               "certificateStoreLocation": "LocalMachine",
               "accounts": [
                   "Network Service"
               ]
           },
           {
               "url": "https://<examplekv>.vault.azure.net/secrets/certificate2",
               "certificateStoreName": "MY",
               "certificateStoreLocation": "LocalMachine",
               "keyExportable": true,
               "accounts": [
                   "Network Service",
                   "Local Service"
               ]
           }
       ]
       },
         "authenticationSettings": {
         "msiEndpoint":  "http://169.254.169.254/metadata/identity/oauth2/token",
         "msiClientId":  "00001111-aaaa-2222-bbbb-3333cccc4444"
       }
    }
```

Deploy on a VM

Azure CLI

```
# Start the deployment
az vm extension set --name "KeyVaultForWindows" `
 --publisher Microsoft.Azure.KeyVault `
 --resource-group "<resourcegroup>" `
 --vm-name "<vmName>" `
 --settings "@settings.json"
```

Deploy on a Virtual Machine Scale Sets instance

```
# Start the deployment
az vmss extension set --name "KeyVaultForWindows" `
 --publisher Microsoft.Azure.KeyVault `
 --resource-group "<resourcegroup>" `
 --vmss-name "<vmssName>" `
 --settings "@settings.json"
```

Troubleshoot issues

Here are some suggestions for how to troubleshoot deployment issues.

Check frequently asked questions

Is there a limit on the number of observed certificates?

No. The Key Vault VM extension doesn't limit the number of observed certificates (`observedCertificates`).

What's the default permission when no account is specified?

By default, Administrators and SYSTEM receive Full Control.

How do you determine if a certificate key is CAPI1 or CNG?

The extension relies on the default behavior of the PFXImportCertStore API. By default, if a certificate has a Provider Name attribute that matches with CAPI1, then the certificate is imported by using CAPI1 APIs. Otherwise, the certificate is imported by using CNG APIs.

Does the extension support certificate auto-rebinding?

Yes, the Azure Key Vault VM extension supports certificate auto-rebinding. The Key Vault VM extension does support S-channel binding on certificate renewal when the `linkOnRenewal` property is set to true.

For IIS, you can configure auto-rebind by enabling automatic rebinding of certificate renewals in IIS. The Azure Key Vault VM extension generates Certificate Lifecycle Notifications when a certificate with a matching SAN is installed. IIS uses this event to auto-rebind the certificate. For more information, see Certifcate Rebind in IIS.

View extension status

Check the status of your extension deployment in the Azure portal, or by using PowerShell or the Azure CLI.

To see the deployment state of extensions for a given VM, run the following commands.

- Azure PowerShell:

  PowerShell

  ```
  Get-AzVMExtension -ResourceGroupName <myResourceGroup> -VMName <myVM> -Name
  <myExtensionName>
  ```

- The Azure CLI:

  Azure CLI

  ```
  az vm get-instance-view --resource-group <myResourceGroup> --name <myVM> --query "instanceView.extensions"
  ```

Review logs and configuration

The Key Vault VM extension logs exist only locally on the VM. Review the log details to help with troubleshooting.

Expand table

Log file	Description
C:\WindowsAzure\Logs\WaAppAgent.log`	Shows when updates occur to the extension.
C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.KeyVault.KeyVaultForWindows<*most recent version*>\	Shows the status of certificate download. The download location is always the Windows computer's MY store (certlm.msc).
C:\Packages\Plugins\Microsoft.Azure.KeyVault.KeyVaultForWindows<*most recent version*>\RuntimeSettings\	The Key Vault VM Extension service logs show the status of the akvvm_service service.
C:\Packages\Plugins\Microsoft.Azure.KeyVault.KeyVaultForWindows<*most recent version*>\Status\	The configuration and binaries for the Key Vault VM Extension service.

Certificate Installation on Windows

The Key Vault VM extension for Windows installs certificates into the Windows certificate store. When a certificate is downloaded from Key Vault, the extension:

1. Installs all intermediate and leaf certificates, regardless of how many intermediate certificates are present. Root certificates are not installed, as the extension is not authorized to perform root installation. It is the responsibility of the service owner to ensure that the root certificate is trusted on the system.

   - Leaf certificates are installed in the specified certificate store (`certificateStoreName`) and location (`certificateStoreLocation`)
   - Intermediate CA certificates are installed in the Intermediate Certificate Authorities store

2. Places the certificates in the specified certificate store (`certificateStoreName`) and location (`certificateStoreLocation`)
3. Applies appropriate permissions to the private key based on the `accounts` specified in the configuration
4. Sets the `linkOnRenewal` property (if enabled) to ensure certificate bindings in applications like IIS automatically update when certificates are renewed

Default Certificate Stores

If not specified, certificates are installed in the following locations by default:

- Store Name: MY (Personal)
- Store Location: LocalMachine

Certificate Access Control

By default, Administrators and SYSTEM receive Full Control permissions on installed certificates. You can customize access using the `accounts` array in the certificate configuration:

JSON

```
"accounts": ["Network Service", "Local Service"]
```

This grants read access to the specified accounts, allowing applications running under those identities to use the certificates.

Certificate Renewal

When certificates are renewed in Key Vault, the extension automatically:

1. Downloads the new certificate version
2. Installs it in the configured certificate store
3. Maintains existing bindings through the `linkOnRenewal` feature if enabled

Managing Certificate Lifecycle

For applications like IIS that support Certificate Lifecycle Notifications, the extension generates events when certificates with matching Subject Alternative Names (SANs) are installed, allowing automatic rebinding without service interruption.

Get support

Here are some other options to help you resolve deployment issues:

- For assistance, contact the Azure experts on the Q&A and Stack Overflow forums.

- If you don't find an answer on the site, you can post a question for input from Microsoft or other members of the community.
- You can also Contact Microsoft Support. For information about using Azure support, read the Azure support FAQ.

Last updated on 11/10/2025

Azure Machine Configuration extension

09/04/2025

The Machine Configuration extension performs audit and configuration operations inside virtual machines (VMs).

To check policies inside VMs, such as Azure compute security baseline definitions for Linux and Windows, the Machine Configuration extension must be installed.

Prerequisites

To enable your VM to authenticate to the Machine Configuration service, your VM must have a system-assigned managed identity. You can satisfy the identity requirement for your VM by setting the `"type": "SystemAssigned"` property:

JSON

```
"identity": {
   "type": "SystemAssigned"
}
```

Operating systems

Operating system support for the Machine Configuration extension is the same as documented operating system support for the end-to-end solution.

Internet connectivity

The agent installed by the Machine Configuration extension must be able to reach content packages listed by guest configuration assignments, and report status to the Machine Configuration service. The VM can connect by using outbound HTTPS over TCP port 443, or a connection provided through private networking.

To learn more about private networking, see the following articles:

- Azure Machine Configuration, Communicate over Azure Private Link
- Use private endpoints for Azure Storage

Install the extension

You can install and deploy the Azure Machine Configuration extension directly from the Azure portal, Azure CLI or PowerShell.

Azure Portal

1. Open the Azure portal.
2. In the search box, enter **Virtual machines** and then select **Virtual machines** to display the list of available VMs.
3. Select the virtual machines you want to use.
4. In the search box of virtual machine page, enter **Extensions+applications** and then select it.
5. Click on Add in the extensions page.
6. In the search box of extension page, enter **Azure Machine Configuration extension for Windows** or **Azure Machine Configuration extension for Linux** based on the OS type and select it.
7. Click Next and then select **Review + create** to install the extension.
8. Once validation passes, select **Create**.
9. Once installation finishes, you can see **AzurePolicyforWindows** or **AzurePolicyforLinux** extension installed in the extension page.

Using Application Health extension with Azure Virtual Machines

Article • 09/12/2024

Monitoring your application health is an important signal for managing your VMs. Azure Virtual Machines provides support for Automatic VM Guest Patching, which rely on health monitoring of the individual instances to safely update your VMs.

This article describes how you can use the two types of Application Health extension, **Binary Health States** or **Rich Health States**, to monitor the health of your applications deployed on Azure virtual machines.

Application health monitoring is also available on virtual machine scale sets and helps enable functionalities such as Rolling Upgrades, Automatic OS-Image Upgrades, and Automatic Instance Repairs. To experience these capabilities with the added benefits of scale, availability, and flexibility on scale sets, you can attach your VM to an existing scale set or create a new scale set.

Prerequisites

This article assumes that you're familiar with Azure virtual machine extensions.

> **⊗ Caution**
>
> Application Health Extension expects to receive a consistent probe response at the configured port `tcp` or request path `http/https` in order to label a VM as *Healthy*. If no application is running on the VM, or you're unable to configure a probe response, your VM is going to show up as *Unhealthy* (Binary Health States) or *Unknown* (Rich Health States). See **application health samples** for examples of health probe responses being emitted to a local endpoint.

When to use the Application Health extension

Application Health Extension reports on application health from inside the Virtual Machine. The extension probes on a local application endpoint and updates the health status based on TCP/HTTP(S) responses received from the application. This health status is used by Azure to monitor and detect patching failures during Automatic VM Guest Patching.

The extension reports health from within a VM and can be used in situations where an external probe such as the Azure Load Balancer health probes can't be used.

Application health is a customer-provided signal on the status of your application running inside the VM. Application health is different from resource health, which is a platform-provided signal used to report service-level events impacting the performance of your VM.

Binary versus Rich Health States

Application Health Extensions has two options available: **Binary Health States** and **Rich Health States**. The following table highlights some key differences between the two options. See the end of this section for general recommendations.

Expand table

Features	Binary Health States	Rich Health States
Available Health States	Two available states: *Healthy*, *Unhealthy*	Four available states: *Healthy*, *Unhealthy*, *Initializing*, *Unknown*[1]
Sending Health Signals	Health signals are sent through HTTP/HTTPS response codes or TCP connections.	Health signals on HTTP/HTTPS protocol are sent through the probe response code and response body. Health signals through TCP protocol remain unchanged from Binary Health States.
Identifying *Unhealthy* Instances	Instances automatically fall into *Unhealthy* state if a *Healthy* signal isn't received from the application. An *Unhealthy* instance can indicate either an issue with the extension configuration (for example, unreachable endpoint) or an issue with the application (for example, non-200 status code).	Instances only go into an *Unhealthy* state if the application emits an *Unhealthy* probe response. Users are responsible for implementing custom logic to identify and flag instances with *Unhealthy* applications[2]. Instances with incorrect extension settings (for example, unreachable endpoint) or invalid health probe responses will fall under the *Unknown* state[2].
Initializing state for newly created instances	*Initializing* state isn't available. Newly created instances may take some time before settling into a steady state.	*Initializing* state allows newly created instances to settle into a steady Health State before surfacing the health state as *Healthy*, *Unhealthy*, or *Unknown*.
HTTP/HTTPS protocol	Supported	Supported

Features	Binary Health States	Rich Health States
TCP protocol	Supported	Limited Support – *Unknown* state is unavailable on TCP protocol. See Rich Health States protocol table for Health State behaviors on TCP.

[1] The *Unknown* state is unavailable on TCP protocol. [2] Only applicable for HTTP/HTTPS protocol. TCP protocol follows the same process of identifying *Unhealthy* instances as in Binary Health States.

Use **Binary Health States** if:

- You're not interested in configuring custom logic to identify and flag an unhealthy instance
- You don't require an *initializing* grace period for newly created instances

Use **Rich Health States** if:

- You send health signals through HTTP/HTTPS protocol and can submit health information through the probe response body
- You would like to use custom logic to identify and mark unhealthy instances
- You would like to set an *initializing* grace period allowing newly created instances to settle into a steady health state

Binary Health States

Binary Health State reporting contains two Health States, *Healthy* and *Unhealthy*. The following tables provide a brief description for how the Health States are configured.

HTTP/HTTPS Protocol

Expand table

Protocol	Health State	Description
http/https	Healthy	To send a *Healthy* signal, the application is expected to return a 200 response code.
http/https	Unhealthy	The instance is marked as *Unhealthy* if a 200 response code isn't received from the application.

TCP Protocol

Expand table

Protocol	Health State	Description
TCP	Healthy	To send a *Healthy* signal, a successful handshake must be made with the provided application endpoint.
TCP	Unhealthy	The instance is marked as *Unhealthy* if a failed or incomplete handshake occurred with the provided application endpoint.

Some common scenarios that result in an *Unhealthy* state include:

- When the application endpoint returns a non-200 status code
- When there's no application endpoint configured inside the virtual machine to provide application health status
- When the application endpoint is incorrectly configured
- When the application endpoint isn't reachable

Rich Health States

Rich Health States reporting contains four Health States, *Initializing*, *Healthy*, *Unhealthy*, and *Unknown*. The following tables provide a brief description for how each Health State is configured.

HTTP/HTTPS Protocol

Expand table

Protocol	Health State	Description
http/https	Healthy	To send a *Healthy* signal, the application is expected to return a probe response with: **Probe Response Code**: Status 2xx, **Probe Response Body**: `{"ApplicationHealthState": "Healthy"}`
http/https	Unhealthy	To send an *Unhealthy* signal, the application is expected to return a probe response with: **Probe Response Code**: Status 2xx, **Probe Response Body**: `{"ApplicationHealthState": "Unhealthy"}`
http/https	Initializing	The instance automatically enters an *Initializing* state at extension start time. For more information, see Initializing state.
http/https	Unknown	An *Unknown* state may occur in the following scenarios: when a non-2xx status code is returned by the application, when the probe request times out, when the application endpoint is unreachable or incorrectly configured, when a missing or invalid value is provided for

Protocol	Health State	Description
		`ApplicationHealthState` in the response body, or when the grace period expires. For more information, see Unknown state.

TCP Protocol

Expand table

Protocol	Health State	Description
TCP	Healthy	To send a *Healthy* signal, a successful handshake must be made with the provided application endpoint.
TCP	Unhealthy	The instance is marked as *Unhealthy* if a failed or incomplete handshake occurred with the provided application endpoint.
TCP	Initializing	The instance automatically enters an *Initializing* state at extension start time. For more information, see Initializing state.

Initializing state

This state only applies to Rich Health States. The *Initializing* state only occurs once at extension start time and can be configured by the extension settings `gracePeriod` and `numberOfProbes`.

At extension startup, the application health remains in the *Initializing* state until one of two scenarios occurs:

- The same Health State (*Healthy* or *Unhealthy*) is reported a consecutive number of times as configured through *numberOfProbes*
- The `gracePeriod` expires

If the same Health State (*Healthy* or *Unhealthy*) is reported consecutively, the application health transitions out of the *Initializing* state and into the reported Health State (*Healthy* or *Unhealthy*).

Example

If `numberOfProbes` = 3, that would mean:

- To transition from *Initializing* to *Healthy* state: Application health extension must receive three consecutive *Healthy* signals via HTTP/HTTPS or TCP protocol

- To transition from *Initializing* to *Unhealthy* state: Application health extension must receive three consecutive *Unhealthy* signals via HTTP/HTTPS or TCP protocol

If the `gracePeriod` expires before a consecutive health status is reported by the application, the instance health is determined as follows:

- HTTP/HTTPS protocol: The application health transitions from *Initializing* to *Unknown*
- TCP protocol: The application health transitions from *Initializing* to *Unhealthy*

Unknown state

The *Unknown* state only applies to Rich Health States. This state is only reported for `http` or `https` probes and occurs in the following scenarios:

- When a non-2xx status code is returned by the application
- When the probe request times out
- When the application endpoint is unreachable or incorrectly configured
- When a missing or invalid value is provided for `ApplicationHealthState` in the response body
- When the grace period expires

Extension schema for Binary Health States

The following JSON shows the schema for the Application Health extension. The extension requires at a minimum either a "tcp", "http" or "https" request with an associated port or request path respectively.

JSON

```
{
  "extensionProfile" : {
     "extensions" : [
      {
        "name": "HealthExtension",
        "properties": {
          "publisher": "Microsoft.ManagedServices",
          "type": "<ApplicationHealthLinux or ApplicationHealthWindows>",
          "autoUpgradeMinorVersion": true,
          "typeHandlerVersion": "1.0",
          "settings": {
            "protocol": "<protocol>",
            "port": <port>,
            "requestPath": "</requestPath>",
            "intervalInSeconds": 5,
```

```
            "numberOfProbes": 1
          }
        }
      }
    ]
  }
}
```

Property values

Expand table

Name	Value / Example	Data Type
apiVersion	`2018-10-01` or above	date
publisher	`Microsoft.ManagedServices`	string
type	`ApplicationHealthLinux` (Linux), `ApplicationHealthWindows` (Windows)	string
typeHandlerVersion	`1.0`	string

Settings

Expand table

Name	Value / Example	Data Type
protocol	`http` or `https` or `tcp`	string
port	Optional when protocol is `http` or `https`, mandatory when protocol is `tcp`	int
requestPath	Mandatory when protocol is `http` or `https`, not allowed when protocol is `tcp`	string
intervalInSeconds	Optional, default is 5 seconds. This setting is the interval between each health probe. For example, if intervalInSeconds == 5, a probe is sent to the local application endpoint once every 5 seconds.	int
numberOfProbes	Optional, default is 1. This setting is the number of consecutive probes required for the health status to change. For example, if numberOfProbles == 3, you will need 3 consecutive "Healthy" signals to change the health status from "Unhealthy" into "Healthy"	int

Name	Value / Example	Data Type
	state. The same requirement applies to change health status into "Unhealthy" state.	

Extension schema for Rich Health States

The following JSON shows the schema for the Rich Health States extension. The extension requires at a minimum either an "http" or "https" request with an associated port or request path respectively. TCP probes are also supported, but cannot set the `ApplicationHealthState` through the probe response body and do not have access to the *Unknown* state.

JSON

```
{
  "extensionProfile" : {
     "extensions" : [
      {
        "name": "HealthExtension",
        "properties": {
          "publisher": "Microsoft.ManagedServices",
          "type": "<ApplicationHealthLinux or ApplicationHealthWindows>",
          "autoUpgradeMinorVersion": true,
          "typeHandlerVersion": "2.0",
          "settings": {
            "protocol": "<protocol>",
            "port": <port>,
            "requestPath": "</requestPath>",
            "intervalInSeconds": 5,
            "numberOfProbes": 1,
            "gracePeriod": 600
          }
        }
      }
    ]
  }
}
```

Property values

Expand table

Name	Value / Example	Data Type
apiVersion	`2018-10-01` or above	date
publisher	`Microsoft.ManagedServices`	string
type	`ApplicationHealthLinux` (Linux), `ApplicationHealthWindows` (Windows)	string
typeHandlerVersion	`2.0`	string

Settings

Expand table

Name	Value / Example	Data Type
protocol	`http` or `https` or `tcp`	string
port	Optional when protocol is `http` or `https`, mandatory when protocol is `tcp`	int
requestPath	Mandatory when protocol is `http` or `https`, not allowed when protocol is `tcp`	string
intervalInSeconds	Optional, default is 5 seconds. This setting is the interval between each health probe. For example, if intervalInSeconds == 5, a probe is sent to the local application endpoint once every 5 seconds.	int
numberOfProbes	Optional, default is 1. This setting is the number of consecutive probes required for the health status to change. For example, if numberOfProbles == 3, you will need 3 consecutive "Healthy" signals to change the health status from "Unhealthy"/"Unknown" into "Healthy" state. The same requirement applies to change health status into "Unhealthy" or "Unknown" state.	int
gracePeriod	Optional, default = `intervalInSeconds` * `numberOfProbes`; maximum grace period is 7200 seconds	int

Deploy the Application Health extension

There are multiple ways of deploying the Application Health extension to your VMs as detailed in the following examples.

Binary Health States

REST API

The following example adds the Application Health extension named *myHealthExtension* to a Windows-based virtual machine.

You can also use this example to change an existing extension from Rich Health States to Binary Health by making a PATCH call instead of a PUT.

```
PUT on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers
/Microsoft.Compute/virtualMachines/myVM/extensions/myHealthExtension?
api-version=2018-10-01`
```

JSON

```
{
  "name": "myHealthExtension",
  "location": "<location>",
  "properties": {
    "publisher": "Microsoft.ManagedServices",
    "type": "ApplicationHealthWindows",
    "autoUpgradeMinorVersion": true,
    "typeHandlerVersion": "1.0",
    "settings": {
      "protocol": "<protocol>",
      "port": <port>,
      "requestPath": "</requestPath>"
    }
  }
}
```

Use `PATCH` to edit an already deployed extension.

Rich Health States

REST API

The following example adds the **Application Health - Rich States** extension (with name myHealthExtension) to a Windows-based virtual machine.

You can also use this example to upgrade an existing extension from Binary to Rich Health States by making a PATCH call instead of a PUT.

```
PUT on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers
/Microsoft.Compute/virtualMachines/myVM/extensions/myHealthExtension?
api-version=2018-10-01`
```

JSON

```
{
  "name": "myHealthExtension",
  "location": "<location>",
  "properties": {
    "publisher": "Microsoft.ManagedServices",
    "type": "ApplicationHealthWindows",
    "autoUpgradeMinorVersion": true,
    "typeHandlerVersion": "2.0",
    "settings": {
      "requestPath": "</requestPath>",
      "intervalInSeconds": <intervalInSeconds>,
      "numberOfProbes": <numberOfProbes>,
      "gracePeriod": <gracePeriod>
    }
  }
}
```

Use `PATCH` to edit an already deployed extension.

Troubleshoot

Need help configuring a probe response

See application health samples for examples of health probe responses being emitted to a local endpoint.

View VMHealth

REST API

```
GET https://management.azure.com/subscriptions/{subscription-
id}/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMa
chines/myVM/instanceView?api-version=2023-07-01
```

Sample Response (see "vmHealth" object for the latest VM health status)

```
"vmHealth": {
    "status": {
      "code": "HealthState/unknown",
      "level": "Warning",
      "displayStatus": "The VM health is unknown",
      "time": "2023-12-04T22:25:39+00:00"
    }
}
```

Extension execution output log

Extension execution output is logged to files found in the following directories:

Windows

```
C:\WindowsAzure\Logs\Plugins\Microsoft.ManagedServices.ApplicationHealthWind
ows\<version>\
```

Linux

```
/var/lib/waagent/Microsoft.ManagedServices.ApplicationHealthLinux-
<extension_version>/status
/var/log/azure/applicationhealth-extension
```

The logs also periodically capture the application health status.

Use the Azure Custom Script Extension Version 2 with Linux virtual machines

08/18/2025

The Custom Script Extension Version 2 downloads and runs scripts on Azure virtual machines (VMs). Use this extension for post-deployment configuration, software installation, or any other configuration or management task. You can download scripts from Azure Storage or another accessible internet location, or you can provide them to the extension runtime.

The Custom Script Extension integrates with Azure Resource Manager templates. You can also run it by using the Azure CLI, Azure PowerShell, or the Azure Virtual Machines REST API.

This article describes how to use the Custom Script Extension from the Azure CLI, and how to run the extension by using an Azure Resource Manager template. This article also provides troubleshooting steps for Linux systems.

There are two versions of the Custom Script Extension:

- Version 1: Microsoft.OSTCExtensions.CustomScriptForLinux
- Version 2: Microsoft.Azure.Extensions.CustomScript

Use Version 2 for new and existing deployments. The new version is a drop-in replacement. The migration is as easy as changing the name and version. You don't need to change your extension configuration.

Prerequisites

Supported Linux distributions

Expand table

Publisher	Distribution	x64	ARM64
Alma Linux Community	Alma Linux	8.x+, 9.x+	8.x+, 9.x+
Credativ	Debian	10+	11.x+
Kinvolk	Flatcar Linux	3374.2.x+	3374.2.x+
Microsoft	Azure Linux	2.x	2.x
openSUSE Project	openSUSE	12.3+	*Not supported*
Oracle	Oracle Linux	6.4+, 7.x+, 8.x+	*Not supported*
Red Hat	Red Hat Enterprise Linux	6.7+, 7.x+, 8.x+, 9.x+, 10.x+	8.6+, 9.0+, 10.x+
CIQ	Rocky Linux	9.x+	9.x+
SUSE	SLES	12.x+, 15.x+	15.x SP4+
Canonical	Ubuntu (LTS releases)	18.04+, 20.04+, 22.04+, 24.04+	20.04+, 22.04+, 24.04+

Script location

You can set the extension to use your Azure Blob Storage credentials so that it can access Azure Blob Storage. The script location can be anywhere, as long as the VM can route to that endpoint, for example, GitHub or an internal file server.

Internet connectivity

To download a script externally, such as from GitHub or Azure Storage, you need to open other firewall or network security group (NSG) ports. For example, if your script is located in Azure Storage, you can allow access by using Azure NSG service tags for Storage.

If your script is on a local server, you might still need to open other firewall or NSG ports.

Tips

- The highest failure rate for this extension is due to syntax errors in the script. Verify that the script runs without errors. Put more logging into the script to make it easier to find failures.
- Write scripts that are idempotent, so that running them more than once accidentally doesn't cause system changes.
- Ensure that the scripts don't require user input when they run.
- The script is allowed 90 minutes to run. Anything longer results in a failed provision of the extension.
- Don't put reboots inside the script. Restarting causes problems with other extensions that are being installed, and the extension doesn't continue after the reboot.
- If you have a script that causes a reboot before installing applications and running scripts, schedule the reboot by using a cron job or by using tools such as DSC, Chef, or Puppet extensions.
- Don't run a script that causes a stop or update of the Azure Linux Agent. It might leave the extension in a transitioning state and lead to a time-out.
- The extension runs a script only once. If you want to run a script on every startup, you can use a cloud-init image and use a Scripts Per Boot module. Alternatively, you can use the script to create a systemd service unit.
- You can have only one version of an extension applied to the VM. To run a second custom script, update the existing extension with a new configuration. Alternatively, you can remove the Custom Script Extension and reapply it with the updated script.
- If you want to schedule when a script runs, use the extension to create a cron job.
- When the script is running, you only see a *transitioning* extension status from the Azure portal or CLI. If you want more frequent status updates for a running script, create your own solution.
- The Custom Script Extension doesn't natively support proxy servers. However, you can use a file transfer tool, such as `Curl`, that supports proxy servers within your script.
- Be aware of nondefault directory locations that your scripts or commands might rely on. Have logic to handle this situation.

Extension schema

The Custom Script Extension configuration specifies things like script location and the command to be run. You can store this information in configuration files, specify it on the command line, or specify it in an Azure Resource Manager template.

You can store sensitive data in a protected configuration, which is encrypted and only decrypted on the target VM. The protected configuration is useful when the execution command includes secrets such as a password. Here's an example:

JSON

```
{
  "name": "config-app",
  "type": "Extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2019-03-01",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "skipDos2Unix":false,
      "timestamp":123456789
    },
    "protectedSettings": {
       "commandToExecute": "<command-to-execute>",
       "script": "<base64-script-to-execute>",
       "storageAccountName": "<storage-account-name>",
       "storageAccountKey": "<storage-account-key>",
       "fileUris": ["https://.."],
       "managedIdentity" : "<managed-identity-identifier>"
    }
  }
}
```

> **Note**
>
> The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

Property values

Expand table

Name	Value or example	Data type
apiVersion	`2019-03-01`	date
publisher	`Microsoft.Azure.Extensions`	string
type	`CustomScript`	string
typeHandlerVersion	`2.1`	int

Name	Value or example	Data type
fileUris	`https://github.com/MyProject/Archive/MyPythonScript.py`	array
commandToExecute	`python MyPythonScript.py \<my-param1>`	string
script	`IyEvYmluL3NoCmVjaG8gIlVwZGF0aW5nIHBhY2thZ2VzIC4uLiIKYXB0IHVwZGF0ZQphcHQgdXBncmFkZSAteQo=`	string
skipDos2Unix	`false`	boolean
timestamp	`123456789`	32-bit integer
storageAccountName	`examplestorageacct`	string
storageAccountKey	`TmJK/1N3AbAZ3q/+hOXoi/l73zOqsaxXDhqa9Y83/v5UpXQp2DQIBuv2Tifp60cE/OaHsJZmQZ7teQfczQj8hg==`	string
managedIdentity	`{ }` or `{ "clientId": "00001111-aaaa-2222-bbbb-3333cccc4444" }` or `{ "objectId": "aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb" }`	JSON object

Property value details

Expand table

Property	Optional or required	Details
apiVersion	Not applicable	You can find the most up-to-date API version by using Resource Explorer or by using the command `az provider list -o json` in the Azure CLI.
fileUris	Optional	URLs for files to be downloaded.
commandToExecute	Required if `script` isn't set	The entry point script to run. Use this property instead of `script` if your command contains secrets such as passwords.
script	Required if `commandToExecute` isn't set	A Base64-encoded and optionally gzip'ed script run by `/bin/sh`.
skipDos2Unix	Optional	Set this value to `false` if you want to skip dos2unix conversion of script-based file URLs or scripts.
timestamp	Optional	Change this value only to trigger a rerun of the script. Any integer value is acceptable, as long as it's different from the previous value.
storageAccountName	Optional	The name of storage account. If you specify storage credentials, all `fileUris` values must be URLs for Azure blobs.
storageAccountKey	Optional	The access key of the storage account.
managedIdentity	Optional	The managed identity for downloading files. Values are `clientId` (optional, string), which is the client ID of the managed identity, and `objectId` (optional, string), which is the object ID of the managed identity.

Public settings are sent in clear text to the VM where the script runs. *Protected settings* are encrypted through a key known only to Azure and the VM. The settings are saved to the VM as they were sent. That is, if the settings

were encrypted, they're saved encrypted on the VM. The certificate that's used to decrypt the encrypted values is stored on the VM. The certificate is also used to decrypt settings, if necessary, at runtime.

Using public settings might be useful for debugging, but we strongly recommend that you use protected settings.

You can set the following values in either public or protected settings. The extension rejects any configuration where these values are set in both public and protected settings.

- `commandToExecute`
- `script`
- `fileUris`

Property: skipDos2Unix

The previous version of the Custom Script Extension, `Microsoft.OSTCExtensions.CustomScriptForLinux`, automatically converts DOS files to UNIX files by translating `\r\n` to `\n`. This translation still exists and is on by default. This conversion is applied to all files downloaded from `fileUris` or the script setting based on either of the following criteria:

- The extension is *.sh*, *.txt*, *.py*, or *.pl*. The script setting always matches this criterion because it's assumed to be a script run with */bin/sh*. The script setting is saved as *script.sh* on the VM.
- The file starts with `#!`.

The default value is `false`, which means dos2unix conversion *is* executed. You can skip the dos2unix conversion by setting `skipDos2Unix` to `true`:

JSON

```
{
  "fileUris": ["<url>"],
  "commandToExecute": "<command-to-execute>",
  "skipDos2Unix": true
}
```

Property: script

The Custom Script Extension supports execution of a user-defined script. The script settings combine `commandToExecute` and `fileUris` into a single setting. Instead of having to set up a file for download from Azure Storage or a GitHub gist, you can encode the script as a setting. You can use the script to replace `commandToExecute` and `fileUris`.

Here are some requirements:

- The script must be Base64 encoded.
- The script can optionally be gzip'ed.
- You can use the script setting in public or protected settings.
- The maximum size of the script parameter's data is 256 KB. If the script exceeds this size, it doesn't run.

For example, the following script is saved to the file */script.sh/*:

```sh
#!/bin/sh
echo "Creating directories ..."
mkdir /data
chown user:user /data
mkdir /appdata
chown user:user /appdata
```

You would construct the correct Custom Script Extension script setting by taking the output of the following command:

```Bash
cat script.sh | base64 -w0
```

```JSON
{
  "script":
"IyEvYmluL3NoCmVjaG8gIlVwZGF0aW5nIHBhY2thZ2VzIC4uLiIKYXB0IHVwZGF0ZQphcHQgdXBncmFkZSAteQo="
}
```

In most cases, the script can optionally be gzip'ed to further reduce size. The Custom Script Extension automatically detects the use of gzip compression.

```Bash
cat script | gzip -9 | base64 -w 0
```

The Custom Script Extension uses the following algorithm to run a script:

1. Assert that the length of the script's value doesn't exceed 256 KB.
2. Base64 decode the script's value.
3. *Try* to gunzip the Base64-decoded value.
4. Write the decoded and optionally decompressed value to disk: */var/lib/waagent/custom-script/#/script.sh*.
5. Run the script by using `_/bin/sh -c /var/lib/waagent/custom-script/#/script.sh`.

Property: managedIdentity

> **Note**
>
> This property *must* be specified in protected settings only.

The Custom Script Extension, version 2.1 and later, supports managed identities for downloading files from URLs provided in the `fileUris` setting. This approach allows the Custom Script Extension to access Azure Storage private blobs or containers without the user having to pass secrets like shared access signature (SAS) tokens or storage account keys.

To use this feature, add a system-assigned or user-assigned identity to the VM or Virtual Machine Scale Set where the Custom Script Extension is expected to run. Then grant the managed identity access to the Azure Storage container or blob.

To use the system-assigned identity on the target VM or Virtual Machine Scale Set, set `managedidentity` to an empty JSON object.

JSON

```
{
  "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.sh"],
  "commandToExecute": "sh script1.sh",
  "managedIdentity" : {}
}
```

To use the user-assigned identity on the target VM or Virtual Machine Scale Set, configure `managedidentity` with the client ID or the object ID of the managed identity.

JSON

```
{
  "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.sh"],
  "commandToExecute": "sh script1.sh",
  "managedIdentity" : { "clientId": "00001111-aaaa-2222-bbbb-3333cccc4444" }
}
```

JSON

```
{
  "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.sh"],
  "commandToExecute": "sh script1.sh",
  "managedIdentity" : { "objectId": "aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb" }
}
```

> **Note**
>
> The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

Template deployment

You can deploy Azure VM extensions by using Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Custom Script Extension during the template's deployment. You can find a sample template that includes the Custom Script Extension on GitHub.

JSON

```
{
  "name": "config-app",
  "type": "extensions",
```

```
  "location": "[resourceGroup().location]",
  "apiVersion": "2019-03-01",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      },
    "protectedSettings": {
      "commandToExecute": "sh hello.sh <param2>",
      "fileUris": ["https://github.com/MyProject/Archive/hello.sh"
      ]
    }
  }
}
```

> **Note**
>
> These property names are case-sensitive. To avoid deployment problems, use the names as shown here.

Azure CLI

When you use the Azure CLI to run the Custom Script Extension, create a configuration file or files. At a minimum, the configuration file must contain `commandToExecute`. The `az vm extension set` command refers to the configuration file:

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM --name customScript \
  --publisher Microsoft.Azure.Extensions \
  --protected-settings ./script-config.json
```

Alternatively, you can specify the settings in the command as a JSON-formatted string. This approach allows the configuration to be specified during execution and without a separate configuration file.

Azure CLI

```
az vm extension set \
  --resource-group exttest \
  --vm-name exttest \
  --name customScript \
  --publisher Microsoft.Azure.Extensions \
  --protected-settings '{"fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"],"commandToExecute": "./config-music.sh"}'
```

Example: Public configuration with script file

This example uses the following script file named *script-config.json*:

JSON

```
{
  "fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"],
  "commandToExecute": "./config-music.sh"
}
```

1. Create the script file by using the text editor of your choice or by using the following CLI command:

   Azure CLI

   ```
   cat <<EOF > script-config.json
   {
     "fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"],
     "commandToExecute": "./config-music.sh"
   }
   EOF
   ```

2. Run the following command:

   Azure CLI

   ```
   az vm extension set \
     --resource-group myResourceGroup \
     --vm-name myVM --name customScript \
     --publisher Microsoft.Azure.Extensions \
     --settings ./script-config.json
   ```

Example: Public configuration with no script file

This example uses the following JSON-formatted content:

JSON

```
{
  "commandToExecute": "apt-get -y update && apt-get install -y apache2"
}
```

Run the following command:

Azure CLI

```
az vm extension set \
  --resource-group tim0329vmRG \
  --vm-name tim0329vm --name customScript \
  --publisher Microsoft.Azure.Extensions \
  --settings '{"commandToExecute": "apt-get -y update && apt-get install -y apache2"}'
```

Example: Public and protected configuration files

Use a public configuration file to specify the script file's URI:

JSON

```
{
  "fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"]
}
```

Use a protected configuration file to specify the command to be run:

JSON

```
{
  "commandToExecute": "./config-music.sh"
}
```

1. Create the public configuration file by using the text editor of your choice or by using the following CLI command:

   Azure CLI

   ```
   cat <<EOF > script-config.json
   {
     "fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"]
   }
   EOF
   ```

2. Create the protected configuration file by using the text editor of your choice or by using the following CLI command:

   Azure CLI

   ```
   cat <<EOF > protected-config.json
   {
     "commandToExecute": "./config-music.sh"
   }
   EOF
   ```

3. Run the following command:

   Azure CLI

   ```
   az vm extension set \
     --resource-group myResourceGroup \
     --vm-name myVM \
     --name customScript \
     --publisher Microsoft.Azure.Extensions \
     --settings ./script-config.json \
     --protected-settings ./protected-config.json
   ```

Virtual Machine Scale Sets

If you deploy the Custom Script Extension from the Azure portal, you don't have control over the expiration of the SAS token to access the script in your storage account. The initial deployment works, but when the storage account's SAS token expires, any subsequent scaling operation fails because the Custom Script Extension can no longer access the storage account.

We recommend that you use PowerShell, the Azure CLI, or an Azure Resource Manager template when you deploy the Custom Script Extension on a Virtual Machine Scale Set. This way, you can choose to use a managed identity or have direct control of the expiration of the SAS token for accessing the script in your storage account for as long as you need.

Troubleshooting

When the Custom Script Extension runs, the script is created or downloaded into a directory that's similar to the following example. The command output is also saved into this directory in `stdout` and `stderr` files.

Bash

```
sudo ls -l /var/lib/waagent/custom-script/download/0/
```

To troubleshoot, first check the Linux Agent log and ensure that the extension ran:

Bash

```
sudo cat /var/log/waagent.log
```

Look for the extension execution. It looks something like:

Output

```
2018/04/26 17:47:22.110231 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] [Enable] current
handler state is: notinstalled
2018/04/26 17:47:22.306407 INFO Event: name=Microsoft.Azure.Extensions.customScript, op=Download,
message=Download succeeded, duration=167
2018/04/26 17:47:22.339958 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Initialize
extension directory
2018/04/26 17:47:22.368293 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Update settings
file: 0.settings
2018/04/26 17:47:22.394482 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Install extension
[bin/custom-script-shim install]
2018/04/26 17:47:23.432774 INFO Event: name=Microsoft.Azure.Extensions.customScript, op=Install,
message=Launch command succeeded: bin/custom-script-shim install, duration=1007
2018/04/26 17:47:23.476151 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Enable extension
[bin/custom-script-shim enable]
2018/04/26 17:47:24.516444 INFO Event: name=Microsoft.Azure.Extensions.customScript, op=Enable,
message=Launch command succeeded: bin/custom-sc
```

In the preceding output:

- `Enable` is when the command starts running.

- `Download` relates to the downloading of the Custom Script Extension package from Azure, not the script files specified in `fileUris`.

The Azure Script Extension produces a log, which you can find here:

Bash

```
sudo cat /var/log/azure/custom-script/handler.log
```

Look for the individual execution. It looks something like:

Output

```
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event=start

protected commandToExecute" output=/var/lib/waagent/custom-script/download/0
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event="executed
command" output=/var/lib/waagent/custom-script/download/0
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event=enabled
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event=end
```

Here you can see:

- The `enable` command that starts this log.
- The settings passed to the extension.
- The extension downloading the file and the result of that action.

- The command being run and the result.

You can also retrieve the execution state of the Custom Script Extension, including the actual arguments passed as `commandToExecute`, by using the Azure CLI:

Azure CLI

```
az vm extension list -g myResourceGroup --vm-name myVM
```

The output looks like the following text:

Output

```
[
  {
    "autoUpgradeMinorVersion": true,
    "forceUpdateTag": null,
    "id":

]
```

Azure CLI syntax issues

The Azure CLI can run in several shell environments, but with slight format variations. If you have unexpected results with Azure CLI commands, see How to use the Azure CLI successfully.

Next steps

To see the code, current issues, and versions, see custom-script-extension-linux.

Custom Script Extension for Windows

08/18/2025

The Custom Script Extension downloads and runs scripts on Azure virtual machines (VMs). Use this extension for post-deployment configuration, software installation, or any other configuration or management task. You can download scripts from Azure Storage or GitHub, or provide them to the Azure portal at extension runtime.

The Custom Script Extension integrates with Azure Resource Manager templates. You can also run it by using the Azure CLI, Azure PowerShell, the Azure portal, or the Azure Virtual Machines REST API.

This article describes how to use the Custom Script Extension by using the Azure PowerShell module and Azure Resource Manager templates. It also provides troubleshooting steps for Windows systems.

Prerequisites

> **Note**
>
> Don't use the Custom Script Extension to run `Update-AzVM` with the same VM as its parameter. The extension will wait for itself.

Supported Windows operating systems

Expand table

OS Version	x64	ARM64
Windows 10	Supported	Supported
Windows 11	Supported	Supported
Windows Server 2016	Supported	Supported
Windows Server 2016 Core	Supported	Supported
Windows Server 2019	Supported	Supported
Windows Server 2019 Core	Supported	Supported
Windows Server 2022	Supported	Supported
Windows Server 2022 Core	Supported	Supported
Windows Server 2025	Supported	Supported
Windows Server 2025 Core	Supported	Supported

Script location

You can set the extension to use your Azure Blob Storage credentials so that it can access Azure Blob Storage. The script location can be anywhere, as long as the VM can route to that endpoint, for example, GitHub or an internal file server.

Internet connectivity

To download a script externally, such as from GitHub or Azure Storage, you need to open other firewall or network security group (NSG) ports. For example, if your script is located in Azure Storage, you can allow access by using Azure NSG service tags for Storage.

The Custom Script Extension doesn't have any way to bypass certificate validation. If you're downloading from a secured location with, for example, a self-signed certificate, you might get errors like *The remote certificate is invalid according to the validation procedure*. Make sure that the certificate is correctly installed in the *Trusted Root Certification Authorities* store on the VM.

If your script is on a local server, you might still need to open other firewall or NSG ports.

Tips

- Output is limited to the last 4,096 bytes.

- Properly escaping characters will help ensure that strings are parsed correctly. For example, you always need two backslashes to escape a single literal backslash when dealing with file paths. Sample: `{"commandToExecute": "C:\\Windows\\System32\\systeminfo.exe >> D:\\test.txt"}`
- The highest failure rate for this extension is due to syntax errors in the script. Verify that the script runs without errors. Put more logging into the script to make it easier to find failures.
- Write scripts that are idempotent, so that running them more than once accidentally doesn't cause system changes.
- Ensure that the scripts don't require user input when they run.
- The script is allowed 90 minutes to run. Anything longer results in a failed provision of the extension.
- Don't put restarts inside the script. This action causes problems with other extensions that are being installed, and the extension doesn't continue after the restart.
- If you have a script that causes a restart before installing applications and running scripts, schedule the restart by using a Windows Scheduled Task or by using tools such as DSC, Chef, or Puppet extensions.
- Don't run a script that causes a stop or update of the VM agent. It might leave the extension in a transitioning state and lead to a time-out.
- The extension runs a script only once. If you want to run a script on every startup, use the extension to create a Windows Scheduled Task.
- If you want to schedule when a script runs, use the extension to create a Windows Scheduled Task.
- When the script is running, you only see a *transitioning* extension status from the Azure portal or Azure CLI. If you want more frequent status updates for a running script, create your own solution.
- The Custom Script Extension doesn't natively support proxy servers. However, you can use a file transfer tool, such as Invoke-WebRequest, that supports proxy servers within your script.
- Be aware of nondefault directory locations that your scripts or commands might rely on. Have logic to handle this situation.
- Ensure you don't have any custom setting in the registry key `HKLM\SOFTWARE\Microsoft\Command Processor\AutoRun` (*detailed here*). This would trigger during the Custom Script Extension install or enable phases and cause an error like `'XYZ is not recognized as an internal or external command, operable program or batch file'`.
- The Custom Script Extension runs under the `LocalSystem` account.
- If you plan to use the `storageAccountName` and `storageAccountKey` properties, these properties must be collocated in `protectedSettings`.
- You can have only one version of an extension applied to the VM. To run a second custom script, you can update the existing extension with a new configuration. Alternatively, you can remove the custom script extension and reapply it with the updated script

Extension schema

The Custom Script Extension configuration specifies things like script location and the command to be run. You can store this configuration in configuration files, specify it on the command line, or specify it in an Azure Resource Manager template.

You can store sensitive data in a protected configuration, which is encrypted and only decrypted inside the VM. The protected configuration is useful when the execution command includes secrets such as a password or a shared access signature (SAS) file reference. Here's an example:

JSON

```
{
    "apiVersion": "2018-06-01",
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "name": "virtualMachineName/config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'),copyindex())]",
        "[variables('musicstoresqlName')]"
    ],
    "tags": {
        "displayName": "config-app"
    },
    "properties": {
        "publisher": "Microsoft.Compute",
        "type": "CustomScriptExtension",
        "typeHandlerVersion": "1.10",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "timestamp":123456789
        },
        "protectedSettings": {
            "commandToExecute": "myExecutionCommand",
            "storageAccountName": "myStorageAccountName",
            "storageAccountKey": "myStorageAccountKey",
            "managedIdentity" : {},
            "fileUris": [
                "script location"
            ]
        }
```

```
    }
}
```

> **Note**
>
> The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

Only one version of an extension can be installed on a VM at a time. Specifying a custom script twice in the same Azure Resource Manager template for the same VM fails.

You can use this schema inside the VM resource or as a standalone resource. If this extension is used as a standalone resource in the Azure Resource Manager template, the name of the resource has to be in the format *virtualMachineName/extensionName*.

Property values

Expand table

Name	Value or example	Data type
apiVersion	`2018-06-01`	date
publisher	`Microsoft.Compute`	string
type	`CustomScriptExtension`	string
typeHandlerVersion	`1.10`	int
fileUris	`https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1`	array
timestamp	`123456789`	32-bit integer

> **Note**
>
> These property names are case-sensitive. To avoid deployment problems, use the names as shown here.

Property value details

Expand table

Property	Optional or required	Details
fileUris	Optional	URLs for files to be downloaded. If URLs are sensitive, for example, if they contain keys, this field should be specified in `protectedSettings`.
commandToExecute	Required	The entry point script to run. Use this property if your command contains secrets such as passwords or if your file URIs are sensitive.
timestamp	Optional	Change this value only to trigger a rerun of the script. Any integer value is acceptable, as long as it's different from the previous value.
storageAccountName	Optional	The name of storage account. If you specify storage credentials, all `fileUris` values must be URLs for Azure blobs.
storageAccountKey	Optional	The access key of the storage account.
managedIdentity	Optional	The managed identity for downloading files. Valid values are `clientId` (optional, string), which is the client ID of the managed identity, and `objectId` (optional, string), which is the object ID of the managed identity.

Public settings are sent in clear text to the VM where the script runs. *Protected settings* are encrypted through a key known only to Azure and the VM. The settings are saved to the VM as they were sent. That is, if the settings were encrypted, they're saved encrypted on the VM. The certificate that's used to decrypt the encrypted values is stored on the VM. The certificate is also used to decrypt settings, if necessary, at runtime.

Using public settings might be useful for debugging, but we recommend that you use protected settings.

You can set the following values in either public or protected settings. The extension rejects any configuration where these values are set in both public and protected settings.

- `commandToExecute`
- `fileUris`

Property: managedIdentity

> ⓘ Note
>
> This property *must* be specified in protected settings only.

The Custom Script Extension, version 1.10 and later, supports managed identities for downloading files from URLs provided in the `fileUris` setting. The property allows the Custom Script Extension to access Azure Storage private blobs or containers without the user having to pass secrets like SAS tokens or storage account keys.

> ⓘ Note
>
> The Custom Script Extension does not currently support using Managed Identity authentication on Azure Arc–enabled servers.

To use this feature, add a system-assigned or user-assigned identity to the VM or Virtual Machine Scale Set where the Custom Script Extension runs. Then grant the managed identity access to the Azure Storage container or blob.

To use the system-assigned identity on the target VM or Virtual Machine Scale Set, set `managedidentity` to an empty JSON object.

JSON

```
{
  "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.ps1"],
  "commandToExecute": "powershell.exe script1.ps1",
  "managedIdentity" : {}
}
```

To use the user-assigned identity on the target VM or Virtual Machine Scale Set, configure `managedidentity` with the client ID or the object ID of the managed identity.

JSON

```
{
  "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.ps1"],
  "commandToExecute": "powershell.exe script1.ps1",
  "managedIdentity" : { "clientId": "00001111-aaaa-2222-bbbb-3333cccc4444" }
}
```

JSON

```
{
  "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.ps1"],
  "commandToExecute": "powershell.exe script1.ps1",
  "managedIdentity" : { "objectId": "aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb" }
}
```

> ⓘ Note
>
> The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

Template deployment

You can deploy Azure VM extensions by using Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Custom Script Extension during the template's deployment. The following samples show how to use the Custom Script Extension:

- Deploy virtual machine extensions with Azure Resource Manager templates
- Deploy Two Tier Application on Windows and Azure SQL Database

PowerShell deployment

You can use the `Set-AzVMCustomScriptExtension` command to add the Custom Script Extension to an existing virtual machine. For more information, see Set-AzVMCustomScriptExtension.

PowerShell

```
Set-AzVMCustomScriptExtension -ResourceGroupName <resourceGroupName> `
    -VMName <vmName> `
    -Location myLocation `
    -FileUri <fileUrl> `
    -Run 'myScript.ps1' `
    -Name DemoScriptExtension
```

Examples

Using multiple scripts

This example uses three scripts to build your server. The `commandToExecute` property calls the first script. You then have options on how the others are called. For example, you can have a lead script that controls the execution, with the right error handling, logging, and state management. The scripts are downloaded to the local machine to run.

For example, in *1_Add_Tools.ps1*, you would call *2_Add_Features.ps1* by adding `.\2_Add_Features.ps1` to the script. Repeat this process for the other scripts that you define in `$settings`.

PowerShell

```
$fileUri = @("https://xxxxxxx.blob.core.windows.net/buildServer1/1_Add_Tools.ps1",
"https://xxxxxxx.blob.core.windows.net/buildServer1/2_Add_Features.ps1",
"https://xxxxxxx.blob.core.windows.net/buildServer1/3_CompleteInstall.ps1")

$settings = @{"fileUris" = $fileUri};

$storageAcctName = "xxxxxxx"
$storageKey = "1234ABCD"
$protectedSettings = @{"storageAccountName" = $storageAcctName; "storageAccountKey" = $storageKey; "commandToExecute" =
"powershell -ExecutionPolicy Unrestricted -File 1_Add_Tools.ps1"};

#run command
Set-AzVMExtension -ResourceGroupName <resourceGroupName> `
    -Location <locationName> `
    -VMName <vmName> `
    -Name "buildserver1" `
    -Publisher "Microsoft.Compute" `
    -ExtensionType "CustomScriptExtension" `
    -TypeHandlerVersion "1.10" `
    -Settings $settings `
    -ProtectedSettings $protectedSettings;
```

Running scripts from a local share

In this example, you might want to use a local Server Message Block (SMB) server for your script location. You then don't need to provide any other settings, except `commandToExecute`.

PowerShell

```
$protectedSettings = @{"commandToExecute" = "powershell -ExecutionPolicy Unrestricted -File \\filesvr\build\serverUpdate1.ps1"};

Set-AzVMExtension -ResourceGroupName <resourceGroupName> `
    -Location <locationName> `
```

```
    -VMName <vmName> `
    -Name "serverUpdate"
    -Publisher "Microsoft.Compute" `
    -ExtensionType "CustomScriptExtension" `
    -TypeHandlerVersion "1.10" `
    -ProtectedSettings $protectedSettings
```

Running a custom script more than once by using the CLI

The Custom Script Extension handler prevents rerunning a script if the *exact* same settings have been passed. This behavior prevents accidental rerunning, which might cause unexpected behaviors if the script isn't idempotent. To confirm whether the handler blocked the rerunning, look at `C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.CustomScriptExtension\<HandlerVersion>\CustomScriptHandler.log*`. Searching for a warning like this one:

Output

```
Current sequence number, <SequenceNumber>, is not greater than the sequence number
of the most recently executed configuration. Exiting...
```

If you want to run the Custom Script Extension more than once, you can do that only under these conditions:

- The extension's `Name` parameter is the same as the previous deployment of the extension.
- You've updated the configuration. You can add a dynamic property to the command, such as a timestamp. If the handler detects a change in the configuration settings, it considers that change as an explicit desire to rerun the script.

Alternatively, you can set the ForceUpdateTag property to `true`.

Using Invoke-WebRequest

If you're using Invoke-WebRequest in your script, you must specify the parameter `-UseBasicParsing`. If you don't specify the parameter, you get the following error when checking the detailed status:

Output

```
The response content cannot be parsed because the Internet Explorer engine
is not available, or Internet Explorer's first-launch configuration
is not complete. Specify the UseBasicParsing parameter and try again.
```

Virtual Machine Scale Sets

If you deploy the Custom Script Extension from the Azure portal, you don't have control over the expiration of the SAS token for accessing the script in your storage account. The initial deployment works, but when the storage account's SAS token expires, any subsequent scaling operation fails because the Custom Script Extension can no longer access the storage account.

We recommend that you use PowerShell, the Azure CLI, or an Azure Resource Manager template when you deploy the Custom Script Extension on a Virtual Machine Scale Set. This way, you can choose to use a managed identity or have direct control of the expiration of the SAS token for accessing the script in your storage account for as long as you need.

Troubleshoot and support

You can retrieve data about the state of extension deployments from the Azure portal and by using the Azure PowerShell module. To see the deployment state of extensions for a VM, run the following command:

PowerShell

```
Get-AzVMExtension -ResourceGroupName <resourceGroupName> `
    -VMName <vmName> -Name myExtensionName
```

Extension output is logged to files found under the following folder on the target virtual machine:

Windows Command Prompt

```
C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.CustomScriptExtension
```

The specified files are downloaded into the following folder on the target virtual machine:

Windows Command Prompt

```
C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.*\Downloads\<n>
```

In the preceding path, `<n>` is a decimal integer that might change between executions of the extension. The `1.*` value matches the actual, current `typeHandlerVersion` value of the extension. For example, the actual directory could be `C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.8\Downloads\2`.

When you run the `commandToExecute` command, the extension sets this directory, for example, `...\Downloads\2`, as the current working directory. This process enables the use of relative paths to locate the files downloaded by using the `fileURIs` property. Here are examples of downloaded files:

Expand table

URI in `fileUris`	Relative download location	Absolute download location
`https://someAcct.blob.core.windows.net/aContainer/scripts/myscript.ps1`	`./scripts/myscript.ps1`	`C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1`
`https://someAcct.blob.core.windows.net/aContainer/topLevel.ps1`	`./topLevel.ps1`	`C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1`

The absolute directory paths change over the lifetime of the VM, but not within a single execution of the Custom Script Extension.

Because the absolute download path might vary over time, it's better to opt for relative script/file paths in the `commandToExecute` string, whenever possible. For example:

JSON

```
"commandToExecute": "powershell.exe . . . -File \"./scripts/myscript.ps1\""
```

Path information after the first URI segment is kept for files downloaded by using the `fileUris` property list. As shown in the earlier table, downloaded files are mapped into download subdirectories to reflect the structure of the `fileUris` values.

Microsoft Antimalware Extension for Windows

Overview

The threat landscape in cloud environments is constantly evolving, making it essential for organizations to maintain strong security and compliance. Microsoft Antimalware for Azure provides free, real-time protection to help detect and remove viruses, spyware, and other malicious software. It offers configurable alerts when known threats or unwanted software attempt to install or run on your Azure systems. This solution is built on the same antimalware platform as Microsoft Security Essentials (MSE), Microsoft Forefront Endpoint Protection, Microsoft System Center Endpoint Protection, Windows Intune, and Windows Defender for Windows 8.0 and later.

Microsoft Antimalware for Azure is a single-agent solution for applications and tenant environments, designed to run in the background without human intervention. You can deploy protection based on the needs of your application workloads, with either basic secure-by-default or advanced custom configuration, including antimalware monitoring.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

Operating system

The Microsoft Antimalware for Azure solution includes the Microsoft Antimalware Client, and Service, Antimalware classic deployment model, Antimalware PowerShell cmdlets, and Azure Diagnostics Extension. The Microsoft Antimalware solution is supported on Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 operating system families. It isn't supported on the Windows Server 2008 operating system, and also isn't supported in Linux.

Windows Defender is the built-in Antimalware enabled in Windows Server 2016. The Windows Defender Interface is also enabled by default on some Windows Server 2016 SKUs. The Azure VM Antimalware extension can still be added to a Windows Server 2016 and above Azure VM

with Windows Defender. In this scenario, the extension applies any optional configuration policies to be used by Windows Defender. The extension doesn't deploy any other antimalware service. For more information, see Microsoft Antimalware for Azure Cloud Services and Virtual Machines: Samples.

Internet connectivity

The Microsoft Antimalware for Windows requires that the target virtual machine is connected to the internet to receive regular engine and signature updates.

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration such as onboarding to Azure Antimalware.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the VM extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
      "type": "Microsoft.Compute/virtualMachines/extensions",
      "name": "[concat(parameters('vmName'),'/', parameters('vmExtensionName'))]",
      "apiVersion": "2019-07-01",
      "location": "[resourceGroup().location]",
      "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
      ],

      "properties": {
        "publisher": "Microsoft.Azure.Security",
        "type": "IaaSAntimalware",
        "typeHandlerVersion": "1.3",
        "autoUpgradeMinorVersion": true,
        "settings": {
          "AntimalwareEnabled": "true",
          "Exclusions": {
            "Extensions": ".ext1;.ext2",
            "Paths": "c:\excluded-path-1;c:\excluded-path-2",
```

```
            "Processes": "excludedproc1.exe;excludedproc2.exe"
          },

          "RealtimeProtectionEnabled": "true",
          "ScheduledScanSettings": {
            "isEnabled": "true",
            "scanType": "Quick",
            "day": "7",
            "time": "120"
          }
        },
        "protectedSettings": null
      }
}
```

You must include, at a minimum, the following content to enable the Microsoft Antimalware extension:

`{ "AntimalwareEnabled": true }`

Microsoft Antimalware JSON configuration sample:

JSON

```
{ "AntimalwareEnabled": true, "RealtimeProtectionEnabled": true,
"ScheduledScanSettings": { "isEnabled": true, "day": 1, "time": 120, "scanType":
"Full" },

"Exclusions": { "Extensions": ".ext1;.ext2", "Paths": "c:\excluded-path-
1;c:\excluded-path-2", "Processes": "excludedproc1.exe;excludedproc2.exe" }
}
```

AntimalwareEnabled:

- required parameter
- Values: true/false
  - true = Enable
  - false = Error out, as false isn't a supported value

RealtimeProtectionEnabled:

- Values: true/false, default is true
  - true = Enable
  - false = Disable

ScheduledScanSettings:

- isEnabled = true/false

- day = 0-8 (0-daily, 1-Sunday, 2-Monday, ..., 7-Saturday, 8-Disabled)
- time = 0-1440 (measured in minutes after midnight - 60->1AM, 120 -> 2AM, ...)
- scanType = Quick/Full, default is Quick
- If isEnabled = true is the only setting provided, the following defaults are set: day=7 (Saturday), time=120 (2 AM), scanType="Quick"

Exclusions

- Semicolons delimit multiple exclusions in the same list.
- If no exclusions are specified, the system overwrites existing exclusions with blanks.

PowerShell deployment

Use the appropriate commands to deploy the Azure Antimalware extension to an existing virtual machine, based on your deployment type.

- Azure Resource Manager based Virtual Machine
- Azure Service Fabric Clusters
- Azure Arc-enabled servers

Troubleshoot and support

Troubleshoot

Microsoft Antimalware extension logs are available at - %Systemdrive%\WindowsAzure\Logs\Plugins\Microsoft.Azure.Security.IaaSAntimalware(OrPaaSAntimalware)\1.5.5.x(version#)\CommandExecution.log

Error codes and their meanings

VM Snapshot Linux extension for Azure Backup

Summarize this article for me

Azure Backup provides support for backing up workloads from on-premises to cloud and backing up cloud resources to Recovery Services vault. Azure Backup uses VM snapshot extension to take an application consistent backup of the Azure virtual machine without the need to shutdown the VM. VM Snapshot Linux extension is published and supported by Microsoft as part of Azure Backup service. Azure Backup will install the extension as part of first scheduled backup triggered post enabling backup. This document details the supported platforms, configurations, and deployment options for the VM Snapshot extension.

The VMSnapshot extension appears in the Azure portal only for non-managed VMs.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

Operating system

For a list of supported operating systems, please refer to Operating Systems supported by Azure Backup

Extension schema

The following JSON shows the schema for the VM snapshot extension. The extension requires the task ID - this identifies the backup job which triggered snapshot on the VM, status blob uri - where status of the snapshot operation is written, scheduled start time of the snapshot, logs blob uri - where logs corresponding to snapshot task are written, objstr- representation of VM disks and meta data. Because these settings should be treated as sensitive data, it should be stored in a protected setting configuration. Azure VM extension protected setting data is encrypted, and only decrypted on the target virtual machine. Please note that these settings are recommended to be passed from Azure Backup service only as part of Backup job.

JSON

```
{
  "type": "extensions",
  "name": "VMSnapshot",
  "location":"<myLocation>",
  "properties": {
    "publisher": "Microsoft.RecoveryServices",
    "type": "VMSnapshot",
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "locale":"<location>",
      "taskId":"<taskId used by Azure Backup service to communicate with extension>",
      "commandToExecute": "snapshot",
```

```
      "commandStartTimeUTCTicks": "<scheduled start time of the snapshot task>",
      "vmType": "microsoft.compute/virtualmachines"
    },
    "protectedSettings": {
      "objectStr": "<blob SAS uri representation of VM sent by Azure Backup service to extension>",
      "logsBlobUri": "<blob uri where logs of command execution by extension are written to>",
      "statusBlobUri": "<blob uri where status of the command executed by extension is written>"
    }
  }
}
```

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. However, the recommended way of adding a VM snapshot extension to a virtual machine is by enabling backup on the virtual machine. This can be achieved through a Resource Manager template. A sample Resource Manager template that enables backup on a virtual machine can be found on the Azure Quick Start Gallery.

Azure CLI deployment

The Azure CLI can be used to enable backup on a virtual machine. Post enable backup, first scheduled backup job will install the Vm snapshot extension on the VM.

Azure CLI

```
az backup protection enable-for-vm \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --vm myVM \
    --policy-name DefaultPolicy
```

Azure PowerShell deployment

Azure PowerShell can be used to enable backup on a virtual machine. Once the backup is configured, first scheduled backup job will install the Vm snapshot extension on the VM.

Azure PowerShell

```
$targetVault = Get-AzRecoveryServicesVault -ResourceGroupName "myResourceGroup" -Name
"myRecoveryServicesVault"
$pol = Get-AzRecoveryServicesBackupProtectionPolicy Name DefaultPolicy -VaultId $targetVault.ID
Enable-AzRecoveryServicesBackupProtection -Policy $pol -Name "myVM" -ResourceGroupName
"myVMResourceGroup" -VaultId $targetVault.ID
```

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file:

```
/var/log/waagent.log
```

Error codes and their meanings

Troubleshooting information can be found on the Azure VM backup troubleshooting guide.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to the Azure support site and select Get support. For information about using Azure Support, read the Microsoft Azure support FAQ.

VM Snapshot Windows extension for Azure Backup

Summarize this article for me

Azure Backup provides support for backing up workloads from on-premises to cloud and backing up cloud resources to Recovery Services vault. Azure Backup uses VM snapshot extension to take an application consistent backup of the Azure virtual machine without the need to shutdown the VM. VM Snapshot extension is published and supported by Microsoft as part of Azure Backup service. Azure Backup will install the extension as part of first scheduled backup triggered post enabling backup. This document details the supported platforms, configurations, and deployment options for the VM Snapshot extension.

The VMSnapshot extension appears in the Azure portal only for non-managed VMs.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

Operating system

For a list of supported operating systems, refer to Operating Systems supported by Azure Backup

Extension schema

The following JSON shows the schema for the VM snapshot extension. The extension requires the task ID - this identifies the backup job which triggered snapshot on the VM, status blob uri - where status of the snapshot operation is written, scheduled start time of the snapshot, logs blob uri - where logs corresponding to snapshot task are written, objstr- representation of VM disks and meta data. Because these settings should be treated as sensitive data, it should be stored in a protected setting configuration. Azure VM extension protected setting data is encrypted, and only decrypted on the target virtual machine. Note that these settings are recommended to be passed from Azure Backup service only as part of Backup job.

JSON

```

Manage Network Watcher Agent virtual machine extension for Linux

09/23/2025

The Network Watcher Agent virtual machine extension is a requirement for some of Azure Network Watcher features that capture network traffic to diagnose and monitor Azure virtual machines (VMs). For more information, see What is Azure Network Watcher?

In this article, you learn how to install and uninstall Network Watcher Agent for Linux. Installation of the agent doesn't disrupt, or require a reboot of the virtual machine. If the virtual machine is deployed by an Azure service, check the documentation of the service to determine whether or not it permits installing extensions in the virtual machine.

> **Note**
>
> Network Watcher Agent extension is not supported on AKS clusters.

Prerequisites

Portal

- An Azure Linux virtual machine (VM). For more information, see Supported Linux distributions and versions.
- Outbound TCP connectivity to `169.254.169.254` over `port 80` and `168.63.129.16` over `port 8037`. The agent uses these IP addresses to communicate with the Azure platform.
- Internet connectivity: Network Watcher Agent requires internet connectivity for some features to properly work. For example, it requires connectivity to your storage account to upload packet captures.

Supported operating systems

Network Watcher Agent extension for Linux can be installed on the following Linux distributions:

Expand table

Distribution	Version
AlmaLinux	9.2
Azure Linux	2.0
CentOS [1]	6.10 and 7
Debian	7 and 8
openSUSE Leap	42.3+
Oracle Linux	6.10 [2], 7 and 8+
Red Hat Enterprise Linux (RHEL)	6.10 [3], 7, 8 and 9.2
Rocky Linux	9.1
SUSE Linux Enterprise Server (SLES)	12 and 15 (SP2, SP3, and SP4)
Ubuntu	16+

[1] CentOS Linux reached its end-of-life (EOL) on June 30, 2024. For more information, see the CentOS End Of Life guidance.

[2] Extended life cycle (ELS) support for Oracle Linux version 6.X ended on July 1, 2024.

[3] Extended life cycle (ELS) support for Red Hat Enterprise Linux 6.X ended on June 30, 2024.

Extension schema

The following JSON shows the schema for the Network Watcher Agent extension. The extension doesn't require, or support, any user-supplied settings. The extension relies on its default configuration.

JSON

```
{
    "name": "[concat(parameters('vmName'), '/AzureNetworkWatcherExtension')]",
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "apiVersion": "2023-03-01",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
    ],
    "properties": {
```

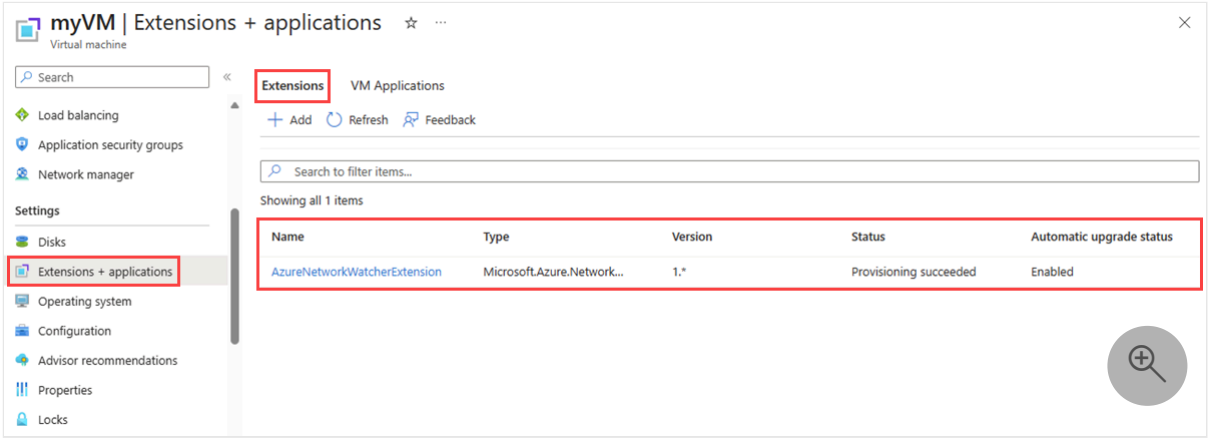
```
        "autoUpgradeMinorVersion": true,
        "publisher": "Microsoft.Azure.NetworkWatcher",
        "type": "NetworkWatcherAgentLinux",
        "typeHandlerVersion": "1.4"
    }
}
```

List installed extensions

Portal

From the virtual machine page in the Azure portal, you can view the installed extension by following these steps:

1. Under **Settings**, select **Extensions + applications**.
2. In the **Extensions** tab, you can see all installed extensions on the virtual machine. If the list is long, you can use the search box to filter the list.

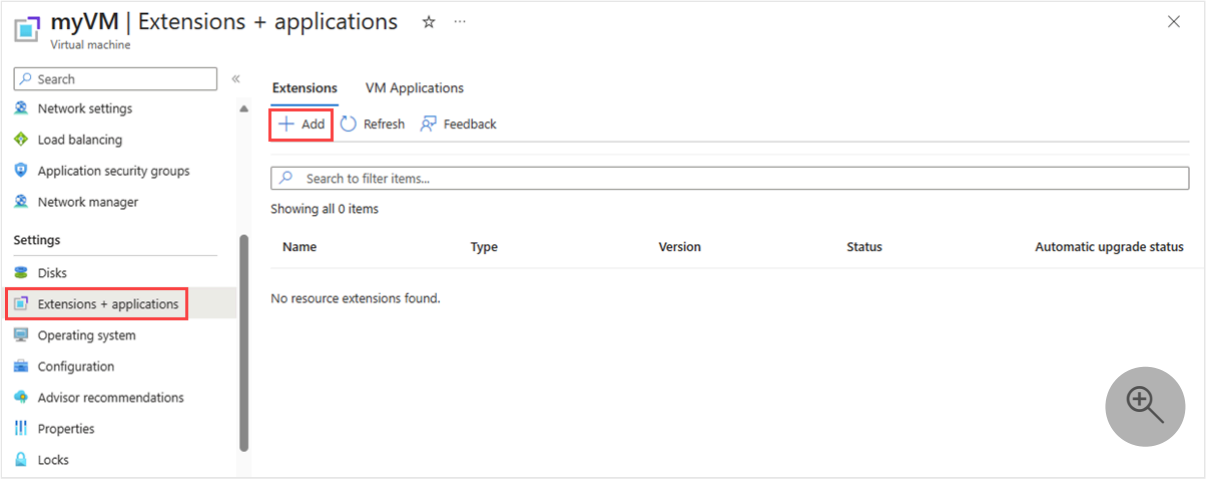


Install Network Watcher Agent VM extension

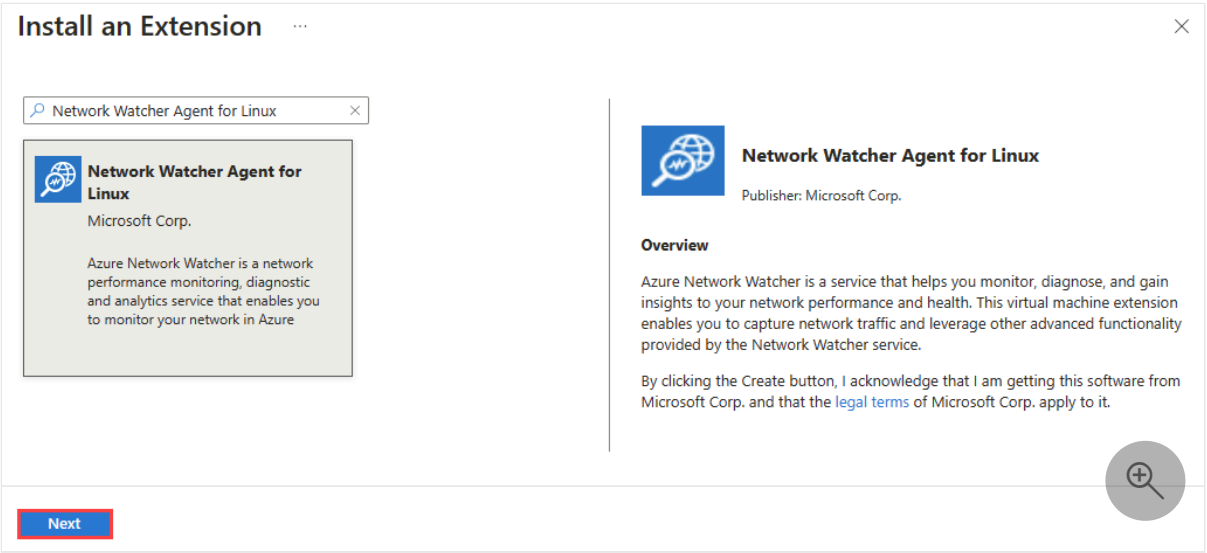
Portal

From the virtual machine page in the Azure portal, you can install the Network Watcher Agent VM extension by following these steps:

1. Under **Settings**, select **Extensions + applications**.
2. Select **+ Add** and search for **Network Watcher Agent** and install it. If the extension is already installed, you can see it in the list of extensions.



3. In the search box of **Install an Extension**, enter *Network Watcher Agent for Linux*. Select the extension from the list and select **Next**.



4. Select **Review + create** and then select **Create**.

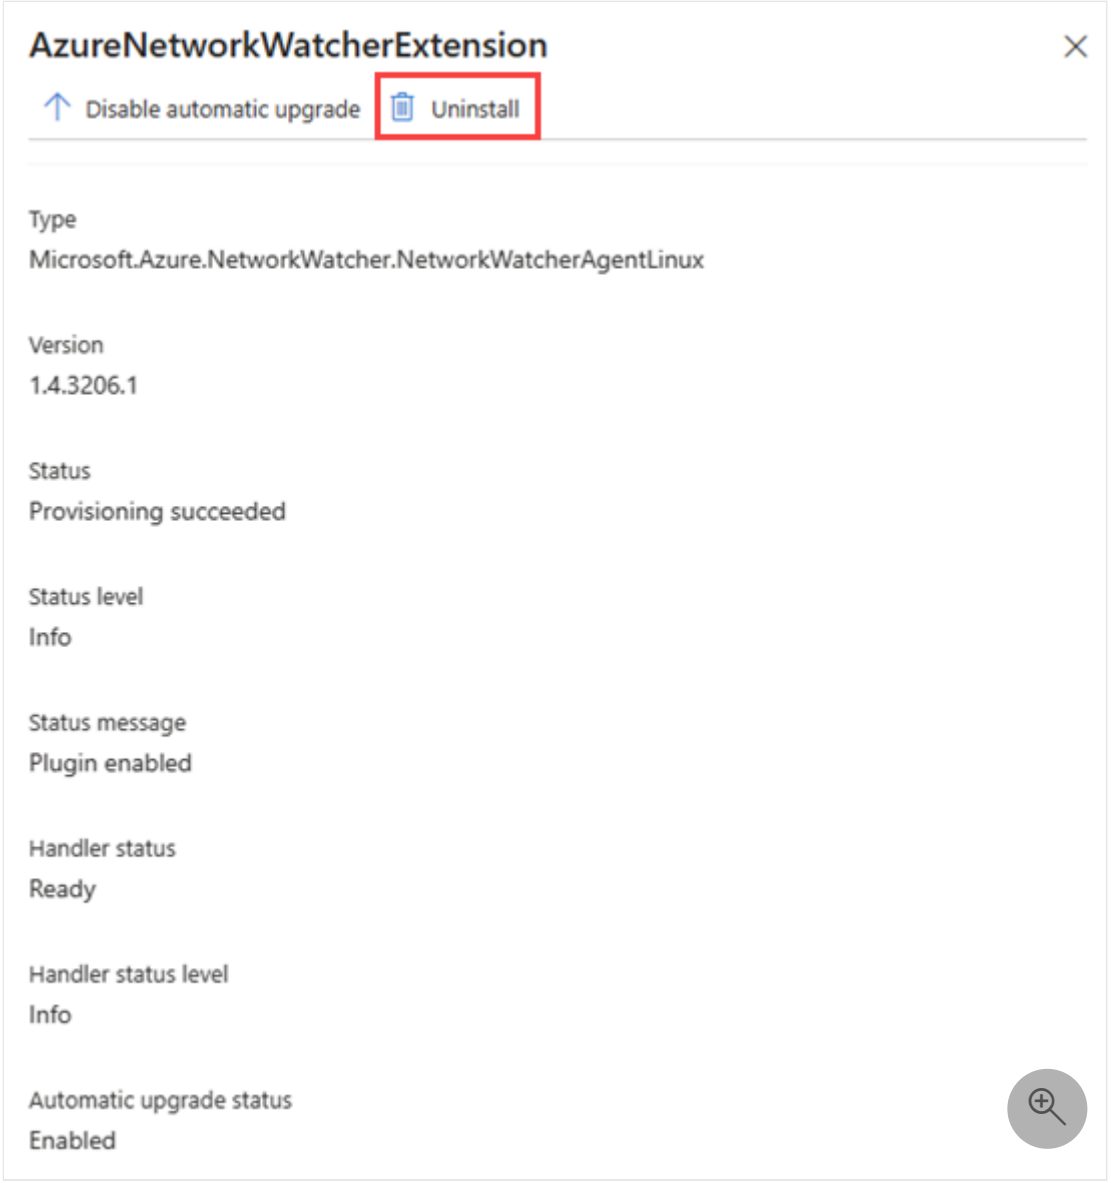
Uninstall Network Watcher Agent VM extension

Portal

From the virtual machine page in the Azure portal, you can uninstall the Network Watcher Agent VM extension by following these steps:

1. Under **Settings**, select **Extensions + applications**.

2. Select **AzureNetworkWatcherExtension** from the list of extensions, and then select **Uninstall**.



> **Note**
>
> You might see Network Watcher Agent VM extension named differently than **AzureNetworkWatcherExtension**.

Update Azure Network Watcher extension to the latest version

Summarize this article for me

Azure Network Watcher is a network performance monitoring, diagnostic, and analytics service that monitors Azure networks. The Network Watcher Agent virtual machine (VM) extension is a requirement for capturing network traffic on demand and using other advanced functionality on Azure VMs. It's used by connection monitor, connection troubleshoot, and packet capture.

Prerequisites

- An Azure account with an active subscription. If you don't have one, create a free account.
- An Azure virtual machine (VM) that has the Network Watcher extension installed.

Latest version

The latest version of the Network Watcher extension is `1.4.3783.1`.

> **Note**
>
> When automatic extension upgrade is enabled, there may be a delay of up to 30 days between the release of a new extension version and its automatic upgrade on your virtual machines and scale sets.

Identify latest version

Use az vm extension image list command to identify the latest version of the Network Watcher extension for your VM's operating system.

Windows

Azure CLI

```
# Identify latest version of Network Watcher extension for Windows.
az vm extension image list --name 'NetworkWatcherAgentWindows' --publisher
'Microsoft.Azure.NetworkWatcher' --latest --location 'eastus'
```

Update your extension using a PowerShell script

If you have large deployments, use a PowerShell script to update multiple VMs at once. The following PowerShell script updates Network Watcher extension of all Windows VMs in a subscription:

PowerShell

```
<#
    .SYNOPSIS
    This script will scan all VMs in the provided subscription and upgrade any out
of date AzureNetworkWatcherExtensions
    .DESCRIPTION
    This script should be no-op if AzureNetworkWatcherExtensions are up to date
    Requires Azure PowerShell 4.2 or higher to be installed (e.g. Install-Module
AzureRM).
    .EXAMPLE
    .\UpdateVMAgentsInSub.ps1 -SubID F4BC4873-5DAB-491E-B713-1358EF4992F2 -NoUpdate
#>

[CmdletBinding()]
param(
    [Parameter(Mandatory=$true)]
    [string] $SubID,
    [Parameter(Mandatory=$false)]
    [Switch] $NoUpdate = $false,
    [Parameter(Mandatory=$false)]
    [string] $MinVersion = "1.4.2.1"
)
function NeedsUpdate($version)
{
    if ([Version]$version -lt [Version]$MinVersion)
    {
        $lessThan = $true
    }else{
        $lessThan = $false
    }
    return $lessThan
}
Write-Host "Scanning all VMs in the subscription: $($SubID)"
Set-AzContext -SubscriptionId $SubID
$vms = Get-AzVM
$foundVMs = $false

else
{
    Write-Host "All AzureNetworkWatcherExtensions up to date"
}
```

Update your extension manually

To update your extension, you need to know your extension version.

Check your extension version

You can check your extension version by using the Azure portal, the Azure CLI, or PowerShell.

Use the Azure portal

1. Go to the **Extensions** pane of your VM in the Azure portal.
2. Select the **AzureNetworkWatcher** extension to see the details pane.
3. Locate the version number in the **Version** field.

Use the Azure CLI

Run the following command from an Azure CLI prompt:

Azure CLI

```
az vm get-instance-view --resource-group  "SampleRG" --name "Sample-VM"
```

Locate "**AzureNetworkWatcherExtension**" in the output and identify the version number from the *"TypeHandlerVersion"* field in the output.

Information about the extension appears multiple times in the JSON output. The full version number of the extension is available under the Extensions block.

You should see something like the below:

Use PowerShell

Run the following commands from a PowerShell prompt:

PowerShell

```
Get-AzVM -ResourceGroupName "SampleRG" -Name "Sample-VM" -Status
```

Locate the Azure Network Watcher extension in the output and identify the version number from the *"TypeHandlerVersion"* field in the output.

You should see something like the below:

```
ExtensionHandlers[1]     :
  Type                   : Microsoft.Azure.NetworkWatcher.NetworkWatcherAgentWindows
  TypeHandlerVersion     : 1.4.1654.1
  Status                 :
    Code                 : ProvisioningState/succeeded
    Level                : Info
```

Update your extension

If your version is below the latest version mentioned above, update your extension by using any of the following options.

Option 1: Use PowerShell

Run the following commands:

PowerShell

```powershell
#Linux command
Set-AzVMExtension -ResourceGroupName "myResourceGroup1" -Location "WestUS" -VMName
"myVM1" -Name "AzureNetworkWatcherExtension" -Publisher
"Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentLinux"

#Windows command
Set-AzVMExtension -ResourceGroupName "myResourceGroup1" -Location "WestUS" -VMName
"myVM1" -Name "AzureNetworkWatcherExtension" -Publisher
"Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentWindows" -ForceRerun
"True"
```

If that doesn't work. Remove and install the extension again, using the steps below, to install latest version.

Removing the extension

PowerShell

```powershell
#Same command for Linux and Windows
Remove-AzVMExtension -ResourceGroupName "SampleRG" -VMName "Sample-VM" -Name
"AzureNetworkWatcherExtension"
```

Installing the extension again

PowerShell

```
#Linux command
Set-AzVMExtension -ResourceGroupName "SampleRG" -Location "centralus" -VMName
"Sample-VM" -Name "AzureNetworkWatcherExtension" -Publisher
"Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentLinux" -
typeHandlerVersion "1.4"

#Windows command
Set-AzVMExtension -ResourceGroupName "SampleRG" -Location "centralus" -VMName
"Sample-VM" -Name "AzureNetworkWatcherExtension" -Publisher
"Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentWindows" -
typeHandlerVersion "1.4"
```

Option 2: Use the Azure CLI

Force an upgrade.

Azure CLI

```
#Linux command
az vm extension set --resource-group "myResourceGroup1" --vm-name "myVM1" --name
"NetworkWatcherAgentLinux" --publisher "Microsoft.Azure.NetworkWatcher" --force-
update

#Windows command
az vm extension set --resource-group "myResourceGroup1" --vm-name "myVM1" --name
"NetworkWatcherAgentWindows" --publisher "Microsoft.Azure.NetworkWatcher" --force-
update
```

If that doesn't work, remove and install the extension again, and follow these steps to automatically add the latest version.

Remove the extension.

Azure CLI

```
#Same for Linux and Windows
az vm extension delete --resource-group "myResourceGroup1" --vm-name "myVM1" -n
"AzureNetworkWatcherExtension"
```

Install the extension again.

Azure CLI

```
#Linux command
az vm extension set --resource-group "DALANDEMO" --vm-name "Linux-01" --name
```

```
"NetworkWatcherAgentLinux" --publisher "Microsoft.Azure.NetworkWatcher"

#Windows command
az vm extension set --resource-group "DALANDEMO" --vm-name "Linux-01" --name
"NetworkWatcherAgentWindows" --publisher "Microsoft.Azure.NetworkWatcher"
```

Option 3: Reboot your VMs

If you have auto-upgrade set to true for the Network Watcher extension, reboot your VM installation to the latest extension.

Support

If you need more help at any point in this article, see the Network Watcher extension documentation for Linux or Windows. You can also contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, file an Azure support incident. Go to the Azure support site, and select **Get support**. For information about using Azure Support, read the Microsoft Azure support FAQ.

Last updated on 02/25/2026

InfiniBand Driver Extension for Linux

This extension installs InfiniBand OFED drivers on InfiniBand and SR-IOV-enabled ('r' sizes) HB-series and N-series VMs running Linux. Depending on the VM family, the extension installs the appropriate drivers for the Connect-X NIC. It does not install the InfiniBand ND drivers on the non-SR-IOV enabled HB-series and N-series VMs.

Instructions on manual installation of the OFED drivers are available in Enable InfiniBand on HPC VMs.

An extension is also available to install InfiniBand drivers for Windows VMs.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

Operating system

This extension supports the following OS distros, depending on driver support for specific OS version. For latest list of supported OS and driver versions, refer to resources.json

Expand table

Distribution	Version	InfiniBand NIC drivers
Ubuntu	18.04 LTS, 20.04 LTS, 22.04 LTS	CX3-Pro, CX5, CX6
Red Hat Enterprise Linux	7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.1, 8,2	CX3-Pro, CX5, CX6

> **Important**
>
> This document references a release version of Linux that is nearing or at, End of Life (EOL). Please consider updating to a more current version.

Internet connectivity

The Microsoft Azure Extension for InfiniBand Drivers requires that the target VM is connected to and has access to the internet.

Extension schema

The following JSON shows the schema for the extension.

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverLinux",
    "typeHandlerVersion": "1.2",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

Properties

Expand table

Name	Value / Example	Data Type
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	InfiniBandDriverLinux	string
typeHandlerVersion	1.2	int

Deployment

Azure Resource Manager Template

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
  "name": "myExtensionName",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverLinux",
    "typeHandlerVersion": "1.2",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

PowerShell

PowerShell

```
Set-AzVMExtension
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Location "southcentralus" `
    -Publisher "Microsoft.HpcCompute" `
    -ExtensionName "InfiniBandDriverLinux" `
    -ExtensionType "InfiniBandDriverLinux" `
    -TypeHandlerVersion 1.2 `
    -SettingString '{ `
    }'
```

Azure CLI

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name InfiniBandDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.2
```

Add extension to a Virtual Machine Scale Set

The following example installs the latest version 1.2 InfiniBandDriverLinux extension on all RDMA-capable VMs in an existing virtual machine scale set named *myVMSS* deployed in the resource group named *myResourceGroup*:

PowerShell

```
$VMSS = Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS"
Add-AzVmssExtension -VirtualMachineScaleSet $VMSS -Name "InfiniBandDriverLinux" -
Publisher "Microsoft.HpcCompute" -Type "InfiniBandDriverLinux" -TypeHandlerVersion
"1.2"
Update-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "MyVMSS" -
VirtualMachineScaleSet $VMSS
Update-AzVmssInstance -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS"
-InstanceId "*"
```

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using Azure PowerShell and Azure CLI. To see the deployment state of extensions for a given VM, run the following command.

PowerShell

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name
myExtensionName
```

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file. Refer to this file to track the status of the installation as well as for troubleshooting any failures.

```
Bash
/var/log/azure/ib-vmext-status
```

Exit codes

The following table describes the meaning and recommended action based on the exit codes of the extension installation process.

Expand table

Exit Code	Meaning	Possible Action
0	Operation successful	
1	Incorrect usage of extension	Check execution output log
10	Linux Integration Services for Hyper-V and Azure not available or installed	Check output of lspci
11	Mellanox InfiniBand not found on this VM size	Use a supported VM size and OS
12	Image offer not supported	
13	VM size not supported	Use an InfiniBand-enabled ('r' size) H-series and N-seriesN-series VM to deploy
14	Operation unsuccessful	Check execution output log

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file a support incident through the Azure support site. For information about using Azure Support, read the Microsoft Azure support FAQ.

Next steps

For more information about InfiniBand-enabled ('r' sizes), see HB-series and N-series VMs.

Learn more about Linux VMs extensions and features

Last updated on 11/10/2025

InfiniBand Driver Extension for Windows

This extension installs InfiniBand ND drivers (for non-SR-IOV enabled) and OFED drivers (for SR-IOV-enabled) ('r' sizes) H-series and N-series VMs running Windows. Depending on the VM family, the extension installs the appropriate drivers for the Connect-X NIC.

An extension is also available to install InfiniBand drivers for Linux VMs.

> ⓘ Note
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

Operating system

This extension supports the following OS distros, depending on driver support for specific OS version. Note the appropriate InfiniBand NIC for the H and N-series VM sizes of interest.

Expand table

Distribution	InfiniBand NIC drivers
Windows 10	CX5, CX6
Windows Server 2019	CX5, CX6
Windows Server 2016	CX5, CX6
Windows Server 2012 R2	CX5, CX6

For latest list of supported OS and driver versions, refer to resources.json

Internet connectivity

The Microsoft Azure Extension for InfiniBand Drivers requires that the target VM is connected to and has access to the internet.

Extension schema

The following JSON shows the schema for the extension.

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverWindows",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

Properties

Expand table

Name	Value / Example	Data Type
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	InfiniBandDriverWindows	string
typeHandlerVersion	1.5	int

Deployment

Azure Resource Manager Template

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template.

The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
  "name": "myExtensionName",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverWindows",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

PowerShell

PowerShell

```
Set-AzVMExtension
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Location "southcentralus" `
    -Publisher "Microsoft.HpcCompute" `
    -ExtensionName "InfiniBandDriverWindows" `
    -ExtensionType "InfiniBandDriverWindows" `
    -TypeHandlerVersion 1.5 `
    -SettingString '{ `
    }'
```

Azure CLI

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
```

```
  --vm-name myVM \
  --name InfiniBandDriverWindows \
  --publisher Microsoft.HpcCompute \
  --version 1.5
```

Add extension to a Virtual Machine Scale Set

The following example installs the latest version 1.5 InfiniBandDriverWindows extension on all RDMA-capable VMs in an existing virtual machine scale set named *myVMSS* deployed in the resource group named *myResourceGroup*:

PowerShell

```
$VMSS = Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS"
Add-AzVmssExtension -VirtualMachineScaleSet $VMSS -Name "InfiniBandDriverWindows" -
Publisher "Microsoft.HpcCompute" -Type "InfiniBandDriverWindows" -TypeHandlerVersion
"1.5"
Update-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "MyVMSS" -
VirtualMachineScaleSet $VMSS
Update-AzVmssInstance -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS"
-InstanceId "*"
```

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using Azure PowerShell and Azure CLI. To see the deployment state of extensions for a given VM, run the following command.

PowerShell

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name
myExtensionName
```

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file. Refer to this file to track the status of the installation as well as for troubleshooting any failures.

Windows Command Prompt

```
C:\WindowsAzure\Logs\Plugins\Microsoft.HpcCompute.InfiniBandDriverWindows\
```

Exit codes

The following table describes the meaning and recommended action based on the exit codes of the extension installation process.

Expand table

Error Code	Meaning	Possible Action
0	Operation successful	
3010	Operation successful. Reboot required.	
100	Operation not supported or could not be completed.	Possible causes: PowerShell version not supported, VM size is not an InfiniBand-enabled VM, Failure downloading data. Check the log files to determine cause of error.
240, 840	Operation timeout.	Retry operation.
-1	Exception occurred.	Check the log files to determine cause of exception.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file a support incident through the Azure support site. For information about using Azure Support, read the Microsoft Azure support FAQ.

Next steps

For more information about InfiniBand-enabled ('r' sizes), see H-series and N-series VMs.

Last updated on 11/10/2025

Enable InfiniBand

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

RDMA capable HB-series and N-series VMs communicate over the low latency and high bandwidth InfiniBand network. The RDMA capability over such an interconnect is critical to boost the scalability and performance of distributed-node HPC and AI workloads. The InfiniBand enabled HB-series and N-series VMs are connected in a non-blocking fat tree with a low-diameter design for optimized and consistent RDMA performance.

There are various ways to enable InfiniBand on the capable VM sizes.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

VM Images with InfiniBand drivers

See VM Images for a list of supported VM Images on the Marketplace, which come pre-loaded with InfiniBand drivers (for SR-IOV or non-SR-IOV VMs) or can be configured with the appropriate drivers for RDMA capable VMs. The Ubuntu-HPC and AlmaLinux-HPC VM images in the marketplace are the easiest way to get started.

InfiniBand Driver VM Extensions

On Linux, the InfiniBandDriverLinux VM extension can be used to install the Mellanox OFED drivers and enable InfiniBand on the SR-IOV enabled HB-series and N-series VMs.

On Windows, the InfiniBandDriverWindows VM extension installs Windows Network Direct drivers (on non-SR-IOV VMs) or Mellanox OFED drivers (on SR-IOV VMs) for RDMA connectivity. In certain deployments of A8 and A9 instances, the HpcVmDrivers extension is added automatically. Note that the HpcVmDrivers VM extension is being deprecated; it will not be updated.

To add the VM extension to a VM, you can use Azure PowerShell cmdlets. For more information, see Virtual machine extensions and features. You can also work with extensions for

VMs deployed in the classic deployment model.

Manual installation

Mellanox OpenFabrics drivers (OFED) can be manually installed on the SR-IOV enabled HB-series and N-series VMs.

Linux

The OFED drivers for Linux can be installed with the example below. Though the example here is for RHEL, but the steps are general and can be used for any compatible Linux operating system such as Ubuntu (22.04, 24.04) and SLES (12 SP4+ and 15). More examples for other distros are on the azhpc-images repo. The inbox drivers also work as well, but the Mellanox OFED drivers provide more features.

Bash

```
MLNX_OFED_DOWNLOAD_URL=http://content.mellanox.com/ofed/MLNX_OFED-5.0-
2.1.8.0/MLNX_OFED_LINUX-5.0-2.1.8.0-rhel7.7-x86_64.tgz
# Optionally verify checksum
wget --retry-connrefused --tries=3 --waitretry=5 $MLNX_OFED_DOWNLOAD_URL
tar zxvf MLNX_OFED_LINUX-5.0-2.1.8.0-rhel7.7-x86_64.tgz

KERNEL=( $(rpm -q kernel | sed 's/kernel\-//g') )
KERNEL=${KERNEL[-1]}
# Uncomment the lines below if you are running this on a VM
#RELEASE=( $(cat /etc/redhat-release | awk '{print $4}') )
#yum -y install
http://olcentgbl.trafficmanager.net/redhat/${RELEASE}/updates/x86_64/kernel-
devel-${KERNEL}.rpm
sudo yum install -y kernel-devel-${KERNEL}
sudo ./MLNX_OFED_LINUX-5.0-2.1.8.0-rhel7.7-x86_64/mlnxofedinstall --kernel $KERNEL -
-kernel-sources /usr/src/kernels/${KERNEL} --add-kernel-support --skip-repo
```

Windows

For Windows, download and install the Mellanox OFED for Windows drivers.

Enable IP over InfiniBand (IB)

If you plan to run MPI jobs, you typically don't need IPoIB. The MPI library will use the verbs interface for IB communication (unless you explicitly use the TCP/IP channel of MPI library). But if you have an app that uses TCP/IP for communication and you want to run over IB, you can

use IPoIB over the IB interface. Use the following commands (for RHEL) to enable IP over InfiniBand.

> **Important**
>
> To avoid issues, ensure you aren't running older versions of Microsoft Azure Linux Agent (waagent). We recommend using at least version 2.4.0.2 before enabling IP over IB.

Bash

```
sudo sed -i -e 's/# OS.EnableRDMA=n/OS.EnableRDMA=y/g' /etc/waagent.conf
sudo systemctl restart waagent
```

Next steps

- Learn more about installing and running various supported MPI libraries on the VMs.
- Review the HBv3-series overview and HC-series overview.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Last updated on 12/03/2025

NVIDIA GPU Driver Extension for Linux

This extension installs NVIDIA GPU drivers on Linux N-series virtual machines (VMs). Depending on the VM family, the extension installs CUDA or GRID drivers. When you install NVIDIA drivers by using this extension, you're accepting and agreeing to the terms of the NVIDIA End-User License Agreement. During the installation process, the VM might reboot to complete the driver setup.

Instructions on manual installation of the drivers and the current supported versions are available. An extension is also available to install NVIDIA GPU drivers on Windows N-series VMs.

> **Note**
>
> With Secure Boot enabled, all OS boot components (boot loader, kernel, kernel drivers) must be signed by trusted publishers (key trusted by the system). Secure Boot is not supported using Windows or Linux extensions. For more information on manually installing GPU drivers with Secure Boot enabled, see Azure N-series GPU driver setup for Linux.

> **Note**
>
> The GPU driver extensions do not automatically update the driver after the extension is installed. If you need to move to a newer driver version then either manually download and install the driver or remove and add the extension again.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

Operating system

This extension supports the following OS distros, depending on driver support for the specific OS version:

Expand table

Driver	Linux: Ubuntu	Linux: Red Hat Enterprise Linux
CUDA	20.04 LTS	7.9
GRID	22.04 LTS 24.04 LTS	8.2

> **Note**
>
> The latest supported CUDA drivers for NC-series VMs are currently 470.82.01. Later driver versions aren't supported on the K80 cards in NC. While the extension is being updated with this end of support for NC, install CUDA drivers manually for K80 cards on the NC-series.

> **Important**
>
> This document references a release version of Linux that is nearing or at, End of Life (EOL). Please consider updating to a more current version.

Internet connectivity

The Microsoft Azure Extension for NVIDIA GPU Drivers requires that the target VM is connected to the internet and has access.

Extension schema

The following JSON shows the schema for the extension:

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
```

```
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverLinux",
    "typeHandlerVersion": "1.6",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

Properties

Expand table

Name	Value/Example	Data type
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	NvidiaGpuDriverLinux	string
typeHandlerVersion	1.6	int

Settings

All settings are optional. The default behavior is to not update the kernel if not required for driver installation and install the latest supported driver and the CUDA toolkit (as applicable).

Expand table

Name	Description	Default value	Valid values	Data type
updateOS	Update the kernel even if not required for driver installation.	false	true, false	boolean
driverVersion	NV: GRID driver version. NC/ND: CUDA toolkit version. The latest drivers for the chosen CUDA are installed automatically.	latest	List of supported driver versions	string
installCUDA	Install CUDA toolkit. Only relevant for NC/ND series VMs.	true	true, false	boolean

Deployment

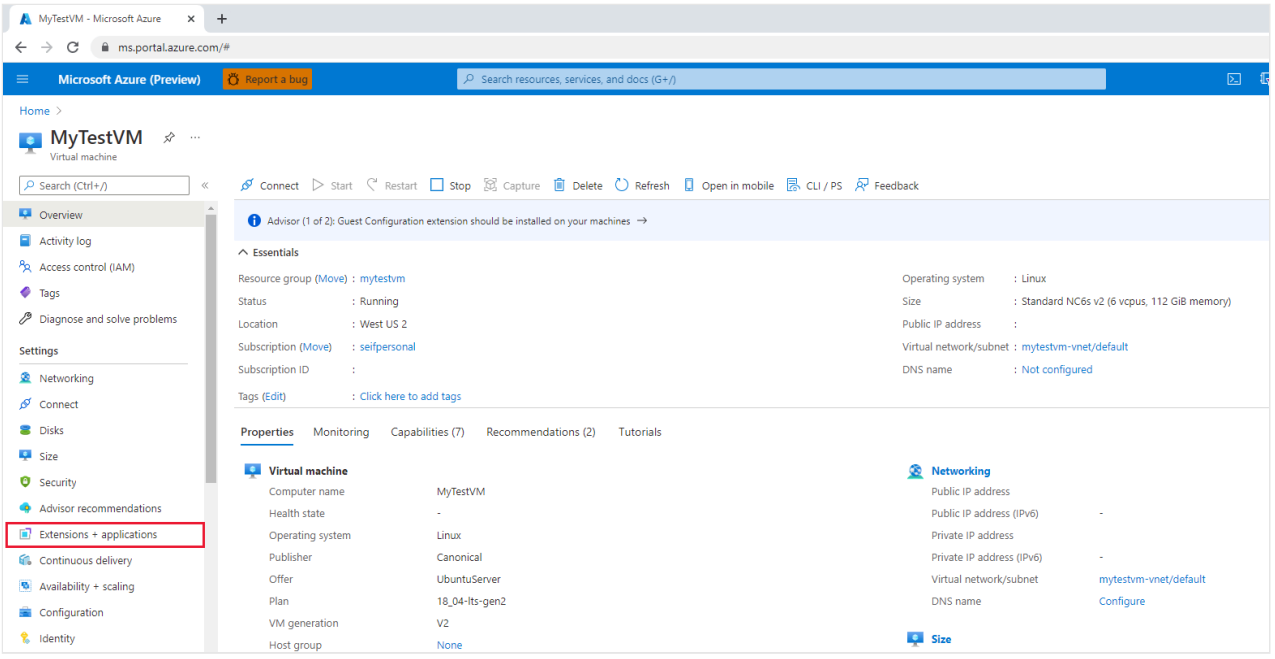
Azure portal

You can deploy Azure NVIDIA VM extensions in the Azure portal.

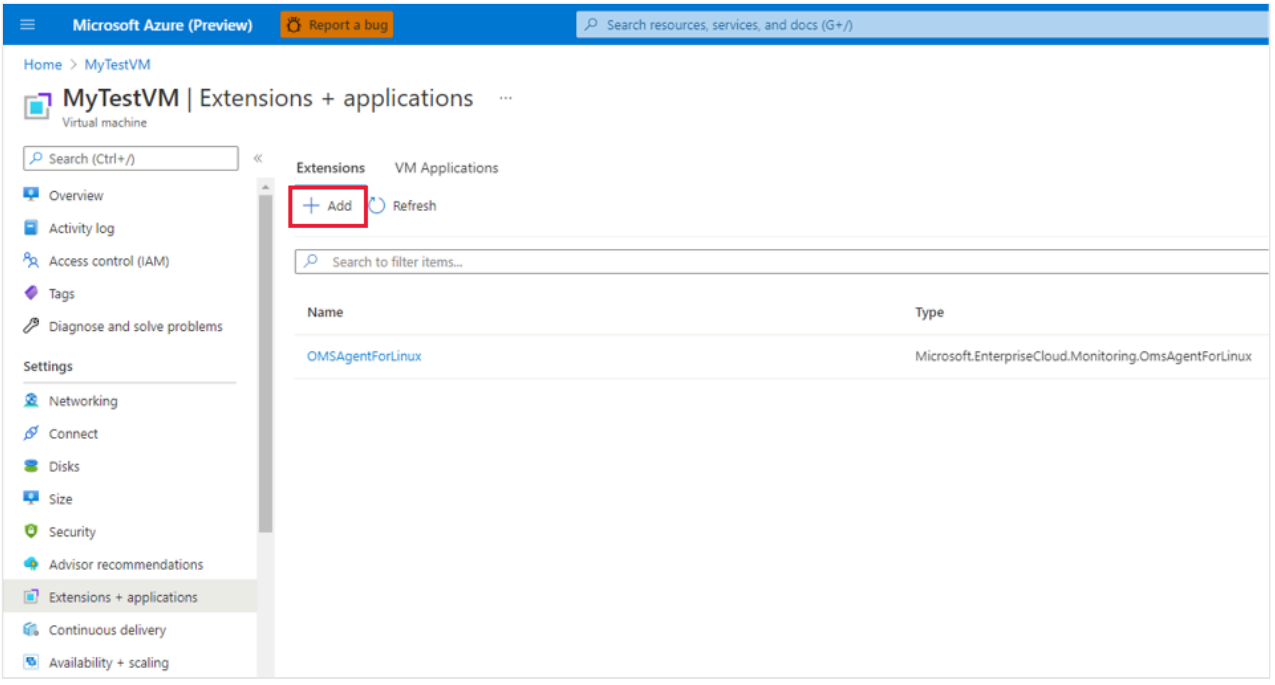
1. In a browser, go to the Azure portal.

2. Go to the virtual machine on which you want to install the driver.

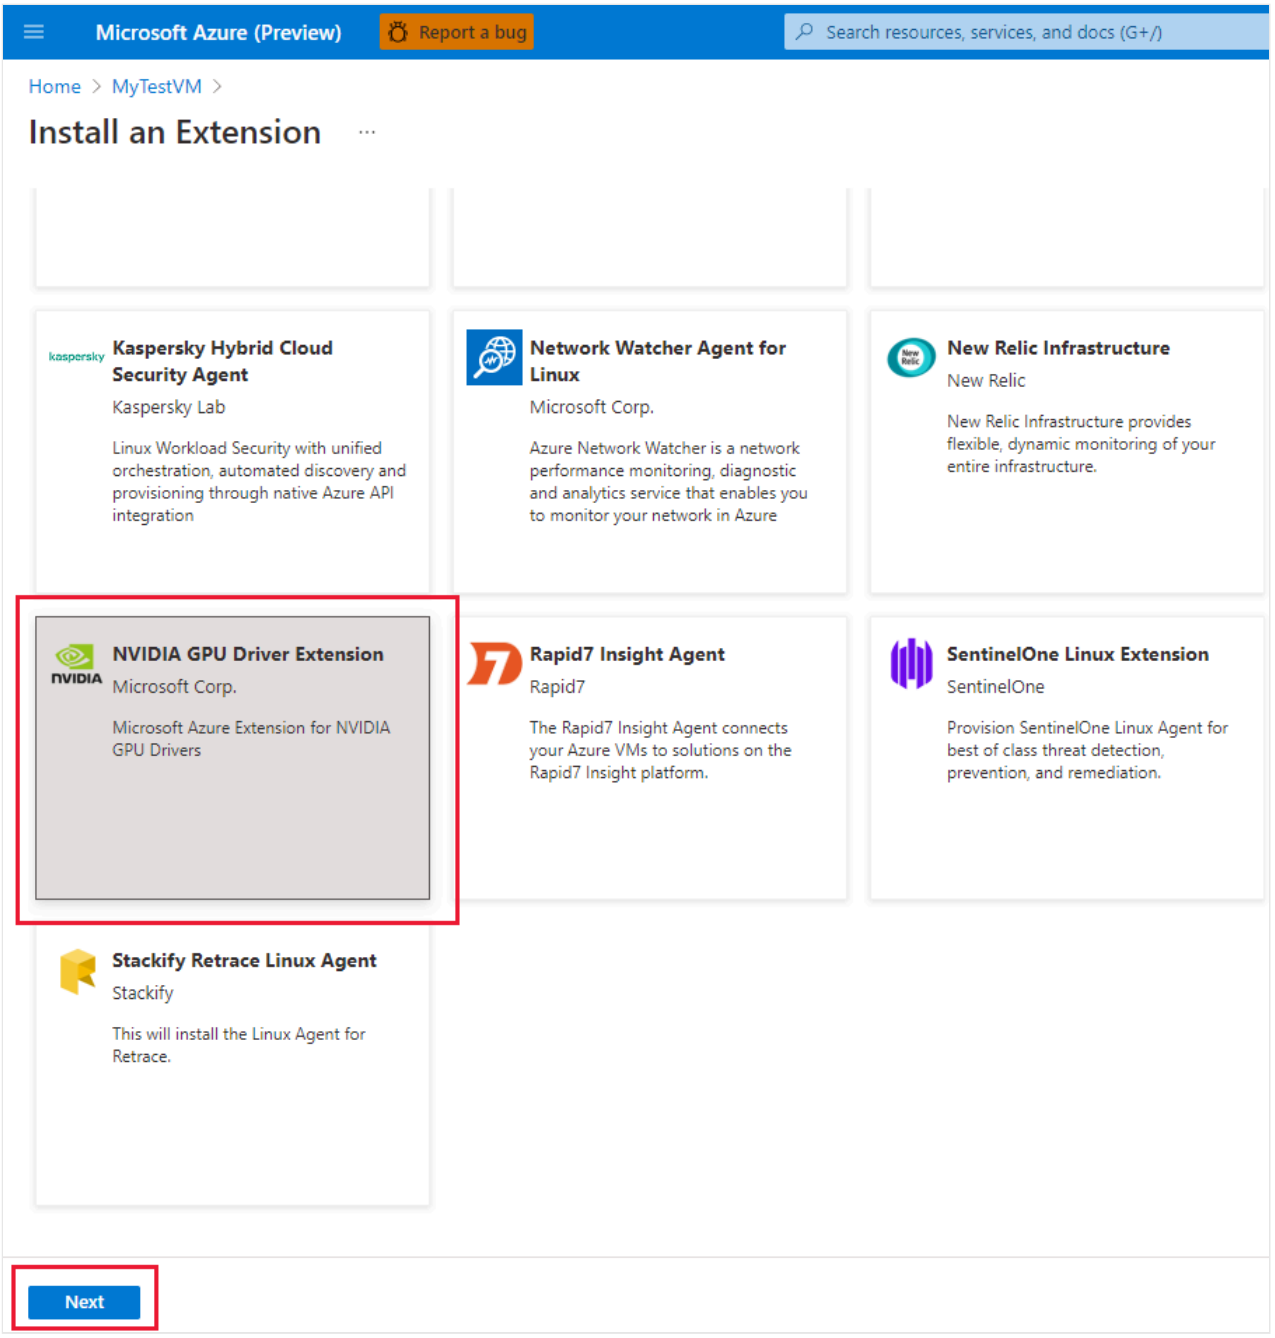
3. On the left menu, select **Extensions**.



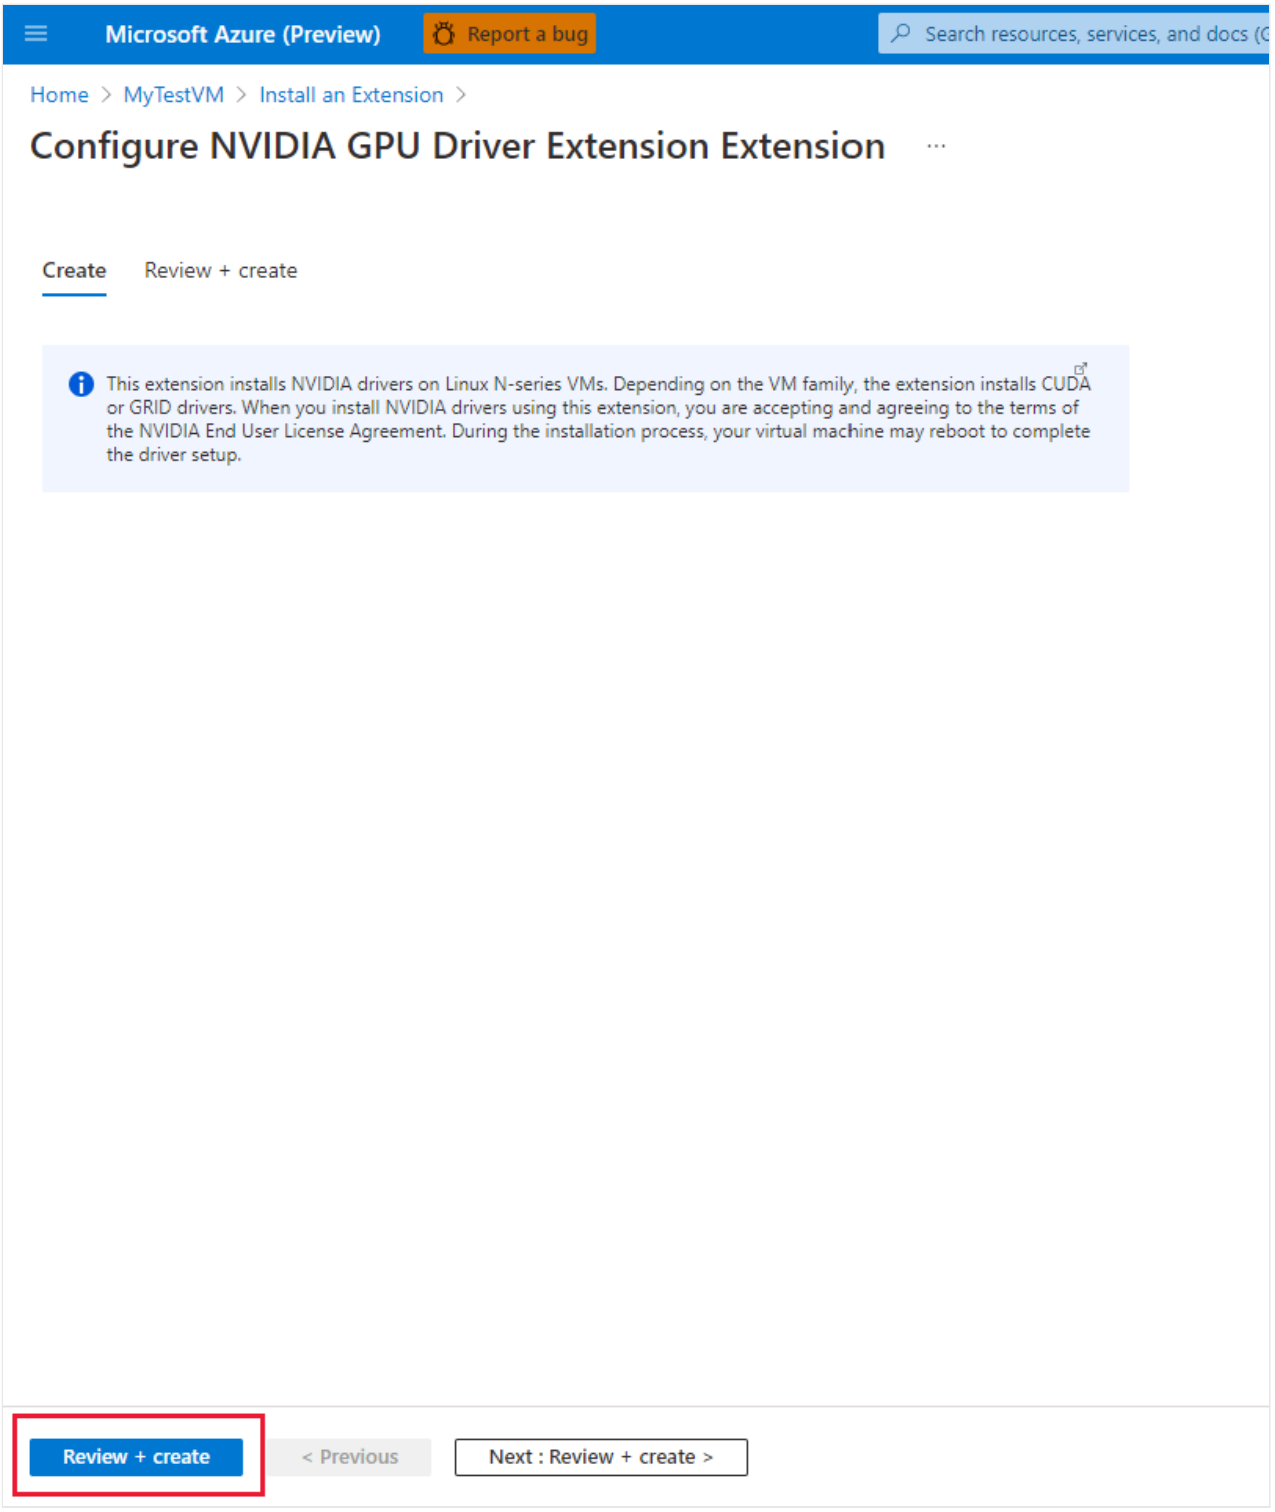
4. Select **Add**.



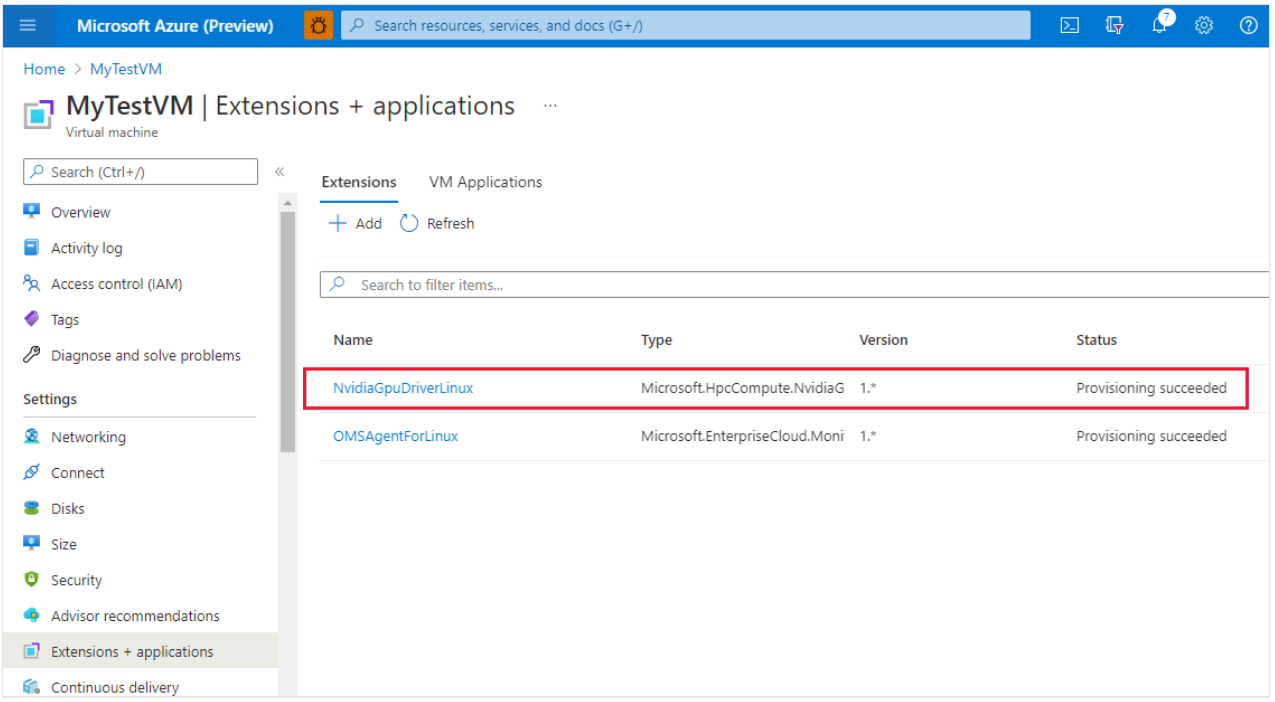
5. Scroll to find and select **NVIDIA GPU Driver Extension**, and then select **Next**.



6. Select **Review + create**, and select **Create**. Wait a few minutes for the driver to deploy.



7. Verify that the extension was added to the list of installed extensions.



Azure Resource Manager template

You can use Azure Resource Manager templates to deploy Azure VM extensions. Templates are ideal when you deploy one or more virtual machines that require post-deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
  "name": "myExtensionName",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverLinux",
    "typeHandlerVersion": "1.6",
    "autoUpgradeMinorVersion": true,
```

```
    "settings": {
    }
  }
}
```

PowerShell

PowerShell

```
Set-AzVMExtension
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Location "southcentralus" `
    -Publisher "Microsoft.HpcCompute" `
    -ExtensionName "NvidiaGpuDriverLinux" `
    -ExtensionType "NvidiaGpuDriverLinux" `
    -TypeHandlerVersion 1.6 `
    -SettingString '{ `
    }'
```

Azure CLI

The following example mirrors the preceding Resource Manager and PowerShell examples:

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name NvidiaGpuDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.6
```

The following example also adds two optional custom settings as an example for nondefault driver installation. Specifically, it updates the OS kernel to the latest and installs a specific CUDA toolkit version driver. Again, note the `--settings` are optional and default. Updating the kernel might increase the extension installation times. Also, choosing a specific (older) CUDA toolkit version might not always be compatible with newer kernels.

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name NvidiaGpuDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.6 \
```

```
  --settings '{ \
    "updateOS": true, \
    "driverVersion": "10.0.130" \
  }'
```

Troubleshoot and support

Troubleshoot

You can retrieve data about the state of extension deployments from the Azure portal and by using Azure PowerShell and the Azure CLI. To see the deployment state of extensions for a given VM, run the following command:

PowerShell

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name
myExtensionName
```

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file. Refer to this file to track the status of any long-running installation and for troubleshooting any failures.

Bash

```
/var/log/azure/nvidia-vmext-status
```

Exit codes

Expand table

Exit code	Meaning	Possible action
0	Operation successful	
1	Incorrect usage of extension	Check the execution output log.
10	Linux Integration Services for Hyper-V and Azure not available or installed	Check the output of lspci.

Exit code	Meaning	Possible action
11	NVIDIA GPU not found on this VM size	Use a supported VM size and OS.
12	Image offer not supported	
13	VM size not supported	Use an N-series VM to deploy.
14	Operation unsuccessful	Check the execution output log.

Known issues

1. GRID driver 16.x and 17.x are having installation issues on Azure kernel 6.11. Nvidia is working on solving this issue, meanwhile, downgrade the Azure kernel to 6.8 by following these steps. Try to reinstall the drivers manually or by using an extension after downgrading the kernel to 6.8.

```
// Get the installed kernel. If kernel 6.11 is installed,  downgrade it to 6.8.
uname -a

// Install  kernel 6.8. Note that kernel  6.11  is not supported.
$ sudo apt install linux-image-6.8.0-1015-azure

// Get the list of installed kernels.
dpkg --list | egrep -i --color 'linux-image|linux-headers|linux-modules' | awk '{
print $2 }'

// Uninstall any 6.11 kernels.
sudo apt purge linux-headers-6.11.0-1013-azure  linux-image-6.11.0-1013-azure
linux-modules-6.11.0-1013-azure

// Run the following command to ensure only 6.8 images, headers, and modules are
installed and no other versions are present.
dpkg --list | egrep -i --color 'linux-image|linux-headers|linux-modules' | awk '{
print $2 }'

// Results from the previous command:
linux-headers-6.8.0-1015-azure
linux-image-6.8.0-1015-azure
linux-modules-6.8.0-1015-azure

// Open the grub settings and modify the GRUB_DEFAULT="0" to GRUB_DEFAULT="Advanced
options for Ubuntu>Ubuntu, with Linux 6.8.0-1015-azure".
$ sudo vim /etc/default/grub
```

```
// The grub file will look like the following:
GRUB_DEFAULT="Advanced options for Ubuntu>Ubuntu, with Linux 6.8.0-1015-azure"
GRUB_TIMEOUT_STYLE=hidden
GRUB_TIMEOUT=0
GRUB_DISTRIBUTOR=`lsb_release -i -s 2> /dev/null || echo Debian`
GRUB_CMDLINE_LINUX_DEFAULT="quiet splash"
GRUB_CMDLINE_LINUX=""
//////////////////

// Update GRUB and reboot.
$ sudo update-grub && sudo update-grub2
$ sudo reboot

// Reinstall the driver after reboot.
```

2. `NvidiaGpuDriverLinux` currently installs the latest `17.5` GRID drivers, which is having issues with CUDA on A10 series. NVIDIA is working on solving this issue, meanwhile, use GRID driver `16.5` by passing a runtime setting to the extension.

Azure CLI

```
az vm extension set  --resource-group <rg-name> --vm-name <vm-name>  --name
NvidiaGpuDriverLinux --publisher Microsoft.HpcCompute --settings "
{'driverVersion':'535.161'}"
```

ARM

```
{
  "name": "NvidiaGpuDriverLinux",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverLinux",
    "typeHandlerVersion": "1.11",
    "autoUpgradeMinorVersion": true,
    "settings": {
         "driverVersion": "535.161"
    }
  }
}
```

3. GRID Driver version `17.x` is incompatible on NVv3 (NVIDIA Tesla M60). GRID drivers up to version `16.5` are supported. `NvidiaGpuDriverLinux` installs the latest drivers which are incompatible on NVv3 SKU. Instead, use the following runtime settings to force the

extension to install an older version of the driver. For more information on driver versions, see NVIDIA GPU resources.

Azure CLI

```
az vm extension set  --resource-group <rg-name> --vm-name <vm-name>  --name
NvidiaGpuDriverLinux --publisher Microsoft.HpcCompute --settings "
{'driverVersion':'535.161'}"
```

ARM

```
{
  "name": "NvidiaGpuDriverLinux",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverLinux",
    "typeHandlerVersion": "1.11",
    "autoUpgradeMinorVersion": true,
    "settings": {
         "driverVersion": "535.161"
    }
  }
}
```

4. Grid 17.5 linux driver has a bug where it impacts CUDA related workload. Error signature typically involves CUDA devices unavailable. While Azure is working to resolve this issue, use GRID driver 16.5 to continue running your workload.

Support

If you need more help at any point in this article, contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to Azure support and select **Get support**. For information about using Azure support, read the Azure support FAQ.

Next steps

- For more information about extensions, see Virtual machine extensions and features for Linux.
- For more information about N-series VMs, see GPU optimized virtual machine sizes.

Last updated on 12/02/2025

NVIDIA GPU Driver Extension for Windows

The NVIDIA GPU Driver Extension for Windows installs NVIDIA GPU drivers on Windows N-series virtual machines (VMs). Depending on the VM family, the extension installs CUDA or GRID drivers. When you install NVIDIA drivers by using this extension, you accept and agree to the terms of the NVIDIA End-User License Agreement. During the installation process, the VM might reboot to complete the driver setup.

The instructions for manual installation of the drivers, and the list of current supported versions are available for review. For more information, see Install NVIDIA GPU drivers on N-series VMs running Windows.

The NVIDIA GPU Driver Extension can also be deployed on Linux N-series VMs. For more information, see NVIDIA GPU Driver Extension for Linux.

> **Note**
>
> For NVadsA10v5-series VMs, this extension will continue to use v17.x until we finish the v18.x rollout in sovereign clouds in January 2026.

> **Note**
>
> The GPU driver extensions do not automatically update the driver after the extension is installed. If you need to move to a newer driver version then either manually download and install the driver or remove and add the extension again.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

Confirm your virtual machine satisfies the prerequisites for using the NVIDIA GPU Driver Extension.

Operating system support

The NVIDIA GPU Driver Extension supports the following Windows versions:

Expand table

Distribution	Version
Windows 11	Core
Windows 10	Core
Windows Server 2022	Core
Windows Server 2019	Core
Windows Server 2016	Core
Windows Server 2012 R2	Core

Internet connection required

The NVIDIA GPU Driver Extension requires that the target VM is connected to the internet and has access.

Review the extension schema

The following JSON snippet shows the schema for the extension:

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverWindows",
    "typeHandlerVersion": "1.10",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

Properties

The JSON schema includes values for the following parameters.

Expand table

Name	Value/Example	Data type
`apiVersion`	2015-06-15	date
`publisher`	Microsoft.HpcCompute	string
`type`	NvidiaGpuDriverWindows	string
`typeHandlerVersion`	1.10	int

Deploy the extension

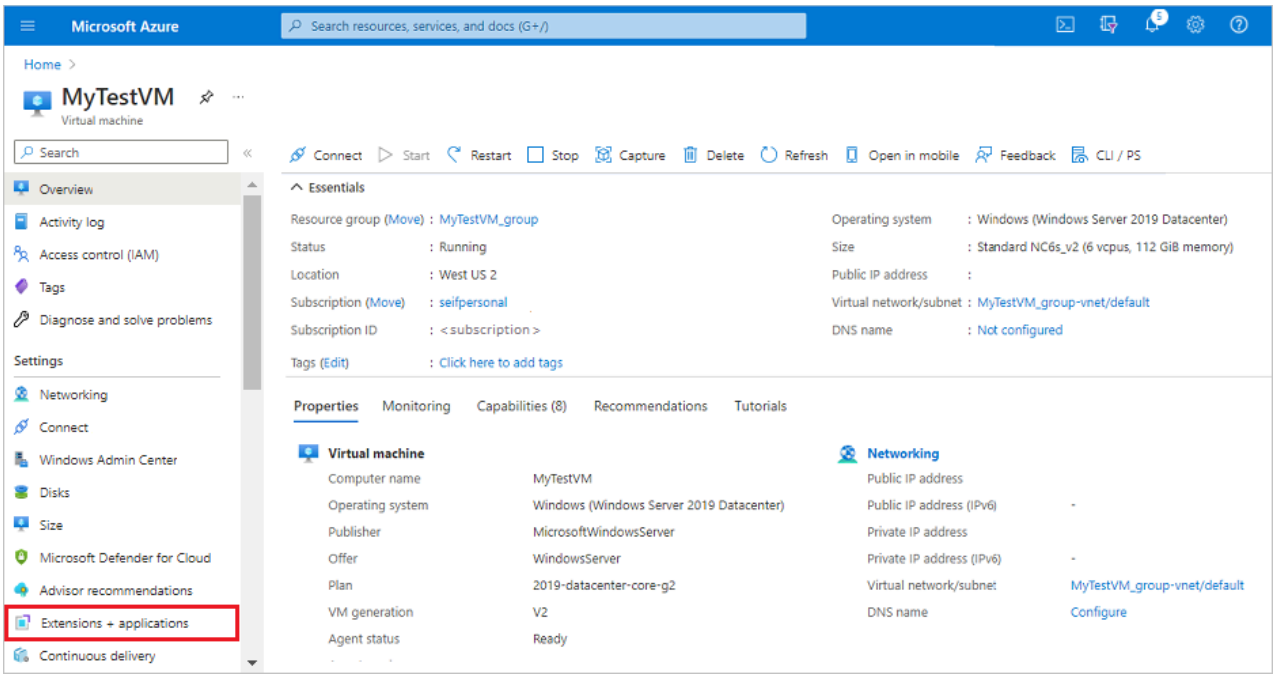
Azure VM extensions can be managed by using the Azure CLI, PowerShell, Azure Resource Manager (ARM) templates, and the Azure portal.

> **Note**
>
> Some of the following examples use `<placeholder>` parameter values in the commands. Before you run each command, make sure to replace any placeholder values with specific values for your configuration.

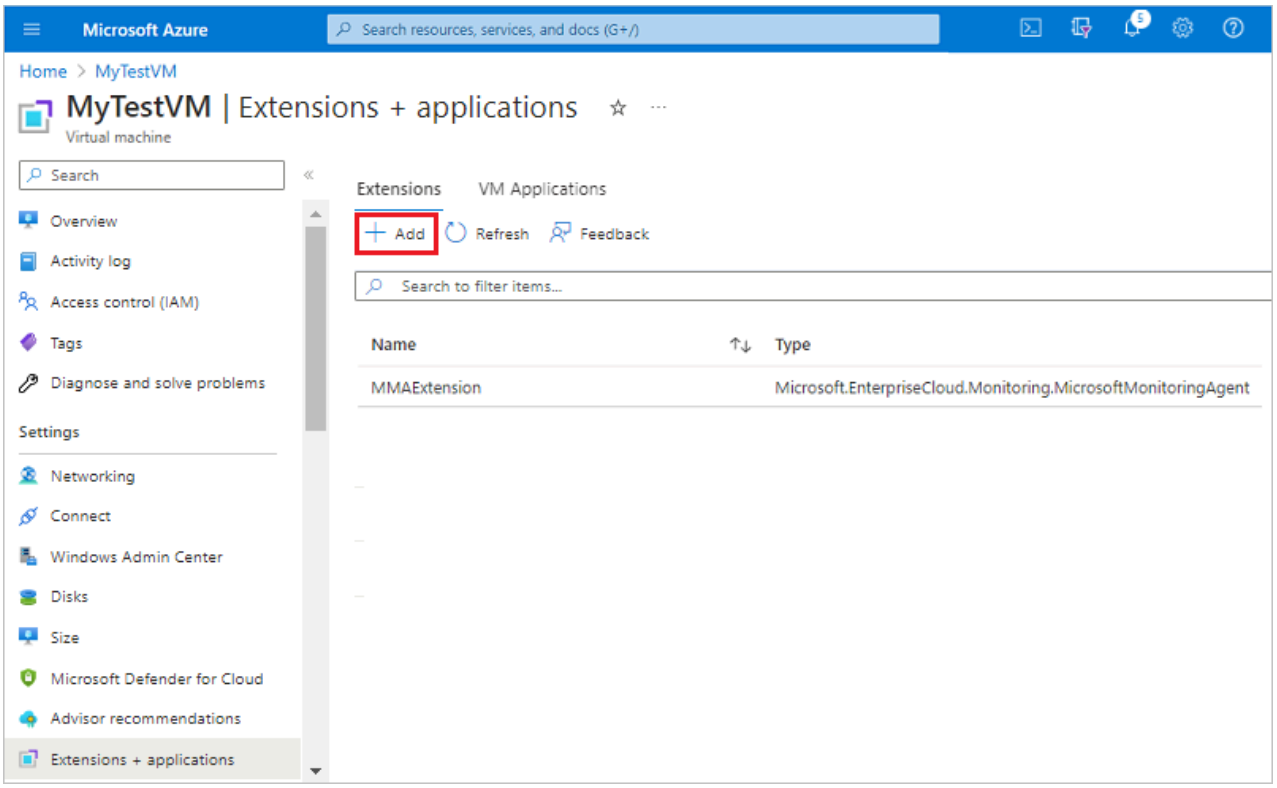
Azure portal

To install the NVIDIA GPU Driver Extension in the Azure portal, follow these steps:

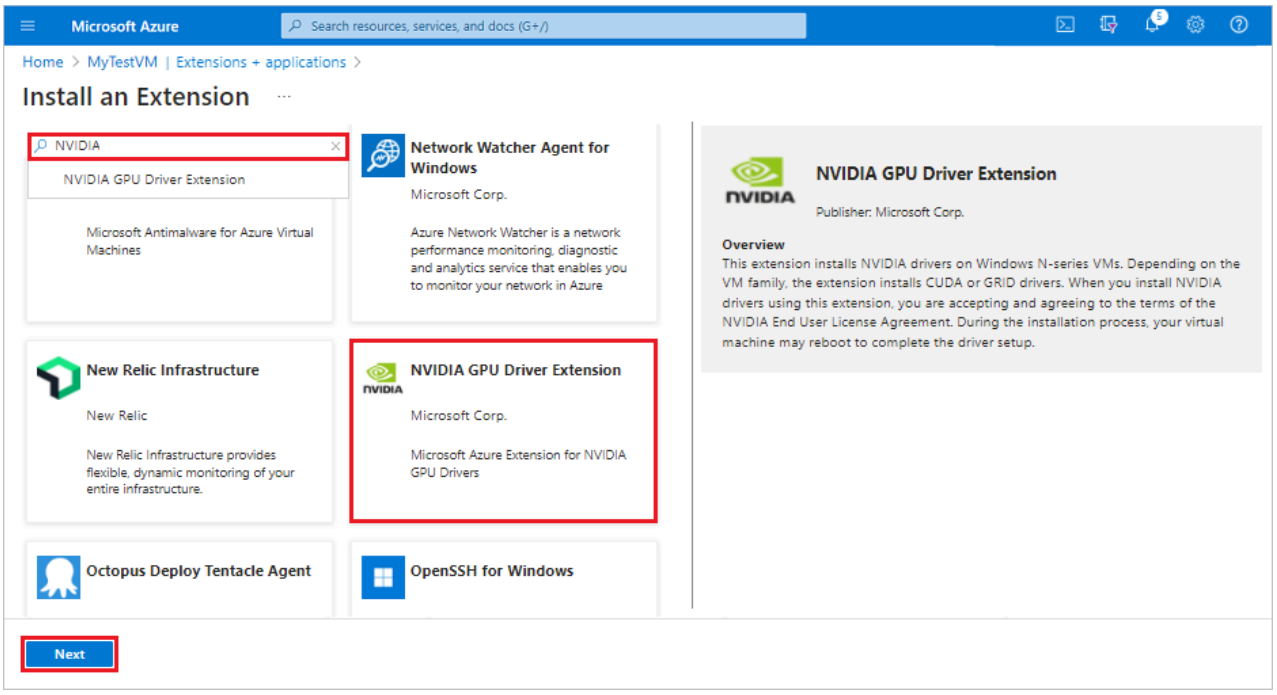
1. In the Azure portal, go to the virtual machine on which you want to install the extension.
2. Under **Settings**, select **Extensions + Applications**.



3. Under **Extensions**, select **+ Add**.

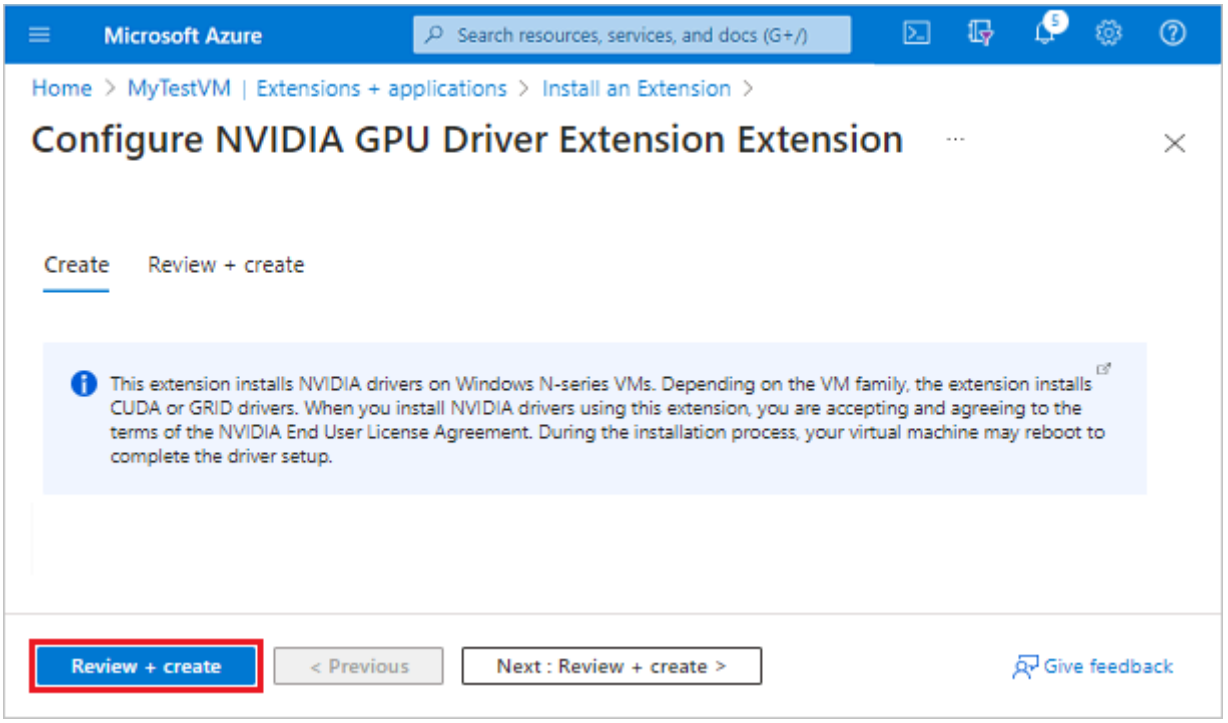


4. Locate and select **NVIDIA GPU Driver Extension**, then select **Next**.

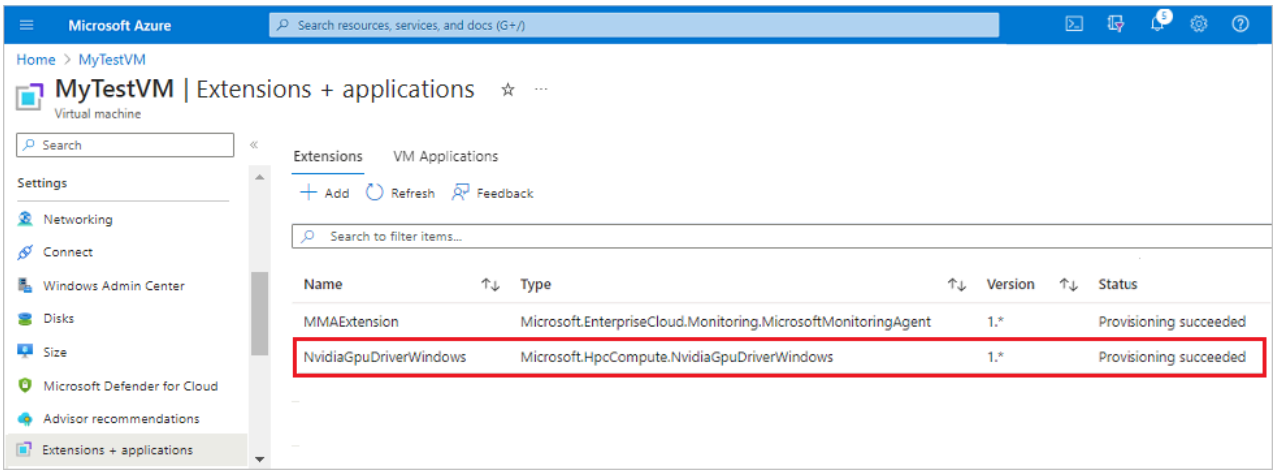


5. Select **Review + create**. Confirm the deployment action, and select **Create**.

   Wait a few minutes for the extension to deploy.



6. Confirm the extension is listed as an installed extension for the virtual machine.



ARM template

ARM templates are ideal when you deploy one or more virtual machines that require post-deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource or placed at the root or top level of a JSON ARM template. The placement of the JSON configuration affects the value of the resource `name` and `type`. For more information, see Set name and type for child resources.

The following example assumes the extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "location": "[<resourceGroup().location>]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverWindows",
    "typeHandlerVersion": "1.10",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

PowerShell

Use the following PowerShell command to deploy the NVIDIA GPU Driver Extension to a virtual machine.

PowerShell

```
Set-AzVMExtension
    -ResourceGroupName "<myResourceGroup>" `
    -VMName "<myVM>" `
    -Location "<location>" `
    -Publisher "Microsoft.HpcCompute" `
    -ExtensionName "NvidiaGpuDriverWindows" `
    -ExtensionType "NvidiaGpuDriverWindows" `
    -TypeHandlerVersion 1.10 `
    -SettingString '{ `
    }'
```

Azure CLI

Run the following command in the Azure CLI to deploy the NVIDIA GPU Driver Extension to a virtual machine.

Azure CLI

```
az vm extension set \
  --resource-group <myResourceGroup> \
  --vm-name <myVM> \
  --name NvidiaGpuDriverWindows \
  --publisher Microsoft.HpcCompute \
  --version 1.10 \
  --settings '{ \
  }'
```

Troubleshoot issues

Here are some suggestions for how to troubleshoot deployment issues.

Check extension status

Check the status of your extension deployment in the Azure portal, or by using PowerShell or the Azure CLI.

To see the deployment state of extensions for a given VM, run the following commands:

PowerShell

```
Get-AzVMExtension -ResourceGroupName <myResourceGroup> -VMName <myVM> -Name
<myExtensionName>
```

Azure CLI

```
az vm extension list --resource-group <myResourceGroup> --vm-name <myVM> -o table
```

Review output logs

View output logs for the NVIDIA GPU Driver Extension deployment under `C:\WindowsAzure\Logs\Plugins\Microsoft.HpcCompute.NvidiaGpuDriverWindows\`.

Respond to error codes

The following table lists common error codes for deployment and potential follow-up actions.

Expand table

Error	Description	Action
0	Operation successful.	No required action.
1	Operation successful.	Reboot.
100	Operation not supported or couldn't be completed.	Check log files to determine cause of error, such as: - PowerShell version isn't supported. - VM size isn't an N-series VM. - Failure during data download.
240, 840	Operation timeout.	Retry operation.
-1	Exception occurred.	Check log files to determine cause of exception.
-5x	Operation interrupted due to pending reboot.	Reboot the VM. Installation continues after reboot. Uninstall should be invoked manually.

Known issues

GRID Driver version `17.x` is incompatible on NVv3 (NVIDIA Tesla M60). GRID drivers up to version `16.5` are supported. `NvidiaGpuDriverWindows` installs the latest drivers which are incompatible on NVv3 SKU. Instead, use the following runtime settings to force the extension

to install an older version of the driver. For more information on driver versions, see NVIDIA GPU resources.

Azure CLI

```
az vm extension set  --resource-group <rg-name> --vm-name <vm-name>  --name
NvidiaGpuDriverWindows --publisher Microsoft.HpcCompute --settings "
{'driverVersion':'538.46'}"
```

ARM

```
{
  "name": "NvidiaGpuDriverWindows",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverWindows",
    "typeHandlerVersion": "1.10",
    "autoUpgradeMinorVersion": true,
    "settings": {
         "driverVersion": "538.46"
    }
  }
}
```

Get support

Here are some other options to help you resolve deployment issues:

- For assistance, contact the Azure experts on the Q&A and Stack Overflow forums.
- If you don't find an answer on the site, you can post a question for input from Microsoft or other members of the community.
- You can also Contact Microsoft Support. For information about using Azure support, read the Azure support FAQ.

Next steps

- For more information about extensions, see Virtual machine extensions and features for Windows.
- For more information about N-series VMs, see GPU optimized virtual machine sizes.

Last updated on 12/17/2025

AMD GPU Driver Extension for Windows

This article provides an overview of the virtual machine (VM) extension to deploy AMD GPU drivers on Windows N-series VMs. When you install AMD drivers by using this extension, you're accepting and agreeing to the terms of the AMD End-User License Agreement. During the installation process, the VM might reboot to complete the driver setup.

Instructions on manual installation of the drivers and the current supported versions are available. For more information, see Azure N-series AMD GPU driver setup for Windows.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

Internet connectivity

The Microsoft Azure Extension for AMD GPU Drivers requires that the target VM is connected to the internet and has access.

Extension schema

The following JSON shows the schema for the extension:

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "AmdGpuDriverWindows",
    "typeHandlerVersion": "1.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
```

```
  }
}
```

Properties

Expand table

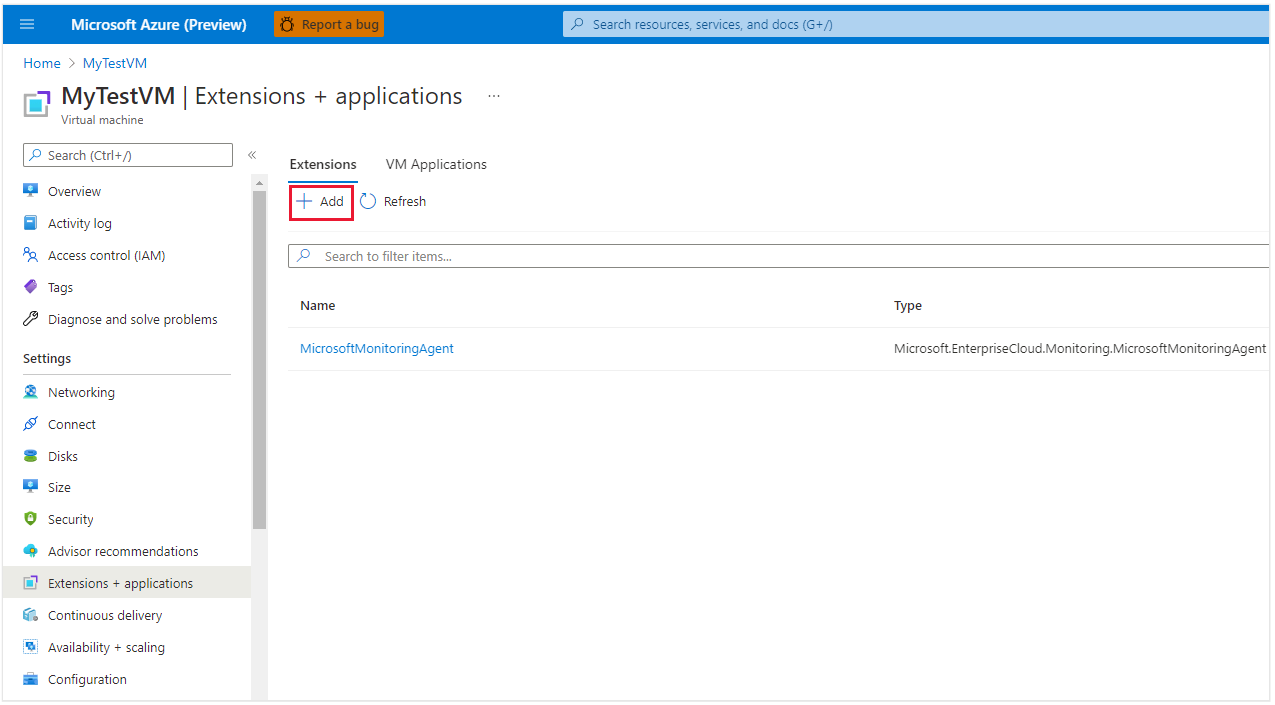
Name	Value/Example	Data type
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	AmdGpuDriverWindows	string
typeHandlerVersion	1.1	int

Deployment

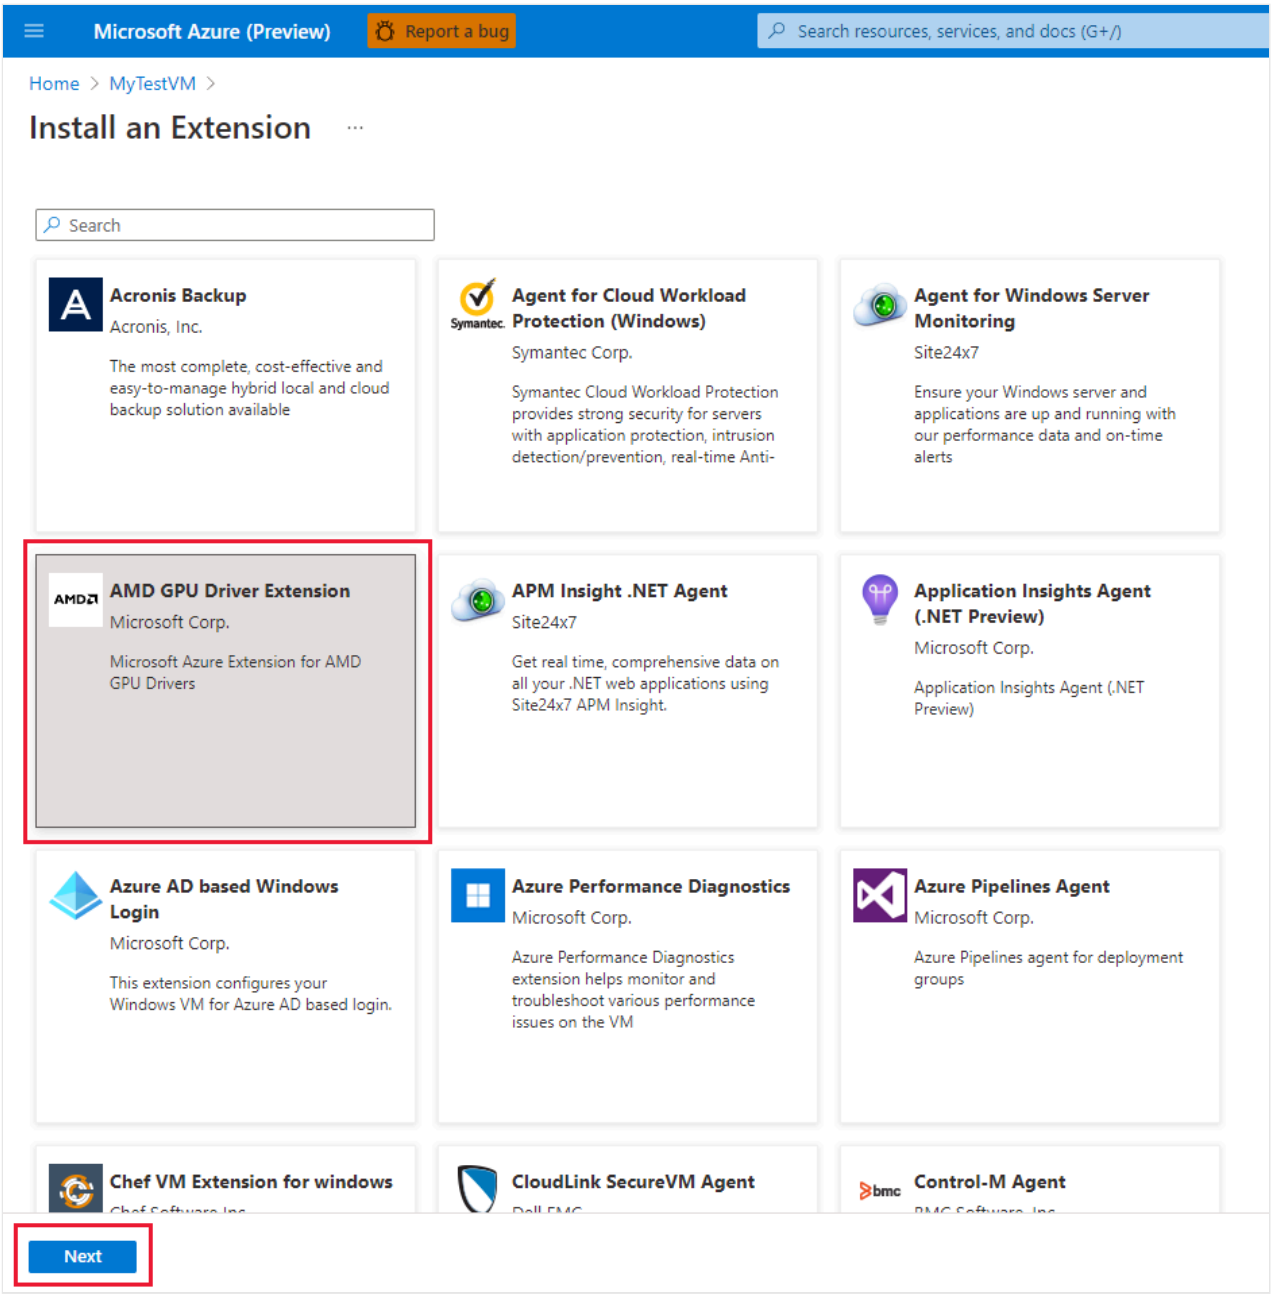
Azure portal

You can deploy Azure AMD VM extensions in the Azure portal.

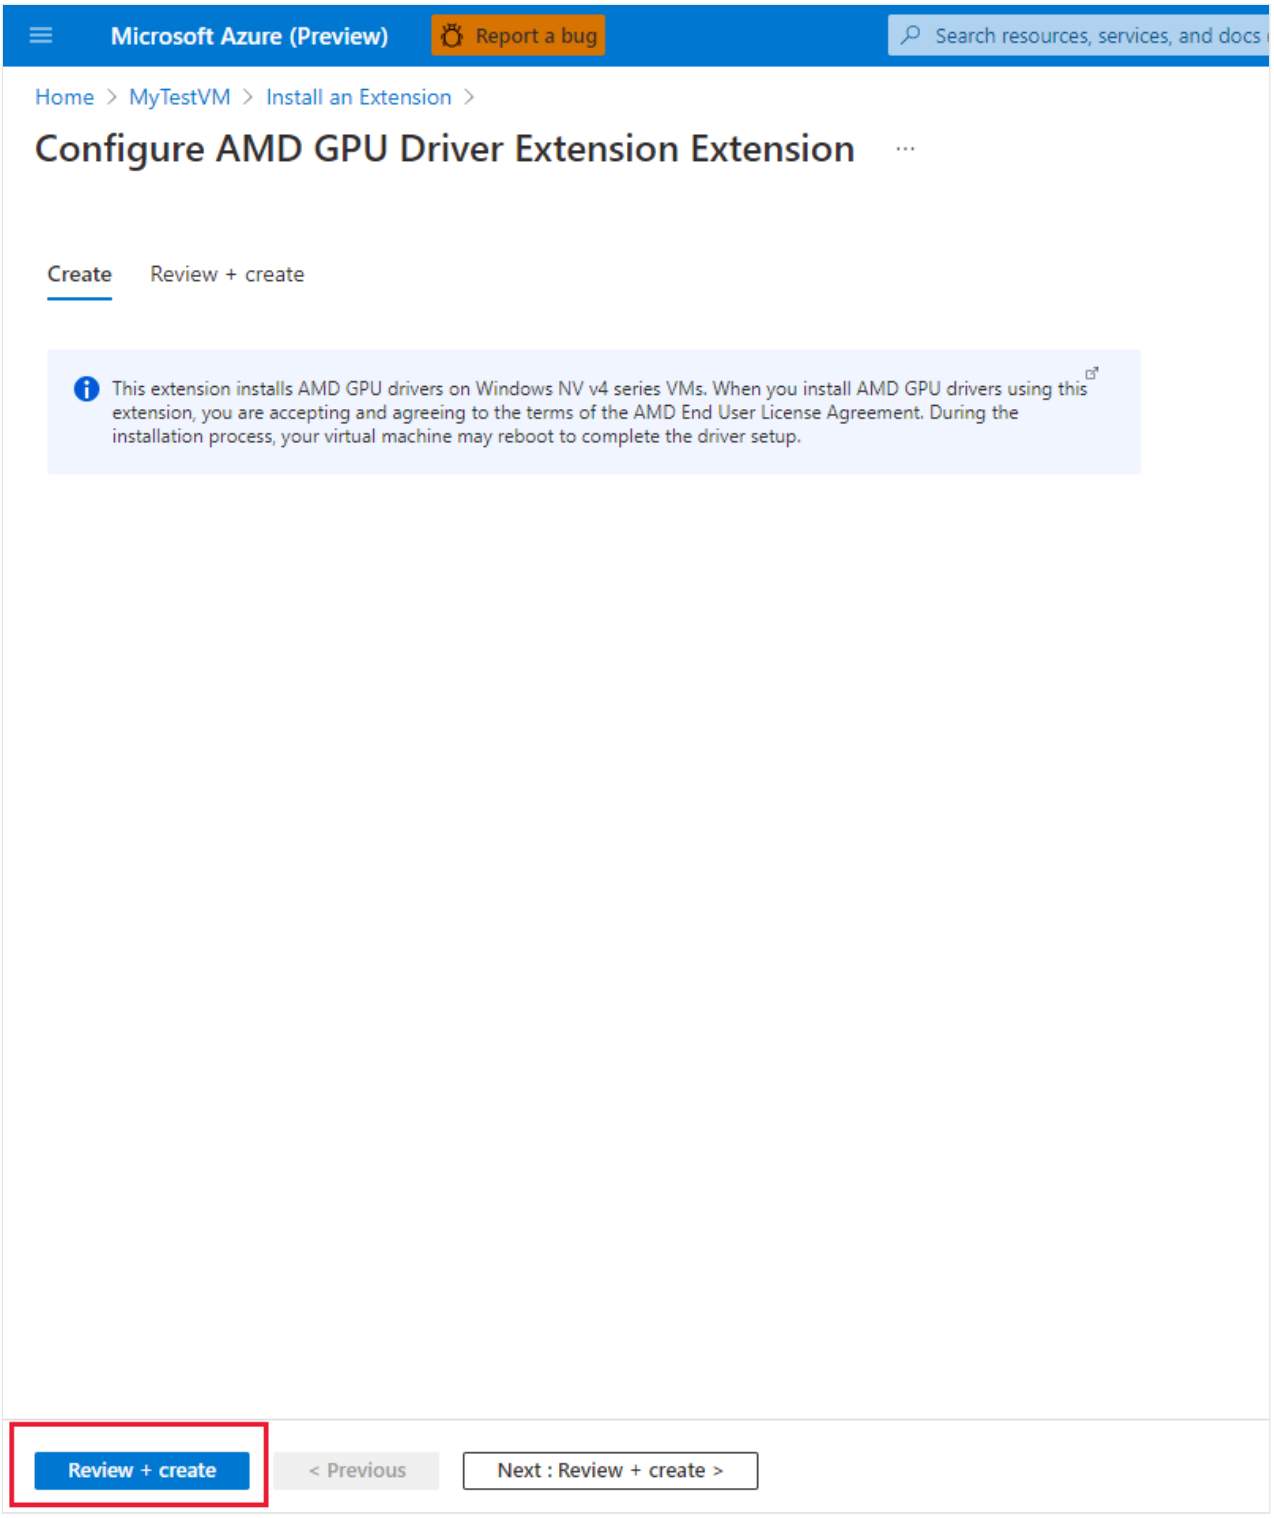
1. In a browser, go to the Azure portal.
2. Go to the virtual machine on which you want to install the driver.
3. On the left menu, select **Extensions**.
4. Select **Add**.



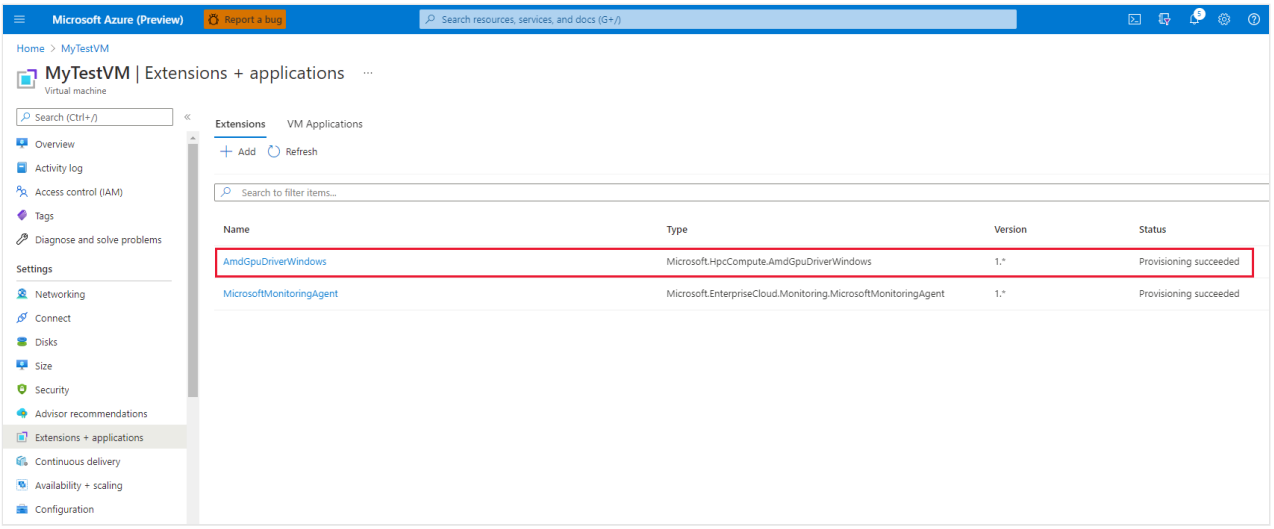
5. Scroll to find and select **AMD GPU Driver Extension**, and then select **Next**.



6. Select **Review + create**, and select **Create**. Wait a few minutes for the driver to deploy.



7. Verify that the extension was added to the list of installed extensions.



Azure Resource Manager template

You can use Azure Resource Manager templates to deploy Azure VM extensions. Templates are ideal when you deploy one or more virtual machines that require post-deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
  "name": "myExtensionName",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "AmdGpuDriverWindows",
    "typeHandlerVersion": "1.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

PowerShell

PowerShell

```
Set-AzVMExtension `
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Location "southcentralus" `
    -Publisher "Microsoft.HpcCompute" `
    -ExtensionName "AmdGpuDriverWindows" `
    -ExtensionType "AmdGpuDriverWindows" `
    -TypeHandlerVersion 1.1 `
    -SettingString '{ `
    }'
```

Azure CLI

Azure CLI

```
az vm extension set `
  --resource-group myResourceGroup `
  --vm-name myVM `
  --name AmdGpuDriverWindows `
  --publisher Microsoft.HpcCompute `
  --version 1.1 `
  --settings '{ `
  }'
```

Troubleshoot and support

Troubleshoot

After extension is installed successfully, to run 'amd-smi' install WMIC using

PowerShell

```
DISM /Online /Add-Capability /CapabilityName:WMIC
```

You can retrieve data about the state of extension deployments from the Azure portal and by using Azure PowerShell and the Azure CLI. To see the deployment state of extensions for a given VM, run the following command:

PowerShell

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name
myExtensionName
```

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following directory:

Windows Command Prompt

```
C:\WindowsAzure\Logs\Plugins\Microsoft.HpcCompute.AmdGpuDriverMicrosoft\
```

Error codes

Expand table

Error Code	Meaning	Possible action
0	Operation successful.	
1	Operation successful. Reboot required.	
100	Operation not supported or couldn't be completed.	Possible causes are that the PowerShell version isn't supported, the VM size isn't an N-series VM, and a failure occurred in downloading data. Check the log files to determine the cause of the error.
240, 840	Operation timeout.	Retry operation.
-1	Exception occurred.	Check the log files to determine the cause of the exception.
-5x	Operation interrupted due to pending reboot.	Reboot VM. Installation continues after the reboot. Uninstall should be invoked manually.

Support

If you need more help at any point in this article, contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to Azure support and select **Get support**. For information about using Azure support, read the Azure support FAQ.

Next steps

- For more information about extensions, see Virtual machine extensions and features for Windows.
- For more information about N-series VMs, see GPU optimized virtual machine sizes.

Last updated on 11/10/2025

AMD GPU Driver Extension for Linux

This extension installs AMD GPU drivers on Linux N-series virtual machines (VMs). When you install AMD drivers by using this extension, you're accepting and agreeing to the terms of the AMD End-User License Agreement. During the installation process, the VM might reboot to complete the driver setup.

Instructions on manual installation of the drivers and the current supported versions are available. An extension is also available to install AMD GPU drivers on Linux N-series VMs.

> **Note**
>
> With Secure Boot enabled, all OS boot components, including the boot loader, kernel, and kernel drivers, must be signed by trusted publishers whose keys are trusted by the system. For more information on manually installing GPU drivers with Secure Boot enabled, see Azure N-series GPU driver setup for Linux.
>
> The GPU driver extensions do not automatically update the driver once the extension is installed. To upgrade to a newer driver version, you will need to either uninstall and reinstall the extension or manually install the driver.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

Operating system

This extension supports the following OS distros, depending on driver support for the specific OS version:

Expand table

Distribution	Version
Linux: Ubuntu	22.04 24.04

> **Note**
>
> For installation instructions on other Linux distributions, please visit AMD's documentation

Internet connectivity

The AMD GPU Drivers Extension requires that the target VM is connected to the internet and has access.

Review the extension schema

The following JSON snippet shows the schema for the extension:

JSON

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "AmdGpuDriverLinux",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

Properties

The JSON schema includes values for the following parameters.

Expand table

Name	Value/Example	Data type
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string

Name	Value/Example	Data type
type	AmdGpuDriverLinux	string
typeHandlerVersion	1.0	int

Settings

All settings are optional. The default behavior is to not update the kernel if not required for driver installation and install the latest supported driver.

Expand table

Name	Default value	Valid values	Data type
driverVersion	Latest	List of supported driver versions	string

Deploy the extension

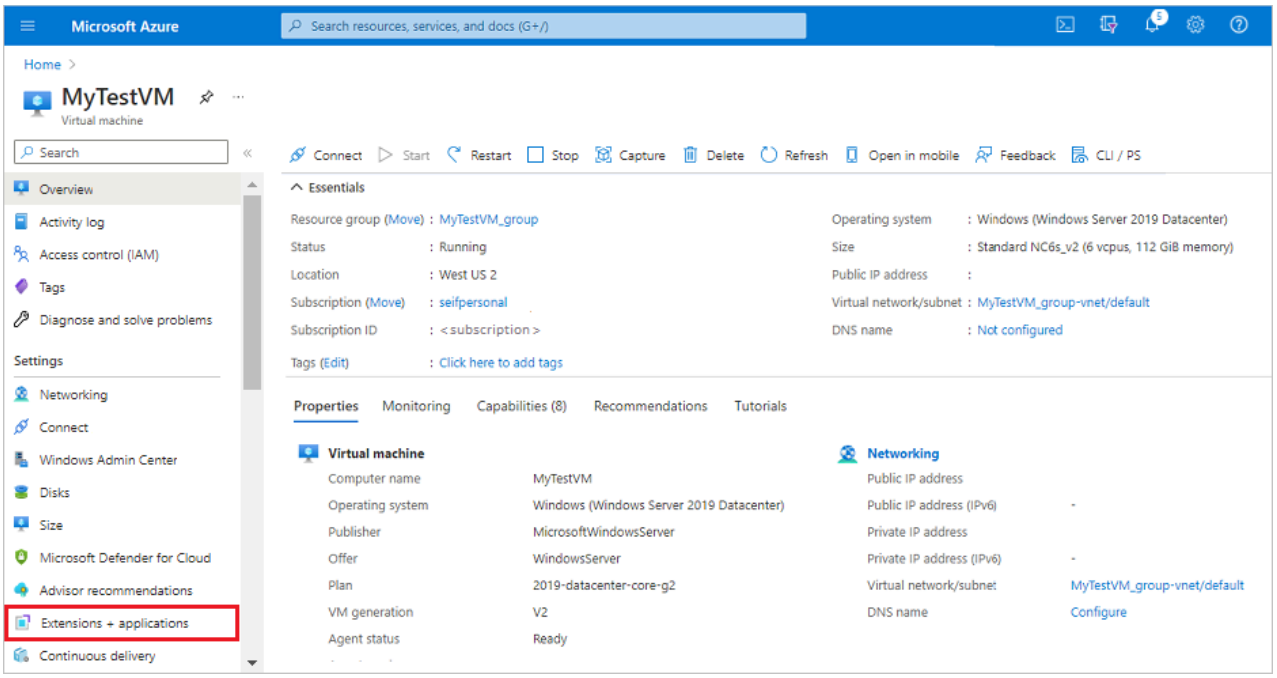
Azure VM extensions can be managed by using the Azure CLI, PowerShell, Azure Resource Manager (ARM) templates, and the Azure portal.

Azure portal

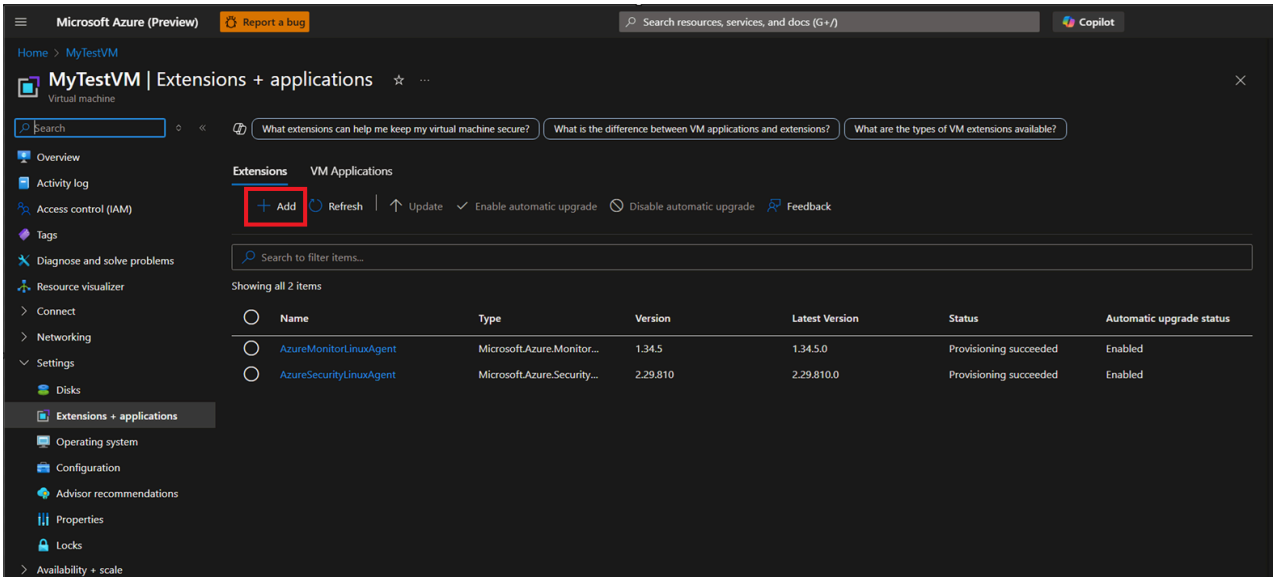
To install the Azure AMD VM extension in the Azure portal, follow these steps:

1. In the Azure portal, go to the virtual machine on which you want to install the extension.

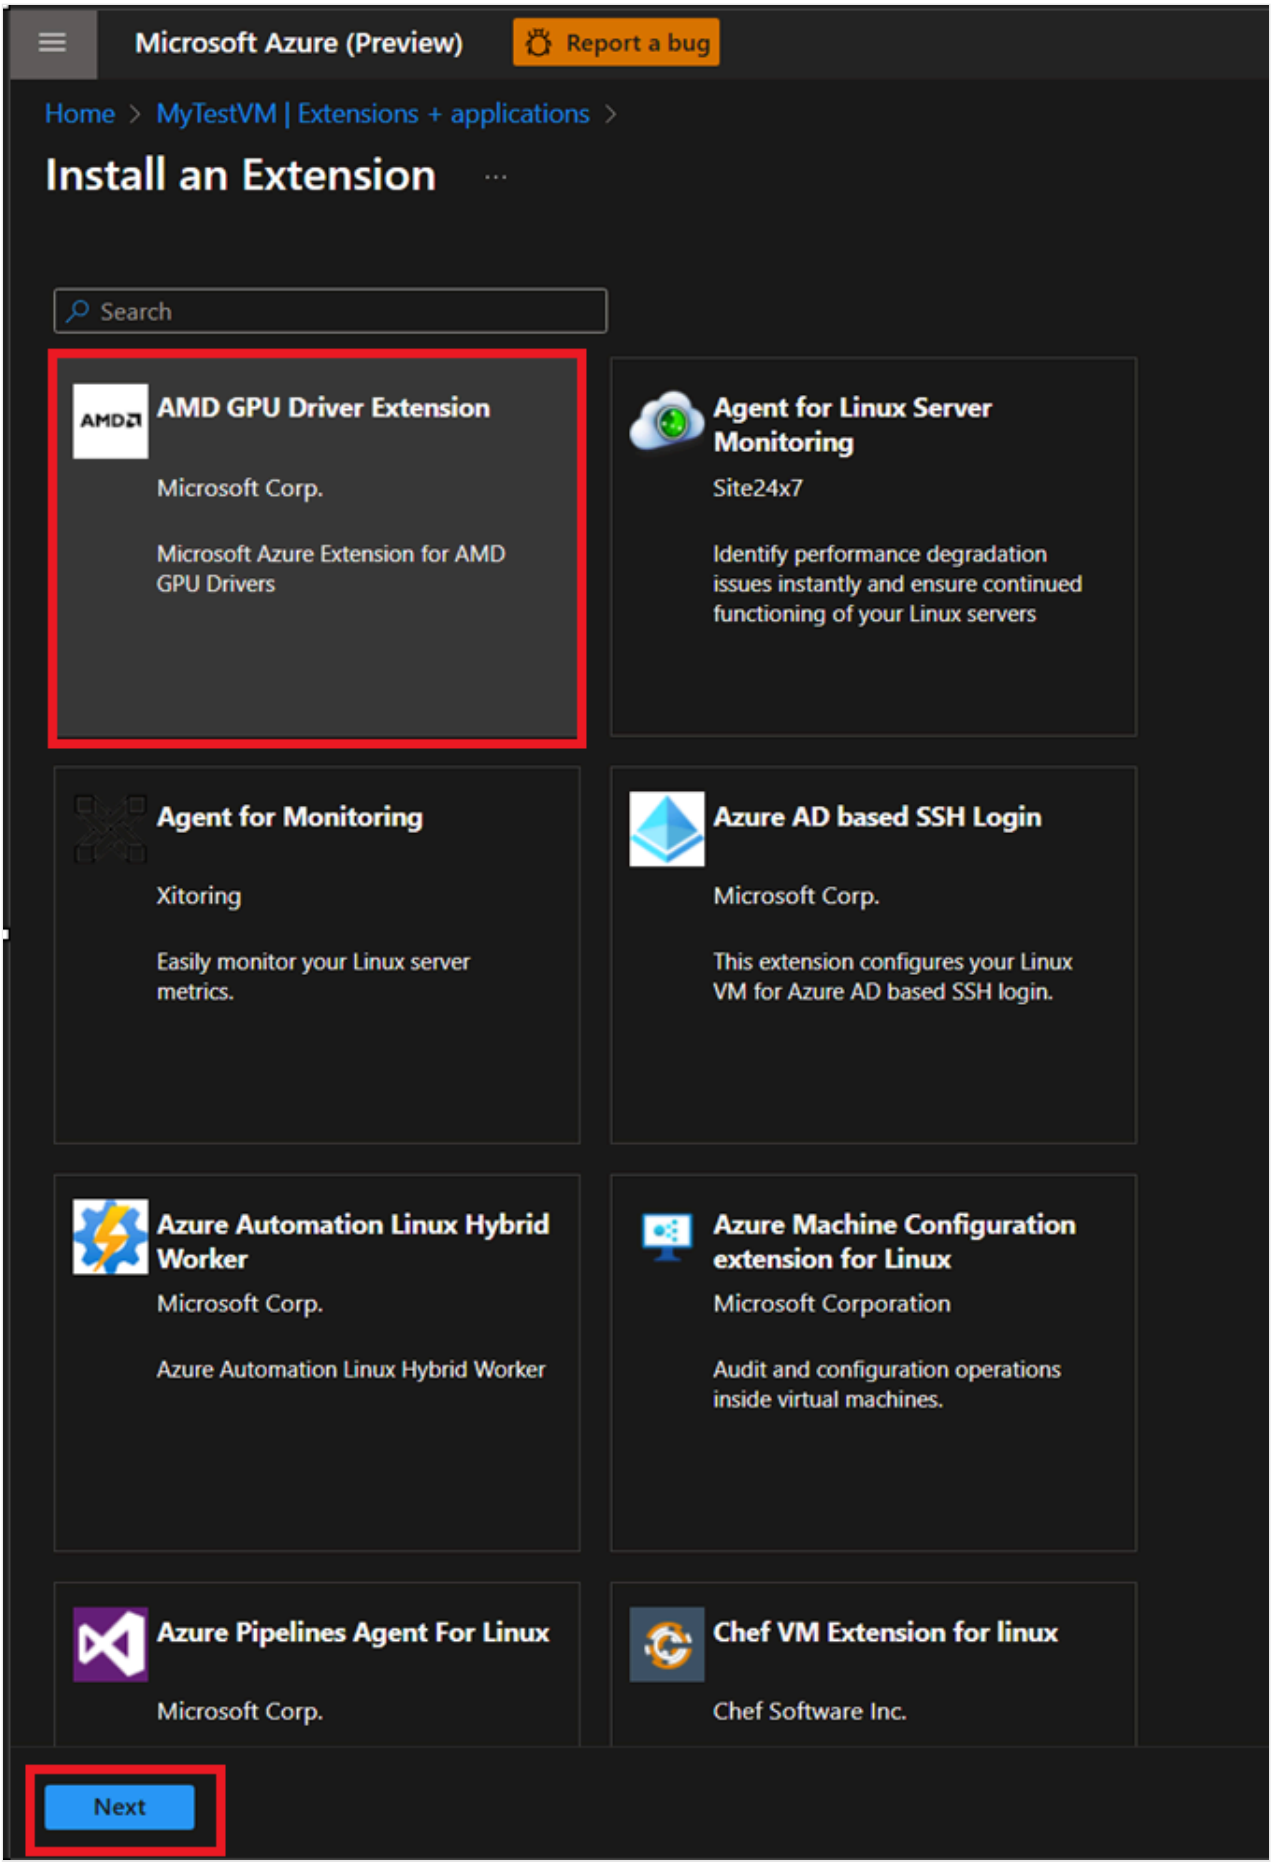
2. Under **Settings**, select **Extensions + Applications**.



3. Under **Extensions**, select **+ Add**.

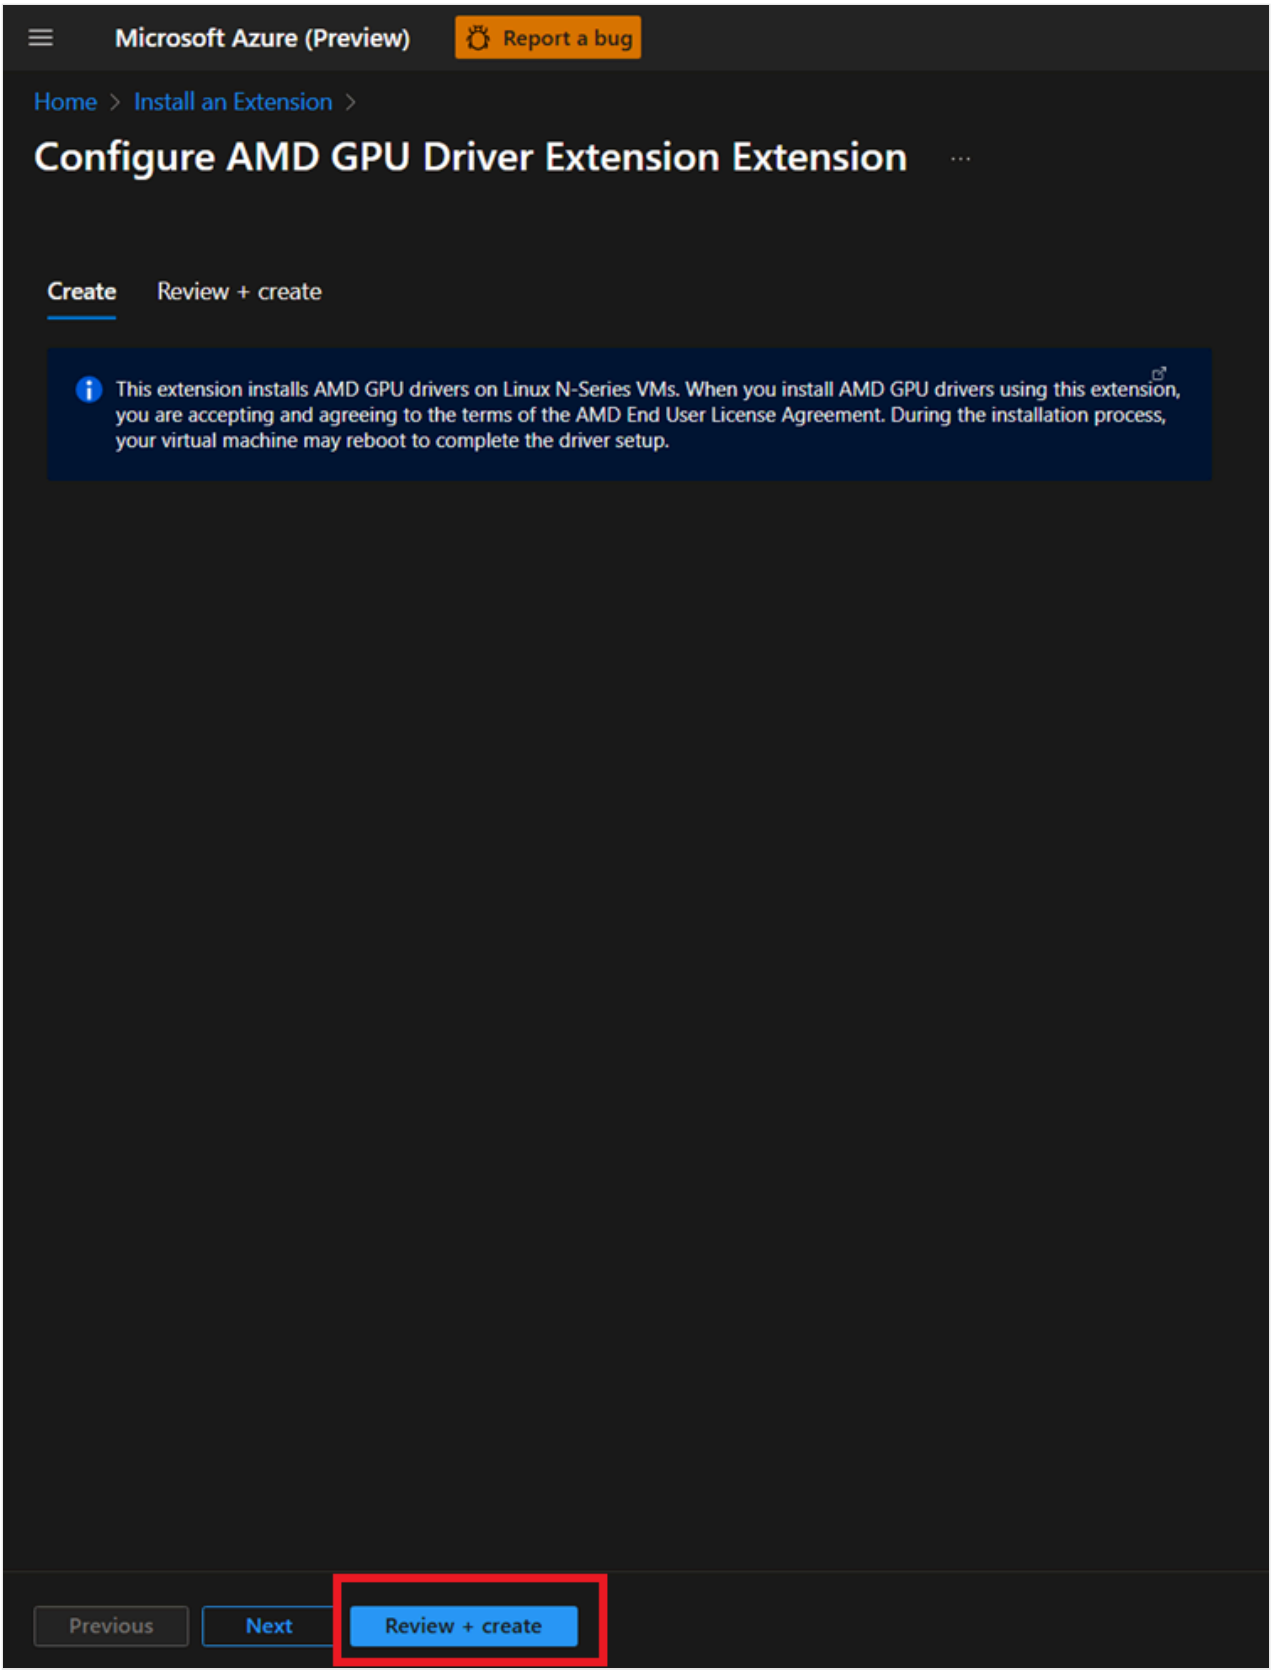


4. Scroll to find and select **AMD GPU Driver Extension**, and then select **Next**.

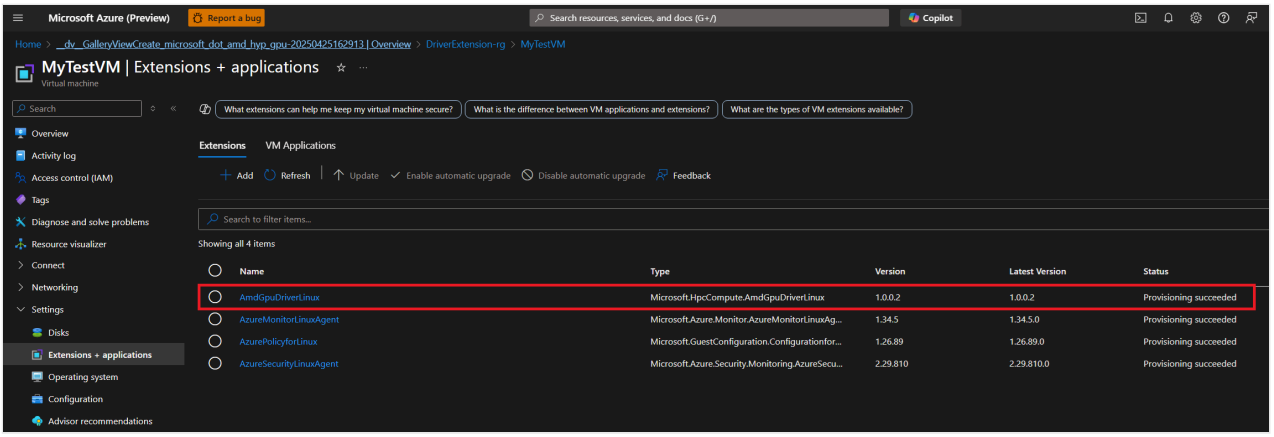


5. Select **Review + create**, and select **Create**.

   Wait a few minutes for the driver to deploy.



6. Confirm the extension is listed as an installed extension for the virtual machine.



Azure Resource Manager template

You can use Azure Resource Manager templates to deploy Azure VM extensions. Templates are ideal when you deploy one or more virtual machines that require post-deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
  "name": "myExtensionName",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "AmdGpuDriverLinux",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

PowerShell

PowerShell

```
Set-AzVMExtension
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Location "southcentralus" `
    -Publisher "Microsoft.HpcCompute" `
    -ExtensionName "AmdGpuDriverLinux" `
    -ExtensionType "AmdGpuDriverLinux" `
    -TypeHandlerVersion 1.0 `
    -SettingString '{}'
```

Azure CLI

The following example mirrors the preceding Resource Manager and PowerShell examples:

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name AmdGpuDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.0
```

The following example also adds two optional custom settings as an example for nondefault driver installation.

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name AmdGpuDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.0 \
  --settings '{ \
    "driverVersion": "6.3.3" \
  }'
```

Troubleshooting

Check extension status

Check the status of your extension deployment in the Azure portal, or by using PowerShell or the Azure CLI.

To see the deployment state of extensions for a given VM, run the following commands:

PowerShell

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name
myExtensionName
```

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Review output logs

View output logs for the Azure AMD VM extension deployment. Refer to this file to track the status of any long-running installation and for troubleshooting any failures.

Bash

```
/var/log/azure/amd-vmext-status
```

Respond to exit codes

The following table lists common exit codes for deployment and potential follow-up actions.

Expand table

Exit code	Meaning	Possible action
0	Operation successful	No required action.
1	Incorrect usage of extension	Check the execution output log.
2	Python not found	Check the execution output log.
10	Linux Integration Services for Hyper-V and Azure not available or installed	Check the output of lspci.
11	AMD GPU not found on this VM size	Use a supported VM size and OS..
14	DPKG frontend (`/var/lib/dpkg/lock-frontend`) is locked by another process	Please try reinstalling after sometime.

Exit code	Meaning	Possible action
15	DPKG (`/var/lib/dpkg/lock`) is locked by another process	Please try reinstalling after sometime.
17	Failed to download the driver	Check the execution output log.
18	Failed to download the driver	Check the execution output log.
19	Failed to install the driver	Check the execution output log.

Install and manage the Azure Monitor Agent

This article describes the different methods you can use to install, uninstall, update, and configure the Azure Monitor Agent on Azure virtual machines, virtual machine scale sets, and Azure Arc-enabled servers.

Prerequisites

For prerequisites and other requirements for using the Azure Monitor Agent, see these articles:

- Azure Monitor Agent supported operating systems and environments
- Azure Monitor Agent requirements
- Azure Monitor Agent network configuration

> **Important**
>
> If the agent is going to connect to the Log Analytics workspace using Azure private link, see **Enable private link for monitoring virtual machines and Kubernetes clusters in Azure Monitor**.

> **Important**
>
> Installing, upgrading, or uninstalling the Azure Monitor Agent doesn't require a machine restart.

Installation options

The following table lists the options for installing the Azure Monitor Agent on Azure VMs and Azure Arc-enabled servers.

For any machine that isn't in Azure, the Azure Arc agent must be installed on the machine before the Azure Monitor Agent can be installed.

Expand table

Installation method	Description
Virtual machine (VM) extension	Use any of the methods described in this article to install the agent via the Azure extension framework. This method doesn't create a DCR, so you must create at least one DCR and associate it with the agent before data collection begins.
Create a DCR	When you create a DCR in the Azure portal, the Azure Monitor Agent is installed on any machine that's added as a resource for the DCR. The agent immediately begins to collect data as defined in the DCR.
VM insights	When you enable VM insights on a machine, the Azure Monitor Agent is installed and a DCR is created to collect a predefined set of data. You shouldn't modify this DCR, but you can create more DCRs to collect more data.
Container insights	When you enable collection of Prometheus metrics or container logs on a Kubernetes cluster, a containerized version of the Azure Monitor Agent is installed in the cluster and a DCR is created to immediately begin collecting data. You can modify the DCR by using the guidance in Configure data collection and cost optimization in Container insights by using DCRs.
Client installer	Install the agent by using a Windows MSI installer for Windows 11 and Windows 10 clients.
Azure Policy	Use Azure Policy to automatically install the agent on Azure virtual machines and Azure Arc-enabled servers, and to automatically associate them with required DCRs.

> **Note**
>
> - To send data across tenants, you must first enable Azure Lighthouse.
> - Cloning a machine that has Azure Monitor Agent installed isn't supported. The best practice for this scenario is to use Azure Policy or an infrastructure as a code (IaaC) tool to deploy the Azure Monitor Agent at scale.

Install the agent extension

Azure portal

To install the agent and create a DCR to collect data by using the Azure portal, use the guidance in Collect data by using the Azure Monitor Agent.

Uninstall

Azure portal

To uninstall the Azure Monitor Agent by using the Azure portal, go to your virtual machine, scale set, or Azure Arc-enabled server. Select the **Extensions** tab, and then select **AzureMonitorWindowsAgent** or **AzureMonitorLinuxAgent**. In the dialog that opens, select **Uninstall**.

Update

> **Note**
>
> We strongly recommend that you always update to the latest version of the agent or opt in to automatic extension upgrade.
>
> Automatic extension rollout follows standard Azure deployment practices to safely deploy the latest version of the agent. You should expect automatic updates to take weeks to roll out the latest version.
>
> Upgrades are issued in batches, so some of your virtual machines, scale sets, or Azure Arc-enabled servers might be upgraded before others.
>
> If you need to upgrade an extension immediately, you can use the manual instructions that are described in this article. Only agents released in the past year are supported.

Azure portal

To do a one-time update of the agent, go to your virtual machine or scale set. Select the **Extensions** tab, then check the agent and click **Update**.

We recommend that you enable automatic update of the agent by enabling automatic extension upgrade. Go to your virtual machine or scale set, select the **Extensions** tab, and then select **AzureMonitorWindowsAgent** or **AzureMonitorLinuxAgent**. In the dialog that opens, select **Enable automatic upgrade**.

Configure (preview)

Data collection rules (DCRs) serve as a management tool for the Azure Monitor Agent on your machine. The AgentSettings DCR can be used to configure certain Azure Monitor Agent

parameters to configure the agent to your specific monitoring needs.

> **Note**
>
> Important considerations when you work with the AgentSettings DCR:
>
> - Currently, the AgentSettings DCR can be configured only by using an Azure Resource Manager template.
> - AgentSettings must be a single DCR with no other settings.
> - The virtual machine and the AgentSettings DCR must be in the same region.

Supported parameters

The AgentSettings DCR currently supports setting the following parameters:

Expand table

Parameter	Description	Valid values
`MaxDiskQuotaInMB`	To provide resiliency, the agent collects data in a local cache when the agent can't send data. The agent sends the data in the cache after the connection is restored. This parameter is the amount of disk space used (in MB) by the Azure Monitor Agent log files and cache.	Linux: `4,000` to `1,000,000` `default: 10,000` Windows: `4,000` to `1,000,000`
`UseTimeReceivedForForwardedEvents`	Changes the **WEF** column in the Microsoft Sentinel Windows Event Forwarding (WEF) table to use `TimeReceived` instead of `TimeGenerated` data	`0` or `1`

Set up the AgentSettings DCR

Azure portal

Currently not supported.

Azure Diagnostics extension overview

Azure Diagnostics extension is an agent in Azure Monitor that collects monitoring data from the guest operating system of Azure compute resources including virtual machines. This article provides an overview of Azure Diagnostics extension, the specific functionality that it supports, and options for installation and configuration.

Important

Migrate from Azure Diagnostic extension

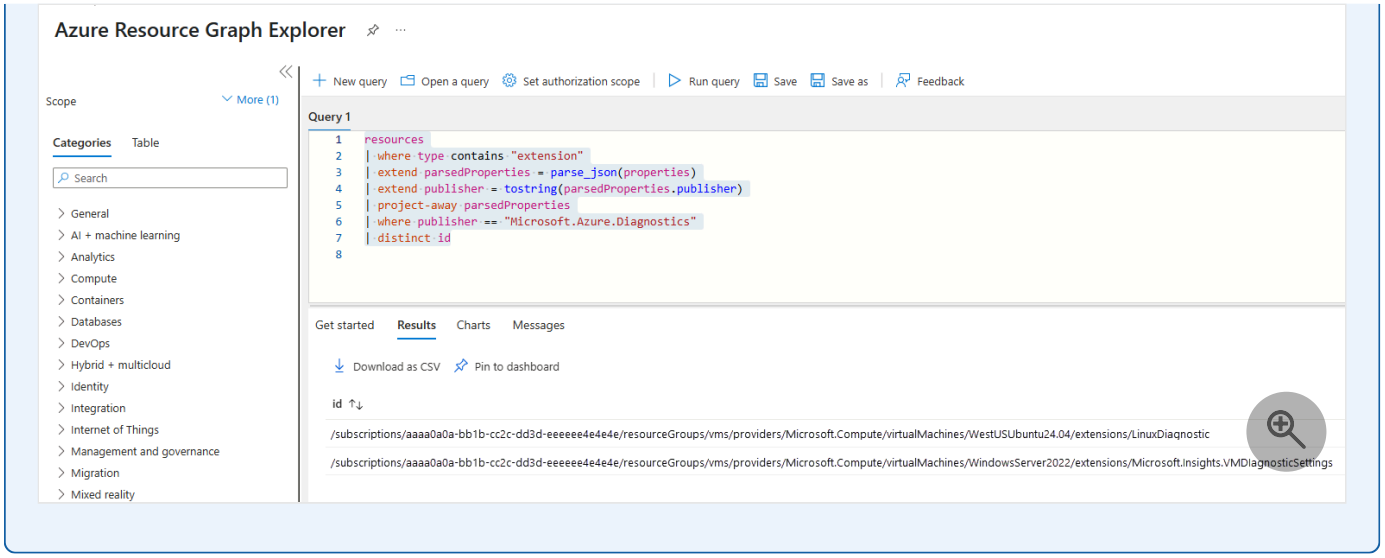
Azure Diagnostics extension was deprecated on **March 31, 2026** and is no longer supported. Don't use new deployments of the extension.

To ensure continued support and access to new features, migrate from Azure Diagnostics extensions for Linux (LAD) and Windows (WAD) to alternative solutions following the migration guidance. Remove LAD or WAD after you configure Azure Monitor Agent to avoid duplicate data.

To check which extensions are installed on a single VM, select **Extensions + applications** under **Settings** on your VM. To review the extensions installed on all virtual machines in subscriptions where you have access, use the following query in Azure Resource Graph:

```kql
resources
| where type contains "extension"
| extend parsedProperties = parse_json(properties)
| extend publisher = tostring(parsedProperties.publisher)
| project-away parsedProperties
| where publisher == "Microsoft.Azure.Diagnostics"
| distinct id
```

It produces results similar to the following example:



Migration guidance

The Azure Diagnostics extension was deprecated on March 31, 2026. To ensure continued support and access to new features, migrate using the following options based on the data destination:

Expand table

Destination	Migration options
Azure Storage blobs	If you're using WAD or LAD agents to send data to storage for longer term storage and lower costs, migrate to Azure Monitor Agent. Then you can send data to custom tables with low-cost Auxiliary plan for cost-effective logging and added benefits of Log Analytics
Azure Event Hubs	If you're using WAD or LAD agents to send data to Event Hubs, migrate to using Azure Monitor Logs data export capability to send logs to Event Hub(s).
Azure Monitor metrics	For VM Guest OS Perf Counter scenarios, migrate to using AMW as a destination for OpenTelemetry performance counters. For custom metric scenarios, migrate to using AMW as a destination for OpenTelemetry metrics.

Primary scenarios

Use the Azure Diagnostics extension if you need to:

- Send data to Azure Storage for archiving or to analyze it by using tools such as Azure Storage Explorer.
- Send data to Azure Monitor Metrics to analyze it by using metrics explorer and to take advantage of features such as near-real-time metric alerts and autoscale (Windows only).
- Send data to third-party tools by using Azure Event Hubs.

- Collect boot diagnostics to investigate VM boot problems. Boot diagnostics is a native VM feature and doesn't require the Azure Diagnostics extension. Use Microsoft-managed storage for boot diagnostics to avoid dependencies on customer-managed storage accounts and SAS tokens.

Limitations of Azure Diagnostics extension:

- It's deprecated on March 31, 2026.
- It works only with Azure resources.
- It has limited ability to send data to Azure Monitor Logs.

Costs

There's no cost for Azure Diagnostics extension, but you might incur charges for the data ingested. Check Azure Monitor pricing for the destination where you're collecting data.

Data collected

The following tables list the data that can get collected by the Windows and Linux diagnostics extension.

Windows diagnostics extension (WAD)

Expand table

Data source	Description
Windows event logs	Events from Windows event log.
Performance counters	Numerical values measuring performance of different aspects of operating system and workloads.
IIS logs	Usage information for IIS websites running on the guest operating system.
Application logs	Trace messages written by your application.
.NET EventSource logs	Code writing events using the .NET EventSource class.
Manifest-based ETW logs	Event tracing for Windows events generated by any process.
Crash dumps (logs)	Information about the state of the process if an application crashes.
File-based logs	Logs created by your application or service.

Data source	Description
Agent diagnostic logs	Information about Azure Diagnostics itself.

Linux diagnostics extension (LAD)

Expand table

Data source	Description
Syslog	Events sent to the Linux event logging system
Performance counters	Numerical values measuring performance of different aspects of operating system and workloads
Log files	Entries sent to a file-based log

Data destinations

The Azure Diagnostics extension for both Windows and Linux always collects data into an Azure Storage account. For a list of specific tables and blobs where this data is collected, see Install and configure Azure Diagnostics extension for Windows and Use Azure Diagnostics extension for Linux to monitor metrics and logs.

Configure one or more *data sinks* to send data to other destinations. The following sections list the sinks available for the Windows and Linux diagnostics extension.

Windows diagnostics extension (WAD)

Expand table

Destination	Description
Azure Monitor Metrics	Collect performance data to Azure Monitor Metrics. See Send Guest OS metrics to the Azure Monitor metric database.
Event hubs	Use Azure Event Hubs to send data outside of Azure. See Streaming Azure Diagnostics data to Azure Event Hubs.
Azure Storage blobs	Write data to blobs in Azure Storage in addition to tables.
Application Insights	To integrate with other application monitoring, collect data from applications running in your VM to Application Insights. See Send diagnostic data to Application Insights.

You can also collect WAD data from storage into a Log Analytics workspace to analyze it with Azure Monitor Logs, although the Log Analytics agent is typically used for this functionality. It can send data directly to a Log Analytics workspace and supports solutions and insights that provide more functionality. See Collect Azure diagnostic logs from Azure Storage.

Linux diagnostics extension (LAD)

LAD writes data to tables in Azure Storage. It supports the sinks in the following table.

Expand table

Destination	Description
Event hubs	Use Azure Event Hubs to send data outside of Azure.
Azure Storage blobs	Write data to blobs in Azure Storage in addition to tables.
Azure Monitor Metrics	Install the Telegraf agent in addition to LAD. See Collect custom metrics for a Linux VM with the InfluxData Telegraf agent.

Installation and configuration

The diagnostics extension is implemented as a virtual machine extension in Azure, so it supports the same installation options using Azure Resource Manager templates, PowerShell, and the Azure CLI. For information on installing and maintaining virtual machine extensions, see Virtual machine extensions and features for Windows and Virtual machine extensions and features for Linux.

You can also install and configure both the Windows and Linux diagnostics extension in the Azure portal under **Diagnostic settings** in the **Monitoring** section of the virtual machine's menu.

See the following articles for information on installing and configuring the diagnostics extension for Windows and Linux:

- Install and configure Azure Diagnostics extension for Windows
- Use Linux diagnostics extension to monitor metrics and logs

Supported operating systems

The following tables list the operating systems supported by WAD and LAD. See the documentation for each agent for unique considerations and for the installation process. See

Telegraf documentation for its supported operating systems. All operating systems are assumed to be x64. x86 isn't supported for any operating system.

Azure Monitor Dependency virtual machine extension for Linux

Article • 01/14/2025

The Azure Monitor for VMs Map feature gets its data from the Microsoft Dependency agent. The Azure VM Dependency agent virtual machine extension for Linux installs the Dependency agent on Azure virtual machines. This document details the supported platforms, configurations, and deployment options for the Azure VM Dependency agent virtual machine extension for Linux.

Prerequisites

Operating system

Because the Azure VM Dependency agent works at the kernel level, operating system support is also dependent on the kernel version. As of Dependency agent version 9.10.* the agent supports * kernels. The following table lists the major and minor Linux OS release and supported kernel versions for the Dependency agent.

> **Note**
>
> With Dependency agent 9.10.15 and above, installation is not blocked for unsupported kernel versions, but the agent will run in degraded mode. In this mode, connection and port data stored in VMConnection and VMBoundport tables is not collected. The VMProcess table may have some data, but it will be minimal.

Expand table

SUSE Linux 15 Enterprise Server	15 SP1	4.12.14-197.*-default, 4.12.14-8.*-azure
	15	4.12.14-150.*-default
Debian	9	4.9

> **Note**
>
> Dependency agent is not supported for Azure Virtual Machines with Ampere Altra ARM–based processors.

Extension schema

The following JSON shows the schema for the Azure VM Dependency agent extension on an Azure Linux VM.

JSON

```
{
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {
      "vmName": {
```

```
        "type": "string",
        "metadata": {
            "description": "The name of existing Linux Azure VM."
      }
    }
  },
  "variables": {
      "vmExtensionsApiVersion": "2017-03-30"
  },
  "resources": [
    {
      "type": "Microsoft.Compute/virtualMachines/extensions",
      "name": "[concat(parameters('vmName'),'/DAExtension')]",
      "apiVersion": "[variables('vmExtensionsApiVersion')]",
      "location": "[resourceGroup().location]",
      "dependsOn": [],
      "properties": {
          "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
          "type": "DependencyAgentLinux",
          "typeHandlerVersion": "9.5",
          "autoUpgradeMinorVersion": true,
          "settings": {
              "enableAMA": "true"
        }
      }
    }
  ],
    "outputs": {
    }
}
```

Property values

Expand table

Name	Value/Example
apiVersion	2015-01-01
publisher	Microsoft.Azure.Monitoring.DependencyAgent
type	DependencyAgentLinux
typeHandlerVersion	9.5
settings	"enableAMA": "true"

Important

Be sure to add `enableAMA` to your template if you're using Azure Monitor Agent; otherwise, Dependency agent attempts to send data to the legacy Log Analytics agent.

Template deployment

You can deploy Azure VM extensions with Azure Resource Manager templates. You can use the JSON schema detailed in the previous section in an Azure Resource Manager template to run the Azure VM Dependency agent extension during an Azure Resource Manager template deployment.

The JSON for a virtual machine extension can be nested inside the virtual machine resource. Or, you can place it at the root or top level of a Resource Manager JSON template. The placement of the JSON affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the Dependency agent extension is nested inside the virtual machine resource. When you nest the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
    "type": "extensions",
    "name": "DAExtension",
    "apiVersion": "[variables('apiVersion')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
      "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
    ],
    "properties": {
        "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
        "type": "DependencyAgentLinux",
        "typeHandlerVersion": "9.5",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "enableAMA": "true"
        }
    }
}
```

When you place the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine. The type reflects the nested configuration.

JSON

```
{
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "name": "<parentVmResource>/DAExtension",
    "apiVersion": "[variables('apiVersion')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
      "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
    ],
    "properties": {
        "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
        "type": "DependencyAgentLinux",
        "typeHandlerVersion": "9.5",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "enableAMA": "true"
        }
    }
}
```

Azure CLI deployment

You can use the Azure CLI to deploy the Dependency agent VM extension to an existing virtual machine.

Azure CLI

```
az vm extension set \
    --resource-group myResourceGroup \
    --vm-name myVM \
    --name DependencyAgentLinux \
    --publisher Microsoft.Azure.Monitoring.DependencyAgent \
    --version 9.10 \
    --settings '{"enableAMA": "true"}'
```

Automatic extension upgrade

A new feature to automatically upgrade minor versions of Dependency extension is now available.

To enable automatic extension upgrade for an extension, you must ensure the property `enableAutomaticUpgrade` is set to `true` and added to the extension template. This property must be enabled on every VM or VM scale set individually. Use one of the methods described in the enablement section enable the feature for your VM or VM scale set.

When automatic extension upgrade is enabled on a VM or VM scale set, the extension is upgraded automatically whenever the extension publisher releases a new version for that extension. The upgrade is applied safely following availability-first principles as described here.

The `enableAutomaticUpgrade` attribute's functionality is different from that of the `autoUpgradeMinorVersion`. The `autoUpgradeMinorVersion` attribute doesn't automatically trigger a minor version update when the extension publisher releases a new version. The `autoUpgradeMinorVersion` attribute indicates whether the extension should use a newer minor version if one is available at deployment time. Once deployed, however, the extension won't upgrade minor versions unless redeployed, even with this property set to true.

To keep your extension version updated, we recommend using `enableAutomaticUpgrade` with your extension deployment.

> **Important**
>
> If you add the `enableAutomaticUpgrade` to your template, make sure that you use at API version 2019-12-01 or higher.

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command by using the Azure CLI:

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o
table
```

Extension execution output is logged to the following file:

```
/var/opt/microsoft/dependency-agent/log/install.log
```

Support

If you need more help at any point in this article, contact the Azure experts on the Microsoft Q & A and Stack Overflow forums. Or, you can file an Azure support incident. Go to the Azure support site and select **Get support**. For information about how to use Azure Support, read the Microsoft Azure support FAQ.

Azure Monitor Dependency virtual machine extension for Windows

The Azure Monitor for VMs Map feature gets its data from the Microsoft Dependency agent. The Azure VM Dependency agent virtual machine extension for Windows installs the Dependency agent on Azure virtual machines. This document details the supported platforms, configurations, and deployment options for the Azure VM Dependency agent virtual machine extension for Windows.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Operating system

The Azure VM Dependency agent extension for Windows can be run against the supported operating systems listed in the following table. All operating systems in the following table are assumed to be x64. x86 isn't supported for any operating system.

Property values

Expand table

Name	Value/Example
apiVersion	2015-01-01
publisher	Microsoft.Azure.Monitoring.DependencyAgent
type	DependencyAgentWindows
typeHandlerVersion	9.10
autoUpgradeMinorVersion	true
settings	"enableAMA": "true"

> **Important**
>
> Be sure to add `enableAMA` to your template if you're using Azure Monitor Agent; otherwise, Dependency agent attempts to send data to the legacy Log Analytics agent.

Template deployment

You can deploy the Azure VM extensions with Azure Resource Manager templates. You can use the JSON schema detailed in the previous section in an Azure Resource Manager template to run the Azure VM Dependency agent extension during an Azure Resource Manager template deployment.

The JSON for a virtual machine extension can be nested inside the virtual machine resource. Or, you can place it at the root or top level of a Resource Manager JSON template. The placement

of the JSON affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the Dependency agent extension is nested inside the virtual machine resource. When you nest the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

JSON

```
{
    "type": "extensions",
    "name": "DAExtension",
    "apiVersion": "[variables('apiVersion')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
    ],
    "properties": {
      "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
      "type": "DependencyAgentWindows",
      "typeHandlerVersion": "9.10",
      "autoUpgradeMinorVersion": true,
      "settings": {
            "enableAMA": "true"
                }
    }
}
```

When you place the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine. The type reflects the nested configuration.

JSON

```
{
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "name": "<parentVmResource>/DAExtension",
    "apiVersion": "[variables('apiVersion')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
    ],
    "properties": {
      "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
      "type": "DependencyAgentWindows",
      "typeHandlerVersion": "9.10",
      "autoUpgradeMinorVersion": true,
      "settings": {
            "enableAMA": "true"
                }
    }
}
```

PowerShell deployment

You can use the `Set-AzVMExtension` command to deploy the Dependency agent virtual machine extension to an existing virtual machine. Before you run the command, the public and private configurations need to be stored in a PowerShell hash table.

PowerShell

```
Set-AzVMExtension -ExtensionName "Microsoft.Azure.Monitoring.DependencyAgent" `
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Publisher "Microsoft.Azure.Monitoring.DependencyAgent" `
    -ExtensionType "DependencyAgentWindows" `
    -TypeHandlerVersion 9.10 `
    -Settings @{"enableAMA" = "true"}
```

PowerShell deployment for Azure Monitor Agent

If you are using the Azure Monitor Agent, you must use the `enableAMA` setting. Otherwise, Dependency agent attempts to send data to the legacy Log Analytics agent. For example:

PowerShell

```
Set-AzVMExtension -ExtensionName "Microsoft.Azure.Monitoring.DependencyAgent" `
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Publisher "Microsoft.Azure.Monitoring.DependencyAgent" `
    -ExtensionType "DependencyAgentWindows" `
    -TypeHandlerVersion 9.10 `
    -Location WestUS `
    -Settings @{"enableAMA" = "true"}
```

Automatic extension upgrade

A new feature to automatically upgrade minor versions of Dependency extension is now available.

To enable automatic extension upgrade for an extension, you must ensure the property `enableAutomaticUpgrade` is set to `true` and added to the extension template. This property must be enabled on every VM or VM scale set individually. Use one of the methods described in the enablement section enable the feature for your VM or VM scale set.

When automatic extension upgrade is enabled on a VM or VM scale set, the extension is upgraded automatically whenever the extension publisher releases a new version for that

extension. The upgrade is applied safely following availability-first principles as described here.

The `enableAutomaticUpgrade` attribute's functionality is different from that of the `autoUpgradeMinorVersion`. The `autoUpgradeMinorVersion` attribute doesn't automatically trigger a minor version update when the extension publisher releases a new version. The `autoUpgradeMinorVersion` attribute indicates whether the extension should use a newer minor version if one is available at deployment time. Once deployed, however, the extension won't upgrade minor versions unless redeployed, even with this property set to true.

To keep your extension version updated, we recommend using `enableAutomaticUpgrade` with your extension deployment.

> **Important**
>
> If you add the `enableAutomaticUpgrade` to your template, make sure that you use at API version 2019-12-01 or higher.

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal and by using the Azure PowerShell module. To see the deployment state of extensions for a given VM, run the following command by using the Azure PowerShell module:

PowerShell

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name
myExtensionName
```

Extension execution output is logged to files found in the following directory:

Windows Command Prompt

```
C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.Monitoring.DependencyAgent\
```

Support

If you need more help at any point in this article, you can contact the Azure experts on the Microsoft Q & A and Stack Overflow forums. Or, you can file an Azure support incident. Go

to the Azure support site and select **Get support**. For information about how to use Azure Support, read the Microsoft Azure support FAQ.

Last updated on 11/10/2025

Introduction to the Azure Desired State Configuration extension handler

> **Note**
>
> DSC extension will be retired on March 31, 2028. Please move to Azure Machine Configuration by that date. For more information, see the blog post announcement. The Azure Machine Configuration service combines certain features of DSC Extension, Azure Automation State Configuration, and commonly requested features from customer feedback. Azure Machine Configuration also includes hybrid machine support through Arc-enabled servers.

The Azure VM Extension for Azure virtual machines (VM) and the associated extensions are part of Microsoft Azure infrastructure services. Azure VM extensions are software components that extend VM functionality and simplify various VM management operations.

The DSC extension only pushes a configuration to the VM. No ongoing reporting is available, other than locally in the VM.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Available DSC versions

The DSC extension supports configurations from version 1.1 of the DSC platform. For more information, see PSDesiredStateConfiguration v1.1.

Prerequisites

- **Developer workstation**: To interact with the Azure DSC extension, you must use either the Azure portal or the Azure PowerShell/CLI SDK.

- **Guest agent**: The Azure VM that's prepared by the DSC configuration must use an operating system that supports Windows Management Framework (WMF) 4.0 or later. For the full list of supported operating system versions, see the Azure DSC extension version history.

Terms and concepts

This article assumes familiarity with the following concepts:

- **Configuration** refers to a DSC configuration document.
- **Node** identifies a target for a DSC configuration. In this article, *node* always refers to an Azure VM.
- **Configuration data** is stored in a PowerShell DSC format file (.psd1) that has environmental data for a configuration.

Architecture

The Azure DSC extension uses the Azure VM Extension framework to deliver, enact, and report on DSC configurations running on Azure VMs. The DSC extension accepts a configuration document and a set of parameters.

When the extension is deployed the first time, it installs a version of WMF by using the following logic:

- If the Azure VM operating system is Windows Server 2016, no action is taken. Windows Server 2016 already has the latest version of PowerShell installed.
- If the `wmfVersion` property is specified, the specified version of WMF is installed, unless the specified version is incompatible with the operating system on the VM.
- If no `wmfVersion` property is specified, the latest applicable version of WMF is installed.

The WMF installation process requires a restart. After you restart, the extension automates the download of the `.zip` file specified in the `modulesUrl` property, if provided. If this location is in Azure Blob Storage, you can specify an SAS token in the `sasToken` property to access the file. Next, the configuration function defined in `configurationFunction` runs to generate a Managed Object Format (MOF) file (.mof). The extension then runs the `Start-DscConfiguration -Force` command by using the generated .mof file. The extension captures output and writes it to the Azure status channel.

Node configuration name

For the `NodeConfigurationName` parameter, be sure to provide the name of the node configuration and not the Configuration.

The Configuration is defined in a script that's used to compile the node configuration (MOF file). The name of the node configuration is always the name of the Configuration followed by a period `.` and either `localhost` or a specific computer name.

ARM template deployment

The most common approach for deploying the DSC extension is to use Azure Resource Manager templates. For more information and for examples of how to include the DSC extension in ARM templates, see Desired State Configuration extension with ARM templates.

PowerShell cmdlet deployment

PowerShell cmdlets for managing the DSC extension are ideal for interactive troubleshooting and information-gathering scenarios. You can use the cmdlets to package, publish, and monitor DSC extension deployments.

Here are some of the PowerShell cmdlets that are available:

- The **Publish-AzVMDscConfiguration** cmdlet takes in a configuration file, scans it for dependent DSC resources, and then creates a `.zip` file. The `.zip` file contains the configuration and DSC resources that are needed to enact the configuration. The cmdlet can also create the package locally by using the `-OutputArchivePath` parameter. Otherwise, the cmdlet publishes the `.zip` file to Blob Storage, and then secures it with an SAS token.

  The PowerShell configuration script (`.ps1`) created by the cmdlet is in the `.zip` file at the root of the archive folder. The module folder is placed in the archive folder in resources.

- The **Set-AzVMDscExtension** cmdlet injects the settings that the PowerShell DSC extension requires into a VM configuration object.

- The **Get-AzVMDscExtension** cmdlet retrieves the DSC extension status of a specific VM.

- The **Get-AzVMDscExtensionStatus** cmdlet retrieves the status of the DSC configuration that's enacted by the DSC extension handler. This action can be performed on a single VM or a group of VMs.

- The **Remove-AzVMDscExtension** cmdlet removes the extension handler from a specific VM. Keep in mind that this cmdlet doesn't remove the configuration, uninstall WMF, or change the applied settings on the VM. The cmdlet only removes the extension handler.

Important considerations

There are several considerations to keep in mind when working with Azure Resource Manager cmdlets.

- Azure Resource Manager cmdlets are synchronous.
- Several parameters are required, including `ResourceGroupName`, `VMName`, `ArchiveStorageAccountName`, `Version`, and `Location`.
- `ArchiveResourceGroupName` is an optional parameter. Specify this parameter when your storage account belongs to a different resource group than the one where the VM is created.
- Use the `AutoUpdate` switch to automatically update the extension handler to the latest version when it's available. This parameter has the potential to cause restarts on the VM when a new version of WMF is released.

Configuration with PowerShell cmdlets

The Azure DSC extension can use DSC configuration documents to directly configure Azure VMs during deployment. This step doesn't register the node to Automation or Machine Configuration. Keep in mind that the node isn't centrally managed.

The following code shows a simple example configuration. To work with this example, save this configuration locally as the **iisInstall.ps1** script file.

PowerShell

```
configuration IISInstall
{
    node "localhost"
    {
        WindowsFeature IIS
        {
            Ensure = "Present"
            Name = "Web-Server"
        }
    }
}
```

The following PowerShell commands place the `iisInstall.ps1` script on the specified VM. The commands also execute the configuration, and then report back on status.

PowerShell

```
$resourceGroup = 'dscVmDemo'
$vmName = 'myVM'
$storageName = 'demostorage'
#Publish the configuration script to user storage
Publish-AzVMDscConfiguration -ConfigurationPath .\iisInstall.ps1 -ResourceGroupName
$resourceGroup -StorageAccountName $storageName -force
#Set the VM to run the DSC configuration
Set-AzVMDscExtension -Version '2.76' -ResourceGroupName $resourceGroup -VMName
$vmName -ArchiveStorageAccountName $storageName -ArchiveBlobName
'iisInstall.ps1.zip' -AutoUpdate -ConfigurationName 'IISInstall'
```

Azure CLI deployment

The Azure CLI can be used to deploy the DSC extension to an existing VM. The following examples show how to deploy a VM on Windows.

For a VM running Windows, use the following command:

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name DSC \
  --publisher Microsoft.Powershell \
  --version 2.77 --protected-settings '{}' \
  --settings '{}'
```

Azure portal deployment

To set up the DSC extension in the Azure portal, follow these steps:

1. Go to a VM.
2. Under **Settings**, select **Extensions + Applications**.
3. Under **Extensions**, select **+ Add**.
4. Select **PowerShell Desired State Configuration**, then select **Next**.
5. Configure the following parameters for the DSC extension.

- **Configuration Modules or Script**: (Required) Provide the Configuration modules or script file for your VM.

  Configuration modules and scripts require a `.ps1` file that has a configuration script or a `.zip` file with a `.ps1` configuration script at the root. If you use a `.zip` file, all dependent resources must be included in module folders in the `.zip` file. You can create the `.zip` file by using the **Publish-AzureVMDscConfiguration -OutputArchivePath** cmdlet that's included in the Azure PowerShell SDK. The `.zip` file is uploaded to your user Blob Storage and secured by an SAS token.

- **Module-qualified Name of Configuration**: (Required) Specify this setting to include multiple configuration functions in a single `.ps1` script file. For this setting, enter the name of the configuration `.ps1` script file followed by a slash `\` and then the name of the configuration function. For example, if the `.ps1` script file has the name **configuration.ps1** and the configuration name is **IisInstall**, enter the value `configuration.ps1\IisInstall` for the setting.

- **Configuration Arguments**: If the configuration function takes arguments, enter the values by using the format `argumentName1=value1,argumentName2=value2`. Notice that this format differs from the format that's used to specify configuration arguments in PowerShell cmdlets or ARM templates.

- **Configuration Data PSD1 File**: If your configuration requires a configuration data file in `.psd1` format, use this setting to select the data file and upload it to your user Blob Storage. The configuration data file is secured with an SAS token in Blob Storage.

- **WMF Version**: Specify the version of Windows Management Framework to install on your VM. If you choose **latest**, which is the default value, the system installs the most recent version of WMF. Other possible values include 4.0, 5.0, and 5.1. The possible values are subject to updates.

- **Data Collection**: Enable this setting if you want the DSC extension to collect telemetry about your VM. For more information, see Azure DSC extension data collection.

- **Version**: (Required) Specify the version of the DSC extension to install. For information about versions, see Azure DSC extension version history.

- **Auto Upgrade Minor Version**: This setting maps to the `AutoUpdate` switch in the cmdlets. Configure this setting to enable the DSC extension to automatically update to the latest version during installation. **Yes** instructs the DSC extension handler to

use the latest available version. **No** (default) forces installation of the version you specify in the **Version** setting.

6. After you configure the parameters, select **Review + Create**, and then select **Create**.

DSC extension logs

You can view logs for the Azure DSC extension on the VM under `C:\WindowsAzure\Logs\Plugins\Microsoft.Powershell.DSC\<version number>`.

Next steps

- For more information about PowerShell DSC, go to the PowerShell documentation center.
- Examine the ARM template for the Azure DSC extension.
- For more functionality that you can manage by using PowerShell DSC, and for more DSC resources, browse the PowerShell gallery.
- For details about passing sensitive parameters into configurations, see Manage credentials securely with the Azure DSC extension handler.

PowerShell DSC Extension

> **Note**
>
> DSC extension will be retired on March 31, 2028. Move to Azure Machine Configuration by that date. For more information, see the blog post announcement. The Azure Machine Configuration service combines certain features of DSC Extension, Azure Automation State Configuration, and commonly requested features from customer feedback. Azure Machine Configuration also includes hybrid machine support through Arc-enabled servers.

Overview

The PowerShell DSC Extension for Windows uploads and applies a PowerShell DSC Configuration on an Azure virtual machine. The DSC Extension calls into PowerShell DSC to enact the received DSC configuration on the virtual machine. This document details the supported platforms, configurations, and deployment options for the DSC virtual machine extension for Windows.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Prerequisites

Operating system

The DSC Extension supports the following operating systems

Windows Server 2022, Windows Server 2019, Windows Server 2016, Windows Server 2012R2, Windows Server 2012, Windows Server 2008 R2 SP1, Windows Client 7/8.1/10

Internet connectivity

The DSC extension for Windows requires that the target virtual machine is able to communicate with Azure and the location of the configuration package (.zip file) if stored outside of Azure.

Extension schema

The following JSON shows the schema for the settings portion of the DSC Extension in an Azure Resource Manager template.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "Microsoft.Powershell.DSC",
  "apiVersion": "2018-10-01",
  "location": "<location>",
  "properties": {
    "publisher": "Microsoft.Powershell",
    "type": "DSC",
    "typeHandlerVersion": "2.77",
    "autoUpgradeMinorVersion": true,
    "settings": {
        "wmfVersion": "latest",
        "configuration": {
            "url": "http://validURLToConfigLocation",
            "script": "ConfigurationScript.ps1",
            "function": "ConfigurationFunction"
        },
        "configurationArguments": {
            "argument1": "Value1",
            "argument2": "Value2"
        },
        "configurationData": {
            "url": "https://foo.psd1"
        },
        "privacy": {
            "dataCollection": "enable"
        },
        "advancedOptions": {
            "forcePullAndApply": false,
            "downloadMappings": {
             "specificDependencyKey": "https://myCustomDependencyLocation"
            }
        }
    },
    "protectedSettings": {
        "configurationArguments": {
            "parameterOfTypePSCredential1": {
                "userName": "UsernameValue1",
                "password": "PasswordValue1"
            },
```

```
            "parameterOfTypePSCredential2": {
                "userName": "UsernameValue2",
                "password": "PasswordValue2"
            }
        },
        "configurationUrlSasToken": "?g!bber1sht0k3n",
        "configurationDataUrlSasToken": "?dataAcC355T0k3N"
    }
  }
}
```

Property values

Expand table

Name	Value / Example	Data Type
apiVersion	2018-10-01	date
publisher	Microsoft.Powershell.DSC	string
type	DSC	string
typeHandlerVersion	2.77	int

Settings Property values

Expand table

Name	Data Type	Description
settings.wmfVersion	string	Specifies the version of the Windows Management Framework that should be installed on your VM. Setting this property to 'latest' installs the most updated version of WMF. The only current possible values for this property are ‘4.0’, ‘5.0’, and 'latest'. These possible values are subject to updates. The default value is 'latest'.
settings.configuration.url	string	Specifies the URL location from which to download your DSC configuration zip file. If the URL provided requires a SAS token for access, set the protectedSettings.configurationUrlSasToken property to the value of your SAS token. This property is required if

Name	Data Type	Description
		settings.configuration.script and/or settings.configuration.function are defined.
settings.configuration.script	string	Specifies the file name of the script that contains the definition of your DSC configuration. This script must be in the root folder of the zip file downloaded from the URL specified by the configuration.url property. This property is required if settings.configuration.url and/or settings.configuration.script are defined.
settings.configuration.function	string	Specifies the name of your DSC configuration. The configuration named must be contained in the script defined by configuration.script. This property is required if settings.configuration.url and/or settings.configuration.function are defined.
settings.configurationArguments	Collection	Defines any parameters you would like to pass to your DSC configuration. This property won't be encrypted.
settings.configurationData.url	string	Specifies the URL from which to download your configuration data (.pds1) file to use as input for your DSC configuration. If the URL provided requires a SAS token for access, set the protectedSettings.configurationDataUrlSasToken property to the value of your SAS token.
settings.privacy.dataEnabled	string	Enables or disables telemetry collection. The only possible values for this property are 'Enable', 'Disable', '', or $null. Leaving this property blank or null enables telemetry
settings.advancedOptions.forcePullAndApply	Bool	This setting is designed to enhance the experience of working with the extension to register nodes with Azure Automation DSC. If the value is `$true`, the extension waits for the first run of the configuration pulled from the service before returning success/failure. If the value is set to $false, the status returned by the extension refers to whether the node was registered with Azure Automation State Configuration successfully and the node configuration won't run during the registration.
settings.advancedOptions.downloadMappings	Collection	Defines alternate locations to download dependencies such as WMF and .NET

Protected Settings Property values

Expand table

Name	Data Type	Description
protectedSettings.configurationArguments	string	Defines any parameters you would like to pass to your DSC configuration.
protectedSettings.configurationUrlSasToken	string	Specifies the SAS token to access the URL defined by configuration.url.
protectedSettings.configurationDataUrlSasToken	string	Specifies the SAS token to access the URL defined by configurationData.url.

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration. A sample Resource Manager template that includes the DSC extension for Windows can be found on the Azure Quick Start Gallery.

Troubleshoot and support

Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension package is downloaded and deployed to this location on the Azure VM

```
C:\Packages\Plugins\{Extension_Name}\{Extension_Version}
```

Extension status file contains the sub status and status success/error codes along with the detailed error and description for each extension run.

```
C:\Packages\Plugins\{Extension_Name}\{Extension_Version}\Status\{0}.Status  -> {0}
being the sequence number
```

Extension output logs are logged to the following directory:

```
C:\WindowsAzure\Logs\Plugins\{Extension_Name}\{Extension_Version}
```

Error codes and their meanings

Expand table

Error Code	Meaning	Possible Action
1000	Generic error	The message for this error is provided by the specific exception in extension logs
52	Extension Install Error	The message for this error is provided by the specific exception
1002	Wmf Install Error	Error while installing WMF.
1004	Invalid Zip Package	Invalid zip ; Error unpacking the zip
1100	Argument Error	Indicates a problem in the input provided by the user. The message for the error is provided by the specific exception

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to the Azure support site and select Get support. For information about using Azure Support, read the Microsoft Azure support FAQ.

Last updated on 11/10/2025

Pass credentials to the Azure DSCExtension handler

> **Note**
>
> DSC extension will be retired on March 31, 2028. Please transition to Azure Machine Configuration by that date. For more information, see the blog post announcement. The Azure Machine Configuration service combines certain features of DSC Extension, Azure Automation State Configuration, and commonly requested features from customer feedback. Azure Machine Configuration also includes hybrid machine support through Arc-enabled servers.

This article covers the Desired State Configuration (DSC) extension for Azure. For an overview of the DSC extension handler, see Introduction to the Azure Desired State Configuration extension handler.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Pass in credentials

As part of the configuration process, you might need to set up user accounts, access services, or install a program in a user context. To do these things, you need to provide credentials.

You can use DSC to set up parameterized configurations. In a parameterized configuration, credentials are passed into the configuration and securely stored in .mof files. The Azure extension handler simplifies credential management by providing automatic management of certificates.

The following DSC configuration script creates a local user account with the specified password:

PowerShell

```
configuration Main
{
    param(
        [Parameter(Mandatory=$true)]
```

```
        [ValidateNotNullorEmpty()]
        [PSCredential]
        $Credential
    )
    Node localhost {
        User LocalUserAccount
        {
            Username = $Credential.UserName
            Password = $Credential
            Disabled = $false
            Ensure = "Present"
            FullName = "Local User Account"
            Description = "Local User Account"
            PasswordNeverExpires = $true
        }
    }
}
```

It's important to include **node localhost** as part of the configuration. The extension handler specifically looks for the **node localhost** statement. If this statement is missing, the following steps don't work. It's also important to include the typecast **[PsCredential]**. This specific type triggers the extension to encrypt the credential.

To publish this script to Azure Blob storage:

```
Publish-AzVMDscConfiguration -ConfigurationPath .\user_configuration.ps1
```

To set the Azure DSC extension and provide the credential:

PowerShell

```
$configurationName = 'Main'
$configurationArguments = @{ Credential = Get-Credential }
$configurationArchive = 'user_configuration.ps1.zip'
$vm = Get-AzVM -Name 'example-1'

$vm = Set-AzVMDscExtension -VMName $vm -ConfigurationArchive $configurationArchive -
ConfigurationName $configurationName -ConfigurationArgument @configurationArguments

$vm | Update-AzVM
```

How a credential is secured

Running this code prompts for a credential. After the credential is provided, it's briefly stored in memory. When the credential is published by using the **Set-AzVMDscExtension** cmdlet, the credential is transmitted over HTTPS to the VM. In the VM, Azure stores the credential encrypted on disk by using the local VM certificate. The credential is briefly decrypted in memory, and then it's re-encrypted to pass it to DSC.

This process is different than using secure configurations without the extension handler. The Azure environment gives you a way to transmit configuration data securely via certificates. When you use the DSC extension handler, you don't need to provide **$CertificatePath** or a **$CertificateID**/ **$Thumbprint** entry in **ConfigurationData**.

Next steps

- Get an introduction to Azure DSC extension handler.
- Examine the Azure Resource Manager template for the DSC extension.
- For more information about PowerShell DSC, go to the PowerShell documentation center.
- For more functionality that you can manage by using PowerShell DSC, and for more DSC resources, browse the PowerShell gallery.

Desired State Configuration extension with Azure Resource Manager templates

> **Note**
>
> DSC extension will be retired on March 31, 2028. Please move to Azure Machine Configuration by that date. For more information, see the blog post announcement. The Azure Machine Configuration service combines certain features of DSC Extension, Azure Automation State Configuration, and commonly requested features from customer feedback. Azure Machine Configuration also includes hybrid machine support through Arc-enabled servers.

This article describes the Azure Resource Manager template for the Desired State Configuration (DSC) extension handler.

> **Note**
>
> You might encounter slightly different schema examples. The change in schema occurred in the October 2016 release. For details, see Update from a previous format.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Bicep example for a virtual machine

The DSC extension inherits default extension properties. For more information, see VirtualMachineExtension class.

Bicep

```
@description('URI of the configuration package')
param configUri string

@description('first configuration parameter')
param arg1 string

@description('second configuration parameter')
```

```
@secure()
param arg2 string

var configName = split(split(configUri, '/')[4], '.')[0]

resource vm 'Microsoft.Compute/virtualMachines@2023-09-01' existing = {
  name: srvName
}

resource configuration_dscext 'Microsoft.Compute/virtualMachines/extensions@2024-07-
01' = {
  name: 'configurationname_dscext'
  parent: vm
  location: location
  properties: {
    publisher: 'Microsoft.Powershell'
    type: 'DSC'
    typeHandlerVersion: '2.77'
    autoUpgradeMinorVersion: true
    settings: {
      wmfVersion: 'latest'
      configuration: {
        url: configUri
        script: 'configurationname_dscext.ps1'
        function: 'configurationname_dscext'
      }
      configurationArguments: {
        arg1: arg1
      }
      advancedOptions: {
        rebootNodeIfNeeded: true
      }
    }
    protectedSettings: {
      configurationArguments: {
        arg2: arg2
      }
    }
  }
}
```

Bicep example for Windows virtual machine scale sets

A virtual machine scale set node has a section that includes an **extensionProfile** attribute. Under **extensions**, add the details for DSC Extension.

For the latest details about authoring templates that deploy extensions for Virtual Machine Scale Sets, see the document Microsoft.Compute virtualMachineScaleSets

The DSC extension inherits default extension properties. For more information, see VirtualMachineScaleSetExtension class.

Settings vs. protectedSettings

All settings are saved in a settings text file on the VM. Properties listed under **settings** are public properties. Public properties aren't encrypted in the settings text file. Properties listed under **protectedSettings** are encrypted with a certificate and aren't shown in plain text in the settings file on the VM.

If the configuration needs credentials, you can include the credentials in **protectedSettings**:

JSON

```
"protectedSettings": {
    "configurationArguments": {
        "parameterOfTypePSCredential1": {
               "userName": "UsernameValue1",
               "password": "PasswordValue1"
        }
    }
}
```

Example using the configuration script in Azure Storage

The following example is from the DSC extension handler overview. This example uses Resource Manager templates instead of cmdlets to deploy the extension. Save the IisInstall.ps1 configuration, place it in a .zip file (example: `iisinstall.zip`), and then upload the file in an accessible URL. This example uses Azure Blob storage, but you can download .zip files from any arbitrary location.

In the Resource Manager template, the following code instructs the VM to download the correct file, and then run the appropriate PowerShell function:

JSON

```
"settings": {
    "configuration": {
        "url": "https://demo.blob.core.windows.net/iisinstall.zip",
        "script": "IisInstall.ps1",
        "function": "IISInstall"
    }
},
"protectedSettings": {
```

```
    "configurationUrlSasToken": "odLPL/U1p9lvcnp..."
}
```

Update from a previous format

Any settings in a previous format of the extension (and which have the public properties **ModulesUrl**, **ModuleSource**, **ModuleVersion**, **ConfigurationFunction**, **SasToken**, or **Properties**) automatically adapt to the current format of the extension. They run just as they did before.

The following schema shows what the previous settings schema looked like:

JSON

```
"settings": {
    "WMFVersion": "latest",
    "ModulesUrl": "https://UrlToZipContainingConfigurationScript.ps1.zip",
    "SasToken": "SAS Token if ModulesUrl points to private Azure Blob Storage",
    "ConfigurationFunction": "ConfigurationScript.ps1\\ConfigurationFunction",
    "Properties": {
        "ParameterToConfigurationFunction1": "Value1",
        "ParameterToConfigurationFunction2": "Value2",
        "ParameterOfTypePSCredential1": {
            "UserName": "UsernameValue1",
            "Password": "PrivateSettingsRef:Key1"
        },
        "ParameterOfTypePSCredential2": {
            "UserName": "UsernameValue2",
            "Password": "PrivateSettingsRef:Key2"
        }
    }
},
"protectedSettings": {
    "Items": {
        "Key1": "PasswordValue1",
        "Key2": "PasswordValue2"
    },
    "DataBlobUri": "https://UrlToConfigurationDataWithOptionalSasToken.psd1"
}
```

Here's how the previous format adapts to the current format:

Expand table

Current Property name	Previous schema equivalent
settings.wmfVersion	settings.WMFVersion
settings.configuration.url	settings.ModulesUrl

Current Property name	Previous schema equivalent
settings.configuration.script	First part of settings.ConfigurationFunction (before \\)
settings.configuration.function	Second part of settings.ConfigurationFunction (after \\)
settings.configuration.module.name	settings.ModuleSource
settings.configuration.module.version	settings.ModuleVersion
settings.configurationArguments	settings.Properties
settings.configurationData.url	protectedSettings.DataBlobUri (without SAS token)
settings.privacy.dataCollection	settings.Privacy.dataCollection
settings.advancedOptions.downloadMappings	settings.AdvancedOptions.DownloadMappings
protectedSettings.configurationArguments	protectedSettings.Properties
protectedSettings.configurationUrlSasToken	settings.SasToken
protectedSettings.configurationDataUrlSasToken	SAS token from protectedSettings.DataBlobUri

Troubleshooting

Here are some of the errors you might run into and how you can fix them.

Invalid values

"Privacy.dataCollection is '{0}'. The only possible values are '', 'Enable', and 'Disable'".
"WmfVersion is '{0}'. Only possible values are ... and 'latest'".

Problem: A provided value isn't allowed.

Solution: Change the invalid value to a valid value.

Invalid URL

"ConfigurationData.url is '{0}'. This is not a valid URL" "DataBlobUri is '{0}'. This is not a valid URL" "Configuration.url is '{0}'. This is not a valid URL"

Problem: A provided URL isn't valid.

Solution: Check all your provided URLs. Ensure that all URLs resolve to valid locations that the extension can access on the remote machine.

Invalid ConfigurationArgument type

"Invalid configurationArguments type {0}"

Problem: The *ConfigurationArguments* property can't resolve to a **Hash table** object.

Solution: Make your *ConfigurationArguments* property a **Hash table**. Follow the format provided in the preceding examples. Watch for quotes, commas, and braces.

Duplicate ConfigurationArguments

"Found duplicate arguments '{0}' in both public and protected configurationArguments"

Problem: The *ConfigurationArguments* in public settings and the *ConfigurationArguments* in protected settings have properties with the same name.

Solution: Remove one of the duplicate properties.

Missing properties

"settings.Configuration.function requires that settings.configuration.url or settings.configuration.module is specified"

"settings.Configuration.url requires that settings.configuration.script is specified"

"settings.Configuration.script requires that settings.configuration.url is specified"

"settings.Configuration.url requires that settings.configuration.function is specified"

"protectedSettings.ConfigurationUrlSasToken requires that settings.configuration.url is specified"

"protectedSettings.ConfigurationDataUrlSasToken requires that settings.configurationData.url is specified"

Problem: A defined property needs another property, which is missing.

Solutions:

- Provide the missing property.
- Remove the property that needs the missing property.

Next steps

- Learn about using virtual machine scale sets with the Azure DSC extension.

- Find more details about DSC's secure credential management.
- Get an introduction to the Azure DSC extension handler.
- For more information about PowerShell DSC, go to the PowerShell documentation center.

VMAccess Extension for Linux

08/27/2025

The VMAccess Extension is used to manage administrative users, configure SSH, and check or repair disks on Azure Linux virtual machines. The extension integrates with Azure Resource Manager templates. It can also be invoked using Azure CLI, Azure PowerShell, the Azure portal, and the Azure Virtual Machines REST API.

This article describes how to run the VMAccess Extension from the Azure CLI and through an Azure Resource Manager template. This article also provides troubleshooting steps for Linux systems.

> **Note**
>
> If you use the VMAccess extension to reset the password of your VM after you install the Microsoft Entra sign-in extension, rerun the Microsoft Entra sign-in extension to re-enable Microsoft Entra sign-in for your VM.

Prerequisites

Supported Linux distributions

Expand table

Publisher	Distribution	x64	ARM64
Alma Linux Community	Alma Linux	8.x+, 9.x+	8.x+, 9.x+
Credativ	Debian	10+	11.x+
Kinvolk	Flatcar Linux	3374.2.x+	3374.2.x+
Microsoft	Azure Linux	2.x	2.x
openSUSE Project	openSUSE	12.3+	*Not supported*
Oracle	Oracle Linux	6.4+, 7.x+, 8.x+	*Not supported*
Red Hat	Red Hat Enterprise Linux	6.7+, 7.x+, 8.x+, 9.x+, 10.x+	8.6+, 9.0+, 10.x+
CIQ	Rocky Linux	9.x+	9.x+

Publisher	Distribution	x64	ARM64
SUSE	SLES	12.x+, 15.x+	15.x SP4+
Canonical	Ubuntu (LTS releases)	18.04+, 20.04+, 22.04+, 24.04+	20.04+, 22.04+, 24.04+

Tips

- VMAccess was designed for regaining access to a VM given that access is lost. Based on this principle, it grants sudo permission to account specified in the username field. If you don't wish a user to gain sudo permissions, sign-in to the VM and use built-in tools (for example, usermod, change, etc.) to manage unprivileged users.
- You can only have one version of the extension applied to a VM. To run a second action, update the existing extension with a new configuration.
- During a user update, VMAccess alters the `sshd_config` file and takes a backup of it beforehand. It changes `ChallengeResponseAuthentication` to `no` and `PasswordAuthentication` to `yes`. To restore the original backed-up SSH configuration, run VMAccess with `restore_backup_ssh` set to `True`.

Extension schema

The VMAccess Extension configuration includes settings for username, passwords, SSH keys, etc. You can store this information in configuration files, specify it on the command line, or include it in an Azure Resource Manager (ARM) template. The following JSON schema contains all the properties available to use in public and protected settings.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "<name>",
  "apiVersion": "2023-09-01",
  "location": "<location>",
  "dependsOn": [
          "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
  ],
  "properties": {
    "publisher": "Microsoft.OSTCExtensions",
    "type": "VMAccessForLinux",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "check_disk": true,
      "repair_disk": false,
```

```
      "disk_name": "<disk-name>",
    },
    "protectedSettings": {
      "username": "<username>",
      "password": "<password>",
      "ssh_key": "<ssh-key>",
      "reset_ssh": false,
      "remove_user": "<username>",
      "expiration": "<expiration>",
      "remove_prior_keys": false,
      "restore_backup_ssh": true
    }
  }
}
```

Property values

Expand table

Name	Value / Example	Data Type
apiVersion	2023-09-01	date
publisher	Microsoft.OSTCExtensions	string
type	VMAccessForLinux	string
typeHandlerVersion	1.5	int

Settings property values

Expand table

Name	Data Type	Description
check_disk	boolean	Whether or not to check disk (optional). Only one between `check_disk` and `repair_disk` can be set to true.
repair_disk	boolean	Whether or not to check disk (optional). Only one between `check_disk` and `repair_disk` can be set to true.
disk_name	string	Name of disk to repair (required when `repair_disk` is true).
username	string	The name of the user to manage (required for all actions on a user account).
password	string	The password to set for the user account.

Name	Data Type	Description
ssh_key	string	The SSH public key to add for the user account. The SSH key can be in `ssh-rsa`, `ssh-ed25519`, or `.pem` format.
reset_ssh	boolean	Whether or not to reset the SSH. If `true`, it replaces the sshd_config file with an internal resource file corresponding to the default SSH config for that distro.
remove_user	string	The name of the user to remove. Can't be used with `reset_ssh`, `restore_backup_ssh`, and `password`.
expiration	string	Expiration to set to for the account, in the form of `yyyy-mm-dd`. Defaults to never.
remove_prior_keys	boolean	Whether or not to remove old SSH keys when adding a new one. Must be used with `ssh_key`.
restore_backup_ssh	boolean	Whether or not to restore the original backed-up sshd_config.

Template deployment

Azure VM Extensions can be deployed with Azure Resource Manager (ARM) templates. The JSON schema detailed in the previous section can be used in an ARM template to run the VMAccess Extension during the template's deployment. You can find a sample template that includes the VMAccess extension on GitHub.

The JSON configuration for a virtual machine extension must be nested inside the virtual machine resource fragment of the template, specifically `"resources": []` object for the virtual machine template and for a virtual machine scale set under `"virtualMachineProfile":"extensionProfile":{"extensions" :[]` object.

Azure CLI deployment

Using Azure CLI VM user commands

The following CLI commands under az vm user use the VMAccess Extension. To use these commands, you need to install the latest Azure CLI and sign in to an Azure account by using az sign-in.

Update SSH key

The following example updates the SSH key for the user `azureUser` on the VM named `myVM`:

Azure CLI

```
az vm user update \
  --resource-group myResourceGroup \
  --name myVM \
  --username azureUser \
  --ssh-key-value ~/.ssh/id_rsa.pub
```

> **Note**
>
> The az vm user update command appends the new public key text to the `~/.ssh/authorized_keys` file for the admin user on the VM. This command doesn't replace or remove any existing SSH keys. This command doesn't remove prior keys set at deployment time or subsequent updates by using the VMAccess Extension.

Reset password

The following example resets the password for the user `azureUser` on the VM named `myVM`:

Azure CLI

```
az vm user update \
  --resource-group myResourceGroup \
  --name myVM \
  --username azureUser \
  --password myNewPassword
```

Restart SSH

The following example restarts the SSH daemon and resets the SSH configuration to default values on a VM named `myVM`:

Azure CLI

```
az vm user reset-ssh \
  --resource-group myResourceGroup \
  --name myVM
```

> **Note**

The az vm user reset-ssh command replaces the sshd_config file with a default config file from the internal resources directory. This command doesn't restore the original SSH configuration found on the virtual machine.

Create an administrative/sudo user

The following example creates a user named `myNewUser` with sudo permissions. The account uses an SSH key for authentication on the VM named `myVM`. This method helps you regain access to a VM when current credentials are lost or forgotten. As a best practice, accounts with sudo permissions should be limited.

Azure CLI

```
az vm user update \
  --resource-group myResourceGroup \
  --name myVM \
  --username myNewUser \
  --ssh-key-value ~/.ssh/id_rsa.pub
```

Delete a user

The following example deletes a user named `myNewUser` on the VM named `myVM`:

Azure CLI

```
az vm user delete \
  --resource-group myResourceGroup \
  --name myVM \
  --username myNewUser
```

Using Azure CLI VM/Virtual Machine Scale Sets extension commands

You can also use the az vm extension set and az vmss extension set commands to run the VMAccess Extension with the specified configuration.

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name VMAccessForLinux \
  --publisher Microsoft.OSTCExtensions \
```

```
  --version 1.5 \
  --settings '{"check_disk":true}'
  --protected-settings '{"username":"user1","password":"userPassword"}'
```

The `--settings` and `--protected-settings` parameters also accept JSON file paths. For example, to update the SSH public key of a user, create a JSON file named `update_ssh_key.json` and add settings in the following format. Replace the values within the file with your own information:

JSON

```
{
  "username":"azureuser",
  "ssh_key":"ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAACAQCZ3S7gGp3rcbKmG2Y4vGZFMuMZCwoUzZNGxxxxxx2XV2x9FfAhy8
iGD+lF8UdjFX3t5ebMm6BnnMh8fHwkTRdOt3LDQq8o8ElTBrZaKPxZN2thMZnODs5Hlemb2UX0oRIGRcvW
qsd4oJmxsXa/Si98Wa6RHWbc9QZhw80KAcOVhmndZAZAGR+Wq6yslNo5TMOr1/ZyQAook5C4FtcSGn3Y+W

jO1+X+4x6L1H5HTPuqUkyZGgDO4ynUHbko4dhlanALcriF7tIfQR9i2r2xOyv5gxJEW/zztGqWma/d4rBo
Pjnf6tO7rLFHXMt/DVTkAfn5wxxtLDwkn5FMyvThRmex3BDf0gujoI1y6cOWLe9Y5geNX0oj+MXg/W0cXA
tzSFocstV1PoVqy883hNoeQZ3mIGB3Q0rIUm5d9MA2bMMt31m1g3Sin6EQ== azureuser@myVM"
}
```

Run the VMAccess Extension through the following command:

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name VMAccessForLinux \
  --publisher Microsoft.OSTCExtensions \
  --version 1.5 \
  --protected-settings update_ssh_key.json
```

Azure PowerShell deployment

Azure PowerShell can be used to deploy the VMAccess Extension to an existing virtual machine or virtual machine scale set. You can deploy the extension to a VM by running:

Azure PowerShell

```
$username = "<username>"
$sshKey = "<cert-contents>"
```

```
$settings = @{"check_disk" = $true};
$protectedSettings = @{"username" = $username; "ssh_key" = $sshKey};

Set-AzVMExtension -ResourceGroupName "<resource-group>" `
    -VMName "<vm-name>" `
    -Location "<location>" `
    -Publisher "Microsoft.OSTCExtensions" `
    -ExtensionType "VMAccessForLinux" `
    -Name "VMAccessForLinux" `
    -TypeHandlerVersion "1.5" `
    -Settings $settings `
    -ProtectedSettings $protectedSettings
```

You can also provide and modify extension settings by using strings:

Azure PowerShell

```
$username = "<username>"
$sshKey = "<cert-contents>"

$settingsString = '{"check_disk":true}';
$protectedSettingsString = '{"username":"' + $username + '","ssh_key":"' + $sshKey
+ '"}';

Set-AzVMExtension -ResourceGroupName "<resource-group>" `
    -VMName "<vm-name>" `
    -Location "<location>" `
    -Publisher "Microsoft.OSTCExtensions" `
    -ExtensionType "VMAccessForLinux" `
    -Name "VMAccessForLinux" `
    -TypeHandlerVersion "1.5" `
    -SettingString $settingsString `
    -ProtectedSettingString $protectedSettingsString
```

To deploy to a virtual machine scale set, run the following command:

Azure PowerShell

```
$resourceGroupName = "<resource-group>"
$vmssName = "<vmss-name>"

$protectedSettings = @{
  "username" = "azureUser"
  "password" = "userPassword"
}

$publicSettings = @{
  "repair_disk" = $true
  "disk_name" = "<disk_name>"
}

$vmss = Get-AzVmss `
```

```
            -ResourceGroupName $resourceGroupName `
            -VMScaleSetName $vmssName

Add-AzVmssExtension -VirtualMachineScaleSet $vmss `
    -Name "<extension-name>" `
    -Publisher "Microsoft.OSTCExtensions" `
    -Type "VMAccessForLinux" `
    -TypeHandlerVersion "1.5"" `
    -AutoUpgradeMinorVersion $true `
    -Setting $publicSettings `
    -ProtectedSetting $protectedSettings

Update-AzVmss `
    -ResourceGroupName $resourceGroupName `
    -Name $vmssName `
    -VirtualMachineScaleSet $vmss
```

Troubleshoot and support

The VMAccess extension logs exist locally on the VM and are most informative when it comes to troubleshooting.

Expand table

Location	Description
/var/log/waagent.log	Contains logs from the Linux Agent and shows when an update to the extension occurred. We can check it to ensure the extension ran.
/var/log/azure/Microsoft.OSTCExtensions.VMAccessForLinux/*	The VMAccess Extension produces logs, which can be found here. The directory contains `CommandExecution.log` where you can find each command executed along with its result, along with `extension.log`, which contains individual logs for each execution.
/var/lib/waagent/Microsoft.OSTCExtensions.VMAccessForLinux-<most recent version>/config/*	The configuration and binaries for VMAccess VM Extension.

You can also retrieve the execution state of the VMAccess Extension, along with other extensions on a given VM, by running the following command:

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Error messages

Expand table

Error	Description
Provisioning of VM extension enablevmaccess has timed out. Extension provisioning has taken too long to complete. The extension didn't report a message. More information on troubleshooting is available at https://aka.ms/vmextensionlinuxtroubleshoot.	The error message indicates that the provisioning of the VM extension 'enablevmaccess' has timed out due to taking too long to complete. Additionally, the extension didn't provide any status message during the process. To resolve this issue, consider checking the VM's performance and network conditions, and retry the provisioning operation. For more information, see Troubleshoot VM extensions.
VM has reported a failure when processing extension 'enablevmaccess' (publisher 'Microsoft.OSTCExtensions' and type 'VMAccessForLinux'). Error message: 'Enable failed: No password or ssh_key is specified.'. More information on troubleshooting is available at https://aka.ms/vmextensionlinuxtroubleshoot.	The error message indicates that the VM failed to process the 'enablevmaccess' extension because no password or SSH key was specified. This failure is associated with the 'Microsoft.OSTCExtensions' publisher and the 'VMAccessForLinux' type. To resolve this issue, ensure that either a password or an SSH key is provided during the extension configuration.

For more help, you can contact the Azure experts at Azure Community Support. Alternatively, you can file an Azure support incident. Go to Azure support and select **Get support**. For more information about Azure Support, read the Azure support plans FAQ.

Next steps

To see the code, current versions, and more documentation, see VMAccess Linux - GitHub.

VMAccess Extension for Windows

The VMAccess Extension is used to manage administrative users, configure RDP, and check or repair disks on Azure Windows virtual machines. The extension integrates with Azure Resource Manager templates. It can also be invoked using Azure CLI, Azure PowerShell, the Azure portal, and the Azure Virtual Machines REST API.

This article describes how to run the VMAccess Extension from the Azure PowerShell and through an Azure Resource Manager template. This article also provides troubleshooting steps for Windows systems.

> **Note**
>
> If you use the VMAccess extension to reset the password of your VM after you install the Microsoft Entra Login extension, rerun the Microsoft Entra Login extension to re-enable Microsoft Entra Login for your VM.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

Tips

- VMAccess is designed for regaining access to a VM when access is lost. Based on this principle, it grants administrator privileges to the specified account in the username field. If you don't want a user to have admin permissions, log in to the VM and use built-in tools (such as `net user` and `Local Users and Groups`) to manage user privileges.
- You can only have one version of the extension applied to a VM. To run a second action, update the existing extension with a new configuration.
- When updating a user, VMAccess modifies the Remote Desktop settings to allow login.
- Not supported on Domain Controllers

Extension schema

The VMAccess Extension configuration includes settings for username, passwords, and resetting the administrator password. You can store this information in configuration files, specify it in PowerShell, or include it in an Azure Resource Manager (ARM) template. The following JSON schema contains all the properties available to use in public and protected settings.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "<name>",
  "apiVersion": "2023-09-01",
  "location": "<location>",
  "dependsOn": [
          "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
  ],
  "properties": {
    "publisher": "Microsoft.Compute",
    "type": "VMAccessAgent",
```

```
    "typeHandlerVersion": "2.4",
    "autoUpgradeMinorVersion": true,

  -ProtectedSettingString $PrivateConf `
  -SettingString $settings
```

Set-AzVMExtension - Reset RDP Configuration

Set-AzVMExtension

PowerShell

```
Set-AzVMExtension `
  -ResourceGroupName "myRG" `
  -VMName "myVM" `
  -Location "myLocation" `
  -Name "VMAccessAgent" `
  -Publisher "Microsoft.Compute" `
  -ExtensionType "VMAccessAgent" `
  -TypeHandlerVersion "2.0" `
  -SettingString '{}' `
  -ForceRerun $true
```

CLI

Azure CLI - Reset Password

az vm extension set

```
az vm extension set --name VMAccessAgent --publisher Microsoft.Compute --version 2.0
--vm-name "myVM" --resource-group "myRG" --settings '{"username":"myuser"}' --
protected-settings '{"password":"myPassWord"}'
```

Azure CLI - Reset RDP Configuration

```
az vm extension set --name VMAccessAgent --publisher Microsoft.Compute --version 2.0
--vm-name "myVM" --resource-group "myRG" --settings '{}'
```

Virtual machine scale sets

PowerShell

PowerShell

```
$resourceGroupName = "<resource-group>"
$vmssName = "<vmss-name>"

$settings = @{"UserName"= "myuser"}
$protectedSettings = @{"Password"= "myPassWord"}

$vmss = Get-AzVmss `
    -ResourceGroupName $resourceGroupName `
    -VMScaleSetName $vmssName

Add-AzVmssExtension -VirtualMachineScaleSet $vmss `
    -Name "VMAccessAgent" `
    -Publisher "Microsoft.Compute" `
    -Type "VMAccessAgent" `
    -TypeHandlerVersion "2.0" `
    -AutoUpgradeMinorVersion $true `
    -ProtectedSetting $protectedSettings
    -Setting $settings

Update-AzVmss `
    -ResourceGroupName $resourceGroupName `
    -Name $vmssName `
    -VirtualMachineScaleSet $vmss
```

CLI

```
az vmss extension set --vmss-name my-vmss --name VMAccessAgent --resource-group my-group --version 2.0 --publisher Microsoft.Compute --settings '{"username":"myuser"}' --protected-settings '{"password":"myPassWord"}'
```

Troubleshoot and support

The VMAccess extension logs exist locally on the VM and are particularly useful for troubleshooting.

Expand table

Location	Description
`C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.VMAccessAgent\`	Contains logs from the Windows Agent that show when an update to the extension occurred. Verify these

Location	Description
	logs to ensure the extension ran successfully.
`C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.VMAccessAgent\<version>\`	The VMAccess Extension produces detailed logs in this directory. It includes `CommandExecution.log`, which records each command executed along with its result, and `extension.log`, which contains individual execution logs.
`C:\WindowsAzure\Logs\WaAppAgent\`	Contains configuration details and binary logs related to the VMAccess extension.

You can also retrieve the execution state of the VMAccess Extension by running the following command:

PowerShell

```
Get-AzVMExtension -ResourceGroupName "RG Name" -VMName "VM Name" -Name "Extension Name"
```

Error messages

Expand table

Error	Description
"internalErrorCode": "CannotModifyExtensionsWhenVMNotRunning", "code": "OperationNotAllowed","message": "Cannot modify extensions in the VM when the VM is not running."	The error indicates that the operation to modify extensions in the VM is not allowed because the VM is not running. Ensure that the VM is in a running state before attempting to modify extensions.
Error message: 'VMAccess Extension does not support Domain Controller.'	The error indicates that the VM extension 'enablevmAccess' failed because it does not support Domain Controller. Ensure that the VM is not configured as a Domain Controller when using this extension. For more information, see Reset Remote Desktop Services or its administrator password in a Windows VM.
VM 'vmname' has not reported status for VM agent or extensions. Verify that the OS is up and healthy, the VM	See Troubleshoot Azure Windows VM Agent issues.

Error	Description
has a running VM agent, and that it can establish outbound connections to Azure storage.	
Error message: 'Cannot update Remote Desktop Connection settings for Administrator account. The password does not meet the password policy requirements. Check the minimum password length, password complexity, and password history requirements.	The error indicates that the VM extension 'enablevmAccess' failed to update Remote Desktop Connection settings for the Administrator account due to a password policy violation. Ensure that the password meets Windows password policy requirements, including minimum length, complexity, and history.
The Admin User Account password cannot be null or empty if provided the username.	The error indicates that the VM extension 'enablevmAccess' failed because the Admin User Account password was not provided. Ensure that a non-null and non-empty password is specified for the Admin User Account to resolve this issue.
Provisioning of VM extension enablevmaccess has timed out. Extension provisioning has taken too long to complete. The extension did not report a message.	The error message indicates that the provisioning of the VM extension 'enablevmaccess' has timed out due to taking too long to complete. Additionally, the extension did not provide any status message during the process. To resolve this issue, consider checking the VM's performance and network conditions, and retry the provisioning operation. For more information, see Troubleshooting Azure Windows VM extension failures.
Error message: 'Cannot update Remote Desktop Connection settings for Administrator account. Error: User account username already exists but cannot be updated because it is not in the Administrators group.	The error indicates that the VM extension 'enablevmAccess' failed because the user account 'username' already exists but is not in the Administrators group. Ensure that the user account is added to the Administrators group to resolve this issue.
"internalErrorCode": "MultipleExtensionsPerHandlerNotAllowed", "code": "BadRequest","message": "Multiple VMExtensions per handler not supported for OS type 'Windows'. VMExtension 'enablevmaccess' with handler 'Microsoft.Compute.VMAccessAgent' already added or specified in input."	The error message indicates that multiple VM extensions per handler are not supported for the OS type 'Windows'. The 'enablevmaccess' extension with the handler 'Microsoft.Compute.VMAccessAgent' has already been added or specified in the input. To resolve this issue, ensure that only one extension per handler is configured for the VM. Manually remove extension and retry operation `Remove-AzVMExtension -ResourceGroupName`

Error	Description
	`"ResourceGroup11" -Name "ExtensionName" -VMName "VirtualMachineName"`

For more help, you can contact the Azure experts at Azure Community Support. Alternatively, you can file an Azure support incident. Go to Azure support and select **Get support**. For more information about Azure Support, read the Azure support plans FAQ.

Chef VM Extension for Linux and Windows

Chef Software provides a DevOps automation platform for Linux and Windows that enables the management of both physical and virtual server configurations. The Chef VM Extension is an extension that enables Chef on virtual machines.

> ⓘ Note
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

Operating system

The Chef VM Extension is supported on all the Extension Supported OS's in Azure.

Internet connectivity

The Chef VM Extension requires that the target virtual machine is connected to the internet in order to retrieve the Chef Client payload from the content delivery network (CDN).

Extension schema

The following JSON shows the schema for the Chef VM Extension. The extension requires at a minimum the Chef Server URL, the Validation Client Name and the Validation Key for the Chef Server; these values can be found in the `knife.rb` file in the starter-kit.zip that is downloaded when you install Chef Automate or a standalone Chef Server. Because the validation key should be treated as sensitive data, it should be configured under the **protectedSettings** element, meaning that it will only be decrypted on the target virtual machine.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "[concat(variables('vmName'),'/', parameters('chef_vm_extension_type'))]",
  "apiVersion": "2017-12-01",
  "location": "[parameters('location')]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Chef.Bootstrap.WindowsAzure",
```

```
    "type": "[parameters('chef_vm_extension_type')]",
    "typeHandlerVersion": "1210.13",
    "settings": {
      "bootstrap_options": {
        "chef_server_url": "[parameters('chef_server_url')]",
        "validation_client_name": "[parameters('chef_validation_client_name')]"
      },
      "runlist": "[parameters('chef_runlist')]"
    },
    "protectedSettings": {
      "validation_key": "[parameters('chef_validation_key')]"
    }
  }
}
```

Core property values

Expand table

Name	Value / Example	Data Type
apiVersion	`2017-12-01`	string (date)
publisher	`Chef.Bootstrap.WindowsAzure`	string
type	`LinuxChefClient` (Linux), `ChefClient` (Windows)	string
typeHandlerVersion	`1210.13`	string (double)

Settings

Expand table

Name	Value / Example	Data Type	Required?
settings/bootstrap_options/chef_server_url	`https://api.chef.io/organizations/myorg`	string (url)	Y
settings/bootstrap_options/validation_client_name	`myorg-validator`	string	Y
settings/runlist	`recipe[mycookbook::default]`	string	Y

Protected settings

Expand table

Name	Example	Data Type	Required?
protectedSettings/validation_key	`-----BEGIN RSA PRIVATE KEY-----\nKEYDATA\n----- END RSA PRIVATE KEY-----`	string	Y

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates can be used to deploy one or more virtual machines, install the Chef Client, connect to the Chef Server and perform the initial configuration on the server as defined by the Run-list

A sample Resource Manager template that includes the Chef VM Extension can be found in the Azure quickstart gallery .

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see Set name and type for child resources.

Azure CLI deployment

The Azure CLI can be used to deploy the Chef VM Extension to an existing VM. Replace the **validation_key** with the contents of your validation key (this file as a `.pem` extension). Replace **validation_client_name**, **chef_server_url** and **run_list** with those values from the `knife.rb` file in your Starter Kit.

Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myExistingVM \
  --name LinuxChefClient \
  --publisher Chef.Bootstrap.WindowsAzure \
  --version 1210.13 --protected-settings '{"validation_key": "<validation_key>"}' \
  --settings '{ "bootstrap_options": { "chef_server_url": "<chef_server_url>",
"validation_client_name": "<validation_client_name>" }, "runlist": "<run_list>" }'
```

Troubleshooting and support

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

Azure CLI

```
az vm extension list --resource-group myResourceGroup --vm-name myExistingVM -o table
```

Extension execution output is logged to the following file:

Linux

Bash

```
/var/lib/waagent/Chef.Bootstrap.WindowsAzure.LinuxChefClient
```

Windows

PowerShell

```
C:\Packages\Plugins\Chef.Bootstrap.WindowsAzure.ChefClient\
```

Error codes and their meanings

Expand table

Error Code	Meaning	Possible Action
51	This extension is not supported on the VM's operating system	

Additional troubleshooting information can be found in the Chef VM Extension readme.

> **Note**
>
> For anything else directly related to Chef, contact Chef Support.

Next steps

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to the Azure support site and select Get support. For information about using Azure Support, read the Microsoft Azure support FAQ.

Qualys Agent on Linux or Windows VM

> **Important**
>
> Qualys has removed support for the Windows Cloud Agent extension version 3.1.3.34. This version will become inoperable starting January 31, 2026. We recommend that you uninstall it and install the latest Windows Cloud Agent extension version (1.6.x.x) on your Azure portal. To learn more about the uninstallation steps, refer to Uninstalling and Reinstalling Qualys Extension on Azure VMs.

The Qualys Cloud Agent is a lightweight, cloud-based security and monitoring tool installed on servers, virtual machines (VMs), and workstations. It continuously collects system data and sends it to Qualys Enterprise TruRisk Platform (ETP) for analysis and reporting.

Qualys supports Cloud Agent deployment on Windows and Linux Azure VMs via Microsoft's Azure portal. The Cloud Agent Platform Availability Matrix provides more information about the supported platforms.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Installation Methods

The following are the different deployment methods to deploy Cloud Agent extensions on Azure VMs.

Deploying Qualys Cloud Agent for Single Azure VM

The Microsoft Azure platform has the option to deploy a Cloud Agent extension for a single Azure VM. To learn more about the deployment steps, refer to Deploy Cloud Agent for Single Azure VM.

Embedding Qualys Cloud Agent via Golden Machine Image

The Qualys Cloud Agent supports configuration and deployment into cloned images in cloud environments like Microsoft Azure.

To learn more about embedding Qualys Cloud Agent as a part of Golden Machine Image, refer to the following links:

- **For Windows VMs:** Steps to Install Qualys Cloud Agent for Windows in Gold Image
- **For Linux VMs:** Steps to Install Qualys Cloud Agent for Linux in Gold Image

Deploy Qualys Cloud Agent via Azure Resource Manager Template

Qualys supports the Azure Resource Manager (ARM) templates to deploy and install Qualys Cloud Agent as a virtual machine extension on a list of Azure Windows and Linux VMs. VM extensions can be used whenever a virtual machine requires software installation, anti-virus protection, or running a script inside of it.

To learn more about deployment steps, refer to Cloud Agent Deployment via ARM Template.

Deploy Qualys Cloud Agent via Azure Deployment Policy

Qualys supports the Azure Deployment Policy to schedule auto-deployment of Cloud Agent Extensions on Windows and Linux VMs.

To learn more about deployment steps, refer to:

- **For Windows VM:** Deploy Cloud Agent for Windows VMs via Azure Deployment Policy
- **For Linux VM:** Deploy Cloud Agent for Linux VMs via Azure Deployment Policy

Deploy Cloud Agent via PowerShell

Qualys supports the PowerShell command-line tool to deploy Cloud Agent Extensions on Windows and Linux VMs. To learn more about deployment steps, refer to:

- **For Windows VM:** Deploy Cloud Agent For Windows via PowerShell
- **For Linux VM:** Deploy Cloud Agent For Linux via PowerShell

Deploy Qualys Cloud Agent via Other Tool Sets

Qualys Cloud Agent can be deployed via automation, orchestration, or configuration management tools in your environment, such as Ansible, Chef, and Puppet. Qualys provides a template for deploying Qualys Cloud Agent via Ansible. You can use this to deploy and configure Qualys Cloud Agent in their Azure environment.

To learn more, refer to Cloud Agent Deployment via Other Tool Sets.

Support

Contact Qualys Support if you encounter an issue when deploying Cloud Agent on Azure VMs.

Install Salt Minion on Linux or Windows VMs using the VM Extension

Prerequisites

- A Microsoft Azure account with one (or more) Windows or Linux VMs
- A Salt Master (either on-premises or in a cloud) that can accept connections from Salt minions hosted on Azure
- The Salt Minion VM Extension requires that the target VM is connected to the internet in order to fetch Salt packages

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Supported platforms

Azure VM running any of the following supported OS:

- Ubuntu 20.04, 22.04 (x86_64)
- Debian 10, 11 (x86_64)
- Oracle Linux 7, 8, 9 (x86_64)
- RHEL 7, 8, 9 (x86_64)
- Microsoft Windows 10, 11 Pro (x86_64)
- Microsoft Windows Server 2012 R2, 2016, 2019, 2022 Datacenter (x86_64)

If you want another distro to be supported (assuming Salt supports it), an issue can be filed on GitLab.

Supported Salt Minion versions

- 3006 and up (onedir)

Extension details

- Publisher name: `turtletraction.oss`

- Linux extension name: `salt-minion.linux`
- Windows extension name: `salt-minion.windows`

Salt Minion settings

- `master_address` - Salt Master address to connect to (`localhost` by default)
- `minion_id` - Minion ID (hostname by default)
- `salt_version` - Salt Minion version to install, for example `3006.1` (`latest` by default)

Install Salt Minion using the Azure portal

1. Select one of your VMs.
2. In the left menu click **Extensions + applications**.
3. Click **+ Add**.
4. In the gallery, type **Salt Minion** in the search bar.
5. Select the **Salt Minion** tile and click **Next**.
6. Enter configuration parameters in the provided form (see Salt Minion settings).
7. Click **Review + create**.

Install Salt Minion using the Azure CLI

shell

```
az vm extension set --resource-group my-group --vm-name vm-ubuntu22 --name salt-minion.linux --publisher turtletraction.oss --settings '{"master_address": "10.x.x.x"}'
az vm extension set --resource-group my-group --vm-name vm-windows11 --name salt-minion.windows --publisher turtletraction.oss --settings '{"master_address": "10.x.x.x"}'
```

To uninstall it:

shell

```
az vm extension delete --resource-group my-group --vm-name vm-ubuntu22 --name salt-minion.linux
az vm extension delete --resource-group my-group --vm-name vm-windows11 --name salt-minion.windows
```

Install Salt Minion using the Azure ARM template

JSON

```
{
    "$schema": "http://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {
        "vmName": {
            "type": "string"
        },
        "master_address": {
            "type": "string"
        },
        "salt_version": {
            "type": "string"
        },
        "minion_id": {
            "type": "string"
        }
    },
    "resources": [
        {
            "name": "[concat(parameters('vmName'),'/salt-minion.linux')]",
            "type": "Microsoft.Compute/virtualMachines/extensions",
            "location": "[resourceGroup().location]",
            "apiVersion": "2015-06-15",
            "properties": {
                "publisher": "turtletraction.oss",
                "type": "salt-minion.linux",
                "typeHandlerVersion": "1.0",
                "autoUpgradeMinorVersion": true,
                "settings": {
                    "master_address": "[parameters('master_address')]",
                    "salt_version": "[parameters('salt_version')]",
                    "minion_id": "[parameters('minion_id')]"
                }
            }
        }
    ]
}
```

Install Salt Minion using Terraform

Assuming that you have defined a VM resource in TerraForm named `vm_ubuntu`, then use something like this to install the extension on it:

HashiCorp Configuration Language

```
resource "azurerm_virtual_machine_extension" "vmext_ubuntu" {
  name                 = "vmext_ubuntu"
  virtual_machine_id   = azurerm_linux_virtual_machine.vm_ubuntu.id
  publisher            = "turtletraction.oss"
```

```
  type                 = "salt-minion.linux"
  type_handler_version = "1.0"

  settings = <<SETTINGS
{
  "salt_version": "3006.1",
  "master_address": "x.x.x.x",
  "minion_id": "ubuntu22"
}
SETTINGS
}
```

Support

- For commercial support or assistance with Salt, you can visit the extension creator, TurtleTraction
- The source code of this extension is available on GitLab
- For Azure related issues, you can file an Azure support incident. Go to the Azure support site and select Get support

---

Stackify Retrace Linux Agent Extension

> ⊗ **Caution**
>
> This article references CentOS, a Linux distribution that is end of support status. Please consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Overview

Stackify provides products that track details about your application to help find and fix problems quickly. For developer teams, Retrace is a fully integrated, multi-environment, app performance super-power. It combines several tools every development team needs.

Retrace is the ONLY tool that delivers all of the following capabilities across all environments in a single platform.

- Application performance management (APM)
- Application and server logging
- Error tracking and monitoring
- Server, application, and custom metrics

> ⓘ **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

About Stackify Linux Agent Extension

This extension provides an install path for the Linux Agent for Retrace.

Prerequisites

Operating system

The Retrace agent can be run against these Linux distributions

Expand table

Distribution	Version
Ubuntu	16.04 LTS
Debian	9
Red Hat	6.10, 7.1+
CentOS	6.10, 7.0+

ⓘ Important

> Keep in consideration Red Hat Enterprise Linux 6.X is already deprecated. RHEL 6.10 has available ELS support, which will end on 06/2024.

Internet connectivity

The Stackify Agent extension for Linux requires that the target virtual machine is connected to the internet.

You may need to adjust your network configuration to allow connections to Stackify, see https://support.stackify.com/hc/en-us/articles/207891903-Adding-Exceptions-to-a-Firewall.

Extension schema

The following JSON shows the schema for the Stackify Retrace Agent extension. The extension requires the `environment` and `activationKey`.

JSON

```
{
  "type": "extensions",
  "name": "StackifyExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[resourceId('Microsoft.Compute/virtualMachines',variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Stackify.LinuxAgent.Extension",
    "type": "StackifyLinuxAgentExtension",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
```

```
        "environment": "myEnvironment"
      },
      "protectedSettings": {
        "activationKey": "myActivationKey"
      }
    }
  }
```

Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Stackify Retrace Linux Agent extension during an Azure Resource Manager template deployment.

The JSON for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON affects the value of the resource name and type. For more information, see Set name and type for child resources.

The following example assumes the Stackify Retrace Linux extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the "resources": [] object of the virtual machine.

The extension requires the `environment` and `activationKey`.

JSON

```
  {
    "type": "extensions",
    "name": "StackifyExtension",
    "apiVersion": "[variables('apiVersion')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
      "[resourceId('Microsoft.Compute/virtualMachines',variables('vmName'))]"
    ],
    "properties": {
      "publisher": "Stackify.LinuxAgent.Extension",
      "type": "StackifyLinuxAgentExtension",
      "typeHandlerVersion": "1.0",
      "autoUpgradeMinorVersion": true,
      "settings": {
        "environment": "myEnvironment"
      },
      "protectedSettings": {
        "activationKey": "myActivationKey"
      }
```

```
    }
}
```

When placing the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine, and the type reflects the nested configuration.

JSON

```
{
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "name": "<parentVmResource>/StackifyExtension",
    "apiVersion": "[variables('apiVersion')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
    ],
    "properties": {
        "publisher": "Stackify.LinuxAgent.Extension",
        "type": "StackifyLinuxAgentExtension",
        "typeHandlerVersion": "1.0",
        "autoUpgradeMinorVersion": true,
        "settings": {
          "environment": "myEnvironment"
        },
        "protectedSettings": {
          "activationKey": "myActivationKey"
        }
    }
}
```

PowerShell deployment

The `Set-AzVMExtension` command can be used to deploy the Stackify Retrace Linux Agent virtual machine extension to an existing virtual machine. Before running the command, the public and private configurations need to be stored in a PowerShell hash table.

The extension requires the `environment` and `activationKey`.

PowerShell

```
$PublicSettings = @{"environment" = "myEnvironment"}
$ProtectedSettings = @{"activationKey" = "myActivationKey"}

Set-AzVMExtension -ExtensionName "Stackify.LinuxAgent.Extension" `
    -ResourceGroupName "myResourceGroup" `
    -VMName "myVM" `
    -Publisher "Stackify.LinuxAgent.Extension" `
    -ExtensionType "StackifyLinuxAgentExtension" `
    -TypeHandlerVersion 1.0 `
```

```
    -Settings $PublicSettings `
    -ProtectedSettings $ProtectedSettings `
    -Location WestUS `
```

Azure CLI deployment

The Azure CLI tool can be used to deploy the Stackify Retrace Linux Agent virtual machine extension to an existing virtual machine.

The extension requires the `environment` and `activationKey`.

Azure CLI

```
az vm extension set --publisher 'Stackify.LinuxAgent.Extension' --version 1.0 --name 'StackifyLinuxAgentExtension' --protected-settings '{"activationKey":"myActivationKey"}' --settings '{"environment":"myEnvironment"}' --resource-group 'myResourceGroup' --vm-name 'myVmName'
```

Tenable One-Click Nessus Agent

Tenable now supports a One-Click deployment of Nessus Agents via Microsoft's Azure portal. This solution provides an easy way to install the latest version of Nessus Agent on Azure virtual machines (VM) (whether Linux or Windows) by either clicking on an icon within the Azure portal or by writing a few lines of PowerShell script.

> ⓘ **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Prerequisites

- A Tenable Vulnerability Management (Tenable.io), or Nessus Manager, account.
- A Microsoft Azure account with one (or more) Windows or Linux VMs.

Supported Platforms

Azure VM running any of the following:

- Debian 11 (x86_64)
- Oracle Linux 7 and 8 (x86_64)
- Red Hat ES 7, 8 and 9 (x86_64)
- Rocky Linux 9 (x86_64)
- Ubuntu 18.04, 20.04 and 22.04 (x86_64)
- Red Hat ES 8 and 9 (ARM64)
- Windows 10 and 11 (x86_64)
- Windows Server 2012 and 2012 R2 (x86_64)
- Windows Server 2016, 2019 and 2022 (x86_64)

Deploy with the Tenable User Interface (UI)

1. Select one of your VMs.
2. In the left column click **Extensions + applications**.
3. Click **+ Add**.
4. In the gallery, scroll down to **N** (for Nessus Agent) or type **nessus** in the search bar.
5. Select the **Nessus Agent** tile and click **Next**.
6. Enter configuration parameters in the Tenable user interface.
7. Click **Review + create**.

Deploy From Command-line

There is also a command-line interface available through PowerShell.

For example, you can type:

```
PS>
```

```
PS> $typeName="Linux" (or $typeName="Windows")
PS> $name = $publisherName + "." + $typeName
PS> $version="1.0"
PS> $Settings = @{"nessusManagerApp" = "IO"; "nessusAgentName" = "NA_name1";
"nessusAgentGroup" = "GROUP1"}
PS> $ProtectedSettings = @{"nessusLinkingKey" =
"abcd1234vxyz5678abcd1234vxyz5678abcd1234vxyz5678abcd1234vxyz5678"}
PS> Set-AzVMExtension -ResourceGroupName "EXAMPLE-resource-group" -Location "East US
2" -VMName "canary-example" -Name $name -Publisher $publisherName -ExtensionType
$typeName -TypeHandlerVersion $version -Settings $Settings -ProtectedSettings
$ProtectedSettings
```

Lines 1-4 identify the One-Click agent extension.

Lines 5-6 in the PowerShell example are equivalent to Step 6 in the UI procedure. This is where the user enters their configuration parameters for their Nessus Agent install.

Nessus Linking Key

The most important field is the Nessus Linking Key (**nessusLinkingKey**, required). It is always required. This document explains where to find it: Retrieve the Tenable Nessus Agent Linking Key (Tenable Nessus Agent 10.4). In the PowerShell interface, specify nessusLinkingKey under `-ProtectedSettings` so that it will be encrypted by Azure. All other fields are passed unencrypted through -Settings.

You can choose whether to link with Nessus Manager or Tenable.io. In the command-line interface, this is done by setting `nessusManagerApp` (**nessusManagerApp**, required) to `cloud`, or to `local`. Those are the only two choices.

If you choose Nessus Manager, you must provide the Nessus Manager host (**nessusManagerHost**) and port number (**nessusManagerPort**). The extension accepts an IP address or fully qualified domain name.

If you choose Tenable.io, then there is an optional field called **tenableIoNetwork**.

The Agent Name (**nessusAgentName**, optional) and Agent Group (**nessusAgentGroup**, optional) (actually "groups", a comma-delimited list of group names) are always optional.

Parameter names:

"nessusLinkingKey"

```
"nessusManagerApp"
"nessusManagerHost"
"nessusManagerPort"
"tenableIoNetwork"
"nessusAgentName"
"nessusAgentGroup"
```

Parameter descriptions:

"nessusLinkingKey" is called "--key" in this doc

"nessusManagerApp" is unique to our VM extension

"nessusManagerHost" equals "--host"

"nessusManagerPort" equals "--port"

"tenableIoNetwork" is "--network"

"nessusAgentName" is "--name"

"nessusAgentGroup" is "--groups"

For more definitions of these parameters, see Nessuscli Agent.

Support

If you need more help at any point in this article, you can contact the Azure experts on the MSDN Azure and Stack Overflow forums. Alternatively, you can file an Azure support incident. Go to the Azure support site and select Get support. For information about using Azure

Support, read the Microsoft Azure support FAQ. If you experience issues with the extension, contact Tenable support.

Use Azure Policy to restrict extensions installation on Linux VMs

If you want to prevent the installation of certain extensions on your Linux VMs, you can create an Azure Policy definition using the Azure CLI to restrict extensions for VMs within a resource group. To learn the basics of Azure VM extensions for Linux, see Virtual machine extensions and features for Linux.

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. If you want to run the Azure CLI locally, you need to install version 2.0.26 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Create a rules file

In order to restrict what extensions are available, you need to create a rule to identify the extension.

This example demonstrates how to deny the installation of disallowed VM extensions by defining a rules file in Azure Cloud Shell. However, if you're working in Azure CLI locally, you can create a local file and replace the path (~/clouddrive) with the path to the file on your local file system.

1. In a bash Cloud Shell create the file `~/clouddrive/azurepolicy.rules.json` using any text editor.
2. Copy and paste the following `.json` contents into the new file and save it.

JSON

```
{
    "if": {
        "allOf": [
            {
                "field": "type",
                "equals": "Microsoft.Compute/virtualMachines/extensions"
            },
            {
```

```
                "field": "Microsoft.Compute/virtualMachines/extensions/publisher",
                "equals": "Microsoft.OSTCExtensions"
            },
            {
                "field": "Microsoft.Compute/virtualMachines/extensions/type",
                "in": "[parameters('notAllowedExtensions')]"
            }
        ]
    },
    "then": {
        "effect": "deny"
    }
}
```

Create a parameters file

You also need a parameters file that creates a structure for you to use for passing in a list of the unauthorized extensions.

This example shows you how to create a parameter file for Linux VMs in Cloud Shell.

1. In the bash Cloud Shell opened before, create the file ~/clouddrive/azurepolicy.parameters.json using any text editor.

2. Copy and paste the following `.json` contents into the new file and save it.

JSON

```
{
    "notAllowedExtensions": {
        "type": "Array",
        "metadata": {
            "description": "The list of extensions that will be denied. Example: CustomScriptForLinux, VMAccessForLinux etc.",
            "displayName": "Denied extension"
        }
    }
}
```

Create the policy

A *policy definition* is an object used to store the configuration that you would like to use. The policy definition uses the rules and parameters files to define the policy. Create the policy definition using az policy definition create.

In this example, the rules and parameters are the files you created and stored as .json files in Cloud Shell or in your local file system.

Azure CLI

```
az policy definition create \
   --name 'not-allowed-vmextension-linux' \
   --display-name 'Block VM Extensions' \
   --description 'This policy governs which VM extensions that are blocked.' \
   --rules '~/clouddrive/azurepolicy.rules.json' \
   --params '~/clouddrive/azurepolicy.parameters.json' \
   --mode All
```

Assign the policy

This example assigns the policy to a resource group using az policy assignment create. Any VM created in the **myResourceGroup** resource group will be unable to install the Linux VM Access or the Custom Script Extensions for Linux.

> **Note**
>
> The resource group must exist before you can assign the policy.

Use az account list to find your subscription ID and replace the placeholder in the following example:

Azure CLI

```
az policy assignment create \
   --name 'not-allowed-vmextension-linux' \
   --scope /subscriptions/<subscription Id>/resourceGroups/myResourceGroup \
   --policy "not-allowed-vmextension-linux" \
   --params '{
        "notAllowedExtensions": {
            "value": [
                "VMAccessForLinux",
                "CustomScriptForLinux"
            ]
        }
    }'
```

Test the policy

Test the policy by creating a new VM and adding a new user.

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image myImage \
    --generate-ssh-keys
```

> **Note**
>
> Replace `myResourceGroup`, `myVM` and `myImage` values accordingly.

Try to create a new user named **myNewUser** using the VM Access extension.

Azure CLI

```
az vm user update \
  --resource-group myResourceGroup \
  --name myVM \
  --username myNewUser \
  --password 'mynewuserpwd123!'
```

Remove the assignment

Azure CLI

```
az policy assignment delete --name 'not-allowed-vmextension-linux' --resource-group
myResourceGroup
```

Remove the policy

Azure CLI

```
az policy definition delete --name 'not-allowed-vmextension-linux'
```

Next steps

For more information, see Azure Policy.

Last updated on 11/10/2025

Use Azure Policy to restrict extensions installation on Windows VMs

If you want to prevent the use or installation of certain extensions on your Windows VMs, you can create an Azure Policy definition using PowerShell to restrict extensions for VMs within a resource group.

This tutorial uses Azure PowerShell within the Cloud Shell, which is constantly updated to the latest version.

> **Note**
>
> **New! Try VM assist for Faster Diagnostics`** We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Create a rules file

In order to restrict what extensions can be installed, you need to have a rule to provide the logic to identify the extension.

This example shows you how to deny extensions published by 'Microsoft. Compute' by creating a rules file in Azure Cloud Shell, but if you're working in PowerShell locally, you can also create a local file and replace the path ($home/clouddrive) with the path to the local file on your machine.

1. In a Cloud Shell, create the file `$home/clouddrive/rules.json` using any text editor.

2. Copy and paste the following .json contents into the file and save it:

JSON

```
{
    "if": {
        "allOf": [
            {
                "field": "type",
                "equals": "Microsoft.Compute/virtualMachines/extensions"
            },
            {
                "field": "Microsoft.Compute/virtualMachines/extensions/publisher",
                "equals": "Microsoft.Compute"
            },
            {
```

```
                "field": "Microsoft.Compute/virtualMachines/extensions/type",
                "in": "[parameters('notAllowedExtensions')]"
            }
        ]
    },
    "then": {
        "effect": "deny"
    }
}
```

Create a parameters file

You also need a parameters file that creates a structure for you to use for passing in a list of the extensions to block.

This example shows you how to create a parameters file for VMs in Cloud Shell, but if you're working in PowerShell locally, you can also create a local file and replace the path ($home/clouddrive) with the path to the local file on your machine.

1. In Cloud Shell, create the file `$home/clouddrive/parameters.json` using any text editor.

2. Copy and paste the following .json contents into the file and save it:

JSON

```
{
    "notAllowedExtensions": {
        "type": "Array",
        "metadata": {
            "description": "The list of extensions that will be denied.",
            "displayName": "Denied extension"
        }
    }
}
```

Create the policy

A policy definition is an object used to store the configuration that you would like to use. The policy definition uses the rules and parameters files to define the policy. Create a policy definition using the New-AzPolicyDefinition cmdlet.

The policy rules and parameters are the files you created and stored as .json files in your cloud shell. Replace the example `-Policy` and `-Parameter` file paths as needed.

Azure PowerShell

```
$definition = New-AzPolicyDefinition `
   -Name "not-allowed-vmextension-windows" `
   -DisplayName "Not allowed VM Extensions" `
   -description "This policy governs which VM extensions that are explicitly
denied."   `
   -Policy 'C:\Users\ContainerAdministrator\clouddrive\rules.json' `
   -Parameter 'C:\Users\ContainerAdministrator\clouddrive\parameters.json'
```

Assign the policy

This example assigns the policy to a resource group using New-AzPolicyAssignment. Any VM created in the **myResourceGroup** resource group won't be able to install the VM Access Agent or Custom Script extensions.

Use the Get-AzSubscription | Format-Table cmdlet to get your subscription ID to use in place of the one in the example.

Azure PowerShell

```
$scope = "/subscriptions/<subscription id>/resourceGroups/myResourceGroup"
$assignment = New-AzPolicyAssignment `
   -Name "not-allowed-vmextension-windows" `
   -Scope $scope `
   -PolicyDefinition $definition `
   -PolicyParameter '{
    "notAllowedExtensions": {
        "value": [
            "VMAccessAgent",
            "CustomScriptExtension"
        ]
    }
}'
$assignment
```

Test the policy

To test the policy, try to use the VM Access extension. The following should fail with the message "Set-AzVMAccessExtension: Resource 'myVMAccess' was disallowed by policy."

Azure PowerShell

```
Set-AzVMAccessExtension `
   -ResourceGroupName "myResourceGroup" `
   -VMName "myVM" `
   -Name "myVMAccess" `
   -Location EastUS
```

In the portal, the password change should fail with the "The template deployment failed because of policy violation." message.

Remove the assignment

Azure PowerShell

```
Remove-AzPolicyAssignment -Name not-allowed-vmextension-windows -Scope $scope
```

Remove the policy

Azure PowerShell

```
Remove-AzPolicyDefinition -Name not-allowed-vmextension-windows
```

Next steps

For more information, see Azure Policy.

How to update the Azure Linux Agent on a VM

> **Caution**
>
> This article references CentOS, a Linux distribution that is end of support (EOS) status. Consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

To update your Azure Linux Agent on a Linux VM in Azure, you must already have:

- A running Linux VM in Azure.
- A connection to that Linux VM using SSH.

You should always check for a package in the Linux distro repository first. It's possible the package available might not be the latest version, however, enabling autoupdate ensures the Linux Agent always gets the latest update. Should you have issues installing from the package managers, you should seek support from the distro vendor.

> **Note**
>
> For more information, see Endorsed Linux distributions on Azure

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Verify the Minimum version support for virtual machine agents in Azure before proceeding.

Ubuntu

1. Check your current package version

```bash
sudo apt list --installed | grep walinuxagent
```

2. Update package cache

Bash

```
sudo apt-get -qq update
```

3. Install the latest package version

Bash

```
sudo apt-get install walinuxagent
```

4. Ensure auto update is enabled.

- First, check to see if auto update is enabled:

Bash

```
sudo cat /etc/waagent.conf | grep -i autoupdate
```

- Find 'AutoUpdate.Enabled" if you see this output when auto update is enabled:

config

```
AutoUpdate.Enabled=y
```

- To enable it, run:

Bash

```
sudo sed -i 's/# AutoUpdate.Enabled=y/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

5. Restart the waagent service

Bash

```
sudo systemctl restart walinuxagent
```

6. Validate waagent service is up and running

Bash

```
sudo systemctl status walinuxagent
```

Typically all you need, but if for some reason you need to install it from https://github.com directly, use the following steps.

Update the Linux Agent when no agent package exists for distribution

For more information regarding updating the Azure Linux Agent when no package exists, see Azure Linux Agent README.

Last updated on 11/10/2025

Export resource groups that contain VM extensions

08/18/2025

You can export Azure resource groups into a new Azure Resource Manager template that you can then redeploy. The export process interprets existing resources and creates a Resource Manager template that, when deployed, results in a similar resource group. When you're using the export option against a resource group that contains virtual machine (VM) extensions, you need to consider items such as extension compatibility and protected settings.

This article details how the resource group export process works for virtual machine extensions. It includes a list of supported extensions and details on how to handle secured data.

Supported VM extensions

Many VM extensions are available. You can't export all extensions into a Resource Manager template by using the automation script feature. If a virtual machine extension is not supported, you need to manually place it back into the exported template.

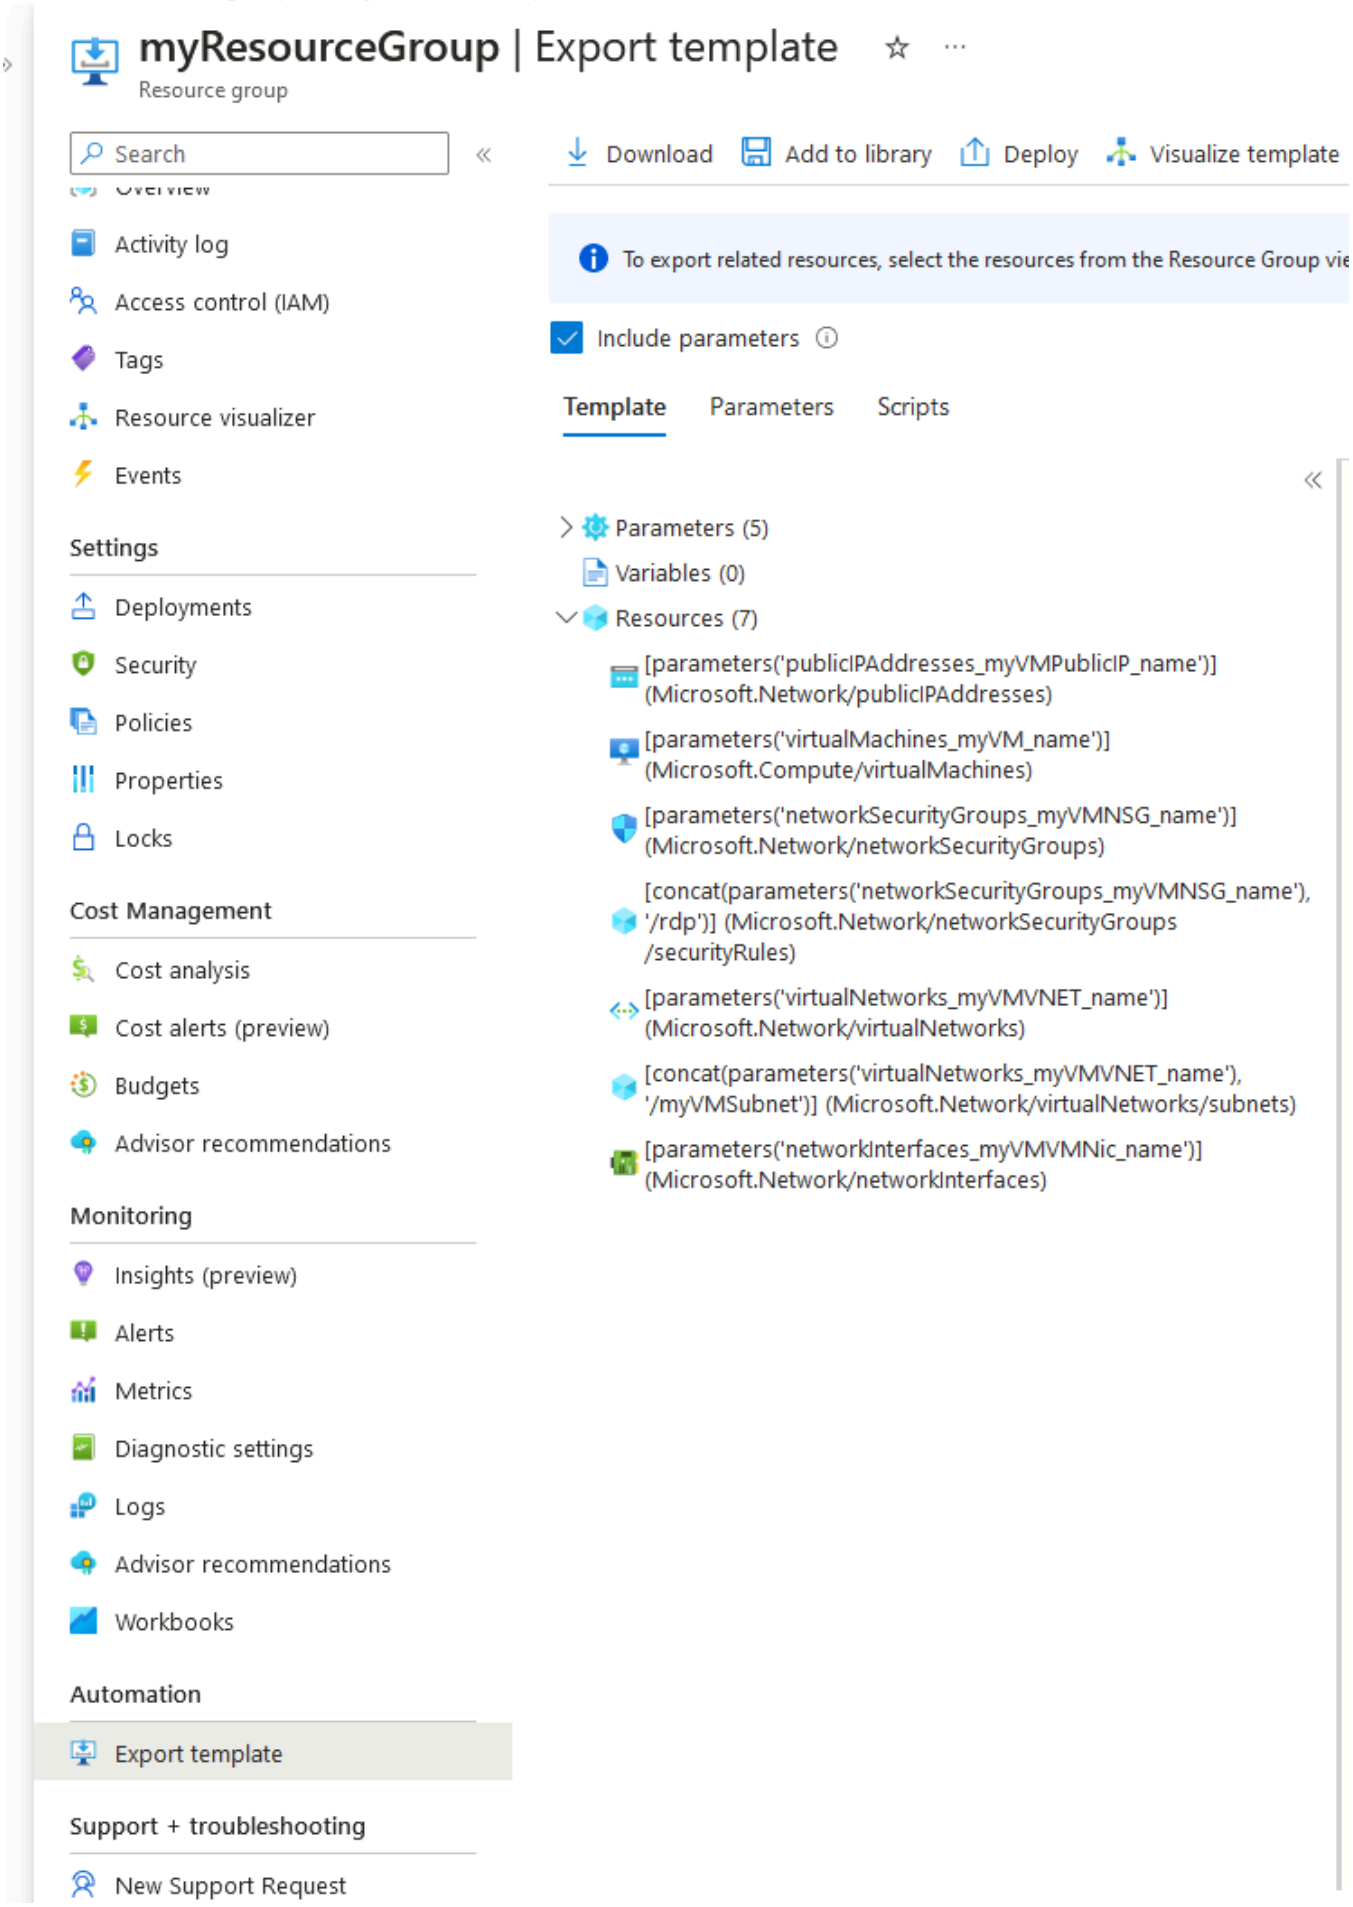
You can export the following extensions by using the automation script feature:

> Acronis Backup, Acronis Backup Linux, BGInfo, BMC Control-M Agent Linux, BMC Control-M Agent Windows, Chef Client, Custom Script, Custom Script Extension, Custom Script for Linux, Datadog Linux Agent, Datadog Windows Agent, Docker Extension, Dynatrace Linux, Dynatrace Windows, HPE Security Application Defender for Cloud, IaaS Antimalware, IaaS Diagnostics, Linux Chef Client, Linux Diagnostic, OS Patching for Linux, Puppet Agent, Site24x7 APM Insight, Site24x7 Linux Server, Site24x7 Windows Server, Trend Micro DSA, Trend Micro DSA Linux, VM Access For Linux, VM Access For Linux, VM Snapshot, VM Snapshot Linux

Export the resource group

To export a resource group into a reusable template, complete the following steps:

1. Sign in to the Azure portal.
2. On the **Hub** menu, select **Resource Groups**.
3. Select the target resource group from the list.
4. On the **Resource group** pane, select **Export template** under the **Automation** section.



The Azure Resource Manager automation script produces a Resource Manager template, a parameters file, and several sample deployment scripts, such as PowerShell and Azure CLI

scripts. At this point, you can download the exported template by using the download button, add the template to the template library, or redeploy the template by using the **Deploy** button.

Configure protected settings

Many Azure VM extensions include a protected settings configuration that encrypts sensitive data, such as credentials and configuration strings. Protected settings are not exported with the automation script. If necessary, reinsert protected settings into the exported template.

Step 1: Remove the template parameter

When you export a resource group, a single template parameter is created to provide a value to the exported protected settings. You can remove this parameter.

To remove the parameter, look through the list of parameters and delete the one that looks similar to this JSON example:

JSON

```
"extensions_extensionname_protectedSettings": {
    "defaultValue": null,
    "type": "SecureObject"
}
```

Step 2: Get properties for protected settings

Because each protected setting has a set of required properties, you need to gather a list of these properties. You can find each parameter of the protected settings configuration in the Azure Resource Manager schema on GitHub. This schema includes only the parameter sets for the extensions that are listed in the overview section of this article.

From within the schema repository, search for the desired extension. After you find the extension's `protectedSettings` object, take note of each parameter. In the following example of the `IaasDiagnostic` extension, the required parameters are `storageAccountName`, `storageAccountKey`, and `storageAccountEndPoint`:

JSON

```
"protectedSettings": {
    "type": "object",
    "properties": {
        "storageAccountName": {
            "type": "string"
```

```
        },
        "storageAccountKey": {
            "type": "string"
        },
        "storageAccountEndPoint": {
            "type": "string"
        }
    },
    "required": [
        "storageAccountName",
        "storageAccountKey",
        "storageAccountEndPoint"
    ]
}
```

Step 3: Re-create the protected configuration

On the exported template, search for `protectedSettings`. Replace the exported protected setting object with a new one that includes the required extension parameters and a value for each one.

In the example of the `IaasDiagnostic` extension, the new protected setting configuration would look like the following example:

JSON

```
"protectedSettings": {
    "storageAccountName": "[parameters('storageAccountName')]",
    "storageAccountKey": "[parameters('storageAccountKey')]",
    "storageAccountEndPoint": "https://core.windows.net"
}
```

The final extension resource looks similar to the following JSON example:

JSON

```
{
    "name": "Microsoft.Insights.VMDiagnosticsSettings",
    "type": "extensions",
    "location": "[resourceGroup().location]",
    "apiVersion": "[variables('apiVersion')]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
    ],
    "tags": {
        "displayName": "AzureDiagnostics"
    },
    "properties": {
        "publisher": "Microsoft.Azure.Diagnostics",
```

```
        "type": "IaaSDiagnostics",
        "typeHandlerVersion": "1.5",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "xmlCfg": "[base64(concat(variables('wadcfgxstart'),
variables('wadmetricsresourceid'), variables('vmName'),
variables('wadcfgxend')))]",
            "storageAccount": "
[parameters('existingdiagnosticsStorageAccountName')]"
        },
        "protectedSettings": {
            "storageAccountName": "[parameters('storageAccountName')]",
            "storageAccountKey": "[parameters('storageAccountKey')]",
            "storageAccountEndPoint": "https://core.windows.net"
        }
    }
}
```

If you're using template parameters to provide property values, you need to create them. When you're creating template parameters for protected setting values, use the `SecureString` parameter type to help secure sensitive values. For more information on using parameters, see Authoring Azure Resource Manager templates.

In the example of the `IaasDiagnostic` extension, the following parameters would be created in the parameters section of the Resource Manager template:

JSON

```
"storageAccountName": {
    "defaultValue": null,
    "type": "SecureString"
},
"storageAccountKey": {
    "defaultValue": null,
    "type": "SecureString"
}
```

At this point, you can deploy the template by using any template deployment method.

Troubleshooting Azure Windows VM extension failures

08/27/2025

Overview of Azure Resource Manager templates

Azure Resource Manager templates allows you to declaratively specify the Azure IaaS infrastructure in JSON language by defining the dependencies between resources.

See Authoring extension templates to learn more about authoring templates for using extensions.

In this article we'll learn about troubleshooting some of the common VM extension failures.

Viewing extension status

Azure Resource Manager templates can be executed from Azure PowerShell. Once the template is executed, the extension status can be viewed from Azure Resource Explorer or the command-line tools.

Here's an example:

Azure PowerShell:

Azure PowerShell

```
Get-AzVM -ResourceGroupName $RGName -Name $vmName -Status
```

Here's the sample output:

Output

```
Extensions:  {
  "ExtensionType": "Microsoft.Compute.CustomScriptExtension",
  "Name": "myCustomScriptExtension",
  "SubStatuses": [
    {
      "Code": "ComponentStatus/StdOut/succeeded",
      "DisplayStatus": "Provisioning succeeded",
      "Level": "Info",
      "Message": "    Directory: C:\\temp\\n\\n\\nMode
LastWriteTime     Length Name
          \\n----                -------------     ------ ----
\\n-a---          9/1/2015   2:03 AM         11
```

```
          test.txt                          \\n\\n",
                  "Time": null
      },
    {
      "Code": "ComponentStatus/StdErr/succeeded",
      "DisplayStatus": "Provisioning succeeded",
      "Level": "Info",
      "Message": "",
      "Time": null
    }
  ]
}
```

Troubleshooting extension failures

Verify that the VM Agent is running and Ready

The VM Agent is required to manage, install and execute extensions. If the VM Agent isn't running or is failing to report a Ready status to the Azure platform, then the extension isn't working correctly.

The following pages to troubleshoot the VM Agent:

- Troubleshooting Windows Azure Guest Agent for a Windows VM
- Troubleshoot the Azure Linux Agent for a Linux VM

Check for your specific extension troubleshooting guide

Some extensions have a specific page describing how to troubleshoot them. You can find the list of these extensions and pages on Troubleshoot extensions .

View the extension's status

As explained previously, the extension's status can be found by running the PowerShell cmdlet:

Azure PowerShell

```
Get-AzVM -ResourceGroupName $RGName -Name $vmName -Status
```

Or the CLI command:x

Azure CLI

```
az vm extension show -g <RG Name> --vm-name <VM Name>  --name <Extension Name>
```

Or in the Azure portal, by browsing to the VM Blade / Settings / Extensions. You can then click on the extension and check its status and message.

Rerun the extension on the VM

If you're running scripts on the VM using Custom Script Extension, you could sometimes run into an error where VM was created successfully but the script fails. Under these conditions, the recommended way to recover from this error is to remove the extension and rerun the template again.

> **Note**
>
> In future, this functionality would be enhanced to remove the need for uninstalling the extension.

Remove the extension from Azure PowerShell

Azure PowerShell

```
Remove-AzVMExtension -ResourceGroupName $RGName -VMName $vmName -Name
"myCustomScriptExtension"
```

Once the extension is removed, the template can be re-executed to run the scripts on the VM.

Trigger a new GoalState to the VM

You might see that an extension isn't running because the 'Windows Azure CRP Certificate Generator' is missing. This certificate helps protect the extension's settings during transport. That certificate is automatically regenerated by restarting the Windows Guest Agent from inside the Virtual Machine:

- Open the Task Manager
- Go to the Details tab
- Locate the WindowsAzureGuestAgent.exe process
- Right-click, and select "End Task". The process is automatically restarted

You can also trigger a new GoalState to the VM, by executing a "VM Reapply". VM Reapply is an API introduced in 2020 to reapply a VM's state. We recommend doing this at a time when

you can tolerate a short VM downtime. Reapply usually doesn't reboot the VM, but in rare cases, it might trigger a pending update that does require a restart.

Azure portal:

In the portal, select the VM and in the left pane under the **Support + troubleshooting**, select **Redeploy + reapply**, then select **Reapply**.

Azure PowerShell *(replace the RG Name and VM Name with your values)*:

Azure PowerShell

```
Set-AzVM -ResourceGroupName <RG Name> -Name <VM Name> -Reapply
```

Azure CLI *(replace the RG Name and VM Name with your values)*:

Azure CLI

```
az vm reapply -g <RG Name> -n <VM Name>
```

If a "VM Reapply" didn't work, you can add a new empty Data Disk to the VM from the Azure Management Portal, and then remove it later once the certificate is added back.

Look at the extension logs inside the VM

If the previous steps didn't work and if your extension is still in a failed state, the next step is to look at its logs inside the Virtual Machine.

On a **Windows** VM, the extension logs by default reside in

```
C:\WindowsAzure\Logs\Plugins
```

And the Extension settings and status files by default are in

```
C:\Packages\Plugins
```

On a **Linux** VM, the extension logs be default reside in

```
/var/log/azure/
```

And the Extension settings and status files by details is in

```
/var/lib/waagent/
```

Each extension is different, but they usually follow similar principles:

Extension packages and binaries are downloaded on the VM (example: "*/var/lib/waagent/custom-script/download/1*" for Linux or "*C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\Downloads\0*" for Windows).

Their configuration and settings are passed from Azure Platform to the extension handler through the VM Agent (example: "*/var/lib/waagent/Microsoft.Azure.Extensions.CustomScript-2.1.3/config*" for Linux or "*C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\RuntimeSettings*" for Windows)

Extension handlers inside the VM are writing to a status file (example: "*/var/lib/waagent/Microsoft.Azure.Extensions.CustomScript-2.1.3/status/1.status*" for Linux or "*C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\Status*" for Windows) which is reported to the Azure Platform. That status is the one reported through PowerShell, CLI or in the VM's extension blade in the Azure portal.

They also write detailed logs of their execution (example: "*/var/log/azure/custom-script/handler.log*" for Linux or "*C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\CustomScriptHandler.log*" for Windows).

If the VM is recreated from an existing VM

It could happen that you're creating an Azure VM based on a specialized Disk coming from another Azure VM. In that case, it's possible that the old VM contained extensions, and binaries, logs, and status files left over. The new VM model isn't aware of the previous VM's extensions states, and it might report an incorrect status for these extensions. We strongly recommend you to remove the extensions from the old VM before creating the new one, and then reinstall these extensions once the new VM is created. The same can happen when you create a generalized image from an existing Azure VM. We invite you to remove extensions to avoid inconsistent state from the extensions.

Known issues

PowerShell isn't recognized as an internal or external command

You notice the following error entries in the RunCommand extension's output:

```
Log

RunCommandExtension failed with "'powershell' isn't recognized as an internal or
external command,"
```

Analysis

Extensions run under Local System account, so it's possible that powershell.exe works fine when you RDP into the VM, but fails when run with RunCommand.

Solution

- Check that PowerShell is properly listed in the PATH environment variable:
  - Open Control Panel
  - System and Security
  - System
  - Advanced tab -> Environmental Variables
- Under 'System variables' click edit and ensure that PowerShell is in the PATH environment variable (usually: "C:\Windows\System32\WindowsPowerShell\v1.0")
- Reboot the VM or restart the WindowsAzureGuestAgent service then try the Run Command again.

Command isn't recognized as an internal or external command

You see the following in the C:\WindowsAzure\Logs\Plugins<ExtensionName><Version>\CommandExecution.log file:

```
Log

Execution Error: '<command>' isn't recognized as an internal or external command,
operable program or batch file.
```

Analysis

Extensions run under Local System account, so it's possible that powershell.exe works fine when you RDP into the VM, but fails when run with RunCommand.

Solution

- Open a Command Prompt in the VM and execute a command to reproduce the error. The VM Agent uses the Administrator cmd.exe and you may have some preconfigured command to execute every time cmd is started.
- It's also likely that your PATH variable is misconfigured, but that depends on the command that is having the problem.

VMAccessAgent is failing with Cannot update Remote Desktop Connection settings for Administrator account. Error: System.Runtime.InteropServices.COMException (0x800706D9): There are no more endpoints available from the endpoint mapper.

You see the following in the extension's status:

Log

```
Type Microsoft.Compute.VMAccessAgent
Version 2.4.8
Status Provisioning failed
Status level Error
Status message Cannot update Remote Desktop Connection settings for Administrator
account. Error: System.Runtime.InteropServices.COMException (0x800706D9): There
are no more endpoints available from the endpoint mapper. (Exception from HRESULT:
0x800706D9) at NetFwTypeLib.INetFwRules.GetEnumerator() at
Microsoft.WindowsAzure.GuestAgent.Plugins.JsonExtensions.VMAccess.RemoteDesktopMan
ager.EnableRemoteDesktopFirewallRules()
at
Microsoft.WindowsAzure.GuestAgent.Plugins.JsonExtensions.VMAccess.RemoteDesktopMan
ager.EnableRemoteDesktop() at
```

Analysis

This error can happen when the Windows Firewall service isn't running.

Solution

Check if the Windows Firewall service is enabled and running. If it's not, enable and start it - then try again to run the VMAccessAgent.

The remote certificate is invalid according to the validation procedure.

You see the following in the WaAppAgent.log

```
Log

System.Net.WebException: The underlying connection was closed: Could not establish
trust relationship for the SSL/TLS secure channel. ---> System.Security.
Authentication.AuthenticationException: The remote certificate is invalid
according to the validation procedure.
```

Analysis

Your VM is probably missing the Baltimore CyberTrust Root certificate in "Trusted Root Certification Authorities".

Solution

Open the certificates console with certmgr.msc, and check if the certificate is there.

A third-party SSL inspection tool, like ZScaler, might break the certificate chain. You should configure such tools to bypass SSL inspection.

Issues using VM extensions in Python 3-enabled Linux Azure Virtual Machines systems

> ⓘ Note
>
> Microsoft encourages users to adopt **Python 3.x** in their systems unless your workload requires **Python 2.x** support. Examples of this requirement might include legacy administration scripts, or extensions such as **Azure Disk Encryption** and **Azure Monitor**.
>
> Before installing **Python 2.x** in production, consider the question of long-term support of Python 2.x, particularly their ability to receive security updates. As products, including some of the extension mentioned, update with **Python 3.8** support, you should discontinue use of Python 2.x.

Some Linux distributions have transitioned to Python 3.8 and removed the legacy `/usr/bin/python` entrypoint for Python altogether. This transition impacts the out-of-the-box, automated deployment of certain virtual machine (VM) extensions with these two conditions:

- Extensions that are still transitioning to Python 3.x support
- Extensions that use the legacy `/usr/bin/python` entrypoint

Linux distribution users who have transitioned to **Python 3.x** must ensure the legacy `/usr/bin/python` entrypoint exists before attempting to deploy those extensions to their VMs. Otherwise, the extension deployment might fail.

- Endorsed Linux distributions that are affected include **Ubuntu Server 20.04 LTS** and **Ubuntu Pro 20.04 LTS**.
- Affected VM Extensions include **Azure Disk Encryption**, **Log Analytics**, **VM Access** (used for Password Reset), and **Guest Diagnostics** (used for additional performance counters).

In-place upgrades, such as upgrading from **Ubuntu 18.04 LTS** to **Ubuntu 20.04 LTS**, should retain the `/usr/bin/python` symlink, and remain unaffected.

> ⓘ Note
>
> **New! Try VM assist for Faster Diagnostics**` We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.

Resolution

Consider these general recommendations before deploying extensions in the known-affected scenarios described previously in the Summary:

1. Before deploying the extension, reinstate the `/usr/bin/python` symlink by using the Linux distribution vendor-provided method.

   - For example, for **Python 2.7**, use: `sudo apt update && sudo apt install python-is-python2`

2. This recommendation is for Azure customers and isn't supported in Azure Stack:

   - If you've already deployed an instance that exhibits this problem, use the Run command functionality in the VM blade to run the commands mentioned above. The Run command extension itself isn't affected by the transition to Python 3.8.

3. If you're deploying a new instance, and need to set an extension at provisioning time, use **cloud-init** user data to install the packages mentioned above.

   For example, for Python 2.7:

   Python

   ```
   # create cloud-init config
   cat > cloudinitConfig.json <<EOF
   #cloud-config
   package_update: true

   runcmd:
   - sudo apt update
   - sudo apt install python-is-python2
   EOF

   # create VM
   az vm create \
       --resource-group <resourceGroupName> \
       --name <vmName> \
       --image <Ubuntu 20.04 Image URN> \
       --admin-username azadmin \
       --ssh-key-value "<sshPubKey>" \
       --custom-data ./cloudinitConfig.json
   ```

4. If your organization's policy administrators determine that extensions shouldn't be deployed in VMs, you can disable extension support at provisioning time:

   - REST API

To disable and enable extensions when you can deploy a VM with this property:

Python

```
"osProfile": {
  "allowExtensionOperations": false
},
```

Next steps

Please refer to Other base system changes since 18.04 LTS - Python 3 by default for additional information.

What is Nested Virtualization?

07/25/2025

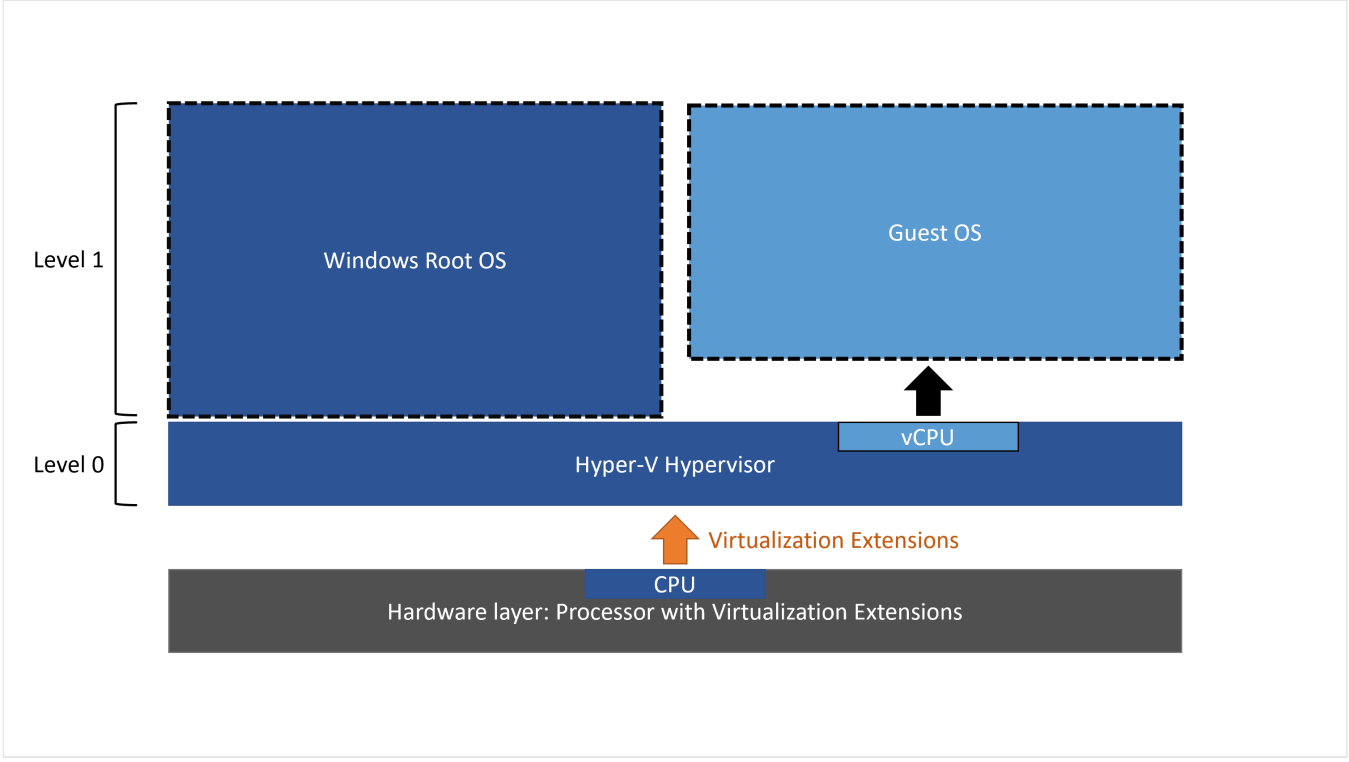
Applies to: ✅ Windows Server 2025, ✅ Windows Server 2022, ✅ Windows Server 2019, ✅ Windows Server 2016, ✅ Windows 11, ✅ Windows 10, ✅ Azure Local 2311.2 and later

Nested virtualization is a feature that lets you run Hyper-V inside a Hyper-V virtual machine (VM). This article explains how nested virtualization works, its benefits, and when to use it in your environment. For example, nested virtualization can be useful for:

- Running applications or emulators in a nested VM
- Testing software releases on VMs
- Reducing deployment times for training environments
- Using Hyper-V isolation for containers

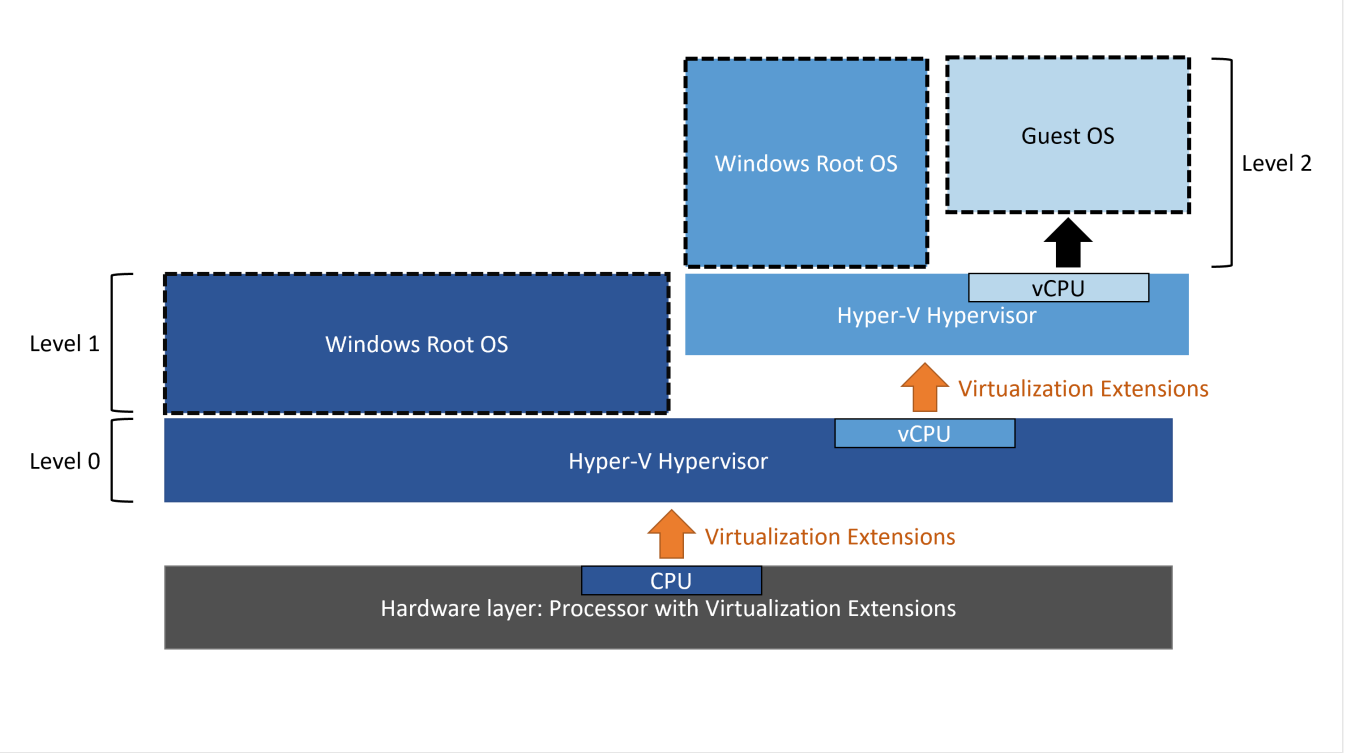
Modern processors include hardware features that make virtualization faster and more secure. Hyper-V relies on these processor extensions to run virtual machines, for example, Intel VT-x and AMD-V. Nested virtualization makes this hardware support available to guest virtual machines.

The following diagram shows Hyper-V without nesting. The Hyper-V hypervisor takes full control of the hardware virtualization capabilities (orange arrow), and doesn't expose them to the guest operating system.



In contrast, the following diagram shows Hyper-V with Nested Virtualization enabled. In this case, Hyper-V exposes the hardware virtualization extensions to its virtual machines. With

nesting enabled, a guest virtual machine can install its own hypervisor and run its own guest VMs.



Dynamic Memory and Runtime Memory Resize

When Hyper-V is running inside a virtual machine, the virtual machine must be turned off to adjust its memory. Meaning that even if dynamic memory is enabled, the amount of memory doesn't fluctuate. Simply enabling nested virtualization has no effect on dynamic memory or runtime memory resize.

For virtual machines without dynamic memory enabled, attempting to adjust the amount of memory while running fails. The incompatibility only occurs while Hyper-V is running in the VM.

Non-Microsoft virtualization apps

Virtualization applications other than Hyper-V aren't supported in Hyper-V virtual machines, and are likely to fail. Virtualization applications include any software that requires hardware virtualization extensions.

Supported scenarios

Using a nested Hyper-V VM in production is supported for both Azure and on-premises in the following scenarios. We also recommend you make sure that your services and applications are

also supported.

Nested Virtualization isn't suitable for Windows Server Failover Clustering, and performance sensitive applications. We recommended you fully evaluate the services and applications.

Hyper-V VMs on Hyper-V VMs

Running Hyper-V VMs nested on Hyper-V VMs is great for test labs and evaluation environments. Especially where configurations can be easily modified and saved states can be used to revert to specific configurations. Test labs don't typically require the same service level agreement (SLA) as production environments.

Production environments running Hyper-V VMs running on Hyper-V VMs are supported. Ensure that your services and applications are also supported. If you use a nested Hyper-V VM in production, make sure you fully evaluate whether your services or applications provide the expected behavior.

To learn more about setting up Nested Virtualization on Azure, see our Tech Community blog How to Setup Nested Virtualization for Azure VM/VHD.

Non-Microsoft virtualization on Hyper-V virtualization

While it might be possible for non-Microsoft virtualization to run on Hyper-V, Microsoft doesn't test this scenario. Non-Microsoft virtualization on Hyper-V virtualization isn't supported. Ensure your hypervisor vendor supports this scenario.

Hyper-V virtualization on non-Microsoft virtualization

While it might be possible for Hyper-V virtualization to run on non-Microsoft virtualization, Microsoft doesn't test this scenario. Hyper-V virtualization on non-Microsoft virtualization isn't supported. Ensure your hypervisor vendor supports this scenario.

Azure Local nested on Hyper-V VMs

Azure Local is designed and tested to run on validated physical hardware. Azure Local can run nested in a virtual machine for evaluation, but production environments in a nested configuration aren't supported.

To learn more about Azure Local nested on Hyper-V VMs, see Nested virtualization in Azure Local.

Hyper-V isolated containers running nested on Hyper-V

Microsoft offers Hyper-V isolation for containers. This isolation mode offers enhanced security and broader compatibility between host and container versions. With Hyper-V isolation, multiple container instances run concurrently on a host. Each container runs inside of a highly optimized virtual machine and effectively gets its own kernel. Since a Hyper-V isolated container offers isolation through a hypervisor layer between itself and the container host, when the container host is a Hyper-V based virtual machine, there's performance overhead. The associated performance overhead occurs in terms of container start-up time, storage, network, and CPU operations.

When a Hyper-V isolated container is run in a Hyper-V VM, it's running nested. Using a Hyper-V VM opens many useful scenarios but also increases latency, as there are two levels of hypervisors running above the physical host.

Running Hyper-V isolated containers nested on Hyper-V is supported. One level of nested virtualization is supported in production, which allows for isolated container deployments.

To learn more about Nested Hyper-V Containers, see Performance tuning Windows Server Containers.

Run WSL2 in a Hyper-V VM running nested on Hyper-V

Windows Subsystem for Linux (WSL) is a feature of the Windows operating system that enables you to run a Linux file system, along with Linux command-line tools and GUI apps, directly on Windows.

Running WSL2 in a Hyper-V VM running nested on Hyper-V is supported.

To learn more about how to enabled WSL 2 to run in a VM, see Frequently Asked Questions about Windows Subsystem for Linux.

Estimate the cost of creating a Virtual Machine in the Azure portal (Preview)

Article • 08/22/2024

> **Important**
>
> The estimated cost card feature for virtual machines in the Azure portal is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Azure virtual machines (VM) can be created through the Azure portal. This method provides a browser-based user interface to create VMs and their associated resources. As you create VMs in the Azure portal and configure them through the different tabs during the creation process, the cost card reflects the pricing estimations based on your selections.

The cost displayed in this card doesn't reflect usage and other costs incurred on the VMs beyond the creation of the resources. The final price of your VMs may factor in other respective networking, storage, and extra costs that pertain to the usage and application of the VMs.

> **Note**
>
> Costs reflected in the card are estimates only. Pricing may vary depending on your Microsoft agreement, date of purchase, subscription type, usage costs, licensing, and currency exchange rates. Total costs may include other resource costs, licensing, and subscription implications. The costs indicated on the card may vary across regions, subscription types, sizes, and images.

Prerequisites

Currently, the estimated cost card feature for VMs in the Azure portal is limited to Pay-as-you-go customers. This feature isn't available or visible for other subscription types and other discount plans, such as the Savings Plan and Reserved Instances.

If your subscription has policy restrictions for specific users, those users aren't able to view the cost card unless those restrictions are lifted. If your subscription has policy

restrictions to not show costs, cost card will not be shown unless those restrictions are lifted.

Cost card

The following sections reflect the various tabs during the VM creation process in the Azure portal. The listed resources and features are included in the estimated cost card. For further pricing information, refer to their respective pricing pages linked in the following tables.

Costs associated with selecting existing resources during the VM creation process are only reflected in the cost card if those resources may incur extra charges.

Basics

Expand table

Resource or feature	Notes
Image and Size (Windows)	Estimates of VM size and Windows based image are displayed.
Image and Size (Linux)	Estimates of VM size and Linux based image are displayed.
Spot	If selected, the discounted Spot price is shown.
Azure Hybrid Benefit (AHB) licensing	If selected, the AHB discounts are applied and shown.

Disks

Expand table

Resource or feature	Notes
OS Disk	Estimate for using the selected disk to host the selected operating system is displayed.
Ultra disk Reservation charge	A reservation charge is only imposed if Ultra Disk compatibility is enabled on the VM without attaching an Ultra Disk.
Data Disk	Estimate for using the selected disk, to store and access data, is displayed. A disk share estimate is displayed if enabled and other charges apply. Transaction and bursting costs aren't included in the estimate.

Networking

Expand table

Resource or feature	Notes
Public IP	Estimated cost of running a public IP Address. A Standard Public IP is selected when a new IP is created as part of the default selection.
VM Data transfer	Estimated cost is based on inter-region data transfer routed via Microsoft Premium Global Network.
Azure Load Balancer	A new Standard Azure Load Balancer estimate includes the cost of one rule and estimated data processed. For an existing Azure load balancer, the estimate includes only the estimated data transfer and Azure assumes rules already exist.
Azure Application Gateway	A new Application Gateway v2 estimate includes Fixed, Capacity units and estimate outbound data transfer costs. For this estimate, one capacity unit consumption is assumed. For an existing Azure Application gateway, only the outbound data transfer estimate is displayed. Azure assumes that other fixed costs are already paid for.

Management

Expand table

Resource or feature	Notes
Azure Backup	Monthly average backup cost is based on the operating system disk size of the VM that needs backup, the backup policy selected, and estimated moderate daily data churn. Storage consumed by Azure Backup grows incrementally over a period; the monthly cost of Azure Back also increases as consumption grows. Azure models the growth of consumed storage over a year, aggregates it and uses the average monthly consumption to propose the estimate.
Azure Site Recovery	Estimate for recovering a VM to Azure.

Monitoring

Expand table

Resource or feature	Notes
Alerts	Estimate for the selected alerting rules.
Boot Diagnostics	Estimate for enabling boot diagnostics can vary based the storage account and number of transactions performed. If enabled, a charged is incurred. However, due to the variability in consumption, the charge isn't included in the estimate.

Advanced

Expand table

Resource or feature	Notes
Azure Dedicated Host	Adding an existing Azure Dedicated Host deducts the cost of the VM size as the host had been prepaid for.

Next steps

The Azure pricing calculator is another tool that can be referenced for price estimations for different parts of your workload.

Availability options for Azure Virtual Machines

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article provides an overview of the availability options for Azure virtual machines (VMs).

Availability zones

Availability zones expands the level of control you have to maintain the availability of the applications and data on your VMs. An Availability Zone is a physically separate zone, within an Azure region. There are three Availability Zones per supported Azure region.

Each Availability Zone has a distinct power source, network, and cooling. By designing your solutions to use replicated VMs in zones, you can protect your apps and data from the loss of a data center. If one zone is compromised, then replicated apps and data are instantly available in another zone.

> ⓘ **Note**
>
> Regional resources may or may not exist in an Availability zone, and there is no insight into what physical or logical zone a regional resource is in. A failure in any of the availability zones in a region has the potential to bring down a regional VM.

Virtual Machines Scale Sets

Azure virtual machine scale sets let you create and manage a group of load balanced VMs. The number of VM instances can automatically increase or decrease in response to demand or a defined schedule. Scale sets provide high availability to your applications, and allow you to centrally manage, configure, and update many VMs. There is no cost for the scale set itself, you only pay for each VM instance that you create.

Virtual machines in a scale set can also be deployed into multiple availability zones, a single availability zone, or regionally. Availability zone deployment options may differ based on the orchestration mode.

Availability sets

An availability set is a logical grouping of VMs that allows Azure to understand how your application is built to provide for redundancy and availability. We recommended that two or more VMs are created within an availability set to provide for a highly available application and to meet the 99.95% Azure SLA. There is no cost for the Availability Set itself, you only pay for each VM instance that you create.

Load balancer

Combine the Azure Load Balancer with availability zones and scale sets to get the most application resiliency. The Azure Load Balancer distributes traffic between multiple virtual machines. For our Standard tier virtual machines, the Azure Load Balancer is included. Not all virtual machine tiers include the Azure Load Balancer. For more information about load balancing your virtual machines, see the Load Balancer quickstarts using the CLI or PowerShell.

Azure Storage redundancy

Azure Storage always stores multiple copies of your data so that it is protected from planned and unplanned events, including transient hardware failures, network or power outages, and massive natural disasters. Redundancy ensures that your storage account meets its availability and durability targets even in the face of failures.

When deciding which redundancy option is best for your scenario, consider the tradeoffs between lower costs and higher availability. The factors that help determine which redundancy option you should choose include:

- How your data is replicated in the primary region
- Whether your data is replicated to a second region that is geographically distant to the primary region, to protect against regional disasters
- Whether your application requires read access to the replicated data in the secondary region if the primary region becomes unavailable for any reason

For more information, see Azure Storage redundancy

Azure Site Recovery

As an organization you need to adopt a business continuity and disaster recovery (BCDR) strategy that keeps your data safe, and your apps and workloads online, when planned and unplanned outages occur.

Azure Site Recovery helps ensure business continuity by keeping business apps and workloads running during outages. Site Recovery replicates workloads running on physical and virtual

machines (VMs) from a primary site to a secondary location. When an outage occurs at your primary site, you fail over to secondary location, and access apps from there. After the primary location is running again, you can fail back to it.

Site Recovery can manage replication for:

- Azure VMs replicating between Azure regions.
- On-premises VMs, Azure Stack VMs, and physical servers.

Next steps

- Create a virtual machine in an availability zone
- Create a virtual machine in an availability set
- Create a virtual machine scale set

Last updated on 12/05/2025

What are availability zones?

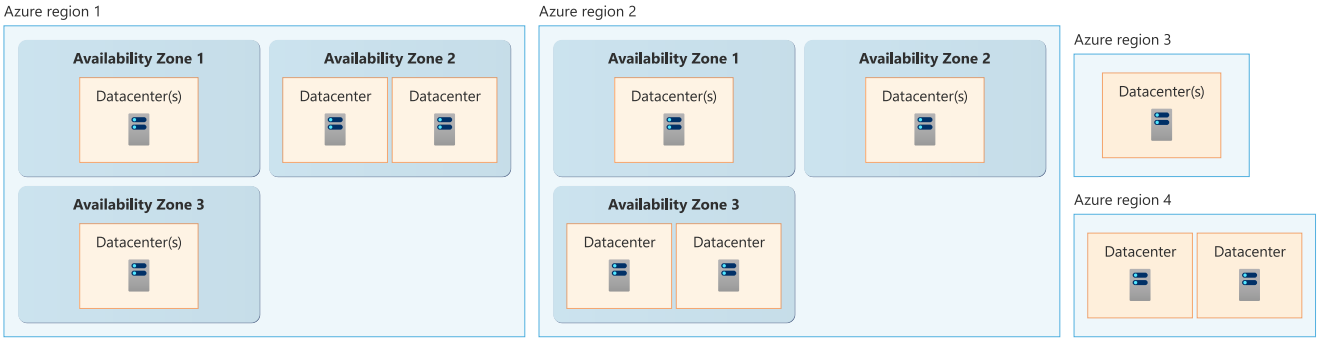
Summarize this article for me

https://learn-video.azurefd.net/vod/player?id=d36b5b2d-8bd2-43df-a796-b0c77b2f82fc&locale=en-us&embedUrl=%2Fazure%2Freliability%2Favailability-zones-overview

Many Azure regions provide *availability zones*, which are separated groups of datacenters within a region. Each availability zone has independent power, cooling, and networking infrastructure, so that if one zone experiences an outage, then regional services, capacity, and high availability are supported by the remaining zones. Some Azure services automatically use multiple zones, while others require you to configure multiple-zone deployment.

Availability zones don't only protect against large-scale outages that affect an entire zone. They also provide resilience against smaller-scoped failures, such as a server rack or cluster failure within a zone. In these scenarios, workloads can continue running in other zones, even if parts of the affected zone remain operational.

The following diagram shows several example Azure regions. Regions 1 and 2 support availability zones, and regions 3 and 4 don't have availability zones. Some zones have one datacenter and others have multiple.



> **Tip**
>
> To see which regions support availability zones, see List of Azure regions.

Datacenters and availability zones

An availability zone is a *logical grouping* of one or more physically separate datacenters within a region. Each availability zone is built in a way that if something goes wrong in one (like a power outage or network issue), the others keep working. A single datacenter doesn't offer this level of protection on its own.

Availability zones are typically separated by several kilometers, and usually are within 100 kilometers of each other. This provides low-latency connectivity while reducing the likelihood local outages or weather events impact multiple zones simultaneously.

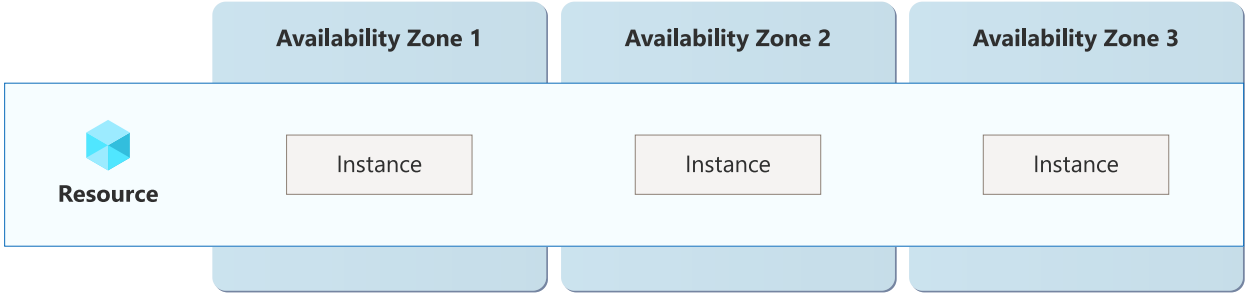
Datacenter locations are selected by using rigorous vulnerability risk assessment criteria. This process identifies all significant datacenter-specific risks and considers shared risks between availability zones.

Types of availability zone support

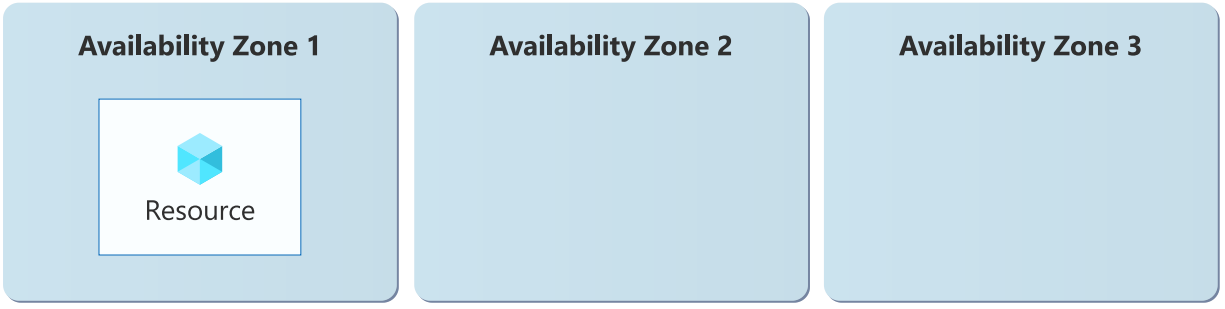
Azure services can provide different types of availability zone support for their resources, and most services support deploying either *zone-redundant* or *zonal* resources:

- **Zone-redundant resources**: Zone-redundant resources are replicated or distributed across multiple availability zones by the service. For example, zone-redundant data services replicate the data across multiple zones so that a failure in one zone doesn't affect the availability of the data. Some services are automatically zone-redundant in supported regions, while other services require that you configure your resource to be zone-redundant. For most services, Microsoft selects the zones your resources use, but sometimes you can select the set of zones.

  With zone-redundant deployments, Microsoft manages spreading requests across zones and the replication of data across zones. If an outage occurs in an availability zone, Microsoft manages failover to another zone automatically.



- **Zonal resources**: A zonal resource is deployed to a single availability zone that you select yourself.



Zonal deployments don't automatically provide resiliency to availability zone outages. However, zonal resources are isolated from faults in other zones. They can also help you achieve unusually stringent latency or performance requirements. For example, for a chatty workload built using virtual machines, you might choose to deploy multiple virtual machines to the same zone to reduce the latency of the connections between them.

To make zonal resources resilient to availability zone outages, you need to design an architecture with separate resources in multiple availability zones within the region. Microsoft doesn't manage the process for you. If an outage occurs in an availability zone, you're responsible for failover to another zone.

When you configure a resource to be zone redundant, or if you use multiple instances of a zonal resource in different availability zones, then your resource is considered to be *zone-resilient*: that is, it's resilient to the outage of a single availability zone. To learn more about how to use zonal deployments and maintain zone resiliency, see Zonal resources and zone resiliency.

When designing your reliability strategy, make sure that you understand how each service in your workload supports availability zones. For example, some services may have extra requirements to meet for availability zone support, such as certain tiers or SKUs. Reliability guides contain details of any such requirements.

If a resource isn't configured to use availability zones, either due to the region you use not supporting zones or because of your configuration choices, it's called a *nonzonal* or *regional* deployment. Azure might place nonzonal resources across any zones in the region. You don't choose which resources go into which zones. If any availability zone in the region experiences an outage, nonzonal resources might be in the affected zone and could experience downtime.

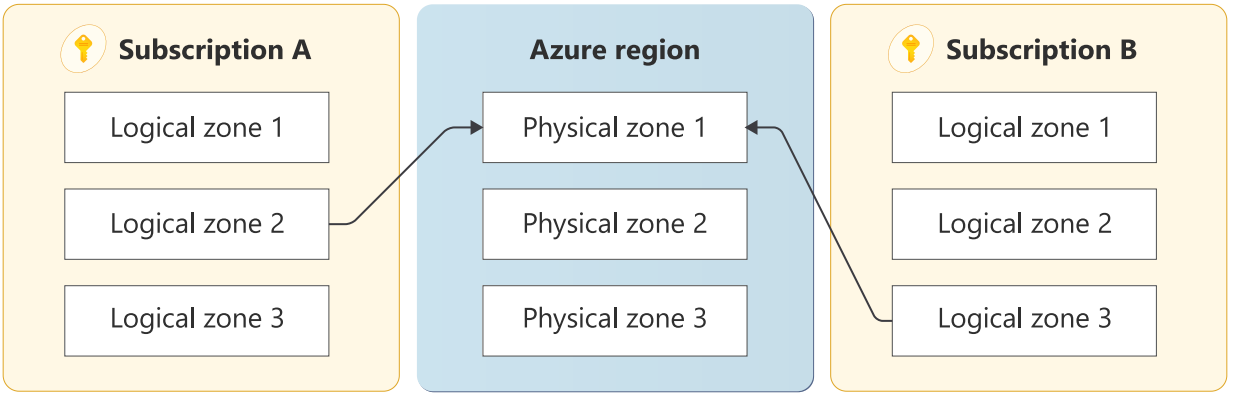
Configuring resources for availability zone support

Each service has its own method for configuring availability zone support, and some services don't require any configuration. To learn about how each service supports availability zones and how to configure that support, see Azure reliability guides by service.

Physical and logical availability zones

Each datacenter is assigned to a physical zone. Physical zones are mapped to logical zones in your Azure subscription, and different subscriptions might have a different mapping order. Azure subscriptions are automatically assigned their mapping at the time the subscription is created. Because of this, the zone mapping for one subscription could be different for other subscriptions.

For example, subscription A may have physical zone 1 mapped to logical zone 2, while subscription B has physical zone 1 mapped to logical zone 3:



To understand the mapping between logical and physical zones for your subscription, use the Azure CLI or Azure PowerShell, or the Azure Resource Manager APIs.

Azure CLI

Use the az account list-locations command:

Azure CLI

```
az account list-locations \
    --query "[?availabilityZoneMappings].{availabilityZoneMappings:
availabilityZoneMappings, displayName: displayName, name: name}"
```

Availability zones and Azure updates

For each region, Microsoft aims to deploy updates to Azure services within a single availability zone at a time. This approach reduces the impact that updates might have on an active workload, allowing the workload to continue to run in other zones while the update is in process. To take advantage of sequenced zone updates, your workload must be already configured to run across multiple zones. For more information about how Azure deploys updates, see Advancing safe deployment practices.

Inter-zone networking

Within each region, availability zones are connected through a high-performance network. Microsoft strives to achieve an inter-zone communication with round-trip latency of less than approximately 2 milliseconds. Low latency allows for high-performance communication within a region, and for synchronous replication of data across multiple availability zones. The target latency refers to the latency of the network links. Depending on the communication protocol you use and the network hops required for any specific network flow, the latency you observe might be different.

In most workloads, you can distribute components of your solution across availability zones without a noticeable effect on your performance. If you have a workload with a high degree of sensitivity to inter-zone latency, it's important to test the latency between your selected availability zones with your actual protocols and configuration. To reduce inter-zone traffic, it's possible to use zonal deployments, but optimally, you should use multiple availability zones in your reliability strategy plan. To learn more about how to use zonal deployments and maintain zone resiliency, see Zonal resources and zone resiliency.

Azure doesn't charge for data transfer between availability zones in the same region, whether you use private or public IP addressing.

Availability zone architectural guidance

To achieve reliable workloads:

- Production workloads should be configured to use multiple availability zones if the region they are in supports availability zones.
- For mission-critical workloads, you should consider a solution that is *both* multi-region and multi-zone.

For more detailed information on how to use regions and availability zones in a solution architecture, see Recommendations for using availability zones and regions.

Create a virtual machine in an availability zone using Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article steps through using the Azure CLI to create a Linux VM in an Azure availability zone. An availability zone is a physically separate zone in an Azure region. Use availability zones to protect your apps and data from an unlikely failure or loss of an entire datacenter.

To use an availability zone, create your virtual machine in a supported Azure region.

Make sure that you have installed the latest Azure CLI and logged in to an Azure account with az login.

Check VM SKU availability

The availability of VM sizes, or SKUs, may vary by region and zone. To help you plan for the use of Availability Zones, you can list the available VM SKUs by Azure region and zone. This ability makes sure that you choose an appropriate VM size, and obtain the desired resiliency across zones. For more information on the different VM types and sizes, see VM Sizes overview.

You can view the available VM SKUs with the az vm list-skus command. The following example lists available VM SKUs in the *eastus2* region:

Azure CLI

```
az vm list-skus --location eastus2 --output table
```

The output is similar to the following condensed example, which shows the Availability Zones in which each VM size is available:

Output

```
ResourceType      Locations  Name              [...]    Tier       Size
Zones
----------------  ---------  ----------------          ---------  -------
-------
virtualMachines   eastus2    Standard_DS1_v2           Standard   DS1_v2
1,2,3
virtualMachines   eastus2    Standard_DS2_v2           Standard   DS2_v2
```

```
1,2,3
[...]
virtualMachines   eastus2    Standard_F1s               Standard   F1s
1,2,3
virtualMachines   eastus2    Standard_F2s               Standard   F2s
1,2,3
[...]
virtualMachines   eastus2    Standard_D2s_v3            Standard   D2_v3
1,2,3
virtualMachines   eastus2    Standard_D4s_v3            Standard   D4_v3
1,2,3
[...]
virtualMachines   eastus2    Standard_E2_v3             Standard   E2_v3
1,2,3
virtualMachines   eastus2    Standard_E4_v3             Standard   E4_v3
1,2,3
```

Create resource group

Create a resource group with the az group create command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine. In this example, a resource group named *myResourceGroupVM* is created in the *eastus2* region. East US 2 is one of the Azure regions that supports availability zones.

Azure CLI

```
az group create --name myResourceGroupVM --location eastus2
```

The resource group is specified when creating or modifying a VM, which can be seen throughout this article.

Create virtual machine

Create a virtual machine with the az vm create command.

When creating a virtual machine, several options are available such as operating system image, disk sizing, and administrative credentials. In this example, a virtual machine is created with a name of *myVM* running Ubuntu Server. The VM is created in availability zone *1*. By default, the VM is created in the *Standard_DS1_v2* size.

Azure CLI

```
az vm create --resource-group myResourceGroupVM --name myVM --location
eastus2 --image Ubuntu2204 --generate-ssh-keys --zone 1
```

It may take a few minutes to create the VM. Once the VM has been created, the Azure CLI outputs information about the VM. Take note of the `zones` value, which indicates the availability zone in which the VM is running.

Output

```
{
  "fqdns": "",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/vi
rtualMachines/myVM",
  "location": "eastus2",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroupVM",
  "zones": "1"
}
```

Confirm zone for managed disk and IP address

When the VM is deployed in an availability zone, a managed disk for the VM is created in the same availability zone. By default, a public IP address is also created in that zone. The following examples get information about these resources.

To verify that the VM's managed disk is in the availability zone, use the az vm show command to return the disk ID. In this example, the disk ID is stored in a variable that is used in a later step.

Azure CLI

```
osdiskname=$(az vm show -g myResourceGroupVM -n myVM --query
"storageProfile.osDisk.name" -o tsv)
```

Now you can get information about the managed disk:

Azure CLI

```
az disk show --resource-group myResourceGroupVM --name $osdiskname
```

The output shows that the managed disk is in the same availability zone as the VM:

Output

```
{
  "creationData": {
    "createOption": "FromImage",
    "imageReference": {
      "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westeurope/Publishers/Can
onical/ArtifactTypes/VMImage/Offers/UbuntuServer/Skus/16.04-
LTS/Versions/latest",
      "lun": null
    },
    "sourceResourceId": null,
    "sourceUri": null,
    "storageAccountId": null
  },
  "diskSizeGb": 30,
  "encryptionSettings": null,
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/di
sks/osdisk_761c570dab",
  "location": "eastus2",
  "managedBy": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/vi
rtualMachines/myVM",
  "name": "myVM_osdisk_761c570dab",
  "osType": "Linux",
  "provisioningState": "Succeeded",
  "resourceGroup": "myResourceGroupVM",
  "sku": {
    "name": "Premium_LRS",
    "tier": "Premium"
  },
  "tags": {},
  "timeCreated": "2018-03-05T22:16:06.892752+00:00",
  "type": "Microsoft.Compute/disks",
  "zones": [
    "1"
  ]
}
```

Use the az vm list-ip-addresses command to return the name of public IP address resource in *myVM*. In this example, the name is stored in a variable that is used in a later step.

Azure CLI

```
ipaddressname=$(az vm list-ip-addresses -g myResourceGroupVM -n myVM --query
"[].virtualMachine.network.publicIpAddresses[].name" -o tsv)
```

Now you can get information about the IP address:

Azure CLI

```
az network public-ip show --resource-group myResourceGroupVM --name
$ipaddressname
```

The output shows that the IP address is in the same availability zone as the VM:

Output

```
{
  "dnsSettings": null,
  "etag": "W/\"b7ad25eb-3191-4c8f-9cec-c5e4a3a37d35\"",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Network/pu
blicIPAddresses/myVMPublicIP",
  "idleTimeoutInMinutes": 4,
  "ipAddress": "52.174.34.95",
  "ipConfiguration": {
    "etag": null,
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Network/ne
tworkInterfaces/myVMVMNic/ipConfigurations/ipconfigmyVM",
    "name": null,
    "privateIpAddress": null,
    "privateIpAllocationMethod": null,
    "provisioningState": null,
    "publicIpAddress": null,
    "resourceGroup": "myResourceGroupVM",
    "subnet": null
  },
  "location": "eastUS2",
  "name": "myVMPublicIP",
  "provisioningState": "Succeeded",
  "publicIpAddressVersion": "IPv4",
  "publicIpAllocationMethod": "Dynamic",
  "resourceGroup": "myResourceGroupVM",
  "resourceGuid": "8c70a073-09be-4504-0000-000000000000",
  "tags": {},
  "type": "Microsoft.Network/publicIPAddresses",
  "zones": [
    "1"
  ]
}
```

Create a virtual machine in an availability zone using Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Windows VMs

This article details using Azure PowerShell to create an Azure virtual machine running Windows Server 2016 in an Azure availability zone. An availability zone is a physically separate zone in an Azure region. Use availability zones to protect your apps and data from an unlikely failure or loss of an entire datacenter.

To use an availability zone, create your virtual machine in a supported Azure region.

Sign in to Azure

Sign in to your Azure subscription with the `Connect-AzAccount` command and follow the on-screen directions.

PowerShell

```
Connect-AzAccount
```

Check VM SKU availability

The availability of VM sizes, or SKUs, may vary by region and zone. To help you plan for the use of Availability Zones, you can list the available VM SKUs by Azure region and zone. This ability makes sure that you choose an appropriate VM size, and obtain the desired resiliency across zones. For more information on the different VM types and sizes, see VM Sizes overview.

You can view the available VM SKUs with the Get-AzComputeResourceSku command. The following example lists available VM SKUs in the *eastus2* region:

PowerShell

```
Get-AzComputeResourceSku | where {$_.Locations.Contains("eastus2")};
```

The output is similar to the following condensed example, which shows the Availability Zones in which each VM size is available:

PowerShell

```
ResourceType                Name  Location      Zones   [...]
------------                ----  --------      -----
virtualMachines  Standard_DS1_v2   eastus2  {1, 2, 3}
virtualMachines  Standard_DS2_v2   eastus2  {1, 2, 3}
[...]
virtualMachines     Standard_F1s   eastus2  {1, 2, 3}
virtualMachines     Standard_F2s   eastus2  {1, 2, 3}
[...]
virtualMachines  Standard_D2s_v3   eastus2  {1, 2, 3}
virtualMachines  Standard_D4s_v3   eastus2  {1, 2, 3}
[...]
virtualMachines   Standard_E2_v3   eastus2  {1, 2, 3}
virtualMachines   Standard_E4_v3   eastus2  {1, 2, 3}
```

Create resource group

Create an Azure resource group with New-AzResourceGroup. A resource group is a logical container into which Azure resources are deployed and managed. In this example, a resource group named *myResourceGroup* is created in the *eastus2* region.

PowerShell

```
New-AzResourceGroup -Name myResourceGroup -Location EastUS2
```

Create networking resources

Create a virtual network, subnet, and a public IP address

These resources are used to provide network connectivity to the virtual machine and connect it to the internet. Create the IP address in an availability zone, *2* in this example. In a later step, you create the VM in the same zone used to create the IP address.

PowerShell

```
# Create a subnet configuration
$subnetConfig = New-AzVirtualNetworkSubnetConfig -Name mySubnet -
AddressPrefix 192.168.1.0/24

# Create a virtual network
$vnet = New-AzVirtualNetwork -ResourceGroupName myResourceGroup -Location
eastus2 `
    -Name myVNet -AddressPrefix 192.168.0.0/16 -Subnet $subnetConfig
```

```
# Create a public IP address in an availability zone and specify a DNS name
$pip = New-AzPublicIpAddress -ResourceGroupName myResourceGroup -Location
eastus2 -Zone 2 `
    -AllocationMethod Static -IdleTimeoutInMinutes 4 -Name
"mypublicdns$(Get-Random)" -Sku Standard
```

Create a network security group and a network security group rule

The network security group secures the virtual machine using inbound and outbound rules. In this case, an inbound rule is created for port 3389, which allows incoming remote desktop connections. We also want to create an inbound rule for port 80, which allows incoming web traffic.

PowerShell

```
# Create an inbound network security group rule for port 3389 - change -
Access to "Allow" if you want to allow RDP access
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name
myNetworkSecurityGroupRuleRDP  -Protocol Tcp `
    -Direction Inbound -Priority 1000 -SourceAddressPrefix * -
SourcePortRange * -DestinationAddressPrefix * `
    -DestinationPortRange 3389 -Access Deny

# Create an inbound network security group rule for port 80 - - change -
Access to "Allow" if you want to allow TCP traffic over port 80
$nsgRuleWeb = New-AzNetworkSecurityRuleConfig -Name
myNetworkSecurityGroupRuleWWW  -Protocol Tcp `
    -Direction Inbound -Priority 1001 -SourceAddressPrefix * -
SourcePortRange * -DestinationAddressPrefix * `
    -DestinationPortRange 80 -Access Deny

# Create a network security group
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName myResourceGroup -
Location eastus2 `
    -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP,$nsgRuleWeb
```

Create a network card for the virtual machine

Create a network card with New-AzNetworkInterface for the virtual machine. The network card connects the virtual machine to a subnet, network security group, and public IP address.

PowerShell

```
# Create a virtual network card and associate with public IP address and NSG
$nic = New-AzNetworkInterface -Name myNic -ResourceGroupName myResourceGroup
```

```
-Location eastus2 `
    -SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -
NetworkSecurityGroupId $nsg.Id
```

Create virtual machine

Create a virtual machine configuration. This configuration includes the settings that are used when deploying the virtual machine such as a virtual machine image, size, and authentication configuration. The *Standard_DS1_v2* size in this example is supported in availability zones. This configuration also specifies the availability zone you set when creating the IP address. When running this step, you are prompted for credentials. The values that you enter are configured as the user name and password for the virtual machine.

PowerShell

```
# Define a credential object
$cred = Get-Credential

# Create a virtual machine configuration
$vmConfig = New-AzVMConfig -VMName myVM -VMSize Standard_DS1_v2 -Zone 2 | `
    Set-AzVMOperatingSystem -Windows -ComputerName myVM -Credential $cred |
`
    Set-AzVMSourceImage -PublisherName MicrosoftWindowsServer -Offer
WindowsServer `
    -Skus 2016-Datacenter -Version latest | Add-AzVMNetworkInterface -Id
$nic.Id
```

Create the virtual machine with New-AzVM.

PowerShell

```
New-AzVM -ResourceGroupName myResourceGroup -Location eastus2 -VM $vmConfig
```

Confirm zone for managed disk

You created the VM's IP address resource in the same availability zone as the VM. The managed disk resource for the VM is created in the same availability zone. You can verify this with Get-AzDisk:

PowerShell

```
Get-AzDisk -ResourceGroupName myResourceGroup
```

The output shows that the managed disk is in the same availability zone as the VM:

```PowerShell
ResourceGroupName  : myResourceGroup
AccountType        : PremiumLRS
OwnerId            : /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroup/providers/Microsoft.
                     Compute/virtualMachines/myVM
ManagedBy          : /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx//resourceGroups/myResourceGroup/providers/Microsoft.
                     Compute/virtualMachines/myVM
Sku                : Microsoft.Azure.Management.Compute.Models.DiskSku
Zones              : {2}
TimeCreated        : 9/7/2017 6:57:26 PM
OsType             : Windows
CreationData       : Microsoft.Azure.Management.Compute.Models.CreationData
DiskSizeGB         : 127
EncryptionSettings :
ProvisioningState  : Succeeded
Id                 : /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroup/providers/Microsoft.

Compute/disks/myVM_OsDisk_1_bd921920bb0a4650becfc2d830000000
Name               : myVM_OsDisk_1_bd921920bb0a4650becfc2d830000000
Type               : Microsoft.Compute/disks
Location           : eastus2
Tags               : {}
```

Create virtual machines in an availability zone using the Azure portal

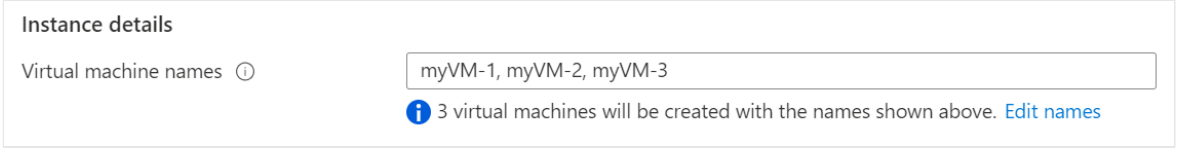
Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

This article steps through using the Azure portal to create highly resilient virtual machines in availability zones. Azure availability zones are physically separate locations within each Azure region that are tolerant to local failures. Use availability zones to protect your applications and data against unlikely datacenter failures.

To use availability zones, create your virtual machines in a supported Azure region.

1. Sign in to the Azure portal.
2. Click **Create a resource** > **Compute** > **Virtual machine**.
3. In the **Virtual machines** page, select **Create** and then **Virtual machine**. The **Create a virtual machine** page opens.
4. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected and then choose a resource group or create a new one.
5. Under **Instance details**, type a name for the **Virtual machine name**.
6. For **Availability options**, leave the default of **Availability zone**.
7. For **Availability zone**, the drop-down defaults to *Zone 1*. If you choose multiple zones, a new VM is created in each zone. For example, if you select all three zones, then three VMs are created. The VM names are the original name you entered, with **-1**, **-2**, and **-3** appended to the name based on number of zones selected. If you want, you can edit each of the default VM names.



8. Complete the rest of the page as usual. If you want to create a load balancer, go to the **Networking** tab > **Load Balancing** > **Load balancing options**. You can choose either an Azure load balancer or an Application gateway.

   For an **Azure load balancer**:
   a. You can select an existing load balancer or select **Create a load balancer**.

b. To create a new load balancer, for **Load balancer name** type a load balancer name.
c. Select the **Type** of load balancer, either *Public* or *Internal*.
d. Select the **Protocol**, either **TCP** or **UDP**.
e. You can leave the default **Port** and **Backend port**, or change them if needed. The backend port you select will be opened up on the Network Security Group (NSG) of the VM.
f. When you're done, select **Create**.

For an **Application Gateway**:

a. Select either an existing application gateway or **Create an application gateway**.
b. To create a new gateway, type the name for the application gateway. The Application Gateway can load balance multiple applications. Consider naming the Application Gateway according to the workloads you wish to load balance, rather than specific to the virtual machine name.
c. In **Routing rule**, type a rule name. The rule name should describe the workload you are load balancing.
d. For HTTP load balancing, you can leave the defaults and then select **Create**. For HTTPS load balancing, you have two options:

- Upload a certificate and add the password (application gateway manages certificate storage). For certificate name, type a friendly name for the certificate.
- Use a key vault (application gateway will pull a defined certificate from a defined key vault). Select your **Managed identity**, **Key Vault**, and **Certificate**.

> **ⓘ Important**
>
> After the VMs and application gateway are deployed, log in to the VMs to ensure that either the application gateway certificate is uploaded onto the VMs or the domain name of the VM certificate matches with the domain name of the application gateway.

> **ⓘ Note**
>
> A separate subnet will be defined for Application Gateway upon creation. For more information, see Application Gateway infrastructure configuration.

9. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.

10. On the **Create a virtual machine** page, you can see the details about the VM you are about to create. When you're ready, select **Create**.

11. If you are creating a Linux VM and the **Generate new key pair** window opens, select **Download private key and create resource**. Your key file will download as **myKey.pem**.

12. When the deployment is finished, select **Go to resource**.

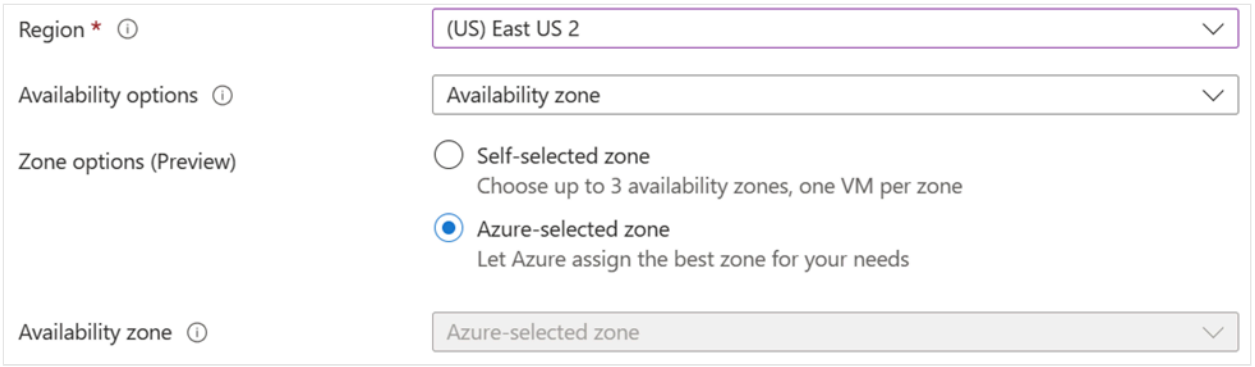
Create a Zonal Virtual Machine in an Azure-selected Zone

> **Important**
>
> These features are currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

If you would like the resiliency benefits of a Zonal Virtual Machine and want help with selecting a zone, you can have Azure select the best-fit zone for your deployment.

> **Note**
>
> Please review the Restrictions section before deploying your VM using an Azure-Selected Zone.

1. Sign in to the Azure portal using this link enabling the feature.
2. In the Basics tab, under Project details, make sure the correct subscription is selected and then choose a resource group or create a new one.
3. Under Instance details, type a name for the Virtual machine name.
4. For Availability options, Ensure Availability zone is selected.
5. For Zone options (Preview), select Azure-selected zone. The Availability zone selection should now be grayed out.
6. Configure the rest of your Virtual Machine as normal for deployment.



Restrictions

Regions

Deploying a VM into an Azure-selected zone is available in all Zonal Regions except the following regions.

- BrazilSouth
- CentralIndia
- EastUS
- JapanEast
- KoreaCentral

Disks

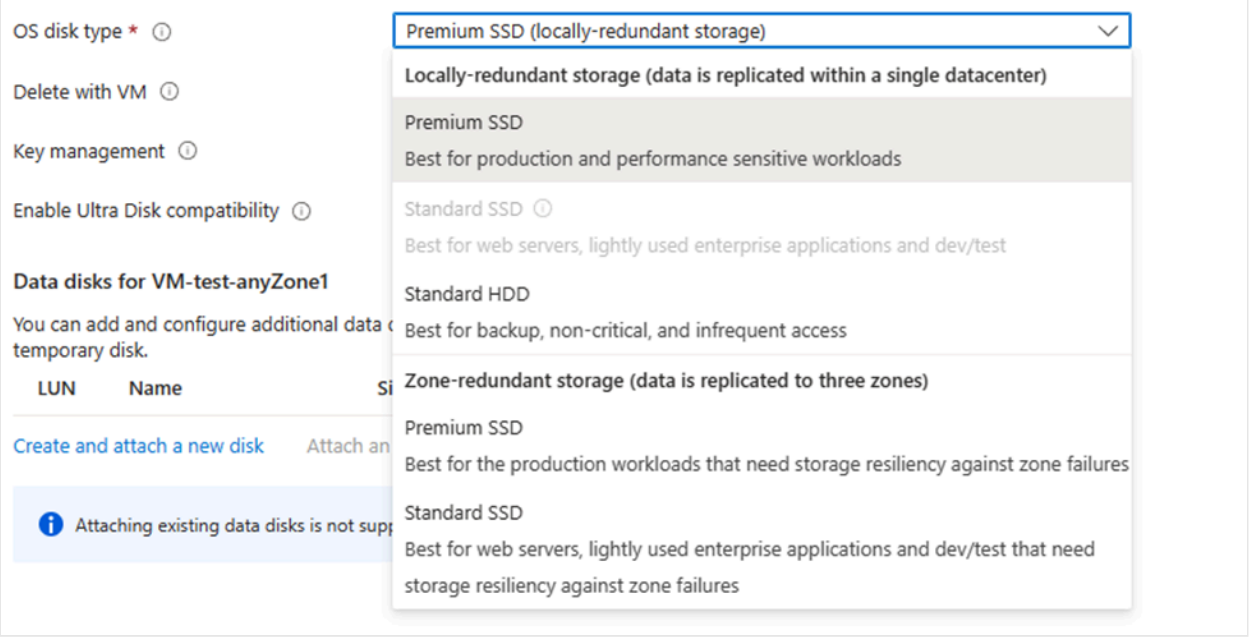
Existing OS and Data Disks are currently not supported. New Data Disk Source Type must be "none".

Supported Disk types

- Standard HDDs (hard disk drives)
- Premium SSDs
- Premium SSD V2
- Ultra Disks
- Standard SSD ZRS

Unsupported Disk types

- Standard SSD LRS



Other resources

- Existing Public IPs aren't supported for an Azure-selected zone. They can be added after deployment.
- New Public IPs must be Zone Redundant or use an Azure-Selected Zone.
- Load Balancers and Application Gateways must be Zonally Resilient to attach during the VM deployment.
- Proximity Placement Groups, Capacity Reservation Groups, and Azure Dedicated Host aren't supported.
- Site Recovery configuration isn't available during VM creation but can be configured after deployment.

Reliability in Azure Virtual Machines

Azure Virtual Machines provides on-demand, scalable compute resources. As a foundational infrastructure service, it's designed to deliver enterprise-grade reliability and availability for mission-critical workloads.

When you use Azure, reliability is a shared responsibility. Microsoft provides a range of capabilities to support resiliency and recovery. You're responsible for understanding how those capabilities work within all of the services you use, and selecting the capabilities you need to meet your business objectives and uptime goals.

This article describes how to make Virtual Machines resilient to a variety of potential outages and problems, including transient faults, availability zone outages, region outages, and service maintenance. It also describes how you can use backups to recover from other types of problems, and highlights some key information about the Virtual Machines service level agreement (SLA).

> **Important**
>
> When you consider the reliability of a virtual machine (VM), you also need to consider the reliability of your disks, network infrastructure, and applications that run on your VMs. Improving the resiliency of the VM alone might have limited impact if the other components aren't equally resilient. Depending on your resiliency requirements, you might need to make configuration changes across multiple areas.

Production deployment recommendations

For more information about how to deploy VMs to support your solution's reliability requirements and how reliability affects other aspects of your architecture, see Architecture best practices for Virtual Machines and scale sets in the Azure Well-Architected Framework.

Reliability architecture overview

VMs are the fundamental compute unit in Azure, whether you provision the VMs yourself or use other Azure compute services that transparently provision and manage them for you.

An individual VM is also known as a *single instance VM*. It runs on a specific host, which is a physical server. Most VMs share their host with other VMs.

When you create your VMs, you can influence where they run within the underlying infrastructure. Typically, you make placement decisions based on your requirements for reliability, latency, and isolation. Azure provides several configuration options that affect how your VMs are placed.

- **Region:** You can select which Azure region that your VM should run in. A region is a geographic area that might contain multiple datacenters, each with a large number of hosts.

- **Availability zone:** Availability zones are physically separate groups of datacenters within each Azure region. In regions that support availability zones, you can select which zone the VM runs in. For more information, see Resilience to availability zone failures.

- **Availability sets:** An availability set is a logical grouping of VMs that allows Azure to understand how your application is built to provide for redundancy and availability.

  When you use availability sets, Azure distributes a group of VMs across different fault domains. This distribution minimizes the risk of localized hardware failures by grouping VMs that share a common power source and network switch.

  Availability sets can also place different VMs in different update domains, which controls how the Azure platform rolls out platform updates. By using update domains, you can ensure that only a subset of your VMs is restarted for updates at one time.

- **Proximity placement groups:** For workloads that need to achieve the lowest possible latency between VMs, you can use a proximity placement group to ensure that Azure places the VMs physically close to each other. However, proximity placement means that an outage of the datacenter can affect all of the VMs in the group. To achieve high reliability, you might need to provision multiple proximity placement groups in different availability zones.

- **Dedicated hosts:** You can use Azure Dedicated Host to provision your own physical server that runs one or more VMs, such as for strict compliance requirements. However, when you provision a dedicated host, an outage in its datacenter can affect all of the VMs on that host. To achieve high reliability, you might need to provision multiple dedicated hosts in different availability zones.

If you create a set of VMs that perform similar functions, consider using Azure Virtual Machine Scale Sets to create and manage the VMs as a group. Scale sets also provide more reliability options, such as spreading the VMs across multiple availability zones.

For more information about availability for VMs, see Availability options for Virtual Machines.

Resilience to transient faults

Transient faults are short, intermittent failures in components. They occur frequently in a distributed environment like the cloud, and they're a normal part of operations. Transient faults correct themselves after a short period of time. It's important that your applications can handle transient faults, usually by retrying affected requests.

All cloud-hosted applications should follow the Azure transient fault handling guidance when they communicate with any cloud-hosted APIs, databases, and other components. For more information, see Recommendations for handling transient faults.

Applications that run on your VMs should implement appropriate fault-handling strategies to ensure that any temporary interruptions in service don't affect your workload.

Resilience to availability zone failures

Availability zones are physically separate groups of datacenters within an Azure region. When one zone fails, services can fail over to one of the remaining zones.

An individual VM can be deployed in a *zonal* configuration, which means that it's pinned to a single availability zone that you select. By itself, a zonal VM isn't resilient to zone outages. However, you can create multiple VMs and place them in different availability zones, then spread your applications and data across the VM instances. Alternatively, you can use virtual machine scale sets to deploy a set of VMs across multiple availability zones.

If you don't configure a VM to be zonal, it's considered *nonzonal* or *regional*. Nonzonal VMs might be placed in any availability zone within the region. If any availability zone in the region experiences an outage, nonzonal VMs might be in the affected zone and can experience downtime.

Requirements

Region support: Zonal VMs can be deployed into any region that supports availability zones.

However, some VM types and sizes are only available in specific regions, or specific zones within a region. To check which regions and zones support the VM types that you need, use the following resources:

- To check the VM types available in each region, see Products available by region.
- To check the supported VM types and sizes within each zone of a specific region, see Check VM SKU availability.

Cost

There's no cost difference between a zonal and nonzonal VM.

Configure availability zone support

This section explains how to configure availability zone support for your VM instance.

> **Note**
>
> When you select which availability zones to use, you're actually selecting the *logical availability zone*. If you deploy other workload components in a different Azure subscription, they might use a different logical availability zone number to access the same physical availability zone. For more information, see Physical and logical availability zones.

- **Create a zonal VM.** You can create a zonal VM by using the following guides:
  - Create VMs in an availability zone by using the Azure portal
  - Create a VM in an availability zone by using the Azure CLI
  - Create a VM in an availability zone by using Azure PowerShell
- **Convert existing VMs to a zonal configuration.** You can move from a nonzonal VM to a zonal VM. This process creates a new VM in the target availability zone and requires that the VM be stopped during the move process. For more information, see Move Azure single instance VMs from regional to zonal target availability zones.
- **Change the availability zone of an existing zonal VM.** Zonal VMs can't be moved to a different availability zone. You need to deploy a new zonal VM in the desired availability zone instead.

- **Convert a zonal VM to a nonzonal configuration.** Zonal VMs can't be converted to a nonzonal configuration. You need to deploy a new nonzonal VM instead.

Behavior when all zones are healthy

This section describes what to expect when VM instances are configured with availability zone support and all availability zones are operational.

- **Traffic routing between zones:** You're responsible for routing traffic between VMs, including VMs that are in different availability zones. Common approaches include Azure Load Balancer and Azure Application Gateway. For more information, see Load balancing options.

- **Data replication between zones:** You're responsible for any data replication that needs to happen between VMs, including across VMs in different availability zones. Databases and other similar stateful applications that run on VMs often provide capabilities to replicate data.

Behavior during a zone failure

This section describes what to expect when VM instances are configured with availability zone support and there's an outage in their availability zones.

- **Detection and response:** You're responsible for detecting and responding to zone failures that affect your VMs.

- **Notification**: Microsoft doesn't automatically notify you when a zone is down. However, you can use Azure Resource Health to monitor for the health of an individual resource, and you can set up Resource Health alerts to notify you of problems. You can also use Azure Service Health to understand the overall health of the service, including any zone failures, and you can set up Service Health alerts to notify you of problems.

- **Active requests:** Any active requests or other work that occurs on the VM during the zone failure are likely to be terminated.

- **Expected data loss:** Zonal LRS disks might be unavailable during a zone failure.

  If you use zone-redundant storage (ZRS) disks and an outage affects your VM, you can force detach your ZRS disks from the failed VM. This approach allows you to attach the ZRS disks to another VM.

For more information about how to make disks resilient to availability zone failures and other problems, see Reliability in Azure Disk Storage.

- **Expected downtime:** VMs remain down until the availability zone recovers.
- **Traffic rerouting:** You're responsible for rerouting traffic to other VMs in healthy zones.

  If you configure a zone-resilient load balancer and it performs health checks, the load balancer typically detects failed VMs and can route traffic to other VM instances in healthy zones.

Zone recovery

When the zone is healthy, VMs in the zone restart. You're responsible for any zone recovery procedures and data synchronization that your workloads require.

Test for zone failures

You can use Azure Chaos Studio to simulate the loss of a VM as part of an experiment. Chaos Studio provides built-in faults for VMs, including the ability to shut down a VM. You can use these capabilities to simulate zone-level failures and test your failover processes.

Custom multi-zone solutions for resiliency

When you deploy multiple VMs into different zones, you're responsible for configuring and managing replication, load balancing, failover, and failback processes.

Some applications provide built-in capabilities that can help when you deploy across multiple VMs. For example, SQL Server on Azure VMs provides a set of capabilities to simplify your configuration and management processes across availability zones.

You can consider using Azure Site Recovery zone-to-zone disaster recovery (DR) when your application runs in a single zone at a time and you don't require near-instant failover between zones. Zone-to-zone DR has some important limitations, so review your requirements thoroughly.

Resilience to region-wide failures

VMs are single-region resources. If the region becomes unavailable, your VM is also unavailable.

Custom multi-region solutions for resiliency

You can deploy multiple VMs into different regions, but you need to implement replication, load balancing, and failover processes.

Site Recovery is a service that enables DR by replicating VMs and their data to a secondary region. You can select almost any Azure region as your secondary region, including nonpaired region combinations. For more information, see Azure to Azure DR architecture.

Some applications create clusters or other constructs to replicate data and distribute work across multiple VMs, including in different regions. These applications can simplify the configuration of a multi-region solution.

For an example architecture that illustrates using VMs across multiple regions, see Multi-region load balancing with Azure Traffic Manager, Azure Firewall, and Application Gateway.

Resilience to service maintenance

Azure performs regular periodic maintenance on VMs to ensure reliability. There are multiple ways that you can ensure your workloads remain operational during maintenance activities:

- When you use availability sets or virtual machine scale sets, you can configure update domains. Update domains help distribute maintenance activities across different VMs at different times, so your VMs don't all restart simultaneously.
- You can customize the timing that maintenance is applied to your VMs by using *maintenance control*. You can use maintenance configurations to schedule it at a time that suits your workload.
- You can receive notifications of upcoming maintenance activities.

For more information, see Guest updates and host maintenance overview.

Backup and restore

Azure Backup provides native backup support for VMs. Azure Backup creates and manages backups, and provides application-consistent protection for the entire VM, including all attached disks. A VM backup solution with Azure Backup is ideal when you need coordinated backup of multiple disks or application-aware backups. However, for database workloads, consider application-specific backup solutions that provide transaction-consistent protection and faster recovery options.

With Azure Backup for VMs, you can customize the backup frequency, retention duration, and storage configuration to suit your needs. For more information, see Azure Backup for VMs.

Backup also supports disks that are attached to VMs. For more information, see Overview of Azure Disk Backup.

For most solutions, you shouldn't rely exclusively on backups. Instead, use the other capabilities described in this guide to support your resiliency requirements. However, backups protect against some risks that other approaches don't. For more information, see What are redundancy, replication, and backup?.

Service-level agreement

The service-level agreement (SLA) for Azure services describes the expected availability of each service and the conditions that your solution must meet to achieve that availability expectation. For more information, see SLAs for online services.

For Virtual Machines, the SLA provides a base level of availability. The uptime percentage defined in the SLA increases when you have two or more VMs and you take the following actions:

- Configure those VMs to be deployed across two or more availability zones.
- Configure those VMs to be deployed into an availability set.

Move Azure single-instance virtual machines from regional to zonal availability

This article explains how to move a single-instance Azure virtual machine (VM) from a regional deployment to a zonal deployment in the same Azure region.

Prerequisites

Before you begin, verify the following:

- **Availability Zone support**: Confirm that your target region supports Availability Zones. Learn more.
- **VM SKU availability**: VM size (SKU) availability can vary by region and zone. Check SKU availability before you start. Learn more.
- **Subscription permissions**: Verify that you have *Owner* access to the subscription that contains the VMs you want to move. The first time you move a VM to a zonal deployment, Azure requires a trusted system-assigned managed identity. The account you use must have Owner permissions so Azure can create the identity and assign the required role (Contributor or User Access Administrator) in the source subscription. Learn more.
- **VM support**: Confirm that the VM configuration is supported for this move workflow. Learn more.
- **Subscription quota**: Ensure the subscription has enough quota to create the target zonal VM and related networking resources. If needed, request additional limits.
- **Regional or zonal capacity**: Quota approval doesn't guarantee that capacity is available in the target zone. If the move validation reports capacity constraints, select a different target zone or VM size.
- **VM health**: Ensure the VM is healthy and that required reboots or mandatory updates are complete.

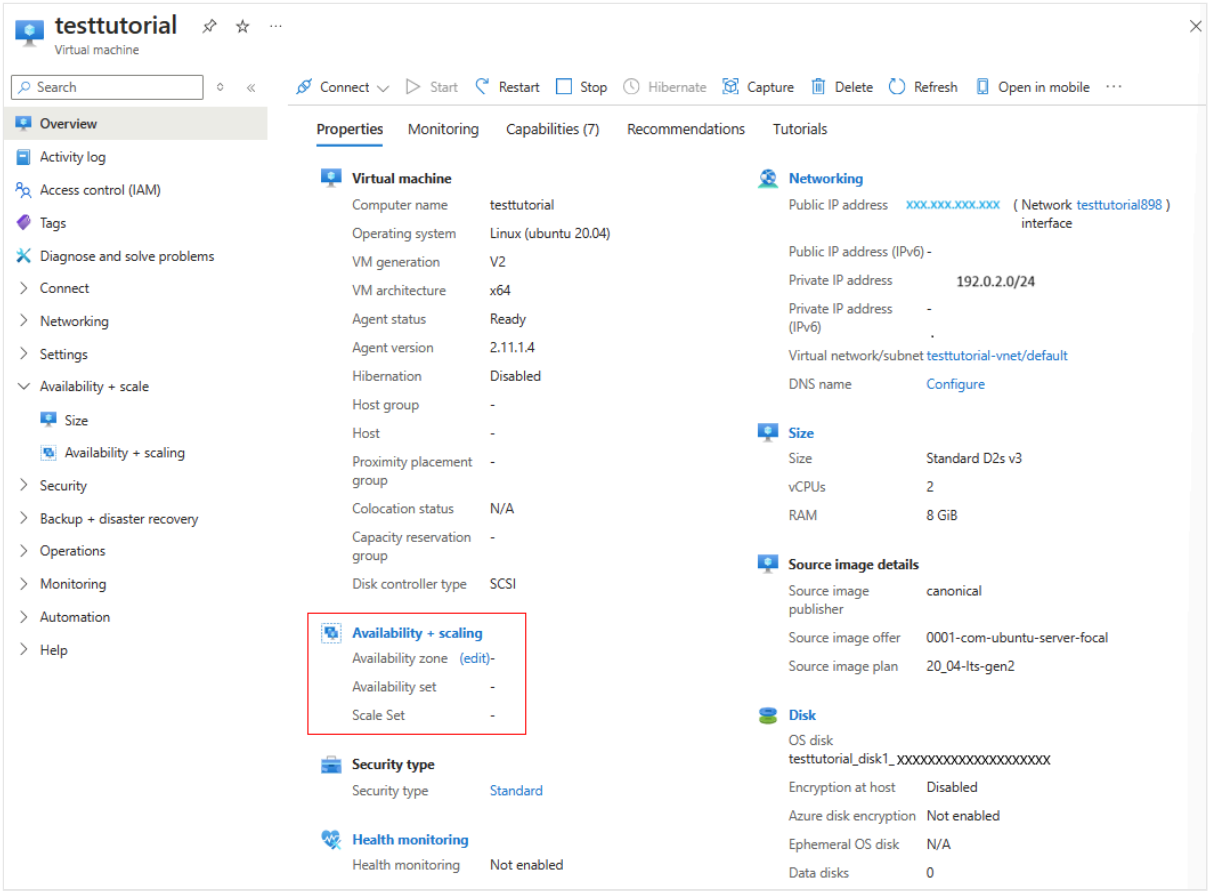
Select and move VMs

Choose a tool to move a VM from regional to zonal deployment in the same region.

Portal

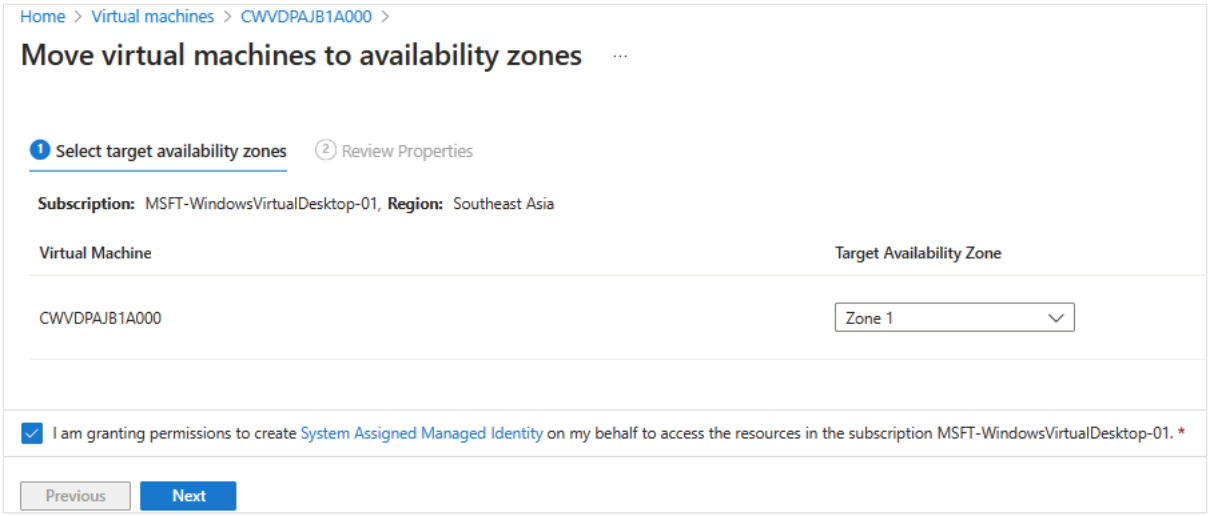
Portal: Select the VM

1. In the Azure portal, go to your VM.
2. In the VM overview, select **Availability + scaling** > **Edit**.



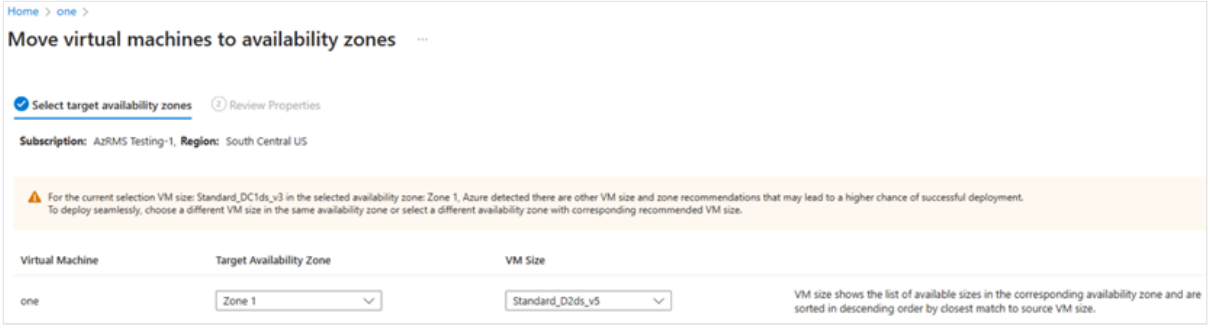
Portal: Select the target availability zone

1. Under **Target availability zone**, select the zone you want to use (for example, Zone 1).



If the selected VM configuration isn't supported for move, validation fails and you must restart with a supported VM configuration. See the support matrix.

2. If Azure recommends a different VM size to improve deployment success in the selected zone, choose the recommended size, or choose a different zone and keep the current size.



3. Select the consent statement for the **System Assigned Managed Identity** process, then select **Next**.

The managed identity setup can take a few minutes. Progress updates are shown in the portal.

Portal: Review VM properties before move

On **Review properties**, review the target VM configuration.

The following source VM properties are retained by default in the target zonal VM:

Expand table

Property	Description
VM name	The source VM name is retained in the target zonal VM.

Property	Description
Virtual network/subnet	The source virtual network (VNET) and subnet are retained, and the target zonal VM is created in the same VNET and subnet by default. You can also select or create a different VNET and subnet.
Network Security Group (NSG)	The source NSG is retained by default. You can select or create a different NSG.
Load balancer (Standard SKU)	Standard SKU load balancers support zonal deployment and are retained.
Public IP (Standard SKU)	Standard SKU public IP addresses support zonal deployment and are retained.

The following properties are newly created by default in the target zonal VM as needed:

Expand table

Property	Description
VM	A copy of the source VM is created in the target zonal configuration. The source VM remains intact and is stopped after the move. Source VM ARM ID isn't retained.
Resource group	A new resource group is created by default. The source resource group can't be reused when the target VM uses the same name in the same region. You can select an existing target resource group.
NIC	A new NIC is created for the target zonal VM. The source NIC remains intact and is stopped after move. Source NIC ARM ID isn't retained.
Disks	New disks are created in the target zonal configuration and attached to the new zonal VM.
Load balancer (Basic SKU)	Basic SKU load balancers don't support zonal deployment and aren't retained. A new Standard SKU load balancer is created by default. You can edit this or select an existing target load balancer.
Public IP (Basic SKU)	Basic SKU public IP addresses don't support zonal deployment and aren't retained. A new Standard SKU public IP is created by default. You can edit this or select an existing target public IP.

After reviewing the target configuration:

1. Resolve any validation errors.
2. Select the consent statement at the bottom of the page to show you understand that the source VM(s) will be stopped during the process.

3. Select **Move** to complete the move.

During the move:

- The source VM is **stopped**, so brief downtime occurs.
- A target zonal VM is created and started.

Configure settings after move

- Review source VM settings and reconfigure as needed (for example, extensions, RBAC, Public IP configuration, backup, and disaster recovery settings).
- After move completion, the source VM remains stopped. You can delete it or keep it for another purpose.
- After the move, you can manually delete the move collection. To remove the move collection:

    1. Enable hidden resources (the move collection is hidden by default).
    2. Go to the move collection resource group by searching for *ZonalMove-MC-RG-SourceRegion*.
    3. Delete the move collection (for example, *ZonalMove-MC-RG-UKSouth*).

Delete source regional VMs

After you commit the move and verify that the resources work as expected in the target region, you can delete each source resource using:

- Azure portal
- PowerShell
- Azure CLI

Frequently asked questions - Move Azure single instance virtual machines from regional to zonal target availability zones

Article • 08/22/2024

This article answers common questions about Azure single instance virtual machines - regional to zonal move.

Regional to zonal move

Can I move virtual machine(s) in all Azure regions?

Currently, you can move virtual machine(s) across all public regions that are supported by Availability Zones. Learn more about the availability zone service and regional support.

> **Note**
>
> Azure China (China North 3) and Azure Govt (US Gov Virginia) are also supported.

Where is the metadata stored?

The service doesn't retain any customer data, and all data remains within the source virtual machine region. The following table shows the mapping between the virtual machine region and metadata region:

Expand table

Region group	Region	Metadata region
Americas	eastus2	eastus2
	eastus	eastus2
	westus2	eastus2
	southcentralus	eastus2

Region group	Region	Metadata region
	brazilsouth	brazilsouth
	canadacentral	canadacentral
	westus3	eastus2
Europe	northeurope	northeurope
	westeurope	northeurope
	uksouth	uksouth
	francecentral	francecentral
	switzerlandnorth	switzerlandnorth
	germanywestcentral	germanywestcentral
	norwayeast	norwayeast
	swedencentral	swedencentral
	polandcentral	polandcentral
	spaincentral	northeurope
	italynorth	northeurope
Middle East	uaenorth	uaenorth
	qatarcentral	qatarcentral
Asia Pacific	japaneast	japaneast
	eastasia	southeastasia
	southeastasia	southeastasia
	australiaeast	australiaeast
	centralindia	centralindia
	koreacentral	koreacentral
Africa	southafricanorth	southeastasia

Is the collected metadata encrypted?

Yes, the collected metadata is encrypted both during transit and at rest. While in transit, the metadata is securely sent to the Resource Mover service over the internet using HTTPS. The metadata is also encrypted while in storage.

What resources are supported for this Zonal Move?

Currently, managed disks are supported for virtual machines that only have a single instance.

What source resources can be used in the target zonal configuration, if preferred?

The following resources can be used in the target zonal configuration:

- Networking resources such as VNET, Subnet, and NSG can be reused.
- Public IP address (Standard SKU)
- Load Balancers (Standard SKU)

What resources are created new by default in the target zonal configuration?

The following resources are created in the target zonal configuration:

- **Resource group**: By default, a new resource group is automatically created. The source resource group can't be used, as we're using the same source virtual machine name in the target zone and two identical virtual machines can't coexist in the same resource group. However, you can still modify the properties of the new resource group or choose a different target resource group.
- **Virtual machine**: A copy of the source virtual machine is created in the target zonal configuration. The source virtual machine remains unchanged and is stopped after the transfer.
- **Disks**: The disks attached to the source virtual machine are recreated in the target zonal configuration.
- **NIC**: A new network interface card (NIC) is produced and linked to the newly created virtual machine in the designated zone.

What permissions do I need to use managed identity?

To use the managed identity service, you must have the following permissions:

- Permission to write or create resources in your subscription (which is available with the *Contributor* role).
- Permission to create role assignments (which is available with the *Owner* or *User Access Administrator* roles, or, custom roles that have the Microsoft.Authorization or role assignments or write permission assigned). This permission isn't required if the data share resource's managed identity has already been granted access to the Azure data store.

When adding resources in the portal, permissions to use managed identity are handled automatically as long as you have the appropriate role assignments.

> **Important**
>
> We recommend that you don't modify or remove identity role assignments.

What if I don't have permissions to assign role identity?

There are a couple of reasons you might not have the permissions. Consider the following scenarios:

Expand table

Scenario	Resolution
You don't have Contributor and User Access Administrator (or Owner) permissions when you add a resource for the first time.	Use an account with Contributor and User Access Administrator (or Owner) permissions for the subscription.
The Resource Mover managed identity doesn't have the necessary role.	Add the Contributor and User Access Administrator roles.

How is managed identity used?

Managed identity previously known as Managed Service Identity (MSI), is a feature that provides Azure services with an automatically managed identity in Microsoft Entra ID. This identity is used to access Azure subscriptions and perform various tasks, such as moving resources to Availability Zones.

- Managed identity is used so that you can access Azure subscriptions to move resources to availability zones.
- To move resources using a move collection, you need a system-assigned identity that has access to the subscription containing the resources you want to move.

- If you're using the Azure portal to move the virtual machines, this process is automated once the user consent is provided. The process typically takes a few minutes to complete.

Can I move my resources from Regional to Zonal and across subscriptions?

You can use virtual machine Regional to Zonal Move capability to move virtual machines from a regional to a zonal deployment within the same subscription and then use Azure Resource Manager to move them across subscriptions.

Are Azure Backup/DR, RBAC, Tags, Policies, and extensions on virtual machines supported?

Only tags and user assigned managed identities are replicated to the target zones. RBAC, policies and extensions must be reconfigured after the move. See the support matrix for further details.

Is customer data stored during the move?

Customer data isn't stored during the move. The system only stores metadata information that helps track and monitor the progress of the resources being moved.

What happens to the source virtual machine(s)?

When you select **Move**, the following steps are performed on the source virtual machines:

1. The source virtual machines are stopped and left intact in their original configuration.

   > ⓘ **Note**
   >
   > Stopping the VMs could lead to a brief downtime.

2. Virtual machine restore points of the source virtual machine are taken. These restore points contain a disk restore point for each of the attached disks and a disk restore point consists of a snapshot of an individual managed disk.
3. Using these restore points, a new virtual machine with its associated disks (a copy of the source VM) is created in the zonal configuration.
4. After the move is complete, you can choose to delete the source virtual machines.

Is there any cost associated as part of this move?

The Zonal Move feature of virtual machines is offered free of cost, but you may incur cost of goods for the creation of disk snapshots or restore points.

> **Note**
>
> The snapshot of virtual machine or disks is automatically deleted after the move is complete.

Can I retain my Public IP of the source virtual machine?

Review the following scenarios where you can or can't retain Public IP addresses associated with the source virtual machine.

Expand table

Source Property	Description
Public IP addresses (Basic SKU) attached to source virtual machine NIC	The source public IP address isn't retained. The source public IP SKU doesn't support target zonal configuration. By default, a copy of the source virtual machine and a new network interface card (NIC) is created. The source virtual machine and NIC are left intact after the move and the source virtual machine will be in a shutdown state.
Public IP addresses (Standard SKU) attached to source virtual machine NIC	The source Public IP address isn't retained. A new NIC and a copy of the source virtual machine (VM) is created, and both the source virtual machine and NIC will remain intact after the move. However, the virtual machine will be in a shutdown state. **Note**: After the move, if you wish, you can separate the source public IP from the source NIC and connect it to a new target zonal virtual machine NIC.
Public IP address (Basic SKU) attached to Load Balancer (Basic SKU)	The source public IP address isn't retained. Source Public IP SKU doesn't support target zonal configuration.
Public IP address (Standard SKU) with Non-Zonal configuration	Source Public IP address is retained.

Source Property	Description
attached to Load Balancer (Standard SKU)	
Public IP address (Standard SKU) with Zone pined configuration attached to Load Balancer (Standard SKU)	Source Public IP address will be retained. **Note:** The target virtual machine zone# might not be the same as the zone pinned Public IP.
Public IP address (Standard SKU) with Zone redundant configuration attached to Load Balancer (Standard SKU)	Source Public IP address is retained.

What are Virtual Machine Scale Sets?

Azure Virtual Machine Scale Sets let you create and manage a group of load balanced virtual machines (VM) instances. The number of VM instances can automatically increase or decrease in response to demand or a defined schedule. Scale sets provide the following key benefits:

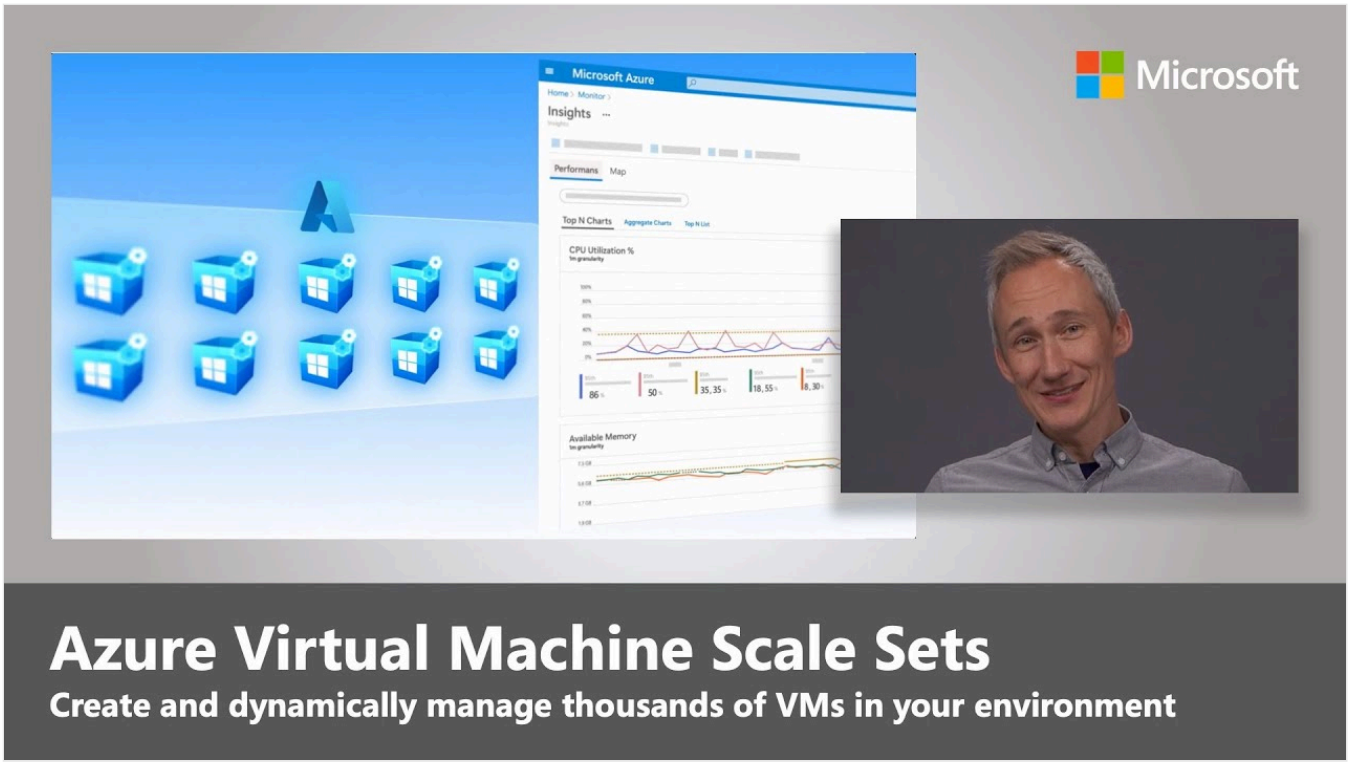
- Easy to create and manage multiple VMs
- Provides high availability and application resiliency by distributing VMs across availability zones or fault domains
- Allows your application to automatically scale as resource demand changes
- Works at large-scale

With Flexible orchestration, Azure provides a unified experience across the Azure VM ecosystem. Flexible orchestration offers high availability guarantees (up to 1,000 VMs) by spreading VMs across fault domains in a region or within an Availability Zone. This enables you to scale out your application while maintaining fault domain isolation that is essential to run workloads, including:

- Quorum-based workloads
- Open-source databases
- Stateful applications
- Services that require high availability and large scale
- Services that want to mix virtual machine types or use Spot and on-demand VMs together
- Existing Availability Set applications

Learn more about the differences between Uniform scale sets and Flexible scale sets in Orchestration Modes.

> ⓘ **Important**
>
> The orchestration mode is defined when you create the scale set and cannot be changed or updated later.



Why use Virtual Machine Scale Sets?

To provide redundancy and improved performance, applications are typically distributed across multiple instances. Customers may access your application through a load balancer that distributes requests to one of the application instances. If you need to perform maintenance or update an application instance, your customers must be distributed to another available application instance. To keep up with extra customer demand, you may need to increase the number of application instances that run your application.

Azure Virtual Machine Scale Sets provide the management capabilities for applications that run across many VMs, automatic scaling of resources, and load balancing of traffic. Scale sets provide the following key benefits:

- **Easy to create and manage multiple VMs**
  - When you have many VMs that run your application, it's important to maintain a consistent configuration across your environment. For reliable performance of your application, the VM size, disk configuration, and application installs should match across all VMs.
  - With scale sets, all VM instances are created from the same base OS image and configuration. This approach lets you easily manage hundreds of VMs without extra configuration tasks or network management.
  - Scale sets support the use of the Azure load balancer for basic layer-4 traffic distribution, and Azure Application Gateway for more advanced layer-7 traffic distribution and TLS termination.

- **Provides high availability and application resiliency**
  - Scale sets are used to run multiple instances of your application. If one of these VM instances has a problem, customers continue to access your application through one of the other VM instances with minimal interruption.
  - For more availability, you can use Availability Zones to automatically distribute VM instances in a scale set within a single datacenter or across multiple datacenters. A scale set alone can't protect you against data center failures. Deploying VMs across Availability Zones within a scale set can protect you against data center failure.

- **Allows your application to automatically scale as resource demand changes**
  - Customer demand for your application may change throughout the day or week. To match customer demand, scale sets can automatically increase the number of VM instances as application demand increases, then reduce the number of VM instances as demand decreases.
  - Autoscale helps reduce the number of unnecessary VMs when demand is low. As demand increases, the scale set automatically adds more VMs to maintain an acceptable level of performance for your application. This ability helps reduce costs and efficiently create Azure resources as required.

- **Works at large-scale**
  - Scale sets support up to 1,000 VM instances for standard marketplace images and custom images through the Azure Compute Gallery (formerly known as Shared Image Gallery). If you create a scale set using a managed image, the limit is 600 VM instances.
  - For the best performance with production workloads, use Azure managed disks.

- **Cost-effective service**
  - There's no extra cost for using scale sets. You're charged based on the compute, network, and storage resources that the scale set uses.
  - For virtual machine pricing information, see Azure pricing.

Next steps

Flexible orchestration mode for your scale sets with Azure portal.

Last updated on 03/21/2025

Scaling profile

Article • 01/10/2025

Virtual machine scale sets allow you to define a scaling profile or template, which specifies the properties of virtual machine instances. Examples of properties set in the virtual machine scaling profile include:

- VM Image
- Admin credentials
- Network interface settings
- Load balancer backend pool
- OS and Data disk settings

When you increase the capacity or instance count of the scale set, the scale set will add new virtual machines to the set based on the configuration defined in the profile. Scale sets with scaling profile are also eligible for orchestrations such as reimaging, rolling upgrades, instance repair, and automatic OS updates.

> **Important**
>
> Virtual machine scaling profile settings are required for scale sets in Uniform Orchestration Mode, and optional for scale sets in Flexible Orchestration Mode.

Create a scale set with a scaling profile

By default, scale sets are created with a virtual machine scaling profile. See Create an Azure Virtual Machine and Create and manage Azure Virtual Machines for examples.

Create a scale set without a scaling profile

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Virtual machine scale sets in Flexible Orchestration Mode can optionally be created without a virtual machine scaling profile. This configuration is similar to creating and deploying an Availability Set in that you add to the set by manually creating virtual machine instances and adding them to the set. It's useful to create a scale set without a scaling profile when:

- You need complete control over all VM properties.
- You need to follow your own VM naming conventions.
- You want to add different types of VMs to the same scale set.
- You need to control the placement of virtual machines into a specific availability zone or fault domain.

Expand table

Feature	Virtual machine scale sets (no scaling profile)	Availability Sets
Maximum capacity	1000	200
Supports Availability Zones	Yes	No
Maximum Aligned Fault Domains Count	3	3
Add new VM to set	Yes	Yes
Add VM to specific fault domain	Yes	No
Maximum Update Domain count	N/A. Update domains are deprecated	20

Once you have created the virtual machine scale set, you can manually attach virtual machines.

Azure portal

1. Navigate to the **Create a Virtual Machine Scale Set (VMSS)** blade.
2. Set your resource group, scale set name, region, availability zone, and orchestration mode.
3. In the **Scaling** section, select **No scaling profile**.
4. Complete the **Advanced** and **Tags** section before selecting the **Review + create** button.

Next steps

- Create a new Virtual Machine Scale Set with a scale profile using the Azure portal.
- If you have created a virtual machine scale set without a scaling profile, you can manually attach a virtual machine.

Attach or detach a Virtual Machine to or from a Virtual Machine Scale Set

Article • 04/23/2025

Attaching a Virtual Machine to a Virtual Machine Scale Set

> **Important**
>
> You can only attach Virtual Machines to a Virtual Machine Scale Set in **Flexible orchestration mode**. For more information, see Orchestration modes for Virtual Machine Scale Sets.

There are times where you need to attach a virtual machine (VM) to a Virtual Machine Scale Set to benefit from the scale, availability, and flexibility that comes with scale sets. There are two ways to attach VMs to scale sets: manually create a new standalone VM in the scale set or attach an existing VM to the scale set.

You can attach a new standalone VM to a scale set when you need a different configuration on a specific VM than what's defined in the scaling profile, or when the scale set doesn't have a scaling profile. Manually attaching VMs gives you full control over instance naming and placement into a specific availability zone or fault domain. The VM doesn't have to match the configuration in the scale set's scaling profile, so you can specify parameters like operating system, networking configuration, on-demand or Spot, and VM size.

You can attach an existing VM to an existing Virtual Machine Scale Set by specifying which scale set you would like to attach to. The VM doesn't have to be the same as the VMs already running in the scale set, meaning it can have a different operating system, network configuration, priority, disk, and more.

Attach a new Virtual Machine to a Virtual Machine Scale Set

Attach a virtual machine to a Virtual Machine Scale Set at the time of VM creation by specifying the `virtualMachineScaleSet` property.

> **Note**
>
> Attaching a virtual machine to Virtual Machine Scale Set doesn't by itself update any VM networking parameters such as load balancers. If you would like this virtual machine to receive traffic from any load balancer, you must manually configure the VM network interface to receive traffic from the load balancer. Learn more about Load balancers.

Azure portal

1. Go to **Virtual Machines**.
2. Select **Create**.
3. Select **Azure virtual machine**.
4. In the **Basics** tab, open the **Availability options** dropdown and select **Virtual Machine Scale Set**.
5. In the **Virtual Machine Scale Set** dropdown, select the scale set to which you want to add this virtual machine.
6. Optionally, specify the Availability zone or Fault domain to place the VM.

Exceptions to attaching a new Virtual Machine to a Virtual Machine Scale Set

- The VM must be in the same resource group as the scale set.
- Regional virtual machines (no availability zones specified) can be attached to regional scale sets.
- Zonal virtual machines can be attached to scale sets that specify one or more zone. The virtual machine must be in one of the zones spanned by the scale set. For example, you can't create a virtual machine in Zone 1, and place it in a scale set that spans Zones 2 and 3.
- The scale set must be in Flexible orchestration mode, and the `singlePlacementGroup` property must be `false`.

Attach an existing Virtual Machine to a Virtual Machine Scale Set

Attach an existing virtual machine to a Virtual Machine Scale Set after the time of VM creation by specifying the `virtualMachineScaleSet` property. Attaching an existing VM to a scale set with a fault domain count of 1 doesn't require downtime.

> **Note**
>
> Attaching a virtual machine to Virtual Machine Scale Set doesn't by itself update any VM networking parameters such as load balancers. If you would like this virtual machine to receive traffic from any load balancer, you must manually configure the VM network interface to receive traffic from the load balancer. Learn more about Load balancers.

Azure portal

1. Go to **Virtual Machines**.
2. Select the name of the virtual machine you'd like to attach to your scale set.
3. Under **Settings** select **Availability + scaling**.

4. In the **Scaling** section, select the **Get started** button. If the button is grayed out, your VM currently doesn't meet the requirements to be attached to a scale set.
5. In the **Attach to a VMSS** blade on the right side of the page, select the scale set you'd like to attach the VM to in the **Select a VMSS** dropdown.
6. Select the **Attach** button at the bottom to attach the VM.

Limitations for attaching an existing Virtual Machine to a scale set

- The scale set must use Flexible orchestration mode.
- The scale set must have a `platformFaultDomainCount` of **1**.
- The VM and scale set must be in the same resource group.
- The VM and target scale set must both be zonal, or they must both be regional. You can't attach a zonal VM to a regional scale set.
- The VM can't be in a self-defined availability set.
- The VM can't be in a `ProximityPlacementGroup`.
- The VM can't be in an Azure Dedicated Host.
- The VM must have a managed disk.
- The scale set must have `singlePlacementGroup` set to `False`.
- Scale sets created without a scaling profile default to `singlePlacementGroup` set to `null`. To attach VMs to a scale set without a scaling profile, `singlePlacementGroup` needs to be set to `False` at the time of the scale set's creation.
- The VM can't be a Remote Direct Memory Access (RDMA) capable HB-series or N-series VM (Preview feature).

Detaching a Virtual Machine from a Virtual Machine Scale Set

Should you need to detach a VM from a scale set, you can follow the below steps to remove the VM from the scale set.

Azure portal

1. Go to **Virtual Machines**.
2. Select the name of the virtual machine you'd like to attach to your scale set.
3. Under **Settings** select **Availability + scaling**.
4. Select the **Detach from the VMSS** button at the top of the page.
5. When prompted to confirm, select the **Detach** button.
6. Portal sends a notification when the VM is detached.

Limitations for detaching a Virtual Machine from a scale set

- The scale set must use Flexible orchestration mode.
- The scale set must have a `platformFaultDomainCount` of **1**.
- Scale sets created without a scaling profile default to `singlePlacementGroup` set to `null`. To detach VMs from a scale set without a scaling profile, `singlePlacementGroup` needs to be set to `False`.
- The VM can't be an RDMA capable HB-series or N-series VM (Preview feature).

Moving Virtual Machines between scale sets

To move a VM from one scale set to another, use the following steps:

1. Detach the VM from scale set A.
2. Once the detach completes, attach the VM to scale set B.

Limitations

The limitations for VMs to be attached or detached to or from a scale set remain the same.

Standby pools for Virtual Machine Scale Sets

Article • 05/12/2025

> **Important**
>
> For standby pools to successfully create and manage resources, it requires access to the associated resources in your subscription. Ensure the correct permissions are assigned to the standby pool resource provider in order for your standby pool to function properly. For detailed instructions, see configure role permissions for standby pools.

Standby pools for Virtual Machine Scale Sets enables you to increase scaling performance by creating a pool of pre-provisioned virtual machines. The virtual machines in the standby pool complete all post provisioning processes such as installing applications, downloading data packages, etc. Once the virtual machines are fully provisioned, they are be maintained in a running, stopped (deallocated), or hibernated (preview) state. When your scale set requires more instances, the instances in the standby pool are automatically moved into the scale set. A standby pool significantly reduces the time it takes to scale-out a Virtual Machine Scale Set.

If maintaining a standby pool of running virtual machines, the machines are immediately ready to receive traffic after being moved into the scale set. If maintaining a standby pool of stopped (deallocated) or hibernated virtual machines, the virtual machines are automatically started or resumed after moving into the scale set.

Feature Registration

Register the standby pool resource provider with your subscription using Azure Cloud Shell. Registration can take up to 30 minutes to successfully show as registered. You can rerun the below commands to determine when the feature is successfully registered.

> **Note**
>
> To enable standby pool functionality in the Azure portal, the `StandbyPoolVMPoolPreview` feature flag is required. This is requirement is temporary and is in progress of being removed.

Azure PowerShell

```
Register-AzResourceProvider -ProviderNamespace Microsoft.StandbyPool
Register-AzProviderFeature -FeatureName StandbyVMPoolPreview -ProviderNameSpace
```

```
Microsoft.StandbyPool
```

Scaling

Moving virtual machines between the standby pool into the scale set happens automatically whenever a scale-out event is triggered. There's no extra configuration required. As long as there's an available instance in the standby pool that has completed all provisioning steps, the scale set by default uses that instance when scaling up.

When scaling back down, the instances are deleted from your scale set based on the scale-in policy and the standby pool refills to meet the max ready capacity configured. If at any point in time your scale set needs to scale beyond the number of instances you have in your standby pool, the scale set defaults to standard scale-out methods and creates new instances.

Standby pools only give out virtual machines from the pool that match the desired power state configured. For example, if your desired power state is set as stopped (deallocated), the standby pool only gives the scale set instances matching that current power state. If virtual machines are in a creating, failed or any other state than the expected state the scale set defaults to new virtual machine creation instead.

Standby pool size

There are three settings that determine how many instances are in your standby pool at any given point in time. This includes the scale set instance count, the minimum ready capacity and the maximum ready capacity.

The **scale set instance count** is how many instances are currently deployed in your scale set. This is a scale set level property that can be changed at any point in time by either scaling up or scaling down. Regardless of how you're managing the scaling rules for your scale set, the standby pool keeps track of how many instances are deployed and adjust accordingly.

The **minimum ready capacity** is a user defined parameter. By default, the minimum ready capacity for any new standby pool is zero. By setting the minimum ready capacity, it informs the standby pool that it should maintain that many instances at minimum. For example, if you have a minimum ready capacity of 5, anytime a virtual machine is moved from the pool into the scale set which reduces the minimum ready capacity to less than 5, the standby pool automatically creates another instance and begins preparing it for scale-out.

The **maximum ready capacity** is a user defined parameter. This setting tells the standby pool how many instances at most should be maintained in the pool. Maximum ready capacity is directly tied to the scale set instance count. If you have a maximum ready capacity of 20 and

you currently have 10 instances in your scale set, the pool size would equal 10. If your scale set scales down to 5, the pool size would increase to 15. This continues to dynamically adjust as the scale set increases and decreases instance count.

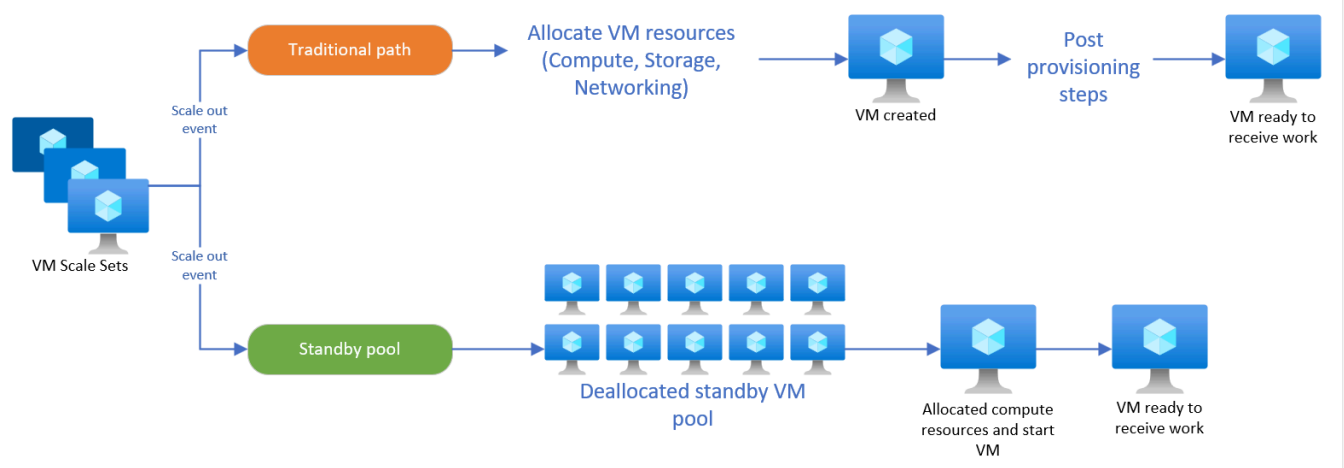
Expand table

Setting	Description
maxReadyCapacity	The maximum number of virtual machines to be created in the pool.
minReadyCapacity	The minimum number of virtual machines to be maintained in the pool.
instanceCount	The current number of virtual machines already deployed in the scale set.
Standby pool size	Standby pool size = `maxReadyCapacity` – `instanceCount`

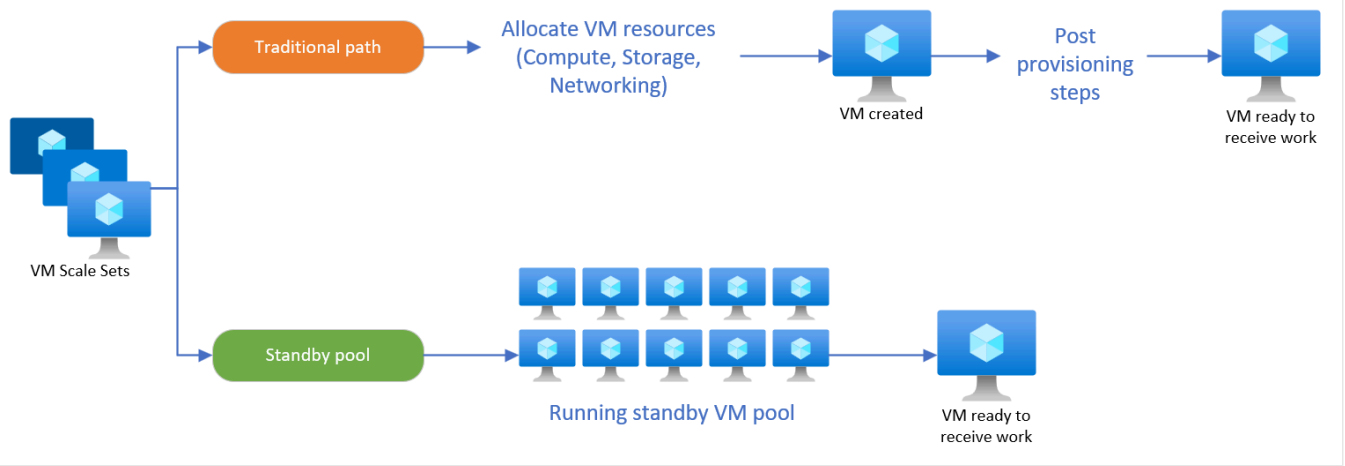
Virtual machine states

The virtual machines in the standby pool can be kept in a running, hibernated, or stopped (deallocated) state.

Deallocated: Deallocated virtual machines are shut down and keep any associated disks, network interfaces, and any static IPs. Ephemeral OS disks don't support the deallocated state.

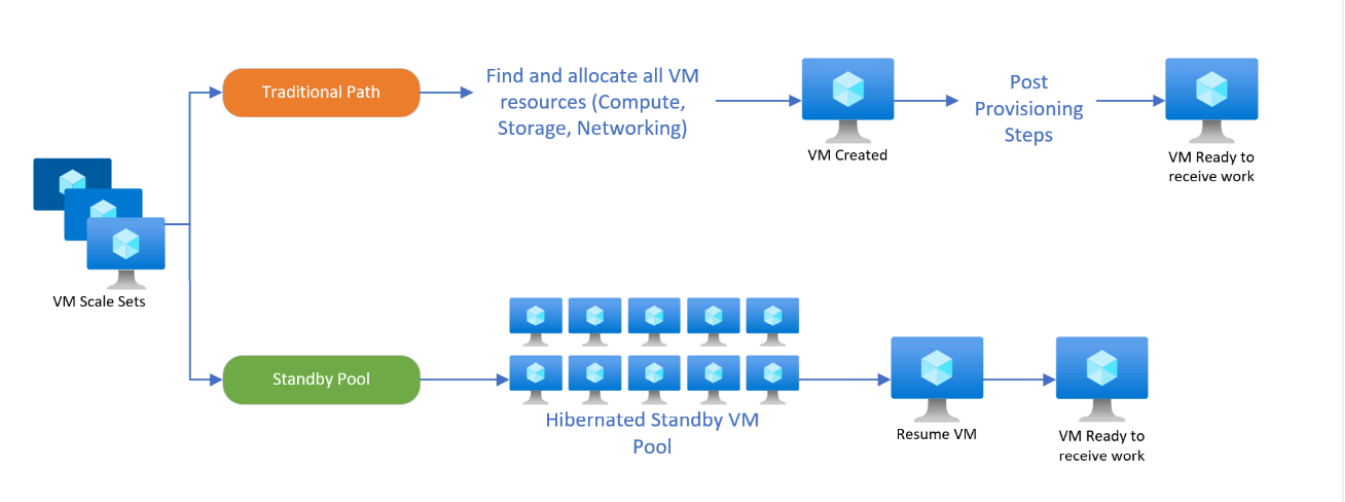


Running: Using virtual machines in a running state is recommended when latency and reliability requirements are strict. Virtual machines in a running state remain fully provisioned.



Hibernated (Preview): Using virtual machines in a hibernated state is recommended for systems with long boot times due to memory-intensive applications. These applications can be initialized on VMs and hibernated. These hibernated VMs can then be quickly started when needed, with the applications already up and running in the desired state.

> **Note**
>
> To use the hibernated VM state in your standby pool, the instances must be fully eligible and configured to support hibernation. For more information, see the Azure VM hibernation documentation.



Availability zones

When using standby pools with a Virtual Machine Scale Set spanning availability zones, the instances in the pool are spread across the same zones the Virtual Machine Scale Set is using.

When a scale-out is triggered in one of the zones, a virtual machine in the pool in that same zone is used. If a virtual machine is needed in a zone where you no longer have any pooled virtual machines left, the scale set creates a new virtual machine directly in the scale set.

Pricing

Users are charged based on the resources deployed in the standby pool. For example, virtual machines in a running state incur compute, networking, and storage costs. Virtual machines in a deallocated state doesn't incur any compute costs, but any persistent disks or networking configurations continue incur cost. Thus, a pool of running virtual machines incur more cost than a pool of deallocated virtual machines. For more information on virtual machine billing, see states and billing status of Azure Virtual Machines.

Limitations and considerations

When using standby pools with Virtual Machine Scale Sets, there are specific limitations and considerations to keep in mind:

- **Azure Autoscale**: Standby pools can't be created or attached to a Virtual Machine Scale Set with Azure autoscale enabled. Ensure autoscale is disabled before configuring a standby pool.
- **Fault Domains**: Standby pools aren't supported with Virtual Machine Scale Sets configured with a fault domain count greater than 1.
- **Region and Subscription**: The standby pool must be in the same region and subscription as the Virtual Machine Scale Set it's attached to. Cross-region or cross-subscription configurations aren't supported.
- **Single Standby Pool**: A Virtual Machine Scale Set can only have one standby pool attached at a time. Attaching multiple standby pools to the same scale set is not supported.
- **Orchestration Mode**: Standby pools are only supported with Virtual Machine Scale Sets using Flexible Orchestration. Uniform Orchestration is not supported.

Proximity placement groups

Article • 08/22/2024

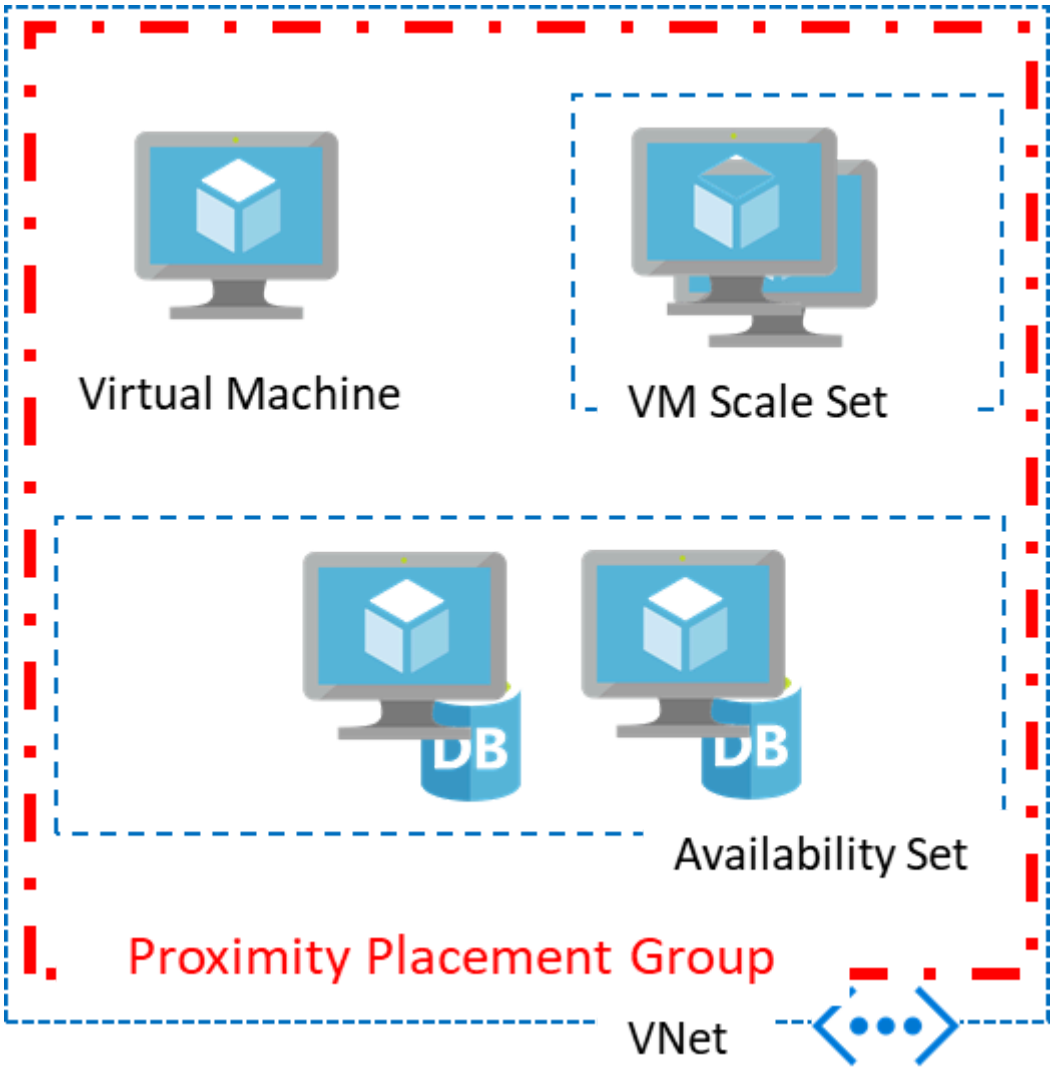
Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Placing VMs in a single region reduces the physical distance between the instances. Placing them within a single availability zone will also bring them physically closer together. However, as the Azure footprint grows, a single availability zone may span multiple physical data centers, which may result in a network latency impacting your application.

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a proximity placement group.

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

- Low latency between stand-alone VMs.
- Low Latency between VMs in a single availability set or a virtual machine scale set.
- Low latency between stand-alone VMs, VMs in multiple Availability Sets, or multiple scale sets. You can have multiple compute resources in a single placement group to bring together a multi-tiered application.
- Low latency between multiple application tiers using different hardware types. For example, running the backend using M-series in an availability set and the front end on a D-series instance, in a scale set, in a single proximity placement group.



Using Proximity Placement Groups

A proximity placement group is a resource in Azure. You need to create one before using it with other resources. Once created, it could be used with virtual machines, availability sets, or virtual machine scale sets. You specify a proximity placement group when creating compute resources providing the proximity placement group ID.

You can also move an existing resource into a proximity placement group. When moving a resource into a proximity placement group, you should stop (deallocate) the asset first since it will be redeployed potentially into a different data center in the region to satisfy the colocation constraint.

In the case of availability sets and virtual machine scale sets, you should set the proximity placement group at the resource level rather than the individual virtual machines.

A proximity placement group is a colocation constraint rather than a pinning mechanism. It's pinned to a specific data center with the deployment of the first resource to use it. Once all resources using the proximity placement group have been

stopped (deallocated) or deleted, it's no longer pinned. Therefore, whenever you use a proximity placement group with multiple VM series, it's important to specify all the required types upfront in a template if possible or follow a deployment sequence, which will improve your chances for a successful deployment. If your deployment fails, restart the deployment with the VM size, which has failed as the first size to be deployed.

Use intent to specify VM sizes

You can use the optional `intent` parameter to provide the intended VM Sizes to be part of the proximity placement group. This parameter can be specified at the time of creating a proximity placement group or it can be added/modified while updating a proximity placement group after deallocating all of the VMs.

When specifying `intent`, you can also add the optional `zone` parameter to specify an availability zone, indicating that the proximity placement group must be created within a specific availability zone. Note the following points when providing the `zone` parameter:

- The availability zone parameter can only be provided during the creation of the proximity placement group and can't be modified later.
- The `zone` parameter can only be use with `intent`, it can't be used alone.
- Only one availability zone can be specified.

Proximity Placement Group creation or update will succeed only when at least one data center supports all the VM Sizes specified in the intent. Otherwise, the creation or update will fail with "OverconstrainedAllocationRequest", indicating that the combination of VM Sizes can't be supported within a proximity placement group. The **intent does not provide any capacity reservation or guarantee**. The VM Sizes and zone given in `intent` are used to select an appropriate data center, reducing the chances of failure if the desired VM size isn't available in a data center. Allocation failures can still occur if there is no more capacity for a VM size at the time of deployment.

> **Note**
>
> To use intent for your proximity placement groups, ensure that the API version is 2021-11-01 or higher

Best Practices while using intent

- Provide an availability zone for your proximity placement group only when you provide an intent. Providing an availability zone without an intent will result in an error when creating the proximity placement group.
- If you provide an availability zone in the intent, ensure that the availability zone of the VMs you deploy match with what that specified in the intent, to avoid errors while deploying VMs.
- Creating or adding VMs with sizes that are not included in the intent is allowed, but not recommended. The size may not exist in the selected datacenter and can result in failures at the time of VM deployment.
- For existing placement groups, we recommend you include the sizes of the existing VMs when updating the intent, in order to avoid failure when redeploying the VMs.

Intent can be affected with decommissioning

- It is possible that after creating a proximity placement group with intent and before deploying VMs, planned maintenance events such as hardware decommissioning at an Azure datacenter could occur, resulting in the combination of VM Sizes specified in the intent not being available in the data center. In such cases, an "OverconstrainedAllocationRequest" error will occur, even while deploying VMs of sizes specified in the intent. You can try deallocating all the resources in the proximity placement group and recreate them to get a data center that can accommodate the intent. If there is no datacenter with the specified VM Sizes after the decommissioning, you may have to modify the intent to use a different combination of VM Sizes, since the combination of VM sizes is no longer supported.
- Azure may retire an entire VM family or a specific set of VM sizes. If you have such a VM size in the intent, you may have to either remove it or replace it with a different size before the retirement date for the original VM size. Otherwise, the intent will no longer be valid.

What to expect when using Proximity Placement Groups

Proximity placement groups offer colocation in the same data center. However, because proximity placement groups represent an additional deployment constraint, allocation failures can occur. There are few use cases where you may see allocation failures when using proximity placement groups:

- When you ask for the first virtual machine in the proximity placement group, the data center is automatically selected. In some cases, a second request for a

different VM size, may fail if it doesn't exist in that data center. In this case, an **OverconstrainedAllocationRequest** error is returned. To avoid this error, try changing the order in which you deploy your VM sizes or have both resources deployed using a single ARM template.

- If the proximity placement group is created with intent, the VMs are not required to be deployed in any particular order and are not required to be batched using a single ARM template, since the intent is used to select a datacenter that supports all VM sizes indicated in the intent.
- In the case of elastic workloads, where you add and remove VM instances, having a proximity placement group constraint on your deployment may result in a failure to satisfy the request resulting in **AllocationFailure** error.
- Stopping (deallocate) and starting your VMs as needed is another way to achieve elasticity. Since the capacity is not kept once you stop (deallocate) a VM, starting it again may result in an **AllocationFailure** error.
- VM start and redeploy operations will continue to respect the Proximity Placement Group once successfully configured.

Planned maintenance and Proximity Placement Groups

Planned maintenance events, like hardware decommissioning at an Azure datacenter, could potentially affect the alignment of resources in proximity placement groups. Resources may be moved to a different data center, disrupting the collocation and latency expectations associated with the proximity placement group.

Check the alignment status

You can do the following to check the alignment status of your proximity placement groups.

- Proximity placement group colocation status can be viewed using the portal, CLI, and PowerShell.
    - PowerShell - colocation status can be obtained through Get-AzProximityPlacementGroup cmdlet by including the optional parameter '-ColocationStatus`.
    - CLI - colocation status can be obtained through `az ppg show` by including the optional parameter '--include-colocation-status`.

- For each proximity placement group, a **colocation status** property provides the current alignment status summary of the grouped resources.
    - **Aligned**: Resource is within the same latency envelop of the proximity placement group.
    - **Unknown**: At least one of the VM resources are deallocated. After re-starting them successfully, the status should go back to **Aligned**.
    - **Not aligned**: At least one VM resource is not aligned with the proximity placement group. The specific resources that are not aligned will also be called out separately in the membership section
- For Availability Sets, you can see information about alignment of individual VMs in the Availability Set Overview page.
- For scale sets, information about alignment of individual instances can be seen in the **Instances** tab of the **Overview** page for the scale set.

Realign resources

If a proximity placement group is `Not Aligned`, you can stop\deallocate, and then restart the affected resources. If the VM is in an availability set or a scale set, all VMs in the availability set or scale set must be stopped\deallocated first before restarting them.

If there is an allocation failure due to deployment constraints, you may have to stop\deallocate all resources in the affected proximity placement group (including the aligned resources) first, and then restart them to restore alignment.

Best practices

- For the lowest latency, use proximity placement groups together with accelerated networking. For more information, see Create a Linux virtual machine with Accelerated Networking or Create a Windows virtual machine with Accelerated Networking.
- In order to avoid landing on hardware that doesn't support all the VM SKUs and sizes you require, use intent for proximity placement groups. If it is an already existing proximity placement group without intent, you can use a single ARM template with all VM sizes specified to avoid this issue.
- When reusing an existing placement group from which VMs were deleted, wait for the deletion to fully complete before adding VMs to it.

- If latency is your first priority, put VMs in a proximity placement group and the entire solution in an availability zone. But, if resiliency is your top priority, spread your instances across multiple availability zones (a single proximity placement group cannot span zones).

Deploy VMs to proximity placement groups using Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a proximity placement group.

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

Create the proximity placement group

Create a proximity placement group using az ppg create.

Azure CLI

```
az group create --name myPPGGroup --location eastus
az ppg create \
   -n myPPG \
   -g myPPGGroup \
   -l eastus \
   -t standard \
   --intent-vm-sizes Standard_E64s_v4 Standard_M416ms_v2 \
   -z 1
```

List proximity placement groups

You can list all of your proximity placement groups using az ppg list.

Azure CLI

```
az ppg list -o table
```

Show proximity placement group

You can see the proximity placement group details and resources using az ppg show

Azure CLI

```
az ppg show --name myPPG --resource-group myPPGGroup
{  "availabilitySets": [],
   "colocationStatus": null,
   "id":
"/subscriptions/[subscriptionId]/resourceGroups/myPPGGroup/providers/Microso
ft.Compute/proximityPlacementGroups/MyPPG",
   "intent": {
    "vmSizes": [
      "Standard_E64s_v4",
      "Standard_M416ms_v2"
    ]
   },
   "location": "eastus",
   "name": "MyPPG",
   "proximityPlacementGroupType": "Standard",
   "resourceGroup": "myPPGGroup",
   "tags": {},
   "type": "Microsoft.Compute/proximityPlacementGroups",
   "virtualMachineScaleSets": [],
   "virtualMachines": [],
   "zones": [
    "1"
   ]
}
```

Create a VM

> **ⓘ Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Create a VM within the proximity placement group using new az vm.

Azure CLI

```
az vm create \
   -n myVM \
   -g myPPGGroup \
   --image Ubuntu2204 \
   --orchestration-mode "Uniform"
   --ppg myPPG  \
   --generate-ssh-keys \
```

```
    --size Standard_E64s_v4 \
    -l eastus
```

You can see the VM in the proximity placement group using az ppg show.

Azure CLI

```
az ppg show --name myppg --resource-group myppggroup --query
"virtualMachines"
```

Availability Sets

You can also create an availability set in your proximity placement group. Use the same `--ppg` parameter with az vm availability-set create to add all VMs in the availability set to the same proximity placement group.

Scale sets

You can also create a scale set in your proximity placement group. Use the same `--ppg` parameter with az vmss create to create a scale set and all of the instances will be created in the same proximity placement group.

Next steps

Learn more about the Azure CLI commands for proximity placement groups.

Deploy VMs to proximity placement groups using Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a proximity placement group.

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

Create a proximity placement group

Create a proximity placement group using the New-AzProximityPlacementGroup cmdlet.

Azure PowerShell

```
$resourceGroup = "myPPGResourceGroup"
$location = "East US"
$ppgName = "myPPG"
$zone = "1"
$vmSize1 = "Standard_E64s_v4"
$vmSize2 = "Standard_M416ms_v2"
New-AzResourceGroup -Name $resourceGroup -Location $location
$ppg = New-AzProximityPlacementGroup `
   -Location $location `
   -Name $ppgName `
   -ResourceGroupName $resourceGroup `
   -ProximityPlacementGroupType Standard `
   -Zone $zone `
   -IntentVMSizeList $vmSize1, $vmSize2
```

List proximity placement groups

You can list all of the proximity placement groups using the Get-AzProximityPlacementGroup cmdlet.

Azure PowerShell

```
Get-AzProximityPlacementGroup -ResourceGroupName $resourceGroup -Name
$ppgName

ResourceGroupName           : myPPGResourceGroup
ProximityPlacementGroupType : Standard
Id                          :
/subscriptions/[subscriptionId]/resourceGroups/myPPGResourceGroup/providers/
Microsoft.Compute/proximityPlacementGroups/myPPG
Name                        : myPPG
Type                        : Microsoft.Compute/proximityPlacementGroups
Location                    : eastus
Tags                        : {}
Intent                      :

Create a VM

Create a VM in the proximity placement group using `-ProximityPlacementGroup $ppg.Id` to refer to the proximity placement group ID when you use New-AzVM to create the VM.

Azure PowerShell

```
$vmName = "myVM"

New-AzVm `
  -ResourceGroupName $resourceGroup `
  -Name $vmName `
  -Location $location `
  -ProximityPlacementGroup $ppg.Id
```

You can see the VM in the placement group using Get-AzProximityPlacementGroup.

Azure PowerShell

```
Get-AzProximityPlacementGroup -ResourceId $ppg.Id |
    Format-Table -Property VirtualMachines -Wrap
```

Move an existing VM into a proximity placement group

You can also add an existing VM to a proximity placement group. You need to stop\deallocate the VM first, then update the VM and restart.

Azure PowerShell

```
$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPGResourceGroup -
Name myPPG
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Stop-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
Update-AzVM -VM $vm -ResourceGroupName $vm.ResourceGroupName -
ProximityPlacementGroupId $ppg.Id
Start-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
```

Move an existing VM out of a proximity placement group

To remove a VM from a proximity placement group, you need to stop\deallocate the VM first, then update the VM and restart.

Azure PowerShell

```
$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPGResourceGroup -
Name myPPG
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Stop-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
$vm.ProximityPlacementGroup = ""
Update-AzVM -VM $vm -ResourceGroupName $vm.ResourceGroupName
Start-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
```

Availability Sets

You can also create an availability set in your proximity placement group. Use the same `-ProximityPlacementGroup` parameter with the New-AzAvailabilitySet cmdlet to create an availability set and all of the VMs created in the availability set will also be created in the same proximity placement group.

To add or remove an existing availability set to a proximity placement group, you first need to stop all of the VMs in the availability set.

Move an existing availability set into a proximity placement group

Azure PowerShell

```
$resourceGroup = "myResourceGroup"
$avSetName = "myAvailabilitySet"
$avSet = Get-AzAvailabilitySet -ResourceGroupName $resourceGroup -Name
$avSetName
```

```
$vmIds = $avSet.VirtualMachinesReferences
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Stop-AzVM -ResourceGroupName $resourceGroup -Name $vmName -Force
    }

$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPG -Name myPPG
Update-AzAvailabilitySet -AvailabilitySet $avSet -ProximityPlacementGroupId
$ppg.Id
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Start-AzVM -ResourceGroupName $resourceGroup -Name $vmName
    }
```

Move an existing availability set out of a proximity placement group

Azure PowerShell

```
$resourceGroup = "myResourceGroup"
$avSetName = "myAvailabilitySet"
$avSet = Get-AzAvailabilitySet -ResourceGroupName $resourceGroup -Name
$avSetName
$vmIds = $avSet.VirtualMachinesReferences
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Stop-AzVM -ResourceGroupName $resourceGroup -Name $vmName -Force
    }

$avSet.ProximityPlacementGroup = ""
Update-AzAvailabilitySet -AvailabilitySet $avSet
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Start-AzVM -ResourceGroupName $resourceGroup -Name $vmName
    }
```

Scale sets

You can also create a scale set in your proximity placement group. Use the same `-ProximityPlacementGroup` parameter with New-AzVmss to create a scale set and all of the instances will be created in the same proximity placement group.

To add or remove an existing scale set to a proximity placement group, you first need to stop the scale set.

Move an existing scale set into a proximity placement group

Azure PowerShell

```
$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPG -Name myPPG
$vmss = Get-AzVmss -ResourceGroupName myVMSSResourceGroup -VMScaleSetName
myScaleSet
Stop-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName
$vmss.ResourceGroupName
Update-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName
$vmss.ResourceGroupName -ProximityPlacementGroupId $ppg.Id
Start-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName
$vmss.ResourceGroupName
```

Move an existing scale set out of a proximity placement group

Azure PowerShell

```
$vmss = Get-AzVmss -ResourceGroupName myVMSSResourceGroup -VMScaleSetName
myScaleSet
Stop-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName
$vmss.ResourceGroupName
$vmss.ProximityPlacementGroup = ""
Update-AzVmss -VirtualMachineScaleSet $vmss -VMScaleSetName $vmss.Name -
ResourceGroupName $vmss.ResourceGroupName
Start-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName
$vmss.ResourceGroupName
```

Next steps

You can also use the Azure CLI to create proximity placement groups.

Create a proximity placement group using the Azure portal

Article • 12/04/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a proximity placement group.

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

> ⓘ **Note**
>
> Proximity placement groups cannot be used with dedicated hosts.
>
> Intent for proximity placement groups is not supported on Azure portal. Use ARM templates or other client tools like Powershell or CLI to provide intent for proximity placement groups.
>
> If you want to use availability zones together with placement groups, you need to make sure that the VMs in the placement group are also all in the same availability zone.
>
> Accelerated networking will only work if the virtual machines are deployed to an availability set or a virtual machine scale set that is linked to a proximity placement group. Having only a proximity placement group will disable the hardware acceleration feature which affects network performance.

Create the proximity placement group

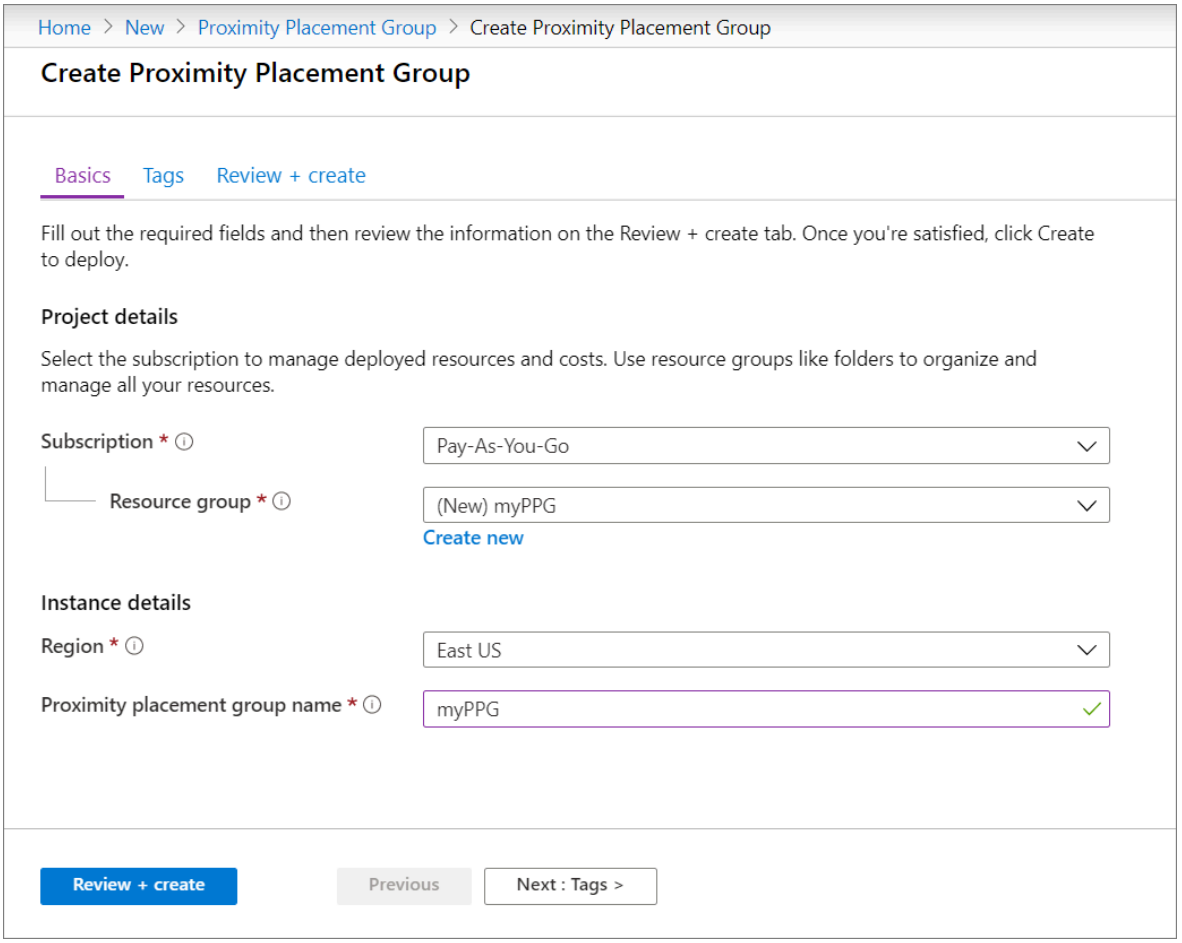
1. Type **proximity placement group** in the search.
2. Under **Services** in the search results, select **Proximity placement groups**.
3. In the **Proximity placement groups** page, select **Add**.
4. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected.

5. In **Resource group** either select **Create new** to create a new group or select an empty resource group that already exists, from the drop-down.

6. In **Region** select the location where you want the proximity placement group to be created.

7. In **Proximity placement group name** type a name and then select **Review + create**.

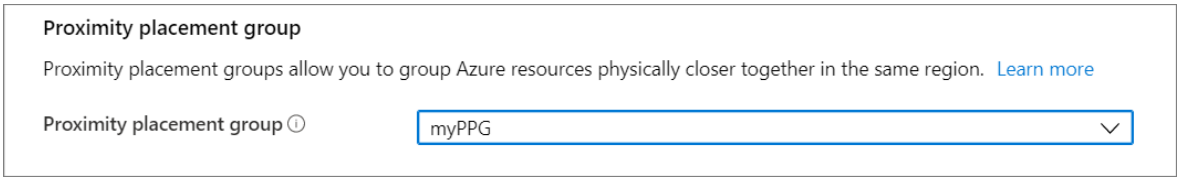
8. After validation passes, select **Create** to create the proximity placement group.



Create a VM

1. While creating a VM in the portal, go to the **Advanced** tab.

2. In the **Proximity placement group** selection, select the correct placement group.



3. When you are done making all of the other required selections, select **Review + create**.

4. After it passes validation, select **Create** to deploy the VM in the placement group.

Add VMs in an availability set to a proximity placement group

If the VM is part of the Availability set, you need to add the availability set into the placement group, before adding the VMs.

1. In the portal search for *Availability sets* and select your availability set from the results.
2. Stop\deallocate each VM in the availability set by selecting the VM, then selecting **Stop** on the page for the VM, and then select **OK** to stop the VM.
3. On the page for your availability set, make sure all of the VMs have the **Status** listed as **Stopped (deallocated)**.
4. In the left menu, select **Configuration**.
5. Under **Proximity placement group**, select a placement group from the drop-down, and then select **Save**.
6. Select **Overview** from the left menu to see the list of VMs again.
7. Select each VM in the availability set, and then select **Start** on the page for each VM.

Add existing VM to placement group

1. On the page for the VM, select **Stop**.
2. Once the status of the VM is listed as **Stopped (deallocated)**, select **Configuration** on the left menu.
3. Under **Proximity placement group**, select a placement group from the drop-down, and then select **Save**.
4. Select **Overview** from the left menu, then select **Start** to restart the VM.

Next steps

You can also use the Azure PowerShell to create proximity placement groups.

Compute throttling limits

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Microsoft Compute implements throttling mechanism to help with the overall performance of the service and to give a consistent experience to the customers. API requests that exceed the maximum allowed limits are throttled and users get an HTTP 429 error. All Compute throttling policies are implemented on a per-region basis.

How do the throttling policies work?

Microsoft Compute implements throttling policies that limit the number of API requests made per resource and per subscription per region per minute. If the number of API requests exceeds these limits, the requests are throttled. Here's how these limits work:

- **Per Resource Limit** – Each resource, such as a virtual machine (VM), has a specific limit for API requests. For instance, let us assume that a user creates 10 VMs in a subscription. The user can invoke up to 12 update requests for each VM in one minute. If the user exceeds the limit for the VM, API requests are throttled. This limit ensures that a few resources don’t consume the subscription level limits and throttle other resources.
- **Subscription Limit** – In addition to resource limits, there's an overarching limit on the number of API requests across all resources within a subscription. Any API requests beyond this limit are throttled, regardless of whether the limit for an individual resource has been reached. For instance, let us assume that a user has 200 VMs in a subscription. Even though user is entitled to initiate up to 12 Update VM requests for each VM, the aggregate limit for Update VM API requests is capped at 1500 per min. Any Update VM API requests for the subscription exceeding 1500 are throttled.

How does Microsoft Compute determine throttling limits?

To determine the limits for each resource and subscription, Microsoft Compute uses **Token Bucket Algorithm.** This algorithm creates buckets for each limit and holds a specific number of tokens in each bucket. The number of tokens in a bucket represent the throttling limit at any given minute.

At the start of throttling window, when the resource is created, the bucket is filled to its *Maximum Capacity*. Each API request initiated by the user consumes one token. When the token count depletes to zero, subsequent API requests are throttled. Bucket is replenished with new tokens every minute at a consistent rate called *Bucket Refill Rate* for a resource and a subscription.

For Instance: Let us consider the 'throttling policy for VM Update API' that stipulates a Bucket Refill Rate of four tokens per minute, and a Maximum Bucket Capacity of 12 tokens. The user invokes the Update VM API request for a virtual machine (VM) as per the following table. Initially, the bucket is filled with 12 tokens at the start of the throttling window. By the fourth minute, the user utilizes all 12 tokens, leaving the bucket empty. In the fifth minute, the bucket is replenished with four new tokens in accordance with the Bucket Refill Rate. So, four API requests can be made in the fifth minute, while Microsoft Compute throttles one API request due to insufficient tokens.

Expand table

(min)	1st	2nd	3rd	4th	5th	6th
Number of tokens in the beginning (A)	12	12	8	12	4	4
Requests per minute (B)	0	8	0	13	5	0
Throttled requests (C)	0	0	0	1	1	0
Remaining tokens at the end of period D = Max(A-B, 0)	12	4	8	0	0	4

Similar process is followed for determining the throttling limits at subscription level. The following sections detail the Bucket refill rate and Maximum bucket capacity that is used to determine throttling limits for Virtual Machines, Virtual Machine Scale Sets and Virtual Machines Scale Set VMs.

Throttling limits for Virtual Machines

API requests for Virtual Machines are categorized into seven distinct policies. Each policy has its own limits, depending upon how resource intensive the API requests under that policy are. Following table contains a comprehensive list of these policies, the corresponding REST APIs, and their respective throttling limits:

Expand table

Policy category	REST APIs	Resource Level	Resource Level	Subscription Level	Subscription Level
		Bucket refill rate (Per Min)	Maximum Bucket capacity (Per Min)	Bucket refill rate (Per Min)	Maximum Bucket capacity (Per Min)
Put VM (Create new VMs)	Create	4	12	500	1,500
Update VM (Update existing VMs)	Update Reapply Restart Power Off Start Generalize Convert To Managed Disks Redeploy Perform Maintenance Capture Run Command Create Or Update Extensions - Update Extensions - Delete Reimage Update Run Commands - Update Run Commands - Delete Run Commands - Create Or Update	4	12	500	1,500
Delete VM (Delete VMs)	Delete Simulate Eviction Deallocate	4	12	500	1,500
Low Cost Get VM (Get information on single VM)	Get Instance View Extensions - Get List Available Sizes Retrieve Boot	12	36	8,000	24,000

Policy category	REST APIs	Resource Level	Resource Level	Subscription Level	Subscription Level
	Diagnostics Data Run Commands - Get By Virtual Machine Run Commands - List By Virtual Machine				
High Cost Get VM[1] (Get information on multiple VMs)	List List All List By Location	NA	NA	300	900
Get Operation (Get information on async VM operations)	Status of asynchronous operations	15	45	5,000	15,000
VM Guest Patch Operations (Assess & install guest patches)	Assess Patches Install Patches	2	6	200	600

[1] Only subscription level policies are applicable.

Throttling limits for Virtual Machine Scale Sets

API requests for Virtual Machine Scale Set(Uniform & Flex) are categorized into 5 distinct policies. Each policy has its own limits, depending upon how resource intensive the API requests under that policy are. These policies are applicable to both Flex and Uniform orchestration modes. Following table contains a comprehensive list of these policies, the corresponding REST APIs, and their respective throttling limits:

Expand table

Policy category	REST APIs	Resource Level	Resource Level	Subscription Level	Subscription Level
		Bucket refill rate	Maximum Bucket	Bucket refill rate (Per Min)	Maximum Bucket

Policy category	REST APIs	Resource Level (Per Min)	Resource Level capacity (Per Min)	Subscription Level	Subscription Level capacity (Per Min)
Put (Create new scale set)	Create	4	12	125	375
Update (Update existing scaleset)	Update Start[2] Restart[2] Redeploy[2] Perform Maintenance[2] Reimage[2] Reimage All[2] Create Or Update Rolling Upgrades - Cancel Extensions - Create Extensions - Update Extensions - Delete Force Recovery Service Fabric Platform Update Domain Walk Convert To Single Placement Group Set Orchestration Service State	4	12	500	1,500
Delete (Delete scale set)	Delete Power Off[2] Deallocate	4	12	175	525
Low Cost Get (Get information on single scale set)	Get List Skus Rolling Upgrades - Get Latest Get OS Upgrade History	12	36	800	2,400

Policy category	REST APIs	Resource Level	Resource Level	Subscription Level	Subscription Level
intensive information)	List All[2] List By Location[2]				

[2] Only subscription level policies are applicable.

Throttling limits for Virtual Machine Scale Set Virtual Machines

API requests for Virtual Machine Scale Set Virtual Machines are categorized into 3 distinct policies. Each policy has its own limits, depending upon how resource intensive the API requests under that policy are. Following table contains a comprehensive list of these policies, the corresponding REST APIs, and their respective throttling limits:

Expand table

Policy category	REST APIs	Resource Level	Resource Level	Subscription Level	Subscription Level
		Bucket refill rate (Per Min)	Maximum Bucket capacity (Per Min)	Bucket refill rate (Per Min)	Maximum Bucket capacity (Per Min)
Update scale set VMs (Update existing VMs in a scale set)	Start Restart Reimage ReimageAll Update SimulateEviction Extensions- Create Or Update RunCommands - Create Or Update RunCommands - Update	4	12	500	1,500
Delete scale set VMs (Delete scale set VMs)	Delete PowerOff Deallocate Extensions- Delete RunCommands - Delete	4	12	500	1,500

Policy category	REST APIs	Resource Level	Resource Level	Subscription Level	Subscription Level
Get scale set VMs (Get information on scale set VMs)	Get GetInstance View Extensions- Get RunCommands - Get RetrieveBoot Diagnostics Data	12	36	2,000	6,000

Troubleshooting guidelines

In case users are still facing challenges due to Compute throttling, refer to Troubleshooting throttling errors in Azure - Virtual Machines. It has details on how to troubleshoot throttling issues, and best practices to avoid being throttled.

FAQs

Is there any action required from users?

Users don't need to change anything in their configuration or workloads. All existing APIs continue to work as is.

What benefits do the throttling policies provide?

The throttling policies offer several benefits:

- All Compute resources have a uniform window of 1 min. Users can successfully invoke API calls, 1 min after getting throttled.
- No single resource can use up all the limits under a subscription as limits are defined at resource level.
- Microsoft Compute is introducing a new algorithm, Token Bucket Algorithm, for determining the limits. The algorithm provides extra buffer to the customers, while making high number of API requests.

Does the customer get an alert when they're about to reach their throttling limits?

As part of every response, Microsoft Compute returns **x-ms-ratelimit-remaining-resource** which can be used to determine the throttling limits against the policies. A list of applicable throttling policies is returned as a response to Call rate informational headers.

Regions for virtual machines in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

It is important to understand how and where your virtual machines (VMs) operate in Azure, along with your options to maximize performance, availability, and redundancy. This article provides you with an overview of the availability and redundancy features of Azure.

What are Azure regions?

Azure operates in multiple datacenters around the world. These datacenters are grouped in to geographic regions, giving you flexibility in choosing where to build your applications.

You create Azure resources in defined geographic regions like 'West US', 'North Europe', or 'Southeast Asia'. You can review the list of regions and their locations. Within each region, multiple datacenters exist to provide for redundancy and availability. This approach gives you flexibility as you design applications to create VMs closest to your users and to meet any legal, compliance, or tax purposes.

Special Azure regions

Azure has some special regions that you may wish to use when building out your applications for compliance or legal purposes. These special regions include:

- **US Gov Virginia** and **US Gov Iowa**
  - A physical and logical network-isolated instance of Azure for US government agencies and partners, operated by screened US persons. Includes additional compliance certifications such as FedRAMP and DISA. Read more about Azure Government.
- **China East** and **China North**
  - These regions are available through a unique partnership between Microsoft and 21Vianet, whereby Microsoft does not directly maintain the datacenters.
- **Germany Central** and **Germany Northeast**
  - These regions are available via a data trustee model whereby customer data remains in Germany under control of T-Systems, a Deutsche Telekom company, acting as the German data trustee.

Region pairs

Each Azure region is paired with another region within the same geography (such as US, Europe, or Asia). This approach allows for the replication of resources, such as VM storage, across a geography that should reduce the likelihood of natural disasters, civil unrest, power outages, or physical network outages affecting both regions at once. Additional advantages of region pairs include:

- In the event of a wider Azure outage, one region is prioritized out of every pair to help reduce the time to restore for applications.
- Planned Azure updates are rolled out to paired regions one at a time to minimize downtime and risk of application outage.
- Data continues to reside within the same geography as its pair (except for Brazil South) for tax and law enforcement jurisdiction purposes.

Examples of region pairs include:

Expand table

Primary	Secondary
West US	East US
North Europe	West Europe
Southeast Asia	East Asia

You can see the full list of regional pairs here.

Feature availability

Some services or VM features are only available in certain regions, such as specific VM sizes or storage types. There are also some global Azure services that do not require you to select a particular region, such as Microsoft Entra ID, Traffic Manager, or Azure DNS. To assist you in designing your application environment, you can check the availability of Azure services across each region. You can also programmatically query the supported VM sizes and restrictions in each region.

Storage availability

Understanding Azure regions and geographies becomes important when you consider the available storage replication options. Depending on the storage type, you have

different replication options.

Azure Managed Disks

- Locally redundant storage (LRS)
  - Replicates your data three times within the region in which you created your storage account.

Storage account-based disks

- Locally redundant storage (LRS)
  - Replicates your data three times within the region in which you created your storage account.
- Zone redundant storage (ZRS)
  - Replicates your data three times across two to three facilities, either within a single region or across two regions.
- Geo-redundant storage (GRS)
  - Replicates your data to a secondary region that is hundreds of miles away from the primary region.
- Read-access geo-redundant storage (RA-GRS)
  - Replicates your data to a secondary region, as with GRS, but also then provides read-only access to the data in the secondary location.

The following table provides a quick overview of the differences between the storage replication types:

Expand table

Replication strategy	LRS	ZRS	GRS	RA-GRS
Data is replicated across multiple facilities.	No	Yes	Yes	Yes
Data can be read from the secondary location and from the primary location.	No	No	No	Yes
Number of copies of data maintained on separate nodes.	3	3	6	6

You can read more about Azure Storage replication options here. For more information about managed disks, see Azure Managed Disks overview.

Next steps

For more information, see Azure regions.

Availability sets overview

Applies to: ✔ Linux VMs ✔ Windows VMs

This article provides an overview of the availability features of Azure virtual machines (VMs).

> ⓘ **Note**
>
> We recommend that customers choose Virtual Machine Scale Sets with flexible orchestration mode for high availability with the widest range of features. Virtual Machine Scale Sets:
>
> - Allow VM instances to be centrally managed, configured, and updated.
> - Automatically increase or decrease the number of VM instances in response to demand or a defined schedule.
>
> Availability sets provide high availability but don't offer the same level of resiliency as availability zones.

What is an availability set?

Availability sets are logical groupings of VMs that reduce the chance of correlated failures bringing down related VMs at the same time. Availability sets distribute VMs across multiple fault domains, improving reliability. This configuration is especially useful in regions that don't support availability zones.

When you use availability sets, create two or more VMs within an availability set. Using two or more VMs in an availability set helps keep applications highly available and meets the 99.95% Azure service-level agreement (SLA). There's no extra cost for using availability sets. You only pay for each VM instance that you create.

Availability sets provide lower VM-to-VM latency than availability zones because the VMs are placed in closer physical proximity. Availability sets have fault isolation for many possible failures, to minimize single points of failure and to offer high availability. Availability sets are still susceptible to certain shared infrastructure failures, such as datacenter-level network outages, which can affect multiple fault domains.

For more reliability than availability sets offer, use availability zones. Availability zones have the highest reliability. Each VM is deployed in multiple datacenters to help protect you from loss of power, networking, or cooling in an individual datacenter. If your highest priority is the best reliability for your workload, replicate your VMs across multiple availability zones.

How do availability sets work?

The underlying Azure platform assigns an *update domain* and a *fault domain* to each virtual machine in your availability set. Each availability set can have up to 3 fault domains and 20 update domains. These settings can't be changed after the availability set is created.

Update domains

Update domains indicate groups of virtual machines and underlying physical hardware that can be restarted at the same time.

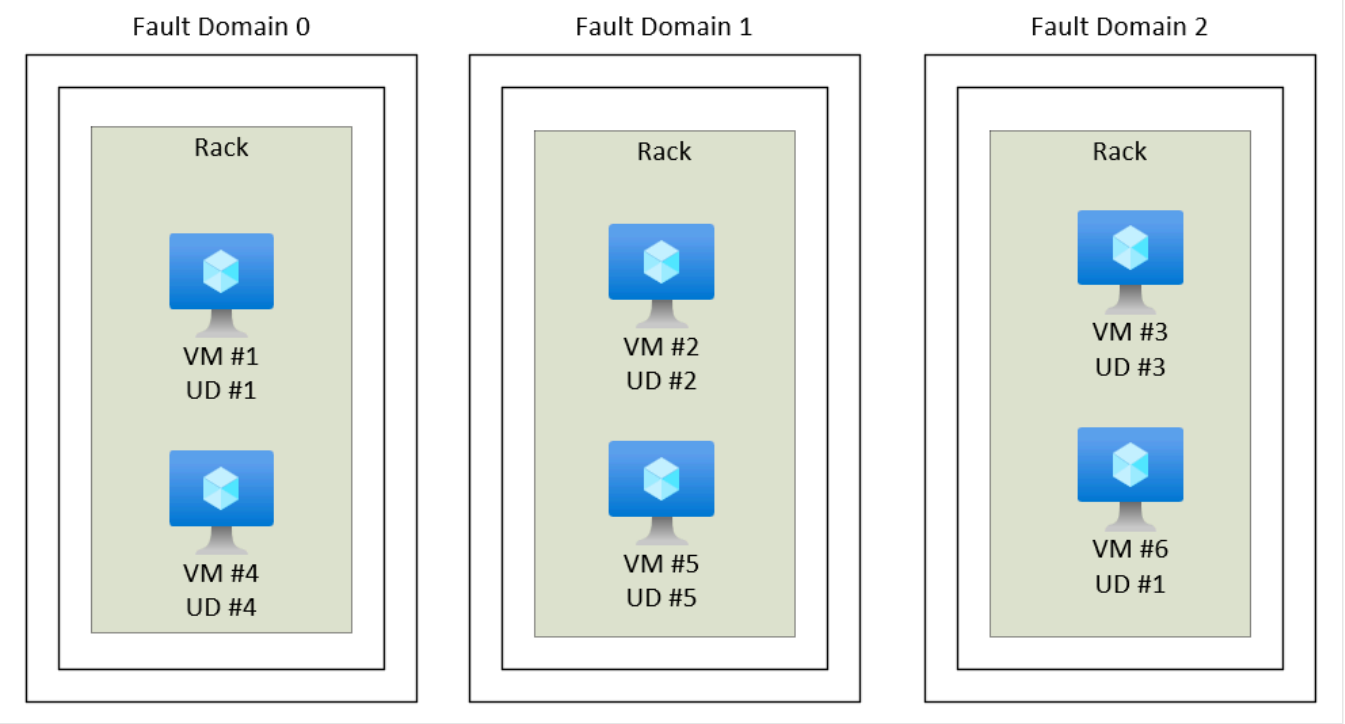
If more than five VMs are configured in an availability set with five update domains, the sixth VM is placed in the same update domain as the first, the seventh with the second, and so on.

The order of update domains being restarted might not proceed sequentially during planned maintenance, but only one update domain is restarted at a time. A restarted update domain has 30 minutes to recover before maintenance starts on a different update domain.

Fault domains

Fault domains define the group of virtual machines that share a common power source and network switch. By default, the virtual machines configured within your availability set are separated across up to three fault domains.

Placing your virtual machines into an availability set doesn't protect your application from operating system or application-specific failures. But it does limit the impact of potential physical hardware failures, network outages, or power interruptions.



Disk fault domains

VMs are also aligned with disk fault domains. This alignment ensures that all the managed disks attached to a VM are within the same fault domains.

Only VMs with managed disks can be created in a managed availability set. The number of managed-disk fault domains varies by region: either two or three managed-disk fault domains per region.

The following command retrieves a list of fault domains per region:

Azure CLI

```
az vm list-skus --resource-type availabilitySets --query '[?name==`Aligned`].
{Location:locationInfo[0].location, MaximumFaultDomainCount:capabilities[0].value}'
-o Table
```

Shared fault domains

Under certain circumstances, two VMs in the same availability set might share a fault domain. You can confirm a shared fault domain by going to your availability set and checking the **Fault Domain** column.

If your VMs have a shared fault domain, it could be because you took these actions when deploying your VMs:

1. Deploy the first VM.
2. Stop or deallocate the first VM.
3. Deploy the second VM.

Under these circumstances, the OS disk of the second VM might be created on the same fault domain as the first VM, so the two VMs will be on same fault domain. To avoid this problem, don't stop or deallocate VMs between deployments.

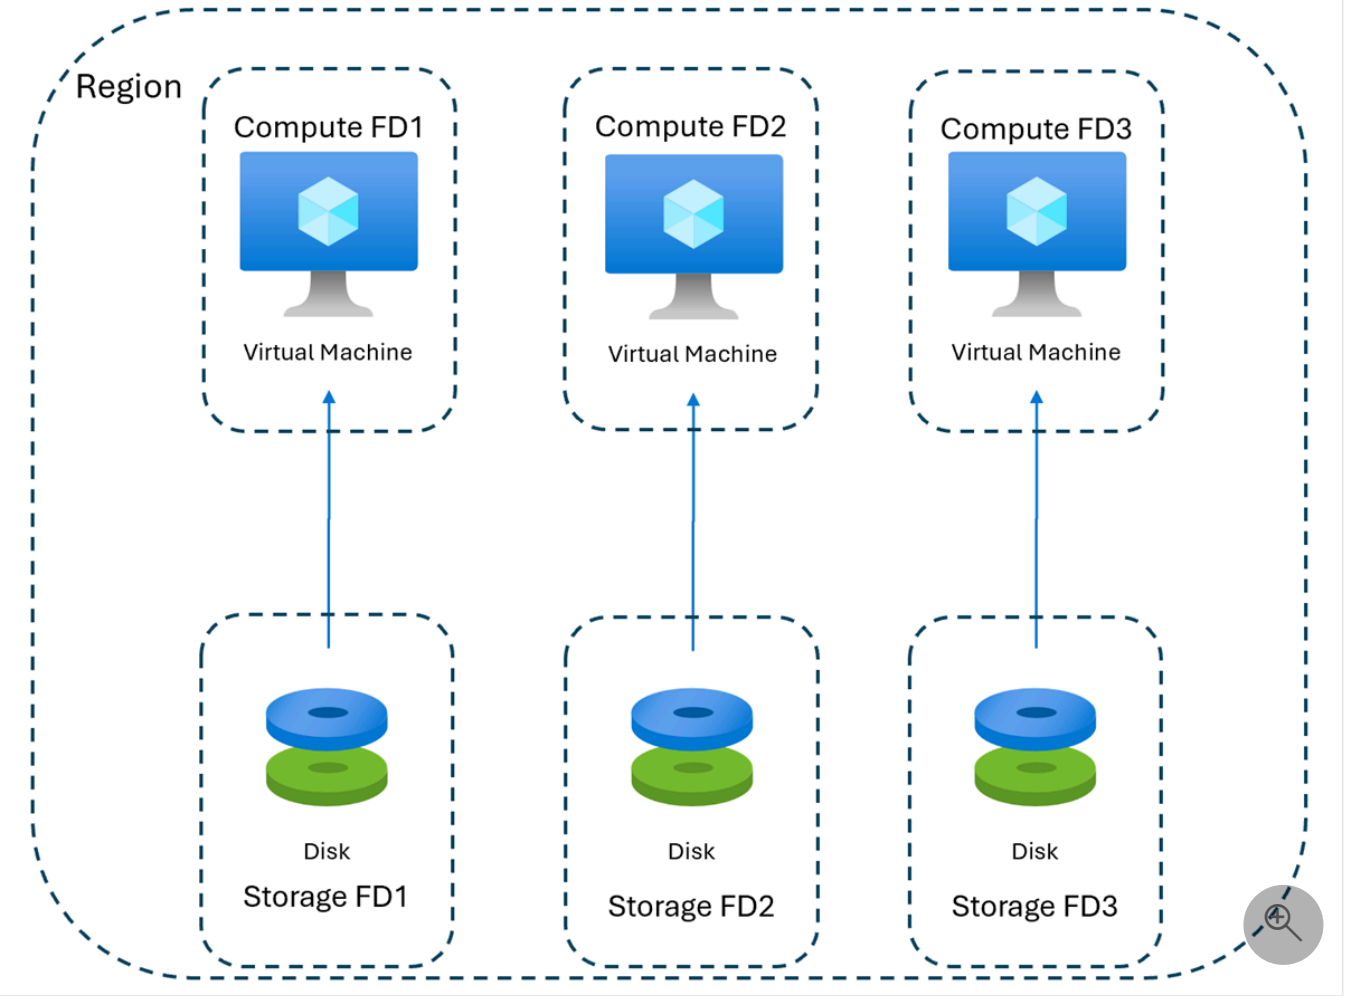
Use premium SSD v2 with VMs in availability set

05/20/2025

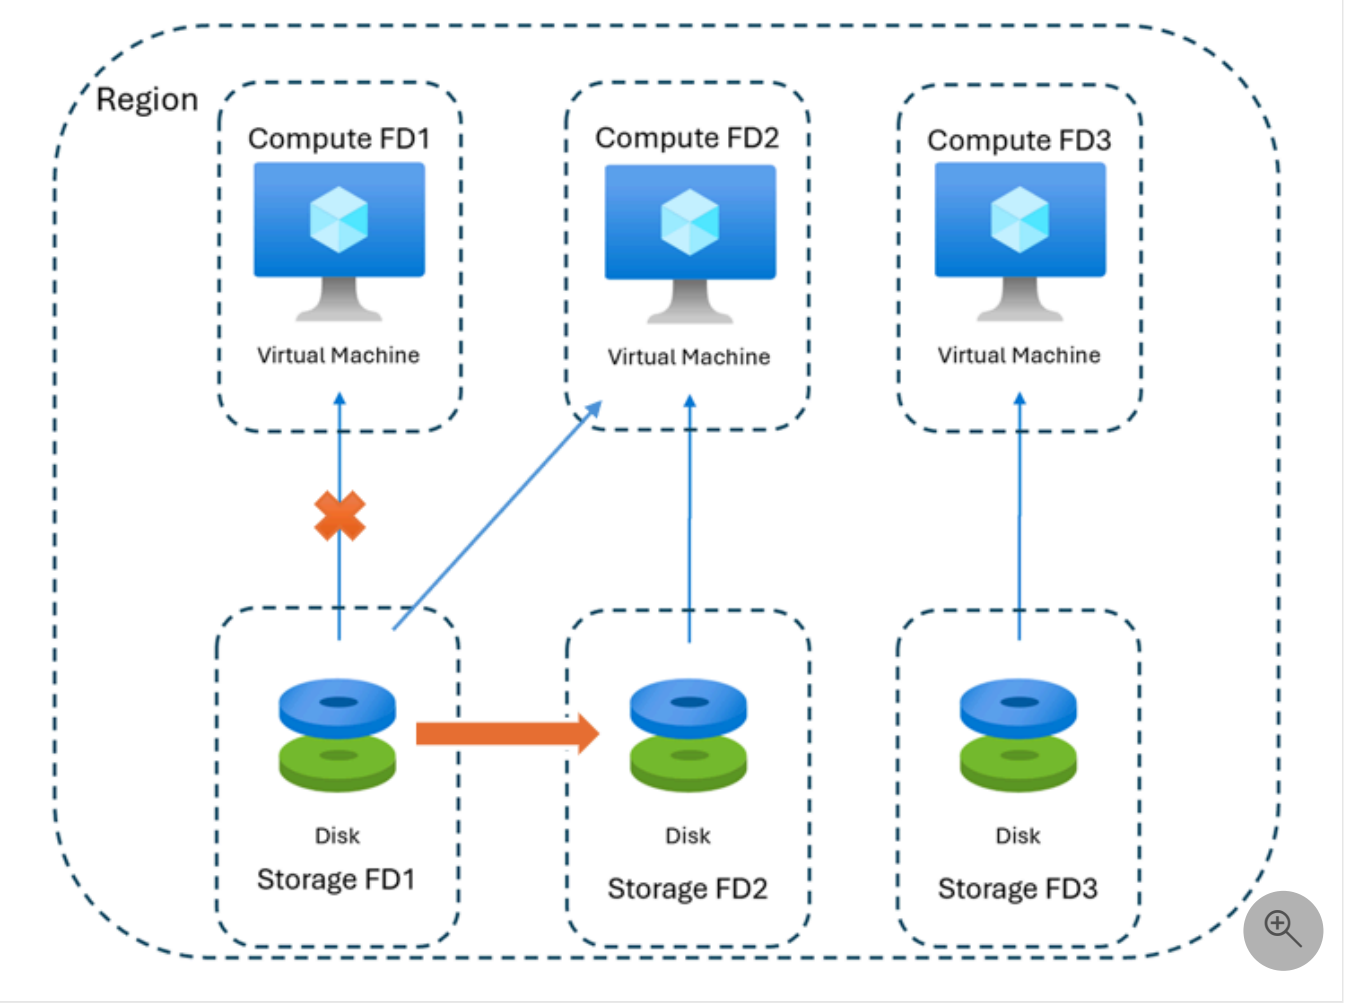
Introduction

Premium SSD v2 managed disks are supported with Azure Virtual Machines in availability sets to enhance the high availability of your applications. When VMs using Premium SSD v2 are part of an availability set, the platform ensures that their disks are automatically distributed across multiple storage fault domains. This distribution minimizes the risk of a single point of failure.



Availability sets have fault isolation for many possible failures, to minimize single points of failure and to offer high availability. If there's a failure in one storage fault domain, only the virtual machine (VM) instances with Premium SSD v2 disks on that specific fault domain are affected. Other VM instances, whose disks are placed on separate fault domains, remain unaffected and continue to operate normally. Availability sets are susceptible to certain shared infrastructure failures, like datacenter network failures, physical hardware failures or power interruptions which can affect multiple fault domains.

When a Premium SSD v2 disk located in one fault domain is attached to a VM in another fault domain, the system triggers a background copy. This process moves the disk to match the VM's fault domain, helping ensure consistent alignment between compute and storage for better reliability and availability.



As the previous diagram illustrates, if a disk located in fault domain 1 is attached to a VM in fault domain 1 and is later detached and attached to a VM in fault domain 2, the system automatically triggers a background copy of the disk to move it from fault domain 1 to fault domain 2 for compute and storage fault domain alignment. This background move process can take up to 24 hours to complete.

Regional availability

Premium SSD v2 support for VMs in an availability set is currently limited to the following regions that lack availability zone support:

- Australia Southeast
- Canada East
- North Central US
- UK West

- West Central US
- West US

Limitations

- Premium SSD v2 is supported for VMs in availability set in select regions without availability zones.
- You must register your subscription to use this feature. Follow the steps in Register Premium SSD v2 with VMs in availability sets in regions without availability zones.
- Only one background data copy can run per disk at a time. When attaching a disk to a VM in an availability set, the system might start a background copy to align with the fault domain. If you try to detach and reattach the disk while this move is in progress, the operation fails with an error. To prevent operation failure, wait until the move finishes, or set the OptimizedForFrequentAttach property on the disk. This setting skips fault domain-alignment background copies for future attachments. For more information on OptimizedForFrequentAttach, follow the instructions Optimize background data copy of the disk.
- You can't attach a disk created from a snapshot to VMs in an availability set while it's still copying data in the background. Wait until the copy process finishes before attaching the disk. To check the status of background data copy from a snapshot, follow the instructions here.
- Disk size increase and changing customer-managed key (CMK) are not supported while a background data copy for Fault Domain alignment is in progress.
- Premium SSD v2 managed disks have their own separate set of limitations, as well.

Register Premium SSD v2 with VMs in availability sets in supported regions without availability zones

The feature is only available in regions that do not support Availability Zones. If you're targeting a supported region without availability zones, ensure your subscription is registered for the required feature.

To proceed, register the feature manually:

- Use the following command to register the feature with your subscription:

Azure CLI

```
az feature registration create --namespace Microsoft.Compute --name
PV2WithAVSetRegionWithoutZone
```

- Use the command below to verify if the feature is registered :

Azure CLI

```
az feature registration show --provider Microsoft.Compute --name
PV2WithAVSetRegionWithoutZone
```

Deploy a VM and a Premium SSD v2 disk within an availability set

Azure CLI

- Create a resource group:

Azure CLI

```
az group create --name myResourceGroup --location myLocation
```

- The number of storage fault domains varies by region. The following command retrieves a list of maximum suported fault domains per region:

Azure CLI

```
az vm list-skus --resource-type availabilitySets --query '[?name==`Aligned`].
{Location:locationInfo[0].location,
MaximumFaultDomainCount:capabilities[0].value}' -o Table
```

- Create an availability set:

Azure CLI

```
az vm availability-set create -n myAvSet -g myResourceGroup --platform-fault-
domain-count myFDCount --platform-update-domain-count myUDCount

## The value for platform-fault-domain-count should be determined based on the
number of maximum supported fault domains in a given region. See previous step
to check the available fault domains per region.
```

- Create a VM:

Azure CLI

```
az vm create -n myVMname -g myResourceGroupName --availability-set myAvSetName
```

```
--image Win2016Datacenter --count MyCount
```

- Attach a new Premium SSD v2 disk to existing VMs in an availability set

Azure CLI

```
az vm disk attach -g MyResourceGroupName --vm-name MyVMname --name MyDiskName
--new --sku PremiumV2_LRS --size-gb MySize
```

- Attach existing Premium SSD v2 disk to existing VMs in an Availability Set:

Azure CLI

```
az vm disk attach -g MyResourceGroupName --vm-name MyVMname --disks MyDiskName
```

Optimize background data copy of the disk

Change optimized-for-frequent-attach disk property

If your workload often moves disks between VMs in the same or different availability sets, turn on the `optimized-for-frequent-attach` property. Setting this property to true prevents the system from triggering a background copy of the disk for fault domain alignment during reattachments. `optimized-for-frequent-attach` can be set when creating a new unattached disk or update it later for an existing disk. If the disk is currently attached to a VM, first detach the disk. Update the `optimized-for-frequent-attach` disk property and then reattach the disk to the VM.

To set the property while creating a new unattached disk:

Azure CLI

```
az disk create --name myDiskName --resource-group myResourceGroup --location
myLocation --sku PremiumV2_LRS --size-gb myGB --optimized-for-frequent-attach true
```

To update the property on an existing unattached disk:

Azure CLI

```
az disk update --name myDiskName --resource-group myResourceGroup --set
optimizedForFrequentAttach=true
```

Introduction to Azure managed disks

Article • 04/01/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure managed disks are block-level storage volumes managed by Azure and used with Azure Virtual Machines. Managed disks are like physical disks in an on-premises server, but they're virtualized. With managed disks, you only have to specify the disk type and the disk size, then provision the disk. After you provision the disk, Azure handles the rest.

There are five types of managed disks: Ultra Disks, Premium solid-state drives (SSD) v2, Premium SSD, Standard SSD, and Standard hard disk drives (HDD). To learn about each disk type and decide which fits your needs, see Azure managed disk types.

An alternative is to use Azure Elastic SAN as the storage for your virtual machine (VM). With Elastic SAN, you can consolidate the storage for all your workloads into a single storage back end. Elastic SAN can be more cost effective if you have many large-scale, I/O-intensive workloads and top-tier databases. To learn more, see What is Azure Elastic SAN?.

High durability and availability

Managed disks are designed for 99.999% availability, to achieve this availability, managed disks provide three replicas of your data. If one or two replicas experience problems, the remaining replicas help ensure persistence of your data and high tolerance against failures.

This architecture helps Azure consistently deliver high durability for infrastructure as a service (IaaS) disks, with a 0% annualized failure rate. Locally redundant storage (LRS) disks provide at least 99.999999999% (11 9's) of durability over a year. Zone-redundant storage (ZRS) disks provide at least 99.9999999999% (12 9's) of durability over a year.

Simple and scalable VM deployment

With managed disks, you can create up to 50,000 disks of each disk type in a subscription per region. You can then create thousands of VMs in a single subscription.

Managed disks increase the scalability of virtual machine scale sets. You can create up to 1,000 VMs in a virtual machine scale set by using an Azure Marketplace image or an

Azure Compute Gallery image with managed disks.

Failure isolation

Integration with availability sets

Managed disks are integrated with availability sets to help ensure that the disks of VMs in an availability set are sufficiently isolated from each other to avoid a single point of failure.

Disks are automatically placed in different storage scale units (stamps). If a stamp fails due to hardware or software failure, only the VM instances with disks on those stamps fail.

For example, say you have an application running on five VMs that are in an availability set. The disks for those VMs aren't all stored in the same stamp. So if one stamp goes down, the other instances of the application continue to run.

Integration with availability zones

Managed disks support availability zones, which help protect your applications from datacenter failures. Availability zones are unique physical locations within an Azure region. Each zone consists of one or more datacenters equipped with independent power, cooling, and networking. To ensure resiliency, there's a minimum of three separate zones in all enabled regions.

For information about the service-level agreement (SLA) for VM uptime with availability zones, see the page for Azure SLAs.

Performance options

The demands and needs of your workload can shift over time, either due to high demand during a holiday, sudden bursts of traffic, or scaling up to meet client needs. Azure managed disks have several capabilities you can take advantage of to improve their performance and match the shifting needs of your workloads. Different disk types offer different capabilities, some disk types have capabilities you can use to ensure their performance automatically shifts to meet the changing demands of your workload, others require manual adjustment, and other disk types can't do either.

To learn about the options each disk type has, see Overview of options to improve Azure managed disk performance

Backup and disaster recovery options

Managed disks support several backup and disaster recovery options. These options include built-in redundancy options (locally redundant storage, and zone-redundant storage), Azure Backup, managed disk snapshots, restore points, and Azure Site Recovery. The ideal configuration of backup and disaster recovery options for your needs can vary. To decide which works best for your needs, see Backup and disaster recovery for Azure managed disks.

Snapshots

A managed disk snapshot is a read-only, crash-consistent full copy of a managed disk that's stored as a standard managed disk by default. With snapshots, you can back up your managed disks at any point in time. These snapshots exist independently of the source disk, and you can use them to create new managed disks.

To learn how to create managed disk snapshots, see Create a snapshot of a virtual hard disk.

Images

Managed disks support creating managed custom images. You can create an image from your custom VHD in a storage account or directly from a generalized (via Sysprep) VM. The image contains all managed disks associated with a VM, including both the OS and data disks. A managed custom image lets you create hundreds of VMs without the need to copy or manage any storage accounts.

For information on creating images, see Create a legacy managed image of a generalized VM in Azure.

Images vs snapshots

It's important to understand the difference between images and snapshots. With managed disks, you can take an image of a generalized VM that you deallocated. This image includes all of the disks attached to the VM. You can use this image to create a VM.

A snapshot is a copy of a disk at a point in time. It applies only to one disk. If you have a VM that has one disk (the OS disk), you can take a snapshot or an image of it and create a VM from either the snapshot or the image.

A snapshot doesn't have awareness of any disk except the one that it contains. Using snapshots in scenarios that require the coordination of multiple disks, such as striping, is problematic. Snapshots would need to be able to coordinate with each other, and that's not supported.

Upload your VHD or VHDX

You can reduce costs by uploading data to managed disks directly, without attaching them to VMs. With direct upload, you can upload VHDs up to 32 TiB in size. To learn how to upload your VHD to Azure, see the Azure CLI or Azure PowerShell articles.

Security

Control access to managed disk imports and exports

You have several options for protecting your managed disks from being imported or exported. You can create a custom Azure role-based access control (RBAC) role with a limited permission set, you can use Microsoft Entra ID, Private Links, Azure Policy, or configure the `NetworkAccessPolicy` parameter on your disk resources. To learn more, see Restrict managed disks from being imported or exported.

Encryption

Several kinds of encryption are available for your managed disks, including Server-Side Encryption (SSE), Azure Disk Encryption (ADE), encryption at host, and confidential disk encryption. You can use either platform-managed keys or customer-managed keys with these encryption options. To learn more about your encryption options, see Overview of managed disk encryption options

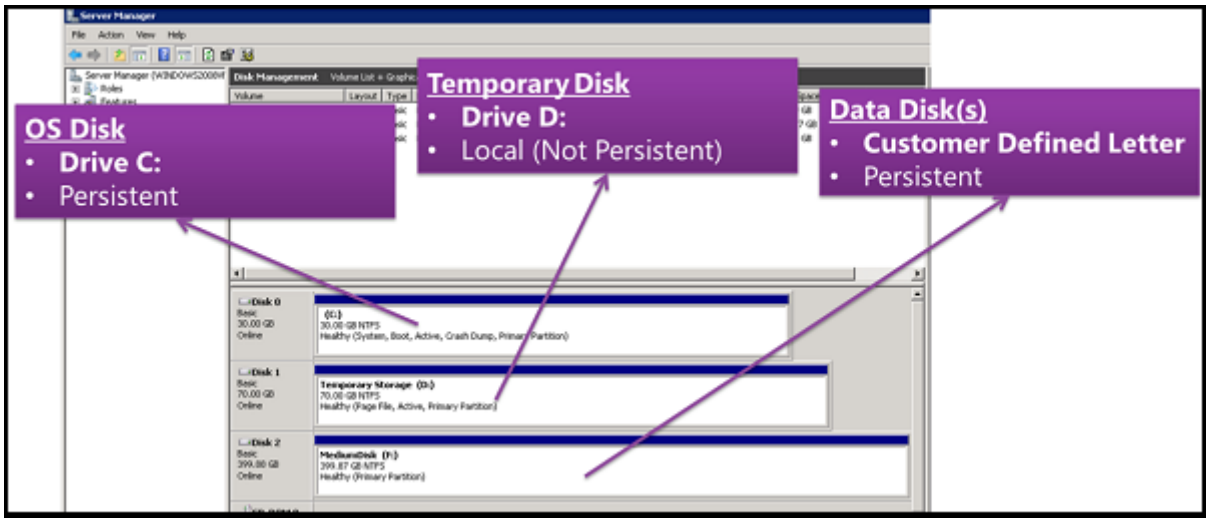
Shared disks

For use with cluster applications, you can attach an individual managed disk to multiple VMs simultaneously, allowing you to either deploy new or migrate existing clustered applications to Azure. This configuration requires a cluster manager, like Windows Server Failover Cluster (WSFC), or Pacemaker, that handles cluster node communication and write locking. To learn more about this configuration, see Share an Azure managed disk.

Disk roles

There are three main disk roles in Azure: the OS disk, the data disk, and the temporary disk. These roles map to disks that are attached to your virtual machine.

Performance for each disk role works differently. To learn more about how performance works for each role, see Disk allocation and performance.



OS disk

Every virtual machine has one attached OS disk. This disk has a preinstalled operating system, which you selected when creating the VM. This disk contains the boot volume.

Generally, you should store only your OS information on the OS disk. The data disk is where you should store all applications and data. If cost is a concern, you can use the OS disk instead of creating a data disk.

The OS disk has a maximum capacity of 4,095 gibibytes (GiB). However, many operating systems are partitioned with master boot records (MBRs) by default. An MBR limits the usable size to 2 TiB. If you need more than 2 TiB, create and attach data disks and use them for data storage. If you need to store data on the OS disk and require extra space, convert it to a GUID partition table (GPT). To learn about the differences between an MBR and a GPT on Windows deployments, see Windows and GPT FAQ.

On Azure Windows VMs, drive C is your OS disk and is persistent storage, unless you're using ephemeral OS disks.

Data disk

A data disk is a managed disk attached to a virtual machine to store application data or other data. Data disks are registered as SCSI drives and are labeled with a letter that you

choose. The size and type of the virtual machine determines how many data disks you can attach to the VM and the disk types you can use with the VM.

Generally, you should use data disks to store your applications and data, instead of storing them on an OS disk. Using data disks to store applications and data offers the following benefits over using OS disks:

- Improved backup and disaster recovery
- More flexibility and scalability
- Performance isolation
- Easier maintenance
- Improved security and access control

For more information on these benefits, see Why should I use the data disk to store applications and data instead of the OS disk?.

Temporary disk

Most VMs contain a temporary disk, which isn't a managed disk. The temporary disk provides short-term storage for applications and processes. It's intended for storing only data such as page files, swap files, or SQL Server tempdb files.

Data on the temporary disk might be lost during a maintenance event, when you redeploy a VM, or when you stop the VM. During a successful standard restart of the VM, data on the temporary disk persists. For more information about VMs without temporary disks, see Azure VM sizes with no local temporary disk.

On Azure Linux VMs, the temporary disk is typically */dev/sdb*. On Windows VMs, the temporary disk is drive D by default. The temporary disk isn't encrypted unless:

- You're using an Azure VM that is version 5 and above (such as Dsv5 or Dsv6). Azure VMs version 5 and above automatically encrypt their temporary disks and (if in use) their ephemeral OS disks with encryption-at-rest.
- For server-side encryption, you enable encryption at host.
- For Azure Disk Encryption, you set the `VolumeType` parameter to All on Windows or EncryptFormatAll on Linux.

Azure managed disk types

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure managed disks currently offers five disk types, each intended to address a specific customer scenario:

- Ultra Disks
- Premium SSD v2
- Premium SSDs (solid-state drives)
- Standard SSDs
- Standard HDDs (hard disk drives)

Disk type comparison

The following table provides a comparison of the five disk types to help you decide which to use.

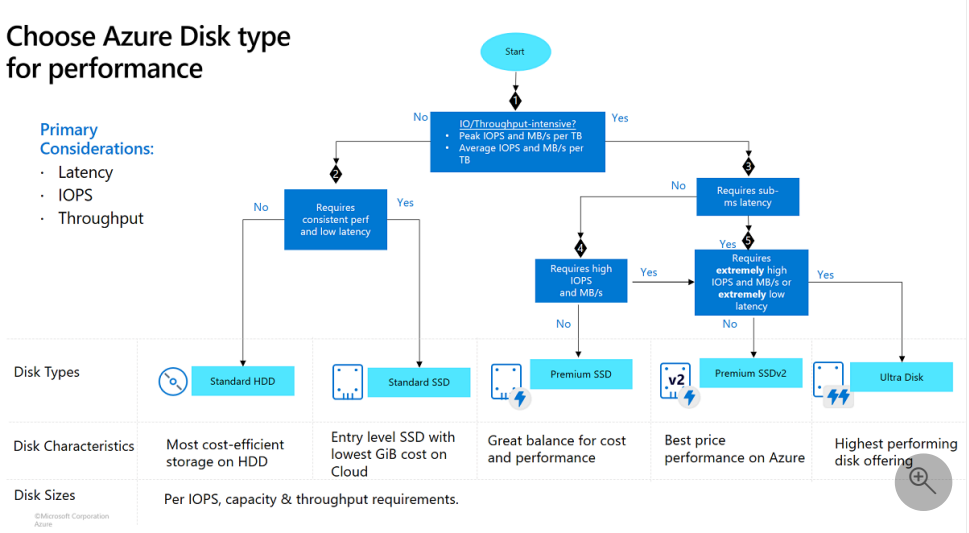
> ⓘ Note
>
> On September 8, 2028, the ability to use Standard HDDs as OS disks will be retired. To learn more, see Migrate your Standard HDD OS disks by September 08, 2028.

Expand table

	Ultra Disk	Premium SSD v2	Premium SSD	Standard SSD	Standard HDD
Disk type	SSD	SSD	SSD	SSD	HDD
Scenario	IO-intensive workloads such as SAP HANA, top tier databases (for example, SQL, Oracle), and other transaction-heavy workloads.	Production and performance-sensitive workloads that consistently require low latency and high IOPS and throughput	Production and performance sensitive workloads	Web servers, lightly used enterprise applications and dev/test	Backup, non-critical, infrequent access
Max disk size	65,536 GiB	65,536 GiB	32,767 GiB	32,767 GiB	32,767 GiB
Max throughput	10,000 MB/s	1,200 MB/s	900 MB/s	750 MB/s	500 MB/s
Max IOPS	400,000	80,000	20,000	6,000	2,000, 3,000*
Usable as OS Disk?	No	No	Yes	Yes	Yes (retiring Sept 8, 2028)

* Only applies to disks with performance plus enabled.

For more help deciding which disk type suits your needs, this decision tree should help with typical scenarios:



For a video that covers some high level differences for the different disk types, and some ways for determining what impacts your workload requirements, see Block storage options with Azure Disk Storage and Elastic SAN.

Ultra Disks

Azure Ultra Disks are the highest-performing storage option for Azure virtual machines (VMs). You can change the performance parameters of an Ultra Disk without having to restart your VMs. Ultra Disks are suited for data-intensive workloads such as SAP HANA, top-tier databases, and transaction-heavy workloads.

Ultra Disks must be used as data disks and can only be created as empty disks. When using Ultra Disks as data disks, use Premium solid-state drives (SSDs) as operating system (OS) disks.

Ultra Disk size

Ultra Disk sizes range from 4 GiB up to 64 TiB, in 1 GiB increments. Ultra Disk capacity works like Premium SSD v2 disks and you're billed on a per GiB ratio.

By default, for each individual region, you can deploy a total of 100 TiB of capacity as Ultra Disks per subscription. If you need more than 100 TiB of Ultra Disk capacity per region per subscription, request a quota increase or contact Azure Support.

The following table provides an example of performance caps an Ultra Disk has depending on the size you set for the disk.

Expand table

Disk Size (GiB)	IOPS Cap	Throughput Cap (MB/s)
4	4,000 (1,200)*	1,000 (300)*
8	8,000 (2,400)*	2,000 (600)*
16	16,000 (4,800)*	4,000 (1,200)*
32	32,000 (9,600)*	8,000 (2,400)*
64	64,000 (19,200)*	10,000 (4,900)*
128	128,000 (38,400)*	10,000 (9,800)*
256	256,000 (76,000)*	10,000
512	400,000 (153,000)*	10,000

Disk Size (GiB)	IOPS Cap	Throughput Cap (MB/s)
1,024	400,000 (307,200)*	10,000
2,048-65,536	400,000	10,000

* Only applies during deployment of Virtual Machine Scale Sets with Uniform orchestration mode. Setting a higher value during deployment results in a failed deployment. After deployment completes you can increase the performance of your disks.

Ultra Disk performance

Ultra Disks are designed to provide consistently low sub millisecond latencies and the highest limits for IOPS and throughput. With Ultra Disks, you can individually set the capacity, throughput, and IOPS of a disk based on your workload needs, increasing flexibility and reducing costs. Each of these values determine the cost of your disk. Within a 24 hour period, you can change the performance of a disk four times. It can take up to an hour for a performance change to take effect.

Ultra Disk IOPS

Ultra Disks support IOPS limits of 1000 IOPS/GiB, up to a maximum of 400,000 IOPS per disk. To achieve the target IOPS for the disk, ensure that the selected disk IOPS are less than the VM IOPS limit. Ultra Disks with greater IOPS can be used as shared disks to support multiple VMs. The minimum baseline IOPS per disk is 100.

> **Note**
>
> Only during deployment of Ultra Disks while using Uniform Virtual Machine Scale Sets: The minimum IOPS per disk are 1 IOPS/GiB, with an overall baseline minimum of 100 IOPS. The maximum IOPS per disk are 300 IOPS/GiB, up to a maximum of 400,000 IOPS per disk. If you exceed these limits at deployment, the deployment fails. You can **increase the performance** of these disks once deployment completes.

For more information about IOPS, see Virtual machine and disk performance.

Ultra Disk throughput

The maximum throughput limit of an Ultra Disk is .25 MB/s for each provisioned IOPS, up to a maximum of 10,000 MB/s per disk (where MB/s = 10^6 Bytes per second). The minimum guaranteed throughput of an Ultra Disk is 1 MB/s.

> **Note**
>
> Only during deployment of Ultra Disks while using Uniform Virtual Machine Scale Sets: The minimum throughput of an Ultra Disk is 4-KB/s per provisioned IOPS. So if you provision a 500 GiB, 500 IOPS Ultra Disk, the minimum throughput for that disk would be 2 MB/s and the maximum throughput that can be provisioned is 125 MB/s.

You can adjust Ultra Disk IOPS and throughput performance at runtime without detaching the disk from the virtual machine. After a performance resize operation has been issued on a disk, it can take up to an hour for the change to take effect. Up to four performance resize operations are permitted during a 24-hour window.

It's possible for a performance resize operation to fail because of a lack of performance bandwidth capacity.

Ultra Disk limitations

The following list contains Ultra Disk's limitations:

- Only during deployment with Virtual Machine Scale Sets with Uniform orchestration mode: At time of deployment, Ultra Disks used with Uniform Virtual Machine Scale Sets use different formulas for IOPS and throughput for their performance. Exceeding the limits of these formulas results in a deployment failure. Once the deployment succeeds you can increase the performance of these disks. See Ultra Disk IOPS and Ultra Disk throughput for details.
- Ultra Disks can't be used as an OS disk or with Azure Compute Gallery.
- Currently, Ultra Disks only support Single VM and Availability zone infrastructure options as locally redundant storage (LRS). Ultra Disks don't support zone redundant storage (ZRS).
- Ultra Disks don't support availability sets.
- Ultra Disks don't support disk caching.

Ultra Disks support a 4k physical sector size by default but also supports a 512E sector size. Most applications are compatible with 4k sector sizes, but some require 512-byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks. For older versions of Oracle DB, 512-byte sector size is required.

The following table outlines the regions Ultra Disks are available in, and their corresponding availability options.

> **Note**
>
> If a region in the following list lacks availability zones that support Ultra Disks, then a VM in that region must be deployed without infrastructure redundancy to attach an Ultra Disk.

Expand table

Redundancy options	Regions
Regional	Australia Central, Australia Central 2 Brazil Southeast Canada East Korea South Norway West UK West North Central US, West US US Gov Arizona, US Gov Texas

Three availability zones	Australia East Canada Central China North 3 North Europe, West Europe France Central Italy North Japan East Poland Central South Africa North Southeast Asia Sweden Central Switzerland North UAE North UK South Central US, East US, East US 2, West US 2, West US 3

Not every VM size is available in every supported region with Ultra Disks. The following table lists VM series that are compatible with Ultra Disks.

Expand table

VM Type	Sizes	Description
General purpose	DSv3-series, Ddsv4-series, Dsv4-series, Dasv4-series, Dsv5-series, Ddsv5-series, Dasv5-series, Dplsv6-series, Dpldsv6-series, Dpsv6-series, Dpdsv6-series	Balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.
Compute optimized	FSv2-series, Famsv6-series	High CPU-to-memory ratio. Good for medium traffic web servers, network appliances, batch processes, and application servers.
Memory optimized	ESv3-series, Easv4-series, Edsv4-series, Esv4-series, Esv5-series, Edsv5-series, Easv5-series, Ebsv5 series, Ebdsv5 series, M-series, Mv2-series, Msv2, Mdsv2-series, Mbsv3, Mbdsv3-series, Epsv6-series, Epdsv6-series	High memory-to-CPU ratio. Great for relational database servers, medium to large caches, and in-memory analytics.
Storage optimized	LSv2-series, Lsv3-series, Lasv3-series	High disk throughput and IO ideal for Big Data, SQL, NoSQL databases, data warehousing, and large transactional databases.
GPU optimized	NCv3-series, NCasT4_v3-series, ND-series, NDv2-series, NVv3-series, NVv4-series, NVadsA10 v5-series	Specialized virtual machines targeted for heavy graphic rendering and video editing, as well as model training and inferencing (ND) with deep learning. Available with single or multiple GPUs.
Performance optimized	HC-series, HBv2-series	The fastest and most powerful CPU virtual machines with optional high-throughput network interfaces (RDMA).

If you would like to start using Ultra Disks, see the article on using Azure Ultra Disks.

Premium SSD v2

Premium SSD v2 offers higher performance than Premium SSDs while also generally being less costly. You can individually tweak the performance (capacity, throughput, and IOPS) of Premium SSD v2 disks at any time, allowing workloads to be cost efficient while meeting shifting performance needs. For example, a transaction-intensive database may need a large amount of IOPS at a small size, or a gaming application may need a large amount of IOPS but

only during peak hours. Because of this, for most general purpose workloads, Premium SSD v2 can provide the best price performance.

Premium SSD v2 is suited for a broad range of workloads such as SQL server, Oracle, MariaDB, SAP, Cassandra, Mongo DB, big data/analytics, and gaming, on virtual machines or stateful containers.

Premium SSD v2 support a 4k physical sector size by default, but can be configured to use a 512E sector size as well. While most applications are compatible with 4k sector sizes, some require 512 byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks.

Differences between Premium SSD and Premium SSD v2

Unlike Premium SSDs, Premium SSD v2 doesn't have dedicated sizes. You can set a Premium SSD v2 to any supported size you prefer, and make granular adjustments to the performance without downtime. Premium SSD v2 doesn't support host caching but, benefits significantly from lower latency, which addresses some of the same core problems host caching addresses. The ability to adjust IOPS, throughput, and size at any time also means you can avoid the maintenance overhead of having to stripe disks to meet your needs.

Premium SSD v2 limitations

- Premium SSD v2 disks can't be used as an OS disk or with Azure Compute Gallery.
- For regions that support availability zones, Premium SSD v2 disks can only be attached to zonal VMs. When creating a new VM, specify the availability zone you want before adding Premium SSD v2 disks to your configuration.
- Premium SSD v2 doesn't support host caching.

Regional availability

Currently only available in the following regions:

Expand table

Regions without Availability Zone	*Two Availability Zones*	*Three Availability Zones*
- Australia Central 2 - Australia Southeast - Brazil Southeast - Canada East - Germany North - North Central US - Norway West - South India - Switzerland West - Taiwan North - UK West - US Gov Arizona - West Central US - West US	- Japan West	- Austria East - Australia East - Brazil South - Canada Central - Central India - Central US - China North 3 - East Asia - East US - East US 2 - France Central - Germany West Central - Indonesia Central - Israel Central - Italy North - Japan East - Korea Central - Malaysia West - Mexico Central - New Zealand North - North Europe - Norway East

Regions without Availability Zone	*Two Availability Zones*	*Three Availability Zones*
		- Poland Central - Spain Central - South African North - South Central US - Southeast Asia - Sweden Central - Switzerland North - UAE North - UK South - US Gov Virginia - West Europe - West US 2 - West US 3

To learn when support for particular regions was added, see either Azure Updates or What's new for Azure Disk Storage.

Premium SSD v2 performance

Premium SSD v2 disks are designed to provide provisioned IOPS and throughput 99.9% of the time. Premium SSD v2 disks are also designed to provide sub millisecond latencies. With Premium SSD v2 disks, you can individually set the capacity, throughput, and IOPS of a disk based on your workload needs, providing you with more flexibility and reduced costs. Each of these values determines the cost of your disk. You can adjust the performance of a Premium SSD v2 four times within a 24 hour period. Creating a disk counts as one of these times, so for the first 24 hours after creating a Premium SSD v2 you can only adjust its performance up to three times.

Premium SSD v2 capacities

Premium SSD v2 capacities range from 1 GiB to 64 TiBs, in 1-GiB increments. You're billed on a per GiB ratio, see the pricing page for details.

Premium SSD v2 offers up to 100 TiB per region per subscription by default, but supports higher capacity by request. To request an increase in capacity, request a quota increase or contact Azure Support.

Premium SSD v2 IOPS

All Premium SSD v2 disks have a baseline IOPS of 3000 that is free of charge. After 6 GiB, the maximum IOPS a disk can have increases at a rate of 500 per GiB, up to 80,000 IOPS. So an 8 GiB disk can have up to 4,000 IOPS, and a 10 GiB can have up to 5,000 IOPS. To be able to set 80,000 IOPS on a disk, that disk must have at least 160 GiBs. Increasing your IOPS beyond 3000 increases the price of your disk.

Premium SSD v2 throughput

All Premium SSD v2 disks have a baseline throughput of 125 MB/s that is free of charge. After 6 GiB, the maximum throughput that can be set increases by 0.25 MB/s per set IOPS. If a disk has 3,000 IOPS, the max throughput it can set is 750 MB/s. To raise the throughput for this disk beyond 750 MB/s, its IOPS must be increased. For example, if you increased the IOPS to 4,000, then the max throughput that can be set is 1,000. 1,200 MB/s is the maximum throughput supported for disks that have 5,000 IOPS or more. Increasing your throughput beyond 125 increases the price of your disk.

Premium SSD v2 Sector Sizes

Premium SSD v2 supports a 4k physical sector size by default. A 512E sector size is also supported. While most applications are compatible with 4k sector sizes, some require 512-byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks.

Summary

The following table provides an overview of disk capacities and performance maximums to help you decide which to use.

Expand table

Disk Size	Maximum available IOPS	Maximum available throughput (MB/s)
1 GiB-64 TiBs	3,000-80,000 (Increases by 500 IOPS per GiB)	125-1,200 (increases by 0.25 MB/s per set IOPS)

To deploy a Premium SSD v2, see Deploy a Premium SSD v2.

Premium SSDs

Azure Premium SSDs deliver high-performance and low-latency disk support for virtual machines (VMs) with input/output (IO)-intensive workloads. To take advantage of the speed and performance of Premium SSDs, you can migrate existing VM disks to Premium SSDs. Premium SSDs are suitable for mission-critical production applications, but you can use them only with compatible VM series. Premium SSDs support the 512E sector size.

To learn more about individual Azure VM types and sizes for Windows or Linux, including size compatibility for premium storage, see Sizes for virtual machines in Azure. You'll need to check each individual VM size article to determine if it's premium storage-compatible.

*Applies only to disks with on-demand bursting enabled.
** Only applies to disks with performance plus enabled.

Capacity, IOPS, and throughput are guaranteed when a premium storage disk is provisioned. For example, if you create a P50 disk, Azure provisions 4,095-GB storage capacity, 7,500 IOPS, and 250-MB/s throughput for that disk. Your application can use all or part of the capacity and performance. Premium SSDs are designed to provide the single-digit millisecond latencies, target IOPS, and throughput described in the preceding table 99.9% of the time.

Premium SSD bursting

Premium SSDs offer disk bursting, which provides better tolerance on unpredictable changes of IO patterns. Disk bursting is especially useful during OS disk boot and for applications with spiky traffic. To learn more about how bursting for Azure disks works, see Disk-level bursting.

Premium SSD transactions

For Premium SSDs, each I/O operation less than or equal to 256 kB of throughput is considered a single I/O operation. I/O operations larger than 256 kB of throughput are considered multiple I/Os of size 256 kB.

Standard SSDs

Azure Standard SSDs are optimized for workloads that need consistent performance at lower IOPS levels. They're an especially good choice for customers with varying workloads supported by on-premises hard disk drive (HDD) solutions. Compared to Standard HDDs, Standard SSDs deliver better availability, consistency, reliability, and latency. Standard SSDs are suitable for web servers, low IOPS application servers, lightly used enterprise applications, and non-production workloads. Like Standard HDDs, Standard SSDs are available on all Azure VMs. Standard SSDs support the 512E sector size.

Standard SSD size

Max burst throughput per disk	150 MB/s	150 MB/s	150 MB/s	150 MB/s	150 MB/s	150 MB/s	150 MB/s	150 MB/s	250 MB/s					
Max burst duration	30 min	30 min	30 min	30 min	30 min	30 min	30 min	30 min	30 min					

* Only applies to disks with performance plus enabled.

Standard SSDs are designed to provide single-digit millisecond latencies and the IOPS and throughput up to the limits described in the preceding table 99% of the time. Actual IOPS and throughput may vary sometimes depending on the traffic patterns. Standard SSDs provide more consistent performance than the HDD disks with the lower latency.

Standard SSD transactions

For Standard SSDs, each I/O operation less than or equal to 256 kB of throughput is considered a single I/O operation. I/O operations larger than 256 kB of throughput are considered multiple I/Os of size 256 kB. These transactions incur a billable cost but, there's an hourly limit on the number of transactions that can incur a billable cost. If that hourly limit is reached, additional transactions during that hour no longer incur a cost. For details, see the blog post.

Standard SSD Bursting

Standard SSDs offer disk bursting, which provides better tolerance for the unpredictable IO pattern changes. OS boot disks and applications prone to traffic spikes will both benefit from disk bursting. To learn more about how bursting for Azure disks works, see Disk-level bursting.

Standard HDDs

Azure Standard HDDs are suitable for latency-tolerant workloads using large, sequential IO, such as light data processing workloads that read or write large files sequentially. Standard HDDs are not suitable for workloads requiring low latency, or frequent small-block access - such as OS disks or transactional databases. Use either Standard SSDs or Premium SSD managed disks for these workloads. Standard HDDs are designed to deliver write latencies of less than 10 ms and read latencies of less than 20 ms for most IO operations. Performance may vary more widely than that of SSD-based disks, and actual performance may vary depending

on IO size and workload pattern. Standard HDDs are available in all Azure regions and can be used with all Azure VMs. Standard HDDs support the 512E sector size.

Standard HDD size

*Expanded throughput per disk	N/A	N/A	N/A	N/A	N/A	Up to 150 MB/s	Up to 300 MB/s	Up to 500 MB/s	Up to 500 MB/s	Up to 500 MB/s	Up to 500 MB/s

* Only applies to disks with performance plus enabled.

Standard HDD Transactions

Standard HDD transactions incur a billable cost for every 10,000 disk operations.

Billing

When using managed disks, the following billing considerations apply:

- Disk type
- Managed disk Size
- Snapshots
- Outbound data transfers
- Number of transactions

Managed disk size: managed disks are billed according to their provisioned size. Azure maps the provisioned size (rounded up) to the nearest offered disk size. For details of the disk sizes offered, see the previous tables. Each disk maps to a supported provisioned disk-size offering and is billed accordingly. For example, if you provisioned a 200-GiB Standard SSD, it maps to the disk size offer of E15 (256 GiB). Billing for any provisioned disk is prorated hourly by using the monthly price for the storage offering. For example, you provision an E10 disk and delete it after 20 hours of use. In this case, you're billed for the E10 offering prorated to 20 hours, regardless of the amount of data written to the disk.

Snapshots: Snapshots are billed based on the size used. For example, you create a snapshot of a managed disk with provisioned capacity of 64 GiB and actual used data size of 10 GiB. In this case, the snapshot is billed only for the used data size of 10 GiB.

For more information on snapshots, see Create a snapshot of a virtual hard disk.

Outbound data transfers: Outbound data transfers (data going out of Azure data centers) incur billing for bandwidth usage.

Transactions: You're billed for the number of transactions performed on a standard managed disk. For Standard SSDs, each I/O operation less than or equal to 256 kB of throughput is considered a single I/O operation. I/O operations larger than 256 kB of throughput are considered multiple I/Os of size 256 kB. Standard HDD transactions incur a billable cost for every 10,000 disk operations.

For detailed information on pricing for managed disks (including transaction costs), see managed disk pricing.

Ultra Disks VM reservation fee

Azure VMs have the capability to indicate if they're compatible with Ultra Disks. An Ultra Disk-compatible VM allocates dedicated bandwidth capacity between the compute VM instance and the block storage scale unit to optimize the performance and reduce latency. When you add this capability on the VM, it results in a reservation charge. The reservation charge is only imposed if you enabled Ultra Disk capability on the VM without an attached Ultra Disk. When an Ultra Disk is attached to the Ultra Disk compatible VM, the reservation charge wouldn't be applied. This charge is per vCPU provisioned on the VM.

> **Note**
>
> For **constrained core VM sizes**, the reservation fee is based on the actual number of vCPUs and not the constrained cores. For Standard_E32-8s_v3, the reservation fee will be based on 32 cores.

For Ultra Disk pricing details, see the Azure Disks pricing page.

Azure disk reservation

Disk reservation provides you with a discount on the advance purchase of one year's of disk storage, reducing your total cost. When you purchase a disk reservation, you select a specific disk SKU in a target region. For example, you may choose five P30 (1 TiB) Premium SSDs in the Central US region for a one year term. The disk reservation experience is similar to Azure reserved VM instances. You can bundle VM and Disk reservations to maximize your savings. For now, Azure Disks Reservation offers one year commitment plan for Premium SSD SKUs from P30 (1 TiB) to P80 (32 TiB) in all production regions. For more information about reserved disks pricing, see Azure Disks pricing page.

Last updated on 04/09/2026

Understand Azure Disk Storage billing

This article helps you understand how Azure managed disks are billed and how billing is laid out in your Azure Disk Storage bill. Some disks have unique attributes that affect their billing, but most disk types have the same set of attributes and are affected differently by these attributes depending on the disk type. You can also take snapshots of your disks, which are reflected in your bill.

For detailed Azure Disk Storage pricing information, see Azure Disks pricing page.

Snapshots

There are two kinds of snapshots offered for Azure managed disks: Full snapshots and incremental snapshots. Full snapshots can be stored on standard hard disk drives (HDDs) or premium solid-state drives (SSDs) while incremental snapshots are only stored on Standard HDDs. With snapshots, you're billed based on the used size of data. So if you take a full snapshot of a disk with 500-GiB size but only 50 GiB of that size is being used, then your snapshot is billed only for the used size of 50 GiB. Incremental snapshots are more cost efficient than full snapshots, as each snapshot you take only consists of the differences since the last snapshot.

Managed disk snapshots have two redundancy options, locally redundant storage (LRS) and zone-redundant storage (ZRS). For snapshots, the pricing for each redundancy option is the same.

Ultra Disks

The price of an Azure Ultra Disk is determined by the combination of how large the disk is (its disk size) and what performance you select (IOPS and throughput) for your disk. If you share an Ultra Disk between multiple VMs that can affect its price as well. The following sections focus on these factors as they relate to the price of your Ultra Disk. For more information on how these factors work, see the Ultra Disks section of the Azure managed disk types article.

Ultra Disk size

Ultra Disk capacities range from 4 GiB to 64 TiBs, in 1-GiB increments. You're billed on a per GiB ratio.

Ultra Disk IOPS

Pricing of an Azure Ultra Disk increases as you provision more IOPS to your disk. Ultra Disks supports 1000 IOPS/GiB, up to a maximum of 400,000 IOPS per disk.

Ultra Disk throughput

Pricing of an Ultra Disk increases as you increase the disk's throughput limit. Ultra Disk supports .25 MB/s for each provisioned IOPS, up to a maximum of 10,000 MB/s per disk (where MB/s = 10^6 Bytes per second). The minimum guaranteed throughput of an Ultra Disk is 1 MB/s.

Shared Ultra Disks

Ultra Disks can be used as shared disks, where you attach one disk to multiple VMs. For Ultra Disks, there isn't an extra charge for each VM that the disk is mounted to. Ultra Disks that are shared are billed on the total IOPS and MB/s that the disk is configured for. Normally, an Ultra Disk has two performance throttles that determine its total IOPS/MB/s. However, when configured as a shared Ultra Disk, two more performance throttles are exposed, for a total of four. These two extra throttles allow for increased performance at an extra expense and each meter has a default value, which raises the performance and cost of the disk. For more information, see Share an Azure managed disk.

Ultra Disk billing example

In this example, we provisioned an Ultra Disk with LRS redundancy with a total provisioned capacity of 3 TiB, a target performance of 100,000 IOPS and 2,000 MB/s of throughput. We also created and stored incremental snapshots for our used capacity. We're billed for the provisioned capacity of the disk, the extra IOPS and throughput past the baseline values, and the used snapshot capacity that shows as the following tier and meters in our bill:

Expand table

Tier	Meter
Ultra Disks	Ultra LRS provisioned capacity
Ultra Disks	Ultra LRS provisioned IOPS
Ultra Disks	Ultra LRS provisioned throughput (MB/s)

Tier	Meter
Standard HDD managed disks	ZRS snapshots

Premium SSD v2

The price of an Azure Premium SSD v2 is determined by the combination of how large the disk is (its capacity) and what performance you select (IOPS and throughput) for your disk. If you share a Premium SSD v2 between multiple VMs that can affect its price as well. The following sections focus on these factors as they relate to the price of your Premium SSD v2. For more information on how these factors work, see the Premium SSD v2 section of the Azure managed disk types article.

Premium SSD v2 capacities

Premium SSD v2 capacities range from 1 GiB to 64 TiBs, in 1-GiB increments. You're billed on a per GiB ratio. See the pricing page for details.

Premium SSD v2 IOPS

All Premium SSD v2 disks have a baseline IOPS of 3,000 that is free of charge. After 6 GiB, the maximum IOPS a disk can have increases at a rate of 500 per GiB, up to 80,000 IOPS. So an 8-GiB disk can have up to 4,000 IOPS, and a 10 GiB can have up to 5,000 IOPS. To set 80,000 IOPS on a disk, that disk must have at least 160 GiBs. Increasing your IOPS beyond 3,000 increases the price of your disk.

Premium SSD v2 throughput

All Premium SSD v2 disks have a baseline throughput of 125 MB/s that is free of charge. After 6 GiB, the maximum throughput that can be provisioned increases by 0.25 MB/s per provisioned IOPS. If a disk has 3,000 IOPS, the max throughput it can set is 750 MB/s. To raise the throughput for this disk beyond 750 MB/s, its IOPS must be increased. For example, if you increased the IOPS to 4,000, then the max throughput that can be set is 1,000. 1,200 MB/s is the maximum throughput supported for disks that have 5,000 IOPS or more. Increasing your provisioned throughput beyond 125 MB/s increases the price of your disk.

Shared Premium SSD v2

Premium SSD v2 managed disks can be used as shared disks, where you attach one disk to multiple VMs. For Premium SSD v2 disks there isn't an extra charge for each VM that the disk is mounted to. Premium SSD v2 disks that are shared are billed on the total IOPS and MB/s that the disk is configured for. Normally, a Premium SSD v2 has two performance throttles that determine its total IOPS/MB/s. However, when configured as a shared Premium SSD v2, two more performance throttles are exposed, for a total of four. These two extra throttles allow for increased performance at an extra expense and each meter has a default value, which raises the performance and cost of the disk. For more information, see Share an Azure managed disk.

Premium SSD v2 billing example

In this example, we provision a Premium SSD v2 with LRS redundancy with a total provisioned capacity of 512 GiB, a target performance of 40,000 IOPS and 200 MB/s of throughput. We also create and store incremental snapshots for our current used capacity. We're billed for the provisioned capacity of the disk, the IOPS and throughput past the baseline values, and the used snapshot capacity that show as the following tier and meters in our bill:

Expand table

Tier	Meter
Azure Premium SSD v2	Premium LRS provisioned capacity
Azure Premium SSD v2	Premium LRS provisioned IOPS
Azure Premium SSD v2	Premium LRS provisioned throughput (MB/s)
Standard HDD managed disks	LRS snapshots

Premium SSD

The price of an Azure Premium SSD is determined by the performance tier of the disk, whether bursting is enabled, what redundancy options you select, and whether or not you share the disk between multiple VMs. The following sections focus on these factors as they relate to the price of your Premium SSD. For more information on how these factors work, see the Premium SSDs section of the Azure managed disk types article.

Performance tier

The initial billing of Premium SSDs is determined by the performance tier of the disk. Generally, the performance tier is set when you select the capacity you require (if you deploy a 1 TiB

Premium SSD, it has the P30 tier by default) but certain disk sizes can select higher performance tiers. When you select a higher performance tier, your disk is billed at that tier until you change its performance tier again. To learn more about performance tiers, see Performance tiers for managed disks.

Premium SSD bursting

Premium SSDs offer two bursting models, credit-based bursting and on-demand bursting. Only on-demand bursting has billing impact and you must explicitly enable on-demand bursting. Premium SSD managed disks using on-demand bursting are charged an hourly burst enablement flat fee, and transaction costs apply to any burst transactions beyond the provisioned target. Transaction costs are charged using a pay-as-you go model, based on uncached disk IOs, including reads and writes that exceed provisioned targets.

Premium SSD transactions

For Premium SSD managed disks, each I/O operation less than or equal to 256 kB of throughput is considered a single I/O operation. I/O operations larger than 256 kB of throughput are considered multiple I/Os of size 256 kB. Unless you enable on-demand bursting, there are no transaction costs for Premium SSDs.

Redundancy options

Premium SSD managed disks can be deployed either with locally redundant storage (LRS) or zone-redundant storage (ZRS). The redundancy you select for your disk changes its pricing. For details see the Azure pricing page.

Shared Premium SSD

Premium SSD managed disks can be used as shared disks, where you attach one disk to multiple VMs. For shared Premium SSDs, there's a charge that increases with each VM the SSD is mounted to. See managed disks pricing for details.

Premium SSD billing example

In this example, we provision a Premium SSD at 512 GiB with LRS redundancy with bursting enabled.

We're billed for the provisioned capacity of the Premium SSD, the burst enablement flat fee, and transaction costs apply to any burst transactions beyond the provisioned target that show

as the following tier and meters in our bill:

Expand table

Tier	Meter
Premium SSD managed disks	P20 LRS Disk
Premium SSD managed disks	LRS Burst Enablement*
Premium SSD managed disks	LRS Burst Transactions*

*To see a more detailed example of how bursting is billed, see Disk-level bursting.

Standard SSD

The price of an Azure Standard SSD is determined by the performance tier of the disk, number of transactions, what redundancy options you select, and whether or not you share the disk between multiple VMs. The following sections focus on these factors as they relate to the price of your Standard SSD. For more information on how these factors work, see the Standard SSDs section of the Azure managed disk types article.

Performance tier

The initial billing of Standard SSDs is determined by the performance tier. The performance tier is set when you select the capacity you require (if you deploy a 1 TiB Standard SSD, it has the E30 tier), your disk is billed at that tier. If you increase the capacity of your disk into the next tier, it's then billed at that tier. For example, if you increased your 1-TiB disk to a 3-TiB disk, it's billed at the E50 tier.

Standard SSD transactions

For Standard SSDs, each I/O operation less than or equal to 256 kB of throughput is considered a single I/O operation. I/O operations larger than 256 kB of throughput are considered multiple I/Os of size 256 kB. These transactions incur a billable cost but, there's an hourly limit on the number of transactions that can incur a billable cost. If that hourly limit is reached, extra transactions during that hour no longer incur a cost. For details, see the blog post.

Redundancy options

Standard SSDs can be deployed either with locally redundant storage (LRS) or zone-redundant storage (ZRS). The redundancy you select for your disk changes its pricing. For details see the Azure pricing page.

Shared Standard SSDs

Standard SSDs can be used as shared disks, where you attach one disk to multiple VMs. For shared Standard SSDs, there's a charge that increases with each VM the SSD is mounted to. See managed disks pricing for details.

Standard SSD billing example

In this example, we provision a 1 TiB Standard SSD with LRS redundancy, where we also have snapshots created on the current used data capacity of 120 GiB. You're billed for the provisioned capacity of the SSD disk, the transactions performed on the disk, and the used snapshot capacity that will show as the following tier and meters in our bill:

Expand table

Tier	Meter
Standard SSD managed disks	E30 LRS Disk
Standard SSD managed disks	E4 LRS Disk Operations
Standard HDD managed disks	LRS snapshots

Standard HDD

The price of an Azure Standard HDD is determined by the performance tier of the disk and the number of transactions. The following sections focus on these factors as they relate to the price of your Standard HDD. For more information on how these factors work, see the Standard HDDs section of the Azure managed disk types article.

Performance tier

The initial billing of Standard HDDs is determined by the performance tier. The performance tier is set when you select the capacity you require (if you deploy a 1 TiB Standard HDD, it has the S30 tier), your disk is billed at that tier. If you increase the capacity of your disk into the next tier, it's billed at that tier. For example, if you increased your 1-TiB disk to a 3-TiB disk, it's billed at the S50 tier.

Standard HDD Transactions

Standard HDD transactions incur a billable cost for every 10,000 disk operations.

Standard HDD billing example

In this example, we provision a 512 GiB Standard HDD with LRS redundancy. We're billed for the provisioned capacity of the HDD disk and the transactions performed on the disk, which shows as the following tier and meters in our bill:

Expand table

Tier	Meter
Standard HDD managed disks	S20 LRS Disk
Standard HDD managed disks	S4 LRS Disk Operations

Last updated on 04/09/2026

Redundancy options for managed disks

07/02/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure managed disks offer two storage redundancy options, zone-redundant storage (ZRS), and locally redundant storage. ZRS provides higher availability for managed disks than locally redundant storage (LRS) does. However, the write latency for LRS disks is better than ZRS disks because LRS disks synchronously write data to three copies in a single data center.

Locally redundant storage for managed disks

Locally redundant storage (LRS) replicates your data three times within a single data center in the selected region. LRS protects your data against server rack and drive failures. LRS disks provide at least 99.999999999% (11 9's) of durability over a given year. To protect an LRS disk from a zonal failure like a natural disaster or other issues, take the following steps:

- Use applications that can synchronously write data to two zones, and automatically failover to another zone during a disaster.
  - An example would be SQL Server Always On.
- Take frequent backups of LRS disks with ZRS snapshots.
- Enable cross-zone disaster recovery for LRS disks via Azure Site Recovery. However, cross-zone disaster recovery doesn't provide zero Recovery Point Objective (RPO).

If your workflow doesn't support application-level synchronous writes across zones, or your application must meet zero RPO, then ZRS disks would ideal.

Zone-redundant storage for managed disks

Zone-redundant storage (ZRS) synchronously replicates your Azure managed disk across three Azure availability zones in the region you select. Each availability zone is a separate physical location with independent power, cooling, and networking. ZRS disks provide at least 99.9999999999% (12 9's) of durability over a given year.

A ZRS disk lets you recover from failures in availability zones. If a zone went down and your virtual machine (VM) wasn't affected, then your workloads continue running. But if your VM was affected by an outage and you want to recover before it's resolved, you can force detach your ZRS disks from the failed VM, freeing them to attach to another VM.

ZRS disks can also be shared between VMs for improved availability with clustered or distributed applications like SQL FCI, SAP ASCS/SCS, or GFS2. A shared ZRS disk can be

attached to primary and secondary VMs in different zones to take advantage of both ZRS and availability zones. If your primary zone fails, you can quickly fail over to the secondary VM using SCSI persistent reservation.

For more information on ZRS disks, see Zone Redundant Storage (ZRS) option for Azure Disks for high availability.

Limitations

ZRS for managed disks is only supported with Premium SSD and Standard SSD managed disks. ZRS for managed disks isn't supported with Premium SSD v2 managed disks or Ultra Disks. Force detach only supports data disks.

Regional availability

ZRS disks are available in all regions that have availability zone support. For a list of these regions, see Azure regions list.

Billing implications

For details see the Azure pricing page.

Comparison with other disk types

Except for more write latency, disks using ZRS are identical to disks using LRS, they have the same scale targets. Benchmark your disks to simulate the workload of your application and compare the latency between LRS and ZRS disks.

Next steps

- To learn how to create a ZRS disk, see Deploy a ZRS managed disk.
- To convert an LRS disk to ZRS, see Convert a disk from LRS to ZRS.

What's new for Azure Disk Storage

Summarize this article for me

Azure Disk Storage regularly receives updates for new features and enhancements. This article provides information about what's new in Azure Disk Storage.

Update summary

- What's new in 2026
  - Quarter 1 (January, February, March)
    - Expanded regional availability for Premium SSD v2
- What's new in 2025
  - Quarter 4 (October, November, December)
    - Expanded regional availability for Premium SSD v2
    - Public preview: Instant Access Snapshot for Premium SSD v2 and Ultra Disks
    - Generally available: Azure Site Recovery for Virtual Machines with Premium SSD v2 and Ultra Disks
  - Quarter 3 (July, August, September)
    - Generally available: Live Resize for Premium SSD v2 and Ultra Disks using NVMe controllers
    - Generally available: Ultra Disk price reduction in West US 2, Central US, and UK South
  - Quarter 2 (April, May, June)
    - Generally available: Troubleshoot Disk Performance with Copilot in Azure
    - Generally available: Availability Set support for Premium SSD v2 Storage
    - Expanded regional availability for Premium SSD v2
  - Quarter 1 (January, February, March)

What's new in 2026

Quarter 1 (January, February, March)

Expanded regional availability for Premium SSD v2

Premium SSD v2 disks are now available in Brazil Southeast, Germany North, Switzerland West and in a third Availability Zone in Indonesia Central, Malaysia West and New Zealand North.

What's new in 2025

Quarter 4 (October, November, December)

Expanded regional availability for Premium SSD v2

Premium SSD v2 disks are now available in Austria East and in a second Availability Zone in Japan West.

Public preview: Instant Access Snapshot for Premium SSD v2 and Ultra Disks

By using Instant Access Snapshots for Premium SSD v2 and Ultra Disks, you can restore new disks right after creating snapshots of Premium SSD v2 and Ultra Disks. Restore disks deliver high performance instantly, while data hydration continues rapidly in the background. For more information, see instant access for Azure Managed Disk.

Generally available: Azure Site Recovery for Virtual Machines with Premium SSD v2 and Ultra Disks

Azure Site Recovery support for Virtual Machines with Premium SSD v2 and Ultra disks is generally available. Azure Site Recovery provides seamless disaster recovery for Virtual Machines across Azure Regions and from on-premises to Azure, helping organizations maintain business continuity. It offers cost-effective replication, automated failover, and easy disaster recovery simulation, ensuring minimal production impact during disaster events. Learn more.

Quarter 3 (July, August, September)

Generally available: Live Resize for Premium SSD v2 and Ultra Disks using NVMe controllers

You can dynamically expand the storage capacity of your Premium SSD v2 and Ultra Disks using NVMe controllers without any disruption to your applications. To optimize costs, you can start with smaller disks and gradually increase their storage capacity as needed, without experiencing downtime. For more information, see expand with Ultra Disks and Premium SSD v2.

Generally available: Ultra Disk price reduction in West US 2, Central US, and UK South

To better support performance sensitive and mission critical workloads on Azure, Ultra Disk offers improved cost efficiency in West US 2, Central US, and UK South. These enhancements give you access to the same high-performance storage at a lower cost. For details, see West US 2, Central US, and UK South.

Quarter 2 (April, May, June)

Public preview: Azure Site Recovery for Virtual Machines with Premium SSD v2 and Ultra Disks

Azure Site Recovery support for Virtual Machines with Premium SSD v2 and Ultra disks is in public preview. Azure Site Recovery provides seamless disaster recovery for Virtual Machines across Azure Regions and from on-premises to Azure, helping organizations maintain business continuity. It offers cost-effective replication, automated failover, and easy disaster recovery simulation, ensuring minimal production impact during disaster events. With built-in security, compliance support, and native integration with Azure services, Azure Site Recovery helps your organization stay resilient and minimize downtime. Learn more.

Generally available: Troubleshoot Disk Performance with Copilot in Azure

The Disk Performance Troubleshooting Capability for Copilot in Azure is now generally available as a part of the Copilot in Azure General Availability. Now, you can use Copilot in Azure to analyze your disk metrics and resolve any performance degradation issues when your application requires higher performance than what you configured for your VMs and disks. To learn more, see Troubleshoot Disk Performance using Microsoft Copilot in Azure.

Generally available: Availability Set support for Premium SSD v2 Storage

Availability Set support for Premium SSD v2 storage is now generally available. Availability Set enhances application availability by distributing virtual machines and their associated Premium SSD v2 disks across multiple fault domains, reducing the risk of a single point of failure. Premium SSD v2 provides low latency, consistent performance, flexible scalability, and cost efficiency making it an ideal choice for enterprise workloads such as SAP, SQL Server, and Oracle. The combination of Availability Set and Premium SSD v2 enables customers to achieve higher availability, performance, and cost optimization for their critical applications. For more information, see Availability Sets with Premium SSD v2 documentation.

Expanded regional availability for Premium SSD v2

Premium SSD v2 disks are available in Australia Central 2, Australia Southeast, Canada East, Indonesia Central, Japan West, Malaysia West, New Zealand North, North Central US, Norway West, UK West, US West, and West Central US.

Quarter 1 (January, February, March)

Public preview: Troubleshoot disk performance with Copilot in Azure

The Disk Performance Troubleshooting Capability for Copilot in Azure is now available in Public Preview. Now, you can use Copilot in Azure to analyze your disk metrics and resolve any performance degradation problems when your application requires higher performance than what you configured for your VMs and disks. To learn more, see Troubleshoot Disk Performance using Microsoft Copilot in Azure.

What's new in 2024

Quarter 4 (October, November, December)

Generally available: Convert existing disks to Premium SSD v2 disks

Directly converting a disk to a Premium SSD v2 is generally available. This feature makes it easier to move your workloads from Standard HDD, Standard SSD, and Premium Disks, to Premium SSD v2 disks, and take advantage of its balance of price and performance capabilities. To learn more, see Convert Premium SSD v2 disks.

Generally available: Expand Ultra Disks and Premium SSD v2 without downtime

Expanding Ultra Disks and Premium SSD v2 disks without downtime is generally available. This feature allows you to dynamically increase the capacity of your storage without causing disruptions to existing applications. To learn more, see the Windows or Linux articles.

Expanded regional availability for Premium SSD v2

Premium SSD v2 disks are available in Germany West Central, Israel Central, Italy North, Spain Central, and Mexico Central regions. For more information, see the Azure Update.

Quarter 2 (April, May, June)

Generally available: New property for disks - LastOwnershipUpdateTime

The `LastOwnershipUpdateTime` property is now available for disks in the Azure portal, Azure PowerShell module, and Azure CLI. This property reflects the time when a disk's state was last changed. This property can be used with the `diskState` to identify the current state of a disk, and when it was last updated. To learn more, see the Azure Update post or the documentation.

Quarter 1 (January, February, March)

Generally available: Azure VM Backup support for Ultra Disks and Premium SSD v2

Azure Backup enabled support on Azure VMs using Ultra Disks and Premium SSD v2 that offers high throughput, high IOPS, and low latency. Azure VM Backup support allows you to ensure business continuity for your virtual machines and to recover from any disasters or ransomware attacks. Enabling backup on VMs using Ultra Disks and Premium SSD v2 is available in all regions where Ultra Disks and Premium SSD v2 disks are supported. For more information, see the documentation and enable backup on your Azure VMs.

Generally available: Trusted launch support for Ultra Disks and Premium SSD v2

Trusted launch VMs added support for Ultra Disks and Premium SSD v2, so you can combine the foundational compute security of Trusted Launch with the high throughput, high IOPS, and low latency of Ultra Disks and Premium SSD v2. For more information, see Trusted launch for Azure virtual machines or the Azure Update.

Expanded regional availability for Ultra Disks

Ultra Disks are available in the UK West and Poland Central regions.

Expanded regional availability for zone-redundant storage disks

Zone-redundant storage (ZRS) disks are available in West US 3 and Germany Central regions.

What's new in 2023

Quarter 4 (October, November, December)

Encryption at host is generally available for Premium SSD v2 and Ultra Disks

Encryption at host was previously only available for Standard HDDs, Standard SSDs, and Premium SSDs. Encryption at host is now also available as a GA offering for Premium SSD v2 and Ultra Disks. For more information on encryption at host, see Encryption at host - End-to-end encryption for your VM data.

Some additional restrictions apply to Premium SSD v2 and Ultra Disks that enable encryption at host. For more information, see Restrictions.

New latency metrics (preview)

Metrics dedicated to monitoring latency are now available as a preview feature. To learn more, see either the metrics article or the Azure Update.

Expanded regional availability for Premium SSD v2

Premium SSD v2 disks are available in Poland Central, China North 3, and US Gov Virginia. For more information, see the Azure Update.

Expanded regional availability for ZRS disks

ZRS disks are available in the Norway East and UAE North regions. For more information, see the Azure Update.

Quarter 3 (July, August, September)

Expanded regional availability for ZRS disks

In quarter 3, ZRS disks became available in the China North 3, East Asia, India Central, Switzerland North, South Africa North, and Sweden Central regions.

Expanded regional availability for Premium SSD v2

In quarter 3, Premium SSD v2 became available in the Australia East, Brazil South, Canada Central, Central India, Central US, East Asia, France Central, Japan East, Korea Central, Norway East, South Africa North, Sweden Central, Switzerland North, and UAE North regions.

General availability - Incremental snapshots for Premium SSD v2 and Ultra Disks

Incremental snapshots for Premium SSD v2 and Ultra Disks are now generally available (GA). For more information, see either the documentation or the Azure Update.

Quarter 2 (April, May, June)

Expanded regional availability for Premium SSD v2

In quarter 2, Premium SSD v2 disks became available in the Southeast Asia, UK South, South Central US, and West US 3 regions.

Expanded regional availability for ZRS disks

In quarter 2, ZRS disks became available in the Australia East, Brazil South, Japan East, Korea Central, Qatar Central, UK South, East US, East US 2, South Central US, and Southeast Asia regions.

Azure Backup support (preview) for Premium SSD v2

Azure Backup added preview support for Azure virtual machines using Premium SSD v2 disks in the East US and West Europe regions. For more information, see the Azure Update.

Quarter 1 (January, February, March)

Expanded regional availability for Premium SSD v2

In quarter 1, Premium SSD v2 disks became available in the East US 2, North Europe, and West US 2 regions.

Preview - Performance plus

Azure Disk Storage added a new preview feature, performance plus. Performance plus enhances the IOPS and throughput performance for Premium SSDs, Standard SSDs, and Standard HDDs that are 513 GiB and larger. For details, see Increase IOPS and throughput limits for Azure Premium SSDs and Standard SSD/HDDs.

Expanded regional availability for Ultra Disks

In quarter 1, Ultra Disks became available in the Brazil Southeast, China North 3, Korea South, South Africa North, Switzerland North, and UAE North regions.

More transactions at no extra cost - Standard SSDs

In quarter 1, an hourly limit was added to the number of transactions that can occur before a billable cost. Any transactions beyond that limit don't incur a cost. For more information, see the blog post or Standard SSD transactions.

GA: Create disks from snapshots encrypted with customer-managed keys across subscriptions

In quarter 1, support was added for creating disks from snapshots or other disks encrypted with customer-managed keys in different subscriptions while within the same tenant. For more information, see either the Azure Update or the documentation.

GA: Entra ID support for managed disks

In quarter 1, support was added for using Entra ID to secure uploads and downloads of managed disks. For details, see Secure downloads and uploads of Azure Managed Disks.

- Introduction to Azure Managed Disks

Last updated on 02/19/2026

Using Azure Ultra Disks

07/02/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article explains how to deploy and use an Ultra Disk, for conceptual information about Ultra Disks, refer to What disk types are available in Azure?.

Azure Ultra Disks offer high throughput, high IOPS, and consistent low latency disk storage for Azure IaaS virtual machines (VMs). This new offering provides top of the line performance at the same availability levels as our existing disks offerings. One major benefit of Ultra Disks is the ability to dynamically change the performance of the SSD along with your workloads without the need to restart your VMs. Ultra Disks are suited for data-intensive workloads such as SAP HANA, top tier databases, and transaction-heavy workloads.

GA scope and limitations

The following list contains Ultra Disk's limitations:

- Ultra Disks can't be used as an OS disk or with Azure Compute Gallery.
- Currently, Ultra Disks only support Single VM and Availability zone infrastructure options as locally redundant storage (LRS). Ultra Disks don't support zone redundant storage (ZRS).
- Ultra Disks don't support availability sets.
- Ultra Disks don't support disk caching.
- (Preview) You can encrypt Ultra Disks with customer-managed keys using Azure Key Vaults stored in a different Microsoft Entra ID tenant.

Ultra Disks support a 4k physical sector size by default but also supports a 512E sector size. Most applications are compatible with 4k sector sizes, but some require 512-byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks. For older versions of Oracle DB, 512-byte sector size is required.

The following table outlines the regions Ultra Disks are available in, and their corresponding availability options.

> ⓘ **Note**
>
> If a region in the following list lacks availability zones that support Ultra disks, then a VM in that region must be deployed without infrastructure redundancy to attach an Ultra Disk.

Expand table

Redundancy options	Regions
Regional	Australia Central, Australia Central 2 Brazil Southeast Canada East Korea South Norway West UK West North Central US, West US US Gov Arizona, US Gov Texas
One availability zone	Brazil South Central India East Asia Germany West Central Korea Central South Central US Spain Central US Gov Virginia
Two availability zones	Indonesia Central Malaysia West New Zealand North Qatar Central
Three availability zones	Australia East Canada Central China North 3 North Europe, West Europe France Central Italy North Japan East Poland Central South Africa North Southeast Asia Sweden Central Switzerland North UAE North UK South Central US, East US, East US 2, West US 2, West US 3

Not every VM size is available in every supported region with Ultra Disks. The following table lists VM series that are compatible with Ultra Disks.

Expand table

VM Type	Sizes	Description
General purpose	DSv3-series, Ddsv4-series, Dsv4-series, Dasv4-series, Dsv5-series, Ddsv5-series, Dasv5-series, Dplsv6-series, Dpldsv6-series, Dpsv6-series, Dpdsv6-series	Balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.
Compute optimized	FSv2-series, Famsv6-series	High CPU-to-memory ratio. Good for medium traffic web servers, network appliances, batch processes, and application servers.
Memory optimized	ESv3-series, Easv4-series, Edsv4-series, Esv4-series, Esv5-series, Edsv5-series, Easv5-series, Ebsv5 series, Ebdsv5 series, M-series, Mv2-series, Msv2, Mdsv2-series, Mbsv3, Mbdsv3-series, Epsv6-series, Epdsv6-series	High memory-to-CPU ratio. Great for relational database servers, medium to large caches, and in-memory analytics.
Storage optimized	LSv2-series, Lsv3-series, Lasv3-series	High disk throughput and IO ideal for Big Data, SQL, NoSQL databases, data warehousing, and large transactional databases.
GPU optimized	NCv3-series, NCasT4_v3-series, ND-series, NDv2-series, NVv3-series, NVv4-series, NVadsA10 v5-series	Specialized virtual machines targeted for heavy graphic rendering and video editing, as well as model training and inferencing (ND) with deep learning. Available with single or multiple GPUs.
Performance optimized	HC-series, HBv2-series	The fastest and most powerful CPU virtual machines with optional high-throughput network interfaces (RDMA).

Determine VM size and region availability

VMs using availability zones

To use Ultra Disks, you need to determine which availability zone you are in. Not every region supports every VM size with Ultra Disks. To determine if your region, zone, and VM size support Ultra Disks, run either of the following commands, make sure to replace the **region**, **vmSize**, and **subscriptionId** values first:

CLI

Azure CLI

```
subscriptionId="<yourSubID>"
# Example value is southeastasia
region="<yourLocation>"
# Example value is Standard_E64s_v3
vmSize="<yourVMSize>"

az vm list-skus --resource-type virtualMachines --location $region --query "[?
name=='$vmSize'].locationInfo[0].zoneDetails[0].Name" --subscription
$subscriptionId
```

PowerShell

PowerShell

```
# Example value is southeastasia
$region = "<yourLocation>"
# Example value is Standard_E64s_v3
$vmSize = "<yourVMSize>"
$sku = (Get-AzComputeResourceSku | where {$_.Locations -icontains($region) -and
($_.Name -eq $vmSize) -and $_.LocationInfo[0].ZoneDetails.Count -gt 0})
if($sku){$sku[0].LocationInfo[0].ZoneDetails} Else {Write-host "$vmSize is not
supported with Ultra Disk in $region region"}
```

The response will be similar to the form below, where X is the zone to use for deploying in your chosen region. X could be either 1, 2, or 3.

Preserve the **Zones** value, it represents your availability zone and you'll need it in order to deploy an Ultra disk.

Expand table

ResourceType	Name	Location	Zones	Restriction	Capability	Value
disks	UltraSSD_LRS	eastus2	X			

> **Note**
>
> If there was no response from the command, then the selected VM size is not supported with Ultra Disks in the selected region.

Now that you know which zone to deploy to, follow the deployment steps in this article to either deploy a VM with an Ultra Disk attached or attach an Ultra Disk to an existing VM.

VMs with no redundancy options

Ultra disks deployed in select regions must be deployed without any redundancy options, for now. However, not every VM size that supports Ultra Disks are necessarily in these regions. To determine which VM sizes support Ultra Disks, use either of the following code snippets. Make sure to replace the `vmSize`, `region`, and `subscriptionId` values first:

Azure CLI

```
subscriptionId="<yourSubID>"
# Example value is westus
region="<yourLocation>"
# Example value is Standard_E64s_v3
vmSize="<yourVMSize>"

az vm list-skus --resource-type virtualMachines --location $region --query "[?
name=='$vmSize'].capabilities" --subscription $subscriptionId
```

PowerShell

```
# Example value is westus
$region = "<yourLocation>"
# Example value is Standard_E64s_v3
$vmSize = "<yourVMSize>"
(Get-AzComputeResourceSku | where {$_.Locations -icontains($region) -and ($_.Name
-eq $vmSize) })[0].Capabilities
```

The response will be similar to the following form, `UltraSSDAvailable True` indicates whether the VM size supports Ultra Disks in this region.

```
Name                                        Value
----                                        -----
MaxResourceVolumeMB                         884736
OSVhdSizeMB                                 1047552
vCPUs                                       64
HyperVGenerations                           V1,V2
MemoryGB                                    432
MaxDataDiskCount                            32
LowPriorityCapable                          True
PremiumIO                                   True
VMDeploymentTypes                           IaaS
vCPUsAvailable                              64
ACUs                                        160
vCPUsPerCore                                2

CombinedTempDiskAndCachedReadBytesPerSecond 1073741824
CombinedTempDiskAndCachedWriteBytesPerSecond 1073741824
CachedDiskBytes                             1717986918400
UncachedDiskIOPS                            80000
```

```
UncachedDiskBytesPerSecond              1258291200
EphemeralOSDiskSupported                True
AcceleratedNetworkingEnabled            True
RdmaEnabled                             False
MaxNetworkInterfaces                    8
UltraSSDAvailable                       True
```

Deploy an Ultra Disk using Azure Resource Manager

First, determine the VM size to deploy. For a list of supported VM sizes, see the GA scope and limitations section.

If you would like to create a VM with multiple Ultra Disks, refer to the sample Create a VM with multiple Ultra Disks.

If you intend to use your own template, make sure that **apiVersion** for `Microsoft.Compute/virtualMachines` and `Microsoft.Compute/Disks` is set as `2018-06-01` (or later).

Set the disk sku to **UltraSSD_LRS**, then set the disk capacity, IOPS, availability zone, and throughput in MBps to create an Ultra Disk.

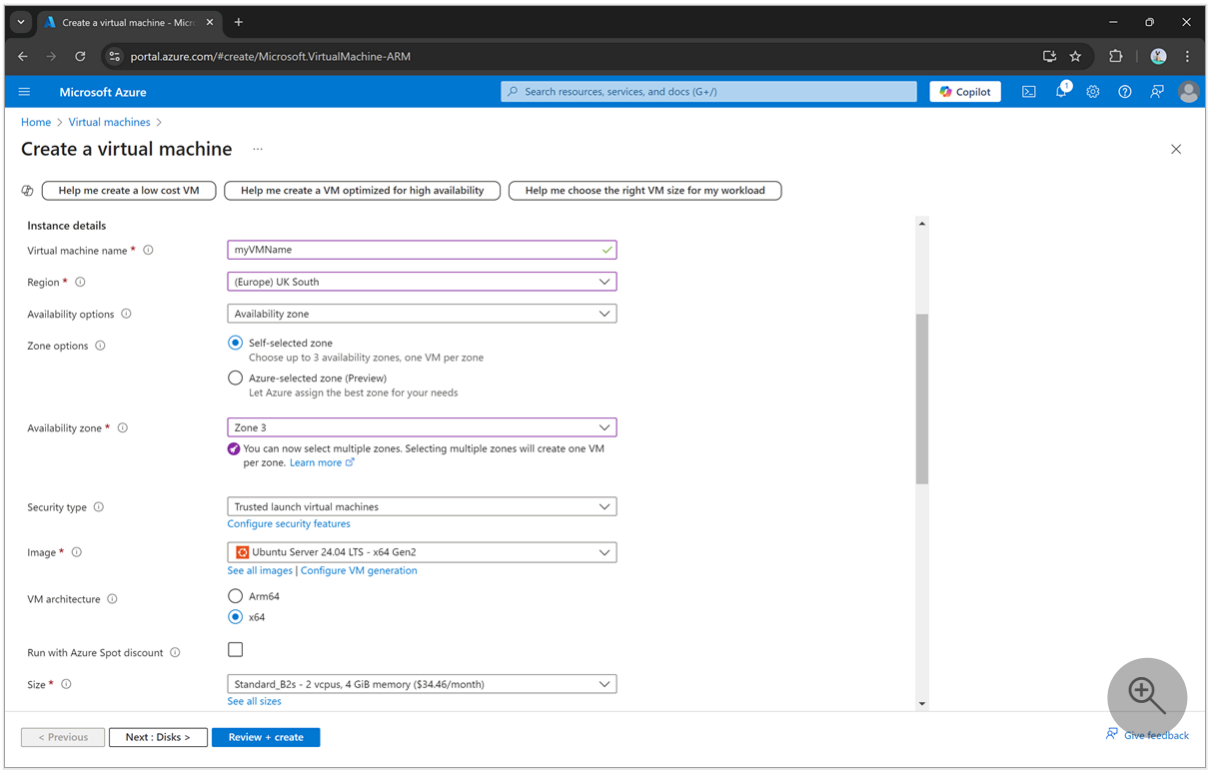
Once the VM is provisioned, you can partition and format the data disks and configure them for your workloads.

Deploy an Ultra Disk

Portal

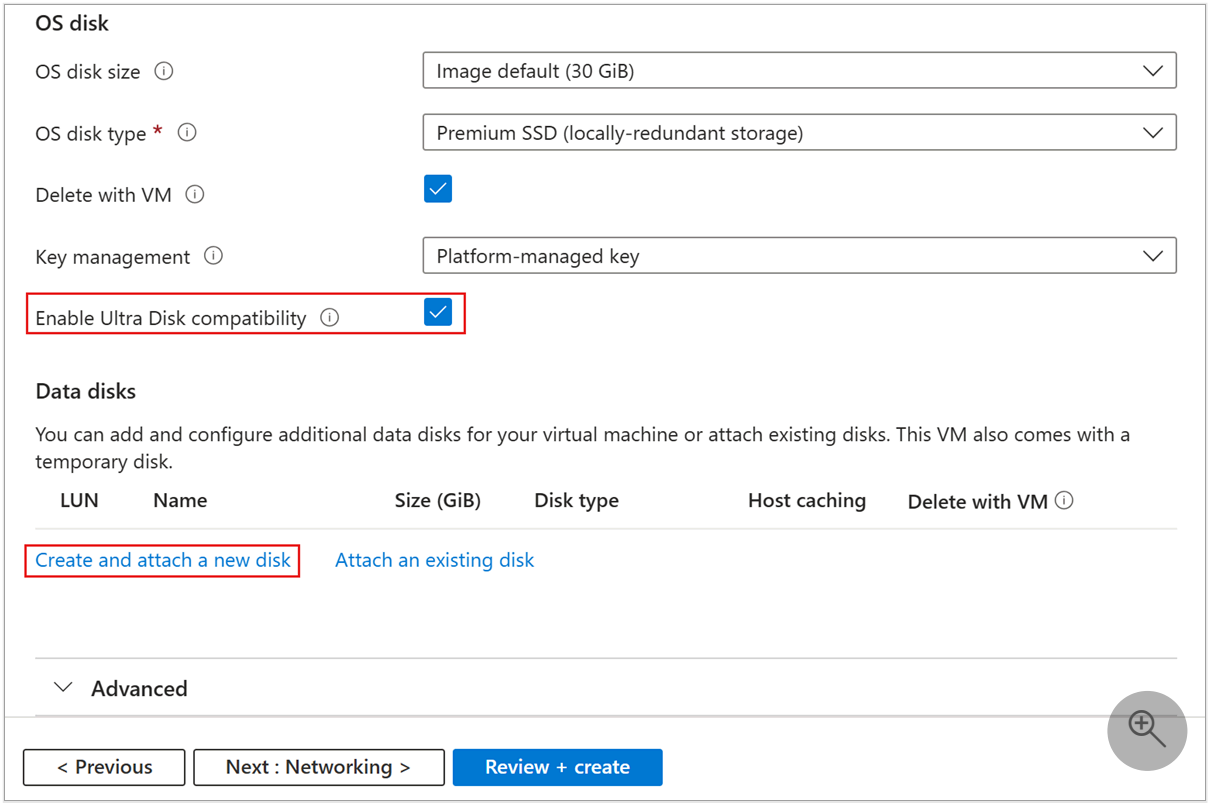
This section covers deploying a virtual machine equipped with an Ultra Disk as a data disk. It assumes you have familiarity with deploying a virtual machine, if you don't, see our Quickstart: Create a Windows virtual machine in the Azure portal.

1. Sign in to the Azure portal and navigate to deploy a virtual machine (VM).
2. Make sure to choose a supported VM size and region.
3. Select **Availability zone** in **Availability options**.
4. Fill in the remaining entries with selections of your choice.
5. Select **Disks**.

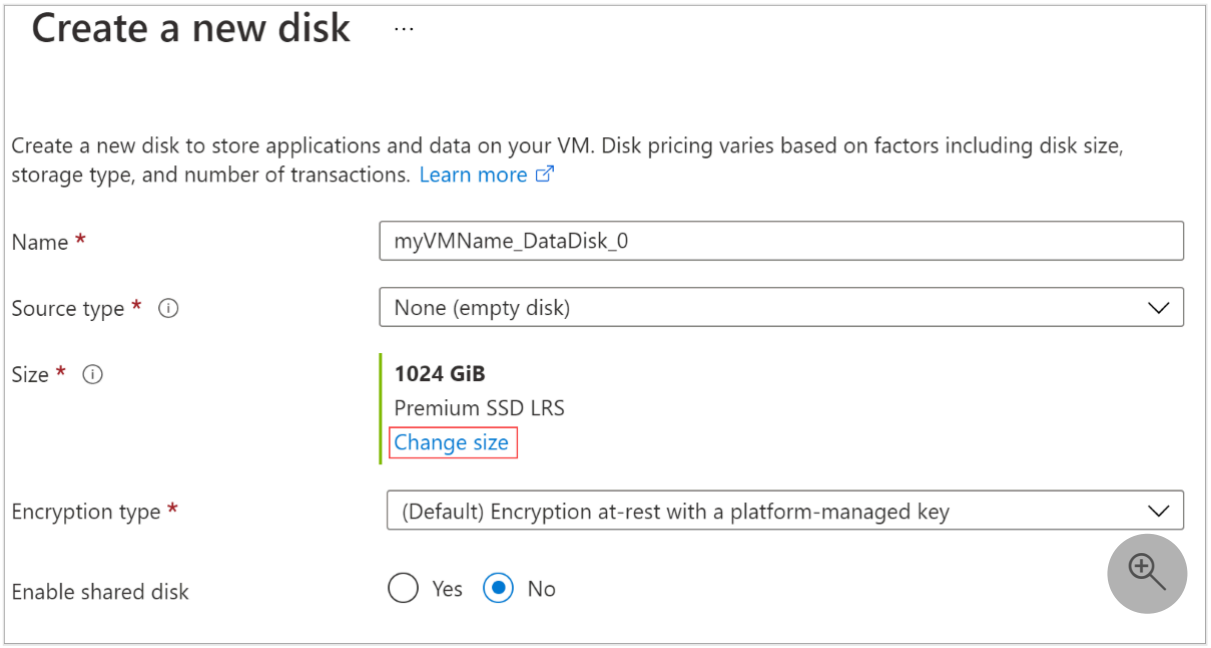


6. On the Disks blade, select **Yes** for **Enable Ultra Disk compatibility**.

7. Select **Create and attach a new disk** to attach an Ultra disk now.



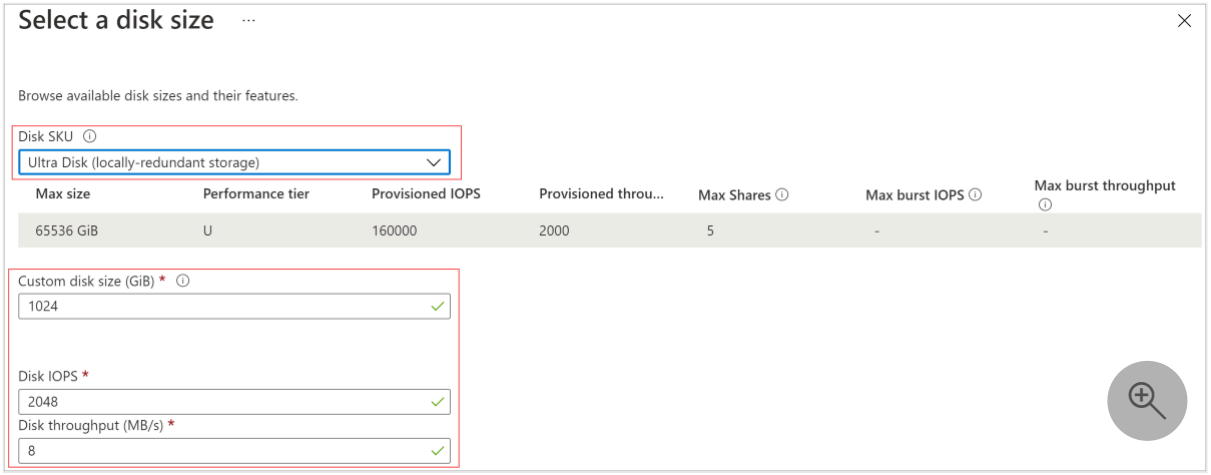
8. On the **Create a new disk** blade, enter a name, then select **Change size**.



9. Change the **Disk SKU** to **Ultra Disk**.

10. Change the values of **Custom disk size (GiB)**, **Disk IOPS**, and **Disk throughput** to ones of your choice.

11. Select **OK** in both blades.



12. Continue with the VM deployment, the same as you would deploy any other VM.

Deploy an Ultra Disk - 512-byte sector size

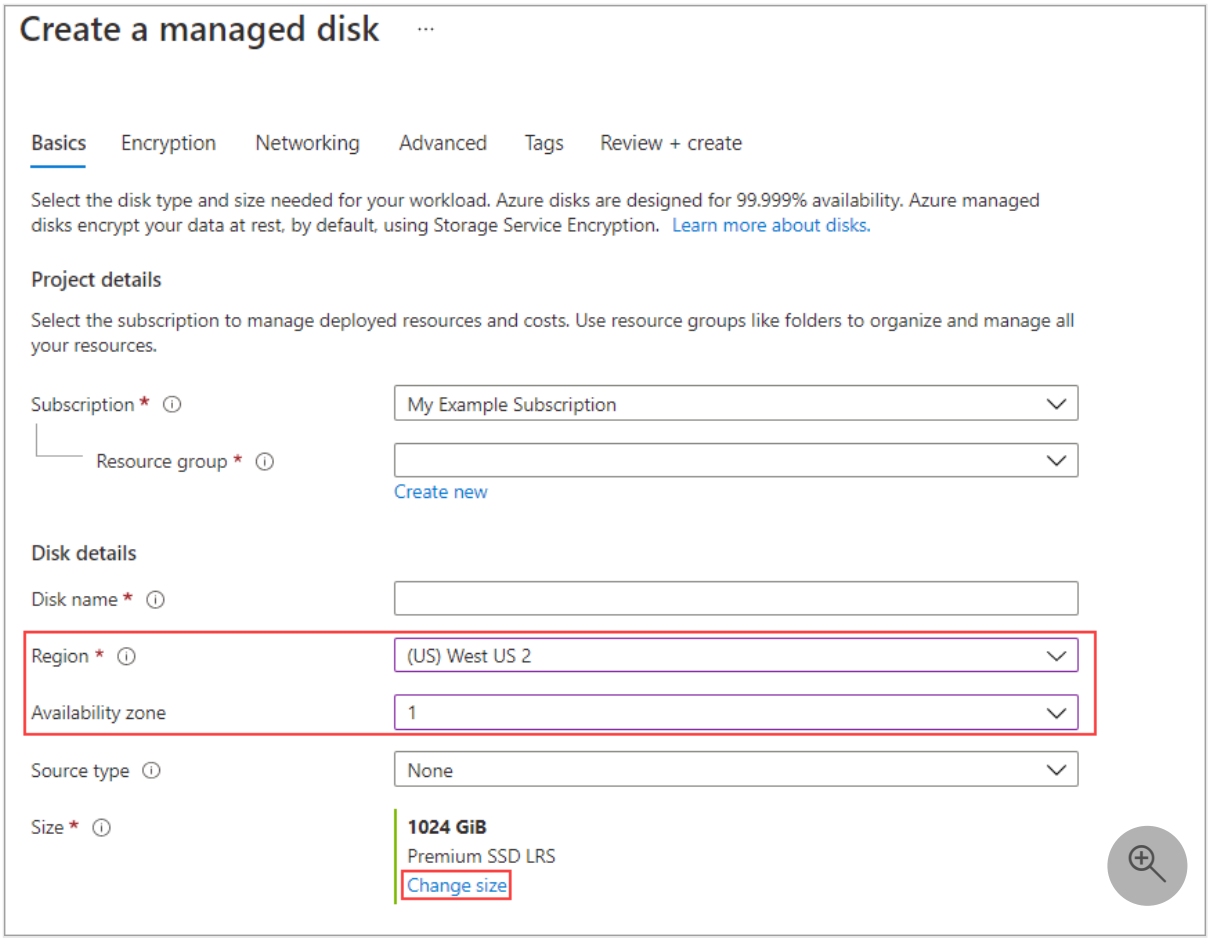
Portal

1. Sign in to the Azure portal, then search for and select **Disks**.

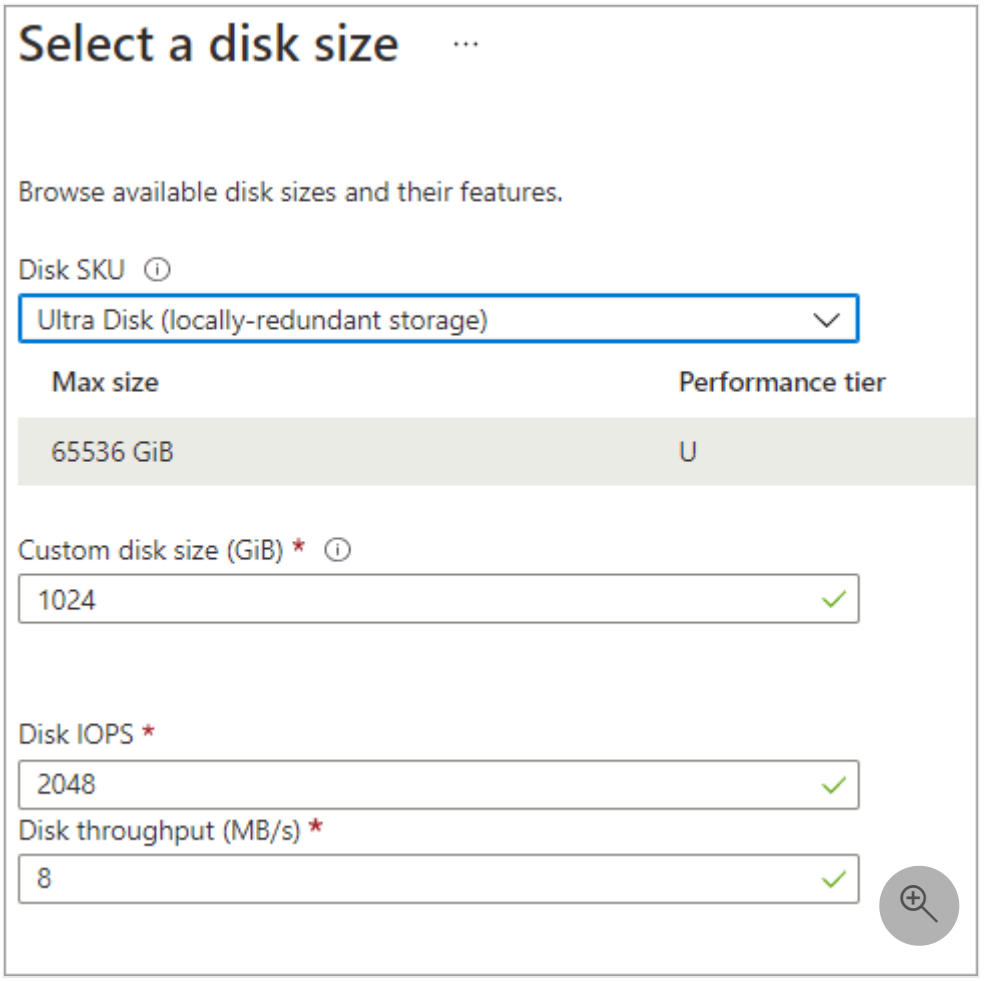
2. Select **+ New** to create a new disk.

3. Select a region that supports Ultra Disks and select an availability zone, fill in the rest of the values as you desire.

4. Select **Change size**.

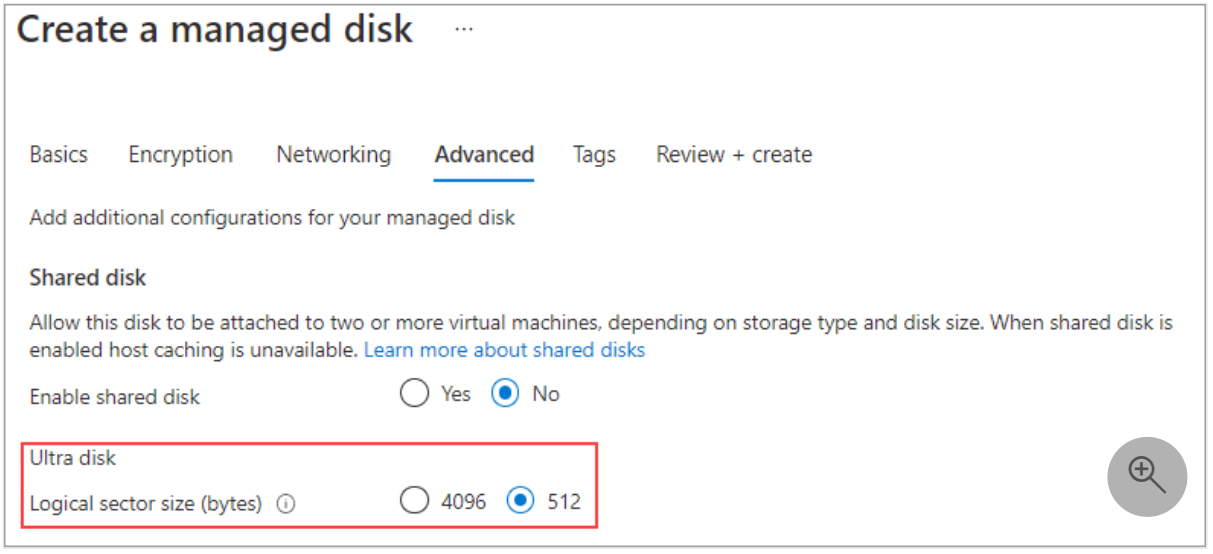


5. For **Disk SKU** select **Ultra Disk**, then fill in the values for the desired performance and select **OK**.



6. On the **Basics** blade, select the **Advanced** tab.

7. Select **512** for **Logical sector size**, then select **Review + Create**.

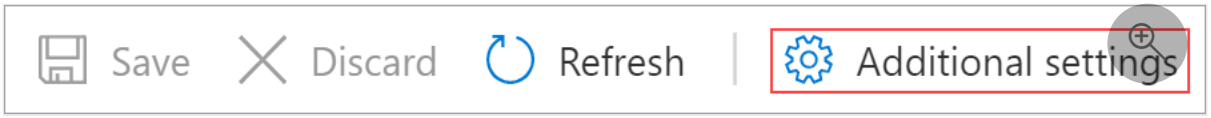


Attach an Ultra Disk

Portal

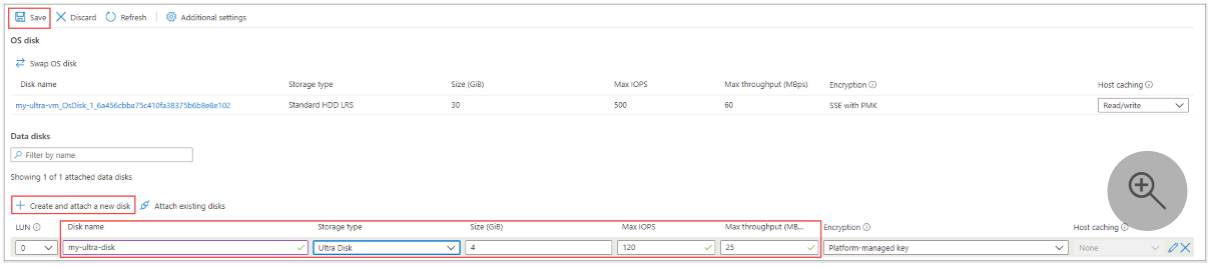
Alternatively, if your existing VM is in a region/availability zone that is capable of using Ultra Disks, you can make use of Ultra Disks without having to create a new VM. By enabling Ultra Disks on your existing VM, then attaching them as data disks. To enable Ultra Disk compatibility, you must stop the VM. After you stop the VM, you can enable compatibility, then restart the VM. Once compatibility is enabled, you can attach an Ultra Disk:

1. Navigate to your VM and stop it, wait for it to deallocate.
2. Once your VM has been deallocated, select **Disks**.
3. Select **Additional settings**.



4. Select **Yes** for **Enable Ultra Disk compatibility**.

5. Select **Save**.
6. Select **Create and attach a new disk** and fill in a name for your new disk.
7. For **Storage type** select **Ultra Disk**.
8. Change the values of **Size (GiB)**, **Max IOPS**, and **Max throughput** to ones of your choice.
9. After you're returned to your disk's blade, select **Save**.



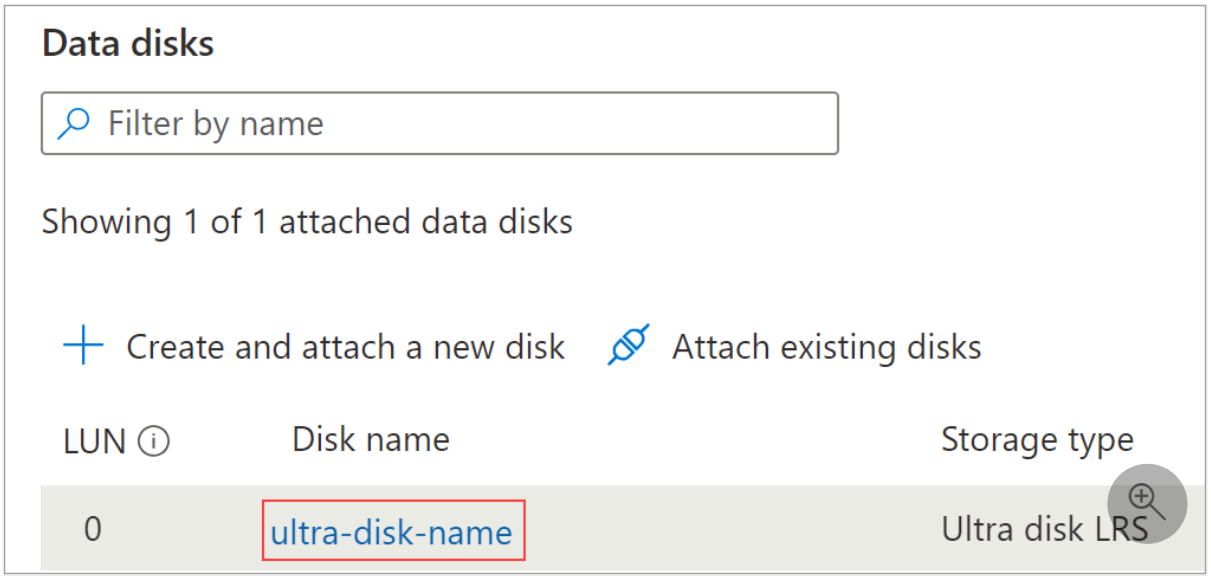
10. Start your VM again.

Adjust the performance of an Ultra Disk

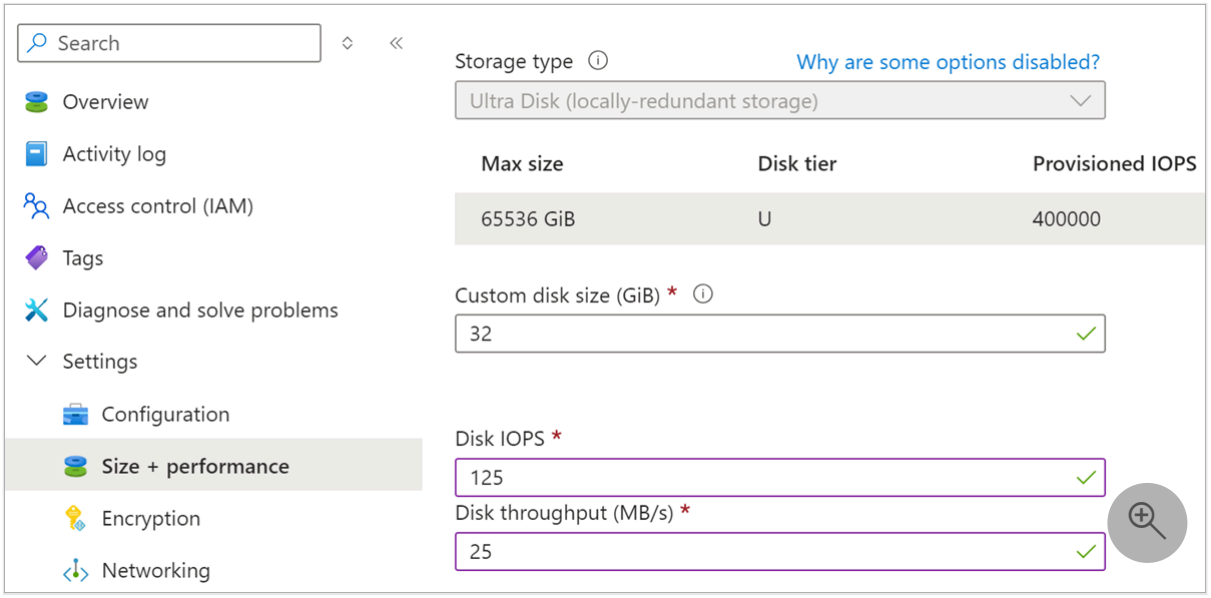
Portal

Ultra Disks offer a unique capability that allows you to adjust their performance. You can adjust the performance of an Ultra Disk four times within a 24 hour period.

1. Navigate to your VM and select **Disks**.
2. Select the Ultra Disk you'd like to modify the performance of.



3. Select **Size + performance** and then make your modifications.
4. Select **Save**.



Next steps

- Use Azure Ultra Disks on Azure Kubernetes Service (preview).

- Migrate log disk to an Ultra Disk.
- For more questions on Ultra Disks, see the Ultra Disks section of the FAQ.

Deploy a Premium SSD v2

Summarize this article for me

Deploy to Azure

Azure Premium SSD v2 is designed for IO-intense enterprise workloads that require sub-millisecond disk latencies and high IOPS and throughput at a low cost. Premium SSD v2 is suited for a broad range of workloads such as SQL server, Oracle, MariaDB, SAP, Cassandra, Mongo DB, big data/analytics, gaming, on virtual machines or stateful containers. For conceptual information on Premium SSD v2, see Premium SSD v2.

Premium SSD v2 disks support a 4k physical sector size by default, but can be configured to use a 512E sector size as well. While most applications are compatible with 4k sector sizes, some require 512 byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks.

Limitations

- Premium SSD v2 disks can't be used as an OS disk or with Azure Compute Gallery.
- For regions that support availability zones, Premium SSD v2 disks can only be attached to zonal VMs. When creating a new VM, specify the availability zone you want before adding Premium SSD v2 disks to your configuration.
- Premium SSD v2 doesn't support host caching.

Regional availability

Currently only available in the following regions:

Expand table

Regions without Availability Zone	*One Availability Zone*	*Two Availability Zones*	*Three Availability Zones*
- Australia Central 2 - Australia Southeast - Brazil Southeast - Canada East - Germany North - North Central US - Norway West - Switzerland West - Taiwan North		- Japan West	- Austria East - Australia East - Brazil South - Canada Central - Central India - Central US - China North 3 - East Asia - East US

Regions without Availability Zone	*One Availability Zone*	*Two Availability Zones*	*Three Availability Zones*
- UK West - West Central US - West US			- East US 2 - France Central - Germany West Central - Indonesia Central - Israel Central - Italy North - Japan East - Korea Central - Malaysia West - Mexico Central - New Zealand North - North Europe - Norway East - Poland Central - Spain Central - South African North - South Central US - Southeast Asia - Sweden Central - Switzerland North - UAE North - UK South - US Gov Virginia - West Europe - West US 2 - West US 3

To learn when support for particular regions was added, see either Azure Updates or What's new for Azure Disk Storage.

Prerequisites

- Install either the latest Azure CLI or the latest Azure PowerShell module.

Determine region availability programmatically

Since not every region and zone support Premium SSD v2 disks, you can use the Azure CLI or PowerShell to determine region and zone supportability.

Azure CLI

To determine the regions and zones that support Premium SSD v2 disks, replace `yourSubscriptionId` with your subscription, and then run the az vm list-skus command:

Azure CLI

```
az login

subscriptionId="<yourSubscriptionId>"

az account set --subscription $subscriptionId

az vm list-skus --resource-type disks --query "[?name=='PremiumV2_LRS'].
{Region:locationInfo[0].location, Zones:locationInfo[0].zones}"
```

Now that you know the region and zone to deploy to, follow the deployment steps in this article to create a Premium SSD v2 and attach it to a VM.

Use Premium SSD v2 in Regions with Availability Zones

Currently, Premium SSD v2 disks are only available in select regions with Availability Zones (AZs).

Azure CLI

Create a Premium SSD v2 in an availability zone by using the az disk create command. Then create a VM in the same region and availability zone that supports Premium Storage and attach the disk to it by using the az vm create command.

The following script creates a Premium SSD v2 with a 4k sector size, to deploy one with a 512 sector size, update the `$logicalSectorSize` parameter. Replace the values of all the variables with your own, then run the following script:

Azure CLI

```
## Initialize variables
diskName="yourDiskName"
resourceGroupName="yourResourceGroupName"
region="yourRegionName"
zone="yourZoneNumber"
##Replace 4096 with 512 to deploy a disk with 512 sector size
logicalSectorSize=4096
vmName="yourVMName"
vmImage="Win2016Datacenter"
```

```
adminPassword="yourAdminPassword"
adminUserName="yourAdminUserName"
vmSize="Standard_D4s_v3"

## Create a Premium SSD v2
az disk create -n $diskName -g $resourceGroupName \
--size-gb 100 \
--disk-iops-read-write 5000 \
--disk-mbps-read-write 150 \
--location $region \
--zone $zone \
--sku PremiumV2_LRS \
--logical-sector-size $logicalSectorSize

## Create the VM
az vm create -n $vmName -g $resourceGroupName \
--image $vmImage \
--zone $zone \
--authentication-type password --admin-password $adminPassword --admin-username
$adminUserName \
--size $vmSize \
--location $region \
--attach-data-disks $diskName
```

Use a Premium SSD v2 in non-AZ Regions

Currently, Premium SSD v2 disks are only available in select regions without Availability Zones (AZs). Regions without AZ support may experience slightly higher average latency for Premium SSD v2 disks compared to regions with AZ support.

Azure CLI

Create a Premium SSD v2 in a region without availability zone support by using the az disk create command. Then create a VM in the same region that supports Premium Storage and attach the disk to it by using the az vm create command.

The following script creates a Premium SSD v2 with a 4k sector size. To create a disk with a 512 sector size, update the `$logicalSectorSize` parameter. Replace the values of all the variables with your own, then run the following script:

Azure CLI

```
## Initialize variables
diskName="yourDiskName"
resourceGroupName="yourResourceGroupName"
region="yourRegionName"
##Replace 4096 with 512 to deploy a disk with 512 sector size
```

```
logicalSectorSize=4096
vmName="yourVMName"
vmImage="Win2016Datacenter"
adminPassword="yourAdminPassword"
adminUserName="yourAdminUserName"
vmSize="Standard_D4s_v3"

## Create a Premium SSD v2
az disk create -n $diskName -g $resourceGroupName \
--size-gb 100 \
--disk-iops-read-write 5000 \
--disk-mbps-read-write 150 \
--location $region \
--sku PremiumV2_LRS \
--logical-sector-size $logicalSectorSize

## Create the VM
az vm create -n $vmName -g $resourceGroupName \
--image $vmImage \
--zone $zone \
--authentication-type password --admin-password $adminPassword --admin-username
$adminUserName \
--size $vmSize \
--location $region \
--attach-data-disks $diskName
```

Adjust disk performance

You can adjust the performance of a Premium SSD v2 four times within a 24 hour period. Creating a disk counts as one of these times, so for the first 24 hours after creating a Premium SSD v2 you can only adjust its performance up to three times.

For conceptual information on adjusting disk performance, see Premium SSD v2 performance.

Azure CLI

Use the az disk update command to change the performance configuration of your Premium SSD v2. For example, you can use the `disk-iops-read-write` parameter to adjust the max IOPS limit, and the `disk-mbps-read-write` parameter to adjust the max throughput limit of your Premium SSD v2.

The following command adjusts the performance of your disk. Update the values in the command, and then run it:

Azure CLI

```
az disk update --subscription $subscription --resource-group $rgname --name
$diskName --disk-iops-read-write=5000 --disk-mbps-read-write=200
```

Next steps

Add a data disk by using either the Azure portal, Azure CLI, or PowerShell.

Provide feedback on Premium SSD v2.

Deploy a managed disk that uses zone-redundant storage

07/02/2025

This article covers how to deploy a disk that uses zone-redundant storage (ZRS) as a redundancy option. ZRS replicates your Azure managed disk synchronously across three Azure availability zones in the selected region. Each availability zone is a separate physical location with independent power, cooling, and networking.

For conceptual information on ZRS, see Zone-redundant storage for managed disks

Limitations

ZRS for managed disks is only supported with Premium SSD and Standard SSD managed disks. ZRS for managed disks isn't supported with Premium SSD v2 managed disks or Ultra Disks. Force detach only supports data disks.

Regional availability

ZRS disks are currently available in the following regions:

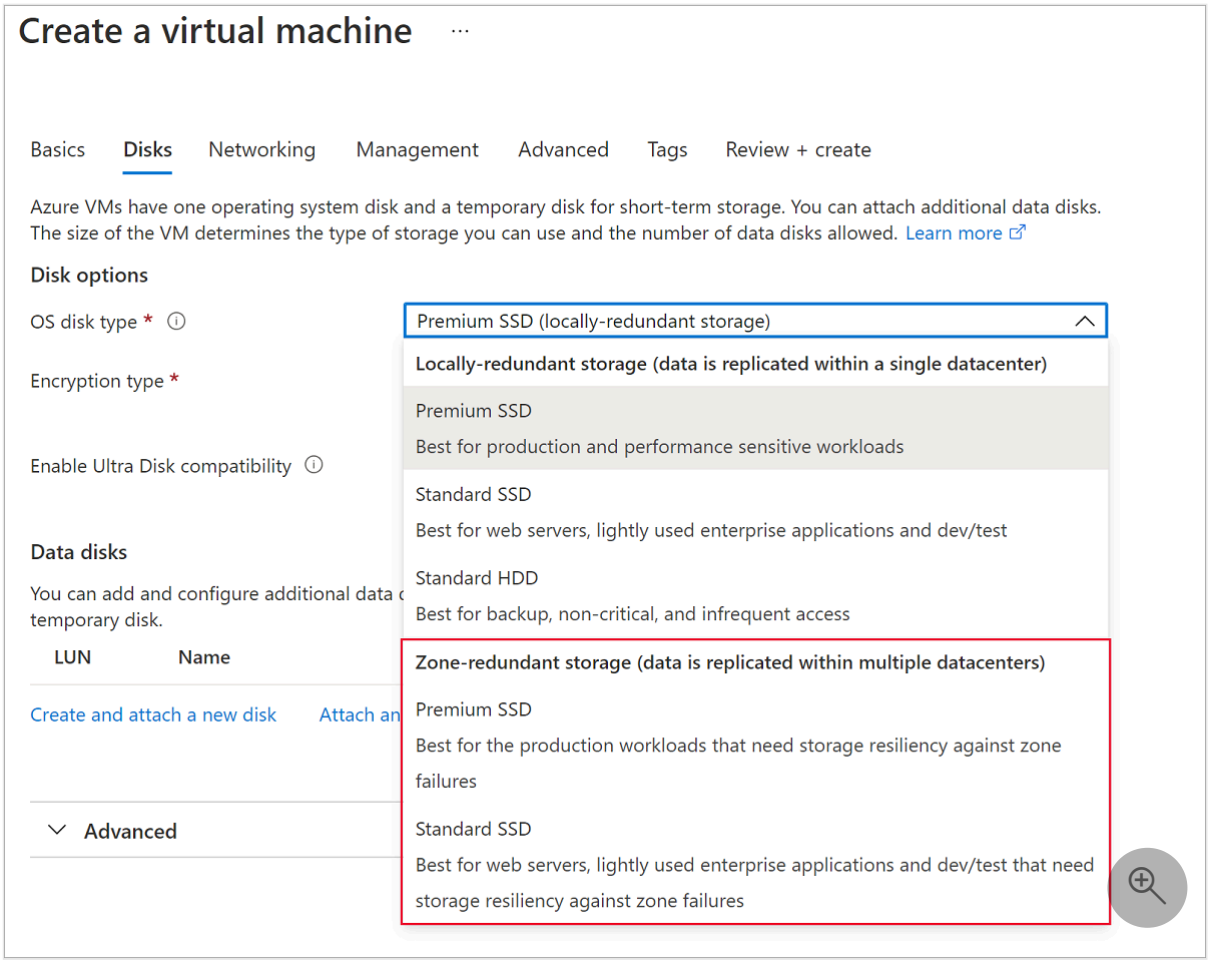
- South Africa North
- East Asia
- Southeast Asia
- Australia East
- US Gov Virginia
- Brazil South
- Canada Central
- China North 3
- North Europe
- West Europe
- France Central
- Germany West Central
- Central India
- Israel Central
- Italy North
- Japan East
- Korea Central
- Mexico Central

- New Zealand North
- Norway East
- Poland Central
- Qatar Central
- Spain Central
- Sweden Central
- Switzerland North
- UAE North
- UK South
- Central US
- East US
- East US 2
- South Central US
- West US 2
- West US 3

Azure portal

Create a VM with a ZRS OS disk

1. Sign in to the Azure portal.
2. Navigate to **Virtual machines** and follow the normal VM creation process.
3. Proceed to the **Disks** pane.
4. Select your disk and select one of the ZRS disks in the drop-down.

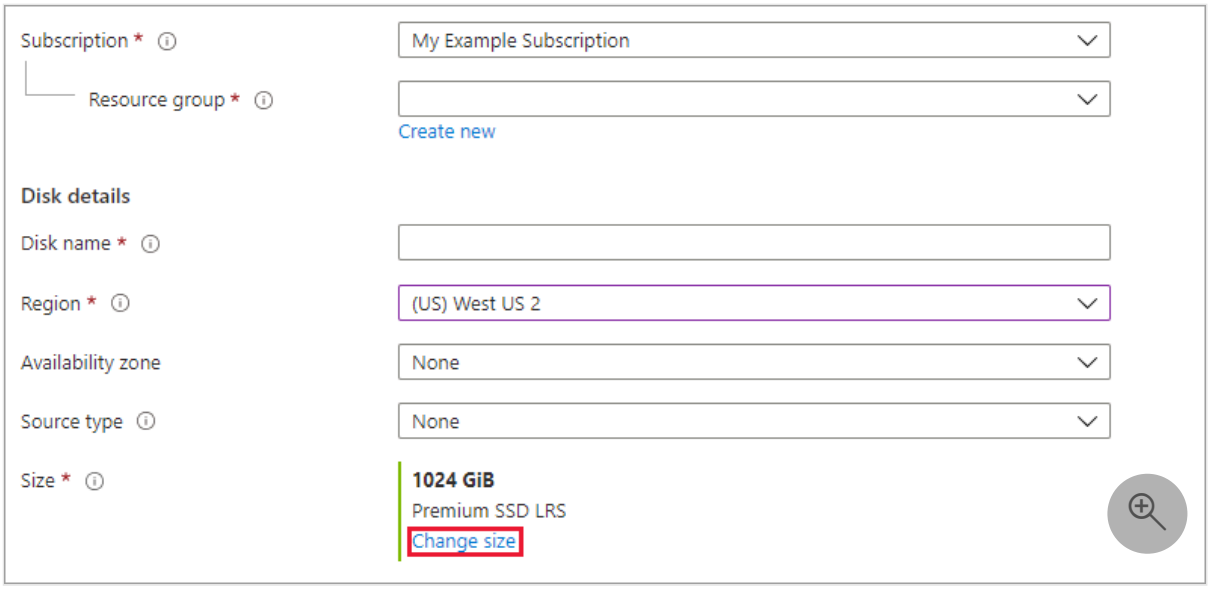


5. Proceed through the rest of the VM deployment, making any choices that you desire.

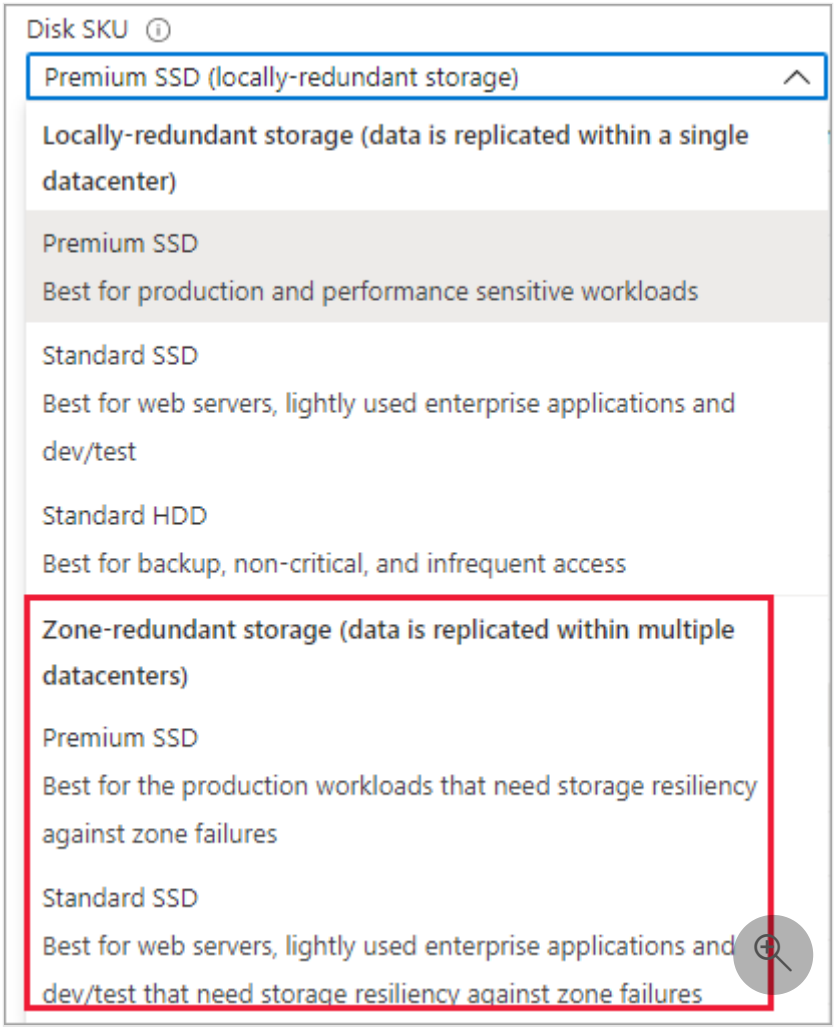
You've now deployed a VM with a ZRS OS disk.

Create a ZRS disk

1. In the Azure portal, search for and select **Disks**.
2. Select **+ Add** to create a new disk.
3. Select a supported region and **Availability zone** to **None**.
4. Select **Change size**.



5. Select one of the available ZRS disks and select **OK**.



6. Continue through the deployment process.

You have now created a managed disk that uses ZRS.

Next steps

- Check out more Azure Resource Manager templates to create a VM with ZRS disks .

Best practices for achieving high availability with Azure virtual machines and managed disks

Azure offers several configuration options for ensuring high availability of Azure virtual machines (VMs) and Azure managed disks. This article covers the default availability and durability of managed disks and provides recommendations to further increase your application's availability and resiliency.

At a glance

Expand table

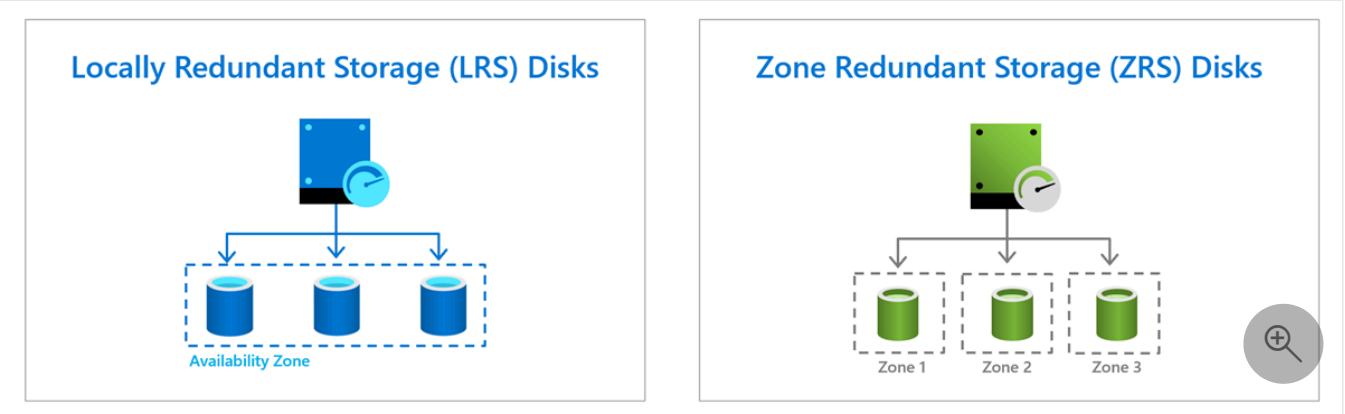
Configuration	Recommendation	Benefits
Applications running on a single VM	Use Ultra Disks, Premium SSD v2, and Premium SSD disks.	Single VMs using only Premium SSD disks as the OS disks, and either Ultra Disks, Premium SSD v2, or Premium SSD disks as data disks have the highest uptime service level agreement (SLA), and these disk types offer the best performance.
	Use zone-redundant storage (ZRS) disks.	Access to your data even if an entire zone experiences an outage.
Applications running on multiple VMs	Distribute VMs and disks across multiple availability zones using a zone-spanning Virtual Machine Scale Set with flexible orchestration mode or by deploying VMs and disks across three availability zones.	Multiple VMs have the highest uptime SLA when deployed across multiple zones.
	Deploy VMs and disks across multiple fault domains with either regional Virtual Machine Scale Sets with flexible orchestration mode or availability sets.	Multiple VMs have the second highest uptime SLA when deployed across fault domains.
	Use ZRS disks when sharing disks between VMs.	Prevents a shared disk from becoming a single point of failure.

Availability and durability of managed disks

Before going over recommendations for achieving higher availability, you should understand the default availability and durability of managed disks.

Managed disks are designed for 99.999% availability and provide at least 99.999999999% (11 9's) of durability. With managed disks, your data is replicated three times. If one of the three copies becomes unavailable, Azure automatically spawns a new copy of the data in the background. This ensures the persistence of your data and high fault tolerance.

Managed disks have two redundancy models, locally redundant storage (LRS) disks, and zone-redundant storage (ZRS) disks. The following diagram depicts how data is replicated with either model.



LRS disks provide at least 99.999999999% (11 9's) of durability over a given year and ZRS disks provide at least 99.9999999999% (12 9's) of durability over a given year. This architecture helps Azure consistently deliver enterprise-grade durability for infrastructure as a service (IaaS) disks, with an industry-leading zero percent annualized failure rate.

Recommendations for applications running on a single VM

Legacy applications, traditional web servers, line-of-business applications, development and testing environments, and small workloads are all examples of applications that may run on a single VM. These applications can't benefit from replication across multiple VMs, but the data on the disks is still replicated three times, and you can take the following steps to further increase availability.

Use Ultra Disks, Premium SSD v2, or Premium SSD

Single VMs using only Premium SSD disks as the OS disk, and either Ultra Disks, Premium SSD v2, or Premium SSD disks as data disks have the highest single VM uptime SLA, and these disk types offer the best performance.

Use zone-redundant storage disks

Zone-redundant storage (ZRS) disks synchronously replicate data across three availability zones, which are separated groups of data centers in a region that have independent power, cooling, and networking infrastructure. With ZRS disks, your data is accessible even in the event of a zonal outage. Also, ZRS data disks allow you to forcibly detach them from VMs experiencing issues. ZRS disks have limitations, see the limitations section of the redundancy options article for details.

Recommendations for applications running on multiple VMs

Quorum-based applications, clustered databases (SQL, MongoDB), enterprise-grade web applications, and gaming applications are all examples of applications running on multiple VMs. Applications running on multiple VMs can designate a primary VM and multiple secondary VMs and replicate data across these VMs. This setup enables failover to a secondary VM if the primary VM goes down.

Multiple VMs have the highest uptime service level agreement (SLA) when deployed across multiple availability zones, and they have the second highest uptime SLA when deployed across multiple storage and compute fault domains.

Distribute VMs and disks across availability zones

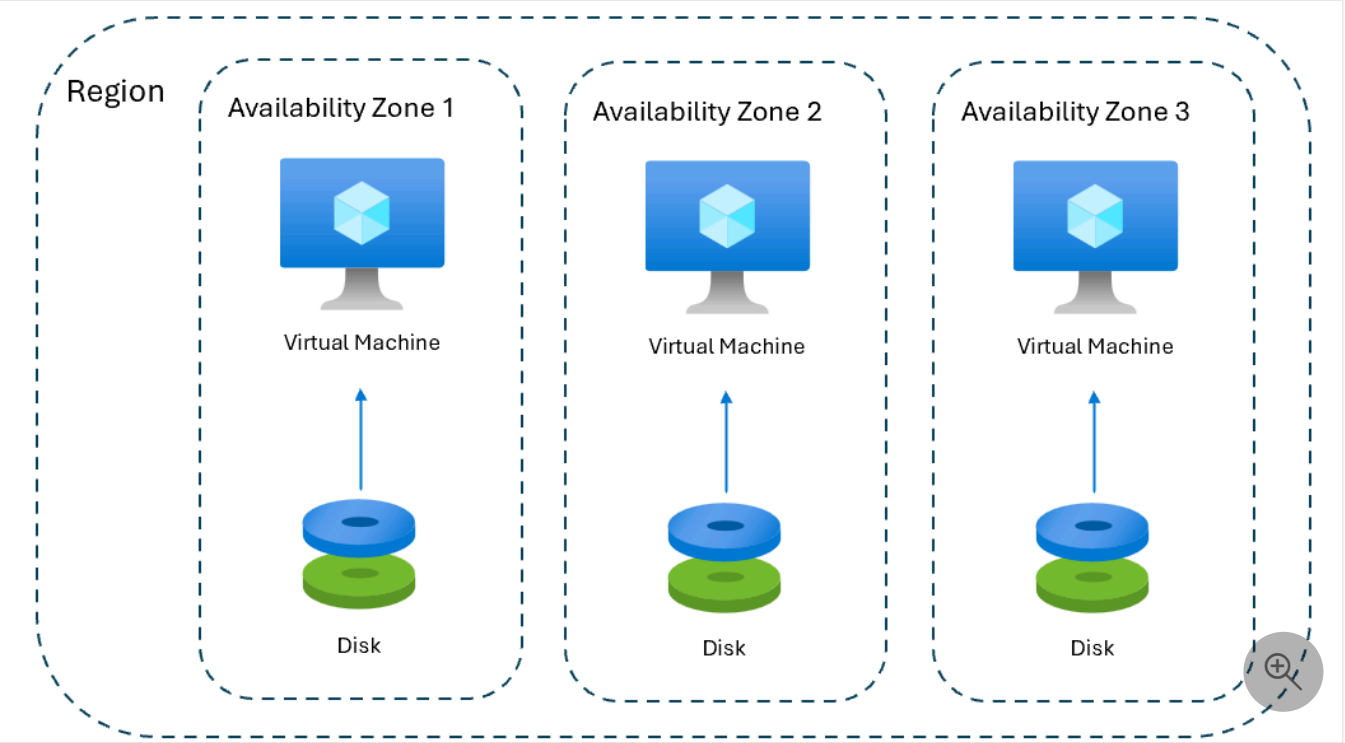
Availability zones are separated groups of data centers within a region that have independent power, cooling, and networking infrastructure. They're close enough to have low-latency connections to other availability zones but far enough to reduce the possibility that more than one is affected by local outages or weather. See What are availability zones? for details.

Multiple VMs have the highest SLA when distributed across three availability zones. For VMs and disks distributed across multiple availability zones, the disks and their parent VMs are respectively collocated in the same zone, which prevents multiple VMs from going down even if an entire zone experiences an outage. Availability zones aren't currently available in every region, see Azure regions with availability zone support.

VMs distributed across multiple availability zones may have higher network latency than VMs distributed in a single availability zone, which could be a concern for workloads that require ultra-low latency. If low latency is your top priority, consider the methods described in Deploy VMs and disks across multiple fault domains.

To deploy resources across availability zones, you can either use zone-spanning Virtual Machine Scale Sets or deploy resources across availability zones.

The following diagram depicts how VMs and disks are collocated in the same zones when deployed across availability zones directly or using zone-spanning Virtual Machine Scale Sets.



Use zone-spanning Virtual Machine Scale Sets with flexible orchestration

Virtual Machine Scale Sets let you create and manage a group of load balanced VMs. The number of VM instances can automatically adjust in response to demand or follow a schedule you define. A zone-spanning Virtual Machine Scale Set is a Virtual Machine Scale Set that has been deployed across multiple availability zones. See Zone spanning.

With zone-spanning Virtual Machine Scale Sets using the flexible orchestration mode, VMs, and their disks are replicated to one or more zones within the region they're deployed in to improve the resiliency and availability of your applications and data. This configuration spreads VMs across selected zones in a best effort approach by default but also provides the ability to specify strict zone balance in the deployment.

Deploy VMs and disks across three availability zones

Another method to distribute VMs and disks across availability zones is to deploy the VMs and disks across three availability zones. This deployment provides redundancy in VMs and disks across multiple data centers in a region, allowing you to fail over to another zone if there's a data center or zonal outage.

Deploy VMs and disks across multiple fault domains

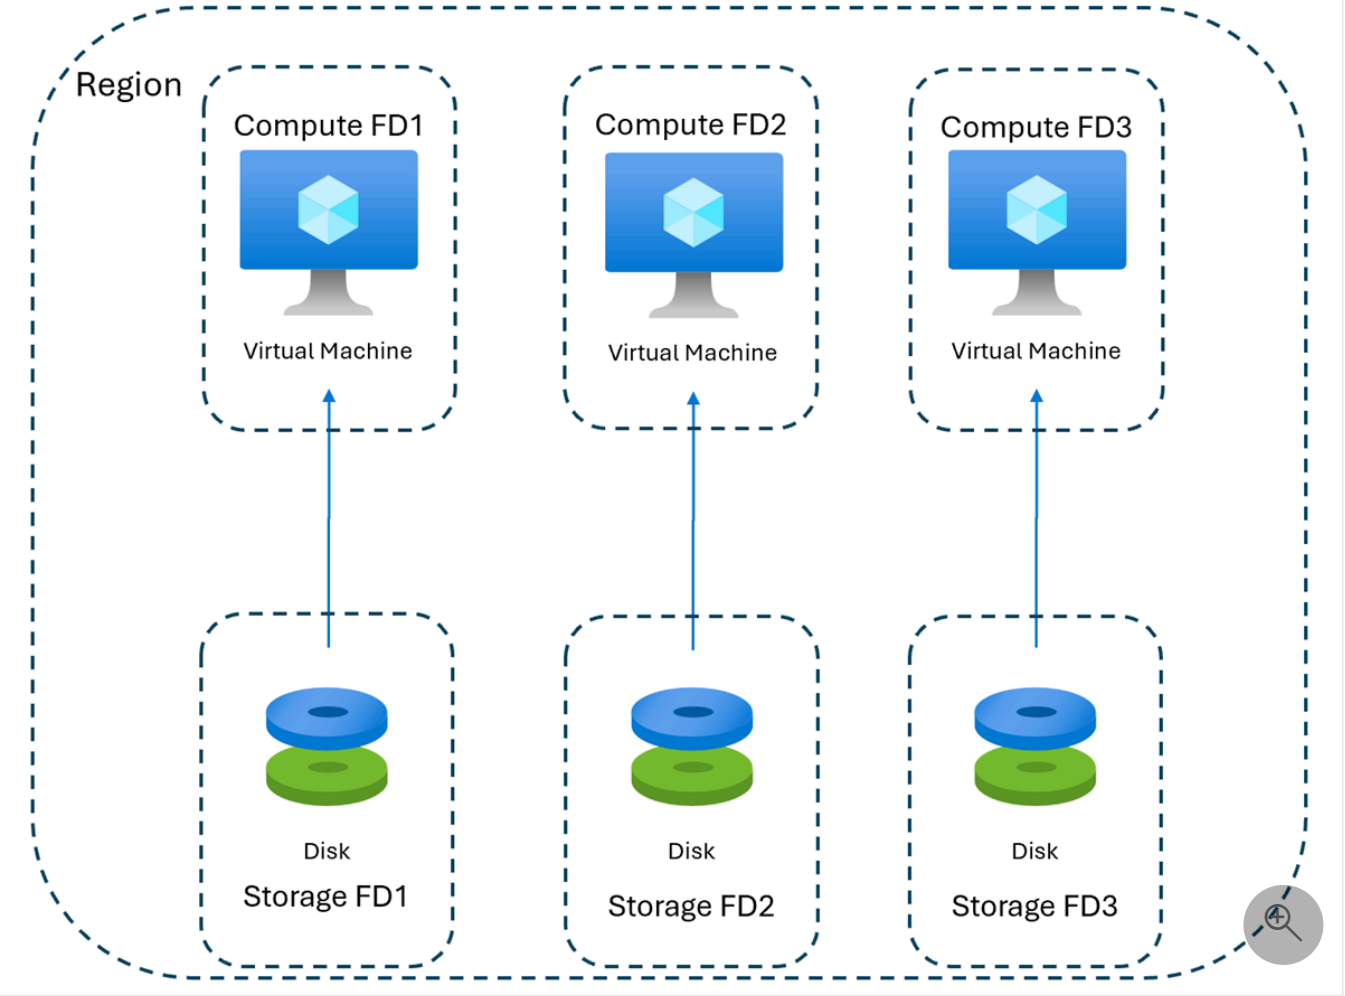
If you can't deploy your VMs and disks across availability zones or have ultra-low latency requirements, you can deploy them across fault domains instead. Fault domains define groups of VMs that share a common power source and a network switch. For details, see How do availability sets work?.

For VMs and disks deployed across fault domains via the following methods, the storage fault domains of the disks are aligned with the compute fault domains of their respective parent VMs, which prevents multiple VMs from going down if a single storage fault domain experiences an outage.

Multiple VMs have the second highest uptime SLA when deployed across fault domains. To learn more, see the Virtual Machines section of the SLA.

To deploy resources across multiple fault domains, you can either use regional Virtual Machine Scale Sets or availability sets.

The following diagram depicts the alignment of compute and storage fault domains when using either regional Virtual Machine Scale Sets or availability sets.



Use regional Virtual Machine Scale Sets with flexible orchestration

A regional Virtual Machine Scale Set is a Virtual Machine Scale Set that has no explicitly defined availability zones. With regional virtual machine scale sets, VM resources are replicated across fault domains within the region they're deployed in to improve the resiliency and availability of applications and data. This configuration spreads VMs across fault domains by default but also provides the ability to assign fault domains on VM creation. See this section for details.

Regional Virtual Machine Scale Sets don't protect against large-scale outages like a data center or region outage, and don't currently support Ultra Disks or Premium SSD v2 disks.

Use availability sets

Availability sets are logical groupings of VMs that place VMs in different fault domains to limit the chance of correlated failures bringing related VMs down at the same time. Availability sets also have better VM to VM latencies compared to availability zones.

Availability sets don't let you select the fault domains for your VMs, can't be used with availability zones, don't protect against data center or region-wide outages, and don't currently support Ultra Disks. Premium SSD v2 disks are supported with some limitations.

Use ZRS disks when sharing disks between VMs

You should use ZRS when sharing a disk between multiple VMs. If you use LRS, the shared disk becomes a single point of failure for your clustered application. This means that if your shared LRS disk experiences an outage, all the VMs to which this disk is attached will experience downtime. Using a ZRS disk mitigates this, since the disk's data is in three different availability zones. To learn more about shared disks, see Share an Azure managed disk.

Next steps

- Zone-redundant storage for managed disks
- What are availability zones?
- Create a Virtual Machine Scale Set that uses Availability Zones

Share an Azure managed disk across VMs

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure shared disks is a feature for Azure managed disks that allows you to attach a managed disk to multiple virtual machines (VMs) simultaneously. This capability enables you to deploy new or migrate existing clustered applications to Azure without modifying your architecture. Shared disks ensure high availability for clustered applications, as other VMs in the cluster retain full access to the disk if one VM fails.

Shared disks require a cluster manager, like Windows Server Failover Cluster (WSFC), or Pacemaker, that handles cluster node communication and write locking. Shared managed disks don't natively offer a fully managed file system that can be accessed using SMB/NFS.

How it works

VMs in the cluster can read or write to their attached disk based on the reservation chosen by the clustered application using SCSI Persistent Reservations (SCSI PR). SCSI PR is an industry standard used by applications running on Storage Area Network (SAN) on-premises. Enabling SCSI PR on a managed disk allows you to migrate these applications to Azure as-is.

Shared managed disks offer shared block storage that can be accessed from multiple VMs, these are exposed as logical unit numbers (LUNs). LUNs are then presented to an initiator (VM) from a target (disk). These LUNs look like direct-attached-storage (DAS) or a local drive to the VM.

Limitations

General limitations

Shared disks have general limitations that apply to all shared disks, regardless of disk type. They also have more limitations that only apply to specific types of shared disks. The following list is the list of general limitations:

- Currently, only Ultra Disks, Premium SSD v2, Premium SSD, and Standard SSDs can be used as a shared disk
- Shared disks can be attached to individual Virtual Machine Scale Sets but can't be defined in the Virtual Machine Scale Set models or automatically deployed
- A shared disk can't be expanded without either deallocating all VMs the disk is attached to, or detaching the disk from all of these VMs
- Write accelerator isn't supported for shared disks

- Host caching isn't supported for shared disks

Each managed disk that has shared disks enabled are also subject to the following limitations, organized by disk type:

Ultra disks

Ultra disks have their own separate list of limitations, unrelated to shared disks. For ultra disk limitations, refer to Using Azure ultra disks.

When sharing ultra disks, they have the following additional limitations:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Can't be shared across availability zones.

Premium SSD v2

Premium SSD v2 managed disks have their own separate list of limitations, unrelated to shared disks. For these limitations, see Premium SSD v2 limitations.

When sharing Premium SSD v2 disks, they have the following additional limitation:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Can't be shared across availability zones.

Premium SSD

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for premium SSD disks with `maxShares>1`.
- Disk bursting isn't available for premium SSD disks with `maxShares>1`.
- When using Availability sets or Virtual Machine Scale Sets with Azure shared disks, storage fault domain alignment with virtual machine fault domain isn't enforced for the shared data disk.
- When using proximity placement groups (PPG), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Azure Site Recovery support isn't yet available.
- Azure Backup is available through Azure Disk Backup.
- Only server-side encryption is supported, Azure Disk Encryption isn't currently supported.

- Can only be shared across availability zones if using Zone-redundant storage for managed disks.

Standard SSDs

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for standard SSDs with `maxShares>1`.
- When using Availability sets and Virtual Machine Scale Sets with Azure shared disks, storage fault domain alignment with virtual machine fault domain isn't enforced for the shared data disk.
- When using proximity placement groups (PPG), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Azure Site Recovery support isn't yet available.
- Azure Backup is available through Azure Disk Backup.
- Only server-side encryption is supported, Azure Disk Encryption isn't currently supported.
- Can only be shared across availability zones if using Zone-redundant storage for managed disks.

Operating system requirements

Shared disks support several operating systems. See the Windows or Linux sections for the supported operating systems.

Billing implications

When you share a disk, your billing could be impacted in two different ways, depending on the type of disk.

For shared Premium SSD disks, in addition to cost of the disk's tier, there's an extra charge that increases with each VM the SSD is mounted to. See managed disks pricing for details.

Both shared Ultra Disks and shared Premium SSD v2 disks don't have an extra charge for each VM that they're mounted to. They're billed on the total IOPS and MB/s that the disk is configured for. Normally, Ultra Disks and Premium SSD v2 has two performance throttles that determine its total IOPS/MB/s. However, when configured as a shared disk, two more performance throttles are exposed, for a total of four. These two extra throttles allow for increased performance at an extra expense and each meter has a default value, which raises the performance and cost of the disk.

The four performance throttles a shared Ultra Disk and shared Premium SSD v2 disk have are diskIOPSReadWrite, diskMB/sReadWrite, diskIOPSReadOnly, and diskMB/sReadOnly. Each performance throttle can be configured to change the performance of your disk. The performance of shared Ultra Disks and Premium SSD v2 disks are calculated in the following ways: total provisioned IOPS (diskIOPSReadWrite + diskIOPSReadOnly) and for total provisioned throughput MB/s (diskMB/sReadWrite + diskMB/sReadOnly).

Once you've determined your total provisioned IOPS and total provisioned throughput, you can use them in the pricing calculator to determine the cost of an Ultra shared disk or a Premium SSD v2 shared disk.

Disk sizes

For now, only ultra disks, premium SSD v2, premium SSD, and standard SSDs can enable shared disks. Different disk sizes may have a different `maxShares` limit, which you can't exceed when setting the `maxShares` value.

For each disk, you can define a `maxShares` value that represents the maximum number of nodes that can simultaneously share the disk. For example, if you plan to set up a 2-node failover cluster, you would set `maxShares=2`. The maximum value is an upper bound. Nodes can join or leave the cluster (mount or unmount the disk) as long as the number of nodes is lower than the specified `maxShares` value.

> **Note**
>
> The `maxShares` value can only be set or edited when the disk is detached from all nodes.

Premium SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by premium SSD sizes:

Expand table

Disk sizes	maxShares limit
P1,P2,P3,P4,P6,P10,P15,P20	3
P30, P40, P50	5
P60, P70, P80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a P15 disk is 1100 whether maxShares = 1 or maxShares > 1.

Standard SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by standard SSD sizes:

Expand table

Disk sizes	maxShares limit
E1,E2,E3,E4,E6,E10,E15,E20	3
E30, E40, E50	5
E60, E70, E80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a E15 disk is 500 whether maxShares = 1 or maxShares > 1.

Ultra disk ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on ultra disks, any size ultra disk can use any value for `maxShares`, up to and including the maximum value.

Premium SSD v2 ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on Premium SSD v2, any size Premium SSD v2 disk can use any value for `maxShares`, up to and including the maximum value.

Sample workloads

Windows

Azure shared disks are supported on Windows Server 2008 and newer. Most Windows-based clustering builds on WSFC, which handles all core infrastructure for cluster node communication, allowing your applications to take advantage of parallel access patterns. WSFC

enables both CSV and non-CSV-based options depending on your version of Windows Server. For details, refer to Create a failover cluster.

Some popular applications running on WSFC include:

- Create an FCI with Azure shared disks (SQL Server on Azure VMs)
  - Migrate your failover cluster instance to SQL Server on Azure VMs with shared disks
- File servers. You can use the Scale-Out File Server features deployed on a Windows Server failover cluster, which uses shared disk in active-active mode. Cluster witness resources are stored on Azure shared disks and all file shares are simultaneously online on all nodes. For an example, see the Scale-out File Server (SoFS) template
- SAP application servers use clustered shared disks to store SAP Central Services (ASCS for ABAP and SCS for Java) and SAP global host files. SAP ASCS/SCS template
- File Server for General Use (IW workload) - shared disks enable high availability for file servers in general
- Remote Desktop Server User Profile Disk (RDS UPD)

Linux

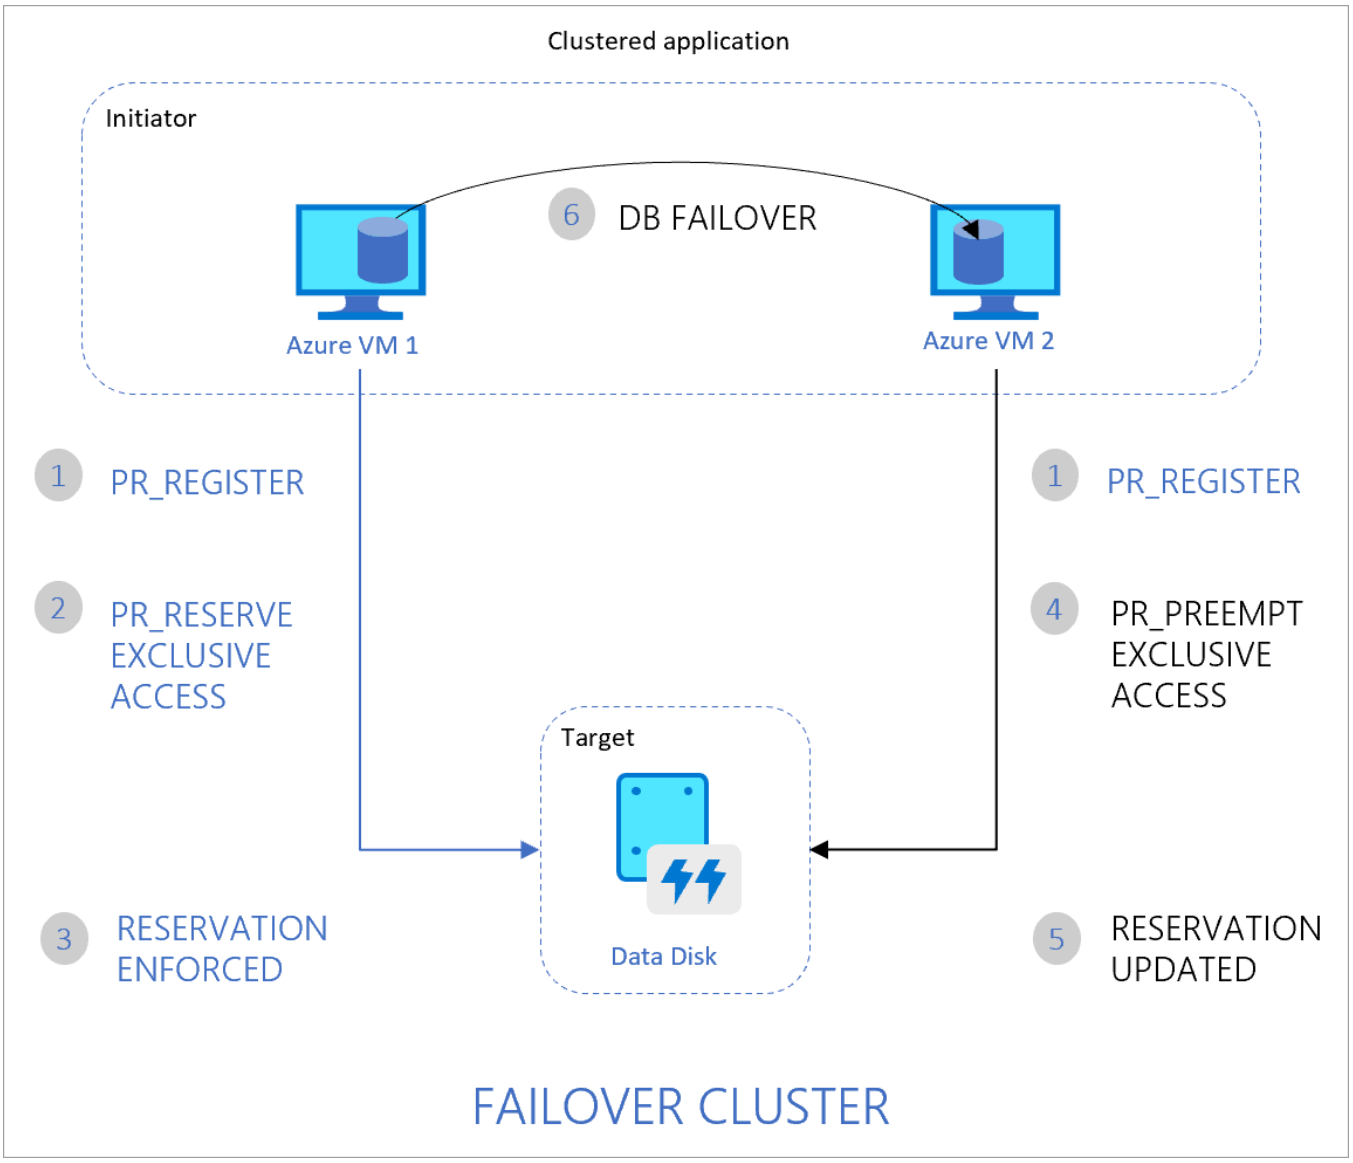
Azure shared disks are supported on:

- SUSE SLE HA 15 SP1 and above
- Ubuntu 18.04 and above
- Red Hat Enterprise Linux (RHEL) (support policy)
  - RHEL 7.9
  - RHEL 8.3 and above
- Oracle Enterprise Linux

Linux clusters can use cluster managers such as Pacemaker. Pacemaker builds on Corosync, enabling cluster communications for applications deployed in highly available environments. Some common clustered filesystems include ocfs2 and gfs2. You can use SCSI Persistent Reservation (SCSI PR) and/or STONITH Block Device (SBD) based clustering models for arbitrating access to the disk. When using SCSI PR, you can manipulate reservations and registrations using utilities such as fence_scsi and sg_persist.

Persistent reservation flow

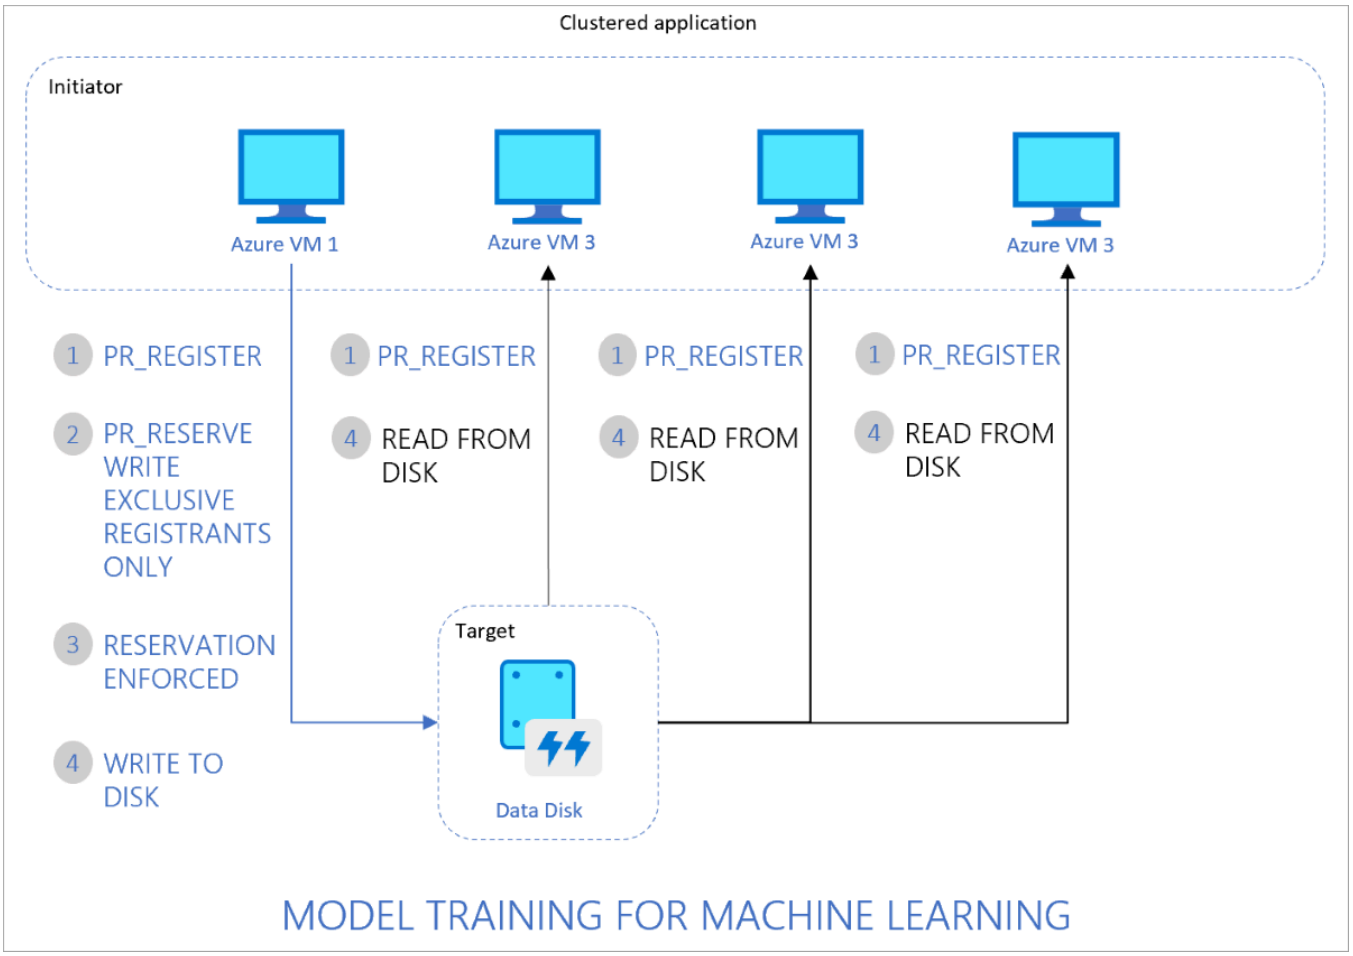
The following diagram illustrates a sample 2-node clustered database application that uses SCSI PR to enable failover from one node to the other.



The flow is as follows:

1. The clustered application running on both Azure VM1 and VM2 registers its intent to read or write to the disk.
2. The application instance on VM1 then takes exclusive reservation to write to the disk.
3. This reservation is enforced on your Azure disk and the database can now exclusively write to the disk. Any writes from the application instance on VM2 won't succeed.
4. If the application instance on VM1 goes down, the instance on VM2 can now initiate a database failover and take-over of the disk.
5. This reservation is now enforced on the Azure disk and the disk will no longer accept writes from VM1. It will only accept writes from VM2.
6. The clustered application can complete the database failover and serve requests from VM2.

The following diagram illustrates another common clustered workload consisting of multiple nodes reading data from the disk for running parallel processes, such as training of machine learning models.



The flow is as follows:

1. The clustered application running on all VMs registers the intent to read or write to the disk.
2. The application instance on VM1 takes an exclusive reservation to write to the disk while opening up reads to the disk from other VMs.
3. This reservation is enforced on your Azure disk.
4. All nodes in the cluster can now read from the disk. Only one node writes back results to the disk, on behalf of all nodes in the cluster.

Ultra Disk and Premium SSD v2 reservation flow

Both Ultra disks and Premium SSD v2 managed disks offer two extra throttles, giving each of them a total of four throttles. Due to this, the reservation flow can work as described in the earlier section, or it can throttle and distribute performance more granularly.

	Reservation Holder		Registered		Others	
Reservation Type	ReadOnly	ReadWrite	ReadOnly	ReadWrite	ReadOnly	ReadWrite
No Reservation	N/A	N/A	N/A	Yes	N/A	Yes
Write Exclusive	N/A	Yes	Yes	N/A	Yes	N/A
Exclusive Access	N/A	Yes	N/A	N/A	N/A	N/A
Write Exclusive – Registrants Only	N/A	Yes	N/A	Yes	Yes	N/A
Exclusive Access – Registrants Only	N/A	Yes	N/A	Yes	N/A	N/A
Write Exclusive – All Registrants	N/A	Yes	N/A	Yes	Yes	N/A
Exclusive Access – All Registrants	N/A	Yes	N/A	Yes	N/A	N/A

Performance throttles

Premium SSD performance throttles

With Premium SSD, the disk IOPS and throughput is fixed, for example, IOPS of a P30 is 5000. This value remains whether the disk is shared across 2 VMs or 5 VMs. The disk limits can be reached from a single VM or divided across two or more VMs.

Ultra Disk and Premium SSD v2 performance throttles

Both Ultra Disks and Premium SSD v2 managed disks have the unique capability of allowing you to set your performance by exposing modifiable attributes and allowing you to modify them. By default, there are only two modifiable attributes but, shared Ultra Disks and shared Premium SSD v2 managed disks have two more attributes. Ultra Disks and Premium SSD v2 split these attributes across each attached VM. For some examples on how this distribution of capacity, IOPS, and throughput works, see the Examples section.

Expand table

Attribute	Description
DiskIOPSReadWrite (Read/write disk IOPS)	The total number of IOPS allowed across all VMs mounting the shared disk with write access.
DiskMB/sReadWrite (Read/write disk throughput)	The total throughput (MB/s) allowed across all VMs mounting the shared disk with write access.
DiskIOPSReadOnly* (Read-only disk IOPS)	The total number of IOPS allowed across all VMs mounting the shared disk as `ReadOnly`.
DiskMB/sReadOnly* (Read-only disk throughput)	The total throughput (MB/s) allowed across all VMs mounting the shared disk as `ReadOnly`.

* Applies to shared Ultra Disks and shared Premium SSD v2 managed disks only

The following formulas explain how the performance attributes can be set, since they're user modifiable:

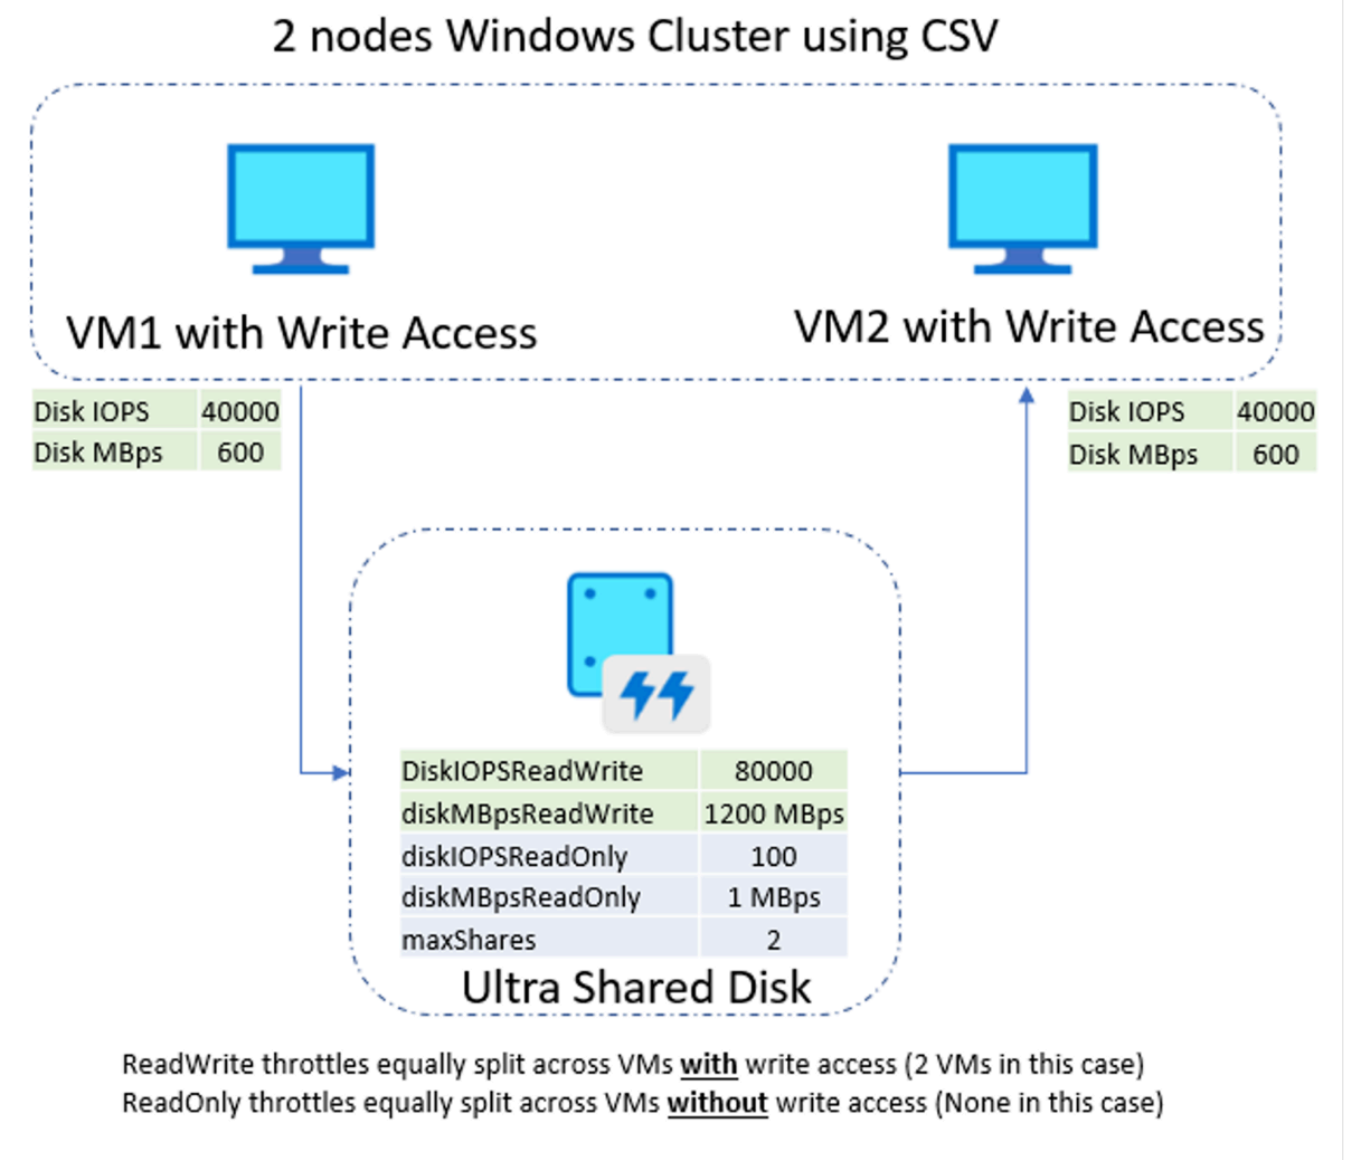
- DiskIOPSReadWrite (Read/write disk IOPS):
  - Has a baseline minimum IOPS of 100, for disks 100 GiB and smaller.
    - For disks larger than 100 GiB, the baseline minimum IOPS you can set increases by 1 per GiB. So the lowest you can set DiskIOPSReadWrite for a 101 GiB disk is 101 IOPS.
  - The maximum you can set this attribute is determined by the size of your disk, the formula is 300 * GiB, up to a maximum of 400,000.
- DiskMB/sReadWrite (Read/write disk throughput)
  - The minimum throughput (MB/s) of this attribute is determined by your IOPS, the formula is 4 KiB per second per IOPS. So if you had 101 IOPS, the minimum MB/s you can set is 1.
  - The maximum you can set this attribute is determined by the amount of IOPS you set, the formula is 256 KiB per second per IOPS, up to a maximum of 10,000 MB/s.
- DiskIOPSReadOnly (Read-only disk IOPS)
  - The minimum baseline IOPS for this attribute is 100. For DiskIOPSReadOnly, the baseline doesn't increase with disk size.
  - The maximum you can set this attribute is determined by the size of your disk, the formula is 300 * GiB, up to a maximum of 400,000.
- DiskMB/sReadOnly (Read-only disk throughput)
  - The minimum throughput (MB/s) for this attribute is 1. For DiskMB/sReadOnly, the baseline doesn't increase with IOPS.
  - The maximum you can set this attribute is determined by the amount of IOPS you set, the formula is 256 KiB per second per IOPS, up to a maximum of 10,000 MB/s.

Examples

The following examples depict a few scenarios that show how the throttling can work with shared Ultra Disks, specifically.

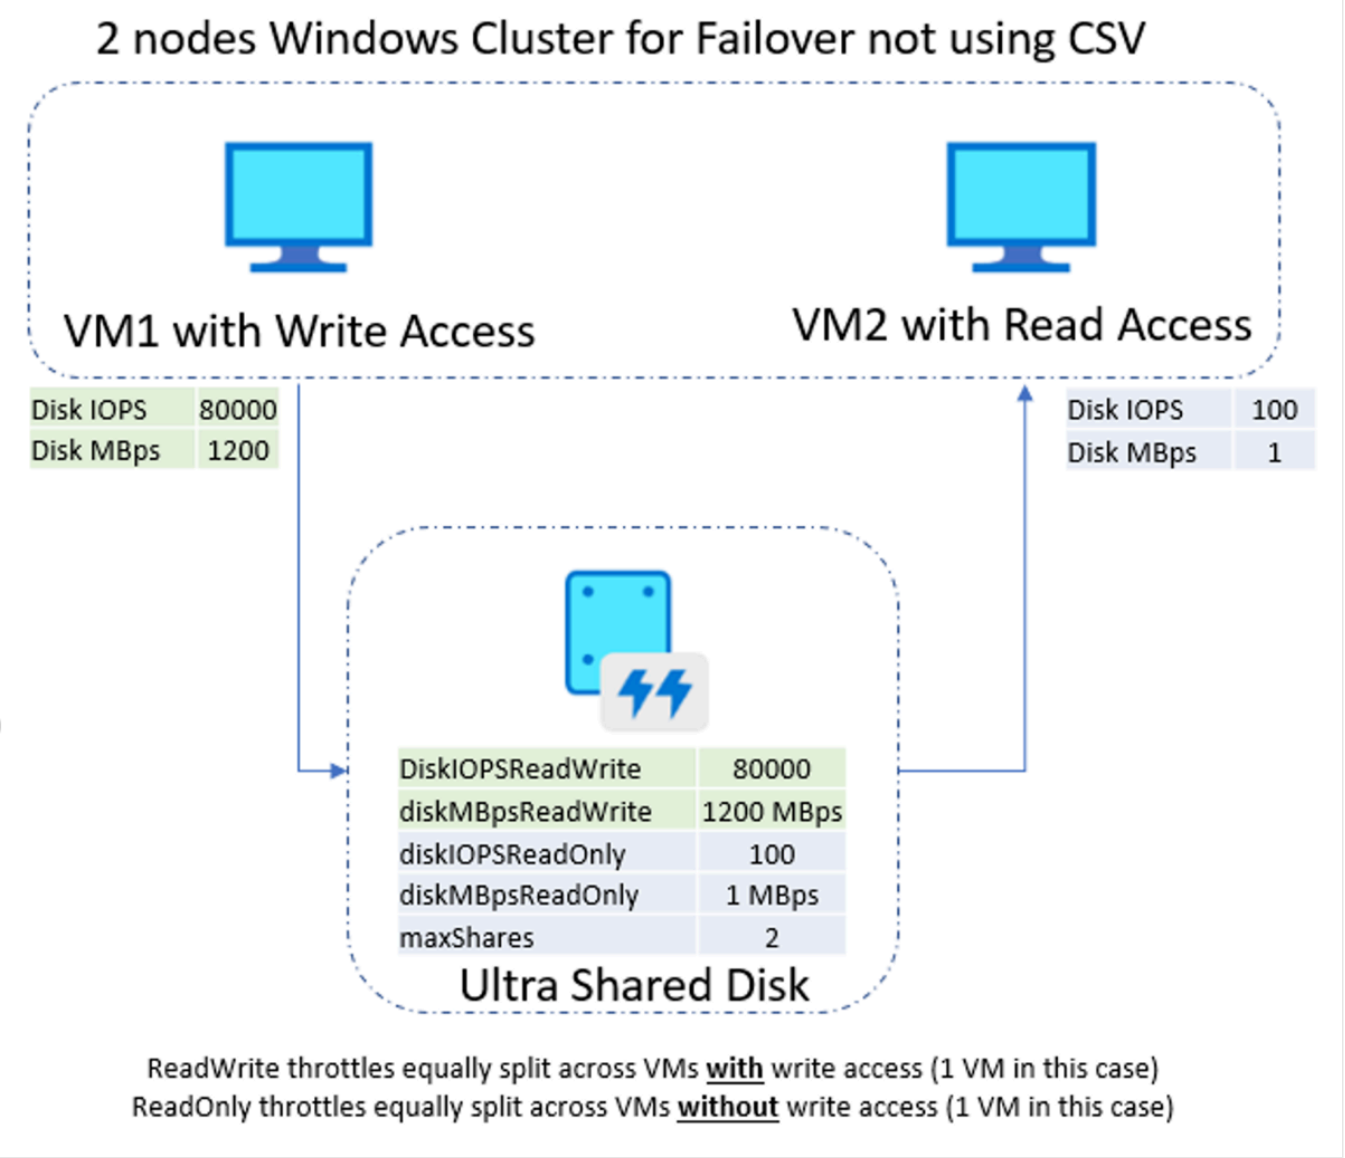
Two nodes cluster using cluster shared volumes

The following is an example of a 2-node WSFC using clustered shared volumes. With this configuration, both VMs have simultaneous write-access to the disk, which results in the `ReadWrite` throttle being split across the two VMs and the `ReadOnly` throttle not being used.



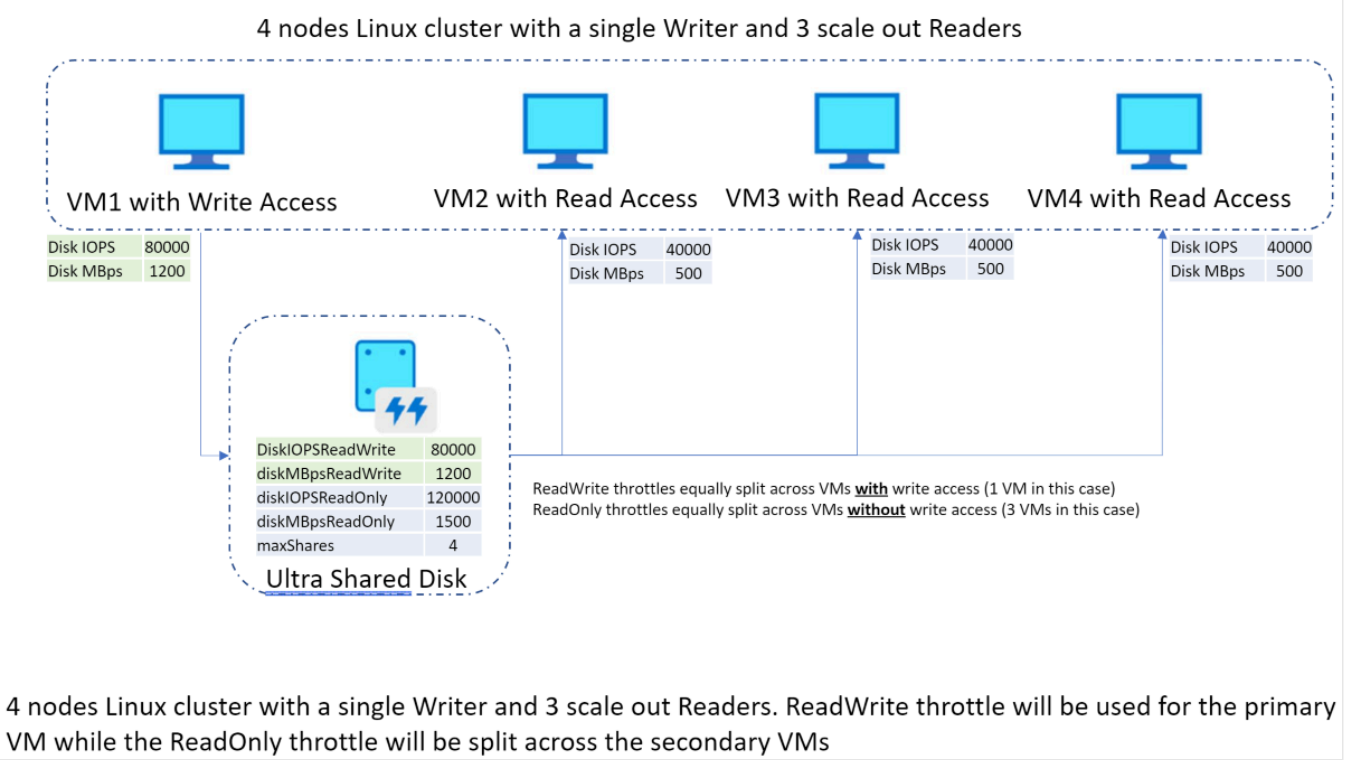
Two node cluster without cluster share volumes

The following is an example of a 2-node WSFC that isn't using clustered shared volumes. With this configuration, only one VM has write-access to the disk. This results in the `ReadWrite` throttle being used exclusively for the primary VM and the `ReadOnly` throttle only being used by the secondary.



Four node Linux cluster

The following is an example of a 4-node Linux cluster with a single writer and three scale-out readers. With this configuration, only one VM has write-access to the disk. This results in the `ReadWrite` throttle being used exclusively for the primary VM and the `ReadOnly` throttle being split by the secondary VMs.



4 nodes Linux cluster with a single Writer and 3 scale out Readers. ReadWrite throttle will be used for the primary VM while the ReadOnly throttle will be split across the secondary VMs

Shared Ultra Disk and Premium SSD v2 pricing

Both shared Ultra Disks and shared Premium SSD v2 managed disks are priced based on provisioned capacity, total provisioned IOPS (diskIOPSReadWrite + diskIOPSReadOnly) and total provisioned Throughput MB/s (diskMB/sReadWrite + diskMB/sReadOnly). There's no extra charge for each additional VM mount. For example, a shared Ultra Disk with the following configuration (diskSizeGB: 1024, DiskIOPSReadWrite: 10000, DiskMB/sReadWrite: 600, DiskIOPSReadOnly: 100, DiskMB/sReadOnly: 1) is charged with 1024 GiB, 10100 IOPS, and 601 MB/s regardless of whether it's mounted to two VMs or five VMs.

Next steps

If you're interested in enabling and using shared disks for your managed disks, proceed to our article Enable shared disk

If you have additional questions, see the shared disks section of the FAQ.

Last updated on 12/03/2025

Enable shared disks

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article explains how to enable the shared disks feature for Azure Managed Disks. With Azure shared disks, you can attach a managed disk to multiple virtual machines (VMs) simultaneously, enabling the deployment or migration of clustered applications to Azure.

If you're looking for conceptual information on managed disks that have shared disks enabled, see Azure shared disks.

Prerequisites

The scripts and commands in this article require either:

- Version 6.0.0 or newer of the Azure PowerShell module.

Or

- The latest version of the Azure CLI.

Limitations

General limitations

Shared disks have general limitations that apply to all shared disks, regardless of disk type. They also have more limitations that only apply to specific types of shared disks. The following list is the list of general limitations:

- Currently, only Ultra Disks, Premium SSD v2, Premium SSD, and Standard SSDs can be used as a shared disk
- Shared disks can be attached to individual Virtual Machine Scale Sets but can't be defined in the Virtual Machine Scale Set models or automatically deployed
- A shared disk can't be expanded without either deallocating all VMs the disk is attached to, or detaching the disk from all of these VMs
- Write accelerator isn't supported for shared disks
- Host caching isn't supported for shared disks

Each managed disk that has shared disks enabled are also subject to the following limitations, organized by disk type:

Ultra Disks

Ultra Disks have their own separate list of limitations, unrelated to shared disks. For Ultra Disk limitations, refer to Using Azure Ultra Disks.

When sharing Ultra Disks, they have the following additional limitations:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Can't be shared across availability zones.

Premium SSD v2

Premium SSD v2 managed disks have their own separate list of limitations, unrelated to shared disks. For these limitations, see Premium SSD v2 limitations.

When sharing Premium SSD v2 disks, they have the following additional limitation:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Can't be shared across availability zones.

Premium SSD

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for Premium SSDs with `maxShares>1`.
- Disk bursting isn't available for Premium SSDs with `maxShares>1`.
- When using Availability sets or Virtual Machine Scale Sets with Azure shared disks, storage fault domain alignment with virtual machine fault domain isn't enforced for the shared data disk.
- When using proximity placement groups (PPG), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Azure Site Recovery is supported in certain scenarios.
- Azure Backup is available through Azure Disk Backup.
- Only server-side encryption is supported, Azure Disk Encryption isn't currently supported.
- Can only be shared across availability zones if using Zone-redundant storage for managed disks.

Standard SSDs

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for Standard SSDs with `maxShares>1`.
- When using Availability sets and Virtual Machine Scale Sets with Azure shared disks, storage fault domain alignment with virtual machine fault domain isn't enforced for the shared data disk.
- When using proximity placement groups (PPG), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see Failover clustering hardware requirements and storage options.
- Azure Site Recovery is supported in certain scenarios.
- Azure Backup is available through Azure Disk Backup.
- Only server-side encryption is supported, Azure Disk Encryption isn't currently supported.
- Can only be shared across availability zones if using Zone-redundant storage for managed disks.

Supported operating systems

Shared disks support several operating systems. See the Windows and Linux sections of the conceptual article for the supported operating systems.

Disk sizes

For now, only Ultra Disks, Premium SSD v2, Premium SSD, and Standard SSDs can enable shared disks. Different disk sizes may have a different `maxShares` limit, which you can't exceed when setting the `maxShares` value.

For each disk, you can define a `maxShares` value that represents the maximum number of nodes that can simultaneously share the disk. For example, if you plan to set up a 2-node failover cluster, you would set `maxShares=2`. The maximum value is an upper bound. Nodes can join or leave the cluster (mount or unmount the disk) as long as the number of nodes is lower than the specified `maxShares` value.

> **Note**
>
> The `maxShares` value can only be set or edited when the disk is detached from all nodes.

Premium SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by Premium SSD sizes:

Expand table

Disk sizes	maxShares limit
P1,P2,P3,P4,P6,P10,P15,P20	3
P30, P40, P50	5
P60, P70, P80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a P15 disk is 1100 whether maxShares = 1 or maxShares > 1.

Standard SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by Standard SSD sizes:

Expand table

Disk sizes	maxShares limit
E1,E2,E3,E4,E6,E10,E15,E20	3
E30, E40, E50	5
E60, E70, E80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a E15 disk is 500 whether maxShares = 1 or maxShares > 1.

Ultra Disk ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on Ultra Disks, any size Ultra Disk can use any value for `maxShares`, up to and including the maximum value.

Premium SSD v2 ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on Premium SSD v2, any size Premium SSD v2 can use any value for `maxShares`, up to and including the maximum value.

Deploy shared disks

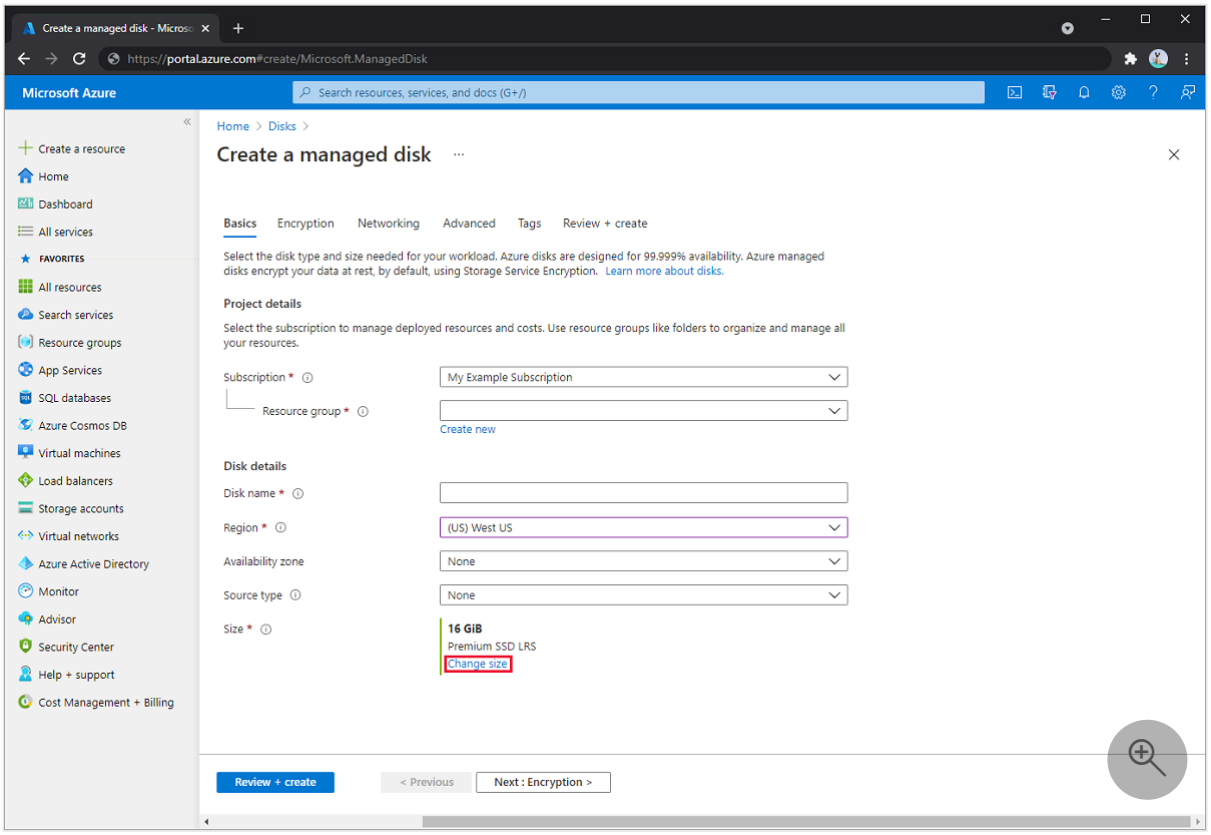
Deploy a Premium SSD as a shared disk

To deploy a managed disk with the shared disk feature enabled, use the new property `maxShares` and define a value greater than 1. This makes the disk shareable across multiple VMs.

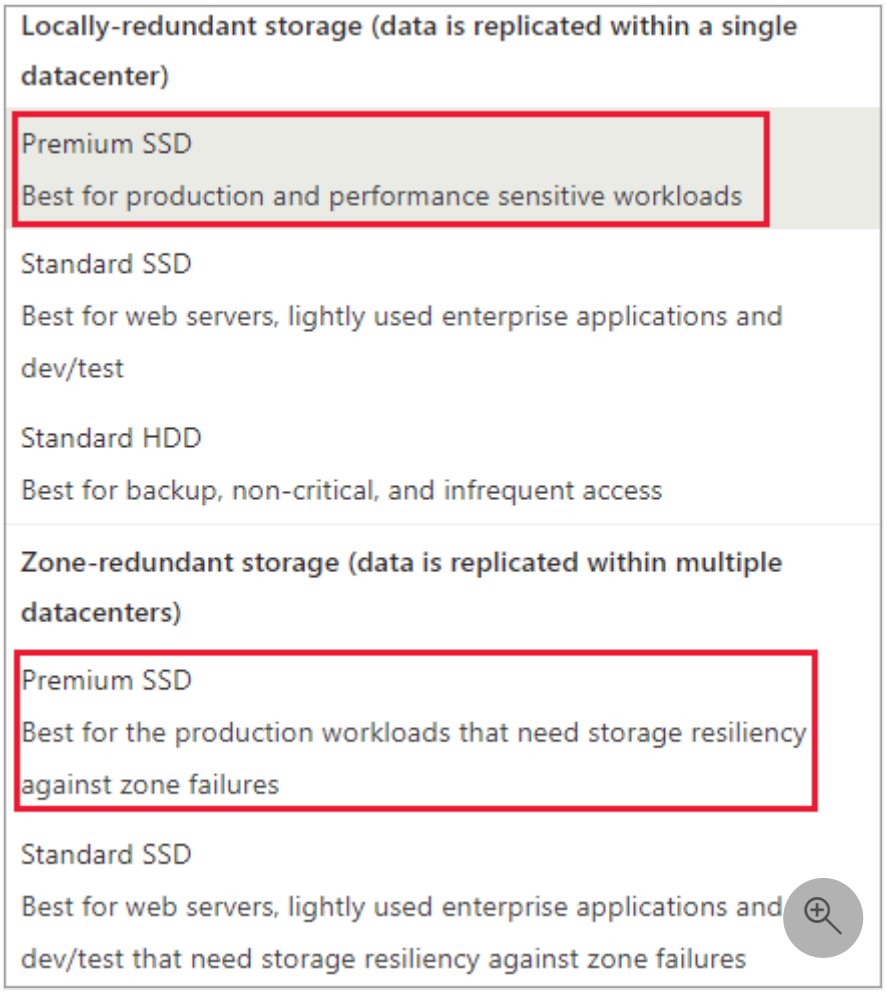
> **ⓘ Important**
>
> Host caching isn't supported for shared disks.
>
> The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the Disk sizes for the allowed values for `maxShares`.

Portal

1. Sign in to the Azure portal.
2. Search for and Select **Disks**.
3. Select **+ Create** to create a new managed disk.
4. Fill in the details and select an appropriate region, then select **Change size**.

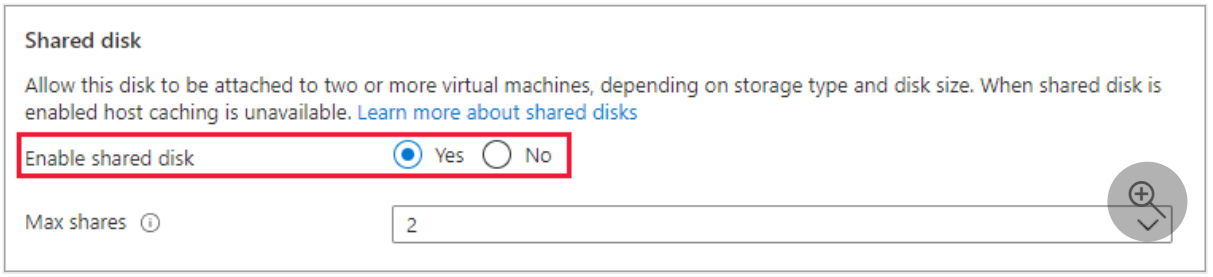


5. Select the Premium SSD size and SKU that you want and select **OK**.



6. Proceed through the deployment until you get to the **Advanced** pane.

7. Select **Yes** for **Enable shared disk** and select the amount of **Max shares** you want.



8. Select **Review + Create**.

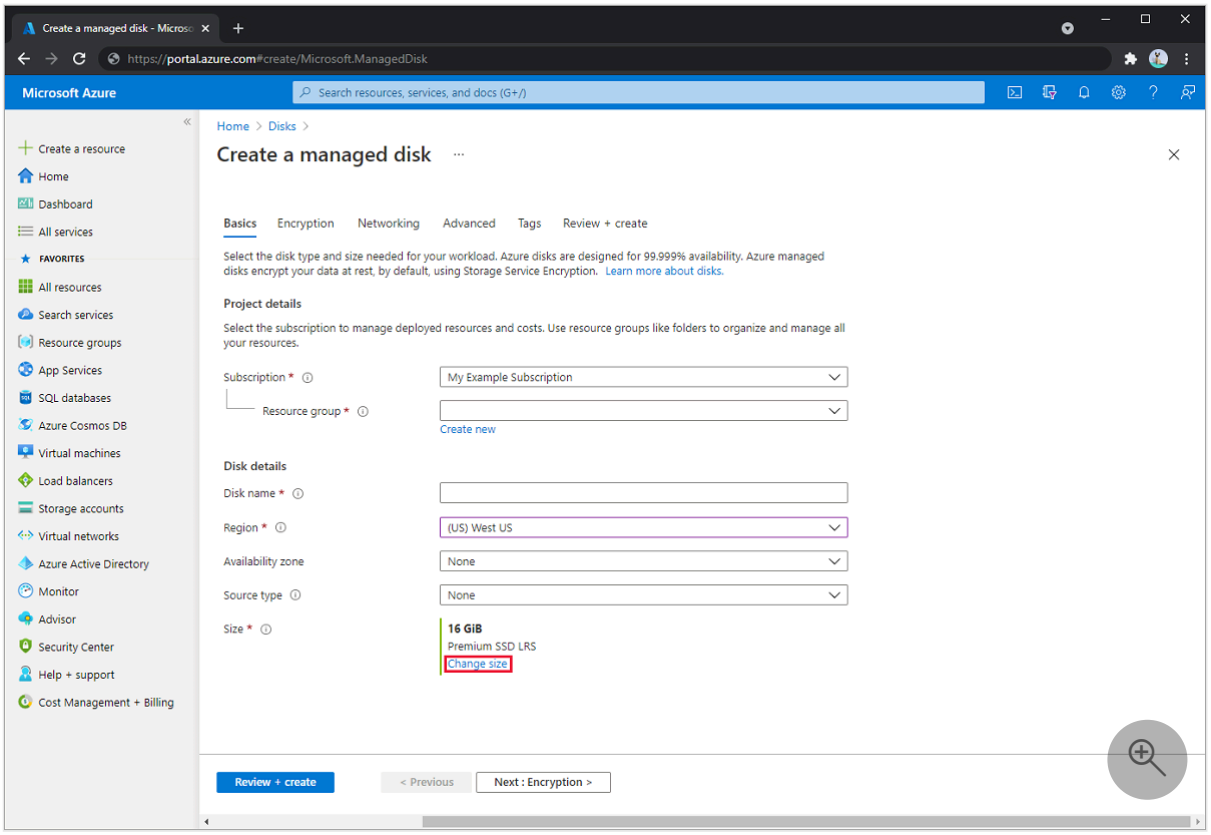
Deploy a Standard SSD as a shared disk

To deploy a managed disk with the shared disk feature enabled, use the new property `maxShares` and define a value greater than 1. This makes the disk shareable across multiple VMs.

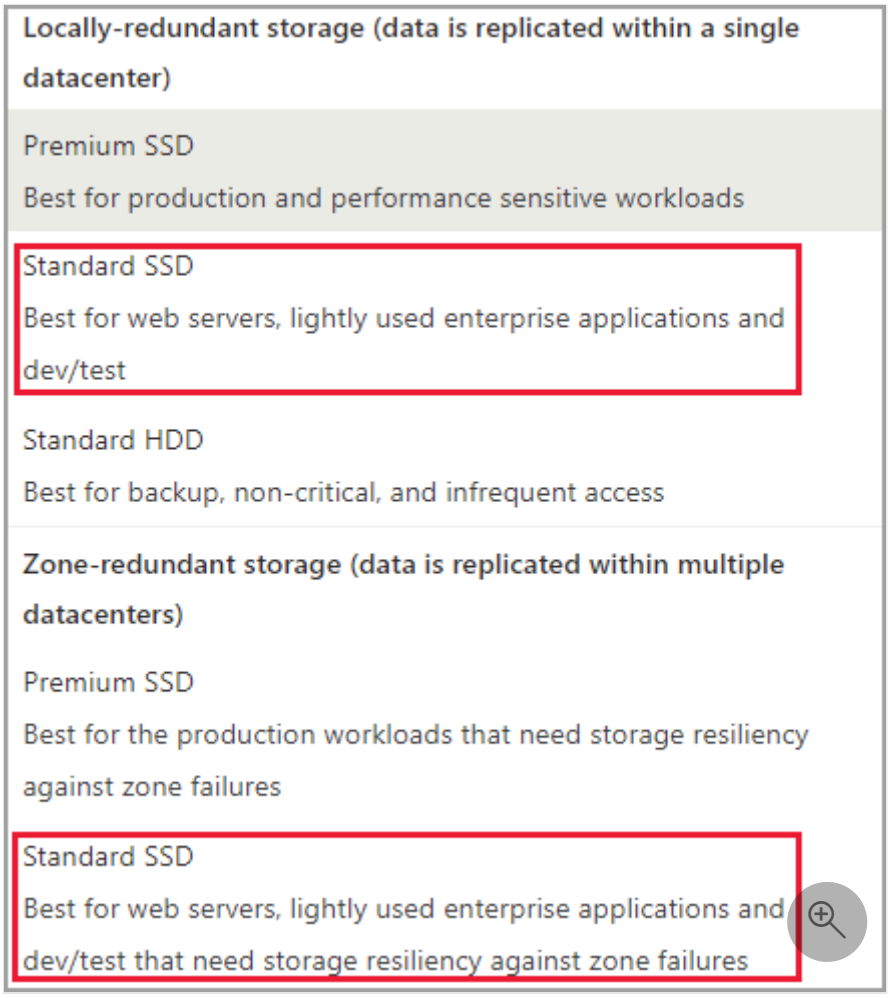
> **Important**
>
> Host caching isn't supported for shared disks.
>
> The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the Disk sizes for the allowed values for `maxShares`.

Portal

1. Sign in to the Azure portal.
2. Search for and Select **Disks**.
3. Select **+ Create** to create a new managed disk.
4. Fill in the details and select an appropriate region, then select **Change size**.

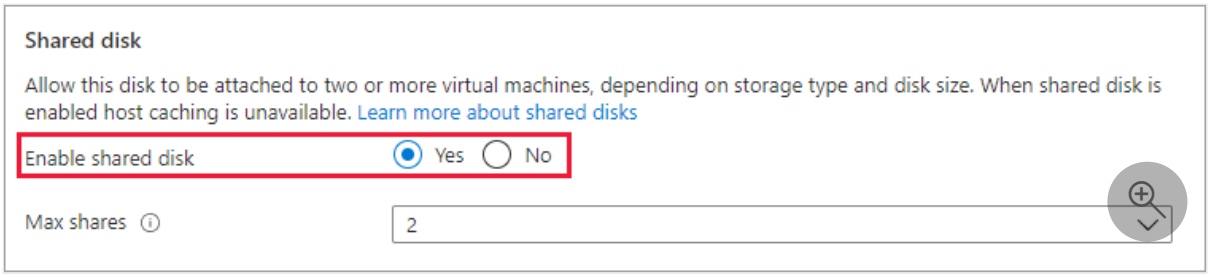


5. Select the Standard SSD size and SKU that you want and select **OK**.



6. Proceed through the deployment until you get to the **Advanced** pane.

7. Select **Yes** for **Enable shared disk** and select the amount of **Max shares** you want.



8. Select **Review + Create**.

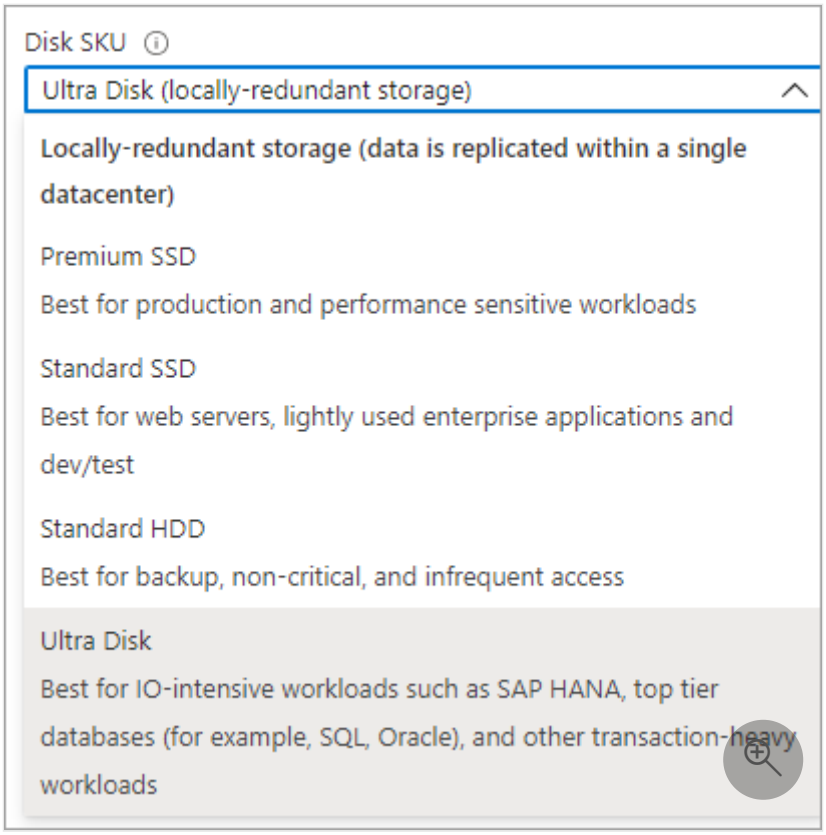
Deploy an Ultra Disk as a shared disk

To deploy a managed disk with the shared disk feature enabled, change the `maxShares` parameter to a value greater than 1. This makes the disk shareable across multiple VMs.

> **Important**
>
> The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the Disk sizes for the allowed values for `maxShares`.

Portal

1. Sign in to the Azure portal.
2. Search for and Select **Disks**.
3. Select **+ Create** to create a new managed disk.
4. Fill in the details, then select **Change size**.
5. Select Ultra Disk for the **Disk SKU**.

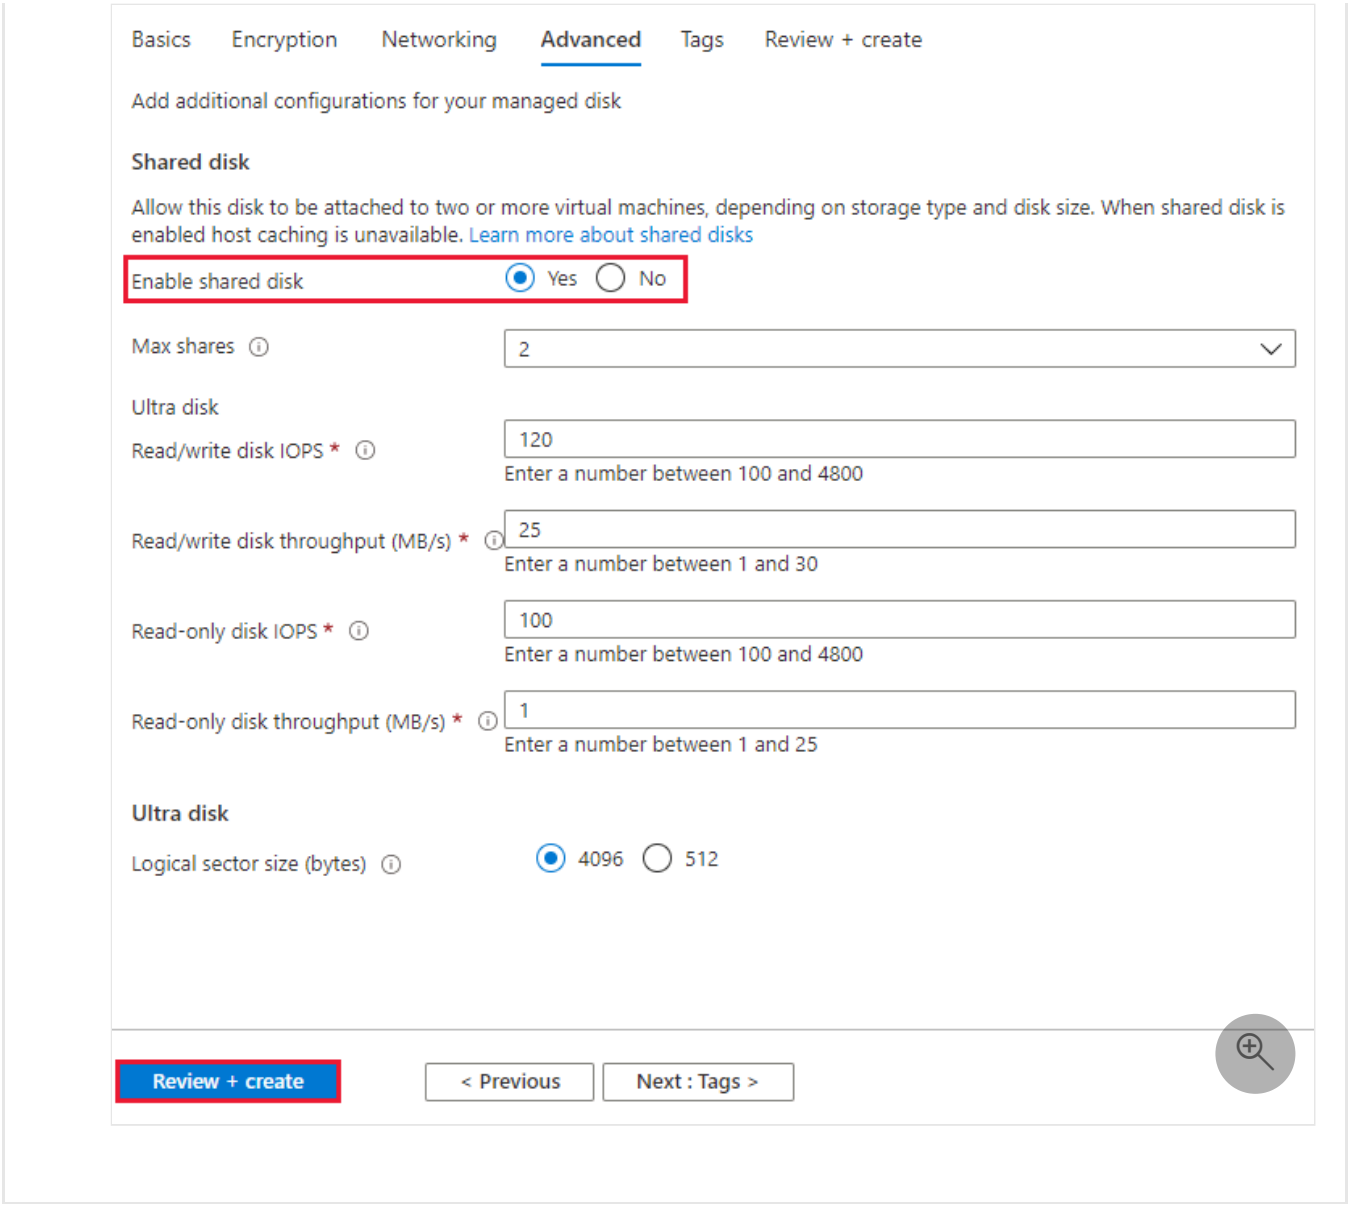


6. Select the disk size that you want and select **OK**.

7. Proceed through the deployment until you get to the **Advanced** pane.

8. Select **Yes** for **Enable shared disk** and select the amount of **Max shares** you want.

9. Select **Review + Create**.



Share an existing disk

To share an existing disk, or update how many VMs it can mount to, set the `maxShares` parameter with either the Azure PowerShell module or Azure CLI. You can also set `maxShares` to 1, if you want to disable sharing.

> **ⓘ Important**
>
> Host caching isn't supported for shared disks.
>
> The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the Disk sizes for the allowed values for `maxShares`. Before detaching a disk, record the LUN ID for when you reattach it.

PowerShell

Azure PowerShell

```
$datadiskconfig = Get-AzDisk -DiskName "mySharedDisk"
$datadiskconfig.maxShares = 3

Update-AzDisk -ResourceGroupName 'myResourceGroup' -DiskName 'mySharedDisk' -Disk
$datadiskconfig
```

CLI

Azure CLI

```
#Modifying a disk to enable or modify sharing configuration

az disk update --name mySharedDisk --max-shares 5 --resource-group myResourceGroup
```

Using Azure shared disks with your VMs

After you deploy a shared disk with `maxShares>1`, you can mount the disk to one or more of your VMs.

> **Note**
>
> Host caching isn't supported for shared disks.
>
> If you're deploying an Ultra Disk, make sure it matches the necessary requirements. See Using Azure Ultra Disks for details.

Azure PowerShell

```
$resourceGroup = "myResourceGroup"
$location = "WestCentralUS"

$vm = New-AzVm -ResourceGroupName $resourceGroup -Name "myVM" -Location $location -
VirtualNetworkName "myVnet" -SubnetName "mySubnet" -SecurityGroupName
"myNetworkSecurityGroup" -PublicIpAddressName "myPublicIpAddress"

$dataDisk = Get-AzDisk -ResourceGroupName $resourceGroup -DiskName "mySharedDisk"

$vm = Add-AzVMDataDisk -VM $vm -Name "mySharedDisk" -CreateOption Attach -
ManagedDiskId $dataDisk.Id -Lun 0

update-AzVm -VM $vm -ResourceGroupName $resourceGroup
```

Supported SCSI PR commands

Once you've mounted the shared disk to your VMs in your cluster, you can establish quorum and read/write to the disk using SCSI PR. The following PR commands are available when using Azure shared disks:

To interact with the disk, start with the persistent-reservation-action list:

```
PR_REGISTER_KEY

PR_REGISTER_AND_IGNORE

PR_GET_CONFIGURATION

PR_RESERVE

PR_PREEMPT_RESERVATION

PR_CLEAR_RESERVATION

PR_RELEASE_RESERVATION
```

When using PR_RESERVE, PR_PREEMPT_RESERVATION, or PR_RELEASE_RESERVATION, provide one of the following persistent-reservation-type:

```
PR_NONE

PR_WRITE_EXCLUSIVE

PR_EXCLUSIVE_ACCESS

PR_WRITE_EXCLUSIVE_REGISTRANTS_ONLY

PR_EXCLUSIVE_ACCESS_REGISTRANTS_ONLY

PR_WRITE_EXCLUSIVE_ALL_REGISTRANTS

PR_EXCLUSIVE_ACCESS_ALL_REGISTRANTS
```

You also need to provide a persistent-reservation-key when using PR_RESERVE, PR_REGISTER_AND_IGNORE, PR_REGISTER_KEY, PR_PREEMPT_RESERVATION, PR_CLEAR_RESERVATION, or PR_RELEASE-RESERVATION.

Next steps

If you have more questions, see the shared disks section of the FAQ.

Overview of managed disk encryption options

09/24/2025

There are several types of encryption available for your managed disks, including Azure Disk Encryption (ADE), Server-Side Encryption (SSE), and encryption at host.

- **Azure Disk Storage Server-Side Encryption** (also referred to as encryption-at-rest or Azure Storage encryption) is always enabled and automatically encrypts data stored on Azure managed disks (OS and data disks) when persisting on the Storage Clusters. When configured with a Disk Encryption Set (DES), it supports customer-managed keys as well. It doesn't encrypt temp disks or disk caches. For full details, see Server-side encryption of Azure Disk Storage.

- **Encryption at host** is a Virtual Machine option that enhances Azure Disk Storage Server-Side Encryption to ensure that all temp disks and disk caches are encrypted at rest and flow encrypted to the Storage clusters. For full details, see Encryption at host - End-to-end encryption for your VM data.

- **Confidential disk encryption** binds disk encryption keys to the virtual machine's TPM and makes the protected disk content accessible only to the VM. The TPM and VM guest state is always encrypted in attested code using keys released by a secure protocol that bypasses the hypervisor and host operating system. Currently only available for the OS disk; temp disk support is in preview. Encryption at host may be used for other disks on a Confidential VM in addition to Confidential Disk Encryption. For full details, see DCasv5 and ECasv5 series confidential VMs.

- **Azure Disk Encryption** helps protect and safeguard your data to meet your organizational security and compliance commitments. ADE encrypts the OS and data disks of Azure virtual machines (VMs) inside your VMs by using the DM-Crypt feature of Linux or the BitLocker feature of Windows. ADE is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets, with the option to encrypt with a key encryption key (KEK). For full details, see Azure Disk Encryption for Linux VMs or Azure Disk Encryption for Windows VMs.

  > **Important**
  >
  > Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use **encryption at host** for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to

encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Encryption is part of a layered approach to security and should be used with other recommendations to secure Virtual Machines and their disks. For full details, see Security recommendations for virtual machines in Azure and Restrict import/export access to managed disks.

Comparison

Here's a comparison of Disk Storage SSE, ADE, encryption at host, and Confidential disk encryption.

Expand table

	Azure Disk Storage Server-Side Encryption	Encryption at Host	Azure Disk Encryption	Confidential disk encryption (For the OS disk only)
Encryption at rest (OS and data disks)	✅	✅	✅	✅
Temp disk encryption	❌	✅ Only supported with platform managed key	✅	✅ In Preview
Encryption of caches	❌	✅	✅	✅
Data flows encrypted between Compute and Storage	❌	✅	✅	✅
Customer control of keys	✅ When configured with DES	✅ When configured with DES	✅ When configured with KEK	✅ When configured with DES
HSM Support	Azure Key Vault Premium and Managed HSM	Azure Key Vault Premium and Managed HSM	Azure Key Vault Premium	Azure Key Vault Premium and Managed HSM
Does not use your VM's CPU	✅	✅	❌	❌

	Azure Disk Storage Server-Side Encryption	Encryption at Host	Azure Disk Encryption	Confidential disk encryption (For the OS disk only)
Works for custom images	✅	✅	❌ Does not work for custom Linux images	✅
Enhanced Key Protection	❌	❌	❌	✅
Microsoft Defender for Cloud disk encryption status*	Unhealthy	Healthy	Healthy	Not applicable

> **ⓘ Important**
>
> For Confidential disk encryption, Microsoft Defender for Cloud does not currently have a recommendation that is applicable.

* Microsoft Defender for Cloud has the following disk encryption recommendations:

- Virtual machines and virtual machine scale sets should have encryption at host enabled (Only detects Encryption at Host)
- Virtual machines should encrypt temp disks, caches, and data flows between Compute and Storage resources (Only detects Azure Disk Encryption)
- Windows virtual machines should enable Azure Disk Encryption or EncryptionAtHost (Detects both Azure Disk Encryption and EncryptionAtHost)
- Linux virtual machines should enable Azure Disk Encryption or EncryptionAtHost (Detects both Azure Disk Encryption and EncryptionAtHost)

Migrate from Azure Disk Encryption to encryption at host

> **ⓘ Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

This article provides step-by-step guidance for migrating your virtual machines from Azure Disk Encryption (ADE) to encryption at host. The migration process requires creating new disks and VMs, as in-place conversion is not supported.

Migration overview

Azure Disk Encryption (ADE) encrypts data within the VM using BitLocker (Windows) or dm-crypt (Linux), while encryption at host encrypts data at the VM host level without consuming VM CPU resources. Encryption at host enhances Azure's default server-side encryption (SSE) by providing end-to-end encryption for all VM data, including temp disks, caches, and data flows between compute and storage.

For more information, see Overview of managed disk encryption options and Enable end-to-end encryption using encryption at host.

Migration limitations and considerations

Before starting the migration process, be aware of these important limitations and considerations that affect your migration strategy:

- **No in-place migration**: You cannot directly convert ADE-encrypted disks to encryption at host. Migration requires creating new disks and VMs.
- **Linux OS disk limitation**: Disabling ADE on Linux OS disks is not supported. For Linux VMs with ADE-encrypted OS disks, you must create a new VM with a new OS disk.

- **Windows ADE encryption patterns**: On Windows VMs, Azure Disk Encryption can only encrypt the OS disk alone OR all disks (OS + data disks). It's not possible to encrypt only data disks on Windows VMs.
- **UDE flag persistence**: Disks encrypted with Azure Disk Encryption have a Unified Data Encryption (UDE) flag that persists even after decryption. Both snapshots and disk copies using the Copy option retain this UDE flag. The migration requires creating new managed disks using the Upload method and copying the VHD blob data, which creates a new disk object without any metadata from the source disk.
- **Downtime required**: The migration process requires VM downtime for disk operations and VM recreation.
- **Domain-joined VMs**: If your VMs are part of an Active Directory domain, more steps are required:
  - The original VM must be removed from the domain before deletion
  - After creating the new VM, it must be rejoined to the domain
  - For Linux VMs, domain joining can be accomplished using Azure AD extensions

  For more information, see What is Microsoft Entra Domain Services?

Prerequisites

Before starting the migration:

1. **Backup your data**: Create backups of all critical data before beginning the migration process.
2. **Test the process**: If possible, test the migration process on a nonproduction VM first.
3. **Prepare encryption resources**: Ensure your VM size supports encryption at host. Most current VM sizes support this feature. For more information about VM size requirements, see Enable end-to-end encryption using encryption at host.
4. **Document configuration**: Record your current VM configuration, including network settings, extensions, and attached resources.

Migration steps

The following migration steps work for most scenarios, with specific differences noted for each operating system.

> **Important**

Linux VMs with encrypted OS disks cannot be decrypted in-place. For these VMs, you must create a new VM with a new OS disk and migrate your data. See the **Migrating Linux VMs with encrypted OS disks** section after reviewing the general process below.

Disable Azure Disk Encryption

First step is to disable the existing Azure Disk Encryption when possible:

- **Windows**: Follow the instructions in Disable encryption and remove the encryption extension on Windows
- **Linux**: If **only data disks** are encrypted, follow Disable encryption and remove the encryption extension on Linux. If **the OS disk is encrypted**, see the Migrating Linux VMs with encrypted OS disks.

After running the ADE disable command, the VM encryption status in the Azure portal changes to "SSE + PMK" immediately. However, the actual decryption process at the OS level takes time and depends on the amount of data encrypted. You must verify that OS-level decryption is completed before proceeding to the next step.

For Windows VMs:

- Open Command Prompt as Administrator and run: `manage-bde -status`
- Verify that all volumes show "Fully Decrypted" status
- The decryption percentage should show 100% for all encrypted volumes

For Linux VMs (data disks only):

- Run: `sudo cryptsetup status /dev/mapper/<device-name>`
- Verify that encrypted devices are no longer active
- Check with: `lsblk` to confirm no encrypted mappings remain

Wait for complete decryption before continuing with disk migration to ensure data integrity.

Create new managed disks

Create new disks that don't carry over the ADE encryption metadata. This process works for both Windows and Linux VMs, with some specific considerations for Linux OS disks.

CLI

Important

You need to add an offset of 512 bytes when copying a managed disk from Azure. This is because Azure omits the footer when reporting the disk size. The copy will fail if you don't do this. The following script already does this for you.

If you are creating an OS disk, add `--hyper-v-generation <yourGeneration>` to `az disk create`.

Azure CLI

```
# Set variables
sourceDiskName="MySourceDisk"
sourceRG="MyResourceGroup"
targetDiskName="MyTargetDisk"
targetRG="MyResourceGroup"
targetLocation="eastus"
# For OS disks, specify either "Windows" or "Linux"
# For data disks, omit the targetOS variable and --os-type parameter
targetOS="Windows"

# Get source disk size in bytes
sourceDiskSizeBytes=$(az disk show -g $sourceRG -n $sourceDiskName --query
'[diskSizeBytes]' -o tsv)

# Create a new empty target disk with upload capability
az disk create -g $targetRG -n $targetDiskName -l $targetLocation --os-type
$targetOS --for-upload --upload-size-bytes $(($sourceDiskSizeBytes+512)) --sku
standard_lrs

# Generate SAS URIs for both disks
targetSASURI=$(az disk grant-access -n $targetDiskName -g $targetRG --access-
level Write --duration-in-seconds 86400 --query [accessSas] -o tsv)

sourceSASURI=$(az disk grant-access -n $sourceDiskName -g $sourceRG --access-
level Read --duration-in-seconds 86400 --query [accessSas] -o tsv)

# Copy the disk data using AzCopy
azcopy copy $sourceSASURI $targetSASURI --blob-type PageBlob

# Revoke SAS access when complete
az disk revoke-access -n $sourceDiskName -g $sourceRG

az disk revoke-access -n $targetDiskName -g $targetRG
```

This method creates new disks without the Azure Disk Encryption metadata (UDE flag), which is essential for a clean migration.

Create a new VM with encryption

Create a new VM using the newly created disks with your chosen encryption method.

You can choose from several encryption options, depending on your security requirements. This article provides steps for creating a new VM with encryption at host, which is the most common migration path. Other encryption options are covered in Overview of managed disk encryption options.

Create a new VM with encryption at host

Encryption at host provides the closest equivalent to Azure Disk Encryption's coverage, and is covered in this section.

CLI

For OS disks:

Azure CLI

```
# For Windows OS disks
az vm create
  --resource-group "MyResourceGroup"
  --name "MyVM-New"
  --os-type "Windows"
  --attach-os-disk "MyTargetDisk"
  --encryption-at-host true

# For Linux OS disks
# az vm create
#   --resource-group "MyResourceGroup"
#   --name "MyVM-New"
#   --os-type "Linux"
#   --attach-os-disk "MyTargetDisk"
#   --encryption-at-host true
```

For data disks:

Azure CLI

```
# Enable encryption at host on the VM
az vm update
  --resource-group "MyResourceGroup"
  --name "MyVM-New"
  --encryption-at-host true

# Attach the newly created data disk
az vm disk attach
  --resource-group "MyResourceGroup"
```

```
    --vm-name "MyVM-New"
    --name "MyTargetDisk"
```

Verify and configure the new disks

After creating the new VM with encryption at host, you need to verify and configure the disks properly for your operating system.

CLI

For Windows VMs:

- Verify disk letters are assigned correctly
- Check that applications can access the disks correctly
- Update any applications or scripts that reference specific disk IDs

For Linux VMs:

- Update `/etc/fstab` with the new disk UUIDs
- Mount the data disks to the correct mount points

Bash

```
# Get UUIDs of all disks
sudo blkid

# Mount all disks defined in fstab
sudo mount -a
```

Both Windows and Linux may require additional configuration steps specific to your applications or workloads.

Verify encryption and cleanup

Verify that encryption at host is properly configured on both Windows and Linux VMs.

CLI

Azure CLI

```
# Check encryption at host status
az vm show --resource-group "MyResourceGroup" --name "MyVM-New" --query
```

```
"securityProfile.encryptionAtHost"
```

After confirming that encryption at host is working properly:

1. Test VM functionality to ensure applications work correctly
2. Verify that data is accessible and intact
3. Delete the original resources when you're satisfied with the migration:

Azure CLI

```
# Delete the original VM
az vm delete --resource-group "MyResourceGroup" --name "MyVM-Original" --yes

# Delete the original disk
az disk delete --resource-group "MyResourceGroup" --name "MySourceDisk" --yes
```

Migrating Linux VMs with encrypted OS disks

Since you cannot disable encryption on Linux OS disks, the process is different from Windows.

CLI

1. Create a new VM with encryption at host enabled

   Azure CLI

   ```
   az vm create \
     --resource-group "MyResourceGroup" \
     --name "MyVM-New" \
     --image "Ubuntu2204" \
     --encryption-at-host true \
     --admin-username "azureuser" \
     --generate-ssh-keys
   ```

2. For data migration options:

   - For application data: Use SCP, rsync, or other file transfer methods to copy data
   - For configuration: Replicate important configuration files and settings
   - For complex applications: Use backup/restore procedures appropriate for your applications

   Azure CLI

   ```
   # Example of using SCP to copy files from source to new VM
   az vm run-command invoke -g MyResourceGroup -n MyVM-Original --command-id
   ```

```
RunShellScript \
  --scripts "scp -r /path/to/data azureuser@new-vm-ip:/path/to/destination"
```

After creating the new VM:

1. Configure the new VM to match the original environment
    - Set up the same network configurations
    - Install the same applications and services
    - Apply the same security settings
2. Test thoroughly before decommissioning the original VM

This approach works for both Windows and Linux VMs, but is especially important for Linux VMs with encrypted OS disks that cannot be decrypted in-place.

For guidance on data migration, see Upload a VHD to Azure and Copy files to a Linux VM using SCP.

Domain-joined VM considerations

If your VMs are members of an Active Directory domain, additional steps are required during the migration process:

Premigration domain steps

1. **Document domain membership**: Record the current domain, organizational unit (OU), and any special group memberships
2. **Note computer account**: The computer account in Active Directory needs to be managed
3. **Backup domain-specific configurations**: Save any domain-specific settings, group policies, or certificates

Domain removal process

1. **Remove from domain**: Before deleting the original VM, remove it from the domain using one of these methods:
    - Use `Remove-Computer` PowerShell cmdlet on Windows
    - Use the System Properties dialog to change to workgroup
    - Manually delete the computer account from Active Directory Users and Computers
2. **Clean up Active Directory**: Remove any orphaned computer accounts or DNS entries

Post-migration domain rejoining

1. **Join new VM to domain**: After creating the new VM with encryption at host:
    - For Windows: Use `Add-Computer` PowerShell cmdlet or System Properties
    - For Linux: Use Azure AD domain join extension or manual configuration
2. **Restore domain settings**: Reapply any domain-specific configurations, group policies, or certificates
3. **Verify domain functionality**: Test domain authentication, group policy application, and network resource access

Linux domain joining

For Linux VMs, you can use the Azure AD Domain Services VM extension:

Azure CLI

```
az vm extension set \
    --resource-group "MyResourceGroup" \
    --vm-name "MyLinuxVM-New" \
    --name "AADSSHLoginForLinux" \
    --publisher "Microsoft.Azure.ActiveDirectory"
```

For more information, see What is Microsoft Entra Domain Services?

Important domain considerations

- The new VM has a different computer SID, which may affect some applications
- Kerberos tickets and cached credentials must be refreshed
- Some domain-integrated applications may require reconfiguration
- Plan for potential temporary loss of domain services during migration

Post-migration verification

After completing the migration, verify that encryption at host is working correctly:

1. **Check encryption at host status**: Verify that encryption at host is enabled:

    Azure CLI

    ```
    az vm show --resource-group "MyResourceGroup" --name "MyVM-New" --query
    "securityProfile.encryptionAtHost"
    ```

2. **Test VM functionality**: Ensure your applications and services are working correctly.

3. **Verify disk encryption**: Confirm that disks are properly encrypted:

   Azure PowerShell

   ```
   Get-AzDisk -ResourceGroupName "MyResourceGroup" -DiskName "MyVM-OS-New" |
   Select-Object Name, DiskState
   ```

4. **Monitor performance**: Compare performance before and after migration to confirm the expected improvements.

For more information about encryption verification, see Enable end-to-end encryption using encryption at host.

Cleanup

After successful migration and verification:

1. **Delete old VM**: Remove the original ADE-encrypted VM

2. **Delete old disks**: Remove the original encrypted disks

3. **Update Key Vault access policies**: Other disk encryption solutions use standard Key Vault authorization mechanisms. If you no longer need the Key Vault for Azure Disk Encryption, update its access policies to disable the special disk encryption setting:

   CLI

   Azure CLI

   ```
   az keyvault update --name "YourKeyVaultName" --resource-group
   "YourResourceGroup" --enabled-for-disk-encryption false
   ```

---

4. **Clean up resources**: Remove any temporary resources created during migration
5. **Update documentation**: Update your infrastructure documentation to reflect the migration to encryption at host

Common issues and solutions

VM size doesn't support encryption at host

Solution: Check the list of supported VM sizes and resize your VM if necessary

VM fails to start after migration

Solution: Check that all disks are properly attached and that the OS disk is set as the boot disk

Encryption at host not enabled

Solution: Verify that the VM was created with the `--encryption-at-host true` parameter and that your subscription supports this feature

Performance issues persist

Solution: Verify that encryption at host is properly enabled and that the VM size supports the expected performance.

Server-side encryption of Azure Disk Storage

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Most Azure managed disks are encrypted with Azure Storage encryption, which uses server-side encryption (SSE) to protect your data and to help you meet your organizational security and compliance commitments. Azure Storage encryption automatically encrypts your data stored on Azure managed disks (OS and data disks) at rest by default when persisting it to the cloud. Disks with encryption at host enabled, however, aren't encrypted through Azure Storage. For disks with encryption at host enabled, the server hosting your VM provides the encryption for your data, and that encrypted data flows into Azure Storage.

Data in Azure managed disks is encrypted transparently using 256-bit AES encryption, one of the strongest block ciphers available, and is FIPS 140-2 compliant. For more information about the cryptographic modules underlying Azure managed disks, see Cryptography API: Next Generation

Azure Storage encryption doesn't impact the performance of managed disks and there's no extra cost. For more information about Azure Storage encryption, see Azure Storage encryption.

> **Important**
>
> Temporary disks are not managed disks and are not encrypted by SSE, unless you enable encryption at host.
>
> Azure VMs that are version 5 and above (such as Dsv5 or Dsv6) automatically encrypt their temporary disks and (if in use) their ephemeral OS disks with encryption at rest.

About encryption key management

You can rely on platform-managed keys for the encryption of your managed disk, or you can manage encryption using your own keys. If you choose to manage encryption with your own keys, you can specify a *customer-managed key* to use for encrypting and decrypting all data in managed disks.

The following sections describe each of the options for key management in greater detail.

Platform-managed keys

By default, managed disks use platform-managed encryption keys. All managed disks, snapshots, images, and data written to existing managed disks are automatically encrypted-at-rest with platform-managed keys. Platform-managed keys are managed by Microsoft.

Customer-managed keys

You can choose to manage encryption at the level of each managed disk, with your own keys. When you specify a customer-managed key, that key is used to protect and control access to the key that encrypts your data. Customer-managed keys offer greater flexibility to manage access controls.

You must use one of the following Azure key stores to store your customer-managed keys:

- Azure Key Vault (Premium tier recommended for HSM-backed key protection)
- Azure Key Vault Managed Hardware Security Module (HSM)

You can either import your RSA keys to your Key Vault or generate new RSA keys in Azure Key Vault. Azure managed disks handles the encryption and decryption in a fully transparent fashion using envelope encryption. It encrypts data using an AES 256 based data encryption key (DEK), which is, in turn, protected using your keys. The Storage service generates data encryption keys and encrypts them with customer-managed keys using RSA encryption. The envelope encryption allows you to rotate (change) your keys periodically as per your compliance policies without impacting your VMs. When you rotate your keys, the Storage service re-wraps the data encryption keys with the new customer-managed key version. The underlying disk data itself is not re-encrypted. Both old and new key versions must remain enabled until re-wrapping is complete.

Managed disks and the Key Vault or managed HSM must be in the same Azure region, but they can be in different subscriptions. They must also be in the same Microsoft Entra tenant, unless you're using Encrypt managed disks with cross-tenant customer-managed keys.

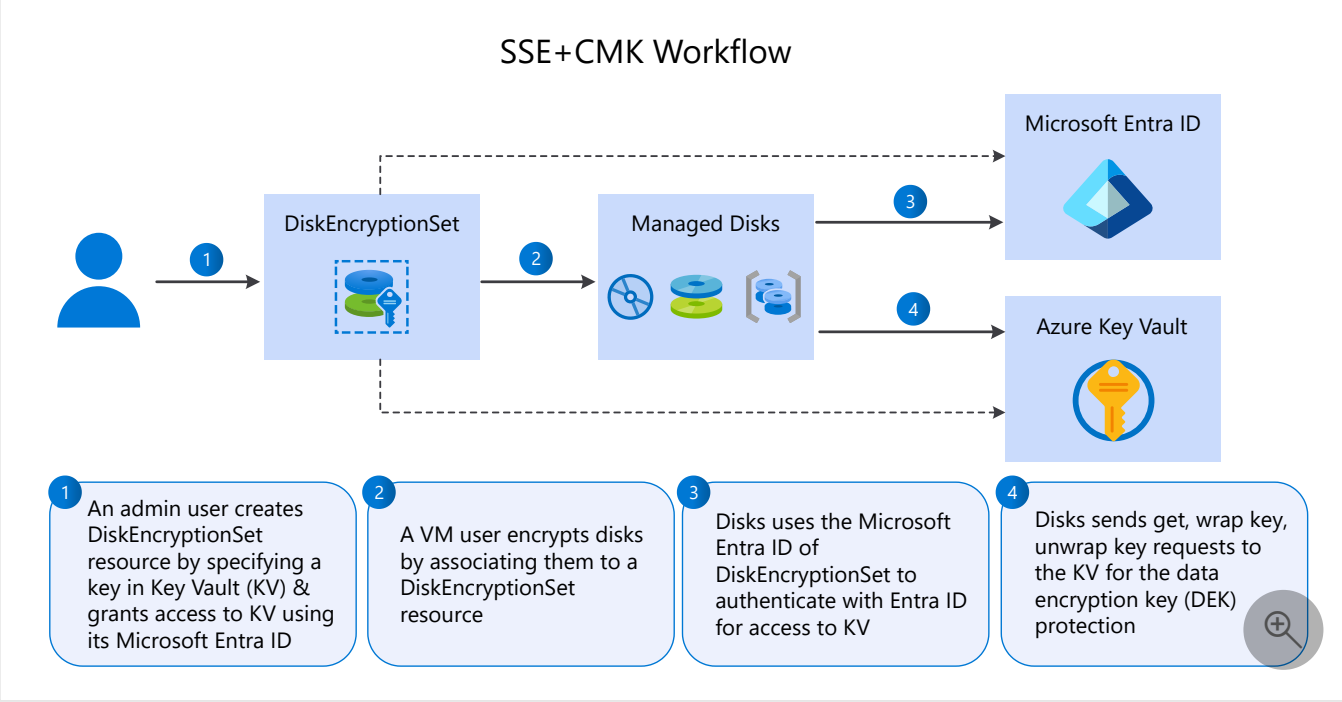
Full control of your keys

You must grant access to managed disks in your Key Vault or managed HSM to use your keys for encrypting and decrypting the DEK. This allows you full control of your data and keys. You can disable your keys or revoke access to managed disks at any time. You can also audit the

encryption key usage with Azure Key Vault monitoring to ensure that only managed disks or other trusted Azure services are accessing your keys.

> **Important**
>
> When a key is either disabled, deleted, or expired, any VMs with either OS or data disks using that key will automatically shut down. After the automated shut down, VMs won't boot until the key is enabled again, or you assign a new key.
>
> Generally, disk I/O (read or write operations) start to fail one hour after a key is either disabled, deleted, or expired.

The following diagram shows how managed disks use Microsoft Entra ID and Azure Key Vault to make requests using the customer-managed key:



The following list explains the diagram in more detail:

1. An Azure Key Vault administrator creates key vault resources.
2. The key vault admin either imports their RSA keys to Key Vault or generate new RSA keys in Key Vault.
3. That administrator creates an instance of Disk Encryption Set resource, specifying an Azure Key Vault ID and a key URL. Disk Encryption Set is a new resource introduced for simplifying the key management for managed disks.
4. When a disk encryption set is created, a system-assigned managed identity is created in Microsoft Entra ID and associated with the disk encryption set.

5. The Azure key vault administrator then grants the managed identity permission to perform operations in the key vault.
6. A VM user creates disks by associating them with the disk encryption set. The VM user can also enable server-side encryption with customer-managed keys for existing resources by associating them with the disk encryption set.
7. Managed disks use the managed identity to send requests to the Azure Key Vault.
8. For reading or writing data, managed disks sends requests to Azure Key Vault to encrypt (wrap) and decrypt (unwrap) the data encryption key in order to perform encryption and decryption of the data.

To revoke access to customer-managed keys, see Azure Key Vault PowerShell and Azure Key Vault CLI. Revoking access effectively blocks access to all data in the storage account, as the encryption key is inaccessible by Azure Storage.

Automatic key rotation of customer-managed keys

Generally, if you're using customer-managed keys, you should enable automatic key rotation to the latest key version. Automatic key rotation helps ensure your keys are secure. A disk references a key via its disk encryption set. When you enable automatic rotation for a disk encryption set, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour. To learn how to enable customer-managed keys with automatic key rotation, see Set up an Azure Key Vault and DiskEncryptionSet with automatic key rotation.

> **Note**
>
> Virtual Machines aren't rebooted during automatic key rotation.

If you can't enable automatic key rotation, you can use other methods to alert you before keys expire. This way, you can make sure to rotate your keys before expiration and keep business continuity. You can use either an Azure Policy or Azure Event Grid to send a notification when a key expires soon.

Restrictions

For now, customer-managed keys have the following restrictions:

- If this feature is enabled for a disk with incremental snapshots, it can't be disabled on that disk or its snapshots. To work around this, copy all the data to an entirely different

managed disk that isn't using customer-managed keys. You can do that with either the Azure CLI or the Azure PowerShell module.

- A disk and all of its associated incremental snapshots must have the same disk encryption set.
- Only software and HSM RSA keys of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - HSM keys require the **premium** tier of Azure Key vaults.
- For Ultra Disks and Premium SSD v2 disks only:
  - (Preview) User-assigned managed identities are available for Ultra Disks and Premium SSD v2 disks encrypted with customer-managed keys.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region as your disk encryption set. Azure Key Vaults in different Microsoft Entra tenants are supported for managed disks. For details, see Encrypt managed disks with cross-tenant customer-managed keys.
- Disks encrypted with customer-managed keys can only move to another resource group if the VM they're attached to is deallocated.
- Disks, snapshots, and images encrypted with customer-managed keys can't be moved between subscriptions.
- Managed disks currently or previously encrypted using Azure Disk Encryption can't be encrypted using customer-managed keys.
- Can only create up to 5000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see Preview: Use customer-managed keys for encrypting images.

Supported regions

Customer-managed keys are available in all regions that managed disks are available.

> **Important**
>
> Customer-managed keys rely on managed identities for Azure resources, a feature of Microsoft Entra ID. When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Microsoft Entra directory to another, the managed identity associated with managed disks isn't transferred to the new

tenant, so customer-managed keys may no longer work. For more information, see Transferring a subscription between Microsoft Entra directories.

To enable customer-managed keys for managed disks, see our articles covering how to enable it with either the Azure PowerShell module, the Azure CLI or the Azure portal.

See Create a managed disk from a snapshot with CLI for a code sample.

Encryption at host - End-to-end encryption for your VM data

When you enable encryption at host, that encryption starts on the VM host itself, the Azure server that your VM is allocated to. The data for your temporary disk and OS/data disk caches are stored on that VM host. After enabling encryption at host, all this data is encrypted at rest and flows encrypted to the Storage service, where it's persisted. Essentially, encryption at host encrypts your data from end-to-end. Encryption at host doesn't use your VM's CPU and doesn't impact your VM's performance.

Temporary disks and ephemeral OS disks are encrypted at rest with platform-managed keys when you enable end-to-end encryption. The OS and data disk caches are encrypted at rest with either customer-managed or platform-managed keys, depending on the selected disk encryption type. For example, if a disk is encrypted with customer-managed keys, then the cache for the disk is encrypted with customer-managed keys, and if a disk is encrypted with platform-managed keys then the cache for the disk is encrypted with platform-managed keys.

Restrictions

- Can't be enabled on virtual machines (VMs) or virtual machine scale sets that currently or ever had Azure Disk Encryption enabled.
- Azure Disk Encryption can't be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale sets. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.

The following restrictions only apply to Ultra Disks and Premium SSD v2:

- Disks using a 512e sector size need to have been created after 5/13/2023.
  - If your disk was created before this date, snapshot your disk, and create a new disk using the snapshot.

Supported VM sizes

The complete list of supported VM sizes can be pulled programmatically. To learn how to retrieve them programmatically, refer to the finding supported VM sizes section of either the Azure PowerShell module or Azure CLI articles.

To enable end-to-end encryption using encryption at host, see our articles covering how to enable it with either the Azure PowerShell module, the Azure CLI, or the Azure portal.

Double encryption at rest

High security sensitive customers who are concerned of the risk associated with any particular encryption algorithm, implementation, or key being compromised can now opt for extra layer of encryption using a different encryption algorithm/mode at the infrastructure layer using platform managed encryption keys. This new layer can be applied to persisted OS and data disks, snapshots, and images, all of which will be encrypted at rest with double encryption.

Restrictions

Double encryption at rest isn't currently supported with either Ultra Disks or Premium SSD v2 disks.

To enable double encryption at rest for managed disks, see Enable double encryption at rest for managed disks.

Encryption at host versus Azure disk encryption

Azure Disk Encryption leverages either the DM-Crypt feature of Linux or the BitLocker feature of Windows to encrypt managed disks with customer-managed keys within the guest VM. Server-side encryption with encryption at host improves on ADE. With encryption at host, data for your temporary disk and OS/data disk caches are stored on that VM host. After enabling encryption at host, all this data is encrypted at rest and flows encrypted to the Storage service, where it's persisted. Essentially, encryption at host encrypts your data from end-to-end. Encryption at host doesn't use your VM's CPU and doesn't impact your VM's performance.

> **Important**
>
> Customer-managed keys rely on managed identities for Azure resources, a feature of Microsoft Entra ID. When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the

subscription, resource group, or managed disk from one Microsoft Entra directory to another, the managed identity associated with managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see Transferring a subscription between Microsoft Entra directories.

Azure PowerShell - Enable customer-managed keys with server-side encryption - managed disks

Article • 08/23/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Disk Storage allows you to manage your own keys when using server-side encryption (SSE) for managed disks, if you choose. For conceptual information on SSE with customer-managed keys, and other managed disk encryption types, see the Customer-managed keys section of our disk encryption article.

Restrictions

For now, customer-managed keys have the following restrictions:

- If this feature is enabled for a disk with incremental snapshots, it can't be disabled on that disk or its snapshots. To work around this, copy all the data to an entirely different managed disk that isn't using customer-managed keys. You can do that with either the Azure CLI or the Azure PowerShell module.
- Only software and HSM RSA keys of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - HSM keys require the **premium** tier of Azure Key vaults.
- For Ultra Disks and Premium SSD v2 disks only:
  - Snapshots created from disks that are encrypted with server-side encryption and customer-managed keys must be encrypted with the same customer-managed keys.
  - User-assigned managed identities aren't supported for Ultra Disks and Premium SSD v2 disks encrypted with customer-managed keys.
  - Not currently supported in Azure Government or Azure China.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region as your disk encryption set. As a preview, you can use Azure Key Vaults from different Microsoft Entra tenants.
- Disks encrypted with customer-managed keys can only move to another resource group if the VM they are attached to is deallocated.
- Disks, snapshots, and images encrypted with customer-managed keys can't be moved between subscriptions.

- Managed disks currently or previously encrypted using Azure Disk Encryption can't be encrypted using customer-managed keys.
- Can only create up to 5000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see Preview: Use customer-managed keys for encrypting images.

Set up an Azure Key Vault and DiskEncryptionSet optionally with automatic key rotation

To use customer-managed keys with SSE, you must set up an Azure Key Vault and a DiskEncryptionSet resource.

1. Make sure that you have installed latest Azure PowerShell version, and you are signed in to an Azure account in with Connect-AzAccount

2. Create an instance of Azure Key Vault and encryption key.

   When creating the Key Vault instance, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

   PowerShell

   ```
   $ResourceGroupName="yourResourceGroupName"
   $LocationName="westcentralus"
   $keyVaultName="yourKeyVaultName"
   $keyName="yourKeyName"
   $keyDestination="Software"
   $diskEncryptionSetName="yourDiskEncryptionSetName"

   $keyVault = New-AzKeyVault -Name $keyVaultName `
   -ResourceGroupName $ResourceGroupName `
   -Location $LocationName `
   -EnablePurgeProtection

   $key = Add-AzKeyVaultKey -VaultName $keyVaultName `
         -Name $keyName `
         -Destination $keyDestination
   ```

3. Create an instance of a DiskEncryptionSet. You can set RotationToLatestKeyVersionEnabled equal to $true to enable automatic rotation of

the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

PowerShell

```
$desConfig=New-AzDiskEncryptionSetConfig -Location $LocationName `
    -SourceVaultId $keyVault.ResourceId `
    -KeyUrl $key.Key.Kid `
    -IdentityType SystemAssigned `
    -RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $diskEncryptionSetName `
       -ResourceGroupName $ResourceGroupName `
       -InputObject $desConfig
```

4. Grant the DiskEncryptionSet resource access to the key vault.

> **Note**
>
> It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Microsoft Entra ID. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ObjectId
$des.Identity.PrincipalId -PermissionsToKeys wrapkey,unwrapkey,get
```

Use a key vault in a different subscription

Alternatively, you can manage your Azure Key Vaults centrally from a single subscription, and use the keys stored in the Key Vault to encrypt managed disks and snapshots in other subscriptions in your organization. This allows your security team to enforce and easily manage a robust security policy to a single subscription.

> **Important**
>
> For this configuration, both your Key Vault and your disk encryption set must be in the same region and be using the same tenant.

The following script is an example of how you would configure a disk encryption set to use a key from a Key Vault in a different subscription, but same region:

Azure PowerShell

```
$sourceSubscriptionId="<sourceSubID>"
$sourceKeyVaultName="<sourceKVName>"
$sourceKeyName="<sourceKeyName>"

$targetSubscriptionId="<targetSubID>"
$targetResourceGroupName="<targetRGName>"
$targetDiskEncryptionSetName="<targetDiskEncSetName>"
$location="<targetRegion>"

Set-AzContext -Subscription $sourceSubscriptionId

$key = Get-AzKeyVaultKey -VaultName $sourceKeyVaultName -Name $sourceKeyName

Set-AzContext -Subscription $targetSubscriptionId

$desConfig=New-AzDiskEncryptionSetConfig -Location $location `
-KeyUrl $key.Key.Kid `
-IdentityType SystemAssigned `
-RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $targetDiskEncryptionSetName `
-ResourceGroupName $targetResourceGroupName `
-InputObject $desConfig
```

Examples

Now that you've created and configured these resources, you can use them to secure your managed disks. The following are example scripts, each with a respective scenario, that you can use to secure your managed disks.

Create a VM using a Marketplace image, encrypting the OS and data disks with customer-managed keys

Copy the script, replace all of the example values with your own parameters, and then run it.

PowerShell

```
$VMLocalAdminUser = "yourVMLocalAdminUserName"
$VMLocalAdminSecurePassword = ConvertTo-SecureString <password> -AsPlainText
-Force
$LocationName = "yourRegion"
```

```
$ResourceGroupName = "yourResourceGroupName"
$ComputerName = "yourComputerName"
$VMName = "yourVMName"
$VMSize = "yourVMSize"
$diskEncryptionSetName="yourdiskEncryptionSetName"

$NetworkName = "yourNetworkName"
$NICName = "yourNICName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -
AddressPrefix $SubnetAddressPrefix
$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName
$ResourceGroupName -Location $LocationName -AddressPrefix $VnetAddressPrefix
-Subnet $SingleSubnet
$NIC = New-AzNetworkInterface -Name $NICName -ResourceGroupName
$ResourceGroupName -Location $LocationName -SubnetId $Vnet.Subnets[0].Id

$Credential = New-Object System.Management.Automation.PSCredential
($VMLocalAdminUser, $VMLocalAdminSecurePassword);

$VirtualMachine = New-AzVMConfig -VMName $VMName -VMSize $VMSize
$VirtualMachine = Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -
ComputerName $ComputerName -Credential $Credential -ProvisionVMAgent -
EnableAutoUpdate
$VirtualMachine = Add-AzVMNetworkInterface -VM $VirtualMachine -Id $NIC.Id
$VirtualMachine = Set-AzVMSourceImage -VM $VirtualMachine -PublisherName
'MicrosoftWindowsServer' -Offer 'WindowsServer' -Skus '2012-R2-Datacenter' -
Version latest

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName
$ResourceGroupName -Name $diskEncryptionSetName

$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name $($VMName
+"_OSDisk") -DiskEncryptionSetId $diskEncryptionSet.Id -CreateOption
FromImage

$VirtualMachine = Add-AzVMDataDisk -VM $VirtualMachine -Name $($VMName
+"DataDisk1") -DiskSizeInGB 128 -StorageAccountType Premium_LRS -
CreateOption Empty -Lun 0 -DiskEncryptionSetId $diskEncryptionSet.Id

New-AzVM -ResourceGroupName $ResourceGroupName -Location $LocationName -VM
$VirtualMachine -Verbose
```

Create an empty disk encrypted using server-side encryption with customer-managed keys and attach it to a VM

Copy the script, replace all of the example values with your own parameters, and then run it.

PowerShell

```
$vmName = "yourVMName"
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$diskName = "yourDiskName"
$diskSKU = "Premium_LRS"
$diskSizeinGiB = 30
$diskLUN = 1
$diskEncryptionSetName="yourDiskEncryptionSetName"

$vm = Get-AzVM -Name $vmName -ResourceGroupName $ResourceGroupName

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName
$ResourceGroupName -Name $diskEncryptionSetName

$vm = Add-AzVMDataDisk -VM $vm -Name $diskName -CreateOption Empty -
DiskSizeInGB $diskSizeinGiB -StorageAccountType $diskSKU -Lun $diskLUN -
DiskEncryptionSetId $diskEncryptionSet.Id

Update-AzVM -ResourceGroupName $ResourceGroupName -VM $vm
```

Encrypt existing managed disks

Your existing disks must not be attached to a running VM in order for you to encrypt them using the following script:

PowerShell

```
$rgName = "yourResourceGroupName"
$diskName = "yourDiskName"
$diskEncryptionSetName = "yourDiskEncryptionSetName"

$diskEncryptionSet = Get-AzDiskEncryptionSet -ResourceGroupName $rgName -
Name $diskEncryptionSetName

New-AzDiskUpdateConfig -EncryptionType "EncryptionAtRestWithCustomerKey" -
DiskEncryptionSetId $diskEncryptionSet.Id | Update-AzDisk -ResourceGroupName
$rgName -DiskName $diskName
```

Encrypt an existing virtual machine scale set (uniform orchestration mode) with SSE and customer-managed

keys

This script will work for scale sets in uniform orchestration mode only. For scale sets in flexible orchestration mode, follow the Encrypt existing managed disks for each VM.

Copy the script, replace all the example values with your own parameters, and then run it:

PowerShell

```
#set variables
$vmssname = "name of the vmss that is already created"
$diskencryptionsetname = "name of the diskencryptionset already created"
$vmssrgname = "vmss resourcegroup name"
$diskencryptionsetrgname = "diskencryptionset resourcegroup name"

#get vmss object and create diskencryptionset object attach to vmss os disk
$ssevmss = get-azvmss -ResourceGroupName $vmssrgname -VMScaleSetName
$vmssname
$ssevmss.VirtualMachineProfile.StorageProfile.OsDisk.ManagedDisk.DiskEncrypt
ionSet = New-Object -TypeName
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSetParameters

#get diskencryption object and retrieve the resource id
$des = Get-AzDiskEncryptionSet -ResourceGroupName $diskencryptionsetrgname -
Name $diskencryptionsetname
write-host "the diskencryptionset resource id is:" $des.Id

#associate DES resource id to os disk and update vmss
$ssevmss.VirtualMachineProfile.StorageProfile.OsDisk.ManagedDisk.DiskEncrypt
ionSet.id = $des.Id
$ssevmss | update-azvmss
```

Create a virtual machine scale set using a Marketplace image, encrypting the OS and data disks with customer-managed keys

Copy the script, replace all of the example values with your own parameters, and then run it.

> **ⓘ Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to

[Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub](#)

PowerShell

```
$VMLocalAdminUser = "yourLocalAdminUser"
$VMLocalAdminSecurePassword = ConvertTo-SecureString Password@123 -
AsPlainText -Force
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$ComputerNamePrefix = "yourComputerNamePrefix"
$VMScaleSetName = "yourVMSSName"
$VMSize = "Standard_DS3_v2"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$NetworkName = "yourVNETName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -
AddressPrefix $SubnetAddressPrefix

$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName
$ResourceGroupName -Location $LocationName -AddressPrefix $VnetAddressPrefix
-Subnet $SingleSubnet

$ipConfig = New-AzVmssIpConfig -Name "myIPConfig" -SubnetId
$Vnet.Subnets[0].Id

$VMSS = New-AzVmssConfig -Location $LocationName -SkuCapacity 2 -SkuName
$VMSize -UpgradePolicyMode 'Automatic' -OrchestrationMode 'Uniform'

$VMSS = Add-AzVmssNetworkInterfaceConfiguration -Name "myVMSSNetworkConfig"
-VirtualMachineScaleSet $VMSS -Primary $true -IpConfiguration $ipConfig

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName
$ResourceGroupName -Name $diskEncryptionSetName

# Enable encryption at rest with customer managed keys for OS disk by
setting DiskEncryptionSetId property

$VMSS = Set-AzVmssStorageProfile $VMSS -OsDiskCreateOption "FromImage" -
DiskEncryptionSetId $diskEncryptionSet.Id -ImageReferenceOffer
'WindowsServer' -ImageReferenceSku '2012-R2-Datacenter' -
ImageReferenceVersion latest -ImageReferencePublisher
'MicrosoftWindowsServer'

$VMSS = Set-AzVmssOsProfile $VMSS -ComputerNamePrefix $ComputerNamePrefix -
AdminUsername $VMLocalAdminUser -AdminPassword $VMLocalAdminSecurePassword

# Add a data disk encrypted at rest with customer managed keys by setting
DiskEncryptionSetId property
```

```
$VMSS = Add-AzVmssDataDisk -VirtualMachineScaleSet $VMSS -CreateOption Empty
-Lun 1 -DiskSizeGB 128 -StorageAccountType Premium_LRS -DiskEncryptionSetId
$diskEncryptionSet.Id

$Credential = New-Object System.Management.Automation.PSCredential
($VMLocalAdminUser, $VMLocalAdminSecurePassword);

New-AzVmss -VirtualMachineScaleSet $VMSS -ResourceGroupName
$ResourceGroupName -VMScaleSetName $VMScaleSetName
```

Change the key of a DiskEncryptionSet to rotate the key for all the resources referencing the DiskEncryptionSet

Copy the script, replace all of the example values with your own parameters, and then run it.

PowerShell

```
$ResourceGroupName="yourResourceGroupName"
$keyVaultName="yourKeyVaultName"
$keyName="yourKeyName"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName
$ResourceGroupName

$keyVaultKey = Get-AzKeyVaultKey -VaultName $keyVaultName -Name $keyName

Update-AzDiskEncryptionSet -Name $diskEncryptionSetName -ResourceGroupName
$ResourceGroupName -SourceVaultId $keyVault.ResourceId -KeyUrl
$keyVaultKey.Id
```

Find the status of server-side encryption of a disk

PowerShell

```
$ResourceGroupName="yourResourceGroupName"
$DiskName="yourDiskName"

$disk=Get-AzDisk -ResourceGroupName $ResourceGroupName -DiskName $DiskName
$disk.Encryption.Type
```

Important

Customer-managed keys rely on managed identities for Azure resources, a feature of Microsoft Entra ID. When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Microsoft Entra directory to another, the managed identity associated with the managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see **Transferring a subscription between Microsoft Entra directories**.

Use the Azure CLI to enable server-side encryption with customer-managed keys for managed disks

Article • 08/23/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Disk Storage allows you to manage your own keys when using server-side encryption (SSE) for managed disks, if you choose. For conceptual information on SSE with customer managed keys, as well as other managed disk encryption types, see the Customer-managed keys section of our disk encryption article.

Restrictions

For now, customer-managed keys have the following restrictions:

- If this feature is enabled for a disk with incremental snapshots, it can't be disabled on that disk or its snapshots. To work around this, copy all the data to an entirely different managed disk that isn't using customer-managed keys. You can do that with either the Azure CLI or the Azure PowerShell module.
- Only software and HSM RSA keys of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - HSM keys require the **premium** tier of Azure Key vaults.
- For Ultra Disks and Premium SSD v2 disks only:
  - Snapshots created from disks that are encrypted with server-side encryption and customer-managed keys must be encrypted with the same customer-managed keys.
  - User-assigned managed identities aren't supported for Ultra Disks and Premium SSD v2 disks encrypted with customer-managed keys.
  - Not currently supported in Azure Government or Azure China.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region as your disk encryption set. As a preview, you can use Azure Key Vaults from different Microsoft Entra tenants.
- Disks encrypted with customer-managed keys can only move to another resource group if the VM they are attached to is deallocated.

- Disks, snapshots, and images encrypted with customer-managed keys can't be moved between subscriptions.
- Managed disks currently or previously encrypted using Azure Disk Encryption can't be encrypted using customer-managed keys.
- Can only create up to 5000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see Preview: Use customer-managed keys for encrypting images.

Create resources

Once the feature is enabled, you'll need to set up a DiskEncryptionSet and either an Azure Key Vault or an Azure Key Vault Managed HSM.

Azure Key Vault

- Install the latest Azure CLI and log to an Azure account in with az login.
- Create an Azure Key Vault and encryption key.

When creating the Key Vault, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

> **ⓘ Important**
>
> Don't camel case the region, if you do so, you may experience problems when assigning additional disks to the resource in the Azure portal.

Azure CLI

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az group create --resource-group $rgName --location $location

az keyvault create -n $keyVaultName \
-g $rgName \
```

```
-l $location \
--enable-purge-protection true

az keyvault key create --vault-name $keyVaultName \
-n $keyName \
--protection software
```

- Create a DiskEncryptionSet. You can set enable-auto-key-rotation equal to true to enable automatic rotation of the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

Azure CLI

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name
$keyName --query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName \
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

- Grant the DiskEncryptionSet resource access to the key vault.

> **Note**
>
> It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Microsoft Entra ID. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

Azure CLI

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g
$rgName --query [identity.principalId] -o tsv)

az keyvault set-policy -n $keyVaultName \
-g $rgName \
--object-id $desIdentity \
--key-permissions wrapkey unwrapkey get
```

Azure Key Vault Managed HSM

Alternatively, you can use a Managed HSM to handle your keys.

To do this, you must complete the following prerequisites:

- Install the latest Azure CLI and log in to an Azure account in with az login.
- Create and configure a managed HSM.
- Assign permissions to a user, so they can manage your Managed HSM.

Configuration

Once you've created a Managed HSM and added permissions, enable purge protection and create an encryption key.

Azure CLI

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault update-hsm --subscription $subscriptionId -g $rgName --hsm-name
$keyVaultName --enable-purge-protection true

az keyvault key create --hsm-name  $keyVaultName --name $keyName --ops
wrapKey unwrapKey --kty RSA-HSM --size 2048
```

Then, create a DiskEncryptionSet.

Azure CLI

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name
$keyName --query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName \
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

Finally, grant the DiskEncryptionSet access to the Managed HSM.

Azure CLI

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g
$rgName --query [identity.principalId] -o tsv)
```

```
az keyvault role assignment create --hsm-name $keyVaultName --role "Managed
HSM Crypto Service Encryption User" --assignee $desIdentity --scope /keys
```

Now that you've created and configured these resources, you can use them to secure your managed disks. The following links contain example scripts, each with a respective scenario, that you can use to secure your managed disks.

Examples

Create a VM using a Marketplace image, encrypting the OS and data disks with customer-managed keys

Azure CLI

```
rgName=yourResourceGroupName
vmName=yourVMName
location=westcentralus
vmSize=Standard_DS3_V2
image=LinuxImageURN
diskEncryptionSetName=yourDiskencryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName
-g $rgName --query [id] -o tsv)

az vm create -g $rgName -n $vmName -l $location --image $image --size
$vmSize --generate-ssh-keys --os-disk-encryption-set $diskEncryptionSetId --
data-disk-sizes-gb 128 128 --data-disk-encryption-sets $diskEncryptionSetId
$diskEncryptionSetId
```

Encrypt existing managed disks

Your existing disks must not be attached to a running VM in order for you to encrypt them using the following script:

Azure CLI

```
rgName=yourResourceGroupName
diskName=yourDiskName
diskEncryptionSetName=yourDiskEncryptionSetName

az disk update -n $diskName -g $rgName --encryption-type
EncryptionAtRestWithCustomerKey --disk-encryption-set $diskEncryptionSetId
```

Create a virtual machine scale set using a Marketplace image, encrypting the OS and data disks with customer-managed keys

Azure CLI

```
rgName=yourResourceGroupName
vmssName=yourVMSSName
location=westcentralus
vmSize=Standard_DS3_V2
image=LinuxImageURN
diskEncryptionSetName=yourDiskencryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName
-g $rgName --query [id] -o tsv)
az vmss create -g $rgName -n $vmssName --image $image --upgrade-policy
automatic --admin-username azureuser --generate-ssh-keys --os-disk-
encryption-set $diskEncryptionSetId --data-disk-sizes-gb 64 128 --data-disk-
encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

Create an empty disk encrypted using server-side encryption with customer-managed keys and attach it to a VM

Azure CLI

```
vmName=yourVMName
rgName=yourResourceGroupName
diskName=yourDiskName
diskSkuName=Premium_LRS
diskSizeinGiB=30
location=westcentralus
diskLUN=2
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName
-g $rgName --query [id] -o tsv)

az disk create -n $diskName -g $rgName -l $location --encryption-type
EncryptionAtRestWithCustomerKey --disk-encryption-set $diskEncryptionSetId -
-size-gb $diskSizeinGiB --sku $diskSkuName

diskId=$(az disk show -n $diskName -g $rgName --query [id] -o tsv)

az vm disk attach --vm-name $vmName --lun $diskLUN --ids $diskId
```

Change the key of a DiskEncryptionSet to rotate the key for all the resources referencing the DiskEncryptionSet

Azure CLI

```
rgName=yourResourceGroupName
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName

keyVaultId=$(az keyvault show --name $keyVaultName--query [id] -o tsv)

keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name
$keyName --query [key.kid] -o tsv)

az disk-encryption-set update -n keyrotationdes -g keyrotationtesting --key-
url $keyVaultKeyUrl --source-vault $keyVaultId
```

Find the status of server-side encryption of a disk

Azure CLI

```
az disk show -g yourResourceGroupName -n yourDiskName --query
[encryption.type] -o tsv
```

> **Important**
>
> Customer-managed keys rely on managed identities for Azure resources, a feature of Microsoft Entra ID. When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Microsoft Entra directory to another, the managed identity associated with the managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see Transferring a subscription between Microsoft Entra directories.

Next steps

- Explore the Azure Resource Manager templates for creating encrypted disks with customer-managed keys

- Replicate machines with customer-managed keys enabled disks
- Set up disaster recovery of VMware VMs to Azure with PowerShell
- Set up disaster recovery to Azure for Hyper-V VMs using PowerShell and Azure Resource Manager
- See Create a managed disk from a snapshot with CLI for a code sample.

Encrypt managed disks with cross-tenant customer-managed keys

06/12/2025

This article covers building a solution where you encrypt managed disks with customer-managed keys using Azure Key Vaults stored in a different Microsoft Entra tenant. This configuration can be ideal for several scenarios, one example being Azure support for service providers that want to offer bring-your-own encryption keys to their customers where resources from the service provider's tenant are encrypted with keys from their customer's tenant.

A disk encryption set with federated identity in a cross-tenant CMK workflow spans service provider/ISV tenant resources (disk encryption set, managed identities, and app registrations) and customer tenant resources (enterprise apps, user role assignments, and key vault). In this case, the source Azure resource is the service provider's disk encryption set.

If you have questions about cross-tenant customer-managed keys with managed disks, email crosstenantcmkvteam@service.microsoft.com.

Limitations

- Managed Disks and the customer's Key Vault must be in the same Azure region, but they can be in different subscriptions.

Preview - Ultra Disk and Premium SSD v2

This configuration is also available for Ultra Disks and Premium SSD v2 disks, as a preview configuration, in select regions.

Sign up for the preview using either the PowerShell:

Azure PowerShell

```
Register-AzProviderFeature -FeatureName UserAssignedIdentityForDirectDriveDisks -
ProviderNamespace Microsoft.Compute
Register-AzProviderFeature -FeatureName CrossTenantCMKForDirectDriveDisks -
ProviderNamespace Microsoft.Compute
```

Or the CLI:

Azure CLI

```
az feature register --name UserAssignedIdentityForDirectDriveDisks  --namespace
Microsoft.Compute
az feature register --name CrossTenantCMKForDirectDriveDisks  --namespace
Microsoft.Compute
```

Preview regional availability

The preview for Ultra Disks and Premium SSD v2 disks is currently only available in the following regions:

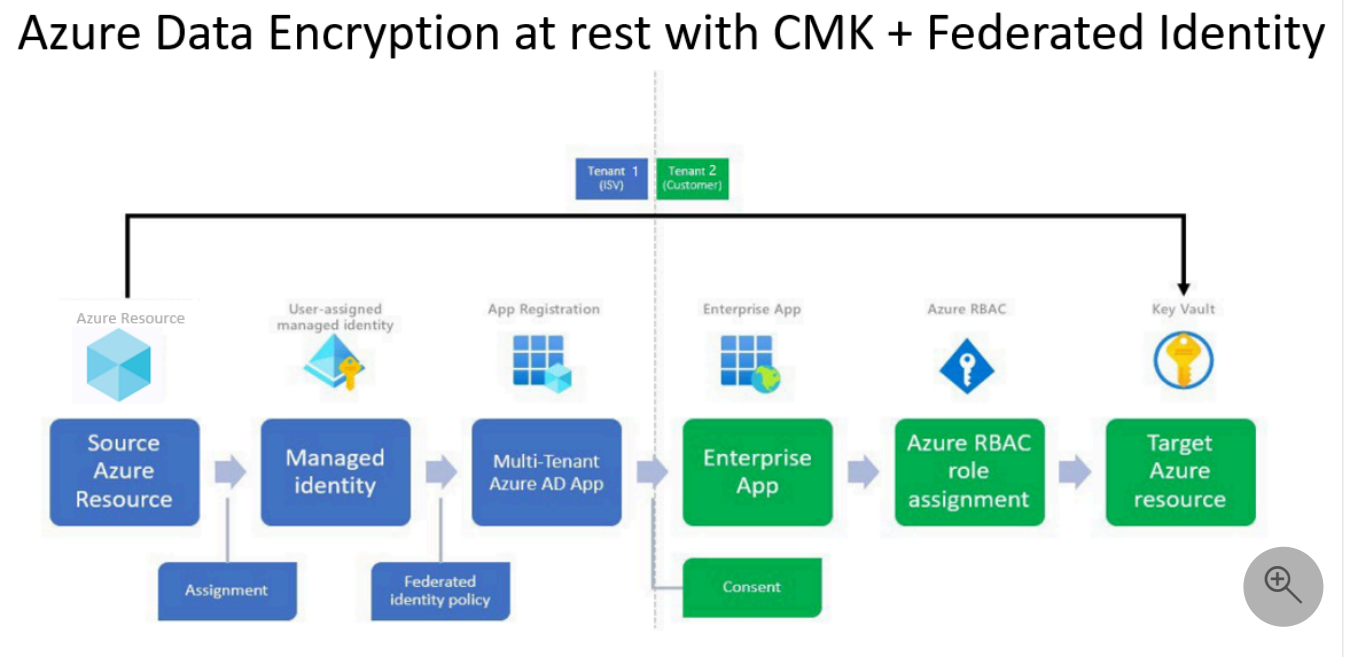
- Australia East
- Southeast Asia
- Canada Central
- North Europe
- France Central
- Germany West Central
- Korea Central
- Sweden Central
- UK South
- West US
- Central US

About cross-tenant customer-managed keys

Many service providers building Software as a Service (SaaS) offerings on Azure want to offer their customers the option to manage their own encryption keys. Customer-managed keys allow a service provider to encrypt the customer's data using an encryption key that is managed by the service provider's customer and that isn't accessible to the service provider. In Azure, the service provider's customer can use Azure Key Vault to manage their encryption keys in their own Microsoft Entra tenant and subscription.

Azure platform services and resources that are owned by the service provider and that reside in the service provider's tenant require access to the key from the customer's tenant to perform the encryption/decryption operations.

The image below shows a data encryption at rest with federated identity in a cross-tenant CMK workflow spanning a service provider and its customer.



In the example above, there are two Microsoft Entra tenants: an independent service provider's tenant (*Tenant 1*), and a customer's tenant (*Tenant 2*). *Tenant 1* hosts Azure platform services and *Tenant 2* hosts the customer's key vault.

A multitenant application registration is created by the service provider in *Tenant 1*. A federated identity credential is created on this application using a user-assigned managed identity. Then, the name and application ID of the app is shared with the customer.

A user with the appropriate permissions installs the service provider's application in the customer tenant, *Tenant 2*. A user then grants the service principal associated with the installed application access to the customer's key vault. The customer also stores the encryption key, or customer-managed key, in the key vault. The customer shares the key location (the URL of the key) with the service provider.

The service provider now has:

- An application ID for a multitenant application installed in the customer's tenant, which has been granted access to the customer-managed key.
- A managed identity configured as the credential on the multitenant application.
- The location of the key in the customer's key vault.

With these three parameters, the service provider provisions Azure resources in *Tenant 1* that can be encrypted with the customer-managed key in *Tenant 2*.

Let's divide the above end-to-end solution into three phases:

1. The service provider configures identities.
2. The customer grants the service provider's multitenant app access to an encryption key in Azure Key Vault.

3. The service provider encrypts data in an Azure resource using the CMK.

Operations in Phase 1 would be a one-time setup for most service provider applications. Operations in Phases 2 and 3 would repeat for each customer.

Phase 1 - The service provider configures a Microsoft Entra application

Expand table

Step	Description	Minimum role in Azure RBAC	Minimum role in Microsoft Entra RBAC
1.	Create a new multitenant Microsoft Entra application registration or start with an existing application registration. Note the application ID (client ID) of the application registration using Azure portal, Microsoft Graph API, Azure PowerShell, or Azure CLI	None	Application Developer
2.	Create a user-assigned managed identity (to be used as a Federated Identity Credential). Azure portal / Azure CLI / Azure PowerShell/ Azure Resource Manager Templates	Managed identity contributor	None
3.	Configure user-assigned managed identity as a *federated identity credential* on the application, so that it can impersonate the identity of the application. Graph API reference / Azure portal/ Azure CLI/ Azure PowerShell	None	Owner of the application
4.	Share the application name and application ID with the customer, so that they can install and authorize the application.	None	None

Considerations for service providers

- Azure Resource Manager (ARM) templates aren't recommended for creating Microsoft Entra applications.
- The same multitenant application can be used to access keys in any number of tenants, like *Tenant 2*, *Tenant 3*, *Tenant 4*, and so on. In each tenant, an independent instance of the application is created that has the same application ID but a different object ID. Each instance of this application is thus authorized independently. Consider how the application object used for this feature is used to partition your application across all customers.

    - Application can have a maximum of 20 federated identity credentials, which requires a service provider to share federated identities among its customers. For more information about federated identities design considerations and restrictions, see Configure an app to trust an external identity provider
- In rare scenarios, a service provider might use a single Application object per its customer, but that requires significant maintenance costs to manage applications at scale across all customers.
- In the service provider tenant, it isn't possible to automate the Publisher Verification.

Phase 2 - The customer authorizes access to the key vault

Expand table

Step	Description	Least privileged Azure RBAC roles	Least privileged Microsoft Entra roles
1.	• *Recommended*: Send the user to sign in to your app. If the user can sign in, then a service principal for your app exists in their tenant. • Use Microsoft Graph, Microsoft Graph PowerShell, Azure PowerShell, or Azure CLI to create the service principal. • Construct an admin-consent URL and grant tenant-wide consent to create the service principal using the application ID.	None	Users with permissions to install applications
2.	Create an Azure Key Vault and a key used as the customer-managed key.	A user must be assigned the Key Vault Contributor role to create the key vault A user must be assigned the Key Vault Crypto Officer role to add a key to the key vault	None
3.	Grant the consented application identity access to the Azure key vault by assigning the role Key Vault Crypto Service Encryption User	To assign the **Key Vault Crypto Service Encryption User** role to the application, you must have been assigned the User Access Administrator role.	None
4.	Copy the key vault URL and key name into the customer-managed	None	None

Step	Description	Least privileged Azure RBAC roles	Least privileged Microsoft Entra roles
	keys configuration of the SaaS offering.		

> **Note**
>
> To authorize access to the Managed HSM for encryption using CMK, see example for Storage Account here. For more information about managing keys with Managed HSM, see Manage a Managed HSM using the Azure CLI

Considerations for customers of service providers

- In the customer tenant, *Tenant 2*, an admin can set policies to block non-admin users from installing applications. These policies can prevent non-admin users from creating service principals. If such a policy is configured, then users with permissions to create service principals need to be involved.
- Access to Azure Key Vault can be authorized using Azure RBAC or access policies. When granting access to a key vault, make sure to use the active mechanism for your key vault.
- A Microsoft Entra application registration has an application ID (client ID). When the application is installed in your tenant, a service principal is created. The service principal shares the same application ID as the app registration, but generates its own object ID. When you authorize the application to have access to resources, you might need to use the service principal `Name` or `ObjectID` property.

Phase 3 - The service provider encrypts data in an Azure resource using the customer-managed key

After phases 1 and 2 are complete, the service provider can configure encryption on the Azure resource with the key and key vault in the customer's tenant and the Azure resource in the ISV's tenant. The service provider can configure cross-tenant customer-managed keys with the client tools supported by that Azure resource, with an ARM template, or with the REST API.

Configure cross-tenant customer-managed keys

This section describes how to configure a cross-tenant customer-managed key (CMK) and encrypt customer data. You learn how to encrypt customer data in a resource in *Tenant1* using

a CMK stored in a key vault in *Tenant2*. You can use the Azure portal, Azure PowerShell, or Azure CLI.

Portal

Sign in to the Azure portal and follow these steps.

The service provider configures identities

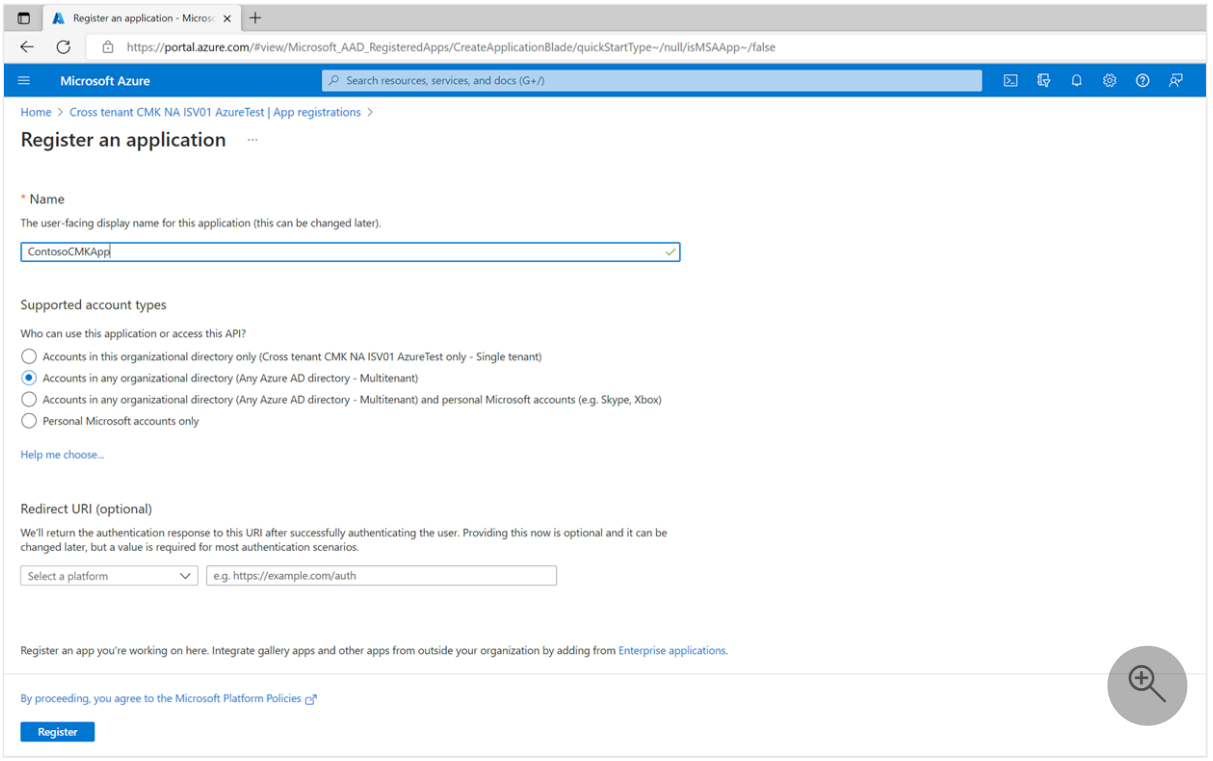
The following steps are performed by the service provider in the service provider's tenant *Tenant1*.

The service provider creates a new multi-tenant app registration

You can either create a new multi-tenant Microsoft Entra application registration or start with an existing multi-tenant application registration. If starting with an existing application registration, note the application ID (client ID) of the application.

To create a new registration:

1. Search for **Microsoft Entra ID** in the search box. Locate and select the **Microsoft Entra ID** extension.
2. Select **Manage** > **App registrations** from the left pane.
3. Select **+ New registration**.
4. Provide the name for the application registration and select *Account in any organizational directory (Any Microsoft Entra directory – Multitenant)*.
5. Select **Register**.
6. Note the **ApplicationId/ClientId** of the application.

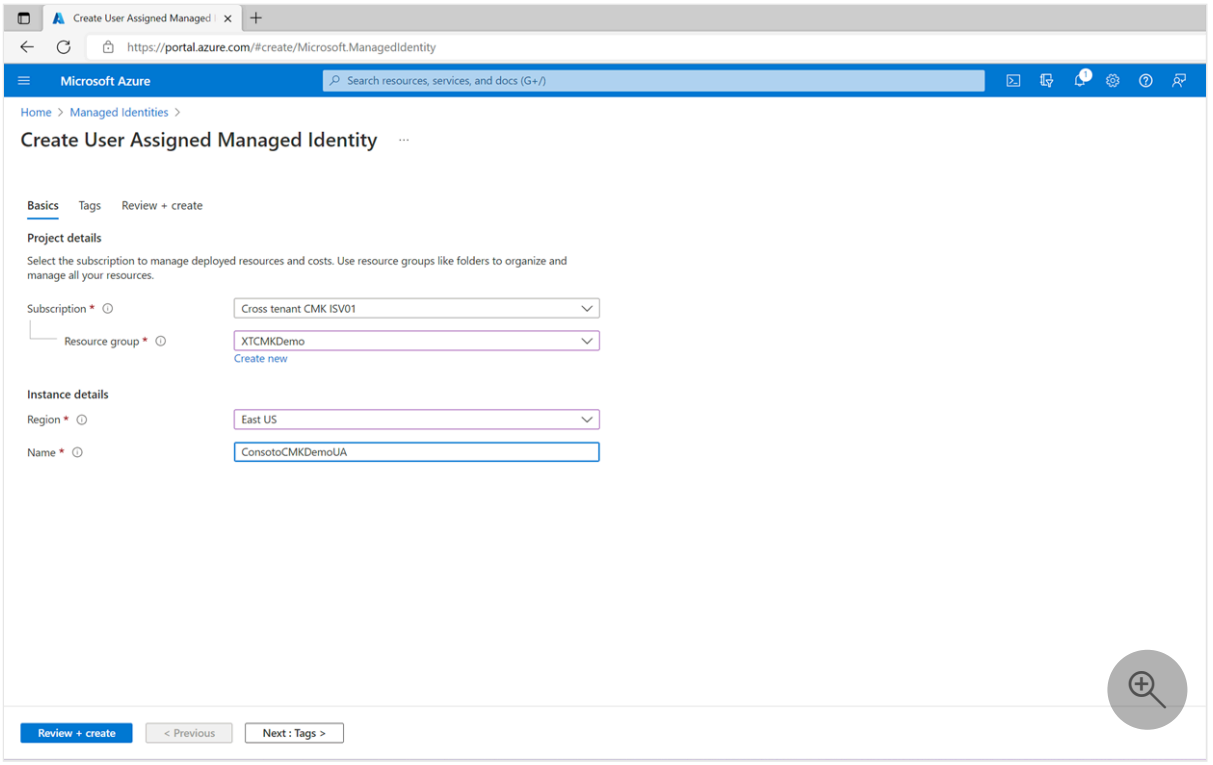


The service provider creates a user-assigned managed identity

Create a user-assigned managed identity to be used as a federated identity credential.

1. Search for **Managed Identities** in the search box. Locate and select the **Managed Identities** extension.
2. Select **+ Create**.
3. Provide the resource group, region, and name for the managed identity.
4. Select **Review + create**.
5. On successful deployment, note the **Azure ResourceId** of the user-assigned managed identity, which is available under **Properties**. For example:

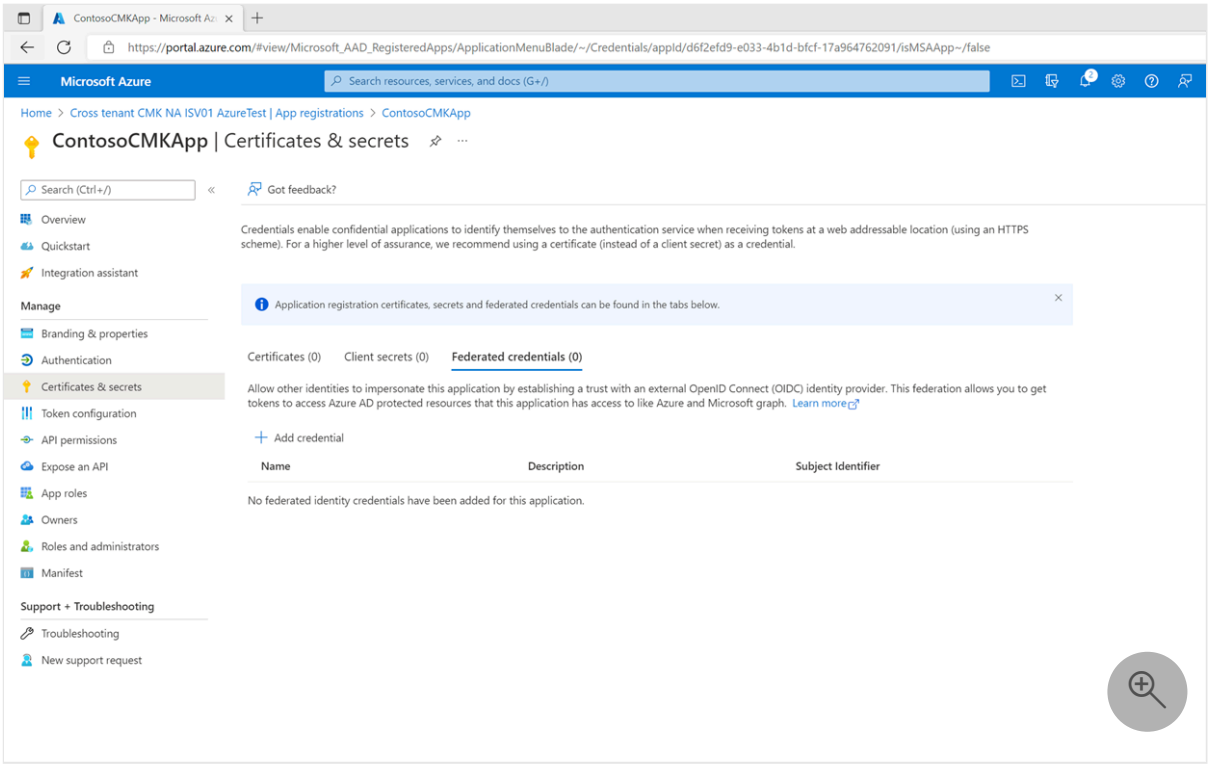
   `/subscriptions/tttttttt-0000-tttt-0000-tttt0000tttt/resourcegroups/XTCMKDemo/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ConsotoCMKDemoUA`



The service provider configures the user-assigned managed identity as a federated credential on the application

Configure a user-assigned managed identity as a federated identity credential on the application, so that it can impersonate the identity of the application.

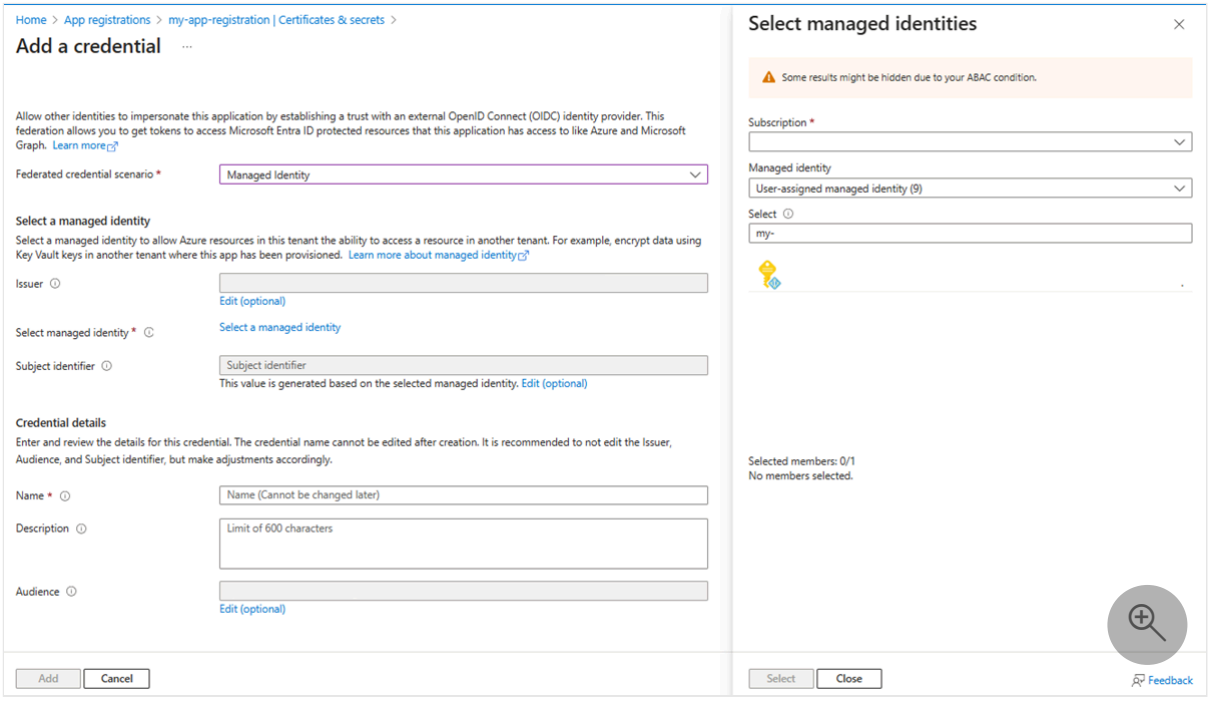
1. Navigate to **Microsoft Entra ID > App registrations > your application**.
2. Select **Certificates & secrets**.
3. Select **Federated credentials**.



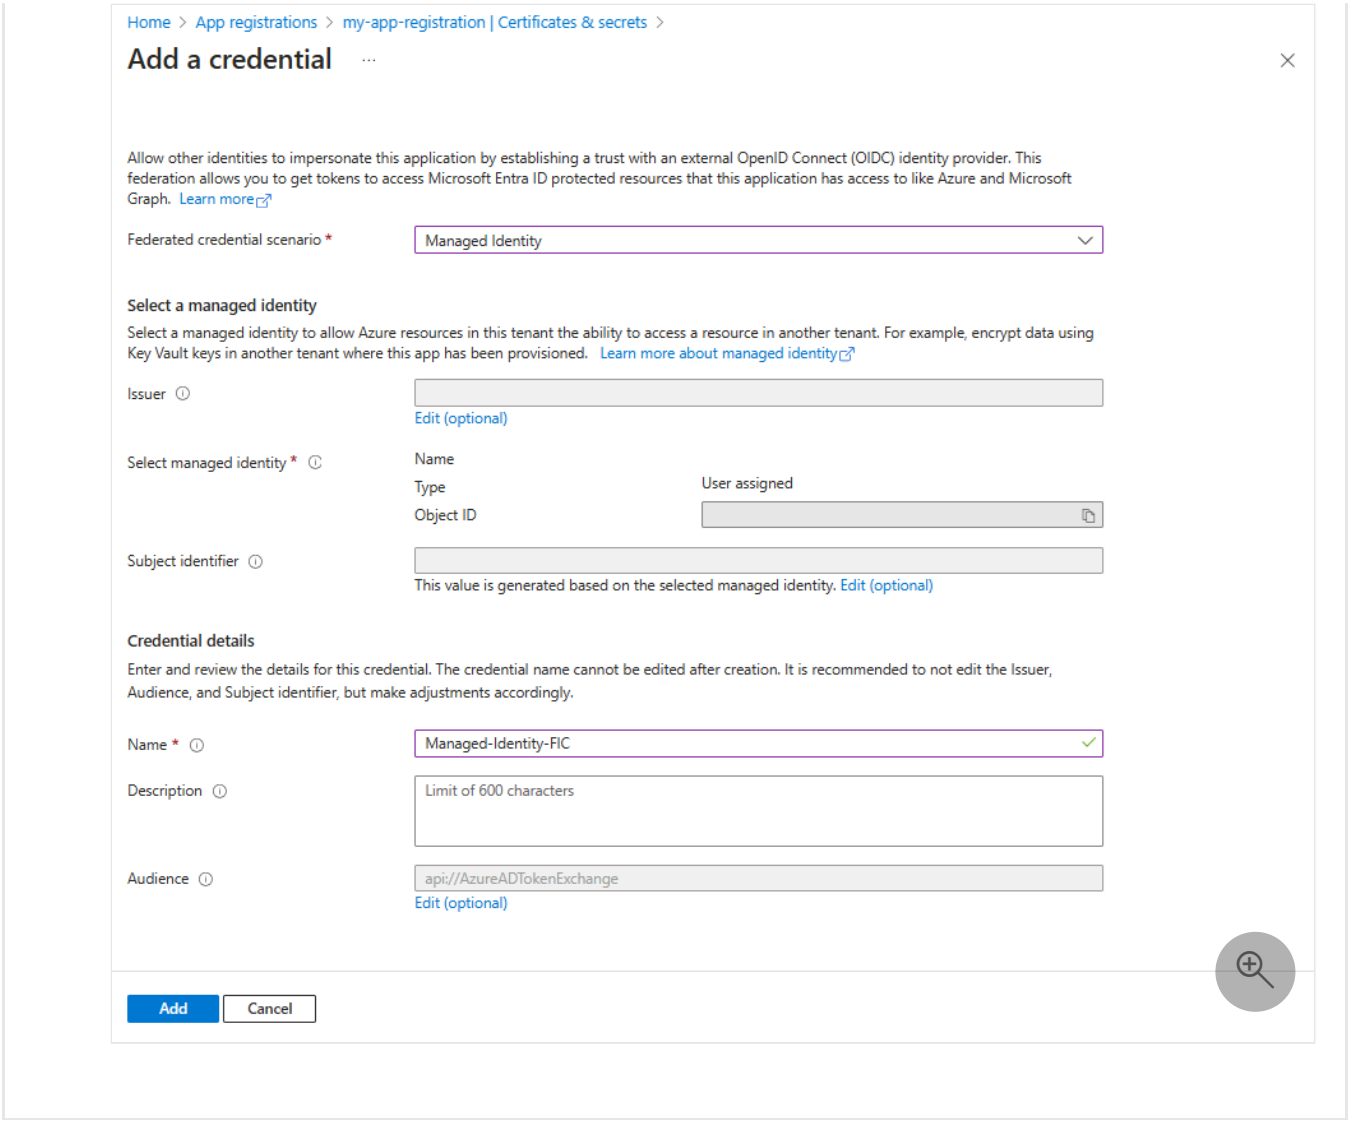
4. Select **+ Add credential**.

5. Under **Federated credential scenario**, select **Managed Identity**.

6. Click **Select a managed identity**. From the pane, select the subscription. Under **Managed identity**, select **User-assigned managed identity**. In the **Select** box, search for the managed identity you created earlier, then click **Select** at the bottom of the pane.



7. Under **Credential details**, provide a name and optional description for the credential and select **Add**.



The service provider shares the application ID with the customer

Find the application ID (client ID) of the multi-tenant application and share it with the customer.

The customer grants the service provider's app access to the key in the key vault

The following steps are performed by the customer in the customer's tenant *Tenant2*. The customer can use the Azure portal, Azure PowerShell, or Azure CLI.

The user executing the steps must be an administrator with a privileged role such as Application Administrator, Cloud Application Administrator, or Global Administrator.

Portal

Sign in to the Azure portal and follow these steps.

The customer installs the service provider application in the customer tenant

To install the service provider's registered application in the customer's tenant, you create a service principal with the application ID from the registered app. You can create the service principal in either of the following ways:

- Use Microsoft Graph, Microsoft Graph PowerShell, Azure PowerShell, or Azure CLI to manually create the service principal.
- Construct an admin-consent URL and grant tenant-wide consent to create the service principal. You'll need to provide them with your AppId.

The customer creates a key vault

To create the key vault, the user's account must be assigned the **Key Vault Contributor** role or another role that permits creation of a key vault.

1. From the Azure portal menu, or from the Home page, select **+ Create a resource**. In the Search box, enter **Key vaults**. From the results list, select **Key vaults**. On the **Key vaults** page, select **Create**.

2. On the **Basics** tab, choose a subscription. Under **Resource group**, select **Create new** and enter a resource group name.

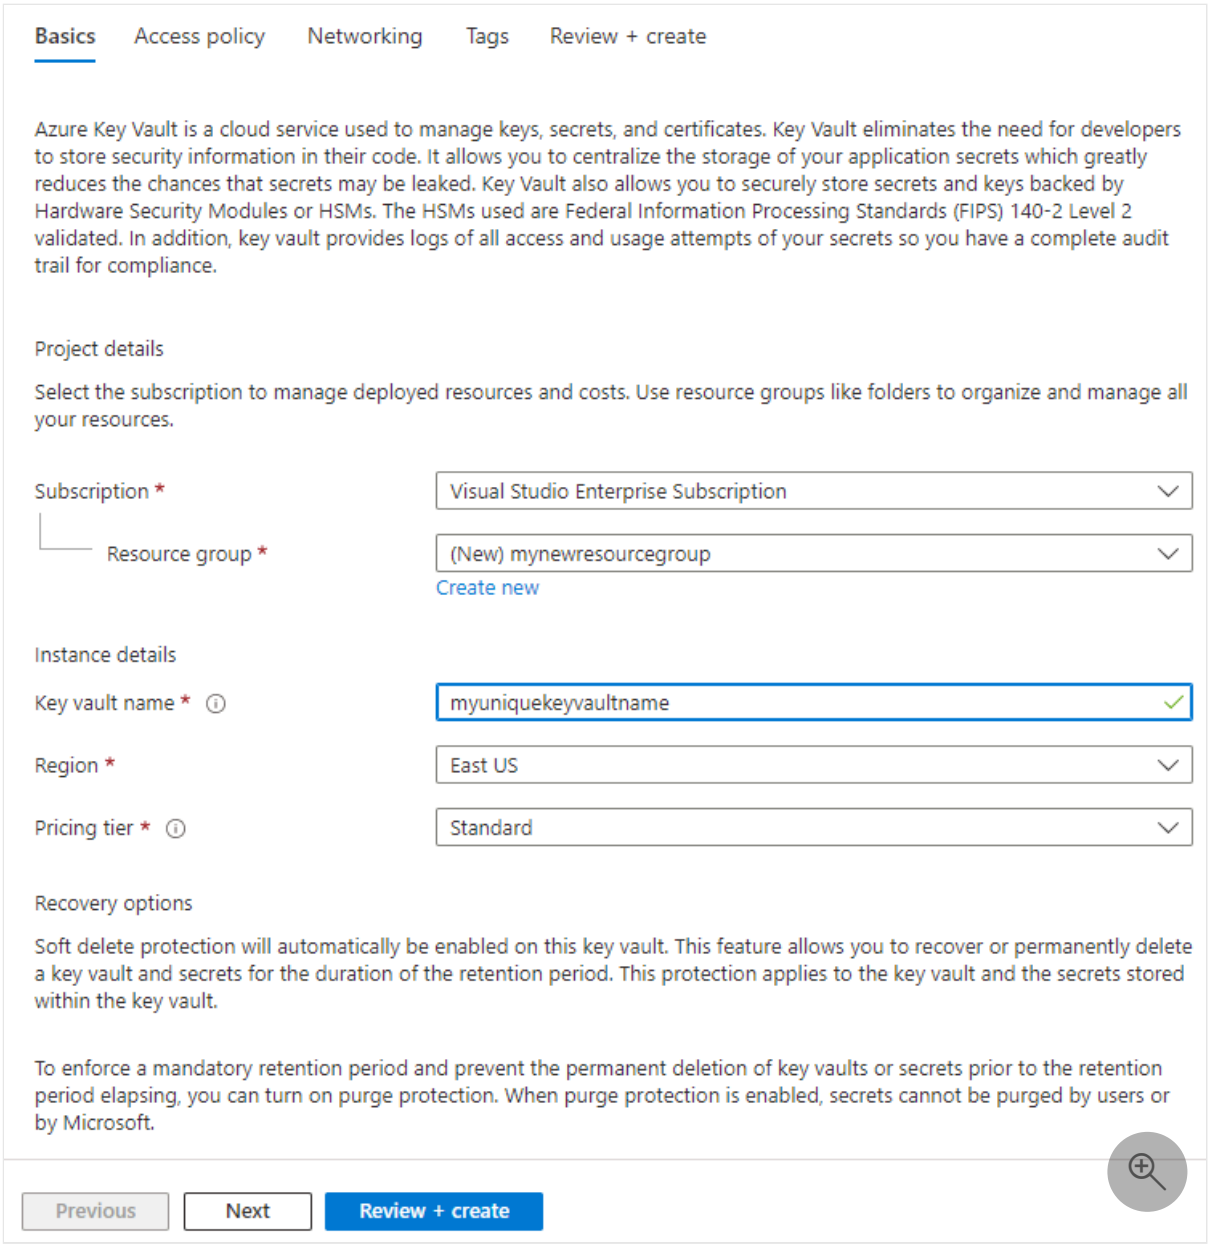
3. Enter a unique name for the key vault.

4. Select a region and pricing tier.

5. Enable purge protection for the new key vault.

6. On the **Access policy** tab, select **Azure role-based access control** for **Permission model**.

7. Select **Review + create** and then **Create**.



Take note of the key vault name and URI Applications that access your key vault must use this URI.

For more information, see Quickstart - Create an Azure Key Vault with the Azure portal.

The customer assigns Key Vault Crypto Officer role to a user account

This step ensures that you can create encryption keys.

1. Navigate to your key vault and select **Access Control (IAM)** from the left pane.
2. Under **Grant access to this resource**, select **Add role assignment**.
3. Search for and select **Key Vault Crypto Officer**.
4. Under **Members**, select **User, group, or service principal**.
5. Select **Members** and search for your user account.
6. Select **Review + Assign**.

The customer creates an encryption key

To create the encryption key, the user's account must be assigned the **Key Vault Crypto Officer** role or another role that permits creation of a key.

1. On the Key Vault properties page, select **Keys**.
2. Select **Generate/Import**.
3. On the **Create a key** screen, specify a name for the key. Leave the other values to their defaults.
4. Select **Create**.
5. Copy the key URI.

The customer grants the service provider application access to the key vault

Assign the Azure RBAC role **Key Vault Crypto Service Encryption User** to the service provider's registered application so that it can access the key vault.

1. Navigate to your key vault and select **Access Control (IAM)** from the left pane.
2. Under **Grant access to this resource**, select **Add role assignment**.
3. Search for and select **Key Vault Crypto Service Encryption User**.
4. Under **Members**, select **User, group, or service principal**.
5. Select **Members** and search for the application name of the application you installed from the service provider.
6. Select **Review + Assign**.

Now you can configure customer-managed keys with the key vault URI and key.

Create a disk encryption set

Now that you've created your Azure Key Vault and performed the required Microsoft Entra configurations, deploy a disk encryption set configured to work across tenants and associate it with a key in the key vault. You can do this using the Azure portal, Azure PowerShell, or Azure CLI. You can also use an ARM template or REST API.

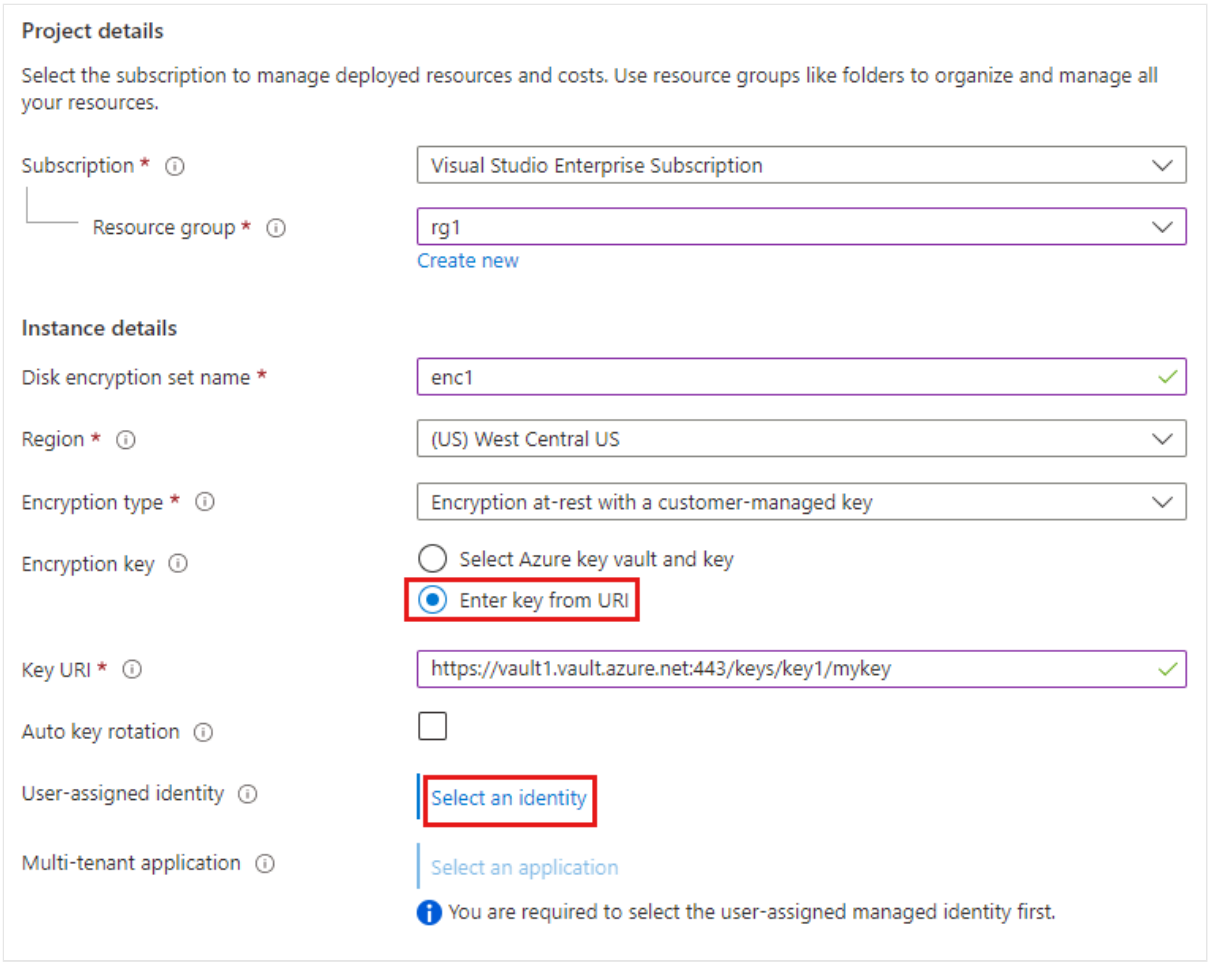
Portal

To use the Azure portal, sign in to the portal and follow these steps.

1. Select **+ Create a resource**, search for **Disk encryption set**, and select **Create** > **Disk encryption set**.

2. Under **Project details**, select the subscription and resource group in which to create the disk encryption set.

3. Under **Instance details**, provide a name for the disk encryption set.



4. Select the **Region** in which to create the disk encryption set.

5. For **Encryption type**, select **Encryption at-rest with a customer-managed key**.

6. Under **Encryption key**, select the **Enter key from URI** radio button, and then enter the Key URI of the key created in the customer's tenant.

7. Under **User-assigned identity**, select **Select an identity**.

8. Select the user-assigned managed identity that you created previously in the ISV's tenant, and then select **Add**.

9. Under **Multi-tenant application**, select **Select an application**.

10. Select the multi-tenant registered application that you created previously in the ISV's tenant, and click **Select**.

11. Select **Review + create**.

Use an ARM template

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {

- Encrypt disks using customer-managed keys in Azure DevTest Labs
- Use the Azure portal to enable server-side encryption with customer-managed keys for managed disks

Use the Azure portal to enable end-to-end encryption using encryption at host

Applies to: ✔ Linux VMs ✔ Windows VMs

When you enable encryption at host, data stored on the VM host is encrypted at rest and flows encrypted to the Storage service. For conceptual information on encryption at host, and other managed disk encryption types, see: Encryption at host - End-to-end encryption for your VM data.

Temporary disks and ephemeral OS disks are encrypted at rest with platform-managed keys when you enable end-to-end encryption. The OS and data disk caches are encrypted at rest with either customer-managed or platform-managed keys, depending on the selected disk encryption type. For example, if a disk is encrypted with customer-managed keys, then the cache for the disk is encrypted with customer-managed keys, and if a disk is encrypted with platform-managed keys then the cache for the disk is encrypted with platform-managed keys.

Restrictions

- Can't be enabled on virtual machines (VMs) or virtual machine scale sets that currently or ever had Azure Disk Encryption enabled.
- Azure Disk Encryption can't be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale sets. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.

The following restrictions only apply to Ultra Disks and Premium SSD v2:

- Disks using a 512e sector size need to have been created after 5/13/2023.
  - If your disk was created before this date, snapshot your disk, and create a new disk using the snapshot.

Supported VM sizes

Legacy VM Sizes aren't supported. You can find the list of supported VM sizes by either using the Azure PowerShell module or Azure CLI.

Prerequisites

You must enable the feature for your subscription before you can use encryption at host for either your VM or Virtual Machine Scale Set. Use the following steps to enable the feature for your subscription:

1. **Azure portal**: Select the Cloud Shell icon on the Azure portal:

2. Execute the following command to set context to current subscription

Azure PowerShell

PowerShell

```
Set-AzContext -SubscriptionId "<yourSubIDHere>"
```

3. Execute the following command to register the feature for your subscription

Azure PowerShell

PowerShell

```
Register-AzProviderFeature -FeatureName "EncryptionAtHost" -
ProviderNamespace "Microsoft.Compute"
```

4. Confirm that the registration state is **Registered** (registration might take a few minutes) using the following command before trying out the feature.

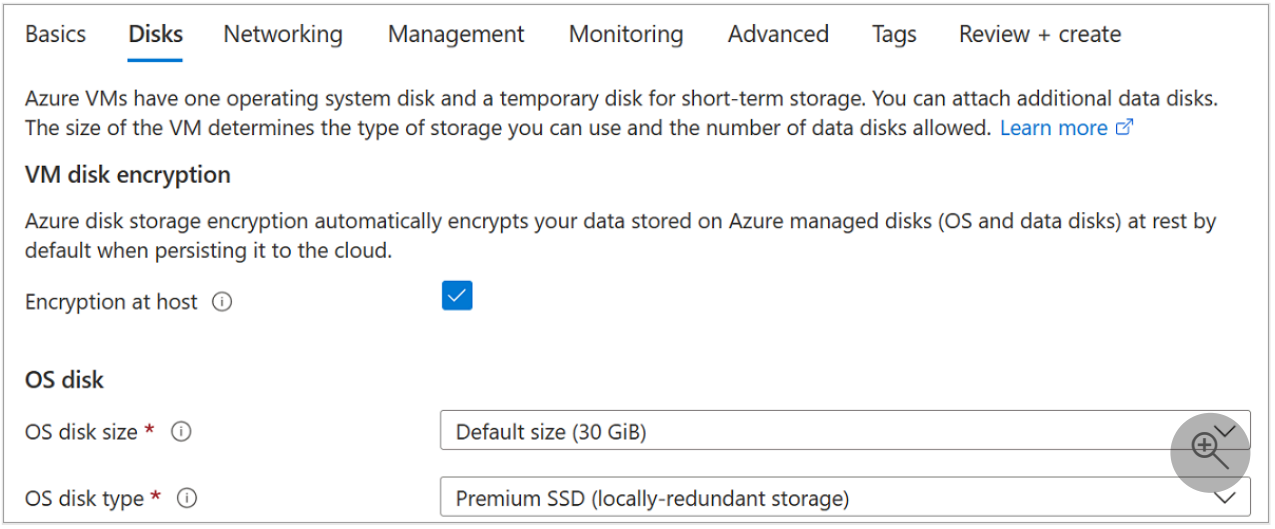
Azure PowerShell

PowerShell

```
Get-AzProviderFeature -FeatureName "EncryptionAtHost" -ProviderNamespace
"Microsoft.Compute"
```

Deploy a VM with platform-managed keys

1. Sign in to the Azure portal.
2. Search for **Virtual Machines** and select **+ Create** to create a VM.
3. Select an appropriate region and a supported VM size.
4. Fill in the other values on the **Basic** pane as you like, and then proceed to the **Disks** pane.
5. On the **Disks** pane, select **Encryption at host**.
6. Make the remaining selections as you like.



7. For the rest of the VM deployment process, make selections that fit your environment, and complete the deployment.

You've now deployed a VM with encryption at host enabled, and the cache for the disk is encrypted using platform-managed keys.

Deploy a VM with customer-managed keys

Alternatively, you can use customer-managed keys to encrypt your disk caches.

Create an Azure Key Vault and disk encryption set

Once the feature is enabled, you need to set up an Azure Key Vault and a disk encryption set, if you haven't already.

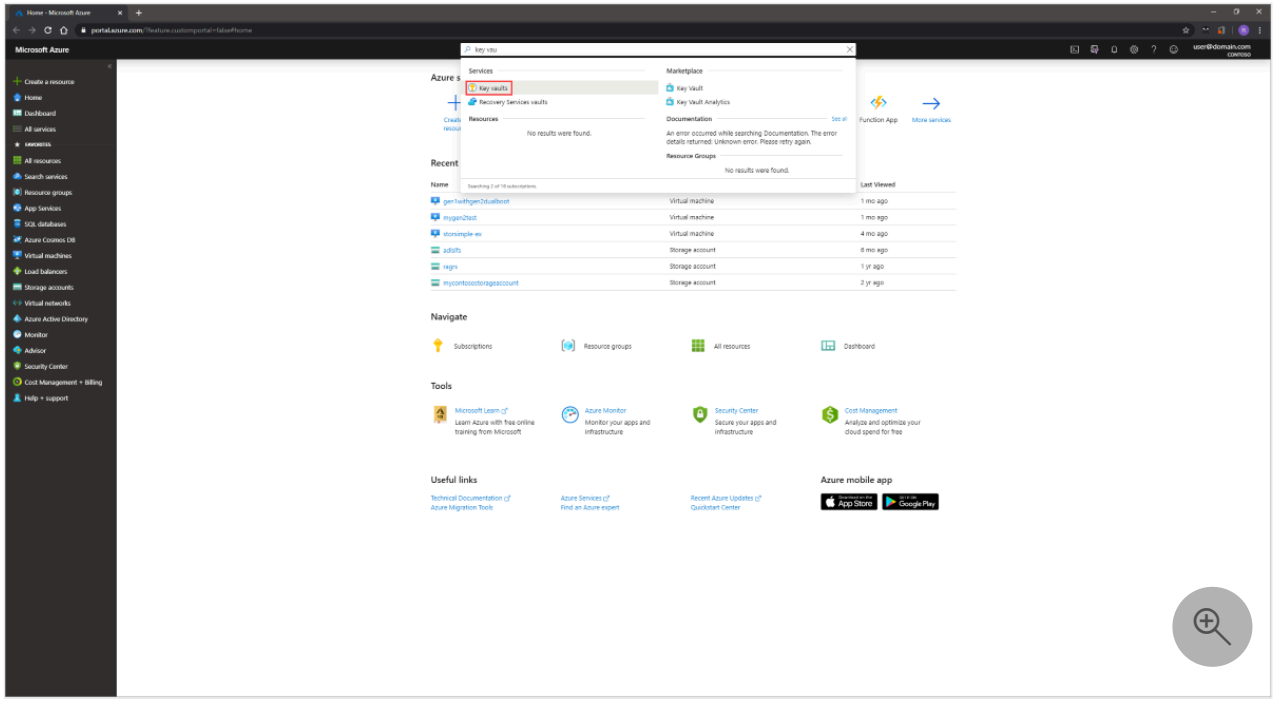
Setting up customer-managed keys for your disks requires you to create resources in a particular order, if you're doing it for the first time. First, you'll need to create and set up an

Azure Key Vault.

Set up your Azure Key Vault

1. Sign in to the Azure portal.

2. Search for and select **Key Vaults**.



> **Important**
>
> Your disk encryption set, VM, disks, and snapshots must all be in the same region and subscription for deployment to succeed.
>
> - Azure Key Vaults may be used from a different subscription, but they must be in the same region as your disk encryption set.
> - Azure Key Vaults in different Microsoft Entra tenants are supported for managed disks. For prerequisites, see Encrypt managed disks with cross-tenant customer-managed keys.

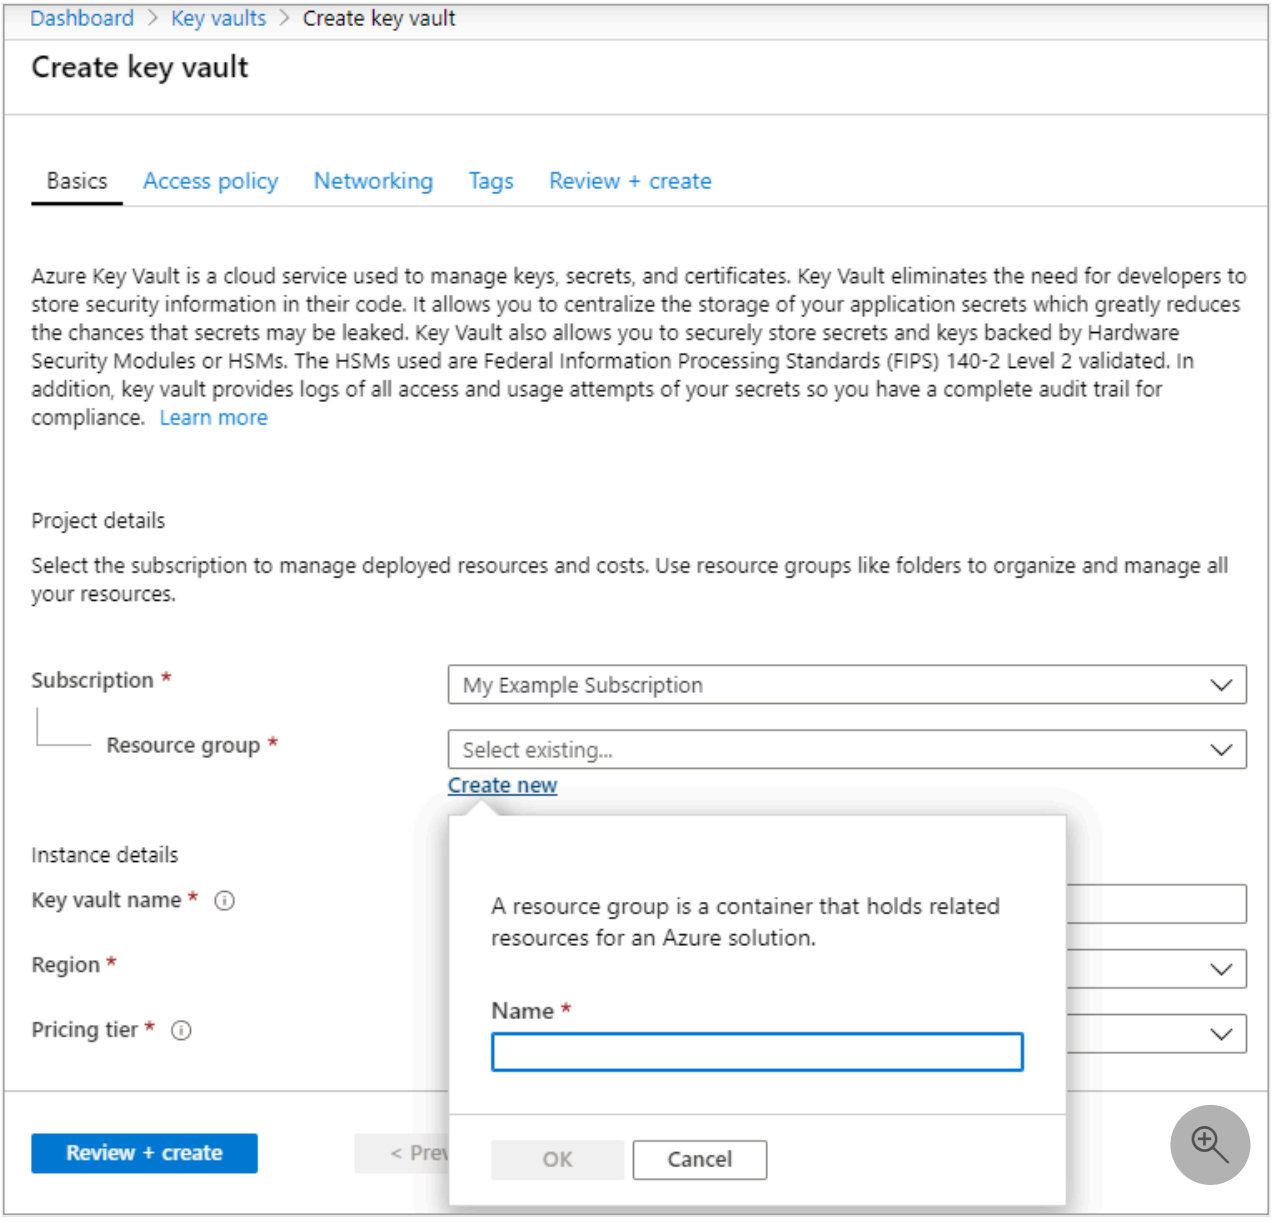
3. Select **+Create** to create a new Key Vault.

4. Create a new resource group.

5. Enter a key vault name, select a region, and select a pricing tier.

> **Note**
>
> When creating the Key Vault instance, you must enable soft delete and purge protection. Soft delete ensures that the Key Vault holds a deleted key for a given retention period (90 day default). Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

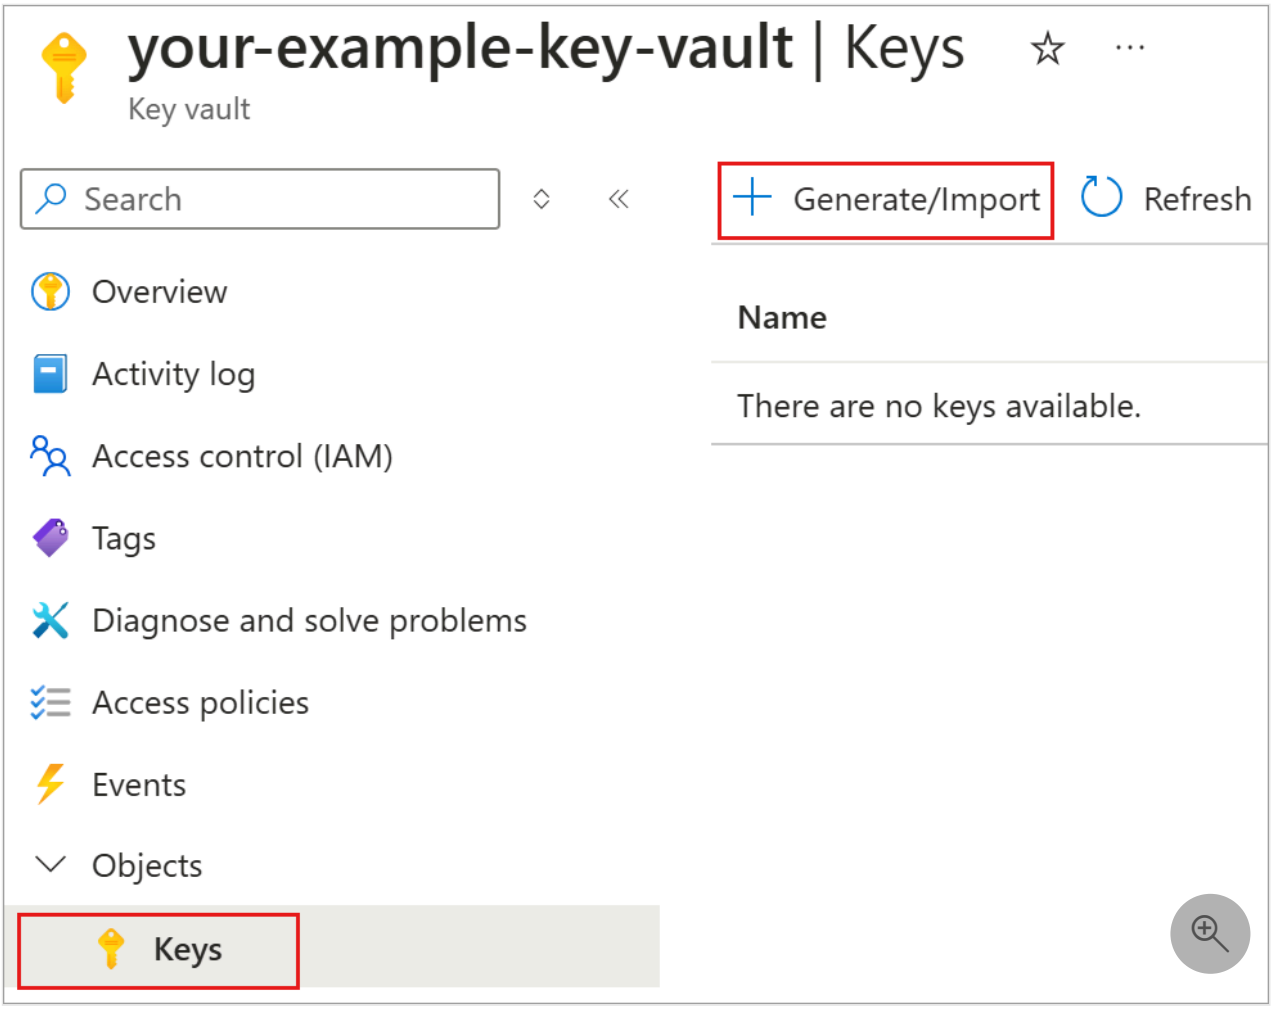
6. Select **Review + Create**, verify your choices, then select **Create**.



7. Once your key vault finishes deploying, select it.

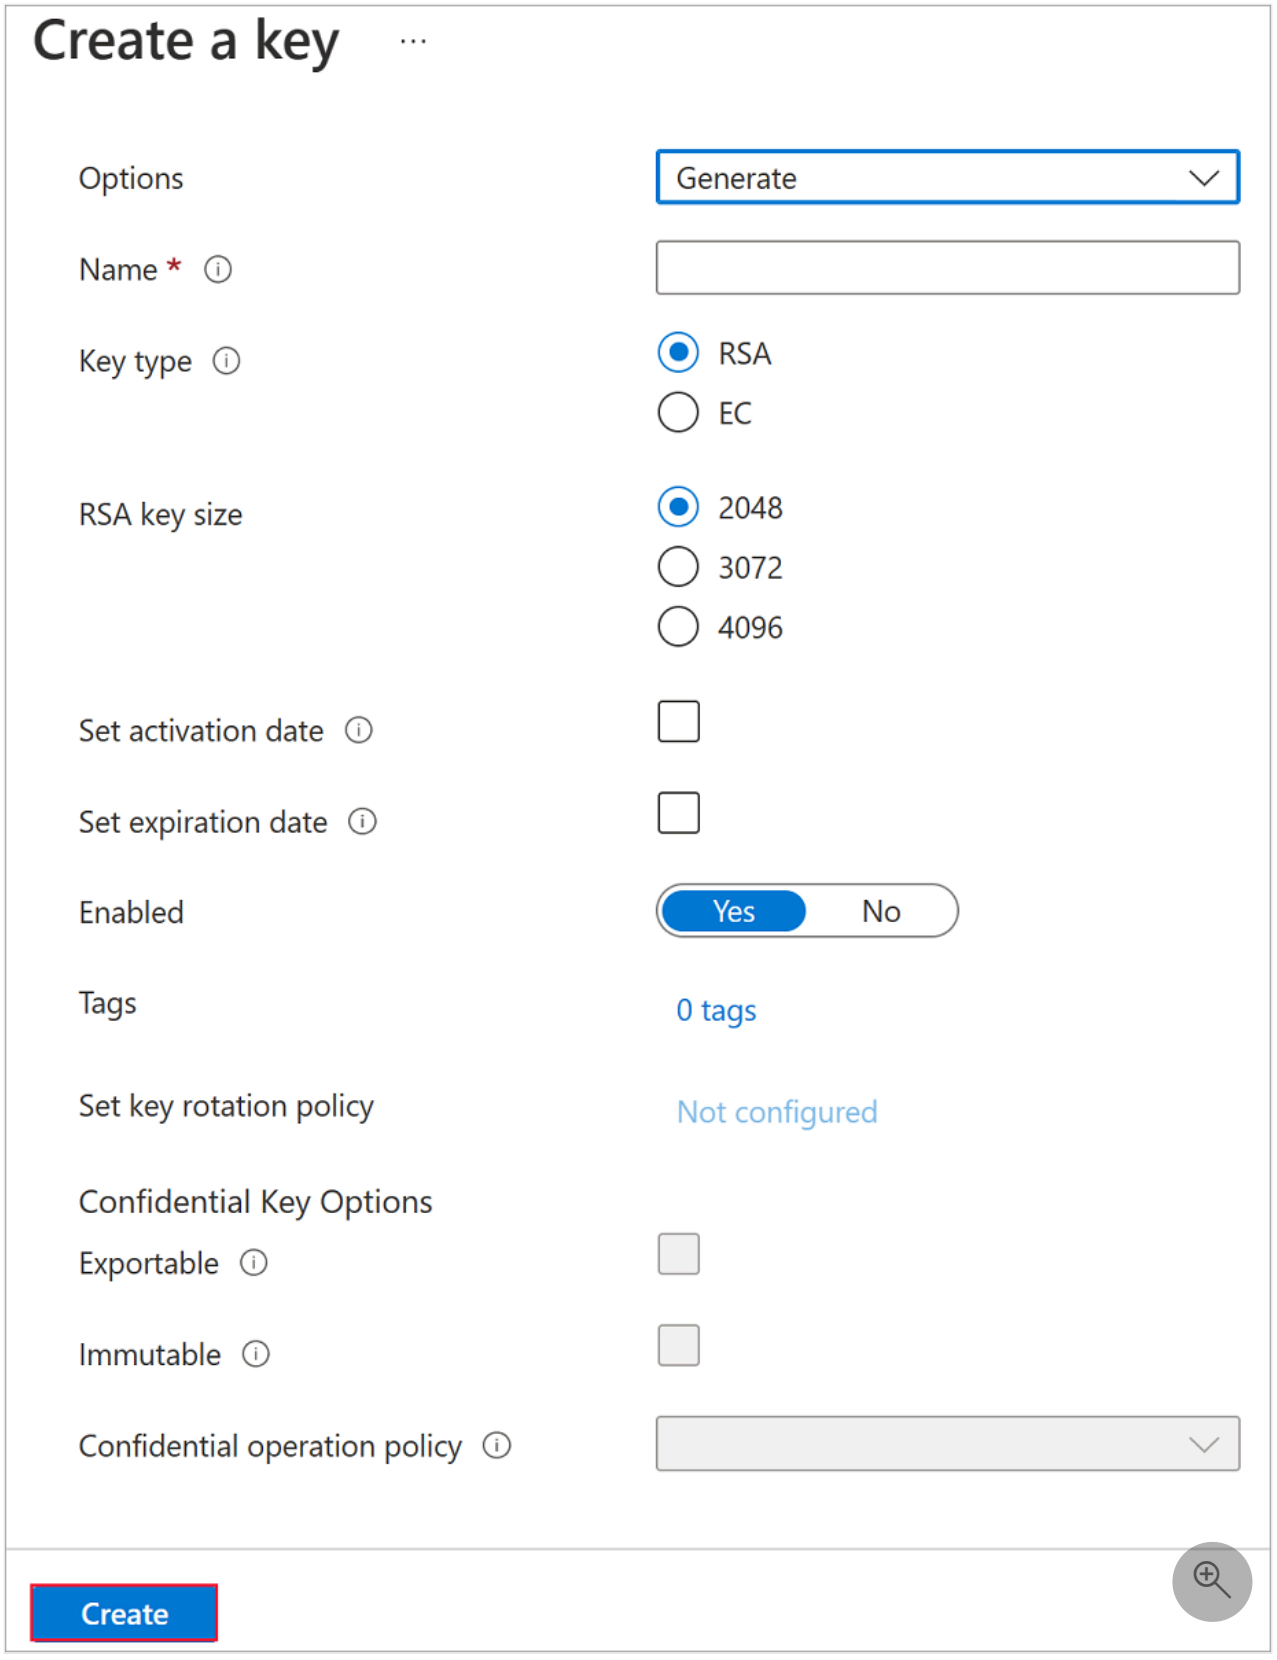
8. Select **Keys** under **Objects**.

9. Select **Generate/Import**.



10. Leave both **Key Type** set to **RSA** and **RSA Key Size** set to **2048**.

11. Fill in the remaining selections as you like and then select **Create**.



Add an Azure RBAC role

Now that you've created the Azure key vault and a key, you must add an Azure RBAC role, so you can use your Azure key vault with your disk encryption set.

1. Select **Access control (IAM)** and add a role.
2. Add either the **Key Vault Administrator**, **Owner**, or **Contributor** roles.

Set up your disk encryption set

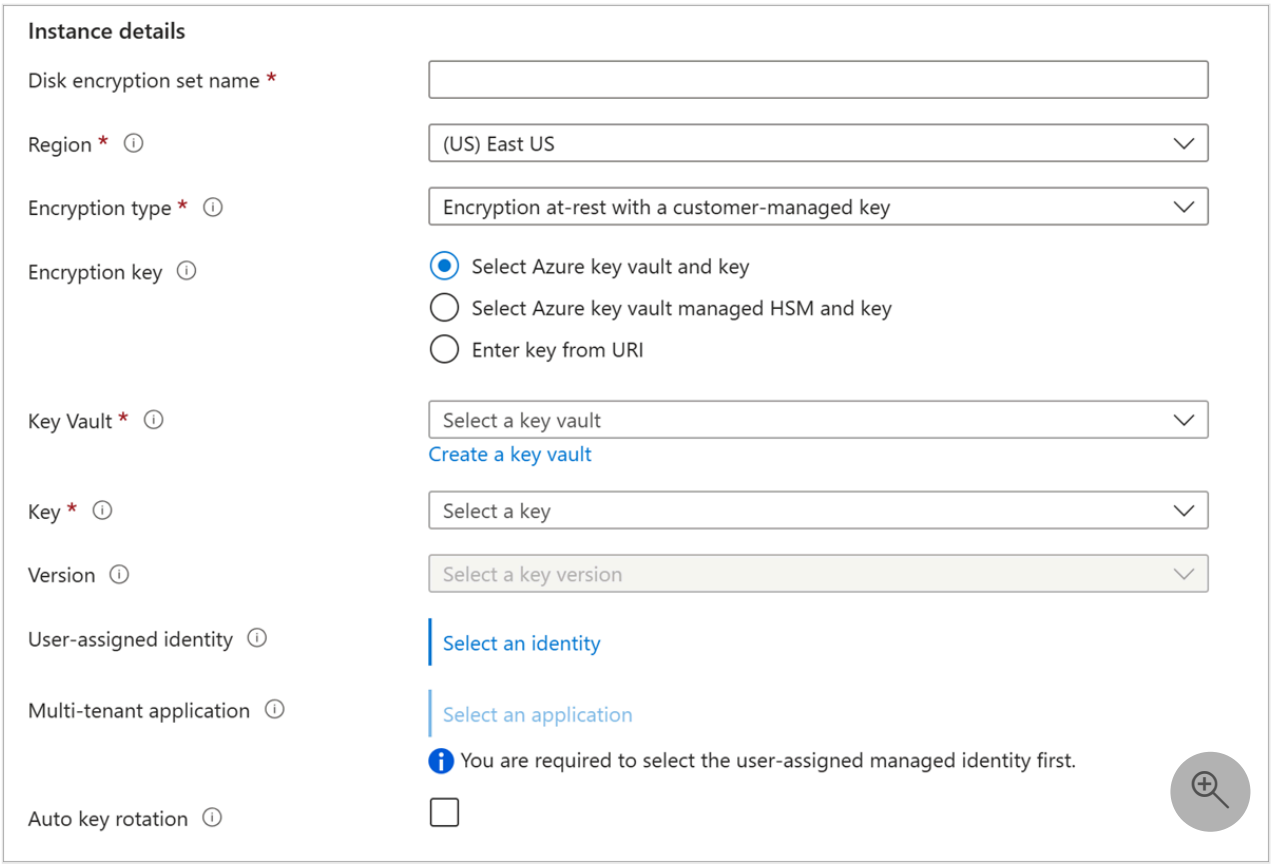
1. Search for **Disk Encryption Sets** and select it.
2. On the **Disk Encryption Sets** pane, select **+Create**.
3. Select your resource group, name your encryption set, and select the same region as your key vault.
4. For **Encryption type**, select **Encryption at-rest with a customer-managed key**.

   > ⓘ **Note**
   >
   > Once you create a disk encryption set with a particular encryption type, it cannot be changed. If you want to use a different encryption type, you must create a new disk encryption set.

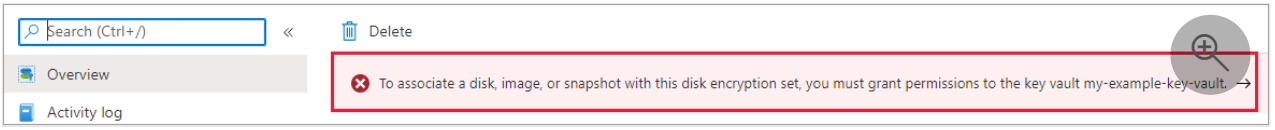
5. Make sure **Select Azure key vault and key** is selected.
6. Select the key vault and key you created previously, and the version.

   > ⓘ **Note**
   >
   > For managed disks with cross-tenant customer-managed keys, the selected key can be in a Key Vault in a different Microsoft Entra tenant.

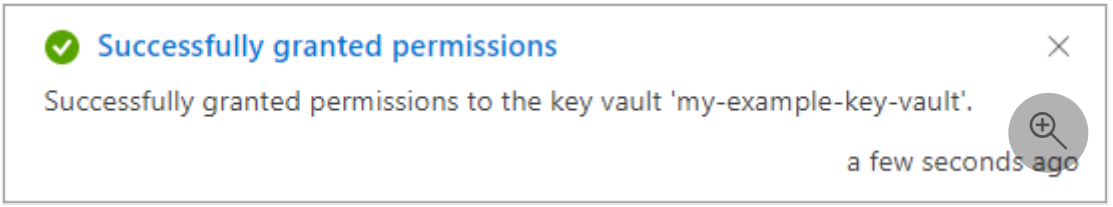
7. If you want to enable automatic rotation of customer managed keys, select **Auto key rotation**.
8. Select **Review + Create** and then **Create**.



9. Navigate to the disk encryption set once it's deployed, and select the displayed alert.



10. This will grant your key vault permissions to the disk encryption set.



Deploy a VM

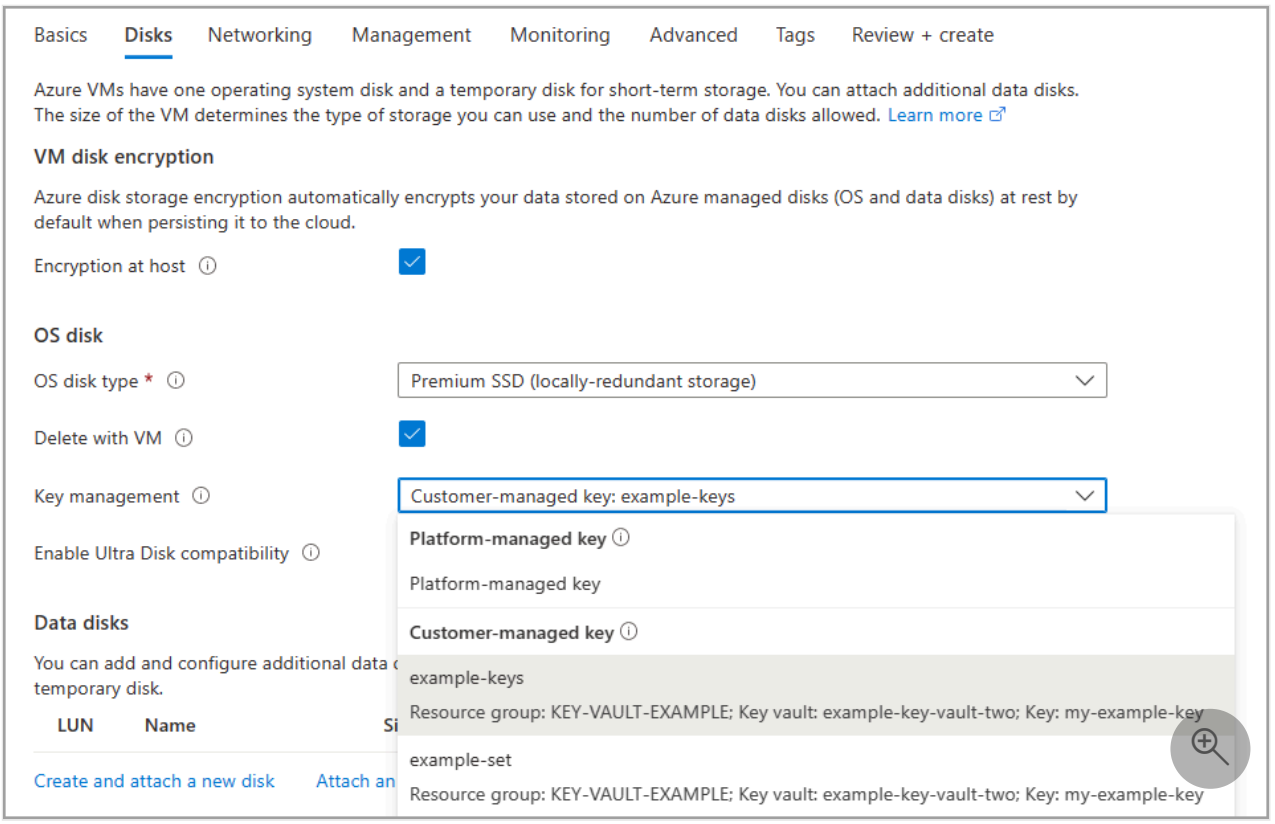
Now that you have setup an Azure Key Vault and disk encryption set, you can deploy a VM and it uses encryption at host.

1. Sign in to the Azure portal.
2. Search for **Virtual Machines** and select **+ Add** to create a VM.
3. Create a new virtual machine, select an appropriate region and a supported VM size.
4. Fill in the other values on the **Basic** pane as you like, then proceed to the **Disks** pane.

5. On the **Disks** pane, select **Encryption at host**.

6. Select **Key management** and select one of your customer-managed keys.

7. Make the remaining selections as you like.



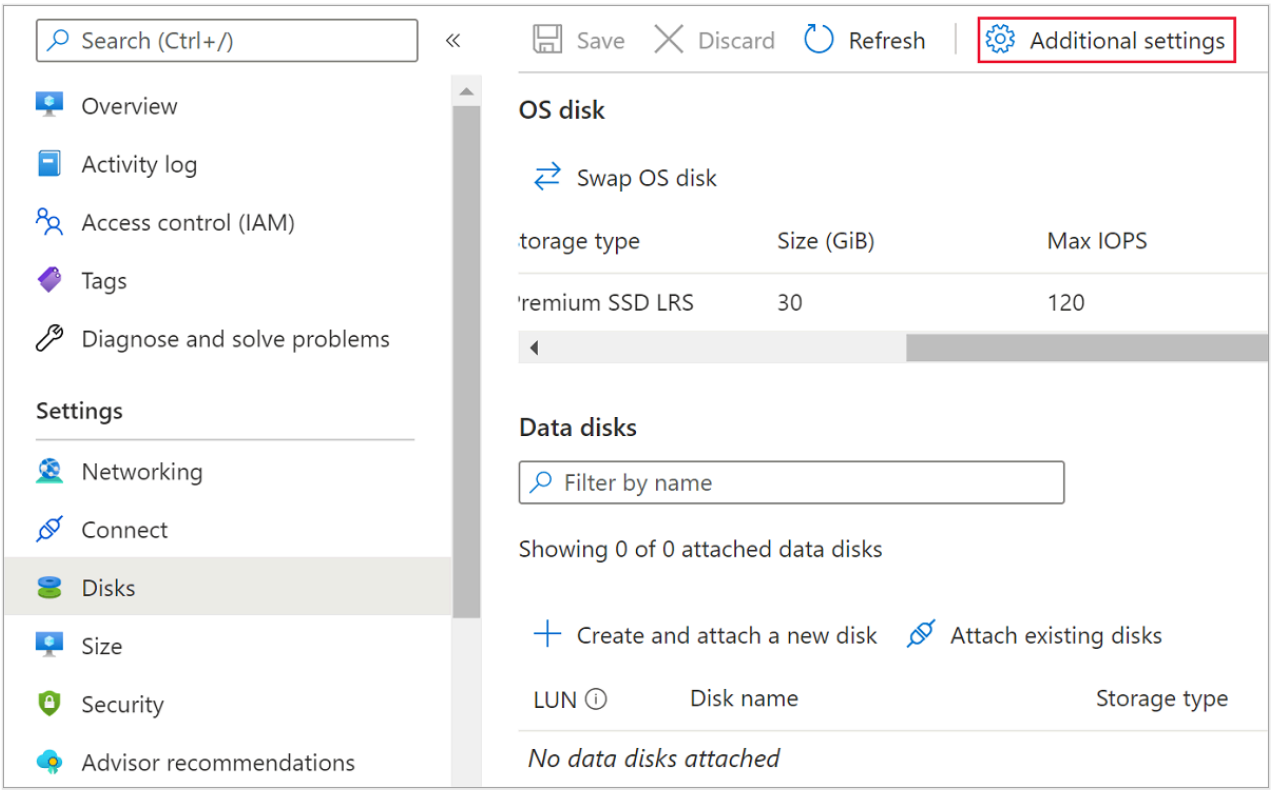
8. For the rest of the VM deployment process, make selections that fit your environment, and complete the deployment.

You've now deployed a VM with encryption at host enabled using customer-managed keys.

Disable host based encryption

Deallocate your VM first, encryption at host can't be disabled unless your VM is deallocated.

1. On your VM, select **Disks** and then select **Additional settings**.



2. Select **No** for **Encryption at host** then select **Save**.

Use the Azure PowerShell module to enable end-to-end encryption using encryption at host

Article • 02/25/2025

Applies to: ✔ Windows VMs

When you enable encryption at host, data stored on the VM host is encrypted at rest and flows encrypted to the Storage service. For conceptual information on encryption at host, and other managed disk encryption types, see Encryption at host - End-to-end encryption for your VM data.

Restrictions

- Supported for 4k sector size Ultra Disks and Premium SSD v2.
- Only supported on 512e sector size Ultra Disks and Premium SSD v2 if they were created after 5/13/2023.
  - For disks created before this date, snapshot your disk and create a new disk using the snapshot.
- Can't be enabled on virtual machines (VMs) or virtual machine scale sets that currently or ever had Azure Disk Encryption enabled.
- Azure Disk Encryption can't be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale sets. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.

Supported VM sizes

The complete list of supported VM sizes can be pulled programmatically. To learn how to retrieve them programmatically, refer to the Finding supported VM sizes section. Upgrading the VM size results in validation to check if the new VM size supports the EncryptionAtHost feature.

Prerequisites

You must enable the feature for your subscription before you use the EncryptionAtHost property for your VM/VMSS. Use the following steps to enable the feature for your

subscription:

1. Execute the following command to register the feature for your subscription

```PowerShell
 Register-AzProviderFeature -FeatureName "EncryptionAtHost" -
ProviderNamespace "Microsoft.Compute"
```

2. Check that the registration state is Registered (takes a few minutes) using the following command before trying out the feature.

```PowerShell
 Get-AzProviderFeature -FeatureName "EncryptionAtHost" -
ProviderNamespace "Microsoft.Compute"
```

Create an Azure Key Vault and DiskEncryptionSet

> **Note**
>
> This section only applies to configurations with customer-managed keys. If you're using platform-managed keys, you can skip to the Example scripts section.

Once the feature is enabled, you need to set up an Azure Key Vault and a DiskEncryptionSet, if you haven't already.

1. Make sure that you have installed latest Azure PowerShell version, and you are signed in to an Azure account in with Connect-AzAccount

2. Create an instance of Azure Key Vault and encryption key.

   When creating the Key Vault instance, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

```PowerShell
$ResourceGroupName="yourResourceGroupName"
$LocationName="westcentralus"
$keyVaultName="yourKeyVaultName"
$keyName="yourKeyName"
```

```
$keyDestination="Software"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$keyVault = New-AzKeyVault -Name $keyVaultName `
-ResourceGroupName $ResourceGroupName `
-Location $LocationName `
-EnablePurgeProtection

$key = Add-AzKeyVaultKey -VaultName $keyVaultName `
      -Name $keyName `
      -Destination $keyDestination
```

3. Create an instance of a DiskEncryptionSet. You can set RotationToLatestKeyVersionEnabled equal to $true to enable automatic rotation of the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

PowerShell

```
$desConfig=New-AzDiskEncryptionSetConfig -Location $LocationName `
    -SourceVaultId $keyVault.ResourceId `
    -KeyUrl $key.Key.Kid `
    -IdentityType SystemAssigned `
    -RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $diskEncryptionSetName `
       -ResourceGroupName $ResourceGroupName `
       -InputObject $desConfig
```

4. Grant the DiskEncryptionSet resource access to the key vault.

> **Note**
>
> It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Microsoft Entra ID. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ObjectId
$des.Identity.PrincipalId -PermissionsToKeys wrapkey,unwrapkey,get
```

Use a key vault in a different subscription

Alternatively, you can manage your Azure Key Vaults centrally from a single subscription, and use the keys stored in the Key Vault to encrypt managed disks and snapshots in other subscriptions in your organization. This allows your security team to enforce and easily manage a robust security policy to a single subscription.

> **ⓘ Important**
>
> For this configuration, both your Key Vault and your disk encryption set must be in the same region and be using the same tenant.

The following script is an example of how you would configure a disk encryption set to use a key from a Key Vault in a different subscription, but same region:

Azure PowerShell

```
$sourceSubscriptionId="<sourceSubID>"
$sourceKeyVaultName="<sourceKVName>"
$sourceKeyName="<sourceKeyName>"

$targetSubscriptionId="<targetSubID>"
$targetResourceGroupName="<targetRGName>"
$targetDiskEncryptionSetName="<targetDiskEncSetName>"
$location="<targetRegion>"

Set-AzContext -Subscription $sourceSubscriptionId

$key = Get-AzKeyVaultKey -VaultName $sourceKeyVaultName -Name $sourceKeyName

Set-AzContext -Subscription $targetSubscriptionId

$desConfig=New-AzDiskEncryptionSetConfig -Location $location `
-KeyUrl $key.Key.Kid `
-IdentityType SystemAssigned `
-RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $targetDiskEncryptionSetName `
-ResourceGroupName $targetResourceGroupName `
-InputObject $desConfig
```

Enable encryption at host for disks attached to VM and Virtual Machine Scale Sets

You can enable encryption at host by setting a new property EncryptionAtHost under securityProfile of VMs or Virtual Machine Scale Sets using the API version **2020-06-01** and above.

```
"securityProfile": { "encryptionAtHost": "true" }
```

Example scripts

Create a VM with encryption at host enabled with customer-managed keys.

Create a VM with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

PowerShell

```
$VMLocalAdminUser = "yourVMLocalAdminUserName"
$VMLocalAdminSecurePassword = ConvertTo-SecureString <password> -AsPlainText
-Force
$LocationName = "yourRegion"
$ResourceGroupName = "yourResourceGroupName"
$ComputerName = "yourComputerName"
$VMName = "yourVMName"
$VMSize = "yourVMSize"
$diskEncryptionSetName="yourdiskEncryptionSetName"

$NetworkName = "yourNetworkName"
$NICName = "yourNICName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -
AddressPrefix $SubnetAddressPrefix
$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName
$ResourceGroupName -Location $LocationName -AddressPrefix $VnetAddressPrefix
-Subnet $SingleSubnet
$NIC = New-AzNetworkInterface -Name $NICName -ResourceGroupName
$ResourceGroupName -Location $LocationName -SubnetId $Vnet.Subnets[0].Id

$Credential = New-Object System.Management.Automation.PSCredential
($VMLocalAdminUser, $VMLocalAdminSecurePassword);

# Enable encryption at host by specifying EncryptionAtHost parameter

$VirtualMachine = New-AzVMConfig -VMName $VMName -VMSize $VMSize -
EncryptionAtHost
$VirtualMachine = Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -
ComputerName $ComputerName -Credential $Credential -ProvisionVMAgent -
EnableAutoUpdate
$VirtualMachine = Add-AzVMNetworkInterface -VM $VirtualMachine -Id $NIC.Id
$VirtualMachine = Set-AzVMSourceImage -VM $VirtualMachine -PublisherName
```

```
'MicrosoftWindowsServer' -Offer 'WindowsServer' -Skus '2012-R2-Datacenter' -
Version latest

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName
$ResourceGroupName -Name $diskEncryptionSetName

# Enable encryption with a customer managed key for OS disk by setting
DiskEncryptionSetId property

$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name $($VMName
+"_OSDisk") -DiskEncryptionSetId $diskEncryptionSet.Id -CreateOption
FromImage

# Add a data disk encrypted with a customer managed key by setting
DiskEncryptionSetId property

$VirtualMachine = Add-AzVMDataDisk -VM $VirtualMachine -Name $($VMName
+"DataDisk1") -DiskSizeInGB 128 -StorageAccountType Premium_LRS -
CreateOption Empty -Lun 0 -DiskEncryptionSetId $diskEncryptionSet.Id

New-AzVM -ResourceGroupName $ResourceGroupName -Location $LocationName -VM
$VirtualMachine -Verbose
```

Create a VM with encryption at host enabled with platform-managed keys.

Create a VM with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

PowerShell

```
$VMLocalAdminUser = "yourVMLocalAdminUserName"
$VMLocalAdminSecurePassword = ConvertTo-SecureString <password> -AsPlainText
-Force
$LocationName = "yourRegion"
$ResourceGroupName = "yourResourceGroupName"
$ComputerName = "yourComputerName"

$ResourceGroupName = "yourResourceGroupName"
$VMName = "yourVMName"
```

```
$VM = Get-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName

$VM.SecurityProfile.EncryptionAtHost
```

Disable encryption at host

You must deallocate your VM before you can disable encryption at host.

PowerShell

```
$ResourceGroupName = "yourResourceGroupName"
$VMName = "yourVMName"

$VM = Get-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName

Stop-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName -Force

Update-AzVM -VM $VM -ResourceGroupName $ResourceGroupName -EncryptionAtHost
$false
```

Create a Virtual Machine Scale Set with encryption at host enabled with customer-managed keys.

> **ⓘ Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Create a Virtual Machine Scale Set with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

PowerShell

```
$VMLocalAdminUser = "yourLocalAdminUser"
$VMLocalAdminSecurePassword = ConvertTo-SecureString Password@123 -
AsPlainText -Force
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$ComputerNamePrefix = "yourComputerNamePrefix"
```

```
$VMScaleSetName = "yourVMSSName"
$VMSize = "Standard_DS3_v2"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$NetworkName = "yourVNETName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -
AddressPrefix $SubnetAddressPrefix

$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName
$ResourceGroupName -Location $LocationName -AddressPrefix $VnetAddressPrefix
-Subnet $SingleSubnet

$ipConfig = New-AzVmssIpConfig -Name "myIPConfig" -SubnetId
$Vnet.Subnets[0].Id

# Enable encryption at host by specifying EncryptionAtHost parameter

$VMSS = New-AzVmssConfig -Location $LocationName -SkuCapacity 2 -SkuName
$VMSize -OrchestrationMode "Flexible" -EncryptionAtHost

$VMSS = Add-AzVmssNetworkInterfaceConfiguration -Name "myVMSSNetworkConfig"
-VirtualMachineScaleSet $VMSS -Primary $true -IpConfiguration $ipConfig

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName
$ResourceGroupName -Name $diskEncryptionSetName

# Enable encryption with a customer managed key for the OS disk by setting
DiskEncryptionSetId property

$VMSS = Set-AzVmssStorageProfile $VMSS -OsDiskCreateOption "FromImage" -
DiskEncryptionSetId $diskEncryptionSet.Id -ImageReferenceOffer
'WindowsServer' -ImageReferenceSku '2012-R2-Datacenter' -
ImageReferenceVersion latest -ImageReferencePublisher
'MicrosoftWindowsServer'

$VMSS = Set-AzVmssOsProfile $VMSS -ComputerNamePrefix $ComputerNamePrefix -
AdminUsername $VMLocalAdminUser -AdminPassword $VMLocalAdminSecurePassword

# Add a data disk encrypted with a customer managed key by setting
DiskEncryptionSetId property

$VMSS = Add-AzVmssDataDisk -VirtualMachineScaleSet $VMSS -CreateOption Empty
-Lun 1 -DiskSizeGB 128 -StorageAccountType Premium_LRS -DiskEncryptionSetId
$diskEncryptionSet.Id
```

Create a Virtual Machine Scale Set with encryption at host enabled with platform-managed keys.

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to [Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub]

Create a Virtual Machine Scale Set with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

PowerShell

```
$VMLocalAdminUser = "yourLocalAdminUser"
$VMLocalAdminSecurePassword = ConvertTo-SecureString Password@123 -
AsPlainText -Force
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$ComputerNamePrefix = "yourComputerNamePrefix"
$VMScaleSetName = "yourVMSSName"
$VMSize = "Standard_DS3_v2"

$NetworkName = "yourVNETName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -
AddressPrefix $SubnetAddressPrefix

$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName
$ResourceGroupName -Location $LocationName -AddressPrefix $VnetAddressPrefix
-Subnet $SingleSubnet

$ipConfig = New-AzVmssIpConfig -Name "myIPConfig" -SubnetId
$Vnet.Subnets[0].Id

# Enable encryption at host by specifying EncryptionAtHost parameter

$VMSS = New-AzVmssConfig -Location $LocationName -SkuCapacity 2 -SkuName
$VMSize -OrchestrationMode "Flexible" -EncryptionAtHost

$VMSS = Add-AzVmssNetworkInterfaceConfiguration -Name "myVMSSNetworkConfig"
-VirtualMachineScaleSet $VMSS -Primary $true -IpConfiguration $ipConfig

$VMSS = Set-AzVmssStorageProfile $VMSS -OsDiskCreateOption "FromImage" -
ImageReferenceOffer 'WindowsServer' -ImageReferenceSku '2012-R2-Datacenter'
-ImageReferenceVersion latest -ImageReferencePublisher
'MicrosoftWindowsServer'
```

```
$VMSS = Set-AzVmssOsProfile $VMSS -ComputerNamePrefix $ComputerNamePrefix -
AdminUsername $VMLocalAdminUser -AdminPassword $VMLocalAdminSecurePassword

$VMSS = Add-AzVmssDataDisk -VirtualMachineScaleSet $VMSS -CreateOption Empty
-Lun 1 -DiskSizeGB 128 -StorageAccountType Premium_LRS

$Credential = New-Object System.Management.Automation.PSCredential
($VMLocalAdminUser, $VMLocalAdminSecurePassword);

New-AzVmss -VirtualMachineScaleSet $VMSS -ResourceGroupName
$ResourceGroupName -VMScaleSetName $VMScaleSetName
```

Update a Virtual Machine Scale Set to enable encryption at host.

PowerShell

```
$ResourceGroupName = "yourResourceGroupName"
$VMScaleSetName = "yourVMSSName"

$VMSS = Get-AzVmss -ResourceGroupName $ResourceGroupName -Name
$VMScaleSetName

Update-AzVmss -VirtualMachineScaleSet $VMSS -Name $VMScaleSetName -
ResourceGroupName $ResourceGroupName -EncryptionAtHost $true
```

Check the status of encryption at host for a Virtual Machine Scale Set

PowerShell

```
$ResourceGroupName = "yourResourceGroupName"
$VMScaleSetName = "yourVMSSName"

$VMSS = Get-AzVmss -ResourceGroupName $ResourceGroupName -Name
$VMScaleSetName

$VMSS.VirtualMachineProfile.SecurityProfile.EncryptionAtHost
```

Update a Virtual Machine Scale Set to disable encryption at host.

You can disable encryption at host on your Virtual Machine Scale Set but, this will only affect VMs created after you disable encryption at host. For existing VMs, you must

deallocate the VM, disable encryption at host on that individual VM, then reallocate the VM.

PowerShell

```
$ResourceGroupName = "yourResourceGroupName"
$VMScaleSetName = "yourVMSSName"

$VMSS = Get-AzVmss -ResourceGroupName $ResourceGroupName -Name
$VMScaleSetName

Update-AzVmss -VirtualMachineScaleSet $VMSS -Name $VMScaleSetName -
ResourceGroupName $ResourceGroupName -EncryptionAtHost $false
```

Finding supported VM sizes

Legacy VM Sizes aren't supported. You can find the list of supported VM sizes by either:

Calling the Resource Skus API and checking that the `EncryptionAtHostSupported` capability is set to **True**.

JSON

```
    {
        "resourceType": "virtualMachines",
        "name": "Standard_DS1_v2",
        "tier": "Standard",
        "size": "DS1_v2",
        "family": "standardDSv2Family",
        "locations": [
        "CentralUS"
        ],
        "capabilities": [
        {
            "name": "EncryptionAtHostSupported",
            "value": "True"
        }
        ]
    }
```

Or, calling the Get-AzComputeResourceSku PowerShell cmdlet.

PowerShell

```
Get-AzComputeResourceSku -Location "centralus" |
    Where-Object { $_.ResourceType -eq 'virtualMachines' -and
$_.capabilities.where({ $_.Name -eq 'EncryptionAtHostSupported' },
```

```
'First').Value -eq 'True' } |
    Select-Object -ExpandProperty Name
```

Next steps

Now that you've created and configured these resources, you can use them to secure your managed disks. The following link contains example scripts, each with a respective scenario, that you can use to secure your managed disks.

Use the Azure CLI to enable end-to-end encryption using encryption at host

06/26/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When you enable encryption at host, data stored on the VM host is encrypted at rest and flows encrypted to the Storage service. For conceptual information on encryption at host, and other managed disk encryption types, see Encryption at host - End-to-end encryption for your VM data.

Restrictions

- Can't be enabled on virtual machines (VMs) or virtual machine scale sets that currently or ever had Azure Disk Encryption enabled.
- Azure Disk Encryption can't be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale sets. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.

The following restrictions only apply to Ultra Disks and Premium SSD v2:

- Disks using a 512e sector size need to have been created after 5/13/2023.
  - If your disk was created before this date, snapshot your disk, and create a new disk using the snapshot.

Supported VM sizes

The complete list of supported VM sizes can be pulled programmatically. To learn how to retrieve them programmatically, see the Finding supported VM sizes section. Upgrading the VM size results in validation to check if the new VM size supports the EncryptionAtHost feature.

Prerequisites

You must enable the feature for your subscription before you use the EncryptionAtHost property for your VM/VMSS. Use the following steps to enable the feature for your subscription:

- Execute the following command to register the feature for your subscription

Azure CLI

```
az feature register --namespace Microsoft.Compute --name EncryptionAtHost
```

- Check that the registration state is **Registered** (takes a few minutes) using the command below before trying out the feature.

Azure CLI

```
az feature show --namespace Microsoft.Compute --name EncryptionAtHost
```

Create resources

> ⓘ **Note**
>
> This section only applies to configurations with customer-managed keys. If you're using platform-managed keys, you can skip to the **Example scripts** section.

Once the feature is enabled, you need to set up a DiskEncryptionSet and either an Azure Key Vault or an Azure Key Vault Managed HSM.

Azure Key Vault

- Install the latest Azure CLI and log to an Azure account in with az login.
- Create an Azure Key Vault and encryption key.

When creating the Key Vault, you must enable purge protection. Purge protection ensures that a deleted key can't be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

> ⓘ **Important**
>
> Don't camel case the region, if you do so, you may experience problems when assigning additional disks to the resource in the Azure portal.

Azure CLI

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
```

```
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az group create --resource-group $rgName --location $location

az keyvault create -n $keyVaultName \
-g $rgName \
-l $location \
--enable-purge-protection true

az keyvault key create --vault-name $keyVaultName \
-n $keyName \
--protection software
```

- Create a DiskEncryptionSet. You can set *enable-auto-key-rotation* to **true** to enable automatic rotation of the key. When you enable automatic rotation, the system automatically updates all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

Azure CLI

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName -
-query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName \
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

- Grant the DiskEncryptionSet resource access to the key vault.

> **Note**
>
> It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Microsoft Entra ID. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

Azure CLI

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --
query [identity.principalId] -o tsv)

az keyvault set-policy -n $keyVaultName \
```

```
-g $rgName \
--object-id $desIdentity \
--key-permissions wrapkey unwrapkey get
```

Azure Key Vault Managed HSM

Alternatively, you can use a Managed HSM to handle your keys.

To do this, you must complete the following prerequisites:

- Install the latest Azure CLI and log in to an Azure account in with az login.
- Create and configure a managed HSM.
- Assign permissions to a user, so they can manage your Managed HSM.

Configuration

Once you've created a Managed HSM and added permissions, enable purge protection and create an encryption key.

Azure CLI

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault update-hsm --subscription $subscriptionId -g $rgName --hsm-name
$keyVaultName --enable-purge-protection true

az keyvault key create --hsm-name  $keyVaultName --name $keyName --ops wrapKey
unwrapKey --kty RSA-HSM --size 2048
```

Then, create a DiskEncryptionSet.

Azure CLI

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName -
-query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName \
-l $location \
-g $rgName \
```

```
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

Finally, grant the DiskEncryptionSet access to the Managed HSM.

Azure CLI

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --
query [identity.principalId] -o tsv)

az keyvault role assignment create --hsm-name $keyVaultName --role "Managed HSM
Crypto Service Encryption User" --assignee $desIdentity --scope /keys
```

Example scripts

Create a VM with encryption at host enabled with customer-managed keys

Create a VM with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

Azure CLI

```
rgName=yourRGName
vmName=yourVMName
location=eastus
vmSize=Standard_DS2_v2
image=LinuxImageURN
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g
$rgName --query [id] -o tsv)

az vm create -g $rgName \
-n $vmName \
-l $location \
--encryption-at-host \
--image $image \
--size $vmSize \
--generate-ssh-keys \
--os-disk-encryption-set $diskEncryptionSetId \
--data-disk-sizes-gb 128 128 \
--data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

Create a VM with encryption at host enabled with platform-managed keys

Create a VM with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

Azure CLI

```
rgName=yourRGName
vmName=yourVMName
location=eastus
vmSize=Standard_DS2_v2
image=LinuxImageURN

az vm create -g $rgName \
-n $vmName \
-l $location \
--encryption-at-host \
--image $image \
--size $vmSize \
--generate-ssh-keys \
--data-disk-sizes-gb 128 128 \
```

Update a VM to enable encryption at host

Azure CLI

```
rgName=yourRGName
vmName=yourVMName

az vm update -n $vmName \
-g $rgName \
--set securityProfile.encryptionAtHost=true
```

Check the status of encryption at host for a VM

Azure CLI

```
rgName=yourRGName
vmName=yourVMName

az vm show -n $vmName \
-g $rgName \
--query [securityProfile.encryptionAtHost] -o tsv
```

Update a VM to disable encryption at host

You must deallocate your VM before you can disable encryption at host.

Azure CLI

```
rgName=yourRGName
vmName=yourVMName

az vm update -n $vmName \
-g $rgName \
--set securityProfile.encryptionAtHost=false
```

Create a Virtual Machine Scale Set with encryption at host enabled with customer-managed keys

Create a Virtual Machine Scale Set with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Azure CLI

```
rgName=yourRGName
vmssName=yourVMSSName
location=westus2
vmSize=Standard_DS3_V2
image=Ubuntu2204
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g
$rgName --query [id] -o tsv)

az vmss create -g $rgName \
-n $vmssName \
--encryption-at-host \
--image $image \
--orchestration-mode flexible \
--admin-username azureuser \
--generate-ssh-keys \
```

```
--os-disk-encryption-set $diskEncryptionSetId \
--data-disk-sizes-gb 64 128 \
--data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

Create a Virtual Machine Scale Set with encryption at host enabled with platform-managed keys

Create a Virtual Machine Scale Set with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Azure CLI

```
rgName=yourRGName
vmssName=yourVMSSName
location=westus2
vmSize=Standard_DS3_V2
image=Ubuntu2204

az vmss create -g $rgName \
-n $vmssName \
--encryption-at-host \
--image $image \
--orchestration-mode flexible \
--admin-username azureuser \
--generate-ssh-keys \
--data-disk-sizes-gb 64 128 \
```

Update a Virtual Machine Scale Set to enable encryption at host

Azure CLI

```
rgName=yourRGName
vmssName=yourVMName

az vmss update -n $vmssName \
```

```
-g $rgName \
--set virtualMachineProfile.securityProfile.encryptionAtHost=true
```

Check the status of encryption at host for a Virtual Machine Scale Set

Azure CLI

```
rgName=yourRGName
vmssName=yourVMName

az vmss show -n $vmssName \
-g $rgName \
--query [virtualMachineProfile.securityProfile.encryptionAtHost] -o tsv
```

Update a Virtual Machine Scale Set to disable encryption at host

You can disable encryption at host on your Virtual Machine Scale Set but, this will only affect VMs created after you disable encryption at host. For existing VMs, you must deallocate the VM, disable encryption at host on that individual VM, then reallocate the VM.

Azure CLI

```
rgName=yourRGName
vmssName=yourVMName

az vmss update -n $vmssName \
-g $rgName \
--set virtualMachineProfile.securityProfile.encryptionAtHost=false
```

Finding supported VM sizes

Legacy VM Sizes aren't supported. You can find the list of supported VM sizes by either using resource SKU APIs or the Azure CLI.

When calling the Resource Skus API, check that the `EncryptionAtHostSupported` capability is set to **True**.

JSON

```
    {
        "resourceType": "virtualMachines",
```

```
        "name": "Standard_DS1_v2",
        "tier": "Standard",
        "size": "DS1_v2",
        "family": "standardDSv2Family",
        "locations": [
        "CentralUS"
        ],
        "capabilities": [
        {
            "name": "EncryptionAtHostSupported",
            "value": "True"
        }
        ]
    }
```

For the Azure CLI, use the az vm image list-skus command.

Azure CLI

```
location=centralus

az vm list-skus --location $location --all \
--resource-type virtualMachines \
--query "[?capabilities[?name=='EncryptionAtHostSupported' && value=='True']].
{VMName:name, EncryptionAtHost:capabilities[?
name=='EncryptionAtHostSupported'].value | [0]}" \
--output table
```

Next steps

Now that you've created and configured these resources, you can use them to secure your managed disks. The following link contains example scripts, each with a respective scenario, that you can use to secure your managed disks.

Azure Resource Manager template samples

Enable double encryption at rest for managed disks

Article • 09/27/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔

Azure Disk Storage supports double encryption at rest for managed disks. For conceptual information on double encryption at rest, and other managed disk encryption types, see the Double encryption at rest section of our disk encryption article.

Restrictions

Double encryption at rest isn't currently supported with either Ultra Disks or Premium SSD v2 disks.

Prerequisites

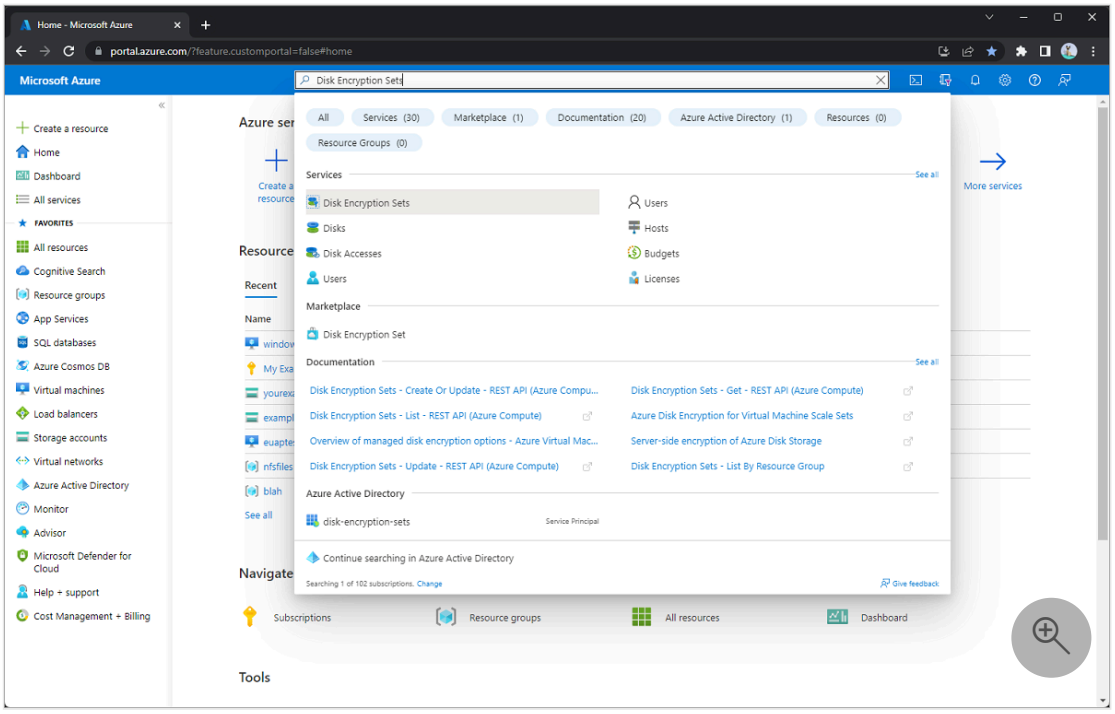
If you're going to use Azure CLI, install the latest Azure CLI and sign in to an Azure account with az login.

If you're going to use the Azure PowerShell module, install the latest Azure PowerShell version, and sign in to an Azure account using Connect-AzAccount.

Getting started

Azure portal

1. Sign in to the Azure portal.
2. Search for and select **Disk Encryption Sets**.



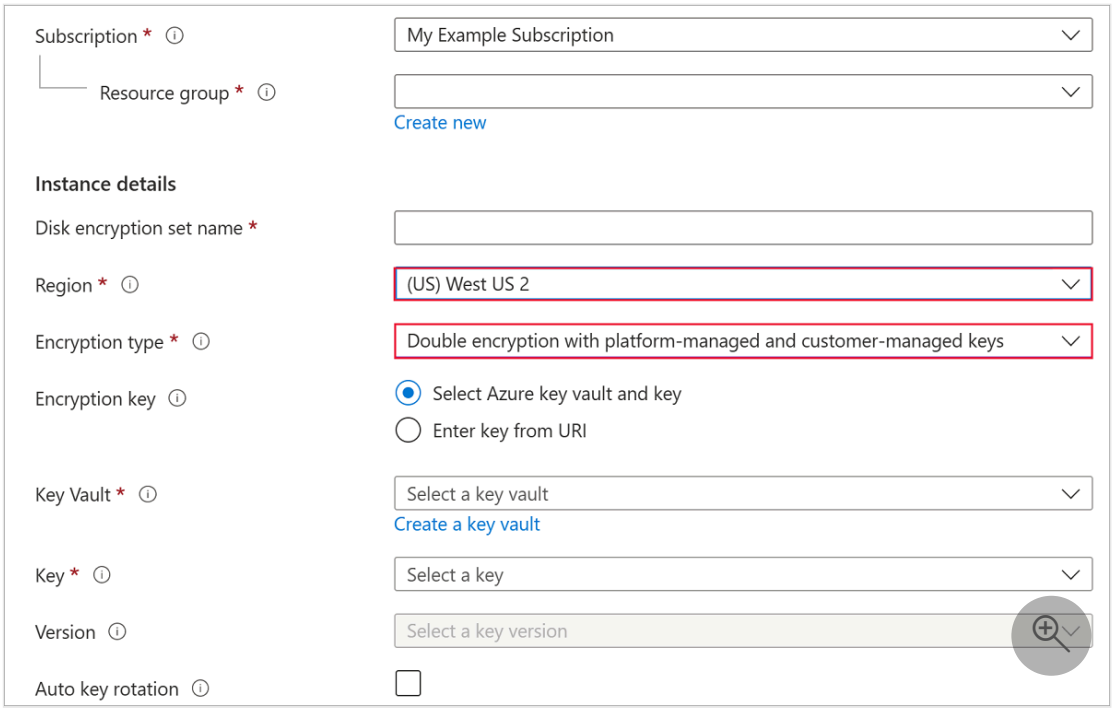
3. Select + **Create**.

4. Select one of the supported regions.

5. For **Encryption type**, select **Double encryption with platform-managed and customer-managed keys**.

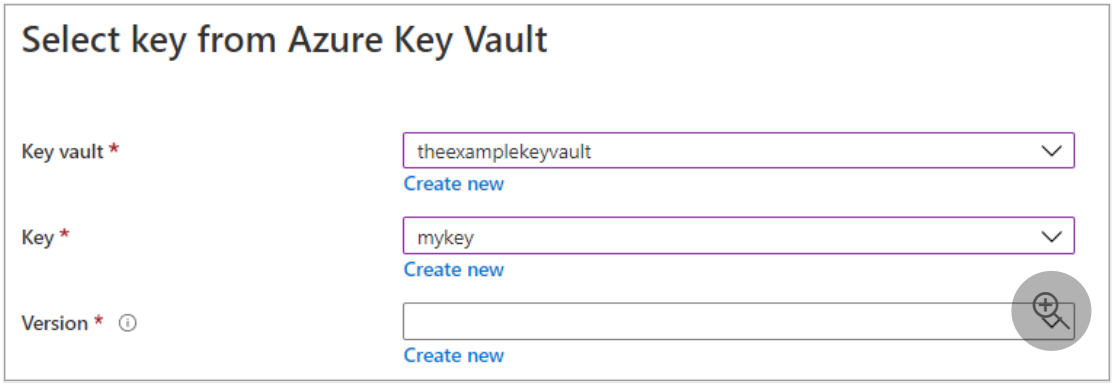
> ⓘ **Note**
>
> Once you create a disk encryption set with a particular encryption type, it cannot be changed. If you want to use a different encryption type, you must create a new disk encryption set.

6. Fill in the remaining info.



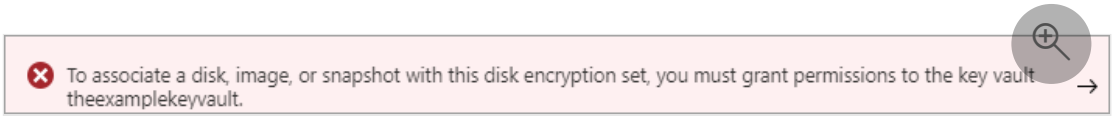
7. Select an Azure Key Vault and key, or create a new one if necessary.

> **Note**
>
> If you create a Key Vault instance, you must enable soft delete and purge protection. These settings are mandatory when using a Key Vault for encrypting managed disks, and protect you from losing data due to accidental deletion.

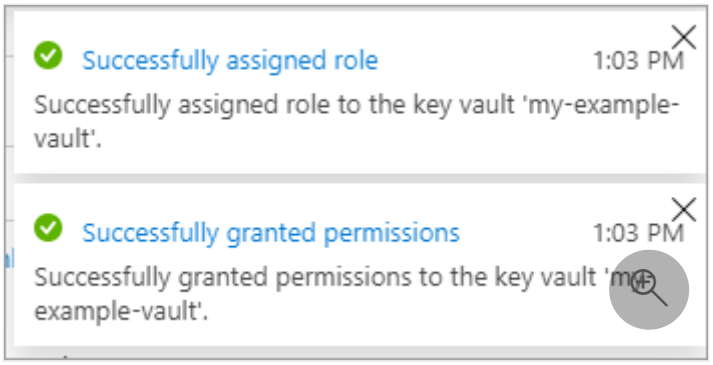


8. Select **Create**.

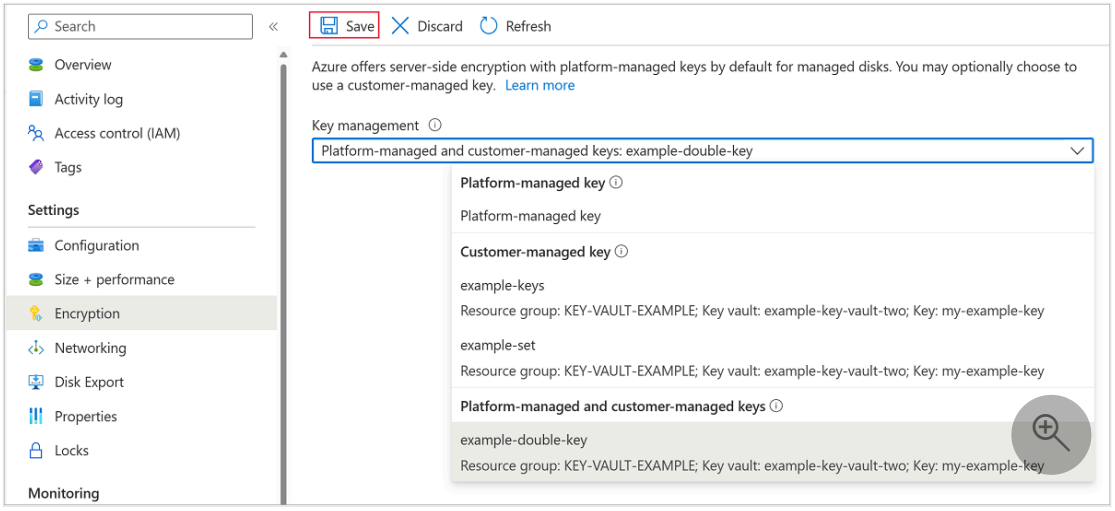
9. Navigate to the disk encryption set you created, and select the error that is displayed. This will configure your disk encryption set to work.



A notification should pop up and succeed. Doing this will allow you to use the disk encryption set with your key vault.



10. Navigate to your disk.
11. Select **Encryption**.
12. For **Key management**, select one of the keys under **Platform-managed and customer-managed keys**.
13. select **Save**.



You have now enabled double encryption at rest on your managed disk.

Next steps

- Azure PowerShell - Enable customer-managed keys with server-side encryption - managed disks
- Azure Resource Manager template samples
- Enable customer-managed keys with server-side encryption - Examples

Azure Disk Encryption for Linux VMs

Summarize this article for me

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

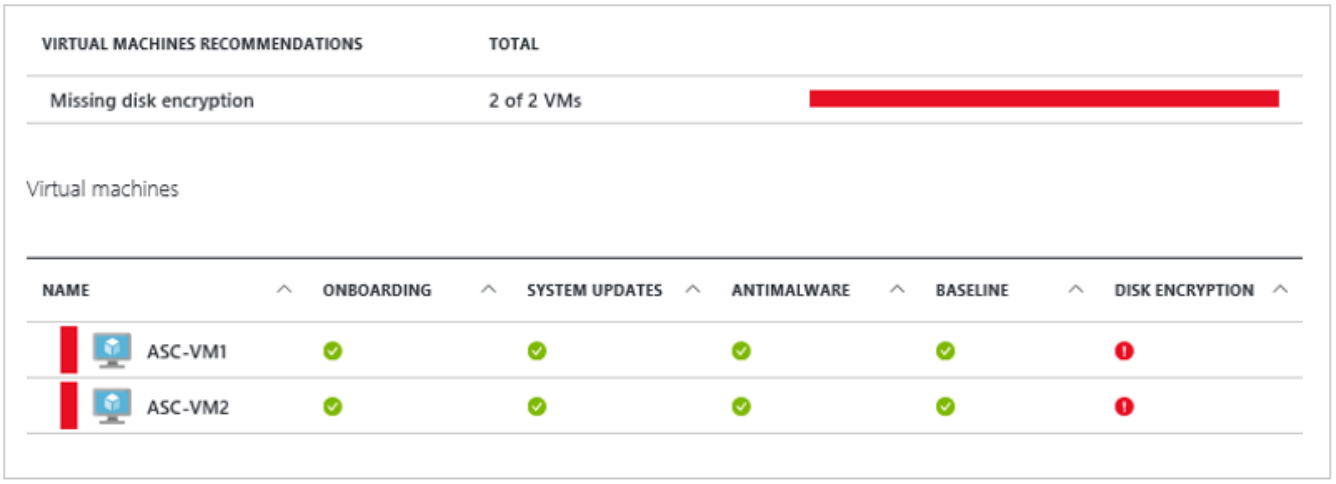
> **Caution**
>
> **CentOS End Of Life Notice**: This article references CentOS, which has reached End Of Life status. If you're using CentOS, review your deployment plans and consider migrating to a supported Linux distribution. For migration guidance and timelines, see CentOS End Of Life guidance.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure Disk Encryption helps protect and safeguard your data to meet your organizational security and compliance commitments. It uses the DM-Crypt feature of Linux to provide volume encryption for the OS and data disks of Azure virtual machines (VMs), and is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets.

Azure Disk Encryption is zone resilient, the same way as Virtual Machines. For details, see Azure Services that support Availability Zones.

If you use Microsoft Defender for Cloud, you're alerted if you have VMs that aren't encrypted. The alerts show as High Severity and the recommendation is to encrypt these VMs.



> ⚠ **Warning**
>
> - If you have previously used Azure Disk Encryption with Microsoft Entra ID to encrypt a VM, you must continue to use this option to encrypt your VM. See Azure Disk Encryption with Microsoft Entra ID (previous release) for details.
> - Certain recommendations might increase data, network, or compute resource usage, resulting in additional license or subscription costs. You must have a valid active Azure subscription to create resources in Azure in the supported regions.

You can learn the fundamentals of Azure Disk Encryption for Linux in just a few minutes with the Create and encrypt a Linux VM with Azure CLI quickstart or the Create and encrypt a Linux VM with Azure PowerShell quickstart.

Supported VMs and operating systems

Supported VMs

Linux VMs are available in a range of sizes. Azure Disk Encryption is supported on Generation 1 and Generation 2 VMs. Azure Disk Encryption is also available for VMs with premium storage.

See Azure VM sizes with no local temporary disk.

Azure Disk Encryption is not available on Basic, A-series VMs,v6 series VMs, v7 series VMs, or newer, or on virtual machines that do not meet these minimum memory requirements:

Memory requirements

Expand table

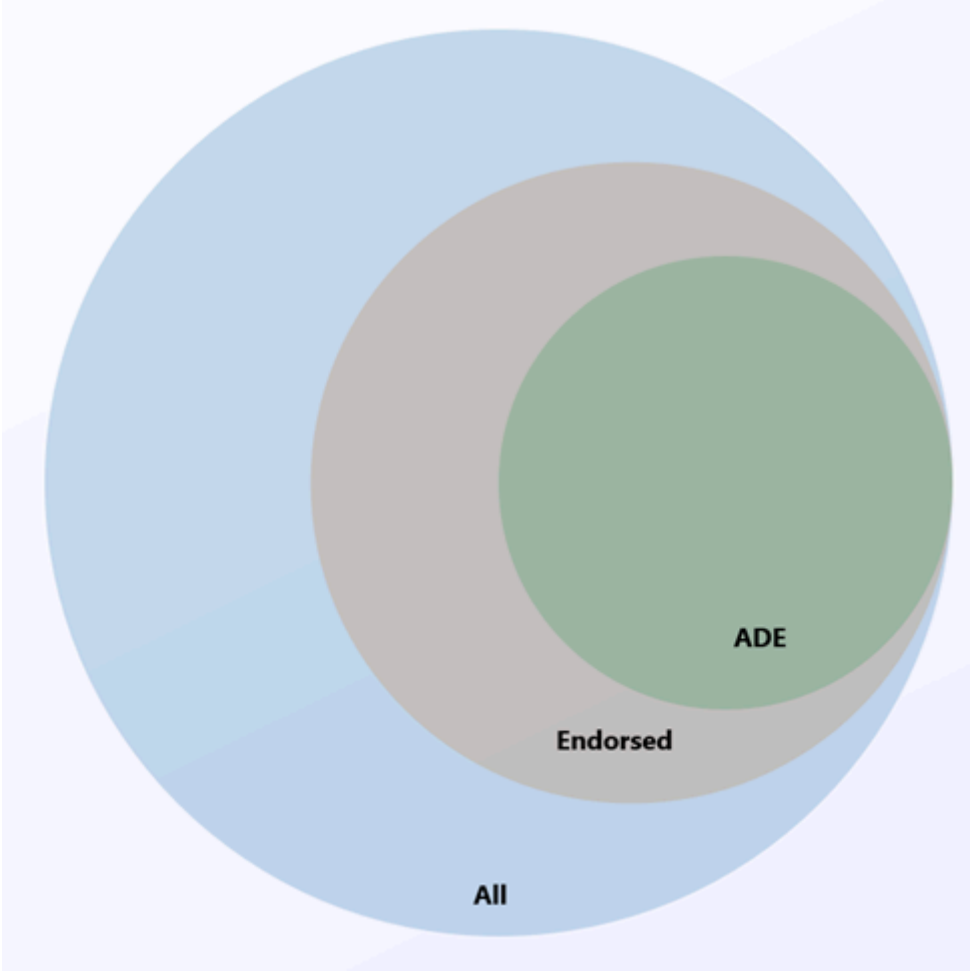
Virtual machine	Minimum memory requirement
Linux VMs when only encrypting data volumes	2 GB
Linux VMs when encrypting both data and OS volumes, and where the root (/) file system usage is 4 GB or less	8 GB
Linux VMs when encrypting both data and OS volumes, and where the root (/) file system usage is greater than 4 GB	The root file system usage * 2. For instance, a 16 GB of root file system usage requires at least 32 GB of RAM

Once the OS disk encryption process is complete on Linux virtual machines, the VM can be configured to run with less memory.

For more exceptions, see Azure Disk Encryption: Restrictions.

Supported operating systems

Azure Disk Encryption is supported on a subset of the Azure-endorsed Linux distributions, which is itself a subset of all Linux server possible distributions.



Linux server distributions that are not endorsed by Azure do not support Azure Disk Encryption; of those that are endorsed, only the following distributions and versions support Azure Disk Encryption:

* For image versions greater than or equal to May 2023.

> ⓘ **Note**
>
> RHEL:
>
> - The new Azure Disk Encryption implementation is supported for RHEL OS and data disk for RHEL7 pay-as-you-go images.
> - ADE is also supported for RHEL Bring-Your-Own-Subscription Gold Images, but only **after** the subscription has been registered . For more information, see Red Hat Enterprise Linux Bring-Your-Own-Subscription Gold Images in Azure
>
> All distros:
>
> - ADE support for a particular offer type does not extend beyond the end-of-life date provided by the publisher.
> - The legacy ADE solution (using Microsoft Entra credentials) is not recommended for new VMs and is not compatible with RHEL versions later than RHEL 7.8 or with Python 3 as default.

Additional VM requirements

Azure Disk Encryption requires the dm-crypt and vfat modules to be present on the system. Removing or disabling vfat from the default image will prevent the system from reading the

key volume and obtaining the key needed to unlock the disks on subsequent reboots. System hardening steps that remove the vfat module from the system or enforce expanding the OS mountpoints/folders on data drives are not compatible with Azure Disk Encryption.

Before enabling encryption, the data disks to be encrypted must be properly listed in /etc/fstab. Use the "nofail" option when creating entries, and choose a persistent block device name (as device names in the "/dev/sdX" format may not be associated with the same disk across reboots, particularly after encryption; for more detail on this behavior, see: Troubleshoot Linux VM device name changes).

Make sure the /etc/fstab settings are configured properly for mounting. To configure these settings, run the mount -a command or reboot the VM and trigger the remount that way. Once that is complete, check the output of the lsblk command to verify that the drive is still mounted.

- If the /etc/fstab file doesn't mount the drive properly before enabling encryption, Azure Disk Encryption won't be able to mount it properly.
- The Azure Disk Encryption process will move the mount information out of /etc/fstab and into its own configuration file as part of the encryption process. Don't be alarmed to see the entry missing from /etc/fstab after data drive encryption completes.
- Before starting encryption, be sure to stop all services and processes that could be writing to mounted data disks and disable them, so that they do not restart automatically after a reboot. These could keep files open on these partitions, preventing the encryption procedure to remount them, causing failure of the encryption.
- After reboot, it will take time for the Azure Disk Encryption process to mount the newly encrypted disks. They won't be immediately available after a reboot. The process needs time to start, unlock, and then mount the encrypted drives before being available for other processes to access. This process may take more than a minute after reboot depending on the system characteristics.

Here is an example of the commands used to mount the data disks and create the necessary /etc/fstab entries:

Bash

```
sudo UUID0="$(blkid -s UUID -o value /dev/sda1)"
sudo UUID1="$(blkid -s UUID -o value /dev/sda2)"
sudo mkdir /data0
sudo mkdir /data1
sudo echo "UUID=$UUID0 /data0 ext4 defaults,nofail 0 0" >>/etc/fstab
sudo echo "UUID=$UUID1 /data1 ext4 defaults,nofail 0 0" >>/etc/fstab
sudo mount -a
```

Networking requirements

To enable the Azure Disk Encryption feature, the Linux VMs must meet the following network endpoint configuration requirements:

- The Linux VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the Internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see Azure Key Vault behind a firewall.

Encryption key storage requirements

Azure Disk Encryption requires an Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For details, see Creating and configuring a key vault for Azure Disk Encryption.

Terminology

The following table defines some of the common terms used in Azure disk encryption documentation:

Expand table

Terminology	Definition
Azure Key Vault	Key Vault is a cryptographic, key management service that's based on Federal Information Processing Standards (FIPS) validated hardware security modules. These standards help to safeguard your cryptographic keys and sensitive secrets. For more information, see the Azure Key Vault documentation and Creating and configuring a key vault for Azure Disk Encryption.
Azure CLI	The Azure CLI is optimized for managing and administering Azure resources from the command line.
DM-Crypt	DM-Crypt is the Linux-based, transparent disk-encryption subsystem that's used to enable disk encryption on Linux VMs.
Key encryption key (KEK)	The asymmetric key (RSA 2048) that you can use to protect or wrap the secret. You can provide a hardware security module (HSM)-protected key or software-protected key. For more information, see the Azure Key Vault documentation and Creating and configuring a key vault for Azure Disk Encryption.

Terminology	Definition
PowerShell cmdlets	For more information, see Azure PowerShell cmdlets.

Quickstart: Create and encrypt a Linux VM with the Azure CLI

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. This quickstart shows you how to use the Azure CLI to create and encrypt a Linux virtual machine (VM).

If you don't have an Azure subscription, create a free account before you begin.

If you choose to install and use the Azure CLI locally, this quickstart requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Create a resource group

Create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

Azure CLI

```
az group create --name "myResourceGroup" --location "eastus"
```

Create a virtual machine

Create a VM with az vm create. The following example creates a VM named *myVM*.

Azure CLI

```
az vm create \
    --resource-group "myResourceGroup" \
    --name "myVM" \
    --image "Canonical:UbuntuServer:20.04-LTS:latest" \
    --size "Standard_D2S_V3"\
    --generate-ssh-keys
```

> **Note**
>
> Any ADE supported Linux image version could be used instead of an Ubuntu VM. Replace `Canonical:UbuntuServer:20.04-LTS:latest` accordingly.

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

JSON

```
{
  "fqdns": "",
  "id":
"/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroup"
}
```

Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with az keyvault create. To enable the Key Vault to store encryption keys, use the `--enabled-for-disk-encryption` parameter.

> **Important**
>
> Every key vault must have a name that is unique across Azure. Replace <your-unique-keyvault-name> with the name you choose.

Azure CLI

```
az keyvault create --name "<your-unique-keyvault-name>" --resource-group
"myResourceGroup" --location "eastus" --enabled-for-disk-encryption
```

Encrypt the virtual machine

Encrypt your VM with az vm encryption, providing your unique Key Vault name to the `--disk-encryption-keyvault parameter.

Azure CLI

```
az vm encryption enable -g "MyResourceGroup" --name "myVM" --disk-encryption-
keyvault "<your-unique-keyvault-name>"
```

After a moment the process returns, "The encryption request was accepted. Use 'show' command to monitor the progress.". The "show" command is az vm show.

Azure CLI

```
az vm encryption show --name "myVM" -g "MyResourceGroup"
```

When encryption is enabled, you will see "EnableEncryption" in the returned output:

Output

```
"EncryptionOperation": "EnableEncryption"
```

Clean up resources

When no longer needed, you can use the az group delete command to remove the resource group, VM, and Key Vault.

Azure CLI

```
az group delete --name "myResourceGroup"
```

Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enabled for encryption keys, and encrypted the VM. Advance to the next article to learn more about more Azure Disk Encryption for Linux VMs.

Azure Disk Encryption overview

Last updated on 10/10/2025

Quickstart: Create and encrypt a Linux VM in Azure with Azure PowerShell

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to create a Linux virtual machine (VM), create a Key Vault for the storage of encryption keys, and encrypt the VM. This quickstart uses the Ubuntu 16.04 LTS marketplace image from Canonical and a VM Standard_D2S_V3 size. However, any ADE supported Linux image version could be used instead of an Ubuntu VM.

If you don't have an Azure subscription, create a free account before you begin.

Create a resource group

Create an Azure resource group with New-AzResourceGroup. A resource group is a logical container into which Azure resources are deployed and managed:

Azure PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

Create a virtual machine

Create an Azure virtual machine with New-AzVM, passing it to the VM configuration object you created in the previous step.

PowerShell

```
$cred = Get-Credential

New-AzVM -Name MyVm -Credential $cred -ResourceGroupName MyResourceGroup -Image
Canonical:UbuntuServer:18.04-LTS:latest -Size Standard_D2S_V3
```

It takes a few minutes for your VM to be deployed.

Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with New-AzKeyvault. To enable the Key Vault to store encryption keys, use the -EnabledForDiskEncryption parameter.

> **Important**
>
> Every key vault must have a name that is unique across Azure. In the following examples, replace <your-unique-keyvault-name> with the name you choose.

Azure PowerShell

```
New-AzKeyvault -name "<your-unique-keyvault-name>" -ResourceGroupName
"myResourceGroup" -Location EastUS -EnabledForDiskEncryption
```

Encrypt the virtual machine

Encrypt your VM with Set-AzVmDiskEncryptionExtension.

Set-AzVmDiskEncryptionExtension requires some values from your Key Vault object. You can obtain these values by passing the unique name of your key vault to Get-AzKeyvault.

Azure PowerShell

```
$KeyVault = Get-AzKeyVault -VaultName "<your-unique-keyvault-name>" -
ResourceGroupName "MyResourceGroup"

Set-AzVMDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName "MyVM" -
DiskEncryptionKeyVaultUrl $KeyVault.VaultUri -DiskEncryptionKeyVaultId
$KeyVault.ResourceId -SkipVmBackup -VolumeType All
```

After a few minutes the process returns:

Output

```
RequestId IsSuccessStatusCode StatusCode ReasonPhrase
--------- ------------------- ---------- ------------
                         True         OK OK
```

You can verify the encryption process by running Get-AzVmDiskEncryptionStatus.

Azure PowerShell

```
Get-AzVmDiskEncryptionStatus -VMName MyVM -ResourceGroupName MyResourceGroup
```

When encryption is enabled, you see this information in the returned output:

Output

```
OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : NotMounted
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : OS disk encryption started
```

Clean up resources

When no longer needed, you can use the Remove-AzResourceGroup cmdlet to remove the resource group, VM, and all related resources:

Azure PowerShell

```
Remove-AzResourceGroup -Name "myResourceGroup"
```

Next steps

In this quickstart you created a virtual machine, created a Key Vault enabled for encryption keys, and encrypted the VM. Advance to the next article to learn more about Azure Disk Encryption for Linux VMs.

Azure Disk Encryption overview

Last updated on 10/10/2025

Quickstart: Create and encrypt a virtual machine with the Azure portal

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure virtual machines (VMs) can be created through the Azure portal. The Azure portal is a browser-based user interface to create VMs and their associated resources. In this quickstart you'll use the Azure portal to deploy a Linux virtual machine (VM) running Ubuntu 18.04 LTS, create a key vault for the storage of encryption keys, and encrypt the VM. However, any ADE supported Linux image version could be used instead of an Ubuntu VM.

If you don't have an Azure subscription, create a free account before you begin.

Sign in to Azure

Sign in to the Azure portal.

Create a virtual machine

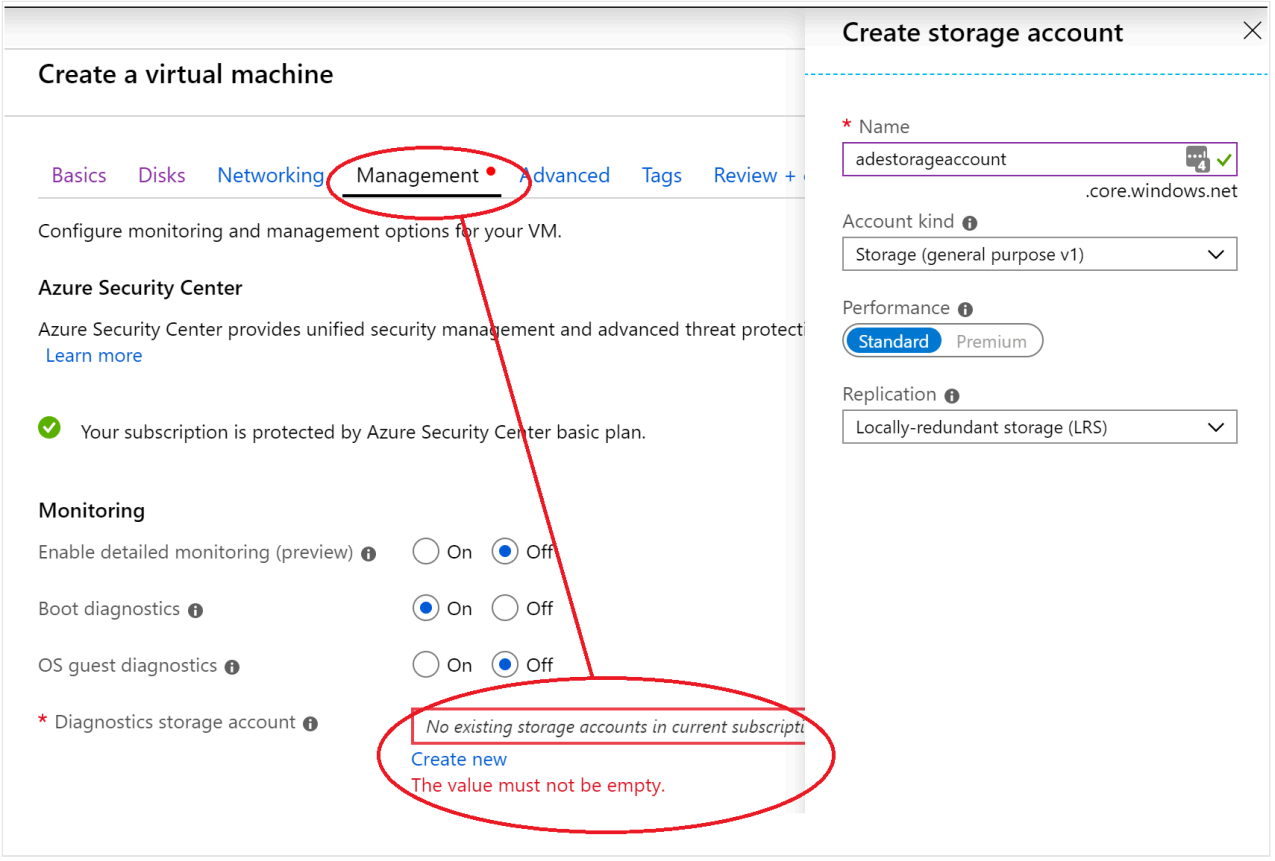
1. Choose **Create a resource** in the upper left corner of the Azure portal.
2. In the New page, under Popular, select **Ubuntu Server 18.04 LTS**.
3. In the Basics tab, under Project details, verify sure the correct subscription is selected.
4. For "Resource Group", select **Create new**. Enter *myResourceGroup* as the name and select **Ok**.
5. For **Virtual machine name**, enter *MyVM*.
6. For **Region**, select *(US) East US*.

7. Make sure the **Size** is *Standard D2s v3*.

8. Under **Administrator account**, select *Password* as the **Authentication type**. Enter a user name and a password.

> ⚠ **Warning**
>
> The "Disks" tab features an "Encryption Type" field under **Disk options**. This field is used to specify encryption options for Managed Disks + CMK, **not** for Azure Disk Encryption.
>
> To avoid confusion, we suggest you skip the *Disks* tab entirely while completing this tutorial.

9. Select the "Monitoring" tab and verify that you have a Diagnostics Storage Account. If you have no storage accounts, select *Create New*, name your storage account *myStorageAccount*, and select "Ok"



10. Select "Review + Create".

11. On the **Create a virtual machine** page, you can see the details about the VM you are about to create. When you are ready, select **Create**.

It takes a few minutes for your VM to be deployed. When the deployment is finished, move on to the next section.

Encrypt the virtual machine

1. When the VM deployment is complete, select **Go to resource**.
2. On the left-hand sidebar, select **Disks**.
3. On the top bar, select **Additional Settings** .
4. Under **Encryption settings** > **Disks to encrypt**, select **OS and data disks**.

   Screenshot that highlights OS and data disks.
5. Under **Encryption settings**, choose **Select a key vault and key for encryption**.
6. On the **Select key from Azure Key Vault** screen, select **Create New**.

      Screenshot that highlights Create new.
7. To the left of **Key vault and key**, select **Click to select a key**.
8. On the **Select key from Azure Key Vault**, under the **Key Vault** field, select **Create new**.
9. On the **Create key vault** screen, ensure that the Resource Group is *myResourceGroup*, and give your key vault a name. Every key vault across Azure must have a unique name.
10. On the **Access Policies** tab, check the **Azure Disk Encryption for volume encryption** box.

    disks and encryption selection
11. Select **Review + create**.
12. After the key vault passes validation, select **Create**. This returns you to the **Select key from Azure Key Vault** screen.
13. Leave the **Key** field blank and choose **Select**.
14. At the top of the encryption screen, click **Save**. A popup will warn you that the VM will reboot. Select **Yes**.

Clean up resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources. To do so, select the resource group for the virtual machine, select Delete, then

confirm the name of the resource group to delete.

Next steps

In this quickstart, you created a Key Vault that was enabled for encryption keys, created a virtual machine, and enabled the virtual machine for encryption.

Azure Disk Encryption overview

Last updated on 11/20/2025

Azure Disk Encryption scenarios on Linux VMs

Summarize this article for me

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure Disk Encryption for Linux virtual machines (VMs) uses the DM-Crypt feature of Linux to provide full disk encryption of the OS disk and data disks. Additionally, it provides encryption of the temporary disk when using the EncryptFormatAll feature.

Azure Disk Encryption is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets. For an overview of the service, see Azure Disk Encryption for Linux VMs.

Prerequisites

You can only apply disk encryption to virtual machines of supported VM sizes and operating systems. You must also meet the following prerequisites:

- Requirements for VMs
- Networking requirements
- Encryption key storage requirements

In all cases, you should take a snapshot and/or create a backup before disks are encrypted. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. Once a backup is made, you can use the Set-AzVMDiskEncryptionExtension cmdlet to encrypt managed disks by specifying the -skipVmBackup parameter. For more information about how to back up and restore encrypted VMs, see the Azure Backup article.

Restrictions

If you previously used Azure Disk Encryption with Microsoft Entra ID to encrypt a virtual machine, you must continue use this option to encrypt your virtual machine. See Azure Disk Encryption with Microsoft Entra ID (previous release) for details.

When encrypting Linux OS volumes, the VM should be considered unavailable. We strongly recommend to avoid SSH logins while the encryption is in progress to avoid issues blocking any open files that need to be accessed during the encryption process. To check progress, use the Get-AzVMDiskEncryptionStatus PowerShell cmdlet or the vm encryption show CLI command. This process can be expected to take a few hours for a 30GB OS volume, plus extra time for encrypting data volumes. Data volume encryption time is proportional to the size and quantity of the data volumes unless the encrypt format all option is used.

Disabling encryption on Linux VMs is only supported for data volumes. Disabling encryption is not supported on data or OS volumes if the OS volume is encrypted.

Azure Disk Encryption does not work for the following Linux scenarios, features, and technology:

- Encrypting basic tier VM or VMs created through the classic VM creation method.
- Encrypting v6 series VMs with temporary disks (Ddsv6, Dldsv6, Edsv6, Dadsv6, Daldsv6, Eadsv6, Dpdsv6, Dpldsv6, Epdsv6, or Endsv6). For more information, see the individual pages for each of these VM sizes listed on Sizes for virtual machines in Azure
- Encrypting V7 series and newer VM sizes.
- Disabling encryption on an OS drive or data drive of a Linux VM when the OS drive is encrypted.
- Encrypting the OS drive for Linux Virtual Machine Scale Sets.
- Encrypting custom images on Linux VMs.
- Integration with an on-premises key management system.
- Azure Files (shared file system).
- Network File System (NFS).
- Dynamic volumes.
- Ephemeral OS disks.
- Encryption of shared/distributed file systems like (but not limited to): DFS, GFS, DRDB, and CephFS.
- Moving an encrypted VM to another subscription or region.
- Creating an image or snapshot of an encrypted VM and using it to deploy more VMs.
- Kernel Crash Dump (kdump).
- Oracle ACFS (ASM Cluster File System).
- NVMe disks such as those on High performance computing VM sizes or Storage optimized VM sizes.

- A VM with "nested mount points"; that is, multiple mount points in a single path (such as "/1stmountpoint/data/2ndmountpoint").
- A VM with a data drive mounted on top of an OS folder.
- A VM on which a root (OS disk) logical volume is extended using a data disk.
- Resizing of the OS disk.
- 'L' family storage optimized VM size series.
- M-series VMs with Write Accelerator disks.
- Applying ADE to a VM that has disks encrypted with Encryption at Host or server-side encryption with customer-managed keys (SSE + CMK). Applying SSE + CMK to a data disk or adding a data disk with SSE + CMK configured to a VM encrypted with ADE is an unsupported scenario as well.
- Migrating a VM that is encrypted with ADE, or was **ever** encrypted with ADE, to Encryption at Host or server-side encryption with customer-managed keys.
- Encrypting VMs in failover clusters.
- Encryption of Azure Ultra Disks.
- Encryption of Premium SSD v2 disks.
- Encryption of VMs in subscriptions that have the Secrets should have the specified maximum validity period policy enabled with the DENY effect.

Install tools and connect to Azure

Azure Disk Encryption can be enabled and managed through the Azure CLI and Azure PowerShell. To do so, you must install the tools locally and connect to your Azure subscription.

Azure CLI

The Azure CLI 2.0 is a command-line tool for managing Azure resources. The CLI is designed to flexibly query data, support long-running operations as non-blocking processes, and make scripting easy. You can install it locally by following the steps in Install the Azure CLI.

To Sign in to your Azure account with the Azure CLI, use the az login command.

Azure CLI

```
az login
```

If you would like to select a tenant to sign in under, use:

Azure CLI

```
az login --tenant <tenant>
```

If you have multiple subscriptions and want to specify a specific one, get your subscription list with az account list and specify with az account set.

Azure CLI

```
az account list
az account set --subscription "<subscription name or ID>"
```

For more information, see Get started with Azure CLI 2.0.

Enable encryption on an existing or running Linux VM

In this scenario, you can enable encryption by using the Resource Manager template, PowerShell cmdlets, or CLI commands. If you need schema information for the virtual machine extension, see the Azure Disk Encryption for Linux extension article.

> **ⓘ Important**
>
> It is mandatory to snapshot and/or backup a managed disk based VM instance outside of, and before enabling Azure Disk Encryption. A snapshot of the managed disk can be taken from the portal, or through Azure Backup. Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. Once a backup is made, the Set-AzVMDiskEncryptionExtension cmdlet can be used to encrypt managed disks by specifying the -skipVmBackup parameter. The Set-AzVMDiskEncryptionExtension command fails against managed disk based VMs until a backup is made and this parameter is specified.
>
> Encrypting or disabling encryption may cause the VM to reboot.

To disable the encryption, see Disable encryption and remove the encryption extension.

Using Azure CLI

You can enable disk encryption on your encrypted VHD by installing and using the Azure CLI command-line tool. You can use it in your browser with Azure Cloud Shell, or you can install it on your local machine and use it in any PowerShell session. To enable encryption on existing or running Linux VMs in Azure, use the following CLI commands:

Use the az vm encryption enable command to enable encryption on a running virtual machine in Azure.

- **Encrypt a running VM:**

  Azure CLI

  ```
  az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type [All|OS|Data]
  ```

- **Encrypt a running VM using KEK:**

  Azure CLI

  ```
  az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault  "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
  ```

  > **Note**
  >
  > The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
  > The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of a VM, use the az vm encryption show command.

  Azure CLI

  ```
  az vm encryption show --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup"
  ```

To disable the encryption, see Disable encryption and remove the encryption extension.

Use EncryptFormatAll feature for data disks on Linux VMs

The **EncryptFormatAll** parameter reduces the time for Linux data disks to be encrypted. Partitions meeting certain criteria are formatted, along with their current file systems, then remounted back to where they were before command execution. If you wish to exclude a data disk that meets the criteria, you can unmount it before running the command.

After running this command, any drives that were mounted previously are formatted, and the encryption layer will be started on top of the now empty drive. When this option is selected, the temporary disk attached to the VM is also encrypted. If the temporary disk is reset, Azure Disk Encryption will reformat and re-encrypt the VM's temporary disk at the next opportunity. Once the resource disk is encrypted, the Microsoft Azure Linux Agent is not able to manage the resource disk and enable the swap file, but you may manually configure the swap file.

> ⚠ **Warning**
>
> EncryptFormatAll shouldn't be used when there is needed data on a VM's data volumes. You may exclude disks from encryption by unmounting them. You should first try out the EncryptFormatAll first on a test VM, understand the feature parameter and its implication before trying it on the production VM. The EncryptFormatAll option formats the data disk and all the data on it will be lost. Before proceeding, verify that disks you wish to exclude are properly unmounted.
>
> If you're setting this parameter while updating encryption settings, it might lead to a reboot before the actual encryption. In this case, you should remove the disk you don't want formatted from the fstab file. Similarly, you should add the partition you want encrypt-formatted to the fstab file before initiating the encryption operation.

EncryptFormatAll criteria

The parameter goes through all partitions and encrypts them as long as they meet **all** of the criteria below:

- Is not a root/OS/boot partition
- Is not already encrypted
- Is not a BEK volume
- Is not a RAID volume
- Is not an LVM volume
- Is mounted

Encrypt the disks that compose the RAID or LVM volume rather than the RAID or LVM volume.

Use the EncryptFormatAll parameter with Azure CLI

Use the az vm encryption enable command to enable encryption on a running virtual machine in Azure.

- **Encrypt a running VM using EncryptFormatAll:**

  Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type "data" --encrypt-format-all
```

Use the EncryptFormatAll parameter with Logical Volume Manager (LVM)

We recommend an LVM-on-crypt setup. For detailed instructions about the LVM on crypt configuration, see Configure LVM and RAID on ADE encrypted devices.

New VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can enable encrypting by using PowerShell cmdlets or CLI commands.

Use the instructions in the Azure Disk encryption same scripts for preparing pre-encrypted images that can be used in Azure. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

- Prepare a pre-encrypted Linux VHD

> ⓘ **Important**
>
> It is mandatory to snapshot and/or backup a managed disk based VM instance outside of, and before enabling Azure Disk Encryption. A snapshot of the managed disk can be taken from the portal, or **Azure Backup** can be used. Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. Once a backup is made, the Set-AzVMDiskEncryptionExtension cmdlet can be used to encrypt managed disks by specifying the -skipVmBackup parameter. The Set-AzVMDiskEncryptionExtension

command fails against managed disk based VMs until a backup is made and this parameter is specified.

Encrypting or disabling encryption may cause the VM to reboot.

Use Azure PowerShell to encrypt VMs with pre-encrypted VHDs

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet Set-AzVMOSDisk. This example gives you some common parameters.

Azure PowerShell

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri
"os.vhd" Caching ReadWrite -Linux -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaaa
" -DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myresourcegroup/providers/Microsoft.KeyVault/vaults/myt
estvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

Enable encryption on a newly added data disk

You can add a new data disk using az vm disk attach, or through the Azure portal. Before you can encrypt, you need to mount the newly attached data disk first. You must request encryption of the data drive since the drive is not usable while encryption is in progress.

Using Azure CLI

If the VM was previously encrypted with "All", then the --volume-type parameter should remain "All". All includes both OS and data disks. If the VM was previously encrypted with a volume type of "OS", then the --volume-type parameter should be changed to "All" so that both the OS and the new data disk are included. If the VM was encrypted with only the volume type of "Data", then it can remain "Data" as demonstrated below. Adding and attaching a new data disk to a VM is not sufficient preparation for encryption. The newly attached disk must also be formatted and properly mounted within the VM before enabling encryption. On Linux, the disk must be mounted in /etc/fstab with a persistent block device name.

In contrast to PowerShell syntax, the CLI does not require the user to provide a unique sequence version when enabling encryption. The CLI automatically generates and uses its

own unique sequence version value.

- **Encrypt data volumes of a running VM:**

  Azure CLI

  ```
  az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type "Data"
  ```

- **Encrypt data volumes of a running VM using KEK:**

  Azure CLI

  ```
  az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault  "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type "Data"
  ```

Disable encryption and remove the encryption extension

You can disable the Azure disk encryption, and you can remove the Azure disk encryption extension. Disabling and removing are two distinct operations.

To remove ADE, it is recommended that you first disable encryption, and then remove the extension. If you remove the encryption extension without disabling ADE, the disks remain encrypted. If you disable encryption **after** removing the extension, the extension will be reinstalled (to perform the decrypt operation) and will need to be removed a second time.

> ⚠ **Warning**
>
> You can **not** disable encryption if the OS disk is encrypted. (OS disks are encrypted when the original encryption operation specifies volumeType=ALL or volumeType=OS.)
>
> Disabling encryption works only when data disks are encrypted but the OS disk is not.

Disable encryption

You can disable encryption using Azure PowerShell, the Azure CLI, or with a Resource Manager template. Disabling encryption does **not** remove the extension (see Remove the encryption

extension).

- **Disable disk encryption with Azure PowerShell:** To disable the encryption, use the Disable-AzVMDiskEncryption cmdlet.

  Azure PowerShell

  ```
  Disable-AzVMDiskEncryption -ResourceGroupName "MyVirtualMachineResourceGroup"
  -VMName "MySecureVM" -VolumeType "data"
  ```

- **Disable encryption with the Azure CLI:** To disable encryption, use the az vm encryption disable command.

  Azure CLI

  ```
  az vm encryption disable --name "MySecureVM" --resource-group
  "MyVirtualMachineResourceGroup" --volume-type "data"
  ```

- **Disable encryption with a Resource Manager template:**

  1. Click **Deploy to Azure** from the Disable disk encryption on running Linux VM template.
  2. Select the subscription, resource group, location, VM, volume type, legal terms, and agreement.
  3. Click **Purchase** to disable disk encryption on a running Linux VM.

> ⚠ **Warning**
>
> Once decryption starts, it is advisable not to interfere with the process.
>
> To check the progress of decryption, use the **Get-AzVMDiskEncryptionStatus** PowerShell cmdlet or the **az vm encryption show** CLI command, once the decryption process is completed, you can proceed to remove the encryption extension

Remove the encryption extension

If you want to decrypt your disks and remove the encryption extension, you must disable encryption **before** removing the extension; see disable encryption.

You can remove the encryption extension using Azure PowerShell or the Azure CLI.

- **Disable disk encryption with Azure PowerShell:** To remove the encryption, use the Remove-AzVMDiskEncryptionExtension cmdlet.

Azure PowerShell

```
Remove-AzVMDiskEncryptionExtension -ResourceGroupName
"MyVirtualMachineResourceGroup" -VMName "MySecureVM"
```

- **Disable encryption with the Azure CLI:** To remove encryption, use the az vm extension delete command.

Azure CLI

```
az vm extension delete -g "MyVirtualMachineResourceGroup" --vm-name
"MySecureVM" -n "AzureDiskEncryptionForLinux"
```

Creating and configuring a key vault for Azure Disk Encryption

09/23/2025

> **ⓘ Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see Get started with Azure Key Vault and Secure your key vault.

> **⚠ Warning**
>
> - If you have previously used Azure Disk Encryption with Microsoft Entra ID to encrypt a VM, you must continue to use this option to encrypt your VM. See Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release) for details.

Creating and configuring a key vault for use with Azure Disk Encryption involves three steps:

1. Creating a resource group, if needed.
2. Creating a key vault.
3. Setting key vault advanced access policies.

These steps are illustrated in the following quickstarts:

- Create and encrypt a Linux VM with Azure CLI
- Create and encrypt a Linux VM with Azure PowerShell

You may also, if you wish, generate or import a key encryption key (KEK).

> **ⓘ Note**

The steps in this article are automated in the Azure Disk Encryption prerequisites CLI script and Azure Disk Encryption prerequisites PowerShell script.

Install tools and connect to Azure

The steps in this article can be completed with the Azure CLI, the Azure PowerShell Az PowerShell module module, or the Azure portal.

While the portal is accessible through your browser, Azure CLI and Azure PowerShell require local installation; see Azure Disk Encryption for Linux: Install tools for details.

Connect to your Azure account

Before using the Azure CLI or Azure PowerShell, you must first connect to your Azure subscription. You do so by Signing in with Azure CLI, Signing in with Azure PowerShell, or supplying your credentials to the Azure portal when prompted.

Azure CLI

```
az login
```

Azure PowerShell

```
Connect-AzAccount
```

Create a resource group

If you already have a resource group, you can skip to Create a key vault.

A resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group using the az group create Azure CLI command, the New-AzResourceGroup Azure PowerShell command, or from the Azure portal.

Azure portal

Azure CLI

Azure CLI

```
az group create --name "myResourceGroup" --location eastus
```

Azure PowerShell

Azure PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

Create a key vault

If you already have a key vault, you can skip to Set key vault advanced access policies.

Create a key vault using the az keyvault create Azure CLI command, the New-AzKeyvault Azure PowerShell command, the Azure portal, or a Resource Manager template.

> ⚠ **Warning**
>
> To ensure that encryption secrets don't cross regional boundaries, you must create and use a key vault that's in the **same region and tenant** as the VMs to be encrypted.

Each Key Vault must have a unique name. Replace <your-unique-keyvault-name> with the name of your key vault in the following examples.

Azure CLI

When creating a key vault by using the Azure CLI, add the "--enabled-for-disk-encryption" flag.

Azure CLI

```
az keyvault create --name "<your-unique-keyvault-name>" --resource-group
"myResourceGroup" --location "eastus" --enabled-for-disk-encryption
```

Azure PowerShell

When creating a key vault using Azure PowerShell, add the "-EnabledForDiskEncryption" flag.

Azure PowerShell

```
New-AzKeyvault -name "<your-unique-keyvault-name>" -ResourceGroupName
"myResourceGroup" -Location "eastus" -EnabledForDiskEncryption
```

Resource Manager template

You can also create a key vault by using the Resource Manager template.

1. On the Azure Quickstart Template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then click **Purchase**.

Set key vault advanced access policies

> **Important**
>
> Newly-created key vaults have soft-delete on by default. If you are using a pre-existing key vault, you **must** enable soft-delete. See Azure Key Vault soft-delete overview.

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes.

If you didn't enable your key vault for disk encryption, deployment, or template deployment at the time of creation (as demonstrated in the previous step), you must update its advanced access policies.

Azure CLI

Use az keyvault update to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

  Azure CLI

  ```
  az keyvault update --name "<your-unique-keyvault-name>" --resource-group
  "MyResourceGroup" --enabled-for-disk-encryption "true"
  ```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

Azure CLI

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group
"MyResourceGroup" --enabled-for-deployment "true"
```

- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

Azure CLI

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group
"MyResourceGroup" --enabled-for-template-deployment "true"
```

Azure PowerShell

Use the key vault PowerShell cmdlet Set-AzKeyVaultAccessPolicy to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

Azure PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -
ResourceGroupName "MyResourceGroup" -EnabledForDiskEncryption
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

Azure PowerShell

```
 Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -
ResourceGroupName "MyResourceGroup" -EnabledForDeployment
```

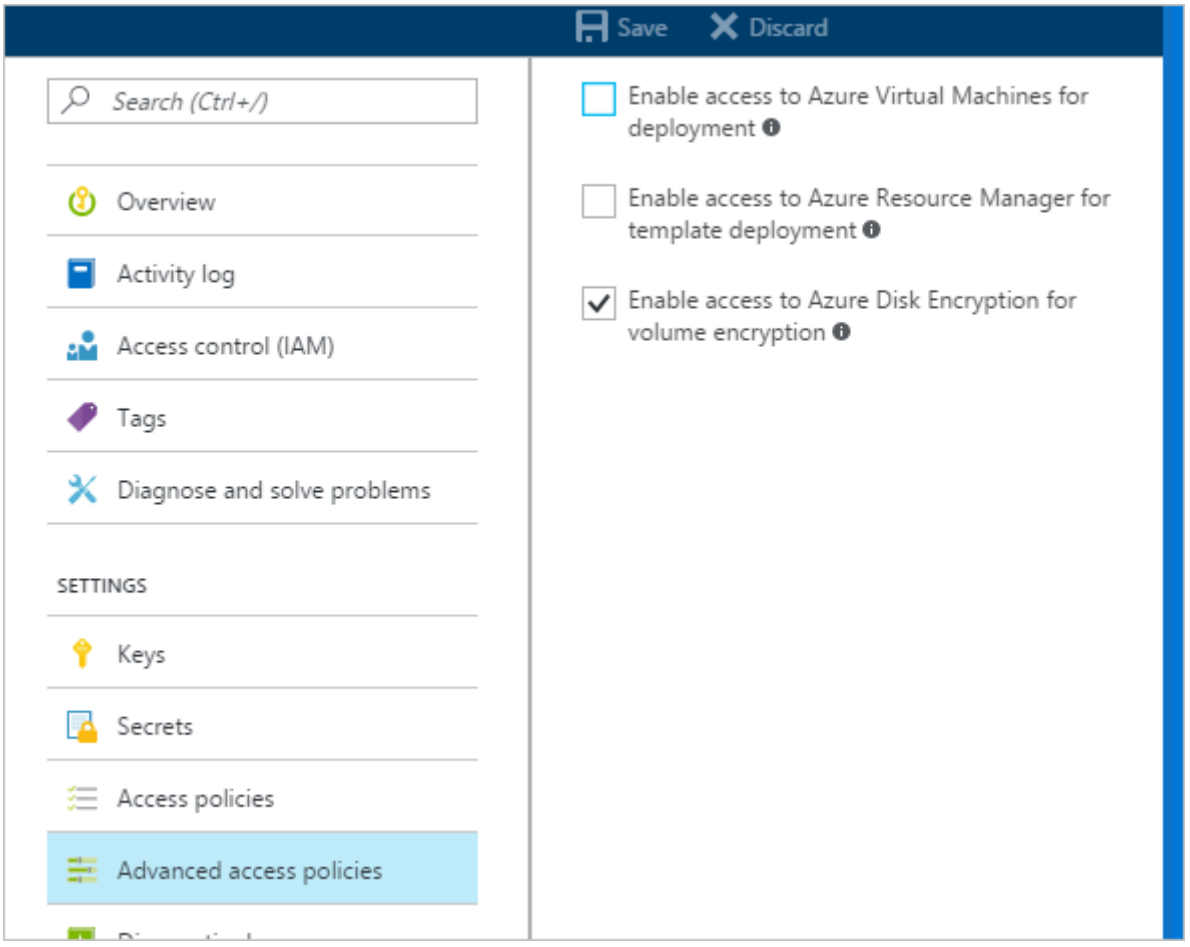
- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

Azure PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -
ResourceGroupName "MyResourceGroup" -EnabledForTemplateDeployment
```

Azure portal

1. Select your key vault and go to **Access Policies**.
2. Under "Enable Access to", select the box labeled **Azure Disk Encryption for volume encryption**.
3. Select **Azure Virtual Machines for deployment** and/or **Azure Resource Manager for template deployment**, if needed.
4. Click **Save**.



Azure Disk Encryption and auto-rotation

Although Azure Key Vault now has key auto-rotation, it isn't currently compatible with Azure Disk Encryption. Specifically, Azure Disk Encryption will continue to use the original encryption key, even after it has been auto-rotated.

Rotating an encryption key won't break Azure Disk Encryption, but disabling the "old" encryption key (in other words, the key Azure Disk Encryption is still using) will.

Set up a key encryption key (KEK)

> **Important**
>
> The account running to enable disk encryption over the key vault must have "reader" permissions.

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

You can generate a new KEK by using the Azure CLI az keyvault key create command, the Azure PowerShell Add-AzKeyVaultKey cmdlet, or the Azure portal. You must generate an RSA key type; Azure Disk Encryption doesn't currently support using Elliptic Curve keys.

You can instead import a KEK from your on-premises key management HSM. For more information, see Key Vault Documentation.

Your key vault KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:

- Example of a valid secret URL: `https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx`
- Example of a valid KEK URL: `https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx`

Azure CLI

Use the Azure CLI az keyvault key create command to generate a new KEK and store it in your key vault.

Azure CLI

```
az keyvault key create --name "myKEK" --vault-name "<your-unique-keyvault-name>" --kty RSA --size 4096
```

You may instead import a private key by using the Azure CLI az keyvault key import command:

In either case, you supply the name of your KEK to the Azure CLI az vm encryption enable --key-encryption-key parameter.

Azure CLI

```
az vm encryption enable -g "MyResourceGroup" --name "myVM" --disk-encryption-keyvault "<your-unique-keyvault-name>" --key-encryption-key "myKEK"
```

Azure PowerShell

Use the Azure PowerShell Add-AzKeyVaultKey cmdlet to generate a new KEK and store it in your key vault.

PowerShell

```
Add-AzKeyVaultKey -Name "myKEK" -VaultName "<your-unique-keyvault-name>" -Destination "HSM" -Size 4096
```

You may instead import a private key using the Azure PowerShell az keyvault key import command.

In either case, you will supply the ID of your KEK key Vault and the URL of your KEK to the Azure PowerShell Set-AzVMDiskEncryptionExtension -KeyEncryptionKeyVaultId and -KeyEncryptionKeyUrl parameters. This example assumes that you are using the same key vault for both the disk encryption key and the KEK.

PowerShell

```
$KeyVault = Get-AzKeyVault -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "myResourceGroup"
$KEK = Get-AzKeyVaultKey -VaultName "<your-unique-keyvault-name>" -Name "myKEK"

Set-AzVMDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName "MyVM" -DiskEncryptionKeyVaultUrl $KeyVault.VaultUri -DiskEncryptionKeyVaultId $KeyVault.ResourceId -KeyEncryptionKeyVaultId $KeyVault.ResourceId -KeyEncryptionKeyUrl $KEK.Id -SkipVmBackup -VolumeType All
```

Azure Disk Encryption sample scripts for Linux VMs

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

> **Caution**
>
> This article references CentOS, a Linux distribution that is End Of Life (EOL) status. Please consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article provides sample scripts for preparing pre-encrypted VHDs and other tasks.

> **Note**
>
> All scripts refer to the latest, non-AAD version of ADE, except where noted.

Sample PowerShell scripts for Azure Disk Encryption

- **List all encrypted VMs in your subscription**

  You can find all ADE-encrypted VMs and the extension version, in all resource groups present in a subscription, using this PowerShell script.

  Alternatively, these cmdlets will show all ADE-encrypted VMs (but not the extension version):

  ```
  Azure PowerShell
  ```

```
$osVolEncrypted = {(Get-AzVMDiskEncryptionStatus -ResourceGroupName
$_.ResourceGroupName -VMName $_.Name).OsVolumeEncrypted}
$dataVolEncrypted= {(Get-AzVMDiskEncryptionStatus -ResourceGroupName
$_.ResourceGroupName -VMName $_.Name).DataVolumesEncrypted}
Get-AzVm | Format-Table @{Label="MachineName"; Expression={$_.Name}},
@{Label="OsVolumeEncrypted"; Expression=$osVolEncrypted},
@{Label="DataVolumesEncrypted"; Expression=$dataVolEncrypted}
```

- **List all encrypted VMSS instances in your subscription**

  You can find all ADE-encrypted VMSS instances and the extension version, in all resource groups present in a subscription, using this PowerShell script.

- **List all disk encryption secrets used for encrypting VMs in a key vault**

  Azure PowerShell

```
Get-AzKeyVaultSecret -VaultName $KeyVaultName | where
{$_.Tags.ContainsKey('DiskEncryptionKeyFileName')} | format-table
@{Label="MachineName"; Expression={$_.Tags['MachineName']}},
@{Label="VolumeLetter"; Expression={$_.Tags['VolumeLetter']}},
@{Label="EncryptionKeyURL"; Expression={$_.Id}}
```

Using the Azure Disk Encryption prerequisites PowerShell script

If you're already familiar with the prerequisites for Azure Disk Encryption, you can use the Azure Disk Encryption prerequisites PowerShell script. For an example of using this PowerShell script, see the Encrypt a VM Quickstart. You can remove the comments from a section of the script, starting at line 211, to encrypt all disks for existing VMs in an existing resource group.

The following table shows which parameters can be used in the PowerShell script:

Expand table

Parameter	Description	Mandatory?
$resourceGroupName	Name of the resource group to which the KeyVault belongs to. A new resource group with this name will be created if one doesn't exist.	True
$keyVaultName	Name of the KeyVault in which encryption keys are to be placed. A new vault with this name will be created if one doesn't exist.	True

Parameter	Description	Mandatory?
$location	Location of the KeyVault. Make sure the KeyVault and VMs to be encrypted are in the same location. Get a location list with `Get-AzLocation`.	True
$subscriptionId	Identifier of the Azure subscription to be used. You can get your Subscription ID with `Get-AzSubscription`.	True
$aadAppName	Name of the Microsoft Entra application that will be used to write secrets to KeyVault. A new application with this name will be created if one doesn't exist. If this app already exists, pass aadClientSecret parameter to the script.	False
$aadClientSecret	Client secret of the Microsoft Entra application that was created earlier.	False
$keyEncryptionKeyName	Name of optional key encryption key in KeyVault. A new key with this name will be created if one doesn't exist.	False

Encrypt or decrypt VMs without a Microsoft Entra app

- Enable disk encryption on an existing or running Linux VM
- Disable encryption on a running Linux VM
  - Disabling encryption is only allowed on Data volumes for Linux VMs.

Encrypt or decrypt VMs with a Microsoft Entra app (previous release)

- Enable disk encryption on an existing or running Linux VM
- Disable encryption on a running Linux VM
  - Disabling encryption is only allowed on Data volumes for Linux VMs.
- Create a new encrypted managed disk from a pre-encrypted VHD/storage blob
  - Creates a new encrypted managed disk provided a pre-encrypted VHD and its corresponding encryption settings

Encrypting an OS drive on a running Linux VM

Prerequisites for OS disk encryption

- The VM must be using a distribution compatible with OS disk encryption as listed in the Azure Disk Encryption supported operating systems
- The VM must be created from the Marketplace image in Azure Resource Manager.

- Azure VM with at least 4 GB of RAM (recommended size is 7 GB). See Memory requirements for further information.
- (For RHEL and CentOS) Disable SELinux. To disable SELinux, see "4.4.2. Disabling SELinux" in the SELinux User's and Administrator's Guide on the VM.
- After you disable SELinux, reboot the VM at least once.

Steps

1. Create a VM by using one of the distributions specified previously.

2. Configure the VM according to your needs. If you're going to encrypt all the (OS + data) drives, the data drives need to be specified and mountable from /etc/fstab.

   > **Note**
   >
   > Use UUID=... to specify data drives in /etc/fstab instead of specifying the block device name (for example, /dev/sdb1). During encryption, the order of drives changes on the VM. If your VM relies on a specific order of block devices, it will fail to mount them after encryption.

3. Sign out of the SSH sessions.

4. To encrypt the OS, specify volumeType as **All** or **OS** when you enable encryption.

   > **Note**
   >
   > All user-space processes that are not running as `systemd` services should be killed with a `SIGKILL`. Reboot the VM. When you enable OS disk encryption on a running VM, plan on VM downtime.

5. Periodically monitor the progress of encryption by using the instructions in the next section.

6. After Get-AzVmDiskEncryptionStatus shows "VMRestartPending", restart your VM either by signing in to it or by using the portal, PowerShell, or CLI.

   Azure PowerShell

   ```
   C:\> Get-AzVmDiskEncryptionStatus  -ResourceGroupName $ResourceGroupName -
   VMName $VMName
   -ExtensionName $ExtensionName
   ```

Output

```
OsVolumeEncrypted          : VMRestartPending
DataVolumesEncrypted       : NotMounted
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : OS disk successfully encrypted, reboot the VM
```

Before you reboot, we recommend that you save boot diagnostics of the VM.

Monitoring OS encryption progress

You can monitor OS encryption progress in three ways:

- Use the `Get-AzVmDiskEncryptionStatus` cmdlet and inspect the ProgressMessage field:

Azure PowerShell

```
Get-AzVMDiskEncryptionStatus -ResourceGroupName $_.ResourceGroupName -VMName
$_.Name
```

Output

```
OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : NotMounted
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : OS disk encryption started
```

After the VM reaches "OS disk encryption started", it takes about 40 to 50 minutes on a Premium-storage backed VM.

Because of issue #388 in WALinuxAgent, `OsVolumeEncrypted` and `DataVolumesEncrypted` show up as `Unknown` in some distributions. With WALinuxAgent version 2.1.5 and later, this issue is fixed automatically. If you see `Unknown` in the output, you can verify disk-encryption status by using the Azure Resource Explorer.

Go to Azure Resource Explorer, and then expand this hierarchy in the selection panel on left:

```
|-- subscriptions
   |-- [Your subscription]
        |-- resourceGroups
```

```
|-- [Your resource group]
     |-- providers
          |-- Microsoft.Compute
               |-- virtualMachines
                    |-- [Your virtual machine]
                         |-- InstanceView
```

In the InstanceView, scroll down to see the encryption status of your drives.

- Look at boot diagnostics. Messages from the ADE extension should be prefixed with `[AzureDiskEncryption]`.

- Sign in to the VM via SSH, and get the extension log from:

  /var/log/azure/Microsoft.Azure.Security.AzureDiskEncryptionForLinux

  We recommend that you don't sign-in to the VM while OS encryption is in progress. Copy the logs only when the other two methods have failed.

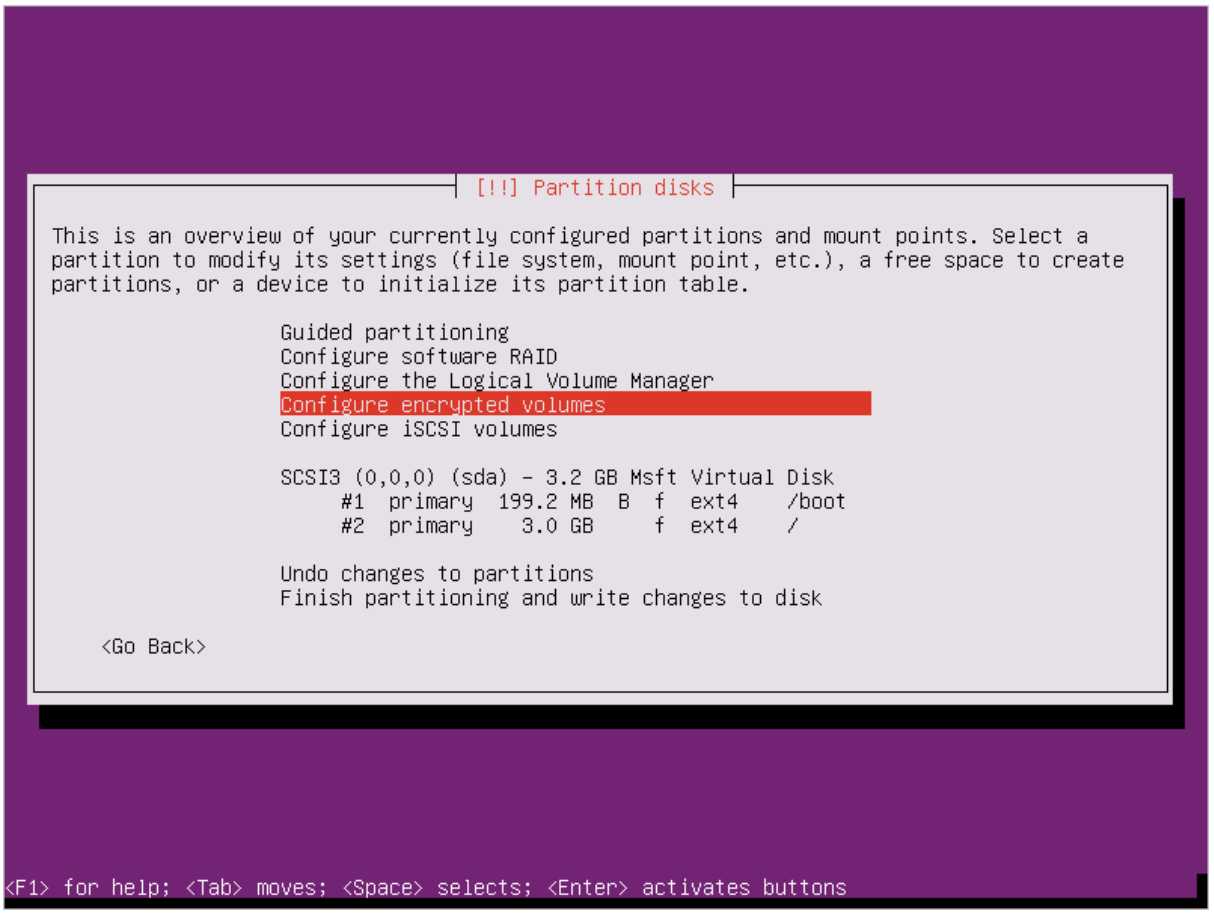
Prepare a pre-encrypted Linux VHD

The preparation for pre-encrypted VHDs can vary depending on the distribution. Examples on preparing Ubuntu, openSUSE, and CentOS 7 are available.

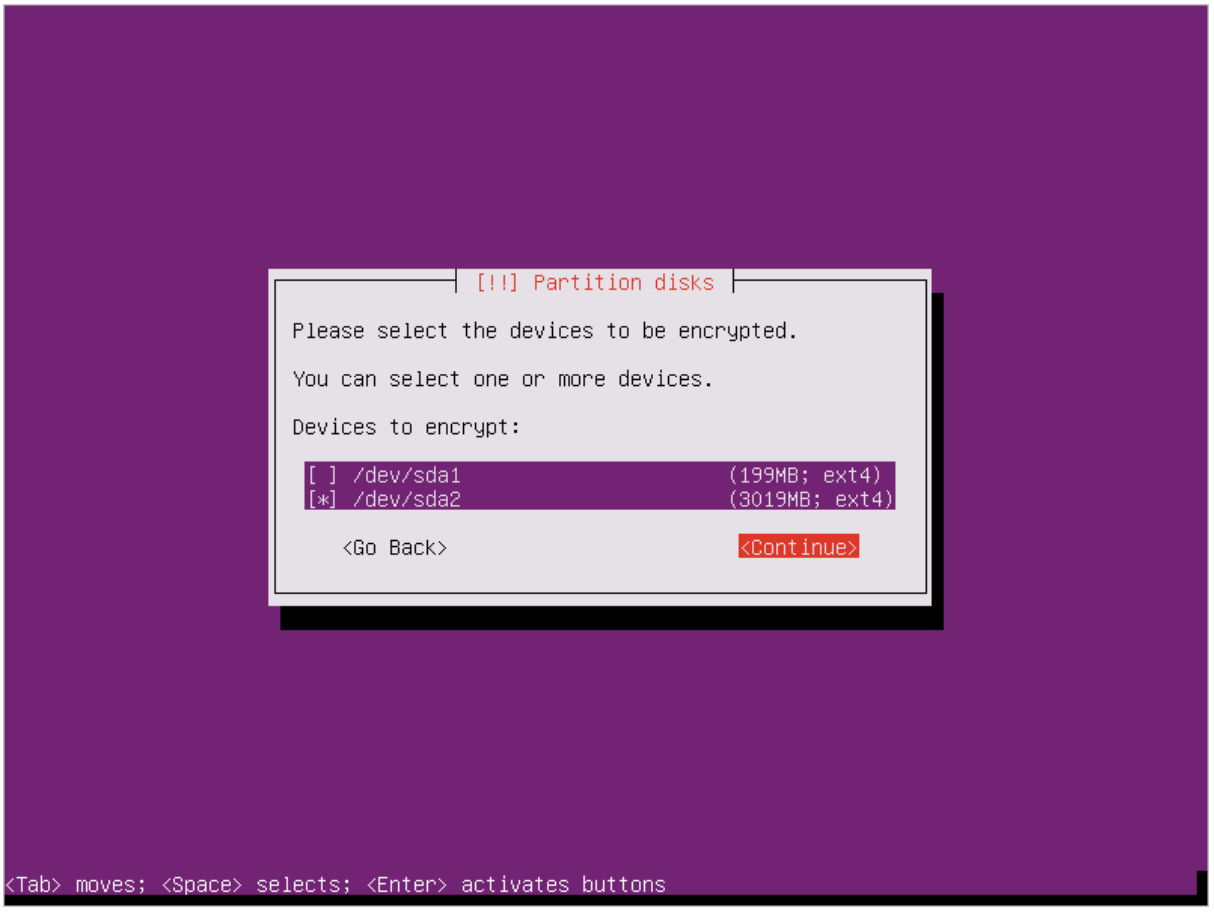
Ubuntu

Configure encryption during the distribution installation by doing the following steps:

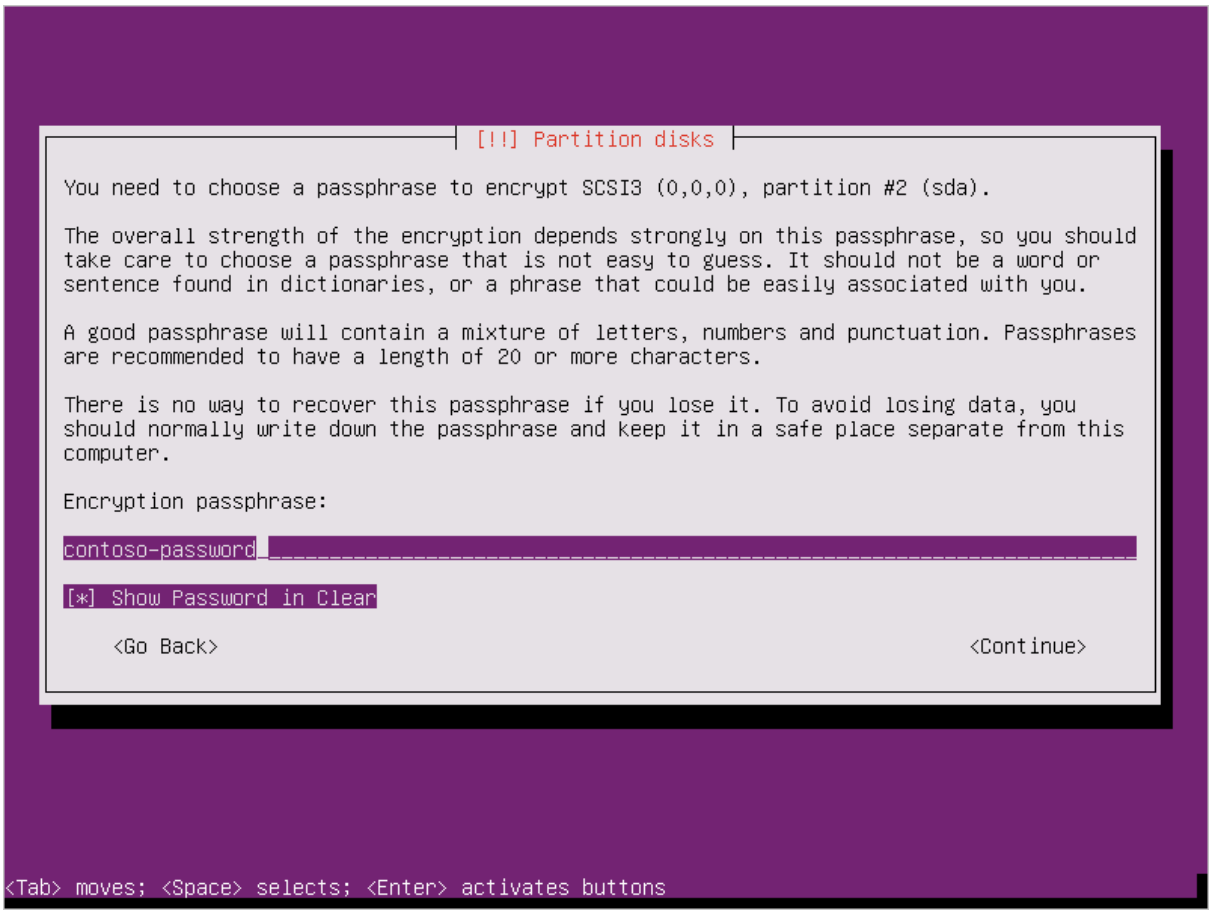
1. Select **Configure encrypted volumes** when you partition the disks.



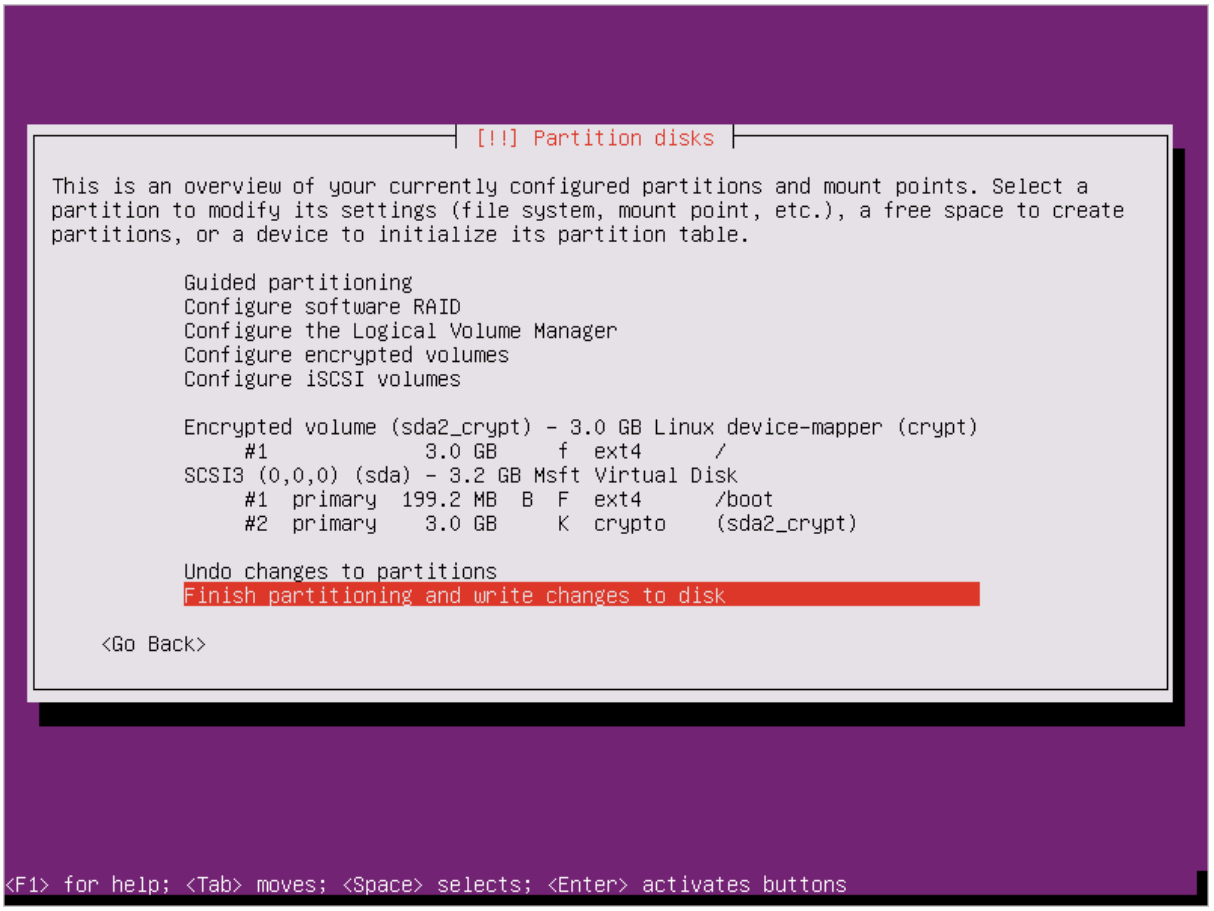
2. Create a separate boot drive, which must not be encrypted. Encrypt your root drive.



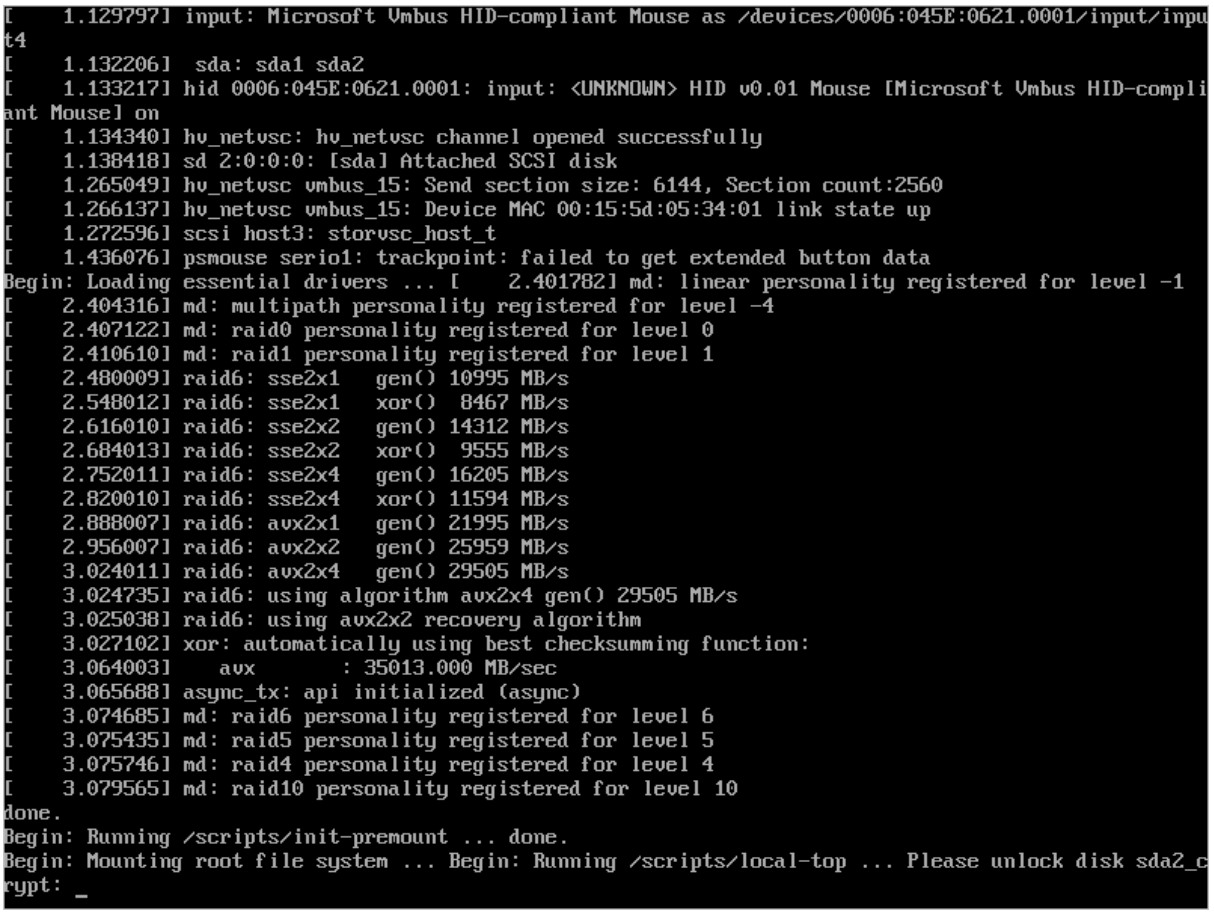
3. Provide a passphrase. This is the passphrase that you uploaded to the key vault.



4. Finish partitioning.



5. When you boot the VM and are asked for a passphrase, use the passphrase you provided in step 3.



6. Prepare the VM for uploading into Azure using these instructions. Don't run the last step (deprovisioning the VM) yet.

Configure encryption to work with Azure by doing the following steps:

1. Create a file under `/usr/local/sbin/azure_crypt_key.sh`, with the content in the following script. Pay attention to the KeyFileName, because it's the passphrase file name used by Azure.

Bash

```
#!/bin/sh
MountPoint=/tmp-keydisk-mount
KeyFileName=LinuxPassPhraseFileName
echo "Trying to get the key from disks ..." >&2
mkdir -p $MountPoint
modprobe vfat >/dev/null 2>&1
modprobe ntfs >/dev/null 2>&1
sleep 2
OPENED=0
cd /sys/block
for DEV in sd*; do

    echo "> Trying device: $DEV ..." >&2
    mount -t vfat -r /dev/${DEV}1 $MountPoint >/dev/null||
    mount -t ntfs -r /dev/${DEV}1 $MountPoint >/dev/null
    if [ -f $MountPoint/$KeyFileName ]; then
            cat $MountPoint/$KeyFileName
```

```
            umount $MountPoint 2>/dev/null
            OPENED=1
            break
    fi
    umount $MountPoint 2>/dev/null
done

  if [ $OPENED -eq 0 ]; then
    echo "FAILED to find suitable passphrase file ..." >&2
    echo -n "Try to enter your password: " >&2
    read -s -r A </dev/console
    echo -n "$A"
 else
    echo "Success loading keyfile!" >&2
fi
```

2. Change the crypt config in */etc/crypttab*. It should look like this:

```config
 xxx_crypt uuid=xxxxxxxxxxxxxxxxxxxx none
luks,discard,keyscript=/usr/local/sbin/azure_crypt_key.sh
```

3. Add executable permissions to the script:

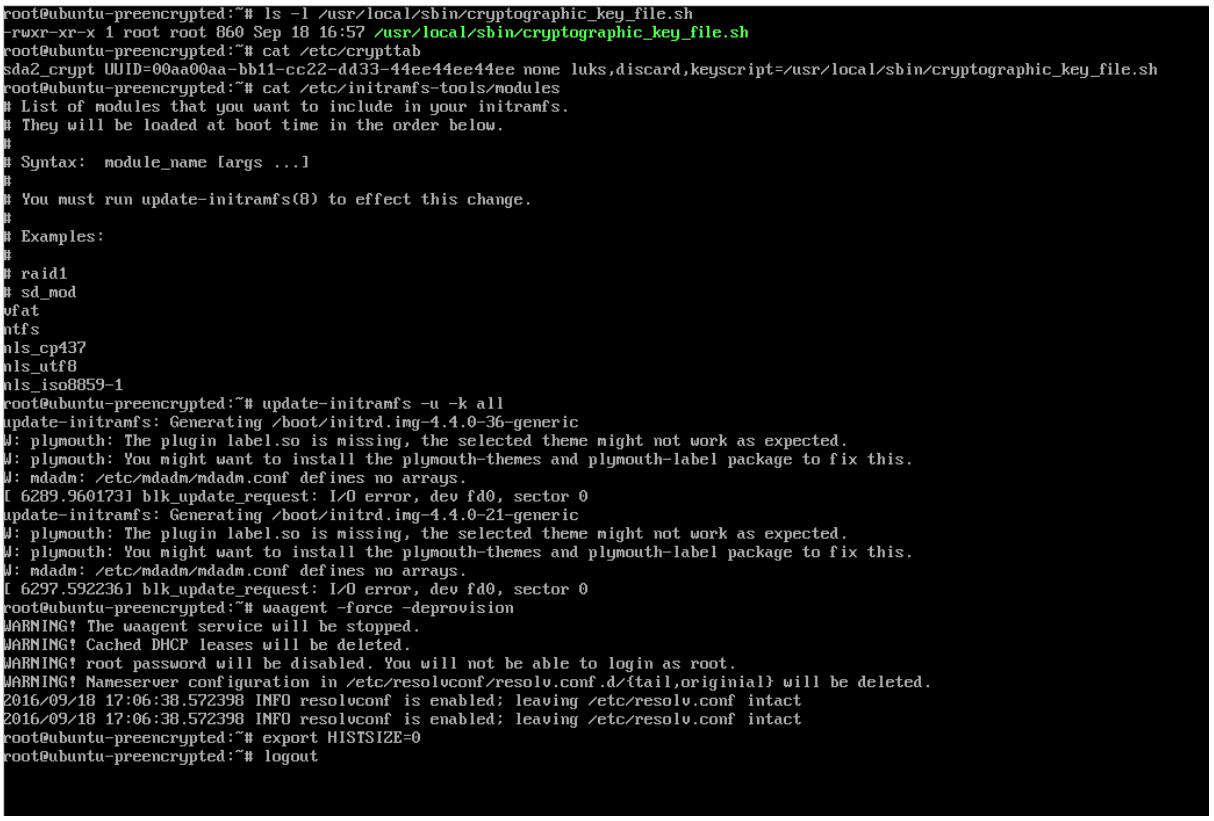
```Bash
 sudo chmod +x /usr/local/sbin/azure_crypt_key.sh
```

4. Edit `/etc/initramfs-tools/modules` by appending lines:

```config
 vfat
 ntfs
 nls_cp437
 nls_utf8
 nls_iso8859-1
```

5. Run `update-initramfs -u -k all` to update the initramfs to make the `keyscript` take effect.

6. Now you can deprovision the VM.



7. Continue to the next step and upload your VHD into Azure.

Upload encrypted VHD to an Azure storage account

After DM-Crypt encryption is enabled, the local encrypted VHD needs to be uploaded to your storage account.

PowerShell

```
    Add-AzVhd [-Destination] <Uri> [-LocalFilePath] <FileInfo> [[-
NumberOfUploaderThreads] <Int32> ] [[-BaseImageUriToPatch] <Uri> ] [[-OverWrite]]
[ <CommonParameters>]
```

Upload the secret for the pre-encrypted VM to your key vault

When encrypting using a Microsoft Entra app (previous release), the disk-encryption secret that you obtained previously must be uploaded as a secret in your key vault. The key vault needs to have disk encryption and permissions enabled for your Microsoft Entra client.

Azure PowerShell

```
 $AadClientId = "My-AAD-Client-Id"
 $AadClientSecret = "My-AAD-Client-Secret"

 $key vault = New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$ResourceGroupName -Location $Location

 Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$ResourceGroupName -ServicePrincipalName $AadClientId -PermissionsToKeys all -
PermissionsToSecrets all
 Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$ResourceGroupName -EnabledForDiskEncryption
```

Disk encryption secret not encrypted with a KEK

To set up the secret in your key vault, use Set-AzKeyVaultSecret. The passphrase is encoded as a base64 string and then uploaded to the key vault. In addition, make sure that the following tags are set when you create the secret in the key vault.

Azure PowerShell

```
 # This is the passphrase that was provided for encryption during the distribution
installation
 $passphrase = "contoso-password"

 $tags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP";
"DiskEncryptionKeyFileName" = "LinuxPassPhraseFileName"}
 $secretName = [guid]::NewGuid().ToString()
 $secretValue =
[Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($passphrase))
 $secureSecretValue = ConvertTo-SecureString $secretValue -AsPlainText -Force

 $secret = Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $secretName -
SecretValue $secureSecretValue -tags $tags
 $secretUrl = $secret.Id
```

Use the `$secretUrl` in the next step for attaching the OS disk without using KEK.

Disk encryption secret encrypted with a KEK

Before you upload the secret to the key vault, you can optionally encrypt it by using a key encryption key. Use the wrap API to first encrypt the secret using the key encryption key. The output of this wrap operation is a base64 URL encoded string, which you can then upload as a secret by using the Set-AzKeyVaultSecret cmdlet.

Azure PowerShell

```
    # This is the passphrase that was provided for encryption during the
distribution installation
    $passphrase = "contoso-password"

    Add-AzKeyVaultKey -VaultName $KeyVaultName -Name "keyencryptionkey" -
Destination Software
    $KeyEncryptionKey = Get-AzKeyVaultKey -VaultName $KeyVault.OriginalVault.Name
-Name "keyencryptionkey"

    $apiversion = "2015-06-01"

    ###############################
    # Get Auth URI
    ###############################

    $uri = $KeyVault.VaultUri + "/keys"
    $headers = @{}

    $response = try { Invoke-RestMethod -Method GET -Uri $uri -Headers $headers }
catch { $_.Exception.Response }

    $authHeader = $response.Headers["www-authenticate"]
    $authUri = [regex]::match($authHeader, 'authorization="
(.*?)"').Groups[1].Value

    Write-Host "Got Auth URI successfully"

    ###############################
    # Get Auth Token
    ###############################

    $uri = $authUri + "/oauth2/token"
    $body = "grant_type=client_credentials"
    $body += "&client_id=" + $AadClientId
    $body += "&client_secret=" + [Uri]::EscapeDataString($AadClientSecret)
    $body += "&resource=" + [Uri]::EscapeDataString("https://vault.azure.net")
    $headers = @{}

    $response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body
$body

    $access_token = $response.access_token

    Write-Host "Got Auth Token successfully"

    ###############################
    # Get KEK info
    ###############################

    $uri = $KeyEncryptionKey.Id + "?api-version=" + $apiversion
    $headers = @{"Authorization" = "Bearer " + $access_token}

    $response = Invoke-RestMethod -Method GET -Uri $uri -Headers $headers
```

```
    $keyid = $response.key.kid

    Write-Host "Got KEK info successfully"

    ##############################
    # Encrypt passphrase using KEK
    ##############################

    $passphraseB64 =
[Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Passphrase))
    $uri = $keyid + "/encrypt?api-version=" + $apiversion
    $headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" =
"application/json"}
    $bodyObj = @{"alg" = "RSA-OAEP"; "value" = $passphraseB64}
    $body = $bodyObj | ConvertTo-Json

    $response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body
$body

    $wrappedSecret = $response.value

    Write-Host "Encrypted passphrase successfully"

    ##############################
    # Store secret
    ##############################

    $secretName = [guid]::NewGuid().ToString()
    $uri = $KeyVault.VaultUri + "/secrets/" + $secretName + "?api-version=" +
$apiversion
    $secretAttributes = @{"enabled" = $true}
    $secretTags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP";
"DiskEncryptionKeyFileName" = "LinuxPassPhraseFileName"}
    $headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" =
"application/json"}
    $bodyObj = @{"value" = $wrappedSecret; "attributes" = $secretAttributes;
"tags" = $secretTags}
    $body = $bodyObj | ConvertTo-Json

    $response = Invoke-RestMethod -Method PUT -Uri $uri -Headers $headers -Body
$body

    Write-Host "Stored secret successfully"

    $secretUrl = $response.id
```

Use `$KeyEncryptionKey` and `$secretUrl` in the next step for attaching the OS disk using KEK.

Specify a secret URL when you attach an OS disk

Without using a KEK

While you're attaching the OS disk, you need to pass `$secretUrl`. The URL was generated in the "Disk-encryption secret not encrypted with a KEK" section.

powershazurepowershell-interactiveell

```
    Set-AzVMOSDisk `
            -VM $VirtualMachine `
            -Name $OSDiskName `
            -SourceImageUri $VhdUri `
            -VhdUri $OSDiskUri `
            -Linux `
            -CreateOption FromImage `
            -DiskEncryptionKeyVaultId $KeyVault.ResourceId `
            -DiskEncryptionKeyUrl $SecretUrl
```

Using a KEK

When you attach the OS disk, pass `$KeyEncryptionKey` and `$secretUrl`. The URL was generated in the "Disk encryption secret encrypted with a KEK" section.

Azure PowerShell

```
    Set-AzVMOSDisk `
            -VM $VirtualMachine `
            -Name $OSDiskName `
            -SourceImageUri $CopiedTemplateBlobUri `
            -VhdUri $OSDiskUri `
            -Linux `
            -CreateOption FromImage `
            -DiskEncryptionKeyVaultId $KeyVault.ResourceId `
            -DiskEncryptionKeyUrl $SecretUrl `
            -KeyEncryptionKeyVaultId $KeyVault.ResourceId `
            -KeyEncryptionKeyURL $KeyEncryptionKey.Id
```

Azure Disk Encryption on an isolated network

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

> **Caution**
>
> This article references CentOS, a Linux distribution that is End Of Life (EOL) status. Consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Applies to: ✔ Linux VMs ✔ Flexible scale sets.

When connectivity is restricted by a firewall, proxy requirement, or network security group (NSG) settings, the ability of the extension to perform needed tasks might be disrupted. This disruption can result in status messages such as "Extension status not available on the VM."

Package management

Azure Disk Encryption depends on many components, which are typically installed as part of ADE enablement if not already present. When behind a firewall or otherwise isolated from the Internet, these packages must be preinstalled or available locally.

Here are the packages necessary for each distribution. For a full list of supported distros and volume types, see supported VMs and operating systems.

- **Ubuntu 14.04, 16.04, 18.04**: lsscsi, psmisc, at, cryptsetup-bin, python-parted, python-six, procps, grub-pc-bin
- **CentOS 7.2 - 7.9, 8.1, 8.2**: lsscsi, psmisc, lvm2, uuid, at, patch, cryptsetup, cryptsetup-reencrypt, pyparted, procps-ng, util-linux
- **CentOS 6.8**: lsscsi, psmisc, lvm2, uuid, at, cryptsetup-reencrypt, parted, python-six

- **RedHat 7.2 - 7.9, 8.1, 8.2**: lsscsi, psmisc, lvm2, uuid, at, patch, cryptsetup, cryptsetup-reencrypt, procps-ng, util-linux
- **RedHat 6.8**: lsscsi, psmisc, lvm2, uuid, at, patch, cryptsetup-reencrypt
- **openSUSE 42.3, SLES 12-SP4, 12-SP3**: lsscsi, cryptsetup

On Red Hat, when a proxy is required, you must make sure that the subscription-manager and yum are set up properly. For more information, see How to troubleshoot subscription-manager and yum problems.

When packages are installed manually, they must also be manually upgraded as new versions are released.

Network security groups

Any network security group settings that are applied must still allow the endpoint to meet the documented network configuration prerequisites for disk encryption. See Azure Disk Encryption: Networking requirements

Azure Disk Encryption with Microsoft Entra ID (previous version)

If using Azure Disk Encryption with Microsoft Entra ID (previous version), the Microsoft Authentication Library must be installed manually for all distros (in addition to the packages appropriate for the distro).

When encryption is being enabled with Microsoft Entra credentials, the target VM must allow connectivity to both Microsoft Entra endpoints and Key Vault endpoints. Current Microsoft Entra authentication endpoints are maintained in sections 56 and 59 of the Microsoft 365 URLs and IP address ranges documentation. Key Vault instructions are provided in the documentation on how to Access Azure Key Vault behind a firewall.

Azure Instance Metadata Service

The virtual machine must be able to access the Azure Instance Metadata service endpoint, which uses a well-known nonroutable IP address (`169.254.169.254`) that can be accessed only from within the VM. Proxy configurations that alter local HTTP traffic to this address (for example, adding an X-Forwarded-For header) aren't supported.

Verify encryption status for Linux

Summarize this article for me

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The scope of this article is to validate the encryption status of a virtual machine by using different methods: the Azure portal, PowerShell, the Azure CLI, or the operating system of the virtual machine (VM).

You can validate the encryption status during or after the encryption, by either:

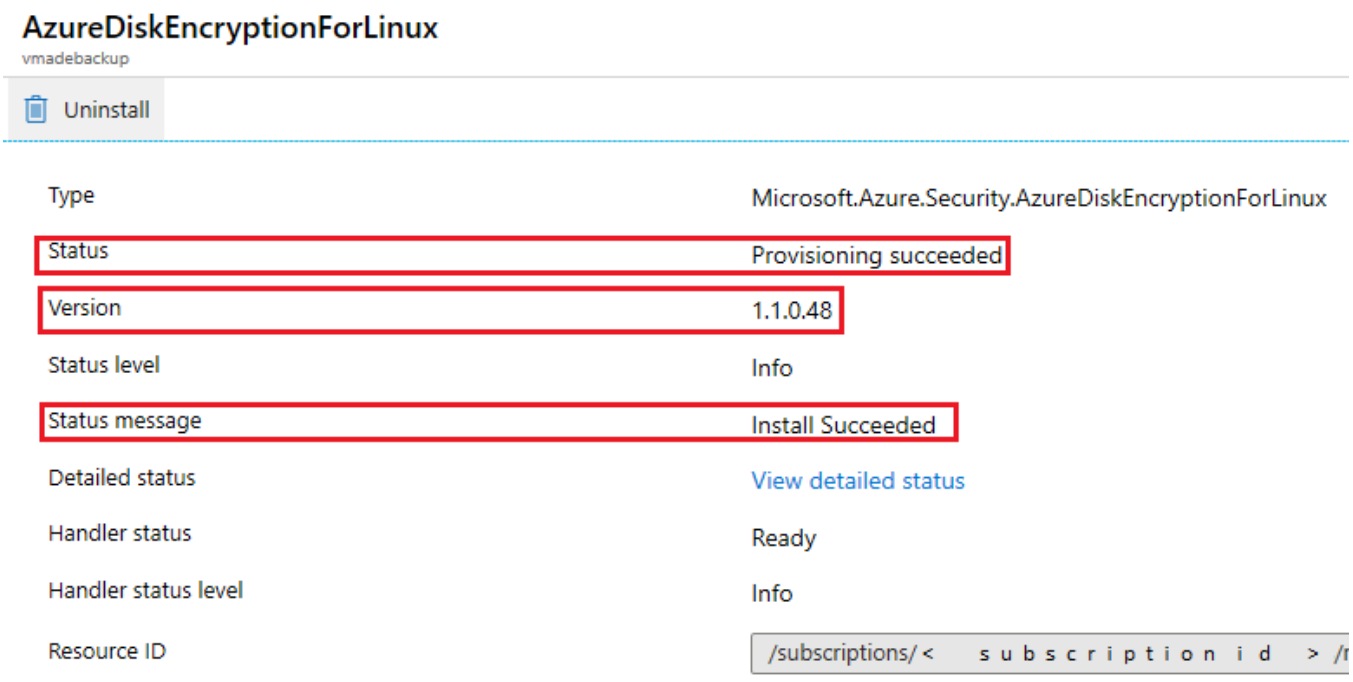
- Checking the disks attached to a particular VM.
- Querying the encryption settings on each disk, whether the disk is attached or unattached.

This scenario applies for Azure Disk Encryption dual-pass and single-pass extensions. Linux distributions are the only environment for this scenario.

> **Note**
>
> We're using variables throughout the article. Replace the values accordingly.

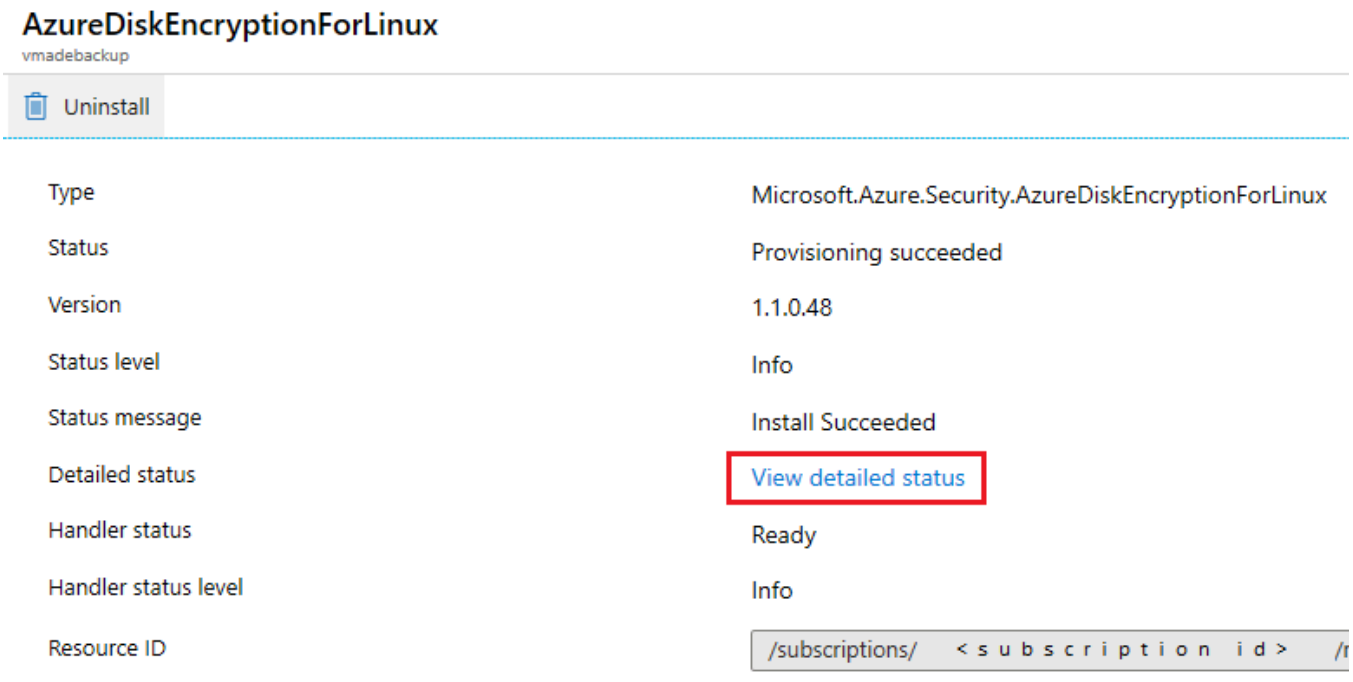
Portal

In the Azure portal, inside the **Extensions** section, select the Azure Disk Encryption extension in the list. The information for **Status message** indicates the current encryption status:

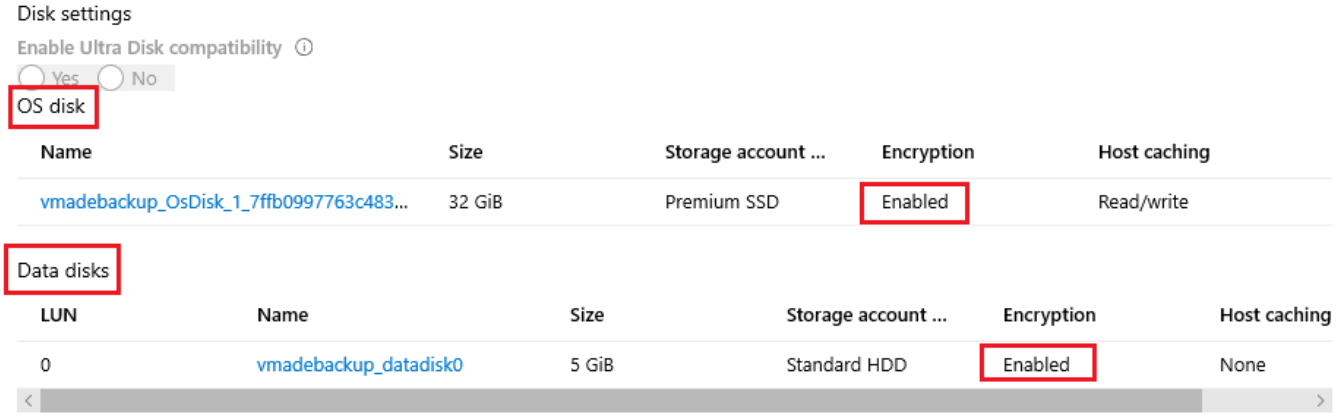


In the list of extensions, you'll see the corresponding Azure Disk Encryption extension version. Version 0.x corresponds to Azure Disk Encryption dual pass, and version 1.x corresponds to Azure Disk Encryption single pass.

You can get more details by selecting the extension and then selecting **View detailed status**. The detailed status of the encryption process appears in JSON format.



Another way to validate the encryption status is by looking at the **Disk settings** section.



> **Note**
>
> This status means the disks have encryption settings stamped, not that they were actually encrypted at the OS level.
>
> By design, the disks are stamped first and encrypted later. If the encryption process fails, the disks may end up stamped but not encrypted.
>
> To confirm if the disks are truly encrypted, you can double check the encryption of each disk at the OS level.

PowerShell

You can validate the *general* encryption status of an encrypted VM by using the following PowerShell commands:

Azure PowerShell

```
$VMNAME="VMNAME"
$RGNAME="RGNAME"
```

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName  ${RGNAME} -VMName ${VMNAME}
```

```
PS Azure:\> Get-AzVmDiskEncryptionStatus -ResourceGroupName ${RGNAME} -VMName ${VMNAME}

OsVolumeEncrypted          : NotEncrypted
DataVolumesEncrypted       : Encrypted
OsVolumeEncryptionSettings :
ProgressMessage            : Provisioning succeeded
```

You can capture the encryption settings from each disk by using the following PowerShell commands.

Single pass

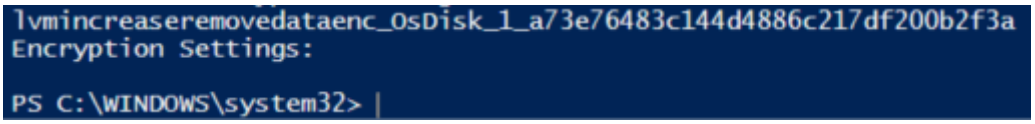
In a single pass, the encryption settings are stamped on each of the disks (OS and data). You can capture the encryption settings for an OS disk in a single pass as follows:

Azure PowerShell

```
$RGNAME = "RGNAME"
$VMNAME = "VMNAME"

$VM = Get-AzVM -Name ${VMNAME} -ResourceGroupName ${RGNAME}
 $Sourcedisk = Get-AzDisk -ResourceGroupName ${RGNAME} -DiskName
$VM.StorageProfile.OsDisk.Name
 Write-Host
"================================================================================
================================================================================"
 Write-Host "Encryption Settings:"
 Write-Host
"================================================================================
================================================================================"
 Write-Host "Enabled:" $Sourcedisk.EncryptionSettingsCollection.Enabled
 Write-Host "Version:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettingsVersion
 Write-Host "Source Vault:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Sourc
eVault.Id
 Write-Host "Secret URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Secre
tUrl
 Write-Host "Key URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.KeyEncryptionKey.KeyUrl
 Write-Host
"================================================================================
================================================================================"
```

If the disk doesn't have encryption settings stamped, the output will be empty:

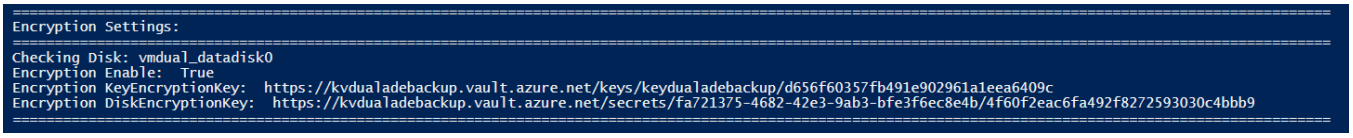


Use the following commands to capture encryption settings for data disks:

Azure PowerShell

```
$RGNAME = "RGNAME"
$VMNAME = "VMNAME"

$VM = Get-AzVM -Name ${VMNAME} -ResourceGroupName ${RGNAME}
 clear
 foreach ($i in $VM.StorageProfile.DataDisks|ForEach-Object{$_.Name})
 {
 Write-Host
"================================================================================
================================================================================"
 Write-Host "Encryption Settings:"
 Write-Host
"================================================================================
================================================================================"
 Write-Host "Checking Disk:" $i
 $Disk=(Get-AzDisk -ResourceGroupName ${RGNAME} -DiskName $i)
 Write-Host "Encryption Enable: " $Sourcedisk.EncryptionSettingsCollection.Enabled
 Write-Host "Encryption KeyEncryptionKey: "
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.KeyEncryptionKey.KeyUrl
;
 Write-Host "Encryption DiskEncryptionKey: "
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Secre
tUrl;
 Write-Host
"================================================================================
================================================================================"
 }
```



Dual pass

In a dual pass, the encryption settings are stamped in the VM model and not on each individual disk.

To verify that the encryption settings were stamped in a dual pass, use the following commands:

Azure PowerShell

```
$RGNAME = "RGNAME"
$VMNAME = "VMNAME"

$vm = Get-AzVm -ResourceGroupName ${RGNAME} -Name ${VMNAME};
$Sourcedisk = Get-AzDisk -ResourceGroupName ${RGNAME} -DiskName
$VM.StorageProfile.OsDisk.Name
clear
Write-Host
"================================================================================
================================================================================"
Write-Host "Encryption Settings:"
Write-Host
"================================================================================
================================================================================"
Write-Host "Enabled:" $Sourcedisk.EncryptionSettingsCollection.Enabled
Write-Host "Version:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettingsVersion
Write-Host "Source Vault:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Sourc
eVault.Id
Write-Host "Secret URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Secre
tUrl
Write-Host "Key URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.KeyEncryptionKey.KeyUrl
Write-Host
"================================================================================
================================================================================"
```

Unattached disks

Check the encryption settings for disks that aren't attached to a VM.

Managed disks

Azure PowerShell

```
$Sourcedisk = Get-AzDisk -ResourceGroupName ${RGNAME} -DiskName ${TARGETDISKNAME}
Write-Host
"================================================================================
================================================================================"
Write-Host "Encryption Settings:"
Write-Host
"================================================================================
================================================================================"
```

```
Write-Host "Enabled:" $Sourcedisk.EncryptionSettingsCollection.Enabled
Write-Host "Version:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettingsVersion
Write-Host "Source Vault:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Sourc
eVault.Id
Write-Host "Secret URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.Secre
tUrl
Write-Host "Key URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.KeyEncryptionKey.KeyUrl
Write-Host
"================================================================================
================================================================================"
```

Azure CLI

You can validate the *general* encryption status of an encrypted VM by using the following Azure CLI commands:

Azure CLI

```
VMNAME="VMNAME"
RGNAME="RGNAME"
az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} --query
"substatus"
```

```
$ az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} --query "substatus" -o table
Code                                                                    Level    DisplayStatus          Message
----------------------------------------------------------------------  -------  ---------------------  ----------------------------------------
ComponentStatus/Microsoft.Azure.Security.AzureDiskEncryptionForLinux/succeeded  Info     Provisioning succeeded  {"os": "Encrypted", "data": "Encrypted"}
```

Single pass

You can validate the encryption settings for each disk by using the following Azure CLI commands:

Azure CLI

```
az vm encryption show -g ${RGNAME} -n ${VMNAME} --query "disks[*].[name,
statuses[*].displayStatus]"  -o table
```

```
Column1                                                                 Column2
----------------------------------------------------------------------  --------------------------------
lvmincreaseremovedataenc_OsDisk_1_a73e76483c144d4886c217df200b2f3a  ['Disk is not encrypted']
lvmincreaseremovedataenc_datadisk1                                  ['Encryption is enabled on disk']
lvmincreaseremovedataenc_datadisk2                                  ['Encryption is enabled on disk']
lvmincreaseremovedataenc_datadisk3                                  ['Encryption is enabled on disk']
lvmincreaseremovedataenc_datadisk4                                  ['Encryption is enabled on disk']
```

> **ⓘ Important**
>
> If the disk doesn't have encryption settings stamped, you'll see the text **Disk is not encrypted**.

Use the following commands to get detailed status and encryption settings.

OS disk:

Azure CLI

```
RGNAME="RGNAME"
VMNAME="VNAME"

disk=`az vm show -g ${RGNAME} -n ${VMNAME} --query storageProfile.osDisk.name -o
tsv`
for disk in $disk; do \
echo
"================================================================================
================================================================================"
echo -ne "Disk Name: "; az disk show -g ${RGNAME} -n ${disk} --query name -o tsv; \
echo -ne "Encryption Enabled: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.enabled -o tsv; \
echo -ne "Version: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query
encryptionSettingsCollection.encryptionSettingsVersion -o tsv; \
echo -ne "Disk Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.encryptionSettings[].diskEncryptionKey.secretUrl -o
tsv; \
echo -ne "key Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.encryptionSettings[].keyEncryptionKey.keyUrl -o tsv; \
echo
"================================================================================
================================================================================"
done
```

```
================================================================================
Disk Name: vmadebackup_OsDisk_1_7ffb0997763c483881d53c54e58f4898
Encryption Enabled: true
Disk Encryption Key: https://kvadebackup.vault.azure.net/secrets/5dfe7d9d-c77e-478f-aa2d-321f62c394d9/6588ab5e10f54423b0f35ec6a3a64f1d
key Encryption Key: https://kvadebackup.vault.azure.net/keys/keyadebackup/1551be9b670947428b04b6aa0a31a040
================================================================================
```

Data disks:

Azure CLI

```
RGNAME="RGNAME"
VMNAME="VMNAME"
az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} --query
"substatus"

for disk in `az vm show -g ${RGNAME} -n ${VMNAME} --query
```

```
storageProfile.dataDisks[].name -o tsv`; do \
echo
"================================================================================
================================================================================"; \
echo -ne "Disk Name: "; az disk show -g ${RGNAME} -n ${disk} --query name -o tsv; \
echo -ne "Encryption Enabled: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.enabled -o tsv; \
echo -ne "Version: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query
encryptionSettingsCollection.encryptionSettingsVersion -o tsv; \
echo -ne "Disk Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.encryptionSettings[].diskEncryptionKey.secretUrl -o
tsv; \
echo -ne "key Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.encryptionSettings[].keyEncryptionKey.keyUrl -o tsv; \
echo
"================================================================================
================================================================================"
done
```

```
================================================================================================================================================================
Disk Name: vmadebackup_datadisk0
Encryption Enabled: true
Disk Encryption Key: https://kvadebackup.vault.azure.net/secrets/5dfe7d9d-c77e-478f-aa2d-321f62c394d9/4d0c7805d33e47dd81838aabccfff85a
key Encryption Key: https://kvadebackup.vault.azure.net/keys/keyadebackup/1551be9b670947428b04b6aa0a31a040
================================================================================================================================================================
```

Dual pass

Azure CLI

```
az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} -o table
```

```
OsDisk     DataDisk    OsType    ProgressMessage
---------  ----------  --------  ------------------------------------------------------------------------------------------------------------------------
Encrypted  Encrypted   Linux     https://kvdualadebackup.vault.azure.net/secrets/fa721375-4682-42e3-9ab3-bfe3f6ec8e4b/4f60f2eac6fa492f8272593030c4bbb9
```

You can also check the encryption settings on the VM Model Storage profile of the OS disk:

Azure CLI

```
disk=`az vm show -g ${RGNAME} -n ${VMNAME} --query storageProfile.osDisk.name -o
tsv`
for disk in $disk; do \
echo
"================================================================================
================================================================================"; \
echo -ne "Disk Name: "; az disk show -g ${RGNAME} -n ${disk} --query name -o tsv; \
echo -ne "Encryption Enabled: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.enabled -o tsv; \
echo -ne "Version: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query
encryptionSettingsCollection.encryptionSettingsVersion -o tsv; \
echo -ne "Disk Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.encryptionSettings[].diskEncryptionKey.secretUrl -o
tsv; \
```

```
echo -ne "key Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query
encryptionSettingsCollection.encryptionSettings[].keyEncryptionKey.keyUrl -o tsv; \
echo
"================================================================================
================================================================================"
done
```

```
================================================================================

tsv; \
echo
"================================================================================
================================================================================"
```

Unmanaged disks

On March 31st, 2026, unmanaged disks are being retired. If you're using unmanaged disks, migrate to managed disks before that date. For details on the retirement, see Migrate your Azure unmanaged disks by March 31st, 2026.

Unmanaged disks are VHD files that are stored as page blobs in Azure storage accounts.

To get the details for a specific disk, you need to provide:

- The ID of the storage account that contains the disk.
- A connection string for that particular storage account.
- The name of the container that stores the disk.
- The disk name.

This command lists all the IDs for all your storage accounts:

Azure CLI

```
az storage account list --query [].[id] -o tsv
```

The storage account IDs are listed in the following form:

/subscriptions/<subscription id>/resourceGroups/<resource group name>/providers/Microsoft.Storage/storageAccounts/<storage account name>

Select the appropriate ID and store it on a variable:

Azure CLI

```
id="/subscriptions/<subscription id>/resourceGroups/<resource group name>/providers/Microsoft.Storage/storageAccounts/<storage account name>"
```

This command gets the connection string for one particular storage account and stores it on a variable:

Azure CLI

```
ConnectionString=$(az storage account show-connection-string --ids $id --query connectionString -o tsv)
```

The following command lists all the containers under a storage account:

Azure CLI

```
az storage container list --connection-string $ConnectionString --query [].[name] -o tsv
```

The container used for disks is normally named "vhds."

Store the container name on a variable:

Azure CLI

```
ContainerName="name of the container"
```

Use this command to list all the blobs on a particular container:

Azure CLI

```
az storage blob list -c ${ContainerName} --connection-string $ConnectionString --query [].[name] -o tsv
```

Choose the disk that you want to query and store its name on a variable:

Azure CLI

```
DiskName="diskname.vhd"
```

Query the disk encryption settings:

Azure CLI

```
az storage blob show -c ${ContainerName} --connection-string ${ConnectionString} -n ${DiskName} --query metadata.DiskEncryptionSettings
```

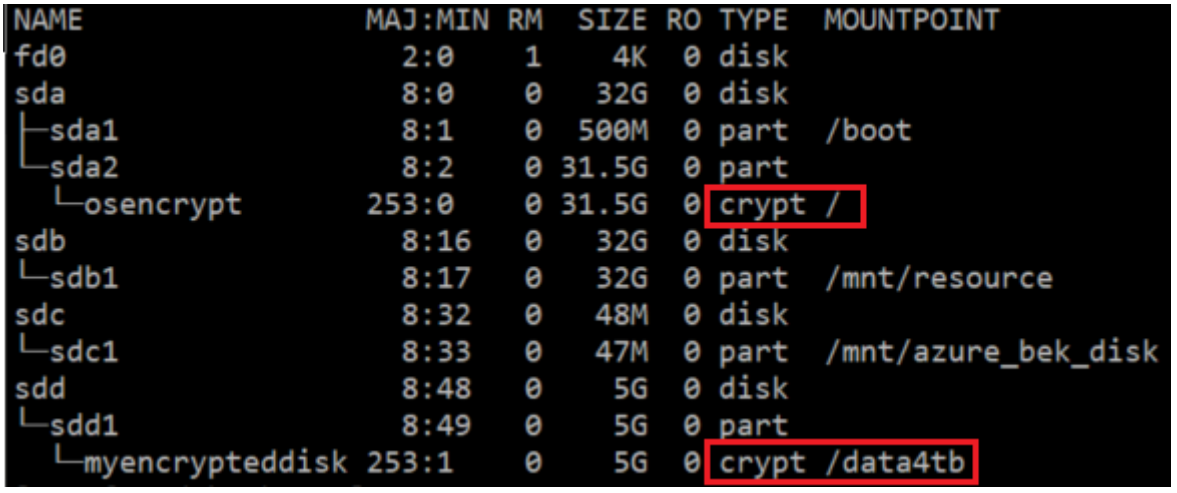
Operating system

Validate if the data disk partitions are encrypted (and the OS disk isn't).

When a partition or disk is encrypted, it's displayed as a **crypt** type. When it's not encrypted, it's displayed as a **part/disk** type.

Bash

```
sudo lsblk
```

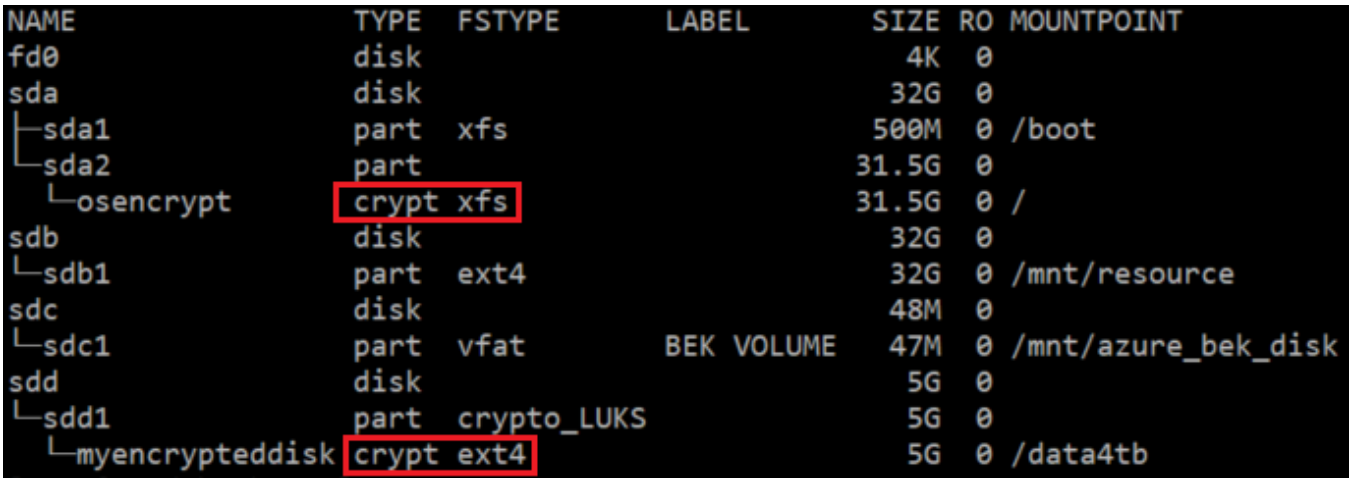


You can get more details by using the following **lsblk** variant.

You'll see a **crypt** type layer that is mounted by the extension. The following example shows logical volumes and normal disks having **crypto_LUKS FSTYPE**.

Bash

```
sudo lsblk -o NAME,TYPE,FSTYPE,LABEL,SIZE,RO,MOUNTPOINT
```



As an extra step, you can validate if the data disk has any keys loaded:

Bash

```
sudo cryptsetup luksDump /dev/VGNAME/LVNAME
```

Bash

```
sudo cryptsetup luksDump /dev/sdd1
```

And you can check which **dm** devices are listed as **crypt**:

Bash

```
sudo dmsetup ls --target crypt
```

Configure LVM and RAID on encrypted devices

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article is a step-by-step process for how to perform Logical Volume Management (LVM) and RAID on encrypted devices. The process applies to the following environments:

- Linux distributions
  - RHEL 7.6+
  - Ubuntu 18.04+
  - SUSE 12+
- Azure Disk Encryption single-pass extension
- Azure Disk Encryption dual-pass extension

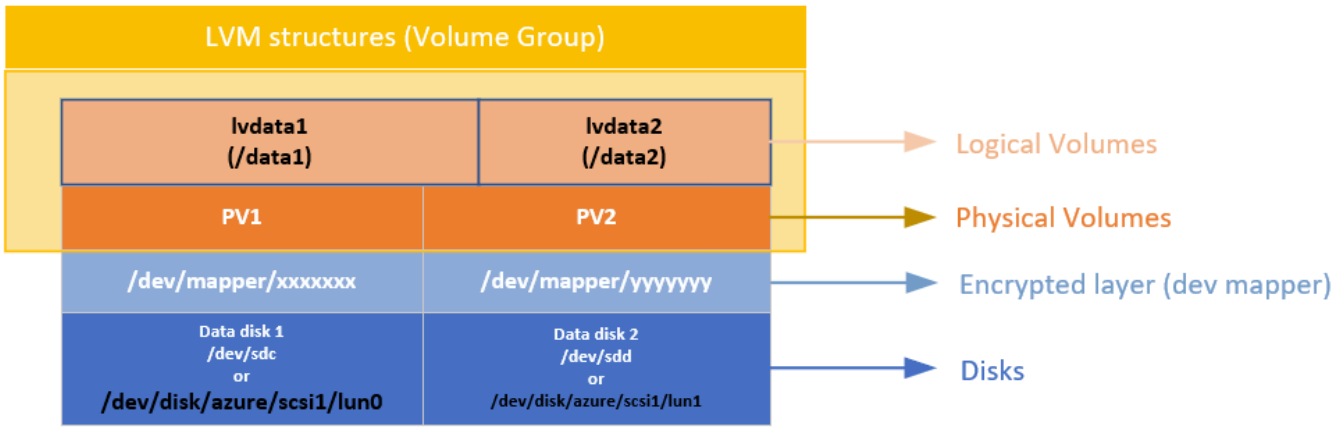
Scenarios

The procedures in this article support the following scenarios:

- Configure LVM on top of encrypted devices (LVM-on-crypt)
- Configure RAID on top of encrypted devices (RAID-on-crypt)

After the underlying device or devices are encrypted, then you can create the LVM or RAID structures on top of that encrypted layer.

The physical volumes (PVs) are created on top of the encrypted layer. The physical volumes are used to create the volume group. You create the volumes and add the required entries on /etc/fstab.



In a similar way, the RAID device is created on top of the encrypted layer on the disks. A file system is created on top of the RAID device and added to /etc/fstab as a regular device.

Considerations

We recommend that you use LVM-on-crypt. RAID is an option when LVM can't be used because of specific application or environment limitations.

You'll use the **EncryptFormatAll** option. For more information about this option, see Use the EncryptFormatAll feature for data disks on Linux VMs.

Although you can use this method when you're also encrypting the OS, we're just encrypting data drives here.

The procedures assume that you already reviewed the prerequisites in Azure Disk Encryption scenarios on Linux VMs and in Quickstart: Create and encrypt a Linux VM with the Azure CLI.

The Azure Disk Encryption dual-pass version is on a deprecation path and should no longer be used on new encryptions.

General steps

When you're using the "on-crypt" configurations, use the process outlined in the following procedures.

> ⓘ **Note**
>
> We're using variables throughout the article. Replace the values accordingly.

Deploy a VM

The following commands are optional, but we recommend that you apply them on a newly deployed virtual machine (VM).

PowerShell:

PowerShell

```
New-AzVm -ResourceGroupName ${RGNAME} `
-Name ${VMNAME} `
-Location ${LOCATION} `
-Size ${VMSIZE} `
-Image ${OSIMAGE} `
-Credential ${creds} `
-Verbose
```

Azure CLI:

Azure CLI

```
az vm create \
-n ${VMNAME} \
-g ${RGNAME} \
--image ${OSIMAGE} \
--admin-username ${username} \
--admin-password ${password} \
-l ${LOCATION} \
--size ${VMSIZE} \
-o table
```

Attach disks to the VM

Repeat the following commands for `$N` number of new disks that you want to attach to the VM.

PowerShell:

PowerShell

```
$storageType = 'Standard_LRS'
$dataDiskName = ${VMNAME} + '_datadisk0'
$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $LOCATION -
CreateOption Empty -DiskSizeGB 5
$dataDisk1 = New-AzDisk -DiskName $dataDiskName -Disk $diskConfig -
ResourceGroupName ${RGNAME}
$vm = Get-AzVM -Name ${VMNAME} -ResourceGroupName ${RGNAME}
$vm = Add-AzVMDataDisk -VM $vm -Name $dataDiskName -CreateOption Attach -
```

```
ManagedDiskId $dataDisk1.Id -Lun 0
Update-AzVM -VM ${VM} -ResourceGroupName ${RGNAME}
```

Azure CLI:

Azure CLI

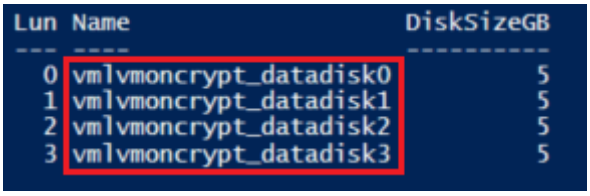
```
az vm disk attach \
-g ${RGNAME} \
--vm-name ${VMNAME} \
--name ${VMNAME}datadisk1 \
--size-gb 5 \
--new \
-o table
```

Verify that the disks are attached to the VM

PowerShell:

PowerShell

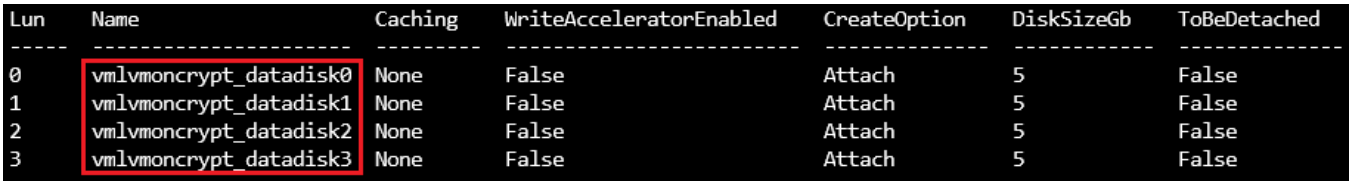
```
$VM = Get-AzVM -ResourceGroupName ${RGNAME} -Name ${VMNAME}
$VM.StorageProfile.DataDisks | Select-Object Lun,Name,DiskSizeGB
```



Azure CLI:

Azure CLI

```
az vm show -g ${RGNAME} -n ${VMNAME} --query storageProfile.dataDisks -o table
```



Portal:

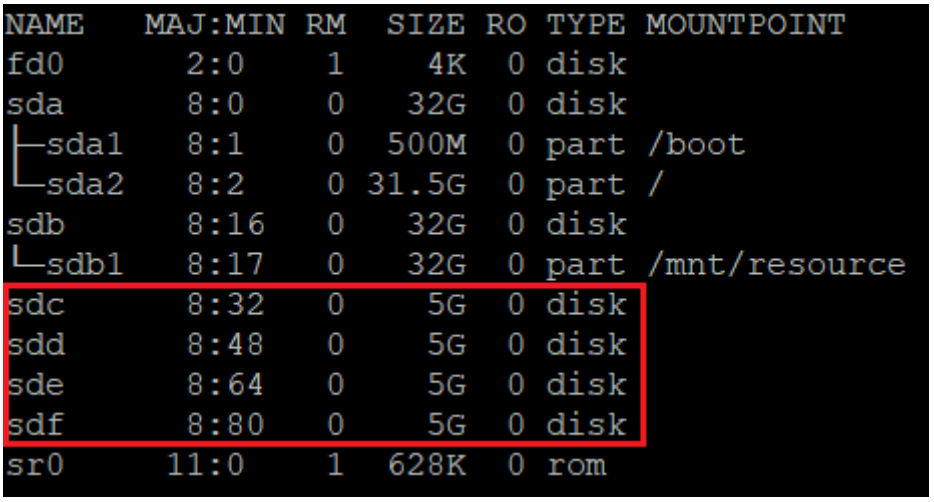
Data disks

LUN	Name	Size	Storage account ...	Encryption	Host caching
0	vmlvmoncrypt_datadisk0	5 GiB	Standard HDD	Not enabled	None
1	vmlvmoncrypt_datadisk1	5 GiB	Standard HDD	Not enabled	None
2	vmlvmoncrypt_datadisk2	5 GiB	Standard HDD	Not enabled	None
3	vmlvmoncrypt_datadisk3	5 GiB	Standard HDD	Not enabled	None

OS:

Bash

```
lsblk
```



Configure the disks to be encrypted

This configuration is done at the operating system level. The corresponding disks are configured for a traditional encryption through Azure Disk Encryption:

- File systems are created on top of the disks.
- Temporary mount points are created to mount the file systems.
- File systems are configured on /etc/fstab to be mounted at boot time.

Check the device letter assigned to the new disks. In this example, we're using four data disks.

Bash

```
lsblk
```

```
NAME    MAJ:MIN RM   SIZE RO TYPE MOUNTPOINT
fd0       2:0    1     4K  0 disk
sda       8:0    0    32G  0 disk
├─sda1    8:1    0   500M  0 part /boot
└─sda2    8:2    0 31.5G  0 part /
sdb       8:16   0    32G  0 disk
└─sdb1    8:17   0    32G  0 part /mnt/resource
sdc       8:32   0     5G  0 disk
sdd       8:48   0     5G  0 disk
sde       8:64   0     5G  0 disk
sdf       8:80   0     5G  0 disk
sr0      11:0    1   628K  0 rom
```

Create a file system on top of each disk

This command iterates the creation of an ext4 file system on each disk defined on the "in" part of the "for" cycle.

Bash

```
for disk in c d e f; do echo mkfs.ext4 -F /dev/sd${disk}; done |bash
```

```
[root@vmlvmoncrypt ~]# for disk in c d e; do echo mkfs.ext4 -F /dev/sd${disk}; d
one |bash
mke2fs 1.42.9 (28-Dec-2013)
Discarding device blocks: done
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)
Stride=0 blocks, Stripe width=0 blocks
327680 inodes, 1310720 blocks
65536 blocks (5.00%) reserved for the super user
First data block=0
Maximum filesystem blocks=1342177280
40 block groups
32768 blocks per group, 32768 fragments per group
8192 inodes per group
Superblock backups stored on blocks:
        32768, 98304, 163840, 229376, 294912, 819200, 884736

Allocating group tables: done
Writing inode tables: done
Creating journal (32768 blocks): done
Writing superblocks and filesystem accounting information: done
```

Find the universally unique identifier (UUID) of the file systems that you recently created, create a temporary folder, add the corresponding entries on /etc/fstab, and mount all the file systems.

This command also iterates on each disk defined on the "in" part of the "for" cycle:

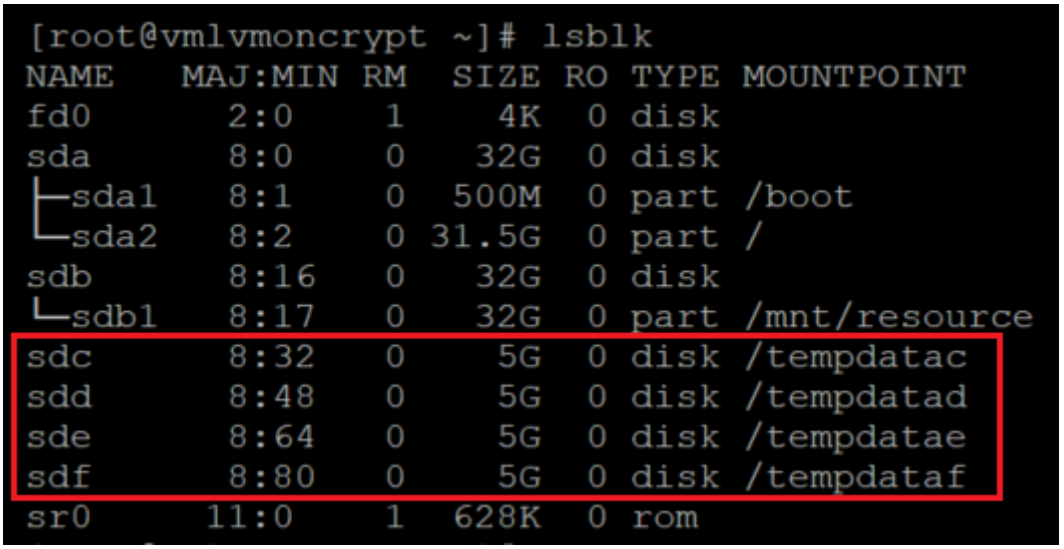
Bash

```
for disk in c d e f; do diskuuid="$(blkid -s UUID -o value /dev/sd${disk})"; \
mkdir /tempdata${disk}; \
echo "UUID=${diskuuid} /tempdata${disk} ext4 defaults,nofail 0 0" >> /etc/fstab; \
mount -a; \
done
```

Verify that the disks are mounted properly

Bash

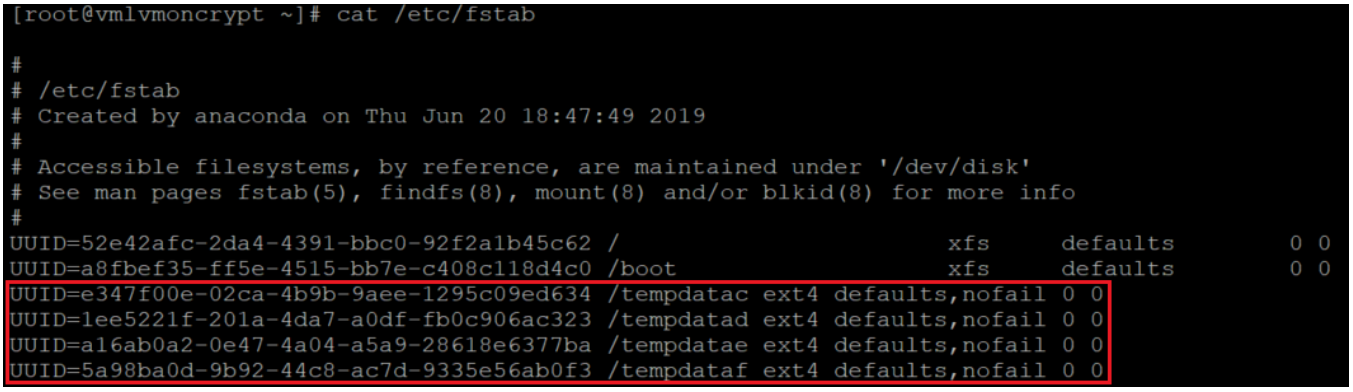
```
lsblk
```



Also verify that the disks are configured:

Bash

```
cat /etc/fstab
```



Encrypt the data disks

PowerShell using a key encryption key (KEK):

PowerShell

```
$sequenceVersion = [Guid]::NewGuid()
Set-AzVMDiskEncryptionExtension -ResourceGroupName $RGNAME `
-VMName ${VMNAME} `
-DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl `
-DiskEncryptionKeyVaultId $KeyVaultResourceId `
-KeyEncryptionKeyUrl $keyEncryptionKeyUrl `
-KeyEncryptionKeyVaultId $KeyVaultResourceId `
-VolumeType 'DATA' `
-EncryptFormatAll `
-SequenceVersion $sequenceVersion `
-skipVmBackup;
```

Azure CLI using a KEK:

Azure CLI

```
az vm encryption enable \
--resource-group ${RGNAME} \
--name ${VMNAME} \
--disk-encryption-keyvault ${KEYVAULTNAME} \
--key-encryption-key ${KEYNAME} \
--key-encryption-keyvault ${KEYVAULTNAME} \
--volume-type "DATA" \
--encrypt-format-all \
-o table
```

Verify the encryption status

Continue to the next step only when all the disks are encrypted.

PowerShell:

PowerShell

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName ${RGNAME} -VMName ${VMNAME}
```

```
OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : EncryptionInProgress
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : Encryption succeeded for data volumes
```

Azure CLI:

Azure CLI

```
az vm encryption show -n ${VMNAME} -g ${RGNAME} -o table
```

```
user@Azure>az vm encryption show -n ${VMNAME} -g ${RGNAME} -o table
Status                 Message
---------------------  ------------------------------------
Provisioning succeeded Encryption succeeded for data volumes
```

Portal:

Data disks

LUN	Name	Size	Storage account ...	Encryption	Host caching
0	vmlvmoncrypt_datadisk0	5 GiB	Standard HDD	Enabled	None
1	vmlvmoncrypt_datadisk1	5 GiB	Standard HDD	Enabled	None
2	vmlvmoncrypt_datadisk2	5 GiB	Standard HDD	Enabled	None
3	vmlvmoncrypt_datadisk3	5 GiB	Standard HDD	Enabled	None

OS level:

Bash

```
lsblk
```

```
[root@vmlvmoncrypt ~]# lsblk
NAME                                  MAJ:MIN RM   SIZE RO TYPE  MOUNTPOINT

└─6712ad6f-65ce-487b-aa52-462f381611a1 253:1    0     5G  0 crypt /tempdatad
sdf                                     8:80   0     5G  0 disk
└─ea607dfd-c396-48d6-bc54-603cf741bc2a 253:2    0     5G  0 crypt /tempdatae
sdg                                     8:96   0     5G  0 disk
└─4159c60a-a546-455b-985f-92865d51158c 253:3    0     5G  0 crypt /tempdataf
sr0                                    11:0    1  1024M  0 rom
```

The extension will add the file systems to /var/lib/azure_disk_encryption_config/azure_crypt_mount (an old encryption) or to /etc/crypttab (new encryptions).

> ⓘ **Note**
>
> Do not modify any of these files.

This file will take care of activating these disks during the boot process so that LVM or RAID can use them later.

Don't worry about the mount points on this file. Azure Disk Encryption will lose the ability to get the disks mounted as a normal file system after we create a physical volume or a RAID device on top of those encrypted devices. (This will remove the file system format that we used during the preparation process.)

Remove the temporary folders and temporary fstab entries

You unmount the file systems on the disks that will be used as part of LVM.

Bash

```
for disk in c d e f; do umount /tempdata${disk}; done
```

And remove the /etc/fstab entries:

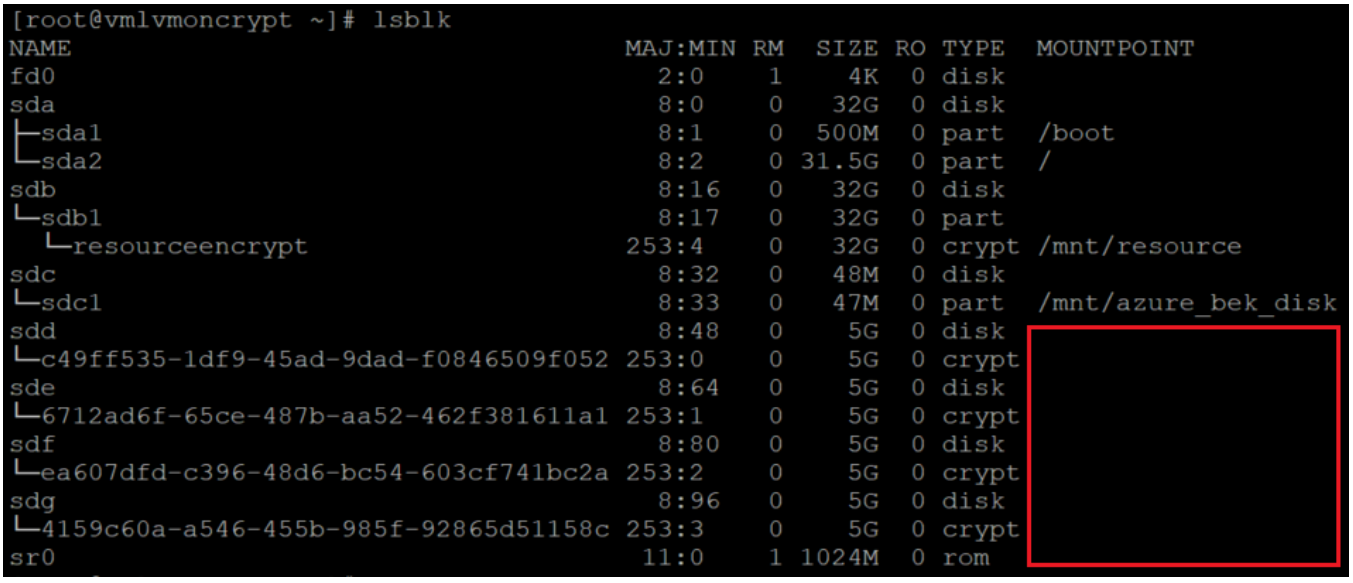
Bash

```
vi /etc/fstab
```

Verify that the disks are not mounted and that the entries on /etc/fstab were removed

Bash

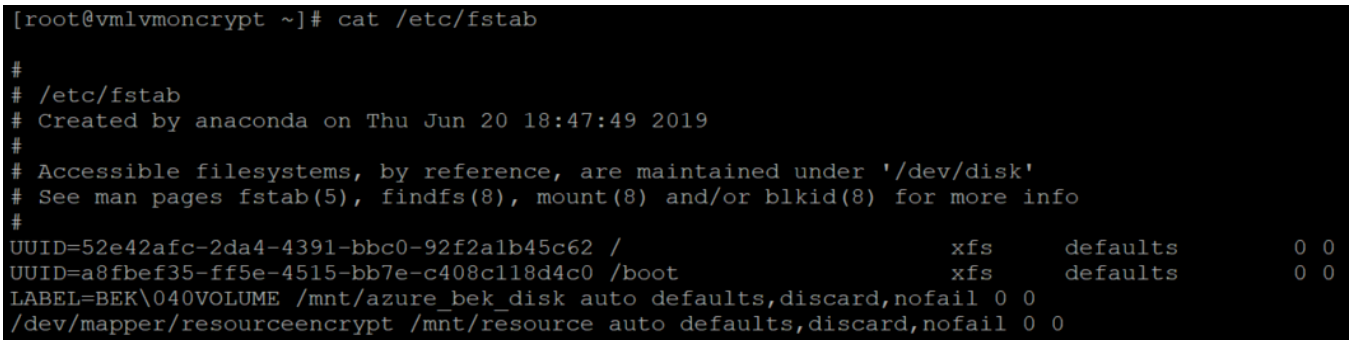
```
lsblk
```



And verify that the disks are configured:

Bash

```
cat /etc/fstab
```



Steps for LVM-on-crypt

Now that the underlying disks are encrypted, you can create the LVM structures.

Instead of using the device name, use the /dev/mapper paths for each of the disks to create a physical volume (on the crypt layer on top of the disk, not on the disk itself).

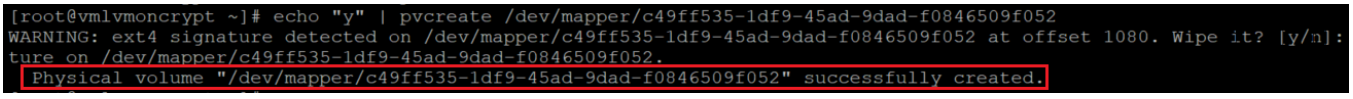
Configure LVM on top of the encrypted layers

Create the physical volumes

You'll get a warning that asks if it's OK to wipe out the file system signature. Continue by entering **y**, or use **echo "y"** as shown:

Bash

```
echo "y" | pvcreate /dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052
echo "y" | pvcreate /dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1
echo "y" | pvcreate /dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a
echo "y" | pvcreate /dev/mapper/4159c60a-a546-455b-985f-92865d51158c
```



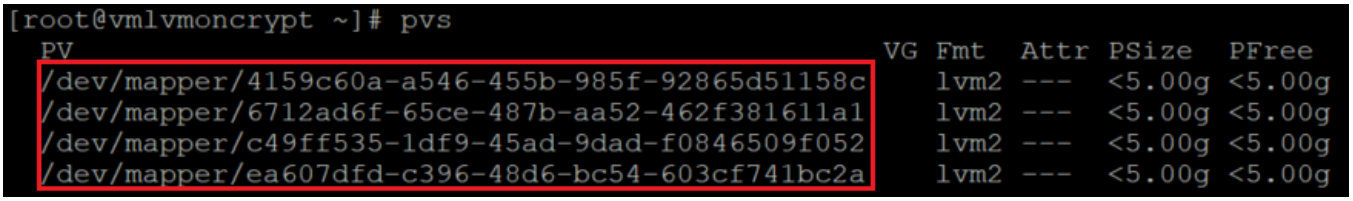
> ⓘ Note

The /dev/mapper/device names here need to be replaced for your actual values based on the output of **lsblk**.

Verify the information for physical volumes

Bash

```
pvs
```



Create the volume group

Create the volume group by using the same devices already initialized:

Bash

```
vgcreate vgdata /dev/mapper/
```

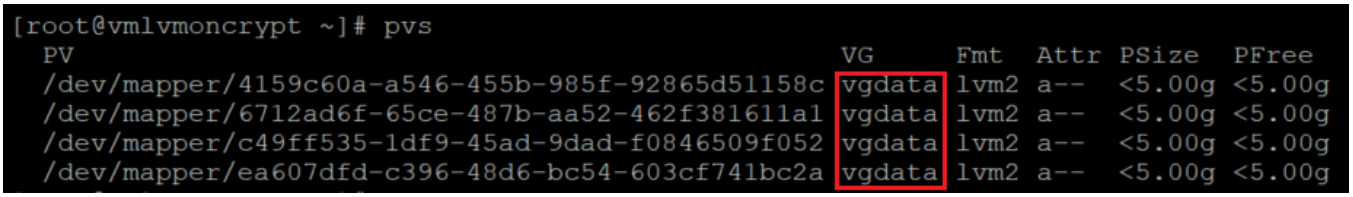
Check the information for the volume group

Bash

```
vgdisplay -v vgdata
```

Bash

```
pvs
```



Create logical volumes

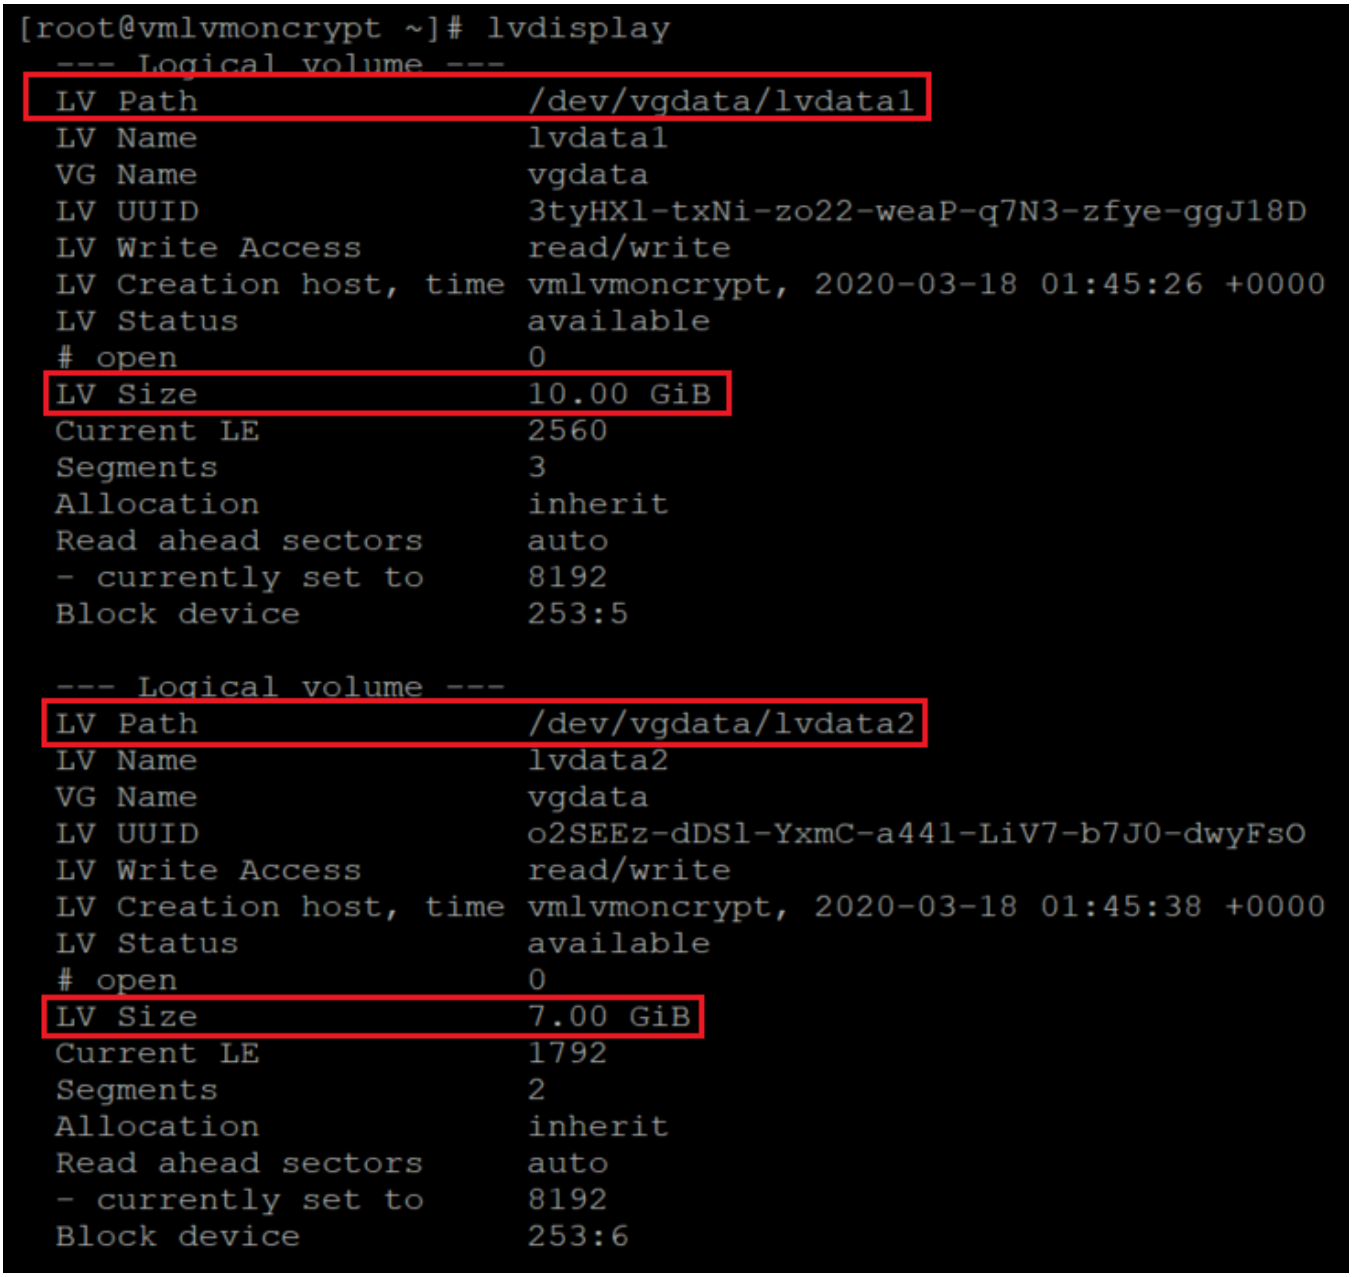
Bash

```
lvcreate -L 10G -n lvdata1 vgdata
lvcreate -L 7G -n lvdata2 vgdata
```

Check the created logical volumes

Bash

```
lvdisplay
lvdisplay vgdata/lvdata1
lvdisplay vgdata/lvdata2
```



Create file systems on top of the structures for logical volumes

Bash

```
echo "yes" | mkfs.ext4 /dev/vgdata/lvdata1
echo "yes" | mkfs.ext4 /dev/vgdata/lvdata2
```

Create the mount points for the new file systems

Bash

```
mkdir /data0
mkdir /data1
```

Add the new file systems to /etc/fstab and mount them

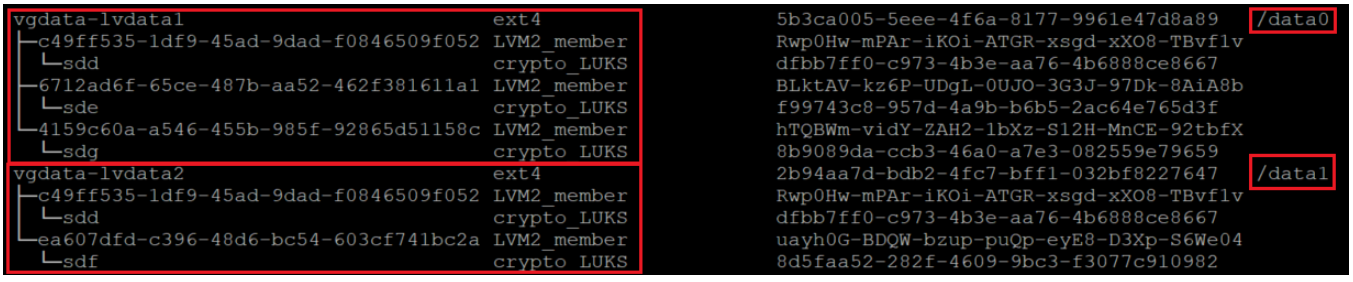
Bash

```
echo "/dev/mapper/vgdata-lvdata1 /data0 ext4 defaults,nofail 0 0" >>/etc/fstab
echo "/dev/mapper/vgdata-lvdata2 /data1 ext4 defaults,nofail 0 0" >>/etc/fstab
mount -a
```

Verify that the new file systems are mounted

Bash

```
lsblk -fs
df -h
```



On this variation of **lsblk**, we're listing the devices showing the dependencies in reverse order. This option helps to identify the devices grouped by the logical volume instead of the original /dev/sd[disk] device names.

It's important to make sure that the **nofail** option is added to the mount point options of the LVM volumes created on top of a device encrypted through Azure Disk Encryption. It prevents the OS from getting stuck during the boot process (or in maintenance mode).

If you don't use the **nofail** option:

- The OS will never get into the stage where Azure Disk Encryption is started and the data disks are unlocked and mounted.
- The encrypted disks will be unlocked at the end of the boot process. The LVM volumes and file systems will be automatically mounted until Azure Disk Encryption unlocks them.

You can test rebooting the VM and validate that the file systems are also automatically getting mounted after boot time. This process might take several minutes, depending on the number and sizes of file systems.

Reboot the VM and verify after reboot

Bash

```
shutdown -r now
```

Bash

```
lsblk
df -h
```

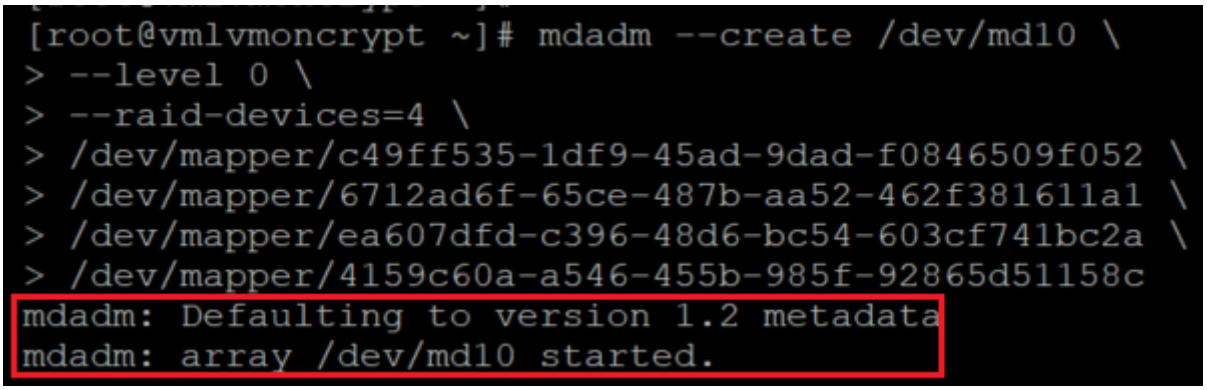
Steps for RAID-on-crypt

Now that the underlying disks are encrypted, you can continue to create the RAID structures. The process is the same as the one for LVM, but instead of using the device name, use the /dev/mapper paths for each disk.

Configure RAID on top of the encrypted layer of the disks

Bash

```
mdadm --create /dev/md10 \
--level 0 \
--raid-devices=4 \
/dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052 \
/dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1 \
/dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a \
/dev/mapper/4159c60a-a546-455b-985f-92865d51158c
```

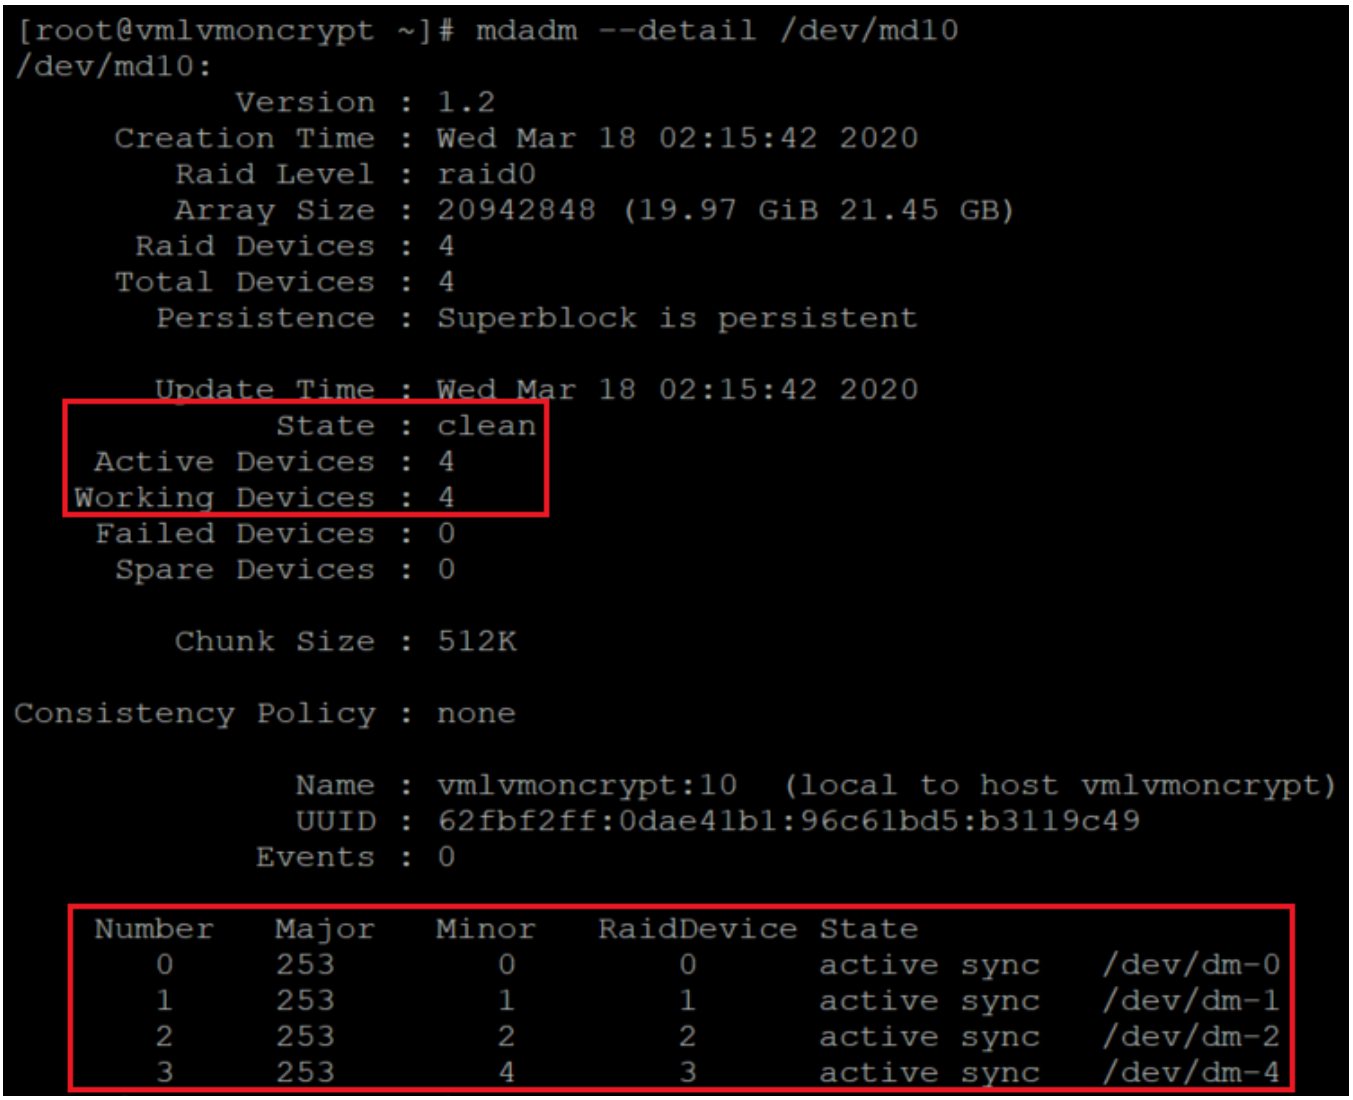


> ⓘ Note
>
> The /dev/mapper/device names here need to be replaced with your actual values, based on the output of **lsblk**.

Check/monitor RAID creation

Bash

```
watch -n1 cat /proc/mdstat
mdadm --examine /dev/mapper/[]
mdadm --detail /dev/md10
```



Create a file system on top of the new RAID device

Bash

```
mkfs.ext4 /dev/md10
```

Create a new mount point for the file system, add the new file system to /etc/fstab, and mount it:

> ⓘ **Note**
>
> This cycle iterates only on one device for this particular example, is built this way to be used for multiple md devices if needed.

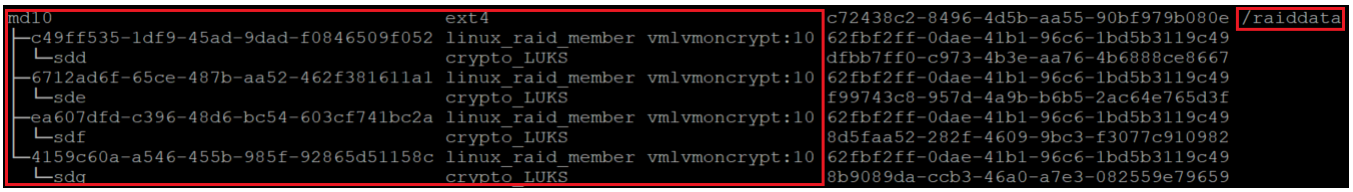
Bash

```
for device in md10; do diskuuid="$(blkid -s UUID -o value /dev/${device})"; \
mkdir /raiddata; \
echo "UUID=${diskuuid} /raiddata ext4 defaults,nofail 0 0" >> /etc/fstab; \
```

```
mount -a; \
done
```

Verify that the new file system is mounted:

```Bash
lsblk -fs
df -h
```



It's important to make sure that the **nofail** option is added to the mount point options of the RAID volumes created on top of a device encrypted through Azure Disk Encryption. It prevents the OS from getting stuck during the boot process (or in maintenance mode).

If you don't use the **nofail** option:

- The OS will never get into the stage where Azure Disk Encryption is started and the data disks are unlocked and mounted.
- The encrypted disks will be unlocked at the end of the boot process. The RAID volumes and file systems will be automatically mounted until Azure Disk Encryption unlocks them.

You can test rebooting the VM and validate that the file systems are also automatically getting mounted after boot time. This process might take several minutes, depending on the number and sizes of file systems.

```Bash
shutdown -r now
```

And when you can log in:

```Bash
lsblk
df -h
```

- Azure Disk Encryption troubleshooting

How to resize logical volume management devices that use Azure Disk Encryption

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

In this article, you'll learn how to resize data disks that use Azure Disk Encryption. To resize the disks, you'll use logical volume management (LVM) on Linux. The steps apply to multiple scenarios.

You can use this resizing process in the following environments:

- Linux distributions:
  - Red Hat Enterprise Linux (RHEL) 7 or later
  - Ubuntu 18.04 or later
  - SUSE 12 or later
- Azure Disk Encryption versions:
  - Single-pass extension
  - Dual-pass extension

Prerequisites

This article assumes that you have:

- An existing LVM configuration. For more information, see Configure LVM on a Linux VM.
- Disks that are already encrypted by Azure Disk Encryption. For more information, see Configure LVM and RAID on encrypted devices.
- Experience using Linux and LVM.
- Experience using */dev/disk/scsi1/* paths for data disks on Azure. For more information, see Troubleshoot Linux VM device name problems.

Scenarios

The procedures in this article apply to the following scenarios:

- Traditional LVM and LVM-on-crypt configurations
- Traditional LVM encryption
- LVM-on-crypt
- Data disks only. OS disk resizing is not supported.

Traditional LVM and LVM-on-crypt configurations

Traditional LVM and LVM-on-crypt configurations extend a logical volume (LV) when the volume group (VG) has available space.

Traditional LVM encryption

In traditional LVM encryption, LVs are encrypted. The whole disk isn't encrypted.

By using traditional LVM encryption, you can:

- Extend the LV when you add a new physical volume (PV).
- Extend the LV when you resize an existing PV.

LVM-on-crypt

The recommended method for disk encryption is LVM-on-encrypt. This method encrypts the entire disk, not just the LV.

By using LVM-on-crypt, you can:

- Extend the LV when you add a new PV.
- Extend the LV when you resize an existing PV.

> ⓘ **Note**
>
> We don't recommend mixing traditional LVM encryption and LVM-on-crypt on the same VM.

The following sections provide examples of how to use LVM and LVM-on-crypt. The examples use preexisting values for disks, PVs, VGs, LVs, file systems, universally unique identifiers (UUIDs), and mount points. Replace these values with your own values to fit your environment.

Extend an LV when the VG has available space

The traditional way to resize LVs is to extend an LV when the VG has space available. You can use this method for nonencrypted disks, traditional LVM-encrypted volumes, and LVM-on-crypt configurations.

1. Verify the current size of the file system that you want to increase:

   ```
   Bash

   df -h /mountpoint
   ```

   ```
   [root@azurevm]# df -h /datalv02
   Filesystem                                      Size  Used Avail Use% Mounted on
   /dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5  974M  958M     0 100% /datalv02
   ```

2. Verify that the VG has enough space to increase the LV:

   ```
   Bash

   sudo vgs
   ```

   ```
   [root@azurevm]#  vgs
     VG     #PV #LV #SN Attr   VSize   VFree
     datavg   3   4   0 wz--n- <14.99g <4.99g
   ```

   You can also use `vgdisplay`:

   ```
   Bash

   sudo vgdisplay vgname
   ```

```
[root@azurevm]# vgdisplay datavg
  --- Volume group ---
  VG Name               datavg
  System ID
  Format                lvm2
  Metadata Areas        3
  Metadata Sequence No  5
  VG Access             read/write
  VG Status             resizable
  MAX LV                0
  Cur LV                4
  Open LV               4
  Max PV                0
  Cur PV                3
  Act PV                3
  VG Size               <14.99 GiB
  PE Size               4.00 MiB
  Total PE              3837
  Alloc PE / Size       2560 / 10.00 GiB
  Free  PE / Size       1277 / <4.99 GiB
  VG UUID               jvc1Kz-FXLd-dNjC-14q7-k85I-Pp8z-bMqFLY
```

3. Identify which LV needs to be resized:

Bash

```
sudo lsblk
```

```
[root@azurevm]#  lsblk
NAME                                    MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                                       2:0    1    4K  0 disk
sda                                       8:0    0   32G  0 disk
├─sda1                                    8:1    0  500M  0 part  /boot
└─sda2                                    8:2    0 31.5G  0 part  /
sdb                                       8:16   0   32G  0 disk
└─sdb1                                    8:17   0   32G  0 part  /mnt/resource
sdc                                       8:32   0   48M  0 disk

sr0                                      11:0    1 1024M  0 rom
```

For LVM-on-crypt, the difference is that this output shows that the encrypted layer is at the disk level.

```
[root@vmresizelv ~]# lsblk
NAME                                    MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT

  └─datavg-datalv04                     253:7    0    3G  0 lvm   /datalv04
```

4. Check the LV size:

Bash

```
sudo lvdisplay lvname
```

```
[root@azurevm]#  lvdisplay /dev/datavg/datalv02
  --- Logical volume ---
  LV Path                /dev/datavg/datalv02
  LV Name                datalv02
  VG Name                datavg
  LV UUID                Isacy4-ukYq-UKCB-tG48-tjfc-LW1r-kWTyfy
  LV Write Access        read/write
  LV Creation host, time vmresizelv, 2020-09-18 20:13:14 +0000
  LV Status              available
  # open                 1
  LV Size                1.00 GiB
  Current LE             256
  Segments               1
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:1
```

5. Increase the LV size by using `-r` to resize the file system online:

Bash

```
sudo lvextend -r -L +2G /dev/vgname/lvname
```

```
[root@azurevm]# lvextend -r -L +2G /dev/datavg/datalv02
  Size of logical volume datavg/datalv02 changed from 1.00 GiB (256 extents) to 3.00 GiB (768 extents).
  Logical volume datavg/datalv02 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5 is mounted on /datalv02; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5 is now 785920 blocks long.
```

6. Verify the new sizes for the LV and the file system:

```
Bash

df -h /mountpoint
```

```
[root@azurevm]# df -h /datalv02/
Filesystem                                      Size  Used Avail Use% Mounted on
/dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5  3.0G  959M  1.9G  34% /datalv02
```

The size output indicates that the LV and file system were successfully resized.

You can check the LV information again to confirm the changes at the level of the LV:

```
Bash

sudo lvdisplay lvname
```

```
[root@azurevm]#  lvdisplay /dev/datavg/datalv02
  --- Logical volume ---
  LV Path                /dev/datavg/datalv02
  LV Name                datalv02
  VG Name                datavg
  LV UUID                Isacy4-ukYq-UKCB-tG48-tjfc-LW1r-kWTyfy
  LV Write Access        read/write
  LV Creation host, time vmresizelv, 2020-09-18 20:13:14 +0000
  LV Status              available
  # open                 1
  LV Size                3.00 GiB
  Current LE             768
  Segments               3
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:1
```

Extend a traditional LVM volume by adding a new PV

When you need to add a new disk to increase the VG size, extend your traditional LVM volume by adding a new PV.

1. Verify the current size of the file system that you want to increase:

```
Bash
```

```
df -h /mountpoint
```

```
[root@azurevm]# df -h /datalv01
Filesystem                                      Size  Used Avail Use% Mounted on
/dev/mapper/55b4afd2-a160-426b-9bd7-588af6c46e9b  974M  958M     0 100% /datalv01
```

2. Verify the current PV configuration:

Bash

```
sudo pvs
```

```
[root@azurevm]# pvs
  PV         VG     Fmt  Attr PSize  PFree
  /dev/sdd   datavg lvm2 a--  <5.00g     0
  /dev/sde   datavg lvm2 a--  <5.00g     0
  /dev/sdf   datavg lvm2 a--  <5.00g     0
```

3. Check the current VG information:

Bash

```
sudo vgs
```

```
[root@azurevm]# vgs
  VG     #PV #LV #SN Attr   VSize   VFree
  datavg   3   4   0 wz--n- <14.99g    0
```

4. Check the current disk list. Identify data disks by checking the devices in */dev/disk/azure/scsi1/*.

Bash

```
sudo ls -l /dev/disk/azure/scsi1/
```

```
[root@azurevm]# ls -l /dev/disk/azure/scsi1/
total 0
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun0 -> ../../../sdd
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun1 -> ../../../sde
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun2 -> ../../../sdf
```

5. Check the output of `lsblk`:

Bash

```
sudo lsbk
```

```
[root@azurevm]#  lsblk
NAME                                    MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                                       2:0    1    4K  0 disk
sda                                       8:0    0   32G  0 disk
├─sda1                                    8:1    0  500M  0 part  /boot
└─sda2                                    8:2    0 31.5G  0 part  /
sdb                                       8:16   0   32G  0 disk
└─sdb1                                    8:17   0   32G  0 part  /mnt/resource

```

6. Attach the new disk to the VM by following the instructions in Attach a data disk to a Linux VM.

7. Check the disk list, and notice the new disk.

Bash

```
sudo ls -l /dev/disk/azure/scsi1/
```

```
[root@azurevm]#  ls -l /dev/disk/azure/scsi1/
total 0
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun0 -> ../../../sdd
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun1 -> ../../../sde
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun2 -> ../../../sdf
lrwxrwxrwx. 1 root root 12 Sep 18 22:20 lun3 -> ../../../sdg
```

Bash

```
sudo lsblk
```

```
[root@azurevm]# lsblk
NAME                                    MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                                       2:0    1    4K  0 disk
sda                                       8:0    0   32G  0 disk
├─sda1                                    8:1    0  500M  0 part  /boot

sr0                                      11:0    1 1024M  0 rom
```

8. Create a new PV on top of the new data disk:

```
Bash

sudo pvcreate /dev/newdisk
```

```
[root@azurevm]#  pvcreate /dev/sdg
  Physical volume "/dev/sdg" successfully created.
[root@azurevm]#
```

This method uses the whole disk as a PV without a partition. Alternatively, you can use `fdisk` to create a partition and then use that partition for `pvcreate`.

9. Verify that the PV was added to the PV list:

```
Bash

sudo pvs
```

```
[root@azurevm]#  pvs
  PV         VG     Fmt  Attr PSize  PFree
  /dev/sdd   datavg lvm2 a--  <5.00g     0
  /dev/sde   datavg lvm2 a--  <5.00g     0
  /dev/sdf   datavg lvm2 a--  <5.00g     0
  /dev/sdg          lvm2 ---   5.00g 5.00g
```

10. Extend the VG by adding the new PV to it:

```
```

Bash

```
sudo vgextend vgname /dev/newdisk
```

```
[root@azurevm]#  vgextend datavg /dev/sdg
  Volume group "datavg" successfully extended
```

11. Check the new VG size:

Bash

```
sudo vgs
```

```
[root@azurevm]#  vgs
  VG      #PV #LV #SN Attr   VSize  VFree
  datavg    4   4   0 wz--n- 19.98g <5.00g
```

13. Use `lsblk` to identify the LV that needs to be resized:

Bash

```
sudo lsblk
```

```
[root@azurevm]#  lsblk
NAME                                    MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                                       2:0    1    4K  0 disk
sda                                       8:0    0   32G  0 disk
├─sda1                                    8:1    0  500M  0 part  /boot
└─sda2                                    8:2    0 31.5G  0 part  /
sdb                                       8:16   0   32G  0 disk
└─sdb1                                    8:17   0   32G  0 part  /mnt/resource

└─datavg-datalv03                       253:2    0    1G  0 lvm
  └─70abfc58-b0fd-441b-8b77-f86c9249af5e 253:6    0 1022M  0 crypt /datalv03
sde                                       8:64   0    5G  0 disk
└─datavg-datalv04                       253:3    0    7G  0 lvm
  └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7    0    7G  0 crypt /datalv04
sdf                                       8:80   0    5G  0 disk
├─datavg-datalv02                       253:1    0    6G  0 lvm
│ └─78b259a1-956b-4f3a-8e6b-c05bf5040bc5 253:5    0    6G  0 crypt /datalv02
└─datavg-datalv04                       253:3    0    7G  0 lvm
  └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7    0    7G  0 crypt /datalv04
sdg                                       8:96   0    5G  0 disk
```

14. Extend the LV size by using `-r` to increase the file system online:

Bash

```
sudo lvextend -r -L +2G /dev/vgname/lvname
```

```
[root@azurevm]#  lvextend -r -L +2G /dev/datavg/datalv01
  Size of logical volume datavg/datalv01 changed from 1.00 GiB (256 extents) to 3.00 GiB (768 extents).
  Logical volume datavg/datalv01 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/55b4afd2-a160-426b-9bd7-588af6c46e9b is mounted on /datalv01; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/55b4afd2-a160-426b-9bd7-588af6c46e9b is now 785920 blocks long.
```

15. Verify the new sizes of the LV and file system:

```
Bash

df -h /mountpoint
```

```
[root@azurevm]# df -h /datalv01
Filesystem                                      Size  Used Avail Use% Mounted on
/dev/mapper/55b4afd2-a160-426b-9bd7-588af6c46e9b  3.0G  959M  1.9G  34% /datalv01
```

> **ⓘ Important**
>
> When Azure Data Encryption is used on traditional LVM configurations, the encrypted layer is created at the LV level, not at the disk level.
>
> At this point, the encrypted layer is expanded to the new disk. The actual data disk has no encryption settings at the platform level, so its encryption status isn't updated.
>
> These are some of the reasons why LVM-on-crypt is the recommended approach.

16. Check the encryption information from the portal:

LUN ⓘ	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (...	Encryption ⓘ
0	vmresizelv_datadisk0	Standard HDD	5	500	60	SSE with PMK & ADE
1	vmresizelv_datadisk1	Standard HDD	5	500	60	SSE with PMK & ADE
2	vmresizelv_datadisk2	Standard HDD	5	500	60	SSE with PMK & ADE
3	vmresizelv_datadisk3	Standard HDD	5	500	60	SSE with PMK

To update the encryption settings on the disk, add a new LV and enable the extension on the VM.

17. Add a new LV, create a file system on it, and add it to `/etc/fstab`.

18. Set the encryption extension again. This time you'll stamp the encryption settings on the new data disk at the platform level. Here's a CLI example:

```
azurecliazurecli

az vm encryption enable -g ${RGNAME} --name ${VMNAME} --disk-encryption-
keyvault "<your-unique-keyvault-name>"
```

19. Check the encryption information from the portal:

LUN	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (MBps)	Encryption
0	vmresizelv_datadisk0	Standard HDD	5	500	60	SSE with PMK & ADE
1	vmresizelv_datadisk1	Standard HDD	5	500	60	SSE with PMK & ADE
2	vmresizelv_datadisk2	Standard HDD	5	500	60	SSE with PMK & ADE
3	vmresizelv_datadisk3	Standard HDD	5	500	60	SSE with PMK & ADE

After the encryption settings are updated, you can delete the new LV. Also delete the entry from the `/etc/fstab` and `/etc/crypttab` that you created.

```
[root@azurevm]#  cat /etc/fstab

#
# /etc/fstab
# Created by anaconda on Thu Jun 20 18:47:49 2019
#
# Accessible filesystems, by reference, are maintained under '/dev/disk'
# See man pages fstab(5), findfs(8), mount(8) and/or blkid(8) for more info
#
UUID=52e42afc-2da4-4391-bbc0-92f2a1b45c62 /                       xfs     defaults        0 0

[root@azurevm]#
[root@azurevm]#
[root@azurevm]#  cat /etc/crypttab

55b4afd2-a160-426b-9bd7-588af6c46e9b /dev/mapper/datavg-datalv01 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_0 luks,nofail

78b259a1-956b-4f3a-8e6b-c05bf5040bc5 /dev/mapper/datavg-datalv02 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_0 luks,nofail

70abfc58-b0fd-441b-8b77-f86c9249af5e /dev/mapper/datavg-datalv03 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_0 luks,nofail

e5dee6bc-0f22-4579-b6c0-6103a9aba86c /dev/mapper/datavg-datalv04 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_2 luks,nofail

9157c7b5-8bad-4a84-84e2-0ca2bffcfce4 /dev/mapper/datavg-datalv05 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_3 luks,nofail
[root@azurevm]#
```

Follow these steps to finish cleaning up:

1. Unmount the LV:

   ```
   Bash

   sudo umount /mountpoint
   ```

2. Close the encrypted layer of the volume:

   ```
   Bash

   sudo cryptsetup luksClose /dev/vgname/lvname
   ```

3. Delete the LV:

   ```
   Bash

   sudo lvremove /dev/vgname/lvname
   ```

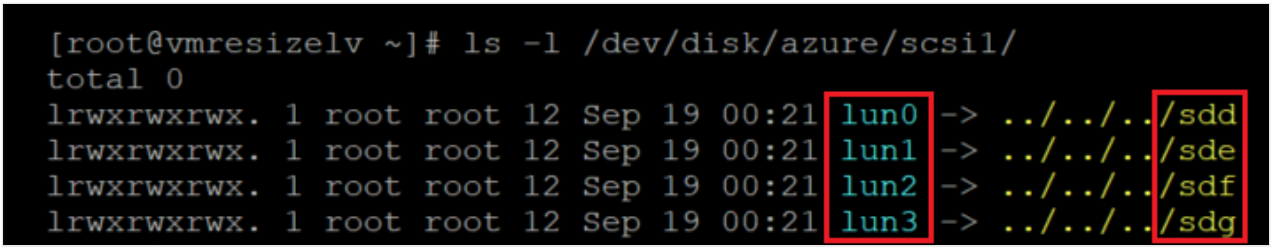
Extend a traditional LVM volume by resizing an existing PV

Im some scenarios, your limitations might require you to resize an existing disk. Here's how:

1. Identify your encrypted disks:

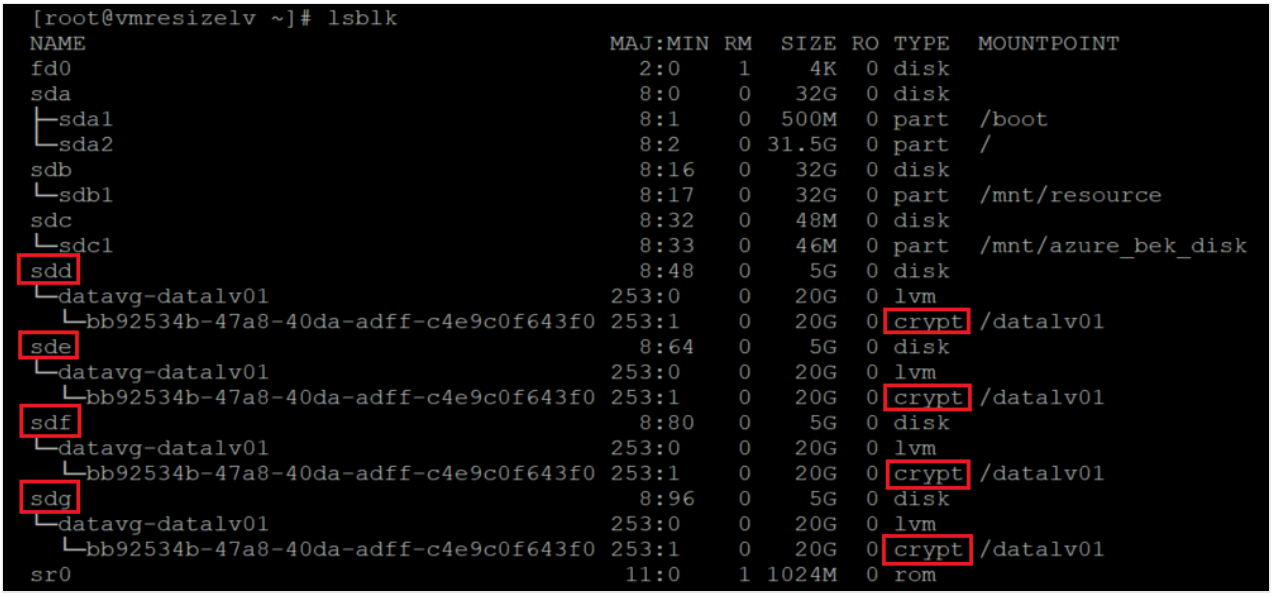
Bash

```
sudo ls -l /dev/disk/azure/scsi1/
```



Bash

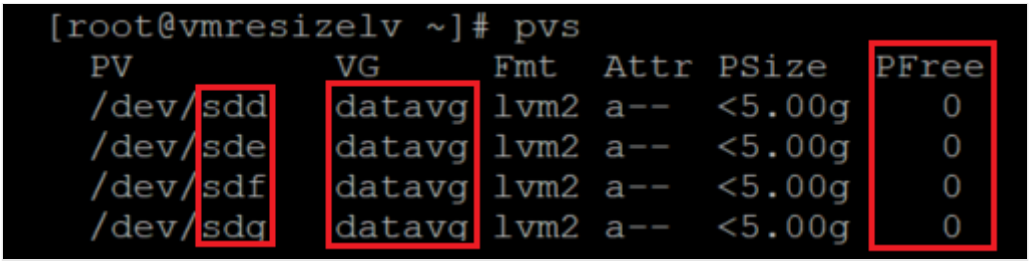
```
sudo lsblk -fs
```



2. Check the PV information:

Bash

```
sudo pvs
```



The results in the image show that all of the space on all of the PVs is currently used.

3. Check the VG information:

```
Bash

sudo vgs
sudo vgdisplay -v vgname
```

```
[root@vmresizelv ~]# vgs
  VG     #PV #LV #SN Attr   VSize  VFree
  datavg   4   1   0 wz--n- 19.98g    0
[root@vmresizelv ~]# vgdisplay datavg
  --- Volume group ---
  VG Name               datavg
  System ID
  Format                lvm2
  Metadata Areas        4
  Metadata Sequence No  16
  VG Access             read/write
  VG Status             resizable
  MAX LV                0
  Cur LV                1
  Open LV               1
  Max PV                0
  Cur PV                4
  Act PV                4
  VG Size               19.98 GiB
  PE Size               4.00 MiB
  Total PE              5116
  Alloc PE / Size       5116 / 19.98 GiB
  Free  PE / Size       0 / 0
  VG UUID               jvc1Kz-FXLd-dNjC-14q7-k85I-Pp8z-bMqFLY
```

4. Check the disk sizes. You can use `fdisk` or `lsblk` to list the drive sizes.

```
Bash

for disk in `sudo ls -l /dev/disk/azure/scsi1/* | awk -F/ '{print $NF}'` ; do
echo "sudo fdisk -l /dev/${disk} | grep ^Disk "; done | bash

sudo lsblk -o "NAME,SIZE"
```

```
Disk /dev/sdd: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sde: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdg: 5368 MB, 5368709120 bytes, 10485760 sectors
```

Here we identified which PVs are associated with which LVs by using `lsblk -fs`. You can identify the associations by running `lvdisplay`.

Bash

```
sudo lvdisplay --maps VG/LV
sudo lvdisplay --maps datavg/datalv1
```

```
[root@vmresizelv ~]# lvdisplay --maps datavg/datalv01
  --- Logical volume ---
  LV Path                /dev/datavg/datalv01
  LV Name                datalv01
  VG Name                datavg
  LV UUID                oiTd6A-PTqY-AbzV-Kd0J-0891-dlMP-jBUJUC
  LV Write Access        read/write
  LV Creation host, time vmresizelv, 2020-09-19 00:21:25 +0000
  LV Status              available
  # open                 1
  LV Size                19.98 GiB
  Current LE             5116
  Segments               4
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:0

  --- Segments ---
  Logical extents 0 to 1278:
    Type                linear
    Physical volume     /dev/sdd
    Physical extents    0 to 1278

  Logical extents 1279 to 2557:
    Type                linear
    Physical volume     /dev/sde
    Physical extents    0 to 1278

  Logical extents 2558 to 3836:
    Type                linear
    Physical volume     /dev/sdf
    Physical extents    0 to 1278

  Logical extents 3837 to 5115:
    Type                linear
    Physical volume     /dev/sdg
    Physical extents    0 to 1278
```

In this case, all four data drives are part of the same VG and a single LV. Your configuration might differ.

5. Check the current file system utilization:

Bash

```
df -h /datalvm*
```

```
[root@vmresizelv ~]# df -h /datalv01/
Filesystem                                Size  Used Avail Use% Mounted on
/dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0   20G   20G     0 100% /datalv01
```

6. Resize the data disks by following the instructions in Expand an Azure managed disk. You can use the portal, the CLI, or PowerShell.

> **ⓘ Important**
>
> Some data disks on Linux VMs can be resized without Deallocating the VM, please check [Expand virtual hard disks on a Linux VM](/azure/virtual-machines/linux/expand-disks? tabs=ubuntu#expand-an-azure-managed-disk) in order to verify your disks meet the requirements.

7. Start the VM and check the new sizes by using `fdisk`.

Bash

```
for disk in `sudo ls -l /dev/disk/azure/scsi1/* | awk -F/ '{print $NF}'` ; do
echo "sudo fdisk -l /dev/${disk} | grep ^Disk "; done | bash

sudo lsblk -o "NAME,SIZE"
```

```
Disk /dev/sdd: 21.5 GB, 21474836480 bytes, 41943040 sectors
Disk /dev/sde: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdg: 5368 MB, 5368709120 bytes, 10485760 sectors
```

In this case, `/dev/sdd` was resized from 5 G to 20 G.

8. Check the current PV size:

Bash

```
sudo pvdisplay /dev/resizeddisk
```

```
[root@vmresizelv ~]# pvdisplay /dev/sdd
  --- Physical volume ---
  PV Name               /dev/sdd
  VG Name               datavg
  PV Size               5.00 GiB / not usable 4.00 MiB
  Allocatable           yes (but full)
  PE Size               4.00 MiB
  Total PE              1279
  Free PE               0
  Allocated PE          1279
  PV UUID               gy2E19-BHhh-lHyl-MGJg-P6tu-iSeh-vYpO8U
```

Even though the disk was resized, the PV still has the previous size.

9. Resize the PV:

```
Bash

sudo pvresize /dev/resizeddisk
```

```
[root@vmresizelv ~]# pvresize /dev/sdd
  Physical volume "/dev/sdd" changed
  1 physical volume(s) resized / 0 physical volume(s) not resized
```

10. Check the PV size:

```
Bash

sudo pvdisplay /dev/resizeddisk
```

```
[root@vmresizelv ~]# pvdisplay /dev/sdd
  --- Physical volume ---
  PV Name               /dev/sdd
  VG Name               datavg
  PV Size               <20.00 GiB / not usable 3.00 MiB
  Allocatable           yes
  PE Size               4.00 MiB
  Total PE              5119
  Free PE               3840
  Allocated PE          1279
  PV UUID               gy2E19-BHhh-lHyl-MGJg-P6tu-iSeh-vYpO8U
```

Apply the same procedure for all of the disks that you want to resize.

11. Check the VG information.

```
Bash

sudo vgdisplay vgname
```

```
[root@vmresizelv ~]# vgdisplay datavg
  --- Volume group ---
  VG Name               datavg
  System ID
  Format                lvm2
  Metadata Areas        4
  Metadata Sequence No  17
  VG Access             read/write
  VG Status             resizable
  MAX LV                0
  Cur LV                1
  Open LV               1
  Max PV                0
  Cur PV                4
  Act PV                4
  VG Size               34.98 GiB
  PE Size               4.00 MiB
  Total PE              8956
  Alloc PE / Size       5116 / 19.98 GiB
  Free  PE / Size       3840 / 15.00 GiB
  VG UUID               jvclKz-FXLd-dNjC-14q7-k85I-Pp8z-bMqFLY
```

The VG now has enough space to be allocated to the LVs.

12. Resize the LV:

```
Bash

sudo lvresize -r -L +5G vgname/lvname
sudo lvresize -r -l +100%FREE /dev/datavg/datalv01
```

```
[root@vmresizelv ~]# lvresize -r -L +5G /dev/datavg/datalv01
  Size of logical volume datavg/datalv01 changed from 19.98 GiB (5116 extents) to 24.98 GiB (6396 extents).
  Logical volume datavg/datalv01 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0 is mounted on /datalv01; on-line resizing required
old_desc_blocks = 3, new_desc_blocks = 4
The filesystem on /dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0 is now 6548992 blocks long.
```

13. Check the size of the file system:

```
Bash

df -h /datalvm2
```

```
[root@vmresizelv ~]# df -h /datalv01/
Filesystem                                      Size  Used Avail Use% Mounted on
/dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0   35G   20G   14G  60% /datalv01
```

Extend an LVM-on-crypt volume by adding a new PV

You can also extend an LVM-on-crypt volume by adding a new PV. This method closely follows the steps in Configure LVM and RAID on encrypted devices. See the sections that explain how

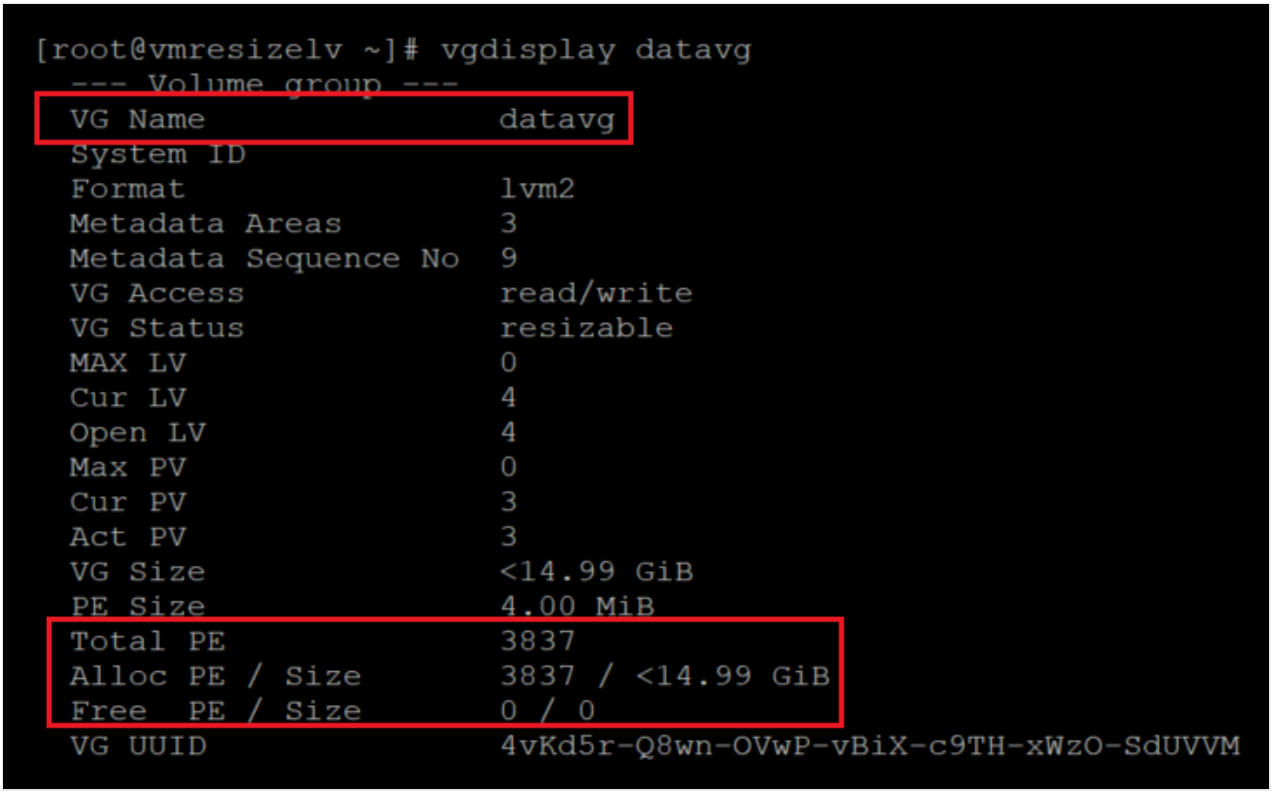
to add a new disk and set it up in an LVM-on-crypt configuration.

You can use this method to add space to an existing LV. Or you can create new VGs or LVs.

1. Verify the current size of your VG:

```
Bash

sudo vgdisplay vgname
```



2. Verify the size of the file system and LV that you want to expand:

```
Bash

sudo lvdisplay /dev/vgname/lvname
```

```
[root@vmresizelv ~]# lvdisplay /dev/datavg/datalv01
  --- Logical volume ---
  LV Path                /dev/datavg/datalv01
  LV Name                datalv01
  VG Name                datavg
  LV UUID                K8zZjy-brpp-Lx74-atfR-lTVu-h26Q-urRi7z
  LV Write Access        read/write
  LV Creation host, time vmresizelv, 2020-09-21 14:44:27 +0000
  LV Status              available
  # open                 1
  LV Size                1.00 GiB
  Current LE             256
  Segments               1
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:4
```

Bash

```
df -h mountpoint
```

```
[root@vmresizelv ~]# df -h /datalv01
Filesystem                  Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv01  976M  960M     0 100% /datalv01
```

3. Add a new data disk to the VM and identify it.

   Before you add the new disk, check the disks:

Bash

```
sudo fdisk -l | egrep ^"Disk /"
```

```
[root@vmresizelv ~]# fdisk -l | egrep ^"Disk /"
Disk /dev/sdc: 50 MB, 50331648 bytes, 98304 sectors
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdg: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sde: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdb: 34.4 GB, 34359738368 bytes, 67108864 sectors
Disk /dev/sda: 34.4 GB, 34359738368 bytes, 67108864 sectors
Disk /dev/mapper/resourceencrypt: 34.4 GB, 34356527104 bytes, 67102592 sectors
Disk /dev/mapper/e19fcd77-e974-4e5c-a874-e78e4b6d2f48: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/49de5df0-1c65-48bf-809c-588805eda921: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/8a33198f-fa7e-491f-a9c6-e9d0a1d25d57: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/datavg-datalv01: 1073 MB, 1073741824 bytes, 2097152 sectors
Disk /dev/mapper/datavg-datalv02: 6442 MB, 6442450944 bytes, 12582912 sectors
Disk /dev/mapper/datavg-datalv03: 4294 MB, 4294967296 bytes, 8388608 sectors
Disk /dev/mapper/datavg-datalv04: 4282 MB, 4282384384 bytes, 8364032 sectors
```

   Here's another way to check the disks before you add the new disk:

Bash

```
sudo lsblk
```

```
[root@vmresizelv ~]# lsblk
NAME                                    MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                                       2:0    1    4K  0 disk
sda                                       8:0    0   32G  0 disk
├─sda1                                    8:1    0  500M  0 part  /boot
└─sda2                                    8:2    0 31.5G  0 part  /

  └─datavg-datalv04                     253:7    0    3G  0 lvm   /datalv04
```

To add the new disk, you can use PowerShell, the Azure CLI, or the Azure portal. For more information, see Attach a data disk to a Linux VM.

The kernel name scheme applies to the newly added device. A new drive is normally assigned the next available letter. In this case, the added disk is `sdd`.

4. Check the disks to make sure the new disk has been added:

Bash

```
sudo fdisk -l | egrep ^"Disk /"
```

```
[root@vmresizelv ~]# fdisk -l | egrep ^"Disk /"
Disk /dev/sdc: 50 MB, 50331648 bytes, 98304 sectors
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors

  ├─datavg-datalv03                     253:6    0    4G  0 lvm   /datalv03
  └─datavg-datalv04                     253:7    0    4G  0 lvm   /datalv04
```

5. Create a file system on top of the recently added disk. Match the disk to the linked devices on `/dev/disk/azure/scsi1/`.

Bash

```
sudo ls -la /dev/disk/azure/scsi1/
```

```
[root@vmresizelv ~]# ls -la /dev/disk/azure/scsi1/*
lrwxrwxrwx. 1 root root 12 Sep 21 14:32 /dev/disk/azure/scsi1/lun1 -> ../../../sde
lrwxrwxrwx. 1 root root 12 Sep 21 14:32 /dev/disk/azure/scsi1/lun2 -> ../../../sdf
lrwxrwxrwx. 1 root root 12 Sep 21 14:32 /dev/disk/azure/scsi1/lun3 -> ../../../sdg
lrwxrwxrwx. 1 root root 12 Sep 21 16:39 /dev/disk/azure/scsi1/lun4 -> ../../../sdd
```

Bash

```
sudo mkfs.ext4 /dev/disk/azure/scsi1/${disk}
```

```
[root@vmresizelv ~]# mkfs.ext4 /dev/disk/azure/scsi1/lun4
mke2fs 1.42.9 (28-Dec-2013)
/dev/disk/azure/scsi1/lun4 is entire device, not just one partition!
Proceed anyway? (y,n) y
Discarding device blocks: done
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)
Stride=0 blocks, Stripe width=0 blocks
327680 inodes, 1310720 blocks
65536 blocks (5.00%) reserved for the super user
First data block=0
Maximum filesystem blocks=1342177280
40 block groups
32768 blocks per group, 32768 fragments per group
8192 inodes per group
Superblock backups stored on blocks:
        32768, 98304, 163840, 229376, 294912, 819200, 884736

Allocating group tables: done
Writing inode tables: done
Creating journal (32768 blocks): done
Writing superblocks and filesystem accounting information: done
```

6. Create a temporary mount point for the new added disk:

```
Bash

newmount=/data4
sudo mkdir ${newmount}
```

7. Add the recently created file system to `/etc/fstab`.

```
Bash

sudo blkid /dev/disk/azure/scsi1/lun4| awk -F\" '{print "UUID="$2"
'${newmount}' "$4" defaults,nofail 0 0"}' >> /etc/fstab
```

8. Mount the newly created file system:

```
Bash

sudo mount -a
```

9. Verify that the new file system is mounted:

```
Bash

df -h
```

```
[root@vmresizelv ~]# df -h
Filesystem                  Size  Used Avail Use% Mounted on
/dev/sda2                    32G  2.7G   29G   9% /

  ├─datavg-datalv02                 253:5    0    6G  0 lvm   /datalv02
  └─datavg-datalv04                 253:7    0    4G  0 lvm   /datalv04
sdg                                   8:96   0    5G  0 disk
└─8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 253:3    0    5G  0 crypt
  ├─datavg-datalv03                 253:6    0    4G  0 lvm   /datalv03
  └─datavg-datalv04                 253:7    0    4G  0 lvm   /datalv04
```

10. Restart the encryption that you previously started for data drives.

> **Tip**
>
> For LVM-on-crypt, we recommend that you use `EncryptFormatAll`. Otherwise, you might see a double encryption while you set additional disks.
>
> For more information, see Configure LVM and RAID on encrypted devices.

Here's an example:

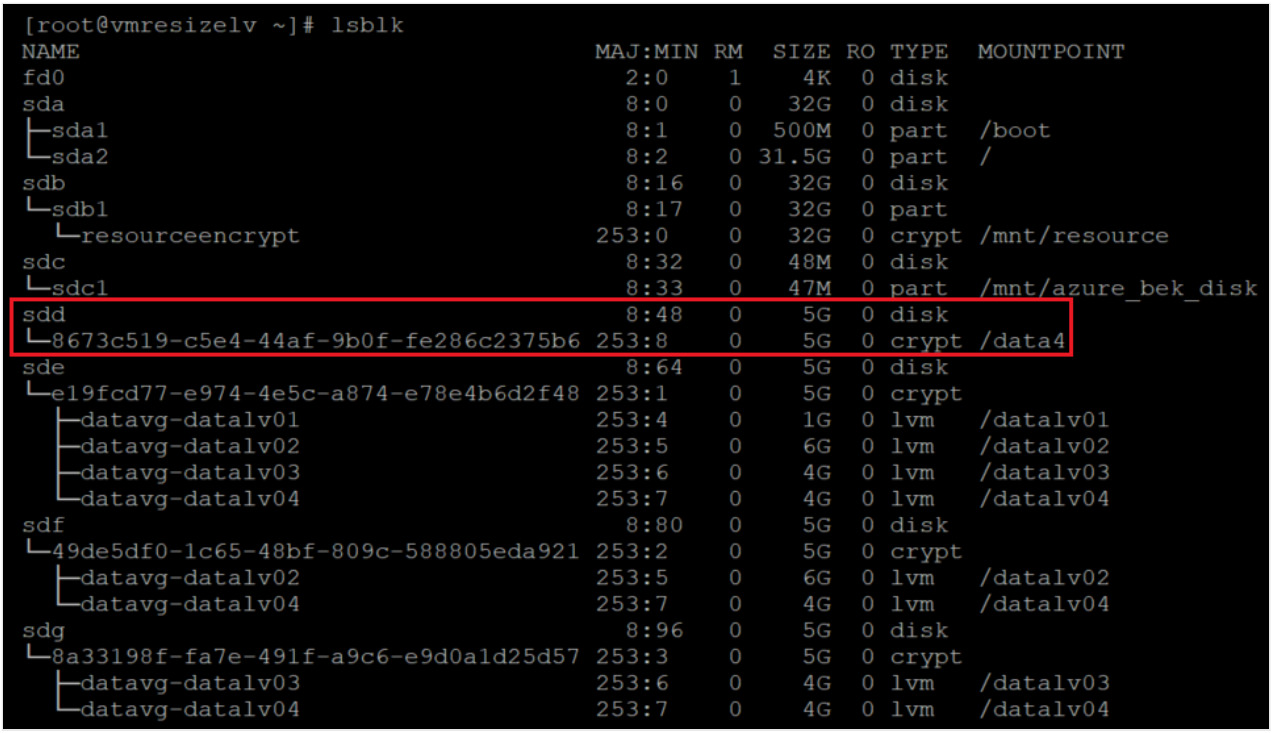
Azure CLI

```
az vm encryption enable \
--resource-group ${RGNAME} \
--name ${VMNAME} \
--disk-encryption-keyvault ${KEYVAULTNAME} \
--key-encryption-key ${KEYNAME} \
--key-encryption-keyvault ${KEYVAULTNAME} \
--volume-type "DATA" \
--encrypt-format-all \
-o table
```

When the encryption finishes, you see a crypt layer on the newly added disk:

Bash

```
sudo lsblk
```



11. Unmount the encrypted layer of the new disk:

Bash

```
sudo umount ${newmount}
```

12. Check the current PV information:

Bash

```
sudo pvs
```

```
[root@vmresizelv ~]# pvs
  PV                                            VG     Fmt  Attr PSize  PFree
  /dev/mapper/49de5df0-1c65-48bf-809c-588805eda921 datavg lvm2 a--  <5.00g    0
  /dev/mapper/8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 datavg lvm2 a--  <5.00g    0
  /dev/mapper/e19fcd77-e974-4e5c-a874-e78e4b6d2f48 datavg lvm2 a--  <5.00g    0
```

13. Create a PV on top of the encrypted layer of the disk. Take the device name from the previous `lsblk` command. Add a `/dev/` mapper in front of the device name to create the PV:

```
Bash

sudo pvcreate /dev/mapper/mapperdevicename
```

```
[root@vmresizelv ~]# pvcreate /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6
WARNING: ext4 signature detected on /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6 at offset 1080. Wipe it? [y/n]: y
  Wiping ext4 signature on /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6.
  Physical volume "/dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6" successfully created.
```

You see a warning about wiping the current `ext4 fs` signature. This warning is expected. Answer this question with `y`.

14. Verify that the new PV was added to the LVM configuration:

```
Bash

sudo pvs
```

```
[root@vmresizelv ~]# pvs
  PV                                            VG     Fmt  Attr PSize  PFree
  /dev/mapper/49de5df0-1c65-48bf-809c-588805eda921 datavg lvm2 a--  <5.00g    0
  /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6       lvm2 ---  <5.00g <5.00g
  /dev/mapper/8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 datavg lvm2 a--  <5.00g    0
  /dev/mapper/e19fcd77-e974-4e5c-a874-e78e4b6d2f48 datavg lvm2 a--  <5.00g    0
```

15. Add the new PV to the VG that you need to increase.

```
Bash

sudo vgextend vgname /dev/mapper/nameofhenewpv
```

```
[root@vmresizelv ~]# vgextend datavg /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6
  Volume group "datavg" successfully extended
```

16. Verify the new size and free space of the VG:

```
Bash
```

```
sudo vgdisplay vgname
```

```
[root@vmresizelv ~]# vgdisplay datavg
  --- Volume group ---
  VG Name               datavg
  System ID
  Format                lvm2
  Metadata Areas        4
  Metadata Sequence No  10
  VG Access             read/write
  VG Status             resizable
  MAX LV                0
  Cur LV                4
  Open LV               4
  Max PV                0
  Cur PV                4
  Act PV                4
  VG Size               19.98 GiB
  PE Size               4.00 MiB
  Total PE              5116
  Alloc PE / Size       3837 / <14.99 GiB
  Free  PE / Size       1279 / <5.00 GiB
  VG UUID               4vKd5r-Q8wn-OVwP-vBiX-c9TH-xWzO-SdUVVM
```

Note the increase of the `Total PE` count and the `Free PE / Size`.

17. Increase the size of the LV and the file system. Use the `-r` option on `lvextend`. In this example, we're adding the total available space in the VG to the given LV.

Bash

```
sudo lvextend -r -l +100%FREE /dev/vgname/lvname
```

```
[root@vmresizelv ~]# lvextend -r -l +100%FREE datavg/datalv01
  Size of logical volume datavg/datalv01 changed from 1.00 GiB (256 extents) to <6.00 GiB (1535 extents).
  Logical volume datavg/datalv01 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/datavg-datalv01 is mounted on /datalv01; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/datavg-datalv01 is now 1571840 blocks long.
```

Follow the next steps to verify your changes.

1. Verify the size of the LV:

Bash

```
sudo lvdisplay /dev/vgname/lvname
```

```
[root@vmresizelv ~]# lvdisplay /dev/datavg/datalv01
  --- Logical volume ---
  LV Path                /dev/datavg/datalv01
  LV Name                datalv01
  VG Name                datavg
  LV UUID                K8zZjy-brpp-Lx74-atfR-lTVu-h26Q-urRi7z
  LV Write Access        read/write
  LV Creation host, time vmresizelv, 2020-09-21 14:44:27 +0000
  LV Status              available
  # open                 1
  LV Size                <6.00 GiB
  Current LE             1535
  Segments               2
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:4
```

2. Verify the new size of the file system:

Bash

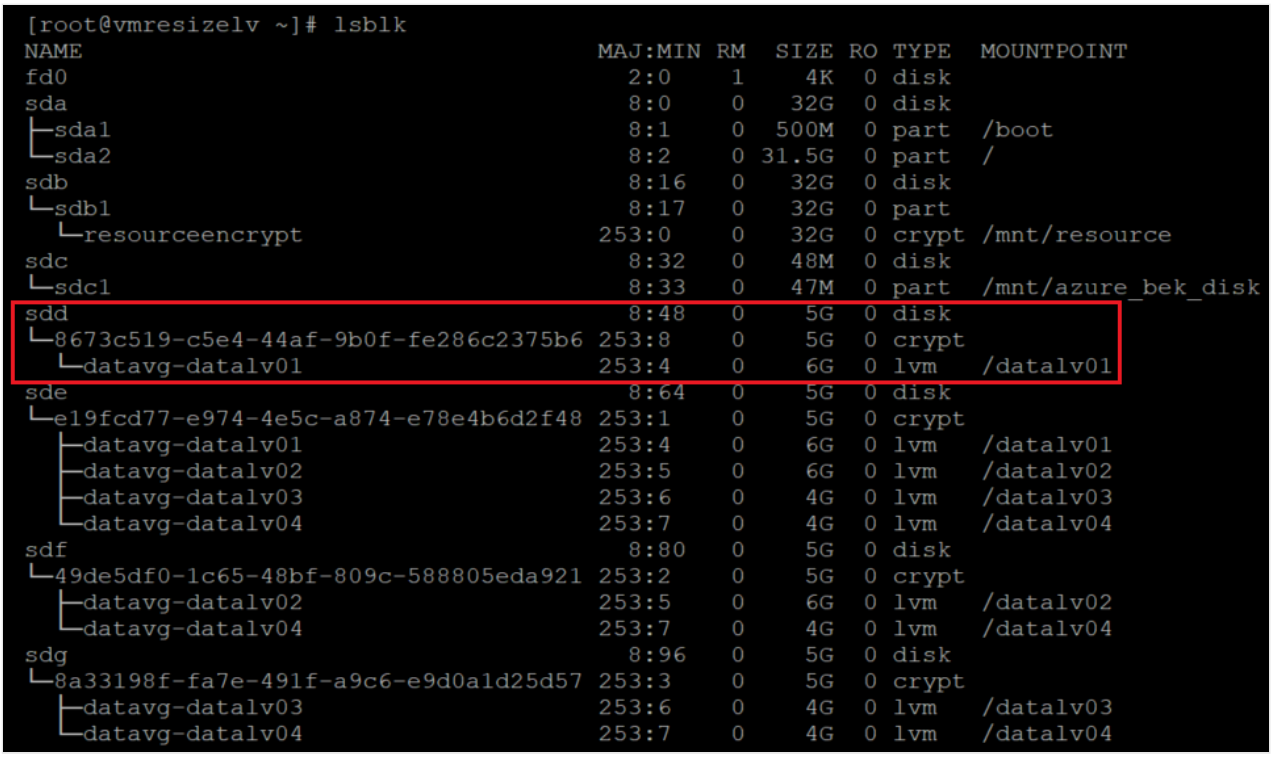
```
df -h /mountpoint
```

```
[root@vmresizelv ~]# df -h /datalv01/
Filesystem                  Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv01  5.9G  962M  4.7G  17% /datalv01
```

3. Verify that the LVM layer is on top of the encrypted layer:

Bash

```
sudo lsblk
```

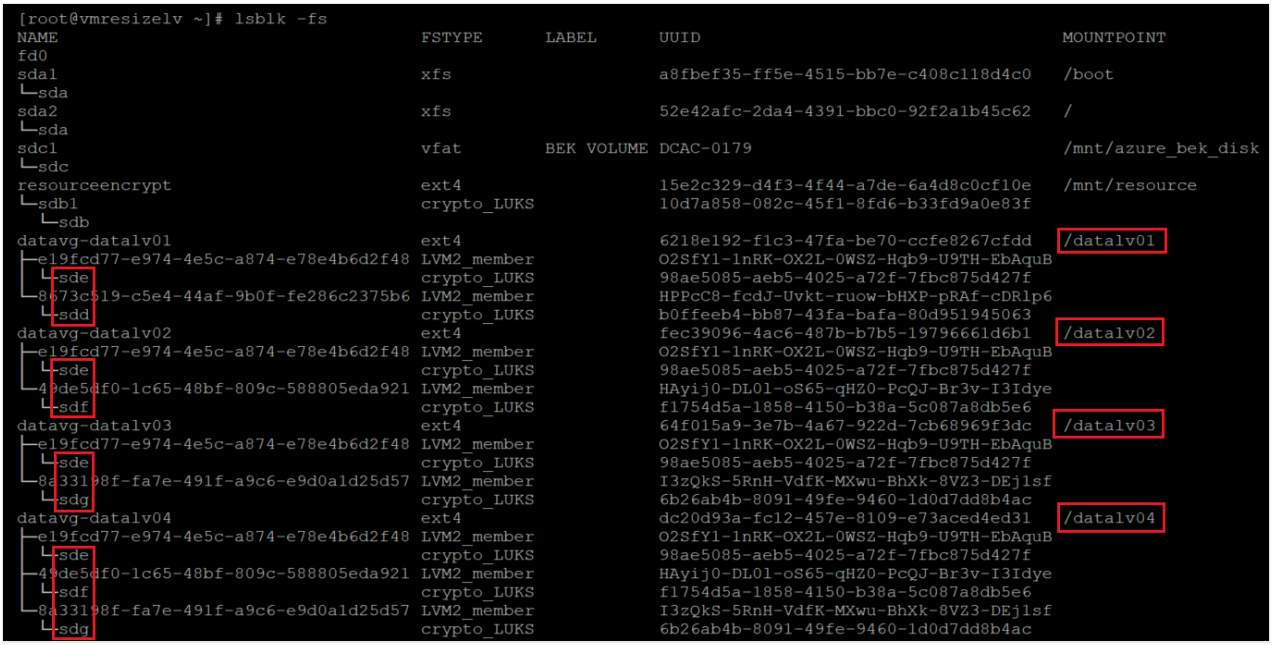


If you use `lsblk` without options, then you see the mount points multiple times. The command sorts by device and LVs.

You might want to use `lsblk -fs`. In this command, `-fs` reverses the sort order so that the mount points are shown once. The disks are shown multiple times.

Bash

```
sudo lsblk -fs
```

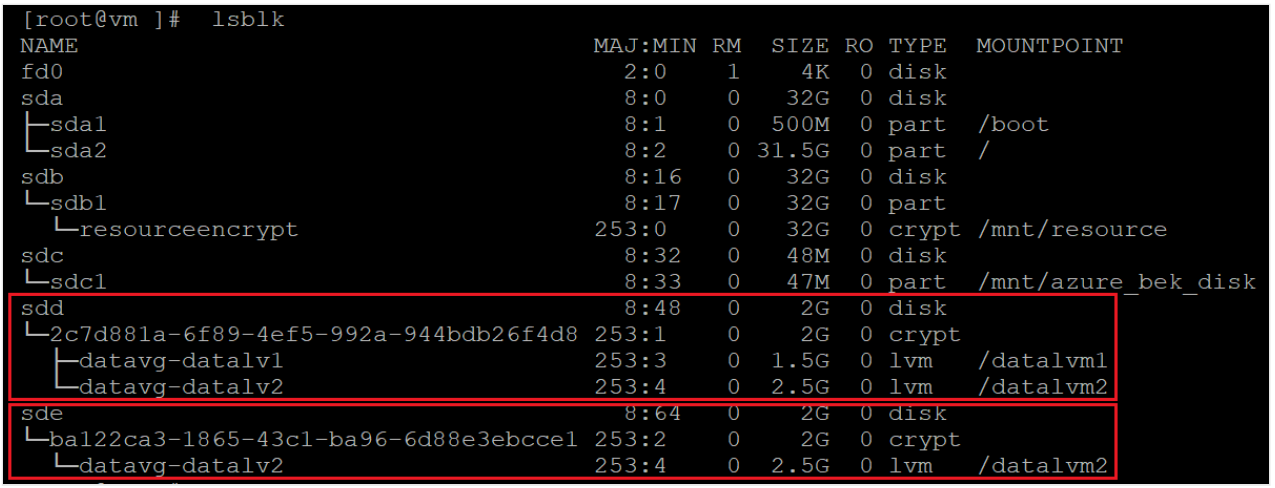


Extend an LVM on a crypt volume by resizing an existing PV

1. Identify your encrypted disks:

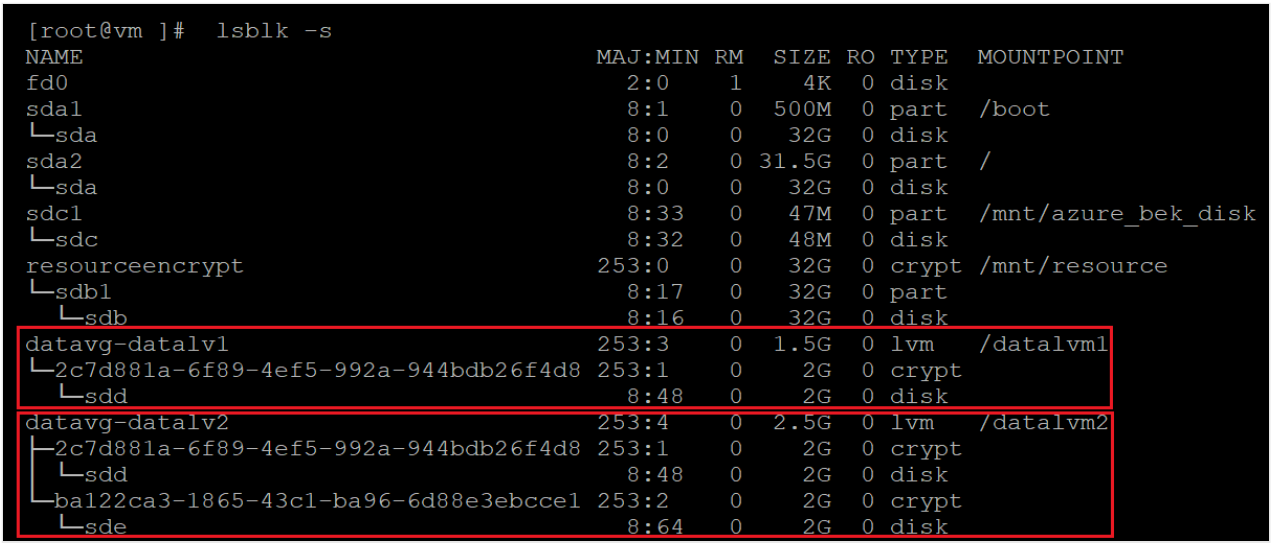
Bash

```
sudo lsblk
```



Bash

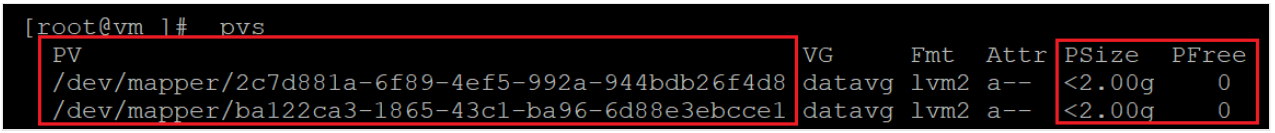
```
sudo lsblk -s
```



2. Check your PV information:

Bash

```
sudo pvs
```



3. Check your VG information:

```
Bash

sudo vgs
```

```
[root@vm ]#  vgdisplay  datavg
  --- Volume group ---
  VG Name               datavg
  System ID
  Format                lvm2
  Metadata Areas        2
  Metadata Sequence No  3
  VG Access             read/write
  VG Status             resizable
  MAX LV                0
  Cur LV                2
  Open LV               2
  Max PV                0
  Cur PV                2
  Act PV                2
  VG Size               3.99 GiB
  PE Size               4.00 MiB
  Total PE              1022
  Alloc PE / Size       1022 / 3.99 GiB
  Free  PE / Size       0 / 0
  VG UUID               24nwHl-raFN-igfO-0wk9-WTvc-sSTO-cXVYUX
```

4. Check your LV information:

```
Bash

sudo lvs
```

```
[root@vm ]#  lvs
  LV      VG     Attr       LSize Pool Origin Data%  Meta%  Move Log Cpy%Sync Convert
  datalv1 datavg -wi-ao---- 1.50g
  datalv2 datavg -wi-ao---- 2.49g
```

5. Check the file system utilization:

```
Bash

df -h /mountpoint(s)
```

```
[root@vm ]#  df -h  /datalvm*
Filesystem                   Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv1   1.5G  1.5G     0 100% /datalvm1
/dev/mapper/datavg-datalv2   2.4G  2.4G     0 100% /datalvm2
```

6. Check the sizes of your disks:

Bash

```
sudo fdisk
sudo fdisk -l | egrep ^"Disk /"
sudo lsblk
```

```
[root@vm ]#  fdisk -l /dev/sdd

Disk /dev/sdd: 2147 MB, 2147483648 bytes, 4194304 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes

[root@vm ]#  fdisk -l /dev/sde

Disk /dev/sde: 2147 MB, 2147483648 bytes, 4194304 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes
```

7. Resize the data disk. You can use the portal, CLI, or PowerShell. For more information, see the disk-resize section in Expand virtual hard disks on a Linux VM.

> **ⓘ Important**
>
> You can't resize virtual disks while the VM is running. Deallocate your VM for this step.

8. Check your disks sizes:

Bash

```
sudo fdisk
sudo fdisk -l | egrep ^"Disk /"
sudo lsblk
```

```
[root@vmresizelvm ~]# fdisk -l /dev/sdd

Disk /dev/sdd: 4294 MB, 4294967296 bytes, 8388608 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes

[root@vmresizelvm ~]# fdisk -l /dev/sde

Disk /dev/sde: 4294 MB, 4294967296 bytes, 8388608 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes
```

In this case, both disks were resized from 2 GB to 4 GB. But the size of the file system, LV, and PV remain the same.

9. Check the current PV size. Remember that on LVM-on-crypt, the PV is the `/dev/mapper/` device, not the `/dev/sd*` device.

Bash

```
sudo pvdisplay /dev/mapper/devicemappername
```

```
[root@vmresizelvm ~]# pvdisplay /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
  --- Physical volume ---
  PV Name               /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
  VG Name               datavg
  PV Size               <2.00 GiB / not usable 2.00 MiB
  Allocatable           yes (but full)
  PE Size               4.00 MiB
  Total PE              511
  Free PE               0
  Allocated PE          511
  PV UUID               30iBnM-fZgv-1sXe-FJo2-052x-wjxu-8Fb6Mw
```

10. Resize the PV:

Bash

```
sudo pvresize /dev/mapper/devicemappername
```

```
[root@vmresizelvm ~]# pvresize /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
  Physical volume "/dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8" changed
  1 physical volume(s) resized / 0 physical volume(s) not resized
```

11. Check the new PV size:

Bash

```
sudo pvdisplay /dev/mapper/devicemappername
```

```
[root@vmresizelvm ~]# pvdisplay /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
  --- Physical volume ---
  PV Name               /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
  VG Name               datavg
  PV Size               <4.00 GiB / not usable 0
  Allocatable           yes
  PE Size               4.00 MiB
  Total PE              1023
  Free PE               512
  Allocated PE          511
  PV UUID               30iBnM-fZgv-1sXe-FJo2-052x-wjxu-8Fb6Mw
```

12. Resize the encrypted layer on the PV:

```
Bash

sudo cryptsetup resize /dev/mapper/devicemappername
```

Apply the same procedure for all of the disks that you want to resize.

13. Check your VG information:

```
Bash

sudo vgdisplay vgname
```

```
[root@vmresizelvm ~]# vgdisplay datavg
  --- Volume group ---
  VG Name               datavg
  System ID
  Format                lvm2
  Metadata Areas        2
  Metadata Sequence No  4
  VG Access             read/write
  VG Status             resizable
  MAX LV                0
  Cur LV                2
  Open LV               2
  Max PV                0
  Cur PV                2
  Act PV                2
  VG Size               5.99 GiB
  PE Size               4.00 MiB
  Total PE              1534
  Alloc PE / Size       1022 / 3.99 GiB
  Free  PE / Size       512 / 2.00 GiB
  VG UUID               24nwHl-raFN-igfO-0wk9-WTvc-sSTO-cXVYUX
```

The VG now has enough space to be allocated to the LVs.

14. Check the LV information:

```
Bash

sudo lvdisplay vgname/lvname
```

```
[root@vmresizelvm ~]# lvdisplay datavg/datalv2
  --- Logical volume ---
  LV Path                /dev/datavg/datalv2
  LV Name                datalv2
  VG Name                datavg
  LV UUID                iK3HYF-wYPX-XAso-0WGB-Zite-D1aT-dFae2o
  LV Write Access        read/write
  LV Creation host, time vmresizelvm, 2020-05-18 18:33:54 +0000
  LV Status              available
  # open                 1
  LV Size                2.49 GiB
  Current LE             638
  Segments               2
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:3
```

15. Check the file system utilization:

```
Bash

df -h /mountpoint
```

```
[root@vmresizelvm ~]# df -h /datalvm2/
Filesystem                Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv2  2.4G  2.4G     0 100% /datalvm2
```

16. Resize the LV:

```
Bash

sudo lvresize -r -L +2G /dev/vgname/lvname
```

```
[root@vmresizelvm]#  lvresize -r -L +2G /dev/datavg/datalv2
  Size of logical volume datavg/datalv2 changed from 2.50 GiB (640 extents) to 4.50 GiB (1152 extents).
  Logical volume datavg/datalv2 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/datavg-datalv2 is mounted on /datalvm2; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/datavg-datalv2 is now 1179648 blocks long.
```

Here we use the `-r` option to also resize the file system.

17. Check the LV information:

Bash

```
sudo lvdisplay vgname/lvname
```

```
[root@vmresizelvm ~]# lvdisplay datavg/datalv2
  --- Logical volume ---
  LV Path                /dev/datavg/datalv2
  LV Name                datalv2
  VG Name                datavg
  LV UUID                iK3HYF-wYPX-XAso-0WGB-Zite-D1aT-dFae2o
  LV Write Access        read/write
  LV Creation host, time vmresizelvm, 2020-05-18 18:33:54 +0000
  LV Status              available
  # open                 1
  LV Size                4.49 GiB
  Current LE             1150
  Segments               3
  Allocation             inherit
  Read ahead sectors     auto
  - currently set to     8192
  Block device           253:3
```

18. Check the file system utilization:

Bash

```
df -h /mountpoint
```

```
[root@vmresizelvm ~]# df -h /datalvm2/
Filesystem                Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv2  4.4G  2.4G  1.8G  58% /datalvm2
```

Apply the same resizing procedure to any other LV that requires it.

Next steps

Troubleshoot Azure Disk Encryption

Azure Disk Encryption for Linux VMs troubleshooting guide

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This guide is for IT professionals, information security analysts, and cloud administrators whose organizations use Azure Disk Encryption. This article is to help with troubleshooting disk-encryption-related problems.

Before taking any of these steps, first ensure that the VMs you are attempting to encrypt are among the supported VM sizes and operating systems, and that you meet all the prerequisites:

- Additional requirements for VMs
- Networking requirements
- Encryption key storage requirements

Troubleshooting Linux OS disk encryption

Linux operating system (OS) disk encryption must unmount the OS drive before running it through the full disk encryption process. If it can't unmount the drive, an error message of "failed to unmount after ..." is likely to occur.

This error can occur when OS disk encryption is attempted on a VM with an environment that has been changed from the supported stock gallery image. Deviations from the supported image can interfere with the extension's ability to unmount the OS drive. Examples of deviations can include the following items:

- Customized images no longer match a supported file system or partitioning scheme.
- Large applications such as SAP, MongoDB, Apache Cassandra, and Docker aren't supported when they're installed and running in the OS before encryption. Azure Disk Encryption is unable to shut down these processes safely as required in preparation of the

OS drive for disk encryption. If there are still active processes holding open file handles to the OS drive, the OS drive can't be unmounted, resulting in a failure to encrypt the OS drive.

- Custom scripts that run in close time proximity to the encryption being enabled, or if any other changes are being made on the VM during the encryption process. This conflict can happen when an Azure Resource Manager template defines multiple extensions to execute simultaneously, or when a custom script extension or other action runs simultaneously to disk encryption. Serializing and isolating such steps might resolve the issue.
- Security Enhanced Linux (SELinux) hasn't been disabled before enabling encryption, so the unmount step fails. SELinux can be reenabled after encryption is complete.
- The OS disk uses a Logical Volume Manager (LVM) scheme. Although limited LVM data disk support is available, an LVM OS disk isn't.
- Minimum memory requirements aren't met (7 GB is suggested for OS disk encryption).
- Data drives are recursively mounted under the /mnt/ directory, or each other (for example, /mnt/data1, /mnt/data2, /data3 + /data3/data4).

Update the default kernel for Ubuntu 14.04 LTS

The Ubuntu 14.04 LTS image ships with a default kernel version of 4.4. This kernel version has a known issue in which Out of Memory Killer improperly terminates the dd command during the OS encryption process. This bug has been fixed in the most recent Azure tuned Linux kernel. To avoid this error, prior to enabling encryption on the image, update to the Azure tuned kernel 4.15 or later using the following commands:

```
sudo apt-get update
sudo apt-get install linux-azure
sudo reboot
```

After the VM has restarted into the new kernel, the new kernel version can be confirmed using:

```
uname -a
```

Update the Azure Virtual Machine Agent and extension versions

Azure Disk Encryption operations may fail on virtual machine images using unsupported versions of the Azure Virtual Machine Agent. Linux images with agent versions earlier than 2.2.38 should be updated prior to enabling encryption. For more information, see How to update the Azure Linux Agent on a VM and Minimum version support for virtual machine agents in Azure.

The correct version of the Microsoft.Azure.Security.AzureDiskEncryption or Microsoft.Azure.Security.AzureDiskEncryptionForLinux guest agent extension is also required. Extension versions are maintained and updated automatically by the platform when Azure Virtual Machine agent prerequisites are satisfied and a supported version of the virtual machine agent is used.

The Microsoft.OSTCExtensions.AzureDiskEncryptionForLinux extension has been deprecated and is no longer supported.

Unable to encrypt Linux disks

In some cases, the Linux disk encryption appears to be stuck at "OS disk encryption started" and SSH is disabled. The encryption process can take between 3-16 hours to finish on a stock gallery image. If multi-terabyte-sized data disks are added, the process might take days.

The Linux OS disk encryption sequence unmounts the OS drive temporarily. It then performs block-by-block encryption of the entire OS disk, before it remounts it in its encrypted state. Linux Disk Encryption doesn't allow for concurrent use of the VM while the encryption is in progress. The performance characteristics of the VM can make a significant difference in the time required to complete encryption. These characteristics include the size of the disk and whether the storage account is standard or premium (SSD) storage.

While the OS drive is being encrypted, the VM enters a servicing state and disables SSH to prevent any disruption to the ongoing process. To check the encryption status, use the Azure PowerShell Get-AzVmDiskEncryptionStatus command, and check the **ProgressMessage** field. **ProgressMessage** will report a series of statuses as the data and OS disks are encrypted:

Azure PowerShell

```
PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName
"myVM"

OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : EncryptionInProgress
OsVolumeEncryptionSettings :
ProgressMessage            : Transitioning

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName
"myVM"
```

```
OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : EncryptionInProgress
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : Encryption succeeded for data volumes

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName
"myVM"

OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : EncryptionInProgress
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : Provisioning succeeded

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName
"myVM"

OsVolumeEncrypted          : EncryptionInProgress
DataVolumesEncrypted       : EncryptionInProgress
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : OS disk encryption started
```

The **ProgressMessage** will remain in **OS disk encryption started** for most of the encryption process. When encryption is complete and successful, **ProgressMessage** will return:

Azure PowerShell

```
PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName
"myVM"

OsVolumeEncrypted          : Encrypted
DataVolumesEncrypted       : NotMounted
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : Encryption succeeded for all volumes
```

After this message is available, the encrypted OS drive is expected to be ready for use and the VM is ready to be used again.

If the boot information, the progress message, or an error reports that OS encryption has failed in the middle of this process, restore the VM to the snapshot or backup taken immediately before encryption. An example of a message is the "failed to unmount" error that is described in this guide.

Before reattempting encryption, reevaluate the characteristics of the VM and make sure that all of the prerequisites are satisfied.

Troubleshooting Azure Disk Encryption behind a firewall

See Disk Encryption on an isolated network

Troubleshooting encryption status

The portal may display a disk as encrypted even after it has been unencrypted within the VM. This can occur when low-level commands are used to directly unencrypt the disk from within the VM, instead of using the higher level Azure Disk Encryption management commands. The higher level commands not only unencrypt the disk from within the VM, but outside of the VM they also update important platform level encryption settings and extension settings associated with the VM. If these are not kept in alignment, the platform will not be able to report encryption status or provision the VM properly.

To disable Azure Disk Encryption with PowerShell, use Disable-AzVMDiskEncryption followed by Remove-AzVMDiskEncryptionExtension. Running Remove-AzVMDiskEncryptionExtension before the encryption is disabled will fail.

To disable Azure Disk Encryption with CLI, use az vm encryption disable.

In this document, you learned more about some common problems in Azure Disk Encryption and how to troubleshoot those problems. For more information about this service and its capabilities, see the following articles:

- Apply disk encryption in Microsoft Defender for Cloud
- Azure data encryption at rest

Azure Disk Encryption for Linux virtual machines FAQ

This article provides answers to frequently asked questions (FAQ) about Azure Disk Encryption for Linux virtual machines (VMs). For more information about this service, see Azure Disk Encryption overview.

What is Azure Disk Encryption for Linux virtual machines?

Azure Disk Encryption for Linux virtual machines uses the dm-crypt feature of Linux to provide full disk encryption of the OS disk* and data disks. Additionally, it provides encryption of the temporary disk when using the EncryptFormatAll feature. The content flows encrypted from the VM to the Storage backend with a customer-managed key.

See Supported virtual machines and operating systems.

Where is Azure Disk Encryption in general availability (GA)?

Azure Disk Encryption for Linux virtual machines is in general availability in all Azure public regions.

What user experiences are available with Azure Disk Encryption?

Azure Disk Encryption GA supports Azure Resource Manager templates, Azure PowerShell, and Azure CLI. The different user experiences give you flexibility. You have three different options for enabling disk encryption for your virtual machines. For more information on the user experience and step-by-step guidance available in Azure Disk Encryption, see Azure Disk Encryption scenarios for Linux.

How much does Azure Disk Encryption cost?

There's no charge for encrypting VM disks with Azure Disk Encryption, but there are charges associated with the use of Azure Key Vault. For more information on Azure Key Vault costs, see the Key Vault pricing page.

How can I start using Azure Disk Encryption?

To get started, read the Azure Disk Encryption overview.

What VM sizes and operating systems support Azure Disk Encryption?

The Azure Disk Encryption overview article lists the VM sizes and VM operating systems that support Azure Disk Encryption.

Can I encrypt both boot and data volumes with Azure Disk Encryption?

Yes, you can encrypt both boot and data volumes, or you can encrypt the data volume without having to encrypt the OS volume first.

After you've encrypted the OS volume, disabling encryption on the OS volume isn't supported. For Linux virtual machines in a scale set, only the data volume can be encrypted.

Can I encrypt an unmounted volume with Azure Disk Encryption?

No, Azure Disk Encryption only encrypts mounted volumes.

What is Storage server-side encryption?

Storage server-side encryption encrypts Azure managed disks in Azure Storage. Managed disks are encrypted by default with Server-side encryption with a platform-managed key (as of June 10, 2017). You can manage encryption of managed disks with your own keys by specifying a customer-managed key. For more information see: Server-side encryption of Azure managed disks.

How is Azure Disk Encryption different from other disk encryption solutions and when should I use each solution?

See Overview of managed disk encryption options.

How do I rotate secrets or encryption keys?

To rotate secrets, just call the same command you used originally to enable disk encryption, specifying a different Key Vault. To rotate the key encryption key, call the same command you used originally to enable disk encryption, specifying the new key encryption.

> ⚠ **Warning**
>
> - If you previously used **Azure Disk Encryption with Microsoft Entra app** by specifying Microsoft Entra credentials to encrypt this VM, you must continue to use this option to encrypt your VM. You can't use Azure Disk Encryption on this encrypted VM as this isn't a supported scenario, meaning switching away from Microsoft Entra application for this encrypted VM isn't supported yet.

How do I add or remove a key encryption key if I didn't originally use one?

To add a key encryption key, call the enable command again passing the key encryption key parameter. To remove a key encryption key, call the enable command again without the key encryption key parameter.

Does Azure Disk Encryption allow you to bring your own key (BYOK)?

Yes, you can supply your own key encryption keys. These keys are safeguarded in Azure Key Vault, which is the key store for Azure Disk Encryption. For more information on the key encryption keys support scenarios, see Creating and configuring a key vault for Azure Disk Encryption.

Can I use an Azure-created key encryption key?

Yes, you can use Azure Key Vault to generate a key encryption key for Azure disk encryption use. These keys are safeguarded in Azure Key Vault, which is the key store for Azure Disk Encryption. For more information on the key encryption key, see Creating and configuring a key vault for Azure Disk Encryption.

Can I use an on-premises key management service or HSM to safeguard the encryption keys?

You can't use the on-premises key management service or HSM to safeguard the encryption keys with Azure Disk Encryption. You can only use the Azure Key Vault service to safeguard the encryption keys. For more information on the key encryption key support scenarios, see Creating and configuring a key vault for Azure Disk Encryption.

What are the prerequisites to configure Azure Disk Encryption?

There are prerequisites for Azure Disk Encryption. See the Creating and configuring a key vault for Azure Disk Encryption article to create a new key vault, or set up an existing key vault for disk encryption access to enable encryption, and safeguard secrets and keys. For more information on the key encryption key support scenarios, see Creating and configuring a key vault for Azure Disk Encryption.

What are the prerequisites to configure Azure Disk Encryption with a Microsoft Entra app (previous release)?

There are prerequisites for Azure Disk Encryption. See the Azure Disk Encryption with Microsoft Entra ID content to create an Microsoft Entra application, create a new key vault, or set up an existing key vault for disk encryption access to enable encryption, and safeguard secrets and

keys. For more information on the key encryption key support scenarios, see Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID.

Is Azure Disk Encryption using a Microsoft Entra app (previous release) still supported?

Yes. Disk encryption using a Microsoft Entra app is still supported. However, when encrypting new virtual machines it's recommended that you use the new method rather than encrypting with a Microsoft Entra app.

Can I migrate virtual machines that were encrypted with a Microsoft Entra app to encryption without a Microsoft Entra app?

Currently, there isn't a direct migration path for machines that were encrypted with a Microsoft Entra app to encryption without a Microsoft Entra app. Additionally, there isn't a direct path from encryption without a Microsoft Entra app to encryption with an AD app.

What version of Azure PowerShell does Azure Disk Encryption support?

Use the latest version of the Azure PowerShell SDK to configure Azure Disk Encryption. Download the latest version of Azure PowerShell. Azure Disk Encryption is *not* supported by Azure SDK version 1.1.0.

> **Note**
>
> The Linux Azure disk encryption preview extension "Microsoft.OSTCExtension.AzureDiskEncryptionForLinux" is deprecated. This extension was published for Azure disk encryption preview release. You should not use the preview version of the extension in your testing or production deployment.

> For deployment scenarios like Azure Resource Manager (ARM), where you have a need to deploy Azure disk encryption extension for Linux VM to enable encryption on your Linux

> IaaS VM, you must use the Azure disk encryption production supported extension "Microsoft.Azure.Security.AzureDiskEncryptionForLinux".

Can I apply Azure Disk Encryption on my custom Linux image?

You can't apply Azure Disk Encryption on your custom Linux image. Only the gallery Linux images for the supported distributions called out previously are supported. Custom Linux images aren't currently supported.

Can I apply updates to a Linux Red Hat VM that uses the yum update?

Yes, you can perform a yum update on a Red Hat Linux VM. For more information, see Azure Disk Encryption on an isolated network.

What is the recommended Azure disk encryption workflow for Linux?

The following workflow is recommended to have the best results on Linux:

- Start from the unmodified stock gallery image corresponding to the needed OS distro and version
- Back up any mounted drives you want encrypted. This back up allows for recovery if there's a failure, for example if the VM is rebooted before encryption has completed.
- Encrypt (can take several hours or even days depending on VM characteristics and size of any attached data disks)
- Customize, and add software to the image as needed.

If this workflow isn't possible, relying on Storage Service Encryption (SSE) at the platform storage account layer may be an alternative to full disk encryption using dm-crypt.

What is the disk "Bek Volume" or "/mnt/azure_bek_disk"?

The "Bek volume" is a local data volume that securely stores the encryption keys for Encrypted Azure virtual machines.

> **Note**
>
> Do not delete or edit any contents in this disk. Do not unmount the disk since the encryption key presence is needed for any encryption operations on the IaaS VM.

What encryption method does Azure Disk Encryption use?

Azure Disk Encryption uses the decrypt default of aes-xts-plain64 with a 256-bit volume master key.

If I use EncryptFormatAll and specify all volume types, will it erase the data on the data drives that we already encrypted?

No, data won't be erased from data drives that are already encrypted using Azure Disk Encryption. Similar to how EncryptFormatAll didn't re-encrypt the OS drive, it won't re-encrypt the already encrypted data drive. For more information, see the EncryptFormatAll criteria.

Is XFS filesystem supported?

Encryption of XFS OS disks is supported.

Encryption of XFS data disks is supported only when the EncryptFormatAll parameter is used. This option reformats the volume, erasing any data previously there. For more information, see the EncryptFormatAll criteria.

Is resizing the OS partition supported?

Resize of an Azure Disk Encryption encrypted OS disk isn't supported.

Can I backup and restore an encrypted VM?

Azure Backup provides a mechanism to backup and restore encrypted VM's within the same subscription and region. For instructions, please see Back up and restore encrypted virtual machines with Azure Backup. Restoring an encrypted VM to a different region is not currently supported.

Where can I go to ask questions or provide feedback?

You can ask questions or provide feedback on the Microsoft Q&A question page for Azure Disk Encryption.

Next steps

In this document, you learned more about the most frequent questions related to Azure Disk Encryption. For more information about this service, see the following articles:

- Azure Disk Encryption Overview
- Apply disk encryption in Azure Security Center
- Azure data encryption at rest

Upgrading the Azure Disk Encryption version

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

The first version of Azure Disk Encryption (ADE) relied on Microsoft Entra ID for authentication; the current version doesn't. We strongly encourage the use of the newest version.

Determine ADE version

The versions of ADE in scope for migration are:

- **Windows**: 1.1.* (ADE on the VM must be upgraded to 2.2)
- **Linux**: 0.1.* (ADE on the VM must be upgraded to 1.2)

You can determine the version of ADE with which a VM was encrypted via Azure CLI, Azure PowerShell, or the Azure portal.

CLI

To determine the ADE version, run the Azure CLI az vm get-instance-view command.

Azure CLI

```
az vm get-instance-view --resource-group  <ResourceGroupName> --name <VMName>
```

Locate the AzureDiskEncryption extension in the output and identify the version number from the "TypeHandlerVersion" field in the output.

How to migrate

Migration from Azure Disk Encryption (with Microsoft Entra ID) to Azure Disk Encryption (without Microsoft Entra ID) is only available through Azure PowerShell. Ensure you have the latest version of Azure PowerShell and at least the Azure PowerShell Az module version 5.9.0 installed.

To upgrade from Azure Disk Encryption (with Microsoft Entra ID) to Azure Disk Encryption (without Microsoft Entra ID), use the Set-AzVMDiskEncryptionExtension PowerShell cmdlet.

> **⚠ Warning**
>
> The Set-AzVMDiskEncryptionExtension cmdlet must only be used on VMs encrypted with Azure Disk Encryption (with Microsoft Entra ID). Attempting to migrate an unencrypted VM, or a VM encrypted with Azure Disk Encryption (without Microsoft Entra ID), will result in a terminal error.

Azure PowerShell

```
Set-AzVMDiskEncryptionExtension -ResourceGroupName <resourceGroupName> -VMName
<vmName> -Migrate
```

When the cmdlet prompts you for confirmation, enter "Y". The ADE version is updated and the VM rebooted. The output looks similar to the following:

Output

```
Update AzureDiskEncryption version?
This cmdlet updates Azure Disk Encryption version to single pass (Azure Disk
Encryption without Azure AD). This may reboot
the machine and takes 10-15 minutes to finish. Are you sure you want to continue?
[Y] Yes  [N] No  [S] Suspend  [?] Help (default is "Y"): Y

- Azure Disk Encryption troubleshooting

Azure Disk Encryption with Microsoft Entra ID (previous release)

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The new release of Azure Disk Encryption eliminates the requirement for providing a Microsoft Entra application parameter to enable VM disk encryption. With the new release, you're no longer required to provide Microsoft Entra credentials during the enable encryption step. All new VMs must be encrypted without the Microsoft Entra application parameters by using the new release. For instructions on how to enable VM disk encryption by using the new release, see Azure Disk Encryption for Linux VMs. VMs that were already encrypted with Microsoft Entra application parameters are still supported and should continue to be maintained with the Microsoft Entra syntax.

This article provides supplements to Azure Disk Encryption for Linux VMs with additional requirements and prerequisites for Azure Disk Encryption with Microsoft Entra ID (previous release).

The information in these sections remains the same:

- Supported VMs and operating systems
- Additional VM requirements

Networking and Group Policy

To enable the Azure Disk Encryption feature by using the older Microsoft Entra parameter syntax, the infrastructure as a service (IaaS) VMs must meet the following network endpoint configuration requirements:

- To get a token to connect to your key vault, the IaaS VM must be able to connect to a Microsoft Entra endpoint, [login.microsoftonline.com].

- To write the encryption keys to your key vault, the IaaS VM must be able to connect to the key vault endpoint.
- The IaaS VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see Azure Key Vault behind a firewall.
- On Windows, if TLS 1.0 is explicitly disabled and the .NET version isn't updated to 4.6 or higher, the following registry change enables Azure Disk Encryption to select the more recent TLS version:

config-registry

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001

[HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001`
```

Group Policy

- The Azure Disk Encryption solution uses the BitLocker external key protector for Windows IaaS VMs. For domain-joined VMs, don't push any Group Policies that enforce TPM protectors. For information about the Group Policy for the option **Allow BitLocker without a compatible TPM**, see BitLocker Group Policy reference.

- BitLocker policy on domain-joined virtual machines with a custom Group Policy must include the following setting: Configure user storage of BitLocker recovery information -> Allow 256-bit recovery key. Azure Disk Encryption fails when custom Group Policy settings for BitLocker are incompatible. On machines that don't have the correct policy setting, apply the new policy, force the new policy to update (gpupdate.exe /force), and then restart if it's required.

Encryption key storage requirements

Azure Disk Encryption requires Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For more information, see Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release).

Next steps

- Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release)
- Enable Azure Disk Encryption with Microsoft Entra ID on Linux VMs (previous release)
- Azure Disk Encryption prerequisites CLI script
- Azure Disk Encryption prerequisites PowerShell script

Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release) for Linux VMs

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The new release of Azure Disk Encryption eliminates the requirement for providing a Microsoft Entra application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Microsoft Entra credentials during the enable encryption step. All new VMs must be encrypted without the Microsoft Entra application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see Azure Disk Encryption. VMs that were already encrypted with Microsoft Entra application parameters are still supported and should continue to be maintained with the Microsoft Entra syntax.

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see Get started with Azure Key Vault and Secure your key vault.

Creating and configuring a key vault for use with Azure Disk Encryption with Microsoft Entra ID (previous release) involves three steps:

1. Create a key vault.
2. Set up a Microsoft Entra application and service principal.
3. Set the key vault access policy for the Microsoft Entra app.
4. Set key vault advanced access policies.

You may also, if you wish, generate or import a key encryption key (KEK).

See the main Creating and configuring a key vault for Azure Disk Encryption article for steps on how to Install tools and connect to Azure.

> **Note**
>
> The steps in this article are automated in the Azure Disk Encryption prerequisites CLI script and Azure Disk Encryption prerequisites PowerShell script.

Create a key vault

Azure Disk Encryption is integrated with Azure Key Vault to help you control and manage the disk-encryption keys and secrets in your key vault subscription. You can create a key vault or use an existing one for Azure Disk Encryption. For more information about key vaults, see Get started with Azure Key Vault and Secure your key vault. You can use a Resource Manager template, Azure PowerShell, or the Azure CLI to create a key vault.

> **Warning**
>
> In order to make sure the encryption secrets don't cross regional boundaries, Azure Disk Encryption needs the Key Vault and the VMs to be co-located in the same region. Create and use a Key Vault that is in the same region as the VM to be encrypted.

Create a key vault with PowerShell

You can create a key vault with Azure PowerShell using the New-AzKeyVault cmdlet. For additional cmdlets for Key Vault, see Az.KeyVault.

1. Create a new resource group, if needed, with New-AzResourceGroup. To list data center locations, use Get-AzLocation.

   Azure PowerShell

   ```
   # Get-AzLocation
   New-AzResourceGroup -Name 'MyKeyVaultResourceGroup' -Location 'East US'
   ```

2. Create a new key vault using New-AzKeyVault

   Azure PowerShell

   ```
   New-AzKeyVault -VaultName 'MySecureVault' -ResourceGroupName
   'MyKeyVaultResourceGroup' -Location 'East US'
   ```

3. Note the **Vault Name**, **Resource Group Name**, **Resource ID**, **Vault URI**, and the **Object ID** that are returned for later use when you encrypt the disks.

Create a key vault with Azure CLI

You can manage your key vault with Azure CLI using the az keyvault commands. To create a key vault, use az keyvault create.

1. Create a new resource group, if needed, with az group create. To list locations, use az account list-locations

   Azure CLI

   ```
   # To list locations: az account list-locations --output table
   az group create -n "MyKeyVaultResourceGroup" -l "East US"
   ```

2. Create a new key vault using az keyvault create.

   Azure CLI

   ```
   az keyvault create --name "MySecureVault" --resource-group
   "MyKeyVaultResourceGroup" --location "East US"
   ```

3. Note the **Vault Name** (name), **Resource Group Name**, **Resource ID** (ID), **Vault URI**, and the **Object ID** that are returned for use later.

Create a key vault with a Resource Manager template

You can create a key vault by using the Resource Manager template.

1. On the Azure Quickstart Template, select **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then select **Purchase**.

Set up a Microsoft Entra app and service principal

When you need encryption to be enabled on a running VM in Azure, Azure Disk Encryption generates and writes the encryption keys to your key vault. Managing encryption keys in your key vault requires Microsoft Entra authentication. Create a Microsoft Entra application for this purpose. For authentication purposes, you can use either client secret-based authentication or client certificate-based Microsoft Entra authentication.

Set up a Microsoft Entra app and service principal with Azure PowerShell

To execute the following commands, get and use the Azure PowerShell module.

1. Use the New-AzADApplication PowerShell cmdlet to create a Microsoft Entra application. MyApplicationHomePage and the MyApplicationUri can be any values you wish.

   Azure PowerShell

   ```
   $aadClientSecret = "My AAD client secret"
   $aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -
   AsPlainText -Force
   $azureAdApplication = New-AzADApplication -DisplayName "My Application
   Display Name" -HomePage "https://MyApplicationHomePage" -IdentifierUris
   "https://MyApplicationUri" -Password $aadClientSecretSec
   $servicePrincipal = New-AzADServicePrincipal -ApplicationId
   $azureAdApplication.ApplicationId -Role Contributor
   ```

2. The $azureAdApplication.ApplicationId is the Microsoft Entra ClientID and the $aadClientSecret is the client secret that you'll use later to enable Azure Disk Encryption. Safeguard the Microsoft Entra client secret appropriately. Running `$azureAdApplication.ApplicationId` will show you the ApplicationID.

Set up a Microsoft Entra app and service principal with Azure CLI

You can manage your service principals with Azure CLI using the az ad sp commands. For more information, see Create an Azure service principal.

1. Create a new service principal.

   Azure CLI

   ```
   az ad sp create-for-rbac --name "ServicePrincipalName" --password "My-AAD-
   client-secret" --role Contributor --scopes /subscriptions/<subscription_id>
   ```

2. The appId returned is the Microsoft Entra ClientID used in other commands. It's also the SPN you'll use for az keyvault set-policy. The password is the client secret that you should use later to enable Azure Disk Encryption. Safeguard the Microsoft Entra client secret appropriately.

Set up a Microsoft Entra app and service principal through the Azure portal

Use the steps from the Use portal to create a Microsoft Entra application and service principal that can access resources article to create a Microsoft Entra application. Each step listed below will take you directly to the article section to complete.

1. Verify required permissions
2. Create a Microsoft Entra application

    - You can use any name and sign-on URL you would like when creating the application.

3. Get the application ID and the authentication key.

    - The authentication key is the client secret and is used as the AadClientSecret for Set-AzVMDiskEncryptionExtension.
        - The authentication key is used by the application as a credential to sign in to Microsoft Entra ID. In the Azure portal, this secret is called keys, but has no relation to key vaults. Secure this secret appropriately.
    - The application ID will be used later as the AadClientId for Set-AzVMDiskEncryptionExtension and as the ServicePrincipalName for Set-AzKeyVaultAccessPolicy.

Set the key vault access policy for the Microsoft Entra app

To write encryption secrets to a specified Key Vault, Azure Disk Encryption needs the Client ID and the Client Secret of the Microsoft Entra application that has permissions to write secrets to the Key Vault.

> **Note**
>
> Azure Disk Encryption requires you to configure the following access policies to your Microsoft Entra client application: *WrapKey* and *Set* permissions.

Set the key vault access policy for the Microsoft Entra app with Azure PowerShell

Your Microsoft Entra application needs rights to access the keys or secrets in the vault. Use the Set-AzKeyVaultAccessPolicy cmdlet to grant permissions to the application, using the client ID (which was generated when the application was registered) as the *–ServicePrincipalName* parameter value. To learn more, see the blog post Azure Key Vault - Step by Step.

1. Set the key vault access policy for the AD application with PowerShell.

Azure PowerShell

```
$keyVaultName = 'MySecureVault'
$aadClientID = 'MyAadAppClientID'
$KVRGname = 'MyKeyVaultResourceGroup'
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName $KVRGname
```

Set the key vault access policy for the Microsoft Entra app with Azure CLI

Use az keyvault set-policy to set the access policy. For more information, see Manage Key Vault using CLI 2.0.

Give the service principal you created via the Azure CLI access to get secrets and wrap keys with the following command:

Azure CLI

```
az keyvault set-policy --name "MySecureVault" --spn "<spn created with CLI/the
Azure AD ClientID>" --key-permissions wrapKey --secret-permissions set
```

Set the key vault access policy for the Microsoft Entra app with the portal

1. Open the resource group with your key vault.
2. Select your key vault, go to **Access Policies**, then select **Add new**.
3. Under **Select principal**, search for the Microsoft Entra application you created and select it.
4. For **Key permissions**, check **Wrap Key** under **Cryptographic Operations**.
5. For **Secret permissions**, check **Set** under **Secret Management Operations**.
6. Select **OK** to save the access policy.

Set key vault advanced access policies

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes. Enable disk encryption on the key vault or deployments will fail.

Set key vault advanced access policies with Azure PowerShell

Use the key vault PowerShell cmdlet Set-AzKeyVaultAccessPolicy to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

  Azure PowerShell

  ```
  Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName
  'MyKeyVaultResourceGroup' -EnabledForDiskEncryption
  ```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft. Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in

resource creation, for example when creating a virtual machine.

Azure PowerShell

```
 Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName
'MyKeyVaultResourceGroup' -EnabledForDeployment
```

- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

Azure PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName
'MyKeyVaultResourceGroup' -EnabledForTemplateDeployment
```

Set key vault advanced access policies using the Azure CLI

Use az keyvault update to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

Azure CLI

```
az keyvault update --name "MySecureVault" --resource-group
"MyKeyVaultResourceGroup" --enabled-for-disk-encryption "true"
```

- **Enable Key Vault for deployment, if needed:** Allow Virtual Machines to retrieve certificates stored as secrets from the vault.

Azure CLI

```
az keyvault update --name "MySecureVault" --resource-group
"MyKeyVaultResourceGroup" --enabled-for-deployment "true"
```

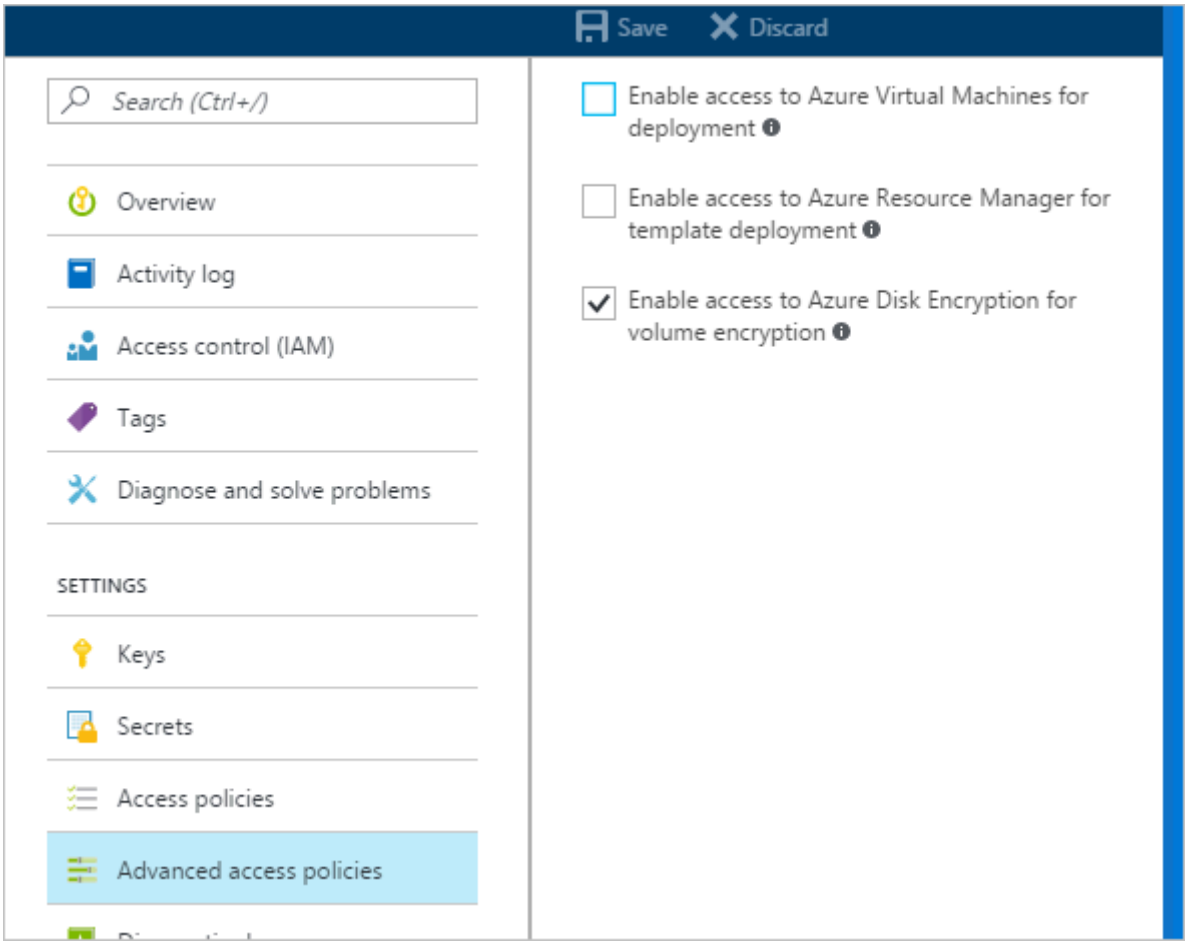
- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

Azure CLI

```
az keyvault update --name "MySecureVault" --resource-group
"MyKeyVaultResourceGroup" --enabled-for-template-deployment "true"
```

Set key vault advanced access policies through the Azure portal

1. Select your keyvault, go to **Access Policies**, and **Click to show advanced access policies**.
2. Select the box labeled **Enable access to Azure Disk Encryption for volume encryption**.
3. Select **Enable access to Azure Virtual Machines for deployment** and/or **Enable Access to Azure Resource Manager for template deployment**, if needed.
4. Select **Save**.



Set up a key encryption key (optional)

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. Use the Add-AzKeyVaultKey cmdlet to create a key encryption key in the key vault. You can also import a KEK from your on-premises key management HSM. For more information, see Key Vault Documentation. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

- When generating keys, use an RSA key type. Azure Disk Encryption doesn't yet support using Elliptic Curve keys.

- Your key vault secret and KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:
  - Example of a valid secret URL:
    `https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxx xxxxxxxxxxxxxxxxxxxx`
  - Example of a valid KEK URL:
    `https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxx xxxxxxxxxx`

- Azure Disk Encryption doesn't support specifying port numbers as part of key vault secrets and KEK URLs. For examples of non-supported and supported key vault URLs, see the following examples:
  - Unacceptable key vault URL
    `https://contosovault.vault.azure.net:443/secrets/contososecret/xxxxxxxxxxxxxxxxx xxxxxxxxxxxxx`
  - Acceptable key vault URL:
    `https://contosovault.vault.azure.net/secrets/contososecret/xxxxxxxxxxxxxxxxxxxx xxxxxxxxx`

Set up a key encryption key with Azure PowerShell

Before using the PowerShell script, you should be familiar with the Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment. This script creates all Azure Disk Encryption prerequisites and encrypts an existing IaaS VM, wrapping the disk encryption key by using a key encryption key.

PowerShell

```
# Step 1: Create a new resource group and key vault in the same location.
     # Fill in 'MyLocation', 'MyKeyVaultResourceGroup', and 'MySecureVault' with
your values.
     # Use Get-AzLocation to get available locations and use the DisplayName.
     # To use an existing resource group, comment out the line for New-
AzResourceGroup

    $Loc = 'MyLocation';
    $KVRGname = 'MyKeyVaultResourceGroup';
    $KeyVaultName = 'MySecureVault';
    New-AzResourceGroup –Name  $KVRGname –Location $Loc;
    New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname -Location
$Loc;
    $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
    $KeyVaultResourceId = (Get-AzKeyVault -VaultName $KeyVaultName -
ResourceGroupName  $KVRGname).ResourceId;
```

```
    $diskEncryptionKeyVaultUrl = (Get-AzKeyVault -VaultName $KeyVaultName -
ResourceGroupName  $KVRGname).VaultUri;

# Step 2: Create the AD application and service principal.
     # Fill in 'MyAADClientSecret', "<My Application Display Name>", "
<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your
values.
     # MyApplicationHomePage and the MyApplicationUri can be any values you wish.

     $aadClientSecret =  'MyAADClientSecret';
    $aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -
AsPlainText -Force;
    $azureAdApplication = New-AzADApplication -DisplayName "<My Application
Display Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "
<https://MyApplicationUri>" -Password $aadClientSecretSec
    $servicePrincipal = New-AzADServicePrincipal –ApplicationId
$azureAdApplication.ApplicationId -Role Contributor;
    $aadClientID = $azureAdApplication.ApplicationId;

#Step 3: Enable the vault for disk encryption and set the access policy for the
Microsoft Entra application.

     Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$KVRGname -EnabledForDiskEncryption;
    Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName  $KVRGname;

#Step 4: Create a new key in the key vault with the Add-AzKeyVaultKey cmdlet.
     # Fill in 'MyKeyEncryptionKey' with your value.

     $keyEncryptionKeyName = 'MyKeyEncryptionKey';
    Add-AzKeyVaultKey -VaultName $KeyVaultName -Name $keyEncryptionKeyName -
Destination 'Software';
    $keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;

#Step 5: Encrypt the disks of an existing IaaS VM
     # Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

     $VMName = 'MySecureVM';
     $VMRGName = 'MyVirtualMachineResourceGroup';
    Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $KeyVaultResourceId;
```

Certificate-based authentication (optional)

If you would like to use certificate authentication, you can upload one to your key vault and deploy it to the client. Before using the PowerShell script, you should be familiar with the Azure

Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

PowerShell

```
# Fill in "MyKeyVaultResourceGroup", "MySecureVault", and 'MyLocation' ('My
location' only if needed)

  $KVRGname = 'MyKeyVaultResourceGroup'
  $KeyVaultName= 'MySecureVault'

  # Create a key vault and set enabledForDiskEncryption property on it.
  # Comment out the next three lines if you already have an existing key vault
enabled for encryption. No need to set 'My location' in this case.

  $Loc = 'MyLocation'
  New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname -Location
$Loc
  Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $KVRGname
-EnabledForDiskEncryption

  #Setting some variables with the key vault information
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname
  $DiskEncryptionKeyVaultUrl = $KeyVault.VaultUri
  $KeyVaultResourceId = $KeyVault.ResourceId

  # Create the Microsoft Entra application and associate the certificate with it.
  # Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display
Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with
your values.
  # MyApplicationHomePage and the MyApplicationUri can be any values you wish

  $CertPath = "C:\certificates\mycert.pfx"
  $CertPassword = "Password"
  $Cert = New-Object
System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
  $CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

  $AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display
Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "
<https://MyApplicationUri>" -CertValue $CertValue
  $ServicePrincipal = New-AzADServicePrincipal -ApplicationId
$AzureAdApplication.ApplicationId -Role Contributor

  $AADClientID = $AzureAdApplication.ApplicationId
  $aadClientCertThumbprint= $cert.Thumbprint

  Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName $KVRGname

  # Upload the pfx file to the key vault.
```

```
  # Fill in "MyAADCert".

  $KeyVaultSecretName = "MyAADCert"
  $FileContentBytes = get-content $CertPath -Encoding Byte
  $FileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
          $JSONObject = @"
          {
              "data" : "$filecontentencoded",
              "dataType" : "pfx",
              "password" : "$CertPassword"
          }
"@

  $JSONObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
  $JSONEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

  #Set the secret and set the key vault policy for -EnabledForDeployment

  $Secret = ConvertTo-SecureString -String $JSONEncoded -AsPlainText -Force
  Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $KeyVaultSecretName -
SecretValue $Secret
  Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $KVRGname
-EnabledForDeployment

  # Deploy the certificate to the VM
  # Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

  $VMName = 'MySecureVM'
  $VMRGName = 'MyVirtualMachineResourceGroup'
  $CertUrl = (Get-AzKeyVaultSecret -VaultName $KeyVaultName -Name
$KeyVaultSecretName).Id
  $SourceVaultId = (Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGName).ResourceId
  $VM = Get-AzVM -ResourceGroupName $VMRGName -Name $VMName
  $VM = Add-AzVMSecret -VM $VM -SourceVaultId $SourceVaultId -CertificateStore
"My" -CertificateUrl $CertUrl
  Update-AzVM -VM $VM -ResourceGroupName $VMRGName

  #Enable encryption on the VM using Microsoft Entra client ID and the client
certificate thumbprint

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -
AadClientID $AADClientID -AadClientCertThumbprint $AADClientCertThumbprint -
DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId
```

Certificate-based authentication and a KEK (optional)

If you would like to use certificate authentication and wrap the encryption key with a KEK, you can use the below script as an example. Before using the PowerShell script, you should be

familiar with all of the previous Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

> **Important**
>
> Microsoft Entra certificate-based authentication is currently not supported on Linux VMs.

PowerShell

```
# Fill in 'MyKeyVaultResourceGroup', 'MySecureVault', and 'MyLocation' (if needed)

   $KVRGname = 'MyKeyVaultResourceGroup'
   $KeyVaultName= 'MySecureVault'

   # Create a key vault and set enabledForDiskEncryption property on it.
   # Comment out the next three lines if you already have an existing key vault
enabled for encryption.

   $Loc = 'MyLocation'
   New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname -Location
$Loc
   Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$KVRGname -EnabledForDiskEncryption

   # Create the Azure AD application and associate the certificate with it.
   # Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display
Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with
your values.
   # MyApplicationHomePage and the MyApplicationUri can be any values you wish

   $CertPath = "C:\certificates\mycert.pfx"
   $CertPassword = "Password"
   $Cert = New-Object
System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
   $CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

   $AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display
Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "
<https://MyApplicationUri>" -CertValue $CertValue
   $ServicePrincipal = New-AzADServicePrincipal -ApplicationId
$AzureAdApplication.ApplicationId -Role Contributor

   $AADClientID = $AzureAdApplication.ApplicationId
   $aadClientCertThumbprint= $cert.Thumbprint

   ## Give access for setting secrets and wraping keys
   Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName $KVRGname

   # Upload the pfx file to the key vault.
```

```
   # Fill in "MyAADCert".

   $KeyVaultSecretName = "MyAADCert"
   $FileContentBytes = get-content $CertPath -Encoding Byte
   $FileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
           $JSONObject = @"
           {
               "data" : "$filecontentencoded",
               "dataType" : "pfx",

Next steps

Enable Azure Disk Encryption with Microsoft Entra ID on Linux VMs (previous release)

Enable Azure Disk Encryption with Microsoft Entra ID on Linux VMs (previous release)

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The new release of Azure Disk Encryption eliminates the requirement for providing a Microsoft Entra application parameter to enable VM disk encryption. With the new release, you're no longer required to provide Microsoft Entra credentials during the enable encryption step. All new VMs must be encrypted without the Microsoft Entra application parameters by using the new release. For instructions on how to enable VM disk encryption by using the new release, see Azure Disk Encryption for Linux VMS. VMs that were already encrypted with Microsoft Entra application parameters are still supported and should continue to be maintained with the Microsoft Entra syntax.

You can enable many disk-encryption scenarios, and the steps might vary according to the scenario. The following sections cover the scenarios in greater detail for Linux infrastructure as a service (IaaS) VMs. You can only apply disk encryption to virtual machines of supported VM sizes and operating systems. You must also meet the following prerequisites:

- Additional requirements for VMs
- Networking and Group Policy
- Encryption key storage requirements

Take a snapshot, make a backup, or both before you encrypt the disks. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. After a backup is made, you can use the Set-AzVMDiskEncryptionExtension cmdlet to encrypt managed disks by specifying the -skipVmBackup parameter. For more information about how to back up and restore encrypted VMs, see Azure Backup.

> ⚠ **Warning**
>
> - If you previously used Azure Disk Encryption with the Microsoft Entra app to encrypt this VM, you must continue to use this option to encrypt your VM. You can't use Azure Disk Encryption on this encrypted VM because this isn't a supported scenario, which means switching away from the Microsoft Entra application for this encrypted VM isn't supported yet.
> - To make sure the encryption secrets don't cross regional boundaries, Azure Disk Encryption needs the key vault and the VMs to be colocated in the same region. Create and use a key vault that's in the same region as the VM to be encrypted.
> - When you encrypt Linux OS volumes, the process can take a few hours. It's normal for Linux OS volumes to take longer than data volumes to encrypt.
> - When you encrypt Linux OS volumes, the VM should be considered unavailable. We strongly recommend that you avoid SSH logins while the encryption is in progress to avoid blocking any open files that need to be accessed during the encryption process. To check progress, use the Get-AzVMDiskEncryptionStatus or vm encryption show commands. You can expect this process to take a few hours for a 30-GB OS volume, plus more time for encrypting data volumes. Data volume encryption time is proportional to the size and quantity of the data volumes unless the **encrypt format all** option is used.
> - Disabling encryption on Linux VMs is only supported for data volumes. It's not supported on data or OS volumes if the OS volume has been encrypted.

Enable encryption on an existing or running IaaS Linux VM

In this scenario, you can enable encryption by using the Azure Resource Manager template, PowerShell cmdlets, or Azure CLI commands.

> ⓘ **Important**
>
> It's mandatory to take a snapshot or back up a managed disk-based VM instance outside of and prior to enabling Azure Disk Encryption. You can take a snapshot of the managed disk from the Azure portal, or you can use Azure Backup. Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. After a backup is made, use the Set-AzVMDiskEncryptionExtension cmdlet to encrypt managed disks by

specifying the -skipVmBackup parameter. The Set-AzVMDiskEncryptionExtension command fails against managed disk-based VMs until a backup is made and this parameter is specified.

Encrypting or disabling encryption might cause the VM to reboot.

Enable encryption on an existing or running Linux VM by using the Azure CLI

You can enable disk encryption on your encrypted VHD by installing and using the Azure CLI 2.0 command-line tool. You can use it in your browser with Azure Cloud Shell, or you can install it on your local machine and use it in any PowerShell session. To enable encryption on existing or running IaaS Linux VMs in Azure, use the following CLI commands:

Use the az vm encryption enable command to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM by using a client secret:**

  Azure CLI

  ```
  az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --volume-type [All|OS|Data]
  ```

- **Encrypt a running VM by using KEK to wrap the client secret:**

  Azure CLI

  ```
  az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI which is the Azure AD ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault  "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
  ```

  > **Note**
  >
  > The syntax for the value of the disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name].

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id].

- **Verify that the disks are encrypted:** To check on the encryption status of an IaaS VM, use the az vm encryption show command.

Azure CLI

```
    az vm encryption show --name "MySecureVM" --resource-group
"MyVirtualMachineResourceGroup"
```

- **Disable encryption:** To disable encryption, use the az vm encryption disable command. Disabling encryption is only allowed on data volumes for Linux VMs.

Azure CLI

```
    az vm encryption disable --name "MySecureVM" --resource-group
"MyVirtualMachineResourceGroup" --volume-type DATA
```

Enable encryption on an existing or running Linux VM by using PowerShell

Use the Set-AzVMDiskEncryptionExtension cmdlet to enable encryption on a running IaaS virtual machine in Azure. Take a snapshot or make a backup of the VM with Azure Backup before the disks are encrypted. The -skipVmBackup parameter is already specified in the PowerShell scripts to encrypt a running Linux VM.

- **Encrypt a running VM by using a client secret:** The following script initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, key vault, Microsoft Entra app, and client secret should have already been created as prerequisites. Replace MyVirtualMachineResourceGroup, MyKeyVaultResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values. Modify the -VolumeType parameter to specify which disks you're encrypting.

Azure PowerShell

```
    $VMRGName = 'MyVirtualMachineResourceGroup';
    $KVRGname = 'MyKeyVaultResourceGroup';
    $vmName = 'MySecureVM';
    $aadClientID = 'My-AAD-client-ID';
    $aadClientSecret = 'My-AAD-client-secret';
    $KeyVaultName = 'MySecureVault';
    $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
```

```
    $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
    $KeyVaultResourceId = $KeyVault.ResourceId;
    $sequenceVersion = [Guid]::NewGuid();

    Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName
$vmName -AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -VolumeType '[All|OS|Data]' -
SequenceVersion $sequenceVersion -skipVmBackup;
```

- **Encrypt a running VM by using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to the key vault. Modify the -VolumeType parameter to specify which disks you're encrypting.

Azure PowerShell

```
    $KVRGname = 'MyKeyVaultResourceGroup';
    $VMRGName = 'MyVirtualMachineResourceGroup';
    $aadClientID = 'My-AAD-client-ID';
    $aadClientSecret = 'My-AAD-client-secret';
    $KeyVaultName = 'MySecureVault';
    $keyEncryptionKeyName = 'MyKeyEncryptionKey';
    $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
    $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
    $KeyVaultResourceId = $KeyVault.ResourceId;
    $keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;
    $sequenceVersion = [Guid]::NewGuid();

    Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName
$vmName -AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -KeyEncryptionKeyUrl
$keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $KeyVaultResourceId -VolumeType
'[All|OS|Data]' -SequenceVersion $sequenceVersion -skipVmBackup;
```

> **Note**
>
> The syntax for the value of the disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[KVresource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name].
>
> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id].

- **Verify that the disks are encrypted:** To check on the encryption status of an IaaS VM, use the Get-AzVmDiskEncryptionStatus cmdlet.

  Azure PowerShell

  ```
  Get-AzVmDiskEncryptionStatus -ResourceGroupName
  MyVirtualMachineResourceGroup -VMName MySecureVM
  ```

- **Disable disk encryption:** To disable the encryption, use the Disable-AzureRmVMDiskEncryption cmdlet. Disabling encryption is only allowed on data volumes for Linux VMs.

  Azure PowerShell

  ```
  Disable-AzVMDiskEncryption -ResourceGroupName
  'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
  ```

Enable encryption on an existing or running IaaS Linux VM with a template

You can enable disk encryption on an existing or running IaaS Linux VM in Azure by using the Resource Manager template.

1. Select **Deploy to Azure** on the Azure quickstart template.
2. Select the subscription, resource group, resource group location, parameters, legal terms, and agreement. Select **Create** to enable encryption on the existing or running IaaS VM.

The following table lists Resource Manager template parameters for existing or running VMs that use a Microsoft Entra client ID:

Expand table

Parameter	Description
AADClientID	Client ID of the Microsoft Entra application that has permissions to write secrets to the key vault.
AADClientSecret	Client secret of the Microsoft Entra application that has permissions to write secrets to your key vault.
keyVaultName	Name of the key vault that the key should be uploaded to. You can get it by using the Azure CLI command `az keyvault show --name "MySecureVault" --query KVresourceGroup`.
keyEncryptionKeyURL	URL of the key encryption key that's used to encrypt the generated key. This parameter is optional if you select **nokek** in the **UseExistingKek** drop-down list. If

Parameter	Description
	you select **kek** in the **UseExistingKek** drop-down list, you must enter the *keyEncryptionKeyURL* value.
volumeType	Type of volume that the encryption operation is performed on. Valid supported values are *OS* or *All*. (See supported Linux distributions and their versions for OS and data disks in the prerequisites section earlier.)
sequenceVersion	Sequence version of the BitLocker operation. Increment this version number every time a disk-encryption operation is performed on the same VM.
vmName	Name of the VM that the encryption operation is to be performed on.
passphrase	Type a strong passphrase as the data encryption key.

Use the EncryptFormatAll feature for data disks on Linux IaaS VMs

The EncryptFormatAll parameter reduces the time for Linux data disks to be encrypted. Partitions that meet certain criteria are formatted (with their current file system). Then they're remounted back to where they were before command execution. If you want to exclude a data disk that meets the criteria, you can unmount it before you run the command.

After you run this command, any drives that were mounted previously are formatted. Then the encryption layer starts on top of the now empty drive. When this option is selected, the temporary disk attached to the VM is also encrypted. If the ephemeral drive is reset, it's reformatted and re-encrypted for the VM by the Azure Disk Encryption solution at the next opportunity.

> **⚠ Warning**
>
> EncryptFormatAll shouldn't be used when there's needed data on a VM's data volumes. You can exclude disks from encryption by unmounting them. Try out the EncryptFormatAll parameter on a test VM first to understand the feature parameter and its implication before you try it on the production VM. The EncryptFormatAll option formats the data disk, so all the data on it will be lost. Before you proceed, verify that any disks you want to exclude are properly unmounted.
>
> If you set this parameter while you update encryption settings, it might lead to a reboot before the actual encryption. In this case, you also want to remove the disk you don't want formatted from the fstab file. Similarly, you should add the partition you want encrypt-formatted to the fstab file before you initiate the encryption operation.

EncryptFormatAll criteria

The parameter goes through all partitions and encrypts them as long as they meet *all* of the following criteria:

- Is not a root/OS/boot partition
- Is not already encrypted
- Is not a BEK volume
- Is not a RAID volume
- Is not an LVM volume
- Is mounted

Encrypt the disks that compose the RAID or LVM volume rather than the RAID or LVM volume.

Use the EncryptFormatAll parameter with a template

To use the EncryptFormatAll option, use any preexisting Azure Resource Manager template that encrypts a Linux VM and change the **EncryptionOperation** field for the AzureDiskEncryption resource.

1. As an example, use the Resource Manager template to encrypt a running Linux IaaS VM.
2. Select **Deploy to Azure** on the Azure quickstart template.
3. Change the **EncryptionOperation** field from **EnableEncryption** to **EnableEncryptionFormatAl**.
4. Select the subscription, resource group, resource group location, other parameters, legal terms, and agreement. Select **Create** to enable encryption on the existing or running IaaS VM.

Use the EncryptFormatAll parameter with a PowerShell cmdlet

Use the Set-AzVMDiskEncryptionExtension cmdlet with the EncryptFormatAll parameter.

Encrypt a running VM by using a client secret and EncryptFormatAll: As an example, the following script initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet with the EncryptFormatAll parameter. The resource group, VM, key vault, Microsoft Entra app, and client secret should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values.

Azure PowerShell

```
  $KVRGname = 'MyKeyVaultResourceGroup';
  $VMRGName = 'MyVirtualMachineResourceGroup';
  $aadClientID = 'My-AAD-client-ID';
  $aadClientSecret = 'My-AAD-client-secret';
  $KeyVaultName = 'MySecureVault';
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
  $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
  $KeyVaultResourceId = $KeyVault.ResourceId;

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId -EncryptFormatAll
```

Use the EncryptFormatAll parameter with Logical Volume Manager (LVM)

We recommend an LVM-on-crypt setup. For all the following examples, replace the device-path and mountpoints with whatever suits your use case. This setup can be done as follows:

- Add the data disks that will compose the VM.
- Format, mount, and add these disks to the fstab file.

    1. Format the newly added disk. We use symlinks generated by Azure here. Using symlinks avoids problems related to device names changing. For more information, see Troubleshoot device names problems.

        Console

        ```
        mkfs -t ext4 /dev/disk/azure/scsi1/lun0
        ```

    2. Mount the disks.

        Console

        ```
        mount /dev/disk/azure/scsi1/lun0 /mnt/mountpoint
        ```

    3. Add to fstab.

        Console

        ```
        echo "/dev/disk/azure/scsi1/lun0 /mnt/mountpoint ext4 defaults,nofail 1
        2" >> /etc/fstab
        ```

4. Run the Set-AzVMDiskEncryptionExtension PowerShell cmdlet with -EncryptFormatAll to encrypt these disks.

   Azure PowerShell

   ```
   Set-AzVMDiskEncryptionExtension -ResourceGroupName "MySecureGroup" -VMName "MySecureVM" -DiskEncryptionKeyVaultUrl "https://mykeyvault.vault.azure.net/" -EncryptFormatAll
   ```

5. Set up LVM on top of these new disks. Note the encrypted drives are unlocked after the VM has finished booting. So, the LVM mounting will also have to be subsequently delayed.

New IaaS VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can enable encrypting by using the Resource Manager template, PowerShell cmdlets, or CLI commands. The following sections explain in greater detail the Resource Manager template and CLI commands.

Use the instructions in the appendix for preparing pre-encrypted images that can be used in Azure. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

- Prepare a pre-encrypted Linux VHD

> **ⓘ Important**
>
> It's mandatory to take a snapshot or back up a managed disk-based VM instance outside of and prior to enabling Azure Disk Encryption. You can take a snapshot of the managed disk from the portal, or you can use Azure Backup. Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. After a backup is made, use the Set-AzVMDiskEncryptionExtension cmdlet to encrypt managed disks by specifying the -skipVmBackup parameter. The Set-AzVMDiskEncryptionExtension command fails against managed disk-based VMs until a backup is made and this parameter is specified.
>
> Encrypting or disabling encryption might cause the VM to reboot.

Use Azure PowerShell to encrypt IaaS VMs with pre-encrypted VHDs

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet Set-AzVMOSDisk. The following example gives you some common parameters.

PowerShell

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri
"os.vhd" Caching ReadWrite -Windows -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaa
a" -DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myresourcegroup/providers/Microsoft.KeyVault/vaults/my
testvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

Enable encryption on a newly added data disk

You can add a new data disk by using az vm disk attach or through the Azure portal. Before you can encrypt, you need to mount the newly attached data disk first. You must request encryption of the data drive because the drive will be unusable while encryption is in progress.

Enable encryption on a newly added disk with the Azure CLI

If the VM was previously encrypted with "All," then the --volume-type parameter should remain All. All includes both OS and data disks. If the VM was previously encrypted with a volume type of "OS," then the --volume-type parameter should be changed to All so that both the OS and the new data disk will be included. If the VM was encrypted with only the volume type of "Data," then it can remain Data as demonstrated here. Adding and attaching a new data disk to a VM isn't sufficient preparation for encryption. The newly attached disk must also be formatted and properly mounted within the VM before you enable encryption. On Linux, the disk must be mounted in /etc/fstab with a persistent block device name.

In contrast to PowerShell syntax, the CLI doesn't require you to provide a unique sequence version when you enable encryption. The CLI automatically generates and uses its own unique sequence version value.

- **Encrypt a running VM by using a client secret:**

  Azure CLI

  ```
      az vm encryption enable --resource-group "MyVirtualMachineResourceGroup"
  --name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD
  ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-encryption-
  keyvault "MySecureVault" --volume-type "Data"
  ```

- **Encrypt a running VM by using KEK to wrap the client secret:**

Azure CLI

```
    az vm encryption enable --resource-group "MyVirtualMachineResourceGroup"
--name "MySecureVM" --aad-client-id "<my spn created with CLI which is the
Azure AD ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-
encryption-keyvault  "MySecureVault" --key-encryption-key "MyKEK_URI" --key-
encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type "Data"
```

Enable encryption on a newly added disk with Azure PowerShell

When you use PowerShell to encrypt a new disk for Linux, a new sequence version needs to be specified. The sequence version has to be unique. The following script generates a GUID for the sequence version.

- **Encrypt a running VM by using a client secret:** The following script initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, key vault, Microsoft Entra app, and client secret should have already been created as prerequisites. Replace MyVirtualMachineResourceGroup, MyKeyVaultResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values. The -VolumeType parameter is set to data disks and not the OS disk. If the VM was previously encrypted with a volume type of "OS" or "All," then the -VolumeType parameter should be changed to All so that both the OS and the new data disk will be included.

Azure PowerShell

```
    $KVRGname = 'MyKeyVaultResourceGroup';
    $VMRGName = 'MyVirtualMachineResourceGroup';
    $vmName = 'MySecureVM';
    $aadClientID = 'My-AAD-client-ID';
    $aadClientSecret = 'My-AAD-client-secret';
    $KeyVaultName = 'MySecureVault';
    $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
    $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
    $KeyVaultResourceId = $KeyVault.ResourceId;
    $sequenceVersion = [Guid]::NewGuid();

    Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName
$vmName -AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -VolumeType 'data' –
SequenceVersion $sequenceVersion;
```

- **Encrypt a running VM by using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to the key vault. The -VolumeType parameter is set to data disks and not the OS disk. If the VM was previously encrypted with a volume type of "OS" or "All," then the -VolumeType parameter should be changed to All so that both the OS and the new data disk will be included.

Azure PowerShell

```
    $KVRGname = 'MyKeyVaultResourceGroup';
    $VMRGName = 'MyVirtualMachineResourceGroup';
    $vmName = 'MyExtraSecureVM';
    $aadClientID = 'My-AAD-client-ID';
    $aadClientSecret = 'My-AAD-client-secret';
    $KeyVaultName = 'MySecureVault';
    $keyEncryptionKeyName = 'MyKeyEncryptionKey';
    $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
    $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
    $KeyVaultResourceId = $KeyVault.ResourceId;
    $keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;
    $sequenceVersion = [Guid]::NewGuid();

    Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName
$vmName -AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -KeyEncryptionKeyUrl
$keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $KeyVaultResourceId -VolumeType
'data' –SequenceVersion $sequenceVersion;
```

> **Note**
>
> The syntax for the value of the disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name].
>
> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id].

Disable encryption for Linux VMs

You can disable encryption by using Azure PowerShell, the Azure CLI, or a Resource Manager template.

> **Important**
>
> Disabling encryption with Azure Disk Encryption on Linux VMs is only supported for data volumes. It's not supported on data or OS volumes if the OS volume has been encrypted.

- **Disable disk encryption with Azure PowerShell:** To disable encryption, use the Disable-AzureRmVMDiskEncryption cmdlet.

  Azure PowerShell

  ```
  Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM' [--volume-type {ALL, DATA, OS}]
  ```

- **Disable encryption with the Azure CLI:** To disable encryption, use the az vm encryption disable command.

  Azure CLI

  ```
  az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --volume-type [ALL, DATA, OS]
  ```

- **Disable encryption with a Resource Manager template:** To disable encryption, use the Disable encryption on a running Linux VM template.

  1. Select **Deploy to Azure**.
  2. Select the subscription, resource group, location, VM, legal terms, and agreement.
  3. Select **Purchase** to disable disk encryption on a running Windows VM.

Azure Disk Encryption for Windows VMs

Summarize this article for me

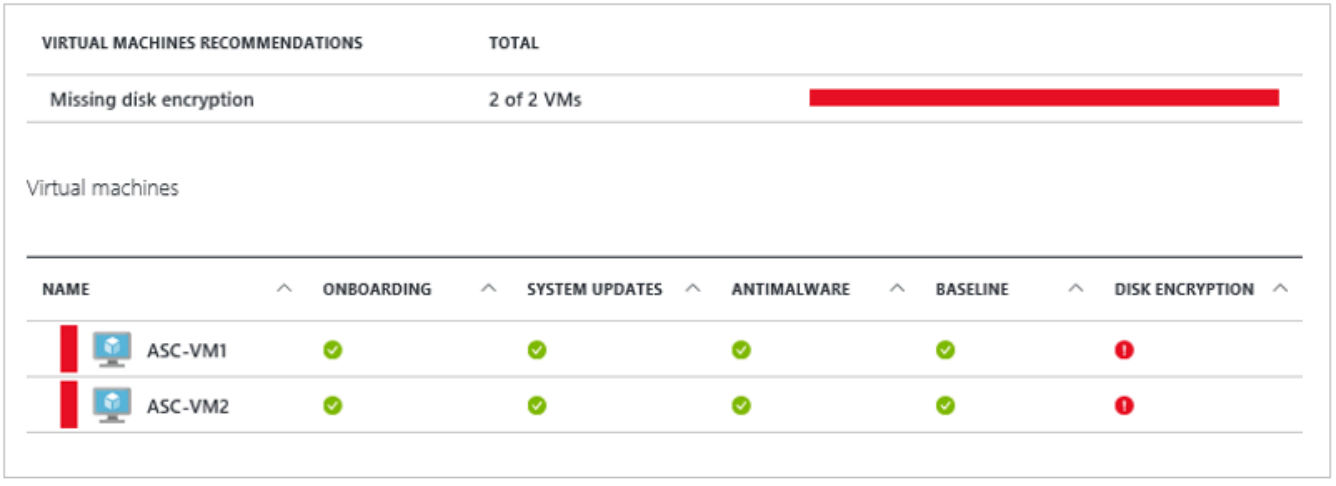
> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Windows VMs ✔ Flexible scale sets.

Azure Disk Encryption helps protect and safeguard your data to meet your organizational security and compliance commitments. It uses the BitLocker feature of Windows to provide volume encryption for the OS and data disks of Azure virtual machines (VMs), and is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets.

Azure Disk Encryption is zone resilient, the same way as Virtual Machines. For details, see Azure Services that support Availability Zones.

If you use Microsoft Defender for Cloud, you're alerted if you have VMs that aren't encrypted. The alerts show as High Severity and the recommendation is to encrypt these VMs.



> **Warning**

- For VMs previously encrypted using Azure Disk Encryption with Microsoft Entra ID, you must continue using that same method. See **Azure Disk Encryption with Microsoft Entra ID (previous release)** for details.
- Implementation of these recommendations may increase your data, network, or compute resource usage, potentially resulting in more license or subscription costs. A valid active Azure subscription is required to create resources in supported regions.
- Never use BitLocker directly to decrypt VMs or disks that were encrypted through Azure Disk Encryption, as this can lead to data loss.

You can learn the fundamentals of Azure Disk Encryption for Windows in just a few minutes with the Create and encrypt a Windows VM with Azure CLI quickstart or the Create and encrypt a Windows VM with Azure PowerShell quickstart.

Supported VMs and operating systems

Supported VMs

Windows VMs are available in a range of sizes. Azure Disk Encryption is supported on Generation 1 and Generation 2 VMs. Azure Disk Encryption is also available for VMs with premium storage.

Azure Disk Encryption is not available on Basic, A-series VMs, v6 series VMs, v7 series VMs, or newer, or on virtual machines with a less than 2 GB of memory. For more exceptions, see Azure Disk Encryption: Restrictions.

Supported operating systems

All versions of Windows that support BitLocker and are configured to meet the requirements of BitLocker. For more information, see BitLocker overview.

> **Note**
>
> Windows Server 2022 and Windows 11 do not support an RSA 2048 bit key. For more information, see **FAQ: What size should I use for my key encryption key?**
>
> Windows Server 2012 R2 Core and Windows Server 2016 Core requires the bdehdcfg component to be installed on the VM for encryption.

Windows Server 2008 R2 requires the .NET Framework 4.5 to be installed for encryption; install it from Windows Update with the optional update Microsoft .NET Framework 4.5.2 for Windows Server 2008 R2 x64-based systems (KB2901983).

Networking requirements

To enable Azure Disk Encryption, the VMs must meet the following network endpoint configuration requirements:

- The Windows VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the Internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see Azure Key Vault behind a firewall.

Group Policy requirements

Azure Disk Encryption uses the BitLocker external key protector for Windows VMs. For domain joined VMs, don't push any group policies that enforce TPM protectors. For information about the group policy for "Allow BitLocker without a compatible TPM," see BitLocker Group Policy Reference.

BitLocker policy on domain joined virtual machines with custom group policy must include the following setting: Configure user storage of BitLocker recovery information -> Allow 256-bit recovery key. Azure Disk Encryption will fail when custom group policy settings for BitLocker are incompatible. On machines that didn't have the correct policy setting, apply the new policy, and force the new policy to update (gpupdate.exe /force). Restarting may be required.

Microsoft BitLocker Administration and Monitoring (MBAM) group policy features aren't compatible with Azure Disk Encryption.

> ⚠ **Warning**
>
> Azure Disk Encryption **does not store recovery keys**. If the **Interactive logon: Machine account lockout threshold** security setting is enabled, machines can only be recovered by providing a recovery key via the serial console. Instructions for ensuring the appropriate recovery policies are enabled can be found in the **Bitlocker recovery guide plan**.

Azure Disk Encryption will fail if domain level group policy blocks the AES-CBC algorithm, which is used by BitLocker.

Encryption key storage requirements

Azure Disk Encryption requires an Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For details, see Creating and configuring a key vault for Azure Disk Encryption.

Terminology

The following table defines some of the common terms used in Azure disk encryption documentation:

Expand table

Terminology	Definition
Azure Key Vault	Key Vault is a cryptographic, key management service that's based on Federal Information Processing Standards (FIPS) validated hardware security modules. These standards help to safeguard your cryptographic keys and sensitive secrets. For more information, see the Azure Key Vault documentation and Creating and configuring a key vault for Azure Disk Encryption.
Azure CLI	The Azure CLI is optimized for managing and administering Azure resources from the command line.
BitLocker	BitLocker is an industry-recognized Windows volume encryption technology that's used to enable disk encryption on Windows VMs.
Key encryption key (KEK)	The asymmetric key (RSA 2048) that you can use to protect or wrap the secret. You can provide a hardware security module (HSM)-protected key or software-protected key. For more information, see the Azure Key Vault documentation and Creating and configuring a key vault for Azure Disk Encryption.
PowerShell cmdlets	For more information, see Azure PowerShell cmdlets.

Quickstart: Create and encrypt a Windows VM with the Azure CLI

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Windows VMs ✔ Flexible scale sets

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. This quickstart shows you how to use the Azure CLI to create and encrypt a Windows Server 2016 virtual machine (VM).

If you don't have an Azure account, create a free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Get started with Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Authenticate to Azure using Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use and manage extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

- This article requires version 2.0.30 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

Create a resource group

Create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Create a virtual machine

Create a VM with az vm create. The following example creates a VM named *myVM*. This example uses *azureuser* for an administrative user name and *myPassword12* as the password.

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image win2016datacenter \
    --admin-username azureuser \
    --admin-password myPassword12
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

Console

```
{
  "fqdns": "",
  "id":
"/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/
virtualMachines/myVM",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroup"
}
```

Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with az keyvault create. To enable the Key Vault to store encryption keys, use the --enabled-for-disk-encryption parameter.

> **ⓘ Important**
>
> Each Key Vault must have a unique name. This example creates a Key Vault named *myKV*, but you must name yours something different.

Azure CLI

```
az keyvault create --name "myKV" --resource-group "myResourceGroup" --location
eastus --enabled-for-disk-encryption
```

Encrypt the virtual machine

Encrypt your VM with az vm encryption, providing your unique Key Vault name to the --disk-encryption-keyvault parameter.

Azure CLI

```
az vm encryption enable -g MyResourceGroup --name MyVM --disk-encryption-keyvault
myKV
```

You can verify that encryption is enabled on your VM with az vm show

Azure CLI

```
az vm encryption show --name MyVM -g MyResourceGroup
```

You will see the following in the returned output:

Console

```
"EncryptionOperation": "EnableEncryption"
```

Clean up resources

When no longer needed, you can use the az group delete command to remove the resource group, VM, and Key Vault.

Azure CLI

```
az group delete --name myResourceGroup
```

Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enabled for encryption keys, and encrypted the VM. Advance to the next article to learn more about Azure Disk Encryption prerequisites for IaaS VMs.

Azure Disk Encryption overview

Quickstart: Create and encrypt a Windows virtual machine in Azure with PowerShell

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Windows VMs

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to create a Windows virtual machine (VM), create a Key Vault for the storage of encryption keys, and encrypt the VM.

If you don't have an Azure subscription, create a free account before you begin.

Create a resource group

Create an Azure resource group with New-AzResourceGroup. A resource group is a logical container into which Azure resources are deployed and managed:

PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

Create a virtual machine

Create an Azure virtual machine with New-AzVM. You must supply credentials to the cmdlet.

PowerShell

```
$cred = Get-Credential
```

```
New-AzVM -Name MyVm -Credential $cred -ResourceGroupName MyResourceGroup -Image
win2016datacenter -Size Standard_D2S_V3
```

It will take a few minutes for your VM to be deployed.

Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with New-AzKeyvault. To enable the Key Vault to store encryption keys, use the -EnabledForDiskEncryption parameter.

> **Important**
>
> Each Key Vault must have a unique name. The following example creates a Key Vault named *myKV*, but you must name yours something different.

PowerShell

```
New-AzKeyvault -name MyKV -ResourceGroupName myResourceGroup -Location EastUS -
EnabledForDiskEncryption
```

Encrypt the virtual machine

Encrypt your VM with Set-AzVmDiskEncryptionExtension.

Set-AzVmDiskEncryptionExtension requires some values from your Key Vault object. You can obtain these values by passing the unique name of your key vault to Get-AzKeyvault.

PowerShell

```
$KeyVault = Get-AzKeyVault -VaultName MyKV -ResourceGroupName MyResourceGroup

Set-AzVMDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName MyVM -
DiskEncryptionKeyVaultUrl $KeyVault.VaultUri -DiskEncryptionKeyVaultId
$KeyVault.ResourceId
```

After a few minutes the process will return the following output:

```
RequestId IsSuccessStatusCode StatusCode ReasonPhrase
--------- ------------------- ---------- ------------
                         True         OK OK
```

You can verify the encryption process by running Get-AzVmDiskEncryptionStatus.

PowerShell

```powershell
Get-AzVmDiskEncryptionStatus -VMName MyVM -ResourceGroupName MyResourceGroup
```

When encryption is enabled, you will see the following fields in the returned output:

```
OsVolumeEncrypted          : Encrypted
DataVolumesEncrypted       : NoDiskFound
OsVolumeEncryptionSettings :
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage            : Provisioning succeeded
```

Clean up resources

When no longer needed, you can use the Remove-AzResourceGroup cmdlet to remove the resource group, VM, and all related resources:

PowerShell

```powershell
Remove-AzResourceGroup -Name "myResourceGroup"
```

Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enabled for encryption keys, and encrypted the VM. Advance to the next article to learn more about Azure Disk Encryption prerequisites for IaaS VMs.

Azure Disk Encryption overview

Last updated on 10/10/2025

Quickstart: Create and encrypt a Windows virtual machine with the Azure portal

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Windows VMs

Azure virtual machines (VMs) can be created through the Azure portal. The Azure portal is a browser-based user interface to create VMs and their associated resources. In this quickstart you use the Azure portal to deploy a Windows virtual machine, create a key vault for the storage of encryption keys, and encrypt the VM.

If you don't have an Azure subscription, create a free account before you begin.

Sign in to Azure

Sign in to the Azure portal.

Create a virtual machine

1. Choose **Create a resource** in the upper left corner of the Azure portal.
2. In the New page, under Popular, select **Windows Server 2016 Datacenter**.
3. In the Basics tab, under Project details, make sure the correct subscription is selected.
4. For "Resource Group", select **Create new**. Enter *myResourceGroup* as the name and select **Ok**.
5. For **Virtual machine name**, enter *MyVM*.
6. For **Region**, select *(US) East US*.

7. Verify that the **Size** is *Standard D2s v3*.

8. Under **Administrator account**, select **Password**. Enter a user name and a password.

Home > New > Create a virtual machine

Create a virtual machine

Complete the Basics tab then Review + create to provision a virtual machine with defau
customization.
Looking for classic VMs? Create VM from Azure Marketplace

Project details

Select the subscription to manage deployed resources and costs. Use resource groups l
your resources.

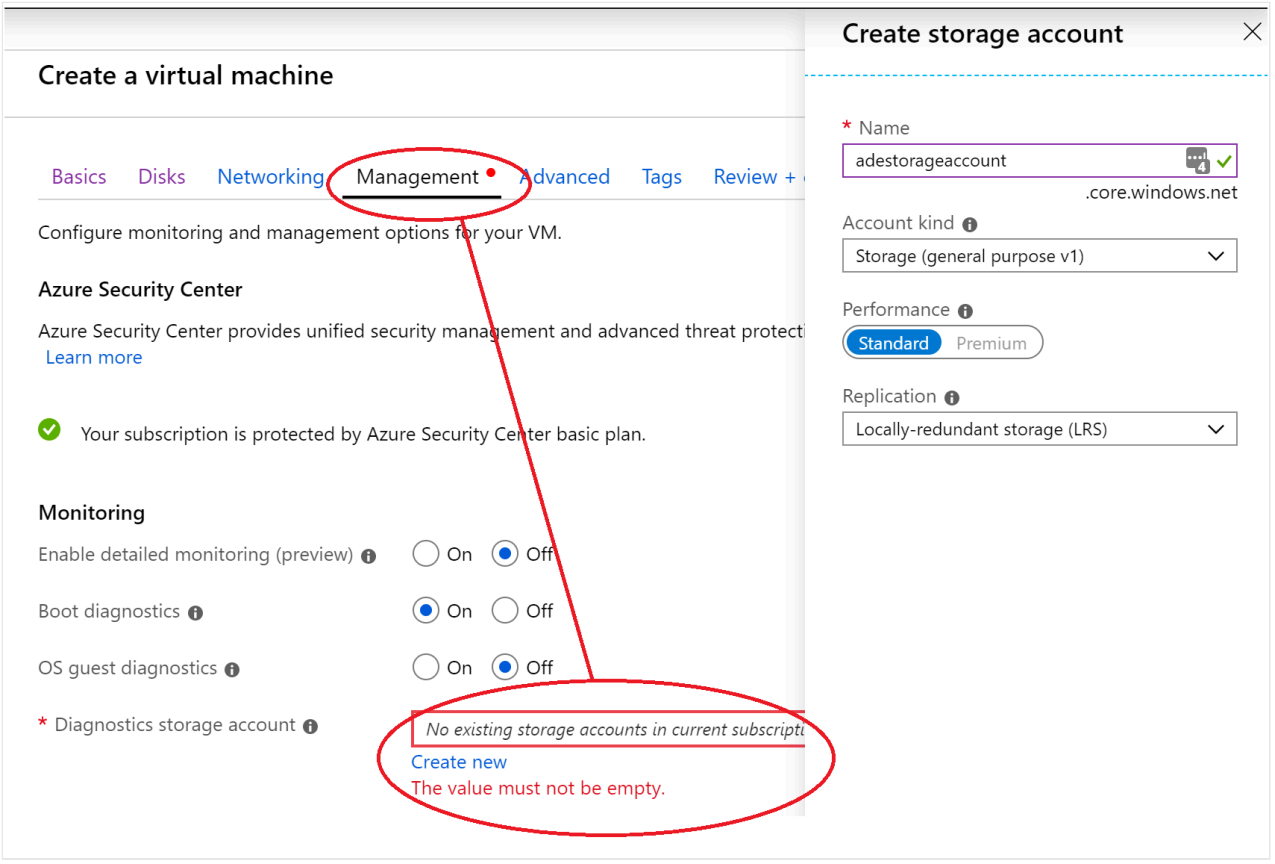
Review + create | < Previous | Next : Disks >

> **⚠ Warning**
>
> The "Disks" tab features an "Encryption Type" field under **Disk options**. This field is used to specify encryption options for Managed Disks + CMK, not for Azure Disk Encryption.
>
> To avoid confusion, we suggest you skip the *Disks* tab entirely while completing this tutorial.

9. Select the "Management" tab and verify that you have a Diagnostics Storage Account. If you have no storage accounts, select "Create New", give your new account a name, and select "Ok"



10. Select "Review + Create".

11. On the **Create a virtual machine** page, you can see the details about the VM you're about to create. When you're ready, select **Create**.

It takes a few minutes for your VM to be deployed. When the deployment is finished, move on to the next section.

Encrypt the virtual machine

1. When the VM deployment is complete, select **Go to resource**.
2. On the left-hand sidebar, select **Disks**.
3. On the top bar, select **Additional Settings** .
4. Under **Encryption settings** > **Disks to encrypt**, select **OS and data disks**.

      Screenshot that shows OS and data disks.
5. Under **Encryption settings**, choose **Select a key vault and key for encryption**.
6. On the **Select key from Azure Key Vault** screen, select **Create New**.

      Screenshot that shows the Create new option.
7. To the left of **Key vault and key**, select **Click to select a key**.
8. On the **Select key from Azure Key Vault**, under the **Key Vault** field, select **Create new**.
9. On the **Create key vault** screen, ensure that the Resource Group is *myResourceGroup*, and give your key vault a name. Every key vault across Azure must have a unique name.
10. On the **Access Policies** tab, check the **Azure Disk Encryption for volume encryption** box.

    disks and encryption selection
11. Select **Review + create**.
12. After the key vault has passed validation, select **Create**. You return to the **Select key from Azure Key Vault** screen.
13. Leave the **Key** field blank and choose **Select**.
14. At the top of the encryption screen, select **Save**. A popup warns you that the VM will reboot. Select **Yes**.

Clean up resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources. To do so, select the resource group for the virtual machine, select Delete, then confirm the name of the resource group to delete.

Next steps

In this quickstart, you created a Key Vault that was enabled for encryption keys, created a virtual machine, and enabled the virtual machine for encryption.

Azure Disk Encryption overview

Last updated on 11/20/2025

Azure Disk Encryption scenarios on Windows VMs

Summarize this article for me

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Applies to: ✔ Windows VMs ✔ Flexible scale sets

Azure Disk Encryption for Windows virtual machines (VMs) uses the BitLocker feature of Windows to provide full disk encryption of the OS disk and data disk. Additionally, it provides encryption of the temporary disk when the VolumeType parameter is All.

Azure Disk Encryption is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets. For an overview of the service, see Azure Disk Encryption for Windows VMs.

Prerequisites

You can only apply disk encryption to virtual machines of supported VM sizes and operating systems. You must also meet the following prerequisites:

- Networking requirements
- Group Policy requirements
- Encryption key storage requirements

Restrictions

If you have previously used Azure Disk Encryption with Microsoft Entra ID to encrypt a VM, you must continue use this option to encrypt your VM. See Azure Disk Encryption with Microsoft Entra ID (previous release) for details.

You should take a snapshot and/or create a backup before disks are encrypted. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. Once a backup is made, you can use the Set-AzVMDiskEncryptionExtension cmdlet to encrypt managed disks by specifying the -skipVmBackup parameter. For more information about how to back up and restore encrypted VMs, see Back up and restore encrypted Azure VM.

Encrypting or disabling encryption may cause a VM to reboot.

Azure Disk Encryption does not work for the following scenarios, features, and technology:

- Encrypting basic tier VM or VMs created through the classic VM creation method.
- Encrypting v6 series VMs with temporary disks (Ddsv6, Dldsv6, Edsv6, Dadsv6, Daldsv6, Eadsv6, Dpdsv6, Dpldsv6, Epdsv6, or Endsv6). For more information, see the individual pages for each of these VM sizes listed on Sizes for virtual machines in Azure
- Encrypting V7 series and newer VM sizes.
- All requirements and restrictions of BitLocker, such as requiring NTFS. For more information, see BitLocker overview.
- Encrypting VMs configured with software-based RAID systems.
- Encrypting VMs configured with Storage Spaces Direct (S2D), or Windows Server versions before 2016 configured with Windows Storage Spaces.
- Integration with an on-premises key management system.
- Azure Files (shared file system).
- Network File System (NFS).
- Dynamic volumes.
- Windows Server containers, which create dynamic volumes for each container.
- Ephemeral OS disks.
- iSCSI disks.
- Encryption of shared/distributed file systems like (but not limited to) DFS, GFS, DRDB, and CephFS.
- Moving an encrypted VM to another subscription or region.
- Creating an image or snapshot of an encrypted VM and using it to deploy additional VMs.
- 'L' family storage optimized VM size series.
- M-series VMs with Write Accelerator disks.
- Applying ADE to a VM that has disks encrypted with Encryption at Host or server-side encryption with customer-managed keys (SSE + CMK). Applying SSE + CMK to a data disk or adding a data disk with SSE + CMK configured to a VM encrypted with ADE is an unsupported scenario as well.
- Migrating a VM that is encrypted with ADE, or has **ever** been encrypted with ADE, to Encryption at Host or server-side encryption with customer-managed keys.
- Encrypting VMs in failover clusters.

- Encryption of Azure Ultra Disks.
- Encryption of Premium SSD v2 disks.
- Encryption of VMs in subscriptions that have the Secrets should have the specified maximum validity period policy enabled with the DENY effect.
- Encryption of VMs in subscriptions that have the Key Vault secrets should have an expiration date policy enabled with the DENY effect

Install tools and connect to Azure

Azure Disk Encryption can be enabled and managed through the Azure CLI and Azure PowerShell. To do so you must install the tools locally and connect to your Azure subscription.

Azure CLI

The Azure CLI 2.0 is a command-line tool for managing Azure resources. The CLI is designed to flexibly query data, support long-running operations as non-blocking processes, and make scripting easy. You can install it locally by following the steps in Install the Azure CLI.

To Sign in to your Azure account with the Azure CLI, use the az login command.

Azure CLI

```
az login
```

If you would like to select a tenant to sign in under, use:

Azure CLI

```
az login --tenant <tenant>
```

If you have multiple subscriptions and want to specify a specific one, get your subscription list with az account list and specify with az account set.

Azure CLI

```
az account list
az account set --subscription "<subscription name or ID>"
```

For more information, see Get started with Azure CLI 2.0.

Azure PowerShell

The Azure PowerShell az module provides a set of cmdlets that uses the Azure Resource Manager model for managing your Azure resources. You can use it in your browser with Azure Cloud Shell, or you can install it on your local machine using the instructions in Install the Azure PowerShell module.

If you already have it installed locally, make sure you use the latest version of Azure PowerShell SDK version to configure Azure Disk Encryption. Download the latest version of Azure PowerShell release.

To Sign in to your Azure account with Azure PowerShell, use the Connect-AzAccount cmdlet.

PowerShell

```
Connect-AzAccount
```

If you have multiple subscriptions and want to specify one, use the Get-AzSubscription cmdlet to list them, followed by the Set-AzContext cmdlet:

PowerShell

```
Set-AzContext -Subscription <SubscriptionId>
```

Running the Get-AzContext cmdlet will verify that the correct subscription has been selected.

To confirm the Azure Disk Encryption cmdlets are installed, use the Get-command cmdlet:

PowerShell

```
Get-command *diskencryption*
```

For more information, see Getting started with Azure PowerShell.

Enable encryption on an existing or running Windows VM

In this scenario, you can enable encryption by using the Resource Manager template, PowerShell cmdlets, or CLI commands. If you need schema information for the virtual machine extension, see the Azure Disk Encryption for Windows extension article.

Enable encryption on existing or running VMs with Azure PowerShell

Use the Set-AzVMDiskEncryptionExtension cmdlet to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM:** The script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, and key vault should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, and MySecureVault with your values.

  Azure PowerShell

  ```
  $KVRGname = 'MyKeyVaultResourceGroup';
  $VMRGName = 'MyVirtualMachineResourceGroup';
  $vmName = 'MySecureVM';
  $KeyVaultName = 'MySecureVault';
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
  $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
  $KeyVaultResourceId = $KeyVault.ResourceId;

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName
-DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId;
  ```

- **Encrypt a running VM using KEK:**

  Azure PowerShell

  ```
  $KVRGname = 'MyKeyVaultResourceGroup';
  $VMRGName = 'MyVirtualMachineResourceGroup';
  $vmName = 'MyExtraSecureVM';
  $KeyVaultName = 'MySecureVault';
  $keyEncryptionKeyName = 'MyKeyEncryptionKey';
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
  $KVRGname;
  $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
  $KeyVaultResourceId = $KeyVault.ResourceId;
  $keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
  $keyEncryptionKeyName).Key.kid;

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName -
  DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
  $KeyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
  KeyEncryptionKeyVaultId $KeyVaultResourceId;
  ```

  > **Note**
  >
  > The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-

name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the Get-AzVmDiskEncryptionStatus cmdlet.

Azure PowerShell

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName
'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

To disable the encryption, see Disable encryption and remove the encryption extension.

Enable encryption on existing or running VMs with the Azure CLI

Use the az vm encryption enable command to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --
name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type
[All|OS|Data]
```

- **Encrypt a running VM using KEK:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --
name "MySecureVM" --disk-encryption-keyvault  "MySecureVault" --key-
encryption-key "MyKEK_URI" --key-encryption-keyvault
"MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
```

> ⓘ Note
>
> The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]

> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the az vm encryption show command.

Azure CLI

```
az vm encryption show --name "MySecureVM" --resource-group
"MyVirtualMachineResourceGroup"
```

To disable the encryption, see Disable encryption and remove the encryption extension.

Using the Resource Manager template

You can enable disk encryption on existing or running IaaS Windows VMs in Azure by using the Resource Manager template to encrypt a running Windows VM.

1. On the Azure quickstart template, click **Deploy to Azure**.
2. Select the subscription, resource group, location, settings, legal terms, and agreement. Click **Purchase** to enable encryption on the existing or running IaaS VM.

The following table lists the Resource Manager template parameters for existing or running VMs:

Expand table

Parameter	Description
vmName	Name of the VM to run the encryption operation.
keyVaultName	Name of the key vault that the BitLocker key should be uploaded to. You can get it by using the cmdlet `(Get-AzKeyVault -ResourceGroupName <MyKeyVaultResourceGroupName>). Vaultname` or the Azure CLI command `az keyvault list --resource-group "MyKeyVaultResourceGroup"`
keyVaultResourceGroup	Name of the resource group that contains the key vault
keyEncryptionKeyURL	The URL of the key encryption key, in the format https://<keyvault-name>.vault.azure.net/key/<key-name>. If you do not wish to use a KEK, leave this field blank.
volumeType	Type of volume that the encryption operation is performed on. Valid values are *OS*, *Data*, and *All*.

Parameter	Description
forceUpdateTag	Pass in a unique value like a GUID every time the operation needs to be force run.
resizeOSDisk	Should the OS partition be resized to occupy full OS VHD before splitting system volume.
location	Location for all resources.

New IaaS VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can create a new VM from a pre-encrypted VHD and the associated encryption keys using PowerShell cmdlets or CLI commands.

Use the instructions in Prepare a pre-encrypted Windows VHD. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

Encrypt VMs with pre-encrypted VHDs with Azure PowerShell

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet Set-AzVMOSDisk. The example below gives you some common parameters.

Azure PowerShell

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri
"os.vhd" Caching ReadWrite -Windows -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaaa
" -DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myKVresourcegroup/providers/Microsoft.KeyVault/vaults/m
ytestvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

Enable encryption on a newly added data disk

You can add a new disk to a Windows VM using PowerShell, or through the Azure portal.

> **Note**

Newly added data disk encryption must be enabled via Powershell, or CLI only. Currently, the Azure portal does not support enabling encryption on new disks.

Enable encryption on a newly added disk with Azure PowerShell

When using PowerShell to encrypt a new disk for Windows VMs, a new sequence version should be specified. The sequence version has to be unique. The script below generates a GUID for the sequence version. In some cases, a newly added data disk might be encrypted automatically by the Azure Disk Encryption extension. Auto encryption usually occurs when the VM reboots after the new disk comes online. This is typically caused because "All" was specified for the volume type when disk encryption previously ran on the VM. If auto encryption occurs on a newly added data disk, we recommend running the Set-AzVmDiskEncryptionExtension cmdlet again with new sequence version. If your new data disk is auto encrypted and you do not wish to be encrypted, decrypt all drives first then re-encrypt with a new sequence version specifying OS for the volume type.

- **Encrypt a running VM:** The script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, and key vault should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, and MySecureVault with your values. This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

  Azure PowerShell

  ```
  $KVRGname = 'MyKeyVaultResourceGroup';
  $VMRGName = 'MyVirtualMachineResourceGroup';
  $vmName = 'MySecureVM';
  $KeyVaultName = 'MySecureVault';
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
  $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
  $KeyVaultResourceId = $KeyVault.ResourceId;
  $sequenceVersion = [Guid]::NewGuid();

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName
-DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -VolumeType "All" -
SequenceVersion $sequenceVersion;
  ```

- **Encrypt a running VM using KEK:** This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS

volume, use "OS" for the -VolumeType parameter.

Azure PowerShell

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$KeyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$KeyVaultResourceId = $KeyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $KeyVaultResourceId -VolumeType "All" -SequenceVersion
$sequenceVersion;
```

> **Note**
>
> The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

Enable encryption on a newly added disk with Azure CLI

The Azure CLI command will automatically provide a new sequence version for you when you run the command to enable encryption. The example uses "All" for the volume-type parameter. You may need to change the volume-type parameter to OS if you're only encrypting the OS disk. In contrast to PowerShell syntax, the CLI does not require the user to provide a unique sequence version when enabling encryption. The CLI automatically generates and uses its own unique sequence version value.

- **Encrypt a running VM:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --
name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type
"All"
```

- **Encrypt a running VM using KEK:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --
name "MySecureVM" --disk-encryption-keyvault  "MySecureVault" --key-
encryption-key "MyKEK_URI" --key-encryption-keyvault
"MySecureVaultContainingTheKEK" --volume-type "All"
```

Disable encryption and remove the encryption extension

You can disable the Azure disk encryption extension, and you can remove the Azure disk encryption extension. These are two distinct operations.

To remove ADE, it is recommended that you first disable encryption and then remove the extension. If you remove the encryption extension without disabling it, the disks will still be encrypted. If you disable encryption **after** removing the extension, the extension will be reinstalled (to perform the decrypt operation) and will need to be removed a second time.

Disable encryption

You can disable encryption using Azure PowerShell, the Azure CLI, or with a Resource Manager template. Disabling encryption does **not** remove the extension (see Remove the encryption extension).

> ⚠ **Warning**
>
> Disabling data disk encryption when both the OS and data disks have been encrypted can have unexpected results. Disable encryption on all disks instead.
>
> Disabling encryption will start a background process of BitLocker to decrypt the disks. This process should be given sufficient time to complete before attempting to any re-enable encryption.

- **Disable disk encryption with Azure PowerShell:** To disable the encryption, use the Disable-AzVMDiskEncryption cmdlet.

Azure PowerShell

```
Disable-AzVMDiskEncryption -ResourceGroupName "MyVirtualMachineResourceGroup"
-VMName "MySecureVM" -VolumeType "all"
```

- **Disable encryption with the Azure CLI:** To disable encryption, use the az vm encryption disable command.

Azure CLI

```
az vm encryption disable --name "MySecureVM" --resource-group
"MyVirtualMachineResourceGroup" --volume-type "all"
```

- **Disable encryption with a Resource Manager template:**

  1. Click **Deploy to Azure** from the Disable disk encryption on running Windows VM template.
  2. Select the subscription, resource group, location, VM, volume type, legal terms, and agreement.
  3. Click **Purchase** to disable disk encryption on a running Windows VM.

Remove the encryption extension

If you want to decrypt your disks and remove the encryption extension, you must disable encryption **before** removing the extension; see disable encryption.

You can remove the encryption extension using Azure PowerShell or the Azure CLI.

- **Disable disk encryption with Azure PowerShell:** To remove the encryption, use the Remove-AzVMDiskEncryptionExtension cmdlet.

Azure PowerShell

```
Remove-AzVMDiskEncryptionExtension -ResourceGroupName
"MyVirtualMachineResourceGroup" -VMName "MySecureVM"
```

- **Disable encryption with the Azure CLI:** To remove encryption, use the az vm extension delete command.

Azure CLI

```
az vm extension delete -g "MyVirtualMachineResourceGroup" --vm-name
"MySecureVM" -n "AzureDiskEncryption"
```

Azure Disk Encryption sample scripts

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Windows VMs

This article provides sample scripts for preparing pre-encrypted VHDs and other tasks.

> **Note**
>
> All scripts refer to the latest, non-AAD version of ADE, except where noted.

Sample PowerShell scripts for Azure Disk Encryption

- **List all encrypted VMs in your subscription**

  You can find all ADE-encrypted VMs and the extension version, in all resource groups present in a subscription, using this PowerShell script.

  Alternatively, these cmdlets will show all ADE-encrypted VMs (but not the extension version):

  Azure PowerShell

```
$osVolEncrypted = {(Get-AzVMDiskEncryptionStatus -ResourceGroupName
$_.ResourceGroupName -VMName $_.Name).OsVolumeEncrypted}
$dataVolEncrypted= {(Get-AzVMDiskEncryptionStatus -ResourceGroupName
$_.ResourceGroupName -VMName $_.Name).DataVolumesEncrypted}
Get-AzVm | Format-Table @{Label="MachineName"; Expression={$_.Name}},
@{Label="OsVolumeEncrypted"; Expression=$osVolEncrypted},
@{Label="DataVolumesEncrypted"; Expression=$dataVolEncrypted}
```

- **List all encrypted VMSS instances in your subscription**

You can find all ADE-encrypted Virtual Machine Scale Sets instances and the extension version, in all resource groups present in a subscription, using this PowerShell script.

- **List all disk encryption secrets used for encrypting VMs in a key vault**

Azure PowerShell

```
Get-AzKeyVaultSecret -VaultName $KeyVaultName | where
{$_.Tags.ContainsKey('DiskEncryptionKeyFileName')} | format-table
@{Label="MachineName"; Expression={$_.Tags['MachineName']}},
@{Label="VolumeLetter"; Expression={$_.Tags['VolumeLetter']}},
@{Label="EncryptionKeyURL"; Expression={$_.Id}}
```

Using the Azure Disk Encryption prerequisites PowerShell script

If you're already familiar with the prerequisites for Azure Disk Encryption, you can use the Azure Disk Encryption prerequisites PowerShell script. For an example of using this PowerShell script, see the Encrypt a VM Quickstart. You can remove the comments from a section of the script, starting at line 211, to encrypt all disks for existing VMs in an existing resource group.

The following table shows which parameters can be used in the PowerShell script:

Expand table

Parameter	Description	Mandatory?
$resourceGroupName	Name of the resource group to which the KeyVault belongs. A new resource group with this name will be created if one doesn't exist.	True
$keyVaultName	Name of the KeyVault in which encryption keys are to be placed. A new vault with this name will be created if one doesn't exist.	True
$location	Location of the KeyVault. Make sure the KeyVault and VMs to be encrypted are in the same location. Get a location list with `Get-AzLocation`.	True
$subscriptionId	Identifier of the Azure subscription to be used. You can get your Subscription ID with `Get-AzSubscription`.	True
$aadAppName	Name of the Microsoft Entra application that will be used to write secrets to KeyVault. A new application with this name will	False

Parameter	Description	Mandatory?
	be created if one doesn't exist. If this app already exists, pass aadClientSecret parameter to the script.	
$aadClientSecret	Client secret of the Microsoft Entra application that was created earlier.	False
$keyEncryptionKeyName	Name of optional key encryption key in KeyVault. A new key with this name will be created if one doesn't exist.	False

Resource Manager templates

Encrypt or decrypt VMs without a Microsoft Entra app

- Enable disk encryption on an existing or running Windows VM
- Disable encryption on a running Windows VM

Encrypt or decrypt VMs with a Microsoft Entra app (previous release)

- Enable disk encryption on an existing or running Windows VM
- Disable encryption on a running Windows VM
- Create a new encrypted managed disk from a pre-encrypted VHD/storage blob
  - Creates a new encrypted managed disk provided a pre-encrypted VHD and its corresponding encryption settings

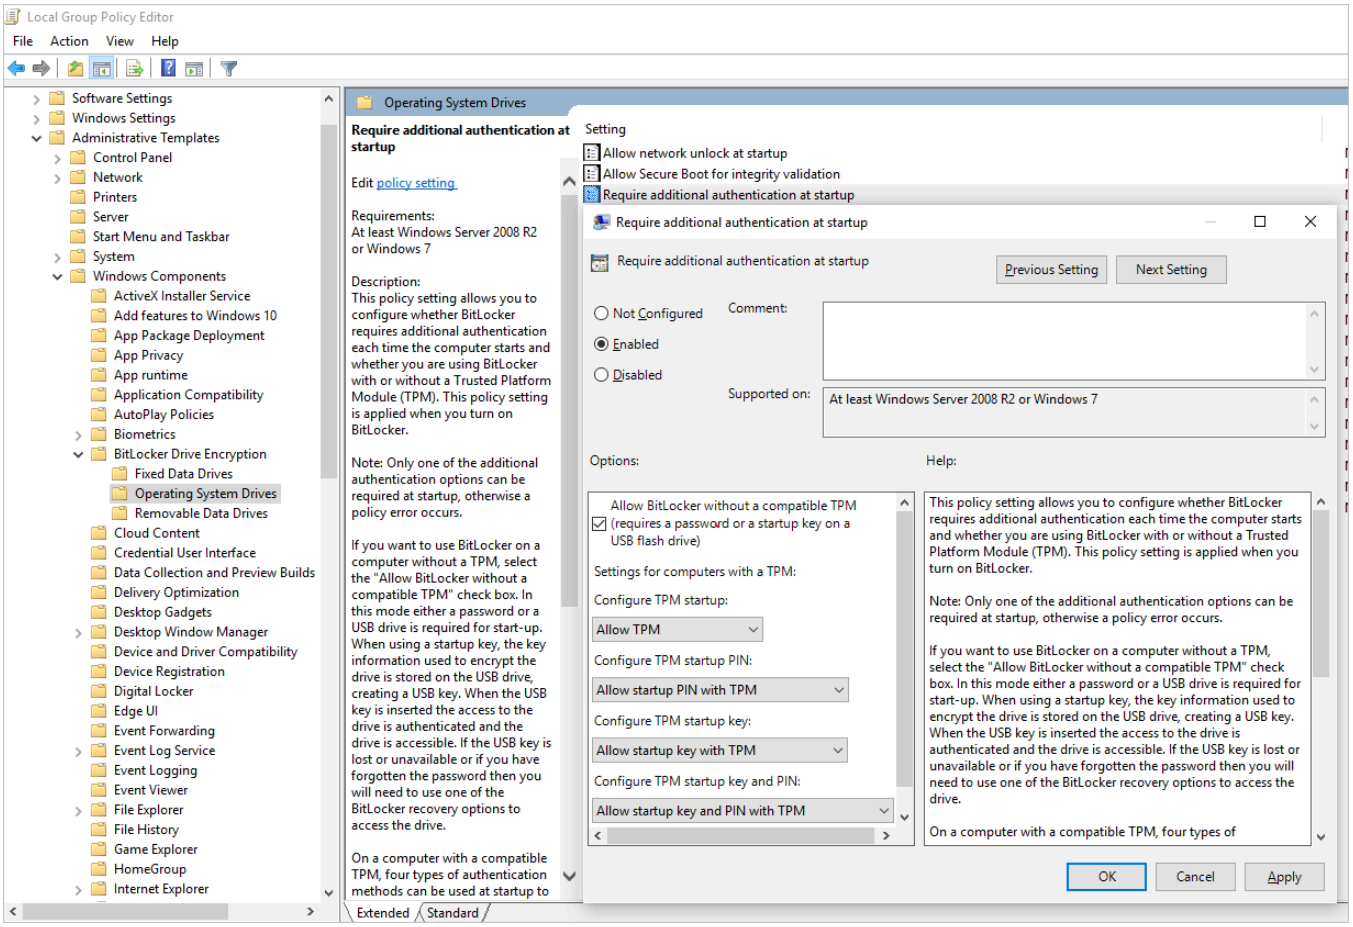
Prepare a pre-encrypted Windows VHD

The sections that follow are necessary to prepare a pre-encrypted Windows VHD for deployment as an encrypted VHD in Azure IaaS. Use the information to prepare and boot a fresh Windows VM (VHD) on Azure Site Recovery or Azure. For more information on how to prepare and upload a VHD, see Upload a generalized VHD and use it to create new VMs in Azure.

Update group policy to allow non-TPM for OS protection

Configure the BitLocker Group Policy setting **BitLocker Drive Encryption**, which you'll find under **Local Computer Policy** > **Computer Configuration** > **Administrative Templates** > **Windows Components**. Change this setting to **Operating System Drives** > **Require additional**

authentication at startup > **Allow BitLocker without a compatible TPM**, as shown in the following figure:



Install BitLocker feature components

For Windows Server 2012 and later, use the following command:

```
Console

dism /online /Enable-Feature /all /FeatureName:BitLocker /quiet /norestart
```

For Windows Server 2008 R2, use the following command:

```
Console

ServerManagerCmd -install BitLockers
```

Prepare the OS volume for BitLocker by using `bdehdcfg`

To compress the OS partition and prepare the machine for BitLocker, execute the bdehdcfg if needed:

Console

```
bdehdcfg -target c: shrink -quiet
```

Protect the OS volume by using BitLocker

Use the manage-bde command to enable encryption on the boot volume using an external key protector. Also place the external key (.bek file) on the external drive or volume. Encryption is enabled on the system/boot volume after the next reboot.

Console

```
manage-bde -on %systemdrive% -sk [ExternalDriveOrVolume]
reboot
```

> **Note**
>
> Prepare the VM with a separate data/resource VHD for getting the external key by using BitLocker.

Upload encrypted VHD to an Azure storage account

After BitLocker encryption is enabled, the local encrypted VHD needs to be uploaded to your storage account.

PowerShell

```
    Add-AzVhd [-Destination] <Uri> [-LocalFilePath] <FileInfo> [[-
NumberOfUploaderThreads] <Int32> ] [[-BaseImageUriToPatch] <Uri> ] [[-OverWrite]]
[ <CommonParameters>]
```

Upload the secret for the pre-encrypted VM to your key vault

The disk encryption secret that you obtained previously must be uploaded as a secret in your key vault. To do so, you must grant the set secret permission and the wrapkey permission to the account that will upload the secrets.

PowerShell

```
# Typically, account Id is the user principal name (in user@domain.com format)
$upn = (Get-AzureRmContext).Account.Id
Set-AzKeyVaultAccessPolicy -VaultName $kvname -UserPrincipalName $acctid -
PermissionsToKeys wrapKey -PermissionsToSecrets set

# In cloud shell, the account ID is a managed service identity, so specify the
username directly
# $upn = "user@domain.com"
# Set-AzKeyVaultAccessPolicy -VaultName $kvname -UserPrincipalName $acctid -
PermissionsToKeys wrapKey -PermissionsToSecrets set

# When running as a service principal, retrieve the service principal ID from the
account ID, and set access policy to that
# $acctid = (Get-AzureRmContext).Account.Id
# $spoid = (Get-AzureRmADServicePrincipal -ServicePrincipalName $acctid).Id
# Set-AzKeyVaultAccessPolicy -VaultName $kvname -ObjectId $spoid -
BypassObjectIdValidation -PermissionsToKeys wrapKey -PermissionsToSecrets set
```

Disk encryption secret not encrypted with a KEK

To set up the secret in your key vault, use Set-AzKeyVaultSecret. The passphrase is encoded as a base64 string and then uploaded to the key vault. In addition, make sure that the following tags are set when you create the secret in the key vault.

PowerShell

```
 # This is the passphrase that was provided for encryption during the distribution
installation
 $passphrase = "contoso-password"

 $tags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP";
"DiskEncryptionKeyFileName" = "LinuxPassPhraseFileName"}
 $secretName = [guid]::NewGuid().ToString()
 $secretValue =
[Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($passphrase))
 $secureSecretValue = ConvertTo-SecureString $secretValue -AsPlainText -Force

 $secret = Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $secretName -
SecretValue $secureSecretValue -tags $tags
 $secretUrl = $secret.Id
```

Use the `$secretUrl` in the next step for attaching the OS disk without using KEK.

Disk encryption secret encrypted with a KEK

Before you upload the secret to the key vault, you can optionally encrypt it by using a key encryption key. Use the wrap API to first encrypt the secret using the key encryption key. The output of this wrap operation is a base64 URL encoded string, which you can then upload as a secret by using the Set-AzKeyVaultSecret cmdlet.

PowerShell

```
    # This is the passphrase that was provided for encryption during the
distribution installation
    $passphrase = "contoso-password"

    Add-AzKeyVaultKey -VaultName $KeyVaultName -Name "keyencryptionkey" -
Destination Software
    $KeyEncryptionKey = Get-AzKeyVaultKey -VaultName $KeyVault.OriginalVault.Name
-Name "keyencryptionkey"

    $apiversion = "2015-06-01"

    ###############################
    # Get Auth URI
    ###############################

    $uri = $KeyVault.VaultUri + "/keys"
    $headers = @{}

    $response = try { Invoke-RestMethod -Method GET -Uri $uri -Headers $headers }
catch { $_.Exception.Response }

    $authHeader = $response.Headers["www-authenticate"]
    $authUri = [regex]::match($authHeader, 'authorization="
(.*?)"').Groups[1].Value

    Write-Host "Got Auth URI successfully"

    ###############################
    # Get Auth Token
    ###############################

    $uri = $authUri + "/oauth2/token"
    $body = "grant_type=client_credentials"
    $body += "&client_id=" + $AadClientId
    $body += "&client_secret=" + [Uri]::EscapeDataString($AadClientSecret)
    $body += "&resource=" + [Uri]::EscapeDataString("https://vault.azure.net")
    $headers = @{}

    $response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body
$body

    $access_token = $response.access_token

    Write-Host "Got Auth Token successfully"

    ###############################
```

```
    # Get KEK info
    ##############################

    $uri = $KeyEncryptionKey.Id + "?api-version=" + $apiversion
    $headers = @{"Authorization" = "Bearer " + $access_token}

    $response = Invoke-RestMethod -Method GET -Uri $uri -Headers $headers

    $keyid = $response.key.kid

    Write-Host "Got KEK info successfully"

    ##############################
    # Encrypt passphrase using KEK
    ##############################

    $passphraseB64 =
[Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Passphrase))
    $uri = $keyid + "/encrypt?api-version=" + $apiversion
    $headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" =
"application/json"}
    $bodyObj = @{"alg" = "RSA-OAEP"; "value" = $passphraseB64}
    $body = $bodyObj | ConvertTo-Json

    $response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body
$body

    $wrappedSecret = $response.value

    Write-Host "Encrypted passphrase successfully"

    ##############################
    # Store secret
    ##############################

    $secretName = [guid]::NewGuid().ToString()
    $uri = $KeyVault.VaultUri + "/secrets/" + $secretName + "?api-version=" +
$apiversion
    $secretAttributes = @{"enabled" = $true}
    $secretTags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP";
"DiskEncryptionKeyFileName" = "LinuxPassPhraseFileName"}
    $headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" =
"application/json"}
    $bodyObj = @{"value" = $wrappedSecret; "attributes" = $secretAttributes;
"tags" = $secretTags}
    $body = $bodyObj | ConvertTo-Json

    $response = Invoke-RestMethod -Method PUT -Uri $uri -Headers $headers -Body
$body

    Write-Host "Stored secret successfully"

    $secretUrl = $response.id
```

Use `$KeyEncryptionKey` and `$secretUrl` in the next step for attaching the OS disk using KEK.

Specify a secret URL when you attach an OS disk

Without using a KEK

While you're attaching the OS disk, you need to pass `$secretUrl`. The URL was generated in the "Disk-encryption secret not encrypted with a KEK" section.

PowerShell

```
Set-AzVMOSDisk `
        -VM $VirtualMachine `
        -Name $OSDiskName `
        -SourceImageUri $VhdUri `
        -VhdUri $OSDiskUri `
        -Windows `
        -CreateOption FromImage `
        -DiskEncryptionKeyVaultId $KeyVault.ResourceId `
        -DiskEncryptionKeyUrl $SecretUrl
```

Using a KEK

When you attach the OS disk, pass `$KeyEncryptionKey` and `$secretUrl`. The URL was generated in the "Disk encryption secret encrypted with a KEK" section.

PowerShell

```
Set-AzVMOSDisk `
        -VM $VirtualMachine `
        -Name $OSDiskName `
        -SourceImageUri $CopiedTemplateBlobUri `
        -VhdUri $OSDiskUri `
        -Windows `
        -CreateOption FromImage `
        -DiskEncryptionKeyVaultId $KeyVault.ResourceId `
        -DiskEncryptionKeyUrl $SecretUrl `
        -KeyEncryptionKeyVaultId $KeyVault.ResourceId `
        -KeyEncryptionKeyURL $KeyEncryptionKey.Id
```

Azure Disk Encryption troubleshooting guide

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Windows VMs ✔ Flexible scale sets

This guide is for IT professionals, information security analysts, and cloud administrators who use Azure Disk Encryption. This article helps troubleshoot disk encryption problems.

Before taking these steps, ensure the VMs you want to encrypt are among the supported VM sizes and operating systems and that you meet all the prerequisites:

- Networking requirements
- Group policy requirements
- Encryption key storage requirements

Troubleshooting 'failed to send DiskEncryptionData'

When encrypting a VM fails with the error message "Failed to send DiskEncryptionData...", it's usually caused by one of the following situations:

- The Key Vault exists in a different region or subscription than the virtual machine
- Advanced access policies in the Key Vault aren't set to allow Azure Disk Encryption
- The Key Encryption Key is disabled or deleted in the Key Vault
- A typo exists in the Resource ID or URL for the Key Vault or Key Encryption Key (KEK)
- Special characters are used in the names of the VM, data disks, or keys. For example, "_VMName" or "élite".
- The encryption scenario isn't supported
- Network issues prevent the VM or host from accessing the required resources

Suggestions for resolving the issue

- Make sure the Key Vault exists in the same region and subscription as the Virtual Machine
- Ensure you set key vault advanced access policies correctly
- If you are using KEK, ensure the key exists and is enabled in Key Vault
- Check that the VM name, data disks, and keys follow key vault resource naming restrictions.
- Check for typos in the Key Vault name or KEK name in PowerShell or CLI commands

> **Note**
>
> The syntax for the value of the `disk-encryption-keyvault` parameter is the full identifier string: `/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]`
> The syntax for the value of the `key-encryption-key` parameter is the full URI to the KEK, such as: `https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]`

- Ensure you are not violating any restrictions
- Ensure you are meeting network requirements and try again

Troubleshooting Azure Disk Encryption behind a firewall

When connectivity is restricted by a firewall, proxy requirement, or network security group (NSG) settings, the extension may be unable to perform the needed tasks. This disruption can result in status messages such as "Extension status not available on the VM." In typical scenarios, the encryption doesn't finish. The sections that follow have some common firewall problems that you might investigate.

Network security groups

Any network security group settings that are applied must still allow the endpoint to meet the documented network configuration prerequisites for disk encryption.

Azure Key Vault behind a firewall

When encryption is being enabled with Microsoft Entra credentials, the target VM must allow connectivity to both Microsoft Entra endpoints and Key Vault endpoints. Current Microsoft Entra authentication endpoints are maintained in sections 56 and 59 of the Microsoft 365 URLs

and IP address ranges documentation. Key Vault instructions are provided in the documentation on how to Access Azure Key Vault behind a firewall.

Azure Instance Metadata Service

The VM must be able to access the Azure Instance Metadata service endpoint (`169.254.169.254`) and the virtual public IP address (`168.63.129.16`) used for communication with Azure platform resources. Proxy configurations that alter local HTTP traffic to these addresses, like adding an X-Forwarded-For header, aren't supported.

Troubleshooting Windows Server 2016 Server Core

On Windows Server 2016 Server Core, the `bdehdcfg` component isn't available by default. Azure Disk Encryption requires this component. It's used to split the system volume from the OS volume, which is done only once for the lifetime of the VM. These binaries aren't required during later encryption operations.

To work around this issue, copy the following four files from a Windows Server 2016 Data Center VM to the same location on Server Core:

```
\windows\system32\bdehdcfg.exe
\windows\system32\bdehdcfglib.dll
\windows\system32\en-US\bdehdcfglib.dll.mui
\windows\system32\en-US\bdehdcfg.exe.mui
```

1. Run the following command:

   ```
   bdehdcfg.exe -target default
   ```

2. This command creates a 550 MB system partition. Restart the system.

3. Use DiskPart to check the volumes. Then proceed.

For example:

```
DISKPART> list vol

  Volume ###  Ltr  Label        Fs     Type        Size     Status     Info
```

```
----------  ---  -----------  -----  ----------  -------  ---------  --------
Volume 0     C                NTFS   Partition    126 GB  Healthy    Boot
Volume 1                      NTFS   Partition    550 MB  Healthy    System
Volume 2     D   Temporary S  NTFS   Partition     13 GB  Healthy    Pagefile
```

Troubleshooting encryption status

The portal might display a disk as encrypted even after it is unencrypted within the VM. This situation can occur when low-level commands are used to directly unencrypt the disk from within the VM instead of using the higher-level Azure Disk Encryption management commands. The higher-level commands not only unencrypt the disk from within the VM but also update important platform-level encryption settings and extension settings associated with the VM. If these are not kept in alignment, the platform is unable to report encryption status or provision the VM properly.

To disable Azure Disk Encryption with PowerShell, use Disable-AzVMDiskEncryption followed by Remove-AzVMDiskEncryptionExtension. Running Remove-AzVMDiskEncryptionExtension before the encryption is disabled fails.

To disable Azure Disk Encryption with the CLI, use az vm encryption disable.

- Azure data encryption at rest

Azure Disk Encryption for Windows virtual machines FAQ

This article provides answers to frequently asked questions (FAQ) about Azure Disk Encryption for Windows VMs. For more information about this service, see Azure Disk Encryption overview.

What is Azure Disk Encryption for Windows VMs?

Azure Disk Encryption for Windows VMs uses the BitLocker feature of Windows to provide full disk encryption of the OS disk and data disks. Additionally, it provides encryption of the temporary disk when the VolumeType parameter is All. The content flows encrypted from the VM to the Storage backend. Thereby, providing end-to-end encryption with a customer-managed key.

See Supported VMs and operating systems.

Where is Azure Disk Encryption in general availability (GA)?

Azure Disk Encryption is in general availability in all Azure public regions.

What user experiences are available with Azure Disk Encryption?

Azure Disk Encryption GA supports Azure Resource Manager templates, Azure PowerShell, and Azure CLI. The different user experiences give you flexibility. You have three different options for enabling disk encryption for your VMs. For more information on the user experience and step-by-step guidance available in Azure Disk Encryption, see Azure Disk Encryption scenarios for Windows.

How much does Azure Disk Encryption cost?

There's no charge for encrypting VM disks with Azure Disk Encryption, but there are charges associated with the use of Azure Key Vault. For more information on Azure Key Vault costs, see the Key Vault pricing page.

How can I start using Azure Disk Encryption?

To get started, read the Azure Disk Encryption overview.

What VM sizes and operating systems support Azure Disk Encryption?

The Azure Disk Encryption overview article lists the VM sizes and VM operating systems that support Azure Disk Encryption.

Can I encrypt both boot and data volumes with Azure Disk Encryption?

You can encrypt both boot and data volumes, but you can't encrypt the data without first encrypting the OS volume.

Can I encrypt an unmounted volume with Azure Disk Encryption?

No, Azure Disk Encryption only encrypts mounted volumes.

What is Storage server-side encryption?

Storage server-side encryption encrypts Azure managed disks in Azure Storage. Managed disks are encrypted by default with Server-side encryption with a platform-managed key (as of June 10, 2017). You can manage encryption of managed disks with your own keys by specifying a customer-managed key. For more information, see Server-side encryption of Azure managed disks.

How is Azure Disk Encryption different from Storage server-side encryption with customer-

managed key and when should I use each solution?

Azure Disk Encryption provides end-to-end encryption for the OS disk, data disks, and the temporary disk with a customer-managed key.

- If your requirements include encrypting all of the above and end-to-end encryption, use Azure Disk Encryption.
- If your requirements include encrypting only data at rest with customer-managed key, then use Server-side encryption with customer-managed keys. You can't encrypt a disk with both Azure Disk Encryption and Storage server-side encryption with customer managed keys.
- If you're using a scenario called out in Restrictions, consider Server-side encryption with customer-managed keys.
- If your organization's policy allows you to encrypt content at rest with an Azure-managed key, then no action is needed - the content is encrypted by default. For managed disks, the content inside storage is encrypted by default with Server-side encryption with platform-managed key. The key is managed by the Azure Storage service.

How do I rotate secrets or encryption keys?

To rotate secrets, just call the same command you used originally to enable disk encryption, specifying a different Key Vault. To rotate the key encryption key, call the same command you used originally to enable disk encryption, specifying the new key encryption.

> ⚠ **Warning**
>
> - If you've previously used **Azure Disk Encryption with Microsoft Entra app** by specifying Microsoft Entra credentials to encrypt this VM, you must continue to use this option. Using Azure Disk Encryption without Microsoft Entra ID on a VM that's been encrypted using Azure Disk Encryption with Microsoft Entra ID isn't yet a supported scenario.

How do I add or remove a key encryption key (KEK) if I didn't originally use one?

To add a key encryption key, call the enable command again passing the key encryption key parameter. To remove a key encryption key, call the enable command again without the key encryption key parameter.

What size should I use for my key encryption key (KEK)?

Windows Server 2022 and Windows 11 include a newer version of BitLocker and currently doesn't work with RSA 2048 bit Key Encryption Keys. Until resolved, use an RSA 3072 or RSA 4096-bit keys, as described in Supported operating systems.

For earlier version of Windows, you may instead use RSA 2048 Key Encryption Keys.

Does Azure Disk Encryption allow you to bring your own key (BYOK)?

Yes, you can supply your own key encryption keys. These keys are safeguarded in Azure Key Vault, which is the key store for Azure Disk Encryption. For more information on the key encryption keys support scenarios, see Creating and configuring a key vault for Azure Disk Encryption.

Can I use an Azure-created key encryption key?

Yes, you can use Azure Key Vault to generate a key encryption key for Azure disk encryption use. These keys are safeguarded in Azure Key Vault, which is the key store for Azure Disk Encryption. For more information on the key encryption key, see Creating and configuring a key vault for Azure Disk Encryption.

Can I use an on-premises key management service or HSM to safeguard the encryption keys?

You can't use the on-premises key management service or HSM to safeguard the encryption keys with Azure Disk Encryption. You can only use the Azure Key Vault service to safeguard the

encryption keys. For more information on the key encryption key support scenarios, see Creating and configuring a key vault for Azure Disk Encryption.

What are the prerequisites to configure Azure Disk Encryption?

There are prerequisites for Azure Disk Encryption. See the Creating and configuring a key vault for Azure Disk Encryption article to create a new key vault, or set up an existing key vault for disk encryption access to enable encryption, and safeguard secrets and keys. For more information on the key encryption key support scenarios, see Creating and configuring a key vault for Azure Disk Encryption.

What are the prerequisites to configure Azure Disk Encryption with a Microsoft Entra app (previous release)?

There are prerequisites for Azure Disk Encryption. See the Azure Disk Encryption with Microsoft Entra ID content to create an Microsoft Entra application, create a new key vault, or set up an existing key vault for disk encryption access to enable encryption, and safeguard secrets and keys. For more information on the key encryption key support scenarios, see Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID.

Is Azure Disk Encryption using a Microsoft Entra app (previous release) still supported?

Yes. Disk encryption using a Microsoft Entra app is still supported. However, when encrypting new VMs it's recommended that you use the new method rather than encrypting with a Microsoft Entra app.

Can I migrate VMs that were encrypted with a Microsoft Entra app to encryption without a Microsoft Entra app?

Currently, there isn't a direct migration path for machines that were encrypted with a Microsoft Entra app to encryption without a Microsoft Entra app. Additionally, there isn't a direct path from encryption without a Microsoft Entra app to encryption with an AD app.

What version of Azure PowerShell does Azure Disk Encryption support?

Use the latest version of the Azure PowerShell SDK to configure Azure Disk Encryption. Download the latest version of Azure PowerShell. Azure Disk Encryption is *not* supported by Azure SDK version 1.1.0.

What is the disk "Bek Volume" or "/mnt/azure_bek_disk"?

The "Bek volume" is a local data volume that securely stores the encryption keys for Encrypted Azure VMs.

> **Note**
>
> Don't delete or edit any contents in this disk. Don't unmount the disk since the encryption key presence is needed for any encryption operations on the IaaS VM.

What encryption method does Azure Disk Encryption use?

Azure Disk Encryption selects the encryption method in BitLocker based on the version of Windows as follows:

Expand table

Windows Versions	Version	Encryption Method
Windows Server 2012, Windows 10, or greater	>=1511	XTS-AES 256 bit
Windows Server 2012, Windows 8, 8.1, 10	< 1511	AES 256 bit *

Windows Versions	Version	Encryption Method
Windows Server 2008R2		AES 256 bit with Diffuser

* AES 256 bit with Diffuser isn't supported in Windows 2012 and later.

To determine Windows OS version, run the 'winver' tool in your virtual machine.

Can I back up and restore an encrypted VM?

Azure Backup provides a mechanism to back up and restore encrypted VMs within the same subscription and region. For instructions, see Back up and restore encrypted virtual machines with Azure Backup. Restoring an encrypted VM to a different region isn't currently supported.

Where can I go to ask questions or provide feedback?

You can ask questions or provide feedback on the Microsoft Q&A question page for Azure Disk Encryption.

Next steps

In this document, you learned more about the most frequent questions related to Azure Disk Encryption. For more information about this service, see the following articles:

- Azure Disk Encryption Overview
- Apply disk encryption in Azure Security Center
- Azure data encryption at rest

Azure Disk Encryption with Azure AD (previous release)

09/24/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Windows VMs

The new release of Azure Disk Encryption eliminates the requirement for providing a Microsoft Entra application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Microsoft Entra credentials during the enable encryption step. All new VMs must be encrypted without the Microsoft Entra application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see Azure Disk Encryption for Windows VMs. VMs that were already encrypted with Microsoft Entra application parameters are still supported and should continue to be maintained with the Microsoft Entra syntax.

This article supplements Azure Disk Encryption for Windows VMs with additional requirements and prerequisites for Azure Disk Encryption with Microsoft Entra ID (previous release). The Supported VMs and operating systems section remains the same.

Networking and Group Policy

To enable the Azure Disk Encryption feature using the older Microsoft Entra parameter syntax, the IaaS VMs must meet the following network endpoint configuration requirements:

- To get a token to connect to your key vault, the IaaS VM must be able to connect to a Microsoft Entra endpoint, [login.microsoftonline.com].
- To write the encryption keys to your key vault, the IaaS VM must be able to connect to the key vault endpoint.
- The IaaS VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.

- If your security policy limits access from Azure VMs to the Internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see Azure Key Vault behind a firewall.
- The VM to be encrypted must be configured to use TLS 1.2 as the default protocol. If TLS 1.0 has been explicitly disabled and the .NET version hasn't been updated to 4.6 or higher, the following registry change will enable ADE to select the more recent TLS version:

```
Console

[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001

[HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001`
```

Group Policy:

- The Azure Disk Encryption solution uses the BitLocker external key protector for Windows IaaS VMs. For domain joined VMs, don't push any group policies that enforce TPM protectors. For information about the group policy for "Allow BitLocker without a compatible TPM," see BitLocker Group Policy Reference.

- BitLocker policy on domain joined virtual machines with custom group policy must include the following setting: Configure user storage of BitLocker recovery information -> Allow 256-bit recovery key. Azure Disk Encryption will fail when custom group policy settings for BitLocker are incompatible. On machines that didn't have the correct policy setting, apply the new policy, force the new policy to update (gpupdate.exe /force), and then restarting may be required.

Encryption key storage requirements

Azure Disk Encryption requires an Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For details, see Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release).

Next steps

- Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release)

- Enable Azure Disk Encryption with Microsoft Entra ID on Windows VMs (previous release)
- Azure Disk Encryption prerequisites CLI script
- Azure Disk Encryption prerequisites PowerShell script

Creating and configuring a key vault for Azure Disk Encryption with Microsoft Entra ID (previous release)

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Windows VMs

The new release of Azure Disk Encryption eliminates the requirement for providing a Microsoft Entra application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Microsoft Entra credentials during the enable encryption step. All new VMs must be encrypted without the Microsoft Entra application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see Azure Disk Encryption. VMs that were already encrypted with Microsoft Entra application parameters are still supported and should continue to be maintained with the Microsoft Entra syntax.

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see Get started with Azure Key Vault and Secure your key vault.

Creating and configuring a key vault for use with Azure Disk Encryption with Microsoft Entra ID (previous release) involves three steps:

1. Create a key vault.
2. Set up a Microsoft Entra application and service principal.
3. Set the key vault access policy for the Microsoft Entra app.
4. Set key vault advanced access policies.

You may also, if you wish, generate or import a key encryption key (KEK).

See the main Creating and configuring a key vault for Azure Disk Encryption article for steps on how to Install tools and connect to Azure.

> **Note**
>
> The steps in this article are automated in the Azure Disk Encryption prerequisites CLI script and Azure Disk Encryption prerequisites PowerShell script.

Create a key vault

Azure Disk Encryption is integrated with Azure Key Vault to help you control and manage the disk-encryption keys and secrets in your key vault subscription. You can create a key vault or use an existing one for Azure Disk Encryption. For more information about key vaults, see Get started with Azure Key Vault and Secure your key vault. You can use a Resource Manager template, Azure PowerShell, or the Azure CLI to create a key vault.

> **Warning**
>
> In order to make sure the encryption secrets don't cross regional boundaries, Azure Disk Encryption needs the Key Vault and the VMs to be co-located in the same region. Create and use a Key Vault that is in the same region as the VM to be encrypted.

Create a key vault with PowerShell

You can create a key vault with Azure PowerShell using the New-AzKeyVault cmdlet. For another cmdlets for Key Vault, see Az.KeyVault.

1. Create a new resource group, if needed, with New-AzResourceGroup. To list data center locations, use Get-AzLocation.

   Azure PowerShell

   ```
   # Get-AzLocation
   New-AzResourceGroup –Name 'MyKeyVaultResourceGroup' –Location 'East US'
   ```

2. Create a new key vault using New-AzKeyVault

   Azure PowerShell

   ```
   New-AzKeyVault -VaultName 'MySecureVault' -ResourceGroupName
   'MyKeyVaultResourceGroup' -Location 'East US'
   ```

3. Note the **Vault Name**, **Resource Group Name**, **Resource ID**, **Vault URI**, and the **Object ID** that are returned for later use when you encrypt the disks.

Create a key vault with Azure CLI

You can manage your key vault with Azure CLI using the az keyvault commands. To create a key vault, use az keyvault create.

1. Create a new resource group, if needed, with az group create. To list locations, use az account list-locations

   Azure CLI

   ```
   # To list locations: az account list-locations --output table
   az group create -n "MyKeyVaultResourceGroup" -l "East US"
   ```

2. Create a new key vault using az keyvault create.

   Azure CLI

   ```
   az keyvault create --name "MySecureVault" --resource-group
   "MyKeyVaultResourceGroup" --location "East US"
   ```

3. Note the **Vault Name** (name), **Resource Group Name**, **Resource ID** (ID), **Vault URI**, and the **Object ID** that are returned for use later.

Create a key vault with a Resource Manager template

You can create a key vault by using the Resource Manager template.

1. On the Azure Quickstart Template, select **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then select **Purchase**.

Set up a Microsoft Entra app and service principal

When you need encryption to be enabled on a running VM in Azure, Azure Disk Encryption generates and writes the encryption keys to your key vault. Managing encryption keys in your key vault requires Microsoft Entra authentication. Create a Microsoft Entra application for this purpose. For authentication purposes, you can use either client secret-based authentication or client certificate-based Microsoft Entra authentication.

Set up a Microsoft Entra app and service principal with Azure PowerShell

To execute the following commands, get and use the Azure PowerShell module.

1. Use the New-AzADApplication PowerShell cmdlet to create a Microsoft Entra application. MyApplicationHomePage and the MyApplicationUri can be any values you wish.

   Azure PowerShell

   ```
   $aadClientSecret = "My AAD client secret"
   $aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -
   AsPlainText -Force
   $azureAdApplication = New-AzADApplication -DisplayName "My Application
   Display Name" -HomePage "https://MyApplicationHomePage" -IdentifierUris
   "https://MyApplicationUri" -Password $aadClientSecretSec
   $servicePrincipal = New-AzADServicePrincipal -ApplicationId
   $azureAdApplication.ApplicationId -Role Contributor
   ```

2. The $azureAdApplication.ApplicationId is the Microsoft Entra ClientID and the $aadClientSecret is the client secret that you'll use later to enable Azure Disk Encryption. Safeguard the Microsoft Entra client secret appropriately. Running `$azureAdApplication.ApplicationId` will show you the ApplicationID.

Set up a Microsoft Entra app and service principal with Azure CLI

You can manage your service principals with Azure CLI using the az ad sp commands. For more information, see Create an Azure service principal.

1. Create a new service principal.

   Azure CLI

   ```
   az ad sp create-for-rbac --name "ServicePrincipalName" --password "My-AAD-
   client-secret" --role Contributor --scopes /subscriptions/<subscription_id>
   ```

2. The appId returned is the Microsoft Entra ClientID used in other commands. It's also the SPN you'll use for az keyvault set-policy. The password is the client secret that you should use later to enable Azure Disk Encryption. Safeguard the Microsoft Entra client secret appropriately.

Set up a Microsoft Entra app and service principal through the Azure portal

Use the steps from the Use portal to create a Microsoft Entra application and service principal that can access resources article to create a Microsoft Entra application. Each of these steps will take you directly to the article section to complete.

1. Verify required permissions
2. Create a Microsoft Entra application

    - You can use any name and sign-on URL you would like when creating the application.

3. Get the application ID and the authentication key.

    - The authentication key is the client secret and is used as the AadClientSecret for Set-AzVMDiskEncryptionExtension.
        - The authentication key is used by the application as a credential to sign in to Microsoft Entra ID. In the Azure portal, this secret is called keys, but has no relation to key vaults. Secure this secret appropriately.
    - The application ID will be used later as the AadClientId for Set-AzVMDiskEncryptionExtension and as the ServicePrincipalName for Set-AzKeyVaultAccessPolicy.

Set the key vault access policy for the Microsoft Entra app

To write encryption secrets to a specified Key Vault, Azure Disk Encryption needs the Client ID and the Client Secret of the Microsoft Entra application that has permissions to write secrets to the Key Vault.

> **Note**
>
> Azure Disk Encryption requires you to configure the following access policies to your Microsoft Entra client application: *WrapKey* and *Set* permissions.

Set the key vault access policy for the Microsoft Entra app with Azure PowerShell

Your Microsoft Entra application needs rights to access the keys or secrets in the vault. Use the Set-AzKeyVaultAccessPolicy cmdlet to grant permissions to the application, using the client ID (which was generated when the application was registered) as the *–ServicePrincipalName* parameter value. To learn more, see the blog post Azure Key Vault - Step by Step.

1. Set the key vault access policy for the AD application with PowerShell.

Azure PowerShell

```
$keyVaultName = 'MySecureVault'
$aadClientID = 'MyAadAppClientID'
$KVRGname = 'MyKeyVaultResourceGroup'
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName $KVRGname
```

Set the key vault access policy for the Microsoft Entra app with Azure CLI

Use az keyvault set-policy to set the access policy. For more information, see Manage Key Vault using CLI 2.0.

Give the service principal you created via the Azure CLI access to get secrets and wrap keys with the following command:

Azure CLI

```
az keyvault set-policy --name "MySecureVault" --spn "<spn created with CLI/the
Azure AD ClientID>" --key-permissions wrapKey --secret-permissions set
```

Set the key vault access policy for the Microsoft Entra app with the portal

1. Open the resource group with your key vault.
2. Select your key vault, go to **Access Policies**, then select **Add new**.
3. Under **Select principal**, search for the Microsoft Entra application you created and select it.
4. For **Key permissions**, check **Wrap Key** under **Cryptographic Operations**.
5. For **Secret permissions**, check **Set** under **Secret Management Operations**.
6. Select **OK** to save the access policy.

Set key vault advanced access policies

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes. Enable disk encryption on the key vault or deployments will fail.

Set key vault advanced access policies with Azure PowerShell

Use the key vault PowerShell cmdlet Set-AzKeyVaultAccessPolicy to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

  Azure PowerShell

  ```
  Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName
  'MyKeyVaultResourceGroup' -EnabledForDiskEncryption
  ```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft. Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in

resource creation, for example when creating a virtual machine.

Azure PowerShell

```
 Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName
'MyKeyVaultResourceGroup' -EnabledForDeployment
```

- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

Azure PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName
'MyKeyVaultResourceGroup' -EnabledForTemplateDeployment
```

Set key vault advanced access policies using the Azure CLI

Use az keyvault update to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

Azure CLI

```
az keyvault update --name "MySecureVault" --resource-group
"MyKeyVaultResourceGroup" --enabled-for-disk-encryption "true"
```

- **Enable Key Vault for deployment, if needed:** Allow Virtual Machines to retrieve certificates stored as secrets from the vault.

Azure CLI

```
az keyvault update --name "MySecureVault" --resource-group
"MyKeyVaultResourceGroup" --enabled-for-deployment "true"
```

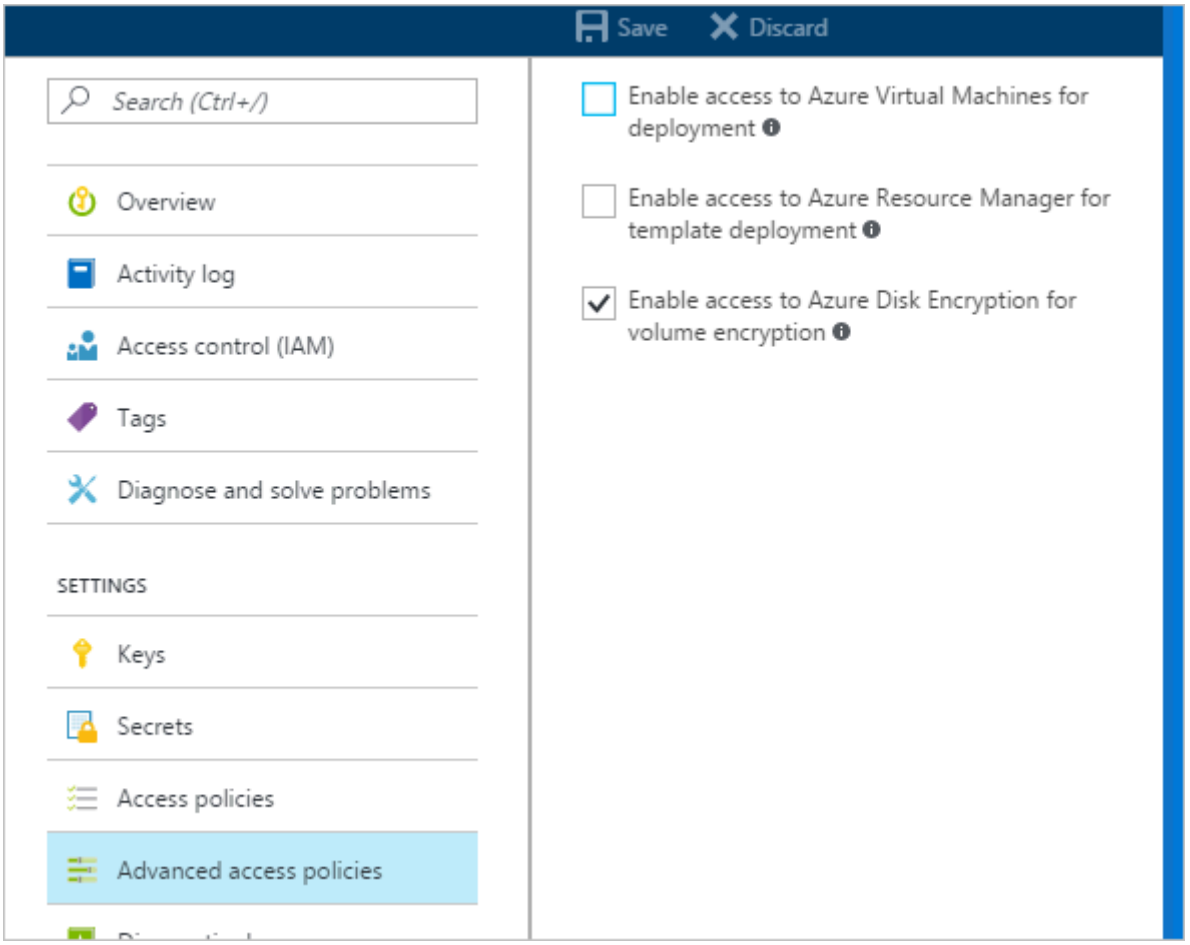
- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

Azure CLI

```
az keyvault update --name "MySecureVault" --resource-group
"MyKeyVaultResourceGroup" --enabled-for-template-deployment "true"
```

Set key vault advanced access policies through the Azure portal

1. Select your keyvault, go to **Access Policies**, and **Click to show advanced access policies**.
2. Select the box labeled **Enable access to Azure Disk Encryption for volume encryption**.
3. Select **Enable access to Azure Virtual Machines for deployment** and/or **Enable Access to Azure Resource Manager for template deployment**, if needed.
4. Select **Save**.



Set up a key encryption key (optional)

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. Use the Add-AzKeyVaultKey cmdlet to create a key encryption key in the key vault. You can also import a KEK from your on-premises key management HSM. For more information, see Key Vault Documentation. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

- When generating keys, use an RSA key type. Azure Disk Encryption doesn't yet support using Elliptic Curve keys.

- Your key vault secret and KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:
  - Example of a valid secret URL:
    `https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxx xxxxxxxxxxxxxxxxxxxx`
  - Example of a valid KEK URL:
    `https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxx xxxxxxxxxx`

- Azure Disk Encryption doesn't support specifying port numbers as part of key vault secrets and KEK URLs. For examples of non-supported and supported key vault URLs, see the following examples:
  - Unacceptable key vault URL
    `https://contosovault.vault.azure.net:443/secrets/contososecret/xxxxxxxxxxxxxxxxx xxxxxxxxxxxxx`
  - Acceptable key vault URL:
    `https://contosovault.vault.azure.net/secrets/contososecret/xxxxxxxxxxxxxxxxxxxx xxxxxxxxx`

Set up a key encryption key with Azure PowerShell

Before using the PowerShell script, you should be familiar with the Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment. This script creates all Azure Disk Encryption prerequisites and encrypts an existing IaaS VM, wrapping the disk encryption key by using a key encryption key.

PowerShell

```
# Step 1: Create a new resource group and key vault in the same location.
     # Fill in 'MyLocation', 'MyKeyVaultResourceGroup', and 'MySecureVault' with
your values.
     # Use Get-AzLocation to get available locations and use the DisplayName.
     # To use an existing resource group, comment out the line for New-
AzResourceGroup

    $Loc = 'MyLocation';
    $KVRGname = 'MyKeyVaultResourceGroup';
    $KeyVaultName = 'MySecureVault';
    New-AzResourceGroup –Name  $KVRGname –Location $Loc;
    New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname -Location
$Loc;
    $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
    $KeyVaultResourceId = (Get-AzKeyVault -VaultName $KeyVaultName -
ResourceGroupName  $KVRGname).ResourceId;
```

```
    $diskEncryptionKeyVaultUrl = (Get-AzKeyVault -VaultName $KeyVaultName -
ResourceGroupName  $KVRGname).VaultUri;

# Step 2: Create the AD application and service principal.
     # Fill in 'MyAADClientSecret', "<My Application Display Name>", "
<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your
values.
     # MyApplicationHomePage and the MyApplicationUri can be any values you wish.

     $aadClientSecret =  'MyAADClientSecret';
    $aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -
AsPlainText -Force;
    $azureAdApplication = New-AzADApplication -DisplayName "<My Application
Display Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "
<https://MyApplicationUri>" -Password $aadClientSecretSec
    $servicePrincipal = New-AzADServicePrincipal –ApplicationId
$azureAdApplication.ApplicationId -Role Contributor;
    $aadClientID = $azureAdApplication.ApplicationId;

#Step 3: Enable the vault for disk encryption and set the access policy for the
Microsoft Entra application.

     Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$KVRGname -EnabledForDiskEncryption;
    Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName  $KVRGname;

#Step 4: Create a new key in the key vault with the Add-AzKeyVaultKey cmdlet.
     # Fill in 'MyKeyEncryptionKey' with your value.

     $keyEncryptionKeyName = 'MyKeyEncryptionKey';
    Add-AzKeyVaultKey -VaultName $KeyVaultName -Name $keyEncryptionKeyName -
Destination 'Software';
    $keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;

#Step 5: Encrypt the disks of an existing IaaS VM
     # Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

     $VMName = 'MySecureVM';
     $VMRGName = 'MyVirtualMachineResourceGroup';
    Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $KeyVaultResourceId;
```

Certificate-based authentication (optional)

If you would like to use certificate authentication, you can upload one to your key vault and deploy it to the client. Before using the PowerShell script, you should be familiar with the Azure

Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

PowerShell

```
# Fill in "MyKeyVaultResourceGroup", "MySecureVault", and 'MyLocation' ('My
location' only if needed)

  $KVRGname = 'MyKeyVaultResourceGroup'
  $KeyVaultName= 'MySecureVault'

  # Create a key vault and set enabledForDiskEncryption property on it.
  # Comment out the next three lines if you already have an existing key vault
enabled for encryption. No need to set 'My location' in this case.

  $Loc = 'MyLocation'
  New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname -Location
$Loc
  Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $KVRGname
-EnabledForDiskEncryption

  #Setting some variables with the key vault information
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname
  $DiskEncryptionKeyVaultUrl = $KeyVault.VaultUri
  $KeyVaultResourceId = $KeyVault.ResourceId

  # Create the Microsoft Entra application and associate the certificate with it.
  # Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display
Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with
your values.
  # MyApplicationHomePage and the MyApplicationUri can be any values you wish

  $CertPath = "C:\certificates\mycert.pfx"
  $CertPassword = "Password"
  $Cert = New-Object
System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
  $CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

  $AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display
Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "
<https://MyApplicationUri>" -CertValue $CertValue
  $ServicePrincipal = New-AzADServicePrincipal -ApplicationId
$AzureAdApplication.ApplicationId -Role Contributor

  $AADClientID = $AzureAdApplication.ApplicationId
  $aadClientCertThumbprint= $cert.Thumbprint

  Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName $KVRGname

  # Upload the pfx file to the key vault.
```

```
  # Fill in "MyAADCert".

  $KeyVaultSecretName = "MyAADCert"
  $FileContentBytes = get-content $CertPath -Encoding Byte
  $FileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
          $JSONObject = @"
          {
              "data" : "$filecontentencoded",
              "dataType" : "pfx",
              "password" : "$CertPassword"
          }
"@

  $JSONObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
  $JSONEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

  #Set the secret and set the key vault policy for -EnabledForDeployment

  $Secret = ConvertTo-SecureString -String $JSONEncoded -AsPlainText -Force
  Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $KeyVaultSecretName -
SecretValue $Secret
  Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $KVRGname
-EnabledForDeployment

  # Deploy the certificate to the VM
  # Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

  $VMName = 'MySecureVM'
  $VMRGName = 'MyVirtualMachineResourceGroup'
  $CertUrl = (Get-AzKeyVaultSecret -VaultName $KeyVaultName -Name
$KeyVaultSecretName).Id
  $SourceVaultId = (Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGName).ResourceId
  $VM = Get-AzVM -ResourceGroupName $VMRGName -Name $VMName
  $VM = Add-AzVMSecret -VM $VM -SourceVaultId $SourceVaultId -CertificateStore
"My" -CertificateUrl $CertUrl
  Update-AzVM -VM $VM -ResourceGroupName $VMRGName

  #Enable encryption on the VM using Microsoft Entra client ID and the client
certificate thumbprint

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -
AadClientID $AADClientID -AadClientCertThumbprint $AADClientCertThumbprint -
DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId
```

Certificate-based authentication and a KEK (optional)

If you would like to use certificate authentication and wrap the encryption key with a KEK, you can use the below script as an example. Before using the PowerShell script, you should be

familiar with all of the previous Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

PowerShell

```
# Fill in 'MyKeyVaultResourceGroup', 'MySecureVault', and 'MyLocation' (if needed)

   $KVRGname = 'MyKeyVaultResourceGroup'
   $KeyVaultName= 'MySecureVault'

   # Create a key vault and set enabledForDiskEncryption property on it.
   # Comment out the next three lines if you already have an existing key vault
enabled for encryption.

   $Loc = 'MyLocation'
   New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname -Location
$Loc
   Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$KVRGname -EnabledForDiskEncryption

   # Create the Azure AD application and associate the certificate with it.
   # Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display
Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with
your values.
   # MyApplicationHomePage and the MyApplicationUri can be any values you wish

   $CertPath = "C:\certificates\mycert.pfx"
   $CertPassword = "Password"
   $Cert = New-Object
System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
   $CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

   $AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display
Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "
<https://MyApplicationUri>" -CertValue $CertValue
   $ServicePrincipal = New-AzADServicePrincipal -ApplicationId
$AzureAdApplication.ApplicationId -Role Contributor

   $AADClientID = $AzureAdApplication.ApplicationId
   $aadClientCertThumbprint= $cert.Thumbprint

   ## Give access for setting secrets and wraping keys
   Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName
$aadClientID -PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -
ResourceGroupName $KVRGname

   # Upload the pfx file to the key vault.
   # Fill in "MyAADCert".

   $KeyVaultSecretName = "MyAADCert"
   $FileContentBytes = get-content $CertPath -Encoding Byte
   $FileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
           $JSONObject = @"
```

```
            {
                "data" : "$filecontentencoded",
                "dataType" : "pfx",
                "password" : "$CertPassword"
            }
"@

   $JSONObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
   $JSONEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

   #Set the secret and set the key vault policy for deployment

   $Secret = ConvertTo-SecureString -String $JSONEncoded -AsPlainText -Force
   Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $KeyVaultSecretName -
SecretValue $Secret
   Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName
$KVRGname -EnabledForDeployment

Next steps

Enable Azure Disk Encryption with Microsoft Entra ID on Windows VMs (previous release)

Azure Disk Encryption with Microsoft Entra ID for Windows VMs (previous release)

09/23/2025

> **Important**
>
> Azure Disk Encryption for Virtual Machines and Virtual Machine Scale Sets will be retired on **September 15, 2028**. New customers should use encryption at host for all new VMs. Existing customers should plan to migrate current ADE-enabled VMs to encryption at host before the retirement date to avoid service disruption -- see Migrate from Azure Disk Encryption to encryption at host.

Applies to: ✔ Windows VMs

The new release of Azure Disk Encryption eliminates the requirement for providing a Microsoft Entra application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Microsoft Entra credentials during the enable encryption step. All new VMs must be encrypted without the Microsoft Entra application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see Azure Disk Encryption for Windows VMS. VMs that were already encrypted with Microsoft Entra application parameters are still supported and should continue to be maintained with the Microsoft Entra syntax. You can enable many disk-encryption scenarios, and the steps may vary according to the scenario. The following sections cover the scenarios in greater detail for Windows IaaS VMs. Before you can use disk encryption, the Azure Disk Encryption prerequisites need to be completed.

> **Important**
>
> - You should take a snapshot and/or create a backup before disks are encrypted. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. Once a backup is made, you can use the Set-AzVMDiskEncryptionExtension cmdlet to encrypt managed disks by specifying the -skipVmBackup parameter. For more information about how to back up and restore encrypted VMs, see Back up and restore encrypted Azure VM.
>
> - Encrypting or disabling encryption may cause a VM to reboot.

Enable encryption on new IaaS VMs created from the Marketplace

You can enable disk encryption on new IaaS Windows VM from the Marketplace in Azure using a Resource Manager template. The template creates a new encrypted Windows VM using the Windows Server 2012 gallery image.

1. On the Resource Manager template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, parameters, legal terms, and agreement. Click **Purchase** to deploy a new IaaS VM where encryption is enabled.
3. After you deploy the template, verify the VM encryption status using your preferred method:

   - Verify with the Azure CLI by using the az vm encryption show command.

     Azure CLI

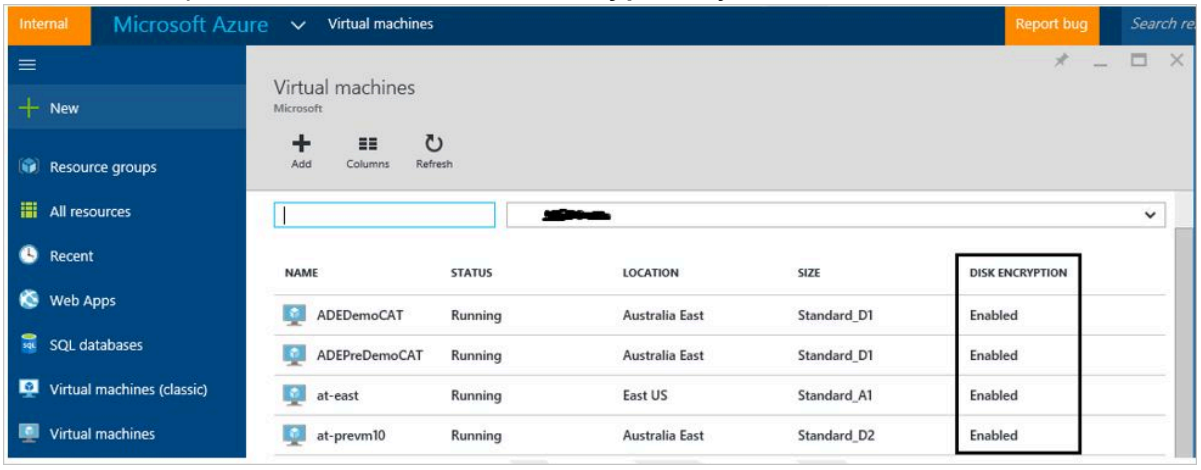
     ```
     az vm encryption show --name "MySecureVM" --resource-group
     "MyVirtualMachineResourceGroup"
     ```

   - Verify with Azure PowerShell by using the Get-AzVmDiskEncryptionStatus cmdlet.

     Azure PowerShell

     ```
     Get-AzVmDiskEncryptionStatus -ResourceGroupName
     'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
     ```

   - Select the VM, then click on **Disks** under the **Settings** heading to verify encryption status in the portal. In the chart under **Encryption**, you'll see if it's enabled.



The following table lists the Resource Manager template parameters for new VMs from the Marketplace scenario using Microsoft Entra client ID:

Expand table

Parameter	Description
adminUserName	Admin user name for the virtual machine.
adminPassword	Admin user password for the virtual machine.
newStorageAccountName	Name of the storage account to store OS and data VHDs.
vmSize	Size of the VM. Currently, only Standard A, D, and G series are supported.
virtualNetworkName	Name of the VNet that the VM NIC should belong to.
subnetName	Name of the subnet in the VNet that the VM NIC should belong to.
AADClientID	Client ID of the Microsoft Entra application that has permissions to write secrets to your key vault.
AADClientSecret	Client secret of the Microsoft Entra application that has permissions to write secrets to your key vault.
keyVaultURL	URL of the key vault that the BitLocker key should be uploaded to. You can get it by using the cmdlet `(Get-AzKeyVault -VaultName "MyKeyVault" -ResourceGroupName "MyKeyVaultResourceGroupName").VaultURI` or the Azure CLI `az keyvault show --name "MySecureVault" --query properties.vaultUri`
keyEncryptionKeyURL	URL of the key encryption key that's used to encrypt the generated BitLocker key (optional). KeyEncryptionKeyURL is an optional parameter. You can bring your own KEK to further safeguard the data encryption key (Passphrase secret) in your key vault.
keyVaultResourceGroup	Resource group of the key vault.
vmName	Name of the VM that the encryption operation is to be performed on.

Enable encryption on existing or running IaaS Windows VMs

In this scenario, you can enable encryption by using a template, PowerShell cmdlets, or CLI commands. The following sections explain in greater detail how to enable Azure Disk Encryption.

Enable encryption on existing or running VMs with Azure PowerShell

Use the Set-AzVMDiskEncryptionExtension cmdlet to enable encryption on a running IaaS virtual machine in Azure. For information about enabling encryption with Azure Disk Encryption by using PowerShell cmdlets, see the blog posts Explore Azure Disk Encryption with Azure PowerShell - Part 1 and Explore Azure Disk Encryption with Azure PowerShell - Part 2.

- **Encrypt a running VM using a client secret:** The script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, key vault, Microsoft Entra app, and client secret should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values.

  Azure PowerShell

  ```
  $KVRGname = 'MyKeyVaultResourceGroup';
  $VMRGName = 'MyVirtualMachineResourceGroup';
  $vmName = 'MySecureVM';
  $aadClientID = 'My-AAD-client-ID';
  $aadClientSecret = 'My-AAD-client-secret';
  $KeyVaultName = 'MySecureVault';
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
  $KVRGname;
  $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
  $KeyVaultResourceId = $KeyVault.ResourceId;

  Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName
  -AadClientID $aadClientID -AadClientSecret $aadClientSecret -
  DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
  DiskEncryptionKeyVaultId $KeyVaultResourceId;
  ```

- **Encrypt a running VM using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

  Azure PowerShell

  ```
  $KVRGname = 'MyKeyVaultResourceGroup';
  $VMRGName = 'MyVirtualMachineResourceGroup';
  $vmName = 'MyExtraSecureVM';
  $aadClientID = 'My-AAD-client-ID';
  $aadClientSecret = 'My-AAD-client-secret';
  $KeyVaultName = 'MySecureVault';
  $keyEncryptionKeyName = 'MyKeyEncryptionKey';
  $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
  $KVRGname;
  $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
  $KeyVaultResourceId = $KeyVault.ResourceId;
  $keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
  $keyEncryptionKeyName).Key.kid;
  ```

```
Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName
-AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -KeyEncryptionKeyUrl
$keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $KeyVaultResourceId;
```

> **Note**
>
> The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the Get-AzVmDiskEncryptionStatus cmdlet.

Azure PowerShell

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName
'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

- **Disable disk encryption:** To disable the encryption, use the Disable-AzureRmVMDisk Encryption cmdlet.

Azure PowerShell

```
Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup'
-VMName 'MySecureVM'
```

Enable encryption on existing or running VMs with Azure CLI

Use the az vm encryption enable command to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM using a client secret:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --
name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD
```

```
ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-encryption-
keyvault "MySecureVault" --volume-type [All|OS|Data]
```

- **Encrypt a running VM using KEK to wrap the client secret:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --
name "MySecureVM" --aad-client-id "<my spn created with CLI which is the
Azure AD ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-
encryption-keyvault  "MySecureVault" --key-encryption-key "MyKEK_URI" --key-
encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type
[All|OS|Data]
```

> **Note**
>
> The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the az vm encryption show command.

Azure CLI

```
az vm encryption show --name "MySecureVM" --resource-group
"MyVirtualMachineResourceGroup"
```

- **Disable encryption:** To disable encryption, use the az vm encryption disable command.

Azure CLI

```
az vm encryption disable --name "MySecureVM" --resource-group
"MyVirtualMachineResourceGroup" --volume-type [ALL, DATA, OS]
```

Using the Resource Manager template

You can enable disk encryption on existing or running IaaS Windows VMs in Azure by using the Resource Manager template to encrypt a running Windows VM.

1. On the Azure quickstart template, click **Deploy to Azure**.

2. Select the subscription, resource group, resource group location, parameters, legal terms, and agreement. Click **Purchase** to enable encryption on the existing or running IaaS VM.

The following table lists the Resource Manager template parameters for existing or running VMs that use a Microsoft Entra client ID:

Expand table

Parameter	Description
AADClientID	Client ID of the Microsoft Entra application that has permissions to write secrets to the key vault.
AADClientSecret	Client secret of the Microsoft Entra application that has permissions to write secrets to the key vault.
keyVaultName	Name of the key vault that the BitLocker key should be uploaded to. You can get it by using the cmdlet `(Get-AzKeyVault -ResourceGroupName <MyKeyVaultResourceGroupName>). Vaultname` or the Azure CLI command `az keyvault list --resource-group "MySecureGroup"`
keyEncryptionKeyURL	URL of the key encryption key that's used to encrypt the generated BitLocker key. This parameter is optional if you select **nokek** in the UseExistingKek drop-down list. If you select **kek** in the UseExistingKek drop-down list, you must enter the *keyEncryptionKeyURL* value.
volumeType	Type of volume that the encryption operation is performed on. Valid values are *OS*, *Data*, and *All*.
sequenceVersion	Sequence version of the BitLocker operation. Increment this version number every time a disk-encryption operation is performed on the same VM.
vmName	Name of the VM that the encryption operation is to be performed on.

New IaaS VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can enable encrypting by using the Resource Manager template, PowerShell cmdlets, or CLI commands. The following sections explain in greater detail the Resource Manager template and CLI commands.

Use the instructions in the appendix for preparing pre-encrypted images that can be used in Azure. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

- Prepare a pre-encrypted Windows VHD

Encrypt VMs with pre-encrypted VHDs with Azure PowerShell

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet Set-AzVMOSDisk. The example below gives you some common parameters.

PowerShell

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri
"os.vhd" Caching ReadWrite -Windows -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaa
a" -DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myKVresourcegroup/providers/Microsoft.KeyVault/vaults/
mytestvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

Enable encryption on a newly added data disk

You can add a new disk to a Windows VM using PowerShell, or through the Azure portal.

Enable encryption on a newly added disk with Azure PowerShell

When using PowerShell to encrypt a new disk for Windows VMs, a new sequence version should be specified. The sequence version has to be unique. The script below generates a GUID for the sequence version. In some cases, a newly added data disk might be encrypted automatically by the Azure Disk Encryption extension. Auto encryption usually occurs when the VM reboots after the new disk comes online. This is typically caused because "All" was specified for the volume type when disk encryption previously ran on the VM. If auto encryption occurs on a newly added data disk, we recommend running the Set-AzVmDiskEncryptionExtension cmdlet again with new sequence version. If your new data disk is auto encrypted and you do not wish to be encrypted, decrypt all drives first then re-encrypt with a new sequence version specifying OS for the volume type.

- **Encrypt a running VM using a client secret:** The script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, key vault, Microsoft Entra app, and client secret should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values. This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

Azure PowerShell

```
 $sequenceVersion = [Guid]::NewGuid();
 $KVRGname = 'MyKeyVaultResourceGroup';
 $VMRGName = 'MyVirtualMachineResourceGroup';
 $vmName = 'MySecureVM';
 $aadClientID = 'My-AAD-client-ID';
 $aadClientSecret = 'My-AAD-client-secret';
 $KeyVaultName = 'MySecureVault';
 $KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
 $diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
 $KeyVaultResourceId = $KeyVault.ResourceId;

 Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName
-AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -VolumeType 'all' –
SequenceVersion $sequenceVersion;
```

- **Encrypt a running VM using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault. This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

Azure PowerShell

```
$sequenceVersion = [Guid]::NewGuid();
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$KeyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName
$KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$KeyVaultResourceId = $KeyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName
-AadClientID $aadClientID -AadClientSecret $aadClientSecret -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId -KeyEncryptionKeyUrl
$keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $KeyVaultResourceId -VolumeType
```

```
'all' -SequenceVersion $sequenceVersion;
```

> **Note**
>
> The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
> The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

Enable encryption on a newly added disk with Azure CLI

The Azure CLI command will automatically provide a new sequence version for you when you run the command to enable encryption. Acceptable values for the volume-yype parameter are All, OS, and Data. You may need to change the volume-type parameter to OS or Data if you're only encrypting one type of disk for the VM. The examples use "All" for the volume-type parameter.

- **Encrypt a running VM using a client secret:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --volume-type "All"
```

- **Encrypt a running VM using KEK to wrap the client secret:**

Azure CLI

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI which is the Azure AD ClientID>"  --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault  "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type "all"
```

Enable encryption using Microsoft Entra client certificate-based authentication.

You can use client certificate authentication with or without KEK. Before using the PowerShell scripts, you should already have the certificate uploaded to the key vault and deployed to the VM. If you're using KEK too, the KEK should already exist. For more information, see the Certificate-based authentication for Microsoft Entra ID section of the prerequisites article.

Enable encryption using certificate-based authentication with Azure PowerShell

PowerShell

```
## Fill in 'MyVirtualMachineResourceGroup', 'MyKeyVaultResourceGroup', 'My-AAD-client-ID', 'MySecureVault, and 'MySecureVM'.

$VMRGName = 'MyVirtualMachineResourceGroup'
$KVRGname = 'MyKeyVaultResourceGroup';
$AADClientID ='My-AAD-client-ID';
$KeyVaultName = 'MySecureVault';
$VMName = 'MySecureVM';
$KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$KeyVaultResourceId = $KeyVault.ResourceId;

# Fill in the certificate path and the password so the thumbprint can be set as a variable.

$certPath = '$CertPath = "C:\certificates\mycert.pfx';
$CertPassword ='Password'
$Cert = New-Object
System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
$aadClientCertThumbprint = $cert.Thumbprint;

# Enable disk encryption using the client certificate thumbprint

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -
AadClientID $AADClientID -AadClientCertThumbprint $AADClientCertThumbprint -
DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId
```

Enable encryption using certificate-based authentication and a KEK with Azure PowerShell

PowerShell

```
# Fill in 'MyVirtualMachineResourceGroup', 'MyKeyVaultResourceGroup', 'My-AAD-client-ID', 'MySecureVault,, 'MySecureVM', and "KEKName.

$VMRGName = 'MyVirtualMachineResourceGroup';
```

```
$KVRGname = 'MyKeyVaultResourceGroup';
$AADClientID ='My-AAD-client-ID';
$KeyVaultName = 'MySecureVault';
$VMName = 'MySecureVM';
$keyEncryptionKeyName ='KEKName';
$KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$KeyVaultResourceId = $KeyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $KeyVaultName -Name
$keyEncryptionKeyName).Key.kid;

## Fill in the certificate path and the password so the thumbprint can be read and
set as a variable.

$certPath = '$CertPath = "C:\certificates\mycert.pfx';
$CertPassword ='Password'
$Cert = New-Object
System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
$aadClientCertThumbprint = $cert.Thumbprint;

# Enable disk encryption using the client certificate thumbprint and a KEK

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -
AadClientID $AADClientID -AadClientCertThumbprint $AADClientCertThumbprint -
DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId
$KeyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $KeyVaultResourceId
```

Disable encryption

You can disable encryption using Azure PowerShell, the Azure CLI, or with a Resource Manager template.

- **Disable disk encryption with Azure PowerShell:** To disable the encryption, use the Disable-AzureRmVMDiskEncryption cmdlet.

  Azure PowerShell

  ```
  Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup'
  -VMName 'MySecureVM'
  ```

- **Disable encryption with the Azure CLI:** To disable encryption, use the az vm encryption disable command.

  Azure CLI

  ```
  az vm encryption disable --name "MySecureVM" --resource-group
  ```

```
"MyVirtualMachineResourceGroup" --volume-type [ALL, DATA, OS]
```

- **Disable encryption with a Resource Manager Template:**

    1. Click **Deploy to Azure** from the Disable disk encryption on running Windows VM template.
    2. Select the subscription, resource group, location, VM, legal terms, and agreement.
    3. Click **Purchase** to disable disk encryption on a running Windows VM.

Azure Disk Encryption overview

Overview of options to improve Azure managed disk performance

Article • 04/14/2025

This article outlines the capabilities each disk type offers to adjust its performance. Use the headings to navigate to the disk types you're interested in to get a quick overview of the capabilities available to it.

The demands and needs of your workload can shift over time, either due to high demand during a holiday, sudden bursts of traffic, or scaling up to meet client needs. Azure managed disks have several capabilities you can take advantage of to improve their performance and match the shifting needs of your workloads. Different disk types offer different capabilities, some disk types have capabilities you can use to ensure their performance automatically shifts to meet the changing demands of your workload, others require manual adjustment, and other disk types can't do either.

Ultra Disks and Premium SSD v2

Ultra Disks and Premium solid-state drives (SSD) v2 are designed to be highly performant and easily adjustable. They offer the most flexibility and ease among all the disk types when fine tuning your disk's performance, letting you programmatically (or directly) set the performance of these disk types. Within every 24 hours, you can adjust the performance of these disks up to four times. If you just created one of these disks, for the first 24 hours you can only adjust its performance up to three times. To learn how to adjust the performance of Ultra Disks and Premium SSD v2, see Adjust disk performance for Premium SSD v2 or Adjust the performance of an Ultra Disk.

Premium SSD

Premium SSD supports several performance options, each geared towards different use cases. The following table outlines the main differences and ideal uses.

Expand table

	Credit-based bursting	On-demand bursting	Changing performance tier	Caching	Write accelerator	Performance plus
Scenarios	Ideal for short-term	Ideal for short-term uses like	Ideal if your workload would	Ideal for workloads that can be	Ideal for scenarios where log	Ideal for workloads that require

	Credit-based bursting	On-demand bursting	Changing performance tier	Caching	Write accelerator	Performance plus
	scaling (30 minutes or less).	determining your workloads performance needs.	otherwise continually be running in burst.	configured to rely on data from the cache.	files are required to persist to a disk in a performant manner for modern databases.	higher sustained performance.
Cost	Free	Cost is variable, see the Billing section of the bursting article for details.	The cost of each performance tier is fixed, see Managed Disks pricing for details.	Free.	Free.	Free.
Availability	Only available for Premium SSD managed disks 512 GiB and smaller, and Standard SSDs 1,024 GiB and smaller.	Only available for Premium SSD managed disks larger than 512 GiB.	Available to all Premium SSD sizes.	Available to all Premium SSD managed disk, Standard SSD, and Standard HDD sizes.	Only available to M-series Azure Virtual Machines, but can be configured with all Premium SSD sizes attached to M-series virtual machines.	Available for Standard HDD, Standard SSD, and Premium SSD managed disks 513 GiB and larger.
Enablement	Enabled by default on eligible disks.	User must enable manually.	User must manually change their tier.	User must manually configure both their cache settings and their workloads and applications.	User must manually configure and enable.	Must enable performance plus when you create the disk, can't be enabled on existing disks.

Credit-based disk bursting

With credit-based bursting, a disk bursts only if it has burst credits accumulated in its credit bucket. This model doesn't incur extra charges when the disk bursts. For Premium SSD managed disks, credit-based bursting is available for disk sizes P20 and smaller. By default, disk bursting is enabled on all new and existing deployments of supported disk sizes. For more information, see the credit-based bursting section of the disk bursting models article.

On-demand disk bursting

With on-demand disk bursting enabled, the disk bursts whenever its needs exceed its current capacity. This model incurs extra charges anytime the disk bursts. On-demand bursting is only available for Premium SSDs larger than 512 GiB. To learn more, see the on-demand bursting section of the disk bursting models article.

Change performance tiers

The performance of a Premium SSD is set when you create your disk, in the form of their performance tier. When you set the provisioned size of your disk, a performance tier is automatically selected. The performance tier determines the IOPS and throughput your managed disk has. For Premium SSD disks only, the performance tier can be changed at deployment or afterwards, without changing the size of the disk, and without downtime. To learn more, see Performance tiers for managed disks.

Caching

High-scale Azure Virtual Machines that can use premium storage have a multitier caching technology called **BlobCache**. **BlobCache** is a caching solution built on RAM and SSDs that are locally attached to the server hosting the virtual machine (VM). This cache is available for Standard HDD, Standard SSD, and Premium SSD managed disks. With disk caching enabled, high-scale VMs can achieve levels of performance that exceed the underlying disk performance. To learn more, see Disk caching.

Write accelerator

Write accelerator is a disk capability for M-Series VMs on Premium SSD managed disks. Write accelerator improves the I/O latency of writes against Premium SSD disks. Write accelerator is optimized for volumes that contain the transaction log or redo logs of a DBMS, and shouldn't be used for data volumes. To learn more, see the write accelerator article.

Performance plus

Enabling performance plus increases the Input/Output Operations Per Second (IOPS) and throughput limits for Azure Premium SSDs that are 513 GiB and larger. Enabling performance plus improves the experience for workloads that require high IOPS and throughput, such as database and transactional workloads. There's no extra charge for enabling performance plus on a disk. To learn more about performance plus, see Increase IOPS and throughput limits for Azure Premium SSDs and Standard SSD/HDDs.

Standard SSD

Credit-based bursting

With credit-based bursting, a disk bursts only if it has burst credits accumulated in its credit bucket. This model doesn't incur extra charges when the disk bursts. For Standard SSDs, credit-based bursting is available for disk sizes E30 and smaller. By default, disk bursting is enabled on all new and existing deployments of supported disk sizes. For more information, see the credit-based bursting section of the disk bursting models article.

Caching

High-scale Azure Virtual Machines that can use premium storage have a multitier caching technology called **BlobCache**. **BlobCache** is a caching solution built on RAM and SSDs that are locally attached to the server hosting the virtual machine (VM). This cache is available for Standard HDD, Standard SSD, and Premium SSD managed disks. With disk caching enabled, high-scale VMs can achieve levels of performance that exceed the underlying disk performance. To learn more, see Disk caching.

Performance plus

Enabling performance plus increases the Input/Output Operations Per Second (IOPS) and throughput limits for Azure Standard SSDs that are 513 GiB and larger. Enabling performance plus improves the experience for workloads that require high IOPS and throughput, such as database and transactional workloads. There's no extra charge for enabling performance plus on a disk. To learn more about performance plus, see Increase IOPS and throughput limits for Azure Premium SSDs and Standard SSD/HDDs.

Standard HDD

Caching

High-scale Azure Virtual Machines that can use premium storage have a multitier caching technology called **BlobCache**. **BlobCache** is a caching solution built on RAM and SSDs that are locally attached to the server hosting the virtual machine (VM). This cache is available for Standard HDD, Standard SSD, and Premium SSD managed disks. With disk caching enabled, high-scale VMs can achieve levels of performance that exceed the underlying disk performance. To learn more, see Disk caching.

Performance plus

Enabling performance plus increases the Input/Output Operations Per Second (IOPS) and throughput limits for Azure Standard hard disk drives (HDD) that are 513 GiB and larger. Enabling performance plus improves the experience for workloads that require high IOPS and throughput, such as database and transactional workloads. There's no extra charge for enabling performance plus on a disk. To learn more about performance plus, see Increase IOPS and throughput limits for Azure Premium SSDs and Standard SSD/HDDs.

Increase IOPS and throughput limits for Azure Premium SSDs and Standard SSD/HDDs

Article • 04/14/2025

The Input/Output Operations Per Second (IOPS) and throughput limits for Azure Premium solid-state drives (SSD), Standard SSDs, and Standard hard disk drives (HDD) that are 513 GiB and larger can be increased by enabling performance plus. Enabling performance plus improves the experience for workloads that require high IOPS and throughput, such as database and transactional workloads. There's no extra charge for enabling performance plus on a disk.

Once enabled, the IOPS and throughput limits for an eligible disk increase to the higher maximum limits. To see the new IOPS and throughput limits for eligible disks, consult the columns that begin with "*Expanded" in the Scalability and performance targets for VM disks article.

Limitations

- Can only be enabled on Standard HDD, Standard SSD, and Premium SSD managed disks that are 513 GiB or larger
- Can only be enabled on new disks
  - To work around this, create a snapshot of your disk, then create a new disk from the snapshot
- Not supported for disks recovered with Azure Site Recovery

Prerequisites

Either use the Azure Cloud Shell to run your commands or install a version of the Azure PowerShell module 9.5 or newer, or a version of the Azure CLI that is 2.44.0 or newer.

Enable performance plus

You need to create a new disk to use performance plus. The following scripts show how to create a disk with performance plus enabled and, if desired, attach it to a VM. The commands have been organized into self-contained steps for reliability.

Azure CLI

Create a resource group

This step creates a resource group with a unique name.

Azure CLI

```
export RANDOM_SUFFIX=$(openssl rand -hex 3)
export MY_RG="PerfPlusRG$RANDOM_SUFFIX"
export REGION="WestUS2"
az group create -g $MY_RG -l $REGION
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxx/resourceGroups/PerfPlusRGxxx",
  "location": "WestUS2",
  "name": "PerfPlusRGxxx",
  "properties": {
    "provisioningState": "Succeeded"
  }
}
```

Create a new disk with performance plus enabled

This step creates a new disk of 513 GiB (or larger) with performance plus enabled using a valid SKU value.

Azure CLI

```
export MY_DISK="PerfPlusDisk$RANDOM_SUFFIX"
export SKU="Premium_LRS"
export DISK_SIZE=513
az disk create -g $MY_RG -n $MY_DISK --size-gb $DISK_SIZE --sku $SKU -l
$REGION --performance-plus true
```

Results:

JSON

```
{
  "id":
"/subscriptions/xxxxx/resourceGroups/PerfPlusRGxxx/providers/Microsoft.Compute
/disks/PerfPlusDiskxxx",
```

```
  "location": "WestUS2",
  "name": "PerfPlusDiskxxx",
  "properties": {
    "provisioningState": "Succeeded",
    "diskSizeGb": 513,
    "sku": "Premium_LRS",
    "performancePlus": true
  },
  "type": "Microsoft.Compute/disks"
}
```

Attempt to attach the disk to a VM

This optional step attempts to attach the disk to an existing VM. It first checks if the VM exists and then proceeds accordingly.

Azure CLI

```
export MY_VM="NonExistentVM"
if az vm show -g $MY_RG -n $MY_VM --query "name" --output tsv >/dev/null 2>&1;
then
    az vm disk attach --vm-name $MY_VM --name $MY_DISK --resource-group $MY_RG
else
    echo "VM $MY_VM not found. Skipping disk attachment."
fi
```

Results:

text

```
VM NonExistentVM not found. Skipping disk attachment.
```

Create a new disk from an existing disk or snapshot with performance plus enabled

This series of steps creates a separate resource group and then creates a new disk from an existing disk or snapshot. Replace the SOURCE_URI with a valid source blob URI that belongs to the same region (WestUS2) as the disk.

Create a resource group for migration

Azure CLI

```
export RANDOM_SUFFIX=$(openssl rand -hex 3)
export MY_MIG_RG="PerfPlusMigrRG$RANDOM_SUFFIX"
```

```
export REGION="WestUS2"
az group create -g $MY_MIG_RG -l $REGION
```

Results:

JSON

```
{

Prevent torn writes with Azure managed disks

Azure managed disks have native protection against torn writes for 8-KiB and 16-KiB blocks of data to ensure data integrity, which you can use to reduce your performance overhead.

A torn write (or a partial write) can occur when a power loss or system crash interrupts a disk write, leaving a data block only partially updated. A partially updated data block results in an inconsistent page containing a mix of old and new data, essentially a torn page. Torn writes compromise data integrity, and data integrity is critical for applications like databases. Databases must detect and resolve torn writes to avoid corrupt records or indexes

Applications can use managed disk's native torn write prevention through atomic write operations for 8-KiB and 16-KiB blocks of data if the issued write aligns with the respective block offset. For example, a 16 KiB I/O issued to the disk at an offset that is a multiple of 16-KiB guarantees atomicity. With atomic writes, managed disks persist the entire block or nothing, so there's never a partial update. Using atomic writes with managed disk's protection against torn writes allows applications to improve transaction throughput and reduce write latency without traditional software overhead for preventing torn writes.

Traditional torn write protection

PostgreSQL uses full page writes, so the entire page is logged to the write ahead log before updating data files. MySQL (InnoDB) uses a doublewrite buffer, writing each page twice (first to a protected area, then to main storage) to ensure at least one intact copy. Both of these methods are effective but, introduce performance overhead due to extra I/Os. With managed disk's torn write prevention, there's no extra performance overhead.

Limitations

- Your filesystem and your operating system must guarantee large atomic write support
  - Only supported for Linux VMs using version 6.13 or newer of the Linux kernel
    - As of 6.13, the Linux kernel introduced support for large atomic writes with direct IO for XFS and Ext4
- Atomic write operations are only available when using managed disks with NVMe controllers

Prerequisites

- Deploy a Linux VM with Linux kernel 6.13 or newer with a managed disk that's using an NVMe controller
- Install the **nvme-cli** package on your VM
  - If your distribution uses the Advanced Package Tool (APT), use `sudo apt install nvme-cli`
- 8-KiB and 16-KiB issued writes must align with their respective block offsets to ensure torn writes are prevented

Confirm your VM supports atomic writes

Access your VM and run `lsblk`, your disk should show up under the NVMe namespace (like nvme0n2).

Check the namespace parameters of the NVMe from the `lsblk` output with `sudo nvme id-ns <your-nvme-here>` (an example would be /dev/nvme0n2). Verify that the values of `nawun`, `nawupf`, and `nabspf` report values that indicate 16-KiB atomic wrote support. The output of these values should be either `31 (lbads:9)` or `3 (lbads:12)`.

Verify kernel atomic write support

Next, inspect atomic write parameters for 16-KiB atomic write size and alignment boundaries.

Bash

```
cat /sys/class/block/nvme0n2/queue/atomic_write_unit_max_bytes
cat /sys/class/block/nvme0n2/queue/atomic_write_unit_min_bytes
cat /sys/class/block/nvme0n2/queue/atomic_write_boundary_bytes
cat /sys/class/block/nvme0n2/queue/atomic_write_max_bytes
```

Set up and use the filesystem

Once you confirm that both the VM and the kernel support atomic writes, create an XFS filesystem with 16-KiB block size. You can create an XFS filesystem with the `mkfs.xfs` command. Include the following parameters `-b size=16384 <your-nvme-here>` (an example value for your NVMe is /dev/nvme0n2).

Now that you have setup the filesystem. Configure your application to write atomically with direct IO and the same block size formatted. One way of doing this is with the `fio` command. Include the following parameters: `direct=1 atomic=1 bs=16k`.

Virtual machine and disk performance

Article • 04/01/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article helps clarify disk performance and how it works when you combine Azure Virtual Machines and Azure disks. It also describes how you can diagnose bottlenecks for your disk IO and the changes you can make to optimize for performance.

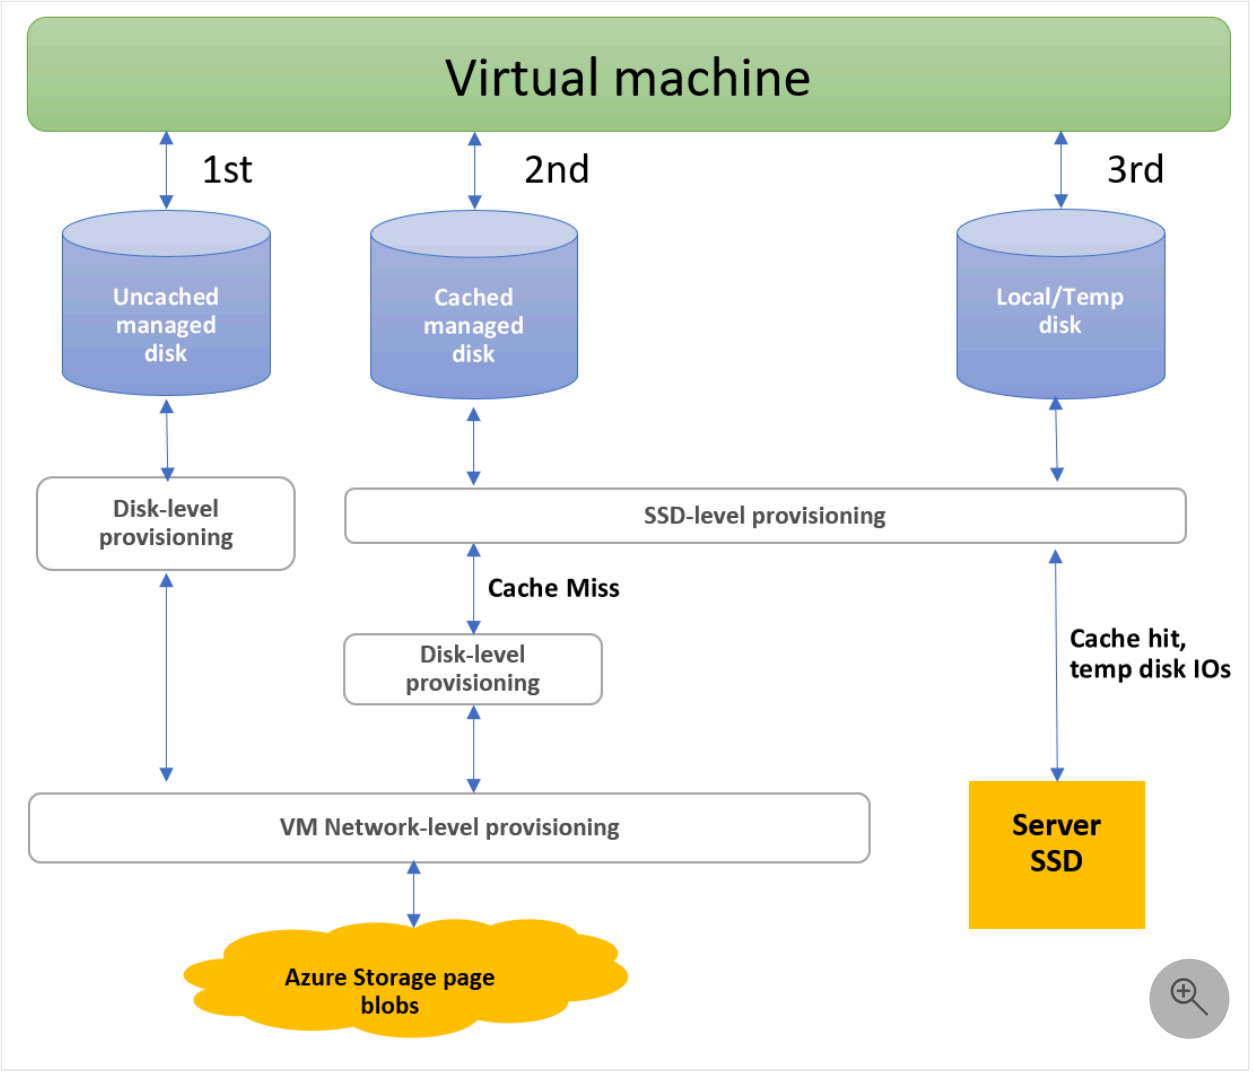
How does disk performance work?

Azure virtual machines (VM) have input/output operations per second (IOPS) and throughput performance limits based on the VM type and size. OS disks and data disks can be attached to virtual machines. The disks have their own IOPS and throughput limits.

Disk allocation and performance

There are three paths that bandwidth and I/O operations per second (IOPS) can take to disks attached to a VM in Azure. The following diagram depicts real-time allocation of these paths.

The following diagram depicts real-time allocation of bandwidth and I/O operations per second (IOPS) for disks, with three paths that I/O can take.



The first I/O path is the uncached managed disk path. I/O operations use this path when you're using a managed disk and you set the host caching to `none`. I/O operations that use this path run based on disk-level provisioning and then VM network-level provisioning for IOPS and throughput.

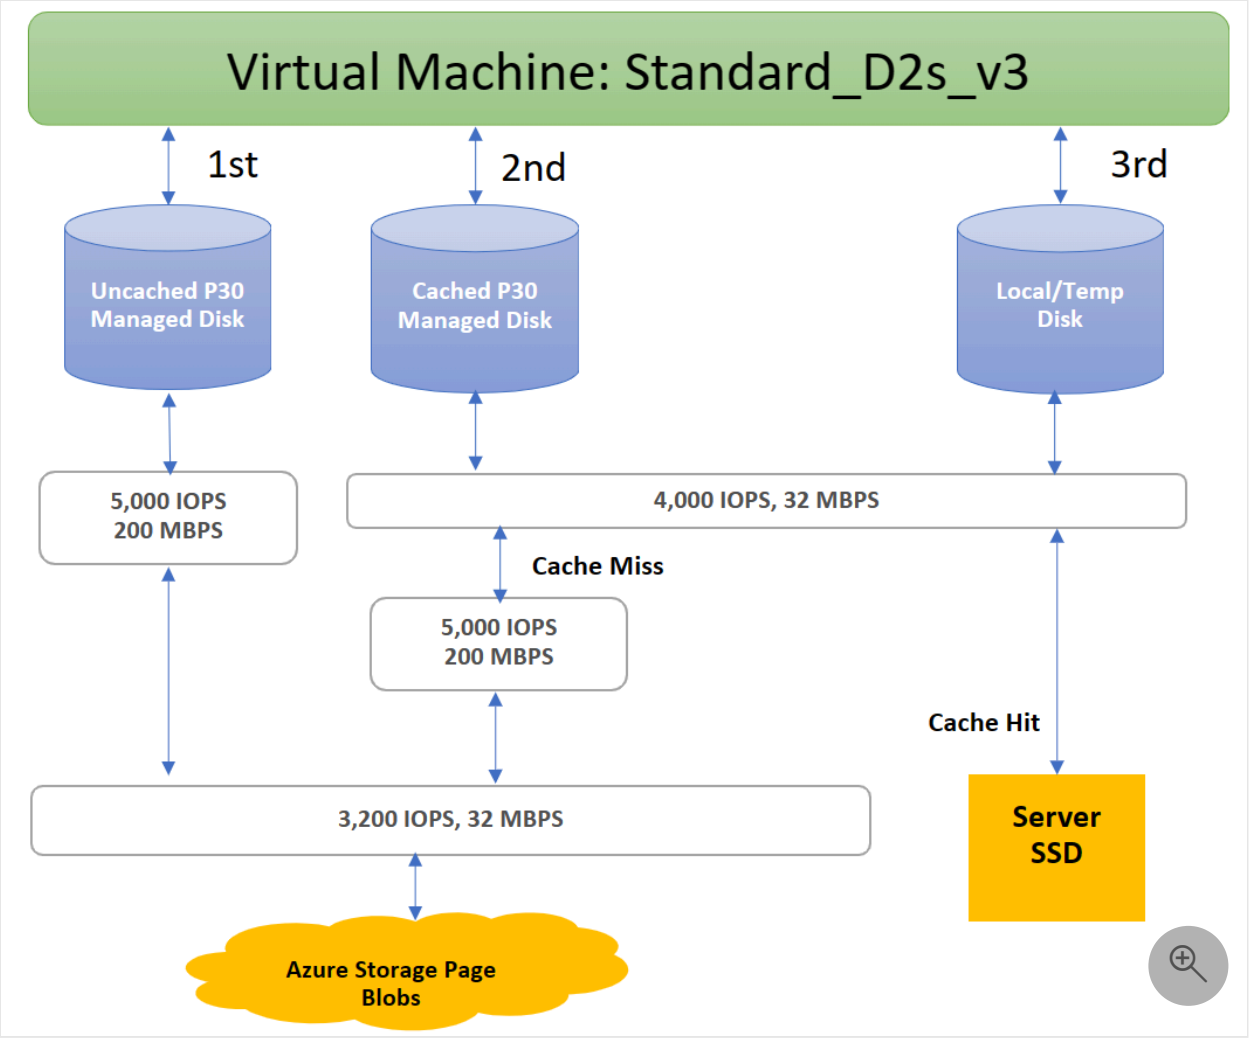
The second I/O path is the cached managed disk path. Cached managed disk I/O uses an SSD that's close to the VM. This SSD has its own IOPS and throughput provisioned, and it appears as "SSD-level provisioning" in the diagram.

When a cached managed disk initiates a read, the request first checks to see if the data is in the server SSD. If the data isn't present, a cached miss occurs. Then the I/O runs based on SSD-level provisioning, disk-level provisioning, and then VM network-level provisioning for IOPS and throughput.

When the server SSD initiates reads on cached I/O that are present on the server SSD, a cache hit occurs. The I/O then runs based on the SSD-level provisioning. Writes that a cached managed disk initiates always follow the path of a cached miss. They go through SSD-level, disk-level, and VM network-level provisioning.

The third path is for the *Local/Temp* disk. It's only available on VMs that support *Local/Temp* disks. An I/O operation that uses this path runs based on SSD-level provisioning for IOPS and throughput.

The following diagram depicts an example of these limitations. The system prevents a Standard_D2s_v3 VM from achieving the 5,000 IOPS potential of a P30 disk, whether it's cached or not, because of limits at the SSD and network levels.



Azure uses a prioritized network channel for disk traffic. Disk traffic takes precedence over low-priority network traffic. This prioritization helps disks maintain their expected performance if there's network contention.

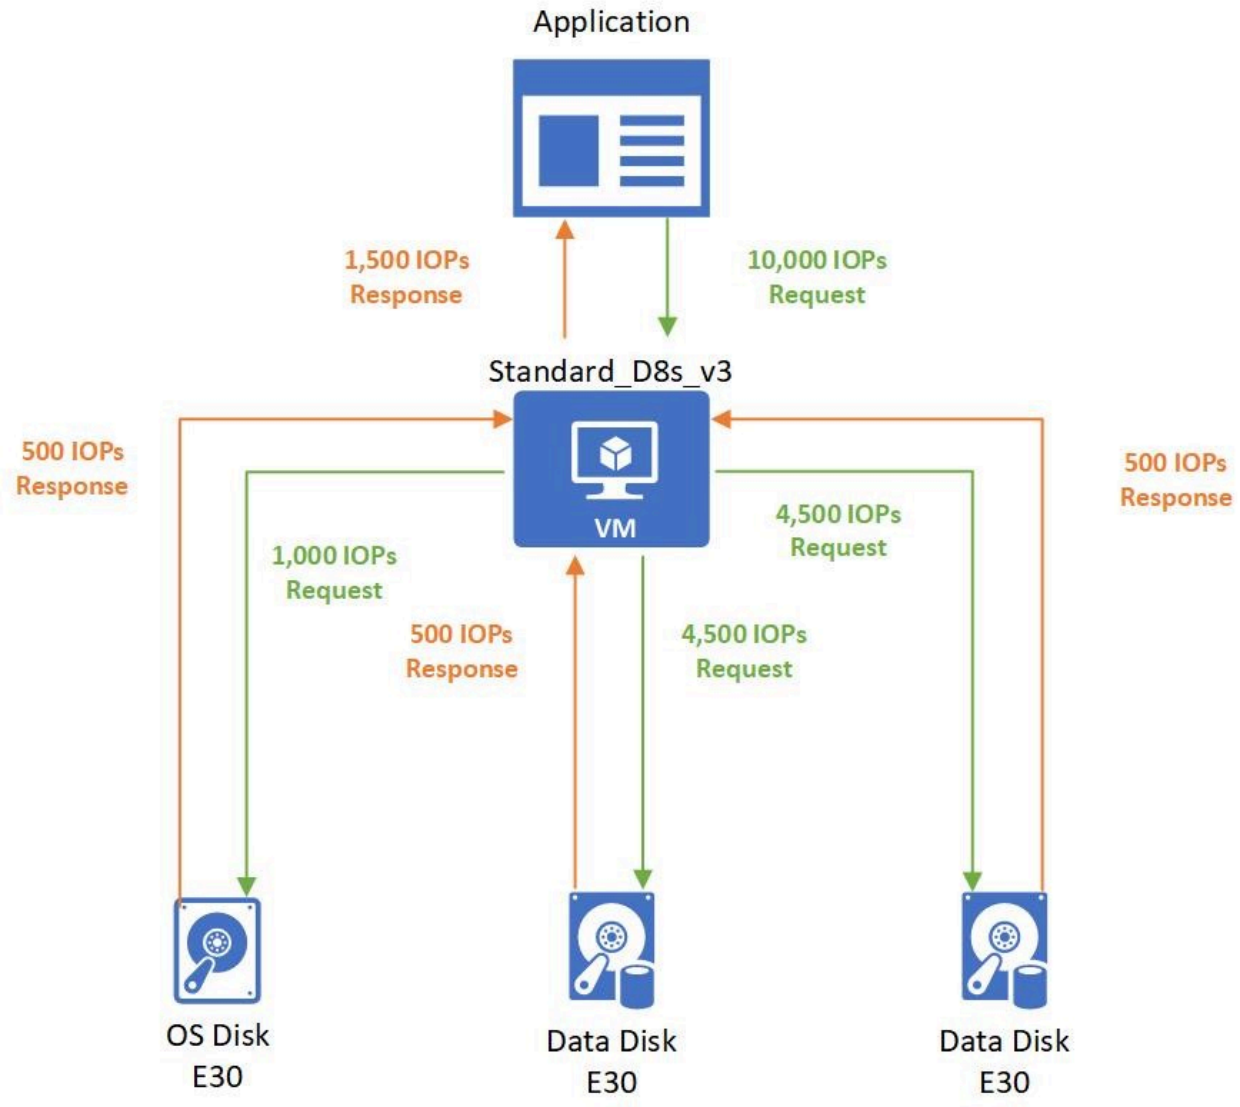
Similarly, Azure Storage handles resource contentions and other issues in the background with automatic load balancing. Azure Storage allocates required resources when you create a disk, and it applies proactive and reactive balancing of resources to handle the traffic level. This behavior further ensures that disks can sustain their expected IOPS and throughput targets. Use VM-level and disk-level metrics to track the performance and set up alerts as needed.

Disk IO capping

Your application's performance gets capped when it requests more IOPS or throughput than what is allotted for the virtual machines or attached disks. When capped, the application experiences suboptimal performance. This can lead to negative consequences like increased latency. Let's run through a couple of examples to clarify this concept. To make these examples easy to follow, we'll only look at IOPS. But, the same logic applies to throughput.

Setup:

- Standard_D8s_v3
  - Uncached IOPS: 12,800
- E30 OS disk
  - IOPS: 500
- Two E30 data disks × 2
  - IOPS: 500



The application running on the virtual machine makes a request that requires 10,000 IOPS to the virtual machine. All of which are allowed by the VM because the Standard_D8s_v3 virtual machine can execute up to 12,800 IOPS.

The 10,000 IOPS requests are broken down into three different requests to the different disks:

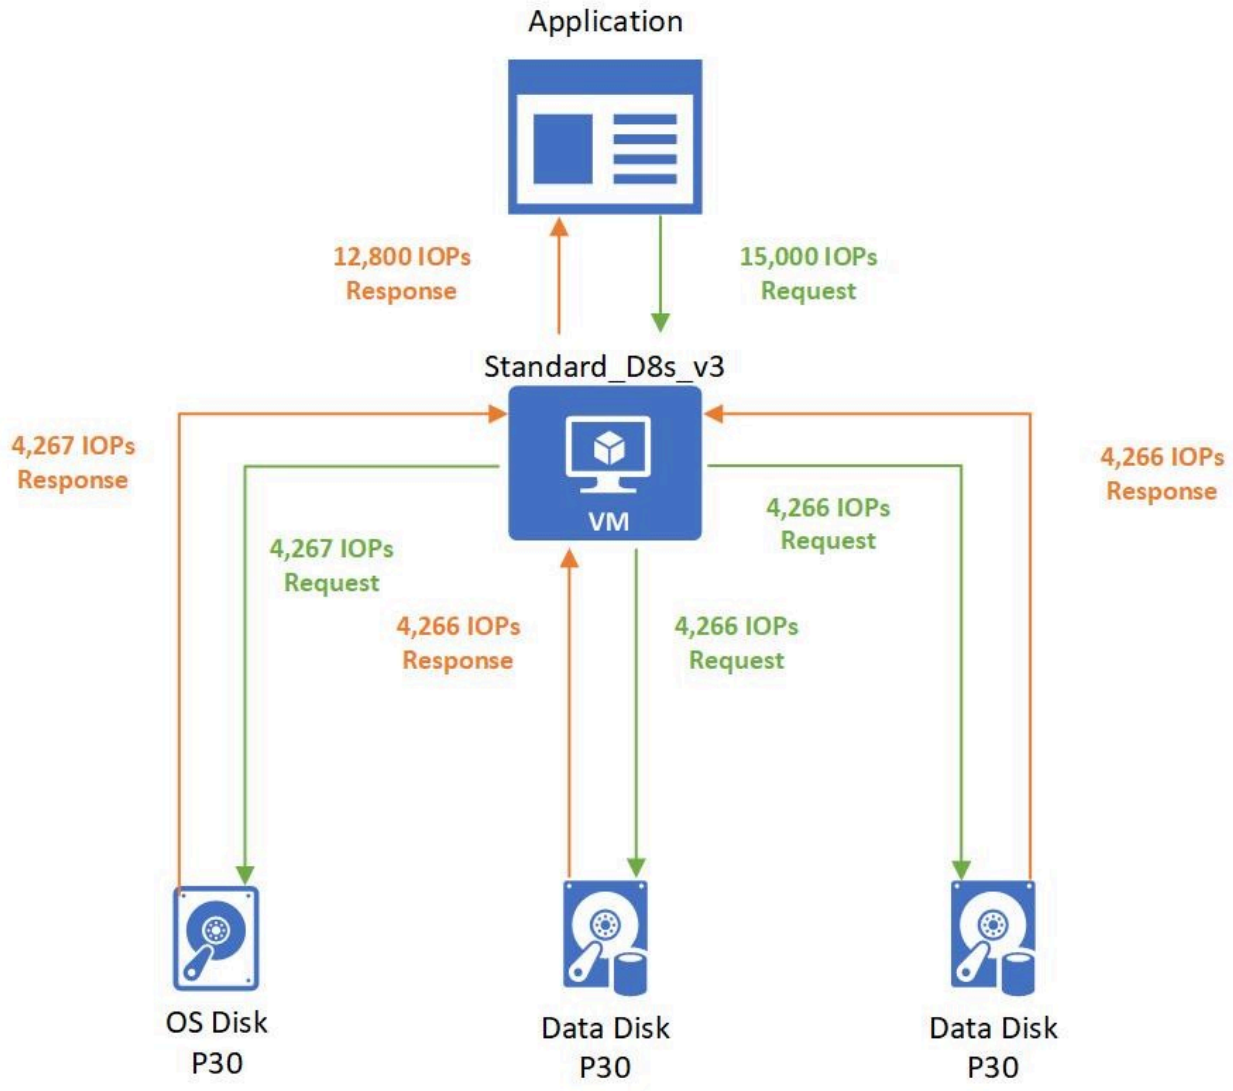
- 1,000 IOPS are requested to the operating system disk.
- 4,500 IOPS are requested to each data disk.

All attached disks are E30 disks and can only handle 500 IOPS. So, they respond back with 500 IOPS each. The application's performance is capped by the attached disks, and it can only process 1,500 IOPS. The application could work at peak performance at 10,000 IOPS if better-performing disks are used, such as Premium SSD P30 disks.

Virtual machine IO capping

Setup:

- Standard_D8s_v3
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
- Two P30 data disks × 2
  - IOPS: 5,000



The application running on the virtual machine makes a request that requires 15,000 IOPS. Unfortunately, the Standard_D8s_v3 virtual machine is only provisioned to handle 12,800 IOPS. The application is capped by the virtual machine limits and must allocate the allotted 12,800 IOPS.

Those 12,800 IOPS requested are broken down into three different requests to the different disks:

- 4,267 IOPS are requested to the operating system disk.
- 4,266 IOPS are requested to each data disk.

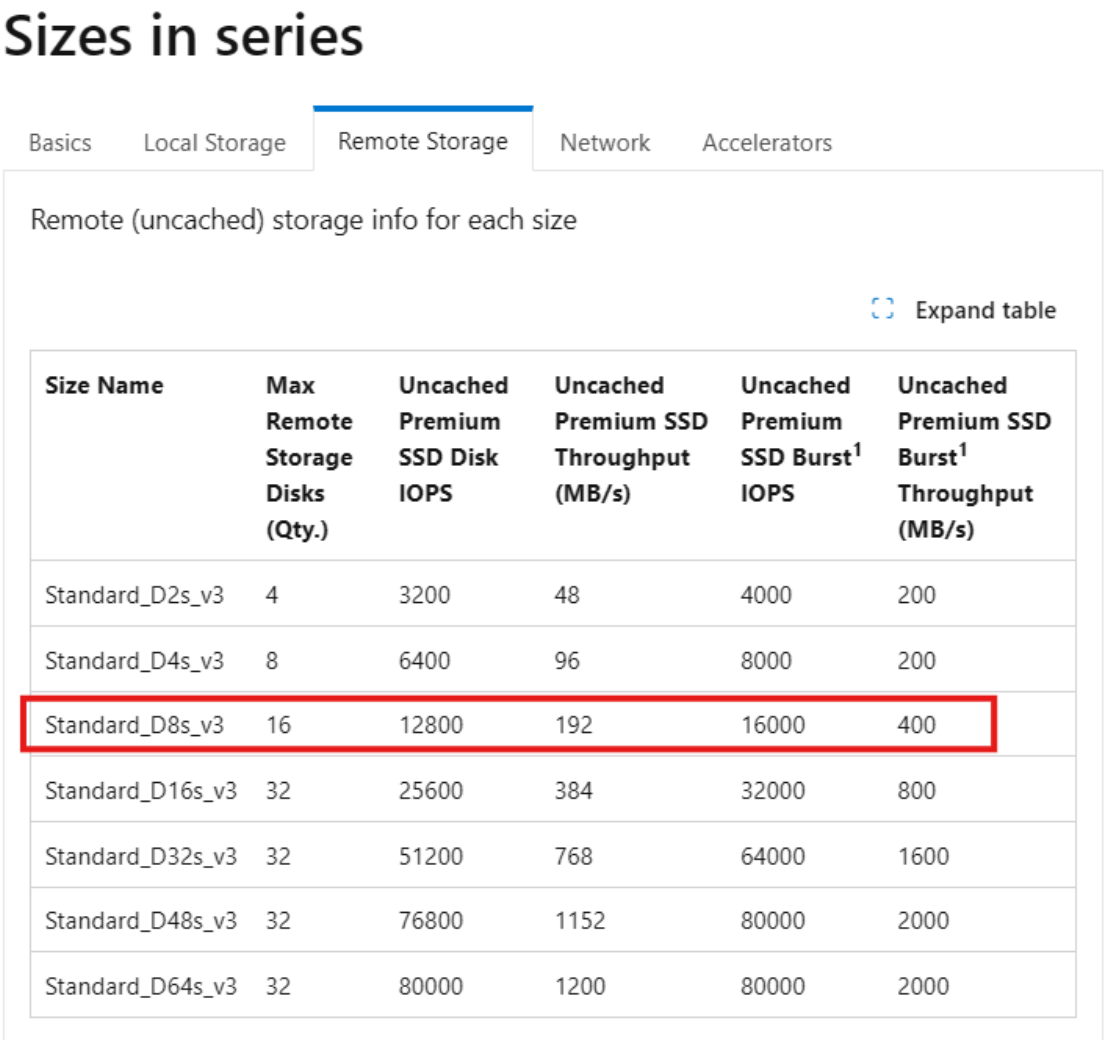
All attached disks are P30 disks that can handle 5,000 IOPS. So, they respond back with their requested amounts.

Virtual machine uncached vs cached limits

Virtual machines that are enabled for both premium storage and premium storage caching have two different storage bandwidth limits. Let's look at the Standard_D8s_v3

virtual machine as an example. Here is the documentation on the Dsv3-series and the Standard_D8s_v3:

- The "*Uncached*" disk data under the **Remote Storage** are the default storage maximum limits that the virtual machine can handle.



Sizes in series

Size Name	Max Remote Storage Disks (Qty.)	Uncached Premium SSD Disk IOPS	Uncached Premium SSD Throughput (MB/s)	Uncached Premium SSD Burst[1] IOPS	Uncached Premium SSD Burst[1] Throughput (MB/s)
Standard_D2s_v3	4	3200	48	4000	200
Standard_D4s_v3	8	6400	96	8000	200
Standard_D8s_v3	16	12800	192	16000	400
Standard_D16s_v3	32	25600	384	32000	800
Standard_D32s_v3	32	51200	768	64000	1600
Standard_D48s_v3	32	76800	1152	80000	2000
Standard_D64s_v3	32	80000	1200	80000	2000

- The "*Cached*" disk data under the **Local Storage** tab are separate limits when you enable host caching.

Sizes in series

Basics | Local Storage | Remote Storage | Network | Accelerators

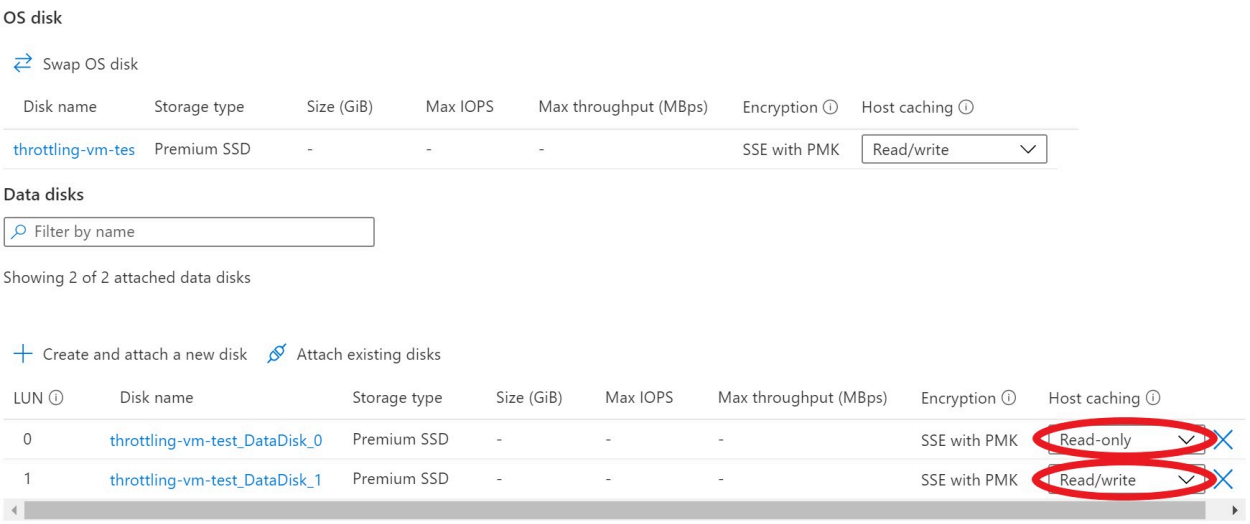
Local (cached & temp) storage info for each size

Expand table

Size Name	Max Temp Storage Disks (Qty.)	Temp Disk Size (GiB)	Disk Cache Size (GiB)	Cached Disk Random Read (RR)[1] IOPS	Cached Disk Random Read (RR)[1] Throughput (MB/s)
Standard_D2s_v3	1	16	50	4000	32
Standard_D4s_v3	1	32	100	8000	64
Standard_D8s_v3	1	64	200	16000	128
Standard_D16s_v3	1	128	400	32000	256
Standard_D32s_v3	1	256	800	64000	512
Standard_D48s_v3	1	384	1200	96000	768
Standard_D64s_v3	1	512	1600	128000	1024

Host caching works by bringing storage closer to the VM that can be written or read to quickly. The amount of storage that is available to the VM for host caching is in the documentation. For example, you can see the Standard_D8s_v3 comes with 200 GiB of cache storage.

You can enable host caching when you create your virtual machine and attach disks. You can also turn on and off host caching on your disks on an existing VM. By default, cache-capable data disks do not have caching enabled. Cache-capable OS disks have read/write caching enabled.



You can adjust the host caching to match your workload requirements for each disk. You can set your host caching to be:

- **Read-only**: For workloads that only do read operations
- **Read/write**: For workloads that do a balance of read and write operations

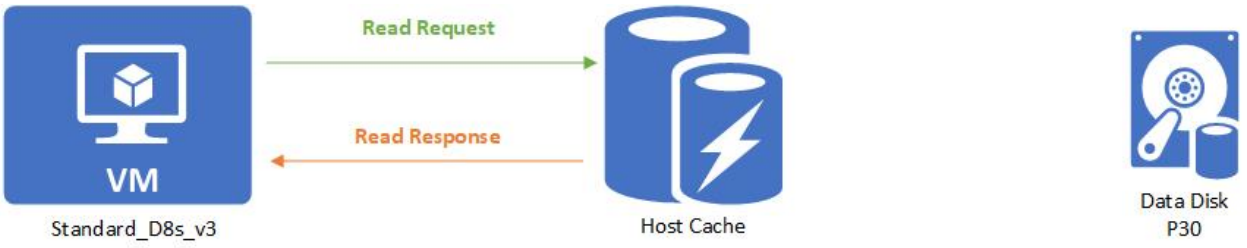
If your workload doesn't follow either of these patterns, we don't recommend that you use host caching.

Let's run through a couple examples of different host cache settings to see how it affects the data flow and performance. In this first example, we see what happens with IO requests when the host caching setting is set to **Read-only**.

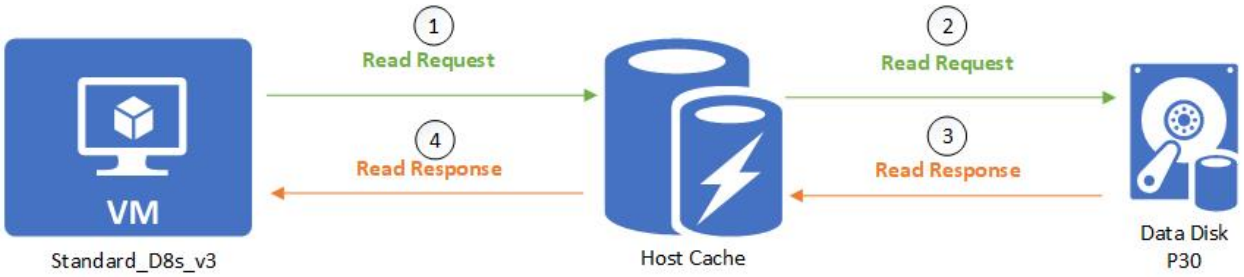
Setup:

- Standard_D8s_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 data disk
  - IOPS: 5,000
  - Host caching: **Read-only**

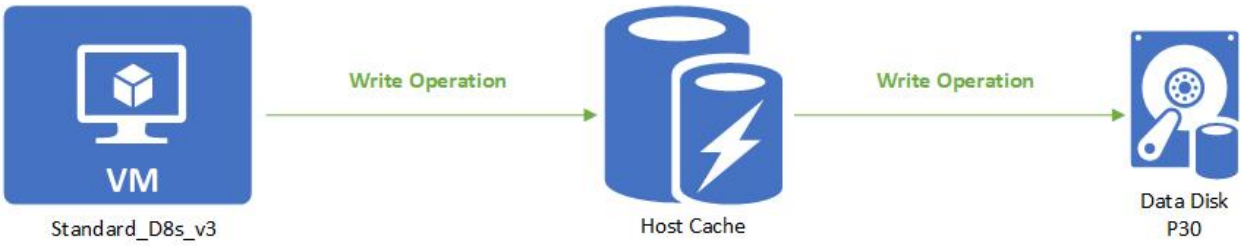
When a read is performed and the desired data is available on the cache, the cache returns the requested data. There's no need to read from the disk. This read is counted toward the VM's cached limits.



When a read is performed and the desired data *isn't* available on the cache, the read request is relayed to the disk. Then the disk surfaces it to both the cache and the VM. This read is counted toward both the VM's uncached limit and the VM's cached limit.



When a write is performed, the write has to be written to both the cache and the disk before it's considered complete. This write is counted toward the VM's uncached limit and the VM's cached limit.

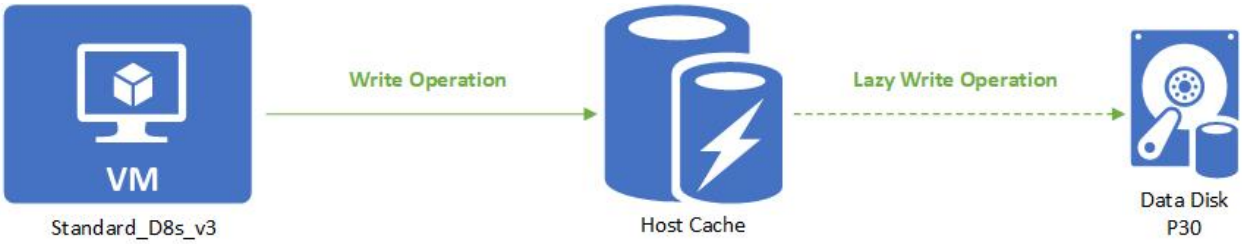


Next let's look at what happens with IO requests when the host cache setting is set to **Read/write**.

Setup:

- Standard_D8s_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 data disk
  - IOPS: 5,000
  - Host caching: **Read/write**

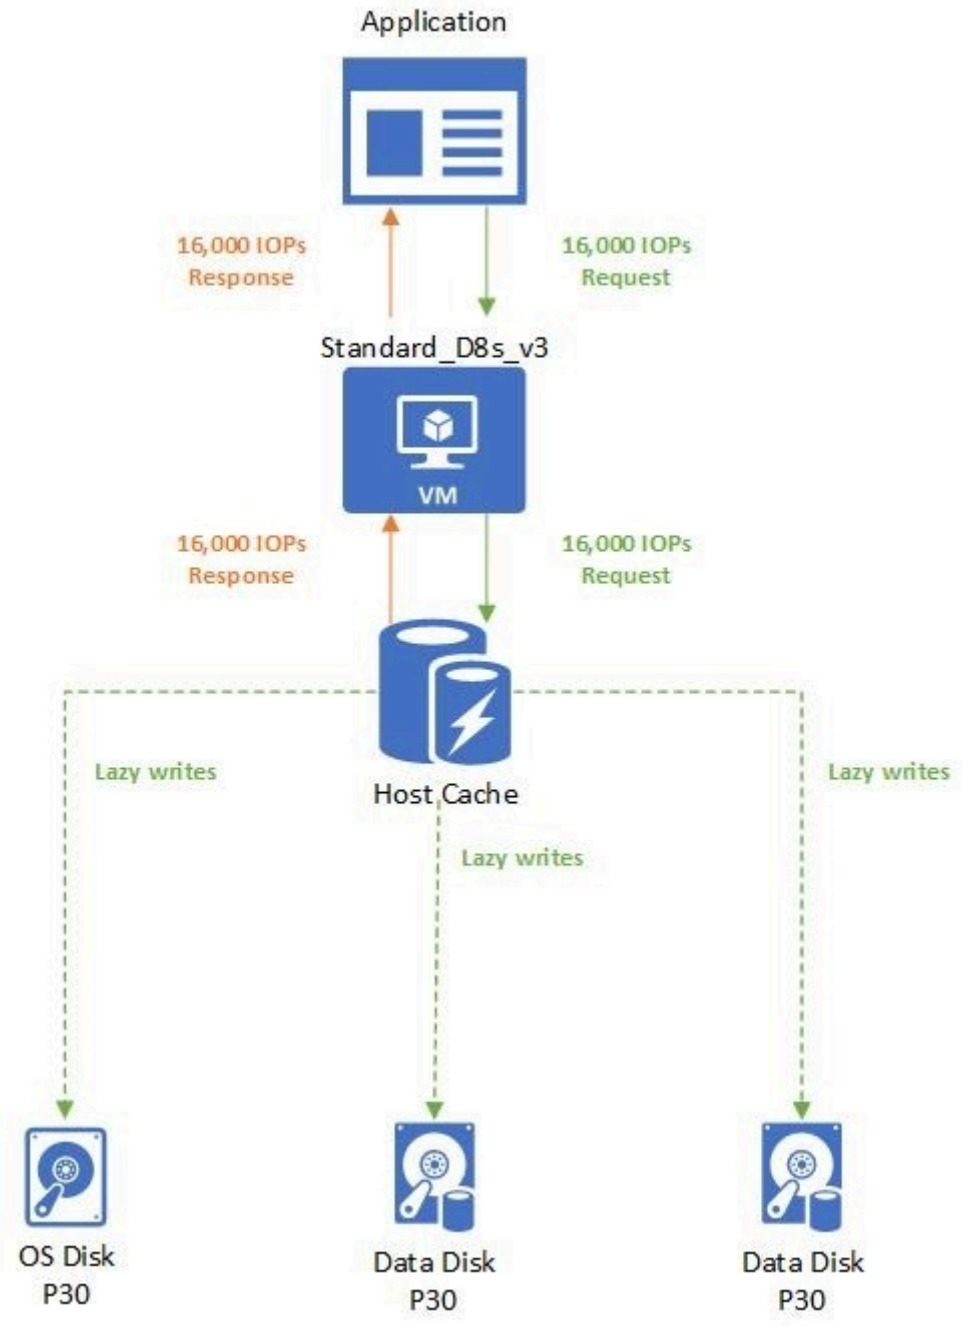
A read is handled the same way as a read-only. Writes are the only thing that's different with read/write caching. When writing with host caching is set to **Read/write**, the write only needs to be written to the host cache to be considered complete. The write is then lazily written to the disk when the cache is flushed periodically. Customers can additionally force a flush by issuing an `f/sync` or `fua` command. This means that a write is counted toward cached IO when it's written to the cache. When it's lazily written to the disk, it counts toward the uncached IO.



Let’s continue with our Standard_D8s_v3 virtual machine. Except this time, we enable host caching on the disks. This makes the VM's IOPS limit 16,000 IOPS. Attached to the VM are three underlying P30 disks that can each handle 5,000 IOPS.

Setup:

- Standard_D8s_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Read/write**



The application uses a Standard_D8s_v3 virtual machine with caching enabled. It makes a request for 16,000 IOPS. The requests are completed as soon as they're read or written to the cache. Writes are then lazily written to the attached Disks.

Combined uncached and cached limits

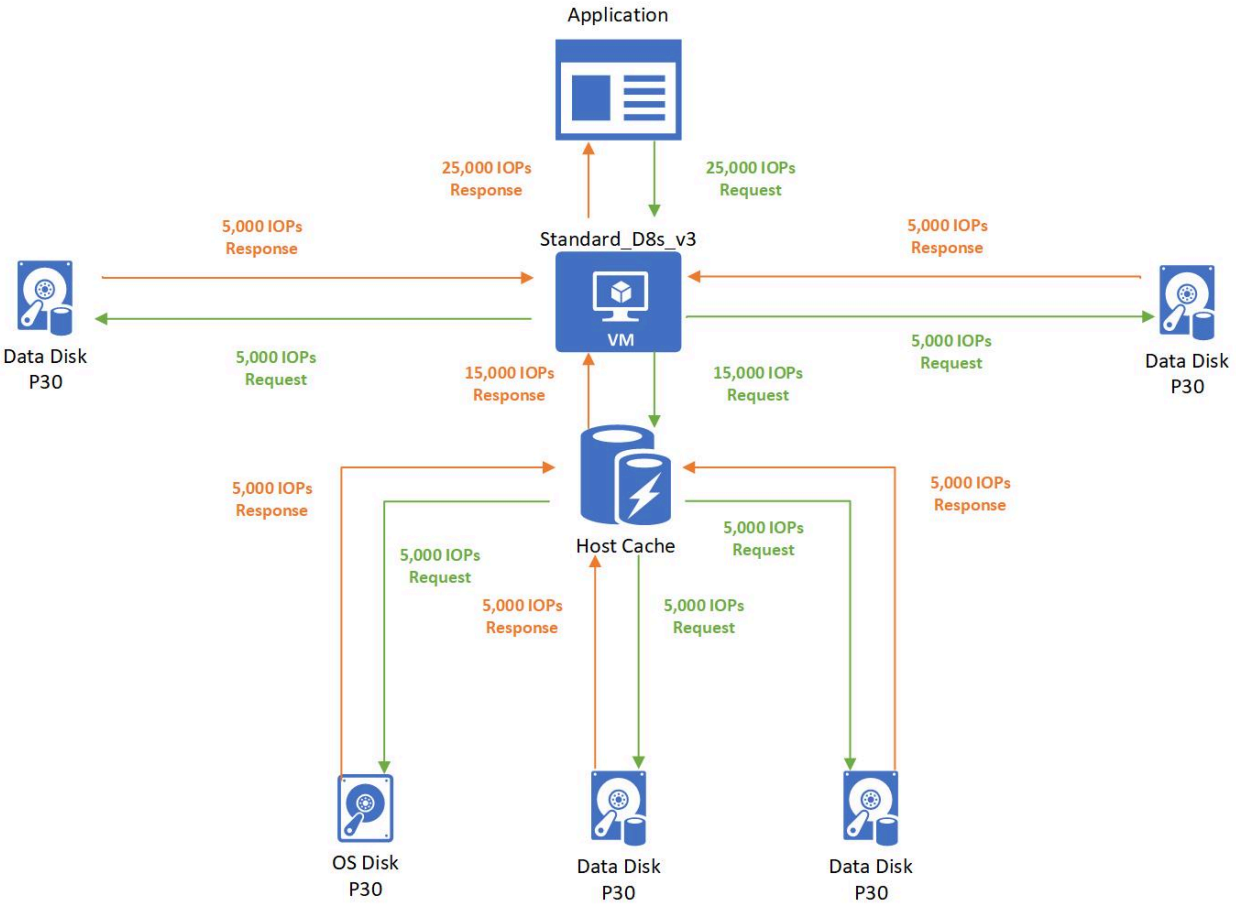
A virtual machine's cached limits are separate from its uncached limits. This means you can enable host caching on disks attached to a VM while not enabling host caching on other disks. This configuration allows your virtual machines to get a total storage IO of the cached limit plus the uncached limit.

Let's run through an example to help you understand how these limits work together. We continue with the Standard_D8s_v3 virtual machine and premium disks attached

configuration.

Setup:

- Standard_D8s_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Disabled**



In this case, the application running on a Standard_D8s_v3 virtual machine makes a request for 25,000 IOPS. The request is broken down as 5,000 IOPS to each of the attached disks. Three disks use host caching and two disks don't use host caching.

- Since the three disks that use host caching are within the cached limits of 16,000, those requests are successfully completed. No storage performance capping

occurs.

- Since the two disks that don't use host caching are within the uncached limits of 12,800, those requests are also successfully completed. No capping occurs.

Understand how your reservation discount is applied to Azure disk storage

After you purchase Azure disk reserved capacity, a reservation discount is automatically applied to disk resources that match the terms of your reservation. The reservation discount only applies to managed disks, disk snapshots are charged at pay-as-you-go rates.

For more information about Azure disk reservation, see Save costs with Azure disk reservation. For information about pricing for Azure disk reservation, see Azure Managed Disks pricing.

How the reservation discount is applied

The Azure disk reservation discount is a use-it-or-lose-it discount that applies to managed disk resources hourly. For a given hour, if you have no managed disk resources that meet the reservation terms, you lose a reservation quantity for that hour. Unused hours don't carry forward.

When you delete a resource, the reservation discount automatically applies to another matching resource in the specified scope. If no matching resource is found, the reserved hours are lost.

Stopped resources are billed and continue to use reservation hours. Deallocate or delete resources or scale-in other resources to use your available reservation hours with other workloads.

Discount examples

The following examples show how the Azure disk reservation discount applies depending on your deployment.

Suppose you purchase and reserve 100 P30 disks in the US West 2 region for a one-year term. Each disk has approximately 1 TiB of storage. Assume the cost of this sample reservation is $140,100. You can choose to pay either the full amount up front or fixed monthly installments of $11,675 for the next 12 months.

The following scenarios describe what happens if you underuse, overuse, or tier your reserved capacity. For these examples, assume you signed up for a monthly reservation-payment plan.

Underusing your capacity

Suppose you deploy only 99 of your 100 reserved Azure Premium SSD P30 disks for an hour within the reservation period. The remaining P30 disk isn't applied during that hour. It also doesn't carry over.

Overusing your capacity

Suppose that for an hour within the reservation period, you use 101 Premium SSD P30 disks. The reservation discount applies only to 100 P30 disks. The remaining P30 disk is charged at pay-as-you-go rates for that hour. For the next hour, if your usage goes down to 100 P30 disks, all usage is covered by the reservation.

Tiering your capacity

Suppose that in a given hour within your reservation period, you want to use a total of 200 P30 Premium SSDs. Also suppose you use only 100 for the first 30 minutes. During this period, your use is fully covered because you made a reservation for 100 P30 disks. If you then discontinue the use of the first 100 (so that you're using zero) and then begin to use the other 100 for the remaining 30 minutes, that usage is also covered under your reservation.

Reduce costs with Azure Disks Reservation

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Save on your Azure Disk Storage usage with reserved capacity. Azure Disk Storage reservations combined with Azure Reserved Virtual Machine Instances let you lower your total virtual machine (VM) costs. The reservation discount is applied automatically to the matching disks in the selected reservation scope. Because of this automatic application, you don't need to assign a reservation to a managed disk to get the discounts.

Discounts are applied hourly depending on the disk usage. Unused reserved capacity doesn't carry over. Azure Disk Storage reservation discounts don't apply to unmanaged disks, ultra disks, or page blob consumption.

Determine your storage needs

Before you purchase a reservation, determine your storage needs. Currently, Azure Disk Storage reservations are available only for select Azure premium SSD SKUs. The SKU of a premium SSD determines the disk's size and performance.

When determining your storage needs, don't think of disks based on just capacity. For example, you can't have a reservation for a P40 disk and use that to pay for two smaller P30 disks. When purchasing a reservation, you're only purchasing a reservation for the total number of disks per SKU.

A disk reservation is made per disk SKU. As a result, the reservation consumption is based on the unit of the disk SKUs instead of the provided size.

For example, assume you reserve one P40 disk that has 2 TiB of provisioned storage capacity. Also assume you allocate only two P30 disks. The P40 reservation in that case doesn't account for P30 consumption, and you pay the pay-as-you-go rate on the P30 disks.

Purchase considerations

We recommend the following practices when considering disk reservation purchase:

- Analyze your usage information to help determine which reservations you should purchase. Make sure you track the usage in disk SKUs instead of provisioned or used disk capacity.
- Examine your disk reservation along with your VM reservation. We highly recommend making reservations for both VM usage and disk usage for maximum savings. You can start with determining the right VM reservation and then evaluate the disk reservation. Generally, you'll have a standard configuration for each of your workloads. For example, a SQL Server server might have two P40 data disks and one P30 operating system disk.

  This kind of pattern can help you determine the reserved amount you might purchase. This approach can simplify the evaluation process and ensure that you have an aligned plan for both your VM and disks. The plan contains considerations like subscriptions or regions.

Purchase restrictions

Reservation discounts are currently unavailable for the following:

- Unmanaged disks or page blobs
- Ultra Disks
- Premium SSD v2 disks
- Standard solid-state drives (SSDs) or standard hard-disk drives (HDDs)
- Premium SSD SKUs smaller than P30: P1, P2, P3, P4, P6, P10, P15, and P20 SSD SKUs
- Disks in Azure Government, Azure Germany, or Microsoft Azure operated by 21Vianet regions

In rare circumstances, Azure limits the purchase of new reservations to a subset of disk SKUs because of low capacity in a region.

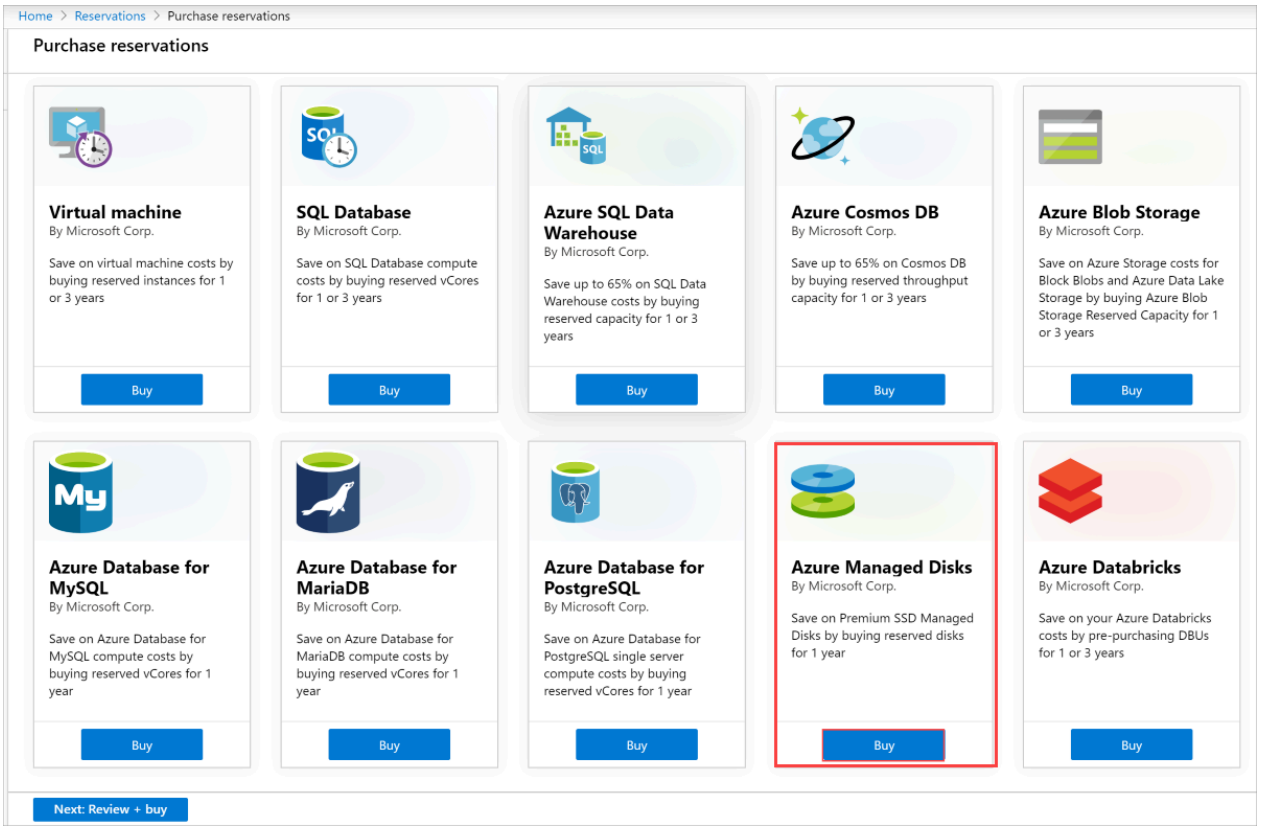
Buy a disk reservation

You can purchase Azure Disk Storage reservations through the Azure portal. You can pay for the reservation either up front or with monthly payments. For more information about purchasing with monthly payments, see Purchase reservations with monthly payments.

To buy a reservation, you must have owner role or reservation purchaser role on an Azure subscription.

Follow these steps to purchase reserved capacity:

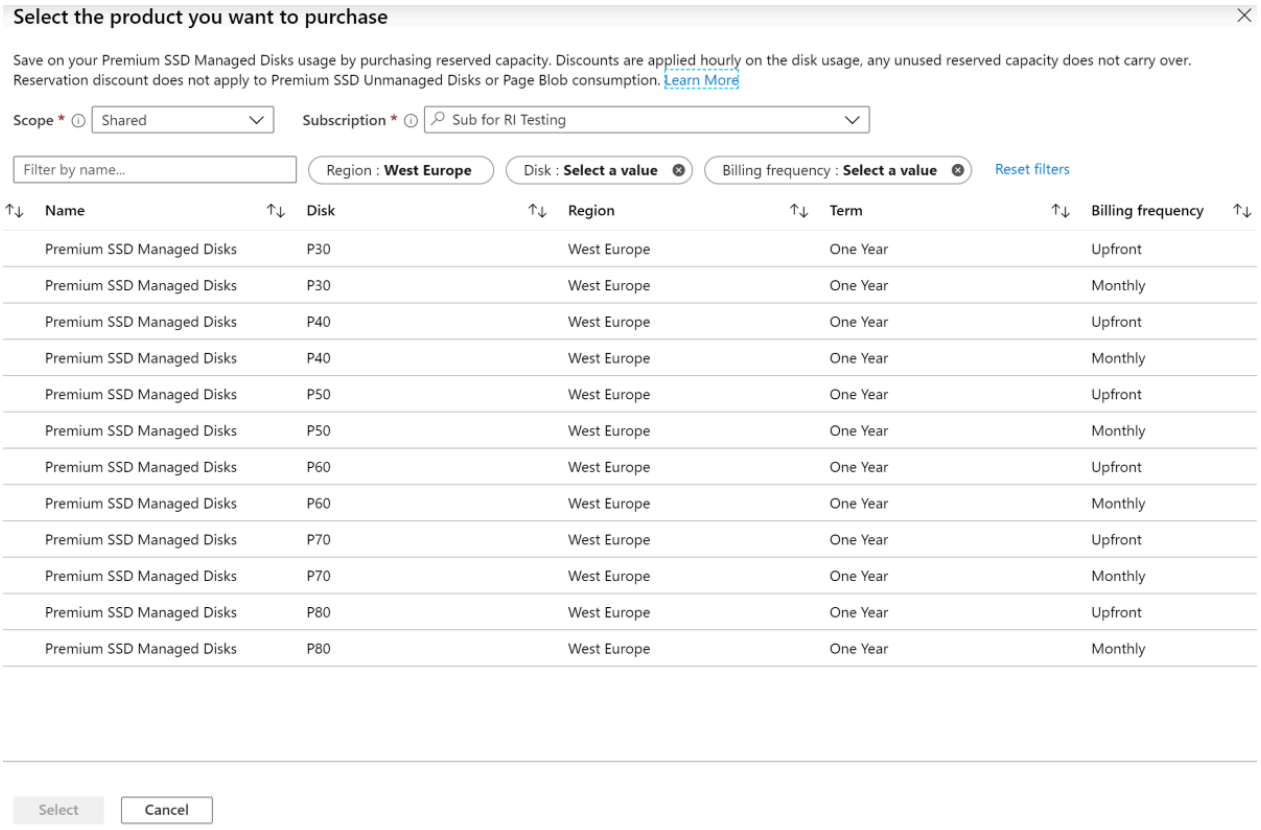
1. Go to the Purchase reservations pane in the Azure portal.
2. Select **Azure Managed Disks** to purchase a reservation.



3. Specify the required values described in the following table:

Expand table

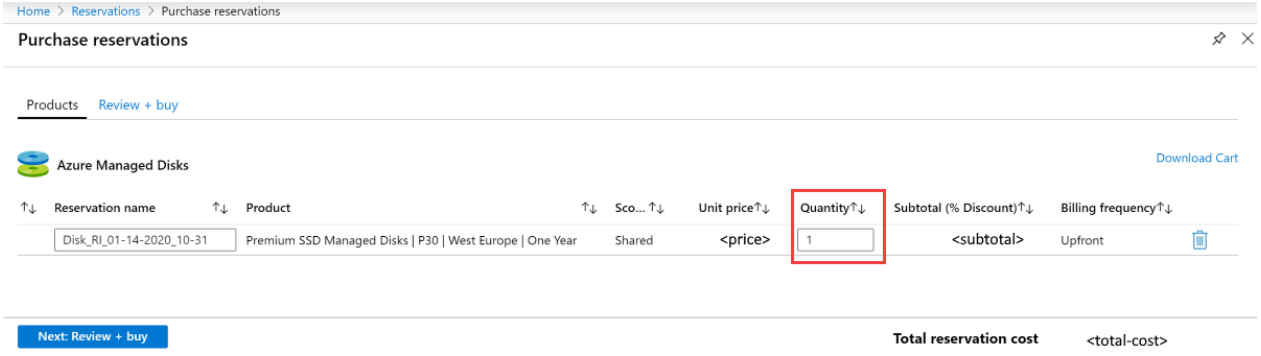
Element	Description
Scope	How many subscriptions can use the billing benefit associated with the reservation. This value also specifies how the reservation is applied to specific subscriptions. If you select **Shared**, the reservation discount is applied to Azure Storage capacity in every subscription within your billing context. The billing context is based on how you signed up for Azure. For enterprise customers, the shared scope is the enrollment and includes all subscriptions within the enrollment. For pay-as-you-go customers, the shared scope includes all individual subscriptions with pay-as-you-go rates created by the account administrator. If you select **Management group**, the reservation discount is applied to Azure Storage capacity in every subscription that is part of the management group and the billing scope. If you select **Single subscription**, the reservation discount is applied to Azure Storage capacity in the selected subscription. If you select **Single resource group**, the reservation discount is applied to Azure Storage capacity in the selected subscription and in that subscription's selected resource group. You can change the reservation scope after you purchase the reservation.
Subscription	The subscription you use to pay for the Azure Storage reservation. The payment method on the selected subscription is used in charging the costs. The subscription must be one of the following types: • Enterprise Agreement (offer numbers MS-AZR-0017P and MS-AZR-0148P). For an Enterprise subscription, the charges are deducted from the enrollment's Azure Prepayment (previously called monetary commitment) balance or charged as overage. • Individual subscription with pay-as-you-go rates (offer numbers MS-AZR-0003P and MS-AZR-0023P). For an individual subscription with pay-as-you-go rates, the charges are billed to the credit card or invoice payment method on the subscription.
Disks	The SKU you want to create.
Region	The region where the reservation is in effect.
Billing frequency	How often the account is billed for the reservation. Options include **Monthly** and **Upfront**.



4. After you specify the values for your reservation, the Azure portal displays the cost. The portal also shows the discount percentage over pay-as-you-go billing. Select **Next** to continue to the **Purchase reservations** pane.

5. On the **Purchase reservations** pane, you can name your reservation and select the total quantity of reservations you want to make. The number of reservations maps to the number of disks. For example, if you want to reserve a hundred disks, enter the **Quantity** value **100**.

6. Review the total cost of the reservation.



After you purchase a reservation, it's automatically applied to any existing Disk Storage resources that match the reservation terms. If you haven't created any Disk Storage resources yet, the reservation applies whenever you create a resource that matches the reservation terms. In either case, the reservation term begins immediately after a successful purchase.

Cancel, exchange, or refund reservations

You can cancel, exchange, or refund reservations within certain limitations. For more information, see Self-service exchanges and refunds for Azure Reservations.

Expiration of a reservation

When a reservation expires, any Azure Disk Storage capacity that you use under that reservation is billed at the pay-as-you-go rate. Reservations don't renew automatically.

You'll receive an email notification 30 days before the expiration of the reservation and again on the expiration date. To continue taking advantage of the cost savings that a reservation provides, renew it no later than the expiration date.

Azure premium storage: Design for high performance

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article provides guidelines for building high-performance applications by using Azure premium storage. You can use the instructions provided in this document combined with performance best practices applicable to technologies used by your application. To illustrate the guidelines, we use SQL Server running on premium storage as an example throughout this document.

While we address performance scenarios for the storage layer in this article, you need to optimize the application layer. For example, if you're hosting a SharePoint Farm on premium storage, you can use the SQL Server examples from this article to optimize the database server. You can also optimize the SharePoint Farm's web server and application server to get the most performance.

This article helps to answer the following common questions about optimizing application performance on premium storage:

- How can you measure your application performance?
- Why aren't you seeing expected high performance?
- Which factors influence your application performance on premium storage?
- How do these factors influence performance of your application on premium storage?
- How can you optimize for input/output operations per second (IOPS), bandwidth, and latency?

We provide these guidelines specifically for premium storage because workloads running on premium storage are highly performance sensitive. We provide examples where appropriate. You can also apply some of these guidelines to applications running on infrastructure as a service (IaaS) VMs with standard storage disks.

> **Note**
>
> Sometimes what appears to be a disk performance issue is actually a network bottleneck. In these situations, you should optimize your network performance.
>
> If you're looking to benchmark your disk, see the following articles:
>
> - For Linux: Benchmark your application on Azure Disk Storage
> - For Windows: Benchmark a disk
>
> If your VM supports accelerated networking, make sure it's enabled. If it's not enabled, you can enable it on already deployed VMs on both Windows and Linux.

Before you begin, if you're new to premium storage, first read Select an Azure disk type for IaaS VMs and Scalability targets for premium page blob storage accounts.

Application performance indicators

We assess whether an application is performing well or not by using performance indicators like:

- How fast an application is processing a user request.
- How much data an application is processing per request.
- How many requests an application is processing in a specific period of time.
- How long a user has to wait to get a response after submitting their request.

The technical terms for these performance indicators are IOPS, throughput or bandwidth, and latency.

In this section, we discuss the common performance indicators in the context of premium storage. In the section Performance application checklist for disks, you learn how to measure these performance indicators for your application. Later in Optimize application performance, you learn about the factors that affect these performance indicators and recommendations to optimize them.

IOPS

IOPS is the number of requests that your application is sending to storage disks in one second. An input/output operation could be read or write, sequential, or random. Online transaction processing (OLTP) applications like an online retail website need to process many concurrent user requests immediately. The user requests are insert- and update-intensive database transactions, which the application must process quickly. For this reason, OLTP applications require very high IOPS.

OLTP applications handle millions of small and random I/O requests. If you have such an application, you must design the application infrastructure to optimize for IOPS. For more information on all the factors to consider to get high IOPS, see Optimize application performance.

When you attach a premium storage disk to your high-scale VM, Azure provisions for you a guaranteed number of IOPS according to the disk specification. For example, a P50 disk provisions 7,500 IOPS. Each high-scale VM size also has a specific IOPS limit that it can sustain. For example, a Standard GS5 VM has an 80,000 IOPS limit.

Throughput

Throughput, or bandwidth, is the amount of data that your application is sending to the storage disks in a specified interval. If your application is performing input/output operations with large I/O unit sizes, it requires high throughput. Data warehouse applications tend to issue scan-intensive operations that access large portions of data at a time and commonly perform bulk operations. In other words, such applications require higher throughput. If you have such an application, you must design its infrastructure to optimize for throughput. In the next section, we discuss the factors you must tune to achieve this optimization.

When you attach a premium storage disk to a high-scale VM, Azure provisions throughput according to that disk specification. For example, a P50 disk provisions 250 MB/sec disk throughput. Each high-scale VM size also has a specific throughput limit that it can sustain. For example, Standard GS5 VM has a maximum throughput of 2,000 MB/sec.

There's a relation between throughput and IOPS, as shown in the following formula.

It's important to determine the optimal throughput and IOPS values that your application requires. As you try to optimize one, the other is also affected. For more information about optimizing IOPS and throughput, see Optimize application performance.

Latency

Latency is the time it takes an application to receive a single request, send it to storage disks, and send the response to the client. Latency is a critical measure of an application's performance in addition to IOPS and throughput. The latency of a premium storage disk is the time it takes to retrieve the information for a request and communicate it back to your application. Premium storage provides consistently low latencies. Premium disks are designed to provide single-digit millisecond latencies for most I/O operations. If you enable **ReadOnly** host caching on premium storage disks, you can get much lower read latency. For more information on disk caching, see Disk caching.

When you optimize your application to get higher IOPS and throughput, it affects the latency of your application. After you tune the application performance, evaluate the latency of the application to avoid unexpected high latency behavior.

Some control plane operations on managed disks might move the disk from one storage location to another. Moving the disk between storage locations is orchestrated via a background copy of data, which can take several hours to complete. Typically, the time is less than 24 hours depending on the amount of data in the disks. During that time, your application can experience higher than usual read latency because some reads can get redirected to the original location and take longer to complete.

During a background copy, there's no effect on write latency for most disk types. For Premium SSD v2 and Ultra Disks, if the disk has a 4K sector size, it experiences higher read latency. If the disk has a 512e sector size, it experiences higher read and write latency.

The following control plane operations might move the disk between storage locations, and cause increased latency:

- Update the storage type.

- Detach and attach a disk from one VM to another.
- Create a managed disk from a VHD.
- Create a managed disk from a snapshot.
- Convert unmanaged disks to managed disks.

Performance application checklist for disks

The first step in designing high-performance applications running on premium storage is understanding the performance requirements of your application. After you gather performance requirements, you can optimize your application to achieve the most optimal performance.

In the previous section, we explained the common performance indicators: IOPS, throughput, and latency. You must identify which of these performance indicators are critical to your application to deliver the desired user experience. For example, high IOPS matters most to OLTP applications processing millions of transactions in a second. High throughput is critical for data warehouse applications processing large amounts of data in a second. Extremely low latency is crucial for real-time applications like live video-streaming websites.

Next, measure the maximum performance requirements of your application throughout its lifetime. Use the following sample checklist as a start. Record the maximum performance requirements during normal, peak, and off-hour workload periods. By identifying requirements for all workload levels, you can determine the overall performance requirement of your application.

For example, the normal workload of an e-commerce website is the transactions it serves during most days in a year. The peak workload of the website is the transactions it serves during holiday seasons or special sale events. The peak workload is typically experienced for a limited period but can require your application to scale two or more times its normal operation. Find out the 50 percentile, 90 percentile, and 99 percentile requirements. This information helps filter out any outliers in the performance requirements, and you can focus your efforts on optimizing for the right values.

Application performance requirements checklist

Expand table

Performance requirements	50 percentile	90 percentile	99 percentile
Maximum transactions per second			
% Read operations			
% Write operations			
% Random operations			
% Sequential operations			
I/O request size			
Average throughput			
Maximum throughput			
Minimum latency			
Average latency			
Maximum CPU			
Average CPU			
Maximum memory			
Average memory			
Queue depth			

Note

Consider scaling these numbers based on expected future growth of your application. It's a good idea to plan for growth ahead of time because it could be harder to change the infrastructure for improving performance later.

If you have an existing application and want to move to premium storage, first build the preceding checklist for the existing application. Then, build a prototype of your application on premium storage and design the application based on guidelines described in Optimize application performance. The next article describes the tools you can use to gather the performance measurements.

Counters to measure application performance requirements

The best way to measure performance requirements of your application is to use `PerfMon`-monitoring tools provided by the operating system of the server. You can use `PerfMon` for Windows and `iostat` for Linux. These tools capture counters corresponding to each measure explained in the preceding section. You must capture the values of these counters when your application is running its normal, peak, and off-hour workloads.

The `PerfMon` counters are available for processor, memory, and each logical disk and physical disk of your server. When you use premium storage disks with a VM, the physical disk counters are for each premium storage disk, and logical disk counters are for each volume created on the premium storage disks. You must capture the values for the disks that host your application workload. If there's a one-to-one mapping between logical and physical disks, you can refer to physical disk counters. Otherwise, refer to the logical disk counters.

On Linux, the `iostat` command generates a CPU and disk utilization report. The disk utilization report provides statistics per physical device or partition. If you have a database server with its data and logs on separate disks, collect this data for both disks. The following table describes counters for disks, processors, and memory.

Expand table

Counter	Description	PerfMon	iostat
IOPS or transactions/sec	Number of I/O requests issued to the storage disk/sec	Disk reads/sec Disk writes/sec	tps r/s w/s
Disk reads and writes	% of read and write operations performed on the disk	% Disk read time % Disk write time	r/s w/s
Throughput	Amount of data read from or written to the disk/sec	Disk read bytes/sec Disk write bytes/sec	kB_read/s kB_wrtn/s
Latency	Total time to complete a disk I/O request	Average disk sec/read Average disk sec/write	await svctm
I/O size	The size of I/O request issues to the storage disks	Average disk bytes/read Average disk bytes/write	avgrq-sz
Queue depth	Number of outstanding I/O requests waiting to be read from or written to the storage disk	Current disk queue length	avgqu-sz
Maximum memory	Amount of memory required to run the application smoothly	% Committed bytes in use	Use vmstat
Maximum CPU	Amount of CPU required to run the application smoothly	% Processor time	%util

Learn more about iostat and PerfMon.

Optimize application performance

The main factors that influence performance of an application running on premium storage are the nature of I/O requests, VM size, disk size, number of disks, disk caching, multithreading, and queue depth. You can control some of these factors with knobs provided by the system.

Most applications might not give you an option to alter the I/O size and queue depth directly. For example, if you're using SQL Server, you can't choose the I/O size and queue depth. SQL Server chooses the optimal I/O size and queue depth values to get the

most performance. It's important to understand the effects of both types of factors on your application performance so that you can provision appropriate resources to meet performance needs.

Throughout this section, refer to the application requirements checklist that you created to identify how much you need to optimize your application performance. Based on the checklist, you can determine which factors from this section you need to tune.

To witness the effects of each factor on your application performance, run benchmarking tools on your application setup. For steps to run common benchmarking tools on Windows and Linux VMs, see the benchmarking articles at the end of this document.

Optimize IOPS, throughput, and latency at a glance

The following table summarizes performance factors and the steps necessary to optimize IOPS, throughput, and latency. The sections following this summary describe each factor in more depth.

For more information on VM sizes and on the IOPS, throughput, and latency available for each type of VM, see Sizes for virtual machines in Azure.

Expand table

Performance factors	IOPS	Throughput	Latency
Example scenario	Enterprise OLTP application requiring very high transactions per second rate.	Enterprise Data warehousing application processing large amounts of data.	Near real-time applications requiring instant responses to user requests, like online gaming.
Performance factors			
I/O size	Smaller I/O size yields higher IOPS.	Larger I/O size yields higher throughput.	
VM size	Use a VM size that offers IOPS greater than your application requirement.	Use a VM size with a throughput limit greater than your application requirement.	Use a VM size that offers scale limits greater than your application requirement.
Disk size	Use a disk size that offers IOPS greater than your application requirement.	Use a disk size with a throughput limit greater than your application requirement.	Use a disk size that offers scale limits greater than your application requirement.
VM and disk scale limits	IOPS limit of the VM size chosen should be greater than the total IOPS driven by the storage disks attached to it.	Throughput limit of the VM size chosen should be greater than the total throughput driven by the premium storage disks attached to it.	Scale limits of the VM size chosen must be greater than the total scale limits of the attached premium storage disks.
Disk caching	Enable **ReadOnly** cache on premium storage disks with read-heavy operations to get higher read IOPS.		Enable **ReadOnly** cache on premium storage disks with read-heavy operations to get very low read latencies.
Disk striping	Use multiple disks and stripe them together to get a combined higher IOPS and throughput limit. The combined limit per VM should be higher than the combined limits of attached premium disks.		
Stripe size	Smaller stripe size for random small I/O pattern seen in OLTP applications. For example, use a 64-KB stripe size for a SQL Server OLTP application.	Larger stripe size for sequential large I/O pattern seen in data warehouse applications. For example, use a 256-KB stripe size for a SQL Server data warehouse application.	
Multithreading	Use multithreading to push a higher number of requests to premium storage to lead to higher IOPS and throughput. For example, on SQL Server, set a high MAXDOP value to allocate more CPUs to SQL Server.		
Queue depth	Larger queue depth yields higher IOPS.	Larger queue depth yields higher	Smaller queue depth yields

Performance factors	IOPS	Throughput	Latency
		throughput.	lower latencies.

Nature of I/O requests

An I/O request is a unit of input/output operation that your application is performing. Identifying the nature of I/O requests, random or sequential, read or write, small or large, helps you determine the performance requirements of your application. It's important to understand the nature of I/O requests to make the right decisions when you design your application infrastructure. I/Os must be distributed evenly to achieve the best performance possible.

I/O size is one of the more important factors. The I/O size is the size of the input/output operation request generated by your application. The I/O size affects performance significantly, especially on the IOPS and bandwidth that the application can achieve. The following formula shows the relationship between IOPS, I/O size, and bandwidth/throughput.

Some applications allow you to alter their I/O size, while some applications don't. For example, SQL Server determines the optimal I/O size itself and doesn't provide users with any knobs to change it. On the other hand, Oracle provides a parameter called DB_BLOCK_SIZE, which you can use to configure the I/O request size of the database.

If you're using an application, which doesn't allow you to change the I/O size, use the guidelines in this article to optimize the performance KPI that's most relevant to your application. For example:

- An OLTP application generates millions of small and random I/O requests. To handle these types of I/O requests, you must design your application infrastructure to get higher IOPS.
- A data warehousing application generates large and sequential I/O requests. To handle these types of I/O requests, you must design your application infrastructure to get higher bandwidth or throughput.

If you're using an application that allows you to change the I/O size, use this rule of thumb for the I/O size in addition to other performance guidelines:

- Smaller I/O size to get higher IOPS. For example, 8 KB for an OLTP application.
- Larger I/O size to get higher bandwidth/throughput. For example, 1,024 KB for a data warehouse application.

Here's an example of how you can calculate the IOPS and throughput/bandwidth for your application.

Consider an application that uses a P30 disk. The maximum IOPS and throughput/bandwidth a P30 disk can achieve is 5,000 IOPS and 200 MB/sec, respectively. If your application requires the maximum IOPS from the P30 disk and you use a smaller I/O size, like 8 KB, the resulting bandwidth you can get is 40 MB/sec. If your application requires the maximum throughput/bandwidth from a P30 disk and you use a larger I/O size, like 1,024 KB, the resulting IOPS is less, such as 200 IOPS.

Tune the I/O size so that it meets both your application's IOPS and throughput/bandwidth requirement. The following table summarizes the different I/O sizes and their corresponding IOPS and throughput for a P30 disk.

Expand table

Application requirement	I/O size	IOPS	Throughput/Bandwidth
Maximum IOPS	8 KB	5,000	40 MB/sec
Maximum throughput	1,024 KB	200	200 MB/sec
Maximum throughput + high IOPS	64 KB	3,200	200 MB/sec
Maximum IOPS + high throughput	32 KB	5,000	160 MB/sec

To get IOPS and bandwidth higher than the maximum value of a single premium storage disk, use multiple premium disks striped together. For example, stripe two P30 disks to get a combined IOPS of 10,000 IOPS or a combined throughput of 400 MB/sec. As explained in the next section, you must use a VM size that supports the combined disk IOPS and throughput.

> **Note**
>
> As you increase either IOPS or throughput, the other also increases. Make sure you don't hit throughput or IOPS limits of the disk or VM when you increase either one.

To witness the effects of I/O size on application performance, you can run benchmarking tools on your VM and disks. Create multiple test runs and use different I/O size for each run to see the effect. For more information, see the benchmarking articles at the end of this document.

High-scale VM sizes

When you start designing an application, one of the first things to do is choose a VM to host your application. Premium storage comes with high-scale VM sizes that can run applications requiring higher compute power and a high local disk I/O performance. These VMs provide faster processors, a higher memory-to-core ratio, and a solid-state drive (SSD) for the local disk. Examples of high-scale VMs supporting premium storage are the DS and GS series VMs.

High-scale VMs are available in different sizes with a different number of CPU cores, memory, OS, and temporary disk size. Each VM size also has a maximum number of data disks that you can attach to the VM. The chosen VM size affects how much processing, memory, and storage capacity are available for your application. It also affects the compute and storage cost. For example, the following specifications are for the largest VM size in a DS series and a GS series.

Expand table

VM size	CPU cores	Memory	VM disk sizes	Maximum data disks	Cache size	IOPS	Bandwidth cache I/O limits
Standard_DS14	16	112 GB	OS = 1,023 GB Local SSD = 224 GB	32	576 GB	50,000 IOPS 512 MB/sec	4,000 IOPS and 33 MB/sec
Standard_GS5	32	448 GB	OS = 1,023 GB Local SSD = 896 GB	64	4224 GB	80,000 IOPS 2,000 MB/sec	5,000 IOPS and 50 MB/sec

To view a complete list of all available Azure VM sizes, see Sizes for virtual machines in Azure. Choose a VM size that can meet and scale to your desired application performance requirements. Also take into account the following important considerations when you choose VM sizes.

Scale limits

The maximum IOPS limits per VM and per disk are different and independent of each other. Make sure that the application is driving IOPS within the limits of the VM and the premium disks attached to it. Otherwise, application performance experiences throttling.

As an example, suppose an application requirement is a maximum of 4,000 IOPS. To achieve this level, you provision a P30 disk on a DS1 VM. The P30 disk can deliver up to 5,000 IOPS. However, the DS1 VM is limited to 3,200 IOPS. So, the application performance is constrained by the VM limit at 3,200 IOPS and performance is degraded. To prevent this situation, choose a VM and disk size that both meet application requirements.

Cost of operation

In many cases, it's possible that your overall cost of operation using premium storage is lower than using standard storage.

For example, consider an application requiring 16,000 IOPS. To achieve this performance, you need a Standard_D14 Azure IaaS VM, which can give a maximum IOPS of 16,000 by using 32 standard storage 1-TB disks. Each 1-TB standard storage disk can achieve a maximum of 500 IOPS.

- The estimated cost of this VM per month is $1,570.
- The monthly cost of 32 standard storage disks is $1,638.
- The estimated total monthly cost is $3,208.

If you hosted the same application on premium storage, you need a smaller VM size and fewer premium storage disks, reducing the overall cost. A Standard_DS13 VM can meet the 16,000 IOPS requirement by using four P30 disks. The DS13 VM has a maximum IOPS of 25,600, and each P30 disk has a maximum IOPS of 5,000. Overall, this configuration can achieve 5,000 x 4 = 20,000 IOPS.

- The estimated cost of this VM per month is $1,003.
- The monthly cost of four P30 premium storage disks is $544.34.
- The estimated total monthly cost is $1,544.

The following table summarizes the cost breakdown of this scenario for standard and premium storage.

Expand table

Monthly cost	Standard	Premium
Cost of VM per month	$1,570.58 (Standard_D14)	$1,003.66 (Standard_DS13)
Cost of disks per month	$1,638.40 (32 x 1-TB disks)	$544.34 (4 x P30 disks)
Overall cost per month	$3,208.98	$1,544.34

Linux distros

With premium storage, you get the same level of performance for VMs running Windows and Linux. We support many flavors of Linux distros. For more information, see Linux distributions endorsed on Azure.

Different distros are better suited for different types of workloads. You see different levels of performance depending on the distro on which your workload is running. Test the Linux distros with your application and choose the one that works best.

When you run Linux with premium storage, check the latest updates about required drivers to ensure high performance.

Premium storage disk sizes

Premium storage offers various sizes so you can choose one that best suits your needs. Each disk size has a different scale limit for IOPS, bandwidth, and storage. Choose the right premium storage disk size depending on the application requirements and the high-scale VM size. The following table shows the disks sizes and their capabilities. P4, P6, P15, P60, P70, and P80 sizes are currently only supported for managed disks.

Expand table

Premium SSD sizes	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80

*Applies only to disks with on-demand bursting enabled.
** Only applies to disks with performance plus (preview) enabled.

How many disks you choose depends on the disk size chosen. You could use a single P50 disk or multiple P10 disks to meet your application requirement. Take into account considerations listed here when you're making the choice.

Scale limits (IOPS and throughput)

The IOPS and throughput limits of each premium disk size is different and independent from the VM scale limits. Make sure that the total IOPS and throughput from the disks are within scale limits of the chosen VM size.

For example, if an application requirement is a maximum of 250 MB/sec throughput and you're using a DS4 VM with a single P30 disk, the DS4 VM can give up to 256 MB/sec throughput. However, a single P30 disk has a throughput limit of 200 MB/sec. So, the application is constrained at 200 MB/sec because of the disk limit. To overcome this limit, provision more than one data disk to the VM or resize your disks to P40 or P50.

> ⓘ **Note**
>
> Reads served by the cache aren't included in the disk IOPS and throughput, so they aren't subject to disk limits. Cache has its separate IOPS and throughput limit per VM.
>
> For example, initially your reads and writes are 60 MB/sec and 40 MB/sec, respectively. Over time, the cache warms up and serves more and more of the reads from the cache. Then, you can get higher write throughput from the disk.

Number of disks

Determine the number of disks you need by assessing application requirements. Each VM size also has a limit on the number of disks that you can attach to the VM. Typically, this amount is twice the number of cores. Ensure that the VM size you choose can support the number of disks needed.

Remember, the premium storage disks have higher performance capabilities compared to standard storage disks. If you're migrating your application from an Azure IaaS VM using standard storage to premium storage, you likely need fewer premium disks to achieve the same or higher performance for your application.

Disk caching

High-scale VMs that use premium storage have a multitier caching technology called **BlobCache**. **BlobCache** uses a combination of the host RAM and local SSD for caching. This cache is available for the premium storage persistent disks and the VM local disks. By default, this cache setting is set to **ReadWrite** for OS disks and **ReadOnly** for data disks hosted on premium storage. With disk caching enabled on the premium storage disks, the high-scale VMs can achieve extremely high levels of performance that exceed the underlying disk performance.

> ⚠ **Warning**

Disk caching isn't supported for disks 4 TiB and larger. If multiple disks are attached to your VM, each disk that's smaller than 4 TiB supports caching.

Changing the cache setting of an Azure disk detaches and reattaches the target disk. If it's the operating system disk, the VM is restarted. Stop all applications and services that might be affected by this disruption before you change the disk cache setting. Not following those recommendations could lead to data corruption.

To learn more about how **BlobCache** works, see the Inside Azure premium storage blog post.

It's important to enable caching on the right set of disks. Whether you should enable disk caching on a premium disk or not depends on the workload pattern that disk is handling. The following table shows the default cache settings for OS and data disks.

Expand table

Disk type	Default cache setting
OS disk	ReadWrite
Data disk	ReadOnly

We recommend the following disk cache settings for data disks.

Expand table

Disk caching setting	Recommendation for when to use this setting
None	Configure host-cache as **None** for write-only and write-heavy disks.
ReadOnly	Configure host-cache as **ReadOnly** for read-only and read-write disks.
ReadWrite	Configure host-cache as **ReadWrite** only if your application properly handles writing cached data to persistent disks when needed.

ReadOnly

By configuring **ReadOnly** caching on premium storage data disks, you can achieve low read latency and get very high read IOPS and throughput for your application for two reasons:

1. Reads performed from cache, which is on the VM memory and local SSD, are faster than reads from the data disk, which is on Azure Blob Storage.
2. Premium storage doesn't count the reads served from the cache toward the disk IOPS and throughput. For this reason, your application can achieve higher total IOPS and throughput.

ReadWrite

By default, the OS disks have **ReadWrite** caching enabled. We recently added support for **ReadWrite** caching on data disks too. If you're using **ReadWrite** caching, you must have a proper way to write the data from cache to persistent disks. For example, SQL Server handles writing cached data to the persistent storage disks on its own. Using **ReadWrite** cache with an application that doesn't handle persisting the required data can lead to data loss, if the VM crashes.

None

Currently, **None** is only supported on data disks. It isn't supported on OS disks. If you set **None** on an OS disk, it overrides this setting internally and sets it to **ReadOnly**.

As an example, you can apply these guidelines to SQL Server running on premium storage by following these steps:

1. Configure the **ReadOnly** cache on premium storage disks hosting data files.
    a. The fast reads from cache lower the SQL Server query time because data pages are retrieved faster from the cache compared to directly from the data disks.

   b. Serving reads from cache means there's more throughput available from premium data disks. SQL Server can use this extra throughput toward retrieving more data pages and other operations like backup/restore, batch loads, and index rebuilds.
2. Configure the **None** cache on premium storage disks hosting the log files.
   a. Log files have primarily write-heavy operations, so they don't benefit from the **ReadOnly** cache.

Optimize performance on Linux VMs

For all Premium SSDs or Ultra Disks, you might be able to disable *barriers* for file systems on the disk to improve performance when it's known that there are no caches that could lose data. If Azure disk caching is set to **ReadOnly** or **None**, you can disable barriers. But if caching is set to **ReadWrite**, barriers should remain enabled to ensure write durability. Barriers are typically enabled by default, but you can disable barriers by using one of the following methods depending on the file system type:

- **reiserFS**: Use the **barrier=none** mount option to disable barriers. To explicitly enable barriers, use **barrier=flush**.
- **ext3/ext4**: Use the **barrier=0** mount option to disable barriers. To explicitly enable barriers, use **barrier=1**.
- **XFS**: Use the **nobarrier** mount option to disable barriers. To explicitly enable barriers, use **barrier**. As of version 4.10 of the mainline Linux kernel, the design of the XFS file system always ensures durability. Disabling barriers has no effect and the **nobarrier** option is deprecated. However, some Linux distributions might have backported the changes to a distribution release with an earlier kernel version. Check with your distribution vendor for the status in the distribution and version that you're running.

Disk striping

When a high-scale VM is attached with several premium storage persistent disks, the disks can be striped together to aggregate their IOPs, bandwidth, and storage capacity.

On Windows, you can use Storage Spaces to stripe disks together. You must configure one column for each disk in a pool. Otherwise, the overall performance of striped volume can be lower than expected because of uneven distribution of traffic across the disks.

By using the Server Manager UI, you can set the total number of columns up to `8` for a striped volume. When you're attaching more than eight disks, use PowerShell to create the volume. By using PowerShell, you can set the number of columns equal to the number of disks. For example, if there are 16 disks in a single stripe set, specify `16` columns in the `NumberOfColumns` parameter of the `New-VirtualDisk` PowerShell cmdlet.

On Linux, use the MDADM utility to stripe disks together. For steps on how to stripe disks on Linux, see Configure Software RAID on Linux.

Stripe size

An important configuration in disk striping is the stripe size. The stripe size or block size is the smallest chunk of data that an application can address on a striped volume. The stripe size you configure depends on the type of application and its request pattern. If you choose the wrong stripe size, it could lead to I/O misalignment, which leads to degraded performance of your application.

For example, if an I/O request generated by your application is bigger than the disk stripe size, the storage system writes it across stripe unit boundaries on more than one disk. When it's time to access that data, it has to seek across more than one stripe unit to complete the request. The cumulative effect of such behavior can lead to substantial performance degradation. On the other hand, if the I/O request size is smaller than the stripe size, and if it's random in nature, the I/O requests might add up on the same disk, causing a bottleneck and ultimately degrading the I/O performance.

Depending on the type of workload your application is running, choose an appropriate stripe size. For random small I/O requests, use a smaller stripe size. For large sequential I/O requests, use a larger stripe size. Find out the stripe size recommendations for the application you'll be running on premium storage. For SQL Server, configure a stripe size of 64 KB for OLTP workloads and 256 KB for data warehousing workloads. For more information, see Performance best practices for SQL Server on Azure VMs.

> ⓘ **Note**

You can stripe together a maximum of 32 premium storage disks on a DS series VM and 64 premium storage disks on a GS series VM.

Multithreading

Azure designed the premium storage platform to be massively parallel. For this reason, a multithreaded application achieves higher performance than a single-threaded application. A multithreaded application splits up its tasks across multiple threads and increases efficiency of its execution by utilizing the VM and disk resources to the maximum.

For example, if your application is running on a single core VM using two threads, the CPU can switch between the two threads to achieve efficiency. While one thread is waiting on a disk I/O to complete, the CPU can switch to the other thread. In this way, two threads can accomplish more than a single thread would. If the VM has more than one core, it further decreases running time because each core can run tasks in parallel.

You might not be able to change the way an off-the-shelf application implements single threading or multithreading. For example, SQL Server is capable of handling multi-CPU and multicore. However, SQL Server decides under what conditions it uses one or more threads to process a query. It can run queries and build indexes by using multithreading. For a query that involves joining large tables and sorting data before returning to the user, SQL Server likely uses multiple threads. A user can't control whether SQL Server runs a query by using a single thread or multiple threads.

There are configuration settings that you can alter to influence the multithreading or parallel processing of an application. For example, for SQL Server it's the `max degree of parallelism` configuration. This setting called MAXDOP allows you to configure the maximum number of processors SQL Server can use when parallel processing. You can configure MAXDOP for individual queries or index operations. This capability is beneficial when you want to balance resources of your system for a performance critical application.

For example, say your application that's using SQL Server is running a large query and an index operation at the same time. Let's assume that you wanted the index operation to be more performant compared to the large query. In such a case, you can set the MAXDOP value of the index operation to be higher than the MAXDOP value for the query. This way, SQL Server has more processors than it can use for the index operation compared to the number of processors it can dedicate to the large query. Remember, you don't control the number of threads that SQL Server uses for each operation. You can control the maximum number of processors being dedicated for multithreading.

Learn more about degrees of parallelism in SQL Server. Find out how such settings influence multithreading in your application and their configurations to optimize performance.

Queue depth

The queue depth or queue length or queue size is the number of pending I/O requests in the system. The value of queue depth determines how many I/O operations your application can line up, which the storage disks process. It affects all three application performance indicators discussed in this article: IOPS, throughput, and latency.

Queue depth and multithreading are closely related. The queue depth value indicates how much multithreading can be achieved by the application. If the queue depth is large, the application can run more operations concurrently, in other words, more multithreading. If the queue depth is small, even though the application is multithreaded, it won't have enough requests lined up for concurrent execution.

Typically, off-the-shelf applications don't allow you to change queue depth, because if it's set incorrectly, it does more harm than good. Applications set the right value of queue depth to get the optimal performance. It's important to understand this concept so that you can troubleshoot performance issues with your application. You can also observe the effects of queue depth by running benchmarking tools on your system.

Some applications provide settings to influence the queue depth. For example, the MAXDOP setting in SQL Server explained in the previous section. MAXDOP is a way to influence queue depth and multithreading, although it doesn't directly change the queue depth value of SQL Server.

High queue depth

A high queue depth lines up more operations on the disk. The disk knows the next request in its queue ahead of time. So, the disk can schedule operations ahead of time and process them in an optimal sequence. Because the application is sending more requests to the disk, the disk can process more parallel I/Os. Ultimately, the application can achieve higher IOPS. Because the application is processing more requests, the total throughput of the application also increases.

Typically, an application can achieve maximum throughput with 8 to 16+ outstanding I/Os per attached disk. If a queue depth is one, the application isn't pushing enough I/Os to the system, and it processes a smaller amount in a given period. In other words, less throughput.

For example, in SQL Server, setting the MAXDOP value for a query to `4` informs SQL Server that it can use up to four cores to run the query. SQL Server determines the best queue depth value and the number of cores for the query execution.

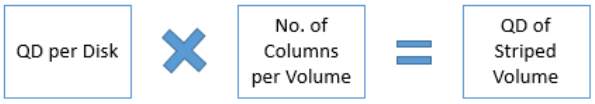
Optimal queue depth

A very high queue depth value also has its drawbacks. If the queue depth value is too high, the application tries to drive very high IOPS. Unless the application has persistent disks with sufficient provisioned IOPS, a very high queue depth value can negatively affect application latencies. The following formula shows the relationship between IOPS, latency, and queue depth.

You shouldn't configure queue depth to any high value, but to an optimal value, which can deliver enough IOPS for the application without affecting latencies. For example, if the application latency needs to be 1 millisecond, the queue depth required to achieve 5,000 IOPS is QD = 5,000 x 0.001 = 5.

Queue depth for striped volume

For a striped volume, maintain a high-enough queue depth so that every disk has a peak queue depth individually. For example, consider an application that pushes a queue depth of `2` and there are four disks in the stripe. The two I/O requests go to two disks and the remaining two disks are idle. Therefore, configure the queue depth so that all the disks can be busy. The following formula shows how to determine the queue depth of striped volumes.



Throttling

Premium storage provisions a specified number of IOPS and throughput depending on the VM sizes and disk sizes you choose. Anytime your application tries to drive IOPS or throughput above these limits of what the VM or disk can handle, premium storage throttles it. The result is degraded performance in your application, which can mean higher latency, lower throughput, or lower IOPS.

If premium storage doesn't throttle, your application could completely fail by exceeding what its resources are capable of achieving. To avoid performance issues because of throttling, always provision sufficient resources for your application. Take into consideration what we discussed in the previous VM sizes and disk sizes sections. Benchmarking is the best way to figure out what resources you need to host your application.

Disk performance metrics

Article • 08/29/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure offers metrics in the Azure portal that provide insight on how your virtual machines (VM) and disks perform. The metrics can also be retrieved through an API call. This article is broken into 3 subsections:

- **Disk IO, throughput, queue depth and latency metrics** - These metrics allow you to see the storage performance from the perspective of a disk and a virtual machine.
- **Disk bursting metrics** - These are the metrics provide observability into our bursting feature on our premium disks.
- **Storage IO utilization metrics** - These metrics help diagnose bottlenecks in your storage performance with disks.

All metrics are emitted every minute, except for the bursting credit percentage metric, which is emitted every 5 minutes.

Disk IO, throughput, queue depth and latency metrics

The following metrics are available to get insight on VM and disk IO, throughput, and queue depth performance:

- **OS Disk Latency (Preview)**: The average time to complete IOs during the monitoring for the OS disk. Metric is only available for disks attached to VMs using SCSI disk controller and not with disk attached to VMs using the NVMe disk controller. Values are in milliseconds.
- **OS Disk Queue Depth**: The number of current outstanding IO requests that are waiting to be read from or written to the OS disk.
- **OS Disk Read Bytes/Sec**: The number of bytes that are read in a second from the OS disk. If Read-only or Read/write disk caching is enabled, this metric is inclusive of bytes read from the cache.
- **OS Disk Read Operations/Sec**: The number of input operations that are read in a second from the OS disk. If Read-only or Read/write disk caching is enabled, this metric is inclusive of IOPs read from the cache.

- **OS Disk Write Bytes/Sec**: The number of bytes that are written in a second from the OS disk.
- **OS Disk Write Operations/Sec**: The number of output operations that are written in a second from the OS disk.
- **Data Disk Latency (Preview)**: The average time to complete IOs during the monitoring for the data disk. Metric is only available for disks attached to VMs using SCSI disk controller and not with disk attached to VMs using the NVMe disk controller. Values are in milliseconds.
- **Data Disk Queue Depth**: The number of current outstanding IO requests that are waiting to be read from or written to the data disk(s).
- **Data Disk Read Bytes/Sec**: The number of bytes that are read in a second from the data disk(s). If Read-only or Read/write disk caching is enabled, this metric is inclusive of bytes read from the cache.
- **Data Disk Read Operations/Sec**: The number of input operations that are read in a second from data disk(s). If Read-only or Read/write disk caching is enabled, this metric is inclusive of IOPs read from the cache.
- **Data Disk Write Bytes/Sec**: The number of bytes that are written in a second from the data disk(s).
- **Data Disk Write Operations/Sec**: The number of output operations that are written in a second from data disk(s).
- **Disk Read Bytes**: The number of total bytes that are read in a minute from all disks attached to a VM. If Read-only or Read/write disk caching is enabled, this metric is inclusive of bytes read from the cache.
- **Disk Read Operations/Sec**: The number of input operations that are read in a second from all disks attached to a VM. If Read-only or Read/write disk caching is enabled, this metric is inclusive of IOPs read from the cache.
- **Disk Write Bytes**: The number of bytes that are written in a minute from all disks attached to a VM.
- **Disk Write Operations/Sec**: The number of output operations that are written in a second from all disks attached to a VM.
- **Temp Disk Latency (Preview)**: The average time to complete IOs during the monitoring for the temporary disk. This metric is not available for NVMe temporary storage disks. Values are in milliseconds.
- **Temp Disk Queue Depth**: The number of current outstanding IO requests that are waiting to be read from or written to the temporary disk. This metric is not available for NVMe temporary storage disks.
- **Temp Disk Read Bytes/Sec**: The number of bytes that are read in a second from the temporary disk. This metric is not available for NVMe temporary storage disks.
- **Temp Disk Read Operations/Sec**: The number of input operations that are read in a second from the temporary disk. This metric is not available for NVMe temporary storage disks.

- **Temp Disk Write Bytes/Sec**: The number of bytes that are written in a second from the temporary disk. This metric is not available for NVMe temporary storage disks.
- **Temp Disk Write Operations/Sec**: The number of output operations that are written in a second from the temporary disk. This metric is not available for NVMe temporary storage disks.

> ⓘ **Note**
>
> Disk metrics can't log CRUD (Create, Read, Update, Delete) operations inside managed disks.

Bursting metrics

The following metrics help with observability into our bursting feature on our premium disks:

- **Data Disk Max Burst Bandwidth**: The throughput limit that the data disk(s) can burst up to.
- **OS Disk Max Burst Bandwidth**: The throughput limit that the OS disk can burst up to.
- **Data Disk Max Burst IOPS**: the IOPS limit that the data disk(s) can burst up to.
- **OS Disk Max Burst IOPS**: The IOPS limit that the OS disk can burst up to.
- **Data Disk Target Bandwidth**: The throughput limit that the data(s) disk can achieve without bursting.
- **OS Disk Target Bandwidth**: The throughput limit that the OS disk can achieve without bursting.
- **Data Disk Target IOPS**: The IOPS limit that the data disk(s) can achieve without bursting.
- **OS Disk Target IOPS**: The IOPS limit that the data disk(s) can achieve without bursting.
- **Data Disk Used Burst BPS Credits Percentage**: The accumulated percentage of the throughput burst used for the data disk(s). Emitted on a 5 minute interval.
- **OS Disk Used Burst BPS Credits Percentage**: The accumulated percentage of the throughput burst used for the OS disk. Emitted on a 5 minute interval.
- **Data Disk Used Burst IO Credits Percentage**: The accumulated percentage of the IOPS burst used for the data disk(s). Emitted on a 5 minute interval.
- **OS Disk Used Burst IO Credits Percentage**: The accumulated percentage of the IOPS burst used for the OS disk. Emitted on a 5 minute interval.
- **Disk On-demand Burst Operations**: The accumulated operations of burst transactions used for disks with on-demand bursting enabled. Emitted on an hour

interval.

VM Bursting metrics

The following metrics provide insight on VM-level bursting:

- **VM Uncached Used Burst IO Credits Percentage**: The accumulated percentage of the VM's uncached IOPS burst used. Emitted on a 5 minute interval.
- **VM Uncached Used Burst BPS Credits Percentage**: The accumulated percentage of the VM's uncached throughput burst used. Emitted on a 5 minute interval.
- **VM Cached Used Burst IO Credits Percentage**: The accumulated percentage of the VM's cached IOPS burst used. Emitted on a 5 minute interval.
- **VM Cached Used Burst BPS Credits Percentage**: The accumulated percentage of the VM's cached throughput burst used. Emitted on a 5 minute interval.

Storage IO utilization metrics

The following metrics help diagnose bottleneck in your Virtual Machine and Disk combination. These metrics are only available on VM series that support premium storage.

Metrics that help diagnose disk IO capping:

- **Data Disk IOPS Consumed Percentage**: The percentage calculated by dividing the actual data disk IOPS completed by the provisioned data disk IOPS. If this amount is at 100%, your application running is IO capped from your data disk's IOPS limit.
- **Data Disk Bandwidth Consumed Percentage**: The percentage calculated by dividing the actual data disk throughput completed by the provisioned data disk throughput. If this amount is at 100%, your application running is IO capped from your data disk's bandwidth limit.
- **OS Disk IOPS Consumed Percentage**: The percentage calculated by dividing the actual OS disk IOPS completed by the provisioned OS disk IOPS. If this amount is at 100%, your application running is IO capped from your OS disk's IOPS limit.
- **OS Disk Bandwidth Consumed Percentage**: The percentage calculated by dividing the actual OS disk throughput completed by the provisioned OS disk throughput. If this amount is at 100%, your application running is IO capped from your OS disk's bandwidth limit.

Metrics that help diagnose VM IO capping:

- **VM Cached IOPS Consumed Percentage**: The percentage calculated by dividing the total actual cached IOPS completed by the max cached virtual machine IOPS

limit. If this amount is at 100%, your application running is IO capped from your VM's cached IOPS limit.

- **VM Cached Bandwidth Consumed Percentage**: The percentage calculated by dividing the total actual cached throughput completed by the max cached virtual machine throughput. If this amount is at 100%, your application running is IO capped from your VM's cached bandwidth limit.
- **VM uncached IOPS Consumed Percentage**: The percentage calculated by dividing the total actual uncached IOPS on a virtual machine completed by the max uncached virtual machine IOPS limit. If this amount is at 100%, your application running is IO capped from your VM's uncached IOPS limit.
- **VM Uncached Bandwidth Consumed Percentage**: The percentage calculated by dividing the total actual uncached throughput on a virtual machine completed over the max provisioned virtual machine throughput. If this amount is at 100%, your application running is IO capped from your VM's uncached bandwidth limit.

Storage IO metrics example

Let's run through an example of how to use these new Storage IO utilization metrics to help us debug where a bottleneck is in our system. The system setup is the same as the previous example, except this time the attached OS disk is *not* cached.

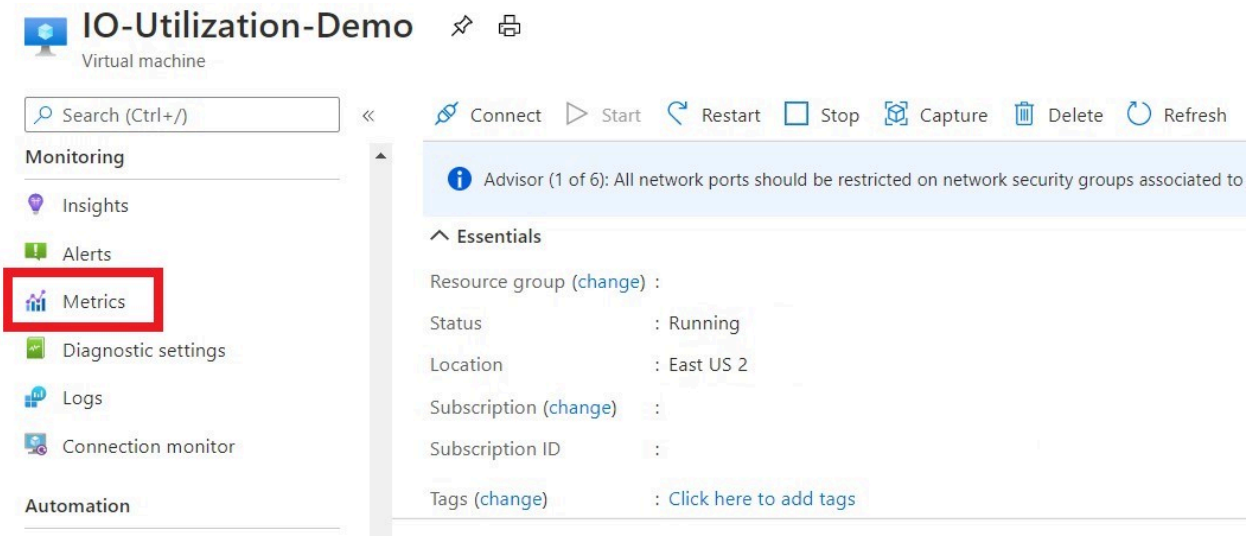
Setup:

- Standard_D8s_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
  - Host caching: **Disabled**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Disabled**

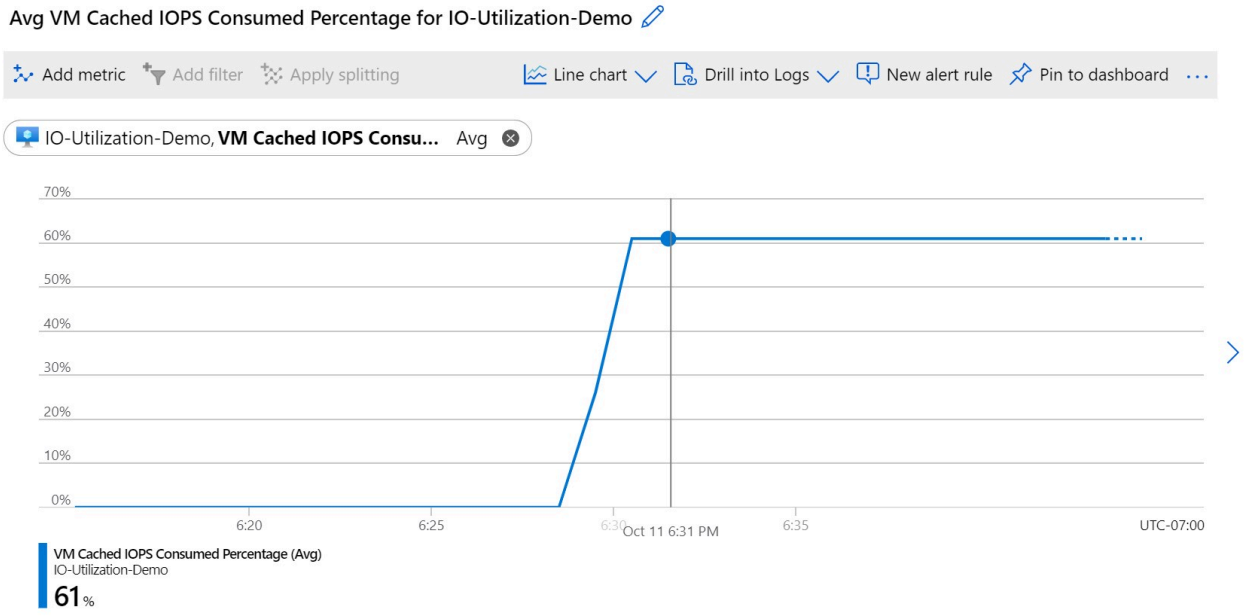
Let's run a benchmarking test on this virtual machine and disk combination that creates IO activity. To learn how to benchmark storage IO on Azure, see Benchmark your application on Azure Disk Storage. From the benchmarking tool, you can see that the VM and disk combination can achieve 22,800 IOPS:

```
demouser@IO-Utilization-Demo:~$ sudo fio fioread.ini
reader1: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader3: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader5: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader10: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader12: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
fio-3.1
Starting 5 processes
Jobs: 5 (f=5), 0-22800 IOPS: [r(5)][0.4%][r=178MiB/s,w=0KiB/s] [r=22.8k,w=0 IOPS][eta 27m:06s]
```

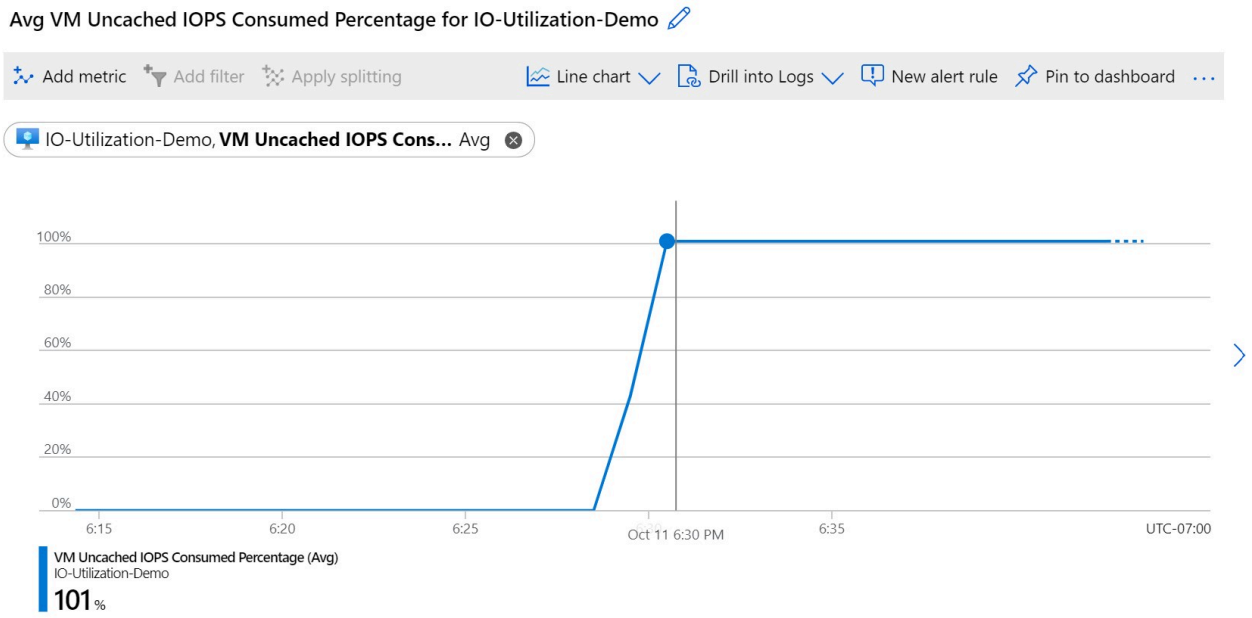
The Standard_D8s_v3 can achieve a total of 28,600 IOPS. Using the metrics, let's investigate what's going on and identify our storage IO bottleneck. On the left pane, select **Metrics**:



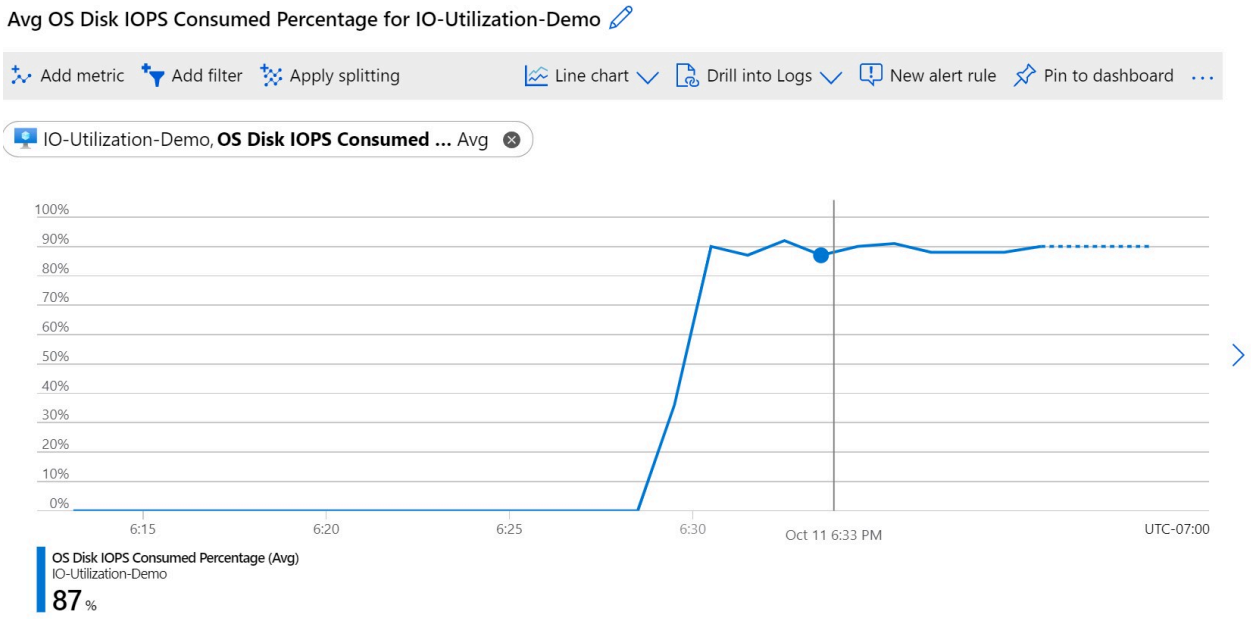
Let's first take a look at our **VM Cached IOPS Consumed Percentage** metric:



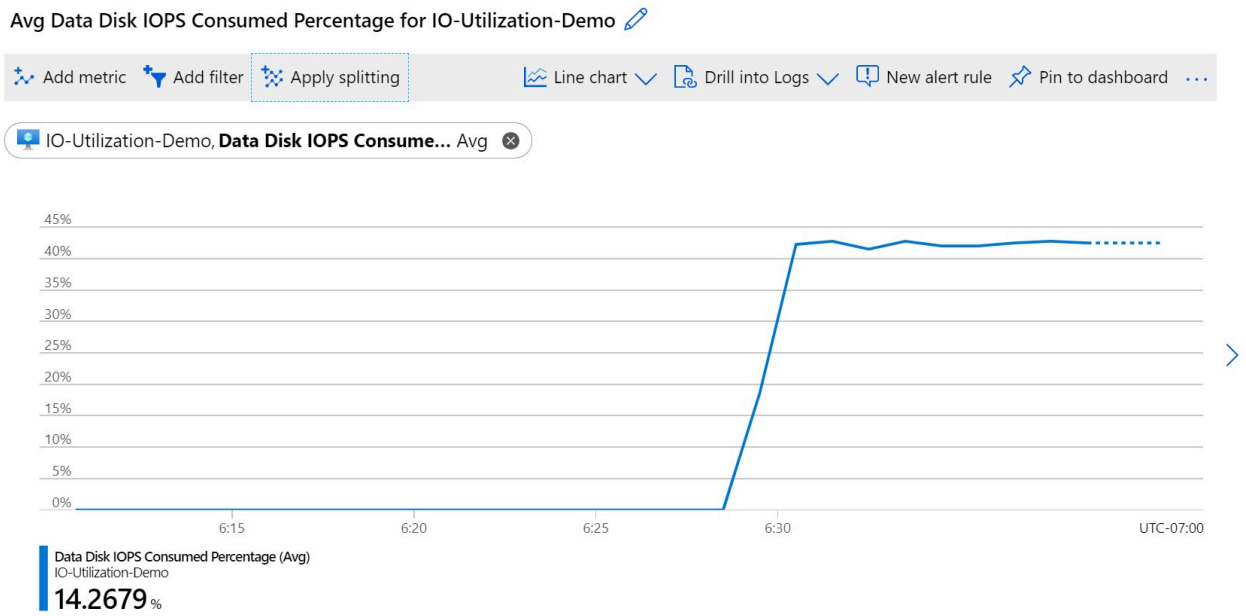
This metric tells us that 61% of the 16,000 IOPS allotted to the cached IOPS on the VM is being used. This percentage means that the storage IO bottleneck isn't with the disks that are cached because it isn't at 100%. Now let's look at our **VM Uncached IOPS Consumed Percentage** metric:



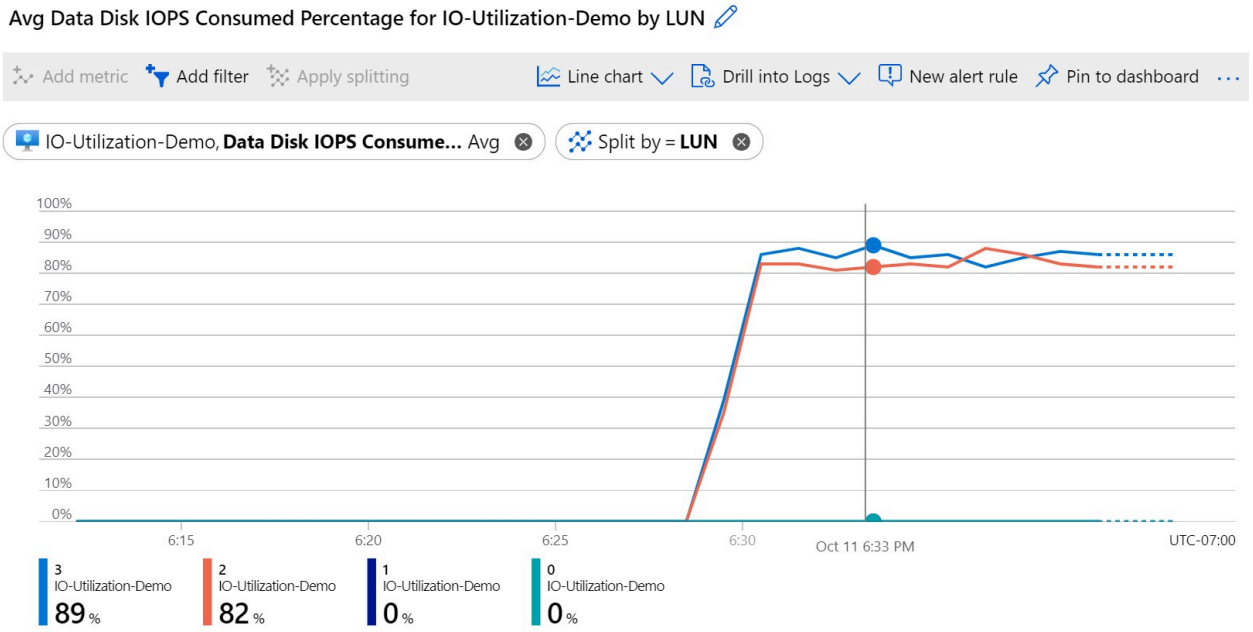
This metric is at 100%. It tells us that all of the 12,800 IOPS allotted to the uncached IOPS on the VM are being used. One way we can remediate this issue is to change the size of our VM to a larger size that can handle the additional IO. But before we do that, let's look at the attached disk to find out how many IOPS they are seeing. Check the OS Disk by looking at the **OS Disk IOPS Consumed Percentage**:



This metric tells us that around 90% of the 5,000 IOPS provisioned for this P30 OS disk is being used. This percentage means there's no bottleneck at the OS disk. Now let's check the data disks that are attached to the VM by looking at the **Data Disk IOPS Consumed Percentage**:



This metric tells us that the average IOPS consumed percentage across all the disks attached is around 42%. This percentage is calculated based on the IOPS that are used by the disks, and aren't being served from the host cache. Let's drill deeper into this metric by applying *splitting* on these metrics and splitting by the LUN value:



This metric tells us the data disks attached on LUN 3 and 2 are using around 85% of their provisioned IOPS. Here is a diagram of what the IO looks like from the VM and disks architecture:

Managed disk bursting

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure offers the ability to boost disk storage IOPS and MB/s performance, this is referred to as bursting for both virtual machines (VM) and disks. You can effectively use VM and disk bursting to achieve better bursting performance on both your VMs and disk.

Bursting for Azure VMs and disk resources aren't dependent on each other. You don't need a burst-capable VM for an attached burst-capable disk to burst. Similarly, you don't need a burst-capable disk attached to your burst-capable VM for the VM to burst.

Common scenarios

The following scenarios can benefit greatly from bursting:

- **Improve startup times** – With bursting, your instance starts up faster. For example, the default OS disk for premium enabled VMs is the P4 disk, which is a provisioned performance of up to 120 IOPS and 25 MB/s. With bursting, the P4 can go up to 3,500 IOPS and 170 MB/s, so startup accelerates by up to 6x.
- **Handle batch jobs** – Some application workloads are cyclical in nature. They require a baseline performance most of the time, and higher performance for short periods of time. An example of this nature is an accounting program that processes daily transactions that require a small amount of disk traffic. At the end of the month, this program completes reconciling reports that need a much higher amount of disk traffic.
- **Traffic spikes** – Web servers and their applications can experience traffic surges at any time. If your web server is backed by VMs or disks that use bursting, the servers are better equipped to handle traffic spikes.

Disk-level bursting

Currently, two managed disk types support bursting: Premium SSD managed disks and Standard SSDs. Other disk types don't support bursting. There are two models of bursting for disks:

- An on-demand bursting model, where the disk bursts whenever its needs exceed its current capacity. This model incurs extra charges anytime the disk bursts. On-demand bursting is only available for Premium SSDs larger than 512 GiB.

- A credit-based model, where the disk bursts only if it has burst credits accumulated in its credit bucket. This model doesn't incur extra charges when the disk bursts. Credit-based bursting operates on a best effort basis and isn't guaranteed. Credit-based bursting is only available for Premium SSD managed disks 512 GiB and smaller, and Standard SSDs 1,024 GiB and smaller.

Azure Premium SSD managed disks can use either bursting model, but Standard SSDs currently only offer credit-based bursting.

You can also change the performance tier of managed disks, which could be ideal if your workload would otherwise be running in burst.

Expand table

	Credit-based bursting	On-demand bursting	Changing performance tier
Scenarios	Ideal for short-term scaling (30 minutes or less).	Ideal for short-term scaling(Not time restricted).	Ideal if your workload would otherwise continually be running in burst.
Cost	Free	Cost is variable, see the Billing section for details.	The cost of each performance tier is fixed, see managed disk pricing for details.
Availability	Only available for Premium SSD managed disks 512 GiB and smaller, and Standard SSDs 1,024 GiB and smaller.	Only available for Premium SSD managed disks larger than 512 GiB.	Available to all Premium SSD sizes.
Enablement	Enabled by default on eligible disks.	Must be enabled by user.	User must manually change their tier.

On-demand bursting

Premium SSD managed disks using the on-demand bursting model of disk bursting can burst beyond original provisioned targets, as often as needed by their workload, up to the max burst target. For example, on a 1-TiB P30 disk, the provisioned IOPS is 5000 IOPS. When disk bursting is enabled on this disk, your workloads can issue IOs to this disk up to the max burst performance of 30,000 IOPS and 1,000 MBps. For the max burst targets on each supported disk, see Scalability and performance targets for VM disks.

If you expect your workloads to frequently run beyond the provisioned perf target, disk bursting won't be cost-effective. In this case, we recommend that you change your disk's

performance tier to a higher tier instead, for better baseline performance. Review your billing details and assess that against the traffic pattern of your workloads.

Before you enable on-demand bursting, understand the following:

- On-demand bursting cannot be enabled on a Premium SSD that has less than or equal to 512 GiB. Premium SSDs less than or equal to 512 GiB will always use credit-based bursting.
- On-demand bursting is only supported on Premium SSDs. If a Premium SSD with on-demand bursting enabled is switched to another disk type, then disk bursting is disabled.
- On-demand bursting doesn't automatically disable itself when the performance tier is changed. If you want to change your performance tier but do not want to keep disk bursting, you must disable it.
- On-demand bursting can only be enabled when the disk is detached from a VM or when the VM is stopped. On-demand bursting can be disabled 12 hours after it has been enabled.

Billing

Premium SSD managed disks using the on-demand bursting model are charged an hourly burst enablement flat fee and transaction costs apply to any burst transactions beyond the provisioned target. Transaction costs are charged using the pay-as-you go model, based on uncached disk IOs, including both reads and writes that exceed provisioned targets. The following is an example of disk traffic patterns over a billing hour:

Disk configuration: Premium SSD – 1 TiB (P30), Disk bursting enabled.

- 00:00:00 – 00:10:00 Disk IOPS below provisioned target of 5,000 IOPS
- 00:10:01 – 00:10:10 Application issued a batch job causing the disk IOPS to burst at 6,000 IOPS for 10 seconds
- 00:10:11 – 00:59:00 Disk IOPS below provisioned target of 5,000 IOPS
- 00:59:01 – 01:00:00 Application issued another batch job causing the disk IOPS to burst at 7,000 IOPS for 60 seconds

In this billing hour, the cost of bursting consists of two charges:

The first charge is the burst enablement flat fee of $X (determined by your region). This flat fee is always charged on the disk disregard of the attach status until it's disabled.

Second is the burst transaction cost. Disk bursting occurred in two time slots. From 00:10:01 – 00:10:10, the accumulated burst transaction is (6,000 – 5,000) X 10 = 10,000. From 00:59:01 –

01:00:00, the accumulated burst transaction is (7,000 – 5,000) X 60 = 120,000. The total burst transactions are 10,000 + 120,000 = 130,000. Burst transaction cost is charged at $Y based on 13 units of 10,000 transactions (based on regional pricing).

With that, the total cost on disk bursting of this billing hour equals to $X + $Y. The same calculation would apply for bursting over provisioned target of MBps. We translate the overage of MB to transactions with IO size of 256 KB. If your disk traffic exceed both provisioned IOPS and MBps target, you can refer to the example below to calculate the burst transactions.

Disk configuration: Premium SSD – 1 TB (P30), Disk bursting enabled.

- 00:00:01 – 00:00:05 Application issued a batch job causing the disk IOPS to burst at 10,000 IOPS and 300 MBps for five seconds.
- 00:00:06 – 00:00:10 Application issued a recovery job causing the disk IOPS to burst at 6,000 IOPS and 600 MBps for five seconds.

The burst transaction is accounted as the max number of transactions from either IOPS or MBps bursting. From 00:00:01 – 00:00:05, the accumulated burst transaction is Max((10,000 – 5,000), (300 - 200) * 1024 / 256)) * 5 = 25,000 transactions. From 00:00:06 – 00:00:10, the accumulated burst transaction is Max((6,000 – 5,000), (600 - 200) * 1024 / 256)) * 5 = 8,000 transactions. On top of that, you include the burst enablement flat fee to get the total cost for enabling on-demand based disk bursting.

You can refer to the managed disks pricing page for details on pricing and use Azure Pricing Calculator to make the assessment for your workload.

To enable on-demand bursting, see Enable on-demand bursting.

Credit-based bursting

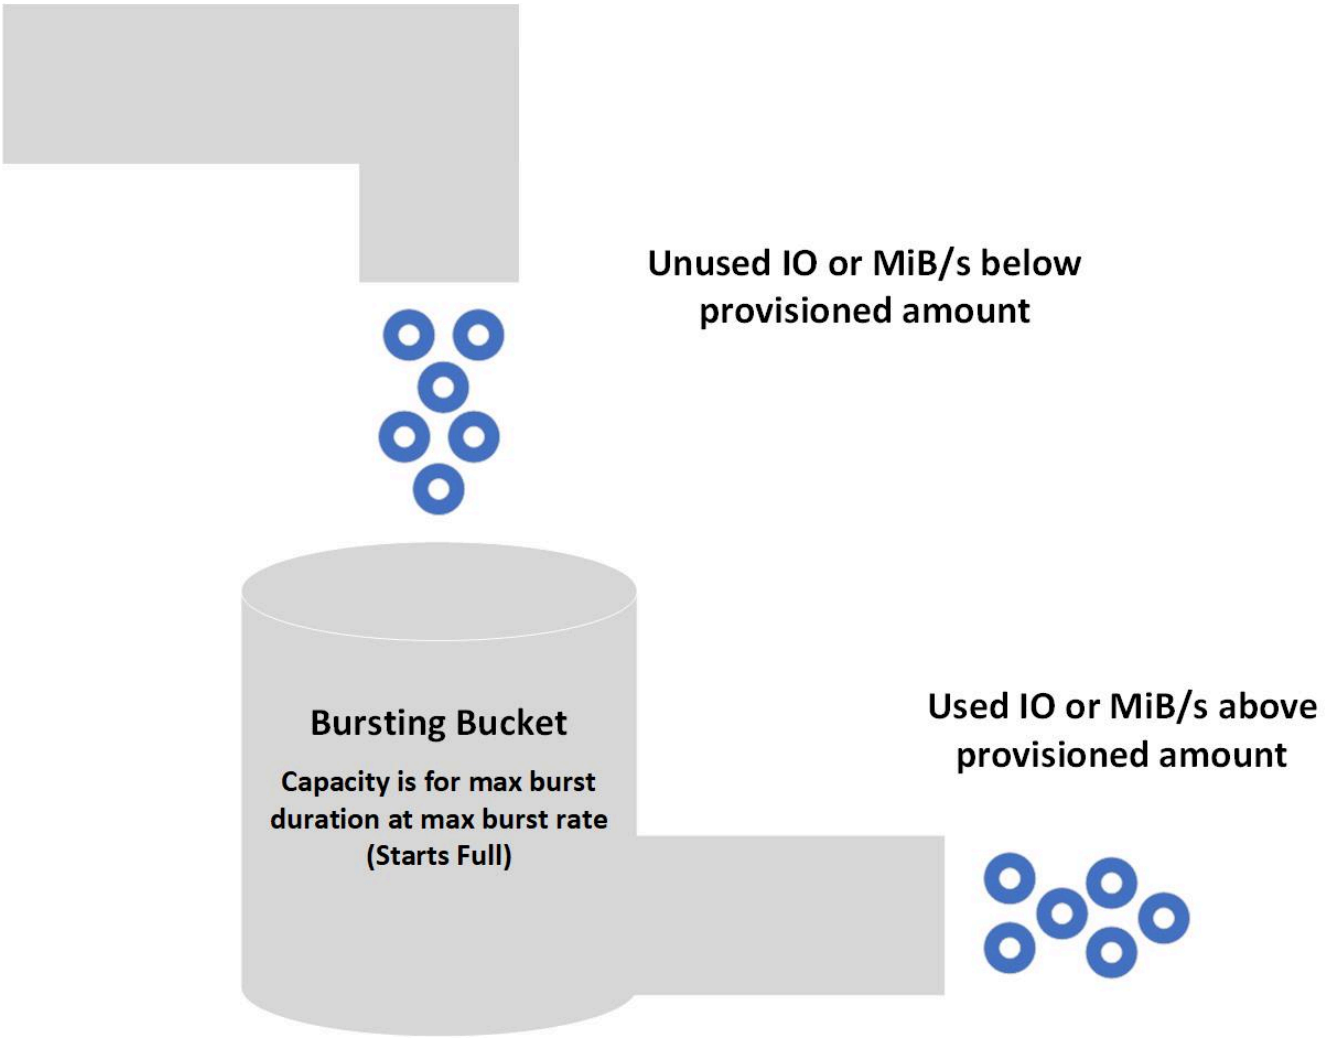
For Premium SSD managed disks, credit-based bursting is available for disk sizes P20 and smaller. For Standard SSDs, credit-based bursting is available for disk sizes E30 and smaller. For both standard and Premium SSD managed disks, credit-based bursting is available in all regions in Azure Public, Government, and China Clouds. By default, disk bursting is enabled on all new and existing deployments of supported disk sizes. VM-level bursting only uses credit-based bursting.

Virtual machine-level bursting

VM-level bursting only uses the credit-based model for bursting, it's enabled by default for most Premium Storage supported VMs.

Bursting flow

The bursting credit system applies in the same manner at both the VM level and disk level. Your resource, either a VM or disk, will start with fully stocked credits in its own burst bucket. These credits allow you to burst for up to 30 minutes at the maximum burst rate. You accumulate credits whenever the resource's IOPS or MB/s are being utilized below the resource's performance target. If your resource has accrued bursting credits and your workload needs the extra performance, your resource can use those credits to go above its performance limits on a best-effort basis to help meet workload demands.



How you spend your available credits is up to you. You can use your 30 minutes of burst credits consecutively or sporadically throughout the day. When resources are deployed, they come with a full allocation of credits. When those deplete, it takes less than a day to restock. Credits can be spent at your discretion. The burst bucket doesn't need to be full in order for resources to burst. Burst accumulation varies depending on each resource, since it's based on unused

IOPS and MB/s below their performance targets. Higher baseline performance resources can accrue their bursting credits faster than lower baseline performing resources. For example, a P1 disk idling accrues 120 IOPS per second, whereas an idling P20 disk would accrue 2,300 IOPS per second.

Bursting states

There are three states your resource can be in with bursting enabled:

- **Accruing** – The resource's IO traffic is using less than the performance target. Accumulating bursting credits for IOPS and MB/s are done separate from one another. Your resource can be accruing IOPS credits and spending MB/s credits or vice versa.
- **Bursting** – The resource's traffic is using more than the performance target. The burst traffic will independently consume credits from IOPS or bandwidth.
- **Constant** – The resource's traffic is exactly at the performance target.

Bursting examples

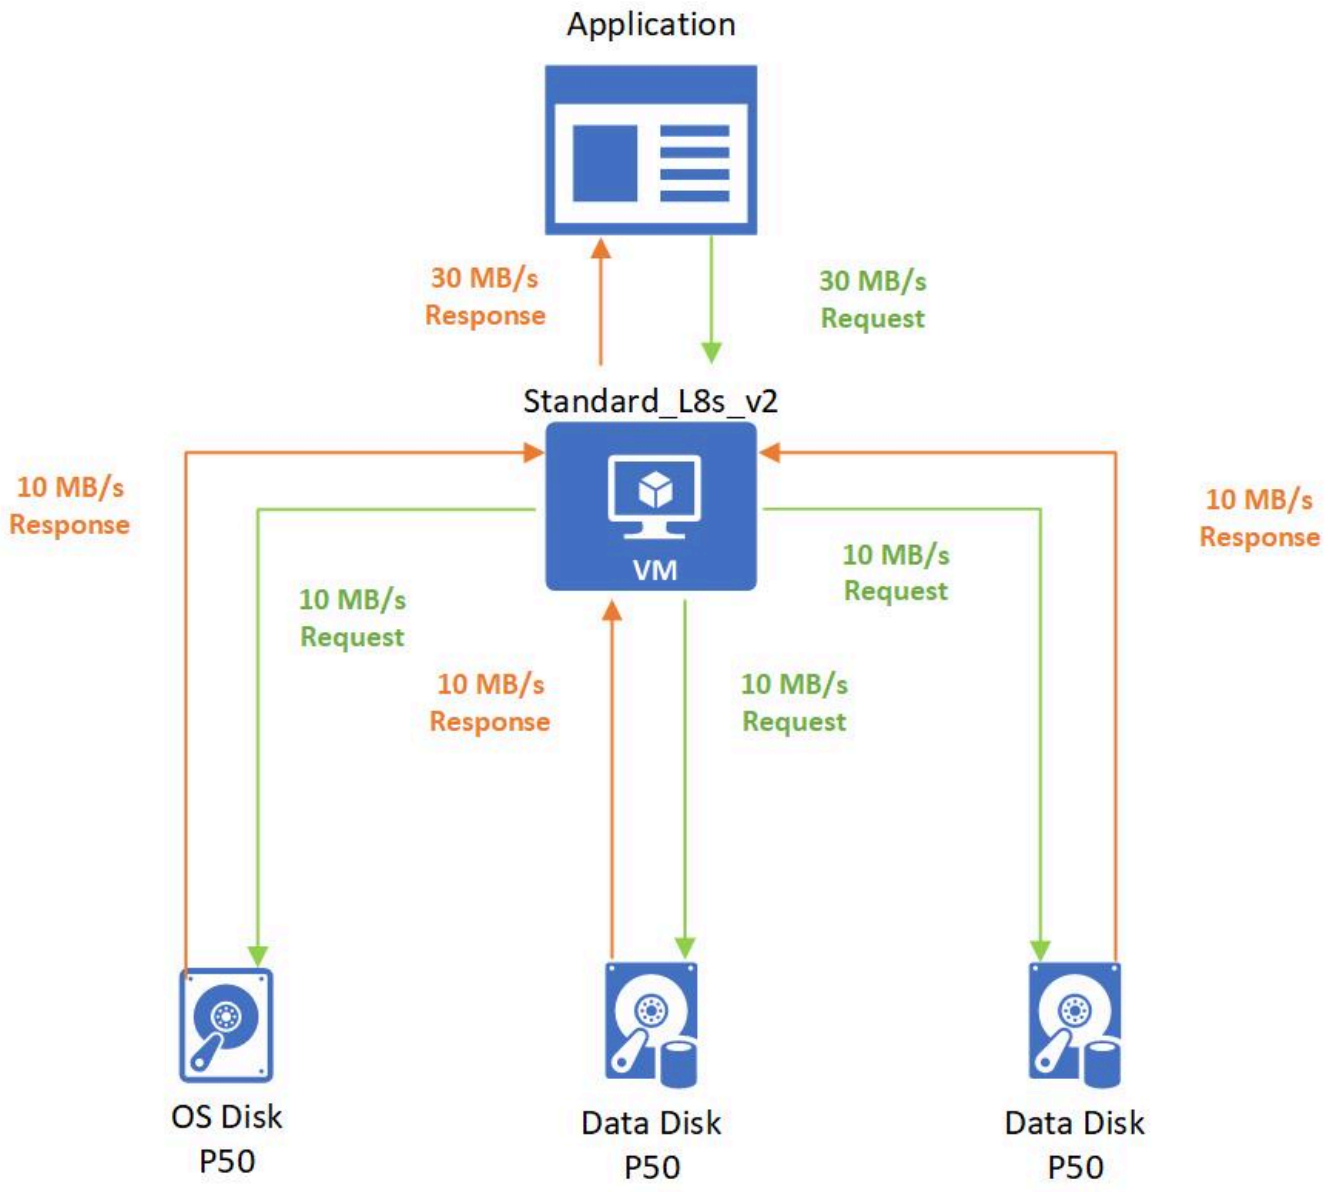
The following examples show how bursting works with various VM and disk combinations. To make the examples easy to follow, we focus on MB/s, but the same logic is applied independently to IOPS.

Burstable virtual machine with nonburstable disks

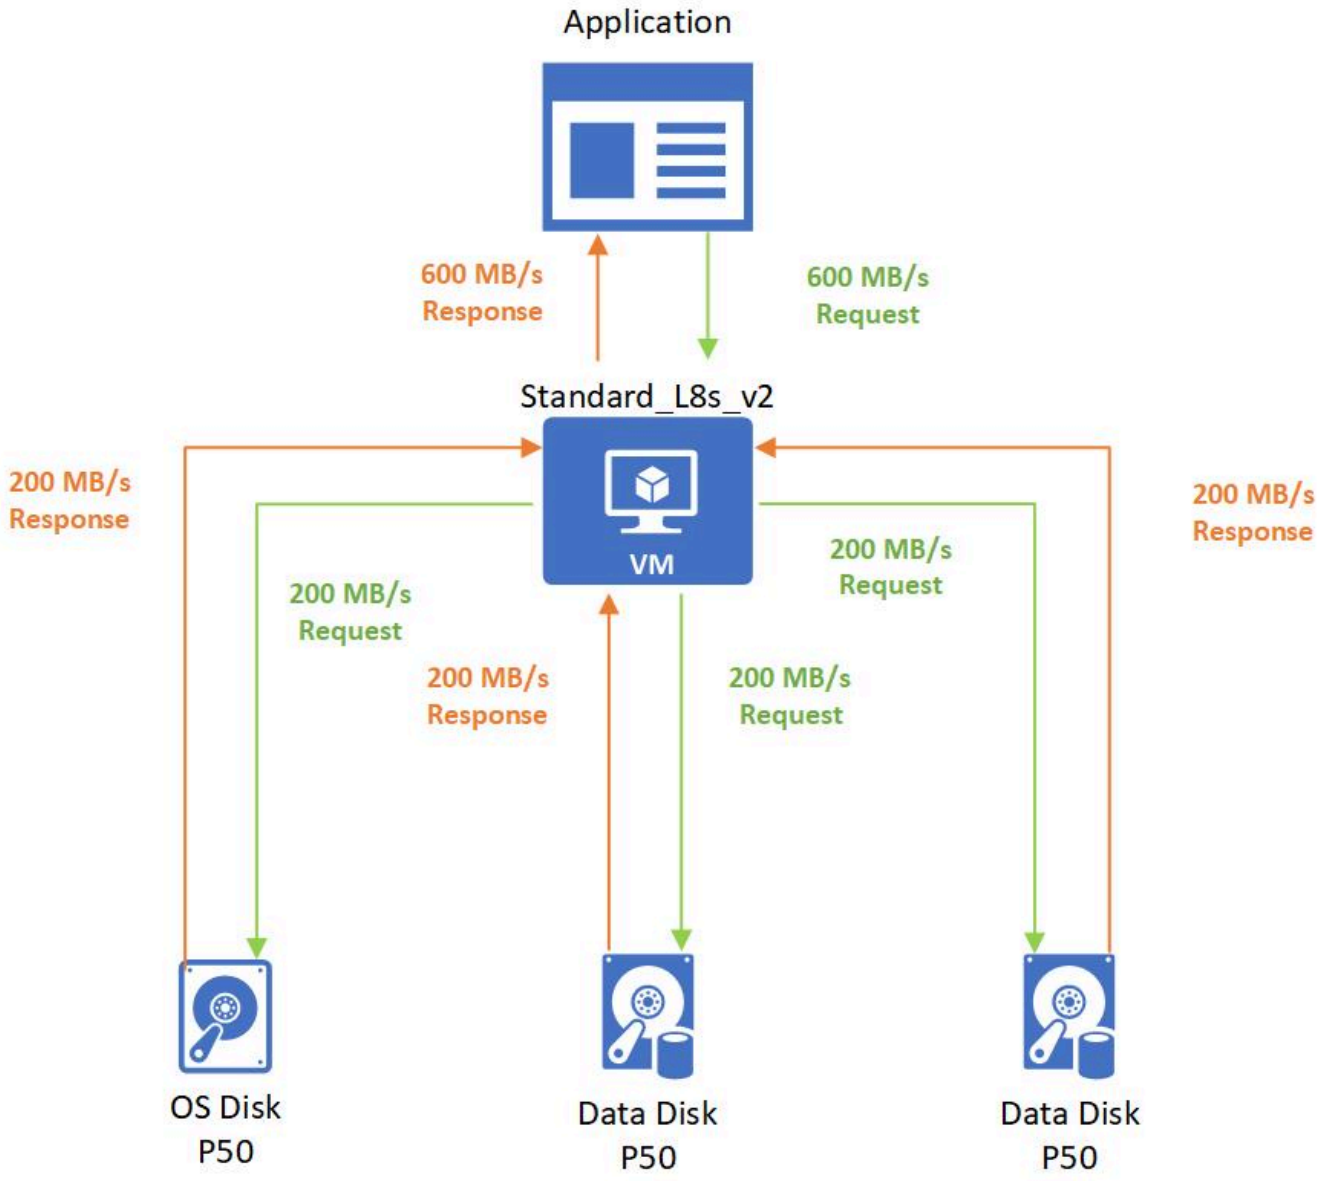
VM and disk combination:

- Standard_L8s_v2
  - Uncached MB/s: 160
  - Max burst MB/s: 1,280
- P50 OS Disk
  - Provisioned MB/s: 250
  - On-Demand Bursting: **not enabled**
- 2 P50 Data Disks
  - Provisioned MB/s: 250
  - On-Demand Bursting: **not enabled**

After the initial boot up, an application is run on the VM and has a noncritical workload. This workload requires 30 MB/s that gets spread evenly across all the disks.



Then the application needs to process a batched job that requires 600 MB/s. The Standard_L8s_v2 bursts to meet this demand and then requests to the disks get evenly spread out to P50 disks.

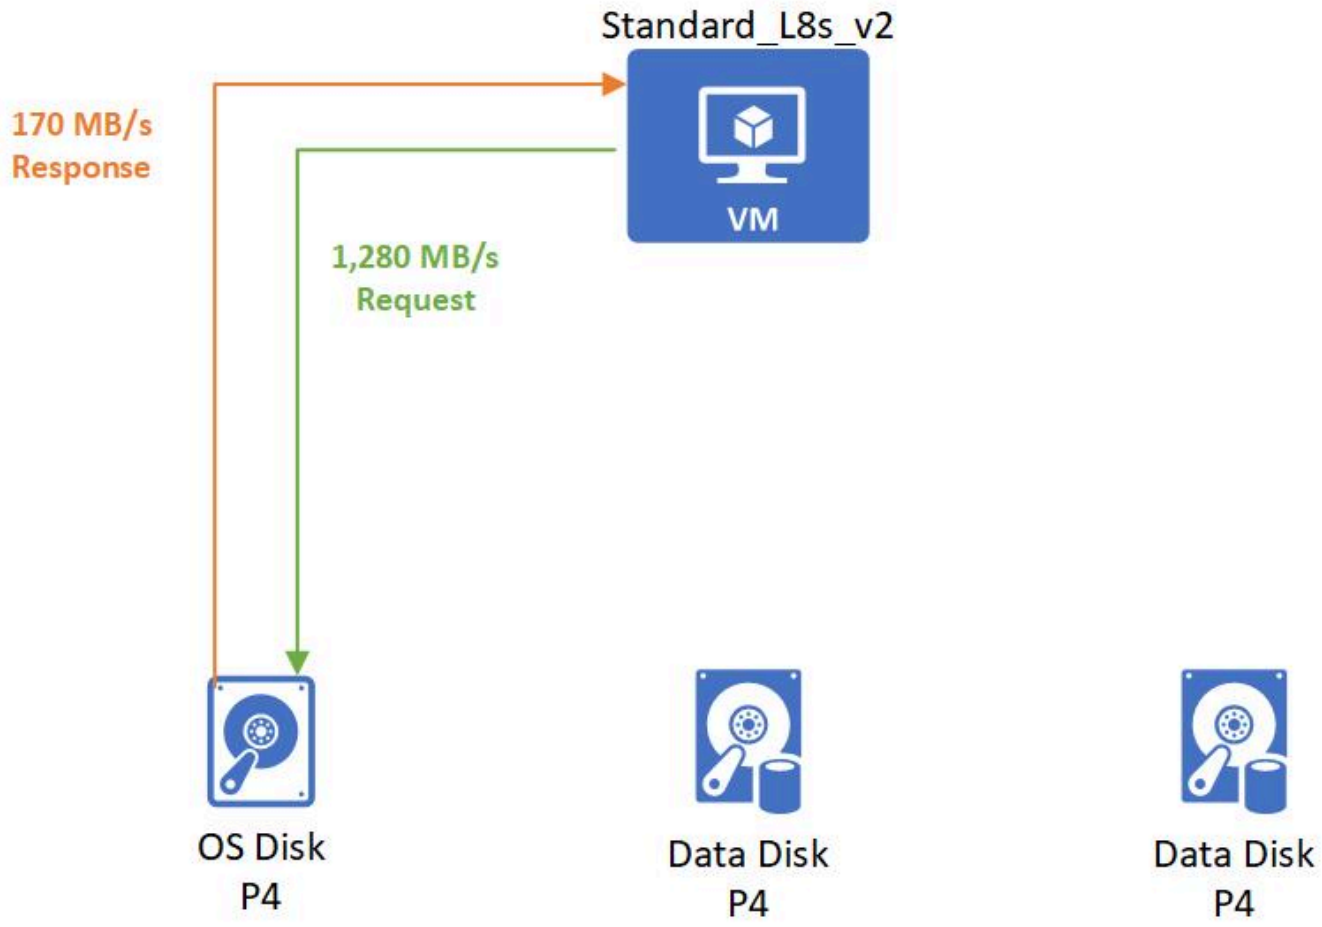


Burstable virtual machine with burstable disks

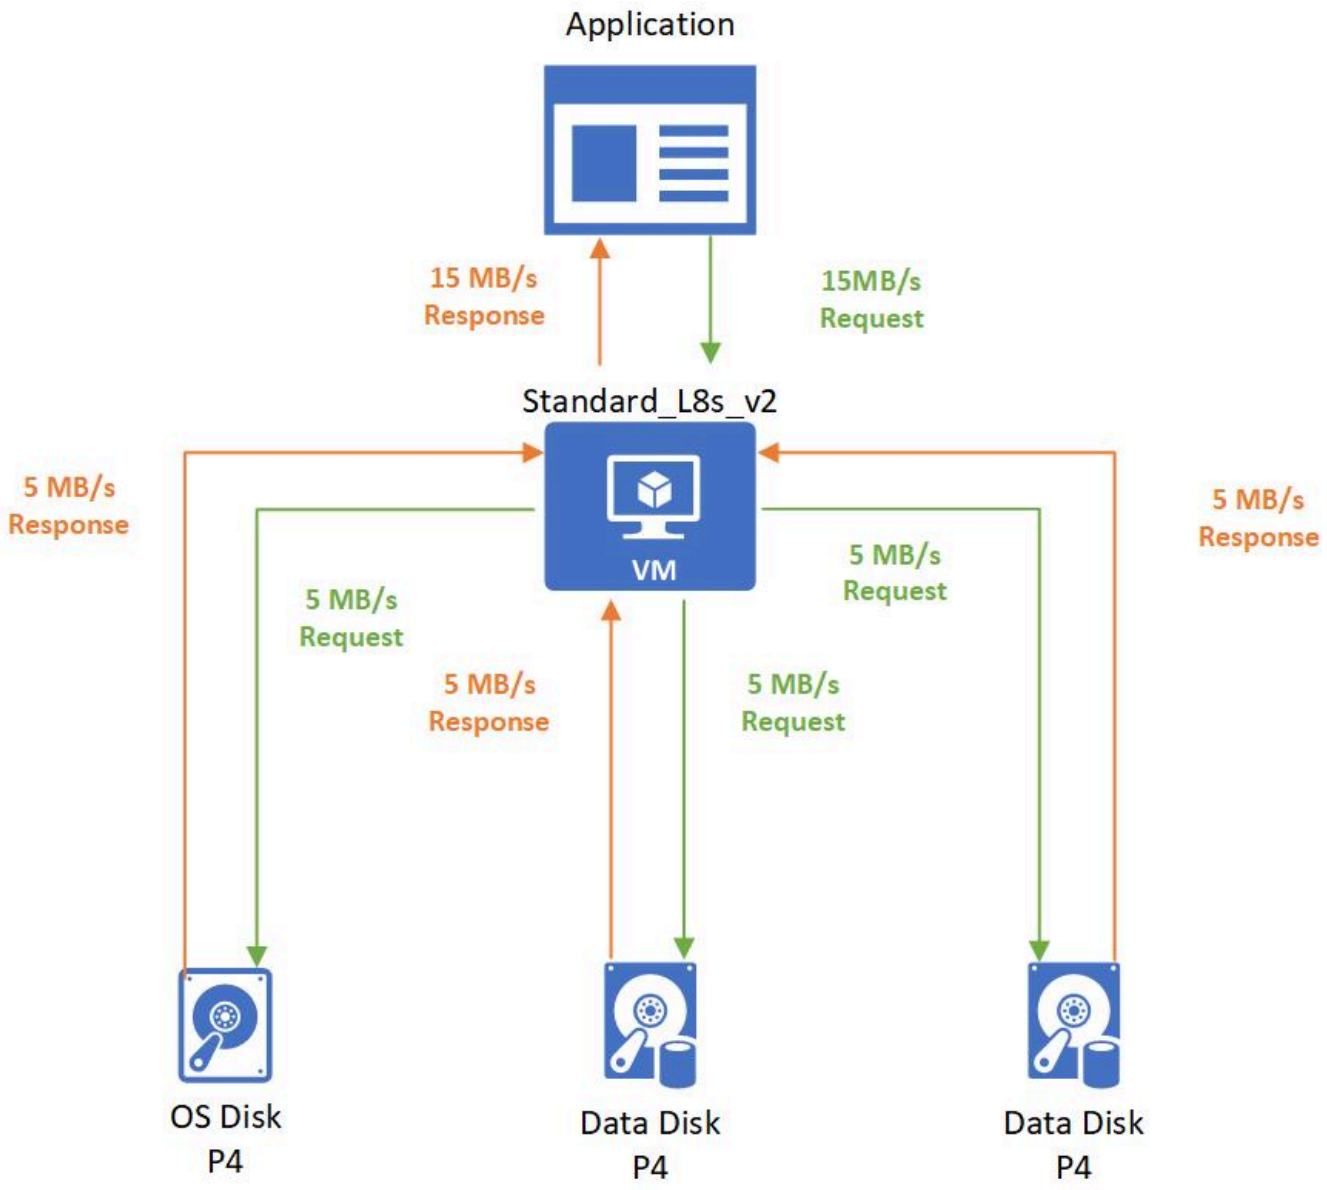
VM and disk combination:

- Standard_L8s_v2
  - Uncached MB/s: 160
  - Max burst MB/s: 1,280
- P4 OS Disk
  - Provisioned MB/s: 25
  - Max burst MB/s: 170
- 2 P4 Data Disks
  - Provisioned MB/s: 25
  - Max burst MB/s: 170

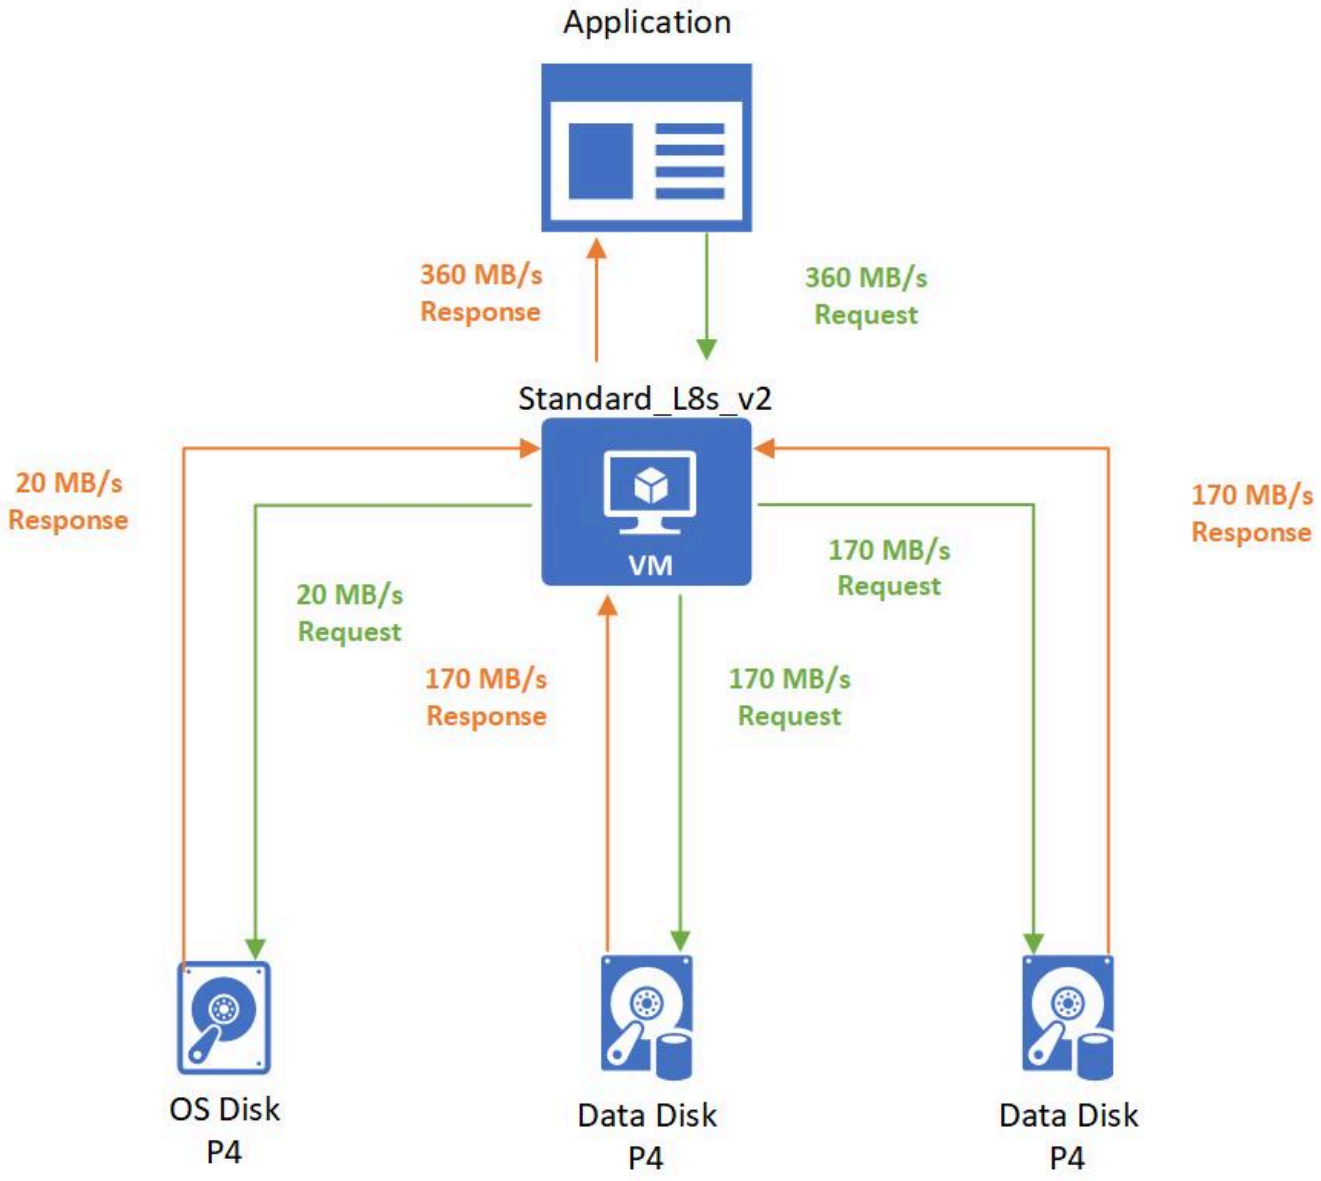
When the VM starts, it will burst to request its burst limit of 1,280 MB/s from the OS disk, and the OS disk will respond with its burst performance of 170 MB/s.



After startup, you start an application that has a noncritical workload. This application requires 15 MB/s that gets spread evenly across all the disks.



Then the application needs to process a batched job that requires 360 MB/s. The Standard_L8s_v2 bursts to meet this demand and then requests. Only 20 MB/s are needed by the OS disk. The remaining 340 MB/s are handled by the bursting P4 data disks.



Next steps

- To enable on-demand bursting, see Enable on-demand bursting.
- To learn how to gain insight into your bursting resources, see Disk bursting metrics.
- To see exactly how much each applicable disk size can burst, see Scalability and performance targets for VM disks.

Enable on-demand bursting

Article • 01/14/2025

Premium solid-state drives (SSD) have two available bursting models; credit-based bursting and on-demand bursting. This article covers how to switch to on-demand bursting. Disks that use the on-demand model can burst beyond their original provisioned targets. On-demand bursting occurs as often as needed by the workload, up to the maximum burst target. On-demand bursting incurs additional charges.

For details on disk bursting, see Managed disk bursting.

For the max burst targets on each supported disk, see Scalability and performance targets for VM disks.

> **Important**
>
> You don't need to follow the steps in this article to use credit-based bursting. By default, credit-based bursting is enabled on all eligible disks.

Before you enable on-demand bursting, understand the following:

- On-demand bursting cannot be enabled on a premium SSD that has less than or equal to 512 GiB. Premium SSDs less than or equal to 512 GiB will always use credit-based bursting.
- On-demand bursting is only supported on premium SSDs. If a premium SSD with on-demand bursting enabled is switched to another disk type, then disk bursting is disabled.
- On-demand bursting doesn't automatically disable itself when the performance tier is changed. If you want to change your performance tier but do not want to keep disk bursting, you must disable it.
- On-demand bursting can only be enabled when the disk is detached from a VM or when the VM is stopped. On-demand bursting can be disabled 12 hours after it has been enabled.

Get started

On-demand bursting can be enabled with either the Azure portal, the Azure PowerShell module, the Azure CLI, or Azure Resource Manager templates. The following examples cover how to create a new disk with on-demand bursting enabled and enabling on-demand bursting on existing disks.

Portal

A managed disk must be larger than 512 GiB to enable on-demand bursting.

To enable on-demand bursting for an existing disk:

1. Sign in to the Azure portal and navigate to your disk.
2. Select **Configuration** and select **Enable on-demand bursting**.
3. Select **Save**.

Next steps

To learn how to gain insight into your bursting resources, see Disk bursting metrics.

Performance tiers for managed disks

Article • 01/23/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

> **Note**
>
> This article covers what performance tiers are, conceptually. If you want to learn how to change the performance of disks that don't use performance tiers, like Ultra Disks or Premium SSD v2, see either Adjust the performance of an ultra disk or Adjust disk performance of a Premium SSD v2

When you set the provisioned size of a Premium solid-state drive (SSD), a performance tier is automatically selected based on the size you set. The performance tier determines the IOPS and throughput your managed disk has. For Premium SSD disks only, the performance tier can be changed at deployment or afterwards, without changing the size of the disk, and without downtime.

Changing the performance tier allows you to prepare to meet higher demand without using your disk's bursting capability. It can be more cost-effective to change your performance tier rather than rely on bursting, depending on how long the extra performance is necessary. This is ideal for events that temporarily require a consistently higher level of performance, like holiday shopping, performance testing, or running a training environment. To handle these events, you can switch a disk to a higher performance tier without downtime, for as long as you need the extra performance. You can then return to the original tier without downtime when the extra performance is no longer necessary.

To learn more about how the performance of a disk works with the performance of a virtual machine, see Virtual machine and disk performance.

Restrictions

- Changing the performance tier is currently only supported for Premium SSD managed disks.
- Performance tiers of shared disks can't be changed while attached to running VMs.
  - To change the performance tier of a shared disk, stop all the VMs the disk is attached to.
- Only disks larger than 4,096 GiB can use the P60, P70, and P80 performance tiers.

- A disk's performance tier can be downgraded only once every 12 hours.
- The system doesn't return `Performance Tier` for disks created before June 2020. You can take advantage of `Performance Tier` for an older disk by updating it with the baseline Tier.

How it works

When you first deploy or provision a disk, the baseline performance tier for that disk is set based on the provisioned disk size. You can use a performance tier higher than the original baseline to meet higher demand. When you no longer need that performance level, you can return to the initial baseline performance tier.

Billing impact

Disk billing changes as its performance tier changes. For example, if you provision a P10 disk (128 GiB), your baseline performance tier is set as P10 (500 IOPS and 100 MBps). Your disk is billed at the P10 rate. You can set the disk's performance tier to P50 (7,500 IOPS and 250 MBps) without increasing the disk size. While the disk's performance tier is set to P50, your disk is billed at the P50 rate. When you no longer need the higher performance, you can set the performance tier of the disk back to the P10 tier and your disk's billing will return to the P10 rate.

For billing information, see Managed disk pricing.

What tiers can be changed

The following table depicts which tiers each baseline performance tier can upgrade to.

Expand table

Disk size	Baseline performance tier	Can be upgraded to
4 GiB	P1	P2, P3, P4, P6, P10, P15, P20, P30, P40, P50
8 GiB	P2	P3, P4, P6, P10, P15, P20, P30, P40, P50
16 GiB	P3	P4, P6, P10, P15, P20, P30, P40, P50
32 GiB	P4	P6, P10, P15, P20, P30, P40, P50
64 GiB	P6	P10, P15, P20, P30, P40, P50
128 GiB	P10	P15, P20, P30, P40, P50

Disk size	Baseline performance tier	Can be upgraded to
256 GiB	P15	P20, P30, P40, P50
512 GiB	P20	P30, P40, P50
1 TiB	P30	P40, P50
2 TiB	P40	P50
4 TiB	P50	None
8 TiB	P60	P70, P80
16 TiB	P70	P80
32 TiB	P80	None

Next steps

To learn how to change your performance tier, see Change your performance tier without downtime.

Change your performance tier without downtime

Article • 01/16/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

> **Note**
>
> This article focuses on how to change performance tiers. To learn how to change the performance of disks that don't use performance tiers, like Ultra Disks or Premium SSD v2, see either Adjust the performance of an ultra disk or Adjust disk performance of a Premium SSD v2

The performance of your Azure managed disk is set when you create your disk, in the form of its performance tier. The performance tier determines the IOPS and throughput your managed disk has. When you set the provisioned size of your disk, a performance tier is automatically selected. The performance tier can be changed at deployment or afterwards, without changing the size of the disk and without downtime. To learn more about performance tiers, see Performance tiers for managed disks.

Changing your performance tier has billing implications. See Billing impact for details.

Restrictions

- Changing the performance tier is currently only supported for Premium SSD managed disks.
- Performance tiers of shared disks can't be changed while attached to running VMs.
  - To change the performance tier of a shared disk, stop all the VMs the disk is attached to.
- Only disks larger than 4,096 GiB can use the P60, P70, and P80 performance tiers.
- A disk's performance tier can be downgraded only once every 12 hours.
- The system doesn't return `Performance Tier` for disks created before June 2020. You can take advantage of `Performance Tier` for an older disk by updating it with the baseline Tier.

Prerequisites

Azure CLI

Install the latest Azure CLI and sign in to an Azure account with az login.

Create an empty data disk with a tier higher than the baseline tier

Azure CLI

Azure CLI

```
subscriptionId=<yourSubscriptionIDHere>
resourceGroupName=<yourResourceGroupNameHere>
diskName=<yourDiskNameHere>
diskSize=<yourDiskSizeHere>
performanceTier=<yourDesiredPerformanceTier>
region=westcentralus

az account set --subscription $subscriptionId

az disk create -n $diskName -g $resourceGroupName -l $region --sku
Premium_LRS --size-gb $diskSize --tier $performanceTier
```

Create an OS disk with a tier higher than the baseline tier from an Azure Marketplace image

Azure CLI

```
resourceGroupName=<yourResourceGroupNameHere>
diskName=<yourDiskNameHere>
performanceTier=<yourDesiredPerformanceTier>
region=westcentralus
image=Canonical:UbuntuServer:18.04-LTS:18.04.202002180

az disk create -n $diskName -g $resourceGroupName -l $region --image-
reference $image --sku Premium_LRS --tier $performanceTier
```

Update the tier of a disk without downtime

A disk's performance tier can be changed without downtime, so you don't have to deallocate your VM or detach your disk to change the tier.

Azure CLI

1. Update the tier of a disk even when it is attached to a running VM

```
Azure CLI
```

```
resourceGroupName=<yourResourceGroupNameHere>
diskName=<yourDiskNameHere>
performanceTier=<yourDesiredPerformanceTier>

az disk update -n $diskName -g $resourceGroupName --set
tier=$performanceTier
```

Show the tier of a disk

Azure CLI

```
Azure CLI
```

```
az disk show -n $diskName -g $resourceGroupName --query [tier] -o tsv
```

Next steps

If you need to resize a disk to take advantage of the higher performance tiers, see these articles:

- Expand virtual hard disks on a Linux VM with the Azure CLI
- Expand a managed disk attached to a Windows virtual machine

Enable Write Accelerator

Article • 01/14/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Write Accelerator is a disk capability for M-Series Virtual Machines (VMs) on Premium SSD managed disks. As the name states, the purpose of the functionality is to improve the I/O latency of writes against Premium SSD disks. Write Accelerator is ideally suited where log file updates are required to persist to disk in a highly performant manner for modern databases.

Write Accelerator is generally available for M-series VMs in the Public Cloud.

Prerequisites

- Only supported with Premium SSD managed disks
- Only supported by M-series VMs

Planning for using Write Accelerator

Write Accelerator should be used for the volumes that contain the transaction log or redo logs of a DBMS. You shouldn't use Write Accelerator for the data volumes of a DBMS as the feature is optimized to be used against log disks.

> **ⓘ Important**
>
> Enabling Write Accelerator for the operating system disk of the VM reboots the VM.
>
> To enable Write Accelerator to an existing Azure disk that isn't part of a volume build out of multiple disks with Windows disk or volume managers, Windows Storage Spaces, Windows Scale-out file server (SOFS), Linux LVM, or MDADM, the workload accessing the Azure disk needs to be shut down. Database applications using the Azure disk must be shut down.
>
> To enable or disable Write Accelerator for an existing volume that is built out of multiple Azure Premium SSD disks and striped using Windows disk or volume managers, Windows Storage Spaces, Windows Scale-out file server (SOFS), Linux LVM or MDADM, all disks building the volume must be enabled or disabled for

Write Accelerator in separate steps. Shut down the VM Before enabling or disabling Write Accelerator in such a configuration.

Enabling Write Accelerator for OS disks shouldn't be necessary for SAP-related VM configurations.

Restrictions when using Write Accelerator

When using Write Accelerator for an Azure disk/VHD, these restrictions apply:

- The Premium disk caching must be set to 'None' or 'Read Only'. All other caching modes aren't supported.
- Snapshots are currently supported for only Write Accelerator-enabled data disks, and not the OS disk. During backup, the Azure Backup service automatically backs up and protects Write Accelerator-enabled data disks attached to the VM.
- Only smaller I/O sizes (<=64 KiB) are taking the accelerated path. In workload situations where data is getting bulk loaded or where the transaction log buffers of the different DBMS are filled to a larger degree before getting persisted to the storage, chances are that the I/O written to disk is not taking the accelerated path.

There are limits of Azure Premium SSD disks per VM that can be supported by Write Accelerator. The current limits are:

Expand table

VM SKU	Number of Write Accelerator disks	Write Accelerator Disk IOPS per VM
M416ms_v2, M416s_8_v2, M416s_v2	16	20000
M208ms_v2, M208s_v2	8	10000
M192ids_v2, M192idms_v2, M192is_v2, M192ims_v2,	16	20000
M128ms, M128s, M128ds_v2, M128dms_v2, M128s_v2, M128ms_v2	16	20000
M64ms, M64ls, M64s, M64ds_v2, M64dms_v2, M64s_v2, M64ms_v2	8	10000
M32ms, M32ls, M32ts, M32s, M32dms_v2, M32ms_v2	4	5000
M16ms, M16s	2	2500

VM SKU	Number of Write Accelerator disks	Write Accelerator Disk IOPS per VM
M8ms, M8s	1	1250
Standard_M12s_v3, Standard_M12ds_v3	1	5000
Standard_M24s_v3, Standard_M24ds_v3	2	5000
Standard_M48s_1_v3, Standard_M48ds_1_v3	4	5000
Standard_M96s_1_v3, Standard_M96ds_1_v3, Standard_M96s_2_v3, Standard_M96ds_2_v3	8	10000
Standard_M176s_3_v3, Standard_M176ds_3_v3, Standard_M176s_4_v3, Standard_M176ds_4_v3	16	20000

The IOPS limits are per VM and not per disk. All Write Accelerator disks share the same IOPS limit per VM. Attached disks can't exceed the write accelerator IOPS limit for a VM. For an example, even though the attached disks can do 30,000 IOPS, the system doesn't allow the disks to go above 20,000 IOPS for M416ms_v2.

Enabling Write Accelerator on a specific disk

The next few sections describe how Write Accelerator can be enabled on Azure Premium SSD VHDs.

Enabling Azure Write Accelerator using Azure PowerShell

The Azure PowerShell module from version 5.5.0 include the changes to the relevant cmdlets to enable or disable Write Accelerator for specific Azure Premium SSD disks. In order to enable or deploy disks supported by Write Accelerator, the following PowerShell commands got changed, and extended to accept a parameter for Write Accelerator.

A new switch parameter, **-WriteAccelerator** has been added to the following cmdlets:

- Set-AzVMOsDisk
- Add-AzVMDataDisk
- Set-AzVMDataDisk
- Add-AzVmssDataDisk

> **Note**
>
> If enabling Write Accelerator on Virtual Machine Scale Sets using Flexible Orchestration Mode, you need to enable it on each individual instance.

Not giving the parameter sets the property to false and will deploy disks that have no support by Write Accelerator.

A new switch parameter, **-OsDiskWriteAccelerator** was added to the following cmdlets:

- Set-AzVmssStorageProfile

Not specifying the parameter sets the property to false by default, returning disks that don't use Write Accelerator.

A new optional Boolean (non-nullable) parameter, **-OsDiskWriteAccelerator** was added to the following cmdlets:

- Update-AzVM
- Update-AzVmss

Specify either `$true` or `$false` to control support of Azure Write Accelerator with the disks.

Examples of commands could look like:

Azure PowerShell

```
New-AzVMConfig | Set-AzVMOsDisk | Add-AzVMDataDisk -Name "datadisk1" | Add-
AzVMDataDisk -Name "logdisk1" -WriteAccelerator | New-AzVM

Get-AzVM | Update-AzVM -OsDiskWriteAccelerator $true

New-AzVmssConfig | Set-AzVmssStorageProfile -OsDiskWriteAccelerator | Add-
AzVmssDataDisk -Name "datadisk1" -WriteAccelerator:$false | Add-
AzVmssDataDisk -Name "logdisk1" -WriteAccelerator | New-AzVmss

Get-AzVmss | Update-AzVmss -OsDiskWriteAccelerator:$false
```

Two main scenarios can be scripted as shown in the following sections.

Adding a new disk supported by Write Accelerator using PowerShell

You can use this script to add a new disk to your VM. The disk created with this script uses Write Accelerator.

Replace `myVM`, `myWAVMs`, `log001`, size of the disk, and LunID of the disk with values appropriate for your specific deployment.

Azure PowerShell

```
# Specify your VM Name
$vmName="myVM"
#Specify your Resource Group
$rgName = "myWAVMs"
#data disk name
$datadiskname = "log001"
#LUN Id
$lunid=8
#size
$size=1023
#Pulls the VM info for later
$vm=Get-AzVM -ResourceGroupName $rgname -Name $vmname
#add a new VM data disk
Add-AzVMDataDisk -CreateOption empty -DiskSizeInGB $size -Name
$vmname-$datadiskname -VM $vm -Caching None -WriteAccelerator:$true -lun
$lunid
#Updates the VM with the disk config - does not require a reboot
Update-AzVM -ResourceGroupName $rgname -VM $vm
```

Enabling Write Accelerator on an existing Azure disk using PowerShell

You can use this script to enable Write Accelerator on an existing disk. Replace `myVM`, `myWAVMs`, and `test-log001` with values appropriate for your specific deployment. The script adds Write Accelerator to an existing disk where the value for **$newstatus** is set to '$true'. Using the value '$false' will disable Write Accelerator on a given disk.

Azure PowerShell

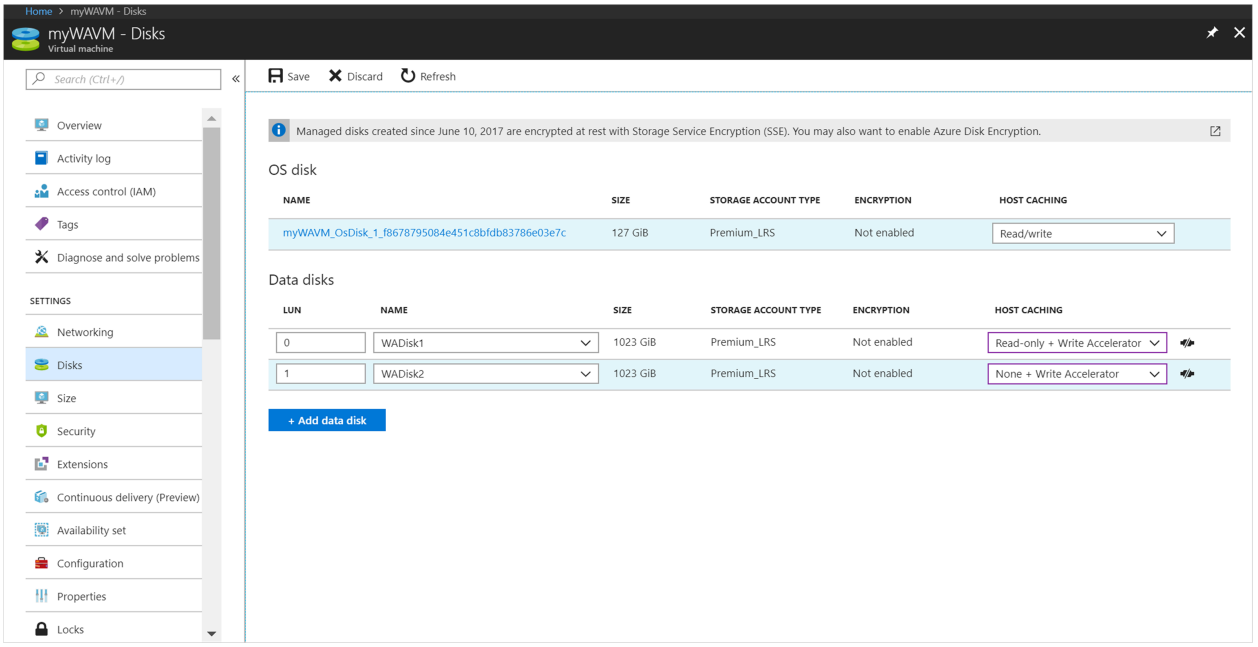
```
#Specify your VM Name
$vmName="myVM"
#Specify your Resource Group
$rgName = "myWAVMs"
#data disk name
$datadiskname = "test-log001"
#new Write Accelerator status ($true for enabled, $false for disabled)
$newstatus = $true
#Pulls the VM info for later
$vm=Get-AzVM -ResourceGroupName $rgname -Name $vmname
#add a new VM data disk
```

```
Set-AzVMDataDisk -VM $vm -Name $datadiskname -Caching None -
WriteAccelerator:$newstatus
#Updates the VM with the disk config - does not require a reboot
Update-AzVM -ResourceGroupName $rgname -VM $vm
```

> **Note**
>
> Executing the script above will detach the disk specified, enable Write Accelerator against the disk, and then attach the disk again

Enabling Write Accelerator using the Azure portal

You can enable Write Accelerator via the portal where you specify your disk caching settings:



Enabling Write Accelerator using the Azure CLI

You can use the Azure CLI to enable Write Accelerator.

To enable Write Accelerator on an existing disk, use az vm update, you can use the following examples if you replace the `diskName`, `VMName`, and `ResourceGroup` with your own values: `az vm update -g group1 -n vm1 -write-accelerator 1=true`

To attach a disk with Write Accelerator enabled use az vm disk attach, you can use the following example if you substitute in your own values: `az vm disk attach -g group1 -`

`vm-name vm1 -disk d1 --enable-write-accelerator`

To disable Write Accelerator, use az vm update, setting the properties to false: `az vm update -g group1 -n vm1 -write-accelerator 0=false 1=false`

Enabling Write Accelerator using REST APIs

To deploy through Azure REST API, you need to install the Azure armclient.

Install armclient

To run armclient, you need to install it through Chocolatey. You can install it through cmd.exe or PowerShell. Use elevated rights for these commands ("Run as Administrator").

Using cmd.exe, run the following command: `@"%SystemRoot%\System32\WindowsPowerShell\v1.0\powershell.exe" -NoProfile -InputFormat None -ExecutionPolicy Bypass -Command "iex ((New-Object System.Net.WebClient).DownloadString('https://chocolatey.org/install.ps1'))" && SET "PATH=%PATH%;%ALLUSERSPROFILE%\chocolatey\bin"`

Using PowerShell, run the following command: `Set-ExecutionPolicy Bypass -Scope Process -Force; iex ((New-Object System.Net.WebClient).DownloadString('https://chocolatey.org/install.ps1'))`

Now you can install the armclient by using the following command in either cmd.exe or PowerShell `choco install armclient`

Getting your current VM configuration

To change the attributes of your disk configuration, you first need to get the current configuration in a JSON file. You can get the current configuration by executing the following command: `armclient GET /subscriptions/<<subscription-ID<</resourceGroups/<<ResourceGroup>>/providers/Microsoft.Compute/virtualMachines/<<virtualmachinename>>?api-version=2017-12-01 > <<filename.json>>`

Replace the terms within '<< >>' with your data, including the file name the JSON file should have.

The output could look like:

```
```

Output

```

sap/providers/Microsoft.Compute/disks/mylittlesap_OsDisk_1_754a1b8bb390468e9
b4c429b81cc5f5a"
        },
        "diskSizeGB": 30
      },
      "dataDisks": [
        {
          "lun": 0,
          "name": "data1",
          "createOption": "Attach",
          "caching": "None",
          "managedDisk": {
            "storageAccountType": "Premium_LRS",
            "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Compute/disks/data1"
          },
          "diskSizeGB": 1023
        },
        {
          "lun": 1,
          "name": "log1",
          "createOption": "Attach",
          "caching": "None",
          "managedDisk": {
            "storageAccountType": "Premium_LRS",
            "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Compute/disks/data2"
          },
```

```
          "diskSizeGB": 1023
        }
      ]
    },
    "osProfile": {
      "computerName": "mylittlesapVM",
      "adminUsername": "pl",
      "linuxConfiguration": {
        "disablePasswordAuthentication": false
      },
      "secrets": []
    },
    "networkProfile": {
      "networkInterfaces": [
        {
          "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Network/networkInterfaces/mylittlesap518"
        }
      ]
    },
    "diagnosticsProfile": {
      "bootDiagnostics": {
        "enabled": true,
        "storageUri": "https://mylittlesapdiag895.blob.core.windows.net/"
      }
    },
    "provisioningState": "Succeeded"
  },
  "type": "Microsoft.Compute/virtualMachines",
  "location": "westeurope",
  "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Compute/virtualMachines/mylittlesapVM",
  "name": "mylittlesapVM"
```

Next, update the JSON file and to enable Write Accelerator on the disk called 'log1'. This can be accomplished by adding this attribute into the JSON file after the cache entry of the disk.

JSON

```
        {
          "lun": 1,
          "name": "log1",
          "createOption": "Attach",
          "caching": "None",
          "writeAcceleratorEnabled": true,
          "managedDisk": {
            "storageAccountType": "Premium_LRS",
            "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
```

```
sap/providers/Microsoft.Compute/disks/data2"
          },
          "diskSizeGB": 1023
        }
```

Then update the existing deployment with this command: `armclient PUT /subscriptions/<<subscription-ID<</resourceGroups/<<ResourceGroup>>/providers/Microsoft.Compute/virtualMachines/<<virtualmachinename>>?api-version=2017-12-01 @<<filename.json>>`

The output should look like the one below. You can see that Write Accelerator enabled for one disk.

Output

```
{
  "properties": {
    "vmId": "2444c93e-f8bb-4a20-af2d-1658d9dbbbcb",
    "hardwareProfile": {

sap/providers/Microsoft.Compute/disks/data1"
          },
          "diskSizeGB": 1023
        },
        {
          "lun": 1,
          "name": "log1",
          "createOption": "Attach",
          "caching": "None",
          "writeAcceleratorEnabled": true,
          "managedDisk": {
            "storageAccountType": "Premium_LRS",
            "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Compute/disks/data2"
          },
          "diskSizeGB": 1023
        }
      ]
    },
    "osProfile": {
      "computerName": "mylittlesapVM",
      "adminUsername": "pl",
      "linuxConfiguration": {
        "disablePasswordAuthentication": false
      },
      "secrets": []
    },
    "networkProfile": {
      "networkInterfaces": [
        {
          "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Network/networkInterfaces/mylittlesap518"
        }
      ]
    },
    "diagnosticsProfile": {
      "bootDiagnostics": {
        "enabled": true,
        "storageUri": "https://mylittlesapdiag895.blob.core.windows.net/"
      }
    },
    "provisioningState": "Succeeded"
  },
  "type": "Microsoft.Compute/virtualMachines",
  "location": "westeurope",
  "id":
"/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittle
sap/providers/Microsoft.Compute/virtualMachines/mylittlesapVM",
  "name": "mylittlesapVM"
```

Once you've made this change, the drive should be supported by Write Accelerator.

Benchmark a disk

Article • 01/07/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Benchmarking is the process of simulating different workloads on your application and measuring the application performance for each workload. Using the steps described in the designing for high performance article, you have gathered the application performance requirements. By running benchmarking tools on the VMs hosting the application, you can determine the performance levels that your application can achieve with premium SSDs. In this article, we provide you examples of benchmarking a Standard_D8ds_v4 VM provisioned with Azure premium SSDs.

We have used common benchmarking tools DiskSpd and FIO, for Windows and Linux respectively. These tools spawn multiple threads simulating a production like workload, and measure the system performance. Using the tools you can also configure parameters like block size and queue depth, which you normally cannot change for an application. This gives you more flexibility to drive the maximum performance on a high scale VM provisioned with premium SSDs for different types of application workloads. To learn more about each benchmarking tool visit DiskSpd and FIO.

To follow the examples below, create a Standard_D8ds_v4 and attach four premium SSDs to the VM. Of the four disks, configure three with host caching as "None" and stripe them into a volume called NoCacheWrites. Configure host caching as "ReadOnly" on the remaining disk and create a volume called CacheReads with this disk. Using this setup, you are able to see the maximum Read and Write performance from a Standard_D8ds_v4 VM. For detailed steps about creating a Standard_D8ds_v4 with premium SSDs, see Designing for high performance.

Warm up the Cache

The disk with ReadOnly host caching is able to give higher IOPS than the disk limit. To get this maximum read performance from the host cache, first you must warm up the cache of this disk. This ensures that the Read IOs that the benchmarking tool will drive on CacheReads volume, actually hits the cache, and not the disk directly. The cache hits result in more IOPS from the single cache enabled disk.

> **Important**

You must warm up the cache before running benchmarks every time VM is rebooted.

DISKSPD

Download the DISKSP tool on the VM. DISKSPD is a tool that you can customize to create your own synthetic workloads. We will use the same setup described above to run benchmarking tests. You can change the specifications to test different workloads.

In this example, we use the following set of baseline parameters:

- -c200G: Creates (or recreates) the sample file used in the test. It can be set in bytes, KiB, MiB, GiB, or blocks. In this case, a large file of 200-GiB target file is used to minimize memory caching.
- -w100: Specifies the percentage of operations that are write requests (-w0 is equivalent to 100% read).
- -b4K: Indicates the block size in bytes, KiB, MiB, or GiB. In this case, 4K block size is used to simulate a random I/O test.
- -F4: Sets a total of four threads.
- -r: Indicates the random I/O test (overrides the -s parameter).
- -o128: Indicates the number of outstanding I/O requests per target per thread. This is also known as the queue depth. In this case, 128 is used to stress the CPU.
- -W7200: Specifies the duration of the warm-up time before measurements start.
- -d30: Specifies the duration of the test, not including warm-up.
- -Sh: Disable software and hardware write caching (equivalent to -Suw).

For a complete list of parameters, see the GitHub repository.

Maximum write IOPS

We use a high queue depth of 128, a small block size of 8 KB, and four worker threads for driving Write operations. The write workers are driving traffic on the "NoCacheWrites" volume, which has three disks with cache set to "None".

Run the following command for 30 seconds of warm-up and 30 seconds of measurement:

```
diskspd -c200G -w100 -b8K -F4 -r -o128 -W30 -d30 -Sh testfile.dat
```

Results show that the Standard_D8ds_v4 VM is delivering its maximum write IOPS limit of 12,800.

```

```

Maximum throughput

To get the maximum read and write throughput, you can change to a larger block size of 64 KB.

FIO

FIO is a popular tool to benchmark storage on the Linux VMs. It has the flexibility to select different IO sizes, sequential or random reads and writes. It spawns worker threads or processes to perform the specified I/O operations. You can specify the type of I/O operations each worker thread must perform using job files. We created one job file per scenario illustrated in the examples below. You can change the specifications in these job files to benchmark different workloads running on Premium Storage. In the examples, we are using a Standard_D8ds_v4 running **Ubuntu**. Use the same setup described in the beginning of the benchmark section and warm up the cache before running the benchmark tests.

Before you begin, download FIO and install it on your virtual machine.

Run the following command for Ubuntu,

```
apt-get install fio
```

We use four worker threads for driving Write operations and four worker threads for driving Read operations on the disks. The write workers are driving traffic on the "nocache" volume, which has three disks with cache set to "None". The read workers are driving traffic on the "readcache" volume, which has one disk with cache set to "ReadOnly".

Maximum write IOPS

Create the job file with following specifications to get maximum Write IOPS. Name it "fiowrite.ini".

ini

```
[global]
size=30g
direct=1
iodepth=256
ioengine=libaio
bs=4k
numjobs=4

[writer1]
rw=randwrite
directory=/mnt/nocache
```

Note the follow key things that are in line with the design guidelines discussed in previous sections. These specifications are essential to drive maximum IOPS,

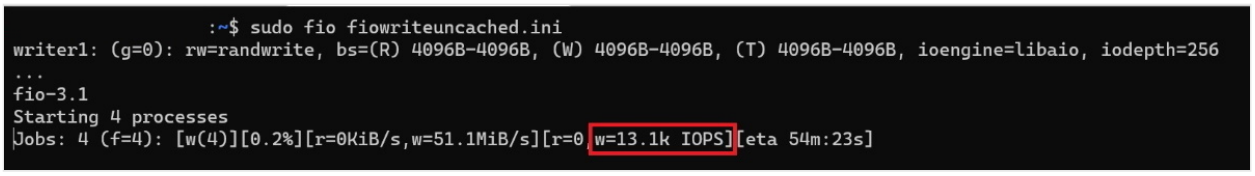
- A high queue depth of 256.
- A small block size of 4 KB.
- Multiple threads performing random writes.

Run the following command to kick off the FIO test for 30 seconds,

```
sudo fio --runtime 30 fiowrite.ini
```

While the test runs, you are able to see the number of write IOPS the VM and Premium disks are delivering. As shown in the sample below, the Standard_D8ds_v4 VM is

delivering its maximum write IOPS limit of 12,800 IOPS.



Maximum read IOPS

Create the job file with following specifications to get maximum Read IOPS. Name it "fioread.ini".

ini

```
[global]
size=30g
direct=1
iodepth=256
ioengine=libaio
bs=4k
numjobs=4

[reader1]
rw=randread
directory=/mnt/readcache
```

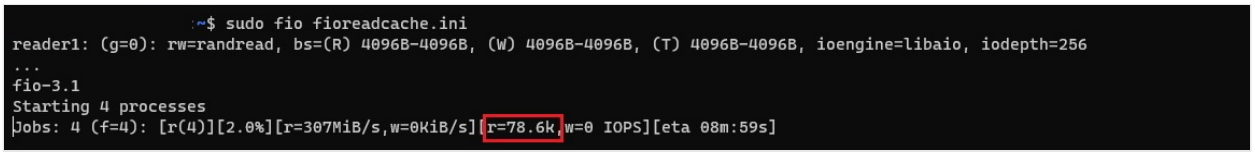
Note the follow key things that are in line with the design guidelines discussed in previous sections. These specifications are essential to drive maximum IOPS,

- A high queue depth of 256.
- A small block size of 4 KB.
- Multiple threads performing random writes.

Run the following command to kick off the FIO test for 30 seconds,

```
sudo fio --runtime 30 fioread.ini
```

While the test runs, you are able to see the number of read IOPS the VM and Premium disks are delivering. As shown in the sample below, the Standard_D8ds_v4 VM is delivering more than 77,000 Read IOPS. This is a combination of the disk and the cache performance.



Maximum read and write IOPS

Create the job file with following specifications to get maximum combined Read and Write IOPS. Name it "fioreadwrite.ini".

ini

```
[global]
size=30g
direct=1
iodepth=128
ioengine=libaio
bs=4k
numjobs=4

[reader1]
rw=randread
directory=/mnt/readcache

[writer1]
rw=randwrite
directory=/mnt/nocache
rate_iops=3200
```

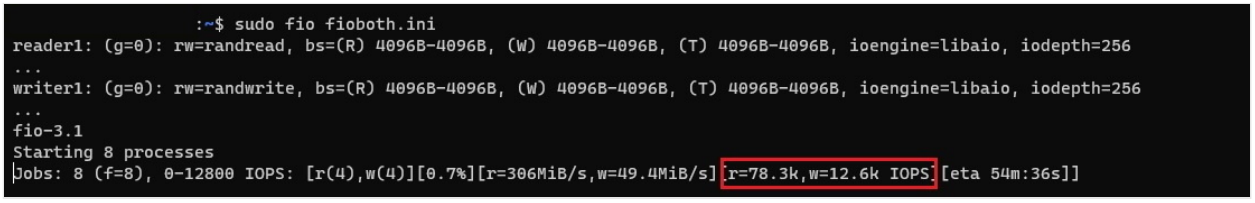
Note the follow key things that are in line with the design guidelines discussed in previous sections. These specifications are essential to drive maximum IOPS,

- A high queue depth of 128.
- A small block size of 4 KB.
- Multiple threads performing random reads and writes.

Run the following command to kick off the FIO test for 30 seconds,

```
sudo fio --runtime 30 fioreadwrite.ini
```

While the test runs, you are able to see the number of combined read and write IOPS the VM and Premium disks are delivering. As shown in the sample below, the Standard_D8ds_v4 VM is delivering more than 90,000 combined Read and Write IOPS. This is a combination of the disk and the cache performance.



Maximum combined throughput

To get the maximum combined Read and Write Throughput, use a larger block size and large queue depth with multiple threads performing reads and writes. You can use a block size of 64 KB and queue depth of 128.

Next steps

Proceed to our article on designing for high performance.

In that article, you create a checklist similar to your existing application for the prototype. Using Benchmarking tools you can simulate the workloads and measure performance on the prototype application. By doing so, you can determine which disk offering can match or surpass your application performance requirements. Then you can implement the same guidelines for your production application.

Scalability and performance targets for VM disks

Article • 12/09/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can attach a number of data disks to an Azure virtual machine (VM). Based on the scalability and performance targets for a VM's data disks, you can determine the number and type of disk that you need to meet your performance and capacity requirements.

> **Important**
>
> For optimal performance, limit the number of highly utilized disks attached to the virtual machine to avoid possible throttling. If all attached disks aren't highly utilized at the same time, the virtual machine can support a larger number of disks. Additionally, when creating a managed disk from an existing managed disk, only 49 disks can be created concurrently. More disks can be created after some of the initial 49 have been created.

For Azure managed disks:

The following table illustrates the default and maximum limits of the number of resources per region per subscription. The limits remain the same irrespective of disks encrypted with either platform-managed keys or customer-managed keys. There is no limit for the number of Managed Disks, snapshots and images per resource group.

Expand table

Resource	Limit
Standard managed disks	50,000
Standard SSD managed disks	50,000
Premium SSD managed disks	50,000
Premium SSD v2 managed disks	1,000
Premium SSD v2 managed disks capacity[2]	32,768
Ultra disks	1,000
Ultra disk capacity[2]	32,768
Standard_LRS snapshots[1]	75,000
Standard_ZRS snapshots[1]	75,000
Managed image	50,000

[1]An individual disk can have 500 incremental snapshots.

[2]This is the default max but higher capacities are supported by request. To request an increase in capacity, request a quota increase or contact Azure Support.

For standard storage accounts:

A Standard storage account has a maximum total request rate of 20,000 IOPS. The total IOPS across all of your virtual machine disks in a Standard storage account should not exceed this limit.

For unmanaged disks, you can roughly calculate the number of highly utilized disks supported by a single standard storage account based on the request rate limit. For example, for a Basic tier VM, the maximum number of highly utilized disks is about 66, which is 20,000/300 IOPS per disk. The maximum number of highly utilized disks for a Standard tier VM is about 40, which is 20,000/500 IOPS per disk.

For premium storage accounts:

A premium storage account has a maximum total throughput rate of 50 Gbps. The total throughput across all of your VM disks should not exceed this limit.

See VM sizes for more details.

Create an incremental snapshot for managed disks

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Incremental snapshots are point-in-time backups for managed disks that, when taken, consist only of the changes since the last snapshot. The first incremental snapshot is a full copy of the disk. The subsequent incremental snapshots occupy only delta changes to disks since the last snapshot. When you restore a disk from an incremental snapshot, the system reconstructs the full disk that represents the point in time backup of the disk when the incremental snapshot was taken. This capability for managed disk snapshots potentially allows them to be more cost-effective, since, unless you choose to, you don't have to store the entire disk with each individual snapshot. Just like full snapshots, incremental snapshots can be used to either create a full managed disk or a full snapshot. Both full snapshots and incremental snapshots can be used immediately after being taken. In other words, once you take either snapshot, you can immediately read the underlying data and use it to restore disks.

There are a few differences between an incremental snapshot and a full snapshot. Incremental snapshots will always use Standard HDD storage, irrespective of the storage type of the disk, whereas full snapshots can use Premium SSDs. If you're using full snapshots on Premium Storage to scale up VM deployments, we recommend you use custom images on standard storage in the Azure Compute Gallery. It will help you achieve a more massive scale with lower cost. Additionally, incremental snapshots potentially offer better reliability with zone-redundant storage (ZRS). If ZRS is available in the selected region, an incremental snapshot will use ZRS automatically. If ZRS isn't available in the region, then the snapshot will default to locally redundant storage (LRS). You can override this behavior and select one manually but, we don't recommend that.

Incremental snapshots are billed for the used size only. You can find the used size of your snapshots by looking at the Azure usage report. For example, if the used data size of a snapshot is 10 GiB, the **daily** usage report will show 10 GiB/(31 days) = 0.3226 as the consumed quantity.

Restrictions

- Incremental snapshots currently can't be moved between subscriptions.
- You can currently only generate SAS URIs of up to five snapshots of a particular snapshot family at any given time.

- You can't create an incremental snapshot for a particular disk outside of that disk's subscription.
- Incremental snapshots can't be moved to another resource group. But, they can be copied to another resource group or region.
- Up to seven incremental snapshots per disk can be created every five minutes.
- A total of 500 incremental snapshots can be created for a single disk. The 500 quota limit isn't over the lifetime of a disk, but at any given point in time. You can always delete older snapshots of a disk to make room for newer snapshots.completion
- You can't get the changes between snapshots taken before and after you changed the size of the parent disk across 4-TB boundary. For example, You took an incremental snapshot `snapshot-a` when the size of a disk was 2 TB. Now you increased the size of the disk to 6 TB and then took another incremental snapshot `snapshot-b`. You can't get the changes between `snapshot-a` and `snapshot-b`. You have to download the full copy of `snapshot-b` created after the resize. Subsequently, you can get the changes between `snapshot-b` and snapshots created after `snapshot-b`.
- When you create a managed disk from a snapshot, it starts a background copy process. You can attach a disk to a VM while this process is running but you'll experience performance impact. You can use `CompletionPercent` property to check the status of the background copy only for Premium SSD v2 and Ultra Disk. You can't use the `CompletionPercent` property to gauge the progress of the background data copy for snapshots created from Premium SSD, Standard SSD, and Standard HDDs, or the disk hydration process from snapshots.

Incremental snapshots of Premium SSD v2 and Ultra Disks

Incremental snapshots of Premium SSD v2 and Ultra Disks have the following extra restrictions:

- Snapshots with a 512 logical sector size are stored as VHD, and can be used to create any disk type. Snapshots with a 4096 logical sector size are stored as VHDX and can only be used to create Ultra Disks and Premium SSD v2 disks, they can't be used to create other disk types. To determine which sector size your snapshot is, see check sector size.
- Up to five disks may be simultaneously created from a snapshot of a Premium SSD v2 or an Ultra Disk.
- When an incremental snapshot of either a Premium SSD v2 or an Ultra Disk is created, a background copy process for that disk is started. While a background copy is ongoing, you can have up to three total snapshots pending. The process must complete before any more snapshots of that disk can be created.
- Incremental snapshots of a Premium SSD v2 or an Ultra Disk can't be used immediately after they're created. The background copy must complete before you can create a disk from the snapshot. See Check snapshot status for details.

- When you increase the size of a Premium SSD v2 or an Ultra Disk, any incremental snapshots that are under background copy will fail.
- Encryption settings can't be updated for Premium SSD v2 and Ultra Disk snapshot where background data copy is in progress.
- When you attach a Premium SSD v2 or Ultra Disk created from snapshot to a running Virtual Machine while `CompletionPercent` property hasn't reached 100, the disk suffers performance impact. Specifically, if the disk has a 4k sector size, it may experience slower read. If the disk has a 512e sector size, it may experience slower read and write. To track the progress of this background copy process, see the check disk status section of either the Azure PowerShell sample or the Azure CLI.
- You can have up to 50 currently active background copies per subscription. The following activities count against the total number of active background copies:
  - Creating Premium SSD v2 and Ultra Disks with snapshots
  - Creating Premium SSD v2 and Ultra Disks with restore points
  - Uploading VHDX files into Premium SSD v2 and Ultra Disks
  - Converting existing Premium SSDs to Premium SSD v2 disks.

> **Note**
>
> Normally, when you take an incremental snapshot, and there aren't any changes, the size of that snapshot is 0 MiB. Currently, empty snapshots of disks with a 4096 logical sector size instead have a size of 6 MiB, when they'd normally be 0 MiB.

Create incremental snapshots

Azure CLI

You can use the Azure CLI to create an incremental snapshot. You need the latest version of the Azure CLI. See the following articles to learn how to either install or update the Azure CLI.

The following script creates an incremental snapshot of a particular disk:

Azure CLI

```
# Declare variables
diskName="yourDiskNameHere"
resourceGroupName="yourResourceGroupNameHere"
snapshotName="desiredSnapshotNameHere"

# Get the disk you need to backup
yourDiskID=$(az disk show -n $diskName -g $resourceGroupName --query "id" --
```

```
output tsv)

# Create the snapshot
az snapshot create -g $resourceGroupName -n $snapshotName --source $yourDiskID
--incremental true
```

You can identify incremental snapshots from the same disk with the `SourceResourceId` property of snapshots. `SourceResourceId` is the Azure Resource Manager resource ID of the parent disk.

You can use `SourceResourceId` to create a list of all snapshots associated with a particular disk. Replace `yourResourceGroupNameHere` with your value and then you can use the following example to list your existing incremental snapshots:

Azure CLI

```
# Declare variables and create snapshot list
subscriptionId="yourSubscriptionId"
resourceGroupName="yourResourceGroupNameHere"
diskName="yourDiskNameHere"

az account set --subscription $subscriptionId

diskId=$(az disk show -n $diskName -g $resourceGroupName --query [id] -o tsv)

az snapshot list --query "[?creationData.sourceResourceId=='$diskId' &&
incremental]" -g $resourceGroupName --output table
```

Check snapshot status

Incremental snapshots of Premium SSD v2 or Ultra Disks can't be used to create new disks until the background process copying the data into the snapshot has completed.

You can use either the CLI or PowerShell sections to check the status of the background copy from a disk to a snapshot.

> **ⓘ Important**
>
> You can't use the following sections to get the status of the background copy process for disk types other than Ultra Disk or Premium SSD v2. Snapshots of other disk types always report 100%.

CLI

You have two options for getting the status of snapshots. You can either get a list of all incremental snapshots associated with a specific disk, and their respective status, or you can get the status of an individual snapshot.

CLI - List incremental snapshots

The following script returns a list of all snapshots associated with a particular disk. The value of the `CompletionPercent` property of any snapshot must be 100 before it can be used. Replace `yourResourceGroupNameHere`, `yourSubscriptionId`, and `yourDiskNameHere` with your values then run the script:

Azure CLI

```
# Declare variables and create snapshot list
subscriptionId="yourSubscriptionId"
resourceGroupName="yourResourceGroupNameHere"
diskName="yourDiskNameHere"
az account set --subscription $subscriptionId
diskId=$(az disk show -n $diskName -g $resourceGroupName --query [id] -o tsv)
az snapshot list --query "[?creationData.sourceResourceId=='$diskId' &&
incremental]" -g $resourceGroupName --output table
```

CLI - Individual snapshot

You can also check the status of an individual snapshot by checking the `CompletionPercent` property. Replace `$sourceSnapshotName` with the name of your snapshot then run the following command. The value of the property must be 100 before you can use the snapshot for restoring disk or generate a SAS URI for downloading the underlying data.

Azure CLI

```
az snapshot show -n $sourceSnapshotName -g $resourceGroupName --query
[completionPercent] -o tsv
```

PowerShell

You have two options for getting the status of snapshots. You can either get a list of all incremental snapshots associated with a particular disk and their respective status, or you can get the status of an individual snapshot.

PowerShell - List incremental snapshots

The following script returns a list of all incremental snapshots associated with a particular disk that haven't completed their background copy. Replace `yourResourceGroupNameHere` and `yourDiskNameHere`, then run the script.

Azure PowerShell

```
$resourceGroupName = "yourResourceGroupNameHere"
$snapshots = Get-AzSnapshot -ResourceGroupName $resourceGroupName
$diskName = "yourDiskNameHere"
$yourDisk = Get-AzDisk -DiskName $diskName -ResourceGroupName $resourceGroupName
$incrementalSnapshots = New-Object System.Collections.ArrayList
foreach ($snapshot in $snapshots)
{
    if($snapshot.Incremental -and $snapshot.CreationData.SourceResourceId -eq
$yourDisk.Id -and $snapshot.CreationData.SourceUniqueId -eq $yourDisk.UniqueId)
    {
    $targetSnapshot=Get-AzSnapshot -ResourceGroupName $resourceGroupName -
SnapshotName $snapshotName
        {
        if($targetSnapshot.CompletionPercent -lt 100)
            {
            $incrementalSnapshots.Add($targetSnapshot)
            }
        }
    }
}
$incrementalSnapshots
```

PowerShell - individual snapshots

You can check the `CompletionPercent` property of an individual snapshot to get its status. Replace `yourResourceGroupNameHere` and `yourSnapshotName` then run the script. The value of the property must be 100 before you can use the snapshot for restoring disk or generate a SAS URI for downloading the underlying data.

Azure PowerShell

```
$resourceGroupName = "yourResourceGroupNameHere"
$snapshotName = "yourSnapshotName"
$targetSnapshot=Get-AzSnapshot -ResourceGroupName $resourceGroupName -SnapshotName
$snapshotName
$targetSnapshot.CompletionPercent
```

Check sector size

Snapshots with a 4096 logical sector size can only be used to create Premium SSD v2 or Ultra Disks. They can't be used to create other disk types. Snapshots of disks with 4096 logical sector size are stored as VHDX, whereas snapshots of disks with 512 logical sector size are stored as VHD. Snapshots inherit the logical sector size from the parent disk.

To determine whether or your Premium SSD v2 or Ultra Disk snapshot is a VHDX or a VHD, get the `LogicalSectorSize` property of the snapshot.

The following command displays the logical sector size of a snapshot:

Azure CLI

```
az snapshot show -g resourcegroupname -n snapshotname --query
[creationData.logicalSectorSize] -o tsv
```

Next steps

See the following articles to create disks from your snapshots using the Azure CLI or Azure PowerShell module.

See Copy an incremental snapshot to a new region to learn how to copy an incremental snapshot across regions.

If you have more questions on snapshots, see the snapshots section of the FAQ.

If you'd like to see sample code demonstrating the differential capability of incremental snapshots, using .NET, see Copy Azure Managed Disks backups to another region with differential capability of incremental snapshots.

Last updated on 07/02/2025

Instant access snapshots for Azure Managed Disks

Summarize this article for me

Azure Managed Disk snapshots provide point-in-time backups of disks that can be used as backup during software upgrades, disaster recovery, or to create new environments. When creating snapshots from Azure Managed Disks, Azure automatically copies the data from the disk to the snapshot in the background.

Snapshots of Premium SSD, Standard SSD, and Standard HDDs are by default instant access. Immediately upon creation, these snapshots can be used to restore new disks, download underlying data, and copy to other Azure regions.

Snapshots of Ultra Disks and Premium SSD v2 aren't instant access by default and require the background data copy to complete before they can be used. To create instant access snapshots, you can opt in to enable instant access using the existing snapshot API at the time of snapshot creation.

Snapshots of Premium SSD, Standard SSD, and Standard HDDs

Snapshots of Premium SSD, Standard SSD, and Standard HDDs are instant access by default. As soon as snapshots are created, you can immediately use these snapshots to create new disks of any supported disk types, generate SAS URIs to download data, or copy snapshots to other Azure regions for regional disaster recovery. After snapshot creation, Azure automatically initiates a background data copy from the source disk to snapshot.

Disks created from snapshots of Premium SSD, Standard SSD, and Standard HDD can be immediately attached to running virtual machines. During disk creation, Azure automatically initiates a background data copy to hydrate the disk from snapshot data. During this process, the disk may experience temporary performance degradation until the background copy completes. To reduce the performance impact, you can create a full snapshot on Premium Storage and restore the disk from that snapshot.

Snapshots of Ultra Disk and Premium SSD v2

Snapshots of Ultra Disk and Premium SSD v2 aren't instant access by default and can only be used after snapshot's background data copy completes. To bypass this, you can choose to configure instant access by specifying a value in the `InstantAccessDurationMins` parameter at

the time of snapshot creation. This will allow you to create an instant access snapshot and can be immediately used to create new disks. Disks created from instant access snapshots are rapidly hydrated with minimal performance impact and can be immediately attached to a running VM.

After the time specified in `InstantAccessDurationMins` elapses, the snapshot automatically transitions to a Standard Storage snapshot and can be used once the background data copy has completed. You can monitor the snapshot's state via the `SnapshotAccessState` property.

Until the data is fully copied to Standard Storage, snapshots in the InstantAccess state depend on the availability of the source disk and do not provide protection against disk or zonal failures. To ensure durability and protection, the snapshot must complete its background data copy.

Until the data is fully copied to Standard Storage, snapshots in the **InstantAccess** state depend on the availability of the source disk and don't provide protection against disk or zonal failures. To ensure zonal redundancy, the snapshot must complete its background data copy to Standard ZRS. You can monitor a snapshot's background data copy progress by checking SnapshotAccessState property.

Limitations

- Only Ultra Disks and Premium SSD v2 can be created from instant access snapshots of Ultra Disks and Premium SSD v2 disks
- `InstantAccessDurationMins` must be between 60 and 300 minutes
- Instant access snapshots count towards the Ultra Disk and Premium SSD v2 limit of three in-progress snapshots per disk
- You can create up to 15 disks concurrently from all instant access snapshots of an individual disk
- You can't use an instant access snapshot to create an Ultra Disk or a Premium SSD v2 larger than the snapshot's size
- If a Ultra Disk or Premium SSD v2 is being hydrated from a snapshot, you can't create an instant access snapshot of that disk
  - Check the `CompletionPercent` property of the disk, if it's below 100 then it's currently being hydrated
- Instant access snapshots of Ultra Disk or Premium SSD v2 can't be copied across regions and the underlying data can't be downloaded until the background data copy completes
  - Check the `CompletionPercent` property on the snapshot, when it reaches 100 then it can be copied across regions and the underlying data can be downloaded
- The encryption property of a disk created from an instant access snapshot can't be updated during disk hydration and you can't update the encryption settings for Ultra

Disks and Premium SSD v2 that currently have active instant access snapshots
- Attaching Ultra Disks and Premium SSD v2 across fault domains (using either a VM in an availability set or a Virtual Machine Scale Set) triggers the background data copy and prevents you from creating an instant access snapshot during the background data copy.
- Ultra Disk and Premium SSD v2 that have active instant access snapshots can't be attached across fault domains
- To create instant access snapshots from Ultra Disks, the snapshot must be created from a newly provisioned Ultra Disks.
- The greatest read latency improvements for disks created from instant access snapshots are currently available in Germany West Central, East Asia, Southeast Asia, Central India, and Sweden Central.

Regional availability

Instant access snapshots are currently supported in all pulic regions.

Billing of instant access snapshots of Ultra Disks and Premium SSD v2 disks

Instant access snapshots use a usage-based billing model with two components: a storage charge and a one-time restore fee.

- Storage charge: You are billed only for the additional storage consumed by an instant access snapshot during its active lifetime. When a snapshot is first created, it starts at zero additional cost, as it references the source disk as its base. As data on the source disk changes or is deleted over time, the snapshot preserves the original point-in-time state, and its used size grows accordingly. This means you pay only for incremental changes of instant access snapshot, not for a full copy of the disk.
- Restore charge: Each time you restore a disk from an instant access snapshot, a one-time restore operation fee is applied. This fee is calculated based on the provisioned size of the disk at the time of restore, providing predictable billing for restore operations.

Learn more about Instant Access Snapshot billing in here.

Create an instant access snapshot

Instant access snapshots of Ultra Disk and Premium SSD v2 are not a separate snapshot resource class to manage. They are incremental snapshots that temporarily enter Instant Access state for the specified duration. When this duration expires, snapshots automatically transition out of the Instant Access state and continue as Standard ZRS snapshots for better reliability and long-term retention.

To create instant access snapshots of Ultra Disk and Premium SSD v2, you use the same Snapshot API and commands, but add an additional parameter that specifies the how long the snapshot remains in the instant access state (minimum 60 minutes, maximum 300 minutes). After the specified duration expires, the snapshot automatically transitions to a Standard Storage snapshot. You can monitor your snapshot's state by checking the snapshot's access state.

In the Azure portal, you can't specify a duration, so snapshots created through the portal remain instant access snapshots for 300 minutes (5 hours).

Azure CLI

Azure CLI

```
# Declare variables

subscriptionId="yourSubscriptionId"
diskName="yourDiskName"
resourceGroupName="yourResourceGroupName"
snapshotName="desiredInstantAaccessSnapshotName"

# Set Subscription Id

az account set --subscription $subscriptionId

# Get the disk you need to create an instant access snapshot

yourDiskID=$(az disk show -n $diskName -g $resourceGroupName --query "id" --
output tsv)

# Create an instant access snapshot

az snapshot create -g $resourceGroupName -n $snapshotName --source $yourDiskID
--incremental true --location eastus2euap  --sku Standard_ZRS --ia-duration 300
```

Check snapshot access state

You can monitor Managed Disk Snapshot across different states using the `SnapshotAccessState` property of the snapshot resource. This property indicates the current access state of a snapshot, helping you understand its readiness for operations. Here are the states and what they imply:

Expand table

State	Description	Applies To
Pending	This snapshot can't be used to create a new disk, download data, or copy to another region.	Incremental snapshots from Ultra Disks and Premium SSD v2 disks during background data copy; snapshots being copied across regions.
Available	This snapshot can be used to create a new disk (with a performance impact), download data, or copy to another region.	Snapshots of Premium SSD, Standard SSD, and Standard HDDs; incremental snapshots for Ultra Disks and Premium SSD v2 disks after background copy completes; snapshots copied within the same region using shallow copy.
InstantAccess	This snapshot can be used to create rapidly hydrated disk with minimal performance impact, but the underlying data can't be downloaded and it can't be copied to another region.	Instant access snapshots for Ultra Disks and Premium SSD v2 disks when the instant access duration hasn't lapsed and the background data copy is ongoing.
AvailableWithInstantAccess	This snapshot can be used to create rapidly hydrated disk with minimal performance impact, the underlying data can be downloaded, and it can be copied to another region.	Instant access snapshots for Ultra Disks and Premium SSD v2 disks when the instant access duration hasn't lapsed and the background data copy completes.

CLI

Azure CLI

```
snapshotName="DesiredInstantAccessSnapshotTestName"
resourceGroupName="yourResourceGroupName"

snapshotId=$(az snapshot show --name $snapshotName --resource-group
$resourceGroupName --query [id] -o tsv)

az resource show --ids $snapshotId --query "properties.snapshotAccessState" --
output tsv

az resource show --ids $snapshotId --query
"properties.creationData.instantAccessDurationMinutes" --output tsv
```

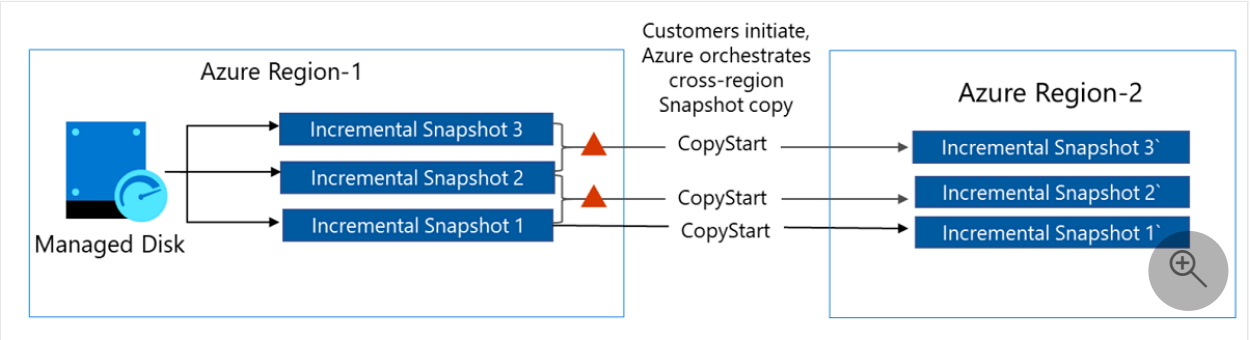
Copy an incremental snapshot to a new region

Article • 08/22/2024

There are two options for copying an incremental snapshot across regions. The first option, a managed process (recommended), that will perform the copy for you. This process is handled by Azure and removes the maintenance overhead of managing the copy process by staging a storage account in the target region. Azure ensures that only changes since the last snapshot in the target region are copied to the target region to reduce the data footprint, reducing the recovery point objective. You can check the process of a copy so you know when a target snapshot is ready to restore disks. For this managed process, you're only billed for the bandwidth cost of the data transfer across the region, and the read transactions on the source snapshot. Don't delete your source snapshot while the target snapshot is being copied.

The second option is a manual copy, where you get the changes between two incremental snapshots, down to the block level, and manually copy it from one region to another. Most users should use the managed process but, if you're interested in improving the copy speed, the second option allows you to use your compute resources to make the copy faster.

This article covers copying an incremental snapshot from one region to another. See Create an incremental snapshot for managed disks for conceptual details on incremental snapshots.



Restrictions

- You can copy 100 incremental snapshots in parallel at the same time per subscription per region.
- If you use the REST API, you must use version 2020-12-01 or newer of the Azure Compute REST API.
- You can only copy one incremental snapshot of a particular disk at a time.

- Snapshots must be copied in the order they were created.
- Only incremental snapshots can be copied across regions. Full snapshots can't be copied across regions.

Managed copy

Azure CLI

You can use the Azure CLI to copy an incremental snapshot. You need the latest version of the Azure CLI. See the following articles to learn how to either install or update the Azure CLI.

The following script copies an incremental snapshot from one region to another:

Azure CLI

```
subscriptionId=<yourSubscriptionID>
resourceGroupName=<yourResourceGroupName>
targetSnapshotName=<name>
sourceSnapshotName=<name>
targetRegion=<validRegion>

sourceSnapshotId=$(az snapshot show -n $sourceSnapshotName -g
$resourceGroupName --query [id] -o tsv)

az snapshot create -g $resourceGroupName -n $targetSnapshotName -l
$targetRegion --source $sourceSnapshotId --incremental --copy-start
```

Check copy status

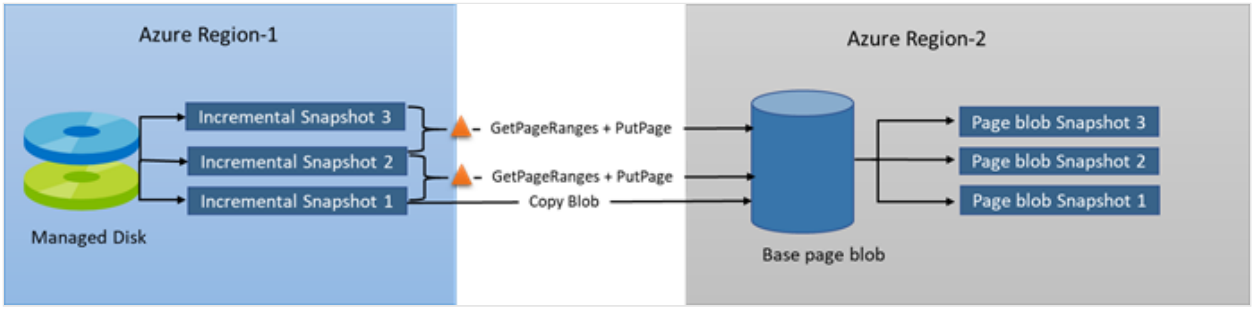
You can check the status of an individual snapshot by checking the `CompletionPercent` property. Replace `$sourceSnapshotName` with the name of your snapshot then run the following command. The value of the property must be 100 before you can use the snapshot for restoring disk or generate a SAS URI for downloading the underlying data.

Azure CLI

```
az snapshot show -n $sourceSnapshotName -g $resourceGroupName --query
[completionPercent] -o tsv
```

Manual copy

Incremental snapshots offer a differential capability. They enable you to get the changes between two incremental snapshots of the same managed disk, down to the block level. You can use this to reduce your data footprint when copying snapshots across regions. For example, you can download the first incremental snapshot as a base blob in another region. For the subsequent incremental snapshots, you can copy only the changes since the last snapshot to the base blob. After copying the changes, you can take snapshots on the base blob that represent your point in time backup of the disk in another region. You can restore your disk either from the base blob or from a snapshot on the base blob in another region.



Next steps

If you'd like to see sample code demonstrating the differential capability of incremental snapshots, using .NET, see Copy Azure Managed Disks backups to another region with differential capability of incremental snapshots.

If you have additional questions on snapshots, see the snapshots section of the FAQ.

Overview of Azure Disk Backup

Summarize this article for me

Azure Disk Backup is a native, cloud-based backup solution that protects your data in managed disks. It's a simple, secure, and cost-effective solution that enables you to configure protection for managed disks in a few steps. It assures that you can recover your data in a disaster scenario.

Azure Disk Backup offers a turnkey solution that provides snapshot lifecycle management for managed disks by automating periodic creation of snapshots and retaining it for configured duration using backup policy. You can manage the disk snapshots with zero infrastructure cost and without the need for custom scripting or any management overhead. This is a crash-consistent backup solution that takes point-in-time backup of a managed disk using incremental snapshots with support for multiple backups per day. It's also an agent-less solution and doesn't impact production application performance. It supports backup and restore of both OS and data disks (including shared disks), whether or not they're currently attached to a running Azure virtual machine.

If you require application-consistent backup of virtual machine including the data disks, or an option to restore an entire virtual machine from backup, restore a file or folder, or restore to a secondary region, then use the Azure VM backup solution. Azure Backup offers side-by-side support for backup of managed disks using Disk Backup in addition to Azure VM backup solutions. This is useful when you need once-a-day application consistent backups of virtual machines and also more frequent backups of OS disks or a specific data disk that are crash consistent, and don't impact the production application performance.

Azure Disk Backup is integrated into Resiliency, which provides a **single unified management experience** in Azure for enterprises to govern, monitor, operate, and analyze backups at scale.

> **Note**
>
> - If the target disk is attached as a Persistent Volume to an AKS cluster, choose Azure Backup for AKS over the standalone Disk Backup solution. It enables backing up the disk as snapshots along with the containerized application in a Kubernetes-aware manner, all as a single unit. Additionally, you get Cross Region Restore and ransomware protection capabilities with AKS Backup.

Key benefits of Disk Backup

Azure Disk backup is an agentless and crash consistent solution that uses incremental snapshots and offers the following advantages:

- More frequent and quick backups without interrupting the virtual machine.
- Doesn't affect the performance of the production application.
- No security concerns since it doesn't require running custom scripts or installing agents.
- A cost-effective solution to back up specific disks when compared to backing up entire virtual machine.

Azure Disk backup solution is useful in the following scenarios:

- Need for frequent backups per day without application being quiescent.
- Apps running in a cluster scenario: both Windows Server Failover Cluster and Linux clusters are writing to shared disks.
- Specific need for agentless backup because of security or performance concerns on the application.
- Application consistent backup of VM isn't feasible since line-of-business apps don't support Volume Shadow Copy Service (VSS).

Consider Azure Disk Backup in scenarios where:

- A mission-critical application is running on an Azure Virtual machine that demands multiple backups per day to meet the recovery point objective, but without impacting the production environment or application performance.
- Your organization or industry regulation restricts installing agents because of security concerns.
- Executing custom pre or post scripts and invoking freeze and thaw on Linux virtual machines to get application-consistent backup puts undue overhead on production workload availability.
- Containerized applications running on Azure Kubernetes Service (AKS cluster) are using managed disks as persistent storage. Today, you must back up the managed disk via automation scripts that are hard to manage.
- A managed disk is holding critical business data, used as a file-share, or contains database backup files, and you want to optimize backup cost by not investing in Azure VM backup.
- You have many Linux and Windows single-disk virtual machines (that is, a virtual machine with just an OS disk and no data disks attached) that host web server, state-less machines, or serves as a staging environment with application configuration settings, and you need a cost efficient backup solution to protect the OS disk. For example, to trigger a quick on-demand backup before upgrading or patching the virtual machine.
- A virtual machine is running an OS configuration that is unsupported by Azure VM backup solution (for example, Windows 2008 32-bit Server).

How the backup and restore process works

- The first step in configuring backup for Azure Managed Disks is creating a Backup vault. The vault gives you a consolidated view of the backups configured across different workloads. Azure Disk backup supports only Operational Tier backup. Copying of backups to the vault storage tier is not supported. So, the Backup vault storage redundancy setting (LRS/GRS) doesn't apply to the backups stored in Operational Tier.

- Then create a Backup policy that allows you to configure backup frequency and retention duration.

- To configure backup, go to the Backup vault, assign a backup policy, select the managed disk that needs to be backed up and provide a resource group where the snapshots are to be stored and managed. Azure Backup automatically triggers scheduled backup jobs that create an incremental snapshot of the disk according to the backup frequency. Older snapshots are deleted according to the retention duration specified by the backup policy.

- Azure Backup uses incremental snapshots of the managed disk. Incremental snapshots are a cost-effective, point-in-time backup of managed disks that are billed for the delta changes to the disk since the last snapshot. These are always stored on the most cost-effective storage, standard HDD storage regardless of the storage type of the parent disks. The first snapshot of the disk will occupy the used size of the disk, and consecutive incremental snapshots store delta changes to the disk since the last snapshot. Azure Backup automatically assigns tag to the snapshots it creates to uniquely identify them.

- Once you configure the backup of a managed disk, a backup instance will be created within the backup vault. Using the backup instance, you can find health of backup operations, trigger on-demand backups, and perform restore operations. You can also view health of backups across multiple vaults and backup instances using Resiliency, which provides a single pane of glass view.

- To restore, just select the recovery point from which you want to restore the disk. Provide the resource group where the restored disk is to be created from the snapshot. Azure Backup provides an instant restore experience since the snapshots are stored locally in your subscription.

- Backup Vault uses Managed Identity to access other Azure resources. To configure backup of a managed disk and to restore from past backup, Backup Vault's managed identity requires a set of permissions on the source disk, the snapshot resource group where snapshots are created and managed, and the target resource group where you want to restore the backup. You can grant permissions to the managed identity by using Azure role-based access control (Azure RBAC). Managed identity is a service principal of a

special type that may only be used with Azure resources. Learn more about Managed Identities.

- Currently Azure Disk Backup supports operational backup of managed disks and doesn't copy the backups to Backup Vault storage. Refer to the support matrix for a detailed list of supported and unsupported scenarios, and region availability.

How does the disk backup scheduling and retention period work?

Azure Disk Backup currently supports only the Operational Tier, which helps store backups as Disk Snapshots in your tenant that aren't moved to the vault. The backup policy defines the schedule and retention period of your backups in the Operational Tier (when the snapshots will be taken and how long they will be retained).

By using the Azure Disk backup policy, you can define the backup schedule with Hourly frequency of 1, 2, 4, 6, 8, or 12 hours and Daily frequency. Although backups have scheduled timing as per the policy, there can be a difference in the actual start time of the backups from the scheduled one.

The retention period of snapshots is governed by the snapshot limit for a disk. Currently, a maximum of 500 snapshots can be retained for a disk. If the limit is reached, no new snapshots can be taken, and you need to delete the older snapshots.

The retention period for a backup also follows the maximum limit of 450 snapshots with 50 snapshots kept aside for on-demand backups.

For example, if the scheduling frequency for backups is set as Daily, then you can set the retention period for backups at a maximum value of 450 days. Similarly, if the scheduling frequency for backups is set as Hourly with a 1-hour frequency, then you can set the retention for backups at a maximum value of 18 days.

> **Note**
>
> - For Azure Disks belonging to Standard HDD, Standard SSD, and Premium SSD SKUs, you can define the backup schedule with *Hourly* frequency (of 1, 2, 4, 6, 8, or 12 hours) and *Daily* frequency.
> - For Azure Disks belonging to Premium V2 and Ultra Disk SKUs, you can define the backup schedule with *Hourly* frequency of only 12 hours and *Daily* frequency.

Why do I see more snapshots than my retention policy?

If a retention policy is set as *1*, you can find two snapshots. This configuration ensures that at least one latest recovery point is always present in the vault, if all subsequent backups fail due to any issue. This causes the presence of two snapshots.

So, if the policy is for *n* snapshots, you can find *n+1* snapshots at times. Further, you can even find *n+1+2* snapshots if there is a delay in deletion of recovery points whose retention period is over (garbage collection). This can happen at rare times when:

- You clean up snapshots, which are past retentions.
- The garbage collector (GC) in the backend is under heavy load.

Pricing

Azure Backup uses incremental snapshots of the managed disk. Incremental snapshots are charged per GiB of the storage occupied by the delta changes since the last snapshot. For example, if you're using a managed disk with a provisioned size of 128 GiB, with 100 GiB used, the first incremental snapshot is billed only for the used size of 100 GiB. 20 GiB of data is added on the disk before you create the second snapshot. Now, the second incremental snapshot is billed for only 20 GiB.

Incremental snapshots are always stored on standard storage, irrespective of the storage type of parent-managed disks, and are charged based on the pricing of standard storage. For example, incremental snapshots of a Premium SSD-Managed Disk are stored on standard storage. By default, they are stored on ZRS in regions that support ZRS. Otherwise, they are stored on locally redundant storage (LRS). The per GiB pricing of both the options, LRS and ZRS, is the same.

The snapshots created by Azure Backup are stored in the resource group within your Azure subscription and incur Snapshot Storage charges. For more details about the snapshot pricing, see Managed Disk Pricing. Because the snapshots aren't copied to the Backup Vault, Azure Backup doesn't charge a Protected Instance fee and Backup Storage cost doesn't apply.

The number of recovery points is determined by the Backup policy used to configure backups of the disk backup instances. Older block blobs are deleted according to the garbage collection process as the corresponding older recovery points are pruned.

Back up Azure Disks using Azure portal

Summarize this article for me

This article describes how to back up Azure Disk using the Azure portal. You can also use REST API to create a Backup policy and configure backup for Azure Managed Disk.

To view the supported Azure Disk backup and restore scenarios, region availability, and limitations, see the support matrix. For common questions, see the frequently asked questions.

> **Note**
>
> If the target disk is attached as a Persistent Volume to an AKS cluster, choose Azure Backup for AKS over the standalone Disk Backup solution. It enables backing up the disk as snapshots along with the containerized application in a Kubernetes-aware manner, all as a single unit. Additionally, you get Cross Region Restore and ransomware protection capabilities with AKS Backup.

Create a Backup vault

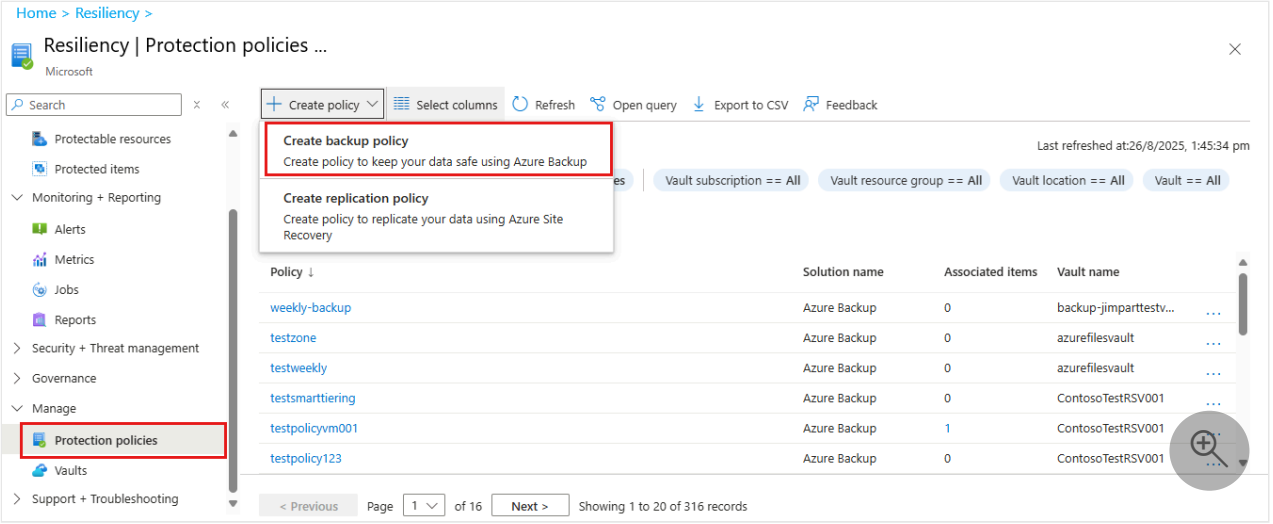
A Backup vault is a storage entity in Azure that holds backup data for various newer workloads that Azure Backup supports, such as Azure Database for PostgreSQL servers and Azure Disks. Backup vaults make it easy to organize your backup data, while minimizing management overhead. Backup vaults are based on the Azure Resource Manager model of Azure, which provides enhanced capabilities to help secure backup data.

Learn how to create a Backup vault.

Create backup policy for Azure Disks

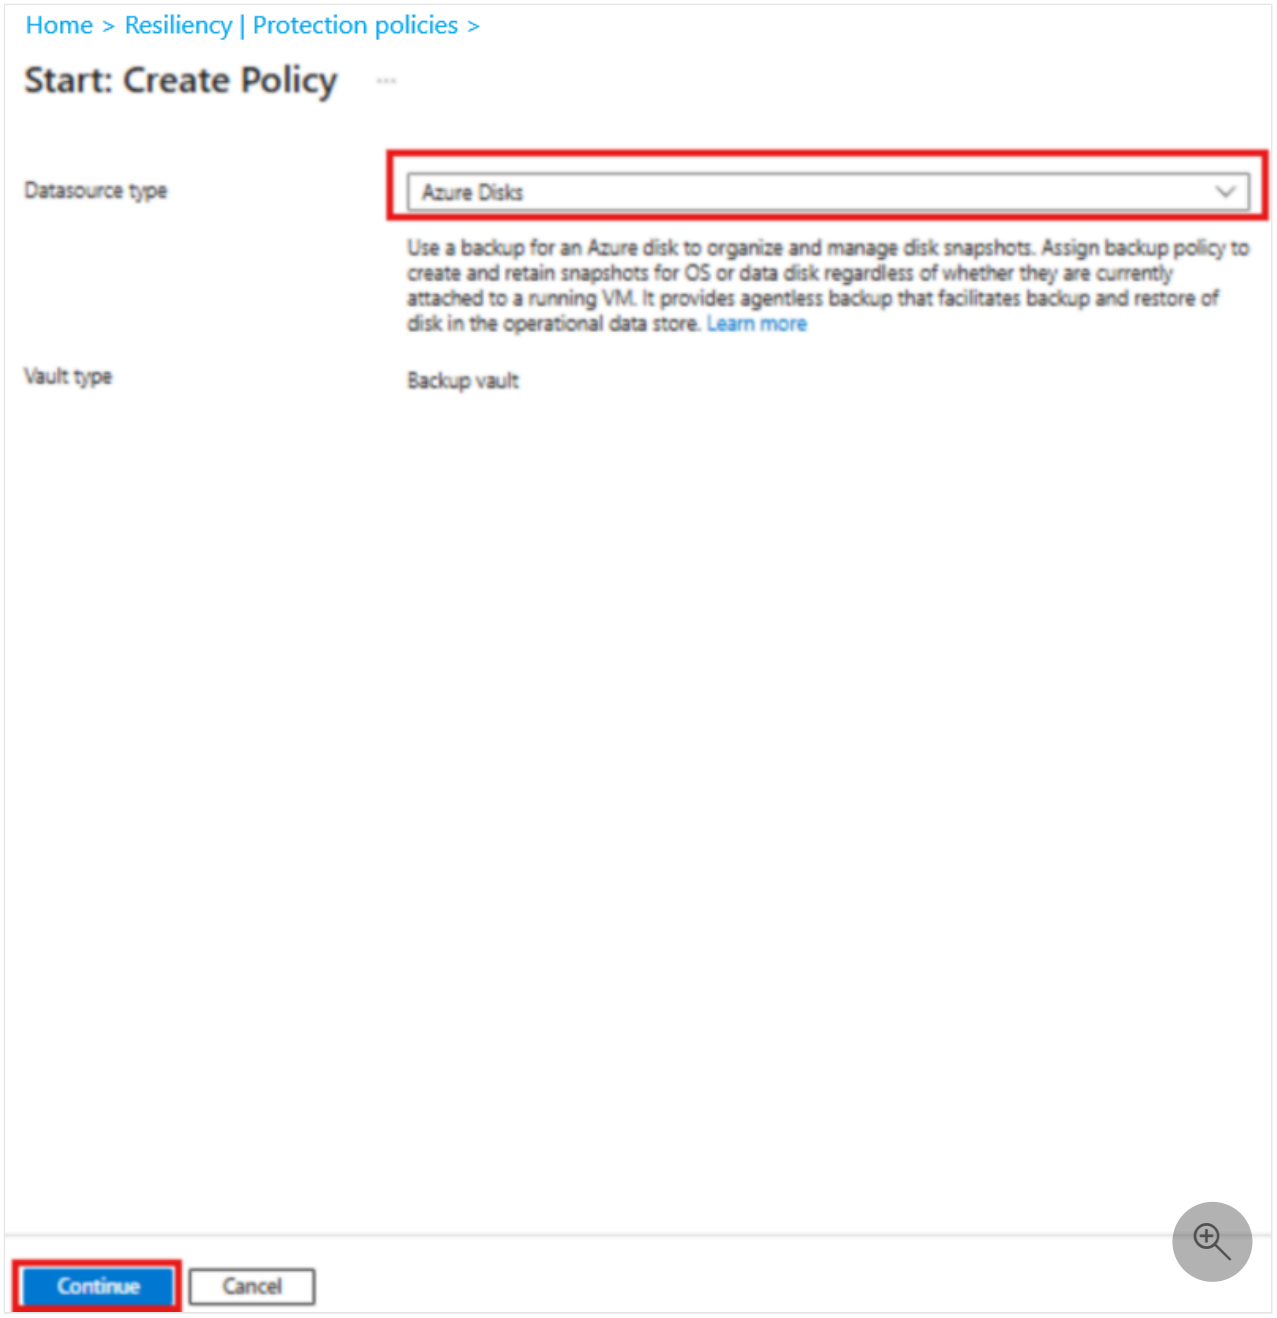
To create a backup policy for Azure Disks, follow these steps:

1. Go to **Resiliency**, and then select **Manage** > **Protection policies**.



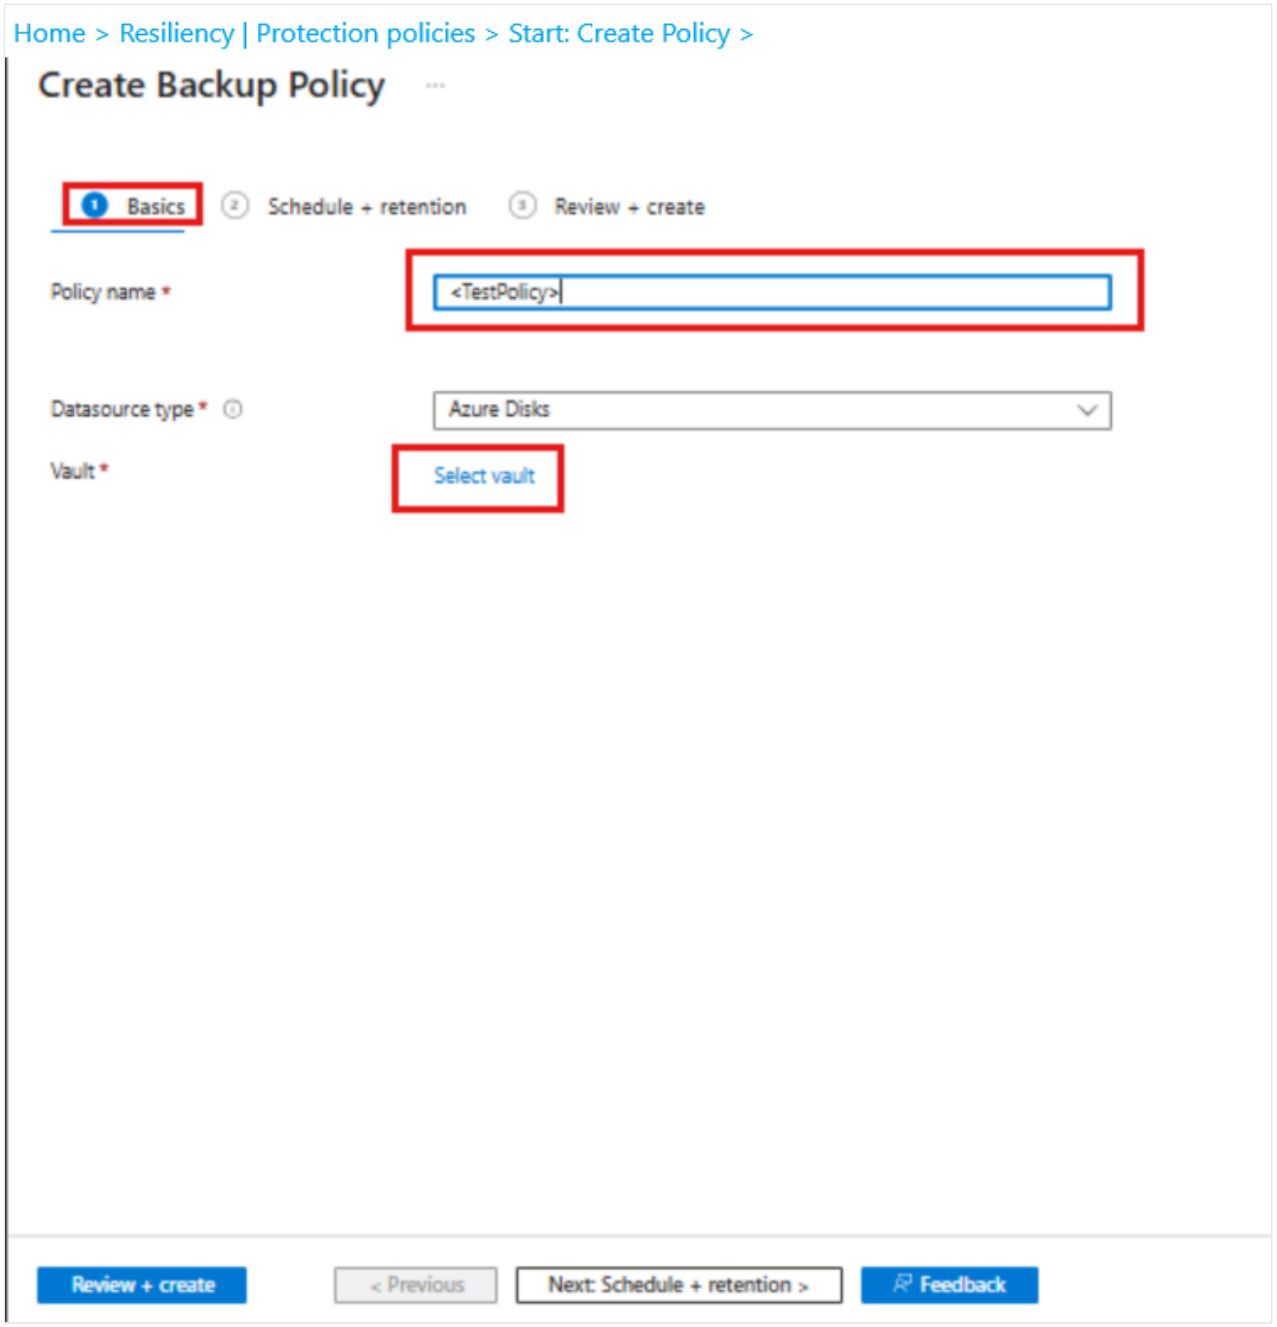
2. On the **Protection policies** pane, select **+ Create policy** > **Create backup policy**.

3. On the **Start: Create Policy** pane, select the **Datasource type** as **Azure Disks**, and then select **Continue**.



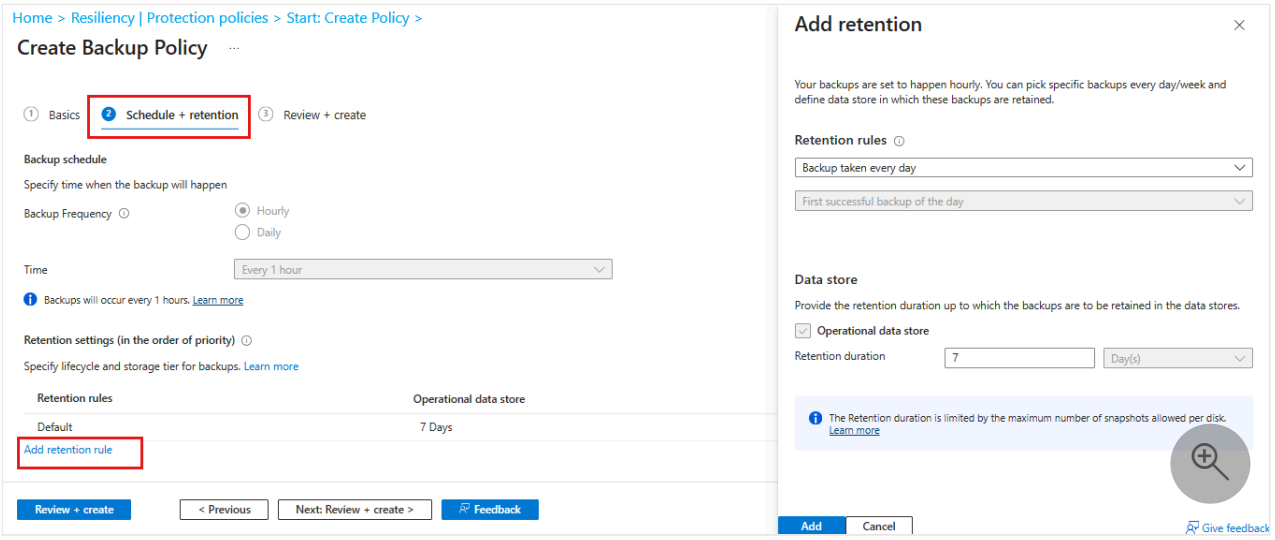
4. On the **Create Backup Policy** pane, on the **Basics** tab, enter a **Policy name**, and then under **Vault**, click **Select**.

> ⓘ **Note**
>
> Although the selected vault may have the global-redundancy setting, currently Azure Disk Backup supports snapshot datastore only. All backups are stored in a resource group in your subscription and aren't copied to backup vault storage.



5. On the **Select a Vault** pane, select the vault from the list that you created, and then click **Select**.

6. On the **Create Backup Policy** pane, on the **Schedule + retention** tab, under **Backup schedule**, select the backup frequency.



Azure Disk Backup offers multiple backups per day. If you require more frequent backups, choose the **Hourly** backup frequency with the ability to take backups with intervals of every *1*, *2*, *4*, *6*, *8*, or *12* hours. The backups are scheduled based on the **Time** interval selected. For example, if you select **Every 4 hours**, then the backups are taken at approximately in the interval of every 4 hours so the backups are distributed equally across the day. If a once a day backup is sufficient, then choose the **Daily** backup frequency. In the daily backup frequency, you can specify the time of the day when your backups are taken. It's important to note that the time of the day indicates the backup start time and not the time when the backup completes. The time required for completing the backup operation is dependent on various factors including size of the disk, and churn rate between consecutive backups. However, Azure Disk backup is an agentless backup that uses incremental snapshots, which doesn't impact the production application performance.

7. Under **Retention rules**, select retention settings that meet the recovery point objective (RPO) requirement.

   The default retention rule applies if no other retention rule is specified. The default retention rule can be modified to change the retention duration, but it cannot be deleted. You can add a new retention rule by selecting **Add retention rule**.

   You can pick **first successful backup** taken daily or weekly, and provide the retention duration that the specific backups are to be retained before they're deleted. This option is useful to retain specific backups of the day or week for a longer duration of time. All other frequent backups can be retained for a shorter duration.

   > **Note**
   >
   > Azure Backup for Managed Disks uses incremental snapshots, which are limited to 500 snapshots per disk. At a point in time, you can have 500 snapshots for a disk.

Thus, to prevent backup failure the retention duration is limited by the snapshot limit. To allow you to take on-demand backups aside from scheduled backups, backup policy limits the total backups to 450. Learn more about incremental snapshots for managed disks.

You can either set a maximum retention limit of 1 year or 450 disk snapshots, whichever reaches first. For example, if you opt for a backup frequency of 12 hours, then you can retain each recovery point for maximum 225 days as the snapshot limit is breached beyond that.

8. On the **Review + create** tab, select **Create** to complete the backup policy creation.

> **Note**
>
> - For Azure Disks belonging to Standard HDD, Standard SSD, and Premium SSD SKUs, you can define the backup schedule with *Hourly* frequency (of 1, 2, 4, 6, 8, or 12 hours) and *Daily* frequency.
> - For Azure Disks belonging to Premium V2 and Ultra Disk SKUs, you can define the backup schedule with *Hourly* frequency of only 12 hours and *Daily* frequency.

Configure Azure Disk backup

- Azure Disk backup supports only the operational tier backup. Copying of backups to the vault storage tier is currently not supported. The Backup vault storage redundancy setting (LRS/GRS) doesn't apply to the backups stored in the operational tier.
  Incremental snapshots are stored in a Standard HDD storage, irrespective of the selected storage type of the parent disk. For more reliability, incremental snapshots are stored on Zone Redundant Storage (ZRS) by default in ZRS supported regions.

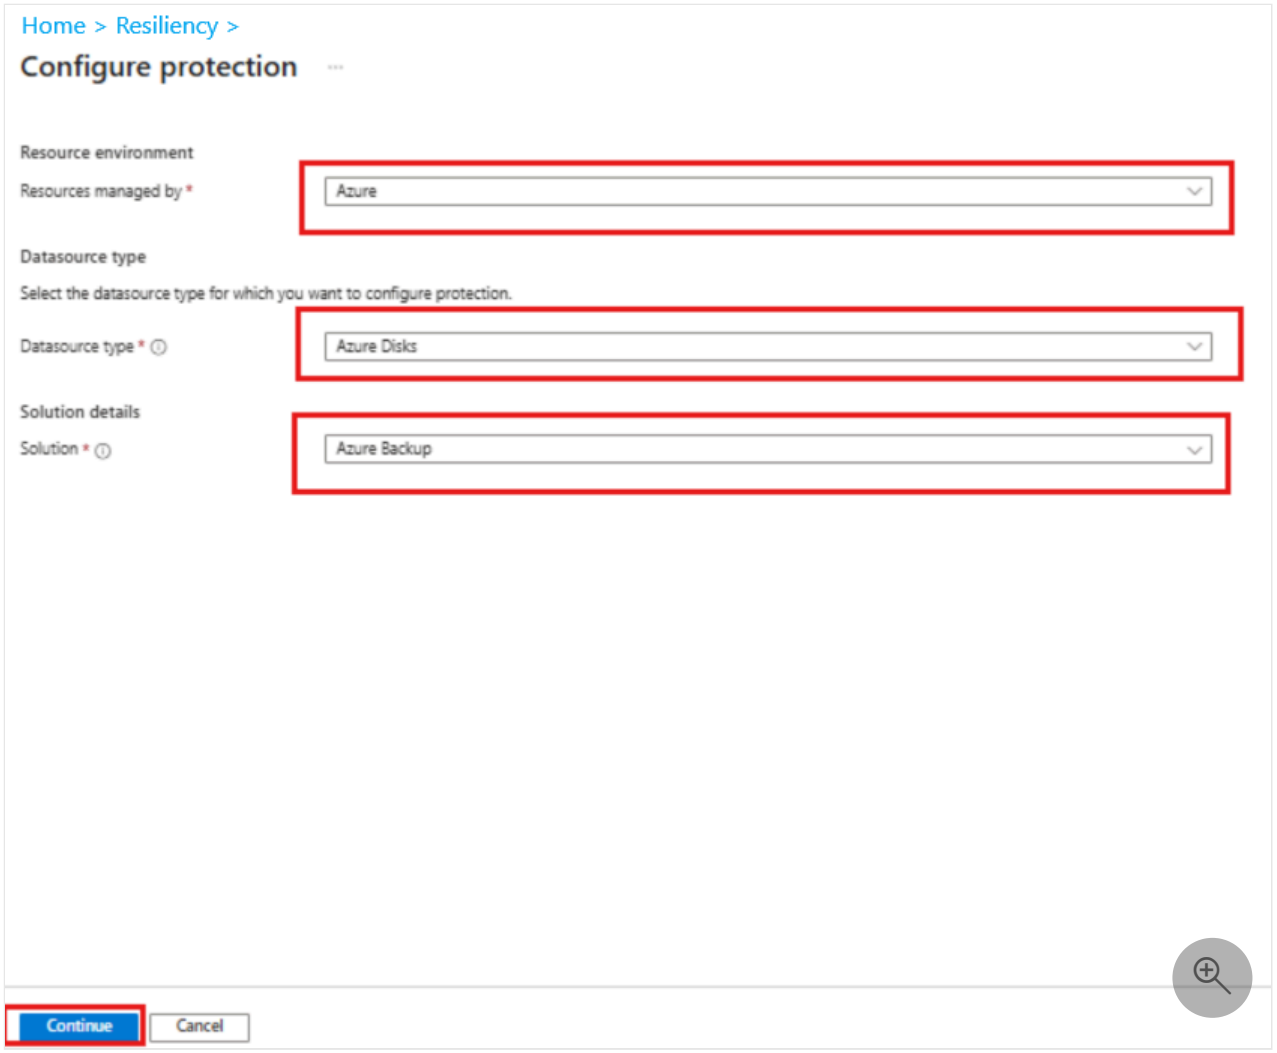
- Azure Disk backup supports cross-subscription (backup vault in one subscription and the source disk in another) backup and restore. Currently, cross-region backup and restore aren't supported by Azure Disk backup, that is, the backup vault and disk to back up are in different regions.
  So, to use Azure Disk backup, ensure that the backup vault and disk to back up are in the same region.

- Once you configure the disk backup, you can't change the Snapshot Resource Group that's assigned to a backup instance.

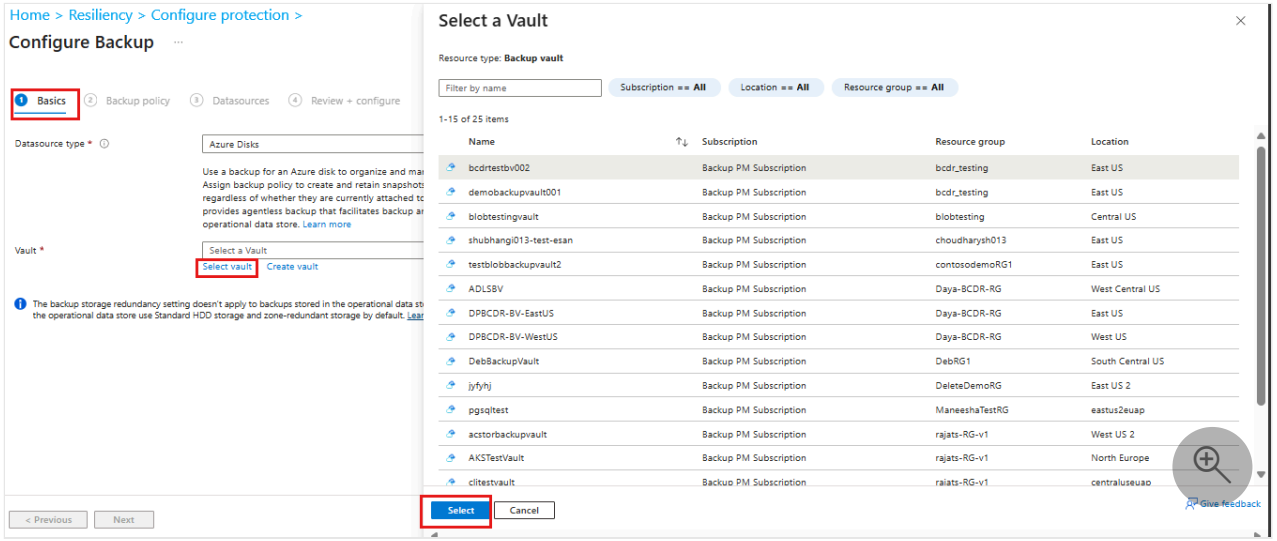
To configure Azure Disk backup, follow these steps:

1. Go to **Resiliency**, and then select **+ Configure protection**.

2. On the **Configure protection** pane, select **Resource managed by** as **Azure**, **Datasource type** as **Azure Disks**, **Solution** as **Azure Backup**, and then select **Continue**.

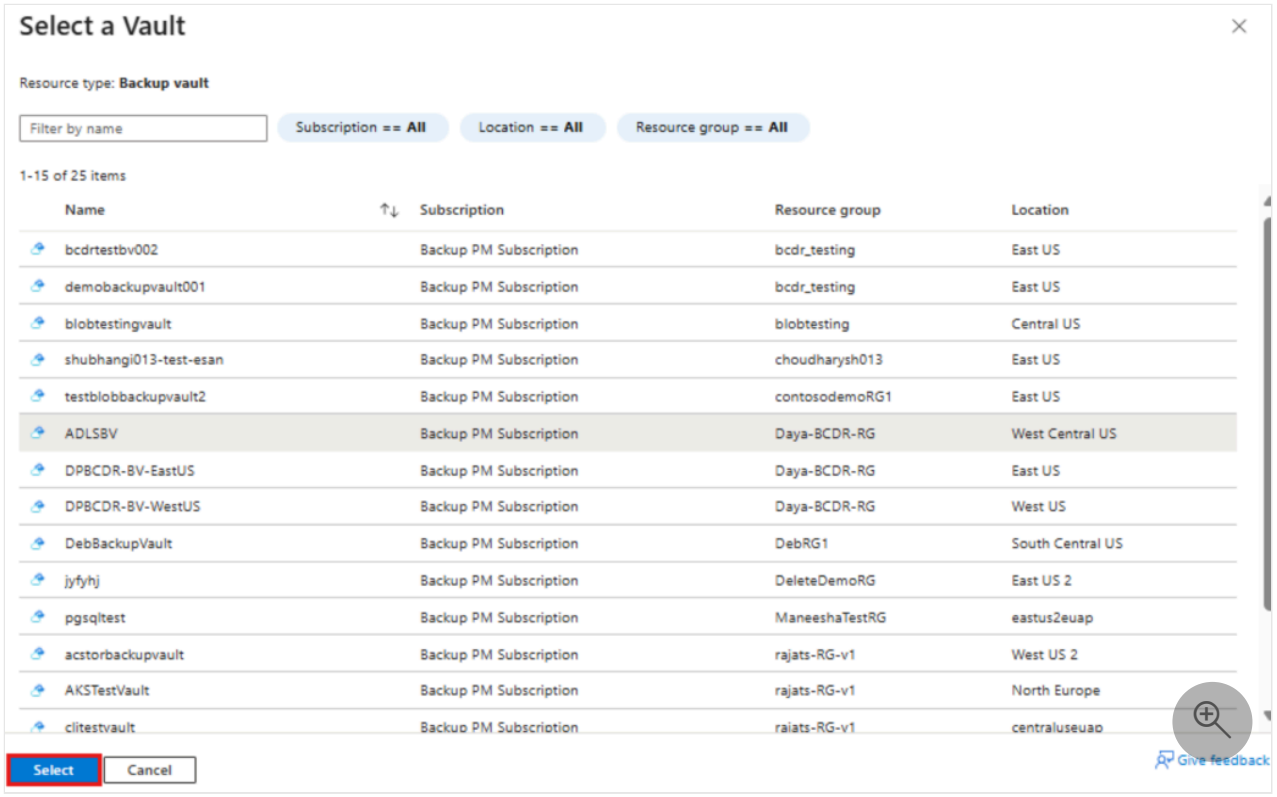


3. On the **Configure Backup** pane, on the **Basics** tab, under **Vault**, click **Select vault**.



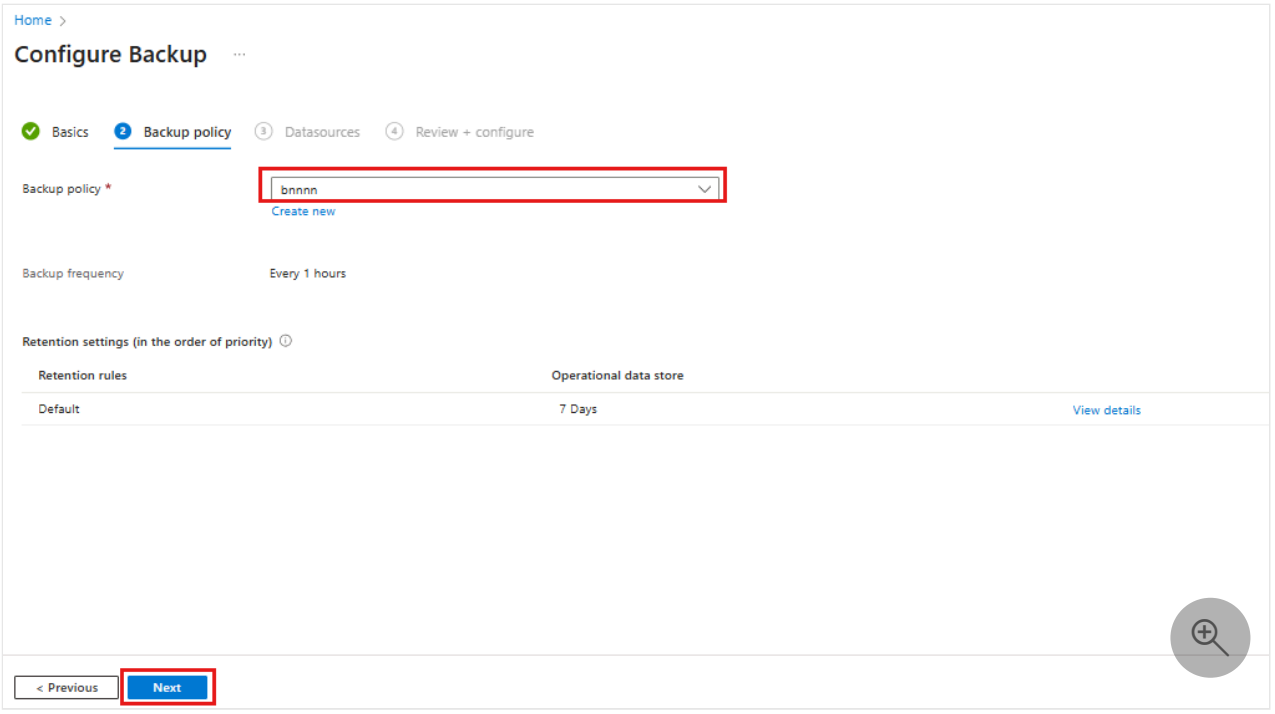
4. On the **Select a Vault** pane, select the Backup vault from the list you created, and then click **Select**.

> **Note**
>
> - Ensure that both the backup vault and the disk to be backed up are in same location.
> - Azure Backup uses ***incremental snapshots*** of managed disks, which store only the delta changes to the disk as the last snapshot on Standard HDD storage, regardless of the storage type of the parent disk. For additional reliability, incremental snapshots are stored on Zone Redundant Storage (ZRS) by default in the ZRS supported regions. Currently, Azure Disk Backup supports operational backup of managed disks that doesn't copy backups to the Backup vault storage. So, the backup storage redundancy setting of the Backup vault doesn't apply to the recovery points.

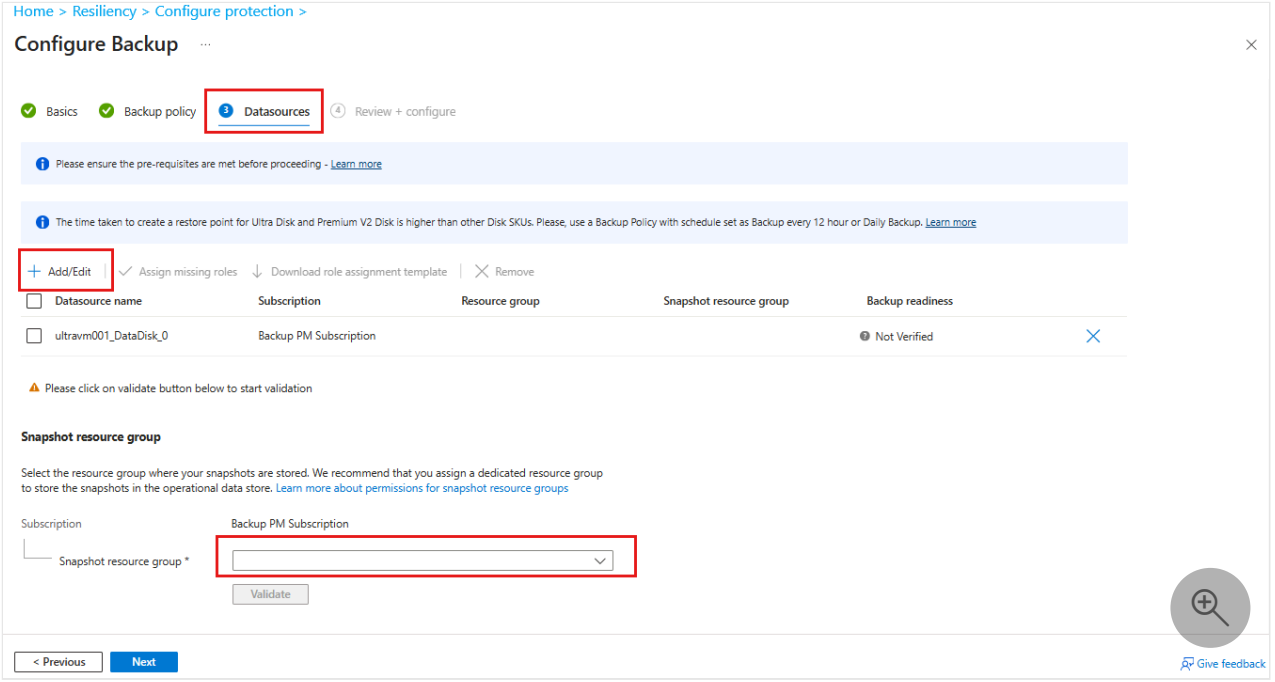


5. On the **Configure Backup** pane, on the **Basics** tab, select **Next**.

6. On the **Backup policy** tab, choose a Backup policy, and then select **Next**.



7. On the **Datasources** tab, select **+ Add/Edit** to choose one or more Azure Managed Disks for which you want to configure backup.



> **Note**
>
> While the portal allows you to select multiple disks and configure backup, each disk is an individual backup instance. Currently, Azure Disk Backup only supports backup of individual disks. Point-in-time backup of multiple disks attached to a virtual machine isn't supported.
>
> In the Azure portal, you can only select disks within the same subscription. If you have several disks to be backed up or if the disks reside in different subscriptions,

you can use scripts (PowerShell/CLI) to automate.

See the support matrix for more information on the Azure Disk backup region availability, supported scenarios, and limitations.

8. Select **Snapshot resource group** and then select **Validate** to initiate prerequisites checks.

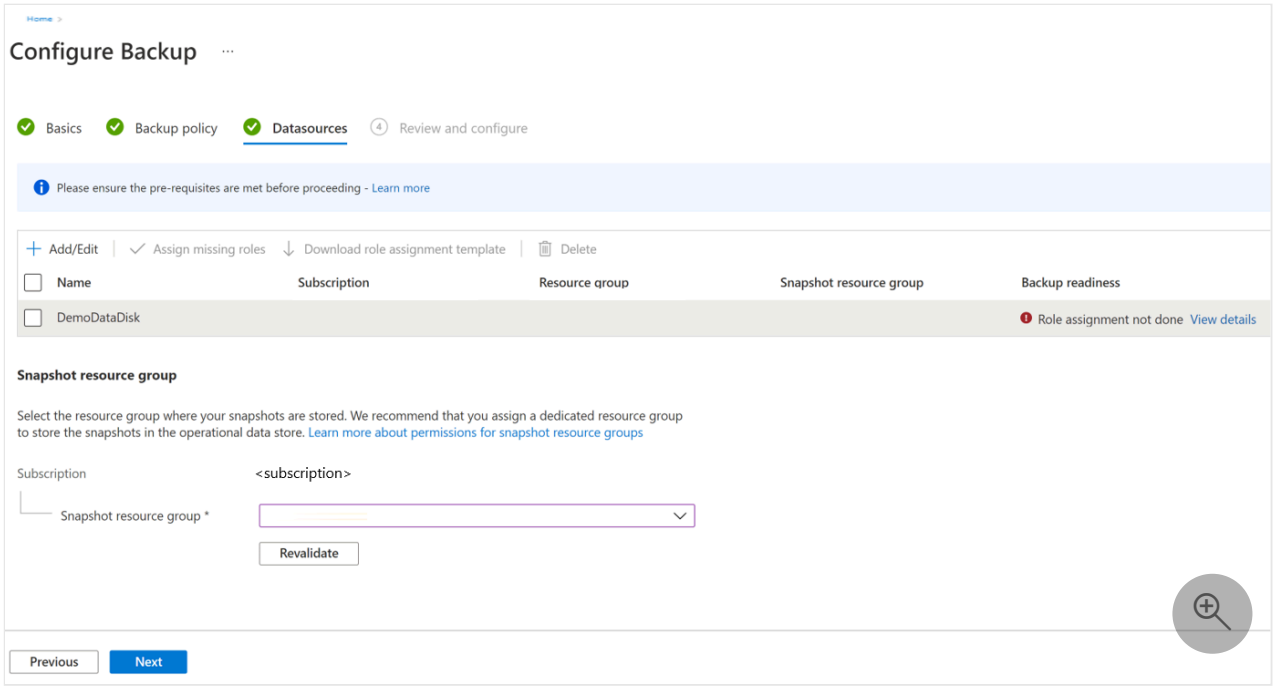
   Choosing resource group for storing and managing snapshots:

   - Don't select the same resource group as that of the source disk.
   - As a guideline, it's recommended to create a dedicated resource group as a snapshot datastore to be used by the Azure Backup service. Having a dedicated resource group allows restricting access permissions on the resource group, providing safety and ease of management of the backup data.
   - You can use this resource group for storing snapshots across multiple disks that are being (or planned to be) backed up.
   - You can't create an incremental snapshot for a particular disk outside of that disk's subscription. So, choose the resource group within the same subscription where the disk needs to be backed up. Learn more about incremental snapshot for managed disks.
   - Once you configure the backup of a disk, you can't change the Snapshot Resource Group that's assigned to a backup instance.

9. When the validation is complete, check if there are any errors reported in the Backup readiness column.

   > ⓘ **Note**
   >
   > Validation might take few minutes to complete. Validation may fail if:
   >
   > - A disk is unsupported. See the support matrix for unsupported scenarios for more information.
   > - The Backup vault managed identity does not have valid role assignments on the *disk* to be backed up or on the *snapshot resource group* where incremental snapshots are stored.

   If the *Role assignment not done* error message displays in the **Backup readiness** column, the Backup vault managed identity needs role permissions on one or more selected disk(s) and/or on the Snapshot resource group.



To configure backup of managed disks, the following prerequisites are required:

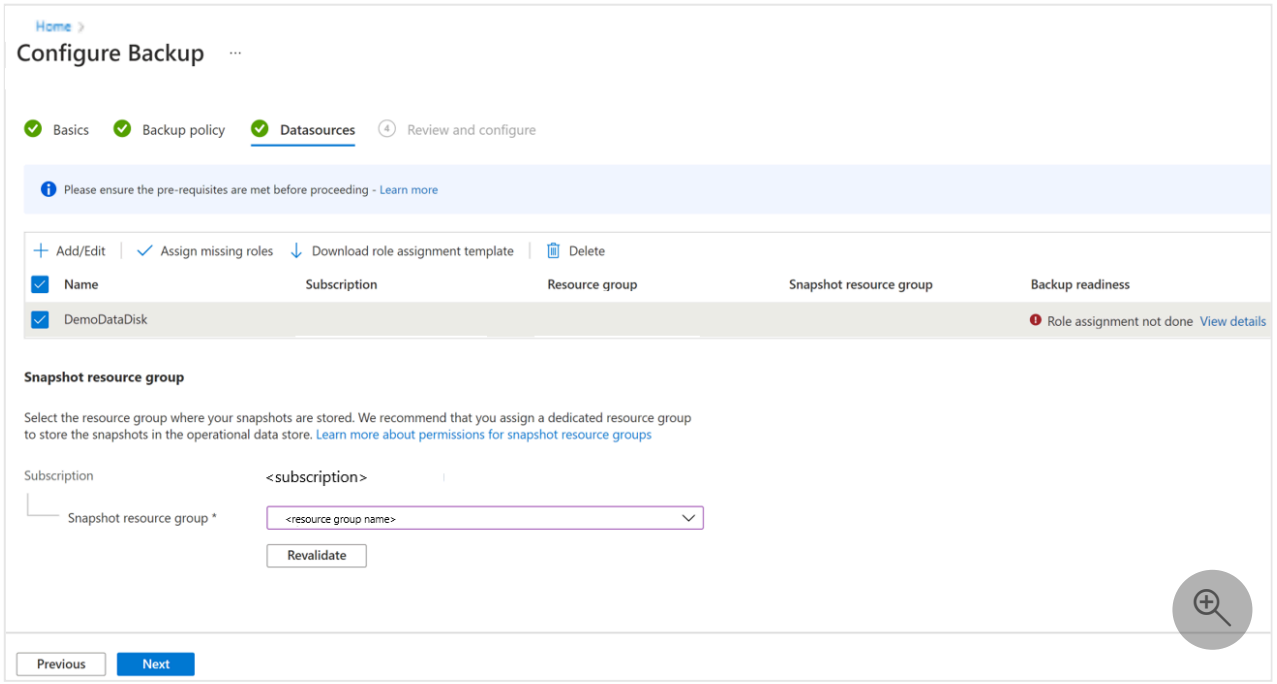
> **Note**
>
> Backup vault uses managed identity to access other Azure resources. To configure a backup of managed disks, Backup Vault's managed identity requires a set of permissions on the source disks and resource groups where snapshots are created and managed.

A system-assigned managed identity is restricted to one per resource and is tied to the lifecycle of this resource. To grant permissions to the managed identity, use Azure role-based access control (Azure RBAC). Managed identity is a service principal of a special type that may only be used with Azure resources. Learn more about managed identities.

- Assign the **Disk Backup Reader** role to Backup Vault's managed identity on the Source disk that needs to be backed up.
- Assign the Disk Snapshot Contributor role to the Backup vault's managed identity on the Resource group where backups are created and managed by the Azure Backup service. The disk snapshots are stored in a resource group within your subscription. To allow Azure Backup service to create, store, and manage snapshots, you need to provide permissions to the backup vault.

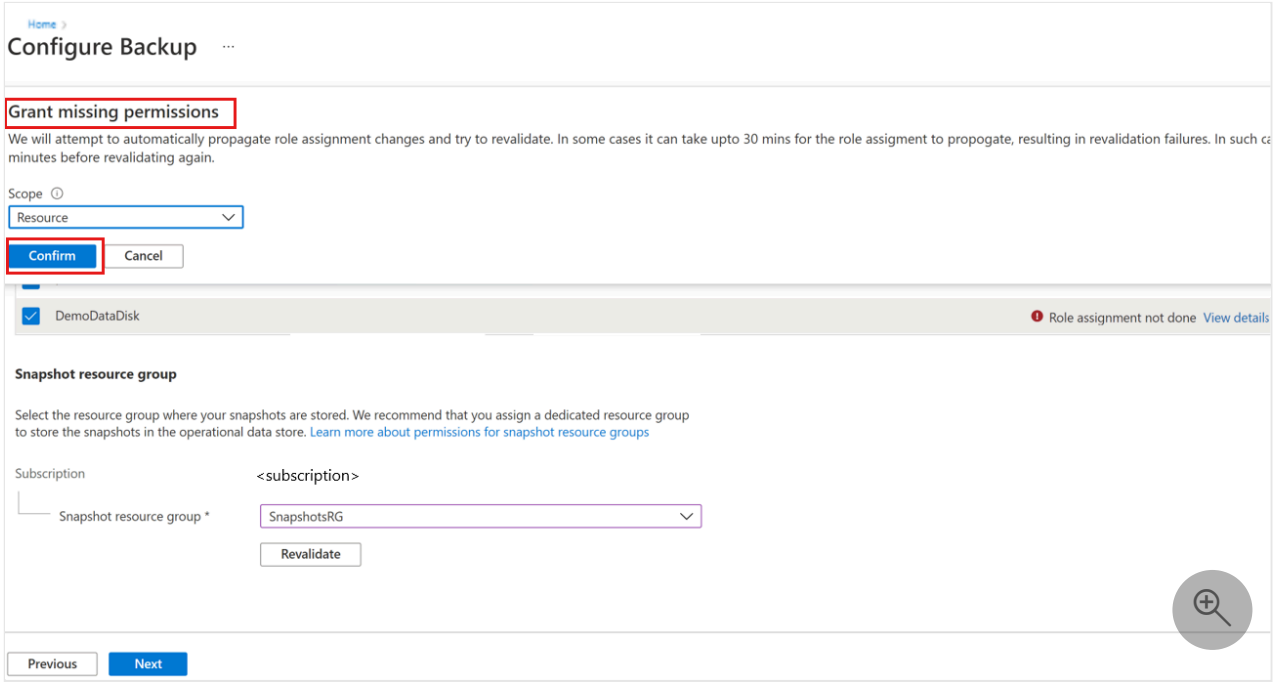
> **Note**
>
> The Configure Backup flow using Azure portal helps you in granting required role permissions to the above resources.

10. Select the checkbox next to each row with the *Role assignment not done* error message status in the Backup readiness column and select **Add missing roles** to automatically grant required role permissions for the Backup vault managed identity on selected resources.



11. Select **Confirm** to provide consent. Azure Backup automatically propagates role assignment changes on your behalf and tries to revalidate.

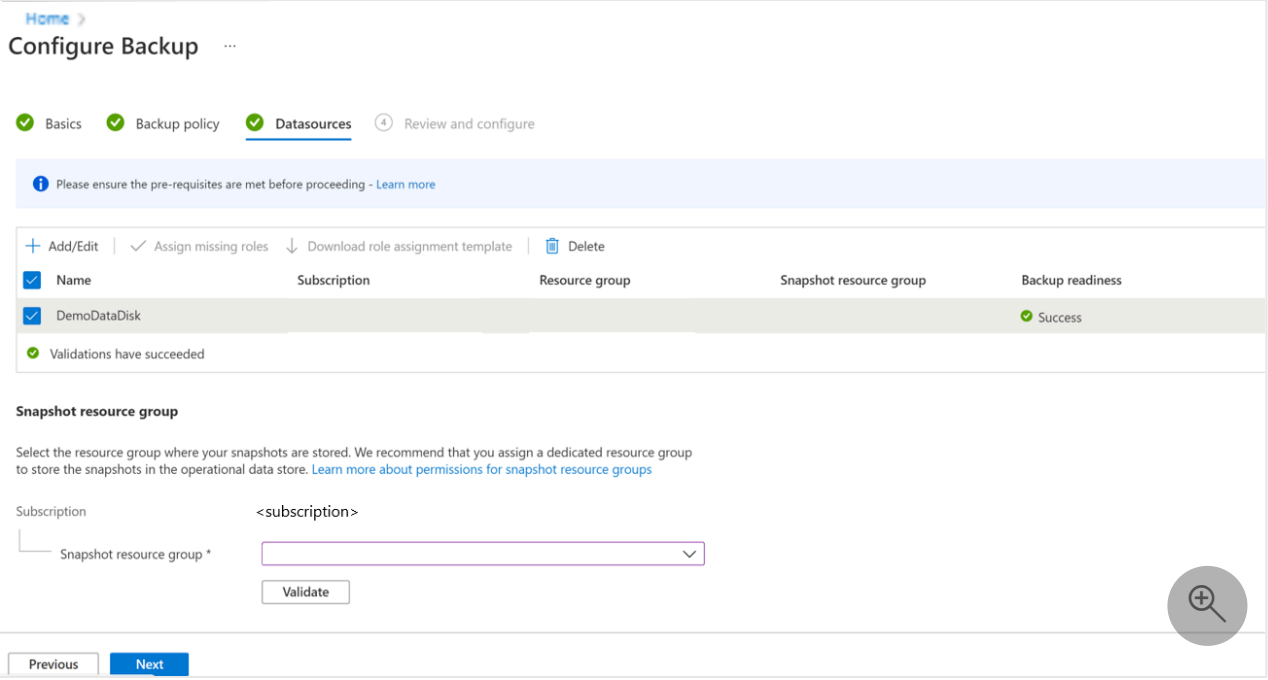
    If you want to grand permission for the Backup vault managed identity to the selected disk(s) and snapshot resource group, select **Resource** in the **Scope** drop-down list.



> **Tip**

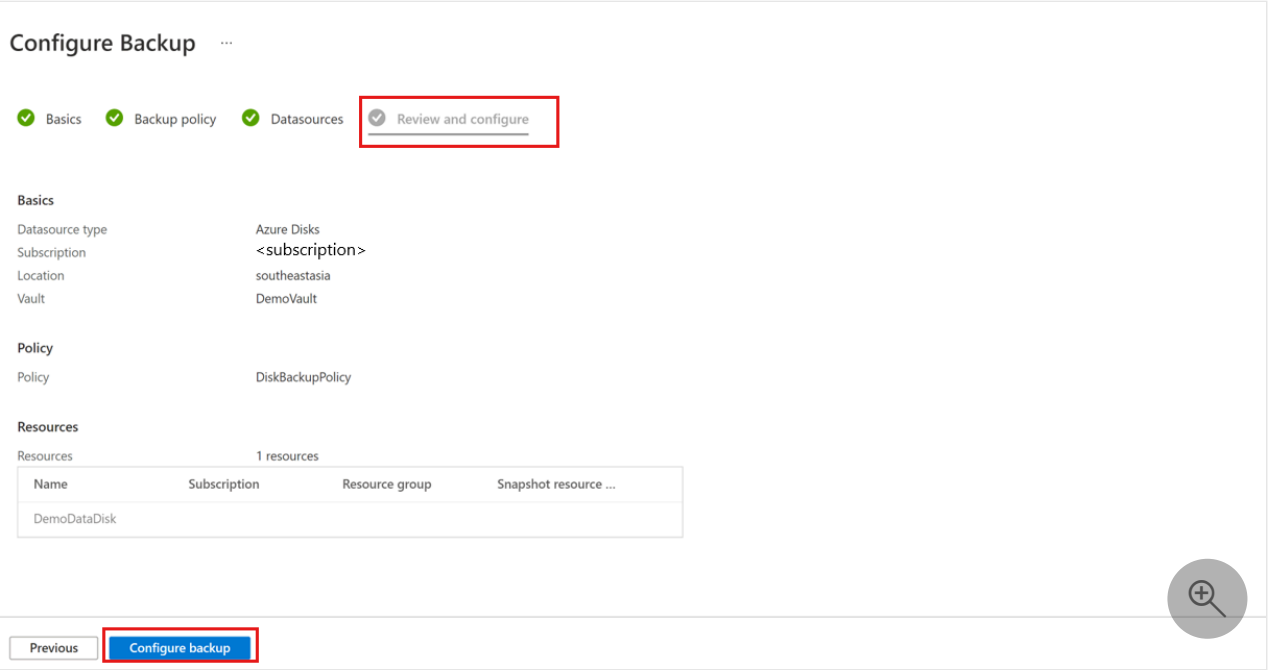
If you plan to configure backup for other disks in the same resource group/subscription in future, you can choose to provide permission at the scope of resource group or subscription.

> **Note**
>
> - In some cases, it can take up to 30 minutes for the role assignments to propagate, causing revalidation failure. In this scenario, retry after some time.
> - If the **Add missing roles** action fails to assign permissions with the error 'Insufficient permission for role assignment' in Backup readiness column, it indicates that you don't have the privilege to assign role permissions. Choose Download role assignment template to download role assignments as scripts and seek support from your IT Administrator to run the scripts to complete the prerequisites.



12. After a successful validation, select **Next**.

13. On the **Review and configure** tab, select **Configure backup** to complete the backup configuration of selected disks.

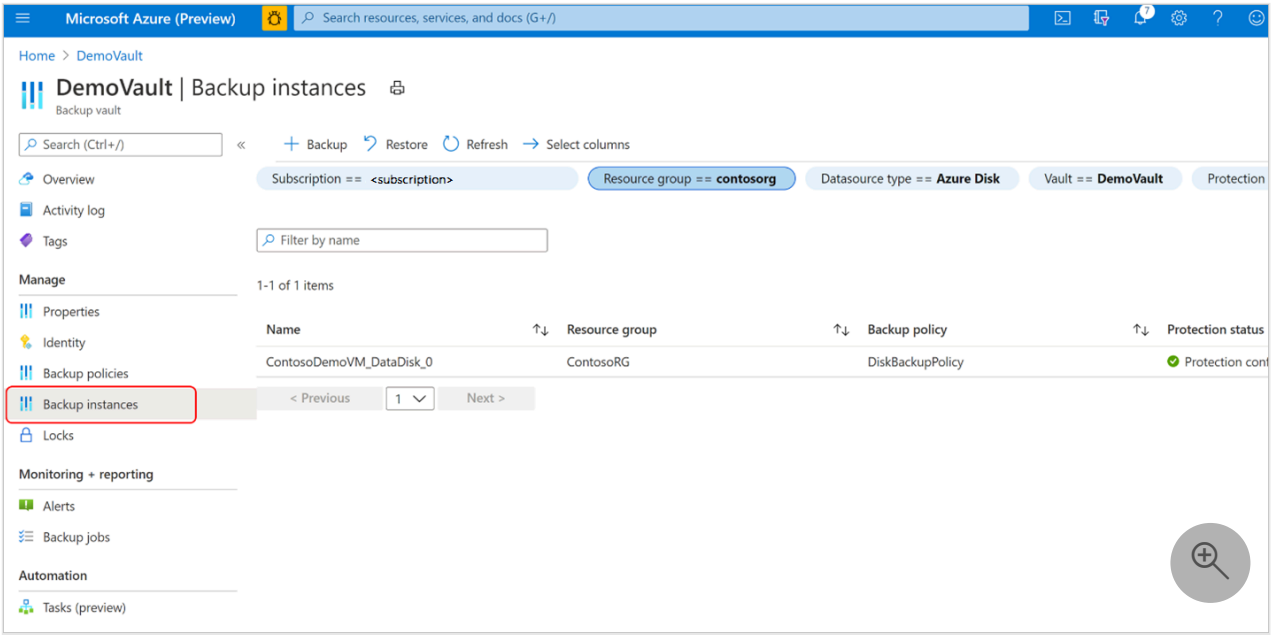


Run an on-demand backup for Azure Disks

You can run an on-demand backup for Azure Disks at any time. This operation is useful if you want to create a backup outside of the scheduled backup times defined in the backup policy.

To run an on-demand backup for Azure Disks, follow these steps:

1. In the *DemoVault* **Backup vault** created in the previous step, go to **Backup instances** and select a backup instance.

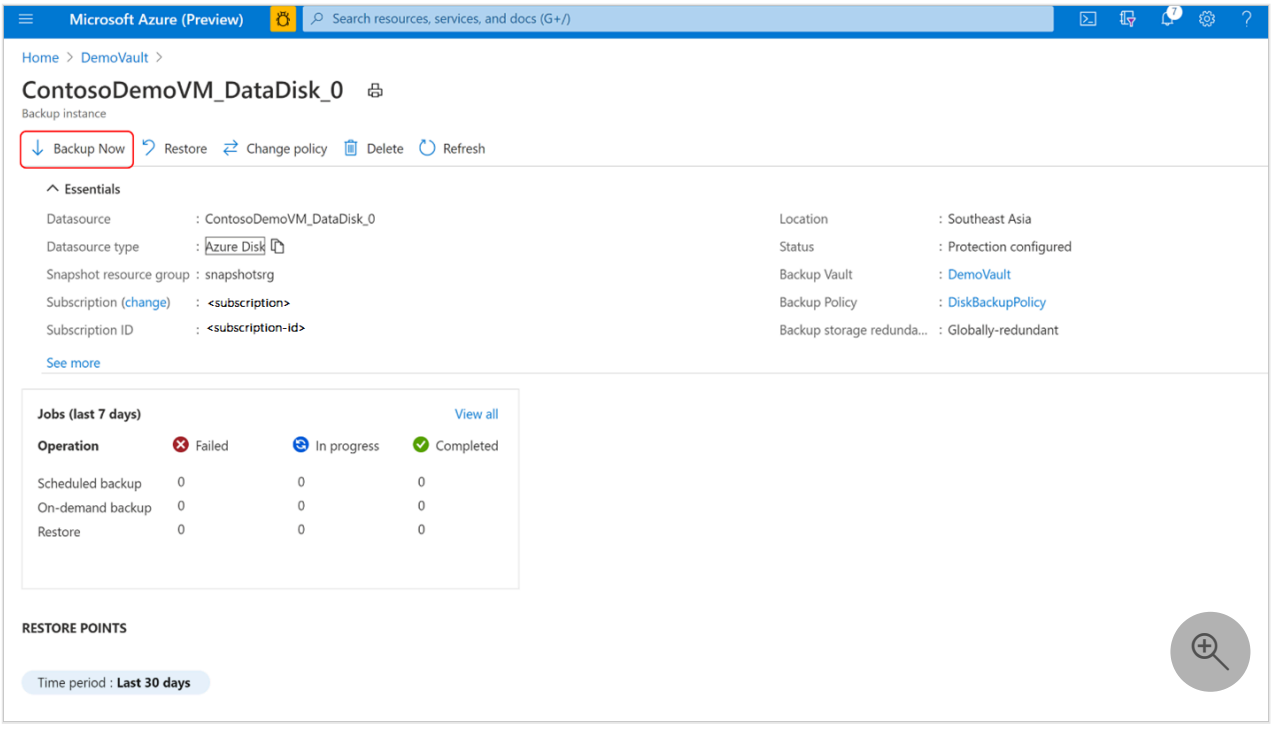


2. On the **Backup instances** pane, you can find:

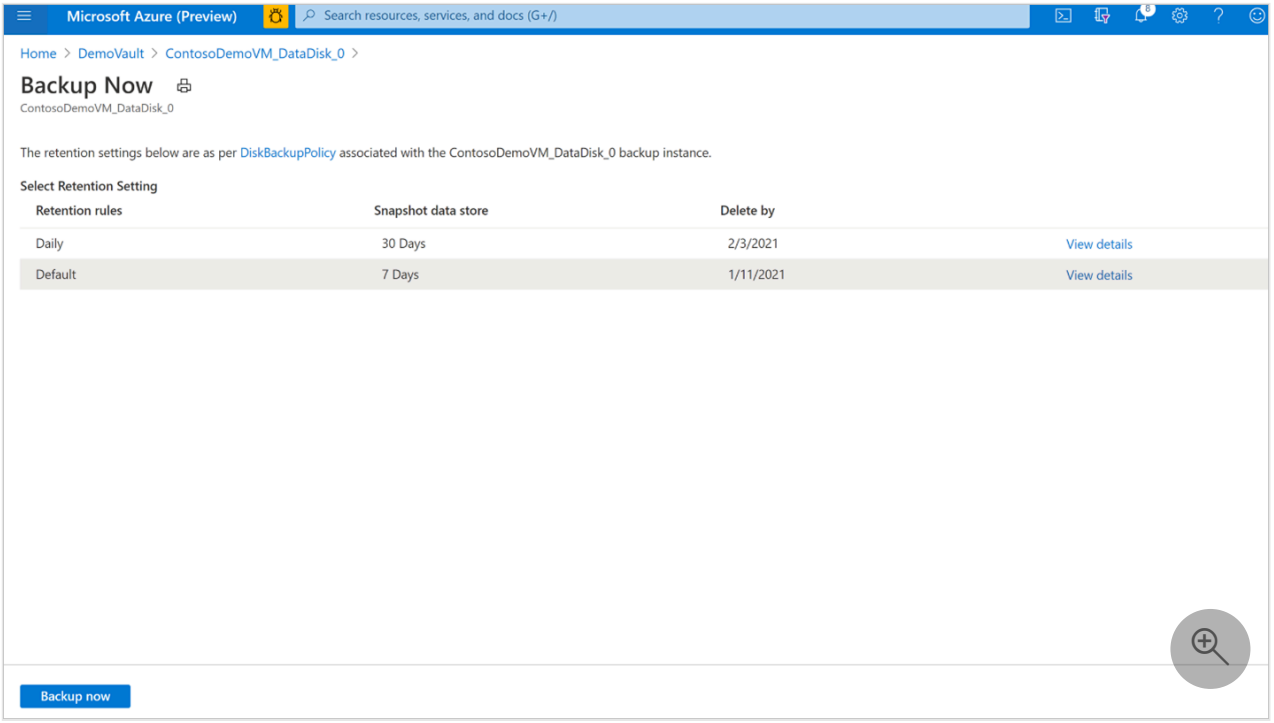
   - **essential** information including source disk name, the snapshot resource group where incremental snapshots are stored, backup vault, and backup policy.

- **Job status** showing summary of backup and restore operations and their status in the last seven days.
- A list of **restore points** for the selected time period.

3. Select **Backup** to initiate an on-demand backup.



4. Select one of the retention rules associated with the backup policy. This retention rule determines the retention duration of this on-demand backup. Select **Backup now** to start the backup.



Track Azure Disk backup operations

The Azure Backup service creates a job for scheduled backups or if you trigger on-demand backup operation for tracking. Learn how to view the backup job status and details.

Restore Azure Managed Disks

Summarize this article for me

This article describes how to restore Azure Managed Disks from a restore point created by Azure Backup. You can also restore Managed Disk using Azure PowerShell, Azure CLI, REST API.

Backup Vault uses Managed Identity to access other Azure resources. To restore from backup, Backup vault's managed identity requires a set of permissions on the resource group where the disk is to be restored.

Backup vault uses a system assigned managed identity, which is restricted to one per resource and is tied to the lifecycle of this resource. You can grant permissions to the managed identity by using Azure role-based access control (RBAC). Managed identity is a service principal of a special type that may only be used with Azure resources. Learn more about Managed Identities.

> **Note**
>
> Currently, the Original-Location Recovery (OLR) option of restoring by replacing existing the source disk from where the backups were taken isn't supported. You can restore from a recovery point to create a new disk either in the same resource group as that of the source disk from where the backups were taken or in any other resource group. This is known as Alternate-Location Recovery (ALR) and this helps to keep both the source disk and the restored (new) disk.

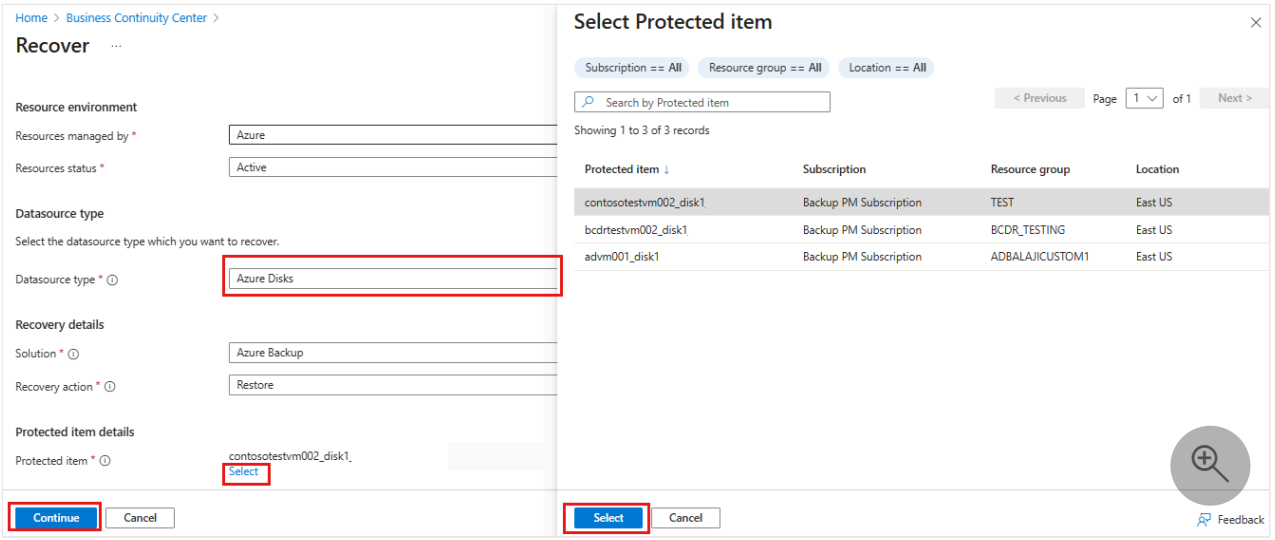
Restore a new disk from a recovery point

To restore a new disk from a recovery point, follow these steps:

1. Go to **Resiliency**, and then select **Recover**.

   Alternately, you can perform this operation from the Backup vault you used to configure backup for the disk.

2. On the **Recover** pane, select **Datasource type** as **Azure Disks**, and then under **Protected item**, click **Select** to choose a disk instance.

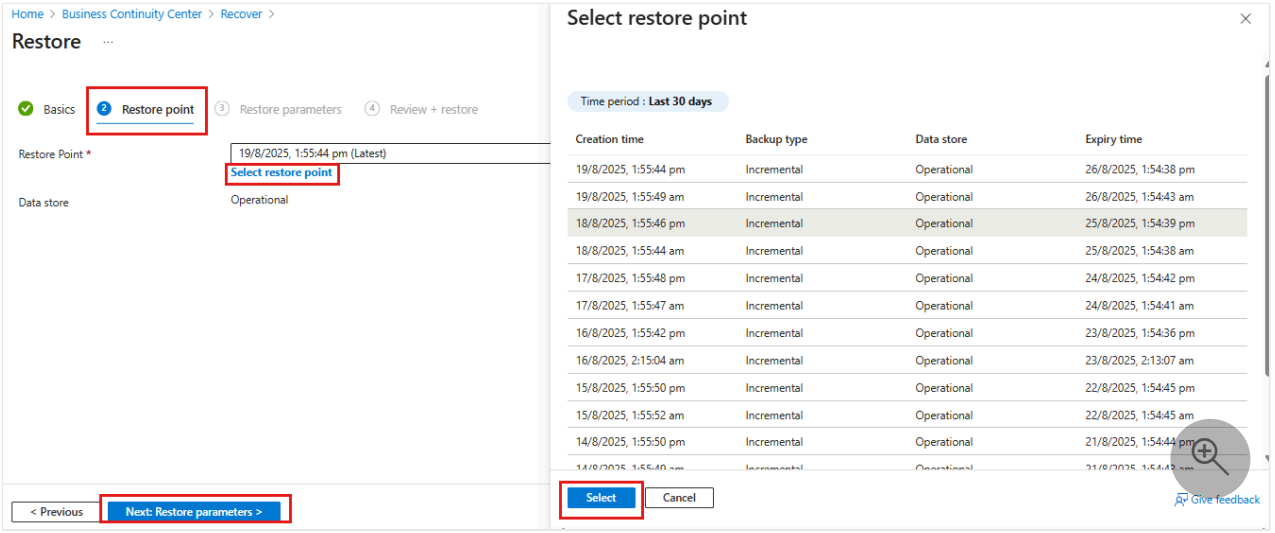


3. On the **Select Protected item** pane, select a disk instance from the list, and then click **Select**.

4. On the **Recover** pane, select **Continue**.

5. On the **Restore** pane, on the **Basics** tab, select **Next: Restore point**.

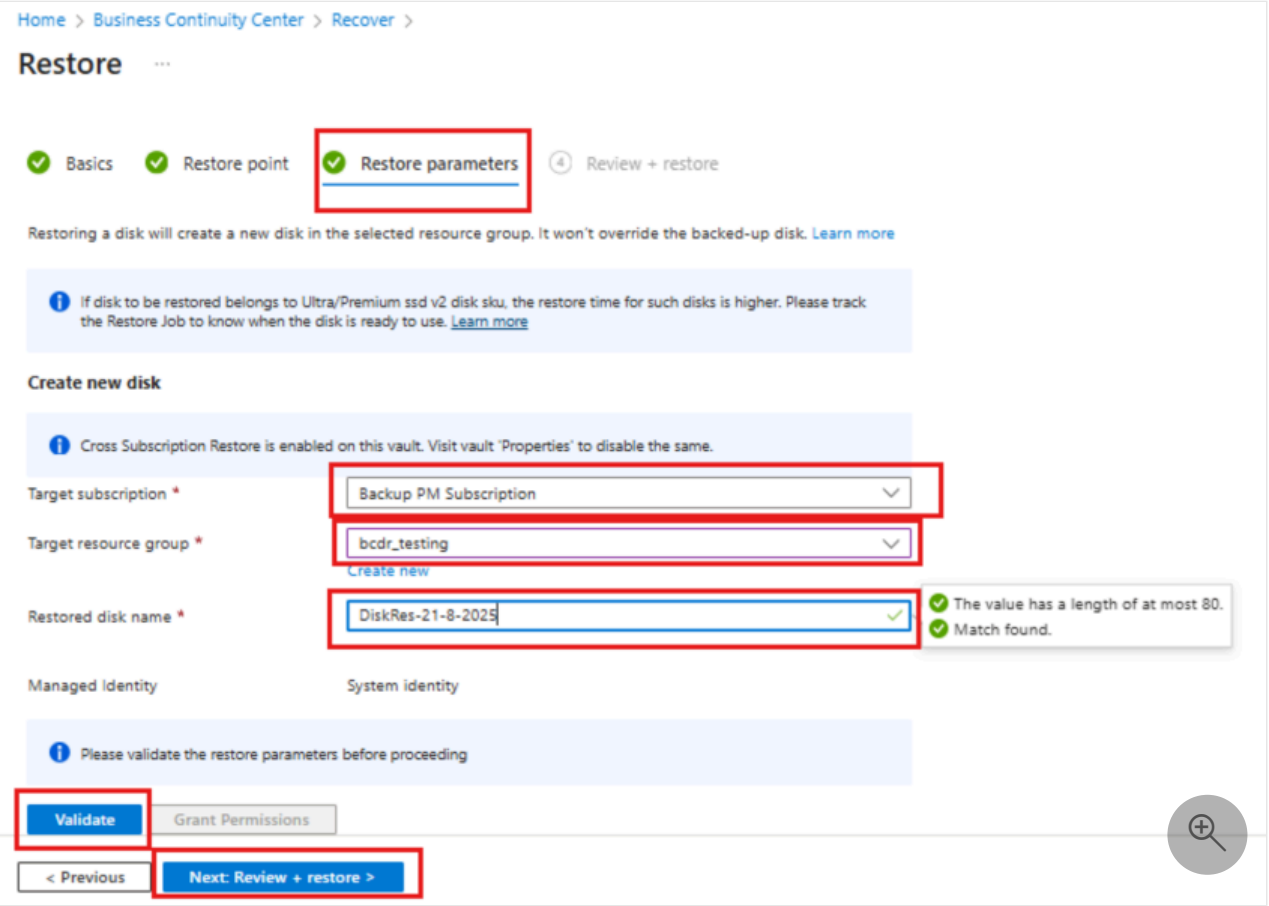
6. On the **Restore point** tab, under **Restore Point**, click **Select restore point**.



7. On the **Select restore point** pane, choose a restore point from the list, and then click **Select**.

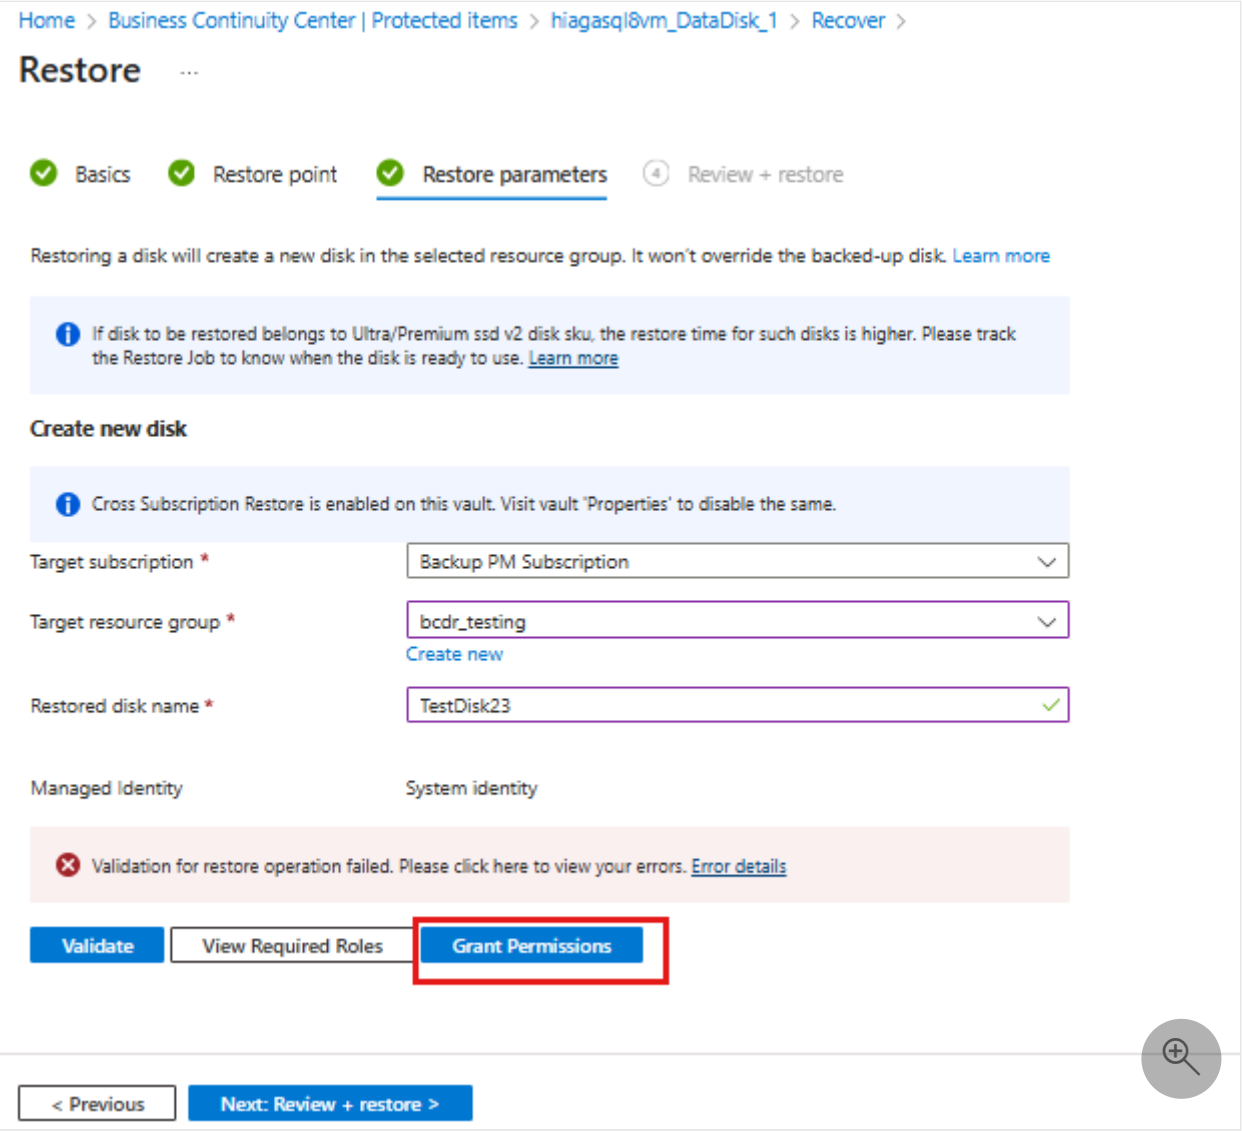
8. On the **Restore** pane, select **Next: Restore parameters**.

9. On the **Restore parameters** pane, select the **Target subscription** and **Target resource group** where you want to restore the backup to, enter a value under **Restored disk name**, and then select **Validate**.



> **Tip**
>
> You can protect disks with Azure Backup using either the Disk Backup solution or the Azure Virtual Machine (VM) backup solution with a Recovery Services vault. If the Azure VM is already protected that uses this disk, you can restore the VM, individual disks, or files and folders from the VM backup recovery point. For more information, see Azure VM backup.

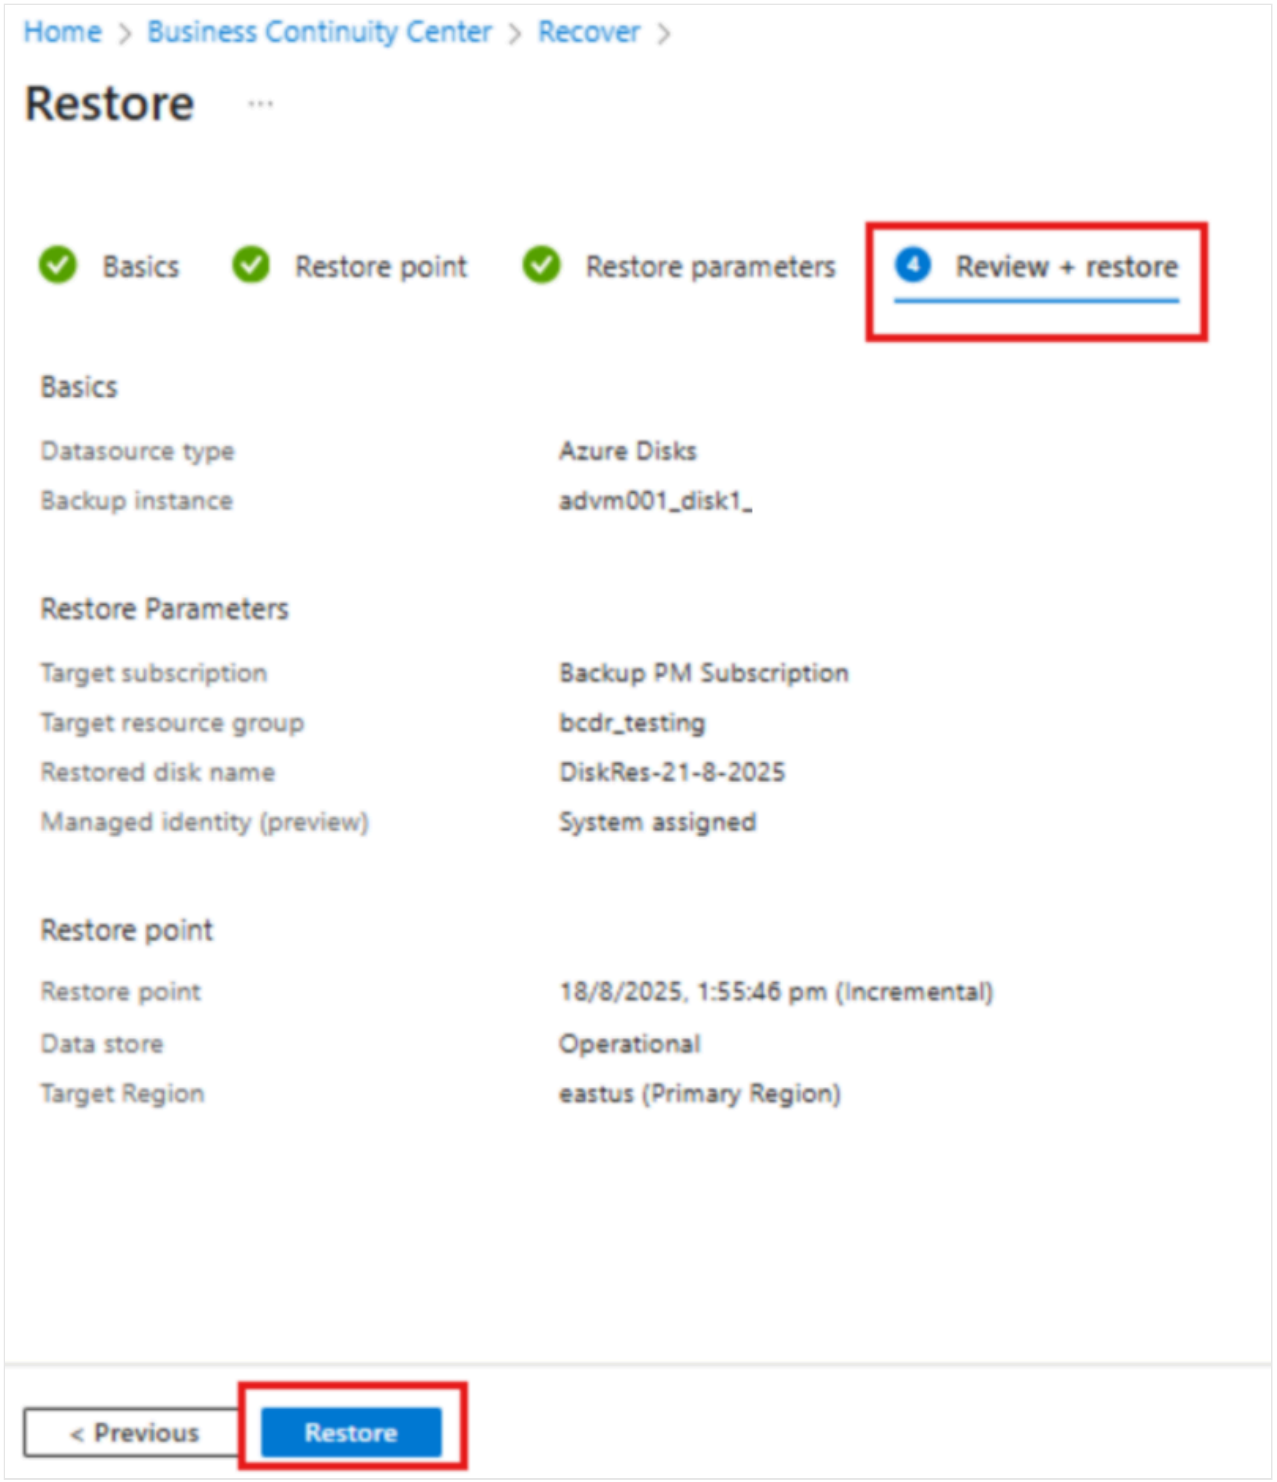
If the validation fails due to role assignment not done, select **Grant Permissions**. After the role assignment is complete, the revalidation runs automatically.



> ⓘ **Note**
>
> While the role assignments are reflected correctly on the portal, it may take approximately 15 minutes for the permission to be applied on the backup vault's managed identity.
>
> During scheduled backups or an on-demand backup operation, Azure Backup stores the disk incremental snapshots in the Snapshot Resource Group provided during configuring backup of the disk. Azure Backup uses these incremental snapshots during the restore operation. If the snapshots are deleted or moved from the Snapshot Resource Group or if the Backup vault role assignments are revoked on the Snapshot Resource Group, the restore operation fails.

10. When the validation is successful, select **Next: Review + restore**.

11. On the **Review + restore** pane, review the restore settings, and then select **Restore** to start the restore operation.

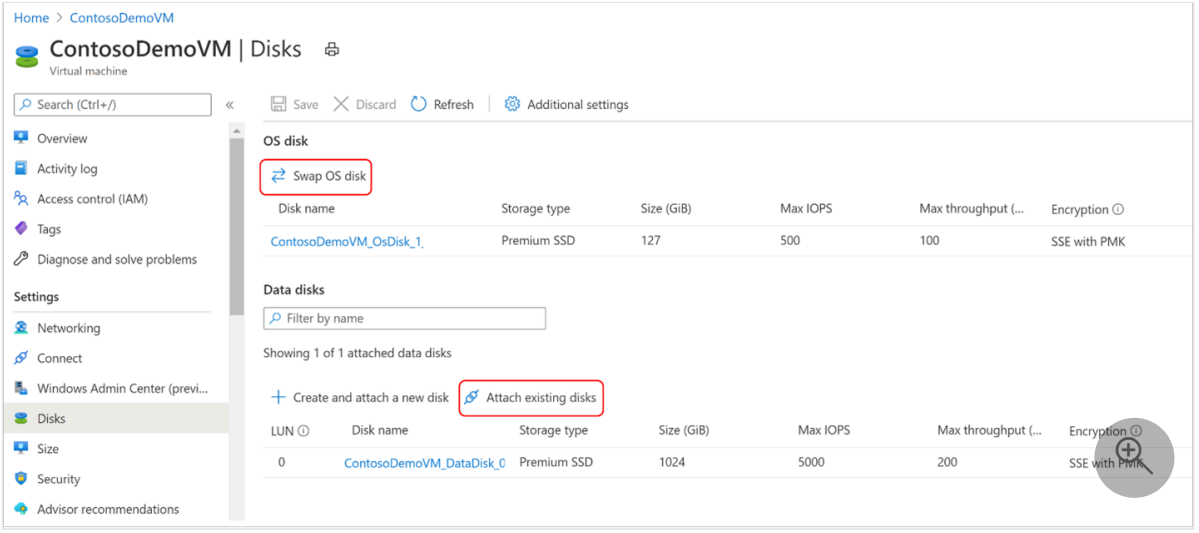


> ⓘ Note
>
> Validation might take few minutes to complete before you can trigger restore operation. Validation may fail if:
>
> - a disk with the same name provided in **Restored disk name** already exists in the **Target resource group**
> - the Backup vault's managed identity doesn't have valid role assignments on the **Target resource group**

- the Backup vault's managed identity role assignments are revoked on the **Snapshot resource group** where incremental snapshots are stored
- If incremental snapshots are deleted or moved from the snapshot resource group

The restore operation creates a new disk from the selected recovery point in the target resource group provided during the restore operation. To use the restored disk on an existing virtual machine, do the following actions:

- If the restored disk is a data disk, you can attach an existing disk to a virtual machine. If the restored disk is OS disk, you can swap the OS disk of a virtual machine from the Azure portal under the **Virtual machine** pane - > **Disks** menu in the **Settings** section.



- For Windows virtual machines, if the restored disk is a data disk, follow the instructions to detach the original data disk from the virtual machine. Then attach the restored disk to the virtual machine. Follow the instructions to swap the OS disk of the virtual machine with the restored disk.

- For Linux virtual machines, if the restored disk is a data disk, follow the instructions to detach the original data disk from the virtual machine. Then attach the restored disk to the virtual machine. Follow the instructions to swap the OS disk of the virtual machine with the restored disk.

> **Note**
>
> We recommend revoking the **Disk Restore Operator** role assignment from the Backup vault's managed identity on the **Target resource group** after the restore operation completes successfully.

Track a restore operation

After you trigger the restore operation, the backup service creates a job for tracking. Azure Backup displays notifications about the job in the portal. Learn how to view the restore job progress.

Backup and disaster recovery for Azure managed disks

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This article explains how to plan for backup and disaster recovery for Azure managed disks. It introduces Azure built-in redundancy and some common failure types. After that, it covers typical backup and disaster recovery scenarios. Finally, it compares each backup and disaster recovery option for Azure managed disks.

Azure built-in redundancy options

Azure managed disks have two built-in redundancy options to protect your data against failures:

- Locally redundant storage (LRS) replicates your data three times within a single data center in a particular region. LRS protects your data against server rack and drive failures.
- Zone-redundant storage (ZRS) provides synchronous replication of data across zones in a region, enabling disks to tolerate zonal failures that may occur due to natural disasters or hardware issues.

However, major disasters (such as earthquakes, fires, or hurricanes) can result in outages or inaccessibility of large-scale storage servers, sometimes impacting a whole data center or zone (impacting LRS disks), or an entire region (impacting ZRS disks). In addition to platform failures, problems with an application or data can also occur (such as accidental deletes and ransomware attack). When these happen, you might want to revert the application and the data to a prior version that contains the last known good state. Reverting to a good state requires regular backups.

To protect your IaaS workloads from outages, plan for redundancy, and create regular backups. To protect IaaS workloads from regional disasters, create backups in a different geographic location than your primary site. This ensures your backups aren't affected by the same events that affected your other resources. For more information, see Disaster Recovery for Azure Applications.

Backup and Disaster Recovery Scenarios

Let's look at a few examples of application workload scenarios and things to consider when planning for backup and disaster recovery.

Scenario 1: Major database solutions

In this scenario, you have a production database server (such as SQL Server and Oracle) that supports high availability. Critical production applications and users depend on this database. The disaster recovery plan for this system should include the following requirements:

- The data must be protected and recoverable.
- The server must be available for use.
- (Optional) A replica of the database in a different region as backup

Depending on your requirements for server availability and data recovery, solutions could range from an active-active or active-passive replica site to periodic offline backups of the data. Relational databases, such as SQL Server and Oracle, provide various options for replication. For SQL Server, use SQL Server Always On Availability Groups for high availability.

NoSQL databases, like MongoDB, also support replicas for redundancy. The replicas for high availability are used.

Scenario 2: A cluster of redundant VMs

In this scenario, you have a workload handled by a cluster of VMs that provide redundancy and load balancing, like a Cassandra cluster deployed in a region. This type of architecture already provides a high level of redundancy within that region. However, to protect the workload from a regional-level failure, consider spreading the cluster across two regions or making periodic backups to another region.

Scenario 3: IaaS application workload

In this scenario, you have an application with a typical production workload running on an Azure VM (IaaS application workload). It could be a web server or file server holding content and other resources of a site, or a custom-built business application running on a VM that stored its data, resources, and application state on the VM disks. In this case, it's important to make sure you take backups regularly. Backup frequency should be based on the nature of the VM workload. For example, if the application runs daily and modifies data, then the backup should be taken hourly.

Another common scenario involves a reporting server that pulls data from other sources and generates aggregated reports. The loss of this VM or disks could lead to the loss of the reports. However, it's possible to regenerate the output by rerunning the reporting process. In this case, you don't really experience data loss, even if the reporting server is hit with a disaster. So you have a higher level of tolerance for losing part of the data on the reporting server. In this case, taking backups less often would reduce your cost.

Scenario 4: IaaS application data issues

IaaS application data issues are another possibility. Consider an application that computes, maintains, and serves critical commercial data, such as pricing information. A new version of your application had a software bug that incorrectly computed the pricing and corrupted the existing commerce data served by the platform. Here, the best course of action is to revert to the earlier version of the application and the data. To enable this, take periodic backups of your system.

Backup and Disaster Recovery Solutions

Comparison Overview

This section covers some of Azure's options for backup and disaster recovery. You can refer to the following comparison table for a high level overview.

Expand table

Solution	Snapshot	Restore Points	Azure Backup	Azure Site Recovery
Description	Snapshot is a ready-only poin-in-time copy of the disk that you can use for backup.	Restore Points can be used to implement granular backup of all disks attached to your Virtual Machine	Azure Backup is a fully managed Azure service to provide simple, secure, and cost-effective solution to back up your data and recover it	Azure Site Recovery helps ensure your organization's business continuity by keeping apps and workloads running during outages
Incremental Backup	Yes	Yes	Yes	Yes
Cross-Region Copy	Yes	Available in public preview	Yes, with Azure VM backup	Yes

Solution	Snapshot	Restore Points	Azure Backup	Azure Site Recovery
Pricing	See Azure Disk Pricing	N/A	See Estimate costs for backing up Azure VMs or on-premises servers	See Azure Site Recovery Pricing
Operational Maintenance	High	Medium	Low	Low
Key benefits	Most cost effective, suitable for disk backup	Back up disks at VM level, Application consistent for VM running Windows OS, File system consistency for VMs running Linux OS	Frequent and quick backup without interrupting the VM, custom backup policy, agentless solution	Simple BCDR solution, keep application consistency over failover, orchestrate replication without intercepting application data

Snapshots

A snapshot is a read-only point in time copy of the disk. You can take a snapshot at any time. Snapshots exist independently of the source disk and can only be used to create new managed disks. You can't use them to change the state of an existing disk. You can also use incremental snapshots for periodic incremental backup of your managed disks.

Generally, you should use incremental snapshots for backup and disaster recovery purposes since they lower your costs and offer a faster recovery time. Incremental snapshots are point-in-time backups for managed disks that, when taken, consist only of the changes since the last snapshot. The first incremental snapshot is a full copy of the disk. Any incremental snapshots after the first one consists only of the changes to a disk since the last snapshot. When you create a disk from a snapshot, the system reconstructs the full disk that represents the point in time backup of the disk when the incremental snapshot was taken. You can also Copy an incremental snapshot to a new region for disaster recovery.

You can implement backup mechanisms through snapshots. To do this, you need to create consistent snapshots for all disks used by a VM and then replicate them to another region. An option to create consistent backups with snapshot is to shut down the VM and take snapshots of each disk. If applications running on the VM can pause the IOs, you should take advantage of pausing it and then take snapshots of all the disks attached to VMs. Taking offline snapshots is easier than coordinating snapshots of a running VM, but it requires a few minutes of downtime.

You can take a snapshot anytime, but if you're taking snapshots while the VM is running, keep these things in mind:

- When the VM is running, data is still being streamed to the disks. As a result, snapshots of a running VM might contain partial operations that were in flight.
- If there are several disks involved in a VM, snapshots of different disks might have occurred at different times.

In the described scenario, snapshots weren't coordinated. This lack of coordination is a problem for striped volumes whose files might be corrupted if changes were being made during a backup. So the backup process must implement the following steps:

1. Freeze all the disks.
2. Flush all the pending writes.
3. Create an incremental snapshot for managed disks for all the disks.

Some Windows applications, like SQL Server, provide a coordinated backup mechanism through a volume shadow service to create application-consistent backups. On Linux, you can use a tool like fsfreeze to coordinate disks (this tool provides file-consistent backups, not application-consistent snapshots). This backup procedure is complex, so you should consider Overview of Azure Disk Backup or a third-party backup solution that already implements this procedure. This would result a collection of coordinated snapshots for all the VM disks, representing a specific point-in-time view of the VM - in other words, a backup restore point for the VM. You can repeat the process at scheduled intervals to create periodic backups.

Restore Points

Azure VM Restore Points can be used to implement granular backup and retention policies of all disks attached to your virtual machine. Individual VM restore point is a resource that stores VM configuration and point-in-time application consistent snapshots of all the managed disks attached to the VM. You can use VM Restore Points to easily capture multi-disk consistent backups of all disks attached to your VM.

Restore points have three levels of hierarchy – VM Restore Point Collection, VM Restore Points, and Disk Restore Points:

- Level 1: VM Restore Points are organized into Restore Point Collections. A Restore Point collection is an Azure Resource Management resource that contains the restore points for a specific VM.
- Level 2: VM Restore Points contain a disk restore point for each of the attached disks.
- Level 3: A Disk Restore Point consists of a snapshot of an individual managed disk.

Restore points are incremental. First restore point stores a full copy of all disks attached to the VM, while successive restore point only contains incremental changes to VM disks. With Restore Points, you can:

- Copy VM restore points between regions, restore VMs in a different region than the source VM and track the progress of copy operation.
- Create disks using disk restore points and get a shared access signature for the disk. These disks can then be used to create a new VM.

See the following articles to learn how to Create VM restore points and Manage VM restore points.

Azure Backup

Azure Backup provides simple, secure, and cost-effective solutions to backup your data and recover it from Azure. Azure Disk Backup is a native, cloud-based backup solution that protects your data in managed disks. It's a simple, secure, and cost-effective solution that enables you to configure protection for managed disks in a few steps. It ensures your data is protected in the event of a disaster.

Azure Disk Backup offers a turnkey solution that provides snapshot lifecycle management for managed disks by automating periodic creation of snapshots and retaining it for however long you specify, using backup policy. You can manage disk snapshots, with no infrastructure costs, without the need for custom scripting, or any management overhead.

Azure Disk Backup is a crash-consistent backup solution that takes point-in-time backup of a managed disk using incremental snapshots and supports multiple backups per day. It's also an agent-less solution, and doesn't impact production application performance. It supports backup and restore of both OS and data disks (including shared disks), whether they're currently attached to a running Azure VM or not.

Azure Disk Backup is integrated into Backup Center, which provides a single unified management experience in Azure for enterprises to govern, monitor, operate, and analyze backups at scale. If you need an application-consistent backup of virtual machine including the data disks, or an option to restore an entire virtual machine from backup, restore a file or folder, or restore to a secondary region, use the Azure VM backup solution. If you're unable to use Azure Backup, you can implement your own backup mechanism by using snapshots. But creating consistent snapshots for all the disks used by a VM, replicating those snapshots to another region, and continually managing this process is complicated and time consuming.

Azure Site Recovery

Azure Site Recovery helps ensure your organization's business continuity by keeping apps and workloads running during outages. It's a paid, fully managed service to help you achieve your business continuity and disaster recovery (BCDR) strategy.

Azure Site Recovery replicates workloads running on physical and virtual machines from a primary site to a secondary location. When an outage occurs at your primary site, your workload failover to a secondary location and can be accessed from there. After the primary location is running again, your workloads can fail back to it.

You can easily set up disaster recovery to a secondary Azure region with a few steps. Azure Site Recovery enables many disaster recovery scenarios – Azure to Azure, VMware to Azure, Physical to Azure, Azure Stack VM, Hyper-V to Azure, DR for apps, DR to a secondary site. For a full list of benefits that Azure Site Recovery provides, refer to About Site Recovery.

Other options

SQL Server running in a VM has its own built-in capabilities to back up your SQL Server database to Azure Blob storage or a file share. For more information, see Back up and restore for SQL Server in Azure virtual machines. In addition to back up and restore, SQL Server Always On availability groups can maintain secondary replicas of databases. This ability greatly reduces the disaster recovery time.

Create a snapshot of a virtual hard disk

Article • 04/01/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

A snapshot is a full, read-only copy of a virtual hard disk (VHD). You can use a snapshot as a point-in-time backup, or to help troubleshoot virtual machine (VM) issues. You can take a snapshot of both operating system (OS) or data disk VHDs. With snapshots, you can back up your managed disks at any point in time. These snapshots exist independently of the source disk, and you can use them to create new managed disks.

Snapshots are billed based on the used size. For example, if you create a snapshot of a managed disk with provisioned capacity of 64 GiB and an actual used data size of 10 GiB, that snapshot is billed only for the used data size of 10 GiB. You can see the used size of your snapshots by checking the Azure usage report. For example, if the used data size of a snapshot is 10 GiB, the *daily* usage report shows 10 GiB/(31 days) = 0.3226 as the consumed quantity. Snapshots are billed separately from their original disk. For details, see the pricing page.

Create a snapshot of a VHD

If you want to use a snapshot to create a new VM, ensure that you first cleanly shut down the VM. This action clears any processes that are in progress.

Portal

To create a snapshot using the Azure portal, complete these steps.

1. In the Azure portal, select **Create a resource**.
2. Search for and select **Snapshot**.
3. In the **Snapshot** window, select **Create**. The **Create snapshot** window appears.
4. For **Resource group**, select an existing resource group or enter the name of a new one.
5. Enter a **Name**, then select a **Region** and **Snapshot type** for the new snapshot. If you would like to store your snapshot in zone-resilient storage, you need to select a region that supports availability zones. For a list of supporting regions, see Azure regions with availability zones.
6. For **Source subscription**, select the subscription that contains the managed disk to be backed up.
7. For **Source disk**, select the managed disk to snapshot.

8. For **Storage type**, select **Standard HDD**, unless you require zone-redundant storage or high-performance storage for your snapshot.
9. If needed, configure settings on the **Encryption**, **Networking**, and **Tags** tabs. Otherwise, default settings are used for your snapshot.
10. Select **Review + create**.

Next steps

To recover using a snapshot, you must create a new disk from the snapshot, then either deploy a new VM, and use the managed disk as the OS disk, or attach the disk as a data disk to an existing VM.

Portal

For more information, see the example in Create a VM from a VHD by using the Azure portal.

Back up Azure unmanaged Virtual Machine disks with incremental snapshots

Article • 09/25/2024

Overview

Azure Storage provides the capability to take snapshots of blobs. Snapshots capture the blob state at that point in time. In this article, we describe a scenario in which you can maintain backups of virtual machine disks using snapshots. You can use this methodology when you choose not to use Azure Backup and Recovery Service, and wish to create a custom backup strategy for your virtual machine disks. For virtual machines running business or mission critical workloads, it's recommended to use Azure Backup as part of the backup strategy.

Azure virtual machine disks are stored as page blobs in Azure Storage. Since we are describing a backup strategy for virtual machine disks in this article, we refer to snapshots in the context of page blobs. To learn more about snapshots, refer to Creating a Snapshot of a Blob.

What is a snapshot?

A blob snapshot is a read-only version of a blob that is captured at a point in time. Once a snapshot has been created, it can be read, copied, or deleted, but not modified. Snapshots provide a way to back up a blob as it appears at a moment in time. Until REST version 2015-04-05, you had the ability to copy full snapshots. With the REST version 2015-07-08 and above, you can also copy incremental snapshots.

Full snapshot copy

Snapshots can be copied to another storage account as a blob to keep backups of the base blob. You can also copy a snapshot over its base blob, which is like restoring the blob to an earlier version. When a snapshot is copied from one storage account to another, it occupies the same space as the base page blob. Therefore, copying whole snapshots from one storage account to another is slow and consumes much space in the target storage account.

> **Note**
>
> If you copy the base blob to another destination, the snapshots of the blob are not copied along with it. Similarly, if you overwrite a base blob with a copy, snapshots associated with the base blob are not affected and stay intact under the base blob name.

Back up disks using snapshots

As a backup strategy for your virtual machine disks, you can take periodic snapshots of the disk or page blob, and copy them to another storage account using tools like Copy Blob operation or AzCopy. You can copy a snapshot to a destination page blob with a different name. The resulting destination page blob is a writeable page blob and not a snapshot. Later in this article, we describe steps to take backups of virtual machine disks using snapshots.

Restore disks using snapshots

When it is time to restore your disk to a stable version that was previously captured in one of the backup snapshots, you can copy a snapshot over the base page blob. After the snapshot is promoted to the base page blob, the snapshot remains, but its source is overwritten with a copy that can be both read and written. Later in this article we describe steps to restore a previous version of your disk from its snapshot.

Implementing full snapshot copy

You can implement a full snapshot copy by doing the following,

- First, take a snapshot of the base blob using the Snapshot Blob operation.
- Then, copy the snapshot to a target storage account using Copy Blob.
- Repeat this process to maintain backup copies of your base blob.

Incremental snapshot copy

The new feature in the GetPageRanges API provides a much better way to back up the snapshots of your page blobs or disks. The API returns the list of changes between the base blob and the snapshots, which reduces the amount of storage space used on the backup account. The API supports page blobs on Premium Storage as well as Standard

Storage. Using this API, you can build faster and more efficient backup solutions for Azure VMs. This API will be available with the REST version 2015-07-08 and higher.

Incremental Snapshot Copy allows you to copy from one storage account to another the difference between,

- Base blob and its Snapshot OR
- Any two snapshots of the base blob

Provided the following conditions are met,

- The blob was created on Jan-1-2016 or later.
- The blob was not overwritten with PutPage or Copy Blob between two snapshots.

> ⓘ **Note**
>
> This feature is available for Premium and Standard Azure Page Blobs.

When you have a custom backup strategy using snapshots, copying the snapshots from one storage account to another can be slow and can consume much storage space. Instead of copying the entire snapshot to a backup storage account, you can write the difference between consecutive snapshots to a backup page blob. This way, the time to copy and the space to store backups is substantially reduced.

Implementing Incremental Snapshot Copy

You can implement incremental snapshot copy by doing the following,

- Take a snapshot of the base blob using Snapshot Blob.
- Copy the snapshot to the target backup storage account in same or any other Azure region using Copy Blob. This is the backup page blob. Take a snapshot of the backup page blob and store it in the backup account.
- Take another snapshot of the base blob using Snapshot Blob.
- Get the difference between the first and second snapshots of the base blob using GetPageRanges. Use the new parameter **prevsnapshot**, to specify the DateTime value of the snapshot you want to get the difference with. When this parameter is present, the REST response includes only the pages that were changed between target snapshot and previous snapshot including clear pages.
- Use PutPage to apply these changes to the backup page blob.
- Finally, take a snapshot of the backup page blob and store it in the backup storage account.

In the next section, we will describe in more detail how you can maintain backups of disks using Incremental Snapshot Copy

Scenario

In this section, we describe a scenario that involves a custom backup strategy for virtual machine disks using snapshots.

Consider a DS-series Azure VM with a premium storage P30 disk attached. The P30 disk called *mypremiumdisk* is stored in a premium storage account called *mypremiumaccount*. A standard storage account called *mybackupstdaccount* is used for storing the backup of *mypremiumdisk*. We would like to keep a snapshot of *mypremiumdisk* every 12 hours.

To learn about creating a storage account, see Create a storage account.

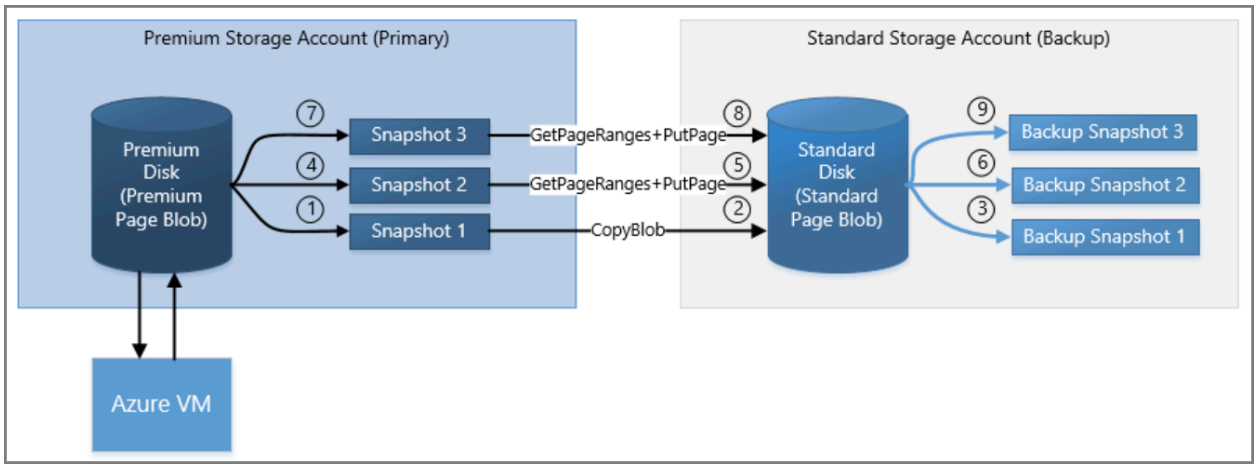
To learn about backing up Azure VMs, refer to Plan Azure VM backups.

Steps to maintain backups of a disk using incremental snapshots

The following steps describe how to take snapshots of *mypremiumdisk* and maintain the backups in *mybackupstdaccount*. The backup is a standard page blob called *mybackupstdpageblob*. The backup page blob always reflects the same state as the last snapshot of *mypremiumdisk*.

1. Create the backup page blob for your premium storage disk, by taking a snapshot of *mypremiumdisk* called *mypremiumdisk_ss1*.
2. Copy this snapshot to mybackupstdaccount as a page blob called *mybackupstdpageblob*.
3. Take a snapshot of *mybackupstdpageblob* called *mybackupstdpageblob_ss1*, using Snapshot Blob and store it in *mybackupstdaccount*.
4. During the backup window, create another snapshot of *mypremiumdisk*, say *mypremiumdisk_ss2*, and store it in *mypremiumaccount*.
5. Get the incremental changes between the two snapshots, *mypremiumdisk_ss2* and *mypremiumdisk_ss1*, using GetPageRanges on *mypremiumdisk_ss2* with the **prevsnapshot** parameter set to the timestamp of *mypremiumdisk_ss1*. Write these incremental changes to the backup page blob *mybackupstdpageblob* in *mybackupstdaccount*. If there are deleted ranges in the incremental changes, they must be cleared from the backup page blob. Use PutPage to write incremental changes to the backup page blob.

6. Take a snapshot of the backup page blob *mybackupstdpageblob*, called *mybackupstdpageblob_ss2*. Delete the previous snapshot *mypremiumdisk_ss1* from premium storage account.
7. Repeat steps 4-6 every backup window. In this way, you can maintain backups of *mypremiumdisk* in a standard storage account.



Steps to restore a disk from snapshots

The following steps, describe how to restore the premium disk, *mypremiumdisk* to an earlier snapshot from the backup storage account *mybackupstdaccount*.

1. Identify the point in time that you wish to restore the premium disk to. Let's say that it is snapshot *mybackupstdpageblob_ss2*, which is stored in the backup storage account *mybackupstdaccount*.
2. In mybackupstdaccount, promote the snapshot *mybackupstdpageblob_ss2* as the new backup base page blob *mybackupstdpageblobrestored*.
3. Take a snapshot of this restored backup page blob, called *mybackupstdpageblobrestored_ss1*.
4. Copy the restored page blob *mybackupstdpageblobrestored* from *mybackupstdaccount* to *mypremiumaccount* as the new premium disk *mypremiumdiskrestored*.
5. Take a snapshot of *mypremiumdiskrestored*, called *mypremiumdiskrestored_ss1* for making future incremental backups.
6. Point the DS series VM to the restored disk *mypremiumdiskrestored* and detach the old *mypremiumdisk* from the VM.
7. Begin the Backup process described in previous section for the restored disk *mypremiumdiskrestored*, using the *mybackupstdpageblobrestored* as the backup page blob.

Backup and disaster recovery for Azure unmanaged disks

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This article explains how to plan for backup and disaster recovery (DR) of IaaS virtual machines (VMs) and disks in Azure. This document covers unmanaged disks, or page blobs.

First, we cover the built-in fault tolerance capabilities in the Azure platform that helps guard against local failures. We then discuss the disaster scenarios not fully covered by the built-in capabilities. We also show several examples of workload scenarios where different backup and DR considerations can apply. We then review possible solutions for the DR of IaaS disks.

Introduction

The Azure platform uses various methods for redundancy and fault tolerance to help protect customers from localized hardware failures. Local failures can include problems with an Azure Storage server machine that stores part of the data for a virtual disk or failures of an SSD or HDD on that server. Such isolated hardware component failures can happen during normal operations.

The Azure platform is designed to be resilient to these failures. Major disasters can result in failures or the inaccessibility of many storage servers or even a whole datacenter. Although your VMs and disks are normally protected from localized failures, additional steps are necessary to protect your workload from region-wide catastrophic failures, such as a major disaster, that can affect your VM and disks.

In addition to the possibility of platform failures, problems with a customer application or data can occur. For example, a new version of your application might inadvertently make a change to the data that causes it to break. In that case, you might want to revert the application and the data to a prior version that contains the last known good state. This requires maintaining regular backups.

For regional disaster recovery, you must back up your IaaS VM disks to a different region.

Before we look at backup and DR options, let’s recap a few methods available for handling localized failures.

Azure IaaS resiliency

Resiliency refers to the tolerance for normal failures that occur in hardware components. Resiliency is the ability to recover from failures and continue to function. It's not about avoiding failures, but responding to failures in a way that avoids downtime or data loss. The goal of resiliency is to return the application to a fully functioning state following a failure. Azure virtual machines and disks are designed to be resilient to common hardware faults. Let's look at how the Azure IaaS platform provides this resiliency.

A virtual machine consists mainly of two parts: a compute server and the persistent disks. Both affect the fault tolerance of a virtual machine.

If the Azure compute host server that houses your VM experiences a hardware failure, which is rare, Azure is designed to automatically restore the VM on another server. If this scenario, your computer reboots, and the VM comes back up after some time. Azure automatically detects such hardware failures and executes recoveries to help ensure the customer VM is available as soon as possible.

Regarding IaaS disks, the durability of data is critical for a persistent storage platform. Azure customers have important business applications running on IaaS, and they depend on the persistence of the data. Azure designs protection for these IaaS disks, with three redundant copies of the data that is stored locally. These copies provide for high durability against local failures. If one of the hardware components that holds your disk fails, your VM is not affected, because there are two additional copies to support disk requests. It works fine, even if two different hardware components that support a disk fail at the same time (which is rare).

To ensure that you always maintain three replicas, Azure Storage automatically spawns a new copy of the data in the background if one of the three copies becomes unavailable. Therefore, it should not be necessary to use RAID with Azure disks for fault tolerance. A simple RAID 0 configuration should be sufficient for striping the disks, if necessary, to create larger volumes.

Because of this architecture, Azure has consistently delivered enterprise-grade durability for IaaS disks, with an industry-leading zero percent annualized failure rate.

Localized hardware faults on the compute host or in the Storage platform can sometimes result in of the temporary unavailability of the VM that is covered by the Azure SLA for VM availability. Azure also provides an industry-leading SLA for single VM instances that use Azure premium SSDs.

To safeguard application workloads from downtime due to the temporary unavailability of a disk or VM, customers can use availability sets. Two or more virtual machines in an

availability set provide redundancy for the application. Azure then creates these VMs and disks in separate fault domains with different power, network, and server components.

Because of these separate fault domains, localized hardware failures typically do not affect multiple VMs in the set at the same time. Having separate fault domains provides high availability for your application. It's considered a good practice to use availability sets when high availability is required. The next section covers the disaster recovery aspect.

Backup and disaster recovery

Disaster recovery is the ability to recover from rare, but major, incidents. These incidents include non-transient, wide-scale failures, such as service disruption that affects an entire region. Disaster recovery includes data backup and archiving, and might include manual intervention, such as restoring a database from a backup.

The Azure platform's built-in protection against localized failures might not fully protect the VMs/disks if a major disaster causes large-scale outages. These large-scale outages include catastrophic events, such as if a datacenter is hit by a hurricane, earthquake, fire, or if there is a large-scale hardware unit failure. In addition, you might encounter failures due to application or data issues.

To help protect your IaaS workloads from outages, you should plan for redundancy and have backups to enable recovery. For disaster recovery, you should back up in a different geographic location away from the primary site. This approach helps ensure your backup is not affected by the same event that originally affected the VM or disks. For more information, see Disaster recovery for Azure applications.

Your DR considerations might include the following aspects:

- High availability: The ability of the application to continue running in a healthy state, without significant downtime. By *healthy state*, this state means that the application is responsive, and users can connect to the application and interact with it. Certain mission-critical applications and databases might be required to always be available, even when there are failures in the platform. For these workloads, you might need to plan redundancy for the application, as well as the data.

- Data durability: In some cases, the main consideration is ensuring that the data is preserved if a disaster happens. Therefore, you might need a backup of your data in a different site. For such workloads, you might not need full redundancy for the application, but only a regular backup of the disks.

Backup and DR scenarios

Let's look at a few typical examples of application workload scenarios and the considerations for planning for disaster recovery.

Scenario 1: Major database solutions

Consider a production database server, like SQL Server or Oracle, that can support high availability. Critical production applications and users depend on this database. The disaster recovery plan for this system might need to support the following requirements:

- The data must be protected and recoverable.
- The server must be available for use.

The disaster recovery plan might require maintaining a replica of the database in a different region as a backup. Depending on the requirements for server availability and data recovery, the solution might range from an active-active or active-passive replica site to periodic offline backups of the data. Relational databases, such as SQL Server and Oracle, provide various options for replication. For SQL Server, use SQL Server Always On Availability Groups for high availability.

NoSQL databases, like MongoDB, also support replicas for redundancy. The replicas for high availability are used.

Scenario 2: A cluster of redundant VMs

Consider a workload handled by a cluster of VMs that provide redundancy and load balancing. One example is a Cassandra cluster deployed in a region. This type of architecture already provides a high level of redundancy within that region. However, to protect the workload from a regional-level failure, you should consider spreading the cluster across two regions or making periodic backups to another region.

Scenario 3: IaaS application workload

Let's look at the IaaS application workload. For example, this application might be a typical production workload running on an Azure VM. It might be a web server or file server holding the content and other resources of a site. It might also be a custom-built business application running on a VM that stored its data, resources, and application state on the VM disks. In this case, it's important to make sure you take backups on a regular basis. Backup frequency should be based on the nature of the VM workload. For

example, if the application runs every day and modifies data, then the backup should be taken every hour.

Another example is a reporting server that pulls data from other sources and generates aggregated reports. The loss of this VM or disks might lead to the loss of the reports. However, it might be possible to rerun the reporting process and regenerate the output. In that case, you don't really have a loss of data, even if the reporting server is hit with a disaster. As a result, you might have a higher level of tolerance for losing part of the data on the reporting server. In that case, less frequent backups are an option to reduce costs.

Scenario 4: IaaS application data issues

IaaS application data issues are another possibility. Consider an application that computes, maintains, and serves critical commercial data, such as pricing information. A new version of your application had a software bug that incorrectly computed the pricing and corrupted the existing commerce data served by the platform. Here, the best course of action is to revert to the earlier version of the application and the data. To enable this, take periodic backups of your system.

Disaster recovery solution: Azure Backup

Azure Backup is used for backups and DR, and it works with managed disks as well as unmanaged disks. You can create a backup job with time-based backups, easy VM restoration, and backup retention policies.

If you use premium SSDs, managed disks, or other disk types with the locally redundant storage option, it's especially important to make periodic DR backups. Azure Backup stores the data in your recovery services vault for long-term retention. Choose the geo-redundant storage option for the backup recovery services vault. That option ensures that backups are replicated to a different Azure region for safeguarding from regional disasters.

For unmanaged disks, you can use the locally redundant storage type for IaaS disks, but ensure that Azure Backup is enabled with the geo-redundant storage option for the recovery services vault.

> **Note**
>
> If you use the geo-redundant storage or read-access geo-redundant storage option for your unmanaged disks, you still need consistent snapshots for backup

and DR. Use either Azure Backup or consistent snapshots.

The following table is a summary of the solutions available for DR.

Expand table

Scenario	Automatic replication	DR solution
Premium SSD disks	Local (locally redundant storage)	Azure Backup
Managed disks	Local (locally redundant storage)	Azure Backup
Unmanaged locally redundant storage disks	Local (locally redundant storage)	Azure Backup
Unmanaged geo-redundant storage disks	Cross region (geo-redundant storage)	Azure Backup Consistent snapshots
Unmanaged read-access geo-redundant storage disks	Cross region (read-access geo-redundant storage)	Azure Backup Consistent snapshots

High availability is best met by using managed disks in an availability set along with Azure Backup. If you use unmanaged disks, you can still use Azure Backup for DR. If you are unable to use Azure Backup, then taking consistent snapshots, as described in a later section, is an alternative solution for backup and DR.

Your choices for high availability, backup, and DR at application or infrastructure levels can be represented as follows:

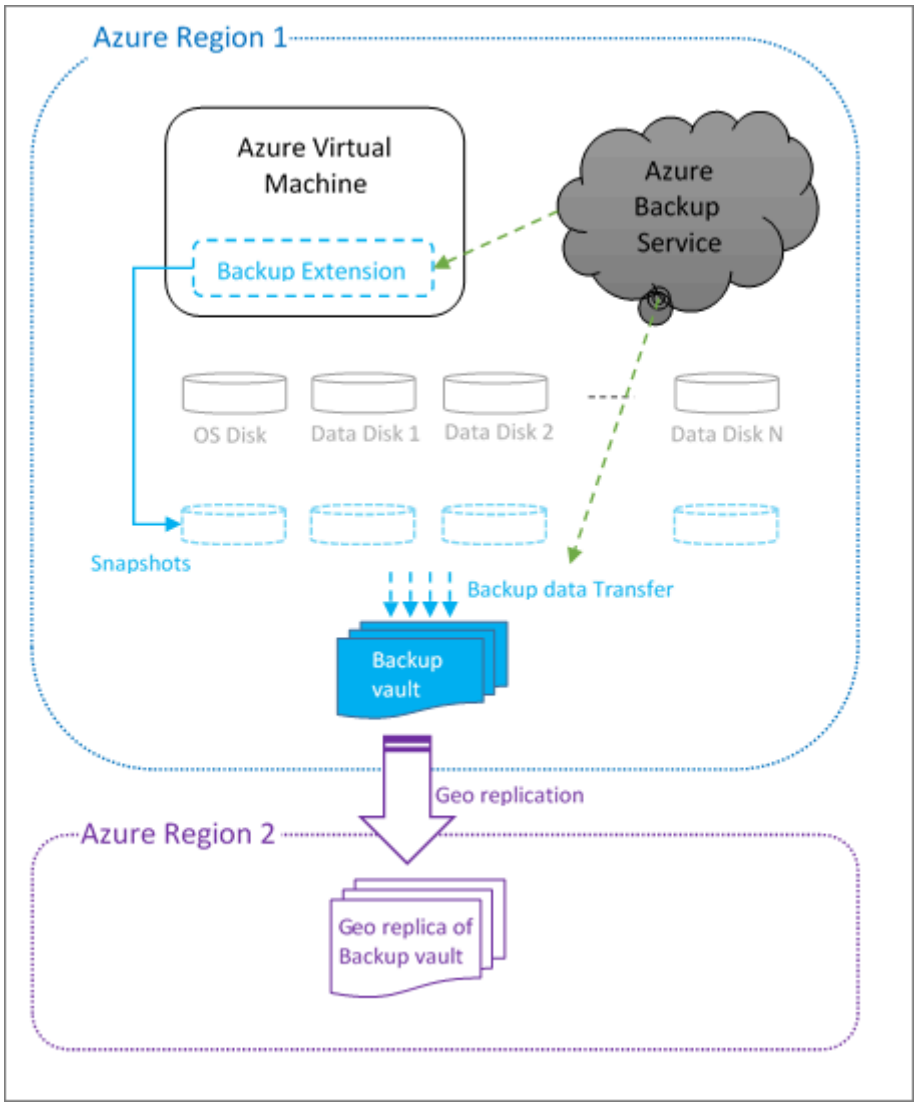
Expand table

Level	High availability	Backup or DR
Application	SQL Server Always On	Azure Backup
Infrastructure	Availability set	Geo-redundant storage with consistent snapshots

Using Azure Backup

Azure Backup can back up your VMs running Windows or Linux to the Azure recovery services vault. Backing up and restoring business-critical data is complicated by the fact that business-critical data must be backed up while the applications that produce the data are running.

To address this issue, Azure Backup provides application-consistent backups for Microsoft workloads. It uses the volume shadow service to ensure that data is written correctly to storage. For Linux VMs, the default backup consistency mode is file-consistent backups, because Linux does not have functionality equivalent to the volume shadow service as in the case of Windows. For Linux machines, see Application-consistent backup of Azure Linux VMs.



When Azure Backup initiates a backup job at the scheduled time, it triggers the backup extension installed in the VM to take a point-in-time snapshot. A snapshot is taken in coordination with the volume shadow service to get a consistent snapshot of the disks in the virtual machine without having to shut it down. The backup extension in the VM flushes all writes before taking a consistent snapshot of all of the disks. After taking the snapshot, the data is transferred by Azure Backup to the backup vault. To make the backup process more efficient, the service identifies and transfers only the blocks of data that have changed after the last backup.

To restore, you can view the available backups through Azure Backup and then initiate a restore. You can create and restore Azure backups through the Azure portal, by using PowerShell, or by using the Azure CLI.

Steps to enable a backup

Use the following steps to enable backups of your VMs by using the Azure portal. There is some variation depending on your exact scenario. Refer to the Azure Backup documentation for full details. Azure Backup also supports VMs with managed disks.

1. Create a recovery services vault for a VM:

   a. In the Azure portal, browse **All resources** and find **Recovery Services vaults**.

   b. On the **Recovery Services vaults** menu, click **Add** and follow the steps to create a new vault in the same region as the VM. For example, if your VM is in the West US region, pick West US for the vault.

2. Verify the storage replication for the newly created vault. Access the vault under **Recovery Services vaults** and go to **Properties** > **Backup Configuration** > **Update**. Ensure the **geo-redundant storage** option is selected by default. This option ensures that your vault is automatically replicated to a secondary datacenter. For example, your vault in West US is automatically replicated to East US.

3. Configure the backup policy and select the VM from the same UI.

4. Make sure the Backup Agent is installed on the VM. If your VM is created by using an Azure gallery image, then the Backup Agent is already installed. Otherwise (that is, if you use a custom image), use the instructions to install the VM agent on a virtual machine.

5. After the previous steps are completed, the backup runs at regular intervals as specified in the backup policy. If necessary, you can trigger the first backup manually from the vault dashboard on the Azure portal.

For automating Azure Backup by using scripts, refer to PowerShell cmdlets for VM backup.

Steps for recovery

If you need to repair or rebuild a VM, you can restore the VM from any of the backup recovery points in the vault. There are a couple of different options for performing the recovery:

- You can create a new VM as a point-in-time representation of your backed-up VM.
- You can restore the disks, and then use the template for the VM to customize and rebuild the restored VM.

For more information, see the instructions to use the Azure portal to restore virtual machines. This document also explains the specific steps for restoring backed-up VMs to a paired datacenter by using your geo-redundant backup vault if there is a disaster at the primary datacenter. In that case, Azure Backup uses the Compute service from the secondary region to create the restored virtual machine.

You can also use PowerShell for creating a new VM from restored disks.

Alternative solution: Consistent snapshots

If you are unable to use Azure Backup, you can implement your own backup mechanism by using snapshots. Creating consistent snapshots for all the disks used by a VM and then replicating those snapshots to another region is complicated. For this reason, Azure considers using the Backup service as a better option than building a custom solution.

If you use read-access geo-redundant storage/geo-redundant storage for disks, snapshots are automatically replicated to a secondary datacenter. If you use locally redundant storage for disks, you need to replicate the data yourself. For more information, see Back up Azure-unmanaged VM disks with incremental snapshots.

A snapshot is a representation of an object at a specific point in time. A snapshot incurs billing for the incremental size of the data it holds. For more information, see Create a blob snapshot.

Create snapshots while the VM is running

Although you can take a snapshot at any time, if the VM is running, there is still data being streamed to the disks. The snapshots might contain partial operations that were in flight. Also, if there are several disks involved, the snapshots of different disks might have occurred at different times. These scenarios may cause to the snapshots to be uncoordinated. This lack of coordination is especially problematic for striped volumes whose files might be corrupted if changes were being made during backup.

To avoid this situation, the backup process must implement the following steps:

1. Freeze all the disks.
2. Flush all the pending writes.
3. Create a blob snapshot for all the disks.

Some Windows applications, like SQL Server, provide a coordinated backup mechanism via a volume shadow service to create application-consistent backups. On Linux, you can

use a tool like *fsfreeze* for coordinating the disks. This tool provides file-consistent backups, but not application-consistent snapshots. This process is complex, so you should consider using Azure Backup or a third-party backup solution that already implements this procedure.

The previous process results in a collection of coordinated snapshots for all of the VM disks, representing a specific point-in-time view of the VM. This is a backup restore point for the VM. You can repeat the process at scheduled intervals to create periodic backups. See Copy the backups to another region for steps to copy the snapshots to another region for DR.

Create snapshots while the VM is offline

Another option to create consistent backups is to shut down the VM and take blob snapshots of each disk. Taking blob snapshots is easier than coordinating snapshots of a running VM, but it requires a few minutes of downtime.

1. Shut down the VM.
2. Create a snapshot of each virtual hard drive blob, which only takes a few seconds.

   To create a snapshot, you can use PowerShell, the Azure Storage REST API, Azure CLI, or one of the Azure Storage client libraries, such as the Storage client library for .NET.
3. Start the VM, which ends the downtime. Typically, the entire process finishes within a few minutes.

This process yields a collection of consistent snapshots for all the disks, providing a backup restore point for the VM.

Copy the snapshots to another region

Creation of the snapshots alone might not be sufficient for DR. You must also replicate the snapshot backups to another region.

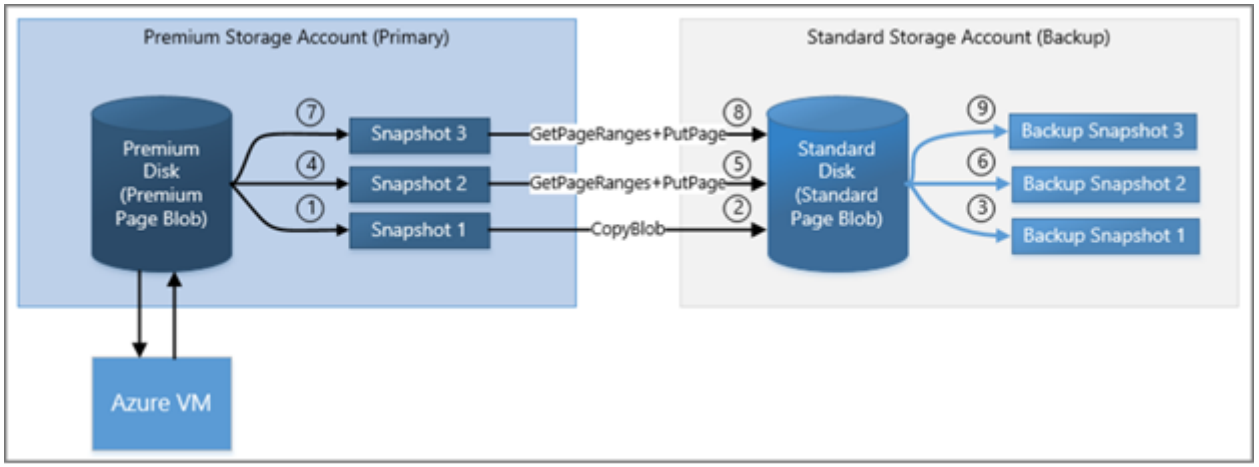
If you use geo-redundant storage or read-access geo-redundant storage for your disks, then the snapshots are replicated to the secondary region automatically. There can be a few minutes of lag before the replication. If the primary datacenter goes down before the snapshots finish replicating, you cannot access the snapshots from the secondary datacenter. The likelihood of this is small.

> **Note**

> Only having the disks in a geo-redundant storage or read-access geo-redundant storage account does not protect the VM from disasters. You must also create coordinated snapshots or use Azure Backup. This is required to recover a VM to a consistent state.

If you use locally redundant storage, you must copy the snapshots to a different storage account immediately after creating the snapshot. The copy target might be a locally redundant storage account in a different region, resulting in the copy being in a remote region. You can also copy the snapshot to a read-access geo-redundant storage account in the same region. In this case, the snapshot is lazily replicated to the remote secondary region. Your backup is protected from disasters at the primary site after the copying and replication is complete.

To copy your incremental snapshots for DR efficiently, review the instructions in Back up Azure unmanaged VM disks with incremental snapshots.



Recovery from snapshots

To retrieve a snapshot, copy it to make a new blob. If you are copying the snapshot from the primary account, you can copy the snapshot over to the base blob of the snapshot. This process reverts the disk to the snapshot. This process is known as promoting the snapshot. If you are copying the snapshot backup from a secondary account, in the case of a read-access geo-redundant storage account, you must copy it to a primary account. You can copy a snapshot by using PowerShell or by using the AzCopy utility. For more information, see Transfer data with the AzCopy command-line utility.

For VMs with multiple disks, you must copy all the snapshots that are part of the same coordinated restore point. After you copy the snapshots to writable VHD blobs, you can use the blobs to recreate your VM by using the template for the VM.

Other options

SQL Server

SQL Server running in a VM has its own built-in capabilities to back up your SQL Server database to Azure Blob storage or a file share. If the storage account is geo-redundant storage or read-access geo-redundant storage, you can access those backups in the storage account's secondary datacenter in the event of a disaster, with the same restrictions as previously discussed. For more information, see Back up and restore for SQL Server in Azure virtual machines. In addition to back up and restore, SQL Server Always On availability groups can maintain secondary replicas of databases. This ability greatly reduces the disaster recovery time.

Other considerations

This article has discussed how to back up or take snapshots of your VMs and their disks to support disaster recovery and how to use those backups or snapshots to recover your data. With the Azure Resource Manager model, many people use templates to create their VMs and other infrastructures in Azure. You can use a template to create a VM that has the same configuration every time. If you use custom images for creating your VMs, you must also make sure that your images are protected by using a read-access geo-redundant storage account to store them.

Consequently, your backup process can be a combination of two things:

- Back up the data (disks).
- Back up the configuration (templates and custom images).

Depending on the backup option you choose, you might have to handle the backup of both the data and the configuration, or the backup service might handle all of that for you.

Appendix: Understanding the impact of data redundancy

For storage accounts in Azure, there are three types of data redundancy that you should consider regarding disaster recovery: locally redundant, geo-redundant, or geo-redundant with read access.

Locally redundant storage retains three copies of the data in the same datacenter. When the VM writes the data, all three copies are updated before success is returned to the caller, so you know they are identical. Your disk is protected from local failures, because it's unlikely that all three copies are affected at the same time. In the case of locally redundant storage, there is no geo-redundancy, so the disk is not protected from catastrophic failures that can affect an entire datacenter or storage unit.

With geo-redundant storage and read-access geo-redundant storage, three copies of your data are retained in the primary region that is selected by you. Three more copies of your data are retained in a corresponding secondary region that is set by Azure. For example, if you store data in West US, the data is replicated to East US. Copy retention is done asynchronously, and there is a small delay between updates to the primary and secondary sites. Replicas of the disks on the secondary site are consistent on a per-disk basis (with the delay), but replicas of multiple active disks might not be in sync with each other. To have consistent replicas across multiple disks, consistent snapshots are needed.

The main difference between geo-redundant storage and read-access geo-redundant storage is that with read-access geo-redundant storage, you can read the secondary copy at any time. If there is a problem that renders the data in the primary region inaccessible, the Azure team makes every effort to restore access. While the primary is down, if you have read-access geo-redundant storage enabled, you can access the data in the secondary datacenter. Therefore, if you plan to read from the replica while the primary is inaccessible, then read-access geo-redundant storage should be considered.

If it turns out to be a significant outage, the Azure team might trigger a geo-failover and change the primary DNS entries to point to secondary storage. At this point, if you have either geo-redundant storage or read-access geo-redundant storage enabled, you can access the data in the region that used to be the secondary. In other words, if your storage account is geo-redundant storage and there is a problem, you can access the secondary storage only if there is a geo-failover.

For more information, see What to do if an Azure Storage outage occurs.

Ephemeral OS disks for Azure VMs

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

> **Note**
>
> NVMe disk placement for Ephemeral OS disks is now Generally Available (GA). Customers can use Ephemeral OS disks for production workloads on supported v6 VM series.

Ephemeral OS disks are created on the local virtual machine (VM) storage and not saved to the remote Azure Storage. Ephemeral OS disks are ideal for stateless workloads, where applications can tolerate individual VM failures but are sensitive to VM deployment times or the reimaging of individual VM instances. With Ephemeral OS disk, you get lower read/write latency to the OS disk and faster VM reimage.

The key features of ephemeral disks are:

- Ephemeral OS disks are supported on VM sizes with local SSD storage, including Premium SSD, NVMe, and temp disks. The performance and reliability of the ephemeral OS disk are directly tied to the underlying local SSD storage of the VM. For best results, select VM sizes that offer Premium SSD or NVMe-based local storage.
- Designed for stateless applications.
- Supported on all images - Marketplace, custom images, and Azure Compute Gallery (formerly known as Shared Image Gallery).
- Provides fast reimage to reset virtual machines (VMs) and scale set instances to their original boot state.
- Offers lower latency, similar to a temporary disk.
- Supports Premium SSD & Standard SSD for higher SLA
- Supported in all Azure regions.

Key differences between persistent and ephemeral OS disks:

Expand table

	Persistent OS Disk	Ephemeral OS Disk
Size limit for OS disk	4* TiB	Cache, temp, or NVMe disk size for the VM size or 2,040 GiB, whichever is smaller. For the **cache, temp or NVMe size in GiB**, see DSv3, Esv3, M, FS, and GS
VM sizes supported	All	VM sizes with local storage such as D(a)dsv4, D(a)dsv5, D(a)dsv6, FXmdsv2, E(a)dsv5,

	Persistent OS Disk	Ephemeral OS Disk
		L(a)sv3, etc.
Disk type support	Managed and unmanaged OS disk	Managed OS disk only
Region support	All regions	All regions
Data persistence	OS disk data written to OS disk are stored in Azure Storage	Data written to OS disk is stored on local VM storage and isn't persisted to Azure Storage.
Stop-deallocated state	VMs and scale set instances can be stop-deallocated and restarted from the stop-deallocated state	Not Supported
Specialized OS disk support	Yes	No
OS disk resize	Supported during VM creation and after VM is stop-deallocated	Supported during VM creation only
Resizing to a new VM size	OS disk data is preserved	Data on the OS disk is deleted, OS is reprovisioned
Redeploy	OS disk data is preserved	Data on the OS disk is deleted, OS is reprovisioned
Stop/ Start of VM	OS disk data is preserved	Not Supported
Page file placement	For Windows, page file is stored on the temp disk	For Windows, page file is stored on the OS disk (for cache placement, Temp disk placement & NVMe disk placement).
Maintenance of VM/VMSS using healing	OS disk data is preserved	OS disk data isn't preserved
Maintenance of VM/VMSS using Live Migration	OS disk data is preserved	OS disk data is preserved

* 4 TiB is the maximum supported OS disk size for managed (persistent) disks. However, many OS disks are partitioned with master boot record (MBR) by default and are limited to 2 TiB. For details, see OS disk.

Placement options for Ephemeral OS disks

Ephemeral OS Disk utilizes local storage within the VM. Since different VMs have different types of local storage (cache disk, temp disk, and NVMe disk), the placement option defines where the Ephemeral OS Disk is stored. Placement option however doesn't impact the performance or cost of Ephemeral OS disk. Its performance is dependent upon the VM's local storage. Depending upon the VM type, we offer three different types of placement:

- **NVMe Disk Placement (Generally Available)** - NVMe disk placement type is now generally available (GA) on the latest generation v6 VM series onwards like Dadsv6, Ddsv6, Dpdsv6, etc.
- **Temp Disk Placement (also known as Resource Disk Placement)** - Temp disk placement type is available on VMs with Temp disk like Dadsv5, Ddsv5, etc.
- **Cache Disk Placement** - Cache disk placement type is available on older VMs that had cache disk like Dsv2, Dsv3, etc.

DiffDiskPlacement is the property that can be used to specify where you want to place the Ephemeral OS disk. By default, Azure will pick up the right placement type, depending on the VM SKU. The customers are recommended to use the latest VM series (v5/v6) with either Temp Disk or NVMe Disk placement.

Size requirements

You can choose to deploy Ephemeral OS Disk on NVMe disk, temp disk, or cache on the VM. The image OS disk's size should be less than or equal to the NVMe/temp/cache size of the VM size chosen.

For **OS cache placement**: Standard Windows Server images from the marketplace are about 127 GiB, which means that you need a VM size that has a cache equal to or larger than 127 GiB. The Standard_DS3_v2 has a cache size of 127 GiB, which is large enough. In this case, the Standard_DS3_v2 is the smallest size in the DSv2 series that you can use with this image.

For **Temp disk placement**: Standard Ubuntu server image from marketplace is about 30 GiB. To enable Ephemeral OS disk on temp, the temp disk size must be equal to or larger than 30 GiB. Standard_B4ms has a temp size of 32 GiB, which can fit the 30-GiB OS disk. Upon creation of the VM, the temp disk space would be 2 GiB.

For **NVMe disk placement (GA)**: Standard Ubuntu server image from marketplace is about 30 GiB. To enable Ephemeral OS disk on NVMe, the NVMe disk size must be equal to or larger than 30 GiB. Standard_D2ads_v6 has a Nvme disk size of 110 GiB, which can easily fit the 30-GiB OS disk. However, Ephemeral OS disk occupies the entire NVMe disk and there's no NVMe disk space given back. One way to maximize the use of NVMe disk is by maximizing the OS disk Size property to 110 GiB.

> **ⓘ Important**
>
> If opting for temp disk placement the Final Temp disk size = (Initial temp disk size - OS image size).
>
> If opting for NVMe disk placement (GA), Final NVMe Disk size = (Total no. of NVMe disks - NVMe Disks used for OS) * Size of each NVMe disk. Where NVMe Disks used for OS is the minimum number of disks required for OS disk depending on the size of OS disk and the size of each NVMe disk.

If Ephemeral OS disk is using **Temp Disk Placement**, it shares the IOPS(input/output operations per second) with temp disk. If Ephemeral OS disk is using **NVMe Disk Placement**, it provides the IOPS(input/output operations per second) of NVMe disks being used.

Basic Linux and Windows Server images in the Marketplace that are denoted with `[smallsize]` tend to be around 30 GiB and can use most of the available VM sizes.

> **ⓘ Note**
>
> Ephemeral disks aren't accessible through the portal. You receive a "Resource not Found" or "404" error when accessing the ephemeral disk which is expected.

Unsupported features

- VM Image Capture
- Disk snapshots
- Azure Disk Encryption
- Azure Backup
- Azure Site Recovery
- OS Disk Swaps

Trusted Launch for Ephemeral OS disks

Ephemeral OS disks can be created with Trusted launch. All regions are supported for Trusted Launch; not all virtual machines sizes are supported. Check Virtual machines sizes supported for supported sizes. VM guest state (VMGS) is specific to trusted launch VMs. It's an Azure-managed blob and contains the unified extensible firmware interface (UEFI) secure boot signature databases and other security information. VMs using trusted launch by default

reserve **1 GiB** from the **OS cache** or **temp disk** or **Nvme Disk** based on the chosen placement option for VMGS. The lifecycle of the VMGS blob is tied to that of the OS Disk.

For example, If you try to create a Trusted launch Ephemeral OS disk VM using OS image of size 75 GiB with VM size Standard_D2ads_v5 using temp disk placement you would get an error as **"OS disk of Ephemeral VM with size greater than 74 GB is not allowed for VM size Standard_Dads_v5 when the DiffDiskPlacement is ResourceDisk."** This error occurs because the temp disk for Standard_D2ads_v5 is 75 GiB, and 1 GiB is reserved for VMGS when using trusted launch. For the same example, if you create a standard Ephemeral OS disk VM you wouldn't get any errors and it would be a successful operation.

> **Important**
>
> If you use ephemeral disks with Trusted Launch VMs, any keys or secrets that the vTPM generates or seals after the VM is created might not be saved. As a result, these keys and secrets could be lost during actions such as reimaging or service healing events.

For more information on how to deploy a trusted launch VM

Confidential VMs using Ephemeral OS disks

AMD-based Confidential VMs cater to high security and confidentiality requirements of customers. These VMs provide a strong, hardware-enforced boundary to help meet your security needs. There are limitations to use Confidential VMs. Check the region, size, and OS supported limitations for confidential VMs. Virtual machine guest state (VMGS) blob contains the security information of the confidential VM. Confidential VMs using Ephemeral OS disks by default **1 GiB** from the **OS cache** or **temp storage** based on the chosen placement option is reserved for VMGS. The lifecycle of the VMGS blob is tied to that of the OS Disk.

> **Important**
>
> When choosing a confidential VM with full OS disk encryption before VM deployment that uses a customer-managed key (CMK). **Updating a CMK key version** or **key rotation** isn't supported with Ephemeral OS disk. Confidential VMs using Ephemeral OS disks need to be deleted before updating or rotating the keys and can be re-created later.

For more information on confidential VM

Customer Managed key

You can choose to use customer managed keys or platform managed keys when you enable end-to-end encryption for VMs using Ephemeral OS disk. Currently this option is available only via PowerShell, CLI, and SDK in all regions.

> **Important**
>
> Updating a CMK key version or key rotation of customer managed key isn't supported with Ephemeral OS disk. VMs using Ephemeral OS disks need to be deleted before updating or rotating the keys and can be re-created later.

For more information on Encryption at host

SSD storage account support for Ephemeral OS disks

SSD support is a new option that allows customers to choose the type of base disk that is used for the ephemeral OS disk. Previously, the base disk could only be Standard HDD. Now, customers can choose between the three types of disks: Standard HDD(Standard_LRS), Standard SSD (StandardSSD_LRS) or Premium SSD (Premium_LRS). By utilizing SSD with Ephemeral OS disk, customers can benefit from the following enhancements:

- **Enhanced SLA**: VMs created with Premium SSD provide higher SLA than VMs created with Standard HDD. Customers can enhance SLA for their Ephemeral VMs by choosing Premium SSD as base disk.
- **Improved performance**: By choosing Premium SSD as the base disk, customers can enhance the disk read performance of their VMs. While most writes occur on the local temp disk, some reads are performed from managed disks. Premium SSD disks provide 8-10 times higher IOPS than Standard HDD.

Local temporary storage

Some Azure VM sizes include local temporary storage, with some of the newer sizes using Temporary local NVMe disks. Local temporary disks are different from Ephemeral OS disks.

Local temporary storage, also known as local ephemeral storage, are additional disks provisioned directly as local storage to an Azure virtual machine host, rather than on remote Azure Storage. This type of storage is best suited for data that does not need to be retained permanently, such as caches, buffers, and temporary files. Local ephemeral storage is not backed up and is lost when the VM is deallocated or deleted. The ephemeral storage is recreated on startup.

Azure VM sizes featuring a 'd' in their naming convention - such as the Da***d***sv6, Ea***d***sv6, and FXm***d***sv2 series - include dedicated local temporary disks.

Next steps

Create a VM with ephemeral OS disk using Azure Portal/CLI/PowerShell/ARM template. Check out the frequently asked questions on ephemeral os disk.

Last updated on 12/01/2025

How to deploy Ephemeral OS disks for Azure VMs

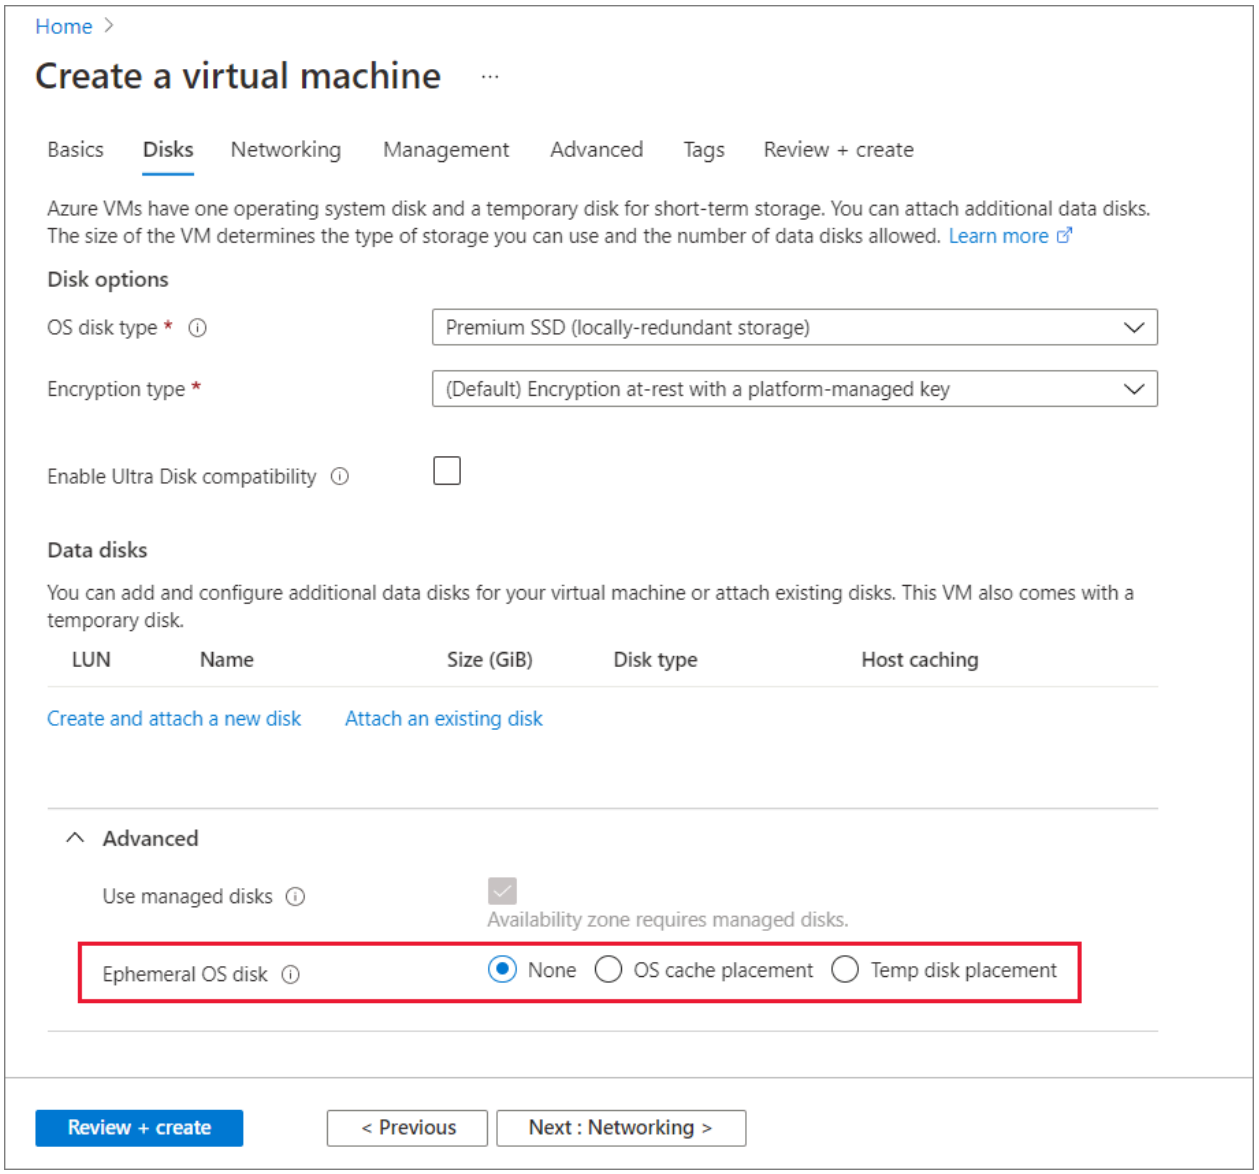
Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article shows you how to create a virtual machine or virtual machine scale sets with Ephemeral OS disks through Portal, ARM template deployment, CLI and PowerShell.

Portal

In the Azure portal, you can choose to use ephemeral disks when deploying a virtual machine or virtual machine scale sets by opening the **Advanced** section of the **Disks** tab. For choosing placement of Ephemeral OS disk, select **OS cache placement** or **Temp disk placement**.



If the option for using an ephemeral disk or OS cache placement or Temp disk placement is greyed out, you might have selected a VM size that doesn't have a cache/temp size larger than the OS image or that doesn't support Premium storage. Go back to the **Basics** page and try choosing another VM size.

Scale set template deployment

The process to create a scale set that uses an ephemeral OS disk is to add the `diffDiskSettings` property to the `Microsoft.Compute/virtualMachineScaleSets/virtualMachineProfile` resource type in the template. Also, the caching policy must be set to `ReadOnly` for the ephemeral OS disk. placement can be changed to `CacheDisk` for OS cache disk placement.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachineScaleSets",
```

```
  "name": "myScaleSet",
  "location": "East US 2",
  "apiVersion": "2019-12-01",
  "sku": {
    "name": "Standard_DS2_v2",
    "capacity": "2"
  },
  "properties": {
    "upgradePolicy": {
      "mode": "Automatic"
    },
    "virtualMachineProfile": {
       "storageProfile": {
        "osDisk": {
          "diffDiskSettings": {
            "option": "Local" ,
            "placement": "ResourceDisk"
          },
          "caching": "ReadOnly",
          "createOption": "FromImage"
        },
        "imageReference":  {
          "publisher": "publisherName",
          "offer": "offerName",
          "sku": "skuName",
          "version": "imageVersion"
        }
      },
      "osProfile": {
        "computerNamePrefix": "myvmss",
        "adminUsername": "azureuser",
        "adminPassword": "P@ssw0rd!"
      }
    }
  }
}
```

> ⓘ **Note**
>
> Replace all the other values accordingly.

VM template deployment

You can deploy a VM with an ephemeral OS disk using a template. The process to create a VM that uses ephemeral OS disks is to add the `diffDiskSettings` property to Microsoft.Compute/virtualMachines resource type in the template. Also, the caching policy must be set to `ReadOnly` for the ephemeral OS disk. placement option can be changed to `CacheDisk` for OS cache disk placement.

JSON

```
{
  "type": "Microsoft.Compute/virtualMachines",
  "name": "myVirtualMachine",
  "location": "East US 2",
  "apiVersion": "2019-12-01",
  "properties": {
       "storageProfile": {
            "osDisk": {
              "diffDiskSettings": {
                "option": "Local" ,
                "placement": "ResourceDisk"
              },
              "caching": "ReadOnly",
              "createOption": "FromImage"
            },
            "imageReference": {
                "publisher": "MicrosoftWindowsServer",
                "offer": "WindowsServer",
                "sku": "2016-Datacenter-smalldisk",
                "version": "latest"
            },
            "hardwareProfile": {
                 "vmSize": "Standard_DS2_v2"
             }
      },
      "osProfile": {
        "computerNamePrefix": "myvirtualmachine",
        "adminUsername": "azureuser",
        "adminPassword": "P@ssw0rd!"
      }
    }
 }
```

CLI

To use an ephemeral disk for a CLI VM deployment, set the `--ephemeral-os-disk` parameter in az vm create to `true` and the `--ephemeral-os-disk-placement` parameter to `ResourceDisk` for temp disk placement or `CacheDisk` for cache disk placement and the `--os-disk-caching` parameter to `ReadOnly`.

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --image imageName \
  --ephemeral-os-disk true \
  --ephemeral-os-disk-placement ResourceDisk \
```

```
  --os-disk-caching ReadOnly \
  --admin-username azureuser \
  --generate-ssh-keys
```

> **Note**
>
> Replace `myVM`, `myResourceGroup`, `imageName` and `azureuser` accordingly.

For scale sets, you use the same `--ephemeral-os-disk true` parameter for az-vmss-create and set the `--os-disk-caching` parameter to `ReadOnly` and the `--ephemeral-os-disk-placement` parameter to `ResourceDisk` for temp disk placement or `CacheDisk` for cache disk placement.

Reimage a VM using REST

You can reimage a Virtual Machine instance with ephemeral OS disk using REST API as described below and via Azure portal by going to Overview pane of the VM. For scale sets, reimaging is already available through PowerShell, CLI, and the portal.

```
POST https://management.azure.com/subscriptions/{sub-id}/resourceGroups/{rgName}/providers/Microsoft.Compute/VirtualMachines/{vmName}/reimage?api-version=2019-12-01"
```

PowerShell

To use an ephemeral disk for a PowerShell VM deployment, use Set-AzVMOSDisk in your VM configuration. Set the `-DiffDiskSetting` to `Local` and `-Caching` to `ReadOnly` and `-DiffDiskPlacement` to `ResourceDisk`.

PowerShell

```
Set-AzVMOSDisk -DiffDiskSetting Local -DiffDiskPlacement ResourceDisk -Caching ReadOnly
```

To use an ephemeral disk on cache disk for a PowerShell VM deployment, use Set-AzVMOSDisk in your VM configuration. Set the `-DiffDiskSetting` to `Local` , `-Caching` to `ReadOnly` and `-DiffDiskPlacement` to `CacheDisk`.

PowerShell

```
Set-AzVMOSDisk -DiffDiskSetting Local -DiffDiskPlacement CacheDisk -Caching
ReadOnly
```

For scale set deployments, use the Set-AzVmssStorageProfile cmdlet in your configuration. Set the `-DiffDiskSetting` to `Local` , `-Caching` to `ReadOnly` and `-DiffDiskPlacement` to `ResourceDisk` or `CacheDisk`.

PowerShell

```
Set-AzVmssStorageProfile -DiffDiskSetting Local -DiffDiskPlacement
ResourceDisk -OsDiskCaching ReadOnly
```

Frequently asked questions about Ephemeral OS disks

Article • 10/18/2024

Q: What is the size of the Ephemeral OS Disks?

A: We support platform, Shared Image Gallery, and custom images. Size of Ephemeral OS disk depends on the local storage (cache disk, temp disk, or NVMe disk) available on the Virtual Machine (VM). Max size of Ephemeral OS disk can be 2 TiB. All writes to the OS disk are local on the same node as the Virtual Machine.

Q: Can the ephemeral OS disk be resized?

A: No, once the ephemeral OS disk is provisioned, the OS disk can't be resized.

Q: Can the ephemeral OS disk placement be modified after creation of VM?

A: No, once the ephemeral OS disk is provisioned, the OS disk placement can't be changed. But the VM can be recreated via ARM template deployment/PowerShell/CLI by updating the OS disk placement of choosing. This results in the recreation of the VM with Data on the OS disk deleted and OS is reprovisioned.

Q: Is there any Temp disk created if image size equals to Temp disk size of VM size selected?

A: No, in that case, Temp disk is not created.

Q: How is NVMe disk placement different from temp disk placement?

A: Nvme disk placement utilizes the entire Nvme disk, while temp disk placement utilizes space equal to the OS disk size. For example, if you're using Standard Ubuntu image on Standard_D2ads_v5 with temp disk placement, you get an OS disk size of 30 GiB & temp disk size of 45 GiB. If you're using the same Standard Ubuntu image on Standard_D2ads_v6 with NVMe disk placement, then you get and OS disk size of 30 GiB with no NVMe disk.

Q: How does NVMe disk placement work for VMs with multiple NVMe disks?

A: NVMe Disk Placement utilizes the minimum number of disks required for the OS disk. For example, Standard_D16ads_v6 has two disks of 440 GiB each. If you create and Ephemeral OS disk of size less than 440 GiB, then only one disk is used for creating the ephemeral OS disk. The second NVMe disk is returned to you as a raw local disk.

Q: Are Ephemeral OS disks supported on low-priority VMs and Spot VMs?

A: Yes. There's no option of Stop-Deallocate for Ephemeral VMs, rather users need to Delete instead of deallocating them.

Q: Can I attach a Managed Disks to an Ephemeral VM?

A: Yes, you can attach a managed data disk to a VM that uses an ephemeral OS disk.

Q: Will all VM sizes be supported for ephemeral OS disks?

A: No, most Premium Storage VM sizes are supported (DS, ES, FS, GS, M, etc.). To know whether a particular VM size supports ephemeral OS disks for an OS image size, you can use the following script. It takes the OS image size and location as inputs and provides a list of VMs and corresponding placement supported. If cache, temp, and NVMe disk placement are marked as not supported then Ephemeral OS disk can't be used for the given OS image size.

Azure PowerShell

```
[CmdletBinding()]
param([Parameter(Mandatory=$true)]
      [ValidateNotNullOrEmpty()]
      [string]$Location,
      [Parameter(Mandatory=$true)]
      [long]$OSImageSizeInGB
      )

Function HasSupportEphemeralOSDisk([object[]] $capability)
{
    return $capability | where { $_.Name -eq "EphemeralOSDiskSupported" -and
$_.Value -eq "True"}
}

Function Get-MaxTempDiskAndCacheSize([object[]] $capabilities)
{
    $MaxResourceVolumeGB = 0;
    $CachedDiskGB = 0;
    $NvmeDiskGB = 0;

    foreach($capability in $capabilities)
    {
        if ($capability.Name -eq "MaxResourceVolumeMB")
        { $MaxResourceVolumeGB = [int]($capability.Value / 1024) }

        if ($capability.Name -eq "CachedDiskBytes")
        { $CachedDiskGB = [int]($capability.Value / (1024 * 1024 * 1024)) }

         if ($capability.Name -eq "NvmeDiskSizeInMiB")
        { $NvmeDiskGB = [int]($capability.Value / (1024)) }
```

```
        if ($capability.Name -eq "SupportedEphemeralOSDiskPlacements")
        { $NvmeSupported = [bool]($capability.Value -contains "NvmeDisk") }

    }

    if (!$NvmeSupported)
    { $NvmeDiskGB = 0; }
    return ($MaxResourceVolumeGB, $CachedDiskGB, $NvmeDiskGB)
}

Function Get-EphemeralSupportedVMSku
{
    [CmdletBinding()]
    Param
    (
        [Parameter(Mandatory=$true)]
        [long]$OSImageSizeInGB,
        [Parameter(Mandatory=$true)]
        [string]$Location
    )

    $VmSkus = Get-AzComputeResourceSku $Location | Where-Object {

MaxTempDiskAndCacheSize $sku.Capabilities

        $Response += New-Object PSObject -Property @{
            ResourceSKU = $sku.Size
            NvmeDiskPlacement = @{ $true = "NOT SUPPORTED"; $false =
"SUPPORTED"}[$NvmeDiskGB -lt $OSImageSizeInGB]
            TempDiskPlacement = @{ $true = "NOT SUPPORTED"; $false =
"SUPPORTED"}[$MaxResourceVolumeGB -lt $OSImageSizeInGB]
            CacheDiskPlacement = @{ $true = "NOT SUPPORTED"; $false =
"SUPPORTED"}[$CachedDiskGB -lt $OSImageSizeInGB]
         };
    }

    return $Response
}

Get-EphemeralSupportedVMSku -OSImageSizeInGB $OSImageSizeInGB -Location
$Location | Format-Table
```

Q: Can the ephemeral OS disk be applied to existing VMs and scale sets?

A: No, ephemeral OS disk can only be used during VM and scale set creation.

Q: Can you mix ephemeral and normal OS disks in a scale set?

A: No, you can't have a mix of ephemeral and persistent OS disk instances within the same scale set.

Q: Can the ephemeral OS disk be created using PowerShell or CLI?

A: Yes, you can create VMs with Ephemeral OS Disk using REST, Templates, PowerShell, and CLI.

Restrict managed disks from being imported or exported

Summarize this article for me

This article provides an overview of your options for preventing your Azure Managed Disks from being imported or exported.

Custom role

To limit the number of people who can import or export managed disks or snapshots using Azure RBAC, create a custom RBAC role that doesn't have the following permissions:

- Microsoft.Compute/disks/beginGetAccess/action
- Microsoft.Compute/disks/endGetAccess/action
- Microsoft.Compute/snapshots/beginGetAccess/action
- Microsoft.Compute/snapshots/endGetAccess/action

Any custom role without those permissions can't upload or download managed disks.

Microsoft Entra authentication

If you're using Microsoft Entra ID to control resource access, you can also use it to restrict uploading of Azure Managed Disks. When a user attempts to upload a disk, Azure validates the identity of the requesting user in Microsoft Entra ID, and confirms that user has the required permissions. To learn more, see Secure downloads and uploads of Azure Managed Disks.

Private links

You can use private endpoints to restrict the upload and download of managed disks and more securely access data over a private link from clients on your Azure virtual network. The private endpoint uses an IP address from the virtual network address space for your managed disks. Network traffic between clients on their virtual network and managed disks only traverses over the virtual network and a private link on the Microsoft backbone network, eliminating exposure from the public internet. Use a disk access resource to facilitate private link connections to your disks. For details, see either the portal or CLI articles.

Azure policy

Configure an Azure Policy to disable public network access to your managed disks.

Configure the Network access policy

Each managed disk and snapshot has its own NetworkAccessPolicy parameter that can prevent the resource from being exported. You can use the Azure CLI or Azure PowerShell module to set the parameter to **DenyAll**, which prevents the resource from being exported.

Last updated on 02/19/2026

Secure downloads and uploads of Azure managed disks

If you use Microsoft Entra ID to control resource access, you can also use it to restrict uploads and downloads of Azure managed disks. When a user tries to upload or download a disk, Azure validates the identity of the requesting user in Microsoft Entra ID, and confirms that user has the required permissions. If a user doesn't have the required permissions, they can't upload or download managed disks.

At a higher level, a system administrator can set a policy at the Azure account or subscription level, to ensure that all disks and snapshots must use Microsoft Entra ID for uploads or downloads. If you have any questions on securing uploads or downloads by using Microsoft Entra ID, reach out to: azuredisks@microsoft .com.

Restrictions

- VHDs can't be uploaded to empty snapshots.
- Azure Backup doesn't currently support disks secured with Microsoft Entra ID.
- Azure Site Recovery doesn't currently support disks secured with Microsoft Entra ID.

Prerequisites

Install the latest Azure PowerShell module or the latest Azure CLI.

Assign RBAC role

To access managed disks secured by using Microsoft Entra ID, users must have either the Data Operator for Managed Disks role or a custom role with the following permissions:

- **Microsoft.Compute/disks/download/action**
- **Microsoft.Compute/disks/upload/action**
- **Microsoft.Compute/snapshots/download/action**
- **Microsoft.Compute/snapshots/upload/action**

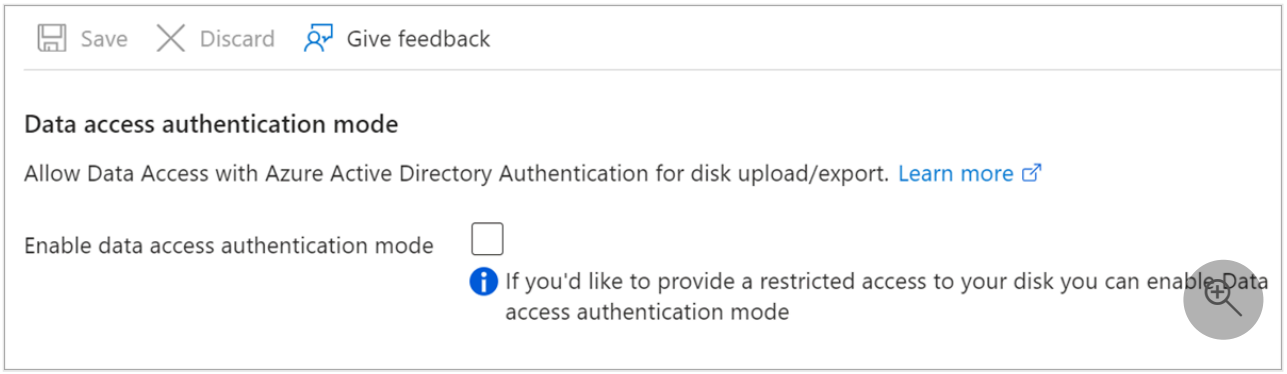
For detailed steps on assigning a role, see the following articles for portal, PowerShell, or CLI. To create or update a custom role, see the following articles for portal, PowerShell, or CLI.

Restrict access to an individual disk

To restrict access to an individual disk, enable **data access authentication mode** on that disk.

Portal

You can enable this setting when creating the disk, or you can enable it on the **Disk Export** page under **Settings** for existing disks.



Assign Azure policy

You can also assign an Azure policy with a remediation task. A policy with a remediation task continuously audits your resources and notifies you when any of them don't comply. The built-in policy definition you'd assign is **Protect your data with authentication requirements when exporting or uploading to a disk or snapshot**. To learn how to assign an Azure policy see the Azure portal, Azure CLI, or Azure PowerShell module articles.

Azure CLI - Restrict import/export access for managed disks with Private Links

Applies to: ✔ Linux VMs ✔ Flexible scale sets

You can use private endpoints to restrict the export and import of managed disks and securely access data over a Private Link from clients on your Azure virtual network. The private endpoint uses an IP address from the virtual network address space for your managed disks service. Network traffic between clients on their virtual network and managed disks only traverses over the virtual network and a private link on the Microsoft backbone network, eliminating exposure from the public internet.

To use Private Links to export/import managed disks, first you create a disk access resource and link it to a virtual network in the same subscription by creating a private endpoint. Then, associate a disk or a snapshot with an instance of disk access. Finally, set the NetworkAccessPolicy property of the disk or the snapshot to `AllowPrivate`. This will limit access to your virtual network.

You can set the NetworkAccessPolicy property to `DenyAll` to prevent anybody from exporting data of a disk or a snapshot. The default value for the NetworkAccessPolicy property is `AllowAll`.

Limitations

- You can't import or export more than 100 disks or snapshots at the same time with the same disk access resource
- You can't upload to a disk with both a disk access resource and a disk encryption set
- In addition to the scale targets that apply to individual disks, disk access resources have more scale targets that are centered around ingress/egress of data. These limits apply cumulatively to all disks associated with a disk access resource. For details see here

Log in into your subscription and set your variables

Azure CLI

```
subscriptionId=yourSubscriptionId
resourceGroupName=yourResourceGroupName
region=northcentralus
diskAccessName=yourDiskAccessForPrivateLinks
vnetName=yourVNETForPrivateLinks
subnetName=yourSubnetForPrivateLinks
privateEndPointName=yourPrivateLinkForSecureMDExportImport
```

```
privateEndPointConnectionName=yourPrivateLinkConnection

#The name of an existing disk which is the source of the snapshot
sourceDiskName=yourSourceDiskForSnapshot

#The name of the new snapshot which will be secured via Private Links
snapshotNameSecuredWithPL=yourSnapshotNameSecuredWithPL

az login

az account set --subscription $subscriptionId
```

Create a disk access using Azure CLI

Azure CLI

```
az disk-access create -n $diskAccessName -g $resourceGroupName -l $region

diskAccessId=$(az disk-access show -n $diskAccessName -g $resourceGroupName --query
[id] -o tsv)
```

Create a Virtual Network

Network policies like network security groups (NSG) are not supported for private endpoints. In order to deploy a Private Endpoint on a given subnet, an explicit disable setting is required on that subnet.

Azure CLI

```
az network vnet create --resource-group $resourceGroupName \
    --name $vnetName \
    --subnet-name $subnetName
```

Disable subnet private endpoint policies

Azure deploys resources to a subnet within a virtual network, so you need to update the subnet to disable private endpoint network policies.

Azure CLI

```
az network vnet subnet update --resource-group $resourceGroupName \
    --name $subnetName  \
    --vnet-name $vnetName \
    --disable-private-endpoint-network-policies true
```

Create a private endpoint for the disk access object

Azure CLI

```
az network private-endpoint create --resource-group $resourceGroupName \
    --name $privateEndPointName \
    --vnet-name $vnetName  \
    --subnet $subnetName \
    --private-connection-resource-id $diskAccessId \
    --group-ids disks \
    --connection-name $privateEndPointConnectionName
```

Configure the Private DNS Zone

Create a Private DNS Zone for Storage blob domain, create an association link with the Virtual Network and create a DNS Zone Group to associate the private endpoint with the Private DNS Zone.

Azure CLI

```
az network private-dns zone create --resource-group $resourceGroupName \
    --name "privatelink.blob.core.windows.net"

az network private-dns link vnet create --resource-group $resourceGroupName \
    --zone-name "privatelink.blob.core.windows.net" \
    --name yourDNSLink \
    --virtual-network $vnetName \
    --registration-enabled false

az network private-endpoint dns-zone-group create \
   --resource-group $resourceGroupName \
   --endpoint-name $privateEndPointName \
   --name yourZoneGroup \
   --private-dns-zone "privatelink.blob.core.windows.net" \
   --zone-name disks
```

Create a disk protected with Private Links

Azure CLI

```
resourceGroupName=yourResourceGroupName
region=northcentralus
diskAccessName=yourDiskAccessName
diskName=yourDiskName
diskSkuName=Standard_LRS
diskSizeGB=128
```

```
diskAccessId=$(az resource show -n $diskAccessName -g $resourceGroupName --namespace
Microsoft.Compute --resource-type diskAccesses --query [id] -o tsv)

az disk create -n $diskName \
-g $resourceGroupName \
-l $region \
--size-gb $diskSizeGB \
--sku $diskSkuName \
--network-access-policy AllowPrivate \
--disk-access $diskAccessId
```

Create a snapshot of a disk protected with Private Links

Azure CLI

```
resourceGroupName=yourResourceGroupName
region=northcentralus
diskAccessName=yourDiskAccessName
sourceDiskName=yourSourceDiskForSnapshot
snapshotNameSecuredWithPL=yourSnapshotName

diskId=$(az disk show -n $sourceDiskName -g $resourceGroupName --query [id] -o tsv)

diskAccessId=$(az resource show -n $diskAccessName -g $resourceGroupName --namespace
Microsoft.Compute --resource-type diskAccesses --query [id] -o tsv)

az snapshot create -n $snapshotNameSecuredWithPL \
-g $resourceGroupName \
-l $region \
--source $diskId \
--network-access-policy AllowPrivate \
--disk-access $diskAccessId
```

Next steps

- Upload a VHD to Azure or copy a managed disk to another region - Azure CLI or Azure PowerShell module
- Download a VHD - Windows or Linux
- FAQ on Private Links
- Export/Copy managed snapshots as VHD to a storage account in different region with CLI

Last updated on 11/05/2025

Upload a VHD to Azure or copy a managed disk to another region - Azure PowerShell

Summarize this article for me

Applies to: ✔ Windows VMs

This article explains how to either upload a VHD from your local machine to an Azure Managed Disk or copy a managed disk to another region, using the Azure PowerShell module. The process of uploading a managed disk, also known as direct upload, enables you to upload a VHD up to 32 TiB in size directly into a managed disk. Currently, direct upload is supported for Ultra Disks, Premium SSD v2, Premium SSD, Standard SSD, and Standard HDD.

If you're providing a backup solution for IaaS VMs in Azure, you should use direct upload to restore customer backups to managed disks. When uploading a VHD from a source external to Azure, speeds depend on your local bandwidth. When uploading or copying from an Azure VM, your bandwidth would be the same as Standard HDDs.

If you're using Microsoft Entra ID to control resource access, you can use it to restrict uploading of Azure Managed Disks. See Secure downloads and uploads of Azure Managed Disks for details.

Get started

There are two ways you can upload a VHD with the Azure PowerShell module: You can either use the Add-AzVHD command, which will automate most of the process for you, or you can perform the upload manually with AzCopy.

For Premium SSDs, Standard SSDs, and Standard HDDs, you should generally use Add-AzVHD. However, if you're uploading to an Ultra Disk, or a Premium SSD v2, or if you need to upload a VHD that is larger than 50 GiB, you must upload the VHD or VHDX manually with AzCopy. VHDs 50 GiB and larger upload faster using AzCopy and Add-AzVhd doesn't currently support uploading to an Ultra Disk or a Premium SSD v2.

For guidance on how to copy a managed disk from one region to another, see Copy a managed disk.

Use Add-AzVHD

Prerequisites

- Install the Azure PowerShell module.
- A VHD has been prepared for Azure, stored locally.
  - On Windows: You don't need to convert your VHD to VHDx, convert it a fixed size, or resize it to include the 512-byte offset. `Add-AZVHD` performs these functions for you.
    - Hyper-V must be enabled for Add-AzVHD to perform these functions.
  - On Linux: You must perform these actions manually. See Resizing VHDs for details.

Upload a VHD

(Optional) Grant access to the disk

If Microsoft Entra ID is used to enforce upload restrictions on a subscription or at the account level, Add-AzVHD only succeeds if attempted by a user that has the appropriate RBAC role or necessary permissions. You'll need to assign RBAC permissions to grant access to the disk and generate a writeable SAS.

Azure PowerShell

```
New-AzRoleAssignment -SignInName <emailOrUserprincipalname> `
-RoleDefinitionName "Data Operator for Managed Disks" `
-Scope /subscriptions/<subscriptionId>
```

Use Add-AzVHD

The following example uploads a VHD from your local machine to a new Azure Managed Disk using Add-AzVHD. Replace `<your-filepath-here>`, `<your-resource-group-name>`, `<desired-region>`, and `<desired-managed-disk-name>` with your parameters:

> **Note**
>
> If you're using Microsoft Entra ID to secure disk uploads, add `-DataAccessAuthMode 'AzureActiveDirectory'` to the end of your `Add-AzVhd` command.

Azure PowerShell

```
# Required parameters
$path = <your-filepath-here>.vhd
$resourceGroup = <your-resource-group-name>
$location = <desired-region>
$name = <desired-managed-disk-name>

# Optional parameters
```

```
# $Zone = <desired-zone>
# $sku=<desired-SKU>
# -DataAccessAuthMode 'AzureActiveDirectory'
# -DiskHyperVGeneration = V1 or V2. This applies only to OS disks.

# To use $Zone or #sku, add -Zone or -DiskSKU parameters to the command
Add-AzVhd -LocalFilePath $path -ResourceGroupName $resourceGroup -Location
$location -DiskName $name
```

Manual upload

Prerequisites

- Download the latest version of AzCopy v10.
- Install the Azure PowerShell module.
- A fixed size VHD that has been prepared for Azure, stored locally.

To upload your VHD to Azure, you'll need to create an empty managed disk that is configured for this upload process. Before you create one, there's some additional information you should know about these disks.

This kind of managed disk has two unique states:

- ReadyToUpload, which means the disk is ready to receive an upload but, no secure access signature (SAS) has been generated.
- ActiveUpload, which means that the disk is ready to receive an upload and the SAS has been generated.

> **Note**
>
> While in either of these states, the managed disk will be billed at Standard HDD pricing, regardless of the actual type of disk. For example, a P10 will be billed as an S10. This will be true until `revoke-access` is called on the managed disk, which is required in order to attach the disk to a VM.

Create an empty managed disk

Before you can create an empty Standard HDD for uploading, you'll need the file size of the VHD you want to upload, in bytes. The example code will get that for you but, to do it yourself you can use: `$vhdSizeBytes = (Get-Item "<fullFilePathHere>").length`. This value is used when specifying the **-UploadSizeInBytes** parameter.

Now, on your local shell, create an empty Standard HDD for uploading by specifying the **Upload** setting in the **-CreateOption** parameter as well as the **-UploadSizeInBytes** parameter in the New-AzDiskConfig cmdlet. Then call New-AzDisk to create the disk.

Replace `<yourdiskname>`, `<yourresourcegroupname>`, and `<yourregion>` then run the following commands:

> **Important**
>
> If you're creating an OS disk, add `-HyperVGeneration '<yourGeneration>'` to `New-AzDiskConfig`.
>
> If you're using Microsoft Entra ID to secure disk uploads, add `-dataAccessAuthMode 'AzureActiveDirectory'` to `New-AzDiskConfig`.
>
> When uploading to an Ultra Disk or Premium SSD v2 you need to select the correct sector size of the target disk. If you're using a VHD file with a 512 logical sector size, the target disk must be set to 512. If you're using a VHDX file with a 4k logical sector size, the target disk must be set to 4k, and target disk size must match VHDX file size. Note that uploading a VHDX file will result in a size expansion to the next 256 MiB alignment.
>
> VHDX files with logical sector size of 512 aren't supported.

PowerShell

```
$vhdSizeBytes = (Get-Item "<fullFilePathHere>").length

## For Ultra Disks or Premium SSD v2, add -LogicalSectorSize and specify either
4096 or 512, depending on if you're using a VHDX or a VHD

$diskconfig = New-AzDiskConfig -SkuName 'Standard_LRS' -OsType 'Windows' -
UploadSizeInBytes $vhdSizeBytes -Location '<yourregion>' -CreateOption 'Upload'

New-AzDisk -ResourceGroupName '<yourresourcegroupname>' -DiskName '<yourdiskname>'
-Disk $diskconfig
```

If you would like to upload a different disk type, replace **Standard_LRS** with **Premium_LRS**, **Premium_ZRS**, **StandardSSD_ZRS**, **StandardSSD_LRS**, or **UltraSSD_LRS**.

Generate writeable SAS

Now that you've created an empty managed disk that is configured for the upload process, you can upload a VHD to it. To upload a VHD to the disk, you'll need a writeable SAS, so that you can reference it as the destination for your upload.

> **Important**
>
> On February 15th, 2025, the Shared Access Signature (SAS) access time for disks and snapshots will be limited to a maximum of 60 days. Trying to generate a SAS with an expiration longer than 60 days results in an error. Any existing disk or snapshot SAS created with an expiration longer than 60 days may stop working 60 days after the date of creation and will result in a 403 error during authorization.

If a managed disk or snapshot SAS's expiration is longer than 60 days, revoke its access, and generate a new SAS that requests access for 60 days (5,184,000 seconds) or less. Improve your overall security by using SAS with shorter expiration dates. Make these changes before February 15, 2025 to prevent service interruption. The following links can be used to find, revoke, and request a new SAS.

- To check if a disk has an active SAS, you can either use the REST API, the Azure CLI, or the Azure PowerShell module, and examine the **DiskState** property.
- To revoke a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module.
- To create a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module, and set the access duration to 5,184,000 seconds or less.

To generate a writable SAS of your empty managed disk, replace `<yourdiskname>` and `<yourresourcegroupname>`, then use the following commands:

PowerShell

```
$diskSas = Grant-AzDiskAccess -ResourceGroupName '<yourresourcegroupname>' -
DiskName '<yourdiskname>' -DurationInSecond 86400 -Access 'Write'

$disk = Get-AzDisk -ResourceGroupName '<yourresourcegroupname>' -DiskName
'<yourdiskname>'
```

Upload a VHD or VHDX

Now that you have a SAS for your empty managed disk, you can use it to set your managed disk as the destination for your upload command.

Use AzCopy v10 to upload your local VHD or VHDX file to a managed disk by specifying the SAS URI you generated.

> **Note**

If you need to upload VHDx files larger than 2TB (which exceeds the VHD format limit) and can't convert them to VHD due to their size, please be aware that VHDx files are only supported for upload to PremiumSSDv2 and UltraSSD disk SKUs. For files smaller than 2TB, it's recommended to convert them to the VHD format before uploading.

This upload has the same throughput as the equivalent Standard HDD. For example, if you have a size that equates to S4, you'll have a throughput of up to 60 MiB/s. But, if you have a size that equates to S70, you'll have a throughput of up to 500 MiB/s.

```
AzCopy.exe copy "c:\somewhere\mydisk.vhd" $diskSas.AccessSAS --blob-type PageBlob
```

After the upload is complete, and you no longer need to write any more data to the disk, revoke the SAS. Revoking the SAS will change the state of the managed disk and allow you to attach the disk to a VM.

Replace `<yourdiskname>` and `<yourresourcegroupname>`, then run the following command:

PowerShell

```
Revoke-AzDiskAccess -ResourceGroupName '<yourresourcegroupname>' -DiskName
'<yourdiskname>'
```

Copy a managed disk

Direct upload also simplifies the process of copying a managed disk. You can either copy within the same region or copy your managed disk to another region.

The following script will do this for you, the process is similar to the steps described earlier, with some differences, since you're working with an existing disk.

> **ⓘ Important**
>
> You must add an offset of 512 when you're providing the disk size in bytes of a managed disk from Azure. This is because Azure omits the footer when returning the disk size. The copy will fail if you don't do this. The following script already does this for you.

Replace the `<sourceResourceGroupHere>`, `<sourceDiskNameHere>`, `<targetDiskNameHere>`, `<targetResourceGroupHere>`, `<yourOSTypeHere>` and `<yourTargetLocationHere>` (an example of a

location value would be uswest2) with your values, then run the following script in order to copy a managed disk.

> **Tip**
>
> If you're creating an OS disk, add `-HyperVGeneration '<yourGeneration>'` to `New-AzDiskConfig`.

PowerShell

```
$sourceRG = <sourceResourceGroupHere>
$sourceDiskName = <sourceDiskNameHere>
$targetDiskName = <targetDiskNameHere>
$targetRG = <targetResourceGroupHere>
$targetLocate = <yourTargetLocationHere>
$targetVmGeneration = "V1" # either V1 or V2
#Expected value for OS is either "Windows" or "Linux"
$targetOS = <yourOSTypeHere>

$sourceDisk = Get-AzDisk -ResourceGroupName $sourceRG -DiskName $sourceDiskName

# Adding the sizeInBytes with the 512 offset, and the -Upload flag
$targetDiskconfig = New-AzDiskConfig -SkuName 'Standard_LRS' -osType $targetOS -
UploadSizeInBytes $($sourceDisk.DiskSizeBytes+512) -Location $targetLocate -
CreateOption 'Upload' -HyperVGeneration $targetVmGeneration

$targetDisk = New-AzDisk -ResourceGroupName $targetRG -DiskName $targetDiskName -
Disk $targetDiskconfig

$sourceDiskSas = Grant-AzDiskAccess -ResourceGroupName $sourceRG -DiskName
$sourceDiskName -DurationInSecond 86400 -Access 'Read'

$targetDiskSas = Grant-AzDiskAccess -ResourceGroupName $targetRG -DiskName
$targetDiskName -DurationInSecond 86400 -Access 'Write'

azcopy copy $sourceDiskSas.AccessSAS $targetDiskSas.AccessSAS --blob-type PageBlob

Revoke-AzDiskAccess -ResourceGroupName $sourceRG -DiskName $sourceDiskName

Revoke-AzDiskAccess -ResourceGroupName $targetRG -DiskName $targetDiskName
```

Next steps

Now that you've successfully uploaded a VHD to a managed disk, you can attach your disk to a VM and begin using it.

To learn how to attach a data disk to a VM, see our article on the subject: Attach a data disk to a Windows VM with PowerShell. To use the disk as the OS disk, see Create a Windows VM from a specialized disk.

If you have additional questions, see the section on uploading a managed disk in the FAQ.

Last updated on 02/19/2026

Upload a VHD to Azure or copy a managed disk to another region - Azure CLI

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This article explains how to either upload a VHD from your local machine to an Azure Managed Disk or copy a managed disk to another region, using AzCopy. This process, direct upload, enables you to upload a VHD up to 32 TiB in size directly into a managed disk. Currently, direct upload is supported for Ultra Disks, Premium SSD v2, Premium SSD, Standard SSD, and Standard HDD.

If you're providing a backup solution for IaaS VMs in Azure, you should use direct upload to restore customer backups to managed disks. When uploading a VHD from a source external to Azure, speeds depend on your local bandwidth. When uploading or copying from an Azure VM, your bandwidth would be the same as Standard HDDs.

If you're using Microsoft Entra ID to control resource access, you can use it to restrict uploading of Azure Managed Disks. See Secure downloads and uploads of Azure Managed Disks for details.

Get started

If you'd prefer to upload disks through a GUI, you can do so using Azure Storage Explorer. For details refer to: Use Azure Storage Explorer to manage Azure Managed Disks

Prerequisites

- Download the latest version of AzCopy v10.
- Install the Azure CLI.
- If you intend to upload a VHD from on-premises: A fixed size VHD that has been prepared for Azure, stored locally.
- Or, a managed disk in Azure, if you intend to perform a copy action.

To upload your VHD to Azure, you need to create an empty managed disk that is configured for this upload process. Before you create one, there's some additional information you should know about these disks.

This kind of managed disk has two unique states:

- ReadToUpload, which means the disk is ready to receive an upload but, no secure access signature (SAS) has been generated.
- ActiveUpload, which means that the disk is ready to receive an upload and the SAS has been generated.

> **Note**
>
> While in either of these states, the managed disk will be billed at Standard HDD pricing, regardless of the actual type of disk. For example, a P10 will be billed as an S10. This will be true until `revoke-access` is called on the managed disk, which is required in order to attach the disk to a VM.

Create an empty managed disk

Before you can create an empty Standard HDD for uploading, you need the file size of the VHD you want to upload, in bytes. To get that, you can use either `wc -c <yourFileName>.vhd` or `ls -al <yourFileName>.vhd`. This value is used when specifying the **--upload-size-bytes** parameter.

Create an empty Standard HDD for uploading by specifying both the **--for-upload** parameter and the **--upload-size-bytes** parameter in a disk create cmdlet:

Replace `<yourdiskname>`, `<yourresourcegroupname>`, `<yourregion>` with values of your choosing. The `--upload-size-bytes` parameter contains an example value of `34359738880`, replace it with a value appropriate for you.

> **Important**
>
> If you're creating an OS disk, add `--hyper-v-generation <yourGeneration>` to `az disk create`.
>
> If you're using Microsoft Entra ID to secure disk uploads, add `-dataAccessAuthmode 'AzureActiveDirectory'`.
>
> When uploading to an Ultra Disk or Premium SSD v2 you need to select the correct sector size of the target disk. If you're using a VHDX file with a 4k logical sector size, the target disk must be set to 4k. If you're using a VHD file with a 512 logical sector size, the target disk must be set to 512.
>
> VHDX files with logical sector size of 512k aren't supported.

Azure CLI

```
##For Ultra Disk or Premium SSD v2, add --logical-sector-size and specify either
512 or 4096, depending on if you're using a VHD or VHDX

az disk create -n <yourdiskname> -g <yourresourcegroupname> -l <yourregion> --os-
type Linux --for-upload --upload-size-bytes 34359738880 --sku standard_lrs
```

If you would like to upload a different disk type, replace **standard_lrs** with **premium_lrs**, **premium_zrs**, **standardssd_lrs**, **standardssd_zrs**, **premiumv2_lrs**, or **ultrassd_lrs**.

(Optional) Grant access to the disk

If you're using Microsoft Entra ID to secure disk uploads, you need to assign RBAC permissions to grant access to the disk and generate a writeable SAS.

Azure CLI

```
az role assignment create --assignee "{assignee}" \
--role "{Data Operator for Managed Disks}" \
--scope
"/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/{prov
iderName}/{resourceType}/{resourceSubType}/{diskName}"
```

Generate writeable SAS

Now that you've created an empty managed disk that is configured for the upload process, you can upload a VHD to it. To upload a VHD to the disk, you need a writeable SAS, so that you can reference it as the destination for your upload.

> **ⓘ Important**
>
> On February 15th, 2025, the Shared Access Signature (SAS) access time for disks and snapshots will be limited to a maximum of 60 days. Trying to generate a SAS with an expiration longer than 60 days results in an error. Any existing disk or snapshot SAS created with an expiration longer than 60 days may stop working 60 days after the date of creation and will result in a 403 error during authorization.

If a managed disk or snapshot SAS's expiration is longer than 60 days, revoke its access, and generate a new SAS that requests access for 60 days (5,184,000 seconds) or less. Improve your overall security by using SAS with shorter expiration dates. Make these changes before February 15, 2025 to prevent service interruption. The following links can be used to find, revoke, and request a new SAS.

- To check if a disk has an active SAS, you can either use the REST API, the Azure CLI, or the Azure PowerShell module, and examine the **DiskState** property.
- To revoke a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module.
- To create a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module, and set the access duration to 5,184,000 seconds or less.

To generate a writable SAS of your empty managed disk, replace `<yourdiskname>` and `<yourresourcegroupname>`, then use the following command:

Azure CLI

```
az disk grant-access -n <yourdiskname> -g <yourresourcegroupname> --access-level
Write --duration-in-seconds 86400
```

Sample returned value:

Output

```
{
  "accessSas": "https://md-impexp-
t0rdsfgsdfg4.blob.core.windows.net/w2c3mj0ksfgl/abcd?sv=2017-04-
17&sr=b&si=600a9281-d39e-4cc3-91d2-
923c4a696537&sig=xXaT6mFgf139ycT87CADyFxb%2BnPXBElYirYRlbnJZbs%3D"
}
```

Upload a VHD or VHDX

Now that you have a SAS for your empty managed disk, you can use it to set your managed disk as the destination for your upload command.

Use AzCopy v10 to upload your local VHD or VHDX file to a managed disk by specifying the SAS URI you generated.

This upload has the same throughput as the equivalent Standard HDD. For example, if you have a size that equates to S4, you'll have a throughput of up to 60 MiB/s. But, if you have a size that equates to S70, you'll have a throughput of up to 500 MiB/s.

Bash

```
AzCopy.exe copy "c:\somewhere\mydisk.vhd" "sas-URI" --blob-type PageBlob
```

After the upload is complete, and you no longer need to write any more data to the disk, revoke the SAS. Revoking the SAS changes the state of the managed disk and allow you to

attach the disk to a VM.

Replace `<yourdiskname>` and `<yourresourcegroupname>`, then use the following command to make the disk usable:

Azure CLI

```
az disk revoke-access -n <yourdiskname> -g <yourresourcegroupname>
```

Copy a managed disk

Direct upload also simplifies the process of copying a managed disk. You can either copy within the same region or cross-region (to another region).

The following script does this for you. The process is similar to the steps described earlier, with some differences since you're working with an existing disk.

> **ⓘ Important**
>
> You need to add an offset of 512 when you're providing the disk size in bytes of a managed disk from Azure. This is because Azure omits the footer when returning the disk size. The copy will fail if you don't do this. The following script already does this for you.

Replace the `<sourceResourceGroupHere>`, `<sourceDiskNameHere>`, `<targetDiskNameHere>`, `<targetResourceGroupHere>`, and `<yourTargetLocationHere>` (an example of a location value would be uswest2) with your values, then run the following script in order to copy a managed disk.

> **Tip**
>
> If you are creating an OS disk, add `--hyper-v-generation <yourGeneration>` to `az disk create`.

Azure CLI

```
sourceDiskName=<sourceDiskNameHere>
sourceRG=<sourceResourceGroupHere>
targetDiskName=<targetDiskNameHere>
targetRG=<targetResourceGroupHere>
targetLocation=<yourTargetLocationHere>
#Expected value for OS is either "Windows" or "Linux"
targetOS=<yourOSTypeHere>
```

```
sourceDiskSizeBytes=$(az disk show -g $sourceRG -n $sourceDiskName --query
'[diskSizeBytes]' -o tsv)

az disk create -g $targetRG -n $targetDiskName -l $targetLocation --os-type
$targetOS --for-upload --upload-size-bytes $(($sourceDiskSizeBytes+512)) --sku
standard_lrs

targetSASURI=$(az disk grant-access -n $targetDiskName -g $targetRG  --access-level
Write --duration-in-seconds 86400 --query [accessSas] -o tsv)

sourceSASURI=$(az disk grant-access -n $sourceDiskName -g $sourceRG --duration-in-
seconds 86400 --query [accessSas] -o tsv)

azcopy copy $sourceSASURI $targetSASURI --blob-type PageBlob

az disk revoke-access -n $sourceDiskName -g $sourceRG

az disk revoke-access -n $targetDiskName -g $targetRG
```

Next steps

Now that you've successfully uploaded a VHD to a managed disk, you can attach the disk as a data disk to an existing VM or attach the disk to a VM as an OS disk, to create a new VM.

If you've more questions, see the uploading a managed disk section in the FAQ.

Export/Copy a snapshot to a storage account in different region with CLI

Article • 08/22/2024

This script exports a managed snapshot to a storage account in different region. It first generates the SAS URI of the snapshot and then uses it to copy it to a storage account in different region. Use this script to maintain backup of your managed disks in different region for disaster recovery.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Run the script

Azure CLI

```
#Provide the subscription Id where snapshot is created
subscriptionId="<subscriptionId>"

#Provide the name of your resource group where snapshot is created
resourceGroupName=myResourceGroupName

#Provide the snapshot name
snapshotName=mySnapshotName

#Provide Shared Access Signature (SAS) expiry duration in seconds e.g. 3600.
#Know more about SAS here: https://docs.microsoft.com/azure/storage/storage-dotnet-shared-access-signature-part-1
sasExpiryDuration=3600

#Provide storage account name where you want to copy the snapshot.
storageAccountName=mystorageaccountname

#Name of the storage container where the downloaded snapshot will be stored
storageContainerName=mystoragecontainername
```

```
#Provide the key of the storage account where you want to copy snapshot.
storageAccountKey=mystorageaccountkey

#Provide the name of the VHD file to which snapshot will be copied.
destinationVHDFileName=myvhdfilename

az account set --subscription $subscriptionId

sas=$(az snapshot grant-access --resource-group $resourceGroupName --name
$snapshotName --duration-in-seconds $sasExpiryDuration --query [accessSas] -
o tsv)

az storage blob copy start --destination-blob $destinationVHDFileName --
destination-container $storageContainerName --account-name
$storageAccountName --account-key $storageAccountKey --source-uri $sas
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name myResourceGroupName
```

Sample reference

This script uses following commands to generate SAS URI for a managed snapshot and copies the snapshot to a storage account using SAS URI. Each command in the table links to command specific documentation.

Expand table

Command	Notes
az snapshot grant-access	Generates read-only SAS that is used to copy underlying VHD file to a storage account or download it to on-premises
az storage blob copy start	Copies a blob asynchronously from one storage account to another

Next steps

Create a managed disk from a VHD

Create a virtual machine from a managed disk

For more information on the Azure CLI, see Azure CLI documentation.

Additional virtual machine and managed disks CLI script samples can be found in the Azure Linux VM documentation.

Export/Copy a managed disk to a storage account using the Azure CLI

Article • 08/22/2024

This script exports the underlying VHD of a managed disk to a storage account in same or different region. It first generates the SAS URI of the managed disk and then uses it to copy the VHD to a storage account. Use this script to copy managed disks to another region for regional expansion. If you want to publish the VHD file of a managed disk in Azure Marketplace, you can use this script to copy the VHD file to a storage account and then generate a SAS URI of the copied VHD to publish it in the Marketplace.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Run the script

Azure CLI

```
#Provide the subscription Id where managed disk is created
subscriptionId="<subscriptionId>"

#Provide the name of your resource group where managed disk is created
resourceGroupName=myResourceGroupName

#Provide the managed disk name
diskName=myDiskName

#Provide Shared Access Signature (SAS) expiry duration in seconds e.g. 3600.
#Know more about SAS here: https://docs.microsoft.com/azure/storage/storage-dotnet-shared-access-signature-part-1
sasExpiryDuration=3600

#Provide storage account name where you want to copy the underlying VHD file of the managed disk.
```

```
storageAccountName=mystorageaccountname

#Name of the storage container where the downloaded VHD will be stored
storageContainerName=mystoragecontainername

#Provide the key of the storage account where you want to copy the VHD
storageAccountKey=mystorageaccountkey

#Provide the name of the destination VHD file to which the VHD of the
managed disk will be copied.
destinationVHDFileName=myvhdfilename.vhd

az account set --subscription $subscriptionId

sas=$(az disk grant-access --resource-group $resourceGroupName --name
$diskName --duration-in-seconds $sasExpiryDuration --query [accessSas] -o
tsv)

Export/Copy managed snapshots as VHD to a storage account in different region with PowerShell

Article • 01/23/2025

This script exports a managed snapshot to a storage account in different region. It first generates the SAS URI of the snapshot and then uses it to copy it to a storage account in different region. Use this script to maintain backup of your managed disks in different region for disaster recovery.

If needed, install the Azure PowerShell module using the instructions found in the Azure PowerShell guide, and then run `Connect-AzAccount` to create a connection with Azure. Also, you need to have an SSH public key named `id_rsa.pub` in the .ssh directory of your user profile.

If you don't have an Azure subscription, create an Azure free account before you begin.

Sample script

PowerShell

```
#Provide the subscription Id of the subscription where snapshot is created
$subscriptionId = "yourSubscriptionId"

#Provide the name of your resource group where snapshot is created
$resourceGroupName ="yourResourceGroupName"

#Provide the snapshot name
$snapshotName = "yourSnapshotName"

#Provide Shared Access Signature (SAS) expiry duration in seconds e.g. 3600.
#Know more about SAS here: https://docs.microsoft.com/en-us/Az.Storage/storage-dotnet-shared-access-signature-part-1
$sasExpiryDuration = "3600"

#Provide storage account name where you want to copy the snapshot.
$storageAccountName = "yourstorageaccountName"

#Name of the storage container where the downloaded snapshot will be stored
$storageContainerName = "yourstoragecontainername"

#Provide the key of the storage account where you want to copy snapshot.
$storageAccountKey = 'yourStorageAccountKey'
```

```
#Provide the name of the VHD file to which snapshot will be copied.
$destinationVHDFileName = "yourvhdfilename"

# Set the context to the subscription Id where Snapshot is created
Select-AzSubscription -SubscriptionId $SubscriptionId

#Generate the SAS for the snapshot
$sas = Grant-AzSnapshotAccess -ResourceGroupName $ResourceGroupName -
SnapshotName $SnapshotName  -DurationInSecond $sasExpiryDuration -Access
Read
#Create the context for the storage account which will be used to copy
snapshot to the storage account
$destinationContext = New-AzStorageContext -StorageAccountName
$storageAccountName -StorageAccountKey $storageAccountKey

#Copy the snapshot to the storage account
Start-AzStorageBlobCopy -AbsoluteUri $sas.AccessSAS -DestContainer
$storageContainerName -DestContext $destinationContext -DestBlob
$destinationVHDFileName
```

Script explanation

This script uses following commands to generate SAS URI for a managed snapshot and copies the snapshot to a storage account using SAS URI. Each command in the table links to command specific documentation.

Expand table

Command	Notes
Grant-AzSnapshotAccess	Generates SAS URI for a snapshot that is used to copy it to a storage account.
New-AzStorageContext	Creates a storage account context using the account name and key. This context can be used to perform read/write operations on the storage account.
Start-AzStorageBlobCopy	Copies the underlying VHD of a snapshot to a storage account

Next steps

Create a managed disk from a VHD

Create a virtual machine from a managed disk

For more information on the Azure PowerShell module, see Azure PowerShell documentation.

Additional virtual machine PowerShell script samples can be found in the Azure Linux VM documentation.

Export/Copy the VHD of a managed disk to a storage account in different region with PowerShell (Windows)

Article • 08/23/2024

This script exports the VHD of a managed disk to a storage account in different region. It first generates the SAS URI of the managed disk and then uses it to copy the underlying VHD to a storage account in different region. Use this script to copy managed disks to another region for regional expansion.

If needed, install the Azure PowerShell module using the instructions found in the Azure PowerShell guide, and then run `Connect-AzAccount` to create a connection with Azure. Also, you need to have an SSH public key named `id_rsa.pub` in the .ssh directory of your user profile.

If you don't have an Azure subscription, create an Azure free account before you begin.

Sample script

PowerShell

```
#Provide the subscription Id of the subscription where managed disk is
created
$subscriptionId = "yourSubscriptionId"

#Provide the name of your resource group where managed is created
$resourceGroupName ="yourResourceGroupName"

#Provide the managed disk name
$diskName = "yourDiskName"

#Provide Shared Access Signature (SAS) expiry duration in seconds e.g. 3600.
#Know more about SAS here: https://docs.microsoft.com/en-
us/Az.Storage/storage-dotnet-shared-access-signature-part-1
$sasExpiryDuration = "3600"

#Provide storage account name where you want to copy the underlying VHD of
the managed disk.
$storageAccountName = "yourstorageaccountName"

#Name of the storage container where the downloaded VHD will be stored
$storageContainerName = "yourstoragecontainername"
```

```
#Provide the key of the storage account where you want to copy the VHD of
the managed disk.
$storageAccountKey = 'yourStorageAccountKey'

#Provide the name of the destination VHD file to which the VHD of the
managed disk will be copied.
$destinationVHDFileName = "yourvhdfilename"

#Set the value to 1 to use AzCopy tool to download the data. This is the
recommended option for faster copy.
#Download AzCopy v10 from the link here: https://docs.microsoft.com/en-
us/azure/storage/common/storage-use-azcopy-v10
#Ensure that AzCopy is downloaded in the same folder as this file
#If you set the value to 0 then Start-AzStorageBlobCopy will be used. Azure
storage will asynchronously copy the data.
$useAzCopy = 1

# Set the context to the subscription Id where managed disk is created
Select-AzSubscription -SubscriptionId $SubscriptionId

#Generate the SAS for the managed disk
$sas = Grant-AzDiskAccess -ResourceGroupName $ResourceGroupName -DiskName
$diskName -DurationInSecond $sasExpiryDuration -Access Read

#Create the context of the storage account where the underlying VHD of the
managed disk will be copied
$destinationContext = New-AzStorageContext -StorageAccountName
$storageAccountName -StorageAccountKey $storageAccountKey

#Copy the VHD of the managed disk to the storage account
if($useAzCopy -eq 1)
{
    $containerSASURI = New-AzStorageContainerSASToken -Context
$destinationContext -ExpiryTime(get-date).AddSeconds($sasExpiryDuration) -
FullUri -Name $storageContainerName -Permission rw
    azcopy copy $sas.AccessSAS $containerSASURI

}else{

    Start-AzStorageBlobCopy -AbsoluteUri $sas.AccessSAS -DestContainer
$storageContainerName -DestContext $destinationContext -DestBlob
$destinationVHDFileName
}
```

Script explanation

This script uses the following commands to generate SAS URI of a managed disk and copies the underlying VHD to a storage account using the SAS URI. Each command in the table links to the command specific documentation.

Expand table

Command	Notes
Grant-AzDiskAccess	Generates SAS URI for a managed disk that is used to copy the underlying VHD to a storage account.
New-AzureStorageContext	Creates a storage account context using the account name and key. This context can be used to perform read/write operations on the storage account.
Start-AzureStorageBlobCopy	Copies the underlying VHD of a snapshot to a storage account

Next steps

Create a managed disk from a VHD

Create a virtual machine from a managed disk

For more information on the Azure PowerShell module, see Azure PowerShell documentation.

Additional virtual machine PowerShell script samples can be found in the Azure Windows VM documentation.

Download a Linux VHD from Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article describes how to download a Linux virtual hard disk (VHD) file from Azure. To download a VHD, the disk can't be attached to a running VM, which means the VM experiences downtime. Some configurations can safely avoid downtime by snapshotting the disk and downloading the VHD from the snapshot.

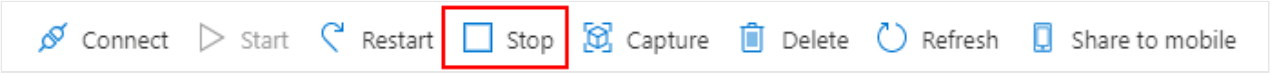
If you're using Microsoft Entra ID to control resource access, you can use it to restrict uploading of Azure Managed Disks. For more information, see Secure downloads and uploads of Azure Managed Disks.

Stop the VM

You can't download a VHD from Azure if the VHD is attached to a running VM. If you want to keep the VM running, you can create a snapshot and then download the snapshot.

To stop the VM:

1. Sign in to the Azure portal.
2. On the left menu, select **Virtual Machines**.
3. Select the VM from the list.
4. On the page for the VM, select **Stop**.



Once the VM is stopped,

Alternative: Snapshot the VM disk

> **Note**
>
> If feasible, stop a VM before taking a snapshot of it. Otherwise, the snapshot isn't clean. Snapshots of running VMs are in the same state as if their VMs were power cycled or crashed when you take a snapshot. Usually, this state is safe but it could cause problems if the running applications at the time aren't crash resistant.

Generally, you should only use snapshots of running VMs if the only disk associated with them is a single OS disk. If a VM has one or more data disks, stop the VM before creating a snapshot of the OS or data disks.

Take a snapshot of the disk to download.

1. Select the VM in the portal.
2. Select **Disks** in the left menu and then select the disk you want to snapshot. The details of the disk are displayed.
3. Select **Create Snapshot** from the menu at the top of the page. The **Create snapshot** page opens.
4. In **Name**, type a name for the snapshot.
5. For **Snapshot type**, select **Full** or **Incremental**.
6. When you're done, select **Review + create**.

After you create your snapshot, you can use it to download a VHD or create another VM.

Generate SAS URL

To download the VHD file, you need to generate a shared access signature (SAS) URL. When the URL is generated, an expiration time is assigned to the URL.

Important

On February 15th, 2025, the Shared Access Signature (SAS) access time for disks and snapshots will be limited to a maximum of 60 days. Trying to generate a SAS with an expiration longer than 60 days results in an error. Any existing disk or snapshot SAS created with an expiration longer than 60 days may stop working 60 days after the date of creation and will result in a 403 error during authorization.

If a managed disk or snapshot SAS's expiration is longer than 60 days, revoke its access, and generate a new SAS that requests access for 60 days (5,184,000 seconds) or less. Improve your overall security by using SAS with shorter expiration dates. Make these changes before February 15, 2025 to prevent service interruption. The following links can be used to find, revoke, and request a new SAS.

- To check if a disk has an active SAS, you can either use the REST API, the Azure CLI, or the Azure PowerShell module, and examine the **DiskState** property.
- To revoke a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module.

- To create a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module, and set the access duration to 5,184,000 seconds or less.

Portal

1. On the menu of the page for the VM, select **Disks**.
2. Select the operating system disk for the VM, and then select **Disk Export**.
3. If necessary, update the value of **URL expires in (seconds)** to give you enough time to complete the download. The default is 3,600 seconds (one hour).
4. Select **Generate URL**.

Download VHD

> **Note**
>
> If you're using Microsoft Entra ID to secure managed disk downloads, the user downloading the VHD needs the appropriate RBAC permissions.

Portal

1. Under the generated URL, select **Download the VHD file**.

2. You might need to select **Save** in the browser to start the download. The default name for the VHD file is *abcd*.

Download a Windows VHD from Azure

Summarize this article for me

Applies to: ✔ Windows VMs

This article explains how to download a Windows virtual hard disk (VHD) file from Azure. To download a VHD, the disk can't be attached to a running VM, which means the VM experiences downtime. However, some configurations can safely avoid downtime by snapshotting the disk and downloading the VHD from the snapshot.

If you're using Microsoft Entra ID to control resource access, you can use it to restrict uploading of Azure Managed Disks. For more information, see Secure downloads and uploads of Azure Managed Disks.

Optional: Generalize the VM

If you want to use the VHD as an image to create other VMs, use Sysprep to generalize the operating system. Otherwise, you need to make a copy of the disk for each VM you want to create.

To use the VHD as an image to create other VMs, generalize the VM.

1. Sign in to the Azure portal.
2. Connect to the VM.
3. On the VM, open the Command Prompt window as an administrator.
4. Change the directory to *%windir%\system32\sysprep* and run sysprep.exe.
5. In the System Preparation Tool dialog box, select **Enter System Out-of-Box Experience (OOBE)**, and make sure that **Generalize** is selected.
6. In Shutdown Options, select **Shutdown**, and then select **OK**.

If you don't want to generalize your current VM, you can still create a generalized image by first making a snapshot of the OS disk, creating a new VM from the snapshot, and then generalizing the copy.

Stop the VM

You can't download a VHD from Azure if it's attached to a running VM. If you want to keep the VM running, you can create a snapshot and then download the snapshot.

1. On the Hub menu in the Azure portal, select **Virtual Machines**.
2. Select the VM from the list.

3. On the blade for the VM, select **Stop**.

Alternative: Snapshot the VM disk

> **Note**
>
> If feasible, stop a VM before taking a snapshot of it, otherwise the snapshot isn't clean. Snapshots of running VMs are in the same state as if their VMs were power cycled or crashed when you take a snapshot. Usually this state is safe but, it could cause problems if the running applications aren't crash resistant.
>
> Generally, you should only use snapshots of running VMs if the only disk associated with them is a single OS disk. If a VM has one or more data disks, stop the VM before creating a snapshot of the OS or data disks.

Take a snapshot of the disk to download.

1. Select the VM in the portal.
2. Select **Disks** in the left menu and then select the disk you want to snapshot. The details of the disk are displayed.
3. Select **Create Snapshot** from the menu at the top of the page. The **Create snapshot** page opens.
4. In **Name**, type a name for the snapshot.
5. For **Snapshot type**, select **Full** or **Incremental**.
6. When you're done, select **Review + create**.

Your snapshot is created shortly, and you can then use it to download or create another VM.

Generate download URL

To download the VHD file, you need to generate a shared access signature (SAS) URL. When you generate the URL, you assign an expiration time to it.

> **Important**
>
> On February 15th, 2025, the Shared Access Signature (SAS) access time for disks and snapshots will be limited to a maximum of 60 days. - To check if a disk has an active SAS, you can either use the REST API, the Azure CLI, or the Azure PowerShell module, and examine the **DiskState** property.
- To revoke a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module.
- To create a SAS, you can use either the REST API, the Azure CLI, or the Azure PowerShell module, and set the access duration to 5,184,000 seconds or less.

Portal

1. On the page for the VM, select **Disks** in the left menu.
2. Select the operating system disk for the VM.
3. On the page for the disk, select **Disk Export** from the left menu.
4. The default expiration time of the URL is *3,600 seconds (one hour). You might need to increase this value for Windows OS disks or large data disks. In these situations, **36000** seconds (10 hours) is usually sufficient.
5. Select **Generate URL**.

> **Note**
>
> When downloading a Windows OS disk, you might need a longer expiration time to download a large VHD file. Large VHDs can take up to several hours to download depending on your connection and the size of the VM.
>
> While the SAS URL is active, attempting to start the VM results in the error **There is an active shared access signature outstanding for disk** *diskname*. You can revoke the SAS URL by selecting **Cancel export** on the **Disk Export** page.

Download VHD

> **Note**

If you're using Microsoft Entra ID to secure managed disk downloads, the user downloading the VHD needs the appropriate RBAC permissions.

Portal

1. Under the generated URL, select **Download the VHD file**.
2. You might need to select **Save** in your browser to start the download. The default name for the VHD file is *abcd*.

Next steps

- Learn how to upload a VHD file to Azure.
- Create managed disks from unmanaged disks in a storage account.
- Manage Azure disks with PowerShell.

Convert the disk type of an Azure Managed Disk

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows

There are five disk types of Azure Managed Disks: Azure Ultra Disks, Premium SSD v2, Premium SSD, Standard SSD, and Standard HDD. You can easily switch between Premium SSD, Standard SSD, and Standard HDD based on your performance needs. Premium SSD and Standard SSD are also available with Zone-redundant storage. For most cases, you can't yet switch from or to an Ultra Disk, you must deploy a new one with a snapshot of an existing disk. However, you can switch from existing disks to a Premium SSD v2. See Convert Premium SSD v2 disks for details.

This functionality isn't supported for unmanaged disks. But you can easily convert an unmanaged disk to a managed disk with CLI or PowerShell to be able to switch between disk types.

Before you begin

Because conversion requires a restart of the virtual machine (VM), schedule the migration of your disk during a pre-existing maintenance window.

Restrictions

- You can only change disk type twice per day.
- You can only change the disk type of managed disks. If your disk is unmanaged, convert it to a managed disk with CLI or PowerShell to switch between disk types.
- You can't migrate a disk to Premium SSD v2 if your original disk was created from an Azure Compute Gallery image.

Change the type of an individual managed disk

For your dev/test workload, you might want a mix of Standard and Premium disks to reduce your costs. You can choose to upgrade only those disks that need better performance. This example shows how to convert a single VM disk from Standard to Premium storage. However, by changing the $storageType variable in this example, you can convert the VM's disks type to Standard SSD or Standard HDD. To use Premium managed disks, your VM must use a VM size that supports Premium storage. You can also use these examples to change a disk from Locally

redundant storage (LRS) disk to a Zone-redundant storage (ZRS) disk or vice-versa. This example also shows how to switch to a size that supports Premium storage:

Azure PowerShell

> **Note**
>
> You can change the type of an existing disk to a Premium SSD v2 the same way you would for other disk types. To learn about the feature see Premium SSD v2 migration.

Azure PowerShell

```
$diskName = 'yourDiskName'
# resource group that contains the managed disk
$rgName = 'yourResourceGroupName'
# Choose between Standard_LRS, StandardSSD_LRS, StandardSSD_ZRS, Premium_ZRS,
and Premium_LRS based on your scenario
$storageType = 'Premium_LRS'
# Premium capable size
$size = 'Standard_DS2_v2'

$disk = Get-AzDisk -DiskName $diskName -ResourceGroupName $rgName

# Get parent VM resource
$vmResource = Get-AzResource -ResourceId $disk.ManagedBy

# Stop and deallocate the VM before changing the storage type
Stop-AzVM -ResourceGroupName $vmResource.ResourceGroupName -Name
$vmResource.Name -Force

$vm = Get-AzVM -ResourceGroupName $vmResource.ResourceGroupName -Name
$vmResource.Name

# Change the VM size to a size that supports Premium storage
# Skip this step if converting storage from Premium to Standard
$vm.HardwareProfile.VmSize = $size
Update-AzVM -VM $vm -ResourceGroupName $rgName

# Update the storage type
$disk.Sku =
[Microsoft.Azure.Management.Compute.Models.DiskSku]::new($storageType)
$disk | Update-AzDisk

Start-AzVM -ResourceGroupName $vm.ResourceGroupName -Name $vm.Name
```

Switch all managed disks of a VM from one account to another

This example shows how to convert all of a VM's disks to premium storage. However, by changing the $storageType variable in this example, you can convert the VM's disks type to Standard SSD or Standard HDD. To use Premium managed disks, your VM must use a VM size that supports Premium storage. This example also switches to a size that supports premium storage:

Azure PowerShell

Azure PowerShell

```
# Name of the resource group that contains the VM
$rgName = 'yourResourceGroup'

# Name of the your virtual machine
$vmName = 'yourVM'

# Choose between Standard_LRS, StandardSSD_LRS, StandardSSD_ZRS, Premium_ZRS,
Premium_LRS, and PremiumV2_LRS based on your scenario
$storageType = 'Premium_LRS'

# Premium capable size
# Required only if converting storage from Standard to Premium
$size = 'Standard_DS2_v2'

# Stop and deallocate the VM before changing the size
Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force

$vm = Get-AzVM -Name $vmName -resourceGroupName $rgName

# Change the VM size to a size that supports Premium storage
# Skip this step if converting storage from Premium to Standard
$vm.HardwareProfile.VmSize = $size
Update-AzVM -VM $vm -ResourceGroupName $rgName

# Get all disks in the resource group of the VM
$vmDisks = Get-AzDisk -ResourceGroupName $rgName

# For disks that belong to the selected VM, convert to Premium storage
foreach ($disk in $vmDisks)
{
    if ($disk.ManagedBy -eq $vm.Id)
    {
        $disk.Sku =
[Microsoft.Azure.Management.Compute.Models.DiskSku]::new($storageType)
        $disk | Update-AzDisk
    }
```

```
}

Start-AzVM -ResourceGroupName $rgName -Name $vmName
```

Convert Premium SSD v2 disks

You can switch existing disks to Premium SSD v2 disks the same way you do for other disk types. Premium SSD v2 disks have some limitations, see the Premium SSD v2 limitations section of their article to learn more.

Switching to Premium SSD v2 disks has some additional limitations:

- You can't switch an OS disk to a Premium SSD v2.
- Existing disks can only be directly switched to 512 sector size Premium SSD v2 disks.
- You can only perform 50 conversions at the same time per subscription per region.
- If your existing disk is a shared disk, detach all VMs before changing to Premium SSD v2.
- If your existing disk is using host caching, set it to none before changing to Premium SSD v2.
- If your existing disk is using bursting, disable it before changing to Premium SSD v2.
- If your existing disk is using double encryption, switch to one of the single encryption options before changing to Premium SSD v2.
- You can't directly switch from a Premium SSD v2 to another disk type. If you want to change a Premium SSD v2 to another disk type, migrate using snapshots.
- You can't directly switch from Ultra Disks to Premium SSD v2 disks, migrate using snapshots.
- If your disk has Azure Site Recovery configured on it, disable it before changing to Premium SSD v2.
- If your disk is attached to a VM with Azure Backup enabled, switch to the Enhanced Backup policy before converting to Premium SSD v2.
- If you're using the rest API, use an API version `2020-12-01` or newer for both the Compute Resource Provider and the Disk Resource Provider.
- Until the conversion process from your previous disk type to Premium SSD v2 is completed, the performance of the disk is degraded, and you can't change or rotate customer-managed keys for the disk if they're in use.
  - You can use the following command to check the conversion process, replace `$diskName` and `$resourceGroupName` with your values: `az disk show -n $diskName -g $resourceGroupName --query [completionPercent] -o tsv`

> **Note**

If you're using Azure Backup and you convert a disk to Premium SSD v2, a full snapshot is taken of the new disk. This is a billable event and you'll be charged for that snapshot.

Disable host caching

If your disk is using host caching, you must disable it before converting to Premium SSD v2. You'll need the LUN of the disk you want to disable host caching on. The following script outputs the name of the disks attached to your VM, and their LUNs. You can use this to identify the LUN of the disk. Replace `yourResourceGroup` and `nameOfYourVM` with your own values, then run the script.

Azure CLI

```
myRG="yourResourceGroup"
myVM="nameOfYourVM"

az vm show -g $myRG -n $myVM --query "[storageProfile.dataDisks[].name,
storageProfile.dataDisks[].lun]"
```

Once you've got the disk's LUN, replace `LunHere` with the LUN and run the following command to disable host caching:

Azure CLI

```
lun=LunHere

az vm update --resource-group $myRG --name $myVM --disk-caching $lun=None
```

Disable bursting

If your disk is using bursting, you must disable it before converting to Premium SSD v2. If you enabled bursting within 12 hours, you have to wait until the 13th hour or later to disable it.

You can use the following command to disable disk bursting: `az disk update --name "yourDiskNameHere" --resource-group "yourRGNameHere" --enable-bursting false`

Disable double encryption

If your disk is using double encryption, you must disable it before converting to Premium SSD v2. You can use the following command to change your disk from double encryption to encryption at rest with customer-managed keys:

Azure CLI

```
az disk-encryption-set update --name "nameOfYourDiskEncryptionSetHere" --resource-group "yourRGNameHere" --key-url yourKeyURL --source-vault "yourKeyVaultName" --encryption-type EncryptionAtRestWithCustomerKey
```

Migrate to Premium SSD v2 or Ultra Disk using snapshots

> **Note**
>
> You can change the type of an existing disk to a Premium SSD v2 the same way you would for other disk types. To learn about the feature see Premium SSD v2 migration.

Premium SSD, Standard SSD, and Standard HDDs support both incremental and full snapshots. However, migration using full snapshots is not supported for these disk types. To create Premium SSD v2 or Ultra Disks from a snapshot, you must use incremental snapshots.

Both Premium SSD v2 disks and Ultra Disks have their own set of restrictions. For example, neither can be used as an OS disk, and also aren't available in all regions. See the Premium SSD v2 limitations and Ultra Disk GA scope and limitations sections of their articles for more information.

> **Important**
>
> When migrating a Standard HDD, Standard SSD, or Premium SSD to either an Ultra Disk or Premium SSD v2, the logical sector size must be 512.

Azure PowerShell

The following script migrates a snapshot of a Standard HDD, Standard SSD, or Premium SSD to either an Ultra Disk or a Premium SSD v2.

PowerShell

```
$diskName = "yourDiskNameHere"
$resourceGroupName = "yourResourceGroupNameHere"
$snapshotName = "yourDesiredSnapshotNameHere"

# Valid values are 1, 2, or 3
$zone = "yourZoneNumber"
```

```
#Provide the size of the disks in GB. It should be greater than the VHD file
size.
$diskSize = '128'

#Provide the storage type. Use PremiumV2_LRS or UltraSSD_LRS.
$storageType = 'PremiumV2_LRS'

#Provide the Azure region (e.g. westus) where Managed Disks will be located.
#This location should be same as the snapshot location
#Get all the Azure location using command below:
#Get-AzLocation

#Select the same location as the current disk
#Note that Premium SSD v2 and Ultra Disks are only supported in a select number
of regions
$location = 'eastus'

#When migrating a Standard HDD, Standard SSD, or Premium SSD to either an Ultra
Disk or Premium SSD v2, the logical sector size must be 512
$logicalSectorSize=512

# Get the disk that you need to backup by creating an incremental snapshot
$yourDisk = Get-AzDisk -DiskName $diskName -ResourceGroupName
$resourceGroupName

# Create an incremental snapshot by setting the SourceUri property with the
value of the Id property of the disk
$snapshotConfig=New-AzSnapshotConfig -SourceUri $yourDisk.Id -Location
$yourDisk.Location -CreateOption Copy -Incremental
$snapshot = New-AzSnapshot -ResourceGroupName $resourceGroupName -SnapshotName
$snapshotName -Snapshot $snapshotConfig

$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $location -
CreateOption Copy -SourceResourceId $snapshot.Id -DiskSizeGB $diskSize -
LogicalSectorSize $logicalSectorSize -Zone $zone

New-AzDisk -Disk $diskConfig -ResourceGroupName $resourceGroupName -DiskName
$diskName
```

Next steps

Make a read-only copy of a VM by using a snapshot.

Convert a disk from LRS to ZRS

07/02/2025

This article explains how to convert an existing disk from locally redundant storage (LRS) to zone-redundant storage (ZRS).

For conceptual information on ZRS, see Zone-redundant storage for managed disks

Limitations

ZRS for managed disks is only supported with Premium SSD and Standard SSD managed disks. ZRS for managed disks isn't supported with Premium SSD v2 managed disks or Ultra Disks. Force detach only supports data disks.

Regional availability

ZRS disks are available in all regions that have availability zone support. For a list of these regions, see Azure regions list.

Determine infrastructure redundancy

Before you convert a disk from LRS to ZRS, you must first identify whether the disk is zonal or regional. How you migrate your disk changes based on whether it's zonal or regional.

Portal

1. Sign in to the Azure portal
2. Navigate to your disk and look under **Availability zone** on the **Overview** tab.
   a. If the value is **No infrastructure redundancy required** you have a regional disk. Use Regional migration to migrate your disk.
   b. If the value is anything else, you have a zonal disk. Use Zonal migration to migrate your disk.

Regional migration

You can directly change the disk type of regional disks with the following options.

Portal

Follow these steps:

1. Sign in to the Azure portal.
2. Select the VM from the list of **Virtual machines**.
3. If the VM isn't stopped, select **Stop** at the top of the VM **Overview** pane, and wait for the VM to stop.
4. In the pane for the VM, select **Disks** from the menu.
5. Select the disk that you want to convert.
6. Select **Size + performance** from the menu.
7. Change the **Account type** from the original disk type to the desired disk type.
8. Select **Save**, and close the disk pane.

The disk type conversion is instantaneous. You can start your VM after the conversion.

Zonal migration

In this section, you migrate the data from your current managed disks to ZRS managed disks.

If you have a zonal disk, you can't directly change its type. You must take a snapshot and use that snapshot to create a new ZRS disk.

Step 1: Create your snapshot

The easiest and cleanest way to create a snapshot is to take one while the VM is offline. See Snapshots. If you choose this approach, some downtime should be expected. To create a snapshot of your VM using the Azure portal, PowerShell, or Azure CLI, see Create a snapshot of a virtual hard disk

If you're taking a snapshot of a disk that's attached to a running VM, read the guidance in Snapshots before continuing.

> **Note**
>
> The source managed disks remain intact with their current configurations and you'll continue to be billed for them. To avoid this, you must manually delete the disks once you've finished your migration and confirmed the new disks are working. For more information, see Find and delete unattached Azure managed and unmanaged disks.

Step 2: Migrate the data on your managed disks

Now that you have snapshots of your original disks, you can use them to create ZRS managed disks.

Migrate your data to ZRS managed disks

1. Create a ZRS managed disk from the source disk snapshot by using the following Azure CLI snippet:

Azure CLI

```
# Create a new ZRS Managed Disks using the snapshot Id and the SKU supported
storageType=Premium_ZRS
location=westus2

az disk create --resource-group $resourceGroupName --name $diskName --sku
$storageType --size-gb $diskSize --source $snapshotId
```

Step 3: Create a new VM with your new disks

Now that you have migrated your data to ZRS managed disks or zonal managed disks, create a new VM with these new disks set as the OS and data disks:

Azure CLI

```
    az vm create -g MyResourceGroup -n MyVm --attach-os-disk newZonalOSDiskCopy --
attach-data-disks newZonalDataDiskCopy --os-type linux
```

Copy managed disks to same or different subscription with CLI

Article • 08/22/2024

This article contains two scripts. The first script copies a managed disk that's using platform-managed keys to same or different subscription but in the same region. The second script copies a managed disk that's using customer-managed keys to the same or a different subscription in the same region. Either copy only works when the subscriptions are part of the same Microsoft Entra tenant.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Disks with platform-managed keys

Azure CLI

```
#Provide the subscription Id of the subscription where managed disk exists
sourceSubscriptionId="<subscriptionId>"

#Provide the name of your resource group where managed disk exists
sourceResourceGroupName=mySourceResourceGroupName

#Provide the name of the managed disk
managedDiskName=myDiskName

#Set the context to the subscription Id where managed disk exists
az account set --subscription $sourceSubscriptionId

#Get the managed disk Id
managedDiskId=$(az disk show --name $managedDiskName --resource-group
$sourceResourceGroupName --query [id] -o tsv)

#If managedDiskId is blank then it means that managed disk does not exist.
echo 'source managed disk Id is: ' $managedDiskId

#Provide the subscription Id of the subscription where managed disk will be
```

```
copied to
targetSubscriptionId=6492b1f7-f219-446b-b509-314e17e1efb0

#Name of the resource group where managed disk will be copied to
targetResourceGroupName=mytargetResourceGroupName

#Set the context to the subscription Id where managed disk will be copied to
az account set --subscription $targetSubscriptionId

#Copy managed disk to different subscription using managed disk Id
az disk create --resource-group $targetResourceGroupName --name
$managedDiskName --source $managedDiskId
```

Disks with customer-managed keys

Azure CLI

```
#Provide the subscription Id of the subscription where managed disk exists
sourceSubscriptionId="<subscriptionId>"

#Provide the name of your resource group where managed disk exists
sourceResourceGroupName=mySourceResourceGroupName

#Provide the name of the managed disk
managedDiskName=myDiskName

#Provide the name of the target disk encryption set
diskEncryptionSetName=myName

#Provide the target disk encryption set resource group
diskEncryptionResourceGroup=myGroup

#Set the context to the subscription Id where managed disk exists
az account set --subscription $sourceSubscriptionId

#Get the managed disk Id
managedDiskId=$(az disk show --name $managedDiskName --resource-group
$sourceResourceGroupName --query [id] -o tsv)

#If managedDiskId is blank then it means that managed disk does not exist.
echo 'source managed disk Id is: ' $managedDiskId

#Get the disk encryption set ID
diskEncryptionSetId=$(az disk-encryption-set show --name
$diskEncryptionSetName --resource-group $diskEncryptionResourceGroup)

#Provide the subscription Id of the subscription where managed disk will be
copied to
targetSubscriptionId=6492b1f7-f219-446b-b509-314e17e1efb0

#Name of the resource group where managed disk will be copied to
targetResourceGroupName=mytargetResourceGroupName
```

```
#Set the context to the subscription Id where managed disk will be copied to
az account set --subscription $targetSubscriptionId

#Copy managed disk to different subscription using managed disk Id and disk
encryption set ID
#Add --location parameter to change the location
az disk create -g $targetResourceGroupName -n $managedDiskName --source
$managedDiskId --disk-encryption-set $diskEncrpytonSetId
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name mySourceResourceGroupName
```

Sample reference

This script uses following commands to create a new managed disk in the target subscription using the `Id` of the source managed disk. Each command in the table links to command specific documentation.

Expand table

Command	Notes
az disk show	Gets all the properties of a managed disk using the name and resource group properties of the managed disk. The `Id` property is used to copy the managed disk to different subscription.
az disk create	Copies a managed disk by creating a new managed disk in different subscription using the `Id` and name the parent managed disk.

Next steps

Create a virtual machine from a managed disk

For more information on the Azure CLI, see Azure CLI documentation.

More virtual machine and managed disks CLI script samples can be found in the Azure Linux VM documentation.

Copy snapshot of a managed disk to same or different subscription with CLI

Article • 08/22/2024

This article contains two scripts. The first script copies a snapshot of a managed disk that was using platform-managed keys to the same or a different subscription. The second script copies a snapshot of a managed disk that was using customer-managed keys to the same or a different subscription. These scripts can be used for the following scenarios:

- Migrate a snapshot in Premium storage (Premium_LRS) to Standard storage (Standard_LRS or Standard_ZRS) to reduce your cost.
- Migrate a snapshot from locally redundant storage (Premium_LRS, Standard_LRS) to zone redundant storage (Standard_ZRS) to benefit from the higher reliability of ZRS storage.
- Move a snapshot to different subscription in the same region for longer retention.

> **Note**
>
> Both subscriptions must be located under the same tenant

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.

- When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
- Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Disks with platform-managed keys

Azure CLI

```
#Provide the subscription Id of the subscription where snapshot exists
sourceSubscriptionId="<subscriptionId>"
```

```
#Provide the name of your resource group where snapshot exists
sourceResourceGroupName=mySourceResourceGroupName

#Provide the name of the snapshot
snapshotName=mySnapshotName

#Set the context to the subscription Id where snapshot exists
az account set --subscription $sourceSubscriptionId

#Get the snapshot Id
snapshotId=$(az snapshot show --name $snapshotName --resource-group
$sourceResourceGroupName --query [id] -o tsv)

#If snapshotId is blank then it means that snapshot does not exist.
echo 'source snapshot Id is: ' $snapshotId

#Provide the subscription Id of the subscription where snapshot will be
copied to
#If snapshot is copied to the same subscription then you can skip this step
targetSubscriptionId=6492b1f7-f219-446b-b509-314e17e1efb0

#Name of the resource group where snapshot will be copied to
targetResourceGroupName=mytargetResourceGroupName

#Set the context to the subscription Id where snapshot will be copied to
#If snapshot is copied to the same subscription then you can skip this step
az account set --subscription $targetSubscriptionId

#Copy snapshot to different subscription using the snapshot Id
#We recommend you to store your snapshots in Standard storage to reduce
cost. Please use Standard_ZRS in regions where zone redundant storage (ZRS)
is available, otherwise use Standard_LRS
#Please check out the availability of ZRS here:
https://docs.microsoft.com/azure/storage/common/storage-redundancy-
zrs#support-coverage-and-regional-availability
az snapshot create --resource-group $targetResourceGroupName --name
$snapshotName --source $snapshotId --sku Standard_LRS
```

Disks with customer-managed keys

Azure CLI

```
#Provide the subscription Id of the subscription where snapshot exists
sourceSubscriptionId="<subscriptionId>"

#Provide the name of your resource group where snapshot exists
sourceResourceGroupName=mySourceResourceGroupName

#Provide the name of the target disk encryption set
diskEncryptionSetName=myName
```

```
#Provide the target disk encryption set resource group
diskEncryptionResourceGroup=myGroup

#Provide the name of the snapshot
snapshotName=mySnapshotName

#Set the context to the subscription Id where snapshot exists
az account set --subscription $sourceSubscriptionId

#Get the snapshot Id
snapshotId=$(az snapshot show --name $snapshotName --resource-group
$sourceResourceGroupName --query [id] -o tsv)

#If snapshotId is blank then it means that snapshot does not exist.
echo 'source snapshot Id is: ' $snapshotId

#Get the disk encryption set ID
diskEncryptionSetId=$(az disk-encryption-set show --name
$diskEncryptionSetName --resource-group $diskEncryptionResourceGroup)

#Provide the subscription Id of the subscription where snapshot will be
copied to
#If snapshot is copied to the same subscription then you can skip this step
targetSubscriptionId=6492b1f7-f219-446b-b509-314e17e1efb0

#Name of the resource group where snapshot will be copied to
targetResourceGroupName=mytargetResourceGroupName

#Set the context to the subscription Id where snapshot will be copied to
#If snapshot is copied to the same subscription then you can skip this step
az account set --subscription $targetSubscriptionId

#Copy snapshot to different subscription using the snapshot Id
#We recommend you to store your snapshots in Standard storage to reduce
cost. Please use Standard_ZRS in regions where zone redundant storage (ZRS)
is available, otherwise use Standard_LRS
#Please check out the availability of ZRS here:
https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-
zrs#support-coverage-and-regional-availability
#To change the region, use the --location parameter
az snapshot create -g $targetResourceGroupName -n $snapshotName --source
$snapshotId --disk-encryption-set $diskEncryptionSetID --sku Standard_LRS --
encryption-type EncryptionAtRestWithCustomerKey
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name mySourceResourceGroupName
```

Sample reference

This script uses following commands to create a snapshot in the target subscription using the `Id` of the source snapshot. Each command in the table links to command specific documentation.

Expand table

Command	Notes
az snapshot show	Gets all the properties of a snapshot using the name and resource group properties of the snapshot. The `Id` property is used to copy the snapshot to different subscription.
az snapshot create	Copies a snapshot by creating a snapshot in different subscription using the `Id` and name of the parent snapshot.

Next steps

Create a virtual machine from a snapshot

For more information on the Azure CLI, see Azure CLI documentation.

Copy snapshot of a managed disk in same subscription or different subscription with PowerShell (Windows)

Article • 08/23/2024

This script copies a snapshot of a managed disk to same or different subscription. Use this script for the following scenarios:

1. Migrate a snapshot in Premium storage (Premium_LRS) to Standard storage (Standard_LRS or Standard_ZRS) to reduce your cost.
2. Migrate a snapshot from locally redundant storage (Premium_LRS, Standard_LRS) to zone redundant storage (Standard_ZRS) to benefit from the higher reliability of ZRS storage.
3. Move a snapshot to different subscription in the same region for longer retention.

If needed, install the Azure PowerShell module using the instructions found in the Azure PowerShell guide, and then run `Connect-AzAccount` to create a connection with Azure. Also, you need to have an SSH public key named `id_rsa.pub` in the .ssh directory of your user profile.

If you don't have an Azure subscription, create an Azure free account before you begin.

Sample script

PowerShell

```
#Provide the subscription Id of the subscription where snapshot exists
$sourceSubscriptionId='yourSourceSubscriptionId'

#Provide the name of your resource group where snapshot exists
$sourceResourceGroupName='yourResourceGroupName'

#Provide the name of the snapshot
$snapshotName='yourSnapshotName'

#Set the context to the subscription Id where snapshot exists
Select-AzSubscription -SubscriptionId $sourceSubscriptionId

#Get the source snapshot
$snapshot= Get-AzSnapshot -ResourceGroupName $sourceResourceGroupName -Name
$snapshotName
```

```
#Provide the subscription Id of the subscription where snapshot will be
copied to
#If snapshot is copied to the same subscription then you can skip this step
$targetSubscriptionId='yourTargetSubscriptionId'

#Name of the resource group where snapshot will be copied to
$targetResourceGroupName='yourTargetResourceGroupName'

#Set the context to the subscription Id where snapshot will be copied to
#If snapshot is copied to the same subscription then you can skip this step
Select-AzSubscription -SubscriptionId $targetSubscriptionId

#We recommend you to store your snapshots in Standard storage to reduce
cost. Please use Standard_ZRS in regions where zone redundant storage (ZRS)
is available, otherwise use Standard_LRS
#Please check out the availability of ZRS here:
https://docs.microsoft.com/en-us/Az.Storage/common/storage-redundancy-
zrs#support-coverage-and-regional-availability
$snapshotConfig = New-AzSnapshotConfig -SourceResourceId $snapshot.Id -
Location $snapshot.Location -CreateOption Copy -SkuName Standard_LRS

#Create a new snapshot in the target subscription and resource group
New-AzSnapshot -Snapshot $snapshotConfig -SnapshotName $snapshotName -
ResourceGroupName $targetResourceGroupName
```

Script explanation

This script uses following commands to create a snapshot in the target subscription using the Id of the source snapshot. Each command in the table links to command specific documentation.

Expand table

Command	Notes
New-AzSnapshotConfig	Creates snapshot configuration that is used for snapshot creation. It includes the resource Id of the parent snapshot and location that is same as the parent snapshot.
New-AzSnapshot	Creates a snapshot using snapshot configuration, snapshot name, and resource group name passed as parameters.

Next steps

Create a virtual machine from a snapshot

For more information on the Azure PowerShell module, see Azure PowerShell documentation.

Additional virtual machine PowerShell script samples can be found in the Azure Windows VM documentation.

Migrate from Amazon Web Services (AWS) and other platforms to managed disks in Azure

Article • 08/22/2024

Applies to: ✔ Windows VMs

You can upload VHD files from AWS or on-premises virtualization solutions to Azure to create virtual machines (VMs) that use managed disks. Azure managed disks removes the need to manage storage accounts for Azure IaaS VMs. You just specify the type of disk, and the size of that disk that you need, and Azure creates and manages the disk for you.

You can upload either generalized and specialized VHDs.

- **Generalized VHD** - has had all of your personal account information removed using Sysprep.
- **Specialized VHD** - maintains the user accounts, applications, and other state data from your original VM.

> **ⓘ Important**
>
> Before uploading any VHD to Azure, you should follow **Prepare a Windows VHD or VHDX to upload to Azure**

Expand table

Scenario	Documentation
You have existing AWS EC2 instances that you would like to migrate to Azure VMs using managed disks	Move a VM from Amazon Web Services (AWS) to Azure
You have a VM from another virtualization platform that you would like to use as an image to create multiple Azure VMs.	Upload a generalized VHD and use it to create a new VM in Azure
You have a uniquely customized VM that you would like to recreate in Azure.	Upload a specialized VHD to Azure and create a new VM

Overview of managed disks

Azure managed disks simplifies VM management by removing the need to manage storage accounts. Managed disks also benefit from better reliability of VMs in an Availability Set. It ensures that the disks of different VMs in an Availability Set are sufficiently isolated from each other to avoid a single point of failure. It automatically places disks of different VMs in an Availability Set in different Storage scale units (stamps) which limits the impact of single Storage scale unit failures caused due to hardware and software failures. Based on your needs, you can choose from four types of storage options. To learn about the available disk types, see our article Select a disk type.

Plan for the migration to managed disks

This section helps you to make the best decision on VM and disk types.

If you are planning on migrating from unmanaged disks to managed disks, you should be aware that users with the Virtual Machine Contributor role will not be able to change the VM size (as they could pre-conversion). This is because VMs with managed disks require the user to have the Microsoft.Compute/disks/write permission on the OS disks.

Location

Pick a location where Azure managed disks are available. If you are migrating to premium SSDs, also ensure that premium storage is available in the region where you are planning to migrate to. See Azure Services by Region for up-to-date information on available locations.

VM sizes

If you are migrating to premium SSDs, you have to update the size of the VM to premium storage capable size available in the region where VM is located. Review the VM sizes that are premium storage capable. The Azure VM size specifications are listed in Sizes for virtual machines. Review the performance characteristics of virtual machines that work with premium storage and choose the most appropriate VM size that best suits your workload. Make sure that there is sufficient bandwidth available on your VM to drive the disk traffic.

Disk sizes

For information on available disk types and sizes, see What disk types are available in Azure?.

Disk caching policy

Premium Managed Disks

By default, disk caching policy is *Read-Only* for all the Premium data disks, and *Read-Write* for the Premium operating system disk attached to the VM. This configuration setting is recommended to achieve the optimal performance for your application's IOs. For write-heavy or write-only data disks (such as SQL Server log files), disable disk caching so that you can achieve better application performance.

Pricing

Review the pricing for managed disks.

Next Steps

- Before uploading any VHD to Azure, you should follow Prepare a Windows VHD or VHDX to upload to Azure

Use Site Recovery to migrate to Premium Storage

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

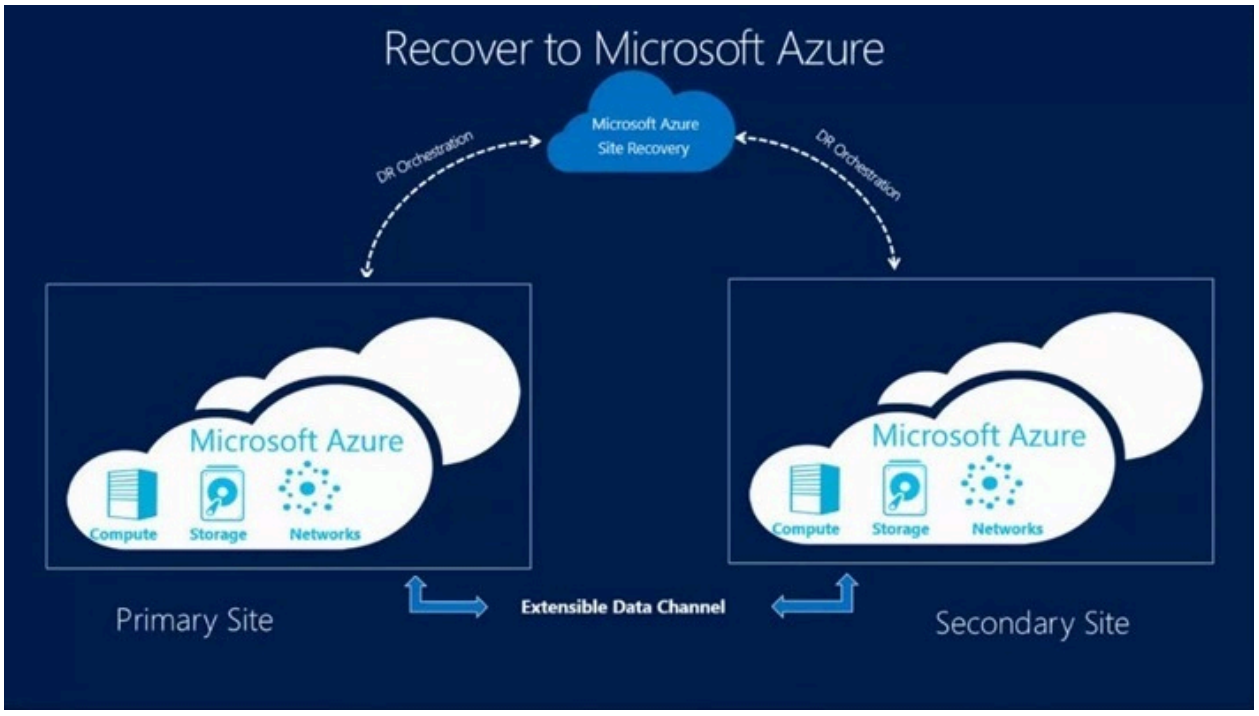
Azure premium SSDs delivers high-performance, low-latency disk support for virtual machines (VMs) that are running I/O-intensive workloads. This guide helps you migrate your VM disks from a standard storage account to a premium storage account by using Azure Site Recovery.

Site Recovery is an Azure service that contributes to your strategy for business continuity and disaster recovery by orchestrating the replication of on-premises physical servers and VMs to the cloud (Azure) or to a secondary datacenter. When outages occur in your primary location, you fail over to the secondary location to keep applications and workloads available. You fail back to your primary location when it returns to normal operation.

Site Recovery provides test failovers to support disaster recovery drills without affecting production environments. You can run failovers with minimal data loss (depending on replication frequency) for unexpected disasters. In the scenario of migrating to Premium Storage, you can use the failover in Site Recovery to migrate target disks to a premium storage account.

We recommend migrating to Premium Storage by using Site Recovery because this option provides minimal downtime. This option also avoids the manual execution of copying disks and creating new VMs. Site Recovery will systematically copy your disks and create new VMs during failover.

Site Recovery supports a number of types of failover with minimal or no downtime. To plan your downtime and estimate data loss, see the types of failover in Site Recovery. If you prepare to connect to Azure VMs after failover, you should be able to connect to the Azure VM by using RDP after failover.



Azure Site Recovery components

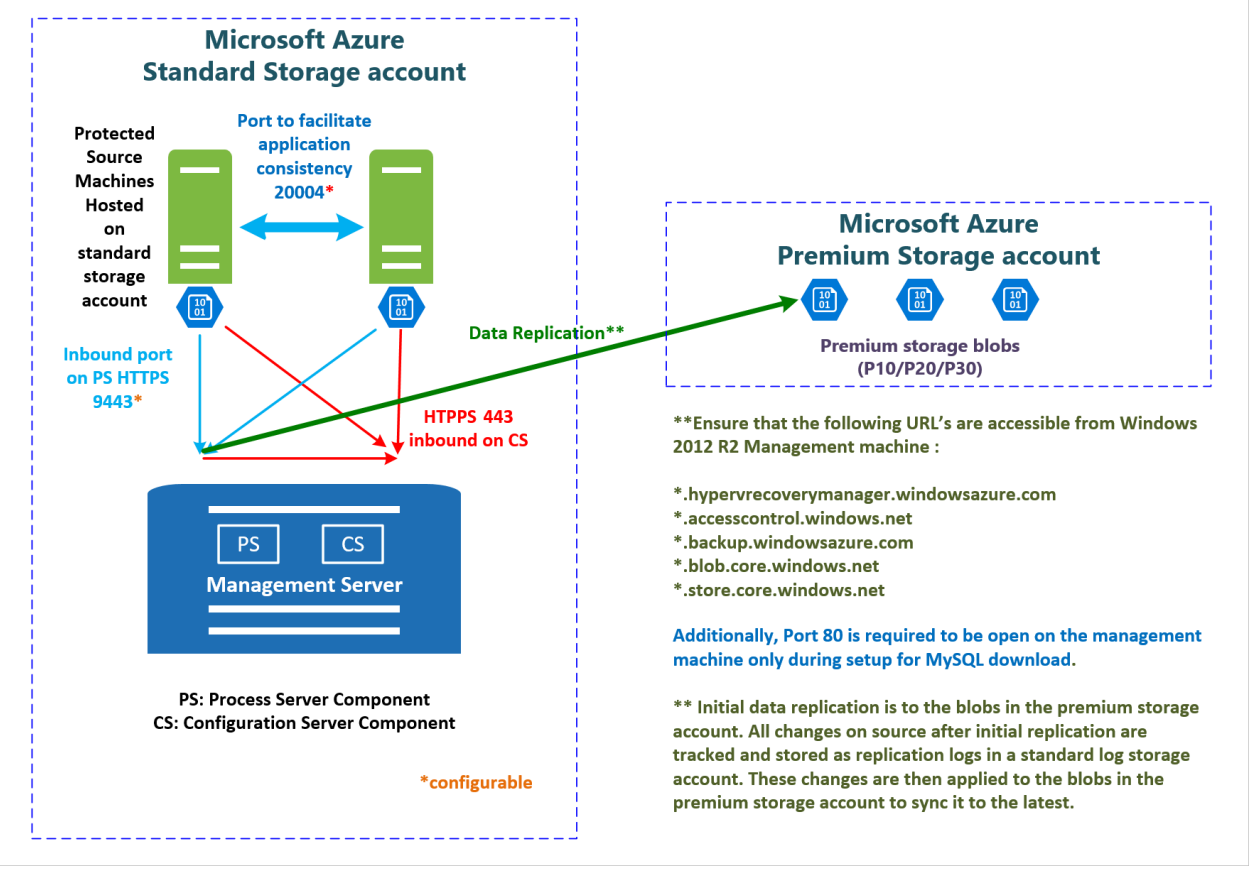
These Site Recovery components are relevant to this migration scenario:

- **Configuration server** is an Azure VM that coordinates communication and manages data replication and recovery processes. On this VM, you run a single setup file to install the configuration server and an additional component, called a process server, as a replication gateway. Read about configuration server prerequisites. You set up the configuration server only once, and you can use it for all migrations to the same region.
- **Process server** is a replication gateway that:

  1. Receives replication data from source VMs.
  2. Optimizes the data with caching, compression, and encryption.
  3. Sends the data to a storage account.

  It also handles push installation of the mobility service to source VMs and performs automatic discovery of source VMs. The default process server is installed on the configuration server. You can deploy additional standalone process servers to scale your deployment. Read about best practices for process server deployment and deploying additional process servers. You set up the process server only once, and you can use it for all migrations to the same region.
- **Mobility service** is a component that is deployed on every standard VM that you want to replicate. It captures data writes on the standard VM and forwards them to the process server. Read about replicated machine prerequisites.

This graphic shows how these components interact:



> **Note**
>
> Site Recovery does not support the migration of Storage Spaces disks.

For additional components for other scenarios, see Scenario architecture.

Azure essentials

These are the Azure requirements for this migration scenario:

- An Azure subscription.
- An Azure premium storage account to store replicated data.
- An Azure virtual network to which VMs will connect when they're created at failover. The Azure virtual network must be in the same region as the one in which Site Recovery runs.
- An Azure standard storage account to store replication logs. This can be the same storage account for the VM disks that are being migrated.

Prerequisites

- Understand the relevant migration scenario components in the preceding section.
- Plan your downtime by learning about failover in Site Recovery.

Setup and migration steps

You can use Site Recovery to migrate Azure IaaS VMs between regions or within same region. The following instructions are tailored for this migration scenario from the article Replicate VMware VMs or physical servers to Azure. Please follow the links for detailed steps in addition to the instructions in this article.

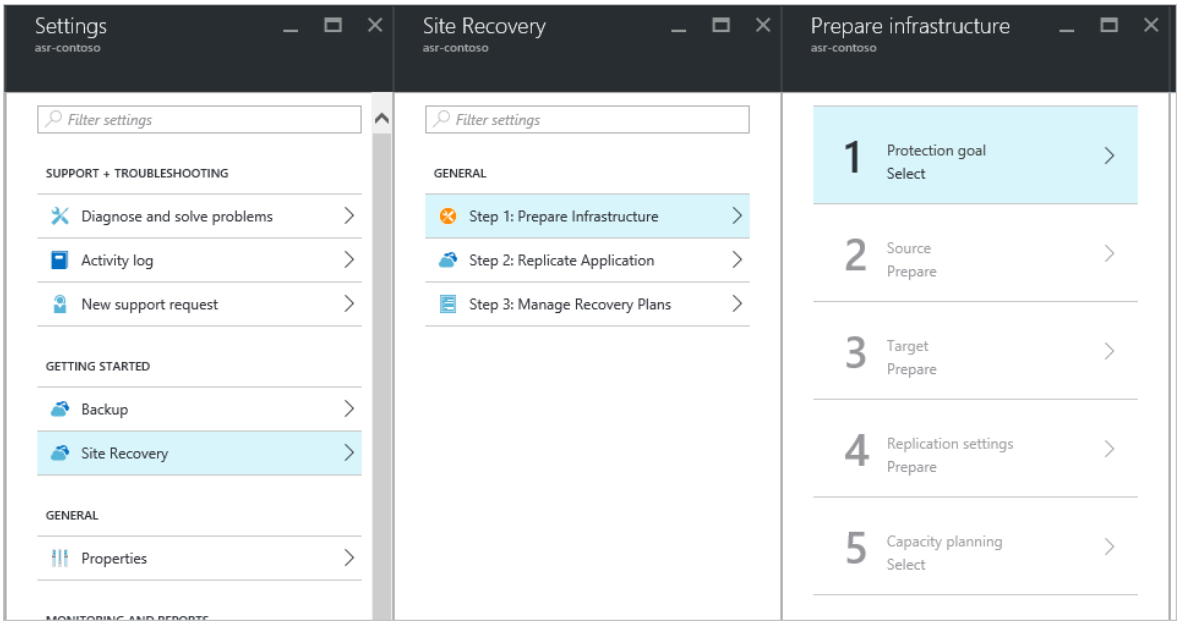
Step 1: Create a Recovery Services vault

1. Open the Azure portal.
2. Select **Create a resource** > **Management** > **Backup** and **Site Recovery (OMS)**. Alternatively, you can select **Browse** > **Recovery Services Vault** > **Add**.
3. Specify a region that VMs will be replicated to. For the purpose of migration in the same region, select the region where your source VMs and source storage accounts are.

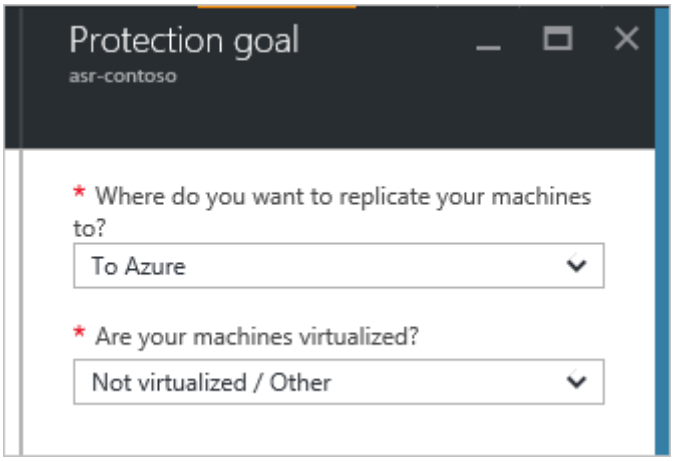
Step 2: Choose your protection goals

1. On the VM where you want to install the configuration server, open the Azure portal.

2. Go to **Recovery Services vaults** > **Settings** > **Site Recovery** > **Step 1: Prepare Infrastructure** > **Protection goal**.



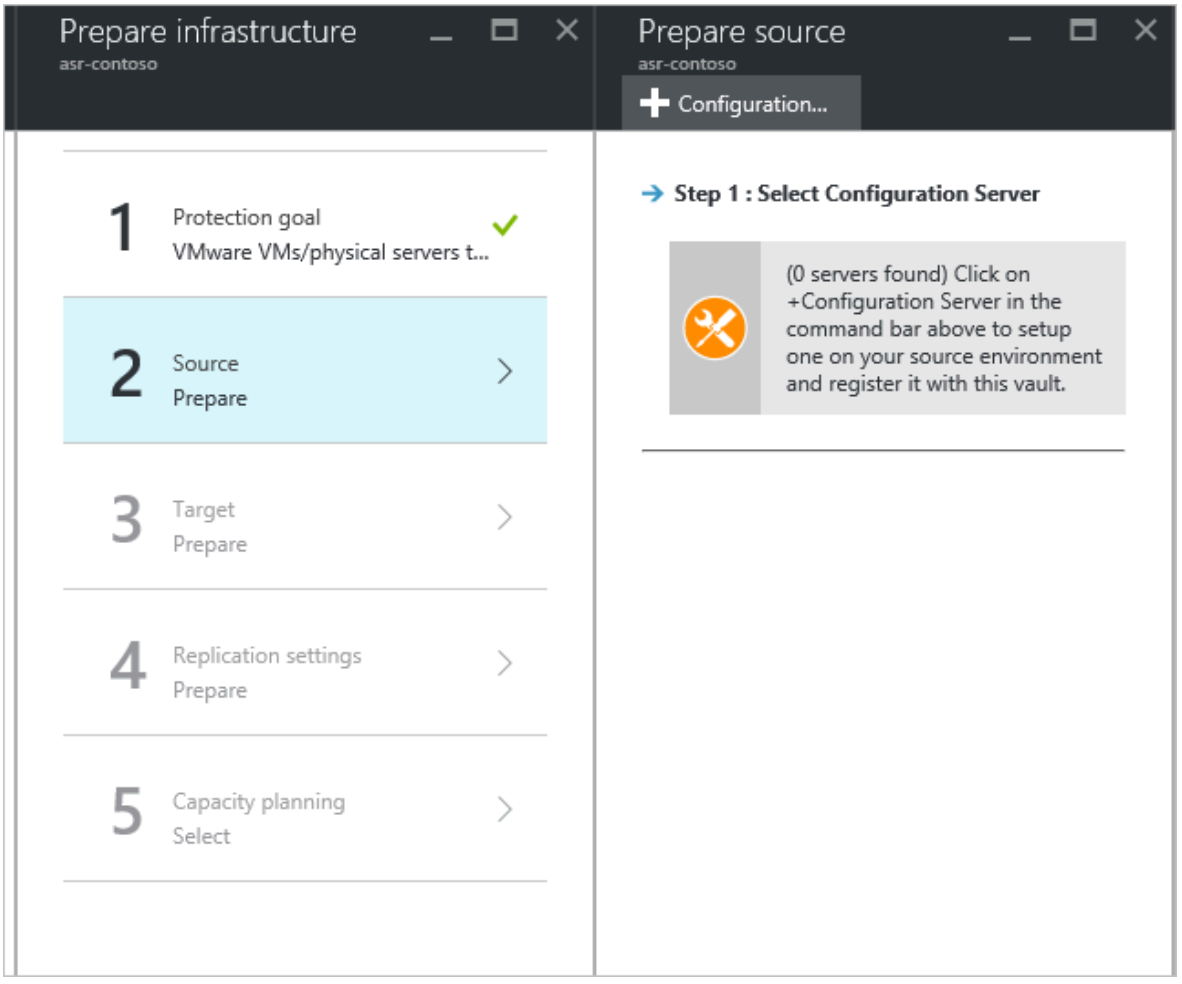
3. Under **Protection goal**, in the first drop-down list, select **To Azure**. In the second drop-down list, select **Not virtualized / Other**, and then select **OK**.



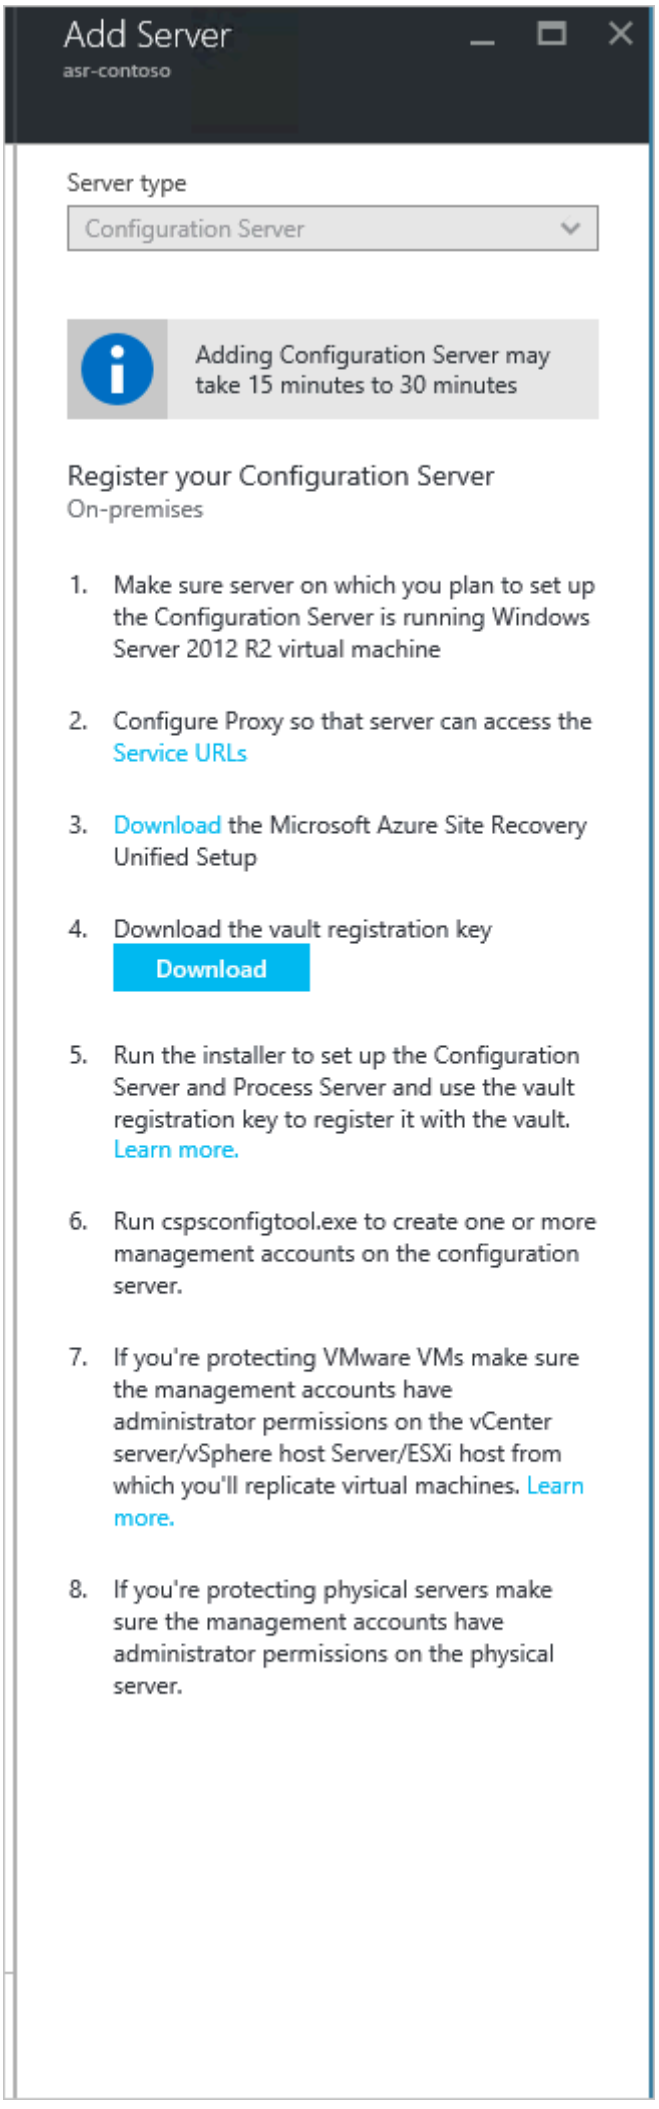
Step 3: Set up the source environment (configuration server)

1. Download **Azure Site Recovery Unified Setup** and the vault registration key by going to the **Prepare infrastructure** > **Prepare source** > **Add Server** panes.

   You will need the vault registration key to run the unified setup. The key is valid for five days after you generate it.



2. In the **Add Server** pane, add a configuration server.



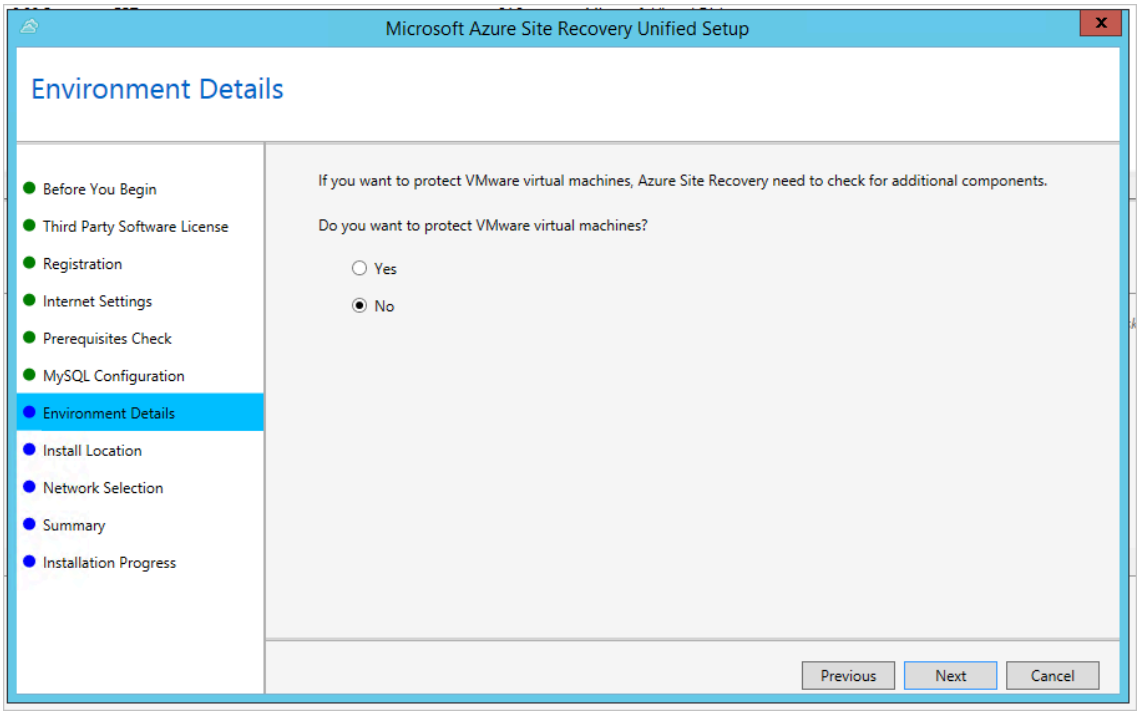
Add Server
asr-contoso
Server type
Configuration Server
Adding Configuration Server may take 15 minutes to 30 minutes
Register your Configuration Server
On-premises
1. Make sure server on which you plan to set up the Configuration Server is running Windows Server 2012 R2 virtual machine
2. Configure Proxy so that server can access the Service URLs
3. Download the Microsoft Azure Site Recovery Unified Setup
4. Download the vault registration key
Download
5. Run the installer to set up the Configuration Server and Process Server and use the vault registration key to register it with the vault. Learn more.
6. Run cspsconfigtool.exe to create one or more management accounts on the configuration server.
7. If you're protecting VMware VMs make sure the management accounts have administrator permissions on the vCenter server/vSphere host Server/ESXi host from which you'll replicate virtual machines. Learn more.
8. If you're protecting physical servers make sure the management accounts have administrator permissions on the physical server.

3. On the VM that you're using as the configuration server, run Unified Setup to install the configuration server and the process server. You can walk through the screenshots to complete the installation. You can refer to the following screenshots for steps specified for this migration scenario.

   a. In **Before You Begin**, select **Install the configuration server and process server**.

   b. In **Registration**, browse and select the registration key that you downloaded from the vault.

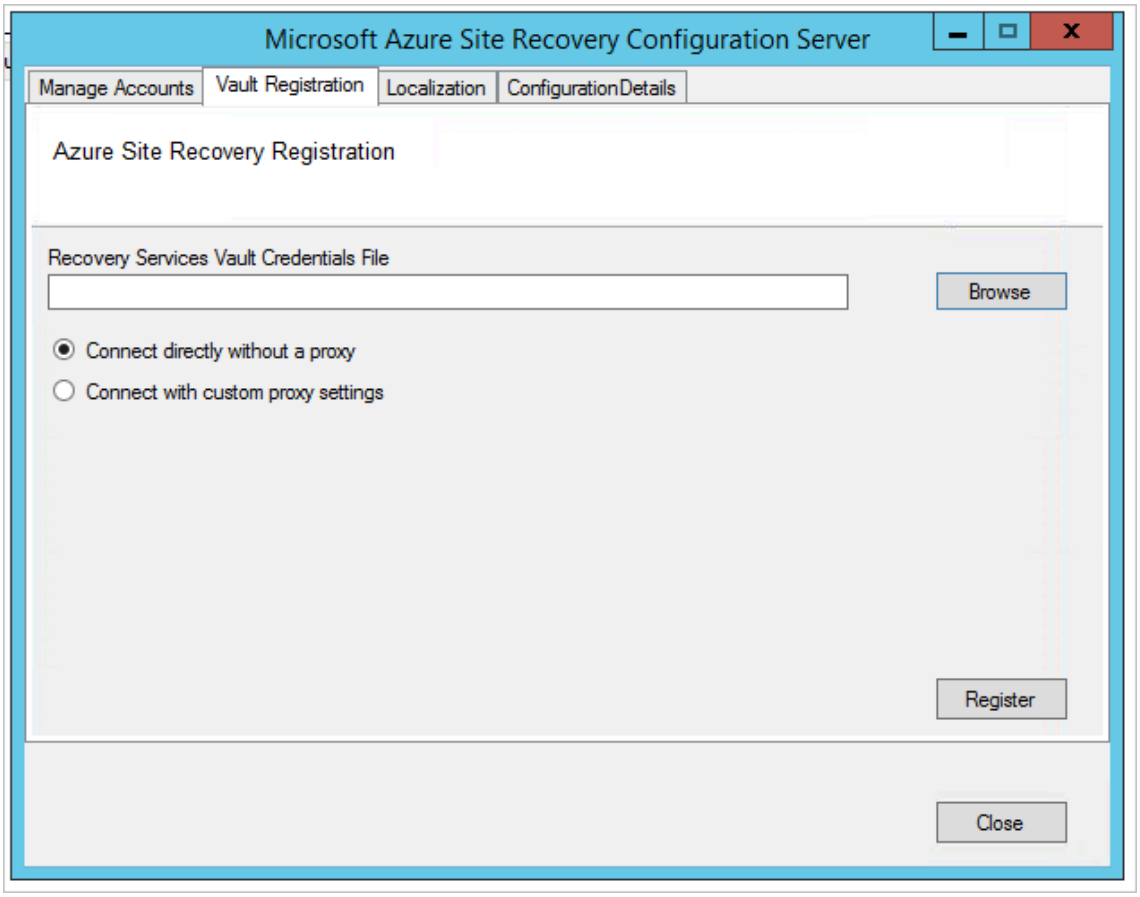
   c. In **Environment Details**, select whether you're going to replicate VMware VMs. For this migration scenario, choose **No**.



4. After the installation is complete, do the following in the **Microsoft Azure Site Recovery Configuration Server** window:

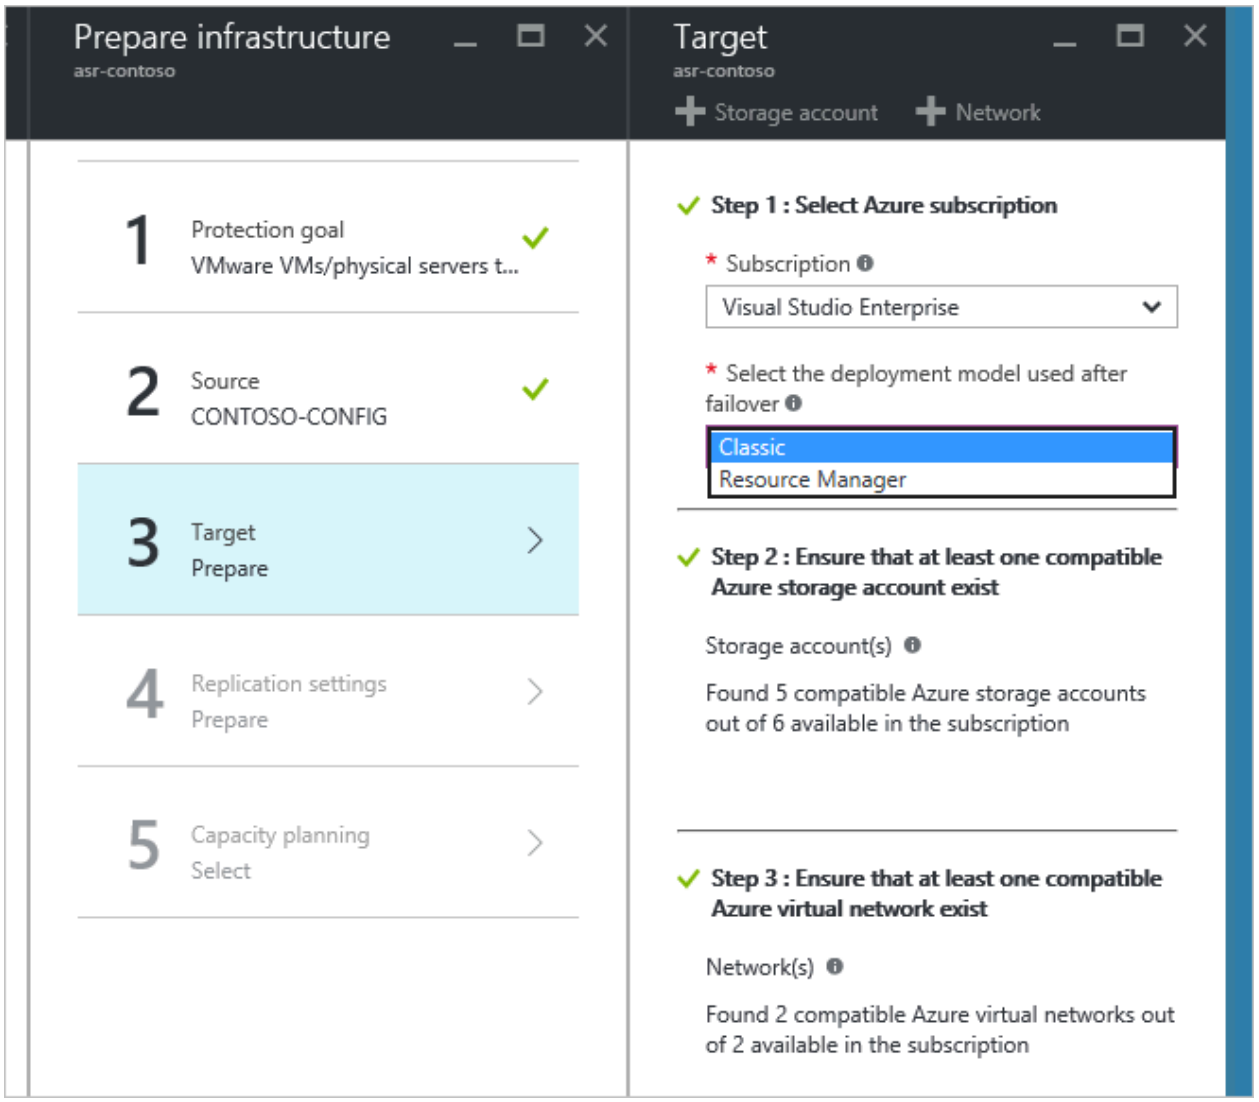
   a. Use the **Manage Accounts** tab to create the account that Site Recovery can use for automatic discovery. (In the scenario about protecting physical machines, setting up the account isn't relevant, but you need at least one account to enable one of the following steps. In this case, you can name the account and password as any.)

   b. Use the **Vault Registration** tab to upload the vault credential file.



Step 4: Set up the target environment

Select **Prepare infrastructure** > **Target**, and specify the deployment model that you want to use for VMs after failover. You can choose **Classic** or **Resource Manager**, depending on your scenario.



Site Recovery checks that you have one or more compatible Azure storage accounts and networks.

> **Note**
>
> If you're using a premium storage account for replicated data, you need to set up an additional standard storage account to store replication logs.

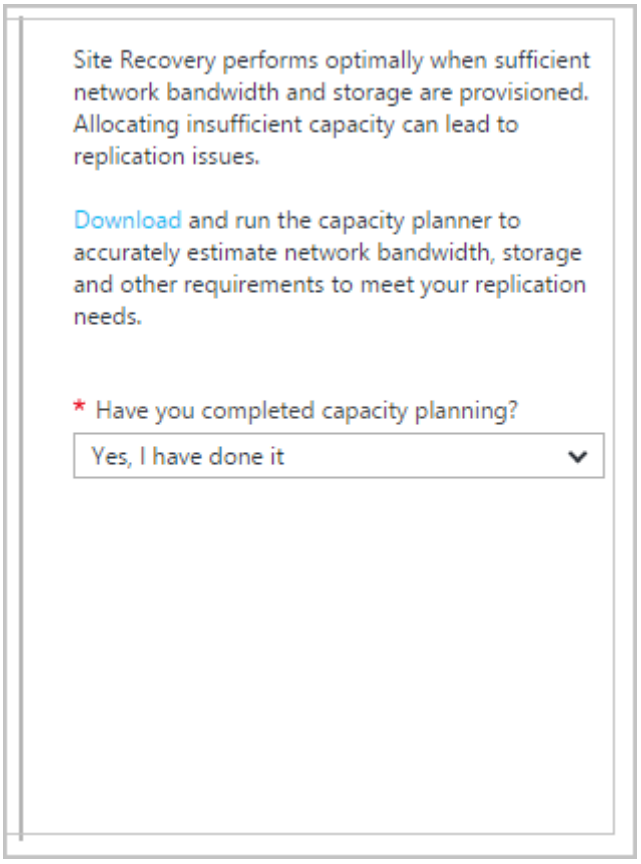
Step 5: Set up replication settings

To verify that your configuration server is successfully associated with the replication policy that you create, follow Set up replication settings.

Step 6: Plan capacity

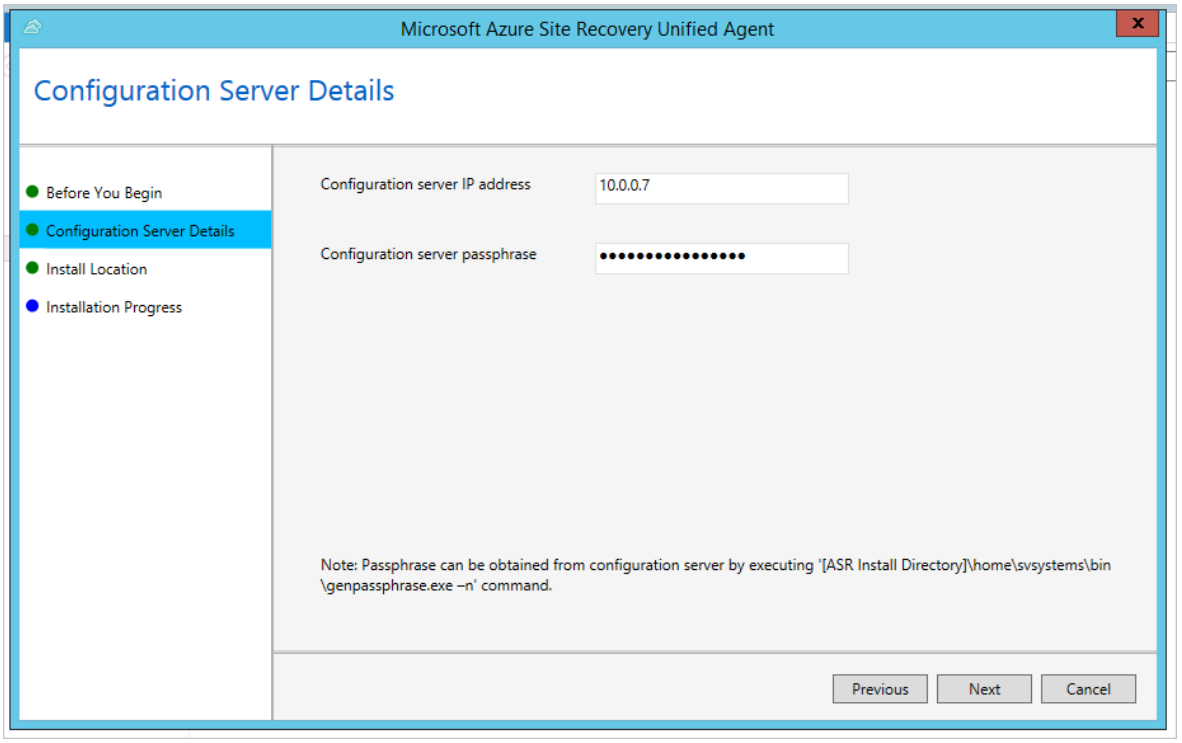
1. Use the capacity planner to accurately estimate network bandwidth, storage, and other requirements to meet your replication needs.

2. When you're done, select **Yes, I have done it** in **Have you completed capacity planning?**.



Step 7: Install the mobility service and enable replication

1. You can choose to push installation to your source VMs or to manually install the mobility service on your source VMs. You can find the requirement of pushing installation and the path of the manual installer in the provided link. If you're doing a manual installation, you might need to use an internal IP address to find the configuration server.

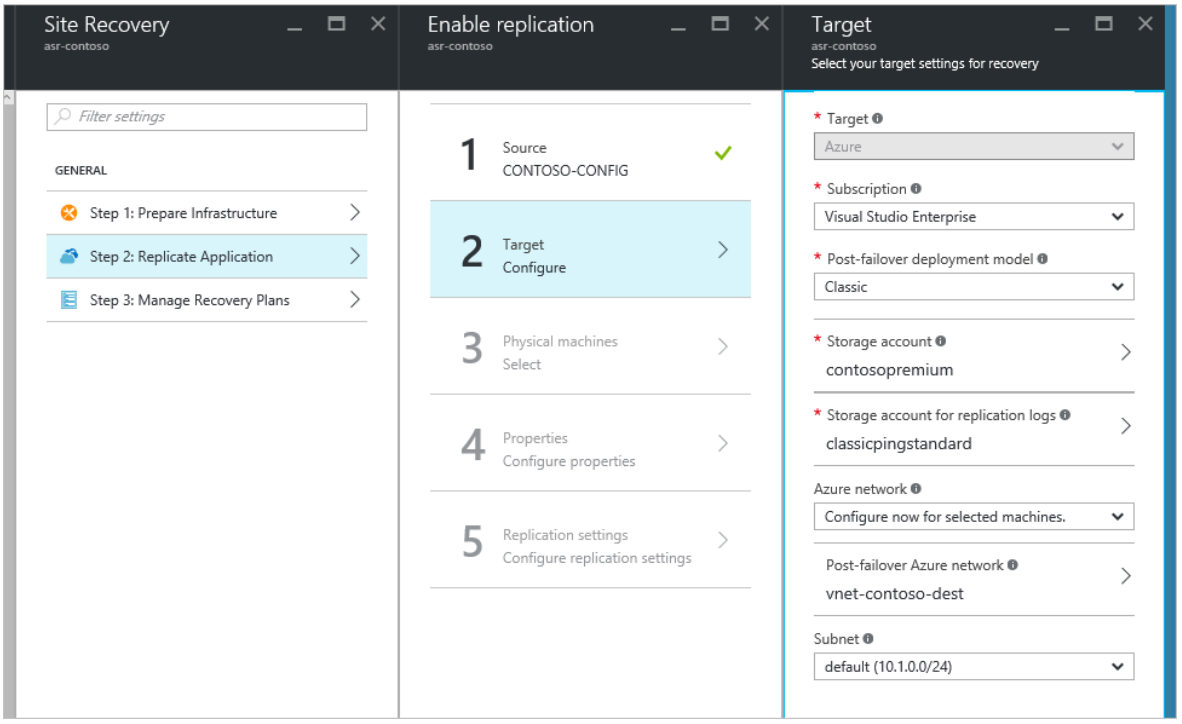


The failed-over VM will have two temporary disks: one from the primary VM and the other created during the provisioning of the VM in the recovery region. To exclude the temporary disk before replication, install the mobility service before you enable replication. To learn more about how to exclude the temporary disk, see Exclude disks from replication.

2. Enable replication as follows:
   a. Select **Replicate Application** > **Source**. After you've enabled replication for the first time, select **+Replicate** in the vault to enable replication for additional machines.
   b. In step 1, set up **Source** as your process server.
   c. In step 2, specify the post-failover deployment model, a premium storage account to migrate to, a standard storage account to save logs, and a virtual network to fail to.
   d. In step 3, add protected VMs by IP address. (You might need an internal IP address to find them.)
   e. In step 4, configure the properties by selecting the accounts that you set up previously on the process server.
   f. In step 5, choose the replication policy that you created previously in "Step 5: Set up replication settings."
   g. Select **OK**.

> **Note**
>
> When an Azure VM is deallocated and started again, there is no guarantee that it will get the same IP address. If the IP address of the configuration

server/process server or the protected Azure VMs changes, the replication in this scenario might not work correctly.



When you design your Azure Storage environment, we recommend that you use separate storage accounts for each VM in an availability set. We recommend that you follow the best practice in the storage layer to use multiple storage accounts for each availability set. Distributing VM disks to multiple storage accounts helps to improve storage availability and distributes the I/O across the Azure storage infrastructure.

If your VMs are in an availability set, instead of replicating disks of all VMs into one storage account, we highly recommend migrating multiple VMs multiple times. That way, the VMs in the same availability set do not share a single storage account. Use the **Enable Replication** pane to set up a destination storage account for each VM, one at a time.

You can choose a post-failover deployment model according to your need. If you choose Azure Resource Manager as your post-failover deployment model, you can fail over a VM (Resource Manager) to a VM (Resource Manager), or you can fail over a VM (classic) to a VM (Resource Manager).

Step 8: Run a test failover

To check whether your replication is complete, select your Site Recovery instance and then select **Settings** > **Replicated Items**. You will see the status and percentage of your replication process.

After initial replication is complete, run a test failover to validate your replication strategy. For detailed steps of a test failover, see Run a test failover in Site Recovery.

> **Note**
>
> Before you run any failover, make sure that your VMs and replication strategy meet the requirements. For more information about running a test failover, see Test failover to Azure in Site Recovery.

You can see the status of your test failover in **Settings** > **Jobs** > *YOUR_FAILOVER_PLAN_NAME*. In the pane, you can see a breakdown of the steps and success/failure results. If the test failover fails at any step, select the step to check the error message.

Step 9: Run a failover

After the test failover is completed, run a failover to migrate your disks to Premium Storage and replicate the VM instances. Follow the detailed steps in Run a failover.

Be sure to select **Shut down VMs and synchronize the latest data**. This option specifies that Site Recovery should try to shut down the protected VMs and synchronize the data so that the latest version of the data will be failed over. If you don't select this option or the attempt doesn't succeed, the failover will be from the latest available recovery point for the VM.

Site Recovery will create a VM instance whose type is the same as or similar to a Premium Storage-capable VM. You can check the performance and price of various VM instances by going to Windows Virtual Machines Pricing or Linux Virtual Machines Pricing.

Post-migration steps

1. **Configure replicated VMs to the availability set if applicable**. Site Recovery does not support migrating VMs along with the availability set. Depending on the deployment of your replicated VM, do one of the following:

    - For a VM created through the classic deployment model: Add the VM to the availability set in the Azure portal. For detailed steps, go to Add an existing virtual machine to an availability set.
    - For a VM created through the Resource Manager deployment model: Save your configuration of the VM and then delete and re-create the VMs in the

availability set.

2. **Delete old VMs and disks**. Make sure that the Premium disks are consistent with source disks and that the new VMs perform the same function as the source VMs. Delete the VM and delete the disks from your source storage accounts in the Azure portal. If there's a problem in which the disk is not deleted even though you deleted the VM, see Troubleshoot storage resource deletion errors.

3. **Clean the Azure Site Recovery infrastructure**. If Site Recovery is no longer needed, you can clean its infrastructure. Delete replicated items, the configuration server, and the recovery policy, and then delete the Azure Site Recovery vault.

Troubleshooting

- Monitor and troubleshoot protection for virtual machines and physical servers

Migrate to Premium Storage by using Azure Site Recovery

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

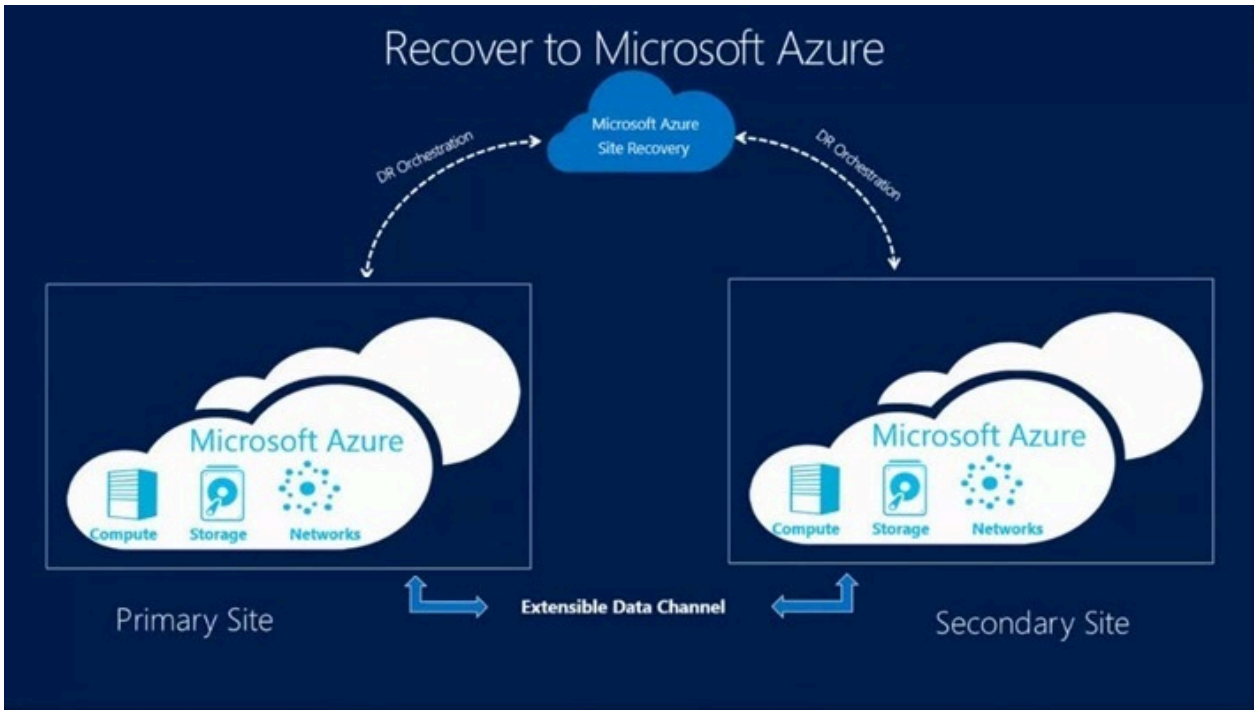
Azure premium SSDs deliver high-performance, low-latency disk support for virtual machines (VMs) that are running I/O-intensive workloads. This guide helps you migrate your VM disks from a standard storage account to a premium storage account by using Azure Site Recovery.

Site Recovery is an Azure service that contributes to your strategy for business continuity and disaster recovery by orchestrating the replication of on-premises physical servers and VMs to the cloud (Azure) or to a secondary datacenter. When outages occur in your primary location, you fail over to the secondary location to keep applications and workloads available. You fail back to your primary location when it returns to normal operation.

Site Recovery provides test failovers to support disaster recovery drills without affecting production environments. You can run failovers with minimal data loss (depending on replication frequency) for unexpected disasters. In the scenario of migrating to Premium Storage, you can use the failover in Site Recovery to migrate target disks to a premium storage account.

We recommend migrating to Premium Storage by using Site Recovery because this option provides minimal downtime. This option also avoids the manual execution of copying disks and creating new VMs. Site Recovery will systematically copy your disks and create new VMs during failover.

Site Recovery supports a number of types of failover with minimal or no downtime. To plan your downtime and estimate data loss, see the types of failover in Site Recovery. If you prepare to connect to Azure VMs after failover, you should be able to connect to the Azure VM by using RDP after failover.



Azure Site Recovery components

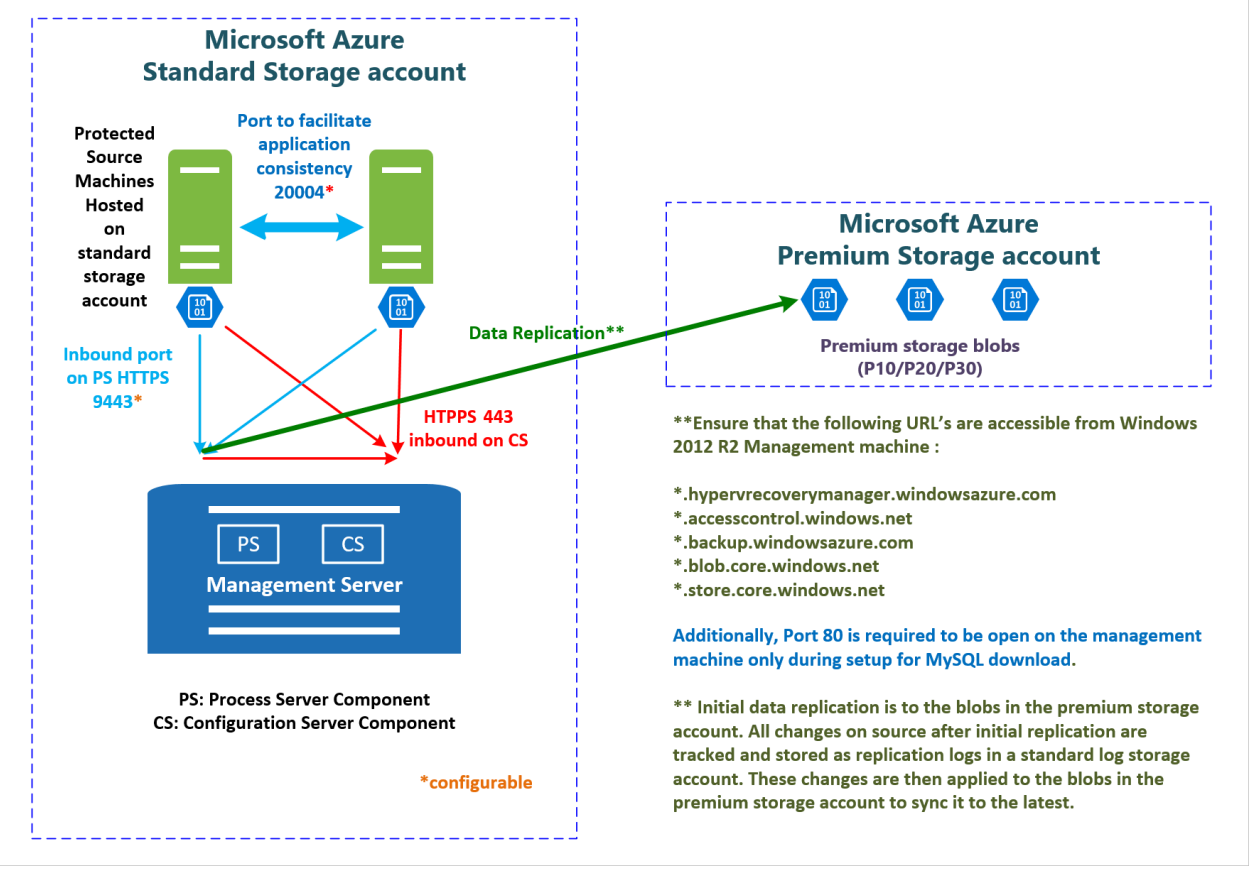
These Site Recovery components are relevant to this migration scenario:

- **Configuration server** is an Azure VM that coordinates communication and manages data replication and recovery processes. On this VM, you run a single setup file to install the configuration server and an additional component, called a process server, as a replication gateway. Read about configuration server prerequisites. You set up the configuration server only once, and you can use it for all migrations to the same region.
- **Process server** is a replication gateway that:

  1. Receives replication data from source VMs.
  2. Optimizes the data with caching, compression, and encryption.
  3. Sends the data to a storage account.

  It also handles push installation of the mobility service to source VMs and performs automatic discovery of source VMs. The default process server is installed on the configuration server. You can deploy additional standalone process servers to scale your deployment. Read about best practices for process server deployment and deploying additional process servers. You set up the process server only once, and you can use it for all migrations to the same region.
- **Mobility service** is a component that is deployed on every standard VM that you want to replicate. It captures data writes on the standard VM and forwards them to the process server. Read about replicated machine prerequisites.

This graphic shows how these components interact:



> **Note**
>
> Site Recovery does not support the migration of Storage Spaces disks.

For additional components for other scenarios, see Scenario architecture.

Azure essentials

These are the Azure requirements for this migration scenario:

- An Azure subscription.
- An Azure premium storage account to store replicated data.
- An Azure virtual network to which VMs will connect when they're created at failover. The Azure virtual network must be in the same region as the one in which Site Recovery runs.
- An Azure standard storage account to store replication logs. This can be the same storage account for the VM disks that are being migrated.

Prerequisites

- Understand the relevant migration scenario components in the preceding section.
- Plan your downtime by learning about failover in Site Recovery.

Setup and migration steps

You can use Site Recovery to migrate Azure IaaS VMs between regions or within same region. The following instructions are tailored for this migration scenario from the article Replicate VMware VMs or physical servers to Azure. Please follow the links for detailed steps in addition to the instructions in this article.

Step 1: Create a Recovery Services vault

1. Open the Azure portal.
2. Select **Create a resource** > **Management** > **Backup and Site Recovery (OMS)**. Alternatively, you can select **Browse** > **Recovery Services Vault** > **Add**.

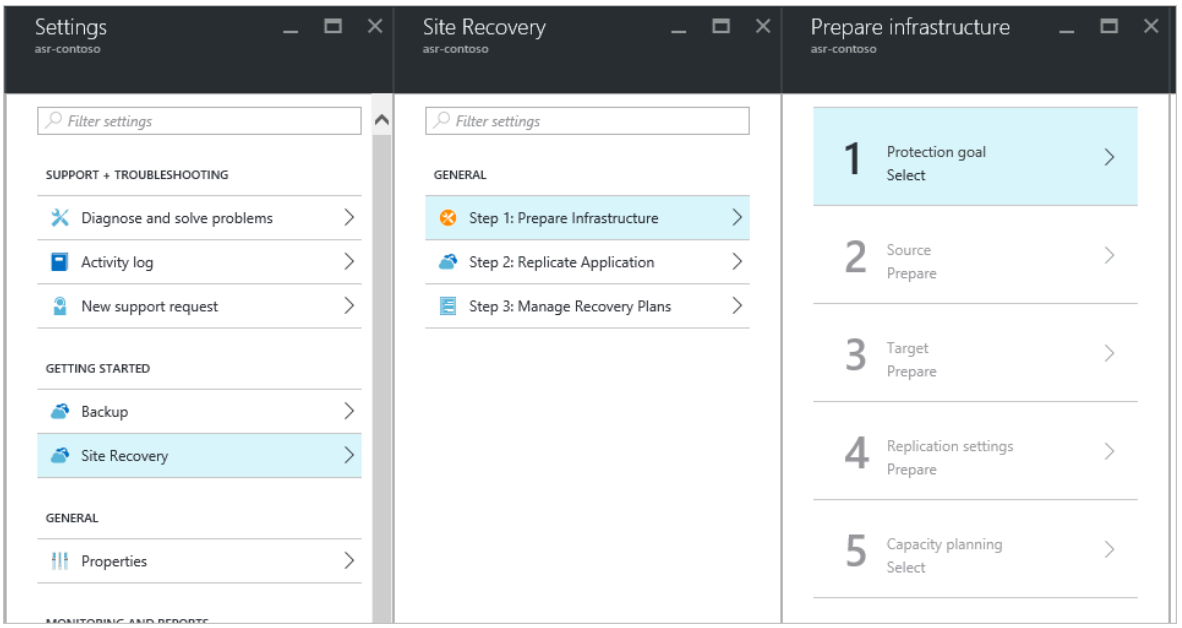
   > **Note**
   >
   > Backup and Site Recovery was formerly part of the OMS suite.

3. Specify a region that VMs will be replicated to. For the purpose of migration in the same region, select the region where your source VMs and source storage accounts are.

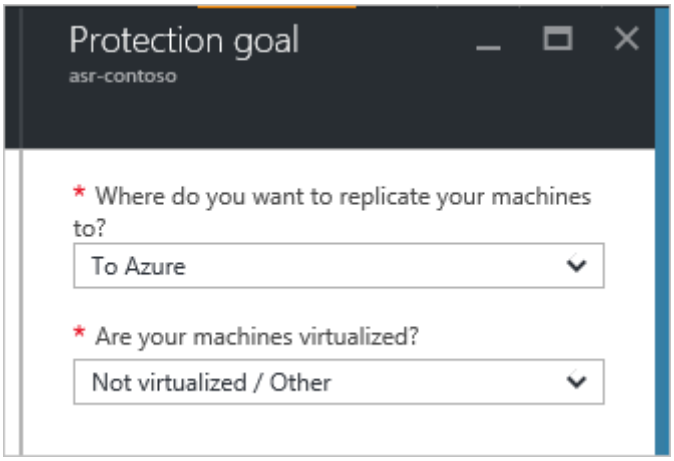
Step 2: Choose your protection goals

1. On the VM where you want to install the configuration server, open the Azure portal.

2. Go to **Recovery Services vaults** > **Settings** > **Site Recovery** > **Step 1: Prepare Infrastructure** > **Protection goal**.



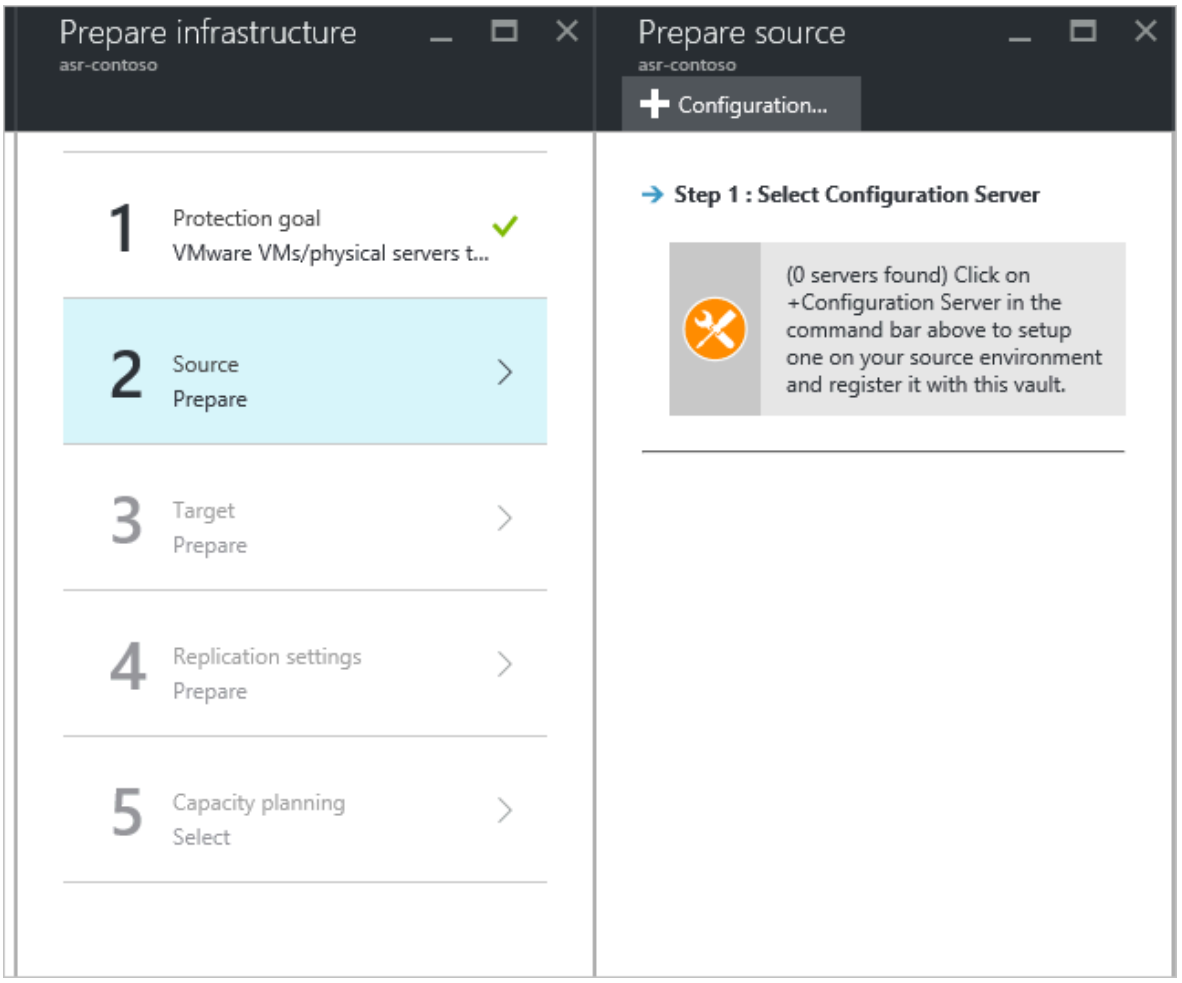
3. Under **Protection goal**, in the first drop-down list, select **To Azure**. In the second drop-down list, select **Not virtualized / Other**, and then select **OK**.



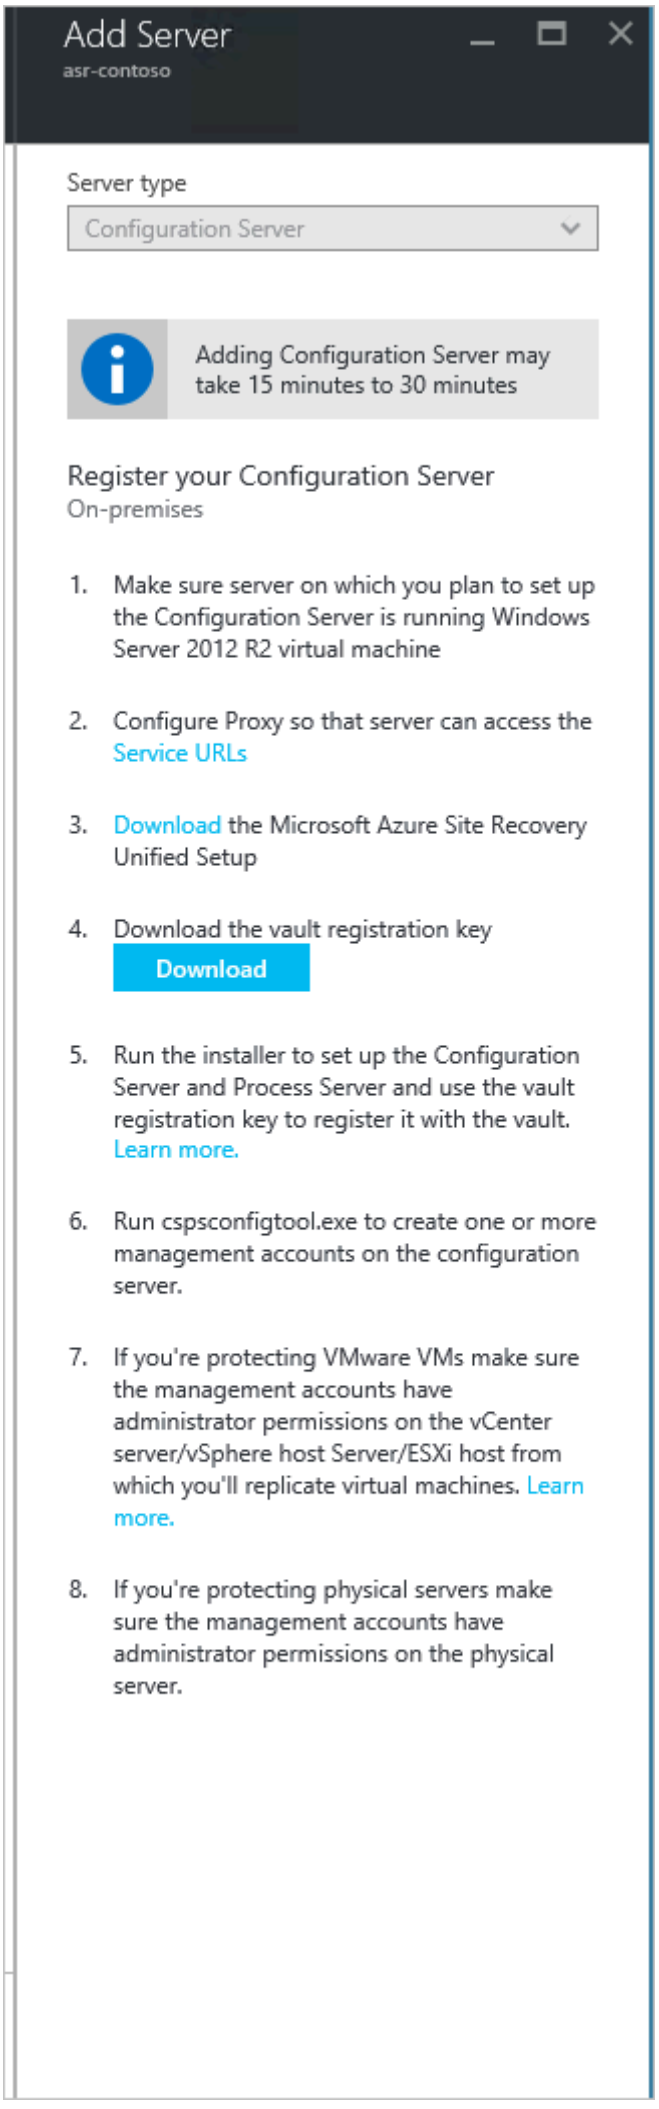
Step 3: Set up the source environment (configuration server)

1. Download **Azure Site Recovery Unified Setup** and the vault registration key by going to the **Prepare infrastructure** > **Prepare source** > **Add Server** panes.

   You will need the vault registration key to run the unified setup. The key is valid for five days after you generate it.



2. In the **Add Server** pane, add a configuration server.



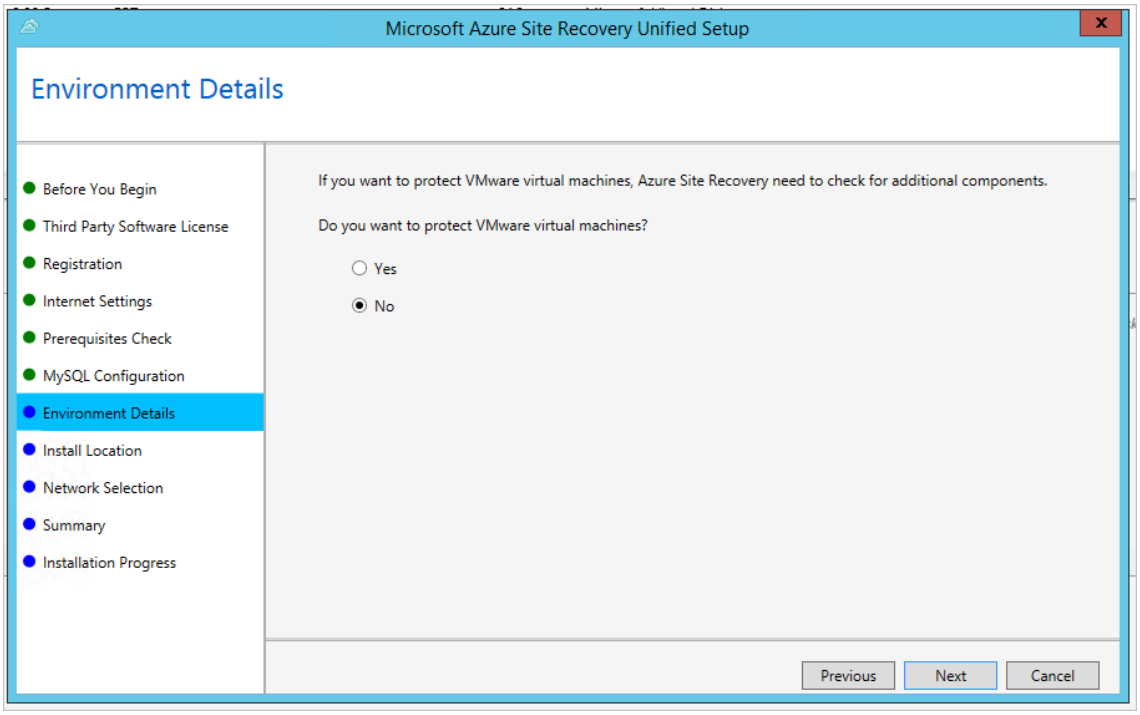
Add Server
asr-contoso
Server type
Configuration Server
Adding Configuration Server may take 15 minutes to 30 minutes
Register your Configuration Server
On-premises
1. Make sure server on which you plan to set up the Configuration Server is running Windows Server 2012 R2 virtual machine
2. Configure Proxy so that server can access the Service URLs
3. Download the Microsoft Azure Site Recovery Unified Setup
4. Download the vault registration key
Download
5. Run the installer to set up the Configuration Server and Process Server and use the vault registration key to register it with the vault. Learn more.
6. Run cspsconfigtool.exe to create one or more management accounts on the configuration server.
7. If you're protecting VMware VMs make sure the management accounts have administrator permissions on the vCenter server/vSphere host Server/ESXi host from which you'll replicate virtual machines. Learn more.
8. If you're protecting physical servers make sure the management accounts have administrator permissions on the physical server.

3. On the VM that you're using as the configuration server, run Unified Setup to install the configuration server and the process server. You can walk through the screenshots to complete the installation. You can refer to the following screenshots for steps specified for this migration scenario.

   a. In **Before You Begin**, select **Install the configuration server and process server**.

   b. In **Registration**, browse and select the registration key that you downloaded from the vault.

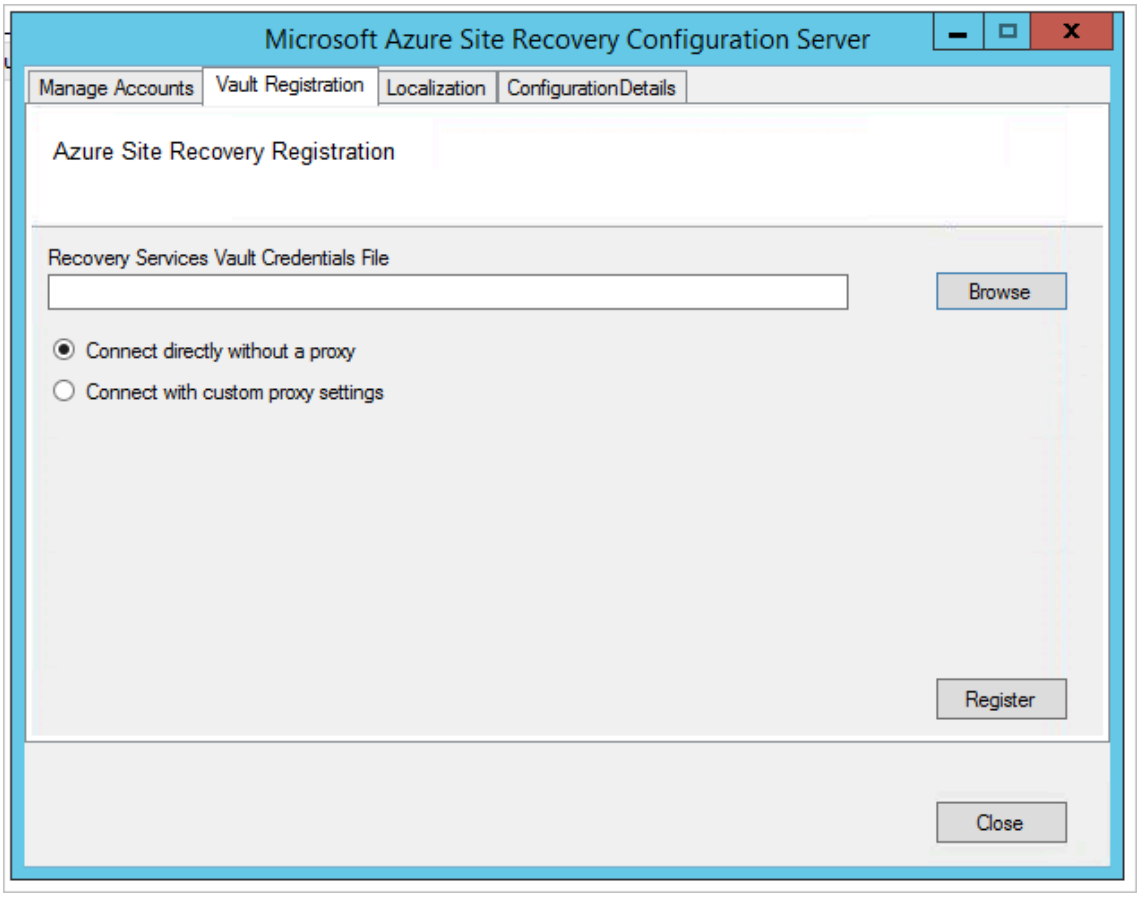
   c. In **Environment Details**, select whether you're going to replicate VMware VMs. For this migration scenario, choose **No**.



4. After the installation is complete, do the following in the **Microsoft Azure Site Recovery Configuration Server** window:

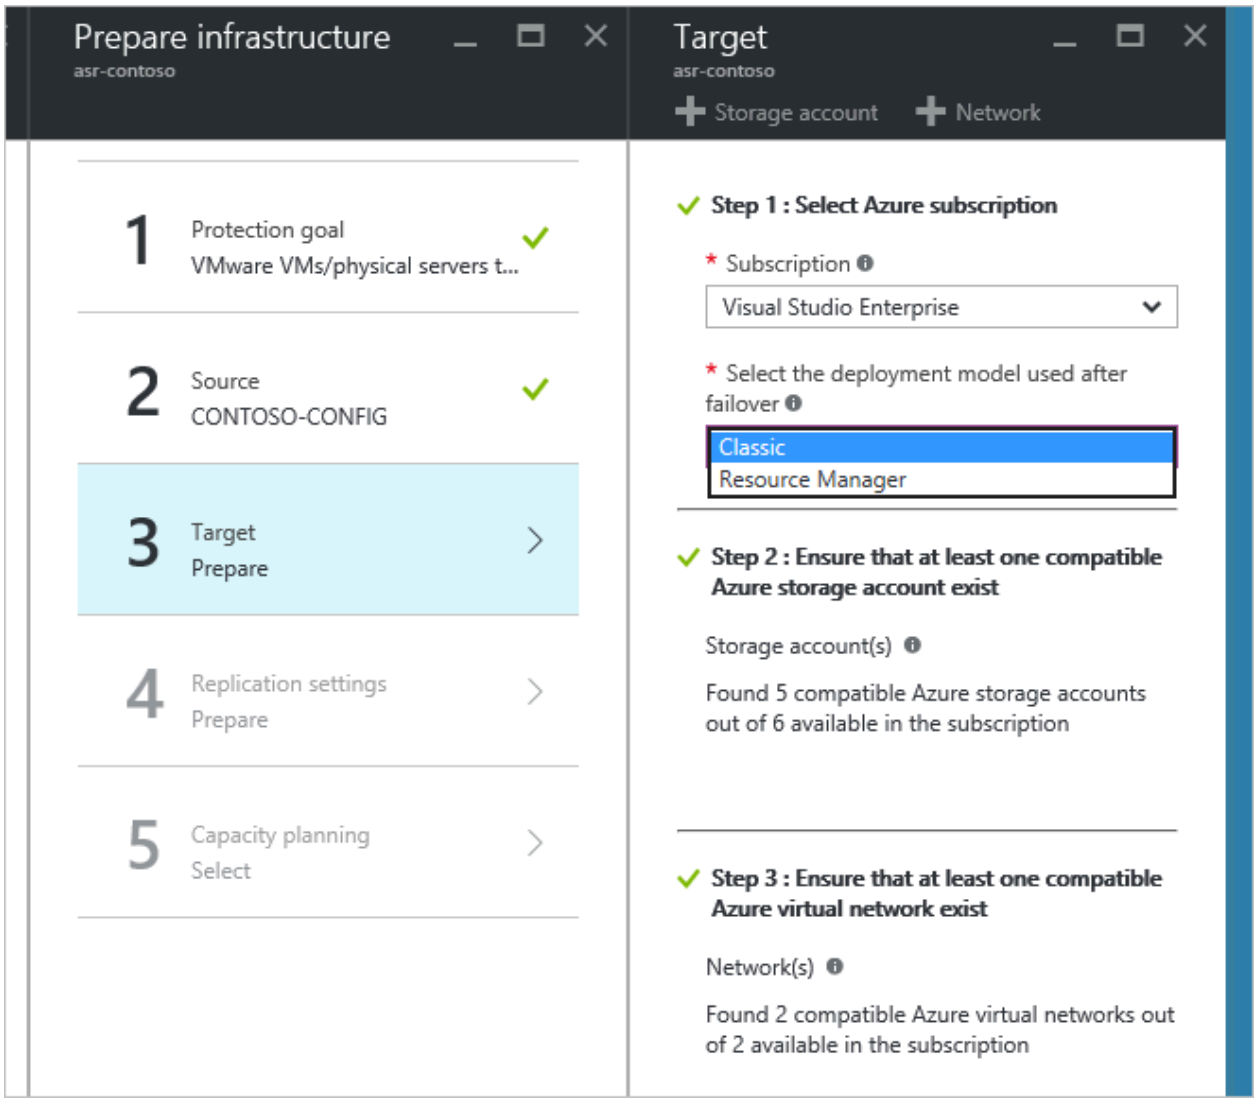
   a. Use the **Manage Accounts** tab to create the account that Site Recovery can use for automatic discovery. (In the scenario about protecting physical machines, setting up the account isn't relevant, but you need at least one account to enable one of the following steps. In this case, you can name the account and password as any.)

   b. Use the **Vault Registration** tab to upload the vault credential file.



Step 4: Set up the target environment

Select **Prepare infrastructure** > **Target**, and specify the deployment model that you want to use for VMs after failover. You can choose **Classic** or **Resource Manager**, depending on your scenario.



Site Recovery checks that you have one or more compatible Azure storage accounts and networks.

> **Note**
>
> If you're using a premium storage account for replicated data, you need to set up an additional standard storage account to store replication logs.

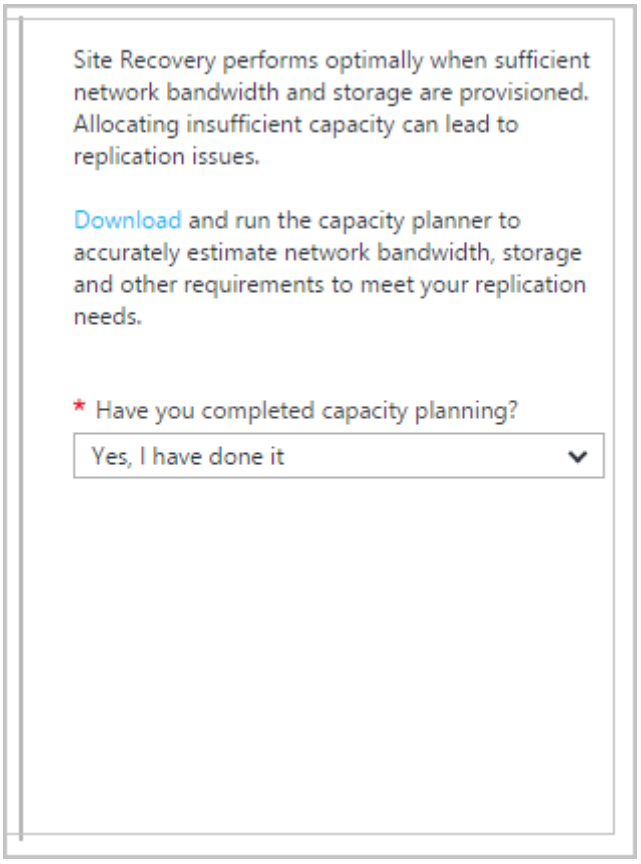
Step 5: Set up replication settings

To verify that your configuration server is successfully associated with the replication policy that you create, follow Set up replication settings.

Step 6: Plan capacity

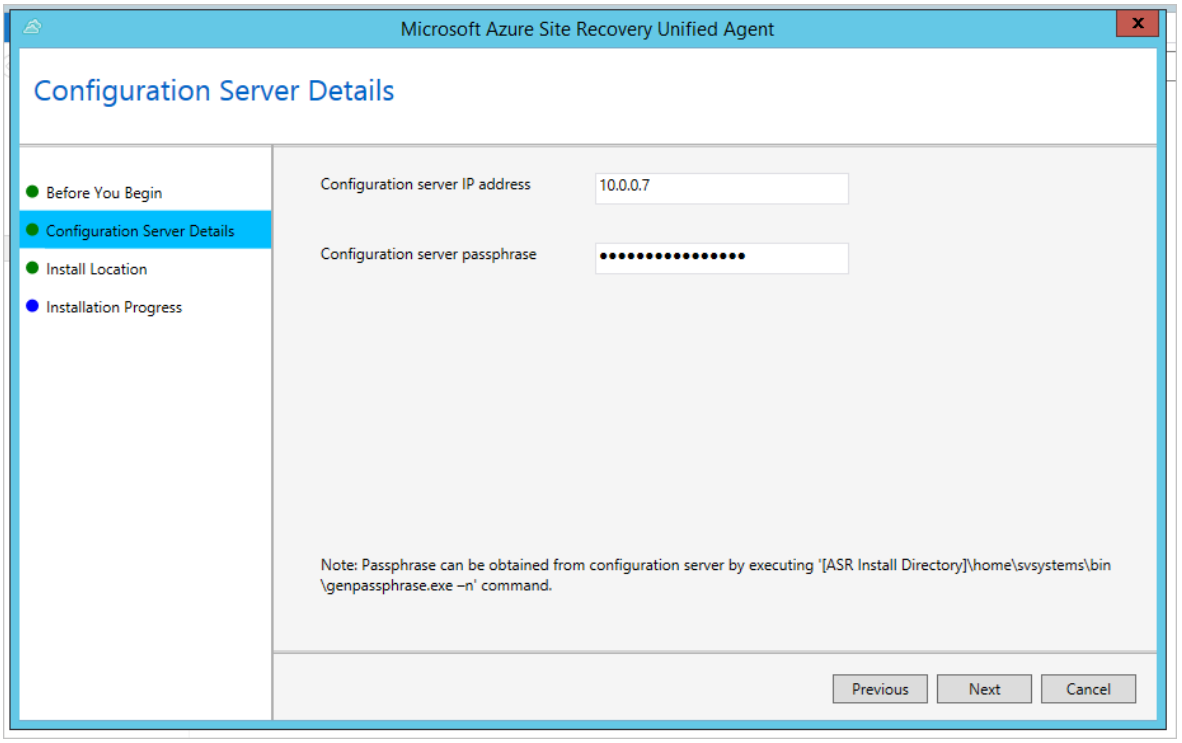
1. Use the capacity planner to accurately estimate network bandwidth, storage, and other requirements to meet your replication needs.

2. When you're done, select **Yes, I have done it** in **Have you completed capacity planning?**.



Step 7: Install the mobility service and enable replication

1. You can choose to push installation to your source VMs or to manually install the mobility service on your source VMs. You can find the requirement of pushing installation and the path of the manual installer in the provided link. If you're doing a manual installation, you might need to use an internal IP address to find the configuration server.

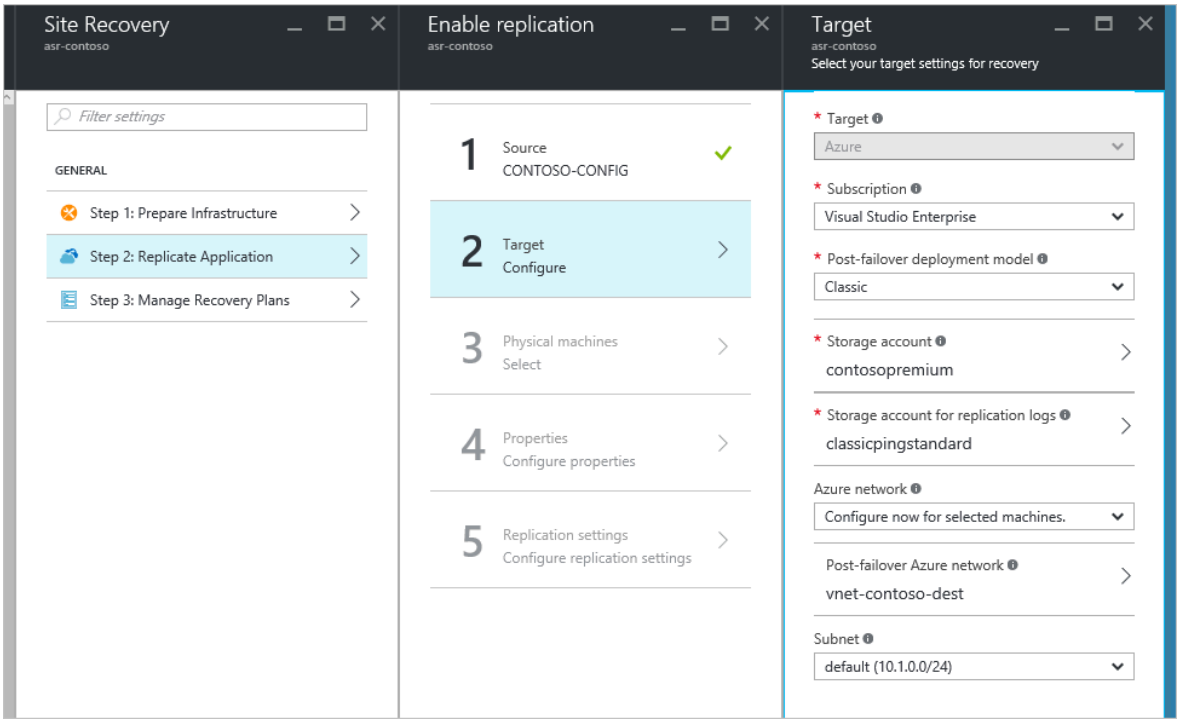


The failed-over VM will have two temporary disks: one from the primary VM and the other created during the provisioning of the VM in the recovery region. To exclude the temporary disk before replication, install the mobility service before you enable replication. To learn more about how to exclude the temporary disk, see Exclude disks from replication.

2. Enable replication as follows:
   a. Select **Replicate Application** > **Source**. After you've enabled replication for the first time, select **+Replicate** in the vault to enable replication for additional machines.
   b. In step 1, set up **Source** as your process server.
   c. In step 2, specify the post-failover deployment model, a premium storage account to migrate to, a standard storage account to save logs, and a virtual network to fail to.
   d. In step 3, add protected VMs by IP address. (You might need an internal IP address to find them.)
   e. In step 4, configure the properties by selecting the accounts that you set up previously on the process server.
   f. In step 5, choose the replication policy that you created previously in "Step 5: Set up replication settings."
   g. Select **OK**.

> **Note**
>
> When an Azure VM is deallocated and started again, there is no guarantee that it will get the same IP address. If the IP address of the configuration

server/process server or the protected Azure VMs changes, the replication in this scenario might not work correctly.



When you design your Azure Storage environment, we recommend that you use separate storage accounts for each VM in an availability set. We recommend that you follow the best practice in the storage layer to use multiple storage accounts for each availability set. Distributing VM disks to multiple storage accounts helps to improve storage availability and distributes the I/O across the Azure storage infrastructure.

If your VMs are in an availability set, instead of replicating disks of all VMs into one storage account, we highly recommend migrating multiple VMs multiple times. That way, the VMs in the same availability set do not share a single storage account. Use the **Enable Replication** pane to set up a destination storage account for each VM, one at a time.

You can choose a post-failover deployment model according to your need. If you choose Azure Resource Manager as your post-failover deployment model, you can fail over a VM (Resource Manager) to a VM (Resource Manager), or you can fail over a VM (classic) to a VM (Resource Manager).

Step 8: Run a test failover

To check whether your replication is complete, select your Site Recovery instance and then select **Settings** > **Replicated Items**. You will see the status and percentage of your replication process.

After initial replication is complete, run a test failover to validate your replication strategy. For detailed steps of a test failover, see Run a test failover in Site Recovery.

> **Note**
>
> Before you run any failover, make sure that your VMs and replication strategy meet the requirements. For more information about running a test failover, see Test failover to Azure in Site Recovery.

You can see the status of your test failover in **Settings** > **Jobs** > *YOUR_FAILOVER_PLAN_NAME*. In the pane, you can see a breakdown of the steps and success/failure results. If the test failover fails at any step, select the step to check the error message.

Step 9: Run a failover

After the test failover is completed, run a failover to migrate your disks to Premium Storage and replicate the VM instances. Follow the detailed steps in Run a failover.

Be sure to select **Shut down VMs and synchronize the latest data**. This option specifies that Site Recovery should try to shut down the protected VMs and synchronize the data so that the latest version of the data will be failed over. If you don't select this option or the attempt doesn't succeed, the failover will be from the latest available recovery point for the VM.

Site Recovery will create a VM instance whose type is the same as or similar to a Premium Storage-capable VM. You can check the performance and price of various VM instances by going to Windows Virtual Machines Pricing or Linux Virtual Machines Pricing.

Post-migration steps

1. **Configure replicated VMs to the availability set if applicable**. Site Recovery does not support migrating VMs along with the availability set. Depending on the deployment of your replicated VM, do one of the following:

    - For a VM created through the classic deployment model: Add the VM to the availability set in the Azure portal. For detailed steps, go to Add an existing virtual machine to an availability set.
    - For a VM created through the Resource Manager deployment model: Save your configuration of the VM and then delete and re-create the VMs in the

availability set.

2. **Delete old VMs and disks**. Make sure that the Premium disks are consistent with source disks and that the new VMs perform the same function as the source VMs. Delete the VM and delete the disks from your source storage accounts in the Azure portal. If there's a problem in which the disk is not deleted even though you deleted the VM, see Troubleshoot storage resource deletion errors.

3. **Clean the Azure Site Recovery infrastructure**. If Site Recovery is no longer needed, you can clean its infrastructure. Delete replicated items, the configuration server, and the recovery policy, and then delete the Azure Site Recovery vault.

Migrate Azure VMs to managed disks in Azure

Applies to: ✔ Linux VMs ✔ Windows VMs

Unmanaged disks are no longer supported. If you're using unmanaged disks, migrate to managed disks. For details, see Migrate unmanaged disks to managed disks.

Azure managed disks simplifies your storage management by removing the need to separately manage storage accounts. Managed disks provide numerous benefits over unmanaged disks, such as high availability, better scalability, large disks, bursting, and shared disks. You can also migrate your existing Azure VMs to managed disks to benefit from better reliability of VMs in an Availability Set. It ensures that the disks of different VMs in an Availability Set are sufficiently isolated from each other to avoid single point of failures. It automatically places disks of different VMs in an Availability Set in different Storage scale units (stamps) which limits the impact of single Storage scale unit failures caused due to hardware and software failures. Based on your needs, you can choose from four types of storage options. To learn about the available disk types, see Select a disk type

Migration scenarios

You can migrate to managed disks in following scenarios:

Expand table

Scenario	Article
Convert stand alone VMs and VMs in an availability set to managed disks	Convert VMs to use managed disks
Convert a single VM from classic to Resource Manager on managed disks	Create a VM from a classic VHD
Convert all the VMs in a vNet from classic to Resource Manager on managed disks	Migrate IaaS resources from classic to Resource Manager and then Convert a VM from unmanaged disks to managed disks
Upgrade VMs with standard unmanaged disks to VMs with managed premium disks	First, Convert a Windows virtual machine from unmanaged disks to managed disks. Then Update the storage type of a managed disk.

> **Important**
>
> VMs created through the classic deployment model will be retired on September 1, 2023.
>
> If you use IaaS resources from Azure Service Management, please complete your migration by September 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.
>
> For more information, see Migrate your IaaS resources to Azure Resource Manager by September 1, 2023.

Next steps

- Learn more about managed disks
- Review the pricing for managed disks.

Last updated on 02/26/2026

Migrate unmanaged disks to managed disks

Applies to: ✔ Linux VMs ✔ Windows VMs

In 2017, we launched Azure managed disks. We've been enhancing capabilities ever since. Because Azure managed disks now have the full capabilities of unmanaged disks and other advancements, we announced the retirement for unmanaged disks on September 13, 2022. Unmanaged disks were fully retired on March 31, 2026 (extended from previously published date of September 30, 2025). If you're still using unmanaged disks, migrate to managed disks as soon as possible.

By using managed disks, you don't need to manage storage accounts for creating a disk, because Azure manages the storage accounts under the hood. This abstraction reduces maintenance overhead for you. Also, it allows managed disks to provide numerous benefits over unmanaged disks, such as high availability, better scalability, large disks, bursting, and shared disks. If you use unmanaged disks, start planning your Windows or Linux migration now.

How am I affected?

After March 31, 2026, you can't start IaaS VMs that use unmanaged disks. Any VMs that use unmanaged disks and are running or allocated will be stopped and deallocated.

What is being retired?

Unmanaged disks are a type of page blob in Azure that is used for storing Virtual Hard Disk (VHD) files associated with virtual machines (VM). When a page blob VHD is attached to a VM, it functions as a virtual disk for that VM. The VM's operating system can read from and write to the attached page blob as if it were a SCSI volume. This retirement only affects page blobs being used as virtual disks that are directly attached to VMs.

Page blobs accessed directly via HTTP or HTTPS REST APIs are standalone entities and have no dependencies on any specific VM. Clients can interact with these page blobs by using standard HTTP or HTTPS protocols, making requests to read from or write to the blobs by using Storage REST APIs. Since these page blobs aren't attached as virtual disks, this retirement doesn't affect them.

Third party storage offerings on Azure that use page blobs via HTTP or HTTPS REST APIs as their underlying storage solution might not be affected by this retirement.

What actions should I take?

Start planning your migration to Azure managed disks today.

- Make a list of all affected VMs:
  - On the Azure portal's VM pane, add the **Uses managed disks** filter and set its value to **No**, to get a list of all the affected VMs within the subscription.
  - You can also query Azure Resource Graph by using the portal to view the list of all flagged VMs and related information for the selected subscriptions.
  - On February 28, 2020, we sent out emails to subscription owners with a list of all subscriptions that contain these VMs. Use them to build this list.
- Now that you have a list of all the affected VMs, see Migrate Azure VMs to managed disks in Azure to learn how to migrate your unmanaged disks to managed disks. If you have other questions, see Frequently asked questions about migrating to managed disks.
- If you have further technical questions, problems, and need help with adding subscriptions to the allow list, contact support.

Complete your migration as soon as possible to prevent business impact and to take advantage of the improved reliability, scalability, security, and new features of Azure managed disks.

What resources are available for this migration?

- Microsoft Q&A: Microsoft and community support for migration.
- Azure Migration Support: Dedicated support team for technical assistance during migration.
- If your company or organization has partnered with Microsoft or works with Microsoft representatives such as cloud solution architects (CSAs) or technical account managers (TAMs), work with them for more resources for migration.

Last updated on 03/31/2026

Migrate your Standard HDD OS disks by September 08, 2028

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs

On September 8, 2028, the ability to use Standard HDDs as OS disks will be retired. After that date, all Standard HDDs being used as OS disks will be automatically converted to Standard SSDs of equivalent size. To avoid potential service disruptions during the conversion to Standard SSD after the retirement date, convert your Standard HDD OS disks to either Standard SSD or Premium SSDs before the retirement date.

If you're using Standard HDD as OS disks, begin planning a migration now. Generally, Standard SSD provides the closest price to performance ratio as Standard HDDs. If you need higher performance, migrate to Premium SSD.

How am I affected?

After September 8, 2028, any existing virtual machines using Standard HDD OS Disks will have their OS disks automatically converted to a Standard SSD of equivalent size. Workloads on these disks may experience a service disruption if they're not migrated before September 8, 2028.

What is being retired?

This retirement is only for the ability to use Standard HDDs as OS disks. None of the other managed disk types or ephemeral OS disks will be affected by this retirement.

What actions should I take?

Stop creating new virtual machines with Standard HDD OS disks. Use Standard SSD or Premium SSD for new OS disks instead.

To start planning a migration to either Standard SSD or Premium SSD OS disks, first, make a list of all affected OS disks and VMs.

If you have multiple subscriptions, use the Disk Storage Center to create a list. Add two filters, one for **Storage type** which should be equal to **Standard HDD LRS** and one for **OS type** which should equal to **Linux and Windows**. This produces a list of all Standard HDD OS disks

across all your subscriptions. The **Owner** column is the name of the virtual machine that uses the listed Standard HDD OS disks.

The Disk Storage Center still works for individual subscriptions. But, if you prefer, you can use the Azure CLI or the Azure PowerShell module to get the same list for an individual subscription. For the Azure PowerShell module, use `Get-AzDisk | Where-Object { $_.Sku.Name -eq "Standard_LRS" -and $_.OsType }` and for the Azure CLI, use `az disk list --query "[?sku.name=='Standard_LRS' && osType!=null]" --output table`.

Once you have a list of Standard HDD OS disks, convert your Standard HDD OS disks to either Standard SSD or Premium SSDs. Review Azure Disk Storage billing guidance to choose the most cost-effective disk type for your workloads.

For technical questions and issues, contact support.

What resources are available for this migration?

Microsoft Q&A: Microsoft and community support for migration.

Migrate a Linux virtual machine from unmanaged disks to managed disks

Article • 08/23/2024

Applies to: ✔ Linux VMs

If you have existing Linux virtual machines (VMs) that use unmanaged disks, you can migrate the VMs to use Azure Managed Disks. This process converts both the OS disk and any attached data disks.

This article shows you how to migrate VMs by using the Azure CLI. If you need to install or upgrade it, see Install Azure CLI.

Before you begin

- Review the FAQ about migration to Managed Disks.
- The migration will restart the VM, so schedule the migration of your VMs during a pre-existing maintenance window.
- The migration isn't reversible.
- Any users with the Virtual Machine Contributor role won't be able to change the VM size (as they could pre-migration). This is because VMs with managed disks require the user to have the Microsoft.Compute/disks/write permission on the OS disks.
- Be sure to test the migration. Migrate a test virtual machine before you perform the migration in production.
- During the migration, you deallocate the VM. The VM receives a new IP address when it's started after the migration. If needed, you can assign a static IP address to the VM.
- Review the minimum version of the Azure VM agent required to support the migration process. For information on how to check and update your agent version, see Minimum version support for VM agents in Azure
- The original VHDs and the storage account used by the VM before migration are not deleted. They continue to incur charges. To avoid being billed for these artifacts, delete the original VHD blobs after you verify that the migration is

complete. If you need to find these unattached disks in order to delete them, see our article Find and delete unattached Azure managed and unmanaged disks.

Migrate single-instance VMs

This section covers how to migrate single-instance Azure VMs from unmanaged disks to managed disks. (If your VMs are in an availability set, see the next section.) You can use this process to migrate the VMs from premium (SSD) unmanaged disks to premium managed disks, or from standard (HDD) unmanaged disks to standard managed disks.

1. Deallocate the VM by using az vm deallocate. The following example deallocates the VM named `myVM` in the resource group named `myResourceGroup`:

   Azure CLI

   ```
   az vm deallocate --resource-group myResourceGroup --name myVM
   ```

2. Migrate the VM to managed disks by using az vm convert. The following process converts the VM named `myVM`, including the OS disk and any data disks:

   Azure CLI

   ```
   az vm convert --resource-group myResourceGroup --name myVM
   ```

3. Start the VM after the migration to managed disks by using az vm start. The following example starts the VM named `myVM` in the resource group named `myResourceGroup`.

   Azure CLI

   ```
   az vm start --resource-group myResourceGroup --name myVM
   ```

Migrate VMs in an availability set

If the VMs that you want to migrate to managed disks are in an availability set, you first need to migrate the availability set to a managed availability set.

All VMs in the availability set must be deallocated before you migrate the availability set. Plan to migrate all VMs to managed disks after the availability set itself has been converted to a managed availability set. Then, start all the VMs and continue operating as normal.

1. List all VMs in an availability set by using az vm availability-set list. The following example lists all VMs in the availability set named `myAvailabilitySet` in the resource group named `myResourceGroup`:

   Azure CLI

   ```
   az vm availability-set show \
       --resource-group myResourceGroup \
       --name myAvailabilitySet \
       --query [virtualMachines[*].id] \
       --output table
   ```

2. Deallocate all the VMs by using az vm deallocate. The following example deallocates the VM named `myVM` in the resource group named `myResourceGroup`:

   Azure CLI

   ```
   az vm deallocate --resource-group myResourceGroup --name myVM
   ```

3. Migrate the availability set by using az vm availability-set convert. The following example converts the availability set named `myAvailabilitySet` in the resource group named `myResourceGroup`:

   Azure CLI

   ```
   az vm availability-set convert \
       --resource-group myResourceGroup \
       --name myAvailabilitySet
   ```

4. Migrate all the VMs to managed disks by using az vm convert. The following process converts the VM named `myVM`, including the OS disk and any data disks:

   Azure CLI

   ```
   az vm convert --resource-group myResourceGroup --name myVM
   ```

5. Start all the VMs after the migration to managed disks by using az vm start. The following example starts the VM named `myVM` in the resource group named `myResourceGroup`:

   Azure CLI

   ```
   az vm start --resource-group myResourceGroup --name myVM
   ```

Migrate using the Azure portal

You can also migrate unmanaged disks to managed disks using the Azure portal.

1. Sign in to the Azure portal.
2. Select the VM from the list of VMs in the portal.
3. In the blade for the VM, select **Disks** from the menu.
4. At the top of the **Disks** blade, select **Migrate to managed disks**.
5. If your VM is in an availability set, there will be a warning on the **Migrate to managed disks** blade that you need to migrate the availability set first. The warning should have a link you can click to migrate the availability set. Once the availability set is converted or if your VM is not in an availability set, click **Migrate** to start the process of migrating your disks to managed disks.

The VM will be stopped and restarted after migration is complete.

Next steps

For more information about storage options, see Azure Managed Disks overview.

Migrate a Windows virtual machine from unmanaged disks to managed disks

Summarize this article for me

Applies to: ✔ Windows VMs

On March 31st, 2026, unmanaged disks are being retired. If you're using unmanaged disks, migrate to managed disks before that date. For details on the retirement, see Migrate your Azure unmanaged disks by March 31st, 2026.

If you have existing Windows virtual machines (VMs) that use unmanaged disks, you can migrate the VMs to use managed disks through the Azure Managed Disks service. This process converts both the operating system (OS) disk and any attached data disks.

Before you begin

- Review Plan for the migration to Managed Disks.
- Review the FAQ about migration to Managed Disks.
- Ensure the VM is in a healthy sate before converting.
- The migration will restart the VM, so schedule the migration of your VMs during a pre-existing maintenance window.
- The migration isn't reversible.
- Be sure to test the migration. Migrate a test virtual machine before you perform the migration in production.
- During the migration, you deallocate the VM. The VM receives a new IP address when it's started after the migration. If needed, you can assign a static IP address to the VM.
- Review the minimum version of the Azure VM agent required to support the migration process. For information on how to check and update your agent version, see Minimum version support for VM agents in Azure
- The original VHDs and the storage account used by the VM before migration are not deleted. They continue to incur charges. To avoid being billed for these artifacts, delete the original VHD blobs after you verify that the migration is complete. If you need to find these unattached disks in order to delete them, see our article Find and delete unattached Azure managed and unmanaged disks.

Migrate single-instance VMs

This section covers how to migrate single-instance Azure VMs from unmanaged disks to managed disks. (If your VMs are in an availability set, see the next section.)

1. Deallocate the VM by using the Stop-AzVM cmdlet. The following example deallocates the VM named `myVM` in the resource group named `myResourceGroup`:

   Azure PowerShell

   ```
   $rgName = "myResourceGroup"
   $vmName = "myVM"
   Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force
   ```

2. Migrate the VM to managed disks by using the ConvertTo-AzVMManagedDisk cmdlet. The following process converts the previous VM, including the OS disk and any data disks, and starts the Virtual Machine:

   Azure PowerShell

   ```
   ConvertTo-AzVMManagedDisk -ResourceGroupName $rgName -VMName $vmName
   ```

Migrate VMs in an availability set

If the VMs that you want to migrate to managed disks are in an availability set, you first need to migrate the availability set to a managed availability set.

1. Migrate the availability set by using the Update-AzAvailabilitySet cmdlet. The following example updates the availability set named `myAvailabilitySet` in the resource group named `myResourceGroup`:

   Azure PowerShell

   ```
   $rgName = 'myResourceGroup'
   $avSetName = 'myAvailabilitySet'

   $avSet = Get-AzAvailabilitySet -ResourceGroupName $rgName -Name $avSetName
   Update-AzAvailabilitySet -AvailabilitySet $avSet -Sku Aligned
   ```

   If the region where your availability set is located has only 2 managed fault domains but the number of unmanaged fault domains is 3, this command shows an error similar to "The specified fault domain count 3 must fall in the range 1 to 2." To resolve the error, update the fault domain to 2 and update `Sku` to `Aligned` as follows:

Azure PowerShell

```
$avSet.PlatformFaultDomainCount = 2
Update-AzAvailabilitySet -AvailabilitySet $avSet -Sku Aligned
```

2. Deallocate and migrate the VMs in the availability set. The following script deallocates each VM by using the Stop-AzVM cmdlet, converts it by using ConvertTo-AzVMManagedDisk, and restarts it automatically as apart of the migration process:

Azure PowerShell

```
$avSet = Get-AzAvailabilitySet -ResourceGroupName $rgName -Name $avSetName

foreach($vmInfo in $avSet.VirtualMachinesReferences)
{
  $vm = Get-AzVM -ResourceGroupName $rgName | Where-Object {$_.Id -eq
$vmInfo.id}
  Stop-AzVM -ResourceGroupName $rgName -Name $vm.Name -Force
  ConvertTo-AzVMManagedDisk -ResourceGroupName $rgName -VMName $vm.Name
}
```

Troubleshooting

- Before converting, make sure all the VM extensions are in the 'Provisioning succeeded' state or the migration will fail with the error code 409.
- If there is an error during migration, or if a VM is in a failed state because of issues in a previous migration, run the `ConvertTo-AzVMManagedDisk` cmdlet again. A simple retry usually unblocks the situation.
- If you are converting a Linux VM to managed disks, use the latest version of the Azure Linux Agent. Operations using Azure Linux Agent versions '2.2.0' and earlier will likely fail. Running the migration on a generalized VM or a VM that belongs to a classic availability set is also not supported.
- If the migration fails with the "SnapshotCountExceeded" error, delete some snapshots and attempt the operation again.

Migrate using the Azure portal

You can also migrate unmanaged disks to managed disks using the Azure portal.

1. Sign in to the Azure portal.
2. Select the VM from the list of VMs in the portal.
3. In the blade for the VM, select **Disks** from the menu.
4. At the top of the **Disks** blade, select **Migrate to managed disks**.

5. If your VM is in an availability set, there will be a warning on the **Migrate to managed disks** blade that you need to migrate the availability set first. The warning should have a link you can click to migrate the availability set. Once the availability set is converted or if your VM is not in an availability set, click **Migrate** to start the process of migrating your disks to managed disks.

The VM will be stopped and restarted after migration is complete.

Next steps

Change the disk type of an Azure Managed Disk.

Take a read-only copy of a VM by using snapshots.

Create a managed disk from a VHD file in a storage account in the same subscription with CLI (Linux)

Article • 08/22/2024

This script creates a managed disk from a VHD file in a storage account in the same subscription. Use this script to import a specialized (not generalized/sysprepped) VHD to managed OS disk to create a virtual machine. Or, use it to import a data VHD to managed data disk.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Run the script

Azure CLI

```
#Provide the subscription Id
subscriptionId="<subscriptionId>"

#Provide the name of your resource group.
#Ensure that resource group is already created
resourceGroupName=myResourceGroupName

#Provide the name of the Managed Disk
diskName=myDiskName

#Provide the size of the disks in GB. It should be greater than the VHD file
size.
diskSize=128

#Provide the URI of the VHD file that will be used to create Managed Disk.
```

```
# VHD file can be deleted as soon as Managed Disk is created.
# e.g.
https://contosostorageaccount1.blob.core.windows.net/vhds/contosovhd123.vhd
vhdUri=https://contosostorageaccount1.blob.core.windows.net/vhds/contosoumd7
8620170425131836.vhd

#Provide the storage type for the Managed Disk. Premium_LRS or Standard_LRS.
storageType=Premium_LRS

#Provide the Azure location (e.g. westus) where Managed Disk will be
located.
#The location should be same as the location of the storage account where
VHD file is stored.
#Get all the Azure location supported for your subscription using command
below:
#az account list-locations
location=westus

#If you're creating an OS disk, uncomment the following lines and replace
the values
#osType = 'yourOSType' #Acceptable values are either Windows or Linux
#hyperVGeneration = 'yourHyperVGen' #Acceptable values are either v1 or v2

#Set the context to the subscription Id where Managed Disk will be created
az account set --subscription $subscriptionId

#Create the Managed disk from the VHD file
#If you're creating an OS disk, add the following: --os-type $osType -hyper-
v-generation $hyperVGeneration
az disk create --resource-group $resourceGroupName --name $diskName --sku
$storageType --location $location --size-gb $diskSize --source $vhdUri
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name myResourceGroupName
```

Sample reference

This script uses following commands to create a managed disk from a VHD. Each command in the table links to command specific documentation.

Expand table

Command	Notes
az disk create	Creates a managed disk using URI of a VHD in a storage account in the same subscription

Next steps

Create a virtual machine by attaching a managed disk as OS disk

For more information on the Azure CLI, see Azure CLI documentation.

Additional virtual machine and managed disks CLI script samples can be found in the Azure Linux VM documentation.

Create a managed disk from a snapshot with CLI (Linux)

Article • 08/22/2024

This article contains two scripts for creating a managed disk from a snapshot. The first script is for a managed disk with platform-managed keys and the second script is for a managed disk with customer-managed keys. Use these scripts to restore a virtual machine from snapshots of OS and data disks. Create OS and data managed disks from respective snapshots and then create a new virtual machine by attaching managed disks. You can also restore data disks of an existing VM by attaching data disks created from snapshots.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Disks with platform-managed keys

Azure CLI

```
#Provide the subscription Id of the subscription where you want to create
Managed Disks
subscriptionId="<subscriptionId>"

#Provide the name of your resource group
resourceGroupName=myResourceGroupName

#Provide the name of the snapshot that will be used to create Managed Disks
snapshotName=mySnapshotName

#Provide the name of the new Managed Disks that will be create
diskName=myDiskName

#Provide the size of the disks in GB. It should be greater than the VHD file
size.
diskSize=128
```

```
#Provide the storage type for Managed Disk. Acceptable values are
Standard_LRS, Premium_LRS, PremiumV2_LRS, StandardSSD_LRS, UltraSSD_LRS,
Premium_ZRS, and StandardSSD_ZRS.
storageType=Premium_LRS

#Required for Premium SSD v2 and Ultra Disks
#Provide the Availability Zone you'd like the disk to be created in, default
is 1
zone=1

#Set the context to the subscription Id where Managed Disk will be created
az account set --subscription $subscriptionId

#Get the snapshot Id
snapshotId=$(az snapshot show --name $snapshotName --resource-group
$resourceGroupName --query [id] -o tsv)

#Create a new Managed Disks using the snapshot Id
#Note that managed disk will be created in the same location as the snapshot
#If you're creating a Premium SSD v2 or an Ultra Disk, add "--zone $zone" to
the end of the command
az disk create --resource-group $resourceGroupName --name $diskName --sku
$storageType --size-gb $diskSize --source $snapshotId
```

Disks with customer-managed keys

Azure CLI

```
#Provide the subscription Id of the subscription where you want to create
Managed Disks
subscriptionId="<subscriptionId>"

#Provide the name of your resource group
resourceGroupName=myResourceGroupName

#Provide the name of the snapshot that will be used to create Managed Disks
snapshotName=mySnapshotName

#Provide the name of the new Managed Disks that will be create
diskName=myDiskName

#Provide the size of the disks in GB. It should be greater than the VHD file
size.
diskSize=128

#Provide the storage type for Managed Disk. Premium_LRS or Standard_LRS.
storageType=Premium_LRS

#Provide the name of the target disk encryption set
diskEncryptionSetName=myName
```

```
#Provide the target disk encryption set resource group
diskEncryptionResourceGroup=myGroup

#Required for Premium SSD v2 and Ultra Disks
#Provide the Availability Zone you'd like the disk to be created in, default
is 1
zone=1

#Set the context to the subscription Id where Managed Disk will be created
az account set --subscription $subscriptionId

#Get the snapshot Id
snapshotId=$(az snapshot show --name $snapshotName --resource-group
$resourceGroupName --query [id] -o tsv)

#Get the disk encryption set ID
diskEncryptionSetId=$(az disk-encryption-set show --name
$diskEncryptionSetName --resource-group $diskEncryptionResourceGroup)

#Create a new Managed Disks using the snapshot Id
#Note that managed disk will be created in the same location as the snapshot
#To change the location, add the --location parameter
#If you're creating a Premium SSD v2 or an Ultra Disk, add "--zone $zone" to
the end of the command
az disk create -g $resourceGroupName -n $diskName --source $snapshotId --
disk-encryption-set $diskEncryptionSetID --location eastus2euap
```

Performance impact - background copy process

When you create a managed disk from a snapshot, it starts a background copy process. You can attach a disk to a VM while this process is running but you'll experience performance impact (4k disks experience read impact, 512e experience both read and write impact) with higher latency, lower IOPS and throughput until background copy completes. For Ultra Disks and Premium SSD v2, you can check the status of the background copy process with the following commands:

> **ⓘ Important**
>
> You can't use the following sections to get the status of the background copy process for disk types other than Ultra Disk or Premium SSD v2. Other disk types will always report 100%.

Azure CLI

```
subscriptionId=yourSubscriptionID
resourceGroupName=yourResourceGroupName
diskName=yourDiskName
az account set --subscription $subscriptionId
az disk show -n $diskName -g $resourceGroupName --query [completionPercent]
-o tsv
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name myResourceGroupName
```

Sample reference

This script uses following commands to create a managed disk from a snapshot. Each command in the table links to command specific documentation.

Expand table

Command	Notes
az snapshot show	Gets all the properties of a snapshot using the name and resource group properties of the snapshot. ID property is used to create managed disk.
az disk create	Creates a managed disk using snapshot ID of a managed snapshot

Next steps

Create a virtual machine by attaching a managed disk as OS disk

For more information on the Azure CLI, see Azure CLI documentation.

More virtual machine and managed disks CLI script samples can be found in the Azure Linux VM documentation.

Create a managed disk from a VHD file in a storage account in same or different subscription with PowerShell

Article • 12/19/2024

This script creates a managed disk from a VHD file in a storage account in same or different subscription. Use this script to import a specialized (not generalized/sysprepped) VHD to managed OS disk to create a virtual machine. Also, use it to import a data VHD to managed data disk.

Don't create multiple identical managed disks from a VHD file in small amount of time. To create managed disks from a vhd file, blob snapshot of the vhd file is created and then it is used to create managed disks. Only one blob snapshot can be created in a minute that causes disk creation failures due to throttling. To avoid this throttling, create a managed snapshot from the vhd file and then use the managed snapshot to create multiple managed disks in short amount of time.

If you don't have an Azure subscription, create an Azure free account before you begin.

Sample script

PowerShell

```
<#

.DESCRIPTION

This sample demonstrates how to create a Managed Disk from a VHD file.
Create Managed Disks from VHD files in following scenarios:
1. Create a Managed OS Disk from a specialized VHD file. A specialized VHD
is a copy of VHD from an exisitng VM that maintains the user accounts,
applications and other state data from your original VM.
   Attach this Managed Disk as OS disk to create a new virtual machine.
2. Create a Managed data Disk from a VHD file. Attach the Managed Disk to an
existing VM or attach it as data disk to create a new virtual machine.

.NOTES

1. Before you use this sample, please install the latest version of Azure
PowerShell from here: http://go.microsoft.com/?linkid=9811175&clcid=0x409
2. Provide the appropriate values for each variable. Note: The angled
brackets should not be included in the values you provide.
```

```
#>

#Provide the subscription Id
$subscriptionId = 'yourSubscriptionId'

#Provide the name of your resource group
$resourceGroupName ='yourResourceGroupName'

#Provide the name of the Managed Disk
$diskName = 'yourDiskName'

#Provide the size of the disks in GB. It should be greater than the VHD file
size.
$diskSize = '128'

#Provide the URI of the VHD file that will be used to create Managed Disk.
# VHD file can be deleted as soon as Managed Disk is created.
# e.g. https://contosostorageaccount1.blob.core.windows.net/vhds/contoso-um-
vm120170302230408.vhd
$vhdUri =
'https://contososts torageaccount1.blob.core.windows.net/vhds/contosovhd123.v
hd'

#Provide the resource Id of the storage account where VHD file is stored.
#e.g. /subscriptions/6472s1g8-h217-446b-b509-
314e17e1efb0/resourceGroups/MDDemo/providers/Microsoft.Storage/storageAccoun
ts/contosostorageaccount
$storageAccountId =
'/subscriptions/yourSubscriptionId/resourceGroups/yourResourceGroupName/prov
iders/Microsoft.Storage/storageAccounts/yourStorageAccountName'

#Provide the storage type for the Managed Disk. PremiumLRS or StandardLRS.
$sku = 'Premium_LRS'

#Provide the Azure location (e.g. westus) where Managed Disk will be
located.
#The location should be same as the location of the storage account where
VHD file is stored.
#Get all the Azure location using command below:
#Get-AzureRmLocation
$location = 'westus'

#Set the context to the subscription Id where Managed Disk will be created
Set-AzContext -Subscription $subscriptionId

#If you're creating an OS disk, add the following lines
#Acceptable values are either Windows or Linux
#$OSType = 'yourOSType'
#Acceptable values are either V1 or V2
#$HyperVGeneration = 'yourHyperVGen'

#If you're creating an OS disk, add -HyperVGeneration and -OSType parameters
$diskConfig = New-AzDiskConfig -SkuName $sku -Location $location -DiskSizeGB
```

```
$diskSize -StorageAccountId $storageAccountId -SourceUri $vhdUri -
CreateOption Import

#Create Managed disk
New-AzDisk -DiskName $diskName -Disk $diskConfig -ResourceGroupName
$resourceGroupName
```

Script explanation

This script uses following commands to create a managed disk from a VHD in different subscription. Each command in the table links to command specific documentation.

Expand table

Command	Notes
New-AzDiskConfig	Creates disk configuration that is used for disk creation. It includes storage type, location, resource ID of the storage account where the parent VHD is stored, VHD URI of the parent VHD.
New-AzDisk	Creates a disk using disk configuration, disk name, and resource group name passed as parameters.

Next steps

Create a virtual machine by attaching a managed disk as OS disk

For more information on the Azure PowerShell module, see Azure PowerShell documentation.

Additional virtual machine PowerShell script samples can be found in the Azure Windows VM documentation.

Create a managed disk from a snapshot with PowerShell

This script creates a managed disk from a snapshot. Use it to restore a virtual machine from snapshots of OS and data disks. Create OS and data managed disks from respective snapshots and then create a new virtual machine by attaching managed disks. You can also restore data disks of an existing VM by attaching data disks created from snapshots.

If you don't have an Azure account, create a free account before you begin.

Sample script

PowerShell

```
#Provide the subscription Id
$subscriptionId = 'yourSubscriptionId'

#Provide the name of your resource group
$resourceGroupName ='yourResourceGroupName'

#Provide the name of the snapshot that will be used to create Managed Disks
$snapshotName = 'yourSnapshotName'

#Provide the name of the Managed Disk
$diskName = 'yourManagedDiskName'

#Provide the size of the disks in GB. It should be greater than the VHD file size.
$diskSize = '128'

#Provide the storage type for Managed Disk. Acceptable values are Standard_LRS,
Premium_LRS, PremiumV2_LRS, StandardSSD_LRS, UltraSSD_LRS, Premium_ZRS and
StandardSSD_ZRS.
$storageType = 'Premium_LRS'

#Required for Premium SSD v2 and Ultra Disks
#Provide the Availability Zone you'd like the disk to be created in, default is 1
$zone=1

#Provide the Azure region (e.g. westus) where Managed Disks will be located.
#This location should be same as the snapshot location
#Get all the Azure location using command below:
#Get-AzLocation
$location = 'westus'

#Set the context to the subscription Id where Managed Disk will be created
Select-AzSubscription -SubscriptionId $SubscriptionId

$snapshot = Get-AzSnapshot -ResourceGroupName $resourceGroupName -SnapshotName
$snapshotName
```

```
#If you're creating a Premium SSD v2 or an Ultra Disk, add "-Zone $zone" to the end
of the command
$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $location -
CreateOption Copy -SourceResourceId $snapshot.Id -DiskSizeGB $diskSize

New-AzDisk -Disk $diskConfig -ResourceGroupName $resourceGroupName -DiskName
$diskName
```

Performance impact - background copy process

When you create a managed disk from a snapshot, it starts a background copy process. You can attach a disk to a VM while this process is running but you'll experience performance impact (4k disks experience read impact, 512e experience both read and write impact). For Ultra Disks and Premium SSD v2, you can check the status of the background copy process with the Azure CLI or Azure PowerShell module. You can only check the status of the background copy process for Ultra Disks or Premium SSD v2 disks, other disk types always report 100%.

Script explanation

This script uses following commands to create a managed disk from a snapshot. Each command in the table links to command specific documentation.

Expand table

Command	Notes
Get-AzSnapshot	Gets snapshot properties.
New-AzDiskConfig	Creates disk configuration that is used for disk creation. It includes the resource Id of the parent snapshot, location that is same as the location of parent snapshot and the storage type.
New-AzDisk	Creates a disk using disk configuration, disk name, and resource group name passed as parameters.

Next steps

Create a virtual machine from a managed disk

For more information on the Azure PowerShell module, see Azure PowerShell documentation.

Additional virtual machine PowerShell script samples can be found in the Azure Windows VM documentation.

Create a snapshot from a VHD to create multiple identical managed disks in small amount of time with PowerShell (Windows)

Article • 08/22/2024

This script creates a snapshot from a VHD file in a storage account in same or different subscription. Use this script to import a specialized (not generalized/sysprepped) VHD to a snapshot and then use the snapshot to create multiple identical managed disks in small amount of time. Also, use it to import a data VHD to a snapshot and then use the snapshot to create multiple managed disks in small amount of time.

If you don't have an Azure subscription, create an Azure free account before you begin.

Sample script

PowerShell

```
#Provide the subscription Id where snapshot will be created
$subscriptionId = 'yourSubscriptionId'

#Provide the name of your resource group where snapshot will be created.
$resourceGroupName ='yourResourceGroupName'

#Provide the name of the snapshot
$snapshotName = 'yourSnapshotName'

#Provide the storage type for snapshot. PremiumLRS or StandardLRS.
$storageType = 'StandardLRS'

#Provide the Azure region (e.g. westus) where snapshot will be located.
#This location should be same as the storage account location where VHD file
is stored
#Get all the Azure location using command below:
#Get-AzLocation
$location = 'westus'

#Provide the URI of the VHD file (page blob) in a storage account. Please
not that this is NOT the SAS URI of the storage container where VHD file is
stored.
#e.g.
https://contosostorageaccount1.blob.core.windows.net/vhds/contosovhd123.vhd
#Note: VHD file can be deleted as soon as Managed Disk is created.
```

```
$sourceVHDURI =
'https://yourStorageAccountName.blob.core.windows.net/vhds/yourVHDName.vhd'

#Provide the resource Id of the storage account where VHD file is stored.
#e.g. /subscriptions/6582b1g7-e212-446b-b509-
314e17e1efb0/resourceGroups/MDDemo/providers/Microsoft.Storage/storageAccoun
ts/contosostorageaccount1
#This is an optional parameter if you are creating snapshot in the same
subscription
$storageAccountId =
'/subscriptions/yourSubscriptionId/resourceGroups/yourResourceGroupName/prov
iders/Microsoft.Storage/storageAccounts/yourStorageAccountName'

#Set the context to the subscription Id where Managed Disk will be created
Select-AzSubscription -SubscriptionId $SubscriptionId

$snapshotConfig = New-AzSnapshotConfig -AccountType $storageType -Location
$location -CreateOption Import -StorageAccountId $storageAccountId -
SourceUri $sourceVHDURI

New-AzSnapshot -Snapshot $snapshotConfig -ResourceGroupName
$resourceGroupName -SnapshotName $snapshotName
```

Create a virtual machine from a snapshot with CLI

Article • 08/22/2024

This script creates a virtual machine from a snapshot of an OS disk.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Run the script

Azure CLI

```
#Provide the subscription Id of the subscription where you want to create
Managed Disks
subscriptionId="<subscriptionId>"

#Provide the name of your resource group
resourceGroupName=myResourceGroupName

#Provide the name of the snapshot that will be used to create Managed Disks
snapshotName=mySnapshotName

#Provide the name of the Managed Disk
osDiskName=myOSDiskName

#Provide the size of the disks in GB. It should be greater than the VHD file
size.
diskSize=128

#Provide the storage type for Managed Disk. Premium_LRS or Standard_LRS.
storageType=Premium_LRS

#Provide the OS type
osType=linux

#Provide the name of the virtual machine
virtualMachineName=myVirtualMachineName
```

```
#Set the context to the subscription Id where Managed Disk will be created
az account set --subscription $subscriptionId

#Get the snapshot Id
snapshotId=$(az snapshot show --name $snapshotName --resource-group
$resourceGroupName --query [id] -o tsv)

#Create a new Managed Disks using the snapshot Id
az disk create --resource-group $resourceGroupName --name $osDiskName --sku
$storageType --size-gb $diskSize --source $snapshotId

#Create VM by attaching created managed disks as OS
az vm create --name $virtualMachineName --resource-group $resourceGroupName
--attach-os-disk $osDiskName --os-type $osType
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name myResourceGroupName
```

Sample reference

This script uses the following commands to create a managed disk, virtual machine, and all related resources. Each command in the table links to command specific documentation.

Expand table

Command	Notes
az snapshot show	Gets snapshot using snapshot name and resource group name. Id property of the returned object is used to create a managed disk.
az disk create	Creates managed disks from a snapshot using snapshot Id, disk name, storage type, and size
az vm create	Creates a VM using a managed OS disk

Next steps

For more information on the Azure CLI, see Azure CLI documentation.

Additional virtual machine CLI script samples can be found in the Azure Linux VM documentation.

Create a virtual machine using an existing managed OS disk with CLI

Article • 08/22/2024

This script creates a virtual machine by attaching an existing managed disk as OS disk. Use this script in preceding scenarios:

- Create a VM from an existing managed OS disk that was copied from a managed disk in different subscription
- Create a VM from an existing managed disk that was created from a specialized VHD file
- Create a VM from an existing managed OS disk that was created from a snapshot

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment, Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an Azure subscription, create an Azure free account before you begin.

Azure CLI

```
subscription="<subscriptionId>" # add subscription here

az account set -s $subscription # ...or use 'az login'
```

For more information, see set active subscription or log in interactively

Run the script

Azure CLI

```
#Provide the subscription Id
subscriptionId="<subscriptionId>"

#Provide the name of your resource group
resourceGroupName=myResourceGroupName

#Provide the name of the Managed Disk
managedDiskName=myDiskName

#Provide the OS type
osType=linux

#Provide the name of the virtual machine
virtualMachineName=myVirtualMachineName123

#Set the context to the subscription Id where Managed Disk exists and where
```

```
VM will be created
az account set --subscription $subscriptionId

#Get the resource Id of the managed disk
managedDiskId=$(az disk show --name $managedDiskName --resource-group
$resourceGroupName --query [id] -o tsv)

#Create VM by attaching existing managed disks as OS
az vm create --name $virtualMachineName --resource-group $resourceGroupName
--attach-os-disk $managedDiskId --os-type $osType
```

Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

Azure CLI

```
az group delete --name myResourceGroupName
```

Sample reference

This script uses the following commands to get managed disk properties, attach a managed disk to a new VM and create a VM. Each item in the table links to command specific documentation.

Expand table

Command	Notes
az disk show	Gets managed disk properties using disk name and resource group name. Id property is used to attach a managed disk to a new VM
az vm create	Creates a VM using a managed OS disk

Next steps

For more information on the Azure CLI, see Azure CLI documentation.

Additional virtual machine CLI script samples can be found in the Azure Linux VM documentation.

Add a disk to a Linux VM

09/18/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to attach a persistent disk to your virtual machine (VM) to preserve your data, even if your VM is reprovisioned due to maintenance or resizing.

Attach a new disk to a VM

If you want to add a new, empty data disk to your VM, use the az vm disk attach command with the `--new` parameter. If your VM is in an Availability Zone, the disk is automatically created in the same zone as the VM. For more information, see Overview of Availability Zones. The following example creates a disk named *myDataDisk* that is 50 GB in size:

Azure CLI

```
az vm disk attach \
   -g myResourceGroup \
   --vm-name myVM \
   --name myDataDisk \
   --new \
   --size-gb 50
```

Lower latency

In select regions, disk attach latency is reduced. In those regions, there's an improvement of up to 15%. This improvement is useful if you have planned or unplanned failovers between VMs, you're scaling your workload, or you're running a high-scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk attach command, `az vm disk attach`. You won't see the performance improvement if you call a command that might implicitly perform an attach, like `az vm update`. You don't need to take any action other than calling the explicit attach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US
- East US 2
- South Central US
- West US 2

- Germany North
- India West
- North Europe
- West Europe

Attach an existing disk

To attach an existing disk, find the disk ID and pass the ID to the az vm disk attach command. The following example queries for a disk named *myDataDisk* in *myResourceGroup*, then attaches it to the VM named *myVM*:

Azure CLI

```
diskId=$(az disk show -g myResourceGroup -n myDataDisk --query 'id' -o tsv)

az vm disk attach -g myResourceGroup --vm-name myVM --name $diskId
```

Identifying disks

Azure Linux VMs use different disk interfaces depending on the VM size and generation:

- VM sizes v6 and newer: Use NVMe interface for improved performance
- VM sizes v5 and older: Use SCSI interface for disk management

For details about SCSI vs NVMe differences, see SCSI to NVMe conversion.

Connect to the virtual machine

To identify disks associated with your Linux VM, connect to the VM by using SSH. For details, see How to use SSH with Linux on Azure. The following example connects to a VM with the public IP address of 10.123.123.25 with the username azureuser:

Bash

```
ssh azureuser@10.123.123.25
```

> **Note**
>
> Before identifying specific disks, determine whether your VM uses SCSI, NVMe, or a combination of both interfaces.

Azure-VM-Utils

The azure-vm-utils package provides utilities to optimize the Linux experience on Azure VMs, making disk identification more reliable across different VM configurations.

Use the following commands to list disks on the VM:

Bash

```
# List all disks
sudo azure-disk-list

# List NVMe disks with detailed information
sudo azure-nvme-id
```

The output from `azure-nvme-id` is similar to:

```
/dev/nvme0n1: type=os
/dev/nvme0n2: type=data, lun=0
/dev/nvme1n1: type=local, index=1, name=nvme-50G-1
```

Next Steps

- Format and mount the disks based on your requirements and use case. Review instructions for formatting and mounting managed disks and temporary disks.
- Learn about Azure-VM-Utils.

Attach a data disk to a Windows VM with PowerShell

Article • 12/09/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

This article shows you how to attach both new and existing disks to a Windows virtual machine by using PowerShell.

First, review these tips:

- The size of the virtual machine controls how many data disks you can attach. For more information, see Sizes for virtual machines.
- To use premium SSDs, you'll need a premium storage-enabled VM type, like the DS-series or GS-series virtual machine.

This article uses PowerShell within the Azure Cloud Shell, which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

Lower latency

In select regions, the disk attach latency has been reduced, so you'll see an improvement of up to 15%. This is useful if you have planned/unplanned failovers between VMs, you're scaling your workload, or are running a high scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk attach command, `Add-AzVMDataDisk`. You won't see the performance improvement if you call a command that may implicitly perform an attach, like `Update-AzVM`. You don't need to take any action other than calling the explicit attach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US
- East US 2
- South Central US
- West US 2
- Germany North
- India West
- North Europe

- West Europe

Add an empty data disk to a virtual machine

This example shows how to add an empty data disk to an existing virtual machine.

Using managed disks

Azure PowerShell

```
$rgName = 'myResourceGroup'
$vmName = 'myVM'
$location = 'East US'
$storageType = 'Premium_LRS'
$dataDiskName = $vmName + '_datadisk1'

$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $location -
CreateOption Empty -DiskSizeGB 128
$dataDisk1 = New-AzDisk -DiskName $dataDiskName -Disk $diskConfig -
ResourceGroupName $rgName

$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName
$vm = Add-AzVMDataDisk -VM $vm -Name $dataDiskName -CreateOption Attach -
ManagedDiskId $dataDisk1.Id -Lun 1

Update-AzVM -VM $vm -ResourceGroupName $rgName
```

Using managed disks in an Availability Zone

To create a disk in an Availability Zone, use New-AzDiskConfig with the `-Zone` parameter. The following example creates a disk in zone *1*.

PowerShell

```
$rgName = 'myResourceGroup'
$vmName = 'myVM'
$location = 'East US 2'
$storageType = 'Premium_LRS'
$dataDiskName = $vmName + '_datadisk1'

$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $location -
CreateOption Empty -DiskSizeGB 128 -Zone 1
$dataDisk1 = New-AzDisk -DiskName $dataDiskName -Disk $diskConfig -
ResourceGroupName $rgName

$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName
$vm = Add-AzVMDataDisk -VM $vm -Name $dataDiskName -CreateOption Attach -
ManagedDiskId $dataDisk1.Id -Lun 1
```

```
Update-AzVM -VM $vm -ResourceGroupName $rgName
```

Initialize the disk

After you add an empty disk, you'll need to initialize it. To initialize the disk, you can sign in to a VM and use disk management. If you enabled WinRM and a certificate on the VM when you created it, you can use remote PowerShell to initialize the disk. You can also use a custom script extension:

Azure PowerShell

```
    $location = "location-name"
    $scriptName = "script-name"
    $fileName = "script-file-name"
    Set-AzVMCustomScriptExtension -ResourceGroupName $rgName -Location
$locName -VMName $vmName -Name $scriptName -TypeHandlerVersion "1.4" -
StorageAccountName "mystore1" -StorageAccountKey "primary-key" -FileName
$fileName -ContainerName "scripts"
```

The script file can contain code to initialize the disks, for example:

> **Note**
>
> The example script uses MBR partition style. If your disk is two tebibytes (TiB) or larger, you must use GPT partitioning. If it's under two TiB, you can use either MBR or GPT.

Azure PowerShell

```
    $disks = Get-Disk | Where partitionstyle -eq 'raw' | sort number

    $letters = 70..89 | ForEach-Object { [char]$_ }
    $count = 0
    $labels = "data1","data2"

    foreach ($disk in $disks) {
        $driveLetter = $letters[$count].ToString()
        $disk |
        Initialize-Disk -PartitionStyle MBR -PassThru |
        New-Partition -UseMaximumSize -DriveLetter $driveLetter |
        Format-Volume -FileSystem NTFS -NewFileSystemLabel $labels[$count] -
Confirm:$false -Force
    $count++
    }
```

Attach an existing data disk to a VM

You can attach an existing managed disk to a VM as a data disk.

Azure PowerShell

```
$rgName = "myResourceGroup"
$vmName = "myVM"
$dataDiskName = "myDisk"
$disk = Get-AzDisk -ResourceGroupName $rgName -DiskName $dataDiskName

$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName

$vm = Add-AzVMDataDisk -CreateOption Attach -Lun 0 -VM $vm -ManagedDiskId
$disk.Id

Update-AzVM -VM $vm -ResourceGroupName $rgName
```

Next steps

You can also deploy managed disks using templates. For more information, see Using Managed Disks in Azure Resource Manager Templates or the quickstart template for deploying multiple data disks.

Use the D: drive as a data drive on a Windows VM

Article • 08/22/2024

Applies to: ✔ Windows VMs

If your application needs to use the D drive to store data, follow these instructions to use a different drive letter for the temporary disk. Never use the temporary disk to store data that you need to keep.

If you resize or **Stop (Deallocate)** a virtual machine, this may trigger placement of the virtual machine to a new hypervisor. A planned or unplanned maintenance event may also trigger this placement. In this scenario, the temporary disk will be reassigned to the first available drive letter. If you have an application that specifically requires the D: drive, you need to follow these steps to temporarily move the pagefile.sys, attach a new data disk and assign it the letter D and then move the pagefile.sys back to the temporary drive. Once complete, Azure will not take back the D: if the VM moves to a different hypervisor.

For more information about how Azure uses the temporary disk, see Understanding the temporary drive on Microsoft Azure Virtual Machines

Attach the data disk

First, you'll need to attach the data disk to the virtual machine. To do this using the portal, see How to attach a managed data disk in the Azure portal.

Temporarily move pagefile.sys to C drive

1. Connect to the virtual machine.
2. Right-click the **Start** menu and select **System**.
3. In the left-hand menu, search for and select **View advanced system settings**.
4. In the **Performance** section, select **Settings**.
5. Select the **Advanced** tab.
6. In the **Virtual memory** section, select **Change**.
7. Select the **C** drive and then click **System managed size** and then click **Set**.
8. Select the **D** drive and then click **No paging file** and then click **Set**.
9. Click Apply. You will get a warning that the computer needs to be restarted for the changes to take affect.

10. Restart the virtual machine.

Change the drive letters

1. Once the VM restarts, log back on to the VM.
2. Click the **Start** menu and type **diskmgmt.msc** and hit Enter. Disk Management will start.
3. Right-click on **D**, the Temporary Storage drive, and select **Change Drive Letter and Paths**.
4. Under Drive letter, select a new drive such as **T** and then click **OK**.
5. Right-click on the data disk, and select **Change Drive Letter and Paths**.
6. Under Drive letter, select drive **D** and then click **OK**.

Move pagefile.sys back to the temporary storage drive

1. Right-click the **Start** menu and select **System**
2. In the left-hand menu, search for and select **View advanced system settings**.
3. In the **Performance** section, select **Settings**.
4. Select the **Advanced** tab.
5. In the **Virtual memory** section, select **Change**.
6. Select the OS drive **C** and click **No paging file** and then click **Set**.
7. Select the temporary storage drive **T** and then click **System managed size** and then click **Set**.
8. Click **Apply**. You will get a warning that the computer needs to be restarted for the changes to take affect.
9. Restart the virtual machine.

Next steps

- You can increase the storage available to your virtual machine by attaching an additional data disk.

Format and mount managed disks

09/18/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article covers how to format, mount, and persist managed disks on Azure Linux virtual machines (VMs). Managed disks are persistent storage attached to your VM that can use either SCSI or NVMe interfaces depending on your VM size.

Prerequisites

Before formatting and mounting a data disk, ensure you have:

- Identify the correct disk to avoid data loss
- SSH access to your VM
- Root or sudo privileges

> ⚠ **Warning**
>
> Always verify you're working with the correct disk before formatting. Formatting the wrong disk can result in data loss.

Format the disk

Use the latest version of `parted` available for your distribution. If the disk size is 2 tebibytes (TiB) or larger, use GPT partitioning. If the disk size is under 2 TiB, then you can use either MBR or GPT partitioning.

Once you've identified the correct disk (for example, `/dev/nvme0n2` for a data disk), you can format it:

SCSI

The following example uses `parted` on `/dev/sdc`, which is where the first data disk typically is on most VMs. Replace `sdc` with the correct option for your disk. It also formats the disk by using the XFS file system.

Bash

```
sudo parted /dev/sdc --script mklabel gpt mkpart xfspart xfs 0% 100%
sudo partprobe /dev/sdc
```

```
sudo mkfs.xfs /dev/sdc1
```

Use the partprobe utility to ensure the kernel is aware of the new partition and file system. If you don't use `partprobe`, then the `blkid` and the `lsblk` commands won't immediately return the UUID for the new file system.

Mount the disk

Now, create a directory to mount the file system by using `mkdir`. The following example creates a directory at `/datadrive`:

Bash

```
sudo mkdir /datadrive
```

Use `mount` to then mount the file system. The following example mounts the `/dev/sdc1` (for SCSI) or `/dev/nvme0n2p1` (for NVMe) partition to the `/datadrive` mount point:

SCSI

Bash

```
# Mount the disk identified earlier (replace sdc1 with your identified disk's partition)
sudo mount /dev/sdc1 /datadrive
```

You can also use the Azure device path:

Bash

```
sudo mount /dev/disk/azure/scsi1/lun0-part1 /datadrive
```

Persist the mount

To ensure that the drive is remounted automatically after a reboot, add it to the `/etc/fstab` file.

It's highly recommended that the UUID (Universally Unique Identifier) is used in `/etc/fstab` to refer to the drive rather than the device path (such as /dev/sdc1). Device paths aren't persistent

and change on reboot. To find the UUID of the new drive, use the `blkid` utility:

Bash

```
sudo blkid
```

The output looks similar to the following example:

```
/dev/sda1: LABEL="cloudimg-rootfs" UUID="11111111-1b1b-1c1c-1d1d-1e1e1e1e1e1e"
TYPE="ext4" PARTUUID="1a1b1c1d-11aa-1234-1a1a1a1a1a1a"
/dev/sda15: LABEL="UEFI" UUID="BCD7-96A6" TYPE="vfat" PARTUUID="1e1g1cg1h-11aa-
1234-1u1u1a1a1u1u"
/dev/sdb1: UUID="22222222-2b2b-2c2c-2d2d-2e2e2e2e2e2e" TYPE="ext4" TYPE="ext4"
PARTUUID="1a2b3c4d-01"
/dev/sda14: PARTUUID="2e2g2cg2h-11aa-1234-1u1u1a1a1u1u"
/dev/sdc1: UUID="33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e" TYPE="xfs"
PARTLABEL="xfspart" PARTUUID="c1c2c3c4-1234-cdef-asdf3456ghjk"
```

> **⚠ Warning**
>
> Improperly editing the `/etc/fstab` file could result in an unbootable system. If you're unsure, see your distribution's documentation for information on how to properly edit this file. You should also create a backup of the `/etc/fstab` file before editing.

Next, open the `/etc/fstab` file in a text editor. Add a line to the end of the file, by using the UUID value for the disk that was created in the previous steps, and the mountpoint of `/datadrive`. Using the example from this article, the new line would look like the following:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e   /datadrive   xfs   defaults,nofail   1
2
```

When you're done editing the file, save and close the editor.

Alternatively, you can run the following command to add the disk to the `/etc/fstab` file:

Bash

```
# For SCSI disks
UUID=$(sudo blkid -s UUID -o value /dev/sdc1)
echo "UUID=$UUID   /datadrive   xfs   defaults,nofail   1   2" | sudo tee -a
/etc/fstab
```

```
# For NVMe disks
UID=$(sudo blkid -s UUID -o value /dev/nvme1n1p1)
echo "UUID=$UUID   /datadrive   xfs   defaults,nofail   1   2" | sudo tee -a
/etc/fstab
```

> ⓘ Note
>
> Later removing a data disk without editing fstab could cause the VM to fail to boot. Most distributions provide either the `nofail` and/or `nobootwait` fstab options. These options allow a system to boot even if the disk fails to mount at boot time. See your distribution's documentation for details on these parameters.

The `nofail` option ensures that the VM starts even if the filesystem is corrupt or the disk doesn't exist at boot time. Without this option, you might encounter behavior as described in Cannot SSH to Linux VM due to FSTAB errors

The Azure VM Serial Console can be used for console access to your VM if modifying fstab results in a boot failure. More details are available in the Serial Console documentation.

TRIM/UNMAP support for Linux in Azure

Some Linux kernels support TRIM/UNMAP operations to discard unused blocks on the disk. This feature is primarily useful to inform Azure that deleted pages are no longer valid and can be discarded. This feature can save money on disks that are billed based on the amount of consumed storage, such as unmanaged standard disks and disk snapshots.

There are two ways to enable TRIM support in your Linux VM. As usual, consult your distribution for the recommended approach:

• Use the `discard` mount option in `/etc/fstab`, for example:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e   /datadrive   xfs   defaults,discard
1   2
```

• In some cases, the `discard` option might have performance implications. Alternatively, you can run the `fstrim` command manually from the command line, or add it to your crontab to run regularly:

Ubuntu

Bash

```
sudo apt install util-linux
sudo fstrim /datadrive
```

Troubleshooting

When adding data disks to a Linux VM, you may encounter errors if a disk does not exist at LUN 0. If you are adding a disk manually using the `az vm disk attach -new` command and you specify a LUN (`--lun`) rather than allowing the Azure platform to determine the appropriate LUN, take care that a disk already exists / will exist at LUN 0.

Consider the following example showing a snippet of the output from `lsscsi`:

Bash

```
[5:0:0:0]    disk    Msft     Virtual Disk     1.0   /dev/sdc
[5:0:0:1]    disk    Msft     Virtual Disk     1.0   /dev/sdd
```

The two data disks exist at LUN 0 and LUN 1 (the first column in the `lsscsi` output details `[host:channel:target:lun]`). Both disks should be accessible from within the VM. If you had manually specified the first disk to be added at LUN 1 and the second disk at LUN 2, you may not see the disks correctly from within your VM.

> **Note**
>
> The Azure `host` value is 5 in these examples, but this may vary depending on the type of storage you select.

This disk behavior is not an Azure problem, but the way in which the Linux kernel follows the SCSI specifications. When the Linux kernel scans the SCSI bus for attached devices, a device must be found at LUN 0 in order for the system to continue scanning for additional devices. As such:

- Review the output of `lsscsi` after adding a data disk to verify that you have a disk at LUN 0.
- If your disk does not show up correctly within your VM, verify a disk exists at LUN 0.

Format and mount temporary disk to Azure Linux VMs

09/18/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article covers how to format and mount temporary disks (also known as resource disks) on Azure Linux virtual machines (VMs). Depending on your VM series, temporary disks use either SCSI or NVMe interfaces. Temporary disks aren't managed disks, and aren't persistent.

Store important data on managed disks instead of local temporary disks. Temporary disks are generally meant to store items like page files, swap files, or SQL Server tempdb files.

Prerequisites

Before formatting temporary disks:

- Identify the correct disk to avoid data loss
- Understand that data isn't persistent across VM stops/deallocations
- Have SSH access to your VM with root or sudo privileges

Format disks

> ⚠ **Warning**
>
> Formatting will permanently erase all data on the disk. Ensure you're working with the correct disk and that no important data exists on it.

Use the latest version of `parted` available for your distribution. If the disk size is 2 tebibytes (TiB) or larger, you must use GPT partitioning. If the disk size is under 2 TiB, then you can use either MBR or GPT partitioning.

SCSI disks

The following example uses `parted` on `/dev/sdb`, which is typically where the SCSI temporary disks appear. Replace `sdb` with the correct device for your disk. We're using the XFS file system for better performance.

Bash

```
sudo parted /dev/disk/azure/resource --script mklabel gpt mkpart xfspart xfs
0% 100%
sudo partprobe /dev/sdb
sudo mkfs.xfs /dev/sdb1
```

Use the partprobe utility to make sure the kernel is aware of the new partition and file system. If you don't use `partprobe`, then `blkid` or `lsblk` commands might not return the UUID for the new file system immediately.

Mount temporary disks

Now, create a directory to mount the file system by using `mkdir`. For temporary storage, common mount points include `/mnt`, `/tmp`, or application-specific directories.

Bash

```
sudo mkdir /mnt/temp
```

SCSI disks

Use `mount` to mount the file system. The following example mounts the `/dev/sdb1` partition to the `/mnt/temp` mount point:

Bash

```
sudo mount /dev/sdb1 /mnt/temp
```

You can also use the Azure device path:

Bash

```
sudo mount /dev/disk/azure/resource-part1 /mnt/temp
```

TRIM/UNMAP support for temporary disks

Local temporary disks support TRIM/UNMAP operations. For optimal performance:

Use the `discard` mount option in `/etc/fstab`:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e   /mnt/temp   xfs
defaults,discard,nobootwait   0   0
```

Alternatively, run `fstrim` periodically:

Ubuntu

Bash

```
sudo apt install util-linux
sudo fstrim /mnt/temp
```

Troubleshooting

When adding data disks to a Linux VM, you may encounter errors if a disk does not exist at LUN 0. If you are adding a disk manually using the `az vm disk attach -new` command and you specify a LUN (`--lun`) rather than allowing the Azure platform to determine the appropriate LUN, take care that a disk already exists / will exist at LUN 0.

Consider the following example showing a snippet of the output from `lsscsi`:

Bash

```
[5:0:0:0]    disk    Msft     Virtual Disk     1.0   /dev/sdc
[5:0:0:1]    disk    Msft     Virtual Disk     1.0   /dev/sdd
```

The two data disks exist at LUN 0 and LUN 1 (the first column in the `lsscsi` output details `[host:channel:target:lun]`). Both disks should be accessible from within the VM. If you had manually specified the first disk to be added at LUN 1 and the second disk at LUN 2, you may not see the disks correctly from within your VM.

> **Note**
>
> The Azure `host` value is 5 in these examples, but this may vary depending on the type of storage you select.

This disk behavior is not an Azure problem, but the way in which the Linux kernel follows the SCSI specifications. When the Linux kernel scans the SCSI bus for attached devices, a device

must be found at LUN 0 in order for the system to continue scanning for additional devices. As such:

- Review the output of `lsscsi` after adding a data disk to verify that you have a disk at LUN 0.
- If your disk does not show up correctly within your VM, verify a disk exists at LUN 0.

How to detach a data disk from a Linux virtual machine

Article • 12/09/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When you no longer need a data disk that's attached to a virtual machine, you can easily detach it. This removes the disk from the virtual machine (VM), but doesn't remove it from storage. In this article, we're working with an Ubuntu LTS 16.04 distribution. If you're using a different distribution, the instructions for unmounting the disk might be different.

> ⚠ **Warning**
>
> If you detach a disk it is not automatically deleted. If you have subscribed to Premium storage, you will continue to incur storage charges for the disk. For more information, see Pricing and Billing when using Premium Storage.

If you want to use the existing data on the disk again, you can reattach it to the same virtual machine, or another one.

Connect to the VM to unmount the disk

Before you can detach the disk using either CLI or the portal, you need to unmount the disk and removed references to if from your fstab file.

Connect to the VM. In this example, the public IP address of the VM is *10.0.1.4* with the username *azureuser*:

Bash

```
ssh azureuser@10.0.1.4
```

First, find the data disk that you want to detach. The following example uses dmesg to filter on SCSI disks:

Bash

```
dmesg | grep SCSI
```

The output is similar to the following example:

Output

```
[    0.294784] SCSI subsystem initialized
[    0.573458] Block layer SCSI generic (bsg) driver version 0.4 loaded
(major 252)
[    7.110271] sd 2:0:0:0: [sda] Attached SCSI disk
[    8.079653] sd 3:0:1:0: [sdb] Attached SCSI disk
[ 1828.162306] sd 5:0:0:0: [sdc] Attached SCSI disk
```

Here, *sdc* is the disk that we want to detach. You also should grab the UUID of the disk.

Bash

```
sudo -i blkid
```

The output looks similar to the following example:

Output

```
/dev/sda1: UUID="11111111-1b1b-1c1c-1d1d-1e1e1e1e1e1e" TYPE="ext4"
/dev/sdb1: UUID="22222222-2b2b-2c2c-2d2d-2e2e2e2e2e2e" TYPE="ext4"
/dev/sdc1: UUID="33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e" TYPE="ext4"
```

Edit the */etc/fstab* file to remove references to the disk.

> **Note**
>
> Improperly editing the **/etc/fstab** file could result in an unbootable system. If unsure, refer to the distribution's documentation for information on how to properly edit this file. It is also recommended that a backup of the /etc/fstab file is created before editing.

Open the **/etc/fstab** file in a text editor and remove the line containing the UUID of your disk. Using the example values in this article, the line would look like the following:

config

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e   /datadrive   ext4
defaults,nofail   1   2
```

Save and close the file when you're done.

Next, use `umount` to unmount the disk. The following example unmounts the */dev/sdc1* partition from the */datadrive* mount point:

```
Bash

sudo umount /dev/sdc1 /datadrive
```

Detach a data disk using Azure CLI

This example detaches the *myDataDisk* disk from VM named *myVM* in *myResourceGroup*.

```
Azure CLI

az vm disk detach -g myResourceGroup --vm-name myVm -n myDataDisk
```

The disk stays in storage but is no longer attached to a virtual machine.

Lower latency

In select regions, the disk detach latency has been reduced, so you see an improvement of up to 15%. This is useful if you have planned/unplanned failovers between VMs, you're scaling your workload, or are running a high scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk detach command, `az vm disk detach`. You won't see the performance improvement if you call a command that may implicitly perform a detach, like `az vm update`. You don't need to take any action other than calling the explicit detach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US
- East US 2
- South Central US
- West US 2
- Germany North
- India West
- North Europe
- West Europe

Detach a data disk using the portal

1. In the left menu, select **Virtual Machines**.
2. In the virtual machine blade, select **Disks**.
3. In the **Disks** blade, to the far right of the data disk that you would like to detach, select the detach button, to detach the disk.
4. After the disk has been removed, select **Save** on the top of the blade.

The disk stays in storage but is no longer attached to a virtual machine. The disk isn't deleted.

Next steps

If you want to reuse the data disk, you can just attach it to another VM.

If you want to delete the disk, so that you no longer incur storage costs, see Find and delete unattached Azure managed and unmanaged disks - Azure portal.

Expand virtual hard disks on a Linux VM

06/19/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article covers expanding operating system (OS) disks and data disks for a Linux virtual machine (VM). You can add data disks to provide more storage space, and you can also expand an existing data disk. The default virtual hard disk size for the OS is typically 30 GB on a Linux VM in Azure. This article covers expanding either OS disks or data disks. You can't expand the size of striped volumes.

An OS disk has a maximum capacity of 4,095 GiB. However, many operating systems are partitioned with master boot record (MBR) by default. MBR limits the usable size to 2 TiB. If you need more than 2 TiB, consider attaching data disks for data storage. If you do need to store data on the OS disk and require extra space, convert it to a GUID Partition Table (GPT).

> **⚠ Warning**
>
> Always make sure that your filesystem is in a healthy state and your disk partition table type (GPT or MBR) can support the new size. Back up your data before you perform disk expansion operations. For more information, see the Azure Backup quickstart.

Identify an Azure data disk object within the operating system

When you expand a data disk that has several data disks on the VM, it might be difficult to relate the Azure logical unit numbers (LUNs) to the Linux devices. If the OS disk needs expansion, it's clearly labeled in the Azure portal as the OS disk.

Start by identifying the relationship between disk utilization, mount point, and device, with the `df` command.

Bash

```
df -Th
```

Output

```
Filesystem              Type      Size  Used Avail Use% Mounted on
/dev/sda1               xfs        97G  1.8G   95G   2% /
<truncated>
```

```
/dev/sdd1                ext4       32G   30G  727M  98% /opt/db/data
/dev/sde1                ext4       32G   49M   30G   1% /opt/db/log
```

Here you can see, for example, that the `/opt/db/data` filesystem is nearly full and is located on the `/dev/sdd1` partition. The output of `df` shows the device path whether the disk is mounted by using the device path or the (preferred) UUID in the fstab. Note the Type column, which indicates filesystem format. The format is important later.

Now locate the LUN that correlates to `/dev/sdd` by examining the contents of `/dev/disk/azure/scsi1`. The output of the following `ls` command shows that the device known as `/dev/sdd` within the Linux OS is located at `LUN1` when you look in the Azure portal.

Bash

```
sudo ls -alF /dev/disk/azure/scsi1/
```

Output

```
total 0
drwxr-xr-x. 2 root root 140 Sep  9 21:54 ./
drwxr-xr-x. 4 root root  80 Sep  9 21:48 ../
lrwxrwxrwx. 1 root root  12 Sep  9 21:48 lun0 -> ../../../sdc
lrwxrwxrwx. 1 root root  12 Sep  9 21:48 lun1 -> ../../../sdd
lrwxrwxrwx. 1 root root  13 Sep  9 21:48 lun1-part1 -> ../../../sdd1
lrwxrwxrwx. 1 root root  12 Sep  9 21:54 lun2 -> ../../../sde
lrwxrwxrwx. 1 root root  13 Sep  9 21:54 lun2-part1 -> ../../../sde1
```

Expand an Azure managed disk

Expand without downtime

You can expand your managed disks without deallocating your VM. The host cache setting of your disk doesn't change whether or not you can expand a data disk without deallocating your VM.

This feature has the following limitations.

> **ⓘ Important**
>
> This limitation doesn't apply to Premium SSD v2 or Ultra Disks.
>
> If a Standard HDD, Standard SSD, or Premium SSD disk is 4 TiB or less, deallocate your VM and detach the disk before you expand it beyond 4 TiB. If one of those disk types is

already greater than 4 TiB, you can expand it without deallocating the VM and detaching the disk.

- Is supported only for data disks.
- Isn't supported for shared disks.
- Must be installed and use one of the following options:
  - The latest Azure CLI.
  - The latest Azure PowerShell module.
  - The Azure portal.
  - An Azure Resource Manager template with an API version that's `2021-04-01` or newer.
- Isn't available on some classic VMs. Use this script to get a list of classic VM products that support expanding without downtime.

Expand with Ultra Disks and Premium SSD v2

Expanding Ultra Disks and Premium SSD v2 disks without downtime has the following additional limitations:

- You can't expand a disk while a background copy of data is also occurring on that disk. An example is when a disk is being backfilled from snapshots.
- You can expand VMs by using NVMe controllers with Ultra Disks or Premium SSD v2 disks without downtime with this public preview. Because this release is a public preview, you should use it only to test the functionality of expanding without downtime. Don't expand VMs in production.

In the following regions, you can expand VMs that are using NVMe controllers with Ultra Disks or Premium SSD v2 disks without downtime. Use either the Azure portal, the Azure CLI, or the Azure PowerShell module:

- Southeast Asia
- Brazil South
- Canada Central
- Germany West Central
- Central India (not currently supported on V6 VMs)

In the following regions, you can expand VMs that are using NVMe controllers with Ultra Disks or Premium SSD v2 disks without downtime. Use only the Azure CLI or an Azure PowerShell module. You can't currently use the Azure portal:

- East Asia
- West Central US (not currently supported on V6 VMs)

Allow up to 10 minutes for the correct size to be reflected in Windows VMs and Linux VMs. For Linux VMs, you must perform a Linux rescan function. For a Windows VM that doesn't have a workload, you must perform a Windows rescan function. You can rescan immediately, but if the time is within 10 minutes, you might need to rescan again to display the correct size.

Expand Azure managed disk

Make sure that you have the latest Azure CLI installed and are signed in to an Azure account by using az login.

This article requires an existing VM in Azure with at least one data disk attached and prepared. If you don't already have a VM that you can use, see Create and prepare a VM with data disks.

In the following samples, replace the placeholder parameter names like *myResourceGroup* and *myVM* with your own values.

> **ⓘ Important**
>
> If your disk meets the requirements in **Expand without downtime**, you can skip steps 1 and 3.

Shrinking an existing disk isn't supported and might result in data loss.

After you expand the disks, expand the volume in the OS to take advantage of the larger disk.

1. Operations on virtual hard disks can't be performed with the VM running. Deallocate your VM with az vm deallocate. The following example deallocates the VM named *myVM* in the resource group named *myResourceGroup*:

   Azure CLI

   ```
   az vm deallocate --resource-group myResourceGroup --name myVM
   ```

   The VM must be deallocated to expand the virtual hard disk. Stopping the VM with `az vm stop` doesn't release the compute resources. To release compute resources, use `az vm deallocate`.

2. View a list of managed disks in a resource group with az disk list. The following example shows a list of managed disks in the resource group named *myResourceGroup*:

   Azure CLI

```
az disk list \
    --resource-group myResourceGroup  \
    --query '[*].{Name:name,size:diskSizeGB,Tier:sku.tier}' \
    --output table
```

Expand the required disk with az disk update. The following example expands the managed disk named *myDataDisk* to *200* GB:

Azure CLI

```
az disk update \
    --resource-group myResourceGroup \
    --name myDataDisk \
    --size-gb 200
```

When you expand a managed disk, the updated size is rounded up to the nearest managed disk size.

3. Start your VM with az vm start. The following example starts the VM named *myVM* in the resource group named *myResourceGroup*:

Azure CLI

```
az vm start --resource-group myResourceGroup --name myVM
```

Expand a disk partition and filesystem

You can use many tools to perform partition resizing. The tools detailed in the remainder of this article are the same ones that certain automated processes use, such as cloud-init. As described here, the `growpart` tool with the `gdisk` package provides universal compatibility with GPT disks because older versions of some tools such as `fdisk` didn't support GPT.

Detect a changed disk size

If you used the previously mentioned procedure to expand a data disk without downtime, the reported disk size doesn't change until the device is rescanned. Rescanning normally happens only during the boot process. To call this rescan on demand, use the following procedure. When you use the methods in this article, notice that in this example the data disk is currently `/dev/sda` and was resized from 256 GiB to 512 GiB.

1. Identify the currently recognized size on the first line of output from `fdisk -l /dev/sda`:

Bash

```
sudo fdisk -l /dev/sda
```

Output

```
Disk /dev/sda: 256 GiB, 274877906944 bytes, 536870912 sectors
Disk model: Virtual Disk
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes
Disklabel type: dos
Disk identifier: 0x43d10aad

Device     Boot Start       End   Sectors  Size Id Type
/dev/sda1        2048 536870878 536868831  256G 83 Linux
```

2. Insert a `1` character into the rescan file for this device. Note the reference to `sda` in the example. The disk identifier changes if a different disk device is resized.

Bash

```
echo 1 | sudo tee /sys/class/block/sda/device/rescan
```

3. Verify that the new disk size is now recognized.

Bash

```
sudo fdisk -l /dev/sda
```

Output

```
Disk /dev/sda: 512 GiB, 549755813888 bytes, 1073741824 sectors
Disk model: Virtual Disk
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes
Disklabel type: dos
Disk identifier: 0x43d10aad

Device     Boot Start       End   Sectors  Size Id Type
/dev/sda1        2048 536870878 536868831  256G 83 Linux
```

The remainder of this article uses the OS disk for the examples of the procedure to increase the size of a volume at the OS level. If the expanded disk is a data disk, use the previous guidance to identify the data disk device. Follow these instructions as a guideline. Substitute the data

disk device (for example, `/dev/sda`), partition numbers, volume names, mount points, and filesystem formats, as necessary.

Consider all Linux OS guidance as generic and that it might apply on any distribution, but it generally matches the conventions of the named marketplace publisher. See the Red Hat documentation for the package requirements on any distribution based on Red Hat or that claims Red Hat compatibility.

Increase the size of the OS disk

The following instructions apply to endorsed Linux distributions.

Before you proceed, make a full backup copy of your VM or, at a minimum, take a snapshot of your OS disk.

Ubuntu

On Ubuntu 16.x and newer, the root partition of the OS disk and filesystems are automatically expanded to use all free contiguous space on the root disk by cloud-init. A small amount of free space must be available for the resize operation. In this case, the sequence is to:

1. Increase the size of the OS disk as previously described.
2. Restart the VM, and then access the VM by using the **root** user account.
3. Verify that the OS disk now displays an increased filesystem size.

As shown in the following example, the OS disk was resized from the portal to 100 GB. The `/dev/sda1` filesystem mounted on `/` now displays 97 GB.

Bash

```
df -Th
```

Output

```
Filesystem     Type      Size  Used Avail Use% Mounted on
udev           devtmpfs  314M     0  314M   0% /dev
tmpfs          tmpfs      65M  2.3M   63M   4% /run
/dev/sda1      ext4       97G  1.8G   95G   2% /
tmpfs          tmpfs     324M     0  324M   0% /dev/shm
tmpfs          tmpfs     5.0M     0  5.0M   0% /run/lock
tmpfs          tmpfs     324M     0  324M   0% /sys/fs/cgroup
/dev/sda15     vfat      105M  3.6M  101M   4% /boot/efi
/dev/sdb1      ext4       20G   44M   19G   1% /mnt
```

```
tmpfs           tmpfs      65M     0   65M   0% /run/user/1000
user@ubuntu:~#
```

Expand without downtime classic VM SKU support

If you're using a classic VM SKU, it might not support expanding disks without downtime.

Use the following PowerShell script to determine which VM SKUs it's available with:

Azure PowerShell

```
Connect-AzAccount
$subscriptionId="yourSubID"
$location="desiredRegion"
Set-AzContext -Subscription $subscriptionId
$vmSizes=Get-AzComputeResourceSku -Location $location | where{$_.ResourceType -eq
'virtualMachines'}

foreach($vmSize in $vmSizes){
    foreach($capability in $vmSize.Capabilities)
    {
       if(($capability.Name -eq "EphemeralOSDiskSupported" -and $capability.Value
-eq "True") -or ($capability.Name -eq "PremiumIO" -and $capability.Value -eq
"True") -or ($capability.Name -eq "HyperVGenerations" -and $capability.Value -
match "V2"))
        {
            $vmSize.Name
       }
   }
}
```

Expand virtual hard disks attached to a Windows virtual machine

07/02/2025

Applies to: ✔ Windows VMs ✔ Flexible scale sets

When you create a new virtual machine (VM) in a resource group by deploying an image from Azure Marketplace, the default operating system (OS) disk is usually 127 GiB. (Some images have smaller OS disk sizes by default.) You can add data disks to your VM. The amount depends on the VM version that you selected.

You should install applications and CPU-intensive workloads on data disks. You might need to expand the OS disk if you're supporting a legacy application that installs components on the OS disk or if you're migrating a physical PC or VM from on-premises that has a larger OS disk. This article covers expanding either OS disks or data disks.

An OS disk has a maximum capacity of 4,095 GiB. However, many operating systems are partitioned with master boot record (MBR) by default. MBR limits the usable size to 2 TiB. If you need more than 2 TiB, create and attach data disks and use them for data storage. If you need to store data on the OS disk and require the extra space, convert it to a GUID Partition Table (GPT). To learn about the differences between MBR and GPT on Windows deployments, see Windows and GPT FAQ.

Unless you use Expand without downtime, expanding a data disk requires the VM to be deallocated. Shrinking an existing disk isn't supported and might result in data loss.

After you expand the disks, expand the volume in the OS to take advantage of the larger disk. You can't expand the size of striped volumes.

Expand without downtime

You can expand data disks without deallocating your VM. The host cache setting of your disk doesn't change whether or not you can expand a data disk without deallocating your VM.

This feature has the following limitations.

> **Important**
>
> This limitation doesn't apply to Premium SSD v2 or Ultra Disks.
>
> If a Standard HDD, Standard SSD, or Premium SSD disk is 4 TiB or less, deallocate your VM and detach the disk before you expand it beyond 4 TiB. If one of those disk types is

already greater than 4 TiB, you can expand it without deallocating the VM and detaching the disk.

- Is supported only for data disks.
- Isn't supported for shared disks.
- Must be installed and use one of the following options:
  - The latest Azure CLI.
  - The latest Azure PowerShell module.
  - The Azure portal.
  - An Azure Resource Manager template with an API version that's `2021-04-01` or newer.
- Isn't available on some classic VMs. Use this script to get a list of classic VM products that support expanding without downtime.

Expand with Ultra Disks and Premium SSD v2

Expanding Ultra Disks and Premium SSD v2 disks without downtime has the following additional limitations:

- You can't expand a disk while a background copy of data is also occurring on that disk. An example is when a disk is being backfilled from snapshots.

You can expand Ultra Disks and Premium SSD v2 disks attached to VMs using NVMe controllers without downtime in all regions that support either of those disk types, except the following:

- US East 2
- US South Central

Use either the Azure CLI or the Azure PowerShell module to make the change.

Allow up to 10 minutes for the correct size to be reflected in Windows VMs and Linux VMs. For Linux VMs, you must perform a Linux rescan function. For a Windows VM that doesn't have a workload, you must perform a Windows rescan function. You can rescan immediately, but if the time is within 10 minutes, you might need to rescan again to display the correct size. If a rescan doesn't work properly, you can either repeat the rescan or restart the VM to display the correct size.

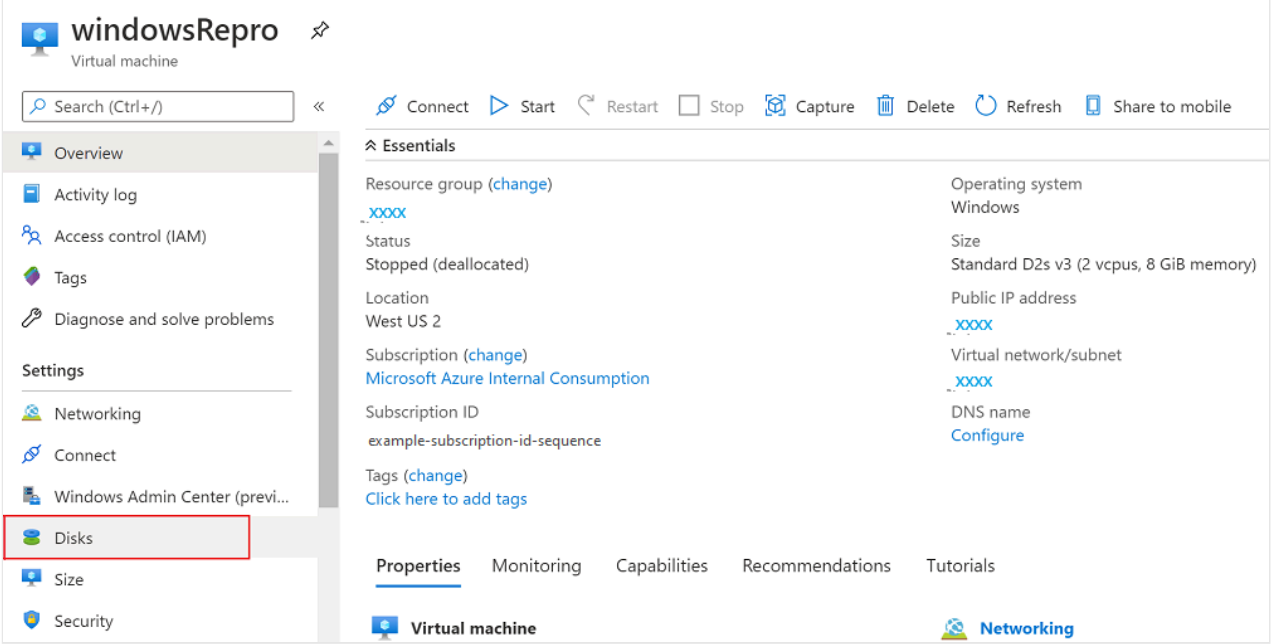
Resize a managed disk in the Azure portal

Important

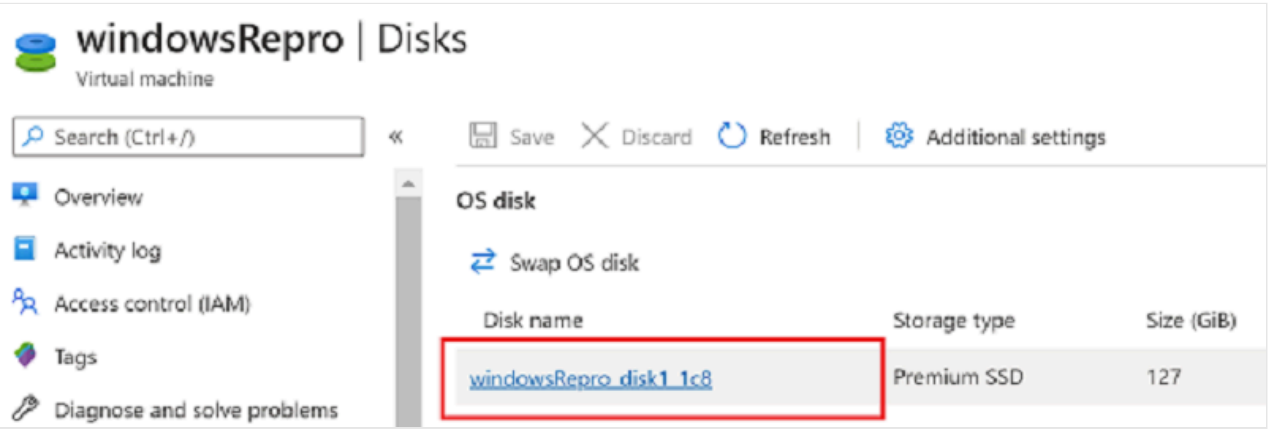
If your disk meets the requirements in Expand without downtime, you can skip step 1.

1. In the Azure portal, go to the VM in which you want to expand the disk. Select **Stop** to deallocate the VM.

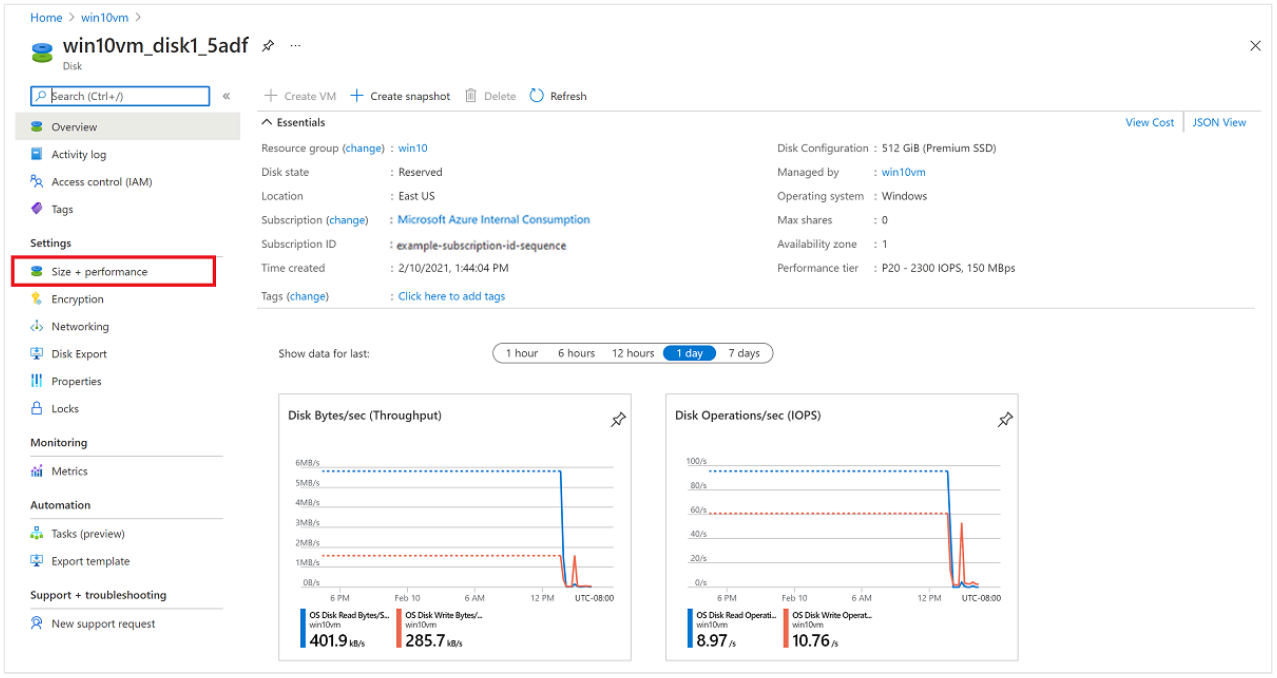
2. On the left menu, under **Settings**, select **Disks**.



3. Under **Disk name**, select the disk that you want to expand.

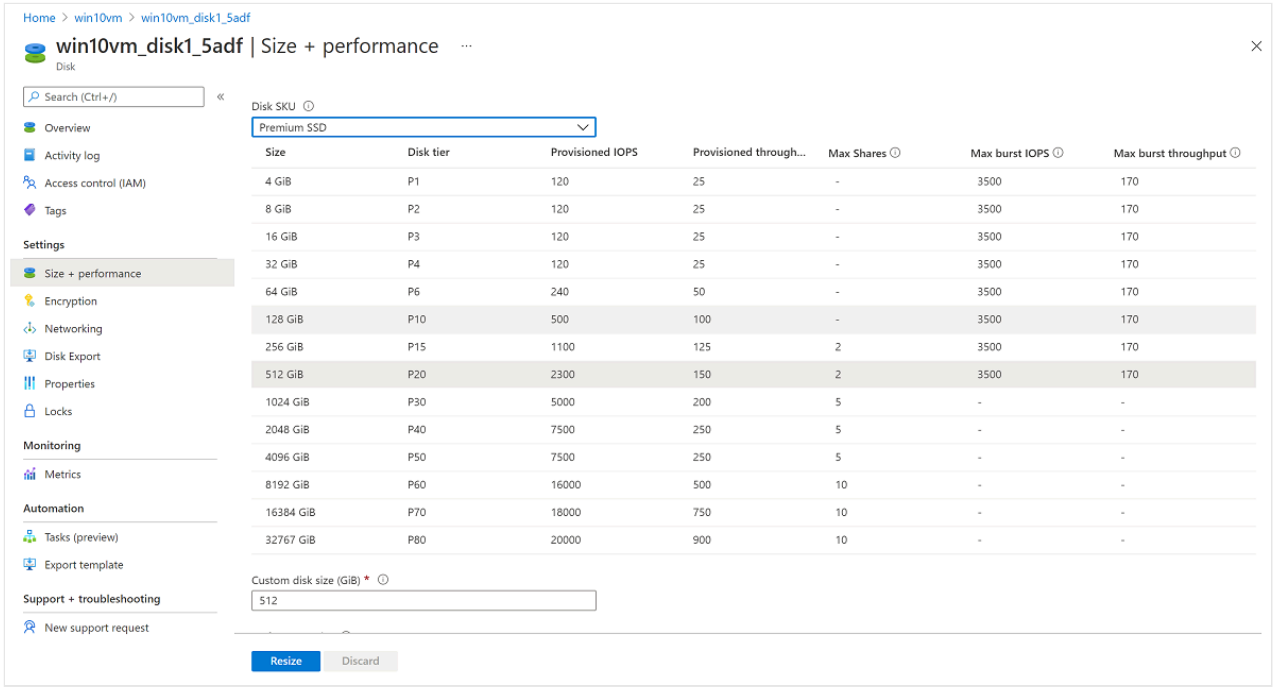


4. On the left menu, under **Settings**, select **Size + performance**.

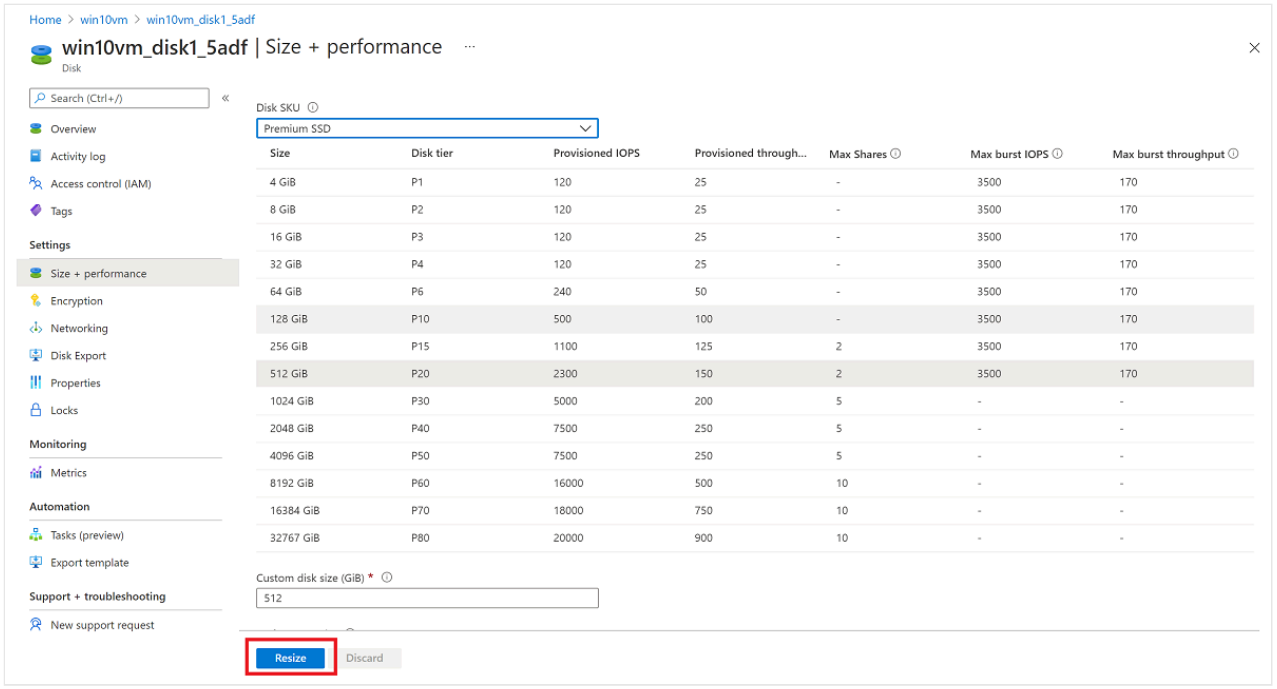


5. On **Size + performance**, select the disk size that you want.

   The new size should be greater than the existing disk size. The maximum allowed is 4,095 GB for OS disks. It's possible to expand the virtual hard disk (VHD) blob beyond that size, but the OS works only with the first 4,095 GB of space.



6. Select **Resize** at the bottom of the page.



Resize a managed disk by using PowerShell

Open a PowerShell window in administrative mode and follow these steps:

1. Sign in to your Azure account in resource management mode, and select your subscription:

   PowerShell

   ```powershell
   Connect-AzAccount
   Select-AzSubscription -SubscriptionName 'my-subscription-name'
   ```

2. Set your resource group name and VM name:

   PowerShell

   ```powershell
   $rgName = 'my-resource-group-name'
   $vmName = 'my-vm-name'
   $diskName = 'my-disk-name'
   ```

3. Obtain a reference to your VM:

   PowerShell

   ```powershell
   $vm = Get-AzVM -ResourceGroupName $rgName -Name $vmName
   ```

> **Important**

> If your disk meets the requirements in **Expand without downtime**, you can skip steps 4 and 6.

4. Stop the VM before you resize the disk:

```
PowerShell

Stop-AzVM -ResourceGroupName $rgName -Name $vmName
```

5. Obtain a reference to the managed OS disk. Set the size of the managed OS disk to the value that you want and update the disk:

```
PowerShell

$disk= Get-AzDisk -ResourceGroupName $rgName -DiskName $diskName
$disk.DiskSizeGB = 1023
Update-AzDisk -ResourceGroupName $rgName -Disk $disk -DiskName $disk.Name
```

   The new size should be greater than the existing disk size. The maximum allowed is 4,095 GB for OS disks. It's possible to expand the VHD blob beyond that size, but the OS works only with the first 4,095 GB of space.

6. Updating the VM might take a few seconds. After the command finishes running, restart the VM:

```
PowerShell

Start-AzVM -ResourceGroupName $rgName -Name $vmName
```

Remote into the VM, open **Computer Management** (or **Disk Management**), and expand the drive by using the newly allocated space.

Expand the volume in the operating system

After you expand the disk for the VM, go into the OS and expand the volume to encompass the new space. There are several methods for expanding a partition. This section covers connecting the VM by using a Remote Desktop Protocol (RDP) connection to expand the partition by using DiskPart or Disk Manager.

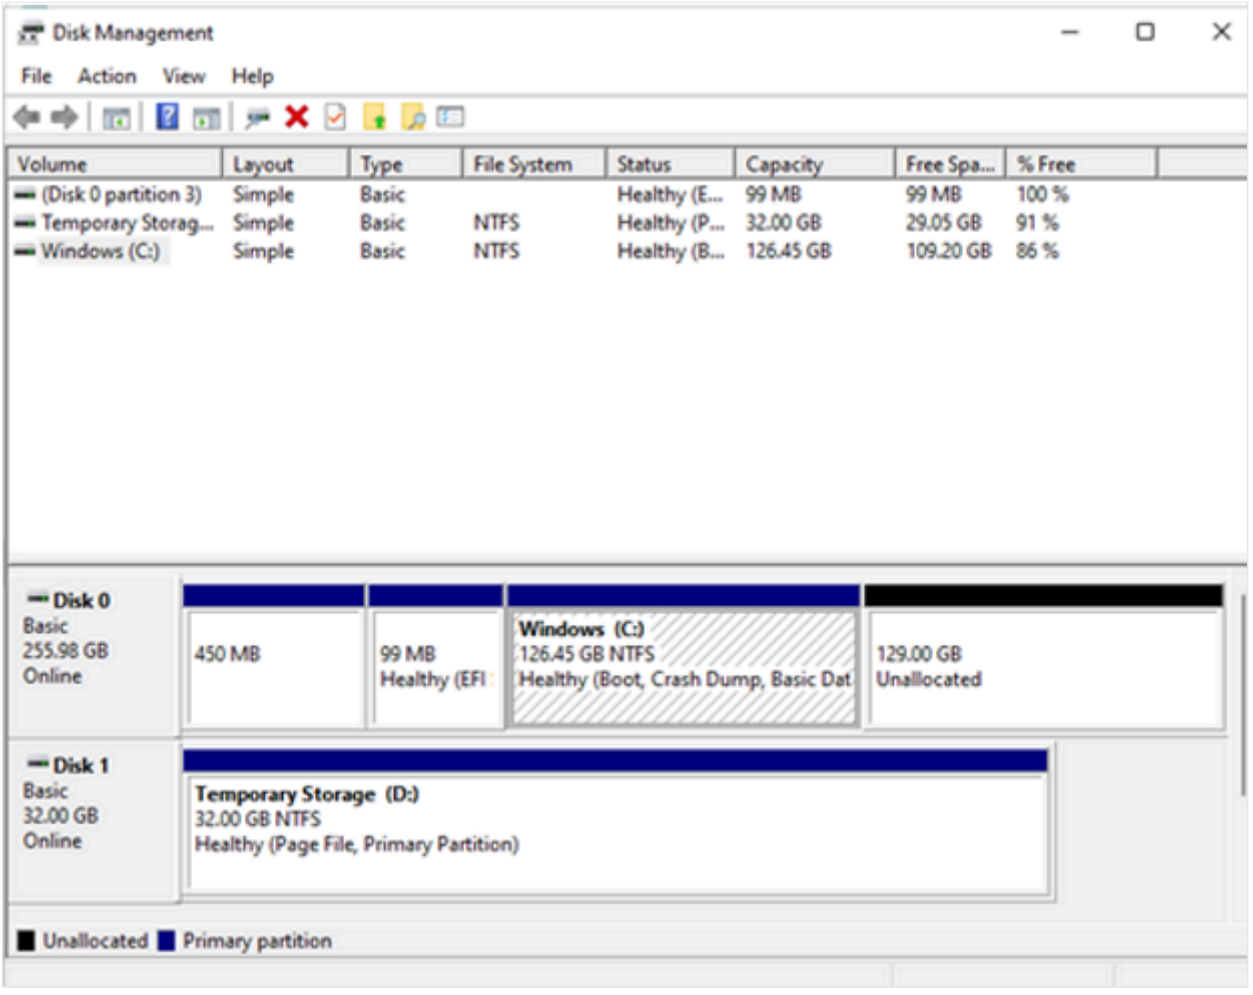
Use DiskPart

1. Open an RDP connection to your VM.

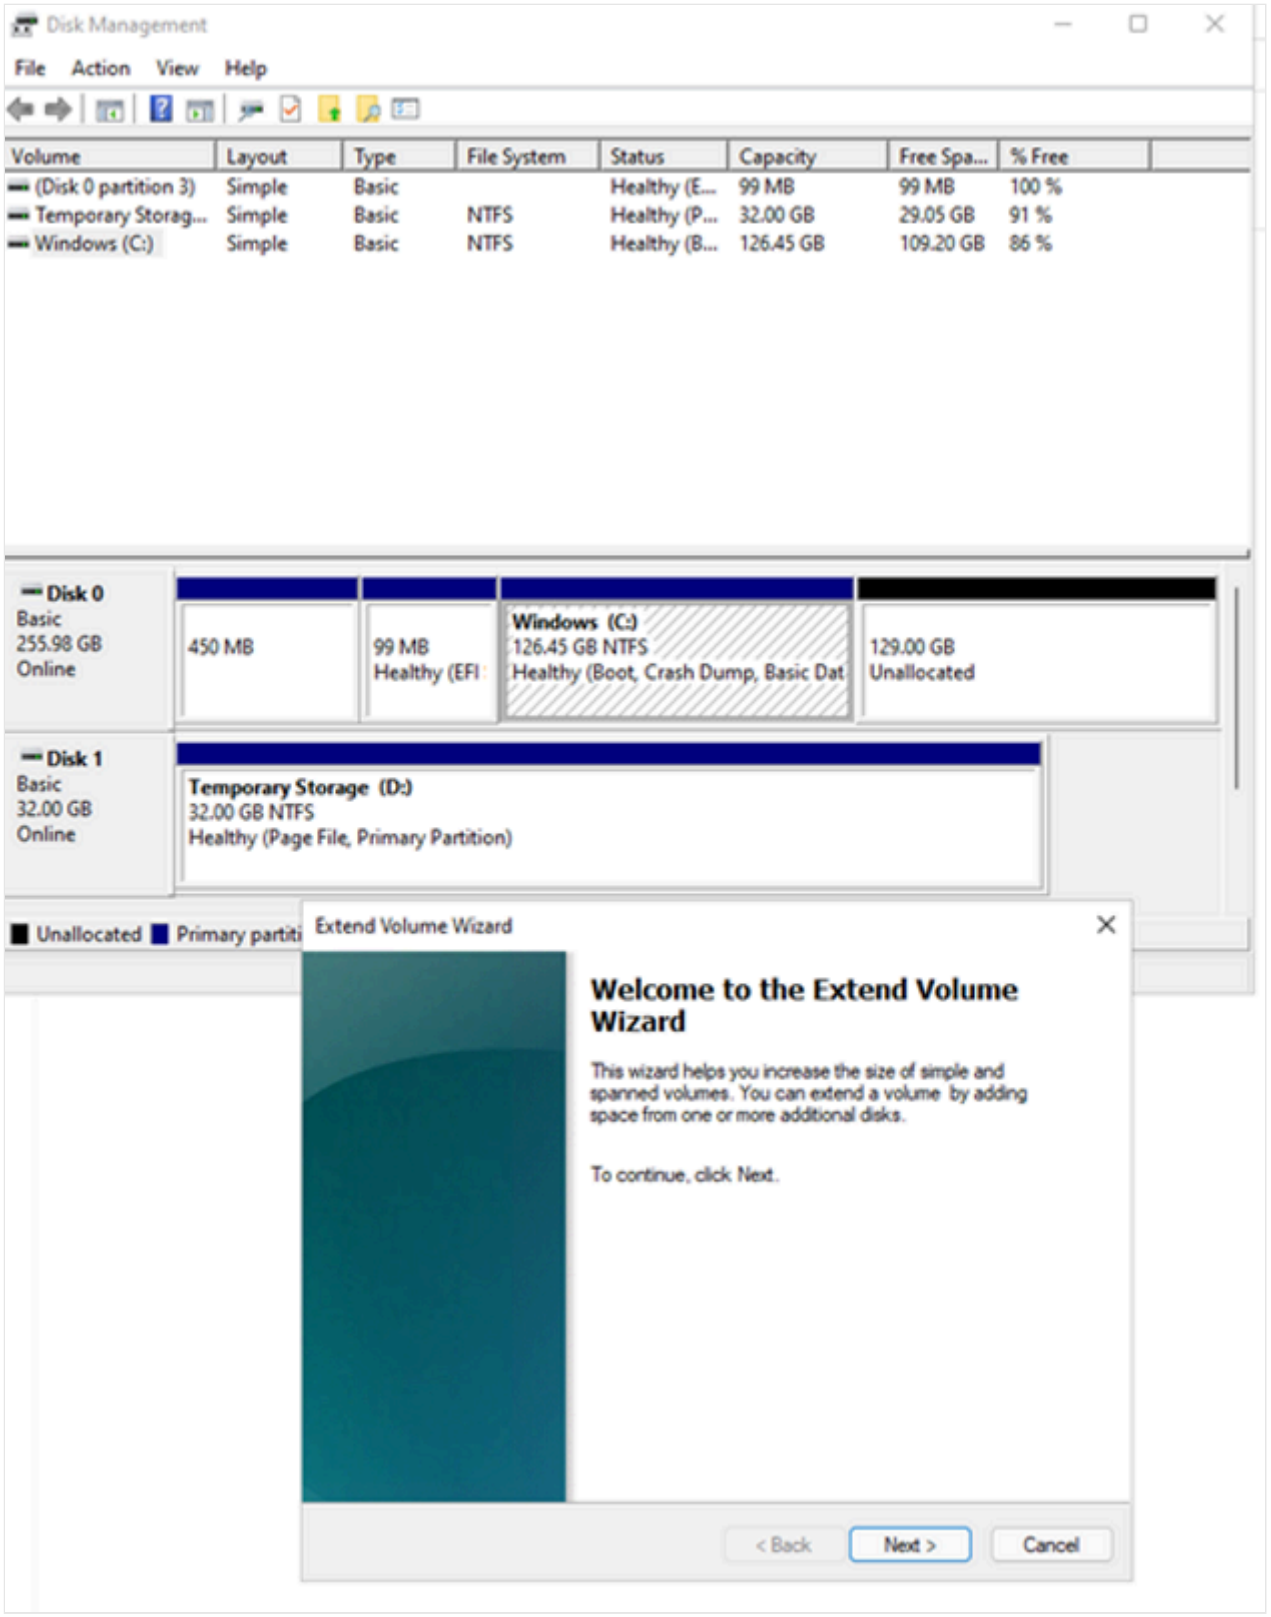
2. Open a command prompt and enter `diskpart`.
3. At the `DISKPART` prompt, enter `list volume`. Make a note of the volume that you want to extend.
4. At the `DISKPART` prompt, enter `select volume <volumenumber>`. This action selects the volume `volumenumber` that you want to extend into contiguous, empty space on the same disk.
5. At the `DISKPART` prompt, enter `extend [size=<size>]`. This action extends the selected volume by size in megabytes (MBs).

Use Disk Manager

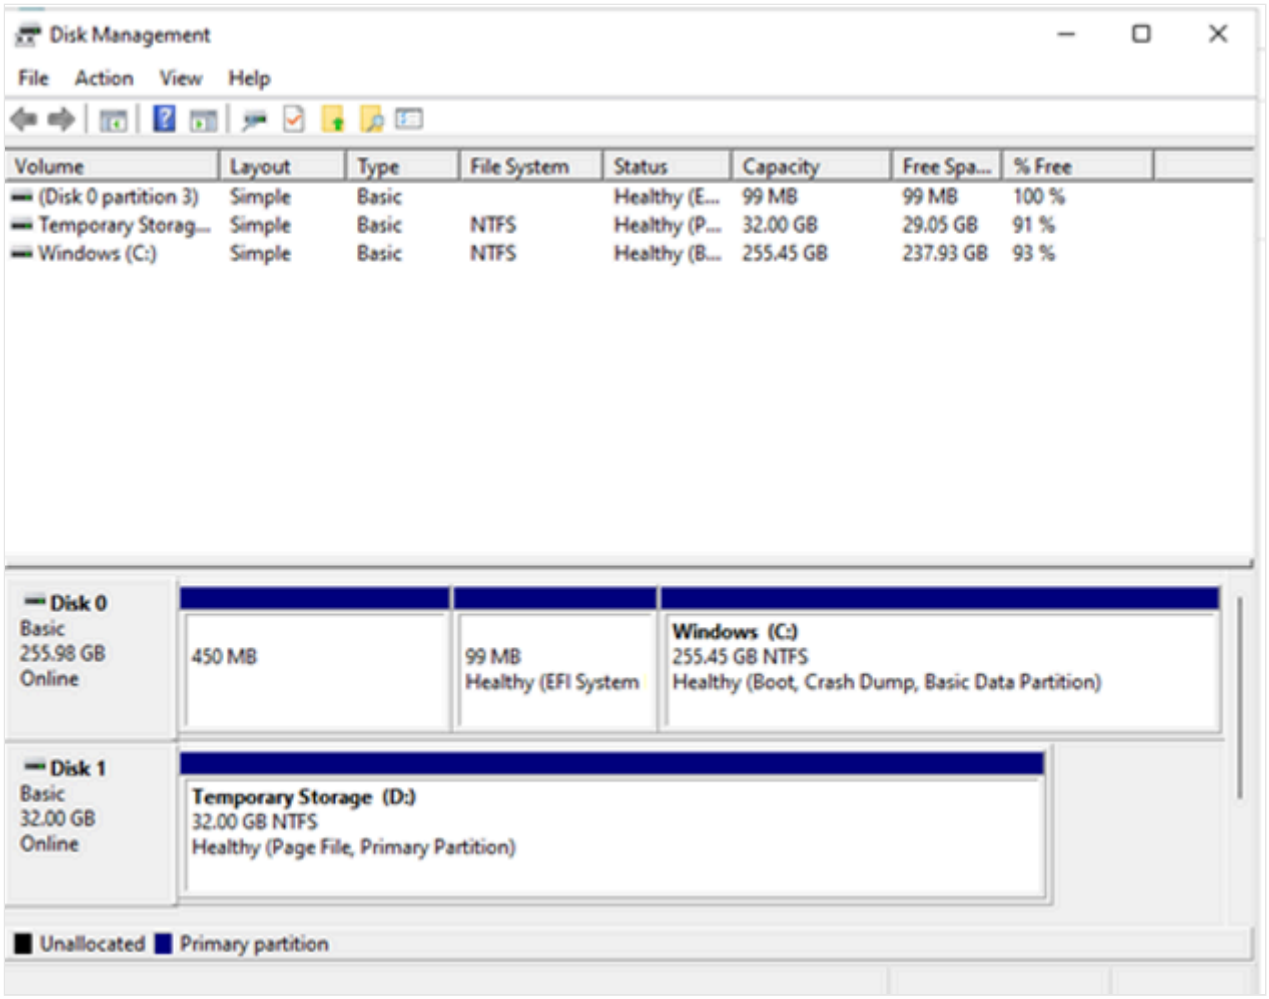
1. Start a remote desktop session with the VM.
2. Open **Disk Management**.



3. Right-click an existing **C:** drive partition and select **Extend Volume**.



4. Follow the steps in the wizard to see the disk with updated capacity.



Expand without downtime classic VM SKU support

If you're using a classic VM SKU, or version, it might not support expanding disks without downtime.

Use the following PowerShell script to determine which VM versions it's available with:

Azure PowerShell

```
Connect-AzAccount
$subscriptionId="yourSubID"
$location="desiredRegion"
Set-AzContext -Subscription $subscriptionId
$vmSizes=Get-AzComputeResourceSku -Location $location | where{$_.ResourceType -eq
'virtualMachines'}

foreach($vmSize in $vmSizes){
    foreach($capability in $vmSize.Capabilities)
    {
       if(($capability.Name -eq "EphemeralOSDiskSupported" -and $capability.Value
-eq "True") -or ($capability.Name -eq "PremiumIO" -and $capability.Value -eq
"True") -or ($capability.Name -eq "HyperVGenerations" -and $capability.Value -
match "V2"))
        {
            $vmSize.Name
```

```
        }
    }
}
```

Related content

You can also attach disks by using the Azure portal.

Expand unmanaged virtual hard disks attached to a virtual machine

Summarize this article for me

This article covers how to expand unmanaged disks. To learn how to expand a managed disk, use either the Windows or Linux articles.

Applies to: ✔ Windows VMs ✔ Linux VMs ✔ Flexible scale sets

On March 31st, 2026, unmanaged disks are being retired. If you're using unmanaged disks, migrate to managed disks before that date. For details on the retirement, see Migrate your Azure unmanaged disks by March 31st, 2026.

When you create a new virtual machine (VM) in a resource group by deploying an image from Azure Marketplace, the default operating system (OS) drive is often 127 GB. (Some images have smaller OS disk sizes by default.) It's possible to add data disks to the VM, and the number depends on the version you chose. We recommend that you install applications and CPU-intensive workloads on these addendum disks, but customers often need to expand the OS drive to support specific scenarios:

- To support legacy applications that install components on the OS drive.
- To migrate a physical PC or VM from on-premises with a larger OS drive.

Resizing an OS or data disk of an Azure VM requires the VM to be deallocated.

Shrinking an existing disk isn't supported and can potentially result in data loss.

After you expand the disks, expand the volume within the OS in either Windows or Linux to take advantage of the larger disk.

Resize an unmanaged disk by using PowerShell

Open your PowerShell Integrated Scripting Environment or PowerShell window in administrative mode and follow these steps:

- Sign in to your Azure account in resource management mode, and select your subscription:

  PowerShell

  ```
  Connect-AzAccount
  Select-AzSubscription -SubscriptionName 'my-subscription-name'
  ```

- Set your resource group name and VM names:

  PowerShell

  ```
  $rgName = 'my-resource-group-name'
  $vmName = 'my-vm-name'
  ```

- Obtain a reference to your VM:

  PowerShell

  ```
  $vm = Get-AzVM -ResourceGroupName $rgName -Name $vmName
  ```

- Stop the VM before you resize the disk:

  PowerShell

  ```
  Stop-AzVM -ResourceGroupName $rgName -Name $vmName
  ```

- Set the size of the unmanaged OS disk to the desired value and update the VM:

  PowerShell

  ```
  $vm.StorageProfile.OSDisk.DiskSizeGB = 1023
  Update-AzVM -ResourceGroupName $rgName -VM $vm
  ```

  The new size should be greater than the existing disk size. The maximum allowed is 2,048 GB for OS disks. It's possible to expand the virtual hard disk blob beyond that size, but the OS can work with only the first 2,048 GB of space.

- Update the size of any data disks that you want to resize. To expand the first data disk attached to the VM, use a numeric index to obtain a reference to the first attached data disk:

  PowerShell

  ```
  $vm.StorageProfile.DataDisks[0].DiskSizeGB = 1023
  ```

  Similarly, you can reference other data disks attached to the VM, either by using an index or the `Name` property of the disk:

  PowerShell

  ```
  ($vm.StorageProfile.DataDisks | Where ({$_.Name -eq 'my-second-data-
  ```

```
disk'})).DiskSizeGB = 1023
```

- Updating the VM might take a few seconds. When the command finishes running, restart the VM:

  PowerShell

  ```powershell
  Start-AzVM -ResourceGroupName $rgName -Name $vmName
  ```

Related content

You can also attach disks by using the Azure portal.

Architecture best practices for Azure Disk Storage

08/13/2025

Azure managed disks are a type of Azure Disk Storage that simplify the management of storage for Azure Virtual Machines. Managed disks are block-level storage volumes that Azure manages. They're similar to physical disks in an on-premises server, but they operate in a virtual environment. When you use a managed disk, you must specify the disk size type and configure the disk. After you configure the disk, Azure manages subsequent operations and maintenance tasks.

This article assumes that as an architect, you've reviewed the storage options and chose Azure Disk Storage as the storage service for your workload. The guidance in this article provides architectural recommendations that are mapped to the principles of the Well-Architected Framework pillars.

This guide focuses on how to make decisions about Azure managed disks. But managed disks are a critical dependency of Azure Virtual Machines. As a prerequisite, read and implement the recommendations in Azure Well-Architected Framework perspective on Virtual Machines and scale sets.

Technology scope

This review focuses on the interrelated decisions for the following Azure resources:

- Azure Disk Storage

Reliability

The purpose of the Reliability pillar is to provide continued functionality by **building enough resilience and the ability to recover fast from failures**.

Reliability design principles provide a high-level design strategy applied for individual components, system flows, and the system as a whole.

Workload design checklist

Start your design strategy based on the design review checklist for Reliability. Determine its relevance to your business requirements while keeping in mind the features and capabilities of Azure Disk Storage. Extend the strategy to include more approaches as needed.

- ✓ **Review best practices to achieve high availability with managed disks.** Optimize your application for high availability by considering these recommendations and how they relate to the configuration of your managed disks and virtual machines (VMs).
- ✓ **Define reliability and recovery targets.** Review the Azure service-level agreements (SLAs). The disk types that you attach to your VM affect the VM SLA. For the highest SLA, only use Azure Ultra Disk Storage, Azure Premium SSD v2, or Premium SSD disks for OS and data disks. For guidance about calculating your reliability targets, see Recommendations for defining reliability targets.
- ✓ **Create a recovery plan.** Evaluate data-protection features, backup and restore operations, and failover procedures. Decide whether to use Azure Backup, Azure Site Recovery, or create your own backup solution by using incremental disk snapshots or restore points. A custom backup solution increases your costs.
- ✓ **Monitor potential availability problems.** Subscribe to the Azure Service Health dashboard. Use disk storage metrics in Azure Monitor to help prevent disk throttling. Manually check VMs to ensure that attached disks don't reach their storage capacity. For guidance about how to integrate these metrics into your overall workload health monitoring strategy, see Health modeling for workloads.
- ✓ **Use failure mode analysis.** Consider internal dependencies, such as the availability of virtual networks or Azure Key Vault, to help minimize points of failure.

Configuration recommendations

Expand table

Recommendation	Benefit
Distribute VMs and disks across multiple availability zones. Use a zone-redundant virtual machine scale set in flexible orchestration mode, or deploy VMs and disks across three availability zones. Use zone balancing to equally spread the instances across zones.	You provision VM and disk instances in physically separate locations within each Azure region. Each location is tolerant to local failures. Depending on resource availability, you might have an uneven number of instances across zones. Zone balancing supports availability by making sure that, if one zone is down, the other zones have sufficient instances. Two instances in each zone provide a buffer during upgrades.
Use Ultra Disk Storage, Premium SSD v2, and Premium SSD disks.	Single-instance VMs that use Premium SSD OS disks and Ultra Disk Storage, Premium SSD v2, or Premium SSD data disks have the highest uptime SLA.

Recommendation	Benefit
For maximum availability and durability, use a zone-redundant storage (ZRS) disk, especially when you share disks between VMs.	ZRS disks minimize the effect of a failure in an availability zone and increase recoverability from such zonal failures. If a zone fails and your VM remains active, workloads on ZRS disks continue to run. But if an outage does affect your VM, and you want to recover disks before the outage resolves, you can force-detach your ZRS disks from the failed VM. Then the ZRS disks can attach to a different VM. When you share a disk among multiple VMs, use a ZRS disk to prevent the shared disk from becoming a single point of failure.
Implement one of the backup options. For managed solutions, use Backup or Site Recovery. If you need to curate your own backup solution, use restore points or snapshots.	Identify the ideal backup option for your needs to help maximize your environment's recoverability.
If you manage your own snapshots, copy them across regions by using scripts.	Use scripts to simplify transferring data from one region to another. Use this option if you can't use Site Recovery. You can still create disaster recovery backups in other regions when you use this option.

Security

The purpose of the Security pillar is to provide **confidentiality, integrity, and availability** guarantees to the workload.

The Security design principles provide a high-level design strategy for achieving those goals by applying approaches to the technical design of Azure Disk Storage.

Workload design checklist

Start your design strategy based on the design review checklist for Security and identify vulnerabilities and controls to improve your security posture. Extend the strategy to include more approaches as needed.

- ✓ **Limit the ability to export or import managed disks.** Use this approach to increase the security of your data. To limit export or import capabilities, you can use one of these methods:

- Create a custom role-based access control (RBAC) role that has the permissions necessary to import and export.
- Use Microsoft Entra ID authentication.
- Set up private links.
- Configure an Azure policy.
- Configure a network access policy.

For more information, see Restrict managed disks from being imported or exported.

- ✓ **Take advantage of encryption options.** By default, managed disks are encrypted with server-side encryption (SSE), which helps you protect your data and meet organization and compliance commitments. You might need other configurations and options. You can:
  - Use SSE with encryption keys that you manage.
  - Enable encryption at host.
  - Enable double encryption at rest.

  For more information, see Server-side encryption of Azure Disk Storage.

- ✓ **Secure your shared access signature (SAS) with Microsoft Entra ID.** Microsoft Entra ID provides extra security compared to a shared key and SAS, and it's easier to use. Grant security principals only necessary permissions to perform their tasks.

- ✓ **Protect secrets.** Protect secrets, such as customer-managed keys and SAS tokens. We generally don't recommend these forms of authorization. But if you use them, make sure to rotate your keys, set key expirations as early as practical, and securely store these secrets.

- ✓ **Detect threats.** Enable Microsoft Defender for Cloud so that you can trigger security alerts when anomalies in activity occur. Defender for Cloud notifies subscription administrators by email. The email includes details about the suspicious activity and recommendations to investigate and remediate threats.

- ✓ **Use tags and labels.** Apply tags and labels to important disks to help ensure that you apply the appropriate levels of protection to the disks.

- ✓ **Harden all workload components.** Reduce extraneous surface area and tighten configurations to help reduce the likelihood of attacks. Properly secure any related resources that you use with your managed disks, such as backup recovery vaults or Azure key vaults.

Configuration recommendations

Expand table

Recommendation	Benefit
Use encryption at host for your managed disks whenever possible.	Encryption at host provides end-to-end encryption for environments that have it enabled. Encryption begins on your VM and flows through to its attached disks.
Apply an Azure Resource Manager lock on the disk.	Lock a disk to help prevent it from being deleted so that you don't lose data.
Disable traffic to the public endpoints of your disk. Create private endpoints for clients that run in Azure.	Disable traffic to the public endpoints so that traffic travels over the Microsoft backbone network, which helps eliminate exposure to the public internet.
If possible, use Azure RBAC to limit access to resources and functions.	Use RBAC to avoid tokens or keys that could be compromised. Microsoft Entra ID authenticates the security principal, such as a user, group, managed identity, or service principal. Microsoft Entra ID returns an OAuth 2.0 token. The token is used to authorize a request against the disk service.
Microsoft discourages the use of SAS tokens. If you must create one, review this list of SAS best practices before you create and distribute it. Set the expiration of SAS tokens to 60 days or less.	Best practices can help you prevent a SAS token from being leaked and quickly recover from a leak if one occurs.
Consider using your own encryption key, or a customer-managed key, to help protect the data in your managed disk.	A customer-managed key provides greater flexibility and control if you need it. For example, you can store encryption keys in Key Vault and automatically rotate them.

Cost Optimization

Cost Optimization focuses on **detecting spend patterns, prioritizing investments in critical areas, and optimizing in others** to meet the organization's budget while meeting business requirements.

The Cost Optimization design principles provide a high-level design strategy for achieving those goals and making tradeoffs as necessary in the technical design related to Azure Disk Storage.

Workload design checklist

Start your design strategy based on the design review checklist for Cost Optimization for investments. Fine-tune the design so that the workload is aligned with the budget that's

allocated for the workload. Your design should use the right Azure capabilities, monitor investments, and find opportunities to optimize over time.

- ✓ **Understand how Azure Disk Storage is billed.** Different disk types are billed in different ways and have different features that can affect billing. To design the most cost-optimized environment, see Understand Azure Disk Storage billing. For exact billing, find the specific pricing details and apply the appropriate settings. For more information, see Managed disks pricing.
- ✓ **Estimate the cost of capacity and operations.** Use the pricing calculator to model the costs that are associated with disk types, transactions, and capabilities. Compare the costs that are associated with various regions, account types, namespace types, and redundancy configurations.
- ✓ **Choose a billing model.** Evaluate whether a commitment-based model is more cost efficient than a consumption-based model. If you don't know how much capacity you need, start with a consumption-based model, monitor capacity metrics, and evaluate your choice later.
- ✓ **Decide which features you need.** Some features, such as snapshots or on-demand bursting, incur extra transaction costs, capacity costs, and other charges. For example, if you enable snapshots, you're billed for the amount of storage that each snapshot uses. When you decide which capabilities your disks need, review the pricing and billing details for those capabilities.
- ✓ **Create guardrails.** Create budgets based on subscriptions and resource groups. Use governance policies to restrict resource types, configurations, and locations. You can also use RBAC to block actions that can lead to overspending.
- ✓ **Monitor costs.** to ensure that you stay within budgets, compare costs against forecasts, and see where overspending might have occurred. Use the cost analysis feature in the Azure portal. You also can export cost data to a storage account and use Excel or Power BI to analyze that data.
- ✓ **Monitor disk resources.** Use sample scripts to search for unattached disks.

Configuration recommendations

Recommendation	Benefit
Carefully select the appropriate disk types for your workloads. Understand the available disk	One of the best ways to reduce costs is to plan for your requirements, and use the pricing calculator to model

Recommendation	Benefit
types and their features before you deploy an environment. Then use the pricing calculator to estimate costs.	the environment.
Use reserved capacity for Premium SSD disks.	Reserved capacity for Premium SSDs reduces the total cost of your environment because you prepay for your capacity at a discount.
Assess whether the features that existing disks offer can improve performance without switching to another disk size or type. Features like disk bursting or changing performance tiers could improve performance to levels that meet your needs.	Depending on your environment and needs, enabling features to improve your disk performance can be more cost effective than switching to a different disk type. These features incur costs but might incur less costs than different disk types.
Directly adjust the performance of your Ultra Disk Storage and Premium SSD v2 disks to fit your performance needs.	These two disk types support a set number of adjustments to the disk's performance within a 24 hour period. This setting allows your workloads to be cost efficient while meeting your performance needs. You can increase performance (increase cost) to meet higher demand and then lower performance (decrease cost) when the increase is no longer needed. For example, a transaction-intensive database might need a large amount of input/output operations per second (IOPS) at a small size. Or a gaming application might need a large amount of IOPS but only during peak hours.

Operational Excellence

Operational Excellence primarily focuses on procedures for **development practices, observability, and release management**.

The Operational Excellence design principles provide a high-level design strategy for achieving those goals towards the operational requirements of the workload.

Workload design checklist

Start your design strategy based on the design review checklist for Operational Excellence for defining processes for observability, testing, and deployment related to Azure Disk Storage.

- ✓ **Create maintenance and emergency recovery plans.** Evaluate data-protection features, backup operations, and restore operations. Select backup solutions that you can use to

recover from regional disasters.

- ✓ **Create internal documentation.** Document your organization's standard practices. Incorporate existing Azure documentation to streamline your processes. Include documentation about attaching a disk to Windows or Linux VMs or expanding a disk on Windows or Linux VMs.

- ✓ **Detect threats.** Enable Defender for Cloud so that you can trigger security alerts when anomalies in activity occur. Defender for Cloud notifies subscription administrators by email. The email includes details about the suspicious activity and recommendations to investigate and remediate threats.

Configuration recommendations

Expand table

Recommendation	Benefit
Use Azure Monitor to analyze metrics and create alerts.	Azure Monitor provides insight about how your disks and VMs perform. Use these metrics to ensure that your performance remains optimal.
Review the available backup options for managed disks.	Understand the available options so that you can select the configuration that best suits your needs.

Performance Efficiency

Performance Efficiency is about **maintaining user experience even when there's an increase in load** by managing capacity. The strategy includes scaling resources, identifying and optimizing potential bottlenecks, and optimizing for peak performance.

The Performance Efficiency design principles provide a high-level design strategy for achieving those capacity goals against the expected usage.

Workload design checklist

Start your design strategy based on the design review checklist for Performance Efficiency. Define a baseline that's based on key performance indicators for Azure Disk Storage.

- ✓ **Choose optimal disk types.** Identify the disk types that you need before you deploy your resources. This approach helps you maximize performance and cost efficiency. The five disk types include Ultra Disk Storage, Premium SSD v2, Premium SSD, Azure Standard SSD,

and Azure Standard HDD. For the highest performance, use Premium SSD for your VM's OS disk, and use Ultra Disk Storage or Premium SSD v2 for your data disks.

- ✓ **Reduce the travel distance between the client and server.** Place data in regions that are closest to connecting clients, ideally in the same region. Default network configurations provide the best performance. Modify network settings only to improve security. In general, network settings don't decrease travel distance and don't improve performance.
- ✓ **Collect performance data.** Monitor your disks and VMs to identify performance bottlenecks that occur from throttling. For more information, see Storage IO metrics.
- ✓ **Benchmark your disks.** Create a test environment and determine whether it meets your needs and expectations. For more information, see Benchmark a disk.

Configuration recommendations

Expand table

Recommendation	Benefit
Create disks in the same region as the VM that you attach them to. If clients from a different region don't require the same data, create a separate disk in each region.	Reduce the physical distance between VMs and their disks, services, and on-premises clients to help improve performance and reduce network latency. This approach also reduces cost for applications that you host in Azure because bandwidth usage within a single region is free.
For workloads and solutions that require the lowest latency, such as e-commerce workloads or databases, use a Premium SSD OS disk and Ultra Disk Storage or Premium SSD v2 data disks.	This configuration offers the best reliability and highest SLA and performance.
Use Azure metrics to monitor your environment and help prevent disk throttling.	Use Azure metrics to identify disks that are being throttled and address them. Throttling leads to suboptimal performance and problems like increased latency.
For disks that are being throttled, evaluate whether changing to a larger disk size or changing to a more performant disk is better for your needs. For Premium SSD disks that are being throttled, if you have short-term bursts of demand, enable on-demand bursting.	Place applications on disks that aren't being throttled to help ensure optimal performance without increased latency.

Recommendation	Benefit
For longer-term extended demand, change the tier of the disk or evaluate whether Premium SSD v2 or Ultra Disk Storage disks better fit your needs.	
Review the expand without downtime limitations, to ensure your data disks qualify. Expanding without downtime allows you to dynamically increase your storage capacity without deallocating attached VMs. Start with smaller disk sizes and expand based on actual demand to implement just-in-time capacity provisioning strategies.	Dynamic disk expansion eliminates downtime traditionally associated with storage expansion while enabling elastic storage scaling. You can reduce upfront costs by avoiding overprovisioning and increasing the size of your disk if you need the additional capacity or performance.
When you upload a virtual hard disk (VHD), use the Add-AzVHD Azure PowerShell command.	The *Add-AzVHD* Azure PowerShell command automates most of the upload process to help streamline the process.
For existing deployments that are on-premises or in another public cloud provider, use Azure Migrate and Modernize.	Azure Migrate and Modernize can evaluate your deployment and provide curated suggestions for the best sizing of disks and VMs in a prospective Azure deployment.

Tradeoffs

You might have to make design tradeoffs if you use the approaches in the pillar checklists. Here are some examples of advantages and drawbacks.

Disk type selection and performance versus cost

- **Higher performance disk types:** Premium SSD v2 and Ultra Disk Storage provide the highest performance with customizable IOPS and throughput. These disk types offer higher availability with lower latency, making them ideal for mission-critical workloads. Premium SSDs provide built-in redundancy and zone-redundant storage options.

  However, Premium disk types can cost significantly more than Standard SSDs or HDDs. Ultra Disk Storage and Premium SSD v2 have limited regional availability and specific VM type requirements. For workloads with predictable, moderate performance needs, the additional cost might not justify the performance gains. Evaluate whether Standard SSD or even Standard HDD can meet your performance requirements at a lower cost.

- **Lower cost disk types:** Standard SSD and Standard HDD provide cost-effective storage for development, testing, and workloads with less demanding performance requirements.

These options help reduce overall infrastructure costs and are suitable for backup storage, archival data, or applications that don't require high IOPS.

These disk types have lower performance ceilings, higher latency, and reduced SLAs compared to premium options. Standard HDDs are particularly unsuitable for performance-sensitive workloads and can become bottlenecks in production environments.

Azure policies

Azure provides an extensive set of built-in policies related to Azure Disk Storage and its dependencies. Some of the preceding recommendations can be audited through Azure Policy. For example, you can check whether:

- Public network access to your managed disks is disabled.
- Backup is enabled.
- Double encryption is enabled.
- Specific disk encryption sets are used with your disks.
- Customer-managed keys are used.
- Managed disks are zone resilient.
- Notification policies for key expiration are configured.
- Autorotate for customer-managed keys is enabled.

For comprehensive governance, review the Azure Policy built-in definitions for Azure compute and other policies that might impact the security of the storage infrastructure.

Azure Advisor recommendations

Azure Advisor is a personalized cloud consultant that helps you follow best practices to optimize your Azure deployments. Here are some recommendations that can help you improve the reliability, security, cost effectiveness, performance, and operational excellence of Azure Disk Storage.

- Reliability
- Security
- Cost Optimization
- Performance
- Operational Excellence

Example architecture

Azure Virtual Machines baseline architecture

Using disks in Azure Resource Manager Templates

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Unmanaged disks are no longer supported. If you're using unmanaged disks, migrate to managed disks. For details, see Migrate unmanaged disks to managed disks.

This document walks through the differences between managed and unmanaged disks when using Azure Resource Manager templates to provision virtual machines. The examples help you to update existing templates that are using unmanaged Disks to managed disks. For reference, we are using the vm-simple-windows template as a guide. You can see the template using both managed disks and a prior version using unmanaged disks if you'd like to directly compare them.

Unmanaged Disks template formatting

To begin, let's take a look at how unmanaged disks are deployed. When creating unmanaged disks, you need a storage account to hold the VHD files. You can create a new storage account or use one that already exists. This article shows you how to create a new storage account. Create a storage account resource in the resources block as shown below.

JSON

```
{
    "type": "Microsoft.Storage/storageAccounts",
    "apiVersion": "2018-07-01",
    "name": "[variables('storageAccountName')]",
    "location": "[resourceGroup().location]",
    "sku": {
        "name": "Standard_LRS"
    },
    "kind": "Storage",
    "properties": {}
}
```

Within the virtual machine object, add a dependency on the storage account to ensure that it's created before the virtual machine. Within the `storageProfile` section, specify the full URI of the VHD location, which references the storage account and is needed for the OS disk and any data disks.

JSON

```
{
    "type": "Microsoft.Compute/virtualMachines",
    "apiVersion": "2018-10-01",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
    "[resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))]",
    "[resourceId('Microsoft.Network/networkInterfaces/', variables('nicName'))]"
    ],
    "properties": {
        "hardwareProfile": {...},
        "osProfile": {...},
        "storageProfile": {
            "imageReference": {
                "publisher": "MicrosoftWindowsServer",
                "offer": "WindowsServer",
                "sku": "[parameters('windowsOSVersion')]",
                "version": "latest"
            },
            "osDisk": {
                "name": "osdisk",
                "vhd": {
                    "uri": "
[concat(reference(resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))).primaryEndpoints.blob, 'vhds/osdisk.vhd')]"
                },
                "caching": "ReadWrite",
                "createOption": "FromImage"
            },
            "dataDisks": [
                {
                    "name": "datadisk1",
                    "diskSizeGB": 1023,
                    "lun": 0,
                    "vhd": {
                        "uri": "
[concat(reference(resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))).primaryEndpoints.blob, 'vhds/datadisk1.vhd')]"
                    },
                    "createOption": "Empty"
                }
            ]
        },
        "networkProfile": {...},
        "diagnosticsProfile": {...}
    }
}
```

Managed disks template formatting

With Azure managed disks, the disk becomes a top-level resource and no longer requires a storage account to be created by the user. Managed disks were first exposed in the `2016-04-30-preview` API version, they are available in all subsequent API versions and are now the default disk type. The following sections walk through the default settings and detail how to further customize your disks.

> ⓘ **Note**
>
> It is recommended to use an API version later than `2016-04-30-preview` as there were breaking changes between `2016-04-30-preview` and `2017-03-30`.

Default managed disk settings

To create a VM with managed disks, you no longer need to create the storage account resource. Referencing the template example below, there are some differences from the previous unmanaged disk examples to note:

- The `apiVersion` is a version that supports managed disks.
- `osDisk` and `dataDisks` no longer refer to a specific URI for the VHD.
- When deploying without specifying additional properties, the disk will use a storage type based on the size of the VM. For example, if you are using a VM size that supports premium storage (sizes with "s" in their name such as Standard_D2s_v3) then premium disks will be configured by default. You can change this by using the sku setting of the disk to specify a storage type.
- If no name for the disk is specified, it takes the format of `<VMName>_OsDisk_1_<randomstring>` for the OS disk and `<VMName>_disk<#>_<randomstring>` for each data disk.
  - If a VM is being created from a custom image then the default settings for storage account type and disk name are retrieved from the disk properties defined in the custom image resource. These can be overridden by specifying values for these in the template.
- By default, Azure disk encryption is disabled.
- By default, disk caching is Read/Write for the OS disk and None for data disks.
- In the example below there is still a storage account dependency, though this is only for storage of diagnostics and is not needed for disk storage.

JSON

```
{
    "type": "Microsoft.Compute/virtualMachines",
    "apiVersion": "2018-10-01",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))]",
        "[resourceId('Microsoft.Network/networkInterfaces/',
variables('nicName'))]"
    ],
    "properties": {
        "hardwareProfile": {...},
        "osProfile": {...},
        "storageProfile": {
            "imageReference": {
                "publisher": "MicrosoftWindowsServer",
                "offer": "WindowsServer",
                "sku": "[parameters('windowsOSVersion')]",
                "version": "latest"
            },
            "osDisk": {
                "createOption": "FromImage"
            },
            "dataDisks": [
                {
                    "diskSizeGB": 1023,
                    "lun": 0,
                    "createOption": "Empty"
                }
            ]
        },
        "networkProfile": {...},
        "diagnosticsProfile": {...}
    }
}
```

Using a top-level managed disk resource

As an alternative to specifying the disk configuration in the virtual machine object, you can create a top-level disk resource and attach it as part of the virtual machine creation. For example, you can create a disk resource as follows to use as a data disk.

JSON

```
{
    "type": "Microsoft.Compute/disks",
    "apiVersion": "2018-06-01",
    "name": "[concat(variables('vmName'),'-datadisk1')]",
    "location": "[resourceGroup().location]",
    "sku": {
```

```
        "name": "Standard_LRS"
    },
    "properties": {
        "creationData": {
            "createOption": "Empty"
        },
        "diskSizeGB": 1023
    }
}
```

Within the VM object, reference the disk object to be attached. Specifying the resource ID of the managed disk created in the `managedDisk` property allows the attachment of the disk as the VM is created. The `apiVersion` for the VM resource is set to `2017-03-30`. A dependency on the disk resource is added to ensure it's successfully created before VM creation.

JSON

```
{
    "type": "Microsoft.Compute/virtualMachines",
    "apiVersion": "2018-10-01",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))]",
        "[resourceId('Microsoft.Network/networkInterfaces/',
variables('nicName'))]",
        "[resourceId('Microsoft.Compute/disks/', concat(variables('vmName'),'-
datadisk1'))]"
    ],
    "properties": {
        "hardwareProfile": {...},
        "osProfile": {...},
        "storageProfile": {
            "imageReference": {
                "publisher": "MicrosoftWindowsServer",
                "offer": "WindowsServer",
                "sku": "[parameters('windowsOSVersion')]",
                "version": "latest"
            },
            "osDisk": {
                "createOption": "FromImage"
            },
            "dataDisks": [
                {
                    "lun": 0,
                    "name": "[concat(variables('vmName'),'-datadisk1')]",
                    "createOption": "attach",
                    "managedDisk": {
                        "id": "[resourceId('Microsoft.Compute/disks/',
concat(variables('vmName'),'-datadisk1'))]"
                    }
```

```
                }
            ]
        },
        "networkProfile": {...},
        "diagnosticsProfile": {...}
    }
}
```

Create managed availability sets with VMs using managed disks

To create managed availability sets with VMs using managed disks, add the `sku` object to the availability set resource and set the `name` property to `Aligned`. This property ensures that the disks for each VM are sufficiently isolated from each other to avoid single points of failure. Also note that the `apiVersion` for the availability set resource is set to `2018-10-01`.

JSON

```
{
    "type": "Microsoft.Compute/availabilitySets",
    "apiVersion": "2018-10-01",
    "location": "[resourceGroup().location]",
    "name": "[variables('avSetName')]",
    "properties": {
        "PlatformUpdateDomainCount": 3,
        "PlatformFaultDomainCount": 2
    },
    "sku": {
        "name": "Aligned"
    }
}
```

Standard SSDs

Below are the parameters needed in the Resource Manager template to create Standard SSDs:

- *apiVersion* for Microsoft.Compute must be set as `2018-04-01` (or later)
- Specify *managedDisk.storageAccountType* as `StandardSSD_LRS`

The following example shows the *properties.storageProfile.osDisk* section for a VM that uses Standard SSDs:

JSON

```
"osDisk": {
    "osType": "Windows",
```

```
    "name": "myOsDisk",
    "caching": "ReadWrite",
    "createOption": "FromImage",
    "managedDisk": {
        "storageAccountType": "StandardSSD_LRS"
    }
}
```

For a complete template example of how to create a Standard SSD with a template, see Create a VM from a Windows Image with Standard SSD Data Disks.

Additional scenarios and customizations

To find full information on the REST API specifications, please review the create a managed disk REST API documentation. You will find additional scenarios, as well as default and acceptable values that can be submitted to the API through template deployments.

Next steps

- For full templates that use managed disks visit the following Azure Quickstart Repo links.
  - Windows VM with managed disk
  - Linux VM with managed disk
- Visit the Azure managed disks Overview document to learn more about managed disks.
- Review the template reference documentation for virtual machine resources by visiting the Microsoft.Compute/virtualMachines template reference document.
- Review the template reference documentation for disk resources by visiting the Microsoft.Compute/disks template reference document.
- For information on how to use managed disks in Azure virtual machine scale sets, visit the Use data disks with scale sets document.

Use Azure Storage Explorer to manage Azure managed disks

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Storage Explorer contains a rich set of features that allows you to:

- Upload, download, and copy managed disks.
- Create snapshots from operating system or data disk virtual hard disk.
- Migrate data from on-premises to Azure.
- Migrate data across Azure regions.

Prerequisites

To complete this article, you'll need:

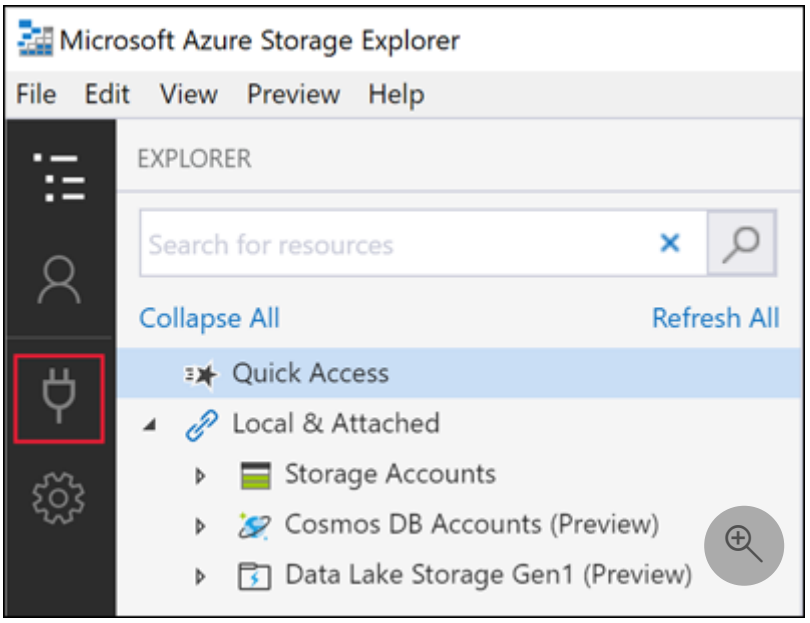
- An Azure subscription.
- At least one Azure managed disk.
- The latest version of Azure Storage Explorer.

If you don't have an Azure subscription, create a free account before you begin.

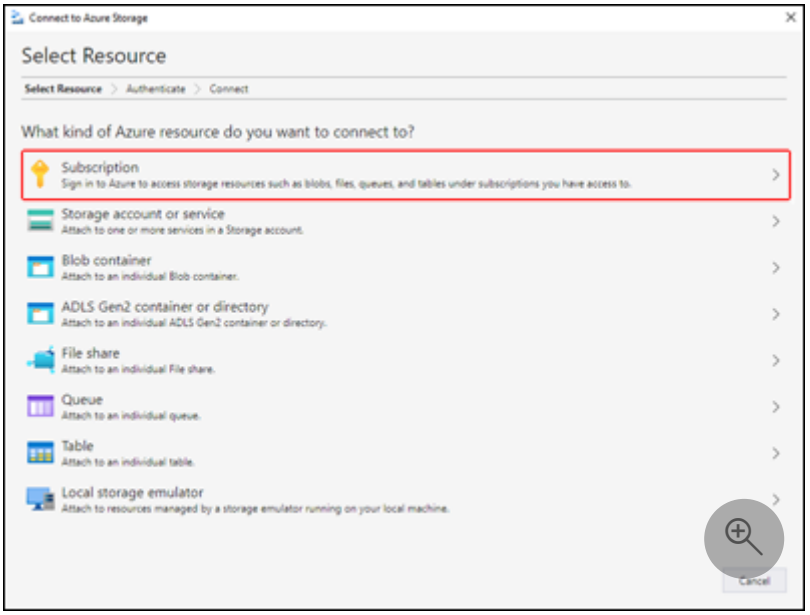
Connect to an Azure subscription

If your Storage Explorer isn't connected to Azure, you can't use it to manage resources. Follow the steps in this section to connect Storage Explorer to your Azure account. Afterward, you can use it to manage your disks.

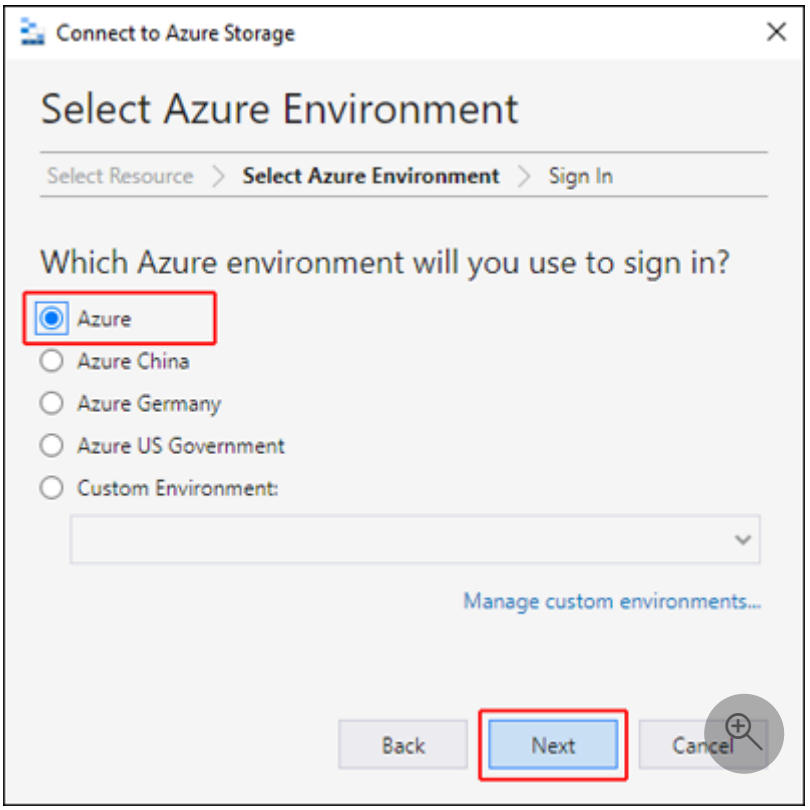
1. Open Azure Storage Explorer and select the **Connect** icon in the toolbar.



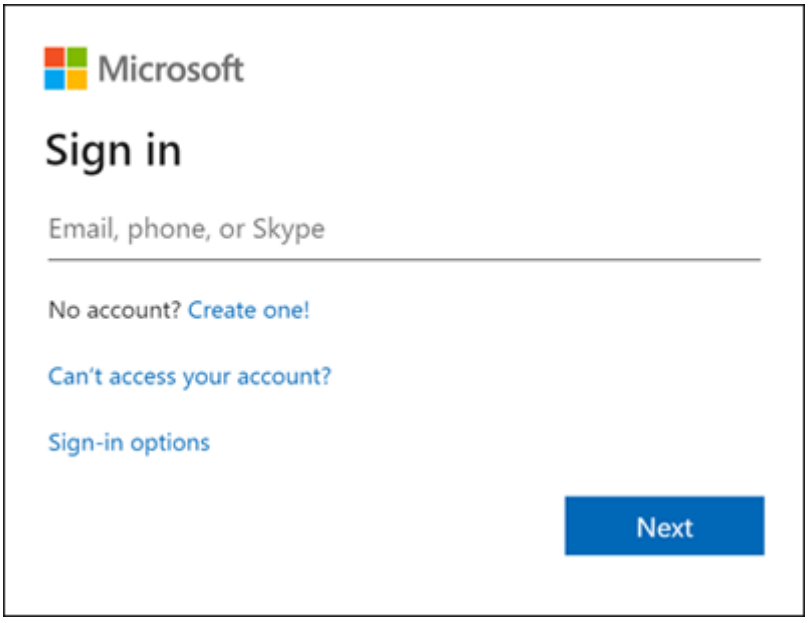
2. In the **Connect to Azure Storage** dialog box, select **Subscription**.



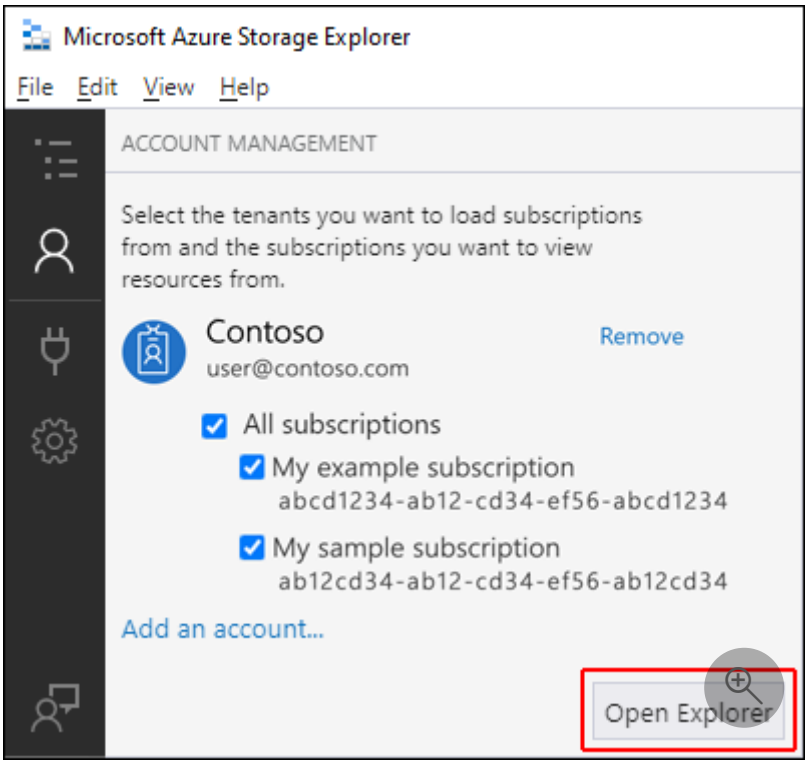
3. Select the appropriate environment and select **Next**. You can also select **Manage custom environments** to configure and add a custom environment.



4. In the **Sign in** dialog box, enter your Azure credentials.



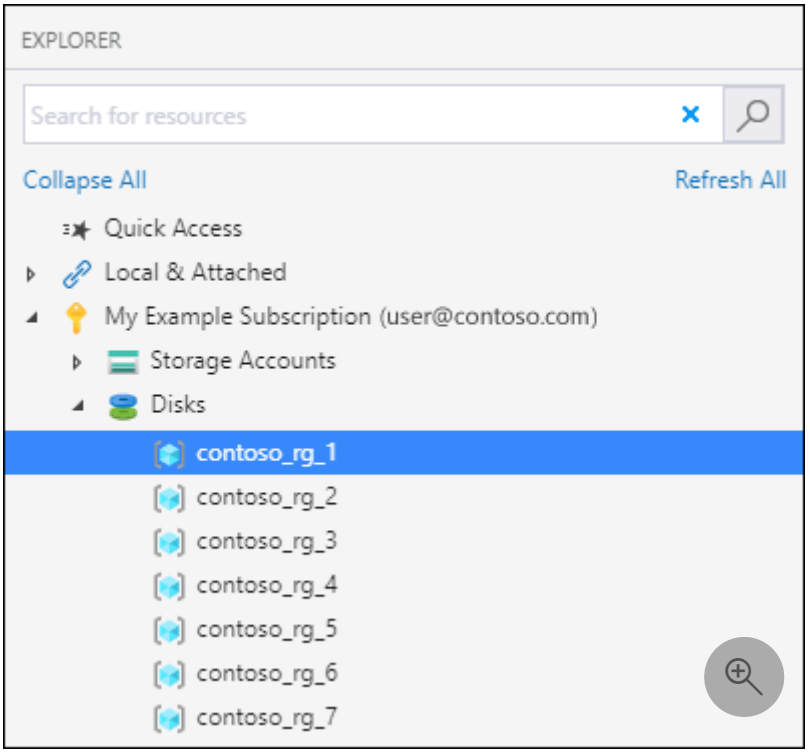
5. Select your subscription from the list and then select **Open Explorer**.



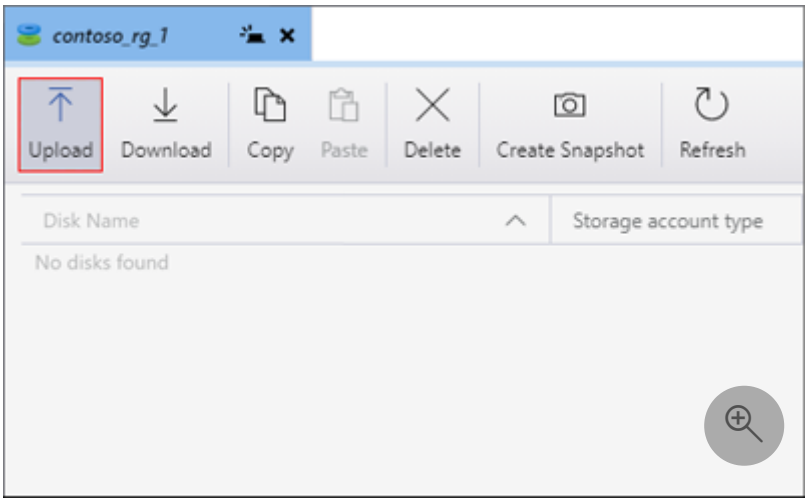
Upload an on-premises VHD

You can upload an on-premises virtual hard disk (VHD) file to Azure and use it to create an image. Follow the steps in this section to upload your source file.

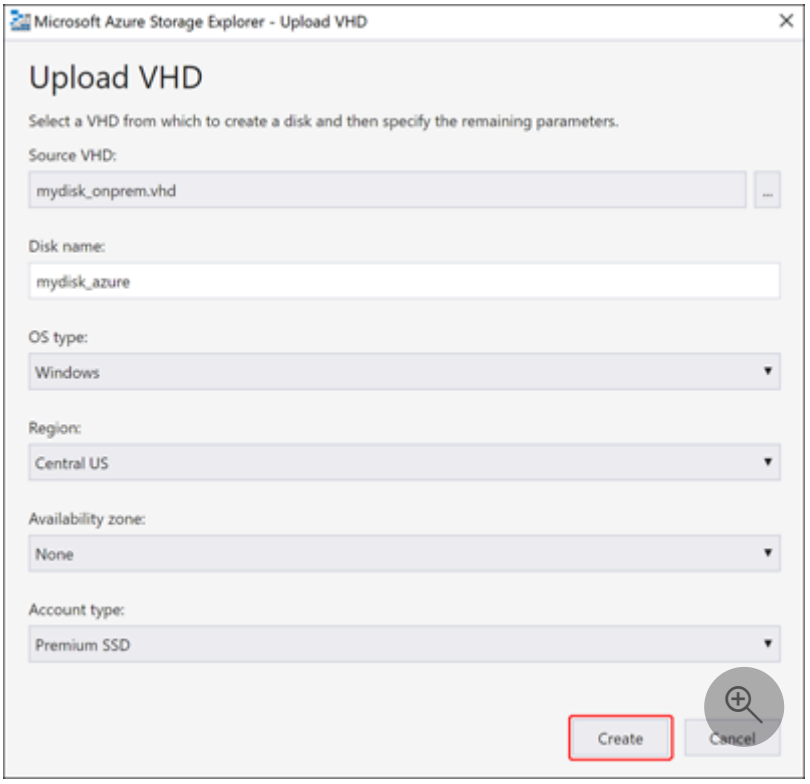
1. In the **Explorer** pane, expand **Disks** and select the resource group to which you'll upload your disk.



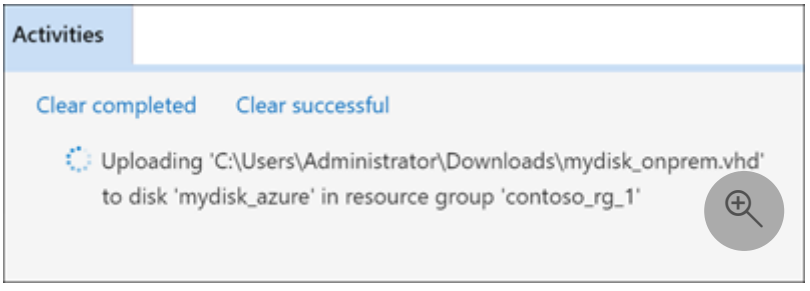
2. In the resource group details pane, select **Upload**.



3. In the **Upload VHD** dialog box, specify your VHD source file, the name of the disk, the operating system type, the region to which you want to upload the disk, and the account type. If the region supports availability zones, you can select a zone of your choice. Select **Create** to begin uploading your disk.



4. The status of the upload will now display in **Activities**.

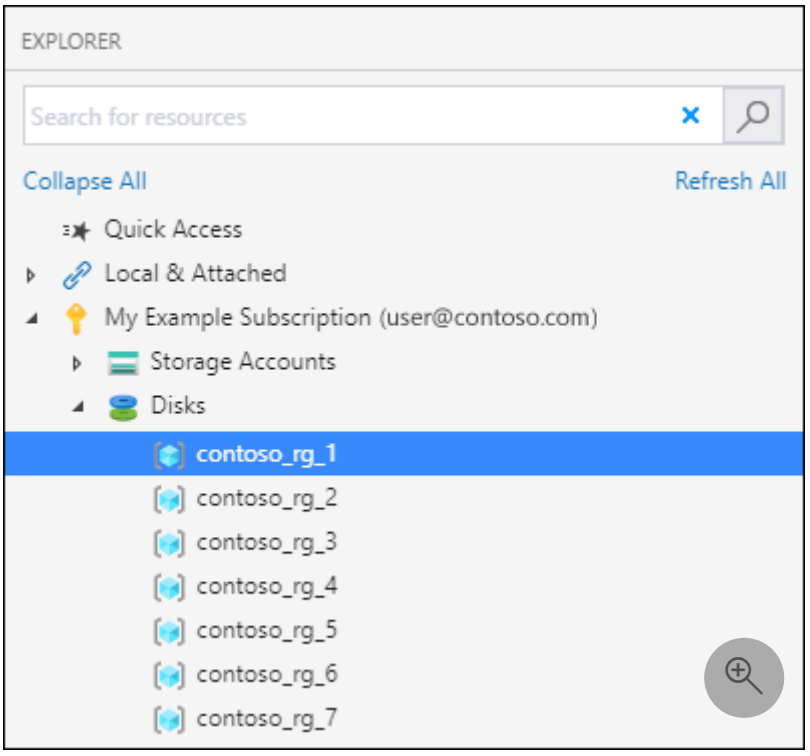


If the upload has finished and you don't see the disk in the **Activities** pane, select **Refresh**.

Download a managed disk

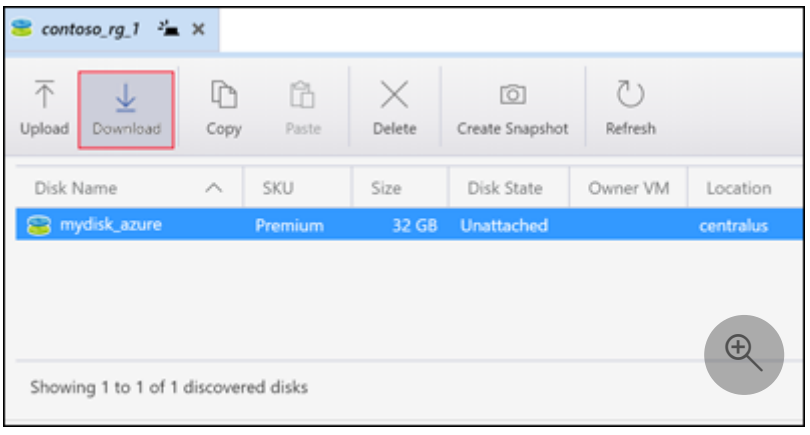
Follow the steps in this section to download a managed disk to an on-premises VHD. A disk's state must be **Unattached** before it can be downloaded.

1. In the **Explorer** pane, expand **Disks** and select the resource group from which you'll download your disk.

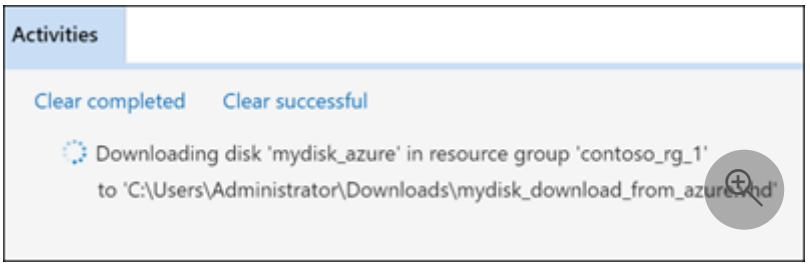


2. In the resource group details pane, select the disk you want to download.

3. Select **Download** and then choose where you would like to save the disk.



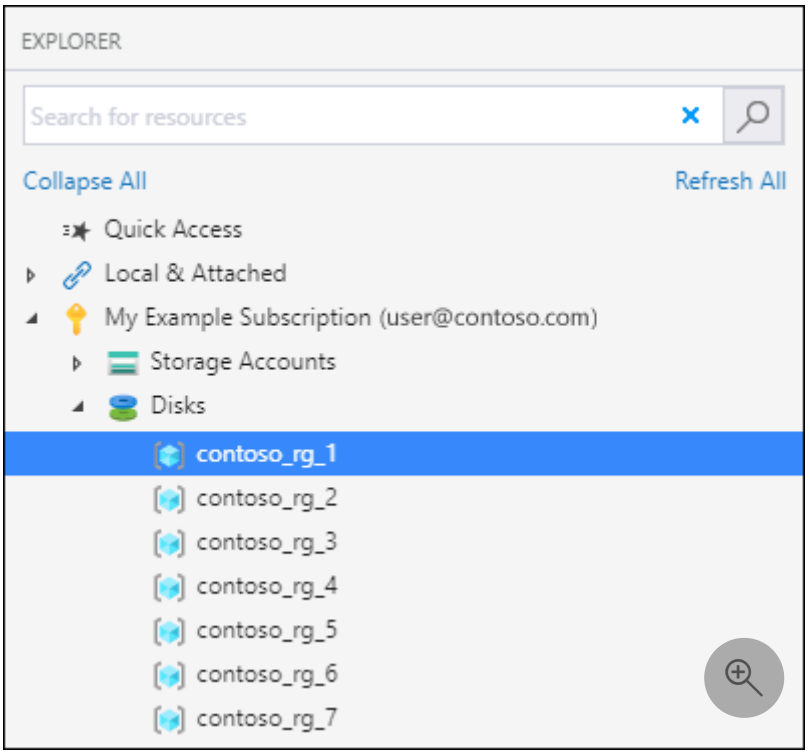
4. Select **Save** the begin the download. The download status will display in **Activities**.



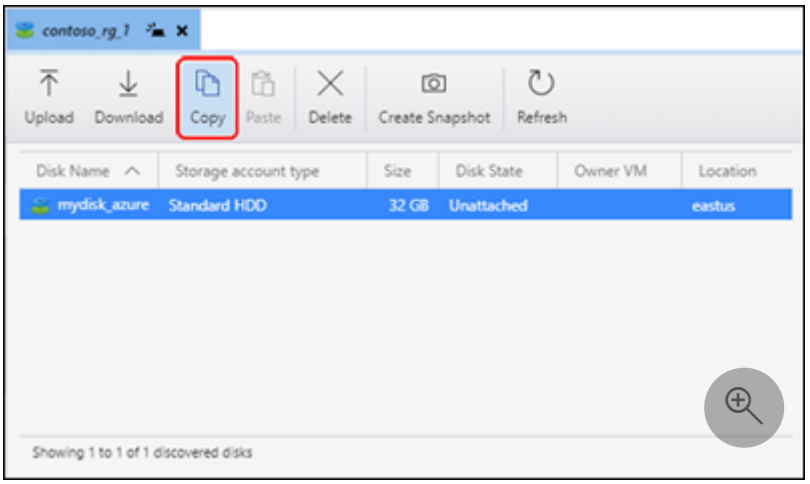
Copy a managed disk

With Storage Explorer, you can copy a manged disk within or across regions. To copy a disk:

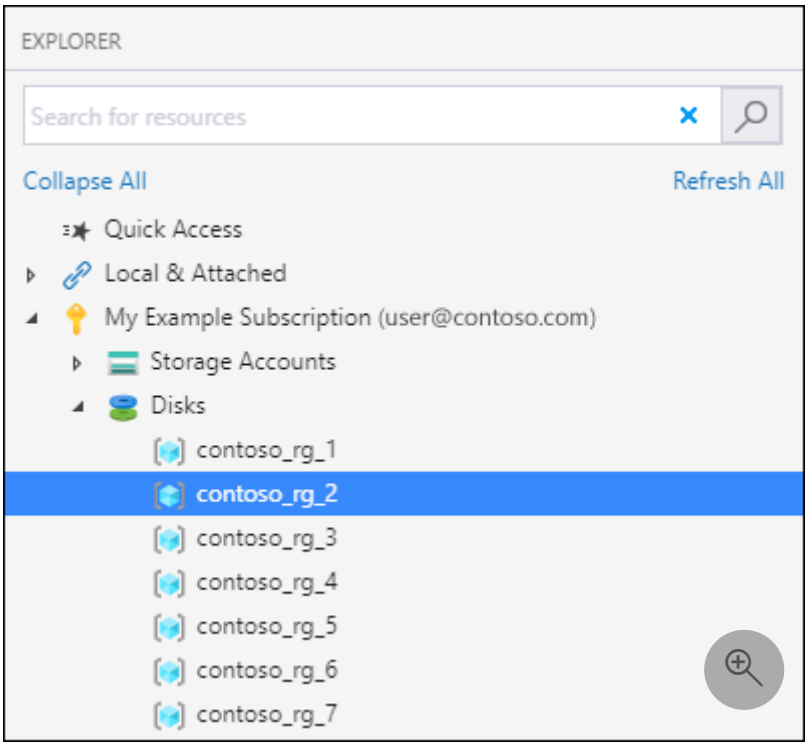
1. In the **Explorer** pane, expand the **Disks** dropdown and select the resource group that contains the disk you want to copy.



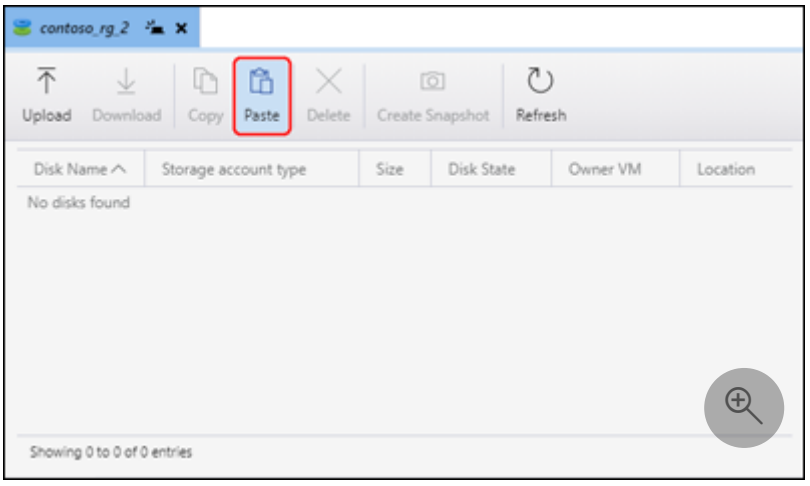
2. In the resource group details pane, select the disk you'd like to copy and select **Copy**.



3. In the **Explorer** pane, expand **Disks** and select the resource group in which you'd like to paste the disk.

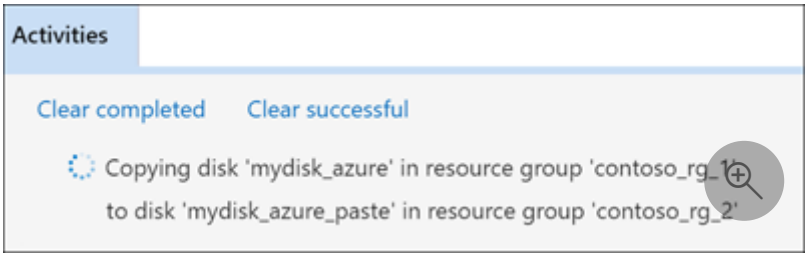


4. Select **Paste** in the resource group details pane.



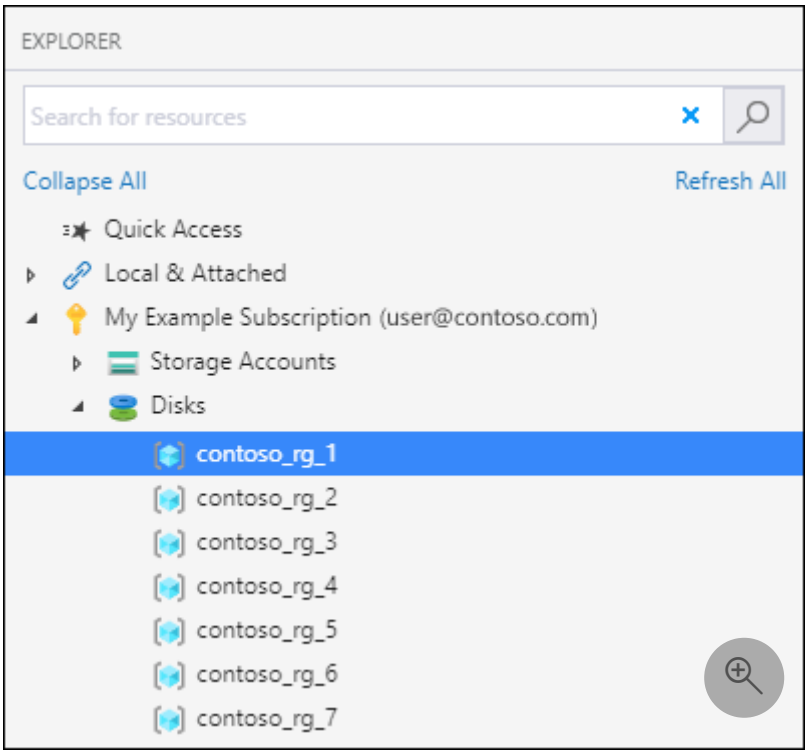
5. In the **Paste Disk** dialog box, fill in the values. You can also specify an availability zone in supported regions.

6. Select **Paste** to begin the disk copy. The status is displayed in **Activities**.

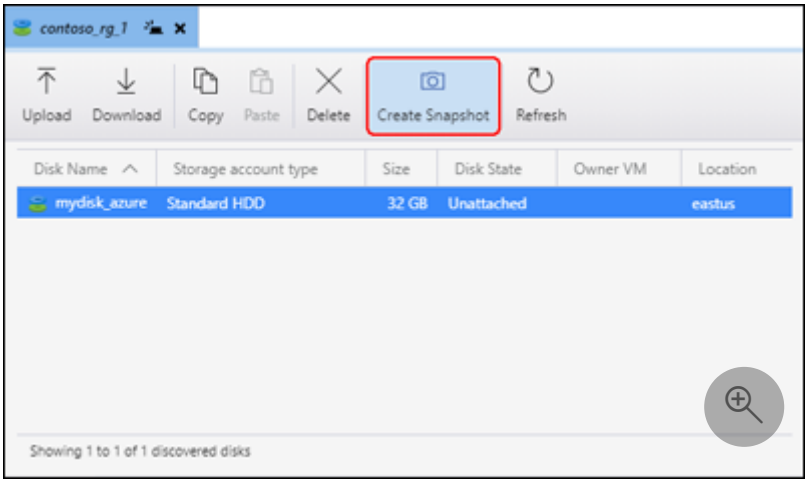


Create a snapshot

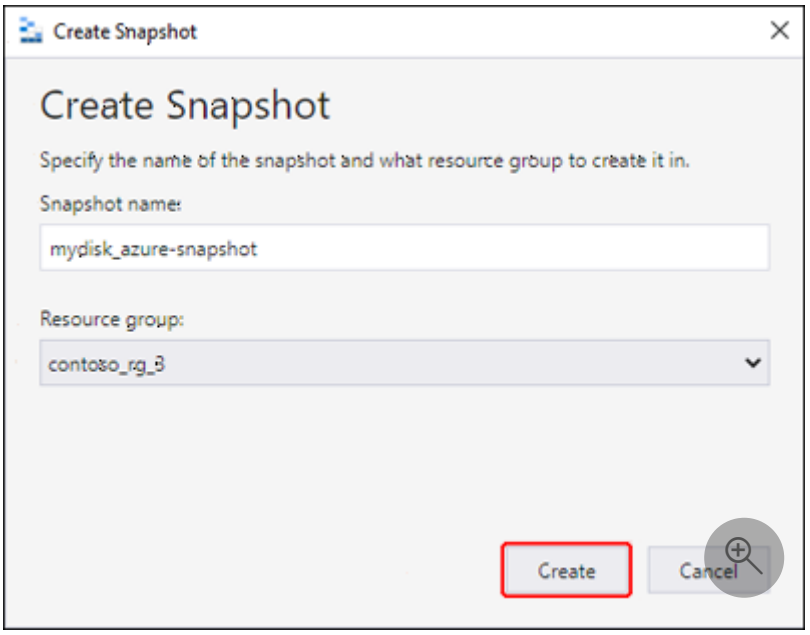
1. In the **Explorer** pane, expand **Disks** and select the resource group that contains the disk you want to snapshot.



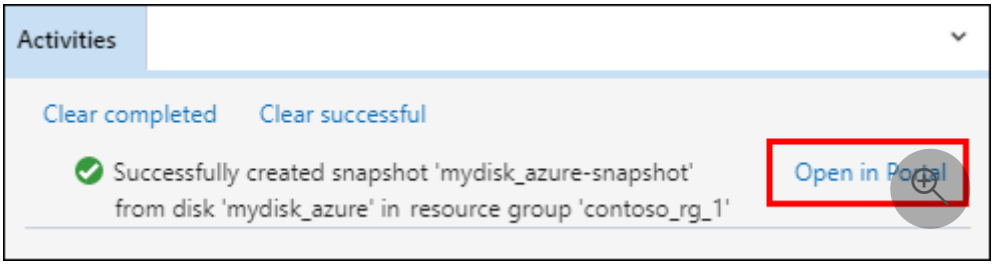
2. In the resource group details pane, select the disk you'd like to snapshot and select **Create Snapshot**.



3. In **Create Snapshot**, specify the name of the snapshot and the resource group in which you'll create it. Select **Create**.



4. After the snapshot has been created, you can select **Open in Portal** in **Activities** to view the snapshot in the Azure portal.



Next steps

- Create a virtual machine from a VHD by using the Azure portal
- Attach a managed data disk to a Windows virtual machine by using the Azure portal

Change the OS disk used by an Azure VM using the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

If you have an existing VM, but you want to swap the disk for a backup disk or another OS disk, you can use the Azure CLI to swap the OS disks. You don't have to delete and recreate the VM. You can even use a managed disk in another resource group, as long as it isn't already in use.

The VM does not need to be stopped\deallocated. The resource ID of the managed disk can be replaced with the resource ID of a different managed disk.

Make sure that the VM size and storage type are compatible with the disk you want to attach. For example, if the disk you want to use is in Premium Storage, then the VM needs to be capable of Premium Storage (like a DS-series size). Both disks must also be the same size. And ensure that you're not mixing an un-encrypted VM with an encrypted OS disk, this is not supported. If the VM doesn't use Azure Disk Encryption, then the OS disk being swapped in shouldn't be using Azure Disk Encryption. If disks are using Disk Encryption Sets, both disks should belong to same Disk Encryption set.

This article requires Azure CLI version 2.0.25 or greater. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Use az disk list to get a list of the disks in your resource group.

Azure CLI

```
az disk list \
   -g myResourceGroupDisk \
   --query '[*].{diskId:id}' \
   --output table
```

(Optional) Use az vm stop to stop\deallocate the VM before swapping the disks.

Azure CLI

```
az vm stop \
   -n myVM \
   -g myResourceGroup
```

Use az vm update with the full resource ID of the new disk for the `--osdisk` parameter

Azure CLI

```
az vm update \
   -g myResourceGroup \
   -n myVM \
   --os-disk /subscriptions/<subscription ID>/resourceGroups/<resource
group>/providers/Microsoft.Compute/disks/myDisk
```

Restart the VM using az vm start.

Azure CLI

```
az vm start \
   -n myVM \
   -g myResourceGroup
```

Next steps

To create a copy of a disk, see Snapshot a disk.

Change the OS disk used by an Azure VM using PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

If you have an existing VM, but you want to swap the disk for a backup disk or another OS disk, you can use Azure PowerShell to swap the OS disks. You don't have to delete and recreate the VM. You can even use a managed disk in another resource group, as long as it isn't already in use.

The VM does not need to be stopped\deallocated. The resource ID of the managed disk can be replaced with the resource ID of a different managed disk.

Make sure that the VM size and storage type are compatible with the disk you want to attach. For example, if the disk you want to use is in Premium Storage, then the VM needs to be capable of Premium Storage (like a DS-series size). Both disks must also be the same size. And ensure that you're not mixing an un-encrypted VM with an encrypted OS disk, this is not supported. If the VM doesn't use Azure Disk Encryption, then the OS disk being swapped in shouldn't be using Azure Disk Encryption. If disks are using Disk Encryption Sets, both disks should belong to same Disk Encryption set.

Get a list of disks in a resource group using Get-AzDisk

Azure PowerShell

```
Get-AzDisk -ResourceGroupName myResourceGroup | Format-Table -Property Name
```

When you have the name of the disk that you would like to use, set that as the OS disk for the VM. This example stop\deallocates the VM named *myVM* and assigns the disk named *newDisk* as the new OS disk.

Azure PowerShell

```
# Get the VM
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM

# (Optional) Stop/ deallocate the VM
Stop-AzVM -ResourceGroupName myResourceGroup -Name $vm.Name -Force

# Get the new disk that you want to swap in
$disk = Get-AzDisk -ResourceGroupName myResourceGroup -Name newDisk

# Set the VM configuration to point to the new disk
```

```
Set-AzVMOSDisk -VM $vm -ManagedDiskId $disk.Id -Name $disk.Name

# Update the VM with the new OS disk
Update-AzVM -ResourceGroupName myResourceGroup -VM $vm

# Start the VM
Start-AzVM -Name $vm.Name -ResourceGroupName myResourceGroup
```

Next steps

To create a copy of a disk, see Snapshot a disk.

How to map Azure Disks to Linux VM guest disks

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

You may need to determine the Azure Disks that back a VM's guest disks. In some scenarios, you can compare the disk or volume size to the size of the attached Azure Disks. In scenarios where there are multiple Azure Disks of the same size attached to the VM you need to use the Logical Unit Number (LUN) of the data disks.

What is a LUN?

A Logical Unit Number (LUN) is a number that is used to identify a specific storage device. Each storage device is assigned a unique numeric identifier, starting at zero. The full path to a device is represented by the bus number, target ID number, and Logical Unit Number (LUN).

For example: ***Bus Number 0, Target ID 0, LUN 3***

For our exercise, you only need to use the LUN.

Finding the LUN

Below we have listed two methods for finding the LUN of a disk in Linux.

lsscsi

1. Connect to the VM
2. `sudo lsscsi`

The first column listed will contain the LUN, the format is [Host:Channel:Target:**LUN**].

Listing block devices

1. Connect to the VM
2. `sudo ls -l /sys/block/*/device`

The last column listed will contain the LUN, the format is [Host:Channel:Target:**LUN**]

Finding the LUN for the Azure Disks

You can locate the LUN for an Azure Disk using the Azure portal, Azure CLI.

Finding an Azure Disk's LUN in the Azure portal

1. In the Azure portal, select "Virtual Machines" to display a list of your Virtual Machines
2. Select the Virtual Machine
3. Select "Disks"
4. Select a data disk from the list of attached disks.
5. The LUN of the disk will be displayed in the disk detail pane. The LUN displayed here correlate to the LUNs that you looked up in the Guest using lsscsi, or listing the block devices.

Finding an Azure Disk's LUN using Azure CLI

Azure CLI

```
az vm show -g myResourceGroup -n myVM --query "storageProfile.dataDisks"
```

How to map Azure Disks to Windows VM guest disks

Article • 08/22/2024

Applies to: ✔ Windows VMs

You may need to determine the Azure Disks that back a VM's guest disks. In some scenarios, you can compare the disk or volume size to the size of the attached Azure Disks. In scenarios where there are multiple Azure Disks of the same size attached to the VM you need to use the Logical Unit Number (LUN) of the data disks.

What is a LUN?

A Logical Unit Number (LUN) is a number that is used to identify a specific storage device. Each storage device is assigned a unique numeric identifier, starting at zero. The full path to a device is represented by the bus number, target ID number, and Logical Unit Number (LUN).

For example: ***Bus Number 0, Target ID 0, LUN 3***

For our exercise, you only need to use the LUN.

Finding the LUN

There are two methods to finding the LUN, which one you choose will depend on if you are using Storage Spaces or not.

Disk Management

If you are not using Storage Pools, you can use Disk Management to find the LUN.

1. Connect to the VM and open Disk Management a. Right-click on the Start button and choose "Disk Management" a. You can also type `diskmgmt.msc` into the Start Search box
2. In the lower pane, right-click any of the Disks and choose "Properties"
3. The LUN will be listed in the "Location" property on the "General" tab

Storage Pools

1. Connect to the VM and open Server Manager
2. Select "File and Storage Services", "Volumes", "Storage Pools"
3. In the bottom-right corner of Server Manager, there will be a "Physical Disks" section. The disks that make up the Storage Pool are listed here as well as the LUN for each disk.

Finding the LUN for the Azure Disks

You can locate the LUN for an Azure Disk using the Azure portal, Azure CLI, or Azure PowerShell

Finding an Azure Disk's LUN in the Azure portal

1. In the Azure portal, select "Virtual Machines" to display a list of your Virtual Machines
2. Select the Virtual Machine
3. Select "Disks"
4. Select a data disk from the list of attached disks.
5. The LUN of the disk will be displayed in the disk detail pane. The LUN displayed here correlates to the LUNs that were looked up in the Guest using Device Manager or Server Manager.

Finding an Azure Disk's LUN using Azure CLI or Azure PowerShell

Azure CLI

```
az vm show -g myResourceGroup -n myVM --query "storageProfile.dataDisks"
```

Learn about Azure-VM-Utils

09/30/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

The azure-vm-utils package provides essential utilities and udev rules to optimize the Linux experience on Azure Virtual Machines. This package consolidates device management tools for Small Computer System Interface (SCSI), Non-Volatile Memory Express (NVMe), Microsoft Azure Network Adapter (MANA), and Mellanox devices, making disk identification and management more reliable and consistent across different VM configurations.

NVMe udev rules

Newer virtual machines (VMs) SKUs on Azure use the NVMe interface for disk management. VMs with NVMe interfaces interpret and present disks differently from VMs that use SCSI interfaces. For details, see SCSI to NVMe conversion.

NVMe udev rules in this package consolidate critical tools and udev rules to create stable, predictable symlinks for Azure disks. This package provides an easy and reliable way to identify disks, making automation, troubleshooting, and management simpler.

Symlinks

WALinuxAgent currently includes udev rules to provide several symlinks for SCSI disks:

- `/dev/disk/azure/resource`
- `/dev/disk/azure/root`
- `/dev/disk/azure/scsi0/lun<lun>`
- `/dev/disk/azure/scsi1/lun<lun>`

The rules found in WALinuxAgent are being extended with azure-vm-utils to add identification support for NVMe devices.

The following symlinks are provided for all instances with NVMe disks:

- `/dev/disk/azure/data/by-lun/<lun>`
- `/dev/disk/azure/local/by-serial/<serial>`
- `/dev/disk/azure/os`

For v6 and newer VM sizes with local NVMe disks that support namespace identifiers, the following links are also available:

- `/dev/disk/azure/local/by-index/<index>`
- `/dev/disk/azure/local/by-name/<name>`

SCSI compatibility

To ensure backward compatibility for disks using SCSI controllers, azure-vm-utils supports the following links:

- `/dev/disk/azure/os`
- `/dev/disk/azure/resource`

> **Note**
>
> Some VM sizes come with both a NVMe temporary disk in addition to a SCSI temporary disk.

Linux distribution support

The following distros and versions currently include az-vm-utils in their official Azure marketplace images:

Expand table

Distribution	Version
Fedora	42
Flatcar	4152.2.3
Azure Linux	2.0

Installation

If the package isn't present in the default platform image, install it via package managers or from the GitHub repository.

Manual installation

For distributions where azure-vm-utils isn't preinstalled, build and install it manually:

```
Bash
```

```
# Clone the repository
git clone https://github.com/Azure/azure-vm-utils.git
cd azure-vm-utils

# Build the package
cmake .
make

# Install (requires root privileges)
sudo make install
```

Utilities

azure-nvme-id

The `azure-nvme-id` utility helps identify Azure NVMe devices and their properties. This utility is useful for troubleshooting and scripting.

To run the utility:

Bash

```
sudo azure-nvme-id
```

To run in udev mode (typically used by udev rules):

Bash

```
DEVNAME=/dev/nvme0n1 azure-nvme-id --udev
```

Using the symlinks

After azure-vm-utils is installed, you can use the predictable symlinks for disk operations instead of relying on device names that might change between reboots.

Examples

List all Azure disk symlinks:

Bash

```
find /dev/disk/azure/ -type l
```

Access the OS disk:

```Bash
ls -la /dev/disk/azure/os
```

Access data disks by LUN:

```Bash
ls -la /dev/disk/azure/data/by-lun/
```

Access local NVMe disks by serial number:

```Bash
ls -la /dev/disk/azure/local/by-serial/
```

Verification

To verify that azure-vm-utils is working correctly on your VM:

1. Check if the package is installed:

   ```Bash
   # For RPM-based systems
   rpm -qa azure-vm-utils

   # For DEB-based systems
   dpkg -l azure-vm-utils
   ```

2. Verify udev rules are in place:

   ```Bash
   ls -al /usr/lib/udev/rules.d/10-azure-unmanaged-sriov.rules
   ls -al /usr/lib/udev/rules.d/80-azure-disk.rules
   ```

3. Check for Azure disk symlinks:

Bash

```
find /dev/disk/azure -type l
```

Use SCP to move files to and from a VM

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This article shows how to move files from your workstation up to an Azure VM, or from an Azure VM down to your workstation, using Secure Copy (SCP). Moving files between your workstation and a VM, quickly and securely, is critical for managing your Azure infrastructure.

For this article, you need a VM deployed in Azure with SSH enabled. You also need an SCP client for your local computer. It's built on top of SSH and included in the default shell of most Linux and Windows (10 and newer) installations.

Quick commands

Upload a file to the VM

```Bash
scp file azureuser@azurehost:directory/targetfile
```

Download a file from the VM

```Bash
scp azureuser@azurehost:directory/file targetfile
```

Detailed walkthrough

As examples, we move an Azure configuration file up to a VM and pull down a log file directory, both using SCP.

SSH key pair authentication

SCP uses SSH for the transport layer. SSH handles the authentication on the destination host, and it moves the file in an encrypted tunnel provided by default with SSH. For SSH authentication, usernames and passwords can be used. However, SSH public and private key authentication are recommended as a security best practice. Once SSH has authenticated the connection, SCP then begins copying the file. When you use a

properly configured `~/.ssh/config` and SSH public and private keys, the SCP connection can be established by just using a server name (or IP address). If you only have one SSH key, SCP looks for it in the `~/.ssh/` directory, and uses it by default to log in to the VM.

For more information on configuring your `~/.ssh/config` and SSH public and private keys, see Create SSH keys.

Upload a file to a VM

For the first example, we copy an Azure configuration file up to a VM that is used to deploy automation. Because this file contains Azure API credentials, which include secrets, security is important. The encrypted tunnel provided by SSH protects the contents of the file.

The following command copies the local *.azure/config* file to an Azure VM with FQDN *myserver.eastus.cloudapp.azure.com*. If you don't have an FQDN set, you can also use the IP address of the VM. The admin user name on the Azure VM is *azureuser*. The file is targeted to the */home/azureuser/* directory. Substitute your own values in this command.

Bash

```
scp ~/.azure/config
azureuser@myserver.eastus.cloudapp.com:/home/azureuser/config
```

Download a directory from a VM

For this example, we copy a directory of log files from the VM down to your workstation. A log file may or may not contain sensitive or secret data. However, using SCP ensures the contents of the log files are encrypted. A log directory may contain too many relevant files to copy one at a time, so downloading the whole directory is preferred in this situation. Using SCP to transfer the files is the easiest way to get the log directory and files down to your workstation while also being secure.

The following command copies files in the */home/azureuser/logs/* directory on the Azure VM to the local /tmp directory:

Bash

```
scp -r azureuser@myserver.eastus.cloudapp.com:/home/azureuser/logs/. /tmp/
```

The `-r` flag instructs SCP to recursively copy the files and directories from the point of the directory listed in the command. Also notice that the command-line syntax is similar to a `cp` copy command.

Next steps

- Manage users, SSH, and check or repair disks on Azure Linux VMs using the 'VMAccess' Extension

Find and delete unattached Azure managed and unmanaged disks by using the Azure CLI

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Flexible scale sets

When you delete a virtual machine (VM) in Azure, by default, any disks that are attached to the VM aren't deleted. This feature helps to prevent data loss due to the unintentional deletion of VMs. After a VM is deleted, you will continue to pay for unattached disks. This article shows you how to find and delete any unattached disks and reduce unnecessary costs.

> **Note**
>
> Use the az disk show command to get the `LastOwnershipUpdateTime` for any disk. This property shows when the disk's state was last updated. For an unattached disk, this property shows the time when the disk was unattached. This property is blank for newly created disks, until their state changes.

Managed disks: Find and delete unattached disks

The following script looks for unattached managed disks by examining the value of the **ManagedBy** property. When you attach a managed disk to a VM, the **ManagedBy** property contains the resource ID of the VM. When a managed disk is unattached, the **ManagedBy** property is null. The script examines all the managed disks in an Azure subscription. When the script locates a managed disk with the **ManagedBy** property set to null, the script determines that the disk is unattached.

> **Important**
>
> First, run the script by setting the **deleteUnattachedDisks** variable to 0. This action lets you find and view all the unattached managed disks.
>
> After you review all the unattached disks, run the script again and set the **deleteUnattachedDisks** variable to 1. This action lets you delete all the unattached managed disks.

Azure CLI

```
# Set deleteUnattachedDisks=1 if you want to delete unattached Managed Disks
# Set deleteUnattachedDisks=0 if you want to see the Id of the unattached Managed
Disks
deleteUnattachedDisks=0
unattachedDiskIds=$(az disk list --query '[?managedBy==`null`].[id]' -o tsv)
for id in ${unattachedDiskIds[@]}
do
    if (( $deleteUnattachedDisks == 1 ))
    then

        echo "Deleting unattached Managed Disk with Id: "$id
        az disk delete --ids $id --yes
        echo "Deleted unattached Managed Disk with Id: "$id

    else
        echo $id
    fi
done
```

Unmanaged disks: Find and delete unattached disks

Unmanaged disks are VHD files that are stored as page blobs in Azure storage accounts. The following script looks for unattached unmanaged disks (page blobs) by checking the value of the **LeaseStatus** property. When you attach an unmanaged disk to a VM, the **LeaseStatus** property is **Locked**. When an unmanaged disk is unattached, the **LeaseStatus** property is **Unlocked**. The script checks all the unmanaged disks in all the Azure storage accounts in an Azure subscription. When the script finds an unmanaged disk with a **LeaseStatus** property set to **Unlocked**, the script determines that the disk is unattached.

> **ⓘ Important**
>
> First, run the script by setting the **deleteUnattachedVHDs** variable to 0. This lets you find and view all the unattached unmanaged VHDs.
>
> After you review all the unattached disks, run the script again and set the **deleteUnattachedVHDs** variable to 1. This deletes all your unattached unmanaged VHDs.

Azure CLI

```
# Set deleteUnattachedVHDs=1 if you want to delete unattached VHDs
# Set deleteUnattachedVHDs=0 if you want to see the details of the unattached VHDs
deleteUnattachedVHDs=0
storageAccountIds=$(az storage account list --query [].[id] -o tsv)
for id in ${storageAccountIds[@]}
```

```
do
    connectionString=$(az storage account show-connection-string --ids $id --query
connectionString -o tsv)
    containers=$(az storage container list --connection-string $connectionString --
query [].[name] -o tsv)

    for container in ${containers[@]}
    do

        blobs=$(az storage blob list --show-next-marker -c $container --connection-
string $connectionString --query "[?properties.blobType=='PageBlob' &&
ends_with(name,'.vhd')].[name]" -o tsv)

        for blob in ${blobs[@]}
        do
            leaseStatus=$(az storage blob show -n $blob -c $container --connection-
string $connectionString --query "properties.lease.status" -o tsv)

            if [ "$leaseStatus" == "unlocked" ]
            then

                if (( $deleteUnattachedVHDs == 1 ))
                then

                    echo "Deleting VHD: "$blob" in container: "$container" in
storage account: "$id

                    az storage blob delete --delete-snapshots include  -n $blob -c
$container --connection-string $connectionString

                    echo "Deleted VHD: "$blob" in container: "$container" in
storage account: "$id
                else
                    echo "StorageAccountId: "$id" container: "$container" VHD:
"$blob
                fi

            fi
        done
    done
done
```

Find and delete unattached Azure managed and unmanaged disks by using Azure PowerShell

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

When you delete a virtual machine (VM) in Azure, by default, any disks that are attached to the VM aren't deleted. This feature helps to prevent data loss due to the unintentional deletion of VMs. After a VM is deleted, you will continue to pay for unattached disks. This article shows you how to find and delete any unattached disks and reduce unnecessary costs.

> **Note**
>
> You can use the `Get-AzureDisk` command to get the `LastOwnershipUpdateTime` for any disk. This property represents when the disk's state was last updated. For an unattached disk, this value shows the time when the disk was unattached. This property is blank for newly created disks, until their state changes.

Managed disks: Find and delete unattached disks

The following script looks for unattached managed disks by examining the value of the **ManagedBy** property. When you attach a managed disk to a VM, the **ManagedBy** property contains the resource ID of the VM. When a managed disk is unattached, the **ManagedBy** property is null. The script examines all the managed disks in an Azure subscription. When the script locates a managed disk with the **ManagedBy** property set to null, the script determines that the disk is unattached.

> **Important**
>
> First, run the script by setting the **deleteUnattachedDisks** variable to 0. This action lets you find and view all the unattached managed disks.
>
> After you review all the unattached disks, run the script again and set the **deleteUnattachedDisks** variable to 1. This action deletes all the unattached managed disks.

Azure PowerShell

```
# Set deleteUnattachedDisks=1 if you want to delete unattached Managed Disks
# Set deleteUnattachedDisks=0 if you want to see the Id of the unattached Managed
Disks
$deleteUnattachedDisks=0
$managedDisks = Get-AzDisk
foreach ($md in $managedDisks) {
    # ManagedBy property stores the Id of the VM to which Managed Disk is attached
to
    # If ManagedBy property is $null then it means that the Managed Disk is not
attached to a VM
    if($md.ManagedBy -eq $null){
        if($deleteUnattachedDisks -eq 1){
            Write-Host "Deleting unattached Managed Disk with Id: $($md.Id)"
            $md | Remove-AzDisk -Force
            Write-Host "Deleted unattached Managed Disk with Id: $($md.Id) "
        }else{
            $md.Id
        }
    }
 }
```

Unmanaged disks: Find and delete unattached disks

On March 31st, 2026, unmanaged disks are being retired. If you're using unmanaged disks, migrate to managed disks before that date. For details on the retirement, see Migrate your Azure unmanaged disks by March 31st, 2026.

Unmanaged disks are VHD files that are stored as page blobs in Azure storage accounts. The following script looks for unattached unmanaged disks (page blobs) by examining the value of the **LeaseStatus** property. When an unmanaged disk is attached to a VM, the **LeaseStatus** property is set to **Locked**. When an unmanaged disk is unattached, the **LeaseStatus** property is set to **Unlocked**. The script examines all the unmanaged disks in all the Azure storage accounts in an Azure subscription. When the script locates an unmanaged disk with a **LeaseStatus** property set to **Unlocked**, the script determines that the disk is unattached.

> **ⓘ Important**
>
> The script has **deleteUnattachedVHDs** variable set to `$false` by default. This setting lets you find and view all the unattached unmanaged VHDs.
>
> After you review all the unattached disks, if you want to delete all those VHDs, set the **deleteUnattachedVHDs** variable to `$true` and run the script again. This action deletes all unattached VHDs.

Azure PowerShell

```
# Set deleteUnattachedVHDs=$true if you want to delete unattached VHDs
# Set deleteUnattachedVHDs=$false if you want to see the Uri of the unattached VHDs
$deleteUnattachedVHDs = $false
$storageAccounts = Get-AzStorageAccount
foreach ($storageAccount in $storageAccounts) {
    $storageKey = (Get-AzStorageAccountKey -ResourceGroupName
$storageAccount.ResourceGroupName -Name $storageAccount.StorageAccountName)
[0].Value

    $context = New-AzStorageContext -StorageAccountName
$storageAccount.StorageAccountName -StorageAccountKey $storageKey

    $containers = Get-AzStorageContainer -Context $context

    foreach ($container in $containers) {
        $blobs = Get-AzStorageBlob -Container $container.Name -Context $context
        #Fetch all the Page blobs with extension .vhd as only Page blobs can be
attached as disk to Azure VMs
        $blobs | Where-Object {$_.BlobType -eq 'PageBlob' -and
$_.Name.EndsWith('.vhd')} | ForEach-Object {
            if ($_.BlobProperties.LeaseStatus -eq 'Unlocked') {
                if ($deleteUnattachedVHDs) {
                    Write-Host "Deleting unattached VHD with Uri:
$($_.ICloudBlob.Uri.AbsoluteUri)"
                    Remove-AzStorageBlob -Blob $_.Name -Container $container.Name -
Context $context -Force
                    Write-Host "Deleted unattached VHD with Uri:
$($_.ICloudBlob.Uri.AbsoluteUri)"
                } else {
                    Write-Host "Unattached VHD Uri:
$($_.ICloudBlob.Uri.AbsoluteUri)"
                }
            }
        }
    }
}
```

Frequently asked questions about Azure IaaS VM disks and managed and unmanaged premium disks

This article answers some frequently asked questions about Azure managed disks and Azure Premium SSDs.

Managed disks

If I create a standard managed disk from an existing VHD that's 80 GiB, how much will that cost me?

A standard managed disk created from an 80-GiB VHD is treated as the next available standard disk size, which is an S10 disk. You're charged according to the S10 disk pricing. For more information, see the pricing page.

For a standard managed disk, will I be charged for the actual size of the data on the disk or for the provisioned capacity of the disk?

You're charged based on the provisioned capacity of the disk. For more information, see the pricing page.

Can I use a VHD file in an Azure storage account to create a managed disk with a different subscription?

Yes.

Can I use a VHD file in an Azure storage account to create a managed disk in a different region?

No.

Are there limits on how many managed disks I can have?

Yes. The maximum limit is 50,000 managed disks per region and per disk type for a subscription.

Can VMs in an availability set consist of a combination of managed and unmanaged disks?

No. The VMs in an availability set must use either all managed disks or all unmanaged disks. When you create an availability set, you can choose which type of disks you want to use.

Can I create an empty managed disk?

Yes. You can create an empty disk. A managed disk can be created independently of a VM, for example, without attaching it to a VM.

What is the supported fault domain count for an availability set that uses managed disks?

Depending on the region where the availability set that uses managed disks is located, the supported fault domain count is 2 or 3.

What kind of Azure role-based access control support is available for managed disks?

Managed disks supports three key default roles:

- Owner: Can manage everything, including access
- Contributor: Can manage everything except access
- Reader: Can view everything, but can't make changes

Can I copy or export a managed disk to a private storage account?

You can generate a read-only shared access signature (SAS) URI for the managed disk and use it to copy the contents to a private storage account or on-premises storage. You can use the

SAS URI using the Azure portal, Azure PowerShell, the Azure CLI, or AzCopy.

Can I create a copy of my managed disk?

You can take a snapshot of a managed disk and then use the snapshot to create another managed disk. You can also create a new managed disk from an existing managed disk.

Are unmanaged disks still supported?

Yes, but they'll be retired on March 31, 2026 (extended from September 30, 2025). As of November 18, 2022, new customer subscriptions aren't eligible to create unmanaged disks. Page blobs aren't affected by this change. Plan and complete migration of any VMs using unmanaged disks to managed disks before March 31, 2026. See pricing and migration guidance for Windows and Linux VMs, or refer to the migration overview. You should use managed disks for new workloads and migrate your current workloads to managed disks.

Can I colocate unmanaged and managed disks on the same VM?

No.

Can I shrink or downsize my managed disks?

No.

Can I change the computer name property when a specialized (not created by using the System Preparation tool or generalized) operating system disk is used to provision a VM?

No. You can't update the computer name property. The new VM inherits it from the parent VM, which was used to create the operating system disk.

Where can I find sample Azure Resource Manager templates to create VMs with managed disks?

- List of templates using managed disks

- https://github.com/chagarw/MDPP

When creating a disk from a blob, is there any continually existing relationship with that source blob?

No, when the new disk is created it's a full standalone copy of that blob at that time and there's no connection between the two. If you like, once you've created the disk, the source blob may be deleted without affecting the newly created disk in any way.

Can I rename a managed or unmanaged disk after it has been created?

Managed disks can't be renamed. However, you may rename an unmanaged disk as long as it isn't currently attached to a VHD or VM.

Can I use GPT partitioning on an Azure Disk?

Generation 1 images can only use GPT partitioning on data disks, not OS disks. OS disks must use the MBR partition style.

Generation 2 images can use GPT partitioning on the OS disk and the data disks.

What options does Azure disk reservation offer?

Azure disk reservation provides the option to purchase Premium SSDs in the specified SKUs from P30 (1 TiB) up to P80 (32 TiB) for a one-year term. There's no limitation on the minimum number of disks necessary to purchase a disk reservation. Additionally, you can choose to pay with a single, upfront payment or monthly payments. There's no additional transactional cost applied for Premium SSD managed disks.

Reservations are made in the form of disks, not capacity. In other words, when you reserve a P80 (32 TiB) disk, you get a single P80 disk, you can't then divide that specific reservation up into two smaller P70 (16 TiB) disks. You can reserve as many or as few disks as you like, including two separate P70 (16 TiB) disks.

How is Azure disk reservation applied?

Disks reservation follows a model similar to reserved virtual machine (VM) instances. The difference is that a disk reservation can't be applied to different SKUs, while a VM instance can. See Save costs with Azure Reserved VM Instances for more information on VM instances.

Can I use my data storage purchased through Azure disks reservation across multiple regions?

Azure disks reservations are purchased for a specific region and SKU (like P30 in East US 2), and can't be used outside these constructs. You can always purchase an additional Azure Disks Reservation for your disk storage needs in other regions or SKUs.

Do managed disks support "single instance VM SLA"?

Yes, all disk types support single instance VM SLA.

Can I attach a disk to a VM in another region?

No. All managed disks, even shared disks, must be in the same region as the VM they're attaching to.

For Premium SSD v2, the Azure pricing calculator gives me different pricing?

Premium SSD v2 provides a baseline performance of 3,000 IOPS and 125 MB/s for any size that is offered at no extra cost. Currently, for the following regions, the pricing calculator has an incorrect price. Until the pricing calculator is corrected, deduct 3000IOPS from target IOPS and 125MB/s for target bandwidth for these regions to correctly estimate the cost: North Central US, West Central US, West US, UK West, UAE Central, UAE North, Switzerland North, Switzerland West, Sweden South, Korea Central, Korea South, Japan East, Japan West, Italy North, Central India, South India, Germany North, Germany West Central, France Central, Canada Central, Canada East, Brazil South, US GOV Arizona, US GOV Virginia, Australia Central, Australia Central 2, Australia Southeast, South Africa North, South Arica West.

Why should I use the data disk to store applications and data instead of the OS disk?

- You can have more efficient backup and recovery operations, reducing downtime in the event of data loss or system failure, by frequently backing up your data disks. If the data disk experiences an issue, it's easier to recover since it's separate from the OS disk.
- You can expand your storage capacity by adding or expanding data disks without affecting the OS disk. Only data disks support live resize, you can't increase the size of OS disks without stopping the VM.
- Separating the OS from your applications and data onto different disks helps ensure that disks IOPs from the operating system and the application data don't interfere with each other. This can enhance overall system performance, and prevent contention issues that might happen when both the OS and applications are competing for disk resources.
- If there's a system failure or corruption occurs on the OS disk, you can reimage or reinstall the operating system without affecting the data disk. This reduces the risk of data loss and makes it easier when troubleshooting and for maintenance procedures.
- You can apply separate access controls and permissions to the OS disk and the data disk. This separation limits access to critical system files on the OS disk, mitigating potential security risks.

Snapshots

Can an encrypted incremental snapshot be copied across regions?

Yes.

Can I copy snapshots in an order other than their order of creation to another region?

No. Snapshots must be copied to other regions in creation order.

If a source incremental snapshot is deleted before a copy across regions completes, what happens?

The copy fails.

Are managed snapshots and images encrypted?

Yes. All managed snapshots and images are automatically encrypted.

What disk types support snapshots?

All disk types support some form of snapshot. For Ultra Disks and Premium SSD v2 disks, they only support incremental snapshots and have some limitations. For details, see Create an incremental snapshot for managed disks. The other disk types support both types of snapshots for all their disk sizes.

What happens if I have multiple incremental snapshots and delete one of them?

Deleting one of your incremental snapshots doesn't affect subsequent incremental snapshots. The system merges the data occupied by the first snapshot with the next snapshot under the hood to ensure that the subsequent snapshots aren't impacted due to the deletion of the first snapshot.

Azure shared disks

If I have an existing disk, can I enable shared disks on it?

Compatible managed disks created with API version 2019-07-01 or newer can enable shared disks. To do this, you need to unmount the disk from all VMs that it's attached to. Then, edit the **maxShares** property on the disk.

If I no longer want to use a disk in shared mode, how do I disable it?

Unmount the disk from all VMs that it's attached to. Then edit the maxShare property on the disk to 1.

Can you increase the size of a shared disk?

Yes.

Ultra Disks

What should I set my Ultra Disk throughput to?

If you're unsure what to set your disk throughput to, we recommend you start by assuming an IO size of 16 KiB and adjust the performance from there as you monitor your application. The formula is: Throughput in MB/s = # of IOPS * 16 / 1000.

I configured my disk to 40000 IOPS but I'm only seeing 12800 IOPS, why am I not seeing the performance of the disk?

In addition to the disk throttle, there's an IO throttle that gets imposed at the VM level. Ensure that the VM size you're using can support the levels that are configured on your disks. For details regarding IO limits imposed by your VM, see Sizes for virtual machines in Azure.

Can I use caching levels with an Ultra Disk?

No, Ultra Disks don't support the different caching methods that are supported on other disk types. Set the disk caching to **None**.

Can I attach an Ultra Disk to my existing VM?

Maybe, your VM has to be in a region and availability zone pair that supports Ultra Disks. See getting started with Ultra Disks for details.

Can I use an Ultra Disk as the OS disk for my VM?

No, Ultra Disks are only supported as data disks. You can migrate data from an existing data disk to an Ultra Disk. Attach both disks to the same VM and directly copy the data to the Ultra Disk, or utilize a third party solution for data migration.

Can I convert an existing disk to an Ultra Disk?

No, but you can migrate the data from an existing disk to an Ultra Disk. To migrate an existing disk to an Ultra Disk, attach both disks to the same VM, and copy the disk's data from one disk to the other or use a third party solution for data migration.

Can I attach an Ultra Disk to a VM running in an availability set?

No, this isn't currently supported.

Uploading to a managed disk

Can I upload data to an existing managed disk?

No, upload can only be used during the creation of a new empty disk with the **ReadyToUpload** state.

Can I attach a disk to a VM while it is in an upload state?

No.

Migrate to managed disks

Is there any impact of migration on the managed disks performance?

Migration involves movement of the disk from one storage location to another. This is orchestrated via background copy of data, which can take several hours to complete, typically less than 24 Hrs depending on the amount of data in the disks. During that time your application can experience higher than usual read latency as some reads can get redirected to the original location, and can take longer to complete. There's no impact on write latency during this period.

What changes are required in a pre-existing Azure Backup service configuration prior/after migration to managed disks?

No changes are required.

Will my VM backups created via Azure Backup service before the migration continue to work?

Yes, backups work seamlessly.

What changes are required in a pre-existing Azure Disks Encryption configuration prior/after migration to managed disks?

No changes are required.

Is automated migration of an existing virtual machine scale set from unmanaged disks to managed disks supported?

No. You can create a new scale set with managed disks using the image from your old scale set with unmanaged disks.

Can I create a managed disk from a page blob snapshot taken before migrating to managed disks?

No. You can export a page blob snapshot as a page blob and then create a managed disk from the exported page blob.

Can I fail over my on-premises machines protected by Azure Site Recovery to a VM with managed disks?

Yes, you can choose to fail over to a VM with managed disks.

Is there any impact of migration on Azure VMs protected by Azure Site Recovery via Azure to Azure replication?

No. Azure Site Recovery Azure to Azure protection for VMs with managed disks is available.

Can I migrate VMs with unmanaged disks that are located on storage accounts that are or were previously encrypted to managed disks?

Yes

managed disks and Storage Service Encryption

Is Server-side Encryption enabled by default when I create a managed disk?

Yes. Managed disks are encrypted with server-side encryption with platform managed keys.

Is the boot volume encrypted by default on a managed disk?

Yes. By default, all managed disks are encrypted, including the OS disk.

Can I disable Server-side Encryption for my managed disks?

No.

Does Azure Site Recovery support server-side encryption with customer-managed key for on-premises to Azure and Azure to Azure disaster recovery scenarios?

Yes.

Can I backup managed disks encrypted with server-side encryption with customer-managed key using Azure Backup service?

Yes.

Can I convert VMs with unmanaged disks that are located on storage accounts that are or were previously encrypted to managed disks?

Yes

Will an exported VHD from a managed disk or a snapshot also be encrypted?

No. But if you export a VHD to an encrypted storage account from an encrypted managed disk or snapshot, then it's encrypted.

Can I switch from Azure Disk Encryption to server-side encryption with either customer-managed keys or encryption at host?

Yes, it's possible to migrate from Azure Disk Encryption to encryption at host, though it requires creating new disks and VMs rather than in-place conversion. For detailed step-by-step instructions, see Migrate from Azure Disk Encryption to encryption at host.

Can I switch from server-side encryption with customer-managed keys to Azure Disk Encryption?

Yes. First, switch your disk to use platform-managed keys with one of the following steps:

Portal

1. Sign in to the Azure portal.
2. Select the disk you'd like to change the encryption type of.
3. Select **Encryption**.
4. For **Key management** select **Platform-managed key** and select save.

Your managed disk has successfully switched from being secured with your own customer-managed key to a platform-managed key.

Then, encrypt your current disk with Azure Disk Encryption.

Premium disks: Managed and unmanaged

If a VM uses a size series that supports Premium SSDs, such as a DSv2, can I attach both premium and standard data disks?

Yes.

Can I deploy a VM with an unmanaged disk in the Azure portal?

Not all OS images support deploying with an unmanaged disk in the Azure portal. If your chosen image doesn't support this method of deployment, we recommend that you use managed disks for new workloads and convert your existing disk to a managed disk. If you're unable to use managed disks, you can deploy a VM using unmanaged disks with either the Azure PowerShell module or the Azure CLI.

Can I attach both premium and standard data disks to a size series that doesn't support Premium SSDs, such as D, Dv2, G, or F series?

No. You can attach only standard data disks to VMs that don't use a size series that supports Premium SSDs.

Are there transaction costs to use Premium SSDs?

There's a fixed cost for each disk size, which comes provisioned with specific limits on IOPS and throughput. The other costs are outbound bandwidth, snapshot capacity, and costs associated with on-demand bursting, if applicable. For more information, see the pricing page.

What are the limits for IOPS and throughput that I can get from the disk cache?

The combined limits for cache and local SSD for a DS series are 4,000 IOPS per core and 33 MB/s per core. The GS series offers 5,000 IOPS per core and 50 MB/s per core.

Is the local SSD supported for a VM using managed disks?

The local SSD is temporary storage that is included with a VM using managed disks. There's no extra cost for this temporary storage. You shouldn't use this local SSD to store application data because it isn't persisted in Azure Storage.

Are there any repercussions for the use of TRIM on premium disks?

There's no downside to the use of TRIM on Azure disks on either premium or standard disks.

New disk sizes

What is the largest managed disk size supported for operating system and data disks on Gen1 VMs?

The partition type that Azure supports for Gen1 operating system disks is the master boot record (MBR). Although Gen1 OS disks only support MBR the data disks support GPT. While you can allocate up to a 4-TiB OS disk, the MBR partition type can only use up to 2 TiB of this disk space for the operating system. Azure supports up to 32 TiB for managed data disks.

What is the largest managed disk size supported for operating system and data disks on Gen2 VMs?

The partition type that Azure supports for Gen2 operating system disks is GUID Partition Table (GPT). Gen2 VMs support up to a 4-TiB OS disk. Azure supports up to 32 TiB for managed data disks.

What is the largest unmanaged disk size supported for operating system and data disks?

The partition type that Azure supports for an operating system disk using unmanaged disks is the master boot record (MBR). While you can allocate up to 4 TiB for an OS disk, the MBR

partition type can only use up to 2 TiB of this disk space for the operating system. Azure supports up to 4 TiB for unmanaged data disks.

What is the largest supported page blob size?

The largest page blob size that Azure supports is 8 TiB (8,191 GiB). The maximum page blob size when attached to a VM as data or operating system disks is 4 TiB (4,095 GiB).

Are P4 and P6 disk sizes supported for unmanaged disks or page blobs?

P4 (32 GiB) and P6 (64 GiB) disk sizes aren't supported as the default disk tiers for unmanaged disks and page blobs. You need to explicitly set the Blob Tier to P4 and P6 to have your disk mapped to these tiers. If you deploy an unmanaged disk or page blob with the disk size or content length less than 32 GiB or between 32 GiB to 64 GiB without setting the Blob Tier, you'll continue to land on P10 with 500 IOPS and 100 MB/s and the mapped pricing tier.

If my existing premium managed disk less than 64 GiB was created before the small disk was enabled (around June 15, 2017), how is it billed?

Existing small premium disks less than 64 GiB continue to be billed according to the P10 pricing tier.

How can I switch the disk tier of small premium disks less than 64 GiB from P10 to P4 or P6?

You can take a snapshot of your small disks and then create a disk to automatically switch the pricing tier to P4 or P6 based on the provisioned size. You can also use performance tiers, see the articles for changing performance tiers with either the Azure CLI/PowerShell module or the Azure portal.

Can I resize existing managed disks from sizes fewer than 4 tebibytes (TiB) to 32 TiB?

Yes.

What are the largest disk sizes supported by Azure Backup and Azure Site Recovery service?

The largest disk size supported by Azure Backup is 32 TiB (4 TiB for encrypted disks). The largest disk size supported by Azure Site Recovery is 8 TiB. Support for the larger disks up to 32 TiB isn't yet available in Azure Site Recovery.

What are the recommended VM sizes for larger disk sizes (>4 TiB) for Standard SSD and Standard HDDs to achieve optimized disk IOPS and Bandwidth?

To achieve the disk throughput of Standard SSD and Standard HDD large disk sizes (>4 TiB) beyond 500 IOPS and 60 MB/s, we recommend you deploy a new VM from one of the following VM sizes to optimize your performance: B-series, DSv2-series, Dsv3-Series, ESv3-Series, Fs-series, Fsv2-series, M-series, GS-series, NCv2-series, NCv3-series, or Ls-series VMs. Attaching large disks to existing VMs or VMs that aren't using the recommended sizes above may experience lower performance.

How can I upgrade my disks (>4 TiB) which were deployed during the larger disk sizes preview in order to get the higher IOPS & bandwidth at GA?

You can either stop and start the VM that the disk is attached to or, detach and reattach your disk. The performance targets of larger disk sizes have been increased for both Premium SSDs and Standard SSDs at GA.

Do we support enabling Host Caching on all disk sizes?

Host Caching (**ReadOnly** and **Read/Write**) is supported on disk sizes less than 4 TiB. This means any disk that is provisioned up to 4,095 GiB can take advantage of Host Caching. Host caching isn't supported for disk sizes more than or equal to 4,096 GiB. For example, a P50 premium disk provisioned at 4,095 GiB can take advantage of Host caching and a P50 disk provisioned at 4,096 GiB can't take advantage of Host Caching. We recommend using caching for smaller disk sizes where you can expect to observe better performance boost with data cached to the VM.

Private Links for managed disks

How can I ensure that a disk can be exported or imported only via Private Links?

Set the `DiskAccessId` property to an instance of a disk access object and set the NetworkAccessPolicy property to `AllowPrivate`.

Can I use the SAS URI of a disk or snapshot to download the underlying VHD of a VM in the same subnet as the subnet of the private endpoint associated with the disk?

Yes.

Can I use a SAS URI of a disk/snapshot to download the underlying VHD of a VM not in the same subnet as the subnet of the private endpoint not associated with the disk?

No.

What if my question isn't answered here?

If your question isn't listed here, let us know and we'll help you find an answer. You can post a question at the end of this article in the comments. To engage with the Azure Storage team and other community members about this article, use the Microsoft Q&A question page for Azure Storage.

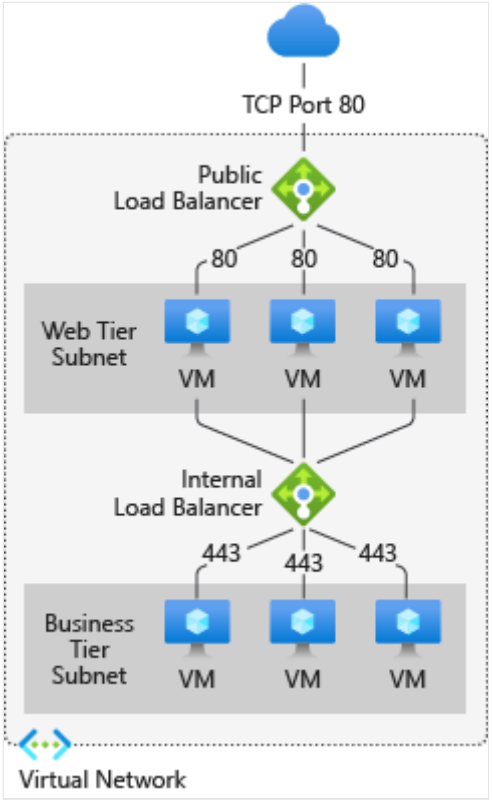
To request features, submit your requests and ideas to the Azure Storage feedback forum.

Virtual networks and virtual machines in Azure

Article • 04/15/2025

When you create a virtual machine (VM), you create a virtual network or use an existing one. Decide how your virtual machines are intended to be accessed on the virtual network. It's important to plan before creating resources and make sure you understand the limits of networking resources.

In the following figure, virtual machines are represented as web servers and application servers. Each set of virtual machines is assigned to separate subnets in the virtual network.



You can create a virtual network before you create a virtual machine or you can create the virtual network as you create a virtual machine.

You create these resources to support communication with a virtual machine:

- Network interfaces
- IP addresses
- Virtual network and subnets

Additionally, consider these optional resources:

- Network security groups

- Load balancers

Network interfaces

A network interface (NIC) is the interconnection between a virtual machine and a virtual network. A virtual machine must have at least one NIC. A virtual machine can have more than one NIC, depending on the size of the VM you create. To learn about the number of NICs each virtual machine size supports, see VM sizes.

You can create a VM with multiple NICs, and add or remove NICs through the lifecycle of a VM. Multiple NICs allow a VM to connect to different subnets.

Each NIC attached to a VM must exist in the same location and subscription as the VM. Each NIC must be connected to a virtual network that exists in the same Azure location and subscription as the NIC. The subnet a VM is connected to can be changed after the VM is created. You can't change the virtual network. Each NIC attached to a VM is assigned a MAC address that doesn't change until the VM is deleted.

This table lists the methods that you can use to create a network interface.

Expand table

Method	Description
Azure portal	When you create a VM in the Azure portal, a network interface is automatically created for you. The portal creates a VM with only one NIC. If you want to create a VM with more than one NIC, you must create it with a different method.
Azure PowerShell	Use New-AzNetworkInterface with the `-PublicIpAddressId` parameter to provide the identifier of the public IP address that you previously created.
Azure CLI	To provide the identifier of the public IP address that you previously created, use az network nic create with the `--public-ip-address` parameter.
Template	For information on deploying a networking interface using a template, see Network Interface in a Virtual Network with Public IP Address.

IP addresses

You can assign these types of IP addresses to a network interface in Azure:

- **Public IP addresses** - Used to communicate inbound and outbound (without network address translation (NAT)) with the Internet and other Azure resources not connected to a virtual network. Assigning a public IP address to a NIC is optional. Public IP addresses

have a nominal charge, and there's a maximum number that can be used per subscription.

- **Private IP addresses** - Used for communication within a virtual network, your on-premises network, and the Internet (with NAT). At least one private IP address must be assigned to a VM. To learn more about NAT in Azure, read Understanding outbound connections in Azure.

You can assign public IP addresses to:

- Virtual machines
- Public load balancers

You can assign private IP address to:

- Virtual machines
- Internal load balancers

You assign IP addresses to a VM using a network interface.

Azure assigns IP addresses dynamically by default. An IP address isn't assigned at creation but is assigned when you create or start a stopped VM. The IP address is released when you stop or delete the VM.

To keep the IP address for the VM the same, set the allocation method to static. The IP address assigns immediately and releases only if you delete the VM or change its allocation method to dynamic.

This table lists the methods that you can use to create an IP address.

Expand table

Method	Description
Azure portal	By default, public IP addresses are dynamic. The IP address might change when the VM is stopped or deleted. To guarantee that the VM always uses the same public IP address, create a static public IP address. By default, the portal assigns a dynamic private IP address to a NIC when creating a VM. You can change this IP address to static after the VM is created.
Azure PowerShell	You use New-AzPublicIpAddress with the `-AllocationMethod` parameter as Dynamic or Static.
Azure CLI	You use az network public-ip create with the `--allocation-method` parameter as Dynamic or Static.

Method	Description
Template	For more information on deploying a public IP address using a template, see Network Interface in a Virtual Network with Public IP Address.

After you create a public IP address, you can associate it with a VM by assigning it to a NIC.

> **Note**
>
> Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.
>
> The default outbound access IP is disabled when one of the following events happens:
>
> - A public IP address is assigned to the VM.
> - The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
> - An Azure NAT Gateway resource is assigned to the subnet of the VM.
>
> VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.
>
> For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Virtual network and subnets

A subnet is a range of IP addresses in the virtual network. You can divide a virtual network into multiple subnets for organization and security. Each NIC in a VM is connected to one subnet in one virtual network. NICs connected to subnets (same or different) within a virtual network can communicate with each other without any extra configuration.

When you set up a virtual network, you specify the topology, including the available address spaces and subnets. Select address ranges that don't overlap if the virtual network is connected to other virtual networks or on-premises networks. The IP addresses are private and can't be accessed from the Internet. Azure treats any address range as part of the private virtual network IP address space. The address range is only reachable within the virtual network, within interconnected virtual networks, and from your on-premises location.

If you work within an organization in which someone else is responsible for the internal networks, talk to that person before selecting your address space. Ensure there's no overlap in the address space. Communicate to them the space you want to use so they don't try to use the same range of IP addresses.

There aren't security boundaries by default between subnets. Virtual machines in each of these subnets can communicate. If your deployment requires security boundaries, use **Network Security Groups (NSGs)**, which control the traffic flow to and from subnets and to and from VMs.

This table lists the methods that you can use to create a virtual network and subnets.

Expand table

Method	Description
Azure portal	If you let Azure create a virtual network when you create a VM, the name is a combination of the resource group name that contains the virtual network and `-vnet`. The address space is 10.0.0.0/24, the required subnet name is **default**, and the subnet address range is 10.0.0.0/24.
Azure PowerShell	You use New-AzVirtualNetworkSubnetConfig and New-AzVirtualNetwork to create a subnet and a virtual network. You can also use Add-AzVirtualNetworkSubnetConfig to add a subnet to an existing virtual network.
Azure CLI	The subnet and the virtual network are created at the same time. Provide a `--subnet-name` parameter to az network vnet create with the subnet name.
Template	For more information on using a template to create a virtual network and subnets, see Virtual Network with two subnets.

Multiple address prefixes on a subnet

Multiple address prefixes on a subnet are a feature that offers the ability to modify IP address spaces on a subnet. With this solution, customers using virtual machines and virtual machine scale sets can add and remove IP address prefixes to meet their scaling requirements.

Limitations:

- Customers can only use a single customer address (CA) configuration per NIC.
- Customers can only use on VM and Virtual Machine Scale Sets subnets. Delegated subnets aren't supported.

Pricing: Multiple address prefixes on a subnet are offered free of charge.

We welcome you to share your feedback about this feature in this quick survey.

> **Important**
>
> Multiple prefix support for Azure Virtual Network subnets is currently in public preview. This preview version has no service level agreement and isn't recommended for production workloads. Certain features might not be supported or might have limited capabilities. For more information, see Supplemental Terms of Use for Microsoft Azure Previews.

For more information about how-to configure multiple address prefixes on a subnet, see Create multiple prefixes for a subnet.

> **Important**
>
> There are two subnet properties for address space, **AddressPrefix** (string), and **AddressPrefixes** (list). The distinction and usage is explained as follows.
>
> - The array property was introduced for dual stack. The property is also used for scenarios with more than one subnet prefixes as discussed previously.
> - As part of the Azure portal customer experience update, the **AddressPrefixes** is the default property for subnet address space when a subnet is created via the portal.
>   - Any new subnets created via portal default to the **AddressPrefixes** list parameter.
> - If customers are using dual-stack in their virtual network or have more than one subnet prefixes, they're updated to use the list property.
>   - For existing deployments using the string, the current behavior is retained unless there are explicit changes in your virtual network to use the list property for subnet address prefixes. An example is adding IPv6 address space or another prefix to the subnet.
> - We recommend that customers should look for both the properties in subnet wherever applicable.

Network security groups

A network security group (NSG) contains a list of Access Control List (ACL) rules that allow or deny network traffic to subnets, NICs, or both. NSGs can be associated with either subnets or individual NICs connected to a subnet. When an NSG is associated with a subnet, the ACL rules

apply to all the VMs in that subnet. Traffic to an individual NIC can be restricted by associating an NSG directly to a NIC.

NSGs contain two sets of rules, inbound and outbound. The priority for a rule must be unique within each set.

Each rule has properties of:

- Protocol
- Source and destination port ranges
- Address prefixes
- Direction of traffic
- Priority
- Access type

All NSGs contain a set of default rules. You can't delete or override these default rules, as they have the lowest priority and any rules you create can't supersede them.

When you associate an NSG to a NIC, the network access rules in the NSG are applied only to that NIC. If an NSG is applied to a single NIC on a multi-NIC VM, it doesn't affect traffic to the other NICs. You can associate different NSGs to a NIC (or VM, depending on the deployment model) and the subnet that a NIC or VM is bound to. Priority is given based on the direction of traffic.

Be sure to plan your NSGs when you plan your virtual machines and virtual network.

This table lists the methods that you can use to create a network security group.

Expand table

Method	Description
Azure portal	When you create a VM in the Azure portal, an NSG is automatically created and associated to the NIC the portal creates. The name of the NSG is a combination of the name of the VM and `-nsg`. This NSG contains one inbound rule: With a priority of 1000. The service set to RDP. The protocol set to TCP. The port set to 3389. The action set to **Allow**. If you want to allow any other inbound traffic to the VM, create another rule or rules.

Method	Description
Azure PowerShell	Use New-AzNetworkSecurityRuleConfig and provide the required rule information. Use New-AzNetworkSecurityGroup to create the NSG. Use Set-AzVirtualNetworkSubnetConfig to configure the NSG for the subnet. Use Set-AzVirtualNetwork to add the NSG to the virtual network.
Azure CLI	Use az network nsg create to initially create the NSG. Use az network nsg rule create to add rules to the NSG. Use az network vnet subnet update to add the NSG to the subnet.
Template	Use Create a Network Security Group as a guide for deploying a network security group using a template.

Load balancers

Azure Load Balancer delivers high availability and network performance to your applications. A load balancer can be configured to balance incoming Internet traffic to VMs or balance traffic between VMs in a virtual network. A load balancer can also balance traffic between on-premises computers and VMs in a cross-premises network, or forward external traffic to a specific VM.

The load balancer maps incoming and outgoing traffic between:

- The public IP address and port on the load balancer.
- The private IP address and port of the VM.

When you create a load balancer, you must also consider these configuration elements:

- **Front-end IP configuration** – A load balancer can include one or more front-end IP addresses. These IP addresses serve as ingress for the traffic.
- **Back-end address pool** – IP addresses that are associated with the NIC to which load is distributed.
- **Port Forwarding** - Defines how inbound traffic flows through the front-end IP and distributed to the back-end IP using inbound NAT rules.
- **Load balancer rules** - Maps a given front-end IP and port combination to a set of back-end IP addresses and port combination. A single load balancer can have multiple load-balancing rules. Each rule is a combination of a front-end IP and port and back-end IP and port associated with VMs.
- **Probes** - Monitors the health of VMs. When a probe fails to respond, the load balancer stops sending new connections to the unhealthy VM. The existing connections aren't

affected, and new connections are sent to healthy VMs.

- **Outbound rules** - An outbound rule configures outbound Network Address Translation (NAT) for all virtual machines or instances identified by the backend pool of your Standard Load Balancer to be translated to the frontend.

This table lists the methods that you can use to create an internet-facing load balancer.

Expand table

Method	Description
Azure portal	You can load balance internet traffic to VMs using the Azure portal.
Azure PowerShell	To provide the identifier of the public IP address that you previously created, use New-AzLoadBalancerFrontendIpConfig with the `-PublicIpAddress` parameter. Use New-AzLoadBalancerBackendAddressPoolConfig to create the configuration of the back-end address pool. Use New-AzLoadBalancerInboundNatRuleConfig to create inbound NAT rules associated with the front-end IP configuration that you created. Use New-AzLoadBalancerProbeConfig to create the probes that you need. Use New-AzLoadBalancerRuleConfig to create the load balancer configuration. Use New-AzLoadBalancer to create the load balancer.
Azure CLI	Use az network lb create to create the initial load balancer configuration. Use az network lb frontend-ip create to add the public IP address that you previously created. Use az network lb address-pool create to add the configuration of the back-end address pool. Use az network lb inbound-nat-rule create to add NAT rules. Use az network lb rule create to add the load balancer rules. Use az network lb probe create to add the probes.
Template	Use 3 VMs in a Load Balancer as a guide for deploying a load balancer using a template.

This table lists the methods that you can use to create an internal load balancer.

Expand table

Method	Description
Azure portal	You can balance internal traffic load with a load balancer in the Azure portal.
Azure PowerShell	To provide a private IP address in the network subnet, use New-AzLoadBalancerFrontendIpConfig with the `-PrivateIpAddress` parameter. Use New-AzLoadBalancerBackendAddressPoolConfig to create the configuration of the back-end address pool. Use New-AzLoadBalancerInboundNatRuleConfig to create inbound NAT rules associated with the front-end IP configuration that you created. Use New-AzLoadBalancerProbeConfig to create the probes that you need. Use New-

Method	Description
	AzLoadBalancerRuleConfig to create the load balancer configuration. Use New-AzLoadBalancer to create the load balancer.
Azure CLI	Use the az network lb create command to create the initial load balancer configuration. To define the private IP address, use az network lb frontend-ip create with the `--private-ip-address` parameter. Use az network lb address-pool create to add the configuration of the back-end address pool. Use az network lb inbound-nat-rule create to add NAT rules. Use az network lb rule create to add the load balancer rules. Use az network lb probe create to add the probes.
Template	Use 2 VMs in a Load Balancer as a guide for deploying a load balancer using a template.

Virtual machines

Virtual machines can be created in the same virtual network and they can connect to each other using private IP addresses. Virtual machines can connect if they're in different subnets. They connect without the need to configure a gateway or use public IP addresses. To put VMs into a virtual network, you create the virtual network. As you create each VM, you assign it to the virtual network and subnet. Virtual machines acquire their network settings during deployment or startup.

Virtual machines are assigned an IP address when they're deployed. When you deploy multiple VMs into a virtual network or subnet, they're assigned IP addresses as they boot up. You can also assign a static IP to a VM. If you assign a static IP, you should consider using a specific subnet to avoid accidentally reusing a static IP for another VM.

If you create a VM and later want to migrate it into a virtual network, it isn't a simple configuration change. Redeploy the VM into the virtual network. The easiest way to redeploy is to delete the VM, but not any disks attached to it, and then re-create the VM using the original disks in the virtual network.

This table lists the methods that you can use to create a VM in a virtual network.

Expand table

Method	Description
Azure portal	Uses the default network settings that were previously mentioned to create a VM with a single NIC. To create a VM with multiple NICs, you must use a different method.
Azure PowerShell	Includes the use of Add-AzVMNetworkInterface to add the NIC that you previously created to the VM configuration.

Method	Description
Azure CLI	Create and connect a VM to a virtual network, subnet, and NIC that builds as individual steps.
Template	Use Very simple deployment of a Windows VM as a guide for deploying a VM using a template.

NAT Gateway

Azure NAT Gateway simplifies outbound-only Internet connectivity for virtual networks. When configured on a subnet, all outbound connectivity uses your specified static public IP addresses. Outbound connectivity is possible without load balancer or public IP addresses directly attached to virtual machines. NAT is fully managed and highly resilient.

Outbound connectivity can be defined for each subnet with NAT. Multiple subnets within the same virtual network can have different NATs. A subnet is configured by specifying which NAT gateway resource to use. All UDP and TCP outbound flows from any virtual machine instance use a NAT gateway. NAT is compatible with standard public IP address resources or public IP prefix resources or a combination of both. You can use a public IP prefix directly or distribute the public IP addresses of the prefix across multiple NAT gateway resources. NAT grooms all traffic to the range of IP addresses of the prefix. Any IP filtering of your deployments is easier.

NAT Gateway automatically processes all outbound traffic without any customer configuration. User-defined routes aren't necessary. NAT takes precedence over other outbound scenarios and replaces the default Internet destination of a subnet.

Virtual machine scale sets that create virtual machines with Flexible Orchestration mode don't have default outbound access. Azure NAT Gateway is the recommended outbound access method for Virtual machine scale sets Flexible Orchestration Mode.

For more information about Azure NAT Gateway, see What is Azure NAT Gateway?.

This table lists the methods that you can use to create a NAT gateway resource.

Expand table

Method	Description
Azure portal	Creates a virtual network, subnet, public IP, NAT gateway, and a virtual machine to test the NAT gateway resource.
Azure PowerShell	Includes the use of New-AzNatGateway to create a NAT gateway resource. Creates a virtual network, subnet, public IP, NAT gateway, and a virtual machine to test the NAT gateway resource.

Method	Description
Azure CLI	Includes the use of az network nat gateway create to create a NAT gateway resource. Creates a virtual network, subnet, public IP, NAT gateway, and a virtual machine to test the NAT gateway resource.
Template	Creates a virtual network, subnet, public IP, and NAT gateway resource.

Azure Bastion

Azure Bastion is deployed to provide secure management connectivity to virtual machines in a virtual network. Azure Bastion Service enables you to securely and seamlessly RDP & SSH to the VMs in your virtual network. Azure bastion enables connections without exposing a public IP on the VM. Connections are made directly from the Azure portal, without the need of an extra client/agent or piece of software. Azure Bastion supports standard public IP addresses.

Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

For more information about Azure Bastion, see What is Azure Bastion?.

This table lists the methods you can use to create an Azure Bastion deployment.

Expand table

Method	Description
Azure portal	Creates a virtual network, subnets, public IP, bastion host, and virtual machines.
Azure PowerShell	Creates a virtual network, subnets, public IP, and bastion host. Includes the use of New-AzBastion to create the bastion host.
Azure CLI	Creates a virtual network, subnets, public IP, and bastion host. Includes the use of az network bastion create to create the bastion host.
Template	For an example of a template deployment that integrates an Azure Bastion host with a sample deployment, see Quickstart: Create a public load balancer to load balance VMs by using an ARM template.

Optimize network throughput for Azure virtual machines

06/12/2025

Azure virtual machines (VMs) have default network settings that can be further optimized for network throughput. This article describes how to optimize network throughput for Windows and Linux VMs, including major distributions such as Ubuntu and Red Hat.

Windows virtual machines

If your Windows VM supports *accelerated networking*, enable that feature for optimal throughput. For more information, see Create a Windows VM with accelerated networking.

For all other Windows VMs, using Receive Side Scaling (RSS) can reach higher maximal throughput than a VM without RSS. RSS might be disabled by default in a Windows VM. To check if RSS is enabled and enable it, follow these steps:

1. See if RSS is enabled for a network adapter with the Get-NetAdapterRss PowerShell command. In the following example, output returned from the `Get-NetAdapterRss` RSS isn't enabled.

   PowerShell

   ```
   Name                    : Ethernet
   InterfaceDescription    : Microsoft Hyper-V Network Adapter
   Enabled                 : False
   ```

2. To enable RSS, enter the following command:

   PowerShell

   ```
   Get-NetAdapter | % {Enable-NetAdapterRss -Name $_.Name}
   ```

   This command doesn't have an output. The command changes network interface card (NIC) settings. It causes temporary connectivity loss for about one minute. A **Reconnecting** dialog appears during the connectivity loss. Connectivity is typically restored after the third attempt.

3. Confirm that RSS is enabled in the VM by entering the `Get-NetAdapterRss` command again. If successful, the following example output is returned:

PowerShell

```
Name                    : Ethernet
InterfaceDescription    : Microsoft Hyper-V Network Adapter
Enabled                 : True
```

Linux virtual machines

RSS is always enabled by default in an Azure Linux Virtual Machine (VM). Linux kernels released since October 2017 include new network optimizations options that enable a Linux VM to achieve higher network throughput.

Enable Azure Accelerated Networking for optimal throughput

Azure provides accelerated networking which can really improve network performance, latency, jitter. There are currently two different technologies that are used depending on the virtual machine size, Mellanox which is wide available and MANA which is developed by Microsoft.

Azure Linux Tuned Kernels

Some distributions such as Ubuntu (Canonical) and SUSE have Azure tuned kernels.

Use the following command to make sure that you're using the Azure kernel, which has usually the `azure` string in the naming.

Bash

```
uname -r

#sample output on Azure kernel on a Ubuntu Linux VM
6.8.0-1017-azure
```

Other Linux distributions

Most modern distributions have significant improvements with newer kernels. Check the current kernel version to make sure that you're running a kernel that is newer than 4.19, which includes some great improvements in networking, for example support for the *BBR Congestion-Based Congestion Control*.

Achieving consistent transfer speeds in Azure Linux VMs

Azure Linux VMs often experience network performance issues, particularly when transferring large files (1 GB to 50 GB) between regions, such as West Europe and West US. These issues are caused by older kernel versions as well as, default kernel configurations, default network buffer settings and default congestion control algorithms, which result in delayed packets, limited throughput, and inefficient resource usage.

To get consistent network performance, consider implementing the following optimizations that are proven effective in many situations on Azure:

- **Network buffer settings**: Adjust kernel parameters to maximize read and write memory buffers. Add these configurations to `/etc/sysctl.d/99-azure-network-buffers.conf`:

plaintext

```
net.ipv4.tcp_mem = 4096 87380 67108864
net.ipv4.udp_mem = 4096 87380 33554432
net.ipv4.tcp_rmem = 4096 87380 67108864
net.ipv4.tcp_wmem = 4096 65536 67108864
net.core.rmem_default = 33554432
net.core.wmem_default = 33554432
net.ipv4.udp_wmem_min = 16384
net.ipv4.udp_rmem_min = 16384
net.core.wmem_max = 134217728
net.core.rmem_max = 134217728
net.core.busy_poll = 50
net.core.busy_read = 50
```

- **Congestion-Based Congestion control for kernels 4.19 and above**: Enabling Bottleneck Bandwidth and Round-trip propagation time (BBR) congestion control can often result in better throughput. Add this configuration to `/etc/sysctl.d/99-azure-congestion-control.conf`:

plaintext

```
net.ipv4.tcp_congestion_control = bbr
```

- **Extra TCP parameters that will usually help with better consistency, throughput**: Add these configurations to `/etc/sysctl.d/99-azure-network-extras.conf`:

plaintext

```
# For deployments where the Linux VM is BEHIND an Azure Load Balancer, timestamps
MUST be set to 0
net.ipv4.tcp_timestamps = 1

# Reuse does require tcp_timestamps to be enabled. If tcp_timestamps are disabled
because of load balancers, you should set reuse to 2.
net.ipv4.tcp_tw_reuse = 1

# Allowed local port range. This will increase the number of locally available
ports (source ports)
net.ipv4.ip_local_port_range = 1024 65535

# Maximum number of packets taken from all interfaces in one polling cycle (NAPI
poll). In one polling cycle interfaces which are # registered to polling are
probed in a round-robin manner.
net.core.netdev_budget = 1000

# For high-performance environments, it's recommended to increase from the default
20KB to 65KB, in some extreme cases, for environments that support 100G+
networking, you can
# increase it to 1048576
net.core.optmem_max = 65535

# F-RTO is not recommended on wired networks.
net.ipv4.tcp_frto = 0

# Increase the number of incoming connections / number of connections backlog
net.core.somaxconn = 32768
net.core.netdev_max_backlog = 32768
net.core.dev_weight = 64
```

- **Queue discipline (qdisc)**: Packet processing in Azure is improved by setting the default qdisc to `fq`. Add this configuration to `/etc/sysctl.d/99-azure-qdisc.conf`:

plaintext

```
net.core.default_qdisc = fq
```

- **Optimize NIC ring buffers for TX/RX**: Create an udev rule in `/etc/udev/rules.d/99-azure-ring-buffer.rules` to ensure they're applied to network interfaces:

plaintext

```
# Setup Accelerated Interface ring buffers (Mellanox / Mana)
SUBSYSTEM=="net", DRIVERS=="hv_pci", ACTION=="add",  RUN+="/usr/sbin/ethtool -G
$env{INTERFACE} rx 1024 tx 1024"

# Setup Synthetic interface ring buffers (hv_netvsc)
```

```
SUBSYSTEM=="net", DRIVERS=="hv_netvsc*", ACTION=="add",  RUN+="/usr/sbin/ethtool -
G $env{INTERFACE} rx 1024 tx 1024"
```

- Create an udev rule in `/etc/udev/rules.d/99-azure-qdisc.rules` to ensure the qdisc is applied to network interfaces:

```
plaintext

ACTION=="add|change", SUBSYSTEM=="net", KERNEL=="enP*", PROGRAM="/sbin/tc qdisc
replace dev \$env{INTERFACE} root noqueue"
ACTION=="add|change", SUBSYSTEM=="net", KERNEL=="eth*", PROGRAM="/sbin/tc qdisc
replace dev \$env{INTERFACE} root fq“
```

- **Interrupt Request (IRQ) scheduling**: Depending on your workload, you may wish to restrict the irqbalance service from scheduling IRQs on certain nodes. When using IRQBalance, you can update `/etc/default/irqbalance` to specify which CPUs shouldn't have IRQs scheduled you will need to determine the mask that will exclude the CPUs that need exclusion.

More information about how to calculate the mask available here.

The example below would assume that you want to exclude CPUs 8-15

```
Bash

IRQBALANCE_BANNED_CPULIST=0000ff00
```

- **UDEV rules**: Add rules to optimize queue length and manage device flags efficiently. Create the following rule in `/etc/udev/rules.d/99-azure-txqueue-len.rules`:

```
plaintext

SUBSYSTEM=="net", ACTION=="add|change", KERNEL=="eth*", ATTR{tx_queue_len}="10000“
```

For Packets delayed twice

When it comes to Linux performance networking we use SR-IOV with Mellanox drivers (mlx4 or mlx5), something specific to Azure is that this creates two interfaces a synthetic and a virtual interface. Learn More.

Additional Notes

System administrators can implement these solutions by editing configuration files such as `/etc/sysctl.d/`, `/etc/modules-load.d/`, and `/etc/udev/rules.d/`. Ensure that kernel driver updates and systemd configurations are reviewed for potential regressions.

For more information on specific configurations and troubleshooting, refer to Azure documentation on networking performance.

Azure Virtual Network concepts and best practices

Azure Virtual Network is a fundamental building block for your private network in Azure. It enables Azure resources to securely communicate with each other, the internet, and on-premises networks.

A virtual network is similar to a traditional network that you'd operate in your own data center. However, it brings extra benefits of Azure's infrastructure such as scale, availability, and isolation.

Understanding virtual network concepts and following best practices helps you design robust, secure, and scalable network architectures. Whether you're migrating existing workloads to Azure or building new cloud-native applications, proper network design is essential for performance, security, and cost optimization.

This article describes key Azure Virtual Network concepts and best practices to help you design efficient, secure, and scalable network infrastructure for your cloud-based applications. Learn about address spaces, subnets, security groups, and architectural guidelines that optimize your Azure networking strategy.

Virtual Network concepts

- **Address space:** When creating a virtual network, you must specify a custom private IP address space using public and private (RFC 1918) addresses. Azure assigns resources in a virtual network a private IP address from the address space that you assign. For example, if you deploy a VM in a virtual network with address space, 10.0.0.0/16, a private IP similar to 10.0.0.4 is assigned to the virtual machine.

- **Subnets:** Subnets enable you to segment the virtual network into one or more sub networks and allocate a portion of the virtual network's address space to each subnet. You can then deploy Azure resources in a specific subnet. Just like in a traditional network, subnets allow you to segment your virtual network address space into segments that are appropriate for the organization's internal network. Segmentation improves address allocation efficiency. You can secure resources within subnets using Network Security Groups. For more information, see Network security groups.

- **Regions**: A virtual network is scoped to a single region/location; however, multiple virtual networks from different regions can be connected together using Virtual Network Peering.

- **Subscription:** A virtual network is scoped to a subscription. You can implement multiple virtual networks within each Azure subscription and Azure region.

Best practices

As you build your network in Azure, it's important to keep in mind the following universal design principles:

- Ensure address spaces don't overlap. Make sure your virtual network address spaces (CIDR blocks) don't overlap with your organization's other in-use network ranges.
  - See the recommended address ranges in the FAQ
- Your subnets shouldn't cover the entire address space of the virtual network. Plan ahead and reserve some address space for the future.
- Use a few large virtual networks instead of multiple small ones to reduce management overhead within a single Azure subscription.
  - You should also follow the Azure landing zone design principle of Subscription Democratization meaning it is recommended to have many subscriptions, each with their own virtual network (possibly multiple), to help you achieve and implement Zero Trust in your Azure networking.
  - Commonly a hub and spoke architecture is used to implement this at scale with a traditional virtual network approach or Virtual WAN
- Secure your virtual networks by assigning Network Security Groups (NSGs) to the subnets beneath them. For more information about network security concepts, see Azure network security overview.

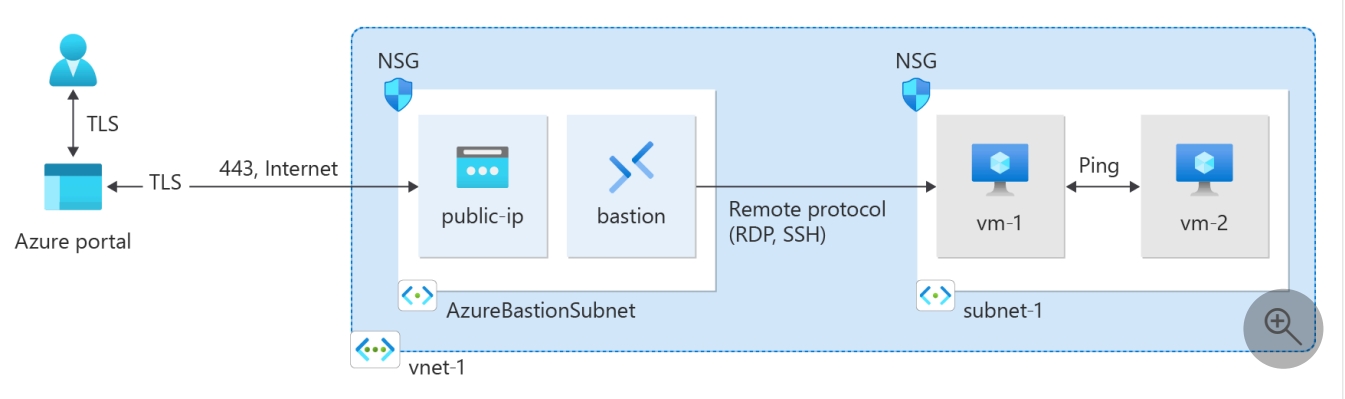
Next steps

To get started using a virtual network, create one, deploy a few VMs to it, and communicate between the VMs. To learn how, see the Create a virtual network quickstart.

Last updated on 12/11/2025

Quickstart: Create an Azure Virtual Network

Learn how to create an Azure Virtual Network using the Azure portal, Azure CLI, Azure PowerShell, Azure Resource Manager (ARM) template, Bicep template, and Terraform. Two virtual machines and an Azure Bastion host are deployed to test connectivity between the virtual machines in the same virtual network. The Azure Bastion host facilitates secure and seamless RDP and SSH connectivity to the virtual machines directly in the Azure portal over SSL.



A virtual network is the fundamental building block for private networks in Azure. Azure Virtual Network enables Azure resources such as virtual machines to securely communicate with each other and the internet.

https://learn-video.azurefd.net/vod/player?id=6b5b138e-8406-406e-8b34-40bdadf9fc6d&locale=en-us&embedUrl=%2Fazure%2Fvirtual-network%2Fquickstart-create-virtual-network

If you don't have an Azure account with an active subscription, create one for free.

Prerequisites

Portal

- An Azure account with an active subscription. You can create an account for free.

Resource values

Use the following values to replace the placeholders of resources in this article:

Expand table

Setting	Placeholder	Value
Resource group	`<resource-group>`	**test-rg**
Region	`<region>`	**East US 2**
Virtual network	`<virtual-network>`	**vnet-1**
Subnet	`<subnet>`	**subnet-1**
Network security group	`<network-security-group>`	**nsg-1**
Bastion	`<bastion>`	**bastion**
Virtual machine 1	`<virtual-machine-1>`	**vm-1**
Virtual machine 2	`<virtual-machine-2>`	**vm-2**

Portal

Create a resource group

1. Sign in to the Azure portal with your Azure account.
2. In the search box at the top of the portal, enter **Resource group**. Select **Resource groups** in the search results.
3. Select **+ Create**.
4. In the **Basics** tab of **Create a resource group**, enter, or select the following information:

   Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Enter **<resource-group>**.
Region	Select **<region>**.

5. Select **Review + create**.
6. Select **Create**.

Create a virtual network

1. In the search box at the top of the portal, enter **Virtual network**. Select **Virtual networks** in the search results.
2. Select **+ Create**.
3. On the **Basics** tab of **Create virtual network**, enter, or select the following information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **<resource-group>**.
Instance details	
Name	Enter **<virtual-network>**.
Region	Select **<region>**.

4. Select **Next** to proceed to the **Security** tab.
5. Select **Next** to proceed to the **IP Addresses** tab.
6. In the address space box in **Subnets**, select the **default** subnet.
7. In **Edit subnet**, enter, or select the following information:

Expand table

Setting	Value
Subnet details	
Subnet template	Leave the default **Default**.
Name	Enter **<subnet>**.
Starting address	Leave the default of **10.0.0.0**.
Subnet size	Leave the default of **/24 (256 addresses)**.

8. Select **Save**.

9. Select **Review + create** at the bottom of the screen, and when validation passes, select **Create**.

Deploy Azure Bastion

Azure Bastion uses your browser to connect to virtual machines (VMs) in your virtual network over secure shell (SSH) or remote desktop protocol (RDP) by using their private IP addresses. The virtual machines don't need public IP addresses, client software, or special configuration. For more information about Azure Bastion, see Azure Bastion.

> **Note**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

1. In the search box at the top of the portal, enter **Bastion**. Select **Bastions** in the search results.
2. Select **+ Create**.
3. In the **Basics** tab of **Create a Bastion**, enter, or select the following information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **<resource-group>**.
Instance details	
Name	Enter **<bastion>**.
Region	Select **<region>**.
Tier	Select **Developer**.
Configure virtual networks	
Virtual network	Select **<virtual-network>**.

4. Select **Review + create**.

5. Select **Create**.

Create virtual machines

The following procedure creates two VMs named **<virtual-machine-1>** and **<virtual-machine-2>** in the virtual network:

1. In the portal, search for and select **Virtual machines**.

2. In **Virtual machines**, select **+ Create**, and then select **Azure virtual machine**.

3. On the **Basics** tab of **Create a virtual machine**, enter, or select the following information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **<resource-group>**.
Instance details	
Virtual machine name	Enter **<virtual-machine-1>**.
Region	Select **<region>**.
Availability options	Select **No infrastructure redundancy required**.
Security type	Leave the default of **Standard**.
Image	Select **Ubuntu Server 22.04 LTS - x64 Gen2**.
VM architecture	Leave the default of **x64**.
Size	Select a size.
Administrator account	
Authentication type	Select **SSH public key**.
Username	Enter **azureuser**.
SSH public key source	Select **Generate new key pair**.

Setting	Value
Key pair name	Enter **<virtual-machine-1>-key**.
Inbound port rules	
Public inbound ports	Select **None**.

4. Select the **Networking** tab. Enter or select the following information:

Expand table

Setting	Value
Network interface	
Virtual network	Select **<virtual-network>**.
Subnet	Select **<subnet> (10.0.0.0/24)**.
Public IP	Select **None**.
NIC network security group	Select **Advanced**.
Configure network security group	Select **Create new**. Enter **<network-security-group>** for the name. Leave the rest at the defaults and select **OK**.

5. Leave the rest of the settings at the defaults and select **Review + create**.

6. Review the settings and select **Create**.

7. Wait for the first virtual machine to deploy then repeat the previous steps to create a second virtual machine with the following settings:

Expand table

Setting	Value
Virtual machine name	Enter **<virtual-machine-2>**.
SSH public key source	Select **Generate new key pair**.
Key pair name	Enter **<virtual-machine-2>-key**.
Virtual network	Select **<virtual-network>**.
Subnet	Select **<subnet> (10.0.0.0/24)**.
Public IP	Select **None**.

Setting	Value
NIC network security group	Select **Advanced**.
Configure network security group	Select **<network-security-group>**.

> **Note**
>
> Virtual machines in a virtual network with an Azure Bastion host don't need public IP addresses. Bastion provides the public IP, and the VMs use private IPs to communicate within the network. You can remove the public IPs from any VMs in Bastion-hosted virtual networks. For more information, see Dissociate a public IP address from an Azure VM.

> **Note**
>
> Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.
>
> The default outbound access IP is disabled when one of the following events happens:
>
> - A public IP address is assigned to the VM.
> - The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
> - An Azure NAT Gateway resource is assigned to the subnet of the VM.
>
> VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.
>
> For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Connect to a virtual machine

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.

2. In **Virtual machines**, select **vm-1**.

3. Select **Connect** then **Connect via Bastion** in the **Overview** section.

4. In the **Bastion** connection page, enter or select the following information:

Expand table

Setting	Value
Authentication Type	Select **SSH Private Key from Local File**.
Username	Enter **azureuser**.
Local File	Select the private key file you downloaded or created.

5. Select **Connect**.

Start communication between virtual machines

1. At the bash prompt for **vm-1**, enter `ping -c 4 vm-2`.

   You get a reply similar to the following message:

   Output

   ```
   azureuser@vm-1:~$ ping -c 4 vm-2
   PING vm-2.3bnkevn3313ujpr5l1kqop4n4d.cx.internal.cloudapp.net (10.0.0.5)
   56(84) bytes of data.
   64 bytes from vm-2.internal.cloudapp.net (10.0.0.5): icmp_seq=1 ttl=64
   time=1.83 ms
   64 bytes from vm-2.internal.cloudapp.net (10.0.0.5): icmp_seq=2 ttl=64
   time=0.987 ms
   64 bytes from vm-2.internal.cloudapp.net (10.0.0.5): icmp_seq=3 ttl=64
   time=0.864 ms
   64 bytes from vm-2.internal.cloudapp.net (10.0.0.5): icmp_seq=4 ttl=64
   time=0.890 ms
   ```

2. Close the Bastion session.

3. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.

4. In **Virtual machines**, select **vm-2**.

5. Select **Connect** then **Connect via Bastion** in the **Overview** section.

6. In the **Bastion** connection page, enter or select the following information:

Expand table

Setting	Value
Authentication Type	Select **SSH Private Key from Local File**.
Username	Enter **azureuser**.
Local File	Select the private key file you downloaded or created.

7. Select **Connect**.

8. At the bash prompt for **vm-2**, enter `ping -c 4 vm-1`.

   You get a reply similar to the following message:

   Output

   ```
   azureuser@vm-2:~$ ping -c 4 vm-1
   PING vm-1.3bnkevn3313ujpr5l1kqop4n4d.cx.internal.cloudapp.net (10.0.0.4)
   56(84) bytes of data.
   64 bytes from vm-1.internal.cloudapp.net (10.0.0.4): icmp_seq=1 ttl=64
   time=0.695 ms
   64 bytes from vm-1.internal.cloudapp.net (10.0.0.4): icmp_seq=2 ttl=64
   time=0.896 ms
   64 bytes from vm-1.internal.cloudapp.net (10.0.0.4): icmp_seq=3 ttl=64
   time=3.43 ms
   64 bytes from vm-1.internal.cloudapp.net (10.0.0.4): icmp_seq=4 ttl=64
   time=0.780 ms
   ```

9. Close the Bastion session.

Clean up resources

Portal

When you finish using the resources that you created, you can delete the resource group and all its resources.

1. In the Azure portal, search for and select **Resource groups**.

2. On the **Resource groups** page, select the **<resource-group>** resource group.

3. On the **<resource-group>** page, select **Delete resource group**.

4. Enter <**resource-group**> in **Enter resource group name to confirm deletion**, and then select **Delete**.

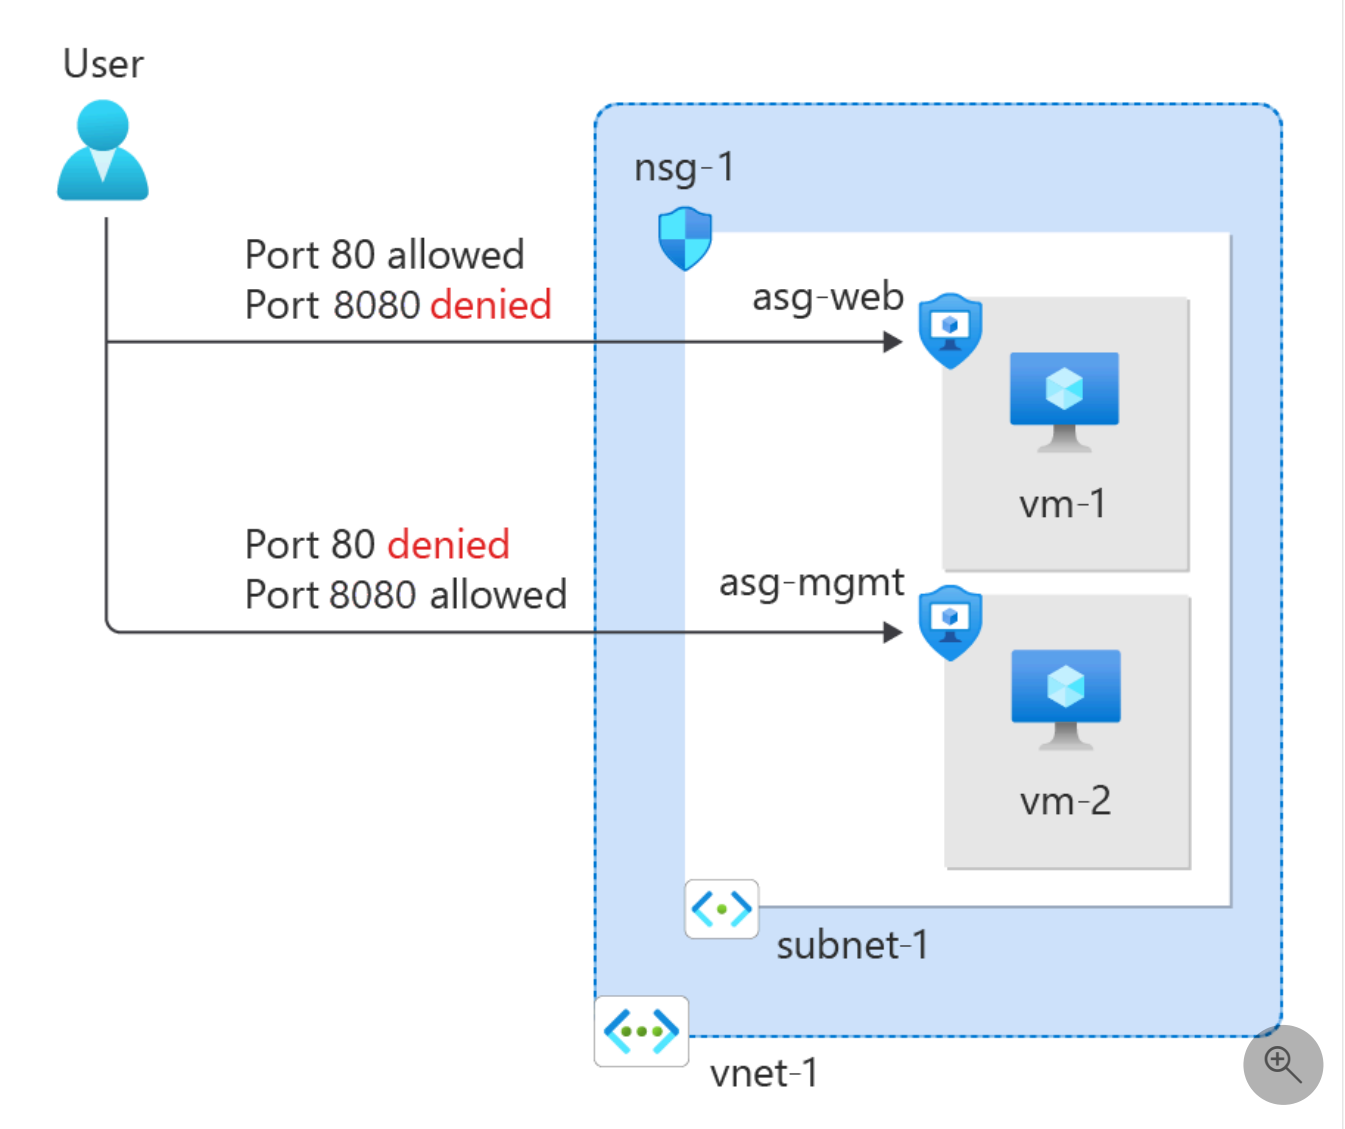
Tutorial: Filter network traffic with a network security group

Summarize this article for me

You can use a network security group to filter inbound and outbound network traffic to and from Azure resources in an Azure virtual network.

Network security groups contain security rules that filter network traffic by IP address, port, and protocol. When a network security group is associated with a subnet, security rules are applied to resources deployed in that subnet.



In this tutorial, you learn how to:

- ✓ Create a network security group and security rules
- ✓ Create application security groups
- ✓ Create a virtual network and associate a network security group to a subnet

- ✓ Deploy virtual machines and associate their network interfaces to the application security groups

Prerequisites

Portal

- An Azure account with an active subscription. You can create an account for free.

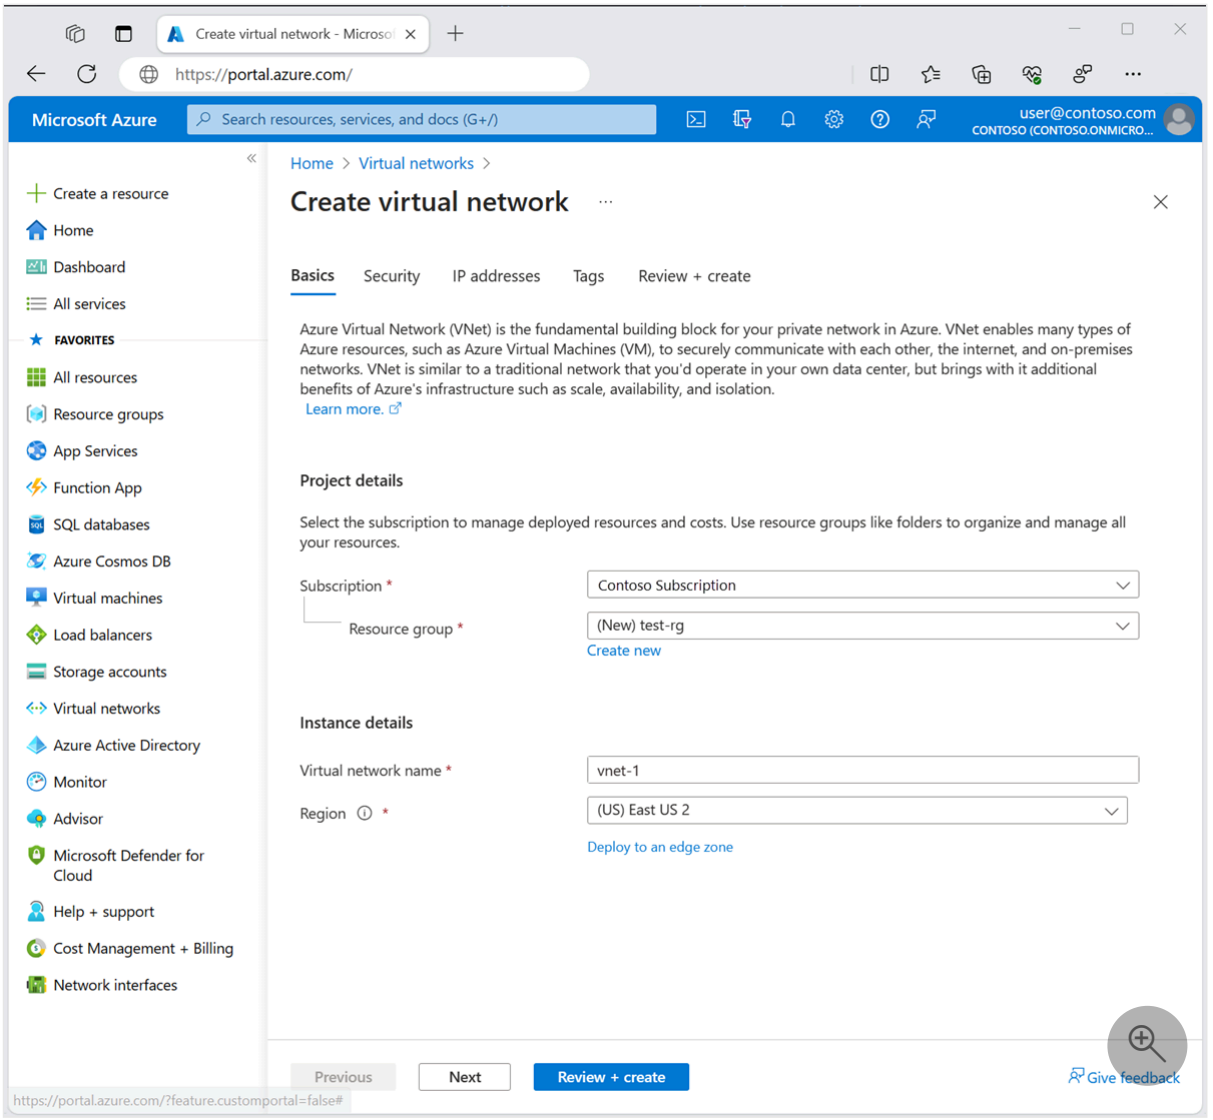
Portal

The following procedure creates a virtual network with a resource subnet.

1. In the portal, search for and select **Virtual networks**.
2. On the **Virtual networks** page, select **+ Create**.
3. On the **Basics** tab of **Create virtual network**, enter or select the following information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **Create new**. Enter **test-rg** in **Name**. Select **OK**.
Instance details	
Name	Enter **vnet-1**.
Region	Select **East US 2**.



4. Select **Next** to proceed to the **Security** tab.

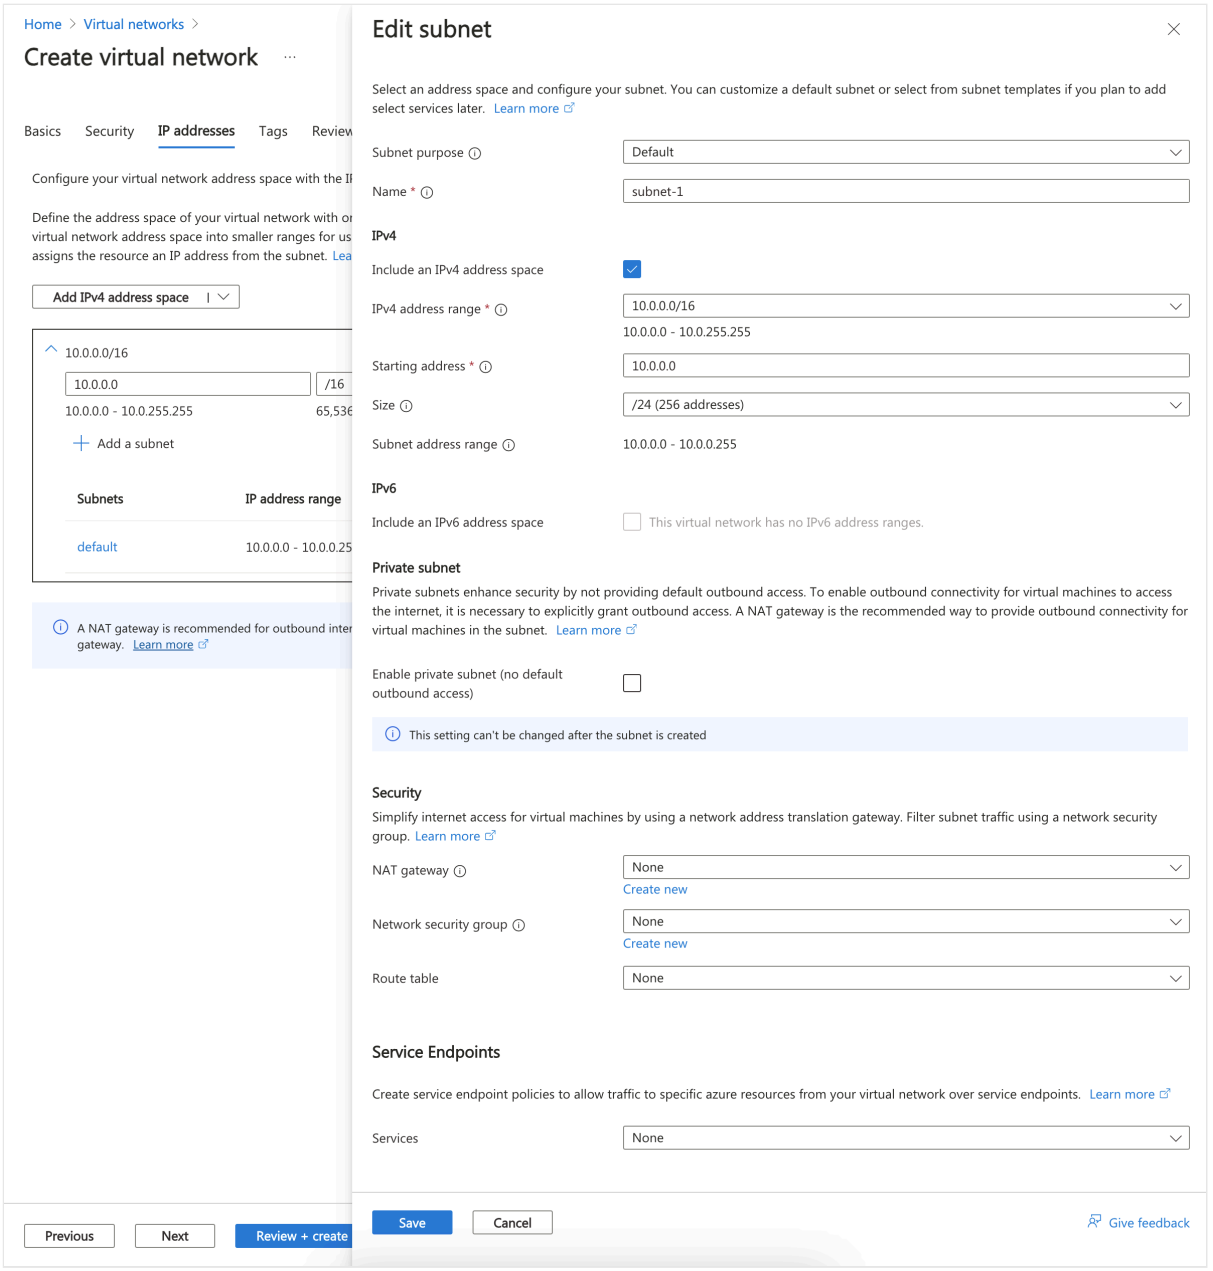
5. Select **Next** to proceed to the **IP addresses** tab.

6. In the address space box under **Subnets**, select the **default** subnet.

7. On the **Edit subnet** pane, enter or select the following information:

Expand table

Setting	Value
Subnet details	
Subnet template	Leave the default as **Default**.
Name	Enter **subnet-1**.
Starting address	Leave the default of **10.0.0.0**.
Subnet size	Leave the default of **/24(256 addresses)**.



8. Select **Save**.

9. Select **Review + create** at the bottom of the screen. After validation passes, select **Create**.

Create application security groups

An application security group (ASGs) enables you to group together servers with similar functions, such as web servers.

Portal

1. In the search box at the top of the portal, enter **Application security group**. Select **Application security groups** in the search results.
2. Select **+ Create**.
3. On the **Basics** tab of **Create an application security group**, enter, or select this information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **asg-web**.
Region	Select **West US 2**.

4. Select **Review + create**.
5. Select **+ Create**.
6. Repeat the previous steps, specifying the following values:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **asg-mgmt**.
Region	Select **West US 2**.

7. Select **Review + create**.

8. Select **Create**.

Create a network security group

A network security group (NSG) secures network traffic in your virtual network.

Portal

1. In the search box at the top of the portal, enter **Network security group**. Select **Network security groups** in the search results.

   > **Note**
   >
   > In the search results for **Network security groups**, you may see **Network security groups (classic)**. Select **Network security groups**.

2. Select **+ Create**.

3. On the **Basics** tab of **Create network security group**, enter, or select this information:

   Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **nsg-1**.
Location	Select **West US 2**.

4. Select **Review + create**.

5. Select **Create**.

Associate network security group to subnet

In this section, you associate the network security group with the subnet of the virtual network you created earlier.

Portal

1. In the search box at the top of the portal, enter **Network security group**. Select **Network security groups** in the search results.
2. Select **nsg-1**.
3. Select **Subnets** from the **Settings** section of **nsg-1**.
4. In the **Subnets** page, select + **Associate**:
5. Under **Associate subnet**, select **vnet-1 (test-rg)** for **Virtual network**.
6. Select **subnet-1** for **Subnet**, and then select **OK**.

Create security rules

Portal

1. Select **Inbound security rules** from the **Settings** section of **nsg-1**.
2. In **Inbound security rules** page, select + **Add**.
3. Create a security rule that allows port 80 to the **asg-web** application security group. In **Add inbound security rule** page, enter or select the following information:

Expand table

Setting	Value
Source	Leave the default of **Any**.
Source port ranges	Leave the default of **(*)**.
Destination	Select **Application security group**.
Destination application security groups	Select **asg-web**.

Setting	Value
Service	Leave the default of **Custom**.
Destination port ranges	Enter **80**.
Protocol	Select **TCP**.
Action	Leave the default of **Allow**.
Priority	Leave the default of **100**.
Name	Enter **allow-http-web**.

4. Select **Add**.

5. Complete the previous steps with the following information:

Expand table

Setting	Value
Source	Leave the default of **Any**.
Source port ranges	Leave the default of **(*)**.
Destination	Select **Application security group**.
Destination application security group	Select **asg-mgmt**.
Service	Leave the default of **Custom**.
Destination port ranges	Enter **8080**.
Protocol	Select **TCP**.
Action	Leave the default of **Allow**.
Priority	Leave the default of **110**.
Name	Enter **allow-8080-mgmt**.

6. Select **Add**.

Create virtual machines

Create two virtual machines (VMs) in the virtual network.

Portal

1. In the portal, search for and select **Virtual machines**.
2. In **Virtual machines**, select + **Create**, then **Virtual machine**.
3. In **Create a virtual machine**, enter or select this information in the **Basics** tab:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Virtual machine name	Enter **vm-web**.
Region	Select **(US) West US 2**.
Availability options	Leave the default of **No infrastructure redundancy required**.
Security type	Select **Standard**.
Image	Select **Ubuntu Server 24.04 LTS - x64 Gen2**.
Azure Spot instance	Leave the default of unchecked.
Size	Select a size.
Administrator account	
Authentication type	Select **SSH public key**.
Username	Enter **azureuser**.
SSH public key source	Select **Generate new key pair**.
Key pair name	Enter **vm-web-key**.
Inbound port rules	
Select inbound ports	Select **None**.

4. Select **Next: Disks** then **Next: Networking**.

5. In the **Networking** tab, enter or select the following information:

Expand table

Setting	Value
Network interface	
Virtual network	Select **vnet-1**.
Subnet	Select **subnet-1 (10.0.0.0/24)**.
Public IP	Leave the default of a new public IP.
NIC network security group	Select **None**.

6. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.
7. Select **Create**.
8. When prompted to **Generate new key pair**, select **Download private key and create resource**. The private key is downloaded to your local computer. The VM might take a few minutes to deploy.
9. Repeat the previous steps to create a second virtual machine named **vm-mgmt** with key pair name **vm-mgmt-key**.

Associate network interfaces to an ASG

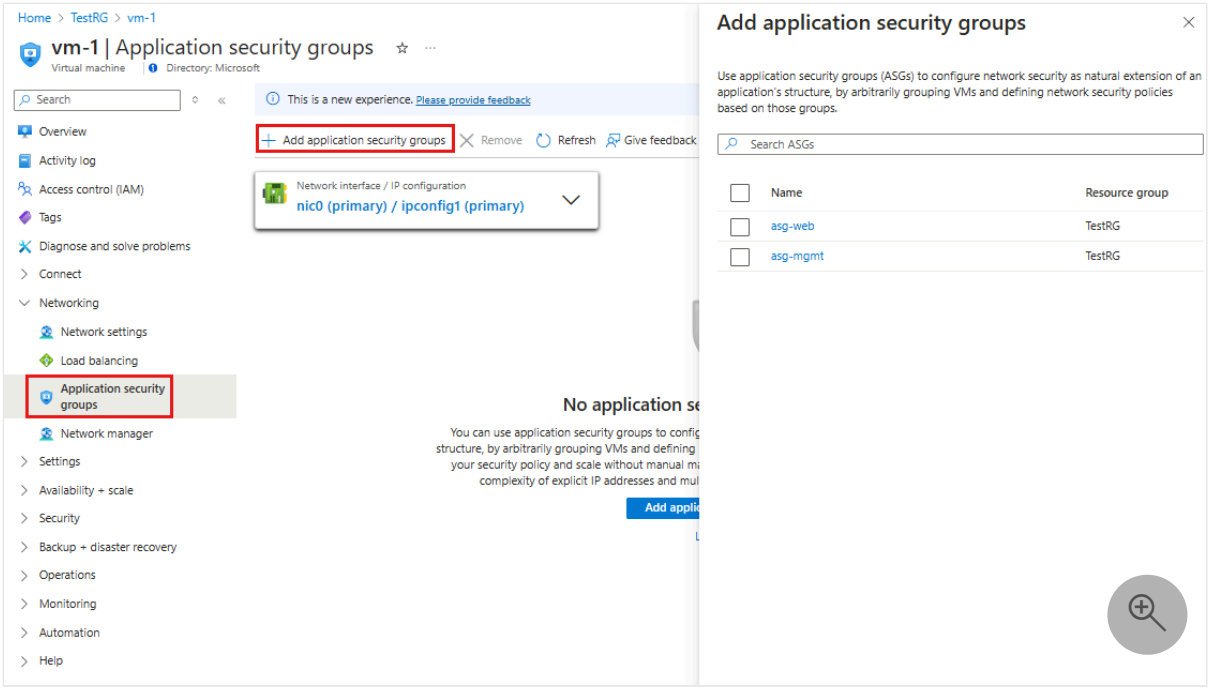
Portal

When you created the VMs, Azure created a network interface for each VM, and attached it to the VM.

Add the network interface of each VM to one of the application security groups you created previously:

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results, then select **vm-web**.
2. Select **Application security groups** from the **Networking** section of **vm-web**.

3. Select **Add application security groups**, then in the **Add application security groups** tab, select **asg-web**. Finally, select **Add**.



4. Repeat the previous steps for **vm-mgmt**, selecting **asg-mgmt** in the **Add application security groups** tab.

Test traffic filters

Portal

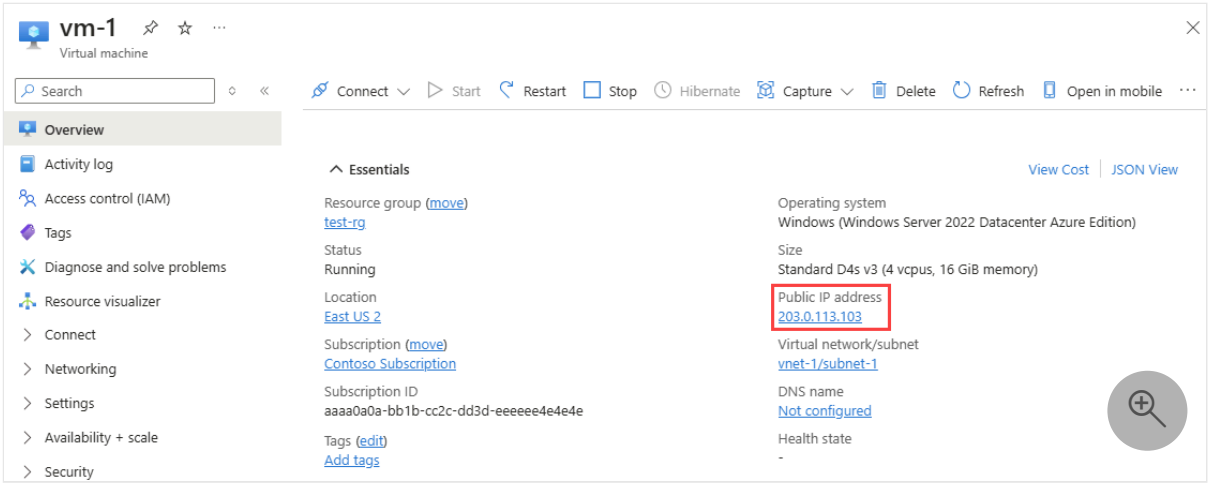
1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
2. Select **vm-web**.
3. Select **Run command** from the **Operations** section.
4. Select **RunShellScript**.
5. In the **Run Command Script** pane, enter the following commands:

Bash

```
sudo apt-get update -y
sudo apt-get install -y nginx
sudo systemctl enable nginx
sudo systemctl start nginx
```

6. Select **Run**. Wait for the script to complete successfully.

7. On the **Overview** page of **vm-web**, note the **Public IP address** for your VM.



8. To confirm that you can access the **vm-web** web server from the internet on port 80, open an internet browser on your computer and browse to `http://<public-ip-address-from-previous-step>`.

   You see the nginx default page, because inbound traffic from the internet to the **asg-web** application security group is allowed through port 80.

   The network interface attached for **vm-web** is associated with the **asg-web** application security group and allows the connection.

9. Try to access **vm-web** on port 443 by browsing to `https://<public-ip-address-vm-web>` in your browser. The connection fails or times out because the security rule for the **asg-web** doesn't allow port 443 inbound from the internet.

10. Now configure **vm-mgmt** with nginx on port 8080. Select **vm-mgmt** from the **Virtual machines** page.

11. Select **Run command** from the **Operations** section.

12. Select **RunShellScript**.

13. In the **Run Command Script** pane, enter the following commands to install nginx on port 8080:

```Bash
sudo apt-get update -y
sudo apt-get install -y nginx

# Configure nginx to listen on port 8080
sudo tee /etc/nginx/sites-available/default > /dev/null <<EOF
```

```
server {
    listen 8080 default_server;
    listen [::]:8080 default_server;
    root /var/www/html;
    index index.html index.htm index.nginx-debian.html;
    server_name _;
    location / {
        try_files \$uri \$uri/ =404;
    }
}
EOF

sudo systemctl restart nginx
```

14. Select **Run**. Wait for the script to complete successfully.

15. On the **Overview** page of **vm-mgmt**, note the **Public IP address** for your VM.

16. To confirm that you can access the **vm-mgmt** web server from the internet on port 8080, open an internet browser on your computer and browse to `http://<public-ip-address-vm-mgmt>:8080`.

    You see the nginx default page because inbound traffic from the internet to the **asg-mgmt** application security group is allowed through port 8080.

17. Try to access **vm-mgmt** on port 80 by browsing to `http://<public-ip-address-vm-mgmt>` in your browser. The connection fails or times out because no security rule allows port 80 inbound to the **asg-mgmt** application security group.

The network interface attached for **vm-web** is associated with the **asg-web** application security group and allows the connection.

Portal

When you finish using the resources that you created, you can delete the resource group and all its resources.

1. In the Azure portal, search for and select **Resource groups**.

2. On the **Resource groups** page, select the **test-rg** resource group.

3. On the **test-rg** page, select **Delete resource group**.

4. Enter **test-rg** in **Enter resource group name to confirm deletion**, and then select **Delete**.

Next steps

In this tutorial, you:

- Created a network security group and associated it to a virtual network subnet.
- Created application security groups for web and management traffic.
- Created two Linux virtual machines with SSH key authentication and associated their network interfaces with the application security groups.
- Installed nginx web servers on both VMs with different port configurations.
- Tested the application security group network filtering by demonstrating that vm-web allows port 80 (HTTP) but denies port 443, while vm-mgmt allows port 8080 but denies port 80 (HTTP).

To learn more about network security groups, see Network security group overview and Manage a network security group.

Azure routes traffic between subnets by default. You might instead, choose to route traffic between subnets through a VM, serving as a firewall, for example.

To learn how to create a route table, advance to the next tutorial.

Create a route table

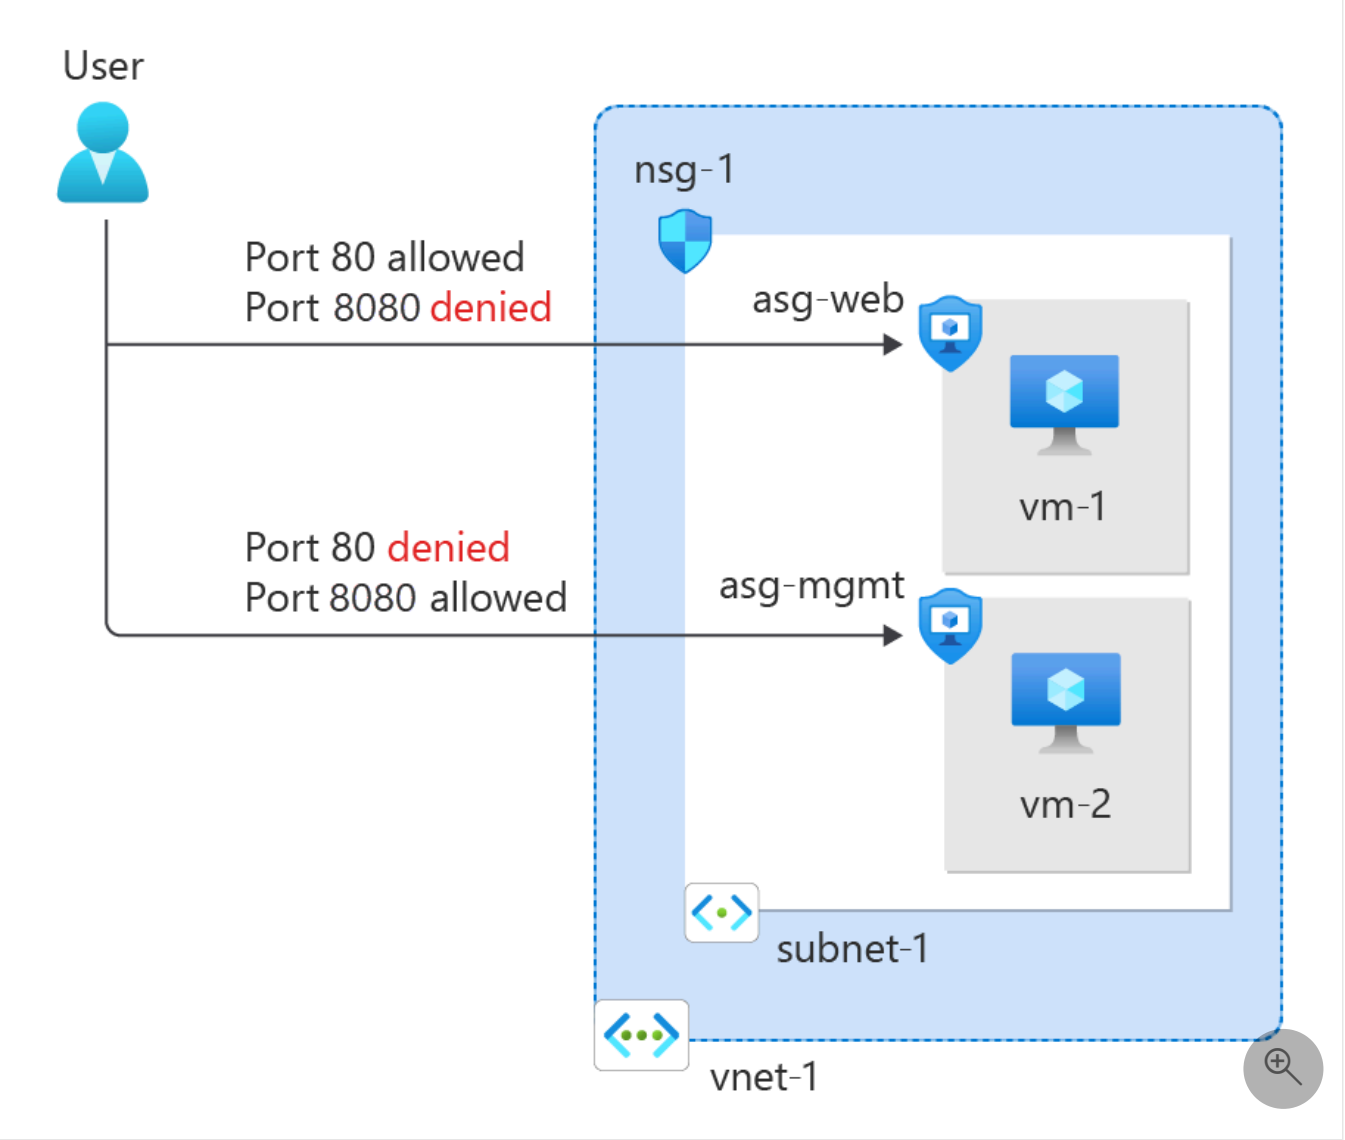
Tutorial: Filter network traffic with a network security group

You can use a network security group to filter inbound and outbound network traffic to and from Azure resources in an Azure virtual network.

Network security groups contain security rules that filter network traffic by IP address, port, and protocol. When a network security group is associated with a subnet, security rules are applied to resources deployed in that subnet.



In this tutorial, you learn how to:

- ✓ Create a network security group and security rules
- ✓ Create application security groups
- ✓ Create a virtual network and associate a network security group to a subnet
- ✓ Deploy virtual machines and associate their network interfaces to the application security groups

Prerequisites

Portal

- An Azure account with an active subscription. You can create an account for free.

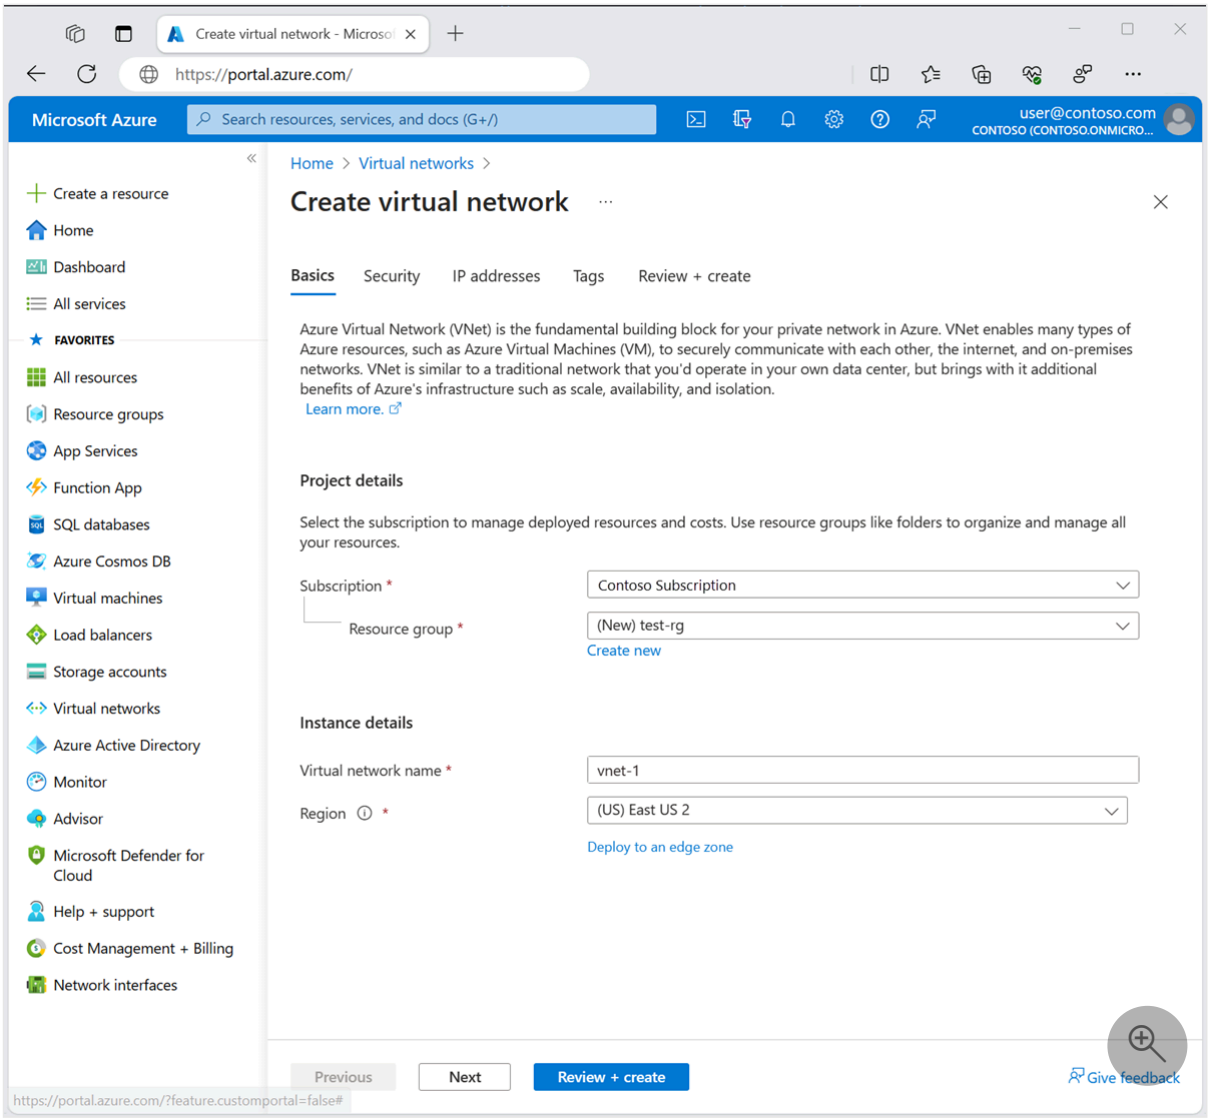
Portal

The following procedure creates a virtual network with a resource subnet.

1. In the portal, search for and select **Virtual networks**.
2. On the **Virtual networks** page, select **+ Create**.
3. On the **Basics** tab of **Create virtual network**, enter or select the following information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **Create new**. Enter **test-rg** in **Name**. Select **OK**.
Instance details	
Name	Enter **vnet-1**.
Region	Select **East US 2**.



4. Select **Next** to proceed to the **Security** tab.

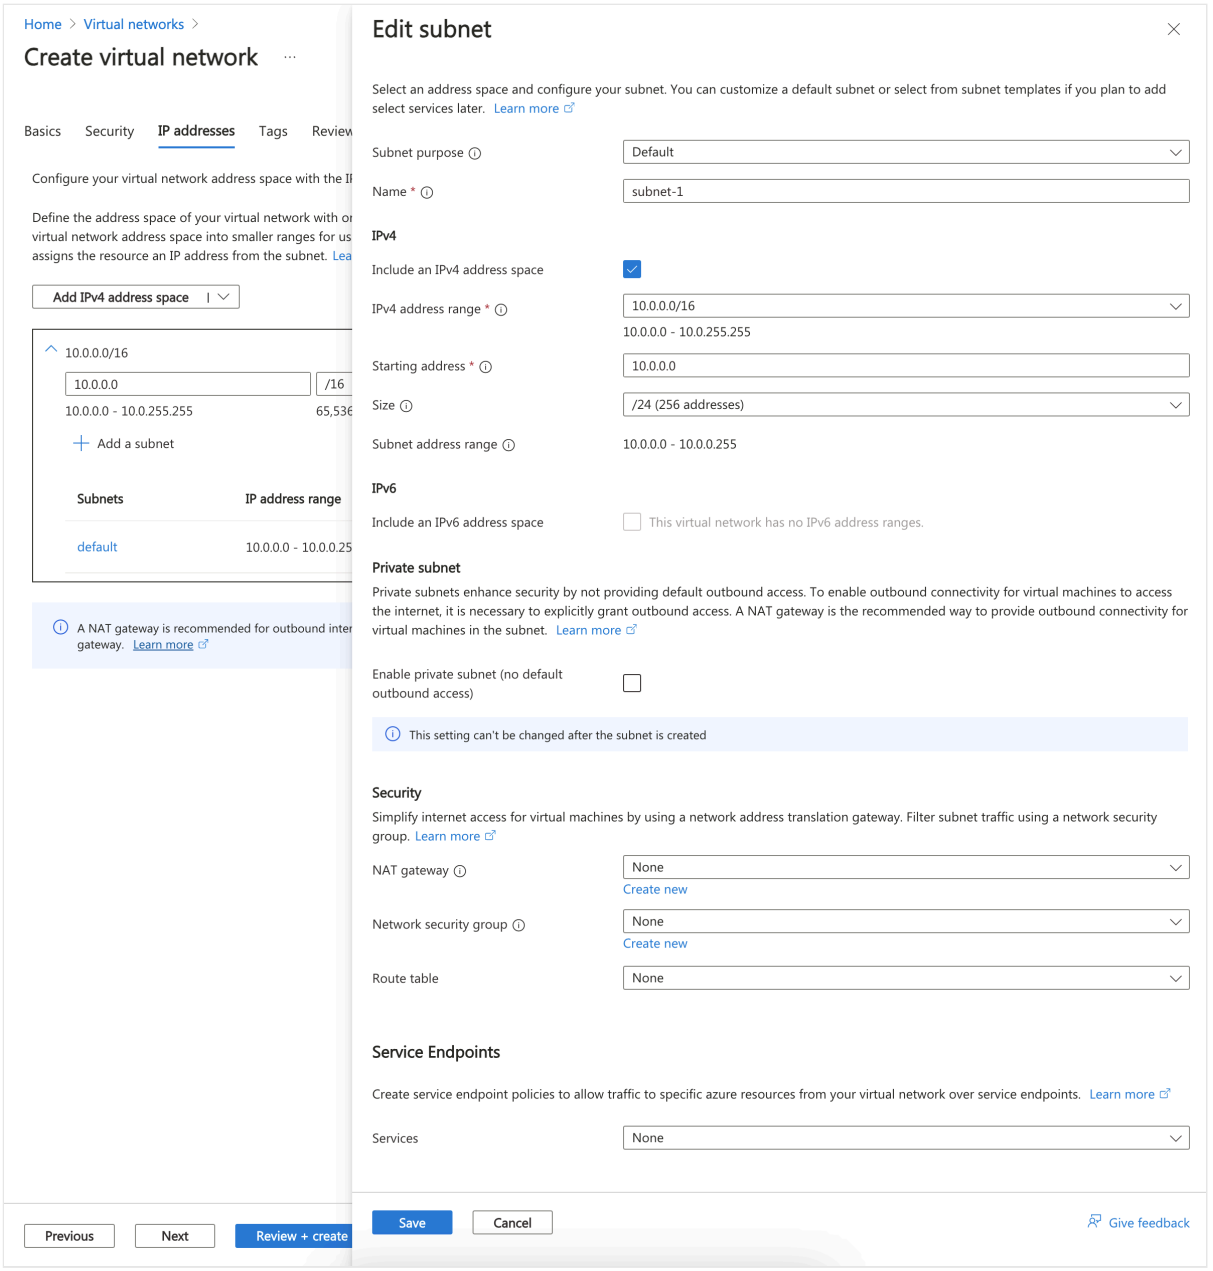
5. Select **Next** to proceed to the **IP addresses** tab.

6. In the address space box under **Subnets**, select the **default** subnet.

7. On the **Edit subnet** pane, enter or select the following information:

Expand table

Setting	Value
Subnet details	
Subnet template	Leave the default as **Default**.
Name	Enter **subnet-1**.
Starting address	Leave the default of **10.0.0.0**.
Subnet size	Leave the default of **/24(256 addresses)**.



8. Select **Save**.

9. Select **Review + create** at the bottom of the screen. After validation passes, select **Create**.

Create application security groups

An application security group (ASGs) enables you to group together servers with similar functions, such as web servers.

Portal

1. In the search box at the top of the portal, enter **Application security group**. Select **Application security groups** in the search results.
2. Select **+ Create**.
3. On the **Basics** tab of **Create an application security group**, enter, or select this information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **asg-web**.
Region	Select **West US 2**.

4. Select **Review + create**.
5. Select **+ Create**.
6. Repeat the previous steps, specifying the following values:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **asg-mgmt**.
Region	Select **West US 2**.

7. Select **Review + create**.

8. Select **Create**.

Create a network security group

A network security group (NSG) secures network traffic in your virtual network.

Portal

1. In the search box at the top of the portal, enter **Network security group**. Select **Network security groups** in the search results.

   > **Note**
   >
   > In the search results for **Network security groups**, you may see **Network security groups (classic)**. Select **Network security groups**.

2. Select **+ Create**.

3. On the **Basics** tab of **Create network security group**, enter, or select this information:

   Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **nsg-1**.
Location	Select **West US 2**.

4. Select **Review + create**.

5. Select **Create**.

Associate network security group to subnet

In this section, you associate the network security group with the subnet of the virtual network you created earlier.

Portal

1. In the search box at the top of the portal, enter **Network security group**. Select **Network security groups** in the search results.
2. Select **nsg-1**.
3. Select **Subnets** from the **Settings** section of **nsg-1**.
4. In the **Subnets** page, select + **Associate**:
5. Under **Associate subnet**, select **vnet-1 (test-rg)** for **Virtual network**.
6. Select **subnet-1** for **Subnet**, and then select **OK**.

Create security rules

Portal

1. Select **Inbound security rules** from the **Settings** section of **nsg-1**.
2. In **Inbound security rules** page, select + **Add**.
3. Create a security rule that allows port 80 to the **asg-web** application security group. In **Add inbound security rule** page, enter or select the following information:

Expand table

Setting	Value
Source	Leave the default of **Any**.
Source port ranges	Leave the default of **(*)**.
Destination	Select **Application security group**.
Destination application security groups	Select **asg-web**.

Setting	Value
Service	Leave the default of **Custom**.
Destination port ranges	Enter **80**.
Protocol	Select **TCP**.
Action	Leave the default of **Allow**.
Priority	Leave the default of **100**.
Name	Enter **allow-http-web**.

4. Select **Add**.

5. Complete the previous steps with the following information:

Expand table

Setting	Value
Source	Leave the default of **Any**.
Source port ranges	Leave the default of **(*)**.
Destination	Select **Application security group**.
Destination application security group	Select **asg-mgmt**.
Service	Leave the default of **Custom**.
Destination port ranges	Enter **8080**.
Protocol	Select **TCP**.
Action	Leave the default of **Allow**.
Priority	Leave the default of **110**.
Name	Enter **allow-8080-mgmt**.

6. Select **Add**.

Create virtual machines

Create two virtual machines (VMs) in the virtual network.

Portal

1. In the portal, search for and select **Virtual machines**.
2. In **Virtual machines**, select + **Create**, then **Virtual machine**.
3. In **Create a virtual machine**, enter or select this information in the **Basics** tab:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Virtual machine name	Enter **vm-web**.
Region	Select **(US) West US 2**.
Availability options	Leave the default of **No infrastructure redundancy required**.
Security type	Select **Standard**.
Image	Select **Ubuntu Server 24.04 LTS - x64 Gen2**.
Azure Spot instance	Leave the default of unchecked.
Size	Select a size.
Administrator account	
Authentication type	Select **SSH public key**.
Username	Enter **azureuser**.
SSH public key source	Select **Generate new key pair**.
Key pair name	Enter **vm-web-key**.
Inbound port rules	
Select inbound ports	Select **None**.

4. Select **Next: Disks** then **Next: Networking**.

5. In the **Networking** tab, enter or select the following information:

Expand table

Setting	Value
Network interface	
Virtual network	Select **vnet-1**.
Subnet	Select **subnet-1 (10.0.0.0/24)**.
Public IP	Leave the default of a new public IP.
NIC network security group	Select **None**.

6. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.
7. Select **Create**.
8. When prompted to **Generate new key pair**, select **Download private key and create resource**. The private key is downloaded to your local computer. The VM might take a few minutes to deploy.
9. Repeat the previous steps to create a second virtual machine named **vm-mgmt** with key pair name **vm-mgmt-key**.

Associate network interfaces to an ASG

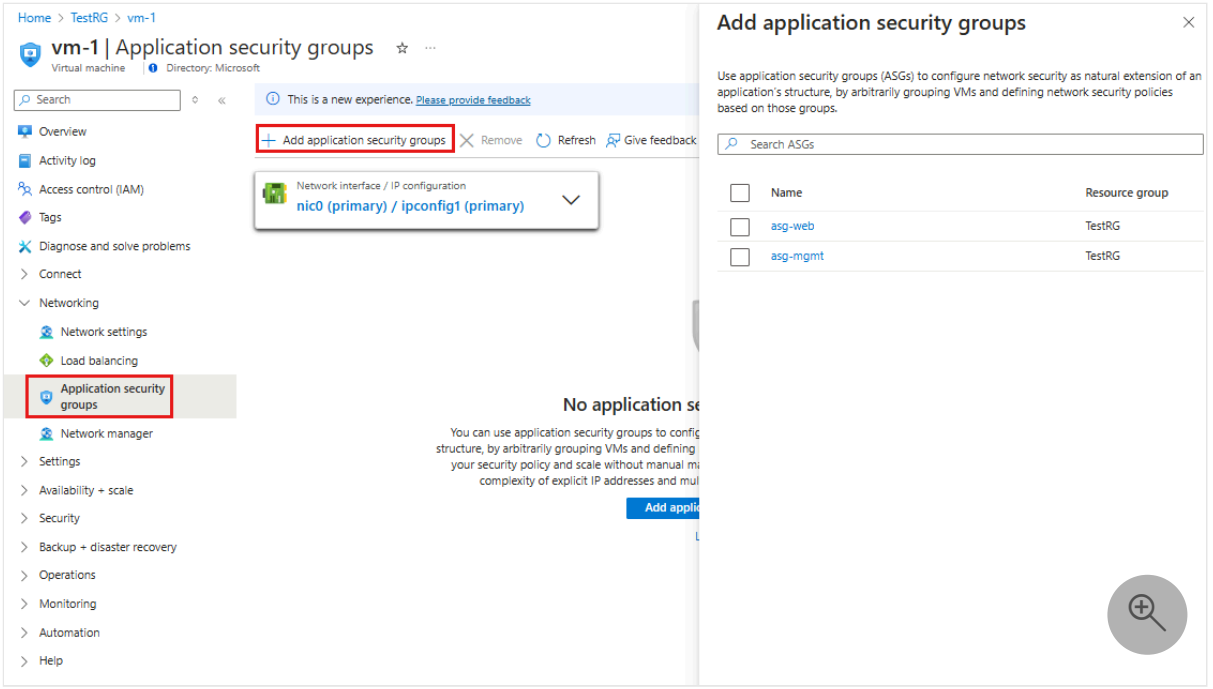
Portal

When you created the VMs, Azure created a network interface for each VM, and attached it to the VM.

Add the network interface of each VM to one of the application security groups you created previously:

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results, then select **vm-web**.
2. Select **Application security groups** from the **Networking** section of **vm-web**.

3. Select **Add application security groups**, then in the **Add application security groups** tab, select **asg-web**. Finally, select **Add**.



4. Repeat the previous steps for **vm-mgmt**, selecting **asg-mgmt** in the **Add application security groups** tab.

Test traffic filters

Portal

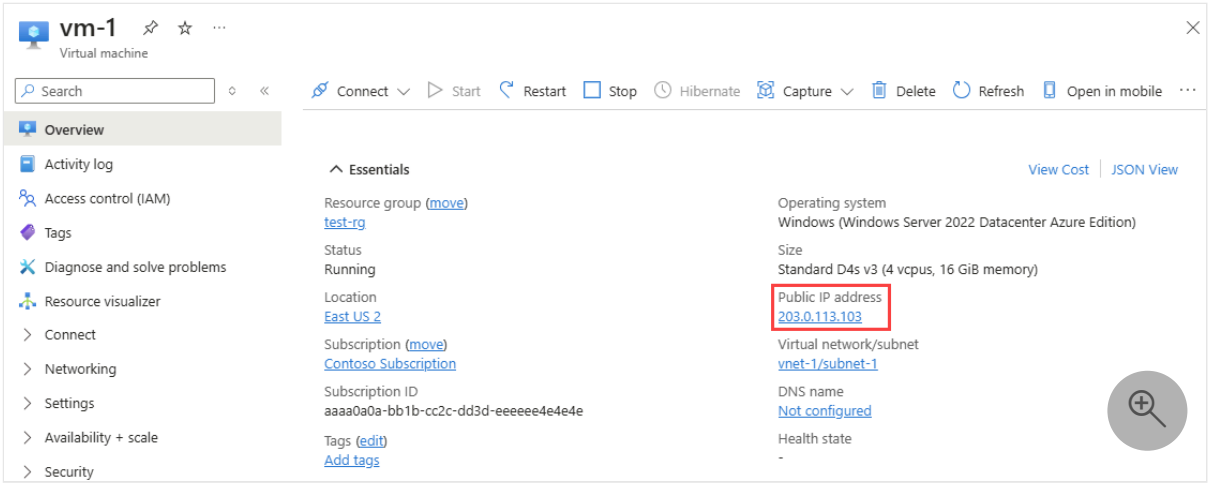
1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
2. Select **vm-web**.
3. Select **Run command** from the **Operations** section.
4. Select **RunShellScript**.
5. In the **Run Command Script** pane, enter the following commands:

Bash

```
sudo apt-get update -y
sudo apt-get install -y nginx
sudo systemctl enable nginx
sudo systemctl start nginx
```

6. Select **Run**. Wait for the script to complete successfully.

7. On the **Overview** page of **vm-web**, note the **Public IP address** for your VM.



8. To confirm that you can access the **vm-web** web server from the internet on port 80, open an internet browser on your computer and browse to `http://<public-ip-address-from-previous-step>`.

   You see the nginx default page, because inbound traffic from the internet to the **asg-web** application security group is allowed through port 80.

   The network interface attached for **vm-web** is associated with the **asg-web** application security group and allows the connection.

9. Try to access **vm-web** on port 443 by browsing to `https://<public-ip-address-vm-web>` in your browser. The connection fails or times out because the security rule for the **asg-web** doesn't allow port 443 inbound from the internet.

10. Now configure **vm-mgmt** with nginx on port 8080. Select **vm-mgmt** from the **Virtual machines** page.

11. Select **Run command** from the **Operations** section.

12. Select **RunShellScript**.

13. In the **Run Command Script** pane, enter the following commands to install nginx on port 8080:

```bash
sudo apt-get update -y
sudo apt-get install -y nginx

# Configure nginx to listen on port 8080
sudo tee /etc/nginx/sites-available/default > /dev/null <<EOF
```

```
server {
    listen 8080 default_server;
    listen [::]:8080 default_server;
    root /var/www/html;
    index index.html index.htm index.nginx-debian.html;
    server_name _;
    location / {
        try_files \$uri \$uri/ =404;
    }
}
EOF

sudo systemctl restart nginx
```

14. Select **Run**. Wait for the script to complete successfully.

15. On the **Overview** page of **vm-mgmt**, note the **Public IP address** for your VM.

16. To confirm that you can access the **vm-mgmt** web server from the internet on port 8080, open an internet browser on your computer and browse to `http://<public-ip-address-vm-mgmt>:8080`.

    You see the nginx default page because inbound traffic from the internet to the **asg-mgmt** application security group is allowed through port 8080.

17. Try to access **vm-mgmt** on port 80 by browsing to `http://<public-ip-address-vm-mgmt>` in your browser. The connection fails or times out because no security rule allows port 80 inbound to the **asg-mgmt** application security group.

The network interface attached for **vm-web** is associated with the **asg-web** application security group and allows the connection.

Portal

When you finish using the resources that you created, you can delete the resource group and all its resources.

1. In the Azure portal, search for and select **Resource groups**.

2. On the **Resource groups** page, select the **test-rg** resource group.

3. On the **test-rg** page, select **Delete resource group**.

4. Enter **test-rg** in **Enter resource group name to confirm deletion**, and then select **Delete**.

Next steps

In this tutorial, you:

- Created a network security group and associated it to a virtual network subnet.
- Created application security groups for web and management traffic.
- Created two Linux virtual machines with SSH key authentication and associated their network interfaces with the application security groups.
- Installed nginx web servers on both VMs with different port configurations.
- Tested the application security group network filtering by demonstrating that vm-web allows port 80 (HTTP) but denies port 443, while vm-mgmt allows port 8080 but denies port 80 (HTTP).

To learn more about network security groups, see Network security group overview and Manage a network security group.

Azure routes traffic between subnets by default. You might instead, choose to route traffic between subnets through a VM, serving as a firewall, for example.

To learn how to create a route table, advance to the next tutorial.

Create a route table

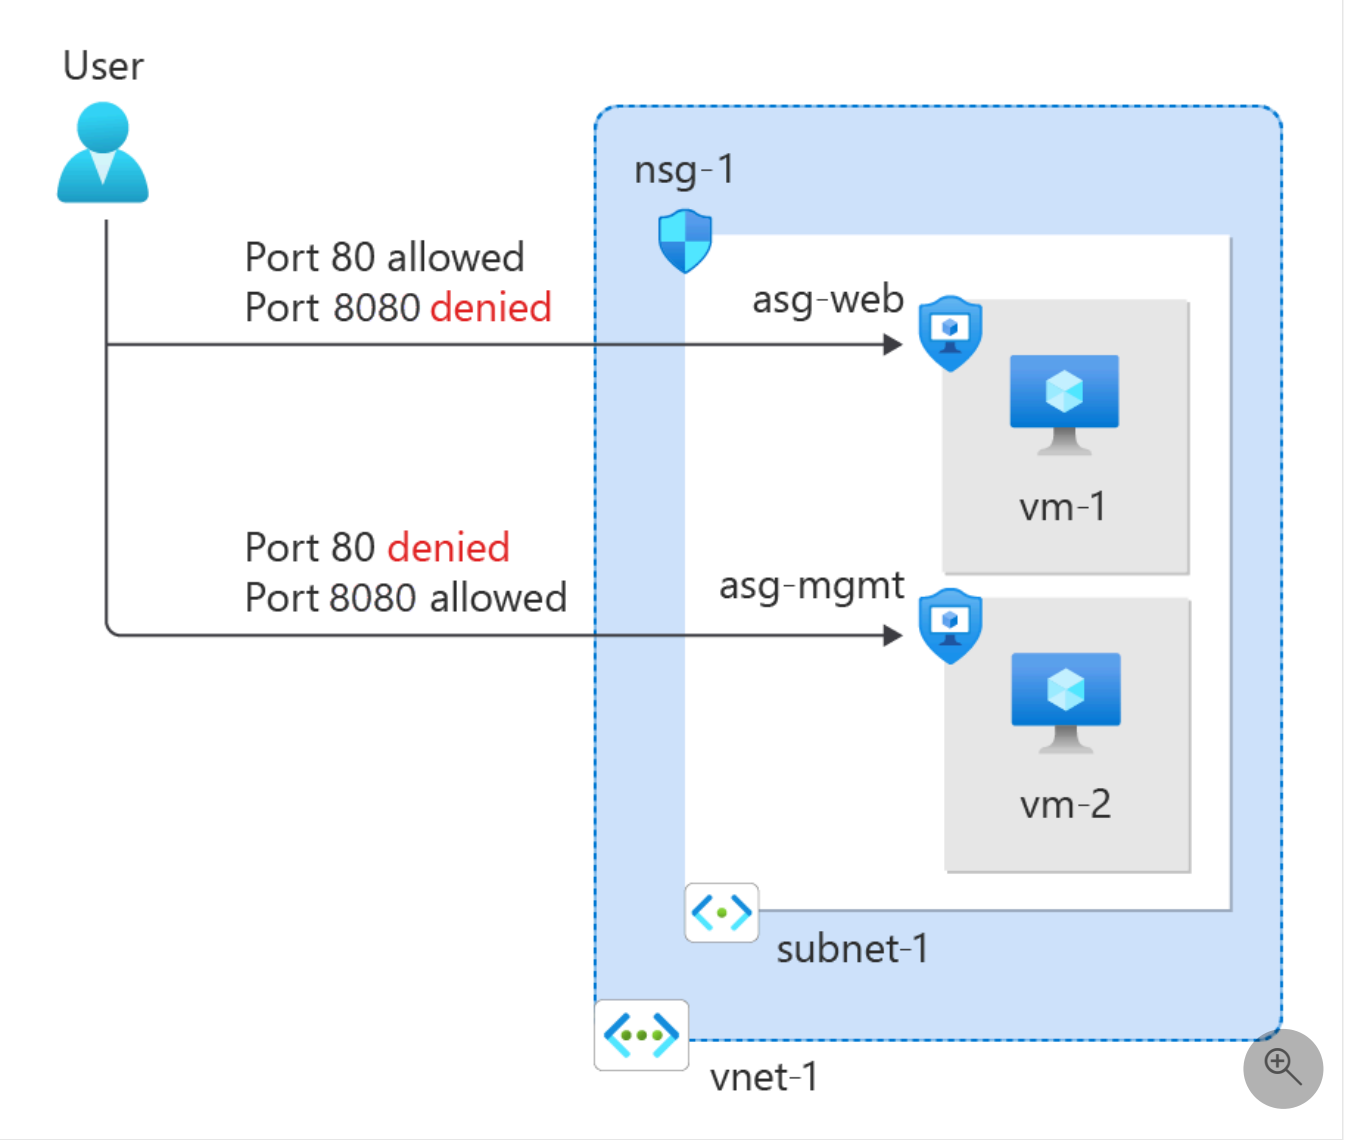
Tutorial: Filter network traffic with a network security group

You can use a network security group to filter inbound and outbound network traffic to and from Azure resources in an Azure virtual network.

Network security groups contain security rules that filter network traffic by IP address, port, and protocol. When a network security group is associated with a subnet, security rules are applied to resources deployed in that subnet.



In this tutorial, you learn how to:

- ✓ Create a network security group and security rules
- ✓ Create application security groups
- ✓ Create a virtual network and associate a network security group to a subnet
- ✓ Deploy virtual machines and associate their network interfaces to the application security groups

Prerequisites

Portal

- An Azure account with an active subscription. You can create an account for free.

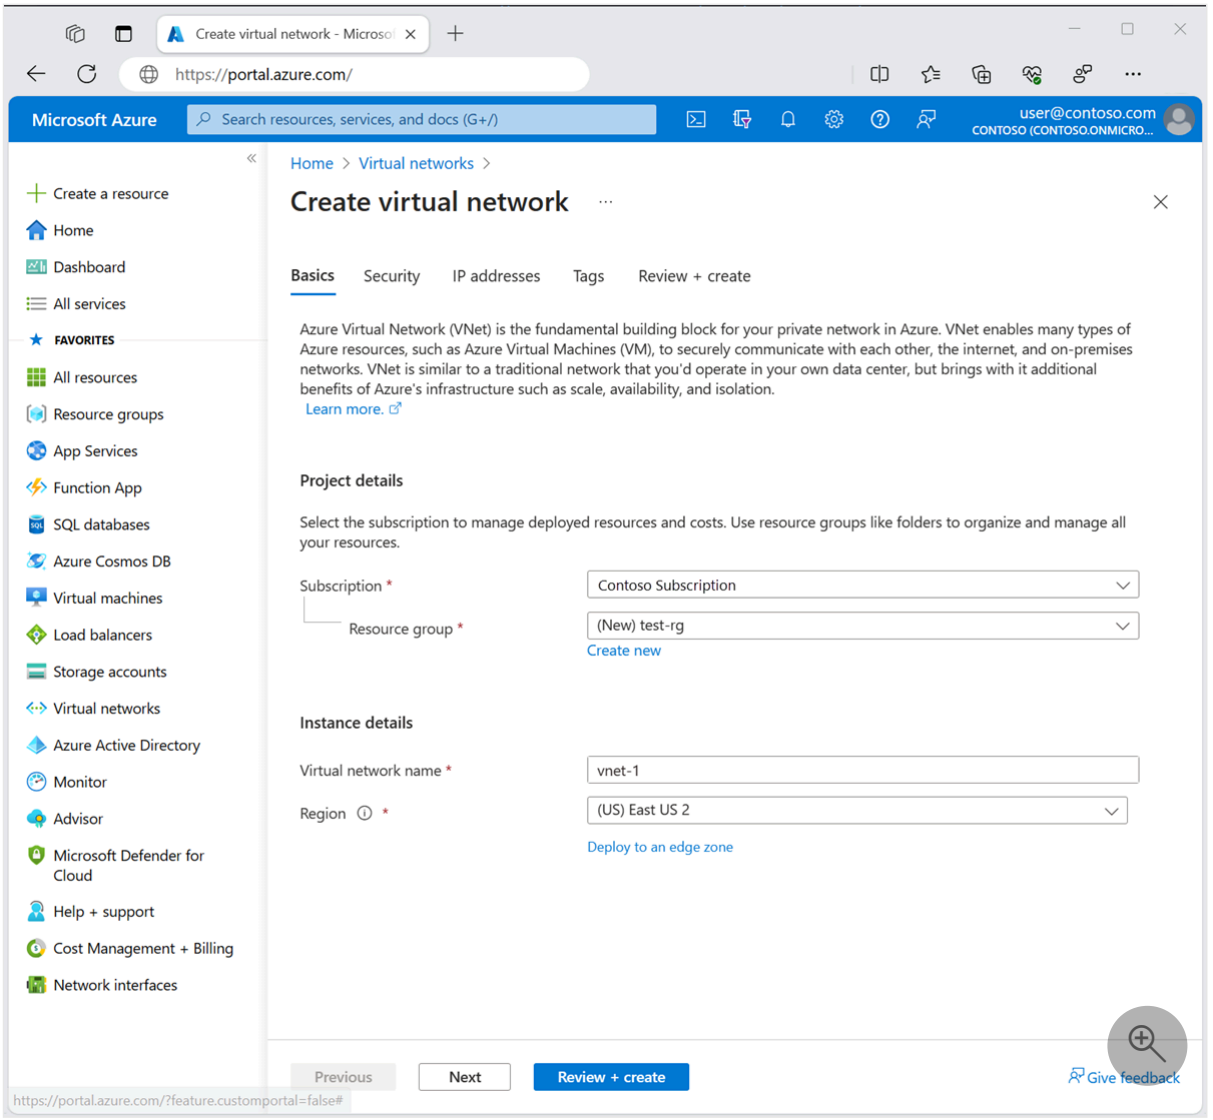
Portal

The following procedure creates a virtual network with a resource subnet.

1. In the portal, search for and select **Virtual networks**.
2. On the **Virtual networks** page, select **+ Create**.
3. On the **Basics** tab of **Create virtual network**, enter or select the following information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **Create new**. Enter **test-rg** in **Name**. Select **OK**.
Instance details	
Name	Enter **vnet-1**.
Region	Select **East US 2**.



4. Select **Next** to proceed to the **Security** tab.

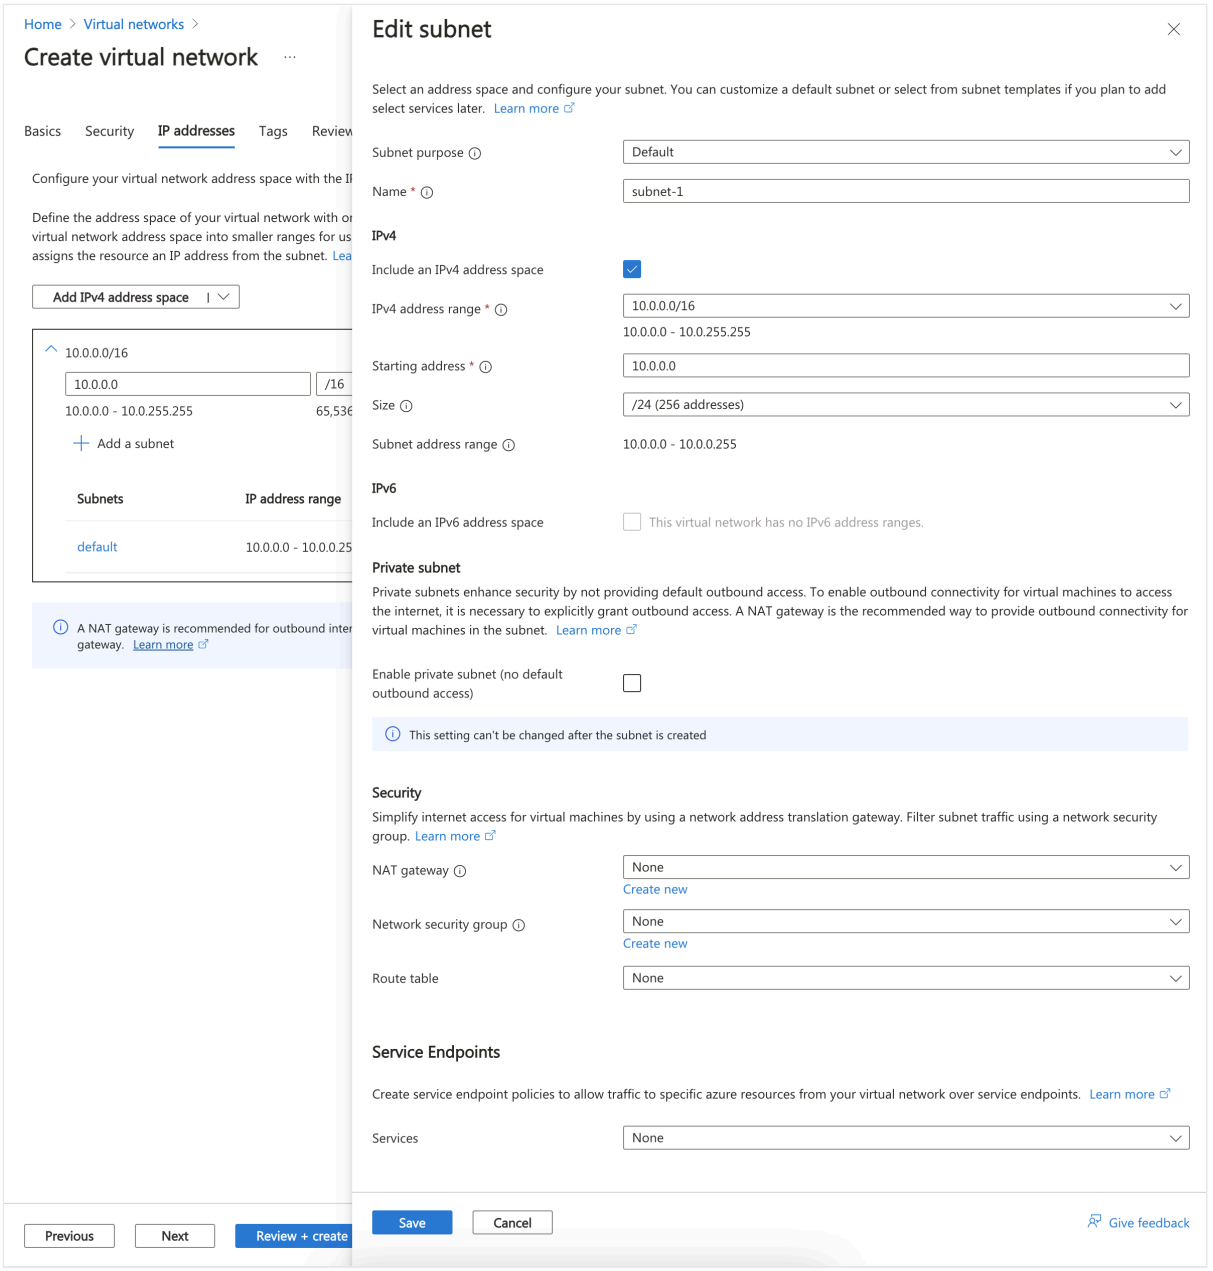
5. Select **Next** to proceed to the **IP addresses** tab.

6. In the address space box under **Subnets**, select the **default** subnet.

7. On the **Edit subnet** pane, enter or select the following information:

Expand table

Setting	Value
Subnet details	
Subnet template	Leave the default as **Default**.
Name	Enter **subnet-1**.
Starting address	Leave the default of **10.0.0.0**.
Subnet size	Leave the default of **/24(256 addresses)**.



8. Select **Save**.

9. Select **Review + create** at the bottom of the screen. After validation passes, select **Create**.

Create application security groups

An application security group (ASGs) enables you to group together servers with similar functions, such as web servers.

Portal

1. In the search box at the top of the portal, enter **Application security group**. Select **Application security groups** in the search results.
2. Select **+ Create**.
3. On the **Basics** tab of **Create an application security group**, enter, or select this information:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **asg-web**.
Region	Select **West US 2**.

4. Select **Review + create**.
5. Select **+ Create**.
6. Repeat the previous steps, specifying the following values:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **asg-mgmt**.
Region	Select **West US 2**.

7. Select **Review + create**.

8. Select **Create**.

Create a network security group

A network security group (NSG) secures network traffic in your virtual network.

Portal

1. In the search box at the top of the portal, enter **Network security group**. Select **Network security groups** in the search results.

   > **Note**
   >
   > In the search results for **Network security groups**, you may see **Network security groups (classic)**. Select **Network security groups**.

2. Select **+ Create**.

3. On the **Basics** tab of **Create network security group**, enter, or select this information:

   Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Name	Enter **nsg-1**.
Location	Select **West US 2**.

4. Select **Review + create**.

5. Select **Create**.

Associate network security group to subnet

In this section, you associate the network security group with the subnet of the virtual network you created earlier.

Portal

1. In the search box at the top of the portal, enter **Network security group**. Select **Network security groups** in the search results.
2. Select **nsg-1**.
3. Select **Subnets** from the **Settings** section of **nsg-1**.
4. In the **Subnets** page, select + **Associate**:
5. Under **Associate subnet**, select **vnet-1 (test-rg)** for **Virtual network**.
6. Select **subnet-1** for **Subnet**, and then select **OK**.

Create security rules

Portal

1. Select **Inbound security rules** from the **Settings** section of **nsg-1**.
2. In **Inbound security rules** page, select + **Add**.
3. Create a security rule that allows port 80 to the **asg-web** application security group. In **Add inbound security rule** page, enter or select the following information:

Expand table

Setting	Value
Source	Leave the default of **Any**.
Source port ranges	Leave the default of **(*)**.
Destination	Select **Application security group**.
Destination application security groups	Select **asg-web**.

Setting	Value
Service	Leave the default of **Custom**.
Destination port ranges	Enter **80**.
Protocol	Select **TCP**.
Action	Leave the default of **Allow**.
Priority	Leave the default of **100**.
Name	Enter **allow-http-web**.

4. Select **Add**.

5. Complete the previous steps with the following information:

Expand table

Setting	Value
Source	Leave the default of **Any**.
Source port ranges	Leave the default of **(*)**.
Destination	Select **Application security group**.
Destination application security group	Select **asg-mgmt**.
Service	Leave the default of **Custom**.
Destination port ranges	Enter **8080**.
Protocol	Select **TCP**.
Action	Leave the default of **Allow**.
Priority	Leave the default of **110**.
Name	Enter **allow-8080-mgmt**.

6. Select **Add**.

Create virtual machines

Create two virtual machines (VMs) in the virtual network.

Portal

1. In the portal, search for and select **Virtual machines**.
2. In **Virtual machines**, select + **Create**, then **Virtual machine**.
3. In **Create a virtual machine**, enter or select this information in the **Basics** tab:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Instance details	
Virtual machine name	Enter **vm-web**.
Region	Select **(US) West US 2**.
Availability options	Leave the default of **No infrastructure redundancy required**.
Security type	Select **Standard**.
Image	Select **Ubuntu Server 24.04 LTS - x64 Gen2**.
Azure Spot instance	Leave the default of unchecked.
Size	Select a size.
Administrator account	
Authentication type	Select **SSH public key**.
Username	Enter **azureuser**.
SSH public key source	Select **Generate new key pair**.
Key pair name	Enter **vm-web-key**.
Inbound port rules	
Select inbound ports	Select **None**.

4. Select **Next: Disks** then **Next: Networking**.

5. In the **Networking** tab, enter or select the following information:

Expand table

Setting	Value
Network interface	
Virtual network	Select **vnet-1**.
Subnet	Select **subnet-1 (10.0.0.0/24)**.
Public IP	Leave the default of a new public IP.
NIC network security group	Select **None**.

6. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.
7. Select **Create**.
8. When prompted to **Generate new key pair**, select **Download private key and create resource**. The private key is downloaded to your local computer. The VM might take a few minutes to deploy.
9. Repeat the previous steps to create a second virtual machine named **vm-mgmt** with key pair name **vm-mgmt-key**.

Associate network interfaces to an ASG

Portal

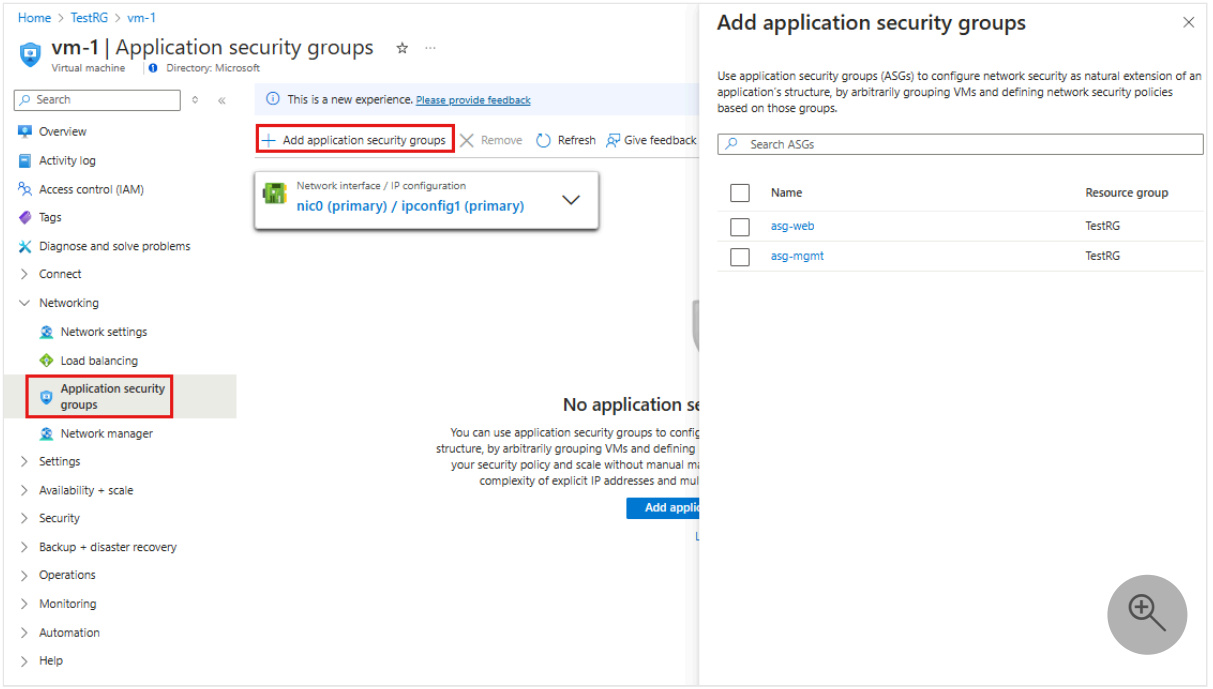
When you created the VMs, Azure created a network interface for each VM, and attached it to the VM.

Add the network interface of each VM to one of the application security groups you created previously:

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results, then select **vm-web**.
2. Select **Application security groups** from the **Networking** section of **vm-web**.

3. Select **Add application security groups**, then in the **Add application security groups** tab, select **asg-web**. Finally, select **Add**.



4. Repeat the previous steps for **vm-mgmt**, selecting **asg-mgmt** in the **Add application security groups** tab.

Test traffic filters

Portal

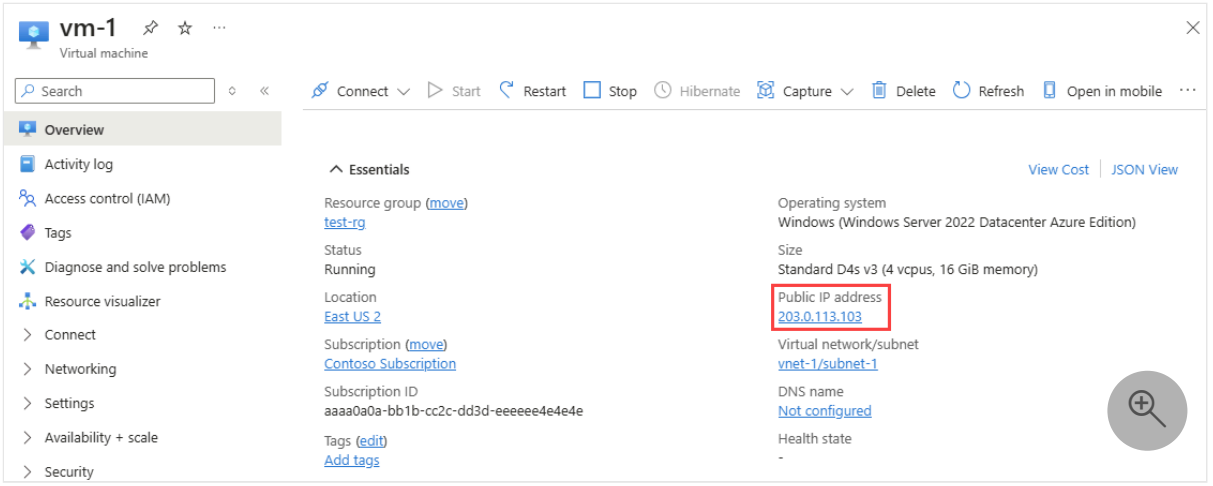
1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
2. Select **vm-web**.
3. Select **Run command** from the **Operations** section.
4. Select **RunShellScript**.
5. In the **Run Command Script** pane, enter the following commands:

Bash

```
sudo apt-get update -y
sudo apt-get install -y nginx
sudo systemctl enable nginx
sudo systemctl start nginx
```

6. Select **Run**. Wait for the script to complete successfully.

7. On the **Overview** page of **vm-web**, note the **Public IP address** for your VM.



8. To confirm that you can access the **vm-web** web server from the internet on port 80, open an internet browser on your computer and browse to `http://<public-ip-address-from-previous-step>`.

   You see the nginx default page, because inbound traffic from the internet to the **asg-web** application security group is allowed through port 80.

   The network interface attached for **vm-web** is associated with the **asg-web** application security group and allows the connection.

9. Try to access **vm-web** on port 443 by browsing to `https://<public-ip-address-vm-web>` in your browser. The connection fails or times out because the security rule for the **asg-web** doesn't allow port 443 inbound from the internet.

10. Now configure **vm-mgmt** with nginx on port 8080. Select **vm-mgmt** from the **Virtual machines** page.

11. Select **Run command** from the **Operations** section.

12. Select **RunShellScript**.

13. In the **Run Command Script** pane, enter the following commands to install nginx on port 8080:

```bash
sudo apt-get update -y
sudo apt-get install -y nginx

# Configure nginx to listen on port 8080
sudo tee /etc/nginx/sites-available/default > /dev/null <<EOF
```

```
server {
    listen 8080 default_server;
    listen [::]:8080 default_server;
    root /var/www/html;
    index index.html index.htm index.nginx-debian.html;
    server_name _;
    location / {
        try_files \$uri \$uri/ =404;
    }
}
EOF

sudo systemctl restart nginx
```

14. Select **Run**. Wait for the script to complete successfully.

15. On the **Overview** page of **vm-mgmt**, note the **Public IP address** for your VM.

16. To confirm that you can access the **vm-mgmt** web server from the internet on port 8080, open an internet browser on your computer and browse to `http://<public-ip-address-vm-mgmt>:8080`.

    You see the nginx default page because inbound traffic from the internet to the **asg-mgmt** application security group is allowed through port 8080.

17. Try to access **vm-mgmt** on port 80 by browsing to `http://<public-ip-address-vm-mgmt>` in your browser. The connection fails or times out because no security rule allows port 80 inbound to the **asg-mgmt** application security group.

The network interface attached for **vm-web** is associated with the **asg-web** application security group and allows the connection.

Portal

When you finish using the resources that you created, you can delete the resource group and all its resources.

1. In the Azure portal, search for and select **Resource groups**.

2. On the **Resource groups** page, select the **test-rg** resource group.

3. On the **test-rg** page, select **Delete resource group**.

4. Enter **test-rg** in **Enter resource group name to confirm deletion**, and then select **Delete**.

Next steps

In this tutorial, you:

- Created a network security group and associated it to a virtual network subnet.
- Created application security groups for web and management traffic.
- Created two Linux virtual machines with SSH key authentication and associated their network interfaces with the application security groups.
- Installed nginx web servers on both VMs with different port configurations.
- Tested the application security group network filtering by demonstrating that vm-web allows port 80 (HTTP) but denies port 443, while vm-mgmt allows port 8080 but denies port 80 (HTTP).

To learn more about network security groups, see Network security group overview and Manage a network security group.

Azure routes traffic between subnets by default. You might instead, choose to route traffic between subnets through a VM, serving as a firewall, for example.

To learn how to create a route table, advance to the next tutorial.

Network security group test

Article • 09/20/2024

You can use network security groups to filter and control inbound and outbound network traffic to and from your virtual machines (VMs). You can also use Azure Virtual Network Manager to apply admin security rules to your VMs to control network traffic.

In this article, you learn how to use **Network security group test** to check if a security rule is blocking traffic to or from your virtual machine by checking what security rules are applied to your VM traffic.

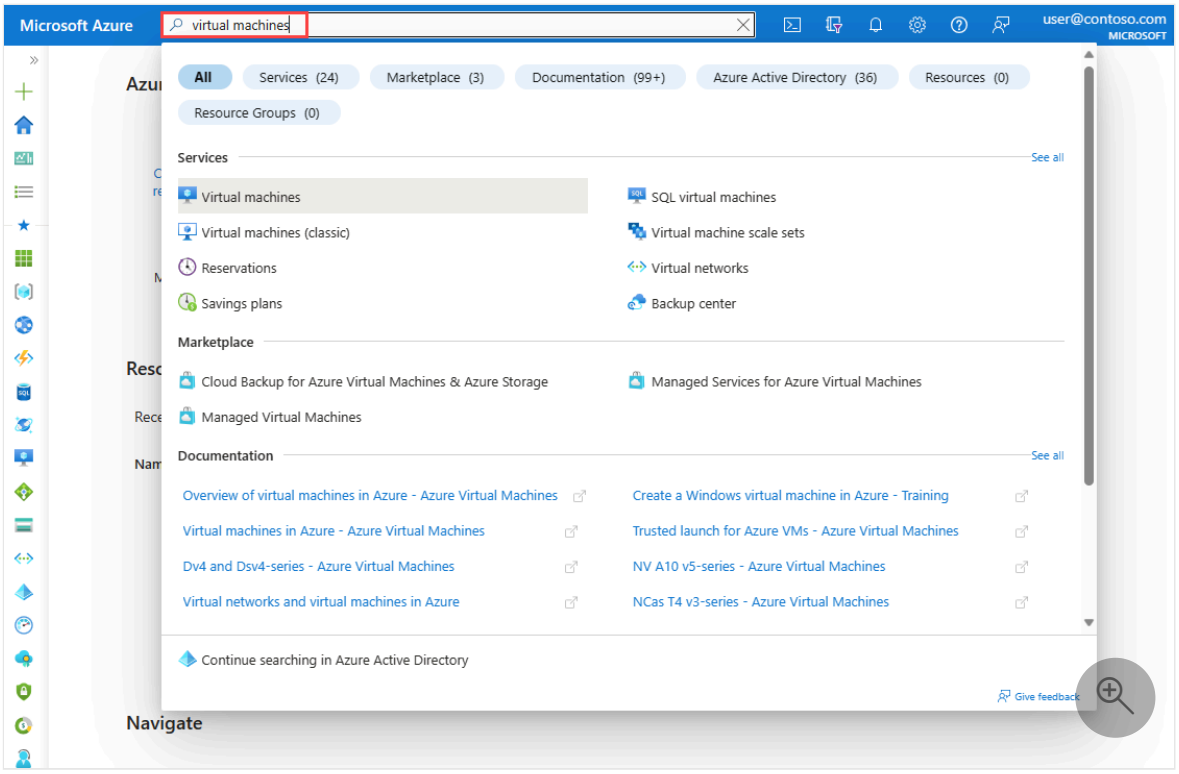
Prerequisites

- An Azure account with an active subscription. If you don't have one, create a free account before you begin.
- Sign in to the Azure portal with your Azure account.
- An Azure virtual machine (VM). If you don't have one, create a Linux VM or a Windows VM.

Test inbound connections

In this section, you test if RDP connections are allowed to your VM from a remote IP address.

1. In the search box at the top of the portal, enter *virtual machines*. Select **Virtual machines** from the search results.

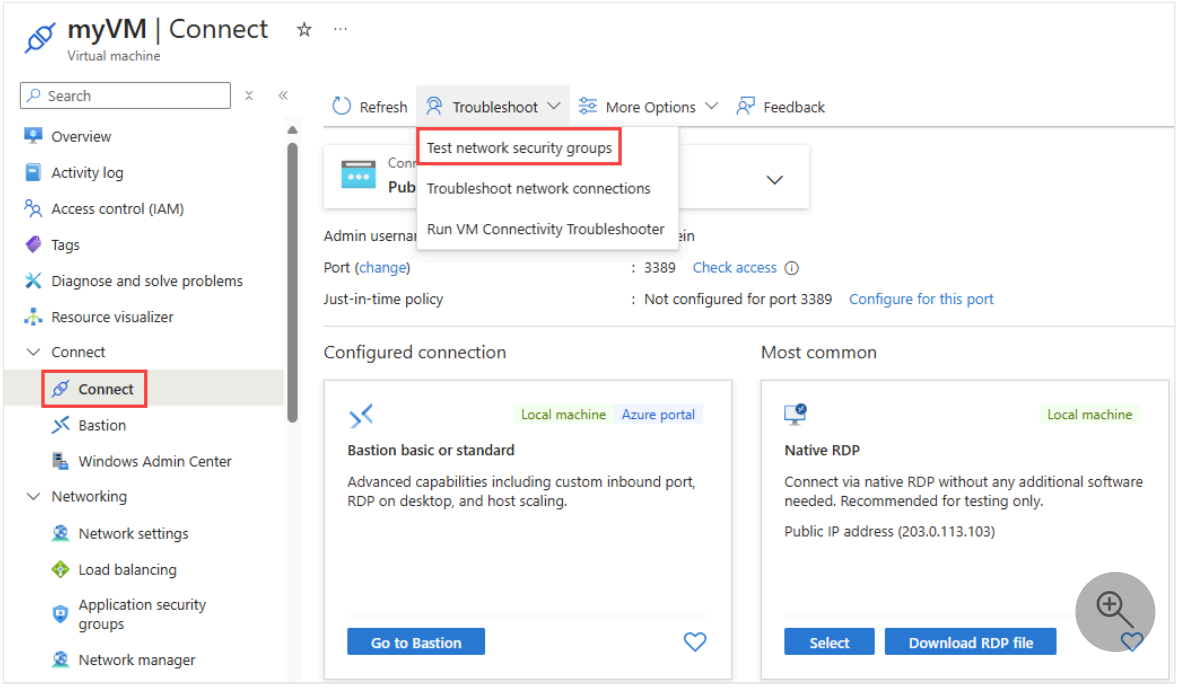


2. Select the VM that you want to test.

3. Under **Connect**, select **Connect**.

> **Note**
>
> The virtual machine must be in running state.

4. Under **Troubleshoot**, select **Test network security groups**.



5. Select **Inbound connections**. The following options are available for **Inbound** tests:

Expand table

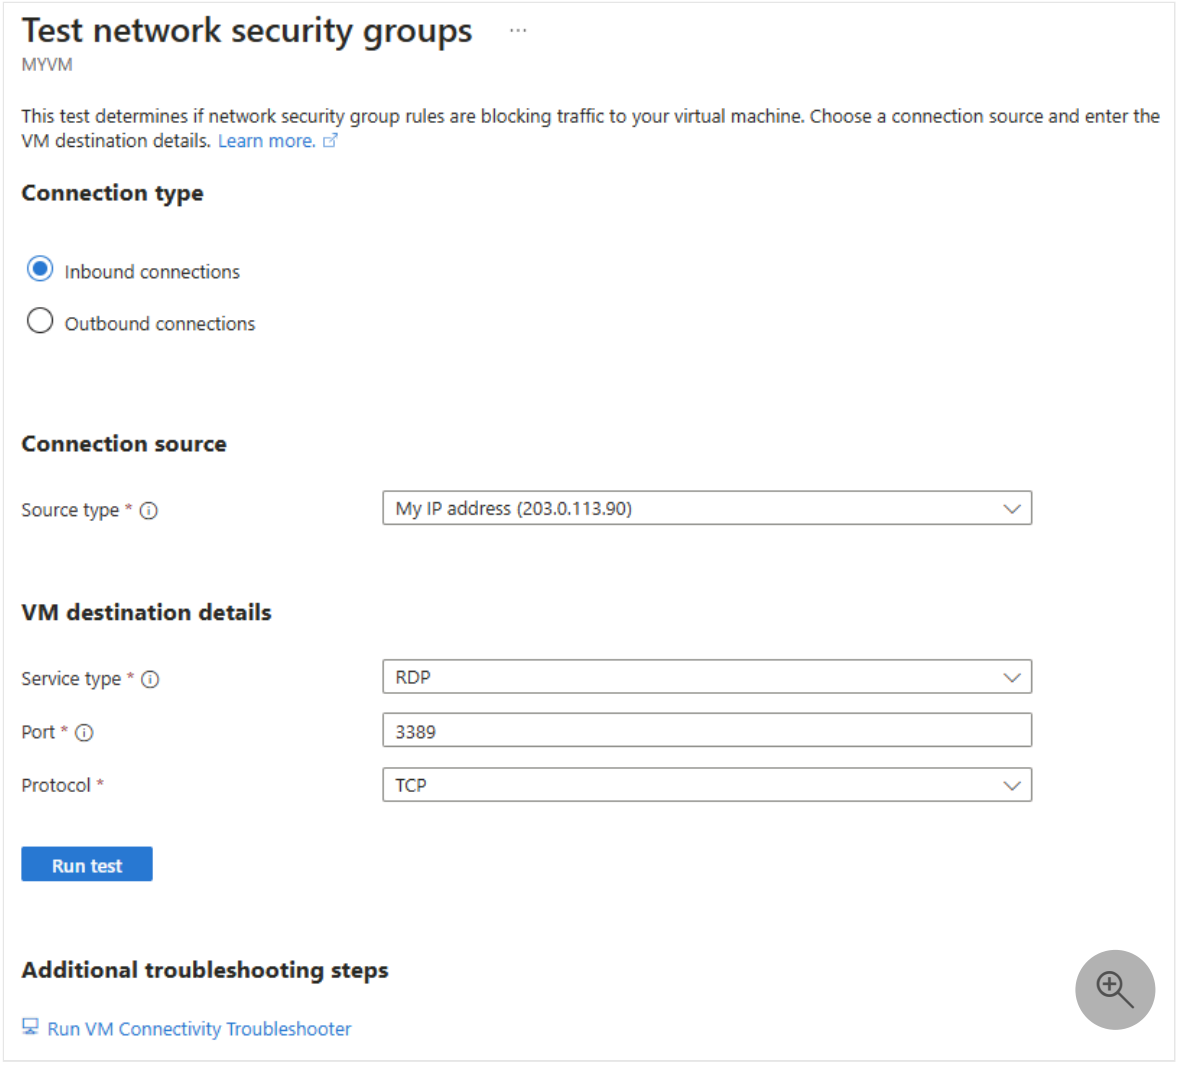
Setting	Value
Source type	- **My IP address**: your public IP address that you're using to access the Azure portal. - **Any IP address**: any source IP address. - **Other IP address/CIDR**: Source IP address or address prefix. - **Service tag**: Source service tag.
IP address/CIDR	The IP address or address prefix that you want to use as the source. **Note**: You see this option if you select **Other IP address/CIDR** for **Source type**.
Service tag	The service tag that you want to use as the source. **Note**: You see this option if you select **Service tag** for **Source type**.
Service type	List of predefined services available for the test. **Notes**: - If you select a predefined service, the service port number and protocol are automatically selected. - If you don't see the port and protocol information that you want, select **Custom**, and then enter the port number and select the protocol that you want.
Port	VM port number. **Note**: If you select one of the predefined services, the correct port number is automatically selected. Manually enter the port number when you select **Custom** for **Service type**.
Protocol	Connection protocol. Available options are: **Any**, **TCP**, and **UDP**. **Note**: If you select one of the predefined services, the correct protocol used by the service is automatically selected. Manually select the protocol when you select **Custom** for **Service type**.

6. To test if RDP connection is allowed to the VM from a remote IP address, select the following values:

Expand table

Setting	Value
Source type	Select **My IP address**.

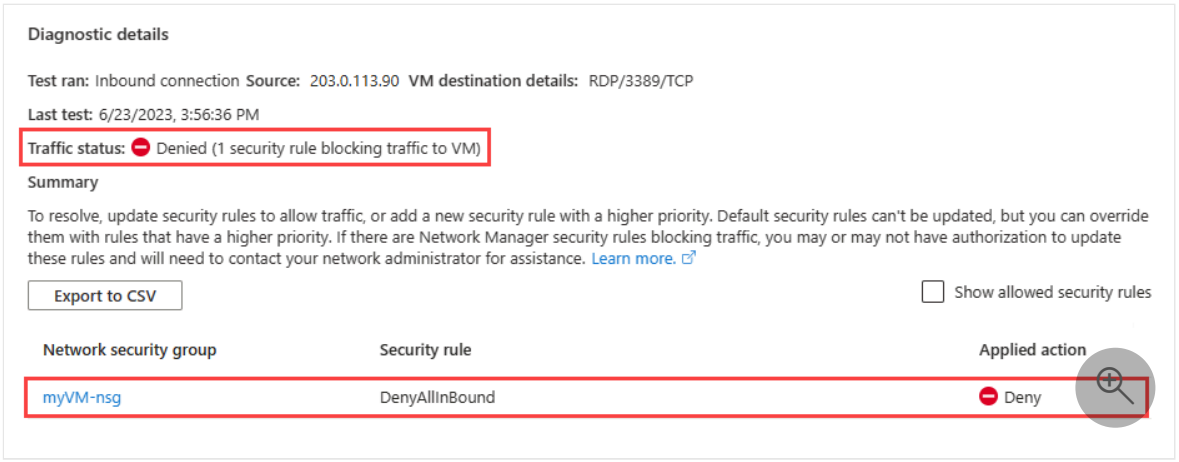
Setting	Value
Service type	Select **RDP**.
Port	Leave the default of **3389**.
Protocol	Leave the default of **TCP**.



7. Select **Run test**.

   After a few seconds, you see the details of the test:

   - If RDP connections are allowed to the VM from the remote IP address, you see **Traffic status: Allowed**.
   - If RDP connections are blocked, you see **Traffic status: Denied**. In the Summary section, you see the security rules that are blocking the traffic.

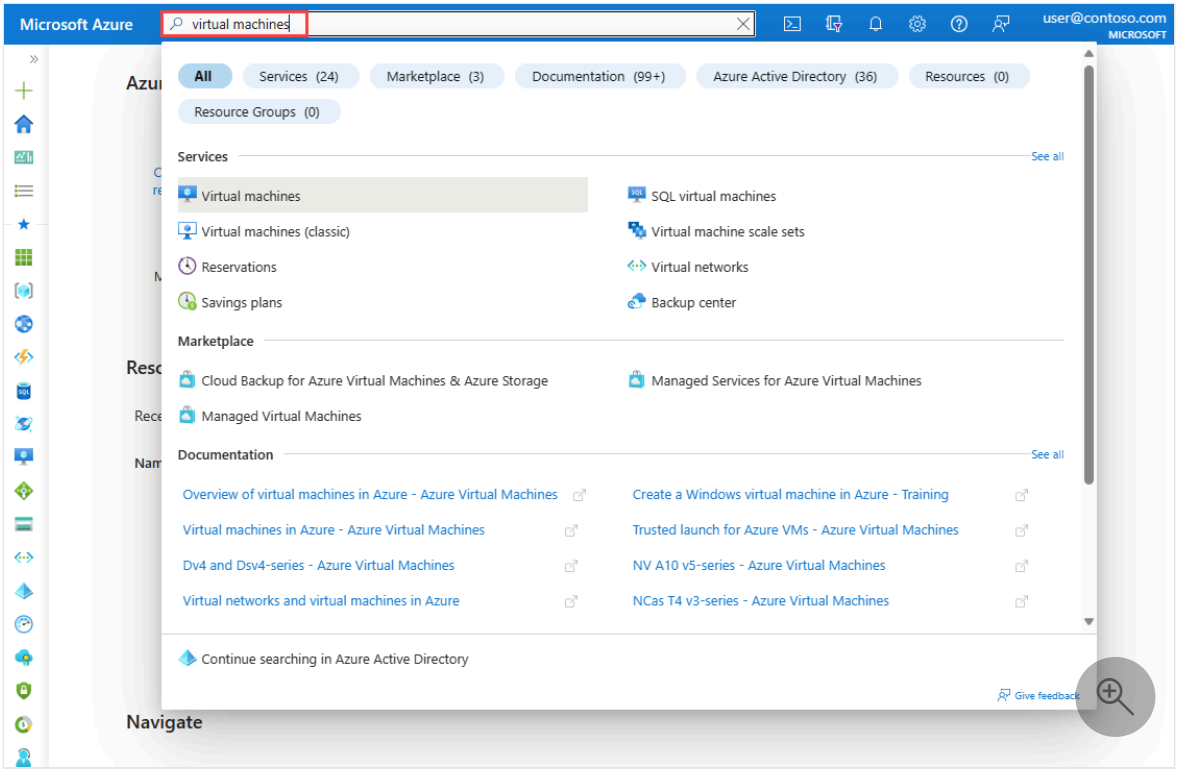


To allow the RDP connection to the VM from the remote IP address, add to the network security group a security rule that allows RDP connections from the remote IP address. This security rule must have a higher priority than the one that's blocking the traffic. For more information, see Create, change, or delete a network security group.

Test outbound connections

In this section, you test your VM can have connect to the internet.

1. In the search box at the top of the portal, enter *virtual machines*. Select **Virtual machines** from the search results.

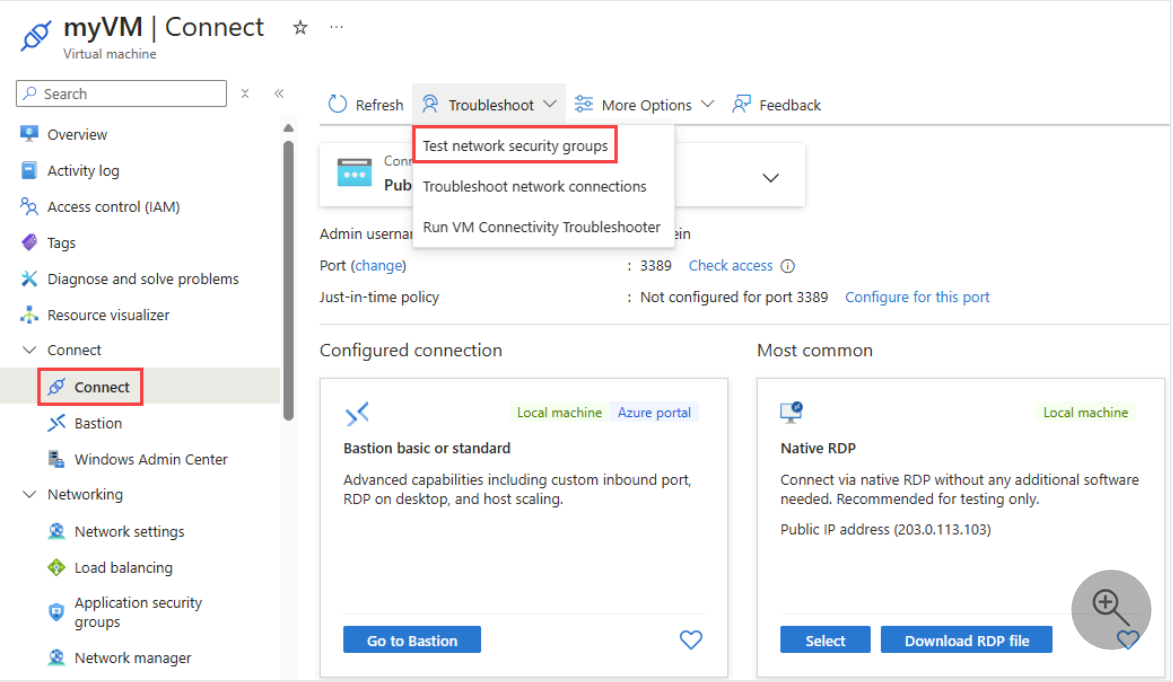


2. Select the VM you want to test.

3. Under **Connect**, select **Connect**.

> **Note**
>
> The virtual machine must be in running state.

4. Under **Troubleshoot**, select **Test network security groups**.



5. Select **Outbound connections**. The following options are available for **Outbound** tests:

Expand table

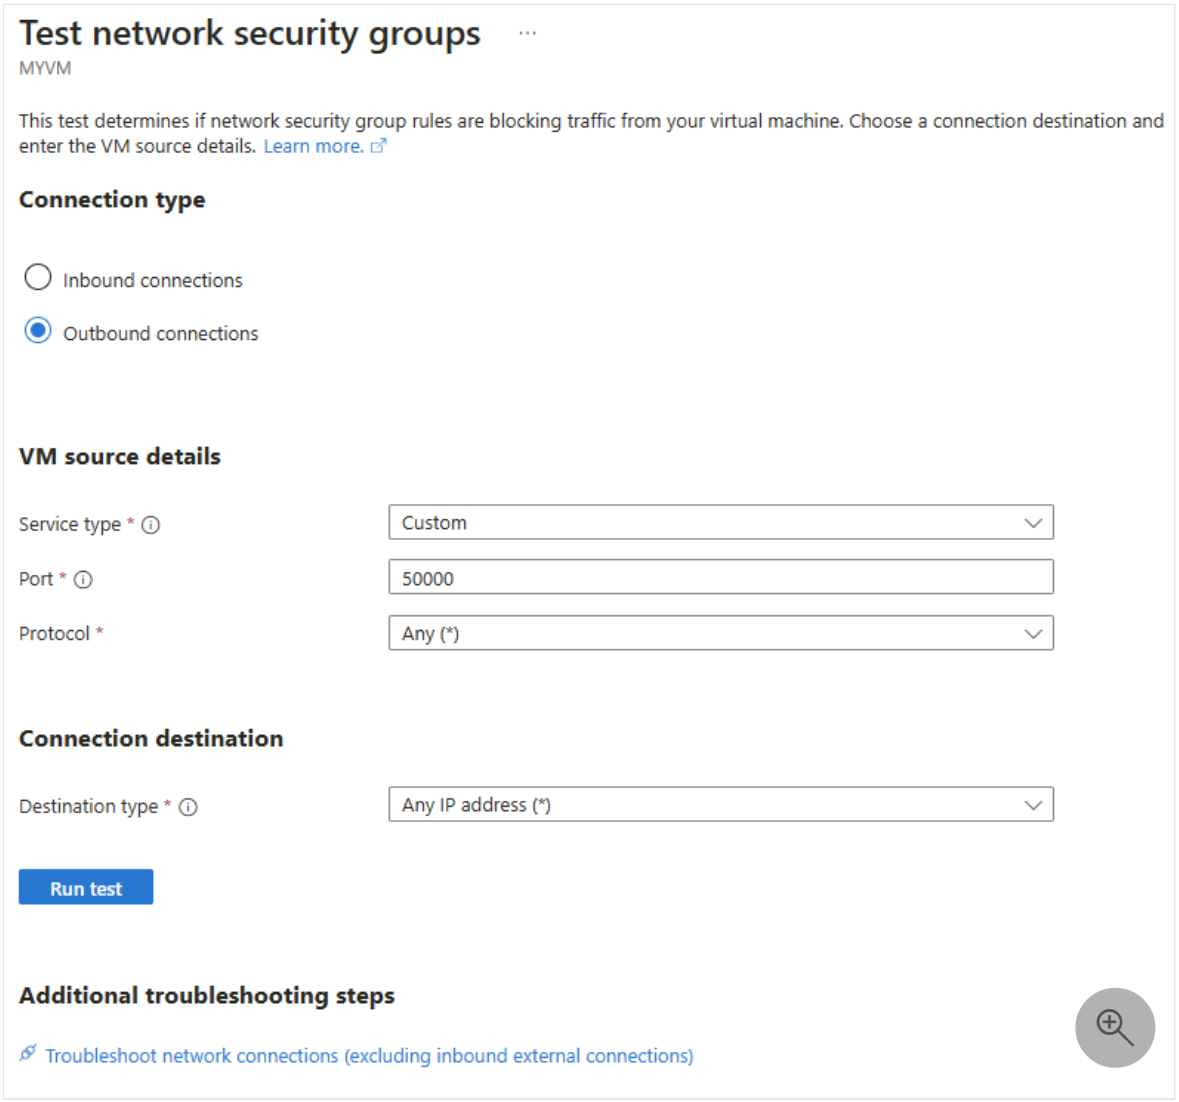
Setting	Value
Service type	List of predefined services available for the test. **Notes**: - If you select a predefined service, the service port number and protocol are automatically selected. - If you don't see the port and protocol information that you want, select **Custom**, and then enter the port number and select the protocol that you want.
Port	VM port number. **Note**: If you select one of the predefined services, the correct port number is automatically selected. Manually enter the port number when you select **Custom** for **Service type**.
Protocol	Connection protocol. Available options are: **Any**, **TCP**, and **UDP**.

Setting	Value
	Note: If you select one of the predefined services, the correct protocol used by the service is automatically selected. Manually select the protocol when you select **Custom** for **Service type**.
Destination type	- **My IP address**: your public IP address that you're using to access the Azure portal. - **Any IP address**: any source IP address. - **Other IP address/CIDR**: Source IP address or address prefix. - **Service tag**: Source service tag.
IP address/CIDR	The IP address or address prefix that you want to use as the destination. **Note**: You see this option if you select **Other IP address/CIDR** for **Source type**.
Service tag	The service tag that you want to use as the destination. **Note**: You see this option if you select **Service tag** for **Source type**.

6. To test if the VM can connect to the internet, select the following values:

Expand table

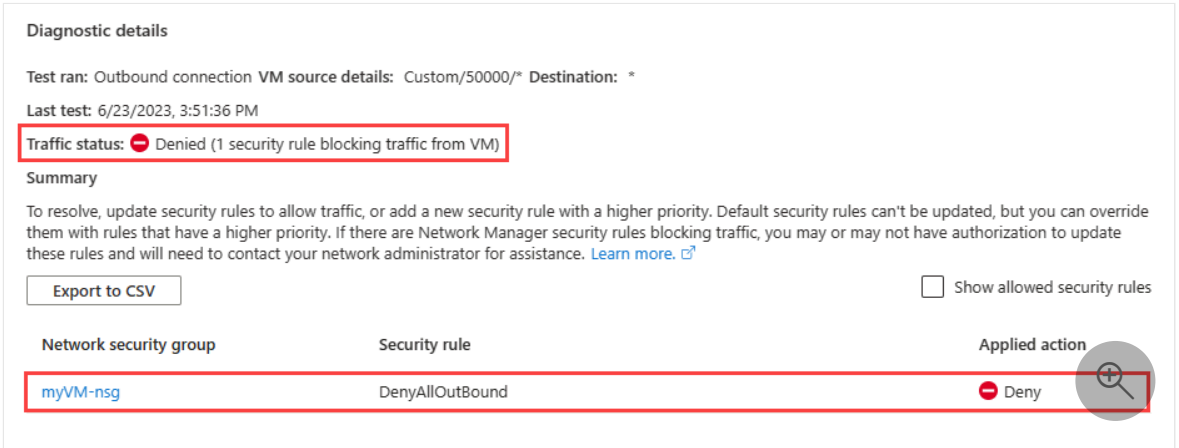
Setting	Value
Service type	Select **Custom**.
Port	Leave the default of **50000**.
Protocol	Leave the default of **Any**.
Destination type	Select **Any IP address**.



7. Select **Run test**.

   After a few seconds, you see the details of the test:

   - If connections to the internet are allowed from the VM, you see **Traffic status: Allowed**.
   - If connections to the internet are blocked, you see **Traffic status: Denied**. In the Summary section, you see the security rules that are blocking the traffic.



To allow internet connections from the VM, add to the network security group a security rule that allows connections to the internet service tag. This security rule must have a higher priority than the one that's blocking the traffic. For more information, see Create, change, or delete a network security group.

Create a virtual machine with a static public IP address using the Azure portal, Azure PowerShell, or Azure CLI

Summarize this article for me

In this article, you create a virtual machine (VM) with a static public IP address. A public IP address enables you to communicate to a VM from the internet. Assign a static public IP address, rather than a dynamic address, to ensure the address never changes.

Public IP addresses have a nominal charge. There's a limit to the number of public IP addresses that you can use per subscription.

You can download the list of ranges (prefixes) for the Azure Public, US government, China, and Germany clouds.

Prerequisites

Azure portal

- An Azure account with an active subscription. You can create an account for free.

Create a virtual machine with a static public IP address

In this section, you create a virtual machine with a static public IP address using the Azure portal, Azure PowerShell, or Azure CLI. Along with the virtual machine, you create a public IP address and the other required resources.

Azure portal

Sign in to Azure

Sign in to the Azure portal.

Create a resource group

1. In the search box at the top of the portal, enter *Resource group*.
2. In the search results, select **Resource groups**.
3. Select **+ Create**.
4. In the **Basics** tab of **Create a resource group**, enter or select the following:

Expand table

Setting	Value
Subscription	Select your Azure subscription
Resource Group	Enter *myResourceGroup*.
Region	Select **East US**.

5. Select **Review + create**, then select **Create**.

Create a virtual machine

1. In the search box at the top of the portal, enter *Virtual machine*.
2. In the search results, select **Virtual machines**.
3. Select **+ Create**, then select **Azure virtual machine**.
4. In **Basics** tab of **Create a virtual machine**, enter or select the following:

Expand table

Setting	Value
Project Details	
Subscription	Select your Azure subscription
Resource Group	Select **myResourceGroup**.
Instance details	
Virtual machine name	Enter *myVM*.
Region	Select **East US**.
Availability Options	Select **No infrastructure redundancy required**.
Security type	Select **Standard**.

Setting	Value
Image	Select **Windows Server 2019 Datacenter - x64 Gen2**.
Size	Choose VM size or take default setting.
Administrator account	
Username	Enter a username.
Password	Enter a password.
Confirm password	Reenter password.
Public inbound ports	Select **None**.

> **Note**
>
> All public inbound ports are closed for this virtual machine. To manage your virtual machines, deploy Azure Bastion. For more information, see Quickstart: Deploy Azure Bastion from the Azure portal.

5. Select the **Networking** tab, or select **Next: Disks**, then **Next: Networking**.

6. In the **Networking** tab, enter or select the following:

Expand table

Setting	Value
Network interface	
Virtual network	Accept the default network name.
Subnet	Accept the default subnet configuration.
Public IP	Select **Create new**. In **Create public IP address**, enter *myPublicIP* in **Name**. **SKU**: select **Standard**. **Assignment**: select **Static**. Select **OK**.

> **Note**

The SKU of the virtual machine's public IP address must match the public IP SKU of Azure public load balancer when added to the backend pool of the load balancer. For details, see Azure Load Balancer.

7. Select **Review + create**.

8. Review the settings, and then select **Create**.

> ⚠ **Warning**
>
> Do not modify the IP address settings within the virtual machine's operating system. The operating system is unaware of Azure public IP addresses. Though you can add private IP address settings to the operating system, we recommend not doing so unless necessary. For more information, see Add a private IP address to an operating system.

> ⓘ **Note**
>
> Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.
>
> The default outbound access IP is disabled when one of the following events happens:
>
> - A public IP address is assigned to the VM.
> - The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
> - An Azure NAT Gateway resource is assigned to the subnet of the VM.
>
> VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.
>
> For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Clean up resources

When resources are no longer needed, delete all resources created in this article to avoid incurring charges.

Azure portal

Use the Azure portal to delete the resource group and all of the resources it contains:

1. Enter *myResourceGroup* in the search box at the top of the portal. When you see **myResourceGroup** in the search results, select it.
2. Select **Delete resource group**.
3. Enter *myResourceGroup* for **TYPE THE RESOURCE GROUP NAME:** and select **Delete**.

Next steps

In this article, you learned how to create a VM with a static public IP.

- Learn how to Configure IP addresses for an Azure network interface.
- Learn how to Assign multiple IP addresses to virtual machines using the Azure portal.

Create a virtual machine with a static public IP address using the Azure portal, Azure PowerShell, or Azure CLI

Summarize this article for me

In this article, you create a virtual machine (VM) with a static public IP address. A public IP address enables you to communicate to a VM from the internet. Assign a static public IP address, rather than a dynamic address, to ensure the address never changes.

Public IP addresses have a nominal charge. There's a limit to the number of public IP addresses that you can use per subscription.

You can download the list of ranges (prefixes) for the Azure Public, US government, China, and Germany clouds.

Prerequisites

Azure portal

- An Azure account with an active subscription. You can create an account for free.

Create a virtual machine with a static public IP address

In this section, you create a virtual machine with a static public IP address using the Azure portal, Azure PowerShell, or Azure CLI. Along with the virtual machine, you create a public IP address and the other required resources.

Azure portal

Sign in to Azure

Sign in to the Azure portal.

Create a resource group

1. In the search box at the top of the portal, enter *Resource group*.
2. In the search results, select **Resource groups**.
3. Select **+ Create**.
4. In the **Basics** tab of **Create a resource group**, enter or select the following:

Expand table

Setting	Value
Subscription	Select your Azure subscription
Resource Group	Enter *myResourceGroup*.
Region	Select **East US**.

5. Select **Review + create**, then select **Create**.

Create a virtual machine

1. In the search box at the top of the portal, enter *Virtual machine*.
2. In the search results, select **Virtual machines**.
3. Select **+ Create**, then select **Azure virtual machine**.
4. In **Basics** tab of **Create a virtual machine**, enter or select the following:

Expand table

Setting	Value
Project Details	
Subscription	Select your Azure subscription
Resource Group	Select **myResourceGroup**.
Instance details	
Virtual machine name	Enter *myVM*.
Region	Select **East US**.
Availability Options	Select **No infrastructure redundancy required**.
Security type	Select **Standard**.

Setting	Value
Image	Select **Windows Server 2019 Datacenter - x64 Gen2**.
Size	Choose VM size or take default setting.
Administrator account	
Username	Enter a username.
Password	Enter a password.
Confirm password	Reenter password.
Public inbound ports	Select **None**.

> **Note**
>
> All public inbound ports are closed for this virtual machine. To manage your virtual machines, deploy Azure Bastion. For more information, see Quickstart: Deploy Azure Bastion from the Azure portal.

5. Select the **Networking** tab, or select **Next: Disks**, then **Next: Networking**.

6. In the **Networking** tab, enter or select the following:

Expand table

Setting	Value
Network interface	
Virtual network	Accept the default network name.
Subnet	Accept the default subnet configuration.
Public IP	Select **Create new**. In **Create public IP address**, enter *myPublicIP* in **Name**. **SKU**: select **Standard**. **Assignment**: select **Static**. Select **OK**.

> **Note**

The SKU of the virtual machine's public IP address must match the public IP SKU of Azure public load balancer when added to the backend pool of the load balancer. For details, see Azure Load Balancer.

7. Select **Review + create**.

8. Review the settings, and then select **Create**.

Associate a public IP address to a virtual machine

In this article, you learn how to associate a public IP address to an existing virtual machine (VM). To do so, you associate the public IP address to an IP configuration of a network interface attached to a VM. You can use the Azure portal, the Azure CLI, or Azure PowerShell by selecting the tab for the method you want to use.

If you want to instead create a new VM with a public IP address, you can use the Azure portal, the Azure CLI, or Azure PowerShell.

Public IP addresses have a nominal fee. For details, see pricing. There's a limit to the number of public IP addresses that you can use per subscription. For details, see limits.

> **Note**
>
> Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.
>
> The default outbound access IP is disabled when one of the following events happens:
>
> - A public IP address is assigned to the VM.
> - The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
> - An Azure NAT Gateway resource is assigned to the subnet of the VM.
>
> VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.
>
> For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Prerequisites

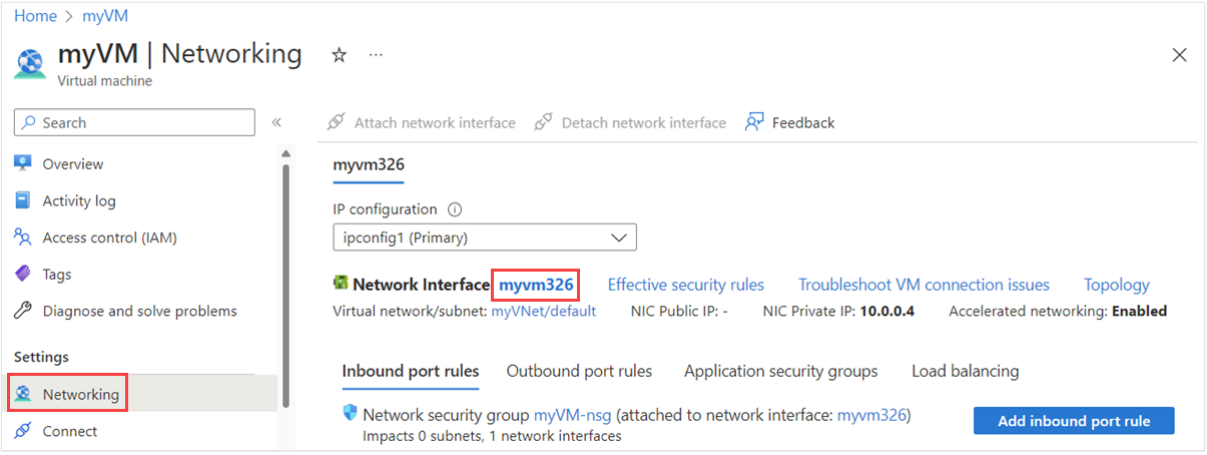
- An Azure account with an active subscription. You can create an account for free.

Azure portal

1. Sign in to the Azure portal.

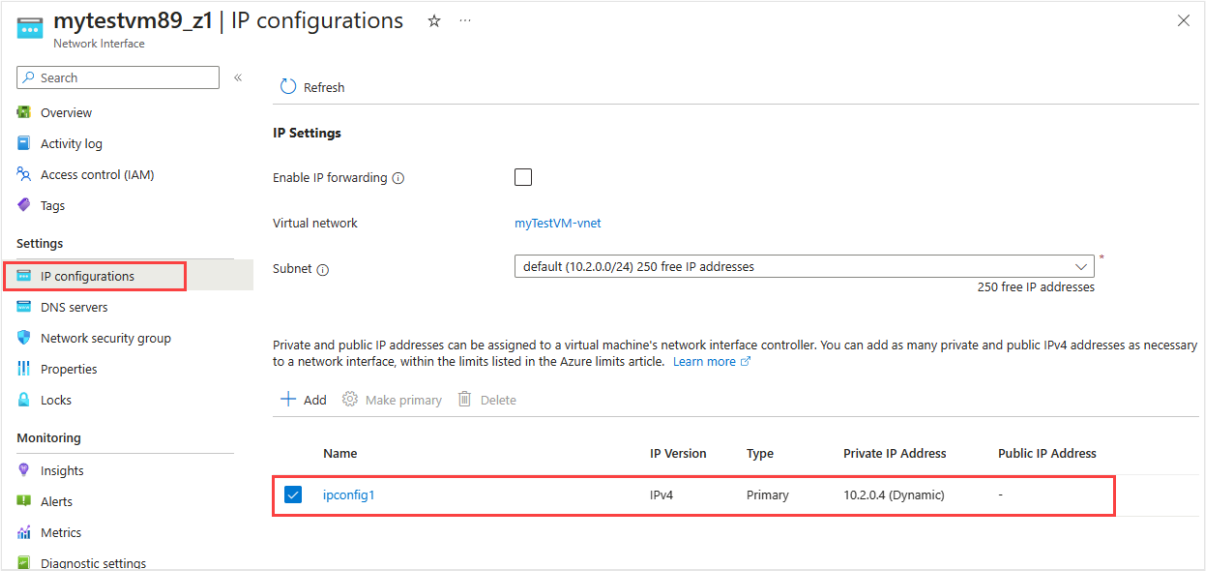
2. In the portal, search for and select the VM that you want to add the public IP address to.

3. Under **Settings** in the left pane, select **Networking**, and then select the network interface you want to add the public IP address to.



> **Note**
>
> Public IP addresses are associated to the network interfaces that are attached to a VM. In this screenshot, the VM has only one network interface. If the VM had multiple network interfaces, they would all appear, and you'd select the network interface you want to associate the public IP address to.

4. From the **Network interface** window, under **Settings**, select **IP configurations***, and then select an IP configuration from the list.



> **Note**
>
> Public IP addresses are associated to the IP configurations for a network interface. In this screenshot, the network interface has only one IP configuration. If the network interface had multiple IP configurations, they would all appear in the list, and you'd select the IP configuration that you want to associate the public IP address to.

5. In the **Edit IP configuration** window, select **Associate public IP address**, then select **Public IP address** to choose an existing public IP address from the drop-down list. If no public IP addresses are listed, you need to create one. To learn how, see Create a public IP address.

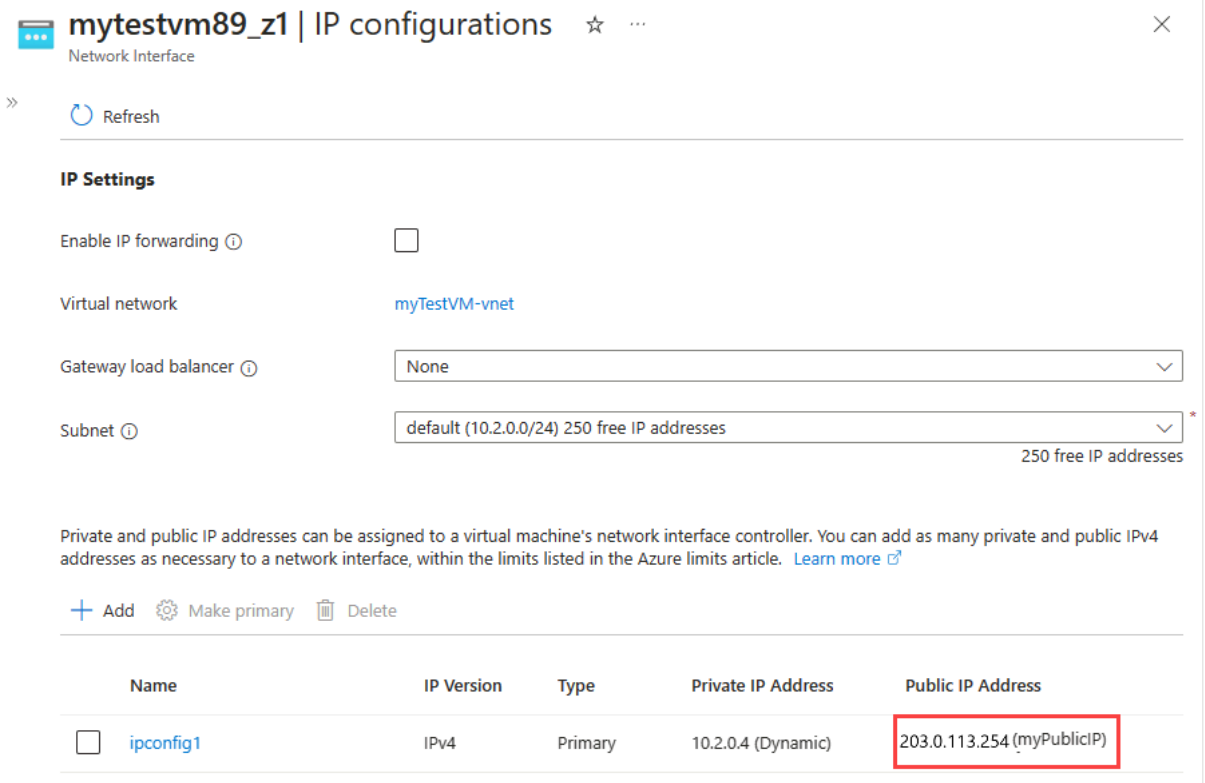
> **Note**
>
> The public IP addresses that appear in the drop-down list exist in the same region as the VM. If you have multiple public IP addresses created in the region, all appear here. Any address already associated to a different resource is grayed out.

6. Select **Save**.

7. In the **IP Configurations** window, view the public IP address assigned to the IP configuration. It might take a few seconds for a newly associated IP address to appear.



> **Note**
>
> An IP address is assigned from the pool of public IP addresses reserved for an Azure region. For a list of the address pools used in each region, see Azure IP ranges and service tags. If you need the address to be assigned from a specific prefix, use a Public IP address prefix.

8. Open the necessary ports in your security groups by adjusting the security rules in the network security groups. For information, see Allow network traffic to the VM.

> **Note**
>
> To share a VM with an external user, you must add a public IP address to the VM. Alternatively, external users can connect to VM's private IP address through Azure Bastion.

Allow network traffic to the VM

Before you can connect to a public IP address from the internet, you must open the necessary ports/protocols in your network security groups. These ports must be open in any network security group that you might have associated to the network interface, the subnet of the network interface, or both. Although network security groups filter traffic to the private IP address of the network interface, after inbound internet traffic arrives at the public IP address, Azure translates the public address to the private IP address. Therefore, if a network security group prevents the traffic flow, the communication with the public IP address fails.

You can view the effective security rules for a network interface and its subnet for the Azure portal, the Azure CLI, or Azure PowerShell.

Limits

- If a new public IP address is added to the VM and traffic needs to switch over to the new IP address, the VM needs to be restarted as this will reset all existing flows.

Next steps

In this article, you learned how to associate a public IP address to a VM using the Azure portal, Azure CLI, or Azure PowerShell.

- Use a network security group to allow inbound internet traffic to your VM.

Dissociate a public IP address from an Azure VM

Article • 11/25/2024

In this article, you learn how to dissociate a public IP address from an Azure virtual machine (VM). Removing the public IP address of your VM removes access to the Internet.

You can use the Azure portal, the Azure CLI, or Azure PowerShell to dissociate a public IP address from a VM.

Prerequisites

Azure portal

- An Azure account with an active subscription. Create an account for free.
- A virtual machine with a public IP address associated to it.

Dissociate a public IP address from a VM

In this step, you dissociate a public IP address from a virtual machine using the Azure portal, Azure CLI, or Azure PowerShell. The IP address is associated to an IP configuration of a network interface attached to the VM.

Azure portal

1. Sign in to the Azure portal.
2. Browse to, or search for the virtual machine that you want to disassociate the public IP address from and then select it.
3. In the VM page, select **Overview**, and then select the public IP address.
4. In the public IP address page, select **Overview**, and then select **Dissociate**.
5. In **Dissociate public IP address**, select **Yes**.

Next steps

In this article, you learned how to dissociate a public IP address from a virtual machine.

- Learn more about public IP addresses in Azure.
- Learn how to associate a public IP address to a VM.
- Learn how to configure IP addresses for an Azure network interface.

Create a virtual machine with a static private IP address

Summarize this article for me

When you create a virtual machine (VM), it's automatically assigned a private IP address from a range that you specify. This IP address is based on the subnet in which the VM is deployed, and the VM keeps this address until the VM is deleted. Azure dynamically assigns the next available private IP address from the subnet you create a VM in. If you want to assign a specific IP address in this subnet for your VM, use a static IP address.

Prerequisites

Azure portal

- An Azure account with an active subscription. You can create an account for free.

Create a resource group and a virtual machine

Azure portal

Create a resource group

1. Sign in to the Azure portal.
2. In the portal, search for and select **Resource groups**.
3. Select + **Create**.
4. On the **Basics** tab, enter or select the following values:

Expand table

Setting	Value
Subscription	Select your subscription
Resource group	Enter *myResourceGroup*

Setting	Value
Region	Select **(US) East US**

5. Select **Review + create**, and then select **Create**.

Create a virtual network

1. In the portal, search for and select **Virtual networks**.
2. Select **+ Create**.
3. On the **Basics** tab of **Create virtual network**, enter or select the following values:

Expand table

Setting	Value
Subscription	Select your subscription
Resource group	Select **myResourceGroup**
Virtual network name	Enter *myVNet*
Region	Select **(US) East US**

4. Select **Review + create**, and then select **Create**.

Create a virtual machine

1. In the portal, search for and select **Virtual machines**.
2. Select **Create** > **Azure virtual machine**.
3. On the **Basics** tab of the **Create a virtual machine** screen, enter or select the following values:

Expand table

Setting	Value
Subscription	Select your subscription
Resource group	Select **myResourceGroup**
Virtual machine name	Enter *myVM*

Setting	Value
Region	Select **(US) East US 2**
Availability options	Select **No infrastructure redundancy required**
Security type	Select **Standard**
Image	Select **Ubuntu Server 22.04 LTS - x64 Gen2**
Size	Accept the default, or drop down and select a size
Authentication type	Select **SSH public key**
Username	Enter *azureuser*
SSH public key source	Select **Generate new key pair**
Key pair name	Enter *mySSHKey*
Public inbound ports	Select **None**

4. Select the **Networking** tab at the top of the page.

5. On the **Networking** page, enter or select the following values:

    - **Virtual network**: Select **myVNet**.
    - **Subnet**: Select **default** if not already selected.
    - **Public IP**: Select **None**.

6. Select **Review + create**. Review the settings, and then select **Create**.

> ⓘ **Note**
>
> The virtual machine is created without a public IP address and with no public inbound ports. To connect to the virtual machine, use Azure Bastion. For more information, see Quickstart: Deploy Azure Bastion with default settings.

Change private IP address to static

Azure portal

In the following steps, you change the private IP address **static** for the VM created previously:

1. In the portal, search for and select **Virtual machines**.
2. In **Virtual machines**, select **myVM** from the list.
3. On the **myVM** page, select **Network settings** under **Networking**.
4. On the **Network settings** page, select the name of the network interface next to **Network interface**.
5. On the **Network interface** page, under **Settings**, select **IP configurations**.
6. In **IP configurations**, select **ipconfig1** in the list.
7. Under **Assignment**, select **Static**. Change the private **IP address** if you want a different one, and then select **Save**.

> ⚠ **Warning**
>
> If you change the private IP address, the VM associated with the network interface will be restarted to utilize the new IP address.
>
> From within the operating system of a VM, avoid associating a static *private* IP address on an Azure VM. Only assign a static private IP when it's necessary, such as when assigning many IP addresses to VMs.
>
> If you manually set the private IP address within the operating system, make sure it matches the private IP address assigned to the Azure network interface. Otherwise, you can lose connectivity to the VM. For more information, see private IP address settings.

Clean up resources

Azure portal

When all the resources are no longer need, delete the resource group and all of the resources it contains:

1. In the portal, search for and select **myResourceGroup**.
2. From the **myResourceGroup** screen, select **Delete resource group**.

3. Enter *myResourceGroup* for **Enter resource group name to confirm deletion**, and then select **Delete**.

Next steps

- Learn more about static public IP addresses in Azure.
- Learn more about public IP addresses in Azure.
- Learn more about Azure public IP address settings.
- Learn more about private IP addresses and assigning a static private IP address to an Azure VM.

Create a virtual machine with a static private IP address

Summarize this article for me

When you create a virtual machine (VM), it's automatically assigned a private IP address from a range that you specify. This IP address is based on the subnet in which the VM is deployed, and the VM keeps this address until the VM is deleted. Azure dynamically assigns the next available private IP address from the subnet you create a VM in. If you want to assign a specific IP address in this subnet for your VM, use a static IP address.

Prerequisites

Azure portal

- An Azure account with an active subscription. You can create an account for free.

Create a resource group and a virtual machine

Azure portal

Create a resource group

1. Sign in to the Azure portal.
2. In the portal, search for and select **Resource groups**.
3. Select + **Create**.
4. On the **Basics** tab, enter or select the following values:

Expand table

Setting	Value
Subscription	Select your subscription
Resource group	Enter *myResourceGroup*

Setting	Value
Region	Select **(US) East US**

5. Select **Review + create**, and then select **Create**.

Create a virtual network

1. In the portal, search for and select **Virtual networks**.
2. Select **+ Create**.
3. On the **Basics** tab of **Create virtual network**, enter or select the following values:

Expand table

Setting	Value
Subscription	Select your subscription
Resource group	Select **myResourceGroup**
Virtual network name	Enter *myVNet*
Region	Select **(US) East US**

4. Select **Review + create**, and then select **Create**.

Create a virtual machine

1. In the portal, search for and select **Virtual machines**.
2. Select **Create** > **Azure virtual machine**.
3. On the **Basics** tab of the **Create a virtual machine** screen, enter or select the following values:

Expand table

Setting	Value
Subscription	Select your subscription
Resource group	Select **myResourceGroup**
Virtual machine name	Enter *myVM*

Setting	Value
Region	Select **(US) East US 2**
Availability options	Select **No infrastructure redundancy required**
Security type	Select **Standard**
Image	Select **Ubuntu Server 22.04 LTS - x64 Gen2**
Size	Accept the default, or drop down and select a size
Authentication type	Select **SSH public key**
Username	Enter *azureuser*
SSH public key source	Select **Generate new key pair**
Key pair name	Enter *mySSHKey*
Public inbound ports	Select **None**

4. Select the **Networking** tab at the top of the page.

5. On the **Networking** page, enter or select the following values:

    - **Virtual network**: Select **myVNet**.
    - **Subnet**: Select **default** if not already selected.
    - **Public IP**: Select **None**.

6. Select **Review + create**. Review the settings, and then select **Create**.

> ⓘ **Note**
>
> The virtual machine is created without a public IP address and with no public inbound ports. To connect to the virtual machine, use Azure Bastion. For more information, see Quickstart: Deploy Azure Bastion with default settings.

Change private IP address to static

Azure portal

In the following steps, you change the private IP address **static** for the VM created previously:

1. In the portal, search for and select **Virtual machines**.
2. In **Virtual machines**, select **myVM** from the list.
3. On the **myVM** page, select **Network settings** under **Networking**.
4. On the **Network settings** page, select the name of the network interface next to **Network interface**.
5. On the **Network interface** page, under **Settings**, select **IP configurations**.
6. In **IP configurations**, select **ipconfig1** in the list.
7. Under **Assignment**, select **Static**. Change the private **IP address** if you want a different one, and then select **Save**.

> ⚠ **Warning**
>
> If you change the private IP address, the VM associated with the network interface will be restarted to utilize the new IP address.
>
> From within the operating system of a VM, avoid associating a static *private* IP address on an Azure VM. Only assign a static private IP when it's necessary, such as when assigning many IP addresses to VMs.
>
> If you manually set the private IP address within the operating system, make sure it matches the private IP address assigned to the Azure network interface. Otherwise, you can lose connectivity to the VM. For more information, see private IP address settings.

Clean up resources

Azure portal

When all the resources are no longer need, delete the resource group and all of the resources it contains:

1. In the portal, search for and select **myResourceGroup**.
2. From the **myResourceGroup** screen, select **Delete resource group**.

3. Enter *myResourceGroup* for **Enter resource group name to confirm deletion**, and then select **Delete**.

Next steps

- Learn more about static public IP addresses in Azure.
- Learn more about public IP addresses in Azure.
- Learn more about Azure public IP address settings.
- Learn more about private IP addresses and assigning a static private IP address to an Azure VM.

Assign multiple IP addresses to virtual machines using the Azure portal

Summarize this article for me

An Azure Virtual Machine (VM) has one or more network interfaces (NIC) attached to it. Any NIC can have one or more static or dynamic public and private IP addresses assigned to it.

Assigning multiple IP addresses to a VM enables the following capabilities:

- Hosting multiple websites or services with different IP addresses and TLS/SSL certificates on a single server.
- Serve as a network virtual appliance, such as a firewall or load balancer.
- The ability to add any (primary or secondary) private IP addresses of the NICs to an Azure Load Balancer backend pool. For more information about load balancing multiple IP configurations, see Load balancing multiple IP configurations and Outbound rules.

Every NIC attached to a VM has one or more IP configurations associated to it. Each configuration is assigned one static or dynamic private IP address. Each configuration may also have one public IP address resource associated to it. To learn more about IP addresses in Azure, see IP addresses in Azure.

> **Note**
>
> All IP configurations on a single NIC must be associated to the same subnet. If multiple IPs on different subnets are desired, multiple NICs on a VM can be used. To learn more about multiple NICs on a VM in Azure, see Create VM with Multiple NICs.

There's a limit to how many private IP addresses can be assigned to a NIC. There's also a limit to how many public IP addresses that can be used in an Azure subscription. See the Azure limits article for details.

This article explains how to add multiple IP addresses to a virtual machine using the Azure portal.

> **Note**
>
> If you want to create a virtual machine with multiple IP addresses, or a static private IP address, you must create it using PowerShell or the Azure CLI.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An existing Azure virtual machine with a Public IP. For more information about creating a virtual machine, see Create a Windows VM or Create a Linux VM.
  - The example used in this article is named **myVM**. Replace this value with your virtual machine name.
  - Windows Server virtual machines require port **3389** to be open for Remote Desktop Protocol (RDP) connections. Linux virtual machines require port **22** to be open for Secure Shell (SSH) connections.
- An Azure Bastion instance deployed for VM management in the same subnet as your virtual machine. For more information, see Deploy Azure Bastion automatically

> **Note**
>
> Though the steps in this article assign all IP configurations to a single NIC, you can also assign multiple IP configurations to any NIC in a multi-NIC VM. To learn how to create a VM with multiple NICs, see Create a VM with multiple NICs.

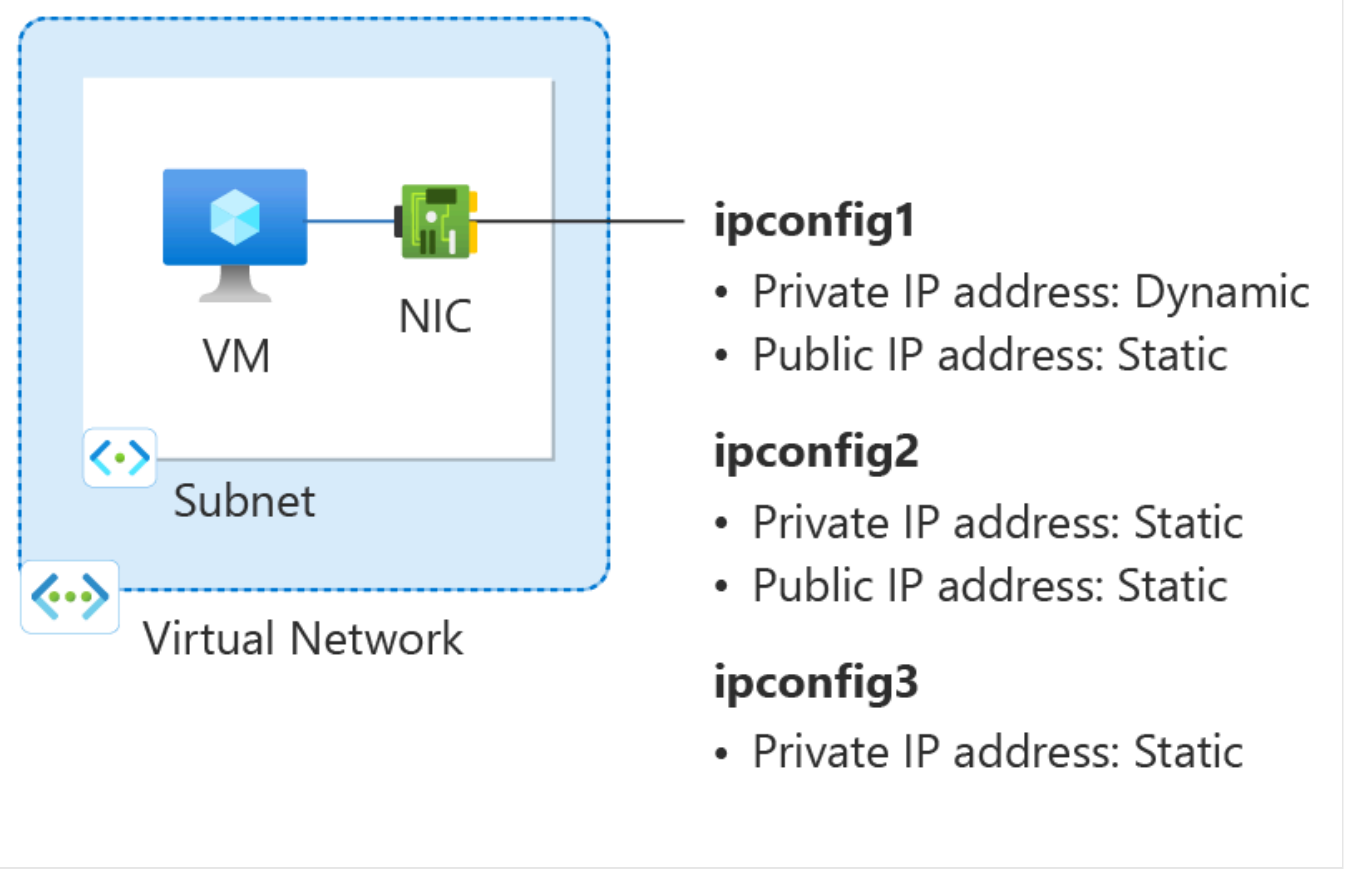

Figure: Diagram of network configuration resources created in this How-to article.

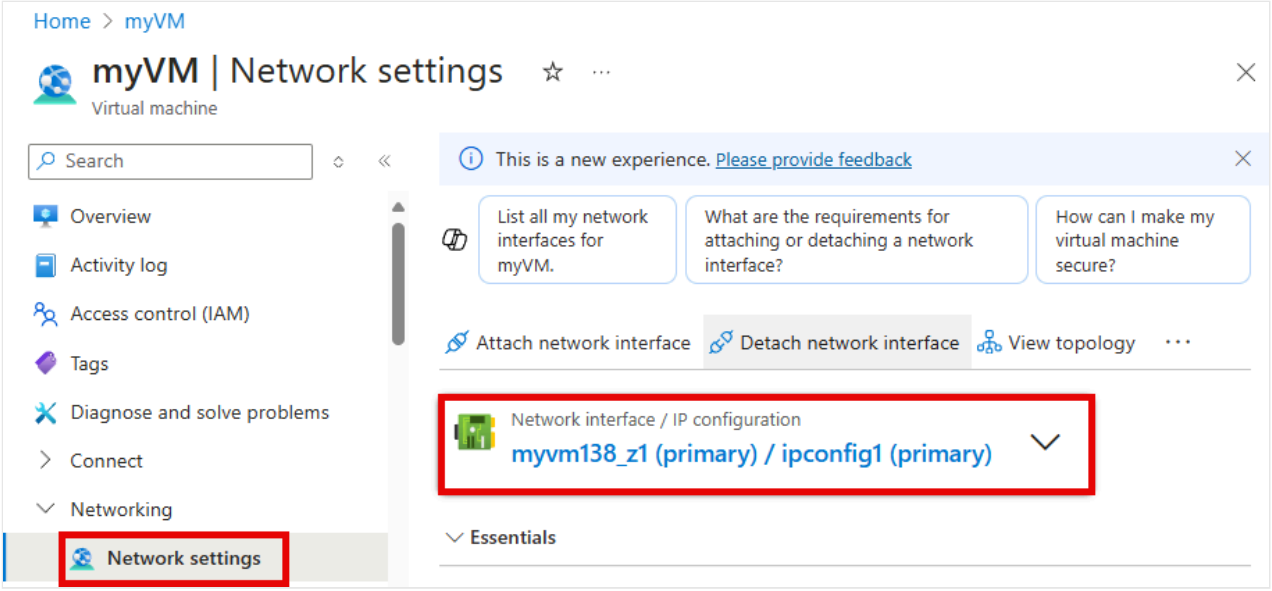
> **ⓘ Important**
>
> Avoid breaking connectivity when adding IP addresses
> When adding additional IP configurations to a VM, you **do not need to convert the existing (primary) private IP address from Dynamic to Static**.
>
> Changing the primary IP allocation type can disrupt RDP/SSH connectivity and may require recovery steps such as adding a temporary IP address. This is unnecessary when your goal is only to add secondary IP addresses.
>
> Recommended approach:
>
> - Leave the primary private IP configuration unchanged.
> - Add new **secondary IP configurations** (static or dynamic) directly to the NIC.
> - Only change the primary IP to Static if a fixed primary address is explicitly required and you understand the impact.

Add public and private IP address to a VM

You can add a private and public IP address to an Azure network interface by completing the following steps.

1. Sign in to the Azure portal.
2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
3. In **Virtual machines**, select **myVM** or the name of your virtual machine.
4. Select **Network settings** under **Networking**.
5. In **Network settings**, Select the name of the network interface and IP configuration of the virtual machine in the **Network interface / IP configuration** dropdown menu. The existing IP configuration is displayed. In this example, it's named **myvm138_z1 (primary) / ipconfig1 (primary)**.



6. In **IP configurations**, select **+ Add** to create a new secondary IP configuration.

7. In **Add IP configuration**, enter or select the following information.

Expand table

Setting	Value
Name	Enter **ipconfig2**.
Private IP address settings	
Allocation	Select **Static**.
Private IP address	Enter an unused address in the network for your virtual machine. For the 10.1.0.0/24 subnet in the example, an IP would be **10.1.0.5**.
Public IP address	Select **Associate public IP address**
Public IP address	Select **Create a public IP address**. Enter **public-ip-02** in **Name**. Select **Standard** in **SKU**. Select **OK**.

8. Select **OK**.

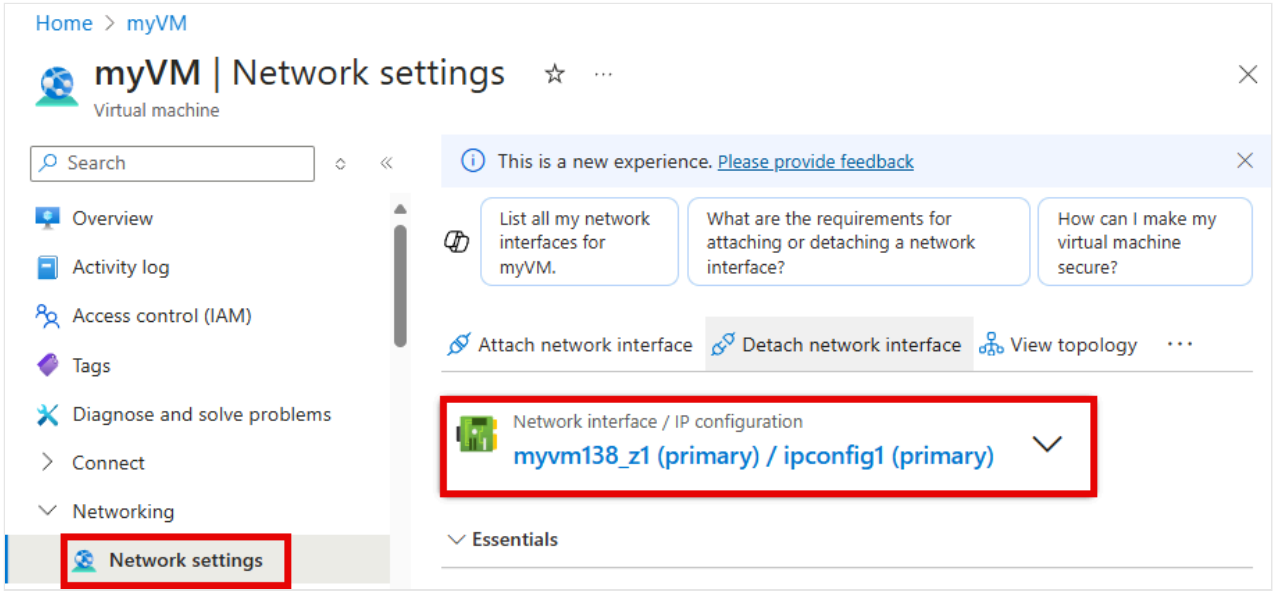
> **Note**
>
> When adding a static IP address, specify an unused and valid address in the subnet. This applies only to the **new secondary IP configuration**. The primary IP configuration does not need to be changed.

> **Important**
>
> Restarting the VM is required for the operating system to recognize newly added IP addresses.
> Adding secondary IP configurations does **not** require changing the primary IP allocation and does not inherently break existing connectivity.

Add private IP address to a VM

You can add a private IP address to a virtual machine by completing the following steps.

1. Sign in to the Azure portal.
2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
3. In **Virtual machines**, select **myVM** or the name of your virtual machine.
4. Select **Networking** in **Settings**.
5. Select the name of the network interface of the virtual machine. In this example, it's named **myvm889_z1**.



6. In the network interface, select **IP configurations** in **Settings**.
7. The existing IP configuration is displayed. This configuration is created when the virtual machine is created. To add a private and public IP address to the virtual machine, select **+ Add**.
8. In **Add IP configuration**, enter or select the following information.

Expand table

Setting	Value
Name	Enter **ipconfig3**.
Private IP address settings	
Allocation	Select **Static**.
IP address	Enter an unused address in the network for your virtual machine. For the 10.1.0.0/24 subnet in the example, an IP would be **10.1.0.6**.

9. Select **OK**.

> **Note**
>
> When adding a static IP address, specify an unused and valid address in the subnet. This applies only to the **new secondary IP configuration**. The primary IP configuration does not need to be changed.

> **Important**
>
> Restarting the VM is required for the operating system to recognize newly added IP addresses.
> Adding secondary IP configurations does **not** require changing the primary IP allocation and does not inherently break existing connectivity.

Add IP addresses to a VM operating system

Connect and sign in to a VM you created with multiple private IP addresses. You must manually add all the private IP addresses, including the primary, that you added to the VM. Complete the following steps for your VM operating system.

Windows Server

▼ Expand

1. Open a command prompt or PowerShell.
2. Enter `ipconfig /all` at the command line. You see the **Primary** private IP address that was assigned through DHCP.

3. Enter `ncpa.cpl` at the command line to open the **Network Connections** configuration.
4. Open the **Properties** for the network adapter assigned the new IP addresses.
5. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.
6. Select **Use the following IP address:**. Enter the following values.

Expand table

Setting	Value
IP address:	Enter the **Primary** private IP address.
Subnet mask:	Enter a subnet mask based on your IP address. For example, if the subnet is a **/24** subnet then the subnet mask is **255.255.255.0**.
Default gateway:	The first IP address in the subnet. If your subnet is **10.0.0.0/24**, then the gateway IP address is **10.0.0.1**.

7. Select **Use the following DNS server addresses:**. Enter the following values.

Expand table

Setting	Value
Preferred DNS server:	Enter your primary DNS server. Enter the IP address of **168.63.129.16** to use the default Azure provided DNS.

8. Select the **Advanced** button.
9. Select **Add**.
10. Enter the private **IP address** you added to the Azure network interface. Enter the corresponding **Subnet mask**. Select **Add**.
11. Repeat the previous steps to add any more private IP addresses that you added to the Azure network interface.

> **Important**
