Builder service region.

Additional considerations

Required permissions for an existing virtual network

VM Image Builder requires specific permissions to use an existing virtual network. For more information, see Configure Azure VM Image Builder permissions by using the Azure CLI or Configure Azure VM Image Builder permissions by using PowerShell.

> **Note**
>
> The virtual network must be in the same region as the VM Image Builder service region.

> **Important**
>
> The Azure VM Image Builder service modifies the WinRM connection configuration on all Windows builds to use HTTPS on port 5986 instead of the default HTTP port on 5985. This configuration change can impact workflows that rely on WinRM communication.

Connectivity model

AIB does not deploy a public IP for direct connectivity, and the AIB service component that runs in the platform subscription does not have network connectivity to the ACI or the build VM. Only the AIB component that runs in the ACI has connectivity to the build VM to perform customization.

Supported subnet combinations

You can configure both subnets (`subnetId` and `containerInstanceSubnetId`) or only the build VM subnet (`subnetId`). A configuration that specifies only the ACI subnet (`containerInstanceSubnetId`) is not supported.

Configure Azure VM Image Builder permissions by using the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When you register for Azure VM Image Builder, your subscription gets access to a VM Image Builder service principal name (SPN). This registration also authorizes the service permission to create, manage, and delete a staging resource group. For the image building process, the Contributor role assignment is also required at the staging resource group.

If you want VM Image Builder to distribute images, you need to create a user-assigned identity in Azure, with permissions to read and write images. For example, you might want to distribute images to managed images or to Azure Compute Gallery. If you're accessing Azure storage, then the user-assigned identity you create needs permissions to read private or public containers.

You must set up permissions and privileges prior to building an image. The following sections detail how to configure possible scenarios by using the Azure CLI.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Create a user-assigned managed identity

VM Image Builder requires you to create an Azure user-assigned managed identity. VM Image Builder uses this identity to read images, write images, and access Azure storage accounts. You grant the identity permission to do specific actions in your subscription.

> **Note**
>
> User-assigned managed identity is the correct way to grant permissions to the image resource groups. The SPN is deprecated for this purpose.

The following example shows you how to create an Azure user-assigned managed identity. Replace the placeholder settings to set your variables.

Expand table

Setting	Description
<Resource group>	The resource group where you want to create the user-assigned managed identity.

Azure CLI

```
identityName="aibIdentity"
imageResourceGroup=<Resource group>

az identity create \
    --resource-group $imageResourceGroup \
    --name $identityName
```

For more information, see Azure user-assigned managed identity.

Allow VM Image Builder to distribute images

For VM Image Builder to distribute images, the service must be allowed to inject the images into resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is built. VM Image Builder doesn't have permission to access resources in other resource groups in the subscription. You need to take explicit actions to allow access, to prevent your builds from failing.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to distribute images. However, the user-assigned managed identity

needs the following Azure `Actions` permissions in the distribution resource group:

```
Actions

Microsoft.Compute/images/write
Microsoft.Compute/images/read
Microsoft.Compute/images/delete
```

If you want to distribute to Azure Compute Gallery, you also need:

```
Actions

Microsoft.Compute/galleries/read
Microsoft.Compute/galleries/images/read
Microsoft.Compute/galleries/images/versions/read
Microsoft.Compute/galleries/images/versions/write
```

Permission to customize existing images

For VM Image Builder to build images from source custom images, the service must be allowed to read the images into these resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is located.

Here's how you build from an existing custom image:

```
Actions

Microsoft.Compute/images/read
```

Here's how you build from an existing Azure Compute Gallery version:

```
Actions

Microsoft.Compute/galleries/read
Microsoft.Compute/galleries/images/read
Microsoft.Compute/galleries/images/versions/read
```

Permission to customize images on your virtual networks

VM Image Builder has the capability to deploy and use an existing virtual network in your subscription, thus allowing customizations access to connected resources.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to deploy a VM to an existing virtual network. However, the user-assigned managed identity needs the following Azure `Actions` permissions on the virtual network resource group:

Actions

```
Microsoft.Network/virtualNetworks/read
Microsoft.Network/virtualNetworks/subnets/join/action
```

Create an Azure role definition

The following examples create an Azure role definition from the actions described in the previous sections. The examples are applied at the resource group level. Evaluate and test if the examples are granular enough for your requirements.

The image actions allow read and write. Decide what is appropriate for your environment. For example, create a role to allow VM Image Builder to read images from resource group *example-rg-1*, and write images to resource group *example-rg-2*.

Custom image Azure role example

The following example creates an Azure role to use and distribute a source custom image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

Expand table

Setting	Description
<Subscription ID>	Your Azure subscription ID.
<Resource group>	Resource group for the custom image.

Azure CLI

```
# Subscription ID - You can get this using `az account show | grep id` or
from the Azure portal.
subscriptionID=$(az account show --query id --output tsv)
# Resource group - image builder will only support creating custom images in
the same Resource Group as the source managed image.
imageResourceGroup=<Resource group>
identityName="aibIdentity"

# Use *cURL* to download the a sample JSON description
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12
_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o
aibRoleImageCreation.json

# Create a unique role name to avoid clashes in the same Azure Active
Directory domain
imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# Update the JSON definition using stream editor
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation
Role/$imageRoleDefName/g" aibRoleImageCreation.json

# Create a custom role from the sample aibRoleImageCreation.json description
file.
az role definition create --role-definition ./aibRoleImageCreation.json

# Get the user-assigned managed identity id
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName -
-query clientId -o tsv)

# Grant the custom role to the user-assigned managed identity for Azure
Image Builder.
az role assignment create \
    --assignee $imgBuilderCliId \
    --role $imageRoleDefName \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup
```

Existing virtual network Azure role example

The following example creates an Azure role to use and distribute an existing virtual network image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

Expand table

Setting	Description
<Subscription ID>	Your Azure subscription ID.
<Resource group>	The virtual network resource group

Azure CLI

```
# Subscription ID - You can get this using `az account show | grep id` or
from the Azure portal.
subscriptionID=$(az account show --query id --output tsv)
VnetResourceGroup=<Resource group>
identityName="aibIdentity"

# Use *cURL* to download the a sample JSON description
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12
_Creating_AIB_Security_Roles/aibRoleNetworking.json -o
aibRoleNetworking.json

# Create a unique role name to avoid clashes in the same domain
netRoleDefName="Azure Image Builder Network Def"$(date +'%s')

# Update the JSON definition using stream editor
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleNetworking.json
sed -i -e "s/<vnetRgName>/$VnetResourceGroup/g" aibRoleNetworking.json
sed -i -e "s/Azure Image Builder Service Networking Role/$netRoleDefName/g"
aibRoleNetworking.json

# Create a custom role from the aibRoleNetworking.json description file.
az role definition create --role-definition ./aibRoleNetworking.json

# Get the user-assigned managed identity id
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName -
-query clientId -o tsv)

# Grant the custom role to the user-assigned managed identity for Azure
Image Builder.
az role assignment create \
    --assignee $imgBuilderCliId \
    --role $netRoleDefName \
    --scope /subscriptions/$subscriptionID/resourceGroups/$VnetResourceGroup
```

Using managed identity for Azure Storage access

If you want to authenticate with Azure Storage and use private containers, VM Image Builder needs a user-assigned managed identity. VM Image Builder uses the identity to authenticate with Azure Storage.

> **Note**
>
> VM Image Builder only uses the identity at the time that you submit the image template. The build VM doesn't have access to the identity during image build.

Use the Azure CLI to create the user-assigned managed identity:

Azure CLI

```
az role assignment create \
    --assignee <Image Builder client ID> \
    --role "Storage Blob Data Reader" \
    --scope /subscriptions/<Subscription ID>/resourceGroups/<Resource
group>/providers/Microsoft.Storage/storageAccounts/$scriptStorageAcc/blobSer
vices/default/containers/<Storage account container>
```

In the VM Image Builder template, provide the user-assigned managed identity:

JSON

```
    "type": "Microsoft.VirtualMachineImages/imageTemplates",
    "apiVersion": "2020-02-14",
    "location": "<Region>",
    ..
    "identity": {
    "type": "UserAssigned",
          "userAssignedIdentities": {
            "<Image Builder ID>": {}
        }
```

Replace the following placeholder settings:

Expand table

Setting	Description
<Region>	Template region
<Resource group>	Resource group
<Storage account container>	Storage account container name
<Subscription ID>	Azure subscription

For more information, see Create an image and use a user-assigned managed identity to access files in Azure Storage. You learn how to create and configure the user-assigned managed identity to access a storage account.

Configure Azure VM Image Builder permissions by using PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When you register for Azure VM Image Builder, this grants the service permission to create, manage, and delete a staging resource group. The service also has rights to add resources to a resource group, required for the image build. During a successful registration, your subscription gets access to a VM Image Builder service principal name (SPN).

If you want VM Image Builder to distribute images, you need to create a user-assigned identity in Azure, with permissions to read and write images. For example, you might want to distribute images to managed images or to Azure Compute Gallery. If you're accessing Azure Storage, then the user-assigned identity you create needs permissions to read private or public containers.

You must set up permissions and privileges prior to building an image. The following sections detail how to configure possible scenarios by using PowerShell.

Create a user-assigned managed identity

VM Image Builder requires you to create an Azure user-assigned managed identity. VM Image Builder uses this identity to read images, write images, and access Azure Storage accounts. You grant the identity permission to do specific actions in your subscription.

> **Note**
>
> User-assigned managed identity is the correct way to grant permissions to the image resource groups. The SPN is deprecated for this purpose.

The following example shows you how to create an Azure user-assigned managed identity. Replace the placeholder settings to set your variables.

Expand table

Setting	Description
<Resource group>	The resource group where you want to create the user-assigned managed identity.

PowerShell

```
## Add AZ PS module to support AzUserAssignedIdentity
Install-Module -Name Az.ManagedServiceIdentity

$parameters = @{
    Name = 'aibIdentity'
    ResourceGroupName = '<Resource group>'
}
# create identity
New-AzUserAssignedIdentity @parameters
```

For more information, see Azure user-assigned managed identity.

Allow VM Image Builder to distribute images

For VM Image Builder to distribute images, the service must be allowed to inject the images into resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is built. VM Image Builder doesn't have permission to access resources in other resource groups in the subscription. You need to take explicit actions to allow access, to prevent your builds from failing.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to distribute images. However, the user-assigned managed identity needs the following Azure `Actions` permissions in the distribution resource group:

Actions

```
Microsoft.Compute/images/write
Microsoft.Compute/images/read
Microsoft.Compute/images/delete
```

If you want to distribute to Azure Compute Gallery, you also need:

Actions

```
Microsoft.Compute/galleries/read
Microsoft.Compute/galleries/images/read
```

```
Microsoft.Compute/galleries/images/versions/read
Microsoft.Compute/galleries/images/versions/write
```

Permission to customize existing images

For VM Image Builder to build images from source custom images, the service must be allowed to read the images into these resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is located.

Here's how you build from an existing custom image:

Actions

```
Microsoft.Compute/images/read
```

Here's how you build from an existing Azure Compute Gallery version:

Actions

```
Microsoft.Compute/galleries/read
Microsoft.Compute/galleries/images/read
Microsoft.Compute/galleries/images/versions/read
```

Permission to customize images on your virtual networks

VM Image Builder has the capability to deploy and use an existing virtual network in your subscription, thus allowing customizations access to connected resources.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to deploy a VM to an existing virtual network. However, the user-assigned managed identity needs the following Azure `Actions` permissions on the virtual network resource group:

Actions

```
Microsoft.Network/virtualNetworks/read
Microsoft.Network/virtualNetworks/subnets/join/action
```

Create an Azure role definition

The following examples create an Azure role definition from the actions described in the previous sections. The examples are applied at the resource group level. Evaluate and test if the examples are granular enough for your requirements.

The image actions allow read and write. Decide what is appropriate for your environment. For example, create a role to allow VM Image Builder to read images from resource group *example-rg-1*, and write images to resource group *example-rg-2*.

Custom image Azure role example

The following example creates an Azure role to use and distribute a source custom image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

Expand table

Setting	Description
<Subscription ID>	Your Azure subscription ID.
<Resource group>	Resource group for the custom image.

PowerShell

```
$sub_id = "<Subscription ID>"
# Resource group - image builder will only support creating custom images in
the same Resource Group as the source managed image.
$imageResourceGroup = "<Resource group>"
$identityName = "aibIdentity"

# Use a web request to download the sample JSON description
$sample_uri="https://raw.githubusercontent.com/azure/azvmimagebuilder/master
/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json"
$role_definition="aibRoleImageCreation.json"

Invoke-WebRequest -Uri $sample_uri -Outfile $role_definition -
UseBasicParsing

# Create a unique role name to avoid clashes in the same Azure Active
Directory domain
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt
```

```
# Update the JSON definition placeholders with variable values
((Get-Content -path $role_definition -Raw) -replace
'<subscriptionID>',$sub_id) | Set-Content -Path $role_definition
((Get-Content -path $role_definition -Raw) -replace '<rgName>',
$imageResourceGroup) | Set-Content -Path $role_definition
((Get-Content -path $role_definition -Raw) -replace 'Azure Image Builder
Service Image Creation Role', $imageRoleDefName) | Set-Content -Path
$role_definition

# Create a custom role from the aibRoleImageCreation.json description file.
New-AzRoleDefinition -InputFile $role_definition

# Get the user-identity properties
$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $identityName).PrincipalId

# Grant the custom role to the user-assigned managed identity for Azure
Image Builder.
$parameters = @{
    ObjectId = $identityNamePrincipalId
    RoleDefinitionName = $imageRoleDefName
    Scope = '/subscriptions/' + $sub_id + '/resourceGroups/' +
$imageResourceGroup
}

New-AzRoleAssignment @parameters
```

Existing virtual network Azure role example

The following example creates an Azure role to use and distribute an existing virtual network image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

Expand table

Setting	Description
<Subscription ID>	Your Azure subscription ID.
<Resource group>	The virtual network resource group.

PowerShell

```
$sub_id = "<Subscription ID>"
$res_group = "<Resource group>"
$identityName = "aibIdentity"

# Use a web request to download the sample JSON description
$sample_uri="https://raw.githubusercontent.com/azure/azvmimagebuilder/master
/solutions/12_Creating_AIB_Security_Roles/aibRoleNetworking.json"
$role_definition="aibRoleNetworking.json"

Invoke-WebRequest -Uri $sample_uri -Outfile $role_definition -
UseBasicParsing

# Create a unique role name to avoid clashes in the same AAD domain
$timeInt=$(get-date -UFormat "%s")
$networkRoleDefName="Azure Image Builder Network Def"+$timeInt

# Update the JSON definition placeholders with variable values
((Get-Content -path $role_definition -Raw) -replace
'<subscriptionID>',$sub_id) | Set-Content -Path $role_definition
((Get-Content -path $role_definition -Raw) -replace '<vnetRgName>',
$res_group) | Set-Content -Path $role_definition
((Get-Content -path $role_definition -Raw) -replace 'Azure Image Builder
Service Networking Role',$networkRoleDefName) | Set-Content -Path
$role_definition

# Create a custom role from the aibRoleNetworking.json description file
New-AzRoleDefinition -InputFile $role_definition

# Get the user-identity properties
$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $identityName).PrincipalId

# Assign the custom role to the user-assigned managed identity for Azure
Image Builder
$parameters = @{
    ObjectId = $identityNamePrincipalId
    RoleDefinitionName = $networkRoleDefName
    Scope = '/subscriptions/' + $sub_id + '/resourceGroups/' + $res_group
}

New-AzRoleAssignment @parameters
```

Azure VM Image Builder service DevOps task (preview)

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

In this article, you learn how to use an Azure DevOps task to inject build artifacts into a virtual machine (VM) image, so that you can install and configure your application and operating system.

> **Important**
>
> Azure DevOps task for VM Image Builder is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

DevOps task versions

At this time, there are two Azure VM Image Builder DevOps tasks:

- *Stable* VM Image Builder task: The latest stable build that's been tested, and reports no General Data Protection Regulation (GDPR) issues.
- *Unstable* VM Image Builder task: We offer a so-called *unstable* task so that you can test the latest updates and features before we release the task code as *stable*. After about a week, if there are no customer-reported or telemetry issues, we promote the task code to *stable*.

Prerequisites

> **Note**
>
> The VM Image Builder task doesn't currently support Windows Restart or running elevated commands as Administrator. That is, the task isn't suitable for Azure Virtual Desktop scenarios or Windows customizations that require those features. To use DevOps with VM Image Builder, nest the template within an Azure Resource Manager task, and use Azure CLI or PowerShell tasks.

Before you begin, you must:

- Install *Stable* DevOps task from Visual Studio Marketplace.
- Have an Azure DevOps Services (formerly Visual Studio Team Services, or VSTS) account, and a Build Pipeline created.
- Register and enable the VM Image Builder feature requirements in the subscription that's used by the pipelines:
  - Azure PowerShell
  - The Azure CLI
- Create a standard Azure storage account in the source image resource group. You can use other resource groups or storage accounts. The storage account is used transfer the build artifacts from the DevOps task to the image.

Azure PowerShell

```
# Azure PowerShell
$timeInt=$(get-date -UFormat "%s")
$storageAccName="aibstorage"+$timeInt
$location=westus
# Create a storage account and blob in the resource group
New-AzStorageAccount -ResourceGroupName $strResourceGroup -Name
$storageAccName -Location $location -SkuName Standard_LRS
```

Azure CLI

```
# The Azure CLI
location=westus
scriptStorageAcc=aibstordot$(date +'%s')
# Create a storage account and blob in the resource group
az storage account create -n $scriptStorageAcc -g $strResourceGroup -l
$location --sku Standard_LRS
```

Add a task to the release pipeline

1. Select **Release Pipeline** > **Edit**.
2. On the User Agent, select the plus sign (+) to add and search for **Image Builder**.
3. Select **Add**.

In the following sections, set the task properties.

Azure subscription

In the dropdown list, select the subscription that you want VM Image Builder to run. Use the subscription where your source images are stored and the images are to be distributed. You need to grant the VM Image Builder contributor access to the subscription or resource group.

Resource group

Use the resource group where the temporary image template artifact will be stored. When you create a template artifact, another temporary VM Image Builder resource group, `IT_<DestinationResourceGroup>_<TemplateName>_guid`, is created. The temporary resource group stores the image metadata, such as scripts. At the end of the task, the image template artifact and temporary VM Image Builder resource group is deleted.

Location

The location is the region where VM Image Builder will run. Only a set number of regions are supported. The source images must be present in this location. For example, if you're using Azure Compute Gallery (formerly Shared Image Gallery), a replica must exist in that region.

Managed identity (required)

VM Image Builder requires a managed identity, which it uses to read source custom images, connect to Azure Storage, and create custom images. For more information, see Learn about VM Image Builder.

Virtual network support

You can configure the created VM to be in a specific virtual network. When you configure the task, provide the resource ID of a pre-existing subnet in the **VNet Configuration (Optional)** input field. Omit the resource ID if no specific virtual network needs to be used. For more information, see Azure VM Image Builder service networking options.

Source

The source images must be of the supported VM Image Builder operating systems. You can choose existing custom images in the same region that VM Image Builder is running

from:

- Managed Image: Pass in the resource ID. For example:

  ```
  JSON

  /subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/images/<imageName>
  ```

- Compute Gallery: Pass in the resource ID of the image version. For example:

  ```
  JSON

  /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/<versionNumber>
  ```

  If you need to get the latest Compute Gallery version, use an Azure PowerShell or Azure CLI task to get it and set a DevOps variable. Use the variable in the VM Image Builder DevOps task. For more information, see the examples in Get the latest image version resource ID.

- (Marketplace) Base image: Use the dropdown list of popular images, which always uses the latest version of the supported operating systems.

  If the base image isn't in the list, you can specify the exact image by using `Publisher:Offer:Sku`.

  (Optional) Base image version: You can supply the version of the image that you want to use. The default version is `latest`.

Customize

The following sections discuss various ways to customize tasks.

Provisioner

Initially, two customizers are supported, Shell and PowerShell. Only inline is supported. If you want to download scripts, you can pass inline commands to do so.

For your operating system, select PowerShell or Shell.

The Windows Update task

For Windows only, the task runs Windows Update at the end of the customizations. It also handles the required reboots.

The task runs the following Windows Update configuration:

JSON

```
    "type": "WindowsUpdate",
    "searchCriteria": "IsInstalled=0",
    "filters": [
        "exclude:$_.Title -like '*Preview*'",
        "include:$true"
```

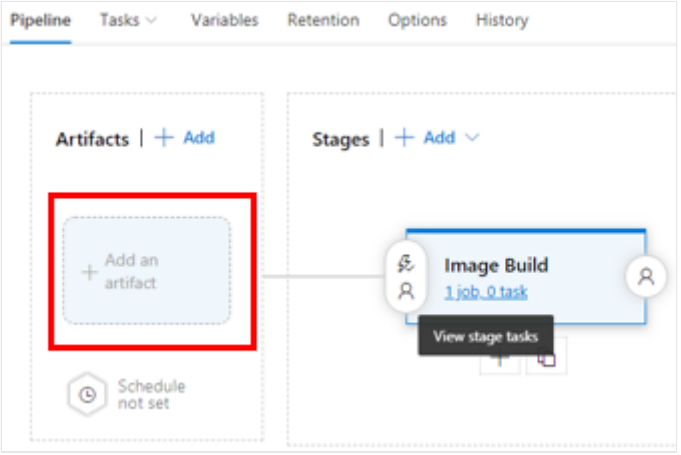
The task installs important and recommended Windows Updates that aren't *preview* versions.

Handling reboots

The DevOps task doesn't currently support rebooting Windows builds. If you try to reboot with PowerShell code, the build fails. However, you can use code to reboot Linux builds.

Build path

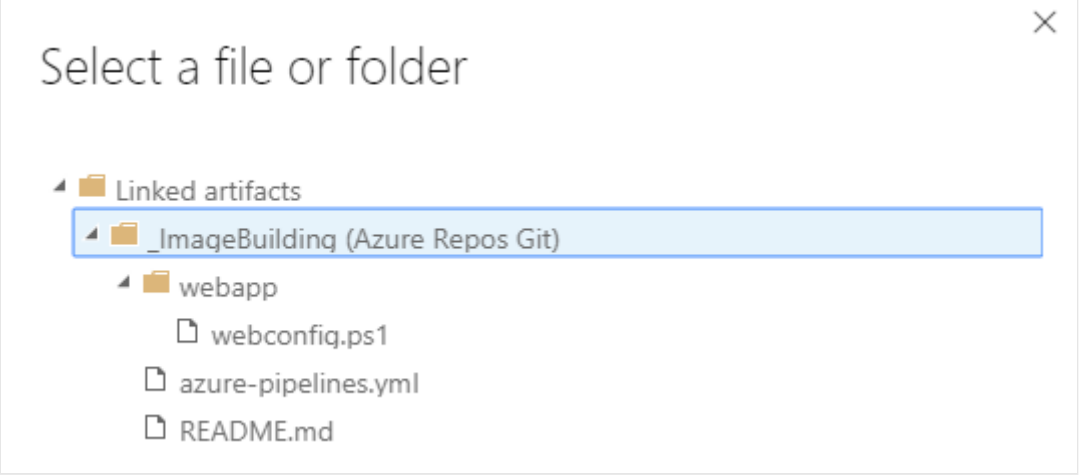
The task is designed to be able to inject DevOps Build release artifacts into the image. To make this work, you need to set up a build pipeline. In the release pipeline setup, add the repo of the build artifacts.



Select the **Build Path** button to choose the build folder that you want to be placed on the image. The VM Image Builder task copies all the files and directories within it. When the image is being created, VM Image Builder deploys the files and directories into different paths, depending on the operating system.

> **Important**
>
> When you're adding a repo artifact, you might find that the directory name is prefixed with an underscore character (_). The underscore can cause issues with the inline commands. Be sure to use the appropriate quotation marks in the commands.

The following example explains how this works:



- For Windows: Files exist in the *C:* drive. A directory named *buildArtifacts* is created, which includes the *webapp* directory.
- For Linux: Files exist in the `/tmp` directory. The `webapp` directory is created, which includes all the files and directories. Because this is a temporary directory, you must move the files out of it. Otherwise, they'll be deleted.

Inline customization script

- For Windows: You can enter PowerShell inline commands, separated by commas. If you want to run a script in your build directory, you can use:

  Azure PowerShell

  ```
  & 'c:\buildArtifacts\webapp\webconfig.ps1'
  ```

  You can reference multiple scripts or add more commands. For example:

  Azure PowerShell

  ```
  & 'c:\buildArtifacts\webapp\webconfig.ps1'
  & 'c:\buildArtifacts\webapp\installAgent.ps1'
  ```

- For Linux: The build artifacts are put into the */tmp* directory. However, on many Linux operating systems, on a reboot, the */tmp* directory contents are deleted. If you want the artifacts to exist in the image, you must create another directory and copy them over. For example:

  Bash

  ```
  sudo mkdir /lib/buildArtifacts
  sudo cp -r "/tmp/_ImageBuilding/webapp" /lib/buildArtifacts/.
  ```

  If you're OK with using the */tmp* directory, you can run the script by using the following code:

  Bash

  ```
  # Grant execute permissions to run scripts
  sudo chmod +x "/tmp/_ImageBuilding/webapp/coreConfig.sh"
  echo "running script"
  sudo . "/tmp/AppsAndImageBuilderLinux/_WebApp/coreConfig.sh"
  ```

What happens to the build artifacts after the image build?

> ⓘ **Note**
>
> VM Image Builder doesn't automatically remove the build artifacts. We strongly suggest that you always use code to remove the build artifacts.

- For Windows: VM Image Builder deploys files to the *C:\buildArtifacts* directory. Because the directory is persisted, you must remove it by running a script. For example:

  Azure PowerShell

  ```
  # Clean up buildArtifacts directory
  Remove-Item -Path "C:\buildArtifacts\*" -Force -Recurse

  # Delete the buildArtifacts directory
  Remove-Item -Path "C:\buildArtifacts" -Force
  ```

- For Linux: The build artifacts are put into the */tmp* directory. However, on many Linux operating systems, the */tmp* directory contents are deleted on reboot. We suggest that you use code to remove the contents and not rely on the operating system to remove the contents. For example:

Bash

```
sudo rm -R "/tmp/AppsAndImageBuilderLinux"
```

Total length of image build

Total length can't be changed in the DevOps pipeline task yet. It uses the default of 240 minutes. If you want to increase the buildTimeoutInMinutes, you can use an Azure CLI task in the release pipeline. Configure the task to copy a template and submit it. For an example solution, see Use environment variables and parameters with VM Image Builder, or use Azure PowerShell.

Storage account

Select the storage account you created in the prerequisites. If you don't see it in the list, VM Image Builder doesn't have permissions to it.

When the build starts, VM Image Builder creates a container called *imagebuilder-vststask*, where the build artifacts from the repo are stored.

> **Note**
>
> You need to manually delete the storage account or container after each build.

Distribute

The following three distribute types are supported.

Managed image

- Resource ID:

  Azure CLI

  ```
  /subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/images/<imageName>
  ```

- Locations

Azure Compute Gallery

The Compute Gallery must already exist.

- Resource ID:

  Azure CLI

  ```
  /subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageDefName>
  ```

- Regions: A list of regions, comma separated. For example, `westus`, `eastus`, `centralus`.

Virtual hard disk

You can't pass any values to this. VM Image Builder emits the virtual hard disk VHD to the temporary VM Image Builder resource group, `IT_<DestinationResourceGroup>_<TemplateName>`, in the *vhds* container. When you start the release build, VM Image Builder emits logs. When VM Image Builder has finished, it emits the VHD URL.

Optional settings

You can override the VM size setting from its default size of *Standard_D1_v2*. You might want to do so to reduce total customization time. Or you might want to create images that depend on certain VM sizes, such as GPU (graphics processing unit), HPC (high-performance computing), and so on.

How the task works

When you create the release, the task creates a container in the storage account, named *imagebuilder-vststask*. It zips (compresses) and uploads your build artifacts and creates a shared access signature token for the zip file.

The task uses the properties that are passed to the task to create the VM Image Builder template artifact. The task does the following:

- Downloads the build artifact zip file and any other associated scripts. The files are saved in a storage account in the temporary VM Image Builder resource group `IT_<DestinationResourceGroup>_<TemplateName>`.

- Creates a template that's prefixed with *t_* and a 10-digit monotonic integer. The template is saved to the resource group that you selected, and it exists for the

duration of the build in the resource group.

Example output:

Output

```
start reading task parameters...
found build at:  /home/vsts/work/r1/a/_ImageBuilding/webapp
end reading parameters
getting storage account details for aibstordot1556933914
created archive /home/vsts/work/_temp/temp_web_package_21475337782320203.zip
Source for image:  { type: 'SharedImageVersion',
  imageVersionId:
'/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft
.Compute/galleries/<galleryName>/images/<imageDefName>/versions/<imgVersionN
umber>' }
template name:  t_1556938436xxx
starting put template...
```

When the image build starts, the run status is reported in the release logs:

Output

```
starting run template...
```

When the image build finishes, the output is similar to following text:

Output

```
2019-05-06T12:49:52.0558229Z starting run template...
2019-05-06T13:36:33.8863094Z run template:  Succeeded
2019-05-06T13:36:33.8867768Z getting runOutput for  SharedImage_distribute
2019-05-06T13:36:34.6652541Z
================================================================================
==
2019-05-06T13:36:34.6652925Z ## task output variables ##
2019-05-06T13:36:34.6658728Z $(imageUri) =
/subscriptions/<subscriptionID>/resourceGroups/aibwinsig/providers/Microsoft

2019-05-06T13:36:34.6663500Z deleting template t_1557146959485...
2019-05-06T13:36:34.6673713Z deleting storage blob imagebuilder-
vststask\webapp/18-1/webapp_1557146958741.zip
2019-05-06T13:36:34.9786039Z blob imagebuilder-vststask\webapp/18-
1/webapp_1557146958741.zip is deleted
2019-05-06T13:38:37.4884068Z delete template:  Succeeded
```

The image template and `IT_<DestinationResourceGroup>_<TemplateName>` are deleted.

You can take the `$(imageUri)` Azure DevOps Services (formerly Visual Studio Team Services, or VSTS) variable and use it in the next task or just use the value and build a VM.

Output DevOps variables

Here is the publisher, offer, SKU, and version of the source marketplace image:

- `$(pirPublisher)`
- `$(pirOffer)`
- `$(pirSku)`
- `$(pirVersion)`

Here's the image URI, which is the resource ID of the distributed image:

- `$(imageUri)`

FAQ

Can I use an existing image template that I've already created, outside of DevOps?

Not at this time.

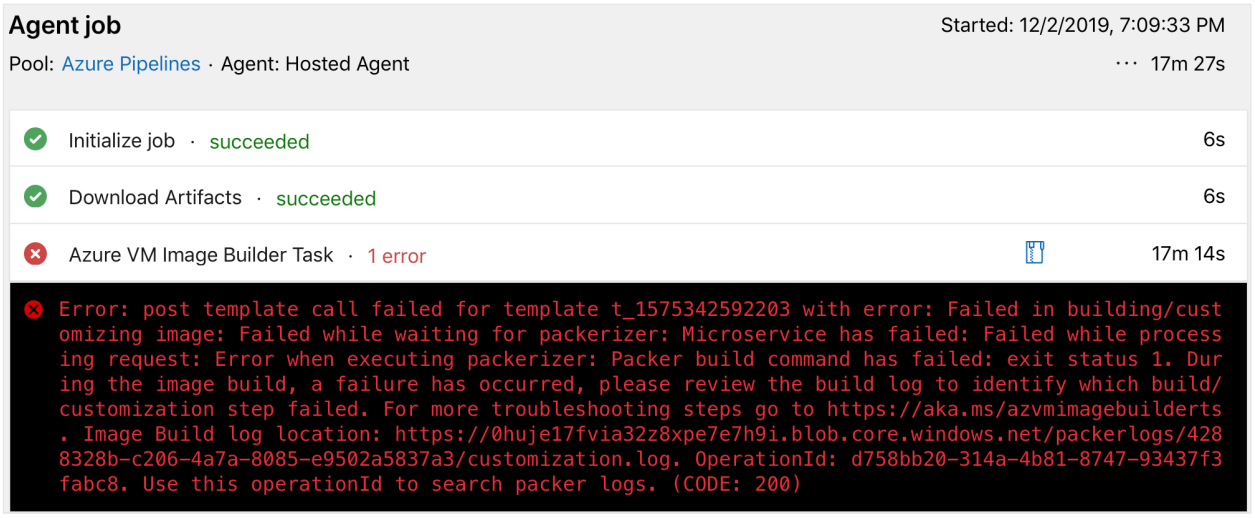
Can I specify the image template name?

No. A unique template name is used and then deleted.

The VM Image Builder task failed. How can I troubleshoot the issue?

If there's a build failure, the DevOps task doesn't delete the staging resource group. You can access the staging resource group that contains the build customization log.

You'll see an error in the DevOps log for the VM Image Builder task, and the message will contain the *customization.log* location. For example:



For more information, see Troubleshoot the VM Image Builder service.

After you've investigated the failure, you can delete the staging resource group. First, delete the VM Image Builder template resource artifact. The artifact is prefixed with *t_*, and you can find it in the DevOps task build log:

```
text

...
Source for image:  { type: 'SharedImageVersion',
  imageVersionId:
'/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft
.Compute/galleries/<galleryName>/images/<imageDefName>/versions/<imgVersionN
umber>' }
...
template name:  t_1556938436xxx
...
```

The VM Image Builder template resource artifact is in the resource group that was specified initially in the task. When you're done troubleshooting, delete the artifact. If you're deleting it by using the Azure portal, within the resource group, select **Show Hidden Types** to view the artifact.

Next steps

For more information, see VM Image Builder overview.

Create an Azure Image Builder Bicep or ARM template JSON template

Article • 10/03/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

Azure Image Builder uses a Bicep file or an ARM template JSON template file to pass information into the Image Builder service. In this article we go over the sections of the files, so you can build your own. For latest API versions, see template reference. To see examples of full .json files, see the Azure Image Builder GitHub.

The basic format is:

JSON

JSON

```
{
  "type": "Microsoft.VirtualMachineImages/imageTemplates",
  "location": "<region>",
  "tags": {
    "<name>": "<value>",
    "<name>": "<value>"
  },
  "identity": {},
  "properties": {
    "buildTimeoutInMinutes": <minutes>,
    "customize": [],
    "errorHandling":[],
    "distribute": [],
    "optimize": [],
    "source": {},
    "stagingResourceGroup": "/subscriptions/<subscriptionID>/resourceGroups/<stagingResourceGroupName>",
    "validate": {},
    "vmProfile": {
      "vmSize": "<vmSize>",
      "osDiskSizeGB": <sizeInGB>,
      "vnetConfig": {
        "subnetId":
"/subscriptions/<subscriptionID>/resourceGroups/<vnetRgName>/providers/Microsoft.Network/virtualNetworks/<vnetName>/subnets/<subnetName1>",
        "containerInstanceSubnetId":
"/subscriptions/<subscriptionID>/resourceGroups/<vnetRgName>/providers/Microsoft.Network/virtualNetworks/<vnetName>/subnets/<subnetName2>",
        "proxyVmSize": "<vmSize>"
      },
      "userAssignedIdentities": [

"/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<identityName1>",

"/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<identityName2>",

"/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<identityName3>",
        ...
      ]
    }
  }
}
```

API version

The API version will change over time as the API changes. See What's new in Azure VM Image Builder for all major API changes and feature updates for the Azure VM Image Builder service.

Type

The `type` is the resource type, which must be `Microsoft.VirtualMachineImages/imageTemplates`.

JSON

```JSON
"type": "Microsoft.VirtualMachineImages/imageTemplates",
```

Location

The location is the region where the custom image is created. The following regions are supported:

- East US
- East US 2
- West Central US
- West US
- West US 2
- West US 3
- South Central US
- North Europe
- West Europe
- South East Asia
- Australia Southeast
- Australia East
- UK South
- UK West
- Brazil South
- Canada Central
- Central India
- Central US
- France Central
- Germany West Central
- Japan East
- North Central US
- Norway East
- Switzerland North
- Jio India West
- UAE North
- East Asia
- Korea Central
- South Africa North
- Qatar Central
- USGov Arizona (Public Preview)
- USGov Virginia (Public Preview)
- China North 3 (Public Preview)
- Sweden Central
- Poland Central
- Italy North
- Israel Central

Important

Register the feature `Microsoft.VirtualMachineImages/FairfaxPublicPreview` to access the Azure Image Builder public preview in Azure Government regions (USGov Arizona and USGov Virginia).

Important

Register the feature `Microsoft.VirtualMachineImages/MooncakePublicPreview` to access the Azure Image Builder public preview in the China North 3 region.

To access the Azure VM Image Builder public preview in the Azure Government regions (USGov Arizona and USGov Virginia), you must register the *Microsoft.VirtualMachineImages/FairfaxPublicPreview* feature. To do so, run the following command in either PowerShell or Azure CLI:

Azure PowerShell

Azure PowerShell

```
Register-AzProviderPreviewFeature -ProviderNamespace Microsoft.VirtualMachineImages -Name FairfaxPublicPreview
```

To access the Azure VM Image Builder public preview in the China North 3 region, you must register the *Microsoft.VirtualMachineImages/MooncakePublicPreview* feature. To do so, run the following command in either PowerShell or Azure CLI:

Azure PowerShell

Azure PowerShell

```
Register-AzProviderPreviewFeature -ProviderNamespace Microsoft.VirtualMachineImages -Name MooncakePublicPreview
```

JSON

JSON

```
"location": "<region>"
```

Data residency

The Azure VM Image Builder service doesn't store or process customer data outside regions that have strict single region data residency requirements when a customer requests a build in that region. If a service outage for regions that have data residency requirements, you need to create Bicep files/templates in a different region and geography.

Zone redundancy

Distribution supports zone redundancy, VHDs are distributed to a Zone Redundant Storage (ZRS) account by default and the Azure Compute Gallery (formerly known as Shared Image Gallery) version will support a ZRS storage type if specified.

Tags

Tags are key/value pairs you can specify for the image that's generated.

Identity

There are two ways to add user assigned identities explained below.

User-assigned identity for Azure Image Builder image template resource

Required - For Image Builder to have permissions to read/write images, and read in scripts from Azure Storage, you must create an Azure user-assigned identity that has permissions to the individual resources. For details on how Image Builder permissions work, and relevant steps, see Create an image and use a user-assigned managed identity to access files in an Azure storage account.

JSON

JSON

```
"identity": {
    "type": "UserAssigned",
    "userAssignedIdentities": {
        "<imgBuilderId>": {}
    }
}
```

The Image Builder service User Assigned Identity:

- Supports a single identity only.
- Doesn't support custom domain names.

To learn more, see What is managed identities for Azure resources?. For more information on deploying this feature, see Configure managed identities for Azure resources on an Azure VM using Azure CLI.

User-assigned identity for the Image Builder Build VM

This property is only available in API versions `2021-10-01` or newer.

Optional - The Image Builder Build VM that is created by the Image Builder service in your subscription is used to build and customize the image. For the Image Builder Build VM to have permissions to authenticate with other services like Azure Key Vault in your subscription, you must create one or more Azure User Assigned Identities that have permissions to the individual resources. Azure Image Builder can then associate these User Assigned Identities with the Build VM. Customizer scripts running inside the Build VM can then fetch tokens for these identities and interact with other Azure resources as needed. Be aware, the user assigned identity for Azure Image Builder must have the "Managed Identity Operator" role assignment on all the user assigned identities for Azure Image Builder to be able to associate them to the build VM.

> **Note**
>
> Be aware that multiple identities can be specified for the Image Builder Build VM, including the identity you created for the image template resource. By default, the identity you created for the image template resource won't automatically be added to the build VM.

JSON

JSON

```
"properties": {
  "vmProfile": {
    "userAssignedIdentities": [

"/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<identityName>"
    ]
  }
}
```

The Image Builder Build VM User Assigned Identity:

- Supports a list of one or more user assigned managed identities to be configured on the VM.
- Supports cross subscription scenarios (identity created in one subscription while the image template is created in another subscription under the same tenant).
- Doesn't support cross tenant scenarios (identity created in one tenant while the image template is created in another tenant).

To learn more, see:

- How to use managed identities for Azure resources on an Azure VM to acquire an access token
- How to use managed identities for Azure resources on an Azure VM for sign-in

Properties: buildTimeoutInMinutes

Maximum duration to wait while building the image template (includes all customizations, validations, and distributions).

If you don't specify the property or set the value to 0, the default value is used, which is 240 minutes or four hours. The minimum value is 6 minutes, and the maximum value is 960 minutes or 16 hours. When the timeout value is hit (whether or not the image build is complete), you see an error similar to:

```text
[ERROR] Failed while waiting for packerizer: Timeout waiting for microservice to
[ERROR] complete: 'context deadline exceeded'
```

For Windows, we don't recommend setting `buildTimeoutInMinutes` below 60 minutes. If you find you're hitting the timeout, review the logs to see if the customization step is waiting on something like user input. If you find you need more time for customizations to complete, increase the `buildTimeoutInMinutes` value. But, don't set it too high because you might have to wait for it to time out before seeing an error.

Properties: customize

Image Builder supports multiple "customizers", which are functions used to customize your image, such as running scripts, or rebooting servers.

When using `customize`:

- You can use multiple customizers.
- Customizers execute in the order specified in the template.
- If one customizer fails, then the whole customization component will fail and report back an error.
- Test the scripts thoroughly before using them in a template. Debugging the scripts by themselves is easier.
- Don't put sensitive data in the scripts. Inline commands can be viewed in the image template definition. If you have sensitive information (including passwords, SAS token, authentication tokens, etc.), it should be moved into scripts in Azure Storage, where access requires authentication.
- The script locations need to be publicly accessible, unless you're using MSI.

The `customize` section is an array. The supported customizer types are: File, PowerShell, Shell, WindowsRestart, and WindowsUpdate.

JSON

```json
"customize": [
  {
    "type": "File",
    "destination": "string",
    "sha256Checksum": "string",
    "sourceUri": "string"
  },
  {
    "type": "PowerShell",
    "inline": [ "string" ],
    "runAsSystem": "bool",
    "runElevated": "bool",
    "scriptUri": "string",
    "sha256Checksum": "string",
    "validExitCodes": [ "int" ]
  },
  {
    "type": "Shell",
    "inline": [ "string" ],
    "scriptUri": "string",
    "sha256Checksum": "string"
  },
  {
    "type": "WindowsRestart",
    "restartCheckCommand": "string",
    "restartCommand": "string",
    "restartTimeout": "string"
  },
  {
    "type": "WindowsUpdate",
    "filters": [ "string" ],
    "searchCriteria": "string",
    "updateLimit": "int"
```

```
  }
]
```

Shell customizer

The `Shell` customizer supports running shell scripts on Linux. The shell scripts must be publicly accessible or you must have configured an MSI for Image Builder to access them.

JSON

```
JSON
```

```
"customize": [
  {
    "type": "Shell",
    "name": "<name>",
    "scriptUri": "<link to script>",
    "sha256Checksum": "<sha256 checksum>"
  }
],
"customize": [
  {
    "type": "Shell",
    "name": "<name>",
    "inline": "<commands to run>"
  }
]
```

Customize properties:

- **type** – Shell.
- **name** - name for tracking the customization.
- **scriptUri** - URI to the location of the file.
- **inline** - array of shell commands, separated by commas.
- **sha256Checksum** - Value of sha256 checksum of the file, you generate this value locally, and then Image Builder will checksum and validate.

  To generate the sha256Checksum, using a terminal on Mac/Linux run: `sha256sum <fileName>`

> ⓘ **Note**
>
> Inline commands are stored as part of the image template definition, you can see these when you dump out the image definition. If you have sensitive commands or values (including passwords, SAS token, authentication tokens etc), it's recommended these are moved into scripts, and use a user identity to authenticate to Azure Storage.

Super user privileges

Prefix the commands with `sudo` to run them with super user privileges. You can add the commands into scripts or use it inline commands, for example:

JSON

```
JSON
```

```
"type": "Shell",
"name": "setupBuildPath",
"inline": [
    "sudo mkdir /buildArtifacts",
    "sudo cp /tmp/index.html /buildArtifacts/index.html"
]
```

Example of a script using sudo that you can reference using scriptUri:

```bash
#!/bin/bash -e

echo "Telemetry: creating files"
mkdir /myfiles

echo "Telemetry: running sudo 'as-is' in a script"
sudo touch /myfiles/somethingElevated.txt
```

Windows restart customizer

The `WindowsRestart` customizer allows you to restart a Windows VM and wait for the VM come back online, this customizer allows you to install software that requires a reboot.

JSON

```json
"customize": [
  {
    "type": "WindowsRestart",
    "restartCommand": "shutdown /r /f /t 0",
    "restartCheckCommand": "echo Azure-Image-Builder-Restarted-the-VM  >
c:\\buildArtifacts\\azureImageBuilderRestart.txt",
    "restartTimeout": "5m"
  }
]
```

Customize properties:

- **Type**: WindowsRestart.
- **restartCommand** - Command to execute the restart (optional). The default is `'shutdown /r /f /t 0 /c \"packer restart\"'`.
- **restartCheckCommand** – Command to check if restart succeeded (optional).
- **restartTimeout** - Restart time out specified as a string of magnitude and unit. For example, `5m` (5 minutes) or `2h` (2 hours). The default is: `5m`.

> **Note**
>
> There is no Linux restart customizer.

PowerShell customizer

The `PowerShell` customizer supports running PowerShell scripts and inline command on Windows, the scripts must be publicly accessible for the IB to access them.

JSON

```json
"customize": [
  {
    "type": "PowerShell",
    "name":   "<name>",
    "scriptUri": "<path to script>",
    "runElevated": <true false>,
    "runAsSystem": <true false>,
    "sha256Checksum": "<sha256 checksum>"
  },
  {
    "type": "PowerShell",
    "name": "<name>",
    "inline": "<PowerShell syntax to run>",
    "validExitCodes": [<exit code>],
    "runElevated": <true or false>,
```

```
    "runAsSystem": <true or false>
  }
]
```

Customize properties:

- **type** – PowerShell.
- **scriptUri** - URI to the location of the PowerShell script file.
- **inline** – Inline commands to be run, separated by commas.
- **validExitCodes** – Optional, valid codes that can be returned from the script/inline command. The property avoids reported failure of the script/inline command.
- **runElevated** – Optional, boolean, support for running commands and scripts with elevated permissions.
- **runAsSystem** - Optional, boolean, determines whether the PowerShell script should be run as the System user.
- **sha256Checksum** - generate the SHA256 checksum of the file locally, update the checksum value to lowercase, and Image Builder will validate the checksum during the deployment of the image template.

  To generate the sha256Checksum, use the Get-FileHash cmdlet in PowerShell.

File customizer

The `File` customizer lets Image Builder download a file from a GitHub repo or Azure storage. The customizer supports both Linux and Windows. If you have an image build pipeline that relies on build artifacts, you can set the file customizer to download from the build share, and move the artifacts into the image.

JSON

JSON

```
"customize": [
  {
    "type": "File",
    "name": "<name>",
    "sourceUri": "<source location>",
    "destination": "<destination>",
    "sha256Checksum": "<sha256 checksum>"
  }
]
```

File customizer properties:

- **sourceUri** - an accessible storage endpoint, this endpoint can be GitHub or Azure storage. You can only download one file, not an entire directory. If you need to download a directory, use a compressed file, then uncompress it using the Shell or PowerShell customizers.

  > ⓘ Note
  >
  > If the sourceUri is an Azure Storage Account, irrespective if the blob is marked public, you'll need to grant the Managed User Identity permissions to read access on the blob. See this **example** to set the storage permissions.

- **destination** – the full destination path and file name. Any referenced path and subdirectories must exist, use the Shell or PowerShell customizers to set up these paths up beforehand. You can use the script customizers to create the path.

This customizer is supported by Windows directories and Linux paths, but there are some differences:

- Linux – the only path Image builder can write to is /tmp.
- Windows – No path restriction, but the path must exist.

If there's an error trying to download the file, or put it in a specified directory, then customize step fails, and this error will be in the customization.log.

> **Note**
>
> The file customizer is only suitable for small file downloads, < 20MB. For larger file downloads, use a script or inline command, then use code to download files, such as, Linux `wget` or `curl`, Windows, `Invoke-WebRequest`. For files that are in Azure storage, ensure that you assign an identity with permissions to view that file to the build VM by following the documentation here: User Assigned Identity for the Image Builder Build VM. Any file that is not stored in Azure must be publicly accessible for Azure Image Builder to be able to download it.

- **sha256Checksum** - generate the SHA256 checksum of the file locally, update the checksum value to lowercase, and Image Builder will validate the checksum during the deployment of the image template.

  To generate the sha256Checksum, use the Get-FileHash cmdlet in PowerShell.

Windows update customizer

The `WindowsUpdate` customizer is built on the community Windows Update Provisioner for Packer, which is an open source project maintained by the Packer community. Microsoft tests and validate the provisioner with the Image Builder service, and will support investigating issues with it, and work to resolve issues, however the open source project isn't officially supported by Microsoft. For detailed documentation on and help with the Windows Update Provisioner, see the project repository.

JSON

```
JSON
"customize": [
  {
    "type": "WindowsUpdate",
    "searchCriteria": "IsInstalled=0",
    "filters": [
      "exclude:$_.Title -like '*Preview*'",
      "include:$true"
    ],
    "updateLimit": 20
  }
]
```

Customizer properties:

- **type** – WindowsUpdate.
- **searchCriteria** - Optional, defines which type of updates are installed (like Recommended or Important), BrowseOnly=0 and IsInstalled=0 (Recommended) is the default.
- **filters** – Optional, allows you to specify a filter to include or exclude updates.
- **updateLimit** – Optional, defines how many updates can be installed, default 1000.

> **Note**
>
> The Windows Update customizer can fail if there are any outstanding Windows restarts, or application installations still running, typically you may see this error in the customization.log, `System.Runtime.InteropServices.COMException (0x80240016): Exception from HRESULT: 0x80240016`. We strongly advise you consider adding in a Windows Restart, and/or allowing applications enough time to complete their installations using sleep or wait commands in the inline commands or scripts before running Windows Update.

Generalize

By default, Azure Image Builder will also run `deprovision` code at the end of each image customization phase, to generalize the image. Generalizing is a process where the image is set up so it can be reused to create multiple VMs. For Windows VMs, Azure Image Builder uses Sysprep. For Linux, Azure Image Builder runs `waagent -deprovision`.

The commands Image Builder users to generalize may not be suitable for every situation, so Azure Image Builder allows you to customize this command, if needed.

If you're migrating existing customization, and you're using different Sysprep/waagent commands, you can use the Image Builder generic commands, and if the VM creation fails, use your own Sysprep or waagent commands.

If Azure Image Builder creates a Windows custom image successfully, and you create a VM from it, then find that the VM creation fails or doesn't complete successfully, you need to review the Windows Server Sysprep documentation or raise a support request with the Windows Server Sysprep Customer Services Support team, who can troubleshoot and advise on the correct Sysprep usage.

Default Sysprep command

Azure PowerShell

```
Write-Output '>>> Waiting for GA Service (RdAgent) to start ...'
while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }
Write-Output '>>> Waiting for GA Service (WindowsAzureTelemetryService) to start ...'
while ((Get-Service WindowsAzureTelemetryService) -and ((Get-Service WindowsAzureTelemetryService).Status -ne 'Running'))
{ Start-Sleep -s 5 }
Write-Output '>>> Waiting for GA Service (WindowsAzureGuestAgent) to start ...'
while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s 5 }
if( Test-Path $Env:SystemRoot\system32\Sysprep\unattend.xml ) {
  Write-Output '>>> Removing Sysprep\unattend.xml ...'
  Remove-Item $Env:SystemRoot\system32\Sysprep\unattend.xml -Force
}
if (Test-Path $Env:SystemRoot\Panther\unattend.xml) {
  Write-Output '>>> Removing Panther\unattend.xml ...'
  Remove-Item $Env:SystemRoot\Panther\unattend.xml -Force
}
Write-Output '>>> Sysprepping VM ...'
& $Env:SystemRoot\System32\Sysprep\Sysprep.exe /oobe /generalize /quiet /quit
while($true) {
  $imageState = (Get-ItemProperty HKLM:\SOFTWARE\Microsoft\Windows\CurrentVersion\Setup\State).ImageState
  Write-Output $imageState
  if ($imageState -eq 'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { break }
  Start-Sleep -s 5
}
Write-Output '>>> Sysprep complete ...'
```

Default Linux deprovision command

Bash

```
WAAGENT=/usr/sbin/waagent
waagent -version 1> /dev/null 2>&1
if [ $? -eq 0 ]; then
  WAAGENT=waagent
fi
$WAAGENT -force -deprovision+user && export HISTSIZE=0 && sync
```

Overriding the Commands

To override the commands, use the PowerShell or Shell script provisioners to create the command files with the exact file name, and put them in the correct directories:

- Windows: c:\DeprovisioningScript.ps1
- Linux: /tmp/DeprovisioningScript.sh

Image Builder reads these commands, these commands are written out to the AIB logs, `customization.log`. See troubleshooting on how to collect logs.

Properties: errorHandling

The `errorHandling` property allows you to configure how errors are handled during image creation.

JSON

JSON

```
{
  "errorHandling": {
    "onCustomizerError": "abort",
    "onValidationError": "cleanup"
```

```
    }
  }
```

The `errorHandling` property allows you to configure how errors are handled during image creation. It has two properties:

- **onCustomizerError** - Specifies the action to take when an error occurs during the customizer phase of image creation.
- **onValidationError** - Specifies the action to take when an error occurs during validation of the image template.

The `errorHandling` property also has two possible values for handling errors during image creation:

- **cleanup** - Ensures that temporary resources created by Packer are cleaned up even if Packer or one of the customizations/validations encounters an error. This maintains backwards compatibility with existing behavior.
- **abort** - In case Packer encounters an error, the Azure Image Builder (AIB) service skips the clean up of temporary resources. As the owner of the AIB template, you are responsible for cleaning up these resources from your subscription. These resources may contain useful information such as logs and files left behind in a temporary VM, which can aid in investigating the error encountered by Packer.

Properties: distribute

Azure Image Builder supports three distribution targets:

- **ManagedImage** - Managed image.
- **sharedImage** - Azure Compute Gallery.
- **VHD** - VHD in a storage account.

You can distribute an image to both of the target types in the same configuration.

> ⓘ **Note**
>
> The default AIB sysprep command doesn't include "/mode:vm", however this property maybe required when create images that will have the HyperV role installed. If you need to add this command argument, you must override the sysprep command.

Because you can have more than one target to distribute to, Image Builder maintains a state for every distribution target that can be accessed by querying the `runOutputName`. The `runOutputName` is an object you can query post distribution for information about that distribution. For example, you can query the location of the VHD, or regions where the image version was replicated to, or SIG Image version created. This is a property of every distribution target. The `runOutputName` must be unique to each distribution target. Here's an example for querying an Azure Compute Gallery distribution:

Azure CLI

```
subscriptionID=<subcriptionID>
imageResourceGroup=<resourceGroup of image template>
runOutputName=<runOutputName>

az resource show \
  --ids
"/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Microsoft.VirtualMachineImages/imageTemplates
/ImageTemplateLinuxRHEL77/runOutputs/$runOutputName" \
--api-version=2023-07-01
```

Output:

Output

```
{
  "id":
"/subscriptions/xxxxxx/resourcegroups/rheltest/providers/Microsoft.VirtualMachineImages/imageTemplates/ImageTemplateLinuxR
HEL77/runOutputs/rhel77",
  "identity": null,
  "kind": null,
  "location": null,
  "managedBy": null,
  "name": "rhel77",
  "plan": null,
  "properties": {
    "artifactId":
"/subscriptions/xxxxxx/resourceGroups/aibDevOpsImg/providers/Microsoft.Compute/galleries/devOpsSIG/images/rhel/versions/0.
24105.52755",
```

```
    "provisioningState": "Succeeded"
  },
  "resourceGroup": "rheltest",
  "sku": null,
  "tags": null,
  "type": "Microsoft.VirtualMachineImages/imageTemplates/runOutputs"
}
```

Distribute: managedImage

The image output is a managed image resource.

JSON

JSON

```
{
  "type":"ManagedImage",
  "imageId": "<resource ID>",
  "location": "<region>",
  "runOutputName": "<name>",
  "artifactTags": {
      "<name>": "<value>",
      "<name>": "<value>"
  }
}
```

Distribute properties:

- **type** – ManagedImage
- **imageId** – Resource ID of the destination image, expected format: /subscriptions/<subscriptionId>/resourceGroups/<destinationResourceGroupName>/providers/Microsoft.Compute/images/<imageName>
- **location** - location of the managed image.
- **runOutputName** – unique name for identifying the distribution.
- **artifactTags** - Optional user specified key\value tags.

> ⓘ **Note**
>
> The destination resource group must exist. If you want the image distributed to a different region, it will increase the deployment time.

Distribute: sharedImage

The Azure Compute Gallery is a new Image Management service that allows managing of image region replication, versioning and sharing custom images. Azure Image Builder supports distributing with this service, so you can distribute images to regions supported by Azure Compute Galleries.

an Azure Compute Gallery is made up of:

- **Gallery** - Container for multiple images. A gallery is deployed in one region.
- **Image definitions** - a conceptual grouping for images.
- **Image versions** - an image type used for deploying a VM or scale set. Image versions can be replicated to other regions where VMs need to be deployed.

Before you can distribute to the gallery, you must create a gallery and an image definition, see Create a gallery.

> ⓘ **Note**
>
> The image version ID needs to be distinct or different from any image versions that are in the existing Azure Compute Gallery.

JSON

JSON

```
{
  "type": "SharedImage",
  "galleryImageId": "<resource ID>",
  "runOutputName": "<name>",
  "artifactTags": {
      "<name>": "<value>",
      "<name>": "<value>"
  }
}
```

The following JSON is an example of how to use the `replicationRegions` field to distribute to an Azure Compute Gallery.

JSON

```
  "replicationRegions": [
      "<region where the gallery is deployed>",
      "<region>"
  ]
```

> **Note**
>
> `replicationRegions` is deprecated for gallery distributions as `targetRegions` is updated property. For more information, see targetRegions.

Distribute: targetRegions

The following JSON is an example of how to use the targetRegions field to distribute to an Azure Compute Gallery.

JSON

```
"distribute": [
      {
        "type": "SharedImage",
        "galleryImageId": "<resource ID>",
        "runOutputName": "<name>",
        "artifactTags": {
          "<name>": "<value>",
          "<name>": "<value>"
        },
        "targetRegions": [
            {
             "name": "eastus",
             "replicaCount": 2,
             "storageAccountType": "Standard_ZRS"
            },
            {
             "name": "eastus2",
             "replicaCount": 3,
             "storageAccountType": "Premium_LRS"
            }
          ]
      },
  ]
```

Distribute properties for galleries:

- **type** - sharedImage
- **galleryImageId** – ID of the Azure Compute Gallery, this property can be specified in two formats:
  - Automatic versioning - Image Builder generates a monotonic version number for you, this property is useful for when you want to keep rebuilding images from the same template: The format is:

`/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<sharedImageGalleryName>/images/<imageGalleryName>`.
    - Explicit versioning - You can pass in the version number you want image builder to use. The format is: `/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<sharedImageGalName>/images/<imageDefName>/versions/<version - for example: 1.1.1>`

- **runOutputName** – unique name for identifying the distribution.
- **artifactTags** - optional user specified key\value tags.
- **replicationRegions** - array of regions for replication. One of the regions must be the region where the Gallery is deployed. Adding regions mean an increase of build time, as the build doesn't complete until the replication has completed. This field is deprecated as of API version 2022-07-01, please use `targetRegions` when distributing a "SharedImage" type.
- **targetRegions** - an array of regions for replication. It's newly introduced as part of the 2022-07-01 API and applies only to the `SharedImage` type distribute.
- **excludeFromLatest** (optional) - allows you to mark the image version you create not be used as the latest version in the gallery definition, the default is 'false'.
- **storageAccountType** (optional) - AIB supports specifying these types of storage for the image version that is to be created:
    - "Standard_LRS"
    - "Standard_ZRS","

> ⓘ **Note**
>
> If the image template and referenced `image definition` aren't in the same location, you'll see additional time to create images. Image Builder currently doesn't have a `location` parameter for the image version resource, we take it from its parent `image definition`. For example, if an image definition is in `westus` and you want the image version replicated to `eastus`, a blob is copied to `westus`, an image version resource in `westus` is created, and then replicate to `eastus`. To avoid the additional replication time, ensure the `image definition` and image template are in the same location.

versioning

The **versioning** property is for the `sharedImage` distribute type only. It's an enum with two possible values:

- **latest** - New strictly increasing schema per design
- **source** - Schema based upon the version number of the source image.

The default version numbering schema is `latest`. The latest schema has an additional property, “major” which specifies the major version under which to generate the latest version.

> ⓘ **Note**
>
> The existing version generation logic for `sharedImage` distribution is deprecated. Two new options are provided: monotonically increasing versions that are always the latest version in a gallery, and versions generated based on the version number of the source image. The enum specifying the version generation schema allows for expansion in the future with additional version generation schemas.

JSON

```
    "distribute": [
        "versioning": {
            "scheme": "Latest",
            "major": 1
        }
    ]
```

---

versioning properties:

- **scheme** - Generate new version number for distribution. `Latest` or `Source` are two possible values.

- **major** - Specifies the major version under which to generate the latest version. Only applicable when the `scheme` is set to `Latest`. For example, in a gallery with the following versions published: 0.1.1, 0.1.2, 1.0.0, 1.0.1, 1.1.0, 1.1.1, 1.2.0, 2.0.0, 2.0.1, 2.1.0
  - With major not set or major set to 2, The `Latest` scheme generates version 2.1.1
  - With major set to 1, the Latest scheme generates version 1.2.1
  - With major set to 0, the Latest scheme generates version 0.1.3

Distribute: VHD

You can output to a VHD. You can then copy the VHD, and use it to publish to Azure MarketPlace, or use with Azure Stack.

JSON

```
{
  "type": "VHD",
  "runOutputName": "<VHD name>",
  "artifactTags": {
      "<name>": "<value>",
      "<name>": "<value>"
  }
}
```

OS Support: Windows and Linux

Distribute VHD parameters:

- **type** - VHD.
- **runOutputName** – unique name for identifying the distribution.
- **tags** - Optional user specified key value pair tags.

Azure Image Builder doesn't allow the user to specify a storage account location, but you can query the status of the `runOutputs` to get the location.

Azure CLI

```
az resource show \
  --ids
"/subscriptions/$subscriptionId/resourcegroups/<imageResourceGroup>/providers/Microsoft.VirtualMachineImages/imageTemplates/<imageTemplateName>/runOutputs/<runOutputName>"  | grep artifactUri
```

> **Note**
>
> Once the VHD has been created, copy it to a different location, as soon as possible. The VHD is stored in a storage account in the temporary resource group created when the image template is submitted to the Azure Image Builder service. If you delete the image template, then you'll lose the VHD.

The following JSON distributes the image as a VHD to a custom storage account.

JSON

```
"distribute": [
  {
    "type": "VHD",
    "runOutputName": "<VHD name>",
    "artifactTags": {
        "<name>": "<value>",
        "<name>": "<value>"
    },
    "uri": "<replace with Azure storage URI>"
  }
]
```

VHD distribute properties:

uri - Optional Azure Storage URI for the distributed VHD blob. Omit to use the default (empty string) in which case VHD would be published to the storage account in the staging resource group.

Properties: optimize

The `optimize` property can be enabled while creating a VM image and allows VM optimization to improve image creation time.

JSON

```
"optimize": {
      "vmBoot": {
        "state": "Enabled"
      }
    }
```

- **vmBoot**: A configuration related to the booting process of the virtual machine (VM), used to control optimizations that can improve boot time or other performance aspects.
- state: The state of the boot optimization feature within `vmBoot`, with the value `Enabled` indicating that the feature is turned on to improve image creation time.

To learn more, see VM optimization for gallery images with Azure VM Image Builder.

Properties: source

The `source` section contains information about the source image that will be used by Image Builder. Azure Image Builder only supports generalized images as source images, specialized images aren't supported at this time.

The API requires a `SourceType` that defines the source for the image build, currently there are three types:

- PlatformImage - indicated the source image is a Marketplace image.
- ManagedImage - used when starting from a regular managed image.
- SharedImageVersion - used when you're using an image version in an Azure Compute Gallery as the source.

> **Note**
>
> When using existing Windows custom images, you can run the Sysprep command up to three times on a single Windows 7 or Windows Server 2008 R2 image, or 1001 times on a single Windows image for later versions; for more information, see the sysprep documentation.

PlatformImage source

Azure Image Builder supports Windows Server and client, and Linux Azure Marketplace images, see Learn about Azure Image Builder for the full list.

JSON

```
"source": {
  "type": "PlatformImage",
  "publisher": "Canonical",
  "offer": "UbuntuServer",
  "sku": "18.04-LTS",
  "version": "latest"
}
```

The properties here are the same that are used to create VM's, using AZ CLI, run the below to get the properties:

Azure CLI

```
az vm image list -l westus -f UbuntuServer -p Canonical --output table --all
```

You can use `latest` in the version, the version is evaluated when the image build takes place, not when the template is submitted. If you use this functionality with the Azure Compute Gallery destination, you can avoid resubmitting the template, and rerun the image build at intervals, so your images are recreated from the most recent images.

Support for market place plan information

You can also specify plan information, for example:

JSON

JSON

```
"source": {
  "type": "PlatformImage",
  "publisher": "RedHat",
  "offer": "rhel-byos",
  "sku": "rhel-lvm75",
  "version": "latest",
  "planInfo": {
    "planName": "rhel-lvm75",
    "planProduct": "rhel-byos",
    "planPublisher": "redhat"
  }
}
```

ManagedImage source

Sets the source image as an existing managed image of a generalized VHD or VM.

> **Note**
>
> The source managed image must be of a supported OS and the image must reside in the same subscription and region as your Azure Image Builder template.

JSON

JSON

```
"source": {
  "type": "ManagedImage",
  "imageId":
"/subscriptions/<subscriptionId>/resourceGroups/{destinationResourceGroupName}/providers/Microsoft.Compute/images/<ima
geName>"
}
```

The `imageId` should be the ResourceId of the managed image. Use `az image list` to list available images.

SharedImageVersion source

Sets the source image as an existing image version in an Azure Compute Gallery.

> **Note**
>
> The source shared image version must be of a supported OS and the image version must reside in the same region as your Azure Image Builder template, if not, replicate the image version to the Image Builder Template region.

JSON

JSON

```
"source": {
  "type": "SharedImageVersion",
  "imageVersionId":
"/subscriptions/<subscriptionId>/resourceGroups/<resourceGroup>/providers/Microsoft.Compute/galleries/<sharedImageGall
eryName>/images/<imageDefinitionName/versions/<imageVersion>"
}
```

- imageVersionId - ARM template resource ID of the image version. When image version name is 'latest', the version is evaluated when the image build takes place. The `imageVersionId` should be the `ResourceId` of the image version. Use az sig image-version list to list image versions.

The following JSON sets the source image as an image stored in a Direct Shared Gallery.

> **Note**
>
> The Direct Shared Gallery is currently in preview availability.

JSON

JSON

```
    source: {
      "type": "SharedImageVersion",
      "imageVersionId": "<replace with resourceId of the image stored in the Direct Shared Gallery>"
    },
```

The following JSON sets the source image as the latest image version for an image stored in an Azure Compute Gallery.

JSON

JSON

```
"properties": {
    "source": {
        "type": "SharedImageVersion",
        "imageVersionId":
"/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<azureComput
eGalleryName>/images/<imageDefinitionName>/versions/latest"
    }
},
```

SharedImageVersion properties:

imageVersionId - ARM template resource ID of the image version. When the image version name is 'latest', the version is evaluated when the image build takes place.

Properties: stagingResourceGroup

The `stagingResourceGroup` property contains information about the staging resource group that the Image Builder service creates for use during the image build process. The `stagingResourceGroup` is an optional property for anyone who wants more control over the resource group created by Image Builder during the image build process. You can create your own resource group and specify it in the `stagingResourceGroup` section or have Image Builder create one on your behalf.

> **Important**
>
> The staging resource group specified cannot be associated with another image template, must be empty (no resources inside), in the same region as the image template, and have either "Contributor" or "Owner" RBAC applied to the identity assigned to the Azure Image Builder image template resource. Image Builder checks the tags on the staging resource group with keys `imageTemplateResourceGroupName` and `imageTemplateName` to determine if any image template uses the staging resource group. If these

tags exist before the image template submission or they do not match the running image template during the image build, the operation will fail.

JSON

```
"properties": {
  "stagingResourceGroup": "/subscriptions/<subscriptionID>/resourceGroups/<stagingResourceGroupName>"
}
```

Template creation scenarios

- **The stagingResourceGroup property is left empty**

  If the `stagingResourceGroup` property isn't specified or specified with an empty string, the Image Builder service creates a staging resource group with the default name convention "IT_***". The staging resource group has the default tags applied to it: `createdBy`, `imageTemplateName`, `imageTemplateResourceGroupName`. Also, the default RBAC is applied to the identity assigned to the Azure Image Builder template resource, which is "Contributor".

- **The stagingResourceGroup property is specified with a resource group that exists**

  If the `stagingResourceGroup` property is specified with a resource group that does exist, then the Image Builder service checks to make sure the resource group isn't associated with another image template, is empty (no resources inside), in the same region as the image template, and has either "Contributor" or "Owner" RBAC applied to the identity assigned to the Azure Image Builder image template resource. If any of the aforementioned requirements aren't met, an error is thrown. The staging resource group has the following tags added to it: `usedBy`, `imageTemplateName`, `imageTemplateResourceGroupName`. Pre-existing tags aren't deleted.

> **Important**
>
> You will need to assign the contributor role to the resource group for the service principal corresponding to Azure Image Builder's first party app when trying to specify a pre-existing resource group and VNet to the Azure Image Builder service with a Windows source image. For the CLI command and portal instructions on how to assign the contributor role to the resource group see the following documentation [Troubleshoot VM Azure Image Builder: Authorization error creating disk]

- **The stagingResourceGroup property is specified with a resource group that doesn't exist**

  If the `stagingResourceGroup` property is specified with a resource group that doesn't exist, then the Image Builder service creates a staging resource group with the name provided in the `stagingResourceGroup` property. There will be an error if the given name doesn't meet Azure naming requirements for resource groups. The staging resource group has the default tags applied to it: `createdBy`, `imageTemplateName`, `imageTemplateResourceGroupName`. By default the identity assigned to the Azure Image Builder image template resource has the "Contributor" RBAC applied to it in the resource group.

Template deletion

Any staging resource group created by the Image Builder service will be deleted after the image template is deleted. The deletion includes staging resource groups that were specified in the `stagingResourceGroup` property, but didn't exist prior to the image build.

If Image Builder didn't create the staging resource group, but the resources inside of the resource group, those resources will be deleted after the image template is deleted, given the Image Builder service has the appropriate permissions or role required to delete resources.

Properties: validate

You can use the `validate` property to validate platform images and any customized images you create regardless of if you used Azure Image Builder to create them.

Azure Image Builder supports a 'Source-Validation-Only' mode that can be set using the `sourceValidationOnly` property. If the `sourceValidationOnly` property is set to true, the image specified in the `source` section will directly be validated. No separate build will be run to generate and then validate a customized image.

The `inVMValidations` property takes a list of validators that will be performed on the image. Azure Image Builder supports File, PowerShell and Shell validators.

The `continueDistributeOnFailure` property is responsible for whether the output image(s) will be distributed if validation fails. By default, if validation fails and this property is set to false, the output image(s) won't be distributed. If validation fails and this property is set to true, the output image(s) will still be distributed. Use this option with caution as it may result in failed images being distributed for use. In either case (true or false), the end to end image run will be reported as a failed if a validation failure. This property has no effect on whether validation succeeds or not.

When using `validate`:

- You can use multiple validators.
- Validators execute in the order specified in the template.
- If one validator fails, then the whole validation component will fail and report back an error.
- It's advised you test the script thoroughly before using it in a template. Debugging the script on your own VM will be easier.
- Don't put sensitive data in the scripts.
- The script locations need to be publicly accessible, unless you're using MSI.

How to use the `validate` property to validate Windows images:

JSON

JSON

```
{
   "properties":{
      "validate":{
         "continueDistributeOnFailure":false,
         "sourceValidationOnly":false,
         "inVMValidations":[
            {
               "type":"File",
               "destination":"string",
               "sha256Checksum":"string",
               "sourceUri":"string"
            },
            {
               "type":"PowerShell",
               "name":"test PowerShell validator inline",
               "inline":[
                  "<command to run inline>"
               ],
               "validExitCodes":"<exit code>",
               "runElevated":"<true or false>",
               "runAsSystem":"<true or false>"
            },
            {
               "type":"PowerShell",
               "name":"<name>",
               "scriptUri":"<path to script>",
               "runElevated":"<true false>",
               "sha256Checksum":"<sha256 checksum>"
            }
         ]
      }
   }
}
```

`inVMValidations` properties:

- **type** – PowerShell.
- **name** - name of the validator
- **scriptUri** - URI of the PowerShell script file.
- **inline** – array of commands to be run, separated by commas.
- **validExitCodes** – Optional, valid codes that can be returned from the script/inline command, this avoids reported failure of the script/inline command.
- **runElevated** – Optional, boolean, support for running commands and scripts with elevated permissions.

- **sha256Checksum** - Value of sha256 checksum of the file, you generate this locally, and then Image Builder will checksum and validate.

  To generate the sha256Checksum, using a PowerShell on Windows Get-Hash

How to use the `validate` property to validate Linux images:

JSON

JSON

```
{
  "properties": {
    "validate": {
      "continueDistributeOnFailure": false,
      "sourceValidationOnly": false,
      "inVMValidations": [
        {
          "type": "Shell",
          "name": "<name>",
          "inline": [
            "<command to run inline>"
          ]
        },
        {
          "type": "Shell",
          "name": "<name>",
          "scriptUri": "<path to script>",
          "sha256Checksum": "<sha256 checksum>"
        },
        {
          "type": "File",
          "destination": "string",
          "sha256Checksum": "string",
          "sourceUri": "string"
        }
      ]
    }
  }
}
```

`inVMValidations` properties:

- **type** – Shell or File specified as the validation type to be performed.
- **name** - name of the validator
- **scriptUri** - URI of the script file
- **inline** - array of commands to be run, separated by commas.
- **sha256Checksum** - Value of sha256 checksum of the file, you generate this locally, and then Image Builder will checksum and validate.

  To generate the sha256Checksum, using a terminal on Mac/Linux run: `sha256sum <fileName>`
- **destination** - Destination of the file.
- **sha256Checksum** - Specifies the SHA256 checksum of the file.
- **sourceUri** - The source URI of the file.

Properties: vmProfile

vmSize (optional)

Image Builder uses a default SKU size of `Standard_D1_v2` for Gen1 images and `Standard_D2ds_v4` for Gen2 images. The generation is defined by the image you specify in the `source`. You can override vmSize for these reasons:

- Performing customizations that require increased memory, CPU and handling large files (GBs).

- Running Windows builds, you should use "Standard_D2_v2" or equivalent VM size.
- Require VM isolation.
- Customize an image that requires specific hardware. For example, for a GPU VM, you need a GPU VM size.
- Require end to end encryption at rest of the build VM, you need to specify the support build VM size that doesn't use local temporary disks.

osDiskSizeGB

By default, Image Builder doesn't change the size of the image, it uses the size from the source image. You can optionally **only** increase the size of the OS Disk (Win and Linux), and a value of 0 means leaving the same size as the source image. You can't reduce the OS Disk size to smaller than the size from the source image.

JSON

JSON

```
{
  "osDiskSizeGB": 100
}
```

vnetConfig (optional)

If you don't specify any VNet properties, Image Builder creates its own VNet, Public IP, and network security group (NSG). The Public IP is used for the service to communicate with the build VM. If you don't want to have a Public IP or you want Image Builder to have access to your existing VNet resources, such as configuration servers (DSC, Chef, Puppet, Ansible), file shares, then you can specify a VNet. For more information, review the networking documentation.

JSON

JSON

```
"vnetConfig": {
  "subnetId":
"/subscriptions/<subscriptionID>/resourceGroups/<vnetRgName>/providers/Microsoft.Network/virtualNetworks/<vnetName>/su
bnets/<subnetName1>",
  "containerInstanceSubnetId":
"/subscriptions/<subscriptionID>/resourceGroups/<vnetRgName>/providers/Microsoft.Network/virtualNetworks/<vnetName>/su
bnets/<subnetName2>",
  "proxyVmSize": "<vmSize>"
}
```

subnetId

Resource ID of a pre-existing subnet on which the build VM and validation VM is deployed.

containerInstanceSubnetId (optional)

Resource ID of a pre-existing subnet on which Azure Container Instance (ACI) is deployed for Isolated Builds. If this field isn't specified, then a temporary Virtual Network, along with subnets and Network Security Groups, is deployed in the staging resource group in addition to other networking resources (Private Endpoint, Private Link Service, Azure Load Balancer, and the Proxy VM) to enable communication between the ACI and the build VM.

[This property is only available in API versions `2024-02-01` or newer though existing templates created using earlier API versions can be updated to specify this property.]

This field can be specified only if `subnetId` is also specified and must meet the following requirements:

- This subnet must be on the same Virtual Network as the subnet specified in `subnetId`.
- This subnet must not be the same subnet as the one specified in `subnetId`.
- This subnet must be delegated to the ACI service so that it can be used to deploy ACI resources. You can read more about subnet delegation for Azure services here. ACI specific subnet delegation information is available here.

- This subnet must allow outbound access to the Internet and to the subnet specified in `subnetId`. These accesses are required so that the ACI can be provisioned and it can communicate with the build VM to perform customizations/validations. On the other end, the subnet specified in `subnetId` must allow inbound access from this subnet. In general, default security rules of Azure Network Security Groups (NSGs) allow these accesses. However, if you add more security rules to your NSGs then the following accesses must still be allowed:

    1. Outbound access from the subnet specified in `containerInstanceSubnetId` to:
        a. To the Internet on port 443 (*for provisioning the container image*).
        b. To the Internet on port 445 (*for mounting file share from Azure Storage*).
        c. To the subnet specified in `subnetId` on port 22 (for ssh/Linux) and port 5986 (for WinRM/Windows) (*for connecting to the build VM*).
    2. Inbound access to the subnet specified in `subnetId`:
        a. To Port 22 (for ssh/Linux) and Port 5986 (for WinRM/Windows) from the subnet specified in `containerInstanceSubnetId` (*for ACI to connect to the build VM*).

- The template identity must have permission to perform 'Microsoft.Network/virtualNetworks/subnets/join/action' action on this subnet's scope. You can read more about Azure permissions for Networking here.

proxyVmSize (optional)

Size of the proxy virtual machine used to pass traffic to the build VM and validation VM. This field must not be specified if `containerInstanceSubnetId` is specified because no proxy virtual machine is deployed in that case. Omit or specify empty string to use the default (Standard_A1_v2).

Properties: autoRun

You can use the `autoRun` property to control whether the image template build process should automatically start when the template is created. It's an enum with two possible values:

- **Enabled** - Auto run is enabled, so your image template build process will automatically start when the template is created.
- **Disabled** - Auto run is disabled, so you will have to manually start the image build process after the template is created.

JSON

```
"properties": {
    "autoRun": {
        "state": "Enabled"
    }
 }
```

> **Note**
>
> When you set `autoRun` to "Enabled," the image build process runs **once** upon template creation. It ensures that the initial image build occurs seamlessly. However, it does not provide consistent and ongoing image builds. For consistent and ongoing image builds that run once an image template is updated, see How to use Azure Image Builder triggers to set up an automatic image build.
>
> Unlike `autoRun`, automatic image creation via the Azure Image Builder trigger resource ensures that image builds occur consistently. Whenever there are changes to the template, the Azure Image Builder service will automatically trigger the image build process.
>
> Choose `autoRun` for immediate image builds upon template creation. Opt for automatic image creation when you need ongoing consistency in image builds. Consider your specific requirements and use the appropriate option based on your workflow.

Properties: managedResourceTags

You can use the `managedResourceTags` property to apply tags to the resources that the Azure Image Builder service creates in the staging resource group during the image build. For more information on the staging resource group, see Azure Image Builder Overview

JSON

```
"properties": {
        "managedResourceTags": {
            "tag1": "value1",
```

```
                "tag2": "value2"
            }
}
```

Image Template Operations

Starting an Image Build

To start a build, you need to invoke 'Run' on the Image Template resource, examples of `run` commands:

Azure PowerShell

```
Invoke-AzResourceAction -ResourceName $imageTemplateName -ResourceGroupName $imageResourceGroup -ResourceType
Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2023-07-01" -Action Run -Force
```

Azure CLI

```
az resource invoke-action \
  --resource-group $imageResourceGroup \
  --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
  -n helloImageTemplateLinux01 \
  --action Run
```

Cancelling an Image Build

If you're running an image build that you believe is incorrect, waiting for user input, or you feel will never complete successfully, then you can cancel the build.

The build can be canceled anytime. If the distribution phase has started you can still cancel, but you need to clean up any images that may not be completed. The cancel command doesn't wait for cancel to complete, monitor `lastrunstatus.runstate` for canceling progress, using these status commands.

Examples of `cancel` commands:

Azure PowerShell

```
Invoke-AzResourceAction -ResourceName $imageTemplateName -ResourceGroupName $imageResourceGroup -ResourceType
Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2023-07-01" -Action Cancel -Force
```

Azure CLI

```
az resource invoke-action \
  --resource-group $imageResourceGroup \
  --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
  -n helloImageTemplateLinux01 \
  --action Cancel
```

Next steps

There are sample .json files for different scenarios in the Azure Image Builder GitHub.

Create a Linux image and distribute it to an Azure Compute Gallery

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how you can use the Azure Image Builder, and the Azure CLI, to create an image version in an Azure Compute Gallery (formerly known as Shared Image Gallery), then distribute the image globally. You can also do this using Azure PowerShell.

We'll be using a sample .json template to configure the image. The .json file we're using is here: helloImageTemplateforSIG.json .

To distribute the image to an Azure Compute Gallery, the template uses sharedImage as the value for the `distribute` section of the template.

Register the providers

To use Azure Image Builder, you need to register the feature.

Check your registration.

Azure CLI

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState
az provider show -n Microsoft.KeyVault | grep registrationState
az provider show -n Microsoft.Compute | grep registrationState
az provider show -n Microsoft.Storage | grep registrationState
az provider show -n Microsoft.Network | grep registrationState
az provider show -n Microsoft.ContainerInstance | grep registrationState
```

If they don't say registered, run the following:

Azure CLI

```
az provider register -n Microsoft.VirtualMachineImages
az provider register -n Microsoft.Compute
az provider register -n Microsoft.KeyVault
az provider register -n Microsoft.Storage
az provider register -n Microsoft.Network
az provider register -n Microsoft.ContainerInstance
```

Set variables and permissions

We'll be using some pieces of information repeatedly, so we'll create some variables to store that information.

Image Builder only supports creating custom images in the same Resource Group as the source managed image. Update the resource group name in this example to be the same resource group as your source managed image.

Azure CLI

```
# Resource group name - we are using ibLinuxGalleryRG in this example
sigResourceGroup=ibLinuxGalleryRG
# Datacenter location - we are using West US 2 in this example
location=westus2
# Additional region to replicate the image to - we are using East US in this example
additionalregion=eastus
# name of the Azure Compute Gallery - in this example we are using myGallery
sigName=myIbGallery
# name of the image definition to be created - in this example we are using myImageDef
imageDefName=myIbImageDef
# image distribution metadata reference name
runOutputName=aibLinuxSIG
```

Create a variable for your subscription ID.

Azure CLI

```
subscriptionID=$(az account show --query id --output tsv)
```

Create the resource group.

Azure CLI

```
az group create -n $sigResourceGroup -l $location
```

Create a user-assigned identity and set permissions on the resource group

Image Builder uses the user-identity provided to inject the image into the Azure Compute Gallery. In this example, you'll create an Azure role definition that has the

granular actions to perform distributing the image to the gallery. The role definition will then be assigned to the user-identity.

Azure CLI

```
# create user assigned identity for image builder to access the storage
account where the script is located
identityName=aibBuiUserId$(date +'%s')
az identity create -g $sigResourceGroup -n $identityName

# get identity id
imgBuilderCliId=$(az identity show -g $sigResourceGroup -n $identityName --
query clientId -o tsv)

# get the user identity URI, needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$sigResourceGroup
/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# this command will download an Azure role definition template, and update
the template with the parameters specified earlier.
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12
_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o
aibRoleImageCreation.json

imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# update the definition
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$sigResourceGroup/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation
Role/$imageRoleDefName/g" aibRoleImageCreation.json

# create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# grant role definition to the user assigned identity
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup
```

Create an image definition and gallery

To use Image Builder with an Azure Compute Gallery, you need to have an existing gallery and image definition. Image Builder won't create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them. First, create a gallery.

Azure CLI

```
az sig create \
    -g $sigResourceGroup \
    --gallery-name $sigName
```

Then, create an image definition.

Azure CLI

```
az sig image-definition create \
   -g $sigResourceGroup \
   --gallery-name $sigName \
   --gallery-image-definition $imageDefName \
   --publisher myIbPublisher \
   --offer myOffer \
   --sku 18.04-LTS \
   --os-type Linux
```

Download and configure the .json

Download the .json template and configure it with your variables.

Azure CLI

```
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickquickst
arts/1_Creating_a_Custom_Linux_Shared_Image_Gallery_Image/helloImageTemplate
forSIG.json -o helloImageTemplateforSIG.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g"
helloImageTemplateforSIG.json
sed -i -e "s/<rgName>/$sigResourceGroup/g" helloImageTemplateforSIG.json
sed -i -e "s/<imageDefName>/$imageDefName/g" helloImageTemplateforSIG.json
sed -i -e "s/<sharedImageGalName>/$sigName/g" helloImageTemplateforSIG.json
sed -i -e "s/<region1>/$location/g" helloImageTemplateforSIG.json
sed -i -e "s/<region2>/$additionalregion/g" helloImageTemplateforSIG.json
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateforSIG.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateforSIG.json
```

Create the image version

This next part will create the image version in the gallery.

Submit the image configuration to the Azure Image Builder service.

Azure CLI

```
az resource create \
    --resource-group $sigResourceGroup \
    --properties @helloImageTemplateforSIG.json \
    --is-full-object \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateforSIG01
```

Start the image build.

Azure CLI

```
az resource invoke-action \
     --resource-group $sigResourceGroup \
     --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
     -n helloImageTemplateforSIG01 \
     --action Run
```

Creating the image and replicating it to both regions can take a while. Wait until this part is finished before moving on to creating a VM.

Create the VM

Create a VM from the image version that was created by Azure Image Builder.

Azure CLI

```
az vm create \
  --resource-group $sigResourceGroup \
  --name myAibGalleryVM \
  --admin-username aibuser \
  --location $location \
  --image
"/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/M
icrosoft.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \
  --generate-ssh-keys
```

SSH into the VM.

Azure CLI

```
ssh aibuser@<publicIpAddress>
```

You should see the image was customized with a *Message of the Day* as soon as your SSH connection is established!

Console

```
**************************************************
**            This VM was built from the:       **
**      !! AZURE VM IMAGE BUILDER Custom Image !!    **
**         You have just been Customized :-)      **
**************************************************
```

Clean up resources

If you want to now try recustomizing the image version to create a new version of the same image, skip the next steps and go on to Use Azure Image Builder to create another image version.

This deletes the image that was created, along with all of the other resource files. Make sure you're finished with this deployment before deleting the resources.

When deleting gallery resources, you need delete all of the image versions before you can delete the image definition used to create them. To delete a gallery, you first need to have deleted all of the image definitions in the gallery.

Delete the image builder template.

Azure CLI

```azure-cli
az resource delete \
    --resource-group $sigResourceGroup \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateforSIG01
```

Delete permissions assignments, roles and identity

Azure CLI

```azure-cli
az role assignment delete \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup

az role definition delete --name "$imageRoleDefName"

az identity delete --ids $imgBuilderId
```

Get the image version created by image builder, this always starts with `0.`, and then delete the image version

Azure CLI

```
sigDefImgVersion=$(az sig image-version list \
   -g $sigResourceGroup \
   --gallery-name $sigName \
   --gallery-image-definition $imageDefName \
   --subscription $subscriptionID --query [].'name' -o json | grep 0. | tr -
d '"')
az sig image-version delete \
   -g $sigResourceGroup \
   --gallery-image-version $sigDefImgVersion \
   --gallery-name $sigName \
   --gallery-image-definition $imageDefName \
   --subscription $subscriptionID
```

Delete the image definition.

Azure CLI

```
az sig image-definition delete \
   -g $sigResourceGroup \
   --gallery-name $sigName \
   --gallery-image-definition $imageDefName \
   --subscription $subscriptionID
```

Delete the gallery.

Azure CLI

```
az sig delete -r $sigName -g $sigResourceGroup
```

Delete the resource group.

Azure CLI

```
az group delete -n $sigResourceGroup -y
```

Create a Windows image and distribute it to an Azure Compute Gallery

Article • 08/22/2024

Applies to: ✔ Windows VMs

In this article, you learn how to use Azure VM Image Builder and Azure PowerShell to create an image version in an Azure Compute Gallery (formerly Shared Image Gallery) and then distribute the image globally. You can also do this by using the Azure CLI.

To configure the image, this article uses a JSON template, which you can find at armTemplateWinSIG.json. You'll download and edit a local version of the template, so you'll also use a local PowerShell session.

To distribute the image to an Azure Compute Gallery, the template uses sharedImage as the value for the `distribute` section of the template.

VM Image Builder automatically runs `Sysprep` to generalize the image. The command is a generic `Sysprep` command, and you can override it if you need to.

Be aware of the number of times you layer customizations. You can run the `Sysprep` command a limited number of times on a single Windows image. After you've reached the `Sysprep` limit, you must re-create your Windows image. For more information, see Limits on how many times you can run Sysprep.

Register the providers

To use VM Image Builder, you need to register the providers.

1. Check your provider registrations. Make sure that each one returns *Registered*.

PowerShell

```
Get-AzResourceProvider -ProviderNamespace
Microsoft.VirtualMachineImages | Format-table -Property
ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.Storage | Format-
table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.Compute | Format-
table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.KeyVault | Format-
table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.Network | Format-
table -Property ResourceTypes,RegistrationState
```

```
Get-AzResourceProvider -ProviderNamespace Microsoft.ContainerInstance |
Format-table -Property ResourceTypes,RegistrationState
```

2. If they don't return *Registered*, register the providers by running the following commands:

```PowerShell
Register-AzResourceProvider -ProviderNamespace
Microsoft.VirtualMachineImages
Register-AzResourceProvider -ProviderNamespace Microsoft.Storage
Register-AzResourceProvider -ProviderNamespace Microsoft.Compute
Register-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
Register-AzResourceProvider -ProviderNamespace
Microsoft.ContainerInstance
```

3. Install PowerShell modules:

```powerShell
'Az.ImageBuilder', 'Az.ManagedServiceIdentity' | ForEach-Object
{Install-Module -Name $_ -AllowPrerelease}
```

Create variables

Because you'll be using some pieces of information repeatedly, create some variables to store that information.

Replace the values for the variables, such as `username` and `vmpassword`, with your own information.

```PowerShell
# Get existing context
$currentAzContext = Get-AzContext

# Get your current subscription ID.
$subscriptionID=$currentAzContext.Subscription.Id

# Destination image resource group
$imageResourceGroup="aibwinsig"

# Location
$location="westus"

# Image distribution metadata reference name
$runOutputName="aibCustWinManImg02ro"
```

```
# Image template name
$imageTemplateName="helloImageTemplateWin02ps"

# Distribution properties object name (runOutput).
# This gives you the properties of the managed image on completion.
$runOutputName="winclientR01"

# Create a resource group for the VM Image Builder template and Azure
Compute Gallery
New-AzResourceGroup `
   -Name $imageResourceGroup `
   -Location $location
```

Create a user-assigned identity and set permissions on the resource group

VM Image Builder uses the provided user-identity to inject the image into Azure Compute Gallery. In this example, you create an Azure role definition with specific actions for distributing the image. The role definition is then assigned to the user identity.

PowerShell

```
# setup role def names, these need to be unique
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt
$identityName="aibIdentity"+$timeInt

## Add an Azure PowerShell module to support AzUserAssignedIdentity
Install-Module -Name Az.ManagedServiceIdentity

# Create an identity
New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName

$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName
$imageResourceGroup -Name $identityName).PrincipalId
```

Assign permissions for the identity to distribute the images

Use this command to download an Azure role definition template, and then update it with the previously specified parameters.

PowerShell

```
$aibRoleImageCreationUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json"
$aibRoleImageCreationPath = "aibRoleImageCreation.json"

# Download the configuration
Invoke-WebRequest -Uri $aibRoleImageCreationUrl -OutFile $aibRoleImageCreationPath -UseBasicParsing

((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<subscriptionID>',$subscriptionID) | Set-Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<rgName>', $imageResourceGroup) | Set-Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace 'Azure Image Builder Service Image Creation Role', $imageRoleDefName) | Set-Content -Path $aibRoleImageCreationPath

# Create a role definition
New-AzRoleDefinition -InputFile  ./aibRoleImageCreation.json

# Grant the role definition to the VM Image Builder service principal
New-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $imageRoleDefName -Scope "/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
```

> **Note**
>
> If you receive the error "New-AzRoleDefinition: Role definition limit exceeded. No more role definitions can be created," see Troubleshoot Azure RBAC (role-based access control).

Create an Azure Compute Gallery

To use VM Image Builder with an Azure Compute Gallery, you need to have an existing gallery and image definition. VM Image Builder doesn't create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them.

PowerShell

```
# Gallery name
$sigGalleryName= "myIBSIG"
```

```
# Image definition name
$imageDefName ="winSvrimage"

# Additional replication region
$replRegion2="eastus"

# Create the gallery
New-AzGallery `
   -GalleryName $sigGalleryName `
   -ResourceGroupName $imageResourceGroup  `
   -Location $location

# Create the image definition
New-AzGalleryImageDefinition `
   -GalleryName $sigGalleryName `
   -ResourceGroupName $imageResourceGroup `
   -Location $location `
   -Name $imageDefName `
   -OsState generalized `
   -OsType Windows `
   -Publisher 'myCompany' `
   -Offer 'WindowsServer' `
   -Sku 'WinSrv2019'
```

Download and configure the template

Download the JSON template and configure it with your variables.

PowerShell

```
$templateFilePath = "armTemplateWinSIG.json"

Invoke-WebRequest `
   -Uri
"https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickquickstarts/1_Creating_a_Custom_Win_Shared_Image_Gallery_Image/armTemplateWinSIG.json" `
   -OutFile $templateFilePath `
   -UseBasicParsing

(Get-Content -path $templateFilePath -Raw ) `
   -replace '<subscriptionID>',$subscriptionID | Set-Content -Path
$templateFilePath
(Get-Content -path $templateFilePath -Raw ) `
   -replace '<rgName>',$imageResourceGroup | Set-Content -Path
$templateFilePath
(Get-Content -path $templateFilePath -Raw ) `
   -replace '<runOutputName>',$runOutputName | Set-Content -Path
$templateFilePath
(Get-Content -path $templateFilePath -Raw ) `
   -replace '<imageDefName>',$imageDefName | Set-Content -Path
```

```
$templateFilePath
(Get-Content -path $templateFilePath -Raw ) `
   -replace '<sharedImageGalName>',$sigGalleryName | Set-Content -Path
$templateFilePath
(Get-Content -path $templateFilePath -Raw ) `
   -replace '<region1>',$location | Set-Content -Path $templateFilePath
(Get-Content -path $templateFilePath -Raw ) `
   -replace '<region2>',$replRegion2 | Set-Content -Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace
'<imgBuilderId>',$identityNameResourceId) | Set-Content -Path
$templateFilePath
```

Create the image version

Your template must be submitted to the service. The following commands will download any dependent artifacts, such as scripts, and store them in the staging resource group, which is prefixed with *IT_*.

PowerShell

```
New-AzResourceGroupDeployment `
   -ResourceGroupName $imageResourceGroup `
   -TemplateFile $templateFilePath `
   -ApiVersion "2022-02-14" `
   -imageTemplateName $imageTemplateName `
   -svclocation $location
```

To build the image, invoke 'Run' on the template.

PowerShell

```
Invoke-AzResourceAction `
   -ResourceName $imageTemplateName `
   -ResourceGroupName $imageResourceGroup `
   -ResourceType Microsoft.VirtualMachineImages/imageTemplates `
   -ApiVersion "2022-02-14" `
   -Action Run
```

Creating the image and replicating it to both regions can take a few moments. Before you begin creating a VM, wait until this part is finished.

PowerShell

```
Get-AzImageBuilderTemplate -ImageTemplateName $imageTemplateName -
ResourceGroupName $imageResourceGroup |
```

```
  Select-Object -Property Name, LastRunStatusRunState, LastRunStatusMessage,
ProvisioningState
```

Create the VM

Create a VM from the image version that you created with VM Image Builder.

1. Get the image version that you created:

   PowerShell

   ```
   $imageVersion = Get-AzGalleryImageVersion `
   -ResourceGroupName $imageResourceGroup `
   -GalleryName $sigGalleryName `
   -GalleryImageDefinitionName $imageDefName
   $imageVersionId = $imageVersion.Id
   ```

2. Create the VM in the second region, where the image was replicated:

   PowerShell

   ```
   $vmResourceGroup = "myResourceGroup"
   $vmName = "myVMfromImage"

   # Create user object
   $cred = Get-Credential -Message "Enter a username and password for the
   virtual machine."

   # Create a resource group
   New-AzResourceGroup -Name $vmResourceGroup -Location $replRegion2

   # Network pieces
   $subnetConfig = New-AzVirtualNetworkSubnetConfig -Name mySubnet -
   AddressPrefix 192.168.1.0/24
   $vnet = New-AzVirtualNetwork -ResourceGroupName $vmResourceGroup -
   Location $replRegion2 `
   -Name MYvNET -AddressPrefix 192.168.0.0/16 -Subnet $subnetConfig
   $pip = New-AzPublicIpAddress -ResourceGroupName $vmResourceGroup -
   Location $replRegion2 `
   -Name "mypublicdns$(Get-Random)" -AllocationMethod Static -
   IdleTimeoutInMinutes 4
   $nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name
   myNetworkSecurityGroupRuleRDP  -Protocol Tcp `
   -Direction Inbound -Priority 1000 -SourceAddressPrefix * -
   SourcePortRange * -DestinationAddressPrefix * `
   -DestinationPortRange 3389 -Access Deny
   $nsg = New-AzNetworkSecurityGroup -ResourceGroupName $vmResourceGroup -
   Location $replRegion2 `
   -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP
   $nic = New-AzNetworkInterface -Name myNic -ResourceGroupName
   ```

```
$vmResourceGroup -Location $replRegion2 `
-SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -
NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration using $imageVersion.Id to
specify the image
$vmConfig = New-AzVMConfig -VMName $vmName -VMSize Standard_D1_v2 | `
Set-AzVMOperatingSystem -Windows -ComputerName $vmName -Credential
$cred | `
Set-AzVMSourceImage -Id $imageVersion.Id | `
Add-AzVMNetworkInterface -Id $nic.Id

# Create a virtual machine
New-AzVM -ResourceGroupName $vmResourceGroup -Location $replRegion2 -VM
$vmConfig
```

Verify the customization

Create a Remote Desktop connection to the VM by using the username and password that you set when you created the VM. In the VM, open a Command Prompt window and run the following command:

Console

```
dir c:\
```

You should see a directory named `buildActions` that was created during image customization.

Clean up your resources

> **Note**
>
> If you now want to try to recustomize the image version to create a new version of the same image, *skip the step outlined here* and go to Use VM Image Builder to create another image version.

If you no longer need the resources that you created as you followed the process in this article, you can delete them.

The following process deletes both the image that you created and all the other resource files. Make sure that you've finished this deployment before you delete the resources.

Delete the resource group template first. Otherwise, the staging resource group (*IT_*) that VM Image Builder uses won't be cleaned up.

1. Get the ResourceID of the image template.

```powerShell
$resTemplateId = Get-AzResource -ResourceName $imageTemplateName -
ResourceGroupName $imageResourceGroup -ResourceType
Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2022-02-14"
```

2. Delete image template.

```powerShell
Remove-AzResource -ResourceId $resTemplateId.ResourceId -Force
```

3. Delete the role assignment.

```powerShell
Remove-AzRoleAssignment -ObjectId $identityNamePrincipalId -
RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
```

4. Remove the definitions.

```powerShell
Remove-AzRoleDefinition -Name "$identityNamePrincipalId" -Force -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
```

5. Delete the identity.

```powerShell
Remove-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -
Name $identityName -Force
```

6. Delete the resource group.

```powerShell
Remove-AzResourceGroup $imageResourceGroup -Force
```

Next steps

To update the image version that you created in this article, see Use VM Image Builder to create another image version.

Create a new VM image from an existing image by using Azure VM Image Builder in Linux

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

In this article, you learn how to update an existing image version in an Azure Compute Gallery (formerly Shared Image Gallery) and publish it to the gallery as a new image version.

To configure the image, you use a sample JSON template, helloImageTemplateforSIGfromSIG.json.

Register the providers

To use VM Image Builder, you need to register the providers.

1. Check your provider registrations. Make sure that each one returns *Registered*.

   Azure CLI

   ```
   az provider show -n Microsoft.VirtualMachineImages | grep
   registrationState
   az provider show -n Microsoft.KeyVault | grep registrationState
   az provider show -n Microsoft.Compute | grep registrationState
   az provider show -n Microsoft.Storage | grep registrationState
   az provider show -n Microsoft.Network | grep registrationState
   az provider show -n Microsoft.ContainerInstance | grep
   registrationState
   ```

2. If they don't return *Registered*, register the providers by running the following commands:

   Azure CLI

   ```
   az provider register -n Microsoft.VirtualMachineImages
   az provider register -n Microsoft.Compute
   az provider register -n Microsoft.KeyVault
   az provider register -n Microsoft.Storage
   az provider register -n Microsoft.Network
   az provider register -n Microsoft.ContainerInstance
   ```

Set variables and permissions

If you've already created an Azure Compute Gallery by using Create an image and distribute it to an Azure Compute Gallery, you've already created some of the variables you need.

1. If you haven't already created the variables, run the following commands:

   Console

   ```
   # Resource group name
   sigResourceGroup=ibLinuxGalleryRG
   # Gallery location
   location=westus2
   # Additional region to replicate the image version to
   additionalregion=eastus
   # Name of the Azure Compute Gallery
   sigName=myIbGallery
   # Name of the image definition to use
   imageDefName=myIbImageDef
   # image distribution metadata reference name
   runOutputName=aibSIGLinuxUpdate
   ```

2. Create a variable for your subscription ID:

   Console

   ```
   subscriptionID=$(az account show --query id --output tsv)
   ```

3. Get the image version that you want to update:

   Azure CLI

   ```
   sigDefImgVersionId=$(az sig image-version list \
     -g $sigResourceGroup \
     --gallery-name $sigName \
     --gallery-image-definition $imageDefName \
     --subscription $subscriptionID --query [].'id' -o tsv)
   ```

Create a user-assigned identity and set permissions on the resource group

You've set up the user identity in an earlier example, so now you need to get the resource ID, which will be appended to the template.

Azure CLI

```
#get identity used previously
imgBuilderId=$(az identity list -g $sigResourceGroup --query "[?
contains(name, 'aibBuiUserId')].id" -o tsv)
```

If you already have an Azure Compute Gallery but didn't set it up by following an earlier example, you need to assign permissions for VM Image Builder to access the resource group so that it can access the gallery. For more information, see Create an image and distribute it to an Azure Compute Gallery.

Modify the helloImage example

You can review the JSON example you're about to use at helloImageTemplateforSIGfromSIG.json. For information about the JSON file, see Create an Azure VM Image Builder template.

1. Download the JSON example, as shown in Create a Linux image and distribute it to an Azure Compute Gallery by using the Azure CLI.

2. Configure the JSON with your variables:

   Console

   ```
   curl
   https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickqu
   ickstarts/8_Creating_a_Custom_Linux_Shared_Image_Gallery_Image_from_SIG
   /helloImageTemplateforSIGfromSIG.json -o
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<subscriptionID>/$subscriptionID/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<rgName>/$sigResourceGroup/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<imageDefName>/$imageDefName/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<sharedImageGalName>/$sigName/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s%<sigDefImgVersionId>%$sigDefImgVersionId%g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<region1>/$location/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<region2>/$additionalregion/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s/<runOutputName>/$runOutputName/g"
   helloImageTemplateforSIGfromSIG.json
   sed -i -e "s%<imgBuilderId>%$imgBuilderId%g"
   helloImageTemplateforSIGfromSIG.json
   ```

Create the image

1. Submit the image configuration to the VM Image Builder service:

   Azure CLI

   ```
   az resource create \
       --resource-group $sigResourceGroup \
       --properties @helloImageTemplateforSIGfromSIG.json \
       --is-full-object \
       --resource-type Microsoft.VirtualMachineImages/imageTemplates \
       -n helloImageTemplateforSIGfromSIG01
   ```

2. Start the image build:

   Azure CLI

   ```
   az resource invoke-action \
       --resource-group $sigResourceGroup \
       --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
       -n helloImageTemplateforSIGfromSIG01 \
       --action Run
   ```

Wait for the image to be built and replicated before you move along to the next step.

Create the VM

1. Create the VM by doing the following:

   Azure CLI

   ```
   az vm create \
   --resource-group $sigResourceGroup \
   --name aibImgVm001 \
   --admin-username azureuser \
   --location $location \
   --image
   "/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \
   --generate-ssh-keys
   ```

2. Create a Secure Shell (SSH) connection to the VM by using the public IP address of the VM.

   Console

```
ssh azureuser@<pubIp>
```

After the SSH connection is established, you should receive a "Message of the Day" saying that the image was customized:

Output

```
*********************************************************
**            This VM was built from the:              **
**      !! AZURE VM IMAGE BUILDER Custom Image !!      **
**         You have just been Customized :-)           **
*********************************************************
```

3. Type `exit` to close the SSH connection.

4. To list the image versions that are now available in your gallery, run:

Azure CLI

```
az sig image-version list -g $sigResourceGroup -r $sigName -i
$imageDefName -o table
```

Next steps

To learn more about the components of the JSON file that you used in this article, see Create an Azure VM Image Builder template.

Create a new Windows VM image from an existing image by using Azure VM Image Builder

Article • 08/22/2024

Applies to: ✔ Windows VMs

In this article, you learn how to update an existing Windows image version in an Azure Compute Gallery (formerly Shared Image Gallery) and publish it to the gallery as a new image version.

To configure the image, you use a sample JSON template, helloImageTemplateforSIGfromWinSIG.json .

Register the providers

To use VM Image Builder, you need to register the providers.

1. Check your provider registrations. Make sure that each one returns *Registered*.

   Azure CLI

   ```
   az provider show -n Microsoft.VirtualMachineImages | grep
   registrationState
   az provider show -n Microsoft.KeyVault | grep registrationState
   az provider show -n Microsoft.Compute | grep registrationState
   az provider show -n Microsoft.Storage | grep registrationState
   az provider show -n Microsoft.Network | grep registrationState
   az provider show -n Microsoft.ContainerInstance | grep
   registrationState
   ```

2. If they don't return *Registered*, register the providers by running the following commands:

   Azure CLI

   ```
   az provider register -n Microsoft.VirtualMachineImages
   az provider register -n Microsoft.Compute
   az provider register -n Microsoft.KeyVault
   az provider register -n Microsoft.Storage
   az provider register -n Microsoft.Network
   az provider register -n Microsoft.ContainerInstance
   ```

Set variables and permissions

If you've already created an Azure Compute Gallery by using Create an image and distribute it to an Azure Compute Gallery, you've already created some of the variables you need.

> **Note**
>
> VM Image Builder supports creating custom images only in the same resource group that the source-managed image is in. In the following example, update the resource group name, *ibsigRG*, with the name of resource group that your source-managed image is in.

1. If you haven't already created the variables, run the following commands:

   Azure CLI

   ```
   # Resource group name - we are using ibsigRG in this example
   sigResourceGroup=myIBWinRG
   # Datacenter location - we are using West US 2 in this example
   location=westus
   # Additional region to replicate the image to - we are using East US in this example
   additionalregion=eastus
   # name of the Azure Compute Gallery - in this example we are using myGallery
   sigName=my22stSIG
   # name of the image definition to be created - in this example we are using myImageDef
   imageDefName=winSvrimages
   # image distribution metadata reference name
   runOutputName=w2019SigRo
   # User name and password for the VM
   username="user name for the VM"
   vmpassword="password for the VM"
   ```

2. Create a variable for your subscription ID:

   Azure CLI

   ```
   subscriptionID=$(az account show --query id --output tsv)
   ```

3. Get the image version that you want to update:

   Azure CLI

```
sigDefImgVersionId=$(az sig image-version list \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID --query [].'id' -o tsv)
```

Create a user-assigned identity and set permissions on the resource group

You've set up the user identity in an earlier example, so now you need to get the resource ID, which will be appended to the template.

Azure CLI

```
#get identity used previously
imgBuilderId=$(az identity list -g $sigResourceGroup --query "[?
contains(name, 'aibBuiUserId')].id" -o tsv)
```

If you already have an Azure Compute Gallery but didn't set it up by following an earlier example, you need to assign permissions for VM Image Builder to access the resource group so that it can access the gallery. For more information, see Create an image and distribute it to an Azure Compute Gallery.

Modify the helloImage example

You can review the JSON example you're about to use at helloImageTemplateforSIGfromSIG.json. For information about the JSON file, see Create an Azure VM Image Builder template.

1. Download the JSON example, as shown in Create a user-assigned identity and set permissions on the resource group.

2. Configure the JSON with your variables:

Azure CLI

```
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickqu
ickstarts/8_Creating_a_Custom_Win_Shared_Image_Gallery_Image_from_SIG/h
elloImageTemplateforSIGfromWinSIG.json -o
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g"
helloImageTemplateforSIGfromWinSIG.json
```

```
sed -i -e "s/<rgName>/$sigResourceGroup/g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s/<imageDefName>/$imageDefName/g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s/<sharedImageGalName>/$sigName/g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s%<sigDefImgVersionId>%$sigDefImgVersionId%g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s/<region1>/$location/g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s/<region2>/$additionalregion/g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s/<runOutputName>/$runOutputName/g"
helloImageTemplateforSIGfromWinSIG.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g"
helloImageTemplateforSIGfromWinSIG.json
```

Create the image

1. Submit the image configuration to the VM Image Builder service:

Azure CLI

```
az resource create \
    --resource-group $sigResourceGroup \
    --location $location \
    --properties @helloImageTemplateforSIGfromWinSIG.json \
    --is-full-object \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n imageTemplateforSIGfromWinSIG01
```

2. Start the image build:

Azure CLI

```
az resource invoke-action \
    --resource-group $sigResourceGroup \
    --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
    -n imageTemplateforSIGfromWinSIG01 \
    --action Run
```

Wait for the image to be built and replicated before you move along to the next step.

Create the VM

Create the VM by doing the following:

Azure CLI

```
az vm create \
--resource-group $sigResourceGroup \
--name aibImgWinVm002 \
--admin-username $username \
--admin-password $vmpassword \
--image
"/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \
--location $location
```

Verify the customization

Create a Remote Desktop connection to the VM by using the username and password you set when you created the VM. Inside the VM, open a Command Prompt window, and then run:

Console

```
dir c:\
```

You should now see two directories:

- *buildActions*: Created in the first image version.
- *buildActions2*: Created when you updated the first image version to create the second image version.

Next steps

To learn more about the components of the JSON file that you used in this article, see Create an Azure VM Image Builder template.

How to enable Automatic Image Creation with Azure Image Builder triggers

Article • 08/29/2024

You can use triggers in Azure Image Builder (AIB) to enable automatic image creation when certain criteria are met in your build pipeline.

> **Important**
>
> Please be informed that there exists a restriction on the number of triggers allowable per region, specifically 100 per region per subscription.

> **Note**
>
> Currently, we only support setting a trigger for a new source image, but we do expect to support different kinds of triggers in the future.

> **Note**
>
> To prevent unnecessary build failures, automatic image creation via triggers will be deactivated if the image template build has failed multiple times consecutively (either manually or automatically triggered). You can still manually build the image template, and once a manual build succeeds, the automatic triggers will be reactivated.

Prerequisites

Before setting up your first trigger, ensure you're using Azure Image Builder API version **2022-07-01**.

How to set up a trigger in Azure Image Builder

Register the providers

To use VM Image Builder with triggers, you need to register the below providers. Check your registration by running the following commands:

Azure CLI

```
az provider show -n Microsoft.VirtualMachineImages -o json | grep
registrationState
az provider show -n Microsoft.KeyVault -o json | grep registrationState
az provider show -n Microsoft.Compute -o json | grep registrationState
az provider show -n Microsoft.Storage -o json | grep registrationState
az provider show -n Microsoft.Network -o json | grep registrationState
az provider show -n Microsoft.ContainerInstance -o json | grep
registrationState
```

If the output doesn't say registered, run the following commands:

Azure CLI

```
az provider register -n Microsoft.VirtualMachineImages
az provider register -n Microsoft.Compute
az provider register -n Microsoft.KeyVault
az provider register -n Microsoft.Storage
az provider register -n Microsoft.Network
az provider register -n Microsoft.ContainerInstance
```

Register the auto image build triggers feature:

Azure CLI

```
az feature register --namespace Microsoft.VirtualMachineImages --name
Triggers
```

Set variables

First, you need to set some variables that you'll repeatedly use in commands.

Azure CLI

```
# Resource group name - ibTriggersTestRG in this example
resourceGroupName=ibTriggersRG
# Datacenter location - West US 2 in this example
location=westus2
# Additional region to replicate the image to - East US in this example
additionalregion=eastus2
# Name of the Azure Compute Gallery - ibTriggersGallery in this example
acgName=ibTriggersGallery
# Name of the image definition to be created - ibTriggersImageDef in this
example
```

```
imageDefName=ibTriggersImageDef
# Name of the Trigger to be created - ibTrigger in this example
ibTriggerName=ibTrigger
# Name of the image template to be created - ibTriggersImageTemplate in this
example
imageTemplateName=ibTriggersImageTemplate
# Reference name in the image distribution metadata
runOutputName=ibTriggersTestRun
# Create a variable for your subscription ID
subscriptionID=$(az account show --query id --output tsv)
```

Create resource group

Now, you need to create a resource group where you can store your image template. Use the following command to make your resource group:

Azure CLI

```
az group create -n $resourceGroupName -l $location
```

Create managed identity for the service

You'll also need to create a managed identity that will be used for the image template (and potentially the Azure Image Builder build VM). In this example, we create a managed identity with "Contributor" access, but you can refine the permissions or role assigned to the managed identity as you like as long as you include the permissions needed for the Azure Image Builder service to function properly.

For more information on the permissions needed for the Azure Image Builder service, see the following documentation: Configure Azure VM Image Builder permissions by using the Azure CLI

For more information on how managed identities can be assigned and used in Azure Image Builder, see the following documentation: VM Image Builder template reference: Identity

Use the following command to create the managed identity that will be used for the image template:

Azure CLI

```
# Create user-assigned identity for VM Image Builder to access the storage
account where the script is stored
identityName=aibBuiUserId$(date +'%s')
az identity create -g $resourceGroupName -n $identityName
```

```
# Get the identity client and principal ID
imgBuilderCliId=$(az identity show -g $resourceGroupName -n $identityName --
query clientId -o tsv)

# Get the user identity URI that's needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$resourceGroupNam
e/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# Grant "Contributor" access to the user-assigned identity
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "Contributor" \
    --scope /subscriptions/$subscriptionID/resourceGroups/$resourceGroupName
```

Create gallery and image definition

To use VM Image Builder with Azure Compute Gallery, you need to have an existing gallery and image definition. VM Image Builder doesn't create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them.

First, create a gallery:

Azure CLI

```
az sig create \
    -g $resourceGroupName \
    --gallery-name $acgName
```

Then, create an image definition:

Azure CLI

```
az sig image-definition create \
   -g $resourceGroupName \
   --gallery-name $acgName \
   --gallery-image-definition $imageDefName \
   --publisher myIbPublisher \
   --offer myOffer \
   --sku 18.04-LTS \
   --os-type Linux
```

Create the image template

Download the example JSON template and configure it with your variables. The following image template uses a Platform Image as its source, but you can change the source to an Azure Compute Gallery image if you'd like to enable automatic image creation anytime there's a new image version in your Azure Compute Gallery.

Azure CLI

```
curl
https://raw.githubusercontent.com/Azure/azvmimagebuilder/main/quickquickstar
ts/9_Setting_up_a_Trigger_with_a_Custom_Linux_Image/helloImageTemplate.json
-o helloImageTemplateforTriggers.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g"
helloImageTemplateforTriggers.json
sed -i -e "s/<rgName>/$resourceGroupName/g"
helloImageTemplateforTriggers.json
sed -i -e "s/<imageDefName>/$imageDefName/g"
helloImageTemplateforTriggers.json
sed -i -e "s/<acgName>/$acgName/g" helloImageTemplateforTriggers.json
sed -i -e "s/<region1>/$location/g" helloImageTemplateforTriggers.json
sed -i -e "s/<region2>/$additionalregion/g"
helloImageTemplateforTriggers.json
sed -i -e "s/<runOutputName>/$runOutputName/g"
helloImageTemplateforTriggers.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g"
helloImageTemplateforTriggers.json
```

Image template requirements:

- The `source` must be either a Platform image or Azure Compute Gallery image (only these two sources are allowed currently)
- If you're using a Platform Image, then the version in the source needs to be `Latest`. For an Azure Compute Gallery image the last part of the resource ID that has the version name needs to be set to `Latest`.
- You can't specify a version if you're distributing the image to an Azure Compute Gallery. The version is automatically incremented.
- When source is set to an Azure Compute Gallery image and distribute is set to an Azure Compute Gallery, the source gallery image and the distribute gallery image can't be the same. The Azure Compute Gallery image definition ID can't be the same for both the source gallery image and the distribute gallery image.
- The image template should have "Succeeded" in the `provisioningState`, meaning the template was created without any issues. If the template isn't provisioned successfully, you won't be able to create a trigger.

After configuring your template use the following command to submit the image configuration to the Azure Image Builder service:

Azure CLI

```
az image builder create -g $resourceGroupName -n $imageTemplateName --image-template helloImageTemplateforTriggers.json
```

You can use the following command to check to make sure the image template was created successfully:

Azure CLI

```
az image builder show --name $imageTemplateName --resource-group $resourceGroupName
```

> **Note**
>
> When running the command above the `provisioningState` should say "Succeeded", which means the template was created without any issues. If the `provisioningState` does not say succeeded, you will not be able to make a trigger use the image template.

Create source trigger

Download the example trigger template and configure it with your variables. The following trigger starts a new image build anytime the source image is updated.

Azure CLI

```
curl https://raw.githubusercontent.com/kof-f/azvmimagebuilder/main/quickquickstarts/9_Setting_up_a_Trigger_with_a_Custom_Linux_Image/trigger.json -o trigger.json
sed -i -e "s/<region1>/$location/g" trigger.json
```

Trigger requirements:

- The location in the trigger needs to be the same as the location in the image template. This is a requirement of the `az resource create` cmdlet.
- We currently support one `kind` of trigger, which is a "SourceImage"
- We only support one "SourceImage" trigger per image. If you already have a "SourceImage" trigger on the image, then you can't create a new one.
- You can't update the `kind` field to another type of trigger. You have to delete the trigger and recreate it or create another trigger with the appropriate configuration.

Use the following command to add the trigger to your resource group.

Azure CLI

```
az image builder trigger create --name $ibTriggerName --resource-group
$resourceGroupName --image-template-name $imageTemplateName --kind
SourceImage
```

You can also use the following command to check that the trigger was created successfully:

Azure CLI

```
az image builder trigger show --name $ibTriggerName --image-template-name
$imageTemplateName --resource-group $resourceGroupName
```

> **Note**
>
> When running the command above the `provisioningState` should say `Succeeded`, which means the trigger was created without any issues. In `status`, the code should say `Healthy` and the message should say `Trigger is active.`

Clean up your resources

Deleting the trigger

Use the following command to delete the trigger:

Azure CLI

```
az image builder trigger delete --name $ibTriggerName --image-template-name
$imageTemplateName --resource-group $resourceGroupName
```

Deleting the image template

Use the following command to delete the image template:

Azure CLI

```
az image builder delete --name $imageTemplateName --resource-group
$resourceGroupName
```

Next steps

Check out the Image Builder template reference for more information.

Create an image and use a user-assigned managed identity to access files in an Azure storage account

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows how to create a customized image by using Azure VM Image Builder. The service uses a user-assigned managed identity to access files in an Azure storage account, and it can achieve blocking unauthenticated access to the storage account.

Azure VM Image Builder supports using scripts and copying files from GitHub, Azure storage accounts, and other locations. If you want to use the locations, they must be externally accessible to VM Image Builder.

In the following example, you'll create two resource groups, one for the custom image and the other to host an Azure storage account that contains a script file. This example simulates a real-life scenario, where you might have build artifacts or image files in various storage accounts. You'll create a user-assigned identity and then grant the identity read permissions on the script file, but you won't allow public access to the file. You'll then use the shell customizer to download and run a script from the storage account.

Create a resource group

1. Because you'll be using some pieces of information repeatedly, create some variables to store that information.

   Console

   ```
   # Image resource group name
   imageResourceGroup=aibmdimsi
   # Storage resource group
   strResourceGroup=aibmdimsistor
   # Location
   location=WestUS2
   # Name of the image to be created
   imageName=aibCustLinuxImgMsi01
   # Image distribution metadata reference name
   runOutputName=u1804ManImgMsiro
   ```

2. Create a variable for your subscription ID:

Console

```
subscriptionID=$(az account show --query id --output tsv)
```

3. Create resource groups for both the image and the script storage:

Console

```
# Create a resource group for the image template
az group create -n $imageResourceGroup -l $location
# Create a resource group for the script storage
az group create -n $strResourceGroup -l $location
```

4. Create a user-assigned identity, and set permissions on the resource group:

   VM Image Builder uses the provided user identity to inject the image into the resource group. In this example, you create an Azure role definition with specific actions for distributing the image. The role definition is then assigned to the user identity.

Console

```
# Create a user-assigned identity for VM Image Builder to access the
storage account where the script is located
identityName=aibBuiUserId$(date +'%s')
az identity create -g $imageResourceGroup -n $identityName

# Get an identity ID
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n
$identityName --query clientId -o tsv)

# Get the user-identity URI, which is needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$imageResour
ceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$ide
ntityName

# Download the preconfigured role definition example
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutio
ns/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o
aibRoleImageCreation.json

# Update the definition
sed -i -e "s/<subscriptionID>/$subscriptionID/g"
aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json

# Create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json
```

```
# Grant the role definition to the user-assigned identity
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "Azure Image Builder Service Image Creation Role" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup
```

5. Create the storage account, and copy the sample script into it from GitHub:

Azure CLI

```
# Script storage account
scriptStorageAcc=aibstorscript$(date +'%s')

# Script container
scriptStorageAccContainer=scriptscont$(date +'%s')

# Script URL
scriptUrl=https://$scriptStorageAcc.blob.core.windows.net/$scriptStorag
eAccContainer/customizeScript.sh

# Create the storage account and blob in the resource group
az storage account create -n $scriptStorageAcc -g $strResourceGroup -l
$location --sku Standard_LRS

az storage container create -n $scriptStorageAccContainer --fail-on-
exist --account-name $scriptStorageAcc

# Copy in an example script from the GitHub repo
az storage blob copy start \
    --destination-blob customizeScript.sh \
    --destination-container $scriptStorageAccContainer \
    --account-name $scriptStorageAcc \
    --source-uri
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickqu
ickstarts/customizeScript.sh
```

6. Give VM Image Builder permission to create resources in the image resource group. The `--assignee` value is the user-identity ID.

Azure CLI

```
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "Storage Blob Data Reader" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$strResourceGroup/provide
rs/Microsoft.Storage/storageAccounts/$scriptStorageAcc/blobServices/def
ault/containers/$scriptStorageAccContainer
```

Modify the example

Download the example JSON file and configure it with the variables you created earlier.

Console

```
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickquickst
arts/7_Creating_Custom_Image_using_MSI_to_Access_Storage/helloImageTemplateM
si.json -o helloImageTemplateMsi.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateMsi.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" helloImageTemplateMsi.json
sed -i -e "s/<region>/$location/g" helloImageTemplateMsi.json
sed -i -e "s/<imageName>/$imageName/g" helloImageTemplateMsi.json
sed -i -e "s%<scriptUrl>%$scriptUrl%g" helloImageTemplateMsi.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateMsi.json
sed -i -e "s%<runOutputName>%$runOutputName%g" helloImageTemplateMsi.json
```

Create the image

1. Submit the image configuration to the VM Image Builder service:

   Azure CLI

   ```
   az resource create \
       --resource-group $imageResourceGroup \
       --properties @helloImageTemplateMsi.json \
       --is-full-object \
       --resource-type Microsoft.VirtualMachineImages/imageTemplates \
       -n helloImageTemplateMsi01
   ```

2. Start the image build:

   Azure CLI

   ```
   az resource invoke-action \
       --resource-group $imageResourceGroup \
       --resource-type  Microsoft.VirtualMachineImages/imageTemplates \
       -n helloImageTemplateMsi01 \
       --action Run
   ```

The build can take about 15 minutes to finish.

Create a VM

1. Create a VM from the image:

Azure CLI

```
az vm create \
--resource-group $imageResourceGroup \
--name aibImgVm00 \
--admin-username aibuser \
--image $imageName \
--location $location \
--generate-ssh-keys
```

2. After the VM has been created, start a Secure Shell (SSH) session with it.

Console

```
ssh aibuser@<publicIp>
```

After the SSH connection is established, you should receive a "Message of the Day" saying that the image was customized:

Output

```
*******************************************************
**            This VM was built from the:            **
**      !! AZURE VM IMAGE BUILDER Custom Image !!    **
**         You have just been Customized :-)         **
*******************************************************
```

Clean up your resources

If you no longer need the resources that were created during this process, you can delete them by running the following code:

Azure CLI

```
az role definition delete --name "$imageRoleDefName"
```azurecli-interactive
az role assignment delete \
    --assignee $imgBuilderCliId \
    --role "$imageRoleDefName" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup
az identity delete --ids $imgBuilderId
az resource delete \
```
```

```
    --resource-group $imageResourceGroup \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n helloImageTemplateMsi01
az group delete -n $imageResourceGroup
az group delete -n $strResourceGroup
```

Next steps

If you have any problems using VM Image Builder, see Troubleshoot Azure VM Image Builder.

What's new in Azure VM Image Builder (AIB)

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article contains all major API changes and feature updates for the Azure VM Image Builder service.

Updates

March 2026

Breaking Change: Virtual Network Default Behavior

After March 31, 2026, new virtual networks in Azure will default to creation of private subnets which can no longer use default outbound access connectivity. This change may affect customers of AIB that specify their own subnets in their image templates (using `subnetId` field or `containerInstanceSubnetId` field.) If the build or validation VMs needs outbound access then the subnet specified in the `subnetId` field must have outbound access enabled. Also, the subnet specified in `containerInstanceSubnetId` field must have outbound access enabled as explained in the template reference. For complete details, see the official update.

Retirement: Azure unmanaged disks

Azure is retiring Azure unmanaged disks. This change affects a subset of AIB customers who use AIB to distribute images as VHDs and then use those VHDs to provision new VMs. After the unmanaged disks retirement, you will still be able to use AIB to create VHD artifacts, but those VHDs will not be able to provision new VMs. For complete details — including scope, timelines, and the recommended mitigation steps — see the official documentation: Migrate your Azure unmanaged disks by March 31, 2026

September 2024

Automatic image creation via triggers is deactivated if the image template build fails multiple times consecutively. This deactivation avoids unnecessary build failures.

You can still manually build the image template. After a manual build succeeds, the automatic triggers are reactivated.

This behavior is the same regardless of which API version you use for the image template resource.

May 2024

Breaking change: Case sensitivity

As of May 21, 2024, VM Image Builder API version 2024-02-01 and later enforces case sensitivity for all fields. The capitalization of letters in your API requests must match exactly with the expected format.

> **Important**
>
> If you're an existing user of VM Image Builder, this change does *not* affect your existing resources. The enforcement of case sensitivity applies only to newly created resources that use API version 2024-02-01 and later. Your existing resources continue to function as expected without any changes.
>
> If you encounter any problems related to case sensitivity, refer to the updated VM Image Builder API documentation for guidance.

Previously, the VM Image Builder API was more forgiving in terms of case. Moving forward, precision is crucial. When you make API calls, ensure that you use the correct capitalization for field names, parameters, and values. For example, if a field is named `vmBoot`, you must use `vmBoot` (not `VMBoot` or `vmboot`).

If you send an API request to VM Image Builder API version 2024-02-01 or later with incorrect case or unrecognized fields, the service rejects it. You receive an error response indicating that the request is invalid. The error looks something like this example:

```
Unmarshalling entity encountered error: unmarshalling type *v2024_02_01.ImageTemplate: struct field Properties: unmarshalling type *v2024_02_01.ImageTemplateProperties: struct field Optimize: unmarshalling type *v2024_02_01.ImageTemplatePropertiesOptimize: unmarshalling type *v2024_02_01.ImageTemplatePropertiesOptimize, unknown field \"vmboot\". There is an issue with the syntax with the JSON template you are submitting. Please check the JSON template for syntax and grammar. For more information on the syntax and grammar of the JSON template, visit http://aka.ms/azvmimagebuildertmplref.
```

The error message mentions an "unknown field" and directs you to the official documentation: Create an Azure VM Image Builder Bicep or Azure Resource Manager JSON template.

> **Note**
>
> When you're making API calls to the VM Image Builder service, always reference the Swagger documentation. This documentation serves as the definitive source of truth for VM Image Builder API specifications. Although the public documentation was updated to include the proper capitalization and field names ahead of the API release, the Swagger definition contains precise details about each VM Image Builder API. These details help ensure that you're making calls to the service correctly.

The following documentation changes were made to match the field names in API version 2024-02-01.

In the Create an Azure VM Image Builder Bicep or Azure Resource Manager JSON template documentation:

- Fields updated:
  - Replaced several mentions of `vmboot` with `vmBoot`.
  - Replaced one mention of `imageVersionID` with `imageVersionId`.
- Field removed:
  - `apiVersion`: We recommend avoiding the inclusion of this field in your requests because it's not explicitly specified in the API. Including it in your JSON template might lead to errors in your image build.

In the Azure VM Image Builder networking options documentation:

- Field updated:
  - Replaced one mention of `VirtualNetworkConfig` with `vnetConfig`.
- Fields removed:
  - `subnetName` in the `vnetConfig` property: This field is deprecated. The new field is `subnetId`.
  - `resourceGroupName` in the `vnetConfig` property: This field is deprecated. The new field is `subnetId`.

Pinning to an older VM Image Builder API version

If you want to avoid making changes to the properties in your image templates due to the new case-sensitivity rules, you have the option to pin your Azure VM Image Builder API calls to a

previous API version. This pinning allows you to continue using the familiar behavior without any modifications.

> **ⓘ Important**
>
> Pinning to an older VM Image Builder API version can provide compatibility with your existing templates, but we don't recommend it due to the following factors:
>
> - Older API versions might eventually be deprecated.
> - By pinning to an older API version, you miss the latest features and improvements introduced in newer versions. These enhancements often improve performance, security, and functionality.

To ensure compatibility with your existing templates when you're creating or updating an image template, specify the desired API version by including the `api-version` parameter in your call to the service. For example:

HTTP

HTTP

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.VirtualMachineImages/imageTemplates/{imageTemplateName}?api-version=2022-07-01
```

Testing your code

After you pin to the older API version, test your code to verify that it behaves as expected. Ensure that your existing templates continue to function correctly.

November 2023

VM Image Builder is enabling Isolated Image Builds via Azure Container Instances in a phased manner. The rollout is expected finish by early 2024. Your existing image templates continue to work, and there's no change in the way you create or build new image templates.

You might observe a different set of transient Azure resources appearing temporarily in the staging resource group. It doesn't affect your actual builds or the way you interact with VM Image Builder. For more information, see Isolated Image Builds.

To use Isolated Image Builds, make sure that:

- Your subscription is registered for the `Microsoft.ContainerInstance` provider.
- There are no policies blocking deployment of Azure Container Instances resources.
- Quota is available for Azure Container Instances resources.

April 2023

New portal functionality was added for VM Image Builder. Search for **Image Templates** in the Azure portal, and then select **Create**. You can also use this template configuration to get started with building and validating custom images inside the portal.

API releases

Version 2024-02-01

Improvements

- You can use the new `autoRun` property to run the image build on template creation or update. For more information, see Properties: autoRun.
- You can use the new `managedResourceTags` property to apply tags to the resources that the VM Image Builder service creates in the staging resource group during the image build. For more information, see Properties: managedResourceTags.
- You can use the new `containerInstanceSubnetId` property to specify a subnet on which Azure Container Instances will be deployed for Isolated Image Builds. You can specify this field only if you specify `subnetId`. This field must be on the same virtual network as the subnet specified in `subnetId`. For more information, see Bring your own build VM subnet and bring your own Container Instances subnet.
- This version adds support for updating the `vmProfile` property, including the following fields:
  - `vmSize`
  - `osDiskSizeGB`
  - `userAssignedIdentities`
  - `vnetConfig`
    - `subnetId`
    - `containerInstanceSubnetId`

For more information on the `vmProfile` property, see vmProfile.

Changes

API version 2024-02-01 introduces a breaking change that enforces case sensitivity for all fields. The capitalization of letters in your API requests must match exactly with the expected format. If you send an API request to VM Image Builder API version 2024-02-01 or later with an incorrect case or unrecognized fields, the service rejects it. You receive an error response indicating that the request is invalid. For more information, see Breaking change: Case sensitivity in this article.

Version 2023-07-01

Changes

The new `errorHandling` property gives you more control over how errors are handled during the image building process. For more information, see errorHandling.

Version 2022-07-01

Improvements

- This version adds support to use the latest image version stored in Azure Compute Gallery as the source for the image template.
- This version adds `versioning` to support generating version numbers for image distributions. For more information, see Properties: versioning.
- This version adds support for per-region configuration when you're distributing to Azure Compute Gallery. For more information, see Distribute: targetRegions.
- This version adds a new `File` validation type. For more information, see Properties: validate.
- You can now distribute virtual hard disks (VHDs) to a custom blob or container in a custom storage account. For more information, see Distribute: VHD.
- This version adds support for using a direct shared gallery image as the source for the image template.

Changes

- `replicationRegions` is now deprecated for gallery distributions. Instead, use gallery-replication-regions.

- You can now distribute VHDs to a custom blob or container in a custom storage account.
- This version adds the `targetRegions` array, which applies only to the `SharedImage` type of distribution. For more information on `targetRegions`, see Store and share resources in Azure Compute Gallery.
- This version adds support for using a direct shared gallery image as the source for the image template. Direct shared galleries are currently in preview.
- Triggers are now available in preview to set up automatic image builds. For more information, see How to enable automatic image creation with Azure VM Image Builder triggers.

Version 2022-02-14

Improvements

- Validation support
  - Shell (Linux): Script or inline
  - PowerShell (Windows): Script or inline, run elevated, run as system
  - Source-validation-only mode
- Customized support for staging resource groups

Version 2021-10-01

Breaking change

API version 2021-10-01 introduces a change to the error schema that will be part of every future API release. If you have any Azure VM Image Builder automations, be aware of the new error output when you switch to API version 2021-10-01 or later.

We recommend, after you switch to the latest API version, that you don't revert to an earlier version. If you revert, you'll have to change your automation again to produce the earlier error schema. We don't expect the error schema to change again in future releases.

Error output for version 2020-02-14 and earlier

```
{
  "code": "ValidationFailed",
  "message": "Validation failed: 'ImageTemplate.properties.source': Field 'imageId'
has a bad value:
'/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsoft
```

```
.Compute/images/imageName'. Please review  http://aka.ms/azvmimagebuildertmplref
for details on fields requirements in the Image Builder Template."
}
```

Error output for version 2021-10-01 and later

```
{
  "error": {
    "code": "ValidationFailed",
    "message": "Validation failed: 'ImageTemplate.properties.source': Field
'imageId' has a bad value:
'/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsoft
.Compute/images/imageName'. Please review  http://aka.ms/azvmimagebuildertmplref
for details on fields requirements in the Image Builder Template."
  }
}
```

Improvements

- Added support for managed identities for the build VM.
- Added support for customization of proxy VM size.

Version 2020-02-14

Improvements

- Added support for creating images from the following sources:
  - Managed image
  - Azure Compute Gallery
  - Platform Image Repository (including Platform Image Purchase Plan)
- Added support for the following customizations:
  - Shell (Linux): Script or inline
  - PowerShell (Windows): Script or inline, run elevated, run as system
  - File (Linux and Windows)
  - Windows restart (Windows)
  - Windows Update (Windows): Search criteria, filters, and update limit
- Added support for the following distribution types:
  - VHD
  - Managed image
  - Azure Compute Gallery

- Added support for customers to use their own virtual network.
- Added support for customers to customize the build VM (VM size, operating system disk size).
- Added support for user-assigned managed identities (for customize/distribute steps).
- Added support for Generation 2 images.

Preview API

The following API is deprecated but still supported:

- Version 2019-05-01-preview

Troubleshoot Azure VM Image Builder

Article • 05/12/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Use this article to troubleshoot and resolve common problems that you might encounter when you're using Azure VM Image Builder.

VM Image Builder failures can happen in two areas:

- During image template submission
- During image building

Prerequisites

These prerequisites are for creating a build:

- The VM Image Builder service communicates to the build virtual machine (VM) by using Windows Remote Management (WinRM) or Secure Shell (SSH). *Don't* disable these settings as part of the build.

- VM Image Builder creates resources in the staging resource group as part of the builds. The exact list of resources depends on the network configuration that the image template specifies. Be sure to verify that Azure Policy doesn't prevent VM Image Builder from creating or using necessary resources.
  - Create an `IT_` resource group.
  - Create a storage account without a firewall.
  - Deploy Azure Container Instances.
  - Deploy Azure Virtual Network resources (and subnets within them).
  - Deploy Azure Private Endpoint resources.
  - Deploy Azure Files.

- Ensure that Azure Policy does not install unintended features on the build VM or other staging resources, such as Azure extensions or tag modifications.

- Ensure that VM Image Builder has the correct permissions to read/write images and to connect to the storage account. For more information, review the permissions documentation for the Azure CLI or Azure PowerShell.

- VM Image Builder fails the build if the scripts or inline commands fail with errors (nonzero exit codes). Ensure that you tested the custom scripts and verified that they run without error (exit code `0`) or require user input. For more information, see Create an Azure Virtual Desktop image by using VM Image Builder and PowerShell.

- Ensure that your subscription has a sufficient quota for Azure Container Instances.

  Each image build might deploy up to one temporary Azure Container Instances resource (of four standard cores) in the staging resource group. These resources are required for Isolated Image Builds.

> **Note**
>
> CIS Hardened Images (Linux or Windows) on Azure Marketplace, managed by the Center for Internet Security (CIS), can cause build failures with the VM Image Builder service due to their configurations. For instance:
>
> - CIS Hardened Images for Windows might disrupt WinRM connectivity, a prerequisite for VM Image Builder builds.
> - CIS Hardened Images for Linux can fail due to `chmod +x` permission issues.

Troubleshoot image template submission errors

Image template submission errors are returned at submission only. No error log exists for image template submission errors. If there's an error during submission, you can return the error by checking the status of the template. Specifically, review `ProvisioningState` and `ProvisioningErrorMessage`/`provisioningError`.

Here's the command for the Azure CLI:

Azure CLI

```
az image builder show --name $imageTemplateName  --resource-group
$imageResourceGroup
```

Here's the command for Azure PowerShell. To use Azure PowerShell, you need to install the VM Image Builder PowerShell modules.

Azure PowerShell

```
Get-AzImageBuilderTemplate -ImageTemplateName  <imageTemplateName> -
ResourceGroupName <imageTemplateResourceGroup> | Select-Object ProvisioningState,
ProvisioningErrorMessage
```

Here's the error output for version 2020-02-14 and earlier:

Output

```
{
  "code": "ValidationFailed",
  "message": "Validation failed: 'ImageTemplate.properties.source': Field
'imageId' has a bad value:
'/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsof
t.Compute/images/imageName'. Please review  http://aka.ms/azvmimagebuildertmplref
for details on fields requirements in the Image Builder Template."
}
```

Here's the error output for version 2021-10-01 and later:

Output

```
{
  "error": {
    "code": "ValidationFailed",
    "message": "Validation failed: 'ImageTemplate.properties.source': Field
'imageId' has a bad value:
'/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsof
t.Compute/images/imageName'. Please review  http://aka.ms/azvmimagebuildertmplref
for details on fields requirements in the Image Builder Template."
  }
}
```

> **ⓘ Important**
>
> API version 2021-10-01 introduces a change to the error schema that will be part of every future API release. If you have any Azure VM Image Builder automations, be aware of the new error output when you switch to API version 2021-10-01 or later.
>
> We recommend, after you switch to the latest API version, that you don't revert to an earlier version. If you revert, you'll have to change your automation again to produce the earlier error schema. We don't expect the error schema to change again in future releases.

The following sections present problem resolution guidance for common image template submission errors.

Update or upgrade of image templates is currently not supported

Error

Output

```
'Conflict'. Details: Update/Upgrade of image templates is currently not supported
```

Cause

The template already exists.

Solution

If you submit an image configuration template and the submission fails, a failed template artifact still exists. Delete the failed template.

Assigned managed identity on an image template can't be used

Error

Output

```
The assigned managed identity cannot be used. Please remove the existing one and
re-assign a new identity. For more troubleshooting steps go to
https://aka.ms/azvmimagebuilderts.
```

Cause

There are cases where a created managed identity assigned to the image template can't be used.

One possible cause is that the VM Image Builder template uses a customer-provided staging resource group, and the managed identity is deleted before the image template is deleted. (This is a staging resource group scenario.)

Solution

Use the Azure CLI to reset the managed identity on the image template. Be sure to update Azure CLI to the 2.45.0 version or later.

Confirm the managed identity from the target VM Image Builder template:

Azure CLI

```
az image builder identity show -g <template resource group> -n <template name>
```

Remove the managed identity from the target VM Image Builder template:

Azure CLI

```
az image builder identity remove -g <template resource group> -n <template name> --user-assigned <identity resource id>
```

Assign a new identity to the target VM Image Builder template:

Azure CLI

```
az image builder identity assign -g <template rg> -n <template name> --user-assigned <identity resource id>
```

For more information about configuring permissions, see Configure VM Image Builder permissions by using the Azure CLI or Configure VM Image Builder permissions by using PowerShell.

Assigned managed identity isn't authorized to access a resource

Error

Output

```
Not authorized to access the resource: <resource-not-able-to-access>. Please check the user assigned identity has the correct permissions. For more details, go to https://aka.ms/azvmimagebuilderts.
```

Cause

The created managed identity assigned to the image template doesn't have all permissions to access the resource shared in the error message.

Solution

Confirm the managed identity from the target VM Image Builder template:

Azure CLI

```
az image builder identity show -g <template resource group> -n <template name>
```

Review the role assignments for the identity:

Azure CLI

```
az role assignment list --assignee <identity_client_id_or_principal_id>
```

Assign the required role. If necessary, create your role with the required permissions.

For more information about configuring permissions, see Configure VM Image Builder permissions by using the Azure CLI or Configure VM Image Builder permissions by using PowerShell.

Resource operation finished with a terminal provisioning state of "Failed"

Error

Output

```
Microsoft.VirtualMachineImages/imageTemplates 'helloImageTemplateforSIG01' failed
with message '{
  "status": "Failed",
  "error": {
    "code": "ResourceDeploymentFailure",
    "message": "The resource operation completed with terminal provisioning state
'Failed'.",
    "details": [
      {
        "code": "InternalOperationError",
        "message": "Internal error occurred."
```

Cause

In most cases, the error about resource deployment failure occurs because of missing permissions. A conflict with the staging resource group might also cause this error.

Solution

Depending on your scenario, VM Image Builder might need permissions to:

- The source image or Azure Compute Gallery (formerly Shared Image Gallery) resource group.
- The distribution image or Azure Compute Gallery resource.
- The storage account, container, or blob that the `File` customizer is accessing.

Also, ensure that the staging resource group name is uniquely specified for each image template.

For more information about configuring permissions, see Configure VM Image Builder permissions by using the Azure CLI or Configure VM Image Builder permissions by using PowerShell.

Error occurs with getting a managed image

Error

Output

```
Build (Managed Image) step failed: Error getting Managed Image
'/subscriptions/.../providers/Microsoft.Compute/images/mymanagedmg1': Error
getting managed image (...): compute.
ImagesClient#Get: Failure responding to request: StatusCode=403 -- Original Error:
autorest/azure: Service returned an error.
Status=403 Code="AuthorizationFailed" Message="The client '......' with object id
'......' doesn't have authorization to perform action
'Microsoft.Compute/images/read' over scope
```

Cause

Permissions are missing.

Solution

Depending on your scenario, VM Image Builder might need permissions to:

- The source image or Azure Compute Gallery resource group.
- The distribution image or Azure Compute Gallery resource.
- The storage account, container, or blob that the `File` customizer is accessing.

For more information about configuring permissions, see Configure VM Image Builder permissions by using the Azure CLI or Configure VM Image Builder permissions by using PowerShell.

Build step failed for the image version

Error

Output

```
Build (Shared Image Version) step failed for Image Version
'/subscriptions/.../providers/Microsoft.Compute/galleries/.../images/...
/versions/0.23768.4001': Error getting Image Version
'/subscriptions/.../resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/
.../images/.../versions/0.23768.4001': Error getting image version '...
:0.23768.4001': compute.GalleryImageVersionsClient#Get: Failure responding to
request: StatusCode=404 -- Original Error: autorest/azure: Service returned an
error.
Status=404 Code="ResourceNotFound" Message="The Resource
'Microsoft.Compute/galleries/.../images/.../versions/0.23768.4001' under resource
group '<rgName>' was not found."
```

Cause

VM Image Builder can't locate the source image.

Solution

Ensure that the source image is correct and exists in the location of VM Image Builder.

Error occurs with downloading an external file to a local file

Error

Output

```
Downloading external file (<myFile>) to local file (xxxxx.0.customizer.fp)
[attempt 1 of 10] failed: Error downloading '<myFile>' to
'xxxxx.0.customizer.fp'..
```

Cause

The file name or location is incorrect, or the location isn't reachable.

Solution

Ensure that the file is reachable. Verify that the name and location are correct.

Certain file repositories might use unsupported cipher suites and cause download errors with VM Image Builder. Store files and scripts in an Azure storage account to help ensure secure cipher suites and accessibility by VM Image Builder. For more information on how to store your files in Azure storage accounts, see Storage account overview.

Authorization error occurs with creating a disk

The VM Image Builder build fails with an authorization error that looks like the following example.

Error

Output

```
Attempting to deploy created Image template in Azure fails with an 'The client
'6df325020-fe22-4e39-bd69-10873965ac04' with object id '6df325020-fe22-4e39-bd69-
10873965ac04' does not have authorization to perform action
'Microsoft.Compute/disks/write' over scope
'/subscriptions/<subscriptionID>/resourceGroups/<resourceGroupName>/providers/Micr
osoft.Compute/disks/proxyVmDiskWin_<timestamp>' or the scope is invalid. If access
was recently granted, please refresh your credentials.'
```

Cause

This error happens when you try to specify a preexisting resource group and virtual network to the VM Image Builder service with a Windows source image.

Solution

You need to assign the Contributor role to the resource group for the service principal that corresponds to VM Image Builder first-party app. Use the following Azure CLI commands or Azure portal instructions.

First, validate that the service principal is associated with the VM Image Builder first-party app by using the following Azure CLI command:

Azure CLI

```
az ad sp show --id {servicePrincipalName, or objectId}
```

Then, to implement this solution by using the Azure CLI, use the following command:

Azure CLI

```
az role assignment create -g {ResourceGroupName} --assignee {AibrpSpOid} --role
Contributor
```

To implement this solution in the portal, follow the instructions in Assign Azure roles using the Azure portal:

- For Step 1: Identify the needed scope, the needed scope is your resource group.
- For Step 3: Select the appropriate role, the role is Contributor.
- For Step 4: Select who needs access, select the **Azure Virtual Machine Image Builder** member.
- In Step 7: Assign role, you assign the role.

Troubleshoot build failures

For image build failures, get the error from `lastRunStatus`, and then review the details in the `customization.log` file.

Azure CLI

```
az image builder show --name $imageTemplateName  --resource-group
$imageResourceGroup
```

Azure PowerShell

```
Get-AzImageBuilderTemplate -ImageTemplateName  <imageTemplateName> -
ResourceGroupName <imageTemplateResourceGroup> | Select-Object LastRunStatus,
LastRunStatusMessage
```

Customization log

Access live logs during image build

To effectively monitor the progress of your image build, you can access the live logs that VM Image Builder generates in Azure Container Instances. These logs provide real-time insights into the build process. They help you identify any problems or confirm that the build is proceeding as expected.

To locate and view the live logs:

1. Start the image build process.
2. Go to the Azure portal and select **Resource Groups**. Filter by the subscription where you initiated the image build.
3. Find and select the staging resource group that's associated with the image build. This resource group contains the build resources for the VM Image Builder service. For more information on the staging resource group, see Properties: stagingResourceGroup.
4. Within this resource group, look for the resource named `vmimagebuilder-build-container-**********`. If it's not visible, wait a few minutes and refresh the page.
5. On the left pane, under **Settings**, select **Containers**.
6. Go to the **Logs** tab to view the live logs during the image build process.

If you don't see any logs, try refreshing the container after a few minutes.

Download the customization and/or validation log after image build

After the image build finishes, the customization and validation logs are stored in a container within the storage account in the staging resource group that the VM Image Builder service created. For more information on the staging resource group, see Properties: stagingResourceGroup.

To locate and download the `customization.log` or `validation.log` file:

1. In the Azure portal, go to the relevant storage account by filtering for storage accounts within the staging resource group that the VM Image Builder service created.
2. Under the storage account, go to **Data Storage**.
3. Select the **Container** option, and then choose the `packerlogs` container.
4. Within the `packerlogs` container, multiple folders appear if the image build ran multiple times. These folders are arranged from the oldest build to the most recent. Select the folder that corresponds to the build that you're interested in.
5. Inside the selected folder, select the `customization.log` and/or `validation.log` file, and then select **Download** to download its contents.

Stages of the customization log

The log is verbose. It covers the image build, including any problems with the image distribution, such as Azure Compute Gallery replication. These problems are surfaced in the error message of the image template status.

The `customization.log` file includes the following stages:

1. *Deploy the build VM and dependencies by using Azure Resource Manager templates to the `IT_` staging resource group*. This stage includes multiple `POST` requests to the VM Image Builder resource provider:

   Output

   ```
   Azure request method="POST"
   request="https://management.azure.com/subscriptions/<subID>/resourceGroups/IT
   _aibImageRG200_window2019VnetTemplate01_dec33089-1cc3-cccc-cccc-
   ccccccc/providers/Microsoft.Storage/storageAccounts
   ..
   PACKER OUT ==> azure-arm: Deploying deployment template ...
   ..
   ```

2. *Get the status of the deployments*. This stage includes the status of each resource deployment:

   Output

   ```
   PACKER ERR 2020/04/30 23:28:50 packer: 2020/04/30 23:28:50 Azure request
   method="GET"
   request="https://management.azure.com/subscriptions/<subID>/resourcegroups/IT
   _aibImageRG200_window2019VnetTemplate01_dec33089-1cc3-4505-ae28-
   6661e43fac48/providers/Microsoft.Resources/deployments/pkrdp51lc0339jg/operat
   ionStatuses/08586133176207523519?[REDACTED]" body=""
   ```

3. *Connect to the build VM*.

   In Windows, VM Image Builder connects by using WinRM:

   Output

   ```
   PACKER ERR 2020/04/30 23:30:50 packer: 2020/04/30 23:30:50 Waiting for WinRM,
   up to timeout: 10m0s
   ..
   PACKER OUT     azure-arm: WinRM connected.
   ```

   In Linux, VM Image Builder connects by using SSH:

   Output

```
PACKER OUT ==> azure-arm: Waiting for SSH to become available...
PACKER ERR 2019/12/10 17:20:51 packer: 2020/04/10 17:20:51 [INFO] Waiting for
SSH, up to timeout: 20m0s
PACKER OUT ==> azure-arm: Connected to SSH!
```

4. *Run customizations*. When customizations run, you can identify them by reviewing the `customization.log` file. Search for `(telemetry)`:

```text
(telemetry) Starting provisioner windows-update
(telemetry) ending windows-update
(telemetry) Starting provisioner powershell
(telemetry) ending powershell
(telemetry) Starting provisioner file
(telemetry) ending file
(telemetry) Starting provisioner windows-restart
(telemetry) ending windows-restart

(telemetry) Finalizing. - This means the build has finished
```

5. *Deprovision*. VM Image Builder adds a hidden customizer. This step is responsible for preparing the VM for deprovisioning. In Windows, it runs `Sysprep` (by using `c:\DeprovisioningScript.ps1`). In Linux, it runs `waagent-deprovision` (by using `/tmp/DeprovisioningScript.sh`).

   For example:

```text
PACKER ERR 2020/03/04 23:05:04 [INFO] (telemetry) Starting provisioner
powershell
PACKER ERR 2020/03/04 23:05:04 packer: 2020/03/04 23:05:04 Found command: if(
TEST-PATH c:\DeprovisioningScript.ps1 ){cat c:\DeprovisioningScript.ps1} else
{echo "Deprovisioning script [c:\DeprovisioningScript.ps1] could not be
found. Image build may fail or the VM created from the Image may not boot.
Please make sure the deprovisioning script is not accidentally deleted by a
Customizer in the Template."}
```

6. *Clean up*. After the build finishes, the VM Image Builder resources are deleted:

```text
PACKER ERR ==> azure-arm: Deleting individual resources ...
...
PACKER ERR 2020/02/04 02:04:23 packer: 2020/02/04 02:04:23 Azure request
method="DELETE"
```

```
request="https://management.azure.com/subscriptions/<subId>/resourceGroups/IT
_aibDevOpsImg_t_vvvvvvv_yyyyyy-de5f-4f7c-92f2-
xxxxxxxx/providers/Microsoft.Network/networkInterfaces/pkrnijamvpo08eo?
[REDACTED]" body=""
...
PACKER ERR ==> azure-arm: The resource group was not created by Packer, not
deleting ...
```

Troubleshoot script or inline customization

The following tips can help you troubleshoot script or inline customization:

- Test the code before you supply it to VM Image Builder.
- Ensure that Azure Policy and Azure Firewall allow connectivity to remote resources.
- Send output comments to the console by using `Write-Host` or `echo`. Doing so lets you search the `customization.log` file.

Troubleshoot common build errors

Template deployment failed because of a policy violation

Error

text

```
{
  "statusCode": "BadRequest",
  "serviceRequestId": null,
  "statusMessage": "{\"error\":
{\"code\":\"InvalidTemplateDeployment\",\"message\":\"The template deployment
failed because of policy violation. Please see details for more
information.\",\"details\":[{\"code\":\"RequestDisallowedByPolicy\",\"target\":\"
<target_name>\",\"message\":\"Resource '<resource_name>' was disallowed by policy.
Policy identifiers: '[{\\\"policyAssignment\\\":{\\\"name\\\":\\\"[Initiative]
KeyVault
(Microsoft.KeyVault)\\\",\\\"id\\\":\\\"/providers/Microsoft.Management/management
Groups/<managementGroup_name>/providers/Microsoft.Authorization/policyAssignments/
Microsoft.KeyVault\\\"},\\\"policyDefinition\\\":{\\\"name\\\":\\\"Azure Key Vault
should disable public network
access\\\",\\\"id\\\":\\\"/providers/Microsoft.Management/managementGroups/<manage
mentGroup_name>/providers/Microsoft.Authorization/policyDefinitions/KeyVault.disab
lePublicNetworkAccess_deny_deny\\\"},\\\"policySetDefinition\\\":
{\\\"name\\\":\\\"[Initiative] KeyVault
(Microsoft.KeyVault)\\\",\\\"id\\\":\\\"/providers/Microsoft.Management/management
Groups/<managementGroup_name>/providers/Microsoft.Authorization/policySetDefinitio
ns/Microsoft.KeyVault\\\"}}]'.\",\"additionalInfo\":
```

```
[{\"type\":\"PolicyViolation\"}]}]}}",
  "eventCategory": "Administrative",
  "entity":
"/subscriptions/<subscription_ID>/<resourcegroups>/<resourcegroupname>/providers/M
icrosoft.Resources/deployments/<deployment_name>",
  "message": "Microsoft.Resources/deployments/validate/action",
  "hierarchy": "
<subscription_ID>/<resourcegroupname>/<policy_name>/<managementGroup_name>/<deploy
ment_ID>"
}
```

Cause

The preceding policy violation error is a result of using an Azure key vault with public access disabled. At this time, VM Image Builder doesn't support this configuration.

Solution

You must create the key vault with public access enabled.

Packer build command fails

Error

text

```
  "provisioningState": "Succeeded",
  "lastRunStatus": {
   "startTime": "2020-04-30T23:24:06.756985789Z",
   "endTime": "2020-04-30T23:39:14.268729811Z",
   "runState": "Failed",
   "message": "Failed while waiting for packerizer: Microservice has failed:
Failed while processing request: Error when executing packerizer: Packer build
command has failed: exit status 1. During the image build, a failure has occurred,
please review the build log to identify which build/customization step failed. For
more troubleshooting steps go to https://aka.ms/azvmimagebuilderts. Image Build
log location: https://xxxxxxxxxx.blob.core.windows.net/packerlogs/xxxxxxx-xxxx-
xxxx-xxxx-xxxxxxxx/customization.log. OperationId: xxxxxx-5a8c-4379-xxxx-
8d85493bc791. Use this operationId to search packer logs."
```

Cause

The failure of a packer build command is a customization failure.

Solution

Review the log to locate customizer failures. Search for `(telemetry)`.

For example:

```
text

(telemetry) Starting provisioner windows-update
(telemetry) ending windows-update
(telemetry) Starting provisioner powershell
(telemetry) ending powershell
(telemetry) Starting provisioner file
(telemetry) ending file
(telemetry) Starting provisioner windows-restart
(telemetry) ending windows-restart

(telemetry) Finalizing. - This means the build has finished
```

Deployment fails due to timeout

Error

```
text

Deployment failed. Correlation ID: xxxxx-xxxx-xxxx-xxxx-xxxxxxxxx. Failed in
building/customizing image: Failed while waiting for packerizer: Timeout waiting
for microservice to complete: 'context deadline exceeded'
```

Cause

The build exceeded the timeout. This error appears in `lastRunStatus`.

Solution

1. Review the `customization.log` file. Identify the last customizer to run. Search for `(telemetry)`, starting from the bottom of the log.

2. Check script customizations. The customizations might not be suppressing user interaction for commands, such as `quiet` options. For example, `apt-get install -y` results in the script execution waiting for user interaction.

3. If you're using the `File` customizer to download artifacts greater than 20 MB, see the workarounds section.

4. Review errors and dependencies in the script that might cause the script to wait.

5. If you expect that the customizations need more time, increase the value of buildTimeoutInMinutes. The default is 4 hours.

6. If you have resource-intensive actions, such as downloading gigabytes of files, consider the size of the underlying build VM.

   The service uses a Standard_D1_v2 VM. The VM has one vCPU and 3.5 GB of memory. If you're downloading 50 GB, you'll likely exhaust the VM resources and cause communication failures between VM Image Builder and the build VM. Retry the build with a larger-memory VM by setting VM_size.

File download time is long

Error

text

```
[086cf9c4-0457-4e8f-bfd4-908cfe3fe43c] PACKER OUT

[086cf9c4-0457-4e8f-bfd4-908cfe3fe43c] PACKER OUT
```

Cause

The `File` customizer is downloading a large file.

Solution

The `File` customizer is suitable only for small (less than 20 MB) file downloads. For larger file downloads, use a script or inline command. For example, in Linux, you can use `wget` or `curl`. In Windows, you can use `Invoke-WebRequest`.

Windows restart continually fails with error code 1190

Error

```

Cause

The Windows Update step is declared prematurely in images based on Windows Server 2016.

Solution

Increase `restartTimeout` from 15 minutes to 30 minutes.

Error occurs with waiting for Azure Compute Gallery

Error

```
text
```

```
Deployment failed. Correlation ID: XXXXXX-XXXX-XXXXXX-XXXX-XXXXXX. Failed in
distributing 1 images out of total 1: {[Error 0] [Distribute 0] Error publishing
MDI to Azure Compute
Gallery:/subscriptions/<subId>/resourceGroups/xxxxxx/providers/Microsoft.Compute/g
alleries/xxxxx/images/xxxxxx, Location:eastus. Error: Error returned from SIG
client while publishing MDI to Azure Compute Gallery for dstImageLocation: eastus,
dstSubscription: <subId>, dstResourceGroupName: XXXXXX, dstGalleryName: XXXXXX,
dstGalleryImageName: XXXXXX. Error: Error waiting on Azure Compute Gallery future
for resource group: XXXXXX, gallery name: XXXXXX, gallery image name:
XXXXXX.Error: Future#WaitForCompletion: context has been cancelled: StatusCode=200
-- Original Error: context deadline exceeded}
```

Cause

VM Image Builder timed out while waiting for the image to be added and replicated to Azure Compute Gallery.

If the image is being injected into the gallery, you can assume that the image build was successful. However, the overall process failed because VM Image Builder was waiting for Azure Compute Gallery to complete the replication.

Even though the build failed, the replication continues. You can get the properties of the image version by checking the distribution `runOutput`:

Azure CLI

```
$runOutputName=<distributionRunOutput>
az resource show \
    --ids
"/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Micro
soft.VirtualMachineImages/imageTemplates/$imageTemplateName/runOutputs/$runOutputN
ame"  \
    --api-version=2020-02-14
```

Solution

Increase the value of `buildTimeoutInMinutes`.

Information events show low Windows resources

unexpected EOF
[45f485cf-5a8c-4379-9937-8d85493bc791] PACKER OUT
```

Cause

The cause is resource exhaustion. This problem commonly happens when Windows Update runs with the default build VM size, D1_V2.

Solution

Increase the build VM size.

Build finished but no artifacts were created

Warning

was not found.\""
  },
```

Cause

Permissions are missing.

Solution

Recheck that VM Image Builder has all the permissions that it requires.

For more information about configuring permissions, see Configure VM Image Builder permissions by using the Azure CLI or Configure VM Image Builder permissions by using PowerShell.

There's a Sysprep timing problem

[922bdf36-b53c-4e78-9cd8-6b70b9674685] PACKER OUT ==> azure-arm: The resource
group was not created by Packer, deleting individual resources ...
[922bdf36-b53c-4e78-9cd8-6b70b9674685] PACKER ERR ==> azure-arm: The resource
group was not created by Packer, deleting individual resources ...
```

Cause

The D1_V2 VM size might be the reason for the timing problem. If customizations are limited and are run in less than three seconds, VM Image Builder runs `Sysprep` commands to deprovision. When VM Image Builder deprovisions, the `Sysprep` command checks for

`WindowsAzureGuestAgent`, which might not be fully installed and might cause the timing problem.

Solution

To avoid the timing problem, you can increase the VM size or add a 60-second PowerShell sleep customization.

Azure Container Instances provider is unregistered

Error

```text
Azure Container Instances provider not registered for your subscription.
```

Cause

Your template subscription doesn't have the Azure Container Instances provider registered.

Solution

Register the Azure Container Instances provider for your template subscription, and add one of the following commands:

- Azure CLI: `az provider register -n Microsoft.ContainerInstance`
- Azure PowerShell: `Register-AzResourceProvider -ProviderNamespace Microsoft.ContainerInstance`

Subscription exceeded the Azure Container Instances quota

Error

```text
Azure Container Instances quota exceeded
```

Cause

Your subscription doesn't have enough Azure Container Instances quota for VM Image Builder to successfully build an image.

Solution

You can take the following actions to make Azure Container Instances quota available for VM Image Builder:

- Look up other usage of Azure Container Instances in your subscription. Remove any unneeded instances to make quota available for VM Image Builder.
- VM Image Builder deploys Azure Container Instances only temporarily during a build. These instances are deleted after the build finishes.

  If too many concurrent image builds are running in your subscription, you can consider delaying some of the image builds. This delay reduces concurrent usage of Azure Container Instances in your subscription.

  If your image templates are set up for automatic image builds via triggers, VM Image Builder automatically retries such failed builds.
- If the current Azure Container Instances limits for your subscription are too low to support your image-building scenarios, you can request an increase in your Azure Container Instances quota.

> **Note**
>
> Azure Container Instances resources are required for **Isolated Image Builds**.

Too many Azure Container Instances resources are deployed within a period of time

Error

"Too many Azure Container Instances deployed within a period of time."

Cause

Your subscription doesn't have enough Azure Container Instances quota for VM Image Builder to successfully build images concurrently.

Solution

You can try these solutions:

- Retry your failed builds in a less concurrent manner.
- If the current Azure Container Instances limits for your subscription are too low to support your image-building scenarios, you can request an increase in your Azure Container Instances quota.

Isolated Image Builds feature causes a failure

Error

VM Image Builder builds are failing due to Isolated Image Builds.

Cause

VM Image Builder builds can fail for reasons listed elsewhere in this article. However, there's a small chance that a build fails due to Isolated Image Builds, depending on your scenario, subscription quotas, or some unforeseen service error. For more information, see Isolated Image Builds.

Solution

If you determine that a build is failing due to Isolated Image Builds, ensure that:

- No Azure policy is blocking the deployment of resources mentioned in the Prerequisites section of this article (specifically, Azure Container Instances).
- Your subscription has sufficient quota for Azure Container Instances to support all your concurrent image builds. For more information, see the Subscription exceeded the Azure Container Instances quota section of this article.

VM Image Builder is currently in the process of deploying Isolated Image Builds. Specific image templates are not tied to Isolated Image Builds, and the same image template might or might not use Isolated Image Builds during different builds.

To temporarily run your build without Isolated Image Builds, retry your build. Because image templates aren't tied to the Isolated Image Builds feature, retrying a build has a high probability of rerunning without Isolated Image Builds.

If none of these solutions mitigate failing image builds, you can contact Azure support to temporarily opt your subscription out of Isolated Image Builds. For more information, see

Create an Azure support request.

> **Note**
>
> If the Isolated Image Builds feature is eventually enabled in all regions and templates, the preceding mitigations will be only temporary. It's best to address the underlying cause of build failures.

Build is canceled after context cancellation

Error

text

```
PACKER ERR 2020/03/26 22:11:23 Cancelling builder after context cancellation
context canceled

command exited without exit status or exit signal.
PACKER ERR 2020/03/26 22:11:25 packer-builder-azure-arm plugin: [INFO] RPC
endpoint: Communicator ended with: 2300218
PACKER ERR 2020/03/26 22:11:25 [INFO] 148974 bytes written for 'stdout'
PACKER ERR 2020/03/26 22:11:25 [INFO] 0 bytes written for 'stderr'
PACKER ERR 2020/03/26 22:11:25 [INFO] RPC client: Communicator ended with: 2300218
PACKER ERR 2020/03/26 22:11:25 [INFO] RPC endpoint: Communicator ended with:
2300218
```

Cause

VM Image Builder uses port 22 (Linux) or 5986 (Windows) to connect to the build VM. This problem occurs when the service is disconnected from the build VM during an image build. The reasons for the disconnection can vary, but enabling or configuring a firewall in the script can block the previously mentioned ports.

Solution

Review your scripts for firewall changes or enablement, or changes to SSH or WinRM. Ensure that any changes allow for constant connectivity between the service and the build VM on the

previously mentioned ports. For more information, see VM Image Builder networking options.

JWT errors appear in the log early in the build

Error

Early in the build process, the build fails and the log indicates a JSON Web Token (JWT) error:

```text
PACKER OUT Error: Failed to prepare build: "azure-arm"
PACKER ERR
PACKER OUT
PACKER ERR * client_jwt will expire within 5 minutes, please use a JWT that is
valid for at least 5 minutes
PACKER OUT 1 error(s) occurred:
```

Cause

The `buildTimeoutInMinutes` value in the template is set to from 1 to 5 minutes.

Solution

As described in Create a VM Image Builder template, the timeout must be set to 0 minutes to use the default or set to more than 5 minutes to override the default. Change the timeout in your template to 0 minutes to use the default, or change it to a minimum of 6 minutes.

Resource deletion errors appear

Error

Intermediate resources are cleaned up toward the end of the build, and the customization log might show several resource deletion errors:

```text
PACKER OUT ==> azure-arm: Error deleting resource. Will retry.
...
PACKER OUT ==> azure-arm: Error: network.PublicIPAddressesClient#Delete: Failure
sending request: StatusCode=0 -- Original Error:
Code="PublicIPAddressCannotBeDeleted" Message=...
...
PACKER ERR 2022/03/07 18:43:06 packer-plugin-azure plugin: 2022/03/07 18:43:06
```

```
Retryable error: network.SecurityGroupsClient#Delete: Failure sending request:
StatusCode=0 -- Original Error: Code="InUseNetworkSecurityGroupCannotBeDeleted"...
```

Cause

These error log messages are mostly harmless, because resource deletions are retried several times. Ordinarily, they eventually succeed. You can verify this behavior by continuing to follow the deletion logs until you observe a success message. Alternatively, you can inspect the staging resource group to confirm whether the resource was deleted.

Making these observations is especially important in build failures. These error messages might lead you to conclude that they're the reason for the failures, even when the actual errors might be elsewhere.

Error

When images are stuck in template deletion, the customization log might show the following error:

Output

```
error deleting resource id
/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Networ
k/networkInterfaces/<networkInterfacName>: resources.Client#DeleteByID: Failure
sending request: StatusCode=400 --
Original Error: Code="NicInUseWithPrivateEndpoint"
Message="Network interface
/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Networ
k/networkInterfaces/<networkInterfacName> cannot be deleted because it is
currently in use with an private endpoint
(/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Netwo
rk/privateEndpoints/<pIname>)." Details=[]
```

Cause

The error occurs because the network interface is currently in use with a private endpoint.

Solution

To resolve the problem, delete the following resources one by one in this specific order:

1. Private endpoint connection. You can find this connection in the Azure Private Link service resource by going to the **Private endpoint connections** tab on the page for the Private

Link service resource.
2. Private Link service.
3. Network interface and load balancer.
4. Resource group.
5. Image template.

For more assistance, you can contact Azure support to resolve the stuck deletion error.

Distribution target is not found in the update request

Error

text

```
Validation failed: Distribute target with Runoutput name <runoutputname> not found
in the update request. Deleting a distribution target is not allowed.
```

Cause

This error occurs when an existing distribution target isn't found in the patch request body.

Solution

The distribution array should contain all the distribution targets: new targets (if any), existing targets with no change, and updated targets. If you want to remove an existing distribution target, delete and re-create the image template. Deleting a distribution target is currently not supported through the Patch API.

Required fields are missing

Error

text

```
Validation failed: 'ImageTemplate.properties.distribute[<index>]': Missing field
<fieldname>. Please review http://aka.ms/azvmimagebuildertmplref for details on
fields required in the Image Builder Template.
```

Cause

This error occurs when a required field is missing from a distribution target.

Solution

When you're creating a request, be sure to provide every required field in a distribution target, even if there's no change.

Troubleshoot Azure DevOps

An Azure DevOps task fails only if an error occurs during customization. When this error happens, the task reports the failure and leaves the staging resource group, with the logs, so that you can identify the problem.

To locate the log:

1. Find the template name. Go to **Pipeline** > **Failed build**, and then drill down into the Azure DevOps task in VM Image Builder. Note the `template name` value.

   ```text
   start reading task parameters...
   found build at:  /home/vsts/work/r1/a/_ImageBuilding/webapp
   end reading parameters
   getting storage account details for aibstordot1556933914
   created archive /home/vsts/work/_temp/temp_web_package_21475337782320203.zip
   Source for image:  { type: 'SharedImageVersion',
     imageVersionId:
   '/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.
   Compute/galleries/<galleryName>/images/<imageDefName>/versions/<imgVersionNum
   ber>' }
   template name:  t_1556938436xxx
   ```

2. Go to the Azure portal, search for the template name in the resource group, and then search for the resource group by entering **IT_**.

3. Select the storage account name, and then select **blobs** > **containers** > **logs**.

You might occasionally need to investigate successful builds and review their logs. As mentioned earlier, if the image build is successful, the staging resource group that contains the logs is deleted as part of the cleanup. To prevent an automatic cleanup, you can introduce `sleep` after the inline command, and then view the logs as the build is paused:

1. Update the inline command by adding `Write-Host / Echo "Sleep"`. This addition gives you time to search in the log.
2. Add a `sleep` value of at least 10 minutes by using a Start-Sleep or `Sleep` Linux command.

3. Use this method to identify the log location, and then keep downloading or checking the log until it gets to `sleep`.

Operation was canceled

2020-05-05T19:33:14.3939721Z ##[section]Finishing: Azure VM Image Builder Task
```

Cause

If a user didn't cancel the build, the Azure DevOps user agent canceled it. Most likely, the one-hour timeout occurred because of Azure DevOps capabilities. If you're using a private project and agent, you get 60 minutes of build time. If the build exceeds the timeout, Azure DevOps cancels the running task.

For more information about Azure DevOps capabilities and limitations, see Microsoft-hosted agents.

Solution

You can host your own Azure DevOps agents or try to reduce the time of your build. For example, if you're distributing to Azure Compute Gallery, you can replicate them to one region or replicate them asynchronously.

Windows logon is slow

Error

This error might occur when you create a Windows 10 image by using VM Image Builder, create a VM from the image, and then use Remote Desktop Protocol (RDP). You wait several minutes at the first logon screen, and then a blue screen displays the following message:

```text
Please wait for the Windows Modules Installer
```

Solution

1. In the image build, ensure that:

    - There are no outstanding restarts required by adding a Windows restart customizer as the last customization.
    - All software installation is complete.

2. Add the /mode:vm option to the default `Sysprep` command that VM Image Builder uses. For more information, see Overriding the commands later in this article.

Troubleshoot VMs created unsuccessfully from VM Image Builder

By default, VM Image Builder runs deprovisioning code at the end of each image customization phase to *generalize* the image. Generalizing an image sets it up for reuse in creating multiple VMs. As part of the process, you can pass in VM settings, such as host name and username.

In Windows, VM Image Builder runs a generic `Sysprep` command. However, this command might not be suitable for every successful Windows generalization. With VM Image Builder, you can customize the `Sysprep` command. VM Image Builder is an image automation tool that's responsible for running `Sysprep` commands successfully. But you might need different `Sysprep` commands to make your image reusable.

In Linux, VM Image Builder runs a generic `waagent -deprovision+user` command. For more information, see the Microsoft Azure Linux Agent documentation.

If you're migrating an existing customization and you're using various `Sysprep` or `waagent` commands, you can try the VM Image Builder generic commands. If the VM creation fails, use your previous `Sysprep` or `waagent` commands.

Let's suppose that you used VM Image Builder successfully to create a Windows custom image, but you failed to create a VM successfully from the image. For example, the VM creation fails to finish or it times out. In this event, do either of the following tasks:

- Review the Windows Server `Sysprep` documentation.
- Raise a support request with the Windows Server `Sysprep` customer support team. That team can help troubleshoot your problem and advise you on the correct `Sysprep` command.

Command locations and file names

In Windows:

```
c:\DeprovisioningScript.ps1
```

In Linux:

Bash

```
/tmp/DeprovisioningScript.sh
```

Sysprep command for Windows

Azure PowerShell

```
Write-Output '>>> Waiting for GA Service (RdAgent) to start ...'
while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }
```

```
Write-Output '>>> Waiting for GA Service (WindowsAzureTelemetryService) to start
...'
while ((Get-Service WindowsAzureTelemetryService) -and ((Get-Service
WindowsAzureTelemetryService).Status -ne 'Running')) { Start-Sleep -s 5 }
Write-Output '>>> Waiting for GA Service (WindowsAzureGuestAgent) to start ...'
while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s
5 }
Write-Output '>>> Sysprepping VM ...'
if( Test-Path $Env:SystemRoot\system32\Sysprep\unattend.xml ) {
  Remove-Item $Env:SystemRoot\system32\Sysprep\unattend.xml -Force
}
& $Env:SystemRoot\System32\Sysprep\Sysprep.exe /oobe /generalize /quiet /quit
while($true) {
  $imageState = (Get-ItemProperty
HKLM:\SOFTWARE\Microsoft\Windows\CurrentVersion\Setup\State).ImageState
  Write-Output $imageState
  if ($imageState -eq 'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { break }
  Start-Sleep -s 5
}
Write-Output '>>> Sysprep complete ...'
```

Deprovision command for Linux

Bash

```
sudo /usr/sbin/waagent -force -deprovision+user && export HISTSIZE=0 && sync
```

Overriding the commands

To override the commands, use the PowerShell or shell script provisioners to create the command files with the exact file name. Put them in the previously listed directories. VM Image Builder reads these commands and writes output to the `customization.log` file.

Get support

If you used the guidance in this article and are still having problems, you can open a support case.

Use the following code to select the correct product and support topic. Doing so ensures that you're connected with the Azure VM Image Builder support team.

text

```
Product Family: Azure
Product: Virtual Machine Running (Window\Linux)
```

```
Support Topic: Azure Features
Support Subtopic: Azure Image Builder
```

Best practices for Azure VM Image Builder

07/30/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article describes best practices to follow while you're using Azure VM Image Builder.

Use resource locks for image templates

To prevent image templates from being accidentally deleted, use resource locks on them. For more information, see Lock your Azure resources to protect your infrastructure.

Set up image templates for disaster recovery

Make sure your image templates are set up for disaster recovery by following the reliability recommendations for VM Image Builder.

Set up triggers

Set up VM Image Builder triggers to automatically rebuild your images and keep them updated.

Enable VM boot optimization

Enable virtual machine (VM) boot optimization in VM Image Builder to improve the creation time for your VMs.

Bring your own subnets

Specify your own build VM subnets (subnetId) and Azure Container Instances subnets (containerInstanceSubnetId) for tighter control over deployment of network-related resources by VM Image Builder in your subscription. Specifying these subnets also leads to faster and more reliable image builds.

You can read more about this network topology in the Isolated Image Builds section.

Follow the principle of least privilege

Follow the principle of least privilege for your VM Image Builder resources.

Image template

A principal that has access to your image template can run, delete, or tamper with it. This access then allows the principal to change the images that image template created.

Make sure that only required principals can access image templates.

Staging resource group

VM Image Builder uses a staging resource group in your subscription to customize your VM image. You must consider this resource group as sensitive and restrict access to only required principals. Keep these risks in mind:

- Because the process of customizing your image happens in this resource group, a principal that has access to the resource group can compromise the image-building process. For example, such a principal can inject malware into the image.
- VM Image Builder delegates privileges associated with the template identity and the build VM identity to resources in this resource group. A principal that has access to the resource group can get access to these identities.
- VM Image Builder maintains a copy of your customizer artifacts in this resource group. A principal that has access to the resource group can inspect these copies.

Template identity

A principal that has access to your template identity can access all resources that the identity has permissions for. This set of resources includes your customizer artifacts (for example, shell and PowerShell scripts), your distribution targets (for example, an Azure Compute Gallery image version), and your virtual network.

You must provide only the minimum required privileges to this identity.

Build VM identity

A principal that has access to your build VM identity can access all resources that the identity has permissions for. This set of resources includes any artifacts and virtual networks that you might be using from within the build VM via this identity.

You must provide only the minimum required privileges to this identity.

Credentials

Do not put any credentials in the image template or in files used for Shell, PowerShell, and File Customizers & Validators. For example:

- While specifying inline commands for customizers and validators, do not specify any password or other login credentials. Instead, such credentials should be stored in an Azure Key Vault and then accessed from the build VM using the Build VM identity.
- While providing files in customizers and validators, do not specify any credentials in the files. Instead, such credentials should be stored in an Azure Key Vault and then accessed from the build VM using the Build VM identity.
- While specifying script or source URIs for customizers and validators in an image template, do not specify SAS URIs or URIs with credentials (like Personal Access Tokens). Instead, store such files in Azure Storage Account and use Template identity to access them.

Though Azure VM Image Builder does not prohibit specifying such credentials, such use is highly discouraged. In case such a credential is indeed specified, ensure that it does not provide access to any privileged resources and is rotated as soon as possible.

Follow Azure Compute Gallery best practices

If you're distributing to Azure Compute Gallery, be sure to also follow best practices for Azure Compute Gallery resources.

How to Connect to the Azure Image Builder Build VM

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Use this article to learn how to connect to the Azure Image Builder Build VM in order to debug problems and errors you might encounter when you're using Azure VM Image Builder.

Retain the Build VM

By default, Azure Image Builder (AIB) deletes the Build VM after the customization or validation phase, regardless of success or failure. However, in case of failures, it's essential to retain the VM for debugging purposes. Here are two options:

Recommended Option: Specify `errorHandling` Property in the Template:

If you anticipate the need for debugging, create your template with the `errorHandling` property set. This ensures that AIB retains the Build VM even if errors occur during the build process. Follow the instructions in the Properties: errorHandling - Azure Image Builder documentation.

Alternative Option (Not Recommended): Lock the Resource Group:

If you can't modify the template directly, follow these steps:

- Get the name of the staging resource group (specified in the `stagingResourceGroup` property of the template).
- Apply a `CanNotDelete` lock to the resource group using Azure Resource Manager locks.
- Once debugging is complete, remove the lock and delete the resources (except storage accounts) from the resource group.

> **Note**

AIB will attempt to delete resources in the resource group after the build, but the lock will prevent deletion. Eventually, AIB will give up, and the build will complete. Note that even if there were no errors during customization or validation, the AIB build will be reported as "Failed" due to deletion errors.

Get the credentials to connect to the VM

After retaining the Build VM, follow these steps to get the credentials needed to connect to the VM:

- Navigate to the Virtual Machine's Health > Reset Password blade.
- Click on "Reset password" mode.
- Make a note of the `Username`.
- Set the `Password` to a desired value and make a note of it. You'll use these credentials in the next step.

Connect to the VM

Once you have the credentials, you can connect to the VM using one of the options below:

Option 1 (Recommended): Connect to the VM using Azure Bastion

Azure Bastion provides a secure way to connect to VMs without exposing public IPs. Follow the instructions for connecting to a Windows VM using SSH or RDP in the Azure Bastion documentation.

> **Note**
>
> No changes to existing Network Security Groups (NSGs) are needed when connecting to the Azure Image Builder Build VM using Azure Bastion.

Option 2 (Recommended, if available): Connect to the VM using Azure Serial Console

Azure Serial Console offers text-based access to VMs running Linux or Windows. Learn more about how to use Azure Serial Console to connect to a VM by reading the Azure

Serial Console documentation.

Option 3 (Not Recommended): Use a Public IP Address Resource

The recommended practice is to use Azure Bastion or Azure Serial Console for connecting to VMs. However, if Bastion or Serial Console cannot be used, you can connect to the Build VM by using public IPs.

Use the following documentation to connect to a VM using public IPs:

- Connect to a Linux VM using Public IP
- Connect to a Windows VM using Public IP

> **Note**
>
> You may need to associate a public IP address to the build VM first and you can do that by following the instructions in the following documentation: **Associate a public IP address to a virtual machine**.
>
> You also should ensure network connectivity from the client device (running WinRM/SSH) to the Build VM over the public network. Check and update your Network Security Groups (NSGs) as needed.

Option 4 (Not Recommended): Deploying a Jump Box

This option should be your last resort. Only use this option when you cannot use Azure Bastion, Azure Serial Console or a public IP address to connect to the Build VM.

Follow the steps below to deploy a jump box:

1. Create or use a separate subnet in the same VNet as the build VM.
2. Deploy a "Jump Box" VM with a public IP in this subnet.
3. Connect from your client device to the Jump Box using any of the methods mentioned earlier.
4. From the Jump Box, connect to the build VM using SSH or WinRM/RDP.

> **Note**
>
> There must be network line-of-sight from the Client Device to the Jump Box over the public network, and from the Jump Box to the Build VM over the private network. Additionally, it's essential to verify and update Network Security Groups

(NSGs) at each hop in between and ensure that the correct ports are open on all three devices.

Reliability in Azure Image Builder (AIB)

This article contains cross-region disaster recovery and business continuity.

Azure Image Builder (AIB) is a regional service with a cluster that serves single regions. The AIB regional setup keeps data and resources within the regional boundary. AIB as a service doesn't do fail over for cluster and SQL database in region down scenarios.

> **Note**
>
> Azure Image Builder doesn't support availability zones.

Cross-region disaster recovery and business continuity

Disaster recovery (DR) refers to practices that organizations use to recover from high-impact events, such as natural disasters or failed deployments that result in downtime and data loss. Regardless of the cause, the best remedy for a disaster is a well-defined and tested DR plan and an application design that actively supports DR. Before you start creating your disaster recovery plan, see Recommendations for designing a disaster recovery strategy.

For DR, Microsoft uses the shared responsibility model. In this model, Microsoft ensures that the baseline infrastructure and platform services are available. However, many Azure services don't automatically replicate data or fall back from a failed region to cross-replicate to another enabled region. For those services, you're responsible for setting up a disaster recovery plan that works for your workload. Most services that run on Azure platform as a service (PaaS) offerings provide features and guidance to support DR. You can use service-specific features to support fast recovery to help develop your DR plan.

To ensure fast and easy recovery for Azure Image Builder (AIB), it's recommended that you run an image template in region pairs or multiple regions when designing your AIB solution. You should also replicate resources from the start when you're setting up your image templates.

Multi-region geography disaster recovery

When a regional disaster occurs, Microsoft is responsible for outage detection, notifications, and support for AIB. However, you're responsible for setting up disaster recovery for the control (service side) and data planes.

Outage detection, notification, and management

Microsoft sends a notification if there's an outage in the Azure Image Builder (AIB) Service. One common outage symptom is image templates getting 500 errors when attempting to run. You can review Azure Image Builder outage notifications and status updates through support request management.

Set up disaster recovery and outage detection

You're responsible for setting up disaster recovery for your Azure Image Builder (AIB) environment, as there isn't a region failover at the AIB service side. You need to configure both the control plane (service side) and data plane.

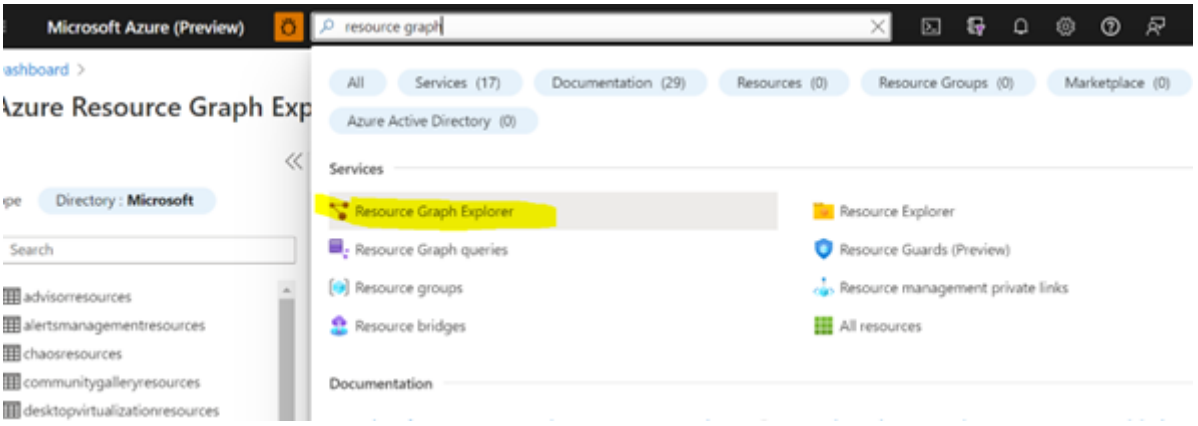
It's recommended that you create an AIB resource in another nearby region, into which you can replicate your resources. For more information, see the supported regions and what resources are included in an AIB creation.

Single-region geography disaster recovery

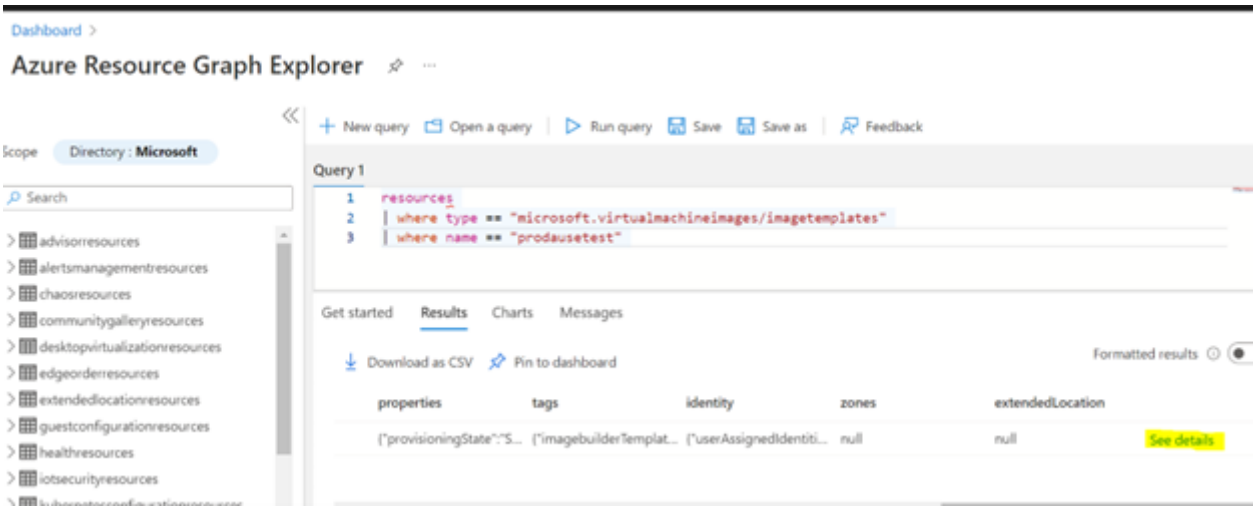
In the case of a disaster for single-region, you still need to get an image template resource from that region even when that region isn't available. You can either maintain a copy of an image template locally or can use Azure Resource Graph from the Azure portal to get an image template resource.

To get an image template resource using Resource Graph from the Azure portal:

1. Go to the search bar in Azure portal and search for *resource graph explorer*.



2. Use the search bar on the far left to search resource by type and name to see how the details give you properties of the image template. The *See details* option on the bottom right shows the image template's properties attribute and tags separately. Template name, location, ID, and tenant ID can be used to get the correct image template resource.



Capacity and proactive disaster recovery resiliency

Microsoft and its customers operate under the shared responsibility model. In customer-enabled DR (customer-responsible services), you're responsible for addressing DR for any service you deploy and control. To ensure that recovery is proactive, you should always pre-deploy secondaries. Without pre-deployed secondaries, there's no guarantee of capacity at time of impact.

When planning where to replicate a template, consider:

- AIB region availability:
  - Choose AIB supported regions close to your users.
  - AIB continually expands into new regions.
- Azure paired regions:
  - For your geographic area, choose two regions paired together.
  - Recovery efforts for paired regions where prioritization is needed.

Additional guidance

In regards to your data processing information, refer to the Azure Image Builder data residency details.

VM optimization for gallery images with Azure VM Image Builder

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Virtual Machine Scale Sets

In this article, you learn how to use Azure VM Image Builder to optimize your ACG (Azure Compute Gallery) Images or Managed Images or VHDs to improve the create time for your VMs.

Azure VM Optimization

Azure VM optimization improves virtual machine creation time by updating the gallery image to optimize the image for a faster boot time.

Image types supported

Optimization for the following images is supported:

Expand table

Features	Details
OS Type	Linux, Windows
Partition	MBR/GPT
Hyper-V	Gen1/Gen2
OS State	Generalized
Architecture	X64, ARM64

The following types of images aren't supported:

- Images with size greater than 2 TB
- Specialized images

Optimization in Azure VM Image Builder

Optimization can be enabled while creating a VM image using the CLI.

Customers can create an Azure VM Image Builder template using CLI. It contains details regarding source, type of customization, and distribution.

In your template, you will need to enable the additional fields for VM optimization. For more information on how to enable the VM optimization fields for your image builder template, see the Optimize property.

> **Note**
>
> To enable VM optimization benefits, you must be using Azure Image Builder API Version `2022-07-01` or later.

FAQs

Can VM optimization be used without Azure VM Image Builder customization?

Yes, customers can opt for only VM optimization without using Azure VM Image Builder customization feature. Customers can simply enable the optimization flag and keep customization field as empty.

Can an existing ACG image version be optimized?

No, this optimization feature won't update an existing SIG image version. However, optimization can be enabled during new version creation for an existing image

How much time does it take for generating an optimized image?

The below latencies have been observed at various percentiles:

Expand table

OS	Size	P50	P95	Average
Linux	30 GB VHD	20 mins	21 mins	20 mins
Windows	127 GB VHD	34 mins	35 mins	33 mins

This is the end to end duration observed. Note, image generation duration varies based on different factors such as, OS Type, VHD size, OS State, etc.

Is OS image copied out of customer subscription for optimization?

Yes, the OS VHD is copied from customer subscription to Azure subscription for optimization in the same geographic location. Once optimization is finished or timed out, Azure internally deletes all copied OS VHDs.

What are the performance improvements observed for VM boot optimization?

Enabling VM boot optimization feature may not always result in noticeable performance improvement as it depends on several factors like source image already optimized, OS type, customization etc. However, to ensure the best VM boot performance, it's recommended to enable this feature.

How to use Packer to create Linux virtual machine images in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Each virtual machine (VM) in Azure is created from an image that defines the Linux distribution and OS version. Images can include pre-installed applications and configurations. The Azure Marketplace provides many first and third-party images for most common distributions and application environments, or you can create your own custom images tailored to your needs. This article details how to use the open source tool Packer to define and build custom images in Azure.

> **Note**
>
> Azure now has a service, Azure Image Builder, for defining and creating your own custom images. Azure Image Builder is built on Packer, so you can even use your existing Packer shell provisioner scripts with it. To get started with Azure Image Builder, see Create a Linux VM with Azure Image Builder.

Create Azure resource group

During the build process, Packer creates temporary Azure resources as it builds the source VM. To capture that source VM for use as an image, you must define a resource group. The output from the Packer build process is stored in this resource group.

Create a resource group with az group create. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

Azure CLI

```
az group create -n myResourceGroup -l eastus
```

Create Azure credentials

Packer authenticates with Azure using a service principal. An Azure service principal is a security identity that you can use with apps, services, and automation tools like Packer.

You control and define the permissions as to what operations the service principal can perform in Azure.

Create a service principal with az ad sp create-for-rbac and output the credentials that Packer needs:

Azure CLI

```
az ad sp create-for-rbac --role Contributor --scopes
/subscriptions/<subscription_id> --query "{ client_id: appId, client_secret:
password, tenant_id: tenant }"
```

An example of the output from the preceding commands is as follows:

Output

```
{
    "client_id": "f5b6a5cf-fbdf-4a9f-b3b8-3c2cd00225a4",
    "client_secret": "0e760437-bf34-4aad-9f8d-870be799c55d",
    "tenant_id": "72f988bf-86f1-41af-91ab-2d7cd011db47"
}
```

To authenticate to Azure, you also need to obtain your Azure subscription ID with az account show:

Azure CLI

```
az account show --query "{ subscription_id: id }"
```

You use the output from these two commands in the next step.

Define Packer template

To build images, you create a template as a JSON file. In the template, you define builders and provisioners that carry out the actual build process. Packer has a provisioner for Azure that allows you to define Azure resources, such as the service principal credentials created in the preceding step.

Create a file named *ubuntu.json* and paste the following content. Enter your own values for the following parameters:

Expand table

Parameter	Where to obtain
client_id	First line of output from `az ad sp` create command - *appId*
client_secret	Second line of output from `az ad sp` create command - *password*
tenant_id	Third line of output from `az ad sp` create command - *tenant*
subscription_id	Output from `az account show` command
managed_image_resource_group_name	Name of resource group you created in the first step
managed_image_name	Name for the managed disk image that is created

JSON

```
{
  "builders": [{
    "type": "azure-arm",

    "client_id": "f5b6a5cf-fbdf-4a9f-b3b8-3c2cd00225a4",
    "client_secret": "0e760437-bf34-4aad-9f8d-870be799c55d",
    "tenant_id": "72f988bf-86f1-41af-91ab-2d7cd011db47",
    "subscription_id": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx",

    "managed_image_resource_group_name": "myResourceGroup",
    "managed_image_name": "myPackerImage",

    "os_type": "Linux",
    "image_publisher": "canonical",
    "image_offer": "0001-com-ubuntu-server-jammy",
    "image_sku": "22_04-lts",

    "azure_tags": {
        "dept": "Engineering",
        "task": "Image deployment"
    },

    "location": "East US",
    "vm_size": "Standard_DS2_v2"
  }],
  "provisioners": [{
    "execute_command": "chmod +x {{ .Path }}; {{ .Vars }} sudo -E sh '{{
.Path }}'",
    "inline": [
      "apt-get update",
      "apt-get upgrade -y",
      "apt-get -y install nginx",

      "/usr/sbin/waagent -force -deprovision+user && export HISTSIZE=0 &&
```

```
sync"
    ],
    "inline_shebang": "/bin/sh -x",
    "type": "shell"
  }]
}
```

> **Note**
>
> Replace the `image_publisher`, `image_offer`, `image_sku` values and `inline` commands accordingly.

You can also create a filed named *ubuntu.pkr.hcl* and paste the following content with your own values as used for the above parameters table.

HCL

```
source "azure-arm" "autogenerated_1" {
  azure_tags = {
    dept = "Engineering"
    task = "Image deployment"
  }
  client_id                         = "f5b6a5cf-fbdf-4a9f-b3b8-3c2cd00225a4"
  client_secret                     = "0e760437-bf34-4aad-9f8d-870be799c55d"
  image_offer                       = "0001-com-ubuntu-server-jammy"
  image_publisher                   = "canonical"
  image_sku                         = "22_04-lts"
  location                          = "East US"
  managed_image_name                = "myPackerImage"
  managed_image_resource_group_name = "myResourceGroup"
  os_type                           = "Linux"
  subscription_id                   = "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx"
  tenant_id                         = "72f988bf-86f1-41af-91ab-2d7cd011db47"
  vm_size                           = "Standard_DS2_v2"
}

build {
  sources = ["source.azure-arm.autogenerated_1"]

  provisioner "shell" {
    execute_command = "chmod +x {{ .Path }}; {{ .Vars }} sudo -E sh '{{
.Path }}'"
    inline          = ["apt-get update", "apt-get upgrade -y", "apt-get -y
install nginx", "/usr/sbin/waagent -force -deprovision+user && export
HISTSIZE=0 && sync"]
    inline_shebang  = "/bin/sh -x"
  }

}
```

This template builds an Ubuntu 22.04 LTS image, installs NGINX, then deprovisions the VM.

> **Note**
>
> If you expand on this template to provision user credentials, adjust the provisioner command that deprovisions the Azure agent to read `-deprovision` rather than `deprovision+user`. The `+user` flag removes all user accounts from the source VM.

Build Packer image

If you don't already have Packer installed on your local machine, follow the Packer installation instructions.

Build the image by specifying your Packer template file as follows:

Bash

```
sudo ./packer build ubuntu.json
```

You can also build the image by specifying the *ubuntu.pkr.hcl* file as follows:

Bash

```
sudo packer build ubuntu.pkr.hcl
```

An example of the output from the preceding commands is as follows:

Output

```
azure-arm output will be in this color.

==> azure-arm:  -> Compute ResourceGroupName : ‘packer-Resource-Group-
swtxmqm7ly’
==> azure-arm:  -> Compute Name              : ‘pkrvmswtxmqm7ly’
==> azure-arm:  -> Compute Location          : ‘East US’
==> azure-arm:  -> Image ResourceGroupName   : ‘myResourceGroup’
==> azure-arm:  -> Image Name                : ‘myPackerImage’
==> azure-arm:  -> Image Location            : ‘eastus’
==> azure-arm: Deleting resource group ...
==> azure-arm:  -> ResourceGroupName : ‘packer-Resource-Group-swtxmqm7ly’
==> azure-arm: Deleting the temporary OS disk ...
==> azure-arm:  -> OS Disk : skipping, managed disk was used...
Build ‘azure-arm’ finished.

==> Builds finished. The artifacts of successful builds are:
--> azure-arm: Azure.ResourceManagement.VMImage:

ManagedImageResourceGroupName: myResourceGroup
ManagedImageName: myPackerImage
ManagedImageLocation: eastus
```

It takes a few minutes for Packer to build the VM, run the provisioners, and clean up the deployment.

Create VM from Azure Image

You can now create a VM from your Image with az vm create. Specify the Image you created with the `--image` parameter. The following example creates a VM named *myVM* from *myPackerImage* and generates SSH keys if they don't already exist:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image myPackerImage \
    --admin-username azureuser \
    --generate-ssh-keys
```

If you wish to create VMs in a different resource group or region than your Packer image, specify the image ID rather than image name. You can obtain the image ID with az image show.

It takes a few minutes to create the VM. Once the VM has been created, take note of the `publicIpAddress` displayed by the Azure CLI. This address is used to access the NGINX site via a web browser.

To allow web traffic to reach your VM, open port 80 from the Internet with az vm open-port:

Azure CLI

```
az vm open-port \
    --resource-group myResourceGroup \
    --name myVM \
    --port 80
```

Test VM and NGINX

Now you can open a web browser and enter `http://publicIpAddress` in the address bar. Provide your own public IP address from the VM create process. The default NGINX page is displayed as in the following example:

Next steps

You can also use existing Packer provisioner scripts with Azure Image Builder.

PowerShell: How to use Packer to create virtual machine images in Azure

Article • 10/28/2024

Applies to: ✔ Windows VMs

Each virtual machine (VM) in Azure is created from an image that defines the Windows distribution and OS version. Images can include pre-installed applications and configurations. The Azure Marketplace provides many first and third-party images for most common OS' and application environments, or you can create your own custom images tailored to your needs. This article details how to use the open-source tool Packer to define and build custom images in Azure.

This article was last tested on 8/5/2020 using Packer version 1.8.1.

> **Note**
>
> Azure now has a service, Azure Image Builder, for defining and creating your own custom images. Azure Image Builder is built on Packer, so you can even use your existing Packer shell provisioner scripts with it. To get started with Azure Image Builder, see Create a Windows VM with Azure Image Builder.

Create Azure resource group

During the build process, Packer creates temporary Azure resources as it builds the source VM. To capture that source VM for use as an image, you must define a resource group. The output from the Packer build process is stored in this resource group.

Create a resource group with New-AzResourceGroup. The following example creates a resource group named *myPackerGroup* in the *eastus* location:

Azure PowerShell

```
$rgName = "myPackerGroup"
$location = "East US"
New-AzResourceGroup -Name $rgName -Location $location
```

Create Azure credentials

Packer authenticates with Azure using a service principal. An Azure service principal is a security identity that you can use with apps, services, and automation tools like Packer. You control and define the permissions as to what operations the service principal can perform in Azure.

Create a service principal with New-AzADServicePrincipal. The value for `-DisplayName` needs to be unique; replace with your own value as needed.

Azure PowerShell

```
$sp = New-AzADServicePrincipal -DisplayName "PackerPrincipal" -role
Contributor -scope /subscriptions/yyyyyyy-yyyy-yyyy-yyyy-yyyyyyyyyyy
$plainPassword = (New-AzADSpCredential -ObjectId $sp.Id).SecretText
```

Then output the password and application ID.

Azure PowerShell

```
$plainPassword
$sp.AppId
```

To authenticate to Azure, you also need to obtain your Azure tenant and subscription IDs with Get-AzSubscription:

Azure PowerShell

```
$subName = "mySubscriptionName"
$sub = Get-AzSubscription -SubscriptionName $subName
```

Define Packer template

To build images, you create a template as a JSON file. In the template, you define builders and provisioners that carry out the actual build process. Packer has a builder for Azure that allows you to define Azure resources, such as the service principal credentials created in the preceding step.

Create a file named *windows.json* and paste the following content. Enter your own values for the following:

Expand table

Parameter	Where to obtain
client_id	View service principal ID with `$sp.AppId`
client_secret	View the auto-generated password with `$plainPassword`
tenant_id	Output from `$sub.TenantId` command
subscription_id	Output from `$sub.SubscriptionId` command
managed_image_resource_group_name	Name of resource group you created in the first step
managed_image_name	Name for the managed disk image that is created

JSON

```
{
  "builders": [{
    "type": "azure-arm",

    "client_id": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx",
    "client_secret": "ppppppp-pppp-pppp-pppp-pppppppppppp",
    "tenant_id": "zzzzzzz-zzzz-zzzz-zzzz-zzzzzzzzzzzz",
    "subscription_id": "yyyyyyy-yyyy-yyyy-yyyy-yyyyyyyyyyy",

    "managed_image_resource_group_name": "myPackerGroup",
    "managed_image_name": "myPackerImage",

    "os_type": "Windows",
    "image_publisher": "MicrosoftWindowsServer",
    "image_offer": "WindowsServer",
    "image_sku": "2016-Datacenter",

    "communicator": "winrm",
    "winrm_use_ssl": true,
    "winrm_insecure": true,
    "winrm_timeout": "5m",
    "winrm_username": "packer",

    "azure_tags": {
        "dept": "Engineering",
        "task": "Image deployment"
    },

    "build_resource_group_name": "myPackerGroup",
    "vm_size": "Standard_D2_v2"
  }],
  "provisioners": [{
    "type": "powershell",
    "inline": [
      "Add-WindowsFeature Web-Server",
      "while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5
}",
```

```
      "while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') {
Start-Sleep -s 5 }",
      "& $env:SystemRoot\\System32\\Sysprep\\Sysprep.exe /oobe /generalize
/quiet /quit",
      "while($true) { $imageState = Get-ItemProperty
HKLM:\\SOFTWARE\\Microsoft\\Windows\\CurrentVersion\\Setup\\State | Select
ImageState; if($imageState.ImageState -ne
'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { Write-Output
$imageState.ImageState; Start-Sleep -s 10  } else { break } }"
    ]
  }]
}
```

You can also create a file named *windows.pkr.hcl* and paste the following content with your own values as used for the above parameters table.

HCL

```
source "azure-arm" "autogenerated_1" {
  azure_tags = {
    dept = "Engineering"
    task = "Image deployment"
  }
  build_resource_group_name         = "myPackerGroup"
  client_id                         = "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx"
  client_secret                     = "ppppppp-pppp-pppp-pppp-pppppppppppp"
  communicator                      = "winrm"
  image_offer                       = "WindowsServer"
  image_publisher                   = "MicrosoftWindowsServer"
  image_sku                         = "2016-Datacenter"
  managed_image_name                = "myPackerImage"
  managed_image_resource_group_name = "myPackerGroup"
  os_type                           = "Windows"
  subscription_id                   = "yyyyyyy-yyyy-yyyy-yyyy-yyyyyyyyyyy"
  tenant_id                         = "zzzzzzz-zzzz-zzzz-zzzz-zzzzzzzzzzzz"
  vm_size                           = "Standard_D2_v2"
  winrm_insecure                    = true
  winrm_timeout                     = "5m"
  winrm_use_ssl                     = true
  winrm_username                    = "packer"
}

build {
  sources = ["source.azure-arm.autogenerated_1"]

  provisioner "powershell" {
    inline = ["Add-WindowsFeature Web-Server", "while ((Get-Service
RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }", "while ((Get-Service
WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s 5 }", "&
$env:SystemRoot\\System32\\Sysprep\\Sysprep.exe /oobe /generalize /quiet
/quit", "while($true) { $imageState = Get-ItemProperty
HKLM:\\SOFTWARE\\Microsoft\\Windows\\CurrentVersion\\Setup\\State | Select
ImageState; if($imageState.ImageState -ne
```

```
'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { Write-Output
$imageState.ImageState; Start-Sleep -s 10  } else { break } }"]
  }

}
```

This template builds a Windows Server 2016 VM, installs IIS, then generalizes the VM with Sysprep. The IIS install shows how you can use the PowerShell provisioner to run additional commands. The final Packer image then includes the required software install and configuration.

The Windows Guest Agent participates in the Sysprep process. The agent must be fully installed before the VM can be sysprep'ed. To ensure that this is true, all agent services must be running before you execute sysprep.exe. The preceding JSON snippet shows one way to do this in the PowerShell provisioner. This snippet is required only if the VM is configured to install the agent, which is the default.

Build Packer image

If you don't already have Packer installed on your local machine, follow the Packer installation instructions.

Build the image by opening a cmd prompt and specifying your Packer template file as follows:

Batchfile

```
packer build windows.json
```

You can also build the image by specifying the *windows.pkr.hcl* file as follows:

Batchfile

```
packer build windows.pkr.hcl
```

An example of the output from the preceding commands is as follows:

HCL

```
azure-arm output will be in this color.

==> azure-arm:  -> Image Name                : ‘myPackerImage’
==> azure-arm:  -> Image Location            : ‘eastus’
==> azure-arm: Deleting resource group ...
==> azure-arm:  -> ResourceGroupName : ‘packer-Resource-Group-pq0mthtbtt’
==> azure-arm: Deleting the temporary OS disk ...
==> azure-arm:  -> OS Disk : skipping, managed disk was used...
Build ‘azure-arm’ finished.

==> Builds finished. The artifacts of successful builds are:
--> azure-arm: Azure.ResourceManagement.VMImage:

ManagedImageResourceGroupName: myResourceGroup
ManagedImageName: myPackerImage
ManagedImageLocation: eastus
```

It takes a few minutes for Packer to build the VM, run the provisioners, and clean up the deployment.

Create a VM from the Packer image

You can now create a VM from your Image with New-AzVM. The supporting network resources are created if they do not already exist. When prompted, enter an administrative username and password to be created on the VM. The following example creates a VM named *myVM* from *myPackerImage*:

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName $rgName `
    -Name "myVM" `
    -Location $location `
    -VirtualNetworkName "myVnet" `
    -SubnetName "mySubnet" `
    -SecurityGroupName "myNetworkSecurityGroup" `
    -PublicIpAddressName "myPublicIpAddress" `
    -OpenPorts 80 `
    -Image "myPackerImage"
```

If you wish to create VMs in a different resource group or region than your Packer image, specify the image ID rather than image name. You can obtain the image ID with Get-AzImage.

It takes a few minutes to create the VM from your Packer image.

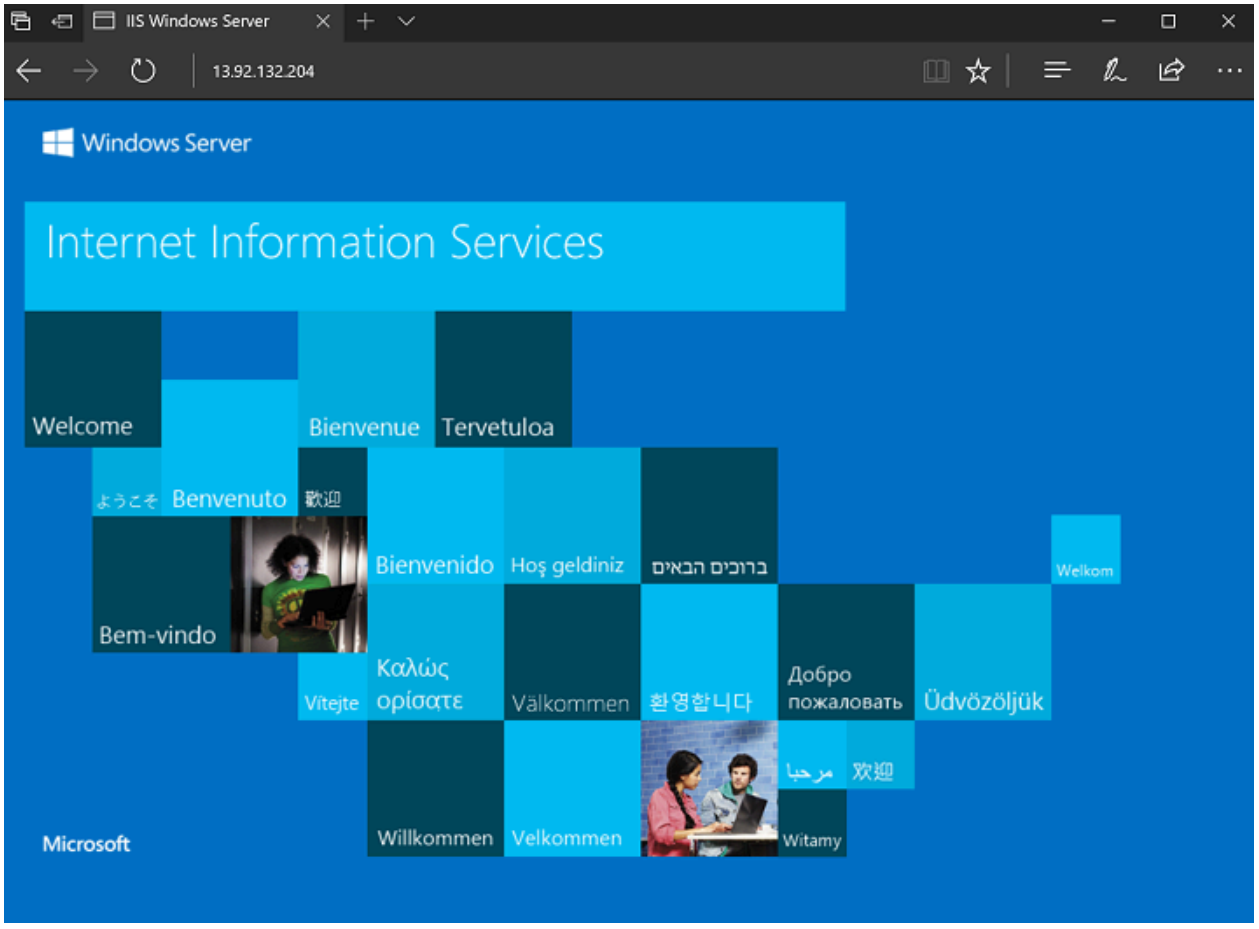
Test VM and webserver

Obtain the public IP address of your VM with Get-AzPublicIPAddress. The following example obtains the IP address for *myPublicIP* created earlier:

Azure PowerShell

```
Get-AzPublicIPAddress `
    -ResourceGroupName $rgName `
    -Name "myPublicIPAddress" | select "IpAddress"
```

To see your VM, that includes the IIS install from the Packer provisioner, in action, enter the public IP address in to a web browser.



Next steps

You can also use existing Packer provisioner scripts with Azure Image Builder.

Azure Dedicated Hosts

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale sets

Azure Dedicated Host is a service that provides physical servers able to host one or more virtual machines assigned to one Azure subscription. Dedicated hosts are the same physical servers used in our data centers, provided instead as a directly accessible hardware resource. You can provision dedicated hosts within a region, availability zone, and fault domain. You can then place VMs directly into your provisioned hosts in whatever configuration best meets your needs.

Video Introduction

https://www.youtube-nocookie.com/embed/Lk9mA1WzfAQ

Benefits

Reserving the entire host provides several benefits beyond those of a standard shared virtual machine host:

- Cost Optimization: With the Azure hybrid benefit, you can bring your own licenses for Windows and SQL to Azure. For more information, see Azure Hybrid Benefit.
- Reliability: You have near complete control over maintenance events initiated by the Azure platform. While most maintenance events have little to no impact on your virtual machines, there are some sensitive workloads where each second of pause can have an impact. With dedicated hosts, you can opt in to a maintenance window to reduce the impact to your service.
- Performance Efficiency: Because you have control over a physical host, you can choose which applications share physical resources such as memory and storage. This can speed up certain workloads that benefit from low latency and high throughput on the host machine.
- Security: Hardware isolation at the physical server level allows for sensitive memory data to remain isolated within a physical host. No other customer's VMs will be placed on your hosts. Dedicated hosts are deployed in the same data centers and share the same network and underlying storage infrastructure as other, non-isolated hosts.

Groups, hosts, and VMs

A **host group** is a resource that represents a collection of dedicated hosts. You create a host group in a region and an availability zone, and add hosts to it.

A **host** is a resource, mapped to a physical server in an Azure data center. The physical server is allocated when the host is created. A host is created within a host group. A host has a SKU describing which VM sizes can be created. Each host can host multiple VMs, of different sizes, as long as they are from the same size series.

High availability considerations

For high availability, you should deploy multiple VMs, spread across multiple hosts (minimum of 2). With Azure Dedicated Hosts, you have several options to provision your infrastructure to shape your fault isolation boundaries.

Use availability zones for fault isolation

Availability zones are unique physical locations within an Azure region. Each zone is made up of one or more datacenters equipped with independent power, cooling, and networking. A host group is created in a single availability zone. Once created, all hosts will be placed within that zone. To achieve high availability across zones, you need to create multiple host groups (one per zone) and spread your hosts between them accordingly.

If you assign a host group to an availability zone, all VMs created on that host must be created in the same zone.

Use Fault Domains for fault isolation

A host can be created in a specific fault domain. Just like VM in a scale set or availability set, hosts in different fault domains will be placed on different physical racks in the data center. When you create a host group, you're required to specify the fault domain count. When creating hosts within the host group, you assign fault domain for each host. The VMs don't require any fault domain assignment.

Fault domains aren't the same as colocation. Having the same fault domain for two hosts doesn't mean they are in proximity with each other.

Fault domains are scoped to the host group. You shouldn't make any assumption on anti-affinity between two host groups (unless they are in different availability zones).

VMs deployed to hosts with different fault domains, will have their underlying managed disks services on multiple storage stamps, to increase the fault isolation protection.

Using Availability Zones and Fault Domains

You can use both capabilities together to achieve even more fault isolation. To use both, specify the availability zone and fault domain count in for each host group, assign a fault domain to each host in the group, then assign an availability zone to each VM.

The Resource Manager sample template uses zones and fault domains to spread hosts for maximum resiliency in a region.

Manual vs. automatic placement

When creating a VM in Azure, you can select which dedicated host to use. You can also use the option to automatically place your VMs on existing hosts, within a host group.

When creating a new host group, make sure the setting for automatic VM placement is selected. When creating your VM, select the host group and let Azure pick the best host for your VM.

Host groups that are enabled for automatic placement don't require all the VMs to be automatically placed. You'll still be able to explicitly pick a host, even when automatic placement is selected for the host group.

Automatic placement limitations

Known issues and limitations when using automatic VM placement:

- You won't be able to redeploy your VM.
- You won't be able to use DCv2, Lsv2, NVasv4, NVsv3, Msv2, or M-series VMs with dedicated hosts.

Host service healing

In case of any failure relating to the underlying node, network connectivity or software issues can push the host and VMs on the host to a non-healthy state causing disruption and downtime to your workloads. The default action is for Azure to automatically service heal the impacted host to a healthy node and move all VMs to the healthy host. Once the VMs are service healed and restarted the impacted host will be deallocated. During the service healing process the host and VMs would become unavailable incurring a slight downtime.

The newly created host would have all the same constraints as the old host:

- Resource group
- Region
- Fault Domain
- Host Group
- ADH SKU
- Auto replace on failure setting

Users with compliance requirements might need a strong affinity between the host and underlying node and would not like to be automatically service healed, in such scenarios users can choose to opt out of auto service healing at host level by disabling the 'Automatically replace host on failure setting'.

Implications

If you decide to disable auto service healing and if the underlying node encounters a failure your host state will change to 'Host Pending Deallocate' and will eventually be deallocated.

To avoid deallocation, you would need to manually redeploy the host by creating a new dedicated host and moving all the VMs from the old host to the new host.

The auto replace host setting is a create time setting and cannot be changed once the host is created. VMs that are manually stopped/deallocated from the impacted host are not moved as part of the automatic service healing.

Virtual Machine Scale Set support

Virtual Machine Scale Sets let you treat a group of virtual machines as a single resource, and apply availability, management, scaling and orchestration policies as a group. Your existing dedicated hosts can also be used for Virtual Machine Scale Sets.

When creating a Virtual Machine Scale Set, you can specify an existing host group to have all of the VM instances created on dedicated hosts.

The following requirements apply when creating a Virtual Machine Scale Set in a dedicated host group:

- Automatic VM placement needs to be enabled.
- The availability setting of your host group should match your scale set.
  - A regional host group (created without specifying an availability zone) should be used for regional scale sets.
  - The host group and the scale set must be using the same availability zone.
  - The fault domain count for the host group level should match the fault domain count for your scale set. The Azure portal lets you specify *max spreading* for your scale set, which sets the fault domain count of 1.
- Dedicated hosts should be created first, with sufficient capacity, and the same settings for scale set zones and fault domains.
- The supported VM sizes for your dedicated hosts should match the one used for your scale set.

Not all scale-set orchestration and optimizations settings are supported by dedicated hosts. Apply the following settings to your scale set:

- Overprovisioning isn't recommended, and it's disabled by default. You can enable overprovisioning, but the scale set allocation will fail if the host group doesn't have capacity for all of the VMs, including the overprovisioned instances.
- Use the ScaleSetVM orchestration mode
- Don't use proximity placement groups for co-location

Ultra disk support for virtual machines on dedicated hosts

Ultra disks offer higher IOPS (maximum of 160,00 IOPS per disk) and higher disk throughput (maximum of 4000 MBps per disk) depending on the disk size. All the limitations of ultra disks would still apply. To use ultra disks on dedicated hosts following requirements needs to be satisfied:

- Host group needs to have Ultra SSD 'Enabled', this property cannot be changed once the host group is created
- Dedicated host's virtual machine series should be compatible with ultra disks.

Dedicated hosts also support ultra disks with specialty VM sizes: LSv2, M, Mv2, Msv2, Mdsv2, NVv3, NVv4. However in these cases below listed additional limitations would

apply:

- Host group should have Automatic Placement 'Disabled'
- Host group's fault domain count should be set to '1' only.

Maintenance control

The infrastructure supporting your virtual machines may occasionally be updated to improve reliability, performance, security, and to launch new features. The Azure platform tries to minimize the impact of platform maintenance whenever possible, however customers with *maintenance sensitive* workloads can't tolerate even few seconds that the VM needs to be shut down for maintenance.

Maintenance Control provides customers with an option to skip regular platform updates scheduled on their dedicated hosts, then apply it at the time of their choice within a 35-day rolling window. Within the maintenance window, you can apply maintenance directly at the host level, in any order. Once the maintenance window is over, Microsoft will move forward and apply the pending maintenance to the hosts in an order that may not follow the user defined fault domains.

For more information, see Managing platform updates with Maintenance Control.

Capacity considerations

Once a dedicated host is provisioned, Azure assigns it to physical server. Doing so guarantees the availability of the capacity when you need to provision your VM. Azure uses the entire capacity in the region (or zone) to pick a physical server for your host. It also means that customers can expect to be able to grow their dedicated host footprint without the concern of running out of space in the cluster.

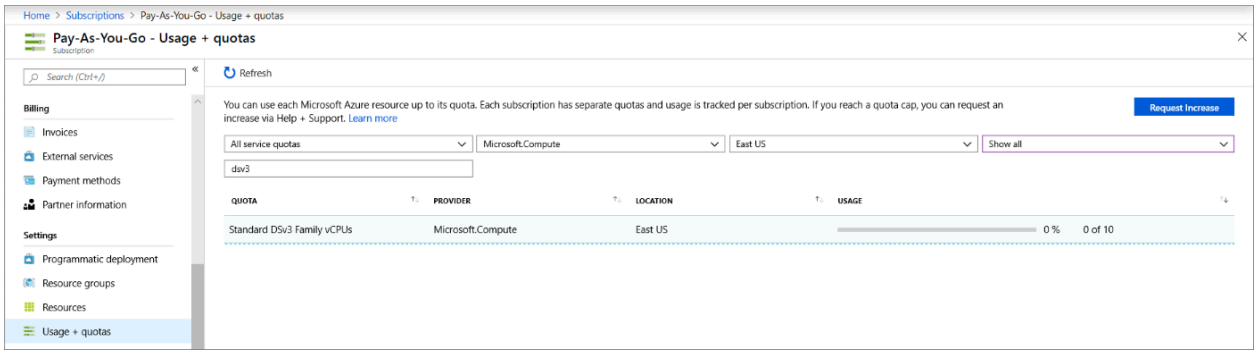
Quotas

There are two types of quota that are consumed when you deploy a dedicated host.

1. Dedicated host vCPU quota. The default quota limit is 3000 vCPUs, per region.
2. VM size family quota. For example, a **Pay-as-you-go** subscription may only have a quota of 10 vCPUs available for the Dsv3 size series, in the East US region. To deploy a Dsv3 dedicated host, you would need to request a quota increase to at least 64 vCPUs before you can deploy the dedicated host.

To request a quota increase, create a support request in the Azure portal.

Provisioning a dedicated host will consume both dedicated host vCPU and the VM family vCPU quota, but it won't consume the regional vCPU. VMs placed on a dedicated host won't count against VM family vCPU quota. Should a VM be moved off a dedicated host into a multi-tenant environment, the VM will consume VM family vCPU quota.



For more information, see Virtual machine vCPU quotas.

Free trial and MSDN subscriptions don't have quota for Azure Dedicated Hosts.

Pricing

Users are charged per dedicated host, regardless how many VMs are deployed. In your monthly statement, you'll see a new billable resource type of hosts. The VMs on a dedicated host will still be shown in your statement, but will carry a price of 0.

The host price is set based on VM family, type (hardware size), and region. A host price is relative to the largest VM size supported on the host.

Software licensing, storage and network usage are billed separately from the host and VMs. There's no change to those billable items.

For more information, see Azure Dedicated Host pricing.

You can also save on costs with a Reserved Instance of Azure Dedicated Hosts.

Sizes and hardware generations

A SKU represents the VM size series and type on a given host. You can mix multiple VMs of different sizes within a single host as long as they are of the same size series.

The *type* is the hardware generation. Different hardware types for the same VM series will be from different CPU vendors and have different CPU generations and number of cores.

The sizes and hardware types vary by region. Refer to the host pricing page to learn more.

> **Note**
>
> Once a Dedicated host is provisioned, you can't change the size or type. If you need a different size of type, you will need to create a new host.

Host life cycle

Azure monitors and manages the health status of your hosts. The following states will be returned when you query your host:

Expand table

Health State	Description
Host Available	There are no known issues with your host.
Host Under Investigation	We're having some issues with the host that we're looking into. This transitional state is required for Azure to try to identify the scope and root cause for the issue identified. Virtual machines running on the host may be impacted.
Host Pending Deallocate	Azure can't restore the host back to a healthy state and ask you to redeploy your virtual machines out of this host. If `autoReplaceOnFailure` is enabled, your virtual machines are *service healed* to healthy hardware. Otherwise, your virtual machine may be running on a host that is about to fail.
Host Deallocated	All virtual machines have been removed from the host. You're no longer being charged for this host since the hardware was taken out of rotation.

Frequently Asked Questions

Q. What happens to my dedicated host in case of a live migration?

A. As of today, Azure dedicated hosts do not support live migration and in case of a hardware failure, we service heal the host to a different node.

Q. Can I run VMs from multiple VM families on the same dedicated host?

A. No, you would be able to run only VMs from the same family as the underlying dedicated host. For e.g., A Dsv3-Type4 host only supports VMs of Dsv3 VM family.

Q. Would I be able to run different VM sizes on a single dedicated host?

A. Yes, you can run multiple sizes of VMs on the same dedicated host as long as the all the VMs belong to the same family as the underlying dedicated host and there is enough capacity on the host to support the VMs sizes. For e.g., on a Dsv3-Type4 host you could run D2sv3, D8sv3, D16sv3 VMs at the same time.

Next steps

- To deploy a dedicated host, see Deploy VMs and scale sets to dedicated hosts.
- There's a sample template that uses both zones and fault domains for maximum resiliency in a region.
- You can also save on costs with a Reserved Instance of Azure Dedicated Hosts.

Deploy VMs and scale sets to dedicated hosts

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale sets

This article guides you through how to create an Azure dedicated host to host your virtual machines (VMs) and scale set instances.

Limitations

- The sizes and hardware types available for dedicated hosts vary by region. Refer to the host pricing page to learn more.
- Not all Azure VM SKUs, regions and availability zones support ultra disks, for more information about this topic, see Azure ultra disks.
- Additional limitations would apply when using ultra disks on the following VM sizes: LSv2, M, Mv2, Msv2, Mdsv2, NVv3, NVv4 on a dedicated host.
- The fault domain count of the virtual machine scale set can't exceed the fault domain count of the host group.
- Users can not select hardware capabilities like accelerated networking when creating a dedicated host.
- Users would not be able to create VMs/VMSS with accelerated networking enabled on a dedicated host.

Create a host group

A **host group** is a resource that represents a collection of dedicated hosts. You create a host group in a region and an availability zone, and add hosts to it. You can use one or both of the following options with your dedicated hosts to ensure high availability:

- Span across multiple availability zones. In this case, you're required to have a host group in each of the zones you wish to use.
- Span across multiple fault domains, which are mapped to physical racks.

In either case, you need to provide the fault domain count for your host group. If you don't want to span fault domains in your group, use a fault domain count of 1.

You can also decide to use both availability zones and fault domains.

Enabling ultra disks is a host group level setting and can't be changed after a host group is created.

Portal

In this example, we'll create a host group using one availability zone and two fault domains.

1. Open the Azure portal.
2. Select **Create a resource** in the upper left corner.
3. Search for **Host group** and then select **Host Groups** from the results.
4. In the **Host Groups** page, select **Create**.
5. Select the subscription you would like to use, and then select **Create new** to create a new resource group.
6. Type *myDedicatedHostsRG* as the **Name** and then select **OK**.
7. For **Host group name**, type *myHostGroup*.
8. For **Location**, select **East US**.
9. For **Availability Zone**, select **1**.
10. Select **Enable Ultra SSD** to use ultra disks with supported Virtual Machines.
11. For **Fault domain count**, select **2**.
12. Select **Automatic placement** to automatically assign VMs and scale set instances to an available host in this group.
13. Select **Review + create** and then wait for validation.
14. Once you see the **Validation passed** message, select **Create** to create the host group.

It should only take a few moments to create the host group.

Create a dedicated host

Now create a dedicated host in the host group. In addition to a name for the host, you're required to provide the SKU for the host. Host SKU captures the supported VM series and the hardware generation for your dedicated host.

For more information about the host SKUs and pricing, see Azure Dedicated Host pricing.

If you set a fault domain count for your host group, you'll need to specify the fault domain for your host.

Portal

1. Select **Create a resource** in the upper left corner.
2. Search for **Dedicated host** and then select **Dedicated hosts** from the results.
3. In the **Dedicated Hosts** page, select **Create**.
4. Select the subscription you would like to use.
5. Select *myDedicatedHostsRG* as the **Resource group**.
6. In **Instance details**, type *myHost* for the **Name** and select *East US* for the location.
7. In **Hardware profile**, select *Standard Es3 family - Type 1* for the **Size family**, select *myHostGroup* for the **Host group** and then select *1* for the **Fault domain**. Leave the defaults for the rest of the fields.
8. Leave the **Automatically replace host on failure** setting *Enabled* to automatically service heal the host in case of any host level failure.
9. When you're done, select **Review + create** and wait for validation.
10. Once you see the **Validation passed** message, select **Create** to create the host.

Create a VM

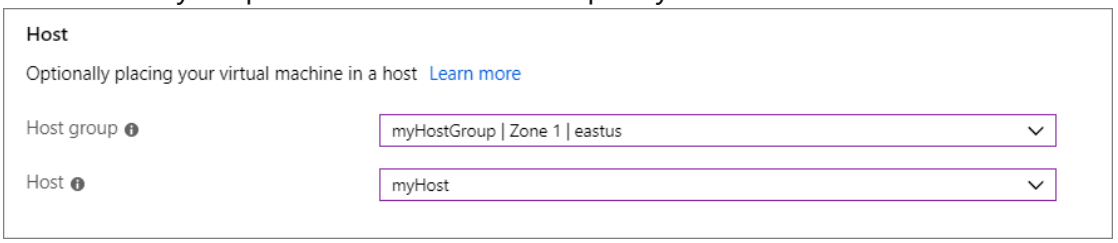
Now create a VM on the host.

If you would like to create a VM with ultra disks support, make sure the host group in which the VM will be placed is ultra SSD enabled. Once you've confirmed, create the VM in the same host group. See Deploy an ultra disk for the steps to attach an ultra disk to a VM.

Portal

1. Choose **Create a resource** in the upper left corner of the Azure portal.
2. In the search box above the list of Azure Marketplace resources, search for and select the image you want use, then choose **Create**.
3. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected and then select *myDedicatedHostsRG* as the **Resource group**.
4. Under **Instance details**, type *myVM* for the **Virtual machine name** and choose *East US* for your **Location**.
5. In **Availability options** select **Availability zone**, select *1* from the drop-down.
6. For the size, select **Change size**. In the list of available sizes, choose one from the Esv3 series, like **Standard E2s v3**. You may need to clear the filter in order to see all of the available sizes.
7. Complete the rest of the fields on the **Basics** tab as needed.

8. If you want to specify which host to use for your VM, then at the top of the page, select the **Advanced** tab and in the **Host** section, select *myHostGroup* for **Host group** and *myHost* for the **Host**. Otherwise, your VM will automatically be placed on a host with capacity.



9. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.
10. When you see the message that validation has passed, select **Create**.

It will take a few minutes for your VM to be deployed.

Create a scale set

You can also create a scale set on your host.

> **ⓘ Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Portal

When you deploy a scale set, you specify the host group.

1. Search for *Scale set* and select **Virtual machine scale sets** from the list.
2. Select **Add** to create a new scale set.
3. Complete the fields on the **Basics** tab as you usually would, but make sure you select a VM size that is from the series you chose for your dedicated host, like **Standard E2s v3**.
4. On the **Advanced** tab, for **Spreading algorithm** select **Max spreading**.
5. In **Host group**, select the host group from the drop-down. If you recently created the group, it might take a minute to get added to the list.

Reassign an existing VM

You can reassign an existing multitenant VM or dedicated host VM to a different dedicated host, but the VM must first be Stop\Deallocated. Before you move a VM to a dedicated host, make sure that the VM configuration is supported:

- The VM size must be in the same size family as the dedicated host. For example, if your dedicated host is DSv3, then the VM size could be Standard_D4s_v3, but it couldn't be a Standard_A4_v2.
- The VM needs to be located in same region as the dedicated host.
- The VM can't be part of a proximity placement group. Remove the VM from the proximity placement group before moving it to a dedicated host. For more information about this topic, see Move a VM out of a proximity placement group.
- The VM can't be in an availability set.
- If the VM is in an availability zone, it must be the same availability zone as the host group. The availability zone settings for the VM and the host group must match.

Portal

Move the VM to a dedicated host using the portal.

1. Open the page for the VM.
2. Select **Stop** to stop\deallocate the VM.
3. Select **Configuration** from the left menu.
4. Select a host group and a host from the drop-down menus.
5. When you're done, select **Save** at the top of the page.
6. After the VM has been added to the host, select **Overview** from the left menu.
7. At the top of the page, select **Start** to restart the VM.

Move a VM from dedicated host to multitenant infrastructure

You can move a VM that is running on a dedicated host to multitenant infrastructure, but the VM must first be Stop\Deallocated.

- Make sure that your subscription has sufficient vCPU quota for the VM in the region where

- Your multitenant VM will be scheduled in the same region and zone as the dedicated host

Portal

Move a VM from dedicated host to multitenant infrastructure using the portal.

1. Open the page for the VM.
2. Select **Stop** to stop\deallocate the VM.
3. Select **Configuration** from the left menu.
4. Select **None** under host group drop-down menu.
5. When you're done, select **Save** at the top of the page.
6. After the VM has been reconfigured as a multitenant VM, select **Overview** from the left menu.
7. At the top of the page, select **Start** to restart the VM.

Check the status of the host

If you need to know how much capacity is still available on a how, you can check the status.

Portal

1. Search for and select the host.
2. In the **Overview** page for the host, scroll down to see the list of sizes still available for the host. It should look similar to:

Available VM capacity

VM Size	Number remaining
Standard_D2ds_v4	32
Standard_D4ds_v4	17
Standard_D8ds_v4	8
Standard_D16ds_v4	4
Standard_D32ds_v4	2
Standard_D48ds_v4	1
Standard_D64ds_v4	1

Restart a host

Restarting a host does not completely power off the host. When the host restarts, the underlying VMs will also restart. The host will remain on the same underlying physical hardware and both the host ID and asset ID will remain the same after the restart. The host SKU will also remain the same after the restart.

Portal

1. Search for and select the host.
2. In the top menu bar, select the **Restart** button.
3. In the **Essentials** section of the Host Resource Pane, Host Status will switch to **Host undergoing restart** during the restart.
4. Once the restart has completed, the Host Status will return to **Host available**.

Resize a host

Moving a host and all associated VMs to newer generation hardware can be done through the host resize feature. Resize simplifies the migration process and avoids having to manually create new hosts and move all VMs individually.

Resize limitations:

- Host can only be resized to an ADH within the same VM family. A Dsv3-Type3 host can be resized to Dsv3-Type4 but **not** to an **E**sv3-Type4.
- You can only resize to newer generation of hardware. A Dsv3-Type3 host can be resized to Dsv3-Type4 but **not** Dsv3-Type2.
- Resizing changes the 'Host Asset ID'. The 'Host ID' remains the same.
- The host and all associated VMs become unavailable during the resize operation.

> ⚠ **Warning**
>
> The resize operation causes the loss of any non-persistent data such as temp disk data. Save all your work to persistent data storage before triggering resize.

> ⓘ **Note**
>
> If the source host is already running on the latest hardware, 'Size' page would display an empty list. If you're looking for enhanced performance, consider

switching to a different VM family.

Portal

1. Search for and select the host.
2. In the left menu under **Settings**, select **Size**.
3. Once on the size page from the list of SKUs, select the desired SKU to resize to.
4. Selecting a target size from the list would enable **Resize** button on the bottom on the page.
5. Click **Resize**, host's 'Provisioning State' changes from 'Provisioning Succeeded' to 'Updating'
6. Once the resizing is complete, the host's 'Provisioning State' reverts to 'Provisioning Succeeded'

Redeploy a host [Preview]

If a VM or the underlying host remains unresponsive after following all the potential troubleshooting steps users can trigger service healing of the host and not wait for the platform to initiate the repair. Redeploying a host will move the host and all associated VMs to a different node of the same SKU. None of the host parameters would change except for the 'Host asset ID', which corresponds to the underlying Node Id.

> ⚠ **Warning**
>
> Redeploy operation involves service healing hence would result in loss of any non-persistent data such as data stored on ephemeral disks. Save your work before redeploying.

Portal

1. Search for and select the host.
2. In the top menu bar, select the **Redeploy** button.
3. In the **Essentials** section of the Host Resource Pane, host's provisioning state will switch to **Updating** during the redeploy operation.
4. Once the redeploy operation is completed, host's provisioning state will revert to **Provisioning succeeded**.

5. In the **Essentials** section of the Host Resource Pane, **Host asset ID** would be updated to a new ID

Deleting a host

You're being charged for your dedicated host even when no virtual machines are deployed on the host. You should delete any hosts you're currently not using to save costs.

You can only delete a host when there are no any longer virtual machines using it.

Portal

1. Search for and select the host.
2. In the left menu, select **Instances**.
3. Select and delete each virtual machine.
4. When all of the VMs have been deleted, go back to the **Overview** page for the host and select **Delete** from the top menu.
5. Once the host has been deleted, open the page for the host group and select **Delete host group**.

Next steps

- For more information about this topic, see the Dedicated hosts overview.
- There's sample template, available at Azure Quickstart Templates, which uses both zones and fault domains for maximum resiliency in a region.

General Purpose Azure Dedicated Host SKUs

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision Dsv3-series VMs.

This document goes through the hardware specifications and VM packings for all general purpose Dedicated Host SKUs.

Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host pricing page to learn more.

Ddsv6

Ddsv6-Type1

The Ddsv6-Type1 is a Dedicated Host SKU utilizing Intel's 8573B processor. It offers 96 physical cores, 192 vCPUs, and 1024 GiB of RAM. The Ddsv6-Type1 runs Ddsv6-series VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Ddsv6-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
96	192	1024 GiB	D2ds v6	32
			D4ds v6	32
			D8ds v6	25
			D16ds v6	12
			D32ds v6	6
			D48ds v6	4
			D64ds v6	3

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
			D96ds v6	2
			D128ds v6	1
			D192ds v6	1

Dsv6

Dsv6-Type1

The Dsv6-Type1 is a Dedicated Host SKU utilizing Intel's 8573B processor. It offers 96 physical cores, 192 vCPUs, and 1024 GiB of RAM. The Dsv6-Type1 runs Dsv6-series VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv6-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
96	192	1024 GiB	D2s v6	32
			D4s v6	32
			D8s v6	25
			D16s v6	12
			D32s v6	6

			D32ads v5	3
			D48ads v5	2
			D64ads v5	1
			D96ads v5	1

Dasv5

Dasv5-Type1

The Dasv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Dasv5-Type1 runs Dasv5-series VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dasv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	768 GiB	D2as v5	32
			D4as v5	28
			D8as v5	14
			D16as v5	7
			D32as v5	3
			D48as v5	2
			D64as v5	1
			D96as v5	1

Dasv4

Dasv4-Type1

The Dasv4-Type1 is a Dedicated Host SKU utilizing AMD's 2.35 GHz EPYC™ 7452 processor. It offers 64 physical cores, 96 vCPUs, and 672 GiB of RAM. The Dasv4-Type1 runs Dasv4-series VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dasv4-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	96	672 GiB	D2as v4	32
			D4as v4	24
			D8as v4	12
			D16as v4	6
			D32as v4	3
			D48as v4	2
			D64as v4	1
			D96as v4	1

You can also mix multiple VM sizes on the Dasv4-Type1. The following are sample combinations of VM packings on the Dasv4-Type1:

- 1 D48asv4 + 3 D16asv4
- 1 D32asv4 + 2 D16asv4 + 8 D4asv4
- 20 D4asv4 + 8 D2asv4

Dasv4-Type2

The Dasv4-Type2 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Dasv4-Type2 runs Dasv4-series VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dasv4-Type2 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs

Compute Optimized Azure Dedicated Host SKUs

Article • 08/22/2024

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision Dsv3-series VMs.

This document goes through the hardware specifications and VM packings for all compute optimized Dedicated Host SKUs.

Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host pricing page to learn more.

Fsv2

Fsv2-Type2

The Fsv2-Type2 is a Dedicated Host SKU utilizing the Intel® Skylake (Xeon® Platinum 8168) processor. It offers 48 physical cores, 72 vCPUs, and 144 GiB of RAM. The Fsv2-Type2 runs Fsv2-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Fsv2-Type2 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
48	72	144 GiB	F2s v2	32
			F4s v2	18
			F8s v2	9
			F16s v2	4
			F32s v2	2
			F48s v2	1

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
			F64s v2	1
			F72s v2	1

Fsv2-Type3

The Fsv2-Type3 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Fsv2-Type3 runs Fsv2-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Fsv2-Type3 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
52	80	504 GiB	F2s v2	32
			F4s v2	21
			F8s v2	10
			F16s v2	5
			F32s v2	2
			F48s v2	1
			F64s v2	1
			F72s v2	1

Fsv2-Type4

The Fsv2-Type4 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Fsv2-Type4 runs Fsv2-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Fsv2-Type4 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	119	768 GiB	F2s v2	32
			F4s v2	24
			F8s v2	12
			F16s v2	6
			F32s v2	3
			F48s v2	2
			F64s v2	1
			F72s v2	1

FXmds

FXmds-Type1

The FXmds-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Gold 6246R) processor. It offers 32 physical cores, 48 vCPUs, and 1,152 GiB of RAM. The FXmds-Type1 runs FX-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a FXmds-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs

Memory Optimized Azure Dedicated Host SKUs

Article • 08/22/2024

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision Dsv3-series VMs.

This document goes through the hardware specifications and VM packings for all memory optimized Dedicated Host SKUs.

Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host pricing page to learn more.

Eadsv5

Eadsv5-Type1

The Eadsv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Eadsv5-Type1 runs Eadsv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Eadsv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	768 GiB	E2ads v5	32
			E4ads v5	21
			E8ads v5	10
			E16ads v5	5
			E20ads v5	4
			E32ads v5	2

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
			E48ads v5	1
			E64ads v5	1
			E96ads v5	1

Easv5

Easv5-Type1

The Easv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Easv5-Type1 runs Easv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Easv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	768 GiB	E2as v5	32
			E4as v5	21
			E8as v5	10
			E16as v5	5
			E20as v5	4
			E32as v5	2
			E48as v5	1
			E64as v5	1
			E96as v5	1

Easv4

Easv4-Type1

The Easv4-Type1 is a Dedicated Host SKU utilizing AMD's 2.35 GHz EPYC™ 7452 processor. It offers 64 physical cores, 96 vCPUs, and 672 GiB of RAM. The Easv4-Type1 runs Easv4-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Easv4-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	96	672 GiB	E2as v4	32
			E4as v4	21
			E8as v4	10
			E16as v4	5
			E20as v4	4
			E32as v4	2
			E48as v4	1
			E64as v4	1
			E96as v4	1

Easv4-Type2

The Easv4-Type2 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Easv4-Type2 runs Easv4-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Easv4-Type2 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	768 GiB	E2as v4	32
			E4as v4	21
			E8as v4	10

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
			E16as v4	5
			E20as v4	4
			E32as v4	2
			E48as v4	1
			E64as v4	1
			E96as v4	1

Ebdsv5

Ebdsv5-Type1

The Ebdsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Ebdsv5-Type1 runs Ebdsv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Ebdsv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	119	768 GiB	E2bds v5	8
			E4bds v5	8
			E8bds v5	6
			E16bds v5	3
			E32bds v5	1
			E48bds v5	1
			E64bds v5	1

Ebsv5

Ebsv5-Type1

The Ebsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Ebsv5-Type1 runs Ebsv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Ebsv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	119	768 GiB	E2bs v5	8
			E4bs v5	8
			E8bs v5	6
			E16bs v5	3
			E32bs v5	1
			E48bs v5	1
			E64bs v5	1

ECadsv5

ECadsv5-Type1

The ECadsv5-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The ECadsv5-Type1 runs ECadsv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an ECadsv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	768 GiB	EC2ads v5	32
			EC4ads v5	21

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
			EC8ads v5	10
			EC16ads v5	5
			EC20ads v5	4
			EC32ads v5	3
			EC48ads v5	1
			EC64ads v5	1
			EC96ads v5	1

ECasv5

ECasv5-Type1

The ECasv5-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The ECasv5-Type1 runs ECasv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an ECasv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	768 GiB	EC2as v5	32
			EC4as v5	21
			EC8as v5	10
			EC16as v5	5
			EC20as v5	4
			EC32as v5	3
			EC48as v5	1
			EC64as v5	1
			EC96as v5	1

Edsv5

Edsv5-Type1

The Edsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Edsv5-Type1 runs Edsv5-series VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Edsv5-Type1 host.

Expand table

Physical cores	Available vCPUs	Available RAM	VM Size	# VMs
64	119	768 GiB	E2ds v5	32
			E4ds v5	21

Azure Dedicated Host SKU Retirement

03/17/2025

We continue to modernize and optimize Azure Dedicated Host by using the latest innovations in processor and datacenter technologies. Azure Dedicated Host is a combination of a virtual machine (VM) series and a specific Intel or AMD-based physical server. As we innovate and work with our technology partners, we also need to plan how we retire aging technology.

UPDATE: Retirement timeline extension

Considering the feedback from several Azure Dedicated Host customers that are running their critical workloads on SKUs that are scheduled for retirement, we have extended the retirement timeline from March 31, 2023 to June 30, 2023. We don't intend to move the retirement timeline any further and recommend all ADH users that are using any of the listed SKUs to migrate to newer generation based SKUs to avoid workload disruptions.

Migrations required by 30 June 2023 [Updated]

All hardware has a finite lifespan, including the underlying hardware for Azure Dedicated Host. As we continue to modernize Azure datacenters, hardware is decommissioned and eventually retired. The hardware that runs the following Dedicated Host SKUs is reaching end of life:

- Dsv3-Type1
- Dsv3-Type2
- Esv3-Type1
- Esv3-Type2

As a result we'll retire these Dedicated Host SKUs on 30 June 2023.

How does the retirement of Azure Dedicated Host SKUs affect you?

The current retirement impacts the following Azure Dedicated Host SKUs:

- Dsv3-Type1
- Esv3-Type1
- Dsv3-Type2
- Esv3-Type2

Note: If you're running a Dsv3-Type3, Dsv3-Type4, an Esv3-Type3, or an Esv3-Type4 Dedicated Host, you are not impacted.

What actions should you take?

For manually placed VMs, you need to create a Dedicated Host of a newer SKU, stop the VMs on your existing Dedicated Host, reassign them to the new host, start the VMs, and delete the old host. For automatically placed VMs or for Virtual Machine Scale Sets, you need to create a Dedicated Host of a newer SKU, stop the VMs or Virtual Machine Scale Set, delete the old host, and then start the VMs or Virtual Machine Scale Set.

Refer to the Azure Dedicated Host Migration Guide for more detailed instructions. We recommend moving to the latest generation of Dedicated Host for your VM family.

If you have any questions, contact us through customer support.

FAQs

Q: Will migration result in downtime?

A: Yes, you would have to stop/deallocate your VMs or Virtual Machine Scale Sets before moving them to the target host.

Q: When will the other Dedicated Host SKUs retire?

A: We'll announce Dedicated Host SKU retirements 12 months in advance of the official retirement date of a given Dedicated Host SKU.

Q: What are the milestones for the Dsv3-Type1, Dsv3-Type2, Esv3-Type1, and Esv3-Type1 retirement?

A:

Expand table

Date	Action
15 March 2022	Dsv3-Type1, Dsv3-Type2, Esv3-Type1, Esv3-Type2 retirement announcement
30 June 2023	Dsv3-Type1, Dsv3-Type2, Esv3-Type1, Esv3-Type2 retirement

Q: What happens to my Azure Reservation?

A: You need to exchange your reservation through the Azure portal to match the new Dedicated Host SKU.

Q: What would happen to my host if I do not migrate by June 30, 2023?

A: After June 30, 2023 any dedicated host running on the SKUs that are marked for retirement will be set to 'Host Pending Deallocate' state before eventually deallocating the host. For more assistance, please reach out to Azure support.

Q: What will happen to my VMs if a Host is automatically deallocated?

A: If the underlying host is deallocated the VMs that were running on the host would be either in failed or stopped state but not deleted.

You could stop/deallocate the VM or virtual machine scale set and dissociate the VM or virtual machine scale set from the host/host group (depending on explicit vs implicit placement) and then you would be able to either create a new host (of the same VM family) and allocate VMs on the host/host group or run the VMs on multitenant infrastructure.

Refer to the Azure Dedicated Host Migration Guide for more detailed instructions.

Azure Dedicated Host SKU Retirement Migration Guide

As hardware ages, it must be retired and workloads must be migrated to newer, faster, and more efficient Azure Dedicated Host SKUs. The legacy Dedicated Host SKUs should be migrated to newer Dedicated Host SKUs. The main differences between the retiring Dedicated Host SKUs and the newly recommended Dedicated Host SKUs are:

- Newer, more efficient processors
- Increased RAM
- Increased available vCPUs
- Greater regional capacity compared to the retiring Dedicated Host SKUs

Review the FAQs before you get started on migration. The next section will go over which Dedicated Host SKUs to migrate to help aid in migration planning and execution.

Host SKUs being retired

Some Azure Dedicated Host SKUs will be retired soon. Refer to the Azure Dedicated Host SKU Retirement documentation to learn more.

Dsv3-Type1 and Dsv3-Type2

The Dsv3-Type1 and Dsv3-Type2 run Dsv3-series VMs, which offer a combination of vCPU, memory, and temporary storage best suited for most general-purpose workloads. We recommend migrating your existing VMs to one of the following Dedicated Host SKUs:

- Dsv3-Type3
- Dsv3-Type4

Note that both the Dsv3-Type3 and Dsv3-Type4 won't be impacted by the 31 March 2023 retirement date. We recommend moving to either the Dsv3-Type3 or Dsv3-Type4 based on regional availability, pricing, and your organization’s needs.

Esv3-Type1 and Esv3-Type2

The Esv3-Type1 and Esv3-Type2 run Esv3-series VMs, which offer a combination of vCPU, memory, and temporary storage best suited for most memory-intensive workloads. We recommend migrating your existing VMs to one of the following Dedicated Host SKUs:

- Esv3-Type3

- Esv3-Type4

Note that both the Esv3-Type3 and Esv3-Type4 won't be impacted by the 31 March 2023 retirement date. We recommend moving to either the Esv3-Type3 or Esv3-Type4 based on regional availability, pricing, and your organization's needs.

Migrating to supported hosts

To migrate your workloads and avoid Dedicated Host SKU retirement, follow the directions for your migration method of choice.

Automatic migration (Resize)

Moving a host and all associated VMs to newer generation hardware can be done through the host resize feature. Resize simplifies the migration process and avoids having to manually create new hosts and move all VMs individually.

Resize limitations:

- Host can only be resized to an ADH within the same VM family. A Dsv3-Type3 host can be resized to Dsv3-Type4 but **not** to an **E**sv3-Type4.
- You can only resize to newer generation of hardware. A Dsv3-Type3 host can be resized to Dsv3-Type4 but **not** Dsv3-Type2.
- Resizing changes the 'Host Asset ID'. The 'Host ID' remains the same.
- The host and all associated VMs become unavailable during the resize operation.

> ⚠ **Warning**
>
> The resize operation causes the loss of any non-persistent data such as temp disk data. Save all your work to persistent data storage before triggering resize.

> ⓘ **Note**
>
> If the source host is already running on the latest hardware, 'Size' page would display an empty list. If you're looking for enhanced performance, consider switching to a different VM family.

Portal

1. Search for and select the host.

2. In the left menu under **Settings**, select **Size**.
3. Once on the size page from the list of SKUs, select the desired SKU to resize to.
4. Selecting a target size from the list would enable **Resize** button on the bottom on the page.
5. Click **Resize**, host's 'Provisioning State' changes from 'Provisioning Succeeded' to 'Updating'
6. Once the resizing is complete, the host's 'Provisioning State' reverts to 'Provisioning Succeeded'

Manual migration

This includes steps for manually placed VMs, automatically placed VMs, and virtual machine scale sets on your Dedicated Hosts:

Manually Placed VMs

1. Choose a target Dedicated Host SKU to migrate to.
2. Ensure you have quota for the VM family associated with the target Dedicated Host SKU in your given region.
3. Provision a new Dedicated Host of the target Dedicated Host SKU in the same Host Group.
4. Stop and deallocate the VM(s) on your old Dedicated Host.
5. Reassign the VM(s) to the target Dedicated Host.
6. Start the VM(s).
7. Delete the old host.

More detailed instructions can be found in the following sections.

> ⓘ **Note**
>
> **Certain sections are different for automatically placed VMs or virtual machine scale set**. These differences will explicitly be called out in the respective steps.

Ensure quota for the target VM family

Be sure that you have enough vCPU quota for the VM family of the Dedicated Host SKU that you'll be using. If you need quota, follow this guide to request an increase in vCPU quota for

your target VM family in your target region. Select the Dsv3-series or Esv3-series as the VM family, depending on the target Dedicated Host SKU.

Create a new Dedicated Host

Within the same Host Group as the existing Dedicated Host, create a Dedicated Host of the target Dedicated Host SKU.

Stop the VM(s) or virtual machine scale set

PowerShell

Refer to the PowerShell documentation to stop a VM through PowerShell or stop a virtual machine scale set through PowerShell.

Reassign the VM(s) to the target Dedicated Host

> ⓘ Note
>
> **Skip this step for automatically placed VMs and virtual machine scale set.**

Once the target Dedicated Host has been created and the VM has been stopped, reassign the VM to the target Dedicated Host.

Start the VM(s) or virtual machine scale set

> ⓘ Note
>
> **Automatically placed VM(s) and virtual machine scale set require that you delete the old host *before* starting the autoplaced VM(s) or virtual machine scale set.**

PowerShell

Refer to the PowerShell documentation to start a VM through PowerShell or start a virtual machine scale set through PowerShell.

Delete the old Dedicated Host

Once all VMs have been migrated from your old Dedicated Host to the target Dedicated Host, delete the old Dedicated Host.

Help and support

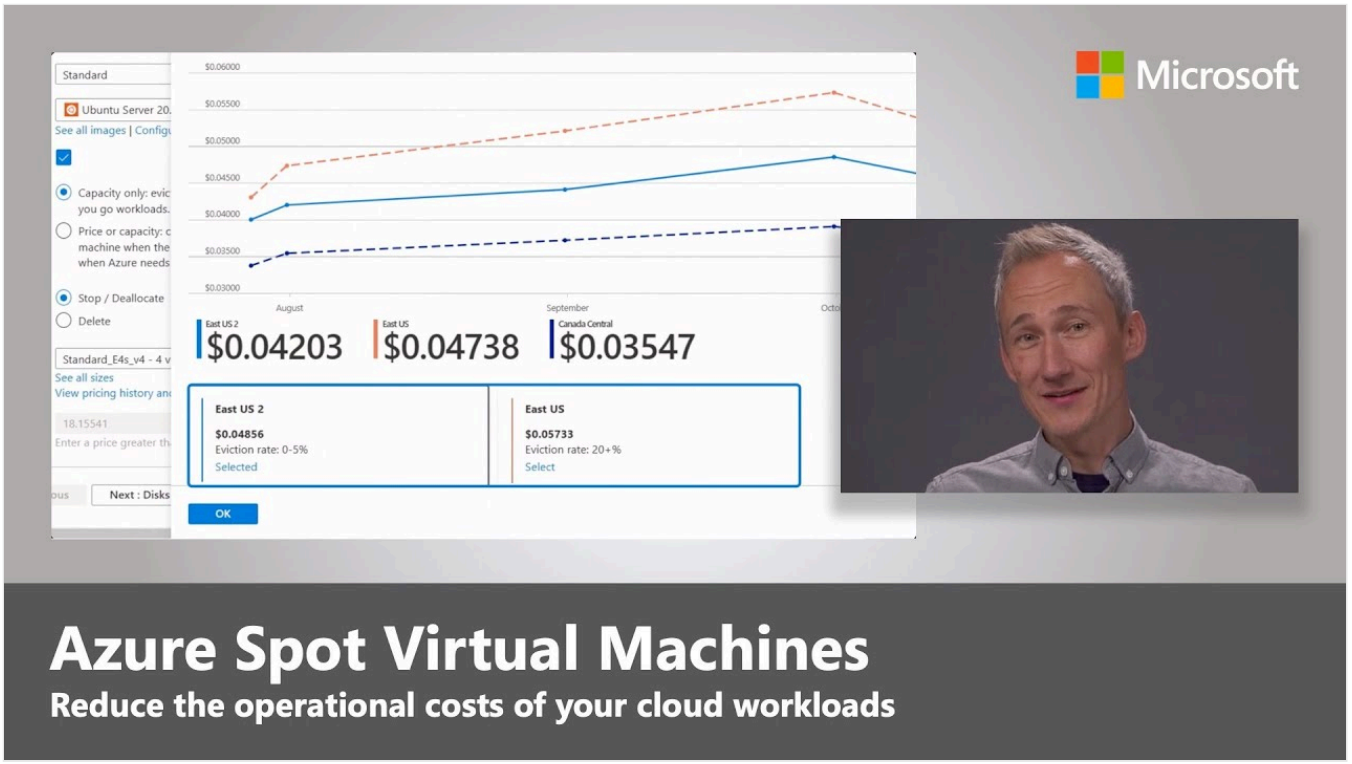
Last updated on 03/17/2025

Azure Spot Virtual Machines

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Using Azure Spot Virtual Machines allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

The amount of available capacity can vary based on size, region, time of day, and more. When deploying Azure Spot Virtual Machines, Azure will allocate the VMs if there's capacity available, but there's no SLA for these VMs. An Azure Spot Virtual Machine offers no high availability guarantees. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines with 30-seconds notice.



Eviction policy

Spot VMs can be stopped if Azure needs capacity for other pay-as-you-go workloads or when the price of the spot instance exceeds the maximum price that you have set. When creating an Azure Spot Virtual Machine, you can set the eviction policy to *Deallocate* (default) or *Delete*.

The *Deallocate* policy moves your VM to the stopped-deallocated state, allowing you to redeploy it later. However, there's no guarantee that the allocation will succeed. The deallocated VMs will count against your quota and you'll be charged storage costs for the underlying disks.

If you would like your VM to be deleted when it's evicted, you can set the eviction policy to *delete*. The evicted VMs are deleted together with their underlying disks, so you'll not continue to be charged for the storage.

You can opt in to receive in-VM notifications through Azure Scheduled Events. These are delivered on a best effort basis up to 30 seconds prior to the eviction.

Expand table

Option	Outcome
Max price is set to >= the current price.	VM is deployed if capacity and quota are available.
Max price is set to < the current price.	The VM isn't deployed. You'll get an error message that the max price needs to be >= current price.
Restarting a stopped/deallocated VM if the max price is >= the current price	If there's capacity and quota, then the VM is deployed.
Restarting a stopped/deallocated VM if the max price is < the current price	You'll get an error message that the max price needs to be >= current price.
Price for the VM has gone up and is now > the max price.	The VM gets evicted. Azure will attempt scheduled event delivery up to 30 seconds before actual eviction.
After eviction, the price for the VM goes back to being < the max price.	The VM won't be automatically restarted. You can restart the VM yourself, and it will be charged at the current price.
If the max price is set to `-1`	The VM won't be evicted for pricing reasons. The max price will be the current price, up to the price for standard VMs. You'll never be charged above the standard price.
Changing the max price	You need to deallocate the VM to change the max price. Deallocate the VM, set a new max price, then update the VM.

Tip

Check out our Azure Virtual Machine Spot Eviction guide to learn how to create a reliable interruptible workload in Azure.

Limitations

The following VM sizes aren't supported for Azure Spot Virtual Machines:

- B-series

- Promo versions of any size (like Dv2, NV, NC, H promo sizes)

Azure Spot Virtual Machines can be deployed to any region, except Microsoft Azure operated by 21Vianet.

The following offer types are currently supported:

- Enterprise Agreement
- Pay-as-you-go offer code (003P)
- Sponsored (0036P and 0136P) - not available in Fairfax
- For Cloud Service Provider (CSP), see the Partner Center or contact your partner directly.

Pricing

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for Linux and Windows.

You can also query pricing information using the Azure retail prices API to query for information about Spot pricing. The `meterName` and `skuName` will both contain `Spot`.

With variable pricing, you have option to set a max price, in US dollars (USD), using up to five decimal places. For example, the value `0.98765` would be a max price of $0.98765 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for spot or the price for a standard VM, which ever is less, as long as there's capacity and quota available.

Pricing and eviction history

Portal

You can see historical pricing and eviction rates per size in a region in the portal while you are creating the VM. After selecting the checkbox to **Run with Azure Spot discount**, a link will appear under the size selection of the VM titled **View pricing history and compare prices in nearby regions**. By selecting that link you will be able to see a table or graph of spot pricing for the specified VM size. The pricing and eviction rates in the following images are only examples.

> **Tip**

Eviction rates are quoted *per hour*. For example, an eviction rate of 10% means a VM has a 10% chance of being evicted within the next hour, based on historical eviction data of the last 7 days.

Chart:

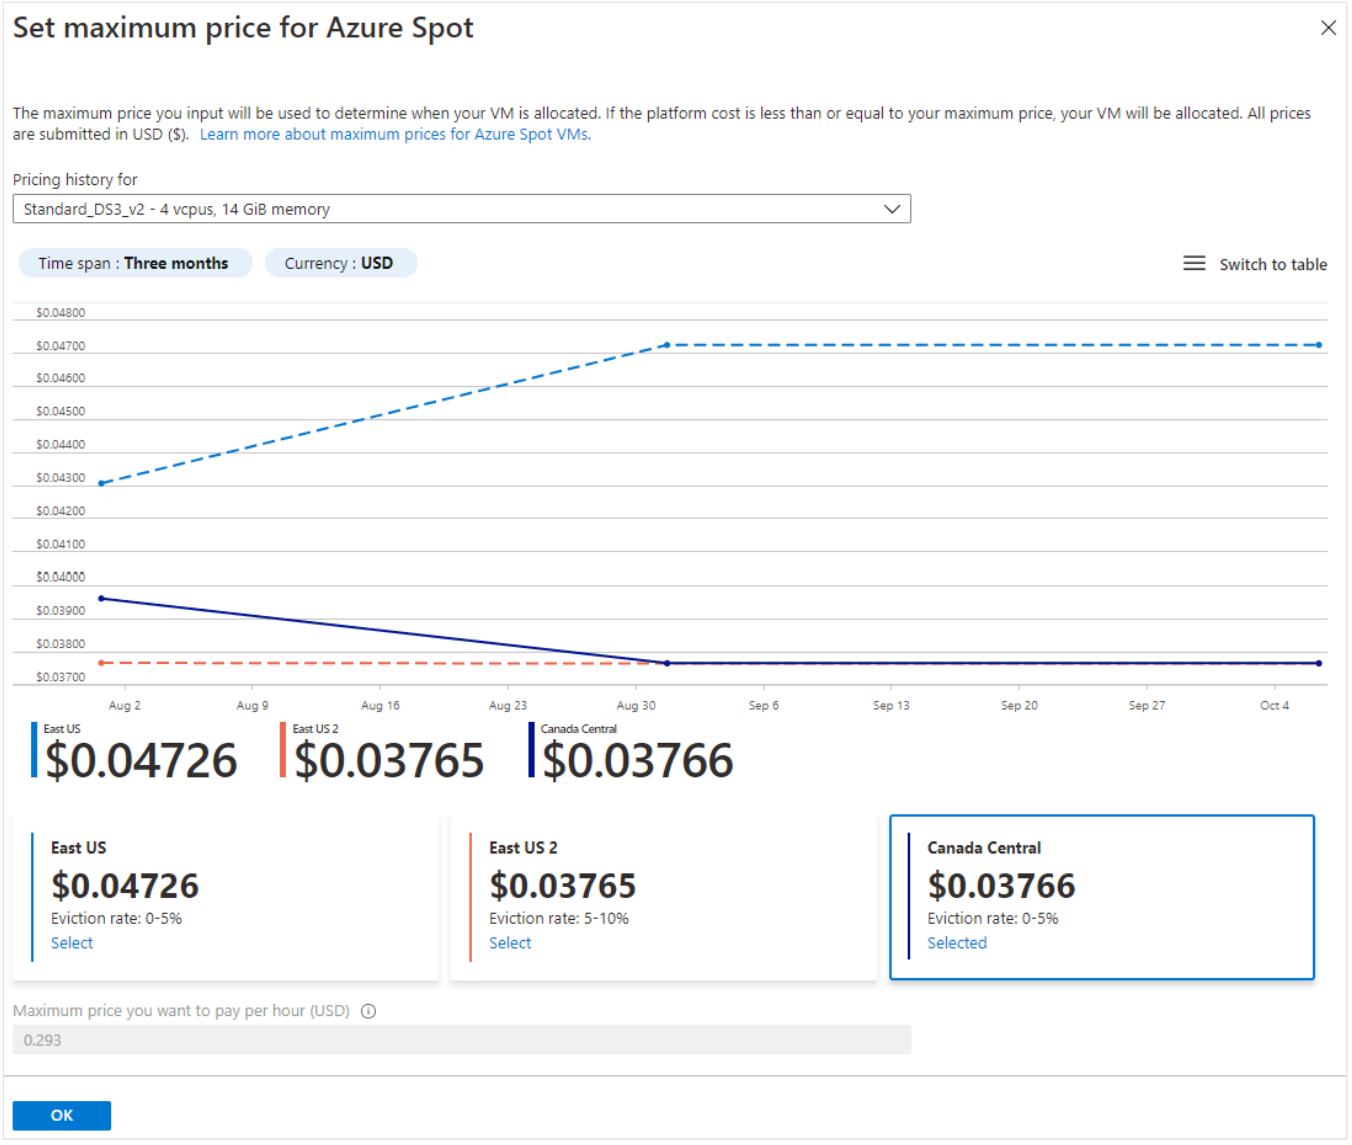


Table:

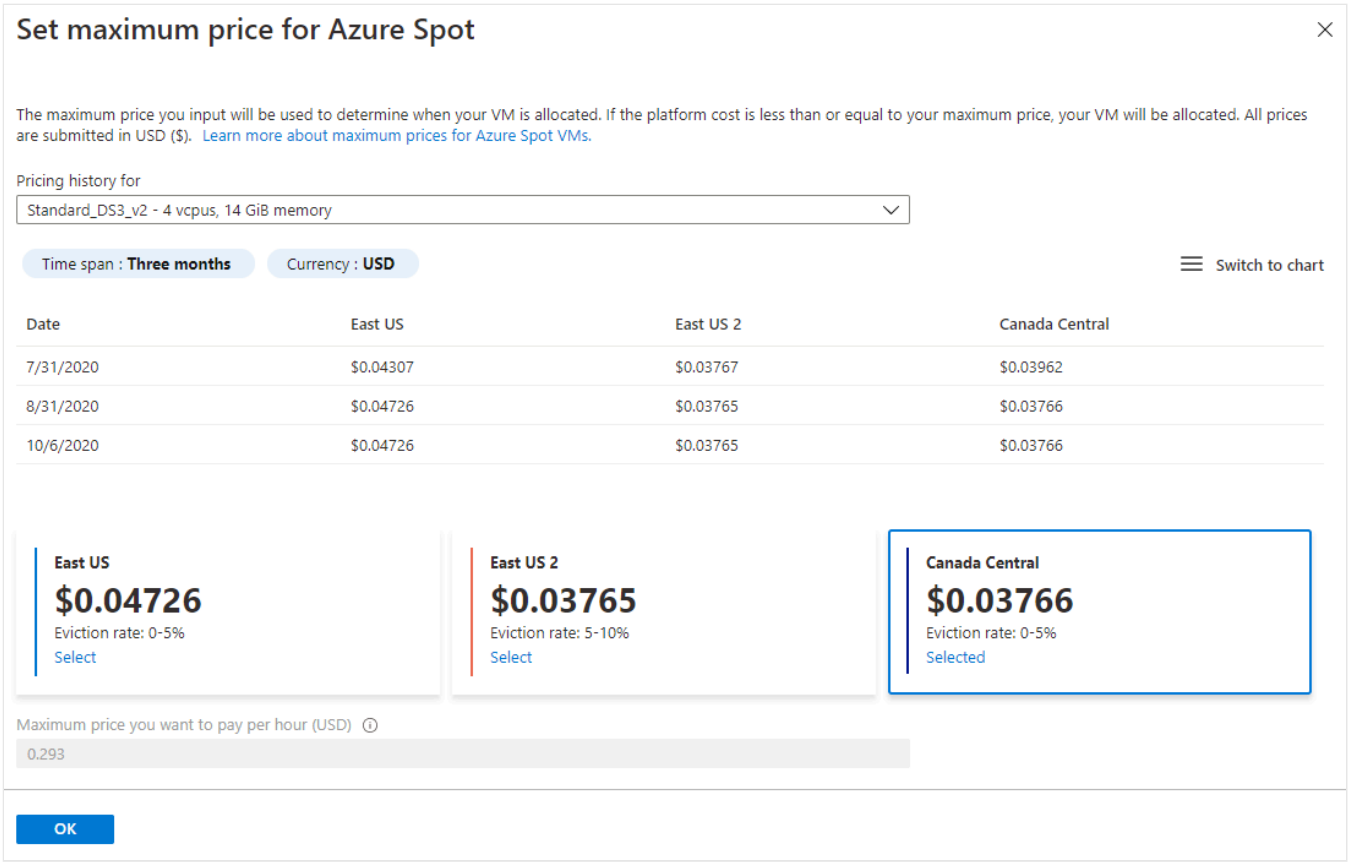

Azure Resource Graph

You can programmatically access relevant Spot VM SKU data through Azure Resource Graph. Get pricing history in the last 90 days and eviction rates for the last 28 trailing days to identify SKUs that better meet your specific needs.

Key benefits:

- Query Spot eviction rates and the last few months of Spot prices programmatically through ARM or the ARG Explorer in Azure portal
- Create a custom query to extract the specific data relevant to your scenario with the ability to filter across a variety of parameters, such as SKU and region
- Easily compare data across multiple regions and SKUs
- Find a different Spot SKU or region with a lower price and/or eviction rate

Try out the following sample queries for Spot pricing history and eviction rates using the ARG Explorer in Azure portal. Spot pricing history and eviction rates data are available in the `SpotResources` table.

Spot pricing history sample query:

SQL

```
SpotResources
| where type =~ 'microsoft.compute/skuspotpricehistory/ostype/location'
```

```
| where sku.name in~ ('standard_d2s_v4', 'standard_d4s_v4')
| where properties.osType =~ 'linux'
| where location in~ ('eastus', 'southcentralus')
|
 project skuName = tostring(sku.name), osType = tostring(properties.osType), locati
on, latestSpotPriceUSD = todouble(properties.spotPrices[0].priceUSD)
| order by latestSpotPriceUSD asc
```

Spot eviction rates sample query:

SQL

```
SpotResources
| where type =~ 'microsoft.compute/skuspotevictionrate/location'
| where sku.name in~ ('standard_d2s_v4', 'standard_d4s_v4')
| where location in~ ('eastus', 'southcentralus')
|
 project skuName = tostring(sku.name), location, spotEvictionRate = tostring(proper
ties.evictionRate)
| order by skuName asc, location asc
```

Alternatively, try out the ARG REST API to get the pricing history and eviction rate history data.

Frequently asked questions

Q: Once created, is an Azure Spot Virtual Machine the same as regular standard VM?

A: Yes, except there's no SLA for Azure Spot Virtual Machines and they can be evicted at any time.

Q: What to do when you get evicted, but still need capacity?

A: We recommend you use standard VMs instead of Azure Spot Virtual Machines if you need capacity right away.

Q: How is quota managed for Azure Spot Virtual Machines?

A: Azure Spot Virtual Machines will have a separate quota pool. Spot quota will be shared between VMs and scale-set instances. For more information, see Azure subscription and service limits, quotas, and constraints.

Q: Can I request for additional quota for Azure Spot Virtual Machines?

A: Yes, you'll be able to submit the request to increase your quota for Azure Spot Virtual Machines through the standard quota request process.

Q: Where can I post questions?

A: You can post and tag your question with `azure-spot` at Q&A.

Q: How can I change the max price for a spot VM?

A: Before you can change the max price, you need to deallocate the VM. Then you can change the max price in the portal, from the **Configuration** section for the VM.

Q: Can I convert existing VMs to Spot VMs?

A: No, setting the Spot flag is only supported at creation time.

Q: Can I convert Spot VMs to Standard VMs?

A: No, Spot VMs cannot be directly converted to Standard VMs.

Next steps

Use the CLI, portal, ARM template, or PowerShell to deploy Azure Spot Virtual Machines.

You can also deploy a scale set with Azure Spot Virtual Machine instances.

If you encounter an error, see Error codes.

Deploy Azure Spot Virtual Machines using the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Using Azure Spot Virtual Machines allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure evicts Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for Linux and Windows.

You have option to set a max price you're willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.98765` is a max price of $0.98765 USD per hour. If you set the max price to be `-1`, the VM is evicted based on price. The price for the VM is the current price for Azure Spot Virtual Machine or the price for a standard VM, which ever is less, as long as there's capacity and quota available. For more information about setting the max price, see Azure Spot Virtual Machines - Pricing.

The process to create an Azure Spot Virtual Machine using the Azure CLI is the same as detailed in the quickstart article. Just add the '--priority Spot' parameter, set the `--eviction-policy` to either `Deallocate` (the default) or `Delete`, and provide a max price or `-1`.

Install Azure CLI

To create Azure Spot Virtual Machines, you need to be running the Azure CLI version 2.0.74 or later. Run **az --version** to find the version. If you need to install or upgrade, see Install the Azure CLI.

Sign in to Azure using az login.

Azure CLI

```
az login
```

Create an Azure Spot Virtual Machine

This example shows how to deploy a Linux Azure Spot Virtual Machine that is not evicted based on price. The eviction policy is set to deallocate the VM, so that it can be restarted at a later time. If you want to delete the VM and the underlying disk when the VM is evicted, set `--eviction-policy` to `Delete`.

Azure CLI

```
az group create -n mySpotGroup -l eastus
az vm create \
    --resource-group mySpotGroup \
    --name myVM \
    --image Ubuntu2204 \
    --admin-username azureuser \
    --generate-ssh-keys \
    --priority Spot \
    --max-price -1 \
    --eviction-policy Deallocate
```

After the VM is created, you can query to see the max billing price for all of the VMs in the resource group.

Azure CLI

```
az vm list \
   -g mySpotGroup \
   --query '[].{Name:name, MaxPrice:billingProfile.maxPrice}' \
   --output table
```

Simulate an eviction

You can simulate an eviction of an Azure Spot Virtual Machine using REST, PowerShell, or the CLI, to test how well your application responds to a sudden eviction.

In most cases, you want to use the REST API Virtual Machines - Simulate Eviction to help with automated testing of applications. For REST, a `Response Code: 204` means the simulated eviction was successful. You can combine simulated evictions with the Scheduled Event service, to automate how your app responds when the VM is evicted.

To see scheduled events in action, watch Azure Friday - Using Azure Scheduled Events to prepare for VM maintenance.

Quick test

For a quick test to show how a simulated eviction works, let's walk through querying the scheduled event service to see what it looks like when you simulate an eviction using the Azure CLI.

The Scheduled Event service is enabled for your service the first time you make a request for events.

Remote into your VM, and then open a command prompt.

From the command prompt on your VM, type:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

This first response could take up to 2 minutes. From now on, they should display output almost immediately.

From a computer that has the Azure CLI installed (like your local machine), simulate an eviction using az vm simulate-eviction. Replace the resource group name and VM name with your own.

Azure CLI

```
az vm simulate-eviction --resource-group mySpotRG --name mySpot
```

The response output has `Status: Succeeded` if the request was successfully made.

Quickly go back to your remote connection to your Spot Virtual Machine and query the Scheduled Events endpoint again. Repeat the following command until you get an output that contains more information:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

When the Scheduled Event Service gets the eviction notification, you get a response that looks similar to the following output:

Output

```
{"DocumentIncarnation":1,"Events":[{"EventId":"A123BC45-1234-5678-AB90-ABCDEF123456","EventStatus":"Scheduled","EventType":"Preempt","ResourceType"
```

```
:"VirtualMachine","Resources":["myspotvm"],"NotBefore":"Tue, 16 Mar 2021
00:58:46 GMT","Description":"","EventSource":"Platform"}]}
```

You can see that `"EventType":"Preempt"`, and the resource is the VM resource `"Resources":["myspotvm"]`.

You can also see the VM's eviction condition by checking the `"NotBefore"` - the VM will not be evicted before the time given, so that is your window for your application to gracefully close out.

Next steps

You can also create an Azure Spot Virtual Machine using Azure PowerShell, portal, or a template.

Query current pricing information using the Azure retail prices API for information about Azure Spot Virtual Machine. The `meterName` and `skuName` both contain `Spot`.

If you encounter an error, see Error codes.

Deploy Azure Spot Virtual Machines using the Azure portal

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale sets

Using Azure Spot Virtual Machines allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for Linux and Windows. For more information about setting the max price, see Azure Spot Virtual Machines - Pricing.

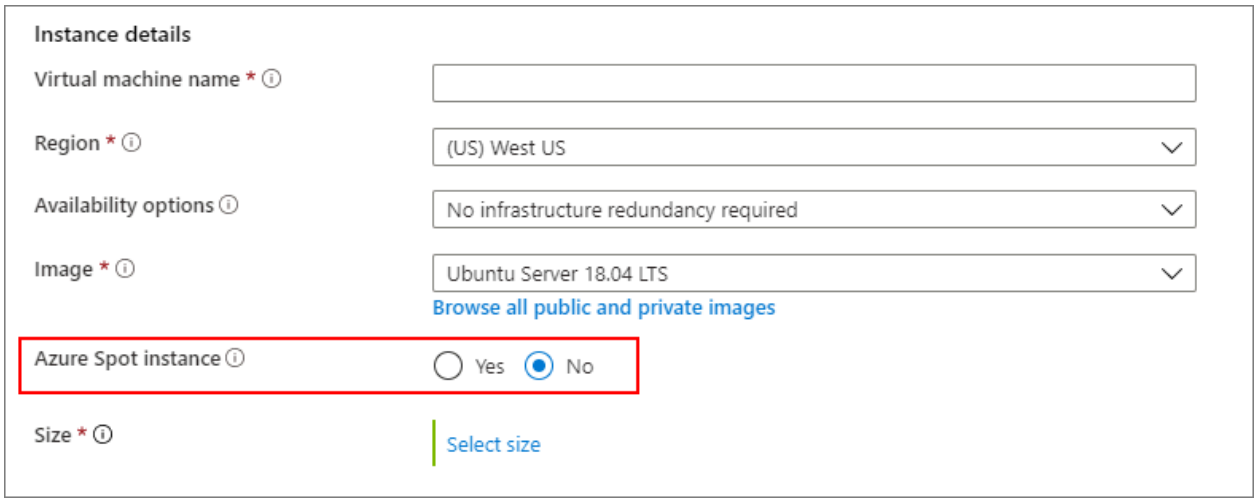
You have option to set a max price you are willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.05701` would be a max price of $0.05701 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for spot or the price for a standard VM, which ever is less, as long as there is capacity and quota available.

When the VM is evicted, you have the option to either delete the VM and the underlying disk or deallocate the VM so that it can be restarted later.

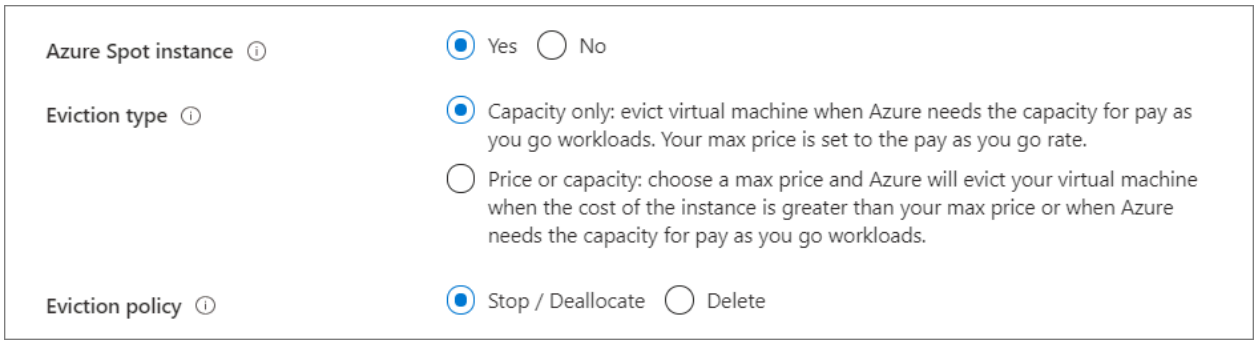
Create the VM

When you are deploying a VM, you can choose to use an Azure spot instance.

On the **Basics** tab, in the **Instance details** section, **No** is the default for using an Azure spot instance.

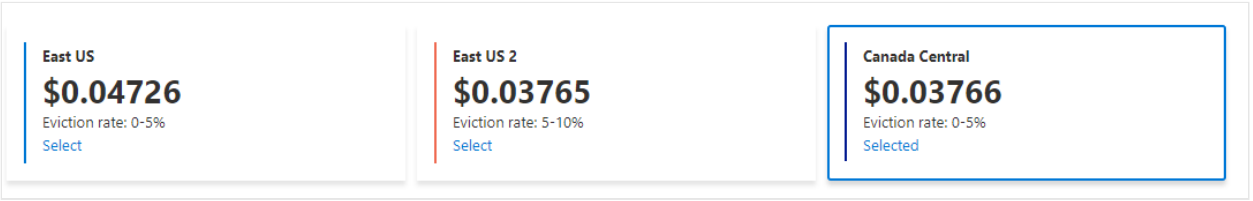


If you select **Yes**, the section expands and you can choose your eviction type and eviction policy.



You can also compare the pricing and eviction rates with other similar regions by selecting **View pricing history and compare prices in nearby regions**.

In this example, the Canada Central region is less expensive and has a lower eviction rate than the East US region.



You can change the region by selecting the choice that works the best for you and then selecting **OK**.

Simulate an eviction

You can simulate an eviction of an Azure Spot Virtual Machine, to testing how well your application will respond to a sudden eviction.

Replace the following with your information:

- `subscriptionId`
- `resourceGroupName`
- `vmName`

rest

```
POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}/simu
lateEviction?api-version=2020-06-01
```

`Response Code: 204` means the simulated eviction was successful.

Next steps

You can also create Azure Spot Virtual Machines using PowerShell, CLI, or a template.

Deploy Azure Spot Virtual Machines using Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

Using Azure Spot Virtual Machines allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for Linux and Windows. For more information about setting the max price, see Azure Spot Virtual Machines - Pricing.

You have option to set a max price you are willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.98765` would be a max price of $0.98765 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for spot or the price for a standard VM, which ever is less, as long as there is capacity and quota available.

Create the VM

Create a spotVM using New-AzVmConfig to create the configuration. Include `-Priority Spot` and set `-MaxPrice` to either:

- `-1` so the VM is not evicted based on price.
- a dollar amount, up to 5 digits. For example, `-MaxPrice .98765` means that the VM will be deallocated once the price for a spotVM goes about $.98765 per hour.

This example creates a spotVM that will not be deallocated based on pricing (only when Azure needs the capacity back). The eviction policy is set to deallocate the VM, so that it can be restarted at a later time. If you want to delete the VM and the underlying disk when the VM is evicted, set `-EvictionPolicy` to `Delete` in `New-AzVMConfig`.

Azure PowerShell

```
$resourceGroup = "mySpotRG"
$location = "eastus"
```

```
$vmName = "mySpotVM"
$cred = Get-Credential -Message "Enter a username and password for the
virtual machine."
New-AzResourceGroup -Name $resourceGroup -Location $location
$subnetConfig = New-AzVirtualNetworkSubnetConfig `
   -Name mySubnet -AddressPrefix 192.168.1.0/24
$vnet = New-AzVirtualNetwork -ResourceGroupName $resourceGroup `
   -Location $location -Name MYvNET -AddressPrefix 192.168.0.0/16 `
   -Subnet $subnetConfig
$pip = New-AzPublicIpAddress -ResourceGroupName $resourceGroup -Location
$location `
  -Name "mypublicdns$(Get-Random)" -AllocationMethod Static -
IdleTimeoutInMinutes 4
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name
myNetworkSecurityGroupRuleRDP  -Protocol Tcp `
  -Direction Inbound -Priority 1000 -SourceAddressPrefix * -SourcePortRange
* -DestinationAddressPrefix * `
  -DestinationPortRange 3389 -Access Deny
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName $resourceGroup -
Location $location `
  -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP
$nic = New-AzNetworkInterface -Name myNic -ResourceGroupName $resourceGroup
-Location $location `
  -SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -
NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration and set this to be an Azure Spot
Virtual Machine

$vmConfig = New-AzVMConfig -VMName $vmName -VMSize Standard_D1 -Priority
"Spot" -MaxPrice -1 -EvictionPolicy Deallocate | `
Set-AzVMOperatingSystem -Windows -ComputerName $vmName -Credential $cred | `
Set-AzVMSourceImage -PublisherName MicrosoftWindowsServer -Offer
WindowsServer -Skus 2016-Datacenter -Version latest | `
Add-AzVMNetworkInterface -Id $nic.Id

New-AzVM -ResourceGroupName $resourceGroup -Location $location -VM $vmConfig
```

After the VM is created, you can query to see the max price for all of the VMs in the resource group.

Azure PowerShell

```
Get-AzVM -ResourceGroupName $resourceGroup | `
   Select-Object Name,@{Name="maxPrice"; Expression=
{$_.BillingProfile.MaxPrice}}
```

Simulate an eviction

You can simulate an eviction of an Azure Spot Virtual Machine using REST, PowerShell, or the CLI, to test how well your application will respond to a sudden eviction.

In most cases, you will want to use the REST API Virtual Machines - Simulate Eviction to help with automated testing of applications. For REST, a `Response Code: 204` means the simulated eviction was successful. You can combine simulated evictions with the Scheduled Event service, to automate how your app will respond when the VM is evicted.

To see scheduled events in action, watch Azure Friday - Using Azure Scheduled Events to prepare for VM maintenance.

Quick test

For a quick test to show how a simulated eviction will work, let's walk through querying the scheduled event service to see what it looks like when you simulate an eviction using PowerShell.

The Scheduled Event service is enabled for your service the first time you make a request for events.

Remote into your VM, and then open a command prompt.

From the command prompt on your VM, type:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

This first response could take up to 2 minutes. From now on, they should display output almost immediately.

From a computer that has the Az PowerShell module installed (like your local machine), simulate an eviction using Set-AzVM. Replace the resource group name and VM name with your own.

Azure PowerShell

```
Set-AzVM -ResourceGroupName "mySpotRG" -Name "mySpotVM" -SimulateEviction
```

The response output will have `Status: Succeeded` if the request was successfully made.

Quickly go back to your remote connection to your Spot Virtual Machine and query the Scheduled Events endpoint again. Repeat the following command until you get an output that contains more information:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

When the Scheduled Event Service gets the eviction notification, you will get a response that looks similar to this:

Output

```
{"DocumentIncarnation":1,"Events":[{"EventId":"A123BC45-1234-5678-AB90-ABCDEF123456","EventStatus":"Scheduled","EventType":"Preempt","ResourceType":"VirtualMachine","Resources":["myspotvm"],"NotBefore":"Tue, 16 Mar 2021 00:58:46 GMT","Description":"","EventSource":"Platform"}]}
```

You can see that `"EventType":"Preempt"`, and the resource is the VM resource `"Resources":["myspotvm"]`.

You can also see when the VM will be evicted by checking the `"NotBefore"` value. The VM will not be evicted before the time given in `NotBefore`, so that is your window for your application to gracefully close out.

Next steps

You can also create an Azure Spot Virtual Machine using the Azure CLI, portal or a template.

Query current pricing information using the Azure retail prices API for information about Azure Spot Virtual Machine pricing. The `meterName` and `skuName` will both contain `Spot`.

If you encounter an error, see Error codes.

Deploy Azure Spot Virtual Machines using a Resource Manager template

Article • 08/22/2024

Applies to: ✔ Linux VMs

Using Azure Spot Virtual Machines allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure evicts Azure Spot VMs. Azure Spot VMs are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for Linux and Windows.

You have option to set a max price you're willing to pay, per hour, for the VM. The max price for an Azure Spot VM can be set in US dollars (USD), using up to five decimal places. For example, the value `0.98765` would be a max price of $0.98765 USD per hour. If you set the max price to be `-1`, the VMs eviction is not based on price and it's price will be the current price for Azure Spot VMs or the price for a standard VM, whichever is less, as long as there's capacity and quota available. For more information about setting the max price, see Azure Spot VMs - Pricing.

Use a template

For Azure Spot VM template deployments, use `"apiVersion": "2019-03-01"` or later. Add the `priority`, `evictionPolicy` and `billingProfile` properties to in your template:

JSON

```
"priority": "Spot",
"evictionPolicy": "Deallocate",
"billingProfile": {
    "maxPrice": -1
}
```

Here's a sample template with added properties for an Azure Spot VM. Replace the resource names with your own and `<password>` with a password for the local administrator account on the VM.

JSON

```
{
    "$schema": "http://schema.management.azure.com/schemas/2019-03-
01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {
    },
    "variables": {
        "vnetId": "/subscriptions/ec9fcd04-e188-48b9-abfc-
abcd515f1836/resourceGroups/spotVM/providers/Microsoft.Network/virtualNetwor
ks/spotVM",
        "subnetName": "default",
        "networkInterfaceName": "spotVMNIC",
        "publicIpAddressName": "spotVM-ip",
        "publicIpAddressType": "Dynamic",
        "publicIpAddressSku": "Basic",
        "virtualMachineName": "spotVM",
        "osDiskType": "Premium_LRS",
        "virtualMachineSize": "Standard_D2s_v3",
        "adminUsername": "azureuser",
        "adminPassword": "<password>",
        "diagnosticsStorageAccountName": "diagstoragespot2019",
        "diagnosticsStorageAccountId":
"Microsoft.Storage/storageAccounts/diagstoragespot2019",
        "diagnosticsStorageAccountType": "Standard_LRS",
        "diagnosticsStorageAccountKind": "Storage",
        "subnetRef": "[concat(variables('vnetId'), '/subnets/',
variables('subnetName'))]"
    },
    "resources": [
        {
            "name": "spotVM",
            "type": "Microsoft.Network/networkInterfaces",

                "[concat('Microsoft.Network/networkInterfaces/',
variables('networkInterfaceName'))]",
                "[concat('Microsoft.Storage/storageAccounts/',
variables('diagnosticsStorageAccountName'))]"
            ],
            "properties": {
                "hardwareProfile": {
                    "vmSize": "[variables('virtualMachineSize')]"
                },
                "storageProfile": {
                    "osDisk": {
                        "createOption": "fromImage",
                        "managedDisk": {
                            "storageAccountType": "
[variables('osDiskType')]"
                        }
                    },
                    "imageReference": {
                        "publisher": "Canonical",
                        "offer": "UbuntuServer",
                        "sku": "22.04-LTS",
                        "version": "latest"
                    }
                },
                "networkProfile": {
                    "networkInterfaces": [
                        {
                            "id": "
[resourceId('Microsoft.Network/networkInterfaces',
variables('networkInterfaceName'))]"
                        }
                    ]
                },
                "osProfile": {
```

```
                    "computerName": "[variables('virtualMachineName')]",
                    "adminUsername": "[variables('adminUsername')]",
                    "adminPassword": "[variables('adminPassword')]"
                },
                "diagnosticsProfile": {
                    "bootDiagnostics": {
                        "enabled": true,
                        "storageUri": "[concat('https://',
variables('diagnosticsStorageAccountName'), '.blob.core.windows.net/')]"
                    }
                },
                "priority": "Spot",
                "evictionPolicy": "Deallocate",
                "billingProfile": {
                    "maxPrice": -1
                }
            }
        },
        {
            "name": "[variables('diagnosticsStorageAccountName')]",
            "type": "Microsoft.Storage/storageAccounts",
            "apiVersion": "2019-04-01",
            "location": "eastus",
            "properties": {},
            "kind": "[variables('diagnosticsStorageAccountKind')]",
            "sku": {
                "name": "[variables('diagnosticsStorageAccountType')]"
            }
        }
    ],
    "outputs": {
        "adminUsername": {
            "type": "string",
            "value": "[variables('adminUsername')]"
        }
    }
}
```

Simulate an eviction

You can simulate an eviction of an Azure Spot VM, to test your application response to a sudden eviction.

Replace the below parameters with your information:

- `subscriptionId`
- `resourceGroupName`
- `vmName`

```
HTTP
```

```
POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}/simu
lateEviction?api-version=2020-06-01
```

Next steps

- You can also create an Azure Spot VM using Azure PowerShell or the Azure CLI.
- For more information about Azure Spot VM current pricing, see Azure retail prices API. Both `meterName` and `skuName` contains `Spot`.
- To learn more about an error, see Error codes.

Spot Priority Mix for high availability and cost savings

10/08/2025

Applies to: ✔ Flexible scale sets

Spot Priority Mix allows you to run a combination of standard Virtual Machines (VMs) and Spot VMs within a single Virtual Machine Scale Set. This feature helps you balance cost savings with availability by letting Azure automatically manage the mix of VM types based on your requirements.

Overview

With Spot Priority Mix, you can:

- **Save up to 90%** on compute costs by using Spot VMs for interruptible workloads
- **Ensure availability** with standard VMs that aren't evicted
- **Protect against mass evictions** by maintaining a guaranteed number of standard VMs
- **Simplify management** with automatic orchestration of VM creation and deletion

How it works

Spot Priority Mix uses two key parameters to control your VM distribution:

1. `baseRegularPriorityCount`: The minimum number of standard (non-Spot) VMs that are always maintained
2. `regularPriorityPercentageAboveBase`: The percentage of standard VMs vs. Spot VMs for any capacity beyond the base count

Example: With a `baseRegularPriorityCount` of 10 and a `regularPriorityPercentageAboveBase` of 50:

- At 10 total VMs: All 10 are standard VMs (at or below base count)
- At 30 total VMs: 10 base standard VMs + 10 other standard VMs (50% of the 20 above base) + 10 Spot VMs (50% of the 20 above base)

Prerequisites

Before you use Spot Priority Mix, ensure you have the following:

- A Virtual Machine Scale Set with Flexible orchestration mode
- Understanding of Azure Spot VMs and their eviction behavior
- Appropriate quota for Spot VMs

Limitations

- Spot Priority Mix requires Flexible orchestration mode
- Not supported with `singlePlacementMode` enabled on the scale set
- Changes to the mix configuration apply only to future scaling operations (existing VMs aren't rebalanced)

Configure your mix

The platform automatically orchestrates scale-out and scale-in operations to maintain your desired distribution of Spot and standard VMs. You configure the mix using two key settings `baseRegularPriorityCount` and `regularPriorityPercentageAboveBase`.

Understanding the parameters

Expand table

Parameter	Description	Details
`baseRegularPriorityCount`	Sets the minimum number of standard VMs	When total capacity is at or below this number, all VMs are standard. Provides guaranteed capacity that isn't evicted.
`regularPriorityPercentageAboveBase`	Defines the standard-to-Spot ratio for VMs beyond the base count	Value between 0-100 (for example, 50 means 50% standard, 50% Spot). Only applies when capacity exceeds the base count.

Common configurations

Expand table

Use Case	Base Count	Percentage Above Base	Description
High availability	20	80%	Most VMs are standard, minimal Spot usage

Use Case	Base Count	Percentage Above Base	Description
Balanced	10	50%	Equal mix above base capacity
Cost-optimized	5	20%	Maximum Spot usage with small standard baseline
Dev/Test	0	0%	All Spot VMs (no availability guarantee)

Eviction policy

When Spot VMs are evicted due to capacity constraints or pricing, the eviction policy determines what happens:

Expand table

Policy	Behavior	Cost Impact
`Deallocate` (default)	Evicted VMs move to a stopped-deallocated state and can be restarted later	No compute charges, storage costs continue
`Delete`	Evicted VMs and their underlying disks are permanently deleted	No charges continue

Scale-in behavior

When you scale in, Spot Priority Mix maintains your configured percentage split by intelligently choosing which VMs to remove (Spot or standard) rather than simply removing the oldest or newest VMs.

ARM Template

Configure Spot Priority Mix in an ARM template by adding the `priorityMixPolicy` properties to a scale set with Flexible orchestration and Spot priority:

JSON

```
"priorityMixPolicy": {
    "baseRegularPriorityCount": 10,
    "regularPriorityPercentageAboveBase": 50
},
```

This example configuration:

- Maintains a minimum of 10 standard VMs
- For any VMs beyond 10, maintains a 50/50 split between standard and Spot VMs
- At 30 total VMs: 10 base + 10 standard + 10 Spot

Portal

Configure Spot Priority Mix when you create a Virtual Machine Scale Set in the Azure portal:

1. Sign in to the Azure portal.
2. Search for and select **Virtual Machine Scale Sets**.
3. Select **Create**.
4. On the **Basics** tab:
    - Fill out the required fields.
    - Set **Orchestration mode** to **Flexible**.
    - Select **Run with Azure Spot discount**.
5. On the **Spot** tab:
    - Select **Scale with VMs and Spot VMs** under **Scale with VMs and discounted Spot VMs**.
    - Set `baseRegularPriorityCount` by using **Base VM (uninterruptible) count**, the minimum number of standard VMs.
    - Set `regularPriorityPercentageAboveBase` by using **Instance distribution**, the percentage of standard VMs above the base count.
6. Complete the remaining configuration and create your scale set.

Update your Spot Priority Mix

You can modify the Spot Priority Mix configuration after your scale set is deployed. The updated configuration applies only to future scaling operations. Existing VMs remain unchanged until the scale set scales in or out.

Portal

Update your existing Spot Priority Mix in the Azure portal:

> **Note**

In the Azure portal, you can only update Spot Priority Mix for scale sets that already have this feature enabled.

1. Navigate to your Virtual Machine Scale Set in the Azure portal.
2. In the left menu, select **Configuration**.
3. Under the Spot Priority Mix section, update:
   - `baseRegularPriorityCount` by using **Base VM (uninterruptible) count**
   - `regularPriorityPercentageAboveBase` by using the **Instance distribution** percentage
4. Select **Save** to apply your changes.

Examples

The following examples demonstrate how Spot Priority Mix works in different scenarios. Each example includes a configuration, a table that shows the VM distribution after various operations, and a detailed walk-through.

Key terminology

- **Total capacity**: The total number of VMs in the Virtual Machine Scale Set.
- **Base standard VMs**: The guaranteed minimum number of standard VMs (set by `baseRegularPriorityCount`).
- **Extra standard VMs**: Standard VMs beyond the base count, calculated by using `regularPriorityPercentageAboveBase`.
- **Spot VMs**: Interruptible VMs that provide cost savings.

Scenario 1: 50/50 split with 10 base VMs

Configuration:

- `baseRegularPriorityCount`: 10
- `regularPriorityPercentageAboveBase`: 50%
- Eviction policy: Delete
- Starting capacity: 10 VMs

VM distribution during scaling:

Expand table

Action	Total capacity	Base standard VMs	Extra standard VMs	Spot VMs
Initial creation	10	10	0	0
Scale out to 20	20	10	5	5
Scale out to 30	30	10	10	10
Scale out to 40	40	10	15	15
Scale out to 41	41	10	15	16
Scale out to 42	42	10	16	16
All Spot VMs evicted	26	10	16	0
Scale out to 30	30	10	16	4
Scale out to 42	42	10	16	16
Scale out to 44	44	10	17	17

Walk-through:

1. **Initial state (10 VMs)**: All VMs are standard because the total is at the base count.
2. **Scale to 20 VMs**: Added 10 VMs above base, which is 5 standard (50%) and 5 Spot (50%).
3. **Scale to 30 VMs**: Added 20 VMs above base, which is 10 standard (50%) and 10 Spot (50%).
4. **Scale to 41 VMs**: With odd numbers, Spot VMs get the extra VM (16 Spot versus 15 standard).
5. **Scale to 42 VMs**: Balance restored with 16 of each type above the 10 base VMs.
6. **Eviction event**: All 16 Spot VMs are deleted, which leaves 26 total VMs (10 base and 16 extra standard).
7. **Scale to 30 VMs**: Only 4 Spot VMs added to rebalance toward the 50/50 target.
8. **Scale to 42 VMs**: Added 8 more Spot VMs and maintained 16 standard to restore balance.
9. **Scale to 44 VMs**: One of each type added to maintain the 50/50 split.

Scenario 2: Cost-optimized with 25% standard VMs

Configuration:

- `baseRegularPriorityCount`: 10
- `regularPriorityPercentageAboveBase`: 25%

- Eviction policy: Deallocate (VMs stop but aren't deleted)
- Starting capacity: 20 VMs

VM distribution during scaling:

Expand table

Action	Total capacity	Base standard VMs	Extra standard VMs	Spot VMs (running)	Spot VMs (deallocated)
Initial creation	20	10	2	8	0
Scale out to 50	50	10	10	30	0
Scale out to 110	110	10	25	75	0
10 Spot VMs evicted	110	10	25	65	10
Scale out to 120	120	10	27	73	10

Walk-through:

1. **Initial state (20 VMs)**: 10 base standard, 2 extra standard (25% of 10), and 8 Spot (75% of 10).
    - Formula: For the 10 VMs above base, 25% standard (2.5 rounded to 2) and 75% Spot (8).
2. **Scale to 50 VMs**: Added 30 VMs above base. Total of 40 above base equals 10 standard (25%) and 30 Spot (75%).
3. **Scale to 110 VMs**: 100 VMs above base, which is 25 standard (25%) and 75 Spot (75%).
4. **Eviction event**: 10 Spot VMs are deallocated (stopped but not deleted).
    - Total capacity remains 110, but only 65 Spot VMs are running.
    - The deallocated VMs count toward capacity but aren't running.
5. **Scale to 120 VMs**: Added 10 more VMs, which is 2 standard and 8 Spot, to maintain the 25/75 ratio.
    - The 10 deallocated VMs remain deallocated.

Troubleshooting

If Spot Priority Mix isn't available to you, be sure to configure the `priorityMixPolicy` to specify a *Spot* priority in the `virtualMachineProfile`. Without enabling the `priorityMixPolicy` setting, you won't be able to access this Spot feature.

Frequently asked questions

Why aren't my existing VMs changing after I updated the Spot Priority Mix?

Spot Priority Mix configuration applies only to future scaling operations. When you change the percentage split, existing VMs remain unchanged. The new distribution takes effect as the scale set scales in or out. To apply the new configuration, you can manually scale your set or wait for autoscale events.

What happens when Spot VMs are evicted?

When Azure needs capacity back, Spot VMs are evicted based on your eviction policy.

Your base standard VMs are never evicted, ensuring minimum capacity availability.

Can I use Spot Priority Mix with Uniform orchestration?

No, Spot Priority Mix is only available with Flexible orchestration mode. Uniform orchestration doesn't support this feature.

Which Azure regions support Spot Priority Mix?

Spot Priority Mix is available in all Azure regions that support Spot VMs. This availability includes all global Azure regions. For the most current region availability, see Spot VMs documentation.

Does changing the mix trigger immediate VM creation or deletion?

No. Updating your Spot Priority Mix configuration doesn't immediately create or delete VMs. The new settings apply during the next scale operation (scale in, scale out, or replacement of evicted VMs).

Can I have zero base standard VMs?

Yes, you can set `baseRegularPriorityCount` to 0, which means all VMs follow the percentage distribution. However, this means you could potentially lose all VMs to eviction during high-demand periods. For production workloads, we recommend that you maintain at least some base standard VMs.

Spot Placement Score

10/07/2025

Spot Placement Score evaluates the likelihood of success for individual Spot deployments by considering parameters like desired Spot Virtual Machine (VM) count, VM size, and your deployment region or zone. This feature enables you to generate a placement score to deploy a desired number of Spot Virtual Machines (VMs) across various combinations of regions, zones, and VM sizes. By inputting lists of up to eight regions and five VM sizes, you can obtain placement scores categorized as either High, Medium, or Low. A score of High indicates that the deployment is highly likely to succeed while a score of Low indicates that the deployment has a low chance of success. These scores are based on analyses of Spot capacity allocation probability of the specified number of Spot VMs within each region and VM size combination. This functionality enhances deployment planning by providing predictive insights into deployment success and optimizing resource allocation for your Spot VMs.

Using Spot Placement Score, you can achieve the following:

- A clear evaluation of how likely your Spot deployment is to succeed based on specified parameters.
- Identify the most suitable combination of regions and VM sizes to maximize Spot VM availability based on placement scores.
- Improve the overall success rate of deploying Spot VMs by applying data-driven placement scores, reducing the risk of capacity issues or failures during deployment.

Cost

There are no costs associated with this feature.

Considerations

- Spot placement scores serve purely as a recommendation based on certain data points like Spot VM availability. A high placement score doesn't guarantee that the Spot request will be fully or partially fulfilled.
- Placement Scores are only valid at the time when it's requested. The same Placement Score isn't valid at a different time of the same day or another day. Any similarities are purely coincidental.

- The Spot Placement Score is only relevant if the Spot request has the same configuration as the Spot Placement Score configuration; desired count, VM size, location, and zone. In all other circumstances, the likelihood of getting available Spot capacity won't align with the placement score generated by the tool.
- Spot Placement Scores don't consider other constraints, such as Virtual Machine Scale Sets `SinglePlacementGroup`.
- A subscription's available Spot VM quota needs to be checked or requested separately.
- Spot Placement Score supports both regionally and zonally scoped placement score.
- Spot Placement Score API internally calls other GET APIs and is part of your GET call quota.
- A score of **High** or **Medium** doesn't guarantee allocation success or no evictions.
- This feature is available for all public Azure regions at this time.

Configure your Spot Placement Score

Configure your Spot Placement Score by defining your Spot specific requirements:

- Number of desired Spot VMs
- Up to five VM sizes
- Up to eight regions
- Availability zones

We recommend that the placement scores for each combination of subscription, desired count, region, zone, and VM size are cached, to avoid calling the API with the same configuration frequently within a short period of time. The suggested cache TTL is a minimum of 15 minutes and a maximum of 30 minutes.

Azure portal

Find the Spot Placement Score in the Spot tab of the Virtual Machine Scale Sets creation process in the Azure portal. The following steps instruct you on how to access this feature during that process.

1. Log in to the Azure portal.
2. In the search bar, search for and select **Virtual Machine Scale Sets**.
3. Select **Create** on the **Virtual Machine Scale Sets** page.

4. In the **Spot** tab, turn on the Spot option under the **Save money with Spot** section.
5. Fill out the *Size*, *Region*, *Availability Zones*, and *Initial instance count* fields in the **Your Placement Score** section.
6. Click on **Save + Apply** to receive your placement score for this configuration.

Examples

The following examples have scenario assumptions and a table with the results score to help you understand how Spot Placement Score works.

Scenario 1

This table is an example of a request returning regionally scoped placement scores for multiple desired VM sizes and regions.

The following scenario assumptions apply to this example:

- **Desired locations:** `westus`, `eastus`
- **Desired sizes:** `Standard_D2_v2`, `Standard_D4_v2`
- **Desired count:** 100
- **Availability zones:** False

Expand table

SKU	Region	Availability zone	Is quota available?	Placement score
Standard_D2_v2	westus	False	True	High
Standard_D4_v2	westus	False	True	Low
Standard_D2_v2	eastus	False	True	Medium
Standard_D4_v2	eastus	False	True	High

Scenario 2

This table is an example of a request returning zonally scoped placement scores for multiple desired VM sizes and regions.

The following scenario assumptions apply to this example:

- **Desired locations:** `westus`, `eastus`
- **Desired sizes:** `Standard_D2_v2`, `Standard_D4_v2`
- **Desired count:** 100
- **Availability zones:** True

Expand table

SKU	Region	Availability zone	Is quota available?	Placement score
Standard_D2_v2	westus	1	True	Medium
Standard_D2_v2	westus	2	True	Medium
Standard_D2_v2	westus	3	True	Medium
Standard_D4_v2	westus	1	True	High
Standard_D4_v2	westus	2	True	High
Standard_D4_v2	westus	3	True	High
Standard_D2_v2	eastus	1	True	Low
Standard_D2_v2	eastus	2	True	Low
Standard_D2_v2	eastus	3	True	Low
Standard_D4_v2	eastus	1	True	Medium
Standard_D4_v2	eastus	2	True	Medium
Standard_D4_v2	eastus	3	True	Medium

Troubleshooting

Expand table

Status code	Type	Condition
200	Successful request	Spot Placement Score operations complete successfully.
400	Bad error request	At least one required input parameter isn't present, or the values of the provided parameters aren't valid. Produces a detailed error message about the failed request.
429	Too many	Unable to generate placement score due to hitting a rate limit.

Status code	Type	Condition
	requests	
500	Internal server error	The placement score generation failed. Produces a detailed error message about the failed request.

Spot Virtual Machine size recommendation

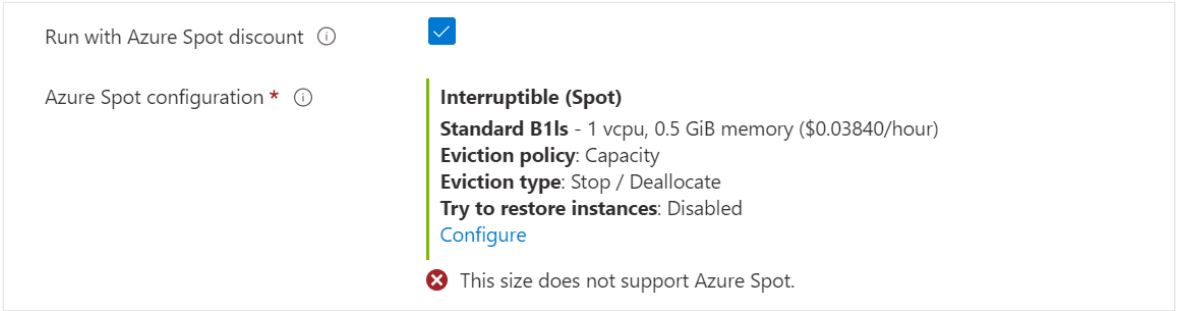
Article • 08/22/2024

The Spot VM size recommendations tool is an easy way to view and select alternative VM sizes that are better suited for your stateless, flexible, and fault tolerant workload needs during the Virtual Machine Scale Set deployment process in the Azure portal. This tool allows Azure to recommend appropriate VM sizes to you after you filter by region, price, and eviction rate. You can further filter the recommended VMs list by size, type, generation, and disk (premium or ephemeral OS disk).

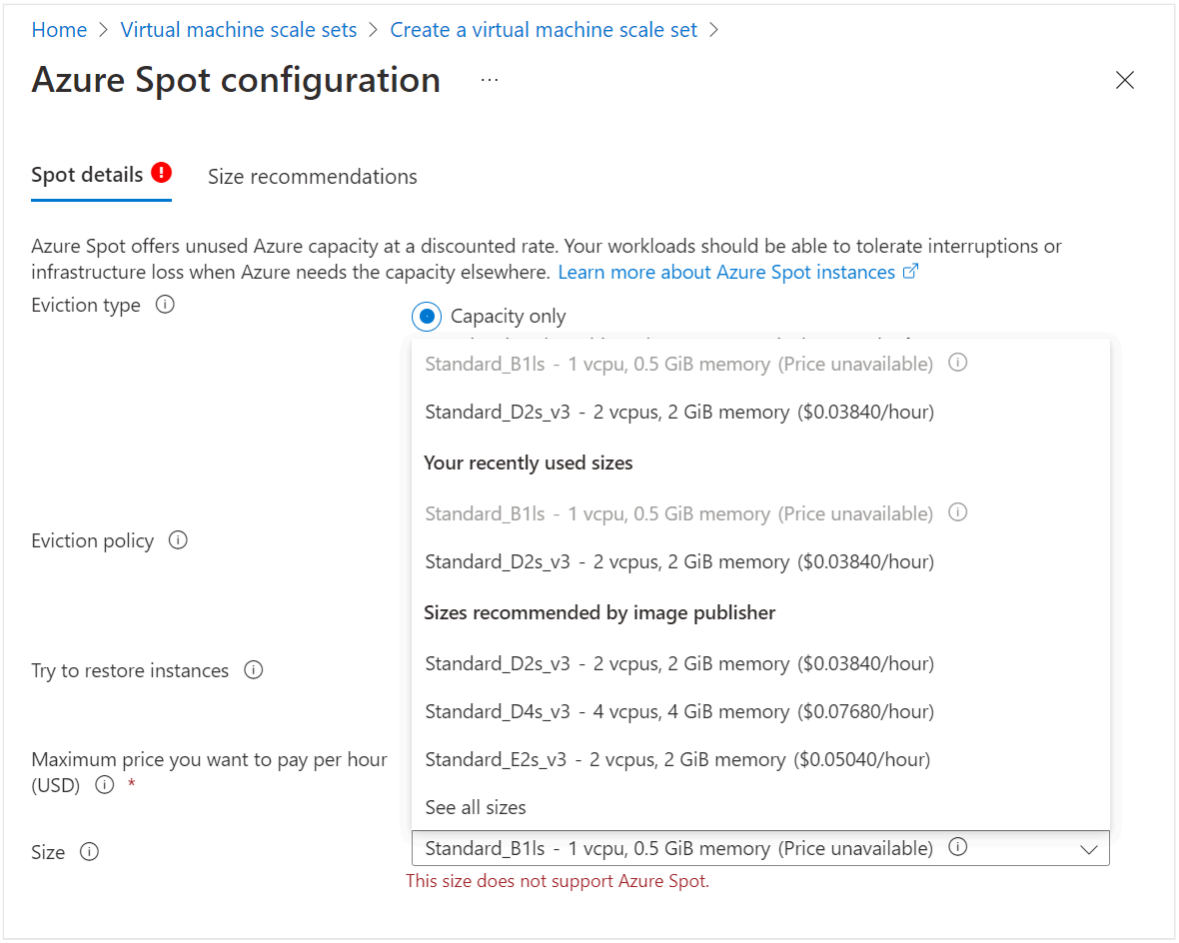
Azure portal

You can access Azure's size recommendations through the Virtual Machine Scale Sets creation process in the Azure portal. The following steps will instruct you on how to access this tool during that process.

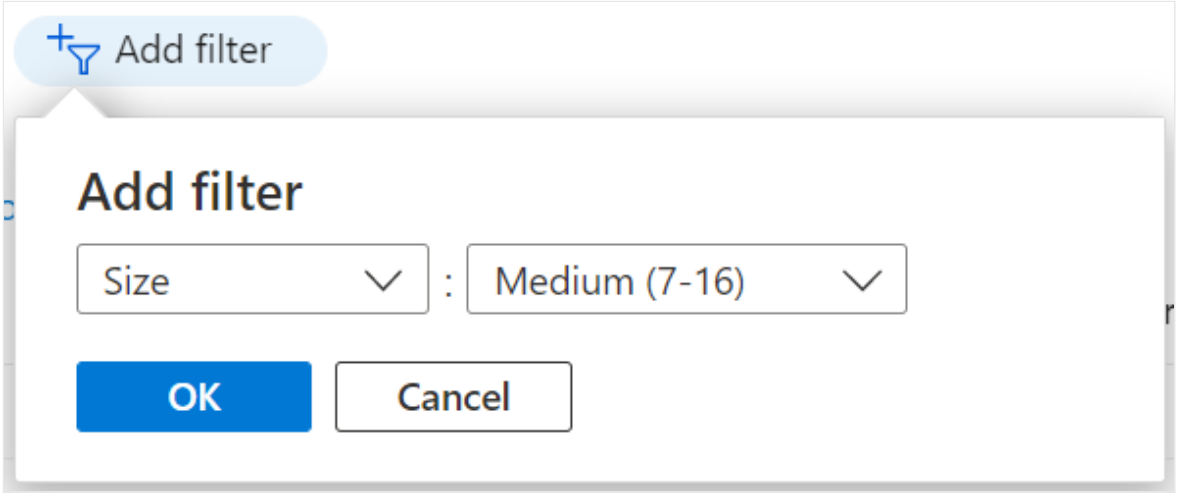
1. Log in to the Azure portal.
2. In the search bar, search for and select **Virtual Machine Scale Sets**.
3. Select **Create** on the **Virtual Machine Scale Sets** page.
4. In the **Basics** tab, fill out the required fields.
5. Under **Instance details**, select **Run with Azure Spot discount**.



6. In the same section, under **Azure Spot configuration**, select **Configure**.
7. On the **Azure Spot configuration** page, in the **Spot details** tab, go to the **Size** selector.
8. Expand the **Size** drop-down and select **See all sizes** option at the bottom of the list.

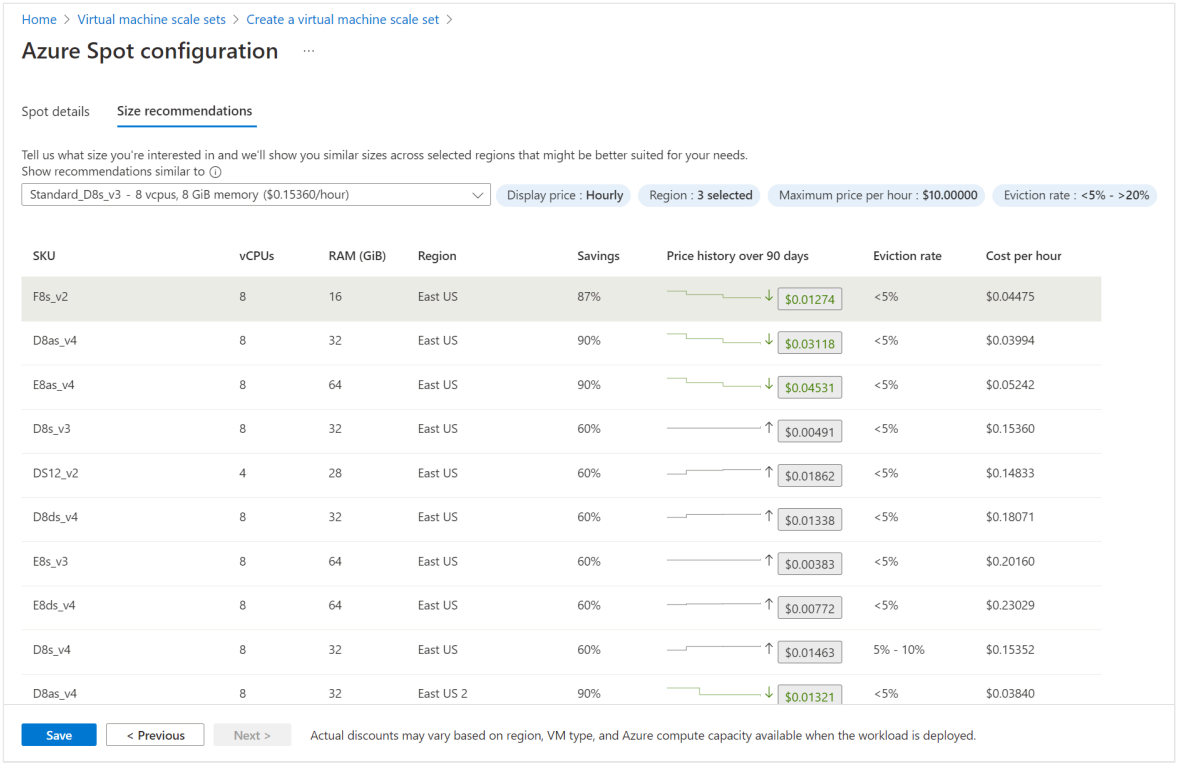


9. On the **Select a VM size** page, click **Add filter**.
10. You can choose which filters to apply. For this example, we will only apply **Size** and set it to *Medium (7-16)* for the number of vCPU.



11. Click **OK**.
12. From the resulting list of VMs, select a preferred VM size.
13. Click **Select** at the bottom to continue.
14. Back on the **Spot details** tab, click **Next** to go to the next tab.

15. The **Size recommendations** tab allows you to view and select alternative VM sizes that are better suited for your stateless, flexible, and fault tolerant workload needs with regard to region, pricing, and eviction rates.



16. Make your selection and click **Save**.

17. Continue through the Virtual Machine Scale Set creation process.

Error messages for Azure Spot Virtual Machines and scale sets

05/22/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Here are some possible error codes you could receive when using Azure Spot Virtual Machines and scale sets.

Expand table

Key	Message	Description
SkuNotAvailable	The requested tier for resource '<resource>' is currently not available in location '<location>' for subscription '<subscriptionID>'. Try another tier or deploy to a different location.	There is not enough Azure Spot Virtual Machine capacity in this location to create your VM or scale set instance.
Standard_XX-XX_XX. This size does not support Azure Spot.	There is insufficient Azure Spot Virtual Machine capacity in this location to create your VM or scale set instance.	For Spot instances, if there is no available capacity, the portal page will fail immediately. This fail-fast feature ensures that users are promptly informed of the allocation failure, preventing them from waiting for an error after attempting deployment.

Key	Message	Description
EvictionPolicyCanBeSetOnlyOnAzureSpotVirtualMachines	Eviction policy can be set only on Azure Spot Virtual Machines.	This VM is not an Azure Spot Virtual Machine, so you can't set the eviction policy.
AzureSpotVMNotSupportedInAvailabilitySet	Azure Spot Virtual Machine is not supported in Availability Set.	You need to choose to either use an Azure Spot Virtual Machine or use a VM in an availability set, you can't choose both.
AzureSpotFeatureNotEnabledForSubscription	Subscription not enabled with Azure Spot Virtual Machine feature.	Use a subscription that supports Azure Spot Virtual Machines.
VMPriorityCannotBeApplied	The specified priority value '{0}' cannot be applied to the Virtual Machine '{1}' since no priority was specified when the Virtual Machine was created.	Specify the priority when the VM is created.
SpotPriceGreaterThanProvidedMaxPrice	Unable to perform operation '{0}' since the provided max price '{1} USD' is lower than the current spot price '{2} USD' for Azure Spot Virtual Machine size '{3}'.	Select a higher max price. For more information, see pricing information for Linux or Windows.
MaxPriceValueInvalid	Invalid max price value. The only supported values for max price are -1 or a decimal greater	Enter a valid max price. For more information, see pricing for

Key	Message	Description
	than zero. Max price value of -1 indicates the Azure Spot Virtual Machine will not be evicted for price reasons.	Linux or Windows.
MaxPriceChangeNotAllowedForAllocatedVMs	Max price change is not allowed when the VM '{0}' is currently allocated. Deallocate and try again.	Stop\Deallocate the VM so that you can change the max price.
MaxPriceChangeNotAllowed	Max price change is not allowed.	You cannot change the max price for this VM.
AzureSpotIsNotSupportedForThisAPIVersion	Azure Spot Virtual Machine is not supported for this API version.	The API version needs to be 2019-03-01.
AzureSpotIsNotSupportedForThisVMSize	Azure Spot Virtual Machine is not supported for this VM size {0}.	Select another VM size. For more information, see Azure Spot Virtual Machines.
MaxPriceIsSupportedOnlyForAzureSpotVirtualMachines	Max price is supported only for Azure Spot Virtual Machines.	For more information, see Azure Spot Virtual Machines.
MoveResourcesWithAzureSpotVMNotSupported	The Move resources request contains an Azure Spot Virtual Machine. Not supported. Check the error details for virtual machine Ids.	You cannot move Azure Spot Virtual Machines.
MoveResourcesWithAzureSpotVmssNotSupported	The Move resources request contains an Azure Spot virtual machine scale set. Not supported.	You cannot move Azure Spot virtual machine scale set instances.

Key	Message	Description
	Check the error details for virtual machine scale set Ids.	
AzureSpotVMNotSupportedInVmssWithVMOrchestrationMode	Azure Spot Virtual Machine is not supported in Virtual machine scale set with VM Orchestration mode.	Set the orchestration mode to virtual machine scale set in order to use Azure Spot Virtual Machine instances.
SpotRestorationIsNotSupportedForThisAPIVersion	Spot restoration feature is not supported for this API version.	For an existing scaleset, perform a PATCH using API version 2021-07-01 or later. For new scale set deployments, add the following property to the Azure Resource Manager template using API version 2021-07-01 or later: SpotRestorationIsSupportedOnlyForAzureSpotScaleSets	Spot restoration feature is supported only for Azure Spot virtual machine scale sets.	Spot restoration feature is only supported for Azure Spot virtual machine scale sets. To use this feature, deploy Azure Spot using virtual machine scale sets.

Build workloads on spot virtual machines

Azure Virtual Machines

This article describes best practices for how to build on Azure Spot Virtual Machines. Spot virtual machines (spot VMs) provide access to compute capacity at lower prices than regular VMs. This discount makes them a good option for organizations that want to optimize costs. But the savings come with a trade-off. Spot VMs can be evicted at any time, which means that they lose access to compute resources. Workloads that run on spot VMs must be able to handle these interruptions in compute. The appropriate workload and a flexible orchestration mechanism are the keys to success. The following recommendations describe how to build on spot VMs.

Understand spot VMs

On a technical level, spot VMs are the same as regular VMs. They use the same images, hardware, and disks that translate to the same performance. The key difference between spot VMs and regular VMs is their priority and availability. Spot VMs have no priority to access compute capacity, and they have no availability guarantees after they access that compute capacity.

- **No priority access.** Regular VMs have priority access to compute capacity. They access compute capacity when they request it. However, spot VMs only deploy when there's spare compute capacity. And they only continue to run when a regular VM doesn't need the underlying hardware.
- **No availability guarantee.** Spot VMs don't have any availability guarantees or service-level agreements (SLAs). Spot VMs can lose access to compute capacity immediately, or anytime after deployment or eviction. Spot VMs are cheaper because they can be evicted. When Azure needs the compute capacity back, an eviction notice is sent and evicts the spot VM. Azure provides a minimum of 30-seconds advance notice before the actual eviction occurs. For more information, see Continuously monitor for eviction.

Understand spot VM pricing

Spot VMs can be up to 90% cheaper than regular pay-as-you-go VMs. The discount varies based on demand, VM size, deployment region, and the operating system. To get a cost savings estimate, see Azure Spot Virtual Machines pricing tool and Spot Virtual Machines pricing overview. You can also query the Azure retail prices API to programmatically obtain the spot pricing for any SKU.

Understand interruptible workloads

Spot VMs are ideal for interruptible workloads, which share several common characteristics. Interruptible workloads have minimal to no time constraints, low organizational priority, and short processing times. They run processes that can stop suddenly and resume later without harming essential organizational processes. Examples of interruptible workloads are batch processing applications, data analytics, and workloads that create a continuous integration and continuous deployment agent for a nonproduction environment. These features compare to regular or mission-critical workloads that have SLAs, sticky sessions, and stateful data.

You can use spot VMs in non-interruptible workloads, but they shouldn't be the only source of compute capacity. Use as many regular VMs as you need to meet your uptime requirements.

Understand eviction

Spot VMs have no SLAs after creation, and they can lose access to compute at any time. We call this compute loss an *eviction*. Compute supply and demand drive evictions. When the demand for a specific VM size exceeds a specific level, Azure evicts spot VMs to make compute available to regular VMs. Demand is location specific. For example, an increase in demand in region A doesn't affect spot VMs in region B.

Spot VMs have two configuration options that affect eviction. These configurations are the *eviction type* and *eviction policy* of the spot VM. You set these configurations when you create the spot VM. The eviction type defines the conditions of an eviction. The eviction policy determines what eviction does to your spot VM.

Eviction type

Capacity changes or price changes cause evictions. The way capacity and price changes affect spot VMs depends on the eviction type that you choose when the VM is created. The type of eviction defines the conditions of an eviction. The eviction types are *capacity-only eviction* and *price or capacity eviction*.

- **Capacity-only eviction:** This eviction type triggers an eviction when excess compute capacity is no longer available. By default, the price is capped at the pay-as-you-go rate. Use this eviction type when you don't want to pay more than the pay-as-you-go VM price.
- **Price or capacity eviction:** This eviction type has two triggers. Azure evicts a spot VM when excess compute capacity is no longer available or the cost of the VM exceeds the maximum price that you set. This eviction type allows you to set a maximum price far less than the pay-as-you-go price. Use this eviction type to set your own price cap.

Eviction policy

The eviction policy that you choose for a spot VM affects its orchestration. Orchestration is the process of handling an eviction and is discussed later in this article. The eviction policies are the *Stop/Deallocate policy* and the *Delete policy*.

Stop/Deallocate policy: The Stop/Deallocate policy is ideal when the workload can wait for release capacity within the same location and VM type. The Stop/Deallocate policy stops the VM and ends its lease with the underlying hardware. Stopping and deallocating a spot VM is the same as stopping and deallocating a regular VM. The VM remains accessible in Azure, and you can restart the same VM later. The VM loses compute capacity and nonstatic IP addresses with the Stop/Deallocate policy. However, the VM data disks remain and continue to incur charges. The VM also occupies cores in the subscription. VMs can't be moved from their region or zone even when they're stopped or deallocated. For more information, see Power states and billing.

Delete policy: Use the Delete policy if the workload can change location or VM size. Changing the location or VM size allows the VM to redeploy faster. The Delete policy deletes the VM and any data disk. The VM doesn't occupy cores in subscriptions. For more information, see Eviction policy. When you use the Delete policy, consider using ephemeral OS disks for your spot VMs. Because the VM and its disks are deleted on eviction, a persistent OS disk incurs storage cost for a resource that doesn't survive eviction. Ephemeral OS disks eliminate that cost and reduce VM provisioning time, which helps your orchestration replace evicted VMs faster. Ephemeral OS disks aren't compatible with the Stop/Deallocate policy because deallocation destroys the OS disk state.

Design for flexible orchestration

Orchestration is the process of replacing a spot VM after an eviction. It's the foundation for building a reliably interruptible workload. A good orchestration system has built-in flexibility. Flexibility means designing your orchestration to have options, use multiple VM sizes, deploy to different regions, have eviction awareness, and account for different eviction scenarios to improve workload reliability and speed.

Design for speed

For a workload that runs on spot VMs, compute capacity is crucial. Because of the potential for eviction, ensure that you understand the allocated compute time so that you can make informed design decisions that prioritize workload speed. Generally, you should optimize the compute time that you have. Build a VM image that has all the required software preinstalled. Preinstalled software helps minimize the time between eviction and a fully operational

application. Avoid using compute time on processes that don't contribute to the workload purpose. For example, a workload for data analytics should focus most of its compute time on data processing and as little time as possible on gathering eviction metadata. Eliminate nonessential processes from your application.

Use multiple VM sizes and locations

To increase flexibility, build an orchestration to use multiple types and sizes of VMs. The goal is to give your orchestration options to replace an evicted VM. Azure has different types and sizes of VMs that provide similar capabilities for about the same price. Filter for the minimum vCPUs or cores, the minimum RAM for VMs, and the maximum price. This process helps you find multiple VMs that fit in your budget and have enough power to run your workload.

Each type of VM has an eviction rate that's expressed as a percentage range, such as 0%-5%, 5%-10%, 10%-15%, 15%-20%, or 20+%. Eviction rates can vary across regions. You might find a better eviction rate for the same type of VM in a different region. You can find the eviction rates for each type of VM in the portal under the **Basics** tab. Next to **Size**, select **View pricing history** or **See all sizes**. You can also programmatically get spot VM data by using Azure Resource Graph.

In your orchestration system, consider using the spot placement score feature to evaluate the likelihood of success for individual spot deployments.

For more information, see the following resources:

- Eviction rates
- Resource Graph
- Spot placement score

Use the most flexible eviction policy

The eviction policy of the evicted spot VM affects the replacement process. For example, a Delete policy is more flexible than a Stop/Deallocate policy.

- **Consider the Delete policy first:** Use a Delete policy if your workload can handle it. Deletion allows the orchestration to deploy replacement spot VMs to new zones and regions. This deployment flexibility could help your workload find spare compute capacity faster than a stopped or deallocated VM. Stopped or deallocated VMs have to wait for spare compute capacity in the same zone that they were created in. For the Delete policy, you need an external process to monitor for evictions and orchestrate deployments to various regions, use different VM SKUs, or both.

- **Understand the Stop/Deallocate policy:** The Stop/Deallocate policy has less flexibility than the Delete policy. The spot VMs must stay in the same region and zone. You can't move a stopped or deallocated VM to another location. Because the VMs have a fixed location, you need something in place to reallocate the VM when compute capacity becomes available. There's no way to predict the availability of compute capacity. So you should use an automated schedule pipeline to attempt a redeployment after an eviction. An eviction should trigger the schedule pipeline, and the redeployment attempts should continuously check for compute capacity until it becomes available.

Expand table

Policy	When to use the policy
Delete policy	- Ephemeral compute and data - Don't want to pay for data disks - Minimal budget
Stop/Deallocate policy	- Need a specific VM size - Can't change location - Long application installation process - Indefinite wait time - Not driven by cost savings alone

Continuously monitor for eviction

Monitoring is the key to workload reliability on spot VMs. Spot VMs have no SLA after creation and can be evicted at any time. The best way to improve workload reliability on spot VMs is to anticipate when they're going to be evicted. If you have this information, you can attempt a workload graceful shutdown and trigger automation to orchestrate the replacement.

- **Use Scheduled Events:** Use the Scheduled Events service for each VM. Azure sends signals to VMs when infrastructure maintenance is going to affect them. Evictions qualify as infrastructure maintenance. Azure sends out the `Preempt` signal to all VMs at a minimum of 30 seconds before they're evicted. The Scheduled Events service allows you

to capture this `Preempt` signal by querying an endpoint at the static, nonroutable IP address `169.254.169.254`.

- **Use frequent queries:** Query the Scheduled Events endpoint often enough to orchestrate a graceful shutdown. You can query the Scheduled Events endpoint up to every second, but a one-second frequency might not be necessary for all use cases. These queries must come from an application that runs on the spot VM. The query can't come from an external source. As a result, the queries consume VM compute capacity and steal processing power from the main workload. You need to balance those competing priorities to meet your specific situation.

- **Automate orchestration:** After you collect the `Preempt` signal, your orchestration should act on that signal. Given the time constraints, the `Preempt` signal should attempt a graceful shutdown of your workload and start an automated process that replaces the spot VM. For more information, see the following resources:
  - Scheduled Events
  - Scheduled event types
  - Endpoint querying frequency

Build a deployment system

Your orchestration needs an automated pipeline to deploy new spot VMs after eviction. The pipeline should run outside the interruptible workload to help ensure permanence. The deployment pipeline should work according to the eviction policy that you choose for your spot VMs.

For a Delete policy, we recommend that you build a pipeline that uses different VM sizes and deploys to different regions. For a Stop/Deallocate policy, the deployment pipeline needs two distinct actions. For the initial creation of a VM, the pipeline needs to deploy the correct size VMs to the correct location. For an evicted VM, the pipeline needs to try to restart the VM until it works. A combination of Azure Monitor alerts and Azure functions is one way to automate a deployment system. The pipeline could use bicep templates. They're declarative and idempotent and represent a best practice for infrastructure deployment.

Prepare for immediate eviction

It's possible for Azure to evict a spot VM as soon as you create it and before your workload runs. In some cases, there might be enough capacity to create a spot VM, but it won't last. Spot VMs have no availability guarantees, or SLAs, after creation. Your orchestration needs to account for immediate evictions. The `Preempt` signal provides a minimum of 30-seconds advance notice of the eviction.

Incorporate VM health checks into your orchestration to prepare for immediate evictions. Orchestration for immediate evictions can't depend on the Scheduled Events `Preempt` signal. Only the VM itself can query the `Preempt` signal, and there's not enough time to start an application, query the Scheduled Events endpoint, and gracefully shut down. So the health check needs to reside outside the workload environment. The health checks need to monitor the status of the spot VM and start the deployment pipeline to replace the spot VM when the status changes to *deallocating* or *stopping*.

Plan for multiple simultaneous evictions

If you run a cluster of spot VMs, architect the workload to withstand multiple simultaneous evictions. Multiple spot VMs in the workload can be evicted at the same time. A simultaneous eviction of multiple VMs could affect the throughput of the application. To prevent this situation, your deployment pipeline should be able to gather signals from multiple VMs and deploy multiple replacement VMs simultaneously.

Design for a graceful shutdown

The VM shutdown process should be less than 30 seconds and allow your VM to shut down before an eviction. The amount of time the shutdown should take depends on how frequently your workload queries the Scheduled Events endpoint. The more often you query the endpoint, the longer the shutdown process can take. The shutdown process should release resources, drain connections, and flush event logs. You should regularly create and save checkpoints to retain the context and build a more efficient recovery strategy. The checkpoint is just information about what processes or transactions the next VM needs to start on. They should indicate if the VM should resume where the previous VM left off or if the new VM should revert the changes and start the entire process again. Store the checkpoints outside the spot VM environment, like in a storage account.

Test the orchestration

Simulate eviction events to test orchestration in dev/test environments. For more information, see Simulate eviction.

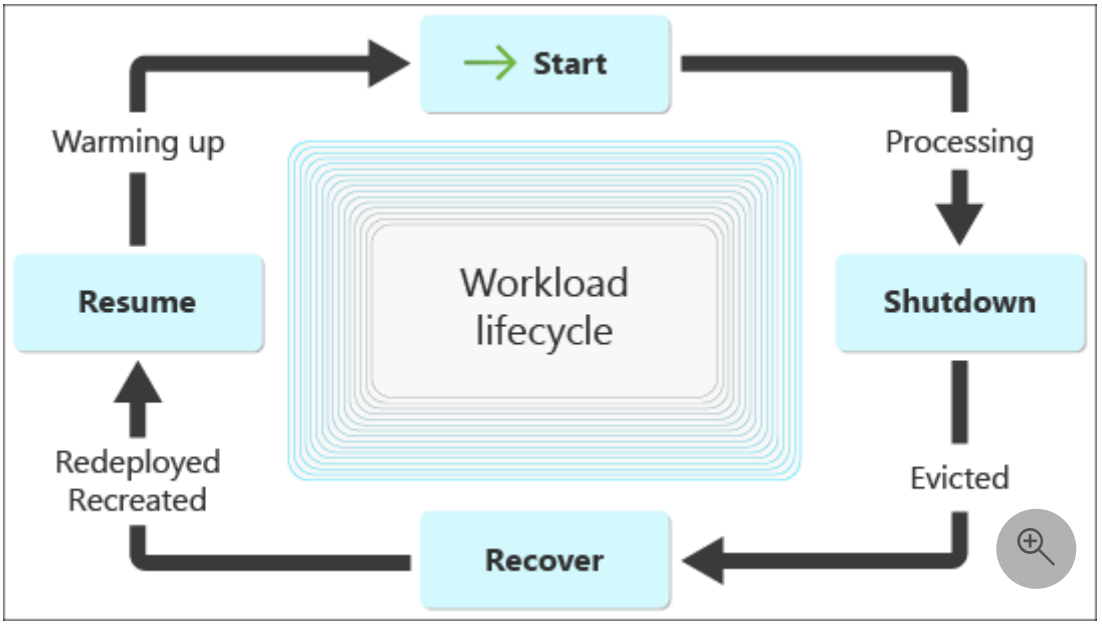
Design an idempotent workload

We recommend that you design an idempotent workload. The outcome of processing an event more than one time should be the same as processing it once. Evictions can result in forced shutdowns, despite efforts to ensure graceful shutdowns. Forced shutdowns can terminate

processes before completion. Idempotent workloads can receive the same message more than one time without changing the outcome. For more information, see Idempotency.

Use an application warmup period

Most interruptible workloads run applications. Applications need time to install and to start up. They also need time to connect to external storage and gather information from checkpoints. Have an application warmup period before you allow it to start processing. During the warmup period, the application should start, establish connections, and prepare to contribute. Only allow an application to start processing data after you validate the health of the application.



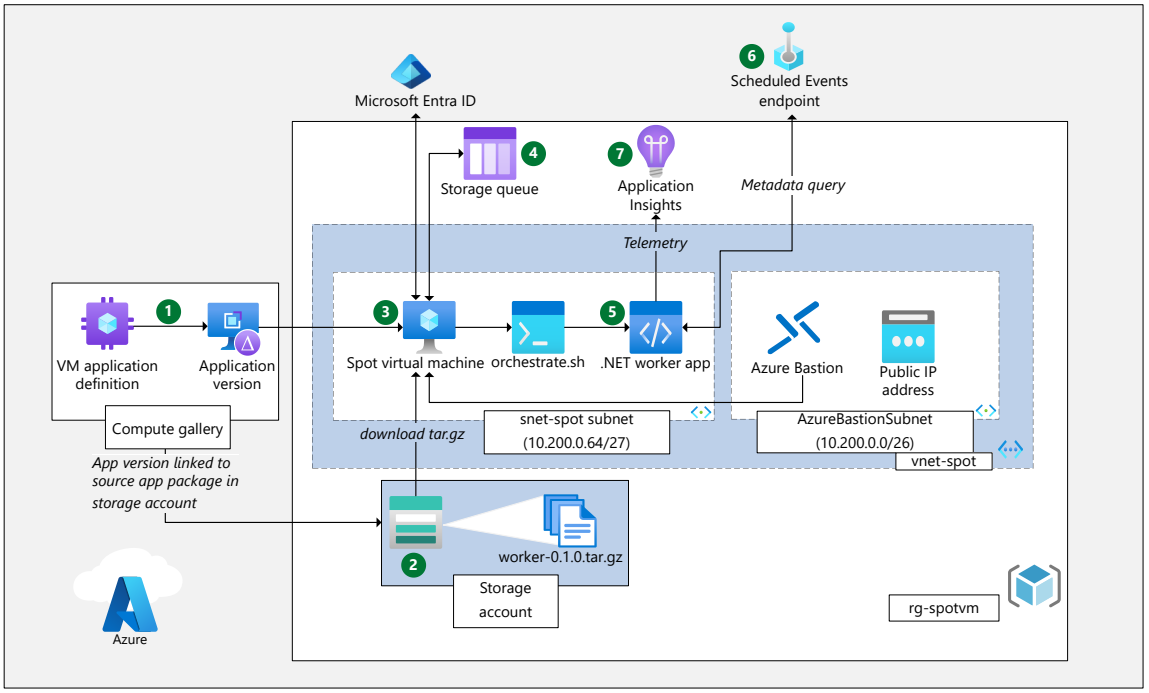
Configure user-assigned managed identities

Assign user-assigned managed identities to streamline the authentication and authorization process. User-assigned managed identities let you avoid putting credentials in code and aren't tied to a single resource like system-assigned managed identities. The user-assigned managed identities contain permissions and access tokens from Microsoft Entra ID that can be reused and assigned to spot VMs during orchestration. Token consistency across spot VMs helps streamline orchestration and simplifies the access to workload resources that the spot VMs have.

If you use system-assigned managed identities, a new spot VM might get a different access token from Microsoft Entra ID. If you need to use system-assigned managed identities, make the workloads resilient to `403 Forbidden Error` responses. Your orchestration needs to get tokens from Microsoft Entra ID with the correct permissions. For more information, see Managed identities.

Example scenario

The example scenario deploys a queue processing application that qualifies as an interruptible workload. The scripts in the scenario serve as examples. The scenario guides you through a one-time, manual push to deploy resources. This implementation doesn't have a deployment pipeline. However, a deployment pipeline is essential to automate the orchestrating process. The following diagram shows the architecture of the example scenario.



Microsoft Azure

[Download a Visio file](#) of this architecture.

The following workflow corresponds to the previous diagram:

1. **VM application definition:** The VM application definition is created in the Azure compute gallery. It defines the application name, location, operating system, and metadata. The application version is a numbered version of the VM application definition. The application version represents the VM application. It needs to be in the same region as the spot VM. The application version links to the source application package in the storage account.

2. **Storage account:** The storage account stores the source application package. In this architecture, it's a compressed tar file named `worker-0.1.0.tar.gz`. It contains two files. One file is the `orchestrate.sh` bash script that installs the .NET worker application.

3. **Spot VM:** The spot VM deploys. It must be in the same region as the application version. It downloads `worker-0.1.0.tar.gz` to the VM after deployment. The bicep template

deploys an Ubuntu image on a standard family VM. These configurations meet the needs of this application and aren't general recommendations for your applications.

4. **Storage queue:** The other service that runs in the .NET worker contains message queue logic. Microsoft Entra ID grants the spot VM access to the storage queue in Azure Queue Storage with a user-assigned identity by using role-based access control.

5. **.NET worker application:** The `orchestrate.sh` script installs a .NET worker application that runs two background services. The first service queries the Scheduled Events endpoint, looks for the `Preempt` signal, and sends this signal to the second service. The second service processes messages from the storage queue and listens for the `Preempt` signal from the first service. When the second service receives the signal, it interrupts storage queue processing and begins to shut down.

6. **Query Scheduled Events endpoint:** An API request is sent to a static nonroutable IP address `169.254.169.254`. The API request queries the Scheduled Events endpoint for infrastructure maintenance signals.

7. **Application Insights:** The architecture uses Application Insights only for learning purposes. It's not an essential component of interruptible workload orchestration, but allows you to validate the telemetry from the .NET worker application. The .NET worker application sends telemetry to Application Insights via the Azure Monitor OpenTelemetry Distro. For more information, see Enable live metrics from the .NET application.

Microsoft Azure Boost

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Sizes

Azure Boost is a system designed by Microsoft that offloads server virtualization processes traditionally performed by the hypervisor and host OS onto purpose-built software and hardware. This offloading frees up CPU resources for the guest virtual machines, resulting in improved performance. Azure Boost also provides a secure foundation for your cloud workloads. Microsoft's in-house developed hardware and software systems provide a secure environment for your virtual machines.

Benefits

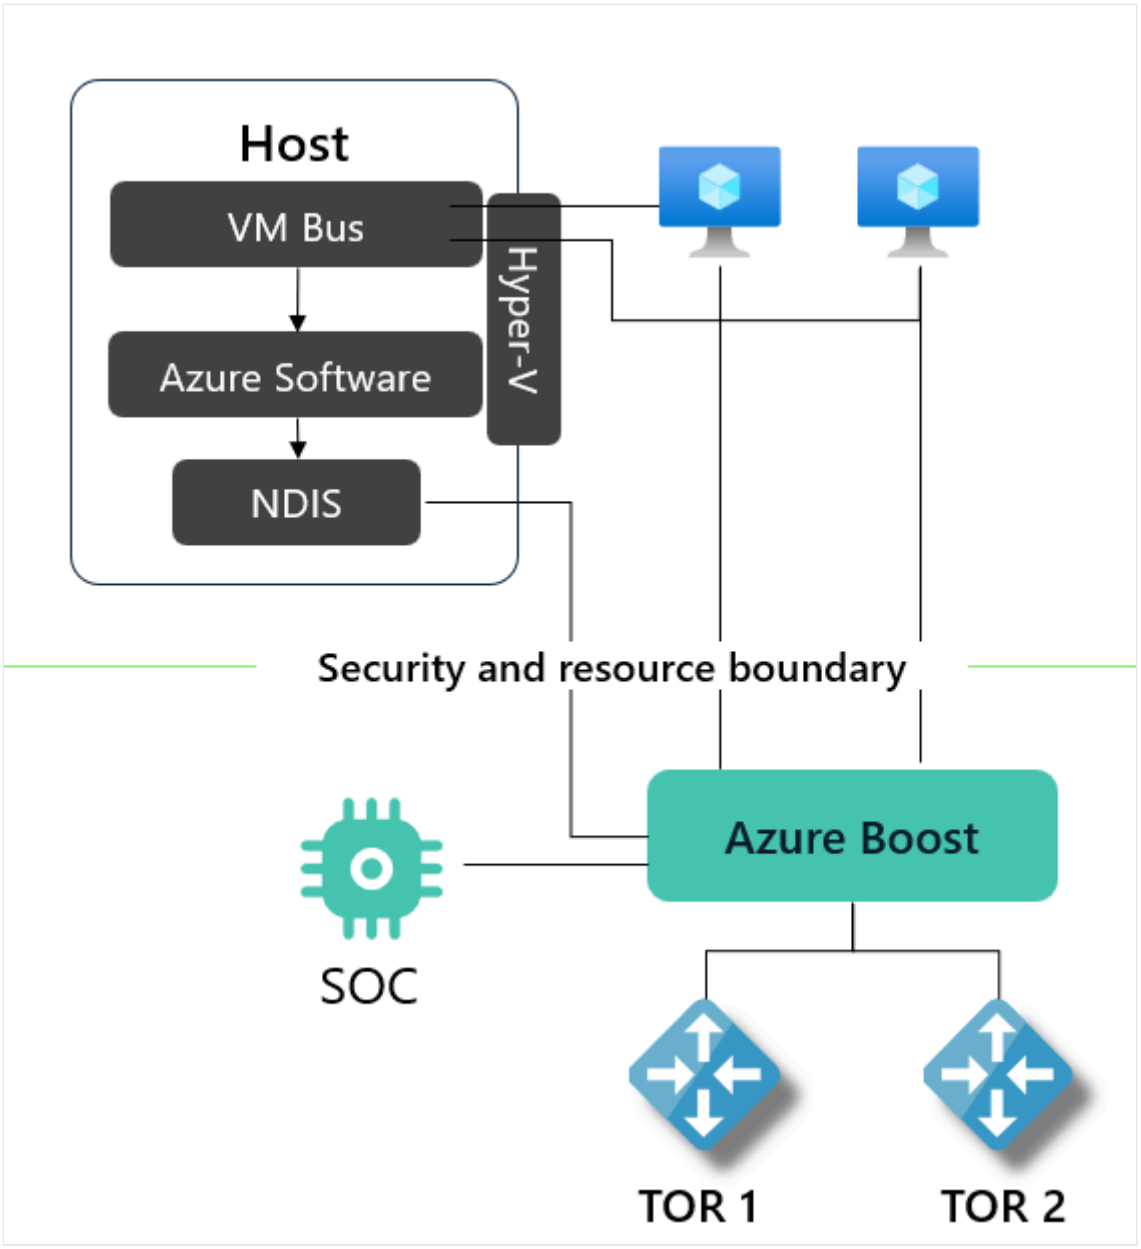
Azure Boost contains several features that can improve the performance and security of your virtual machines. These features are available on select Azure Boost compatible virtual machine sizes.

- **Networking:** Azure Boost includes a suite of software and hardware networking systems that provide a significant boost to both network performance (Up to 200-Gbps network bandwidth) and network security. Azure Boost compatible virtual machine hosts contain the new Microsoft Azure Network Adapter (MANA). Learn more about Azure Boost networking.
- **Storage:** Storage processing operations are offloaded to the Azure Boost FPGA. This offload to FPGA provides leading efficiency and performance while improving security, reducing jitter, and improving latency for workloads. Local storage now runs at up to 36GBps throughput and 6.6 million IOPS, and with remote storage up to 14GBps throughput and 750K IOPS. Learn more about Azure Boost Storage.
- **Security:** Azure Boost uses Cerberus as an independent HW Root of Trust to achieve NIST 800-193 certification. Customer workloads can't run on Azure Boost powered architecture unless the firmware and software running on the system is trusted. Learn more about Azure Boost Security.
- **Performance:** With Azure Boost offloading storage and networking, CPU resources are freed up for increased virtualization performance. Resources that would normally be used for these essential background tasks are now available to the guest VM. Learn more about Azure Boost Performance.

Networking

The next generation of Azure Boost will introduce the Microsoft Azure Network Adapter (MANA). This network interface card (NIC) includes the latest hardware acceleration features and provides competitive performance with a consistent driver interface. This custom hardware and software implementation ensures optimal networking performance, tailored specifically for Azure's demands. MANA's features are designed to enhance your networking experience with:

- **Over 200-Gbps of network bandwidth:** Custom hardware and software drivers facilitating faster and more efficient data transfers. Starting up to 200Gbps network bandwidth with increases in the future.
- **High network availability and stability:** With an active/active network connection to the Top of Rack (ToR) switch, Azure Boost ensures your network is always up and running at the highest possible performance.
- **Native support for DPDK:** Learn more about Azure Boost's support for Data Plane Development Kit (DPDK) on Linux VMs.
- **Consistent driver interface:** Assuring a one-time transition that won't be disrupted during future hardware changes.
- **Integration with future Azure features:** Consistent updates and performance enhancements ensures you're always a step ahead.

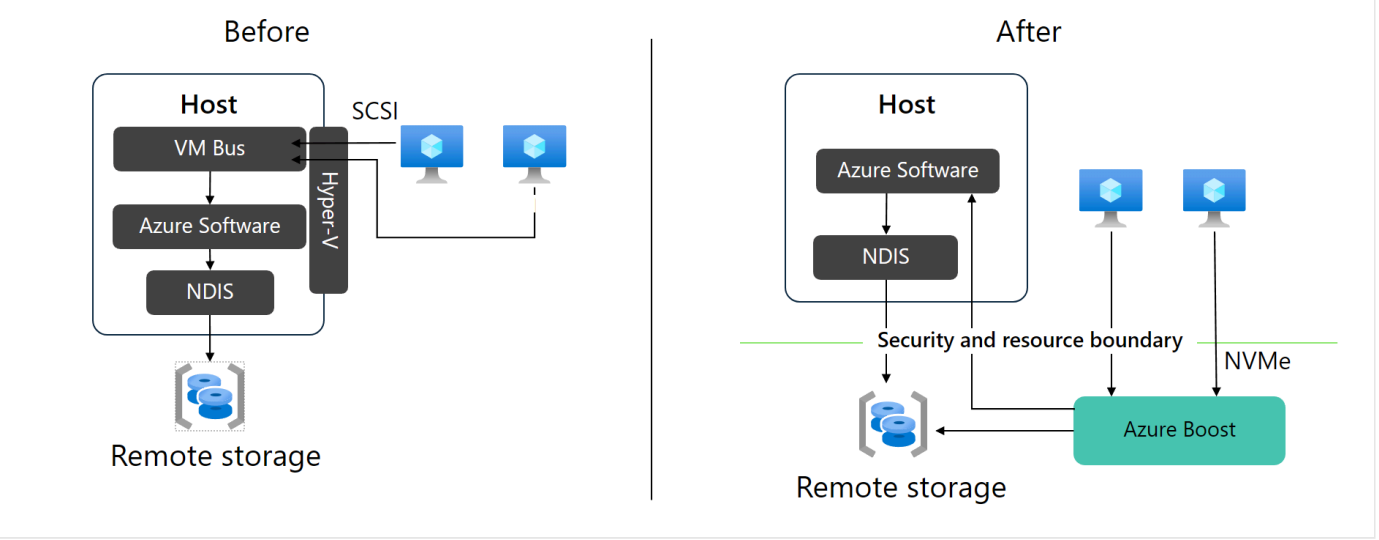


Storage

Azure Boost architecture offloads storage covering local, remote and cached disks that provide leading efficiency and performance while improving security, reducing jitter & improving latency for workloads. Azure Boost already provides acceleration for workloads in the fleet using remote storage including specialized workloads such as the Ebsv5 VM types. Also, these improvements provide potential cost saving for customers by consolidating existing workload into fewer or smaller sized VMs.

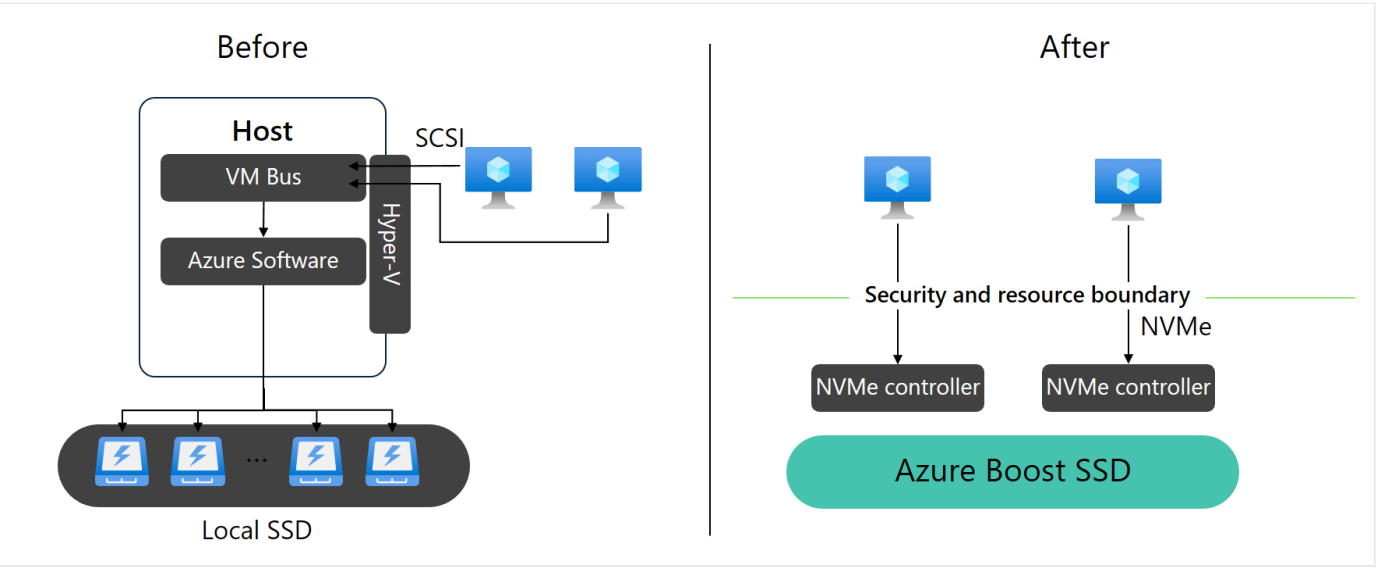
Azure Boost delivers industry leading throughput performance at up to 14GBps throughput and 750K IOPS for remote disk access performance. This performance is enabled by accelerated storage processing and exposing NVMe disk interfaces to VMs. Storage processing tasks are offloaded from the host processor to dedicated programmable Azure Boost hardware in our

dynamically programmable FPGA. This architecture allows us to update the FPGA hardware in the fleet enabling continuous delivery for our customers.



Azure Boost SSD

With Azure Boost SSD architecture, we deliver local, and cached disk performance improvements at up to 36GBps throughput and 6.6M IOPS depending on the VM size of your choice. Azure Boost SSDs are designed to provide high performance optimized encryption at rest, and minimal jitter to NVMe local disks for Azure VMs with local disks.



Security

Azure Boost's security contains several components that work together to provide a secure environment for your virtual machines. Microsoft's in-house developed hardware and software systems provide a secure foundation for your cloud workloads.

- **Security chip:** Boost employs the Cerberus chip as an independent hardware root of trust to achieve NIST 800-193 certification. Customer workloads can't run on Azure Boost powered architecture unless the firmware and software running on the system garners trust.
- **Attestation:** HW RoT identity, Secure Boot, and Attestation through Azure's Attestation Service ensures that Boost and its powered hosts always operate in a healthy and trusted state. Any machine that can't be securely attested is prevented from hosting workloads and it's restored to a trusted state offline.
- **Code integrity:** Boost systems embrace multiple layers of defense-in-depth, including ubiquitous code integrity verification that enforces only Microsoft approved and signed code runs on the Boost system on chip. Microsoft has sought to learn from and contribute back to the wider security community, up streaming advancements to the Integrity Measurement Architecture.
- **Security Enhanced OS:** Azure Boost uses Security Enhanced Linux (SELinux) to enforce principle of least privilege for all software running on its system on chip. All control plane and data plane software running on top of the Boost OS is restricted to running only with the minimum set of privileges required to operate – the operating system restricts any attempt by Boost software to act in an unexpected manner. Boost OS properties make it difficult to compromise code, data, or the availability of Boost and Azure hosting Infrastructure.
- **Rust memory safety:** Rust serves as the primary language for all new code written on the Boost system, to provide memory safety without impacting performance. Control and data plane operations are isolated with memory safety improvements that enhance Azure's ability to keep tenants safe.
- **FIPS certification:** Boost employs a FIPS 140 certified system kernel, providing reliable and robust security validation of cryptographic modules.

Performance

The hardware running virtual machines are a shared resource. The hypervisor (host system) must perform several tasks to ensure that each virtual machine is both isolated from other virtual machines and that each virtual machine receives the resources it needs to run. These tasks include networking between the physical and virtual networks, security, and storage management. Azure Boost reduces the overhead of these tasks by offloading them to dedicated

hardware. This offloading frees up CPU resources for the guest virtual machines, resulting in improved performance.

- **VMs using large sizes:** Large sizes that encompass most of a host's resources benefit from Azure Boost. While a large VM size running on a Boost-enabled host might not directly see extra resources, workloads and applications that stress the host processes replaced by Azure Boost see a performance increase.
- **Dedicated hosts:** Performance improvements also have significant impact to Azure Dedicated Hosts (ADH) users. Azure Boost-enabled hosts can potentially run extra, small VMs or increase the size of existing VMs. This allows you to do more work on a single host, reducing your overall costs.

Current availability

Azure Boost is currently available on several VM size families:

Azure Hybrid Benefit for Linux virtual machines

08/21/2025

You can use Azure Hybrid Benefit for Linux to easily switch the software subscription model for your Linux virtual machine (VM). Change your subscription model without redeploying your VM and with no risk of downtime. You gain flexibility and savings.

You can switch seamlessly between two subscription models on Azure by using Azure Hybrid Benefit:

- **Bring your own subscription (BYOS)**: In the BYOS model, you bring your own Red Hat Enterprise Linux (RHEL) or SUSE Linux Enterprise Server (SLES) subscription directly to Azure. You pay only for the infrastructure costs of your VM on Azure. The software fee is covered by your RHEL or SLES subscription you bought from the vendor.
- **Pay-as-you-go (PAYG)**: Use the PAYG subscription model in Azure to pay for RHEL and SLES subscriptions as you use them.

This article defines the BYOS and PAYG subscription models, compares the benefits of each model, and shows you how to use the Azure Hybrid Benefit to switch between the two subscription models for your Linux VMs on Azure.

This process applies to:

- Azure Virtual Machine Scale Sets
- Azure Spot Virtual Machines
- Custom images

Azure Hybrid Benefit gives you the option to make seamless bidirectional conversions between the two subscription models on eligible VM instances.

You might see combined savings estimated to up to 76% with Azure Hybrid Benefit for Linux and three-year Azure Reserved VM Instances. Savings estimates are based on one standard D2s v5 Azure VM with an RHEL or SLES subscription in the East US region running at a PAYG rate versus a reduced rate for a three-year reserved instance plan. The savings estimates are based on Azure pricing as of September 2024. Prices are subject to change. Actual savings might vary based on location, instance type, or usage.

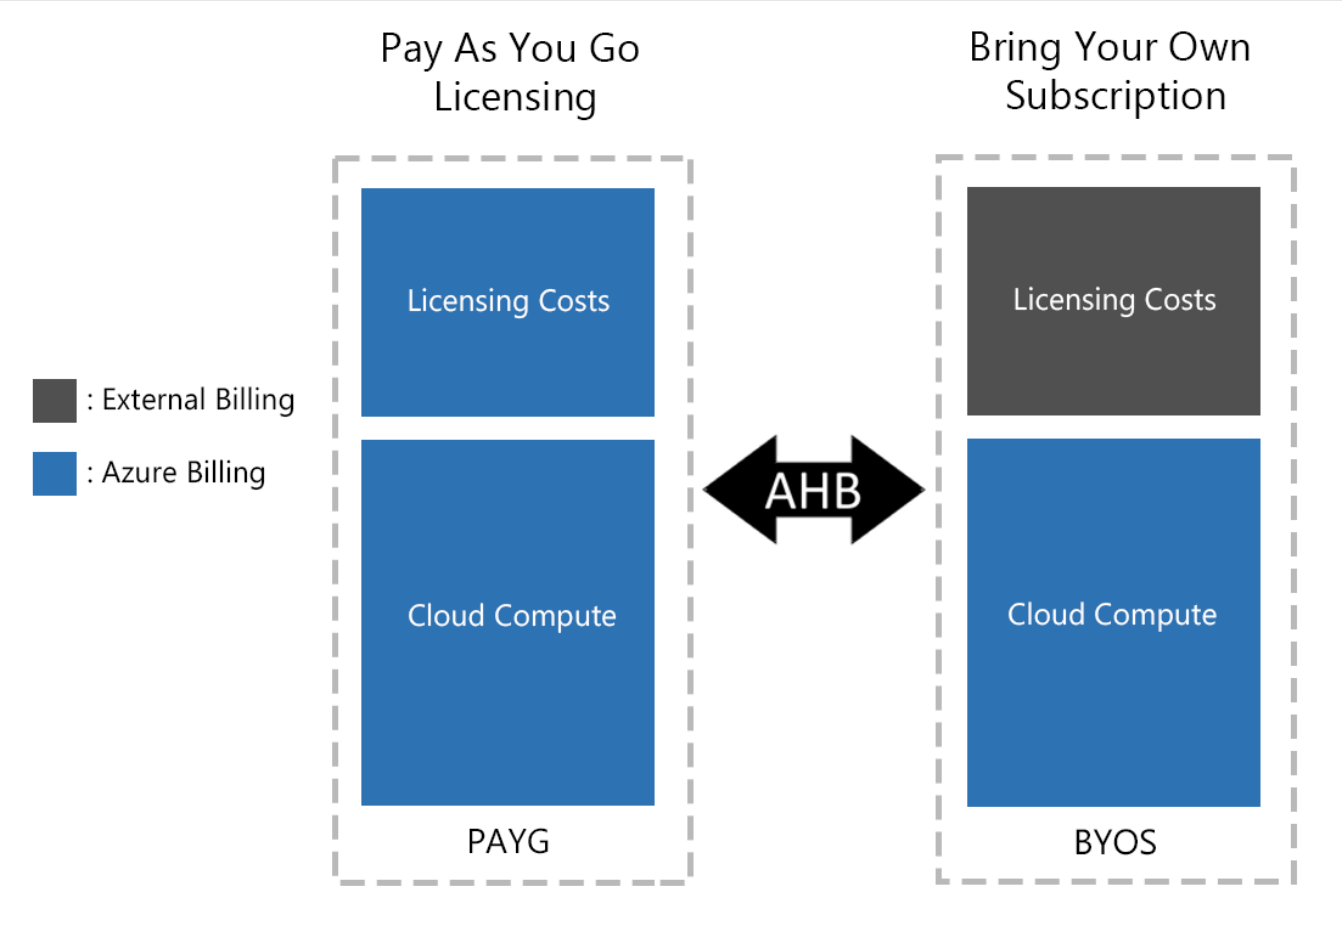
> **Tip**

Try the Azure Pricing calculator to visualize the cost-saving benefits of this feature at a Virtual Machine level.

PAYG vs. BYOS

Azure offers two main licensing pricing options: PAYG and BYOS. With PAYG, you pay only for the resources you use. You can scale up or scale down as needed.

With BYOS, you can use your existing license subscriptions. You don't pay the license fees in Azure.



VMs utilizing a PAYG subscription model, whether deployed from PAYG images or VMs converted to PAYG from BYOS, incur *both* an infrastructure fee and a software fee.

If you have an existing software subscription, use Azure Hybrid Benefit to convert from a PAYG model to a BYOS model.

You can use Azure Hybrid Benefit to switch between the two subscription options at any time.

Linux VMs you can use with Azure Hybrid Benefit

PAYG

The following PAYG RHEL and SLES Marketplace offers are eligible to use with Azure Hybrid Benefit:

RHEL PAYG

Limitations

Only RHEL images *published by Red Hat, Inc.* are eligible for the PAYG to BYOS conversion using the Azure Hybrid Benefit. Images from other vendors aren't supported.

Red Hat-published RHEL PAYG offers eligible for Azure Hybrid Benefit

The following Red Hat-published RHEL PAYG offers are eligible to use with the Azure Hybrid Benefit. Links to the offers in Azure Marketplace are included.

Within these offers, associated images are described as "Pay-As-You-Go".

- Red Hat Enterprise Linux (RHEL)
- Red Hat Enterprise Linux (RHEL)
- Red Hat Enterprise Linux (RHEL) for SAP Apps
- RHEL for SAP with HA and Update Services
- Red Hat Enterprise Linux (RHEL) with High Availability (HA) Add-On
- Red Hat Enterprise Linux (RHEL) Arm64
- Red Hat Enterprise Linux Confidential VM
- Red Hat Enterprise Linux (RHEL) RAW

BYOS

Azure Hybrid Benefit is also available for RHEL and SLES BYOS Azure Marketplace images and images brought from on-prem or other cloud providers.

Currently, one RHEL BYOS offer is available. This offer is a private listing. To gain access to this private listing, you must join the Red Hat Cloud Access program.

You can identify SUSE BYOS marketplace offers by their name, which includes "BYOS". An example is the ** SUSE Linux Enterprise Server 15 SP7 - BYOS** offering.

Azure dedicated host instances and SQL hybrid benefits aren't eligible to use with Azure Hybrid Benefit if you already use Azure Hybrid Benefit with Linux VMs.

> **Note**
>
> For Red Hat VMs, the Azure account must be part of the Red Hat Cloud Access program. Register with Red Hat Cloud Access before you try to enable Azure Hybrid Benefit on your VMs.

Enable Azure Hybrid Benefit

You can enable Azure Hybrid Benefit on new VMs, on existing VMs, and on multiple VMs.

New VM

You can invoke Azure Hybrid Benefit when you create a VM. The benefits of using this approach include:

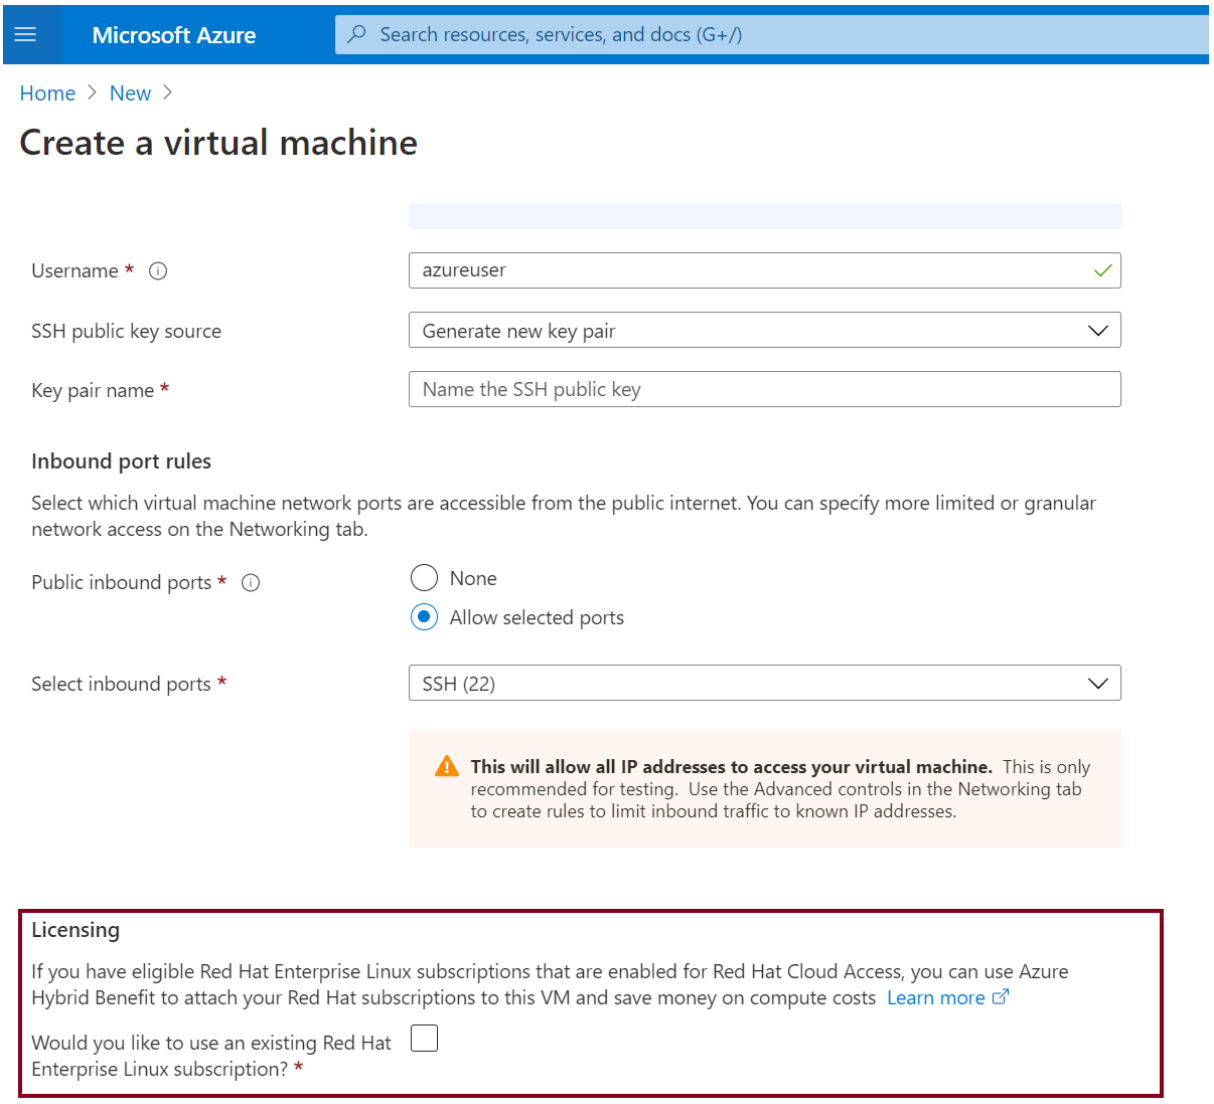
- You can provision both PAYG and BYOS VMs by using the same image and process.
- You can change the licensing mode in the future.
- The PAYG VM is connected to Red Hat Update Infrastructure (RHUI) or SUSE Cloud Update Infrastructure (CUI) by default, to help keep it up to date and secure. You can change the update method after deployment.

Azure portal

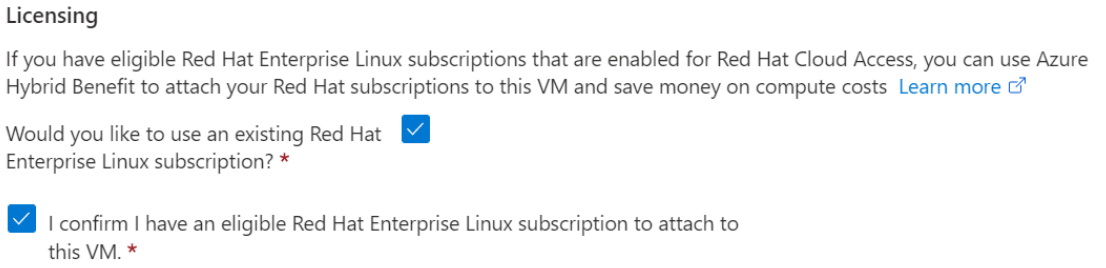
The SUSE workflow is the same as the RHEL example shown here.

To enable Azure Hybrid Benefit when you create a VM:

1. In the Azure portal, go to **Create a virtual machine**.

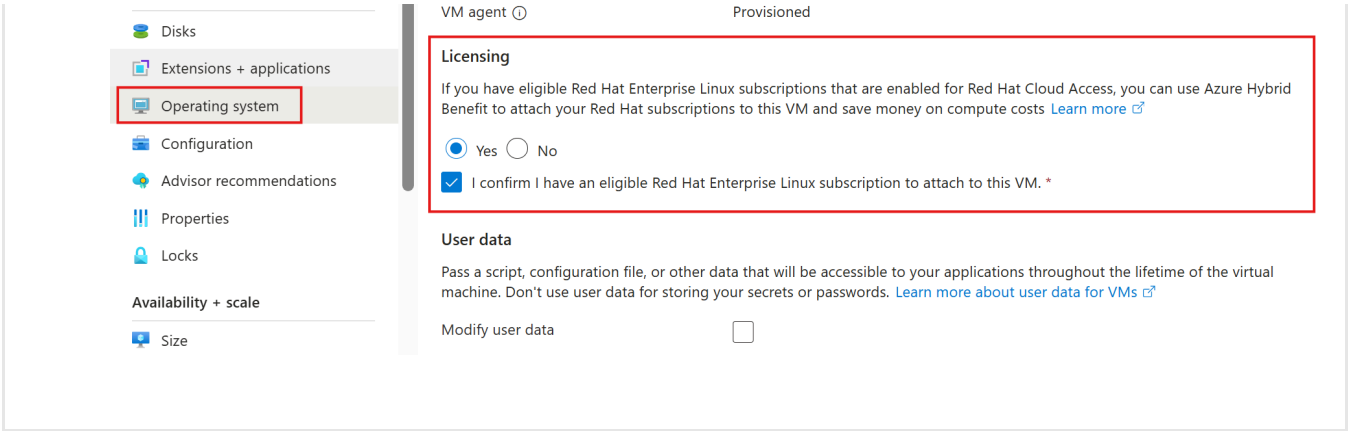


2. In the **Licensing** section, select the checkbox that asks if you want to use an existing RHEL subscription. Select the checkbox to confirm that your subscription is eligible.



3. Create a virtual machine by following the steps that are presented.

4. On the VM service menu, select **Operating System**. Under **Licensing**, verify that the option is enabled.



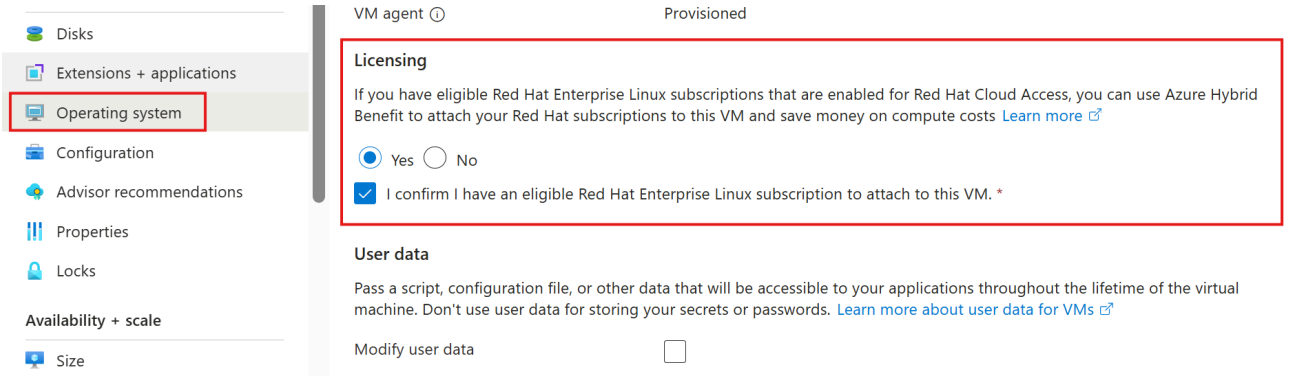
Existing VM

You can enable Azure Hybrid Benefit on an existing VM.

Azure portal

To enable Azure Hybrid Benefit on an existing VM:

1. In the Azure portal, go to the overview pane of the VM that you want to convert.
2. Go to **Operating System** > **Licensing**. To enable the Azure Hybrid Benefit conversion, select **Yes**, and then select the confirmation checkbox.



Check the current licensing model of a VM that has Azure Hybrid Benefit enabled

With Red Hat, the Azure Hybrid Benefit extension must be installed on the VM to switch the licensing model from BYOS to PAYG or vice versa. You can view whether the agent is installed by using the Azure CLI or the Azure Instance Metadata Service.

For SUSE you do not need the extension, the functionality is covered by the SUSE tooling itself.

Azure CLI

1. Red Hat: You can use the `az vm get-instance-view` command to check whether the extension is installed. Look for the `AHBForRHEL` extension. If the corresponding extension is installed, the Azure Hybrid Benefit is enabled. Review the license type to determine which licensing model is applied to your VM.

   Azure CLI

   ```
   az vm get-instance-view -g MyResourceGroup -n myVm --query
   instanceView.extensions
   ```

2. Red Hat and SUSE: Use the following command to review the license type that's applied to the VM:

   Azure CLI

   ```
   az vm get-instance-view -g MyResourceGroup -n myVM --query licenseType
   ```

   The following license types correspond to a **PAYG** subscription model:

   For RHEL:

   - RHEL_BASE
   - RHEL_EUS
   - RHEL_SAPAPPS
   - RHEL_SAPHA
   - RHEL_BASESAPAPPS
   - RHEL_BASESAPHA

   For SLES:

   - SLES
   - SLES_SAP
   - SLES_HPC

   These license types correspond to a **BYOS** subscription model:

   For RHEL:

   - RHEL_BYOS

   For SLES:

   - SLES_BYOS

If the license type of the VM isn't modified, this command returns an empty string and the VM continues to use the billing model of the image that you used to deploy it.

Convert PAYG to BYOS

If you deployed an Azure Marketplace image by using a PAYG licensing model and want to convert licensing to BYOS, complete the following steps.

Convert a PAYG image to BYOS by using the Azure CLI

Use the Azure CLI to convert a PAYG Azure Marketplace image to a BYOS subscription model.

Red Hat (RHEL)

1. Apply the `RHEL_BYOS` license type to the VM:

   Azure CLI

   ```
   # This enables BYOS on a RHEL PAYG VM by using Azure Hybrid Benefit.
   az vm update -g myResourceGroup -n myVmName --license-type RHEL_BYOS
   ```

2. When the PAYG to BYOS conversion is finished, you must register the VM with Red Hat for system updates and usage compliance.

3. If you want to return the original subscription model, set `license-type` to `None`.

   Azure CLI

   ```
   # In order to revert back to the original licensing model, set license-
   type to None.
   az vm update -g myResourceGroup -n myVmName --license-type NONE
   ```

Convert the license type in the VM operating system

Red Hat (RHEL)

To start using Azure Hybrid Benefit for Red Hat:

1. Install the `AHBForRHEL` extension on the VM on which you want to apply the Azure Hybrid Benefit BYOS benefit. You can install the extension by using the Azure CLI or Azure PowerShell.

2. Depending on the software updates that you want, change the license type to a relevant value. Here are the available license type values and the software updates associated with them:

Expand table

License type	Software updates	Allowed VMs
RHEL_BASE	Installs Red Hat regular/base repositories on your VM.	RHEL BYOS VMs, RHEL custom image VMs
RHEL_EUS	Installs Red Hat Extended Update Support (EUS) repositories on your VM.	RHEL BYOS VMs, RHEL custom image VMs
RHEL_SAPAPPS	Installs RHEL for SAP Business Apps repositories on your VM.	RHEL BYOS VMs, RHEL custom image VMs
RHEL_SAPHA	Installs RHEL for SAP with High Availability (HA) repositories on your VM.	RHEL BYOS VMs, RHEL custom image VMs
RHEL_BASESAPAPPS	Installs RHEL regular/base SAP Business Apps repositories on your VM.	RHEL BYOS VMs, RHEL custom image VMs
RHEL_BASESAPHA	Installs regular/base RHEL for SAP with HA repositories on your VM.	RHEL BYOS VMs, RHEL custom image VMs

3. Wait one hour for the extension to read the license type value and install the repositories.

> **Note**
>
> If the extension isn't running by itself, you can run it on demand.

You should now be connected to Azure Red Hat Update. The relevant repositories are installed on your machine.

1. If you want to switch back to the BYOS model, set `license-type` to `None` and run the extension. This action removes all RHUI repositories from your VM and stops associated billing.

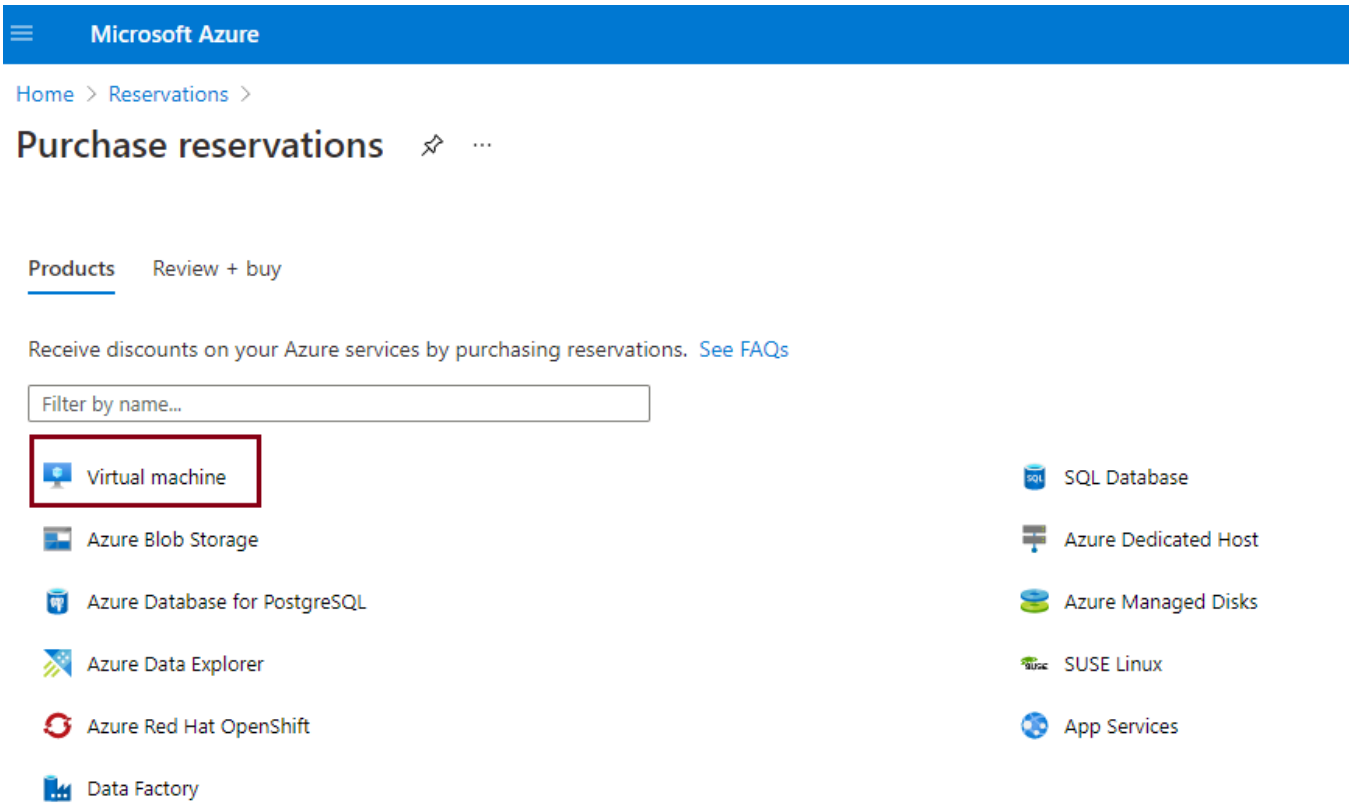
> **Note**

In the unlikely event that the extension can't install repositories or if there are any other issues, switch the license type back to empty and contact Microsoft support. Taking this step ensures that you aren't billed for software updates.

Azure Hybrid Benefit for reserved instance VMs

Azure reservations (Azure Reserved Virtual Machine Instances) help you save money by committing to one-year or three-year plans for multiple products. Azure Hybrid Benefit for PAYG VMs is available for reserved instances.

If you purchased compute costs at a discounted rate by using reserved instances, you can apply Azure Hybrid Benefit on the licensing costs for RHEL and SUSE. The steps to apply Azure Hybrid Benefit for a reserved instance are exactly the same as for a regular VM.



> **Note**
>
> If you already purchased reservations for RHEL or SUSE PAYG software in Azure Marketplace, wait for the reservation tenure to finish before you use Azure Hybrid Benefit for PAYG VMs.

Compliance

Red Hat compliance

Customers who use Azure Hybrid Benefit for PAYG RHEL VMs agree to the standard legal terms and privacy statement associated with Azure Marketplace RHEL offers.

Customers who use Azure Hybrid Benefit for PAYG RHEL VMs have three options for providing software updates and patches to those VMs:

- Red Hat Update Infrastructure (default option)
- Red Hat Satellite Server
- Red Hat Subscription Manager

Customers can use RHUI as the main update source for Azure Hybrid Benefit for PAYG RHEL VMs without attaching subscriptions. Customers who choose the RHUI option are responsible for ensuring RHEL subscription compliance.

Customers using either Red Hat Satellite Server or Red Hat Subscription Manager should remove the RHUI configuration and attach a cloud-access-enabled RHEL subscription to Azure Hybrid Benefit for PAYG RHEL VMs.

For more information about Red Hat subscription compliance, software updates, and sources for Azure Hybrid Benefit for PAYG RHEL VMs, see the Red Hat article about using RHEL subscriptions with Azure Hybrid Benefit.

Customers who use the Azure Hybrid Benefit BYOS to PAYG capability for RHEL agree to the standard legal terms and privacy statement associated with Azure Marketplace RHEL offerings.

Frequently asked questions

- **Q: Can I use a license type of `RHEL_BYOS` with a SLES image or vice versa?**
  - A: No, you can't. Trying to enter a license type that incorrectly matches the distribution running on your VM won't update any billing metadata. But if you accidentally enter the wrong license type, updating your VM again to the correct license type still enables Azure Hybrid Benefit.

- **Q: I've registered with Red Hat Cloud Access but still can't enable Azure Hybrid Benefit on my RHEL VMs. What should I do?**
  - A: It might take some time for your Red Hat Cloud Access subscription registration to propagate from Red Hat to Azure. If you still see the error after one business day, contact Microsoft support.

- **Q: I've deployed a VM by using a RHEL BYOS "golden image." Can I convert the billing on this image from BYOS to PAYG?**
  - A: Yes, you can use Azure Hybrid Benefit for BYOS VMs to convert this subscription model.

- **Q: I've uploaded my own RHEL or SLES image from on-premises (via Azure Migrate, Azure Site Recovery, or otherwise) to Azure. Can I convert the billing on these images from BYOS to PAYG?**
  - A: Yes, you can use Azure Hybrid Benefit for BYOS VMs to convert this subscription model.

- **Q: I've uploaded my own RHEL or SLES image from on-premises (via Azure Migrate, Azure Site Recovery, or otherwise) to Azure. Do I need to do anything to benefit from Azure Hybrid Benefit?**
  - A: No, you don't. RHEL or SLES images that you upload are already considered BYOS, and you're charged only for Azure infrastructure costs. You're responsible for RHEL or SLES subscription costs, just as you are for your on-premises environments.

- **Q: Can I use Azure Hybrid Benefit for PAYG VMs for Azure Marketplace RHEL and SLES SAP images?**
  - A: Yes. You can use the license type of RHEL_BYOS for RHEL VMs and SLES_BYOS for conversions of VMs deployed from Azure Marketplace RHEL and SLES SAP images.

- **Q: Can I use Azure Hybrid Benefit for PAYG VMs on virtual machine scale sets for RHEL and SLES?**
  - A: Yes. Azure Hybrid Benefit on virtual machine scale sets for RHEL and SLES is available to all users. You can learn more about this benefit and how to use it.

- **Q: Can I use Azure Hybrid Benefit for PAYG VMs on reserved instances for RHEL and SLES?**
  - A: Yes. Azure Hybrid Benefit for PAYG VMs on reserved instances for RHEL and SLES is available to all users.

- **Q: Can I use Azure Hybrid Benefit for PAYG VMs on a VM deployed for SQL Server on RHEL images?**
  - A: No, you can't. There's no plan to support these VMs.

- **Q: Can I use Azure Hybrid Benefit on my RHEL for Virtual Datacenters subscription?**
  - A: No. RHEL for Virtual Datacenters isn't supported on Azure at all, including for Azure Hybrid Benefit.

Explore Azure Hybrid Benefit for Windows VMs

Article • 01/02/2025

Maximize your on-premises core licenses for Windows Server to get Windows virtual machines (VMs) on Azure at a reduced cost through Azure Hybrid Benefit for Windows Server. You also can use Azure Hybrid Benefit for Windows Server to deploy new VMs that run the Windows OS.

This article describes the steps to deploy new VMs with Azure Hybrid Benefit for Windows Server and how to update existing running VMs.

To qualify for Azure Hybrid Benefit for Windows Server, you need on-premises core licenses for Windows Server from an applicable program with active Software Assurance or qualifying subscription licenses. Software Assurance and qualifying subscription licenses are available only as part of certain commercial licensing agreements. To learn more about commercial licensing, see Microsoft licensing resources. To learn more about Windows Server core licenses, see Windows Server product licensing.

You can use Azure Hybrid Benefit for Windows Server with any VMs running Windows Server OS in all regions, including VMs that have additional software, such as SQL Server or third-party Azure Marketplace software.

Limitations

To use Azure Hybrid Benefit for Windows Server, you must have a minimum of 8 core licenses (Datacenter edition or Standard edition) per VM. For example, even if you run a 4-core instance, 8 core licenses are required. You also can run instances larger than 8 cores by allocating licenses equal to the core size of the instance. For example, 12 core licenses are required for a 12-core instance.

For customers who have processor licenses, each processor license is equivalent to 16 core licenses.

ⓘ Important

- Workloads that use Azure Hybrid Benefit for Windows Server can run only during the Software Assurance or subscription license term. When the Software Assurance or subscription license term approaches expiration, you must renew your agreement with either Software Assurance or a subscription

license, disable the Azure Hybrid Benefit for Windows Server functionality, or deprovision workloads that use Azure Hybrid Benefit for Windows Server.

- The Microsoft Product Terms for your program take precedence over the information that's presented in this article. For more information, see Microsoft Azure Product Terms and select your program to show the terms.

Classic VMs

For classic VMs, the only supported option is deploying a new VM from an on-premises custom image. To take advantage of the Azure Hybrid Benefit for Windows Server capabilities that this article describes, you must first migrate classic VMs to Azure Resource Manager model VMs.

> **Important**
>
> VMs created through the classic deployment model will be retired on September 1, 2023.
>
> If you use IaaS resources from Azure Service Management, please complete your migration by September 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.
>
> For more information, see Migrate your IaaS resources to Azure Resource Manager by September 1, 2023.

How to use Azure Hybrid Benefit for Windows Server

You have several options to use Windows virtual machines with Azure Hybrid Benefit for Windows Server. You can:

- Deploy VMs from one of the provided Windows Server images on Azure Marketplace.
- Upload a custom VM and deploy by using an Azure Resource Manager template or Azure PowerShell.
- Toggle and convert an existing VM between from running with Azure Hybrid Benefit or the pay-on-demand cost for Windows Server.

- Apply Azure Hybrid Benefit for Windows Server on a virtual machine scale set.

Create a VM that uses Azure Hybrid Benefit for Windows Server

All Windows Server OS-based images are supported for Azure Hybrid Benefit for Windows Server. You can use Azure platform-supported images or upload your own custom Windows Server image.

Azure portal

To create a VM that uses Azure Hybrid Benefit for Windows Server, when you create your VM, on the **Basics** tab under **Licensing**, select the checkbox to use an existing Windows Server license.

Azure PowerShell

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName "myResourceGroup" `
    -Name "myVM" `
    -Location "East US" `
    -ImageName "Win2016Datacenter" `
    -LicenseType "Windows_Server"
```

Azure CLI

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --location eastus \
    --license-type Windows_Server
```

Resource Manager template

In your Resource Manager template, set the `licenseType` parameter. For more information, see Authoring Azure Resource Manager templates.

JSON

```
"properties": {
    "licenseType": "Windows_Server",
    "hardwareProfile": {
        "vmSize": "[variables('vmSize')]"
    }
}
```

Convert an existing VM to use Azure Hybrid Benefit for Windows Server

To convert an existing VM to use Azure Hybrid Benefit for Windows Server, update your VM's license type.

> ⓘ **Note**
>
> Changing the license type on the VM doesn't cause the system to restart, and service is not interrupted. The process changes a metadata licensing flag only.

Azure portal

On the VM service menu, select **Configuration**, and then set **Azure Hybrid Benefit** to **Enable**.

Azure PowerShell

- To convert an existing Windows Server VM to Azure Hybrid Benefit for Windows Server:

  Azure PowerShell

  ```
  $vm = Get-AzVM -ResourceGroup "rg-name" -Name "vm-name"
  $vm.LicenseType = "Windows_Server"
  Update-AzVM -ResourceGroupName rg-name -VM $vm
  ```

- To convert a Windows Server VM that uses Azure Hybrid Benefit for Windows Server back to pay-as-you-go:

  Azure PowerShell

```
$vm = Get-AzVM -ResourceGroup "rg-name" -Name "vm-name"
$vm.LicenseType = "None"
Update-AzVM -ResourceGroupName rg-name -VM $vm
```

Azure CLI

- To convert an existing Windows Server VM to use Azure Hybrid Benefit for Windows Server:

Azure CLI

```
az vm update --resource-group myResourceGroup --name myVM --set
licenseType=Windows_Server
```

Verify that your VM uses the licensing benefit

After you deploy your VM by using either Azure PowerShell, a Resource Manager template, or the Azure portal, you can verify the setting by using one of the following methods.

Azure portal

On the VM service menu, select **Operating system**, and then view the Azure Hybrid Benefit for Windows Server setting.

Azure PowerShell

The following example shows the license type for a single VM:

Azure PowerShell

```
Get-AzVM -ResourceGroup "myResourceGroup" -Name "myVM"
```

Output:

Azure PowerShell

```
Type                    : Microsoft.Compute/virtualMachines
Location                : westus
LicenseType             : Windows_Server
```

The output contrasts with the following VM that's deployed *without* Azure Hybrid Benefit for Windows Server licensing:

Azure PowerShell

```
Type                    : Microsoft.Compute/virtualMachines
Location                : westus
LicenseType             :
```

Azure CLI

Azure CLI

```
az vm get-instance-view -g MyResourceGroup -n MyVM --query "[?
licenseType=='Windows_Server']" -o table
```

> **Note**
>
> Changing the license type on the VM doesn't cause the system to restart, and service is not interrupted. The process changes a metadata licensing flag only.

List all resources that use Azure Hybrid Benefit for Windows Server

To view and get a count of all your VMs and virtual machine scale sets that have Azure Hybrid Benefit for Windows Server enabled, you can use the following options for your subscription.

Azure portal

On the VM or virtual machine scale sets overview pane, get a list of all your VMs and licensing types by setting the table columns to include **OS licensing benefit**. The VM might have the state **Azure Hybrid Benefit for Windows**, **Not enabled**, or **Windows client with multi-tenant hosting**.

Azure PowerShell

For VMs:

Azure PowerShell

```
Get-AzVM | ?{$_.LicenseType -like "Windows_Server"} | select
ResourceGroupName, Name, LicenseType
```

For virtual machine scale sets:

Azure PowerShell

```
Get-AzVmss | Select * -ExpandProperty VirtualMachineProfile | ? LicenseType
-eq 'Windows_Server' | select ResourceGroupName, Name, LicenseType
```

Azure CLI

For VMs:

Azure CLI

```
az vm list --query "[?licenseType=='Windows_Server']" -o table
```

For virtual machine scale sets:

Azure CLI

```
az vmss list --query "[?
virtualMachineProfile.licenseType=='Windows_Server']" -o table
```

Deploy a virtual machine scale set to use Azure Hybrid Benefit for Windows Server

Within your virtual machine scale set Resource Manager templates, the `licenseType` parameter must be set in your `VirtualMachineProfile` property. You can set this parameter when you create or update for your virtual machine scale set by using a Resource Manager template, Azure PowerShell, the Azure CLI, or REST API.

The following example uses a Resource Manager template with a Windows Server 2016 Datacenter image:

JSON

```
"virtualMachineProfile": {
    "storageProfile": {
        "osDisk": {
            "createOption": "FromImage"
```

```
            },
            "imageReference": {
                "publisher": "MicrosoftWindowsServer",
                "offer": "WindowsServer",

What are Azure Reservations?

Azure Reservations help you save money by committing to one-year or three-year plans for multiple products. Committing allows you to get a discount on the resources you use. Reservations can significantly reduce your resource costs by up to 72% from pay-as-you-go prices. Reservations provide a billing discount and don't affect the runtime state of your resources. After you purchase a reservation, the discount automatically applies to matching resources.

You can pay for a reservation up front or monthly. The total cost of up-front and monthly reservations is the same and you don't pay any extra fees when you choose to pay monthly. Monthly payments are for complete month and not prorated based on calendar month. As an example, if you purchased a reservation on January 15, the next charge will be around February 15.

You can buy a reservation in the Azure portal.

Why buy a reservation?

If you have consistent resource usage that supports reservations, buying a reservation gives you the option to reduce your costs. For example, when you continuously run instances of a service without a reservation, you're charged at pay-as-you-go rates. Once a reservation purchase is complete, you get the reservation discount. The resources are no longer charged at the pay-as-you-go rates.

How reservation discount is applied

After purchase, the reservation discount automatically applies to the resource usage that matches the attributes you select when you buy the reservation. Attributes include the SKU, regions (where applicable), and scope. Reservation scope selects where the reservation savings apply.

For more information about how discount is applied, see Reserved instance discount application.

For more information about how reservation scope works, see Scope reservations.

Determine what to purchase

All reservations, except Azure Databricks, are applied on an hourly basis. Consider reservation purchases based on your consistent base usage. You can determine which reservation to

purchase by analyzing your usage data or by using reservation recommendations. Recommendations are available in:

- Azure Advisor (VMs only)
- Reservation purchase experience in the Azure portal
- Cost Management Power BI app
- APIs

For more information, see Determine what reservation to purchase

Buying a reservation

You can purchase reservations from the Azure portal, APIs, PowerShell, and CLI.

Go to the Azure portal to make a purchase.

For more information, see Buy a reservation.

How is a reservation billed?

The reservation is charged to the payment method tied to the subscription. The reservation cost is deducted from your Azure Prepayment (previously called monetary commitment) balance, if available. When your Azure Prepayment balance doesn't cover the cost of the reservation, you're billed the overage. If you have a subscription from an individual plan with pay-as-you-go rates, the credit card you have on your account is billed immediately for up-front purchases. Monthly payments appear on your invoice and your credit card is charged monthly. When you're billed by invoice, you see the charges on your next invoice.

Who can manage a reservation by default

By default, the following users can view and manage reservations:

- The person who buys a reservation and the account administrator of the billing subscription used to buy the reservation are added to the reservation order.
- Enterprise Agreement and Microsoft Customer Agreement billing administrators.

To allow other people to manage reservations, see Manage Reservations for Azure resources.

Get reservation details and utilization after purchase

If you have permission to view to the reservation, you can see it and its use in the Azure portal. You can get the data using APIs, as well.

For more information on how to see reservations in Azure portal, see View reservations in the Azure portal

Manage reservations after purchase

After you buy an Azure reservation, you can update the scope to apply reservation to a different subscription, change who can manage the reservation, split a reservation into smaller parts, or change instance size flexibility.

For more information, see Manage Reservations for Azure resources

Flexibility with Azure reservations

Azure Reservations provide flexibility to help meet your evolving needs. You can exchange a reservation for another reservation of the same type. You can also refund a reservation, up to $50,000 USD in a 12 month rolling window, if you no longer need it. The maximum limit of the refund applies to all reservations in the scope of your agreement with Microsoft.

For more information, see Self-service exchanges and refunds for Azure Reservations

Charges covered by reservation

- **Reserved Virtual Machine Instance** - A reservation only covers the virtual machine and cloud services compute costs. It doesn't cover additional software, Windows, networking, or storage charges.
- **Azure Blob storage reserved capacity** - A reservation covers storage capacity for Blob storage and Azure Data Lake Gen2 storage. The reservation doesn't cover bandwidth or transaction rates.
- **Azure Files reserved capacity** - A reservation covers storage capacity for Azure Files. Reservations for hot and cool tiers don't cover bandwidth or transaction rates.
- **Azure Cosmos DB reserved capacity** - A reservation covers throughput provisioned for your resources. It doesn't cover the storage and networking charges.
- **Azure Data Factory data flows** - A reservation covers integration runtime cost for the compute type and number of cores that you buy.
- **Azure SQL Database** - A reservation only covers the compute costs. It doesn't cover software license, networking, or storage charges. For the General Purpose service tier, reservations are also available to cover compute costs associated with the zone-redundancy add-on.

- **Azure SQL Managed Instance** - A reservation only covers the compute costs. It doesn't cover software license, networking, or storage charges. Reservations are also available to cover compute costs associated with the zone-redundancy add-on.
- **Azure Synapse Analytics** - A reservation covers cDWU usage. It doesn't cover storage or networking charges associated with the Azure Synapse Analytics usage.
- **Azure Databricks** - A reservation covers only the DBU usage. Other charges, such as compute, storage, and networking, are applied separately.
- **App Service stamp fee** - A reservation covers stamp usage. It doesn't apply to workers, so any other resources associated with the stamp are charged separately.
- **Azure Database for MySQL** - Only the compute costs are included with a reservation. A reservation doesn't cover software, networking, or storage charges associated with the MySQL Database server.
- **Azure Database for PostgreSQL** - Only the compute costs are included with a reservation. A reservation doesn't cover software, networking, or storage charges associated with the PostgreSQL Database servers.
- **Azure Data Explorer** - A reservation covers the markup charges. A reservation doesn't apply to compute, networking, or storage charges associated with the clusters.
- **Azure Cache for Redis and Managed Redis** - Only the compute costs are included with a reservation. A reservation doesn't cover networking or storage charges associated with the Redis cache instances.
- **Azure Dedicated Host** - Only the compute costs are included with the Dedicated host.
- **Azure Disk Storage reservations** - A reservation only covers Premium SSDs of P30 size or greater. It doesn't cover any other disk types or sizes smaller than P30.
- **Azure Backup Storage reserved capacity** - A capacity reservation lowers storage costs of backup data in a Recovery Services Vault.
- **Azure NetApp Files** - A capacity reservation covers matching capacity pools in the selected service level and region. When using capacity pools configured with cool access, only "hot" tier consumption is covered by the reservation benefit.

Software plans:

- **SUSE Linux** - A reservation covers the software plan costs. The discounts apply only to SUSE meters and not to the virtual machine usage.
- **Red Hat Plans** (***plans and renewal are temporarily unavailable***) - A reservation covers the software plan costs. The discounts apply only to RedHat meters and not to the virtual machine usage.
- **Azure Red Hat OpenShift** - A reservation applies to the OpenShift costs, not to Azure infrastructure costs.

For Windows virtual machines and SQL Database, the reservation discount doesn't apply to the software costs. You can cover the licensing costs with Azure Hybrid Benefit.

Save costs with Azure Reserved VM Instances

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

When you commit to an Azure reserved VM instance you can save money. The reservation discount is applied automatically to the number of running virtual machines that match the reservation scope and attributes. You don't need to assign a reservation to a virtual machine to get the discounts. A reserved instance purchase covers only the compute part of your VM usage. For Windows VMs, the usage meter is split into two separate meters. There's a compute meter, which is same as the Linux meter, and a Windows server license. The charges that you see when you make the purchase are only for the compute costs. Charges don't include Windows software costs. For more information about software costs, see Software costs not included with Azure Reserved VM Instances.

Reserved VM Instances provide a billing discount only and do not reserve or guarantee compute capacity. Azure still needs available capacity in the target region or availability zone when you deploy a VM. A deployment can fail because of capacity constraints even when quota is approved and you already purchased a Reserved VM Instance. To guarantee capacity for your workloads, use On-demand capacity reservation. You can combine Reserved VM Instances with capacity reservations for both cost savings and capacity assurance.

Determine the right VM size before you buy

Before you buy a reservation, you should determine the size of the VM that you need. The following sections will help you determine the right VM size.

Use reservation recommendations

You can use reservation recommendations to help determine the reservations you should purchase.

- Purchase recommendations and recommended quantities are shown when you purchase a VM reserved instance in the Azure portal.
- Azure Advisor provides purchase recommendations for individual subscriptions.
- You can use the APIs to get purchase recommendations for both shared scope and single subscription scope. For more information, see Reserved instance purchase

recommendation APIs for enterprise customers.

- For Enterprise Agreement (EA) and Microsoft Customer Agreement (MCA) customers, purchase recommendations for shared and single subscription scopes are available with the Azure Consumption Insights Power BI content pack.

Services that get VM reservation discounts

Your VM reservations can apply to VM usage emitted from multiple services - not just for your VM deployments. Resources that get reservation discounts change depending on the instance size flexibility setting.

Instance size flexibility setting

The instance size flexibility setting determines which services get the reserved instance discounts.

Whether the setting is on or off, reservation discounts automatically apply to any matching VM usage when the *ConsumedService* is `Microsoft.Compute`. So, check your usage data for the *ConsumedService* value. Some examples include:

- Virtual machines
- Virtual machine scale sets
- Container service
- Azure Batch deployments (in user subscriptions mode)
- Azure Kubernetes Service (AKS)
- Service Fabric

When the setting is on, reservation discounts automatically apply to matching VM usage when the *ConsumedService* is any of the following items:

- Microsoft.Compute
- Microsoft.ClassicCompute
- Microsoft.Batch
- Microsoft.MachineLearningServices
- Microsoft.Kusto

Check the *ConsumedService* value in your usage data to determine if the usage is eligible for reservation discounts.

For more information about instance size flexibility, see Virtual machine size flexibility with Reserved VM Instances.

Analyze your usage information

Analyze your usage information to help determine which reservations you should purchase. Usage data is available in the usage file and APIs. Use them together to determine which reservation to purchase. Check for VM instances that have high usage on daily basis to determine the quantity of reservations to purchase. Avoid the `Meter` subcategory and `Product` fields in usage data. They don't distinguish between VM sizes that use premium storage. If you use these fields to determine the VM size for reservation purchase, you may buy the wrong size. Then you won't get the reservation discount you expect. Instead, refer to the `AdditionalInfo` field in your usage file or usage API to determine the correct VM size.

Your usage file shows your charges by billing period and daily usage. For information about downloading your usage file, see View and download your Azure usage and charges. Then, by using the usage file information, you can determine what reservation to purchase.

Purchase restriction considerations

Reserved VM Instances are available for most VM sizes with some exceptions. Reservation discounts don't apply for the following VMs:

- **VM series** - A-series, or G-series.

  > ⓘ Note
  >
  > A-series VMs differ from Av2 series VMs. Av2 series VMs are available for reservation purchase.

- **Preview or Promo VMs** - Any VM-series or size that is in preview or uses promotional meter.

- **Insufficient quota** - A reservation that is scoped to a single subscription must have vCPU quota available in the subscription for the new RI. For example, if the target subscription has a quota limit of 10 vCPUs for D-Series, then you can't buy a reservation for 11 Standard_D1 instances. The quota check for reservations includes the VMs already deployed in the subscription. For example, if the subscription has a quota of 10 vCPUs for D-Series and has two standard_D1 instances deployed, then you can buy a reservation for 10 standard_D1 instances in this subscription. You can create quote increase request to resolve this issue.

- **Capacity restrictions** - In rare circumstances, Azure limits the purchase of new reservations for subset of VM sizes, because of low capacity in a region.

Buy a Reserved VM Instance

You can buy a reserved VM instance in the Azure portal. Pay for the reservation up front or with monthly payments. These requirements apply to buying a reserved VM instance:

- To buy a reservation, you must have owner role or reservation purchaser role on an Azure subscription.
- For EA subscriptions, the **Add Reserved Instances** option must be enabled in the EA portal. Or, if that setting is disabled, you must be an EA Admin for the subscription.
- For the Cloud Solution Provider (CSP) program, only the admin agents or sales agents can buy reservations.

To buy an instance:

1. Sign in to the Azure portal.
2. Select **All services** > **Reservations**.
3. Select **Add** to purchase a new reservation and then click **Virtual machine**.
4. Enter required fields. Running VM instances that match the attributes you select qualify to get the reservation discount. The actual number of your VM instances that get the discount depend on the scope and quantity selected.

If you have an EA agreement, you can use the **Add more option** to quickly add additional instances. The option isn't available for other subscription types.

Expand table

Field	Description
Subscription	The subscription used to pay for the reservation. The payment method on the subscription is charged the costs for the reservation. The subscription type must be an enterprise agreement (offer numbers: MS-AZR-0017P or MS-AZR-0148P) or Microsoft Customer Agreement or an individual subscription with pay-as-you-go rates (offer numbers: MS-AZR-0003P or MS-AZR-0023P). The charges are deducted from the Azure Prepayment (previously called monetary commitment) balance, if available, or charged as overage. For a subscription with pay-as-you-go rates, the charges are billed to the credit card or invoice payment method on the subscription.
Scope	The reservation's scope can cover one subscription or multiple subscriptions (shared scope). If you select:

Field	Description
	• **Single resource group scope** — Applies the reservation discount to the matching resources in the selected resource group only. • **Single subscription scope** — Applies the reservation discount to the matching resources in the selected subscription. • **Shared scope** — Applies the reservation discount to matching resources in eligible subscriptions that are in the billing context. For EA customers, the billing context is the enrollment. For individual subscriptions with pay-as-you-go rates, the billing scope is all eligible subscriptions created by the account administrator. • **Management group** - Applies the reservation discount to the matching resource in the list of subscriptions that are a part of both the management group and billing scope.
Region	The Azure region that's covered by the reservation.
VM Size	The size of the VM instances.
Optimize for	VM instance size flexibility is selected by default. Click **Advanced settings** to change the instance size flexibility value to apply the reservation discount to other VMs in the same VM size group. Capacity priority prioritizes data center capacity for your deployments. It offers additional confidence in your ability to launch the VM instances when you need them. Capacity priority is only available when the reservation scope is single subscription.
Term	One year or three years. There's also a 5-year term available only for HBv2 VMs.
Quantity	The number of instances being purchased within the reservation. The quantity is the number of running VM instances that can get the billing discount. For example, if you are running 10 Standard_D2 VMs in the East US, then you would specify quantity as 10 to maximize the benefit for all running VMs.

https://learn-video.azurefd.net/vod/player?id=4e688b15-2bc8-47b5-b67e-16ea39397709&locale=en-us&embedUrl=%2Fazure%2Fvirtual-machines%2Fprepay-reserved-vm-instances

Usage data and reservation utilization

Your usage data has an effective price of zero for the usage that gets a reservation discount. You can see which VM instance received the reservation discount for each reservation.

For more information about how reservation discounts appear in usage data, see Understand Azure reservation usage for your Enterprise enrollment if you are an EA customer. If you have an individual subscription, see Understand Azure reservation usage for your Pay-As-You-Go subscription.

Change a reservation after purchase

You can make the following types of changes to a reservation after purchase:

- Update reservation scope
- Instance size flexibility (if applicable)
- Ownership

You can also split a reservation into smaller chunks and merge already split reservations. None of the changes cause a new commercial transaction or change the end date of the reservation.

You can't make the following types of changes after purchase, directly:

- An existing reservation's region
- SKU
- Quantity
- Duration

However, you can *exchange* a reservation if you want to make changes.

Cancel, exchange, or refund reservations

You can cancel, exchange, or refund reservations with certain limitations. For more information, see Self-service exchanges and refunds for Azure Reservations.

Need help? Contact us.

If you have questions or need help, create a support request.

Save costs with Azure Dedicated Host reservations

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

When you commit to a reserved instance of Azure Dedicated Hosts, you can save money. The reservation discount is applied automatically to the number of running dedicated hosts that match the reservation scope and attributes. You don't need to assign a reservation to a dedicated host to get the discounts. A reserved instance purchase covers only the compute part of your usage and does include software licensing costs. See the Overview of Azure Dedicated Hosts for virtual machines.

Determine the right dedicated host SKU before you buy

Before you buy a reservation, you should determine which dedicated host you need. A SKU is defined for a dedicated host representing the VM series and type.

Start by going over the supported sizes for Windows virtual machine or Linux to identify the VM series.

Next, check whether it is supported on Azure Dedicated Hosts. Azure Dedicated Hosts pricing page has the complete list of dedicated hosts SKUs, their CPU information, and various pricing options (including reserved instances).

You may find several SKUs supporting your selected VM series (with different Types). Identify the best SKU by comparing the capacity of the host (number of vCPUs). Note that you will be able to apply your reservation to multiple dedicated hosts SKUs supporting the same VM series (for example DSv3_Type1 and DSv3_Type2) but not across different VM series (like DSv3 and ESv3). Over the lifetime of the reservation, you may need to switch between different dedicated host SKUs that support the same VM size, depending on the hardware usage fluctuations and lifecycle.

Purchase restriction considerations

Reserved instances are available for most dedicated host sizes, with some exceptions.

Reservation discounts don't apply for the following:

- **Clouds** - Reservations aren't available for purchase in Germany or China regions.
- **Insufficient quota** - A reservation that is scoped to a single subscription must have vCPU quota available in the subscription for the new reserved instance. For example, if the target subscription has a quota limit of 10 vCPUs for DSv3-Series, then you can't buy a reservation dedicated hosts supporting this series. The quota check for reservations includes the VMs and dedicated hosts already deployed in the subscription. You can create quota increase request to resolve this issue.
- **Capacity restrictions** - In rare circumstances, Azure limits the purchase of new reservations for subset of dedicated host SKUs, because of low capacity in a region.

Buy a reservation

You can buy a reserved instance of an Azure Dedicated Host instance in the Azure portal.

Pay for the reservation up front or with monthly payments. These requirements apply to buying a reserved Dedicated Host instance:

- To buy a reservation, you must have owner role or reservation purchaser role on an Azure subscription.
- For EA subscriptions, the **Add Reserved Instances** option must be enabled in the EA portal. Or, if that setting is disabled, you must be an EA Admin for the subscription.
- For the Cloud Solution Provider (CSP) program, only the admin agents or sales agents can buy reservations.

To buy an instance:

1. Sign in to the Azure portal.
2. Select **All services** > **Reservations**.
3. Select **Add** to purchase a new reservation and then click **Dedicated Hosts**.
4. Enter required fields. Running Dedicated Hosts instances that match the attributes you select qualify to get the reservation discount. The actual number of your Dedicated Host instances that get the discount depend on the scope and quantity selected.

If you have an EA agreement, you can use the **Add more option** to quickly add additional instances. The option isn't available for other subscription types.

Expand table

Field	Description
Subscription	The subscription used to pay for the reservation. The payment method on the subscription is charged the costs for the reservation. The subscription type must be an enterprise agreement (offer numbers: MS-AZR-0017P or MS-AZR-0148P) or Microsoft Customer Agreement or an individual subscription with pay-as-you-go rates (offer numbers: MS-AZR-0003P or MS-AZR-0023P). The charges are deducted from the Azure Prepayment (previously called monetary commitment) balance, if available, or charged as overage. For a subscription with pay-as-you-go rates, the charges are billed to the credit card or invoice payment method on the subscription.
Scope	The reservation's scope can cover one subscription or multiple subscriptions (shared scope). If you select:
Region	The Azure region that's covered by the reservation.
Dedicated Host Size	The size of the Dedicated Host instances.
Term	One year or three years.
Quantity	The number of instances being purchased within the reservation. The quantity is the number of running Dedicated Host instances that can get the billing discount.

- **Single resource group scope** — Applies the reservation discount to the matching resources in the selected resource group only.
- **Single subscription scope** — Applies the reservation discount to the matching resources in the selected subscription.
- **Shared scope** — Applies the reservation discount to matching resources in eligible subscriptions that are in the billing context. For EA customers, the billing context is the enrollment. For individual subscriptions with pay-as-you-go rates, the billing scope is all eligible subscriptions created by the account administrator.
- **Management group** — Applies the reservation discount to the matching resource in the list of subscriptions that are a part of both the management group and billing scope.

Usage data and reservation utilization

Your usage data has an effective price of zero for the usage that gets a reservation discount. You can see which VM instance received the reservation discount for each reservation.

For more information about how reservation discounts appear in usage data, see Understand Azure reservation usage for your Enterprise enrollment if you are an EA customer. If you have an individual subscription, see Understand Azure reservation usage for your Pay-As-You-Go subscription.

Change a reservation after purchase

You can make the following types of changes to a reservation after purchase:

- Update reservation scope
- Ownership

You can also split a reservation into smaller chunks and merge already split reservations. None of the changes cause a new commercial transaction or change the end date of the reservation.

You can't make the following types of changes after purchase, directly:

- An existing reservation's region
- SKU
- Quantity
- Duration

However, you can *exchange* a reservation if you want to make changes.

Cancel, exchange, or refund reservations

You can cancel, exchange, or refund reservations with certain limitations. For more information, see Self-service exchanges and refunds for Azure Reservations.

Virtual machine size flexibility with Reserved VM Instances

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

When you buy a Reserved VM Instance, you can choose to optimize for instance size flexibility or capacity priority. For more information about setting or changing the optimize setting for reserved VM instances, see Change the optimize setting for reserved VM instances.

With a reserved virtual machine instance that's optimized for instance size flexibility, the reservation you buy can apply to the virtual machines (VMs) sizes in the same instance size flexibility group. In other words, when you buy a reserved VM instance of any size within an instance flexibility group, the instance applies to all sizes within the group. For example, if you buy a reservation for a VM size that's listed in the DSv2 Series, like Standard_DS3_v2, the reservation discount can apply to the other sizes that are listed in that same instance size flexibility group:

- Standard_DS1_v2
- Standard_DS2_v2
- Standard_DS3_v2
- Standard_DS4_v2

But that reservation discount doesn't apply to VMs sizes that are listed in different instance size flexibility groups, like SKUs in DSv2 Series High Memory: Standard_DS11_v2, Standard_DS12_v2, and so on.

Within the instance size flexibility group, the number of VMs the reservation discount applies to depends on the VM size you pick when you buy a reservation. It also depends on the sizes of the VMs that you have running. The ratio column compares the relative footprint for each VM size in that instance size flexibility group. Use the ratio value to calculate how the reservation discount applies to the VMs you have running.

Examples

The following examples use the sizes and ratios in the DSv2-series table.

You buy a reserved VM instance with the size Standard_DS4_v2 where the ratio or relative footprint compared to the other sizes in that series is 8.

- Scenario 1: Run eight Standard_DS1_v2 sized VMs with a ratio of 1. Your reservation discount applies to all eight of those VMs.
- Scenario 2: Run two Standard_DS2_v2 sized VMs with a ratio of 2 each. Also run a Standard_DS3_v2 sized VM with a ratio of 4. The total footprint is 2+2+4=8. So your reservation discount applies to all three of those VMs.
- Scenario 3: Run one Standard_DS5_v2 with a ratio of 16. Your reservation discount applies to half that VM's compute cost.
- Scenario 4: Run one Standard_DS5_v2 with a ratio of 16 and purchase an additional Standard_DS4_v2 reservation with a ratio of 8. Both reservations combine and apply the discount to entire VM.

The following sections show what sizes are in the same size series group when you buy a reserved VM instance optimized for instance size flexibility. SKUs that have same ratio and are in same size series group, would have no additional cost if you purchase reservation for any of those SKUs for same number of VMs running.

Instance size flexibility ratio

CSV below has the instance size flexibility groups, ArmSkuName and the ratios.

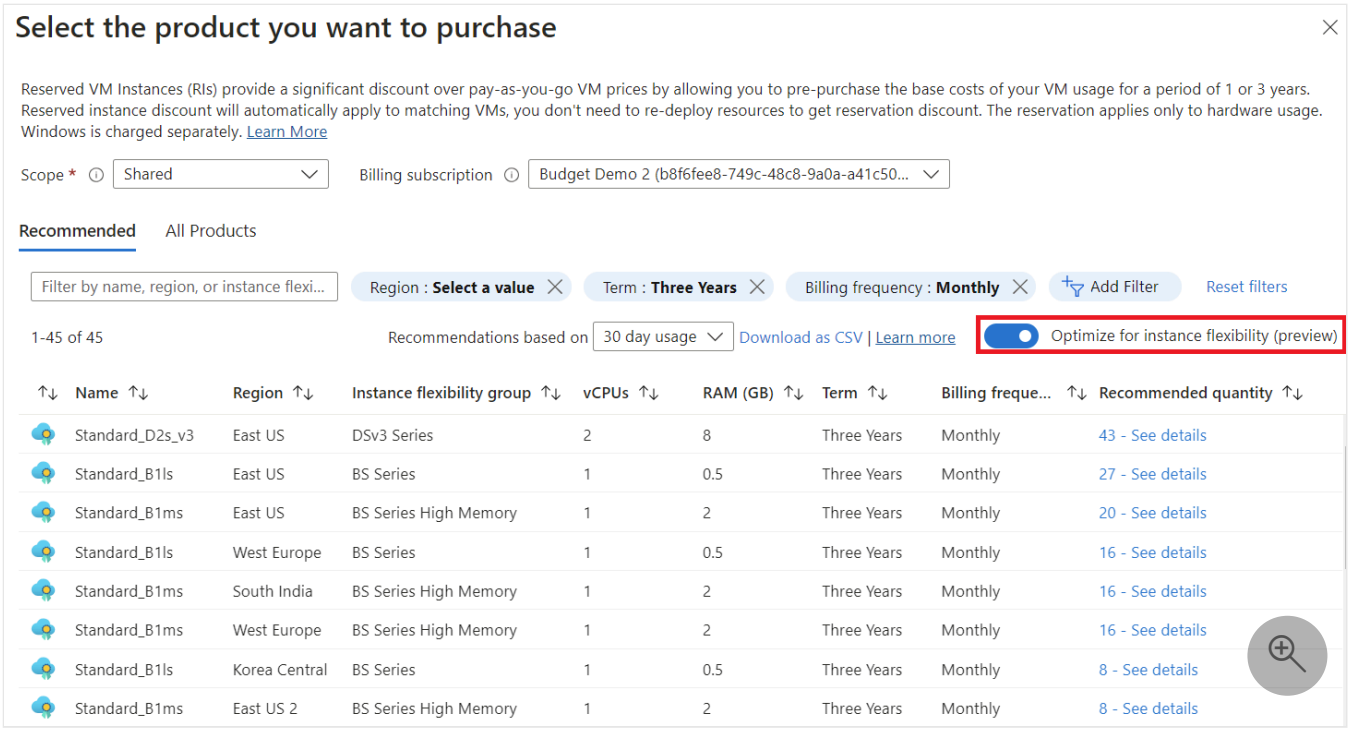
Instance size flexibility ratios

You can also use API or PowerShell to fetch the ratios. The CSV link and schema are kept up to date so you can use them programmatically. Read more here.

> **⊗ Caution**
>
> Beginning May 9, 2026, the CSV file will no longer receive updates and will be removed on August 30, 2026, in favor of accessing data through the API or PowerShell. Read more here.

View VM size recommendations

Azure shows VM size recommendations in the purchase experience. When enabled, the **Optimize for instance size flexibility (preview)** option groups and sorts recommendations by instance size flexibility.



Next steps

For more information, see What are Azure Reservations.

Last updated on 04/13/2026

On-demand capacity reservation

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale set ✔ Flexible scale sets

On-demand capacity reservation enables you to reserve compute capacity in an Azure region or an availability zone for any duration of time. Unlike reserved instances, you don't have to sign up for a one-year or three-year term commitment. You can create and delete reservations at any time and have full control over how you want to manage your reservations.

After you create the capacity reservation, you can use the resources immediately. Capacity is reserved for you until you delete the reservation.

Capacity reservation has some basic properties that are always defined at the time of creation:

- **VM size**: Each reservation is for one virtual machine (VM) size. An example is `Standard_D2s_v3`.
- **Location**: Each reservation is for one location (region). If that location has availability zones, the reservation can also specify one of the zones.
- **Quantity**: Each reservation has a quantity of instances to be reserved.

To create a capacity reservation, the parameters are passed to Azure as a capacity request. If Azure doesn't have capacity available that meets the request, the reservation deployment fails. Your deployment fails if you don't have an adequate subscription quota. Request a higher quota or try a different VM size, location, or zone combination.

Quota and capacity are separate checks. Quota is your subscription's permission to deploy resources, while capacity is the underlying infrastructure available in a specific region or zone.

Capacity reservations and Reserved Instances are also different. Capacity reservation secures capacity availability for deployment. Reserved Instances provide a billing discount only and don't guarantee capacity.

After Azure accepts your reservation request, it's available for VMs with matching configurations. To consume capacity reservation, the VM has to specify the reservation in its properties. Otherwise, the capacity reservation isn't used. One benefit of this design is that you can target only critical workloads to reservations and other noncritical workloads can run without reserved capacity.

Benefits of capacity reservation

- After deployment, capacity is reserved for your use and is always available within the scope of applicable service-level agreements (SLAs).
- Capacity can be deployed and deleted at any time with no term commitment.
- Capacity can be combined automatically with reserved instances to use term-commitment discounts.

SLA for capacity reservation

Read the SLA details in the SLA for capacity reservation .

Any claim against the SLA requires that you calculate the Minutes Not Available for the reserved capacity. Here's an example of how to calculate Minutes Not Available:

- An on-demand capacity reservation has a total capacity of five reserved units. The on-demand capacity reservation starts in the Unused Capacity state with zero VMs allocated.
- A supported deployment with a quantity of 5 is allocated to the on-demand capacity reservation. Three VMs succeed and two fail with a VM capacity error. The result is that two reserved units begin to accumulate Minutes Not Available.
- No action is taken for 20 minutes. The result is that two reserved units each accumulate 15 Minutes Not Available.
- At 20 minutes, a supported deployment with a quantity of 2 is attempted. One VM succeeds and the other VM fails with a VM capacity error. The result is one reserved unit stays at 15 accumulated Minutes Not Available. Another reserved unit resumes accumulating Minutes Not Available.
- Four more supported deployments with a quantity of 1 are made at 10-minute intervals. On the fourth attempt (60 minutes after the first capacity error), the VM is deployed. The result is that the last reserved unit adds 40 minutes of Minutes Not Available (four attempts x 10 minutes between attempts) for a total of 55 Minutes Not Available.

From this example accumulation of Minutes Not Available, here's the calculation of service credit:

- One reserved unit accumulated 15 minutes of downtime. The percentage uptime is 99.97%. This reserved unit doesn't qualify for a service credit.
- Another reserved unit accumulated 55 minutes of downtime. The percentage uptime is 99.87. This reserved unit qualifies for a service credit of 10%.

Limitations and restrictions

- Creating capacity reservations requires a quota in the same manner as when you create VMs.
- Creating capacity reservations is currently limited to certain VM series and sizes. The compute Resource SKUs list advertises the set of supported VM sizes.
- Reserved capacity for these VM series supports high availability using multi-zone or fault domains. The fault domain count for a Virtual Machine Scale Set is limited to 3, enforced at deployment.

  The following VM series support the creation of capacity reservations:

Expand table

Type	VM Series
General Purpose (Burstable)	B (Intel) Bsv2 (Intel), Basv2 (AMD), Bpsv2 (ARM)
General Purpose (General use A, D)	Av2 (Intel) D and Ds series, v2 and newer (Intel) Dd and Dds, v4 and newer (Intel, local disk) Dls and Dlds, v5 and newer (Intel, low memory) Da and Das, v4 series and newer (AMD) Dads, v5 and newer (AMD, local disk) Dals and Dalds, v6 and newer (AMD) Dps and Dpds series, v5 and newer (ARM) Dpls and Dplds series, v5 and newer (ARM, low memory)
General Purpose (General use, high memory, E)	E and Es, all versions (Intel) Ed and Eds series, v4 and newer (Intel, local disk) Ebdsv5 and Ebsv5 series (Intel, block storage) Ea and Eas, v4 and newer (AMD) Eads, v5 and newer series (AMD, local disk) Eps and Epds series, v5 and newer (ARM)
General Purpose (General use, compute optimized, F)	Fsv2 series (Intel) Fas and Fals, v6 and newer series (AMD) Famsv6 and newer (AMD) FX series (Intel) FXmsv2 (Intel) FXmdsv2 (Intel) Fadsv7 (AMD) Famdsv7 (AMD) Faldsv7 (AMD)

Type	VM Series
Storage optimized	Lsv3 (Intel) Lasv3 (AMD) Lasv4 (AMD) Laosv4 (AMD)
Confidential compute	DCsv2 series (Intel) DCasv5 and DCadsv5 series (AMD) DCesv5 and DCedsv5 series (Intel) ECasv5 and ECadsv5 series (AMD) ECesv5 and ECedsv5 series (Intel)

Reserved capacity for these VM series supports only multi-zone high availability. Virtual Machine Scale Sets with a fault domain availability construct is not supported.

- The following deployment types are supported:
  - Single VM
  - Virtual Machine Scale Sets with Uniform Orchestration
  - Virtual Machine Scale Sets with Flexible Orchestration
- The following deployment types aren't supported:
  - Spot VMs
  - Azure Dedicated Host nodes or VMs deployed to dedicated hosts
  - Availability sets
- Other deployment constraints aren't supported. For example:
  - Proximity placement group
  - Update domains
  - Virtual Machine Scale Sets with single placement group set to `true`
  - Azure Ultra Disk Storage (formerly UltraSSD)
  - VMs resuming from hibernation
- A pinned subscription can't use the feature.
- Deployments using On demand capacity reservations are compatible with vNet Encryption when deployed using a supported VM size. For more information on which VM sizes this feature supports, see Virtual Network Encryption.
- Reservations are only available to paid Azure customers. Sponsored accounts such as Free Trial and Azure for Students aren't eligible to use this feature.
- Clouds supported for capacity reservation:
  - Azure Cloud
  - Azure for Government
  - Azure in China

Pricing and billing

Capacity reservations are priced at the same rate as the underlying VM size. For example, if you create a reservation for 10 D2s_v3 VMs, you start getting billed for 10 D2s_v3 VMs, even if the

reservation isn't being used.

If you then deploy a D2s_v3 VM and specify the reservation property, the capacity reservation gets used. After the VM is in use, you pay for only the VM and not the capacity reservation. Let's say you deploy six D2s_v3 VMs against the previously mentioned capacity reservation. You see a bill for six D2s_v3 VMs and four unused capacity reservations, both charged at the same rate as a D2s_v3 VM.

Both used and unused capacity reservations are eligible for Savings Plan and Reserved Instances term commitment discounts. In the previous example, if you have reserved instances for two D2s_v3 VMs in the same Azure region, the billing for two resources (either VM or unused capacity reservation) is zeroed out. The remaining eight D2s_v3 are billed normally. The term commitment discounts could be applied on either the VM or the unused capacity reservation.

Differences between on-demand capacity reservations and reserved instances

Expand table

Differences	On-demand capacity reservation	Reserved instances
Term	No term commitment required. Can be created and deleted as per the customer requirement.	Fixed-term commitment of either one year or three years.
Billing discount	Charged at pay-as-you-go rates for the underlying VM size.*	Significant cost savings over pay-as-you-go rates.
Capacity SLA	Provides capacity guarantee in the specified location (region or availability zone).	Doesn't provide a capacity guarantee. Customers can choose **Capacity priority** to gain better access, but that option doesn't carry an SLA.
Region vs. availability zones	Can be deployed per region or per availability zone.	Only available at the regional level.

*Eligible for the reserved instances discount if purchased separately.

Work with capacity reservation

Capacity reservation is created for a specific VM size in an Azure region or an availability zone. All reservations are created and managed as part of a capacity reservation group.

The group specifies the Azure location:

- The group sets the region in which all reservations are created. Examples are East US, North Europe, or Southeast Asia.
- The group sets the eligible zones. Examples are AZ1, AZ2, and AZ3 in any combination.
- If no zones are specified, then Azure will select the best zone available upon initial capacity reservation creation. All VMs using the capacity reservation group must be deployed without specifying a zone; each associated VM will be deployed to the zone Azure selected for the group.

Each reservation in a group is for one VM size. If eligible zones were selected for the group, the reservation must be for one of the supported zones.

A group can have only one reservation per VM size per zone, or just one reservation per VM size if no zones are selected.

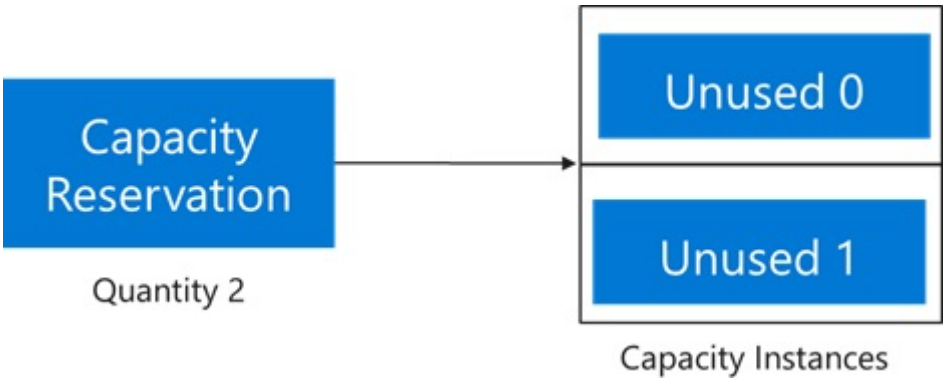
To consume capacity reservation, specify the capacity reservation group as one of the VM properties. If the group doesn't have a reservation matching the size and location, Azure returns an error message.

You can adjust the quantity reserved for reservation after initial deployment by changing the capacity property. Other changes to capacity reservation, such as VM size or location, aren't permitted. We recommend that you create a new reservation, migrate any existing VMs, and then delete the old reservation if it's no longer needed.

Capacity reservation doesn't create limits on the number of VM deployments. Azure supports allocating as many VMs as desired against the reservation. Because the reservation itself requires a quota, the quota checks are omitted for VM deployment up to the reserved quantity. Allocating VMs beyond the reserved quantity is called overallocating the reservation. Overallocating VMs isn't covered by the SLA, and the VMs are subject to quota checks and Azure fulfilling the extra capacity. After they're deployed, these extra VM instances can cause the quantity of VMs allocated against the reservation to exceed the reserved quantity. To learn more, see Overallocate capacity reservation.

Capacity reservation lifecycle

When a reservation is created, Azure sets aside the requested number of capacity instances in the specified location.

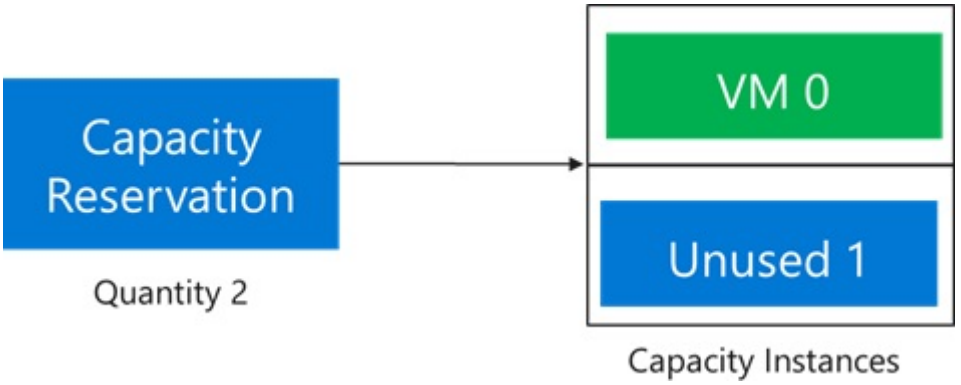


Track the state of the overall reservation through the following properties:

- `capacity`: Total quantity of instances reserved by the customer.
- `virtualMachinesAllocated`: List of VMs allocated against the capacity reservation and count toward consuming the capacity. These VMs are either **Running** or **Stopped** (**Allocated**), or they're in a transitional state such as **Starting** or **Stopping**. This list doesn't include the VMs that are in a deallocated state, which is referred to as **Stopped** (deallocated).
- `virtualMachinesAssociated`: List of VMs associated to the capacity reservation. This list has all the VMs that were configured to use the reservation, including the ones that are in a deallocated state.

The previous example starts with `capacity` as 2 and the length of `virtualMachinesAllocated` and `virtualMachinesAssociated` as 0.

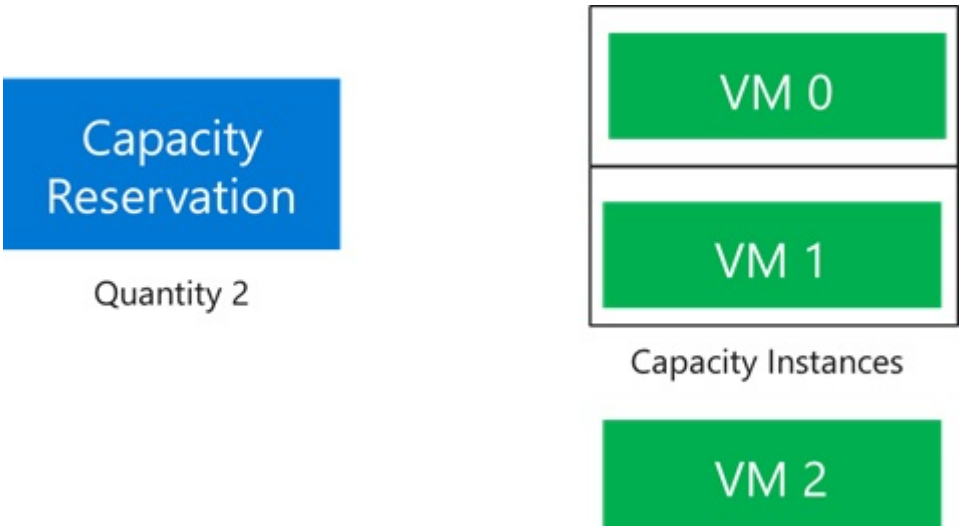
When a VM is then allocated against the capacity reservation, it consumes one of the reserved capacity instances.



The status of the capacity reservation shows `capacity` as 2 and the length of `virtualMachinesAllocated` and `virtualMachinesAssociated` as 1.

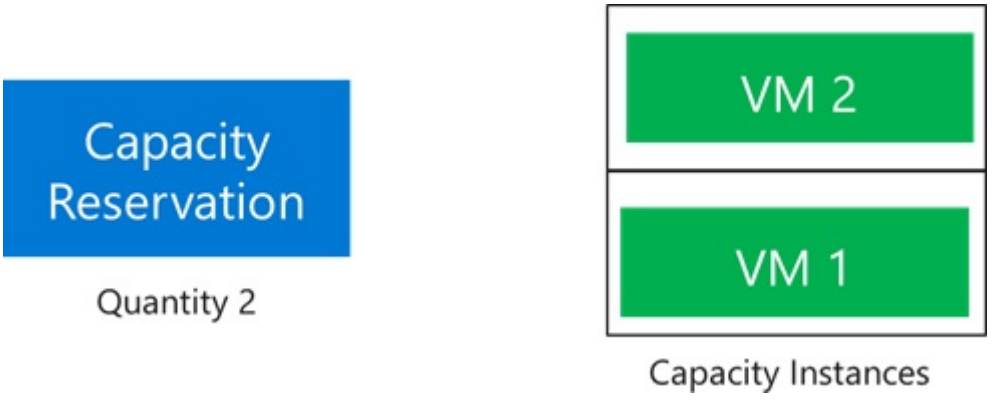
Allocations against the capacity reservation succeed if the VMs have matching properties and there's at least one empty capacity instance.

As shown in our example, when a third VM is allocated against the capacity reservation, the reservation enters the overallocated state. This third VM requires unused quota and extra capacity fulfillment from Azure. After the third VM is allocated, the capacity reservation now looks like this diagram:



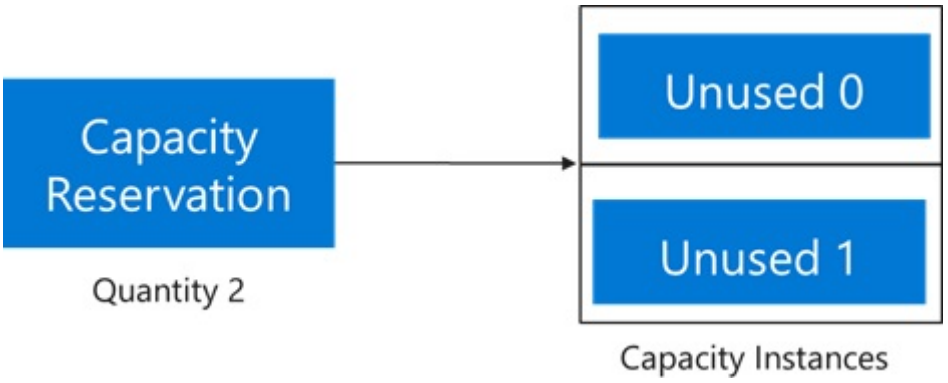
The `capacity` is 2 and the length of `virtualMachinesAllocated` and `virtualMachinesAssociated` is 3.

Now suppose the application scales down to the minimum of two VMs. Because the VM 0 needs an update, it's chosen for deallocation. The reservation automatically shifts to this state:

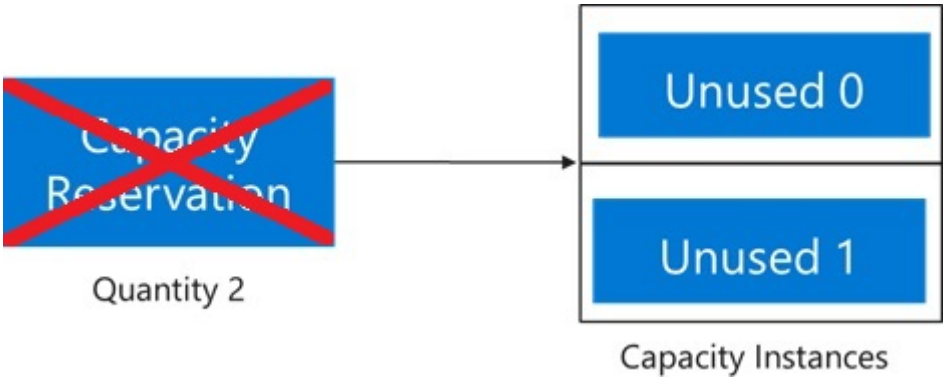


The `capacity` and the length of `virtualMachinesAllocated` are both 2. However, the length for `virtualMachinesAssociated` is still 3 because VM 0, although deallocated, is still associated to the capacity reservation. To prevent a quota overrun, the deallocated VM 0 still counts against the quota allocated to the reservation. If you have enough unused quota, you can deploy new VMs to the capacity reservation and receive the SLA from any unused reserved capacity. Or you can delete VM 0 to remove its use of the quota.

The capacity reservation exists until it's explicitly deleted. To delete a capacity reservation, the first step is to dissociate all the VMs in the `virtualMachinesAssociated` property. After disassociation is finished, the capacity reservation should look like this diagram:



The status of the capacity reservation shows `capacity` as 2 and the length of `virtualMachinesAssociated` and `virtualMachinesAllocated` as 0. From this state, you can delete the capacity reservation. After it's deleted, you don't pay for the reservation anymore.

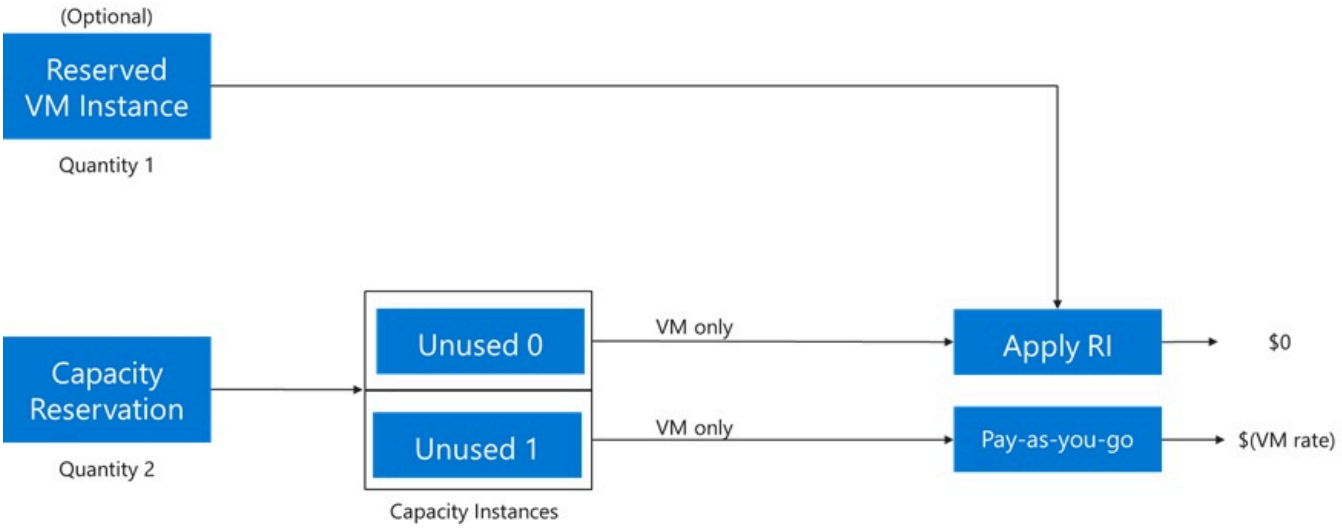


Usage and billing

When a capacity reservation is empty, VM usage is reported for the corresponding VM size and the location. VM reserved instances can cover some or all of the capacity reservation usage even when VMs aren't deployed.

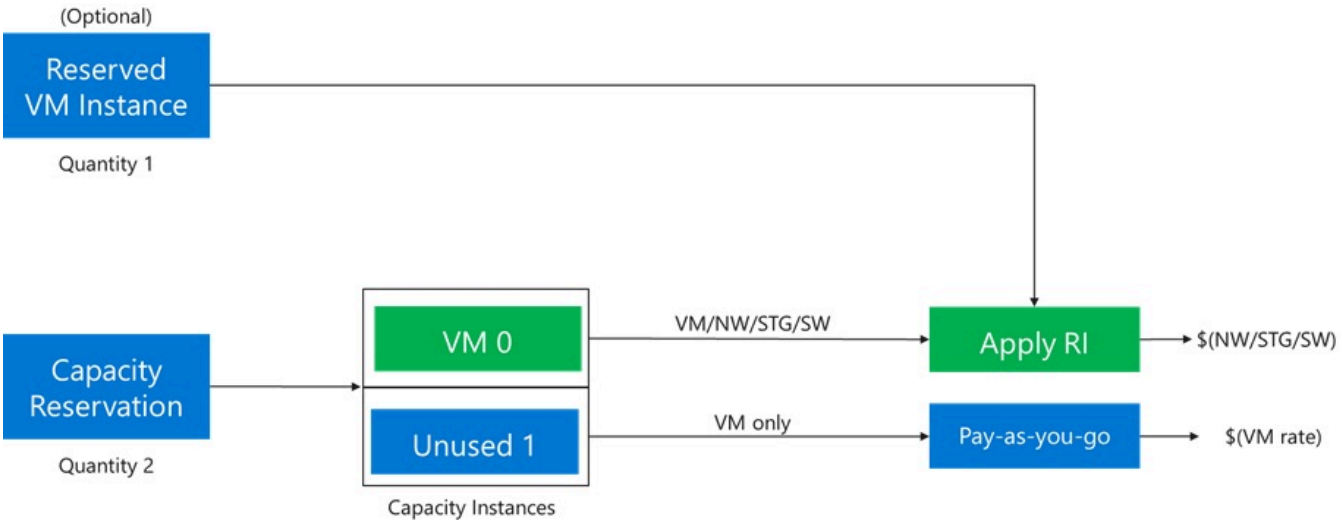
Example

For example, let's say that a capacity reservation with the reserved quantity of 2 was created. The subscription has access to one matching reserved VM instance of the same size. The result is two usage streams for the capacity reservation, one of which is covered by the reserved instance.



In the previous diagram, a reserved VM instance discount is applied to one of the unused instances and the cost for that instance is zeroed out. For the other instance, the pay-as-you-go rate is charged for the VM size reserved.

When a VM is allocated against the capacity reservation, the other VM components such as disks, network, extensions, and any other requested components must also be allocated. In this state, the VM usage reflects one allocated VM and one unused capacity instance. The reserved VM instance will zero out the cost of either the VM or the unused capacity instance. The other charges for disks, networking, and other components associated to the allocated VM also appear on the bill.



In the previous image, the VM reserved instance discount is applied to VM 0, which is only charged for other components, such as disks and networking. The other unused instance is being charged at a pay-as-you-go rate for the VM size reserved.

Frequently asked questions

- **What's the price of on-demand capacity reservation?**

The price of your on-demand capacity reservation is the same as the price of the underlying VM size associated to the reservation. When you use capacity reservation, you're charged for the VM size you selected at pay-as-you-go rates, whether the VM was provisioned or not. For more information, see the Windows and Linux VM pricing pages.

- **Will I get charged twice for the cost of on-demand capacity reservation and for the actual VM when I finally provision it?**

  No, you only get charged once for on-demand capacity reservation.

- **Can I apply Azure Reserved Virtual Machine Instances to on-demand capacity reservations to lower my costs?**

  Yes, you can apply existing or future reserved instances to on-demand capacity reservations and receive reserved instance discounts. Available reserved instances are applied automatically to capacity reservations the same way they're applied to VMs.

- **What's the difference between Reserved Virtual Machine Instances and on-demand capacity reservations?**

  Both reserved instances and on-demand capacity reservations are applicable to Azure VMs. However, reserved instances provide discounted reservation rates for your VMs compared to pay-as-you-go rates as a result of a one-year or three-year term commitment. Conversely, on-demand capacity reservations don't require a commitment.

  You can create or cancel a capacity reservation at any time. However, no discounts are applied, and you incur charges at pay-as-you-go rates after your capacity reservation is successfully provisioned. Unlike reserved instances, which prioritize capacity but don't guarantee it, when you purchase an on-demand capacity reservation, Azure sets aside compute capacity for your VM and provides an SLA guarantee.

- **Which scenarios would benefit the most from on-demand capacity reservations?**

  Typical scenarios include business continuity, disaster recovery, and scale-out of mission-critical applications.

Create a capacity reservation

Article • 09/09/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale set ✔ Flexible scale sets

Capacity reservation is always created as part of a capacity reservation group. The first step is to create a group if a suitable one doesn't exist already, and then create reservations. After reservations are successfully created, they're immediately available for use with virtual machines (VMs). The capacity is reserved for your use as long as the reservation isn't deleted.

A well-formed request for a capacity reservation group should always succeed because it doesn't reserve any capacity. It just acts as a container for reservations. However, a request for capacity reservation could fail if you don't have the required quota for the VM series or if Azure doesn't have enough capacity to fulfill the request. Either request more quota or try a different VM size, location, or zone combination.

Capacity reservation creation succeeds or fails in its entirety. For a request to reserve 10 instances, success is returned only if all 10 instances could be allocated. Otherwise, the capacity reservation creation fails.

Considerations

The capacity reservation must meet the following rules:

- The location parameter must match the location property for the parent capacity reservation group. A mismatch results in an error.
- The VM size must be available in the target region. Otherwise, the reservation creation fails.
- The subscription must have available quota equal to or more than the quantity of VMs being reserved for the VM series and for the region overall. If needed, request more quota.
    - As needed to satisfy existing quota limits, you can do single VMs in stages. Create a capacity reservation with a smaller quantity and reallocate that quantity of VMs. This approach frees up quota to increase the quantity reserved and add more VMs. Alternatively, if the subscription uses different VM sizes in the same series, reserve and redeploy VMs for the first size. Then add a reservation to the group for another size and redeploy the VMs for the new size to the reservation group. Repeat the process until it's complete.
    - For scale sets, available quota is required unless the scale set or you delete its VM instances, capacity is reserved, and the scale set instances are added by

using reserved capacity. If the scale set is updated by using blue green deployment, then reserve the capacity and deploy the new scale set to the reserved capacity at the next update.

- Each capacity reservation group can have exactly one reservation for a specific VM size. For example, you can create only one capacity reservation for the VM size `Standard_D2s_v3`. Attempting to create a second reservation for `Standard_D2s_v3` in the same capacity reservation group results in an error. However, you can create another reservation in the same group for other VM sizes, such as `Standard_D4s_v3` and `Standard_D8s_v3`.
- For a capacity reservation group that supports zones, each reservation type is defined by the combination of **VM size** and **zone**. For example, one capacity reservation for `Standard_D2s_v3` in `Zone 1`, another capacity reservation for `Standard_D2s_v3` in `Zone 2`, and a third capacity reservation for `Standard_D2s_v3` in `Zone 3` are supported.

Check VM sizes that are available for capacity reservation in a region

Before you create a capacity reservation, you can check the VM sizes that are available for the reservation for a particular region.

Portal

1. Open the Azure portal.
2. In the search bar, enter **capacity reservation groups**.
3. Select **Capacity reservation groups** from the options.
4. Select **Create**.
5. On the **Basics** tab, create a capacity reservation group:
   a. Select a **Subscription**.
   b. Select or create a resource group.
   c. Name your group.
   d. Select a region.
   e. Optionally, select **Availability zones** or allow Azure to choose for you.
6. Select **Next**.
7. On **VM size**, select **See all sizes** to check what VM sizes are available for capacity reservation.

Create a capacity reservation

API

1. Create a capacity reservation group.

   To create a capacity reservation group, construct the following `PUT` request on the `Microsoft.Compute` provider:

   ```rest
   PUT
   https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}&api-version=2021-04-01
   ```

   In the request body, include the following parameter:

   ```JSON
   {
     "location":"eastus"
   }
   ```

   This group is created to contain reservations for the US East location.

   The group in the following example only supports regional reservations because zones weren't specified at the time of creation. To create a zonal group, pass an extra parameter `zone` in the request body:

   ```JSON
   {
     "location":"eastus",
     "zones": ["1", "2", "3"]
   }
   ```

2. Create a capacity reservation.

   To create a reservation, construct the following `PUT` request on the `Microsoft.Compute` provider:

   ```rest
   ```

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName}?api-version=2021-04-01
```

In the request body, include the following parameters:

JSON

```
{
  "location": "eastus",
  "sku": {
    "name": "Standard_D2s_v3",
    "capacity": 5
  },
 "tags": {
        "environment": "testing"
}
```

The preceding request creates a reservation in the East US location for five quantities of the D2s_v3 VM size.

Check on your capacity reservation

After the capacity reservation is successfully created, it's immediately available for use with VMs.

API

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName}?api-version=2021-04-01
```

JSON

```
{
    "name": "<CapacityReservationName>",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityRes
```

```
ervationGroupName}/capacityReservations/{CapacityReservationName}",
    "type": "Microsoft.Compute/capacityReservationGroups/capacityReserva
tions",
    "location": "eastus",
    "tags": {
        "environment": "testing"
    },
    "sku": {
        "name": "Standard_D2s_v3",
        "capacity": 5
    },
    "properties": {
        "reservationId": "<reservationId>",
         "provisioningTime": "<provisioningTime>",
         "provisioningState": "Updating"
    }
}
```

Overallocate capacity reservation

Article • 09/09/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale set ✔ Flexible scale sets

Azure permits the association of extra virtual machines (VMs) above the number of capacity reservations. These VMs are available to allow for burst and other scale-out scenarios without the limits of reserved capacity. The only difference is that the count of VMs beyond the quantity reserved doesn't receive the capacity availability service-level agreement (SLA) benefit. As long as Azure has available capacity that meets the VM requirements, the extra allocation succeeds.

The Instance View of a capacity reservation group provides a snapshot of usage for each member capacity reservation. You can use the Instance View to see how overallocation works.

This article assumes you created a capacity reservation group (`myCapacityReservationGroup`), a member capacity reservation (`myCapacityReservation`), and a VM (*myVM1*) that's associated to the group. For more information, see Create a capacity reservation and Associate a VM to a capacity reservation.

Instance View for a capacity reservation group

The Instance View for a capacity reservation group looks like this example:

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/myC
apacityReservationGroup?$expand=instanceview&api-version=2021-04-01
```

JSON

```
{
    "name": "myCapacityReservationGroup",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName
}/providers/Microsoft.Compute/capacityReservationGroups/myCapacityReservatio
nGroup",
    "type": "Microsoft.Compute/capacityReservationGroups",
    "location": "eastus",
    "properties": {
        "capacityReservations": [
            {
```

```
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/MYCAPACI
TYRESERVATIONGROUP/capacityReservations/MYCAPACITYRESERVATION"
            }
        ],
        "virtualMachinesAssociated": [
            {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM1"
            }
        ],
        "instanceView": {
            "capacityReservations": [
                {
                    "name": "myCapacityReservation",
"utilizationInfo": {
                        "virtualMachinesAllocated": [
                            {
                                "id": "/subscriptions/{subscriptionId}/resou
rceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/my
VM1"
                            }
                        ]
                    },
                    "statuses": [
                        {
                            "code": "ProvisioningState/succeeded",
                            "level": "Info",
                            "displayStatus": "Provisioning succeeded",
                            "time": "<time>"
                        }
                    ]
                }
            ]
        }
    }
}
```

Let's say we create another VM named *myVM2* and associate it to the preceding capacity reservation group.

The Instance View for the capacity reservation group now looks like this example:

JSON

```
{
    "name": "myCapacityReservationGroup",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName
}/providers/Microsoft.Compute/capacityReservationGroups/myCapacityReservatio
nGroup",
    "type": "Microsoft.Compute/capacityReservationGroups",
    "location": "eastus",
    "properties": {
```

```
        "capacityReservations": [
            {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/MYCAPACI
TYRESERVATIONGROUP/capacityReservations/MYCAPACITYRESERVATION"
            }
        ],
        "virtualMachinesAssociated": [
            {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM1"
            },
 {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM2"
            }
        ],
        "instanceView": {
            "capacityReservations": [
                {
                    "name": "myCapacityReservation",
"utilizationInfo": {
                        "virtualMachinesAllocated": [
                            {
                                "id": "/subscriptions/{subscriptionId}/resou
rceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/my
VM1"
                            },
{
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM2"
            }
                        ]
                    },
                    "statuses": [
                        {
                            "code": "ProvisioningState/succeeded",
                            "level": "Info",
                            "displayStatus": "Provisioning succeeded",
                            "time": "<time>"
                        }
                    ]
                }
            ]
        }
    }
}
```

The length of `virtualMachinesAllocated` (2) is greater than `capacity` (1). This valid state is referred to as *overallocated*.

> **ⓘ Important**

Azure won't stop allocations because a capacity reservation is fully consumed. Autoscale rules, temporary scale-out, and related requirements work beyond the quantity of reserved capacity if Azure has available capacity and other constraints like available quota are met.

States and considerations

There are three valid states for a specific capacity reservation:

Expand table

State	Status	Considerations
Reserved capacity available	Length of `virtualMachinesAllocated` < `capacity`	Is all the reserved capacity needed? Optionally, reduce the capacity to reduce costs.
Reservation consumed	Length of `virtualMachinesAllocated` == `capacity`	More VMs won't receive the capacity SLA unless some existing VMs are deallocated. Optionally, try to increase the capacity so that extra planned VMs receive an SLA.
Reservation overallocated	Length of `virtualMachinesAllocated` > `capacity`	More VMs won't receive the capacity SLA. Also, the quantity of VMs (length of `virtualMachinesAllocated` – `capacity`) won't receive a capacity SLA if deallocated. Optionally, increase the capacity to add capacity SLA to more of the existing VMs.

Next step

Learn how to remove VMs from a capacity reservation

Modify a capacity reservation

Article • 09/09/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale set ✔ Flexible scale sets

After you create a capacity reservation group and a capacity reservation, you might want to modify your reservations. This article explains how to do the following actions by using the API, the Azure portal, and PowerShell.

- ✔ Update the number of instances reserved in a capacity reservation.
- ✔ Resize VMs associated to a capacity reservation group.
- ✔ Delete the capacity reservation group and capacity reservation.

Update the number of instances reserved

Update the number of virtual machine (VM) instances reserved in a capacity reservation.

> **ⓘ Important**
>
> In rare cases when Azure can't fulfill the request to increase the quantity reserved for existing capacity reservations, a reservation might go into a *Failed* state and become unavailable until the quantity is restored to the original amount.

API

rest

```
    PATCH
https://management.azure.com/subscriptions/{subscriptionId}/resourceGrou
ps/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGr
oups/{CapacityReservationGroupName}/capacityReservations/{capacityReserv
ationName}?api-version=2021-04-01
```

In the request body, update the `capacity` property to the new count that you want to reserve:

JSON

```
{
    "sku":
    {
        "capacity": 5
```

```
    }
}
```

In this example, the `capacity` property is now set to `5`.

Resize VMs associated to a capacity reservation group

You must do one of the following options if the VM being resized is currently attached to a capacity reservation group and that group doesn't have a reservation for the target size:

- Create a new reservation for that size.
- Remove the VM from the reservation group before you resize.

Check if the target size is part of the reservation group.

API

1. Get the names of all capacity reservations within the group.

rest

```
    GET
https://management.azure.com/subscriptions/{subscriptionId}/resourc
eGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityRes
ervationGroups/{CapacityReservationGroupName}?api-version=2021-04-
01
```

JSON

```
{
    "name": "<CapacityReservationGroupName>",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resource
GroupName}/providers/Microsoft.Compute/capacityReservationGroups/{C
apacityReservationGroupName}",
    "type": "Microsoft.Compute/capacityReservationGroups",
    "location": "eastUS",
    "zones": [
        "1"
    ],
    "properties": {
        "capacityReservations": [
            {
                "id": "/subscriptions/{subscriptionId}/resourceGrou
```

```
ps/{resourceGroupName}/providers/Microsoft.Compute/capacityReservat
ionGroups/{CapacityReservationGroupName}/capacityReservations/{capa
cityReservationName1}"
            },
{
                "id": "/subscriptions/{subscriptionId}/resourceGrou
ps/{resourceGroupName}/providers/Microsoft.Compute/capacityReservat
ionGroups/{CapacityReservationGroupName}/capacityReservations/{capa
cityReservationName2}"
            }
        ]
    }
}
```

2. Find out the VM size reserved for each reservation. The following example is for `capacityReservationName1`, but you can repeat this step for other reservations.

rest

```
    GET
https://management.azure.com/subscriptions/{subscriptionId}/resourc
eGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityRes
ervationGroups/{CapacityReservationGroupName}/capacityReservations/
{capacityReservationName1}?api-version=2021-04-01
```

JSON

```
{
    "name": "capacityReservationName1",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resource
GroupName}/providers/Microsoft.Compute/capacityReservationGroups/{C
apacityReservationGroupName}/capacityReservations/{capacityReservat
ionName1}",
    "type": "Microsoft.Compute/capacityReservationGroups/capacityRe
servations",
    "location": "eastUS",
    "sku": {
        "name": "Standard_D2s_v3",
        "capacity": 3
    },
    "zones": [
        "1"
    ],
    "properties": {
        "reservationId": "<reservationId>",
        "provisioningTime": "<provisioningTime>",
        "provisioningState": "Succeeded"
    }
}
```

3. Consider the following scenarios:

   - If the target VM size isn't part of the group, create a new capacity reservation for the target VM.
   - If the target VM size already exists in the group, resize the VM.

Delete a capacity reservation group and capacity reservation

Azure allows a group to be deleted when all the member capacity reservations are deleted and no VMs are associated to the group.

To delete a capacity reservation, first find out all of the VMs that are associated to it. The list of VMs is available under the `virtualMachinesAssociated` property.

API

First, find all the VMs associated to the capacity reservation group and dissociate them:

rest

```
    GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGrou
ps/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGr
oups/{CapacityReservationGroupName}?$expand=instanceView&api-
version=2021-04-01
```

JSON

```
{
    "name": "<capacityReservationGroupName>",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroup
Name}/providers/Microsoft.Compute/capacityReservationGroups/{capacityRes
ervationGroupName}",
    "type": "Microsoft.Compute/capacityReservationGroups",
    "location": "eastus",
    "properties": {
        "capacityReservations": [
            {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{r
esourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/
{capacityReservationGroupName}/capacityReservations/{capacityReservation
Name}"
            }
```

```
        ],
        "virtualMachinesAssociated": [
            {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{r
esourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMa
chineName1}"
            },
            {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{r
esourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMa
chineName2}"
            }
        ],
        "instanceView": {
            "capacityReservations": [
                {
                    "name": "{capacityReservationName}",
                    "utilizationInfo": {
                        "virtualMachinesAllocated": [
                            {
                                "id": "/subscriptions/{subscriptionId}/r
esourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMac
hines/{VirtualMachineName1}"
                            }
                        ]
                    },
                    "statuses": [
                        {
                            "code": "ProvisioningState/succeeded",
                            "level": "Info",
                            "displayStatus": "Provisioning succeeded",
                            "time": "<time>"
                        }
                    ]
                }
            ]
        }
    }
}
```

From the preceding response, find the names of all the VMs under the `virtualMachinesAssociated` property. Remove them from the capacity reservation group by using the steps in Remove a VM association to a capacity reservation.

After all the VMs are removed from the capacity reservation group, delete the member capacity reservations:

rest

```
DELETE
https://management.azure.com/subscriptions/{subscriptionId}/resourceGrou
ps/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGr
```

```
oups/{CapacityReservationGroupName}/capacityReservations/{capacityReserv
ationName}?api-version=2021-04-01
```

Lastly, delete the parent capacity reservation group:

rest

```
DELETE
https://management.azure.com/subscriptions/{subscriptionId}/resourceGrou
ps/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGr
oups/{CapacityReservationGroupName}?api-version=2021-04-01
```

Restore instance quantity

A well-formed request for reducing the reserved quantity should always succeed no matter the number of VMs associated to the reservation. However, increasing the reserved quantity might require more quota and for Azure to fulfill the request for more capacity. In a rare scenario in which Azure can't fulfill the request to increase the reserved quantity for existing reservations, the reservation might go into a *Failed* state and become unavailable until the reserved quantity is restored to the original amount.

> **Note**
>
> If a reservation is in a *Failed* state, all the VMs that are associated to the reservation continue to work as normal.

For example, let's say `myCapacityReservation` has 5 instances reserved. You request 5 extra instances, which makes the total reserved quantity equal to 10. However, because of a constrained capacity situation in the region, Azure can't fulfill the extra 5 instances that you requested. In this case, `myCapacityReservation` fails to meet its intended state of 10 reserved instances and goes into a *Failed* state.

To resolve this failure, follow these steps to locate the old quantity reserved value:

1. In the Azure portal, go to Application Change Analysis.
2. Select the applicable **Subscription**, **Resource group**, and **Time range** settings in the filters. You can only go back up to 14 days in the past in the **Time range** filter.
3. Search for the name of the capacity reservation.
4. Look for the change in the `sku.capacity` property for that reservation. The old quantity reserved is the value under the **Old Value** column.

Update `myCapacityReservation` to the old quantity reserved. After it's updated, the reservation is available immediately for use with your VMs.

Share a Capacity Reservation Group (Preview)

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Uniform scale set ✔ Flexible scale sets

> **Important**
>
> This feature is currently in **Preview**. See the Preview Terms of Use for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

On-demand Capacity Reservation Group (CRG) can be shared with other subscriptions. Using this option can make it easier to manage some common configuration needs:

- **Reuse of capacity reserved for disaster recovery.** Reserved capacity is the primary means to obtain capacity assurance in another region or zone in the event of the primary region or zone becoming unavailable. Reservation sharing supports reuse of disaster recovery capacity by subscriptions, hosting less critical workloads such as development and testing, or subscriptions used to run job-oriented workloads. Capacity reuse can save on total capacity costs and drive more value from the reserved capacity.
- **Central management of capacity.** Quota requests and term commitments are often administered by a central operations team as part of cost management. Now, reserved capacity needs can be assessed and managed more centrally to align on capacity and cost management.
- **Separate security and capacity concerns.** Applications implemented with multiple subscriptions for security reasons can operate from a common pool of capacity. This pattern is common with service providers serving their own end customers.
- **More cost-effective scale-out with capacity assurance.** Applications that scale at different rates and times can share one pool of reserved capacity.

How to share a Capacity Reservation Group

Sharing reserved capacity requires at least two subscriptions:

- **Provider subscription** - the subscription that creates and hosts the Capacity Reservation Group and member Capacity Reservations.
- **Consumer subscription** - another subscription that is granted access to the reserved capacity, obtaining the ability to deploy virtual machines (VMs) with the Capacity Reservation Service Level Agreement (SLA).

A given Capacity Reservation Group can be shared with up to 100 consumer subscriptions. All the member Capacity Reservations in the Group will be accessible from consumer subscriptions.

Configuring a Capacity Reservation Group sharing relationship has three steps:

1. In the Consumer subscription, configure an On Demand capacity Reservation (ODCR) owner from the Producer subscription with the rights `Microsoft.Compute/capacityReservationGroups/share/action`.
2. In the Producer subscription, add the Consumer subscription ID to the Capacity Reservation Group *shared* list. See Share a capacity Reservation Group to learn how to add a Consumer subscription to the sharing profile.
3. In the Producer subscription, configure at least one VM owner in the Consumer subscription with the following rights:

    - `Microsoft.Compute/capacityReservationGroups/read`
    - `Microsoft.Compute/capacityReservationGroups/deploy`
    - `Microsoft.Compute/capacityReservationGroups/capacityReservations/read`
    - `Microsoft.Compute/capacityReservationGroups/capacityReservations/deploy`

If the ODCR owner and the VM owner already have either Owner or Contributor Azure role in both the Provider and Consumer subscriptions, then no further action is needed for granting share, read, and deploy permissions. To learn more on how to assign an Azure role, see Role Assignment Steps or Azure custom role

Once complete, a VM owner in the Consumer subscription can enumerate the shared CRG. View the list of Capacity Reservation Groups for a subscription and deploy VMs by setting the `capacityReservationGroup` property on Virtual Machines or Virtual Machine Scale Sets. Keep in mind, the ability to modify the Capacity Reservation Group (CRG) remains only with the ODCR administrator in the producer subscription.

> **Note**
>
> There are no extra charges for using the shared Capacity Reservation Group feature. Unused reservations are charged to the subscription that owns the reservation. VM usage is charged

to the subscription that uses the capacity reservation as it does today. For details on how Reserved Instance (RI) applies to the feature, see Use of Reserved Instances with shared Capacity Reservation Groups section.

Usage patterns

The Provider subscription sharing a Capacity Reservation Group can allow:

- Consumer subscriptions to access a specific Capacity Reservation Group in the Provider subscription
- Consumer subscription to access all Capacity Reservation Groups created in the Provider subscription
- All Consumer subscriptions in a specific Management Group to access the Capacity Reservation Group

> **Note**
>
> Azure strongly recommends using one main Provider subscription to host Capacity Reservation Groups for each application, workload, or usage scope to share across other subscriptions. Creating Capacity Reservation Groups in many different subscriptions and then cross-sharing in a matrix fashion will create management challenges and lead to confusion at VM deployment.

Prerequisites for sharing a Capacity Reservation Group

- An ODCR owner in the Provider subscription must have sufficient rights to be able to share a CRG
- A VM owner in the Consumer subscription must have sufficient rights to be able to make deployments in capacity reservation (CR) in shared CRG
- A VM being deployed in the shared CRG must match the VM SKU, region, and zone if applicable

Limitations of sharing a Capacity Reservation Group

Limitations by design:

- Sharing works with an explicit list of target Consumer subscriptions. Azure doesn't support wildcard or tenant level sharing.

- A CRG can be shared with a maximum of 100 Consumer subscriptions.
- Sharing is done per Capacity Reservation Group, which grants access to all member Capacity Reservations. Individual Capacity Reservations can't be shared. To isolate specific Capacity Reservations, create multiple Capacity Reservation Groups and share only those Capacity Reservations that contain shared capacity.
- By default, Capacity Reservation Group administrators in the subscription owning a Capacity Reservation Group can't modify VM instances deployed by other subscriptions. If such VM access is desired, more rights to VMs on the shared subscriptions must be granted separately.

Limitations for Preview:

- Reprovisioning of Virtual Machine Scale Set VMs using a shared Capacity Reservation Group isn't supported during a zone outage.
- There is a known issue of Capacity Reservation Groups - List by Subscription ID not giving the right response if there is no CRG created by the subscription making the `GET` call to list shared CRGs in the region. To get the correct response, ensure you have a local CRG created in the subscription making the API call in the same region where you would like to enumerate the shared CRGs. Alternatively, use the Azure Resource Graph query provided to get the list of CRGs shared with your subscription.

Share a Capacity Reservation Group

Capacity Reservation Groups are shared by adding Consumer subscriptions in the sharing profile of newly created or existing Capacity Reservation Groups. Once shared, the subscriptions which are part of the sharing profile can deploy VMs or Virtual Machine Scale Sets in the shared Capacity Reservation Group.

Add sharing profile to a new Capacity Reservation Group

Share a Capacity Reservation Group during creation by adding subscriptions in the sharing profile.

Portal

To create a Capacity Reservation Group with sharing profile from the portal, follow the steps:

1. Open the Azure portal.
2. In the search bar, enter **capacity reservation groups**.

3. Select **Capacity reservation groups** from the options.
4. Select **Create**.
5. On the **Basics** tab, create a capacity reservation group:
    a. Select a subscription.
    b. Select or create a resource group.
    c. Name your group.
    d. Select a region.
    e. Optionally, select **Availability zones** or allow Azure to choose for you.
6. Select **Next**.
7. On the **Reservations** tab, create at least one capacity reservation:
    a. Give each reservation a reservation name, the quantity of VM instances, and select a unique VM size.
    b. Billing information based on your selections appears in the **Cost/month** column.
8. Select **Next**.
9. On **Sharing** tab, share the capacity reservation group:
    a. Select **Add Subscriptions**.
    b. Select subscriptions to add.
    c. Select **Add**.
10. Select **Next**.
11. On the **Tags** tab, optionally create tags.
12. Select **Next**.
13. On the **Review + Create** tab, review your capacity reservation group information.
14. Select **Create**.

Add sharing profile to an existing Capacity Reservation Group

Add a sharing profile and share with subscriptions for an existing Capacity Reservation Group.

Portal

To add subscriptions to the sharing profile of an existing capacity reservation group from the portal, follow the steps:

1. Open the Azure portal.
2. Go to your capacity reservation group.
3. Select **Settings** of the capacity reservation group.
4. Select **Sharing**

5. Select **Add subscriptions**
6. Select the subscriptions to add
7. Select **Add**
8. Select **Save**

Stop sharing a Capacity Reservation Group

The Capacity Reservation Group owner can stop sharing a Capacity Reservation Group with a subscription or all subscriptions at any time.

Unsharing of a Capacity Reservation Group with a cross subscription ID is done while a VM or Virtual Machine Scale Set from cross subscriptions remains associated with the Capacity Reservation Group. The associated resources get SLA until deallocation or reallocation.

Once unsharing happens, any VM or scale set previously associated to the CRG would fail to associate upon deallocation or reallocation. Avoid this failure by removing the association from the CRG.

Unsharing a Capacity Reservation Group with a subscription

To unshare a Capacity Reservation Group with a subscription from the sharing profile, remove the subscription from the sharing profile.

Portal

To remove subscriptions from the sharing profile of an existing capacity reservation group from the portal, follow the steps:

1. Open the Azure portal.
2. Go to your capacity reservation group.
3. Select **Settings** of the capacity reservation group.
4. Select **Sharing**
5. Select the subscriptions to remove
6. Select **Stop sharing**
7. Select **Save**

Unsharing a Capacity Reservation Group with all subscriptions

To unshare a Capacity Reservation Group with all consumer subscriptions, remove all subscriptions from the sharing profile.

Portal

To remove subscriptions from the sharing profile of an existing capacity reservation group from the portal, follow the steps:

1. Open the Azure portal.
2. Go to your capacity reservation group.
3. Select **Settings** of the capacity reservation group.
4. Select **Sharing**
5. Select all subscriptions to remove
6. Select **Stop sharing**
7. Select **Save**

Delete a shared Capacity Reservation Group

See Modify a Capacity Reservation for deletion guidance.

- Users with sufficient rights can delete the shared Capacity Reservation Group.
- Azure allows a Capacity Reservation Group to be deleted when all the member capacity reservations are deleted.
- Azure allows a Capacity Reservation to be deleted when no VMs are associated to the Capacity Reservation.
- Unsharing of a CRG with a shared subscription happens as part of the shared Capacity Reservation Group deletion process.

Using a shared Capacity Reservation Group

Once the Capacity Reservation Group is successfully shared, users with sufficient rights from a Consumer subscription can deploy a VM or Virtual Machine Scale Set in a shared Capacity Reservation Group.

> **Note**
>
> The Provider subscription deploying the shared CRG will need to hold its own quota for deploying the CRG. The Consumer subscription making a deployment in the shared

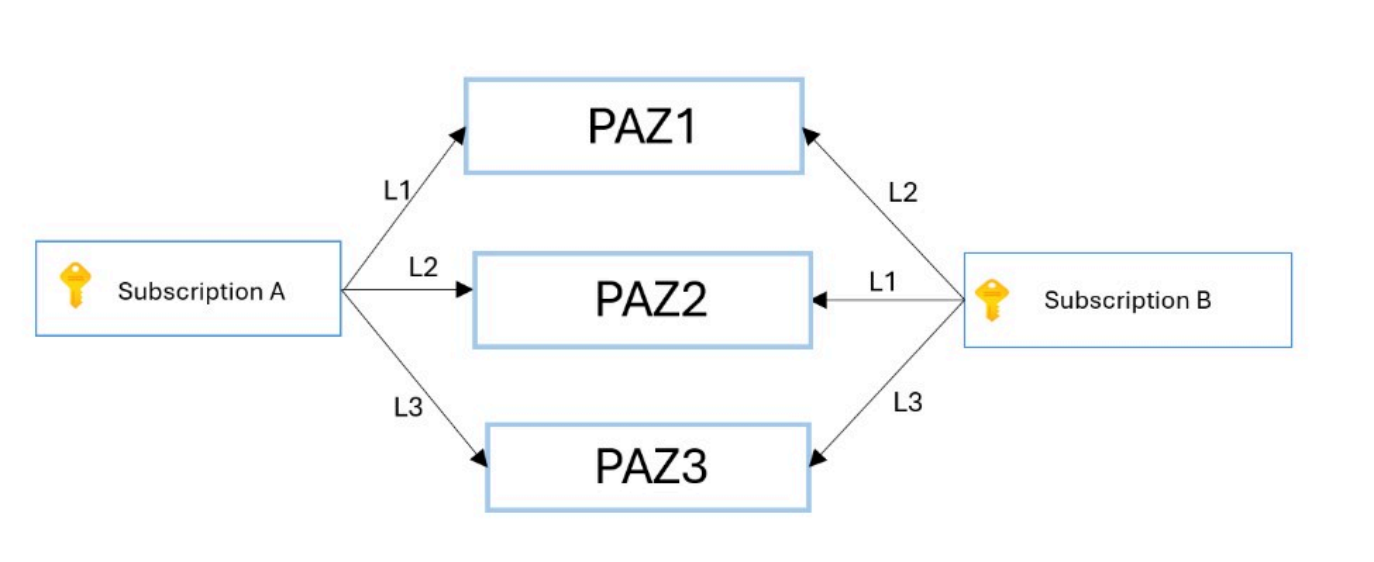
reservation group will need to hold its own quota.

Availability zone mapping with shared zonal Capacity Reservation Groups

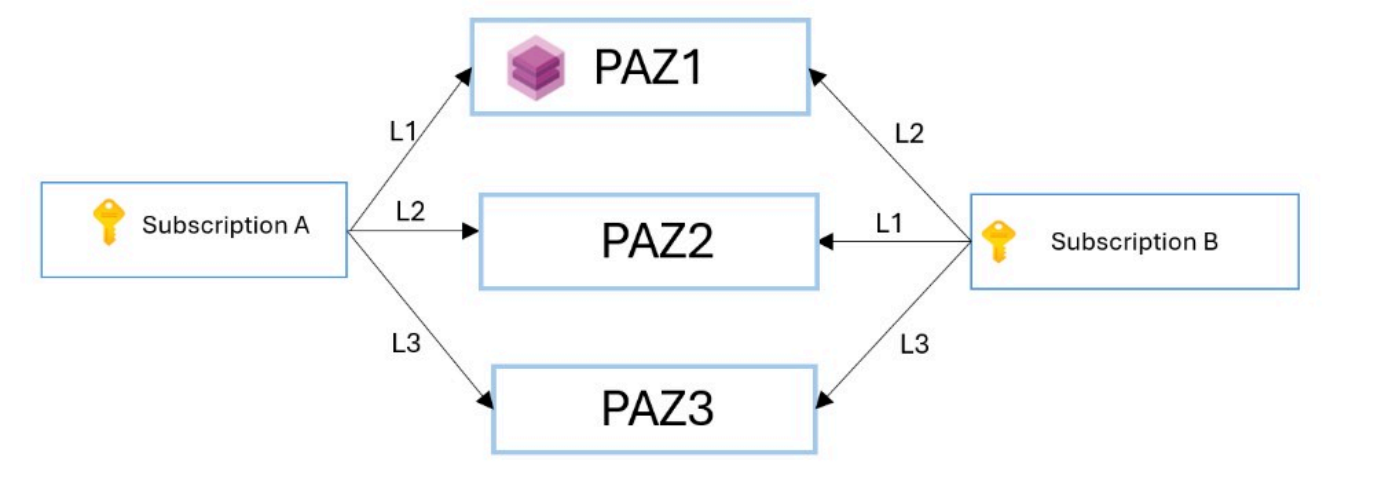
The availability zones visible to each Azure subscription represent a logical mapping to underlying groups of physical data centers that constitute a physical zone. To promote efficient distribution of resources across availability zones, each Azure subscription gets a random logical to physical mapping of zones. For example, subscription A (Provider subscription) and subscription B (Consumer subscription) can have different logical mappings.

Consider the following example:

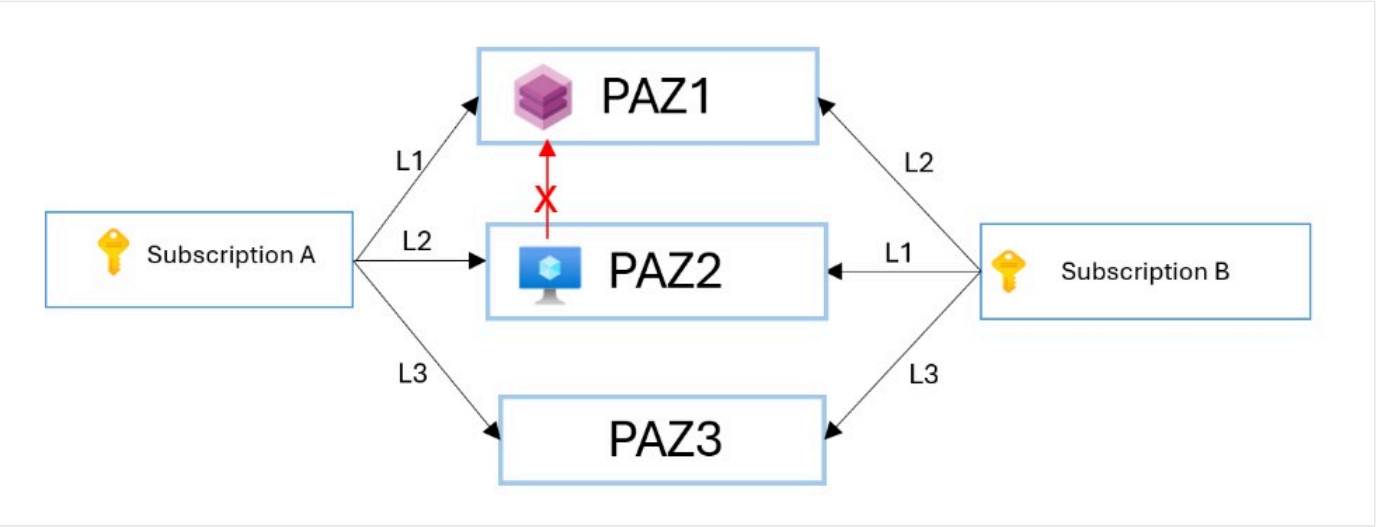
If subscription A deploys to AZ1, the deployment goes to physical zone 1. But if subscription B deploys to AZ1, the deployment goes to physical zone 2:



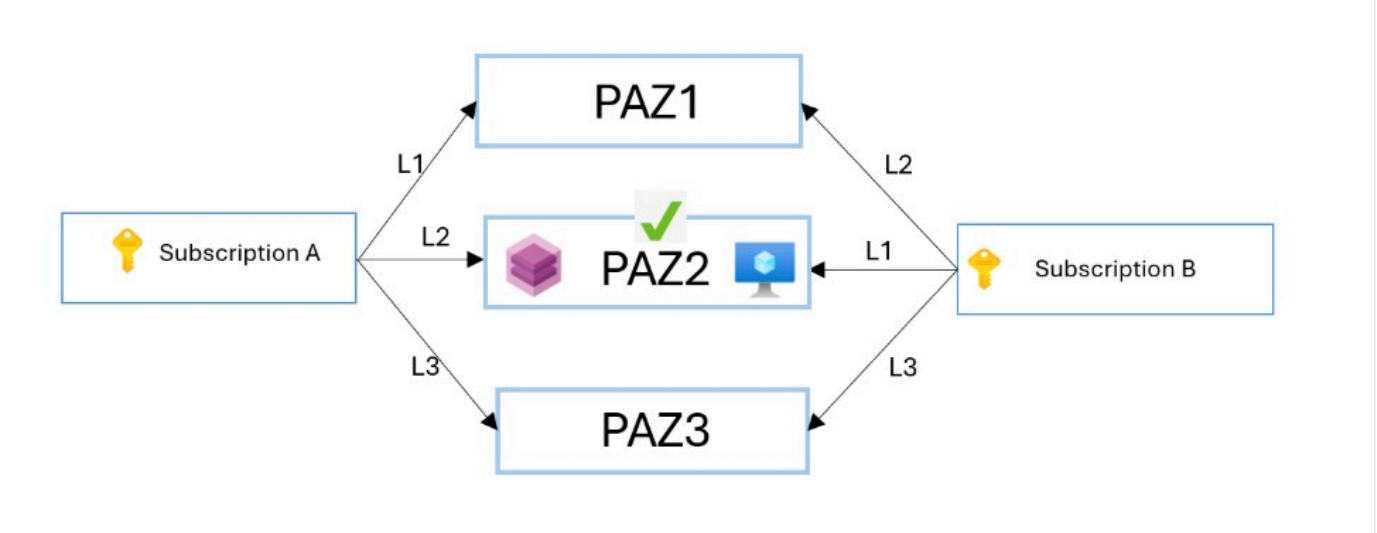
Now consider a Capacity Reservation deployed by Subscription A to logical AZ1. The result is reserved capacity in physical zone 1.



If subscription B deployed a VM to logical AZ1 using the shared Capacity Reservation Group, the deployment would fail because subscription B AZ1 resolves to physical zone 2, and there's no reserved capacity in physical zone 2.



The solution is to reconcile the logical to physical mappings for subscription A and subscription B. Subscription B should deploy to AZ2 to access reserved capacity in physical zone 1.



When using a shared Capacity Reservation Group with zones, all subscriptions have the logical view of availability zones from the CRG subscription, which is likely different than the logical view of availability zones from the target subscription. When deploying a VM or scale set to a shared CRG, you must remap the zones. To ensure that the Azure resources are efficiently distributed across Availability zones in a Region, each subscription has independent logical zone mapping for Availability zones. This means that logical to physical zone mapping may or may not be the same across subscriptions.

To check the Physical Zone and Logical Zone mapping for your subscription, see Subscriptions - List Locations - REST API (Azure Resource Management). For more information, see Physical and Logical availability zones.

Secure existing zonal workloads using zero size reservation in Shared capacity Reservation Group

Zonally deployed virtual machines or virtual machine scale sets from Consumer subscription can be converted to using a shared Capacity Reservation without reallocation. If you do not have capacity in an existing shared capacity reservation group, you can start by creating a zero size matching reservation to secure your workloads. The basic process involves 3 steps:

1. Create a shared Capacity Reservation Group and then matching capacity reservations in each target zone with the reserved quantity set to zero. This requires no additional quota or capacity for the Provider subscription. For more information on how to create a reservation, see Create a capacity reservation.

2. Associate existing running zonal virtual machine or virtual machine scale set from the Consumer subscription to the shared capacity reservation group. Set the Virtual Machine or Virtual Machine Scale Set (VMSS) capacityReservationGroup property to the desired shared Capacity Reservation Group. When complete, each target capacity reservation will be overallocated.

3. Increase the reserved quantity of each capacity reservation (CR) to match the allocated Virtual Machine (VM) count. The Provider subscription must have sufficient quota to accomodate the workloads from the Consumer subscription for this step. See Using a shared Capacity Reservation Group. For more information on how to update the reserved count, see Capacity reservation modify

After the quantity increase, you should see the CR in a fully allocated state with all the virtual machines or virtual machine scale sets allocated. See View VM allocation with the Instance View.

For more information, see Zonal Virtual Machine or Zonal Virtual Machine Scale Set.

Use of Reserved Instances with shared Capacity Reservation Groups

Sharing a Capacity Reservation Group doesn't alter the scope of any Reserved Instances or Savings Plans. If either the CRG or the VM is deployed from a scope not covered by prepaid discounts, the pay-as-you-go price is charged.

To share Reserved Instance discounts between a Capacity Reservation Group and VMs deployed from a Consumer subscription, the Provider subscription and the Consumer subscription must share the same Reserved Instance scope. If the two subscriptions share an enrollment or a

management group, then Reserved Instances set to the corresponding scope works automatically.

Associate or create a single Virtual Machine with shared Capacity Reservation Group

A single Virtual Machine can be deployed in a shared Capacity Reservation Group. See Associate a virtual machine to a Capacity Reservation group.

Remove a single Virtual Machine from Shared Capacity Reservation Group

A single Virtual Machine can be removed from a Shared Capacity Reservation Group. See Remove a virtual machine association from a Capacity Reservation group.

Associate or create a Virtual Machine Scale Set with shared Capacity Reservation Group

Virtual Machine Scale Sets in Flexible and Uniform orchestration mode can be deployed in a shared Capacity Reservation Group. To learn more, see Associate a scale set -Flexible and Associate a scale set - Uniform.

Remove Virtual Machine Scale Set from Shared Capacity Reservation Group

Virtual Machine Scale Sets in Flexible and Uniform orchestration mode can be removed from a shared Capacity Reservation Group. To learn more, see Remove a scale set.

View shared Capacity Reservation Group

Once a Capacity Reservation Group is shared successfully, the reservations are immediately available for use with single Virtual Machines and Virtual Machine Scale Sets.

View the subscription IDs the Capacity Reservation Group are shared with from the sharing profile.

To learn more, see Create a Capacity Reservation.

Portal

1. Open the Azure portal.
2. Go to your capacity reservation group.

3. Select **Settings** of the capacity reservation group.
4. Select **Sharing**.
5. View a list of the subscriptions the capacity reservation group is shared with.

View the list of Capacity Reservation Groups for a subscription

The list of all Capacity Reservation Groups that are created locally or shared with by other subscriptions can be viewed for a given subscription. Extra parameter `resourceIdsonly` needs to be passed to view the shared Capacity Reservation Groups.

Capacity Reservation Groups - List by Subscription ID

By default, obtaining a list of Capacity Reservation Groups returns only those owned by the subscription. To add the Capacity Reservation Groups shared to the subscription, the additional parameter of `resourceIdsOnly` must be set to `sharedwithsubscription`.

API

Enable fetching Resource IDs for all CRG resources shared with the subscription:

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/providers/Microsoft.C
ompute/capacityReservationGroups?api-version=2023-09-
01&resourceIdsOnly=sharedwithsubscription
```

Enable fetching Resource IDs for all CRG resources shared with the subscription and created in the subscription:

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/providers/Microsoft.C
ompute/capacityReservationGroups?api-version=2023-09-01&resourceIdsOnly=All
```

Enable fetching Resource IDs for all CRG resources created in the subscription:

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/providers/Microsoft.Compute/capacityReservationGroups?api-version=2023-09-01&resourceIdsOnly=CreatedInSubscription
```

JSON

```
{
    "value": [
        {
            "id":
"/subscriptions/{subscriptionId1}/resourceGroups/{resourceGroupName1}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName1} ",
            "type": "Microsoft.Compute/capacityReservationGroups",
            "location": "EastUS2"
        },
        {
            "id":
"/subscriptions/{subscriptionId2}/resourceGroups/{resourceGroupName2}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName2} ",
            "type": "Microsoft.Compute/capacityReservationGroups",
            "location": "EastUS2"
        }
    ]
}
```

To learn more, see Capacity Reservation Group - List by subscription.

Azure Resource Graph

Use the Azure Resource Graph to view the list of all Capacity Reservation Groups that are shared with and created locally within a given subscription.

Portal

To view the CRG list, go to Azure Resource Graph Explorer and try this query.

Enable fetching Resource IDs for all CRG resources shared with subscription ID 1 and created within subscription ID 1:

Kusto

```
resources
|where type == "microsoft.compute/capacityreservationgroups"
|where properties["sharingProfile"] contains "{subscriptionId1}" or
```

```
subscriptionId == "{subscriptionId1}"
|project name, id
```

Enable fetching Resource IDs for all CRG resources shared with subscription ID 1:

Kusto

```
resources
|where type == "microsoft.compute/capacityreservationgroups"
|where properties["sharingProfile"] contains "{subscriptionId}"
|project name, id
```

Last updated on 04/20/2026

Associate a VM to a capacity reservation group

Applies to: ✔ Windows Virtual Machines ✔ Linux Virtual Machines

You can use capacity reservation groups with new or existing virtual machines (VMs). To learn more about capacity reservations, see the Capacity reservation overview.

Associate a new virtual machine

To associate a new virtual machine to the capacity reservation group, the group must be explicitly referenced as a property of the VM. This reference protects the matching reservation in the group for applications and workloads intended to use it.

API

To add the `capacityReservationGroup` property to a VM, construct the following `PUT` request to the `Microsoft.Compute` provider:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName}?
api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

JSON

```
{
  "location": "eastus",
  "properties": {
    "hardwareProfile": {
      "vmSize": "Standard_D2s_v3"
    },
    …
   "capacityReservation":{
    "capacityReservationGroup":{

"id":"subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers
/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}"
    }
```

```
    "storageProfile": {
    …
    },
    "osProfile": {
    …
    },
    "networkProfile": {
     …
    }
  }
}
```

Associate an existing virtual machine

Existing zonal virtual machines can simply be updated with Capacity Reservation Group property without the need of deallocation and it will automatically consume the capacity reservation. Existing regional virtual machines must be reallocated.

Regional Virtual Machine

For the initial release of a capacity reservation, a virtual machine must be allocated to a capacity reservation:

1. Follow guidance to create a capacity reservation group and capacity reservation, if necessary. Or increment the quantity of an existing capacity reservation so there's unused reserved capacity.
2. Deallocate the virtual machine.
3. Update the capacity reservation group property on the VM.
4. Restart the VM.

Follow the steps to associate the virtual machine to a capacity reservation group.

API

1. Deallocate the virtual machine:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourcegroupname}/providers/Microsoft.Compute/virtualMachines/{VirtualMachi
neName}/deallocate?api-version=2021-04-01
```

2. Add the `capacityReservationGroup` property to the VM. Construct the following `PUT` request to `Microsoft.Compute` provider:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachi
neName}?api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

JSON

```
{
"location": "eastus",
"properties": {
    "capacityReservation": {
        "capacityReservationGroup": {
            "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/provider
s/Microsoft.Compute/capacityReservationGroups/{capacityReservationGroupName}
"
        }
    }
}
}
```

Zonal Virtual Machine

A zonal virtual machine can be allocated to a capacity reservation without the need of reallocation. If you have capacity in an existing capacity reservation group, you can add an existing zonal virtual machine to the capacity reservation group and update the VM to use a matching capacity reservation in the capacity reservation group.

> **ⓘ Important**
>
> The feature to associate an existing zonal VM to a Capacity Reservation Group without the need to deallocate, is currently in **Preview**. See the Preview Terms of Use for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

1. Follow guidance to create a capacity reservation group and capacity reservation, if necessary. Or increment the quantity of an existing capacity reservation so there's unused reserved capacity.
2. Update the capacity reservation group property on the VM.

Follow the steps to associate the virtual machine to a capacity reservation group.

API

Add the `capacityReservationGroup` property to the VM. Construct the following `PUT` request to `Microsoft.Compute` provider:

rest

```
    PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName}?
api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

JSON

```
    {
    "location": "eastus",
    "properties": {
        "capacityReservation": {
            "capacityReservationGroup": {
                "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Mic
rosoft.Compute/capacityReservationGroups/{capacityReservationGroupName}"
            }
        }
    }
    }
```

Secure existing zonal virtual machine using zero size reservation

Zonal virtual machines can be converted to using an On Demand Capacity Reservation without reallocation. If you do not have capacity in an existing capacity reservation group, you can start by creating a zero size matching reservation to secure your workloads. The basic process involves 3 steps:

1. Create a Capacity Reservation Group and then matching capacity reservations in each target zone with the reserved quantity set to zero. This requires no additional quota or capacity. For more information on how to create a reservation, see Create a capacity reservation.

2. Associate existing running zonal virtual machine to the capacity reservation. Set the Virtual Machine capacityReservationGroup property to the desired Capacity Reservation Group. When complete, each target capacity reservation will be overallocated. See Zonal Virtual Machine.

3. Increase the reserved quantity of each capacity reservation (CR) to match the allocated Virtual Machine (VM) count. Since each CR is already overallocated, this step requires no additional quota or capacity. For more information on how to update the reserved count, see Capacity reservation modify.

After the quantity increase, you should see the CR in a fully allocated state with all the virtual machines allocated. See View VM allocation with the Instance View.

For information on using shared capacity reservation group, see Secure existing zonal workloads using zero size reservation in Shared capacity Reservation Group.

View VM allocation with the Instance View

After the `capacityReservationGroup` property is set, an association now exists between the VM and the group. Azure automatically finds the matching capacity reservation in the group and consumes a reserved slot. The capacity reservation's Instance View reflects the new VM in the `virtualMachinesAllocated` property:

API

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resou
rceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{capacityRese
rvationGroupName}?$expand=instanceView&api-version=2021-04-01
```

JSON

```
{
   "name":"{CapacityReservationGroupName}",

"id":"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/provider
```

```
s/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}",
   "type":"Microsoft.Compute/capacityReservationGroups",
   "location":"eastus",
   "properties":{
      "capacityReservations":[
         {

"id":"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/provider
s/Microsoft.Compute/capacityReservationGroups/
{CapacityReservationGroupName}/capacityReservations/{CapacityReservationName}"
         }
      ],
      "virtualMachinesAssociated":[
         {

"id":"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/provider
s/Microsoft.Compute/virtualMachines/{myVM}"
         }
      ],
      "instanceView":{
         "capacityReservations":[
            {
               "name":"{CapacityReservationName}",
               "utilizationInfo":{
                  "virtualMachinesAllocated":[
                     {

"id":"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/provider
s/Microsoft.Compute/virtualMachines/{myVM}"
                     }
                  ]
               },
               "statuses":[
                  {
                     "code":"ProvisioningState/succeeded",
                     "level":"Info",
                     "displayStatus":"Provisioning succeeded",
                     "time":"2021-05-25T15:12:10.4165243+00:00"
                  }
               ]
            }
         ]
      }
   }
}
```

Next step

Remove a VM's association to a capacity reservation group

Last updated on 04/20/2026

Remove a VM association from a capacity reservation group

This article walks you through the steps of removing a virtual machine (VM) association to a capacity reservation group. To learn more about capacity reservations, see the Capacity reservation overview.

Because both the VM and the underlying capacity reservation logically occupy capacity, Azure imposes some constraints on this process to avoid ambiguous allocation states and unexpected errors.

There are three ways to change an association:

- Deallocate the virtual machine, change the capacity reservation group property, and, optionally, restart the VM.
- Update the reserved quantity to zero and then change the capacity reservation group property.
- Delete a VM.

Deallocate the virtual machine

The first option is to deallocate the virtual machine, change the capacity reservation group property, and, optionally, restart the VM.

API

1. Deallocate the virtual machine:

```rest
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{virtualMachineName}/deallocate?api-version=2021-04-01
```

2. Update the VM to remove the association with the capacity reservation group:

```rest
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{virtualMachineName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to `null` to remove the VM association to the group:

JSON

```
 {
"location": "eastus",
"properties": {
    "capacityReservation": {
        "capacityReservationGroup": {
            "id":null
        }
    }
}
}
```

Update the reserved quantity to zero

The second option involves updating the reserved quantity to zero and then changing the capacity reservation group property.

This option works well when the VM can't be deallocated and when a reservation is no longer needed. For example, you might create a capacity reservation to temporarily assure capacity during a large-scale deployment. After it's finished, the reservation is no longer needed.

API

1. Update the reserved quantity to zero:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/
{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{
CapacityReservationGroupName}/CapacityReservations/{CapacityReservationName
}?api-version=2021-04-01
```

In the request body, include the following parameters:

JSON

```
{
"sku":
    {
```

```
    "capacity": 0
    }
}
```

Note that the `capacity` property is set to `0`.

2. Update the VM to remove the association with the capacity reservation group.

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/
{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMac
hineName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to `null` to remove the association:

JSON

```
{
"location": "eastus",
"properties": {
    "capacityReservation": {
        "capacityReservationGroup": {
            "id":null
        }
    }
}
}
```

Delete a VM

The virtual machine deletion process will remove a VM association from a capacity reservation. A VM delete must complete before Azure removes it from the capacity reservation. Some latency can occur between the delete request and the corresponding change in capacity reservation allocation state. See Delete a VM for more information. Use Capacity Reservation Instance View to check the allocation status as needed.

Next step

Learn how to associate a scale set to a capacity reservation group

Last updated on 10/24/2025

Associate a virtual machine scale set with Flexible Orchestration to a capacity reservation group

Article • 09/09/2024

Applies to: ✔ Flexible scale sets

Azure Virtual Machine Scale Sets has two modes:

- **Uniform Orchestration**: In this mode, virtual machine scale sets use a virtual machine (VM) profile or a template to scale up to the capacity you want. Although there's some ability to manage or customize individual VM instances, Uniform Orchestration uses identical VM instances. These instances are exposed through the virtual machine scale set's VM APIs. They aren't compatible with the API commands that are standard for Azure infrastructure as a service (IaaS) VMs. Because the scale set performs all the actual VM operations, reservations are associated to the virtual machine scale set directly. After the scale set is associated to the reservation, all the subsequent VM allocations are done against the reservation.
- **Flexible Orchestration**: In this mode, you get more flexibility to manage the individual instances of virtual machine scale set VMs. They can use the standard Azure IaaS VM APIs instead of using the scale set interface. To use reservations with Flexible Orchestration mode, define both the virtual machine scale set property and the capacity reservation property on each VM.

To learn more about these modes, see Orchestration modes for Virtual Machine Scale Sets.

This content applies to the Flexible Orchestration mode. For more information about Uniform Orchestration mode, see Associate a virtual machine scale set with Uniform Orchestration to a capacity reservation group.

Associate a new virtual machine scale set to a capacity reservation group

You have two options:

- **Add to the VM profile:** If the scale set with Flexible Orchestration includes a VM profile, add the capacity reservation group property to the profile during scale set

creation. Follow the same process that's used for a scale set that uses Uniform Orchestration. For sample code, see Associate a virtual machine scale set with Uniform Orchestration to a capacity reservation group.

- **Add to the first deployed VM:** If the scale set omits a VM profile, you must add the capacity reservation group to the first VM that you deployed by using the virtual machine scale set. Follow the same process that's used to associate a VM. For sample code, see Associate a VM to a capacity reservation group.

Associate an existing virtual machine scale set to a capacity reservation group

There are two steps:

- **Add to the virtual machine scale set:** For sample code, see Associate a virtual machine scale set with Uniform Orchestration to a capacity reservation group.
- **Add to the deployed VMs:** You must add the capacity reservation group to the VMs that you deployed by using the scale set, depending on the upgrade mode. Follow the same process used to associate a VM. For sample code, see Associate a VM to a capacity reservation group.

Associate a virtual machine scale set to Uniform Orchestration to a capacity reservation group

Applies to: ✔ Uniform scale set

Azure Virtual Machine Scale Sets has two modes:

- **Uniform Orchestration**: In this mode, virtual machine scale sets use a virtual machine (VM) profile or a template to scale up to the capacity you want. Although there's some ability to manage or customize individual VM instances, Uniform Orchestration uses identical VM instances. These instances are exposed through the virtual machine scale set's VM APIs and aren't compatible with the API commands that are standard for Azure infrastructure as a service (IaaS) VMs. Because the scale set performs all the actual VM operations, reservations are associated to the virtual machine scale set directly. After the scale set is associated to the reservation, all the subsequent VM allocations are done against the reservation.
- **Flexible Orchestration**: In this mode, you get more flexibility to manage the individual virtual machine scale set VM instances. They can use the standard Azure IaaS VM APIs instead of by using the scale set interface. To use reservations with Flexible Orchestration mode, define both the virtual machine scale set property and the capacity reservation property on each VM.

To learn more about these modes, see Virtual Machine Scale Sets orchestration modes.

This content applies to the Uniform Orchestration mode. For Flexible Orchestration mode, see Associate a virtual machine scale set with Flexible Orchestration to a capacity reservation group.

Limitations of scale sets in Uniform Orchestration

- For virtual machine scale sets in Uniform Orchestration to be compatible with capacity reservation, the `singlePlacementGroup` property must be set to `False`.
- The **Static Fixed Spreading** availability option for multizone uniform scale sets isn't supported with capacity reservation. This option requires the use of five fault domains. However, the reservations only support up to three fault domains for general purpose sizes. The approach we recommend is to use the **Max Spreading** option that spreads VMs across

as many fault domains as possible within each zone. If needed, configure a custom fault domain configuration of three or less.

There are some other restrictions when you use capacity reservations. For the complete list, see the overview of capacity reservations.

Associate a new virtual machine scale set to a capacity reservation group

> **Important**
>
> Starting November 2023, virtual machine scale sets created by using PowerShell and the Azure CLI default to Flexible Orchestration mode if no orchestration mode is specified. For more information about this change and what actions you should take, see Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub.

API

To associate a new uniform virtual machine scale set to a capacity reservation group, construct the following `PUT` request to the `Microsoft.Compute` provider:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMScaleSetName}?api-version=2021-04-01
```

Add the `capacityReservationGroup` property in the `virtualMachineProfile` property:

JSON

```
{
    "name": "<VMScaleSetName>",
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMScaleSetName}",
    "type": "Microsoft.Compute/virtualMachineScaleSets",
    "location": "eastus",
    "sku": {
        "name": "Standard_D2s_v3",
        "tier": "Standard",
        "capacity": 3
},
```

```
"properties": {
    "virtualMachineProfile": {
        "capacityReservation": {
            "capacityReservationGroup":{

"id":"subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers
/Microsoft.Compute/CapacityReservationGroup/{CapacityReservationGroupName}"
            }
         },
        "osProfile": {
            …
        },
        "storageProfile": {
            …
        },
        "networkProfile": {
            …,
            "extensionProfile": {
                …
            }
        }
    }
```

Associate an existing virtual machine scale set to a capacity reservation group

Existing zonal virtual machine scale set can simply be updated with Capacity Reservation Group property without the need of deallocation. Existing regional virtual machine scale set can include similar process but must be reallocated.

Regional Virtual Machine Scale Set

To add an existing regional capacity reservation group to an existing uniform scale set:

- Stop the scale set to deallocate the VM instances.
- Update the scale set to use a matching capacity reservation group.
- Start the scale set.

This process ensures that the placement for the capacity reservations and scale set in the region are compatible.

Important notes on upgrade policies

- **Automatic upgrade**: In this mode, the scale set VM instances are automatically associated to the capacity reservation group without any further action from you. When the scale set

VMs are reallocated, they start consuming the reserved capacity.

- **Rolling upgrade**: In this mode, scale set VM instances are associated to the capacity reservation group without any further action from you. However, they're updated in batches with an optional pause time between them. When the scale set VMs are reallocated, they start consuming the reserved capacity.
- **Manual upgrade**: In this mode, nothing happens to the scale set VM instances when the virtual machine scale set is attached to a capacity reservation group. You need to update to each scale set VM by upgrading it with the latest scale set model.

API

1. Deallocate the virtual machine scale set:

rest

```
POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourcegroupname}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSc
aleSetName}/deallocate?api-version=2021-04-01
```

2. Add the `capacityReservationGroup` property to the scale set model. Construct the following `PUT` request to `Microsoft.Compute` provider:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourcegroupname}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSc
aleSetName}?api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

JSON

```
"location": "eastus",
"properties": {
    "virtualMachineProfile": {
        "capacityReservation": {
                "capacityReservationGroup": {
                    "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/provider
s/Microsoft.Compute/capacityReservationGroups/{capacityReservationGroupName}
"
                }
            }
```

```
    }
}
```

Zonal Virtual Machine Scale Set

If you have capacity in an existing capacity reservation group and you want to add an existing zonal uniform scale set to it, simply update the scale set to the capacity reservation group to use a matching capacity reservation.

> **Important**
>
> The feature to associate an existing zonal scale set to a reservation group without the need to deallocate, is currently in **Preview**. See the Preview Terms of Use for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Important notes on upgrade policies

- **Automatic upgrade**: In this mode, the scale set VM instances are automatically associated to the capacity reservation group without any further action from you. If already running, the scale set VM instances start consuming the reserved capacity. If the existing scale set VMs are in deallocated state, they start consuming the reserved capacity when reallocated.
- **Rolling upgrade**: In this mode, scale set VM instances are associated to the capacity reservation group without any further action from you. However, they're updated in batches with an optional pause time between them. If already running, the scale set VM instances start consuming the reserved capacity. If the existing scale set VMs are in deallocated state, they start consuming the reserved capacity when reallocated.
- **Manual upgrade**: In this mode, nothing happens to the scale set VM instances when the virtual machine scale set is attached to a capacity reservation group. You need to update to each scale set VM by upgrading it with the latest scale set model.

API

Add the `capacityReservationGroup` property to the scale set model. Construct the following `PUT` request to `Microsoft.Compute` provider:

```
rest
```

```
    PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resou
rcegroupname}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMScaleSetName
}?api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

JSON

```
    "location": "eastus",
    "properties": {
        "virtualMachineProfile": {
             "capacityReservation": {
                      "capacityReservationGroup": {
                            "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Mic
rosoft.Compute/capacityReservationGroups/{capacityReservationGroupName}"
                      }
                }
        }
    }
```

Secure existing zonal virtual machine scale sets using zero size reservation

Zonally deployed virtual machines scale sets can be converted to using an On Demand Capacity Reservation without reallocation. If you do not have capacity in an existing capacity reservation group, you can start by creating a zero size matching reservation to secure your workloads. The basic process involves 3 steps:

1. Create a Capacity Reservation Group and then matching capacity reservations in each target zone with the reserved quantity set to zero. This requires no additional quota or capacity. For more information on how to create a reservation, see Create a capacity reservation.

2. Associate existing running zonal virtual machine scale set to the capacity reservation. Set the Virtual Machine Scale Set (VMSS) capacityReservationGroup property to the desired Capacity Reservation Group, then execute a model update on the VMSS (VMSS uniform) or update each member VM with the capacityReservationGroup property (VMSS Flex). When complete, each target capacity reservation will be overallocated See Zonal Virtual Machine Scale Set

3. Increase the reserved quantity of each capacity reservation (CR) to match the allocated Virtual Machine (VM) count. Since each CR is already overallocated, this step requires no

additional quota or capacity. For more information on how to update the reserved count, see Capacity reservation modify

After the quantity increase, you should see the CR in a fully allocated state with all the VMSS virtual machines allocated. See View VM allocation with the Instance View.

For information on using shared capacity reservation group, see Secure existing zonal workloads using zero size reservation in Shared capacity Reservation Group.

Region and availability zone considerations

You can create virtual machine scale sets regionally or in one or more availability zones to help protect them from datacenter-level failure. To learn more about multizonal virtual machine scale sets, see Virtual machine scale sets that use availability zones.

> **Important**
>
> The location (region and availability zones) of the virtual machine scale set and the capacity reservation group must match for the association to succeed. For a regional scale set, the region must match between the scale set and the capacity reservation group. For a zonal scale set, both the regions and the zones must match between the scale set and the capacity reservation group.

When a scale set is spread across multiple zones, it always attempts to deploy evenly across the included availability zones. Because of that even deployment, a capacity reservation group should always have the same quantity of reserved VMs in each zone. As an illustration of why this even deployment is important, consider the following example.

In this example, each zone has a different quantity reserved. Let's say that the virtual machine scale set scales out to 75 instances. Because a scale set always attempts to deploy evenly across zones, the VM distribution should look like this example:

Expand table

Zone	Quantity reserved	Number of scale set VMs in each zone	Unused quantity reserved	Overallocated
1	40	25	15	0
2	20	25	0	5

Zone	Quantity reserved	Number of scale set VMs in each zone	Unused quantity reserved	Overallocated
3	15	25	0	10

In this case, the scale set incurs extra cost for 15 unused instances in Zone 1. The scale-out is also relying on 5 VMs in Zone 2 and 10 VMs in Zone 3 that aren't protected by capacity reservation. If each zone had 25 capacity instances reserved, then all 75 VMs would be protected by capacity reservation and the deployment wouldn't incur any extra cost for unused instances.

Because the reservations can be overallocated, the scale set can continue to scale normally beyond the limits of the reservation. The only difference is that the VMs allocated above the quantity reserved aren't covered by capacity reservation service-level agreement. To learn more, see Overallocate capacity reservation.

Next step

Learn how to remove a scale set association from a capacity reservation

Last updated on 04/20/2026

Remove a virtual machine scale set association from a capacity reservation group

Applies to: ✔ Uniform scale set ✔ Flexible scale sets

This article walks you through removing a virtual machine scale set association from a capacity reservation group. To learn more about capacity reservations, see the overview of capacity reservations.

Because both the virtual machine (VM) and the underlying capacity reservation logically occupy capacity, Azure imposes some constraints on this process to avoid ambiguous allocation states and unexpected errors.

There are three ways to change an association:

- Deallocate the virtual machine scale set, change the capacity reservation group property at the scale set level, and then update the underlying VMs.
- Update the reserved quantity to zero and then change the capacity reservation group property.
- Delete the virtual machine scale set

Deallocate the virtual machine scale set

The first option is to deallocate the virtual machine scale set, change the capacity reservation group property at the scale set level, and then update the underlying VMs.

For more information about automatic, rolling, and manual upgrades, see Upgrade policies.

API

1. Deallocate the virtual machine scale set:

   rest

   ```
   POST
   https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/
   {resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VM
   ScaleSetName}/deallocate?api-version=2021-04-01
   ```

2. Update the virtual machine scale set to remove the association with the capacity reservation group:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/
{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VM
ScaleSetName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to `null` to remove the virtual machine scale set association to the group:

JSON

```
{
"location": "eastus",
"properties": {
    "virtualMachineProfile": {
        "capacityReservation": {
            "capacityReservationGroup":{
                "id":null
            }
        }
    }
}
}
```

Update the reserved quantity to zero

The second option involves updating the reserved quantity to zero and then changing the capacity reservation group property.

This option works well when the scale set can't be deallocated and when a reservation is no longer needed. For example, you might create a capacity reservation to temporarily assure capacity during a large-scale deployment. After deployment is finished, the reservation is no longer needed.

For more information about automatic, rolling, and manual upgrades, see Upgrade policies.

API

1. Update the reserved quantity to zero:

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/
```

```
{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{
CapacityReservationGroupName}/CapacityReservations/{CapacityReservationName
}?api-version=2021-04-01
```

In the request body, include the following parameters:

JSON

```
{
"sku":
    {
    "capacity": 0
    }
}
```

Note that the `capacity` property is set to `0`.

2. Update the virtual machine scale set to remove the association with the capacity reservation group.

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/
{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VM
ScaleSetName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to `null` to remove the association:

JSON

```
{
"location": "eastus",
"properties": {
    "virtualMachineProfile": {
        "capacityReservation": {
            "capacityReservationGroup":{
                "id":null
            }
        }
    }
}
}
```

Delete the virtual machine scale set

Deletion process of a scale set will remove its association from a capacity reservation. The delete request must complete before Azure removes it from the capacity reservation. Some latency can occur between the delete request and the corresponding change in capacity reservation allocation state. See Delete a VM for more information. Use Capacity Reservation Instance View to check the allocation status as needed.

Upgrade policies

- **Automatic upgrade**: In this mode, the scale set VM instances are automatically dissociated from the capacity reservation group without any further action from you.
- **Rolling upgrade**: In this mode, the scale set VM instances are dissociated from the capacity reservation group without any further action from you. However, they're updated in batches with an optional pause time between them.
- **Manual upgrade**: In this mode, nothing happens to the scale set VM instances when the virtual machine scale set is updated. You need to individually remove each scale set VM by upgrading it with the latest scale set model.

Create a complete Linux virtual machine with the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs

To quickly create a virtual machine (VM) in Azure, you can use a single Azure CLI command that uses default values to create any required supporting resources. Resources such as a virtual network, public IP address, and network security group rules are automatically created. For more control of your environment in production use, you may create these resources ahead of time and then add your VMs to them. This article guides you through how to create a VM and each of the supporting resources one by one.

Make sure that you have installed the latest Azure CLI and logged to an Azure account in with az login.

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myVnet*, and *myVM*.

Create resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine and supporting virtual network resources. Create the resource group with az group create. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

By default, the output of Azure CLI commands is in JSON (JavaScript Object Notation). To change the default output to a list or table, for example, use az config set core.output=table. You can also add `--output` to any command for a one time change in output format. The following example shows the JSON output from the `az group create` command:

JSON

```
{
  "id": "/subscriptions/guid/resourceGroups/myResourceGroup",
  "location": "eastus",
  "name": "myResourceGroup",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null
}
```

Create a virtual network and subnet

Next you create a virtual network in Azure and a subnet in to which you can create your VMs. Use az network vnet create to create a virtual network named *myVnet* with the *192.168.0.0/16* address prefix. You also add a subnet named *mySubnet* with the address prefix of *192.168.1.0/24*:

Azure CLI

```
az network vnet create \
    --resource-group myResourceGroup \
    --name myVnet \
    --address-prefix 192.168.0.0/16 \
    --subnet-name mySubnet \
    --subnet-prefix 192.168.1.0/24
```

The output shows the subnet is logically created inside the virtual network:

JSON

```
{
  "addressSpace": {
    "addressPrefixes": [
      "192.168.0.0/16"
    ]
  },
  "dhcpOptions": {
    "dnsServers": []
  },
  "etag": "W/\"e95496fc-f417-426e-a4d8-c9e4d27fc2ee\"",
  "id":
"/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Netw
ork/virtualNetworks/myVnet",
  "location": "eastus",
  "name": "myVnet",
  "provisioningState": "Succeeded",
  "resourceGroup": "myResourceGroup",
  "resourceGuid": "ed62fd03-e9de-430b-84df-8a3b87cacdbb",
```

```
  "subnets": [
    {
      "addressPrefix": "192.168.1.0/24",
      "etag": "W/\"e95496fc-f417-426e-a4d8-c9e4d27fc2ee\"",
      "id":
"/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Netw
ork/virtualNetworks/myVnet/subnets/mySubnet",
      "ipConfigurations": null,
      "name": "mySubnet",
      "networkSecurityGroup": null,
      "provisioningState": "Succeeded",
      "resourceGroup": "myResourceGroup",
      "resourceNavigationLinks": null,
      "routeTable": null
    }
  ],
  "tags": {},
  "type": "Microsoft.Network/virtualNetworks",
  "virtualNetworkPeerings": null
}
```

Create a public IP address

Now let's create a public IP address with az network public-ip create. This public IP address enables you to connect to your VMs from the Internet. Because the default address is dynamic, create a named DNS entry with the `--domain-name-label` parameter. The following example creates a public IP named *myPublicIP* with the DNS name of *mypublicdns*. Because the DNS name must be unique, provide your own unique DNS name:

Azure CLI

```
az network public-ip create \
    --resource-group myResourceGroup \
    --name myPublicIP \
    --dns-name mypublicdns
```

Output:

JSON

```
{
  "publicIp": {
    "dnsSettings": {
      "domainNameLabel": "mypublicdns",
      "fqdn": "mypublicdns.eastus.cloudapp.azure.com",
      "reverseFqdn": null
    },
```

```
    "etag": "W/\"2632aa72-3d2d-4529-b38e-b622b4202925\"",
    "id":
"/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Netw
ork/publicIPAddresses/myPublicIP",
    "idleTimeoutInMinutes": 4,
    "ipAddress": null,
    "ipConfiguration": null,
    "location": "eastus",
    "name": "myPublicIP",
    "provisioningState": "Succeeded",
    "publicIpAddressVersion": "IPv4",
    "publicIpAllocationMethod": "Dynamic",
    "resourceGroup": "myResourceGroup",
    "resourceGuid": "4c65de38-71f5-4684-be10-75e605b3e41f",
    "tags": null,
    "type": "Microsoft.Network/publicIPAddresses"
  }
}
```

Create a network security group

To control the flow of traffic in and out of your VMs, apply a network security group to a virtual NIC or subnet. The following example uses az network nsg create to create a network security group named *myNetworkSecurityGroup*:

Azure CLI

```
az network nsg create \
    --resource-group myResourceGroup \
    --name myNetworkSecurityGroup
```

You define rules that allow or deny specific traffic. To allow inbound connections on port 22 (to enable SSH access, create an inbound rule with az network nsg rule create. The following example creates a rule named *myNetworkSecurityGroupRuleSSH*:

Azure CLI

```
az network nsg rule create \
    --resource-group myResourceGroup \
    --nsg-name myNetworkSecurityGroup \
    --name myNetworkSecurityGroupRuleSSH \
    --protocol tcp \
    --priority 1000 \
    --destination-port-range 22 \
    --access allow
```

To allow inbound connections on port 80 (for web traffic), add another network security group rule. The following example creates a rule named *myNetworkSecurityGroupRuleHTTP*:

Azure CLI

```
az network nsg rule create \
    --resource-group myResourceGroup \
    --nsg-name myNetworkSecurityGroup \
    --name myNetworkSecurityGroupRuleWeb \
    --protocol tcp \
    --priority 1001 \
    --destination-port-range 80 \
    --access allow
```

Examine the network security group and rules with az network nsg show:

Azure CLI

```
az network nsg show --resource-group myResourceGroup --name
myNetworkSecurityGroup
```

Output:

JSON

```
{
  "defaultSecurityRules": [
    {
      "access": "Allow",
      "description": "Allow inbound traffic from all VMs in VNET",
      "destinationAddressPrefix": "VirtualNetwork",

```

Create a virtual NIC

Virtual network interface cards (NICs) are programmatically available because you can apply rules to their use. Depending on the VM size, you can attach multiple virtual NICs to a VM. In the following az network nic create command, you create a NIC named *myNic* and associate it with your network security group. The public IP address *myPublicIP* is also associated with the virtual NIC.

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic \
    --vnet-name myVnet \
    --subnet mySubnet \
    --public-ip-address myPublicIP \
    --network-security-group myNetworkSecurityGroup
```

Output:

JSON

```
{
  "NewNIC": {
    "dnsSettings": {
      "appliedDnsServers": [],
      "dnsServers": [],
      "internalDnsNameLabel": null,
      "internalDomainNameSuffix":
"brqlt10lvoxedgkeuomc4pm5tb.bx.internal.cloudapp.net",
      "internalFqdn": null
    },

    "virtualMachine": null
```

```
  }
}
```

Create an availability set

Availability sets help spread your VMs across fault domains and update domains. Even though you only create one VM right now, it's best practice to use availability sets to make it easier to expand in the future.

Fault domains define a grouping of virtual machines that share a common power source and network switch. By default, the virtual machines that are configured within your availability set are separated across up to three fault domains. A hardware issue in one of these fault domains does not affect every VM that is running your app.

Update domains indicate groups of virtual machines and underlying physical hardware that can be rebooted at the same time. During planned maintenance, the order in which update domains are rebooted might not be sequential, but only one update domain is rebooted at a time.

Azure automatically distributes VMs across the fault and update domains when placing them in an availability set. For more information, see managing the availability of VMs.

Create an availability set for your VM with az vm availability-set create. The following example creates an availability set named *myAvailabilitySet*:

Azure CLI

```
az vm availability-set create \
    --resource-group myResourceGroup \
    --name myAvailabilitySet
```

The output notes fault domains and update domains:

JSON

```
{
  "id":
"/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Comp
ute/availabilitySets/myAvailabilitySet",
  "location": "eastus",
  "managed": null,
  "name": "myAvailabilitySet",
  "platformFaultDomainCount": 2,
  "platformUpdateDomainCount": 5,
  "resourceGroup": "myResourceGroup",
  "sku": {
```

```
    "capacity": null,
    "managed": true,
    "tier": null
  },
  "statuses": null,
  "tags": {},
  "type": "Microsoft.Compute/availabilitySets",
  "virtualMachines": []
}
```

Create a VM

You've created the network resources to support Internet-accessible VMs. Now create a VM and secure it with an SSH key. In this example, let's create an Ubuntu VM based on the most recent LTS. You can find additional images with az vm image list, as described in finding Azure VM images.

Specify an SSH key to use for authentication. If you do not have an SSH public key pair, you can create them or use the `--generate-ssh-keys` parameter to create them for you. If you already have a key pair, this parameter uses existing keys in `~/.ssh`.

Create the VM by bringing all the resources and information together with the az vm create command. The following example creates a VM named *myVM*:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --location eastus \
    --availability-set myAvailabilitySet \
    --nics myNic \
    --image Ubuntu2204 \
    --admin-username azureuser \
    --generate-ssh-keys
```

SSH to your VM with the DNS entry you provided when you created the public IP address. This `fqdn` is shown in the output as you create your VM:

JSON

```
{
  "fqdns": "mypublicdns.eastus.cloudapp.azure.com",
  "id":
"/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Comp
ute/virtualMachines/myVM",
  "location": "eastus",
```

```
  "macAddress": "00-0D-3A-13-71-C8",
  "powerState": "VM running",
  "privateIpAddress": "192.168.1.5",
  "publicIpAddress": "13.90.94.252",
  "resourceGroup": "myResourceGroup"
}
```

Bash

```
ssh azureuser@mypublicdns.eastus.cloudapp.azure.com
```

Output:

Bash

```
The authenticity of host 'mypublicdns.eastus.cloudapp.azure.com
(13.90.94.252)' can't be established.

Welcome to Ubuntu 16.04.3 LTS (GNU/Linux 4.11.0-1016-azure x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:     https://landscape.canonical.com
 * Support:        https://ubuntu.com/advantage

  Get cloud support with Ubuntu Advantage Cloud Guest:
    https://www.ubuntu.com/business/services/cloud

0 packages can be updated.
0 updates are security updates.

The programs included with the Ubuntu system are free software;
the exact distribution terms for each program are described in the
individual files in /usr/share/doc/*/copyright.

Ubuntu comes with ABSOLUTELY NO WARRANTY, to the extent permitted by
applicable law.

To run a command as administrator (user "root"), use "sudo <command>".
See "man sudo_root" for details.

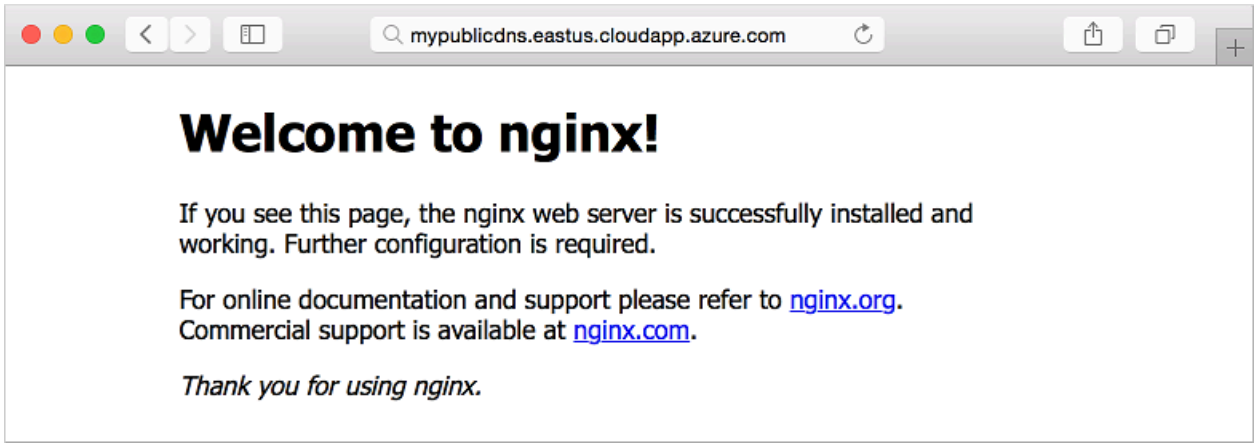
azureuser@myVM:~$
```

You can install NGINX and see the traffic flow to the VM. Install NGINX as follows:

Bash

```
sudo apt-get install -y nginx
```

To see the default NGINX site in action, open your web browser and enter your FQDN:



Export as a template

What if you now want to create an additional development environment with the same parameters, or a production environment that matches it? Resource Manager uses JSON templates that define all the parameters for your environment. You build out entire environments by referencing this JSON template. You can build JSON templates manually or export an existing environment to create the JSON template for you. Use az group export to export your resource group as follows:

Azure CLI

```
az group export --name myResourceGroup > myResourceGroup.json
```

This command creates the `myResourceGroup.json` file in your current working directory. When you create an environment from this template, you are prompted for all the resource names. You can populate these names in your template file by adding the `--include-parameter-default-value` parameter to the `az group export` command. Edit your JSON template to specify the resource names, or create a parameters.json file that specifies the resource names.

To create an environment from your template, use az deployment group create as follows:

Azure CLI

```
az deployment group create \
    --resource-group myNewResourceGroup \
```

```
    --template-file myResourceGroup.json
```

You might want to read more about how to deploy from templates. Learn about how to incrementally update environments, use the parameters file, and access templates from a single storage location.

Next steps

Now you're ready to begin working with multiple networking components and VMs. You can use this sample environment to build out your application by using the core components introduced here.

How to create a Linux virtual machine with Azure Resource Manager templates

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Learn how to create a Linux virtual machine (VM) by using an Azure Resource Manager template and the Azure CLI from the Azure Cloud shell. To create a Windows virtual machine, see Create a Windows virtual machine from a Resource Manager template.

An alternative is to deploy the template from the Azure portal. To open the template in the portal, select the **Deploy to Azure** button.

Templates overview

Azure Resource Manager templates are JSON files that define the infrastructure and configuration of your Azure solution. By using a template, you can repeatedly deploy your solution throughout its lifecycle and have confidence your resources are deployed in a consistent state. To learn more about the format of the template and how you construct it, see Quickstart: Create and deploy Azure Resource Manager templates by using the Azure portal. To view the JSON syntax for resources types, see Define resources in Azure Resource Manager templates.

Quickstart template

> **Note**
>
> The provided template creates an Azure Generation 2 VM by default.

> **Note**
>
> Only SSH authentication is enabled by default when using the quickstart template. When prompted, provide the value of your own SSH public key, such as the contents of *~/.ssh/id_rsa.pub*.

If you don't have an SSH key pair, create and use an SSH key pair for Linux VMs in Azure.

Click **Copy** to add the quickstart template to your clipboard:

JSON

```

            {
              "id": "[resourceId('Microsoft.Network/networkInterfaces',
variables('networkInterfaceName'))]"
            }
          ]
        }
      }
    }
  ]
}
```

You can also download or create a template and specify the local path with the `--template-file` parameter.

Create a quickstart template VM with Azure CLI

After acquiring or creating a quickstart template, create a VM with it using the Azure CLI.

The following command requests several pieces of input from the user. These include:

- Name of the Resource Group (resourceGroupName)
- Location of the Azure datacenter that hosts the VM (location)
- A name for resources related to the VM (projectName)
- Username for the administrator user (username)
- A public SSH key for accessing the VM's terminal (key)

Creating an Azure virtual machine requires a resource group. Quickstart templates include resource group creation as part of the process.

To run the CLI script, click **Open Cloudshell**. Once you have access to the Azure Cloudshell, click **Copy** to copy the command, right-click the shell, then select **Paste**.

Azure CLI

```
echo "Enter the Resource Group name:" &&
read resourceGroupName &&
echo "Enter the location (i.e. centralus):" &&
read location &&
echo "Enter the project name (used for generating resource names):" &&
read projectName &&
```

```
echo "Enter the administrator username:" &&
read username &&
echo "Enter the SSH public key:" &&
read key &&
az group create --name $resourceGroupName --location "$location" &&
az deployment group create --resource-group $resourceGroupName --template-
uri https://raw.githubusercontent.com/azure/azure-quickstart-
templates/master/quickstarts/microsoft.compute/vm-sshkey/azuredeploy.json --
parameters projectName=$projectName adminUsername=$username
adminPublicKey="$key" &&
az vm show --resource-group $resourceGroupName --name "$projectName-vm" --
show-details --query publicIps --output tsv
```

The last line in the command shows the public IP address of the newly created VM. You need the public IP address to connect to the virtual machine.

Connect to virtual machine

You can then SSH to your VM as normal. Provide your own public IP address from the preceding command:

Bash

```
ssh <adminUsername>@<ipAddress>
```

Other templates

In this example, you created a basic Linux VM. For more Resource Manager templates that include application frameworks or create more complex environments, browse the Azure Quickstart Templates.

To learn more about creating templates, view the JSON syntax and properties for the resources types you deployed:

- Microsoft.Network/networkSecurityGroups
- Microsoft.Network/publicIPAddresses
- Microsoft.Network/virtualNetworks
- Microsoft.Network/networkInterfaces
- Microsoft.Compute/virtualMachines

Next steps

- To learn how to develop Resource Manager templates, see Azure Resource Manager documentation.
- To see the Azure virtual machine schemas, see Azure template reference.
- To see more virtual machine template samples, see Azure Quickstart templates.

Virtual Machines - Create Or Update

Service: Compute
API Version: 2025-11-01

The operation to create or update a virtual machine. Please note some properties can be set only during virtual machine creation.

HTTP

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}?api-version=2025-11-01
```

URI Parameters

Expand table

Name	In	Required	Type	Description
`resourceGroupName`	path	True	string minLength: 1 maxLength: 90	The name of the resource group. The name is case insensitive.
`subscriptionId`	path	True	string minLength: 1	The ID of the target subscription.
`vmName`	path	True	string	The name of the virtual machine.
`api-version`	query	True	string minLength: 1	The API version to use for this operation.

Request Header

Expand table

Name	Required	Type	Description
If-Match		string	The ETag of the transformation. Omit this value to always overwrite the current resource. Specify the last-seen ETag value to prevent accidentally overwriting concurrent changes.
If-None-Match		string	Set to '*' to allow a new record set to be created, but to prevent updating an existing record set. Other values will result in error from server as they are not supported.

Request Body

Expand table

Name	Required	Type	Description
location	True	string	The geo-location where the resource lives
extendedLocation		Extended Location	The extended location of the Virtual Machine.
identity		Virtual Machine Identity	The identity of the virtual machine, if configured.
placement		Placement	Placement section specifies the user-defined constraints for virtual machine hardware placement. This property cannot be changed once VM is provisioned. Minimum api-version: 2024-11-01.

plan	Plan	Specifies information about the marketplace image used to create the virtual machine. This element is only used for marketplace images. Before you can use a marketplace image from an API, you must enable the image for programmatic use. In the Azure portal, find the marketplace image that you want to use and then click **Want to deploy programmatically, Get Started ->**. Enter any required information and then click **Save**.
properties.additionalCapabilities	Additional Capabilities	Specifies additional capabilities enabled or disabled on the virtual machine.
properties.applicationProfile	Application Profile	Specifies the gallery applications that should be made available to the VM/VMSS.
properties.availabilitySet	Sub Resource	Specifies information about the availability set that the virtual machine should be assigned to. Virtual machines specified in the same availability set are allocated to different nodes to maximize availability. For more information about availability sets, see Availability sets overview. For more information on Azure planned maintenance, see Maintenance and updates for Virtual Machines in Azure. Currently, a VM can only be added to availability set at creation time. The availability set to which the VM is being added should be under the same resource group as the availability set resource. An existing VM cannot be added to an availability set. This property cannot exist along with a non-null properties.virtualMachineScaleSet reference.
properties.billingProfile	Billing Profile	Specifies the billing related details of a Azure Spot virtual machine. Minimum api-version: 2019-03-01.
properties.capacityReservation	Capacity Reservation Profile	Specifies information about the capacity reservation that is used to allocate virtual machine. Minimum api-version: 2021-04-01.
properties.diagnosticsProfile	Diagnostics Profile	Specifies the boot diagnostic settings state. Minimum api-version: 2015-06-15.
properties.evictionPolicy	Virtual Machine Eviction PolicyTypes	Specifies the eviction policy for the Azure Spot virtual machine and Azure Spot scale set. For Azure Spot virtual machines, both 'Deallocate' and 'Delete' are supported and the minimum api-version is 2019-03-01. For Azure Spot scale sets, both 'Deallocate' and 'Delete' are supported and the minimum api-version is 2017-10-30-preview.
properties.extensionsTimeBudget	string	Specifies the time alloted for all extensions to start. The time duration should be between 15 minutes and 120 minutes (inclusive) and should be specified in ISO 8601 format. The default value is 90 minutes (PT1H30M). Minimum api-version: 2020-06-01.
properties.hardwareProfile	Hardware Profile	Specifies the hardware settings for the virtual machine.
properties.host	Sub Resource	Specifies information about the dedicated host that the virtual machine resides in. Minimum api-version: 2018-10-01.
properties.hostGroup	Sub Resource	Specifies information about the dedicated host group that the virtual machine resides in. **Note:** User cannot specify both host and hostGroup properties. Minimum api-version: 2020-06-01.

properties.licenseType	string	Specifies that the image or disk that is being used was licensed on-premises. Possible values for Windows Server operating system are: Windows_Client Windows_Server Possible values for Linux Server operating system are: RHEL_BYOS (for RHEL) SLES_BYOS (for SUSE) For more information, see Azure Hybrid Use Benefit for Windows Server Azure Hybrid Use Benefit for Linux Server Minimum api-version: 2015-06-15
properties.networkProfile	Network Profile	Specifies the network interfaces of the virtual machine.
properties.osProfile	OSProfile	Specifies the operating system settings used while creating the virtual machine. Some of the settings cannot be changed once VM is provisioned.
properties.platformFaultDomain	integer (int32)	Specifies the scale set logical fault domain into which the Virtual Machine will be created. By default, the Virtual Machine will by automatically assigned to a fault domain that best maintains balance across available fault domains. This is applicable only if the 'virtualMachineScaleSet' property of this Virtual Machine is set. The Virtual Machine Scale Set that is referenced, must have 'platformFaultDomainCount' greater than 1. This property cannot be updated once the Virtual Machine is created. Fault domain assignment can be viewed in the Virtual Machine Instance View. Minimum api-version: 2020-12-01.
properties.priority	Virtual Machine Priority Types	Specifies the priority for the virtual machine. Minimum api-version: 2019-03-01
properties.proximityPlacementGroup	Sub Resource	Specifies information about the proximity placement group that the virtual machine should be assigned to. Minimum api-version: 2018-04-01.
properties.resiliencyProfile	Resiliency Profile	Resiliency profile for the virtual machine.
properties.scheduledEventsPolicy	Scheduled Events Policy	Specifies Redeploy, Reboot and ScheduledEventsAdditionalPublishingTargets Scheduled Event related configurations for the virtual machine.
properties.scheduledEventsProfile	Scheduled Events Profile	Specifies Scheduled Event related configurations.
properties.securityProfile	Security Profile	Specifies the Security related profile settings for the virtual machine.
properties.storageProfile	Storage Profile	Specifies the storage settings for the virtual machine disks.

properties.userData	string	UserData for the VM, which must be base-64 encoded. Customer should not pass any secrets in here. Minimum api-version: 2021-03-01.
properties.virtualMachineScaleSet	Sub Resource	Specifies information about the virtual machine scale set that the virtual machine should be assigned to. Virtual machines specified in the same virtual machine scale set are allocated to different nodes to maximize availability. Currently, a VM can only be added to virtual machine scale set at creation time. An existing VM cannot be added to a virtual machine scale set. This property cannot exist along with a non-null properties.availabilitySet reference. Minimum api-version: 2019-03-01.
tags	object	Resource tags.
zones	string[]	The availability zones.

Responses

Expand table

Name	Type	Description
200 OK	Virtual Machine	Resource 'VirtualMachine' update operation succeeded
201 Created	Virtual Machine	Resource 'VirtualMachine' create operation succeeded Headers • Location: string • Retry-After: integer
Other Status Codes	CloudError	An unexpected error response.

Security

azure_auth

Azure Active Directory OAuth2 Flow.

Type: oauth2
Flow: implicit

Create a Linux vm with a patch settings patchMode and assessmentMode set to AutomaticByPlatform.
Create a platform-image vm with unmanaged os and data disks.
Create a VM from a community gallery image
Create a vm from a custom image.
Create a vm from a generalized shared image.
Create a VM from a shared gallery image
Create a vm from a specialized shared image.
Create a vm in a Virtual Machine Scale Set with customer assigned platformFaultDomain.
Create a vm in an availability set.
Create a vm with a marketplace image plan.
Create a vm with an extensions time budget.
Create a vm with Application Profile.
Create a VM with automatic zone placement
Create a vm with boot diagnostics.
Create a vm with data disks using 'Copy' and 'Restore' options.
Create a VM with Disk Controller Type
Create a vm with DiskEncryptionSet resource id in the os disk and data disk.
Create a vm with empty data disks.
Create a VM with encryption identity
Create a vm with ephemeral os disk and enableFullCaching set to true.
Create a vm with ephemeral os disk provisioning in Cache disk using placement property.
Create a vm with ephemeral os disk provisioning in Nvme disk using placement property.
Create a vm with ephemeral os disk provisioning in Resource disk using placement property.
Create a vm with ephemeral os disk.
Create a VM with FIPS 140-3 Enabled
Create a VM with HibernationEnabled
Create a vm with Host Encryption using encryptionAtHost property.
Create a vm with managed boot diagnostics.
Create a VM with network interface configuration
Create a VM with network interface configuration with public ip address dns settings
Create a vm with password authentication.
Create a vm with premium storage.
Create a VM with ProxyAgent Settings of enabled and mode.
Create a vm with resiliency profile and zone movement enabled.
Create a vm with Scheduled Events Profile
Create a VM with securityType ConfidentialVM with Customer Managed Keys
Create a VM with securityType ConfidentialVM with NonPersistedTPM securityEncryptionType
Create a VM with securityType ConfidentialVM with Platform Managed Keys

Create a vm with ssh authentication.
Create a VM with Uefi Settings of secureBoot and vTPM.
Create a VM with UserData
Create a VM with VM Size Properties
Create a Windows vm with a patch setting assessmentMode of ImageDefault.
Create a Windows vm with a patch setting patchMode of AutomaticByOS.
Create a Windows vm with a patch setting patchMode of AutomaticByPlatform and AutomaticByPlatform Settings.
Create a Windows vm with a patch setting patchMode of AutomaticByPlatform and enableHotpatching set to true.
Create a Windows vm with a patch setting patchMode of Manual.
Create a Windows vm with patch settings patchMode and assessmentMode set to AutomaticByPlatform.
Create or update a VM with capacity reservation

Create a custom-image vm from an unmanaged generalized os image.

Definitions

Expand table

Name	Description

Additional Capabilities	Enables or disables a capability on the virtual machine or virtual machine scale set.
Additional UnattendContent	Specifies additional XML formatted information that can be included in the Unattend.xml file, which is used by Windows Setup. Contents are defined by setting name, component name, and the pass in which the content is applied.
AllInstancesDown	Specifies if Scheduled Events should be auto-approved when all instances are down.
ApiEntity Reference	The API entity reference.
ApiError	Api error.
ApiErrorBase	Api error base.
ApplicationProfile	Contains the list of gallery applications that should be made available to the VM/VMSS
AvailablePatch Summary	Describes the properties of an virtual machine instance view for available patch summary.
BillingProfile	Specifies the billing related details of a Azure Spot VM or VMSS. Minimum api-version: 2019-03-01.
BootDiagnostics	Boot Diagnostics is a debugging feature which allows you to view Console Output and Screenshot to diagnose VM status. You can easily view the output of your console log. Azure also enables you to see a screenshot of the VM from the hypervisor.
BootDiagnostics InstanceView	The instance view of a virtual machine boot diagnostics.
CachingTypes	Specifies the caching requirements. Possible values are: **None, ReadOnly, ReadWrite.** The default values are: **None for Standard storage. ReadOnly for Premium storage**
Capacity ReservationProfile	The parameters of a capacity reservation Profile.
CloudError	An error response from the Compute service.
Common.User AssignedIdentities Value	
Component Names	
createdByType	The type of identity that created the resource.
DataDisk	Describes a data disk.
DeleteOptions	Specify what happens to the network interface when the VM is deleted
DiagnosticsProfile	Specifies the boot diagnostic settings state. Minimum api-version: 2015-06-15.
DiffDiskOptions	Specifies the ephemeral disk option for operating system disk.
DiffDiskPlacement	Specifies the ephemeral disk placement for operating system disk. This property can be used by user in the request to choose the location i.e, cache disk, resource disk or nvme disk space for Ephemeral OS disk provisioning. For more information on Ephemeral OS disk size requirements, please refer Ephemeral OS disk size requirements for Windows VM at https://docs.microsoft.com/azure/virtual-machines/windows/ephemeral-os-disks#size-requirements and Linux VM at https://docs.microsoft.com/azure/virtual-machines/linux/ephemeral-os-disks#size-requirements. Minimum api-version for NvmeDisk: 2024-03-01.
DiffDiskSettings	Describes the parameters of ephemeral disk settings that can be specified for operating system disk. **Note:** The ephemeral disk settings can only be specified for managed disk.
DiskController Types	Specifies the disk controller type configured for the VM and VirtualMachineScaleSet. This property is only supported for virtual machines whose operating system disk and VM sku supports Generation 2 (https://docs.microsoft.com/en-us/azure/virtual-machines/generation-2), please check the HyperVGenerations capability returned as part of VM sku capabilities in the response of Microsoft.Compute SKUs api for the region contains V2 (https://docs.microsoft.com/rest/api/compute/resourceskus/list). For more information about Disk Controller Types supported please refer to https://aka.ms/azure-diskcontrollertypes .

DiskCreateOption Types	Specifies how the virtual machine disk should be created. Possible values are **Attach:** This value is used when you are using a specialized disk to create the virtual machine. **FromImage:** This value is used when you are using an image to create the virtual machine. If you are using a platform image, you should also use the imageReference element described above. If you are using a marketplace image, you should also use the plan element previously described. **Empty:** This value is used when creating an empty data disk. **Copy:** This value is used to create a data disk from a snapshot or another disk. **Restore:** This value is used to create a data disk from a disk restore point.
DiskDeleteOption Types	Specifies the behavior of the managed disk when the VM gets deleted, for example whether the managed disk is deleted or detached. Supported values are: **Delete.** If this value is used, the managed disk is deleted when VM gets deleted. **Detach.** If this value is used, the managed disk is retained after VM gets deleted. Minimum api-version: 2021-03-01.
DiskDetachOption Types	Specifies the detach behavior to be used while detaching a disk or which is already in the process of detachment from the virtual machine. Supported values are: **ForceDetach.** detachOption: **ForceDetach** is applicable only for managed data disks. If a previous detachment attempt of the data disk did not complete due to an unexpected failure from the virtual machine and the disk is still not released then use force-detach as a last resort option to detach the disk forcibly from the VM. All writes might not have been flushed when using this detach behavior. **This feature is still in preview**. To force-detach a data disk update toBeDetached to 'true' along with setting detachOption: 'ForceDetach'.
DiskEncryptionSet Parameters	Describes the parameter of customer managed disk encryption set resource id that can be specified for disk. **Note:** The disk encryption set resource id can only be specified for managed disk. Please refer https://aka.ms/mdssewithcmkoverview for more details.
DiskEncryption Settings	Describes a Encryption Settings for a Disk
DiskInstanceView	The instance view of the disk.
DomainName LabelScopeTypes	The Domain name label scope.The concatenation of the hashed domain name label that generated according to the policy from domain name label scope and vm index will be the domain name labels of the PublicIPAddress resources that will be created
EncryptionIdentity	Specifies the Managed Identity used by ADE to get access token for keyvault operations.
EventGridAnd ResourceGraph	Specifies eventGridAndResourceGraph related Scheduled Event related configurations.
ExtendedLocation	The complex type of the extended location.
ExtendedLocation Types	The type of the extended location.
HardwareProfile	Specifies the hardware settings for the virtual machine.
HostEndpoint Settings	Specifies particular host endpoint settings.
HyperVGeneration Type	Specifies the HyperVGeneration Type associated with a resource
ImageReference	Specifies information about the image to use. You can specify information about platform images, marketplace images, or virtual machine images. This element is required when you want to use a platform image, marketplace image, or virtual machine image, but is not used in other creation operations. NOTE: Image reference publisher and offer can only be set when you create the scale set.
InnerError	Inner error details.
InstanceView Status	Instance view status.
IPVersions	Available from Api-Version 2017-03-30 onwards, it represents whether the specific ipconfiguration is IPv4 or IPv6. Default is taken as IPv4. Possible values are: 'IPv4' and 'IPv6'.
KeyVaultKey Reference	Describes a reference to Key Vault Key
KeyVaultSecret Reference	Describes a reference to Key Vault Secret

LastPatch Installation Summary	Describes the properties of the last installed patch summary.
Linux Configuration	Specifies the Linux operating system settings on the virtual machine. For a list of supported Linux distributions, see Linux on Azure-Endorsed Distributions.
LinuxPatch AssessmentMode	Specifies the mode of VM Guest Patch Assessment for the IaaS virtual machine. Possible values are: **ImageDefault** - You control the timing of patch assessments on a virtual machine. **AutomaticByPlatform** - The platform will trigger periodic patch assessments. The property provisionVMAgent must be true.
LinuxPatch Settings	Specifies settings related to VM Guest Patching on Linux.
LinuxVMGuest PatchAutomatic ByPlatformReboot Setting	Specifies the reboot setting for all AutomaticByPlatform patch installation operations.
LinuxVMGuest PatchAutomatic ByPlatform Settings	Specifies additional settings to be applied when patch mode AutomaticByPlatform is selected in Linux patch settings.
LinuxVMGuest PatchMode	Specifies the mode of VM Guest Patching to IaaS virtual machine or virtual machines associated to virtual machine scale set with OrchestrationMode as Flexible. Possible values are: **ImageDefault** - The virtual machine's default patching configuration is used. **AutomaticByPlatform** - The virtual machine will be automatically updated by the platform. The property provisionVMAgent must be true
Maintenance OperationResult CodeTypes	The Last Maintenance Operation Result Code.
Maintenance RedeployStatus	Maintenance Operation Status.
ManagedDisk Parameters	The parameters of a managed disk.
Mode	Specifies the mode that ProxyAgent will execute on if the feature is enabled. ProxyAgent will start to audit or monitor but not enforce access control over requests to host endpoints in Audit mode, while in Enforce mode it will enforce access control. The default value is Enforce mode.
Modes	Specifies the execution mode. In Audit mode, the system acts as if it is enforcing the access control policy, including emitting access denial entries in the logs but it does not actually deny any requests to host endpoints. In Enforce mode, the system will enforce the access control and it is the recommended mode of operation.
NetworkApi Version	specifies the Microsoft.Network API version used when creating networking resources in the Network Interface Configurations
NetworkInterface AuxiliaryMode	Specifies whether the Auxiliary mode is enabled for the Network Interface resource.
NetworkInterface AuxiliarySku	Specifies whether the Auxiliary sku is enabled for the Network Interface resource.
NetworkInterface Reference	Describes a network interface reference.
NetworkProfile	Specifies the network interfaces or the networking configuration of the virtual machine.
OperatingSystem Types	This property allows you to specify the type of the OS that is included in the disk if creating a VM from a custom image. Possible values are: **Windows, Linux.**

OSDisk	Specifies information about the operating system disk used by the virtual machine. For more information about disks, see About disks and VHDs for Azure virtual machines.
OSImage NotificationProfile	
OSProfile	Specifies the operating system settings for the virtual machine. Some of the settings cannot be changed once VM is provisioned.
PassNames	
PatchOperation Status	The overall success or failure status of the operation. It remains "InProgress" until the operation completes. At that point it will become "Unknown", "Failed", "Succeeded", or "CompletedWithWarnings."
PatchSettings	Specifies settings related to VM Guest Patching on Windows.
Placement	Describes the user-defined constraints for resource hardware placement.
Plan	Specifies information about the marketplace image used to create the virtual machine. This element is only used for marketplace images. Before you can use a marketplace image from an API, you must enable the image for programmatic use. In the Azure portal, find the marketplace image that you want to use and then click **Want to deploy programmatically, Get Started ->**. Enter any required information and then click **Save**.
ProtocolTypes	Specifies the protocol of WinRM listener. Possible values are: **http, https.**
ProxyAgent Settings	Specifies ProxyAgent settings for the virtual machine or virtual machine scale set. Minimum api-version: 2023-09-01.
PublicIPAddress Sku	Describes the public IP Sku. It can only be set with OrchestrationMode as Flexible.
PublicIPAddress SkuName	Specify public IP sku name
PublicIPAddress SkuTier	Specify public IP sku tier
PublicIPAllocation Method	Specify the public IP allocation type
ResiliencyProfile	Gets resiliency solutions enabled on the VM. This includes backup or disaster recovery solutions.
ResourceIdentity Type	The type of identity used for the virtual machine. The type 'SystemAssigned, UserAssigned' includes both an implicitly created identity and a set of user assigned identities. The type 'None' will remove any identities from the virtual machine.
ScheduledEvents Additional PublishingTargets	
ScheduledEvents Policy	Specifies Redeploy, Reboot and ScheduledEventsAdditionalPublishingTargets Scheduled Event related configurations.
ScheduledEvents Profile	
SecurityEncryption Types	Specifies the EncryptionType of the managed disk. It is set to DiskWithVMGuestState for encryption of the managed disk along with VMGuestState blob, VMGuestStateOnly for encryption of just the VMGuestState blob, and NonPersistedTPM for not persisting firmware state in the VMGuestState blob.. **Note:** It can be set for only Confidential VMs.
SecurityProfile	Specifies the Security profile settings for the virtual machine or virtual machine scale set.
SecurityTypes	Specifies the VM securityType; UefiSettings are enabled only when set to TrustedLaunch or ConfidentialVM, and returns a Standard value starting API version 2025-11-01.
SettingNames	Specifies the name of the setting to which the content applies. Possible values are: FirstLogonCommands and AutoLogon.
SshConfiguration	SSH configuration for Linux based VMs running on Azure
SshPublicKey	Contains information about SSH certificate public key and the path on the Linux VM where the public key is placed.

StatusLevelTypes	The level code.
StorageAccountTypes	Specifies the storage account type for the managed disk. Managed OS disk storage account type can only be set when you create the scale set. NOTE: UltraSSD_LRS can only be used with data disks. It cannot be used with OS Disk. Standard_LRS uses Standard HDD. StandardSSD_LRS uses Standard SSD. Premium_LRS uses Premium SSD. UltraSSD_LRS uses Ultra disk. Premium_ZRS uses Premium SSD zone redundant storage. StandardSSD_ZRS uses Standard SSD zone redundant storage. For more information regarding disks supported for Windows Virtual Machines, refer to https://docs.microsoft.com/azure/virtual-machines/windows/disks-types and, for Linux Virtual Machines, refer to https://docs.microsoft.com/azure/virtual-machines/linux/disks-types
StorageAlignmentStatus	Specifies the storage alignment status for the disk.
StorageFaultDomainAlignmentType	Specifies the storage fault domain alignment type for the disk.
StorageProfile	Specifies the storage settings for the virtual machine disks.
SubResource	
systemData	Metadata pertaining to creation and last modification of the resource.
TerminateNotificationProfile	
UefiSettings	Specifies the security settings like secure boot and vTPM used while creating the virtual machine. Minimum api-version: 2020-12-01.
UserInitiatedReboot	Specifies Reboot related Scheduled Event related configurations.
UserInitiatedRedeploy	Specifies Redeploy related Scheduled Event related configurations.
VaultCertificate	Describes a single certificate reference in a Key Vault, and where the certificate should reside on the VM.
VaultSecretGroup	Describes a set of certificates which are all in the same Key Vault.
VirtualHardDisk	Describes the uri of a disk.
VirtualMachine	Describes a Virtual Machine.
VirtualMachineAgentInstanceView	The instance view of the VM Agent running on the virtual machine.
VirtualMachineEvictionPolicyTypes	Specifies the eviction policy for the Azure Spot VM/VMSS
VirtualMachineExtension	Describes a Virtual Machine Extension.
VirtualMachineExtensionHandlerInstanceView	The instance view of a virtual machine extension handler.
VirtualMachineExtensionInstanceView	The instance view of a virtual machine extension.
VirtualMachineHealthStatus	The health status of the VM.
VirtualMachineIdentity	Identity for the virtual machine.
VirtualMachineInstanceView	The instance view of a virtual machine.
VirtualMachineIpTag	Contains the IP tag associated with the public IP address.

VirtualMachine NetworkInterface Configuration	Describes a virtual machine network interface configurations.
VirtualMachine NetworkInterface DnsSettings Configuration	Describes a virtual machines network configuration's DNS settings.
VirtualMachine NetworkInterface IPConfiguration	Describes a virtual machine network profile's IP configuration.
VirtualMachine PatchStatus	The status of virtual machine patch operations.
VirtualMachine PriorityTypes	Specifies the priority for a standalone virtual machine or the virtual machines in the scale set. 'Low' enum will be deprecated in the future, please use 'Spot' as the enum to deploy Azure Spot VM/VMSS.
VirtualMachine PublicIPAddress Configuration	Describes a virtual machines IP Configuration's PublicIPAddress configuration
VirtualMachine PublicIPAddress DnsSettings Configuration	Describes a virtual machines network configuration's DNS settings.
VirtualMachine SizeTypes	Specifies the size of the virtual machine. The enum data type is currently deprecated and will be removed by December 23rd 2023. The recommended way to get the list of available sizes is using these APIs: List all available virtual machine sizes in an availability set, List all available virtual machine sizes in a region, List all available virtual machine sizes for resizing. For more information about virtual machine sizes, see Sizes for virtual machines. The available VM sizes depend on region and availability set.
VMDiskSecurity Profile	Specifies the security profile settings for the managed disk. **Note:** It can only be set for Confidential VMs.
VMGallery Application	Specifies the required information to reference a compute gallery application version
VMSizeProperties	Specifies VM Size Property settings on the virtual machine.
Windows Configuration	Specifies Windows operating system settings on the virtual machine.
WindowsPatch AssessmentMode	Specifies the mode of VM Guest patch assessment for the IaaS virtual machine. Possible values are: **ImageDefault** - You control the timing of patch assessments on a virtual machine. **AutomaticByPlatform** - The platform will trigger periodic patch assessments. The property provisionVMAgent must be true.
WindowsVMGuest PatchAutomatic ByPlatformReboot Setting	Specifies the reboot setting for all AutomaticByPlatform patch installation operations.
WindowsVMGuest PatchAutomatic ByPlatform Settings	Specifies additional settings to be applied when patch mode AutomaticByPlatform is selected in Windows patch settings.
WindowsVMGuest PatchMode	Specifies the mode of VM Guest Patching to IaaS virtual machine or virtual machines associated to virtual machine scale set with OrchestrationMode as Flexible. Possible values are: **Manual** - You control the application of patches to a virtual machine. You do this by applying patches manually inside the VM. In this mode, automatic updates are disabled; the property WindowsConfiguration.enableAutomaticUpdates must be false **AutomaticByOS** - The virtual machine will automatically be updated by the OS. The property WindowsConfiguration.enableAutomaticUpdates must be true.

	AutomaticByPlatform - the virtual machine will automatically updated by the platform. The properties provisionVMAgent and WindowsConfiguration.enableAutomaticUpdates must be true
Win RMConfiguration	Describes Windows Remote Management configuration of the VM
WinRMListener	Describes Protocol and thumbprint of Windows Remote Management listener
ZoneMovement	Describes zone movement configuration. This allows VM to be moved across availability zones during an outage.
ZonePlacement PolicyType	Specifies the policy for resource's placement in availability zone. Possible values are: **Any** (used for Virtual Machines), **Auto** (used for Virtual Machine Scale Sets) - An availability zone will be automatically picked by system as part of resource creation.

AdditionalCapabilities

Object

Enables or disables a capability on the virtual machine or virtual machine scale set.

Expand table

Name	Type	Description
enableFips1403Encryption	boolean	The flag enables the usage of FIPS 140-3 compliant cryptography on the protectedSettings of an extension. Learn more at: https://aka.ms/linuxagentfipssupport.
hibernationEnabled	boolean	The flag that enables or disables hibernation capability on the VM.
ultraSSDEnabled	boolean	The flag that enables or disables a capability to have one or more managed data disks with UltraSSD_LRS storage account type on the VM or VMSS. Managed disks with storage account type UltraSSD_LRS can be added to a virtual machine or virtual machine scale set only if this property is enabled.

AdditionalUnattendContent

Object

Specifies additional XML formatted information that can be included in the Unattend.xml file, which is used by Windows Setup. Contents are defined by setting name, component name, and the pass in which the content is applied.

Expand table

Name	Type	Description
componentName	Component Names	The component name. Currently, the only allowable value is Microsoft-Windows-Shell-Setup.
content	string	Specifies the XML formatted content that is added to the unattend.xml file for the specified path and component. The XML must be less than 4KB and must include the root element for the setting or feature that is being inserted.
passName	PassNames	The pass name. Currently, the only allowable value is OobeSystem.
settingName	SettingNames	Specifies the name of the setting to which the content applies. Possible values are: FirstLogonCommands and AutoLogon.

AllInstancesDown

Object

Specifies if Scheduled Events should be auto-approved when all instances are down.

Expand table

Name	Type	Description
automaticallyApprove	boolean	Specifies if Scheduled Events should be auto-approved when all instances are down. its default value is true

ApiEntityReference

Object

The API entity reference.

Expand table

Name	Type	Description
id	string	The ARM resource id in the form of /subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/...

ApiError

Object

Api error.

Expand table

Name	Type	Description
code	string	The error code.
details	ApiError Base[]	The Api error details
innererror	InnerError	The Api inner error
message	string	The error message.
target	string	The target of the particular error.

ApiErrorBase

Object

Api error base.

Expand table

Name	Type	Description
code	string	The error code.
message	string	The error message.
target	string	The target of the particular error.

ApplicationProfile

Object

Contains the list of gallery applications that should be made available to the VM/VMSS

Expand table

Name	Type	Description
galleryApplications	VMGallery Application[]	Specifies the gallery applications that should be made available to the VM/VMSS

AvailablePatchSummary

Object

Describes the properties of an virtual machine instance view for available patch summary.

Expand table

Name	Type	Description
assessmentActivityId	string	The activity ID of the operation that produced this result. It is used to correlate across CRP and extension logs.
criticalAndSecurityPatchCount	integer (int32)	The number of critical or security patches that have been detected as available and not yet installed.
error	ApiError	The errors that were encountered during execution of the operation. The details array contains the list of them.
lastModifiedTime	string (date-time)	The UTC timestamp when the operation began.
otherPatchCount	integer (int32)	The number of all available patches excluding critical and security.
rebootPending	boolean	The overall reboot status of the VM. It will be true when partially installed patches require a reboot to complete installation but the reboot has not yet occurred.
startTime	string (date-time)	The UTC timestamp when the operation began.
status	Patch Operation Status	The overall success or failure status of the operation. It remains "InProgress" until the operation completes. At that point it will become "Unknown", "Failed", "Succeeded", or "CompletedWithWarnings."

BillingProfile

Object

Specifies the billing related details of a Azure Spot VM or VMSS. Minimum api-version: 2019-03-01.

Expand table

Name	Type	Description
maxPrice	number (double)	Specifies the maximum price you are willing to pay for a Azure Spot VM/VMSS. This price is in US Dollars. This price will be compared with the current Azure Spot price for the VM size. Also, the prices are compared at the time of create/update of Azure Spot VM/VMSS and the operation will only succeed if the maxPrice is greater than the current Azure Spot price. The maxPrice will also be used for evicting a Azure Spot VM/VMSS if the current Azure Spot price goes beyond the maxPrice after creation of VM/VMSS. Possible values are: - Any decimal value greater than zero. Example: 0.01538 -1 – indicates default price to be up-to on-demand. You can set the maxPrice to -1 to indicate that the Azure Spot VM/VMSS should not be evicted for price reasons. Also, the default max price is -1 if it is not provided by you. Minimum api-version: 2019-03-01.

BootDiagnostics

Object

Boot Diagnostics is a debugging feature which allows you to view Console Output and Screenshot to diagnose VM status. You can easily view the output of your console log. Azure also enables you to see a screenshot of the VM from the hypervisor.

Expand table

Name	Type	Description
enabled	boolean	Whether boot diagnostics should be enabled on the Virtual Machine.
storageUri	string	Uri of the storage account to use for placing the console output and screenshot. If storageUri is not specified while enabling boot diagnostics, managed storage will be used.

BootDiagnosticsInstanceView

Object

The instance view of a virtual machine boot diagnostics.

Expand table

Name	Type	Description
consoleScreenshotBlobUri	string	The console screenshot blob URI. **Note:** This will **not** be set if boot diagnostics is currently enabled with managed storage.
serialConsoleLogBlobUri	string	The serial console log blob Uri. **Note:** This will **not** be set if boot diagnostics is currently enabled with managed storage.
status	InstanceView Status	The boot diagnostics status information for the VM. **Note:** It will be set only if there are errors encountered in enabling boot diagnostics.

CachingTypes

Enumeration

Specifies the caching requirements. Possible values are: **None, ReadOnly, ReadWrite.** The default values are: **None for Standard storage. ReadOnly for Premium storage**

Expand table

Value	Description
None	
ReadOnly	
ReadWrite	

CapacityReservationProfile

Object

The parameters of a capacity reservation Profile.

Expand table

Name	Type	Description
capacityReservationGroup	SubResource	Specifies the capacity reservation group resource id that should be used for allocating the virtual machine or scaleset vm instances provided enough capacity has been reserved. Please refer to https://aka.ms/CapacityReservation for more details.

CloudError

Object

An error response from the Compute service.

Expand table

Name	Type	Description
error	ApiError	Api error.

Common.UserAssignedIdentitiesValue

Object

Expand table

Name	Type	Description
clientId	string	The client id of user assigned identity.
principalId	string	The principal id of user assigned identity.

ComponentNames

Enumeration

Expand table

Value	Description
Microsoft-Windows-Shell-Setup	

createdByType

Enumeration

The type of identity that created the resource.

Expand table

Value	Description
User	
Application	
ManagedIdentity	
Key	

DataDisk

Object

Describes a data disk.

Expand table

Name	Type	Description
caching	CachingTypes	Specifies the caching requirements. Possible values are: **None, ReadOnly, ReadWrite.** The defaulting behavior is: **None for Standard storage. ReadOnly for Premium storage.**
createOption	DiskCreateOptionTypes	Specifies how the virtual machine disk should be created. Possible values are **Attach:** This value is used when you are using a specialized disk to create the virtual machine. **FromImage:** This value is used when you are using an image to create the virtual machine data disk. If you are using a platform image, you should also use the imageReference element described above. If you are using

		a marketplace image, you should also use the plan element previously described. **Empty:** This value is used when creating an empty data disk. **Copy:** This value is used to create a data disk from a snapshot or another disk. **Restore:** This value is used to create a data disk from a disk restore point.
deleteOption	DiskDeleteOptionTypes	Specifies whether data disk should be deleted or detached upon VM deletion. Possible values are: **Delete.** If this value is used, the data disk is deleted when VM is deleted. **Detach.** If this value is used, the data disk is retained after VM is deleted. The default value is set to **Detach**.
detachOption	DiskDetachOptionTypes	Specifies the detach behavior to be used while detaching a disk or which is already in the process of detachment from the virtual machine. Supported values: **ForceDetach.** detachOption: **ForceDetach** is applicable only for managed data disks. If a previous detachment attempt of the data disk did not complete due to an unexpected failure from the virtual machine and the disk is still not released then use force-detach as a last resort option to detach the disk forcibly from the VM. All writes might not have been flushed when using this detach behavior. **This feature is still in preview**. To force-detach a data disk update toBeDetached to 'true' along with setting detachOption: 'ForceDetach'.
diskIOPSReadWrite	integer (int64)	Specifies the Read-Write IOPS for the managed disk when StorageAccountType is UltraSSD_LRS.
diskMBpsReadWrite	integer (int64)	Specifies the bandwidth in MB per second for the managed disk when StorageAccountType is UltraSSD_LRS.
diskSizeGB	integer (int32)	Specifies the size of an empty data disk in gigabytes. This element can be used to overwrite the size of the disk in a virtual machine image. The property 'diskSizeGB' is the number of bytes x 1024^3 for the disk and the value cannot be larger than 1023.
image	VirtualHardDisk	The source user image virtual hard disk. The virtual hard disk will be copied before being attached to the virtual machine. If SourceImage is provided, the destination virtual hard drive must not exist.
lun	integer (int32)	Specifies the logical unit number of the data disk. This value is used to identify data disks within the VM and therefore must be unique for each data disk attached to a VM.
managedDisk	ManagedDiskParameters	The managed disk parameters.
name	string	The disk name.
sourceResource	ApiEntityReference	The source resource identifier. It can be a snapshot, or disk restore point from which to create a disk.
storageFaultDomainAlignment	StorageFaultDomainAlignmentType	Specifies the storage fault domain alignment type for the disk.
toBeDetached	boolean	Specifies whether the data disk is in process of detachment from the VirtualMachine/VirtualMachineScaleset
vhd	VirtualHardDisk	The virtual hard disk.
writeAcceleratorEnabled	boolean	Specifies whether writeAccelerator should be enabled or disabled on the disk.

DeleteOptions

Enumeration

Specify what happens to the network interface when the VM is deleted

Expand table

Value	Description
Delete	
Detach	

DiagnosticsProfile

Object

Specifies the boot diagnostic settings state. Minimum api-version: 2015-06-15.

Expand table

Name	Type	Description
bootDiagnostics	Boot Diagnostics	Boot Diagnostics is a debugging feature which allows you to view Console Output and Screenshot to diagnose VM status. **NOTE**: If storageUri is being specified then ensure that the storage account is in the same region and subscription as the VM. You can easily view the output of your console log. Azure also enables you to see a screenshot of the VM from the hypervisor.

DiffDiskOptions

Enumeration

Specifies the ephemeral disk option for operating system disk.

Expand table

Value	Description
Local	

DiffDiskPlacement

Enumeration

Specifies the ephemeral disk placement for operating system disk. This property can be used by user in the request to choose the location i.e, cache disk, resource disk or nvme disk space for Ephemeral OS disk provisioning. For more information on Ephemeral OS disk size requirements, please refer Ephemeral OS disk size requirements for Windows VM at https://docs.microsoft.com/azure/virtual-machines/windows/ephemeral-os-disks#size-requirements and Linux VM at https://docs.microsoft.com/azure/virtual-machines/linux/ephemeral-os-disks#size-requirements. Minimum api-version for NvmeDisk: 2024-03-01.

Expand table

Value	Description
CacheDisk	
ResourceDisk	
NvmeDisk	

DiffDiskSettings

Object

Describes the parameters of ephemeral disk settings that can be specified for operating system disk. **Note:** The ephemeral disk settings can only be specified for managed disk.

Expand table

Name	Type	Description
enableFullCaching	boolean	Specifies whether or not to enable full caching for this VM which will cache the OS disk locally on the host and make this VM more resilient to storage outages
option	DiffDisk Options	Specifies the ephemeral disk settings for operating system disk.
placement	DiffDisk Placement	Specifies the ephemeral disk placement for operating system disk. Possible values are: **CacheDisk, ResourceDisk, NvmeDisk.** The defaulting behavior is: **CacheDisk** if one is configured for the VM size otherwise **ResourceDisk** or **NvmeDisk** is used. Refer to the VM size documentation for Windows VM at https://docs.microsoft.com/azure/virtual-machines/windows/sizes and Linux VM at https://docs.microsoft.com/azure/virtual-machines/linux/sizes to check which VM sizes exposes a cache disk. Minimum api-version for NvmeDisk: 2024-03-01.

DiskControllerTypes

Enumeration

Specifies the disk controller type configured for the VM and VirtualMachineScaleSet. This property is only supported for virtual machines whose operating system disk and VM sku supports Generation 2 (https://docs.microsoft.com/en-us/azure/virtual-machines/generation-2), please check the HyperVGenerations capability returned as part of VM sku capabilities in the response of Microsoft.Compute SKUs api for the region contains V2 (https://docs.microsoft.com/rest/api/compute/resourceskus/list). For more information about Disk Controller Types supported please refer to https://aka.ms/azure-diskcontrollertypes.

Expand table

Value	Description
SCSI	
NVMe	

DiskCreateOptionTypes

Enumeration

Specifies how the virtual machine disk should be created. Possible values are **Attach:** This value is used when you are using a specialized disk to create the virtual machine. **FromImage:** This value is used when you are using an image to create the virtual machine. If you are using a platform image, you should also use the imageReference element described above. If you are using a marketplace image, you should also use the plan element previously described. **Empty:** This value is used when creating an empty data disk. **Copy:** This value is used to create a data disk from a snapshot or another disk. **Restore:** This value is used to create a data disk from a disk restore point.

Expand table

Value	Description
FromImage	
Empty	
Attach	
Copy	
Restore	

DiskDeleteOptionTypes

Enumeration

Specifies the behavior of the managed disk when the VM gets deleted, for example whether the managed disk is deleted or detached. Supported values are: **Delete.** If this value is used, the managed disk is deleted when VM gets deleted. **Detach.** If this value is used, the managed disk is retained after VM gets deleted. Minimum api-version: 2021-03-01.

Expand table

Value	Description
Delete	
Detach	

DiskDetachOptionTypes

Enumeration

Specifies the detach behavior to be used while detaching a disk or which is already in the process of detachment from the virtual machine. Supported values are: **ForceDetach.** detachOption: **ForceDetach** is applicable only for managed data disks. If a previous detachment attempt of the data disk did not complete due to an unexpected failure from the virtual machine and the disk is still not released then use force-detach as a last resort option to detach the disk forcibly from the VM. All writes might not have been flushed when using this detach behavior. **This feature is still in preview**. To force-detach a data disk update toBeDetached to 'true' along with setting detachOption: 'ForceDetach'.

Expand table

Value	Description
ForceDetach	

DiskEncryptionSetParameters

Object

Describes the parameter of customer managed disk encryption set resource id that can be specified for disk. **Note:** The disk encryption set resource id can only be specified for managed disk. Please refer https://aka.ms/mdssewithcmkoverview for more details.

Expand table

Name	Type	Description
id	string	Resource Id

DiskEncryptionSettings

Object

Describes a Encryption Settings for a Disk

Expand table

Name	Type	Description
diskEncryptionKey	KeyVault Secret Reference	Specifies the location of the disk encryption key, which is a Key Vault Secret.
enabled	boolean	Specifies whether disk encryption should be enabled on the virtual machine.
keyEncryptionKey	KeyVaultKey Reference	Specifies the location of the key encryption key in Key Vault.

DiskInstanceView

Object

The instance view of the disk.

Expand table

Name	Type	Description
encryptionSettings	Disk Encryption Settings[]	Specifies the encryption settings for the OS Disk. Minimum api-version: 2015-06-15
name	string	The disk name.
statuses	InstanceView Status[]	The resource status information.
storageAlignmentStatus	Storage Alignment Status	Specifies the storage alignment status for the disk.

DomainNameLabelScopeTypes

Enumeration

The Domain name label scope.The concatenation of the hashed domain name label that generated according to the policy from domain name label scope and vm index will be the domain name labels of the PublicIPAddress resources that will be created

Expand table

Value	Description
TenantReuse	
SubscriptionReuse	
ResourceGroupReuse	
NoReuse	

EncryptionIdentity

Object

Specifies the Managed Identity used by ADE to get access token for keyvault operations.

Expand table

Name	Type	Description
userAssignedIdentityResourceId	string	Specifies ARM Resource ID of one of the user identities associated with the VM.

EventGridAndResourceGraph

Object

Specifies eventGridAndResourceGraph related Scheduled Event related configurations.

Expand table

Name	Type	Description
enable	boolean	Specifies if event grid and resource graph is enabled for Scheduled event related configurations.
scheduledEventsApiVersion	string	Specifies the api-version to determine which Scheduled Events configuration schema version will be delivered.

ExtendedLocation

Object

The complex type of the extended location.

Expand table

Name	Type	Description
name	string	The name of the extended location.
type	Extended Location Types	The type of the extended location.

ExtendedLocationTypes

Enumeration

The type of the extended location.

Expand table

Value	Description
EdgeZone	

HardwareProfile

Object

Specifies the hardware settings for the virtual machine.

Expand table

Name	Type	Description
vmSize	Virtual MachineSize Types	Specifies the size of the virtual machine. The enum data type is currently deprecated and will be removed by December 23rd 2023. The recommended way to get the list of available sizes is using these APIs: List all available virtual machine sizes in an availability set, List all available virtual machine sizes in a region, List all available virtual machine sizes for resizing. For more information about virtual machine sizes, see Sizes for virtual machines. The available VM sizes depend on region and availability set.
vmSizeProperties	VMSize Properties	Specifies the properties for customizing the size of the virtual machine. Minimum api-version: 2021-07-01. This feature is still in preview mode and is not supported for VirtualMachineScaleSet. Please follow the instructions in VM Customization for more details.

HostEndpointSettings

Object

Specifies particular host endpoint settings.

Expand table

Name	Type	Description
inVMAccessControlProfileReferenceId	string	Specifies the InVMAccessControlProfileVersion resource id in the format of /subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Microsoft.
mode	Modes	Specifies the execution mode. In Audit mode, the system acts as if it is enforcing the access c deny any requests to host endpoints. In Enforce mode, the system will enforce the access cor

HyperVGenerationType

Enumeration

Specifies the HyperVGeneration Type associated with a resource

Expand table

Value	Description
V1	
V2	

ImageReference

Object

Specifies information about the image to use. You can specify information about platform images, marketplace images, or virtual machine images. This element is required when you want to use a platform image, marketplace image, or virtual machine image, but is not used in other creation operations. NOTE: Image reference publisher and offer can only be set when you create the scale set.

Expand table

Name	Type	Description
communityGalleryImageId	string	Specified the community gallery image unique id for vm deployment. This can be fetched from communi
exactVersion	string	Specifies in decimal numbers, the version of platform image or marketplace image used to create the virt from 'version', only if the value specified in 'version' field is 'latest'.
id	string	Resource Id
offer	string	Specifies the offer of the platform image or marketplace image used to create the virtual machine.
publisher	string	The image publisher.
sharedGalleryImageId	string	Specified the shared gallery image unique id for vm deployment. This can be fetched from shared gallery
sku	string	The image SKU.
version	string	Specifies the version of the platform image or marketplace image used to create the virtual machine. The 'latest'. Major, Minor, and Build are decimal numbers. Specify 'latest' to use the latest version of an image 'latest', the VM image will not automatically update after deploy time even if a new version becomes avai gallery image deployment, gallery image should always use 'id' field for deployment, to use 'latest' versio '/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/ga in the 'id' field without version input.

InnerError

Object

Inner error details.

Expand table

Name	Type	Description
errordetail	string	The internal error message or exception dump.
exceptiontype	string	The exception type.

InstanceViewStatus

Object

Instance view status.

Expand table

Name	Type	Description
code	string	The status code.
displayStatus	string	The short localizable label for the status.

level	StatusLevel Types	The level code.
message	string	The detailed status message, including for alerts and error messages.
time	string (date-time)	The time of the status.

IPVersions

Enumeration

Available from Api-Version 2017-03-30 onwards, it represents whether the specific ipconfiguration is IPv4 or IPv6. Default is taken as IPv4. Possible values are: 'IPv4' and 'IPv6'.

Expand table

Value	Description
IPv4	
IPv6	

KeyVaultKeyReference

Object

Describes a reference to Key Vault Key

Expand table

Name	Type	Description
keyUrl	string	The URL referencing a key encryption key in Key Vault.
sourceVault	SubResource	The relative URL of the Key Vault containing the key.

KeyVaultSecretReference

Object

Describes a reference to Key Vault Secret

Expand table

Name	Type	Description
secretUrl	string	The URL referencing a secret in a Key Vault.
sourceVault	SubResource	The relative URL of the Key Vault containing the secret.

LastPatchInstallationSummary

Object

Describes the properties of the last installed patch summary.

Expand table

Name	Type	Description
error	ApiError	The errors that were encountered during execution of the operation. The details array contains the list of them.
excludedPatchCount	integer (int32)	The number of all available patches but excluded explicitly by a customer-specified exclusion list match.
failedPatchCount	integer (int32)	The count of patches that failed installation.
installationActivityId	string	The activity ID of the operation that produced this result. It is used to correlate across CRP and extension logs.

installedPatchCount	integer (int32)	The count of patches that successfully installed.
lastModifiedTime	string (date-time)	The UTC timestamp when the operation began.
maintenanceWindowExceeded	boolean	Describes whether the operation ran out of time before it completed all its intended actions
notSelectedPatchCount	integer (int32)	The number of all available patches but not going to be installed because it didn't match a classification or inclusion list entry.
pendingPatchCount	integer (int32)	The number of all available patches expected to be installed over the course of the patch installation operation.
startTime	string (date-time)	The UTC timestamp when the operation began.
status	Patch Operation Status	The overall success or failure status of the operation. It remains "InProgress" until the operation completes. At that point it will become "Unknown", "Failed", "Succeeded", or "CompletedWithWarnings."

LinuxConfiguration

Object

Specifies the Linux operating system settings on the virtual machine. For a list of supported Linux distributions, see Linux on Azure-Endorsed Distributions.

Expand table

Name	Type	Description
disablePasswordAuthentication	boolean	Specifies whether password authentication should be disabled.
enableVMAgentPlatformUpdates	boolean	Indicates whether VMAgent Platform Updates is enabled for the Linux virtual machine. Default value is false.
patchSettings	LinuxPatch Settings	[Preview Feature] Specifies settings related to VM Guest Patching on Linux.
provisionVMAgent	boolean	Indicates whether virtual machine agent should be provisioned on the virtual machine. When this property is not specified in the request body, default behavior is to set it to true. This will ensure that VM Agent is installed on the VM so that extensions can be added to the VM later.
ssh	Ssh Configuration	Specifies the ssh key configuration for a Linux OS.

LinuxPatchAssessmentMode

Enumeration

Specifies the mode of VM Guest Patch Assessment for the IaaS virtual machine.

Possible values are:

ImageDefault - You control the timing of patch assessments on a virtual machine.

AutomaticByPlatform - The platform will trigger periodic patch assessments. The property provisionVMAgent must be true.

Expand table

Value	Description
ImageDefault	
AutomaticByPlatform	

LinuxPatchSettings

Object

Specifies settings related to VM Guest Patching on Linux.

Expand table

Name	Type	Description
assessmentMode	LinuxPatchAssessmentMode	Specifies the mode of VM Guest Patch Assessment for the IaaS virtual machine. Possible values are: **ImageDefault** - You control the timing of patch assessments on a virtual machine. **AutomaticByPlatform** - The platform will trigger periodic patch assessments. The property provisionVMAgent must be true.
automaticByPlatformSettings	LinuxVMGuestPatchAutomaticByPlatformSettings	Specifies additional settings for patch mode AutomaticByPlatform in VM Guest Patching on Linux.
patchMode	LinuxVMGuestPatchMode	Specifies the mode of VM Guest Patching to IaaS virtual machine or virtual machines associated to virtual machine scale set with OrchestrationMode as Flexible. Possible values are: **ImageDefault** - The virtual machine's default patching configuration is used. **AutomaticByPlatform** - The virtual machine will be automatically updated by the platform. The property provisionVMAgent must be true

LinuxVMGuestPatchAutomaticByPlatformRebootSetting

Enumeration

Specifies the reboot setting for all AutomaticByPlatform patch installation operations.

Expand table

Value	Description
Unknown	
IfRequired	
Never	
Always	

LinuxVMGuestPatchAutomaticByPlatformSettings

Object

Specifies additional settings to be applied when patch mode AutomaticByPlatform is selected in Linux patch settings.

Expand table

Name	Type	Description
bypassPlatformSafetyChecksOnUserSchedule	boolean	Enables customer to schedule patching without accidental upgrades
rebootSetting	Linux VMGuest Patch Automatic ByPlatform Reboot Setting	Specifies the reboot setting for all AutomaticByPlatform patch installation operations.

LinuxVMGuestPatchMode

Enumeration

Specifies the mode of VM Guest Patching to IaaS virtual machine or virtual machines associated to virtual machine scale set with OrchestrationMode as Flexible.

Possible values are:

ImageDefault - The virtual machine's default patching configuration is used.

AutomaticByPlatform - The virtual machine will be automatically updated by the platform. The property provisionVMAgent must be true

Expand table

Value	Description
ImageDefault	
AutomaticByPlatform	

MaintenanceOperationResultCodeTypes

Enumeration

The Last Maintenance Operation Result Code.

Expand table

Value	Description
None	
RetryLater	
MaintenanceAborted	
MaintenanceCompleted	

MaintenanceRedeployStatus

Object

Maintenance Operation Status.

Expand table

Name	Type	Description

isCustomerInitiatedMaintenanceAllowed	boolean	True, if customer is allowed to perform Maintenance.
lastOperationMessage	string	Message returned for the last Maintenance Operation.
lastOperationResultCode	MaintenanceOperationResultCodeTypes	The Last Maintenance Operation Result Code.
maintenanceWindowEndTime	string (date-time)	End Time for the Maintenance Window.
maintenanceWindowStartTime	string (date-time)	Start Time for the Maintenance Window.
preMaintenanceWindowEndTime	string (date-time)	End Time for the Pre Maintenance Window.
preMaintenanceWindowStartTime	string (date-time)	Start Time for the Pre Maintenance Window.

ManagedDiskParameters

Object

The parameters of a managed disk.

Expand table

Name	Type	Description
diskEncryptionSet	DiskEncryptionSetParameters	Specifies the customer managed disk encryption set resource id for the managed disk.
id	string	Resource Id
securityProfile	VMDiskSecurityProfile	Specifies the security profile for the managed disk.
storageAccountType	StorageAccountTypes	Specifies the storage account type for the managed disk. NOTE: UltraSSD_LRS can only be used with data disks, it cannot be used with OS Disk.

Mode

Enumeration

Specifies the mode that ProxyAgent will execute on if the feature is enabled. ProxyAgent will start to audit or monitor but not enforce access control over requests to host endpoints in Audit mode, while in Enforce mode it will enforce access control. The default value is Enforce mode.

Expand table

Value	Description
Audit	
Enforce	

Modes

Enumeration

Specifies the execution mode. In Audit mode, the system acts as if it is enforcing the access control policy, including emitting access denial entries in the logs but it does not actually deny any requests to host endpoints. In Enforce mode, the system will enforce the access control and it is the recommended mode of operation.

Expand table

Value	Description
Audit	
Enforce	
Disabled	

NetworkApiVersion

Enumeration

specifies the Microsoft.Network API version used when creating networking resources in the Network Interface Configurations

Expand table

Value	Description
2020-11-01	
2022-11-01	

NetworkInterfaceAuxiliaryMode

Enumeration

Specifies whether the Auxiliary mode is enabled for the Network Interface resource.

Expand table

Value	Description
None	
AcceleratedConnections	
Floating	

NetworkInterfaceAuxiliarySku

Enumeration

Specifies whether the Auxiliary sku is enabled for the Network Interface resource.

Expand table

Value	Description
None	
A1	
A2	
A4	
A8	

NetworkInterfaceReference

Object

Describes a network interface reference.

Expand table

Name	Type	Description
id	string	Resource Id

properties.deleteOption	Delete Options	Specify what happens to the network interface when the VM is deleted
properties.primary	boolean	Specifies the primary network interface in case the virtual machine has more than 1 network interface.

NetworkProfile

Object

Specifies the network interfaces or the networking configuration of the virtual machine.

Expand table

Name	Type	Description
networkApiVersion	NetworkApi Version	specifies the Microsoft.Network API version used when creating networking resources in the Network Interface Configurations
networkInterfaceConfigurations	VirtualMachine Network Interface Configuration[]	Specifies the networking configurations that will be used to create the virtual machine networking resources.
networkInterfaces	Network Interface Reference[]	Specifies the list of resource Ids for the network interfaces associated with the virtual machine.

OperatingSystemTypes

Enumeration

This property allows you to specify the type of the OS that is included in the disk if creating a VM from a custom image. Possible values are: **Windows, Linux.**

Expand table

Value	Description
Windows	
Linux	

OSDisk

Object

Specifies information about the operating system disk used by the virtual machine. For more information about disks, see About disks and VHDs for Azure virtual machines.

Expand table

Name	Type	Description
caching	CachingTypes	Specifies the caching requirements. Possible values are: **None, ReadOnly, ReadWrite.** The defaulting behavior is: **None for Standard storage. ReadOnly for Premium storage.**
createOption	DiskCreate OptionTypes	Specifies how the virtual machine disk should be created. Possible values are **Attach:** This value is used when you are using a specialized disk to create the virtual machine. **FromImage:** This value is used when you are using an image to create the virtual machine. If you are using a platform image, you should also use the imageReference element described above. If you are using a marketplace image, you should also use the plan element previously described.
deleteOption	DiskDelete OptionTypes	Specifies whether OS Disk should be deleted or detached upon VM deletion. Possible values are: **Delete.** If this value

		is used, the OS disk is deleted when VM is deleted. **Detach.** If this value is used, the os disk is retained after VM is deleted. The default value is set to **Detach**. For an ephemeral OS Disk, the default value is set to **Delete**. The user cannot change the delete option for an ephemeral OS Disk.
diffDiskSettings	DiffDisk Settings	Specifies the ephemeral Disk Settings for the operating system disk used by the virtual machine.
diskSizeGB	integer (int32)	Specifies the size of an empty data disk in gigabytes. This element can be used to overwrite the size of the disk in a virtual machine image. The property 'diskSizeGB' is the number of bytes x 1024^3 for the disk and the value cannot be larger than 1023.
encryptionSettings	Disk Encryption Settings	Specifies the encryption settings for the OS Disk. Minimum api-version: 2015-06-15.
image	VirtualHard Disk	The source user image virtual hard disk. The virtual hard disk will be copied before being attached to the virtual machine. If SourceImage is provided, the destination virtual hard drive must not exist.
managedDisk	ManagedDisk Parameters	The managed disk parameters.
name	string	The disk name.
osType	Operating SystemTypes	This property allows you to specify the type of the OS that is included in the disk if creating a VM from user-image or a specialized VHD. Possible values are: **Windows, Linux.**
storageFaultDomainAlignment	StorageFault Domain Alignment Type	Specifies the storage fault domain alignment type for the disk.
vhd	VirtualHard Disk	The virtual hard disk.
writeAcceleratorEnabled	boolean	Specifies whether writeAccelerator should be enabled or disabled on the disk.

OSImageNotificationProfile

Object

Expand table

Name	Type	Description
enable	boolean	Specifies whether the OS Image Scheduled event is enabled or disabled.
notBeforeTimeout	string	Length of time a Virtual Machine being reimaged or having its OS upgraded will have to potentially approve the OS Image Scheduled Event before the event is auto approved (timed out). The configuration is specified in ISO 8601 format, and the value must be 15 minutes (PT15M)

OSProfile

Object

Specifies the operating system settings for the virtual machine. Some of the settings cannot be changed once VM is provisioned.

Expand table

Name	Type	Description

adminPassword	string (password)	Specifies the password of the administrator account. **Minimum-length (Windows):** 8 characters **Minimum-length (Linux):** 6 characters **Max-length (Windows):** 123 characters **Max-length (Linux):** 72 characters **Complexity requirements:** 3 out of 4 conditions below need to be fulfilled Has lower characters Has upper characters Has a digit Has a special character (Regex match [\W_]) **Disallowed values:** "abc@123", "P@$$w0rd", "P@ssw0rd", "P@ssword123", "Pa$$word", "pass@word1", "Password!", "Password1", "Password22", "iloveyou!" For resetting the password, see How to reset the Remote Desktop service or its login password in a Windows VM For resetting root password, see Manage users, SSH, and check or repair disks on Azure Linux VMs using the VMAccess Extension
adminUsername	string	Specifies the name of the administrator account. This property cannot be updated after the VM is created. **Windows-only restriction:** Cannot end in "." **Disallowed values:** "administrator", "admin", "user", "user1", "test", "user2", "test1", "user3", "admin1", "1", "123", "a", "actuser", "adm", "admin2", "aspnet", "backup", "console", "david", "guest", "john", "owner", "root", "server", "sql", "support", "support_388945a0", "sys", "test2", "test3", "user4", "user5". **Minimum-length (Linux):** 1 character **Max-length (Linux):** 64 characters **Max-length (Windows):** 20 characters.
allowExtensionOperations	boolean	Specifies whether extension operations should be allowed on the virtual machine. This may only be set to False when no extensions are present on the virtual machine.
computerName	string	Specifies the host OS name of the virtual machine. This name cannot be updated after the VM is created. **Max-length (Windows):** 15 characters. **Max-length (Linux):** 64 characters. For naming conventions and restrictions see Azure infrastructure services implementation guidelines.
customData	string	Specifies a base-64 encoded string of custom data. The base-64 encoded string is decoded to a binary array that is saved as a file on the Virtual Machine. The maximum length of the binary array is 65535 bytes. **Note: Do not pass any secrets or passwords in customData property.** This property cannot be updated after the VM is created. The property 'customData' is passed to the VM to be saved as a file, for more information see Custom Data on Azure VMs. For using cloud-init for your Linux VM, see Using cloud-init to customize a Linux VM during creation.
linuxConfiguration	Linux Configuration	Specifies the Linux operating system settings on the virtual machine. For a list of supported Linux distributions, see Linux on Azure-Endorsed Distributions.
requireGuestProvisionSignal	boolean	Optional property which must either be set to True or omitted.

secrets	VaultSecret Group[]	Specifies set of certificates that should be installed onto the virtual machine. To install certificates on a virtual machine it is recommended to use the Azure Key Vault virtual machine extension for Linux or the Azure Key Vault virtual machine extension for Windows.
windowsConfiguration	Windows Configuration	Specifies Windows operating system settings on the virtual machine.

PassNames

Enumeration

Expand table

Value	Description
OobeSystem	

PatchOperationStatus

Enumeration

The overall success or failure status of the operation. It remains "InProgress" until the operation completes. At that point it will become "Unknown", "Failed", "Succeeded", or "CompletedWithWarnings."

Expand table

Value	Description
Unknown	
InProgress	
Failed	
Succeeded	
CompletedWithWarnings	

PatchSettings

Object

Specifies settings related to VM Guest Patching on Windows.

Expand table

Name	Type	Description
assessmentMode	Windows Patch Assessment Mode	Specifies the mode of VM Guest patch assessment for the IaaS virtual machine. Possible values are: **ImageDefault** - You control the timing of patch assessments on a virtual machine. **AutomaticByPlatform** - The platform will trigger periodic patch assessments. The property provisionVMAgent must be true.
automaticByPlatformSettings	Windows VMGuest Patch Automatic ByPlatform Settings	Specifies additional settings for patch mode AutomaticByPlatform in VM Guest Patching on Windows.
enableHotpatching	boolean	Enables customers to patch their Azure VMs without requiring a reboot. For enableHotpatching, the

		'provisionVMAgent' must be set to true and 'patchMode' must be set to 'AutomaticByPlatform'.
patchMode	Windows VMGuest PatchMode	Specifies the mode of VM Guest Patching to IaaS virtual machine or virtual machines associated to virtual machine scale set with OrchestrationMode as Flexible. Possible values are: **Manual** - You control the application of patches to a virtual machine. You do this by applying patches manually inside the VM. In this mode, automatic updates are disabled; the property WindowsConfiguration.enableAutomaticUpdates must be false **AutomaticByOS** - The virtual machine will automatically be updated by the OS. The property WindowsConfiguration.enableAutomaticUpdates must be true. **AutomaticByPlatform** - the virtual machine will automatically updated by the platform. The properties provisionVMAgent and WindowsConfiguration.enableAutomaticUpdates must be true

Placement

Object

Describes the user-defined constraints for resource hardware placement.

Expand table

Name	Type	Description
excludeZones	string[]	This property supplements the 'zonePlacementPolicy' property. If 'zonePlacementPolicy' is set to 'Any'/'Auto', availability zone selected by the system must not be present in the list of availability zones passed with 'excludeZones'. If 'excludeZones' is not provided, all availability zones in region will be considered for selection.
includeZones	string[]	This property supplements the 'zonePlacementPolicy' property. If 'zonePlacementPolicy' is set to 'Any'/'Auto', availability zone selected by the system must be present in the list of availability zones passed with 'includeZones'. If 'includeZones' is not provided, all availability zones in region will be considered for selection.
zonePlacementPolicy	Zone Placement PolicyType	Specifies the policy for resource's placement in availability zone. Possible values are: **Any** (used for Virtual Machines), **Auto** (used for Virtual Machine Scale Sets) - An availability zone will be automatically picked by system as part of resource creation.

Plan

Object

Specifies information about the marketplace image used to create the virtual machine. This element is only used for marketplace images. Before you can use a marketplace image from an API, you must enable the image for programmatic use. In the Azure portal, find the marketplace image that you want to use and then click **Want to deploy programmatically, Get Started ->**. Enter any required information and then click **Save**.

Expand table

Name	Type	Description
name	string	The plan ID.
product	string	Specifies the product of the image from the marketplace. This is the same value as Offer under the imageReference element.

promotionCode	string	The promotion code.
publisher	string	The publisher ID.

ProtocolTypes

Enumeration

Specifies the protocol of WinRM listener. Possible values are: **http, https.**

Expand table

Value	Description
Http	
Https	

ProxyAgentSettings

Object

Specifies ProxyAgent settings for the virtual machine or virtual machine scale set. Minimum api-version: 2023-09-01.

Expand table

Name	Type	Description
addProxyAgentExtension	boolean	Specify whether to implicitly install the ProxyAgent Extension. This option is currently applicable only for Linux Os.
enabled	boolean	Specifies whether ProxyAgent feature should be enabled on the virtual machine or virtual machine scale set.
imds	HostEndpoint Settings	Specifies the IMDS endpoint settings while creating the virtual machine or virtual machine scale set. Minimum api-version: 2024-03-01.
keyIncarnationId	integer (int32)	Increase the value of this property allows users to reset the key used for securing communication channel between guest and host.
mode	Mode	Specifies the mode that ProxyAgent will execute on. Warning: this property has been deprecated, please specify 'mode' under particular hostendpoint setting.
wireServer	HostEndpoint Settings	Specifies the Wire Server endpoint settings while creating the virtual machine or virtual machine scale set. Minimum api-version: 2024-03-01.

PublicIPAddressSku

Object

Describes the public IP Sku. It can only be set with OrchestrationMode as Flexible.

Expand table

Name	Type	Description
name	Public IPAddressSku Name	Specify public IP sku name
tier	Public IPAddressSku Tier	Specify public IP sku tier

PublicIPAddressSkuName

Enumeration

Specify public IP sku name

Expand table

Value	Description
Basic	
Standard	

PublicIPAddressSkuTier

Enumeration

Specify public IP sku tier

Expand table

Value	Description
Regional	
Global	

PublicIPAllocationMethod

Enumeration

Specify the public IP allocation type

Expand table

Value	Description
Dynamic	
Static	

ResiliencyProfile

Object

Gets resiliency solutions enabled on the VM. This includes backup or disaster recovery solutions.

Expand table

Name	Type	Description
zoneMovement	Zone Movement	Zone movement configuration.

ResourceIdentityType

Enumeration

The type of identity used for the virtual machine. The type 'SystemAssigned, UserAssigned' includes both an implicitly created identity and a set of user assigned identities. The type 'None' will remove any identities from the virtual machine.

Expand table

Value	Description
SystemAssigned	
UserAssigned	
SystemAssigned, UserAssigned	
None	

ScheduledEventsAdditionalPublishingTargets

Object

Expand table

Name	Type	Description
eventGridAndResourceGraph	EventGridAndResourceGraph	The configuration parameters used while creating eventGridAndResourceGraph Scheduled Event setting.

ScheduledEventsPolicy

Object

Specifies Redeploy, Reboot and ScheduledEventsAdditionalPublishingTargets Scheduled Event related configurations.

Expand table

Name	Type	Description
allInstancesDown	AllInstancesDown	The configuration parameters used while creating AllInstancesDown scheduled event setting creation.
scheduledEventsAdditionalPublishingTargets	ScheduledEventsAdditionalPublishingTargets	The configuration parameters used while publishing scheduledEventsAdditionalPublishingTargets.
userInitiatedReboot	UserInitiatedReboot	The configuration parameters used while creating userInitiatedReboot scheduled event setting creation.
userInitiatedRedeploy	UserInitiatedRedeploy	The configuration parameters used while creating userInitiatedRedeploy scheduled event setting creation.

ScheduledEventsProfile

Object

Expand table

Name	Type	Description
osImageNotificationProfile	OSImageNotificationProfile	Specifies OS Image Scheduled Event related configurations.
terminateNotificationProfile	TerminateNotificationProfile	Specifies Terminate Scheduled Event related configurations.

SecurityEncryptionTypes

Enumeration

Specifies the EncryptionType of the managed disk. It is set to DiskWithVMGuestState for encryption of the managed disk along with VMGuestState blob, VMGuestStateOnly for encryption of just the VMGuestState blob, and NonPersistedTPM for not persisting firmware state in the VMGuestState blob.. **Note:** It can be set for only Confidential VMs.

Expand table

Value	Description
VMGuestStateOnly	

DiskWithVMGuestState
NonPersistedTPM

SecurityProfile

Object

Specifies the Security profile settings for the virtual machine or virtual machine scale set.

Expand table

Name	Type	Description
encryptionAtHost	boolean	This property can be used by user in the request to enable or disable the Host Encryption for the virtual machine or virtual machine scale set. This will enable the encryption for all the disks including Resource/Temp disk at host itself. The default behavior is: The Encryption at host will be disabled unless this property is set to true for the resource.
encryptionIdentity	Encryption Identity	Specifies the Managed Identity used by ADE to get access token for keyvault operations.
proxyAgentSettings	ProxyAgent Settings	Specifies ProxyAgent settings while creating the virtual machine. Minimum api-version: 2023-09-01.
securityType	SecurityTypes	Specifies the SecurityType of the virtual machine. It has to be set to any specified value to enable UefiSettings. The default behavior is: UefiSettings will not be enabled unless this property is set and is not Standard. If not specified, Standard will be returned starting api version 2025-11-01.
uefiSettings	UefiSettings	Specifies the security settings like secure boot and vTPM used while creating the virtual machine. Minimum api-version: 2020-12-01.

SecurityTypes

Enumeration

Specifies the VM securityType; UefiSettings are enabled only when set to TrustedLaunch or ConfidentialVM, and returns a Standard value starting API version 2025-11-01.

Expand table

Value	Description
Standard	Indicates a VM without UEFI features such as SecureBoot or vTPM; returned as the default value when securityType is not specified.
TrustedLaunch	
ConfidentialVM	

SettingNames

Enumeration

Specifies the name of the setting to which the content applies. Possible values are: FirstLogonCommands and AutoLogon.

Expand table

Value	Description
AutoLogon	
FirstLogonCommands	

SshConfiguration

Object

SSH configuration for Linux based VMs running on Azure

Expand table

Name	Type	Description
publicKeys	SshPublicKey[]	The list of SSH public keys used to authenticate with linux based VMs.

SshPublicKey

Object

Contains information about SSH certificate public key and the path on the Linux VM where the public key is placed.

Expand table

Name	Type	Description
keyData	string	SSH public key certificate used to authenticate with the VM through ssh. The key needs to be at least 2048-bit and in ssh-rsa format. For creating ssh keys, see [Create SSH keys on Linux and Mac for Linux VMs in Azure]https://docs.microsoft.com/azure/virtual-machines/linux/create-ssh-keys-detailed).
path	string	Specifies the full path on the created VM where ssh public key is stored. If the file already exists, the specified key is appended to the file. Example: /home/user/.ssh/authorized_keys

StatusLevelTypes

Enumeration

The level code.

Expand table

Value	Description
Info	
Warning	
Error	

StorageAccountTypes

Enumeration

Specifies the storage account type for the managed disk. Managed OS disk storage account type can only be set when you create the scale set. NOTE: UltraSSD_LRS can only be used with data disks. It cannot be used with OS Disk. Standard_LRS uses Standard HDD. StandardSSD_LRS uses Standard SSD. Premium_LRS uses Premium SSD. UltraSSD_LRS uses Ultra disk. Premium_ZRS uses Premium SSD zone redundant storage. StandardSSD_ZRS uses Standard SSD zone redundant storage. For more information regarding disks supported for Windows Virtual Machines, refer to https://docs.microsoft.com/azure/virtual-machines/windows/disks-types and, for Linux Virtual Machines, refer to https://docs.microsoft.com/azure/virtual-machines/linux/disks-types

Expand table

Value	Description
Standard_LRS	
Premium_LRS	
StandardSSD_LRS	

UltraSSD_LRS
Premium_ZRS
StandardSSD_ZRS
PremiumV2_LRS

StorageAlignmentStatus

Enumeration

Specifies the storage alignment status for the disk.

Expand table

Value	Description
Unaligned	Disk does not have Storage Fault Domain to Compute Fault Domain mapping. A single Storage Fault Domain failure may impact all VMs that reference this disk profile.
Aligned	Disk has Storage Fault Domain to Compute Fault Domain mapping. Storage Fault Domain failure is contained to VMs in a single Compute Fault Domain.

StorageFaultDomainAlignmentType

Enumeration

Specifies the storage fault domain alignment type for the disk.

Expand table

Value	Description
Aligned	Disk Storage Fault Domains are mapped to Compute Fault Domains. Deployment fails if disk does not support enough Fault Domains.
BestEffortAligned	Attempt to map Storage Fault Domains to Compute Fault Domains. Disks are unaligned if disk does not support enough Fault Domains.

StorageProfile

Object

Specifies the storage settings for the virtual machine disks.

Expand table

Name	Type	Description
alignRegionalDisksToVMZone	boolean	Specifies whether the regional disks should be aligned/moved to the VM zone. This is applicable only for VMs with placement property set. Please note that this change is irreversible. Minimum api-version: 2024-11-01.
dataDisks	DataDisk[]	Specifies the parameters that are used to add a data disk to a virtual machine. For more information about disks, see About disks and VHDs for Azure virtual machines.
diskControllerType	Disk Controller Types	Specifies the disk controller type configured for the VM. **Note:** This property will be set to the default disk controller type if not specified provided virtual machine is being created with 'hyperVGeneration' set to V2 based on the capabilities of the operating system disk and VM size from the the specified minimum api version. You need to deallocate the VM before updating its disk controller type unless you are updating the VM size in the VM configuration which implicitly deallocates and reallocates the VM. Minimum api-version: 2022-08-01.
imageReference	Image Reference	Specifies information about the image to use. You can specify information about platform images, marketplace images, or virtual machine images. This element is required

		when you want to use a platform image, marketplace image, or virtual machine image, but is not used in other creation operations.
osDisk	OSDisk	Specifies information about the operating system disk used by the virtual machine. For more information about disks, see About disks and VHDs for Azure virtual machines.

SubResource

Object

Expand table

Name	Type	Description
id	string	Resource Id

systemData

Object

Metadata pertaining to creation and last modification of the resource.

Expand table

Name	Type	Description
createdAt	string (date-time)	The timestamp of resource creation (UTC).
createdBy	string	The identity that created the resource.
createdByType	createdByType	The type of identity that created the resource.
lastModifiedAt	string (date-time)	The timestamp of resource last modification (UTC)
lastModifiedBy	string	The identity that last modified the resource.
lastModifiedByType	createdByType	The type of identity that last modified the resource.

TerminateNotificationProfile

Object

Expand table

Name	Type	Description
enable	boolean	Specifies whether the Terminate Scheduled event is enabled or disabled.
notBeforeTimeout	string	Configurable length of time a Virtual Machine being deleted will have to potentially approve the Terminate Scheduled Event before the event is auto approved (timed out). The configuration must be specified in ISO 8601 format, the default value is 5 minutes (PT5M)

UefiSettings

Object

Specifies the security settings like secure boot and vTPM used while creating the virtual machine. Minimum api-version: 2020-12-01.

Expand table

Name	Type	Description
secureBootEnabled	boolean	Specifies whether secure boot should be enabled on the virtual

		machine. Minimum api-version: 2020-12-01.
vTpmEnabled	boolean	Specifies whether vTPM should be enabled on the virtual machine. Minimum api-version: 2020-12-01.

UserInitiatedReboot

Object

Specifies Reboot related Scheduled Event related configurations.

Expand table

Name	Type	Description
automaticallyApprove	boolean	Specifies Reboot Scheduled Event related configurations.

UserInitiatedRedeploy

Object

Specifies Redeploy related Scheduled Event related configurations.

Expand table

Name	Type	Description
automaticallyApprove	boolean	Specifies Redeploy Scheduled Event related configurations.

VaultCertificate

Object

Describes a single certificate reference in a Key Vault, and where the certificate should reside on the VM.

Expand table

Name	Type	Description
certificateStore	string	For Windows VMs, specifies the certificate store on the Virtual Machine to which the certificate should be added. The specified certificate store is implicitly in the LocalMachine account. For Linux VMs, the certificate file is placed under the /var/lib/waagent directory, with the file name <UppercaseThumbprint>.crt for the X509 certificate file and <UppercaseThumbprint>.prv for private key. Both of these files are .pem formatted.

certificateUrl	string	This is the URL of a certificate that has been uploaded to Key Vault as a secret. For adding a secret to the Key Vault, see Add a key or secret to the key vault. In this case, your certificate needs to be It is the Base64 encoding of the following JSON Object which is encoded in UTF-8:
		
		{
		"data":"<Base64-encoded-certificate>",
		"dataType":"pfx",
		"password":"<pfx-file-password>"
		}
		To install certificates on a virtual machine it is recommended to use the Azure Key Vault virtual machine extension for Linux or the Azure Key Vault virtual machine extension for Windows.

VaultSecretGroup

Object

Describes a set of certificates which are all in the same Key Vault.

Expand table

Name	Type	Description

sourceVault	SubResource	The relative URL of the Key Vault containing all of the certificates in VaultCertificates.
vaultCertificates	Vault Certificate[]	The list of key vault references in SourceVault which contain certificates.

VirtualHardDisk

Object

Describes the uri of a disk.

Expand table

Name	Type	Description
uri	string	Specifies the virtual hard disk's uri.

VirtualMachine

Object

Describes a Virtual Machine.

Expand table

Name	Type	Description
etag	string	Etag is property returned in Create/Update/Get response of the VM, so that customer ca
extendedLocation	Extended Location	The extended location of the Virtual Machine.
id	string	Fully qualified resource ID for the resource. Ex - /subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/{resour
identity	Virtual Machine Identity	The identity of the virtual machine, if configured.
location	string	The geo-location where the resource lives
managedBy	string	ManagedBy is set to Virtual Machine Scale Set(VMSS) flex ARM resourceID, if the VM is p internal resource group delete optimization.
name	string	The name of the resource
placement	Placement	Placement section specifies the user-defined constraints for virtual machine hardware pla provisioned. Minimum api-version: 2024-11-01.
plan	Plan	Specifies information about the marketplace image used to create the virtual machine. Tl you can use a marketplace image from an API, you must enable the image for programm image that you want to use and then click **Want to deploy programmatically, Get Starte Save**.
properties.additionalCapabilities	Additional Capabilities	Specifies additional capabilities enabled or disabled on the virtual machine.
properties.applicationProfile	Application Profile	Specifies the gallery applications that should be made available to the VM/VMSS.
properties.availabilitySet	Sub Resource	Specifies information about the availability set that the virtual machine should be assigne set are allocated to different nodes to maximize availability. For more information about information on Azure planned maintenance, see Maintenance and updates for Virtual Ma availability set at creation time. The availability set to which the VM is being added shoul set resource. An existing VM cannot be added to an availability set. This property cannot properties.virtualMachineScaleSet reference.
properties.billingProfile	Billing Profile	Specifies the billing related details of a Azure Spot virtual machine. Minimum api-version
properties.capacityReservation	Capacity Reservation Profile	Specifies information about the capacity reservation that is used to allocate virtual machi

properties.diagnosticsProfile	Diagnostics Profile	Specifies the boot diagnostic settings state. Minimum api-version: 2015-06-15.
properties.evictionPolicy	Virtual Machine Eviction PolicyTypes	Specifies the eviction policy for the Azure Spot virtual machine and Azure Spot scale set. 'Delete' are supported and the minimum api-version is 2019-03-01. For Azure Spot scale the minimum api-version is 2017-10-30-preview.
properties.extensionsTimeBudget	string	Specifies the time alloted for all extensions to start. The time duration should be betweer specified in ISO 8601 format. The default value is 90 minutes (PT1H30M). Minimum api-v
properties.hardwareProfile	Hardware Profile	Specifies the hardware settings for the virtual machine.
properties.host	Sub Resource	Specifies information about the dedicated host that the virtual machine resides in. Minim
properties.hostGroup	Sub Resource	Specifies information about the dedicated host group that the virtual machine resides in. properties. Minimum api-version: 2020-06-01.
properties.instanceView	Virtual Machine Instance View	The virtual machine instance view.
properties.licenseType	string	Specifies that the image or disk that is being used was licensed on-premises. Possible values for Windows Server operating system are: Windows_Client Windows_Server Possible values for Linux Server operating system are: RHEL_BYOS (for RHEL) SLES_BYOS (for SUSE) For more information, see Azure Hybrid Use Benefit for Windows Server Azure Hybrid Use Benefit for Linux Server Minimum api-version: 2015-06-15
properties.networkProfile	Network Profile	Specifies the network interfaces of the virtual machine.
properties.osProfile	OSProfile	Specifies the operating system settings used while creating the virtual machine. Some of provisioned.
properties.platformFaultDomain	integer (int32)	Specifies the scale set logical fault domain into which the Virtual Machine will be created assigned to a fault domain that best maintains balance across available fault domains. Th property of this Virtual Machine is set. The Virtual Machine Scale Set that is referenced, n This property cannot be updated once the Virtual Machine is created. Fault domain assig View. Minimum api-version: 2020-12-01.
properties.priority	Virtual Machine Priority Types	Specifies the priority for the virtual machine. Minimum api-version: 2019-03-01
properties.provisioningState	string	The provisioning state, which only appears in the response.
properties.proximityPlacementGroup	Sub Resource	Specifies information about the proximity placement group that the virtual machine shou
properties.resiliencyProfile	Resiliency Profile	Resiliency profile for the virtual machine.
properties.scheduledEventsPolicy	Scheduled Events Policy	Specifies Redeploy, Reboot and ScheduledEventsAdditionalPublishingTargets Scheduled
properties.scheduledEventsProfile	Scheduled Events Profile	Specifies Scheduled Event related configurations.

properties.securityProfile	Security Profile	Specifies the Security related profile settings for the virtual machine.
properties.storageProfile	Storage Profile	Specifies the storage settings for the virtual machine disks.
properties.timeCreated	string (date-time)	Specifies the time at which the Virtual Machine resource was created. Minimum api-versi
properties.userData	string	UserData for the VM, which must be base-64 encoded. Customer should not pass any se
properties.virtualMachineScaleSet	Sub Resource	Specifies information about the virtual machine scale set that the virtual machine should virtual machine scale set are allocated to different nodes to maximize availability. Current at creation time. An existing VM cannot be added to a virtual machine scale set. This pro properties.availabilitySet reference. Minimum api-version: 2019-03-01.
properties.vmId	string	Specifies the VM unique ID which is a 128-bits identifier that is encoded and stored in all platform BIOS commands.
resources	Virtual Machine Extension[]	The virtual machine child extension resources.
systemData	system Data	Azure Resource Manager metadata containing createdBy and modifiedBy information.
tags	object	Resource tags.
type	string	The type of the resource. E.g. "Microsoft.Compute/virtualMachines" or "Microsoft.Storag
zones	string[]	The availability zones.

VirtualMachineAgentInstanceView

Object

The instance view of the VM Agent running on the virtual machine.

Expand table

Name	Type	Description
extensionHandlers	Virtual Machine Extension Handler Instance View[]	The virtual machine extension handler instance view.
statuses	InstanceView Status[]	The resource status information.
vmAgentVersion	string	The VM Agent full version.

VirtualMachineEvictionPolicyTypes

Enumeration

Specifies the eviction policy for the Azure Spot VM/VMSS

Expand table

Value	Description
Deallocate	
Delete	

VirtualMachineExtension

Object

Describes a Virtual Machine Extension.

Expand table

Name	Type	Description
id	string	Fully qualified resource ID for the resource. Ex - /subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/{res
location	string	The geo-location where the resource lives
name	string	The name of the resource
properties.autoUpgradeMinorVersion	boolean	Indicates whether the extension should use a newer minor version if one is available a extension will not upgrade minor versions unless redeployed, even with this property
properties.enableAutomaticUpgrade	boolean	Indicates whether the extension should be automatically upgraded by the platform if
properties.forceUpdateTag	string	How the extension handler should be forced to update even if the extension configur
properties.instanceView	Virtual Machine Extension Instance View	The virtual machine extension instance view.
properties.protectedSettings		The extension can contain either protectedSettings or protectedSettingsFromKeyVau
properties.protectedSettingsFromKeyVault	KeyVault Secret Reference	The extensions protected settings that are passed by reference, and consumed from
properties.provisionAfterExtensions	string[]	Collection of extension names after which this extension needs to be provisioned.
properties.provisioningState	string	The provisioning state, which only appears in the response.
properties.publisher	string	The name of the extension handler publisher.
properties.settings		Json formatted public settings for the extension.
properties.suppressFailures	boolean	Indicates whether failures stemming from the extension will be suppressed (Operatio suppressed regardless of this value). The default is false.
properties.type	string	Specifies the type of the extension; an example is "CustomScriptExtension".
properties.typeHandlerVersion	string	Specifies the version of the script handler.
systemData	system Data	Azure Resource Manager metadata containing createdBy and modifiedBy informatior
tags	object	Resource tags.
type	string	The type of the resource. E.g. "Microsoft.Compute/virtualMachines" or "Microsoft.Sto

VirtualMachineExtensionHandlerInstanceView

Object

The instance view of a virtual machine extension handler.

Expand table

Name	Type	Description
status	InstanceView Status	The extension handler status.
type	string	Specifies the type of the extension; an example is "CustomScriptExtension".
typeHandlerVersion	string	Specifies the version of the script handler.

VirtualMachineExtensionInstanceView

Object

The instance view of a virtual machine extension.

Expand table

Name	Type	Description
name	string	The virtual machine extension name.
statuses	InstanceView Status[]	The resource status information.
substatuses	InstanceView Status[]	The resource status information.
type	string	Specifies the type of the extension; an example is "CustomScriptExtension".
typeHandlerVersion	string	Specifies the version of the script handler.

VirtualMachineHealthStatus

Object

The health status of the VM.

Expand table

Name	Type	Description
status	InstanceView Status	The health status information for the VM.

VirtualMachineIdentity

Object

Identity for the virtual machine.

Expand table

Name	Type	Description
principalId	string	The principal id of virtual machine identity. This property will only be provided for a system assigned ider
tenantId	string	The tenant id associated with the virtual machine. This property will only be provided for a system assign
type	Resource Identity Type	The type of identity used for the virtual machine. The type 'SystemAssigned, UserAssigned' includes both user assigned identities. The type 'None' will remove any identities from the virtual machine.
userAssignedIdentities	<string, Common. User Assigned Identities Value>	The list of user identities associated with the Virtual Machine. The user identity dictionary key references '/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.ManagedIde

VirtualMachineInstanceView

Object

The instance view of a virtual machine.

Expand table

Name	Type	Description
assignedHost	string	Resource id of the dedicated host, on which the virtual machine is allocated through automatic placement, when the virtual machine is associated with a dedicated host group that has automatic placement enabled. Minimum api-version: 2020-06-01.
bootDiagnostics	Boot Diagnostics	Boot Diagnostics is a debugging feature which allows you to view Console Output and Screenshot to diagnose VM status.

	InstanceView	You can easily view the output of your console log. Azure also enables you to see a screenshot of the VM from the hypervisor.
computerName	string	The computer name assigned to the virtual machine.
disks	DiskInstanceView[]	The virtual machine disk information.
extensions	VirtualMachineExtensionInstanceView[]	The extensions information.
hyperVGeneration	HyperVGenerationType	Specifies the HyperVGeneration Type associated with a resource
isVMInStandbyPool	boolean	[Preview Feature] Specifies whether the VM is currently in or out of the Standby Pool.
maintenanceRedeployStatus	MaintenanceRedeployStatus	The Maintenance Operation status on the virtual machine.
osName	string	The Operating System running on the virtual machine.
osVersion	string	The version of Operating System running on the virtual machine.
patchStatus	VirtualMachinePatchStatus	[Preview Feature] The status of virtual machine patch operations.
platformFaultDomain	integer (int32)	Specifies the fault domain of the virtual machine.
platformUpdateDomain	integer (int32)	Specifies the update domain of the virtual machine.
rdpThumbPrint	string	The Remote desktop certificate thumbprint.
statuses	InstanceViewStatus[]	The resource status information.
vmAgent	VirtualMachineAgentInstanceView	The VM Agent running on the virtual machine.
vmHealth	VirtualMachineHealthStatus	The health status for the VM.

VirtualMachineIpTag

Object

Contains the IP tag associated with the public IP address.

Expand table

Name	Type	Description
ipTagType	string	IP tag type. Example: FirstPartyUsage.
tag	string	IP tag associated with the public IP. Example: SQL, Storage etc.

VirtualMachineNetworkInterfaceConfiguration

Object

Describes a virtual machine network interface configurations.

Expand table

Name	Type	Description
name	string	The network interface configuration name.
properties.auxiliaryMode	Network Interface AuxiliaryMode	Specifies whether the Auxiliary mode is enabled for the Network Interface resource.
properties.auxiliarySku	Network Interface AuxiliarySku	Specifies whether the Auxiliary sku is enabled for the Network Interface resource.
properties.deleteOption	DeleteOptions	Specify what happens to the network interface when the VM is deleted
properties.disableTcpStateTracking	boolean	Specifies whether the network interface is disabled for tcp state tracking.
properties.dnsSettings	VirtualMachine Network InterfaceDns Settings Configuration	The dns settings to be applied on the network interfaces.
properties.dscpConfiguration	SubResource	
properties.enableAcceleratedNetworking	boolean	Specifies whether the network interface is accelerated networking-enabled.
properties.enableFpga	boolean	Specifies whether the network interface is FPGA networking-enabled.
properties.enableIPForwarding	boolean	Whether IP forwarding enabled on this NIC.
properties.ipConfigurations	VirtualMachine Network Interface IPConfiguration[]	Specifies the IP configurations of the network interface.
properties.networkSecurityGroup	SubResource	The network security group.
properties.primary	boolean	Specifies the primary network interface in case the virtual machine has more than 1 network interface.
tags	object	Resource tags applied to the networkInterface address created by this NetworkInterfaceConfiguration

VirtualMachineNetworkInterfaceDns SettingsConfiguration

Object

Describes a virtual machines network configuration's DNS settings.

Expand table

Name	Type	Description
dnsServers	string[]	List of DNS servers IP addresses

VirtualMachineNetworkInterfaceIPConfiguration

Object

Describes a virtual machine network profile's IP configuration.

Expand table

Name	Type	Description

name	string	The IP configuration name.
properties.applicationGatewayBackendAddressPools	Sub Resource[]	Specifies an array of references to backend address pools of application gateways. A virtual machine can reference backend address pools of multiple application gateways. Multiple virtual machines cannot use the same application gateway.
properties.applicationSecurityGroups	Sub Resource[]	Specifies an array of references to application security group.
properties.loadBalancerBackendAddressPools	Sub Resource[]	Specifies an array of references to backend address pools of load balancers. A virtual machine can reference backend address pools of one public and one internal load balancer. [Multiple virtual machines cannot use the same basic sku load balancer].
properties.primary	boolean	Specifies the primary network interface in case the virtual machine has more than 1 network interface.
properties.privateIPAddressVersion	IPVersions	Available from Api-Version 2017-03-30 onwards, it represents whether the specific ipconfiguration is IPv4 or IPv6. Default is taken as IPv4. Possible values are: 'IPv4' and 'IPv6'.
properties.publicIPAddressConfiguration	Virtual Machine Public IPAddress Configuration	The publicIPAddressConfiguration.
properties.subnet	SubResource	Specifies the identifier of the subnet.

VirtualMachinePatchStatus

Object

The status of virtual machine patch operations.

Expand table

Name	Type	Description
availablePatchSummary	Available Patch Summary	The available patch summary of the latest assessment operation for the virtual machine.
configurationStatuses	InstanceView Status[]	The enablement status of the specified patchMode
lastPatchInstallationSummary	LastPatch Installation Summary	The installation summary of the latest installation operation for the virtual machine.

VirtualMachinePriorityTypes

Enumeration

Specifies the priority for a standalone virtual machine or the virtual machines in the scale set. 'Low' enum will be deprecated in the future, please use 'Spot' as the enum to deploy Azure Spot VM/VMSS.

Expand table

Value	Description

Regular
Low
Spot

VirtualMachinePublicIPAddressConfiguration

Object

Describes a virtual machines IP Configuration's PublicIPAddress configuration

Expand table

Name	Type	Description
name	string	The publicIP address configuration name.
properties.deleteOption	Delete Options	Specify what happens to the public IP address when the VM is deleted
properties.dnsSettings	Virtual Machine Public IPAddressDns Settings Configuration	The dns settings to be applied on the publicIP addresses .
properties.idleTimeoutInMinutes	integer (int32)	The idle timeout of the public IP address.
properties.ipTags	Virtual Machine IpTag[]	The list of IP tags associated with the public IP address.
properties.publicIPAddressVersion	IPVersions	Available from Api-Version 2019-07-01 onwards, it represents whether the specific ipconfiguration is IPv4 or IPv6. Default is taken as IPv4. Possible values are: 'IPv4' and 'IPv6'.
properties.publicIPAllocationMethod	Public IPAllocation Method	Specify the public IP allocation type
properties.publicIPPrefix	SubResource	The PublicIPPrefix from which to allocate publicIP addresses.
sku	Public IPAddressSku	Describes the public IP Sku. It can only be set with OrchestrationMode as Flexible.
tags	object	Resource tags applied to the publicIP address created by this PublicIPAddressConfiguration

VirtualMachinePublicIPAddressDns SettingsConfiguration

Object

Describes a virtual machines network configuration's DNS settings.

Expand table

Name	Type	Description
domainNameLabel	string	The Domain name label prefix of the PublicIPAddress resources that will be created. The generated name label is the concatenation of the domain name label and vm network profile unique ID.
domainNameLabelScope	DomainName LabelScope Types	The Domain name label scope of the PublicIPAddress resources that will be created. The generated name label is the concatenation of the hashed domain name label with policy according to the domain name label scope and vm network profile unique ID.

VirtualMachineSizeTypes

Enumeration

Specifies the size of the virtual machine. The enum data type is currently deprecated and will be removed by December 23rd 2023. The recommended way to get the list of available sizes is using these APIs: List all available virtual machine sizes in an availability set, List all available virtual machine sizes in a region, List all available virtual machine sizes for resizing. For more information about virtual machine sizes, see Sizes for virtual machines. The available VM sizes depend on region and availability set.

VMDiskSecurityProfile

Object

Specifies the security profile settings for the managed disk. **Note:** It can only be set for Confidential VMs.

Expand table

Name	Type	Description
diskEncryptionSet	Disk EncryptionSet Parameters	Specifies the customer managed disk encryption set resource id for the managed disk that is used for Customer Managed Key encrypted ConfidentialVM OS Disk and VMGuest blob.
securityEncryptionType	Security Encryption Types	Specifies the EncryptionType of the managed disk. It is set to DiskWithVMGuestState for encryption of the managed disk along with VMGuestState blob, VMGuestStateOnly for encryption of just the VMGuestState blob, and NonPersistedTPM for not persisting firmware state in the VMGuestState blob.. **Note:** It can be set for only Confidential VMs.

VMGalleryApplication

Object

Specifies the required information to reference a compute gallery application version

Expand table

Name	Type	Description
configurationReference	string	Optional, Specifies the uri to an azure blob that will replace the default configuration for the pac
enableAutomaticUpgrade	boolean	If set to true, when a new Gallery Application version is available in PIR/SIG, it will be automatica
order	integer (int32)	Optional, Specifies the order in which the packages have to be installed
packageReferenceId	string	Specifies the GalleryApplicationVersion resource id on the form of /subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Microsoft.Com
tags	string	Optional, Specifies a passthrough value for more generic context.

treatFailureAsDeploymentFailure	boolean	Optional, If true, any failure for any operation in the VmApplication will fail the deployment

VMSizeProperties

Object

Specifies VM Size Property settings on the virtual machine.

Expand table

Name	Type	Description
vCPUsAvailable	integer (int32)	Specifies the number of vCPUs available for the VM. When this property is not specified in the request body the default behavior is to set it to the value of vCPUs available for that VM size exposed in api response of List all available virtual machine sizes in a region.
vCPUsPerCore	integer (int32)	Specifies the vCPU to physical core ratio. When this property is not specified in the request body the default behavior is set to the value of vCPUsPerCore for the VM Size exposed in api response of List all available virtual machine sizes in a region. **Setting this property to 1 also means that hyper-threading is disabled.**

WindowsConfiguration

Object

Specifies Windows operating system settings on the virtual machine.

Expand table

Name	Type	Description
additionalUnattendContent	Additional Unattend Content[]	Specifies additional base-64 encoded XML formatted information that can be included in the Unattend.xml file, which is used by Windows Setup.
enableAutomaticUpdates	boolean	Indicates whether Automatic Updates is enabled for the Windows virtual machine. Default value is true. For virtual machine scale sets, this property can be updated and updates will take effect on OS reprovisioning.
enableVMAgentPlatformUpdates	boolean	Indicates whether VMAgent Platform Updates are enabled for the Windows Virtual Machine.
patchSettings	PatchSettings	[Preview Feature] Specifies settings related to VM Guest Patching on Windows.
provisionVMAgent	boolean	Indicates whether virtual machine agent should be provisioned on the virtual machine. When this property is not specified in the request body, it is set to true by default. This will ensure that VM Agent is installed on the VM so that extensions can be added to the VM later.
timeZone	string	Specifies the time zone of the virtual machine. e.g. "Pacific Standard Time". Possible values can be TimeZoneInfo.Id value from time zones returned by TimeZoneInfo.GetSystemTimeZones.
winRM	Win RMConfiguration	Specifies the Windows Remote Management listeners. This enables remote Windows PowerShell.

WindowsPatchAssessmentMode

Enumeration

Specifies the mode of VM Guest patch assessment for the IaaS virtual machine.

Possible values are:

ImageDefault - You control the timing of patch assessments on a virtual machine.

AutomaticByPlatform - The platform will trigger periodic patch assessments. The property provisionVMAgent must be true.

Expand table

Value	Description
ImageDefault	
AutomaticByPlatform	

WindowsVMGuestPatchAutomaticByPlatformRebootSetting

Enumeration

Specifies the reboot setting for all AutomaticByPlatform patch installation operations.

Expand table

Value	Description
Unknown	
IfRequired	
Never	
Always	

WindowsVMGuestPatchAutomaticByPlatformSettings

Object

Specifies additional settings to be applied when patch mode AutomaticByPlatform is selected in Windows patch settings.

Expand table

Name	Type	Description
bypassPlatformSafetyChecksOnUserSchedule	boolean	Enables customer to schedule patching without accidental upgrades
rebootSetting	WindowsVMGuestPatchAutomaticByPlatformRebootSetting	Specifies the reboot setting for all AutomaticByPlatform patch installation operations.

WindowsVMGuestPatchMode

Enumeration

Specifies the mode of VM Guest Patching to IaaS virtual machine or virtual machines associated to virtual machine scale set with OrchestrationMode as Flexible.

Possible values are:

Manual - You control the application of patches to a virtual machine. You do this by applying patches manually inside the VM. In this mode, automatic updates are disabled; the property WindowsConfiguration.enableAutomaticUpdates must be false

AutomaticByOS - The virtual machine will automatically be updated by the OS. The property

WindowsConfiguration.enableAutomaticUpdates must be true.

AutomaticByPlatform - the virtual machine will automatically updated by the platform. The properties provisionVMAgent and WindowsConfiguration.enableAutomaticUpdates must be true

Expand table

Value	Description
Manual	
AutomaticByOS	
AutomaticByPlatform	

WinRMConfiguration

Object

Describes Windows Remote Management configuration of the VM

Expand table

Name	Type	Description
listeners	WinRMListener[]	The list of Windows Remote Management listeners

WinRMListener

Object

Describes Protocol and thumbprint of Windows Remote Management listener

Expand table

Name	Type	Description

certificateUrl	string	This is the URL of a certificate that has been uploaded to Key Vault as a secret. For adding a secret to the Key Vault, see Add a key or secret to the key vault. In this case, your certificate needs to be the Base64 encoding of the following JSON Object which is encoded in UTF-8:
		
		{
		"data":"<Base64-encoded-certificate>",
		"dataType":"pfx",
		"password":"<pfx-file-password>"
		}
		To install certificates on a virtual machine it is recommended to use the Azure Key Vault virtual machine extension for Linux or the Azure Key Vault virtual machine extension for Windows.

protocol	ProtocolTypes	Specifies the protocol of WinRM listener. Possible values are: **http, https.**

ZoneMovement

Object

Describes zone movement configuration. This allows VM to be moved across availability zones during an outage.

Expand table

Name	Type	Description
isEnabled	boolean	Indicates if zone movement is enabled. By default isEnabled is set to false i.e VM can't be moved from one zone to another.

ZonePlacementPolicyType

Enumeration

Specifies the policy for resource's placement in availability zone. Possible values are: **Any** (used for Virtual Machines), **Auto** (used for Virtual Machine Scale Sets) - An availability zone will be automatically picked by system as part of resource creation.

Expand table

Value	Description
Any	
Auto	Automatic zone placement in a Virtual Machine Scale Set.

Tutorial: Install a LAMP stack on an Azure Linux VM

Article • 05/02/2025

Applies to: ✔ Linux VMs

This article walks you through how to deploy an Apache web server, MySQL, and PHP (the LAMP stack) on an Ubuntu VM in Azure. To see the LAMP server in action, you can optionally install and configure a WordPress site. In this tutorial you learn how to:

- ✔ Create an Ubuntu VM
- ✔ Open port 80 for web traffic
- ✔ Install Apache, MySQL, and PHP
- ✔ Verify installation and configuration
- ✔ Install WordPress

This setup is for quick tests or proof of concept. For more on the LAMP stack, including recommendations for a production environment, see the Ubuntu documentation.

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you're running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Create a resource group

Create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed.

The following example creates a resource group using environment variables and appends a random suffix to ensure uniqueness.

Azure CLI

```
export REGION="eastus2"
export RANDOM_SUFFIX="$(openssl rand -hex 3)"
export MY_RESOURCE_GROUP_NAME="myResourceGroup${RANDOM_SUFFIX}"
az group create --name "${MY_RESOURCE_GROUP_NAME}" --location $REGION
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxx-xxxxx-xxxxx-
xxxxx/resourceGroups/myResourceGroupxxxxx",
  "location": "eastus",
  "name": "myResourceGroupxxxxx",
  "properties": {
      "provisioningState": "Succeeded"
  }
}
```

Create a virtual machine

Create a VM with the az vm create command.

The following example creates a VM using environment variables. It creates a VM named *myVM* and creates SSH keys if they don't already exist in a default key location. To use a specific set of keys, use the `--ssh-key-value` option. The command also sets *azureuser* as an administrator user name. You use this name later to connect to the VM.

Azure CLI

```
export MY_VM_NAME="myVM${RANDOM_SUFFIX}"
export IMAGE="Ubuntu2204"
export ADMIN_USERNAME="azureuser"
az vm create \
    --resource-group "${MY_RESOURCE_GROUP_NAME}" \
    --name $MY_VM_NAME \
    --image $IMAGE \
    --admin-username $ADMIN_USERNAME \
    --generate-ssh-keys
```

When the VM has been created, the Azure CLI shows information similar to the following example. Take note of the `publicIpAddress`. This address is used to access the VM in later steps.

Output

```
{
  "fqdns": "",
  "id": "/subscriptions/<subscription
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myV
M",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
```

```
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "40.68.254.142",
  "resourceGroup": "myResourceGroup"
}
```

Open port 80 for web traffic

By default, only SSH connections are allowed into Linux VMs deployed in Azure. Because this VM is going to be a web server, you need to open port 80 from the internet. Use the az vm open-port command to open the desired port.

Azure CLI

```
az vm open-port --port 80 --resource-group "${MY_RESOURCE_GROUP_NAME}" --name
$MY_VM_NAME
```

For more information about opening ports to your VM, see Open ports.

SSH into your VM

If you don't already know the public IP address of your VM, run the az network public-ip list command. You need this IP address for several later steps.

Azure CLI

```
export PUBLIC_IP=$(az network public-ip list --resource-group
"${MY_RESOURCE_GROUP_NAME}" --query [].ipAddress -o tsv)
```

Use the `ssh` command to create an SSH session with the virtual machine. Substitute the correct public IP address of your virtual machine.

Install Apache, MySQL, and PHP

Run the following command to update Ubuntu package sources and install Apache, MySQL, and PHP. Note the caret (^) at the end of the command, which is part of the `lamp-server^` package name.

Bash

```
ssh -o StrictHostKeyChecking=no azureuser@$PUBLIC_IP "sudo apt-get update && sudo
DEBIAN_FRONTEND=noninteractive apt-get -y install lamp-server^"
```

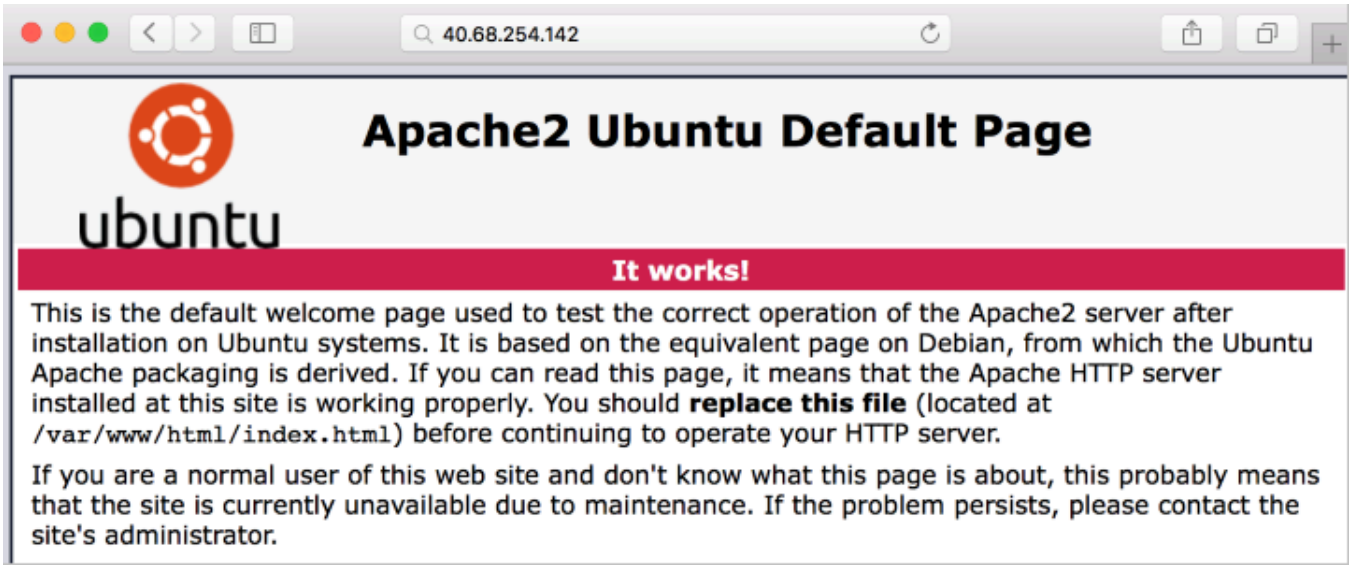
You're prompted to install the packages and other dependencies. This process installs the minimum required PHP extensions needed to use PHP with MySQL.

Verify Apache

Check the version of Apache with the following command:

```bash
ssh -o StrictHostKeyChecking=no azureuser@$PUBLIC_IP "apache2 -v"
```

With Apache installed, and port 80 open to your VM, the web server can now be accessed from the internet. To view the Apache2 Ubuntu Default Page, open a web browser, and enter the public IP address of the VM. Use the public IP address you used to SSH to the VM:



Verify and secure MySQL

Check the version of MySQL with the following command (note the capital `V` parameter):

```bash
ssh -o StrictHostKeyChecking=no azureuser@$PUBLIC_IP "mysql -V"
```

To help secure the installation of MySQL, including setting a root password, you can run the `sudo mysql_secure_installation` command. This command prompts you to answer several questions to help secure your MySQL installation.

You can optionally set up the Validate Password Plugin (recommended). Then, set a password for the MySQL root user, and configure the remaining security settings for your environment.

We recommend that you answer "Y" (yes) to all questions.

If you want to try MySQL features (create a MySQL database, add users, or change configuration settings), login to MySQL. This step isn't required to complete this tutorial. For doing this, you can use the `sudo mysql -u root -p` command in your VM and then enter your root password when prompted. This command connects to your VM via SSH and launches the MySQL command line client as the root user.

When done, exit the mysql prompt by typing `\q`.

Verify PHP

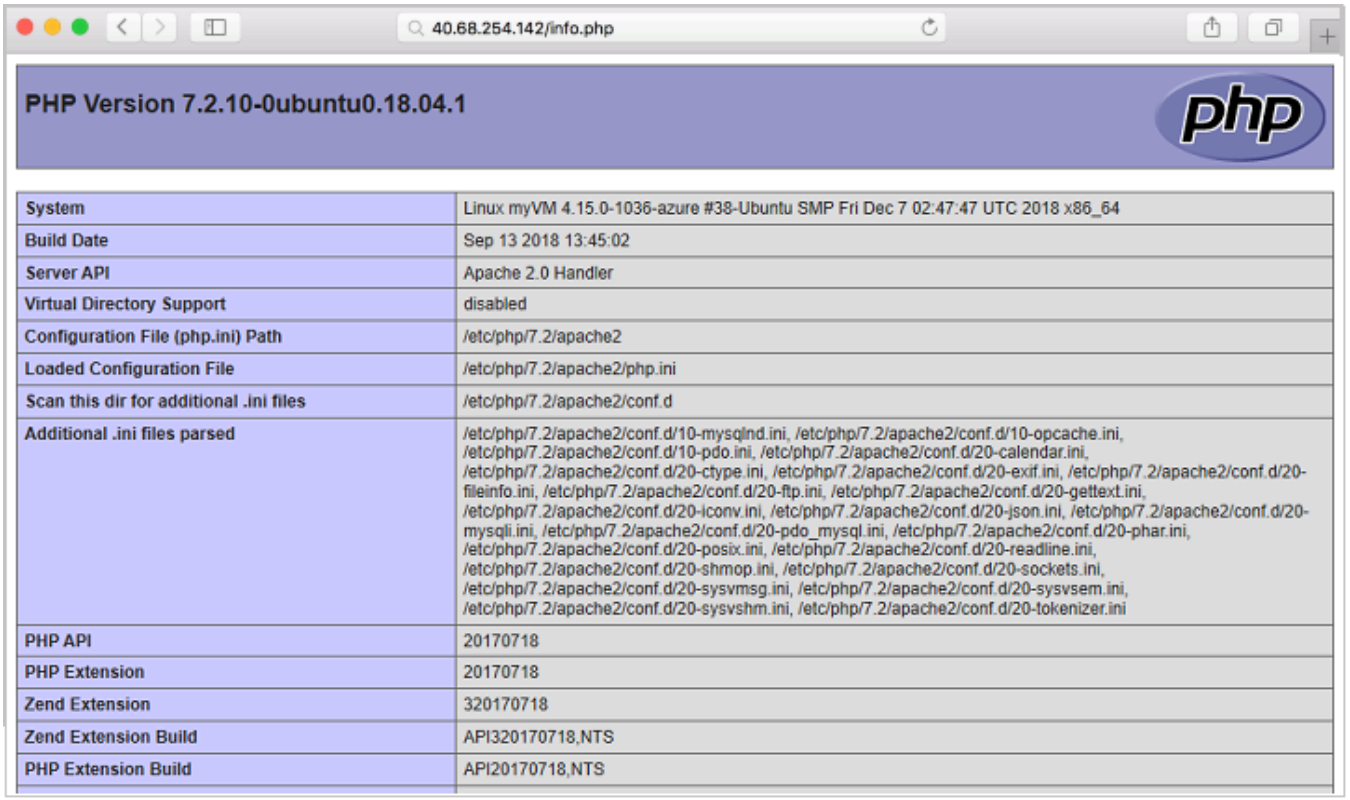
Check the version of PHP with the following command:

```
Bash

ssh -o StrictHostKeyChecking=no azureuser@$PUBLIC_IP "php -v"
```

If you want to test further, you can create a quick PHP info page to view in a browser. The following command creates the PHP info page `sudo sh -c 'echo \"<?php phpinfo\(\)\; ?>\" > /var/www/html/info.php`

Now you can check the PHP info page you created. Open a browser and go to `http://yourPublicIPAddress/info.php`. Substitute the public IP address of your VM. It should look similar to this image.



Install WordPress

If you want to try your stack, install a sample app. As an example, the following steps install the open source WordPress platform to create websites and blogs. Other workloads to try include Drupal and Moodle.

This WordPress setup is only for proof of concept. To install the latest WordPress in production with recommended security settings, see the WordPress documentation.

Install the WordPress package

Run the following command:

```
Bash

sudo apt install wordpress
```

Configure WordPress

Configure WordPress to use MySQL and PHP.

In a working directory, create a text file `wordpress.sql` to configure the MySQL database for WordPress:

```
Bash

sudo sensible-editor wordpress.sql
```

Add the following commands, substituting a database password of your choice for *yourPassword* (leave other values unchanged). If you previously set up a MySQL security policy to validate password strength, make sure the password meets the strength requirements. Save the file.

```
SQL

CREATE DATABASE wordpress;
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,ALTER
ON wordpress.*
TO wordpress@localhost
IDENTIFIED BY 'yourPassword';
```

Run the following command to create the database:

Bash

```
cat wordpress.sql | sudo mysql --defaults-extra-file=/etc/mysql/debian.cnf
```

Because the file `wordpress.sql` contains database credentials, delete it after use:

Bash

```
sudo rm wordpress.sql
```

To configure PHP, run the following command to open a text editor of your choice and create the file `/etc/wordpress/config-localhost.php`:

Bash

```
sudo sensible-editor /etc/wordpress/config-localhost.php
```

Copy the following lines to the file, substituting your WordPress database password for *yourPassword* (leave other values unchanged). Then save the file.

PHP

```
<?php
define('DB_NAME', 'wordpress');
define('DB_USER', 'wordpress');
define('DB_PASSWORD', 'yourPassword');
define('DB_HOST', 'localhost');
define('WP_CONTENT_DIR', '/usr/share/wordpress/wp-content');
?>
```

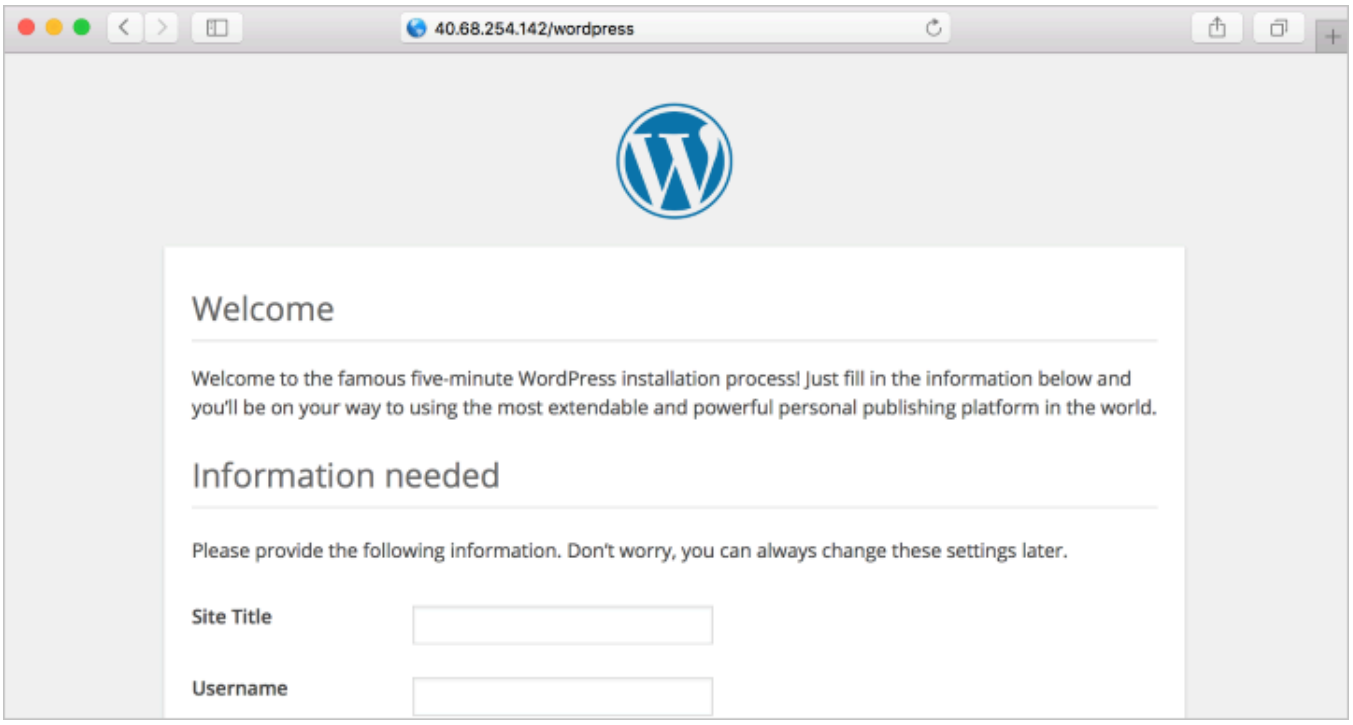
Move the WordPress installation to the web server document root:

Bash

```
sudo ln -s /usr/share/wordpress /var/www/html/wordpress

sudo mv /etc/wordpress/config-localhost.php /etc/wordpress/config-default.php
```

Now you can complete the WordPress setup and publish on the platform. Open a browser and go to `http://yourPublicIPAddress/wordpress`. Substitute the public IP address of your VM. It should look similar to this image.



Next steps

In this tutorial, you deployed a LAMP server in Azure. You learned how to:

- ✓ Create an Ubuntu VM
- ✓ Open port 80 for web traffic
- ✓ Install Apache, MySQL, and PHP
- ✓ Verify installation and configuration
- ✓ Install WordPress on the LAMP server

Advance to the next tutorial to learn how to secure web servers with TLS/SSL certificates.

Secure web server with TLS

Tutorial: Install a LEMP stack on an Azure Linux VM

Article • 09/19/2024

Applies to: ✔ Linux VMs

Deploy to Azure

This article walks you through how to deploy an NGINX web server, Azure MySQL Flexible Server, and PHP (the LEMP stack) on an Ubuntu Linux VM in Azure. To see the LEMP server in action, you can optionally install and configure a WordPress site. In this tutorial you learn how to:

- ✔ Create an Ubuntu VM
- ✔ Open ports 80 and 443 for web traffic
- ✔ Install and Secure NGINX, Azure Flexible MySQL Server, and PHP
- ✔ Verify installation and configuration
- ✔ Install WordPress This setup is for quick tests or proof of concept. For more on the LEMP stack, including recommendations for a production environment, see the Ubuntu documentation.

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you're running the Azure CLI version 2.0.30 or later. Find the version by running the `az --version` command. If you need to install or upgrade, see Install Azure CLI.

Variable declaration

First we need to define a few variables that help with the configuration of the LEMP workload.

Bash

```
export NETWORK_PREFIX="$(($RANDOM % 254 + 1))"
export RANDOM_ID="$(openssl rand -hex 3)"
export MY_RESOURCE_GROUP_NAME="myLEMPResourceGroup$RANDOM_ID"
export REGION="westeurope"
export MY_VM_NAME="myVM$RANDOM_ID"
export MY_VM_USERNAME="azureadmin"
export MY_VM_SIZE='Standard_DS2_v2'
```

```
export MY_VM_IMAGE='Canonical:0001-com-ubuntu-minimal-jammy:minimal-22_04-lts-gen2:latest'
export MY_PUBLIC_IP_NAME="myPublicIP$RANDOM_ID"
export MY_DNS_LABEL="mydnslabel$RANDOM_ID"
export MY_NSG_NAME="myNSG$RANDOM_ID"
export MY_NSG_SSH_RULE="Allow-Access$RANDOM_ID"
export MY_VM_NIC_NAME="myVMNic$RANDOM_ID"
export MY_VNET_NAME="myVNet$RANDOM_ID"
export MY_VNET_PREFIX="10.$NETWORK_PREFIX.0.0/22"
export MY_SN_NAME="mySN$RANDOM_ID"
export MY_SN_PREFIX="10.$NETWORK_PREFIX.0.0/24"
export MY_MYSQL_DB_NAME="mydb$RANDOM_ID"
export MY_MYSQL_ADMIN_USERNAME="dbadmin$RANDOM_ID"
export MY_MYSQL_ADMIN_PW="$(openssl rand -base64 32)"
export MY_MYSQL_SN_NAME="myMySQLSN$RANDOM_ID"
export MY_WP_ADMIN_PW="$(openssl rand -base64 32)"
export MY_WP_ADMIN_USER="wpcliadmin"
export MY_AZURE_USER=$(az account show --query user.name --output tsv)
export FQDN="${MY_DNS_LABEL}.${REGION}.cloudapp.azure.com"
```

Create a resource group

Create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named `$MY_RESOURCE_GROUP_NAME` in the `eastus` location.

Bash

```
az group create \
    --name $MY_RESOURCE_GROUP_NAME \
    --location $REGION -o JSON
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx",
  "location": "eastus",
  "managedBy": null,
  "name": "myLEMPResourceGroupxxxxxx",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null,
```

```
  "type": "Microsoft.Resources/resourceGroups"
}
```

Setup LEMP networking

Create an Azure Virtual Network

A virtual network is the fundamental building block for private networks in Azure. Azure Virtual Network enables Azure resources like VMs to securely communicate with each other and the internet. Use az network vnet create to create a virtual network named `$MY_VNET_NAME` with a subnet named `$MY_SN_NAME` in the `$MY_RESOURCE_GROUP_NAME` resource group.

Bash

```
az network vnet create \
    --name $MY_VNET_NAME \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --location $REGION \
    --address-prefix $MY_VNET_PREFIX \
    --subnet-name $MY_SN_NAME \
    --subnet-prefixes $MY_SN_PREFIX -o JSON
```

Results:

JSON

```
{
  "newVNet": {
    "addressSpace": {
      "addressPrefixes": [
        "10.19.0.0/22"
      ]
    },
    "enableDdosProtection": false,
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Ne
twork/virtualNetworks/myVNetxxxxxx",
    "location": "eastus",
    "name": "myVNetxxxxxx",
    "provisioningState": "Succeeded",
    "resourceGroup": "myLEMPResourceGroupxxxxxx",
    "subnets": [
      {
        "addressPrefix": "10.19.0.0/24",
        "delegations": [],
        "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
```

```
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Network/virtualNetworks/myVNetxxxxxx/subnets/mySNxxxxxx",
        "name": "mySNxxxxxx",
        "privateEndpointNetworkPolicies": "Disabled",
        "privateLinkServiceNetworkPolicies": "Enabled",
        "provisioningState": "Succeeded",
        "resourceGroup": "myLEMPResourceGroupxxxxxx",
        "type": "Microsoft.Network/virtualNetworks/subnets"
      }
    ],
    "type": "Microsoft.Network/virtualNetworks",
    "virtualNetworkPeerings": []
  }
}
```

Create an Azure Public IP

Use az network public-ip create to create a standard zone-redundant public IPv4 address named `MY_PUBLIC_IP_NAME` in `$MY_RESOURCE_GROUP_NAME`.

> **Note**
>
> The below options for zones are only valid selections in regions with Availability Zones.

Bash

```
az network public-ip create \
    --name $MY_PUBLIC_IP_NAME \
    --location $REGION \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --dns-name $MY_DNS_LABEL \
    --sku Standard \
    --allocation-method static \
    --version IPv4 \
    --zone 1 2 3 -o JSON
```

Results:

JSON

```
{
  "publicIp": {
    "ddosSettings": {
      "protectionMode": "VirtualNetworkInherited"
    },
    "dnsSettings": {
```

```
      "domainNameLabel": "mydnslabelxxxxxx",
      "fqdn": "mydnslabelxxxxxx.eastus.cloudapp.azure.com"
    },
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Ne
twork/publicIPAddresses/myPublicIPxxxxxx",
    "idleTimeoutInMinutes": 4,
    "ipTags": [],
    "location": "eastus",
    "name": "myPublicIPxxxxxx",
    "provisioningState": "Succeeded",
    "publicIPAddressVersion": "IPv4",
    "publicIPAllocationMethod": "Static",
    "resourceGroup": "myLEMPResourceGroupxxxxxx",
    "sku": {
      "name": "Standard",
      "tier": "Regional"
    },
    "type": "Microsoft.Network/publicIPAddresses",
    "zones": [
      "1",
      "2",
      "3"
    ]
  }
}
```

Create an Azure Network Security Group

Security rules in network security groups enable you to filter the type of network traffic that can flow in and out of virtual network subnets and network interfaces. To learn more about network security groups, see Network security group overview.

Bash

```
az network nsg create \
    --name $MY_NSG_NAME \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --location $REGION -o JSON
```

Results:

JSON

```
{
  "NewNSG": {
    "defaultSecurityRules":
      {
        "access": "Allow",
```

```
        "description": "Allow inbound traffic from all VMs in VNET",
        "destinationAddressPrefix": "VirtualNetwork",
        "destinationAddressPrefixes": [],
        "destinationPortRange": "*",
        "destinationPortRanges": [],
        "direction": "Inbound",
        "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroup104/providers/Microsoft.Netwo
rk/networkSecurityGroups/protect-vms/defaultSecurityRules/AllowVnetInBound",
        "name": "AllowVnetInBound",
        "priority": 65000,
        "protocol": "*",
        "provisioningState": "Succeeded",
        "resourceGroup": "myLEMPResourceGroup104",
        "sourceAddressPrefix": "VirtualNetwork",
        "sourceAddressPrefixes": [],
        "sourcePortRange": "*",
        "sourcePortRanges": [],
        "type":
"Microsoft.Network/networkSecurityGroups/defaultSecurityRules"
      },
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroup104/providers/Microsoft.Netwo
rk/networkSecurityGroups/protect-vms",
    "location": "eastus",
    "name": "protect-vms",
    "provisioningState": "Succeeded",
    "resourceGroup": "myLEMPResourceGroup104",
    "securityRules": [],
    "type": "Microsoft.Network/networkSecurityGroups"
  }
}
```

Create Azure Network Security Group rules

Create a rule to allow connections to the virtual machine on port 22 for SSH and ports 80, 443 for HTTP and HTTPS. An extra rule is created to allow all ports for outbound connections. Use az network nsg rule create to create a network security group rule.

Bash

```
az network nsg rule create \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --nsg-name $MY_NSG_NAME \
    --name $MY_NSG_SSH_RULE \
    --access Allow \
    --protocol Tcp \
    --direction Inbound \

Create an Azure Network Interface

Use az network nic create to create the network interface for the virtual machine. The public IP addresses and the NSG created previously are associated with the NIC. The network interface is attached to the virtual network you created previously.

Bash

```
az network nic create \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --name $MY_VM_NIC_NAME \
    --location $REGION \
    --ip-forwarding false \
    --subnet $MY_SN_NAME \
    --vnet-name $MY_VNET_NAME \
```

```
    --network-security-group $MY_NSG_NAME \
    --public-ip-address $MY_PUBLIC_IP_NAME -o JSON
```

Results:

JSON

```
{
  "NewNIC": {
    "auxiliaryMode": "None",
    "auxiliarySku": "None",

Cloud-init overview

Cloud-init is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. As cloud-init runs during the initial boot process, there are no other steps or required agents to apply to your configuration.

Cloud-init also works across distributions. For example, you don't use apt-get install or yum install to install a package. Instead you can define a list of packages to install. Cloud-init automatically uses the native package management tool for the distro you select.

We're working with our partners to get cloud-init included and working in the images that they provide to Azure. For detailed information cloud-init support for each distribution, see Cloud-init support for VMs in Azure.

Create cloud-init config file

To see cloud-init in action, create a VM that installs a LEMP stack and runs a simple Wordpress app secured with an SSL certificate. The following cloud-init configuration installs the required packages, creates the Wordpress website, then initialize and starts the website.

Bash

```
cat << EOF > cloud-init.txt
#cloud-config
# Install, update, and upgrade packages
package_upgrade: true
package_update: true
package_reboot_if_require: true
# Install packages
packages:
  - vim
  - certbot
  - python3-certbot-nginx
  - bash-completion
  - nginx
  - mysql-client
```

```
  - php
  - php-cli
  - php-bcmath
  - php-curl
  - php-imagick
  - php-intl
  - php-json
  - php-mbstring
  - php-mysql
  - php-gd
  - php-xml
  - php-xmlrpc
  - php-zip
  - php-fpm
write_files:
  - owner: www-data:www-data
    path: /etc/nginx/sites-available/default.conf
    content: |
        server {
            listen 80 default_server;
            listen [::]:80 default_server;
            root /var/www/html;
            server_name $FQDN;
        }
write_files:
  - owner: www-data:www-data
    path: /etc/nginx/sites-available/$FQDN.conf
    content: |
        upstream php {
            server unix:/run/php/php8.1-fpm.sock;
        }
        server {

```

Create an Azure Private DNS Zone for Azure MySQL Flexible Server

Azure Private DNS Zone integration allows you to resolve the private DNS within the current VNET or any in-region peered VNET where the private DNS Zone is linked. Use az network private-dns zone create to create the private DNS zone.

Bash

```
az network private-dns zone create \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --name $MY_DNS_LABEL.private.mysql.database.azure.com -o JSON
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Ne
twork/privateDnsZones/mydnslabelxxxxxx.private.mysql.database.azure.com",
  "location": "global",
  "maxNumberOfRecordSets": 25000,
  "maxNumberOfVirtualNetworkLinks": 1000,
  "maxNumberOfVirtualNetworkLinksWithRegistration": 100,
  "name": "mydnslabelxxxxxx.private.mysql.database.azure.com",
  "numberOfRecordSets": 1,
  "numberOfVirtualNetworkLinks": 0,
  "numberOfVirtualNetworkLinksWithRegistration": 0,
  "provisioningState": "Succeeded",
  "resourceGroup": "myLEMPResourceGroupxxxxxx",
  "tags": null,
  "type": "Microsoft.Network/privateDnsZones"
}
```

Create an Azure Database for MySQL - Flexible Server

Azure Database for MySQL - Flexible Server is a managed service that you can use to run, manage, and scale highly available MySQL servers in the cloud. Create a flexible server with the az mysql flexible-server create command. A server can contain multiple databases. The following command creates a server using service defaults and variable values from your Azure CLI's local environment:

Bash

```
az mysql flexible-server create \
    --admin-password $MY_MYSQL_ADMIN_PW \
    --admin-user $MY_MYSQL_ADMIN_USERNAME \
    --auto-scale-iops Disabled \
    --high-availability Disabled \
    --iops 500 \
    --location $REGION \
    --name $MY_MYSQL_DB_NAME \
    --database-name wp001 \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --sku-name Standard_B2s \
    --storage-auto-grow Disabled \
    --storage-size 20 \
    --subnet $MY_MYSQL_SN_NAME \
    --private-dns-zone $MY_DNS_LABEL.private.mysql.database.azure.com \
    --tier Burstable \
    --version 8.0.21 \
    --vnet $MY_VNET_NAME \
    --yes -o JSON
```

Results:

JSON

```
{
  "databaseName": "wp001",
  "host": "mydbxxxxxx.mysql.database.azure.com",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.DB
forMySQL/flexibleServers/mydbxxxxxx",
  "location": "East US",
  "resourceGroup": "myLEMPResourceGroupxxxxxx",
  "skuname": "Standard_B2s",
  "subnetId": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Ne
twork/virtualNetworks/myVNetxxxxxx/subnets/myMySQLSNxxxxxx",
  "username": "dbadminxxxxxx",
  "version": "8.0.21"
}
```

The server created has the below attributes:

- The server name, admin username, admin password, resource group name, location are already specified in local context environment of the cloud shell. They're created in the same location as your resource group and other Azure components.
- Service defaults for remaining server configurations: compute tier (Burstable), compute size/SKU (Standard_B2s), backup retention period (7 days), and MySQL

version (8.0.21)
- The default connectivity method is Private access (VNet Integration) with a linked virtual network and an auto-generated subnet.

> **Note**
>
> The connectivity method cannot be changed after creating the server. For example, if you selected `Private access (VNet Integration)` during create then you cannot change to `Public access (allowed IP addresses)` after create. We highly recommend creating a server with Private access to securely access your server using VNet Integration. Learn more about Private access in the concepts article. If you'd like to change any defaults, refer to the Azure CLI reference documentation for the complete list of configurable CLI parameters.

Check the Azure Database for MySQL - Flexible Server status

It takes a few minutes to create the Azure Database for MySQL - Flexible Server and supporting resources.

Bash

```
runtime="10 minute";
endtime=$(date -ud "$runtime" +%s);
while [[ $(date -u +%s) -le $endtime ]]; do
  STATUS=$(az mysql flexible-server show -g $MY_RESOURCE_GROUP_NAME -n
$MY_MYSQL_DB_NAME --query state -o tsv);
  echo $STATUS;
  if [ "$STATUS" == 'Ready' ]; then
    break;
  else
    sleep 10;
  fi;
done
```

Configure server parameters in Azure Database for MySQL - Flexible Server

You can manage Azure Database for MySQL - Flexible Server configuration using server parameters. The server parameters are configured with the default and recommended value when you create the server.

Show server parameter details:

Run the az mysql flexible-server parameter show command to show details about any particular parameter for the server.

Disable Azure Database for MySQL - Flexible Server SSL connection parameter for Wordpress integration

Modify a server parameter value:

You can also modify the value of a certain server parameter, which updates the underlying configuration value for the MySQL server engine. To update the server parameter, use the az mysql flexible-server parameter set command.

Bash

```
az mysql flexible-server parameter set \
    -g $MY_RESOURCE_GROUP_NAME \
    -s $MY_MYSQL_DB_NAME \
    -n require_secure_transport -v "OFF" -o JSON
```

Results:

JSON

```
{
  "allowedValues": "ON,OFF",
  "currentValue": "OFF",
  "dataType": "Enumeration",
  "defaultValue": "ON",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.DB
forMySQL/flexibleServers/mydbxxxxxx/configurations/require_secure_transport"
,
  "isConfigPendingRestart": "False",
  "isDynamicConfig": "True",
  "isReadOnly": "False",
  "name": "require_secure_transport",
  "resourceGroup": "myLEMPResourceGroupxxxxxx",
  "source": "user-override",
  "systemData": null,
  "type": "Microsoft.DBforMySQL/flexibleServers/configurations",
  "value": "OFF"
}
```

Create an Azure Linux Virtual Machine

The following example creates a VM named `$MY_VM_NAME` and creates SSH keys if they don't already exist in a default key location. The command also sets `$MY_VM_USERNAME` as an administrator user name.

To improve the security of Linux virtual machines in Azure, you can integrate with Microsoft Entra ID authentication. Now you can use Microsoft Entra ID as a core authentication platform. You can also SSH into the Linux VM by using Microsoft Entra ID and OpenSSH certificate-based authentication. This functionality allows organizations to manage access to VMs with Azure role-based access control and Conditional Access policies.

Create a VM with the az vm create command.

Bash

```
az vm create \
    --name $MY_VM_NAME \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --admin-username $MY_VM_USERNAME \
    --authentication-type ssh \
    --assign-identity \
    --image $MY_VM_IMAGE \
    --location $REGION \
    --nic-delete-option Delete \
    --os-disk-caching ReadOnly \
    --os-disk-delete-option Delete \
    --os-disk-size-gb 30 \
    --size $MY_VM_SIZE \
    --generate-ssh-keys \
    --storage-sku Premium_LRS \
    --nics $MY_VM_NIC_NAME \
    --custom-data cloud-init.txt -o JSON
```

Results:

JSON

```
{
  "fqdns": "mydnslabelxxxxxx.eastus.cloudapp.azure.com",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Co
mpute/virtualMachines/myVMNamexxxxxx",
  "identity": {
    "principalId": "yyyyyyyy-yyyy-yyyy-yyyy-yyyyyyyyyyyy",
    "tenantId": "zzzzzzzz-zzzz-zzzz-zzzz-zzzzzzzzzzzz",
    "type": "SystemAssigned",
    "userAssignedIdentities": null
```

```
  },
  "location": "eastus",
  "macAddress": "60-45-BD-D8-1D-84",
  "powerState": "VM running",
  "privateIpAddress": "10.19.0.4",
  "resourceGroup": "myLEMPResourceGroupxxxxxx",
  "zones": ""
}
```

Check the Azure Linux Virtual Machine status

It takes a few minutes to create the VM and supporting resources. The provisioningState value of Succeeded appears when the extension is successfully installed on the VM. The VM must have a running VM agent to install the extension.

Bash

```
runtime="5 minute";
endtime=$(date -ud "$runtime" +%s);
while [[ $(date -u +%s) -le $endtime ]]; do
    STATUS=$(ssh -o StrictHostKeyChecking=no $MY_VM_USERNAME@$FQDN "cloud-
init status --wait");
    echo $STATUS;
    if [[ "$STATUS" == *'status: done'* ]]; then
        break;
    else
        sleep 10;
    fi;
done
```

JSON

```
{
  "condition": null,
  "conditionVersion": null,
  "createdBy": null,
  "createdOn": "2023-09-04T09:29:16.895907+00:00",
  "delegatedManagedIdentityResourceId": null,
  "description": null,

  "principalId": "zzzzzzzz-zzzz-zzzz-zzzz-zzzzzzzzzzzz",
  "principalType": "User",
  "resourceGroup": "myLEMPResourceGroupxxxxxx",
  "roleDefinitionId": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/providers/Microsoft.Authorization/roleDefinitions/zzzzzzzz-
zzzz-zzzz-zzzz-zzzzzzzzzzzz",
  "scope": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
```

```
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx",
  "type": "Microsoft.Authorization/roleAssignments",
  "updatedBy": "wwwwwwww-wwww-wwww-wwww-wwwwwwwwwwww",
  "updatedOn": "2023-09-04T09:29:17.237445+00:00"
}
```

Enable Microsoft Entra ID login for a Linux Virtual Machine in Azure

The following installs the extension to enable Microsoft Entra ID login for a Linux VM. VM extensions are small applications that provide post-deployment configuration and automation tasks on Azure virtual machines.

Bash

```
az vm extension set \
    --publisher Microsoft.Azure.ActiveDirectory \
    --name AADSSHLoginForLinux \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --vm-name $MY_VM_NAME -o JSON
```

Results:

JSON

```
{
  "autoUpgradeMinorVersion": true,
  "enableAutomaticUpgrade": null,
  "forceUpdateTag": null,
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myLEMPResourceGroupxxxxxx/providers/Microsoft.Co
mpute/virtualMachines/myVMNamexxxxxx/extensions/AADSSHLoginForLinux",
  "instanceView": null,
  "location": "eastus",
  "name": "AADSSHLoginForLinux",
  "protectedSettings": null,
  "protectedSettingsFromKeyVault": null,
  "provisioningState": "Succeeded",
  "publisher": "Microsoft.Azure.ActiveDirectory",
  "resourceGroup": "myLEMPResourceGroupxxxxxx",
  "settings": null,
  "suppressFailures": null,
  "tags": null,
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "typeHandlerVersion": "1.0",
  "typePropertiesType": "AADSSHLoginForLinux"
}
```

Check and browse your WordPress website

WordPress is an open source content management system (CMS) used by over 40% of the web to create websites, blogs, and other applications. WordPress can be run on a few different Azure services: AKS, Virtual Machines, and App Service. For a full list of WordPress options on Azure, see WordPress on Azure Marketplace.

This WordPress setup is only for proof of concept. To install the latest WordPress in production with recommended security settings, see the WordPress documentation.

Validate that the application is running by curling the application url:

Bash

```
runtime="5 minute";
endtime=$(date -ud "$runtime" +%s);
while [[ $(date -u +%s) -le $endtime ]]; do
    if curl -I -s -f $FQDN > /dev/null ; then
        curl -L -s -f $FQDN 2> /dev/null | head -n 9
        break
    else
        sleep 10
    fi;
done
```

Results:

HTML

```
<!DOCTYPE html>

Configure the rolling deployment strategy for Azure Linux virtual machines

Article • 08/22/2024

Applies to: ✔ Linux VMs

Azure Pipelines provides a fully featured set of CI/CD automation tools for deployments to virtual machines. This article will show you how to set up a classic release pipeline that uses the rolling strategy to deploy your web applications to Linux virtual machines.

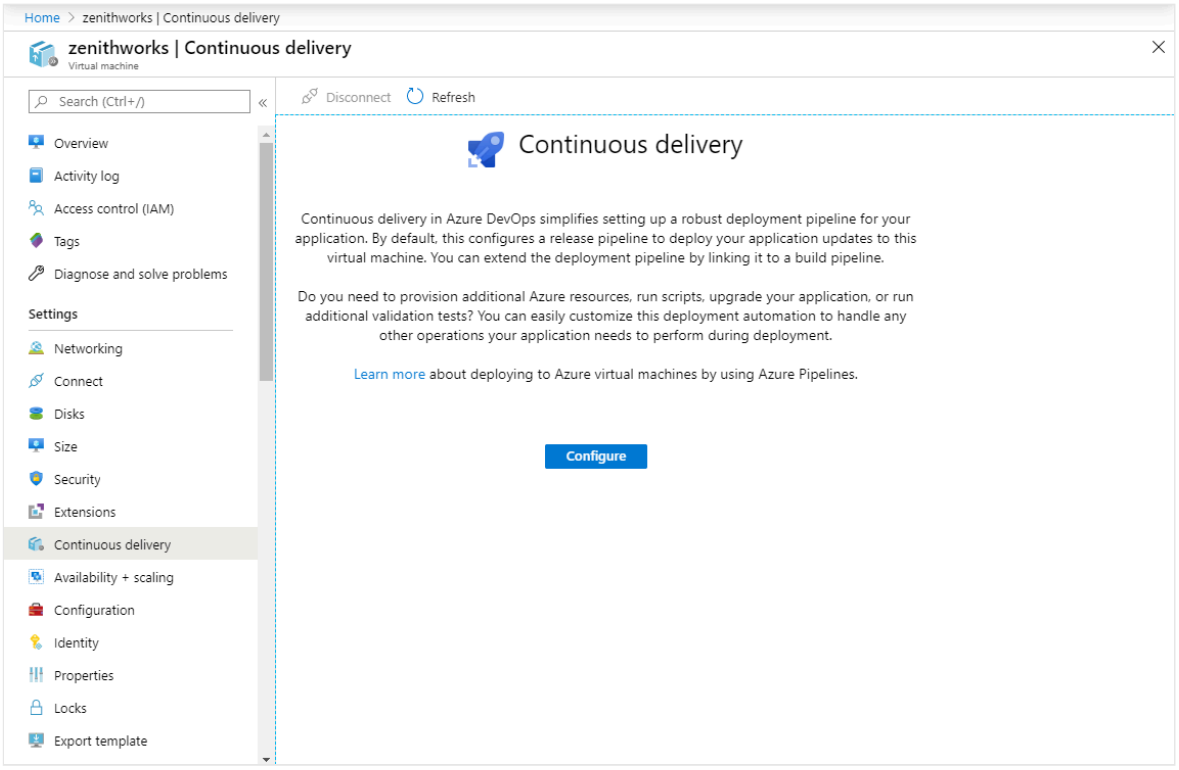
Rolling deployments

In each iteration, a rolling deployment replaces instances of an application's previous version. It replaces them with instances of the new version on a fixed set of machines (rolling set). The following walk-through shows how to configure a rolling update to virtual machines.

Using **Continuous-delivery**, you can configure rolling updates to your virtual machines within the Azure portal.

[!IMPORTANT] Virtual Machine's Continuous delivery setting will be retired on March 31, 2023. Learn more

1. Sign in to Azure portal and navigate to a virtual machine.
2. Select **Continuous delivery**, and then select **Configure**.

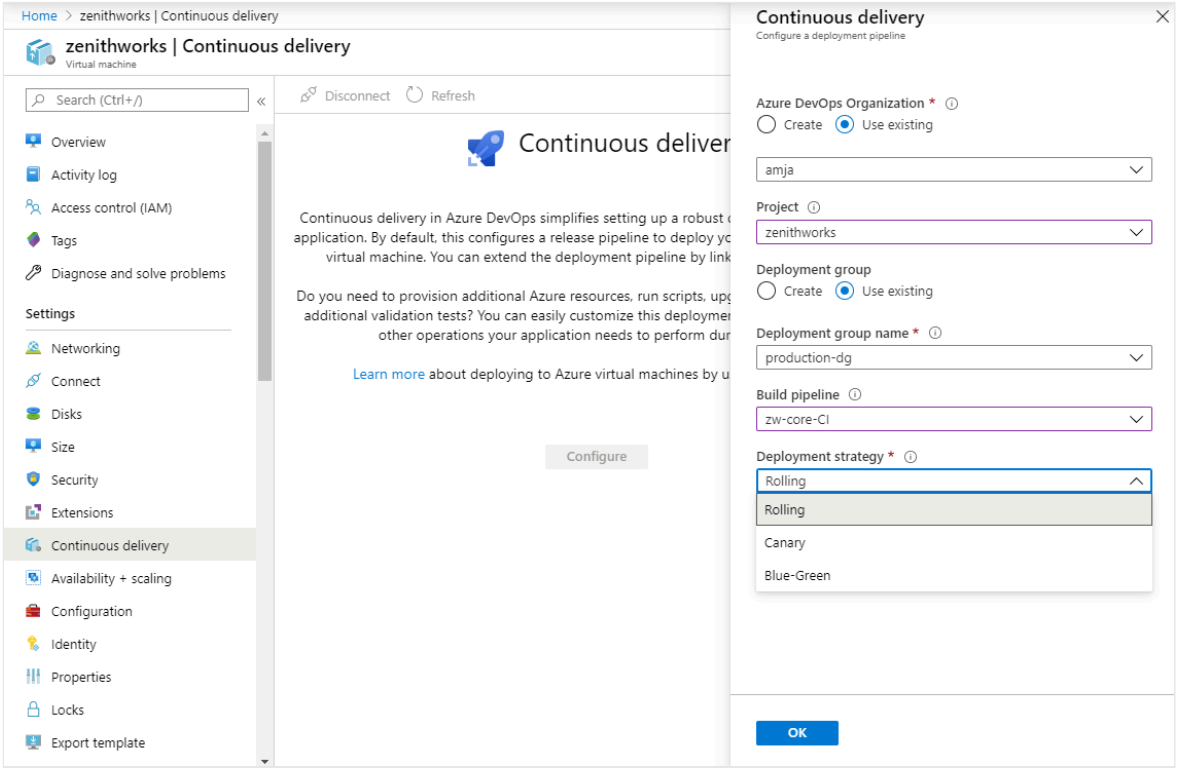


3. Select your **Azure DevOps Organization** and your **Project** from the dropdown menu or **Create** a new one.

4. Select your **Deployment group** from the dropdown menu or **Create** a new one.

5. Select your **Build pipeline**.

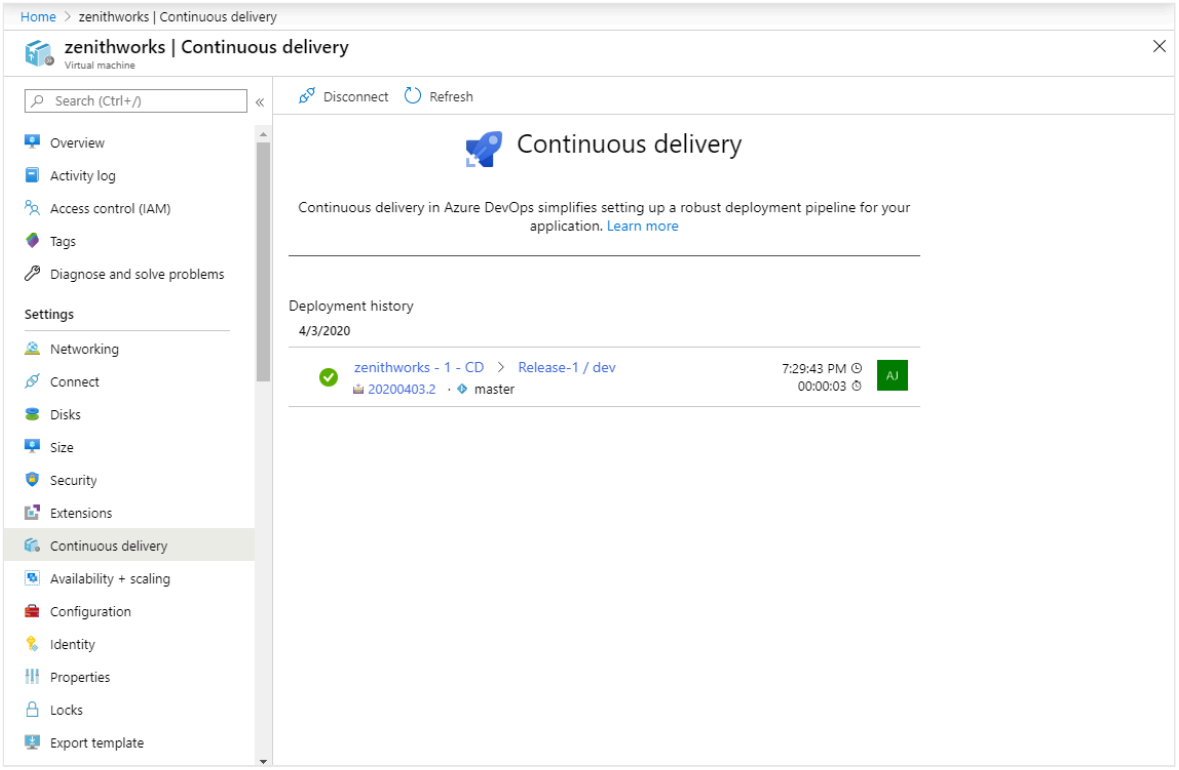
6. Select **Deployment strategy**, and then select **Rolling**.



7. Optionally, you can tag each machine with its role such as *web* or *db*. These tags help you target only VMs that have a specific role.

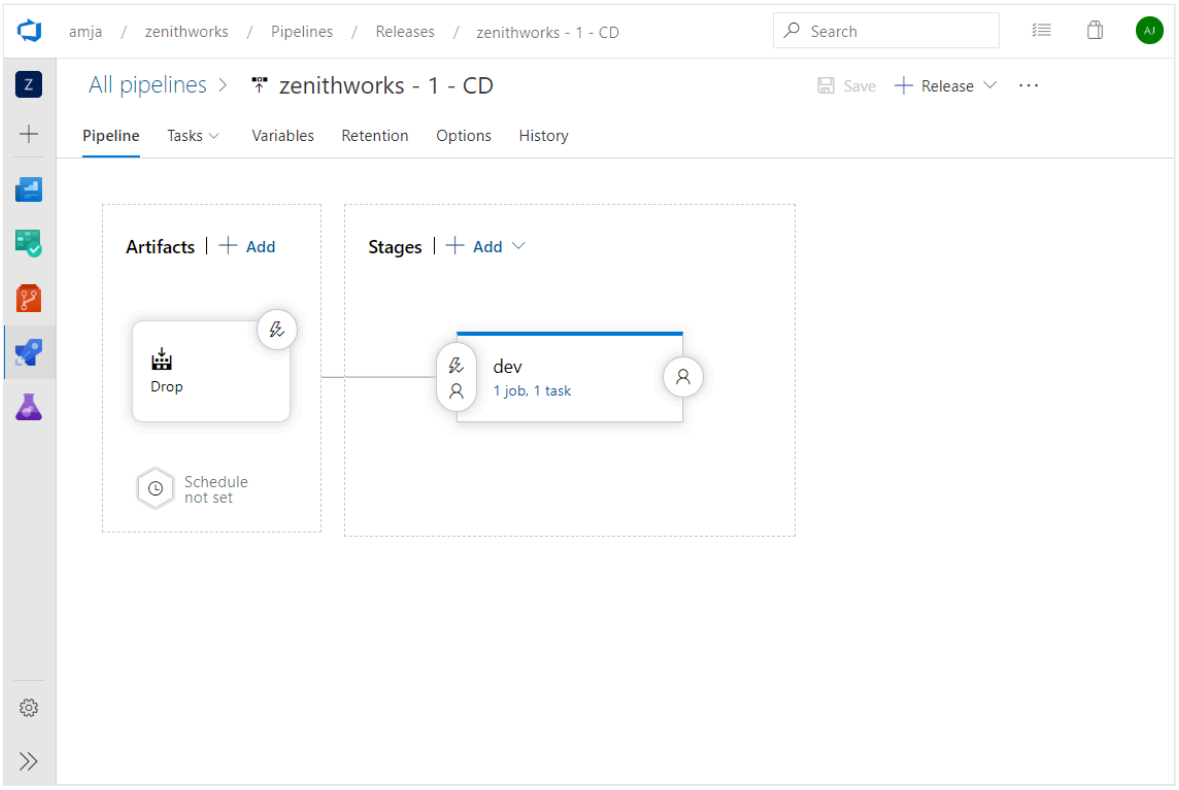
8. Select **OK** to configure the continuous delivery pipeline.

9. After completion, your continuous delivery pipeline should look similar to the following.

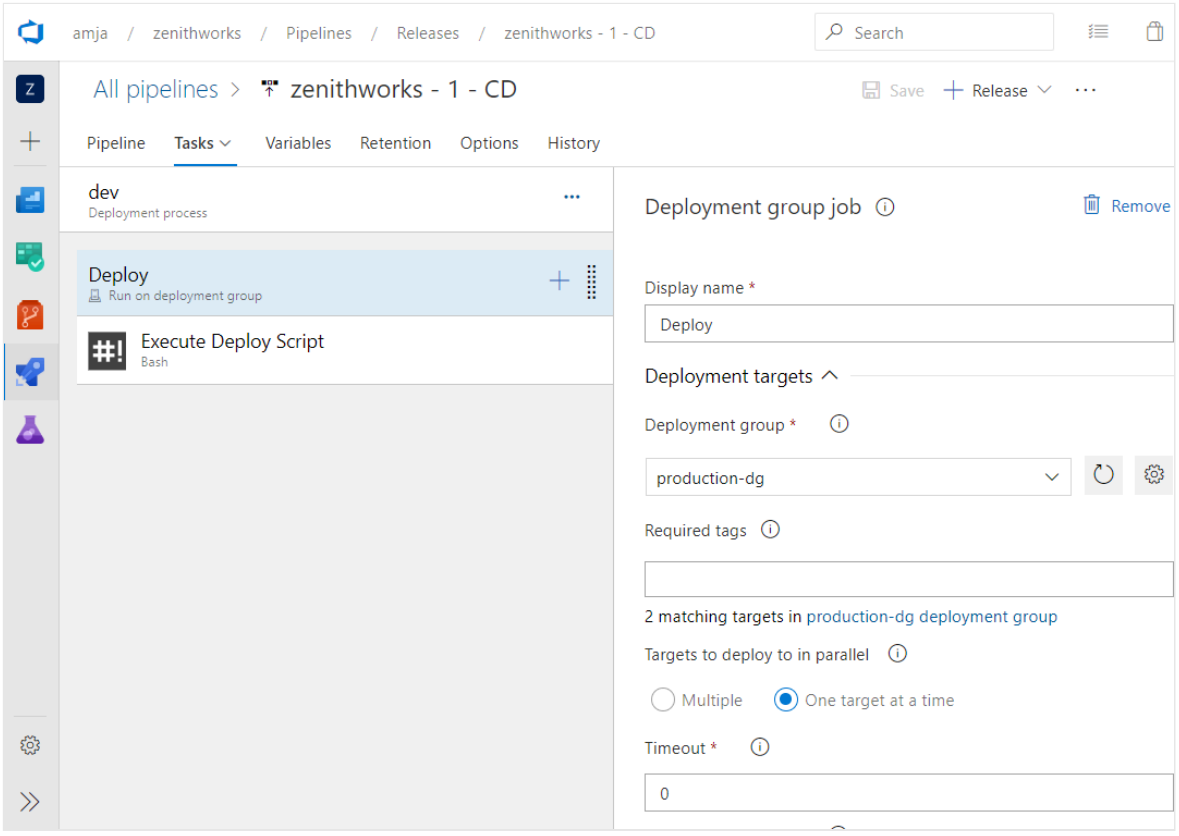


10. If you want to configure multiple VMs, repeat steps 2 through 4 for the other VMs. If you use the same deployment group that already has a configured pipeline, the new VMs will just be added to the deployment group and no new pipelines will be created.

11. Select the link to navigate to your pipeline, and then select**Edit** to modify the pipeline definition.



12. Select the tasks in the **dev** stage to navigate to the pipeline tasks, and then select **Deploy**.



13. You can specify the number of target machines to deploy to in parallel in each iteration. If you want to deploy to multiple machines, you can specify the number of machines as a percentage by using the slider.

14. The **Execute Deploy Script** task will execute the deployment script located in the root folder of the published artifacts.

- Configure the blue-green deployment strategy

Retirement

Continuous delivery setting of Virtual Machines will be retired on March 31, 2023. Please switch to directly using Azure DevOps to create customized pipelines for deployment to Azure VMs. Release pipeline Stage Templates and Deployments Groups Azure DevOps' features provide similar experiences.

Migration Steps

There is no migration required as VM CD experience does not store any information itself, it just helps users with their Day 0 getting started experience on Azure and Azure DevOps. Users will still be able to perform all operations from Azure DevOps after retirement. You won't be able to create and view pipelines from the Azure portal anymore.

FAQ

Where can I set up my CD pipeline after this experience is deprecated?

You won't be able to view or create Azure DevOps pipelines from an Azure portal Virtual Machine blade after retirement. You still can go to Azure DevOps portal and view or update pipelines.

Will I lose my earlier configured pipelines?

No. Your pipelines will still be available in Azure DevOps.

How can I configure different deployment strategies?

The current experience uses deployment groups to create deployment strategies. You can use deployment groups or release pipeline Stage Templates to build your pipeline with templates.

Tutorial: Use TLS/SSL certificates to secure a web server

Article • 08/22/2024

Applies to: ✔ Linux VMs

To secure web servers, a Transport Layer Security (TLS), previously known as Secure Sockets Layer (SSL), certificate can be used to encrypt web traffic. These TLS/SSL certificates can be stored in Azure Key Vault, and allow secure deployments of certificates to Linux virtual machines (VMs) in Azure. In this tutorial you learn how to:

- ✔ Create an Azure Key Vault
- ✔ Generate or upload a certificate to the Key Vault
- ✔ Create a VM and install the NGINX web server
- ✔ Inject the certificate into the VM and configure NGINX with a TLS binding

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you're running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Overview

Azure Key Vault safeguards cryptographic keys and secrets, such as certificates or passwords. Key Vault helps streamline the certificate management process and enables you to maintain control of keys that access those certificates. You can create a self-signed certificate inside Key Vault, or upload an existing, trusted certificate that you already own.

Rather than using a custom VM image that includes certificates baked-in, you inject certificates into a running VM. This process ensures that the most up-to-date certificates are installed on a web server during deployment. If you renew or replace a certificate, you don't also have to create a new custom VM image. The latest certificates are automatically injected as you create more VMs. During the whole process, the certificates never leave the Azure platform or are exposed in a script, command-line history, or template.

Create an Azure Key Vault

Before you can create a Key Vault and certificates, create a resource group with az group create. The following example creates a resource group named *myResourceGroupSecureWeb* in the *eastus* location:

Azure CLI

```
az group create --name myResourceGroupSecureWeb --location eastus
```

Next, create a Key Vault with az keyvault create and enable it for use when you deploy a VM. Each Key Vault requires a unique name, and should be all lowercase. Replace <*mykeyvault*> in the following example with your own unique Key Vault name:

Azure CLI

```
keyvault_name=<mykeyvault>
az keyvault create \
    --resource-group myResourceGroupSecureWeb \
    --name $keyvault_name \
    --enabled-for-deployment
```

Generate a certificate and store in Key Vault

For production use, you should import a valid certificate signed by trusted provider with az keyvault certificate import. For this tutorial, the following example shows how you can generate a self-signed certificate with az keyvault certificate create that uses the default certificate policy:

Azure CLI

```
az keyvault certificate create \
    --vault-name $keyvault_name \
    --name mycert \
    --policy "$(az keyvault certificate get-default-policy)"
```

Prepare a certificate for use with a VM

To use the certificate during the VM create process, obtain the ID of your certificate with az keyvault secret list-versions. Convert the certificate with az vm secret format. The following example assigns the output of these commands to variables for ease of use in the next steps:

Azure CLI

```
secret=$(az keyvault secret list-versions \
          --vault-name $keyvault_name \
          --name mycert \
          --query "[?attributes.enabled].id" --output tsv)
vm_secret=$(az vm secret format --secrets "$secret" -g
myResourceGroupSecureWeb --keyvault $keyvault_name)
```

Create a cloud-init config to secure NGINX

Cloud-init is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. As cloud-init runs during the initial boot process, there are no extra steps or required agents to apply your configuration.

When you create a VM, certificates and keys are stored in the protected */var/lib/waagent/* directory. To automate adding the certificate to the VM and configuring the web server, use cloud-init. In this example, you install and configure the NGINX web server. You can use the same process to install and configure Apache.

Create a file named *cloud-init-web-server.txt* and paste the following configuration:

YAML

```yaml
#cloud-config
package_upgrade: true
packages:
  - nginx
write_files:
  - owner: www-data:www-data
  - path: /etc/nginx/sites-available/default
    content: |
      server {
        listen 443 ssl;
        ssl_certificate /etc/nginx/ssl/mycert.cert;
        ssl_certificate_key /etc/nginx/ssl/mycert.prv;
      }
runcmd:
  - secretsname=$(find /var/lib/waagent/ -name "*.prv" | cut -c -57)
  - mkdir /etc/nginx/ssl
  - cp $secretsname.crt /etc/nginx/ssl/mycert.cert
  - cp $secretsname.prv /etc/nginx/ssl/mycert.prv
  - service nginx restart
```

Create a secure VM

Now create a VM with az vm create. The certificate data is injected from Key Vault with the `--secrets` parameter. You pass in the cloud-init config with the `--custom-data` parameter:

Azure CLI

```
az vm create \
    --resource-group myResourceGroupSecureWeb \
    --name myVM \
    --image Ubuntu2204 \
    --admin-username azureuser \
    --generate-ssh-keys \
    --custom-data cloud-init-web-server.txt \
    --secrets "$vm_secret"
```

It takes a few minutes for the VM to be created, the packages to install, and the app to start. When the VM has been created, take note of the `publicIpAddress` displayed by the Azure CLI. This address is used to access your site in a web browser.

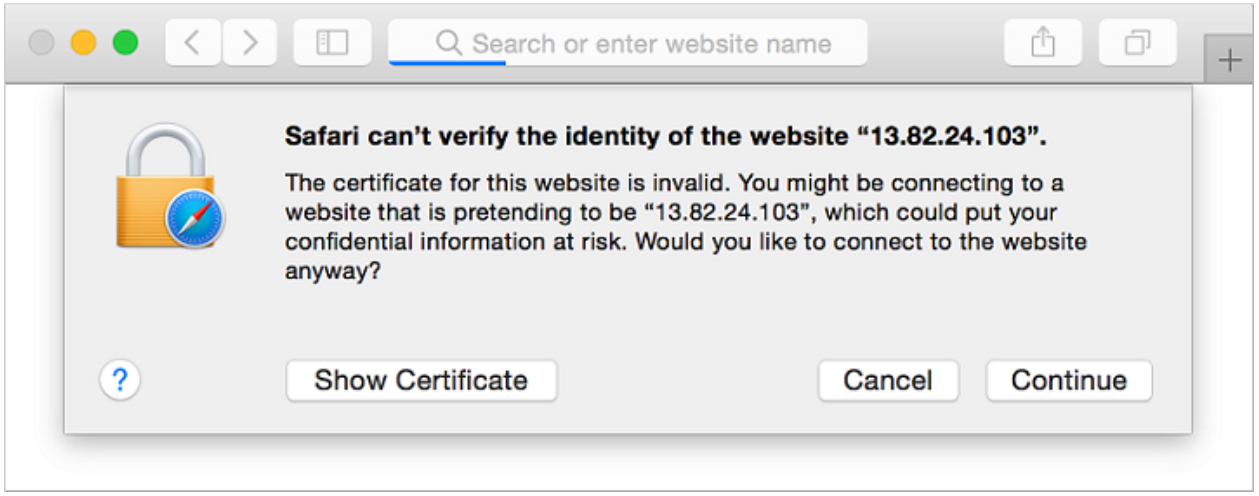
To allow secure web traffic to reach your VM, open port 443 from the Internet with az vm open-port:

Azure CLI

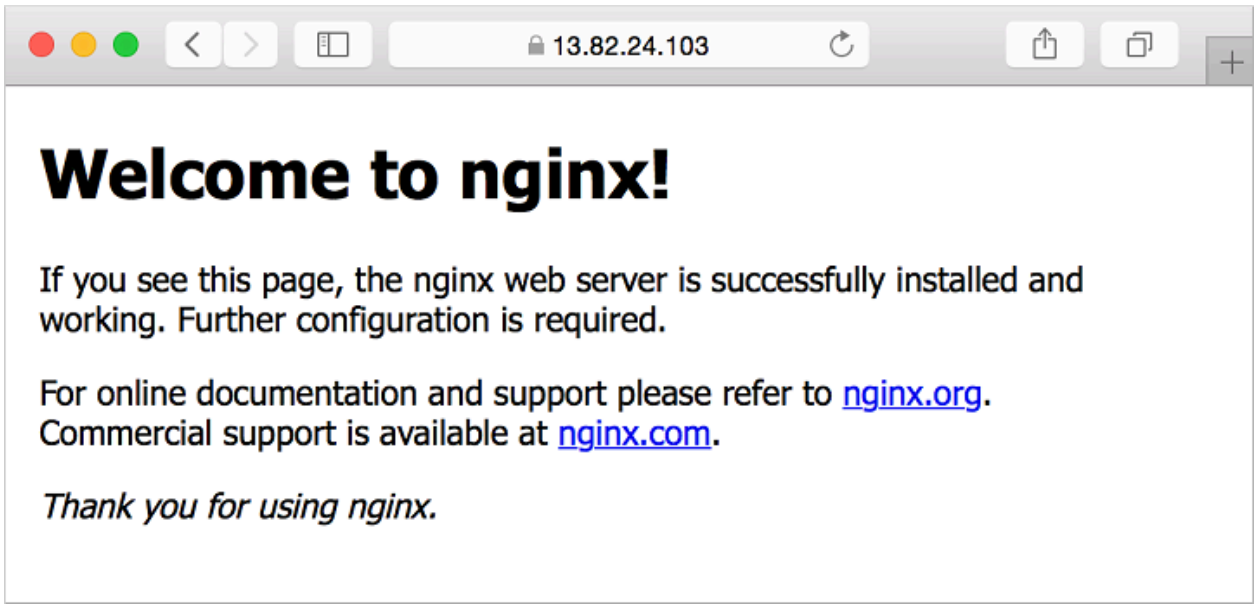
```
az vm open-port \
    --resource-group myResourceGroupSecureWeb \
    --name myVM \
    --port 443
```

Test the secure web app

Now you can open a web browser and enter *https://<publicIpAddress>* in the address bar. Provide your own public IP address from the VM create process. Accept the security warning if you used a self-signed certificate:



Your secured NGINX site is then displayed as in the following example:



Next steps

In this tutorial, you secured an NGINX web server with a TLS/SSL certificate stored in Azure Key Vault. You learned how to:

- ✓ Create an Azure Key Vault
- ✓ Generate or upload a certificate to the Key Vault
- ✓ Create a VM and install the NGINX web server
- ✓ Inject the certificate into the VM and configure NGINX with a TLS binding

Follow this link to see pre-built virtual machine script samples.

Create a Windows virtual machine from a Resource Manager template

Article • 08/22/2024

Applies to: ✔ Windows VMs

Learn how to create a Windows virtual machine by using an Azure Resource Manager template and Azure PowerShell from the Azure Cloud shell. The template used in this article deploys a single virtual machine running Windows Server in a new virtual network with a single subnet. For creating a Linux virtual machine, see How to create a Linux virtual machine with Azure Resource Manager templates.

An alternative is to deploy the template from the Azure portal. To open the template in the portal, select the **Deploy to Azure** button.

Create a virtual machine

Creating an Azure virtual machine usually includes two steps:

- Create a resource group. An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine.
- Create a virtual machine.

The following example creates a generation 2 VM with Trusted Launch enabled by default from an Azure Quickstart template. Here is a copy of the template:

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "metadata": {
    "_generator": {
      "name": "bicep",
      "version": "0.16.2.56959",
      "templateHash": "14427937023370378081"
    }
  },
  "parameters": {
    "adminUsername": {
```

```
      "type": "string",
      "metadata": {
        "description": "Username for the Virtual Machine."
      }
    },
    "adminPassword": {
      "type": "securestring",

    }
  }
}
```

To run the PowerShell script, Select **Try it** to open the Azure Cloud shell. To paste the script, right-click the shell, and then select **Paste**:

Azure PowerShell

```
$resourceGroupName = Read-Host -Prompt "Enter the Resource Group name"
$location = Read-Host -Prompt "Enter the location (i.e. centralus)"
$adminUsername = Read-Host -Prompt "Enter the administrator username"
$adminPassword = Read-Host -Prompt "Enter the administrator password" -
AsSecureString
$dnsLabelPrefix = Read-Host -Prompt "Enter an unique DNS name for the public
IP"

New-AzResourceGroup -Name $resourceGroupName -Location "$location"
New-AzResourceGroupDeployment `
    -ResourceGroupName $resourceGroupName `
    -TemplateUri "https://raw.githubusercontent.com/Azure/azure-quickstart-
templates/master/quickstarts/microsoft.compute/vm-simple-
windows/azuredeploy.json" `
    -adminUsername $adminUsername `
    -adminPassword $adminPassword `
    -dnsLabelPrefix $dnsLabelPrefix

 (Get-AzVm -ResourceGroupName $resourceGroupName).name
```

If you choose to install and use the PowerShell locally instead of from the Azure Cloud shell, this tutorial requires the Azure PowerShell module. Run `Get-Module -ListAvailable Az` to find the version. If you need to upgrade, see Install Azure PowerShell module. If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

In the previous example, you specified a template stored in GitHub. You can also download or create a template and specify the local path with the `-template-file` parameter.

Here are some additional resources:

- To learn how to develop Resource Manager templates, see Azure Resource Manager documentation.
- To see the Azure virtual machine schemas, see Azure template reference.
- To see more virtual machine template samples, see Azure Quickstart templates.

Connect to the virtual machine

The last PowerShell command from the previous script shows the virtual machine name. To connect to the virtual machine, see How to connect and sign on to an Azure virtual machine running Windows.

Next Steps

- If there were issues with the deployment, you might take a look at Troubleshoot common Azure deployment errors with Azure Resource Manager.
- Learn how to create and manage a virtual machine in Create and manage Windows VMs with the Azure PowerShell module.

To learn more about creating templates, view the JSON syntax and properties for the resources types you deployed:

- Microsoft.Network/publicIPAddresses
- Microsoft.Network/virtualNetworks
- Microsoft.Network/networkInterfaces
- Microsoft.Compute/virtualMachines

Tutorial: Secure a web server on a Windows virtual machine in Azure with TLS certificates stored in Key Vault

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

> **Note**
>
> Currently, this doc only works for Generalized images. If you attempt this tutorial by using a Specialized disk you will receive an error.

To secure web servers, a Transport Layer Security (TLS) certificate can be used to encrypt web traffic. TLS certificates can be stored in Azure Key Vault and allow secure deployments of certificates to Windows virtual machines (VMs) in Azure. In this tutorial you learn how to:

- ✔ Create an Azure Key Vault.
- ✔ Generate or upload a certificate to the Key Vault.
- ✔ Create a VM and install the IIS web server.
- ✔ Inject the certificate into the VM and configure IIS with a TLS binding.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Open Cloudshell** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste them into the Cloud Shell, and press enter to run them.

Overview

Azure Key Vault safeguards cryptographic keys and secrets, such as certificates or passwords. Key Vault helps streamline the certificate management process and enables you to maintain control of keys that access those certificates. You can create a self-

signed certificate inside Key Vault, or you can upload an existing, trusted certificate that you already own.

Rather than by using a custom VM image that includes certificates baked-in, inject certificates into a running VM. This process ensures that the most up-to-date certificates are installed on a web server during deployment. If you renew or replace a certificate, you don't also have to create a new custom VM image. The latest certificates are automatically injected as you create more VMs. During the whole process, the certificates never leave the Azure platform or are exposed in a script, command-line history, or template.

Create an Azure Key Vault

Before you can create a Key Vault and certificates, create a resource group with New-AzResourceGroup. The following example creates a resource group named *myResourceGroupSecureWeb* in the *East US* location:

Azure PowerShell

```
$resourceGroup = "myResourceGroupSecureWeb"
$location = "East US"
New-AzResourceGroup -ResourceGroupName $resourceGroup -Location $location
```

Next, create a Key Vault with New-AzKeyVault. Each Key Vault requires a unique name and should be all lower case. Replace `mykeyvault` with your own unique Key Vault name in the following example:

Azure PowerShell

```
$keyvaultName="mykeyvault"
New-AzKeyVault -VaultName $keyvaultName `
    -ResourceGroup $resourceGroup `
    -Location $location `
    -EnabledForDeployment
```

Generate a certificate and store it in Key Vault

For production use, you should import a valid certificate signed by a trusted provider with Import-AzKeyVaultCertificate. For this tutorial, the following example shows how you can generate a self-signed certificate with Add-AzKeyVaultCertificate that uses the default certificate policy from New-AzKeyVaultCertificatePolicy.

Azure PowerShell

```
$policy = New-AzKeyVaultCertificatePolicy `
    -SubjectName "CN=www.contoso.com" `
    -SecretContentType "application/x-pkcs12" `
    -IssuerName Self `
    -ValidityInMonths 12

Add-AzKeyVaultCertificate `
    -VaultName $keyvaultName `
    -Name "mycert" `
    -CertificatePolicy $policy
```

Create a virtual machine

Set an administrator username and password for the VM with Get-Credential:

Azure PowerShell

```
$cred = Get-Credential
```

Now you can create the VM with New-AzVM. The following example creates a VM named *myVM* in the *EastUS* location. If they don't already exist, the supporting network resources are created. To allow secure web traffic, the cmdlet also opens port *443*.

Azure PowerShell

```
# Create a VM
New-AzVm `
    -ResourceGroupName $resourceGroup `
    -Name "myVM" `
    -Location $location `
    -VirtualNetworkName "myVnet" `
    -SubnetName "mySubnet" `
    -SecurityGroupName "myNetworkSecurityGroup" `
    -PublicIpAddressName "myPublicIpAddress" `
    -Credential $cred `
    -OpenPorts 443

# Use the Custom Script Extension to install IIS
Set-AzVMExtension -ResourceGroupName $resourceGroup `
    -ExtensionName "IIS" `
    -VMName "myVM" `
    -Location $location `
    -Publisher "Microsoft.Compute" `
    -ExtensionType "CustomScriptExtension" `
    -TypeHandlerVersion 1.8 `
```

```
    -SettingString '{"commandToExecute":"powershell Add-WindowsFeature Web-
Server -IncludeManagementTools"}'
```

It takes a few minutes for the VM to be created. The last step uses the Azure Custom Script Extension to install the IIS web server with Set-AzVmExtension.

Add a certificate to VM from Key Vault

To add the certificate from Key Vault to a VM, obtain the ID of your certificate with Get-AzKeyVaultSecret. Add the certificate to the VM with Add-AzVMSecret:

Azure PowerShell

```
$certURL=(Get-AzKeyVaultSecret -VaultName $keyvaultName -Name "mycert").id

$vm=Get-AzVM -ResourceGroupName $resourceGroup -Name "myVM"
$vaultId=(Get-AzKeyVault -ResourceGroupName $resourceGroup -VaultName
$keyVaultName).ResourceId
$vm = Add-AzVMSecret -VM $vm -SourceVaultId $vaultId -CertificateStore "My"
-CertificateUrl $certURL | Update-AzVM
```

Configure IIS to use the certificate

Use the Custom Script Extension again with Set-AzVMExtension to update the IIS configuration. This update applies the certificate injected from Key Vault to IIS and configures the web binding:

Azure PowerShell

```
$publicSettings = '{
    "fileUris":["https://raw.githubusercontent.com/Azure-Samples/compute-
automation-configurations/master/secure-iis.ps1"],
    "commandToExecute":"powershell -ExecutionPolicy Unrestricted -File
secure-iis.ps1"
}'

Set-AzVMExtension -ResourceGroupName $resourceGroup `
    -ExtensionName "IIS" `
    -VMName "myVM" `
    -Location $location `
    -Publisher "Microsoft.Compute" `
    -ExtensionType "CustomScriptExtension" `
    -TypeHandlerVersion 1.8 `
    -SettingString $publicSettings
```

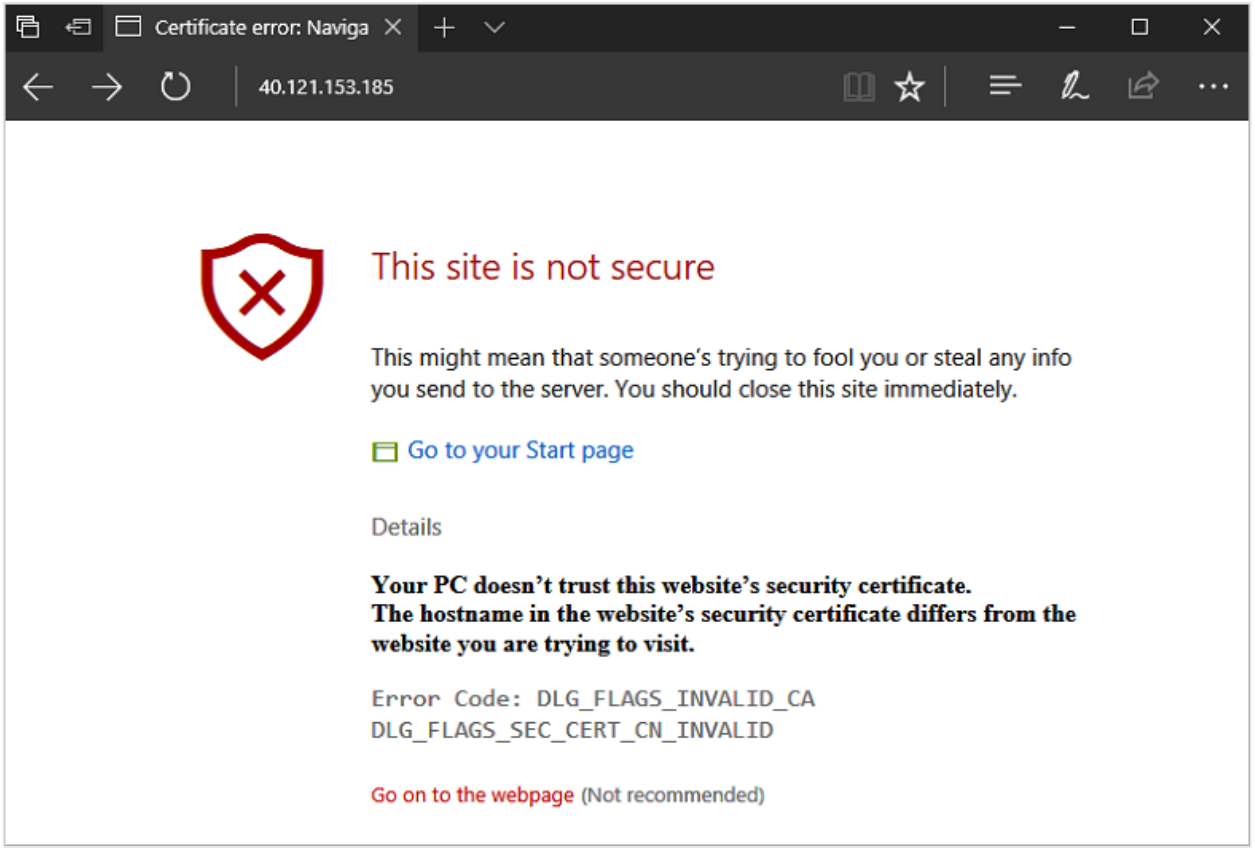
Test the secure web app

Obtain the public IP address of your VM with Get-AzPublicIPAddress. The following example obtains the IP address for `myPublicIP` created earlier:

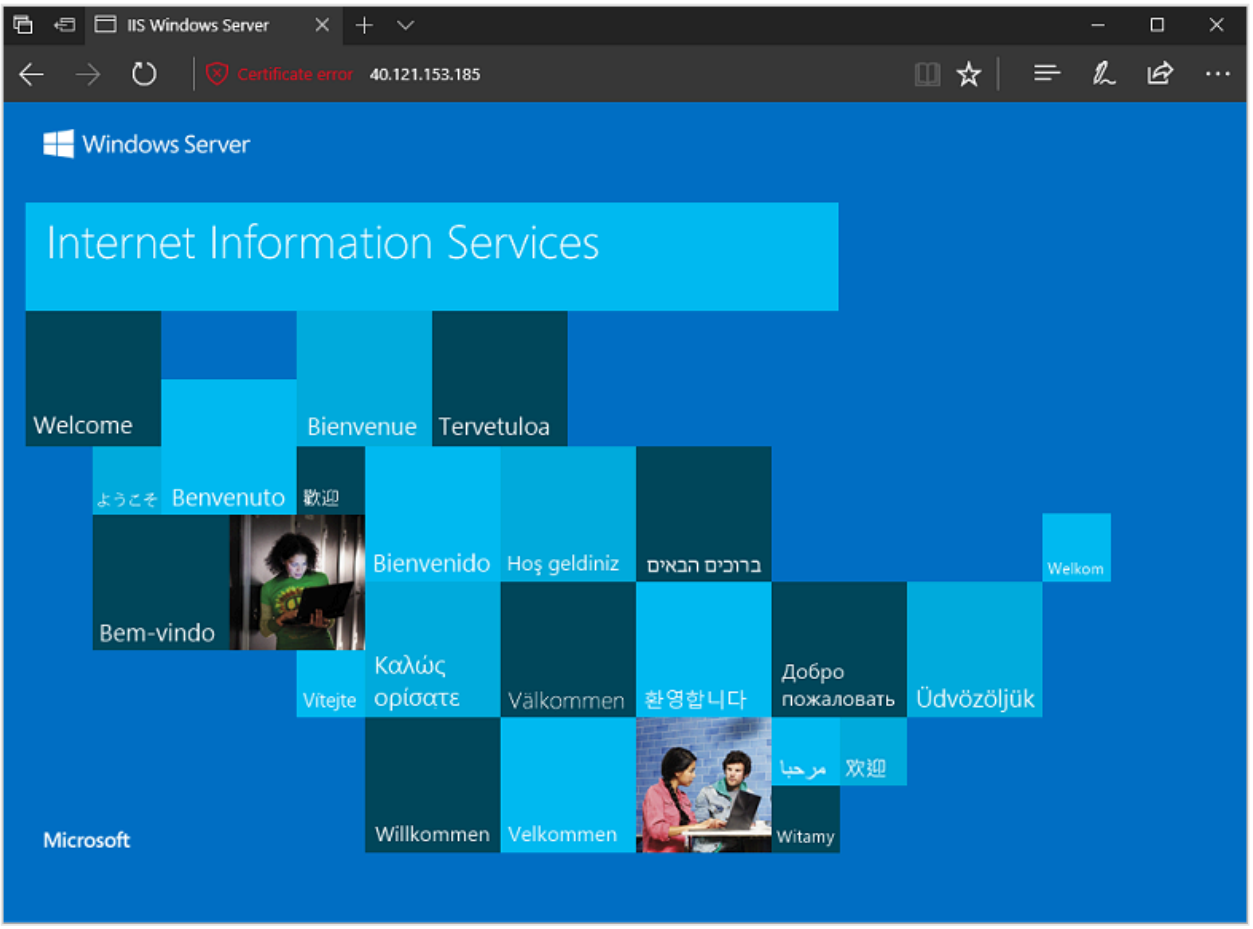
Azure PowerShell

```
Get-AzPublicIPAddress -ResourceGroupName $resourceGroup -Name
"myPublicIPAddress" | select "IpAddress"
```

Now you can open a web browser and enter `https://<myPublicIP>` in the address bar. To accept the security warning if you used a self-signed certificate, select **Details** and then **Go on to the webpage**:



Your secured IIS website is then displayed as in the following example:



Next steps

In this tutorial, you secured an IIS web server with a TLS certificate stored in Azure Key Vault. You learned how to:

- ✓ Create an Azure Key Vault.
- ✓ Generate or upload a certificate to the Key Vault.
- ✓ Create a VM and install the IIS web server.
- ✓ Inject the certificate into the VM and configure IIS with a TLS binding.

For prebuilt virtual machine script samples, see:

Windows virtual machine script samples

Create a VM from a specialized disk using PowerShell

Article • 12/12/2024

Applies to: ✔ Windows VMs

Create a new VM by attaching an existing OS disk to a new VM. This option is useful if you have a VM that isn't working correctly. You can delete the VM and then reuse the disk to create a new VM.

> **Important**
>
> You can also use the VHD as a source to create an Azure Compute Gallery image. For more information, see Create an image definition and image version. Customers are encouraged to use Azure Compute Gallery as all new features like ARM64, Trusted Launch, and Confidential VM, are only supported through Azure Compute Gallery. Creating an image instead of just attaching a disk means you can create multiple VMs from the same source disk.
>
> When you use a specialized disk to create a new VM, the new VM retains the computer name of the original VM. Other computer-specific information (like the CMID) is also kept and, in some cases, this duplicate information could cause issues. When copying a VM, be aware of what types of computer-specific information your applications rely on.

We recommend that you limit the number of concurrent deployments to 20 VMs from a single VHD or snapshot.

Portal

Create a snapshot and then create a disk from the snapshot. This strategy allows you to keep the original VHD as a fallback:

1. Open the Azure portal.
2. In the search box, enter **disks** and then select **Disks** to display the list of available disks.
3. Select the disk that you would like to use. The **Disk** page for that disk appears.
4. From the menu at the top, select **Create snapshot**.
5. Choose a **Resource group** for the snapshot. You can use either an existing resource group or create a new one.

6. Enter a **Name** for the snapshot.
7. For **Snapshot type**, choose **Full**.
8. For **Storage type**, choose **Standard HDD**, **Premium SSD**, or **Zone-redundant** storage.
9. When you're done, select **Review + create** to create the snapshot.
10. After the snapshot has been created, select **Home** > **Create a resource**.
11. In the search box, enter **managed disk** and then select **Managed Disks** from the list.
12. On the **Managed Disks** page, select **Create**.
13. Choose a **Resource group** for the disk. You can use either an existing resource group or create a new one. This selection will also be used as the resource group where you create the VM from the disk.
14. For **Region**, you must select the same region where the snapshot is located.
15. Enter a **Name** for the disk.
16. In **Source type**, ensure **Snapshot** is selected.
17. In the **Source snapshot** drop-down, select the snapshot you want to use.
18. For **Size**, you can change the storage type and size as needed.
19. Make any other adjustments as needed and then select **Review + create** to create the disk. Once validation passes, select **Create**.

After you have the disk that you want to use, you can create the VM in the portal:

1. In the search box, enter **disks** and then select **Disks** to display the list of available disks.
2. Select the disk that you would like to use. The **Disk** page for that disk opens.
3. In the **Essentials** section, ensure that **Disk state** is listed as **Unattached**. If it isn't, you might need to either detach the disk from the VM or delete the VM to free up the disk.
4. In the menu at the top of the page, select **Create VM**.
5. On the **Basics** page for the new VM, enter a **Virtual machine name** and either select an existing **Resource group** or create a new one.
6. For **Size**, select **Change size** to access the **Size** page.
7. The disk name should be pre-filled in the **Image** section.
8. On the **Disks** page, you may notice that the **OS Disk Type** cannot be changed. This preselected value is configured at the point of Snapshot or VHD creation and will carry over to the new VM. If you need to modify disk type take a new snapshot from an existing VM or disk.
9. On the **Networking** page, you can either let the portal create all new resources or you can select an existing **Virtual network** and **Network security group**. The portal always creates a new network interface and public IP address for the new VM.

10. On the **Management** page, make any changes to the monitoring options.
11. On the **Guest config** page, add any extensions as needed.
12. When you're done, select **Review + create**.
13. If the VM configuration passes validation, select **Create** to start the deployment.

Understand VM reboots - maintenance vs. downtime

Article • 01/15/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

There are three scenarios that can lead to virtual machines in Azure being impacted: unplanned hardware maintenance, unexpected downtime, and planned maintenance.

Unplanned hardware maintenance event

Unplanned hardware maintenance occurs when the Azure platform predicts that the hardware or any platform component associated to a physical machine, is about to fail. When the platform predicts a failure, it issues an unplanned hardware maintenance event to reduce the impact to the virtual machines hosted on that hardware. Azure uses Live Migration technology to migrate the Virtual Machines from the failing hardware to a healthy physical machine. Live Migration is a VM preserving operation that only pauses the Virtual Machine for a short time. Memory, open files, and network connections are maintained, but performance might be reduced before and/or after the event. In cases where Live Migration can't be used, the VM experiences Unexpected Downtime. Live migration is only possible when the physical machine is in a degraded but working state.

Unexpected downtime

Unexpected downtime is when the hardware or the physical infrastructure for the virtual machine encounters an issue and fails unexpectedly. Issues can include local network failures, local disk failures, or other rack level failures. When detected, the Azure platform automatically attempts to recover the hardware and make the resources available in the same Host Node. If these efforts fail, then automatically migrates (heals) your virtual machine to a healthy physical machine in the same data center. During the healing procedure, virtual machines experience downtime (reboot) and in some cases loss of the temporary drive. The attached OS and data disks are always preserved.

Virtual machines can also experience downtime in the unlikely event of an outage or disaster that affects an entire data center, or even an entire region. For these scenarios, Azure provides protection options including availability zones and paired regions.

Planned maintenance events

Planned maintenance events are periodic updates made by Microsoft to the underlying Azure platform to improve overall reliability, performance, and security of the platform infrastructure that your virtual machines run on. Most of these updates are performed without any impact upon your Virtual Machines or Cloud Services (see Maintenance that doesn't require a reboot). While the Azure platform attempts to use VM Preserving Maintenance in all possible occasions, there are rare instances when these updates require a reboot of your virtual machine to apply the required updates to the underlying infrastructure. In this case, you can perform Azure Planned Maintenance with Maintenance-Redeploy operation by initiating the maintenance for their VMs in the suitable time window. For more information, see Planned Maintenance for Virtual Machines.

Reduce downtime

To reduce the impact of downtime due to one or more of these events, we recommend the following high availability best practices for your virtual machines:

- Use Availability Zones to protect from data center failures
- Configure multiple virtual machines in an availability set for redundancy
- Use scheduled events for Linux or scheduled events for Windows to proactively respond to VM impacting events
- Configure each application tier into separate availability sets
- Combine a load balancer with availability zones or sets

Next steps

To learn more about availability options in Azure see, see Availability overview.

Auto-shutdown a virtual machine

Learn how to automatically shut down virtual machines (VMs) in Azure. The auto-shutdown feature for Azure VMs can help reduce costs by shutting down the VMs during off hours when they aren't needed and automatically restarting them when they're needed again.

Configure auto-shutdown for a virtual machine

Portal

Sign in to the Azure portal.

1. In the Azure portal, navigate to the virtual machine you want to configure auto-shutdown for.
2. In the virtual machine's detail page, select "Auto-shutdown" under the **Operations** section.
3. In the "Auto-shutdown" configuration screen, toggle the switch to "On."
4. Set the time you want the virtual machine to shut down.
5. If you want to receive notification before shutdown, select "Yes" in the "Send notification before shutdown" option and provide details in "Email Address" or "Webhook URL" as per your choice.
6. Select "Save" to save the auto-shutdown configuration.

> **Note**
>
> Remember to configure the time zone to match your requirements, as Coordinated Universal Time (UTC) is the default setting for the time zone.

Clean up resources

If you no longer need the virtual machine, delete it with the following steps:

1. Navigate to the virtual machine's **Overview** page on the left
2. Select on "Delete" from the top middle option.
3. Follow the prompts to delete the virtual machine.

For more information on how to delete a virtual machine, see delete a VM.

Next steps

Learn about sizes and how to resize a VM:

- Types of virtual machine sizes.
- Change the size of a virtual machine.

Last updated on 01/13/2026

Hibernation for Azure virtual machines

Applies to: ✔ Linux VMs ✔ Windows VMs

Hibernation allows you to pause VMs that aren't being used and save on compute costs. It's an effective cost management feature for scenarios such as:

- Virtual desktops, dev/test servers, and other scenarios where the VMs don't need to run 24/7.
- Systems with long boot times due to memory intensive applications. These applications can be initialized on VMs and hibernated. These “prewarmed” VMs can then be quickly started when needed, with the applications already up and running in the desired state.

How hibernation works

When you hibernate a VM, Azure signals the VM's operating system to perform a suspend-to-disk action. Azure stores the memory contents of the VM in the OS disk, then deallocates the VM. When the VM is started again, the memory contents are transferred from the OS disk back into memory. Applications and processes that were previously running in your VM resume from the state prior to hibernation.

Once a VM is in a hibernated state, you aren't billed for the VM usage. Your account is only billed for the storage (OS disk, data disks) and networking resources (IPs, etc.) attached to the VM.

When hibernating a VM:

- Hibernation is triggered on a VM using the Azure portal, CLI, PowerShell, SDKs, or APIs. Azure then signals the guest operating system to perform suspend-to-disk (S4).
- The VM's memory contents are stored on the OS disk. The VM is then deallocated, releases the lease on the underlying hardware, and is powered off. Refer to VM states and billing for more details on the VM deallocated state.
- Data in the temporary disk isn't persisted.
- The OS disk, data disks, and NICs remain attached to your VM. Any static IPs remain unchanged.
- You aren't billed for the VM usage for a hibernated VM.
- You continue to be billed for the storage and networking resources associated with the hibernated VM.

Supported configurations

Hibernation support is limited to certain VM sizes and OS versions. Make sure you have a supported configuration before using hibernation.

Supported operating systems

Supported operating systems, OS specific limitations, and configuration procedures are listed in the OS's documentation section.

Windows VM hibernation documentation

Linux VM hibernation documentation

Supported VM sizes

VM sizes with up to 64-GB RAM from the following General Purpose VM series support hibernation.

- Dasv5-series
- Dadsv5-series
- Dsv5-series
- Ddsv5-series
- Easv5-series
- Eadsv5-series
- Esv5-series
- Edsv5-series

VM sizes with up to 112-GB RAM from the following GPU VM series support hibernation.

- NVv4-series
- NVadsA10v5-series

If you are using any UVM-enabled compute applications, we recommend idling the application before initiating hibernation.

General limitations

- You can resize VMs that have hibernation enabled, but not when the VM is in a *Hibernated* state. The VM should either be in a *Running* or *Stopped* state.
- Hibernation is only supported with Nested Virtualization when Trusted Launch is enabled on the VM
- When a VM is hibernated, you can't attach, detach, or modify any disks or NICs associated with the VM. The VM must instead be moved to a Stop-Deallocated state.

- When a VM is hibernated, there's no capacity guarantee to ensure that there's sufficient capacity to start the VM later. In the rare case that you encounter capacity issues, you can try starting the VM at a later time. Capacity reservations don't guarantee capacity for hibernated VMs.
- You can only hibernate a VM using the Azure portal, CLI, PowerShell, SDKs and API. Hibernating the VM using guest OS operations don't result in the VM moving to a hibernated state and the VM continues to be billed.

Azure feature limitations

- Ephemeral OS disks
- Shared disks
- Availability Sets
- Virtual Machine Scale Sets in Uniform orchestration mode are not supported. Virtual Machine Scale Sets in Flexible orchestration mode are supported.
- Spot VMs
- Managed images
- Azure Backup
- Capacity reservations

Prerequisites to use hibernation

- Hibernation must be enabled on your VM.
- A persistent OS disk large enough to store the contents of the RAM, OS and other applications running on the VM is connected.
- The VM size supports hibernation.
- The VM OS supports hibernation.
- The Azure VM Agent is installed if you're using the Windows or Linux Hibernate Extensions.
- If a VM is being created from an OS disk or a Compute Gallery image, then the OS disk or Gallery Image definition supports hibernation.

Setting up hibernation

Enabling hibernation is detailed in the OS specific setup and configuration documentation:

Linux VMs

To configure hibernation on a Linux VM, check out the Linux hibernation documentation.

Windows VMs

To configure hibernation on a Windows VM, check out the Windows hibernation documentation.

Troubleshooting

Refer to the Hibernation troubleshooting guide for general troubleshooting information.

Refer to the Windows hibernation troubleshooting guide for issues with Windows guest hibernation.

Refer to the Linux hibernation troubleshooting guide for issues with Linux guest hibernation.

FAQs

- What are the charges for using this feature?
  - Once a VM is placed in a hibernated state, you aren't charged for the VM, just like how you aren't charged for VMs in a stop (deallocated) state. You're only charged for the OS disk, data disks and any static IPs associated with the VM.
- Can I enable hibernation on existing VMs?
  - Yes, you can enable hibernation on existing VMs.
- Can I resize a VM with hibernation enabled?
  - Yes, you can resize a VM with hibernation enabled. You cannot resize the VM if it's in a *Hibernated* state. Move the VM to either a *Running* or *Stopped* state before resizing.
- Can I modify a VM once it is in a hibernated state?
  - No, once a VM is in a hibernated state, you can't perform actions like resizing the VM and modifying the disks. Additionally, you can't detach any disks or networking resources that are currently attached to the VM or attach new resources to the VM. You can however stop(deallocate) or delete the VM if you want to detach these resources.
- What is the difference between stop(deallocating) and hibernating a VM?
  - When you stop(deallocate) a VM, the VM shuts down without persisting the memory contents. You can resize stop(deallocated) VMs and detach/attach disks to the VM.
  - When you hibernate a VM, the memory contents are first persisted in the OS disk, then the VM hibernates. You can't resize VMs in a hibernated state, nor detach/attach disks and networking resources to the VM.

- Can I initiate hibernation from within the VM?
  - To hibernate a VM you should use the Azure portal, CLI, PowerShell commands, SDKs and APIs. Triggering hibernation from inside the VM still results in your VM being billed for the compute resources.
- When a VM is hibernated, is there a capacity assurance at the time of starting the VM?
  - No, there's no capacity assurance for starting hibernated VMs. In rare scenarios if you encounter a capacity issue, then you can try starting the VM at a later time.

Hibernating Linux virtual machines

Article • 01/28/2025

Applies to: ✔ Linux VMs

Hibernation allows you to pause VMs that aren't being used and save on compute costs. It's an effective cost management feature for scenarios such as:

- Virtual desktops, dev/test servers, and other scenarios where the VMs don't need to run 24/7.
- Systems with long boot times due to memory intensive applications. These applications can be initialized on VMs and hibernated. These “prewarmed” VMs can then be quickly started when needed, with the applications already up and running in the desired state.

How hibernation works

To learn how hibernation works, check out the hibernation overview.

Supported configurations

Hibernation support is limited to certain Virtual Machine (VM) sizes and Operating System (OS) versions. Make sure you have a supported configuration before using hibernation.

For a list of hibernation compatible VM sizes, check out the supported VM sizes section in the hibernation overview.

Supported Linux distros

The following Linux operating systems support hibernation:

- Ubuntu 22.04 LTS (Long-Term Support)
- Ubuntu 20.04 LTS (Long-Term Support)
- Ubuntu 18.04 LTS (Long-Term Support)
- Debian 11
- Debian 10 (with backports kernel)

- Red Hat Enterprise Linux 9.0 and higher (with minimum kernel version 5.14.0-70)
- Red Hat Enterprise Linux 8.5 and higher (with minimum kernel version 4.18.0-348)

Prerequisites and configuration limitations

- Hibernation isn't supported with Trusted Launch for Linux VMs

For general limitations, Azure feature limitations supported VM sizes, and feature prerequisites check out the "Supported configurations" section in the hibernation overview.

Creating a Linux VM with hibernation enabled

To hibernate a VM, you must first enable the feature on the VM.

To enable hibernation during VM creation, you can use the Azure portal, CLI, PowerShell, ARM templates, and API.

Portal

To enable hibernation in the Azure portal, check the 'Enable hibernation' box during VM creation.

After creating a VM with hibernation enabled, you'll need to configure the guest OS to successfully hibernate your VM.

Enabling hibernation on an existing Linux VM

To enable hibernation on an existing VM, you can use Azure CLI, PowerShell, or REST API. Before proceeding, ensure that the guest OS version supports hibernation on Azure. For more information, see supported OS versions.

CLI

To enable hibernation on an existing VM using Azure CLI, first deallocate your VM with az vm deallocate. Once the VM is deallocated, update the OS disk and VM.

1. Update the OS disk to set *supportsHibernation* to `true`. If *supportsHibernation* is already set to `true`, you can skip this step and proceed to the next step.

   Azure CLI

   ```
   az disk update --resource-group myResourceGroup \
   --name MyOSDisk \
   --set supportsHibernation=true
   ```

2. To enable hibernation, update the VM setting.

   Azure CLI

   ```
   az vm update --resource-group myResourceGroup \
   --name myVM \
   --enable-hibernation true
   ```

3. Start the VM and then proceed to configuring hibernation in the guest OS.

   Azure CLI

   ```
   az vm start --resource-group myResourceGroup \
   --name myVM \
   ```

Configuring hibernation in the guest OS

After ensuring that your VM configuration is supported, you can enable hibernation on your Linux VM using one of two options:

Option 1: LinuxHibernateExtension

Option 2: hibernation-setup-tool

LinuxHibernateExtension

> ⓘ **Note**

If you've already installed the hibernation-setup-tool, you don't need to install the LinuxHibernateExtension. These steps are redundant ways to enable hibernation on a Linux VM.

When you create a Hibernation-enabled VM via the Azure portal, the LinuxHibernationExtension is automatically installed on the VM.

If the extension is missing, you can manually install the LinuxHibernateExtension on your Linux VM to configure the guest OS for hibernation.

> **Note**
>
> Azure extensions are currently disabled by default for Debian images. To re-enable extensions, check the Linux hibernation troubleshooting guide.

> **Note**
>
> For RHEL LVM, you need to expand the root volume and ensure there's sufficient space available to create the swap file. To expand the volume, check the disk expansion guide.

CLI

To install *LinuxHibernateExtension* with the Azure CLI, run the following command:

Azure CLI

```
az vm extension set -n LinuxHibernateExtension --publisher
Microsoft.CPlat.Core --version 1.0 \    --vm-name MyVm --resource-group
MyResourceGroup --enable-auto-upgrade true
```

Hibernation-setup-tool

> **Note**
>
> If you've already installed the LinuxHibernateExtension, you don't need to install the hibernation-setup-tool. These steps are redundant ways to enable hibernation on a Linux VM.

You can install the hibernation-setup-tool package on your Linux VM from Microsoft's Linux software repository at packages.microsoft.com.

To use the Linux software repository, follow the instructions at Linux package repository for Microsoft software.

Debian/Ubuntu

To use the hibernation-setup-tool in Debian and Ubuntu versions, open git bash and run this command:

```bash
curl -sSL https://packages.microsoft.com/keys/microsoft.asc | sudo tee
etc/apt/trusted.gpg.d/microsoft.asc

sudo apt-add-repository https://packages.microsoft.com/ubuntu/20.04/prod

sudo apt-get update
```

To install the package, run this command in git bash:

```bash
sudo apt-get install hibernation-setup-tool
```

> **Note**
>
> For RHEL LVM, you need to expand the root volume and ensure there's sufficient space available to create the swap file. To expand the volume, check the disk expansion guide.

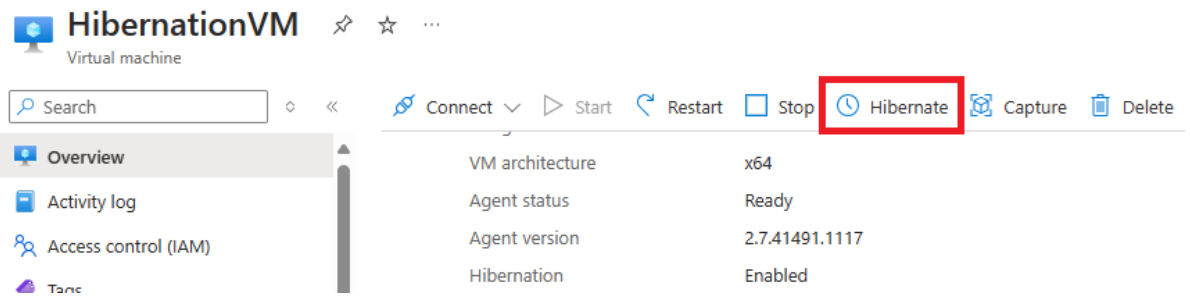
Once the package installs successfully, your Linux guest OS is configured for hibernation. You can also create a new Azure Compute Gallery Image from this VM and use the image to create VMs. VMs created with this image have the hibernation package preinstalled, simplifying your VM creation experience.

Hibernate a VM

Once a VM with hibernation enabled has been created and the guest OS is configured for hibernation, you can hibernate the VM through the Azure portal, the Azure CLI, PowerShell, or REST API.

Portal

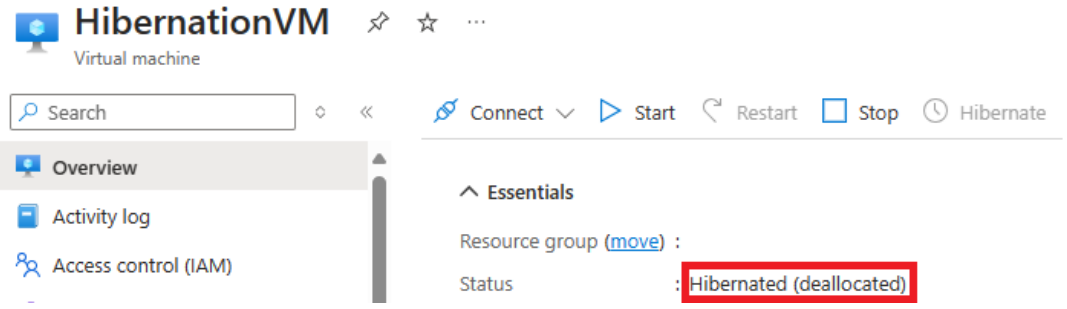
To hibernate a VM in the Azure portal, click the 'Hibernate' button on the VM Overview page.



View state of hibernated VM

Portal

To view the state of a VM in the portal, check the 'Status' on the overview page. It should report as "Hibernated (deallocated)"

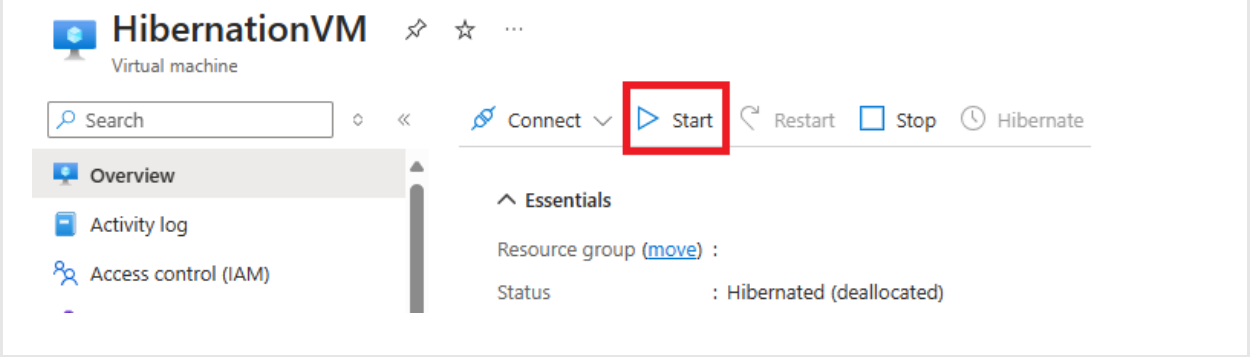


Start hibernated VMs

You can start hibernated VMs just like how you would start a stopped VM. This can be done through the Azure portal, the Azure CLI, PowerShell, or REST API.

Portal

To start a hibernated VM using the Azure portal, click the 'Start' button on the VM Overview page.



Deploy hibernation enabled VMs from the Azure Compute Gallery

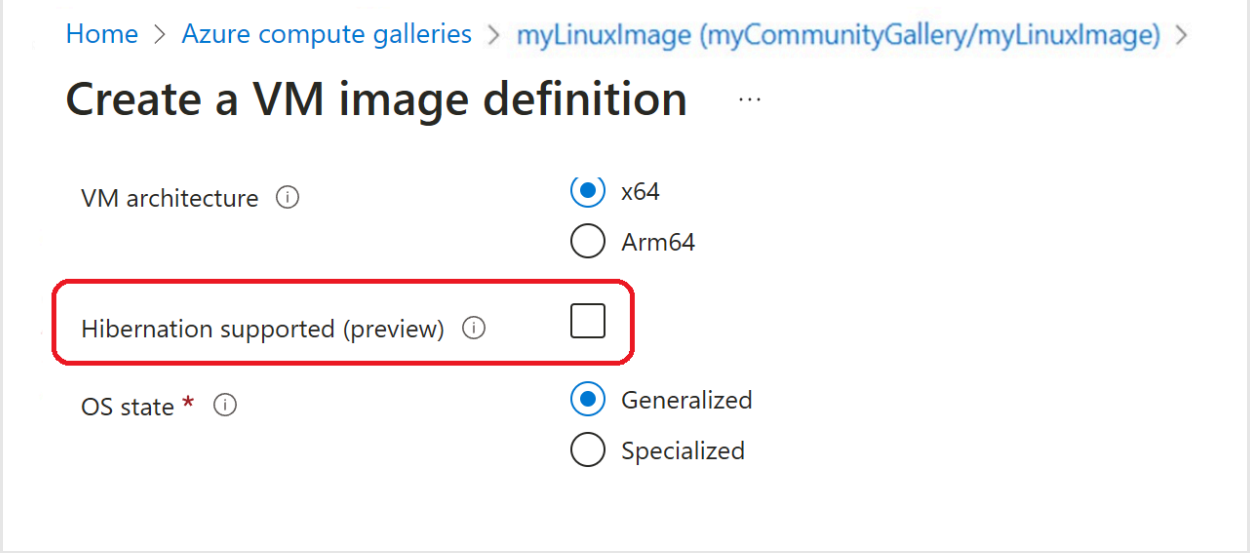
VMs created from Compute Gallery images can also be enabled for hibernation. Ensure that the OS version associated with your Gallery image supports hibernation on Azure. Refer to the list of supported OS versions.

To create VMs with hibernation enabled using Gallery images, you'll first need to create a new image definition with the hibernation property enabled. Once this feature property is enabled on the Gallery Image definition, you can create an image version and use that image version to create hibernation enabled VMs.

> **Note**
>
> For specialized Windows images, the page file location must be set to C: drive in order for Azure to successfully configure your guest OS for hibernation. If you're creating an Image version from an existing VM, you should first move the page file to the OS disk and then use the VM as the source for the Image version.

Portal

To create an image definition with the hibernation property enabled, select the checkmark for 'Enable hibernation'.



Deploy hibernation enabled VMs from an OS disk

VMs created from OS disks can also be enabled for hibernation. Ensure that the OS version associated with your OS disk supports hibernation on Azure. Refer to the list of supported OS versions.

To create VMs with hibernation enabled using OS disks, ensure that the OS disk has the hibernation property enabled. Refer to API example to enable this property on OS disks. Once the hibernation property is enabled on the OS disk, you can create hibernation enabled VMs using that OS disk.

```
PATCH https://management.azure.com/subscriptions/{subscription-
id}/resourceGroups/myResourceGroup/providers/Microsoft.Compute/disks/myDisk?
api-version=2021-12-01

{
  "properties": {
    "supportsHibernation": true
  }
}
```

Hibernating Windows virtual machines

Article • 08/22/2024

Applies to: ✔ Windows VMs

Hibernation allows you to pause VMs that aren't being used and save on compute costs. It's an effective cost management feature for scenarios such as:

- Virtual desktops, dev/test servers, and other scenarios where the VMs don't need to run 24/7.
- Systems with long boot times due to memory intensive applications. These applications can be initialized on VMs and hibernated. These “prewarmed” VMs can then be quickly started when needed, with the applications already up and running in the desired state.

How hibernation works

To learn how hibernation works, check out the hibernation overview.

Supported configurations

Hibernation support is limited to certain VM sizes and OS versions. Make sure you have a supported configuration before using hibernation.

For a list of hibernation compatible VM sizes, check out the supported VM sizes section in the hibernation overview.

Supported Windows versions

The following Windows operating systems support hibernation:

- Windows Server 2022
- Windows Server 2019
- Windows 11 Pro
- Windows 11 Enterprise
- Windows 11 Enterprise multi-session
- Windows 10 Pro
- Windows 10 Enterprise
- Windows 10 Enterprise multi-session

Prerequisites and configuration limitations

- The Windows page file can't be on the temp disk.
- Applications such as Device Guard and Credential Guard that require virtualization-based security (VBS) work with hibernation when you enable Trusted Launch on the VM and Nested Virtualization in the guest OS.

> **Note**
>
> To use VBS and Hibernation, Windows 11 24H2 OS build must be 26100.3037 or later. You can verify OS build using `wmic qfe list` command. Marketplace images of Windows 11 24H2 installed after February 2025 support VBS and Hibernation.

For general limitations, Azure feature limitations supported VM sizes, and feature prerequisites check out the "Supported configurations" section in the hibernation overview.

Creating a Windows VM with hibernation enabled

To hibernate a VM, you must first enable the feature on the VM.

To enable hibernation during VM creation, you can use the Azure portal, CLI, PowerShell, ARM templates and API.

Portal

To enable hibernation in the Azure portal, check the 'Enable hibernation' box during VM creation.

Once you've created a VM with hibernation enabled, you need to configure the guest OS to successfully hibernate your VM.

Enabling hibernation on an existing Windows VM

To enable hibernation on an existing VM, you can use Azure CLI, PowerShell, or REST API. Before proceeding, ensure that the guest OS version supports hibernation on Azure. For more information, see supported OS versions.

> **Note**
>
> Ensure that the page file is located on the `C: drive`. Move the page file to the `C: drive` if necessary, before continuing.

CLI

To enable hibernation on an existing VM using Azure CLI, first deallocate your VM with az vm deallocate. Once the VM is deallocated, update the OS disk and VM.

1. Update the OS disk to set *supportsHibernation* to `true`. If *supportsHibernation* is already set to `true`, you can skip this step and proceed to the next step.

   Azure CLI

   ```
   az disk update --resource-group myResourceGroup \
   --name MyOSDisk \
   --set supportsHibernation=true
   ```

2. Update the VM to enable hibernation.

   Azure CLI

   ```
   az vm update --resource-group myResourceGroup \
   --name myVM \
   --enable-hibernation true
   ```

3. Start the VM and then proceed to configuring hibernation in the guest OS.

   Azure CLI

   ```
   az vm start --resource-group myResourceGroup \
   --name myVM \
   ```

Configuring hibernation in the guest OS

Enabling hibernation while creating a Windows VM automatically installs the 'Microsoft.CPlat.Core.WindowsHibernateExtension' VM extension. This extension configures the guest OS for hibernation. This extension doesn't need to be manually installed or updated, as this extension is managed by the Azure platform.

> **Note**
>
> When you create a VM with hibernation enabled, Azure automatically places the page file on the `C: drive`. If you're enabling hibernation on an existing VM or using a specialized image, then you'll need to follow additional steps to ensure that the page file is located on the `C: drive`.

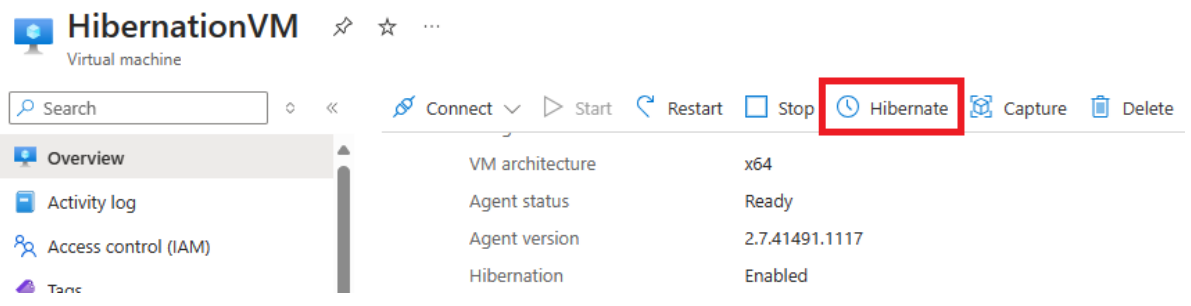
> **Note**
>
> Using the WindowsHibernateExtension requires the Azure VM Agent to be installed on the VM. If you choose to opt-out of the Azure VM Agent, then you can configure the OS for hibernation by running powercfg /h /type full inside the guest. You can then verify if hibernation is enabled inside guest using the powercfg /a command.

Hibernate a VM

Once a VM with hibernation enabled has been created and the guest OS is configured for hibernation, you can hibernate the VM through the Azure portal, the Azure CLI, PowerShell, or REST API.

Portal

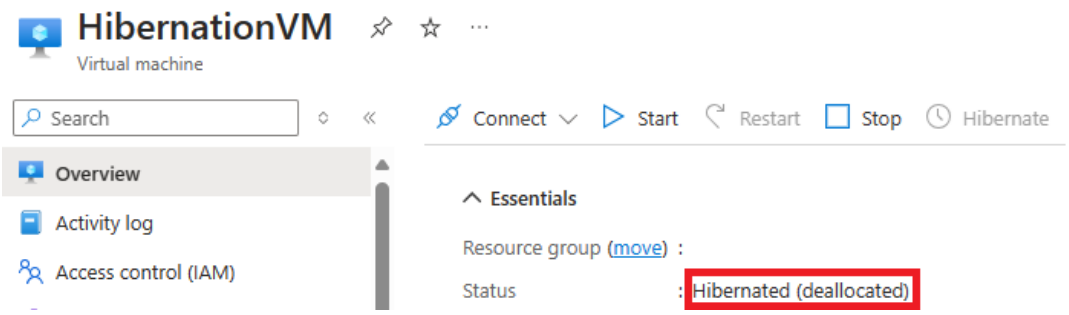
To hibernate a VM in the Azure portal, click the 'Hibernate' button on the VM Overview page.



View state of hibernated VM

Portal

To view the state of a VM in the portal, check the 'Status' on the overview page. It should report as "Hibernated (deallocated)"

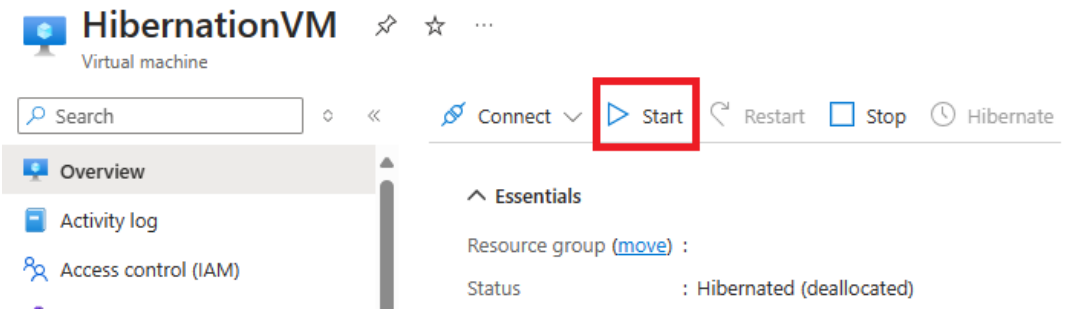


Start hibernated VMs

You can start hibernated VMs just like how you would start a stopped VM. This can be done through the Azure portal, the Azure CLI, PowerShell, or REST API.

Portal

To start a hibernated VM using the Azure portal, click the 'Start' button on the VM Overview page.



Deploy hibernation enabled VMs from the Azure Compute Gallery

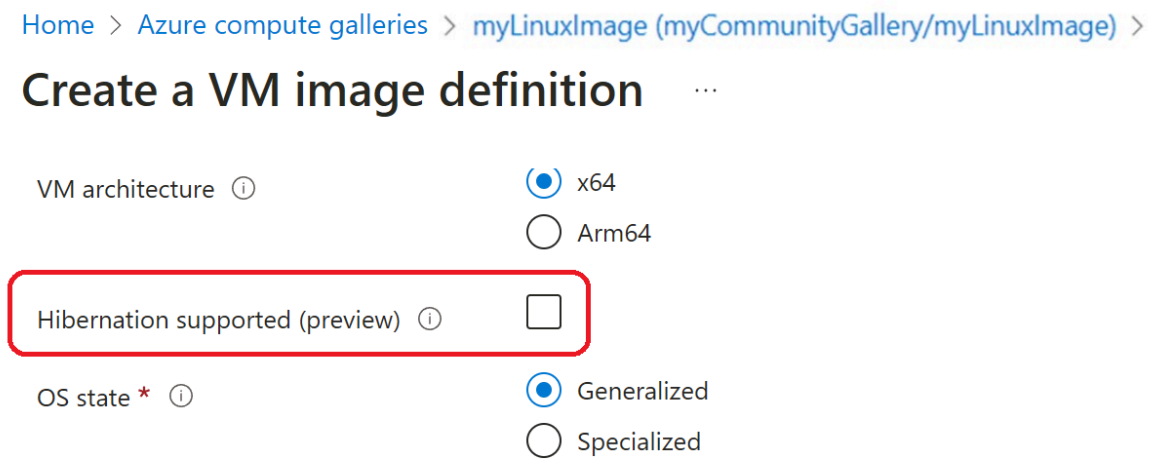
VMs created from Compute Gallery images can also be enabled for hibernation. Ensure that the OS version associated with your Gallery image supports hibernation on Azure. Refer to the list of supported OS versions.

To create VMs with hibernation enabled using Gallery images, you'll first need to create a new image definition with the hibernation property enabled. Once this feature property is enabled on the Gallery Image definition, you can create an image version and use that image version to create hibernation enabled VMs.

> **Note**
>
> For specialized Windows images, the page file location must be set to C: drive in order for Azure to successfully configure your guest OS for hibernation. If you're creating an Image version from an existing VM, you should first move the page file to the OS disk and then use the VM as the source for the Image version.

Portal

To create an image definition with the hibernation property enabled, select the checkmark for 'Enable hibernation'.



Deploy hibernation enabled VMs from an OS disk

VMs created from OS disks can also be enabled for hibernation. Ensure that the OS version associated with your OS disk supports hibernation on Azure. Refer to the list of supported OS versions.

To create VMs with hibernation enabled using OS disks, ensure that the OS disk has the hibernation property enabled. Refer to API example to enable this property on OS disks. Once the hibernation property is enabled on the OS disk, you can create hibernation enabled VMs using that OS disk.

```
PATCH https://management.azure.com/subscriptions/{subscription-
id}/resourceGroups/myResourceGroup/providers/Microsoft.Compute/disks/myDisk?
api-version=2021-12-01

{
  "properties": {
    "supportsHibernation": true
  }
}
```

Troubleshooting hibernation in Azure

Article • 08/22/2024

Hibernating a virtual machine allows you to persist the VM state to the OS disk. This article describes how to troubleshoot issues with the hibernation feature, issues creating hibernation enabled VMs, and issues with hibernating a VM.

For information specific to Linux VMs, check out the Linux VM hibernation troubleshooting guide.

For information specific to Windows VMs, check out the Windows VM hibernation troubleshooting guide.

Unable to create a VM with hibernation enabled

If you're unable to create a VM with hibernation enabled, ensure that you're using a VM size, OS version that supports Hibernation. Refer to the supported VM sizes, OS versions section in the user guide and the limitations section for more details. Here are some common error codes that you might observe:

Expand table

ResultCode	Error Message	Action
OperationNotAllowed	The referenced os disk should support hibernation for a VM with hibernation capability.	Validate that the OS disk has hibernation support enabled.
OperationNotAllowed	The referenced platform image should support hibernation for a VM with hibernation capability.	Use a platform image that supports hibernation.
OperationNotAllowed	The referenced shared gallery image should support hibernation for a VM with hibernation capability.	Validate that the Shared Gallery Image Definition has hibernation support enabled
OperationNotAllowed	Hibernation capability isn't supported for Spot VMs.	
OperationNotAllowed	User VM Image isn't supported for a VM with Hibernation capability.	Use a platform image or Shared Gallery Image if you want to use the hibernation feature

ResultCode	Error Message	Action
OperationNotAllowed	Referencing a Dedicated Host isn't supported for a VM with Hibernation capability.	
OperationNotAllowed	Referencing a Capacity Reservation Group isn't supported for a VM with Hibernation capability.	
OperationNotAllowed	Hibernation can't be enabled on Virtual Machine since the OS Disk Size ({0} bytes) should at least be greater than the VM memory ({1} bytes).	Ensure the OS disk has enough space to be able to persist the RAM contents once the VM is hibernated
OperationNotAllowed	Hibernation can't be enabled on Virtual Machines created in an Availability Set.	Hibernation is only supported for standalone VMs & Virtual Machine Scale Sets Flex VMs

Unable to hibernate a VM

If you're unable to hibernate a VM, first check whether hibernation is enabled on the VM. For example, using the GET VM API, you can check if hibernation is enabled on the VM

```
"properties": {
    "vmId": "XXX",
    "hardwareProfile": {
        "vmSize": "Standard_D4s_v5"
    },
    "additionalCapabilities": {
        "hibernationEnabled": true
    },
```

If hibernation is enabled on the VM, check if hibernation is successfully enabled in the guest OS.

For Linux guests, check out the Linux VM hibernation troubleshooting guide.

For Windows guests, check out the Windows VM hibernation troubleshooting guide.

Common error codes

Expand table

ResultCode	errorDetails	Action
InternalOperationError	The fabric operation failed.	This is usually a transient issue. Retry the Hibernate operation after 5mins.
OperationNotAllowed	Operation 'HibernateAndDeallocate' isn't allowed on VM 'Z0000ZYH000' since VM has extension 'AzureHibernateExtension' in failed state	Customer issue. Confirm that VM creation with hibernation enabled succeeded, and that the extension is in a healthy state
OperationNotAllowed	The Hibernate-Deallocate Operation can only be triggered on a VM that is successfully provisioned and is running.	Customer error. Ensure that the VM is successfully running before attempting to Hibernate-Deallocate the VM.
OperationNotAllowed	The Hibernate-Deallocate Operation can only be triggered on a VM that is enabled for hibernation. Enable the property additionalCapabilities.hibernationEnabled during VM creation, or after stopping and deallocating the VM.	Customer error.
VMHibernateFailed	Hibernating the VM 'hiber_vm_res_5' failed due to an internal error. Retry later.	Retry after 5mins. If it continues to fail after multiple retries, check if the guest is correctly configured to support hibernation or contact Azure support.

ResultCode	errorDetails	Action
VMHibernateNotSupported	The VM 'Z0000ZYJ000' doesn't support hibernation. Ensure that the VM is correctly configured to support hibernation.	Hibernating a VM immediately after boot isn't supported. Retry hibernating the VM after a few minutes.

Unable to resume a VM

Starting a hibernated VM is similar to starting a stopped VM. In addition to commonly seen issues while starting VMs, certain issues are specific to starting a hibernated VM.

Expand table

ResultCode	errorDetails
OverconstrainedResumeFromHibernatedStateAllocationRequest	Allocation failed. VM(s) with the following constraints can't be allocated, because the condition is too restrictive. Remove some constraints and try again. Constraints applied are: Networking Constraints (such as Accelerated Networking or IPv6), Resuming from hibernated state (retry starting the VM after some time or alternatively stop-deallocate the VM and try starting the VM again).
AllocationFailed	VM allocation failed from hibernated state due to insufficient capacity. Try again later or alternatively stop-deallocate the VM and try starting the VM.

Troubleshooting hibernation on Linux VMs

Article • 08/22/2024

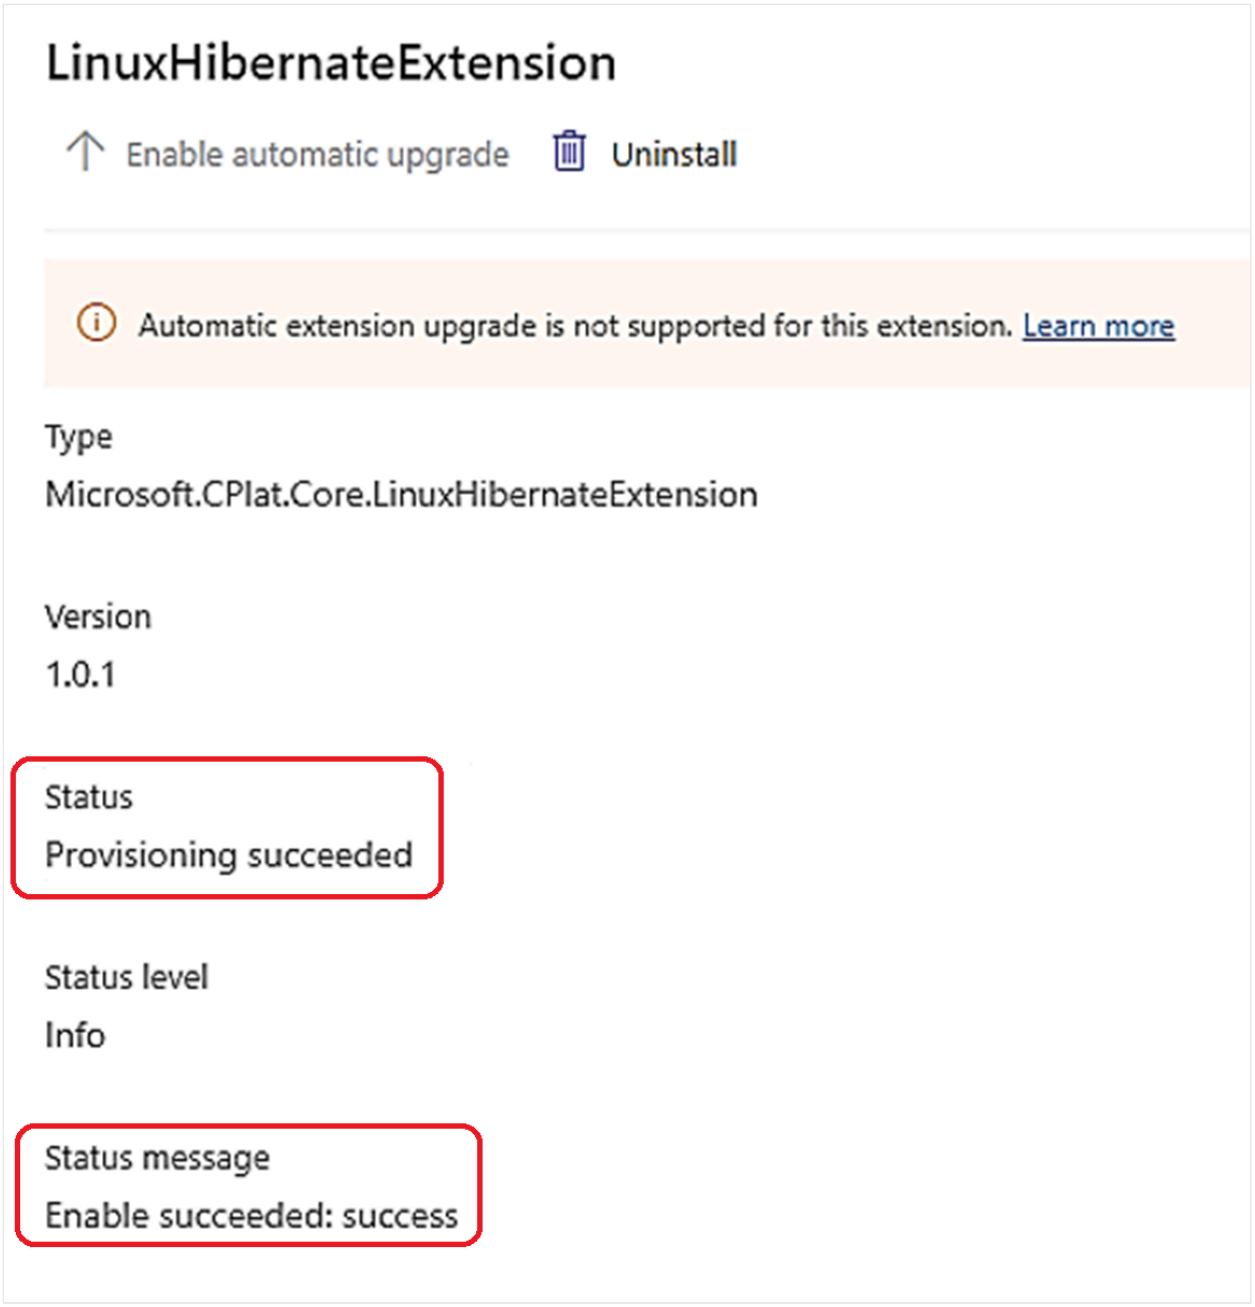
Hibernating a virtual machine allows you to persist the VM state to the OS disk. This article describes how to troubleshoot issues with the hibernation feature on Linux, issues creating hibernation enabled Linux VMs, and issues with hibernating a Linux VM.

To view the general troubleshooting guide for hibernation, check out Troubleshoot hibernation in Azure.

Unable to hibernate a Linux VM

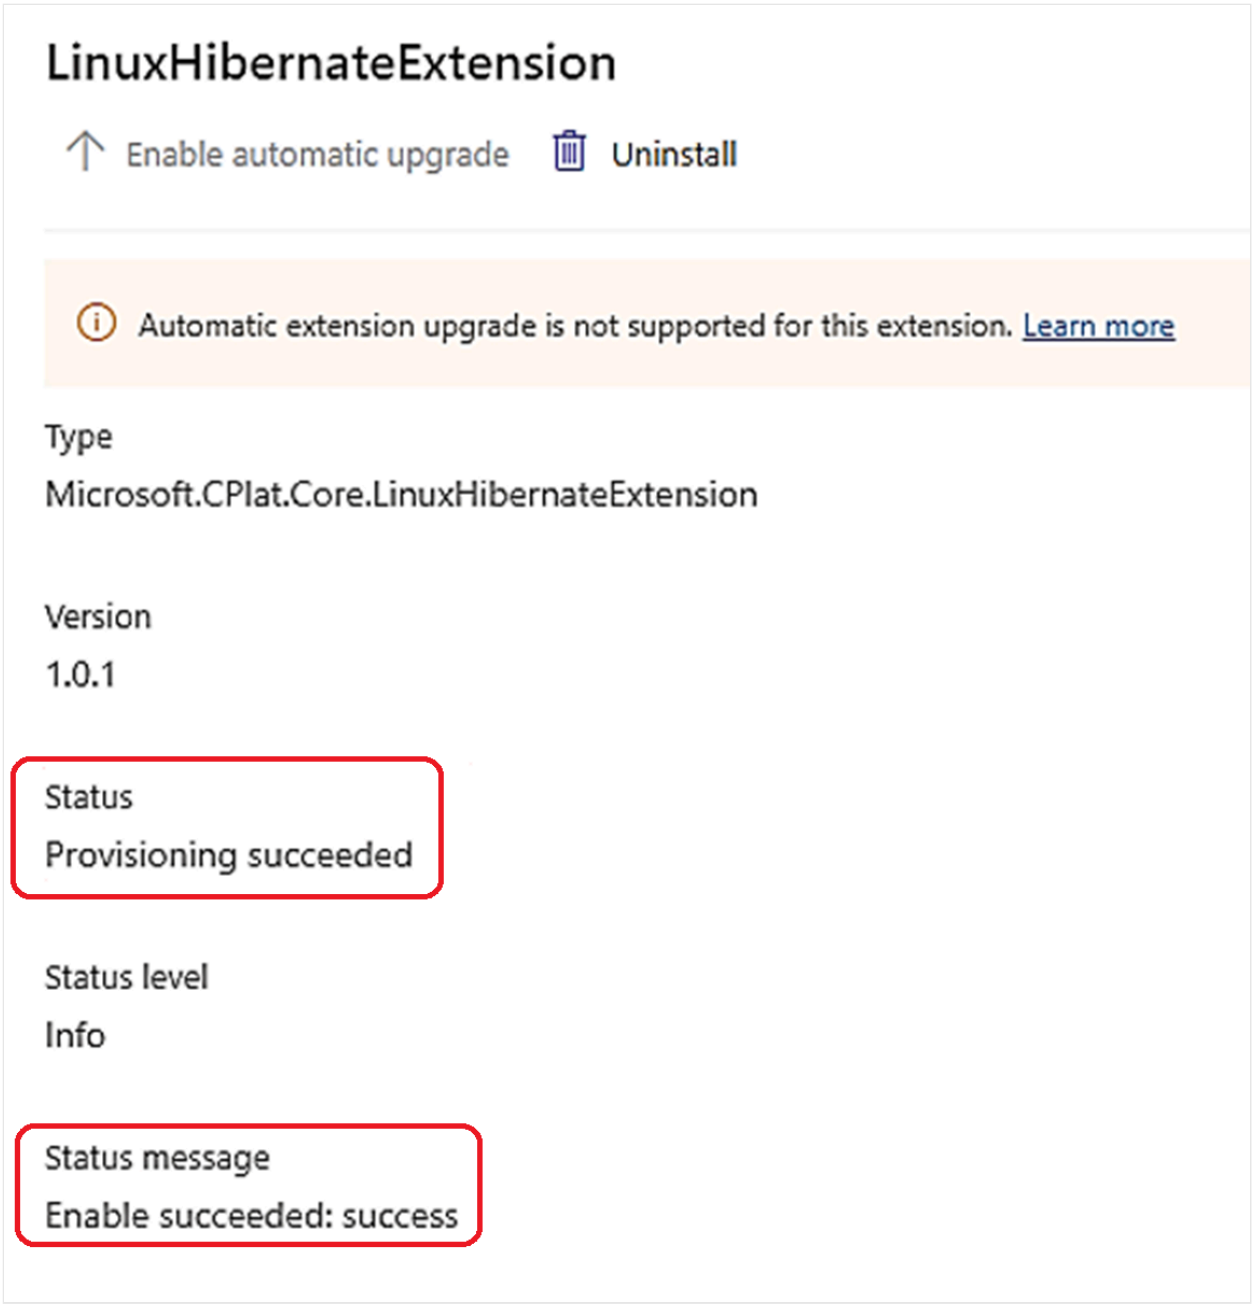
If you're unable to hibernate a VM, first check whether hibernation is enabled on the VM.

If hibernation is enabled on the VM, check if hibernation is successfully enabled in the guest OS. You can check the extension status if you used the extension to enable hibernation in the guest OS.



Guest Linux VMs unable to hibernate

You can check the extension status if you used the extension to enable hibernation in the guest OS.



If you used the hibernation-setup-tool to configure the guest for hibernation, you can check if the tool executed successfully through this command:

```
systemctl status hibernation-setup-tool
```

A successful status should return "Inactive (dead)", and the log messages should say "Swap file for VM hibernation set up successfully"

Example:

```
azureuser@:~$ systemctl status hibernation-setup-tool
● hibernation-setup-tool.service - Hibernation Setup Tool
```

```
   Loaded: loaded (/lib/systemd/system/hibernation-setup-tool.service;
enabled; vendor preset: enabled)
   Active: inactive (dead) since Wed 2021-08-25 22:44:29 UTC; 17min ago
  Process: 1131 ExecStart=/usr/sbin/hibernation-setup-tool (code=exited,
status=0/SUCCESS)
 Main PID: 1131 (code=exited, status=0/SUCCESS)

linuxhib2 hibernation-setup-tool[1131]: INFO: update-grub2 finished
successfully.
linuxhib2 hibernation-setup-tool[1131]: INFO: udev rule to hibernate with
systemd set up in /etc/udev/rules.d/99-vm-hibernation.rules.  Telling udev
about it.
...
...
linuxhib2 hibernation-setup-tool[1131]: INFO: systemctl finished
successfully.
linuxhib2 hibernation-setup-tool[1131]: INFO: Swap file for VM hibernation
set up successfully
```

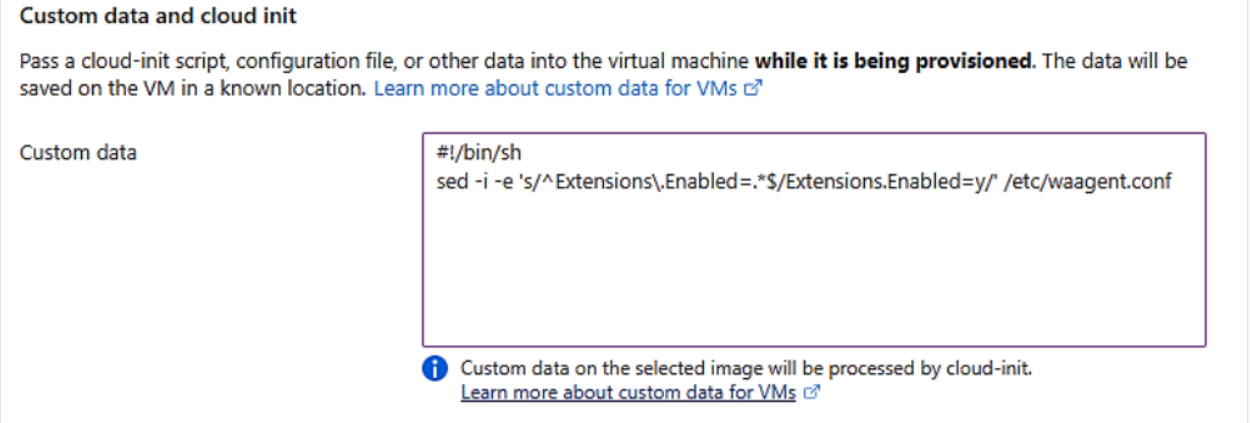
If the guest OS isn't configured for hibernation, take the appropriate action to resolve the issue. For example, if the guest failed to configure hibernation due to insufficient space, resize the OS disk to resolve the issue.

Azure extensions disabled on Debian images

Azure extensions are currently disabled by default for Debian images (more details here: https://lists.debian.org/debian-cloud/2023/07/msg00037.html). If you wish to enable hibernation for Debian based VMs through the LinuxHibernationExtension, then you can re-enable support for VM extensions via cloud-init custom data:

Bash

```
#!/bin/sh
sed -i -e 's/^Extensions\.Enabled =.* $/Extensions.Enabled=y/"
/etc/waagent.conf
```



Alternatively, you can enable hibernation on the guest by installing the hibernation-setup-tool on your Linux VM.

Troubleshooting hibernation on Windows VMs

Article • 08/22/2024

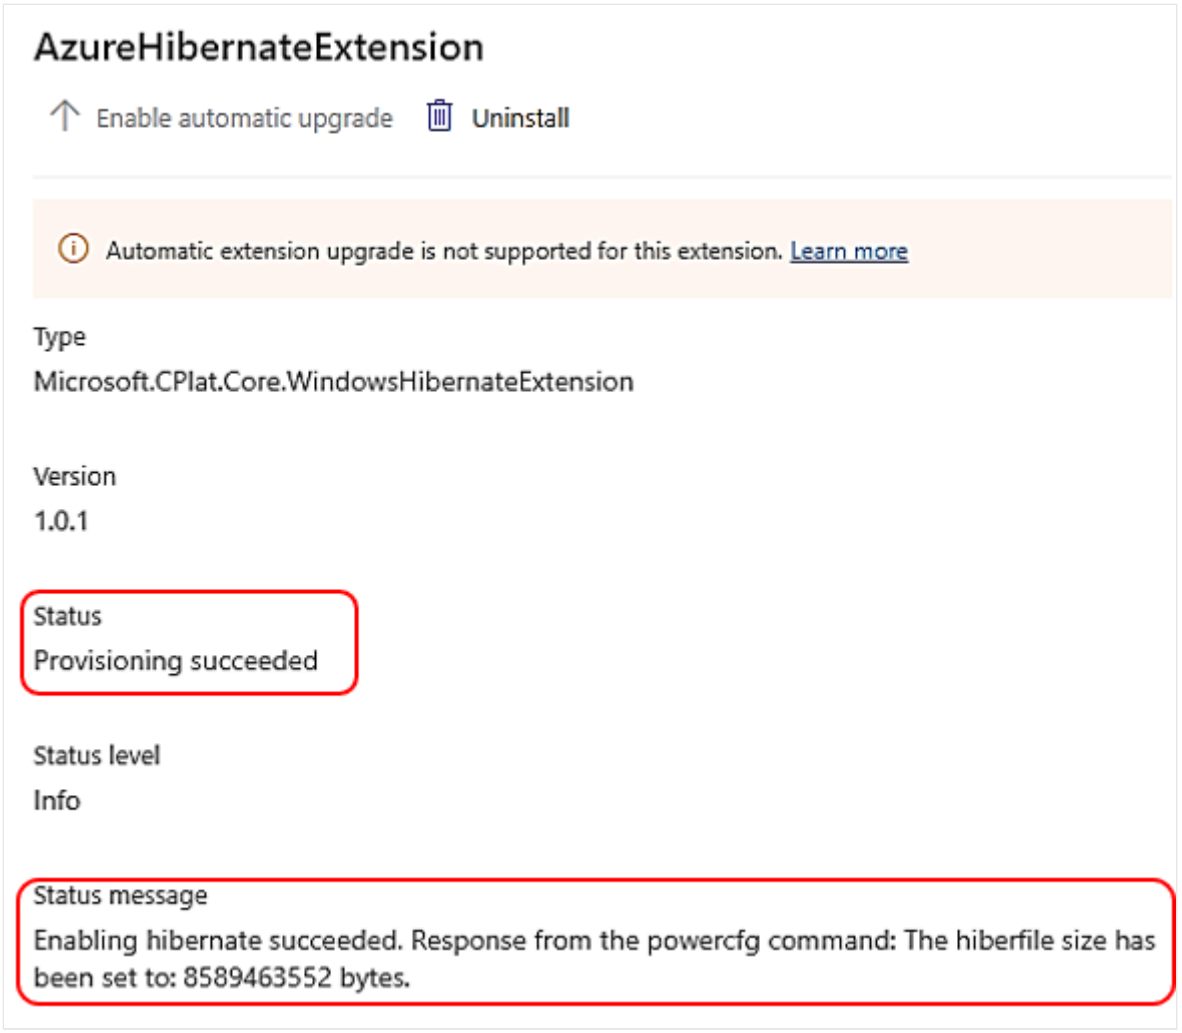
Hibernating a virtual machine allows you to persist the VM state to the OS disk. This article describes how to troubleshoot issues with the hibernation feature in Windows, issues creating hibernation enabled Windows VMs, and issues with hibernating a Windows VM.

To view the general troubleshooting guide for hibernation, check out Troubleshoot hibernation in Azure.

Unable to hibernate a Windows VM

If you're unable to hibernate a VM, first check whether hibernation is enabled on the VM.

If hibernation is enabled on the VM, check if hibernation is successfully enabled in the guest OS. You can check the status of the Hibernation extension to see if the extension was able to successfully configure the guest OS for hibernation.



The VM instance view would have the final output of the extension:

```
"extensions": [
    {
      "name": "AzureHibernateExtension",
      "type": "Microsoft.CPlat.Core.WindowsHibernateExtension",
      "typeHandlerVersion": "1.0.2",
      "statuses": [
        {
          "code": "ProvisioningState/succeeded",
          "level": "Info",
          "displayStatus": "Provisioning succeeded",
          "message": "Enabling hibernate succeeded. Response from the
powercfg command: \tThe hiberfile size has been set to: 17178693632
bytes.\r\n"
        }
      ]
    },
```

Additionally, confirm that hibernate is enabled as a sleep state inside the guest. The expected output for the guest should look like this.

```
C:\Users\vmadmin>powercfg /a
    The following sleep states are available on this system:
        Hibernate
        Fast Startup

    The following sleep states are not available on this system:
        Standby (S1)
            The system firmware does not support this standby state.

        Standby (S2)
            The system firmware does not support this standby state.

        Standby (S3)
            The system firmware does not support this standby state.

        Standby (S0 Low Power Idle)
            The system firmware does not support this standby state.

        Hybrid Sleep
            Standby (S3) isn't available.
```

If Hibernate isn't listed as a supported sleep state, there should be a reason associated with it, which should help determine why hibernate isn't supported. This occurs if guest hibernate isn't configured for the VM.

```
C:\Users\vmadmin>powercfg /a
    The following sleep states are not available on this system:
        Standby (S1)
            The system firmware does not support this standby state.

        Standby (S2)
            The system firmware does not support this standby state.

        Standby (S3)
            The system firmware does not support this standby state.

        Hibernate
            Hibernation hasn't been enabled.

        Standby (S0 Low Power Idle)
            The system firmware does not support this standby state.

        Hybrid Sleep
        Standby (S3) is not available.
            Hibernation is not available.

        Fast Startup
```

```
            Hibernation is not available.
```

If the extension or the guest sleep state reports an error, you'd need to update the guest configurations as per the error descriptions to resolve the issue. After fixing all the issues, you can validate that hibernation has been enabled successfully inside the guest by running the 'powercfg /a' command - which should return Hibernate as one of the sleep states. Also validate that the AzureHibernateExtension returns to a Succeeded state. If the extension is still in a failed state, then update the extension state by triggering reapply VM API

> **Note**
>
> If the extension remains in a failed state, you can't hibernate the VM.

Commonly seen issues where the extension fails.

Expand table

Issue	Action
Page file is in temp disk. Move it to OS disk to enable hibernation.	Move page file to the C: drive and trigger reapply on the VM to rerun the extension
Windows failed to configure hibernation due to insufficient space for the hiberfile	Ensure that C: drive has sufficient space. You can try expanding your OS disk, your C: partition size to overcome this issue. Once you have sufficient space, trigger the Reapply operation so that the extension can retry enabling hibernation in the guest and succeeds.
Extension error message: "A device attached to the system isn't functioning"	Ensure that C: drive has sufficient space. You can try expanding your OS disk, your C: partition size to overcome this issue. Once you have sufficient space, trigger the Reapply operation so that the extension can retry enabling hibernation in the guest and succeeds.
Hibernation is no longer supported after Virtualization Based Security (VBS) was enabled inside the guest	Enable Virtualization in the guest to get VBS capabilities along with the ability to hibernate the guest. Enable virtualization in the guest OS.

Issue	Action
Enabling hibernate failed. Response from the powercfg command. Exit Code: 1. Error message: Hibernation failed with the following error: The request isn't supported. The following items are preventing hibernation on this system. The current Device Guard configuration disables hibernation. An internal system component disabled hibernation. Hypervisor	Enable Virtualization in the guest to get VBS capabilities along with the ability to hibernate the guest. To enable virtualization in the guest, refer to this document

Guest Windows VMs unable to hibernate

If a hibernate operation succeeds, the following events are seen in the guest:

```
Guest responds to the hibernate operation (note that the following event is
logged on the guest on resume)

    Log Name:      System
    Source:        Kernel-Power
    Event ID:      42
    Level:         Information
    Description:
    The system is entering sleep
```

If the guest fails to hibernate, then all or some of these events are missing. Commonly seen issues:

Expand table

Issue	Action
Guest fails to hibernate because Hyper-V Guest Shutdown Service is disabled. You can check this by running *sc query vmicshutdown*.	Ensure that Hyper-V Guest Shutdown Service isn't disabled. Enabling this service should resolve the issue.
Guest fails to hibernate because Power Service is disabled. You can check this by running *sc query power*.	Ensure that Power Service isn't disabled. Enabling this service should resolve the issue.
Guest fails to hibernate because HVCI (Memory integrity) is enabled.	If Memory Integrity is enabled in the guest and you're trying to hibernate the VM, then ensure your guest is running the minimum OS build required to support

Issue	Action
	hibernation with Memory Integrity. Win 11 22H2 – Minimum OS Build - 22621.2134 Win 11 21H1 - Minimum OS Build - 22000.2295 Win 10 22H2 - Minimum OS Build - 19045.3324

Logs needed for troubleshooting:

If you encounter an issue outside of these known scenarios, the following logs can help Azure troubleshoot the issue:

- Relevant event logs on the guest: Microsoft-Windows-Kernel-Power, Microsoft-Windows-Kernel-General, Microsoft-Windows-Kernel-Boot.
- During a bug check, a guest crash dump is helpful.

Unable to resume a Windows VM

When you start a VM from a hibernated state, you can use the VM instance view to get more details on whether the guest successfully resumed from its previous hibernated state or if it failed to resume and instead did a cold boot.

VM instance view output when the guest successfully resumes:

```
{
  "computerName": "myVM",
  "osName": "Windows 11 Enterprise",
  "osVersion": "10.0.22000.1817",
  "vmAgent": {
    "vmAgentVersion": "2.7.41491.1083",
    "statuses": [
      {
        "code": "ProvisioningState/succeeded",
        "level": "Info",
        "displayStatus": "Ready",
        "message": "GuestAgent is running and processing the extensions.",

    },
    {
      "code": "PowerState/running",
      "level": "Info",
      "displayStatus": "VM running"
    }
  ]
}
```

Windows guest events while resuming

If a guest successfully resumes, the following guest events are available:

```
Log Name:      System
    Source:        Kernel-Power
    Event ID:      107
    Level:         Information
    Description:
    The system has resumed from sleep.
```

If the guest fails to resume, all or some of these events are missing. To troubleshoot why the guest failed to resume, the following logs are needed:

- Event logs on the guest: Microsoft-Windows-Kernel-Power, Microsoft-Windows-Kernel-General, Microsoft-Windows-Kernel-Boot.
- On bugcheck, a guest crash dump is needed.

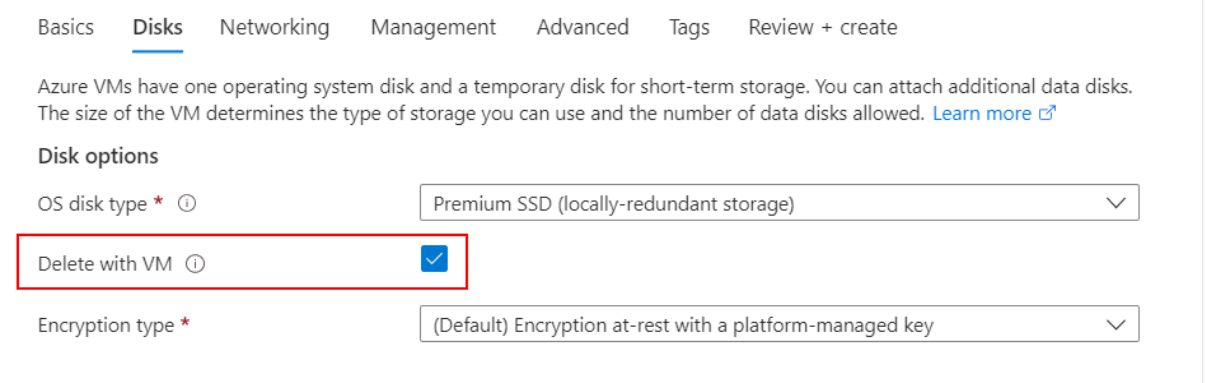
Delete a VM and attached resources

Depending on how you delete a VM, it may only delete the VM resource, not the networking and disk resources. You can change the default settings for what other resources are deleted when you delete a VM.

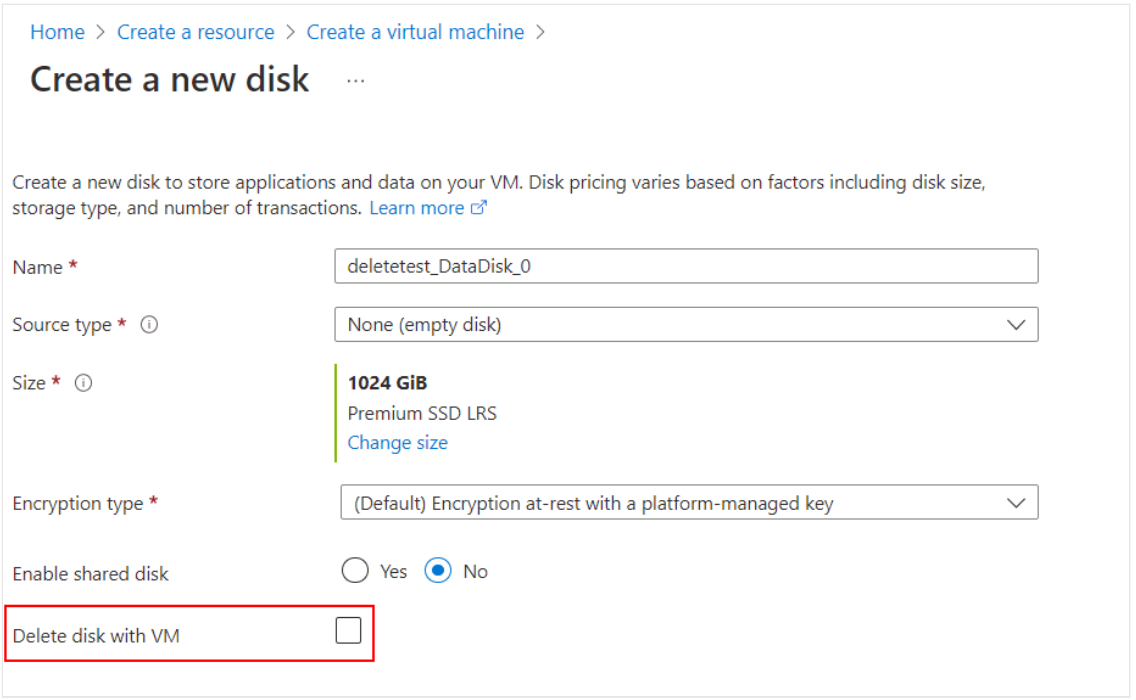
Set delete options when creating a VM

Portal

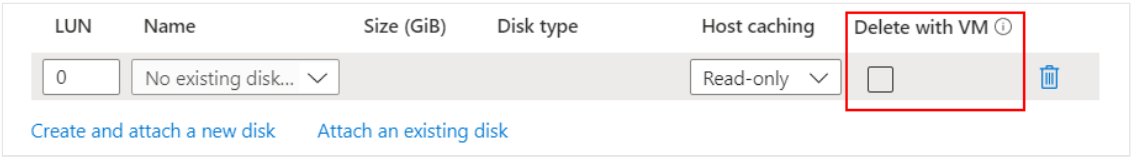
1. Open the portal.
2. Select + **Create a resource**.
3. On the **Create a resource** page, under **Virtual machines**, select **Create**.
4. Make your choices on the **Basics**, then select **Next : Disks >** to open the **Disks** tab.
5. Under **Disk options**, by default the OS disk is set to **Delete with VM**. If you don't want to delete the OS disk, clear the checkbox. If you're using an existing OS disk, the default is to detach the OS disk when the VM is deleted.



6. Under **Data disks**, you can either attach an existing data disk or create a new disk and attach it to the VM.
    - If you choose **Create and attach a new disk**, the **Create a new disk** page opens and you can select whether to delete the disk when you delete the VM.

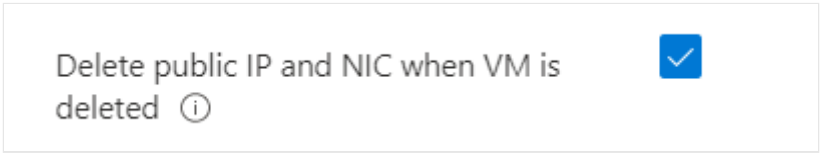


- If you choose to **Attach an existing disk**, can choose the disk, LUN, and whether you want to delete the data disk when you delete the VM.



7. When you're done adding your disk information, select **Next : Networking** > to open the **Networking** tab.

8. Towards the bottom of the page, select **Delete public IP and NIC when VM is deleted**.



9. When you're done making selections, select **Review + create**.

10. You can verify which resources you have chosen to delete when you delete the VM.

11. When you're satisfied with your selections, and validation passes, select **Create** to deploy the VM.

Update the delete behavior on an existing VM

You can change the behavior when you delete a VM.

CLI

The following example uses the Azure CLI to set the delete option to `detach` so you can reuse the disk.

Make sure to login to correct subscription using `az account set --subscription "SubscriptionIDName"`

Azure CLI

```
az resource update --resource-group myResourceGroup --name myVM --resource-type
virtualMachines --namespace Microsoft.Compute --set
properties.storageProfile.osDisk.deleteOption=detach
```

Force Delete for VMs

Force delete allows you to forcefully delete your virtual machine, reducing delete latency and immediately freeing up attached resources. For VMs that don't require graceful shutdown, Force Delete will delete the VM as fast as possible while relieving the logical resources from the VM, bypassing the graceful shutdown and some of the cleanup operations. Force Delete won't immediately free the MAC address associated with a VM, as this is a physical resource that may take up to 10 min to free. If you need to immediately reuse the MAC address on a new VM, Force Delete isn't recommended. Force delete should only be used when you aren't intending to reuse virtual hard disks. You can use force delete through Portal, CLI, PowerShell, and REST API.

Portal

When you go to delete an existing VM, you'll find an option to apply force delete in the delete pane.

1. Open the portal.
2. Navigate to your virtual machine.
3. On the **Overview** page, select **Delete**.
4. In the **Delete virtual machine** pane, select the checkbox for **Apply force delete**.
5. Select **Ok**.

Force Delete for scale sets

Force delete allows you to forcefully delete your Virtual Machine Scale Set, reducing delete latency and immediately freeing up attached resources. Force Delete won't immediately free the MAC address associated with a VM, as this is a physical resource that may take up to 10 min to free. If you need to immediately reuse the MAC address on a new VM, Force Delete is not recommended. Force delete should only be used when you are not intending to reuse virtual hard disks. You can use force delete through Portal, CLI, PowerShell, and REST API.

Portal

When you go to delete an existing scale set, you'll find an option to apply force delete in the delete pane.

1. Open the portal.
2. Navigate to your Virtual Machine Scale Set.
3. On the **Overview** page, select **Delete**.
4. In the **Delete Virtual Machine Scale Set** pane, select the checkbox for **Apply force delete**.
5. Select **Ok**.

FAQ

Q: Does this feature work with shared disks?

A: For shared disks, you can't set the 'deleteOption' property to 'Delete'. You can leave it blank or set it to 'Detach'

Q: Which Azure resources support this feature?

A: This feature is supported on all managed disk types used as OS disks and Data disks, NICs, and Public IPs

Q: What happens to the data on the disks when a VM is deleted?

A: When a VM is deleted, the data on the disks is not automatically deleted. The OS disk and any attached data disks remain in your resource group and continue to incur charges. You need to manually delete these disks if you no longer need them.

Q: What happens to VM backups when I delete the VM?

A: Azure Backup retains VM backups according to the backup policy, even after the VM is deleted. Retained backups continue to incur storage charges until they are deleted. To avoid unnecessary costs, review your backup retention and delete backups you no longer need.

To manage or delete VM backups, go to the Azure portal, navigate to your **Recovery Services** vault, select **Backup items**, then select **Azure Virtual Machine**, and choose the VM whose backups you want to manage. From there, you can stop backup and delete backup data as needed.

Q: Can I use this feature on disks and NICs that aren't associated with a VM?

A: No, this feature is only available on disks and NICs associated with a VM.

Q: How does this feature work with Flexible Virtual Machine Scale Set?

A: For Flexible Virtual Machine Scale Set the disks, NICs, and PublicIPs have `deleteOption` set to `Delete` by default so these resources are automatically cleaned up when the VMs are deleted.

For data disks that were explicitly created and attached to the VMs, you can modify this property to 'Detach' instead of 'Delete' if you want the disks to persist after the VM is deleted.

Q: Do Spot VMs support this feature?

A: Yes, you can use this feature for Spot VMs just the way you would for on-demand VMs.

Q: How do I persist the disks, NIC, and Public IPs associated with a VM?

A: By default, disks, NICs, and Public IPs associated with a VM are persisted when the VM is deleted. If you configure these resources to be automatically deleted, you can update the settings so that the resources remain after the VM is deleted. To keep these resources, set the `deleteOption` property to `Detach`.

Connect to a Linux VM

09/11/2025

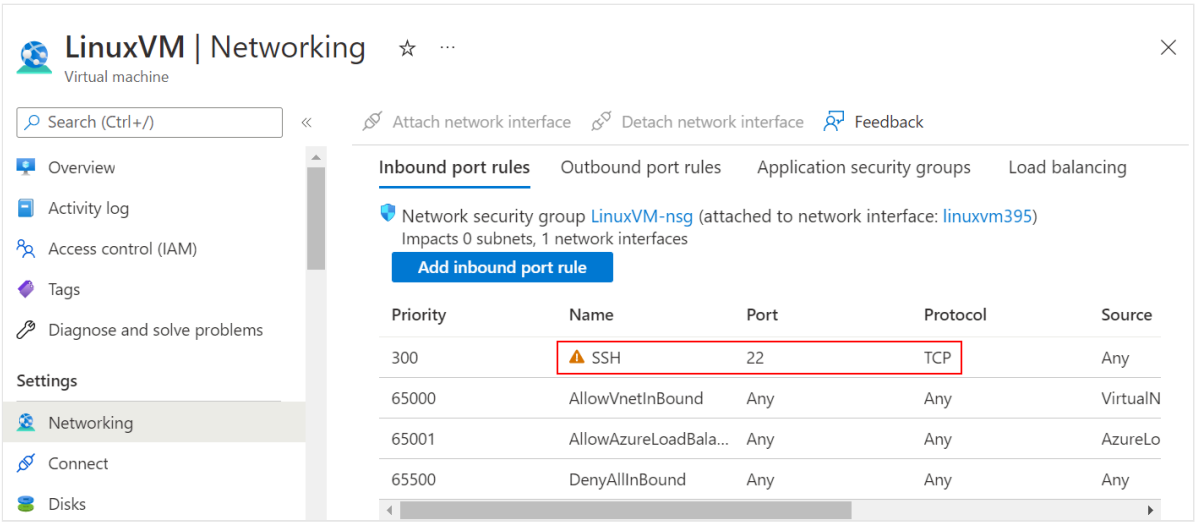
When hosting a Linux virtual machine on Azure, the most common method for accessing that VM is through the Secure Shell Protocol (SSH). Any standard SSH client commonly found in Linux and Windows allows you to connect. You can also use Azure Cloud Shell from any browser.

This document describes how to connect, via SSH, to a VM that has a public IP. If you need to connect to a VM without a public IP, see Azure Bastion Service.

Prerequisites

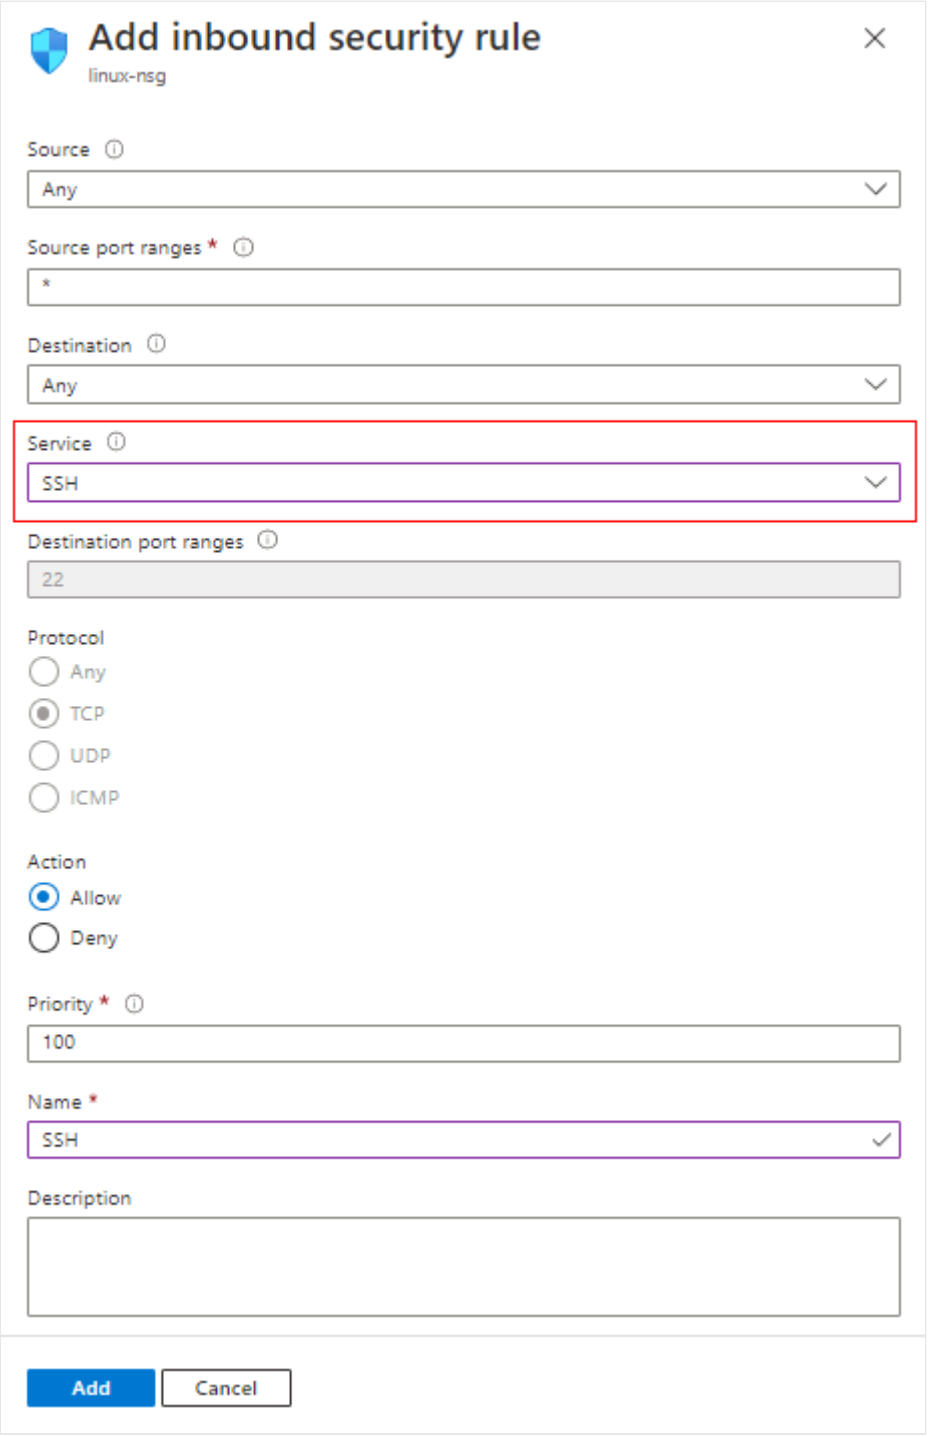
- You need an SSH key pair. If you don't already have one, Azure creates a key pair during the deployment process. If you need help with creating one manually, see Create and use an SSH public-private key pair for Linux VMs in Azure.
- You need an existing Network Security Group (NSG). Most VMs have an NSG by default, but if you don't already have one you can create one and attach it manually. For more information, see Create, change, or delete a network security group.
- To connect to a Linux VM, you need the appropriate port open. Typically SSH uses port 22. The following instructions assume port 22 but the process is the same for other port numbers. You can validate an appropriate port is open for SSH using the troubleshooter or by checking manually in your VM settings. To check if port 22 is open:

    1. On the page for the VM, select **Networking** from the left menu.
    2. On the **Networking** page, check to see if there's a rule that allows TCP on port 22 from the IP address of the computer you're using to connect to the VM. If the rule exists, you can move to the next section.



3. If there isn't a rule, add one by selecting **Add inbound port rule**.

4. For **Service**, select **SSH** from the dropdown.



5. Edit **Priority** and **Source** if necessary

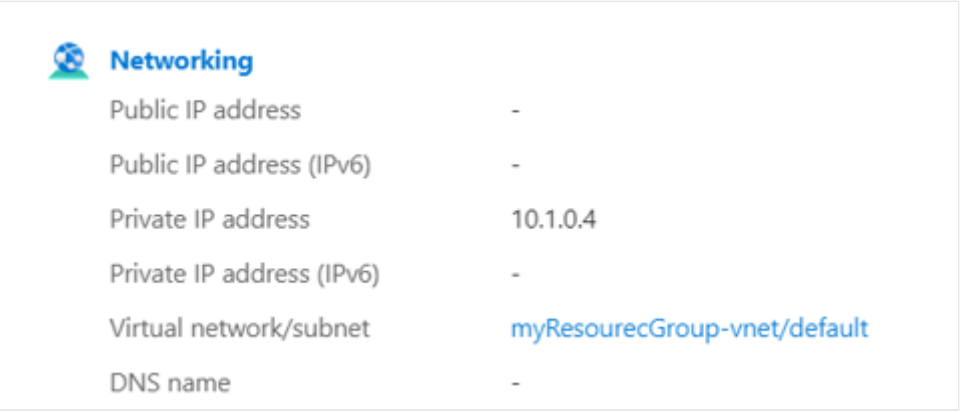
6. For **Name**, type *SSH*.

7. When you're done, select **Add**.

8. You should now have an SSH rule in the table of inbound port rules.

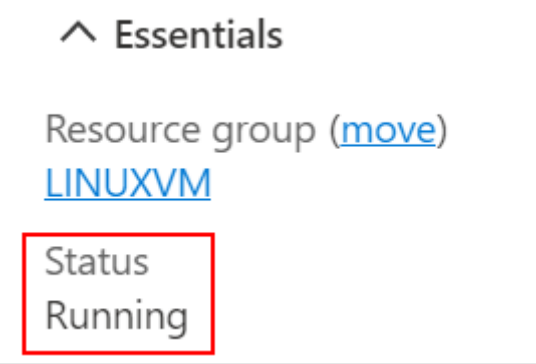
- Your VM must have a public IP address. To check if your VM has a public IP address, select **Overview** from the left menu and look at the **Networking** section. If you see an IP address next to **Public IP address**, then your VM has a public IP

  If your VM doesn't have a public IP Address, it looks like this:



To learn more about adding a public IP address to an existing VM, see Associate a public IP address to a virtual machine

- Verify your VM is running. On the Overview tab, in the **Essentials** section, verify the status of the VM is **Running**. To start the VM, select **Start** at the top of the page.



If you're having trouble connecting, you can also use portal:

1. Go to the Azure portal to connect to a VM. Search for and select **Virtual machines**.
2. Select the virtual machine from the list.
3. Select **Connect** from the left menu.
4. Select the option that fits with your preferred way of connecting. The most common connection method is Native SSH. The portal helps walk you through all prerequisites for a given connection method, and will run a VM Access check with your configured settings.

Connect to the VM

Once the above prerequisites are met, you're ready to connect to your VM. Open your SSH client of choice. The SSH client command is typically included in Linux, macOS, and Windows. If you're using Windows 7 or older, where Win32 OpenSSH isn't included by default, consider installing WSL or using Azure Cloud Shell from the browser.

> ⓘ **Note**

The following examples assume the SSH key is in the key.pem format. If you used CLI or Azure PowerShell to download your keys, they may be in the id_rsa or ED25519 format.

WSL, macOS, or native Linux client

SSH with a new key pair

1. Ensure your public and private keys are in the correct directory. The directory is usually `~/.ssh`.

   If you generated keys manually or generated them with the CLI, then the keys are probably already there. However, if you downloaded them in pem format from the Azure portal, you may need to move them to the right location. Moving the keys is done with the following syntax: `mv PRIVATE_KEY_SOURCE PRIVATE_KEY_DESTINATION`

   For example, if the key is in the `Downloads` folder, and `myKey.pem` is the name of your SSH key, type:

   ```
   Bash

   mv /Downloads/myKey.pem ~/.ssh
   ```

   > **Note**
   >
   > If you're using WSL, local files are found in the `mnt/c/` directory. Accordingly, the path to the downloads folder and SSH key would be `/mnt/c/Users/{USERNAME}/Downloads/myKey.pem`

2. Ensure you have read-only access to the private key by running

   ```
   Bash

   chmod 400 ~/.ssh/myKey.pem
   ```

3. Run the SSH command with the following syntax: `ssh -i PATH_TO_PRIVATE_KEY USERNAME@EXTERNAL_IP`

   For example, if your `azureuser` is the username you created and `20.51.230.13` is the public IP address of your VM, type:

```
Bash

ssh -i ~/.ssh/myKey.pem azureuser@20.51.230.13
```

4. Validate the returned fingerprint.

   If you have never connected to this VM before, you're asked to verify the hosts fingerprint. It's tempting to accept the fingerprint presented, but that exposes you to a potential person in the middle attack. You should always validate the hosts fingerprint. You only need to do this the first time you connect from a client. To get the host fingerprint via the portal, use the Run Command feature to execute the command:

```
Bash

ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'
```

5. Success! You should now be connected to your VM. If you're unable to connect, see Troubleshoot SSH connections.

SSH With existing public key

1. Run the following command in your SSH client. In this example, *20.51.230.13* is the public IP Address of your VM and *azureuser* is the username you created when you created the VM.

```
Bash

ssh azureuser@20.51.230.13
```

2. Validate the returned fingerprint.

   If you have never connected to the desired VM from your current SSH client before you're asked to verify the host's fingerprint. While the default option is to accept the fingerprint presented, you're exposed to a possible "person in the middle attack". You should always validate the host's fingerprint, which only needs to be done the first time your client connects. To obtain the host fingerprint via the portal, use the Run Command feature to execute the command:

```
Bash

ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'
```

3. Success! You should now be connected to your VM. If you're unable to connect, see our troubleshooting guide.

Password authentication

> ⚠ **Warning**
>
> This type of authentication method is not as secure as an SSH key pair and is not recommended.

1. Run the following command in your SSH client. In this example, *20.51.230.13* is the public IP Address of your VM and *azureuser* is the username you created when you created the VM.

   ```
   Bash

   ssh azureuser@20.51.230.13
   ```

   If you forgot your password or username see Reset Access to an Azure VM

2. Validate the returned fingerprint.

   If you have never connected to the desired VM from your current SSH client before you're asked to verify the host's fingerprint. While the default option is to accept the fingerprint presented, you're exposed to a possible "person in the middle attack". You should always validate the host's fingerprint, which only needs to be done the first time your client connects. To obtain the host fingerprint via the portal, use the Run Command feature to execute the command:

   ```
   Bash

   ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'
   ```

3. Success! You should now be connected to your VM. If you're unable to connect, see Troubleshoot SSH connections.

Detailed steps: Create and manage SSH keys for authentication to a Linux VM in Azure

Article • 10/17/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

With a secure shell (SSH) key pair, you can create a Linux virtual machine that uses SSH keys for authentication. This article shows you how to create and use an SSH RSA public-private key file pair for SSH client connections.

If you want quick commands rather than a more in-depth explanation of SSH keys, see How to create an SSH public-private key pair for Linux VMs in Azure.

To create SSH keys and use them to connect to a Linux VM from a **Windows** computer, see How to use SSH keys with Windows on Azure. You can also use the Azure portal to create and manage SSH keys for creating VMs in the portal.

Overview of SSH and keys

SSH is an encrypted connection protocol that provides secure sign-ins over unsecured connections. Although SSH provides an encrypted connection, using passwords with SSH connections still leaves the VM vulnerable to brute-force attacks. We recommend connecting to a VM over SSH using a public-private key pair, also known as *SSH keys*.

- The *public key* is placed on your VM.
- The *private key* remains on your local system. Protect this private key. Do not share it.

When you use an SSH client to connect to your VM (which has the public key), the remote VM tests the client to make sure it has the correct private key. If the client has the private key, it's granted access to the VM.

Depending on your organization's security policies, you can reuse a single public-private key pair to access multiple Azure VMs and services. You do not need a separate pair of keys for each VM or service you wish to access.

Your public key can be shared with anyone, but only you (or your local security infrastructure) should have access to your private key.

Supported SSH key formats

Azure currently supports following key types:

- SSH protocol 2 (SSH-2) RSA (Rivest, Shamir, Adleman) with a minimum length of 2048 bits
- ED25519 Keys with a fixed length of 256 bits

Other key formats such as Elliptic-curve Diffie–Hellman (ECDH) and Elliptic Curve Digital Signature Algorithm (ECDSA) are currently not supported.

SSH keys use and benefits

When you create an Azure VM by specifying the public key, Azure copies the public key (in the `.pub` format) to the `~/.ssh/authorized_keys` folder on the VM. SSH keys in `~/.ssh/authorized_keys` ensure that connecting clients present the corresponding private key during an SSH connection. In an Azure Linux VM that uses SSH keys for authentication, Azure disables the SSH server's password authentication system and only allows for SSH key authentication. By creating an Azure Linux VM with SSH keys, you can help secure the VM deployment and save yourself the typical post-deployment configuration step of disabling passwords in the `sshd_config` file.

If you do not wish to use SSH keys, you can set up your Linux VM to use password authentication. If your VM is not exposed to the Internet, using passwords may be sufficient. However, you still need to manage your passwords for each Linux VM and maintain healthy password policies and practices, such as minimum password length and regular system updates.

Generate keys with ssh-keygen

To create the keys, a preferred command is `ssh-keygen`, which is available with OpenSSH utilities in the Azure Cloud Shell, a macOS or Linux host, and Windows (10 & 11). `ssh-keygen` asks a series of questions and then writes a private key and a matching public key.

SSH keys are by default kept in the `~/.ssh` directory. If you do not have a `~/.ssh` directory, the `ssh-keygen` command creates it for you with the correct permissions. An SSH key is created as a resource and stored in Azure for later use.

> ⓘ **Note**

You can also create keys with the Azure CLI with the az sshkey create command, as described in Generate and store SSH keys.

Basic example

The following `ssh-keygen` command generates 4096-bit SSH RSA public and private key files by default in the `~/.ssh` directory. If an existing SSH key pair is found in the current location, those files are overwritten.

Bash

```
ssh-keygen -m PEM -t rsa -b 4096
```

The following `ssh-keygen` command generates 256-bit ED25519 public and private key files by default in the `~/.ssh` directory. If an existing SSH key pair is found in the current location, those files are overwritten.

Bash

```
ssh-keygen -m PEM -t ed25519
```

Detailed example

The following example shows additional command options to create an SSH RSA key pair. If an SSH key pair exists in the current location, those files are overwritten.

Bash

```
ssh-keygen \
    -m PEM \
    -t rsa \
    -b 4096 \
    -C "azureuser@myserver" \
    -f ~/.ssh/mykeys/myrsaprivatekey \
    -N mypassphrase
```

The following example shows additional command options to create an SSH ED25519 key pair. If an SSH key pair exists in the current location, those files are overwritten.

Bash

```
ssh-keygen \
    -m PEM \
```

```
    -t ed25519 \
    -C "azureuser@myserver" \
    -f ~/.ssh/mykeys/myedprivatekey \
    -N mypassphrase
```

Command explained

`ssh-keygen` = the program used to create the keys

`-m PEM` = format the key as PEM

`-t rsa` = type of key to create, in this case in the RSA format

`-b 4096` = the number of bits in the key, in this case 4096

`-C "azureuser@myserver"` = a comment appended to the end of the public key file to easily identify it. Normally an email address is used as the comment, but use whatever works best for your infrastructure.

`-f ~/.ssh/mykeys/myprivatekey` = the filename of the private key file, if you choose not to use the default name. A corresponding public key file appended with `.pub` is generated in the same directory. The directory must exist.

`-N mypassphrase` = an additional passphrase used to access the private key file.

Example of ssh-keygen (RSA)

Bash

```
ssh-keygen -t rsa -m PEM -b 4096 -C "azureuser@myserver"
Generating public/private rsa key pair.
Enter file in which to save the key (/home/azureuser/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/azureuser/.ssh/id_rsa.
Your public key has been saved in /home/azureuser/.ssh/id_rsa.pub.
The key fingerprint is:
SHA256:vFfHHrpSGQBd/oNdvNiX0sG9Vh+wROlZBktNZw9AUjA azureuser@myserver
The key's randomart image is:
+---[RSA 4096]----+
|        .oE=*B*+ |
|          o+o.*++|
|           .oo++*|
|       .    .B+.O|
|        S   o=BO.|
|         . .o++o |
|        . ... .  |
|         ..  .   |
```

```
|           ..    |
+----[SHA256]-----+
```

Example of ssh-keygen (ED25519)

Bash

```
ssh-keygen -t ed25519 -m PEM -C "azureuser@myserver"
Generating public/private rsa key pair.
Enter file in which to save the key (/home/azureuser/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/azureuser/.ssh/id_ed25519.
Your public key has been saved in /home/azureuser/.ssh/id_ed25519.pub.
The key fingerprint is:
SHA256:vFfHHrpSGQBd/oNdvNiX0sG9Vh+wROlZBktNZw9AUjA azureuser@myserver
The key's randomart image is:
+---[ED25519 256]----+
|                    |
|..  .               |
|o+.o       .        |
|*=o o   o + +       |
|*+o+   oSB + o      |
|**++o.+oo = .       |
|=+*..*.o E          |
|..  o o..           |
|     .o.            |
+----[SHA256]-----+
```

Saved key files

`Enter file in which to save the key (/home/azureuser/.ssh/id_rsa): ~/.ssh/id_rsa`

or

`Enter file in which to save the key (/home/azureuser/.ssh/id_ed25519): ~/.ssh/id_ed25519`

The default key pair names for RSA and ED25519 are `id_rsa` and `id_ed25519` respectively; some tools might expect the `id_rsa` or `id_ed25519` private key file name, so having one is a good idea. The directory `~/.ssh/` is the default location for SSH key pairs and the SSH config file. If not specified with a full path, `ssh-keygen` creates the keys in the current working directory, not the default `~/.ssh`.

List of the `~/.ssh` directory

To view existing files in the `~/.ssh` directory, run the following command. If no files are found in the directory or the directory itself is missing, make sure that all previous commands were successfully run. You may require root access to modify files in this directory on certain Linux distributions.

RSA Key pair:

```Bash
ls -al ~/.ssh
-rw------- 1 azureuser staff  1675 Aug 25 18:04 id_rsa
-rw-r--r-- 1 azureuser staff   410 Aug 25 18:04 id_rsa.pub
```

ED25519 Key pair:

```Bash
ls -al ~/.ssh
-rw------- 1 azureuser staff  1675 Aug 25 18:04 id_ed25519
-rw-r--r-- 1 azureuser staff   410 Aug 25 18:04 id_ed25519.pub
```

Key passphrase

`Enter passphrase (empty for no passphrase):`

It is *strongly* recommended to add a passphrase to your private key. Without a passphrase to protect the key file, anyone with the file can use it to sign in to any server that has the corresponding public key. Adding a passphrase offers more protection in case someone is able to gain access to your private key file, giving you time to change the keys.

Generate keys automatically during deployment

If you use the Azure CLI to create your VM, you can optionally generate both public and private SSH key files by running the az vm create command with the `--generate-ssh-keys` option. This command would default to key type of RSA, in order to generate ED25519 keys you can pass in additional flag `--ssh-key-type` command. The keys are stored in the ~/.ssh directory. Note that this command option does not overwrite keys if they already exist in that location, such as with some pre-configured Compute Gallery images.

Basic example

Create a simple Ubuntu Linux VM along with Ed25519 SSH key pair.

Azure

```
az vm create -n MyVm -g MyResourceGroup --image Ubuntu2204 --generate-ssh-keys --ssh-key-type ed25519
```

Provide SSH public key when deploying a VM

To create a Linux VM that uses SSH keys for authentication, provide your SSH public key when creating the VM using the Azure portal, CLI, Resource Manager templates, or other methods. When using the portal, you enter the public key itself. If you use the Azure CLI to create your VM with an existing public key, specify the value or location of this public key by running the az vm create command with the `--ssh-key-value` option.

If you're not familiar with the format of an SSH public key, you can see your public key by running `cat` as follows, replacing `~/.ssh/id_rsa.pub` with your own public key file location:

RSA key pair

Bash

```
cat ~/.ssh/id_rsa.pub
```

Output is similar to the following (redacted example below):

```
ssh-rsa
XXXXXXXXXXc2EAAAADAXABAAABAXC5Am7+fGZ+5zXBGgXS6GUvmsXCLGc7tX7/rViXk3+eShZzaX
nt75gUmT1I2f75zFn2hlAIDGKWf4g12KWcZxy81TniUOTjUsVlwPymXUXxESL/UfJKfbdstBhTOd
y5EG9rYWA0K43SJmwPhH28BpoLfXXXXXG+/ilsXXXXXKgRLiJ2W19MzXHp8z3Lxw7r9wx3HaVlP4
XiFv9U4hGcp8RMI1MP1nNesFlOBpG4pV2bJRBTXNXeY4l6F8WZ3C4kuf8XxOo08mXaTpvZ3T1841
altmNTZCcPkXuMrBjYSJbA8npoXAXNwiivyoe3X2KMXXXXXdXXXXXXXXXXCXXXXX/
azureuser@myserver
```

If you copy and paste the contents of the public key file into the Azure portal or a Resource Manager template, make sure you don't copy any additional whitespace or introduce additional line breaks. For example, if you use macOS, you can pipe the public

key file (by default, `~/.ssh/id_rsa.pub`) to **pbcopy** to copy the contents (there are other Linux programs that do the same thing, such as `xclip`).

If you prefer to use a public key that is in a multiline format, you can generate an RFC4716 formatted key in a 'pem' container from the public key you previously created.

To create an RFC4716 formatted key from an existing SSH public key:

Bash

```
ssh-keygen \
-f ~/.ssh/id_rsa.pub \
-e \
-m RFC4716 > ~/.ssh/id_ssh2.pem
```

ED25519 key pair

Bash

```
cat ~/.ssh/id_ed25519.pub
```

Output is similar to the following (redacted example below):

```
ssh-ed25519
AAAAC3NzaC1lZDI1NTE5AAAAIP6I5JuhGq3RidMNpxrplIQwEfc4Rh7UyV8JYYH2U2xA
azureuser@myserver
```

If you copy and paste the contents of the public key file into the Azure portal or a Resource Manager template, make sure you don't copy any additional whitespace or introduce additional line breaks. For example, if you use macOS, you can pipe the public key file (by default, `~/.ssh/id_ed25519.pub`) to **pbcopy** to copy the contents (there are other Linux programs that do the same thing, such as `xclip`).

If you prefer to use a public key that is in a multiline format, you can generate an RFC4716 formatted key in a 'pem' container from the public key you previously created.

To create a PEM formatted key from an existing SSH public key:

Bash

```
ssh-keygen \
-f ~/.ssh/id_ed25519.pub \
```

```
-e \
-m RFC4716 > ~/.ssh/id_edssh.pem
```

SSH to your VM with an SSH client

With the public key deployed on your Azure VM, and the private key on your local system, SSH to your VM using the IP address or DNS name of your VM. Replace *azureuser* and *myvm.westus.cloudapp.azure.com* in the following command with the administrator user name and the fully qualified domain name (or IP address):

Bash

```
ssh azureuser@myvm.westus.cloudapp.azure.com
```

If you provided a passphrase when you created your key pair, enter the passphrase when prompted during the sign-in process. (The server is added to your `~/.ssh/known_hosts` folder, and you won't be asked to connect again until the public key on your Azure VM changes or the server name is removed from `~/.ssh/known_hosts`.)

If the VM is using the just-in-time access policy, you need to request access before you can connect to the VM. For more information about the just-in-time policy, see Manage virtual machine access using the just in time policy.

Use ssh-agent to store your private key passphrase

To avoid typing your private key file passphrase with every SSH sign-in, you can use `ssh-agent` to cache your private key file passphrase on your local system. If you are using a Mac, the macOS Keychain securely stores the private key passphrase when you invoke `ssh-agent`.

Verify and use `ssh-agent` and `ssh-add` to inform the SSH system about the key files so that you do not need to use the passphrase interactively.

Bash

```
eval "$(ssh-agent -s)"
```

Now add the private key to `ssh-agent` using the command `ssh-add`.

Bash

```
ssh-add ~/.ssh/id_rsa
```

or

```Bash
ssh-add ~/.ssh/id_ed25519
```

The private key passphrase is now stored in `ssh-agent`.

Use ssh-copy-id to copy the key to an existing VM

If you have already created a VM, you can add a new SSH public key to your Linux VM using `ssh-copy-id`.

```Bash
ssh-copy-id -i ~/.ssh/id_rsa.pub azureuser@myserver
```

Create and configure an SSH config file

You can create and configure an SSH config file (`~/.ssh/config`) to speed up log-ins and to optimize your SSH client behavior.

The following example shows a simple configuration that you can use to quickly sign in as a user to a specific VM using the default SSH private key.

Create the file.

```Bash
touch ~/.ssh/config
```

Edit the file to add the new SSH configuration

```Bash
vim ~/.ssh/config
```

Add configuration settings appropriate for your host VM. In this example, the VM name (Host) is *myvm*, the account name (User) is *azureuser* and the IP Address or FQDN (Hostname) is 192.168.0.255.

Bash

```
# Azure Keys
Host myvm
  Hostname 192.168.0.255
  User azureuser
# ./Azure Keys
```

You can add configurations for additional hosts to enable each to use its own dedicated key pair. See SSH config file for more advanced configuration options.

Now that you have an SSH key pair and a configured SSH config file, you are able to remotely access your Linux VM quickly and securely. When you run the following command, SSH locates and loads any settings from the `Host myvm` block in the SSH config file.

Bash

```
ssh myvm
```

The first time you sign in to a server using an SSH key, the command prompts you for the passphrase for that key file.

Next steps

Next up is to create Azure Linux VMs using the new SSH public key. Azure VMs that are created with an SSH public key as the sign-in are better secured than VMs created with the default sign-in method, passwords.

- Create a Linux virtual machine with the Azure portal
- Create a Linux virtual machine with the Azure CLI
- Create a Linux VM using an Azure template

Generate and store SSH keys in the Azure portal

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

If you frequently use the portal to deploy Linux VMs, you can simplify using SSH keys by integrating them into Azure. There are several ways to create SSH keys for use with Azure.

- You can create SSH keys when you first create a VM. Your keys aren't tied to a specific VM and you can use them in future applications.
- You can create SSH keys in the Azure portal separate from a VM. You can use them with both new and old VMs.
- You can create SSH keys externally and upload them for use in Azure.

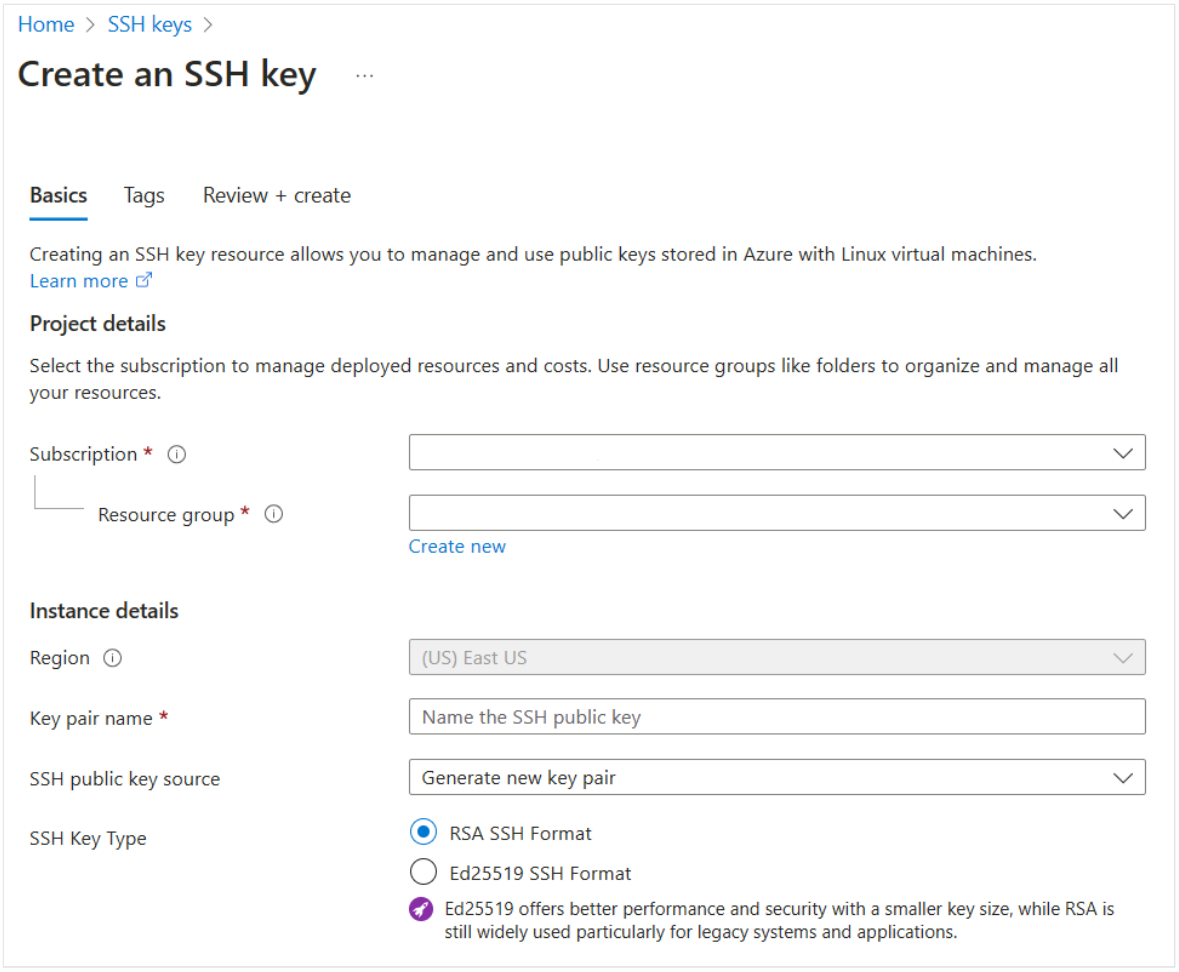
You can reuse your stored keys in various of applications to fit your organization's needs.

For more detailed information about creating and using SSH keys with Linux VMs, see Use SSH keys to connect to Linux VMs.

> **Note**
>
> ED25519 SSH key support for Linux VMs is now in preview in all regions including sovereign clouds.

Generate new keys

1. Open the Azure portal.
2. At the top of the page, type *SSH* to search. Under **Marketplace**, select **SSH keys**.
3. On the **SSH Key** page, select **Create**.



4. In **Resource group** select **Create new** to create a new resource group to store your keys. Type a name for your resource group and select **OK**.

5. In **Region** select a region to store your keys. You can use the keys in any region, this option is just the region where you store them.

6. Type a name for your key in **Key pair name**.

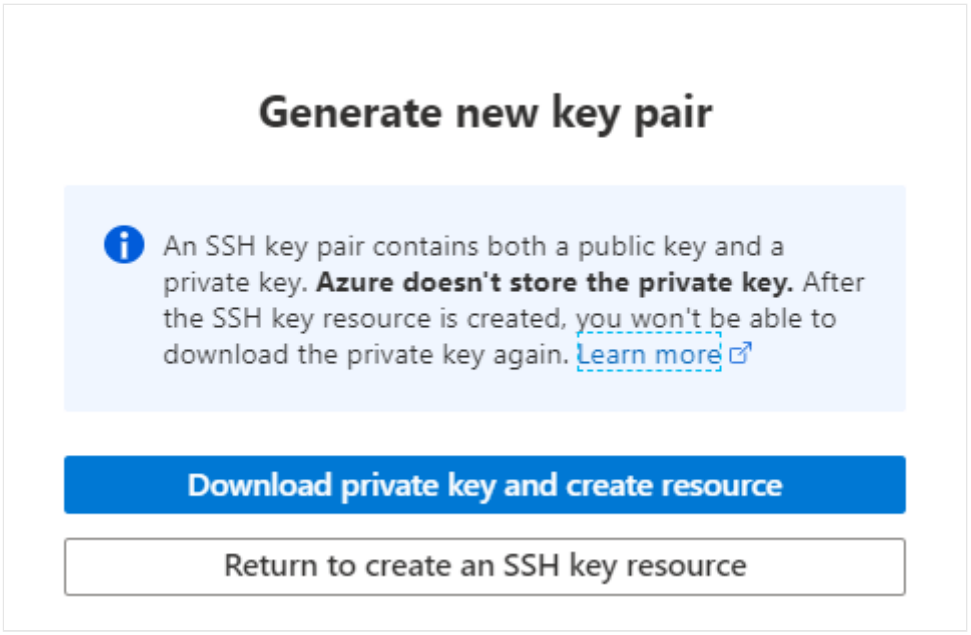
7. In **SSH public key source**, select **Generate public key source**.

8. In **SSH Key Type**, select either **RSA SSH Format** or **Ed25519 SSH Format** [Preview]

9. When you're done, select **Review + create**.

10. After it passes validation, select **Create**.

11. You'll get a pop-up window to, select **Download private key and create resource** that downloads the SSH key as a .pem file.



12. Once you've downloaded the .pem file, you might want to move it somewhere on your computer where it's easy to point to from your SSH client.

Connect to the VM

On your local computer, open a PowerShell prompt and type:

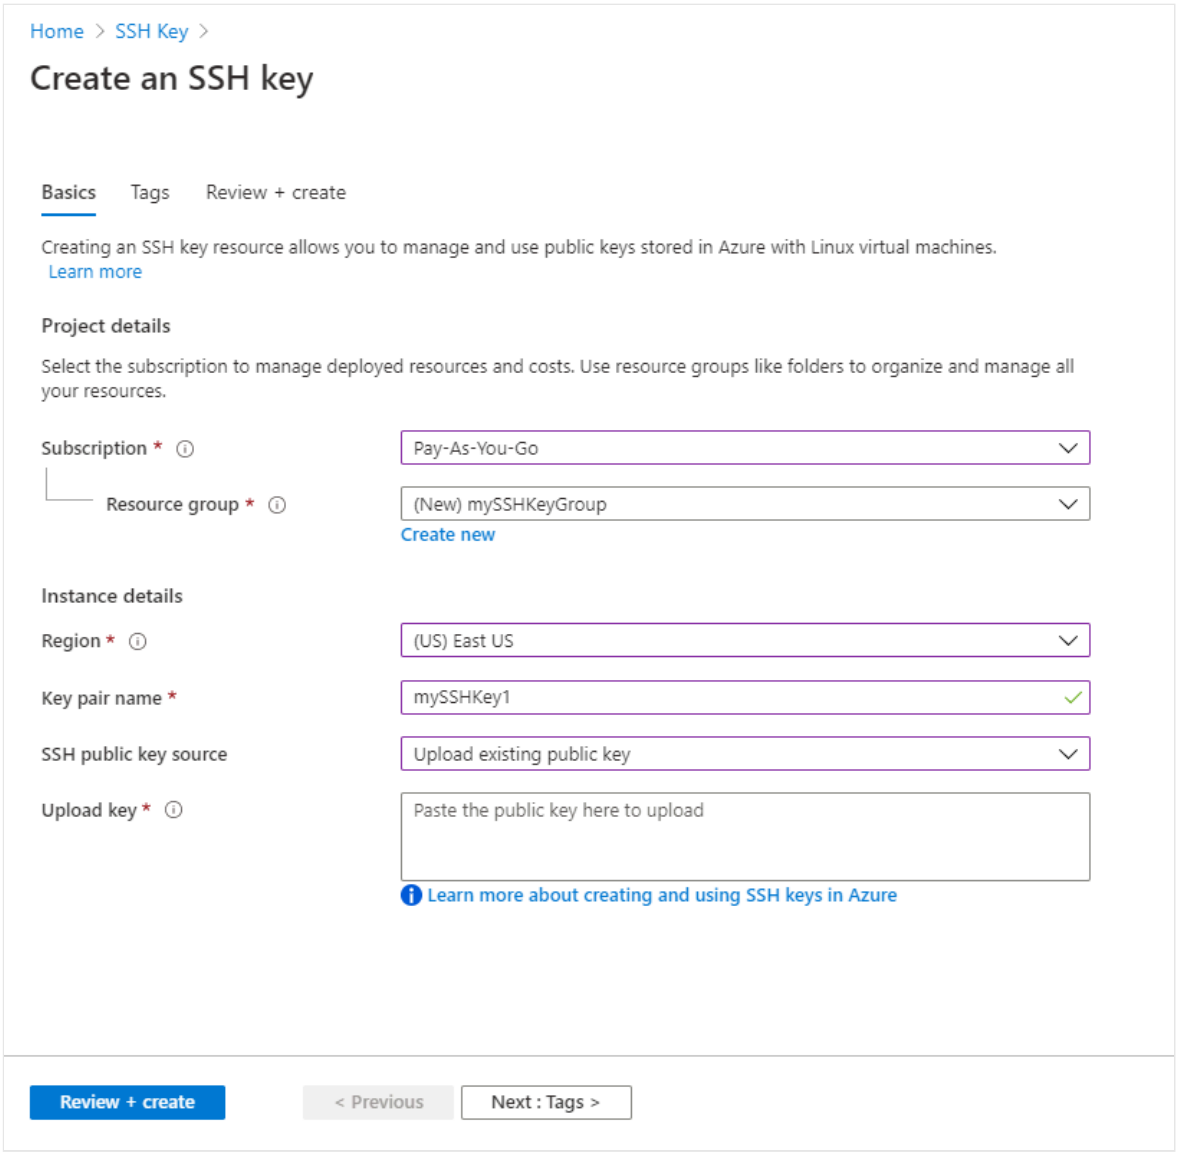
```
PowerShell
ssh -i <path to the .pem file> username@<ipaddress of the VM>
```

For example, type: `ssh -i /Downloads/mySSHKey.pem azureuser@123.45.67.890` and replace the example IP address at the end of the command with your VM's public IP address.

Upload an SSH key

You can also upload a public SSH key to store in Azure. For information about how to create an SSH key pair, see Use SSH keys to connect to Linux VMs.

1. Open the Azure portal.
2. At the top of the page, type *SSH* to search. Under **Marketplace*, select **SSH keys**.
3. On the **SSH Key** page, select **Create**.



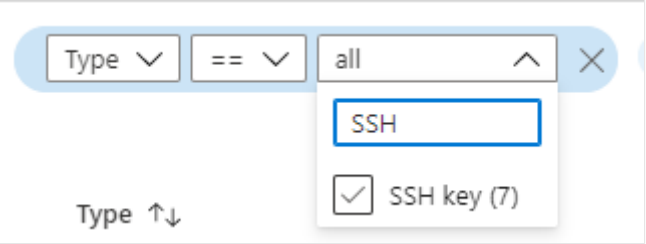
4. In **Resource group** select **Create new** to create a new resource group to store your keys. Type a name for your resource group and select **OK**.
5. In **Region** select a region to store your keys. You can use the keys in any region, this option is just the region where they're stored.
6. Type a name for your key in **Key pair name**.
7. In **SSH public key source**, select **Upload existing public key**.
8. Paste the full contents of the public key into **Upload key** and then select **Review + create**.
9. After validation completes, select **Create**.

Once you upload the key, you can choose to use it when you create a VM.

List keys

Azure stores your SSH keys created in the portal as resources, so you can filter your resources view to see all of them.

1. In the portal, select **All resource**.
2. In the filters, select **Type**, unselect the **Select all** option to clear the list.
3. Type **SSH** in the filter and select **SSH key**.



Get the public key

If you need your public key, you can easily copy it from the portal page for the key. Just list your keys (using the process in the last section) then select a key from the list. The page for your key opens and you can click the **Copy to clipboard** icon next to the key to copy it.

Next steps

Generate and store SSH keys with the Azure CLI

Article • 10/17/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can create SSH keys before creating a VM and store them in Azure. Each newly created SSH key is also stored locally.

If you have existing SSH keys, you can upload and store them in Azure for reuse.

For more information, see Detailed steps: Create and manage SSH keys for authentication to a Linux VM in Azure.

For more information on how to create and use SSH keys with Linux VMs, see Use SSH keys to connect to Linux VMs.

Generate new keys

1. After you sign in, use the az sshkey create command to create the new SSH key:

   Azure CLI

   ```
   az sshkey create --name "mySSHKey" --resource-group "myResourceGroup"
   ```

   > **Note**
   >
   > This command would default to key type of RSA, in order to generate ED25519 keys you can pass in the optional flag `--encryption-type Ed25519`.

2. The resulting output lists the new key files' paths:

   Azure CLI

   ```
   Private key is saved to "/home/user/.ssh/7777777777_9999999".
   Public key is saved to "/home/user/.ssh/7777777777_9999999.pub".
   ```

3. Change the permissions for the private key file for privacy:

   Azure CLI

```
chmod 600 /home/user/.ssh/7777777777_9999999
```

Connect to the VM

On your local computer, open a Bash prompt:

Azure CLI

```
ssh -identity_file <path to the private key file> username@<ipaddress of the VM>
```

For example, enter: `ssh -i /home/user/.ssh/mySSHKey azureuser@123.45.67.890`

Upload an SSH key

You can upload a public SSH key to store in Azure.

Use the az sshkey create command to upload an SSH public key by specifying its file:

Azure CLI

```
az sshkey create --name "mySSHKey" --public-key "@/home/user/.ssh/7777777777_9999999.pub" --resource-group "myResourceGroup"
```

List keys

Use the az sshkey list command to list all public SSH keys, optionally specifying a resource group:

Azure CLI

```
az sshkey list --resource-group "myResourceGroup"
```

Get the public key

Use the az sshkey show command to show the values of a public SSH key:

Azure CLI

```
az sshkey show --name "mySSHKey" --resource-group "myResourceGroup"
```

Next steps

To learn more about how to use SSH keys with Azure VMs, see Use SSH keys to connect to Linux VMs.

Quick steps: Create and use an SSH public-private key pair for Linux VMs in Azure

Article • 10/16/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

With a secure shell (SSH) key pair, you can create virtual machines (VMs) in Azure that use SSH keys for authentication. This article shows you how to quickly generate and use an SSH public-private key file pair for Linux VMs. You can complete these steps with the Azure Cloud Shell, a macOS, or a Linux host.

For help with troubleshooting issues with SSH, see Troubleshoot SSH connections to an Azure Linux VM that fails, errors out, or is refused.

> ⓘ **Note**
>
> VMs created using SSH keys are by default configured with passwords disabled, which greatly increases the difficulty of brute-force guessing attacks.

For more background and examples, see Detailed steps to create SSH key pairs.

For additional ways to generate and use SSH keys on a Windows computer, see How to use SSH keys with Windows on Azure.

Supported SSH key formats

Azure currently supports following key types:

- SSH protocol 2 (SSH-2) RSA (Rivest, Shamir, Adleman) with a minimum length of 2048 bits
- ED25519 Keys with a fixed length of 256 bits

Other key formats such as Elliptic-curve Diffie–Hellman (ECDH) and Elliptic Curve Digital Signature Algorithm (ECDSA) are currently not supported.

Create an SSH key pair

Use the `ssh-keygen` command to generate SSH public and private key files. By default, these files are created in the ~/.ssh directory. You can specify a different location, and an optional password (*passphrase*) to access the private key file. If an SSH key pair with the same name exists in the given location, those files are overwritten.

The following command creates an SSH key pair using RSA encryption and a bit length of 4096:

Bash

```
ssh-keygen -m PEM -t rsa -b 4096 -f ~/.ssh/id_rsa.pem
```

The following command creates an SSH key pair using ED25519 encryption with a fixed length of 256 bits:

Bash

```
ssh-keygen -m PEM -t ed25519 -f ~/.ssh/id_ed25519.pem
```

> **Note**
>
> You can also create key pairs with the Azure CLI with the az sshkey create command, as described in Generate and store SSH keys.

If you use the Azure CLI to create your VM with the az vm create command, you can optionally generate SSH public and private key files using the `--generate-ssh-keys` option. The key files are stored in the ~/.ssh directory unless specified otherwise with the `--ssh-dest-key-path` option. If an ssh key pair already exists and the `--generate-ssh-keys` option is used, a new key pair won't be generated but instead the existing key pair will be used. In the following command, replace *VMname*, *RGname* and *UbuntuLTS* with your own values:

Azure CLI

```
az vm create --name VMname --resource-group RGname --image Ubuntu2204 --
generate-ssh-keys
```

> **Note**
>
> az sshkey create command deafults to RSA encryption and cannot be use to generate ED25519 key pairs, however you can create a ED25519 key pair using ssh-

keygen as described above and then use that public key to create a VM.

Provide an SSH public key when deploying a VM

To create a Linux VM that uses SSH keys for authentication, specify your SSH public key when creating the VM using the Azure portal, Azure CLI, Azure Resource Manager templates, or other methods:

- Create a Linux virtual machine with the Azure portal
- Create a Linux virtual machine with the Azure CLI
- Create a Linux VM using an Azure template

If you're not familiar with the format of an SSH public key, you can display your public key with the following `cat` command, replacing `~/.ssh/id_rsa.pub` with the path and filename of your own public key file if needed:

RSA key pair

Bash

```
cat ~/.ssh/id_rsa.pub
```

A typical RSA public key value looks like this example:

Output

```
ssh-rsa
AAAAB3NzaC1yc2EAABADAQABAAACAQC1/KanayNr+Q7ogR5mKnGpKWRBQU7F3Jjhn7utdf7Z2iUF
ykaYx+MInSnT3XdnBRS8KhC0IP8ptbngIaNOWd6zM8hB6UrcRTlTpwk/SuGMw1Vb40xlEFphBkVE
UgBolOoANIEXriAMvlDMZsgvnMFiQ12tD/u14cxy1WNEMAftey/vX3Fgp2vEq4zHXEliY/sFZLJU
JzcRUI0MOfHXAuCjg/qyqqbIuTDFyfg8k0JTtyGFEMQhbXKcuP2yGx1uw0ice62LRzr8w0mszftX
yMik1PnshRXbmE2xgINYg5xo/ra3mq2imwtOKJpfdtFoMiKhJmSNHBSkK7vFTeYgg0v2cQ2+vL38
lcIFX4Oh+QCzvNF/AXoDVlQtVtSqfQxRVG79Zqio5p12gHFktlfV7reCBvVIhyxc2LlYUkrq4DHz
kxNY5c9OGSHXSle9YsO3F1J5ip18f6gPq4xFmo6dVoJodZm9N0YMKCkZ4k1qJDESsJBk2ujDPmQQ
eMjJX3FnDXYYB182ZCGQzXfzlPDC29cWVgDZEXNHuYrOLmJTmYtLZ4WkdUhLLlt5XsdoKWqlWpbe
gyYtGZgeZNRtOOdN6ybOPJqmYFd2qRtb4sYPniGJDOGhx4VodXAjT09omhQJpE6wlZbRWDvKC55R
2d/CSPHJscEiuudb+1SG2uA/oik/WQ== username@domainname
```

ED25519 key pair

Bash

```
cat ~/.ssh/id_ed25519.pub
```

A typical ED25519 public key value looks like this example:

Output

```
ssh-ed25519
AAAAC3NzaC1lZDI1NTE5AAAAILRjWGWLeiUQ3U9fNnCsNpXIyACpD/Jbm09OZGsz3DIM
username@domainname
```

If you copy and paste the contents of the public key file to use in the Azure portal or a Resource Manager template, make sure you don't copy any trailing whitespace. To copy a public key in macOS, you can pipe the public key file to `pbcopy`. Similarly in Linux, you can pipe the public key file to programs such as `xclip`.

The public key that you place on your Linux VM in Azure is by default stored under `~/.ssh/` directory, unless you specified a different location when you created the key pair. To use the Azure CLI 2.0 to create your VM with an existing public key, specify the value and optionally the location of this public key using the az vm create command with the `--ssh-key-values` option. In the following command, replace *myVM*, *myResourceGroup*, *UbuntuLTS*, *azureuser*, and *mysshkey.pub* with your own values:

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --image Ubuntu2204 \
  --admin-username azureuser \
  --ssh-key-values mysshkey.pub
```

If you want to use multiple SSH keys with your VM, you can enter them in a comma-separated list, like this `--ssh-key-values sshkey-desktop.pub, sshkey-laptop.pub`.

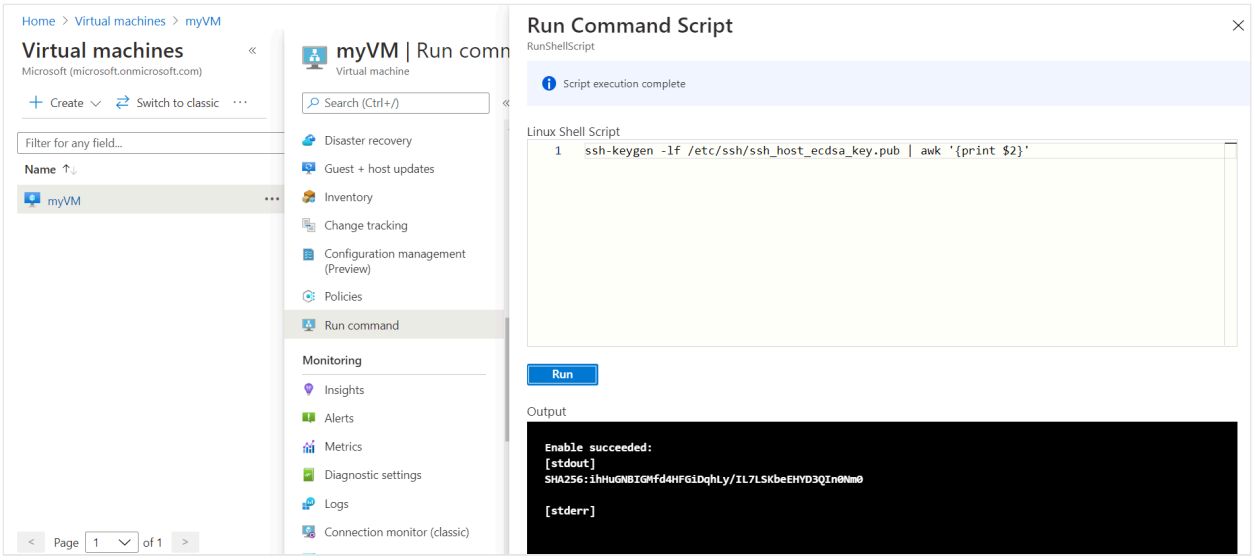
SSH into your VM

With the public key deployed on your Azure VM, and the private key on your local system, SSH into your VM using the IP address or DNS name of your VM. In the following command, replace *azureuser* and *myvm.westus.cloudapp.azure.com* with the administrator user name and the fully qualified domain name (or IP address):

Bash

```
ssh azureuser@myvm.westus.cloudapp.azure.com
```

If you're connecting to this VM for the first time, you'll be asked to verify the host's fingerprint. It's tempting to accept the fingerprint that's presented, but that approach exposes you to a possible person-in-the-middle attack. You should always validate the host's fingerprint. You need to do this only the first time you connect from a client. To obtain the host fingerprint via the portal, use the Run Command feature to execute the command `ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'`.



To run the command using CLI, use az vm run-command invoke.

If you specified a passphrase when you created your key pair, enter that passphrase when prompted during the sign-in process. The VM is added to your ~/.ssh/known_hosts file, and you won't be asked to connect again until either the public key on your Azure VM changes or the server name is removed from ~/.ssh/known_hosts.

If the VM is using the just-in-time access policy, you need to request access before you can connect to the VM. For more information about the just-in-time policy, see Manage virtual machine access using the just in time policy.

Next steps

- For more information on working with SSH key pairs, see Detailed steps to create and manage SSH key pairs.
- If you have difficulties with SSH connections to Azure VMs, see Troubleshoot SSH connections to an Azure Linux VM.

How to use SSH keys with Windows on Azure

Article • 10/16/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article is for Windows users who want to create and use *secure shell* (SSH) keys to connect to Linux virtual machines (VMs) in Azure. You can also generate and store SSH keys in the Azure portal to use when creating VMs in the portal.

To use SSH keys from a Linux or macOS client, see the quick steps. For a more detailed overview of SSH, see Detailed steps: Create and manage SSH keys for authentication to a Linux VM in Azure.

Overview of SSH and keys

SSH is an encrypted connection protocol that allows secure sign-ins over unsecured connections. SSH is the default connection protocol for Linux VMs hosted in Azure. Although SSH itself provides an encrypted connection, using passwords with SSH still leaves the VM vulnerable to brute-force attacks. We recommend connecting to a VM over SSH using a public-private key pair, also known as *SSH keys*.

The public-private key pair is like the lock on your front door. The lock is exposed to the **public**, anyone with the right key can open the door. The key is **private**, and only given to people you trust because it can be used to unlock the door.

- The *public key* is placed on your Linux VM when you create the VM.
- The *private key* remains on your local system. Protect this private key. Don't share it.

When you connect to your Linux VM, the VM tests the SSH client to make sure it has the correct private key. If the client has the private key, it's granted access to the VM.

Depending on your organization's security policies, you can reuse a single key pair to access multiple Azure VMs and services. You don't need a separate pair of keys for each VM.

Your public key can be shared with anyone, but only you (or your local security infrastructure) should have access to your private key.

Supported SSH key formats

Azure currently supports following key types:

- SSH protocol 2 (SSH-2) RSA (Rivest, Shamir, Adleman) with a minimum length of 2048 bits
- ED25519 Keys with a fixed length of 256 bits

Other key formats such as Elliptic-curve Diffie–Hellman (ECDH) and Elliptic Curve Digital Signature Algorithm (ECDSA) are currently not supported.

SSH clients

Recent versions of Windows 10 include OpenSSH client commands to create and use SSH keys and make SSH connections from PowerShell or a command prompt.

You can also use Bash in the Azure Cloud Shell to connect to your VM. You can use Cloud Shell in a web browser, from the Azure portal, or as a terminal in Visual Studio Code using the Azure Account extension.

You can also install the Windows Subsystem for Linux to connect to your VM over SSH and use other native Linux tools within a Bash shell.

Create an SSH key pair

The easiest way to create and manage your SSH keys is to use the portal to create and store them for reuse.

You can also create key pairs with the Azure CLI with the az sshkey create command, as described in Generate and store SSH keys.

To create an SSH key pair on your local computer using the `ssh-keygen` command from PowerShell or a command prompt, use the following command:

PowerShell

```
ssh-keygen -m PEM -t rsa -b 2048
```

Enter a filename, or use the default shown in parenthesis (for example `C:\Users\username/.ssh/id_rsa`). Enter a passphrase for the file, or leave the passphrase blank if you don't want to use a passphrase.

Create a VM using your key

To create a Linux VM that uses SSH keys for authentication, provide your SSH public key when creating the VM.

Using the Azure CLI, you specify the path and filename for the public key using `az vm create` and the `--ssh-key-value` parameter.

Azure CLI

```
az vm create \
   --resource-group myResourceGroup \
   --name myVM \
   --image Ubuntu2204\
   --admin-username azureuser \
   --ssh-key-value ~/.ssh/id_rsa.pub
```

With PowerShell, use `New-AzVM` and add the SSH key to the VM configuration using`. For an example, see Quickstart: Create a Linux virtual machine in Azure with PowerShell.

If you do many deployments using the portal, you might want to upload your public key to Azure, where it can be easily selected when creating a VM from the portal. For more information, see Upload an SSH key.

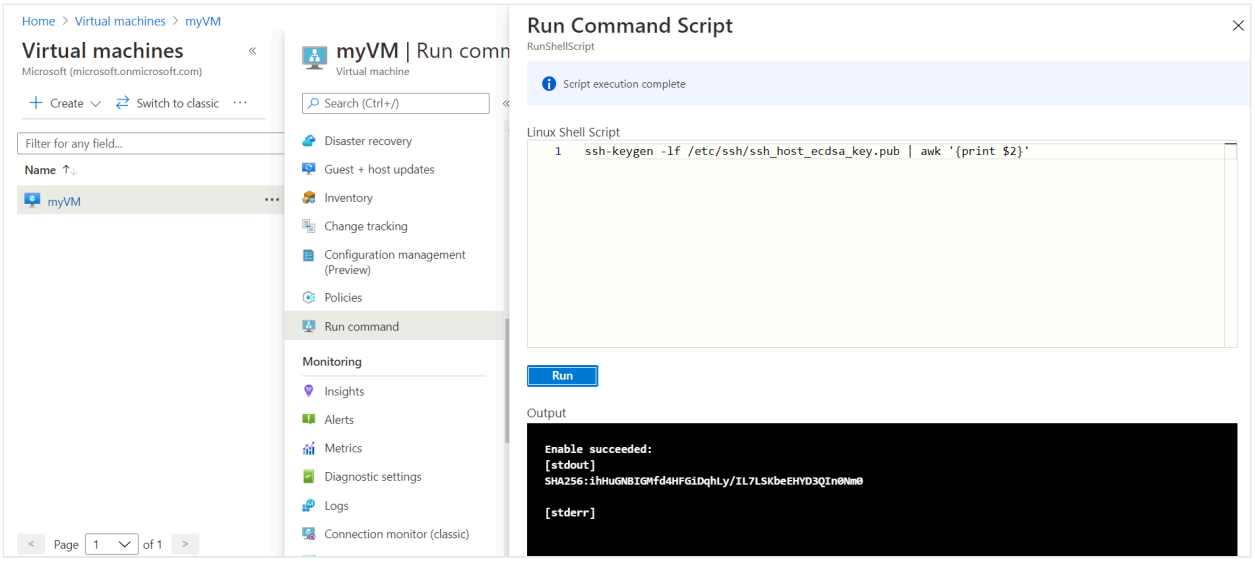
Connect to your VM

With the public key deployed on your Azure VM, and the private key on your local system, SSH to your VM using the IP address or DNS name of your VM. Replace *azureuser* and *10.111.12.123* in the following command with the administrator user name, the IP address (or fully qualified domain name), and the path to your private key:

Bash

```
ssh -i ~/.ssh/id_rsa azureuser@10.111.12.123
```

If you've never connected to this VM before you'll be asked to verify the hosts fingerprint. It's tempting to accept the fingerprint presented, however, this exposes you to a possible person in the middle attack. You should always validate the hosts fingerprint. You only need to do this on the first time you connect from a client. To obtain the host fingerprint via the portal, use the Run Command with the following command: `ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'`.



To run the command using CLI, use the az vm run-command invoke command.

If you configured a passphrase when you created your key pair, enter the passphrase when prompted.

If the VM is using the just-in-time access policy, you need to request access before you can connect to the VM. For more information about the just-in-time policy, see Manage virtual machine access using the just in time policy.

Next steps

- For information about SSH keys in the Azure portal to use when creating VMs, see Generate and store SSH keys in the Azure portal.
- For information about SSH keys in the Azure CLI to use when creating VMs, see Generate and store SSH keys with the Azure CLI.
- For detailed steps, options, and advanced examples of working with SSH keys, see Detailed steps to create SSH key pairs.
- If you have difficulty using SSH to connect to your Linux VMs, see Troubleshoot SSH connections to an Azure Linux VM.

Install and configure xrdp to use Remote Desktop with Ubuntu

10/02/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When new to Linux, or for quick troubleshooting scenarios, the use of remote desktop may be easier than Secure Shell (SSH) access. This article details how to install and configure a desktop environment (xfce) and remote desktop (xrdp) for your Linux VM running Ubuntu.

> **Note**
>
> Using Remote Desktop over the internet will introduce noticeable "lag" (input latency) when compared to local desktop use. This can be influenced by multiple factors including local internet speed and distance from the datacenter where the virtual machine is hosted. This lag does not usually reflect the performance of the VM itself.

> **Important**
>
> Starting with Red Hat 9, xrdp is not supported anymore since it requires third party repositories, Red Hat has specific steps on how to enable this kind of access described here

Prerequisites

This article and steps provided were taken from testing Ubuntu 24.04 and SUSE Enterprise Linux 15.

If you need to create a VM, use one of the following methods:

- The Azure CLI
- The Azure portal

Install a desktop environment on your Linux VM

Most Linux VMs in Azure don't have a desktop environment installed by default. Linux VMs are commonly managed using SSH connections rather than a desktop environment, however there are several desktop environments that you can choose to install. Depending on your choice of

desktop environment, it consumes up to 2 GB of disk space and take up to ten minutes to both install and configure all the required packages.

The following example installs the lightweight xfce4 desktop environment on an Ubuntu VM.

First, SSH to your VM. The following example connects to the VM named *myvm.westus.cloudapp.azure.com* with the username of *azureuser*. Use your own values:

```bash
ssh azureuser@myvm.westus.cloudapp.azure.com
```

If you're using Windows and need more information on using SSH, see How to use SSH keys with Windows.

For Ubuntu 24.04

Install all the required packages using `apt` :

```bash
sudo apt update
sudo apt install xfce4 xfce4-session xrdp
sudo systemctl enable xrdp
```

For SUSE Enterprise Linux 15

Install all the required packages using `zypper` :

```bash
sudo zypper in xorg-x11-server xterm xorg-x11-xauth xrdp ssl-cert xhost xclock
sudo systemctl enable xrdp
```

On Ubuntu 24, you need to give certificate access to an xrdp user:

```bash
sudo adduser xrdp ssl-cert
```

The steps below apply to both distributions (Ubuntu 24 and SUSE Enterprise Linux 15)

Tell xrdp what desktop environment to use when you start your session. Configure xrdp to use xfce as your desktop environment as follows:

```
Bash

echo xfce4-session >~/.xsession
```

Restart the xrdp service for the changes to take effect as follows:

```
Bash

sudo systemctl restart xrdp
```

Set a local user account password

If you created a password for your user account when you created your VM, skip this step. If you only use SSH key authentication and don't have a local account password set, specify a password before you use xrdp to log in to your VM. xrdp can't accept SSH keys for authentication. The following example specifies a password for the user account *azureuser*:

```
Bash

sudo passwd azureuser
```

> **Note**
>
> Specifying a password does not update your SSHD configuration to permit password logins if it currently does not. From a security perspective, you may wish to connect to your VM with an SSH tunnel using key-based authentication and then connect to xrdp. If so, skip the following step on creating a network security group rule to allow remote desktop traffic.

Create a Network Security Group rule for Remote Desktop traffic

To allow Remote Desktop traffic to reach your Linux VM, a network security group rule needs to be created that allows TCP on port 3389 to reach your VM. For more information about network security group rules, see What is a network security group? You can also use the Azure portal to create a network security group rule.

Azure CLI

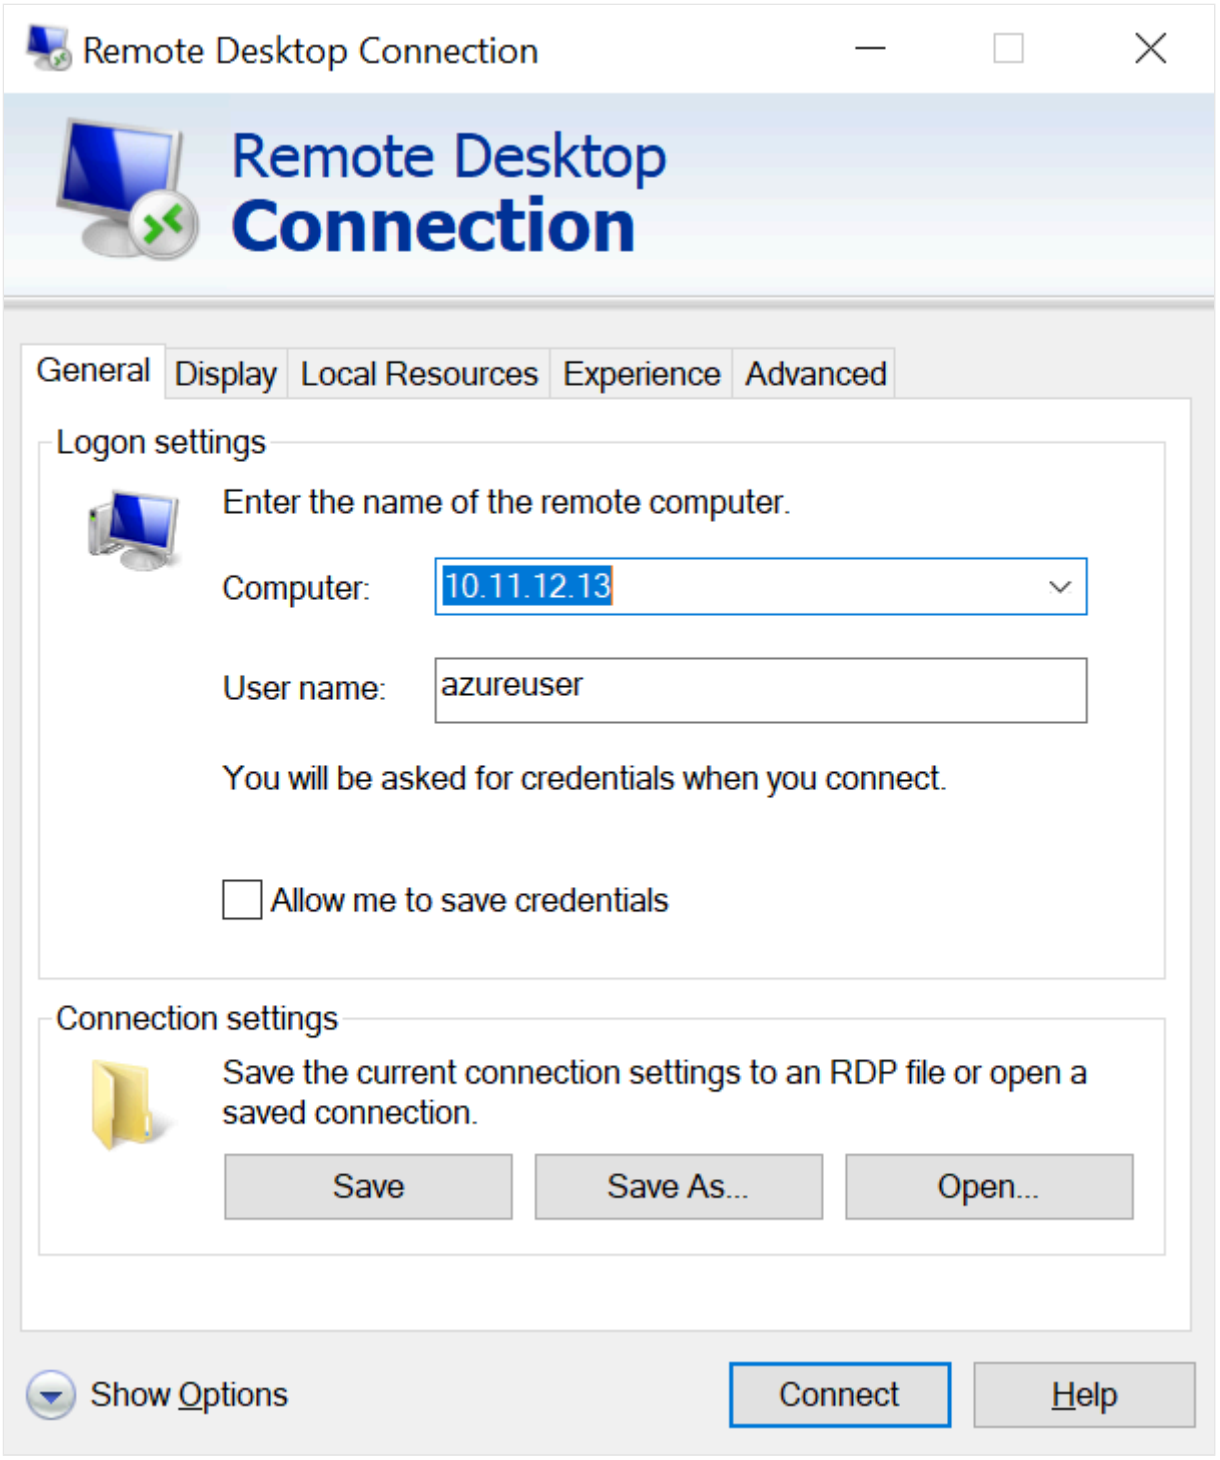
The following example creates a network security group rule with az vm open-port on port *3389*. From the Azure CLI, not the SSH session to your VM, open the following network security group rule:

Azure CLI

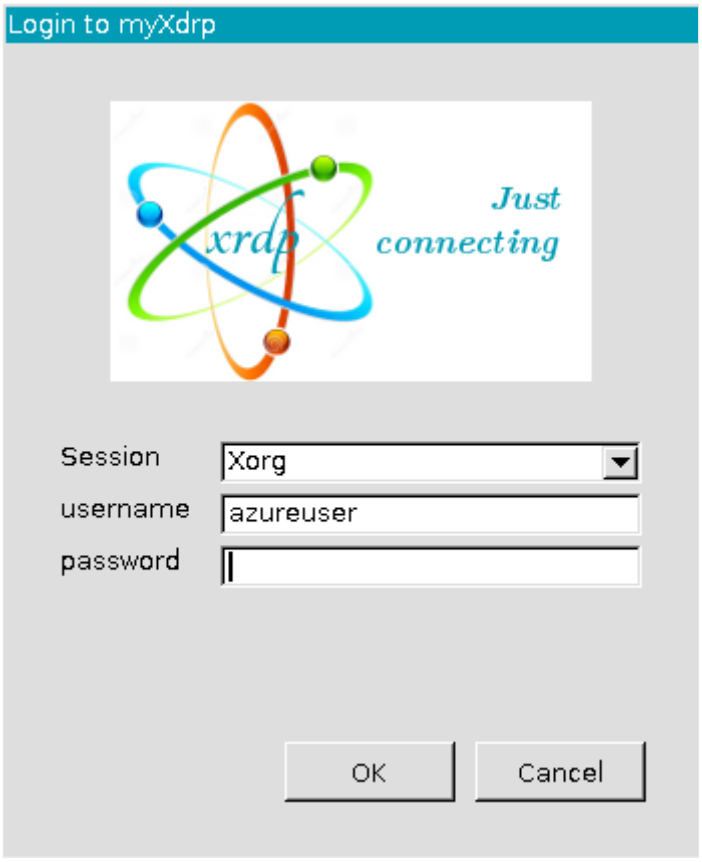
```
az vm open-port --resource-group myResourceGroup --name myVM --port 3389
```

Connect your Linux VM with a Remote Desktop client

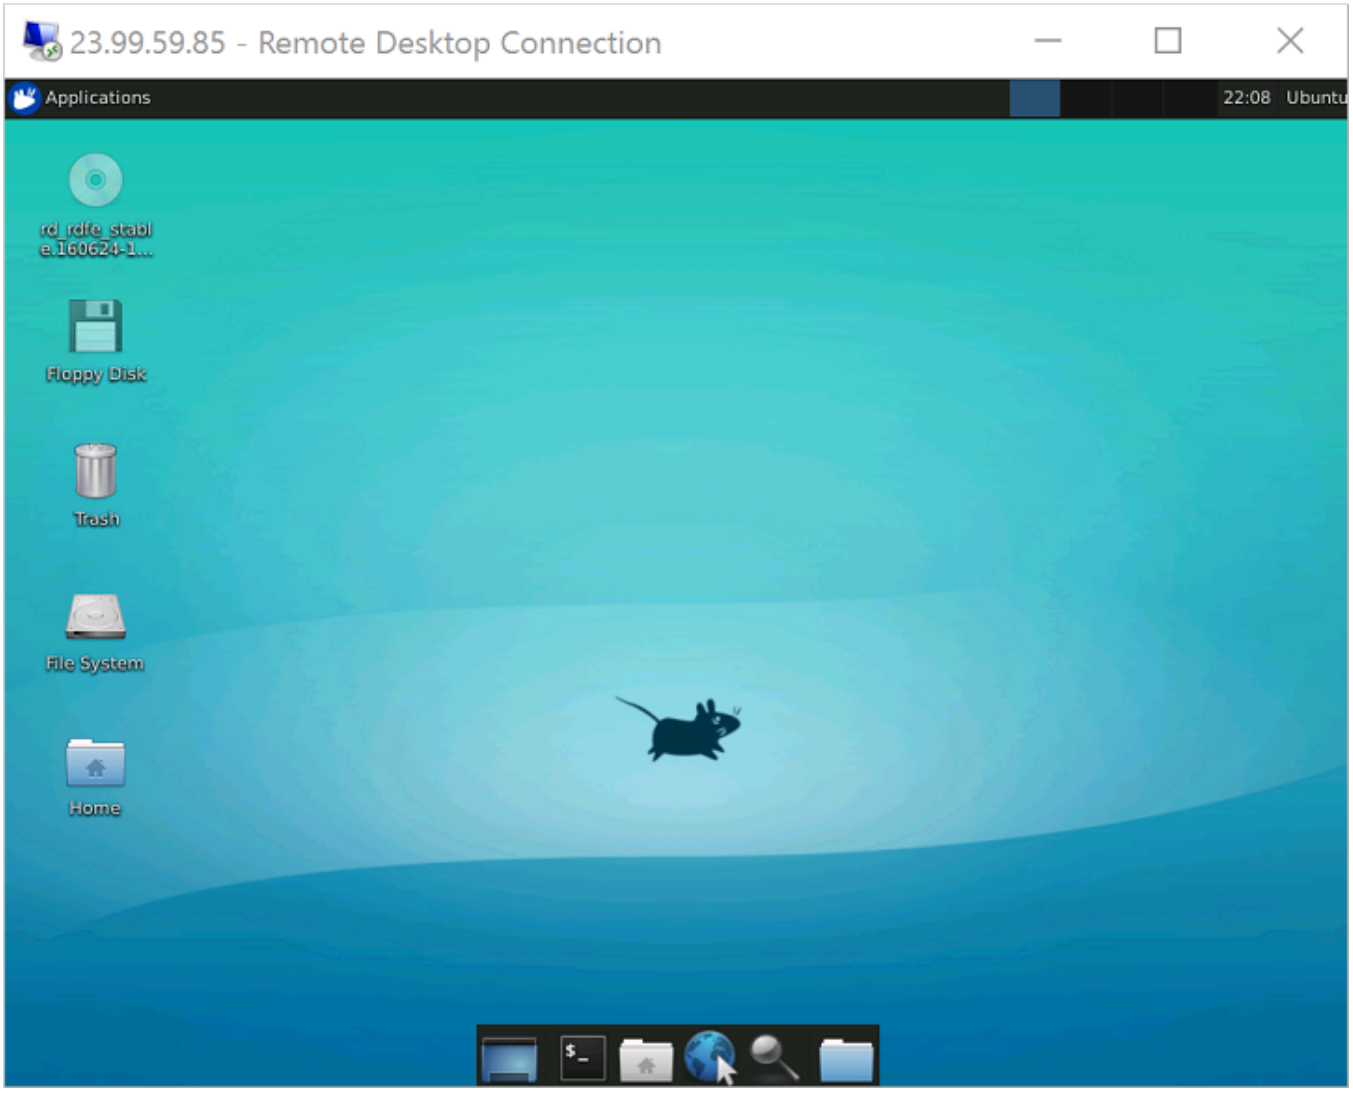
Open your local remote desktop client and connect to the IP address or DNS name of your Linux VM.



Enter the username and password for the user account on your VM as follows:



After authenticating, the xfce desktop environment will load and look similar to the following example:



If your local RDP client uses network level authentication (NLA), you may need to disable that connection setting. XRDP does not currently support NLA. You can also look at alternative RDP solutions that do support NLA, such as FreeRDP.

Troubleshoot

If you can't connect to your Linux VM using a Remote Desktop client, use `netstat` on your Linux VM to verify that your VM is listening for RDP connections as follows:

Bash

```
sudo netstat -plnt | grep rdp
```

The following example shows the VM listening on TCP port 3389 as expected:

Bash

```
tcp      0      0      127.0.0.1:3350      0.0.0.0:*      LISTEN      53192/xrdp-sesman
tcp      0      0      0.0.0.0:3389        0.0.0.0:*      LISTEN      53188/xrdp
```

If the *xrdp-sesman* service isn't listening, on an Ubuntu VM restart the service as follows:

```
Bash

sudo systemctl restart xrdp
```

Review logs in */var/log* on your Ubuntu VM for indications as to why the service may not be responding. You can also monitor the syslog during a remote desktop connection attempt to view any errors:

```
Bash

tail -f /var/log/syslog
```

If you don't receive any response in your remote desktop client and don't see any events in the system log, this behavior indicates that remote desktop traffic can't reach the VM. Review your network security group rules to ensure that you have a rule to permit TCP on port 3389. For more information, see Troubleshoot application connectivity issues.

Next steps

For more information about creating and using SSH keys with Linux VMs, see Create SSH keys for Linux VMs in Azure.

For information on using SSH from Windows, see How to use SSH keys with Windows.

How to connect using Secure Shell (SSH) and sign on to an Azure virtual machine running Windows

Article • 08/23/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

The Win32 OpenSSH project makes remote connectivity with Secure Shell ubiquitous by providing native support in Windows. The capability is provided in Windows Server version 2019 and later, and can be added to older versions of Windows using a virtual machine (VM) extension.

The examples below use variables. You can set variables in your environment as follows.

Expand table

Shell	Example
Bash/ZSH	myResourceGroup='resGroup10'
PowerShell	$myResourceGroup='resGroup10'

Enable SSH

First, you'll need to enable SSH in your Windows machine.

Deploy the SSH extension for Windows. The extension provides an automated installation of the Win32 OpenSSH solution, similar to enabling the capability in newer versions of Windows. Use the following examples to deploy the extension.

Azure CLI

Azure CLI

```
az vm extension set --resource-group $myResourceGroup --vm-name $myVM --
name WindowsOpenSSH --publisher Microsoft.Azure.OpenSSH --version 3.0
```

Open TCP port

Ensure the appropriate port (by default, TCP 22) is open to allow connectivity to the VM.

Azure CLI

Azure CLI

```
az network nsg rule create -g $myResourceGroup --nsg-name $myNSG -n
allow-SSH --priority 1000 --source-address-prefixes 208.130.28.4/32 --
destination-port-ranges 22 --protocol TCP
```

- Your VM must have a public IP address. To check if your VM has a public IP address, select **Overview** from the left menu and look at the **Networking** section. If you see an IP address next to **Public IP address**, then your VM has a public IP. To learn more about adding a public IP address to an existing VM, see Associate a public IP address to a virtual machine
- Verify your VM is running. On the Overview tab, in the essentials section, verify the status of the VM is Running. To start the VM, select **Start** at the top of the page.

Authentication

You can authenticate to Windows machines using either username and password or SSH keys. Azure doesn't support provisioning public keys to Windows machines automatically, however you can copy the key using the RunCommand extension.

Overview of SSH and keys

SSH is an encrypted connection protocol that provides secure sign-ins over unsecured connections. Although SSH provides an encrypted connection, using passwords with SSH connections still leaves the VM vulnerable to brute-force attacks. We recommend connecting to a VM over SSH using a public-private key pair, also known as *SSH keys*.

- The *public key* is placed on your VM.
- The *private key* remains on your local system. Protect this private key. Do not share it.

When you use an SSH client to connect to your VM (which has the public key), the remote VM tests the client to make sure it has the correct private key. If the client has the private key, it's granted access to the VM.

Depending on your organization's security policies, you can reuse a single public-private key pair to access multiple Azure VMs and services. You do not need a separate pair of keys for each VM or service you wish to access.

Your public key can be shared with anyone, but only you (or your local security infrastructure) should have access to your private key.

Supported SSH key formats

Azure currently supports SSH protocol 2 (SSH-2) RSA public-private key pairs with a minimum length of 2048 bits. Support for ED25519 Keys is in preview, other key formats such as ECDH and ECDSA are not supported.

Copy a public key using the RunCommand extension.

The RunCommand extension provides an easy solution to copying a public key into Windows machines and making sure the file has correct permissions.

Azure CLI

Azure CLI

```
az vm run-command invoke -g $myResourceGroup -n $myVM --command-id
RunPowerShellScript --scripts "MYPUBLICKEY | Add-Content
'C:\ProgramData\ssh\administrators_authorized_keys' -Encoding
UTF8;icacls.exe 'C:\ProgramData\ssh\administrators_authorized_keys'
/inheritance:r /grant 'Administrators:F' /grant 'SYSTEM:F'"
```

Connect using Az CLI

Connect to Windows machines using `Az SSH` commands.

Azure CLI

```
az ssh vm  -g $myResourceGroup -n $myVM --local-user $myUsername
```

It's also possible to create a network tunnel for specific TCP ports through the SSH connection. A good use case for this is Remote Desktop which defaults to port 3389.

Azure CLI

```
az ssh vm  -g $myResourceGroup -n $myVM --local-user $myUsername -- -L
3389:localhost:3389
```

Connect from Azure portal

1. Go to the Azure portal to connect to a VM. Search for and select **Virtual machines**.
2. Select the virtual machine from the list.
3. Select **Connect** from the left menu.
4. Select the option that fits with your preferred way of connecting. The portal helps walk you through the prerequisites for connecting.

Next steps

Learn how to transfer files to an existing VM, see Use SCP to move files to and from a VM.

Setting up WinRM access for Virtual Machines in Azure Resource Manager

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

Here are the steps you need to take to set up a VM with WinRM connectivity

1. Create a Key Vault
2. Create a self-signed certificate
3. Upload your self-signed certificate to Key Vault
4. Get the URL for your self-signed certificate in the Key Vault
5. Reference your self-signed certificates URL while creating a VM

Step 1: Create a Key Vault

You can use the below command to create the Key Vault

Azure PowerShell

```
New-AzKeyVault -VaultName "<vault-name>" -ResourceGroupName "<rg-name>" -
Location "<vault-location>" -EnabledForDeployment -
EnabledForTemplateDeployment
```

Step 2: Create a self-signed certificate

You can create a self-signed certificate using this PowerShell script

Azure PowerShell

```
$certificateName = "somename"

$thumbprint = (New-SelfSignedCertificate -DnsName $certificateName -
CertStoreLocation Cert:\CurrentUser\My -KeySpec KeyExchange).Thumbprint

$cert = (Get-ChildItem -Path cert:\CurrentUser\My\$thumbprint)

$password = Read-Host -Prompt "Please enter the certificate password." -
AsSecureString

Export-PfxCertificate -Cert $cert -FilePath ".\$certificateName.pfx" -
Password $password
```

Step 3: Upload your self-signed certificate to the Key Vault

Before uploading the certificate to the Key Vault created in step 1, it needs to be converted into a format the Microsoft.Compute resource provider will understand. The below PowerShell script will allow you to do that

Azure PowerShell

```
$fileName = "<Path to the .pfx file>"
$fileContentBytes = Get-Content $fileName -Encoding Byte
$fileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
[System.Collections.HashTable]$TableForJSON = @{
    "data"     = $fileContentEncoded;
    "dataType" = "pfx";
    "password" = "<password>";
}
[System.String]$jsonObject = $TableForJSON | ConvertTo-Json
$encoding = [System.Text.Encoding]::UTF8
$jsonEncoded =
[System.Convert]::ToBase64String($encoding.GetBytes($jsonObject))
$secret = ConvertTo-SecureString -String $jsonEncoded -AsPlainText –Force
Set-AzKeyVaultSecret -VaultName "<vault name>" -Name "<secret name>" -
SecretValue $secret
```

Step 4: Get the URL for your self-signed certificate in the Key Vault

The Microsoft.Compute resource provider needs a URL to the secret inside the Key Vault while provisioning the VM. This enables the Microsoft.Compute resource provider to download the secret and create the equivalent certificate on the VM.

> ⓘ **Note**
>
> The URL of the secret needs to include the version as well. An example URL looks like below https://contosovault.vault.azure.net:443/secrets/contososecret/01h9db0df2cd4300a20ence585a6s7ve

Templates

You can get the link to the URL in the template using the below code

JSON

```
"certificateUrl": "[reference(resourceId(resourceGroup().name,
'Microsoft.KeyVault/vaults/secrets', '<vault-name>', '<secret-name>'),
'2015-06-01').secretUriWithVersion]"
```

PowerShell

You can get this URL using the below PowerShell command

Azure PowerShell

```
$secretURL = (Get-AzKeyVaultSecret -VaultName "<vault name>" -Name "<secret
name>").Id
```

Step 5: Reference your self-signed certificates URL while creating a VM

Azure Resource Manager Templates

While creating a VM through templates, the certificate gets referenced in the secrets section and the winRM section as below:

JSON

```
"osProfile": {
      ...
      "secrets": [
        {
          "sourceVault": {
            "id": "<resource id of the Key Vault containing the secret>"
          },
          "vaultCertificates": [
            {
              "certificateUrl": "<URL for the certificate you got in Step
4>",
              "certificateStore": "<Name of the certificate store on the
VM>"
            }
          ]
        }
      ],
      "windowsConfiguration": {
        ...
        "winRM": {
          "listeners": [
```

```
            {
              "protocol": "http"
            },
            {
              "protocol": "https",
              "certificateUrl": "<URL for the certificate you got in Step
4>"
            }
          ]
        },
        ...
      }
    },
```

A sample template for the above can be found here at vm-winrm-keyvault-windows

Source code for this template can be found on GitHub

PowerShell

Azure PowerShell

```
$vm = New-AzVMConfig -VMName "<VM name>" -VMSize "<VM Size>"
$credential = Get-Credential
$secretURL = (Get-AzKeyVaultSecret -VaultName "<vault name>" -Name "<secret
name>").Id
$vm = Set-AzVMOperatingSystem -VM $vm -Windows -ComputerName "<Computer
Name>" -Credential $credential -WinRMHttp -WinRMHttps -ProvisionVMAgent -
WinRMCertificateUrl $secretURL
$sourceVaultId = (Get-AzKeyVault -ResourceGroupName "<Resource Group name>"
-VaultName "<Vault Name>").ResourceId
$CertificateStore = "My"
$vm = Add-AzVMSecret -VM $vm -SourceVaultId $sourceVaultId -CertificateStore
$CertificateStore -CertificateUrl $secretURL
```

Step 6: Connecting to the VM

Before you can connect to the VM, you'll need to make sure your machine is configured for WinRM remote management. Start PowerShell as an administrator and execute the below command to make sure you're set up.

Azure PowerShell

```
Enable-PSRemoting -Force
```

Note

You might need to make sure the WinRM service is running if the above does not work. You can do that using `Get-Service WinRM`

Once the setup is done, you can connect to the VM using the below command

Azure PowerShell

```
Enter-PSSession -ConnectionUri https://<public-ip-dns-of-the-vm>:5986 -
Credential $cred -SessionOption (New-PSSessionOption -SkipCACheck -
SkipCNCheck -SkipRevocationCheck) -Authentication Negotiate
```

Time sync for Linux VMs in Azure

Article • 12/09/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

Time sync is important for security and event correlation. Sometimes it's used for distributed transactions implementation. Time accuracy between multiple computer systems is achieved through synchronization. Synchronization can be affected by multiple things, including reboots and network traffic between the time source and the computer fetching the time.

Azure is backed by infrastructure running Windows Server 2016. Windows Server 2016 has improved algorithms used to correct time and condition the local clock to synchronize with UTC. The Windows Server 2016 Accurate Time feature greatly improved how the VMICTimeSync service that governs VMs with the host for accurate time. Improvements include more accurate initial time on VM start or VM restore and interrupt latency correction.

> ⓘ **Note**
>
> For more information, see How the Windows Time Service Works. You can also find information specific to Windows Server 2016 on the Accurate time for Windows Server 2016 page.

Overview

Accuracy for a computer clock is gauged on how close the computer clock is to the Coordinated Universal Time (UTC) time standard. UTC is defined by a multinational sample of precise atomic clocks that can only be off by one second in 300 years. But, reading UTC directly requires specialized hardware. Instead, time servers are synced to UTC and are accessed from other computers to provide scalability and robustness. Every computer has time synchronization service running that knows what time servers to use and periodically checks if computer clock needs to be corrected and adjusts time if needed.

Azure hosts are synchronized to internal Microsoft time servers that take their time from Microsoft-owned Stratum 1 devices, with GPS antennas. Virtual machines in Azure can either depend on their host to pass the accurate time (*host time*) on to the VM or the VM can directly get time from a time server, or a combination of both.

On stand-alone hardware, the Linux OS only reads the host hardware clock on boot. After that, the clock is maintained using the interrupt timer in the Linux kernel. In this configuration, the clock will drift over time. In newer Linux distributions on Azure, VMs can use the VMICTimeSync provider, included in the Linux integration services (LIS), to query for clock updates from the host more frequently.

Virtual machine interactions with the host can also affect the clock. During memory preserving maintenance, VMs are paused for up to 30 seconds. For example, before maintenance begins the VM clock shows 10:00:00 AM and lasts 28 seconds. After the VM resumes, the clock on the VM would still show 10:00:00 AM, which would be 28 seconds off. To correct for this, the VMICTimeSync service monitors what is happening on the host and updates the time-of-day clock in Linux VMs to compensate.

Without time synchronization working, the clock on the VM would accumulate errors. When there's only one VM, the effect might not be significant unless the workload requires highly accurate timekeeping. But in most cases, we have multiple, interconnected VMs that use time to track transactions and the time needs to be consistent throughout the entire deployment. When time between VMs is different, you could see the following effects:

- Authentication will fail. Security protocols like Kerberos or certificate-dependent technology rely on time being consistent across the systems.
- It's hard to figure out what have happened in a system if logs (or other data) don't agree on time. The same event would look like it occurred at different times, making correlation difficult.
- If clock is off, the billing could be calculated incorrectly.

Configuration options

Time sync requires that a time sync service is running in the Linux VM, plus a source of accurate time information against which to synchronize. Typically ntpd or chronyd is used as the time sync service, though there are other open source time sync services that can be used as well. The source of accurate time information can be the Azure host or an external time service that is accessed over the public internet. By itself, the VMICTimeSync service doesn't provide ongoing time sync between the Azure host and a Linux VM except after pauses for host maintenance as described above.

Historically, most Azure Marketplace images with Linux have been configured in one of two ways:

- No time sync service is running by default

- ntpd is running as the time sync service, and synchronizing against an external NTP time source that is accessed over the network. For example, Ubuntu 18.04 LTS Marketplace images use **ntp.ubuntu.com**.

To confirm ntpd is synchronizing correctly, run the `ntpq -p` command.

Some Azure Marketplace images with Linux are being changed to use chronyd as the time sync service, and chronyd is configured to synchronize against the Azure host rather than an external NTP time source. The Azure host time is usually the best time source to synchronize against, as it is maintained accurately and reliably, and is accessible without the variable network delays inherent in accessing an external NTP time source over the public internet.

The VMICTimeSync is used in parallel and provides two functions:

- Immediately updates the Linux VM time-of-day clock after a host maintenance event
- Instantiates an IEEE 1588 Precision Time Protocol (PTP) hardware clock source as a /dev/ptp device that provides the accurate time-of-day from the Azure host. Chronyd can be configured to synchronize against this time source (which is the default configuration in the newest Linux images). Linux distributions with kernel version 4.11 or later (or version 3.10.0-693 or later for RHEL 7) support the /dev/ptp device. For earlier kernel versions that don't support /dev/ptp for Azure host time, only synchronization against an external time source is possible.

The default configuration can be changed. An older image that is configured to use ntpd and an external time source can be changed to use chronyd and the /dev/ptp device for Azure host time. Similarly, an image using Azure host time via a /dev/ptp device can be configured to use an external NTP time source if required by your application or workload.

Tools and resources

There are some basic commands for checking your time synchronization configuration. Documentation for Linux distribution has more details on the best way to configure time synchronization for that distribution.

Integration services

Check to see if the integration service (hv_utils) is loaded.

```
Bash
```

```
$ sudo lsmod | grep hv_utils
```

You should see something similar to this:

```
hv_utils               24418  0
hv_vmbus              397185  7
hv_balloon,hyperv_keyboard,hv_netvsc,hid_hyperv,hv_utils,hyperv_fb,hv_storvs
c
```

Check for PTP Clock Source

With newer versions of Linux, a Precision Time Protocol (PTP) clock source corresponding to the Azure host is available as part of the VMICTimeSync provider. On older versions of Red Hat Enterprise Linux 7.x, the Linux Integration Services can be downloaded and used to install the updated driver. When the PTP clock source is available, the Linux device is of the form /dev/ptp*x*.

See which PTP clock sources are available.

Bash

```
$ ls /sys/class/ptp
```

In this example, the value returned is *ptp0*, so we use that to check the clock name. To verify the device, check the clock name.

Bash

```
$ sudo cat /sys/class/ptp/ptp0/clock_name
```

This should return `hyperv`, meaning the Azure host.

In some Linux VMs you may see multiple PTP devices listed. One example is for Accelerated Networking the Mellanox mlx5 driver also creates a /dev/ptp device. Because the initialization order can be different each time Linux boots, the PTP device corresponding to the Azure host might be `/dev/ptp0` or it might be `/dev/ptp1`, which makes it difficult to configure `chronyd` with the correct clock source. To solve this problem, the most recent Linux images have a `udev` rule that creates the symlink `/dev/ptp_hyperv` to whichever `/dev/ptp` entry corresponds to the Azure host. Chrony

should always be configured to use the `/dev/ptp_hyperv` symlink instead of `/dev/ptp0` or `/dev/ptp1`.

If you are having issues with the `/dev/ptp_hyperv` device not being created, you can use the `udev` rule and steps below to configure it:

NOTE: Most Linux distributions should not need this udev rule as it has been implemented in newer versions of systemd

Create the `udev` rules file:

Bash

```
$ sudo cat > /etc/udev/rules.d/99-ptp_hyperv.rules << EOF
ACTION!="add", GOTO="ptp_hyperv"
SUBSYSTEM=="ptp", ATTR{clock_name}=="hyperv", SYMLINK += "ptp_hyperv"
LABEL="ptp_hyperv"
EOF
```

Reboot the Virtual Machine OR reload the `udev` rules with:

Bash

```
$ sudo udevadm control --reload
$ sudo udevadm trigger --subsystem-match=ptp --action=add
```

chrony

On Ubuntu 19.10 (and later versions) and Red Hat Enterprise Linux 8.x, chrony is configured to use a PTP source clock. Instead of chrony, older Linux releases use the Network Time Protocol daemon (ntpd), which doesn't support PTP sources. To enable PTP in those releases, chrony must be manually installed and configured (in chrony.conf) by using the following statement:

Bash

```
refclock PHC /dev/ptp_hyperv poll 3 dpoll -2 offset 0 stratum 2
```

If the /dev/ptp_hyperv symlink is available, use it instead of /dev/ptp0 to avoid any confusion with the /dev/ptp device created by the Mellanox mlx5 driver.

Stratum information isn't automatically conveyed from the Azure host to the Linux guest. The preceding configuration line specifies that the Azure host time source is to be treated as Stratum 2, which in turn causes the Linux guest to report itself as Stratum 3.

You can change the stratum setting in the configuration line if you want the Linux guest to report itself differently.

By default, chronyd accelerates or slows the system clock to fix any time drift. If the drift becomes too large, chrony fails to fix the drift. To overcome this, the `makestep` parameter in **/etc/chrony.conf** can be changed to force a time sync if the drift exceeds the threshold specified.

Bash

```
makestep 1.0 -1
```

Here, chrony will force a time update if the drift is greater than 1 second. To apply the changes restart the chronyd service:

Bash

```
$ sudo systemctl restart chronyd && sudo systemctl restart chrony
```

Time sync messages related to systemd-timesyncd

In some cases, the systemd-timesyncd service might still be enabled and trying to do a sync upon a reboot, if you are still seeing messages in syslog that look similar to:

```
systemd-timesyncd[945]: Network configuration changed, trying to establish
connection.
Aug  1 12:59:45 vm-name systemd-timesyncd[945]: Network configuration
changed, trying to establish connection.
Aug  1 12:59:45 vm-name systemd-timesyncd[945]: Network configuration
changed, trying to establish connection.
Aug  1 12:59:45 vm-name systemd-timesyncd[945]: Network configuration
changed, trying to establish connection.
Aug  1 12:59:45 vm-name systemd-timesyncd[945]: Network configuration
changed, trying to establish connection.
Aug  1 12:59:45 vm-name systemd-timesyncd[945]: Synchronized to time server
185.125.190.56:123 (ntp.ubuntu.com)
```

You can disable it by using:

Bash

```
$ sudo systemctl disable systemd-timesyncd
```

In most cases, systemd-timesyncd will try during boot but once chrony starts up it will overwrite and become the default time sync source.

For more information about Ubuntu and NTP, see Time Synchronization.

For more information about Red Hat and NTP, see Configure NTP.

For more information about chrony, see Using chrony.

systemd

On SUSE and Ubuntu releases before 19.10, time sync is configured using systemd. For more information about Ubuntu, see Time Synchronization. For more information about SUSE, see Section 4.5.8 in SUSE Linux Enterprise Server 12 SP3 Release Notes.

cloud-init

Images that use cloud-init to provision the VM can use the `ntp` section to setup a time sync service. An example of cloud-init installing chrony and configuring it to use the PTP clock source for Ubuntu VMs:

YAML

```yaml
#cloud-config
ntp:
  enabled: true
  ntp_client: chrony
  config:
    confpath: /etc/chrony/chrony.conf
    packages:
     - chrony
    service_name: chrony
    template: |
       ## template:jinja
       driftfile /var/lib/chrony/chrony.drift
       logdir /var/log/chrony
       maxupdateskew 100.0
       refclock PHC /dev/ptp_hyperv poll 3 dpoll -2 offset 0 stratum 2
       makestep 1.0 -1
```

You can then base64 the above cloud-config for use in the `osProfile` section in an ARM template:

PowerShell

```powershell
[Convert]::ToBase64String((Get-Content -Path ./cloud-config.txt -Encoding
```

```
Byte))
```

JSON

```
"osProfile": {
  "customData":
"I2Nsb3VkLWNvbmZpZwpudHA6CiAgZW5hYmxlZDogdHJ1ZQogIG50cF9jbGllbnQ6IGNocm9ueQo
gIGNvbmZpZzoKICAgIGNvbmZwYXRoOiAvZXRjL2Nocm9ueS9jaHJvbnkuY29uZgogICAgcGFja2F
nZXM6CiAgICAgLSBjaHJvbnkKICAgIHNlcnZpY2VfbmFtZTogY2hyb255CiAgICB0ZW1wbGF0ZTo
gfAogICAgICAgIyMgdGVtcGxhdGU6amluamEKICAgICAgIGRyaWZ0ZmlsZSAvdmFyL2xpYi9jaHJ
vbnkvY2hyb255LmRyaWZ0CiAgICAgICBsb2dkaXIgL3Zhci9sb2cvY2hyb255CiAgICAgICBtYXh
1cGRhdGVza2V5IDEwMC4wCiAgICAgICByZWZjbG9jayBQSEMgL2Rldi9wdHBfaHlwZXJ2IHBvbGw
gMyBkcG9sbCAtMgogICAgICAgbWFrZXN0ZXAgMS4wIC0x"
}
```

For more information about cloud-init on Azure, see Overview of cloud-init support for Linux VMs in Azure.

Time sync for Windows VMs in Azure

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Time sync is important for security and event correlation. Sometimes it is used for distributed transactions implementation. Time accuracy between multiple computer systems is achieved through synchronization. Synchronization can be affected by multiple things, including reboots and network traffic between the time source and the computer fetching the time.

Azure is now backed by infrastructure running Windows Server 2016. Windows Server 2016 has improved algorithms used to correct time and condition the local clock to synchronize with UTC. Windows Server 2016 also improved the VMICTimeSync service that governs how VMs sync with the host for accurate time. Improvements include more accurate initial time on VM start or VM restore and interrupt latency correction for samples provided to Windows Time (W32time).

> ⓘ **Note**
>
> For a quick overview of Windows Time service, take a look at this high-level overview video.
>
> For more information, see Accurate time for Windows Server 2016.

Overview

Accuracy for a computer clock is gauged on how close the computer clock is to the Coordinated Universal Time (UTC) time standard. UTC is defined by a multinational sample of precise atomic clocks that can only be off by one second in 300 years. But, reading UTC directly requires specialized hardware. Instead, time servers are synced to UTC and are accessed from other computers to provide scalability and robustness. Every computer has time synchronization service running that knows what time servers to use and periodically checks if computer clock needs to be corrected and adjusts time if needed.

Azure hosts are synchronized to internal Microsoft time servers that take their time from Microsoft-owned Stratum 1 devices, with GPS antennas. Virtual machines in Azure can either depend on their host to pass the accurate time (*host time*) on to the VM or the VM can directly get time from a time server, or a combination of both.

Virtual machine interactions with the host can also affect the clock. During memory preserving maintenance, VMs are paused for up to 30 seconds. For example, before maintenance begins the VM clock shows 10:00:00 AM and lasts 28 seconds. After the VM resumes, the clock on the VM would still show 10:00:00 AM, which would be 28 seconds off. To correct for this, the VMICTimeSync service monitors what is happening on the host and prompts for changes to happen on the VMs to compensate.

The VMICTimeSync service operates in either sample or sync mode and will only influence the clock forward. In sample mode, which requires W32time to be running, the VMICTimeSync service polls the host every 5 seconds and provides time samples to W32time. Approximately every 30 seconds, the W32time service takes the latest time sample and uses it to influence the guest's clock. Sync mode activates if a guest has been resumed or if a guest's clock drifts more than 5 seconds behind the host's clock. In cases where the W32time service is properly running, the latter case should never happen.

Without time synchronization working, the clock on the VM would accumulate errors. When there is only one VM, the effect might not be significant unless the workload requires highly accurate timekeeping. But in most cases, we have multiple, interconnected VMs that use time to track transactions and the time needs to be consistent throughout the entire deployment. When time between VMs is different, you could see the following effects:

- Authentication will fail. Security protocols like Kerberos or certificate-dependent technology rely on time being consistent across the systems.
- It's very hard to figure out what have happened in a system if logs (or other data) don't agree on time. The same event would look like it occurred at different times, making correlation difficult.
- If clock is off, the billing could be calculated incorrectly.

The best results for Windows deployments are achieved by using Windows Server 2016 as the guest operating system, which ensures you can use the latest improvements in time synchronization.

Configuration options

There are three options for configuring time sync for your Windows VMs hosted in Azure:

- Host time and time.windows.com. This is the default configuration used in Azure Marketplace images.
- Host-only.

- Use another, external time server with or without using host time. For this option follow the Time mechanism for Active Directory Windows Virtual Machines in Azure guide.

Use the default

By default Windows OS VM images are configured for w32time to sync from two sources:

- The NtpClient provider, which gets information from time.windows.com.
- The VMICTimeSync service, used to communicate the host time to the VMs and make corrections after the VM is paused for maintenance. Azure hosts use Microsoft-owned Stratum 1 devices to keep accurate time.

w32time would prefer the time provider in the following order of priority: stratum level, root delay, root dispersion, time offset. In most cases, w32time on an Azure VM would prefer host time due to evaluation it would do to compare both time sources.

For domain joined machines the domain itself establishes time sync hierarchy, but the forest root still needs to take time from somewhere and the following considerations would still hold true.

Host-only

Because time.windows.com is a public NTP server, syncing time with it requires sending traffic over the internet, varying packet delays can negatively affect quality of the time sync. Removing time.windows.com by switching to host-only sync can sometimes improve your time sync results.

Switching to host-only time sync makes sense if you experience time sync issues using the default configuration. Try out the host-only sync to see if that would improve the time sync on VM.

External time server

If you have specific time sync requirements, there is also an option of using external time servers. External time servers can provide specific time, which can be useful for test scenarios, ensuring time uniformity with machines hosted in non-Microsoft datacenters, or handling leap seconds in a special way.

You can combine external servers with the VMICTimeSync service and VMICTimeProvider to provide results similar to the default configuration.

Check your configuration

Check if the NtpClient time provider is configured to use explicit NTP servers (NTP) or domain time sync (NT5DS).

```
w32tm /dumpreg /subkey:Parameters | findstr /i "type"
```

If the VM is using NTP, you will see the following output:

```
Value Name                Value Type          Value Data
Type                      REG_SZ              NTP
```

To see what time server the NtpClient time provider is using, at an elevated command prompt type:

```
w32tm /dumpreg /subkey:Parameters | findstr /i "ntpserver"
```

If the VM is using the default, the output will look like this:

```
NtpServer                 REG_SZ              time.windows.com,0x8
```

To see what time provider is being used currently.

```
w32tm /query /source
```

Here is the output you could see and what it would mean:

- **time.windows.com** - in the default configuration, w32time would get time from time.windows.com. The time sync quality depends on internet connectivity to it and is affected by packet delays. This is the usual output you would get on a physical machine.
- **VM IC Time Synchronization Provider** - the VM is syncing time from the host. This is the usual output you would get on a virtual machine running on Azure.

- *Your domain server* - the current machine is in a domain and the domain defines the time sync hierarchy.
- *Some other server* - w32time was explicitly configured to get the time from that another server. Time sync quality depends on this time server quality.
- **Local CMOS Clock** - clock is unsynchronized. You can get this output if w32time hasn't had enough time to start after a reboot or when all the configured time sources are not available.

Opt in for host-only time sync

Azure is constantly working on improving time sync on hosts and can guarantee that all the time sync infrastructure is collocated in Microsoft-owned datacenters. If you have time sync issues with the default setup that prefers to use time.windows.com as the primary time source, you can use the following commands to opt in to host-only time sync.

Mark the VMIC provider as enabled.

```
reg add
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\TimeProviders\V
MICTimeProvider /v Enabled /t REG_DWORD /d 1 /f
```

Mark the NTPClient provider as disabled.

```
reg add
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\TimeProviders\N
tpClient /v Enabled /t REG_DWORD /d 0 /f
```

Restart the w32time Service.

```
net stop w32time && net start w32time
```

Windows Server 2012 and R2 VMs

Windows Server 2012 and Windows Server 2012 R2 have different default settings for time sync. The w32time by default is configured in a way that prefers low overhead of

the service over precise time.

If you want to move your Windows Server 2012 and 2012 R2 deployments to use the newer defaults that prefer precise time, you can apply the following settings.

Update the w32time poll and update intervals to match Windows Server 2016 settings.

```
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\Config
/v MinPollInterval /t REG_DWORD /d 6 /f
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\Config
/v MaxPollInterval /t REG_DWORD /d 10 /f
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\Config
/v UpdateInterval /t REG_DWORD /d 100 /f
w32tm /config /update
```

For `w32time` to be able to use the new poll intervals the NtpServers need to be marked as using them. If servers are annotated with the `0x1` bitflag mask, that would override this mechanism and `w32time` would use `SpecialPollInterval` instead. Make sure that specified NTP servers are either using the `0x8` flag or no flag at all:

Check what flags are being used for the NTP servers.

```
w32tm /dumpreg /subkey:Parameters | findstr /i "ntpserver"
```

Configure the time mechanism for Active Directory Windows Virtual Machines in Azure

Article • 04/29/2025

Applies to: ✔ Windows Virtual Machines

Use this guide to learn how to set up time synchronization for your Azure Windows Virtual Machines that belong to an Active Directory Domain.

Time sync hierarchy in Active Directory Domain Services

Time synchronization in Active Directory should be managed by only allowing the **PDC** to access an external time source or NTP Server.

All other Domain Controllers would then sync time against the PDC, and all other members will get their time from the Domain Controller that satisfied that member's authentication request.

If you have an Active Directory domain running on virtual machines hosted in Azure, follow these steps to properly set up Time Sync.

> **Note**
>
> This guide focuses on using the **Group Policy Management** console to perform the configuration. You can achieve the same results by using the Command Prompt, PowerShell, or by manually modifying the Registry; however, those methods are not in scope in this article.

GPO to allow the PDC to synchronize with an External NTP Source

To check current time source in your **PDC**, from an elevated command prompt run *w32tm /query /source* and note the output for later comparison.

1. From *Start* run *gpmc.msc*.
2. Browse to the Forest and Domain where you want to create the GPO.
3. Create a new GPO, for example *PDC Time Sync*, in the container *Group Policy Objects*.

4. Right-click on the newly created GPO and Edit.
5. Navigate to the *Global Configuration Settings* policy under *Computer Configuration -> Administrative Templates -> System -> Windows Time Service*.
6. Set it to *Enabled* and configure the *AnnounceFlags* parameter to **5**.
7. Navigate to *Computer Configuration -> Administrative Templates -> System -> Windows Time Service -> Time Providers*.
8. Double click the *Configure Windows NTP Client* policy and set it to *Enabled*, configure the parameter *NTPServer* to point to an IP address or FQDN of a time server followed by `,0x9` for example: `131.107.13.100,0x9` and configure *Type* to **NTP**. For all the other parameters you can use the default values, or use custom ones according to your corporate needs.
9. Click the *Next Setting* button, set the *Enable Windows NTP Client* policy to *Enabled* and click *OK*
10. In the *Scope* tab of the newly created GPO navigate to **Security Filtering** and highlight the *Authenticated Users* group -> Click the *Remove* button -> *OK* -> *OK*
11. Create a WMI Filter to dynamically get the Domain Controller that holds the PDC role:

    - In the *Group Policy Management* console, navigate to *WMI Filters*, right-click on it and select *New*.
    - In the *New WMI Filter* window, give a name to the new filter, for example, *Get PDC Emulator* -> Fill out the *Description* field (optional) -> Click the *Add* button.
    - In the *WMI Query* window leave the *Namespace* as is, in the *Query* text box paste the following string `Select * from Win32_ComputerSystem where DomainRole = 5`, then click the *OK* button.
    - Back in the *New WMI Filter* window click the *Save* button.

12. In the *Scope* tab of the newly created GPO navigate to the **WMI Filtering** drop-down menu and select the previously created WMI filter then click *OK*.
13. In the *Scope* tab of the newly created GPO navigate to the **Security Filtering** click the *Add* button and browse for the *Domain Controllers* group, then click the *OK* button.
14. Link the GPO to the **Domain Controllers** Organizational Unit.

> ⓘ **Note**
>
> It can take up to 15 minutes for these changes to be reflected by the system.

From an elevated command prompt rerun *w32tm /query /source* and compare the output to the one you noted at the beginning of the configuration. Now it will be set to the NTP Server you chose.

> 💡 **Tip**

If you want to speed-up the process of changing the NTP source on your **PDC**, from an elevated command prompt run *gpupdate /force*, followed by *w32tm /resync /nowait*, then rerun *w32tm /query /source*; the output should be the NTP Server you used in the above GPO.

> ⓘ **Note**
>
> If after the changes are applied, you still don't get the output to the NTP Server you chose, you may need to set the value to **0** in the key **Enabled** under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\VMICTimeProvider** on your PDC and DCs too.

GPO for Members

Usually, NTP in Active Directory Domain Services will follow the AD DS Time Hierarchy mentioned at the beginning of this article and no further configuration is required.

Nevertheless, virtual machines hosted in Azure have specific security settings applied to them directly by the Cloud platform.

For all other domain members that are not Domain Controllers, you will need to modify the registry and set the value to **0** in the key **Enabled** under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\VMICTimeProvider**

> ⓘ **Important**
>
> Remember that serious problems might occur if you modify the registry incorrectly. Therefore, make sure that you follow these steps carefully and test them on a couple of test virtual machines to make sure you will get the expected outcome. For added protection, back up the registry before you modify it. Then, you can restore the registry if a problem occurs. For how to back up and restore the Windows Registry follow the steps below.

Back up the Registry

1. From *Start* type *regedit.exe*, and then press `Enter`. If you are prompted for an administrator password or for confirmation, type the password or provide confirmation.

2. In the *Registry Editor* window, locate and click the registry key or subkey that you want to back up.
3. From the *File* menu select *Export*.
4. In the *Export Registry File* dialog box, select the location to which you want to save the backup copy, type a name for the backup file in the *File name* field, and then click *Save*.

Restore a Registry backup

1. From *Start* type *regedit.exe*, and then press `Enter`. If you are prompted for an administrator password or for confirmation, type the password or provide confirmation.
2. In the *Registry Editor* window, from the *File* menu select *Import*.
3. In the *Import Registry File* dialog box, select the location to which you saved the backup copy, select the backup file, and then click *Open*.

GPO to disable the VMICTimeProvider

Configure the following Group Policy Object to enable domain members to synchronize time with Domain Controllers in their corresponding Active Directory Site:

To check current time source, login to any domain member and from an elevated command prompt run *w32tm /query /source* and note the output for later comparison.

1. From a Domain Controller go to *Start* run *gpmc.msc*.
2. Browse to the Forest and Domain where you want to create the GPO.
3. Create a new GPO, for example *Clients Time Sync*, in the container *Group Policy Objects*.
4. Right-click on the newly created GPO and Edit.
5. Navigate to *Computer Configuration* -> *Preferences* -> *Windows Settings* -> Right-click on *Registry* -> *New* -> *Registry Item*
6. In the *New Registry Properties* window set the following values:

    - On **Action:** *Update*
    - On **Hive:** *HKEY_LOCAL_MACHINE*
    - On **Key Path**: browse to *SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\VMICTimeProvider*
    - On **Value Name** type *Enabled*
    - On **Value Type**: *REG_DWORD*
    - On **Value Data**: type *0*

7. For all the other parameters use the default values and click *OK*
8. Link the GPO to the Organizational Unit where your members are located.
9. Wait or manually force a *Group Policy Update* on the domain member.

Go back to the domain member and from an elevated command prompt rerun *w32tm /query /source* and compare the output to the one you noted at the beginning of the configuration. Now it will be set to the Domain Controller that satisfied the member's authentication request.

Run scripts in your VM by using Run Command

Summarize this article for me

Run Command uses the virtual machine (VM) agent to run scripts within an Azure Windows or Linux VM. You can use these scripts for general machine or application management. They can help you to quickly diagnose and remediate VM access and network issues and get the VM back to a good state. Scripts can be embedded in the properties or referenced to a pre published gallery script.

The original set of commands are action orientated. The updated set of commands are management orientated and enable you to run multiple scripts and has less restrictions. This article will explain the difference between the two sets of run commands and help you decide which set is the right one to use in your scenario.

> ⓘ **Important**
>
> **Managed Run Command** is currently available in Azure CLI, PowerShell, and API at this time. Portal functionality isn't currently available.

When to use action or managed commands

The original set of commands are action orientated. You should consider using this set of commands for situations where you need to run:

- A small script to get a content from a VM
- A script to configure a VM (set registry keys, change configuration)
- A one time script for diagnostics

See Action Run Commands for Linux and Action Run Commands for Windows for available action commands and instructions on how to apply them.

The updated set of commands are management orientated. Consider using managed run commands if your needs align to the following examples:

- Script needs to run as part of VM deployment
- Recurrent script execution is needed
- Multiple scripts needs to execute sequentially
- Bootstrap a VM by running installation scripts
- Publish custom script to be shared and reused

See Managed Run Command for Linux and Managed Run Command for Windows to learn how to use them.

> **Note**
>
> The maximum number of allowed Managed Run Commands is currently limited to 25.

Compare feature support

Expand table

Feature support	Action RunCommand	Managed RunCommand
ARM template	No, it's a POST action	Yes, it's a resource type
Long running	90 min limit	Customer specified timeout
Execution account	System account / root	Customer specified user
Multiple run commands	Only one active	Multiple in parallel or sequenced
Large output	Limited to 4k (in status blob)	Uploaded to customer append blob
Progress tracking	Reports only final status	Reports progress and last 4k output during execution
Async execution	Goal state/provisioning waits for script to complete	Customer specified async flag if provisioning waits for the script
Virtual machine scale set support	Only on VM instance	Support virtual machine scale set model and scale out
SAS generation	No blob support	Automated, CRP generates SAS for customer blobs and manages them
Gallery (custom commands)	Only built-in commandIds	Customer can publish scripts and share them

Run scripts in your Linux VM by using action Run Commands

08/27/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The Run Command feature uses the virtual machine (VM) agent to run shell scripts within an Azure Linux VM. You can use these scripts for general machine or application management. They can help you to quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

Benefits

You can access your virtual machines in multiple ways. Run Command can run scripts on your virtual machines remotely by using the VM agent. You use Run Command through the Azure portal, REST API, or Azure CLI for Linux VMs.

This capability is useful in all scenarios where you want to run a script within a virtual machine. It's one of the only ways to troubleshoot and remediate a virtual machine that doesn't have the RDP or SSH port open because of network or administrative user configuration.

Prerequisites

Linux Distro's Supported

Expand table

Publisher	Distribution	x64	ARM64
Alma Linux Community	Alma Linux	8.x+, 9.x+	8.x+, 9.x+
Credativ	Debian	10+	11.x+
Kinvolk	Flatcar Linux	3374.2.x+	3374.2.x+
Microsoft	Azure Linux	2.x	2.x
openSUSE Project	openSUSE	12.3+	*Not supported*
Oracle	Oracle Linux	6.4+, 7.x+, 8.x+	*Not supported*

Publisher	Distribution	x64	ARM64
Red Hat	Red Hat Enterprise Linux	6.7+, 7.x+, 8.x+, 9.x+, 10.x+	8.6+, 9.0+, 10.x+
CIQ	Rocky Linux	9.x+	9.x+
SUSE	SLES	12.x+, 15.x+	15.x SP4+
Canonical	Ubuntu (LTS releases)	18.04+, 20.04+, 22.04+, 24.04+	20.04+, 22.04+, 24.04+

Restrictions

The following restrictions apply when you're using Run Command:

- Output is limited to the last 4,096 bytes.
- The minimum time to run a script is about 20 seconds.
- Scripts run by default as an elevated user on Linux.
- You can run one script at a time.
- Scripts that prompt for information (interactive mode) aren't supported.
- You can't cancel a running script.
- The maximum time a script can run is 90 minutes. After that, the script will time out.
- Outbound connectivity from the VM is required to return the results of the script.

> **Note**
>
> To function correctly, Run Command requires connectivity (port 443) to Azure public IP addresses. If the extension doesn't have access to these endpoints, the scripts might run successfully but not return the results. If you're blocking traffic on the virtual machine, you can use service tags to allow traffic to Azure public IP addresses by using the `AzureCloud` tag.

Available commands

This table shows the list of commands available for Linux VMs. You can use the **RunShellScript** command to run any custom script that you want. When you're using the Azure CLI or PowerShell to run a command, the value that you provide for the `--command-id` or `-CommandId` parameter must be one of the following listed values. When you specify a value that isn't an available command, you receive this error:

```
error
```

```
The entity was not found in this Azure location
```

Expand table

Name	Description	More Info
RunShellScript	Runs a Linux shell script.	
ifconfig	Gets the configuration of all network interfaces.	readme

Azure CLI

The following example uses the az vm run-command command to run a shell script on an Azure Linux VM.

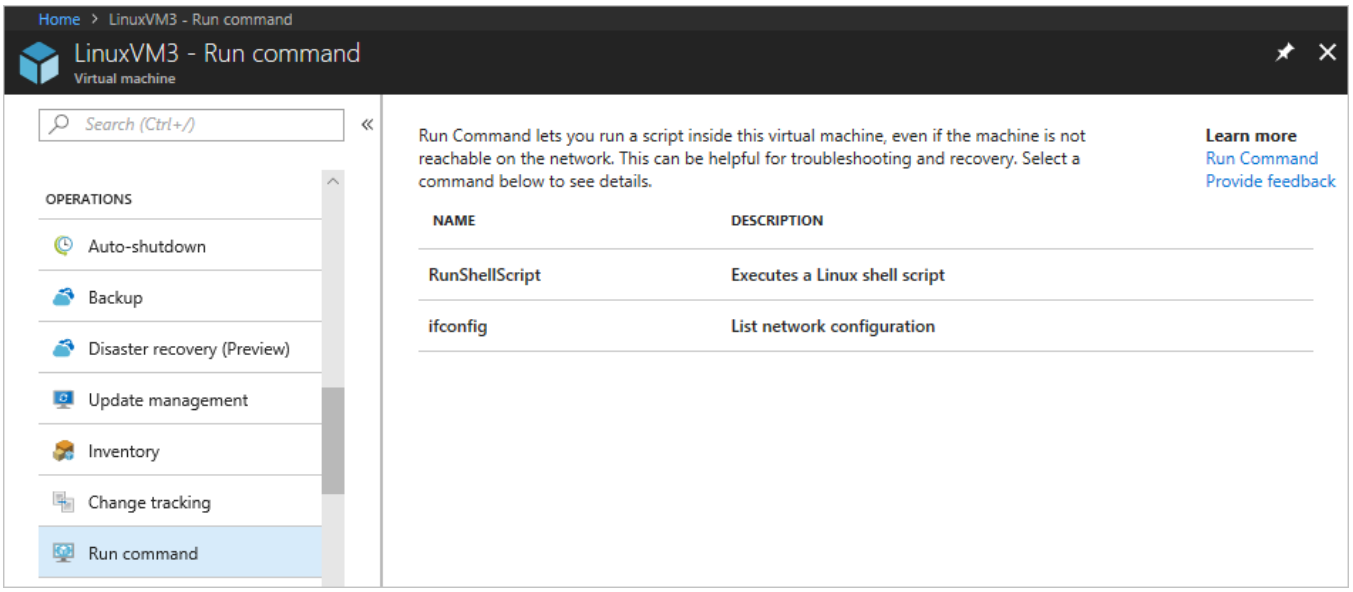
Azure CLI

```
az vm run-command invoke -g myResourceGroup -n myVm --command-id RunShellScript --scripts "apt-get update && apt-get install -y nginx"
```

> **Note**
>
> To run commands as a different user, enter `sudo -u` to specify a user account.

Azure portal

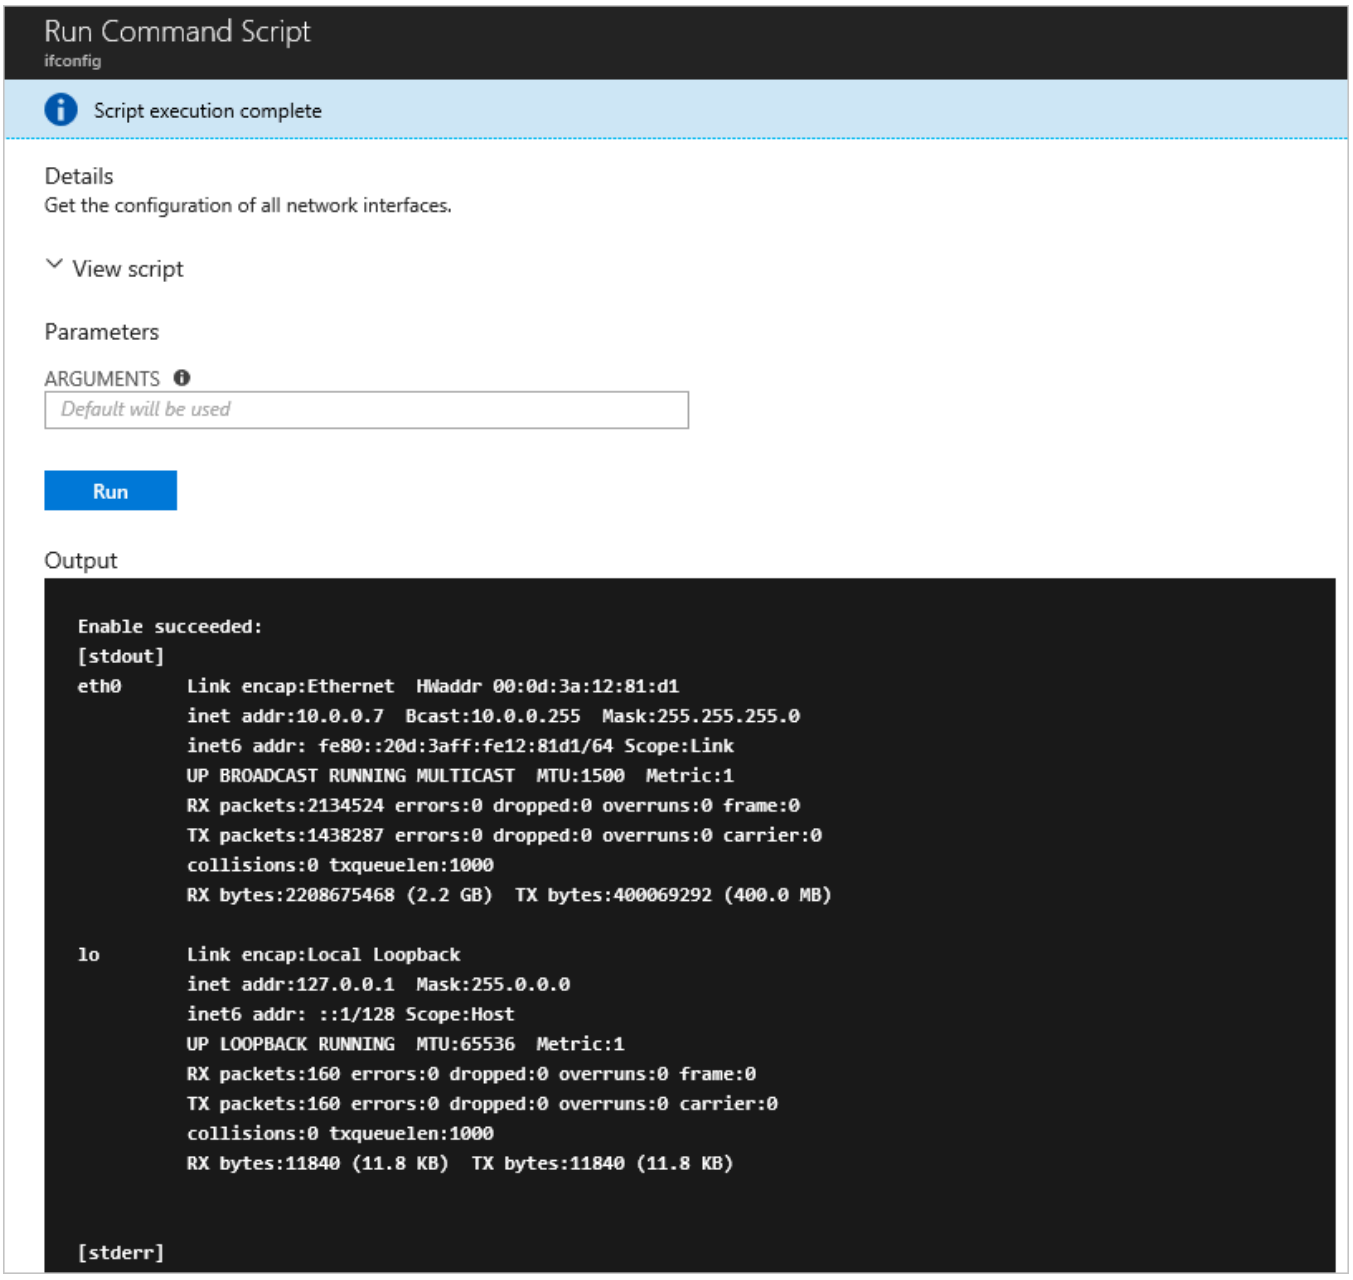
Go to a VM in the Azure portal and select **Run command** in the left menu, under **Operations**. You see a list of the available commands to run on the VM.



Choose a command to run. Some of the commands might have optional or required input parameters. For those commands, the parameters are presented as text fields for you to provide the input values. For each command, you can view the script that's being run by expanding **View script**. **RunShellScript** is different from the other commands, because it allows you to provide your own custom script.

> ⓘ **Note**
>
> The built-in commands are not editable.

After you choose the command, select **Run** to run the script. After the script finishes, it returns the output and any errors in the output window. The following screenshot shows an example output from running the **ifconfig** command.



PowerShell

The following example uses the Invoke-AzVMRunCommand cmdlet to run a PowerShell script on an Azure VM. The cmdlet expects the script referenced in the `-ScriptPath` parameter to be local to where the cmdlet is being run.

PowerShell

```
Invoke-AzVMRunCommand -ResourceGroupName '<myResourceGroup>' -Name '<myVMName>' -
CommandId 'RunShellScript' -ScriptPath '<pathToScript>' -Parameter @{"arg1" =
"var1";"arg2" = "var2"}
```

Limiting access to Run Command

Listing the run commands or showing the details of a command requires the `Microsoft.Compute/locations/runCommands/read` permission on Subscription level. The built-in Reader role and higher levels have this permission.

Running a command requires the `Microsoft.Compute/virtualMachines/runCommands/write` permission. The Virtual Machine Contributor role and higher levels have this permission.

You can use one of the built-in roles or create a custom role to use Run Command.

Action Run Command Linux troubleshooting

When troubleshooting action run command for Linux environments, refer to the *handler* log file typically located in the following directory: `/var/log/azure/run-command-handler/handler.log` for further details.

Known issues

The Linux action run command logs have a few notable differences compared to the action run command Windows logs:

- The sequence number is reported with each line of the log as 'seq=#'
- There won't be a line that contains `Awaiting completion...` as this will be in action run command Windows only.
- The line `Command existed with code: #` is also only present in action run command Windows logging.

Action Run Command Removal

If needing to remove your action run command Linux extension, refer to the below steps for Azure PowerShell and CLI:

Replace *rgname* and *vmname* with your relevant resource group name and virtual machine name in the following removal examples.

PowerShell

```
 Invoke-AzVMRunCommand -ResourceGroupName 'rgname' -VMName 'vmname' -CommandId
'RemoveRunCommandLinuxExtension'
```

Azure CLI

```
az vm run-command invoke  --command-id RemoveRunCommandLinuxExtension --name
vmname -g rgname
```

> **Note**
>
> When you apply a Run Command again, the extension will get installed automatically. You can use the extension removal command to troubleshoot any issues related to the extension.

Next steps

To learn about other ways to run scripts and commands remotely in your VM, see Run scripts in your Linux VM.

Run scripts in your Windows VM by using action Run Commands

The Run Command feature uses the virtual machine (VM) agent to run PowerShell scripts within an Azure Windows VM. You can use these scripts for general machine or application management. They can help you to quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

Benefits

You can access your virtual machines in multiple ways. Run Command can run scripts on your virtual machines remotely by using the VM agent. You use Run Command through the Azure portal, REST API, or PowerShell for Windows VMs.

This capability is useful in all scenarios where you want to run a script within a virtual machine. It's one of the only ways to troubleshoot and remediate a virtual machine that doesn't have the RDP or SSH port open because of improper network or administrative user configuration.

OS Version	x64	ARM64
Windows Server 2025	Supported	Supported
Windows Server 2025 Core	Supported	Supported
Windows Server 2025 Azure Edition	Supported	Supported

Restrictions

The following restrictions apply when you're using Run Command:

- Output is limited to the last 4,096 bytes.
- The minimum time to run a script is about 20 seconds.
- Scripts run as System on Windows.
- One script at a time can run.
- Scripts that prompt for information (interactive mode) aren't supported.
- You can't cancel a running script.
- The maximum time a script can run is 90 minutes. After that, it will time out.
- Outbound connectivity from the VM is required to return the results of the script.
- It isn't recommended to run a script that will cause a stop or update of the VM Agent. This can let the extension in a Transitioning state, leading to a time-out.

> **Note**
>
> To function correctly, Run Command requires connectivity (port 443) to Azure public IP addresses. If the extension doesn't have access to these endpoints, the scripts might run successfully but not return the results. If you're blocking traffic on the virtual machine, you can use service tags to allow traffic to Azure public IP addresses by using the `AzureCloud` tag.
>
> The Run Command feature doesn't work if the VM agent status is NOT READY. Check the agent status in the VM's properties in the Azure portal.

Available commands

This table shows the list of commands available for Windows VMs. You can use the **RunPowerShellScript** command to run any custom script that you want. When you're using the Azure CLI or PowerShell to run a command, the value that you provide for the `--command-id` or `-CommandId` parameter must be one of the following listed values. When you specify a value that isn't an available command, you receive this error:

RDPSettings	Checks registry settings and domain policy settings. Suggests policy actions if machine is part of a domain or modifies the settings to default values.	readme

CommandID	Description	More Info
ResetRDPCert	Removes the SSL certificate tied to the RDP listener and restores the RDP listener security to default. Use this script if you see any issues with the certificate.	readme
SetRDPPort	Sets the default or user specified port number for Remote Desktop connections. Enables firewall rule for inbound access to the port.	readme
WindowsActivationValidation	Checks the current Windows license status (activated or not) and alert is generated if the machine is not property activated.	readme
WindowsGhostedNicValidationScript	This script scans the Windows registry for network adapters on PCI and VMBUS buses, compares them with currently active network adapters, and identifies ghosted NICs. Useful for troubleshooting network issues or cleaning up old NICs.	readme
WindowsUpgradeAssessmentValidation	This script is designed to assess the readiness of a Windows machine (client or server) for an in-place OS upgrade, with special considerations for Azure Virtual Machines. It evaluates OS version, supported upgrade paths, system disk space, and Azure security features like Trusted Launch, Secure Boot, and vTPM.	readme

Limiting access to Run Command

Listing the run commands or showing the details of a command requires the `Microsoft.Compute/locations/runCommands/read` permission on Subscription Level. The built-in Reader role and higher levels have this permission.

Running a command requires the `Microsoft.Compute/virtualMachines/runCommand/action` permission. The Virtual Machine Contributor role and higher levels have this permission.

You can use one of the built-in roles or create a custom role to use Run Command.

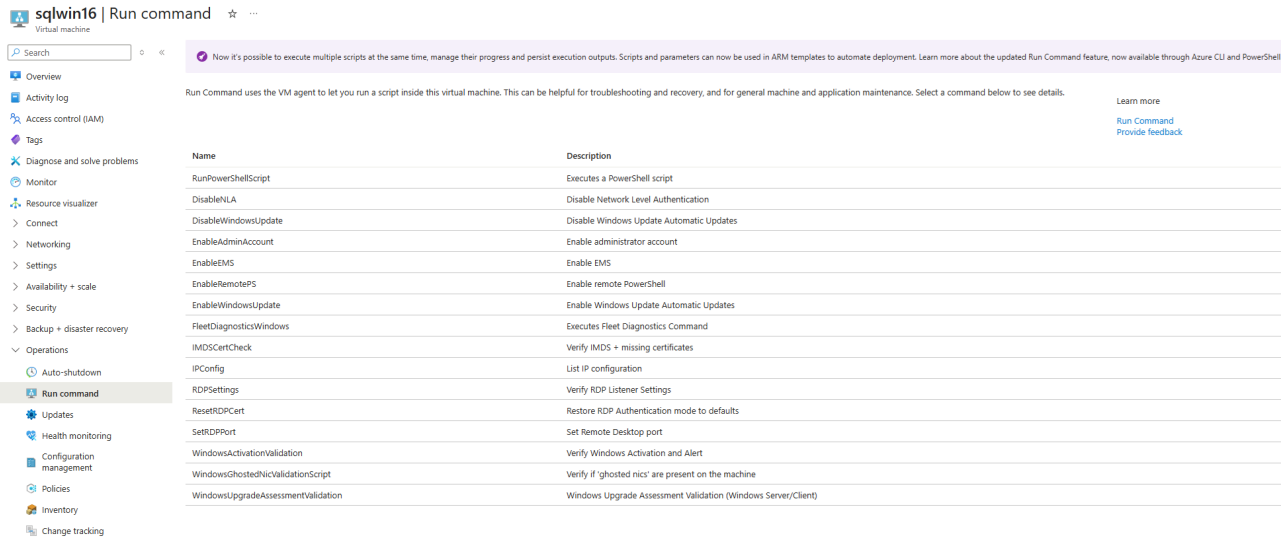
Using Run Commands

> ⓘ Note

- Parameter values can be string type only and the script is responsible for converting them to other types if needed.
- Depending on which modality is used to execute, some escaping may be needed. For example, if you're executing the command in a PowerShell session, the path to the script file will need to have quotes.
- The built-in commands are not editable.

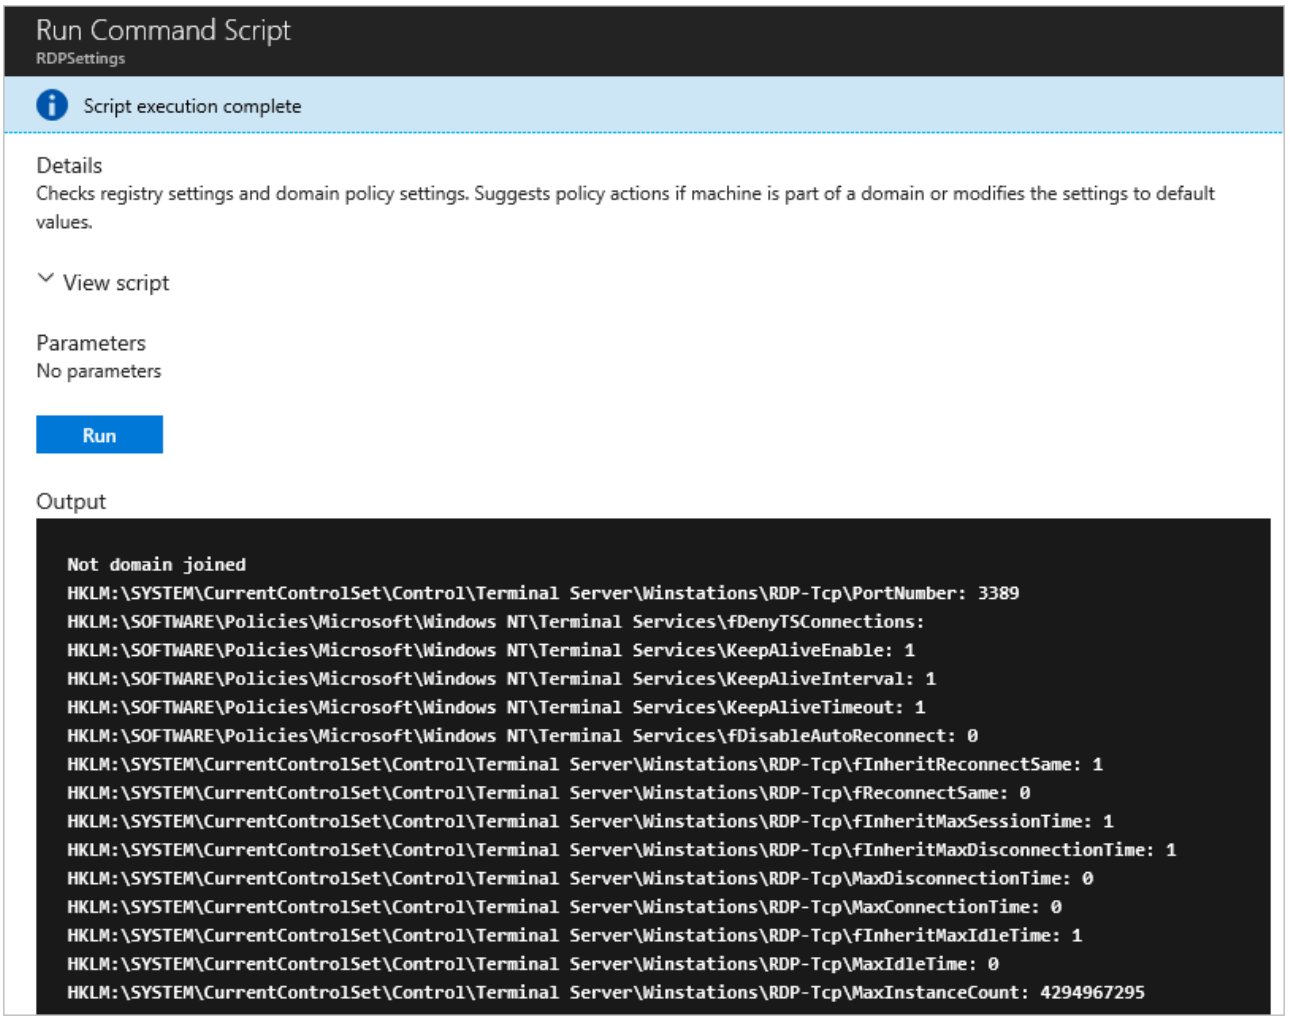
Portal

Go to a VM in the Azure portal and select **Run command** from the left menu, under **Operations**. You see a list of the available commands to run on the VM.



Choose a command to run. Some of the commands might have optional or required input parameters. For those commands, the parameters are presented as text fields for you to provide the input values. For each command, you can view the script that's being run by expanding **View script**. **RunPowerShellScript** is different from the other commands, because it allows you to provide your own custom script.

After you choose the command, select **Run** to run the script. After the script finishes, it returns the output and any errors in the output window. The following screenshot shows an example output from running the **RDPSettings** command.



Action Run Command Windows troubleshooting

When troubleshooting action run command for Windows environments, refer to the *RunCommandExtension* log file typically located in the following directory: `C:\WindowsAzure\Logs\Plugins\Microsoft.CPlat.Core.RunCommandWindows\<version>\RunCommandExtension.log` for further details.

Known issues

- Your Action Run Command Extension might fail to execute in your Windows environment if the command contains reserved characters. For example:

  If the `&` symbol is passed in the parameter of your command such as the below PowerShell script, it might fail.

  PowerShell

  ```
  $paramm='abc&jj'
  Invoke-AzVMRunCommand -ResourceGroupName AzureCloudService1 -Name test -
  ```

```
CommandId 'RunPowerShellScript' -ScriptPath
C:\data\228332902\PostAppConfig.ps1 -Parameter @{"Prefix" = $paramm}
```

Use the `^` character to escape the `&` in the argument, such as `$paramm='abc^&jj'`

- The Run Command extension might also fail to execute if command to be executed contains "\n" in the path, as it will be treated as a new line. For example, `C:\Windows\notepad.exe` contains the `\n` in the file path. Consider replacing `\n` with `\N` in your path.

- Ensure you don't have any custom setting in the registry key `HKLM\SOFTWARE\Microsoft\Command Processor\AutoRun` (detailed here). This could trigger during the RunCommand Extension install or enable phases and cause an error like *'XYZ is not recognized as an internal or external command, operable program or batch file*'.

Action Run Command Removal

If needing to remove your action run command Windows extension, refer to the below steps for Azure PowerShell and CLI:

Replace *rgname* and *vmname* with your relevant resource group name and virtual machine name in the following removal examples.

PowerShell

PowerShell

```
Invoke-AzVMRunCommand -ResourceGroupName 'rgname' -VMName 'vmname' -CommandId
'RemoveRunCommandWindowsExtension'
```

> **Note**
>
> When you apply a Run Command again, the extension will get installed automatically. You can use the extension removal command to troubleshoot any issues related to the extension.

Next steps

Last updated on 12/13/2025

Run scripts in your Linux VM by using managed Run Commands

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Flexible scale sets

> **Important**
>
> **Managed Run Command** is currently available in Azure CLI, PowerShell, and API at this time. Portal functionality is on the roadmap.

The Run Command feature uses the virtual machine (VM) agent to run scripts within an Azure Linux VM. You can use these scripts for general machine or application management. They can help you quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

The *updated* managed Run Command uses the same VM agent channel to execute scripts and provides the following enhancements over the original action oriented Run Command:

- Support for updated Run Command through ARM deployment template
- Parallel execution of multiple scripts
- Sequential execution of scripts
- User specified script timeout
- Support for long running (hours/days) scripts
- Passing secrets (parameters, passwords) in a secure manner

Prerequisites

> **Important**
>
> The minimum supported Linux Guest Agent is version 2.4.0.2 Older versions do not support managed Run Command. For more information, see Troubleshooting known issues.

Linux Distro's Supported

Expand table

Publisher	Distribution	x64	ARM64
Alma Linux Community	Alma Linux	8.x+, 9.x+	8.x+, 9.x+
Credativ	Debian	10+	11.x+
Kinvolk	Flatcar Linux	3374.2.x+	3374.2.x+
Microsoft	Azure Linux	2.x	2.x
openSUSE Project	openSUSE	12.3+	*Not supported*
Oracle	Oracle Linux	6.4+, 7.x+, 8.x+	*Not supported*
Red Hat	Red Hat Enterprise Linux	6.7+, 7.x+, 8.x+, 9.x+, 10.x+	8.6+, 9.0+, 10.x+
CIQ	Rocky Linux	9.x+	9.x+
SUSE	SLES	12.x+, 15.x+	15.x SP4+
Canonical	Ubuntu (LTS releases)	18.04+, 20.04+, 22.04+, 24.04+	20.04+, 22.04+, 24.04+

Available Commands

Expand table

CommandID	Description
RunShellScript	Runs a Linux shell script.
ifconfig	Gets the configuration of all network interfaces. For usage, refer to Run scripts

> **Note**
>
> The above command IDs are applicable to Managed Run Commands for Linux VMs. You can list all commandIds using command "`Get-AzVMRunCommandDocument -Location {RegionName}`".

Limiting access to Run Command

Listing the run commands or showing the details of a command requires the `Microsoft.Compute/locations/runCommands/read` permission on Subscription level. The built-in

Reader role and higher levels have this permission.

Running a command requires the `Microsoft.Compute/virtualMachines/runCommand/write` permission. The Virtual Machine Contributor role and higher levels have this permission.

You can use one of the built-in roles or create a custom role to use Run Command.

Azure CLI

The following examples use az vm run-command to run shell script on an Azure Linux VM.

Execute a script with the VM

This command delivers the script to the VM, execute it, and return the captured output.

Azure CLI

```
az vm run-command create --name "myRunCommand" --vm-name "myVM" --resource-group
"myRG" --script "echo Hello World!"
```

List all deployed RunCommand resources on a VM

This command returns a full list of previously deployed Run Commands along with their properties.

Azure CLI

```
az vm run-command list --vm-name "myVM" --resource-group "myRG"
```

Get execution status and results

This command retrieves current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

Azure CLI

```
az vm run-command show --name "myRunCommand" --vm-name "myVM" --resource-group
"myRG" --expand instanceView
```

> ⓘ Note

Output and error fields in `instanceView` is limited to last 4KB. If you'd like to access the full output and error, you have the option of forwarding the output and error data to storage append blobs using `-outputBlobUri` and `-errorBlobUri` parameters while executing Run Command using `Set-AzVMRunCommand` or `Set-AzVMssRunCommand`.

Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution will be terminated.

Azure CLI

```
az vm run-command delete --name "myRunCommand" --vm-name "myVM" --resource-group "myRG"
```

PowerShell

Execute a script with the VM

This command delivers the script to the VM, execute it, and return the captured output.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -Location "EastUS" -RunCommandName "RunCommandName" –SourceScript "echo Hello World!"
```

Execute a script on the VM using SourceScriptUri parameter

`OutputBlobUri` and `ErrorBlobUri` are optional parameters.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName -VMName -RunCommandName -SourceScriptUri “< SAS URI of a storage blob with read access or public URI>" -OutputBlobUri “< SAS URI of a storage append blob with read, add, create, write access>” -ErrorBlobUri “< SAS URI of a storage append blob with read, add, create, write access>”
```

Execute a long running Run Command on a VM

The execution time should run longer than default timeout of 90 minutes. It should run for 100 minutes (refer 6,000-seconds -TimeoutInSecond parameter) provided script is expected to run that long. After 100 minutes, the script execution should stop.

PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG -VMName MyVM -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceScriptUri <SourceScriptUri> -
AsyncExecution -TimeoutInSecond 6000
```

List all deployed RunCommand resources on a VM

This command returns a full list of previously deployed Run Commands along with their properties.

Azure PowerShell

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM"
```

Get execution status and results

This command retrieves current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

Azure PowerShell

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName
"RunCommandName" -Expand instanceView
```

Create or update Run Command on a VM using SourceScriptURI (storage blob SAS URL)

Create or update Run Command on a Windows VM using a SAS URL of a storage blob that contains a PowerShell script. `SourceScriptUri` can be a storage blob's full SAS URL or public URL.

> **Note**
>
> The SAS URL must provide read access to the blob. An expiration time of 24 hours is suggested for the SAS URL. SAS URLs can be generated on Azure portal using blob's options, or SAS token using `New-AzStorageBlobSASToken`. If generating SAS token using

`New-AzStorageBlobSASToken`, your SAS URL = "base blob URL" + "?" + "SAS token from New-AzStorageBlobSASToken"

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceScriptUri <SourceScriptURI>
```

Get a Run Command Instance View for a VM after Creating or Updating Run Command

Get a Run Command for VM with Instance View. Instance View contains the execution state of Run Command (Succeeded, Failed, etc.), exit code, standard output, and standard error generated by executing the script using Run Command. A nonzero ExitCode indicates an unsuccessful execution.

Azure PowerShell

```
$x = Get-AzVMRunCommand -ResourceGroupName MyRG -VMName MyVM -RunCommandName
MyRunCommand -Expand InstanceView
$x.InstanceView
```

Expected output:

Azure PowerShell

```
ExecutionState   : Succeeded
ExecutionMessage :
ExitCode         : 0
Output           :
output       : uid=0(root) gid=0(root) groups=0(root)
                 HelloWorld

Error            :
StartTime        : 10/27/2022 9:10:52 PM
EndTime          : 10/27/2022 9:10:55 PM
Statuses         :
```

`InstanceView.ExecutionState` -Status of user's Run Command script. Refer this state to know whether your script was successful or not.

`ProvisioningState` - Status of general extension provisioning end to end (whether extension platform was able to trigger Run Command script or not).

Create or update Run Command on a VM using SourceScript (script text)

Create or update Run Command on a VM passing the script content directly to -SourceScript parameter. Use `;` to separate multiple commands.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVML -RunCommandName
MyRunCommand2 -Location EastUS2EUAP -SourceScript "id; echo HelloWorld"
```

Create or update Run Command on a VM using SourceCommandId

Create or update Run Command on a VM using preexisting `commandId`. Available commandIds can be retrieved using Get-AzVMRunCommandDocument.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceCommandId ipconfig
```

Create, or update Run Command on a VM using OutputBlobUri, ErrorBlobUri to stream standard output and standard error messages to output, and error Append blobs

Create or update Run Command on a VM and stream standard output and standard error messages to output and error Append blobs.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVML -RunCommandName
MyRunCommand3 -Location EastUS2EUAP EastUS2EUAP -SourceScriptUri <SourceScriptUri>
-OutputBlobUri <OutputBlobUri> -ErrorBlobUri <errorbloburi>
```

> **Note**
>
> Output and error blobs must be of type `AppendBlob` and their SAS URLs must provide read, append, create, write access to the blob. An expiration time of 24 hours is suggested for the SAS URL. If output or error blob does not exist, a blob of type AppendBlob will be created. SAS URLs can be generated on Azure portal using blob's options, or SAS token

using New-AzStorageBlobSASToken. If generating SAS token using `New-AzStorageBlobSASToken`, SAS URL = base blob URL + "?" + SAS token from `New-AzStorageBlobSASToken`.

Create or update Run Command on a VM, run the Run Command as a different user using RunAsUser and RunAsPassword parameters

Create or update Run Command on a VM, run the Run Command as a different user using `RunAsUser` and `RunAsPassword` parameters. For RunAs to work properly, contact admin of VM, and make sure user is added on the VM, user has access to resources accessed by the Run Command (Directories, Files, Network etc.), and in case of Windows VM, 'Secondary Logon' service is running on the VM.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP EastUS2EUAP -SourceScriptUri <SourceScriptUri> -
RunAsUser myusername -RunAsPassword mypassword
```

Create or update Run Command on a Virtual Machine Scale Sets resource using SourceScriptUri (storage blob SAS URL).

Create or update Run Command on a Virtual Machine Scale Sets resource using a SAS URL of a storage blob that contains a bash script.

Azure PowerShell

```
Set-AzVmssVMRunCommand -ResourceGroupName MyRG0 -VMScaleSetName MyVMSS -InstanceId
0 -RunCommandName MyRunCommand -Location EastUS2EUAP -SourceScriptUri
<SourceScriptUri>
```

> **Note**
>
> Note SAS URL must provide read access to the blob. An expiration time of 24 hours is suggested for SAS URL. SAS URLs can be generated on Azure portal using blob's options, or SAS token using New-AzStorageBlobSASToken. If generating SAS token using New-AzStorageBlobSASToken, SAS URL = base blob URL + "?" + SAS token from `New-AzStorageBlobSASToken`.

Create or update Run Command on a VM instance using Parameter and ProtectedParameter parameters (Public and Protected Parameters to script)

Azure PowerShell

```
$PublicParametersArray =
@([Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInputPa
rameter]@{name='publicParam1';value='publicParam1value'},
>>
[Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInputPara
meter]@{name='publicParam2';value='publicParam2value'})

$ProtectedParametersArray =
@([Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInputPa
rameter]@{name='secret1';value='secret1value'},
>>
[Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInputPara
meter]@{name='secret2';value='secret2value'})

Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceScriptUri <SourceScriptUri> -Parameter
$PublicParametersArray -ProtectedParameter $ProtectedParametersArray
```

Use `ProtectedParameter` to pass any sensitive inputs to script such as passwords, keys etc.

- Windows: Parameters and ProtectedParameters are passed to script as arguments are passed to script and run like this `myscript.ps1 -publicParam1 publicParam1value -publicParam2 publicParam2value -secret1 secret1value -secret2 secret2value`
- Linux: Named Parameters and its values are set to environment config, which should be accessible within the `.sh` script. For Nameless arguments, pass an empty string to name input. Nameless arguments are passed to script and run like this - `myscript.sh publicParam1value publicParam2value secret1value secret2value`

Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution is terminated.

Azure PowerShell

```
Remove-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName
"RunCommandName"
```

REST API

To deploy a new Run Command, execute a PUT on the VM directly and specify a unique name for the Run Command instance.

rest

```
PUT
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Micros
oft.Compute/virtualMachines/<vmName>/runcommands?api-version=2019-12-01
```

JSON

```
{
"location": "<location>",
"properties": {
    "source": {
        "script": "Write-Host Hello World!",
        "scriptUri": "<SAS URI of a storage blob with read access or public URI>",
        "commandId": "<Id>"
        },
    "parameters": [
        {
            "name": "param1",
            "value": "value1"
            },
        {
            "name": "param2",
            "value": "value2"
            }
        ],
    "protectedParameters": [
        {
            "name": "secret1",
            "value": "value1"
            },
        {
            "name": "secret2",
            "value": "value2"
            }
        ],
    "runAsUser": "userName",
    "runAsPassword": "userPassword",
    "timeoutInSeconds": 3600,
    "outputBlobUri": "< SAS URI of a storage append blob with read, add, create,
write access>",
    "errorBlobUri": "< SAS URI of a storage append blob with read, add, create,
write access >"
    }
}
```

Notes

- You can provide an inline script, a script URI, or a built-in script command ID as the input source. Script URI is either storage blob SAS URI with read access or public URI.
- Only one type of source input is supported for one command execution.
- Run Command supports writing output and error to Storage blobs using outputBlobUri and errorBlobUri parameters, which can be used to store large script outputs. Use SAS URI of a storage append blob with read, add, create, write access. The blob should be of type AppendBlob. Writing the script output or error blob would fail otherwise. The blob will be overwritten if it already exists. It will be created if it does not exist.

List running instances of Run Command on a VM

rest

```
GET
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Micros
oft.Compute/virtualMachines/<vmName>/runcommands?api-version=2019-12-01
```

Get output details for a specific Run Command deployment

rest

```
GET
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Micros
oft.Compute/virtualMachines/<vmName>/runcommands/<runCommandName>?
$expand=instanceView&api-version=2019-12-01
```

Delete a specific Run Command deployment

Delete the instance of Run Command

rest

```
DELETE
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Micros
oft.Compute/virtualMachines/<vmName>/runcommands/<runCommandName>?api-version=2019-
12-01
```

Deploy scripts in an ordered sequence

To deploy scripts sequentially, use a deployment template, specifying a `dependsOn` relationship between sequential scripts.

JSON

```
{
    "type":"Microsoft.Compute/virtualMachines/runCommands",
    "name":"secondRunCommand",
    "apiVersion":"2019-12-01",
    "location":"[parameters('location')]",
    "dependsOn":<full resourceID of the previous other Run Command>,
    "properties":{
        "source":{
            "script":"echo Hello World!"
        },
        "timeoutInSeconds":60
    }
}
```

Execute multiple Run Commands sequentially

By default, if you deploy multiple RunCommand resources using deployment template, they will be executed simultaneously on the VM. If you have a dependency on the scripts and a preferred order of execution, you can use the `dependsOn` property to make them run sequentially.

In this example, **secondRunCommand** will execute after **firstRunCommand**.

JSON

```
{
   "$schema":"https://schema.management.azure.com/schemas/2015-01-
01/deploymentTemplate.json#",
   "contentVersion":"1.0.0.0",
   "resources":[
      {
         "type":"Microsoft.Compute/virtualMachines/runCommands",
         "name":"[concat(parameters('vmName'),'/firstRunCommand')]",
         "apiVersion":"2019-12-01",
         "location":"[parameters('location')]",
         "dependsOn":[
            "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
         ],
         "properties":{
            "source":{
               "script":"echo First: Hello World!"
            },
            "parameters":[
               {
```

```
                "name":"param1",
                "value":"value1"
             },
             {
                "name":"param2",
                "value":"value2"
             }
          ],
          "timeoutInSeconds":20
       }
    },
    {
       "type":"Microsoft.Compute/virtualMachines/runCommands",
       "name":"[concat(parameters('vmName'),'/secondRunCommand')]",
       "apiVersion":"2019-12-01",
       "location":"[parameters('location')]",
       "dependsOn":[
          "[concat('Microsoft.Compute/virtualMachines/',
parameters('vmName'),'runcommands/firstRunCommand')]"
       ],
       "properties":{
          "source":{
             "scriptUri":"http://github.com/myscript.ps1"
          },
          "timeoutInSeconds":60
       }
    }
 ]
}
```

Troubleshooting known issues

Unsupported Linux guest agent version

Issue: If you deploy a VM with managed Run Command when the Linux Guest Agent version is 2.4.0.1 or earlier, managed Run Command doesn't execute.

Cause: Managed Run Command requires Linux Guest Agent version 2.4.0.2 or later to install and execute.

Mitigation: Upgrade Linux Guest Agent to version 2.4.0.2 or later before you use managed Run Command. Alternatively, use an image that already has a baked-in Linux Guest Agent version 2.4.0.2 or later.

To check the Linux Guest Agent version, run:

Azure CLI

```
az vm get-instance-view --resource-group $RGName$ --name $VMName$ --subscription
$SUBSCRIPTION --query 'instanceView.vmAgent.vmAgentVersion'
```

Available Commands

Expand table

CommandID	Description	More Info
RunPowerShellScript	Runs a PowerShell script	
DisableNLA	Disables Network Level Authentication (NLA). You must restart the VM after the script completes for the change to take effect. The script itself does not restart the VM.	readme
DisableWindowsUpdate	Disable Automatic Updates through Windows Update.	readme
EnableAdminAccount	Checks if the local Administrator account is disabled, and if so enables it.	readme
EnableEMS	Enable Emergency Management Services (EMS) to allow for serial console connection in troubleshooting scenarios.	readme
EnableRemotePS	Enable remote PowerShell.	readme
EnableWindowsUpdate	Enable Automatic Updates through Windows Update.	readme
IMDSCertCheck	Checks IMDS Health and then analyzes currently installed certificates that IMDS depends upon. If missing, shows additional details and mitigation steps.	readme

CommandID	Description	More Info
IPConfig	Shows detailed information for the IP address, subnet mask and default gateway for each adapter bound to TCP/IP. For usage, refer to Run scripts	readme
RDPSettings	Checks registry settings and domain policy settings. Suggests policy actions if machine is part of a domain or modifies the settings to default values.	readme
ResetRDPCert	Removes the SSL certificate tied to the RDP listener and restores the RDP listener security to default. Use this script if you see any issues with the certificate.	readme
SetRDPPort	Sets the default or user specified port number for Remote Desktop connections. Enables firewall rule for inbound access to the port.	readme
WindowsActivationValidation	Checks the current Windows license status (activated or not) and alert is generated if the machine is not property activated.	readme
WindowsGhostedNicValidationScript	This script scans the Windows registry for network adapters on PCI and VMBUS buses, compares them with currently active network adapters, and identifies ghosted NICs. Useful for troubleshooting network issues or cleaning up old NICs.	readme
WindowsUpgradeAssessmentValidation	This script is designed to assess the readiness of a Windows machine (client or server) for an in-place OS upgrade, with special considerations for Azure Virtual Machines. It evaluates OS version, supported upgrade paths, system disk space, and Azure security features like Trusted Launch, Secure Boot, and vTPM.	readme

> **Note**
>
> The above command IDs are applicable to Managed Run Commands for Windows VMs. You can list all commandIds using command "`Get-AzVMRunCommandDocument -Location {RegionName}`".

Limiting access to Run Command

Listing the run commands or showing the details of a command requires the `Microsoft.Compute/locations/runCommands/read` permission on Subscription Level. The built-in Reader role and higher levels have this permission.

Running a command requires the `Microsoft.Compute/virtualMachines/runCommand/write` permission. The Virtual Machine Contributor role and higher levels have this permission.

You can use one of the built-in roles or create a custom role to use Run Command.

Using Run Commands

PowerShell

Execute a script with the VM

This command delivers the script to the VM, execute it, and return the captured output.

PowerShell

```
Set-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -Location "EastUS" -
RunCommandName "RunCommandName" –SourceScript "echo Hello World!"
```

Execute a script on the VM using SourceScriptUri parameter

`OutputBlobUri` and `ErrorBlobUri` are optional parameters.

PowerShell

```
Set-AzVMRunCommand -ResourceGroupName "myRg" `
-VMName "myVM" `
-RunCommandName "RunCommandName" `
-SourceScriptUri “<SAS_URI_of_a_storage_blob_with_read_access_or_public_URI>" `
-OutputBlobUri
“<SAS_URI_of_a_storage_append_blob_with_read_add_create_write_access>" `
-ErrorBlobUri
“<SAS_URI_of_a_storage_append_blob_with_read_add_create_write_access>”
```

Execute a long running Run Command on a VM

The execution time should run longer than default timeout of 90 minutes. It should run for 100 minutes (refer 6,0000-seconds -TimeoutInSecond parameter) provided script is expected to run that long. After 100 minutes, the script execution should stop.

PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG -VMName MyVM -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceScriptUri <SourceScriptUri> -
AsyncExecution -TimeoutInSecond 6000
```

List all deployed RunCommand resources on a VM

This command returns a full list of previously deployed Run Commands along with their properties.

PowerShell

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM"
```

Get execution status and results

This command retrieves current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

PowerShell

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName
"RunCommandName" -Expand InstanceView
```

Create or update Run Command on a VM using SourceScriptUri (storage blob SAS URL)

Create or update Run Command on a Windows VM using a SAS URL of a storage blob that contains a PowerShell script. `SourceScriptUri` can be a storage blob's full SAS URL or public URL.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceScriptUri <SourceScriptUri>
```

ⓘ Note

SAS URL must provide read access to the blob. An expiration time of 24 hours is suggested for SAS URL. SAS URLs can be generated on Azure portal using blob's options , or SAS token using `New-AzStorageBlobSASToken`. If generating SAS token using `New-AzStorageBlobSASToken`, your SAS URL = "base blob URL" + "?" + "SAS token from `New-AzStorageBlobSASToken`"

Get a Run Command Instance View for a VM after Creating or Updating Run Command

Get a Run Command for VM with Instance View. Instance View contains execution state of run command (Succeeded, Failed, etc.), exit code, standard output, and standard error generated by executing the script using Run Command. A nonzero ExitCode indicates an unsuccessful execution.

Azure PowerShell

```
$x = Get-AzVMRunCommand -ResourceGroupName MyRG -VMName MyVM -RunCommandName
MyRunCommand -Expand InstanceView
$x.InstanceView
```

Example output

Azure PowerShell

```
ExecutionState   : Succeeded
ExecutionMessage :
ExitCode         : 0
Output           :
output       : uid=0(root) gid=0(root) groups=0(root)
                 HelloWorld

Error            :
StartTime        : 10/27/2022 9:10:52 PM
EndTime          : 10/27/2022 9:10:55 PM
Statuses         :
```

`InstanceView.ExecutionState`: Status of user's Run Command script. Refer this state to know whether your script was successful or not. `ProvisioningState`: Status of general extension provisioning end to end (whether extension platform was able to trigger Run Command script or not).

Create or update Run Command on a VM using ScriptLocalPath (local script file)

Create or update Run Command on a VM using a local script file that is on the client machine where cmdlet is executed.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -ScriptLocalPath
"C:\MyScriptsDir\MyScript.ps1"
```

Create or update Run Command on a VM using SourceScript (script text)

Create or update Run Command on a VM passing the script content directly to -SourceScript parameter. Use `;` to separate multiple commands

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVML -RunCommandName
MyRunCommand2 -Location EastUS2EUAP -SourceScript "id; echo HelloWorld"
```

Create or update Run Command on a VM using SourceCommandId

Create or update Run Command on a VM using preexisting commandId. Available commandIds can be retrieved using Get-AzVMRunCommandDocument.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceCommandId DisableWindowsUpdate
```

Create, or update Run Command on a VM using OutputBlobUri, ErrorBlobUri to stream standard output and standard error messages to output, and error Append blobs

Create or update Run Command on a VM and stream standard output and standard error messages to output and error Append blobs.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVML -RunCommandName
MyRunCommand3 -Location EastUS2EUAP -ScriptLocalPath
"C:\MyScriptsDir\MyScript.ps1" -OutputBlobUri <OutPutBlobUrI> -ErrorBlobUri
"ErrorBlobUri
```

> ⓘ Note
>
> Output and error blobs must be the AppendBlob type and their SAS URLs must provide read, append, create, write access to the blob. An expiration time of 24 hours is suggested for SAS URL. If output or error blob does not exist, a blob of type AppendBlob is created. SAS URLs can be generated on Azure portal using blob's options , or SAS token from using `New-AzStorageBlobSASToken`.

Create or update Run Command on a VM as a different user using RunAsUser and RunAsPassword parameters

Create or update Run Command on a VM as a different user using `RunAsUser` and `RunAsPassword` parameters. For RunAs to work properly, contact admin of VM, and make sure user is added on the VM, user has access to resources accessed by the Run Command (Directories, Files, Network etc.), and in case of Windows VM, 'Secondary Logon' service is running on the VM.

Azure PowerShell

```
Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -ScriptLocalPath
"C:\MyScriptsDir\MyScript.ps1" -RunAsUser myusername -RunAsPassword mypassword
```

Create or update Run Command on a Virtual Machine Scale Sets resource using SourceScriptUri (storage blob SAS URL)

Create or update Run Command on a Windows Virtual Machine Scale Sets resource using a SAS URL of a storage blob that contains a PowerShell script.

Azure PowerShell

```
Set-AzVmssVMRunCommand -ResourceGroupName MyRG0 -VMScaleSetName MyVMSS -
InstanceId 0 -RunCommandName MyRunCommand -Location EastUS2EUAP -SourceScriptUri
<SourceScriptUri>
```

> ⓘ Note
>
> SAS URL must provide read access to the blob. An expiry time of 24 hours is suggested for SAS URL. SAS URLs can be generated on Azure portal using blob's options, or SAS token using `New-AzStorageBlobSASToken`. If generating SAS token

using `New-AzStorageBlobSASToken`, the SAS URL format is: base blob URL + "?" + the SAS token from `New-AzStorageBlobSASToken`.

Create or update Run Command on a VM instance using Parameter and ProtectedParameter parameters (Public and Protected Parameters to script)

Use ProtectedParameter to pass any sensitive inputs to script such as passwords, keys etc.

Azure PowerShell

```
$PublicParametersArray =
@([Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInpu
tParameter]@{name='publicParam1';value='publicParam1value'},
>>
[Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInputP
arameter]@{name='publicParam2';value='publicParam2value'})

$ProtectedParametersArray =
@([Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInpu
tParameter]@{name='secret1';value='secret1value'},
>>
[Microsoft.Azure.PowerShell.Cmdlets.Compute.Models.Api20210701.IRunCommandInputP
arameter]@{name='secret2';value='secret2value'})

Set-AzVMRunCommand -ResourceGroupName MyRG0 -VMName MyVMEE -RunCommandName
MyRunCommand -Location EastUS2EUAP -SourceScriptUri <SourceScriptUri> -Parameter
$PublicParametersArray -ProtectedParameter $ProtectedParametersArray
```

- Windows: Parameters and ProtectedParameters are passed to script as arguments are passed to script and run like this - `myscript.ps1 -publicParam1 publicParam1value -publicParam2 publicParam2value -secret1 secret1value -secret2 secret2value`
- Linux: Named Parameters and its values are set to environment config, which should be accessible within the .sh script. For Nameless arguments, pass an empty string to name input. Nameless arguments are passed to script and run like this - `myscript.sh publicParam1value publicParam2value secret1value secret2value`

Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution is terminated.

PowerShell

```
Remove-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName
"RunCommandName"
```

Execute multiple Run Commands sequentially

By default, if you deploy multiple RunCommand resources using deployment template, they will be executed simultaneously on the VM. If you have a dependency on the scripts and a preferred order of execution, you can use the `dependsOn` property to make them run sequentially.

In this example, **secondRunCommand** will execute after **firstRunCommand**.

JSON

```
{
   "$schema":"https://schema.management.azure.com/schemas/2015-01-
01/deploymentTemplate.json#",
   "contentVersion":"1.0.0.0",
   "resources":[
      {
         "type":"Microsoft.Compute/virtualMachines/runCommands",
         "name":"[concat(parameters('vmName'),'/firstRunCommand')]",
         "apiVersion":"2023-03-01",
         "location":"[parameters('location')]",
         "dependsOn":[
            "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
         ],
         "properties":{
            "source":{
               "script":"Write-Host First: Hello World!"
            },
            "parameters":[
               {
                  "name":"param1",
                  "value":"value1"
               },
               {
                  "name":"param2",
                  "value":"value2"
               }
            ],
            "timeoutInSeconds":20
         }
      },
      {
         "type":"Microsoft.Compute/virtualMachines/runCommands",
         "name":"[concat(parameters('vmName'),'/secondRunCommand')]",
         "apiVersion":"2019-12-01",
         "location":"[parameters('location')]",
         "dependsOn":[
```

```
            "[concat('Microsoft.Compute/virtualMachines/',
parameters('vmName'),'runcommands/firstRunCommand')]"
         ],
         "properties":{
            "source":{
               "scriptUri":"http://github.com/myscript.ps1"
            },
            "timeoutInSeconds":60
         }
      }
   ]
}
```

Next steps

To learn about other ways to run scripts and commands remotely in your VM, see Run scripts in your Windows VM.

Azure virtual machine extensions and features

Extensions are small applications that provide post-deployment configuration and automation on Azure virtual machines (VMs). The Azure platform hosts many extensions covering VM configuration, monitoring, security, and utility applications. Publishers take an application, wrap it into an extension, and simplify the installation. All you need to do is provide mandatory parameters.

> **Note**
>
> Extensions are only supported on Endorsed Linux distributions on Azure.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

View available extensions

You can view available extensions for a VM in the Azure portal.

1. In the portal, go to the **Overview** page for a VM.
2. Under **Settings**, select **Extensions + Applications**.

The list of available extensions are displayed. To see the complete list of extensions, see Discovering VM Extensions for Linux and Discovering VM Extensions for Windows.

Install and use extensions

Azure VM extensions can be managed by using the Azure CLI, PowerShell, Azure Resource Manager (ARM) templates, and the Azure portal.

1. From the **Extensions + Applications** for the VM, on the **Extensions** tab, select **+ Add**.
2. Locate the **Custom Script Extension** option. Select the extension option, then select **Next**.

You can then pass in a command or script to run the extension.

For more information, see Linux Custom Script Extension and Windows Custom Script Extension.

Check for prerequisites

Some individual VM extension applications might have their own environmental prerequisites, such as access to an endpoint. Each extension has an article that explains any prerequisites, including which operating systems are supported.

Manage extension application lifecycle

You don't need to connect to a VM directly to install or delete an extension. The Azure extension lifecycle is managed outside of the VM and integrated into the Azure platform.

Automatic extension upgrade can be used to monitor for new minor versions and automatically upgrade extensions in a safe rolling manner.

Troubleshoot extensions

If you're looking for general troubleshooting steps for Windows VM extensions, refer to Troubleshooting Azure Windows VM extension failures .

Otherwise, specific troubleshooting information for each extension can be found in the **Troubleshoot and support** section in the overview for the extension. Here's a list of the troubleshooting information available:

Expand table

Virtual machine extensions and features for Linux

Azure virtual machine (VM) extensions are small applications that provide post-deployment configuration and automation tasks on Azure VMs. For example, if a VM requires software installation, antivirus protection, or the ability to run a script inside it, you can use a VM extension.

You can run Azure VM extensions by using the Azure CLI, Azure PowerShell, Azure Resource Manager templates (ARM templates), and the Azure portal. You can bundle extensions with a new VM deployment or run them against any existing system.

This article provides an overview of Azure VM extensions, prerequisites for using them, and guidance on how to detect, manage, and remove them. This article provides general information because many VM extensions are available. Each one has a potentially unique configuration and its own documentation.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Use cases and samples

Each Azure VM extension has a specific use case. Examples include:

- Configure monitoring of a VM by using the Microsoft Monitoring Agent VM extension.
- Configure monitoring of your Azure infrastructure by using the Chef or Datadog extension.

In addition to process-specific extensions, a Custom Script extension is available for both Windows and Linux VMs. The Custom Script extension for Linux allows any Bash script to be run on a VM. Custom scripts are useful for designing Azure deployments that require configuration beyond what native Azure tooling can provide.

Prerequisites

> **Note**

Extensions are supported only on Endorsed Linux distributions on Azure.

Azure Linux Agent

To handle the extension on the VM, you must have the Azure Linux Agent installed. Some individual extensions have prerequisites, such as access to resources or dependencies.

The Azure Linux Agent manages interactions between an Azure VM and the Azure fabric controller. The agent is responsible for many functional aspects of deploying and managing Azure VMs, including running VM extensions.

The Azure Linux Agent is preinstalled on Azure Marketplace images. You can also install it manually on supported operating systems.

The agent runs on multiple operating systems. However, the extensions framework has a limit for the operating systems that extensions use. Some extensions aren't supported across all operating systems and might emit error code 51 ("Unsupported OS"). Check the individual extension documentation for supportability.

Network access

Extension packages are downloaded from the Azure Storage extension repository. Extension status uploads are posted to Azure Storage.

If you use a supported version of the Azure Linux Agent, you don't need to allow access to Azure Storage in the VM region. You can use the agent to redirect the communication to the Azure fabric controller for agent communications. If you're on an unsupported version of the agent, you need to allow outbound access to Azure Storage in that region from the VM.

> **Important**
>
> If you block access to the private IP address 168.63.129.16 by using the guest firewall, extensions fail even if you use a supported version of the agent or you configure outbound access. Also, if the VM has no outbound access to `*.blob.windows.net` and `*.blob.storage.azure.net`, initialization of the Azure Linux Agent and installation of extensions incurs more delays. To avoid those delays, ensure that access to these endpoints is allowed.

You can use agents only to download extension packages and reporting status. For example, if an extension installation needs to download a script from GitHub (Custom Script extension) or needs access to Azure Storage (Azure Backup), you need to open more firewall or network

security group (NSG) ports. Different extensions have different requirements because they're applications. For extensions that require access to Azure Storage, you can allow access by using Azure NSG service tags.

To redirect agent traffic requests, the Azure Linux Agent has proxy server support. This proxy server support doesn't apply extensions. You must configure each individual extension to work with a proxy.

Discover VM extensions

Azure CLI

Many VM extensions are available for use with Azure VMs. To see a complete list, use az vm extension image list. The following example lists all available extensions in the *westus* location:

Azure CLI

```
az vm extension image list --location westus --output table
```

Run VM extensions

Azure VM extensions run on existing VMs. That capability is useful when you need to make configuration changes or recover connectivity on an already deployed VM. VM extensions can also be bundled with ARM template deployments. By using extensions with ARM templates, you can deploy and configure Azure VMs without post-deployment intervention.

You can use the following methods to run an extension against an existing VM.

Azure CLI

You can run Azure VM extensions against an existing VM by using the az vm extension set command. The following example runs the Custom Script extension against a VM named *myVM* in a resource group named *myResourceGroup*. Replace the example resource group name, VM name, and script to run `https:\//raw.githubusercontent.com/me/project/hello.sh` with your own information.

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
```

```
  --vm-name myVM \
  --name customScript \
  --publisher Microsoft.Azure.Extensions \
  --settings '{"fileUris":
["https://raw.githubusercontent.com/me/project/hello.sh"],"commandToExecute":
"./hello.sh"}'
```

When the extension runs correctly, the output is similar to the following example:

Output

```
info:    Executing command vm extension set
+ Looking up the VM "myVM"
+ Installing extension "CustomScript", VM: "mvVM"
info:    vm extension set command OK
```

Azure PowerShell

You can run Azure VM extensions against an existing VM by using the Set-AzVMExtension command. The following example runs the Custom Script extension against a VM named *myVM* in a resource group named *myResourceGroup*. Replace the example resource group name, VM name, and script to run `https:\//raw.githubusercontent.com/me/project/hello.sh` with your own information.

Azure PowerShell

```
$Params = @{
    ResourceGroupName  = 'myResourceGroup'
    VMName             = 'myVM'
    Name               = 'CustomScript'
    Publisher          = 'Microsoft.Azure.Extensions'
    ExtensionType      = 'CustomScript'
    TypeHandlerVersion = '2.1'
    Settings          = @{fileUris =
@('https://raw.githubusercontent.com/me/project/hello.sh'); commandToExecute =
'./hello.sh'}
}
Set-AzVMExtension @Params
```

When the extension runs correctly, the output is similar to the following example:

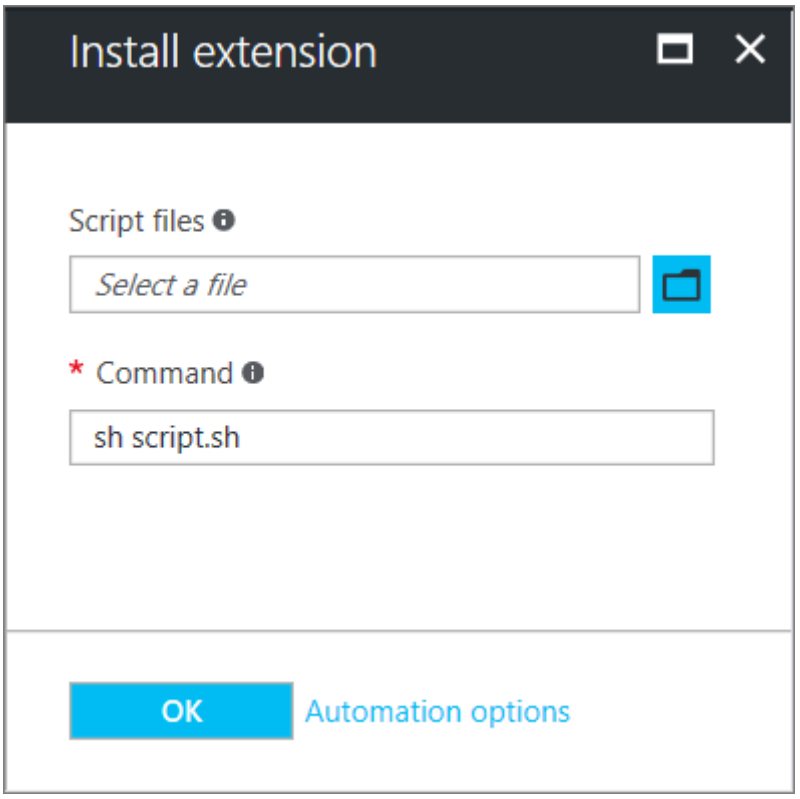
Output

```
RequestId IsSuccessStatusCode StatusCode ReasonPhrase
--------- ------------------- ---------- ------------
                         True         OK OK
```

Azure portal

You can apply VM extensions to an existing VM through the Azure portal. Select the VM in the portal, select **Extensions**, and then select **Add**. Choose the extension that you want from the list of available extensions, and follow the instructions in the wizard.

The following image shows the installation of the Custom Script extension for Linux from the Azure portal.



Azure Resource Manager templates

You can add VM extensions to an ARM template and run them with the deployment of the template. When you deploy an extension with a template, you can create fully configured Azure deployments.

For example, the following JSON is taken from a full ARM template that deploys a set of load-balanced VMs and an Azure SQL database. Then it installs a .NET Core application on each VM. The VM extension takes care of the software installation.

JSON

```
{
    "apiVersion": "2015-06-15",
    "type": "extensions",
    "name": "config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
```

```
    "[concat('Microsoft.Compute/virtualMachines/',
concat(variables('vmName'),copyindex()))]"
    ],
    "tags": {
    "displayName": "config-app"
    },
    "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-linux/scripts/config-music.sh"
        ]
    },
    "protectedSettings": {
        "commandToExecute": "[concat('sudo sh config-music.sh
',variables('musicStoreSqlName'), ' ', parameters('adminUsername'), ' ',
parameters('sqlAdminPassword'))]"
    }
    }
}
```

For more information on how to create ARM templates, see Virtual machines in an Azure Resource Manager template.

Help secure VM extension data

When you run a VM extension, it might be necessary to include sensitive information such as credentials, storage account names, and access keys. Many VM extensions include a protected configuration that encrypts data and only decrypts it inside the target VM. Each extension has a specific protected configuration schema. Each extension is detailed in extension-specific documentation.

The following example shows an instance of the Custom Script extension for Linux. The command to run includes a set of credentials. In this example, the command to run isn't encrypted.

JSON

```
{
  "apiVersion": "2015-06-15",
  "type": "extensions",
  "name": "config-app",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/',
```

```
concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-linux/scripts/config-music.sh"
      ],
      "commandToExecute": "[concat('sudo sh config-music.sh
',variables('musicStoreSqlName'), ' ', parameters('adminUsername'), ' ',
parameters('sqlAdminPassword'))]"
    }
  }
}
```

Moving the `commandToExecute` property to the `protected` configuration helps secure the execution string, as shown in the following example:

JSON

```
{
  "apiVersion": "2015-06-15",
  "type": "extensions",
  "name": "config-app",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/',
concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-linux/scripts/config-music.sh"
      ]
    },
    "protectedSettings": {
      "commandToExecute": "[concat('sudo sh config-music.sh
',variables('musicStoreSqlName'), ' ', parameters('adminUsername'), ' ',
```

```
parameters('sqlAdminPassword'))]"
    }
  }
}
```

How agents and extensions are updated

Agents and extensions share the same automatic update mechanism.

When an update is available and automatic updates are enabled, the update is installed on the VM only after there's a change to an extension or after other VM model changes, such as:

- Data disks
- Extensions
- Extension tags
- Boot diagnostics container
- Guest operating system secrets
- VM size
- Network profile

Publishers make updates available to regions at various times, so you could have VMs in different regions on different versions.

> **Note**
>
> Some updates might require extra firewall rules. For more information, see **Network access**.

Agent updates

The Linux VM Agent contains *Provisioning Agent code* and *extension-handling code* in one package. They can't be separated.

You can disable the Provisioning Agent when you want to provision on Azure by using cloud-init.

Supported versions of the agents can use automatic updates. The only code that can be updated is the extension-handling code, not the Provisioning Agent code. The Provisioning Agent code is run-once code.

The extension-handling code is responsible for:

- Communicating with the Azure fabric.

- Handling the VM extension operations, such as installations, reporting status, updating the individual extensions, and removing extensions. Updates contain security fixes, bug fixes, and enhancements to the extension-handling code.

When the agent is installed, a parent daemon is created. This parent then spawns a child process that handles extensions. If an update is available for the agent, it's downloaded. The parent stops the child process, upgrades it, and then restarts it. If a problem occurs with the update, the parent process rolls back to the previous child version.

The parent process can't be automatically updated. Only a distribution package can update the parent.

To check what version you're running, check `waagent`:

Bash

```
waagent --version
```

The output is similar to the following example:

Output

```
WALinuxAgent-2.2.45 running on <Linux Distro>
Python: 3.6.9
Goal state agent: 2.7.1.0
```

In the preceding example output, the parent (or package deployed version) is `WALinuxAgent-2.2.45`. The `Goal state agent` value is the auto-update version.

We highly recommend that you always enable automatic update for the agent: AutoUpdate.Enabled=y. If you don't enable automatic update, you need to keep manually updating the agent. You also don't get bug and security fixes.

Extension updates

When an extension update is available and automatic updates are enabled, after a change to the VM model occurs, the Azure Linux Agent downloads and upgrades the extension.

Automatic extension updates are either *minor* or *hotfix*. You can opt in or opt out of minor updates when you provision the extension. The following example shows how to automatically upgrade minor versions in an ARM template by using `"autoUpgradeMinorVersion": true,`:

JSON

```
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-linux/scripts/config-music.sh"
        ]
    },
```

To get the latest minor-release bug fixes, we highly recommend that you always select automatic update in your extension deployments. You can't opt out of hotfix updates that carry security or key bug fixes.

If you disable automatic updates or you need to upgrade a major version, use az vm extension set or Set-AzVMExtension and specify the target version.

How to identify extension updates

Identify if the extension is set with autoUpgradeMinorVersion on a VM

Azure CLI

You can see from the VM model if the extension was provisioned with `autoUpgradeMinorVersion`. To check, use az vm show and provide the resource group and VM name:

Azure CLI

```
az vm show --resource-group myResourceGroup --name myVM
```

The following example output shows that `autoUpgradeMinorVersion` is set to `true`:

JSON

```
  "resources": [
    {
      "autoUpgradeMinorVersion": true,
      "forceUpdateTag": null,
      "id":
"/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Compute/
virtualMachines/myVM/extensions/customScript",
```

Identify when an autoUpgradeMinorVersion event occurred

To see when an update to the extension occurred, review the agent logs on the VM at */var/log/waagent.log*.

In the following example, the VM had `Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9025` installed. A hotfix was available to `Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027`.

Bash

```
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Expected handler state:
enabled
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Decide which version to use
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Use version: 2.3.9027
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Current handler state is:
NotInstalled
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Download extension package
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Unpack extension package
INFO Event: name=Microsoft.OSTCExtensions.LinuxDiagnostic, op=Download,
message=Download succeeded
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Initialize extension
directory
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Update settings file:
0.settings
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9025] Disable extension.
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9025] Launch
command:diagnostic.py -disable
...
INFO Event: name=Microsoft.OSTCExtensions.LinuxDiagnostic, op=Disable,
message=Launch command succeeded: diagnostic.py -disable
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Update extension.
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Launch
command:diagnostic.py -update
2017/08/14 20:21:57 LinuxAzureDiagnostic started to handle.
```

Agent permissions

To perform its tasks, the agent needs to run as *root*.

Troubleshoot VM extensions

Each VM extension might have specific troubleshooting steps. For example, when you use the Custom Script extension, you can find script execution details locally on the VM where the extension was run.

The following troubleshooting actions apply to all VM extensions:

- Check the Azure Linux Agent log. Look at the activity when your extension was being provisioned in */var/log/waagent.log*.
- Check the extension logs for more details in */var/log/azure/<extensionName>*.
- Check troubleshooting sections in extension-specific documentation for error codes, known issues, and other extension-specific information.
- Look at the system logs. Check to see if other operations interfered with the extension, such as a long-running installation of another application that required exclusive access to the package manager.

Common reasons for extension failures

- Extensions have 20 minutes to run. (Exceptions are Custom Script and Chef, which have 90 minutes.) If your deployment exceeds this time, it's marked as a timeout. The cause of a timeout can be:
  - Low-resource VMs.
  - Other VM configurations or startup tasks that consume large amounts of resources while the extension is trying to provision.

- Minimum prerequisites aren't met. Some extensions have dependencies on VM versions, such as high-performance computing images. Extensions might have certain networking access requirements, such as communicating with Azure Storage or public services. Other examples might be access to package repositories, running out of disk space, or security restrictions.

- Package manager access is exclusive. In some cases, a long-running VM configuration and extension installation might conflict because they both need exclusive access to the package manager.

View extension status

Azure CLI

After a VM extension runs against a VM, use az vm get-instance-view to return extension status:

Azure CLI

```
az vm get-instance-view \
    --resource-group myResourceGroup \
    --name myVM \
    --query "instanceView.extensions"
```

The output is similar to the following example:

Bash

```
  {
    "name": "customScript",
    "statuses": [
      {
        "code": "ProvisioningState/failed/0",
        "displayStatus": "Provisioning failed",
        "level": "Error",
        "message": "Enable failed: failed to execute command: command terminated
with exit status=127\n[stdout]\n\n[stderr]\n/bin/sh: 1: ech: not found\n",
        "time": null
      }
    ],
    "substatuses": null,
    "type": "Microsoft.Azure.Extensions.CustomScript",
    "typeHandlerVersion": "2.1.6"
  }
```

You can also find extension execution status in the Azure portal. Select the VM, select **Extensions**, and then select the extension that you want.

Rerun a VM extension

There might be cases in which a VM extension must be rerun. To rerun an extension, remove it, and then rerun the extension with an execution method of your choice.

Azure CLI

To remove an extension, use az vm extension delete:

Azure CLI

```
az vm extension delete \
    --resource-group myResourceGroup \
    --vm-name myVM \
    --name customScript
```

You can also remove an extension in the Azure portal:

1. Select a VM.
2. Select **Extensions**.
3. Select the extension.
4. Select **Uninstall**.

Common VM extension reference

Expand table

Extension name	Description
Custom Script extension for Linux	Run scripts against an Azure VM.
VMAccess extension	Regain access to an Azure VM. You can also use it to manage users and credentials.

Azure Linux VM Agent overview

The Azure Linux VM Agent (waagent) manages Linux and FreeBSD provisioning, along with virtual machine (VM) interaction with the Azure fabric controller. In addition to the Linux agent providing provisioning functionality, Azure provides the option of using cloud-init for some Linux operating systems.

> **Important**
>
> FIPS 140-3 Enforced isn't supported on RHEL/Ubuntu with extensions by using `protectedSettings`.
>
> Support for FIPS 140-3 will be added September 2025.

The Linux agent provides the following functionality for Linux and FreeBSD Azure Virtual Machines deployments. For more information, see the Azure Linux VM Agent readme on GitHub.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Image provisioning

- Creates a user account.
- Configures SSH authentication types.
- Deploys Secure Shell (SSH) public keys and key pairs.
- Sets the host name.
- Publishes the host name to the platform Domain Name System (DNS).
- Reports the SSH host key fingerprint to the platform.
- Manages the resource disk.
- Formats and mounts the resource disk.
- Configures swap space.

Networking

- Manages routes to improve compatibility with platform DHCP servers.
- Ensures the stability of the network interface name.

Kernel

- Configures virtual NUMA (disabled for kernel 2.6.37).
- Consumes Hyper-V entropy for */dev/random*.
- Configures SCSI timeouts for the root device, which can be remote.

Diagnostics

- Provides console redirection to the serial port.

System Center Virtual Machine Manager deployments

- Detects and bootstraps the Virtual Machine Manager agent for Linux when it's running in a System Center Virtual Machine Manager 2012 R2 environment.

VM extension

- Injects components authored by Microsoft and partners into Linux VMs to enable software and configuration automation.

You can find a VM extension reference implementation on GitHub.

Communication

Information flow from the platform to the agent occurs through two channels:

- A boot-time attached DVD for VM deployments. This DVD includes an Open Virtualization Format (OVF)-compliant configuration file that contains all provisioning information other than the SSH key pairs.
- A TCP endpoint that exposes a REST API that's used to get deployment and topology configuration.

Requirements

Testing confirms that the following systems work with the Azure Linux VM Agent.

> **Note**
>
> This list might differ from the endorsed Linux distributions on Azure.

Expand table

Publisher	Distribution	x64	ARM64
Alma Linux Community	Alma Linux	8.x+, 9.x+	8.x+, 9.x+
Credativ	Debian	10+	11.x+
Kinvolk	Flatcar Linux	3374.2.x+	3374.2.x+
Microsoft	Azure Linux	2.x	2.x
openSUSE Project	openSUSE	12.3+	*Not supported*
Oracle	Oracle Linux	6.4+, 7.x+, 8.x+	*Not supported*
Red Hat	Red Hat Enterprise Linux	6.7+, 7.x+, 8.x+, 9.x+, 10.x+	8.6+, 9.0+, 10.x+
CIQ	Rocky Linux	9.x+	9.x+
SUSE	SLES	12.x+, 15.x+	15.x SP4+
Canonical	Ubuntu (LTS releases)	18.04+, 20.04+, 22.04+, 24.04+	20.04+, 22.04+, 24.04+

Other supported systems:

- The agent works on more systems than the ones listed in the documentation. However, we don't test or provide support for distros that aren't on the endorsed list. In particular, FreeBSD isn't endorsed. You can try FreeBSD 8. If you run into problems, you can open an issue in our GitHub repository and we might be able to help.

The Linux agent depends on these system packages to function properly:

- Python 2.6+
- OpenSSL 1.0+
- OpenSSH 5.3+
- File system utilities: sfdisk, fdisk, mkfs, parted
- Password tools: chpasswd, sudo
- Text processing tools: sed, grep
- Network tools: ip-route
- Kernel support for mounting UDF file systems

Ensure that your VM has access to IP address 168.63.129.16. For more information, see What is IP address 168.63.129.16?.

Installation

The supported method of installing and upgrading the Azure Linux VM Agent uses an RPM or a DEB package from your distribution's package repository. All the endorsed distribution providers integrate the Azure Linux VM Agent package into their images and repositories. Some Linux distributions might disable the Azure Linux VM Agent **Auto Update** feature. Some of the repositories might also contain older versions. Older versions might have issues with modern extensions, so we recommend that you install the latest stable version.

You need to make sure that the Azure Linux VM Agent is updating properly. We recommend that you have the option `AutoUpdate.Enabled=Y` in the `/etc/waagent.conf` file because commenting out that option results in defaults too. Having `AutoUpdate.Enabled=N` doesn't allow the Azure Linux VM Agent to update properly.

For advanced installation options, such as installing from a source or to custom locations or prefixes, see Microsoft Azure Linux VM Agent. Other than these scenarios, we don't support or recommend upgrading or reinstalling the Azure Linux VM Agent from source.

Command-line options

Flags

- `verbose`: Increases verbosity of the specified command.
- `force`: Skips interactive confirmation for some commands.

Commands

- `help`: Lists the supported commands and flags.

- `deprovision`: Attempts to clean the system and make it suitable for reprovisioning. The operation deletes:
  - All SSH host keys, if `Provisioning.RegenerateSshHostKeyPair` is `y` in the configuration file.
  - `Nameserver` configuration in */etc/resolv.conf*.
  - The root password from */etc/shadow*, if `Provisioning.DeleteRootPassword` is `y` in the configuration file.
  - Cached DHCP client leases.

  The client resets the host name to `localhost.localdomain`.

> ⚠ **Warning**
>
> Deprovisioning doesn't guarantee that the image is cleared of all sensitive information and suitable for redistribution.

- `deprovision+user`: Performs everything in `deprovision` and deletes the last provisioned user account (obtained from */var/lib/waagent*) and associated data. Use this parameter when you deprovision an image that was previously provisioned on Azure so that it can be captured and reused.
- `version`: Displays the version of waagent.
- `serialconsole`: Configures GRUB to mark ttyS0, the first serial port, as the boot console. This option ensures that kernel boot logs are sent to the serial port and made available for debugging.
- `daemon`: Runs waagent as a daemon to manage interaction with the platform. This argument is specified to waagent in the waagent *init* script.
- `start`: Runs waagent as a background process.

Configuration

The */etc/waagent.conf* configuration file controls the actions of waagent. Here's an example of a configuration file:

config

```
Provisioning.Enabled=y
Provisioning.DeleteRootPassword=n
Provisioning.RegenerateSshHostKeyPair=y
Provisioning.SshHostKeyPairType=rsa
Provisioning.MonitorHostName=y
Provisioning.DecodeCustomData=n
Provisioning.ExecuteCustomData=n
Provisioning.AllowResetSysUser=n
Provisioning.PasswordCryptId=6
Provisioning.PasswordCryptSaltLength=10
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.MountOptions=None
ResourceDisk.EnableSwap=n
ResourceDisk.SwapSizeMB=0
LBProbeResponder=y
Logs.Verbose=n
```

```
OS.RootDeviceScsiTimeout=300
OS.OpensslPath=None
HttpProxy.Host=None
HttpProxy.Port=None
AutoUpdate.Enabled=y
```

Configuration options are of three types: `Boolean`, `String`, or `Integer`. You can specify the `Boolean` configuration options as `y` or `n`. The special keyword `None` might be used for some string type configuration entries.

Provisioning.Enabled

txt

```
Type: Boolean
Default: y
```

This option allows the user to enable or disable the provisioning functionality in the agent. Valid values are `y` and `n`. If provisioning is disabled, SSH host and user keys in the image are preserved and configuration in the Azure provisioning API is ignored.

> ⓘ **Note**
>
> The `Provisioning.Enabled` parameter defaults to `n` on Ubuntu Cloud Images that use cloud-init for provisioning.

Provisioning.DeleteRootPassword

txt

```
Type: Boolean
Default: n
```

If the value is `y`, the agent erases the root password in the */etc/shadow* file during the provisioning process.

Provisioning.RegenerateSshHostKeyPair

txt

```
Type: Boolean
Default: y
```

If the value is `y`, the agent deletes all SSH host key pairs from */etc/ssh/* during the provisioning process, including ECDSA, DSA, and RSA. The agent generates a single fresh key pair.

Configure the encryption type for the fresh key pair by using the `Provisioning.SshHostKeyPairType` entry. Some distributions re-create SSH key pairs for any missing encryption types when the SSH daemon is restarted. An example is after a reboot.

Provisioning.SshHostKeyPairType

```txt
Type: String
Default: rsa
```

You can set this option to an encryption algorithm type that the SSH daemon supports on the VM. The typically supported values are `rsa`, `dsa`, and `ecdsa`. The *putty.exe* file on Windows doesn't support `ecdsa`. If you intend to use *putty.exe* on Windows to connect to a Linux deployment, use `rsa` or `dsa`.

Provisioning.MonitorHostName

```txt
Type: Boolean
Default: y
```

If the value is `y`, waagent monitors the Linux VM for a host name change, as returned by the `hostname` command. Waagent then automatically updates the networking configuration in the image to reflect the change. To push the name change to the DNS servers, networking restarts on the VM. This restart results in brief loss of internet connectivity.

Provisioning.DecodeCustomData

```txt
Type: Boolean
Default: n
```

If the value is `y`, waagent decodes `CustomData` from Base64.

Provisioning.ExecuteCustomData

txt

```
Type: Boolean
Default: n
```

If the value is `y`, waagent runs `CustomData` after provisioning.

Provisioning.AllowResetSysUser

txt

```
Type: Boolean
Default: n
```

This option allows the password for the system user to be reset. It's disabled by default.

Provisioning.PasswordCryptId

txt

```
Type: String
Default: 6
```

This option specifies the algorithm that `crypt` uses when it's generating a password hash. Valid values are:

- `1`: MD5
- `2a`: Blowfish
- `5`: SHA-256
- `6`: SHA-512

Provisioning.PasswordCryptSaltLength

txt

```
Type: String
Default: 10
```

This option specifies the length of random salt used in generating a password hash.

ResourceDisk.Format

```txt
Type: Boolean
Default: y
```

If the value is `y`, waagent formats and mounts the resource disk that the platform provides, unless the file system type that the user requested in `ResourceDisk.Filesystem` is `ntfs`. The agent makes a single Linux partition (ID 83) available on the disk. This partition isn't formatted if it can be successfully mounted.

ResourceDisk.Filesystem

```txt
Type: String
Default: ext4
```

This option specifies the file system type for the resource disk. Supported values vary by Linux distribution. If the string is `X`, then `mkfs.X` should be present on the Linux image.

ResourceDisk.MountPoint

```txt
Type: String
Default: /mnt/resource
```

This option specifies the path at which the resource disk is mounted. The resource disk is a *temporary* disk and might be emptied when the VM is deprovisioned.

ResourceDisk.MountOptions

```txt
Type: String
Default: None
```

This option specifies disk mount options to be passed to the `mount -o` command. The value is a comma-separated list of values, for example, `nodev,nosuid`. For more information, see the `mount(8)` manual page.

ResourceDisk.EnableSwap

txt

```
Type: Boolean
Default: n
```

If you set this option, the agent creates a swap file (*/swapfile*) on the resource disk and adds it to the system swap space.

ResourceDisk.SwapSizeMB

txt

```
Type: Integer
Default: 0
```

This option specifies the size of the swap file in megabytes.

Logs.Verbose

txt

```
Type: Boolean
Default: n
```

If you set this option, log verbosity is boosted. Waagent logs to */var/log/waagent.log* and uses the system `logrotate` functionality to rotate logs.

OS.EnableRDMA

txt

```
Type: Boolean
Default: n
```

If you set this option, the agent attempts to install and then load an RDMA kernel driver that matches the version of the firmware on the underlying hardware.

OS.RootDeviceScsiTimeout

txt

```
Type: Integer
Default: 300
```

This option configures the SCSI timeout in seconds on the operating system disk and data drives. If it isn't set, the system defaults are used.

OS.OpensslPath

```txt
Type: String
Default: None
```

You can use this option to specify an alternate path for the *openssl* binary to use for cryptographic operations.

HttpProxy.Host, HttpProxy.Port

```txt
Type: String
Default: None
```

If you set this option, the agent uses this proxy server to access the internet.

AutoUpdate.Enabled

```txt
Type: Boolean
Default: y
```

Enable or disable autoupdate for goal state processing. The default value is `y`.

Automatic log collection in the Azure Linux Guest Agent

As of version 2.7+, the Azure Linux Guest Agent has a feature to automatically collect some logs and upload them. This feature currently requires `systemd`. It uses a new `systemd` slice called `azure-walinuxagent-logcollector.slice` to manage resources while it performs the collection.

The purpose is to facilitate offline analysis. The agent produces a *.zip* file of some diagnostics logs before uploading them to the VM's host. Engineering teams and support professionals

can retrieve the file to investigate issues for the VM owner. For technical information on the files that the Azure Linux Guest Agent collects, see the *azurelinuxagent/common/logcollector_manifests.py* file in the agent's GitHub repository.

You can disable this option by editing */etc/waagent.conf*. Update `Logs.Collect` to `n`.

Ubuntu Cloud Images

Ubuntu Cloud Images use cloud-init to do many configuration tasks that the Azure Linux VM Agent would otherwise manage. The following differences apply:

- `Provisioning.Enabled` defaults to `n` on Ubuntu Cloud Images that use cloud-init to perform provisioning tasks.
- The following configuration parameters have no effect on Ubuntu Cloud Images that use cloud-init to manage the resource disk and swap space:
  - `ResourceDisk.Format`
  - `ResourceDisk.Filesystem`
  - `ResourceDisk.MountPoint`
  - `ResourceDisk.EnableSwap`
  - `ResourceDisk.SwapSizeMB`

To configure the resource disk mount point and swap space on Ubuntu Cloud Images during provisioning, see the following resources:

- Ubuntu wiki: AzureSwapPartitions
- Deploy applications to a Windows virtual machine in Azure with the Custom Script extension

FIPS 140-3 support for Azure Linux VM extensions and guest agent

> **Note**
>
> This feature is currently in public preview. Production workloads are supported.

Linux virtual machine (VM) extensions currently comply with FIPS 140-2, but updates to the platform were required to add support for FIPS 140-3. These changes are currently being enabled across the commercial cloud and Azure Government clouds. Linux VM extensions that use protected settings are also being updated to be able to use a FIPS 140-3-compliant encryption algorithm. This article helps enable support for FIPS 140-3 on Linux VMs where compliance with FIPS 140-3 is enforced. This change isn't needed on Windows images because of the way that FIPS compliance is implemented.

For more information, see What are the Federal Information Processing Standards (FIPS)?.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

You must meet the following four requirements to use a FIPS 140-3-compliant VM in Azure:

- The VM must be in a region where FIPS 140-3 platform changes are rolled out.
- Your Azure subscription must be opted in to FIPS 140-3 enablement.
- Each VM must be enrolled in FIPS 140-3 enablement in Azure Resource Manager.
- Inside the guest operating system (OS), the OS must be configured for FIPS 140 mode. The OS must run a version of the Azure guest agent (waagent), which is also compliant with FIPS 140-3.

Afterward, validate to ensure the functionality of the VM extensions.

Implement prerequisites

1. Subscription enablement/opt-in

Because not all extensions are onboarded by using FIPS 140-3 encryption yet, we require the subscription to opt in to the feature `_Microsoft.Compute/OptInToFips1403Compliance_`.

Azure CLI

```
az feature register --namespace Microsoft.Compute --name OptInToFips1403Compliance
```

Verify with the following command:

```
az feature list | jq '.[] |
select(.name=="Microsoft.Compute/OptInToFips1403Compliance")'
```

JSON

```
{
  "id": "/subscriptions/<SUBSCRIPTION
ID>/providers/Microsoft.Features/providers/Microsoft.Compute/features/OptInToFips14
03Compliance",
  "name": "Microsoft.Compute/OptInToFips1403Compliance",
  "properties": {
    "state": "Registered"
  },
```

```
  "type": "Microsoft.Features/providers/features"
}
```

---

2. Per-VM opt-in

There are different methods available for opting in to each VM. You can make the changes at deployment for a new VM. You can also alter an existing VM to add the FIPS 140-3 enablement on the Azure platform.

> **⚠ Warning**
>
> We don't recommend using the following opt-in methods on Red Hat Enterprise Linux (RHEL) 9.5 and 9.6 by using version 2.7.0.6 of `WALinuxAgent` on production systems. An issue can surface after rebooting, after the FIPS enablement and subsequent reboot. On these VMs, the `waagent.service` enters an internal loop and never comes to a `Ready` state. Because of this error, no extensions can function. For testing, you can try the RHEL 9 workaround.

Deploy a new VM

To deploy a new VM with FIPS 140-3 enablement turned on immediately, use an Azure Resource Manager template (ARM template) or the Azure CLI. Add the `enableFips1403Encryption` property to the `additionalCapabilities` section of the `virtualMachines` object definition.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachines",
  "apiVersion": "2024-11-01",
  "name": "[parameters('vmName')]",
  "location": "[parameters('location')]",
  "properties": {
      "additionalCapabilities": {
      "enableFips1403Encryption": true
    }
  }
}
```

Modify an existing VM

az cli commands

> **Note**
>
> For the Government cloud, use `https://management.usgovcloudapi.net` instead of `https://management.azure.com`.

While updates to the SDK/CLI are still in progress, you can continue to use `az cli` to add the property.

```
az rest \
--method put \
--url 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM
NAME>/?api-version=2024-11-01' \
--body '{"location": "<LOCATION>", "properties": {"additionalCapabilities":
{"enableFips1403Encryption": true}}}'
```

Running the `put` command outputs the resulting JSON for the modified VM. For later verification, you can run this `get` command against the VM object, which outputs the full JSON again.

```
az rest \
--method get \
--url 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM
NAME>/?api-version=2024-11-01'
```

The command output should include:

JSON

```
{
 "enableFips1403Encryption": true
}
```

To more easily find the property in the output, you can add `jq` to parse out the specific section needed. This block is the new command:

```
az rest \
--method get \
--url 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM
NAME>/?api-version=2024-11-01' \
| jq .properties.additionalCapabilities
```

For comparison, one possible outcome when you try to enable FIPS 140-3 on a VM when the VM isn't in an enabled region, the `put` command can output the following code, which indicates that the action isn't possible in the region.

JSON

```
({
  "error": {
    "code": "BadRequest",
    "message": "Creation of VMs using a Fips 140-3 compliant encryption for
extension settings isn't supported in this region."
  }
})
```

---

3. In-guest considerations

Important changes must be made to the Linux OS environment to enable and support FIPS 140-3 compliance.

Configure the OS for FIPS enablement

The following distributions support FIPS 140-3 and provide instructions for enabling:

- Ubuntu 22.04 LTS and newer: Use an Ubuntu pro client or pro image.
- RHEL 9: Use the steps to enable FIPS on RHEL.

Older versions of these operating systems operate at the FIPS 140-2 level and don't require any of these special considerations.

Linux guest agent

Minimum Goal State Agent version: v2.14.0.1. To be sure that the goal state is updating, the `AutoUpdate.Enabled` flag should be `y` or commented out entirely so that the default behavior is used.

`/etc/waagent.conf`:

```
AutoUpdate.Enabled=y
```

RHEL 9 workaround

This workaround is intended for testing purposes only and doesn't support all VM deployment scenarios. After you enable FIPS on a running VM, run the following commands to proceed:

```
systemctl stop waagent

# apply the patch
sed -i -E '/(.+)(self._initialize_telemetry\(\))/s//\1# \2/'
/usr/lib/python3.9/site-packages/azurelinuxagent/daemon/main.py
```

To verify that the previous change was applied successfully, use the following command:

```
grep self\._initialize_telemetry /usr/lib/python3.9/site-
packages/azurelinuxagent/daemon/main.py
```

The output should be exactly this text:

```
        # self._initialize_telemetry()
```

After verification, restart the agent:

```
systemctl start waagent
```

Validation

To validate proper functionality of the VM extensions:

- Check that the agent status is `Ready`.

- Test an extension by using the protected settings of the VM extensions.
  - By using the `Reset Password` function of the Azure portal or `az cli`, reset a password or create a new temporary user.
  - Run a custom script.

If these tests fail, force the Azure platform to generate a new personal information exchange (PFX) package.

Reset password

Use either the Azure portal or an `az cli` command, such as this example, to set a user's password or create a temporary user. Check the execution state for success or failure.

Bash

```
az vm user update \
  --resource-group <YourResourceGroup> \
  --name <YourVMName> \
  --username <NewUsername> \
  --password <NewPassword>
```

Run a custom script

Use the Custom Script extension documentation to send a basic script, such as `cat /etc/os-release`, to test extension functionality.

Fix a validation failure

If the validations fail to execute, force the Azure platform to generate a new PFX package. There are two methods to force this regeneration:

- Reallocate the VM.
- Apply an Azure Key Vault certificate.

Deallocate/Reallocate the VM

You can use the Azure CLI, the Azure portal, or any other method to deallocate the VM. Wait for the deallocation to occur, and then start the VM.

Add a Key Vault certificate

Create the Key Vault certificate, add it to the modified ARM template, and deploy.

For more information, see Get started with Key Vault certificates.

The following example shows the `properties` section of the VM model:

JSON

```
      "secrets": [
        {
          "sourceVault": {
            "id": "/subscriptions/<subId>/resourceGroups/<resource
group>/providers/Microsoft.KeyVault/vaults/<keyvault name>"
          },
          "vaultCertificates": [
            {
              "certificateUrl": "https://<keyvault
name>.vault.azure.net/secrets/rsa/5cc588f8f3404268b2ca4d05e544e7fb"
            }
          ]
        }
      ],
```

Virtual machine extensions and features for Windows

Summarize this article for me

Azure virtual machine (VM) extensions are small applications that provide post-deployment configuration and automation tasks on Azure VMs. For example, if a virtual machine requires software installation, antivirus protection, or the ability to run a script inside of the VM, you can use a VM extension.

You can run Azure VM extensions by using the Azure CLI, PowerShell, Azure Resource Manager (ARM) templates, and the Azure portal. You can bundle extensions with a new VM deployment or run them against any existing system.

This article provides an overview of Azure VM extensions, including prerequisites and guidance on how to detect, manage, and remove extensions. This article provides generalized information because many VM extensions are available. Each extension has a potentially unique configuration and its own documentation.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Use cases and samples

Each Azure VM extension has a specific use case. Here are some examples:

- Configure monitoring of a VM by using the Azure Monitor agent and VM insights.
- Configure an Azure VM by using Chef.
- Configure monitoring of your Azure infrastructure by using the Datadog extension.

In addition to process-specific extensions, a Custom Script Extension is available for both Windows and Linux virtual machines. The Custom Script Extension for Windows allows any PowerShell script to run on a VM. Custom scripts are useful for designing Azure deployments that require configuration beyond what native Azure tooling can provide.

Prerequisites

Review the following prerequisites for working with Azure VM extensions.

Azure VM Agent

To handle extensions on the VM, you need the Azure Virtual Machine Agent for Windows installed. This agent is also referred to as the Azure VM Agent or the Windows Guest Agent. As you prepare to install extensions, keep in mind that some extensions have individual prerequisites, such as access to resources or dependencies.

The Azure VM Agent manages interactions between an Azure VM and the Azure fabric controller. The agent is responsible for many functional aspects of deploying and managing Azure VMs, including running VM extensions.

The Azure VM Agent is preinstalled on Azure Marketplace images. The agent can also be installed manually on supported operating systems.

The agent runs on multiple operating systems. However, the extensions framework has a limit for the operating systems that extensions use. Some extensions aren't supported across all operating systems and might emit error code 51 ("Unsupported OS"). Check the individual extension documentation for supportability.

Network access

Extension packages are downloaded from the Azure Storage extension repository. Extension status uploads are posted to Azure Storage.

If you use a supported version of the Azure VM Agent, you don't need to allow access to Azure Storage in the VM region. You can use the VM Agent to redirect the communication to the Azure fabric controller for agent communications (via the `HostGAPlugin` feature through the privileged channel on private IP address 168.63.129.16). If you're on an unsupported version of the VM Agent, you need to allow outbound access to Azure Storage in that region from the VM.

> **ⓘ Important**
>
> If you block access to IP address 168.63.129.16 by using the guest firewall or via a proxy, extensions fail. Failure occurs even if you use a supported version of the VM Agent or you configure outbound access. Ports 80 and 32526 are required.

Agents can only be used to download extension packages and report status. For example, if an extension installation needs to download a script from GitHub (Custom Script Extension) or requires access to Azure Storage (Azure Backup), then you need to open other firewall or network security group (NSG) ports. Different extensions have different requirements because they're applications in their own right. For extensions that require access to Azure Storage or Microsoft Entra ID, you can allow access by using Azure NSG service tags.

The Azure VM Agent doesn't provide proxy server support to enable redirection of agent traffic requests. The VM Agent relies on your custom proxy (if you have one) to access resources on the internet or on the host through IP address 168.63.129.16.

Discover VM extensions

Many VM extensions are available for use with Azure VMs. To see a complete list, use the Get-AzVMExtensionImage PowerShell cmdlet.

The following command lists all available VM extensions in the West US region location:

PowerShell

```
Get-AzVmImagePublisher -Location "West US" |
Get-AzVMExtensionImageType |
Get-AzVMExtensionImage | Select Type, Version
```

This command provides output similar to the following example:

PowerShell

```
Type                Version
----                -------
AcronisBackup       1.0.33
AcronisBackup       1.0.51
AcronisBackupLinux  1.0.33
AlertLogicLM        1.3.0.1
AlertLogicLM        1.3.0.0
AlertLogicLM        1.4.0.1
```

Run VM extensions

Azure VM extensions run on existing VMs, which is useful when you need to make configuration changes or recover connectivity on an already deployed VM. VM extensions can also be bundled with ARM template deployments. By using extensions with ARM templates, you can deploy and configure Azure VMs without post-deployment intervention.

You can use the following methods to run an extension against an existing VM.

> **Note**
>
> Some of the following examples use `"<placeholder>"` parameter values in the commands. Before you run each command, make sure to replace any `"<placeholder>"` values with specific values for your configuration.

PowerShell

Several PowerShell commands exist for running individual extensions. To see a list, use the Get-Command command and filter on *Extension*:

PowerShell

```powershell
Get-Command Set-Az*Extension* -Module Az.Compute
```

This command provides output similar to the following example:

PowerShell

```
CommandType     Name                                               Version    Source
-----------     ----                                               -------    ------
Cmdlet          Set-AzVMAccessExtension                            4.5.0      Az.Compute
Cmdlet          Set-AzVMADDomainExtension                          4.5.0      Az.Compute
Cmdlet          Set-AzVMAEMExtension                               4.5.0      Az.Compute
Cmdlet          Set-AzVMBackupExtension                            4.5.0      Az.Compute
Cmdlet          Set-AzVMBginfoExtension                            4.5.0      Az.Compute
Cmdlet          Set-AzVMChefExtension                              4.5.0      Az.Compute
Cmdlet          Set-AzVMCustomScriptExtension                      4.5.0      Az.Compute
Cmdlet          Set-AzVMDiagnosticsExtension                       4.5.0      Az.Compute
Cmdlet          Set-AzVMDiskEncryptionExtension                    4.5.0      Az.Compute
Cmdlet          Set-AzVMDscExtension                               4.5.0      Az.Compute
Cmdlet          Set-AzVMExtension                                  4.5.0      Az.Compute
Cmdlet          Set-AzVMSqlServerExtension                         4.5.0      Az.Compute
Cmdlet          Set-AzVmssDiskEncryptionExtension                  4.5.0      Az.Compute
```

The following example uses the Custom Script Extension to download a script from a GitHub repository onto the target virtual machine and then run the script.

PowerShell

```powershell
Set-AzVMCustomScriptExtension -ResourceGroupName "<myResourceGroup>" `
    -VMName "<myVM>" -Name "<myCustomScript>" `
    -FileUri "https://raw.githubusercontent.com/neilpeterson/nepeters-azure-
```

```
templates/master/windows-custom-script-simple/support-scripts/Create-File.ps1" `
    -Run "Create-File.ps1" -Location "<myVMregion>"
```

The following example uses the VMAccess extension to reset the administrative password of a Windows VM to a temporary password. After you run this code, you should reset the password at first sign-in.

PowerShell

```
$cred=Get-Credential

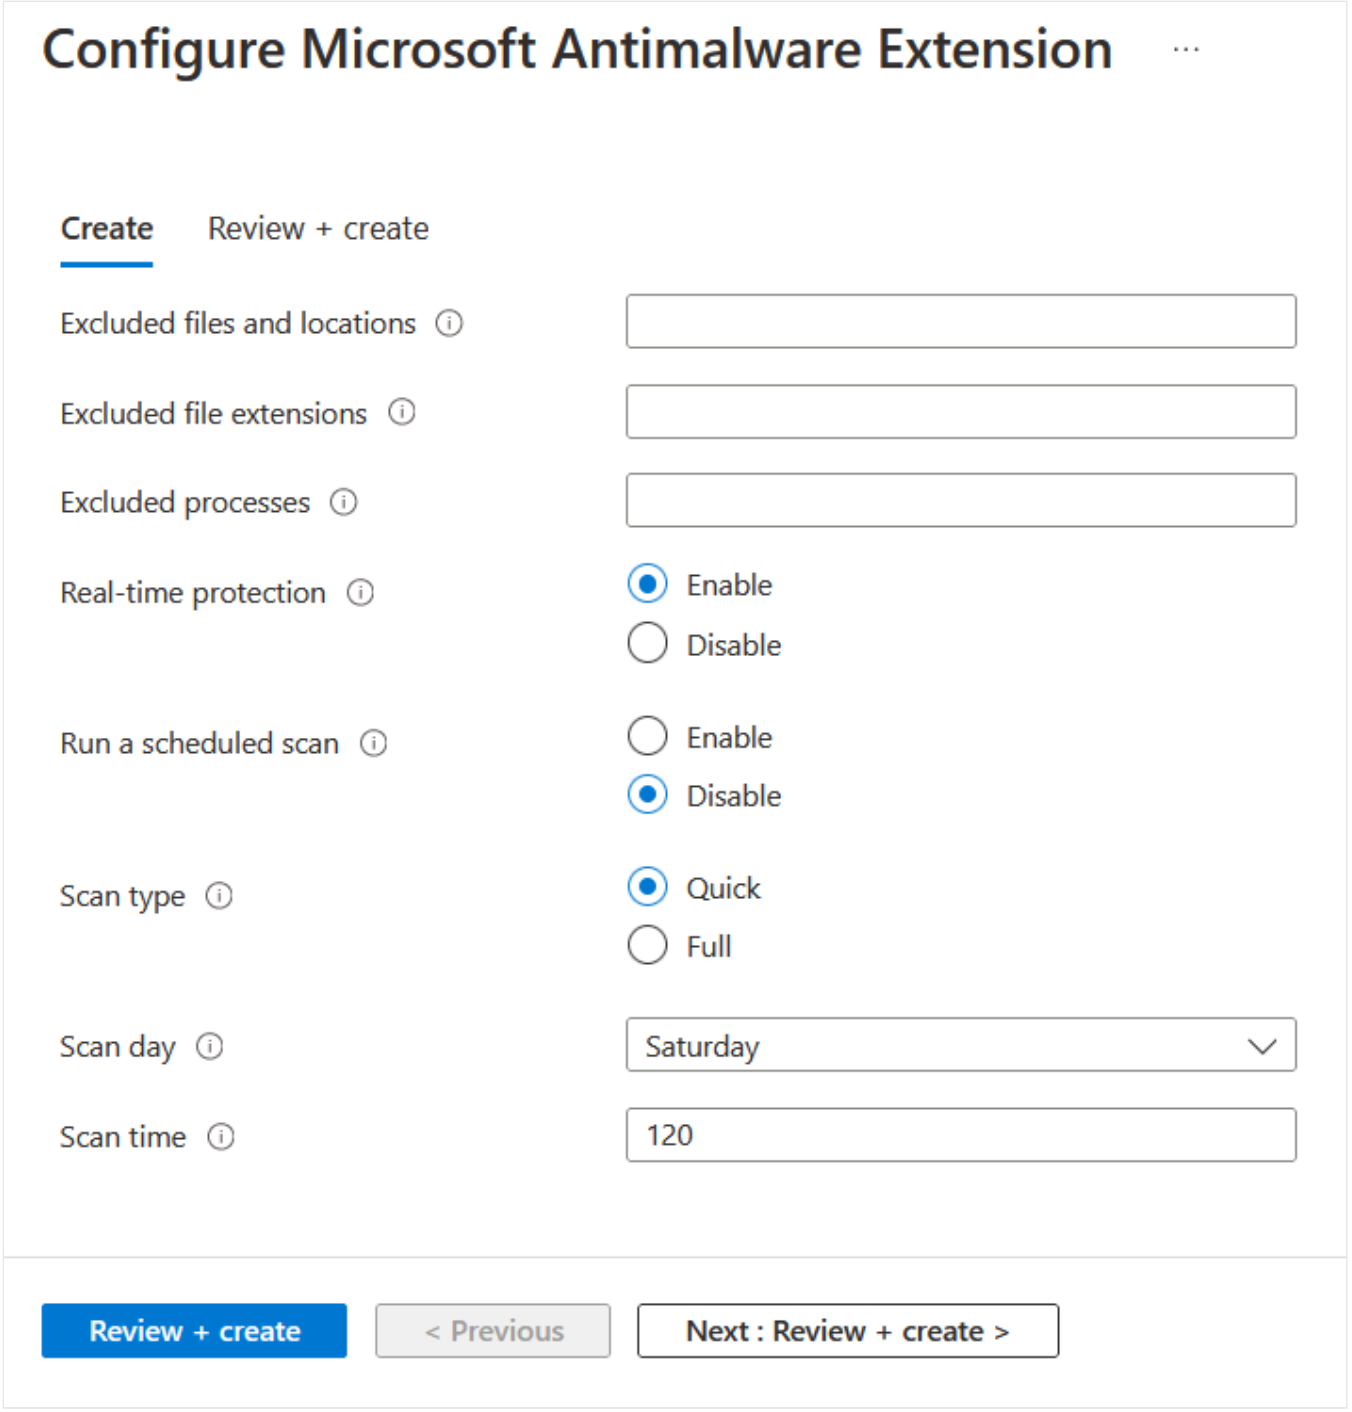
Set-AzVMAccessExtension -ResourceGroupName "myResourceGroup" -VMName "myVM" -Name
"myVMAccess" `
    -Location "myVMregion" -UserName $cred.GetNetworkCredential().Username `
    -Password $cred.GetNetworkCredential().Password -typeHandlerVersion "2.0"
```

You can use the Set-AzVMExtension command to start any VM extension.

Azure portal

You can apply VM extensions to an existing VM through the Azure portal. Select the VM in the portal, select **Extensions + Applications**, and then select **+ Add**. Choose the extension that you want from the list of available extensions, and follow the instructions in the wizard.

The following example shows the installation of the Microsoft Antimalware extension from the Azure portal:



Azure Resource Manager templates

You can add VM extensions to an ARM template and run them with the deployment of the template. When you deploy an extension with a template, you can create fully configured Azure deployments.

The following JSON example is from an ARM template that deploys a set of load-balanced VMs and an Azure SQL database, and then installs a .NET Core application on each VM. The VM extension takes care of the software installation.

JSON

```
{
    "apiVersion": "2015-06-15",
    "type": "extensions",
    "name": "config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/',
variables('vmName'),copyindex())]",
    "[variables('musicstoresqlName')]"
    ],
    "tags": {
    "displayName": "config-app"
    },
    "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
        ]
    },
    "protectedSettings": {
        "commandToExecute": "[concat('powershell -ExecutionPolicy Unrestricted -
File configure-music-app.ps1 -user ',parameters('adminUsername'),' -password
',parameters('adminPassword'),' -sqlserver
',variables('musicstoresqlName'),'.database.windows.net')]"
    }
    }
}
```

For more information on creating ARM templates, see Virtual machines in an ARM template.

Help secure VM extension data

When you run a VM extension, it might be necessary to include sensitive information such as credentials, storage account names, and access keys. Many VM extensions include a protected configuration that encrypts data and only decrypts it inside the target VM. Each extension has a specific protected configuration schema, and each schema is detailed in extension-specific documentation.

The following JSON example shows an instance of the Custom Script Extension for Windows. The command to run includes a set of credentials. In this example, the command to run isn't encrypted.

JSON

```
{
    "apiVersion": "2015-06-15",
    "type": "extensions",
    "name": "config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/',
variables('vmName'),copyindex())]",
    "[variables('musicstoresqlName')]"
    ],
    "tags": {
    "displayName": "config-app"
    },
    "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
        ],
        "commandToExecute": "[concat('powershell -ExecutionPolicy Unrestricted -
File configure-music-app.ps1 -user ',parameters('adminUsername'),' -password
',parameters('adminPassword'),' -sqlserver
',variables('musicstoresqlName'),'.database.windows.net')]"
    }
    }
}
```

Moving the `commandToExecute` property to the `protected` configuration helps secure the execution string, as shown in the following example:

JSON

```
{
    "apiVersion": "2015-06-15",
    "type": "extensions",
    "name": "config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/',
variables('vmName'),copyindex())]",
    "[variables('musicstoresqlName')]"
    ],
    "tags": {
    "displayName": "config-app"
    },
    "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
```

```
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
        ]
    },
    "protectedSettings": {
        "commandToExecute": "[concat('powershell -ExecutionPolicy Unrestricted -
File configure-music-app.ps1 -user ',parameters('adminUsername'),' -password
',parameters('adminPassword'),' -sqlserver
',variables('musicstoresqlName'),'.database.windows.net')]"
    }
    }
}
```

On an Azure infrastructure as a service (IaaS) VM that uses extensions, in the certificates console, you might see certificates that have the subject **Windows Azure CRP Certificate Generator**. On a classic RedDog Front End (RDFE) VM, these certificates have the subject name **Windows Azure Service Management for Extensions**.

These certificates secure the communication between the VM and its host during the transfer of protected settings (password and other credentials) that extensions use. The Azure fabric controller builds the certificates and passes them to the Azure VM Agent. If you stop and start the VM every day, the fabric controller might create a new certificate. The certificate is stored in the computer's personal certificate store. These certificates can be deleted. The Azure VM Agent re-creates certificates if needed.

How agents and extensions are updated

Agents and extensions share the same automatic update mechanism.

When an update is available and automatic updates are enabled, the update is installed on the VM only after an extension or other VM model changes. Changes can include:

- Data disks
- Extensions
- Extension Tags
- Boot diagnostics container
- Guest OS secrets
- VM size
- Network profile

Publishers make updates available to regions at various times. It's possible you can have VMs in different regions on different versions.

> ⓘ Note
>
> Some updates might require additional firewall rules. For more information, see Network access.

List extensions deployed to a VM

You can use the following command to list the extensions deployed to a VM:

PowerShell

```
$vm = Get-AzVM -ResourceGroupName "<myResourceGroup>" -VMName "<myVM>"
$vm.Extensions | select Publisher, VirtualMachineExtensionType, TypeHandlerVersion
```

This command produces output similar to the following example:

PowerShell

```
Publisher             VirtualMachineExtensionType          TypeHandlerVersion
---------             ---------------------------          ------------------
Microsoft.Compute     CustomScriptExtension                1.9
```

Agent updates

The Azure VM Agent contains only *extension-handling code*. The *Windows provisioning code* is separate. You can uninstall the Azure VM Agent. You can't disable the automatic update of the Azure VM Agent.

The extension-handling code is responsible for the following tasks:

- Communicate with the Azure fabric.
- Handle the VM extension operations, such as installations, reporting status, updating the individual extensions, and removing extensions. Updates contain security fixes, bug fixes, and enhancements to the extension-handling code.

To check what version you're running, see Detect the Azure VM Agent.

Extension updates

When an extension update is available and automatic updates are enabled, if a VM model changes, the Azure VM Agent downloads and upgrades the extension.

Automatic extension updates are either *minor* or *hotfix*. You can opt in or opt out of minor updates when you provision the extension. The following example shows how to automatically upgrade minor versions in an ARM template by using the `"autoUpgradeMinorVersion": true,` parameter:

JSON

```
    "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-
templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
        ]
    },
```

To get the latest minor-release bug fixes, we highly recommend that you always select automatic update in your extension deployments. You can't opt out of hotfix updates that carry security or key bug fixes.

If you disable automatic updates or you need to upgrade a major version, use the Set-AzVMExtension command and specify the target version.

Check Extension Version

> ⓘ Note
>
> **Model vs. Instance View**
>
> In Azure, the **model view** captures the configuration you defined for an extension (publisher, type, and requested version), while the **instance view** shows the live state and the actual handler version running on each VM or scale-set instance—use instance view as the source of truth when verifying what's really installed.

Check a single VM

Azure CLI

Bash

```
az vm get-instance-view -g <rg> -n <vm> \
  --query "extensions[].
```

```
{name:name,type:type,version:typeHandlerVersion,status:statuses[0].displayStatus}"
\
  -o table
```

Reads the VM's **instance view** to show the actually installed handler version and status.

PowerShell

PowerShell

```
Get-AzVM -ResourceGroupName <rg> -Name <vmName> -Status |
  Select-Object -ExpandProperty Extensions
```

Inspect `TypeHandlerVersion` and `Statuses` for each extension to confirm the running version and health.

Check scale sets (Uniform or Flexible)

Azure CLI

Bash

```
# Scale set summary (health)
az vmss get-instance-view -g <rg> -n <vmss>

# Per-instance extension versions
az vmss list-instances -g <rg> -n <vmss> --expand instanceView \
  --query "[].{instanceId:instanceId,
extVers:instanceView.extensions[].typeHandlerVersion}"

# Specific instance
az vmss vm get-instance-view -g <rg> -n <vmss> --instance-id <id>
```

Use instance view at the scale-set or per-instance level to validate the actual handler versions.

PowerShell

PowerShell

```
Get-AzVmssVM -ResourceGroupName <rg> -VMScaleSetName <vmss> -InstanceView
```

Returns per-instance runtime state, including extension versions and statuses.

How to identify extension updates

There are a few ways you can identify updates for an extension.

Identify if the extension is set with autoUpgradeMinorVersion on a VM

You can view the VM model to determine if the extension is provisioned with the `autoUpgradeMinorVersion` parameter. To check the VM model, use the Get-AzVm command and provide the resource group and VM name as follows:

powerShell

```
$vm = Get-AzVm -ResourceGroupName "myResourceGroup" -VMName "myVM"
$vm.Extensions
```

The following example output shows the `autoUpgradeMinorVersion` parameter is set to `true`:

PowerShell

```
ForceUpdateTag             :
Publisher                  : Microsoft.Compute
VirtualMachineExtensionType : CustomScriptExtension
TypeHandlerVersion         : 1.9
AutoUpgradeMinorVersion    : True
```

Identify when an autoUpgradeMinorVersion event occurs

To see when an update to the extension occurred, you can review the agent logs on the VM at *C:\WindowsAzure\Logs\WaAppAgent.log*.

The following example shows the VM with `Microsoft.Compute.CustomScriptExtension` version `1.8` installed, and a hotfix available for version `1.9`.

PowerShell

```
[INFO]  Getting plugin locations for plugin
'Microsoft.Compute.CustomScriptExtension'. Current Version: '1.8', Requested
Version: '1.9'
[INFO]  Auto-Upgrade mode. Highest public version for plugin
'Microsoft.Compute.CustomScriptExtension' with requested version: '1.9', is: '1.9'
```

Agent permissions

To perform its tasks, the Azure VM Agent needs to run as *Local System*.

Troubleshoot VM extensions

Each VM extension might have specific troubleshooting steps. For example, when you use the Custom Script Extension, you can find script execution details locally on the VM where the extension is run.

The following troubleshooting actions apply to all VM extensions:

- To check the Azure VM Agent Log, look at the activity when your extension was being provisioned in *C:\WindowsAzure\Logs\WaAppAgent.log*.
- Check the extension logs for more details in *C:\WindowsAzure\Logs\Plugins<extensionName>*.
- Check troubleshooting sections in extension-specific documentation for error codes, known issues, and other extension-specific information.
- Look at the system logs. Check for other operations that might have interfered with the extension, such as a long-running installation of another application that required exclusive access to the package manager.
- In a VM, if there's an existing extension with a failed provisioning state, any other new extension fails to install.

Common reasons for extension failures

Here are some common reasons an extension can fail:

- Extensions have 20 minutes to run. (Exceptions are Custom Script, Chef, and DSC, which have 90 minutes.) If your deployment exceeds this time, it's marked as a timeout. The cause of this issue can be low-resource VMs, or other VM configurations or startup tasks are consuming large amounts of resources while the extension is trying to provision.
- Minimum prerequisites aren't met. Some extensions have dependencies on VM SKUs, such as HPC images. Extensions might have certain networking access requirements, such as communicating with Azure Storage or public services. Other examples might be access to package repositories, running out of disk space, or security restrictions.
- Package manager access is exclusive. In some cases, a long-running VM configuration and extension installation might conflict because they both need exclusive access to the package manager.

View extension status

After a VM extension is run against a VM, use the Get-AzVM command to return extension status. The `Substatuses[0]` result shows that the extension provisioning succeeded, which

means it successfully deployed to the VM. If you see the `Substatuses[1]` result, then the execution of the extension inside the VM failed.

PowerShell

```powershell
Get-AzVM -ResourceGroupName "myResourceGroup" -VMName "myVM" -Status
```

The output is similar to the following example:

PowerShell

```
Extensions[0]           :
  Name                  : CustomScriptExtension
  Type                  : Microsoft.Compute.CustomScriptExtension
  TypeHandlerVersion    : 1.9
  Substatuses[0]        :
    Code                : ComponentStatus/StdOut/succeeded
    Level               : Info
    DisplayStatus       : Provisioning succeeded
    Message             : Windows PowerShell \nCopyright (C) Microsoft Corporation.
All rights reserved.\n
  Substatuses[1]        :
    Code                : ComponentStatus/StdErr/succeeded
    Level               : Info
    DisplayStatus       : Provisioning succeeded
    Message             : The argument 'cseTest%20Scriptparam1.ps1' to the -File
parameter does not exist. Provide the path to an existing '.ps1' file as an
argument to the

-File parameter.
  Statuses[0]           :
    Code                : ProvisioningState/failed/-196608
    Level               : Error
    DisplayStatus       : Provisioning failed
    Message             : Finished executing command
```

You can also find extension execution status in the Azure portal. Select the VM, select **Extensions**, and then select the desired extension.

Rerun a VM extension

In certain cases, you might need to rerun a VM extension. You can rerun an extension by removing the extension, and then rerunning the extension with an execution method of your choice. To remove an extension, use the Remove-AzVMExtension command as follows:

PowerShell

```
Remove-AzVMExtension -ResourceGroupName "myResourceGroup" -VMName "myVM" -Name
"myExtensionName"
```

You can also remove an extension in the Azure portal. Select a VM, select **Extensions**, and then select the desired extension. Select **Uninstall**.

Common VM extension reference

The following table provides some common references for VM extensions.

Expand table

Extension name	Description
Custom Script Extension for Windows	Run scripts against an Azure virtual machine.
Azure Diagnostics extension	Manage Azure Diagnostics.
VMAccess extension	Manage users and credentials.

Next steps

For more information about VM extensions, see Azure virtual machine extensions and features.

Last updated on 02/11/2026

Azure Windows VM Agent overview

The Microsoft Azure Windows VM Agent is a secure, lightweight process that manages virtual machine (VM) interaction with the Azure fabric controller. The Azure Windows VM Agent has a primary role in enabling and executing Azure virtual machine extensions. VM extensions enable post-deployment configuration of VMs, such as installing and configuring software. VM extensions also enable recovery features such as resetting the administrative password of a VM. Without the Azure Windows VM Agent, you can't run VM extensions.

This article describes how to install and detect the Azure Windows VM Agent.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

The Azure Windows VM Agent supports the x64 and ARM64 architecture for these Windows operating systems:

Expand table

OS Version	x64	ARM64
Windows 10	Supported	Supported
Windows 11	Supported	Supported
Windows Server 2016	Supported	Supported
Windows Server 2016 Core	Supported	Supported
Windows Server 2019	Supported	Supported
Windows Server 2019 Core	Supported	Supported
Windows Server 2022	Supported	Supported
Windows Server 2022 Core	Supported	Supported

OS Version	x64	ARM64
Windows Server 2025	Supported	Supported
Windows Server 2025 Core	Supported	Supported

Important

- The Azure Windows VM Agent needs at least Windows Server 2016 (64-bit) to run, with the .NET Framework 4.0. See Minimum version support for virtual machine agents in Azure.
- Ensure that your VM has access to IP address 168.63.129.16. For more information, see What is IP address 168.63.129.16?.
- If you only have one private IP on your VM's NIC, then we highly recommend having DHCP enabled in the guest VM. If you need a static private IP address, you should configure it through the Azure portal or PowerShell, and make sure the DHCP option inside the VM is enabled. Learn more about setting up a static IP address by using PowerShell. This will ensure that the IP configuration will always match what is configured on the VM in Azure.
- If you have multiple private IPs assigned to your VM's NIC, then ensure that you carefully follow the steps to assign the IP configurations correctly. After this, if the Guest Agent isn't able to communicate with 168.63.129.16, then please check that the primary IP in Windows matches the primary IP in your VM's NIC in Azure.
- Running the Azure Windows VM Agent in a nested virtualization VM might lead to unpredictable behavior, so it's not supported in that dev/test scenario.

Install the Azure Windows VM Agent

Azure Marketplace image

The Azure Windows VM Agent is installed by default on any Windows VM deployed from an Azure Marketplace image. When you deploy an Azure Marketplace image from the Azure portal, PowerShell, the Azure CLI, or an Azure Resource Manager template, the Azure Windows VM Agent is also installed.

The Azure Windows VM Agent package has two parts:

- Azure Windows Provisioning Agent (PA)
- Azure Windows Guest Agent (WinGA)

To boot a VM, you must have the PA installed on the VM. However, the WinGA does not need to be installed. At VM deploy time, you can select not to install the WinGA. The following example shows how to select the `provisionVmAgent` option with an Azure Resource Manager template:

JSON

```
{
    "resources": [{
        "name": ["parameters('virtualMachineName')"],
        "type": "Microsoft.Compute/virtualMachines",
        "apiVersion": "2016-04-30-preview",
        "location": ["parameters('location')"],
        "dependsOn": ["[concat('Microsoft.Network/networkInterfaces/',
parameters('networkInterfaceName'))]"],
        "properties": {
            "osProfile": {
                "computerName": ["parameters('virtualMachineName')"],
                "adminUsername": ["parameters('adminUsername')"],
                "adminPassword": ["parameters('adminPassword')"],
                "windowsConfiguration": {
                    "provisionVmAgent": "false"
                }
            }
        }
    }]
}
```

If you don't have the agents installed, you can't use some Azure services, such as Azure Backup or Azure Security. These services require an extension to be installed. If you deploy a VM without the WinGA, you can install the latest version of the agent later.

Manual installation

To manually install the Azure Windows VM Agent, download the installer and select the latest release. You can also search for a specific version in the GitHub page for Azure Windows VM Agent releases. The Azure Windows VM Agent is supported on Windows Server 2008 (64 bit) and later.

> **Note**

- If a VM was created from a custom or Marketplace image without `ProvisionVMAgent` enabled, then it is important to update the `AllowExtensionOperations` to `true` after you manually install the Azure Windows VM Agent.
- This is NOT required if the VM was created from a specialized disk. For example, if the VM was created directly from an existing disk.

PowerShell

```
$vm = Get-AzVM -Name <VM Name> -ResourceGroupName <Resource Group Name>
$vm.OSProfile.AllowExtensionOperations = $true
$vm | Update-AzVM
```

Detect the Azure Windows VM Agent

PowerShell

You can use the Azure Resource Manager PowerShell module to get information about Azure VMs. To see information about a VM, such as the provisioning state for the Azure Windows VM Agent, use Get-AzVM:

PowerShell

```
Get-AzVM
```

The following condensed example output shows the `ProvisionVMAgent` property nested inside `OSProfile`. You can use this property to determine if the VM agent has been deployed to the VM.

PowerShell

```
OSProfile                  :
  ComputerName             : myVM
  AdminUsername            : myUserName
  WindowsConfiguration     :
    ProvisionVMAgent       : True
    EnableAutomaticUpdates : True
```

Use the following script to return a concise list of VM names (running Windows OS) and the state of the Azure Windows VM Agent:

PowerShell

```
$vms = Get-AzVM

foreach ($vm in $vms) {
    $agent = $vm | Select -ExpandProperty OSProfile | Select -ExpandProperty
Windowsconfiguration | Select ProvisionVMAgent
    Write-Host $vm.Name $agent.ProvisionVMAgent
}
```

Use the following script to return a concise list of VM names (running Linux OS) and the state of the Azure Windows VM Agent:

PowerShell

```
$vms = Get-AzVM

foreach ($vm in $vms) {
    $agent = $vm | Select -ExpandProperty OSProfile | Select -ExpandProperty
Linuxconfiguration | Select ProvisionVMAgent
    Write-Host $vm.Name $agent.ProvisionVMAgent
}
```

Manual detection

When you're logged in to a Windows VM, you can use Task Manager to examine running processes. To check for the Azure Windows VM Agent, open Task Manager, select the **Details** tab, and look for a process named *WindowsAzureGuestAgent.exe*. The presence of this process indicates that the VM agent is installed.

Upgrade the Azure Windows VM Agent

The Azure Windows VM Agent for Windows is automatically upgraded on images deployed from Azure Marketplace. The new versions are stored in Azure Storage, so ensure that you don't have firewalls blocking access. As new VMs are deployed to Azure, they receive the latest VM agent at VM provision time. If you installed the agent manually or are deploying custom VM images, you need to manually update to include the new VM agent at image creation time.

Azure Windows Guest Agent automatic log collection

The Azure Windows Guest Agent has a feature to automatically collect some logs. The *CollectGuestLogs.exe* process controls this feature. It exists for both platform as a service (PaaS) cloud services and infrastructure as a service (IaaS) VMs. Its goal is to quickly and automatically collect diagnostics logs from a VM, so they can be used for offline analysis.

The collected logs are event logs, OS logs, Azure logs, and some registry keys. The agent produces a ZIP file that's transferred to the VM's host. Engineering teams and support professionals can then use this ZIP file to investigate issues on the request of the customer who owns the VM.

Azure Windows Guest Agent and OSProfile certificates

The Azure Windows VM Agent installs the certificates referenced in the `OSProfile` value of a VM or a virtual machine scale set. If you manually remove these certificates from the Microsoft Management Console (MMC) Certificates snap-in inside the guest VM, the Azure Windows Guest Agent will add them back. To permanently remove a certificate, you have to remove it from `OSProfile`, and then remove it from within the guest operating system.

For a virtual machine, use Remove-AzVMSecret to remove certificates from `OSProfile`.

For more information on certificates for virtual machine scale sets, see Azure Virtual Machine Scale Sets - How do I remove deprecated certificates?.

Next steps

For more information about VM extensions, see Azure virtual machine extensions and features.

Last updated on 12/08/2025

Azure Diagnostics Extension for Windows VMs

Applies to: ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Overview

The Azure Diagnostics VM extension enables you to collect monitoring data, such as performance counters and event logs, from your Windows VM. You can granularly specify what data you want to collect and where you want the data to go, such as an Azure Storage account or an Azure Event Hub. You can also use this data to build charts in the Azure portal or create metric alerts.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

Operating system

The Azure Diagnostics Extension can be run against Windows 10 Client, Windows Server 2008 R2, 2012, 2012 R2, and 2016.

Internet connectivity

The Azure Diagnostics Extension requires that the target virtual machine is connected to the internet.

Extension schema

The Azure Diagnostics Extension schema and property values are described in this document.

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Azure Diagnostics extension during an Azure Resource Manager template deployment. See Use monitoring and diagnostics with a Windows VM and Azure Resource Manager templates.

Azure CLI deployment

The Azure CLI can be used to deploy the Azure Diagnostics extension to an existing virtual machine. Replace the protected settings and settings properties with valid JSON from the extension schema above.

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name IaaSDiagnostics \
  --publisher Microsoft.Azure.Diagnostics \
  --version 1.9.0.0 --protected-settings protected-settings.json \
  --settings public-settings.json
```

PowerShell deployment

The `Set-AzVMDiagnosticsExtension` command can be used to add the Azure Diagnostics extension to an existing virtual machine. See also Use PowerShell to enable Azure Diagnostics in a virtual machine running Windows.

PowerShell

```
$vm_resourcegroup = "myvmresourcegroup"
$vm_name = "myvm"
$diagnosticsconfig_path = "DiagnosticsPubConfig.xml"

Set-AzVMDiagnosticsExtension -ResourceGroupName $vm_resourcegroup `
  -VMName $vm_name `
  -DiagnosticsConfigurationPath $diagnosticsconfig_path
```

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

See this article for a more comprehensive troubleshooting guide for the Azure Diagnostics extension.

Error: "Profile operation failed"

To enable profiling, please follow Enable Profiler for web apps on an Azure virtual machine.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to the Azure support site and select Get support. For information about using Azure Support, read the Microsoft Azure support FAQ.

Next Steps

- Learn more about the Azure Diagnostics Extension
- Review the extension schema and versions

Last updated on 12/02/2025

Azure Backup for SQL Server running in Azure VM

Azure Backup, amongst other offerings, provides support for backing up workloads such as SQL Server running in Azure VMs. Since the SQL application is running within an Azure VM, the backup service needs permission to access the application and fetch the necessary details. To do that, Azure Backup installs the **AzureBackupWindowsWorkload** extension on the VM, in which the SQL Server is running, during the registration process triggered by the user.

> ⓘ Note
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

For the list of supported scenarios, refer to the supportability matrix supported by Azure Backup.

Network connectivity

Azure Backup supports NSG Tags, deploying a proxy server or listed IP ranges; for details on each of the methods, refer this article.

Extension schema

The extension schema and property values are the configuration values (runtime settings) that service is passing to CRP API. These config values are used during registration and upgrade. **AzureBackupWindowsWorkload** extension also uses this schema. The schema is pre-set; a new parameter can be added in the objectStr field

JSON

```
    "runtimeSettings": [{
    "handlerSettings": {
    "protectedSettingsCertThumbprint": "",
    "protectedSettings": {
    "objectStr": "",
    "logsBlobUri": "",
    "statusBlobUri": ""
    }
    },
    "publicSettings": {
    "locale": "en-us",
    "taskId": "1c0ae461-9d3b-418c-a505-bb31dfe2095d",
    "objectStr": "",
    "commandStartTimeUTCTicks": "636295005824665976",
    "vmType": "vmType"
    }
    }]
    }
```

The following JSON shows the schema for the WorkloadBackup extension.

JSON

```
{
  "type": "extensions",
  "name": "WorkloadBackup",
  "location":"<myLocation>",
  "properties": {
    "publisher": "Microsoft.RecoveryServices",
    "type": "AzureBackupWindowsWorkload",
    "typeHandlerVersion": "1.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "locale":"<location>",
      "taskId":"<TaskId used by Azure Backup service to communicate with extension>",

      "objectStr": "<The configuration passed by Azure Backup service to extension>",

      "commandStartTimeUTCTicks": "<Scheduled start time of registration or upgrade task>",
      "vmType": "<Type of VM where registration got triggered Eg. Compute or ClassicCompute>"
```

```
    },
    "protectedSettings": {
      "objectStr": "<The sensitive configuration passed by Azure Backup service to extension>",
      "logsBlobUri": "<blob uri where logs of command execution by extension are written to>",
      "statusBlobUri": "<blob uri where status of the command executed by extension is written>"
    }
  }
}
```

Property values

Expand table

Name	Value/example
locale	en-us

statusBlobUri	https://seapod01coord1exsapk732.blob.core.windows.net/bcdrextensionlogs-111111111-1111-1111-1111-111111111111/vmubuntu1404lt

Template deployment

We recommended adding AzureBackupWindowsWorkload extension to a virtual machine is by enabling SQL Server backup on the virtual machine. This can be achieved through the Resource Manager template designed for automating backup on a SQL Server VM.

PowerShell deployment

You need to 'register' the Azure VM that contains the SQL application with a Recovery services vault. During registration, AzureBackupWindowsWorkload extension gets installed on the VM. Use Register-AzRecoveryServicesBackupContainerPS cmdlet to register the VM. Replace `VMRG Name` and `VMName` with the target resource group name and VM name.

PowerShell

```
$myVM = Get-AzVM -ResourceGroupName <VMRG Name> -Name <VMName>
Register-AzRecoveryServicesBackupContainer -ResourceId $myVM.ID -BackupManagementType AzureWorkload -WorkloadType MSSQL -VaultId
$targetVault.ID -Force
```

The command will return a **backup container** of this resource and the status will be **registered**.

Next steps

- Learn More about Azure SQL Server VM backup troubleshooting guidelines
- Common questions about backing up SQL Server databases that run on Azure virtual machines (VMs) and that use the Azure Backup service.

Last updated on 11/10/2025

Azure Disk Encryption for Linux (Microsoft.Azure.Security.AzureDiskEncryptionForLinux)

Overview

Azure Disk Encryption leverages the dm-crypt subsystem in Linux to provide full disk encryption on select Azure Linux distributions. This solution is integrated with Azure Key Vault to manage disk encryption keys and secrets.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

For a full list of prerequisites, see Azure Disk Encryption for Linux VMs, specifically the following sections:

- Supported VMs and operating systems
- Additional VM requirements
- Networking requirements
- Encryption key storage requirements

Extension Schema

There are two versions of extension schema for Azure Disk Encryption (ADE):

- v1.1 - A newer recommended schema that does not use Microsoft Entra properties.
- v0.1 - An older schema that requires Microsoft Entra properties.

To select a target schema, the `typeHandlerVersion` property must be set equal to version of schema you want to use.

Schema v1.1: No Microsoft Entra ID (recommended)

The v1.1 schema is recommended and does not require Microsoft Entra properties.

> **Note**
>
> The `DiskFormatQuery` parameter is deprecated. Its functionality has been replaced by the EncryptFormatAll option instead, which is the recommended way to format data disks at time of encryption.

JSON

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
        "publisher": "Microsoft.Azure.Security",
        "type": "AzureDiskEncryptionForLinux",
        "typeHandlerVersion": "1.1",
        "autoUpgradeMinorVersion": true,
        "settings": {
          "DiskFormatQuery": "[diskFormatQuery]",
          "EncryptionOperation": "[encryptionOperation]",
          "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
          "KeyVaultURL": "[keyVaultURL]",
          "KeyVaultResourceId": "[KeyVaultResourceId]",
          "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
          "KekVaultResourceId": "[KekVaultResourceId",
          "SequenceVersion": "sequenceVersion]",
          "VolumeType": "[volumeType]"
        }
  }
}
```

Schema v0.1: with Microsoft Entra ID

The 0.1 schema requires `AADClientID` and either `AADClientSecret` or `AADClientCertificate`.

Using `AADClientSecret`:

JSON

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
```

```
    "protectedSettings": {
      "AADClientSecret": "[aadClientSecret]",
      "Passphrase": "[passphrase]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryptionForLinux",
    "typeHandlerVersion": "0.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "DiskFormatQuery": "[diskFormatQuery]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KeyVaultURL": "[keyVaultURL]",
      "SequenceVersion": "sequenceVersion]",
      "VolumeType": "[volumeType]"
    }
  }
}
```

Using `AADClientCertificate`:

JSON

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientCertificate": "[aadClientCertificate]",
      "Passphrase": "[passphrase]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryptionForLinux",
    "typeHandlerVersion": "0.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "DiskFormatQuery": "[diskFormatQuery]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KeyVaultURL": "[keyVaultURL]",
      "SequenceVersion": "sequenceVersion]",
      "VolumeType": "[volumeType]"
    }
  }
}
```

Property values

Note: All property values are case sensitive.

Expand table

Name	Value / Example	Data Type
apiVersion	2019-07-01	date
publisher	Microsoft.Azure.Security	string
type	AzureDiskEncryptionForLinux	string
typeHandlerVersion	1.1, 0.1	int
(0.1 schema) AADClientID	xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx	guid
(0.1 schema) AADClientSecret	password	string
(0.1 schema) AADClientCertificate	thumbprint	string
(optional) (0.1 schema) Passphrase	password	string
DiskFormatQuery	{"dev_path":"","name":"","file_system":""}	JSON dictionary
EncryptionOperation	EnableEncryption, EnableEncryptionFormatAll	string
(optional - default RSA-OAEP) KeyEncryptionAlgorithm	'RSA-OAEP', 'RSA-OAEP-256', 'RSA1_5'	string
KeyVaultURL	url	string
KeyVaultResourceId	url	string
(optional) KeyEncryptionKeyURL	url	string
(optional) KekVaultResourceId	url	string
(optional) SequenceVersion	uniqueidentifier	string
VolumeType	OS, Data, All	string

Template deployment

For an example of template deployment based on schema v1.1, see the Azure Quickstart Template encrypt-running-linux-vm-without-aad.

For an example of template deployment based on schema v0.1, see the Azure Quickstart Template encrypt-running-linux-vm.

> ⚠ **Warning**
>
> - If you have previously used Azure Disk Encryption with Microsoft Entra ID to encrypt a VM, you must continue use this option to encrypt your VM.
> - When encrypting Linux OS volumes, the VM should be considered unavailable. We strongly recommend to avoid SSH logins while the encryption is in progress to avoid issues blocking any open files that will need to be accessed during the encryption process. To check progress, use the **Get-AzVMDiskEncryptionStatus** PowerShell cmdlet or the **vm encryption show** CLI command. This process can be expected to take a few hours for a 30GB OS volume, plus additional time for encrypting data volumes. Data volume encryption time will be proportional to the size and quantity of the data volumes; the `encrypt format all` option is faster than in-place encryption, but will result in the loss of all data on the disks.
> - Disabling encryption on Linux VMs is only supported for data volumes. It is not supported on data or OS volumes if the OS volume has been encrypted.

> ⓘ **Note**
>
> Also if `VolumeType` parameter is set to All, data disks will be encrypted only if they are properly mounted.

Troubleshoot and support

Troubleshoot

For troubleshooting, refer to the Azure Disk Encryption troubleshooting guide.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums.

Alternatively, you can file an Azure support incident. Go to Azure support and select Get support. For information about using Azure Support, read the Microsoft Azure Support FAQ.

Next steps

- For more information about VM extensions, see Virtual machine extensions and features for Linux.
- For more information about Azure Disk Encryption for Linux, see Linux virtual machines.

Azure Disk Encryption for Windows (Microsoft.Azure.Security.AzureDiskEncryption)

Overview

Azure Disk Encryption uses BitLocker to provide full disk encryption on Azure virtual machines running Windows. This solution is integrated with Azure Key Vault to manage disk encryption keys and secrets in your key vault subscription.

> ⓘ **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

For a full list of prerequisites, see Azure Disk Encryption for Windows VMs, specifically the following sections:

- Supported VMs and operating systems
- Networking requirements
- Group Policy requirements

Extension Schema

There are two versions of extension schema for Azure Disk Encryption (ADE):

- v2.2 - A newer recommended schema that does not use Microsoft Entra properties.
- v1.1 - An older schema that requires Microsoft Entra properties.

To select a target schema, the `typeHandlerVersion` property must be set equal to version of schema you want to use.

Schema v2.2: No Microsoft Entra ID (recommended)

The v2.2 schema is recommended for all new VMs and does not require Microsoft Entra properties.

JSON

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
        "publisher": "Microsoft.Azure.Security",
        "type": "AzureDiskEncryption",
        "typeHandlerVersion": "2.2",
        "autoUpgradeMinorVersion": true,
        "settings": {
          "EncryptionOperation": "[encryptionOperation]",
          "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
          "KeyVaultURL": "[keyVaultURL]",
          "KeyVaultResourceId": "[keyVaultResourceID]",
          "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
          "KekVaultResourceId": "[kekVaultResourceID]",
          "SequenceVersion": "sequenceVersion]",
          "VolumeType": "[volumeType]"
        }
  }
}
```

Schema v1.1: with Microsoft Entra ID

The 1.1 schema requires `aadClientID` and either `aadClientSecret` or `AADClientCertificate` and is not recommended for new VMs.

Using `aadClientSecret`:

JSON

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientSecret": "[aadClientSecret]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryption",
    "typeHandlerVersion": "1.1",
    "settings": {
```

```
      "AADClientID": "[aadClientID]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyVaultURL": "[keyVaultURL]",
      "KeyVaultResourceId": "[keyVaultResourceID]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KekVaultResourceId": "[kekVaultResourceID]",
      "SequenceVersion": "sequenceVersion]",
      "VolumeType": "[volumeType]"
    }
  }
}
```

Using `AADClientCertificate`:

JSON

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientCertificate": "[aadClientCertificate]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryption",
    "typeHandlerVersion": "1.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyVaultURL": "[keyVaultURL]",
      "KeyVaultResourceId": "[keyVaultResourceID]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KekVaultResourceId": "[kekVaultResourceID]",
      "SequenceVersion": "sequenceVersion]",
      "VolumeType": "[volumeType]"
    }
  }
}
```

Property values

Note: All values are case sensitive.

Template deployment

For an example of template deployment based on schema v2.2, see Azure Quickstart Template encrypt-running-windows-vm-without-aad.

For an example of template deployment based on schema v1.1, see Azure Quickstart Template encrypt-running-windows-vm.

> **Note**
>
> Also if `VolumeType` parameter is set to All, data disks will be encrypted only if they are properly formatted.

Troubleshoot and support

Troubleshoot

For troubleshooting, refer to the Azure Disk Encryption troubleshooting guide.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums.

Alternatively, you can file an Azure support incident. Go to Azure support and select Get support. For information about using Azure Support, read the Microsoft Azure Support FAQ.

Next steps

- For more information about extensions, see Virtual machine extensions and features for Windows.
- For more information about Azure Disk Encryption for Windows, see Windows virtual machines.

Last updated on 11/10/2025

Key Vault virtual machine extension for Linux

Summarize this article for me

The Key Vault VM extension provides automatic refresh of certificates stored in an Azure key vault. Specifically, the extension monitors a list of observed certificates stored in key vaults. The extension retrieves and installs the corresponding certificates after detecting a change. This document details the supported platforms, configurations, and deployment options for the Key Vault VM extension for Linux.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Operating system

The Key Vault VM extension supports:

- Ubuntu 22.04 and later
- Azure Linux

Supported certificate content types

- PKCS #12
- PEM

Features

Key Vault VM extension for Linux version 3.0+ supports:

- Add ACL permissions for downloaded certificates to provide read access for users and groups
- Certificate installation location configuration
- Custom symbolic name support
- VM extension logging integration support through Fluentd

Prerequisites

- Key Vault instance with certificate. See Create a Key Vault

- Assigned managed identity on virtual machines/virtual machine scale sets.
- The **Key Vault Secrets User** role at the Key Vault scope level for VMs and Azure Virtual Machine Scale Sets managed identity. This role retrieves a secret's portion of a certificate. For more information, see the following articles:
  - Authentication in Azure Key Vault
  - Use Azure RBAC secret, key, and certificate permissions with Azure Key Vault
  - Key Vault scope role assignment
- Virtual machine scale sets should have the following identity setting: `"identity": { "type": "UserAssigned", "userAssignedIdentities": { "[parameters('userAssignedIdentityResourceId')]": {} } }`
- AKV extension should have this setting: `"authenticationSettings": { "msiEndpoint": "[parameters('userAssignedIdentityEndpoint')]", "msiClientId": "[reference(parameters('userAssignedIdentityResourceId'), variables('msiApiVersion')).clientId]" }`

Upgrading Key Vault VM extension

- If you need to upgrade from an older version to version 3.0+, you would need to delete previous version first, then install version 3.0.

Azure CLI

```
  az vm extension delete --name KeyVaultForLinux --resource-group ${resourceGroup} --vm-name ${vmName}
  az vm extension set -n "KeyVaultForLinux" --publisher Microsoft.Azure.KeyVault --resource-group "${resourceGroup}" --vm-name "${vmName}" -settings .\akvvm.json -version 3.0
```

- If the VM has certificates downloaded by previous version, deleting VM extension doesn't delete the downloaded certificates. After installing the newer version, the existing certificates aren't modified. You would need to delete the certificate files or roll-over the certificate to get the PEM file with full-chain on the VM.

Extension schema

The following JSON provides the schema for the Key Vault VM extension. All settings are specified as plain (unprotected) settings, as none are considered sensitive. To configure the extension, you must specify a list of certificates to monitor, how often to poll for updates, and the destination path for storing certificates. Specifically:

JSON

```
    {
      "type": "Microsoft.Compute/virtualMachines/extensions",
      "name": "KVVMExtensionForLinux",
      "apiVersion": "2022-11-01",
      "location": "<location>",
      "dependsOn": [
          "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
      ],
      "properties": {
      "publisher": "Microsoft.Azure.KeyVault",
      "type": "KeyVaultForLinux",
      "typeHandlerVersion": "3.0",
      "autoUpgradeMinorVersion": true,
      "enableAutomaticUpgrade": true,
      "settings": {
      "loggingSettings": <Optional logging settings, e.g.:
        {
              "logger": <Logger engine name. e.g.: "fluentd">,
              "endpoint": <Logger listening endpoint "tcp://localhost:24224">,
              "format": <Logging format. e.g.: "forward">,
              "servicename": <Service name used in logs. e.g.: "akvvm_service">
        }>,
        "secretsManagementSettings": {
          "pollingIntervalInS": <polling interval in seconds, e.g. "3600">,
          "linkOnRenewal": <Not available on Linux e.g.: false>,
          "requireInitialSync": <initial synchronization of certificates e..g: true>,
          "aclEnabled": <Enables ACLs for downloaded certificates, e.g.: true>,
          "observedCertificates": <An array of KeyVault URIs that represent monitored
certificates, including certificate store location, ACL permission to certificate private
key, and custom symbolic name. e.g.:
             [
                {
                    "url": <A Key Vault URI to the secret portion of the certificate.
e.g.: "https://myvault.vault.azure.net/secrets/mycertificate1">,
                    "certificateStoreLocation": <disk path where certificate is stored,
e.g.: "/var/lib/waagent/Microsoft.Azure.KeyVault/app1">,
                    "customSymbolicLinkName": <symbolic name for the certificate. e.g.:
"app1Cert1">,
                    "acls": [
                        {
                            "user": "app1",
                            "group": "appGroup1"
                        },
                        {
                            "user": "service1"
                        }
                    ]
                },
                {
                    "url": <Example:
"https://myvault.vault.azure.net/secrets/mycertificate2">,
                    "certificateStoreLocation": <disk path where the certificate is
stored, e.g.: "/var/lib/waagent/Microsoft.Azure.KeyVault/app2">,
                    "acls": [
                        {
                            "user": "app2",
                        }
```

```
                    ]
                }
            ]>
        },
        "authenticationSettings": <Optional msi settings, e.g.:
        {
          "msiEndpoint":  <Required when msiClientId is provided. MSI endpoint e.g. for
most Azure VMs: "http://169.254.169.254/metadata/identity">,
          "msiClientId":  <Required when VM has any user assigned identities. MSI
identity e.g.: "00001111-aaaa-2222-bbbb-3333cccc4444".>
        }>
       }
      }
    }
```

> **Note**
>
> Your observed certificates URLs should be of the form `https://myVaultName.vault.azure.net/secrets/myCertName`.
>
> This is because the `/secrets` path returns the full certificate, including the private key, while the `/certificates` path doesn't. More information about certificates can be found here: Key Vault Certificates

> **Important**
>
> The `authenticationSettings` property is required only when your VM or VM scale set uses **user-assigned managed identities** or when using **Azure Arc-enabled VMs**. For **system-assigned managed identities**, omit the `authenticationSettings` section. Including it will cause deployment to fail. Without this section, a VM with user assigned identities will result in the Key Vault extension failing and being unable to download certificates. Set `msiClientId` to the identity that will authenticate to Key Vault.
>
> Also **required** for **Azure Arc-enabled VMs**. Set msiEndpoint to `http://localhost:40342/metadata/identity`.

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment refresh of certificates.

The extension can be deployed to individual VMs or virtual machine scale sets. The schema and configuration are common to both template types.

> **Note**
>
> The VM extension would require system or user managed identity to be assigned to authenticate to Key vault. See How to authenticate to Key Vault and assign a Key Vault access policy.

JSON

```
   {
      "type": "Microsoft.Compute/virtualMachines/extensions",
      "name": "KeyVaultForLinux",
      "apiVersion": "2022-11-01",
      "location": "<location>",
      "dependsOn": [
          "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
      ],
      "properties": {
      "publisher": "Microsoft.Azure.KeyVault",
      "type": "KeyVaultForLinux",
      "typeHandlerVersion": "3.0",

                    [
                        {
                            "user": "app2"
                        }
                    ]>
                }

            ]>
        },
        "authenticationSettings": {
            "msiEndpoint":  <Required when msiClientId is provided. MSI endpoint e.g.
for most Azure VMs: "http://169.254.169.254/metadata/identity">,
            "msiClientId":  <Required when VM has any user assigned identities. MSI
identity e.g.: "00001111-aaaa-2222-bbbb-3333cccc4444">
        }
      }
    }
  }
```

Extension Dependency Ordering

The Key Vault VM extension supports extension ordering if configured. By default the extension reports successful start as soon as polling starts. However, you can configure it to wait until it successfully downloads the complete list of certificates before reporting a successful start. If other extensions depend on installed certificates before they start, then enabling this setting will allow those extensions to declare a dependency on the Key Vault extension. This will prevent those extensions from starting until all certificates they depend on have been installed.

The extension will retry the initial download up to 25 times with increasing backoff periods, during which it remains in a `Transitioning` state. If the retries are exhausted, the extension will report an `Error` state.

To turn on extension dependency, set the following:

```
"secretsManagementSettings": {
    "requireInitialSync": true,
    ...
}
```

> ⓘ Note

Using this feature is not compatible with an ARM template that creates a system assigned identity and updates a Key Vault access policy with that identity. Doing so will result in a deadlock as the vault access policy cannot be updated until all extensions have started. You should instead use a *single user assigned MSI identity* and pre-ACL your vaults with that identity before deploying.

Azure PowerShell deployment

> ⚠ **Warning**
>
> PowerShell clients often add `\` to `"` in the settings.json which will cause akvvm_service fails with error: `[CertificateManagementConfiguration] Failed to parse the configuration settings with:not an object.`

The Azure PowerShell can be used to deploy the Key Vault VM extension to an existing virtual machine or virtual machine scale set.

- To deploy the extension on a VM:

The Azure Key Vault VM extension can be deployed with Azure PowerShell. Save Key Vault VM extension settings to a JSON file (settings.json).

The following JSON snippets provide example settings for deploying the Key Vault VM extension with PowerShell.

JSON

```
{
   "secretsManagementSettings": {
   "pollingIntervalInS": "3600",
   "linkOnRenewal": true,
   "aclEnabled": true,
   "observedCertificates":
   [
      {
          "url": "https://<examplekv>.vault.azure.net/secrets/mycertificate1",
          "certificateStoreLocation":  "/var/lib/waagent/Microsoft.Azure.KeyVault.Store",
          "acls":
          [
              {
                  "user": "app1",
                  "group": "appGroup1"
              },
              {
                  "user": "service1"
              }
          ]
      },
```

```
        {
            "url": "https://<examplekv>.vault.azure.net/secrets/mycertificate2",
            "certificateStoreLocation": "/var/lib/waagent/Microsoft.Azure.KeyVault.Store",
            "acls":
            [
                {
                    "user": "app2"
                }
            ]
        }
    ]},
    "authenticationSettings": {
        "msiEndpoint":  "http://169.254.169.254/metadata/identity/oauth2/token",
        "msiClientId":  "xxxxxx-xxxx-xxxx-xxxx-xxxxxxxx"
    }
}
```

- To deploy the extension on a virtual machine:

PowerShell

```
# Build settings
$settings = (get-content -raw ".\settings.json")
$extName =  "KeyVaultForLinux"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForLinux"

# Start the deployment
Set-AzVmExtension -TypeHandlerVersion "3.0" -ResourceGroupName <ResourceGroupName> -
Location <Location> -VMName <VMName> -Name $extName -Publisher $extPublisher -Type
$extType -SettingString $settings
```

- To deploy the extension on a virtual machine scale set:

PowerShell

```
    # Build settings
    $settings = (get-content -raw ".\settings.json")
    $extName = "KeyVaultForLinux"
    $extPublisher = "Microsoft.Azure.KeyVault"
    $extType = "KeyVaultForLinux"

    # Add extension to Virtual Machine Scale Sets
    $vmss = Get-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName>
    Add-AzVmssExtension -VirtualMachineScaleSet $vmss  -Name $extName -Publisher
$extPublisher -Type $extType -TypeHandlerVersion "3.0" -Setting $settings

    # Start the deployment
    Update-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName> -
VirtualMachineScaleSet $vmss
```

Azure CLI deployment

The Azure CLI can be used to deploy the Key Vault VM extension to an existing virtual machine or virtual machine scale set.

- To deploy the extension on a VM:

The Azure Key Vault VM extension can be deployed by using the Azure CLI. Save Key Vault VM extension settings to a JSON file (settings.json).

The following JSON snippets provide example settings for deploying the Key Vault VM extension with the Azure CLI.

JSON

```
{
   "secretsManagementSettings": {
   "pollingIntervalInS": "3600",
   "linkOnRenewal": true,
   "aclEnabled": true,
   "observedCertificates":
   [
      {
          "url": "https://<examplekv>.vault.azure.net/secrets/mycertificate1",
          "certificateStoreLocation":  "/var/lib/waagent/Microsoft.Azure.KeyVault.Store",
          "acls":
          [
              {
                  "user": "app1",
                  "group": "appGroup1"
              },
              {
                  "user": "service1"
              }
          ]
      },
      {
          "url": "https://<examplekv>.vault.azure.net/secrets/mycertificate2",
          "certificateStoreLocation": "/var/lib/waagent/Microsoft.Azure.KeyVault.Store",
          "acls":
          [
              {
                  "user": "app2"
              }
          ]
      }
   ]},
   "authenticationSettings": {
      "msiEndpoint":  "http://169.254.169.254/metadata/identity/oauth2/token",
      "msiClientId":  "xxxxxx-xxxx-xxxx-xxxx-xxxxxxxx"
   }
}
```

- To deploy the extension on a virtual machine

Azure CLI

```
# Start the deployment
  az vm extension set -n "KeyVaultForLinux" `
  --publisher Microsoft.Azure.KeyVault `
  -g "<resourcegroup>" `
  --vm-name "<vmName>" `
  --version 3.0 `
  --enable-auto-upgrade true `
  --settings "@settings.json"
```

- To deploy the extension on a virtual machine scale set:

Azure CLI

```
# Start the deployment
az vmss extension set -n "KeyVaultForLinux" `
--publisher Microsoft.Azure.KeyVault `
-g "<resourcegroup>" `
--vmss-name "<vmssName>" `
--version 3.0 `
--enable-auto-upgrade true `
--settings "@settings.json"
```

Please be aware of the following restrictions/requirements:

- Key Vault restrictions:
  - It must exist at the time of the deployment
  - The Key Vault Secrets User role must be assigned to Key Vault for VM identity

Troubleshoot and Support

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure PowerShell. To see the deployment state of extensions for a given VM, run the following command using the Azure PowerShell.

Azure PowerShell

PowerShell

```
Get-AzVMExtension -VMName <vmName> -ResourceGroupname <resource group name>
```

Azure CLI

Azure CLI

```
 az vm get-instance-view --resource-group <resource group name> --name  <vmName> --query "instanceView.extensions"
```

The Azure CLI can run in several shell environments, but with slight format variations. If you have unexpected results with Azure CLI commands, see How to use the Azure CLI successfully.

Logs and configuration

The Key Vault VM extension logs exist locally on the VM and are most informative when it comes to troubleshooting. You can use optional logging section to integrate with logging provider through `fluentd`

Expand table

Location	Description
/var/log/waagent.log	Shows when an update to the extension occurred.
/var/log/azure/Microsoft.Azure.KeyVault.KeyVaultForLinux/*	Examine the Key Vault VM Extension service logs to determine the status of the akvvm_service service and certificate download. You can find the download location of PEM files in files with an entry called certificate file name. If certificateStoreLocation is not specified, it will default to /var/lib/waagent/Microsoft.Azure.KeyVault.Store/
/var/lib/waagent/Microsoft.Azure.KeyVault.KeyVaultForLinux-<most recent version>/config/*	The configuration and binaries for Key Vault VM Extension service.

Using Symlink

Symbolic links or Symlinks are advanced shortcuts. To avoid monitoring the folder and to get the latest certificate automatically, you can use this symlink `([VaultName].[CertificateName])` to get the latest version of certificate on Linux.

Certificate Installation on Linux

The Key Vault VM extension for Linux installs certificates as PEM files. When a certificate is downloaded from Key Vault, the extension:

1. Creates a storage folder based on the `certificateStoreLocation` setting (defaults to `/var/lib/waagent/Microsoft.Azure.KeyVault.Store/` if not specified)

2. Installs the certificate chain and private key as stored in Key Vault. The PEM file follows RFC 5246 section 7.4.2 ordering:
    - Leaf certificate (end-entity certificate) comes first
    - Intermediate certificate(s) follow in order, where each certificate directly certifies the one before it (if present in Key Vault)
    - Root certificate, if present (though it's not required for validation if already trusted by the system)
    - Private key, corresponding to the leaf certificate, is placed at the end of the file
3. Automatically creates a symbolic link named `[VaultName].[CertificateName]` that points to the latest version of the certificate

This approach ensures that:

- Applications have access to the certificate chain as stored in Key Vault
- The certificate chain is properly ordered for TLS handshakes according to RFC standards
- The private key is available for use by the service
- Applications can reference a stable symbolic link path that automatically updates when certificates are renewed
- No application reconfiguration is needed when certificates are rotated or renewed

Example Certificate Path Structure

For a certificate from `exampleVault.vault.azure.net` with the name `myCertificate`, the directory structure would look like:

```
/var/lib/waagent/Microsoft.Azure.KeyVault.Store/
├── exampleVault.myCertificate -> exampleVault.myCertificate.1234567890abcdef
├── exampleVault.myCertificate.1234567890abcdef    # Full chain PEM file (current
version)
└── exampleVault.myCertificate.0987654321fedcba    # Previous version (if exists)
```

Applications should be configured to use the symbolic link path (`/var/lib/waagent/Microsoft.Azure.KeyVault.Store/exampleVault.myCertificate`) to ensure they always access the most current certificate version.

When you use custom certificate store locations and the `customSymbolicLinkName` setting, the structure follows this pattern:

```
/path/to/custom/store/
├── customLinkName -> exampleVault.myCertificate.1234567890abcdef
```

```
└── exampleVault.myCertificate.1234567890abcdef    # Full chain PEM file
```

Frequently Asked Questions

- Is there's a limit on the number of observedCertificates you can configure? No, Key Vault VM Extension doesn't have limit on the number of observedCertificates.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to the Azure support site and select Get support. For information about using Azure Support, read the Microsoft Azure support FAQ.

Azure Key Vault virtual machine extension for Windows

The Azure Key Vault virtual machine (VM) extension provides automatic refresh of certificates stored in an Azure key vault. The extension monitors a list of observed certificates stored in key vaults. When it detects a change, the extension retrieves and installs the corresponding certificates. This article describes the supported platforms, configurations, and deployment options for the Key Vault VM extension for Windows.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Operating systems

The Key Vault VM extension supports Windows Server 2019 and later. The Key Vault VM extension is also supported on a custom local VM. The VM should be uploaded and converted into a specialized image for use in Azure by using Windows Server 2019 core install.

Supported certificates

The Key Vault VM extension supports the following certificate content types:

- PKCS #12
- PEM

> **Note**
>
> The Key Vault VM extension downloads all certificates to the Windows certificate store or to the location specified in the `certificateStoreLocation` property in the VM extension settings.

Features

The Key Vault VM extension for Windows version 3.0 supports:

- Add ACL permissions to downloaded certificates
- Enable Certificate Store configuration per certificate

- Export private keys
- IIS Certificate Rebind support

Prerequisites

Review the following prerequisites for using the Key Vault VM extension for Windows:

- An Azure Key Vault instance with a certificate. For more information, see Create a key vault by using the Azure portal.
- A VM with an assigned managed identity.
- The **Key Vault Secrets User** role must be assigned at the Key Vault scope level for VMs and Azure Virtual Machine Scale Sets managed identity. This role retrieves a secret's portion of a certificate. For more information, see the following articles:
  - Authentication in Azure Key Vault
  - Use Azure RBAC secret, key, and certificate permissions with Azure Key Vault
  - Key Vault scope role assignment
- Virtual Machine Scale Sets should have the following `identity` configuration:

  JSON

  ```
  "identity": {
     "type": "UserAssigned",
     "userAssignedIdentities": {
        "[parameters('userAssignedIdentityResourceId')]": {}
     }
  }
  ```

- The Key Vault VM extension should have the following `authenticationSettings` configuration:

  JSON

  ```
  "authenticationSettings": {
      "msiEndpoint": "[parameters('userAssignedIdentityEndpoint')]",
      "msiClientId": "[reference(parameters('userAssignedIdentityResourceId'),
  variables('msiApiVersion')).clientId]"
  }
  ```

> **Note**
>
> The old access policy permission model can also be used to provide access to VMs and Virtual Machine Scale Sets. This method requires policy with **get** and **list** permissions on secrets. For more information, see Assign a Key Vault access policy.

Extension schema

The following JSON shows the schema for the Key Vault VM extension. Before you consider the schema implementation options, review the following important notes.

- The extension doesn't require protected settings. All settings are considered public information.
- Observed certificates URLs should be of the form `https://myVaultName.vault.azure.net/secrets/myCertName`.

  This form is preferred because the `/secrets` path returns the full certificate, including the private key, but the `/certificates` path doesn't. For more information about certificates, see Azure Key Vault keys, secrets and certificates overview.
- The `authenticationSettings` property is **required** for VMs with any **user assigned identities**.

  This property specifies the identity to use for authentication to Key Vault. Define this property with a system-assigned identity to avoid issues with a VM extension with multiple identities.

JSON

```
{
   "type": "Microsoft.Compute/virtualMachines/extensions",
   "name": "KVVMExtensionForWindows",
   "apiVersion": "2022-08-01",
   "location": "<location>",
   "dependsOn": [
      "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
   ],
   "properties": {
      "publisher": "Microsoft.Azure.KeyVault",
      "type": "KeyVaultForWindows",
      "typeHandlerVersion": "3.0",
      "autoUpgradeMinorVersion": true,
      "settings": {
         "secretsManagementSettings": {
             "pollingIntervalInS": <A string that specifies the polling interval in seconds. Example: "3600">,
             "linkOnRenewal": <Windows only. Ensures s-channel binding when the certificate renews without necessitating redeployment. Example: true>,
             "requireInitialSync": <Initial synchronization of certificates. Example: true>,
             "observedCertificates": <An array of KeyVault URIs that represent monitored certificates, including certificate store location and ACL permission to certificate private key. Example:
             [
                {
                    "url": <A Key Vault URI to the secret portion of the certificate. Example: "https://myvault.vault.azure.net/secrets/mycertificate1">,
                    "certificateStoreName": <The certificate store name. Example: "MY">,
                    "certificateStoreLocation": <The certificate store location, which currently works locally only. Example: "LocalMachine">,
                    "accounts": <Optional. An array of preferred accounts with read access to certificate private keys. Administrators and SYSTEM get Full Control by default. Example: ["Network Service", "Local Service"]>
                },
                {
                    "url": <Example:
```

```
"https://myvault.vault.azure.net/secrets/mycertificate2">,
                    "certificateStoreName": <Example: "MY">,
                    "certificateStoreLocation": <Example: "CurrentUser">,
                    "keyExportable": <Optional. Lets the private key be exportable. Example:
"false">,
                    "accounts": <Example: ["Local Service"]>
                }
            ]>
        },
        "authenticationSettings": {
            "msiEndpoint":  <Required when the msiClientId property is used. Specifies the
MSI endpoint. Example for most Azure VMs:
"http://169.254.169.254/metadata/identity/oauth2/token">,
            "msiClientId":  <Required when the VM has any user assigned identities.
Specifies the MSI identity. Example:  "00001111-aaaa-2222-bbbb-3333cccc4444">
        }
    }
  }
}
```

Property values

The JSON schema includes the following properties.

Expand table

Name	Value/Example	Data type
`apiVersion`	2022-08-01	date
`publisher`	Microsoft.Azure.KeyVault	string
`type`	KeyVaultForWindows	string
`typeHandlerVersion`	"3.0"	string
`pollingIntervalInS`	"3600"	string
`linkOnRenewal` (optional)	true	boolean
`requireInitialSync` (optional)	false	boolean
`observedCertificates`	[{...}, {...}]	string array
`observedCertificates/url`	"https://myvault.vault.azure.net/secrets/mycertificate"	string
`observedCertificates/certificateStoreName`	MY	string
`observedCertificates/certificateStoreLocation`	LocalMachine or CurrentUser (case sensitive)	string
`observedCertificates/keyExportable` (optional)	false	boolean

Name	Value/Example	Data type
`observedCertificates/accounts` (optional)	["Network Service", "Local Service"]	string array
`msiEndpoint`	"http://169.254.169.254/metadata/identity/oauth2/token"	string
`msiClientId`	00001111-aaaa-2222-bbbb-3333cccc4444	string

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager (ARM) templates. Templates are ideal when deploying one or more virtual machines that require post deployment refresh of certificates. The extension can be deployed to individual VMs or Virtual Machine Scale Sets instances. The schema and configuration are common to both template types.

The JSON configuration for a key vault extension is nested inside the VM or Virtual Machine Scale Sets template. For a VM resource extension, the configuration is nested under the `"resources": []` virtual machine object. For a Virtual Machine Scale Sets instance extension, the configuration is nested under the `"virtualMachineProfile":"extensionProfile":{"extensions" :[]` object.

The following JSON snippets provide example settings for an ARM template deployment of the Key Vault VM extension.

JSON

```
{
   "type": "Microsoft.Compute/virtualMachines/extensions",
   "name": "KeyVaultForWindows",
   "apiVersion": "2022-08-01",
   "location": "<location>",
   "dependsOn": [
      "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
   ],
   "properties": {
      "publisher": "Microsoft.Azure.KeyVault",
      "type": "KeyVaultForWindows",
      "typeHandlerVersion": "3.0",
      "autoUpgradeMinorVersion": true,
      "settings": {
         "secretsManagementSettings": {
             "pollingIntervalInS": <A string that specifies the polling interval in seconds.
Example: "3600">,
             "linkOnRenewal": <Windows only. Ensures s-channel binding when the certificate
renews without necessitating redeployment. Example: true>,
             "observedCertificates": <An array of KeyVault URIs that represent monitored
certificates, including certificate store location and ACL permission to certificate private
key. Example:
             [
                {
                    "url": <A Key Vault URI to the secret portion of the certificate.
Example: "https://myvault.vault.azure.net/secrets/mycertificate1">,
```

```
                    "certificateStoreName": <The certificate store name. Example: "MY">,
                    "certificateStoreLocation": <The certificate store location, which
currently works locally only. Example: "LocalMachine">,
                    "accounts": <Optional. An array of preferred accounts with read access
to certificate private keys. Administrators and SYSTEM get Full Control by default. Example:
["Network Service", "Local Service"]>
                },
                {
                    "url": <Example:
"https://myvault.vault.azure.net/secrets/mycertificate2">,
                    "certificateStoreName": <Example: "MY">,
                    "certificateStoreLocation": <Example: "CurrentUser">,
                    "keyExportable": <Optional. Lets the private key be exportable. Example:
"false">,
                    "accounts": <Example: ["Local Service"]>
                },
                {
                    "url": <Example:
"https://myvault.vault.azure.net/secrets/mycertificate3">,
                    "certificateStoreName": <Example: "TrustedPeople">,
                    "certificateStoreLocation": <Example: "LocalMachine">
                }
             ]>
         },
         "authenticationSettings": {
            "msiEndpoint":  <Required when the msiClientId property is used. Specifies the
MSI endpoint. Example for most Azure VMs:
"http://169.254.169.254/metadata/identity/oauth2/token">,
            "msiClientId":  <Required when the VM has any user assigned identities.
Specifies the MSI identity. Example: "00001111-aaaa-2222-bbbb-3333cccc4444">
         }
      }
   }
}
```

Extension dependency ordering

You can enable the Key Vault VM extension to support extension dependency ordering. By default, the Key Vault VM extension reports a successful start as soon as polling begins. However, you can configure the extension to report a successful start only after the extension downloads and installs all certificates.

If you use other extensions that require installation of all certificates before they start, you can enable extension dependency ordering in the Key Vault VM extension. This feature allows other extensions to declare a dependency on the Key Vault VM extension.

You can use this feature to prevent other extensions from starting until all dependent certificates are installed. When the feature is enabled, the Key Vault VM extension will retry download and install of certificates up to 25 times with increasing backoff periods, during which it remains in a **Transitioning** state. If the retries are exhausted, the extension will report an **Error** state. After all certificates are successfully installed, the Key Vault VM extension reports a successful start.

To enable the extension dependency ordering feature in the Key Vault VM extension, set the `secretsManagementSettings` property:

JSON

```
"secretsManagementSettings": {
   "requireInitialSync": true,
   ...
}
```

For more information on how to set up dependencies between extensions, see Sequence extension provisioning in Virtual Machine Scale Sets.

> **Important**
>
> The extension dependency ordering feature isn't compatible with an ARM template that creates a system-assigned identity and updates a Key Vault access policy with that identity. If you attempt to use the feature in this scenario, a deadlock occurs because the Key Vault access policy can't update until after all extensions start. Instead, use a *single-user-assigned MSI identity* and pre-ACL your key vaults with that identity before you deploy.

Azure PowerShell deployment

The Azure Key Vault VM extension can be deployed with Azure PowerShell. Save Key Vault VM extension settings to a JSON file (settings.json).

The following JSON snippets provide example settings for deploying the Key Vault VM extension with PowerShell.

JSON

```
{
   "secretsManagementSettings": {
   "pollingIntervalInS": "3600",
   "linkOnRenewal": true,
   "observedCertificates":
   [
      {
          "url": "https://<examplekv>.vault.azure.net/secrets/certificate1",
          "certificateStoreName": "MY",
          "certificateStoreLocation": "LocalMachine",
          "accounts": [
             "Network Service"
          ]
      },
      {
          "url": "https://<examplekv>.vault.azure.net/secrets/certificate2",
          "certificateStoreName": "MY",
          "certificateStoreLocation": "LocalMachine",
          "keyExportable": true,
          "accounts": [
             "Network Service",
             "Local Service"
          ]
```

```
      }
   ]},
   "authenticationSettings": {
      "msiEndpoint":  "http://169.254.169.254/metadata/identity/oauth2/token",
      "msiClientId":  "00001111-aaaa-2222-bbbb-3333cccc4444"
   }
}
```

Deploy on a VM

PowerShell

```
# Build settings
$settings = (get-content -raw ".\settings.json")
$extName =  "KeyVaultForWindows"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForWindows"

# Start the deployment
Set-AzVmExtension -TypeHandlerVersion "3.0" -ResourceGroupName <ResourceGroupName> -Location
<Location> -VMName <VMName> -Name $extName -Publisher $extPublisher -Type $extType -
SettingString $settings
```

Deploy on a Virtual Machine Scale Sets instance

PowerShell

```
# Build settings
$settings = ".\settings.json"
$extName = "KeyVaultForWindows"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForWindows"

# Add extension to Virtual Machine Scale Sets
$vmss = Get-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName>
Add-AzVmssExtension -VirtualMachineScaleSet $vmss  -Name $extName -Publisher $extPublisher -
Type $extType -TypeHandlerVersion "3.0" -Setting $settings

# Start the deployment
Update-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName> -
VirtualMachineScaleSet $vmss
```

Azure CLI deployment

The Azure Key Vault VM extension can be deployed by using the Azure CLI. Save Key Vault VM extension settings to a JSON file (settings.json).

The following JSON snippets provide example settings for deploying the Key Vault VM extension with the Azure CLI.

JSON

```
  {
       "secretsManagementSettings": {
         "pollingIntervalInS": "3600",
         "linkOnRenewal": true,
         "observedCertificates": [
           {
               "url": "https://<examplekv>.vault.azure.net/secrets/certificate1",
               "certificateStoreName": "MY",
