Sender/Author	For email, the person who sent a message. For documents, the person cited in the author field from Office documents. You can type more than one name, separated by commas. Two or more values are logically connected by the **OR** operator. (See Recipient expansion.)
Size (in bytes)	For both email and documents, the size of the item (in bytes).
Subject/Title	For email, the text in the subject line of a message. For documents, the title of the document. The Title property is metadata specified in Microsoft Office documents. You can type the name of more than one subject/title values, separated by commas. Two or more values are logically connected by the **OR** operator. **Note**: Don't include double quotation marks to the values for this condition because quotation marks are automatically added when using this search condition. If you add quotation marks to the value, two pairs of double quotations are added to the condition value, and the search query returns an error.
Retention label	For both email and documents, retention labels applied to messages and documents. Retention labels can be used to declare records and help you manage the data lifecycle of content by enforcing retention and deletion rules specified by the label. **Note**: If using Retention Label names that include unsupported special characters, they will be ignored as a condition for the search. For more information about retention labels, see Retention policies and retention labels.

Conditions for mail properties

Create a condition using mail properties when searching mailboxes or public folders in Exchange Online. The following table lists the email properties that you can use for a condition. These properties are a subset of the email properties listed in Conditions for common properties. These descriptions are repeated for your convenience.

Expand table

Condition	Description
Message kind	The message type to search. This property is the same as the Kind email property. Possible values: • contacts • docs • email • externaldata

Condition	Description
	• fax • im • journals • meetings • microsoftteams • notes • posts • rssfeeds • tasks • voicemail
Participants	All the people fields in an email message. These fields are From, To, Cc, and Bcc. (See Recipient expansion.)
Received	The date that an email message was received by a recipient. This property is the same as the Received email property.
Recipients	All recipient fields in an email message. These fields are To, Cc, and Bcc. For more information, see Recipient expansion in mailbox searches.
Sender	The sender of an email message.
Sent	The date that an email message was sent by the sender. This property is the same as the Sent email property.
Subject	The text in the subject line of an email message. **Note**: Don't include double quotation marks to the values for this condition because quotation marks are automatically added when using this search condition. If you add quotation marks to the value, two pairs of double quotations are added to the condition value, and the search query returns an error.
To	The recipient of an email message in the To field.
Topic[1]	Summary of the main subject or theme discussed in an email thread or conversation.
Item class	The message class property for an email item. It's a multivalue condition. To select multiple message classes, hold the **CTRL** key and select two or more message classes in the drop-down list that you want to add to the condition. Each message class selected in the list are logically connected by the **OR** operator in the corresponding search query. For a list of the message classes (and their corresponding message class ID) used by Exchange and that you can select in the **Message class** list, see Item Types and Message Classes.

Conditions for document properties

Create a condition using document properties when searching for documents on SharePoint and OneDrive sites. The following table lists the document properties that you can use for a condition. These properties are a subset of the site properties listed in Conditions for common properties. These descriptions are repeated for your convenience.

Expand table

Condition	Description
Author	The author field from Office documents.
Created	The date that a document is created.
File type	The extension of a file; for example, docx, one, pptx, or xlsx. This is the same property as the FileExtension site property. **Note:** If you include a File type condition using the **Equals** or **Equals any of** operator in a search query, you can't use a prefix search (by including the wildcard character (*) at the end of the file type) to return all versions of a file type. If you do, the wildcard is ignored. For example if you include the condition `Equals any of doc*`, only files with an extension of `.doc` are returned. Files with an extension of `.docx` aren't returned. To return all versions of a file type, use the *property:value* pair in a keyword query; for example, `filetype:doc*`.
Last modified	The date that a document was last changed.
Path[1]	The URL or location of a file or folder within a SharePoint site.
Sensitive information type (SIT)[1]	Sensitive information types included in documents. SITs are pattern-based classifiers and they detect sensitive information like social security, credit card, or bank account numbers to identify sensitive items. For more information about SITs, see Sensitive information types.
Sensitivity label[1]	Sensitivity labels applied to documents. Sensitivity labels let you classify and protect your organization's data, while making sure that user productivity and their ability to collaborate isn't hindered. For more information about sensitivity labels, see Sensitivity labels.
Title	The title of the document. The Title property is metadata that's specified in Office documents. It's different from the file name of the document.

Operators used with conditions

When you add a condition, select an operator that matches the type of property for the condition. The following table describes the operators that work with conditions and lists the equivalent operator used in the search query.

Expand table

Operator	Query equivalent	Description
After	`property>date`	Use with date conditions. Returns items that were sent, received, or modified after the specified date.
Before	`property<date`	Use with date conditions. Returns items that were sent, received, or modified before the specified date.
Between	`date..date`	Use with date and size conditions. When used with a date condition, returns items that were sent, received, or modified within the specified date range. When used with a size condition, returns items whose size is within the specified range.
Contains any of	`(property:value) OR (property:value)`	Use with conditions for properties that specify a string value. Returns items that contain any part of one or more specified string values.
Doesn't contain any of	`-property:value` `NOT property:value`	Use with conditions for properties that specify a string value. Returns items that don't contain any part of the specified string value.
Doesn't equal any of	`-property=value` `NOT property=value`	Use with conditions for properties that specify a string value. Returns items that don't contain the specific string.
Equals[2]	`size=value`	Returns items that are equal to the specified size.
Equals any of	`(property=value) OR (property=value)`	Use with conditions for properties that specify a string value. Returns items that match one or more specified string values.
Greater[2]	`size>value`	Returns items where the specified property is greater than the specified value.
Greater or equal[2]	`size>=value`	Returns items where the specified property is greater than or equal to the specified value.
Less[2]	`size<value`	Returns items that are less than the specified value.
Less or equal[2]	`size<=value`	Returns items that are less than or equal to the specified value.
Not equal[2]	`size<>value`	Returns items that don't equal the specified size.

Note

[1] This operator is an eDiscovery premium feature condition.

[2] This operator is available only for conditions that use the *Size* property.

Use Keyword Query Language to create search queries in eDiscovery

09/04/2025

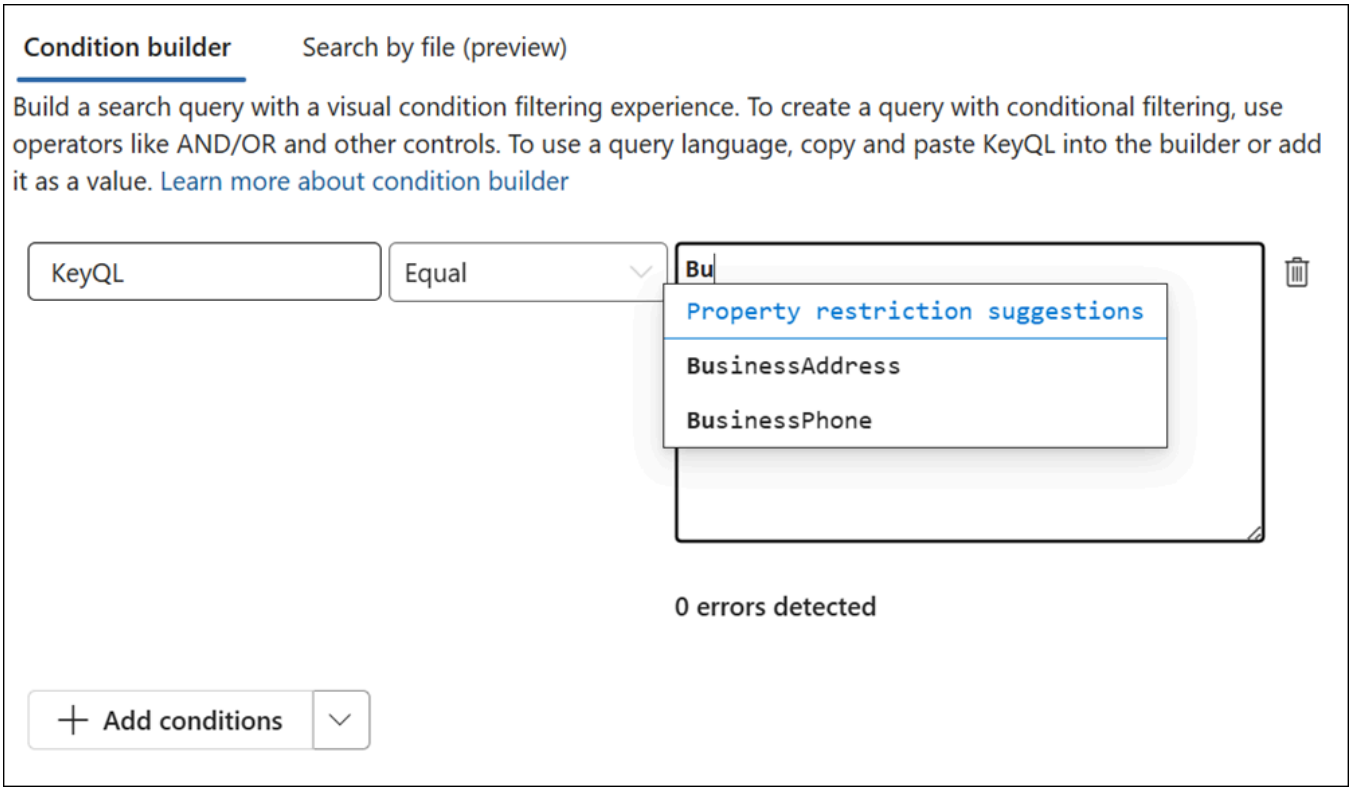
The Keyword Query Language (KeyQL) query condition option provides feedback and guidance when you build search and hold policy queries in eDiscovery. When you enter queries in the editor, it autocompletes supported searchable properties and conditions. It also provides lists of supported values for standard properties and conditions. For example, if you specify the `kind` email property in your query, the editor presents a list of supported values that you can select.

The KeyQL editor also displays potential query errors in real time that you can fix before you run the search. Paste complex queries directly into the editor without manually building queries using the conditions cards in the condition builder. The KeyQL editor is also available when you create query-based holds in eDiscovery.

Here are the key benefits to using the KeyQL editor:

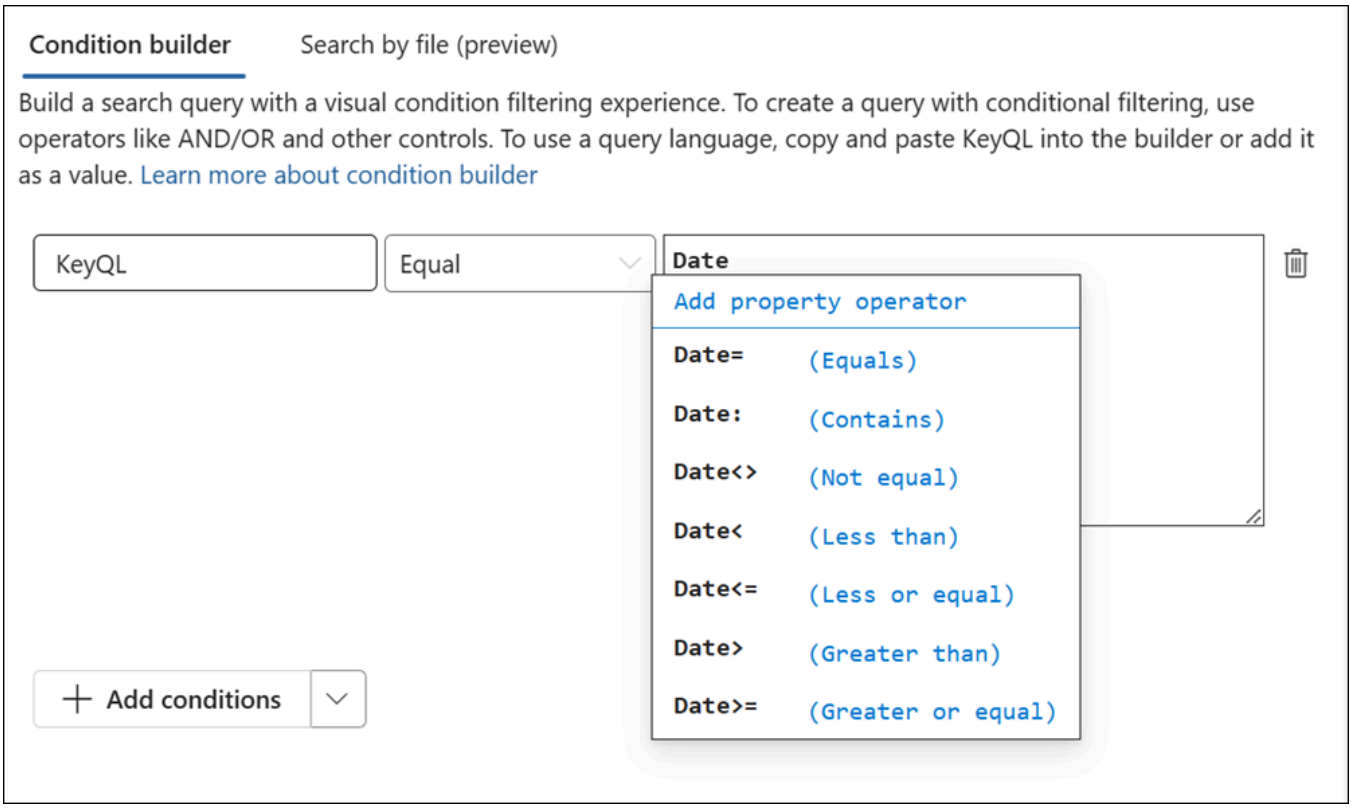
- Provides guidance and helps you build search queries from scratch.
- Lets you quickly paste long, complex queries directly into the editor. For example, if you receive a complex query from opposing counsel, you can paste that into the KeyQL editor instead of having to use the condition builder.
- Quickly identifies potential errors and displays hints about how to resolve issues.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.



Using the KeyQL editor

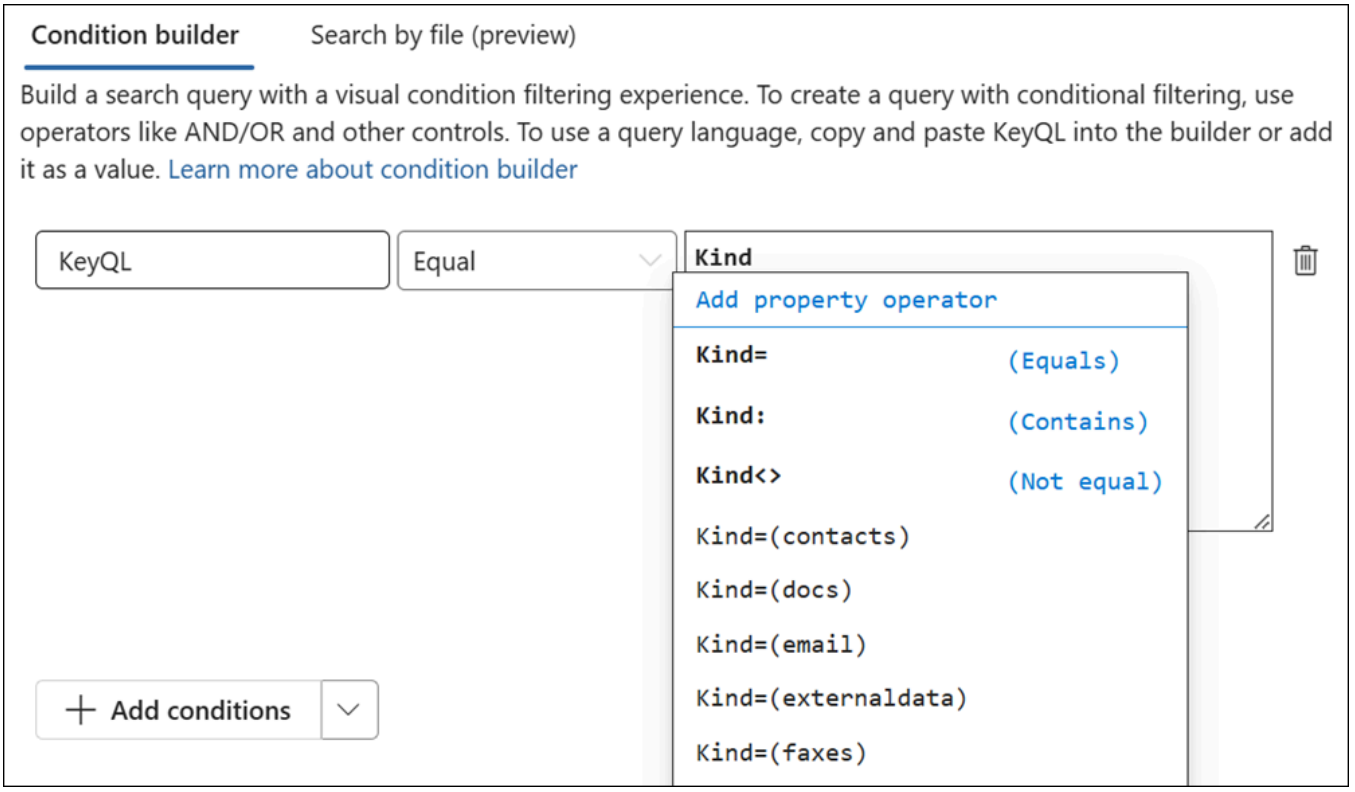
Use the KeyQL editor by selecting **Add conditions** and selecting *KeyQL*. For conditions and values already populated, these conditions and values are automatically converted into KeyQL. KeyQL query conditions can't be used with other conditions and need to be used as standalone conditions in your query.



The following sections show examples of how the KeyQL editor provides suggestions and detects potential errors.

Autocompletion of search properties and operators

When you start to enter a search query in the KeyQL editor, the editor displays suggested autocompletion of supported search properties (also called *property restrictions*) that you can select. You need to type at least two characters to display a list of supported properties that begin with those two characters. For example, the following screenshot shows the suggested search properties that begin with `Bu`.

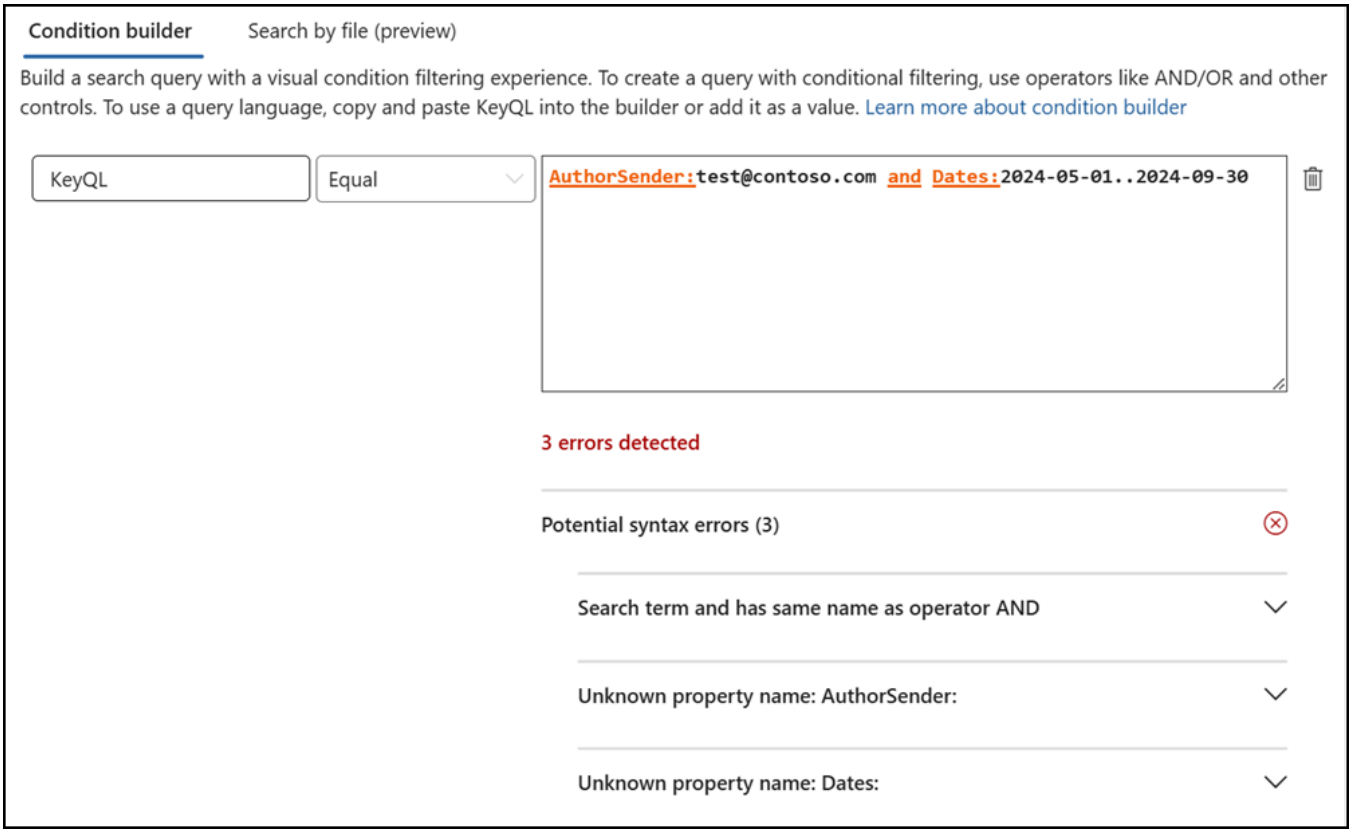


Additionally, the editor suggests a list of supported operators (such as `:`, `=`, and `<>`) when you type in a complete property name. For example, the following screenshot shows the suggested operators for the `Date` property.

For more information about the supported search conditions, see Use the condition builder to create search queries in eDiscovery.

Property value suggestions

The KeyQL editor provides suggestions for possible values of some properties. For example, the following screenshot shows the suggested values for the `Kind` property.



The editor also suggests a list of users (in User Principal Name (UPN) format) when you type email recipient properties, such as `From`, `To`, `Recipients`, and `Participants`.

Detection of potential errors

The KeyQL editor detects potential errors in search queries, and provides a hint of what is causing the error to help you resolve the error. The editor also indicates a potential error when a property doesn't have a corresponding operation or value. Potential errors in the query are highlighted in red text, and explanations and possible fixes for the error are displayed in the **Potential errors** drop-down section.

> **Important**
>
> Nested quotation marks aren't supported in the KeyQL editor.

For example, if you paste the following query into the KeyQL editor, the editor detects three potential errors. Use the potential error hints to help troubleshoot and fix the query.

Data sources in eDiscovery

In Microsoft 365, data is stored across three platforms: Exchange, Microsoft Teams, and SharePoint. These platforms organize and manage data within Microsoft 365 applications. Most Microsoft 365 apps store data in one or more of the following containers:

- **Users**: Data associated with individual users, such as their mail, 1:1 Teams messages, and OneDrive files.
- **Groups**: Data owned by the organization or a group of users within an organization. These groups are often referred to as Unified Groups or Teams.

In Microsoft Purview eDiscovery, the concept of *data source* streamlines the process of identifying and managing data across Microsoft 365 platforms. eDiscovery users select a user or group, which creates a data source. eDiscovery automatically identifies and organizes relevant data stored across platforms. The data source gathers locations related to the user or group (mailboxes, OneDrive sites, SharePoint sites) and adds the locations in the data source hierarchy. eDiscovery users refine the scope by selecting or excluding specific locations as needed.

A user data source typically includes:

- User mailbox
- OneDrive site

SharePoint Embedded application content

SharePoint Embedded container support in eDiscovery (preview) might change before general availability. Review the limitations in this section before using the feature in an investigation.

Some Microsoft 365 applications store content in SharePoint Embedded containers. Examples include Microsoft Loop, Microsoft Copilot Pages, Microsoft Copilot Notebooks, Microsoft Designer, and Outlook Newsletters. The applications represented in the Manage sources experience depend on the supported containers returned for the selected user.

When you add a user as an eDiscovery data source, eDiscovery identifies supported SharePoint Embedded containers relevant to that user and displays them with the user's other data locations. You can review and select the individual containers that are relevant to the investigation.

Add SharePoint Embedded containers as data sources

You can add supported SharePoint Embedded containers as data sources in the following ways:

- **Discover containers for a user:** Add a user as a data source to display supported user-owned and tenant-owned SharePoint Embedded containers relevant to that user. You can select or clear individual containers before saving the data source.
- **Filter containers by application:** When reviewing containers for a selected user, use **Filter by app** to narrow the displayed containers to a specific supported application. The available filters depend on the applications represented in the returned container list.
- **Add a container by URL:** If you know the SharePoint Embedded container URL, enter it when adding a site location. eDiscovery resolves the container URL so you can select the container as a data source.
- **Add container URLs in bulk:** Include supported SharePoint Embedded container URLs when you bulk import data sources. eDiscovery resolves the URLs as data-source locations.

For each supported SharePoint Embedded container, the **Manage sources** pane displays:

- The full container URL
- The container display name
- The associated application label
- The `ContainerTypeId`

Use these details to distinguish between containers and select the locations relevant to the investigation.

> ⓘ **Note**
>
> Microsoft Loop My workspace, Copilot Pages, and Copilot Notebooks use the same user-owned SharePoint Embedded container. In SharePoint Embedded administration and compliance experiences, this shared container is identified as **Loop**. As a result, Copilot Pages and Copilot Notebooks content can appear in a container labeled **Loop** and might not appear as separate application filters. For more information, see Overview of Copilot Pages and Copilot Notebooks storage.

> ⓘ **Important**
>
> **SharePoint Embedded limitations:**
>
> - **Container ownership:** Supported user-owned and tenant-owned SharePoint Embedded containers relevant to a selected user are surfaced in eDiscovery. Group-

owned and app-owned SharePoint Embedded containers aren't currently supported.
- **Compliance boundaries:** eDiscovery compliance boundary enforcement isn't currently supported for SharePoint Embedded containers.

Group and organization-wide data sources

Unified groups are classified into three types, each covering specific data locations:

- **Teams**: Includes Exchange mailbox storage for Teams chats and emails, as well as all associated SharePoint sites for channels and the team.
- **Viva Engage**: Includes Exchange mailbox storage for Viva Engage messages.
- **Classic**: Includes only SharePoint sites.

eDiscovery users can also use organization-wide sources to perform searches across your organization. Organization-wide sources include:

- **All people and groups**: Includes all users and all groups in your organization.
- **All public folders**: Includes all content in Exchange public folders mailboxes.

> **Note**
>
> Organization-wide searches include content from supported SharePoint Embedded containers. However, selecting an organization-wide source doesn't display a tenant-wide list of every SharePoint Embedded container. To review and select individual supported containers, use the user-based **Manage sources** experience.

> **Important**
>
> For large organizations, tenant-wide searches across all Exchange mailboxes and SharePoint sites are long-running processes. Service throttling can affect these searches because of the number of mailboxes and sites to search. Before running these tenant-wide searches, review scale limits and throughput guidance in Limits in eDiscovery. Plan to conduct searches in batches as applicable. To improve performance and operability, break the search into scoped runs by using compliance boundaries (for example, by region, business unit, or department) so each search targets a subset of mailboxes and sites.

It's common to search a set of user mailboxes when you manage the list as a distribution list. Adding distribution lists is supported, and the search includes only the Exchange mailboxes listed

in the group.

You can search for specific data sources or data locations by using user or group's names, mailbox Simple Mail Transfer Protocol (SMTP) addresses, and OneDrive or SharePoint site URLs. When you create a search by using specific data sources, you search only the locations specified in the data source.

If you use the organization-wide source **All people and groups**, the search covers all Exchange mailboxes, OneDrive, and SharePoint sites. To search all Exchange mailboxes only, select mailboxes under **All people and groups** and deselect the sites. To search all SharePoint and OneDrive sites only, select sites under **All people and groups** and deselect the mailboxes.

Real-time data source sync helps ensure that you're always informed about the latest changes in data locations associated with users and groups. You can query if any specific data sources are added to a search, if a hold includes newly provisioned data locations, or if data locations are removed.

For example, if you create a private channel for a Teams group, the sync feature on the data source panel alerts you of the new location. You can quickly and easily include it in searches or holds. This sync ensures that new data doesn't go unnoticed and is included in your investigations. This sync also helps prevent potential data loss from location changes.

For more information about using data sources effectively, check out the following video:

https://learn-video.azurefd.net/vod/player?id=c8081650-7272-4e22-8c7d-52c03ca69bcb&locale=en-us&embedUrl=%2Fpurview%2Fedisc-data-sources

Supported group types

The following table summarizes which group types can be added as data sources in eDiscovery, and how membership is handled for hold policies vs. searches.

Expand table

Group type	Supported as data source	Hold behavior	Search behavior
Distribution list (static)	Yes	Members snapshotted at hold creation. Re-add the group to reflect membership changes.	Members re-resolved each time the search runs.

Group type	Supported as data source	Hold behavior	Search behavior
Exchange Dynamic Distribution Group (DDG)	No	Not supported as a hold data source.	Not supported as a search data source.
Mail-enabled security group	Yes	Same as distribution list.	Same as distribution list.
Microsoft 365 group	Yes	Group mailbox and associated SharePoint site snapshotted at hold creation.	Group mailbox and site re-resolved each time the search runs.
Microsoft Entra ID dynamic Microsoft 365 group	No	Same limitation as Entra dynamic security groups.	Same limitation as Entra dynamic security groups.
Microsoft Entra ID dynamic security group	No	Entra dynamic security groups (groups with a `membershipRule`) aren't supported.	Entra dynamic security groups aren't supported.
Microsoft Teams group	Yes	Group mailbox plus the associated SharePoint site snapshotted at hold creation. Channel sites resolved at hold creation.	Group mailbox and site re-resolved each time the search runs.
Viva Engage group	Yes	Group mailbox snapshotted at hold creation.	Group mailbox re-resolved each time the search runs.

> **Note**
>
> If you need a scope that tracks dynamic membership criteria, create a static mail-enabled security group, synchronize its membership from the dynamic group on a schedule (for example, by using a scheduled Microsoft Graph and Exchange Online PowerShell job), and add the static shadow group as the data source. For holds, re-add the shadow group periodically to reflect updates. For searches, membership is re-resolved at each run.

Add data sources to cases

> **Important**
>
> Data sources in the legacy eDiscovery experience don't synchronize to the same case in the new eDiscovery experience. You must add the data sources in the case in the new eDiscovery

experience in the Microsoft Purview portal again.

After you enable premium eDiscovery features for a case, use the following options to add data sources to the case:

> **Tip**
>
> Want to try premium eDiscovery features? See the **subscription requirements** for Microsoft 365 Enterprise E5 licensing.

Bulk import data sources to a case

In an eDiscovery case, you can add multiple data sources by importing a list of SMTP addresses, SharePoint site URLs, or supported SharePoint Embedded container URLs. The import feature validates the entries before adding the sources, so you can correct any potential problems, such as typos. This streamlined process helps you save time and add many data sources to your cases more efficiently.

Before you import data sources, review the following considerations:

- You can import up to 500 data sources at a time. To minimize the processing time for searching and adding locations, split the import into multiple imports instead of importing the maximum number of data sources at one time.
- You must use the `;` delimiter in your list of SMTP addresses or URLs. Your list should follow the formatting of the following example:

  ```
  abh784@contoso.ms;https://contosodemos2.sharepoint.com/sites/Logistics;https://contosodemos2.sharepoint.com/sites/Mark8Project-UETConference;https://contosodemos2.sharepoint.com/sites/WG-ProjectObsidian;maib31@contoso.ms;rma230@contoso.ms;sva561@contoso.ms;mmz776@contoso.ms;LogisticsDSIGoldenSetDataToloka1@contoso.ms;jka132@contoso.ms;shafar929@contoso.ms;ika636@contoso.ms;brobet@contoso.ms;koka81@contoso.ms;rash95@contoso.ms;mvga66@contoso.ms;mra715@contoso.ms;abe543@contoso.ms;kto888@contoso.ms;moba80@contoso.ms;mian41@contoso.ms;inch48@contoso.ms;Mario.Smith_0803@contoso.ms;yape61@contoso.ms;mwo365@contoso.ms;fasi19@contoso.ms;HumanResourcesDugoPlannerTest@contoso.ms;kamo78@contoso.ms;bga844@contoso.ms;salesteam@contoso.ms;cko475@contoso.ms;ProjectZ@contoso.ms;TalentSourcingDanieltest5@contoso.ms;las450@contoso.ms;elfl69@contoso.ms;jch952@contoso.ms;asch81@contoso.ms;gmu955@contoso.ms;okbo68@contoso.ms
  ```

- Distribution groups aren't expanded to individual members during the import process.
- To import an inactive mailbox as a data source, add a `.` prefix to the email address of the inactive mailbox. For example, `.sarad@contoso.onmicrosoft.com`.
- Unverified SMTP addresses aren't added, but unverified URLs are supported. An unverified URL means the data source can't be verified against a valid SharePoint site that is in a locked state.

To bulk import data sources to a case, complete the following steps:

1. Go to the Microsoft Purview portal and sign in by using the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, and then select **Cases** in the left navigation.
3. Select a case, and then select the **Data sources** tab to add data sources to the case. When you add sources to this tab, you make these data sources available to choose from in all searches and holds in the case.
4. Select **Bulk import**.
5. On **Add data sources**, enter or copy a list of SMTP addresses or URLs separated by a semicolon.
6. Select **Next**.
7. On **Confirm data sources**, view the list of data sources and the verification status.
8. After verification of the data sources finishes, unverified sources are highlighted in red and marked as *Unverified* for you to review.
    - To update unverified sources, select the check box next to the data source and select **Edit** to update the data source information. You can correct any typo, path, or format errors. After editing the selected source, select **Save** and the updated data sources are automatically reverified.
    - To export the list of data sources, select **Export list**. This action creates a .csv file that contains user inputs, matched sources, and the status of the sources.
    - Any input with multiple matches is shown with *(Duplicate)* in front. You can include a subset of duplicated matched sources based on your needs.
    - To remove any data sources from the import, select the data source and select **Delete**.

9. When you're ready to add any of the listed data sources, select the check box for each item you want to add and then select **Add**.

> ⓘ **Note**
>
> Depending on the number of sources selected, it might take some time to process and add the data sources to the case.

Add one or more data sources to a case

1. Go to the Microsoft Purview portal and sign in by using the credentials for a user account assigned eDiscovery permissions.

2. Select the **eDiscovery** solution card, and then select **Cases** in the left navigation.

3. Select a case, and then select the **Data sources** tab to add data sources to the case. When you add sources to this tab, all searches and holds in the case can choose these data sources.

4. Select **Add** and pick choices from the following data source areas:

> ⓘ **Note**
>
> When searching for sources, some sources show up with a *?* in front of the source and labeled as *Unverified*. You can't verify these sources (sites or mailboxes) as valid sources when selected. These mailboxes or sites are external or the site is private or locked. You can add unverified sources to searches or holds and the system tries verification for these sources again when the search runs. Final search and hold results are included in the *location* .csv file in the process report.

   a. The left side of the pane displays the **Filter** options for sources.

   b. In the **Scope items by** section, only **All sources in the tenant (default)** is available. Select any data source available in your organization.

   c. Use one of the following options in the **Show for** filter to help scope your sources in the **Search** section:

      - *All people and groups (default)*
      - *People only*

- *Groups only*

d. If applicable, select **Exclude inactive users** to reduce the scope of sources to only currently active users in your organization.

e. After you filter data sources, use the search control and selectors in the **Search** section to add specific data sources, users, and groups to the search query. Enter the specific users, groups, or organization locations you want to add in the search field and select **Search**. You can use ";" as delimiter to trigger multiple searches at once. For example, input *john@contoso.com;david@contoso.com* allows you to search and find matches to both mailboxes at once. The `;` delimiter doesn't support site URLs.

   To add a supported SharePoint Embedded container directly, enter its full container URL as a site location.

   Search for people using the following values:

   - First and family name of the user display name (for example, John Smith)
   - First name only
   - User SMTP address
   - User alias
   - Exchange GUID
   - URL of the user's OneDrive site

   Search for groups using the following values:

   - Group mailbox SMTP address
   - URL of group site. The URL of a Teams channel site resolves the Teams group as a data source.

     If you add a distribution group, the list of group members isn't listed and the group is added to the search as a data source mailbox. When the search runs, the distribution group member mailboxes are expanded and fully searched.

     To confirm the mailboxes searched for the distribution group members, use the Locations_*the date/time of the report* information in the Process report after the search is completed. To confirm group membership before running the search, select the ellipse menu for the group and *Members*.

5. Select **Add** to add the data source to the selected case. This data source is now available when adding data sources for searches and holds in the case.

> **Important**
>
> You can manage individual data resources for a data source only when you add the case-level data source to an individual search and hold in the case. For example, to include or exclude mailboxes or sites in a search or hold for a data source configured at the case level, add the case-level data source to the search or hold, and then select **Manage**.

Add data sources to searches and holds

Add data sources to a specific search or hold by following these steps:

1. In a new search or hold, select **Add sources**. Or, select + and choose **Add data sources** from the dropdown. You can search for and select specific data sources to search or hold against.

   If you need to perform the search against organizational-wide mailboxes or sites, select **Add tenant-side sources in the empty search** or select the + button and choose an organizational-wide source from the dropdown.

   > **Note**
   >
   > Organizational-wide sources are only available in searches, not holds.

2. The left side of the pane displays the **Filter** options for sources. Use filters to scope the data sources by:

   - **All sources in the tenant (default):** Use this option to search from data sources available in your organization.
   - **All sources in this case**: Use this option to choose from data sources added at the case level. By using this option, you can quickly use data sources added to the case in a search or hold without having to search across your entire organization.
   - Use one of the following options in the **Show for** filter to help scope your sources in the **Search** section:
     - *All people and groups (default)*
     - *People only*
     - *Groups only*

- If applicable, select **Exclude inactive users** to reduce the scope of sources to only currently active users.

- Use **Locations to include control** to specify if the selected data sources added to the search or hold include:
  - *Mailboxes and sites (default)*: Selected people or group sources include the mailbox and site to the search or hold. This selection means selecting the user includes both the mailbox and OneDrive for the user. Selecting a Microsoft 365 group includes the group mailbox and all associated group sites.
  - *Mailboxes only*: Only mailbox associated with the select user or group is included. OneDrive and SharePoint sites aren't included.
  - *Sites only*: Only sites associated with the select user or group are included. Mailboxes aren't included.

3. After you filter the data sources, use the search control and selectors in the **Search** section to add specific data sources, users, and groups to the search query. Enter the specific users, groups, or organization locations you want to add in the search field and select **Search**. Use a semicolon as delimiter for multiple searches at once. For example, *john@contoso.com;david@contoso.com* searches and finds matches for both mailboxes at once. The semicolon delimiter doesn't support site URLs.

   To add a supported SharePoint Embedded container directly, enter its full container URL as a site location.

4. Select **Manage** to review the locations associated with the selected sources.

   If you added a user as a data source, use **Filter by app** as needed, and then select or clear the supported SharePoint Embedded containers relevant to the investigation.

5. Select **Save and close** to add the data source to the current search or hold.

Other considerations

- In the data source picker, you might not find some users or groups. In the **Manage** sources view, some selected sources might not display associated sites. This problem can happen for several reasons:
  - **OneDrive not provisioned, provisioning delay, or sync issues**: If a user doesn't have OneDrive provisioned, their source includes only a mailbox and not a OneDrive site. The OneDrive site exists, but it isn't synced in the compliance directory due to provisioning latency.

- **Deleted or departed user**: If you remove a user from the directory or soft-delete or deactivate their account, their OneDrive site might still exist but isn't linked to their user object. It doesn't appear under their source in the **Manage** view. For email content, consider using an inactive mailbox if the mailbox was placed on hold before deletion. For OneDrive content from a deleted user, add the OneDrive site URL directly as a SharePoint location in the search or hold.
- **Unlicensed user**: The user's Microsoft 365 license was removed, which breaks the link to their OneDrive site and can deactivate their mailbox. Reassign the required license and wait for the service to provision the data source before adding it again.
- **Mailbox converted**: The user's mailbox was converted to a shared mailbox or a mail user. This change might affect how the system associates OneDrive.
- **Multiple site collection admins**: If the OneDrive site has multiple admins and ownership is unclear, the system might not map it to the original user.
- **Retention or hold-only state**: The user has an inactive mailbox or hold-only state, and OneDrive might be cleaned up per retention policies.
- **Unverified source**: When searching for data sources, some mailboxes or sites might appear with a **?** icon and the label *Unverified*. This status means the system couldn't confirm the source as valid at selection time – often because the mailbox or site is external, private, or locked. You can still add unverified sources to searches or holds. Verification is attempted again when the search runs, and the final status is reflected in the **location.csv** file in the **process report**.
- **Ambiguous identity**: Duplicate entries exist in the directory, such as two users with similar names or an old account with the same alias. Work with your Microsoft Entra ID or Exchange admin to identify and remove duplicate objects so each email address corresponds to a single unique mailbox.
- **Unresolved recipient**: The user can't be found in the directory. For newly created accounts, allow up to 24 hours for directory synchronization to complete. Verify in the Exchange admin center that the mailbox exists and is active.

If a user shows *Not available* after adding, remove and re-add the user after the underlying account issue is resolved. You can verify data source availability by checking the Microsoft 365 admin center for the user's account status. To check for duplicate objects, run `Get-Recipient -Filter "EmailAddresses -eq 'user@domain.com'"` in Exchange Online PowerShell.

> **Note**

When sites show as **Not available**, manually add the URLs to the search or hold data sources.

- When you add a distribution group, the list of group members isn't displayed. The distribution group is added to the search as a data source mailbox. When you run the search, the system expands and fully searches the distribution group member mailboxes. To confirm the mailboxes searched for the distribution group members, use the `Locations_*the date/time of the report*` information in the **Process report** after the search completes. To confirm group membership before running the search, select the ellipsis menu for the group and members.

  If the membership of the distribution group changes after adding it as a data source in the search, run the search again to include items for the current members of the group. Each time you run the search, current members are included and former members are excluded.

Inactive mailboxes

You can search, review, and export inactive mailboxes stored in your organization in eDiscovery. To hold inactive mailbox content, first apply the hold policy to the active mailbox, verify success, and then change the mailbox to inactive.

When using inactive mailboxes in eDiscovery searches and holds, consider the following points:

- Search inactive mailboxes in an eDiscovery search. For a list of the inactive mailboxes in your organization, run `Get-Mailbox -InactiveMailboxOnly` in Exchange Online PowerShell. Alternatively, go to **Data lifecycle management** > **Microsoft 365** > **Retention** in the Microsoft Purview portal and select **More** (the navigation bar ellipses).

- If an existing search includes a user mailbox and you update that mailbox to inactive, the search continues to search the inactive mailbox when you rerun the search.

- Some users might have an active mailbox and an inactive mailbox that have different SMTP addresses. In this case, only the specific mailbox you select as a location for a search is searched. If you add a user's mailbox to a search, you can't assume that both active and inactive mailboxes are searched. Only the mailbox you explicitly add to the search is searched.

- Use Security & Compliance PowerShell to create a search for an inactive mailbox. You must append a period to the email address of the inactive mailbox. For example, the following

command creates a content search that searches an inactive mailbox with the email address pavelb@contoso.onmicrosoft.com:

```
New-ComplianceSearch -Name InactiveMailboxSearch -ExchangeLocation
.pavelb@contoso.onmicrosoft.com -AllowNotFoundExchangeLocationsEnabled $true
```

- Avoid having an active mailbox and inactive mailbox with the same SMTP address. If you need to reuse the SMTP address assigned to an inactive mailbox, recover the inactive mailbox or restore the contents of an inactive mailbox to an active mailbox (or the archive of an active mailbox), and then delete the inactive mailbox. For more information, see the following articles:
  - Recover an inactive mailbox in Office 365
  - Restore an inactive mailbox in Office 365
  - Delete an inactive mailbox in Office 365

- Hold policies aren't supported for inactive mailboxes. You must place holds on active mailboxes before the mailbox is deleted. For more information, see Create and manage inactive mailboxes.

Data source options

After you add sources to a search or hold, you can edit the sources or explore related sources as needed. Select the *ellipsis* next to the source you want to edit or remove.

The following options are available in **User or group options**:

- Manage data source
- Include or remove a mailbox
- Include or remove sites

Explore related sources

You can explore and add related sources from existing sources in a search or hold. These options give you the ability to investigate potentially relevant sources and bring in more sources to a specific search or hold.

For users you add in the **Data Sources** pane, you can explore the following connections:

- Manager
- Direct reports
- Frequent collaborators

- Groups the user owns
- Groups the user is a member of

By exploring these relationships, you can quickly identify and include relevant individuals and data sources in a search scope. Use *Manage* to fine-tune whether to include only mailboxes, only sites, or both related sources in a search or hold.

Manager

Use this option to explore upward in the reporting chain. When you select the user's manager, you include supervisory or decision-making context in your investigation.

Direct reports

Use this option to explore downward in the organization hierarchy for the user. This option is useful when the selected user is a manager or team lead, and you want to include their team members' communications or content.

Frequent collaborators

Use this option to find other users that frequently collaborate with the selected user. *Frequent collaborators* are the top 10 users who are most relevant to the selected user. You can select the mailboxes and sites for these users as data sources for searches.

Groups the user owns

This option shows groups that the selected user is listed as an owner. These groups might contain shared content or communications relevant to the investigation.

Groups the user is a member of

This option includes all groups the user is a member of, even if they're not the owner. These groups might provide additional context or shared data sources.

Group members

When you add a group in the **Data Sources** pane, you can explore and expand the group to view its members. By using this feature, you can:

- Identify individual users within the group that might hold relevant data.
- Select specific members as additional data sources for targeted searches.

This feature helps when investigating shared content or communications originating from collaborative groups such as Microsoft 365 Groups, Teams, or distribution lists.

> **Note**
>
> The list of group members and groups that a user is in (or owns) is capped at 100. If a user is included in more than 100 groups, owns more than 100 groups, or if a group has more than 100 members, the portal displays only the first 100 members.

Finding content in mailboxes in eDiscovery

Admins often need to find out who knew what and when. They need to respond to requests about ongoing or potential litigation, internal investigations, and other scenarios in the most efficient and effective way possible. These requests are often urgent, involve multiple stakeholder teams, and have significant impact if not completed in a timely manner. Knowing how to find the right information is critical for admins to complete searches successfully and help their organizations manage the risk and cost associated with eDiscovery requirements.

For more information about finding content in mailboxes in eDiscovery, watch the following video:

https://learn-video.azurefd.net/vod/player?id=6976ca23-3877-4cba-b052-d509d842f896&locale=en-us&embedUrl=%2Fpurview%2Fedisc-search-mailboxes

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

When an eDiscovery request is submitted, admins often receive only partial information to start collecting content that might be related to a particular investigation. The request might include user names, project titles, rough date ranges when the project was active, and not much more. From this information, admins need to create queries to find relevant content across Microsoft 365 services to determine the information needed for a particular project or subject. Understanding how information is stored and managed for these services helps admins more efficiently find what they need quickly and in an effective manner.

Exchange Online stores email, chat, meeting, and Microsoft 365 Copilot and Microsoft 365 Copilot Chat activity data (user prompts and Copilot responses). Many communication properties are available for searching items included in Exchange Online. Some properties such as *From*, *Sent*, *Subject*, and *To* are unique to certain items and aren't relevant when searching for files or documents in SharePoint and OneDrive. Including these types of properties when searching across workloads can sometimes lead to unexpected results.

For example, to find content related to specific users (*User 1* and *User 2*), associated with a project called *Tradewinds*, and during January 2020 through January 2022, you might use a query with the following properties:

- Add User 1 and User 2's Exchange Online locations as data sources to the case
- Select User 1 and User 2's Exchange Online locations as data source.
- For **Keyword**, use *Tradewinds*
- For **Date Range**, use the *January 1, 2020* to *January 31, 2022* range

When searching for emails or other mailbox content that might include cloud attachments, the cloud attachment link to a storage location in SharePoint or OneDrive should be considered as attachments of the message file rather than separate documents.

This behavior is similar to how a search returns emails with embedded local attachments, these attachments are retrieved as if they're part of the emails. Any compliance boundaries for SharePoint or OneDrive aren't reflected in the collection of cloud attachments included in responsive messages.

> ⓘ **Important**
>
> For emails, when you use a keyword, the search includes the subject, body, and many properties related to the participants. However, due to recipient expansion, search might not return expected results when using the alias or part of the alias. Therefore, use the full UPN.

Searchable email properties in KeyQL

> ⓘ **Important**
>
> While email messages might have other properties supported in other Microsoft 365 services, eDiscovery search tools support only the email properties listed in this table. You can't include other email message properties in searches.

The following table lists the email message properties supported in search using the eDiscovery KeyQL editor in the Microsoft Purview portal or by using the New-ComplianceSearch or Set-ComplianceSearch cmdlets. For a list of supported condition builder properties, see Use the condition builder to create search queries in eDiscovery.

The table includes an example of the *property:value* syntax for each property and a description of the search results returned by the examples. You can enter these `property:value` pairs in the keywords box for an eDiscovery search.

> ⓘ **Note**

When searching email properties, you can't search for message headers. Header information isn't indexed for searches. Additionally, you can't search for items in which the specified property is empty or blank. For example, using the *property:value* pair of **subject:""** to search for email messages with an empty subject line returns zero results. This limitation also applies when searching site and contact properties.

Expand table

Property	Property description	Examples	Search results returned by the examples
AttachmentNames	The names of files attached to an email message.	`attachmentnames:annualreport.ppt` `attachmentnames:annual*`	Messages that have an attached file named *annualreport.ppt*. In the second example, using the wildcard character (*) returns messages with the word *annual* in the file name of an attachment.[1]

Bcc	The Bcc field of an email message.[1]	`bcc:pilarp@contoso.com`
		`bcc:pilarp`
		`bcc:"Pilar Pinilla"`
			All examples return messages with *Pilar Pinilla* included in the Bcc field. (See Recipient Expansion)

Category	The categories to search. Users can define categories by using Outlook or Outlook on the web (formerly known as Outlook Web App). The possible values are: • blue • green • orange • purple • red • yellow	`category:"Red Category"`	Messages that are assigned the *red* category in the source mailboxes.
Cc	The Cc field of an email message.[1]	`cc:pilarp@contoso.com` `cc:"Pilar Pinilla"`	In both examples, messages with *Pilar Pinilla* specified in the Cc field.

Property	Property description	Examples	Search results returned by the examples
			(See Recipient Expansion)
From	The sender of an email message.[1]	`from:pilarp@contoso.com`	Messages sent by the specified user. (See Recipient Expansion)
HasAttachment	Indicates whether a message has an attachment. Use the values **true** or **false**.	`from:pilar@contoso.com AND hasattachment:true`	Messages sent by the specified user that have attachments.

Importance	The importance of an email message, which a sender can specify when sending a message. By default, messages are sent with normal importance, unless the sender sets the importance as **high** or **low**.	`importance:high`
		
		`importance:medium`
		
		`importance:low`
			Messages that are marked as high importance, medium importance, or low importance.

IsRead	Indicates whether messages are read. Use the values **true** or **false**.	`isread:true`
		
		`isread:false`
			The first example returns messages with the IsRead property set to **True**. The second example returns messages with the IsRead property set to **False**.

ItemClass	Use this property to search specific third-party data types that your organization imported to Microsoft 365. Use the following syntax for this property: `itemclass:ipm.externaldata.<third-party data type>*`	`itemclass:ipm.externaldata.Facebook* AND subject:contoso`
		
		`itemclass:ipm.externaldata.Twitter* AND from:"Ann Beebe" AND "Northwind Traders"`
			The first example returns Facebook items that contain the word "contoso" in the Subject property. The second example returns Twitter items that were posted by Ann Beebe and that contain the keyword phrase "Northwind Traders".

Kind	The type of email message to search for. Possible values:
	contacts
		`kind:email`
		
		`kind:email OR kind:im OR kind:voicemail`
			The first example returns email messages that meet the search criteria. The second example

Property	Property description	Examples	Search results returned by the examples
	docs email externaldata faxes im journals meetings microsoftteams (returns items from chats, meetings, and calls in Microsoft Teams) notes posts rssfeeds tasks voicemail	`kind:externaldata`	returns email messages, instant messaging conversations (including Skype for Business conversations and chats in Microsoft Teams), and voice messages that meet the search criteria. The third example returns items that were imported to mailboxes in Microsoft 365 from third-party data sources, such as Twitter, Facebook, and Cisco Jabber tha meet the search criteria. For more information, see Archiving third-party data.
Participants	All the people fields in an email message. These fields are From, To, Cc, and Bcc.[1]	`participants:garthf@contoso.com` `participants:contoso.com`	Messages sent by or sent to garthf@contoso.com The second example returns all messages sent by or sent to a user in the contoso.com domain. (See Recipient Expansion)
Received	The date that an email message is received by a recipient.	`received:2021-04-15` `received>=2021-01-01 AND received<=2021-03-31`	Messages that are received on April 15, 2021. The second example returns all messages received between January 1, 2021 and March 31, 2021.

Property	Property description	Examples	Search results returned by the examples

Recipients	All recipient fields in an email message. These fields are To, Cc, and Bcc.[1]	`recipients:garthf@contoso.com`
		
		`recipients:contoso.com`
			Messages sent to garthf@contoso.com The second example returns messages sent to any recipient in the contoso.com domain. (See Recipient Expansion)

Sent	The date that an email message is sent by the sender.	`sent:2021-07-01`
		
		`sent>=2021-06-01 AND sent<=2021-07-01`
			Messages that are sent on the specified date or sent within the specified date range.

Size	The size of an item, in bytes.	`size>26214400`
		
		`size:1..1048567`
			Messages larger than 25 MB. The second example returns messages from 1 through 1,048,567 bytes (1 MB) in size.

Subject	The text in the subject line of an email message. **Note:** When you use the Subject property in a query, the search returns all messages in which the subject line contains the text you're searching for. In other words, the query doesn't return only those messages that have an exact match. For example, if you search for `subject:"Quarterly Financials"`, your results include messages with the subject "Quarterly Financials 2018".	`subject:"Quarterly Financials"`
		
		`subject:northwind`
			Messages that contain the phrase "Quarterly Financials" anywhere in the text of the subject line. The second example returns all messages that contain the word northwind in the subject line.

To	The To field of an email message.[1]	`to:annb@contoso.com`
		
		`to:annb`
		`to:"Ann Beebe"`
			All examples return messages where Ann Beebe is specified in the To: line.

> **Note**
>
> [1] For the value of a recipient property, you can use email address (also called user principal name (UPN)), display name, or alias to specify a user. For example, you can use annb@contoso.com, annb, or "Ann Beebe" to specify the user Ann Beebe.

Searchable sensitive data types

You can use eDiscovery search tools in the Microsoft Purview portal to search for sensitive data, such as credit card numbers or social security numbers, stored in documents in mailboxes. To search for this data, use the `SensitiveType` property and the name or ID of a sensitive information type in a keyword query. For example, the query `SensitiveType:"Credit Card Number"` returns documents that contain a credit card number. The query `SensitiveType:"U.S. Social Security Number (SSN)"` returns documents that contain a U.S. social security number.

To see a list of sensitive information types that you can search for, go to **Data classifications** > **Sensitive info types** in the Microsoft Purview portal. Or, use the **Get-DlpSensitiveInformationType** cmdlet in Security & Compliance PowerShell to display a list of sensitive information types.

`SensitiveType` behavior depends on the workload and how the content is indexed. Use the following matrix to set expectations before running a query:

Expand table

Workload	`SensitiveType` supported?	When the match is evaluated	Common caveats
Exchange Online (mail, calendar, contacts)	Yes	At indexing time, against the message body and indexed attachments	Sensitive types added or modified *after* an item was indexed don't match that item until it's reindexed. Inline images, scanned PDFs, and other non-text content aren't evaluated.
Items that are partially indexed	Not evaluated	N/A	`SensitiveType` queries don't return partially indexed items. To include them, also export partially indexed items separately.
Microsoft Teams (chat and channel messages)	Limited	At indexing time, against message text only	Match accuracy is lower for short messages because most sensitive info types require corroborating context. Attachments in Teams messages follow the SharePoint/OneDrive rules.

Workload	`SensitiveType` supported?	When the match is evaluated	Common caveats
SharePoint Online / OneDrive for Business (documents)	Yes	At indexing time, against the document content	Same reindexing caveat as Exchange. Files larger than the indexing size limit are partially indexed and might not match.

If you expect a hit but don't get one, confirm that (1) the workload is in the supported column, (2) the item was indexed *after* the sensitive type was last published, and (3) the item isn't in the partially indexed set.

Recipient expansion

Mailboxes are flexible storage, and clients connecting to a mailbox control some aspects of recipient information, especially for the sender. Clients can choose the *SMTP*, *Name*, or *LegacyDN* properties as the sender address. To compensate for variations in client behavior and how data is stored, eDiscovery search's recipient expansion is a useful feature.

Often, sender information created by some clients only stores the name of the sender, such as *John Doe*, without including the SMTP address like *johndoe@contoso.com*. Additionally, federated items with legacy systems might only store the LegacyExchangeDN, which is a unique identifier used in older versions of Exchange to represent a mailbox or a distribution list. Federated systems refer to messages or data that are integrated from different systems or organizations, often involving legacy systems that use older formats or identifiers.

The recipient expansion function solves the issue of not searching broadly enough by expanding the search to capture content stored with these variations. Querying Microsoft Entra ID expands any values specified in the participant filter. This expansion includes the user's email address, UPN, alias, display name, and LegacyExchangeDN. This expansion ensures that searches cast a wider net, capturing all relevant content regardless of how participant information is stored and improves the accuracy and comprehensiveness of eDiscovery searches.

> **Note**
>
> Recipient expansion doesn't resolve cases where the user's Microsoft Entra ID object is deleted - typically a departed user whose mailbox was deleted without first being placed on hold. Departed users whose mailboxes are placed on hold remain in Microsoft Entra ID as inactive mailboxes, and recipient expansion still works for them (subject to the SMTP and display name conditions described later in this section). When the Microsoft Entra ID object is gone, you must manually include all known identifiers (for example, previous SMTP

addresses, aliases, or display names) in your query. To preserve recipient expansion for departing employees, place the mailbox on hold before deleting the account.

When you search any of the recipient properties (From, To, Cc, Bcc, Participants, and Recipients), Microsoft 365 attempts to expand the identity of each user by looking them up in Microsoft Entra ID. If the user is found in Microsoft Entra ID, the query is expanded to include the user's email address (or UPN), alias, display name, and LegacyExchangeDN. For example, a query such as `participants:ronnie@contoso.com` expands to `participants:ronnie@contoso.com OR participants:ronnie OR participants:"Ronald Nelson" OR participants:"<LegacyExchangeDN>"`.

To prevent recipient expansion, add a wildcard character (asterisk) to the end of the email address and use a reduced domain name; for example, `participants:"ronnie@contoco*"` Be sure to surround the email address with double quotation marks.

Preventing recipient expansion in the search query might result in relevant items not being returned in the search results. Email messages in Exchange can be saved with different text formats in the recipient fields. Recipient expansion is intended to help mitigate this fact by returning messages that might contain different text formats. So preventing recipient expansion might result in the search query not returning all items that might be relevant to your investigation.

Recipient expansion isn't designed to support scenarios involving user name and alias changes. If the SMTP/UPN for a user changes, Microsoft Entra ID might not find the user, leading to incomplete search results. Also, LegacyExchangeDN, which rarely changes, might not be present in the substrate for all email items. Recipient expansion only handles cases where the client uses LegacyExchangeDN instead of SMTP. If the SMTP address changes but the LegacyExchangeDN doesn't, then recipient expansion doesn't help and you need to manually find and use all variations of these addresses. This limitation can lead to users mistakenly believing that recipient expansion catches all variations, including name and SMTP changes.

When you use the *From* condition with the *equal* condition (=), only the display name is queryable in the index. This means that if you use an SMTP address in the *From* or *Sender* conditions, search returns a result if both of the following conditions are met:

- The SMTP address used in the condition matches an active or inactive user in Microsoft Entra.
- The display name of the active or inactive user hasn't changed since the targeted item was sent or received.

When you use the *Sender* or *From* conditions in an eDiscovery search, the system attempts recipient expansion and expands the query to include *Display Name*. If successful, the query

includes all email addresses assigned to the user's SMTP address and legacy Exchange display name. If recipient expansion isn't successful, the search uses only the value supplied in the *From* and *Sender* conditions to search the index. Conditions that might result in recipient expansion failing are:

- Departed users without a retained inactive mailbox.
- Active or inactive users where the SMTP address is no longer present on an object.
- Active or inactive users where the display name has been changed (when display name is used with the *Sender* or *From* conditions).

In some scenarios, recipient expansion might also cause hits on additional items when organization searches are used. For example, one user's display name might form a part of another user's display name. For example, a user might have a display name of *John Doe* and another user might have a display name of *John Doe Jr*. An organization-wide search might return result hits from both mailboxes. Consider suppressing recipient expansion in this scenario by adding a period at the end of the SMTP address.

Additional considerations include, the recipient expansion only supports sending from your own mailbox and no delegated or send-as activity. Make sure you review relevant limits, including the accuracy of the maximum number of distribution group members and the maximum level of nesting for distribution groups. Security groups are supported, and only distribution groups and the distribution group should be valid when the email is sent.

> ⓘ **Note**
>
> If you need to review or reduce the items returned by a search query due to recipient expansion, consider using premium eDiscovery features. You can search for messages (taking advantage of recipient expansion), add them to a review set, and then use review set queries or filters to review or narrow the results.

Content stored in Exchange Online mailboxes for eDiscovery

You primarily use a mailbox in Exchange Online to store email-related items such as messages, calendar items, tasks, and notes. But that's changing as more cloud-based apps also store their data in a user's mailbox. One advantage of storing data in a mailbox is that you can use the search tools in eDiscovery to find, view, and export the data from these cloud-based apps.

The data from some of these apps is stored in hidden folders located in a non-interpersonal message (non-IPM) subtree in the mailbox. Data from other cloud-based apps might not be

stored *in* the mailbox, but it's *associated with* the mailbox, and is returned in searches if that data matches the search query. Regardless of whether cloud-based data is stored in or associated with a user mailbox, the data is typically not visible in an email client when a user opens their mailbox.

The following table lists the apps that either store or associate data with a cloud-based mailbox. The table also describes the type of content that each app produces.

Expand table

Microsoft 365 app	Description
Class Schedule	Plans you create in Class Schedule are stored in the mailbox of the corresponding Microsoft 365 Group that's provisioned when you create a new plan. The alias for the group mailbox is the name of the plan.
Forms*	Forms and responses to a form are stored in files that are attached to email messages and stored in a hidden folder in the mailbox of the user who created the form. Forms created before April 2020 are stored as a PDF file. Forms created after 2020 are stored as a JSON file. Responses to a form are stored in a CSV file. When you export content from Forms in a PST file, this data is located in the **ApplicationDataRoot** folder in a subfolder named with the following globally unique identified (GUID): **c9a559d2-7aab-4f13-a6ed-e7e9c52aec87**.
Microsoft 365 Copilot and Microsoft 365 Copilot Chat	All Copilot activity data (user prompts and Copilot responses) generated in supported Microsoft 365 apps and services is stored in custodian mailboxes.
Microsoft 365 Groups	Email messages, calendar items, contacts (People), notes, and tasks are stored in the mailbox that's associated with a Microsoft 365 group.
Outlook/Exchange Online	Email messages, calendar items, contacts (People), notes, and tasks are stored in a user's mailbox.
People	Contacts in the People app (which are the same contacts as the ones accessible in Outlook) are stored in a user's mailbox.
Skype for Business	Conversations in Skype for Business are stored in the Conversation History folder in a user's mailbox. If the mailbox of a participant of a Skype meeting is placed on Litigation Hold or assigned to a retention policy, files attached to a meeting are retained in the participants mailbox.
Sway*	Sways are stored as an HTML file that is attached to an email message and stored in a hidden folder in the mailbox of the user who created the sway. When you export content from Sway in a PST file, this data is located in the **ApplicationDataRoot** folder in a subfolder named with the following GUID: **905fcf26-4eb7-48a0-9ff0-8dcc7194b5ba**.
Tasks	Tasks in the Tasks app (which are the same tasks as the ones accessible in Outlook) are stored in a user's mailbox.

Microsoft 365 app	Description
Teams	Conversations that are part of a Teams channel are associated with the Teams mailbox. Conversations that are part of the Chat list in Teams (also called *1 x N chats*) are associated with the mailbox of the users who participate in the chat. Also, summary information for meetings and calls in a Teams channel are associated with mailboxes of users who dialed into the meeting or call. So when searching for Teams content, you search the Teams mailbox for content in channel conversations and search user mailboxes for content in 1 x N chats.
To-Do	Tasks (called *to-dos*, which are saved in to-do lists) in the To-Do app are stored in a user's mailbox.
Viva Engage	Conversations and comments within a Viva Engage community are associated with the Microsoft 365 group mailbox, as well as the user mailbox of the author and any named recipients (@ mentioned or Cc'ed users). Private messages sent outside of a Viva Engage community are stored in the mailbox of the users who participate in the private message.

> **Note**
>
> * At this time, if you place a hold on a mailbox using holds in eDiscovery cases, the hold doesn't preserve content from this app.

Find and delete email messages in eDiscovery

> **Tip**
>
> You can also use the purge feature in Data Security Investigations to search for and permanently delete Exchange mailbox and Microsoft Teams items in your organization. Data Security Investigations provides a built-in search and purge workflow with a purge queue dashboard to help you manage and track purge queries. For more information, see **Purge in Data Security Investigations**.

You can use the search feature to search for and delete email messages from all mailboxes in your organization. This process can help you find and remove potentially harmful or high-risk email, such as:

- Messages that contain dangerous attachments or viruses
- Phishing messages
- Messages that contain sensitive data

However, the eDiscovery purge process isn't intended for general mailbox management tasks such as:

- Reducing mailbox quota
- Clearing out mailboxes
- Enforcing data retention policies

The purge process described in this article is specifically designed to address **data spillage incidents**, such as when a small message is accidentally shared with a large group of users. For routine mailbox management and compliance, use the following tools instead:

- **Retention Policies**: To manage the lifecycle of data and ensure compliance with organizational standards.
- **Archive Policies**: To offload older content and manage mailbox storage effectively.
- **Mailbox Ownership and Manual Deletion**: For precise control over specific mailboxes, especially when content needs to be reviewed or removed by the mailbox owner.

> **Tip**
>
> If your organization has a Defender for Office 365 Plan 2 subscription, use the procedure detailed in Remediate malicious email delivered in Office 365, rather than following the procedure described in this article.

Before you begin

> **Important**
>
> Carefully review the following guidance before starting the search and purge steps for email messages.

- Depending on the eDiscovery subscription for your organization, cases can either be enabled for eDiscovery premium features, if the organization has E5 licenses, or not. Verify the level of feature support for the case to determine if you should use PowerShell or Microsoft Graph to search and purge.
- For cases not configured for eDiscovery premium features, you can only use PowerShell to search and delete email messages. For E3 customers, cases created by cmdlets or the Microsoft Purview portal can only purge email by using PowerShell. You can purge up to 10 items per location.
- For cases configured for eDiscovery premium features, you can use PowerShell or Microsoft Graph to search and delete email messages. Cases configured by using Graph or the Microsoft Purview portal with premium features can only purge email and Teams messages by using Graph. You can purge up to 100 items per location.

  > **Important**
  >
  > Don't use a combination of PowerShell and Microsoft Graph to purge email messages.

- After data is permanently deleted, it can't be recovered. Follow the guidance in this article carefully and validate the scope of the search before issuing the purge command. After you run the purge command, it can't be undone and email messages can't be restored.
- Search conditions such as identifier (including message ID), sensitivity label, and sensitive information type aren't supported for search and delete for non-premium enabled cases in

eDiscovery. Using these conditions results in unexpected data loss.

- Run an export report to review all items that match your search criteria prior to the purge. By using the search and export experience in the Microsoft Purview portal and exporting the results in report-only format, you can examine detailed metadata before deletion. This approach helps refine your search scope and ensures a more targeted and accurate purge.

- Don't use the search and purge workflow described in this article to delete chat messages or other content from Microsoft Teams. If the search that you create in Step 2 returns items from Microsoft Teams, follow the steps outlined in Find and delete Microsoft Teams chat messages in eDiscovery to delete them.

- To create and run a search, you must be a member of the *eDiscovery Manager* role group or be assigned the *Compliance Search* role in the Microsoft Purview portal. To delete messages, you must be a member of the *Organization Management* role group or be assigned the *Search And Purge* role in the Microsoft Purview portal. For information about adding users to a role group, see Assign eDiscovery permissions.

  > **Note**
  >
  > The *Organization Management* role group exists in both Exchange Online and in the Microsoft Purview portal. These are separate role groups that give different permissions. Being a member of *Organization Management* in Exchange Online doesn't grant the required permissions to delete email messages. If you aren't assigned the *Search And Purge* role in the Microsoft Purview portal (either directly or through a role group such as *Organization Management*), you receive an error in Step 3 when you run the *New-ComplianceSearchAction* cmdlet with the message "A parameter can't be found that matches parameter name 'Purge'".

- You must use Security & Compliance PowerShell to delete messages. See Step 1: Connect to Security & Compliance PowerShell for instructions about how to connect.

- You can remove a maximum of 10 items per mailbox at one time. Because the capability to search for and remove messages is intended to be an event-response tool, this limit helps ensure that messages are quickly removed from mailboxes. This feature isn't intended to clean up user mailboxes.

> **Note**

Search and purge isn't supported if a mailbox has a litigation hold. Only 10 items are removed from view of the user. These 10 items aren't permanently deleted, so these 10 items are the only ones processed.

- The maximum number of mailboxes in a content search that you can use to delete items by doing a search and purge action is 50,000. If the search (that you create in Create a search query to find the message to delete) searches more than 50,000 mailboxes, the purge action (that you create in Step 3) fails. Searching more than 50,000 mailboxes in a single search might typically happen when you configure the search to include all mailboxes in your organization. This restriction still applies even when fewer than 50,000 mailboxes contain items that match the search query. See the Frequently asked questions section for guidance about using search permissions filters to search for and purge items from more than 50,000 mailboxes.
- You can only use the procedure in this article to delete items in Exchange Online mailboxes and public folders. You can't use it to delete content from SharePoint or OneDrive sites.
- You can't delete email items in a review set in an eDiscovery case by using the procedures in this article. That's because items in a review set are stored in an Azure Storage location, and not in the live service. This means they're not returned by the content search that you create in Step 1. To delete items in a review set, you have to delete the eDiscovery case that contains the review set.

Step 1: Connect to Security & Compliance PowerShell

First, connect to Security & Compliance PowerShell for your organization. For step-by-step instructions, see Connect to Security & Compliance PowerShell.

ⓘ Important

To use this cmdlet for purge actions in Security & Compliance PowerShell, you need to meet the following requirements:

- Use the Exchange Online PowerShell version 3.9.0 or later (August 2025). For more information, see What's new in the Exchange Online PowerShell module. Installing this version of the module might require you to uninstall previous versions of the module.
- Run the **Connect-IPPSSession** cmdlet with the EnableSearchOnlySession switch.

Step 2: Create a search query to find the message to delete

Next, create and run a search to find the message that you want to remove from mailboxes in your organization. You can create the search by using the Microsoft Purview portal or by running the **New-ComplianceSearch** and **Start-ComplianceSearch** cmdlets in Security & Compliance PowerShell. The messages that match the query for this search are deleted by running the **New-ComplianceSearchAction -Purge** command in Delete the message. For information about creating and configuring search queries, see the following articles:

- Create a search query
- Use the condition builder
- New-ComplianceSearch
- Start-ComplianceSearch

> **Note**
>
> The content locations that you include in the search query can't include SharePoint or OneDrive sites. You can only include mailboxes and public folders in a search that is used for email messages. If the search includes sites, you receive an error when you run the **New-ComplianceSearchAction** cmdlet in Delete the message.

Tips for finding messages to remove

The goal of the search query is to narrow the results to only the messages that you want to remove. Here are some tips:

- If you know the exact text or phrase used in the subject line of the message, use the **Subject** property in the search query.
- If you know the exact date or date range of the message, include the **Received** property in the search query.
- If you know who sent the message, include the **From** property in the search query.
- Preview the search results to verify that the search returns only the messages that you want to delete.
- Use the search estimate statistics, displayed in the details pane of the search in the Microsoft Purview portal or by using the Get-ComplianceSearch cmdlet, to get a count of the total number of results.

Here are two examples of queries to find suspicious email messages.

- This query returns messages that users received between April 13, 2024 and April 14, 2024 and that contain the words "action" and "required" in the subject line.

  PowerShell

  ```
  (Received:4/13/2024..4/14/2024) AND (Subject:'Action required')
  ```

- This query returns messages sent by user@contoso.com and that contain the exact phrase "Update your account information" in the subject line.

  PowerShell

  ```
  (From:user@contoso.com) AND (Subject:"Update your account information")
  ```

Here's an example of using a query to create and start a search by running the **New-ComplianceSearch** and **Start-ComplianceSearch** cmdlets to search all mailboxes in the organization:

PowerShell

```
$Search=New-ComplianceSearch -Name "Remove Phishing Message" -ExchangeLocation All -
ContentMatchQuery '(Received:4/13/2016..4/14/2016) AND (Subject:"Action required")'
Start-ComplianceSearch -Identity $Search.Identity
```

Step 3: Delete the message

After you create and refine a search query to return the messages that you want to remove, run the **New-ComplianceSearchAction -Purge** command in Security & Compliance PowerShell to delete the message.

> **Important**
>
> If you use search in eDiscovery to validate the result and scope what you want to delete, rerun the search cmdlet to validate the search in eDiscovery. The search in eDiscovery isn't run in PowerShell, so the ItemCount is 0 and the JobEndTime isn't set. The search needs to be rerun using PowerShell and you should wait for the search to complete. Verify the results in the cmdlet return the same results before performing the purge.

You can soft-delete or hard-delete the message. A soft-deleted message is moved to a user's Recoverable Items folder and retained until the deleted item retention period expires. Hard-deleted messages are marked for permanent removal from the mailbox and are permanently removed the next time the mailbox is processed by the Managed Folder Assistant. If single item recovery is enabled for the mailbox, hard-deleted items are permanently removed after the deleted item retention period expires. If a mailbox is placed on hold, deleted messages are preserved until the hold duration for the item expires or until the hold is removed from the mailbox.

> ⓘ **Note**
>
> Items from Microsoft Teams that are returned by the search query aren't deleted when you run the **New-ComplianceSearchAction -Purge** command.

To run the following commands to delete messages, make sure you're connected to Security & Compliance PowerShell.

Soft-delete messages

In the following example, the command soft-deletes the search results returned by a search query named "Remove Phishing Message".

PowerShell

```
New-ComplianceSearchAction -SearchName "Remove Phishing Message" -Purge -PurgeType SoftDelete
```

Hard-delete messages

> ⚠ **Warning**
>
> Hard-deleted messages are marked for permanent removal and can't be recovered by the user. If single item recovery is enabled, hard-deleted items are permanently removed after the deleted item retention period expires. Verify your search scope before running this command.

To hard-delete the items returned by the "Remove Phishing Message" content search, run the following command:

PowerShell

```
New-ComplianceSearchAction -SearchName "Remove Phishing Message" -Purge -PurgeType
HardDelete
```

When you run the **New-ComplianceSearchAction -Purge -PurgeType SoftDelete** or **New-ComplianceSearchAction -Purge -PurgeType HardDelete** command, the search specified by the *SearchName* parameter is the search query that you created in Create a search query to find the message to delete.

For more information, see New-ComplianceSearchAction.

Frequently asked questions

The following questions address common issues with search and purge operations.

- **I followed the steps in this article for search, verify, and purge but it still doesn't delete items from a mailbox.**

  Sometimes the items matching the search query are more than 10 items (or 100 items if using Microsoft Graph) for a mailbox. If you run the purge by using the PowerShell cmdlet and only delete 10 items, or run the purge by using Microsoft Graph and only delete 100 items, this behavior is normal. Repeat the process multiple times if you want to delete more than 10 (or 100) items per mailbox. We strongly recommend against working around these limits by continually running the purge command. If you need to delete more data from a single location, see Remediate malicious email delivered in Office 365 or Zero-hour auto purge (ZAP) in Microsoft Defender for Office 365.

  A mailbox on litigation hold can also prevent items from being deleted. If the export report associated to the search run in Step 2 (or done in eDiscovery) indicates items are in the *Recoverable Items* folder, this result means there are holds but the items are moved out of view. If you want to remove items from hold, we strongly recommend using Priority Cleanup. Alternatively, you can release the hold and try purging again. Check the status of the hold by running the following cmdlet in Exchange PowerShell:

  PowerShell

  ```
  Get-Mailbox (or MailUser) | fl *Hold*,*Recovery*
  ```

Verify the following values in the cmdlet results:

- InPlaceHolds should be empty or only have values prefixed with –
  - DelayHold should be false
  - SingleItemRecovery should be false

  Check for tenant level policies by running the following cmdlet:

  ```
  PowerShell
  Get-OrganizationConfig | fl *Hold*
  ```

  If there are any tenant level policies, you must exclude each affected mailbox from the purge:

- Mailbox is on delay hold.
  - Items of interest are still found after purge because they're moved to the *Recoverable items* folder.

- **How do I verify if items are under recoverable items folder?**

  To verify items are in the *Recoverable Items* folder, run an export report for the search and review the file path of the items in the CSV report to see if the items are in the *Recoverable items* folder. If yes, the *New-ComplianceSearch* cmdlet doesn't attempt to delete the item. If the CSV report indicates that the items are in the *Recoverable items* folder and the item's mailbox is archived, the mailbox is being resized. These backup items can't be deleted and eventually are removed automatically.

- **How do you get status on the search and remove operation?**

  Run the **Get-ComplianceSearchAction** to get the status on the delete operation. The object that is created when you run the **New-ComplianceSearchAction** cmdlet is named using this format: `<name of Content Search>_Purge`.

- **What happens after you delete a message?**

  A message that's deleted with the `New-ComplianceSearchAction -Purge -PurgeType HardDelete` command is moved to the Purges folder and can't be accessed by the user. After the message is moved to the Purges folder, the message is retained for the deleted item retention period if single item recovery is enabled for the mailbox. (In Microsoft 365, single item recovery is enabled by default when a new mailbox is created.) After the deleted item retention period expires, the message is marked for permanent deletion and is purged from Microsoft 365 the next time the mailbox is processed by the Managed Folder assistant.

If you use the `New-ComplianceSearchAction -Purge -PurgeType SoftDelete` command, messages are moved to the Deletions folder in the user's Recoverable Items folder. It isn't immediately purged from Microsoft 365. The user can recover messages in the Deleted Items folder for the duration based on the deleted item retention period configured for the mailbox. After this retention period expires (or if user purges the message before it expires), the message is moved to the Purges folder and can no longer be accessed by the user. After the message reaches the Purges folder, the message is retained for the duration based on the deleted item retention period configured for the mailbox if single items recovery is enabled for the mailbox. (In Microsoft 365, single item recovery is enabled by default when a new mailbox is created.) After the deleted item retention period expires, the message is marked for permanent deletion and is purged from Microsoft 365 the next time that the mailbox is processed by the Managed Folder assistant.

- **What if I have to delete a message from more than 50,000 mailboxes?**

  You can perform a search and purge operation on a maximum of 50,000 mailboxes (even if less than 50,000 contain items that match the search query). If you need to do a search and purge operation on more than 50,000 mailboxes, consider creating temporary search permissions filters that reduce the number of mailboxes that would be searched to less than 50,000 mailboxes. For example, if your organization contains mailboxes in different departments, states, or a different country/region, you can create a mailbox search permissions filter based on one of those mailbox properties to search a subset of mailboxes in your organization. After you create the search permissions filter, you would create the search (described in Step 1) and then delete the message (described in Step 3). Then you can edit the search permissions filter to search for and purge messages in a different set of mailboxes. For more information about creating search permissions filters, see Configure search permissions filtering in eDiscovery.

> **Note**
>
> Each mailbox location including primary, archive, and any others are counted as individual locations for this limit.

- **Will unindexed items included in the search results be deleted?**

  No, the `New-ComplianceSearchAction -Purge` command doesn't delete unindexed items.

- **What happens if a message is deleted from a mailbox that is placed on Litigation Hold or assigned to a Microsoft 365 retention policy?**

After the message is purged and moved to the Purges folder, the message is retained until the hold duration expires. If the hold duration is unlimited, then items are retained until the hold is removed or the hold duration is changed.

- **Why is the search and remove workflow divided among different Microsoft Purview portal role groups?**

  A person has to be a member of the *eDiscovery Manager* role group or be assigned the *Compliance Search management* role to search mailboxes. To delete messages, a person has to be a member of the *Organization Management* role group or be assigned the *Search And Purge management* role. This division makes it possible to control who can search mailboxes in the organization and who can delete messages.

Finding content in sites in eDiscovery

When you search for documents and files in SharePoint or OneDrive sites, adjust your query approach based on the metadata for the documents and files you're interested in. Files and documents have relevant properties like *Author*, *Created*, *CreatedBy*, *FileName*, *LastModifiedTime*, and *Title*. Most of these properties aren't relevant when searching for communications content in Exchange Online. Using these properties might lead to unexpected results if you use them across both documents and communications. Additionally, the *FileName* and *Title* of a document might not be the same. Using one or the other to try to find a file with specific content might lead to different or inaccurate results. Keep these properties in mind when searching for specific document and file content in SharePoint and OneDrive.

To learn more about finding content in sites in eDiscovery, watch the following video:

https://learn-video.azurefd.net/vod/player?id=4605a9a1-081f-4018-9bd3-77fb6da223e8&locale=en-us&embedUrl=%2Fpurview%2Fedisc-search-sites

For example, to find content related to documents created by User 1, for a project called *Tradewinds*, for specific files named *Financials*, and from January 2020 to January 2022, use a query with the following properties:

- Add User 1 as a data source to the search.
- Select User 1's OneDrive site as the location of interest.
- Add additional groups and their associated SharePoint sites related to the project as data sources.
- For **FileName**, use *Financials*
- For **Keyword**, use *Tradewinds*
- For **Date Range**, use the *January 1, 2020* to *January 31, 2022* range

Searchable site properties in KeyQL

The following table lists the SharePoint and OneDrive properties supported in search using the eDiscovery KeyQL editor in the Microsoft Purview portal or by using the New-ComplianceSearch or Set-ComplianceSearch cmdlets. For a list of supported condition builder properties, see Use the condition builder to create search queries in eDiscovery.

> **Important**
>
> While documents and files stored on SharePoint and OneDrive might have other properties supported in other Microsoft 365 services, only the document and file properties listed in this table are supported in eDiscovery search tools. Attempting to include other document or file properties in searches isn't supported.

If you set a site status to *Locked* and the site to *NoAccess*, eDiscovery doesn't return search results. For more information about managing site lock statuses, see Lock and unlock sites. In addition, if a document is restricted in the content store, the eDiscovery manager must be a site admin, site owner, or the owner or last modifier of the restricted document to access it in eDiscovery. For more information about restricted content, see Data Loss Prevention policy reference.

> **Important**
>
> If a OneDrive site is archived and then searched within eDiscovery, the search triggers reindexing and the number of items increases over time as the site fully indexes. This effect persists until the site reindexing is complete. To learn more and manually trigger re-indexing, see Manually request crawling and reindexing of a site, a library, or a list.

The table includes an example of the *property:value* syntax for each property and a description of the search results returned by the examples.

Expand table

Property	Property description	Example	Search results returned by the examples
Author	The author field from Office documents, which persists if a document is copied. For example, if a user creates a document and the emails it to someone else who then uploads it to SharePoint, the document still retains the original author. Be sure to use the user's display name for this property.	`author:"Garth Fort"`	All documents authored by Garth Fort.
ContentType	The SharePoint content type of an item, such as Item, Document, or Video.	`contenttype:document`	All documents.
Created	The date that an item is created.	`created>=2021-06-01`	All items created on or after June 1, 2021.
CreatedBy	The person that created or uploaded an item. Be sure to use the user's display name for this property.	`createdby:"Garth Fort"`	All items created or uploaded by Garth Fort.
DetectedLanguage	The language of an item.	`detectedlanguage:english`	All items in English.

DocumentLink	The path (URL) of a specific folder on a SharePoint or OneDrive site. If you use this property, be sure to search the site that the specified folder is located in. Use this property instead of the *Site* and *Path* properties.
	
	To return items located in subfolders of the folder that you specify for the documentlink property, you have to add /* to the URL of the specified folder; for example, `documentlink:"https://contoso.sharepoint.com/Shared Documents/*"`
		`documentlink:"https://contoso-my.sharepoint.com/personal/garthf_contoso_com/Documents/Private/*"`
		
		`documentlink:"https://contoso-my.sharepoint.com/personal/garthf_contoso_com/Documents/Shared with Everyone/*" AND filename:confidential`
			The first example returns all items in the specified OneDrive folder. The second example returns documents in the specified site folder (and all subfolders) that contain the word "confidential" in the file name.

FileExtension	The extension of a file; for example, docx, one, pptx, or xlsx.	`fileextension:xlsx`	All Excel files (Excel 2007 and later)

FileName	The name of a file.	`filename:"marketing plan"`
		
		`filename:estimate`
			The first example returns files with the exact phrase "marketing plan" in the title. The second example returns files with the word "estimate" in the file name.

LastModifiedTime	The date that an item was last changed.	`lastmodifiedtime>=2021-05-01`
		
		`lastmodifiedtime>=2021-05-01 AND lastmodifiedtime<=2021-06-01`
			The first example returns items that were changed on or after May 1, 2021. The

Property	Property description	Example	Search results returned by the examples
			second example returns items changed between May 1, 2021 and June 1, 2021.
MipSensitiveLabel	Search for sensitivity labels applied to items in your organization's data. By using the Condition Builder, users can select the sensitivity label name (for example, Confidential, Highly Confidential, etc.) from the dropdown and then identify the GUID used in KeyQL for the sensitivity label.	`MipSensitiveLabel=f0c0c7ef-3d45-4c95-87bb-6dfc7a081f46`	All items that match the GUID of the sensitivity label.
ModifiedBy	The person who last changed an item. Be sure to use the user's display name for this property.	`modifiedby:"Garth Fort"`	All items that were last changed by Garth Fort.
SensitiveType	Search for identified and classified sensitive information types in your organization's data. By using the Condition Builder, users can select the sensitive information type name (for example, SSN, credit card, bank account numbers, etc.) from the dropdown and then identify the GUID used in KeyQL for the sensitive information type.	`SensitiveType="ba147552-2ed1-4a8f-a441-981e94ab1895"`	All items that match the GUID of the sensitive information type.

SharedWithUsersOWSUser	Documents that are shared with the specified user and displayed on the **Shared with me** page in the user's OneDrive site. These documents are explicitly shared with the specified user by other people in your organization. When you export documents that match a search query that uses the SharedWithUsersOWSUser property, the documents are exported from the original content location of the person who shared the document with the specified user. For more information, see Searching for site content shared within your organization.	`sharedwithusersowsuser:garthf`
		
		`sharedwithusersowsuser:"garthf@contoso.com"`
			Both examples return all internal documents that are explicitly shared with Garth Fort and that appear on the **Shared with me** page in Garth Fort's OneDrive account.

Size	The size of an item, in bytes.	`size>=1`
		
		`size:1..10000`
			The first example returns items larger than 1 byte. The second example returns items from 1 through 10,000 bytes in size.

Title	The title of the document. The Title property is metadata that's specified in Microsoft Office documents. It's different from the file name of the document.	`title:"communication plan"`	Any document that contains the phrase "communication plan" in the Title metadata property of an Office document.

Searchable sensitive data types

You can use eDiscovery search tools in the Microsoft Purview portal to search for sensitive data, such as credit card numbers or social security numbers, stored in documents on SharePoint and OneDrive sites. You can do this by using the `SensitiveType` property and the name (or ID) of a sensitive information type in a keyword query. For example, the query `SensitiveType:"Credit Card Number"` returns documents that contain a credit card number. The query `SensitiveType:"U.S. Social Security Number (SSN)"` returns documents that contain a U.S. social security number.

To see a list of the sensitive information types that you can search for, go to **Data classifications** > **Sensitive info types** in the Microsoft Purview portal. Or you can use the **Get-DlpSensitiveInformationType** cmdlet in Security & Compliance PowerShell to display a list of sensitive information types.

Limitations for searching sensitive data types

- To search for custom sensitive information types, you need to specify the ID of the sensitive information type in the `SensitiveType` property. Using the name of a custom sensitive information type (as shown in the example for built-in sensitive information types in the previous section) returns no results. Use the **Publisher** column on the **Sensitive info types** page in the Microsoft Purview portal (or the **Publisher** property in PowerShell) to differentiate between built-in and custom sensitive information types. Built-in sensitive data types have a value of `Microsoft Corporation` for the **Publisher** property.

  To display the name and ID for the custom sensitive data types in your organization, run the following command in Security & Compliance PowerShell:

  PowerShell

  ```
  Get-DlpSensitiveInformationType | Where-Object {$_.Publisher -ne "Microsoft Corporation"} | FT Name,Id
  ```

  Then you can use the ID in the `SensitiveType` search property to return documents that contain the custom sensitive data type; for example, `SensitiveType:7e13277e-6b04-3b68-94ed-1aeb9d47de37`

- You can't use sensitive information types and the `SensitiveType` search property to search for sensitive data at-rest in Exchange Online mailboxes. This limitation includes 1:1 chat messages, 1:N group chat messages, and team channel conversations in Microsoft Teams because all of this content is stored in mailboxes. However, you can use data loss prevention (DLP) policies to protect sensitive email data in transit. For more information, see Learn about data loss prevention and Search for and find personal data.

Forming a basic query

A basic query has three parts: SensitiveType, count range, and confidence range. For example, **SensitiveType:"<type>"** is required, and both **|<count range>** and **|<confidence range>** are optional.

Sensitive type - required

Queries typically begin with the property `SensitiveType:"` and an information type name from the sensitive information types inventory, and end with a `"`. You can also use the name of a custom sensitive information type that you created for your organization. For example, you might be looking for documents that contain credit card numbers.

In such an instance, use the following format: `SensitiveType:"Credit Card Number"`. Because you didn't include count range or confidence range, the query returns every document in which a credit card number is detected. This is the simplest query that you can run, and it returns the most results. Keep in mind that the spelling and spacing of the sensitive type matters.

Ranges - optional

Both of the next two parts are ranges, so let's quickly examine what a range looks like. In SharePoint queries, a basic range is represented by two numbers separated by two periods, which looks like this: `[number]..[number]`. For instance, if `10..20` is used, that range captures numbers from 10 through 20. This article covers many different range combinations.

Let's add a count range to the query. You can use count range to define the number of occurrences of sensitive information a document needs to contain before it's included in the query results. For example, if you want your query to return only documents that contain exactly five credit card numbers, use this: `SensitiveType:"Credit Card Number|5"`. Count range can also help you identify documents that pose high degrees of risk. For example, your organization might consider documents with five or more credit card numbers a high risk. To find

documents fitting this criterion, use this query: `SensitiveType:"Credit Card Number|5.."`. Alternatively, you can find documents with five or fewer credit card numbers by using this query: `SensitiveType:"Credit Card Number|..5"`.

Confidence range

Finally, confidence range is the level of confidence that the detected sensitive type is actually a match. The values for confidence range work similarly to count range. You can form a query without including a count range. For example, to search for documents with any number of credit card numbers—as long as the confidence range is 85 percent or higher—use this query: `SensitiveType:"Credit Card Number|*|85.."`.

> **Important**
>
> The asterisk (`*`) is a wildcard character that means any value works. You can use the wildcard character (`*`) either in the count range or in the confidence range, but not in a sensitive type.

Additional query properties and search operators

Queries in SharePoint also contain the `LastSensitiveContentScan` property, which can help you search for files scanned within a specific timeframe. For query examples with the `LastSensitiveContentScan` property, see the Examples of complex queries in the next section.

You can use SharePoint eDiscovery search properties such as `Author` or `FileExtension`. You can use operators to build complex queries.

Examples of complex queries

The following examples use different sensitive types, properties, and operators to show how you can refine your queries to find exactly what you're looking for.

Expand table

Query	Explanation
`SensitiveType:"Credit Card Number | 1..4294967295 | 1..100"`	This query returns documents with at least one match to the sensitive type "Credit Card Number." The values for each range are the respective minimum and maximum values. A simpler way to write this query is `SensitiveType:"Credit Card Number"`.
`SensitiveType:"Credit Card Number | 5..25" AND LastSensitiveContentScan:"8/11/2018..8/13/2018" NOT FileExtension:XLSX`	This query returns documents with 5-25 credit card numbers that were scanned from August 11, 2018 through August 13, 2018. Files with an XLSX extension aren't included in the query results. `FileExtension` is one of many properties that you can include in a query. For more information, see Using Search Properties and Operators with eDiscovery.
`SensitiveType:"Credit Card Number | 5..25" AND LastSensitiveContentScan:"8/11/2018..8/13/2018"`	This query returns documents with 5-25 credit card numbers that were scanned from August 11, 2018 through August 13, 2018.
`SensitiveType:"Credit Card Number" OR SensitiveType:"U.S. Social Security Number (SSN)"`	This query returns documents that contain either a credit card number or a social security number.
`SensitiveType:"International Banking Account Number (IBAN)"`	The name might seem strange because it's so long, but it's the correct name for that sensitive type. Make sure to use exact names from the sensitive information types inventory. You can also use the name of a custom sensitive information type that you created for your organization.

Examples of queries to avoid

Not all queries work in SharePoint. The following table gives examples of queries that don't work and describes why.

Expand table

Unsupported query	Reason
`SensitiveType:"Credit Card Number .."`	You must add at least one number.
`SensitiveType:"Credit Card Number 0"`	Zero isn't valid as either the minimum value or the maximum value in a range.

Unsupported query	Reason
`SensitiveType:"Credit Card Number 1. .3"`	The two-period portion shouldn't be separated by a space.
`SensitiveType:"Credit Card Number 1.. 80.."`	There are too many pipe delimiters `|`. Follow this format instead: `SensitiveType: "Credit Card Number 1.. 80.."`
`SensitiveType:"Credit Card Number 1.. 80..101"`	Because confidence values represent a percentage, they can't exceed 100. Choose a number from 1 through 100 instead.
`SensitiveType:"Credit Card Number"`	It might be difficult to see, but there's extra white space between "Credit" and "Card" that makes the query invalid. Use exact sensitive type names from the sensitive information types inventory.
`SensitiveType:"NotARule"`	"NotARule" isn't a valid sensitive type name. Only names in the sensitive information types inventory work in eDiscovery queries.

Searching for site content shared with external users

You can use eDiscovery search tools in the Microsoft Purview portal to search for documents stored on SharePoint and OneDrive sites shared with people outside of your organization. This search can help you identify sensitive or proprietary information that's being shared outside your organization. Use the `ViewableByExternalUsers` property in a keyword query. This property returns documents or sites that you shared with external users by using one of the following sharing methods:

- A sharing invitation that requires users to sign in to your organization as an authenticated user.
- An anonymous guest link, which allows anyone with this link to access the resource without having to be authenticated.

Here are some examples:

- The query `ViewableByExternalUsers:true AND SensitiveType:"Credit Card Number"` returns all items shared with people outside your organization and contains a credit card number.
- The query `ViewableByExternalUsers:true AND ContentType:document AND site:"https://contoso.sharepoint.com/Sites/Teams"` returns a list of documents on all team sites in the organization that you shared with external users.

> **Tip**
>
> A search query such as `ViewableByExternalUsers:true AND ContentType:document` might return numerous .aspx files in the search results. To eliminate these or other types of files, use the `FileExtension` property to exclude specific file types; for example `ViewableByExternalUsers:true AND ContentType:document NOT FileExtension:aspx`.

What content counts as shared with people outside your organization? Documents in your organization's SharePoint and OneDrive sites that you shared by sending a sharing invitation or that you shared in public locations. For example, the following user activities result in content that external users can view:

- A user shares a file or folder with a person outside your organization.
- A user creates and sends a link to a shared file to a person outside your organization. This link allows the external user to view (or edit) the file.
- A user sends a sharing invitation or a guest link to a person outside your organization to view (or edit) a shared file.

Issues using the ViewableByExternalUsers property

While the `ViewableByExternalUsers` property represents the status of whether a document or site is shared with external users, it has some caveats. In the following scenarios, the value of the `ViewableByExternalUsers` property isn't updated, and the results of a search query that uses this property might be inaccurate.

- Changes to sharing policy, such as turning off external sharing for a site or for the organization. The property still shows previously shared documents as being externally accessible even though external access might be revoked.
- Changes to group membership, such as adding or removing external users to Microsoft 365 Groups or Microsoft 365 security groups. The property isn't automatically updated for items the group has access to.

- Sending sharing invitations to external users where the recipient hasn't accepted the invitation, and therefore doesn't yet have access to the content.

In these scenarios, the `ViewableByExternalUsers` property doesn't reflect the current sharing status until the site or document library is recrawled and reindexed.

Searching for site content shared within your organization

You can use the `SharedWithUsersOWSUser` property to search for documents shared between people in your organization. When a person shares a file or folder with another user inside your organization, a link to the shared file appears on the **Shared with me** page in the OneDrive account of the person who the file was shared with. For example, to search for the documents shared with Sara Davis, you can use the query `SharedWithUsersOWSUser:"sarad@contoso.com"`. If you export the results of this search, you download the original documents located in the content location of the person who shared the documents with Sara.

Documents must be explicitly shared with a specific user to be returned in search results when using the `SharedWithUsersOWSUser` property. For example, when a person shares a document in their OneDrive account, they can share it with anyone (inside or outside the organization), share it only with people inside the organization, or share it with a specific person.

Only documents that are shared by using the third option (shared with **Specific people**) are returned by a search query that uses the `SharedWithUsersOWSUser` property.

Character limits for searches

For more information about character limits, see eDiscovery search limits.

Finding content in Microsoft Teams in eDiscovery

This article provides a comprehensive set of procedures, guidelines, and best practices for using eDiscovery to preserve, collect, review, and export content from Microsoft Teams. The goal of this article is to help you optimize your eDiscovery search for Teams content.

To learn more about finding content in Microsoft Teams with eDiscovery, check out the following video:

https://learn-video.azurefd.net/vod/player?id=c077f1d9-33f0-43c3-a44e-eafe3095cf0f&locale=en-us&embedUrl=%2Fpurview%2Fedisc-search-teams

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Where Teams content is stored

To manage Teams content in eDiscovery, you need to understand the type of Teams content you can collect, process, and review in eDiscovery and where Microsoft 365 stores that content. To configure Teams content locations in a case, see Configure data sources. Teams data is stored in Azure Cosmos DB. Exchange Online stores Teams compliance records that the substrate captures, and eDiscovery can access these records. The data stored in Exchange Online is hidden from clients. eDiscovery never operates against the real Teams message data, which remains in Azure Cosmos DB.

The following table lists Teams content types and where Microsoft 365 stores each type for compliance purposes.

Expand table

Teams category	Description	Chat messages/posts location	Files/attachments location	Meeting recordings location
Events	All data from webinars and town halls is stored in Cosmos DB. Substrate (SCD) serves as secondary storage for redundancy and eDiscovery purposes.	N/A	N/A	N/A
Private channels	Message posts, replies, and attachments shared in a private Teams channel.	Messages sent in a private channel are stored in the Exchange Online mailboxes of all members of the private channel.	Files shared in a private channel are stored in a dedicated SharePoint site associated with the private channel.	N/A
Shared channels	Message posts, replies, and attachments shared in a shared Teams channel.	Messages sent in a shared channel are stored in a system mailbox associated with the shared channel.[2]	Files shared in a shared channel are stored in a dedicated SharePoint site associated with the shared channel.	N/A
Teams 1:1 chats	Chat messages, posts, and attachments shared in a Teams conversation between two people. Teams 1:1 chats are also called *conversations*.	Messages in 1:1 chats are stored in the Exchange Online mailbox of all chat participants.	Files shared in a 1:1 chat are stored in the OneDrive account of the person who shared the file.	N/A
Teams channels	Chat messages, posts, replies, and attachments shared in a standard Teams channel.	All channel messages and posts are stored in the Exchange Online mailbox associated with the team.	Files shared in a channel are stored in the SharePoint site associated with the team.	N/A
Teams group chats	Chat messages, posts, and attachments shared in a Teams conversation between three or more people. Also	Messages in group chats are stored in the Exchange Online mailbox of all chat participants.	Files shared in group chats are stored in the OneDrive account of the person who shared the file.	N/A

Teams category	Description	Chat messages/posts location	Files/attachments location	Meeting recordings location
	called *1:N* chats or *group conversations*.			
Teams meetings	Audio and transcripts from recorded Teams meetings.	Chats in recorded meetings are stored in an Exchange Online mailbox. For standard meetings, it's stored in the mailboxes of all participants. For channel meetings, it's stored in the mailbox associated with the team.	Files and attachments shared in recorded meetings are stored in the OneDrive account for the user recording the Teams meeting.	Meeting recordings are stored in the OneDrive account for the user recording the Teams meeting.[1]
Teams reactions	Reactions applied to chat messages, posts, and attachments in a Teams conversation.	Messages in group chats are stored in the Exchange Online mailbox of all chat participants.	Files shared in group chats are stored in the OneDrive account of the person who shared the file.	N/A

> **Note**
>
> [1] To locate Teams meeting audio and transcript content, create an eDiscovery search targeting the organizer's OneDrive. Include the date range and file extension in the query. When the search completes, refine the results in a review set and select only the pertinent data. For example, a date range might be from *March 17, 2025 to March 18, 2025* and the file extension might be *mp4*.
>
> [2] To search for (and preserve) messages sent in a shared channel, you must search or specify the Exchange Online mailbox for the parent Team.

Teams content types

All Microsoft Teams 1:1 or group chats are journaled through to the respective users' mailboxes. All standard channel messages are journaled through to the group mailbox representing the team. Files uploaded in standard channels are covered under the eDiscovery functionality for SharePoint and OneDrive.

eDiscovery of messages and files in private channels works differently than in standard channels. To learn more, see eDiscovery of private channels.

Recorded Teams meetings are stored in the OneDrive account of the meeting organizer or initiator, depending on the *MeetingRecordingOwnership* configuration. Attendee identification information when using the **Hide Attendee Names** functionality for Teams meetings is stored in the user mailbox of the meeting organizer.

Not all Teams content is eDiscoverable. The following table shows the Teams content types that you can search for using Microsoft eDiscovery tools:

Expand table

Content type	Notes
Audio recordings	Audio calls between Teams user and external contacts
Card content	See Search for card content for more information.
Chat links	
Chat messages	This includes content in standard Teams channels, 1:1 chats, 1:N group chats, chats with yourself, and chats with guests.
Code snippets	
Edited messages	If the user is on hold, previous versions of edited messages are also preserved.
Emojis, GIFs, and stickers	
Inline images	
Loop components	Content in a loop component is saved in a .fluid file that's stored in the OneDrive account of the user who sends the loop component. That means you have to include OneDrive as a data source when searching for content in loop components.
Meeting IM conversations	
Meeting metadata[1]	
Meeting recordings and transcripts	Transcripts of the meeting audio are extracted and provided as a separate file. Maximum supported recorded meeting .mp4 file size is 350 MB. If the recorded meeting file size is greater than 350 MB, a processing error occurs and the file is available for download.
Name of channel	

Content type	Notes
Quotes	Quoted content is searchable. However, search results don't indicate that the content was quoted.
Reactions (such as likes, hearts, and other reactions)	Reactions are supported for all commercial customers after June 1, 2022. Reactions before this date aren't available for eDiscovery. Expanded reactions are now supported. To understand reaction history, the content must be on legal hold.
Subject	
Tables	
Teams Video Clip (TVC)	Search TVC with "Video-Clip" keyword and "save as" a .mp4 file for each TVC attachment by right-clicking the preview. TVCs are collected as Teams conversation attachments (if smaller than 200 MB) and separate .mp4 files. TVC file data is discoverable in eDiscovery review sets and can be exported. Preview of video clips isn't currently supported.

[1] Meeting (and call) metadata includes the following:

- Meeting start and end time, and duration
- Meeting join and leave events for each participant
- VOIP joins/calls
- Federated user joins
- Guest joins

> **Important**
>
> Anonymous users joining meetings and calls aren't currently supported in eDiscovery search queries.

Microsoft Teams data appears as IM or Conversations in the Excel eDiscovery export output. You can open the `.pst` file in Outlook to view those messages after you export them.

When viewing the .pst file for the team, all conversations are located in the Team Chat folder under Conversation History. The title of the message contains the team name and channel name.

Private chats in a user's mailbox are stored in the Team Chat folder under Conversation History.

eDiscovery of private and shared channels

Compliance copies of messages in private and shared channels go to different mailboxes depending on the channel type. That difference means you need to search different mailbox locations based on the type of channel a user belongs to.

- **Private channels**: Compliance copies go to the dedicated private channel mailbox. You need to search private channel mailboxes when searching for content in private channel messages.
- **Shared channels**: Compliance copies go to a system mailbox that's associated with the parent team. Because Teams doesn't support an eDiscovery search of a single system mailbox for a shared channel, you need to search the mailbox for the parent team (by selecting the name of the Team mailbox) when searching for message content in shared channels.

Each private and shared channel has its own SharePoint site that's separate from the parent team site. Files in private and shared channels are stored in their own site and managed independently of the parent team. You must identify and search the specific site associated with a channel when searching for content in files and channel message attachments.

Use the following sections to help identify the private or shared channel to include in your eDiscovery search.

Identifying the members of a private channel

Use the following procedure to identify members of a private channel so that you can use eDiscovery tools to search the member's mailbox for content in private channel messages.

Before you perform these steps, make sure you have the latest version of the Teams PowerShell module installed.

1. Run the following command to get the group ID of the team that contains the shared channels you want to search.

   PowerShell

   ```
   Get-Team -DisplayName <display name of the parent team>
   ```

   > **Tip**
   >
   > Run the **Get-Team** cmdlet without any parameters to display a list of all Teams in your organization. The list contains the group ID and DisplayName for every team.

2. Run the following command to get a list of private channels in the parent team. Use the group ID for the team that you obtained in step 1.

```
PowerShell
Get-TeamChannel -GroupId <parent team GroupId> -MembershipType Private
```

3. Run the following command to get a list of private channel owners and members for a specific private channel.

```
PowerShell
Get-TeamChannelUser -GroupId <parent team GroupId> -DisplayName "Partner Shared Channel"
```

4. Include the mailboxes of owners and members of a private channel as part of your eDiscovery search query.

Search for content for guests

You can use eDiscovery tools to search for Teams content related to guests in your organization. Teams chat content that's associated with a guest is preserved in a cloud-based storage location, and you can search for it by using eDiscovery. This content includes 1:1 and 1:N chat conversations where a guest participates with other users in your organization. You can also search for private channel messages where a guest participates and for content in *guest:guest* chat conversations where the only participants are guests.

To search for content for guests:

1. Connect to Microsoft Graph PowerShell. For more information, see the Microsoft Graph PowerShell overview. Be sure to complete Step 1 and Step 2 in the previous article.

2. After you successfully connect to Microsoft Graph PowerShell, run the following command to display the user principal name (UPN) for all guests in your organization. You need to use the UPN of the guest when you create the search in step 4.

```
PowerShell
Get-MgUser -Filter "userType eq 'Guest'" -All $true | FL UserPrincipalName
```

> **Tip**

> Instead of displaying a list of user principal names on the computer screen, you can redirect the output of the command to a text file. You can do this by appending `> filename.txt` to the previous command. The text file with the user principal names is saved to the current folder.

3. In a different Windows PowerShell window, connect to Security & Compliance PowerShell. For instructions, see Connect to Security & Compliance PowerShell. You can connect with or without using multifactor authentication.

4. Create a search query that searches for all content (such as chat messages and email messages) where the specified guest was a participant by running the following command.

   PowerShell

   ```
   New-ComplianceSearch <search name> -ExchangeLocation <guest UPN>  -
   AllowNotFoundExchangeLocationsEnabled $true -IncludeUserAppContent $true
   ```

   For example, to search for content associated with the guest Sara Davis, run the following command.

   PowerShell

   ```
   New-ComplianceSearch "Sara Davis Guest" -ExchangeLocation
   "sara.davis_hotmail.com#EXT#@contoso.onmicrosoft.com" -
   AllowNotFoundExchangeLocationsEnabled $true -IncludeUserAppContent $true
   ```

   For more information about using PowerShell to create searches, see New-ComplianceSearch.

5. Run the following command to start the search that you created in step 4:

   PowerShell

   ```
   Start-ComplianceSearch <search name>
   ```

6. Go to the Microsoft Purview portal and sign in by using the credentials for a user account assigned eDiscovery permissions.

7. Select the **eDiscovery** solution card and then select **Cases** in the left nav.

8. Select a case.

9. In the list of searches on the **Searches** tab, select the search that you created in step 4 to display the flyout page.

10. On the flyout page, you can do the following things:

    - Select **Sample** to view the search results and preview the content.
    - Next to the **Query** field, select **Edit** to edit and then rerun the search. For example, you can add a search query to narrow the results.
    - Select **Export** to export and download the search results.

Search for card content

Apps generate card content in Teams channels, 1:1 chats, and 1xN chats. The content is stored in mailboxes and you can search it. A *card* is a UI container for short pieces of content. Cards can have multiple properties and attachments, and can include items that trigger card actions. For more information, see Cards.

Like other Teams content, where you store card content depends on where you used the card. The Teams group mailbox stores content for cards used in a Teams channel. The mailboxes of the chat participants store card content for 1:1 and 1xN chats.

To search for card content, use the `kind:microsoftteams` or `itemclass:IPM.SkypeTeams.Message` search conditions. When you review search results, you see that bots generate card content in a Teams channel and the **Sender/Author** email property is `<appname>@teams.microsoft.com`, where `appname` is the name of the app that generated the card content. If a user generates card content, the **Sender/Author** value identifies the user.

When you view card content in search results, the content appears as an attachment to the message. The attachment is named `appname.html`, where `appname` is the name of the app that generated the card content.

> **Note**
>
> To display images from card content in search results (such as the checkmarks in the previous screenshot), you need to be signed into Teams (at https://teams.microsoft.com) in a different tab in the same browser session that you use to view the search results. Otherwise, image placeholders are displayed.

Search for Teams meetings by date

Admins can search for Teams meeting content based on the meeting start or end dates. To filter review set items by specific Teams meeting dates, use the *Meeting start date* and *Meeting end date* properties in eDiscovery search tools.

Search for hidden attendees in Teams meetings

The **Hide Attendee Names** feature in Microsoft Teams hides the name of attendees from other attendees so only organizers can see attendees names. Use this feature for meetings or events with external businesses, vendors, confidential meetings, or other meetings where personal privacy between attendees is important. When you enable this feature, the names of attendees are hidden in the meeting roster, meeting chat, and meeting recordings.

To search for the names of attendees in Teams meetings where the **Hide Attendee Names** feature was enabled, you must include the organizer's mailbox in the scope for the search. Hidden attendee names are only available in the organizer's mailbox.

Search for Teams Events data

All data from webinars and town halls is stored in Cosmos DB. Substrate (SCD) serves as secondary storage for redundancy and eDiscovery purposes. For webinars created before September 2024, this data remains in the webinar organizer's SharePoint storage to ensure continuity for V1 webinars.

eDiscovery applies all event-related information, including *Event titles, Descriptions, Attendee registration data, Presenters,* and *Themes*. Event registration details, such as attendee lists and registrant email addresses, are captured in eDiscovery logs. Live attendance data isn't included.

For legal cases, use the **Microsoft Purview portal** to include "*Microsoft Teams Virtual Events*" as an external data source in the processes. After creating a case and selecting data sources, create a search query to collect relevant Teams Event data for legal and compliance needs.

For future updates, see the **Message Center** for feature availability and functionality.

eDiscovery in external access and guest environments

Admins can use eDiscovery to search for content in chat messages in a Teams meeting in external access and guest access environments based on the following restrictions:

- **External access**: In a Teams meeting with users from your organization and users from an external organization where external attendees are using external access, admins in both organizations can search for content in chat messages from the meeting.
- **Guest**: In a Teams meeting with users from your organization and guests, only admins in the organization who hosts the Teams meeting can search for content in chat messages from the meeting.

Searching for Skype for Business conversations

You can use the following keyword query to specifically search for content in Skype for Business conversations:

PowerShell

```
kind:im
```

The previous search query also returns chats from Microsoft Teams. To prevent this issue, you can narrow the search results to include only Skype for Business conversations by using the following keyword query:

PowerShell

```
kind:im AND subject:conversation
```

The previous keyword query excludes chats in Microsoft Teams because Skype for Business conversations are saved as email messages with a Subject line that starts with the word "Conversation".

To search for Skype for Business conversations that occurred within a specific date range, use the following keyword query:

PowerShell

```
kind:im AND subject:conversation AND (received=startdate..enddate)
```

Find and delete Microsoft Teams chat messages in eDiscovery

> **Tip**
>
> You can also use the purge feature in Data Security Investigations to search for and permanently delete Microsoft Teams items in your organization. Data Security Investigations provides a built-in search and purge workflow with a purge queue dashboard to help you manage and track purge queries. For more information, see Purge in Data Security Investigations.

You can use eDiscovery and the Microsoft Graph Explorer to search for and delete chat messages in Microsoft Teams. This feature helps you find and remove sensitive information or inappropriate content. This search and delete workflow helps you respond to a data spillage event, when content containing confidential or malicious information is released through Teams chat messages.

Microsoft Teams chat data is stored in separate copies, one for compliance purposes (used by tools like eDiscovery) and one for user access.

- **Soft delete or hard delete operations** remove the user copy permanently and can't be recovered for user use.
- **Cmdlet-based purges** of Teams messages can remove the compliance copy of Teams messages, but the user copy remains visible. After the compliance copy is deleted, eDiscovery can no longer remove the user-visible message. Verify Teams messages carefully before purging and avoid using cmdlets to purge Teams messages (the user copy isn't deleted).
  - If you use cmdlets, review the export report and exclude Teams items. Deletes are only performed on the compliance copy and don't remove copies from user viewing. Deleting only the compliance copy also prevents any future deletion when using Microsoft Graph APIs.
  - If you use Microsoft Graph to review the report and ensure Teams items being deleted are intentional, there's no recovery of the items after the deletion is complete.

To ensure complete removal of items, plan your purge strategy carefully and understand which copy each deletion method targets.

> **Tip**
>

Before you search and delete chat messages

> **Important**
>
> Carefully review the following guidance before starting the search and purge steps for Teams chat messages.

- Depending on the eDiscovery subscription for your organization, cases can either be enabled for premium features or not. Verify the level of feature support for the case to determine if the search and purge should be conducted using PowerShell or Microsoft Graph. Cases not configured for premium features can only use PowerShell to search and delete email messages and cases configured for premium features can use PowerShell or Microsoft Graph to search and delete email messages. Don't use a combination of PowerShell and Microsoft Graph to purge email messages and chats.
- After data is permanently deleted, it isn't recoverable. Follow the guidance in this article carefully and validate the scope of the search before issuing the purge command. After you run the purge command, you can't undo it and email messages and chats can't be restored.
- Run an export report to review all items that match your search criteria before the purge. Using the search and export experience in the Microsoft Purview portal and exporting the results in report-only format allows you to examine detailed metadata before deletion. This approach helps refine your search scope and ensures a more targeted and accurate purge.
- To create an eDiscovery case and search for chat messages, you need to be a member of the *eDiscovery Manager* role group in the Microsoft Purview portal. To delete chat messages, you need to be assigned the *Search And Purge* role. This role is assigned to the *Data Investigator* and *Organization Management* role groups by default. For more information, see Assign eDiscovery permissions.

- Search and purge are supported for most conversations within your organization. Search and purge for Teams Connect Chat (External Access or Federation) conversations isn't supported.

  > **Important**
  >
  > Chats with yourself (or chats by users with themselves) aren't supported for search and delete.

- You can remove up to 100 items per mailbox at one time. Because the capability to search for and remove chat messages is intended to be an event-response tool, this limit helps ensure that chat messages are quickly removed.

Step 1: Create a case in eDiscovery

The first step is to create a case in eDiscovery to manage the search and delete process.

Step 2: Create a search query

After you create a case, you need to search for the Teams chat messages that you want to delete. The delete process deletes all items that are found in the search (within the 10 item per location limit).

Data sources for chat messages

Use the following table to determine which data sources to search depending on the type of chat message you need to delete.

Expand table

For this type of chat...	Search this data source...
Teams 1:1 chats	The mailbox of chat participants.
Teams group chats	The mailboxes of chat participants.
Teams channels (standard and shared)	The mailbox associated with the parent team.
Teams private channels	A dedicated mailbox for each private channel.

> **Note**

Before deleting messages, you also need to identify and remove any holds and retention policies assigned to the mailbox that contains the type of chat messages you want to delete.

Tips for searching for chat messages

To help ensure the most comprehensive identification of Teams chat conversations (including 1:1 and group chats, and chats from standard, shared, and private chats), use the **Type** condition and select the **Instant messages** option when you build the search query. Include a date range or several keywords to narrow the scope of the search to items relevant to your investigation.

Step 3: Review and verify chat messages to delete

The deletion process deletes all items returned by the search. It's important that you review the search statistics to ensure that the search only returns the items that you want to delete. Additionally, you can use the search statistics (specifically the *Top Locations* statistics) to generate a list of the data sources that contain items returned by the search. Use this list when removing hold and retention policies from the data sources that contain search results.

Step 4: Remove all holds and retention policies from data sources

Before you can delete chat messages from a mailbox, you need to remove all organization-wide holds, site holds, or retention policy holds that are assigned to a target mailbox. If you don't remove these holds, the chat messages you're trying to delete are retained.

Use the list of mailboxes that contain the chat messages you want to delete to determine if there's a hold or retention policy assigned to those mailboxes, and then remove the hold or retention policy. Be sure to identify the hold or retention policy that you remove so that you can reassign it to the mailboxes after deletion is complete.

For instructions about how to identify and remove holds and retention policies, see "Step 3: Remove all holds from the mailbox" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold.

Step 5: Delete chat messages from Teams

ⓘ Note

Because Microsoft Graph Explorer isn't available in some US Government clouds (GCC High and DOD), you must use PowerShell to accomplish these tasks. See **Delete chat messages with PowerShell** for details.

Now you're ready to delete chat messages from Teams. Use the Microsoft Graph Explorer to perform the following tasks:

1. Get the ID of the eDiscovery case that you created in Step 1. This case contains the search results created in Step 2.
2. Get the ID of the search that you created in Step 2 and verified the search results in Step 3. The search query returns the chat messages that you want to delete.
3. Delete the chat messages returned by the search.

For information about using Graph Explorer, see Use Graph Explorer to try Microsoft Graph APIs.

> **Important**
>
> To perform these three tasks in Graph Explorer, you might have to consent to the eDiscovery.Read.All and eDiscovery.ReadWrite.All permissions. For more information, see the "Consent to permissions" section in **Working with Graph Explorer**.

Get the case ID

Use Graph Explorer to retrieve the ID of the eDiscovery case you created earlier.

1. Go to https://developer.microsoft.com/graph/graph-explorer and sign in to the Graph Explorer with an account that's assigned the *Search And Purge* role in the Microsoft Purview portal.

2. Run the following GET request to retrieve the ID for the eDiscovery case. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases` in the address bar of the request query. Be sure to select **v1.0** in the API version dropdown list.

   This request returns information about all cases in your organization on the **Response preview** tab.

3. Scroll through the response to locate the eDiscovery case. Use the **displayName** property to identify the case.

4. Copy the corresponding ID (or copy and paste it to a text file). Use this ID in the next task to get the search ID.

> **Tip**
>
> Instead of using the previous procedure to obtain the case ID, you can open the case in the Microsoft Purview portal and copy the case ID from the URL.

Get the eDiscoverySearchID

Next, retrieve the ID of the search that contains the chat messages you want to purge.

1. In Graph Explorer, run the following GET request to retrieve the ID for the search that you created in Step 2, and contains the items you want to delete. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches` in the address bar of the request query, where *{ediscoveryCaseID}* is the CaseID that you obtained in the previous procedure.

2. Scroll through the response to locate the search that contains the items you want to delete. Use the *displayName* property to identify the search that you created and verified earlier.

   In the response, the search query from the search is displayed in the *contentQuery* property. Items returned by this query are deleted in the next task.

3. Copy the corresponding ID (or copy and paste it to a text file). Use this ID in the next task to delete the chat messages.

Delete the chat messages

After you confirm the correct case and search IDs, use the following request to purge the matching chat messages.

1. In Graph Explorer, run the following POST request to delete the items returned by the search that you created in Step 2. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches/{ediscoverySearchID}/purgeData` in the address bar of the request query, where *{ediscoveryCaseID}* and *{ediscoverySearchID}* are the IDs that you obtained in the previous procedures.

If the POST request is successful, an HTTP response code is displayed in a green banner stating that the request was accepted.

For more information about purgeData, see sourceCollection: purgeData.

Delete chat messages with PowerShell

You can also delete chat messages by using PowerShell. For example, to delete messages in the US Government cloud, you can use a command similar to the following example:

PowerShell

```
Connect-MgGraph -Scopes "ediscovery.ReadWrite.All" -Environment USGov
```

PowerShell

```
Invoke-MgGraphRequest  -Method POST -Uri
'/v1.0/security/cases/ediscoveryCases/<ediscoverySearchID>/searches/<search
ID>/purgeData'
```

For more information about using PowerShell to delete chat messages, see ediscoverySearch: purgeData.

Step 6: Verify chat messages are deleted

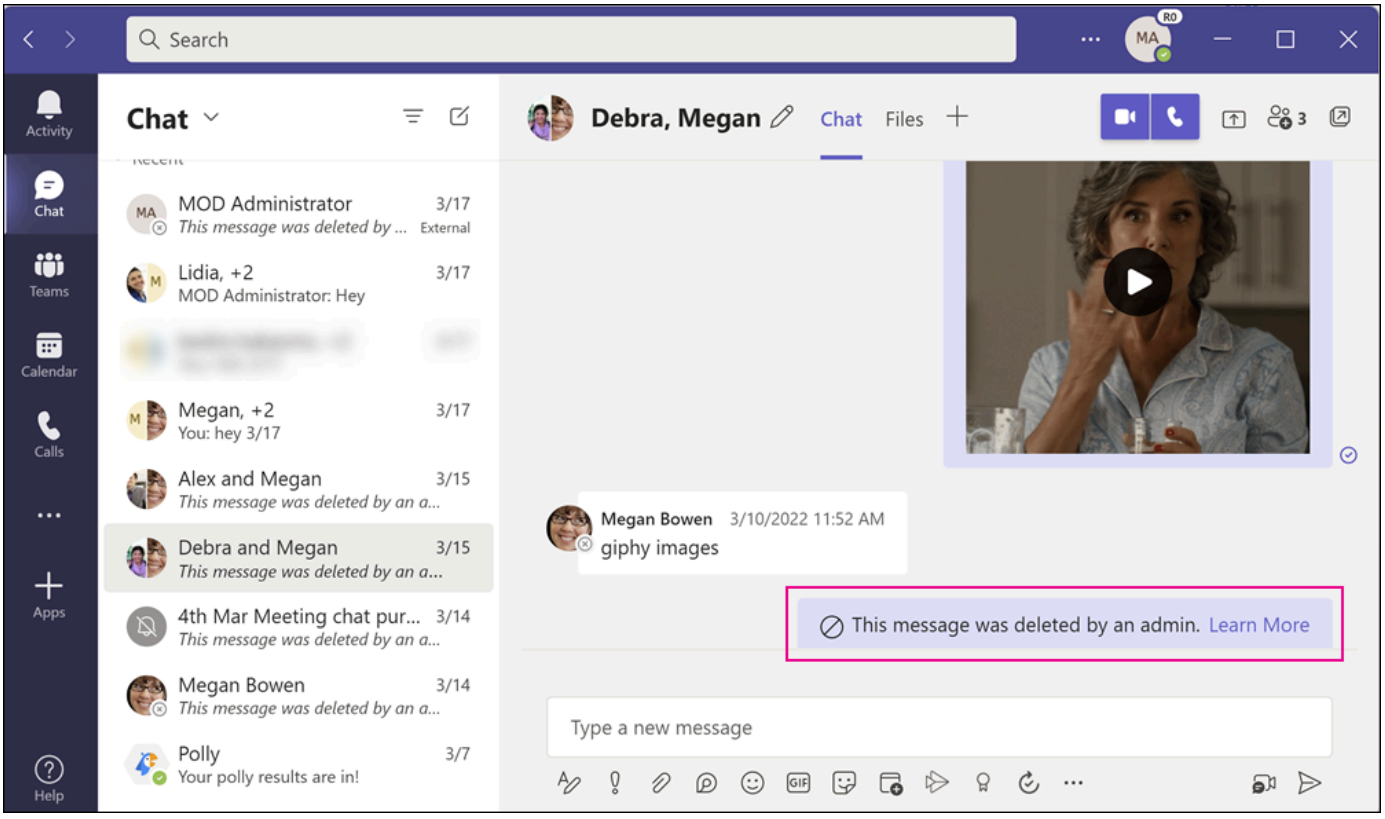
When you run the POST request to delete chat messages, the Teams client removes these messages and replaces them with an automatically generated message stating that an admin removed the message. For an example of this message, see the User experience section in this article.

If you need to confirm a chat message is removed but don't have access to the user message in Teams, rerun the search and check if any matching messages appear. If there aren't any results for the message, the message is removed.

When you issue a purge:

- The **user copy** of the message is deleted immediately and can't be recovered by the user.
- The **compliance copy** (stored in the mailbox's *SubstrateHolds* folder) is retained for at least 24 hours before permanent deletion by a background timer job (typically within 1–7 days). If a hold is removed and then re-applied within that 24-hour window, the compliance copy might be preserved by the new hold.

For more information, see Learn about retention for Microsoft Teams.



> **Note**
>
> Because Microsoft Graph Explorer isn't available in the US Government cloud (GCC, GCC High, and DOD), you must use PowerShell to accomplish these tasks.

Step 7: Reapply holds and retention policies to data sources

After you verify that chat messages are deleted and removed from the Teams client, reapply the holds and retention policies that you removed in Step 4.

User experience after Teams chat messages are deleted

For deleted chat messages, users see an automatically generated message stating *This message was deleted by an admin*.

The message in the previous screenshot replaces the chat message that was deleted.

> **Note**

If you're a user and a chat message was deleted, contact your admin for more information.

Search for and delete AI application data in eDiscovery

You can use eDiscovery and the Microsoft Graph Explorer to search for and delete user prompts and Microsoft Copilot and other AI solutions in supported applications and services. This feature can help you find and remove sensitive information or inappropriate content included in Copilot and other AI application activities. The eDiscovery search-and-deletion workflow described in this article can also help you respond to a data spillage event, when content containing confidential or malicious information is released through AI-related activity.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you search and delete AI data

- To create an eDiscovery case and search for AI activity data, you need to be a member of the *eDiscovery Manager* role group. To delete AI activity data, you need to be assigned the *Search And Purge* role. The *Data Investigator* and *Organization Management* role groups have this role by default. For more information, see Assign eDiscovery permissions.
- You can remove up to 10 items per mailbox at one time. Because the search-and-removal capability is intended to be an event-response tool, the 10-item-per-mailbox limit helps ensure that AI activity data is removed quickly.

Step 1: Create a case in eDiscovery

To begin the search-and-deletion workflow, create an eDiscovery case to manage the process.

Step 2: Create a search in eDiscovery

After you create a case, create an eDiscovery search for the AI application data that you want to delete. The deletion process you perform in Step 5 deletes all AI-related items that are found in the search (within the 10 item per location limit).

Data sources for AI data

The following table lists the application and service sources for Copilot and other AI data. All user prompts and responses from AI applications are stored in a user's mailbox.

Expand table

For this type of Microsoft Copilot or other AI data...	Search this item class...
Microsoft Foundry	`IPM.SkypeTeams.Message.ConnectedAIApp.AzureAI.<AzureResourceName>`

Word	`IPM.SkypeTeams.Message.Copilot.Word`

> **Note**
>
> In step 4, you also need to identify and remove any holds and retention policies assigned to the mailbox that contains the type of Copilot or AI application data that you want to delete.

Tips for searching for Copilot and other AI data

To collect the most comprehensive set of AI data, use the *Item class* condition and select the **Copilot activity** option when you build the eDiscovery search query for this deletion workflow. This condition includes all Copilot and other AI application data. Add a date range or several keywords to narrow the scope of the search to items relevant to your search and delete investigation.

For Copilot memory data, consider the following when working in eDiscovery:

- Inferred memories can be deleted along with other mailbox items using Microsoft Graph.
- Copilot memories are stored as the *IPM.Contact* item class and they match as contacts in the eDiscovery condition builder.

- Deleting a conversation or message from Microsoft Purview or eDiscovery doesn't delete the associated Copilot memory.

How Copilot interactions appear in eDiscovery results

Each Microsoft 365 Copilot interaction is stored in the user's Exchange Online mailbox as an individual message-class item (see the Data sources for AI data table). When these items appear in eDiscovery search results, review sets, or exports (PST files, individual messages, or Microsoft Graph), the email-style headers reflect the two participants of the interaction:

Expand table

Interaction direction	`From`	`To`
User prompt to Copilot	The user's primary SMTP address	The Copilot application identity (for example, `Microsoft 365 Chat`, `Microsoft 365 Copilot Chat`, `WebChat`)
Copilot response to the user	The Copilot application identity	The user's primary SMTP address

The Copilot application identity is the service-principal display name of the Copilot app that handled the interaction. For example:

- **Microsoft 365 Chat** for Microsoft 365 Copilot Chat (BizChat) interactions.
- The **host app name** for in-app Copilot in Word, Excel, PowerPoint, Outlook, OneNote, Loop, and Teams.
- **WebChat** for browser-based Copilot WebChat interactions.

This identity isn't a routable mailbox and can't receive mail; it identifies the Copilot application that participated in the interaction. This representation is by design and is consistent across all tenants and across commercial and US Government clouds.

Step 3: Review and verify Copilot and other AI data to delete in eDiscovery

The deletion process in Step 5 deletes the items returned by the search. Review the search results to ensure that the search only returns the items that you want to delete.

You can use the search statistics (specifically the *Top Locations* statistics) to generate a list of the data sources that contain items returned by the search. Use the list of mailboxes from the Top

Locations statistics to remove hold and retention policies from the user mailboxes that contain search results.

Step 4: Remove holds and retention policies from data sources

Before you can delete Copilot or other AI application data from a mailbox, you have to remove any hold or retention policy that is assigned to a target mailbox. If you don't remove the hold or retention policy, the data you're trying to delete is retained.

Use the list of mailboxes that contain the Copilot and AI data that you want to delete to determine if there's a hold or retention policy assigned to those mailboxes, and then remove the hold or retention policy. Record each hold or retention policy that you remove so that you can reapply that policy to the affected mailboxes after the deletion is complete.

Step 5: Delete Copilot and other AI data in Microsoft Graph Explorer

> **Note**
>
> Because Microsoft Graph Explorer isn't available in some US Government clouds (GCC High and DOD), you must use PowerShell to accomplish these tasks. For more information, see Delete Copilot and other AI data with PowerShell.

Now you're ready to delete Copilot and other AI data from user mailboxes. Use Microsoft Graph Explorer to perform the following three tasks:

1. Get the ID of the eDiscovery case that you created in Step 1. This case contains the search created in Step 2.
2. Get the ID of the search that you created in Step 2 and verified the search results in Step 3. The query in the selected eDiscovery search returns the AI activity data to delete.
3. Delete the data returned by the search.

For information about using Graph Explorer, see Use Graph Explorer to try Microsoft Graph APIs.

> **Important**

To perform these three tasks in Graph Explorer, you might have to consent to the eDiscovery.Read.All and eDiscovery.ReadWrite.All permissions. For more information, see the "Consent to permissions" section in Working with Graph Explorer.

Get the case ID in Microsoft Graph Explorer

Perform the following steps to retrieve the eDiscovery case ID in Graph Explorer:

1. Go to https://developer.microsoft.com/graph/graph-explorer and sign in to Graph Explorer with an account that's assigned the *Search And Purge* role in the Microsoft Purview portal.
2. Run the following GET request to retrieve the ID for the eDiscovery case. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases` in the address bar of the request query. Be sure to select **v1.0** in the API version dropdown list. This request returns information about all cases in your organization on the **Response preview** tab.
3. Scroll through the response to locate the eDiscovery case. Use the **displayName** property to identify the case.
4. Copy the corresponding ID (or copy and paste it to a text file). Save the eDiscovery case ID; you need it in the procedure for retrieving the search ID.

> **Tip**
>
> Instead of using Graph Explorer to obtain the case ID, you can open the case in the Microsoft Purview portal and copy the case ID from the URL.

Get the eDiscoverySearchID in Microsoft Graph Explorer

Perform the following steps to retrieve the eDiscovery search ID in Graph Explorer:

1. In Graph Explorer, run the following GET request to retrieve the ID for the search that you created in Step 2, and contains the items you want to delete. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches` in the address bar of the request query, where *{ediscoveryCaseID}* is the CaseID that you obtained in the previous procedure.
2. Scroll through the response to locate the search that contains the items that you want to delete. Use the *displayName* property to identify the search that you created in Step 3. In the response, the search query from the search is displayed in the *contentQuery* property. The items returned by the selected search query are deleted in the purge request described in the following procedure.

3. Copy the corresponding ID (or copy and paste it to a text file). Save the eDiscovery search ID; you need it in the purge request to delete Copilot and other AI application data.

> **Tip**
>
> Instead of using Graph Explorer to obtain the search ID, you can open the case in the Microsoft Purview portal. Open the case and go to the Jobs tab. Select the relevant search and under Support information, find the job ID (the job ID displayed here's the same as the search ID).

Delete Copilot and other AI data in Microsoft Graph Explorer

Perform the following step to purge the items returned by the search:

1. In Graph Explorer, run the following POST request to delete the items returned by the search that you created in Step 2. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches/{ediscoverySearchID}/purgeData` in the address bar of the request query, where *{ediscoveryCaseID}* and *{ediscoverySearchID}* are the IDs that you obtained in the previous procedures.

   If the purgeData POST request is successful, Graph Explorer displays an HTTP response code in a green banner stating that the request was accepted.

For more information about purgeData, see sourceCollection: purgeData.

Delete Copilot and other AI data with PowerShell

> **Note**
>
> Because Microsoft Graph Explorer isn't available in the US Government cloud (GCC, GCC High, and DOD), you must use PowerShell to accomplish these tasks.

You can also delete Copilot and other AI data with PowerShell. For example, to delete Copilot data in the US Government cloud, use a command similar to the following example:

PowerShell

```
Connect-MgGraph -Scopes "ediscovery.ReadWrite.All" -Environment USGov
```

PowerShell

```
Invoke-MgGraphRequest  -Method POST -Uri
'/v1.0/security/cases/ediscoveryCases/<ediscoverySearchID>/searches/<search
ID>/purgeData'
```

For more information about using PowerShell to delete Copilot and other AI data, see ediscoverySearch: purgeData.

Step 6: Verify Copilot and other AI data is deleted

After you run the purgeData POST request, Microsoft Purview removes the Copilot and other AI data returned by the search from the user's mailbox. The user doesn't receive any visible notification or confirmation that the data is deleted.

Deleted Copilot and other AI data moves to the *SubstrateHolds* folder, which is a hidden mailbox folder. Deleted data stays in the *SubstrateHolds* folder for at least one day. The next time the timer job runs (typically between 1-7 days), the timer job permanently deletes the data.

Step 7: Reapply holds and retention policies to user mailboxes

After you verify that the Copilot and other AI data is deleted, reapply the holds and retention policies to user mailboxes that you removed in Step 4.

Evaluate and refine search results in eDiscovery

Evaluating and refining your search results is an important step in your eDiscovery investigation. The search query you configure and the results that return help you determine if you discover items and information applicable to your investigation or if you need to modify your search to try to discover additional pertinent items. This initial search of items and initial review of information helps you determine what actions are required after you finalize your search parameters.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Evaluate search results

After you create and run a search, view the search statistics to help you verify whether relevant content is found and the content locations with the most hits. You can also review a sample of the search results to further help you determine if the content is within scope of your investigation.

Statistics dashboard

If you select **Statistics** as the initial result type for your search, the search automatically redirects you to this dashboard when the search results complete. If you're already familiar with previous versions of eDiscovery, the information on the **Statistics** tab is similar to collection estimates. The search results for the **Statistics** dashboard are included in the following sections:

- **Summary**: This section shows the number of search hits, locations, data sources, and the total file size of partially indexed items.
  - **Search hits**: Displays the total search hit count and volume from all items matching the query criteria from locations searched.
  - **Locations**: Displays the fraction of locations with hits out of all locations searched. The numerator shows the locations with hits and denominator shows the number of locations searched. Locations with errors are shown in red. To view full details on all the locations and associated hits and errors, select **Download report** to download the full .csv report.

Note that the displayed location count in this card might be different from the number of rows in locations CSV report. If multiple mailboxes share the same SMTP address, the location report might show several rows. This situation occurs because a single SMTP address might include different mailbox subtypes, such as primary, system, or archive. The row count in the CSV location report might exceed the count shown on the location card in the **Statistics** view. The **Statistics** view aggregates all mailboxes under the same SMTP address without distinguishing subtypes. For a more detailed breakdown of hits by sublocation, use the CSV report instead of the **Statistics** view. SharePoint and OneDrive locations can also have archive sites and are counted as separate locations in the report.

- **Retry failed locations**: This action is available when there are failed locations. *Retry failed locations* operation triggers a new search process targeting those locations with error and then aggregate the retried hit count with the original search process' hit count. After the retry process completes, the statistics view shows the new aggregated hit count.
- **Data sources**: Displays the fraction of data sources with hits out of all data sources searched. The numerator shows the data sources with hits and denominator shows the number of data sources included in the search. This data source is consistent with the data source in the search design flow and should match the number of people or groups included in the search. A tenant-wide data source of *All people and all groups* counts as a single data source.
- **Partially indexed items** or "Advanced indexed items hits": Displays the count and volume of partially and unindexed items returned as part of the search. This card displays partially indexed items information if you choose to include partially or unindexed items as part of the search configuration. If you choose to include partially and unindexed items and enable advanced indexing options, this card displays additional hits you get from advanced indexed items. The advanced indexed hit count is from a statistic sample on the partially indexed items, actual hits might be more and should be confirmed using the add to a review set and export search results actions. For more information, see Assess partially indexed items in your organization.

- **Search hit trends**: This section shows the following search result cards. The charts are interactive, hover to display section names, percentages, and item numbers. Select **View top 100** for more information about items included in each trend and to download the results to a .csv file:

  - **Top data sources**: Displays the top five data sources that make up the most search hits matching your query. The name of these data sources (names of users, groups, or organization-wide locations) are listed with the hit count. These data sources should match what you selected in the data sources workflow when building the search query.

- **Top sensitive information types (SITs)**: Displays the top five sensitive information types (SITs) in SharePoint files that are most often included in the search hits matching your query. Adding each SIT's count doesn't necessarily equate to the total count hits because a single item or document might contain more than one SIT type. For example, a document contains both a password and social security number (SSN). In this example, it's counted twice. Select **View top 100** to get a deeper understanding of the locations of these SIT counts to verify if they overlap or not.

- **Top keywords**: Query keywords, which resulted in the most search hits matching your query.

  > ⓘ Note
  >
  > To generate a keyword report in the statistics view, you must populate at least two or more keyword grids. If you enter only a single keyword, the total hit count shown reflects the results for that one keyword, and a keyword report isn't generated.

- **Top items types**: Most frequent item types within search hits matching your query. This count is determined by *itemClass* for Exchange content and *ContentType* for SharePoint content.

- **Indexing status**: Breakdown of unindexed (including partially indexed) and fully indexed data items.

- **Top communication participants**: Senders or recipients for emails, Microsoft Teams chats, and calendar invites in Exchange locations.

- **Top location type**: Hit count by location type (mailbox versus site).

Select **Regenerate view** to rerun the query and to review the most current results. Select **Download report** to combine all **Statistics** results into a single .csv file. When viewing the top 100 results for any trend area, select **Download report** for a .csv file of the top 100 results of the selected hit trend.

> ⓘ Note
>
> Search statistics expire after 14 days. Re-run search statistics for any searches older than 14 days to view current statistics.

Running the **Generate statistics** process is also required to enable sampling options when adding search results to a review set.

Understanding statistics and search results

> **Tip**
>
> For more information about how to use process report CSVs (Summary.csv, Locations.csv, Settings.csv) to investigate count differences, see **Process reports in eDiscovery**.

Depending on when you run a search in eDiscovery, the statistics for the search can show different results. For example, if you run two searches with the exact same conditions but at different times, you likely see different statistics results. These differences might occur for the following reasons:

- **Your organization is active**: Because you have active users in a production environment, data in your organization is constantly moved, added, deleted, and retired. The same search conditions run against the same locations likely return different search results because the data in those locations changed between the time you ran the searches.
- **Transient errors**: When you run a search (or export or add to a review set), transient processing errors might occur, especially for large sets of data. These errors often happen because of processing timeouts and can be mitigated by breaking up searches into smaller date ranges and exporting the data in parallel. Always try to break up searches into smaller sizes with more specific search conditions and more targeted with selected locations. This approach helps the process run more efficiently with less chance of errors.
- **Location access**: Some scenarios cause locations included in a search to be invalid, not accessible, or time out during processing. When you compare the results between two searches with the same conditions, make sure the locations you searched successfully match. For example, a search against 1,000 locations might have one failed location in the first run and no failed locations in the second run. This example means the first run searched only 999 locations successfully and the second run searched 1,000 locations. The difference of one location is the reason why search results between two runs are different. Use the *locations.csv* report for search, export, and add to review set processes to view a comprehensive report on what locations were successful and what locations failed. Rerun searches for any failed locations.
- **User running the search**: Depending on the user starting the search process, the user might or might not have the compliance boundary or compliance search filter applied. This filter either filters locations based on mailbox properties or filters content based on content path

(SharePoint sites). The results for the user might be limited if a compliance boundary or search permission filter is applied. For example, one user doesn't have a compliance boundary applied but a second user has a compliance boundary applied that restricts this user to user mailboxes and OneDrive sites to a specific region. A search by the first user returns all mailbox and OneDrive matches for the search conditions for all regions and a search for the second user returns only matches for mailboxes and OneDrive sites only for the allowed region.

- **Search results counts might vary across searches because of legal holds**: If you run the same search query at different times, the number of items in the search or export might differ. This difference can happen when items are edited or deleted between searches. For example, items under legal hold retain previous versions and might appear in later exports, while items not on hold might change or be removed if they no longer meet the hold criteria.
- **Search statistics are estimates**: Don't use these estimates to compare to OneDrive and SharePoint site storage. Estimates use index-based approximations, so the estimated eDiscovery content size can differ. Site storage often includes data not reflected in eDiscovery estimates, such as file versions and items in the Recycle Bin. For a view of site content, use the export process rather than the statistics dashboard size estimation.

Sample dashboard

If you select **Sample** as the initial result type for your search, you're automatically redirected to this dashboard when the search results complete. The search results for the **Sample** dashboard columns contain the following information for each item:

- **Subject/Title**: The subject or title of the items included in the sample.
- **Date**: The date the item was created or sent.
- **Sender/Author**: The sender or author of the item.

Samples let you inspect a representative subset of individual items and details for each item returned for the search. The number of samples per location and the number of sample locations defined in the search determine the number of sample items and location representation in the sample items.

Select a sample item to view the Source information for the item. If available for the item, this view displays a rich view of a selected item so that you can evaluate the relevancy of the item as it relates to the defined search data source and conditions.

> ⓘ **Note**

Sample items you generate are valid for 24 hours. If you generated the view more than 24 hours ago, regenerate the view to retrieve the latest samples matching your search query.

Select **Regenerate view** to rerun the query and review the most current results. Select **Download reports** to combine all **Sample** results into a single .csv file. Select **View settings** to view the settings applied to the sample view generation.

Refine search results

Based on the estimates and statistics that the search returns, you can edit and refine the search. Change the data sources that the search includes and change the search query to expand or narrow the search. You can update and run the search again until you're confident that the search results contain the content that's most relevant to your case.

After you're satisfied with the search results, you can take the following actions:

- Add search results to a review set
- Export the search results
- Create a hold

Before you open a support ticket about unexpected search results

If your search returns **zero results, fewer results than expected, or items you weren't expecting**, work through this checklist before opening a ticket. Most `RFC` (request for clarification) tickets filed against eDiscovery search are resolved by one of the items in the following list.

Expand table

#	Check	Where to verify
1	**Hold vs. search confusion**: A hold preserves content but doesn't surface it in search results until you run a search across the held locations.	Create holds in eDiscovery
2	**Indexing lag**: Newly ingested or recently modified items can take time to appear in the index. Re-run the search after the lag window.	Limits in eDiscovery — Indexing limits
3	**Partially indexed items**: Encrypted, oversized, or unsupported-format items aren't returned by content queries. You must export them separately as partially indexed items.	Partially indexed items in eDiscovery
4	**Location scope**: Confirm you add every relevant mailbox, site, group, and Teams location as a data source to the search. Add inactive	Data sources in eDiscovery

#	Check	Where to verify
	mailboxes and group members explicitly.	
5	**RBAC and permission filters**: Search permission filters and case-level RBAC silently scope results to what the searcher is entitled to see - even when running the search as an admin.	Search permission filtering and Assign permissions in eDiscovery
6	**Region or sovereign cloud**: Confirm the data source is in the same Microsoft 365 cloud and region as the case. You can't search cross-boundary data from the wrong cloud.	Compliance boundaries in eDiscovery
7	**Recipient expansion behavior**: Departed users whose Microsoft Entra ID object was deleted aren't expanded. You must add their historical SMTP addresses, aliases, and display names manually.	Recipient expansion
8	**Recent service changes**: Check the Microsoft 365 Message Center for service changes (for example, security-filter or Teams-private-channel changes) that affect search scope or results.	Microsoft 365 admin center → Message center

If you complete all eight checks and the result is still unexpected, capture the exact KeyQL of the search, the case ID, the data sources selected, and the run timestamp before opening a ticket. Support's first request is always for these four items.

Differences between statistics and export results

> **Tip**
>
> For guidance on interpreting the Summary.csv and Locations.csv reports that explain count differences for a specific process, see **Interpret count differences between search and export**.

When you run an eDiscovery search, the statistics return an estimate of the number of items (and their total size) that match the search criteria. However, the size and number of actual exported search results that you download differ from the estimated size and number of search results.

Several potential reasons explain these differences:

- **The way results are estimated**: The estimate provides an estimate (and not an actual count) of the items that meet the search query criteria. To compile the estimate of Exchange items, eDiscovery requests from the Exchange database a list of the message IDs that meet the search criteria. But when you export the search results, the search reruns and the actual

messages are retrieved from the Exchange database. Differences might result because of how the estimated number of items and the actual number of items are determined.

- **The way size of results is estimated**: During the estimate, size is approximated. The system gathers large numbers of items and sums the sizes up using approximations. You should consider the size estimate as an order of magnitude, not a specific measure of size. For example, a size estimate of 10 MB indicates the data is expected to be between 1 MB and 100 MB. The larger the number, the more variance there is in the estimate.
  - For Exchange-based content, file size is the size of the text in the message and attachment bytes. When exported, the format is converted to .msg and added to .pst or .zip files. Both these operations can significantly impact size.
  - For SharePoint-based content, the file size is approximate bytes of the file. In many cases for SharePoint-based data, file size can't be estimated during search.

- **Changes that happen between the time when estimating and exporting search results**: When you export search results, the search restarts to collect the most recent items in the search index that meet the search criteria. It's possible additional items were created, sent, or received that meet the search criteria in the time between when the estimated search results were collected and when the search results were exported. It's also possible that items that were in the search index when the search results were estimated are no longer there because they're purged from the content location before the search results are exported. To mitigate this problem, specify a date range for an eDiscovery search or place a hold on content locations so that items are preserved and can't be purged.

  Other issues that can result in differences between estimated and exported search results include:

  - An increase in items when using a date query. This issue is typically caused by the following two things:
    - **Hold versioning in SharePoint**: If a document is deleted from a site that's on hold and document versioning is enabled, all versions of the deleted document are preserved.
    - **Calendar items**: Accept and reject messages and recurring meetings automatically continue creating new items in the background with old dates.

  - With holds, there can be cases where the same item is preserved in a user's primary mailbox and in their archive mailbox. This situation can happen when a user manually moves an item to their archive.

  - Although rare, even in the case when a hold is applied, maintenance of built-in calendar items (which aren't editable by the user, but are included in many search results) might

be removed from time to time. This periodic removal of calendar items results in fewer items that are exported.

- **Unindexed items**: Items that are unindexed for search can cause differences between estimated and actual search results. You can include unindexed items when you export the search results. If you include unindexed items when exporting search results, there might be more items that are exported. This difference causes a difference between the estimated and exported search results.

  When using search, you can include unindexed items when you export search results. The number of unindexed items returned by the search is listed on the statistics page. When you export search results, you can choose to include or not include unindexed items. How you configure these options might result in differences between estimated and the actual results exported.

- **Document versions in SharePoint and OneDrive**: When searching SharePoint sites and OneDrive accounts, multiple versions of a document aren't included in the count of estimated search results. But you have the option to include document versions when you export the search results. If you include document versions when exporting search results, the actual number (and total size) of the exported items increases.

- **SharePoint folders**: If folders in SharePoint match a search query, for example, searching by date, the search estimate includes a count of those folders with the last modified date range (but not the items in those folders). When you export the search results, you have the option to choose export items inside subfolders of a matched folder or only include items that match search query. This option can affect the number of exported items. If a folder is empty, then the number of actual search results exported is reduced by one item, because the actual folder isn't exported.

- **SharePoint lists**: If the name of a SharePoint list matches a search query, the search estimate includes a count of all the items in the list. When you export the search results, the list (and the list items) is exported as a single CSV file. You can choose export setting that include list attachments, the attachments are exported as separate documents, which might increase the number of items exported.

- **Raw file formats versus exported file formats**: For Exchange items, the estimated size of the search results is calculated by using the raw Exchange message sizes. However, email messages are exported in a PST file or as individual messages. Both of these export options use a different file format than raw Exchange messages, which results in the total exported file size being different than the estimated file size.

Export search results in eDiscovery

After you run a search associated with a Microsoft Purview eDiscovery (preview) case, you can export the search results. When you export search results, you download mailbox items in PST files or as individual messages. When you export content from SharePoint and OneDrive sites, you export copies of native Office documents and other documents. When you export items, you prepare the items for download depending on the export options that you define. You can monitor the export's progress and download the results from the **Process manager** page. Larger exports might take longer to complete.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

For more information about new eDiscovery export enhancements and the retirement of the Microsoft Office 365 eDiscovery Export Tool, check out the following video:

https://learn-video.azurefd.net/vod/player?id=0d7dc0af-30dc-410b-a405-66f919e92cd1&locale=en-us&embedUrl=%2Fpurview%2Fediscsearch-export

Export considerations

This section describes important considerations when exporting content from eDiscovery. These considerations include requirements, limitations, and behaviors that might affect how content is accessed, exported, or logged.

- Search export packages expire 14 days after you create the export. After 14 days, the export and all data contained in the export package are automatically deleted and can't be recovered. To retain the exported data, download the export packages before the 14-day expiry. This expiry applies only to search exports, not to review set exports.
- To export content in eDiscovery, assign the eDiscovery user a Microsoft 365 Enterprise E3 or E5 license. When exporting SharePoint content, the account must also have a Microsoft SharePoint E3 license; otherwise, SharePoint items might not export as expected.
- You can't export files that are restricted by DLP action in eDiscovery. These files can appear in search statistics results but are excluded from the export.

- You can't export content stored in SharePoint sites that are in a **Locked** state with **NoAccess**. When a site is locked, eDiscovery can't retrieve items from that site, and the content is skipped during export.
- You can't export individual files if they're restricted by SharePoint access controls. To export restricted files, the collecting user must have direct access to the content (for example, be a site admin, site owner, or the owner or last modifier of the document). Files that don't meet these access requirements might appear in search results but are excluded from export.
- When you add SharePoint items to a review set or export them from eDiscovery, a **FileAccessed** audit event might be recorded in the Microsoft 365 audit log. This event reflects that the eDiscovery service accessed the content to perform the requested operation.
- For large exports - especially tenant-wide search exports that target a large number of locations - running a **Generate statistics** process before exporting can significantly improve performance. When search statistics are available, eDiscovery uses those results to optimize the subsequent export process by limiting processing to only the locations that contain search hits, instead of reprocessing all locations in scope. This location optimization helps reduce process duration and improves reliability for large tenants. If the statistics process is outdated or the search query or data sources changed, eDiscovery processes all locations again to ensure accuracy. To confirm if your export has location optimization applied, refer to settings.csv of the export process report.

> **Note**
>
> Even if the **Generate statistics** process has errored locations, those locations are still included in the subsequent export process. If you retry the **Generate statistics** process, the subsequent export process doesn't have location optimization applied.

Enable CMK (Customer Managed Key) for direct exports (preview)

Organizations that configure Customer Key through the Microsoft 365 Data-at-Rest Encryption Platform (MDEP) with a Data Encryption Policy (DEP) in policy assigned status can extend CMK protections to eDiscovery direct export packages. When enabled, exported investigation data is encrypted at rest using tenant-specific encryption scopes backed by customer-managed keys.

The following prerequisites are required to enable CMK for direct exports:

- The CMK direct export feature is enabled for your organization. To enable this feature, contact Microsoft Support or your Customer Success Account Manager (CSAM) and request CMK for eDiscovery direct exports for your tenant.
- Your organization configured Azure Key Vault following the standard Customer Key setup process. For more information, see Set up Customer Key.
- A Data Encryption Policy (DEP) is in *PolicyAssigned* state via the Microsoft 365 Data-at-Rest Encryption Platform (MDEP) onboarding cmdlets.

> **Note**
>
> This encryption applies to direct exports only. Data at rest in an eDiscovery review set isn't included at this time. Your tenant must remain CMK enabled at the time of the export.

Export search results

> **Tip**
>
> Want an interactive configuration guide experience? Check out the **Export data** guide.

To export search results, complete the following steps:

> **Tip**
>
> Your download speeds might be slower if you don't configure *Enable export download via pre-authorized link* in **eDiscovery export settings**.

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, and then select **Cases**.
3. Select a case, select the **Searches** tab, and then select a search query to export.
4. In the search query, select **Export**.
5. On the **Export** pane, configure export options.
6. Enter a name for the export in **Export name**. This field is required.

7. In **Export description**, enter an optional description for the export.

8. In **Tenant-wide source configuration** options, configure the organization-wide source "All people and groups" to include one or more user or content types:

    - **"All people and groups" should include unlicensed and on-premises users**
    - **"All people and groups" should include guest users**
    - **"All people and groups" should include shared Teams channels**
    - **"All people and groups" should include departed users**

9. In the **Select items to include in your export**, select one of the following options:

    - *Indexed items that match your search query*: This option exports only the indexed items that matched the query.

    - *Indexed items that match your search query and partially indexed items that might not match query*: This option exports only the indexed items that matched the query and the partially indexed or unindexed items that might not completely match the query.

    - *Partially indexed items that might not match query*: This option exports only the partially indexed or unindexed items that might not completely match the query.

      For these options including partially indexed items, you can scope the partially indexed items further by selecting *Exclude partially indexed items in locations without search hits*. When you select this option, the export returns partially indexed items only from mailboxes and sites where the indexed search query already returned at least one match.

      > **ⓘ Important**
      >
      > This option scopes by **location** (a mailbox or a SharePoint or OneDrive site), not by Kusto Query Language (KQL) conditions. Partially indexed items aren't evaluated against your search query. If a location is responsive (has any indexed hit), every partially indexed item in that location is included, regardless of any path, URL, or property restriction in your query. If your scope is a single location, this option has no effect. For details and examples, see Locations and the "in locations without search hits" option.

      > **ⓘ Note**

Partially indexed item settings made on the original search are for statistics and preview only. The authoritative include/exclude decision is made at export time using the options on this dialog. See **Search-time and export-time settings are independent**.

To apply your KQL conditions to partially indexed items, also select *Perform advanced indexing on partially indexed items*. Advanced indexing re-indexes the items so your query restrictions evaluate against them. Learn more about advanced indexing in eDiscovery.

10. In the **OneDrive and SharePoint items** section, select from the following document options:

    - **Select document versions**: Specify how many versions of SharePoint documents to export. Values are *Latest version only*, *Recent 10 versions*, *Recent 100 versions*, *All versions*.
    - **Select folder items**: Export items inside subfolders of a matched folder. Choose *Only include items that match search query* or *All items in folder (even if they don't match search query)*.
    - **Select items in lists and attachments (list expansion)**: Export files attached to SharePoint lists and their child items. Choose *All items in SharePoint list if any item matches search query*. If applicable, select *Include list attachments*.

11. In the **Messages and related items from mailboxes and Exchange Online** section, select one or more of the following options:

    - **Organize conversation into HTML transcript**: Contextual chat messages are threaded into HTML transcripts for ease of review and handling.
    - **Include Teams and Viva Engage conversations**: Include messages posted within a 12-hour window before and after each responsive item.
    - **Access links (cloud attachments) in messages**: Collect items from links to SharePoint or OneDrive.

      Important

      Including **cloud attachments** increases the size and quantity of your exported results. Items that are encrypted don't have embedded entities extracted including attachments. To collect cloud attachments from Shared Channels in

Teams, the Shared Channel SharePoint site must be included in the search to include cloud attachments.

To improve export performance, reduce the size of the export by using date ranges or other types of filters to decrease the total size of the search results. If an export runs for more than seven days without completing, it automatically cancels. To prevent cancellation, divide exports into smaller batches.

When you search for emails or other mailbox content that might include cloud attachments, the cloud attachment link to a storage location in SharePoint or OneDrive is considered as attachments of the message file rather than separate documents.

This behavior is similar to how a search returns emails with embedded local attachments. These attachments are retrieved as if they're part of the emails. Any compliance boundaries for SharePoint or OneDrive aren't reflected in the collection of cloud attachments included in responsive messages.

Select a version for access links. Values are *Latest version only*, *Recent 10 versions*, *Recent 100 versions*, *All versions*.

> **Important**
>
> If you have versions as shared feature enabled, this option retrieves the version of the document when it was shared.

12. In the **Export type** section, choose one of the following options:

    - *Export items report only*: Only the summary and item report are created. The various options for organizing data, folder and path structure, condensing paths, and other structures are hidden.

> **Note**
>
> When you use the *Exporting items report only* option, all string fields in the CSV report are limited to the first 255 characters. This limitation might truncate some items with long compound paths. If you need the full details, use the *Export items with items report* option.

- *Export items with items report*: This option exports items with the item report. Other export format options are available with this option in the **Export format** section.

13. In the **Export format** section, choose one of the following options:

    - *Create PSTs for messages*: This option creates .pst files for messages.
    - *Create .msg files for messages*: This option creates .msg files for messages.

14. In the **Package size settings** section, configure the maximum export package size the export process creates.
    a. If you select *Create PSTs for messages* in the previous step, set the maximum PST package size to 1 GB, 2 GB, 5 GB (default), or 10 GB.
    b. Set the maximum .zip package size to 2 GB, 10 GB (default), 20 GB, or 40 GB. The maximum .zip package size needs to be the same or greater than the maximum PST package size to contain the PST files in .zip packages when downloaded.

15. Select one or more of the following output package options. For details about each option, see Export package options.

    - *Organize data from different locations into separate folders or PSTs*: This option organizes data into separate folders for each data location. When exporting mailbox content, even if you select this export option, items from the primary mailbox and any associated archive mailboxes (including multiple archives) merge into a single PST file.
    - *Include folder and path of the source*: This option includes the original folder and folder path structure for items.
    - *Condense paths to fit within 256 characters*: This option condenses the folder path for each item to 256 characters or less.
    - *Give each item a friendly name*: This option creates a friendly name for each item.

16. Select **Export**.

17. When the export process starts, a confirmation dialog appears. Select **OK** to continue.

For more information about export file types and item.csv report fields, see Document metadata fields in eDiscovery.

Export package options

The export package options control how the system packages content in downloadable export packages. Depending on your needs and the post-export process an eDiscovery user needs to perform, adjust these options.

Organize data from different locations into separate folders or PSTs

This setting controls whether the system groups exported content by its original source. This grouping includes specific mailboxes or specific OneDrive or SharePoint sites, or it combines these items into a single container.

> ⓘ **Note**
>
> Exchange mailboxes store data from many applications, not only email. Some of the data from these applications might be converted to HTML and exported into separate `Items.zip` files. For example, the system might convert data from Microsoft Forms, Sway, and other apps. The list of applications in this category is evolving. These applications generally store data in the `/ApplicationDataRoot/` folder within a mailbox.

For Exchange Mailbox items

- **Selected**: The system exports each mailbox's content into a separate PST file named after the mailbox (for example, *john.doe@contoso.com.pst*).
- **Not selected**: The system merges all mailbox content across the selected data sources into a single PST file (for example, *exchange.pst*), subject to the maximum PST size limit. If the combined data exceeds this limit, the system creates extra PST files.

For OneDrive and SharePoint items

- **Selected**: The system exports content into separate folders per site. Each folder is named after the site and the system places all files from that site in each folder to preserve site-level organization.
- **Not selected**: The system exports all content into a single folder regardless of the originating site. Use the items.csv to understand the original source location and other relevant metadata for the item.

Include folder and path of the source

This setting determines whether the export preserves the original folder structure from the source. The source is the folder where items reside in an Exchange mailbox or OneDrive and SharePoint site.

For Exchange Mailbox items

- **Selected**: The exported PST retains the full folder hierarchy from the mailbox. For example, if a message is located in *Inbox* > *Legal* > *Q2*, this exact path is preserved inside the PST. This structure helps reviewers understand the original context and organization of the content.
- **Not selected**: All messages go to the root of the PST file, with no folder structure retained. While the messages are still exported, the original location within the mailbox is lost in the content itself. To find the original path of the item, review the items.csv in process report.

In both cases, the export process creates one PST file per mailbox if you select the **Organize data from different locations into separate folders or PSTs** option. The **Include folder and path of the source** option only affects the internal folder structure within each PST.

For OneDrive and SharePoint items

- **Selected**: Files are exported with the full folder path preserved. For example, if a file is stored in *Department* > *Legal* > *Contracts* > *Proposal.docx*, the entire path is recreated in the export package for this file. This structure mirrors the original site structure in which the file resides.
- **Not selected**: All files from a site go directly into a single folder for that site, without any subfolders. For example, if a file is stored in *Department* > *Legal* > *Contracts* > *Proposal.docx*, the path is *SharePoint* > *Items* > *Proposal.docx*. This structure flattens the folder hierarchy and might mix files from different folders. To find the original folder structure of the item, review the items.csv in process report.

Condense paths to fit within 259 characters

This setting helps prevent unzipping errors caused by long file paths during export. This problem can happen when you export content from OneDrive and SharePoint sites where deeply nested items are inside many layers of folders.

OneDrive and SharePoint sites might have deeply nested folder structures and long file names. When you export content and select the option to preserve folder and path structure, the resulting file paths can exceed the Windows file system limit of 259 characters. This limit leads to the following error message when unzipping the export package:

```
The file name(s) would be too long for the destination folder. You can shorten the file name and try again.
```

To help avoid this issue, use this option as needed:

- **Selected**: The export process automatically truncates folder paths - by shortening folder names or collapsing intermediate folders - so that the total path length for each file stays within the 259-character limit. This setting helps ensure that you can unzip and access the export package without errors.
- **Not selected**: The export process preserves the full original folder path. While this setting maintains the most accurate representation of the source structure, it increases the risk of hitting the path length limit - especially for deeply nested OneDrive and SharePoint items.

> ⓘ **Note**
>
> Different unzip utilities handle long file names and folder paths differently. The built-in extraction tool in Windows File Explorer might fail if the file name or path exceeds its character limit. Other non-Microsoft tools support longer paths and can extract these files successfully.

Give each item a friendly name

This setting controls whether the export item uses its original friendly name or the unique GUID generated by eDiscovery.

For Exchange Mailbox items

> ⓘ **Note**
>
> This setting doesn't apply when exporting Exchange items to PST format. Regardless of whether you select this option, email messages in PST exports always retain the original subject lines for the message title within the PST file.

When exporting as a .msg file:

- **Selected**: Exported .msg file uses the subject of the email.
- **Not selected**: Exported .msg file uses a system-generated GUID.

For OneDrive and SharePoint items

- **Selected**: Files are exported using the original file names. For example, a file named *Q2_Budget_Plan.docx* in SharePoint is exported with the exact same name in the export package.

    - If multiple files have the same name and the folder structure isn't preserved (the Include folder and path of the source option isn't selected), this situation might lead to file name collisions in the export folder. If this happens, the suffix is appended to the collided file names to differentiate the files.

    - When exporting versions, friendly names include version suffixes to distinguish between versions of the file. For example, *Project Plan.docx*, *Project Plan_v1.docx*, and *Project Plan_v2.docx*.

- **Not selected**: Files are exported using system-generated identifiers. This approach ensures uniqueness and avoids naming conflicts. For example, *Project Plan.docx* might be named b7f3a9c2-4e1e-4c9a-9f3e-2a1d8e7f9c1a.docx in the export package. Use the items.csv in process report to correlate the original title and other relevant metadata for the file.

View the export process status

To view the progress of the export in the Process manager, select **Process manager** and the **Export** process. You can track the process status and download export packages.

The **Overview** tab shows a progress bar that displays the current status, number of locations, and number of items for the export. An estimated completion time and current elapsed time are displayed in hours, minutes, and seconds. The **Overview** tab also contains the following export information:

- **Name**: The name of the export.
- **Completed**: The UTC date and time the export process completed.
- **Duration**: The duration of the export process.
- **Status**: The current status of the export process.
- **Process type**: The *Export* process type value.
- **Created**: The UTC date and time the export was created.
- **Created by**: The user who created the export.

The **Settings** tab displays a summary of the export options you selected for the export process.

View completed exports from a search

To view a list and details about completed exports from a search, select the **Exports** tab in a case. Search exports expire 14 days after creation. You can't download expired exports. On the **Exports** tab, you see the following details for each export process:

- **Export name**: The name of the export.
- **Status**: The current status of the export process.
- **Review set name**: The name of the review set from which the export was created (when you create the export from a review set).
- **Search name**: The name of the search from which the export was created (when you create the export from a search).
- **Created**: The UTC date and time the export was created.
- **Completed**: The UTC date and time the export was completed.
- **Duration**: The duration of the export process.
- **Created by**: The user that created the export process.

To delete an export that you created from a search, complete the following steps:

> ⓘ **Important**
>
> Deleting an export removes the export and all data contained in the export package. This action doesn't delete data in the original location.

1. In a case, select the **Exports** tab.
2. Select a completed export from a previous search. You can't delete in progress exports.
3. Select the ellipsis by the export name, and then select **Delete**.
4. On the **Delete export** dialog, select **Yes**.

Export packages

> ⓘ **Important**
>
> The export package links that the eDiscovery export process generates are for individual use only. Don't share these links. The behavior of these links can change. They might become invalid or inaccessible if others use them or if they're accessed outside the context of the current user. If you need to share data from the portal, use guest accounts.

After the export process finishes, you can download export packages. You can download search export packages for 14 days from the export creation time. After 14 days, the export packages are automatically deleted. The **Export packages** section on the **Overview** tab lists the export packages and shows the package name and size. To download a package, select the package and select **Download packages**.

> **Tip**
>
> You can configure the **Microsoft Purview eDiscovery API** to enable the programmatic download of export packages and the reports from an export process in an eDiscovery case.

Best practices for downloading export packages

To ensure a smooth download experience, consider the following best practices:

- **Use a supported, up-to-date browser**: Use the latest version of Microsoft Edge for the best export download experience. Older browser versions can have issues with the download mechanism.
- **Allow pop-ups from Microsoft Purview**: The download process triggers a pop-up window. Make sure your browser is configured to allow pop-ups from the Microsoft Purview site. For example, see instructions on how to configure pop-ups on Microsoft Edge.
- **Check your browser's automatic download settings**: If the **Automatic Downloads** setting is configured to *Ask* or *Block*, it might prevent multiple files from downloading at the same time. For export package downloads, configure this setting to *Allow* or adjust permissions for the Microsoft Purview portal site. For the Microsoft Edge browser, go to **Settings** > **Privacy, search, and services** > **Site permissions** > **All permissions** > **Automatic downloads** and confirm that the site is **Allowed to automatically download multiple files**.
- **Set your preferred download location**: By default, export packages save to your browser's default download folder. If you want to choose where files are saved, update your browser settings to prompt for a download location each time. See instructions for changing the downloads folder location in Microsoft Edge.
- **Check your organization's network configuration**: Ensure that your organization allows downloads from Microsoft Purview by verifying that all required endpoints and IP addresses are allowlisted. This verification includes enabling access to the Microsoft Purview export service and associated Azure storage endpoints. If your organization uses network security tools such as Zscaler, Microsoft Defender for Endpoint (MDE), or other proxy or firewall solutions, make sure these tools are configured to allow traffic to the export endpoints. In some cases, you might need to isolate specific endpoints from third-party security scanning to prevent download interference. For optimal performance and to avoid download interruptions, consider using a local drive (not a network share), and test your connection

throughput to Azure endpoints. For detailed allowlist guidance, see Microsoft 365 URLs and IP address ranges.

- **Test on a different network if downloads are slow**: If downloads are slow or stalling, try downloading on a different network (for example, a home network or mobile hotspot). If performance improves, the corporate network is likely the bottleneck due to firewall scanning, VPN overhead, or proxy throttling.

- **Enable parallel downloading in your browser settings**: Use parallel downloading to improve download speeds for large eDiscovery export packages. For example, use `edge://flags` in Microsoft Edge. This feature can significantly reduce wait times by allowing simultaneous file chunk downloads. This setting is also available for other chromium-based browsers.

- **Use a download manager**: A download manager can improve the reliability and speed of large file downloads. A download manager allows you to resume interrupted downloads and manage network fluctuations, which is especially helpful when downloading large export packages.

- **Split very large exports**: For exports of tens of gigabytes or more, consider breaking the export into smaller parts by splitting searches by date range or data source. Smaller export packages download faster and are less likely to stall due to network interruptions.

- **Allow first-party and third-party cookies** for the download sites. These sites include the following depending on the global location of the tenant:
  - **APC**: apc.proxyservice.ediscovery.svc.cloud.microsoft
  - **NAM**: nam.proxyservice.ediscovery.svc.cloud.microsoft
  - **EUR**: eur.proxyservice.ediscovery.svc.cloud.microsoft
  - **GCC**: gccm.proxyservice.ediscovery.gcc.svc.cloud.microsoft
  - **GCCH**: gcch.proxyservice.ediscovery.svc.usgovcloud.microsoft
  - **DOD**: dod.proxyservice.ediscovery.svc.usgovcloud.microsoft

- **Unzipping export files**: Data is compressed into a .zip file for improved performance and reliability. Avoid using the built-in Windows .zip utility. Use 7-Zip, WinZip, or similar tools for the best experience.

- **Verify timestamps after extraction**: Microsoft Purview eDiscovery doesn't modify or rewrite timestamps. The export preserves the authoritative date and time metadata from source Microsoft 365 workloads such as Exchange, SharePoint, OneDrive, and Microsoft Teams. When exporting content, these original timestamps are preserved in the export metadata

and within the native file formats. However, local ZIP extraction tools may modify certain file properties. Use the Items.csv report or internal file metadata to confirm original timestamp values.

- Disable **Tracking prevention for this site**: If enabled, it blocks downloads and should be turned off.

Add search results to a review set in eDiscovery

When you're satisfied with the results of a search and ready to review and analyze the results, add them to a review set in the case. You can add all search results or configure sampling to add a statistically representative subset based on confidence or percentage. Copying the original data to the review set also facilitates the review and analysis process by providing you with advanced analytics tools such as themes detection, near-duplicate detection, and email thread identification.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Create or add results to a review set

> **Tip**
>
> Want an interactive configuration guide experience? Check out the Create and manage review sets guide.

When you add the results of a search to a review set (the review sets in a case are listed on the **Review sets** tab), the following things occur:

- The search runs again. This step means the actual search results you copy to the review set might be different from the estimated results that the search returned.
- All items in the search results are copied from the original data source in the live services to a secure Azure Storage location in the Microsoft cloud.
- All items (including the content and metadata) are reindexed so that all data in the review set is fully searchable during the review of the case data. Reindexing the data results in thorough and fast searches when you search the data in the review set during the case investigation.
- A file encrypted with a Microsoft encryption technology and attached to an email message that's returned in the search results is decrypted when the email message and attached file

are added to the review set. You can review and query the decrypted file in the review set. You must be assigned the *RMS Decrypt* role to add decrypted email attachments to a review set. For more information, see Decryption in Microsoft Purview eDiscovery tools.

When you add content to a review set, the items and their metadata are copied to a Microsoft-managed Azure Storage location dedicated to the case.

Expand table

Question	Answer
Is review set content stored in Microsoft-managed Azure Storage?	Yes. The storage is Microsoft-owned and Microsoft-managed. Customers don't see, manage, or pay for these storage resources directly.
Is storage provisioned per review set?	No. Storage is provisioned **per case**. Multiple review sets within the same case share the underlying case storage, with logical separation so each review set's content remains independently queryable, taggable, and exportable.
How are different tenants and cases isolated?	Each case is isolated from other cases and other tenants at the storage boundary. Tenant separation is enforced by the service.
What region hosts the storage?	The storage is provisioned in the region that matches the case's geo, consistent with Microsoft 365 data residency commitments.
Does Customer Key apply to review set content?	Yes. If your tenant is configured with Customer Key, review set content at rest is encrypted with the customer-managed key.
Can customers access the storage directly?	No. There's no customer-accessible SAS token, account key, or storage URL for review set content. Access to review set content is only through the Microsoft Purview portal and approved export workflows.

If the search you're adding to review set is tenant wide or contains large number of data sources, running a **Generate statistics** process before adding to review set can significantly improve performance. When search statistics are available, eDiscovery uses the search statistics to optimize subsequent Add to review set process by limiting processing to only the locations that contain search hits, instead of reprocessing all locations in scope. This location optimization helps reduce process duration and improves reliability for large tenants. If the **Generate statistics** process is outdated or the search query or data sources have changed, eDiscovery processes all locations again to ensure accuracy. To confirm if your Add to review set process has location optimization applied, refer to settings.csv of the Add to review set process report. Additionally, completing the **Generate statistics** process is required to enable sampling options when adding search results to a review set.

> **Note**
>
> Even if the **Generate statistics** process has errored locations, those locations are still included in subsequent Add to review set process. If the **Generate statistics** process is retried, the subsequent Add to review set process doesn't have location optimization applied.

To add data to a review set, complete the following steps:

1. Select a search on the **Searches** tab, and then select **Add to review set**.
2. On the **Add items to review set** flyout, select **Add to a new review set** or **Add to an existing review set**.

   For a new review set, enter a name for the review set. To add data to an existing review set, select a review set from the drop-down choices.

   Adding data to a review set is a long-running process that includes gathering items from the original data sources in Microsoft 365 (for example, from mailboxes and sites), copying them to the Azure Storage location (this copying process is also called *ingestion*), and then reindexing the items. You can track the progress on the **Process manager** page. After the review set processing completes, select the **Review sets** tab in the case, then select the review set to start the process of filtering, reviewing, tagging, and exporting data in the review set.
3. In the **Select items to add to review set** section, choose one of the following options:

   - *Indexed items that match your search query*: This option exports only the indexed items that matched the query.
   - *Indexed items that match your search query and partially indexed items that might not match query*: This option exports only the indexed items that matched the query and the partially indexed or unindexed items that might not completely match the query.
   - *Partially indexed items that might not match query*: This option exports only the partially indexed or unindexed items that might not completely match the query.

   Scope the partially indexed items further by selecting *Exclude partially indexed items in locations without search hits*. With this option selected, only partially indexed items from location where there's already an indexed hit are returned. Additionally, user also has the option to *perform advanced indexing on partially indexed items*. For more information about advanced indexing, see Learn more about advanced indexing in eDiscovery.

4. In the **Configure sampling** section, choose one of the following options to control how many items are added to the review set. Sampling options are only available after you complete the **Generate statistics** process on the search. If statistics haven't been generated, are outdated, or the query or data sources changed since statistics were last run, sampling options are disabled and only the **Add all search results** option is available.

    - **Add all search results to review set** (default): Commits every item that matches the search query to the review set.
    - **Add samples to review set based on confidence**: Commits a statistically derived sample based on a **Confidence level** and **Confidence interval**. The confidence level (default: 95%) is the probability that your sample reflects the characteristics of the entire search result population. The confidence interval (default: 5%) is the range within which the true value is expected to fall. Higher confidence and tighter intervals produce larger samples.
    - **Add samples to review set based on percentage**: Commits a specified percentage of the total estimated items. Enter a value between 1 and 99 in the **Sample size** field (default: 50%). For example, if the search estimates 2,000 items and you select 50%, approximately 1,000 items are added to the review set.

    The actual number of items added to a review set may differ slightly from the calculated sample size. During the add-to-review-set process, items undergo expansion and extraction, which can result in minor variances between the expected and actual item counts.

5. In the **What to include for files from ODSP sites?** section, complete the following options:

    - **Select document versions**: Specify how many versions of SharePoint documents to collect. Choose from *Latest version only*, *Recent 10 versions*, *Recent 100 versions*, or *All versions*.
    - **Select folder items**: Choose one of following options to collect items inside subfolders of a matched folder:
        - **Only include items that matches query**
        - **Include all items in folder even if they don't match query**
    - **Select items in lists and attachments (list expansion)**: Choose of the following to collect files attached to SharePoint lists and their child items.
        - **Include all items in SharePoint if any item matches the query**
        - If applicable, select the **Include attachments of lists** checkbox.
    - **Convert supported file formats to HTML**: Select this option to convert supported cloud-native file formats, such as `.loop` and `.page` files (used by Copilot Notebook and Page content), to HTML when adding items to the review set. Converted content is

indexed and available for keyword search in the review set, making it easier to review and analyze. This option isn't selected by default.

6. In the **What to include for messages and related items from Mailboxes?** section, select the following options as applicable:

   - **Organize conversation into HTML transcript**: Contextual chat messages are threaded into HTML transcript of ease of review/handling.
   - **Include Teams and Viva Engage conversations**: Collect up to 12 hours of related conversations when a message matches a search.
   - **Access links (cloud attachments) in messages**: Collect items from links to SharePoint or OneDrive. Choose from *Latest version only*, *Recent 10 versions*, *Recent 100 versions*, or *All versions*.

     When you search for emails or other mailbox content that might include cloud attachments, the cloud attachment link to a storage location in SharePoint or OneDrive is considered as an attachment of the message file rather than separate documents.

     Treating cloud attachment links as message attachments is similar to how a search returns emails with embedded local attachments. These attachments are retrieved as if they're part of the emails. Any compliance boundaries for SharePoint or OneDrive aren't reflected in the collection of cloud attachments included in responsive messages.

     > **ⓘ Important**
     >
     > Items that are encrypted aren't supported for embedded entity extractions for example attachments. To collect cloud attachments from Shared Channels in Teams,the Shared Channel SharePoint site must be included in the search scope.

7. In **Tenant-wide source configuration** options, configure the organization-wide source **All people and groups** to include one or more user or content types:

   - **All people and groups** should include unlicensed and on-premises users
   - **All people and groups** should include guest users
   - **All people and groups** should include shared Teams channels
   - **All people and groups** should include departed users

8. Review your selections for the review set, and then select **Add to review set**. To cancel, select **Cancel**.

Optical character recognition

When you add search results to a review set, eDiscovery's optical character recognition (OCR) functionality automatically extracts text from images. It includes the image text with the data that it adds to a review set. You can view the extracted text in the Text viewer of the selected image file in the review set. This extracted text is then searchable within the review set. This feature lets you conduct further review and analysis on text in images. OCR supports loose files, email attachments, and embedded images. For a list of image file formats that support OCR, see Supported file types in eDiscovery.

> **Important**
>
> Microsoft Purview eDiscovery OCR extracts text from images only when content is added to a review set, it doesn't make images searchable during the search phase. To find image-based content, first search broadly then use OCR text in the review set. OCR in eDiscovery is separate from the tenant-level Microsoft Purview OCR setting (used by DLP, Insider Risk Management, and Retention). Enabling tenant-level OCR doesn't **enable eDiscovery OCR**. For more information about tenant-level OCR, see **Learn about OCR in Microsoft Purview**.

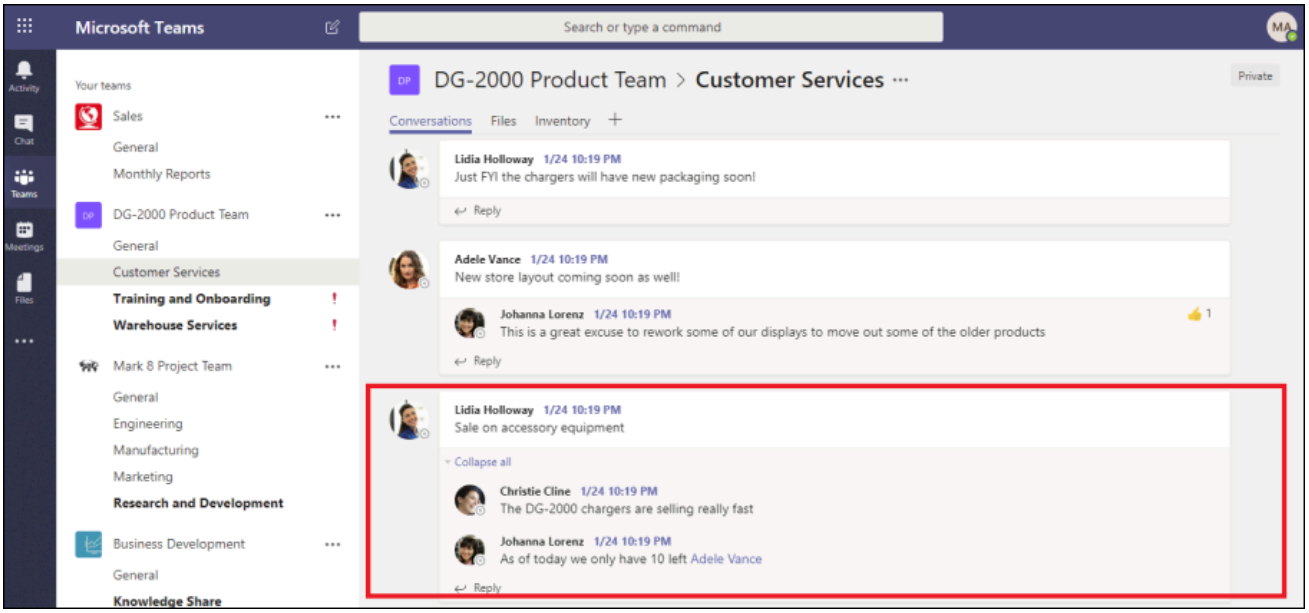
You need to enable OCR functionality for each case that you create in eDiscovery. For more information, see Configure search and analytics settings.

Conversation threading

Instant messaging is a convenient way to ask questions, share ideas, or quickly communicate across large audiences. As instant messaging platforms, like Microsoft Teams and Viva Engage groups, become core to enterprise collaboration, organizations must evaluate how their eDiscovery workflow addresses these new forms of communication and collaboration.

The conversation reconstruction feature in eDiscovery helps you identify contextual content and produce distinct conversation views. This capability allows you to efficiently and rapidly review complete instant message conversations (also called *threaded conversations*) that platforms like Microsoft Teams generate.

By using conversation reconstruction, you can reconstruct, review, and export threaded conversations. Use eDiscovery conversation reconstruction to:



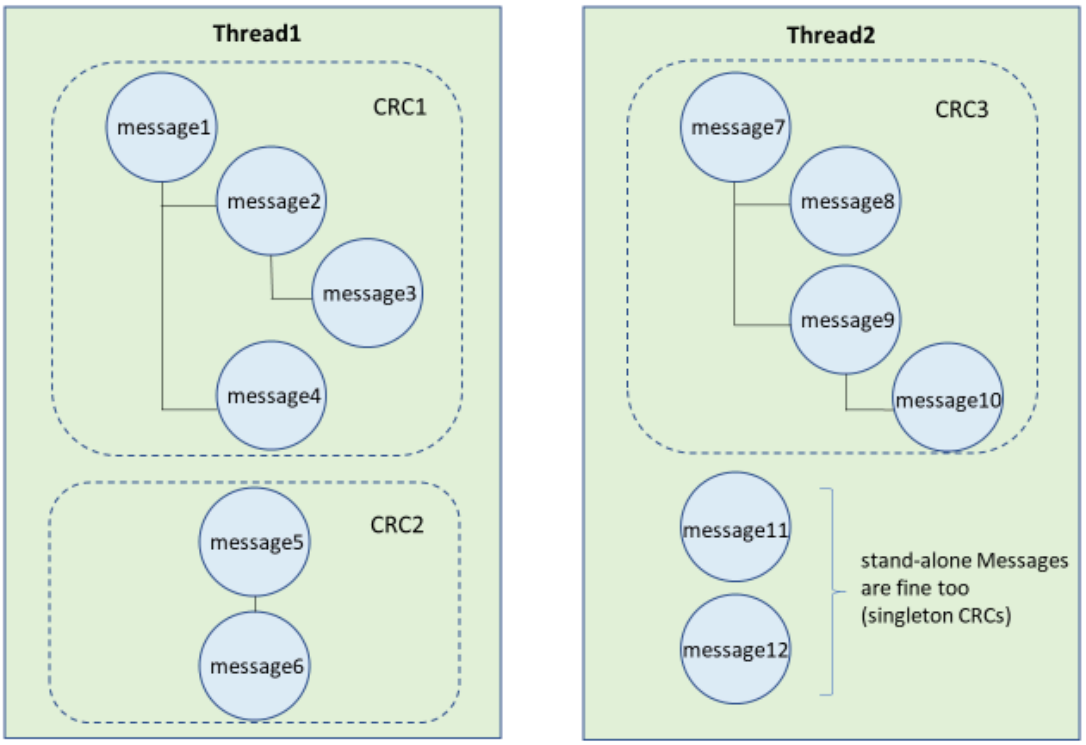
- Preserve unique message-level metadata across all messages within a conversation.
- Collect contextual messages around your search results.
- Review, annotate, and redact threaded conversations.
- Export individual messages or threaded conversations.

Conversation threading terminology

Here are a few definitions to help you get started using conversation reconstruction.

- **Messages:** Represent the smallest unit of a conversation. Messages might vary in size, structure, and metadata.

- **Conversation:** Represents a grouping of one or more messages. Across different applications, conversations might be represented in different ways. In some applications, an explicit action results from replying to an existing message. Conversations form explicitly as a result of this user action. For example, here's a screenshot of a channel conversation in Microsoft Teams.



In other apps (such as group chat messages in Teams), there's no formal reply chain and instead messages appear as a "flat river of messages" within a single thread. In these types of apps, conversations are inferred from a group of messages that occur within a certain time. This "soft-grouping" of messages (as opposed to a reply chain) represent the "back and forth" conversation about a specific subject of interest.

Add conversations to a review set

After you review and finalize the search query, add the search results to a review set. Use the threaded conversations option to collect contextual messages from conversations that contain

items that match the criteria of the search. When you select the thread conversations option, the following things can happen:

1. Using a keyword and date range query, the search returns a hit on *Message 3*. This message is part of a larger conversation, illustrated by *CRC1*.
2. When you add the data into a review set and enable the conversation retrieval options, eDiscovery goes back and collects other items in *CRC1*.
3. After you add the items to the review set, you can review all the individual messages from *CRC1*.

Manage review sets in eDiscovery

Review sets are a static set of documents where you can analyze, query, view, tag, and export data in a case. To view all review sets in a case, select the **Review sets** tab. You can't delete items from a review set, and you can't delete review sets from a case. To delete a review set and its data, you must delete the eDiscovery case that contains the review set.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Review set summary page

The **Review sets** dashboard lists all the review sets in a case. This dashboard lets you create review sets and displays information about review sets in the case. You can filter and group the review sets. The **Review sets** dashboard contains the following information and controls:

- **Review set**: The name of the review set.
- **Size**: The total file size of the items contained in the review set.
- **Created by**: The user that created the review set.
- **Last modified**: The date and time the review set was last modified. Select **Time zone** to switch between using local time and Coordinated Universal Time (UTC).
- **Modified by**: The user that modified the review set.
- **Searches (sources)**: The number of search sources contained in the review set.
- **Exports**: The number of exports from the review set.
- **Description**: The description information for the review set.

To customize the columns display on the **Review sets** dashboard, select **Customize columns** to choose the columns to display or drag and drop the columns in the list to reorder. To search for a specific review set, enter a keyword in the **Search** field.

To download the list of review sets and the column information, select **Download list** to create a .csv file containing this information.

Grouping review sets

When you view a large list of review sets in a case, group the review sets by user information. Select **Group** to group review sets by the following parameters:

- **None**: Review sets aren't grouped on the **Review sets** dashboard.
- **Modified by**: Review sets are grouped by the *Modified by* values.
- **Created by**: Review sets are grouped by the *Created by* values.

Review set management

To open a review set and start working with review set items, select the review set. The review set opens and contains the following tabs and information to help you manage the review set.

All items

> **Important**
>
> Review sets for limited format cases use the legacy eDiscovery experience. Some features aren't available for these cases in the new eDiscovery experience.

After selecting a review set, you're ready to start working with the items contained in the review set. On the **All items** tab, use the controls on the command bar to take the following actions in the review set:

- Search content with the condition builder in a review set. Use the condition builder for visual, no-code filtering with standard conditions like keywords, dates, senders, and file types.
- Search content with the Advanced review set explorer (preview). Use the Advanced review set explorer (preview) for KQL-based queries that support complex filtering, aggregation, pattern matching, and data visualization.
- Group and view items in a review set
- Tag documents in a review set
- Run analytics on a review set
- Export items from a review set
- Add items from a review set to another review set
- Use the Query Report to create keyword reports for KeyQL queries (preview)

> **Tip**

Do you prefer an interactive configuration guide experience? Check out the **Create and manage review sets** guide.

Review set overview

Select **Overview** to display summary information about the review set:

- **Total extracted documents**: The total number of items added to the review set. This number indicates the sum of parent items and child items added to the review set.
- **Total processed items**: The total number of processed items added to the review set.
- **Total number of failed extracted documents**: The total number of documents that failed extraction to the review set.

Pagination

Pagination for review set items is enabled by default in review sets. When pagination is enabled, review set items are displayed as multiple pages of 50 items each. To view specific pages, use the forward and back controls to navigate pages or enter a specific page number. To disable automatic pagination, select **Manage** > **Turn pagination off**.

Advanced review set explorer (preview) tab

The **Advanced review set explorer (preview)** tab provides a Kusto Query Language (KQL) editor for running advanced queries directly against review set data. Use this tab for complex filtering, aggregation, pattern matching, and data visualization.

For detailed guidance, see Search content in a review set with the Advanced review set explorer (preview).

Dashboard (preview) tab

The **Dashboard tab** provides a visual experience to help you quickly understand the composition and trends within the review set. You don't need to create custom queries because the dashboard automatically creates interactive charts and summaries.

> **Note**
>
> The dashboard doesn't render if the review set is empty. Ensure the review set contains data before using the dashboard.

Summary cards

Summary cards provide at-a-glance metrics for:

- Total items in the review set
- Items by type (conversation vs documents)
- Items breakdown by analytics results (items to review excluding duplicates, or immaterial items) if analytics has been run.

Interactive charts

Visualize review set data by using the following charts:

- **Top Communication Participants**: Senders or recipients for emails, Teams chats, and calendar invites in Exchange locations.
- **Top Data Sources**: Data sources that make up the most search hits matching your query.
- **Top item classes**: Top item classes that make up search hits matching your query.
- **Top file extension**: Top file extensions that make up search hits matching your query.

Process manager

Select **Process manager** to display information about processes performed on the review set. For example, if you export data from the review set, an *Export* process appears as an item in the **Process manager** list.

- **Process type**: The type of process.
- **Status**: The status of the process.
- **Export name**: The name of the export. For non-export process types, this value is blank.
- **Created**: The date and time the process was created.
- **Completed**: The date and time the process was completed.
- **Duration**: The duration of the process.
- **Created by**: The user that created the process.

To download the list of processes and the column information, select **Download list** to create a .csv file containing this information.

To view information about all eDiscovery processes, see Use the Process report in eDiscovery.

Search content in a review set with the query condition builder

In most cases, it's useful to dig deeper into the content in a review set and organize it to facilitate a more efficient review. By using filters and queries in a review set, you can focus on a subset of documents that meet the criteria for your review. This article explains how to use the query condition builder to create and run filter queries, work with condition types and load sets, use KeyQL query language, and save queries for reuse.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Use the query condition builder

To use the query condition builder in a review set, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Review sets** tab.
4. Select a review set, then select the **All items** tab.
5. On the **All items** tab, select **Query**.
6. Add conditions as needed. For more information about using conditions, see Use the condition builder to create search queries in eDiscovery.

Query content in a review set

The eDiscovery review set provides a querying experience that you can use to build flexible queries for review sets. The querying experience enables you to:

- Quickly search for review set content matching certain conditions.
- Create complex queries by using *AND* or *OR* conditions in KeyQL.
- Manage saved filters without going to another area and easily change your queries by loading saved queries.

> **ⓘ Important**
>
> Review sets have pagination turned on by default and can display a maximum of 1,000 items per page. Use default or custom filters to adjust the displayed items as needed. Matched item counts are estimates. You can turn off pagination through **Manage** > **Turn pagination off**.

To query content in your review set, use the following controls:

- Select **Query** in the toolbar or the blue bubble above the toolbar. Any applied query also appears in the query bubble above the toolbar.
- **Keyword** condition automatically populates for any new query.
- **AND/OR**: These conditional logical operators enable you to select the query condition that applies to specific filters.
- **Add conditions**: Enables you to add multiple conditions to your query.
- **Select an operator**: Depending on the selected filter, the operators compatible with the filter are available to select. For example, if you select the *Date* filter, you see the available operators *Before*, *After*, and *Between*. If you select the *Size* filter, you see the available operators *Greater than*, *Greater or equal*, *Less than*, *Less or equal*, *Between*, and *Equal*.
- **Value**: Depending on the selected filter, the values compatible with the filter are available. Additionally, some filters support multiple values and some filters support one specific value. For example, if you select the *Date* filter, you select date values. If you select the *Size (in bytes)* filter, you select a value for bytes.
- **Clear a condition value:** To clear the value inside a condition, select the X to the right of each condition line.
- **Remove a filter condition**: To remove an individual filter or subgroup, select the **Delete** icon to the right of each condition line.
- **Clear all**: To clear the entire query of all conditions and their values, select **Clear all**.
- **Save**: Saves the current conditions into a saved query by giving it a name.
- **Load saved filters:** Saved filters allow you to load any saved queries and overwrite existing query that is built.
- **Run query:** For any manually built conditions or opened saved filters, select **Run query** to apply the query to the review set. The last run query is retained and is available the next time you open the review set, even after you exit.
- **Hide and show query**: Use the hide and show button to expand and collapse the query section.

Understand condition types

Every searchable field in a review set has a corresponding condition that you can use to filter items based on a specific property.

There are multiple types of filters:

- **Free-text**: A free-text condition is applied to text fields such as *Subject*. You can list multiple search terms by separating them with a comma.
- **Date**: A date condition is used for date fields such as *Last modified date*.
- **Search options**: A search options condition provides a list of possible values (each value is displayed with a checkbox that you can select) for particular fields in the review. This condition is used for fields, such as *Sender*, where there's a finite number of possible values in the review set.

> ⓘ **Note**
>
> Some search options let you enter free-text to match multiple values. For example, when using the **Sender** condition with **contains any**, entering *john* matches items where the sender is *johndoe@contoso.com*, *johnsmith@contoso.com*, or *johnwei@gmail.com*. Make sure the entered value appears as a pill for the free-text input to apply.

- **Keyword**: A keyword condition is a specific instance of free-text condition that you can use to search for terms. You can also use Kusto-like query language in this type of condition. For example user can type *red AND blue* in a keyword condition grid, run the query and get all items in the review set that has both the word "red" and the word "blue". The matched keywords are also highlighted in the **plain text** view in the preview pane.

Use load sets to filter by collection

A load set is an instance of adding data to a review set. For example, if you add the results of two different searches to the same review set, each one represents a load set. To filter review set items by a specific load, use the **Load Id** condition in the query builder:

1. In the review set, select **+ Add conditions** in the query area.
2. Select **Load Id** as the condition.
3. Set the operator to **Equals any of**.
4. Start typing in the search field. Suggested load IDs from the review set appear automatically.

5. Select one or more load IDs to filter by, then run the query.

This filter is useful when you want to isolate items from a specific collection or compare data across different loads added to the same review set.

To download the list of load sets and the column information, select **Download list** to create a .csv file containing this information.

Save and manage filter queries

After you build your conditions, save the condition combination as a filter query. This saved filter query lets you apply the same query in future review sessions.

To save, select **Save** and give it a name. You or other reviewers can run previously saved filter queries by selecting the **Saved filter** dropdown and selecting a filter query to open and select **Run query** to apply review set documents.

To edit or delete a saved filter query, select **Saved filter** and mouse over the saved filter and select **Edit** or **Delete** options for the saved filter query.

Use query language support for KeyQL and Keyword filters

When you use the *KeyQL* or *Keyword* filters, you can use a Kusto-like query language to build your review set search query. The query language for the KeyQL and Keyword filters supports standard Boolean operators, such as **AND**, **OR**, **NOT**, and **NEAR**. It also supports a single-character wildcard (?) and a multi-character wildcard (*).

> **Note**
>
> Review filters only support wildcards (? or *) on a single term. Using wildcards in searches on phrases that consist of multiple terms isn't supported.

Scenario examples

The following examples show common review set filtering scenarios using the query condition builder.

Filter for untagged items in a review set

An eDiscovery administrator needs to create a query to find all items in the review set without any tagging applied. For this example, the administrator creates the following review set query:

1. For the first condition, the administrator selects *Add conditions* and searches for the *tag* condition. The *Tags* condition is displayed as a matching option. The administrator selects it and selects *Apply*.
2. The administrator then selects *Is empty* operator for the *Tags* condition.
3. The administrator selects *Run query*.

The review set list is updated to show all items that don't have any tags applied.

Filter for native file type items in a review set

An eDiscovery administrator needs to create a query to find all items in the review set that are a certain type, such as .csv, .msg, or .pdf. For this example, the administrator creates the following review set query:

1. For the first condition, the administrator selects *Add conditions* and searches for the *file* in condition search. The condition *Native file extension* is one of the options displayed in the search results. The administrator selects it and selects *Apply*.
2. The administrator then selects the *Equals any of* operator.
3. The administrator selects the value box and chooses the file types in the dropdown such as csv to include in the query.
4. The administrator selects *Run query*.

The review set is updated and only the items that match the selected file types are displayed.

Filter partially indexed items

If you select the option to include partially indexed items when you add the search to a review set, you probably want to identify and view those items. You can determine if an item might be relevant to your investigation and whether you need to fix the error that resulted in the item being partially indexed. Use the KQL (Keyword Query Language) condition to find partially indexed items.

1. Select **Add conditions** in the query building space.
2. Find the condition *KQL* and select **Apply**.
3. Keep the operator as *Equal* and type *AddedBy* in the KQL editor box. You can filter out items added to the review set by applying the KQL of `AddedBy=UnindexedQuery`.
4. Select **Run query**.

The review set is updated and only the items that match the partially indexed query are displayed.

Filter documents by theme

Filtering documents by theme can save time when reviewing documents. For example, if you're looking for documents that discuss a particular subject, you can filter the documents by the dominant theme that relates to that subject. You can also filter documents by other themes in the theme list to find documents that are similar to a document that you're interested in. To display the themes for a document as a column in the document list for the review set, select **Customize columns** and select **Dominant theme** and **Themes list**.

To filter documents by theme, complete the following steps:

1. In a review set, add **Dominant theme** condition.
2. Select an operator to use with the **Dominant theme** and define the value to use with the operator.
3. Use an additional **Themes list** condition and the operator and values to apply to this filter. You can configure the **AND** and **OR** operators to filter documents by a combination of the **Dominant theme** and **Themes list** values.

Search content in a review set with the Advanced review set explorer (preview)

The **Advanced review set explorer (preview)** in Microsoft Purview eDiscovery lets reviewers run real-time big data analytics on review set content by using a defined subset of Kusto Query Language (KQL). With the Advanced review set explorer (preview), you can query, filter, and visualize review set data directly in the Microsoft Purview portal without modifying the underlying content. Queries run against the full set of indexed items and return either tabular results or chart visualizations.

Use the Advanced review set explorer (preview) to:

- Identify top item types, spot patterns, and find trends within the review set.
- Build powerful queries with complex filtering, pattern-based text extraction, and data format parsing.
- Analyze and find key information specific to your case or organization.
- Visualize query results by using charts for a comprehensive understanding of review set data.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Open the Advanced review set explorer (preview)

To open the Advanced review set explorer (preview), complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, and then select **Cases** in the left navigation.
3. Select a case, and then select the **Review sets** tab.
4. Select a review set, and then select the **Advanced review set explorer (preview)** tab.

From here, you can write and run KQL queries directly against the review set data.

> **Tip**
>
> If you prefer a visual, no-code approach to filtering review set content, see **Search content in a review set with the query condition builder**.

Navigate the Advanced review set explorer (preview)

The Advanced review set explorer (preview) includes a left navigation pane and a results area to help you build, discover, and run KQL queries.

> **Tip**
>
> If you're new to KQL, start with the **Getting started** tab to explore basic query patterns, then use the **Sample queries** in the left pane for more targeted analysis.

Left navigation pane

The left navigation pane provides three collapsible sections that let you explore the review set schema and quickly insert query elements into the editor:

- **Schema**: Displays the available table (`ReviewSetTable`) for your review set. Select the table name to insert it into the query editor.
- **Operators**: Lists all supported KQL operators, including count, distinct, extend, limit, mv-expand, order, project, project-away, project-keep, render, sort, summarize, take, top, and where. Select any operator to add it to your query.
- **Sample queries**: Provides ready-to-use query templates for common review set analysis tasks, such as **FileClass count as piechart**, **FileType count**, **ItemClass count**, **Participants count**, **SensitivityLabel count**, and **Source count**. Select a sample query to load it directly into the query editor.

Getting started tab

The **Getting started** tab below the query results area provides a quick reference for building queries. It includes selectable examples organized into two categories.

Select any query name to load the example directly into the query editor:

Expand table

Category	Queries	Description
Basic queries	Limit	Shows 10 results from the specified table.
	Where	Filters the result set by date and file names ending with ".jpg".
	Count	Counts the number of rows that match the specified filter.
	Top	Arranges results by date and shows the first 10 rows.
	Project	Shows only the file name, file type, and date columns in the results.
Advanced queries	Summarize	Shows the top data sources and counts the number of items for each source.
	Extend	Adds a column to combine title and author values.
	Mv-expand	Expands the Participants list and counts occurrences per participant.
	Render	Counts items by file class and renders the results as a pie chart.

How the Advanced review set explorer (preview) works in a review set

Each query runs against the full review set's data and returns:

- A **tabular list** of matching items, or
- A **chart visualization**, depending on the query.

Queries follow standard KQL pipeline syntax, where each line builds on the results of the previous step. The portal automatically adds the `ReviewSetTable` table name as the first line. Each subsequent query line must start with `\|`.

For example:

Kusto

```
ReviewSetTable
| where SubjectTitle has "Case"
| summarize count() by FileClass
```

> ⓘ Note
>
> All queries in the Advanced review set explorer (preview) run against the current review set's indexed items. You don't need to specify a table name. The review set acts as the default

data source.

Best practices

Use the following best practices when writing queries in the Advanced review set explorer:

- Start with `where` filters to narrow data before using `summarize` or `render`.
- Use `take` to validate query logic before running full aggregations.
- Avoid overly broad regex patterns on large review sets.
- Use `where isnotempty(`*ColumnName*`)` to exclude items with empty values for a property, which helps avoid unexpected blank rows in your results.

Other considerations

The Advanced review set explorer (preview) doesn't support all Kusto operators and properties. Keep the following considerations in mind when you create queries:

- Queries are read-only and don't modify review set content. For more information about working with review sets, see Manage review sets in eDiscovery.
- Results reflect the current indexed state of the review set. If you add more data to the review set, the query might return different results.
- Not all file types are queryable. For more information, see Supported file types in eDiscovery.
- If the query returns more than 10,000 results, it returns only the first 10,000 results. Modify the query to narrow down the results.

For Kusto syntax and references, see the following articles:

- Syntax conventions for reference documentation
- Best practices for Kusto Query Language queries

Supported basic operators

> **Tip**
>
> For a complete list of available properties you can use in queries, see **Document metadata fields in eDiscovery**.

Where operator

Use the `where` operator to filter items based on metadata such as subject, keywords, item class, dates, or participants.

The following example filters the review set to return only items whose **Subject** contains the text "Day".

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
```

This query filters the review set to include all calendar-related items whose **ItemClass** begins with `IPM.Appointment`, which covers standard appointments and extended classes like `IPM.AppointmentSnapshot.SkypeTeams.Call`.

Kusto

```
ReviewSetTable
| where ItemClass startswith "IPM.Appointment"
```

Project operator

Use `project` to return only the properties you care about. For example, the following query performs two actions:

- **Filters items by subject text**: The `where SubjectTitle has "Day"` clause limits the results to only those items whose **SubjectTitle** contains the word "Day".
- **Projects a single column**: The `project SubjectTitle` clause then returns only the **SubjectTitle** property for those filtered items, removing all other columns from the output.

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
| project SubjectTitle
```

Project-away operator

The `project-away` operator removes specified columns from the query results while keeping all other columns. Use it when you want to exclude a few properties rather than listing every column you want to keep.

The following example returns all properties for items in the review set except **CompoundPath** and **InternetMessageId**, which are excluded from the output.

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
| project-away CompoundPath, InternetMessageId
```

Project-keep operator

The `project-keep` operator keeps only the columns that match a specified pattern or list, removing everything else. Unlike `project`, `project-keep` preserves the original column order and supports wildcard patterns.

The following example keeps only columns whose names start with "Sender" or "Recipient", making it easy to focus on communication participants without listing each property individually.

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
| project-keep Sender*, Recipient*
```

Mv-expand operator

The `mv-expand` operator expands multi-value properties (such as lists of participants or recipients) into separate rows, with one row per value. This is useful for analyzing individual entries within fields that contain multiple values.

The following example expands the **Participants** field so each participant appears on its own row, then counts the number of items associated with each participant. This helps identify the most active participants in the review set.

Kusto

```
ReviewSetTable
| mv-expand Participants
| summarize count() by tostring(Participants)
```

Extend operator

The `extend` operator adds one or more calculated columns to your query results by creating new values derived from existing fields without altering the underlying data.

The following example classifies review set items into four size categories - **Small (<1MB)**, **Medium (1–5MB)**, **Medium-Large (5–10MB)**, and **Large (>10MB)** - by creating a new column `SizeCategory` using the `case()` function, and then aggregates the count of items in each category by using `summarize`. It helps investigators quickly understand the distribution of file sizes in the review set for risk assessment or prioritization.

Kusto

```
ReviewSetTable
| extend SizeCategory = case(Size > 10485760, "Large (>10MB)", Size >= 5242880 and
Size <= 10485760, "Medium-Large (5–10MB)", Size >= 1048576 and Size < 5242880,
"Medium (1–5MB)", "Small (<1MB)")
| summarize count() by SizeCategory
```

Summarize operator

The `summarize` operator aggregates data by applying functions like `count()`, `sum()`, or `avg()`, and groups results based on specified columns.

The following example counts items grouped by **SubjectTitle** for items containing the word "Day".

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
| summarize count() by SubjectTitle
```

Render barchart, render columnchart, render piechart

The `render barchart` operator takes the tabular results of your query and displays them as a bar chart. This makes it easier to visualize the distribution or comparison of aggregated values.

The following example renders subject title counts as a bar chart.

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
```

```
| summarize count() by SubjectTitle
| render barchart
```

Take (limit) operator

The `take` operator limits the query output to a specified number of rows. It returns only the first *n* results from the dataset. The `limit` operator is a synonym for `take` and you can use them interchangeably.

The following example returns just the first 10 matching items, so you can validate query logic or spot-check content before running a full query. This approach helps when dealing with large review sets or complex filters, where results can take longer to compute and load without `take` limiting the output.

Kusto

```
ReviewSetTable
| where SubjectTitle has "day"
| project SubjectTitle, SenderDomain, Custodian, Size
| take 10
```

Sort operator

The `sort` operator orders the query results based on one or more specified columns in ascending or descending order.

The following example query calculates the total number of items for each **NativeFileExtension** in the review set by using `summarize count()`. Then, it sorts those extension groups in descending order of item count so you can see which file types are most prevalent.

Kusto

```
ReviewSetTable
| summarize ItemCount = count() by NativeFileExtension
| sort by ItemCount desc
```

Distinct operator

The `distinct` operator returns unique values for the specified columns by removing duplicate rows from the query results.

The following example uses `distinct` to remove duplicates so you only see unique custodians, and then uses `sort by Custodian asc` to order them alphabetically, making it easy to scan or export for reporting.

Kusto

```
ReviewSetTable
| distinct Custodian
| sort by Custodian asc
```

Count operator

The `count` operator returns the total number of rows in the query result set, so you can quickly see how many items are in the set.

The following example counts the number of unique subject titles that contain the word "Day".

Kusto

```
ReviewSetTable
| where SubjectTitle has "Day"
| summarize by SubjectTitle
| count
```

Top operator

The `top` operator returns the first *n* rows from the query results, ordered by one or more specified columns. Use it to get the highest or lowest values based on your sort criteria.

The following example gets the top five largest items in your review set.

Kusto

```
ReviewSetTable
| top 5 by Size desc
```

Bin operator

The `bin()` function rounds a datetime or numeric value down to the nearest multiple of a specified bin size. Use this function to group data into time intervals or numeric ranges, such as hourly buckets or size ranges.

The following example groups items in the review set into size buckets of **1 MB** using `bin(Size, 1048576)`, counts how many items fall into each bucket with `summarize count()`, and then sorts the buckets in ascending order so you can see the distribution of file sizes from smallest to largest.

Kusto

```
ReviewSetTable
| summarize ItemCount = count() by bin(Size, 1048576)
| sort by bin(Size, 1048576) asc
```

Common scenarios

The following scenarios demonstrate how Kusto queries in the Advanced review set explorer (preview) can help you analyze and better understand your review set data.

Scenario 1: Communications between two users

Find items exchanged exclusively between two specific users - John and David - with no other participants. This query isolates their direct one-to-one communications and shows only three properties: subject title, sender, and recipients.

Kusto

```
ReviewSetTable
| where isnotempty(Participants)
| extend ParticipantEmails = extract_all(@"\<(\[^\>\]+)\>", tostring(Participants))
| extend ParticipantCount = array_length(ParticipantEmails)
| where ParticipantCount == 2
| where ParticipantEmails has "John@contoso.com" and ParticipantEmails has
"David@contoso.com"
| project SubjectTitle, SenderAuthor, Recipients
```

Scenario 2: Emails sent externally

Find all review set items that include at least one external recipient (outside your organization contoso.com), and list those external email addresses for each item.

Kusto

```
ReviewSetTable
| where isnotempty(Recipients)
| extend Emails = extract_all(@"\<(\[^\>\]+)\>", tostring(Recipients))
| mv-expand Email = Emails
```

```
| extend Email = tostring(Email)
| where Email !contains "@contoso.com"
| summarize ExternalRecipients = make_set(Email) by ImmutableId, SubjectTitle
```

Scenario 3: Identify date and time patterns in the review set

Visualizing data over time helps investigators identify spikes or anomalies in communication or document creation, such as a sudden surge in emails that might correlate with a known incident. Quarterly views align with business cycles, making it easier to correlate findings with financial reporting periods, internal audits, or policy changes.

The following example analyzes how review set items are distributed over time by grouping items by year and quarter and visualizing the results as a column chart. It filters items by date range, extracts the year and quarter from each item's **Date** field, counts the items in each year-quarter combination, creates a readable label (for example, *Q2 2024*), and renders the results as a column chart.

Kusto

```
ReviewSetTable
| where Date > datetime(2015-01-01) and Date < datetime(2025-08-31)
| extend Year = datetime_part("year", Date), Quarter = datetime_part("quarter", Date)
| summarize EventCount = count() by Year, Quarter
| sort by Year asc, Quarter asc
| extend QuarterLabel = strcat("Q", tostring(Quarter), " ", tostring(Year))
| project QuarterLabel, EventCount
| render columnchart
```

Scenario 4: Visualize Microsoft Teams message types in the review set

The following example categorizes and visualizes Microsoft Teams message types in the review set by item class, helping you understand the distribution of different message formats.

Kusto

```
ReviewSetTable
| where ItemClass startswith "IPM.SkypeTeams.Message."
| project SubjectTitle, Date, SenderAuthor, FileClass, ItemClass, InternetMessageId
| summarize ItemCount = count() by ItemClass
| sort by ItemCount desc
| render piechart
```

Use regex in the Advanced review set explorer (preview)

The Advanced review set explorer (preview) supports **regular expressions (regex)** for powerful pattern matching in text fields. Regex support enables you to search for complex sequences of characters, such as alphanumeric combinations, special characters, or structured patterns, beyond simple keyword matching. Use regex to:

- Identify items with specific formats, such as IDs, codes, or structured tokens.
- Detect patterns that standard operators like `has` or `startswith` can't capture.
- Perform advanced filtering for compliance or forensic investigations.

Tips for writing regex in KQL

- Escape backslashes properly (`\\`) when needed.
- Use anchors (`^` for start, `$` for end) for exact positioning.
- Test patterns incrementally to avoid overly broad matches.
- Combine with other operators (for example, `and`, `or`) for precise queries.
- Reference: Regex syntax.

Syntax

Use the `matches regex` operator in your `where` clause:

Kusto

```
where <PropertyName> matches regex "<pattern>"
```

Example: Match a complex pattern in Keywords

The following query finds items whose **Keywords** field matches a pattern of 10 word characters, 10 digits, and 10 non-word characters:

Kusto

```
ReviewSetTable
| where Keywords matches regex "\\w{10}\\d{10}\\W{10}"
| project SubjectTitle, CompoundPath, Date, SenderAuthor, FileClass, ItemClass,
InternetMessageId
```

- Filters items where the **Keywords** property contains:

    - 10 word characters (`\w`)
    - followed by 10 digits (`\d`)
    - followed by 10 non-word characters (`\W`)

- Returns key metadata fields as specified for review.

Fix common KQL syntax errors

When you create queries in the Advanced review set explorer (preview), you might encounter syntax errors.

The following table lists common errors and how to fix them:

Expand table

Error	Cause	Fix
`sort` operator requires a column name	Using `sort` without specifying what to sort by.	Add a column name after `sort by`. For example, `sort by Date desc`.
Expected `)` or `,`	Missing closing parenthesis or incorrect function arguments.	Check that all opening parentheses have matching closing parentheses and that function arguments are separated by commas.
Unknown function	Using a function name that isn't supported or is misspelled.	Verify the function name against the KQL documentation. Common examples include `count()`, `tostring()`, and `datetime()`.
Token expected: `\ |`	A query line is missing the pipe operator at the start.	Ensure every line after `ReviewSetTable` begins with `\ |`.
Column not found	Referencing a property name that doesn't exist in the review set schema.	Check the available column names in your review set. Property names are case-sensitive.
`summarize` requires a `by` clause	Using `summarize` with an aggregation but no grouping column.	Add a `by` clause with one or more columns. For example, `summarize count() by FileClass`.
Unexpected end of query	Query is incomplete or has a trailing pipe with no operator.	Remove any trailing `\ |` at the end of the query, or add the intended operator after it.

> **Note**

Some older review sets might not support certain KQL properties if those properties weren't available when the review set was created and data was generated. Querying an unsupported property in an older review set results in a column not found error. To resolve this error, create a new review set and use the **Add to review set** process to regenerate the data with the latest supported properties.

Review Microsoft Teams content in a review set in eDiscovery

06/21/2025

After you add Microsoft Teams content to a review set, the next step is to review the content for its relevance to your investigation and cull it if necessary. An important prerequisite to reviewing Teams content is understanding how eDiscovery processes Teams meeting, chat conversations, and attachments when adding them to a review set. The following processing of Teams content is taken:

- **Grouping**: Messages, posts, and replies Teams conversations are grouped together and presented in the review set. This processing also includes attachments in chat conversations are extracted and group within the conversation.
- **Conversation transcript threading**: eDiscovery determines what additional content from a conversation to collect to provide context around items that matched the collection criteria.
- **Deduplication**: eDiscovery processes and manages duplicate Teams content.
- **Metadata**: eDiscovery adds metadata content for Teams content after the content is added to a review set.

> **Note**
>
> The date and time for all conversations in Teams are shown in Coordinated Universal Time (UTC).

Understand grouping, conversation threading, deduplication, and Teams metadata to help you optimize the review and analysis of Teams content. This section also has tips for viewing Teams content in a review set.

Grouping

When content from Teams chat conversations is added to a review set, messages, posts, and replies from conversations are aggregated in HTML transcript files when the setting of "Organize conversations into HTML transcript" is selected. A single chat conversation can have multiple transcript files. An important function of these transcript files is to present Teams content as continuous conversations and not as individual (or separate) messages. This helps provides context for items that matched the search criteria of your collections in the previous step and reduce the number of items collected into the review set. Group transcripts and associated items by *family* or *conversation*. Items in the same family have the same value for

the **FamilyId** or **GroupId" metadata property. Items in the same conversation have the same value for the **ConversationId** or **ThreadId" metadata property depending on the grouping configuration selected.

The following table describes how the different types of Teams content are grouped by family and conversation.

Expand table

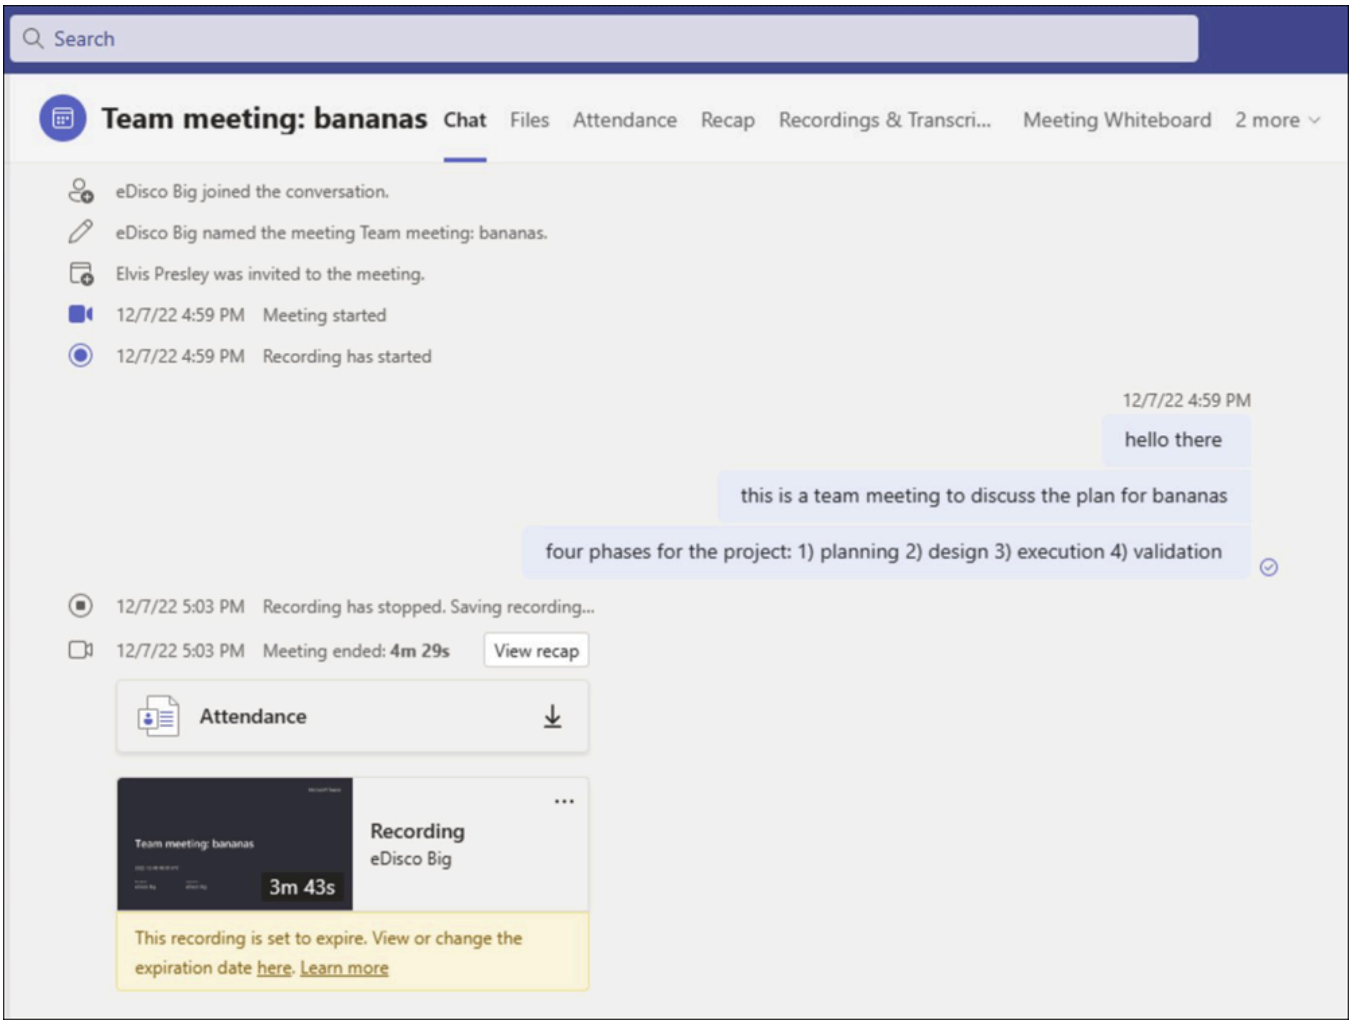
Teams content type	Group by family	Group by conversation
Teams 1:1 and group chats	A transcript and all of its attachments and extracted items share the same **FamilyId**. Each transcript has a unique **FamilyId**.	All transcript files and their family items within the same conversation share the same **ConversationId**. This includes the following items: All extracted items and attachments of all transcripts that share the same **ConversationId**. • All transcripts for the same chat conversation • All custodian copies of each transcript • Transcripts from subsequent collections from the same chat conversation For Teams 1:1 and group chat conversations, you might have multiple transcript files, each one corresponding to a different time frame within the conversation. Because these transcript files are from the same conversation with the same participants, they share the same **ConversationId**.
Standard, private, and shared channel chats	Each post and all replies and attachments are saved to its own transcript. This transcript and all of its attachments and extracted items share the same **FamilyId**.	Each post and its attachments and extracted items have a unique **ConversationId**. If there are subsequent collections or new replies from the same post, the delta transcripts resulting from those collections will also have the same **ConversationId**.
Teams meetings	Each meeting	

Use the **Group** control in the command bar of a review set to view Teams content grouped by family or conversation.

- Select **Group family attachments** to view Teams content grouped by family. Each transcript file is displayed on a line in the list of review set items. Attachments are nested under the item.

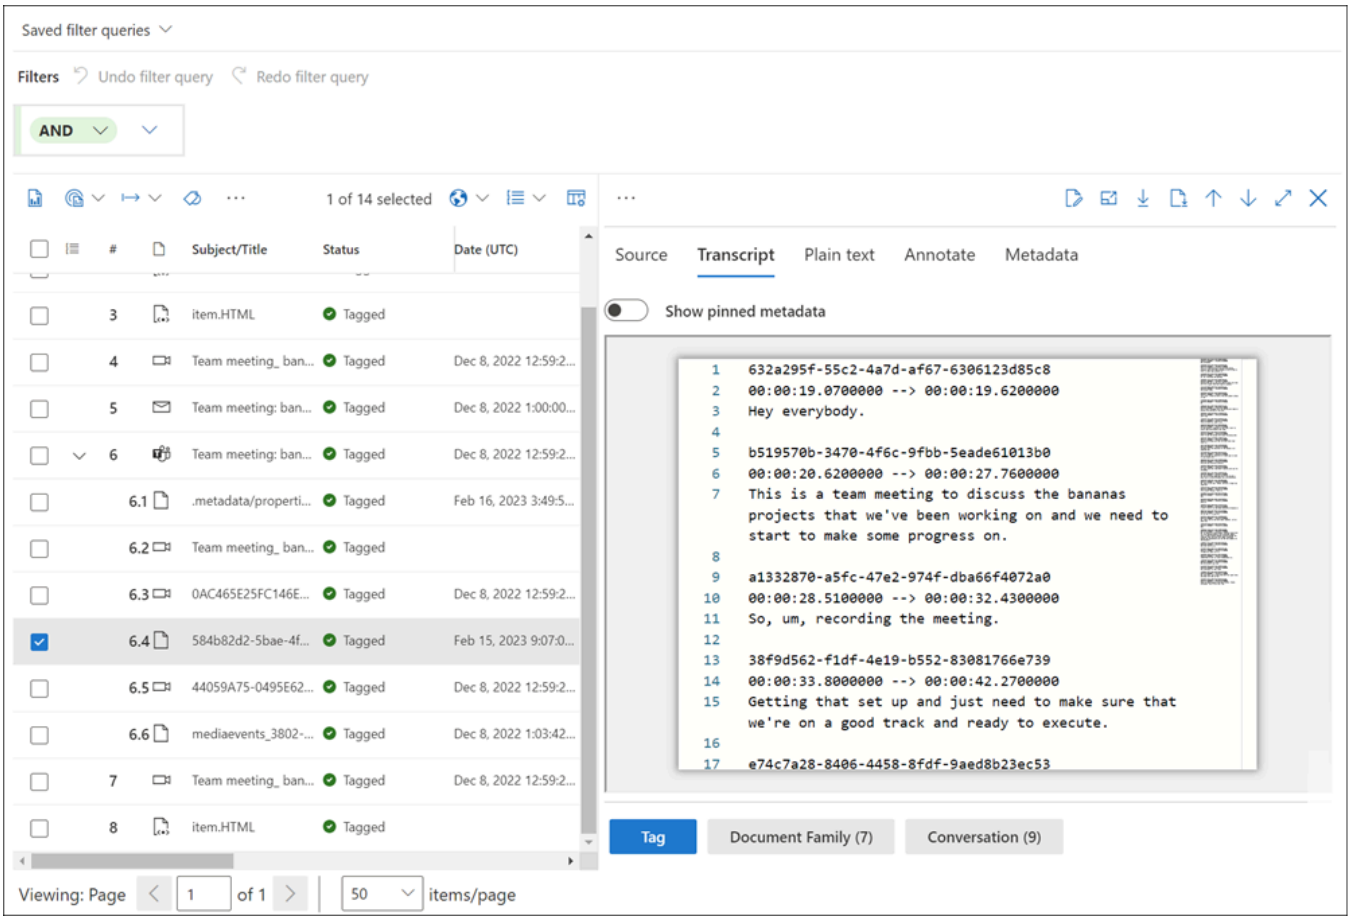
- Select **Group Teams or Viva Engage conversations** to view Teams content grouped by conversation. Each conversation is displayed on a line in the list of review set items. Transcript files and attachments are nested under the top-level conversation.

> ⓘ **Note**
>
> Cloud attachments are grouped with the conversations they appear in. This grouping is accomplished by assigning the same **FamilyId** as the transcript file of the message the file was attached to and the same **ConversationId** as the conversation the message appeared in. This means multiple copies of cloud attachments might be added to the review set if they were attached to different conversations.



Viewing recorded meeting transcripts

The transcript of audio of the recorded meeting is captured as a separate file and indexed automatically for search. Recorded meetings in a review set are stored as a .zip file that contains the following files:

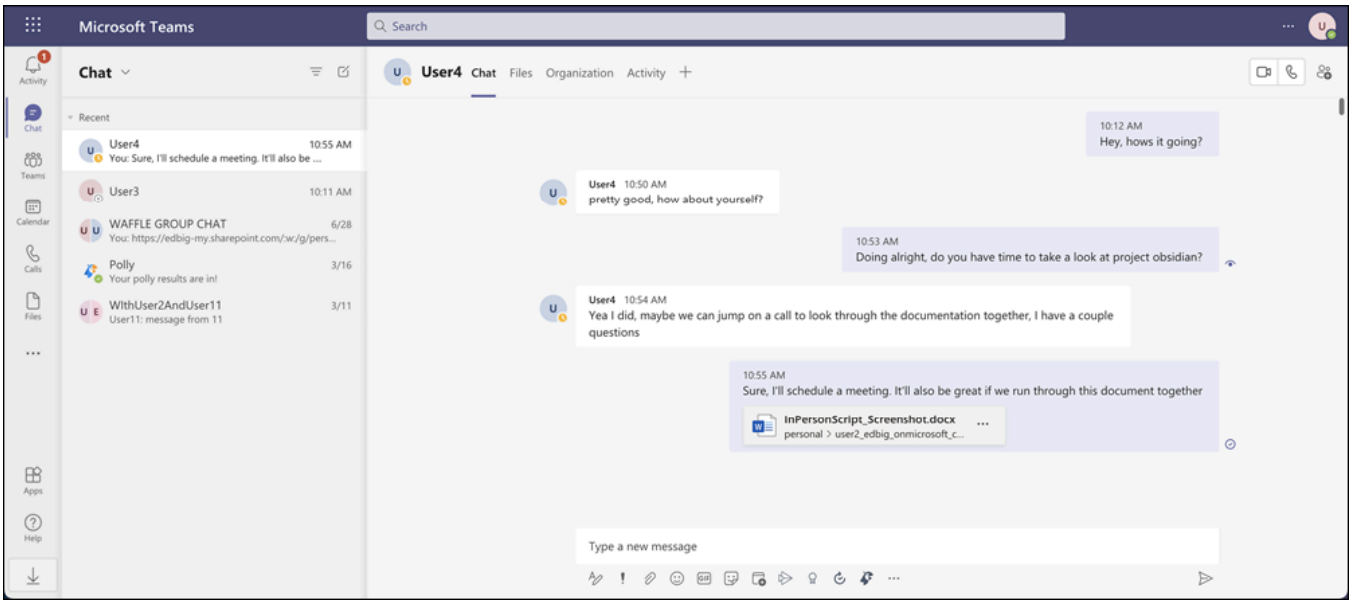


- The transcript of the meeting audio in .txt format
- The video recording of the meeting in .mp4 format
- The thumbnail image of the meeting in .jpg format
- Meeting metadata and meeting chapters (as applicable) in .json format

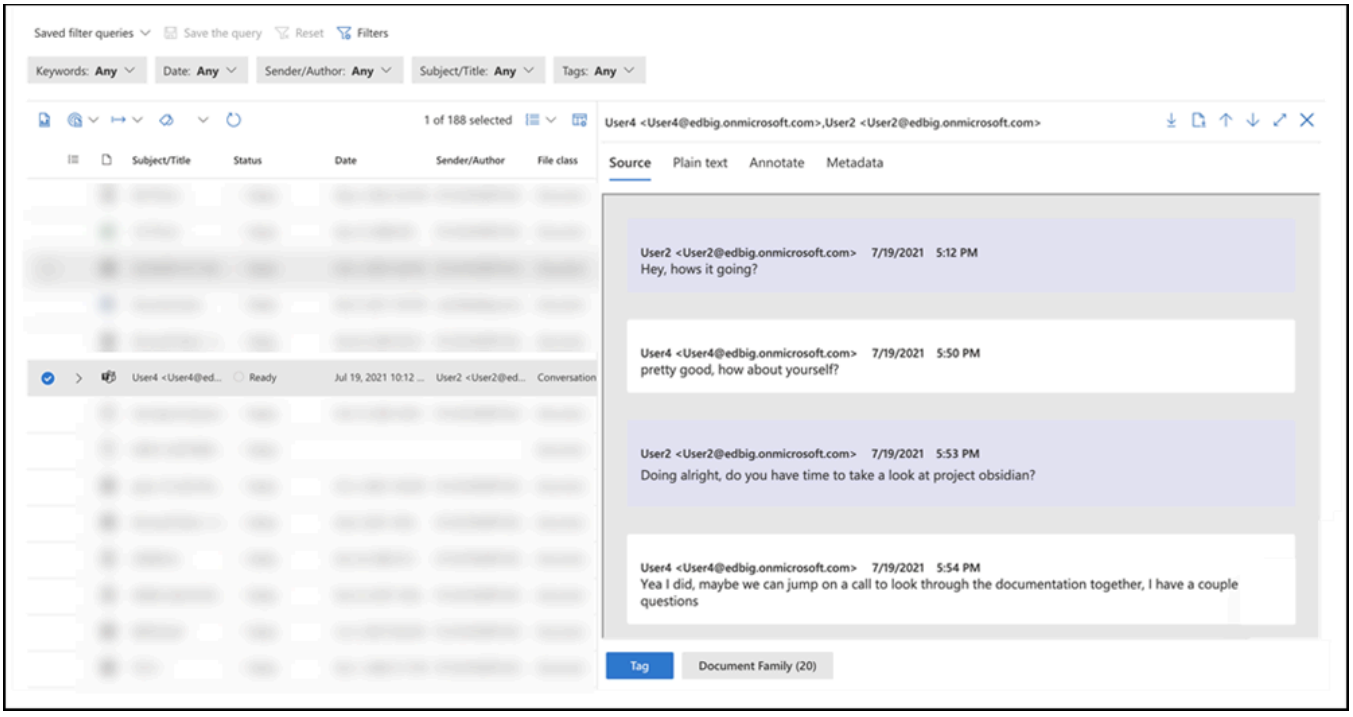
To view meeting audio transcript files in a review set, select the meeting and the **Transcript** viewer on the meeting details pane. The following screenshots show an example of a meeting in the Teams client and the meeting transcript file of the same meeting in the review set.

Meeting in Teams client

Meeting transcript file in a review set



Viewing conversation transcript files



When viewing transcript files in a review set, some of the messages are highlighted in purple. The messages that are highlighted depend on which custodian copy of the transcript you're viewing. For example, in a 1:1 chat between User4 and User2, the messages posted by User4 are highlighted in purple when you view the transcript collected from User4's mailbox. When you view User2's transcript of the same conversation, messages posted by User2 are highlighted in purple. This highlighting behavior is based on the same Teams client experience, where a user's posts are highlighted in purple in the Teams client.

The following screenshots show an example of conversation in the Teams client and the transcript file of the same conversation in the review set. The purple highlighting in the transcript file indicates that the transcript was collected from User2's mailbox.

Conversation in Teams client

Conversation in a transcript file

Include contextual conversations for Teams chat messages

If you select "Include Teams and Viva Engage conversations" setting during the add to review set process, eDiscovery helps you identify contextual content related to items that might be relevant to your investigation. This feature produces distinct conversation views that include chat messages that precede and follow the items match the search query during collection. This capability allows you to review complete chat conversations in Microsoft Teams. This capability is independent from HTML threading and only affects whether contextual conversations are included in the process of adding items to a review set.

Here's the logic used by eDiscovery to include additional messages and replies that provide context around the items match the search query (called *responsive items*) you used when adding Teams content to a review set. Different behaviors are based on the types of chats and the search query used to collect the responsive items. There are two common search scenarios:

- Queries that use search parameters, such as keywords and property:value pairs
- Queries that only use date ranges

Expand table

Teams content type	Queries with search parameters	Queries with date ranges
Teams 1:1 and group chats	Messages that were posted 12 hours before and 12 hours after responsive items are included	Messages that fall in between the data range and any contextual messages within a 24-hour window are included.
Standard, private, and shared Teams channel chats	Each post that contains responsive items and all corresponding replies are included.	Each post that contains responsive items and all corresponding replies are included.

Deduplication of Teams content

The following list describes the deduplication (and duplication) behavior when collecting Teams content into a review set when user chooses to organize conversations in an HTML transcript.

- Each transcript file added to a review set should be a one-to-one mapping to content stored in data locations. That means eDiscovery doesn't collect any Teams content that have already been added to the review set. If a chat message is already collected in a review set, eDiscovery doesn't add the same message from the same data location to the review set in subsequent collections.

- For 1:1 and group chats, copies of messages are stored in the mailbox of each conversation participant. Copies of the same conversation that exist in different participants' mailboxes are collected with different metadata. As a result, each instance of the conversation is treated as unique and brought into the review set in separate transcript files. So if all participants of a 1:1 or group chat are added as custodians in a case and included in the scope of a collection, then copies of each transcript (for the same conservation) are added to the review set and are grouped together with the same **ConversationId** or **ThreadId**. Each of these copies is associated with a corresponding data source.

- In subsequent "Add to review set" processes where there are items from the same conversation, only the delta content that wasn't previously added previously is added to

the review set and grouped (by sharing the same **ConversationId** or **ThreadId**) with the previously added items from the same conversation. Here's an example of this behavior:

1. Process A adds messages in a conversation between User1 and User2 to the review set.
2. Process B adds messages from the same conversation, but there are new messages between User1 and User2 since process A was run.
3. Only the new messages in Process B are added to the review set. These messages are added to a separate transcript file, but the new transcript is grouped with the transcripts from Process A by the same **ConversationId**.

This behavior applies to all the types of Teams chats.

Metadata for Teams content

In large review sets with thousands or millions of items, it can be difficult to narrow the scope of your review to Teams content. To help you focus your review on Teams content, there are metadata properties that are specific to Teams content. You can use these properties to organize the columns in the review list and configure filters and queries to optimize the review of Teams content. These metadata properties are also included when you export Teams content from eDiscovery, to help you organize and view content post-export or in non-Microsoft eDiscovery tools.

The following table describes metadata properties for Teams content.

Expand table

Metadata property	Description
ContainsDeletedMessage	Indicates whether a transcript file contains a deleted message. Deleted messages are identified when viewing the transcript file.
ContainsEditedMessage	Indicates whether a transcript file contains an edited message. Edited messages are identified when viewing the transcript file.
ConversationId	A GUID that identifies the conversation that the item is associated with. Transcript files and attachments from the same conversation have the same value for this property.
Conversation name	The name of the conversation the transcript file or attachment is associated with. For Teams 1:1 and group chats, the value of this property is the User Principal Name (UPN) of all participants of the conversation are concatenated. For example, `User3 <User3@contoso.onmicrosoft.com>,User4 <User4@contoso.onmicrosoft.com>,User2 <User2@contoso.onmicrosoft.com>`. Teams channel (standard, private, and shared) chats use the following format

Metadata property	Description
	for conversation name: `<Team name>,<Channel name>`. For example, `eDiscovery vNext, General`.
ConversationType	Indicates the type of Team chat. For Teams 1:1 and group chats, the value for this property is `Group`. For standard, private, and shared channel chats, the value is `Channel`.
Date	The time stamp of the first message in the transcript file in UTC.
FamilyId	A GUID that identifies the transcript file for a chat conversation. Attachments have the same value for this property as the transcript file that contains the message the file was attached to.
FileClass	Indicates that type of content. Items from Teams chats have the value `Conversation`. In contrast, Exchange email messages have the value `Email`.
MessageKind	The message kind property. Teams content has the value `microsoftteams , im`.
Participants	List of all people who are involved in the chat, includes both senders and recipients in a conversation.
Recipients	A list of all users who received a message within the transcript conversation.
TeamsChannelName	The Teams channel name of the transcript.

For descriptions of other eDiscovery metadata properties, see Document metadata fields in eDiscovery.

Export Teams content

After you review and cull Teams content in a review set, you can export all items that are applicable to your investigation. There aren't any specific export settings for Teams content. If the content was added to review set as a transcript file, then each transcript is exported as an HTML message file. The metadata properties discussed in the previous section are included when Teams content is exported.

Each export item (transcript or individual messages) is referenced in the items.csv report and can be located using the target path field in the report. Transcript files are located in the Conversations folder in the root export folder.

Tips for viewing Teams content in a review set

Here are some tips and best practices for viewing Teams content in a review set.

- Use the **Customize columns** control in the command bar to add and organize columns to optimize the review of Teams content. You can add and remove columns that are useful for Teams content. You can also sequence the order of columns by dragging and dropping them in the **Edit column** flyout page. You can also sort on columns to group Teams content with similar values for the column you sort on.
- Useful columns that to help you review Teams content include **Participants**, **Recipients**, and **File type** or **Message kind**.
- Use filters for Teams-related properties to quickly display Teams content. There are filters for most of the metadata properties described in the previous section.

Deleting Teams chat messages

You can use eDiscovery and the Microsoft Graph Explorer to respond to data spillage incidents, when content containing confidential or malicious information is released through Teams chat messages. Admins in your organization can search for and delete chat messages in Microsoft Teams. This feature can help you remove sensitive information or inappropriate content in Teams chat messages. For more information, see Search and purge chat messages in Teams.

Group and view items in a review set in eDiscovery

eDiscovery review sets display content using different grouping options and include specialized viewers that you can use to examine details about individual items.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Grouping

Use the **Group** control in the command bar of a review set to view review content grouped by the following options:

Option 1: Group items by Group ID and Thread ID

If you're new to eDiscovery or are an existing eDiscovery customer with a steady stream of new cases, group review set items by using Group IDs and Thread IDs. This grouping option makes it easier to find and review related items in a review set by grouping them together in the list view. When the **Enable group** option is enabled in the review set case settings, you see the following grouping options on the **Group** control in the command bar of a review set:

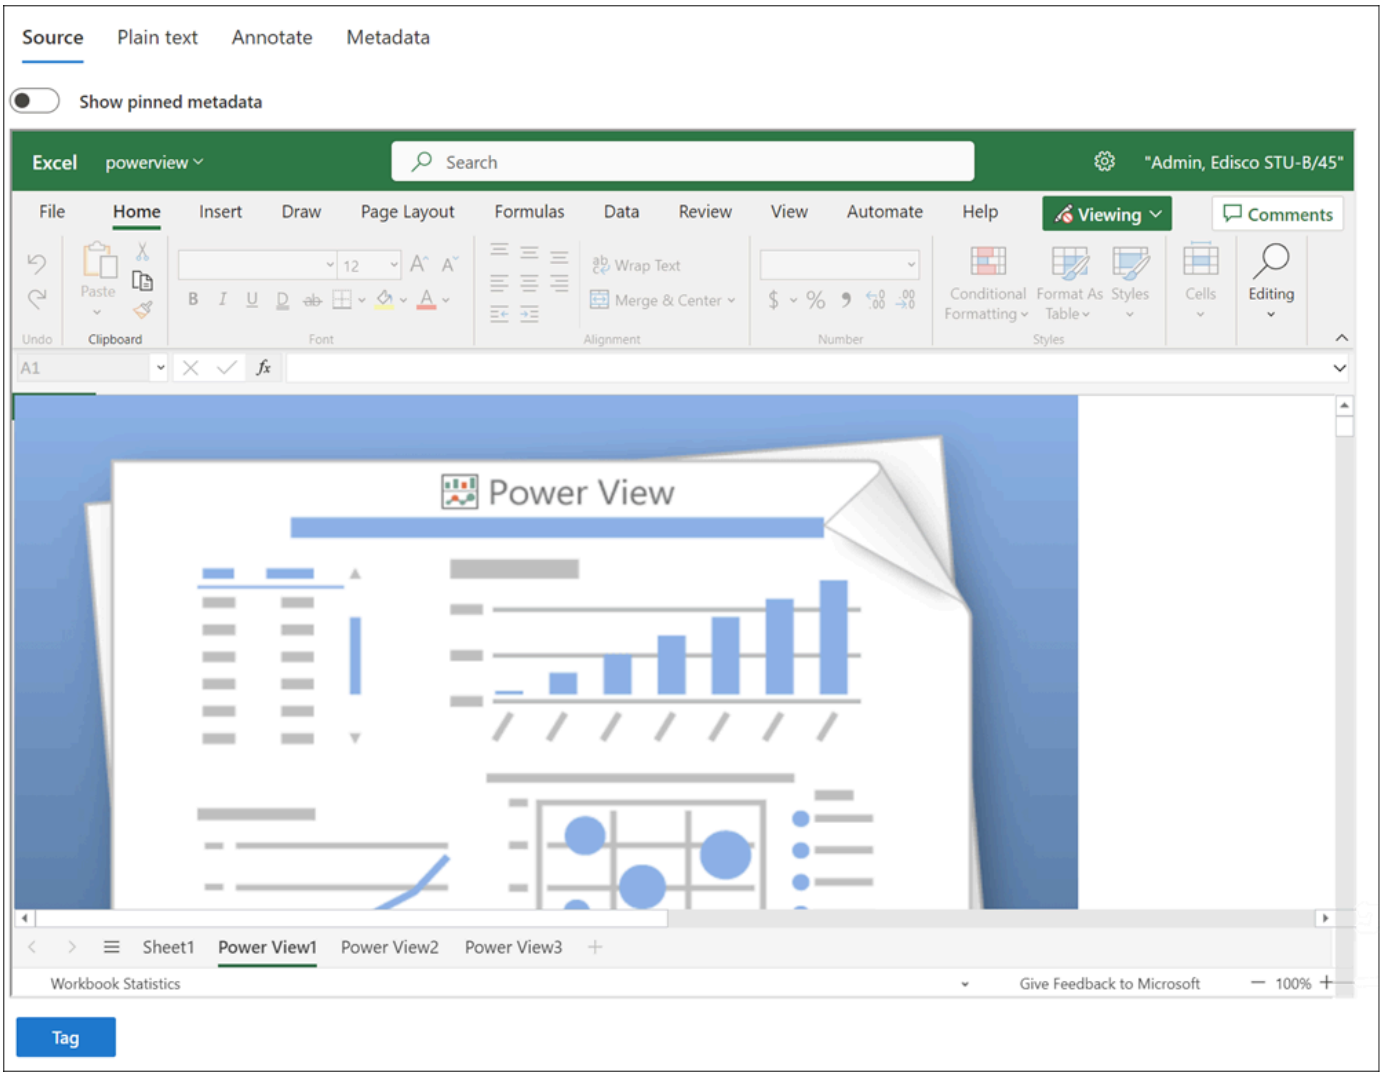
- **Group by families**: All items related to a specific file are grouped together by using the same Group ID. For example, if you have a PowerPoint file in the review set that includes embedded images or .zip files, these images and files are grouped with the PowerPoint file and shown as nested items with the file in the item list view. Microsoft 365 Copilot and Microsoft 365 Copilot Chat user prompts and responses are also grouped together by using the same Group ID when there are multiple prompts and responses associated with a file.
- **Group by conversations**: All email messages, Teams conversations, and Viva Engage conversations are grouped by using the same Thread ID and appear as nested items. Additionally, all associated content for these messages and conversations is also grouped together. For example, if you have an email conversation that includes several email messages, some of which include attachments and some that include embedded images, all

of the email messages, attachments, and images are grouped together in the review set list view under an applicable item.

> ⓘ Note
>
> For cases created before March 15, 2023, the **Enable group** toggle is disabled and the **Group by families** and **Group by conversations** options aren't available. Item grouping in review sets for these cases is based on *Family ID* and *Conversation ID* described in Option 2: Group items by Family ID and Conversation ID.

Option 2: Group items by Family ID and Conversation ID

If you're an existing eDiscovery customer with a large number of existing cases or use existing internal or third-party automation to help process review set items, you might want to continue to group review set items by using Family IDs and Conversation IDs. When the **Enable group** option is disabled in the review set case settings, you see the following grouping options on the **Group** control in the command bar of a review set:



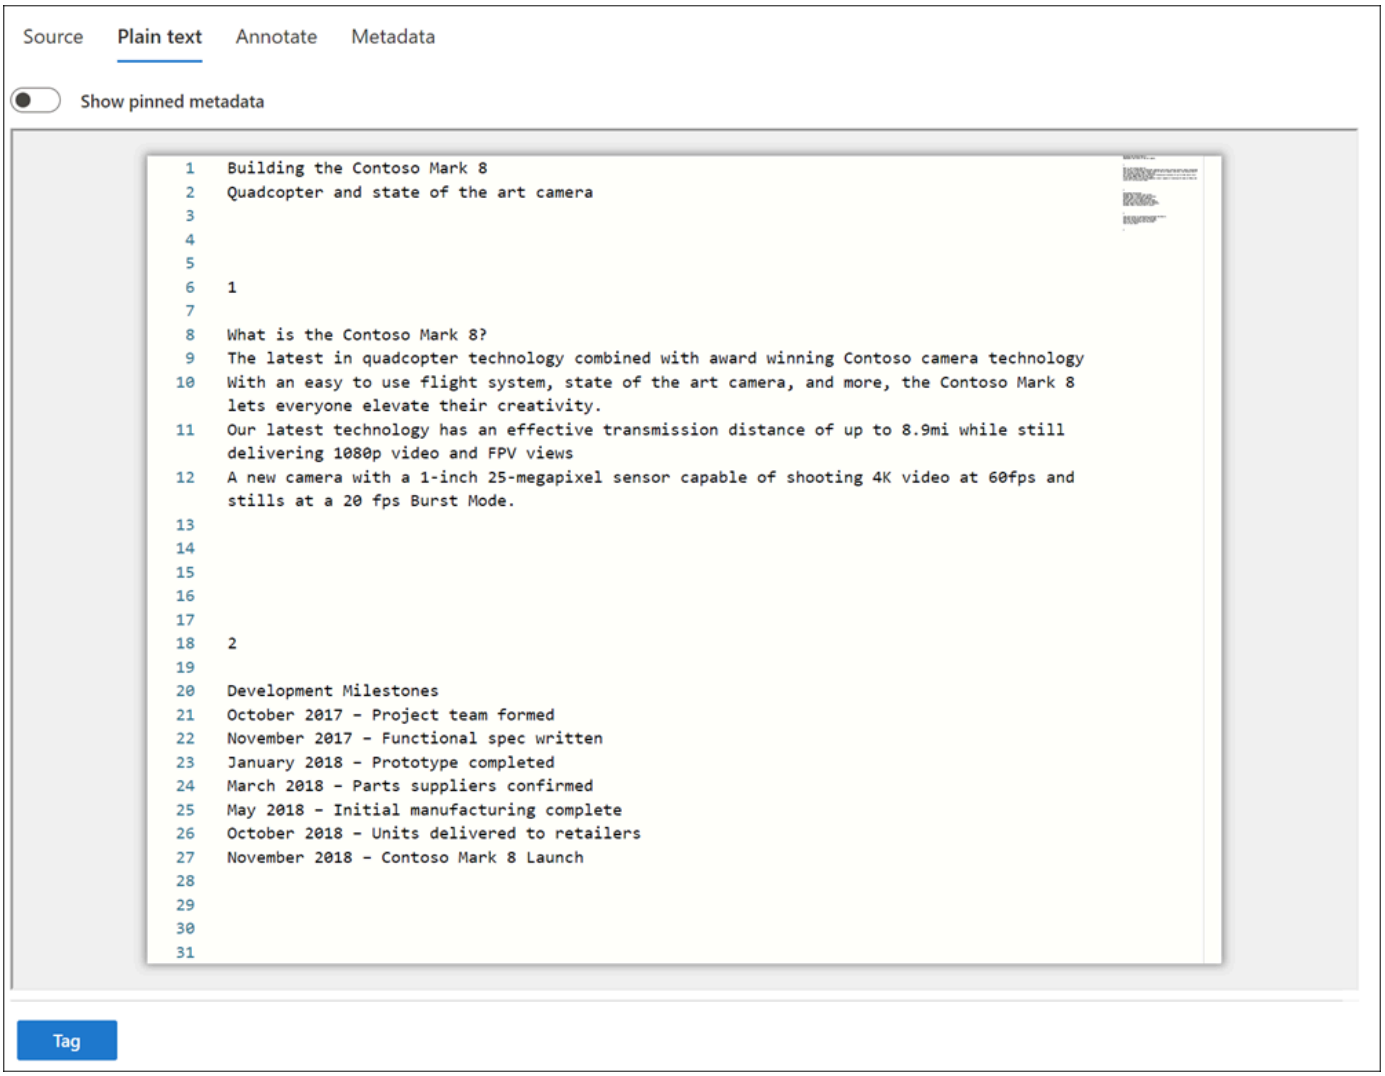
- **Group family attachments**: View review set content grouped by family. Each transcript file is displayed on a line in the list of review set items. Attachments are nested under the item.
- **Group Teams or Viva Engage conversations**: View Teams and Viva Engage content grouped by conversation. Each conversation is displayed on a line in the list of review set items. Transcript files and attachments are nested under the top-level conversation.

> ⓘ Note
>
> Cloud attachments are grouped with the conversations they appear in. Grouping cloud attachments with their conversations is accomplished by assigning the same **GroupID** as the transcript file of the message the file was attached to and the same **ConversationId** as the conversation the message appeared in. This means multiple copies of cloud attachments might be added to the review set if they were attached to different conversations.

Use source view

The **Source** viewer displays the richest view of a selected document. It supports hundreds of file types and is designed to display the truest to native experience possible. For Microsoft Office files, the viewer uses the web version of Office apps to display content such as document

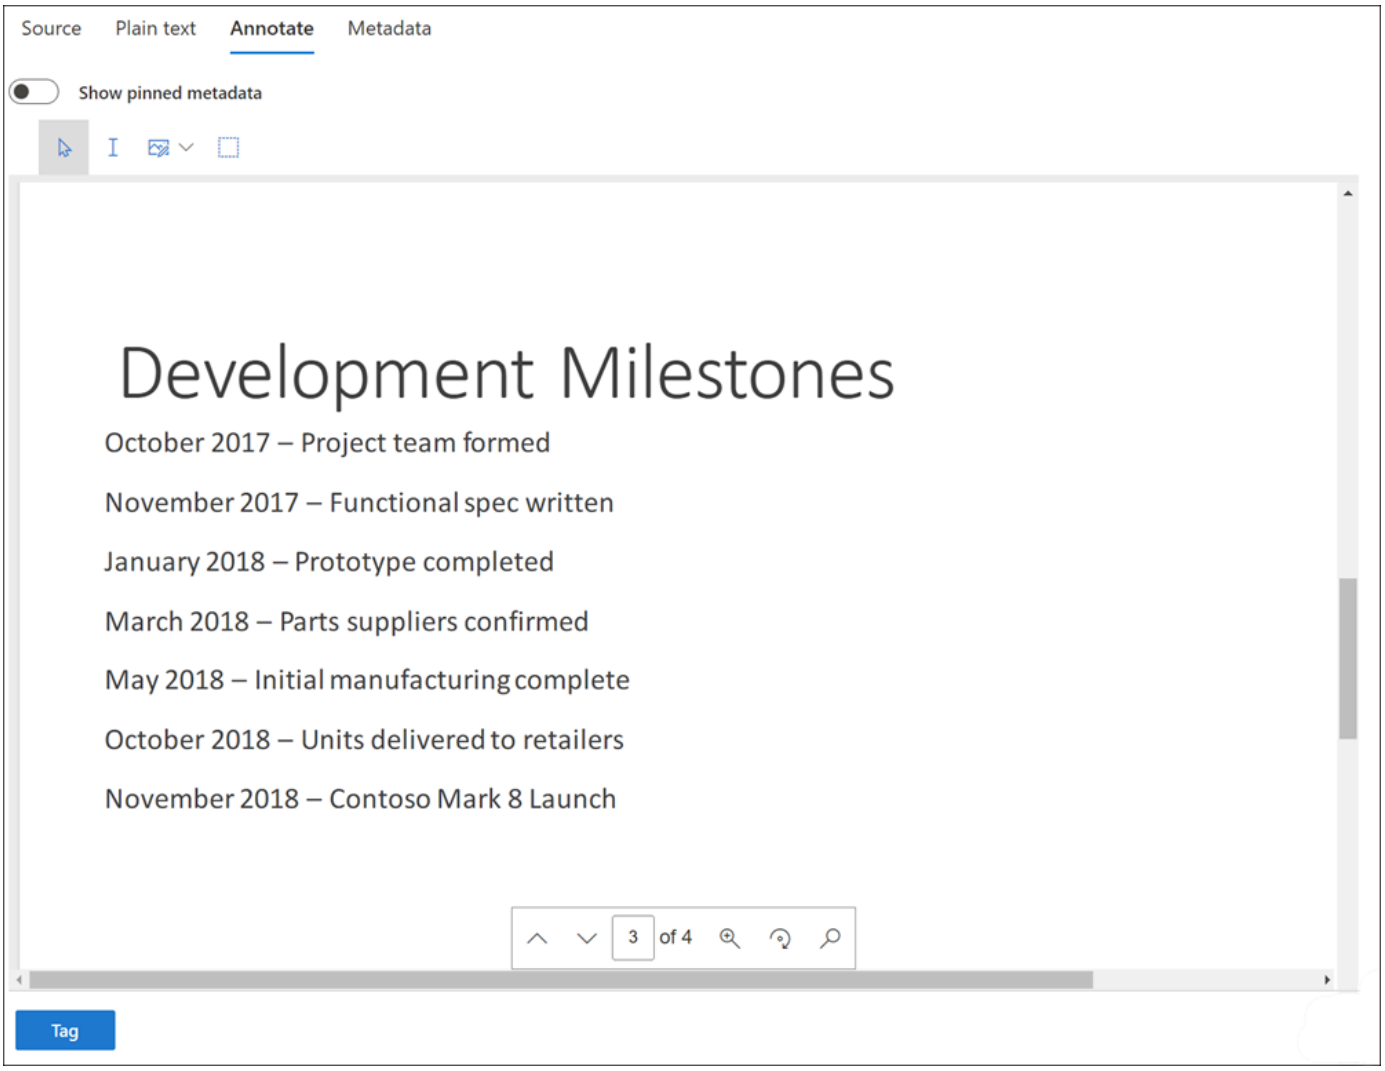
comments, Microsoft Teams chats, Excel formulas, hidden rows and columns, and PowerPoint notes.



The **Source** view doesn't support previewing video and audio files. To view these files, export them from the review set as described in Export from a review set.

Use plain text view

The **Plain text** viewer provides a view of the extracted text of a selected file. It ignores any embedded images and formatting but is useful if you want to understand the content quickly. The text view also includes these features:

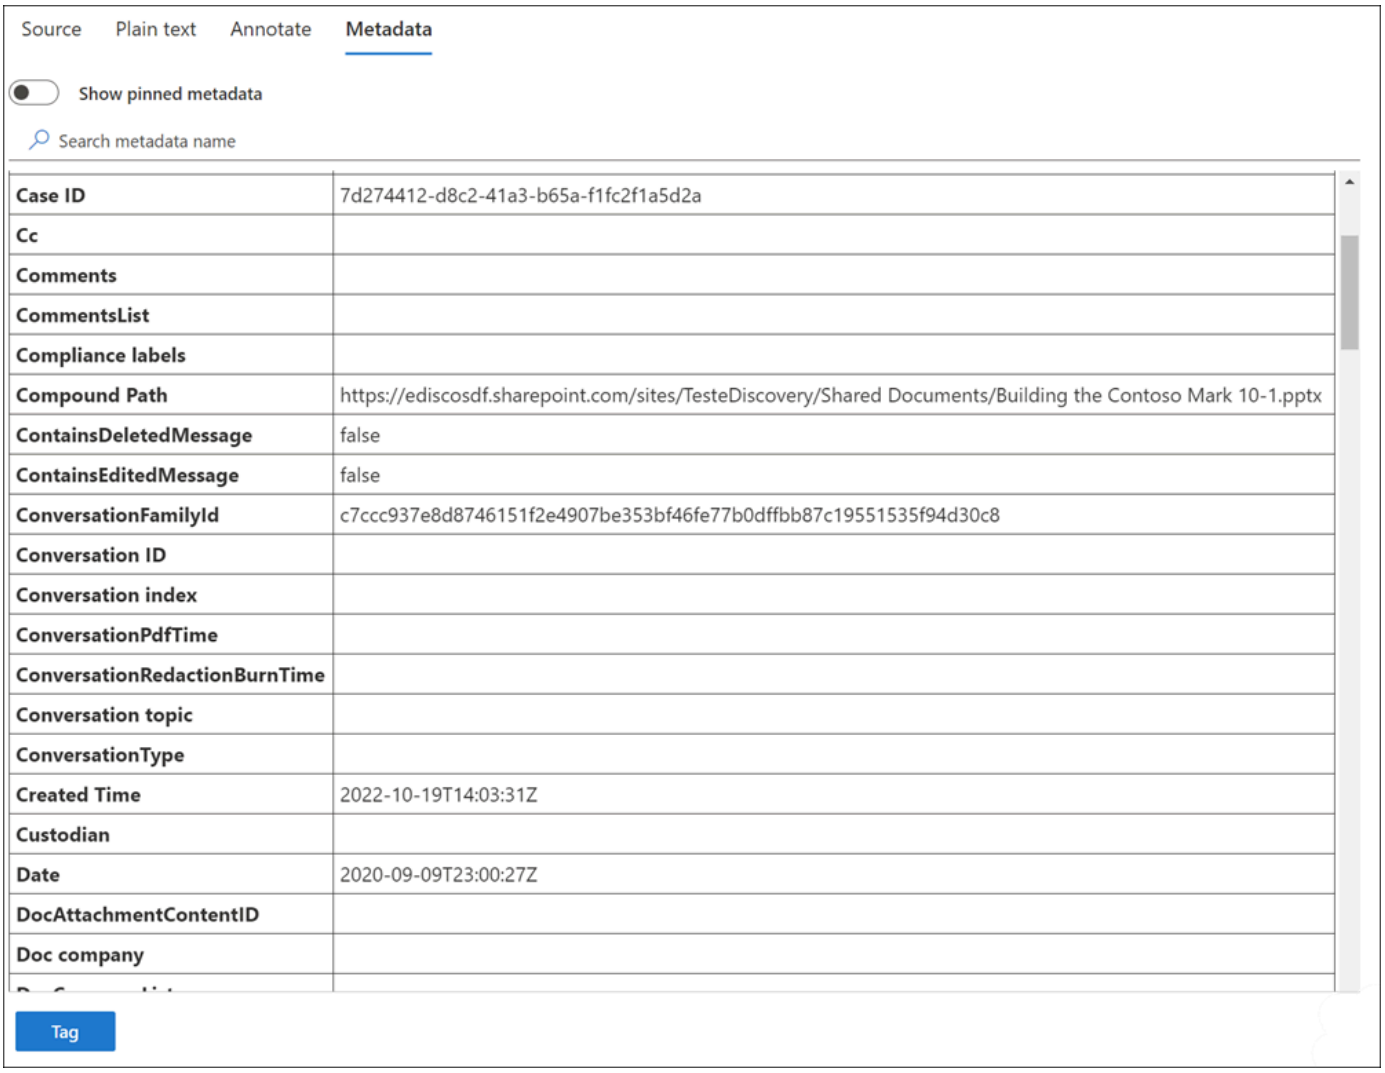


- Line counter makes it easier to reference specific portions of a document
- Search hit highlighting that highlights terms within the document and in the scrollbar

Use annotate view

The **Annotate** view provides features that let you apply markup on a selected document, including the ability to:

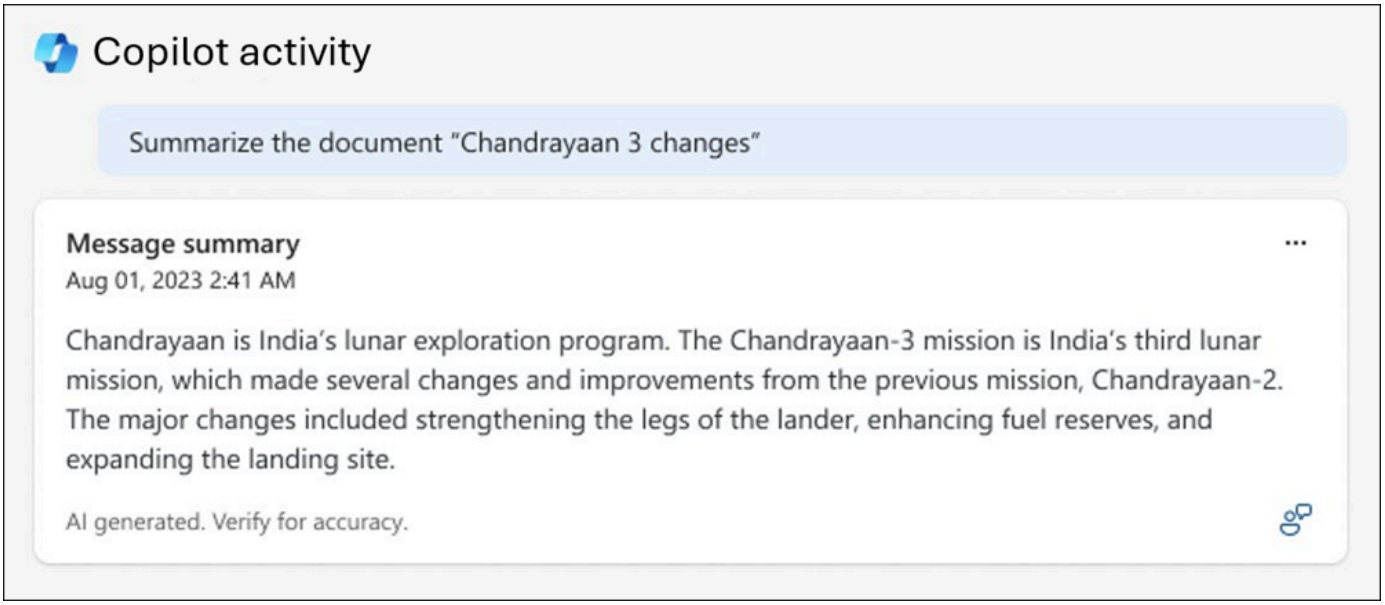
- **Select annotations**: Select annotations on a document to delete.
- **Select text**: Select text on the document to delete.
- **Area redactions**: Draw a box on the document to hide sensitive content.
- **Pencil**: Freehand draw in selectable colors on a document to bring attention to certain portions of a document.
- **Toggle annotation transparency**: Make annotations semi-transparent to view the content behind the annotation.
- **Previous page**: Go to the previous page.
- **Next page**: Go to the next page.
- **Go to page**: Enter a specific page number to go to.
- **Zoom**: Set the zoom level for annotate view.
- **Rotate**: Rotate the document clockwise.



Commit redactions

When you apply annotations in the **Annotate** view (including area redactions, text deletion, and pencil markup), the annotations save with the document but don't change how the document appears in the review set, in search results, or in exports until you **commit** them. When you commit a redaction, it generates a redacted PDF (`{itemId}_burn.pdf`) that's persisted alongside the original item in the review set.

To include redacted PDFs in an export, select *Export redaction* when configuring the export. For details on how redacted items appear in the export package – including how individual documents, attachments, and conversations are handled – see Export from a review set.



Use metadata view

You can toggle the panel in the **Metadata** view on or off to display various metadata associated with the selected document. Although you can customize the search results grid to display specific metadata, there are instances where scrolling horizontally can be difficult while reviewing data. The File metadata panel allows you to toggle on a view within the viewer.

Use Copilot activity view

The **Copilot activity** view displays the Microsoft 365 Copilot and Microsoft 365 Copilot Chat activity associated with the selected item. User prompts and Copilot responses display in the order they're generated.

Summarize an item by using Microsoft Security Copilot

You can use Security Copilot in Microsoft Purview to provide a contextual summary of most items in a review set. The summary is based on the text included in a selected item. The contextual summary saves time for reviewers by quickly identifying information helpful when tagging or exporting items.

Security Copilot summarizes the entire item, including any documents, meetings transcripts, or attachments. Most common document file types are supported.

Limitations

Security Copilot summarization in review sets has the following limitations:

- The *Plain text* view must be available for an item for Security Copilot availability. For more information about which file types support plain text views, see Supported file types in eDiscovery.
- The item content must be at least 100 words and less than 15,000 words. If the item content is fewer than 100 words or more than 15,000 words, Security Copilot doesn't summarize it.
- Summarize items in various languages supported by Security Copilot. For more information, see Supported languages in Microsoft Security Copilot.
- Currently, only individual Teams messages can be summarized. For example. if you summarize an individual Teams message, Copilot doesn't pull in the surrounding conversation (family or conversation groups).

For more information about Microsoft Security Copilot and Microsoft's artificial intelligence (AI) responsibilities, see Responsible AI FAQ.

Prerequisites for using Security Copilot

To summarize an item in a review set in eDiscovery by using Security Copilot, you must:

- Have specific licenses and onboard your organization to Security Copilot. For more information, see Learn more about Security Copilot licensing requirements and onboarding.
- Have an admin assign you at least one of the required roles to access the Security Copilot portal. For more information about these required roles, see Understand authentication in Security Copilot.

> ⓘ **Note**

Currently, eDiscovery only supports Security Copilot in the embedded experience (not the Security Copilot stand-alone experience).

Summarize an item in a review set

1. In eDiscovery, open a review set and filter the items as needed.
2. Select an item in the list. You can select a parent item or a child item.
3. In any item view, select **Summarize**. Selecting **Summarize** opens the **Copilot** panel on the right side of the screen and displays a summary of the item.

   > ⓘ **Note**
   >
   > If the plain text view isn't available for an item, **Summarize** isn't available to select.

4. To use Copilot to create the summary, select one of the suggested prompts at the bottom of the panel. For example, if the item is a legal contract in the Microsoft Word format, select the *Identify key participants*, *Identify key topics*, or *Identify action items* prompt.

   You can also enter an open-ended question in the *Ask questions and get insights about this item* field. Copilot responses are generated without using information from prior messages. For more information about prompts and promptbooks, see Microsoft Copilot in Microsoft Purview prompts and promptbooks.

   > ⓘ **Note**
   >
   > Only item content is summarized. If you ask a question relevant to the item content, Copilot provides a result. If the question isn't relevant to the item content, Copilot instructs you to ask a different question.

5. To provide feedback on the summarized content, select the drop-down arrow in the lower-right corner below the summary, and then enter your feedback.
6. After reviewing the summary, you can take other eDiscovery actions connected with review set items.

Use viewer and management tools

For selected content, you get extra view and management tools that help you work with documents.

You can select the following actions for selected content:

- **View or update notes**: Opens the **Notes** pane where you can view or add notes to the selected document. You can display the notes for the document in a column in the dashboard list by customizing your displayed columns.
- **Show in a new window**: Displays the selected document in a new browser window or tab.
- **Download PDF**: Downloads the selected document as a .pdf file.
- **Move up**: Selects the previous review set item and displays the item in the viewer.
- **Move down**: Selects the next review set item and displays the item in the viewer.
- **Maximize/Minimize**: Maximizes the viewer pane to full screen and minimizes the viewer pane.
- **Close**: Closes the selected item from the viewers.

> **ⓘ Important**
>
> To download a PDF containing items from a review set, you must be assigned the *Export* role or be assigned to a role group that includes the *Export* role. For more information about eDiscovery permissions, see [Assign eDiscovery permissions](#).

Tag items in a review set in eDiscovery

Organizing content in a review set is important to complete various workflows in the eDiscovery process. The review-set organization workflow includes:

- Culling unnecessary content
- Identifying relevant content
- Identifying content that must be reviewed by an expert or attorney

When experts, attorneys, or other users review content in a review set, they can capture their opinions related to the content by using tags. For example, if the intent is to cull unnecessary content, a user can tag documents with a tag such as "nonresponsive". After content is reviewed and tagged, you can create a review set search to exclude any content tagged as "nonresponsive". Excluding tagged nonresponsive content from the review set search eliminates that content from the next steps in the eDiscovery workflow.

You can use *tag templates* to define tags and review workflow across all cases and review sets in your organization. Using tag templates is the recommended approach and helps provide structure and standardization for tagging to ensure searches identify similar content across your organization. You can also use the tagging panel in an individual review set to customize tags for each case when tag templates don't meet your needs, but tags created here are specifically for the individual case and review set.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Tag types

eDiscovery has two types of tags:

- **Single-select tags**: Restricts reviewers to selecting a single tag within a tag group. These types of tags can be useful to ensure that reviewers don't select conflicting tags such as "responsive" and "nonresponsive". Single choice tags appear as radio buttons.
- **Multi-select tags**: Allow reviewers to select multiple tags within a tag group. These types of tags appear as checkboxes.

Tag groups

In addition to the tag types, the structure of how tag groups are organized in the tag panel can make tagging documents more intuitive. Tags are organized in tag groups. Review set search supports the ability to search by tag and by tag groups. Because review set search supports both levels, you can create a review set search to retrieve documents tagged with any tag in a group or the group itself.

For example, if you need to identify and tag privileged content, grouping can be used to make it clear that a reviewer can tag a document as *Privileged* (the tag group) and select *Attorney work product* (specific tag) as the type of privilege within the tag group.

Tag templates (preview)

Use tag templates to define and standardize tags and the review workflow across all cases and review sets in your organization. Each tag template contains tag groups where you can create a grouping structure for individual tags. You can create tag templates in the **Tag templates** tab in **eDiscovery settings**.

Create tag templates

To create a new tag template, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **Settings** solution card, then select **eDiscovery**.
3. Select **Tag templates**.

4. On **Manage tag templates**, select **Create**.
5. On **New tag template**, enter a name and description for the tag template.
6. In the initial tag group, enter a tag group name and use the dropdown to define this as a **Multi-select** or **Single-select** tag group.
7. Enter at least one tag name in the tag group. Select **Add tag** to add more tags to the tag group.
8. If needed, select **Add tag group** to add more tag groups and tags to the tag template.
9. Preview the tag template group and tag structure in the **Preview** pane on the right side of **New tag template**.
10. When complete, select **Save**.

The tag template is now available for use in all cases and review sets in your organization.

Manage tag templates

After you create a tag template, you can edit or delete it. You can also view information about the tag template, including the dates when you created or last modified it.

To edit a tag template, select the tag template name on **Manage tag templates** and select **Edit**. On **Edit tag template**, you can edit the tag template name, description, and tag groups and tags. When you're done, select **Save**.

To delete a tag template, select the tag template name on **Manage tag templates** and select **Delete**. Select **Yes** to confirm the deletion or **No** to cancel the deletion.

Apply tag templates to a case and review sets

After you create a tag template, you can apply it to a review set. You can apply a tag template when you create a new review set or when you edit an existing review set.

To apply a tag template to a new review set, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Review sets** tab.
4. Select a review set, then select the **All items** tab.
5. On the review set command bar, select **Manage** > **Tags**.
6. On **Manage tags**, delete the blank tag group, then select **Import tag templates**.

7. On **Import tag templates**, select the tag template that you want to apply to the review set and then select **Import**.
8. If needed, edit the tag template as it applies to the case and review set.
9. Select **Save** to apply the tag templates to the case and review set.

The applied tag template is now available for use in the case and all included review sets.

Create tags for a specific case or review set

If you don't want to use tag templates for a specific case or review set, you can create tags directly in the review set. This approach is useful when you need tags that are specific to a case or review set. However, these tags are unique to the case or review set and can't be used in other cases or review sets.

Before you apply tags to items in a review set, you need to create a tag structure.

1. Open a review set. On the review set command bar, select **Manage** > **Tags**.
2. On **Manage tags**, enter a *Tag group name* and select either **Multi-select** or **Single-select** for the tag group.
3. Enter one or more tags in the tag group. Select **Add tag** to add more tags to the tag group.
4. Select **Add tag group** if you need more tag groups and tags.
5. Preview the tag template group and tag structure in the **Preview** pane on the right side of **New tag template**.
6. Select **Save** to apply the tag group and tags to the case and review set.

Apply tags

With the tag structure from tag templates or custom tagging in place, reviewers can apply tags to items in a review set by configuring tagging settings.

1. In the review set command bar, select **Tag files** to display the **Tag files** flyout page (also called the *tagging panel*).

2. On the **Tag files** flyout page, set the following options to configure how to tag items displayed in the review set. The filters or filter queries currently applied to the review set determine which items are displayed and therefore the items that you can apply tags to. For more information, see Search content in a review set in eDiscovery.

    - **Choose selection**. Choose one the following options to determine the scope of items to apply tags to.

- **Tag selected items**: Applies tags to the items that you select. You can select items before or after launching the tagging panel. The **Tag selected items** option displays (in real time) the number of selected items that are tagged.
- **Tag all items in list**: Applies tags to all items displayed in the review set. The **Tag all items in list** option displays the total number of items that are tagged.

- **Expand selection**: Use the following options to tag additional items that are related to tagged items in the review set. Depending on the **Enable group** option enabled in the review set settings, you see the following options:

  With *Enable group* in settings disabled:
  - **None**: The **None** option doesn't apply tags to associated family items or associated conversation items. It only applies tags to the items that are selected or to all items in the review set list.
  - **Include family groups**: The **Include family groups** option applies the same tag to the associated family items of items that are tagged. *Family items* are items that share the same **FamilyId** metadata property value. For example, a document that's attached to an email message shares the same **FamilyId** as the email message. So if this option is selected for this example, the email message and the document are tagged, even though the document might not be included in the list of review set items.
  - **Include conversation groups**: The **Include conversation groups** option applies the same tag to all items that are in the same Teams or Viva Engage conversation as the items that are tagged. *Conversation items* are items that share the same **ConversationId** metadata property value. All messages, posts, and corresponding transcript file of a conversation share the same **ConversationId**. If this option is selected, then all items in the same conversation (and transcript file) are tagged, even though some of those conversation items might not be included in the list of review set items.

  > ⓘ Note
  >
  > Including family or conversation groups doesn't change the count of items shown in the **Tag selected items** or **Tag all items in list** options. In other words, the number of grouped items that are tagged isn't displayed.

  With *Enable group* in settings enabled:

    - **None**: The **None** option doesn't apply tags to family group items or conversation group items. It only applies tags to the items that are selected or to all items in the review set list.
    - **Include family groups**: The **Include family groups** option applies the same tag to the associated family items of items that are tagged. *Family group* items are items that share the same **GroupId** metadata property value. For example, a document that's attached to a PowerPoint file shares the same **GroupId** as the document. So if this option is selected for this example, the document and the PowerPoint file are both tagged. Both are grouped together in the list of review set items.
    - **Include conversation groups**: The **Include conversation groups** option applies the same tag to all items that are in the same email, Teams, or Viva Engage conversation as the items that are tagged. *Conversation group* items are items that share the same **ThreadId** metadata property value. All messages, posts, and corresponding transcript files of a conversation share the same **ThreadId**. If this option is selected, then all items in the same conversation (and transcript file) are tagged. All items are grouped together in the list of review set items.

- **Assign tags**: This section displays the tags (organized by tag groups) that you can apply to documents. These tags are either the tag groups and tags assigned using tag templates or custom tag groups and tags that you create for this case. You can only apply one single-choice tag (identified by a radio button) per tag group. However, you can apply multiple multichoice tags (identified by a checkbox).

3. Select **Apply tags** to apply the tags based on your settings.

   The **Applying tags** status message is displayed for each tag group on the tagging panel to indicate a tagging process has started. Tags for each tag group in the **Assign tags** section are greyed out until the process completes.

> **Tip**
>
> If you're in the process of configuring the settings on the tagging panel, but want to start over, select **Reset tag assignment** to clear the current setting. This control doesn't apply to items that are already tagged, and it doesn't change or remove tags from previously tagged items.

Set up smart tags

Machine learning (ML) capabilities in eDiscovery can help you make the decision process more efficient when reviewing case documents in a review set. Smart tags bring the ML capabilities to where you record decisions: when tagging documents during review. When you create a smart tag group, the decisions that result from the ML model you associate with the smart tag group display in-line with the tags in the tag group. Displaying model decisions inline with the tag group helps you see the ML results information in-line when you're reviewing specific documents.

How to set up a smart tag group

To create a smart tag group, complete the following steps:

1. In a review set, select **Manage review set** and then select **Manage tags**.
2. Select **Add tag group** and then select **Add smart tag group**.
3. Select the ML model that you want to associate to the tag group.

   Selecting an ML model creates a tag group and *N* child tags, where *N* is the number of possible outputs of the model. For example, the attorney-client privilege detection model has two possible outputs:

   - **Positive**: Use to tag documents that contain attorney-client privileged content.
   - **Negative**: Use to tag documents that don't contain attorney-client privileged content.

   If you select this model, you create a tag group with two child tags (one child tag named **Positive** and the other named **Negative**) for the review set. In this example, each child tag corresponds to one of the possible outputs from the attorney-client privilege detection model.
4. Optionally, rename the tag group and the child tags. For example, you could rename the **Positive** tag to **Privileged** and the **Negative** tag to **Not privileged**.

How to use smart tags

When reviewing a document, the model's results display next to the appropriate child tag. For example, if you have a smart tag group for attorney-client privilege detection and you review a document that is potentially privileged, the reason for that conclusion displays next to the appropriate tag. The tag isn't automatically applied to the document. The reviewer makes the decision about how to tag the document.

Monitor tagging jobs

When you tag a large number of items or select the **Tag all items in list** option, a **Tagging documents** job is created. You can view the status of this job on the **Jobs** tab in the case. The **Jobs** tab helps you track large tagging jobs that might take a long time to complete. In some cases, a tagging job might be complete, but the **Applying tags** status message in the tagging panel still displays. To update the status of tagging jobs, select **Refresh** in the review set command bar.

Remove tags

You can remove tags from items in a review set. However, you can't remove a single-choice tag that you applied to a review set item. You can only change a single-choice tag to another single-choice tag within the same tag group.

To remove a tag:

1. Select the items that you want to remove the tag from.
2. Select **Tag files** to display the tagging panel.
3. Under **Assign tags**, clear the tag, then select **Apply tags**.

You can also use the previous procedure to change the tag applied to selected items. After clearing the current tag, you can select a different one.

Analyze data in a review set in eDiscovery

When you collect a large number of documents, it can be difficult to review them all. eDiscovery provides tools to analyze the documents so you can reduce the number of documents to review without losing any information. eDiscovery analysis tools also help you organize the documents in a coherent manner. For more information about these capabilities, see:

- Near duplicate detection
- Email threading
- Themes

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Run analytics for a review set

To analyze data in a review set, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, and then select **Cases** in the left navigation.
3. Select a case.
   a. (Optional) select **Case settings**.
   b. On **Case settings**, select **Search & analytics**.
   c. On **Search & analytics**, configure analytics settings for your case.
   d. After selecting the applicable search and analytics options, select **Save**. Close **Case settings**.
4. Select the **Review sets** tab.
5. Select a review set, then select the **All items** tab.
6. Select **Analytics** > **Run document & email analytics**.
7. A notification dialog appears about the time it takes to complete the analytics process. Select **Yes** to continue with running the analytics process or select **Cancel**.
8. Select **OK** when notified that the analyze process is created.

You can check the progress of the analysis process by selecting **Process manager** in the review set. The process type is *Run analytics*.

After the analysis process completes, you can view the analytics report, run queries within your review set on outputs of the analysis, and see related documents of a given document.

Use the For Review (preview) filter query

After running analytics for the review set, use an automatically generated filter query (called *For Review*) to filter your review. This query excludes immaterial, duplicate, or noninclusive items. The For Review filter query leaves you with only the items that are representative, unique, and inclusive in the review set.

To apply the **For Review - Unique items only (preview)** filter query to a review set, select the **Saved filter queries** dropdown list, and then select **[AutoGen] For Review - Unique items only (preview)**. Minimize the query details to view the results.

Here's the syntax for the **For Review - Unique items only (preview)** filter query in Keyword Query Language (KeyQL) format:

```
(((FileClass="Email") AND (IsInclusive="True") AND (MarkAsRepresentative="Unique")) OR ((FileClass="Attachment") AND (MarkAsRepresentative="Unique")) OR ((FileClass="Document") AND (MarkAsRepresentative="Unique")) OR ((FileClass="Conversations") AND (MarkAsRepresentative="Unique")) OR ((FileClass="Attachment" OR FileClass="Conversations" OR FileClass="Document" OR FileClass="Email") AND  isempty (MarkAsRepresentative)))
```

The following list describes the result of the For Review - Unique items only (preview) filter query in terms of what content is displayed after you apply it to the review set.

- **Email**: Displays items that are marked as both **Inclusive** and **Representative**. An email is marked as IsInclusive True when it contains all the unique content from a thread, including all previous replies. It ensures that only the most comprehensive email in a thread is reviewed, which is essential for understanding the full context of the conversation without having to review each individual reply. An email is MarkedAsRepresentative Unique when it's the single representative copy among duplicates.
- **Attachments**: Filters out duplicate attachments in the review set. Only attachments that are unique in the review set are displayed.
- **Documents**: Filters out duplicate documents. Only documents that are unique in the review set are displayed.

- **Teams conversations**: Filter out duplicate Teams (and Viva Engage) conversations. Only conversations that are unique in the review set are displayed.
- **Other**: Any emails, attachments, documents, and conversations in the review set where the *MarkedAsRepresentative* field doesn't contain a value. The empty value means that analytics wasn't able to generate a value, so you should review and assess these items.

For more information about inclusive types and document uniqueness, see Email threading in eDiscovery.

Use the Potentially Immaterial Items filter query

The potentially immaterial query is designed to filter out specific types of files that could be immaterial in a review set. It targets two main categories:

1. Compressed files. It filters out files with extensions commonly associated with compressed or archived formats, such as .zip.
2. Small image files. It filters out image files that are smaller than 3,072 bytes (3 KB). These small image files are typically thumbnails, icons, or low-resolution images.

To apply the **Potentially Immaterial Items** filter query to a review set, select the **Saved filter queries** dropdown list, and then select **[AutoGen] Potentially Immaterial Items**. Minimize the query details to view the results.

View the analytics report

To view the analytics report for a review set, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, and then select **Cases** in the left navigation.
3. Select a case, then select the **Review sets** tab.
4. Select a review set, select the **All items** tab.
5. Select **Analytics** > **Show reports**.

The **Analytics** report has seven components from the analysis. Hover over the results to view counts for each component:

- **Target population:** The number of email messages, attachments, and loose documents found in the review set.

- **Documents (excluding attachments):** The number of loose documents that are pivots, unique near duplicates of a pivot, or an exact duplicate of another document.
- **Emails:** The number of email messages that are marked as *inclusive*.
- **Attachments:** The number of email attachments that are unique or duplicates of another email attachment in the review set.
- **Number documents by file type:** The number of files, identified by file extension.
- **Documents by source:** A summary of content by its original data source.
- **Documents aggregated by process:** A summary of content by review set processes.

Export items from a review set in eDiscovery

The export feature lets you customize the content that's included in the download package when you export items from a review set in eDiscovery. Export processes are retained for the life of the case. However, you must download the content from an export process within 30 days after the export process completes.

> **Tip**
>
> Do you prefer an interactive configuration guide experience? Check out the Export data guide.

To export documents from a review set, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Review sets** tab.
4. Select the review set that you want to export and select the **All items** tab.
5. In the review set, select the items to export.
6. Select **Action** > **Export** on the command bar.
7. The **Export** flyout page appears with the settings to configure the export. Some options are selected by default, but you can change these options. See the export options section for descriptions of the options that you can configure.
8. After you configure the export options, select **Export** to start the export process. Go to the **Process manager** to track the progress and to download exported content.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Choose export options for a review set

Use the following options to configure the export. Some output options don't allow all options. For example, when exporting to the PST format, you can't export text files or redacted PDFs.

- **Export name**: Name of the export job. This value names the downloaded ZIP files.
- **Description for the export**: Free-text field for you to add a description.
- **Select items to include in your export**
  - **Selected documents only**: This option exports only the documents that you currently selected. This option is only available when you select items in a review set.
  - **All filtered documents**: This option exports the documents in an active filter. This option is only available when you apply a filter to the review set.
  - **All documents in the review set**: This option exports all documents in the review set.
- **Expand selected documents to include**: Use the following options to export additional items that are related to filtered or selected items in the review set:
  - **Associated family items**: This option includes associated family items. Family items are items that share the same *FamilyId* metadata property value. For example, a document that's attached to an email message shares the same *FamilyId* as the email message. If you select this option, the email message and the document are exported in this example, even though the document might not be included in the list of review set items.
  - **Associated conversation items**: This option includes associated items that are in the same Teams or Viva Engage conversation. Conversation items are items that share the same *ConversationId* metadata property value. All messages, posts, and corresponding transcript file of a conversation share the same *ConversationId*.

    If you select **Associated family items** or **Associated conversation items**, all items that share the same association ID are exported, even though some of those items might not be in the results of the current review set query.
- **Export type**: Exported content is either available for download directly through a web browser or can be sent to an Azure Storage account. The **Export item report only** and **Export items with item report** options enable direct download.
  - **Export item report only**: Only the summary and item report are created. When you select “Export item report only,” the various options for organizing data, folder and path structure, condensing paths, and other options are hidden to avoid any confusion.
    - *Export tags*: Includes tags you created and applied during review in the Item report.
  - **Export items with item report**: Items are exported with the item report.

- *Export redaction*: When selected, items in the export package that have committed redactions are delivered as the redacted PDF (`{itemId}_burn.pdf`) instead of the original native file. Specifically:
  - **Individual documents and email attachments** with committed redactions: the native file is **replaced** by the redacted PDF in the export package. The original native isn't included alongside.
  - **Conversations** (for example, Microsoft Teams or Viva Engage threads): both the native conversation file and the redacted PDF are included.
  - **Extracted text** files for redacted items contain the OCR'd text from the redacted PDF, not the original text.
  - **Family expansion** applies to redaction the same way it applies to the rest of the export: a redacted child attachment of a responsive parent is included as the redacted PDF.

  If you need both the original native file and the redacted PDF for the same item, run two exports — one with *Export redaction* selected and one without — and combine the packages.

  If you don't select this option, the export contains original native files only, even for items that have committed redactions.

- *Export text files*: This option exports the extracted text of the document in a separate file.

- *Export tags*: This option includes tags you created and applied during review in the Item report.

- *Convert supported file formats to HTML*: This option converts supported cloud-native file formats, such as `.loop` and `.page` files (used by Copilot Notebook and Page content), to HTML during export. This option is useful when your organization's post-export workflows support HTML but lack tooling for native cloud file formats. This option isn't selected by default.

- **Export format**: Exported content options for Exchange items.
  - **Create PSTs for messages where possible**: This option creates .pst files for messages.
  - **Create .msg files for messages**: This option creates .msg files for messages.

  The following settings control whether the output package contains splits based on location of the item and whether to include folder structure and naming convention.

- In the **Package size settings** section, configure the maximum export package size the export process creates.
  - If you chose *Create PSTs for messages*, you can configure the Maximum PST package size to 1 GB, 2 GB, 5 GB (default), or 10 GB.
  - You can configure the maximum .zip package size to 2 GB, 10 GB (default), 20 GB, or 40 GB. The maximum .zip package size needs to be the same or greater than the maximum PST package size to contain the PST files in .zip packages when downloaded.
  - Select one or more of the following options:
    - **Organize data from different locations into separate folders or PSTs**: This option organizes data into separate folders for each data location. When exporting mailbox content, items from the primary mailbox and any associated archive mailboxes (including multiple archives) are merged into a single PST file, even if this export option is selected.
    - **Include folder and path structure of the source**: This option includes the original folder and folder path structure for items.
    - **Condense paths to fit within 259 characters**: This option condenses the folder path for each item to 259 characters or less.
    - **Give each item a friendly name**: This option creates a friendly name for each item.

    The option for a condensed directory structure was previously available in the legacy eDiscovery experience. For a similar experience, deselect the following options in the **Export format** section:
    - *Organize data from different locations into separate folders or PSTs*
    - *Include folder and path structure of the source*
    - *Give each item a friendly name*

For more information about export file types and `item.csv` report fields, see Document metadata fields in eDiscovery.

Monitor your export process and view export settings

After you submit your export process, you can monitor the progress in the Process manager. You can also view the settings you chose for the export and download information for this export process in a consolidated report. If you're working with Microsoft support, you can copy process job information to share with your support representative.

To improve export performance, reduce the size of the exported package using date ranges or other types of filters to decrease the total size of the search results. If an export runs for more than seven days without completing, it's automatically canceled. To prevent cancellation, divide exports into smaller batches.

View completed exports from a review set

To view a list and details about completed exports from a review set, select the **Exports** tab in a case. On the **Exports** tab, you see the following details for each export process:

- **Export name**: The name of the export.
- **Status**: The current status of the export process.
- **Review set name**: The name of the review set from which the export was created (when the export is created from a review set).
- **Search name**: The name of the search from which the export was created (when the export is created from a search).
- **Created**: The UTC date and time the export was created.
- **Completed**: The UTC date and time the export was completed.
- **Duration**: The duration of the export process.
- **Created by**: The user that created the export process.

> **Tip**
>
> You can configure the **Microsoft Purview eDiscovery API** to enable the programmatic download of export packages and the reports from an export process in an eDiscovery case.

Add items from a review set to another review set in eDiscovery

In some cases, you might need to select documents from one review set and work with them individually in another review set. This approach is especially useful if you culled content in a review set and want to run analytics on the subset of data.

Follow the workflow in this article to add content from one review set to another.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Create a review set

Before you start, you need to create a review set to add the data to. You can add a new review set on the **Review sets** tab of the case. For more information, see Create a review set.

Step 1: Identify content to add to another review set

You can add content from one review set to another review set by selecting specific documents in the source review set or by selecting all items returned by a review set query, which filters items based on search criteria you define. If you're adding selected items, select the items, select **Action**, and then select **Add to another review set**.

Step 2: Specify options for adding to another review set

In the **Add to another review set** flyout, complete the following steps:

1. Select the review set you want to add the items to.

2. Choose from the following content options:

   - **Selected documents only**
   - **All filtered documents**
   - **All documents in the review set**

3. In the **Additional information** section, select options to include all metadata (by selecting the **Metadata** check box) from the items and whether to include the tags (by selecting the **Tags** check box) from the source review set when the documents are added to the new review set.

4. After you select **OK**, a new process named **Adding data to another review set** is created to add the content to another review set. You can go to the **Process manager** in the new review set to monitor the progress of this process.

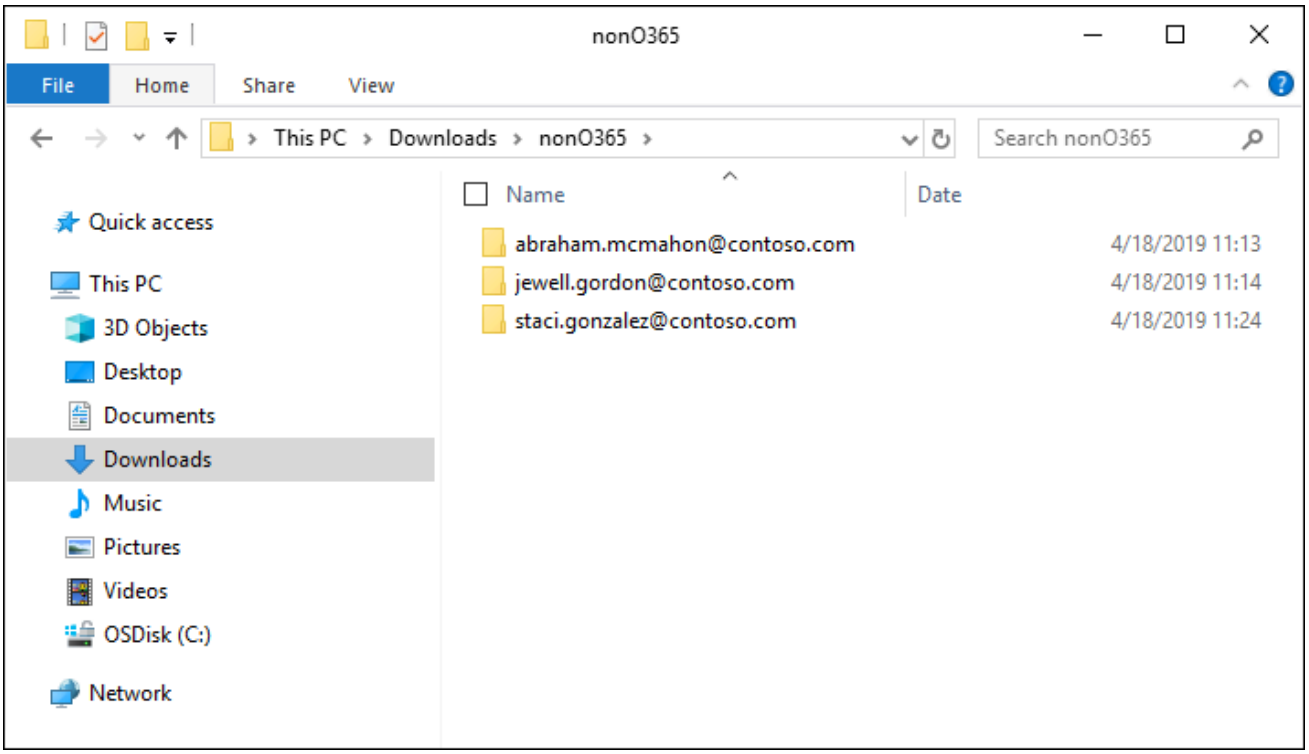
Import external data into a review set in eDiscovery

Not all documents that you need to analyze in Microsoft Purview eDiscovery are in Microsoft 365. With the import external data feature in eDiscovery with premium features, you can upload documents that aren't in Microsoft 365 to a review set. This article shows you how to bring your external data into eDiscovery for analysis.



Requirements to import external data

To use the import external data feature in eDiscovery, you need the following requirements:

- eDiscovery with eDiscovery premium features enabled in your organization.
- All custodians that you want to associate external data to must have the appropriate license. For more information, see Get started with eDiscovery.
- An existing eDiscovery case.
- External data must be a file type supported by eDiscovery. For more information, see Supported file types in eDiscovery.
- All files that you upload to a review set must be located in folders, where each folder is associated with a specific custodian. The names for these folders must use the following naming format: *alias@domainname*. The alias@domainname must be the user's Microsoft 365 alias and domain. You can collect all the alias@domainname folders in a root folder. The root folder can only contain the alias@domainname folders. Loose files in the root folder aren't supported.

  The folder structure for the external data that you want to upload is similar to the following example:
  - c:\nonO365\abraham.mcmahon@contoso.com
  - c:\nonO365\jewell.gordon@contoso.com
  - c:\nonO365\staci.gonzalez@contoso.com

  Where abraham.mcmahon@contoso.com, jewell.gordon@contoso.com, and staci.gonzalez@contoso.com are the SMTP addresses of custodians in the case.

- An account that's assigned to the eDiscovery Manager role group (and added as eDiscovery Administrator). For more information about role groups, see Assign permissions in eDiscovery.

- The AzCopy tool installed on a computer that has access to the external data folder structure. To install AzCopy, see Get started with AzCopy. Be sure to install AzCopy in the default location, which is **%ProgramFiles(x86)%\Microsoft SDKs\Azure\AzCopy**. Use the latest version of AzCopy. Other versions of AzCopy might not work when loading external data in eDiscovery.

Import external data into eDiscovery

To import external data content into eDiscovery, complete the following steps:

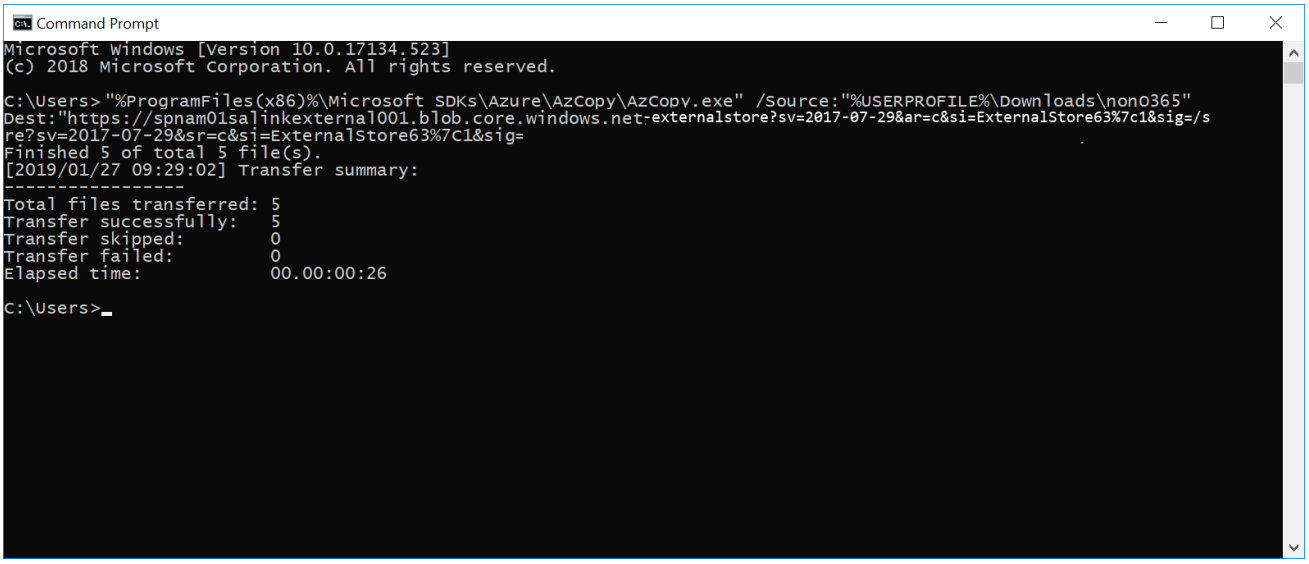
1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery *Administrator* permissions.

2. Select the **eDiscovery** solution card and then select **Cases** in the left navigation.

3. Select a case, then select the **Review sets** tab.

4. Select the review set that you want to import.

5. In the review set, select **Manage**, and then select **Import external data**.



6. Select **Upload files** to start the data import workflow. The first step in the workflow prepares a secure Microsoft-provided Azure Storage location to upload the files to. When the preparation is completed, **Next: Upload files** becomes active.

7. Select **Next: Upload files**.

8. On the **Upload files** page, complete the following steps:

    - In the **Path to location of files** box, verify or type the location of the root folder where you stored the external data you want to upload. For example, for the location of the example files shown in the Requirements to import external data section, type **%USERPROFILE\Downloads\nonO365**. Providing the correct location ensures the AzCopy command displayed in the box under the path is properly updated.
    - Select **Copy to clipboard** to copy the command that is displayed in the box.

9. Start a Windows command prompt, paste the command that you copied in the previous step, and then select **Enter** to start the AzCopy command. After you start the command, the external data files are uploaded to the Azure Storage location that was prepared in step 6.

> **ⓘ Important**
>
> Use the latest version of AzCopy to successfully use the command that's provided on the **Upload files** page.

10. Go back to the Microsoft Purview portal, and select **Next: Process files** in the workflow. Selecting **Next: Process files** initiates processing, text extraction, and indexing of the external data files that you uploaded to the Azure Storage location.

11. Track the progress of processing the files on the **Process files** page or on the Process manager by viewing a job named **Adding external data to a review set**. After the job finishes, the new files are available in the review set.

12. After the processing finishes, you can close the workflow.

Review the upload process report

Use Process Manager to track the upload process. When the process finishes, download a process report that provides information about the imported external data.

The upload Non-Office 365 process report includes both a Summary CSV and an Items CSV report. These reports provide details about the upload process and a list of items added to the review set and associated metadata.

Use the Query Report to create keyword reports for KeyQL queries

When you filter in a review set, it can be difficult to compare filtered results when using multiple saved queries. The Query Report helps you generate and download a consolidated report on multiple queries for a review set. With the consolidated query report, you can quickly see the total count and volume of filtered items on a particular keyword search or multiple compound KeyQL queries.

Select an individual query report item to review specific filtered items. You can select individual items and view the source, plain text, and metadata information for an item.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Create a query report

To create a query report in a review set, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases**.
3. Select a case, then select the **Review sets** tab.
4. Select a review set, then select the **All items** tab.
5. Select **Actions** > **Query Report**.
6. On the **Query Report** page, enter your search queries and separate each with a line break (pressing enter on your keyboard). A report is generated for each search query line.

   For example, if you want to filter by:

   - a keyword *confidential* in items for one query,
   - a filter for two keywords *confidential* and *Project Infinity* in items for another query,

- and filter using a complex KeyQL statement *(((FileClass="Email") AND (InclusiveType="InclusiveMinus" OR InclusiveType="Inclusive")) OR ((FileClass="Attachment") AND (UniqueInEmailSet="true")) OR ((FileClass="Document") AND (MarkAsRepresentative="Unique")) OR (FileClass="Conversations"))* for a third query,

You would use the following values on separate lines in the **Query Report (preview)** search query field:

```
confidential
confidential AND Project Infinity
(((FileClass="Email") AND (InclusiveType="InclusiveMinus" OR InclusiveType="Inclusive")) OR ((FileClass="Attachment") AND (UniqueInEmailSet="true")) OR ((FileClass="Document") AND (MarkAsRepresentative="Unique")) OR (FileClass="Conversations"))
```

7. Select **Generate report**.

The results of the queries are summarized with the following information displayed for each query:

- **KeyQL**: The Keyword Query Language (KeyQL) statement used for the filter query.
- **Locations with hits**: The number of locations with filter query hits.
- **Count**: The number of items in the filter result.
- **Percentage**: The percentage of hits in the total count of items.
- **Size**: The file size of the items with hits.

Use the Query Report

To view the individual items that the filter queries return, double-select the filter query line in the report. Select an individual item to view item details. The item information is read-only, so you can't annotate, modify, or export these items.

To download the report summary information for the filter queries, select **Download report** to create a .csv file containing the report summary information. When you exit the Query Report, the filter queries aren't saved.

Create holds in eDiscovery

Create holds to preserve content that might be relevant to an eDiscovery case. Place a hold on the Exchange mailboxes and OneDrive accounts of people you're investigating in the case. You can also place a hold on the mailboxes and sites that are associated with Microsoft Teams, Microsoft 365 groups, and Viva Engage Groups. When you place content locations on hold, you preserve content until you remove the content location from the hold or until you delete or release the hold.

> **Important**
>
> After you create an eDiscovery hold, it might take up to 24 hours for the hold to take effect. For long term data retention not related to eDiscovery investigations, use retention policies and retention labels. For more information, see Learn about retention policies and retention labels.

eDiscovery holds **require an eligible license on every user whose content you preserve**. Frontline subscriptions such as Office 365 F1 and F3 don't include the rights required to be the *target* of an eDiscovery hold. Before you add a user to a hold, confirm the user's assigned subscription includes eDiscovery hold rights.

The eDiscovery (Premium) hold capabilities required for query-based, time-bound, and custodian-scoped holds are included only in higher tiers (for example, Microsoft 365 E5 / A5 / G5 or the Microsoft 365 E5 Compliance and E5 eDiscovery & Audit add-ons).

For the authoritative list of which hold capabilities are included in each subscription, see Microsoft 365 guidance for security & compliance. If the user's current subscription doesn't include the required rights, assign an add-on (such as Microsoft 365 E5 Compliance) **before** creating the hold. Placing a user on hold without proper licensing isn't supported.

When you create a hold, use the following options to scope the content that's preserved in the specified content locations:

- Create an infinite hold where all content in the specified locations is placed on hold. Alternatively, create a query-based hold where only the content in the specified locations that matches a search query is placed on hold.

- Specify a date range to preserve only the content that was sent, received, or created within that range. Alternatively, hold all content in specified locations regardless of when it was sent, received, or created.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Create a hold

> **Tip**
>
> Do you prefer an interactive configuration guide experience? Check out the Apply a hold guide.

To create an eDiscovery hold associated with an eDiscovery case, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card and then select **Cases** in the left navigation.
3. Select a case, and then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select **Create policy**.
5. On the **Enter details to get started** page, complete the following fields:
   - **Policy name**: Give the hold policy a name (required). The hold policy name must be unique in your organization.
   - **Policy description**: Add an optional description to help others understand this hold policy.
6. Select **Create** to create the new hold policy and start your hold on relevant data for the case.
7. To add data sources to a hold policy, see Data sources in eDiscovery for step-by-step guidance.

8. On the **Manage data sources** flyout pane, add or remove data sources for your hold policy. You can choose one or more users, groups, or organization locations.

- You must select at least one data source to create a hold policy.
- Enter the specific users, groups, or organization locations you want to add to the hold policy.

  Distribution groups: When you create a hold and select a distribution group as a data source, all current members of the distribution group are listed. You can select all mailboxes or sites for each user to include in the hold. For more information about preserving Bcc and expanded distribution group recipients, see Preserve Bcc and expanded distribution group recipients.

  > ⓘ **Important**
  >
  > **Group membership is captured as a point-in-time snapshot when the hold policy is created.** This applies to every supported group type – distribution list, mail-enabled security group, Microsoft 365 group, Microsoft Teams group, and Viva Engage group. When you add any group as a data source, members are expanded and selected at the moment the policy is created. Members added to the group later are **not** automatically placed on hold; members removed from the group remain on hold until you update or release the policy. To reflect current membership, add the group again as a data source. Search behavior differs, search re-resolves group membership each time the search runs. For more information, see **Data sources in eDiscovery**.
  >
  > Distribution list expansion is limited to a maximum of 100 members. If a distribution list contains more than 100 members, the expansion might fail and the distribution list isn't added successfully. In this case, split the distribution list into smaller groups before adding them as data sources, or use **bulk import data sources**.

  Exchange mailboxes: Applicable checkboxes are selected for the mailboxes placed on hold. Use **Edit** to find user mailboxes and distribution groups (the mailboxes of group members) to place on hold. You can also place a hold on the associated mailbox for a Microsoft Team, Microsoft 365 group, and Viva Engage Group. For more information about the application data that is preserved when a mailbox is placed on hold, see Content stored in mailboxes for eDiscovery.

SharePoint sites: Applicable checkboxes are selected for SharePoint sites and OneDrive accounts placed on hold. Use **Edit** to enter the URL for additional sites that you want to place on hold. You can also add the URL for the SharePoint site for a Microsoft Team, Microsoft 365 group, or Viva Engage group. To avoid potential URL truncation, ensure SharePoint site names stay under 70 characters. Hold policies might not be able to locate sites for truncated site URLs and might have access errors. Placing a hold on a subsite isn't allowed even if the subsite is displayed in the location picker. If you select a subsite, the hold is placed on the parent SharePoint site instead.

> **ⓘ Important**
>
> The Recycle Bin in SharePoint sites isn't indexed and therefore unavailable for searching. As a result, eDiscovery searches can't find any Recycle Bin content to place holds.
>
> eDiscovery doesn't continuously monitor location-level changes after a hold is applied. If mailbox or site identities change later (for example, SharePoint or OneDrive URL changes), or if the hold state changes outside the policy workflow, edit the hold policy data sources and reapply or retry the policy so hold status and scope stay accurate.

1. Select **Save**. You've now scoped the data sources for your hold policy.

2. To define the parameters of your hold policy, choose from the following options on the **Hold policy** tab:

   - **Condition builder**: The condition builder option in search provides a visual filtering experience when you build hold policies. Each condition adds a clause that is created and run when you create the hold. For example, you can specify a date range so that email or site documents that were created within the date range are preserved. For detailed information about using the condition builder option, see Use the condition builder to create search queries in eDiscovery.

   - **Keyword Query Language (KeyQL)**: The Keyword Query Language (KeyQL) query option in search provides guidance and lets you quickly paste long, complex queries directly into the editor. For detailed information about building search queries with the KeyQL option, see Use Keyword Query Language to create search queries in eDiscovery.

You can also quickly build KeyQL queries for your search using Microsoft Security Copilot. For more information, see Create a KeyQL search query with Microsoft Copilot (preview).

> **Important**
>
> For the best results when dealing with encrypted or partially indexed items, limit conditions to *Date*, *Participants*, and *Type* in query-based holds. Queries aren't effective on other conditions within encrypted or partially indexed items and holds might not be applied to these items.

3. Select **Apply hold**.

> **Important**
>
> To apply a hold to a SharePoint site, the site must have a title.

After creating a hold, check that the hold is applied successfully by navigating to the **Details** tab for the hold policy. You can review the following information for the hold policy:

- **Name**: The name of the data source.
- **Location**: The specific location (such as the SMTP address of the mailbox or the URL of the site) of the data sources included in the hold policy.
- **Hold status**: The hold status of the location. Indicates whether the location is on hold, not on hold, or if there's an error with the hold.
- **Source type**: Shows whether the data source type is *People* or *Group*.
- **Location type**: Shows whether the location is *Mailbox* or *Site*.

> **Note**
>
> When you create a query-based hold, you initially place all content from the selected locations on hold. Later, the system clears any content that doesn't match the specified query from the hold every seven to 14 days. However, a query-based hold doesn't clear content if you apply more than five holds of any type to a content location. The hold always includes partially or unindexed items from a location with a query-based hold.

Create a hold from a search

You can create an eDiscovery hold directly from search. However, creating a hold directly from a search has the following restrictions:

- The hold removes tenant-wide data sources contained in the search. Holds don't support tenant-wide data sources.
- The hold expands distribution lists contained in the search. You can choose to place all members' mailboxes and sites on hold or a subset or mix of these data sources on hold. Subsequent changes in distribution list membership don't change or update holds or the policy. If the distribution list is empty, it's removed from the hold because there's nothing to expand.
- The query used in the search isn't incorporated into the hold policy. The data sources in scope for the search are included in the hold policy.

To create an eDiscovery hold from a search, complete the following steps:

1. Complete the steps for creating a search query.
2. Select **Create a hold** on the command bar for the search.
3. View the new hold policy and update as needed.

Monitor hold processing in Process manager

The **Process manager** displays information about processes performed on the hold policy.

- **Process type**: The type of process.
- **Status**: The status of the process.
- **Created**: The date and time the process was created.
- **Completed**: The date and time the process was completed.
- **Duration**: The duration of the process.
- **Created by**: The user that created the process.

To download the list of processes and the column information, select **Download list** to create a .csv file containing this information.

To view information about all eDiscovery processes, see Use the Process report in eDiscovery.

Query-based holds placed on sites

Keep the following points in mind when you place a query-based eDiscovery hold on documents located in SharePoint sites:

- A query-based hold initially preserves all documents in a site for a short period of time after you delete them. When you delete a document, you move it to the Preservation Hold library even if it doesn't match the criteria of the query-based hold. However, a timer job removes deleted documents that don't match a query-based hold. The timer job runs periodically and compares all documents in the Preservation Hold library to your query-based eDiscovery holds (and other types of holds and retention policies). The timer job deletes the documents that don't match a query-based hold and preserves the documents that do.
- Use query-based holds to perform targeted preservation such as keywords, date ranges, or other document properties to preserve site documents.

Preserve content in Microsoft Teams

Conversations that are part of a Microsoft Teams channel are stored in the mailbox that's associated with the Microsoft Team. Similarly, files that team members share in a channel are stored on the team's SharePoint site. Therefore, you have to place the Team mailbox and SharePoint site on eDiscovery hold to preserve conversations and files in a channel.

Alternatively, conversations that are part of the Chat list in Teams (called *1:1 chats* or *1:N group chats*) are stored in the mailboxes of the users who participate in the chat. Files that users share in chat conversations are stored in the OneDrive account of the user who shares the file. Therefore, you have to add the individual user mailboxes and OneDrive accounts to an eDiscovery hold to preserve conversations and files in the chat list. It's a good idea to place a hold on the mailboxes of members of a Microsoft Team in addition to placing the team mailbox and site on hold.

> **Note**
>
> If your organization has an Exchange hybrid deployment (or your organization synchronizes an on-premises Exchange organization with Microsoft 365) and has enabled Microsoft Teams, on-premises users can use the Teams chat application and participate in 1:1 chats and 1:N group chats. These conversations are stored in cloud-based storage that's associated with an on-premises user. If you place an on-premises user on an eDiscovery hold, the Teams chat content in the cloud-based storage is preserved. For more information, see Find content in mailboxes.

Preserve card content

Card content generated by apps in Teams channels, 1:1 chats, and 1:N group chats are stored in mailboxes and are preserved when you place a mailbox on an eDiscovery hold. A *card* is a UI

container for short pieces of content. Cards can have multiple properties and attachments, and can include items that trigger card actions. For more information, see Cards. Like other Teams content, where card content is stored is based on where the card was used. Content for cards used in a Teams channel is stored in the Teams group mailbox. Card content for 1:1 and 1xN chats are stored in the mailboxes of the chat participants.

Preserve meeting and call information

Summary information for meetings and calls in a Teams channel is also stored in the mailboxes of users who dialed into the meeting or call. This content is also preserved when you place an eDiscovery hold on user mailboxes.

Preserve content in private channels

You can also preserve content in private channels. Private channel chats are stored in a dedicated private channel mailbox. Private channel message data from each user's mailbox is moved to the private channel's mailbox and message edits and deleted messages aren't copied into the mailbox. For users on hold, copies of message edits and deleted messages remain in the user's preserved library folder until the hold expires, while the latest version of private channel message data from each user's mailbox is copied to the private channel's mailbox.

Preserve wiki content

Every team or team channel also contains a Wiki for note taking and collaboration. The Wiki content automatically saves to a file in the .mht format. The Teams Wiki Data document library on the team's SharePoint site stores this file. You can preserve the wiki content by adding the team's SharePoint site to an eDiscovery hold.

> **Note**
>
> The capability to preserve Wiki content for a Team or team channel (when you place the team's SharePoint site on hold) was released on June 22, 2017. If a team site is on hold, the Wiki content is retained starting on that date. However, if a team site is on hold and the Wiki content was deleted before June 22, 2017, the Wiki content isn't preserved.

Microsoft 365 groups

Teams is built on Microsoft 365 groups. Therefore, placing Microsoft 365 groups on eDiscovery hold is similar to placing Teams content on hold.

Keep the following things in mind when placing both Teams and Microsoft 365 groups on an eDiscovery hold:

- To place content located in Teams and Microsoft 365 groups on hold, you must specify the mailbox and SharePoint site that are associated with a group or team.
- Run the **Get-UnifiedGroup** cmdlet in Exchange Online PowerShell to view properties for Teams and Microsoft 365 groups. This method is a good way to get the URL for the site that's associated with a Team or Microsoft 365 group. For example, the following command displays selected properties for a Microsoft 365 group named Senior Leadership Team:

  text

  ```
  Get-UnifiedGroup "Senior Leadership Team" | FL
  DisplayName,Alias,PrimarySmtpAddress,SharePointSiteUrl

  DisplayName            : Senior Leadership Team
  Alias                  : seniorleadershipteam
  PrimarySmtpAddress     : seniorleadershipteam@contoso.onmicrosoft.com
  SharePointSiteUrl      :
  https://contoso.sharepoint.com/sites/seniorleadershipteam
  ```

  > **Note**
  >
  > To run the **Get-UnifiedGroup** cmdlet, you need the View-Only Recipients role in Exchange Online or membership in a role group that's assigned the View-Only Recipients role.

- When you search a user's mailbox, the search doesn't include any Team or Microsoft 365 group that the user is a member of. Similarly, when you place a Team or Microsoft 365 group on eDiscovery hold, the hold applies only to the group mailbox and group site. The mailboxes and OneDrive sites of group members aren't placed on hold unless you explicitly add them to the eDiscovery hold. So if you have to place a Team or Microsoft 365 group on hold for a legal reason, consider adding the mailboxes and OneDrive accounts of team or group members on the same hold.
- To get a list of the members of a Team or Microsoft 365 group, you can view the properties on the **Groups** page in the Microsoft 365 admin center. Alternatively, you can run the following command in Exchange Online PowerShell:

  PowerShell

```
Get-UnifiedGroupLinks <group or team name> -LinkType Members | FL
DisplayName,PrimarySmtpAddress
```

> **Note**
>
> To run the **Get-UnifiedGroupLinks** cmdlet, you need the View-Only Recipients role in Exchange Online or membership in a role group that's assigned the View-Only Recipients role.

Preserve content in OneDrive accounts

> **Important**
>
> The retention period for deleted OneDrive accounts is different from the retention period for mailboxes. For more information about the retention period for deleted OneDrive accounts, see OneDrive retention and deletion.

To collect a list of the URLs for the OneDrive sites in your organization so you can add them to a hold or search associated with an eDiscovery case, see Create a list of all OneDrive locations in your organization.

The script in this article creates a text file that contains a list of all OneDrive sites in your organization. To run this script, you need to install and use the SharePoint Online Management Shell. Be sure to append the URL for your organization's MySite domain to each OneDrive site that you want to search. This domain contains all your OneDrive sites; for example, `https://contoso-my.sharepoint.com`. Here's an example of a URL for a user's OneDrive site: `https://contoso-my.sharepoint.com/personal/sarad_contoso_onmicrosoft.com`.

> **Important**
>
> The URL for a user's OneDrive account includes their user principal name (UPN) (for example, `https://alpinehouse-my.sharepoint.com/personal/sarad_alpinehouse_onmicrosoft_com`). In the rare case that a person's UPN is changed, their OneDrive URL also changes to incorporate the new UPN. If a user's OneDrive account is part of an eDiscovery hold, and their UPN is changed, you need to update the hold by adding the user's new OneDrive URL and removing the old one. If the URL for the OneDrive site changes, previously placed holds on the site remain effective and

content is preserved. For more information, see [How UPN changes affect the OneDrive URL](#).

Remove content locations from an eDiscovery hold

After you remove a mailbox, SharePoint site, or OneDrive account from an eDiscovery hold, a *delay hold* is applied. This hold delays the actual removal of the hold for 30 days to prevent data from being permanently deleted (purged) from a content location. This delay gives admins an opportunity to search for or recover content that is purged after an eDiscovery hold is removed. The details of how the delay hold works for mailboxes and sites are different.

- **Mailboxes:** A delay hold is placed on a mailbox the next time the Managed Folder Assistant processes the mailbox and detects that an eDiscovery hold was removed. Specifically, a delay hold is applied to a mailbox when the Managed Folder Assistant sets one of the following mailbox properties to **True**:
  - **DelayHoldApplied:** This property applies to email-related content (generated by people using Outlook and Outlook on the web) that's stored in a user's mailbox.
  - **DelayReleaseHoldApplied:** This property applies to cloud-based content (generated by non-Outlook apps such as Microsoft Teams, Microsoft Forms, and Microsoft Viva Engage) that's stored in a user's mailbox. Cloud data generated by a Microsoft app is typically stored in a hidden folder in a user's mailbox.

  When a delay hold is placed on the mailbox (when either of the previous properties is set to **True**), the mailbox is still considered to be on hold for an unlimited hold duration, as if the mailbox was on Litigation Hold. After 30 days, the delay hold expires, and Microsoft 365 automatically attempts to remove the delay hold (by setting the DelayHoldApplied or DelayReleaseHoldApplied property to **False**) so that the hold is removed. After either of these properties are set to **False**, the corresponding items that are marked for removal are purged the next time the mailbox is processed by the Managed Folder Assistant.

- **SharePoint and OneDrive sites:** Any SharePoint or OneDrive content that's being retained in the Preservation Hold library isn't deleted during the 30-day delay hold period after a site is removed from an eDiscovery hold. Retention of content in the Preservation Hold library during the 30-day delay hold period is similar to what happens when a site is released from a retention policy. Additionally, you can't manually delete this content in the Preservation Hold library during the 30-day delay hold period. To release a site from the 30-day delay hold/grace period hold, see the Can't delete a site because of an invalid retention policy or eDiscovery hold troubleshooting article.

For more information, see Releasing a policy for retention.

A delay hold is also applied to content locations on hold when you close an eDiscovery case because holds are turned off when a case is closed. For more information about closing a case, see Learn about case settings in eDiscovery.

Manage holds in eDiscovery

> **Note**
>
> Active hold policies that you create in cases in the legacy eDiscovery experience are automatically migrated and available in the new Microsoft Purview eDiscovery experience. Review the eDiscovery hold policy status report to check policy status and retry any policies that need attention.

Use eDiscovery to create hold policies that preserve content relevant to your cases. When you place content locations on hold, the content is held until you release the hold in the case, remove a specific data location, or delete the hold policy. You can place holds on data sources such as:

- User mailboxes and OneDrive sites.
- Microsoft Teams mailboxes and SharePoint and OneDrive sites.
- Microsoft 365 group mailboxes and SharePoint and OneDrive sites.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Hold policy dashboard

The **Hold policies** dashboard lists all the holds associated with a case. This dashboard lets you create hold policies, displays information about hold policies in the case, and lets you filter and group the hold policies. The **Hold policies** dashboard contains the following information and controls:

- **Name**: The name of the hold policy.
- **Created by**: The user that created the hold policy.
- **Last modified**: The date and time the hold policy was last modified. Select **Time zone** to switch between using local time and Coordinated Universal Time (UTC).
- **Hold policy Status**: The current status of the hold policy.

Select a hold policy to view the details, data sources, and condition and KeyQL filters.

To customize the columns display on the **Hold policies** dashboard, select **Customize columns** to choose the columns to display or drag and drop the columns in the list to reorder. To search for a specific hold policy, enter a keyword in the **Search** field. To download the list of hold policies and the column information, select **Download list** to create a .csv file containing this information.

Hold policy states

The hold policy page shows the state of a hold next to the hold name. Hold policies have the following states:

- **Draft**: Displayed when you create a new policy but don't apply it. If you navigate away from the policy draft, you cancel the draft and lose all policy changes.
- **On**: The policy is applied and all locations in the policy are on hold. Select the **Details** tab to view location information.
- **Off**: The policy is off for a previously applied hold. All included locations aren't on hold.
- **In progress**: The hold policy is in the process of being applied or updated.
- **Pending deletion**: The hold policy is in the process of being deleted.

Check for holds on a mailbox or site

Before you delete content, release a hold, or diagnose why a purge, site deletion, or storage cleanup isn't working as expected, identify every hold source that applies to the location. eDiscovery hold policies are only one of several hold sources. Microsoft Purview retention policies, retention labels, Litigation Hold, delay holds, and Single Item Recovery can independently preserve content, and any one of them is enough to keep items in the Recoverable Items folder or in the Preservation Hold Library.

Symptoms that warrant a hold check

Expand table

Symptom	Most likely hold source
`New-ComplianceSearchAction -Purge -PurgeType HardDelete` succeeds but items remain in `\Recoverable Items\Purges`	Any hold or retention policy on the mailbox; delay hold; Single Item Recovery
You can't delete a SharePoint site or OneDrive site	eDiscovery hold; tenant-wide, site-, or group-scoped retention policy; delay hold
You can't delete a folder or document library	Site-scoped retention policy; Preservation Hold Library content

Symptom	Most likely hold source
The Preservation Hold Library is consuming OneDrive storage and items aren't expiring	Retention policy or eDiscovery hold still applied to the OneDrive site
Mailbox shows as on hold even after you remove all known holds	Delay hold (`DelayHoldApplied` or `DelayReleaseHoldApplied`); retention label hold (`ComplianceTagHoldApplied`)
You can't permanently delete an inactive mailbox	A hold or retention policy is keeping the mailbox alive

Check for holds on a mailbox

Run the following cmdlets in Exchange Online PowerShell, in order. If any cmdlet returns a hold source, clear it before you attempt to delete content or remove the user from the location.

Expand table

#	Cmdlet	What it surfaces
1	`Invoke-HoldRemovalAssistant -Identity <user>`	All applicable hold sources in a single call. Recommended first step.
2	`Get-OrganizationConfig | FL InPlaceHolds`	Tenant-wide and organization-scoped retention policies. Entries with the `mbx`, `skp`, or `grp` prefix are mailbox-, Teams-, or group-scoped policies that surface at the organization level.
3	`Get-Mailbox <user> | FL LitigationHoldEnabled,InPlaceHolds,ComplianceTagHoldApplied,SingleItemRecoveryEnabled`	Mailbox-scoped holds, retention label hold, and

#	Cmdlet	What it surfaces
		Single Item Recovery.
4	`Get-Mailbox <user> | FL DelayHoldApplied,DelayReleaseHoldApplied`	Delay holds. A delay hold is automatically applied after a hold is removed and preserves items for up to 30 days.

Use the following table to identify the hold source for each `InPlaceHolds` prefix that you see, and where to clear it.

Expand table

Prefix	Hold source	Where to clear it
`mbx`	Microsoft Purview retention policy (mailbox-scoped)	Microsoft Purview portal: **Data lifecycle management** > **Retention policies** > exclude the mailbox
`skp`	Teams retention policy	Microsoft Purview portal: **Data lifecycle management** > **Retention policies** (Teams)
`grp`	Microsoft 365 group retention policy	Microsoft Purview portal: **Data lifecycle management** > **Retention policies**
`UniH`	eDiscovery case hold	Microsoft Purview portal: **eDiscovery** > open the case > **Hold policies**
`cld`	Cloud attachment hold	Microsoft Purview portal: **eDiscovery** > open the case > **Hold policies**

For more detail on each hold type and how to identify the associated retention policy or case, see Identify Exchange mailbox hold types in eDiscovery.

Check for holds on a SharePoint or OneDrive site

Run the following cmdlets, in order. If any cmdlet returns a hold source, clear it before you attempt to delete the site, the library, or content that's preserved in the Preservation Hold Library.

Expand table

#	Cmdlet	What it surfaces
1	`Invoke-HoldRemovalAssistant -Identity <siteUrl-or-userUPN>`	All applicable hold sources in a single call. Recommended first step.
2	`Get-OrganizationConfig | FL InPlaceHolds`	Tenant-wide retention policies. Entries with the `grp` prefix are group- or site-scoped policies.
3	`Get-RetentionCompliancePolicy | Where-Object { $_.SharePointLocation -or $_.OneDriveLocation }`	Retention policies that target SharePoint sites or OneDrive accounts.
4	Delay hold on the site	Surfaced in the `Invoke-HoldRemovalAssistant` output.

If the Preservation Hold Library (PHL) on a OneDrive site is consuming storage and items aren't draining, the most common cause is a retention policy or eDiscovery hold that still applies to the site. After you clear every hold source, the Managed Folder Assistant removes expired items from the PHL over time.

Common misconceptions

- **"Setting MRM to True deletes items from the Purges folder."** The Managed Folder Assistant (MRM/MFA) enforces retention. It isn't a delete mechanism. The supported way to permanently delete items from the Recoverable Items folder is the HardDelete purge described in Delete items in the Recoverable Items folder for mailboxes on hold in eDiscovery, and that purge respects every hold source listed earlier in this section.
- **"I removed the Litigation Hold so I can delete the items now."** Wait up to 240 minutes for the change to apply, then check for a delay hold (`DelayHoldApplied` or `DelayReleaseHoldApplied`) before you attempt to delete content. A delay hold is automatically applied after a hold is removed.
- **"`LitigationHoldEnabled` is False, so the mailbox isn't on hold."** This check alone is insufficient. Also check `InPlaceHolds`, `ComplianceTagHoldApplied`, `DelayHoldApplied`, `DelayReleaseHoldApplied`, and `Get-OrganizationConfig | FL InPlaceHolds`.
- **"`Get-OrganizationConfig` returned an `mbx` entry, so the policy applies to the whole organization."** An `mbx`-prefixed entry that surfaces under `Get-OrganizationConfig` is a mailbox-scoped Microsoft Purview retention policy. To clear it, exclude the specific mailbox from the policy in the Microsoft Purview portal. It might take up to 24 hours for the exclusion to replicate.

Create a hold policy

To create a new hold policy, see Create holds in eDiscovery.

Edit a hold policy

You can edit the hold policy name, description, or the policy details (data sources, condition filters, and KeyQL filters) as applicable.

To edit the hold policy name or description, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select the hold policy you want to edit.
5. Select the edit (pencil) icon next to the policy name.
6. Update the policy name or description, then select **Continue**.

To edit hold policy details, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select the hold policy you want to edit.
5. On the **Hold policy** page for the selected policy, select the **Hold policy** tab.
6. Update data sources, condition filters, and KeyQL filters as applicable.
7. Select **Apply hold**.

> **Important**
>
> eDiscovery doesn't continuously monitor workload or location-level changes after a hold operation completes. If mailbox or site identities change (for example, UPN, SharePoint URL, or OneDrive URL changes), or if a hold is changed outside this policy workflow, update the hold policy data sources and then select **Apply hold** to restamp the policy.

Retry a hold policy

A retry hold policy triggers the hold process to restamp all mailboxes and sites in the policy to enforce the hold. You might also encounter errors while placing a hold on data sources. For a list of possible errors, see Manage hold status errors.

Use **Retry policy** after location identity changes or external hold operations so that eDiscovery refreshes the policy state and per-location status.

To retry a hold policy, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select the hold policy you want to retry.
5. On the **Hold policy** page for the selected policy, select **Policy actions** > **Retry policy**.

Turn off a hold policy

Turning off a hold policy might result in the permanent deletion of any content currently being preserved. It doesn't affect content preserved by other hold policies.

To turn off a hold policy, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select the hold policy you want to turn off.
5. On the **Hold policy** page for the selected policy, select **Policy actions** > **Turn off**.

Turn on a hold policy

When you edit a policy, it doesn't affect content preserved by other hold policies.

To turn on a hold policy, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select the hold policy you want to turn on.
5. On the **Hold policy** page for the selected policy, select **Policy actions** > **Turn on**.

Delete a hold policy

When you delete a hold policy, you remove all associated holds and release all sites and mailboxes. This action might result in permanent deletion of any content currently being preserved.

To delete a hold policy, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left navigation.
3. Select a case, then select the **Hold policies** tab.
4. On the **Hold policies** dashboard, select the hold policy you want to delete.
5. On the **Hold policy** page for the selected policy, select **Policy actions** > **Delete policy**.
6. On the **Delete policy?** dialog, select **Yes, delete**.

Manage hold status errors

You might encounter errors while placing a hold on data sources. The following table lists the errors that you might encounter and the recommended resolution.

Expand table

Hold error types	Description	Resolution
Distribution group has too many members	The distribution group associated with the requested hold has more than 1,000 email addresses. Currently, a distribution group with more than 1,000 email addresses can't be expanded and placed on hold.	Add the individual email addresses as data sources or split the distribution group into groups with fewer than 1,000 email addresses. Then select **Policy actions** > **Retry policy** in the hold policy to retry the hold application.
Invalid email address or URL	The location associated with the requested hold has an invalid email address or site URL.	Specify a valid email address or URL that exists within your organization.
Hold changed outside eDiscovery	The hold state for a location was changed outside this case policy workflow (for example, using `Invoke-HoldRemovalAction` in Security & Compliance PowerShell).	In eDiscovery, edit the hold policy so the intended locations are correct, then select **Apply hold** or **Policy actions** > **Retry policy** to restamp and refresh status.
Mailbox not found	The mailbox associated with the requested hold isn't a valid mailbox.	Verify the email address and check that it's a valid Exchange Online mailbox. After you confirm the mailbox, edit the data source for the mailbox and then select **Policy**

Hold error types	Description	Resolution
		actions > **Retry policy** in the hold policy to retry the hold application.
Policy deployment interrupted	A system error indicating a problem was encountered while applying the hold.	Select **Policy actions** > **Retry policy** in the hold policy to retry the hold application.
Site inaccessible	The SharePoint location associated with the requested hold request isn't accessible and might be read only.	Contact your SharePoint site administrator to configure the site as writable. Then select **Policy actions** > **Retry policy** in the hold policy to retry the hold application.
Site failed to apply hold	If the site URL changed for any reason (due to user UPN or tenant domain change), you must update the policy to include the site with the new name and URL.	Update the policy by removing the original site, then add the new site URL to the hold policy and reapply the hold.
Site not found	The SharePoint location associated with the requested hold might have been moved, deleted, or the site URL might not exist.	Check the site URL and confirm if the SharePoint site exists. After you confirm the site exists, edit the data source for the site and then select **Policy actions** > **Retry policy** in the hold policy to retry the hold application.

Hold policies have a *Site not found* error if the policy includes a location that had a UPN change due to change in status, departure policies, name change, or other circumstances. This error occurs when the hold is reapplied after these changes. The hold for site or mailbox can remain stamped on the original location identity, but the policy must be updated to include the new UPN or site URL for the policy to reflect the correct status and to support removal of holds.

After you add the new UPN or site URL to the policy, you can remove the prior SMTP UPN or site URL from the policy.

> **Important**
>
> To apply a hold to a SharePoint site, the site must have a title.

Place a hold on Microsoft Teams and Microsoft 365 groups

Microsoft Teams is built on Microsoft 365 groups. Therefore, placing them on hold in eDiscovery is similar. Keep the following things in mind when placing Microsoft 365 groups and Microsoft

Teams on hold:

- To place content located in Microsoft 365 groups and Microsoft Teams on hold, you need to specify the mailbox and SharePoint site that are associated with a group or team.
- Run the **Get-UnifiedGroup** cmdlet in Exchange Online to view properties for a Microsoft 365 group or Microsoft Team. This cmdlet is a good way to get the URL for the site that's associated with a Microsoft 365 group or a Microsoft Team. For example, the following command displays selected properties for a Microsoft 365 group named Senior Leadership Team:

  Console

  ```
  Get-UnifiedGroup "Senior Leadership Team" | FL
  DisplayName,Alias,PrimarySmtpAddress,SharePointSiteUrl
  DisplayName            : Senior Leadership Team
  Alias                  : seniorleadershipteam
  PrimarySmtpAddress     : seniorleadershipteam@contoso.onmicrosoft.com
  SharePointSiteUrl      :
  https://contoso.sharepoint.com/sites/seniorleadershipteam
  ```

  > **Note**
  >
  > To run the Get-UnifiedGroup cmdlet, you need to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- When you search a user's mailbox, the search doesn't include any Microsoft 365 group or Microsoft Team that the user is a member of. Similarly, when you place a Microsoft 365 group or Microsoft Team hold, only the group mailbox and group site are placed on hold; the mailboxes and OneDrive sites of group members aren't placed on hold unless you explicitly add them to a case or place their data sources hold. Therefore, if you need to place a Microsoft 365 group or Microsoft Team on hold for a specific user, consider mapping the group site and group mailbox to the user. If the Microsoft 365 group or Microsoft Team isn't attributable to a single user, consider adding the source to a hold.
- To get a list of the members of a Microsoft 365 group or Microsoft Team, you can view the properties on the **Home** > **Groups page in the Microsoft 365 admin center**. Alternatively, you can run the following command in Exchange Online PowerShell:

  PowerShell

```
Get-UnifiedGroupLinks <group or team name> -LinkType Members | FL
DisplayName,PrimarySmtpAddress
```

> **Note**
>
> To run the **Get-UnifiedGroupLinks** cmdlet, you need to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- Channel conversations that are part of a Microsoft Teams channel are stored in the mailbox that's associated with the Team. Similarly, files that team members share in a channel are stored on the team's SharePoint site. Therefore, you need to place the Microsoft Team mailbox and SharePoint site on hold to retain conversations and files in a channel.

- Alternatively, conversations that are part of the Chat list in Microsoft Teams are stored in the mailbox of the users who participate in the chat. Files that a user shares in Chat conversations are stored in the OneDrive site of the user who shares the file. Therefore, you need to place the individual user mailboxes and OneDrive sites on hold to retain conversations and files in the Chat list.

- Every Microsoft Team or team channel contains a Wiki for note-taking and collaboration. The Wiki content is automatically saved to a file with a .mht format. This file is stored in the Teams Wiki Data document library on the team's SharePoint site. You can place the content in the Wiki on hold by placing the team's SharePoint site on hold.

  > **Note**
  >
  > The capability to retain Wiki content for a Microsoft Team or team channel (when you place the team's SharePoint site on hold) was released on June 22, 2017. If a team site is on hold, the Wiki content is retained starting on that date. However, if a team site is on hold and the Wiki content was deleted before June 22, 2017, the Wiki content wasn't retained.

Use the hold report (preview) in eDiscovery

The hold report (preview) in eDiscovery lets users with *eDiscovery Administrator* or *eDiscovery Manager (preview)* permissions access a built-in report with information on all holds associated with eDiscovery cases in the Microsoft Purview portal. This report includes eDiscovery holds associated with eDiscovery cases. The hold report shows the data locations and reports on all hold policies within the tenant. It lists all locations that are part of those hold policies, whether enabled or disabled.

> **Important**
>
> The hold report is in public preview and provides a tenant-wide summary of hold policies for all eDiscovery cases. The report syncs policy and location status no more than once every seven days, so the information shown might not reflect recent changes to your hold policies. For the current status of a specific hold policy and its locations, go to the hold policy details page in the Microsoft Purview eDiscovery case. For more information, see Manage holds in eDiscovery.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Step 1: Verify your subscription and permissions

- Your organization must have an organization subscription that supports premium eDiscovery features to generate and access the hold report.
- Users accessing the hold report must be assigned the *eDiscovery Administrator* or *eDiscovery Manager (preview)* role. All eDiscovery Administrators and eDiscovery Managers in your organization can view the Hold Report. eDiscovery Managers can only view hold reports related to the cases they are a member of. For more information about eDiscovery permissions and the eDiscovery Administrator and eDiscovery Manager roles, see Assign eDiscovery permissions.

Step 2: View the hold report

1. Go to **eDiscovery** > **Dashboards** > **Hold report (preview)** to view your hold report.
2. Sort, filter, group by, and customize columns to customize your hold report.
3. Download the hold report to a .csv file for further analysis. The entire report is downloaded regardless of any filtering or grouping option you apply to the report. You can also use a PowerShell script to create a hold report for automated reporting.

The item count at the top of the hold report is the total count of locations within the hold policies in the tenant. If the same location is placed on hold under different policies, the same location appears multiple times in the report under the respective case and hold policy and contributes to multiple item counts.

When you search the report, only the **Case name** and **Location** columns are searched. For example, if you search for the keyword *Test*, the search only returns items that are associated with a case or location that contains the word Test.

Default hold report columns

- **Case Name**: Name of the case that the hold policy is associated with. If the case name changes and you update the hold policy associated with the case, the report immediately reflects the case name change for the associated row. When a full sync of the report occurs (currently every three to seven days), the case name also updates.
- **Hold name**: Name of the Hold Policy that contains the associated locations.
- **Last modified**: The date when the eDiscovery hold policy was last updated.
- **Location**: The Exchange mailbox or SharePoint site in the hold policy. If this field displays *None*, it indicates that the hold policy has no active locations within it. Any previous locations that were part of the policy are released from hold and removed from the policy.
- **Location error**: Displays the error message associated with the location within the hold policy. If this field displays *None*, it indicates that the associated location doesn't have errors, even if it's part of a *Partially Applied/Released* policy.
- **Location type**: Indicates if the location is a SharePoint site or Exchange mailbox.
- **Policy status**: The following policy status values are available:
  - *Applied successfully*: Indicates the location of the hold policy is turned on (enabled), a rule is enabled for the policy, and the policy is applied successfully. This status means the location is placed on hold.

- *Applying*: Indicates that the hold policy that the location is part of is set to be turned on (enabled) and is in progress to apply holds to the locations in it. This job is an asynchronous job, which means some locations might be placed on hold while others might still be in progress. Wait for the hold job to complete checking the final status.
- *Applied Partially*: – Indicates that the hold policy that the location is part of is set to be turned on (enabled) and has some locations where the hold might not be applied. Check the 'Location error' column. If the associated result is 'None' then the location is placed on hold. If there's an associated error, then the location isn't placed on hold and the error message is displayed here. Check the hold policy for more details to remediate and retry the hold.
- *Released successfully*: Indicates that the hold policy that the location is part of is set to be turned off (disabled) and has completed successfully. This status means the associated location is successfully released from hold.
- *Releasing*: Indicates that the hold policy that the location is part of is set to be turned off (disabled) and is in progress to release holds from the locations in it. This job is an asynchronous job, which means some locations might be removed from hold while others might still be in progress. Wait for the hold job to complete checking the final status.
- *Released partially*: Indicates that the hold policy that the location is part of is set to be turned off (disabled) and has some locations where the hold might not be released. Check the 'Location error' column. If the associated result is 'None' then the location is successfully released from hold. If there's an associated error, then the location isn't removed from hold and the error message is displayed here. Check the hold policy for more details to remediate and retry the action.
- *Policy failed*: Indicates that the policy is set up incorrectly. The policy doesn't have a rule or was set up with rule set as disabled. These policies aren't enforced even if the policy status is successful. To ensure these policies are enforced, create a rule and resync the policy. For more information, see New-CaseHoldRule.

> **Note**
>
> If you delete a user account while an eDiscovery hold is active on the mailbox, the mailbox becomes an inactive mailbox. The hold report continues to show the location and hold status. If the location shows an error after you delete the account, this error might indicate that the hold isn't yet in place because you delete the account before the system applies it, or that the mailbox transition is still processing. To confirm that the hold is in place before you delete the account, see **Identify Exchange mailbox hold types in eDiscovery**.

Other available hold report columns

- **Case type**: Indicates if the case is an eDiscovery or eDiscovery case with premium features.
- **Case status**: Shows the status of case. Values are *Active*, *Closing*, *Closed with error*, *Pending delete*, or *Closed*. If the case status changes and you update a hold policy associated with the case, the report immediately reflects the case status change for the associated row. When a full sync of the report occurs (currently every three to seven days), all case status changes are also updated.
- **Policy created by**: Shows the user that created the initial hold policy.
- **Policy last modified by**: Shows the user that last modified the hold policy.
- **Policy last modified**: Shows the last date that the policy was updated on. This date is the policy update date and doesn't necessarily match the date the location was placed on or released from hold.
- **Report last fetched**: Displays the date and time stamp of the latest fetch of policy status and location information by the report for the specific policy.
- **Policy created date**: Shows the first date that the policy was created on. This date is the policy creation date and doesn't necessarily match the date the location was placed on or released from hold.
- **Hold ID**: The unique ID of the hold policy.
- **Case ID**: The unique ID of the case associated with the hold policy.
- **Rule query**: Displays any content match query that is applied to the policy. If there's no content match query applied to the policy, this field is empty.
- **Rule ID**: The unique ID for the rule associated with the hold policy. This status is useful for sending information to Microsoft when reporting any hold errors. If there's no rule associated with the policy, *Rule not available* is displayed in this field. Policies where a rule isn't available aren't set up correctly and not enforced. Create rules and resync the policy. For more information, see New-CaseHoldRule.

Use a script to create a hold report in eDiscovery

This PowerShell script lets eDiscovery administrators and eDiscovery managers generate a report that contains information about all holds that are associated with eDiscovery cases in the Microsoft Purview portal. The report contains information such as the name of the case a hold is associated with, the content locations that are placed on hold, and whether the hold is query-based. If there are cases that don't have any holds, the script creates an additional report with a list of cases without holds.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

What the hold report includes

The case holds report that the script in this article creates contains the following information about each hold:

- The name of the hold and the name of the eDiscovery case that the hold is associated with.
- Whether the hold is associated with an eDiscovery case.
- Whether the eDiscovery case is active or closed.
- Whether the hold is enabled or disabled.
- The members of the eDiscovery case that the hold is associated with. Case members can view or manage a case, depending on assigned eDiscovery permissions.
- The time and date the case was created.
- If a case is closed, the person who closed it and the time and date it was closed.
- The Exchange mailboxes and SharePoint sites locations that are on hold.
- If the hold is query-based, the query syntax.
- The time and date the hold was created and the person who created it.
- The time and date the hold was last changed and the person who changed it.

Admin requirements and script information

- To generate a report on all eDiscovery cases in your organization, you need to be an eDiscovery Administrator in your organization. If you're an eDiscovery Manager, the report only includes information about the cases that you can access. For more information about eDiscovery permissions, see Assign eDiscovery permissions.
- The CaseHoldsReport.ps1 script has minimal error handling. Its primary purpose is to quickly create a report about the holds that are associated with the eDiscovery cases in your organization.

>
> The sample scripts provided in this article aren't supported under any Microsoft standard support program or service. The sample scripts are provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample scripts and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Connect to Security & Compliance PowerShell

First, connect to Security & Compliance PowerShell for your organization. For step-by-step instructions, see Connect to Security & Compliance PowerShell.

Step 2: Run the script to report on holds associated with eDiscovery cases

After you connect to Security & Compliance PowerShell, create and run the script that collects information about the eDiscovery cases in your organization.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of `.ps1`; for example, `CaseHoldsReport.ps1`.

   PowerShell

```
 #script begin
 " "
 write-host "********************************************"
 write-host "Security & Compliance Center   " -foregroundColor yellow -
backgroundcolor darkgreen
 write-host "eDiscovery cases - Holds report         " -foregroundColor yellow -
backgroundcolor darkgreen
 write-host "********************************************"
 " "

 #prompt users to specify a path to store the output files
 $time = get-date -Format dd-MM-yyyy_hh.mm
 $Path = Read-Host 'Enter a folder path to save the report to a .csv file
(filename is created automatically)'
 $outputpath = $Path + '\' + 'CaseHoldsReport' + ' ' + $time + '.csv'
 $noholdsfilepath = $Path + '\' + 'CaseswithNoHolds' + $time + '.csv'

 #add case details to the csv file
 function add-tocasereport {
     Param([string]$casename,
         [String]$casetype,
         [String]$casestatus,
         [datetime]$casecreatedtime,
         [string]$casemembers,
         [datetime]$caseClosedDateTime,
         [string]$caseclosedby,
         [string]$holdname,
         [String]$Holdenabled,
         [string]$holdcreatedby,
         [string]$holdlastmodifiedby,
         [string]$ExchangeLocation,
         [string]$sharePointlocation,
         [string]$ContentMatchQuery,
         [datetime]$holdcreatedtime,
         [datetime]$holdchangedtime,
         [string]$holdstatus,
         [string]$holderror
     )

     $addRow = New-Object PSObject
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case name" -
Value $casename
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case type" -
Value $casetype
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case status"

(($policy.exchangelocation.name) -join ';') -SharePointLocation
(($policy.sharePointlocation.name) -join ';') -ContentMatchQuery
$rule.ContentMatchQuery -holdcreatedtime $policy.WhenCreatedUTC -holdchangedtime
$policy.WhenChangedUTC -holdstatus $policy.DistributionStatus -holderror
$policy.DistributionResults

             }
         }
         else {
             write-host "No hold policies found in case:" $cc.name -
```

```
foregroundColor 'Yellow'
            " "
            [string]$cc.name | out-file -filepath $noholdsfilepath -append
        }
    }
}

" "
Write-host "Script complete! Report files saved to this folder: '$Path'"
" "
#script end
```

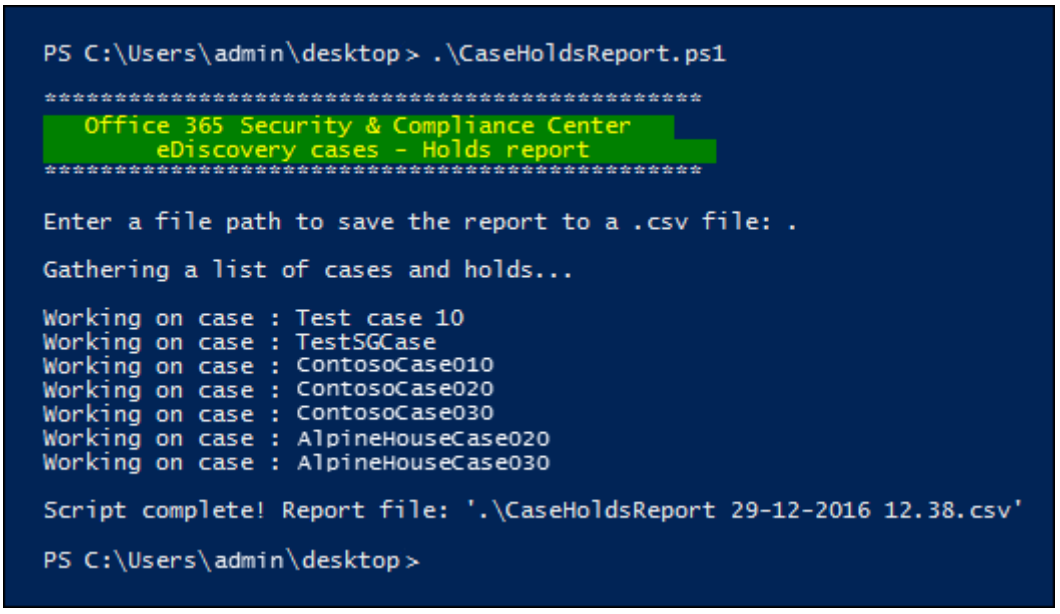
2. In the Windows PowerShell session that opened in Step 1, go to the folder where you saved the script.

3. Run the script; for example:

   PowerShell

   ```
   .\CaseHoldsReport.ps1
   ```

   The script prompts for a target folder to save the report to.



4. Type the full path name of the folder to save the report to, and then press **Enter**.

   > **Tip**
   >
   > To save the report in the same folder that the script is located in, type a period (".") when prompted for a target folder. To save the report in a subfolder in the folder where the script is located, just type the name of the subfolder.

   The script starts to collect information about all the eDiscovery cases in your organization. Don't access the report file while the script is running. After the script completes, a confirmation message is displayed in the Windows PowerShell session. After this message is displayed, you can access the report in the folder that you specified when prompted for a target folder. The file name for the report is `CaseHoldsReport<DateTimeStamp>.csv`.

   Additionally, the script creates a report with a list of cases that don't have any holds. The file name for this report is `CaseswithNoHolds<DateTimeStamp>.csv`.

   Here's an example of running the `CaseHoldsReport.ps1` script.

Identify Exchange mailbox hold types in eDiscovery

Microsoft Purview offers several ways that your organization can prevent mailbox content from being permanently deleted. This protection allows your organization to retain content to meet compliance regulations or during legal and other types of investigations. This article explains how to identify the different types of holds placed on an Exchange Online mailbox and how to use PowerShell cmdlets to get the GUID for each hold.

> **Tip**
>
> To determine *whether* a mailbox or site is on hold (for example, because a content purge or site deletion isn't working), start with the diagnostic checklist in **Check for holds on a mailbox or site**. This article explains the hold types themselves in more depth.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Overview of Exchange mailbox hold types

Here's a list of the retention features (also called *holds*) in Microsoft Purview and Microsoft 365:

- **Litigation Hold**: Holds that you apply to user mailboxes in Exchange Online.
- **eDiscovery hold**: Holds that you associate with an eDiscovery case in the Microsoft Purview portal. You can place a hold on the Exchange mailboxes and OneDrive accounts of people you're investigating in the case. You can also place a hold on the mailboxes and sites that are associated with Microsoft Teams, Microsoft 365 groups, and Viva Engage Groups.
- **Microsoft Purview retention policies**: Can be configured to retain (or retain and then delete) content in user mailboxes in Exchange Online and in the corresponding mailbox for Microsoft 365 Groups and Microsoft Teams. You can also create a retention policy to retain Skype for Business Conversations, which are stored in user mailboxes.

There are two types of Microsoft Purview retention policies that you can assign to mailboxes.

- **Specific location retention policies**: These policies are assigned to the content locations of specific users. Use the **Get-Mailbox** cmdlet in Exchange Online PowerShell to get information about retention policies assigned to specific mailboxes. For more information about this type of retention policy, see the section A policy with specific inclusions or exclusions from the retention policy documentation.
- **Organization-wide retention policies**: These policies are assigned to all content locations in your organization. Use the **Get-OrganizationConfig** cmdlet in Exchange Online PowerShell to get information about organization-wide retention policies. For more information about this type of retention policy, see the section A policy that applies to entire locations from the retention policy documentation.

- **Microsoft Purview retention labels**: If a user applies a Microsoft Purview retention label (one that's configured to retain content or retain and then delete content) to *any* folder or item in their mailbox, a hold is placed on the mailbox as if you placed the mailbox on Litigation Hold or assigned it to a Microsoft Purview retention policy. For more information, see the Identifying mailboxes on hold because a retention label was applied to a folder or item section in this article.

To manage mailboxes on hold, you might need to identify the type of hold that's placed on a mailbox so that you can perform tasks such as changing the hold duration, temporarily or permanently removing the hold, or excluding a mailbox from a Microsoft Purview retention policy. In these cases, the first step is to identify the type of hold placed on the mailbox. Because multiple holds (and different types of holds) can be placed on a single mailbox, you need to identify all holds placed on a mailbox if you want to remove or change a hold.

Step 1: Get the GUID for holds placed on a mailbox

To connect to Exchange Online PowerShell, see Connect to Exchange Online PowerShell. You must connect before you run the cmdlets in this step.

Run the following two cmdlets in Exchange Online PowerShell to get the GUID of the holds that are placed on a mailbox. After you get a GUID, use it to identify the specific hold in Step 2. A Litigation Hold doesn't use a GUID. Litigation Holds are either enabled or disabled for a mailbox.

- **Get-Mailbox**: Use this cmdlet to check if Litigation Hold is enabled for a mailbox and to get the GUIDs for eDiscovery holds and Microsoft Purview retention policies that are assigned

to a mailbox. The output of this cmdlet also shows if a mailbox is explicitly excluded from an organization-wide retention policy.

- **Get-OrganizationConfig**: Use this cmdlet to get the GUIDs for organization-wide retention policies.

Use Get-Mailbox to view holds on a mailbox

Run the following command to get information about the holds and Microsoft Purview retention policies applied to a mailbox.

PowerShell

```
Get-Mailbox <username> | FL LitigationHoldEnabled,InPlaceHolds
```

> **Tip**
>
> If there are too many values in the InPlaceHolds property and not all of them show up, run the `Get-Mailbox <username> | Select-Object -ExpandProperty InPlaceHolds` command to display each GUID on a separate line.

The following table describes how to identify different types of holds based on the values in the *InPlaceHolds* property when you run the **Get-Mailbox** cmdlet.

Expand table

Hold type	Example value	How to identify the hold
Litigation Hold	`True`	Litigation Hold is enabled for a mailbox when the *LitigationHoldEnabled* property is set to `True`.
eDiscovery hold	`UniH7d895d48-7e23-4a8d-8346-533c3beac15d`	The *InPlaceHolds property* contains the GUID of any hold associated with an eDiscovery case in the Microsoft Purview portal. You can tell this is an eDiscovery hold because the GUID starts with the `UniH` prefix (which denotes a Unified Hold).
Microsoft Purview retention policy applied to the mailbox	`mbxcdbbb86ce60342489bff371876e7f224:1` or `skp127d7cf1076947929bf136b7a2a8c36f:3`	The *InPlaceHolds* property contains GUIDs of any specific location retention policy that's applied to the mailbox. You can identify retention policies because the GUID starts with the `mbx` or the `skp` prefix. The `skp`

Hold type	Example value	How to identify the hold
		prefix indicates that the retention policy is applied to Skype for Business conversations in the user's mailbox.
Excluded from an organization-wide Microsoft Purview retention policy	`-mbxe9b52bf7ab3b46a286308ecb29624696`	If a mailbox is excluded from an organization-wide Microsoft Purview retention policy, the GUID for the retention policy that the mailbox is excluded from shows up in the *InPlaceHolds* property and uses the `-mbx` prefix.

Use Get-OrganizationConfig to identify organization-wide holds

If the *InPlaceHolds* property is empty when you run the **Get-Mailbox** cmdlet, one or more organization-wide Microsoft Purview retention policies might still apply to the mailbox. Run the following command in Exchange Online PowerShell to get a list of GUIDs for organization-wide Microsoft Purview retention policies.

PowerShell

```
Get-OrganizationConfig | FL InPlaceHolds
```

> **Tip**
>
> If the `InPlaceHolds` property contains too many values and not all of them display, run the `Get-OrganizationConfig | Select-Object -ExpandProperty InPlaceHolds` command to display each GUID on a separate line.

The following table describes the different types of organization-wide holds and how to identify each type based on the GUIDs contained in the *InPlaceHolds* property when you run the **Get-OrganizationConfig** cmdlet.

Expand table

Hold type	Example value	Description
Microsoft Purview retention policies applied to Exchange mailboxes, Exchange	`mbx7cfb30345d454ac0a989ab3041051209:2`	Organization-wide retention policies applied to Exchange mailboxes, Exchange public folders, and 1xN chats in Microsoft Teams are identified by GUIDs that start

Hold type	Example value	Description
public folders, and Teams chats		with the `mbx` prefix. Note 1xN chats are stored in the mailbox of the individual chat participants.
Microsoft Purview retention policy applied to Microsoft 365 Groups and Teams channel messages	`grp1a0a132ee8944501a4bb6a452ec31171:3`	Organization-wide retention policies applied to Microsoft 365 groups and channel messages in Microsoft Teams are identified by GUIDs that start with the `grp` prefix. Note channel messages are stored in the group mailbox that is associated with a Microsoft Team.

For more information about retention policies applied to Microsoft Teams, see Learn about retention policies for Microsoft Teams.

Understand the format of the InPlaceHolds value for retention policies

In addition to the prefix (`mbx`, `skp`, or `grp`) that identifies an item in the `InPlaceHolds` property as a Microsoft Purview retention policy, the value also contains a suffix that identifies the type of retention action that's configured for the policy. For example, the action suffix is highlighted in bold type in the following examples:

`skp127d7cf1076947929bf136b7a2a8c36f`:1

`mbx7cfb30345d454ac0a989ab3041051209`:2

`grp1a0a132ee8944501a4bb6a452ec31171`:3

The following table defines the three possible retention actions:

Expand table

Value	Description
1	The retention policy is configured to delete items or the retention policy is used to publish retention labels. If the policy is publishing retention labels, check the retention configuration for each published label.
2	The retention policy is configured to hold items. The policy doesn't delete items after the retention period expires.
3	The retention policy is configured to hold items and then delete them after the retention period expires.

> **Note**
>
> Because retention label policies publish or autoapply labels that apply item-level actions, they always show an action value of 1 within the `InPlaceHolds` property of the mailbox.
>
> To identify whether a hold is applied to a folder or item within the mailbox, see **Identifying mailboxes on hold because a retention label has been applied to a folder or item**.

For more information about retention actions, see the Retaining content for a specific period of time section.

Step 2: Use the GUID to identify the hold

After you get the GUID for a hold that's applied to a mailbox, use that GUID to identify the hold. The following sections show how to identify the name of the hold and other information by using the hold GUID.

eDiscovery holds

Run the following commands in Security & Compliance PowerShell to find an eDiscovery hold that's applied to the mailbox. Use the GUID (without the UniH prefix) for the eDiscovery hold that you found in Step 1.

To connect to Security & Compliance PowerShell, see Connect to Security & Compliance PowerShell.

The first command creates a variable that holds information about the eDiscovery hold. Use this variable in the other commands. The second command shows the name of the eDiscovery case that the hold is associated with. The third command shows the name of the hold and lists the mailboxes that the hold applies to.

PowerShell

```
$CaseHold = Get-CaseHoldPolicy <hold GUID without prefix>
```

PowerShell

```
Get-ComplianceCase $CaseHold.CaseId | FL Name
```

PowerShell

```
$CaseHold | FL Name,ExchangeLocation
```

Identify Microsoft Purview retention policies by GUID

Connect to Security & Compliance PowerShell and run the following command to find the Microsoft Purview retention policy (organization-wide or specific location) that's applied to the mailbox. Use the GUID (without the mbx, skp, or grp prefix or the action suffix) that you found in Step 1.

PowerShell

```
Get-RetentionCompliancePolicy <hold GUID without prefix or suffix> -DistributionDetail
| FL Name,*Location
```

New retention policies that apply to the following locations don't stamp directly on organization configuration or Exchange Online objects:

- Enterprise AI apps
- Microsoft Copilot experiences
- Teams chats
- Teams private channel messages
- Viva Engage community messages
- Viva Engage user messages
- Other AI apps

To determine whether these retention compliance policies apply to a mailbox during an investigation, use Policy Lookup or Retention cmdlets for newer locations.

PowerShell

```
Get-AppRetentionCompliancePolicy <hold GUID without prefix or suffix> -
DistributionDetail  | FL Name, Applications, *Location
```

Identify mailboxes on hold because a retention label is applied to a folder or item

When a user applies a retention label that's configured to *retain* or *retain and then delete* content to any folder or item in their mailbox, the *ComplianceTagHoldApplied* mailbox property is set to **True**. When this property is **True**, treat the mailbox as if it's on hold, such as when you assign it to

a Microsoft Purview retention policy or place it on Litigation Hold, but with some caveats. When the *ComplianceTagHoldApplied* property is **True**, the following things occur:

- If you delete the mailbox or the user's Microsoft 365 account, the mailbox becomes an inactive mailbox.
- You can't disable the mailbox (either the primary mailbox or the archive mailbox, if it's enabled).
- Items that you delete from the mailbox follow one of two paths depending on whether they're labeled or not:
  - **Unlabeled items** follow the same path deleted items take when no holds apply to the mailbox. The time that it takes for these items to be permanently deleted is determined by the deleted item retention configuration and whether single item recovery is enabled for the mailbox or not.
  - **Labeled items** are retained within the recoverable items folder in the same way they would be if a Microsoft Purview retention policy applied, but at the individual item level. If multiple items have different labels that are configured to *retain* or *retain and then delete* content at different intervals, each item is retained based on the configuration of the applied label.
- Other holds, such as Microsoft Purview retention policies, eDiscovery holds, or litigation hold can extend how long labeled items are retained based on the principles of retention.

To view the value of the *ComplianceTagHoldApplied* property for a single mailbox, run the following command in Exchange Online PowerShell:

PowerShell

```
Get-Mailbox <username> | FL ComplianceTagHoldApplied
```

For more information about retention labels, see retention labels.

A *True* value for **ComplianceTagHoldApplied** doesn't mean the mailbox currently has items with a retention label. When you apply a retention label to a mailbox, **ComplianceTagHoldApplied** changes to *True*. After it changes to *True*, it doesn't automatically change back to *False*, even when the mailbox no longer has labeled items.

To change the *ComplianceTagHoldApplied* value to *False*, run the following command in Exchange Online PowerShell:

PowerShell

```
Set-Mailbox -Identity <username> -RemoveComplianceTagHoldApplied -ProvideConsent
```

For more information, see Set-Mailbox. For the full procedure to delete items from the Recoverable Items folder, see Delete items in the Recoverable Items folder.

Manage mailboxes on delay hold

When you remove any type of hold from a mailbox, Exchange Online applies a *delay hold*. This hold delays the actual removal of the hold for 30 days to prevent data from being permanently deleted (purged) from the mailbox. This delay gives admins an opportunity to search for or recover mailbox items that are purged after a hold is removed. The Managed Folder Assistant places a delay hold on a mailbox the next time it processes the mailbox and detects that a hold was removed. Specifically, the Managed Folder Assistant applies a delay hold to a mailbox when it sets one of the following mailbox properties to **True**:

- **DelayHoldApplied**: This property applies to email-related content (generated by people using Outlook and Outlook on the web) that's stored in a user's mailbox.
- **DelayReleaseHoldApplied**: This property applies to cloud-based content (generated by non-Outlook apps such as Microsoft Teams, Microsoft Forms, and Microsoft Viva Engage) that's stored in a user's mailbox. Cloud data generated by a Microsoft app is typically stored in a hidden folder in a user's mailbox.

When the Managed Folder Assistant places a delay hold on the mailbox (by setting either of the previous properties to **True**), the mailbox is still considered to be on hold for an unlimited hold duration, as if the mailbox was on Litigation Hold. After 30 days, the delay hold expires, and Microsoft 365 automatically attempts to remove the delay hold (by setting the *DelayHoldApplied* or *DelayReleaseHoldApplied* property to **False**) so that the hold is removed. After either of these properties are set to **False**, the corresponding items that are marked for removal are purged the next time the Managed Folder Assistant processes the mailbox.

> ⓘ **Note**
>
> If the user account for the mailbox is disabled, the Managed Folder Assistant doesn't process the mailbox and the delay hold remains after the 30 days expire. For more information, see Delay hold considerations.

To view the values for the DelayHoldApplied and DelayReleaseHoldApplied properties for a mailbox, run the following command in Exchange Online PowerShell.

PowerShell

```
Get-Mailbox <username> | FL *HoldApplied*
```

To remove the delay hold before it expires, run one (or both) of the following commands in Exchange Online PowerShell, depending on which property you want to change:

PowerShell

```
Set-Mailbox <username> -RemoveDelayHoldApplied
```

Or

PowerShell

```
Set-Mailbox <username> -RemoveDelayReleaseHoldApplied
```

You must be assigned the Legal Hold role in Exchange Online to use the *RemoveDelayHoldApplied* or *RemoveDelayReleaseHoldApplied* parameters.

To remove the delay hold on an inactive mailbox, run one of the following commands in Exchange Online PowerShell:

PowerShell

```
Set-Mailbox <DN or Exchange GUID> -InactiveMailbox -RemoveDelayHoldApplied
```

Or

PowerShell

```
Set-Mailbox <DN or Exchange GUID> -InactiveMailbox -RemoveDelayReleaseHoldApplied
```

> **Tip**
>
> The best way to specify an inactive mailbox in the previous command is to use its Distinguished Name or Exchange GUID value. Using one of these values helps prevent accidentally specifying the wrong mailbox.

For more information about using these parameters for managing delay holds, see Set-Mailbox.

Delay hold considerations

Keep the following points in mind when managing a mailbox on delay hold:

- If you set either the *DelayHoldApplied* or *DelayReleaseHoldApplied* property to **True** and you delete a mailbox (or the corresponding user account), the mailbox becomes an inactive mailbox. A mailbox is considered to be on hold if either property is set to **True**. Deleting a mailbox on hold results in an inactive mailbox. To delete a mailbox and not make it an inactive mailbox, set both properties to **False**.
- A mailbox is on hold for an unlimited hold duration if either the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True**. However, that condition doesn't mean that *all* content in the mailbox is preserved. The value of each property determines what content is preserved. For example, let's say both properties are set to **True** because you remove holds from the mailbox. Then, you remove only the delay hold that applies to non-Outlook cloud data by using the *RemoveDelayReleaseHoldApplied* parameter. The next time the Managed Folder Assistant processes the mailbox, it purges the non-Outlook items marked for removal. It doesn't purge any Outlook items marked for removal because the *DelayHoldApplied* property is still set to **True**. The opposite condition is also true: if *DelayHoldApplied* is set to **False** and *DelayReleaseHoldApplied* is set to **True**, then only Outlook items marked for removal are purged.

How to confirm that an organization-wide retention policy is applied to a mailbox

When you apply or remove an organization-wide retention policy to a mailbox, exporting the mailbox diagnostics logs helps you confirm that Exchange Online applied or removed the retention policy to the mailbox. To view this information, you first need to validate a few things by using Exchange Online PowerShell.

Obtain the GUIDs for any retention policies explicitly applied to a mailbox

Run the following command to list the retention policy GUIDs that are explicitly applied to the mailbox.

PowerShell

```
Get-Mailbox <username> | Select-Object -ExpandProperty InPlaceHolds
```

Obtain the GUIDs for any organization-wide retention policies applied to mailboxes

Run the following command to list the GUIDs for organization-wide retention policies.

PowerShell

```
Get-OrganizationConfig | Select-Object -ExpandProperty InPlaceHolds
```

Get the Mailbox Diagnostics for HoldTracking

The Hold Tracking Mailbox Diagnostics logs maintain a history of the holds applied to a user mailbox. If the object is inactive, include `-IncludeInactiveMailboxes` parameter.

PowerShell

```
$ht = Export-MailboxDiagnosticLogs <username> -ComponentName HoldTracking
$ht.MailboxLog | Convertfrom-Json
```

Get the Mailbox Diagnostics for Substrate HoldTracking

The Substrate Hold Tracking Mailbox Diagnostics logs maintain a history of the holds applied to a user mailbox. If the object is inactive, include `-IncludeInactiveMailboxes` parameter.

PowerShell

```
$sht = Export-MailboxDiagnosticLogs <username> -ComponentName SubstrateHoldTracking
$sht.MailboxLog | Convertfrom-Json
```

Review the results of the Mailbox Diagnostics logs

After you run `Export-MailboxDiagnosticLogs` for HoldTracking or SubstrateHoldTracking, the resulting data might look something like this example:

> **ed** `: 0001-01-01T00:00:00.0000000` **hid** `: mbx7cfb30345d454ac0a989ab3041051209:1` **ht** `: 4`
> **lsd** `: 2020-03-23T18:24:37.1884606Z` **osd** `: 2020-03-23T18:24:37.1884606Z`

Use the following table to help you understand each of the values listed in the diagnostics log.

Expand table

Value	Description
ed	Indicates the end date, which is the date the retention policy was disabled. MinValue means the policy is still assigned to the mailbox.
hid	Indicates the GUID for the retention policy. This value correlates to the GUIDs that you collected for the explicit or organization-wide retention policies assigned to the mailbox.
ht	Indicates the hold type. Values are *0* for LitigationHold, *1* for InPlaceHold, *2* for ComplianceTagHold, *3* for DelayReleaseHold, *4* for OrganizationRetention, *5* for CompliancePolicy, *6* for SubstrateAppPolicy, and *7* for SharepointPolicy.
lsd	Indicates the last start date, which is the date the retention policy was assigned to the mailbox.
osd	Indicates the original start date, which is the date that Exchange first recorded information about the retention policy.

When you remove a retention policy from a mailbox, Exchange places a temporary delay hold on the user to prevent purging content. You can disable a delay hold by running the `Set-Mailbox -RemoveDelayHoldApplied` command.

Next steps

After you identify the holds that are applied to a mailbox, you can perform tasks such as changing the duration of the hold, temporarily or permanently removing the hold, or excluding an inactive mailbox from a Microsoft Purview retention policy. For more information about performing tasks related to holds, see one of the following articles:

- Run the Set-RetentionCompliancePolicy -Identity <Policy Name> -AddExchangeLocationException <user mailbox> command in Security & Compliance PowerShell to exclude a mailbox from an organization-wide Microsoft Purview retention policy. You can only use this command for retention policies where the value for the *ExchangeLocation* property equals `All`.
- Run the Set-AppRetentionCompliancePolicy -Identity <Policy Name> -AddExchangeLocationException <user mailbox> command in Security & Compliance PowerShell to exclude a mailbox from a Teams private channel messages, Viva Engage user messages, Viva Engage community messages, Teams chats, Microsoft Copilot experiences, Enterprise AI apps, and other AI apps. You can only use this command for retention policies where the value for the *ExchangeLocation* property equals `All`.
- Run the Set-Mailbox <\DN or Exchange GUID> -RemoveDelayHoldApplied if needed to remove DelayHoldApplied if that's True. If the object is inactive, include the `-InactiveMailbox` parameter.

- Run the Set-Mailbox <\DN or Exchange GUID> -RemoveDelayReleaseHoldApplied if needed to remove DelayReleaseHoldApplied if that's True. If the object is inactive, include the `-InactiveMailbox` parameter.
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveDelayHoldApplied if needed to remove DelayReleaseHoldApplied if that's True.
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveDelayReleaseHoldApplied if needed to remove DelayReleaseHoldApplied if that's True.
- Run the Set-Mailbox <\DN or Exchange GUID> -LitigationHoldEnabled $False if needed to remove LitigationHold. If the object is inactive, include the `-InactiveMailbox` parameter.
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveLitigationHoldEnabled if needed to remove LitigationHold.
- Run the Set-Mailbox <\DN or Exchange GUID> -InactiveMailbox -RemoveComplianceTagHoldApplied if needed to remove ComplianceTagHoldApplied from inactive mailbox. If the object is active, include the `-ProvideConsent` parameter Set-Mailbox <\DN or Exchange GUID> -RemoveComplianceTagHoldApplied -ProvideConsent
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveComplianceTagHoldApplied if needed to remove ComplianceTagHoldApplied from inactive mailuser.
- Run the Set-Mailbox <\DN or Exchange GUID> -ExcludeFromAllHolds if needed to remove holds from inactive mailbox. Check the Set-Mailbox | ExcludeFromAllHolds to understand which holds this parameter can remove and which it cannot.
- Run the Set-MailUser <\DN or Exchange GUID> -ExcludeFromAllHolds if needed to remove holds from inactive mailuser. Check the Set-MailUser | ExcludeFromAllHolds to understand which holds this parameter can remove and which it cannot.
- Change the hold duration for an inactive mailbox
- Delete an inactive mailbox
- Delete items in the Recoverable Items folder of cloud-based mailboxes on hold

Delete items in the Recoverable Items folder for mailboxes on hold in eDiscovery

The **Recoverable Items** folder for an Exchange Online mailbox protects against accidental or malicious deletions. Exchange Online also uses this folder to store items that compliance features retain and access, such as holds and eDiscovery searches. However, in some situations, organizations might need to delete data unintentionally retained in the Recoverable Items folder.

For example, a user might unknowingly send or forward an email message that contains sensitive information or information that might have serious business consequences. Even if the user permanently deletes the message, it might be retained indefinitely because a legal hold was placed on the mailbox. This scenario is known as *data spillage* because data was unintentionally *spilled* into Microsoft 365. In these situations, you can delete items in a user's Recoverable Items folder for an Exchange Online mailbox, even if you placed the mailbox on hold by using one of the different hold features in Microsoft 365. These types of holds include Litigation Holds, eDiscovery holds, and retention policies created in Microsoft Purview.

The following procedure explains how to delete items from the Recoverable Items folder for cloud-based Exchange Online mailboxes that are on hold. This procedure involves disabling access to the mailbox and disabling single item recovery, disabling the Managed Folder Assistant from processing the mailbox, temporarily removing the hold, deleting items from the Recoverable Items folder, and then reverting the mailbox to its previous configuration.

Here's a summary of the process:

- Step 1: Collect information about the mailbox
- Step 2: Prepare the mailbox
- Step 3: Remove all holds from the mailbox
- Step 4: Remove the delay hold from the mailbox
- Step 5: Delete items in the Recoverable Items folder
- Step 6: Revert the mailbox to its previous state

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you delete items

> **Important**
>
> Before you start, confirm that no hold source still applies to the mailbox. If any hold (eDiscovery hold, Litigation Hold, Microsoft Purview retention policy, retention label hold, or delay hold) is in effect, the HardDelete purge in Step 5 silently leaves items in the Recoverable Items folder by design. For the full diagnostic checklist and the `InPlaceHolds` prefix decoder, see Check for holds on a mailbox or site.

> **Caution**
>
> Following the procedures outlined in this article results in data being permanently deleted (purged) from an Exchange Online mailbox. That means messages that you delete from the Recoverable Items folder can't be recovered and won't be available for legal discovery or other compliance purposes. If you want to delete messages from a mailbox that's placed on hold as part of a Litigation Hold, eDiscovery hold, or retention policy created in the Microsoft Purview portal, check with your records management or legal departments before removing the hold. Your organization might have a policy that defines whether a mailbox on hold or a data spillage activity takes priority.

- To create and run a search, you need to be a member of the eDiscovery Manager role group or be assigned the *Compliance Search* management role. To delete messages, you need to be a member of the *Organization Management* role group or be assigned the Search And Purge management role. For information about adding users to a role group, see Assign eDiscovery permissions.
- If you assign a mailbox to an organization-wide retention policy, you need to exclude the mailbox from the policy before you can delete items from the Recoverable Items folder. It might take up to 24 hours to synchronize the policy change and remove the mailbox from the policy. For more information, see "Remove organization-wide retention policies" in the Remove all holds from the mailbox section in this article.
- You can't perform this procedure for a mailbox that has retention settings assigned with a retention policy locked by using Preservation Lock. This lock prevents you from removing or excluding the mailbox from the policy and from disabling the Managed Folder Assistant on the mailbox. For more information about locking policies for retention, see Use Preservation Lock to restrict changes to retention policies and retention label policies.

- The procedure described in this article isn't supported for inactive mailboxes. That's because you can't reapply a hold (or retention policy) to an inactive mailbox after you remove it. When you remove a hold from an inactive mailbox, the mailbox changes to a normal soft-deleted mailbox and is permanently deleted from your organization after it's processed by the Managed Folder Assistant.
- If a mailbox isn't on hold (or doesn't have single item recovery enabled), you can delete the items from the Recoverable Items folder.

Step 1: Collect information about the mailbox

In this step, collect selected properties from the target mailbox that affect this procedure. Write down these settings or save them to a text file because you change some of these properties and then revert back to the original values in Step 6, after you delete items from the Recoverable Items folder. Here's a list of the mailbox properties you need to collect.

- *SingleItemRecoveryEnabled* and *RetainDeletedItemsFor*. If necessary, you disable single recovery and increase the deleted items retention period in Step 3.
- *LitigationHoldEnabled* and *InPlaceHolds*. You need to identify all the holds placed on the mailbox so that you can temporarily remove them in Step 3. For tips about how to identify the type of hold that might be placed on a mailbox, see Identify hold types by InPlaceHolds property values.

Additionally, you need to get the mailbox client access settings so you can temporarily disable them so the owner (or other users) can't access the mailbox during this procedure. Finally, you get the current size and number of items in the Recoverable Items folder. After you delete items in the Recoverable Items folder in Step 5, you use this information to verify that items were removed.

1. Connect to Exchange Online PowerShell. Be sure to use a user name and password for an administrator account that's been assigned the appropriate management roles in Exchange Online.

2. Run the following command to get information about single item recovery and the deleted item retention period.

   PowerShell

   ```
   Get-Mailbox <username> | FL SingleItemRecoveryEnabled,RetainDeletedItemsFor
   ```

If single item recovery is enabled, you have to disable it in Step 2. If the deleted item retention period isn't set for 30 days (the maximum value in Exchange Online), then you can increase it in Step 2.

3. Run the following command to get the mailbox access settings for the mailbox.

```
PowerShell
Get-CASMailbox <username> | FL
EwsEnabled,ActiveSyncEnabled,MAPIEnabled,OWAEnabled,ImapEnabled,PopEnabled
```

You disable all of these access methods in Step 2.

4. Run the following command to get information about the holds and retention policies applied to the mailbox.

```
PowerShell
Get-Mailbox <username> | FL LitigationHoldEnabled,InPlaceHolds
```

> **Tip**
>
> If there are too many values in the *InPlaceHolds* property and not all of them are displayed, run the `Get-Mailbox <username> | Select-Object -ExpandProperty InPlaceHolds` command to display each value on a separate line.

5. Run the following command to get information about any organization-wide retention policies.

```
PowerShell
Get-OrganizationConfig | FL InPlaceHolds
```

If your organization has any organization-wide retention policies, you have to exclude the mailbox from these policies in Step 3. It might take up to 24 hours to replicate the change.

> **Tip**

If there are too many values in the *InPlaceHolds* property and not all of them are displayed, run the `Get-OrganizationConfig | Select-Object -ExpandProperty InPlaceHolds` command to display each value on a separate line.

6. Run the following command to determine if a delay hold is applied to the mailbox.

```
PowerShell
Get-Mailbox <username> | FL DelayHoldApplied,DelayReleaseHoldApplied
```

If the value of the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True**, a delay hold is applied to the mailbox and must be removed. For more information about delay holds, see Step 4: Remove the delay hold from the mailbox.

If the value of either the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **False**, a delay hold isn't applied to the mailbox, and you can skip Step 4.

7. Run the following command to get the current size and total number of items in folders and subfolders in the Recoverable Items folder in the user's primary mailbox.

```
PowerShell
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems | FL
Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

If the user's archive mailbox is enabled, run the following command to get the size and total number of items in folders and subfolders in the Recoverable Items folder in their archive mailbox.

```
PowerShell
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems -Archive |
FL Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

When you delete items in Step 5, you can choose to delete or not delete items in the Recoverable Items folder in the user's primary archive mailbox. If auto-expanding archiving is enabled for the mailbox, items in an auxiliary archive mailbox won't be deleted.

Step 2: Prepare the mailbox

ⓘ Note

The actions in this step (disabling the Managed Folder Assistant and Single Item Recovery) are preparation. They aren't the delete mechanism. The Managed Folder Assistant (also called messaging records management, or MRM) enforces retention; it doesn't delete items from the Recoverable Items folder. The actual delete happens in Step 5 with the `New-ComplianceSearchAction -Purge -PurgeType HardDelete` command.

After you collect and save information about the mailbox, prepare the mailbox by performing the following tasks:

- **Disable client access to mailbox** so that the mailbox owner can't access their mailbox or make any changes to the mailbox data during this procedure.
- **Increase the deleted item retention period** to 30 days (the maximum value in Exchange Online) so that items aren't purged from the Recoverable Items folder before you can delete them in Step 5.
- **Disable single Item recovery** so that items aren't retained (during the deleted item retention period) after you delete them from the Recoverable Items folder in Step 5.
- **Disable the Managed Folder Assistant** so that it doesn't process the mailbox and retain the items that you delete in Step 5.

Perform the following steps in Exchange Online PowerShell.

1. Run the following command to disable all client access to the mailbox. The command syntax assumes that all client access methods are enabled on the mailbox.

   PowerShell

   ```
   Set-CASMailbox <username> -EwsEnabled $false -ActiveSyncEnabled $false -
   MAPIEnabled $false -OWAEnabled $false -ImapEnabled $false -PopEnabled $false
   ```

   > **Note**
   >
   > It might take up to 60 minutes to disable all client access methods to the mailbox. Disabling these access methods doesn't disconnect the mailbox owner if they're currently signed in. If the owner isn't signed in, they can't access their mailbox after these access methods are disabled.

2. Run the following command to increase the deleted item retention period to the maximum of 30 days. This step assumes that the current setting is less than 30 days.

PowerShell

```
Set-Mailbox <username> -RetainDeletedItemsFor 30
```

3. Run the following command to disable single item recovery.

PowerShell

```
Set-Mailbox <username> -SingleItemRecoveryEnabled $false
```

> ⓘ Note
>
> It might take up to 240 minutes to disable single item recovery. Don't delete items in the Recoverable Items folder until this period has elapsed.

4. Run the following command to prevent the Managed Folder Assistant from processing the mailbox. You can disable the Managed Folder Assistant only if a retention policy with a Preservation Lock isn't applied to the mailbox.

PowerShell

```
Set-Mailbox <username> -ElcProcessingDisabled $true
```

> ⓘ Note
>
> Setting the *ElcProcessingDisabled* parameter to *True* doesn't prevent all messages within the Recoverable Items folder from processing. If holds are removed from mailboxes, the substrate hold folder is deleted over time.

Step 3: Remove all holds from the mailbox

Before you can delete items from the Recoverable Items folder, remove all holds (identified in Step 1) that you placed on the mailbox. Remove all holds so that the system doesn't retain items after you delete them from the Recoverable Items folder. The following sections explain how to remove different types of holds on a mailbox. For tips about how to identify the type of hold that might be placed on a mailbox, see Identify hold types by InPlaceHolds property values. For more information, see How to identify the type of hold placed on an Exchange Online mailbox.

> ⊗ Caution

Check with your records management or legal departments before removing a hold from a mailbox.

Remove Litigation Hold from the mailbox

Run the following command in Exchange Online PowerShell to remove a Litigation Hold from the mailbox.

PowerShell

```
Set-Mailbox <username> -LitigationHoldEnabled $false
```

> **Note**
>
> Similar to disabling single item recovery, it might take up to 240 minutes to remove the Litigation Hold. Don't delete items from the Recoverable Items folder until this period has elapsed.

Remove retention policies applied to specific mailboxes

Run the following command in Security & Compliance PowerShell to identify the retention policy that is applied to the mailbox. This command also returns any Teams conversation retention policies applied to a mailbox. Use the GUID (not including the `mbx` or `skp` prefix) for the retention policy that you identified in Step 1.

PowerShell

```
Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name
```

After you identify the retention policy, go to **Data lifecycle management** > **Retention policies** in the Microsoft Purview portal, edit the retention policy that you identified in the previous step, and remove the mailbox from the list of recipients that are included in the retention policy.

Remove organization-wide retention policies

Organization-wide, Exchange-wide, and Teams-wide retention policies apply to every mailbox in the organization. You apply these policies at the organization level (not the mailbox level). When you run the **Get-OrganizationConfig** cmdlet in Step 1, it returns these policies. Run the following command in Security & Compliance PowerShell to identify the organization-wide retention

policies. Use the GUID (not including the `mbx` prefix) for the organization-wide retention policies that you identified in Step 1.

PowerShell

```
Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name
```

After you identify the organization-wide retention policies, go to the **Data lifecycle management** > **Retention policies** page in the Microsoft Purview portal, edit each organization-wide retention policy that you identified in the previous step, and add the mailbox to the list of excluded recipients. This action removes the user's mailbox from the retention policy.

> ⓘ **Important**
>
> After you exclude a mailbox from an organization-wide retention policy, it might take up to 24 hours to synchronize this change and remove the mailbox from the policy.

Remove retention labels that preserve mailbox items

When a user applies a label that's configured to retain content or retain and then delete content to any folder or item in their mailbox, the *ComplianceTagHoldApplied* mailbox property is set to **True**. When this property is set, the mailbox is considered to be on hold, as if it was placed on Litigation Hold or assigned to a retention policy.

To view the value of the *ComplianceTagHoldApplied* property, run the following command in Exchange Online PowerShell:

PowerShell

```
Get-Mailbox <username> |FL ComplianceTagHoldApplied
```

After you identify that a mailbox is on hold because a retention label is applied to a folder or item, you can use search in the Microsoft Purview portal to search for labeled items by using the **Retention label** condition. To learn how to search for content with specific retention labels, see:

- The "Using Content Search to find all content with a specific retention label" section in Learn about retention policies and retention labels
- The "Search conditions" section in Use the condition builder to create search queries in eDiscovery.

For more information about labels, see Learn about retention policies and retention labels.

> **Tip**
>
> The *ComplianceTagHoldApplied* value doesn't automatically revert to *False* after all labels are removed. For information about how to reset this property, see **Identify mailboxes on hold because a retention label is applied to a folder or item**.

Remove eDiscovery holds from the mailbox

Run the following commands in Security & Compliance PowerShell to identify the hold associated with an eDiscovery case (called *eDiscovery holds*) that you applied to the mailbox. Use the GUID (not including the `UniH` prefix) for the eDiscovery hold that you identified in Step 1. The second command displays the name of the eDiscovery case the hold is associated with; the third command displays the name of the hold.

PowerShell

```
$CaseHold = Get-CaseHoldPolicy <hold GUID without prefix>
```

PowerShell

```
Get-ComplianceCase $CaseHold.CaseId | FL Name
```

PowerShell

```
$CaseHold.Name
```

After you identify the name of the eDiscovery case and the hold, go to **eDiscovery** in the Microsoft Purview portal, open the case, and remove the mailbox from the hold. For more information about identifying eDiscovery holds, see the "eDiscovery holds" section in How to identify the type of hold placed on an Exchange Online mailbox.

Step 4: Remove the delay hold from the mailbox

After you remove any type of hold from a mailbox, the next time the Managed Folder Assistant processes the mailbox and detects that a hold is removed, it sets the value of the *DelayHoldApplied* or *DelayReleaseHoldApplied* mailbox property to **True**. This value is called a *delay hold* and means the actual removal of the hold is delayed for 30 days to prevent data from

being permanently deleted from the mailbox. The purpose of a delay hold is to give admins an opportunity to search for or recover mailbox items purged after a hold is removed. When a delay hold is placed on the mailbox, the mailbox is still considered to be on hold for an unlimited duration, as if the mailbox was on Litigation Hold. After 30 days, the delay hold expires, and Microsoft 365 automatically attempts to remove the delay hold (by setting the *DelayHoldApplied* or *DelayReleaseHoldApplied* property to **False**) so that the hold is removed. For more information about a delay hold, see the "Managing mailboxes on delay hold" section in How to identify the type of hold placed on an Exchange Online mailbox.

You must be assigned the Legal Hold role in Exchange Online to use the *RemoveDelayHoldApplied* or *RemoveDelayReleaseHoldApplied* parameter.

If the value of the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True**, run one of the following commands to remove the delay hold:

PowerShell

```
Set-Mailbox <username> -RemoveDelayHoldApplied
```

Or

PowerShell

```
Set-Mailbox <username> -RemoveDelayReleaseHoldApplied
```

Step 5: Delete items in the Recoverable Items folder

Now you're ready to delete items in the Recoverable Items folder by using the New-ComplianceSearch and New-ComplianceSearchAction cmdlets in Security & Compliance PowerShell.

> **Note**
>
> If the mailbox quota is met and the user mailbox is declining emails, you might receive a 554 5.2.0 error when deleting recoverable items. For more information, see "554 5.2.0 STOREDRV.Deliver.Exception" when sending emails in Exchange Online. For information about increasing the Recoverable Items quota, see Increase the Recoverable Items quota for mailboxes on hold.

Here's an overview of the process to search for and delete items in a user's Recoverable Items folder:

1. **Identify recoverable items in the mailbox**: Use the Get-RecoverableItems cmdlet to retrieve information about items stored in the Recoverable Items folder of the target mailbox. This step helps you understand the volume and characteristics of recoverable items before attempting deletion. For example, you can run the cmdlet to review recoverable items associated with a specific mailbox and determine appropriate criteria for scoping a deletion.

   Review the output to identify common attributes, such as subject, sender, or date range, that you can use to precisely target the items you want to delete.

2. **Create a content search using searchable item properties**. After identifying the recoverable items, use the New-ComplianceSearch cmdlet (in Security & Compliance PowerShell) or use eDiscovery search tools in the Microsoft Purview portal to create a content search that returns items from the target items in the recoverable items folder. Use searchable item properties to target the specific items you want to delete. Use conditions that include properties such as *subject*, *sender*, *recipients*, *message type*, and *date range*.

   Define the search criteria carefully to ensure that only the intended items are included in the search results. After the search is created, run it and validate that the results match the items you identified in the previous step.

3. After you create a content search and validate that it returns the items that you want to delete, use the `New-ComplianceSearchAction -Purge -PurgeType HardDelete` command (in Security & Compliance PowerShell) to permanently delete the items returned by the content search. For example, you can run a command similar to the following command:

   PowerShell

   ```
   New-ComplianceSearchAction -SearchName "RecoverableItems" -Purge -PurgeType
   HardDelete
   ```

4. When you run the previous command, it deletes up to 10 items per mailbox. That limit means you might have to run the `New-ComplianceSearchAction -Purge` command multiple times to delete all the items that you want to delete in the Recoverable Items folder. To delete more items, you first have to remove the previous compliance search purge action. You do this by running the `Remove-ComplianceSearchAction` cmdlet. For example, to delete the purge action that you ran in the previous step, run the following command:

   ```
   ```

PowerShell

```
Remove-ComplianceSearchAction "RecoverableItems_Purge"
```

After you complete this step, you can create a new compliance search purge action to delete more items. You must delete each purge action before creating a new one.

To get a list of the compliance search actions, you can run the `Get-ComplianceSearchAction` cmdlet. Purge actions are identified by `_Purge` appended to the search name.

Verify that you deleted items

To verify that you deleted items from the Recoverable Items folder of a mailbox, use the **Get-MailboxFolderStatistics** cmdlet in Exchange Online PowerShell to check the size and number of items in the Recoverable Items folder. You can compare these statistics with the ones you collected in Step 1.

Run the following command to get the current size and total number of items in folders and subfolders in the Recoverable Items folder in the user's primary mailbox.

PowerShell

```
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems | FL
Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

Run the following command to get the size and total number of items in folders and subfolders in the Recoverable Items folder in the user's archive mailbox.

PowerShell

```
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems -Archive | FL
Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

Step 6: Revert the mailbox to its previous state

The final step is to revert the mailbox to its previous configuration. This step resets the properties that you changed in Step 2 and reapplies the holds that you removed in Step 3. This step includes:

- Changing the deleted item retention period back to its previous value. Alternatively, you can set this value to 30 days, the maximum value in Exchange Online.
- Re-enabling single item recovery.

- Re-enabling the client access methods so that the owner can access their mailbox.
- Reapplying the holds and retention policies that you removed.
- Re-enabling the Managed Folder Assistant to process the mailbox.

> **Important**
>
> Wait 24 hours after reapplying a hold or retention policy (and verifying that it's in place) before you re-enable the Managed Folder Assistant to process the mailbox.

Perform the following steps (in the specified sequence) in Exchange Online PowerShell.

1. Run the following command to change the deleted item retention period back to its original value. This example assumes that the previous setting is less than 30 days, such as 14 days.

   PowerShell

   ```
   Set-Mailbox <username> -RetainDeletedItemsFor 14
   ```

2. Run the following command to re-enable single item recovery.

   PowerShell

   ```
   Set-Mailbox <username> -SingleItemRecoveryEnabled $true
   ```

3. Run the following command to re-enable all client access methods to the mailbox.

   PowerShell

   ```
   Set-CASMailbox <username> -EwsEnabled $true -ActiveSyncEnabled $true -MAPIEnabled $true -OWAEnabled $true -ImapEnabled $true -PopEnabled $true
   ```

4. Reapply the holds that you removed in Step 3. Depending on the type of hold, use one of the following procedures.

   Litigation Hold

   Run the following command to re-enable a Litigation Hold for the mailbox.

   PowerShell

   ```
   Set-Mailbox <username> -LitigationHoldEnabled $true
   ```

Retention policies applied to specific mailboxes

Use the Microsoft Purview portal to add the mailbox back to the retention policy. Go to the **Data lifecycle management** > **Retention policies** page in the Microsoft Purview portal, edit the retention policy, and add the mailbox back to the list of recipients that the retention policy is applied to.

Organization-wide retention policies

If you removed an organization-wide or Exchange-wide retention policy by excluding it from the policy, use the Microsoft Purview portal to remove the mailbox from the list of excluded users. Go to the **Data lifecycle management** > **Retention policies** page in the Microsoft Purview portal, edit the organization-wide retention policy, and remove the mailbox from the list of excluded recipients. Doing this reapplies the retention policy to the user's mailbox.

eDiscovery case holds

Use the Microsoft Purview portal to add the mailbox back the hold that's associated with an eDiscovery case. Go to **eDiscovery**, open the case, and add the mailbox back to the hold.

5. Run the following command to allow the Managed Folder Assistant to process the mailbox again.

```
PowerShell
Set-Mailbox <username> -ElcProcessingDisabled $false
```

6. To verify that the mailbox is reverted back to its previous configuration, run the following commands and then compare the settings to the ones that you collected in Step 1.

```
PowerShell
Get-Mailbox <username> | FL
ElcProcessingDisabled,InPlaceHolds,LitigationHoldEnabled,RetainDeletedItemsFor,Si
ngleItemRecoveryEnabled
```

```
PowerShell
Get-CASMailbox <username> | FL
EwsEnabled,ActiveSyncEnabled,MAPIEnabled,OWAEnabled,ImapEnabled,PopEnabled
```

Identify hold types by InPlaceHolds property values

The following table describes how to identify different types of holds based on the values in the *InPlaceHolds* property when you run the **Get-Mailbox** or **Get-OrganizationConfig** cmdlets. For more detailed information, see How to identify the type of hold placed on an Exchange Online mailbox.

You need to remove all holds and retention policies from a mailbox before you can successfully delete items in the Recoverable Items folder.

Expand table

Hold type	Example value	How to identify the hold
Litigation Hold	`True`	The *LitigationHoldEnabled* property is set to `True`.
Retention policies in the Microsoft Purview portal applied to specific mailboxes	`mbxcdbbb86ce60342489bff371876e7f224` or `skp127d7cf1076947929bf136b7a2a8c36f`	When you run the **Get-Mailbox** cmdlet, the *InPlaceHolds* property also contains GUIDs of retention policies applied to the mailbox. You can identify retention policies because the GUID starts with the `mbx` prefix. If the GUID of the retention policy starts with the `skp` prefix, that indicates that the retention policy is applied to Skype for Business conversations. To identity the retention policy that's applied to the mailbox, run the following command in Security & Compliance PowerShell: `Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name` Be sure to remove the `mbx` or `skp` prefix when you run this command.
Organization-wide retention policies in the Microsoft Purview portal	No value or `-mbxe9b52bf7ab3b46a286308ecb29624696` (indicates that the mailbox is excluded from an organization-wide policy)	Even if the *InPlaceHolds* property is empty when you run the **Get-Mailbox** cmdlet, one or more organization-wide retention policies might still apply to the mailbox. To verify this, run the `Get-OrganizationConfig | FL InPlaceHolds` command in Exchange Online PowerShell to get a list of the GUIDs for organization-wide retention policies. The GUID for organization-wide retention policies applied to Exchange mailboxes starts with the `mbx` prefix. For example, `mbxa3056bb15562480fadb46ce523ff7b02`.

Hold type	Example value	How to identify the hold
		To identity the organization-wide retention policy that's applied to the mailbox, run the following command in Security & Compliance PowerShell: `Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name` If a mailbox is excluded from an organization-wide retention policy, the GUID for the retention policy appears in the *InPlaceHolds* property of the user's mailbox when you run the **Get-Mailbox** cmdlet. It's identified by the prefix `-mbx`. For example, `-mbxe9b52bf7ab3b46a286308ecb29624696`.

eDiscovery case hold in the Microsoft Purview portal	`UniH7d895d48-7e23-4a8d-8346-533c3beac15d`	The *InPlaceHolds* property also contains the GUID of any hold associated with an eDiscovery case in the Microsoft Purview portal that might be placed on the mailbox. You can tell this is an eDiscovery case hold because the GUID starts with the `UniH` prefix.
		You can use the `Get-CaseHoldPolicy` cmdlet in Security & Compliance PowerShell to get information about the eDiscovery case that the hold on the mailbox is associated with. For example, you can run the command `Get-CaseHoldPolicy <hold GUID without prefix> | FL Name` to display the name of the case hold that's on the mailbox. Be sure to remove the `UniH` prefix when you run this command.
		
		To identity the eDiscovery case that the hold on the mailbox is associated with, run the following commands:
		
		`$CaseHold = Get-CaseHoldPolicy <hold GUID without prefix>`
		
		`Get-ComplianceCase $CaseHold.CaseId | FL Name`

Increase the Recoverable Items quota for mailboxes on hold in eDiscovery

The default Exchange retention policy—named *Default MRM Policy*—that automatically applied to new mailboxes in Exchange Online contains a retention tag named Recoverable Items 14 days move to archive. This retention tag moves items from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in the user's archive mailbox after the 14-day retention period expires for an item.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Emails in the Deletions folder retain based on the **RetainDeletedItemsFor** parameter and move to other folders in recoverable deleted items and then to the archive mailbox. For this process to work, the user's archive mailbox must be enabled. If the archive mailbox isn't enabled, no action is taken, which means that items in the Recoverable Items folder for a mailbox on hold aren't moved to the archive mailbox after the 14-day retention period expires. Because nothing is deleted from a mailbox on hold, it's possible that the storage quota for the Recoverable Items folder might be exceeded, especially if the user's archive mailbox isn't enabled. For information about deleting items from the Recoverable Items folder, see Delete Recoverable Items from mailboxes on hold.

To help reduce the chance of exceeding the Recoverable Items folder storage quota, the storage quota for the Recoverable Items folder automatically increases from 30 GB to 100 GB when you create an eDiscovery hold on a mailbox in Exchange Online. If the archive mailbox is enabled, the storage quota for the Recoverable Items folder in the archive mailbox also increases from 30 GB to 100 GB. If archive is enabled on a mailbox that is on hold with auto-expanding archive disabled, the storage quota of the Recoverable Items folder quota increases from 100 GB to 105 GB. If the auto-expanding archiving feature in Exchange Online is enabled, the total storage quota for the user's archive mailbox, including the Recoverable Items folder, is 1.5 TB.

The following table summarizes the storage quota for the Recoverable Items folder.

Expand table

Location of Recoverable Items folder	Mailboxes not on hold	Mailboxes on hold
Primary mailbox	30 GB	100 GB
Archive mailbox, including Recoverable Items folder *	1.5 TB	1.5 TB

> **Note**
>
> * The initial storage quota for the archive mailbox is 100 GB for users with an Exchange Online (Plan 2) license. However, when auto-expanding archiving is turned on for mailboxes on hold, the storage quota for both the archive mailbox and the Recoverable Items folder increases to 110 GB. Additional archive storage space (which includes the Recoverable Items folder) up to 1.5 TB is provisioned when necessary. For more information about auto-expanding archiving, see Learn about auto-expanding archiving.

> **Note**
>
> When archiving is enabled for a specific user whose mailbox is on hold or assigned to a retention policy, the storage quota for the user's primary mailbox's Recoverable Items folder raises from 100 GB to 105 GB and Recoverable items warning quota raises from 90 GB to 95 GB. This extra space supports an efficient archiving experience for users, even if auto-expanding archive isn't enabled.

When the storage quota for the Recoverable Items folder in the primary mailbox of a mailbox on hold is close to reaching its limit, you can do the following things:

- **Enable the archive mailbox and turn on auto-expanding archiving.** You can enable an extra storage capacity for the Recoverable Items folder by enabling the archive mailbox and then turning on the auto-expanding archiving feature in Exchange Online. This change results in 110 GB for the Recoverable Items folder in the primary mailbox and up to 1.5 TB of combined storage capacity for the archive and Recoverable Items folder. For more information, see Enable archive mailboxes and Enable auto-expanding archiving.

  > **Note**
  >
  > After you enable the archive for a mailbox that's close to exceeding the storage quota for the Recoverable Items folder, you might want to run the Managed Folder Assistant to manually trigger the assistant to process the mailbox so that expired items move to

the Recoverable Items folder in the archive mailbox. See Run the Managed Folder Assistant to apply the new retention settings for instructions. Other items in the user's mailbox might move to the new archive mailbox. Consider telling the user that this change might happen after you enable the archive mailbox.

- **Create a custom Exchange retention policy for mailboxes on hold.** In addition to enabling the archive mailbox and auto-expanding archiving for mailboxes on Litigation Hold, you might also want to create a custom Exchange retention policy for mailboxes on hold. This policy lets you apply a retention policy to mailboxes on hold that's different from the Default MRM Policy that's applied to mailboxes that aren't on hold, and lets you apply retention tags that are designed for mailboxes on hold. This policy includes creating a new retention tag for the Recoverable Items folder.

The rest of this article describes the step-by-step procedures to create a custom Exchange retention policy for mailboxes on hold.

- Step 1: Create a custom retention tag for the Recoverable Items folder
- Step 2: Create a new Exchange retention policy for mailboxes on hold
- Step 3: Apply the new Exchange retention policy to mailboxes on hold
- (Optional) Step 4: Run the Managed Folder Assistant to apply the new retention settings

Step 1: Create a custom retention tag for the Recoverable Items folder

First, create a custom retention tag (called a retention policy tag or RPT) for the Recoverable Items folder. This RPT moves items from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in the user's archive mailbox. Use PowerShell to create an RPT for the Recoverable Items folder. You can't use the Exchange admin center (EAC).

1. Connect to Exchange Online PowerShell

2. Run the following command to create a new RPT for the Recoverable Items folder:

   PowerShell

   ```
   New-RetentionPolicyTag -Name <Name of RPT> -Type RecoverableItems -
   AgeLimitForRetention <Number of days> -RetentionAction MoveToArchive
   ```

   For example, the following command creates an RPT for the Recoverable Items folder named "Recoverable Items 30 days for mailboxes on hold", with a retention period of 30

days. This means that after an item has been in the Recoverable Items folder for 30 days, it's moved to the Recoverable Items folder in the user's archive mailbox.

PowerShell

```
New-RetentionPolicyTag -Name "Recoverable Items 30 days for mailboxes on hold" -
Type RecoverableItems -AgeLimitForRetention 30 -RetentionAction MoveToArchive
```

Tip

Set the retention period (defined by the *AgeLimitForRetention* parameter) for the Recoverable Items RPT to match the deleted item retention period for the mailboxes that the RPT applies to. This setup gives users the entire deleted item retention period to recover deleted items before they're moved to the archive mailbox. In the previous example, the retention period was set to 30 days based on the assumption that the deleted item retention period for mailboxes is also 30 days. An Exchange Online mailbox is configured to retain deleted items for 14 days, by default. But you can change this setting to a maximum of 30 days. For more information, see **Change the deleted item retention period for a mailbox in Exchange Online**.

Step 2: Create a new Exchange retention policy for mailboxes on hold

Next, create a new retention policy and add retention tags to it, including the Recoverable Items RPT that you created in Step 1. In Step 3, you apply this new policy to mailboxes on hold.

Before you create the new retention policy, determine the additional retention tags that you want to add. For a list of the retention tags that are added to the Default MRM Policy and for information about creating new retention tags, see the following:

- Default Retention Policy in Exchange Online
- Default folders that support Retention Policy Tags
- The "Create a retention tag" section in the Create a Retention Policy article.

You can use the EAC or Exchange Online PowerShell to create a retention policy.

Use the EAC to create a retention policy

Perform the following steps in the EAC to create the retention policy:

1. In the EAC, go to **Compliance management** > **Retention policies**, and then select **Add** +.
2. On **New retention policy**, under **Name**, type a name that describes the purpose of the retention policy; for example, **MRM Policy for Mailboxes on Hold**.
3. Under **Retention tags**, select **Add** +.
4. In the list of retention tags, select the Recoverable Items RPT that you created in Step 1, and then select **Add**.
5. Select additional retention tags to add to the retention policy. For example, you might want to add the same tags that are included in the Default MRM Policy.
6. When you finish adding retention tags, select **OK**.
7. Select **Save** to create the new retention policy. The details pane displays the retention tags linked to the retention policy.

Use Exchange Online PowerShell to create a retention policy

Run the following command to create new retention policy for mailboxes on hold.

PowerShell

```
New-RetentionPolicy <Name of retention policy>  -RetentionPolicyTagLinks <list of retention tags>
```

For example, the following command creates the retention policy and links the retention tags listed in the EAC procedure earlier in this section.

PowerShell

```
New-RetentionPolicy "MRM Policy for Mailboxes on Hold"  -RetentionPolicyTagLinks "Recoverable Items 30 days for mailboxes on hold","1 Month Delete","1 Week Delete","1 Year Delete","5 Year Delete","6 Month Delete","Default 2 year move to archive","Junk Email","Never Delete","Personal 1 year move to archive","Personal 5 year move to archive"
```

Step 3: Apply the new Exchange retention policy to mailboxes on hold

In the last step, apply the new retention policy that you created in Step 2 to mailboxes on hold in your organization. You can use the EAC or Exchange Online PowerShell to apply the retention policy to a single mailbox or to multiple mailboxes.

Use the EAC to apply the new retention policy

Use the following steps in the EAC to apply the new retention policy to one or more mailboxes:

1. Go to **Recipients** > **Mailboxes**.
2. In the list view, select the mailbox you want to apply the retention policy to, then select **Edit**.
3. On the **User Mailbox** page, select **Mailbox features**.
4. Under **Retention policy**, select the retention policy that you created in Step 2, then select **Save**.

You can also use the EAC to apply the retention policy to multiple mailboxes.

1. Go to **Recipients** > **Mailboxes**.
2. In the list view, use the Shift or Ctrl keys to select multiple mailboxes.
3. In the details pane, select **More options**.
4. Under **Retention Policy**, select **Update**.
5. On the **Bulk assign retention policy** page, select the retention policy that you created in Step 2, then select **Save**.

Use Exchange Online PowerShell to apply the new retention policy

You can use Exchange Online PowerShell to apply a new retention policy to a single mailbox. But the real power of PowerShell is that you can use it to quickly identify all the mailboxes in your organization that are on Litigation Hold, and then apply the new retention policy to all mailboxes on hold in a single command. Here are some examples of using Exchange PowerShell to apply a retention policy to one or more mailboxes. All of the examples apply the retention policy that you created in Step 2.

This example applies the new retention policy to Pilar Pinilla's mailbox.

PowerShell

```
Set-Mailbox "Pilar Pinilla" -RetentionPolicy "MRM Policy for Mailboxes on Hold"
```

This example applies the new retention policy to all mailboxes in the organization that are on Litigation Hold.

PowerShell

```
$LitigationHolds = Get-Mailbox -ResultSize unlimited | Where-Object
{$_.LitigationHoldEnabled -eq 'True'}
```

PowerShell

```
$LitigationHolds.DistinguishedName | Set-Mailbox -RetentionPolicy "MRM Policy for Mailboxes on Hold"
```

You can use the **Get-Mailbox** cmdlet to verify that you applied the new retention policy.

Here are some examples to verify that the commands in the previous examples applied the "MRM Policy for Mailboxes on Hold" retention policy to mailboxes on Litigation Hold.

PowerShell

```
Get-Mailbox "Pilar Pinilla" | Select RetentionPolicy
```

PowerShell

```
Get-Mailbox -ResultSize unlimited | Where-Object {$_.LitigationHoldEnabled -eq 'True'} | FT DisplayName,RetentionPolicy -Auto
```

(Optional) Step 4: Run the Managed Folder Assistant to apply the new retention settings

After you apply the new Exchange retention policy to mailboxes on hold, it can take up to seven days in Exchange Online for the Managed Folder Assistant to process these mailboxes by using the settings in the new retention policy. Instead of waiting for the Managed Folder Assistant to run, you can use the **Start-ManagedFolderAssistant** cmdlet to manually trigger the assistant to process the mailboxes that you applied the new retention policy to.

Run the following command to start the Managed Folder Assistant for Pilar Pinilla's mailbox.

PowerShell

```
Start-ManagedFolderAssistant "Pilar Pinilla"
```

Run the following commands to start the Managed Folder Assistant for all mailboxes on hold.

PowerShell

```
$MailboxesOnHold = Get-Mailbox -ResultSize unlimited | Where-Object {($_.InPlaceHolds -ne $null) -or ($_.LitigationHoldEnabled -eq "True")}
```

PowerShell

```
$MailboxesOnHold.DistinguishedName | Start-ManagedFolderAssistant
```

Additional considerations for archive mailboxes and retention policies

User communication considerations

- When you enable a user's archive mailbox, consider telling the user that other items in their mailbox (not just items in the Recoverable Items folder) might move to the archive mailbox. This behavior occurs because the Default MRM Policy that's assigned to Exchange Online mailboxes contains a retention tag (named Default 2 years move to archive) that moves items to the archive mailbox two years after the date the item is delivered to the mailbox or created by the user. For more information, see Default Retention Policy in Exchange Online.
- When you enable a user's archive mailbox, consider telling the user that they can recover deleted items in the Recoverable Items folder in their archive mailbox. They can do this in Outlook by selecting the **Deleted Items** folder in the archive mailbox, then selecting **Recover Deleted Items from Server** on the **Home** tab. For more information about recovering deleted items, see Recover deleted items in Outlook for Windows.

Preserve Bcc and expanded distribution group recipients for eDiscovery

By creating litigation holds, eDiscovery holds, and retention policies in Microsoft Purview, you can preserve mailbox content to meet regulatory compliance and eDiscovery requirements. All messages include information about recipients directly addressed in the To and Cc fields by default. But your organization might require the ability to search for and reproduce details about all recipients of a message. This requirement includes:

- **Recipients addressed using the Bcc field of a message:** Bcc recipients are stored in the message in the sender's mailbox, but not included in headers of the message delivered to recipients.
- **Expanded distribution group recipients:** Recipients who receive the message because they're members of a distribution group to which the message was addressed, either in the To, Cc, or Bcc fields.

Exchange Online and Exchange Server 2013 (Cumulative Update 7 and later versions) retain information about Bcc and expanded distribution group recipients. You can search for this information by using an eDiscovery tool in the Microsoft Purview portal.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

How Bcc recipients and expanded distribution group recipients are preserved

> **Important**
>
> Only the sender's mailbox's Sent Items contains distribution group expansion.

Information about Bcc recipients is stored with the message in the sender's mailbox. This information is indexed and available to eDiscovery searches and holds.

Information about expanded distribution group recipients is stored with the message after you place a mailbox on Litigation Hold. In Microsoft 365, this information is also stored when a Microsoft Purview retention policy is applied to a mailbox. Distribution group membership is determined at the time the message is sent. The expanded recipients list stored with the message isn't impacted by changes to membership of the group after the message is sent.

Expand table

Information about...	Is stored in...	Is stored by default?	Is accessible to...
To: and Cc: recipients	Message properties in the sender and recipients' mailboxes.	Yes	Sender, recipients, and compliance officers
Bcc: recipients	Message property in the sender's mailbox.	Yes	Sender and compliance officers
Expanded distribution group recipients	Message properties in the sender's mailbox.	No. Expanded distribution group recipient information is stored after a mailbox is placed on Litigation Hold or assigned to a Microsoft Purview retention policy.	Sender and Compliance officers

Searching for messages with expanded distribution group recipients

When you search for messages sent to a recipient, eDiscovery search results now include messages sent to a distribution group that the recipient is a member of, but only in the sender mailbox and if the sender is on hold.

> **Important**
>
> Distribution group expansion details are only available in the sender's mailbox under Sent Items. If you search the recipient's mailbox, messages sent to distribution groups don't show the expanded list of group members.

Scenario: John is a member of the US-Sales distribution group. This table shows eDiscovery search results when Bob sends a message to John directly or indirectly via a distribution group.

Expand table

When you search Bob's mailbox for messages sent...	And the message is sent with...	Results include message?
To: John	John on To:	Yes
To: John	US-Sales on To:	Yes
To: US-Sales	US-Sales on To:	Yes
Cc: John	John on Cc:	Yes
Cc: John	US-Sales on Cc:	Yes
Cc: US-Sales	US-Sales on Cc:	Yes

Expand table

When you search John's mailbox for message...	And the message is sent with...	Results include message?
To/Cc	US-Sales on To/Cc:	No. Only sender mailbox can be searched.

Searching for messages with Bcc

Scenario: Bob sends an email to John (To/Cc) and Jack (Bcc directly, or indirectly via a distribution group). The following tables show the eDiscovery search results.

> **Important**
>
> Distribution group expansion detail is only available if the sender is on hold.

Expand table

When you search Bob's mailbox...	For messages sent...	Results include message?	Notes
Bob's mailbox	To:/Cc: John	Yes	Shows an indication that Jack was Bcc'ed.
Bob's mailbox	Bcc: Jack	Yes	Shows an indication that Jack was Bcc'ed.
Bob's mailbox	Bcc: Jack (via distribution	Yes	List of members of the Bcc'ed distribution group, expanded when the message was sent, is

When you search Bob's mailbox...	For messages sent...	Results include message?	Notes
	group)		visible in eDiscovery search preview, export, and logs.

Expand table

When you search John's mailbox...	For messages sent...	Results include message?	Notes
John's mailbox	To:/Cc: John	Yes	No indication of Bcc recipients.
John's mailbox	Bcc: Jack (directly or via distribution group)	No	Bcc: information isn't stored in the message delivered to recipients. You must search the **sender's mailbox**.

Expand table

When you search Jack's mailbox...	For messages sent...	Results include message?	Notes
Jack's mailbox	To:/Cc: John (directly or via distribution group)	Yes	To:/Cc: information is included in message delivered to all recipients.
Jack's mailbox	Bcc: Jack (directly or via distribution group)	No	Bcc: information isn't stored in the message delivered to recipients. You must search the **sender's mailbox.**

Frequently asked questions

When and where is Bcc recipient information stored?

By default, the original message in the sender's mailbox stores Bcc recipient information. If the Bcc recipient is a distribution group, the system expands distribution group membership only if the sender's mailbox is on hold or assigned to a Microsoft 365 retention policy.

When and where is the list of expanded distribution group recipients stored?

The system expands group membership when the sender sends the message. The original message in the sender's mailbox stores the list of expanded distribution group members. The sender's mailbox must be on Litigation Hold or assigned to a Microsoft 365 retention policy.

Can the To/Cc recipients see which recipients were Bcc'ed?

No. This information isn't included in message headers, and isn't visible to To/Cc recipients. The sender can see the Bcc field stored in the original message stored in their mailbox. Compliance officers can see this information when searching the sender's mailbox.

How can I ensure that expanded distribution group recipients are always preserved?

To ensure that expanded distribution group members are always preserved with a message, Place all mailboxes on hold or create an organization-wide Microsoft 365 retention policy.

Which types of groups are supported?

Distribution groups, mail-enabled security groups, and dynamic distribution groups are supported.

Is there a limit on the number of distribution group recipients that are expanded and stored in the message?

The system preserves up to 10,000 members of a distribution group.

Are nested distribution groups supported?

Yes, the system expands 25 levels of nested distribution groups.

Where is the Bcc and expanded distribution group recipient information visible?

Compliance officers can see Bcc and expanded distribution group recipient information when performing an eDiscovery search. Bcc and expanded distribution group recipients are included in search results copied to a Discovery mailbox or exported to a PST file and in the eDiscovery log included in search results. Bcc recipient information is also available in search preview.

What happens if a member of a distribution group is hidden from the organization's global address list (GAL)?

There's no impact. If recipients are hidden from the GAL, they're still included in the list of recipients for the expanded distribution group.

Process reports in eDiscovery

Every process in Microsoft Purview eDiscovery generates a downloadable process report that contains detailed information about what happened during the process. This article provides scenario-based guidance for interpreting report data in depth. Use it to understand unexpected item counts, identify location errors, see how settings affected results, and know what to look for in reports when investigating specific outcomes.

For more information about the structure and contents of each report, see Use process reports in eDiscovery.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Best practices for using process reports

- **Download reports for every process**: Even when a process completes successfully, download the report package to keep a record of what was collected, from where, and with what settings. This information is valuable for transparency and audit purposes.
- **Check the Summary.csv first**: Start with the Summary CSV to get an overview of the process outcome, including item counts, errors, and the factors that affected the count.
- **Use the Items.csv for item-level investigation**: When you need to understand why a specific item was or wasn't included, look at the Items.csv for detailed per-item status and error information.
- **Use the Locations.csv for scope validation**: Verify that all intended locations were included and successfully processed. Identify any locations with errors that need attention.
- **Compare Settings.csv across processes**: When comparing the results of two processes, compare their Settings CSV reports to confirm the same configuration was used.
- **Use the Statistics.csv for search analysis**: After a *Generate statistics* process, use this report to understand the distribution of search hits across keywords, data types, sensitive information types, and communication participants.

Understanding search result counts

Search result counts can vary between runs and differ from export or collection counts. For a detailed explanation of the behavioral reasons behind these differences, see Understanding statistics and search results and Differences between statistics and export results. The sections below explain how to use the process reports to investigate these differences.

Investigating missing items in search results

If expected content doesn't appear in search results, use the process reports from your *Generate statistics* or *Generate sample* process to identify the cause.

What to look at in the process report:

- **Settings.csv — Partially indexed items setting**: Check whether the process was configured to include partially indexed items. By default, search results exclude content that isn't fully indexed, such as image-only files, unsupported file types, or items with processing errors. If the setting shows that the process didn't include partially indexed items, rerun the search with this option enabled to determine if the missing items are unindexed.
- **Settings.csv — Security filter applied**: If this value is *Yes*, a compliance boundary (search permissions filter) limits which locations the search can access. The search silently excludes items in locations outside the filter scope. The **Location restriction** field shows the filter criteria. If you suspect the filter is excluding expected content, ask an eDiscovery administrator or another user without search permission filter applied to run the same search for comparison.
- **Locations.csv — Status column**: Check for locations with errors. If a location shows a failure status, the **ErrorWarning** field explains why. For more information about common reasons that can affect location access, see Export considerations.
- **Locations.csv — Count column**: If a location you expected to have results shows a count of zero, the search query didn't match any content in that location. Verify the query is correct and that the content exists at the source. Items you recently added to a mailbox or site might not yet be indexed. Rerun the search after a short wait to resolve this condition.
- **Locations.csv — Missing locations**: If an expected location doesn't appear in the report at all, it wasn't included in the search scope. Verify the data sources configured for the search and add any missing mailboxes or sites.

> **Tip**
>
> When investigating missing items, start with the **Locations.csv** to confirm all expected locations were searched successfully, then check the **Settings.csv** to verify the right options were enabled. If both look correct and items are still missing, the content might be deleted or not yet indexed at the time of the search.

Search result differences with tenant-wide searches

When you use a tenant-wide search scope such as **All people and groups**, the results can vary depending on additional source configuration settings that control which user and content types are included. These settings expand or narrow the scope of the search and directly affect item counts.

What to look at in the process report:

- **Settings.csv — Tenant-wide process settings**: When a search uses **All people and groups**, the Settings CSV captures which additional source types were enabled at the time of the search export or **Add to Review** set. Check these settings to understand why certain content was included or excluded:
  - **Include departed users**: When enabled, the search includes mailboxes and OneDrive sites of users who left the organization (soft-deleted or inactive accounts). If this setting wasn't enabled and you expected to find content from former users, it explains why those items are missing from results.
  - **Include shared Teams channels**: When enabled, the search includes content from shared Teams channels. Shared channel data is stored in separate SharePoint sites, so it's only included when this setting is active. If you're missing shared channel content, verify this setting was enabled.
  - **Include unlicensed and on-premises users**: When enabled, the search includes mailboxes for users who don't have a license or are synced from on-premises environments.
  - **Include guest users**: When enabled, the search includes content associated with guest user accounts in your tenant.

> **Note**

You configure tenant-wide source settings at the process level. Including these settings increases the scope of the process and can affect performance.

Interpreting count differences between search and export

When you export search results or add them to a review set, the final item count often differs from the original search estimate. For the full list of reasons, see Differences between statistics and export results. The Summary CSV report shows the specific factors that affected the count for your process.

What to look at in the process report:

- **Information section of Summary.csv**: This section lists every factor that increased or decreased the item count compared to the original estimate, such as cloud attachments, contextual conversations, consolidated transcripts, SharePoint file versions, and duplicates skipped in a review set. For a complete list of these factors and what each one means, see Information section.
- **Search results section of Summary.csv**: Shows the breakdown of indexed items, partially indexed items, and advanced indexed items. If the count is lower than expected, check whether you included partially indexed items in the process settings. For more information, see Assess partially indexed items in your organization.
- **Error section of Summary.csv**: Shows retrieval exceptions — items that couldn't be exported or added to the review set. For the specific exception types tracked in this section, see Error.
- **Sampling configured**: If you configured sampling (confidence-based or percentage-based) when adding search results to a review set, the item count in the review set is intentionally lower than the total search estimate. This reduction reflects the configured sample size, not a processing discrepancy. Check the Settings CSV report to confirm the sampling mode and parameters used.

Understanding the impact of search settings on results

The Settings CSV report captures the exact configuration used when you submitted a process. Compare this report against your intended configuration to identify discrepancies.

Key settings that affect result scope include:

- **Include document versions**: Determines how many versions of each document are collected. Selecting *All versions* can significantly increase the item count and data volume.

- **Organize conversations into HTML transcripts**: When enabled, individual Teams chat messages consolidate into transcript files, which changes the item count.
- **Include contextual Teams and Viva Engage conversations**: When enabled, the search includes messages outside your search date range to provide conversation context. For 1:1 and group chats, this setting adds messages 12 hours before and after each responsive item. For Teams channel posts and Viva Engage posts, the search includes entire conversation threads regardless of date range. If you see items outside your expected date range, check whether this setting is enabled.
- **Access links in messages**: Controls whether the search retrieves cloud attachments from links in emails and Teams conversations.

Understanding export reports

Why certain items weren't exported

When an export finishes, the Items CSV report and the **Error** section of the Summary CSV report explain what happened to each item.

What to look at in the export report:

- **Items.csv — Status column**: Each row represents an item. Items with a status other than success include an **ErrorWarning** field with the failure reason. Common reasons include:
  - **Item deleted or moved**: The search found the item, but someone removed or relocated it at the source between the time of the search and the export. These items count in the search estimate but can't be retrieved at export time.
  - **Access timeout**: The system couldn't retrieve the item within the allowed time, often due to a large file size or transient service issue.
  - **Permission or access issue**: The export process couldn't access the item, possibly because the source location is locked or the user account lacks access.

- **Items.csv — AddedBy column**: Shows how each item was included in the results. For definitions of each value, see Items CSV report.

- **Summary.csv — Retrieval exceptions**: Shows the total count of items that couldn't be exported. This count matches the number of error entries in the Items.csv file.

Understanding file timestamps in exports

When you extract files from an export package, file timestamps might show the current date instead of the original modified date. This behavior occurs because the Windows built-in ZIP

extractor resets file dates during extraction. The original timestamps are preserved in the **Items.csv** report and inside the file formats themselves.

To preserve timestamps during extraction, use a tool like 7-Zip, WinZip, or WinRAR. For emails in PST format, opening the PST in Outlook shows the original sent and received dates.

Understanding export settings and traceability

The Settings CSV report serves as the authoritative record of the configuration used for an export. This report is essential for traceability and transparency, especially when responding to compliance inquiries.

Use this report to:

- Confirm which items were included (indexed, partially indexed, or both).
- Verify the export format (PST or .msg) and package size settings.
- Check whether decryption was enabled for Exchange or SharePoint content.
- Validate that the correct document version settings were applied.

Understanding location reports

Identifying which locations have results

The Locations CSV report provides a breakdown of every content location targeted during a search, export, or add to review set process. Each row represents a location and includes the item count and size.

What to look at in the location report:

- **Count column**: Shows the number of responsive items found in each location. Locations with a count of zero have no search hits for the query used.
- **Size column**: Shows the total size of responsive items from the location, in bytes.
- **Location Subtype column**: Distinguishes between different mailbox and site subtypes. A single user's SMTP address might appear in multiple rows if they have different mailbox subtypes. For the full list of subtype values, see Locations CSV report.
- **Status column**: Shows whether the location was successfully processed. If a location failed, the **ErrorWarning** field includes the reason.

Understanding location-level errors

Location-level errors in the Locations CSV report indicate that the process couldn't access a specific mailbox or site. Common errors include:

Expand table

Error	What it means	What to do
Permission or access issue	The process can't access the mailbox or site. The user might be unlicensed, the site might be locked, or the searching account lacks permissions.	Verify the user's license status and that the site isn't locked. Confirm that the eDiscovery admin or manager role has the required permissions, and then rerun the process.
Timeout	The location took too long to process. This error can happen with very large mailboxes or sites.	Rerun the process. If the timeout persists, narrow the search query or split the search to target fewer locations per run.
Location not found	The mailbox or site doesn't exist. The user might be deleted or the site URL might be incorrect.	Verify the user account or site URL in the Microsoft 365 admin center. If the user was deleted, use an inactive mailbox or add the OneDrive URL directly as a SharePoint location.

If a location has errors, it doesn't mean the entire process failed. Other locations might be processed successfully. Review the Locations CSV to identify which specific locations need attention.

Understanding hold reports

Interpreting hold distribution status

When you create or update a hold, the process report for the *Applying or updating hold* process includes a Locations CSV report that shows the status of each location in the hold.

What to look at in the hold report:

- **Status column**: Shows whether the hold was successfully applied to each location.
- **ErrorWarning column**: If a location failed, this field contains the specific error. Common hold distribution errors include:

Expand table

Error	What it means	What to do
PolicySyncTimeout / PolicyNotifyError	Transient errors. The hold took too long to apply.	Rerun the hold distribution. These errors usually resolve on retry.
FailedToOpenContainer	The mailbox or site can't be accessed. The user might not have a mailbox, or the site doesn't exist.	Verify the user account status in the Microsoft 365 admin center and confirm the mailbox or site is active.
SiteInReadonlyOrNotAccessible / SiteOutOfQuota	The SharePoint site or OneDrive is in a read-only state or has no storage quota left.	Contact your SharePoint admin to unlock the site or increase the storage quota, then rerun the hold.
RecipientTypeNotAllowed	The hold was attempted on an ineligible object, such as a distribution group. Only user mailboxes, group mailboxes, and SharePoint or OneDrive sites can be held.	Remove the ineligible object and add the individual user mailboxes or sites instead.

Understanding the consumption summary

The **Consumption summary** section of the Summary CSV report breaks down the data volume by content type. This information helps you understand storage and billing implications for processes that add data to a review set or export data.

> **Note**
>
> If you don't have an active pay-as-you-go subscription, data isn't exported or added to a review set. For more information, see Enable Microsoft Purview pay-as-you-go features.

Last updated on 04/01/2026

Use Process reports in eDiscovery

Process report for the organization

eDiscovery includes Process reports that list all processes in your organization that count towards case process concurrency and daily limits in eDiscovery. *eDiscovery administrators* and *eDiscovery Managers* can access this report on the **Dashboards** > **Process report**. Use this report to see the process activities across all activities and eDiscovery components. *eDiscovery Managers* can only view processes for the cases to which they're assigned.

> **Important**
>
> You can't delete or remove processes listed on the **Process manager** page. Long-running processes automatically time out after seven days.

Process report for items

eDiscovery also includes a **Process manager** that lists all processes scoped to the current eDiscovery item and page. For example, if you're on the **Search** page, selecting **Process manager** lists all processes relevant to the current search. If you're in a case, selecting **Process manager** lists all processes relevant to the current case. Each process in the Process manager list contains a detailed report .zip file that contains detailed information about the process once the process completes. You can download the process report .zip file for more information about when the process ran, the applied settings, the query used, and if the process had any item-level or location-level errors.

> **Important**
>
> You can't delete or remove processes listed on the **Process manager** page. Long-running processes automatically time out after seven days.

To learn more about Process reports in eDiscovery, watch the following video:

https://learn-video.azurefd.net/vod/player?id=72ab2c79-cbf6-44fe-b365-8a41cda94216&locale=en-us&embedUrl=%2Fpurview%2Fediscprocess-report-use

Process types and descriptions

User actions trigger these processes when managing searches, review sets, and holds.

Expand table

Process type	Area	Description
Add items to another review set	Review set	A user adds documents from one review set to a different review set in the same case. For more information, see Add data to a review set from another review set.
Add to review	Review set	A user adds search results to a review set or adds items into the review set from another review set. The process copies the items to an Azure Storage location and then reindexes those items in the Azure Storage location. This new index is used when querying and analyzing items in the data set.
Applying or updating hold	Hold	A user places data sources on hold or updates a hold.
Export	Search Review set	A user exports documents from a search or a review set. When the export process completes, they can download the exported data to a local computer.
Generate sample	Search	After a user creates and runs a new search estimate (or reruns an existing search estimate), the search tool prepares a sample subset of items (that match the search query) that you can preview. Previewing search results helps you determine the effectiveness of the search.
Generate statistics	Search	After a user creates and runs or reruns a search estimate, the search tool searches the index for items that match the search query and prepares an estimate that includes the number and total size of all items by the search, the number of data sources searched, and other relevant pattern to the search hits like keywords, sensitive information types, and more.
Import external data	Review set	A user uploads external data to a review set. The data is also indexed during this process. For more information, see Import external data into a review set.
Redact	Review set	After a user annotates a document in a review set and redacts a portion of it, they can choose to convert the redacted document to a PDF file. This ensures that the redacted portion won't be visible if the document is exported for presentation. For more information, see View documents in a review set.
Run analytics	Search	A user analyzes data in a review set by running eDiscovery analytics tools such as near duplicate detection, email threading analysis, and themes analysis.
Tag	Review set	This process triggers when a user selects **Start tagging process** in the **Tagging panel** when reviewing documents in a review set. A user can start this process

Process type	Area	Description
		after tagging documents in a review set and then bulk-selecting them in the view document panel.

Process status

The following table describes the different status states for processes:

> **Note**
>
> You can cancel only **Generate statistics** and **generate sample** processes.

Expand table

Status	Description
Abandoned	The process was automatically stopped. This stoppage might be due to excessive processing time or other reasons.
Canceled	The user canceled the process.
Complete	The process completed successfully.
Failed	The process encountered an error and didn't complete. This error might be caused by a wrongly formatted query.
In progress	The process is in progress. You can monitor the progress of the process in the **Process manager** for the area.

Download report

All processes support the ability to download a packaged report. The packaged report name is `Reports-*caseName-EntityName-ProcessName-timestamp*.zip`, with `EntityName` being the user-given name to the search or hold. Depending on the process, the report contains different `.csv` files.

- **Summary**: Tracks the time the process started, when it ended, the number of total items or locations, and the user who submitted the process request. It also contains the search query used and if a compliance boundary is applied. For *Add to review set* and *Export* from search processes, the summary report contains the summary of factors affecting the total item count added to review set or exported. The report name is `Summary_*the date/time of the report*.csv`.

- **Settings**: Contains the enumerated settings parameter for the process and values. The report name is `Settings_*the date/time of the report*`.
- **Statistics**: Contains all statistics details for the process, including all categories (if the setting was selected during process submission) such as sensitive information types, data type, and communication participants. The report name is `Statistics_*the date/time of the report*`.
- **Locations**: Tracks all data sources and associated locations scoped for the process. Includes the user/group entity name, location (mailbox/site URL), and count returned for that location. Also includes the status of the location (success/error and error detail). The report name is `Locations_*the date/time of the report*`.
- **Items**: Track all items processed, including information such as item ID, location of the item, subject/title of the item, item class/type, and success/error status. The report name is `Items_*the date/time of the report*`.

The following table shows the process types and available reports:

Expand table

Process type	Summary	Settings	Statistics	Location	Items
Add to review	✔	✔		✔	✔
Apply hold/rerun policy	✔			✔	
Export (review set)	✔	✔		✔	✔
Export (search)	✔	✔		✔	✔
Generate sample	✔	✔		✔	✔
Generate statistics	✔	✔	✔	✔	
Redact	✔	✔			✔
Tag	✔	✔			

> **Note**
>
> When running an export process using the *report only* option, all string fields in the report are limited to the first 255 characters. This means some items with long compound path

may be truncated. If full details are needed, use the *Export items with items report* option.

Summary CSV report

All reporting packages contain a `Summary-*the date/time of the report*.csv` file. This file contains the following information:

Overview

This section of the report includes the following details:

- **Job ID**: A unique identifier assigned to each eDiscovery process for support reference purposes.
- **Case name**: The name assigned to the eDiscovery case.
- **Search name**: The name given to a specific search within an eDiscovery case when the process runs. This detail only applies to processes like *Generate statistics*, *Generated sample*, *Add to review set*, and *Export* from a search.
- **Review set name**: The name of the review set where search results are added when the process runs. This detail only applies to the *Add to review set* and *Export from a review set* processes.
- **Export name**: The name given to the export. This detail only applies to the *Add to review set* and *Export from a review set* processes.
- **IsRetry**: Indicates if the current process is triggered by the *Retry failed locations* operation. If the value is *Yes*, it contains the aggregated hit count and the location reports detail the failed locations. This detail only applies to the *Generate statistics* process.
- **Query**: The query conditions for the applicable process types.
- **StartTime**: The date and time when the report generation started.
- **EndTime**: The date and time when the report generation completed.
- **SubmittedBySmtp**: The SMTP address for the user creating the report.
- **Security filter applied**: Indicates if security filters were applied during the process run. *Yes* indicates that filters were used to limit results based on specified criteria set by an admin in PowerShell.
- **Location restriction**: The filters applied to limit the search to specific locations. To review which mailboxes are filtered, use the provided query with the Get-Mailbox or Get-Recipient cmdlets and the *-Filter* attribute. For example, if the filter attribute is *Department -eq 'marketing'*, retrieve the relevant mailboxes with *Get-Recipient -Filter "Department -eq 'marketing'*. The output lists all mailboxes allowed to be searched.

- **Content restriction**: The query used to filter content during the search. Content matching this query is included in the search results. The provided query is available to perform KeyQL searches.

Search results

Summary of number of items that matched your search query, including partially indexed items or items where advanced indexing was performed (depending on what setting you selected). This section of the report includes the following details:

- **Indexed items**: Number of items matching the query that were natively indexed by Exchange and SharePoint.
- **Partially indexed items**: Number of partially indexed items that might not match the query. Included if you chose to include partially indexed items.
- **Advanced Indexed Items**: Number of items matching the query if you chose to perform advanced indexing on partially indexed items.

Consumption summary

This section of the report includes the following details:

- **Microsoft 365 content data**: Total size of data for all Microsoft 365 data.
- **Microsoft 365 metadata**: Total size of metadata for all Microsoft 365 data and Microsoft 365 Copilot data.
- **Non-Microsoft 365 AI content data**: Total size of data for all non-Microsoft 365 AI data. Includes data from Microsoft Fabric Copilot, Microsoft Security Copilot, and other AI data from enterprise and cloud applications.
- **Non-Microsoft 365 AI metadata**: Total size of metadata for all non-Microsoft 365 AI data.

> ⓘ **Note**
>
> For more information about the consumption summary and billing implications, see Understanding the consumption summary.

Error

This section of the report includes the following details:

- **Retrieval exceptions**: Number of items that weren't exported or added to review set due to exceptions such as empty files, access time-outs, and similar issues.

Warning

- **Items with processing errors**: Number of items that experienced processing errors but were still exported or added to the review set. These errors might be caused by unsupported file types, decryption problems, and similar issues.

Totals

This section of the report includes the following details:

- **Total items collected**: Total number of items exported or added to the review set. This number factors in items from estimated results, the settings that might increase or decrease the number of items retrieved, and items that weren't collected due to errors.

Information

> **Note**
>
> The **Information** section of this report shows how the item count can increase or decrease based on the settings you choose. The calculation process uses these settings and updates the search estimate count, so the counts don't add up exactly in most cases. This information gives you a sense of the changes and the reasons behind them.

This section of the report includes the following details:

- **Duplicates in review set (skipped)**: Items that are skipped because they already exist in the review set.
- **Cloud attachments**: Number of cloud attachments in email messages and Teams conversations that come from links shared through SharePoint or OneDrive. Maps to the setting *Access links(cloud attachments) in messages*.
- **Cloud attachments versions**: Number of cloud attachment versions that are collected depending on whether you choose to include more than just the latest version in your query.
- **Cloud attachments at time of sharing**: Number of cloud attachment versions that represent the original version shared from SharePoint or OneDrive. This count applies only to cloud attachments that have a retention label applied, which retains a copy of the file at the time of sharing.
- **Contextual conversation**: Number of contextual chat messages that are collected along with the message that matches your query. This count shows the number of additional

messages collected before and after the message with hit. This count corresponds to the setting "Include Teams and Viva Engage conversations".

- **Teams conversations consolidated into transcripts**: Teams chat conversations that are converted to HTML transcript files. This conversion results in many Teams chat messages being consolidated into a single HTML transcript. This count corresponds to the setting "Organize conversations into HTML transcripts".
- **SharePoint file versions**: Number of SharePoint file versions that are collected depending on whether you choose to include more than just the latest version.
- **SharePoint list items collected as .csv files**: Matches from the same SharePoint list are exported or added to review set as a single SharePoint list csv item. This count corresponds to the setting "Collect files attached to SharePoint lists and their child items."
- **List attachments**: Number of list attachments collected. This count corresponds to the setting *Include list attachments* when collecting files attached to SharePoint lists.
- **Items in SharePoint folders**: Number of items expanded from SharePoint folders that match your query. This count corresponds to the setting *Collect all items (even if they don't match search query)*.
- **Items extracted from parent items**: Number of embedded or attached items that the process extracts from parent items. For example, this count might include attachments or embedded images from an email that matches your query.

Settings CSV report

The settings report helps you validate and interpret the configuration of your submitted processes. The downloadable report package includes this report. It captures the specific options you select during the submission of a process, such as **Generate statistics**, **Add to review set**, and **Export**.

These settings directly influence the scope and format of the results. Some examples of these settings include:

- **Include document versions**: Determines the number of versions of a document to include.
- **Organize conversations into HTML transcripts**: Affects how Teams conversations are threaded and presented.
- **Access links in message**: Controls whether cloud attachments from message links are included.
- **Various export formats and options**: Influences how exported content is organized and packaged.

- **Decryption settings**: Indicates whether the specific process has associated Exchange or SharePoint decryption capability enabled.
- **Location optimization**: Indicates if location optimization is applied for the search *Export* or *Add to review set* process. If optimization is applied, the relevant *Generate statistics* process ID used.
- **Sampling mode**: Indicates the sampling method used for the *Add to review set* process. Values include *All items*, *Percentage*, or *Confidence*.
- **Sample percentage**: The percentage value configured when using percentage-based sampling. Present only for the *Percentage* sampling mode.
- **Confidence level**: The confidence level configured when using confidence-based sampling. Present only for the *Confidence* sampling mode.
- **Confidence interval**: The confidence interval configured when using confidence-based sampling. Present only for the *Confidence* sampling mode.

For more information about how these settings affect search result counts, see Understanding the impact of search settings on results. For guidance on using the Settings CSV for traceability and compliance, see Understanding export settings and traceability.

Statistics CSV report

This report provides detailed information for all the patterns derived from search hits when you complete the *Generate statistics* process. The report contains information on the top communication participants, the top item type, the top sensitive information type, and more.

The report includes the following details:

- **DataSourceName**: A list of data source names associated with the process. This information indicates the name of the people or groups.
- **DateSourceType:** Type of data source. For example, *Group* or *TeamsGroup*.
- **Location**: The location information. For example, the URL of the site or SMTP address of the mailbox.
- **LocationType**: Type of location. For example, a mailbox or site.
- **LocationSubType**: The subtype of the location type. If the location type is *Mailbox*, the subtype might have *PrimaryMailbox*, *SystemMailbox*, and other subtypes. If the location type is *Site*, it might have *OneDriveSite* and other subtypes.
- **OriginalStateName**: Native version of StatName.
- **StatName**: Name of the StatType. For example, for StatType *Keywords*, possible values are the keywords you entered in your query.

- **StatType:** The type of statistics information. For example, *Keywords*, *Communication participants*, and more.
- **Value**: The value or count associated with the statistics in the current data source.

Items CSV report

This report provides a detailed inventory of all items processed during an eDiscovery process, such as using the **Add to review set** or **Export** actions. The system automatically generates this report and includes it with the output to support auditing, traceability, and downstream analysis. This report is useful for users who need to validate the scope and accuracy of collected or exported content.

Each row in the file corresponds to a single item and includes the following metadata and more:

- **Date source**: Identifies the originating location of the item (mailbox, SharePoint site, Teams chat).
- **Compound path**: The full path to the item in its source container.
- **Subject/Title**: The subject line (for emails) or title (for documents) of the item.
- **Date**: The timestamp associated with the item, such as sent or last modified date.
- **Added by**: Shows how the item was included in the job:
  - *IndexedQuery*: The item is indexed and matches the search query.
  - *UnindexedQuery*: The item is included based on its partially indexed content and user specified setting.
- **Status**: Shows whether the item was successfully retrieved and processed. If the item failed, the **ErrorWarning** field includes the failure reason. For common item-level errors, see Why certain items weren't exported.
- **Other metadata**: Might include the file extension, content type, workload, and other relevant attributes depending on the source and process type.

Locations CSV report

This report provides an overview of the locations targeted during an eDiscovery process, such as **Search**, **Add to review set**, or **Export**. This report helps you understand the scope of the process and assess the distribution and relevance of search results across different locations.

This report can help with:

- **Heat mapping**: Identifying which locations yielded the most relevant content and which yielded none, helping you visualize the "hot spots" of data relevance.
- **Query refinement**: Understanding which sources you might need to exclude or more precisely target.
- **Audit and validation**: Verifying that the intended locations were included and assessing the effectiveness of the search scope.

By analyzing the `location.csv` report, you can make informed decisions about refining your search strategy and optimizing the scope of future eDiscovery workflows.

> ⓘ **Note**
>
> If multiple mailboxes share the same SMTP address, the location report might show several rows. This situation occurs because a single SMTP address might include different mailbox subtypes, such as primary, system, or archive. The row count in the CSV report might exceed the count shown on the location card in the **Statistics** view. The **Statistics** view aggregates all mailboxes under the same SMTP address without distinguishing subtypes. For a more detailed breakdown of hits by sublocation, use the CSV report instead of the **Statistics** view. SharePoint and OneDrive locations can also have archive sites and are counted as separate locations in the report.

Each row in the report represents a unique content location and includes the following key details:

- **Count**: The number of items in the location that matched the search criteria. This doesn't apply to the *Applying or updating hold* process.
- **Location ID**: Site ID for SharePoint or mailbox ID for mailboxes.
- **Location Subtype**: Specifies the type of location, such as *PrimaryMailbox*, *SystemMailbox*, *ArchiveMailbox*, or *OneDriveSite*.
- **Location**: The full URL or SMTP address of the location. For organization-wide searches, locations are empty for sites without hits. If needed, use the *LocationID* to identify the site URL.
- **Size**: The total size of responsive items from the location in bytes. This doesn't apply to *Applying or updating hold* process.
- **Status**: Indicates whether the location was successfully processed. If a location failed to be searched or exported, the **ErrorWarning** field includes the failure reason. For common

location errors and remediation steps, see Understanding location-level errors.

Last updated on 04/01/2026

Use Process managers in eDiscovery

Each primary area in eDiscovery includes a process manager. These managers let you view processes and related information for a specific area. You can access process managers by selecting **Process manager** in each of the following areas:

- Cases
- Searches
- Review sets
- Holds

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Process manager information

Each area's process manager shows information about processes performed in that area. For example, if you export data from the review set, an *Export* process item appears in the process manager list for the review set, but not in the process manager lists for searches and holds. Each process manager contains the following information for its area:

- **Process type**: The type of process.
- **Status**: The status of the process.
- **Export name**: The name of the export. For nonexport process types, this value is blank.
- **Created**: The date and time the process was created.
- **Completed**: The date and time the process was completed.
- **Duration**: The duration of the process.
- **Created by**: The user that created the process.

To customize the columns display for the process manager, select **Customize columns** to choose the columns to display or drag and drop the columns in the list to reorder. To download the list of processes and the column information, select **Download list** to create a .csv file containing this information.

Grouping processes

When you view a large list of processes for an area, it's often helpful to group processes. Select **Group** to group review sets by the following parameters:

- **None**: Processes are ungrouped in the Process manager.
- **Process type**: Processes grouped by the *Process type* values.
- **Created by**: Processes grouped by the *Created by* values.

Process details

Select a process listed in the process manager for more information in the following areas:

- **Overview** tab: Lists a summary of information for the process. Includes a calculation for the time remaining to completion for in-progress processes. Select **Download report** to combine all **Overview** information into a single .zip file. This file contains the files included in the Download report guidance.
- **Settings** tab: Summarizes the **Search & analytics** setting options selected for the case.

Progress bar

When you select a process in the Process manager, a progress bar appears that shows details about the current state of the process. For long-running processes, there are three phases:

- **Assessment phase**: In this phase, the progress is submitted and backend services assess the scope of the process. This assessment includes examining the input conditions based on data sources, query, and relevant process settings. The service analyzes the scope of the work and identifies the number of locations and number of items for processing. During this phase, a completion estimate isn't available and a flashing progress bar is displayed. The progress bar displays the status of the assessment while the scope is calculated. When all locations and items are identified, the process transitions to the next phase.
- **In progress phase**: In this phase, the progress bar displays the current status, number of locations, and number of items for the process. An estimated completion and current elapsed time are displayed in hours, minutes, and seconds.
- **Catch-up phase (optional)**: If there are locations or items with errors, processing is retried. The progress of the retries is displayed.

Limits in eDiscovery

This article describes the limits in Microsoft Purview eDiscovery.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Case limits

The following table lists the limits for cases in eDiscovery.

Expand table

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Maximum number of cases for an organization.	10,000	50,000

Case and review set limits

The following table lists the limits for cases and review sets in eDiscovery with premium feature support.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

Expand table

Description of limit	Premium eDiscovery feature support
Total number of documents that you can add to a case (for all review sets in a case).	40 million

Description of limit	Premium eDiscovery feature support
Total file size per load set. This limit includes loading non-Office 365 content into a review set.	1 TB
Maximum size per review set.	1 TB
Maximum number of load sets per case.	200
Maximum number of review sets per case.	100
Maximum number of tag groups per case.	1,000
Maximum number of unique tags per case.	1,000
Maximum number of tagged documents per case.	Unlimited

Export limits

> **Note**
>
> When exporting large individual items (5 GB or greater), configure the export job to include only one large item per export. This configuration reduces the likelihood of performance-related issues during the export.

The following table lists the limits when exporting the results of a search.

Expand table

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Export report total items for one report	1 million	1 million
Export report total locations for one report	500,000	500,000
Export results maximum number locations for one export	100,000	100,000
Export results maximum number of items for one export	500,000	500,000
Maximum amount of exportable data from a single search.	2 TB[1]	5 TB
Maximum an organization can export in a single day.[2]	2 TB	5 TB

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Maximum number of exports or reports displayed in Content Search or eDiscovery cases.	1,000	2,000
Maximum size of individual file supported for export	5 GB	5 GB
Maximum size of PST file that can be exported.	10 GB[3]	10 GB
Maximum size per export package.	40 GB	40 GB
Rate at which content from mailboxes are exported	2 GB per hour per mailbox[4]	2 GB per hour per mailbox[4]

> **Note**
>
> [1]If the search results are larger than 200 GB, consider using date ranges or other types of filters to decrease the total size of the search results.
>
> [2] The system resets this limit daily at 12:00 AM UTC.
>
> [3] The export process automatically splits search results larger than 10 GB into multiple PST files, even if you select the option to export results into a single PST.
>
> [4] If an export runs for seven days without completing, the system automatically cancels it. To prevent this issue, divide your export into smaller batches.

Hold limits

> **Tip**
>
> For better performance, limit each case to no more than 1,000 searches, holds, or exports. To spread this activity across more cases, consider updates to your organization processes and workflows.

The following table lists the limits for holds associated with an eDiscovery case.

Expand table

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Maximum number of hold policies for an organization.	10,000	20,000
Maximum number of hold policies within a single case	100	200
Maximum number of mailboxes expanded from a single distribution list when used as a hold data source.[1]	100	100
Maximum number of mailboxes in a single case hold. This limit includes the combined total of user mailboxes, and the mailboxes associated with Microsoft 365 Groups, Microsoft Teams, and Viva Engage Groups.	1,000	2,000
Maximum number of policies applied to a specific location	100	100
Maximum number of sites in a single case hold. This limit includes the combined total of OneDrive sites, SharePoint sites, and the sites associated with Microsoft 365 Groups, Microsoft Teams, and Viva Engage Groups.[2]	1,000	2,000

> **Note**
>
> [1] You can't add distribution lists with more than 100 members directly as a hold data source. Expand the distribution list membership (for example, in Outlook) and then use the **bulk import data sources** feature to import the individual user mailboxes as data sources for the hold. You can also split the distribution list into smaller groups of 100 or fewer members before adding them.
>
> [2] Higher premium limits (for example, 2,000 sites) apply only when the case has premium eDiscovery features enabled. Check that premium features are enabled in **case settings**. Use separate hold policies for Exchange mailboxes and for SharePoint and OneDrive sites instead of combining them in one policy.

To view a list of more than 1,000 cases, holds, searches, or exports, use the corresponding Security & Compliance PowerShell cmdlet:

- Get-ComplianceCase
- Get-CaseHoldPolicy
- Get-ComplianceSearch
- Get-ComplianceSearchAction

Indexing limits

The following table lists the indexing limits in eDiscovery with premium feature support.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

Expand table

Description of limit	Premium eDiscovery feature support
Maximum number of characters extracted from a single file.[1]	10 million
Maximum size of a single file.[1]	150 MB
Maximum depth of embedded items in a document.[1]	25
Maximum size of files processed by Optical Character Recognition (OCR).[1]	24 MB
Maximum Advanced indexing throughput	2 GB per hour

> **Note**
>
> [1] If an item exceeds a single file limit, the process returns an error.

Indexing limits for email messages

The following table describes the indexing limits that might cause an email message to appear as an unindexed item or a partially indexed item in the results of a search.

Expand table

Indexing limit	Maximum value	Description
Maximum attachment size [1]	150 MB	The maximum size of an email attachment that the indexing service parses. The indexing service doesn't parse any attachment that's larger than this limit. It marks the message with the attachment as partially indexed.

Indexing limit	Maximum value	Description
Maximum number of attachments	250	The maximum number of files attached to an email message that the indexing service parses. If a message has more than 250 attachments, the indexing service parses and indexes the first 250 attachments. It marks the message as partially indexed because it didn't parse the extra attachments.
Maximum attachment depth	30	The maximum number of nested attachments that the indexing service parses. For example, if an email message has another message attached to it and the attached message has an attached Word document, the indexing service indexes the Word document and the attached message. This behavior continues for up to 30 nested attachments.
Maximum number of attached images	0	The parser skips an image that's attached to an email message and doesn't index it.
Maximum time spent parsing an item	30 seconds	The indexing service spends a maximum of 30 seconds parsing an item for indexing. If the parsing time exceeds 30 seconds, the indexing service marks the item as partially indexed.
Maximum parser output	2 million characters	The maximum amount of text output from the parser that's indexed. For example, if the parser extracted 8 million characters from a document, the indexing service indexes only the first 2 million characters.
Maximum annotation tokens	2 million	When the indexing service indexes an email message, it annotates each word with different processing instructions that specify how to index that word. Each set of processing instructions is called an annotation token. To maintain the quality of service in Microsoft 365, there's a limit of 2 million annotation tokens for an email message.
Maximum body size in index	67 million characters	The total number of characters in the body of an email message and all its attachments. When the indexing service indexes an email message, it concatenates all text in the body of the message and in all attachments into a single string. The maximum size of this string that is indexed is 67 million characters.
Maximum unique tokens in body	1 million	Tokens result from extracting text from content, removing punctuation and spaces, and then dividing it into words (called tokens) that the indexing service stores in the index. For example, the phrase `"cat, mouse, bird, dog, dog"` contains five tokens, but only four of these are unique tokens. There's a limit of 1 million unique tokens per email message, which helps prevent the index from getting too large with random tokens.

Note

[1] Parsing is the process where the indexing service extracts text from the attachment, removes unnecessary characters like punctuation and spaces, and then divides the text into words (in a process called tokenization) that it stores in the index.

Process limits

The following table lists the process limits in eDiscovery.

Expand table

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Maximum number of concurrent processes in your organization.	50	200
Maximum number of concurrent processes a single user can start at one time.	25	50
Maximum number of concurrent tenant-wide processes (for example, tenant-wide searches) in your organization.	5	50
Maximum number of concurrent tenant-wide processes (for example, tenant-wide searches) that a single user can start at one time.	5	25
Maximum number of jobs per day in your organization. [1]	500	1,000
Maximum duration the process runs before it's canceled.	7 days	7 days

Note

[1]This limit resets daily at 00:00 UTC.

Purge limits

The following table lists the purge limits in eDiscovery.

Expand table

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Items per location in Exchange	10	100

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Items per location in Teams	N/A	100
Total locations per purge	50,000	100,000

Review set download limits

The following table lists the review set download limits in eDiscovery with premium feature support.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

Expand table

Description of limit	Premium eDiscovery feature support
Total file size or maximum number of documents downloaded from a review set.[1]	3 MB or 50 documents

> **Note**
>
> [1] This limit applies to downloading selected documents from a review set. It doesn't apply to exported documents from a review set. For more information about exporting documents from a review set, see Export items from a review set in eDiscovery.

Review set export limits

The following table lists the limits when exporting documents from a review set in eDiscovery with premium feature support.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

Expand table

Description of limit	Premium eDiscovery feature support
Maximum size of a single export.	5 million documents or 500 GB, whichever is smaller.

Review set limits

The following table lists the review set limits in eDiscovery with premium feature support.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

Expand table

Description of limit	Premium eDiscovery feature support
Maximum number of items displayed per page in a review set.[1]	1,000
Add to review set processing	To optimize performance during the *Add to review set* process, the system allocates up to one minute to process each item. If processing isn't completed within one minute, the item might be added to the review set without fully extracting its child items.[2]

> **Note**
>
> [1]Use default or custom filters to adjust the displayed items in a review set as needed.
>
> [2]Use the items.csv process report to review any items that encountered this processing limit after the *Add to review set* process is completed.

Search limits

The following table lists the search limits for Exchange mailboxes and SharePoint sites in eDiscovery with premium feature support.

Expand table

Description of limit	eDiscovery feature support	Premium eDiscovery feature support
Maximum recommended number of locations specified for a single targeted search.[1]	1,000	1,000
Maximum number of locations for a single tenant-wide search, export from search, or add to review set process (organization-wide "All people and groups" source).[1]	500,000	500,000
Maximum number of Sensitive Information Types per search query.[2]	20	20
Maximum number of participants per search query.[2]	25	50
Maximum number of characters for a search query (including operators and conditions).[3, 5]	10,000	10,000
Minimum number of alpha characters for prefix wildcards; for example, `one*` or `set*`.	3	3
Maximum variants returned when using prefix wildcard to search for an exact phrase or when using a prefix wildcard and the NEAR Boolean operator.[4]	10,000	10,000
Maximum number of operators in a query.[5]	100	100
Maximum number of keyword segments in a query for tenant wide search. [6]	5	5
Maximum number of keyword segments in a query for targeted search. [6]	20	100

Note

[1] The 1,000 location limit applies only to targeted searches you manually specify individual mailboxes or sites. It includes the combined total of user mailboxes, and the mailboxes associated with Microsoft 365 Groups, Microsoft Teams, and Viva Engage Groups. Tenant-wide processes that use the organization-wide "All people and groups" source support up to 500,000 locations and aren't subject to the 1,000 targeted search limit. The 500,000 tenant-wide location limit applies to tenant-wide search, tenant-wide export from search, and tenant-wide add to review set processes. [2] Including more than 20 Sensitive Information Types or 25 participants might result in search query timeouts. [3] When searching SharePoint and OneDrive locations, characters in the URLs of searched sites count against this limit. The total number of characters consists of:

- All characters in both the *Users* and *Filters* fields.
- All search permissions filters that apply to the user.
- The characters from any location properties in the search, including *ExchangeLocation*, *PublicFolderLocation*, *SharePointLocation*, *ExchangeLocationExclusion*, *PublicFolderLocationExclusion*, *SharePointLocationExclusion*, and *OneDriveLocationExclusion*. For example, including all SharePoint sites and OneDrive accounts in the search counts as six characters, as the word `ALL` appears for both the *SharePointLocation* and *OneDriveLocation* field.

[4] For non-phrase queries (a keyword value that doesn't use double quotation marks) the system uses a special prefix index. This index tells the system that a word occurs in a document, but not where it occurs in the document. To do a phrase query (a keyword value with double quotation marks), the system needs to compare the position within the document for the words in the phrase. This comparison means that the system can't use the prefix index for phrase queries. In this case, the system internally expands the query with all possible words that the prefix expands to. For example, `time*` can expand to "time OR timer OR times OR timex OR time boxed OR ...". The limit of 10,000 is the maximum number of variants the word can expand to, not the number of documents matching the query. There's no upper limit for non-phrase terms. [5] A search query can include a maximum of 100 operators and up to 10,000 characters. An operator is Boolean operator such as AND, OR, or NEAR. The limit of operators and characters apply to the combined total of operator and characters in the user input search query and any search permission filters that are applied to the user running the search. As a result, users with multiple or complex permission filters, especially filters applied to the same users or groups, are more likely to reach this limit. To reduce the risk of exceeding the maximum number of operator, keep search permission filters to the minimum required to meet your organization's business needs. For more information, see **Configure search permission filtering in eDiscovery**. [6] Keyword segment refers to each individual keyword or keyword phrase entered as a separate row in the Keyword condition of the condition builder. It doesn't refer to the number of words or characters within a keyword or phrase. Each keyword segment is executed as a separate search operation against the selected locations. As a result, using a large number of keyword segments can increase search duration or cause the search to time out or fail. If your scenario requires more keyword segments than supported in a single search, split the keywords across multiple searches and run them separately.

For more information about specific limits, see the following articles:

- Exchange
- SharePoint

Search sample limit

The search sample is a best effort and depends on the following factors. If you need essential data, see export the data or add data to review set.

Expand table

Description of limit	Limit
Maximum item size for sample	10 MB
Time spent per location during sampling	Less than 30 seconds

Export search and export as report limit

The following table lists limits for the **Export as report** and the **export search** results:

Expand table

Description of limit	Limit
Export items report only CSV report string field character limit	255
Exported results (items)	500,000
Exported results (locations)	100,000
Search export expiry	14 days from creation
Total items	1 million
Total locations	500,000

Search times

Microsoft collects performance information for searches run by all organizations. While the complexity of the search query can impact search times, the biggest factor that affects how long searches take is the number of mailboxes searched.

Although Microsoft doesn't provide a service level agreement for search times, the following table lists average search times for collection searches based on the number of mailboxes

included in the search.

Expand table

Number of mailboxes	Average search time
100	30 seconds
1,000	45 seconds
10,000	4 minutes
25,000	10 minutes
50,000	20 minutes
100,000	25 minutes

Themes limits

The limits described in this section relate to manually defining the maximum number of themes in settings for a case in eDiscovery with premium feature support.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

Expand table

Description of limit	Premium eDiscovery feature support
Minimum number for the maximum number of defined themes.	3
Maximum number of defined themes.	10,000

Viewer limits

Expand table

Description of limit	Limit
Maximum size of an Excel file you can view in the native viewer.	4 MB

Tenant region or environment change limits

The same Microsoft 365 region and service environment store eDiscovery case data (cases, searches, holds, review sets, and exports) where you originally created it. This data doesn't move with your tenant if you later relocate the tenant to a different region or to a different service environment.

> **Important**
>
> If you move your Microsoft 365 tenant between regions (for example, through Advanced Data Residency), or migrate it across service environments (for example, from Microsoft 365 commercial to a Microsoft 365 Government environment such as GCC, GCC High, or DoD), you can't access eDiscovery cases and their associated data that you created **before** the move from the destination tenant. Cases created **after** the move work normally in the new location.

There's no in-place migration path for eDiscovery case data across regions or service environments. To avoid losing access to in-flight investigations, complete the following actions before the move:

- Complete or close any active investigations where possible.
- Export the results of any searches you want to retain.
- Export any review sets you want to retain.
- Document the membership of any case holds you need to recreate in the destination tenant.

After the move, recreate the holds, searches, and cases you still need in the destination tenant.

Supported file types in eDiscovery

Microsoft Purview eDiscovery supports many file types at many different levels. The following tables list the currently supported file types.

These tables indicate if a file type is supported for text extraction and Optical Character Recognition (OCR) text extraction for image files, if it's viewable in the native viewer, and if it's supported in the Annotate viewer in eDiscovery.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Document metadata fields in eDiscovery

The following table lists the metadata fields for documents in Microsoft Purview eDiscovery. For more information about searchable properties when searching Microsoft 365 content locations when you're collecting data for an eDiscovery case, see Create a search query for a case in eDiscovery.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

This table provides the following information:

- **Field name**: The name of the metadata field included in the `items.csv` report. Some metadata field values don't appear until analytics runs in the review set. These fields are highlighted with an asterisk (*).
- **Description**: A description of the metadata field.
- **Direct export**: If the metadata field value is populated for direct exports from search.
- **Add to review set**: If the metadata field value is populated when adding search results to a review set.
- **Review set export**: If the metadata field value is populated when exporting items from a review set.

> **Note**
>
> When you export search results by using the **report only** option (without including content), some metadata fields might not be fully populated. Report-only exports rely on indexed properties, which might not reflect the most current or complete metadata for all items. To ensure all metadata fields are accurately populated, export search results **with content**. Export with data fully inspects each item and returns complete metadata values as documented in the following table.

Expand table

Field name	Description	Direct export	Add to review set	Review set export
Added by	Indicates how the item was included in this process, whether it was a match from *IndexQuery*, *AdvancedIndexed*, or *PartiallyIndexed*.	Yes	Yes	Yes
All custodians	Union of the `Custodian` and the `Deduped custodians` fields.	No	Yes	Yes
Attachment names	List of attachment names of the email item.	No	Yes	Yes
Author	Author from the document metadata.	Yes	Yes	Yes
BCC	Bcc field for message types. The format is `DisplayName <SMTPAddress>`. This field is only available when the email is collected from the sender mailbox.	Yes	Yes	Yes
BCC expanded	The value in Bcc field of an email expanded. This field is only available when the email is collected from the sender mailbox. For example, if Bcc is a distribution list, this field shows the Bcc and all of its members.	Yes	Yes	Yes
Category	Category label applied in Outlook to the email item. This field is only available for items residing in the mailbox where the category label is applied.	Yes	Yes	Yes
CC	Cc field for message types. The format is `DisplayName <SMTPAddress>`.	Yes	Yes	Yes
CC expanded	Cc field of the email or message expanded. If the CC field is a distribution list, the Cc expanded field contains a list of its members. This expansion is only available if the item is collected from the sender's mailbox.	Yes	Yes	Yes
Channel Name	Teams channels and private channels: *Channel*.	Yes	Yes	Yes
Client conversation ID	The Exchange email or Teams conversation ID.	No	Yes	Yes
Compound path	Path that shows the full location of an item across its source systems (such as mailbox or SharePoint), including the source name, to describe where the item originated.	Yes	Yes	Yes
Contains deleted message	Boolean field indicating if the item contains a deleted message.	Yes	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
Contains edited message	Boolean field indicating if the item contains an edited message.	Yes	Yes	Yes
Content source application	Application from which the content originates. For example, *SharePoint* for documents and list items stored in SharePoint; *MicrosoftTeams* for Teams messages, chats, and channel content.	No	Yes	Yes
Conversation index	Index of each item within the same conversation.	No	Yes	Yes
Conversation name	Sub-header of Teams announcement posts or the title of Teams channel post.	Yes	Yes	Yes
Conversation topic	This field depends on content type. Emails: typically the subject of the email without the forward or reply. Teams 1:1 chat: the first 40 characters of the first message. Teams 1:N chat: Name of the group chat; if not available, the first 40 characters of the first message. Teams Channel Post: Post title or announcement subheader; if not available, the first 40 characters of the first message.	No	Yes	Yes
Conversation type	The type of chat conversation. Values are: Teams 1:1 and group chats and all Viva Engage conversations: *Group*.	Yes	Yes	Yes
Created	Date and time of the item's creation time.	Yes	Yes	Yes
Created by	*Created by* value from SharePoint.	Yes	Yes	Yes
Custodian	SMTP address of the custodian the item was associated with.	No	Yes	Yes
Data source	The data source name of the person or group from which the item is collected.	Yes	Yes	No
Date[1]	Date is a computed field that depends on the file type: - **Email**: Sent date - **Email attachments**: Last modified date of the document; if not available, the parent's sent date. - **Embedded documents**: Last modified date of the document; if not available, the parent's last modified date. - **SharePoint documents (includes modern attachments)**: Last modified date of the document; if not available, SharePoint last modified date. - **Non-Office 365 documents**: Last modified date.	Yes	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
	- **Meetings**: Meeting start date. - **VoiceMail**: Sent date. - **IM**: Sent date. - **Teams**: Sent date			
Deduped compound path*	List of compound paths of documents that are exact duplicates (email: based on content, documents: based on hash).	N/A	N/A	Yes
Deduped custodians*	List of custodians of documents that are exact duplicates (for email, based on content; for documents, based on hash).	N/A	N/A	Yes
Deduped file IDs*	List of file IDs of documents that are exact duplicates (for email, based on content; for documents, based on hash).	N/A	N/A	Yes
Deduped group file IDs*	List of Group file IDs of documents that are exact duplicates (for email, based on content; for documents, based on hash).	N/A	N/A	Yes
Deduped thread file IDs*	List of thread file IDs of documents that are exact duplicates (for email, based on content; for documents, based on hash).	N/A	N/A	Yes
Detected language	The language identified in the item, typically represented by a locale code (for example, en-us), as determined by SharePoint.	No	Yes	Yes
DG expansion result	Indicates whether the expansion of distribution group membership was successful. When emails are sent to distribution groups, additional fields such as *To Expanded*, *Cc Expanded*, or *Bcc Expanded* capture the expanded membership. These values are saved in the sender's mailbox copy if the sender is on hold. This field records failures in that expansion process.	Yes	Yes	Yes
Doc authors	Author from the document metadata.	Yes	Yes	Yes
Doc comments	Comments from the document metadata.	No	Yes	Yes
Doc company	Company from the document metadata.	No	No	Yes
Doc date created	Create date from document metadata.	No	Yes	Yes
Doc index	Position of a document within its hierarchical family, where a value of 0 represents the root (top-level item)	No	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
	and higher numbers denote increasing levels of embedding within another document.			
Doc keywords	Keywords from the document metadata.	No	No	No
Doc subject	Subject from the document metadata.	No	Yes	Yes
Doc template	Template from the document metadata.	No	No	Yes
Document ID index	An internal index identifier for an item that's unique only within a single mailbox; items in different mailboxes (including different archive mailboxes for the same user) can share the same value.	Yes	Yes	Yes
Document ID path	Represents the hierarchical sequence of item IDs, showing the relationship when an item is embedded within another. A single ID indicates a top-level item with no parent.	No	Yes	Yes
Dominant theme*	Dominant theme as calculated for analytics.	N/A	N/A	Yes
Email action	Values are *None*, *Reply*, or *Forward* and are based on the subject line of a message.	Yes	Yes	Yes
Email date sent	Sent date of the message. For chats, the beginning date from the transcript.	Yes	Yes	Yes
Email delivery receipt	Boolean field indicating whether the sender requested a delivery receipt for the email message.	No	No	Yes
Email importance	Importance of the message: Low; Normal; High	Yes	Yes	Yes
Email internet headers	The full set of email headers from the email message	No	Yes	Yes
Email level	Indicates a message's level within the email thread it belongs to; attachments inherit its parent message's value.	No	No	No
Email participant domains	List of domains of all participants.	Yes	Yes	Yes
Email read receipt	True or false value if a read receipt was received at sender end.	No	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
Email recipient domains	List of all domains of recipients of a message.	Yes	Yes	Yes
Email recipients	List of all recipients of a message (To, Cc, Bcc).	Yes	Yes	Yes
Email sender domain	Domain of the sender.	Yes	Yes	Yes
Email set	**Retired field**.	No	No	No
Email thread	**Retired field**	No	No	No
Error detail	If Status isn't successful, this field shows all the warnings and errors associated with the item.	Yes	Yes	Yes
Extracted content type	MIME media type of the item. For example, image/jpeg, application/vnd.ms-outlook, text/plain; charset=windows-1252, video/mp4. This type identifies the format of the extracted content.	No	Yes	Yes
Extracted text length	Number of characters in the extracted text.	No	Yes	Yes
Extracted text path	The path to the extracted text file in the export. This path applies only to review set export and only when user selects *export text file* in the settings.	No	No	Yes
Family duplicate set*	Numeric identifier for families that are exact duplicates of each other (same content and all the same attachments).	N/A	N/A	Yes
Family ID	Groups together attachments and extracted items from email and chats with its parent item. This grouping includes the chat or email and all attachments and extracted items.	No	Yes	Yes
Family size	Number of documents in the family.	No	Yes	Yes
File class	For content from SharePoint and OneDrive: Document. For content from Exchange: Email or Attachment. For content from Teams or Viva Engage: Conversations.	No	Yes	Yes
File extension	Extension of the file, such as .csv, .pdf, .html, .txt, .jpg, and more.	Yes	Yes	Yes
File ID	Document identifier unique within a case.	No	Yes	Yes
File name	Native file name of the item.	Yes	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
Group ID	Groups together all items for email and documents. For email, this grouping includes the message and all attachments and extracted items. For documents, this grouping includes the document and any embedded items.	No	Yes	Yes
Group representative ID*	Numeric identifier of each set of exact duplicates within the same group. The Group Representative ID corresponds to the document ID of the chosen representative in the group.	N/A	N/A	Yes
Has attachment	Indicates whether the message has attachments. Some items might indicate they have an attachment when they are actually embeddings in the email (.png or .html). When viewed in the review set, the email item won't have any attachments associated with it.	Yes	Yes	Yes
Has text	A Boolean field indicating whether the item contains extractable text content; possible values are True (text is present) or False (no text available).	Yes	Yes	Yes
Has unique attachment*	This field marks emails that contain attachments not found in other emails within the same thread. Even if the email content is duplicated, unique attachments are flagged to ensure that all relevant documents are reviewed. This field is important in the legal review process to ensure that no unique evidence is overlooked, even if the email body isn't unique.	N/A	N/A	Yes
Identifier	The Internet Message ID for Exchange items and the SitePropertyPath for SharePoint items.	No	Yes	Yes
Immutable ID	An unchangeable identifier assigned to each item. This value is unique for parent items across mailboxes, but attachments and extracted items inherit the Immutable ID from their parent, so it isn't unique across all items. To uniquely identify individual items within a case, use the **File ID** field instead.	Yes	Yes	Yes
In reply to ID	In reply to ID from the message. This field identifies the unique message ID of the email or message that the current item is replying to. It's used to track conversational threads and message relationships, especially in threaded discussions or email chains. This field helps reconstruct the context of a reply by linking it	No	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
	back to the original message, but it doesn't contain the full content of the original message itself.			
Inclusive type	**Retired field**.	N/A	N/A	N/A
Input file ID	The file ID of the top level item in the review set. For an attachment, this ID is the ID of the parent. Use this ID to group families together.	No	Yes	Yes
Internet message ID	Internet message ID from the message.	Yes	Yes	Yes
Is attachment from transcript	Is attachment part of teams transcript	Yes	Yes	Yes
Is bcc to me	Boolean metadata field that indicates whether the user was included in the Bcc line of the email.	No	Yes	Yes
Is doc from conversation	Boolean metadata field that indicates whether the document originated from a Microsoft Teams or Viva Engage conversation.	Yes	Yes	Yes
Is draft	Indicate if the email is a draft.	No	Yes	Yes
Is encrypted	Indicate if the item is encrypted.	Yes	Yes	Yes
Is external	Indicate if the email is from an external organization.	No	Yes	Yes
Is group representative*	This field indicates whether an email is marked as the single representative copy within a specific group. Only one email with the same hash from the same group is designated as the group representative.	N/A	N/A	Yes
Is inclusive*	This field identifies whether an email contains all the unique content from a thread, including all previous replies. It ensures that only the most comprehensive email in a thread is reviewed, which is essential for understanding the full context of the conversation without having to review each individual reply. This field helps in efficiently managing long email threads by focusing on the most informative emails.	N/A	N/A	Yes
Is modern attachment	Boolean field indicating if this file is a modern attachment or linked file.	Yes	Yes	Yes
Is read	Boolean field indicates whether an email is opened or viewed by the recipient.	Yes	Yes	No

Field name	Description	Direct export	Add to review set	Review set export
Is representative*	One document in every set of exact duplicates is marked as representative.	N/A	N/A	Yes
Is thread representative*	This field indicates whether an email is marked as the single representative copy within a specific thread. Only one email with the same hash from the same thread is designated as the thread representative.	N/A	N/A	Yes
Is top for group	Boolean field indicating if this item is the parent of the group.	No	Yes	Yes
Item class	Field that categorizes the type and structure of a message item such as *IPM.Note* for email, *IPM.File* for documents, or *IPM.SkypeTeams.Message* for Teams chats.	Yes	Yes	Yes
Item source	Mailbox or site from which the item originates.	Yes	Yes	Yes
Last modified by	The user who last modified the document.	No	Yes	Yes
Last modified time	Last modified date from document metadata.	No	Yes	Yes
Last modified time for retention	SharePoint document upload time for retention purposes.	No	No	No
Load ID	The ID of the load set in which the item was added to a review set. This ID corresponds to the job ID of the specific Add To Review Set job.	No	Yes	Yes
Location ID	Site ID for SharePoint locations and mailbox ID for exchange locations.	Yes	Yes	Yes
Location sub type	Specifies the type of location, such as *PrimaryMailbox*, *SystemMailbox*, *ArchiveMailbox*, or *OneDriveSite*.	Yes	Yes	Yes
Marked as pivot*	Boolean field indicating if This file is the pivot in a near duplicate set.	N/A	N/A	Yes
Meeting end date	End time of the meeting for items of item class. Values are *IPM.Schedule.Meeting.Request*, *IPM.Appointment*, or *IPM.AppointmentSnapshot.SkypeTeams.Meeting*.	Yes	No	Yes
Meeting name	Name of Teams meeting.	No	No	No
Meeting start date	Start time of the meeting for items such as item class. For example,	No	No	Yes

Field name	Description	Direct export	Add to review set	Review set export
	IPM.AppointmentSnapshot.SkypeTeams.Meeting.			
Message kind	The type of message to search for. Possible values: - *contacts* - *docs* - *email* - *externaldata* - *faxes* - *im* - *journals* - *meetings* - *microsoftteams* (returns items from chats, meetings, and calls in Microsoft Teams) - *notes* - *posts* - *rssfeeds* - *tasks* - *voicemail*.	Yes	Yes	Yes
Modern attachment embedded URLs	A modern attachment URL is embedded into item.	No	No	No
Modern attachment parent ID	The Immutable ID of the document's parent.	No	No	Yes
Native copy from	Field that contains the blob URL of the original document.	No	Yes	Yes
Native MD5	MD5 hash (128-bit hash value) of the file stream.	No	Yes	Yes
Native SHA 256	SHA256 hash (256-bit hash value) of the file stream.	No	Yes	Yes
ND ET sort excl attach	**Retired field**.	N/A	N/A	N/A
ND ET sort incl attach	**Retired field**.	N/A	N/A	N/A
ND set	**Retired field**.	N/A	N/A	N/A
Organizer	Meeting organizer's display name.	No	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
Original file extension	The original file extension of the file.	No	Yes	Yes
Original path	Original path of item in mailbox or path in SharePoint.	Yes	Yes	No
Parent ID	ID of the item's parent.	No	Yes	Yes
Parent node	The closest preceding email message in the email thread.	No	No	No
Participant expansion	Lists all individual members of a group participant such as a distribution list by expanding it into its constituent participants.	No	Yes	No
Participants	List of all participants of a message; for example, sender, to, Cc, Bcc.	Yes	Yes	Yes
Pivot ID*	Analytics field value generated after running analytics in review set. The ID of a pivot.	N/A	N/A	Yes
Potentially privileged*	Analytics field value generated after running analytics in review set - True if attorney-client privilege detection model considers the document potentially privileged.	N/A	N/A	Yes
Preservation original URL	This field that captures the original location and version of an item before it was moved to the Preservation Hold Library (PHL).	No	Yes	No
Received	The date and time the email was received in UTC.	Yes	Yes	Yes
Recipient count	Number of recipients in the message.	Yes	Yes	Yes
Redacted file path	The path of the redacted replacement file in the export.	No	No	No
Redacted text path	The path of the redacted text file replacement in the export. For internal Microsoft use only.	No	No	No
Representative ID*	Numeric identifier of each set of exact duplicates.	N/A	N/A	Yes
Retention label	Retention labels applied to content in Office 365.	Yes	Yes	Yes
Retention URL	Captures the SharePoint or OneDrive path of an item under retention, typically pointing to its preserved version in the Preservation Hold Library (PHL).	Yes	No	No

Field name	Description	Direct export	Add to review set	Review set export
Sender	Sender (From) field for message types. The format is `DisplayName <SMTPAddress>`.	Yes	Yes	Yes
Sender/Author	Calculated field comprised of the sender or author of the item.	No	Yes	Yes
Sensitive type	List if SIT GUIDs associated with the item.	Yes	Yes	Yes
Sensitivity label	GUID of the Sensitivity label applied to the item.	Yes	Yes	Yes
Set ID	**Retired field**.	N/A	N/A	N/A
Set order inclusives first	**Retired field**.	N/A	N/A	N/A
Shared with	Lists the users or groups that have access to the SharePoint item.	No	No	No
SharePoint Item Content Type ID	Hexadecimal strings used as SharePoint content type identifiers are stored in the *SharepointItemContentTypeID* field, which helps identify the item's content type and map SharePoint content into the substrate's flexible schema.	Yes	Yes	No
Similarity percent*	Indicates how similar a document is to the pivot of the near duplicate set.	N/A	N/A	Yes
Size	Number of bytes of the item.	Yes	Yes	Yes
Source ID	SMTP for mailbox or URL for site of the item source.	Yes	Yes	No
SPO document link	SharePoint document path associated with an item. It references the location of the document within SharePoint.	No	Yes	Yes
SPO preservation original document unique ID	A unique identifier assigned to a document that's preserved in SharePoint under a preservation policy.	No	Yes	Yes
SPO unique ID	Unique ID of the SharePoint from where the document is retrieved.	No	Yes	Yes
Status	Overall status of the item in the process; indication whether item is successful or it encounters issues. Values are *Successful*, *Retrieval error*, *Skipped*, and more.	Yes	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
Subject/Title	Calculated field comprised of the subject or title of the item.	Yes	Yes	Yes
Tags	Tags applied to the item, only apply to Review set export items.	No	No	Yes
Target path	Target path of the item in the export package .zip files.	Yes	No	Yes
Team name	Name of the Teams channel.	Yes	Yes	No
Teams announcement title	Title of the Teams announcement post.	Yes	Yes	No
Teams channel	Teams channel name. Only applies to Microsoft Teams content.	No	Yes	Yes
Themes list*	Themes list as calculated for analytics.	N/A	N/A	Yes
Thread participant domains*	Domains of all participants in a thread.	N/A	N/A	Yes
Thread participants*	Participants in a thread.	N/A	N/A	Yes
Thread representative ID*	Numeric identifier of each set of exact duplicates within the same thread. The thread Representative ID corresponds to the document ID of the chosen representative in the group.	N/A	N/A	Yes
Title	Title of the document.	No	Yes	Yes
To	To field value of email and messages.	Yes	Yes	Yes
To expanded	The *To* field of the email or message expanded, that is, if the To field is a distribution list, the To expanded field contains a list of its members. This expansion is only available if the item is collected from the sender's mailbox.	Yes	Yes	Yes
Type	Type of the content for the item. For example, *Message*.	Yes	Yes	Yes
Version group ID	Groups together the different versions of the same document.	No	Yes	Yes
Version number	The version number of a document collected from SharePoint or OneDrive. This version number matches	No	Yes	Yes

Field name	Description	Direct export	Add to review set	Review set export
	the one displayed in the version history in the SharePoint and OneDrive user experience.			
Was remediated	Indicate whether this item was remediated by the error remediation process. Only applies to review set exports.	No	No	Yes
Word count	The word count of the extracted text.	No	Yes	Yes
Workload	Indicates which workload the item comes from, Exchange or SharePoint.	Yes	Yes	Yes

Note

[1] When you use the *Date* condition in an eDiscovery search, you might see discrepancies in the results because Microsoft 365 content types store and interpret dates differently. For example, emails, documents, and Teams messages might have several date-related metadata fields, such as *Created*, *Last Modified*, *Received*, and *Sent*. The *Date* condition might apply differently across these items, depending on the content source and query. To improve accuracy and get the results you want, use date ranges instead of specific dates. Combine date conditions with keywords or other metadata filters to narrow your results. Review search statistics and preview results to validate search results before finalizing exports.

Advanced indexing in eDiscovery

09/04/2025

When you add a data source to an eDiscovery case, the system reindexes any content it deems as partially indexed or that has indexing errors. This reindexing process is called *advanced indexing*. Many reasons can cause content to be partially indexed or have indexing errors. These errors might include image files, the presence of images in a file, unsupported file types, or file size indexing limits.

Advanced indexing is available in eDiscovery with premium feature support. The system applies advanced indexing when it runs processes like generating statistics, adding items to review set, and direct export. You don't need to wait for advanced indexing to complete before conducting a search or adding items to a review set like previous versions of eDiscovery. Also, you don't need to manually trigger any update on advanced indexing to ensure newly added content to the target locations need to be reindexed.

> **Tip**
>
> Want to try premium eDiscovery features? See the subscription requirements for Microsoft 365 Enterprise E5 licensing.

For SharePoint files, advanced indexing only runs on items marked as partially indexed or items with indexing errors. In Exchange, email messages with image attachments aren't marked as partially indexed or with indexing errors. This means that those files aren't reindexed by the advanced indexing process.

> **Note**
>
> Optical Character Recognition (OCR) automatically runs during advanced indexing. For more information about how OCR works and to configure OCR related settings, see Learn about search and analytics settings in eDiscovery cases.

View advanced indexing results

On the statistics dashboard, you can review advanced indexing hits and choose where to apply advanced indexing. You can view estimated hits on how many additional items from partially indexed items that match the search query after they're reindexed with advanced indexing. To ensure full advanced indexing runs on all partially indexed items in scope without sampling, use add to a review set and export with advanced indexing.

You can also review advanced indexed items in search results in the process report. This report provides details on natively indexed items, partially indexed items, and items identified by advanced indexing.

For more granular insights, you can use the CSV reports. This might include which specific items were exported or which locations were searched. These reports indicate whether an item was included due to a match with the indexed query or as a result of advanced indexing. The location report provides hit counts and data volume per location, broken down by matches to the standard index versus the advanced index.

Scope advanced indexing

You can scope advanced indexing to partially indexed items in locations where there are already indexed hits, partially indexed items in locations where there aren't any indexed hits, or both.

- **Partially indexed items from locations with indexed hits**: This option is more targeted and limits the scope to only those locations (mailboxes, sites) where some content was successfully indexed and matched the search criteria.

  Choose this option when:
  - You want to reduce noise and focus only on locations already known to be relevant.
  - You're conducting a narrow investigation and want to avoid reviewing irrelevant content.
  - You're optimizing for review efficiency and cost control (for example, in large-scale eDiscovery cases).
  - You want to prioritize the locations and the partially indexed items in locations with high relevancy to the matter first, then later come back to do a more comprehensive analysis that include all locations (including those without indexed hits).

- **Partially indexed items from all locations searched**: This option is more comprehensive and includes partially indexed items from every location searched, regardless of whether any indexed content matched.

  Choose this option when:
  - You need maximum completeness for legal defensibility or regulatory compliance.
  - You're investigating potential data concealment or malicious behavior where relevant content might exist only in unindexed formats (for example, image-based attachments or encrypted files).
  - You're dealing with high-risk scenarios where missing even one critical item could have legal or business consequences.

Partially indexed items in eDiscovery

When you select **Include partially indexed items**, eDiscovery searches automatically include partially indexed items in the estimated search results. Partially indexed items are Exchange mailbox items and documents on SharePoint and OneDrive sites that weren't completely indexed for search. In Exchange, a partially indexed item typically contains a file (of a file type that can't be indexed) attached to an email message.

The following reasons explain why items can't be indexed for search and are returned as partially indexed items:

- The file type is unrecognized or unsupported for indexing.
- Messages have an attached file that can't be opened; this issue is the most common cause of partially indexed email items.
- The file type is supported for indexing but an indexing error occurred for a specific file.
- Too many files attached to an email message.
- A file attached to an email message is too large.
- A file is encrypted with non-Microsoft technologies.
- A file attached to an email message is encrypted with a Microsoft Purview sensitivity label that applies encryption. Exchange doesn't index the attachment content, even though the attachment can be decrypted during export.
- A file is password-protected.

> **Note**
>
> Most organizations have less than 1% of content by volume and less than 12% by size that is partially indexed. The reason for the difference between volume and size is that larger files have a higher probability of containing content that can't be completely indexed.

For legal investigations, your organization might be required to review partially indexed items. You can specify whether to include partially indexed items when you export search results or when you add search results to a review set.

File types not indexed for search

Certain types of files, such as Bitmap (.bmp) or MP3 (.mp3) files, don't contain content that can be indexed. The search indexing servers in Exchange and SharePoint don't perform full-text indexing on these types of files. These file types are considered unsupported file types. There are also file types for which full-text indexing is disabled, either by default or by an administrator. Unsupported and disabled file types are labeled as unindexed items in searches.

For a list of supported and disabled file formats, see the following articles:

- **Exchange**: File formats indexed by Exchange Search
- **Exchange**: Get-SearchDocumentFormat
- **SharePoint**: Default crawled file name extensions and parsed file types in SharePoint

Messages and documents with partially indexed file types returned in search results

Not every email message with a partially indexed file attachment or every partially indexed SharePoint document is automatically returned as a partially indexed item. That's because other message or document properties, such as the **Subject** property in email messages and the **Title** or **Author** properties for documents, are indexed and available to be searched. For example, a keyword search for *financial* returns items with a partially indexed file attachment if that keyword appears in the subject of an email message or in the file name or title of a document. However, if the keyword appears only in the body of the file, the message or document is returned as a partially indexed item.

Similarly, messages with partially indexed file attachments and documents of a partially indexed file type are included in search results when other message or document properties, which are indexed and searchable, match the search criteria. Message properties that are indexed for search include sent and received dates, sender and recipient, the file name of an attachment, and text in the message body. Document properties indexed for search include created and modified dates. So even though a message attachment might be a partially indexed item, the message is included in the regular search results if the value of other message or document properties matches the search criteria.

For a list of email and document properties that you can search for by using eDiscovery tools in the Microsoft Purview portal, see Keyword queries and search conditions for eDiscovery.

> ⓘ **Note**

If you move a mailbox item from a folder that is indexed to a folder that isn't indexed, a flag is set to unindex the item. The item is removed from the index and isn't searchable. Later, if you move that same item back to a folder that is indexed, the flag isn't reset. That means the item remains unindexed, and not searchable.

Partially indexed items included in search results

Your organization might need to identify and analyze partially indexed items to determine what they are, what they contain, and whether they're relevant to a specific investigation. If you select **Include partially indexed items**, the partially indexed items in the content locations that you search are automatically included with the estimated search results. Depending on the specific setting you select, you can control whether to include partially indexed items in locations with indexed search hits, partially indexed items in locations without indexed search hits, or both. You can also include these partially indexed items when you export search results or add items to review sets.

Keep the following points in mind about partially indexed items:

- When you run an eDiscovery search, the total number and size of partially indexed Exchange items (returned by the search query) appear in the search statistics view, and they're labeled as **partially indexed items**. Statistics about partially indexed items don't include partially indexed items in SharePoint sites or OneDrive accounts.

- If you export results from a search of specific content locations or all content locations in your organization, only the unindexed items from content locations that contain items that match the search criteria are exported. In other words, if no search results are found in a mailbox or site, then any unindexed items in that mailbox or site aren't exported. The reason for this behavior is that exporting partially indexed items from many locations in the organization might increase the likelihood of export errors and increase the time it takes to export and download the search results.

  To export partially indexed items from all content locations for a search, configure the search to return all items (by removing any keywords from the search query) and then export only partially indexed items when you export the search results (by selecting **partially indexed items** under Select items to include in your export options).

- If you choose to include all mailbox items in the search results, or if a search query doesn't specify any keywords or only specifies a date range, partially indexed items might not be copied to the PST file that contains the partially indexed items. This behavior occurs because

all items, including any partially indexed items, are automatically included in the regular search results.

- You can't preview partially indexed items. To view partially indexed items returned by the search, you need to export the search results.

  Additionally, when you export search results and include partially indexed items in the export, partially indexed items from SharePoint items are exported to a folder named **Uncrawlable**. When you export partially indexed Exchange items, they're exported differently depending on whether the partially indexed items matched the search query and the configuration of the export settings.

- The following table shows the export behavior of indexed and partially indexed items and whether each is included for the different export configuration settings.

Expand table

Export configuration	Indexed items that match search query	Partially indexed items that match search query	Partially indexed items that don't match search query
Export only indexed items	Exported	Exported (included with the indexed items exported)	Not exported
Export only partially indexed items	Not exported	Exported (as partially indexed items)	Exported (as partially indexed items)
Export indexed and partially indexed items	Exported	Exported (included with the indexed items exported)	Exported (as partially indexed items)

Locations and the "in locations without search hits" option

When you include partially indexed items in an export (or add them to a review set), you can also choose to **exclude partially indexed items in locations without search hits**. Understanding what *location* means in this option determines what your export contains.

A **location** in eDiscovery is one of:

- A single **Exchange Online mailbox**, or
- A single **SharePoint Online site** or **OneDrive for Business site**.

A location is **not** a folder, a URL prefix, a SharePoint document library, or any subset of a mailbox or site defined by a Kusto Query Language (KQL) condition. The smallest unit the partial-index location filter operates on is the entire mailbox or the entire site.

What the option does

Expand table

Setting	Behavior
Exclude partially indexed items in locations without search hits (selected)	Partially indexed items are returned only from mailboxes and sites where at least one item also matched your search query. Mailboxes and sites with zero indexed matches contribute zero partially indexed items.
Exclude partially indexed items in locations without search hits (cleared)	Partially indexed items are returned from every selected mailbox and site, regardless of whether the indexed query matched anything in that mailbox or site.

KQL conditions don't constrain partially indexed items

Partially indexed items are returned based on the **location's index state**, not on whether the item matches your KQL query. If your query uses a path, URL, file-name pattern, or other property restriction (for example, `DocumentLink:"https://contoso.sharepoint.com/sites/Finance/Subfolder/*"`), partially indexed items from **anywhere** in the matched site can still appear in your export. They aren't evaluated against the restriction.

If you need to filter partially indexed items by KQL, select **Perform advanced indexing on partially indexed items** at export time. Advanced indexing re-indexes the items so your KQL conditions apply to them.

Single-location searches

If your scope is a single mailbox or a single site, the *Exclude partially indexed items in locations without search hits* option has **no effect**:

- If the location returns at least one indexed hit, it's considered responsive, and all of its partially indexed items are included.
- If the location returns no indexed hits, no items of any kind are exported from that location.

For single-location scopes, expect the location's full set of partially indexed items whenever you include partially indexed items at export, or use advanced indexing to apply your KQL conditions.

Example

A SharePoint search scoped to a single site uses the query `DocumentLink:"https://contoso.sharepoint.com/sites/Project/Subfolder/*"` and includes partially indexed items at export. Two outcomes are guaranteed:

1. **Indexed items** in the export are limited to the `Subfolder/*` path (the KQL condition applies).
2. **Partially indexed items** in the export include every partially indexed item across the entire `sites/Project` site, not just `Subfolder/*` (KQL doesn't apply to partially indexed items, and the location is the whole site).

To restrict partially indexed items to the same subfolder, enable **Perform advanced indexing on partially indexed items**.

Search-time and export-time settings are independent

eDiscovery search and export are separate jobs. The partially indexed item choices you make on each are independent:

Expand table

Where you set it	What it controls
Search query (search-time *Include partially indexed items*)	The statistics and preview returned by the search. It doesn't carry into a subsequent export.
Export dialog (export-time *Include partially indexed items*, *Exclude … in locations without search hits*, *Perform advanced indexing*)	The contents of the export package. These are the authoritative settings for what is exported.

If you set partial-index inclusion at search but clear it at export, the export contains no partially indexed items, regardless of what your search statistics showed. If you clear it at search but set it at export, the export contains partially indexed items according to the export-dialog settings. Always confirm partial-index behavior at the export step.

Date ranges and excluding partially indexed items

In eDiscovery searches, you can't use a date range to exclude partially indexed items from results in a search query. The search statistics include partially indexed items that fall outside of a date range, and you include them when you export partially indexed items. In eDiscovery with premium feature support, you can add partially indexed items to a review set and then filter them

in a review set before export. Alternatively, use the advanced indexing capability (a premium eDiscovery feature) to ensure these partially indexed items are reindexed to compare to the date range specified and to avoid a large volume of data getting exported.

For more information about indexing limits for email messages, see Limits in eDiscovery.

Assess partially indexed items in your organization

After you run an eDiscovery search, you can see the total number and size of partially indexed items in the locations that you searched in the search result statistics. The detailed statistics for the search show this information.

A few factors affect the number of partially indexed items that appear in the search results:

- If an item is partially indexed and matches the search query, the item is included in both the count and size of search result items and partially indexed items. However, when you export the results of that same search, the item is included only with set of search results and isn't included as a partially indexed item.
- The detailed statistics for the search *don't* include partially indexed items located in SharePoint and OneDrive sites in the estimate of partially indexed items. However, when you export the results of an eDiscovery search, you can include partially indexed items in the export. For example, if you only search sites, the estimated number of partially indexed items is zero.

To understand your organization's exposure to partially indexed items, run a search for all content in all mailboxes or a representative subset of mailboxes by using a blank keyword query.

In the following example, there are 1,629,904 (146.46 GB) fully indexed items and 10,025 (10.27 GB) partially indexed items.

You can determine the percentage of partially indexed items by using the following calculations.

To calculate the ratio of partially indexed items in your organization:

```
(Total number of partially indexed items/Total number of items) x 100
```

```
(10025/1629904) x 100 = 0.62%
```

By using the search results from the previous example, 0.62% of all mailbox items are partially indexed.

To calculate the percentage of the size of partially indexed items in your organization:

`(Size of all partially indexed items/Size of all items) x 100`

`(10.27 GB/146.46 GB) x 100 = 7.0%`

In the previous example, 7% of the total size of mailbox items comes from partially indexed items. Most customers have less than 1% of content by volume and less than 12% of content by size that is partially indexed.

For additional assessment of what types of content make up partially indexed items for your organization, select **Partially indexed items** to include in your export item report or overall export for further investigation.

More information about partially indexed items

- Because message and document properties and their metadata are indexed, a keyword search might return results if that keyword appears in the indexed metadata. However, that same keyword search might not return the same item if the keyword only appears in the content of an item with an unsupported file type. In this case, the item is returned as a partially indexed item.

- If a partially indexed item matches the search query criteria, it's included in the search results. However, it's not included with partially indexed items when you export search results.

- Although a file type is supported for indexing and is indexed, indexing or search errors can cause a file to be returned as a partially indexed item. For example, searching a large Excel file might be partially successful (because the first 4 MB are indexed), but then fails because the file size limit is exceeded. In this case, it's possible that the same file is returned with the search results and as a partially indexed item.

- Files that are encrypted with Microsoft encryption technologies, including Microsoft Purview sensitivity labels that apply encryption, behave differently depending on location:
  - Email attachments: Exchange doesn't index encrypted attachments. Keyword searches don't match content inside these attachments, and they're returned as partially indexed items. However, if the email message itself matches the search criteria (for example, the subject or sender), the message is included in the search results. You can decrypt encrypted attachments during preview and export.
  - SharePoint folders and OneDrive files: Files encrypted with Microsoft encryption technologies are partially indexed.

    - To ensure encrypted attachments are captured, include partially indexed items when exporting search results or adding results to a review set. Use review sets to analyze the decrypted content after collection.

- Email messages encrypted with S/MIME are partially indexed. This limitation includes encrypted messages with or without file attachments.

- Email messages protected using Azure Rights Management are indexed and are included in the search results if they match the search query. Rights-protected email messages are decrypted and can be previewed and exported. This functionality requires that you're assigned the RMS Decrypt role, which is assigned by default to the eDiscovery Manager role group.

- Don't use query-based holds to address encrypted or partially indexed items. Query-based hold with queries that include conditions beyond dates, participants, or item types - such as keywords or paths - might not be applicable for these items. There's a risk that the hold won't be applied as intended. To ensure coverage, limit query-based hold conditions for date ranges, participants, and item types only or apply a location-based hold. For more information, see Create an eDiscovery hold.

Search for eDiscovery activities in the audit log

The audit log records eDiscovery activities that you perform in Microsoft Purview portal or in PowerShell. Events are logged when administrators, eDiscovery managers, or any user assigned eDiscovery permissions perform the following tasks:

- Creating and managing eDiscovery cases.
- Creating and editing eDiscovery searches in cases.
- Performing search actions, such as generating statistics, sample, and exporting from search.
- Creating, editing, and removing eDiscovery holds from cases.
- Creating eDiscovery review sets and performing review activities in cases.

For more information about searching the audit log, the permissions that are required, and exporting search results, see Search the audit log.

How to search for and view eDiscovery activities

Perform the following steps to search for and view eDiscovery activities in the audit log.

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.

2. Select the **Audit** solution card.

3. On the **Search** page, complete the following steps:
   a. In the **Activities - friendly names** drop-down list, under **eDiscovery activities**, select one or more eDiscovery activities to search for. For a complete list of all eDiscovery activities, see Audit log activities.

   > **Note**
   >
   > The **Activities - friendly names** drop-down list also includes a group of activities named **eDiscovery cmdlet activities** that returns records from the cmdlet audit log.

   a. Select a date and time range to display eDiscovery events that occurred within that period.

b. In the **Users** box, select one or more users to display search results for. Leave this box blank to return entries for all users.

c. Select **Search** to run the search using your search criteria.

After the search results are displayed, you can select **Filter results** to filter or sort the resulting activity records. To view details about an activity, select the activity record in the list of search results. A **Details** flyout page is displayed that contains the detailed properties from the event record.

To display additional details, select **More information**. You can export the audit log search results to a .csv file, and then use the Excel Power Query feature to format and filter these records. For more information, see Export, configure, and view audit log records.

A client **IP Address** field is available for all activities performed in eDiscovery. If the **IP Address** column is blank for an activity, the activity was performed in the legacy eDiscovery experience. All eDiscovery activities performed in eDiscovery include an IP address in the **IP Address** column.

Audit activities logged for eDiscovery

For a complete listing of all eDiscovery detailed properties and activities included in the audit log, see Audit log activities.

Decryption in eDiscovery

Encryption is an important part of your file protection and information protection strategy. Organizations of all types use encryption technology to protect sensitive content within their organization and ensure that only the right people have access to that content.

To run common eDiscovery tasks on encrypted content, eDiscovery managers need to decrypt email message content when they export it from eDiscovery cases. Content encrypted with Microsoft encryption technologies isn't available for review until after export.

To make it easier to manage encrypted content in the eDiscovery workflow, eDiscovery tools now incorporate the decryption of encrypted files attached to email messages and sent in Exchange Online.[1] Additionally, encrypted documents stored in SharePoint and OneDrive are decrypted when premium eDiscovery features are enabled.[2]

Before this capability, only the content of an email message protected by rights management (and not attached files) was decrypted. Encrypted documents in SharePoint and OneDrive couldn't be decrypted during the eDiscovery workflow. Now, files that are encrypted with a Microsoft encryption technology and located on a SharePoint or OneDrive account are searchable and decrypted when the search results are prepared for preview, added to a review set, and exported. Additionally, encrypted documents in SharePoint and OneDrive that are attached to an email message (as a copy) are searchable. This decryption capability allows eDiscovery managers to view the content of encrypted email attachments and site documents when previewing search results, and review them after they're added to a review set when premium eDiscovery features are enabled.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Requirements for decryption in eDiscovery

- **Permissions**: You need to be assigned the *RMS Decrypt* role to preview, review, and export files encrypted with Microsoft encryption technologies. You also need this role to review and query encrypted files that are added to a review set in eDiscovery. The Microsoft

Purview portal assigns this role by default to the eDiscovery Manager role group. For more information about the RMS Decrypt role, see Assign eDiscovery permissions.

- **Run the Inbox Repair tool on exported PST files**: After you export PST files, run the Inbox Repair tool (ScanPST.exe) to diagnose and repair any errors in the PST files.

Supported encryption technologies

For Exchange, eDiscovery tools support items encrypted with Microsoft encryption technologies. These technologies are Azure Rights Management (Azure RMS)[1] and Microsoft Purview Information Protection (specifically sensitivity labels). For more information about Microsoft encryption technologies, see Encryption and the various email encryption options available. Content encrypted by S/MIME or third-party encryption technologies isn't supported. For example, previewing or exporting content encrypted with non-Microsoft technologies isn't supported.

> **Note**
>
> Microsoft eDiscovery tools don't support the decryption of email messages sent with a Microsoft Purview Message Encryption custom branding template. When you use an OME custom branding template, email messages are delivered to the encrypted message portal instead of the recipient's mailbox. Therefore, you can't use eDiscovery tools to search for encrypted messages because those messages are never received by the recipient's mailbox.

For SharePoint, content labeled with *SharePoint online service* is decrypted. Items labeled or encrypted in the client before uploading to SharePoint, legacy document library RMS templates or settings, and S/MIME or other standards aren't supported.[2].

eDiscovery activities that support encrypted items

The following table identifies the supported tasks that you can perform in eDiscovery tools on encrypted files attached to email messages and encrypted documents in SharePoint and OneDrive. You can perform these supported tasks on encrypted files that match the criteria of a search. A value of `N/A` indicates the functionality isn't available in eDiscovery.

Expand table

eDiscovery task	eDiscovery	Premium features enabled
Search for content in encrypted files in sites and email attachments[1]	No	Yes
Preview encrypted files attached to email	No	Yes[2]
Preview encrypted documents in SharePoint and OneDrive	No	Yes
Review encrypted files in a review set	N/A	Yes
Export encrypted files attached to email	Yes	Yes
Export encrypted documents in SharePoint and OneDrive	No	Yes

Supported decryption

The following table describes the decryption that eDiscovery supports for email, email with attachments, and files hosted by SharePoint.

Expand table

Item type	Task	eDiscovery	Premium features enabled
Encrypted email	Search	Yes	Yes
Encrypted email	Decryption to .pst	No	Yes
Encrypted email	Decryption to file	No	Yes
Encrypted mail and attachment	Search	No	Yes (with Advanced indexing)[3]
Encrypted mail and attachment	Decryption to .pst	No	Yes
Encrypted mail and attachment	Decryption to file	No	Yes
File in SharePoint with MIP label	Search	No	Yes
File in SharePoint with MIP label	Decryption	No	Yes
File in SharePoint with other encryption[4]	Search, Decryption	No	No

Important

eDiscovery doesn't support legacy encryption protocols.

Decryption limitations with email and attachments

> **Important**
>
> Decryption and searchability are distinct. Email attachments encrypted with sensitivity labels are decrypted during preview and export, but the content in those attachments isn't indexed for search. Keyword searches don't match content inside these attachments. To ensure these attachments are captured, include partially indexed items in your collection and use review sets to analyze decrypted content. For more information, see Partially indexed items.

eDiscovery support for decryption of email messages and attachments is subject to the following limitations:

- Decryption isn't supported when the email or attachment encryption is applied in an external organization. eDiscovery only supports decryption for email and attachments that your organization encrypts.
- When decrypting emails or attachments, the owner of the mailbox must have access to view the encrypted content. Decryption isn't supported if the owner sends or forwards the emails or attachments to other recipients who can't view the encrypted content. Changes in the owner's groups or other organization permissions might also affect decryption support.
- PDFs generated from MIP-labeled Word documents (for example, a .docx file encrypted with a sensitivity label and then saved as .pdf) can only be decrypted when PDF encryption is enabled. PDF encryption and decryption control of the tenant is configured by running the following cmdlet:

  ```
  Set-IRMConfiguration -EnablePdfEncryption $true
  ```

If you don't set the configuration to *True*, eDiscovery doesn't decrypt the PDF generated from MIP labeled document.

Decryption limitations with sensitivity labels in SharePoint and OneDrive

eDiscovery doesn't support encrypted files in SharePoint and OneDrive when a sensitivity label that applies encryption is configured with the following setting:

- User access to the document has an expiration setting that is set to a value other than **Never**.

For more information about these settings, see the "Configure encryption settings" section in Restrict access to content by using sensitivity labels to apply encryption.

An eDiscovery search might return documents encrypted with the previous settings. This result might happen when a document property (such as the title, author, or modified date) matches the search criteria. Although these documents might be included in search results, you can't preview or review them. These documents remain encrypted when they're exported with premium eDiscovery features enabled.

Files in SharePoint with sensitivity labels configured for user-defined permissions are supported for eDiscovery decryption. For more information, see Learn more about support for labels configured for user-defined permissions.

> **Important**
>
> Decryption is supported for files that are locally encrypted and then uploaded to SharePoint or OneDrive as long as the user is signed in to a Microsoft 365 client when encrypting the file. For example, local files that are encrypted by the Microsoft Purview Information Protection client and then uploaded to Microsoft 365. If the encryption applied locally isn't by a user signed in to the Microsoft 365 client, the file isn't supported for decryption.

Decryption scope for nested and container files

eDiscovery decryption applies to root-level items only, such as files stored directly in SharePoint or OneDrive, direct email attachments, and the email messages themselves. If an encrypted file is nested inside a container format, eDiscovery doesn't recursively decrypt it.

For example:

- A MIP-labeled encrypted .pptx file stored directly in a SharePoint document library is decrypted as expected.
- The same MIP-labeled encrypted .pptx file inside a .zip archive stored in SharePoint isn't decrypted. The .zip archive is collected and processed, but encrypted files within the archive aren't decrypted.
- An encrypted attachment on an email message is decrypted. However, if that email message is attached as a nested .msg file inside another email, encrypted attachments

within the nested .msg file aren't decrypted.

This behavior applies to all container formats, including .zip archives and .msg files that contain encrypted items as nested content. Sensitivity label metadata for nested items might also not be available because label information is read from source-level properties of the root item.

Decrypting RMS-protected email messages and encrypted file attachments by using premium eDiscovery features

When you export rights-protected (RMS-protected) email messages that are included in the results of a search, the export process decrypts these messages. Members of the eDiscovery Manager role group have this decryption capability by default because the RMS Decrypt management role is assigned to this role group by default.

Keep the following things in mind when exporting encrypted email messages and attachments:

- To enable decryption of RMS-protected messages when you export them, you must export the search results as individual messages.
- Attachments encrypted separately from an email can be decrypted if the attachments are Microsoft 365 documents. For example, if a user encrypts a Word document and then attaches it to an email message that isn't encrypted, this attachment is decrypted.
- Attachments encrypted as part of the encryption of the associated email message are decrypted. For example, if a user creates an email message, attaches an unencrypted Word document, and then encrypts the message (including the attachment), this attachment is decrypted.
- The **ResultsLog** report identifies messages that are decrypted. This report contains a column named **Decode Status**, and a value of **Decoded** identifies the messages that are decrypted.
- In addition to decrypting file attachments when exporting search results, you can also preview the decrypted file when previewing search results. You can only view the rights-protected email message after you export it.
- To prevent someone from decrypting RMS-protected messages and encrypted file attachments, create a custom role group by copying the built-in eDiscovery Manager role group, then remove the RMS Decrypt management role from the custom role group. Add the person you don't want to decrypt messages as a member of the custom role group.

Notes

[1] When you enable premium eDiscovery features, you can only transparently decrypt content encrypted with RMS keys hosted in Microsoft 365. Double Key Encryption (DKE), Hold Your Own Key (HYOK), on-premises RMS, and similar options aren't supported. For more information, see Key types for the service.

[2] Email attachment decryption is supported only for Microsoft 365 documents (Microsoft Word, Excel, PowerPoint, etc.) and PDF files if PDF decryption is enabled. Encrypted email messages attached as attachments aren't supported.

[3] eDiscovery can decrypt and index encrypted files located on a local computer that a user copies to an email message as long as the encryption was applied when the user was signed in to a Microsoft 365 client. When you enable premium eDiscovery features, you need to advanced index encrypted email and attachments in recipient mailbox to decrypt them.

[4] You can only decrypt items labeled in SharePoint or uploaded to SharePoint after integration with sensitivity labels are enabled. These items must have labels with admin-defined permissions and have no expiration. You can't decrypt all other encrypted files in SharePoint. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

You can't decrypt other documents, including:

- Files encrypted in the client and uploaded before sensitivity labels were integrated with SharePoint.
- Documents encrypted with legacy RMS templates and not labeled.
- Documents with user-defined permissions or with expiration settings (SMIME or other standards).

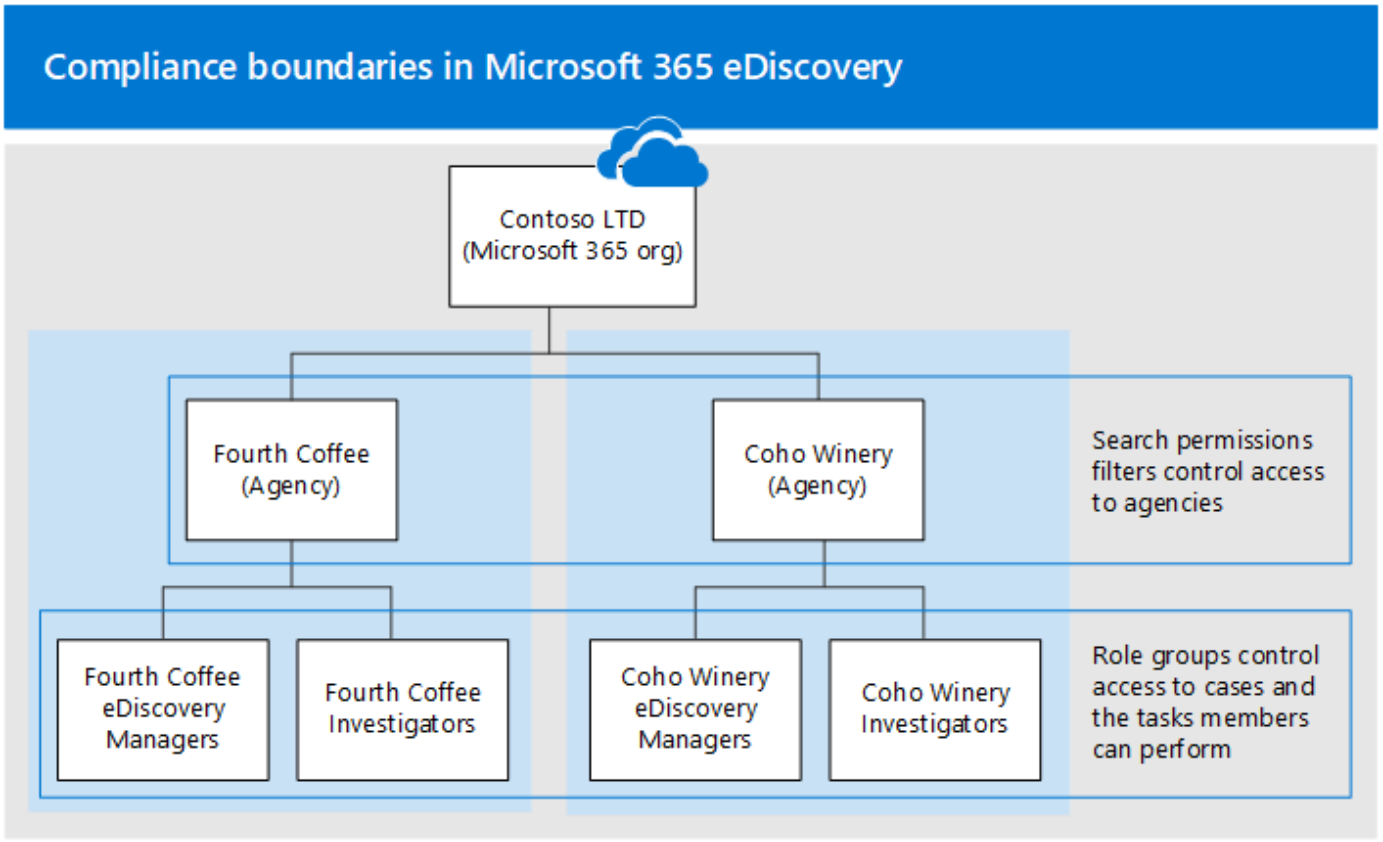
Set up compliance boundaries in eDiscovery

Compliance boundaries create logical boundaries within an organization that control the user content locations, such as mailboxes, OneDrive accounts, and SharePoint sites, that eDiscovery managers can search. Compliance boundaries also apply to searches in Data Security Investigations. Compliance boundaries control who can access eDiscovery cases used to manage the legal, human resources, or other investigations within your organization. Compliance boundaries control search scope within eDiscovery and DSI only. They don't restrict access in other Microsoft Purview or Defender solutions.



You often need compliance boundaries for multinational corporations that have to respect geographical borders and regulations, and for governments that are divided into different agencies. In Microsoft 365, compliance boundaries help you meet these requirements when performing content searches and managing investigations by using eDiscovery cases.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

> **Note**
>
> **SharePoint Embedded container support in eDiscovery (preview):** Compliance boundary enforcement isn't currently supported for SharePoint Embedded containers. For supported container scenarios and other limitations, see Data sources in eDiscovery.

Scenario example

The following illustration shows how compliance boundaries work.

In this example, Contoso LTD is an organization that consists of two subsidiaries, Fourth Coffee and Coho Winery. The business requires that eDiscovery managers and investigators can only search the Exchange mailboxes, OneDrive accounts, and SharePoint sites in their agency. Also, eDiscovery managers and investigators can only see eDiscovery cases in their agency, and they can only access the cases that they're a member of. In this scenario, investigators can't place content locations on hold or export content from a case. Here's how compliance boundaries meet these requirements.

- The search permissions filtering functionality for eDiscovery controls the content locations that eDiscovery managers and investigators can search. This control means eDiscovery managers and investigators in the Fourth Coffee agency can only search content locations in the Fourth Coffee subsidiary. The same restriction applies to the Coho Winery subsidiary.

- Role groups provide the following functions for compliance boundaries:
  - Control who can see the eDiscovery cases in the Microsoft Purview portal. This control means that eDiscovery managers and investigators can only see the eDiscovery cases in their agency.
  - Control who can assign members to an eDiscovery case. This control means eDiscovery managers and investigators can only assign members to cases that they themselves are a member of.
  - Control the eDiscovery-related tasks that members can perform by adding or removing roles that assign specific permissions.

- When a search permissions filter is applied to a role group, members of the role group can perform the following search-related actions as long as the permissions to perform an action are assigned to the role group:
  - Search for content
  - Preview search results
  - Export search results
  - Purge items returned by a search

Before you set up compliance boundaries

- Assign users an Exchange Online license. To verify assignments, use the Get-User cmdlet in Exchange Online PowerShell.

Set up compliance boundaries

Complete the following steps to set up compliance boundaries:

- Step 1: Identify a user attribute to define your agencies
- Step 2: Create a role group for each agency
- Step 3: Create a search permissions filter to enforce the compliance boundary
- Step 4: Create an eDiscovery case for intra-agency investigations

Step 1: Identify a user attribute to define your agencies

Choose an attribute to define your agencies. Use this attribute to create the search permissions filter that limits an eDiscovery manager to search only the content locations of users who are assigned a specific value for this attribute. For example, Contoso uses the **Department** attribute. The value for this attribute for users in the Fourth Coffee subsidiary is `FourthCoffee` and the value for users in Coho Winery subsidiary is `CohoWinery`. In Step 3, use this `attribute:value` pair (for example, *Department:FourthCoffee*) to limit the user content locations that eDiscovery managers can search.

Here are some examples of user attributes that you can use for compliance boundaries:

- Company
- CustomAttribute1 - CustomAttribute15
- Department
- Office
- CountryOrRegion (Two-letter country/region code)

> **Note**
>
> When selecting the attributes for the security filter, consider the attributes supported by different mailbox types in Exchange Online. Use CustomAttribute1 through CustomAttribute15 because all mailbox types in Exchange support these attributes.

Step 2: Create a role group for each agency

Create role groups in the Microsoft Purview portal that align with your agencies.

To create the role groups, go to **Settings** > **Roles and scopes** in the Microsoft Purview portal. Create a role group for each team in each agency that uses compliance boundaries and eDiscovery cases to manage investigations. You can use a single role group to assign both the eDiscovery roles and the security filter to its members. Membership in this role group manages both the roles assigned to the investigator and the content locations they can search.

> **Note**
>
> If you previously configured compliance boundaries using role groups with no roles attached (sometimes called 'empty role groups'), this configuration is no longer supported. Role groups used with search permissions filters must have at least one role assigned.

Use separate role groups. Use one role group to assign the security filter for the compliance boundary and another role group to assign the eDiscovery roles. By using two separate role groups, you manage the roles assigned to an investigator independently from the content locations they search. Use the role group for the compliance boundary only to apply the security filter to members. Use separate built-in (eDiscovery Manager) or custom role groups to assign roles to members. For more information about eDiscovery-related roles, see Assign eDiscovery permissions.

> **Important**
>
> Role groups with a security filter assigned must have at least one role added for it to take effect.

Using the Contoso compliance boundaries scenario, create four role groups and add the appropriate members to each one.

- Fourth Coffee eDiscovery Managers
- Fourth Coffee Investigators
- Coho Winery eDiscovery Managers
- Coho Winery Investigators

> **Important**
>
> If you add or remove a role from a role group that you added as a member of a case, the role group is automatically removed as a member of the case (or any case the role group is a member of). This behavior protects your organization from inadvertently providing extra permissions to members of a case. If you delete a role group, you remove it from all cases it was a member of.

Step 3: Create a search permissions filter to enforce the compliance boundary

After you create role groups for each agency, create search permissions filters that associate each role group with its specific agency and define the compliance boundary. You need to create one search permissions filter for each agency. For more information about creating security permissions filters, see Configure permissions filtering for eDiscovery.

Here's the syntax that's used to create a search permissions filter for compliance boundaries for the scenario in this article.

PowerShell

```
New-ComplianceSecurityFilter -FilterName <name of filter> -Users <role groups> -
Filters "Mailbox_<MailboxPropertyName>  -eq '<Value> '", "SiteContent_Path -like
'<SharePointURL>' -or SiteContent_Path -like '<OneDriveURL>'"
```

Here's a description of each parameter in the command:

- `FilterName`: Specifies the name of the filter. Use a name that describes or identifies the agency that the filter is used in.
- `Users`: Specifies the users or groups who get this filter applied to the search actions they perform. For compliance boundaries, this parameter specifies the role groups (that you created in Step 2) in the agency that you're creating the filter for. This parameter is a multivalue parameter so you can include one or more role groups, separated by commas.

- `Filters`: Specifies the search criteria for the filter. For compliance boundaries, you define the following filters. Each one applies to different content locations.

  - `Mailbox`: Specifies the mailboxes or OneDrive accounts that the role groups defined in the `Users` parameter can search. This filter allows members of the role group to search only the mailboxes or OneDrive accounts in a specific agency; for example, `"Mailbox_Department -eq 'FourthCoffee'"`.

    > **Note**
    >
    > Mailbox filters also apply to Microsoft 365 group mailboxes and connected SharePoint sites. To return results from a SharePoint site connected to a Microsoft 365 group, both the *Mailbox* and *SiteContent* filters must match to both the Microsoft 365 group mailbox and the associated SharePoint site.

- `SiteContent`: This filter includes two separate filters. The first `SiteContent_Path` specifies the SharePoint sites in the agency that the role groups defined in the `Users` parameter can search. For example, `SiteContent_Path -like 'https://contoso.sharepoint.com/sites/FourthCoffee*'`. The second `SiteContent_Path` filter (connected to the first `SiteContent_Path` filter by the `or` operator) specifies the agency's OneDrive domain (also called the *MySite* domain). For example, `SiteContent_Path -like 'https://contoso-my.sharepoint.com/personal*'`. You can also use the `Site_Path` filter in place of the `SiteContent` filter. The `Site` and `SiteContent` filters are interchangeable, and don't affect search permissions filters described in this article.

  > **Important**
  >
  > Why is the `SiteContent` filter for OneDrive included in the previous search permissions filter? Although the `Mailbox` filter applies to *both* mailboxes and OneDrive accounts, the inclusion of the SharePoint filter would exclude OneDrive accounts if you didn't also include the OneDrive `Site` filter. If the search permissions filter didn't include a SharePoint filter, then you wouldn't have to include a separate OneDrive filter because the Mailbox filter would include OneDrive accounts in the scope of the compliance boundary. In other words, a search permissions filter with only the `Mailbox` filter would include both mailboxes and OneDrive accounts.

Here are examples of the two search permissions filters that you create to support the Contoso compliance boundaries scenario. Both of these examples include a comma-separated filters list,

in which the mailbox and site filters are included in the same search permissions filter and are separated by a comma.

Fourth Coffee

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Fourth Coffee Security Filter" -Users
"Fourth Coffee eDiscovery Managers", "Fourth Coffee Investigators" -Filters
"Mailbox_Department -eq 'FourthCoffee'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/FourthCoffee*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'"
```

Coho Winery

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Security Filter" -Users "Coho
Winery eDiscovery Managers", "Coho Winery Investigators" -Filters "Mailbox_Department
-eq 'CohoWinery'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/CohoWinery*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'"
```

> **Note**
>
> The syntax for the `Filters` parameters in the previous examples includes a *filters list*. A filters list is a filter that includes a mailbox filter and a site path filter separated by a comma. In the previous example, notice that a comma separates `Mailbox` and `SiteContent` filters: `-Filters "Mailbox_<MailboxPropertyName> -eq '<Value> '", "SiteContent_Path -like '<SharePointURL>' -or SiteContent_Path -like '<OneDriveURL>'"`. When this filter is processed during the running of an eDiscovery search, two search permissions filters are created from the filters list: one mailbox filter and one SharePoint/OneDrive filter. An alternative to using a filters list would be to create two separate search permissions filters for each agency: one search permissions filter for the mailbox attribute and one filter for the SharePoint and OneDrive site attributes. In either case, the results are the same. Using a filters list or creating separate search permissions filters is a matter of preference.

How do the search permissions filters work in this scenario?

Here's how the search permission filters are applied for each agency in this scenario.

1. The `Mailbox` filter is first applied to define the content locations that eDiscovery managers can search. In this case, Coho Winery eDiscovery managers can only search the mailboxes and OneDrive accounts of users whose *Department* mailbox property has a value of **FourthCoffee**; Coho Winery eDiscovery managers can only search the mailboxes and OneDrive accounts of users whose *Department* mailbox property has a value of **CohoWinery**. The `Mailbox` filter is a *content location filter*, because it specifies the content locations that eDiscovery managers can search. In both filters, eDiscovery managers can only search content locations with a specific mailbox property value.

2. After the content locations that can be searched are defined, the next part of the filter defines the content that eDiscovery managers can search. The first `SiteContent` filter lets Fourth Coffee eDiscovery managers only search for documents that have a site path property that contains (or starts with) `https://contoso.sharepoint.com/sites/FourthCoffee`; Coho Winery eDiscovery managers can only search documents that have a site path property that contains (or starts with) `https://contoso.sharepoint.com/sites/CohoWinery`. Therefore, the two `SiteContent` filters are *content filters* because they define the content that can be searched for. In both filters, eDiscovery managers can only search for documents with a specific document property value. All SharePoint-related filters are content filters because searchable site properties are stamped on all documents. For more information, see Configure permissions filtering for eDiscovery.

   > **Note**
   >
   > Although the scenario in this article doesn't use them, you can also use mailbox content filters to specify the content that eDiscovery managers can search for. The syntax for mailbox content filters is `"MailboxContent_<property> -<comparison operator> '<value>'"`. You can create content filters based on date ranges, recipients, and domains or any searchable email property. For example, this filter would allow eDiscovery managers to only search for mail items sent or received by users in the contoso.com domain: `"MailboxContent_Participants -like 'contoso.com'"`. For more information about mailbox content filters, see Configure search permissions filtering.

3. The search permissions filter is joined to the search query by the **AND** Boolean operator. That means when an eDiscovery manager in one of the agencies runs an eDiscovery search, the items returned by the search must match the search query and the conditions defined in the search permissions filter.

Step 4: Create an eDiscovery case for intra-agency investigations

In the final step, create an eDiscovery case in the Microsoft Purview portal. Then, add the role group that you created in Step 2 as a member of the case. This approach provides two important benefits when using compliance boundaries:

- Only members of the role group added to the case can see and access the case in the Microsoft Purview portal. For example, if the Fourth Coffee Investigators role group is the only member of a case, then members of the Fourth Coffee eDiscovery Managers role group (or members of any other role group) can't see or access the case.
- When a member of the role group assigned to a case runs a search associated with the case, they can only search the content locations within their agency. This restriction is defined by the search permissions filter that you created in Step 3.

To create a case and assign members:

1. Go to **eDiscovery** in the Microsoft Purview portal and create a case.
2. In the list of cases, select the name of the case you created.
3. Add role groups as members to the case.

> ⓘ **Note**
>
> When adding a role group to a case, you can only add the role groups that you're a member of.

Search and export content in multigeo environments

Search permissions filters also let you control where content is routed for export and which datacenter can be searched when searching content locations in a SharePoint multigeo environment.

- **Export search results:** You can export the search results from Exchange mailboxes, SharePoint sites, and OneDrive accounts from a specific datacenter. This feature means that you can specify the datacenter location that search results are exported from.

  Use the *Region* parameter for **New-ComplianceSecurityFilter** or **Set-ComplianceSecurityFilter** cmdlets to create or change which datacenter the export is routed through.

Expand table

Parameter value	Datacenter location
NAM	North American (datacenters are in the US)
EUR	Europe
APC	Asia Pacific
CAN	Canada

- **Route content searches:** You can route the content searches of SharePoint sites and OneDrive accounts to a satellite datacenter. This feature means you can specify the datacenter location where searches are run.

  > **Note**
  >
  > If you're using premium eDiscovery features, the *Region* parameter doesn't control the region that data is exported from. Data is exported from the organization's central location. Also, searching for content in SharePoint and OneDrive isn't bound by the geographic location of datacenters. All datacenters are searched.

  Use one of the following values for the *Region* parameter to control the datacenter location that searches run in when searching SharePoint sites and OneDrive accounts.

Expand table

Parameter value	Datacenter routing locations for SharePoint
NAM	US
EUR	Europe
APC	Asia Pacific
CAN	US
AUS	Asia Pacific
KOR	The organization's default datacenter
GBR	Europe
JPN	Asia Pacific

Parameter value	Datacenter routing locations for SharePoint
IND	Asia Pacific
LAM	US
NOR	Europe
BRA	North American datacenters

If you don't specify the *Region* parameter for a search permissions filter, the organization's primary SharePoint region is searched. Search results are exported to the closest datacenter.

To simplify the concept, the *Region* parameter controls the datacenter that is used to search for content in SharePoint and OneDrive. This parameter doesn't apply to searching for content in Exchange because Exchange content searches aren't bound by the geographic location of datacenters. Also, the same *Region* parameter value might also dictate the datacenter that exports are routed through. This routing is often necessary to control the movement of data across geographic borders.

> **ⓘ Important**
>
> When creating security compliance filter and setting a specific GEO region: ESP, ITA, NZL and SWE aren't valid regions and generate an error redirecting to valid region values. This error includes the following valid regions: ARE, APC, AUS, AUT, BRA, CAN, CHE, CHL, DEU, EUR, FRA, GBR, IDN, IND, JPN, KOR, LAM, MYS, NAM, NOR, POL, QAT, ZAF.

Here are examples of using the *Region* parameter when creating search permission filters for compliance boundaries. This example assumes that the Fourth Coffee subsidiary is located in North America and that Coho Winery is in Europe.

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Fourth Coffee Security Filter" -Users
"Fourth Coffee eDiscovery Managers", "Fourth Coffee Investigators" -Filters
"Mailbox_Department -eq 'FourthCoffee'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/FourthCoffee*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'" -Region NAM
```

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Security Filter" -Users "Coho Winery eDiscovery Managers", "Coho Winery Investigators" -Filters "Mailbox_Department -eq 'CohoWinery'", "SiteContent_Path -like 'https://contoso.sharepoint.com/sites/CohoWinery*' -or SiteContent_Path -like 'https://contoso-my.sharepoint.com/personal*'" -Region EUR
```

Keep the following things in mind when searching and exporting content in multigeo environments.

- The *Region* parameter doesn't control searches of Exchange mailboxes. All datacenters are searched when you search mailboxes. To limit the scope of which Exchange mailboxes are searched, use the *Filters* parameter when creating or changing a search permissions filter.

- If it's necessary for an eDiscovery Manager to search across multiple SharePoint regions, you need to create a different user account for that eDiscovery manager to use in the search permissions filter to specify the region where the SharePoint sites or OneDrive accounts are located. For more information about setting this up, see Configure search permissions filtering in eDiscovery.

- When searching for content in SharePoint and OneDrive, the *Region* parameter directs searches to either the primary or satellite location where the eDiscovery manager conducts eDiscovery investigations. If an eDiscovery manager searches SharePoint and OneDrive sites outside of the region that's specified in the search permissions filter, no search results are returned.

- When exporting search results from eDiscovery, content from all content locations (including Exchange, Skype for Business, SharePoint, OneDrive, and other services that you can search by using the Content Search tool) are uploaded to the Azure Storage location in the datacenter that's specified by the *Region* parameter. This behavior helps organizations stay within compliance by not allowing content to be exported across controlled borders. If you don't specify a region in the search permissions filter, content is uploaded to the organization's primary datacenter.

  When exporting content with premium eDiscovery features enabled, you can't control where content is uploaded by using the *Region* parameter. Content is uploaded to an Azure Storage location in a datacenter in your organization's central location. For a list of geo locations based on your central location, see Microsoft 365 Multi-Geo eDiscovery configuration.

- You can edit an existing search permissions filter to add or change the region by running the following command:

PowerShell

```
Set-ComplianceSecurityFilter -FilterName <Filter name>  -Region <Region>
```

Use compliance boundaries for SharePoint hub sites

SharePoint hub sites often align with the same geographical or agency boundaries that eDiscovery compliance boundaries follow. You can use the site ID property of the hub site to create a compliance boundary. To do this, use the Get-SPOHubSite cmdlet in SharePoint Online PowerShell to get the SiteId for the hub site, then use this value for the department ID property to create a search permissions filter.

Use the following syntax to create a search permissions filter for a SharePoint hub site:

PowerShell

```
New-ComplianceSecurityFilter -FilterName <Filter Name> -Users <User or Group> -Filters
"Site_Departmentid -eq '{SiteId of hub site}'"
```

Here's an example of creating a search permissions filter for a hub site for the Coho Winery agency:

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Hub Site Security Filter" -Users
"Coho Winery eDiscovery Managers", "Coho Winery Investigators" -Filters
"Site_Departmentid -eq '44252d09-62c4-4913-9eb0-a2a8b8d7f863'"
```

Compliance boundary considerations

Keep the following considerations in mind when managing eDiscovery cases and investigations that use compliance boundaries:

- When you create and run a search, you can select content locations that are outside of your agency. However, because of the search permissions filter, content from those locations isn't included in the search results.
- Compliance boundaries don't apply to holds in eDiscovery cases. That condition means an eDiscovery manager in one agency can place a user in a different agency on hold. However, the compliance boundary is enforced if the eDiscovery manager searches the content locations of the user who was placed on hold. That condition means the eDiscovery

manager can't search the user's content locations, even though they were able to place the user on hold.

- If you're assigned a search permissions filter - either mailbox or site filters - and you attempt to export partially indexed items from a search that includes all SharePoint sites in your organization, by using the scope option to include partially indexed items even from locations without search hits (see Export search results), the export contains partially indexed items from all sites, including those outside your assigned compliance boundary.

- When retrieving partially indexed items from sites that contain search hits, eDiscovery uses a prefix-based approach. For example, if a site `http://contoso.com/sales` is identified as a location matching the search query, the results might also include items from a similarly prefixed site such as `http://contoso.com/salesdepartment`, even if the `http://contoso.com/salesdepartment` site falls outside the configured compliance boundary. This behavior can occur when the filter isn't based on the site path. For instance, if the compliance boundary is defined as `Property -eq 'abc'`, a site that doesn't match the property value `'abc'` might be included if its path shares a prefix with a site that does match the property.

- Search permissions filters aren't applied to Exchange public folders.

- Supported search filters include `-and`, `-or`, `-like`, `-not`, `-eq`, and `-ne`. Don't use other exclusion filters, such as `-notlike` or `inotlike`, in a search permissions filter for a content-based compliance boundary. Using these exclusion filters can have unexpected results if content with recently updated attributes hasn't been indexed.

- Respect for compliance boundaries for OneDrive sites in searches might be impacted when:
  - The sites or associated mailboxes are moved or rehomed.
  - OneDrive ownership is reassigned, or more than one owner is added.
  - The OneDrive site is renamed or re-issued.
  - Moving a OneDrive site can change the ownership of the content and might include creating an arbitration mailbox. When you move these resources, there's a chance that content search results might be available across compliance boundaries. When a OneDrive site is reassigned, renamed, or assigned to more than one owner, it's possible that the content from these sites might be available across compliance boundaries.

- Compliance boundaries for mailboxes might be impacted when:
  - The mailbox isn't associated with a licensed user, which includes disabled or deleted users.
  - A mailbox isn't managed or synced from Microsoft Entra ID.

- Additionally, several types of mailboxes might produce content during search, regardless of their compliance boundaries. These mailbox types include:
  - EquipmentMailbox
  - GuestMailUser
  - LinkedMailbox
  - RoomList
  - RoomMailbox
  - SchedulingMailbox
  - SharedMailbox
  - SystemMailbox
  - TeamMailbox

- To make sure that the search respects the compliance boundaries as expected for these mailboxes, set attributes on shared mailboxes, equipment mailboxes, and other mailboxes by using the Set-Mailbox cmdlet or by using Invoke-ComplianceSecurityFilterAction to ensure the attribute is set correctly. If you properly configure the attribute and align it with the compliance boundary attribute, the mailbox respects the compliance boundary.

More information

- If you delicense or soft-delete a mailbox, the user is no longer within the compliance boundary. If you place a hold on the mailbox when you delete it, the content preserved in the mailbox is still subject to a compliance boundary or search permissions filter.
- If you implement compliance boundaries and search permissions filters for a user, don't delete the user's mailbox or their OneDrive account. If you delete a user's mailbox, also remove the user's OneDrive account since `mailbox_RecipientFilter` enforces the search permission filter for OneDrive.
- Compliance boundaries and search permissions filters depend on attributes stamped on content in Exchange, OneDrive, and SharePoint and the subsequent indexing of this stamped content.

Frequently asked questions

Who can create and manage search permissions filters by using the New-ComplianceSecurityFilter and Set-ComplianceSecurityFilter cmdlets?

To create, view, and modify search permissions filters in the Microsoft Purview portal, you need to have the *Organization Management* and *eDiscovery Administrator* roles assigned.

If an eDiscovery manager is assigned to more than one role group that spans multiple agencies, how do they search for content in one agency or the other?

The eDiscovery manager can add parameters to their search query that restrict the search to a specific agency. For example, if an organization specifies the **CustomAttribute10** property to differentiate agencies, they can append the following to their search query to search mailboxes and OneDrive accounts in a specific agency: `CustomAttribute10:<value>`.

What happens if I change the value of the attribute that's used as the compliance attribute in a search permissions filter?

It takes up to three days for a search permission filter to enforce the compliance boundary if you change the value of the attribute used in the filter. For example, let's say that a user in the Fourth Coffee agency is transferred to the Coho Winery agency. As a result, the value of the **Department** attribute on the user object changes from *FourthCoffee* to *CohoWinery*. In this situation, Fourth Coffee eDiscovery and investors get search results for that user for up to three days after the attribute is changed. Similarly, it takes up to three days before Coho Winery eDiscovery managers and investigators get search results for the user.

Can an eDiscovery manager see content from two separate compliance boundaries?

Yes, this capability is available when searching Exchange mailboxes by adding the eDiscovery manager to role groups that have visibility to both agencies. However, when searching SharePoint sites and OneDrive accounts, an eDiscovery manager can search for content in different compliance boundaries only if the agencies are in the same region or geo location.

> **Note**
>
> This limitation for sites doesn't apply when premium eDiscovery features are enabled because searching for content in SharePoint and OneDrive isn't bound by geographic location.

What happens to existing eDiscovery cases when a tenant moves between regions or across security boundaries?

eDiscovery cases, searches, holds, and review sets are created against the tenant's content location at the time of creation. When a tenant moves to a different region or to a different security boundary (for example, from commercial to GCC, GCC High, or DoD), existing artifacts remain bound to the origin location's data plane and might not be reusable from the destination.

Expand table

Move type	Impact on existing eDiscovery artifacts
Tenant relocation within the same security boundary (for example, a region move within commercial — NAM, EUR, APC)	Cases, searches, holds, and review sets created before the move might not be accessible from the destination region. Plan to export any required evidence before initiating the move, or expect to recreate artifacts after the move.
Tenant migration **across** security boundaries (commercial ↔ GCC, GCC High, or DoD)	Cases, searches, holds, and review sets created in the origin cloud **can't** be migrated and aren't accessible from the destination cloud. The artifacts continue to exist in the origin cloud's data plane but can't be opened, exported, or modified from the destination cloud. Plan to complete or export any active matters in the origin cloud before initiating the migration.

Symptoms after a move can include: existing cases appear in the portal but new case or search creation fails (often with a 500 error). If you encounter this error, contact Microsoft Support. There's a routing remediation, but for cross-cloud moves it requires accepting the loss of access to the origin-cloud artifacts in exchange for unblocking new artifact creation in the destination cloud.

For broader planning guidance on tenant migrations to the U.S. Government clouds, see Plan for Microsoft Purview DoD deployments, Plan for Microsoft Purview GCC High deployments, and Plan for Microsoft Purview GCC deployments. For tenant relocation and data residency planning, see Advanced Data Residency in Microsoft 365 and Plan for Microsoft 365 Multi-Geo.

Do search permissions filters work for eDiscovery case holds, Microsoft 365 retention policies, or DLP?

No, not at this time.

If I specify a region to control where content is exported, but I don't have a SharePoint organization in that region, can I still search SharePoint?

If the region specified in the search permissions filter doesn't exist in your organization, the default region is searched.

What is the maximum number of search permissions filters that I can create in an organization?

There's no limit to the number of search permissions filters that you can create in an organization. However, a search query can have a maximum of 100 conditions. In this case, a condition is defined as something that's connected to the query by a Boolean operator (such as

AND, **OR**, and **NEAR**). The limit of the number of conditions includes the search query itself plus all search permissions filters that are applied to the user who runs the search. Therefore, the more search permissions filters you have (especially if these filters are applied to the same user or group of users), the better the chance of exceeding the maximum number of conditions for a search.

To understand how this limit works, you need to understand that a search permissions filter is appended to the search query when a search is run. A search permissions filter is joined to the search query by the **AND** Boolean operator. The query logic for the search query and a single search permissions filter looks like this:

text

```
<SearchQuery> AND <PermissionsFilter>
```

Multiple search permissions filters are combined together by the **OR** Boolean operator, and then those conditions are connected to the search query by the **AND** operator.

The query logic for the search query and multiple search permissions filters looks like this:

text

```
<SearchQuery> AND (<PermissionsFilter1> OR <PermissionsFilter2> OR
<PermissionsFilter3>...)
```

It's possible the search query itself might consist of multiple conditions connected by Boolean operators. Each condition in the search query also counts against the 100-condition limit.

Also, the number of search permissions filters appended to a query depends on the user who is running the search. When a specific user runs a search, the search permissions filters that are applied to the user (which is defined by the *Users* parameter in the filter) are appended to the query. Your organization could have hundreds of search permissions filters, but if you apply more than 100 filters to the same users, then it's likely the 100-condition limit is exceeded when those users run searches.

There's one more thing to keep in mind about the condition limit. The number of specific SharePoint sites that are included in the search query or search permissions filters also count against this limit.

To prevent your organization from reaching the conditions limit, keep the number of search permissions filters in your organization as few as possible to meet your business requirements.

How do mailbox filters impact searches to OneDrive and M365 Group connected SharePoint sites?

OneDrive sites and Microsoft 365 Group connected SharePoint sites are linked to the associated user or Microsoft 365 Group mailbox in Exchange. For security filters that include both a Mailbox and SiteContent filter, to return results from the OneDrive or Microsoft 365 Group connected SharePoint sites both must be a match. The Mailbox filter is evaluated against the connected user or Microsoft 365 Group Mailbox first before evaluating the SharePoint and OneDrive items against the SiteContent filter.

What is an arbitration mailbox in the context of OneDrive sites?

For active and licensed users that have both an Exchange Mailbox and OneDrive account, there's a link between the mailbox and their OneDrive site. This means that the Mailbox filter assigned to a compliance boundary is evaluated against the user's mailbox to check for a match before results are returned.

When this link is lost between a mailbox and a OneDrive site, the OneDrive is associated with an arbitration mailbox instead. This arbitration mailbox doesn't have any of the mailbox properties from the original mailbox applied to it.

How do I check the status of a OneDrive site to determine if it is associated with an arbitration mailbox?

To review a specific OneDrive site and check if it's in arbitration or linked to a user's mailbox, use the Invoke-ComplianceSecurityFilterAction cmdlet.

Use the following syntax to check the status of a OneDrive site:

PowerShell

```
Invoke-ComplianceSecurityFilterAction -Action GetStatus -PropertyName <Boundary
Property> -SiteUrl <SharePoint/OneDrive URL>
```

For a OneDrive site that's not in arbitration, the commands return the *BoundaryType* value as UserMailbox, as shown in the following example:

PowerShell

```
PS C:\> Invoke-ComplianceSecurityFilterAction -action GetStatus -PropertyName
"CustomAttribute10" -siteurl "https://contoso-
my.sharepoint.com/personal/lila_contoso_onmicrosoft_com"
```

```
SiteUrlOrEmailAddress : https://contoso-
my.sharepoint.com/personal/lila_contoso_onmicrosoft_com
BoundaryType          : UserMailbox
BoundaryInstruction   : Set via Set-Mailbox
BoundaryObjectId      : SPO_4531d99e-21df-4903-a8c1-76cc3ec82685@SPO_525ef3f5-fbf7-
4f91-bb4a-e3c24116c8a9
BoundaryStatus        : Success
BoundaryProperty      : CustomAttribute10
BoundaryPropertyValue : Dept-CH
```

For a OneDrive site that's in arbitration, the commands return an empty or null value for the *BoundaryType* value, as shown in the following example.

PowerShell

```
PS C:\> Invoke-ComplianceSecurityFilterAction -action GetStatus -PropertyName
"CustomAttribute10" -siteurl "https://contoso-
my.sharepoint.com/personal/lila_contoso_onmicrosoft_com"

SiteUrlOrEmailAddress : https://contoso-
my.sharepoint.com/personal/lila_contoso_onmicrosoft_com
BoundaryType          :
BoundaryInstruction   :
BoundaryObjectId      : SPO_4531d99e-21df-4903-a8c1-76cc3ec82685@SPO_525ef3f5-fbf7-
4f91-bb4a-e3c24116c8a9
BoundaryStatus        : Success
BoundaryProperty      : CustomAttribute10
BoundaryPropertyValue :
```

How does a OneDrive site in arbitration affect results returned by an eDiscovery Manager with compliance boundaries applied to them?

This behavior depends on how the security filter is configured for the compliance boundary. When a OneDrive site is in arbitration, a Mailbox filter doesn't include it in the returned results.

For security filters that use only a Mailbox filter, items from the OneDrive are returned within the results of a search because the mailbox filter doesn't apply in this scenario.

For security filters that use both a mailbox filter and a SiteContent filter, results are returned if the *SiteContent* filter matches the items in the OneDrive instance that's in arbitration. If there's no match, the results aren't returned. For example, if the SiteContent_Path filter is used as separate agencies have a unique OneDrive URL due to the deployment of Microsoft 365 Multi-Geo, then the OneDrive items' path filters in or out results from the OneDrive in arbitration.

How can I update a OneDrive site in arbitration so that Mailbox filters continue to apply?

Use the Invoke-ComplianceSecurityFilterAction cmdlet to set the CustomAttribute1 through to CustomAttribute15 values on OneDrive instances that link to an arbitration mailbox.

Use the following syntax to set the status of a OneDrive site:

PowerShell

```
Invoke-ComplianceSecurityFilterAction -Action Set -PropertyName <Boundary Property> -SiteUrl <SharePoint/OneDrive URL>
```

After you set it on the OneDrive, it honors the Mailbox filters that use the CustomAttribute property set on the OneDrive.

What scenarios cause a OneDrive site to link to an arbitration mailbox?

Many scenarios can cause a OneDrive site to lose its link to the user's mailbox and link to an arbitration mailbox. See the Compliance Boundary Limitations section for more information. As a result, when you move, change, or reassign a OneDrive, use the Invoke-ComplianceSecurityFilterAction cmdlet to validate that the relevant Mailbox filter behaves as expected.

As part of user deprovisioning processes, run the Invoke-ComplianceSecurityFilterAction cmdlet against the user's OneDrive to set the required CustomAttribute value.

Why should I use CustomAttribute1 through CustomAttribute15 for Mailbox security filters?

Although other Mailbox attributes work with security filters, use the CustomAttributes when you define the Mailbox security filter for the following reasons:

- All Exchange Online mailboxes support these attributes.
- The attributes stamp directly on the mailbox, not the associated user object, so they remain set in scenarios where there's no associated user object.
- The Invoke-ComplianceSecurityFilterAction cmdlet only supports setting CustomAttribute on OneDrive instances linked to an arbitration mailbox. **My organization previously configured compliance boundaries using role groups with no roles attached (empty role groups), how should I update this congifuration?**

First identify roles used in your New-ComplianceSecurityFilter commands by running Get-ComplianceSecurityFilter | FL FIlterName, Users

Then, add a minimal role (such as View-Only Audit Logs) to each role group, or restructure to use the two-role group structure recommended where you set up one role group for the security

filter (with at least one role) and one role group for eDiscovery permissions.

Finally, verify your compliance boundaries are functioning as expected by running a test search.

Note: adding or removing roles from a role group that is a member of a case will automatically remove that role group from the case. Re-add the role group to the affected cases after makeing role changes.

My search returns results outside the expected compliance boundary, what should I do?

Verify the role group used in your security filter has at least one role assigned. Role groups with no roles assigned don't activate the security filter. Confirm the mailbox attribute is set on all target mailboxes, including shared mailboxes and group mailboxes. Check for OneDrive sites in arbitration status as sites linked to arbitration mailboxes don't inherit mailbox attributes. Allow up to three days for attribute changes to take effect in search permissions filters.

Configure search permissions filtering in eDiscovery

Use search permissions filtering to let an eDiscovery manager search only a subset of mailboxes and sites in your organization. You can also use permissions filtering to let that same eDiscovery manager search only for mailbox or site content that meets a specific search criteria.

For example, you might want an eDiscovery manager to search only the mailboxes of users in a specific location or department. Create a filter that uses a supported recipient filter to limit which mailboxes a specific user or group of users can search. You can also create a filter that specifies what mailbox content a user can search for. This filter uses a searchable message property. Similarly, you can let an eDiscovery manager search only specific SharePoint sites in your organization. Create a filter that limits which site can be searched. You can also create a filter that specifies what site content can be searched. This filter uses a searchable site property.

Understand search permissions filters

The Microsoft Purview portal applies search permissions filters when you search for content. When you apply a search permissions filter to a specific user, that user can perform the following search-related actions:

- Search for content
- Preview search results
- Export search results
- Purge items returned by a search

Use search permissions filtering to create logical boundaries (called *compliance boundaries*) within an organization that control the user content locations (such as mailboxes, SharePoint sites, and OneDrive accounts) that specific eDiscovery managers can search. For more information, see Set up compliance boundaries for eDiscovery investigations.

The following four cmdlets in Security & Compliance PowerShell let you configure and manage search permissions filters:

- New-ComplianceSecurityFilter
- Get-ComplianceSecurityFilter
- Set-ComplianceSecurityFilter
- Remove-ComplianceSecurityFilter

Requirements to configure permissions filtering

Before you configure permissions filtering, make sure the following requirements are met:

- To run the compliance security filter cmdlets, you need to be a member of the *Organization Management* role group and have the *eDiscovery administrator* role assigned in the Microsoft Purview portal. For more information, see Permissions in the Security & Compliance Center.
- You need to connect to both Exchange Online and Security & Compliance PowerShell to use the compliance security filter cmdlets. These cmdlets require access to mailbox properties, which is why you need to connect to Exchange Online PowerShell. See the steps in Connect to Exchange Online and Security & Compliance PowerShell in a single session.
- See the Additional considerations for search permissions filtering section for additional information about search permissions filters.
- Search permissions filtering applies to inactive mailboxes, which means you can use mailbox and mailbox content filtering to limit who can search an inactive mailbox. See the Additional considerations for search permissions filtering section for additional information about permissions filtering and inactive mailboxes.
- You can't use search permissions filtering to limit who can search public folders in Exchange.

> **Note**
>
> You can create unlimited search permission filters in an organization. However, a search query can have a maximum of 100 conditions. In this case, a condition is something that's connected to the query by a Boolean operator, such as **AND**, **OR**, and **NEAR**. The limit for the number of conditions includes the search query itself plus all search permissions filters that the user who runs the search applies. Therefore, the more search permissions filters you have - especially if these filters are applied to the same user or group of users - the better the chance of exceeding the maximum number of conditions for a search. To prevent your organization from reaching the conditions limit, keep the number of search permissions

filters in your organization as few as possible to meet your business requirements. For more information, see Set up compliance boundaries for eDiscovery investigations.

Connect to Exchange Online and Security & Compliance PowerShell in a single session

Before you can successfully run the script in this section, you need to download and install the Exchange Online PowerShell module. For information, see Install and maintain the Exchange Online PowerShell module.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of **.ps1**. For example, you could save it to a file named **ConnectEXO-SCC.ps1**.

   PowerShell

   ```
   Import-Module ExchangeOnlineManagement
   $UserCredential = Get-Credential
   Connect-ExchangeOnline -Credential $UserCredential -ShowBanner:$false
   Connect-IPPSSession -Credential $UserCredential
   $Host.UI.RawUI.WindowTitle = $UserCredential.UserName + " (Exchange Online + Security & Compliance)"
   ```

2. On your local computer, open Windows PowerShell, go to the folder where the script that you created in the previous step is located, and then run the script. For example:

   PowerShell

   ```
   .\ConnectEXO-SCC.ps1
   ```

How do you know if this worked? After you run the script, cmdlets from Exchange Online PowerShell and Security & Compliance PowerShell are available. If you don't receive any errors, you connected successfully. A quick test is to run Exchange Online PowerShell and Security & Compliance PowerShell cmdlets. For example, you can run **Get-Mailbox** and **Get-ComplianceSearch**.

For troubleshooting PowerShell connection errors, see:

- Connect to Exchange Online PowerShell
- Connect to Security & Compliance PowerShell

Create a search permissions filter with New-ComplianceSecurityFilter

Use the **New-ComplianceSecurityFilter** cmdlet to create a search permissions filter. Here's the basic syntax for this cmdlet:

PowerShell

```
New-ComplianceSecurityFilter -FilterName <name of filter> -Users <user or role group>
-Filters <filter>
```

The following sections describe the parameters for this cmdlet. You need all parameters to create a search permissions filter.

Specify the FilterName parameter

Use the *FilterName* parameter to specify the name of the permissions filter. Use this name to identify a filter when using the **Get-ComplianceSecurityFilter**, **Set-ComplianceSecurityFilter**, and **Remove-ComplianceSecurityFilter** cmdlets.

Specify the Filters parameter

Use the *Filters* parameter to specify the search criteria for the compliance security filter. You can create three different types of filters:

- **Mailbox or OneDrive filtering:** This filter specifies the mailboxes and OneDrive accounts that assigned users (specified by the *Users* parameter) can search. This filter is called a *content location* filter because it defines the content locations that a user can search. The syntax for this filter is **Mailbox_***MailboxPropertyName*, where *MailboxPropertyName* specifies a mailbox property used to scope the mailboxes and OneDrive accounts that can be searched. For example, the mailbox filter `"Mailbox_CustomAttribute10 -eq 'OttawaUsers'"` allows the user assigned this filter to search only the mailboxes and OneDrive accounts that have the value "OttawaUsers" in the CustomAttribute10 property.

  You can use any supported filterable recipient property for the *MailboxPropertyName* property in a mailbox or OneDrive filter. The following table lists four commonly used recipient properties used to create a mailbox or OneDrive filter. The table also includes an example of using the property in a filter.

Expand table

Property name	Example
Alias	`"Mailbox_Alias -like 'v-'"`
Company	`"Mailbox_Company -eq 'Contoso'"`
CountryOrRegion	`"Mailbox_CountryOrRegion -eq 'United States'"`
Department	`"Mailbox_Department -eq 'Finance'"`

> **Note**
>
> The Mailbox filter applies to user and group mailboxes. The filter also includes the associated OneDrive site for the user mailbox and SharePoint sites associated to the group mailbox.

- **Mailbox content filtering:** This filter applies to the content that can be searched. This filter is called a *content filter* because it specifies the mailbox content or searchable email properties the assigned users can search for. The syntax for this filter is **MailboxContent_**_SearchablePropertyName_, where *SearchablePropertyName* specifies a Keyword Query Language (KeyQL) property that can be specified in a search. For example, the mailbox content filter `"MailboxContent_Recipients -like 'contoso.com'"` allows the user assigned this filter to only search for messages sent to recipients in the contoso.com domain. For a list of searchable email properties, see Keyword queries and search conditions for eDiscovery.

  > **Important**
  >
  > Within a *single component* of the `Filters` parameter, you can't mix a mailbox filter and a mailbox content filter (for example, you can't combine `Mailbox_*` and `MailboxContent_*` together with `-and` inside one quoted string). To combine these types in a single security filter, put each in its own component of a **filters list that combines filter types** — separate them with a comma. A single component can contain a more complex query of the *same* type — for example, `"Mailbox_CustomAttribute10 -eq 'FTE' -and Mailbox_MemberOfGroup -eq '$($DG.DistinguishedName)'"`.

- **Site and site content filtering:** You can use two SharePoint- and OneDrive-related filters to specify what site or site content the assigned users can search.
  - **Site**_*QueryableSiteProperty*
  - **SiteContent**_*QueryableSiteProperty*

  These two filters are interchangeable. For example, `"Site_Path -like 'https://contoso.sharepoint.com/sites/doctors'"` and `"SiteContent_Path -like 'https://contoso.sharepoint.com/sites/doctors'"` return the same results. For a list of searchable site properties, see Keyword queries and search conditions for eDiscovery. For a more complete list, see Overview of crawled and managed properties in SharePoint. Properties marked with a **Yes** in the **Queryable** column can be used to create a site or site content filter.

  > **ⓘ Important**
  >
  > Setting up a site filter with one of the supported properties doesn't mean the site property in the filter propagates to all documents on that site. This condition means the user is still responsible for populating the specific property fields associated with the documents on that site in order for the site filter to work and capture the right content. For example, if the user has a security filter "Site_RefineableString00 -eq 'abc'" applied and then the user runs a search using keyword query "xyz". The security filter gets appended to the query and the actual query running would be "xyz **AND RefineableString0:'abc'**". The user needs to ensure that documents on the site have values in the RefineableString00 field as "abc". If not, the search query won't return any results.

Keep the following considerations in mind when configuring the *Filters* parameter for search permissions filters:

- Unlike mailboxes, there isn't a content location filter for sites even though the *Site* filter looks like a location filter. All filters for SharePoint and OneDrive are content filters (which is also why *Site_* and *SiteContent_* filters are interchangeable) because site-related properties like *Path* are stamped directly on the documents. This design is a result of the way that SharePoint is designed. In SharePoint, there isn't a "site object" with properties, like there is with Exchange mailboxes. Therefore, the *Path* property is stamped on the document and contains the URL of the site where the document is located. This design is why a *Site* filter is considered a content filter and not a content location filter.

- You have to create a search permissions filter to explicitly prevent users from searching content locations in a specific service (such as preventing a user from searching any Exchange mailbox or any SharePoint site). In other words, creating a search permissions filter that allows a user to search all SharePoint sites in the organization doesn't prevent that user from searching mailboxes. For example, to allow SharePoint admins to only search SharePoint sites, you have to create a filter that prevents them from searching mailboxes. Similarly, to allow Exchange admins to only search mailboxes, you have to create a filter that prevents them from searching sites.

Specify the Users parameter

Use the *Users* parameter to specify the users who get the filter applied to their searches. Identify users by their alias or primary SMTP address. You can specify multiple values separated by commas, or you can assign the filter to all users by using the value **All**.

Use the *User* parameter to specify a Microsoft Purview portal role group. This approach lets you create a custom role group and then assign that role group a search permissions filter. For example, suppose you have a custom role group for eDiscovery managers for the U.S. subsidiary of a multinational corporation. You can use the *Users* parameter to specify this role group (by using the Name property of the role group) and then use the *Filter* parameter to allow only mailboxes in the U.S. to be searched. You can't specify distribution groups with this parameter.

Use a filters list to combine filter types

A *filters list* is a `Filters` value that contains more than one filter component, with the components separated by commas. A single security filter can mix two different content-location filters (`Mailbox_*` and `Site_*`), or it can mix a content-location filter with a content filter on the same workload (`Mailbox_*` plus `MailboxContent_*`, or `Site_*` plus `SiteContent_*`). Each component is a separate quoted string in the `Filters` parameter.

PowerShell

```
-Filters "Mailbox_CustomAttribute10 -eq 'OttawaUsers'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/doctors'"
```

How a filters list composes depends on the **classes** of the components. There are two filter classes:

- **Content-location filters** — `Mailbox_*` and `Site_*`. These filters define *which* content locations the assigned user can search.

- **Content filters** — `MailboxContent_*` and `SiteContent_*`. These filters define *what* content can be returned from the locations allowed by the corresponding location filter.

The composition rules are:

Expand table

Components in the filters list	Logical composition
Two content-location filters for different workloads (`Mailbox_*` and `Site_*`)	**OR** across workloads. The user is granted access to mailboxes matching the `Mailbox_*` predicate *or* sites matching the `Site_*` predicate. This composition is the original "comma = OR" behavior described in earlier versions of this article.
A content-location filter and a content filter for the *same* workload (`Mailbox_*` plus `MailboxContent_*`, or `Site_*` plus `SiteContent_*`)	**Layered AND**. The location filter narrows which content locations are searchable, and the content filter further restricts which items can be returned from those locations. Both conditions must be satisfied for an item to be returned.
Multiple components of the *same* class (for example, two `Mailbox_*` components, or two `MailboxContent_*` components)	**OR** within the class. Multiple mailbox rules combine to expand the allowed location set; multiple mailbox-content rules combine to expand the allowed content set. The combined content set is then AND'd with the user's search query (see How does search permissions filtering work?).

The preceding example contains a `Mailbox_*` filter and a `SiteContent_*` filter - two location filters for different workloads - so the comma is OR (mailboxes matching the first predicate *or* SharePoint content matching the second).

Compare that composition to the following example, which contains a `Mailbox_*` location filter and a `MailboxContent_*` content filter for the same workload - the comma here is a layered AND (mailboxes that are members of the group *and*, within those mailboxes, only items that aren't Microsoft 365 Copilot interactions):

PowerShell

```
-Filters "Mailbox_MemberOfGroup -eq 'CN=Litigation Hold
Group,OU=Groups,DC=contoso,DC=com'", "MailboxContent_ItemClass -notlike
'IPM.SkypeTeams.Message.Copilot*'"
```

An alternative to using a filters list is to create two separate search permissions filters and assign them to the same user - the behavior described in How does search permissions filtering work? applies (multiple security filters are OR'd together at evaluation time). When the two components fall into different *classes* (location vs. content), the filters list and the two-separate-filters

approaches are *not* equivalent - prefer the filters list to keep the layered AND semantics within a single filter.

Keep the following things in mind about using a filters list:

- You must use a filters list to create a filter that includes a `Mailbox` filter and a `MailboxContent` filter (or a `Site` filter and a `SiteContent` filter). Within a single quoted component, you can't combine the two classes with `-and`.
- Each component of a filters list can contain a complex filter syntax. For example, the mailbox and site filters can contain multiple filters separated by an **-or** operator:

  PowerShell

  ```
  -Filters "Mailbox_Department -eq 'CohoWinery' -or Mailbox_CustomAttribute10 -eq 'CohoUsers'", "SiteContent_Path -like 'https://contoso.sharepoint.com/sites/CohoWinery*'"
  ```

Examples of creating search permissions filters

The following examples show how to use the **New-ComplianceSecurityFilter** cmdlet to create a search permissions filter.

The first example enables members of the "US Discovery Managers" role group to search only the mailboxes and OneDrive accounts in the United States.

PowerShell

```
New-ComplianceSecurityFilter -FilterName USDiscoveryManagers  -Users "US Discovery Managers" -Filters "Mailbox_CountryOrRegion  -eq 'United States'"
```

The second example enables the user annb@contoso.com to perform search actions only for mailboxes and OneDrive accounts in Canada. This filter contains the three-digit numeric country code for Canada from ISO 3166-1.

PowerShell

```
New-ComplianceSecurityFilter -FilterName CountryFilter  -Users annb@contoso.com -Filters "Mailbox_CountryCode  -eq '124'"
```

The third example enables the users *donh* and *suzanf* to search only the mailboxes and OneDrive accounts that have the value 'Marketing' for the CustomAttribute1 mailbox property.

PowerShell

```
New-ComplianceSecurityFilter -FilterName MarketingFilter  -Users donh,suzanf -Filters
"Mailbox_CustomAttribute1  -eq 'Marketing'"
```

The fourth example enables members of the "Fourth Coffee eDiscovery Managers" role group to search only the mailboxes and OneDrive accounts that have the value 'FourthCoffee' for the Department mailbox property. The filter also enables the role group members to search for documents in the Fourth Coffee SharePoint site.

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Fourth Coffee Security Filter" -Users
"Fourth Coffee eDiscovery Managers", "Fourth Coffee Investigators" -Filters
"Mailbox_Department -eq 'FourthCoffee'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/FourthCoffee*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'"
```

> **Note**
>
> In the previous example, you need to include an additional site content filter (`SiteContent_Path -like 'https://contoso-my.sharepoint.com/personal*'`) so that role group members can search for documents in OneDrive accounts. If you don't include this filter, the filter only enables role group members to search for documents located in `https://contoso.sharepoint.com/sites/FourthCoffee`.

The fifth example enables members of the eDiscovery Manager role group to search only the mailboxes and OneDrive accounts of members of the Ottawa Users distribution group. The `Get-DistributionGroup` cmdlet in Exchange Online PowerShell is used to find the members of the Ottawa Users group.

PowerShell

```
$DG = Get-DistributionGroup "Ottawa Users"
```

PowerShell

```
New-ComplianceSecurityFilter -FilterName DGFilter  -Users eDiscoveryManager -Filters
"Mailbox_MemberOfGroup -eq '$($DG.DistinguishedName)'"
```

The sixth example prevents any user from performing search actions on the mailboxes and OneDrive accounts of members of the Executive Team distribution group. That means users can delete content from these mailboxes. The `Get-DistributionGroup` cmdlet in Exchange Online PowerShell is used to find the members of the Executive Team group.

PowerShell

```
$DG = Get-DistributionGroup "Executive Team"
```

PowerShell

```
New-ComplianceSecurityFilter -FilterName NoExecutivesPreview  -Users All -Filters
"Mailbox_MemberOfGroup -ne '$($DG.DistinguishedName)'"
```

The seventh example enables members of the OneDrive eDiscovery Managers custom role group to only search for content in OneDrive accounts in the organization.

PowerShell

```
New-ComplianceSecurityFilter -FilterName OneDriveOnly  -Users "OneDrive eDiscovery
Managers" -Filters "SiteContent_Path -like 'https://contoso-
my.sharepoint.com/personal*'"
```

The eighth example restricts the user to performing search actions only on email messages sent during the calendar year 2015.

PowerShell

```
New-ComplianceSecurityFilter -FilterName EmailDateRestrictionFilter -Users
donh@contoso.com -Filters "MailboxContent_Received -ge '01-01-2015' -and
MailboxContent_Received -le '12-31-2015'"
```

Similar to the previous example, the ninth example restricts the user to performing search actions only on documents that were last changed sometime in the calendar year 2015.

PowerShell

```
New-ComplianceSecurityFilter -FilterName DocumentDateRestrictionFilter -Users
donh@contoso.com -Filters "SiteContent_LastModifiedTime -ge '01-01-2015' -and
SiteContent_LastModifiedTime -le '12-31-2015'"
```

The tenth example prevents members of the "OneDrive Discovery Managers" role group from performing search actions on any mailbox in the organization.

PowerShell

```
New-ComplianceSecurityFilter -FilterName NoEXO -Users "OneDrive Discovery Managers" -
Filters "Mailbox_Alias -notlike '*'"
```

The eleventh example prevents anyone in the organization from performing search actions on email messages that were sent or received by janets or sarad.

PowerShell

```
New-ComplianceSecurityFilter -FilterName NoSaraJanet -Users All -Filters
"MailboxContent_Participants -notlike 'janets@contoso.onmicrosoft.com' -and
MailboxContent_Participants -notlike 'sarad@contoso.onmicrosoft.com'"
```

The twelfth example uses a filters list to combine mailbox and site filters. In this example, the mailbox filter is a content location filter and the site filter is a content filter.

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Security Filter" -Users "Coho
Winery eDiscovery Managers", "Coho Winery Investigators" -Filters "Mailbox_Department
-eq 'CohoWinery'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/CohoWinery*'"
```

View search permissions filters with Get-ComplianceSecurityFilter

Use **Get-ComplianceSecurityFilter** to return a list of search permissions filters. Use the *FilterName* parameter to return information for a specific search filter.

Modify a search permissions filter with Set-ComplianceSecurityFilter

Use **Set-ComplianceSecurityFilter** to modify an existing search permissions filter. The following sections describe the parameters for this cmdlet. The only required parameter is *FilterName*.

FilterName

Use the *FilterName* parameter to specify the name of the permissions filter.

Users

Use the *Users* parameter to specify the users who get this filter applied to their searches. Because this parameter is a multivalue property, specifying a user or group of users overwrites the existing list of users. See the following examples for the syntax to add and remove selected users.

You can also use the *Users* parameter to specify a Microsoft Purview portal role group. This role group lets you create a custom role group and then assign that role group a search permissions filter. For example, suppose you have a custom role group for eDiscovery managers for the U.S. subsidiary of a multinational corporation. Use the *Users* parameter to specify this role group (by using the Name property of the role group) and then use the *Filters* parameter to allow only mailboxes in the U.S. to be searched. You can't specify distribution groups with this parameter.

Filters

Use the *Filters* parameter to specify the search criteria for the compliance security filter. You can create three different types of filters:

- **Mailbox and OneDrive filtering:** This filter specifies the mailboxes and OneDrive accounts that assigned users (specified by the *Users* parameter) can search. The syntax for this filter is **Mailbox**_ *MailboxPropertyName*. The *MailboxPropertyName* specifies a mailbox property used to scope the mailboxes that can be searched. For example, the mailbox filter `"Mailbox_CustomAttribute10 -eq 'OttawaUsers'"` allows the user assigned this filter to search only the mailboxes that have the value "OttawaUsers" in the CustomAttribute10 property. For the *MailboxPropertyName* property, you can use any supported filterable recipient property. For a list of supported properties, see Filterable properties for the -RecipientFilter parameter.

- **Mailbox content filtering:** This filter applies to the content that can be searched. It specifies the mailbox content that assigned users can search. The syntax for this filter is **MailboxContent**_*SearchablePropertyName*. The *SearchablePropertyName* specifies a Keyword Query Language (KQL) property that you can specify in a search. For example, the mailbox content filter `"MailboxContent_Recipients -like 'contoso.com'"` allows the user assigned this filter to only search for messages sent to recipients in the contoso.com domain. For a list of searchable email properties, see Use the condition builder to create search queries in eDiscovery.

- **Site and site content filtering:** Use two SharePoint and OneDrive for Business site-related filters to specify what site or site content the assigned users can search:
  - **Site**_ *SearchableSiteProperty*
  - **SiteContent**_*SearchableSiteProperty*

These two filters are interchangeable. For example, `"Site_Path -like 'https://contoso.spoppe.com/sites/doctors*'"` and `"SiteContent_Path -like 'https://contoso.spoppe.com/sites/doctors*'"` return the same results. For a list of searchable site properties, see Overview of crawled and managed properties in SharePoint. Properties marked with a **Yes** in the **Queryable** column can be used to create a site or site content filter.

Examples of changing search permissions filters

These examples show how to use the **Get-ComplianceSecurityFilter** and **Set-ComplianceSecurityFilter** cmdlets to add or remove a user from the existing list of users that the filter is assigned to. When you add or remove users from a filter, specify the user by using their SMTP address.

This example adds a user to the filter.

PowerShell

```
$filterusers = Get-ComplianceSecurityFilter -FilterName OttawaUsersFilter
```

PowerShell

```
$filterusers.users.add("pilarp@contoso.com")
```

PowerShell

```
Set-ComplianceSecurityFilter -FilterName OttawaUsersFilter -Users $filterusers.users
```

This example removes a user from the filter.

PowerShell

```
$filterusers = Get-ComplianceSecurityFilter -FilterName OttawaUsersFilter
```

PowerShell

```
$filterusers.users.remove("annb@contoso.com")
```

PowerShell

```
Set-ComplianceSecurityFilter -FilterName OttawaUsersFilter -Users $filterusers.users
```

Remove a search permissions filter with Remove-ComplianceSecurityFilter

Use the **Remove-ComplianceSecurityFilter** cmdlet to delete a search filter. Use the *FilterName* parameter to specify the filter you want to delete.

Additional considerations for search permissions filtering

How does search permissions filtering work? When you run a search, the permissions filter is added to the search query. The **AND** Boolean operator connects the permissions filter to the search query. The query logic for the search query and the permissions filter looks like this:

```
text
<SearchQuery> AND <PermissionsFilter>
```

For example, you have a permissions filter that allows Bob to perform all search actions on the mailboxes of members of the Workers distribution group. Then Bob runs a search on all mailboxes in the organization with the search query `sender:jerry@adatum.com`. Because the permissions filter and the search query are logically combined by an **AND** operator, the search returns any message sent by jerry@adatum.com to any member of the Workers distribution group.

What happens if you have multiple search permissions filters? In a search query, multiple permissions filters are combined by **OR** Boolean operators. So results are returned if any of the filters are true. In a search, all filters (combined by **OR** operators) are then combined with the search query by the **AND** operator.

```
text
<SearchQuery> AND  (<PermissionsFilter1> OR <PermissionsFilter2> OR
<PermissionsFilter3>)
```

Let's take the previous example, where a search filter allows Bob to search only the mailboxes of the members of the Workers distribution group. Then we create another filter that prevents Bob from searching Phil's mailbox ("Mailbox_Alias -ne 'Phil'"). And let's also assume that Phil is a member of the Workers group. When Bob runs a search (from the previous example) on all mailboxes in the organization, search results are returned for Phil's mailbox even though you

applied filter to prevent Bob from searching Phil's mailbox. This is because the first filter, which allows Bob to search the Workers group, is true. And because Phil is a member of the Workers group, Bob can search Phil's mailbox.

How are filter components within a single security filter combined? Filters within a single security filter are evaluated in two layers:

1. **Mailbox filters first.** All `Mailbox_*` components in the filter are evaluated and combined with **OR** to produce the set of allowed mailbox locations. If multiple `Mailbox_*` rules are present (whether across components of a filters list or within a single component using `-or`), they combine as OR to expand the location set.
2. **Mailbox content filters next, scoped to those locations.** All `MailboxContent_*` components are then applied to content within the allowed mailbox locations from step 1. If multiple `MailboxContent_*` rules are present, they combine with **OR**. The combined `MailboxContent_*` predicate is then **AND**'d to the user's search query.

The same two-layer model applies to SharePoint and OneDrive: `Site_*` location filters compose with OR to define the allowed sites, and `SiteContent_*` filters compose with OR and are then AND'd to the user's search query, scoped to those sites.

```text
(<MailboxRule1> OR <MailboxRule2> ...)           // Layer 1: location scope
  AND
((<MailboxContentRule1> OR <MailboxContentRule2> ...) AND <SearchQuery>)   // Layer 2:
content
```

For example, the filter `-Filters "Mailbox_MemberOfGroup -eq 'CN=Litigation Hold Group,...'", "MailboxContent_ItemClass -notlike 'IPM.SkypeTeams.Message.Copilot*'"` means: only mailboxes that are members of the group are searchable, and within those mailboxes, the user can return any item *except* Microsoft 365 Copilot interactions. Items that match the user's search query, are in an allowed mailbox, and pass the content filter are returned.

Does search permissions filtering work for inactive mailboxes? Yes, you can use mailbox and mailbox content filters to limit who can search inactive mailboxes in your organization. Like a regular mailbox, an inactive mailbox must be configured with the recipient property that's used to create a permissions filter. If necessary, you can use the **Get-Mailbox -InactiveMailboxOnly** command to display the properties of inactive mailboxes. For more information, see Create and manage inactive mailboxes.

Does search permissions filtering work for public folders? No. Search permissions filtering can't be used to limit who can search public folders in Exchange. For example, items in public folder locations can't be excluded from the search results by a permissions filter.

Does allowing a user to search all content locations in a specific service also prevent them from searching content locations in a different service? No. You have to create a search permissions filter to explicitly prevent users from searching content locations in a specific service (such as preventing a user from searching any Exchange mailbox or any SharePoint site). In other words, creating a search permissions filter that allows a user to search all SharePoint sites in the organization doesn't prevent that user from searching mailboxes. For example, to allow SharePoint admins to only search SharePoint sites, you have to create a filter that prevents them from searching mailboxes. Similarly, to allow Exchange admins to only search mailboxes, you have to create a filter that prevents them from searching sites.

Do search permissions filters count against search query character limits? Yes. Search permissions filters count against the character limit for search queries. For more information, see Limits in eDiscovery.

What is the maximum number of search permissions filters that can be created in an organization?

There's no limit to the number of search permissions filters that can be created in an organization. However, a search query can have a maximum of 100 conditions. In this case, a condition is defined as something that's connected to the query by a Boolean operator (such as **AND**, **OR**, and **NEAR**). The limit of the number of conditions includes the search query itself plus all search permissions filters that are applied to the user who runs the search. Therefore, the more search permissions filters you have (especially if these filters are applied to the same user or group of users), the better the chance of exceeding the maximum number of conditions for a search.

To understand how this limit works, you need to understand that a search permissions filter is appended to the search query when a search is run. A search permissions filter is joined to the search query by the **AND** Boolean operator. The query logic for the search query and a single search permissions filter looks like this:

```text
<SearchQuery> AND <PermissionsFilter>
```

Multiple search permissions filters are combined together by the **OR** Boolean operator, and then those conditions are connected to the search query by the **AND** operator.

The query logic for the search query and multiple search permissions filters looks like this:

text

```
<SearchQuery> AND (<PermissionsFilter1> OR <PermissionsFilter2> OR
<PermissionsFilter3>...)
```

It's possible the search query itself might consist of multiple conditions connected by Boolean operators. Each condition in the search query also counts against the 100-condition limit.

Also, the number of search permissions filters appended to a query depends on the user who is running the search. When a specific user runs a search, the search permissions filters that are applied to the user (which is defined by the *Users* parameter in the filter) are appended to the query. Your organization could have hundreds of search permissions filters, but if more than 100 filters are applied to the same users, then it's likely the 100-condition limit is exceeded when those users run searches.

There's one more thing to keep in mind about the condition limit. The number of specific SharePoint sites that are included in the search query or search permissions filters also count against this limit.

To prevent your organization from reaching the conditions limit, keep the number of search permissions filters in your organization as few as possible to meet your business requirements.

Cloud attachments in eDiscovery

Summarize this article for me

This article explains how eDiscovery handles cloud (modern or linked) attachments versus traditional (classic) attachments. Cloud attachments are links to files stored in SharePoint or OneDrive rather than embedded copies. Because a cloud attachment points to a live file stored in Microsoft 365 services that you can modify after sharing, eDiscovery offers options to collect the live file, the version that you shared, or multiple versions to preserve context. You can collect cloud attachments as part of the export or add to review set workflow.

Collect cloud attachments

eDiscovery supports the following options for the collection of modern attachments:

- Live version of the linked document at the moment of collection.
- Version at the time of sharing.
- Other version options (collect all versions or specific shared versions).

Regardless of the location of the modern attachment, the process attributes the *Custodian* property to the owner of the message. For example, if User A shares a linked attachment with User B that resides in User C's OneDrive and you collect the message from User B's mailbox, the linked attachment belongs to User B (custodian) and not User C.

To enable the collection of cloud attachments, select the **Access links (cloud attachments) in messages** option so linked content is included in Add to review set and export workflows.

> **Important**
>
> Including attachments increases the size and quantity of export results.

Once the workflow processes completes, you can group the modern attachment and parent message or email together by using **Group by conversations and related items** filter and the **Is modern attachment** column value.

Considerations and unsupported scenarios

Before collecting cloud attachments, review the following considerations and scenarios:

- Plain text emails aren't supported. Only HTML emails are processed.
- Encrypted emails and messages don't support modern attachment extraction.

- Non-clickable links aren't supported. Links that aren't clickable aren't processed. Most links in emails are rewritten to clickable safelinks by the Exchange backends for opt-in tenants.
- Malformed URLs aren't supported. URLs that don't parse correctly aren't stamped.
- Maximum message body length. If the body length is greater than 100,000 characters, any content (modern attachment link) beyond this limit isn't considered.
- Maximum URL length. URLs longer than 2,048 characters are skipped.
- Maximum total property size. If the total property size exceeds 1 MB, it's dropped.
- Maximum number of links per message. Only the first 50 links in a message are processed. Other links beyond 50 are ignored.
- If a message is forwarded and the modern attachment link is expired or stale, the extraction doesn't work. Similarly, if the modern attachment file is renamed or moved, the link isn't extracted.
- Cloud attachment links in forwarded or replied emails aren't extracted from the quoted portion of the original message. Only the original email retains the cloud attachment association. If you need to collect a cloud attachment that was shared in the original email, search for and collect the original message rather than a forward or reply.
- Teams shared channel messages and posts don't support modern attachment link extraction. Users need to include the shared channel site and include the file manually as part of their collection.
- Cloud attachments are treated as part of the parent's message, not separate entities.
  - If an email or Teams message matches the condition of a search, its linked cloud attachments are retrieved - even if the file doesn't meet the condition of the search.
  - If an email or Teams message matches the condition of a search, its linked cloud attachments are retrieved - even if the file resides outside the compliance boundary.
- Advanced indexing isn't applied to cloud attachment files referenced within emails or messages. This limitation means the content of the cloud attachment file itself isn't processed by advanced indexing or OCR.

Collecting the version shared in cloud attachments

By default, the eDiscovery workflow for collecting cloud attachments only includes adding the most current version of a cloud attachment to a review set or for export. This workflow means the version you collect and add to a review set or export might be different from the version that was originally shared in the cloud attachment. So, content that was present in the cloud attachment at the time it was shared might be removed and doesn't exist in the current version that's added to the review set or exported.

Use retention labels to preserve the version of a document at the time when it was shared as a cloud attachment. To do this, create a retention label, choose the option to apply the label to cloud attachments, and then automatically apply the label to documents stored in SharePoint

and OneDrive. After you set up this configuration, a copy of a document is created at the time when the file is shared. Also, if the document is modified and shared again as a cloud attachment, the modified version is also preserved. If the file is modified and shared again, a new copy of the file as a new version is preserved.

Preserving the shared versions of cloud attachments helps you scope the preservation and collection of potentially relevant content to the specific version of the document that you shared rather than the current live version. After you implement this retention solution, both the current live version of a cloud attachment and the version that you shared in the cloud attachment are collected and added to a review set or exported.

For instructions on setting up a retention label and automatically applying it to cloud attachments, see Auto-apply labels to cloud attachments.

Additionally, the current live version and the version that you shared have the same **GroupID** property value, which is the same as the **GroupID** for the parent object (such as an email message or a Teams chat conversation). This property value lets you group cloud attachments with the item in which you shared them.

After you implement the retention label and auto-apply the label to SharePoint documents, select the option to collect cloud attachments when adding items to a review set. When you collect the cloud attachments, both the current live version and the version that was originally shared are added to the review set or exported.

View in eDiscovery reports

eDiscovery includes a Process manager that lists all processes scoped for each area. Each process in the Process manager list contains a detailed report .zip file that contains detailed information about the process once the process completes.

Summary CSV report

All reporting packages include a `Summary-*the date/time of the report*.csv` file. This file includes information related to cloud attachments. This report includes information about the following items:

- Cloud attachments
- Cloud attachments versions
- Cloud attachment versions at time of sharing

For more information about these areas, see Summary CSV: Information.

Items CSV report

Reporting packages also include an Items CSV report. In the `items.csv` file, you can:

- Filter on all modern attachments by using the property **Is modern attachment** = `True`.
- Correlate modern attachment with its parent email or message through group ID and the property **Has attachment** = `True`.

Double-byte character language support in eDiscovery

eDiscovery supports double-byte character set languages (these include Simplified Chinese, Traditional Chinese, Japanese, and Korean, which are collectively known as *CJK* languages) for the following scenarios in a review set:

- When you search for data.
- When you tag documents.
- When you analyze case data using near duplicate detection, email threading, and themes analytics.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Limitations for CJK characters

The following features for CJK characters aren't currently supported in eDiscovery:

- Detecting CJK characters in file metadata.
- Filtering, sorting, or searching by document languages in a review set.
- Optical Character Recognition (OCR) for image files.
- Email files (such as *.eml and *.msg) in Annotate view.
- Search hit highlighting in Text view.
- Query-based holds for cases.
- The Relevance module used to analyze data.

Search for items containing CJK characters

You can use CJK characters when searching for content in eDiscovery. CJK characters are supported for all search operators and search conditions, including the Boolean operators **AND**, **OR**, **NOT**, and **NEAR**.

If you're certain that content locations or items contain CJK characters, but searches don't return any results, select the query language-country/region icon and select the corresponding language-country/region culture code value for the search. The default language/region is neutral.

When searching for phrases in CJK languages, break the phrase into individual words or characters and combine them using the AND operator. CJK phrases aren't natively recognized as single searchable units, so this approach helps to ensure more accurate search results. For example, instead of searching for `(SubjectTitle:Teamsのチャットメッセージ)`, use `(SubjectTitle:Teams) AND (SubjectTitle:の) AND (SubjectTitle:チャット) AND (SubjectTitle:メッセージ)`.

Search multiple languages at the same time

How you search multiple languages at the same time depends on your search scenario.

- When you query data in a review set with premium eDiscovery features enabled, you can search for multiple languages. For review set queries, you don't need to specify a document language. eDiscovery automatically detects document languages when you add content to a review set. This detection helps you optimize your query results in a review set.
- When you create a search to collect data, create separate searches for each language you're targeting. For example, if you're searching for a document that contains both Chinese and Korean, select Chinese for your first search and select Korean for your second search.

Changing your display language to Chinese, Japanese, or Korean

For information about how to change display language and time zone, see How to set language and region settings for Office 365.

Use Microsoft Purview APIs for eDiscovery

The Microsoft Purview Application Programming Interface (API) for eDiscovery in Microsoft Graph enables your organization to automate repetitive tasks and integrate with your existing eDiscovery tools to build repeatable workflows that industry regulations might require. This article provides guidance on how to configure the required prerequisites to enable access to the Microsoft Purview APIs for eDiscovery. This guidance is based on using app-only access to the APIs, with either a client secret or a self-signed certificate to authenticate the requests.

Microsoft Purview APIs

The Microsoft Purview APIs for eDiscovery include two separate APIs:

- **Microsoft Graph**: Part of the `Microsoft.Graph.Security` namespace and used for working with eDiscovery cases.
- **Microsoft Purview eDiscovery API**: Used exclusively to programmatically download packages created when exporting from searches and review sets in eDiscovery.

eDiscovery APIs in Microsoft Graph support eDiscovery cases with and without premium features enabled. Delegated authentication supports core eDiscovery capabilities such as cases, holds, searches, and exports. App-only authentication is available for cases with premium features enabled and supports advanced operations such as review sets, tagging, and analytics.

For a list of supported API calls within the Microsoft Graph calls, see Use the Microsoft Purview eDiscovery API.

Application access to data

Before you can make any calls to the Microsoft Purview APIs for eDiscovery, you must first register an app in the Microsoft Identity Platform, Entra ID.

An application can access data in two ways:

- **Delegated access**: An app acting on behalf of a signed-in user.
- **App-only access**: An app acting with its own identity.

For more information about access scenarios, see Authentication and authorization basics.

> **Important**
>
> App-only authentication requires an eDiscovery case with premium features enabled. Delegated authentication is available for **core eDiscovery capabilities** including cases, legal holds, searches, and exports. Premium API operations (review sets, tagging, analytics) require premium features enabled regardless of authentication method. For more information about subscription requirements, see **subscription requirements for eDiscovery**.

Microsoft Graph API

Prerequisites for Microsoft Graph API

Implementing app-only accessinvolves registering an app in Azure portal, creating client secret/certificates, assigning API permissions, setting up a service principal, and then using app-only access to call Microsoft Graph APIs. To register an app, create client secret/certificates and assign API permissions the account must be a *Cloud Application Administrator*.

For more information about registering an app in the Azure portal, see Register an application with the Microsoft identity platform.

Granting tenant-wide admin consent for Microsoft Purview eDiscovery API application permissions requires you to sign in as a user that is authorized to consent on behalf of your organization. For more information, see Grant tenant-wide admin consent to an application.

Setting up a service principal requires the following prerequisites:

- A machine with the ExchangeOnlineManagement module installed.
- An account that has the *Role Management* role assigned in Microsoft Purview.

For detailed steps on implementing app-only access for eDiscovery, see Set up app-only access for Microsoft Purview eDiscovery.

Connecting to Microsoft Graph API using app-only access

Use the Connect-MgGraph cmdlet in PowerShell to authenticate and connect to Microsoft Graph using the app-only access method. This cmdlet enables your app to interact with Microsoft Graph securely and enables you to explore the Microsoft Purview eDiscovery APIs.

Connecting via client secret

To connect using a client secret, update and run the following example PowerShell code.

PowerShell

```
$clientSecret = "<client secret>" ## Update with client secret added to the registered
app
$appID = "<APP ID>" ## Update with Application ID of registered/Enterprise app
$tenantId = "<Tenant ID>" ## Update with tenant ID
$ClientSecretPW = ConvertTo-SecureString "$clientSecret" -AsPlainText -Force
$clientSecretCred = New-Object System.Management.Automation.PSCredential -ArgumentList
("$appID", $clientSecretPW)
Connect-MgGraph -TenantId "$tenantId" -ClientSecretCredential $clientSecretCred
```

Connecting via certificate

To connect using a certificate, update and run the following example PowerShell code.

PowerShell

```
$certPath = "Cert:\currentuser\my\<xxxxxxxxxx>" ## Update with the cert thumbnail
$appID = "<APP ID>" ## Update with Application ID of registered/Enterprise app
$tenantId = "<Tenant ID>" ## Update with tenant ID
$ClientCert = Get-ChildItem $certPath
Connect-MgGraph -TenantId $TenantId -ClientId $appId -Certificate $ClientCert
```

Invoke Microsoft Graph API calls

After you connect, you can start making calls to the Microsoft Graph API.

For example, you can list the eDiscovery cases within the tenant by using the ediscoveryCases API. The guidance for each operation lists the following information:

- Permissions required to make the API call
- HTTP request and method
- Request header and body information
- Response
- Examples (HTTP, C#, CLI, Go, Java, PHP, PowerShell, Python)

Because you're connected through the Microsoft Graph PowerShell module, you can use either the HTTP or PowerShell method.

First, let's look at the PowerShell example.

```
PS C:\Users        Get-MgSecurityCaseEdiscoveryCase

CreatedDateTime     Description                                DisplayName                          Id
---------------     -----------                                -----------                          --

```

As you can see, it returns a list of all the cases within the tenant. When delving deeper into a case, it's important to record the case *ID*. You need this ID for future API calls.

Now, let's look at an HTTP example. You use the Invoke-MgGraphRequest cmdlet to make the call by using PowerShell.

First, store the URL in a variable:

```
$uri = "https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases"
```

Then use the Invoke-MgGraphRequest cmdlet to make the API call.

PowerShell

```
Invoke-MgGraphRequest -Method Get -Uri $uri
```

As you can see from the following output, you need to extract the values from the returned response.

```
PS C:\Users        $uri = "https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases"
PS C:\Users        Invoke-MgGraphRequest -Method Get -Uri $uri

Name                           Value
----                           -----
@odata.context                 https://graph.microsoft.com/v1.0/$metadata#security/cases/ediscoveryCases
@odata.count                   27
value                          {System.Collections.Hashtable, System.Collections.Hashtable, System.Collections.Hashtable, System.Collections.Hashtable...}
```

You can save the *Value* elements of the response to a new variable by using the following command.

PowerShell

```
$cases = (Invoke-MgGraphRequest -Method Get -Uri $uri).value
```

```
PS C:\Users [redacted]  $cases = (Invoke-MgGraphRequest -Method Get -Uri $uri).value
PS C:\Users [redacted]  $cases.count
27
PS C:\Users [redacted]  $cases | Get-Member

This command returns a collection of hash tables. Optionally, you can run a small bit of PowerShell code to convert the hash tables into PowerShell objects for easier use with cmdlet

parameters such as *format-table* and *format-list*.

PowerShell

```
$CasesAsObjects = @()
foreach($i in $cases) {$CasesAsObjects += [pscustomobject]$i}
$CasesAsObjects | ft displayname,id,status
```

```
PS C:\Users      $CasesAsObjects = @()
PS C:\Users      foreach($i in $cases) {$CasesAsObjects += [pscustomobject]$i}
PS C:\Users      $CasesAsObjects | ft displayname,id,status

displayName                          id                                   status

```

Microsoft Purview eDiscovery API

You can configure the Microsoft Purview eDiscovery API to enable the programmatic download of export packages and the reports from an export process in an eDiscovery case.

Prerequisites for Microsoft Purview eDiscovery API

Before you execute the configuration steps in this section, complete and validate the configuration detailed in the Microsoft Graph API section. Extend the previously registered app in Microsoft Entra ID to include the required permissions to achieve programmatic download of the export package.

This configuration already provides the following prerequisites:

- Registered app in Azure portal configured with the appropriate client secret or certificate.
- Service principal in Microsoft Purview assigned the relevant eDiscovery roles.
- Microsoft eDiscovery API permissions configured for the Microsoft Graph.

To extend the existing registered app's API permissions to enable programmatic download, complete the following steps:

- Register a new Microsoft Application and service principal in the tenant.
- Assign additional API permissions to the previously registered app in the Azure portal.

To grant tenant-wide admin consent for Microsoft Purview eDiscovery APIs application permissions, sign in as a user that is authorized to consent on behalf of the organization. For more information, see Grant tenant-wide admin consent to an application.

Configuration steps

Step 1: Register the MicrosoftPurviewEDiscovery app in Microsoft Entra ID

Complete the following steps:

1. Validate that the **MicrosoftPurviewEDiscovery** app isn't already registered. Sign in to the Azure portal and go to **Microsoft Entra ID** > **Enterprise Applications**.

2. Change the **Application type** filter to show *Microsoft Applications*.

3. In the search box, enter *MicrosoftPurviewEDiscovery*. The **MicrosoftPurviewEDiscovery** app should be displayed. If the **MicrosoftPurviewEDiscovery** app isn't listed, register the app in Microsoft Entra ID.

   To register the app, complete the following steps:

   - Use the Microsoft.Graph PowerShell Module to register the **MicrosoftPurviewEDiscovery** app in Microsoft Entra ID. For more information, see Install the Microsoft Graph PowerShell SDK.
   - After the module is installed on a machine, run the following cmdlet to connect to Microsoft Graph using PowerShell:

   PowerShell

   ```
   Connect-MgGraph -scopes "Application.ReadWrite.All"
   ```

   If this is the first time using Microsoft Graph PowerShell cmdlets, you might be prompted to consent to required permissions.

   To register the **MicrosoftPurviewEDiscovery** app, run the following PowerShell commands:

PowerShell

```
$spId = @{"AppId" = "b26e684c-5068-4120-a679-64a5d2c909d9" }
```

PowerShell

```
New-MgServicePrincipal -BodyParameter $spId;
```

> **Note**
>
> Use the PowerShell script to register a new application in Microsoft Entra ID and assign the Microsoft Purview eDiscovery API permissions for application authentication if applicable. After you register the application, you need to configure the client secret or certificate and grant admin consent through the portal.

Step 2: Assign additional MicrosoftPurviewEDiscovery permissions to the registered app

Now that the service principal is added, update the permissions on your previously registered app created in the Microsoft Graph API section of this article. Sign in to the Azure portal and go to **Microsoft Entra ID** > **App Registrations**.

1. Find and select the app you created in the Microsoft Graph API section of this article.
2. Select **API Permissions** from the navigation menu.
3. Select **Add a permission** and then **APIs my organization uses**.
4. Search for MicrosoftPurviewEDiscovery and select it.
5. Select **Application Permissions**.
6. Select the check box for **eDiscovery.Download.Read**.
7. Select **Add Permissions**.
8. On **API permissions**, select **Grant Admin Consent (your organization)** to approve the added permissions.

After admin consent is granted, the status of the added permissions is updated for your organization.

Downloading the export packages and reports

Retrieving the case ID and export job ID

To download the export packages and reports of an export process in an eDiscovery case, you need the case ID and the operation or job ID for the export job.

To gather this information by using the Microsoft Purview portal:

- Open an eDiscovery case.
- Locate the export process.
- Select **Copy support information**.
- Add this information into a text editor (like Notepad).

Alternatively, access this information programmatically by using the following Graph API calls to locate the case ID and the job ID you want to export:

1. Connect to Microsoft Graph by following the steps in the Connecting to Microsoft Graph API using app-only access section of this article.

2. Use the eDiscovery Graph PowerShell cmdlets with the following command if you know the case name:

   PowerShell

   ```
   Get-MgSecurityCaseEdiscoveryCase | where {$_.displayname -eq "<Name of case>"}
   ```

3. After you have the case ID, look up the operations in the case to identify the job ID for the export by using the following command:

   PowerShell

   ```
   Get-MgSecurityCaseEdiscoveryCaseOperation -EdiscoveryCaseId "<case ID>"
   ```

Export jobs are logged under an action of *exportResult* for a direct export from search or *ContentExport* for an export from a review set. The name of the export jobs isn't returned by this API call. To find the name of the export process, you must query the specific operation ID. Use the following command to find the name of the export process:

PowerShell

```
Get-MgSecurityCaseEdiscoveryCaseOperation -EdiscoveryCaseId "<case ID>" -
CaseOperationId “<operation ID>”
```

The name of the export operation is included in the **AdditionalProperties** field.

To make the HTTP API calls directly to list cases in your organization, see List ediscoveryCases.

To make the HTTP API calls directly to list the operations for a case, see List caseOperations.

Use the case ID in the API call to indicate which case to list the operations from. For example:

```
https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/<CaseID>/operations/
```

The name of the export jobs isn't returned with this API call. To find the name of the export process, you must query the specific job ID. For example:

```
https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/<CaseID>/operations/<OperationID>
```

Downloading an export package

Retrieving the download URLs for export packages

The *exportFileMetaData* property contains the URL you need to download the export packages and reports. To get the URL, you need the case *ID* of the eDiscovery case where you ran the export process and the operation *ID* for the export process.

Use the following eDiscovery Graph PowerShell cmdlets to find this information:

PowerShell

```
$operation = Get-MgSecurityCaseEdiscoveryCaseOperation -EdiscoveryCaseId "<case ID>" -CaseOperationId “<operation ID>”
```

PowerShell

```
$Operation.AdditionalProperties.exportFileMetadata
```

To make the HTTP API calls directly to return the *exportFileMetaData* information for an operation, see List caseOperations.

Each export package in the Microsoft Purview portal has an entry in the *exportFileMetaData* property. Each entry lists the following information:

- The export package file name
- The downloadUrl to retrieve the export package
- The size of the export package

Example scripts to download the export package

Because the Microsoft Purview eDiscovery API is separate from Microsoft Graph API, you need a separate authentication token to authorize a download request. Use the **MSAL.PS PowerShell Module** and the **Get-MSALToken** cmdlet to get a separate token. You also need to connect to the Microsoft Graph APIs by using the Connect-MgGraph cmdlet.

The following example scripts can be used as a reference when developing your own scripts to enable the programmatic download of the export packages.

Connecting with a client secret

If you configured your app to use a client secret, use the following example script as a reference to download the export package and reports programmatically. Copy the contents into Notepad and save it as `DownloadExportUsingApp.ps1`.

PowerShell

```
[CmdletBinding()]
param (
    [Parameter(Mandatory = $true)]
    [string]$tenantId,
    [Parameter(Mandatory = $true)]
    [string]$appId,
    [Parameter(Mandatory = $true)]
    [string]$appSecret,
    [Parameter(Mandatory = $true)]
    [string]$caseId,
    [Parameter(Mandatory = $true)]
    [string]$exportId,
    [Parameter(Mandatory = $true)]
    [string]$path = "D:\Temp",
    [ValidateSet($null, 'USGov', 'USGovDoD')]
    [string]$environment = $null
)

if (-not(Get-Module -Name Microsoft.Graph -ListAvailable)) {
    Write-Host "Installing Microsoft.Graph module"
    Install-Module Microsoft.Graph -Scope CurrentUser
}

if (-not(Get-Module -Name MSAL.PS -ListAvailable)) {
    Write-Host "Installing MSAL.PS module"
    Install-Module MSAL.PS -Scope CurrentUser
}

$password = ConvertTo-SecureString $appSecret -AsPlainText -Force
$clientSecretCred = New-Object System.Management.Automation.PSCredential -ArgumentList
($appId, $password)
```

```
if (-not(Get-MgContext)) {
    Write-Host "Connect with credentials of a ediscovery admin (token for graph)"
    if (-not($environment)) {
        Connect-MgGraph -TenantId $TenantId -ClientSecretCredential $clientSecretCred
    }
    else {
        Connect-MgGraph -TenantId $TenantId -ClientSecretCredential $clientSecretCred
-Environment $environment
    }
}

Write-Host "Connect with credentials of a ediscovery admin (token for export)"
$exportToken = Get-MsalToken -ClientId $appId -Scopes "00001111-aaaa-2222-bbbb-
3333cccc4444/.default" -TenantId $tenantId -RedirectUri "http://localhost" -
ClientSecret $password

$uri = "/v1.0/security/cases/ediscoveryCases/$($caseId)/operations/$($exportId)"

$export = Invoke-MgGraphRequest -Uri $uri;
if (-not($export)){
    Write-Host "Export not found"
    exit
}
else{
    $export.exportFileMetadata | % {
        Write-Host "Downloading $($_.fileName)"
        Invoke-WebRequest -Uri $_.downloadUrl -OutFile "$($path)\$($_.fileName)" -
Headers @{"Authorization" = "Bearer $($exportToken.AccessToken)"; "X-
AllowWithAADToken" = "true" }
    }
}
```

Save the script and open a new PowerShell window with the following PowerShell modules installed:

- Microsoft.Graph
- MSAL.PS

Browse to the directory where you saved the script and run the following command:

PowerShell

```
.\DownloadExportUsingApp.ps1 -tenantId “<tenant ID>” -appId “<App ID>” -appSecret
“<Client Secret>” -caseId “<CaseID>” -exportId “<ExportID>” -path “<Output Path>”
```

Review the folder you specified as the path to view the downloaded files.

Connecting with a certificate

If you configured your app to use a certificate, use the following example script as a reference to download the export package and reports programmatically. Copy the contents into a text editor and save it as `DownloadExportUsingAppCert.ps1`.

PowerShell

```
[CmdletBinding()]
param (
    [Parameter(Mandatory = $true)]
    [string]$tenantId,
    [Parameter(Mandatory = $true)]
    [string]$appId,
    [Parameter(Mandatory = $true)]
    [String]$certPath,
    [Parameter(Mandatory = $true)]
    [string]$caseId,
    [Parameter(Mandatory = $true)]
    [string]$exportId,
    [Parameter(Mandatory = $true)]
    [string]$path = "D:\Temp",
    [ValidateSet($null, 'USGov', 'USGovDoD')]
    [string]$environment = $null
)

if (-not(Get-Module -Name Microsoft.Graph -ListAvailable)) {
    Write-Host "Installing Microsoft.Graph module"
    Install-Module Microsoft.Graph -Scope CurrentUser
}

if (-not(Get-Module -Name MSAL.PS -ListAvailable)) {
    Write-Host "Installing MSAL.PS module"
    Install-Module MSAL.PS -Scope CurrentUser
}

##$password = ConvertTo-SecureString $appSecret -AsPlainText -Force
##$clientSecretCred = New-Object System.Management.Automation.PSCredential -
ArgumentList ($appId, $password)

$ClientCert = Get-ChildItem $certPath

if (-not(Get-MgContext)) {
    Write-Host "Connect with credentials of a ediscovery admin (token for graph)"
    if (-not($environment)) {
        Connect-MgGraph -TenantId $TenantId -ClientId $appId -Certificate $ClientCert
    }
    else {
        Connect-MgGraph -TenantId $TenantId -ClientId $appId -Certificate $ClientCert
-Environment $environment
    }
}

Write-Host "Connect with credentials of a ediscovery admin (token for export)"
```

```
$connectionDetails = @{
    'TenantId'          = $tenantId
    'ClientId'          = $appID
    'ClientCertificate' = $ClientCert
    'Scope' = "00001111-aaaa-2222-bbbb-3333cccc4444/.default"
}

$exportToken = Get-MsalToken @connectionDetails

$uri = "/v1.0/security/cases/ediscoveryCases/$($caseId)/operations/$($exportId)"

$export = Invoke-MgGraphRequest -Uri $uri;
if (-not($export)){
    Write-Host "Export not found"
    exit
}
else{
    $export.exportFileMetadata | % {
        Write-Host "Downloading $($_.fileName)"
        Invoke-WebRequest -Uri $_.downloadUrl -OutFile "$($path)\$($_.fileName)" -
Headers @{"Authorization" = "Bearer $($exportToken.AccessToken)"; "X-
AllowWithAADToken" = "true" }
    }
}
```

When you save the script, open a new PowerShell window with the following PowerShell modules installed:

- Microsoft.Graph
- MSAL.PS

Browse to the directory where you saved the script and run the following command.

PowerShell

```
.\DownloadExportUsingAppCert.ps1 -tenantId “<tenant ID>” -appId “<App ID>” -certPath
“<Certificate Path>” -caseId “<CaseID>” -exportId “<ExportID>” -path “<Output Path>”
```

Review the folder you specified as the path to view the downloaded files.

Microsoft Purview eDiscovery solutions

Article • 05/28/2025

> **Important**
>
> The classic eDiscovery (Premium) experience will be **retired in August 2025** and won't be available as an experience option in the Microsoft Purview portal after retirement.
>
> We recommend that you start planning for this transition early and start using the new eDiscovery experience in the Microsoft Purview portal.

Electronic discovery, or eDiscovery, is the process of identifying and delivering electronic information that can be used as evidence in legal cases. You can use eDiscovery tools in Microsoft Purview to search for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can search mailboxes and sites in the same eDiscovery search, and then export the search results. You can use Microsoft Purview eDiscovery (Standard) cases to identify, hold, and export content found in mailboxes and sites. If your organization has an Office 365 E5 or Microsoft 365 E5 subscription (or related E5 add-on subscriptions), you can further manage custodians and analyze content by using the feature-rich Microsoft Purview eDiscovery (Premium) solution in Microsoft 365.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

eDiscovery solutions

> **Important**
>
> Content Search and eDiscovery (Standard) in the eDiscovery classic experience were retired on May 26, 2025. Unless you're working directly with Microsoft when using these legacy features for specific short-term scenarios, use the guidance for the new Content Search case and eDiscovery cases in the new eDiscovery experience in the Microsoft Purview portal.

Microsoft Purview provides three eDiscovery solutions: Content search, eDiscovery (Standard), and eDiscovery (Premium).

Expand table

Content Search	eDiscovery (Standard)	eDiscovery (Premium)
- Search for content - Keyword queries and search conditions - Export search results - Role-based permissions	- Search and export - Case management - Legal hold	- Custodian management - Legal hold notifications - Advanced indexing - Review set filtering - Tagging - Analytics - Predictive coding models And more...

- **Content search**. Use the Content search tool to search for content across Microsoft 365 data sources and then export the search results to a local computer.
- **eDiscovery (Standard)**. eDiscovery (Standard) builds on the basic search and export functionality of Content search by enabling you to create eDiscovery cases and assign eDiscovery managers to specific cases. eDiscovery managers can only access the cases of which they're members. eDiscovery (Standard) also lets you associate searches and exports with a case and lets you place an eDiscovery hold on content locations relevant to the case.
- **eDiscovery (Premium)**. The eDiscovery (Premium) tool builds on the existing case management, preservation, search, and export capabilities in eDiscovery (Standard). eDiscovery (Premium) provides an end-to-end workflow to identify, preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external investigations. It lets legal teams manage custodians and the legal hold notification workflow to communicate with custodians involved in a case. It allows you to collect and copy data from the live service into review sets, when you can filter, search, and tag content to cull non-relevant content from further review so your workflow can identify and focus on content that's most relevant. eDiscovery (Premium) provides analytics and machine learning-based predictive coding models to further narrow to scope of your investigation to the most relevant content.

Comparison of key capabilities

Conversation threading			✔

Capability	Content search	eDiscovery (Standard)	eDiscovery (Premium)
Collection statistics and reports			✔
Review set filtering			✔
Tagging			✔
Analytics			✔
Predictive coding models			✔
Computed document metadata			✔
Transparency of long-running jobs			✔
Export to customer-owned Azure Storage location			✔

Here's a description of each eDiscovery capability.

- **Search for content**. Search for content that's stored in Exchange mailboxes, OneDrive for Business accounts, SharePoint sites, Microsoft Teams, Microsoft 365 Groups, and Viva Engage Teams. This includes content generated by other Microsoft 365 apps that store data in mailboxes and sites.
- **Keyword queries and search conditions**. Create Keyword Query Language (KQL) search queries to search for content keywords that match query criteria. You can also include conditions to narrow the scope of your search.
- **Search statistics**. After you run a search, you can view statistics of the estimated search results, such as the number and total size of items matching your search criteria. Other statistics include the top content locations that contain search results and the number of items that match different parts of the search query.
- **Export search results**. Export search results to a local computer in your organization in a two-step process. When you export search results, items are copied from their original content location in Microsoft 365 to a Microsoft-provided Azure Storage location. Then you can download those items to a local computer.
- **Role-based permissions**. Use role-based access control (RBAC) permissions to control what eDiscovery-related tasks that different users can perform. You can use a built-in eDiscovery-related role group or create custom role groups that assign specific eDiscovery permissions.

- **Case management**. eDiscovery cases in eDiscovery (Standard) and eDiscovery (Premium) let you associate specific searches and exports with a specific investigation. You can also assign members to a case to control who can access the case and view the contents of the case. eDiscovery (Premium) also supports new case creation integration with Microsoft Purview Insider Risk Management cases.
- **Place content locations on legal hold**. Preserve content relevant to your investigation by placing a legal hold on the content locations in a case. This lets you secure electronically stored information from inadvertent (or intentional) deletion during your investigation.
- **Custodian management**. Manage the people that you've identified as people of interest in the case (called *custodians*) and other data sources that may not be associated with a custodian. When you add custodians and non-custodial data sources to a case, you can place a legal hold on these data sources, communicate with custodians by using the legal hold notification process, and search custodian and non-custodial data sources to collect content relevant to the case.
- **Legal hold notifications**. Manage the process of communicating with case custodians. A legal hold notification instructs custodians to preserve content that's relevant to the case. You can track the notices that were received, read, and acknowledged by custodians. The communications workflow in eDiscovery (Premium) allows you to create and send initial notifications, reminders, and escalations if custodians fail to acknowledge a hold notification.
- **Advanced indexing**. When you add custodial and non-custodian data sources to a case, the associated content locations are reindexed in a process called *Advanced indexing*. Advanced indexing ensures any content deemed as partially indexed is reprocessed to make it fully searchable when you collect data for an investigation.
- **Error remediation**. Fix processing errors using a process called *error remediation*. Error remediation allows you to rectify data issues that prevent eDiscovery (Premium) from properly processing the content during Advanced indexing. For example, files that are password protected can't be processed since the files are locked or encrypted. Using error remediation, you can download files with errors, remove the password protection, and then upload the remediated files.
- **Review sets**. Add relevant data to a review set. A review set is a secure, Microsoft-provided Azure Storage location in the Microsoft cloud. When you add data to a review set, the collected items are copied from their original content location to the review set. Review sets provide a static, known set of content that you can search, filter, tag, analyze, and predict relevancy using predictive coding models. You can also track and report on what content gets added to the review set.
- **Support for cloud attachments and SharePoint versions**. When you add content to a review set, you have the option to include cloud attachments or linked files. This means that the target file of a cloud attachment or linked file is added to the review set. You also have the option to add all versions of a SharePoint document to a review set.

- **Optical character recognition (OCR)**. When content is added to a review set, OCR functionality extracts text from images, and includes the image text with the content that's added to a review set. This lets you search for image text when you query the content in the review set.
- **Conversation threading**. When chat messages from Teams and Viva Engage conversations are added to a review set, you can collect the entire conversation thread. This means that the entire chat conversation that contains items that match the collection criteria is added to the review set. This lets you review chat items in the context of the back-and-forth conversation.
- **Collection statistics and reports**. After you create a collection estimate or commit a collection to a review set, you can view a rich set of statistics on the retrieved items, such as the content locations that contain the most items that matched the search criteria and the number of items returned by the search query. You can also preview a subset of the results.
- **Review set filtering**. After content is added to a review set, you can apply filters to display only the set of items that match your filtering criteria. Then you can save the filter sets as a query, which lets you quickly reapply the saved filters. Review set filtering and saved queries help you quickly select content items that are most relevant to your investigation.
- **Tagging**. Tags also help you omit non-relevant content and identify the most relevant content. When experts, attorneys, or other users review content in a review set, their opinions related to the content can be captured by using tags. For example, if the intent is to exclude unnecessary content, a user can tag documents with a tag such as "non-responsive". After content has been reviewed and tagged, a review set query can be created to exclude any content tagged as "non-responsive". This process eliminates the non-responsive content from subsequent steps in the eDiscovery workflow.
- **Analytics**. eDiscovery (Premium) provides tools to analyze review set documents to help you organize the documents in a coherent manner and reduce the volume of documents to be reviewed. *Near duplicate detection* groups textually similar documents together to help you make your review process more efficient. *Email threading* identifies specific email messages that give a complete context of the conversation in an email thread. *Themes* functionality attempts to analyze themes in review set documents and assign a theme to documents so that you can review documents with related theme. These analytics capabilities help make your review process more efficient so that reviewers can review a fraction of collected documents.
- **Predictive coding models**. Use predictive coding models to reduce large volumes of case content to a relevant set of items that you can prioritize for review. This is accomplished by creating and training your own predictive coding models that help you prioritize the review of the most relevant items in a review set. The system uses the training to apply prediction scores to every item in the review set. This lets you filter items based on the prediction score, which allows you to review the most relevant (or non-relevant) items first.

- **Computed document metadata**. Many of the eDiscovery (Premium) features, such as Advanced indexing, conversation threading, analytics, and predictive coding add metadata properties to review set documents. This metadata contains information related to the function performed by a specific feature. When reviewing documents, you can filter on metadata properties to display documents that match your filter criteria. This metadata can be imported into third-party review applications after review set documents are exported.
- **Transparency of long-running jobs**. Jobs in eDiscovery (Premium) are typically long-running processes that are triggered by user actions, such as the adding custodians to a case, adding content to a review set, running analytics, and training predictive coding models. You can track the status of these jobs and get support information if you need to escalate issues to Microsoft Support.
- **Export to customer-owned Azure Storage location**. When you export documents from a review set, you have the option to export them to an Azure Storage account managed by your organization. Additionally, eDiscovery (Premium) lets you customize what data is exported. This includes exporting file metadata, native files, text files, tags, and redacted documents saved to a PDF file.

eDiscovery subscription comparison

Before you get started, review the subscription requirements for Content search, eDiscovery (Standard), and eDiscovery (Premium). Generally, subscriptions that support eDiscovery (Standard) also support Content search and subscriptions that support eDiscovery (Premium) also support Content search and eDiscovery (Standard).

Get started with eDiscovery

See the following articles to help you learn more and get started using Microsoft Purview eDiscovery solutions.

Get started with eDiscovery (Premium)

- Overview of eDiscovery (Premium)
- Get started with eDiscovery (Premium)
- Create and manage an eDiscovery (Premium) case

Integration with Insider Risk Management

Cases in Microsoft Purview Insider Risk Management can be quickly escalated to new cases in Microsoft Purview eDiscovery (Premium) when additional legal review is needed for potentially risky user activity. The tight integration between these solutions can help your risk and legal teams work more efficiently and can help provide a complete end-to-end view of user activities under review. Check out how to get started with Insider Risk Management and how to easily escalate an Insider Risk Management case to an eDiscovery (Premium) case.

eDiscovery roadmap

To see what eDiscovery features have been launched, are rolling out, or in development, see the Microsoft 365 Roadmap.

Training

Training your IT administrators, eDiscovery managers, and compliance investigation teams in the basics for Content search, eDiscovery (Standard), and eDiscovery (Premium) can help your organization get started more quickly using Microsoft Purview eDiscovery tools. To help these users in your organization getting started with eDiscovery, see Describe the eDiscovery and audit capabilities of Microsoft Purview.

Overview of Content search

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Use the Content search tool in the Microsoft Purview portal to quickly find email in Exchange mailboxes, documents in SharePoint sites and OneDrive locations, and instant messaging conversations in Skype for Business. You can use the content search tool to search for email, documents, and instant messaging conversations in collaboration tools such as Microsoft Teams and Microsoft 365 Groups.

Search for content

The first step is to starting using the Content search tool to choose content locations to search and configure a keyword query to search for specific items. Or, you can just leave the query blank and return all items in the target locations.

- Create and run a Content search.
- Build search queries and use conditions to narrow your search.
- Feature reference for Content search.
- Configure search permissions filtering so that an eDiscovery manager can only search subset of mailboxes or sites in your organization.
- Search cloud-based mailboxes for on-premises users in Microsoft 365.
- View keyword statistics for the results of a search and then refine the query if necessary.
- Search for third-party data that your organization has imported to Microsoft 365.
- Preserve Bcc recipients so you can search for them.
- Search for Microsoft 365 Copilot and Microsoft 365 Copilot Chat data (user prompts and Copilot responses) stored in custodian mailboxes.

Perform actions on content you find

After you run a search and refine it as necessary, the next step is to do something with the results returned by the search. You can export and download the results to your local computer or in the case of an email attack on your organization, you can delete the results of a search from user mailboxes.

- Export the results of a content search and download them to your local computer..
- Search for and delete email messages, such as messages that content a virus, dangerous attachments, or phishing messages.

Learn more about content search

Content search is easy to use, but it's also a powerful tool. Behind-the-scenes, there's a lot going on. The more you know about it and understand its behavior and its limitations, the more successful you'll be using it for your organization's search and investigation needs.

- Estimated and actual search results and the reasons why there might be differences between them when you export and download search results.
- Partially indexed items in Exchange and SharePoint and how to include or exclude them when you export and download search results.
- Investigate partially indexed items and determine your organization's exposure to them.

Use scripts for advanced scenarios

Sometimes you have to perform more advanced, complex, and repetitive content search tasks. In these cases, it's easier and faster to use commands in Security & Compliance PowerShell.

To help make this easier, we've created several Security & Compliance PowerShell scripts to help you complete complex content search-related tasks.

- Search specific mailbox and site folders (called a *targeted* collection) when you're confident that items responsive to a case are located in that folder.
- Search the mailbox and OneDrive location for a list of users.
- Create, report on, and delete multiple searches to quickly and efficiently identify and cull search data.
- Clone a content search and quickly compare the results of different keyword search queries run on the same content locations; or use the script to save time by not having to re-enter a large number of content locations when you create a new search.

Last updated on 11/21/2025

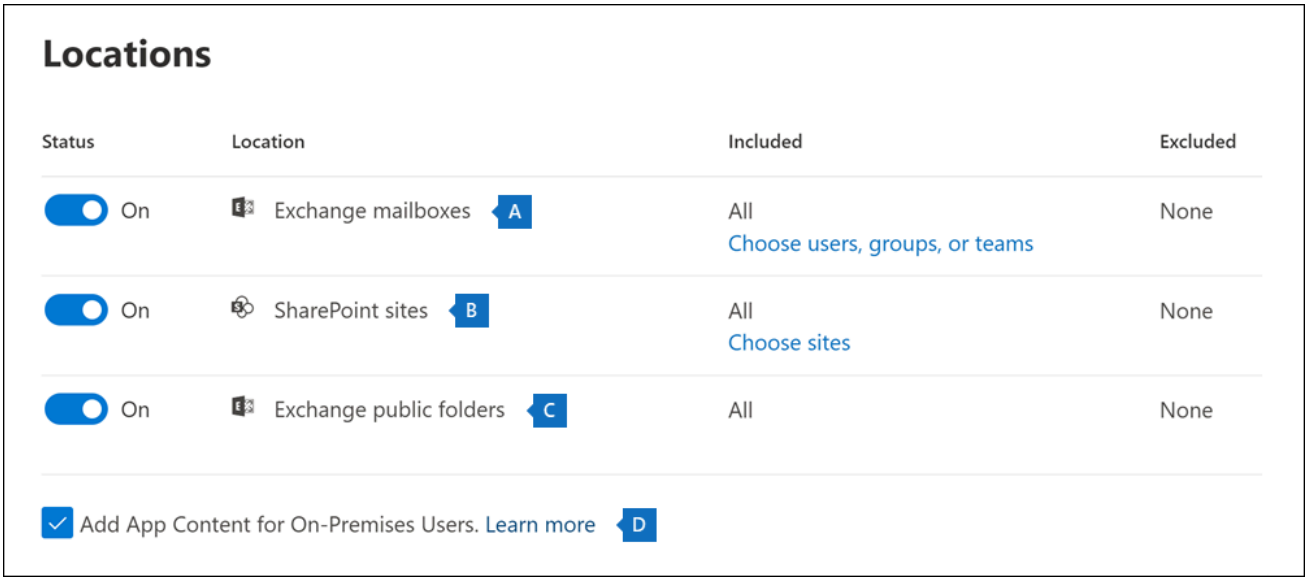
Get started with Content search

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use the Content search eDiscovery tool in the Microsoft Purview portal to search for in-place content such as email, documents, and instant messaging conversations in your organization. Use this tool to search for content in these cloud-based Microsoft 365 data sources:

- Exchange Online mailboxes
- SharePoint Online sites and OneDrive for Business accounts
- Microsoft Teams
- Microsoft 365 Groups
- Viva Engage

After you run a search, the number of content locations and an estimated number of search results are displayed on the search flyout page. You can quickly view statistics, such as the content locations that have the most items that match the search query. After you run a search, you can preview the results or export them to a local computer.



Before you run a search

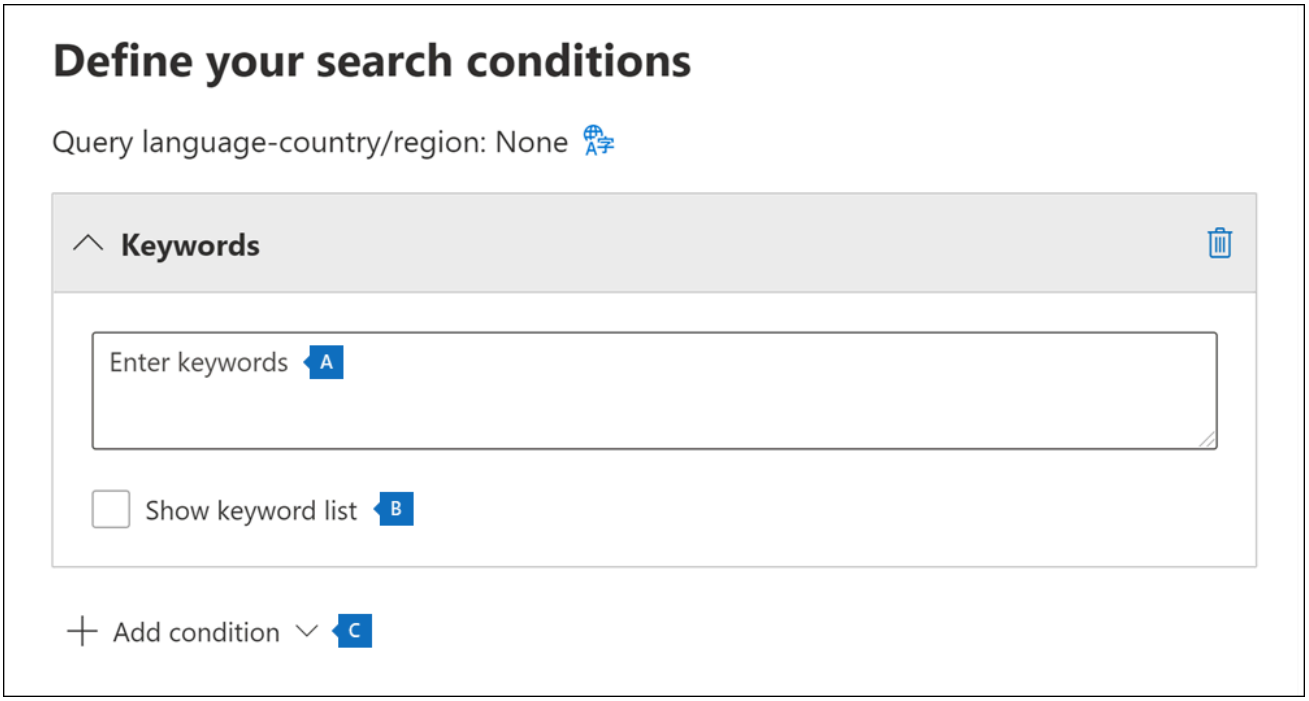
- To access to the Content search tool in the Microsoft Purview portal (to run searches and preview results and export results), an administrator, compliance officer, or eDiscovery manager must be a member of the eDiscovery Manager role group in the Microsoft Purview portal. For more information, see Assign eDiscovery permissions.
- In an Exchange hybrid deployment, you can't use the Content search tool to search emails in on-premises mailboxes. You can only use the tool to search cloud-based mailboxes.
- In an Exchange hybrid deployment, you can search for Teams chat data in on-premises mailboxes. For more information, see Search for and export Teams chat data for on-

premises users.

Create and run a search

1. Go to the Microsoft Purview portal and sign in using the credentials of an account that's been assigned the appropriate permissions.
2. In the left navigation pane, select **Content search**.
3. On the **Content search** page, select **New search**.
4. On the **Name and description** page, enter a name for the search, an optional description that helps identify the search. The name of the search must be unique in your organization.
5. On the **Locations** page, choose the content locations that you want to search. You can search mailboxes, sites, and public folders.

a. **Exchange mailboxes**: Set the toggle to **On**. The option to search all Exchange mailboxes is automatically selected. If needed, select **Choose users, groups, or teams** to specify the mailboxes to search. Use the search box to find user mailboxes and distribution groups. You can also search the mailbox associated with a Microsoft Team (for channel messages), Microsoft 365 Group, and Viva Engage community. All Microsoft 365 Copilot and Microsoft 365 Copilot Chat activity data (user prompts and Copilot responses) generated in supported Microsoft 365 apps and services is stored in custodian mailboxes. For more information about the application data stored in mailboxes, see Content stored in mailboxes for eDiscovery.



b. **SharePoint sites**: Set the toggle to **On**. The option to search all SharePoint sites is automatically selected. Select **Choose sites** to specify SharePoint sites and OneDrive sites

to search. Enter the URL for each site that you want to search. You can also add the URL for the SharePoint site for a Microsoft Team, Microsoft 365 Group, or Viva Engage community. The Recycle Bin in SharePoint sites is not indexed and therefore unavailable for searching. As a result, eDiscovery searches can't find any Recycle Bin content to place holds.

c. **Exchange public folders**: Set the toggle to **On**. The option to search all Exchange public folders is automatically selected to search all public folders in your Exchange Online organization. You can't choose specific public folders to search. Leave the toggle switch off if you don't want search all public folders.

d. Keep this checkbox selected to search for Teams content for on-premises users. For example, if you search all Exchange mailboxes in the organization and this checkbox is selected, the cloud-based storage used to store Teams chat data for on-premises users will be included in the scope of the search. For more information, see Search for Teams chat data for on-premises users.

6. On the **Conditions** page, enter a keyword query and add conditions to the search query if necessary.

a. Specify keywords, message properties such as sent and received dates, or document properties such as file names or the date that a document was last changed. You can use more complex queries that use a Boolean operator, such as **AND**, **OR**, **NOT**, and **NEAR**. If you leave the keyword box empty, all content located in the specified content locations is

included in the search results. For more information, see Keyword queries and search conditions for eDiscovery.

b. Alternatively, you can select the **Show keyword list** checkbox and then enter a keyword in each row. If you do this, the keywords on each row are connected by a logical operator (**c:s**) that is similar in functionality to the **OR** operator in the search query that's created.

   Why use the keyword list? You can get statistics that show how many items match each keyword. This can help you quickly identify which keywords are the most (and least) effective. You can also use a keyword phrase (surrounded by parentheses) in a row. For more information about the keyword list and search statistics, see Get keyword statistics for searches.

   > **Note**
   >
   > To help reduce issues caused by large keyword lists, you're limited to a maximum of 20 rows in the keyword list.

c. You can add search conditions to narrow a search and return a more refined set of results. Each condition adds a clause to the search query that is created and run when you start the search. A condition is logically connected to the keyword query (specified in the keyword box) by a logical operator (**c:c**) that is similar in functionality to the **AND** operator. That means that items have to satisfy both the keyword query and one or more conditions to be included in the results. This is how conditions help to narrow your results. For a list and description of conditions that you can use in a search query, see Search conditions.

7. Review the search settings (and edit if necessary), and then select **Submit** to start the search.

To access this content search again or access other content searches listed on the **Content search** page, select a search to view the search summary and search statistics.

For more information about Content search, such as searching for content in different Microsoft 365 services, see Feature reference for Content search.

Next steps

Here's a list of next steps to perform after you create and run a Content search.

- Preview search results
- View statistics for search results
- Export search results

Last updated on 11/21/2025

Use Content search in Microsoft Teams

Applies to: Microsoft Teams

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

> **Note**
>
> Content search of messages and files in private channels work differently than in standard channels. To learn more, see Content search of private channels.

Content search provides a way to query Microsoft Teams information spanning Exchange, SharePoint Online, and OneDrive for Business. For example, using **Content search** against your *Manufacturing Specs* mailbox and *Manufacturing Specs* SharePoint site, you can search against Teams standard channel conversations from Exchange, file uploads and modifications from SharePoint Online, and OneNote changes.

You can also add query criteria to the **Content Search** to narrow the results returned. In the previous example, you can look for content where the keywords "**New Factory Specs**" were used.

> **Tip**
>
> After adding search conditions, you can export a report or the actual content to your computer for analysis.

Content search of private channels

Records for messages sent in a private channel are delivered to the mailbox of all private channel members, rather than to a group mailbox. The titles of the records are formatted to indicate which private channel they were sent from.

Because each private channel has its own SharePoint site collection that's separate from the parent team site, files in a private channel are managed independently of the parent team.

Teams doesn't support content search of a single channel, so the whole team must be searched. To perform a content search of a private channel, search across the team, the site collection associated with the private channel (to include files), and mailboxes of private channel members (to include messages).

Use the following steps to identify files and messages in a private channel to include in your content search.

Include private channel files in a content search

Before you perform these steps, install the SharePoint Online Management Shell and connect to SharePoint Online.

1. Run the following to get a list of all SharePoint site collections associated with private channels in the team.

   PowerShell

   ```
   Get-SPOSite
   ```

2. Run the following PowerShell script to get a list of all SharePoint site collection URLs associated with private channels in the team and the parent team group ID.

   PowerShell

   ```
   $sites = get-sposite -template "teamchannel#0"
   foreach ($site in $sites) {$x= get-sposite -identity $site.url -detail;
   $x.relatedgroupID; $x.url}
   ```

3. For each team or group ID, run the following PowerShell script to identify all relevant private channel sites.

   PowerShell

   ```
   $sites = get-sposite -template "teamchannel#0"
   $groupID = "e8195240-4a70-4830-9106-80193cf717cb"
   ```

```
foreach ($site in $sites) {$x= Get-SpoSite -Identity $site.url -Detail; if
($x.RelatedGroupId -eq $groupID) {$x.RelatedGroupId;$x.url}}
```

Include private channel messages in a content search

Before you perform these steps, make sure you have the latest version of the Teams PowerShell module installed.

1. Run the following to get a list of private channels in the team.

   PowerShell

   ```
   Get-TeamChannel -GroupId <GroupID> -MembershipType Private
   ```

2. Run the following to get a list of private channel members.

   PowerShell

   ```
   Get-TeamChannelUser -GroupId <GroupID> -DisplayName "Engineering" -Role Member
   ```

3. Include the mailboxes of all members from each private channel in the team as part of your content search query.

Search for and export Teams chat data for on-premises users

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

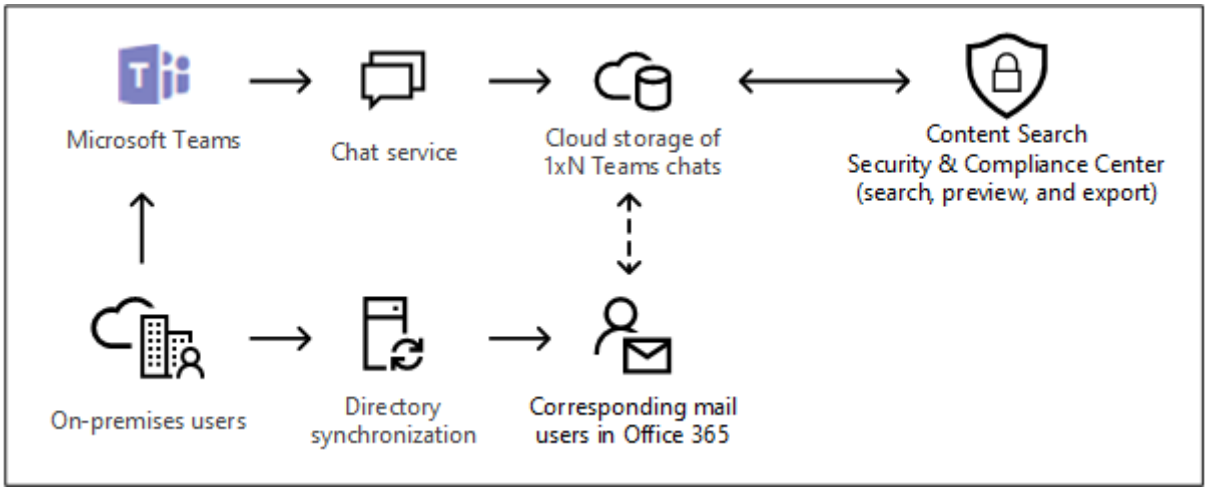
If your organization has an Exchange hybrid deployment, you can use eDiscovery tools to search for and export Teams chat data for on-premises users. This option is also available for organizations that synchronize on-premises Exchange organization with Microsoft 365.

For a cloud-based users using Microsoft Teams enabled in your organization, chat data (also called *1x1 or 1xN chats*) is saved to their primary cloud-based mailbox. When an on-premises user uses the Teams chat application, their chat messages can't be stored in their primary mailbox, which is located on-premises. To get around this limitation, a feature where a cloud-based storage area is created so that you use eDiscovery tools to search for and export Teams chat data for on-premises users.

Here are the requirements and limitations for enabling cloud-based storage for on-premises users:

- The user accounts in your on-premises directory service (such as Active Directory) must be synchronized with Microsoft Entra ID, the directory service in Microsoft 365. This means that a mail user account is created in Microsoft 365 and is associated with a user whose primary mailbox is located in the on-premises organization.
- The user whose primary mailbox is located in the on-premises organization must be assigned a Microsoft Teams license and a minimum of an Exchange Online Plan 1 license.
- If your organization doesn't have an Exchange hybrid deployment, you must synchronize your on-premises Exchange schema to Microsoft Entra ID. If you don't do this, you might

risk creating duplicate cloud-based mailboxes in Exchange Online for users that have a mailbox in your on-premises Exchange organization.



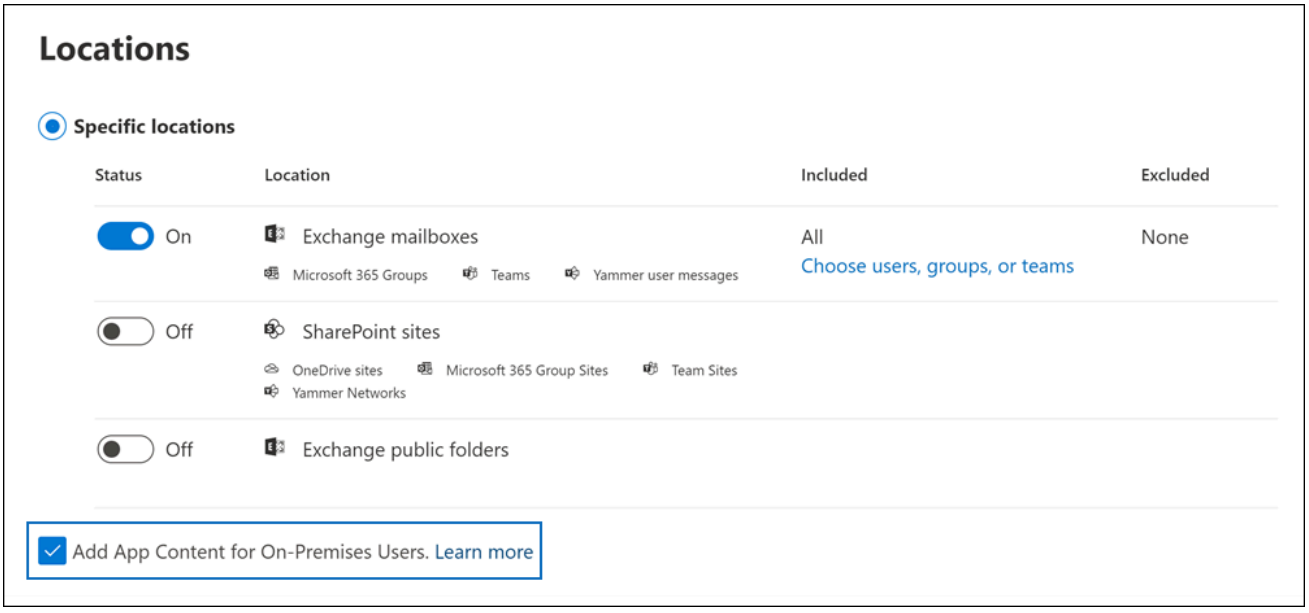
- Only the Teams chat data associated with an on-premises user is stored in the cloud-based storage area. An on-premises user can't access this storage area.

> ⓘ **Note**
>
> Teams channel conversations are always stored in the cloud-based mailbox that's associated with the Team, which means you can search for channel conversations. For more information about searching Teams channel conversations, see Searching Microsoft Teams and Microsoft 365 Groups.

How it works

If a Microsoft Teams-enabled user has an on-premises mailbox and their user account/identity has been synched to the cloud, Microsoft creates cloud-based storage to associate the on-premises user's 1xN Teams chat data with. Teams chat data for on-premises users is indexed for search. This lets you use Content search (and searches associated with Microsoft Purview eDiscovery (Standard) and Microsoft Purview eDiscovery (Premium) cases) to search, preview, and export Teams chat data for on-premises users. You can also use ***ComplianceSearch** cmdlets in Security & Compliance PowerShell to search for Teams chat data for on-premises users.

The following graphic shows the workflow of how Teams chat data for on-premises users is available to search, preview, and export.



In addition to this capability, you can also use eDiscovery tools to search, preview, and export Teams content in the cloud-based SharePoint site and Exchange mailbox associated with each Microsoft Team and 1xN Teams chat data in the Exchange Online mailbox for cloud-based users.

Searching for and exporting Teams chat content for on-premises users

Here's how to use Content search in the Microsoft Purview portal to search for Teams chat data for on-premises users. You can also use the search tool in eDiscovery (Standard) to search for chat data for on-premises users.

1. In the Microsoft Purview portal, go to **Content search**.
2. On the **Searches** tab, select **New search**, and name the new search.
3. On the **Locations** page, set the toggle to **On** for Exchange mailboxes.
4. To search for Teams content for specific users (including on-premises users), select **Choose user, groups, or teams** and choose specific users to include in the search. If you don't list specific users, the search will include all users, including on-premises users.
5. Make sure the **Add app content for on-premises users** checkbox is selected. This ensures that the cloud-bases storage for on-premises users will be searched.

6. On the **Define your search conditions** page, create a keyword query and add conditions to the search query if necessary. To only search for Team chats data, you can add the following query in the **Keywords** box:

```text
kind:im AND kind:microsoftteams
```

7. Submit and run the search. Any search results for on-premises users can be previewed like any other search results. You can also export the search results (including any Teams chat data) to a PST file. For more information, see:

   - Create a search
   - Preview search results
   - Export search results

Using PowerShell to search for Teams chat data for on-premises users

You can use the **New-ComplianceSearch** cmdlets in Security & Compliance PowerShell to search for Teams chat data for on-premises users. As previously explained, you don't have to submit a support request to use PowerShell to search for Teams chat data for on-premises users.

1. Connect to Security & Compliance PowerShell.

2. Run the following PowerShell command to create a content search that searches for Teams chat data for on-premises users.

   PowerShell

   ```
   New-ComplianceSearch <name of new search> -ContentMatchQuery <search query> -
   ExchangeLocation <on-premises user> -IncludeUserAppContent $true -
   AllowNotFoundExchangeLocationsEnabled $true
   ```

   The *IncludeUserAppContent* parameter is used to specify the cloud-based storage for the user or users who are specified by the *ExchangeLocation* parameter. The *AllowNotFoundExchangeLocationsEnabled* allows you to search the cloud-based storage for on-premises users. When you use the `$true` value for this parameter, the search doesn't try to validate the existence of the mailbox before it runs. This is required to search the cloud-based storage for on-premises users because this cloud-based storage doesn't resolve as a regular cloud-based mailbox.

   The following example searches for Teams chats that contain keyword "redstone" in the cloud-based storage for Sara Davis, who is an on-premises user in the Contoso organization.

   PowerShell

```
New-ComplianceSearch "Redstone_Search" -ContentMatchQuery "redstone AND (kind:im
AND kind:microsoftteams)" -ExchangeLocation sarad@contoso.com -
IncludeUserAppContent $true -AllowNotFoundExchangeLocationsEnabled $true
```

After you create a search, be sure to use the **Start-ComplianceSearch** cmdlet to run the search.

For more information using these cmdlets, see:

- New-ComplianceSearch
- Start-ComplianceSearch

Limits

- Currently, you can search, preview, and export Teams chat data for on-premises users. You can also place the Teams chat data for an on-premises user on a hold associated with an eDiscovery (Standard) or eDiscovery (Premium) case, and apply a retention policy for Teams chats or channel messages for on-premises users. However, you can't apply a retention policy for other content locations (such as Exchange mailboxes and SharePoint sites) for on-premises users.

Frequently asked questions

Do I have to submit a support request to search for chat messages for on-premises users?

No. This feature is enabled by default for all organizations. At one point, you did have to contact Microsoft Support but that is no longer the case.

Can eDiscovery tools find older Teams chat data for on-premises users before the time that this feature was enabled by default for all organizations?

Microsoft started storing the Teams chat data for on-premises users on January 31, 2018. If the identity of an on-premises Teams user has been synched between your on-premises Active Directory and Microsoft Entra ID in Microsoft 365 since this date, then their Teams chat data is stored in the cloud and is searchable using eDiscovery tools.

Do on-premises users need a license to store their Teams chat data in the cloud?

Yes. To store Teams chat data for an on-premises user in a cloud-based storage, the user must be assigned a Microsoft Teams license and an Exchange Online Plan license in Office 365 (or Microsoft 365).

Where is the cloud-based storage for on-premises users located?

Teams chat data is stored in the Preferred Data Location (PDL) for an on-premises user. The PDL is honored in both Single-Geo and Multi-Geo environments. For more information, see Microsoft 365 Multi-Geo.

Is there a risk of losing the Teams chat data if the user's on-premises mailbox is migrated to the cloud?

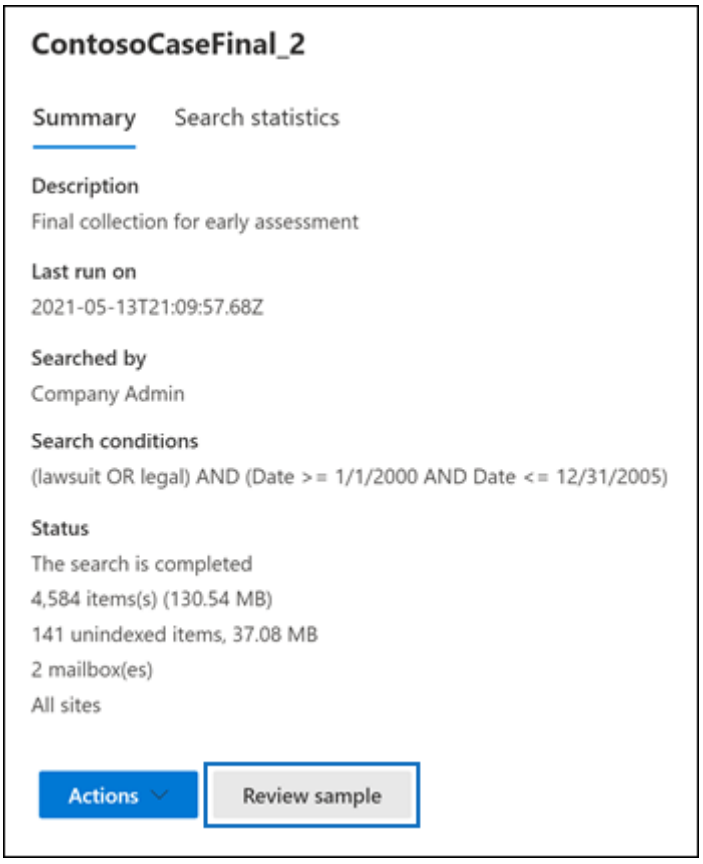
No. When you migrate the primary mailbox of an on-premises user to the cloud, the Teams chat data for that user will be migrated to their new cloud-based primary mailbox.

Can I apply an eDiscovery hold or retention policies to on-premises users?

Yes. You can apply eDiscovery holds or retention policies for Teams chats and channel messages of on-premises users. But to preserve or retain Teams content for on-premises users, an on-premises user must be assigned an Exchange Online Plan 2 license.

Last updated on 09/02/2025

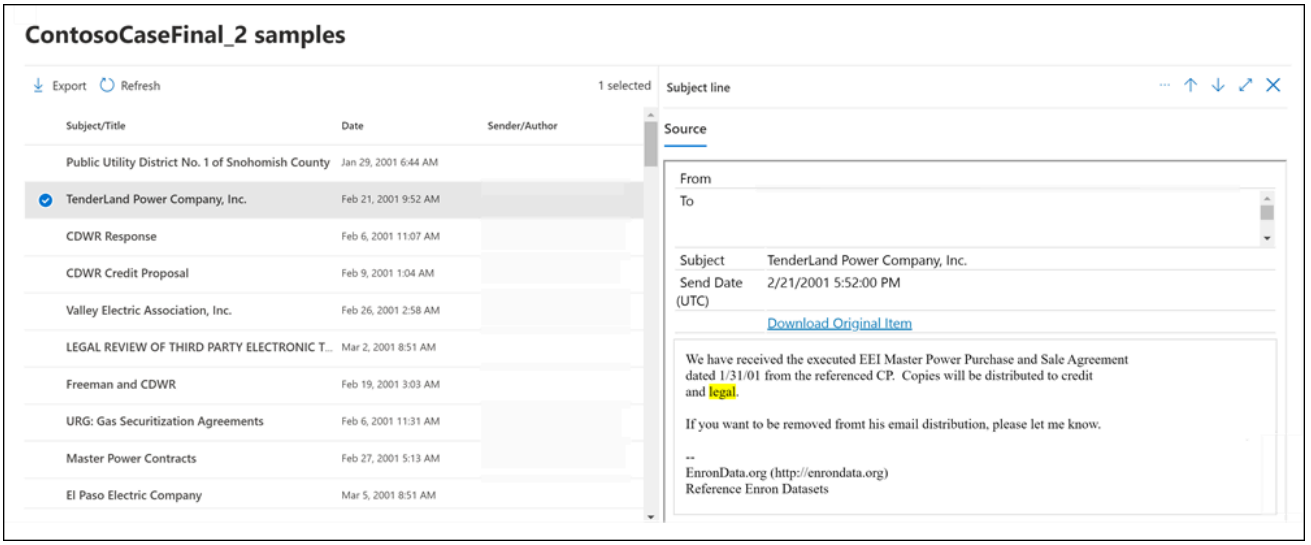
Preview eDiscovery search results



> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After you run a Content search, you can preview a sample of the results returned by the search. Previewing items returned by the search query can help you determine if the search is returning the results you hope for or if you need to change the search query and rerun the search.

> **Note**
>
> There may be scenarios when the preview sample doesn't contain all available results of searches, and sampling is best effort. In some cases (such as in environments operated by 21Vianet in China), the review sample might not function reliably. For the most accurate and complete search results, use export to obtain the full set of search results.



To preview a sample of results returned by a search:

1. In the Microsoft Purview portal, go to the **Content search**.
2. Select search to display the flyout page.
3. On the bottom of the flyout page, select **Review sample**.

A page is displayed containing a sample of the search results.

4. Select an item to view its contents in the reading pane.

In the previous screenshot, the keywords from the search query are highlighted when you preview items.

How the search result samples are selected

A maximum of 1,000 randomly selected items are available to preview. In addition to being randomly selected, items available for preview must also meet the following criteria:

- A maximum of 100 items from a single content location (a mailbox or a site) can be previewed. This maximum means that it's possible that less than 1,000 items might be available for preview. For example, if you search four mailboxes and the search returns 1,500 estimated items, only 400 are available for preview because only 100 items from each mailbox can be previewed.
- For mailbox items, only email messages are available to preview. Preview for items like tasks, calendar items, and contacts aren't available.
- For site items, only documents are available to preview. Preview for items like folders, lists, or list attachments aren't available.

File types supported when previewing search results

You can preview supported file types in the preview pane. If a file type isn't supported, you have to download a copy of the file to your local computer (by selecting **Download original item**). For .aspx Web pages, the URL for the page is included though you may not have permissions to access the page. Unindexed items aren't available for previewing.

The following file types are supported and can be previewed in the search results pane.

- .txt, .html, .mhtml
- .eml
- .doc, .docx, .docm
- .pptm, .pptx
- .pdf

Also, the following file container types are supported. You can view the list of files in the container in the preview pane.

- .zip
- .gzip

Last updated on 01/08/2026

View statistics for eDiscovery search results

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

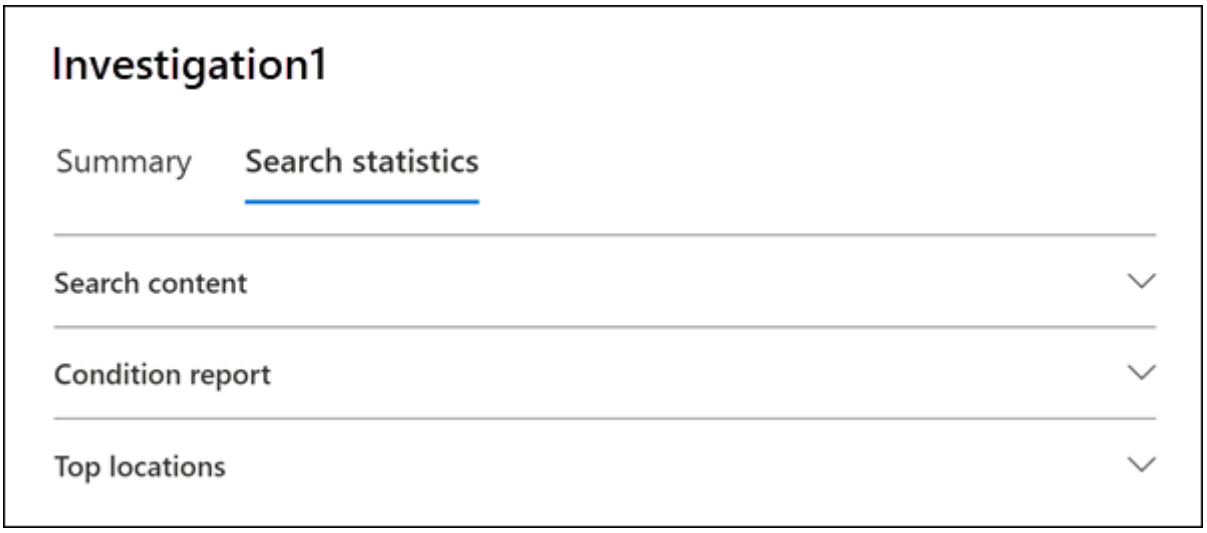
After you create and run a Content search or a search associated with a Microsoft Purview eDiscovery (Standard) case, you can view statistics about the estimated search results. This includes a summary of the search results (similar to the summary of the estimated search results displayed on the search flyout page), the query statistics such as the number of content locations with items that match the search query, and the identity of content locations that have the most matching items.

Additionally, you can use the keywords list to configure a search to return statistics for each keyword in a search query. This lets you compare the number of results returned by each keyword in a query.

You can also download search statistics to a comma-separated value (CSV) file. This lets you use the filtering and sorting features in Excel to compare results, and prepare reports for your search results.

Get statistics for searches

To display statistics for a Content search or a search associated with an eDiscovery (Standard) case.:

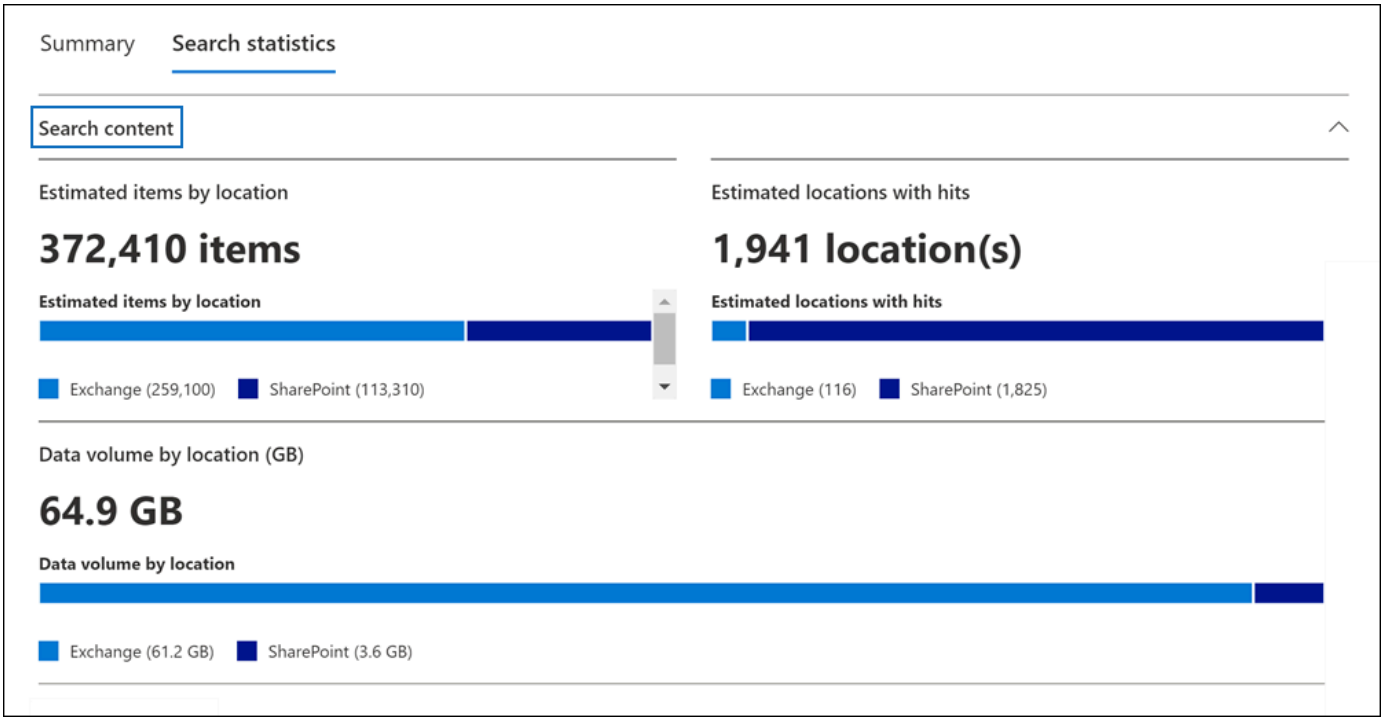


1. In the Microsoft Purview portal, select **Show all**, and then do one of the following:

   - Select **Content search** and then select a search to display the flyout page.

     OR

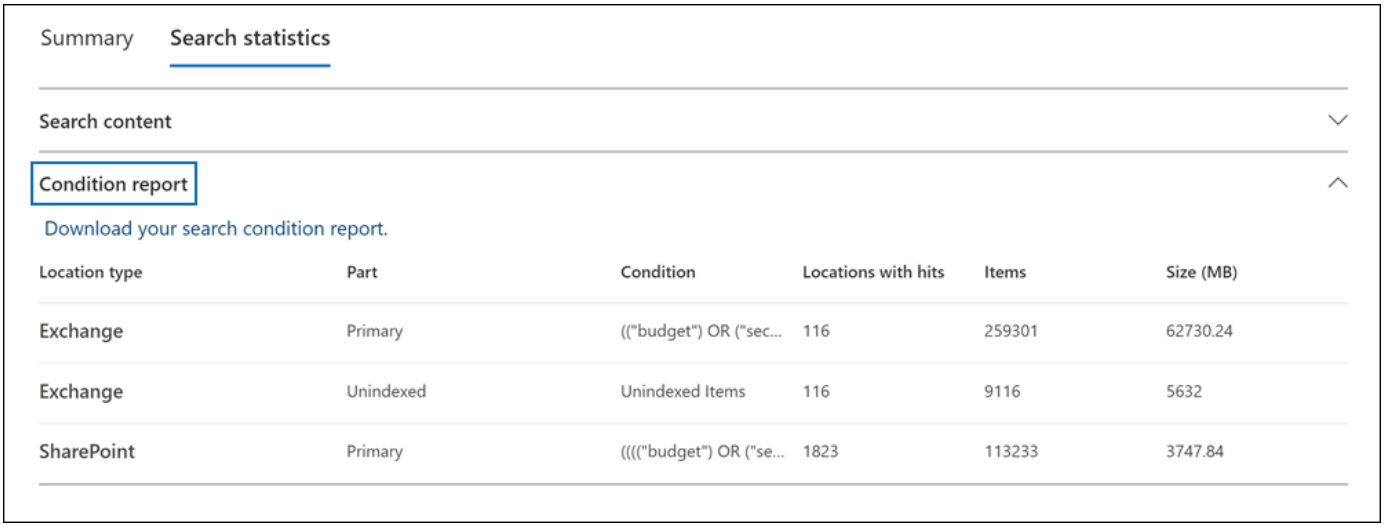
- Select **eDiscovery** > **eDiscovery (Standard)**, select a case, and then select a search on the **Searches** tab to display the flyout page.



2. On the flyout page of the selected search, select the **Search statistics** tab.

The **Search statistics** tab contains for following sections that contain different types of statistics about the search.

Search content



This section displays a graphical summary of the estimated items returned by the search. This indicates the number of items that match the search criteria. This information gives you an idea about the estimated number of items returned by the search.

- **Estimated items by locations**: The total number of estimated items returned by the search. The specific number of items located in mailboxes and located in sites is also displayed.
- **Estimated locations with hits**: The total number of content locations that contain items returned by the search. The specific number of mailbox and site locations is also displayed.
- **Data volume by location (in MB)**: The total size of all estimated items returned by the search. The specific size of mailbox items and site items is also displayed.

Condition report

This section displays statistics about the search query and the number of estimated items that matched different parts of the search query. You can use these statistics to analyze the number of items that match each component of search query. This can help you refine the search criteria and if necessary narrow the scope of the scope. You can also download a copy of this report in CSV format.

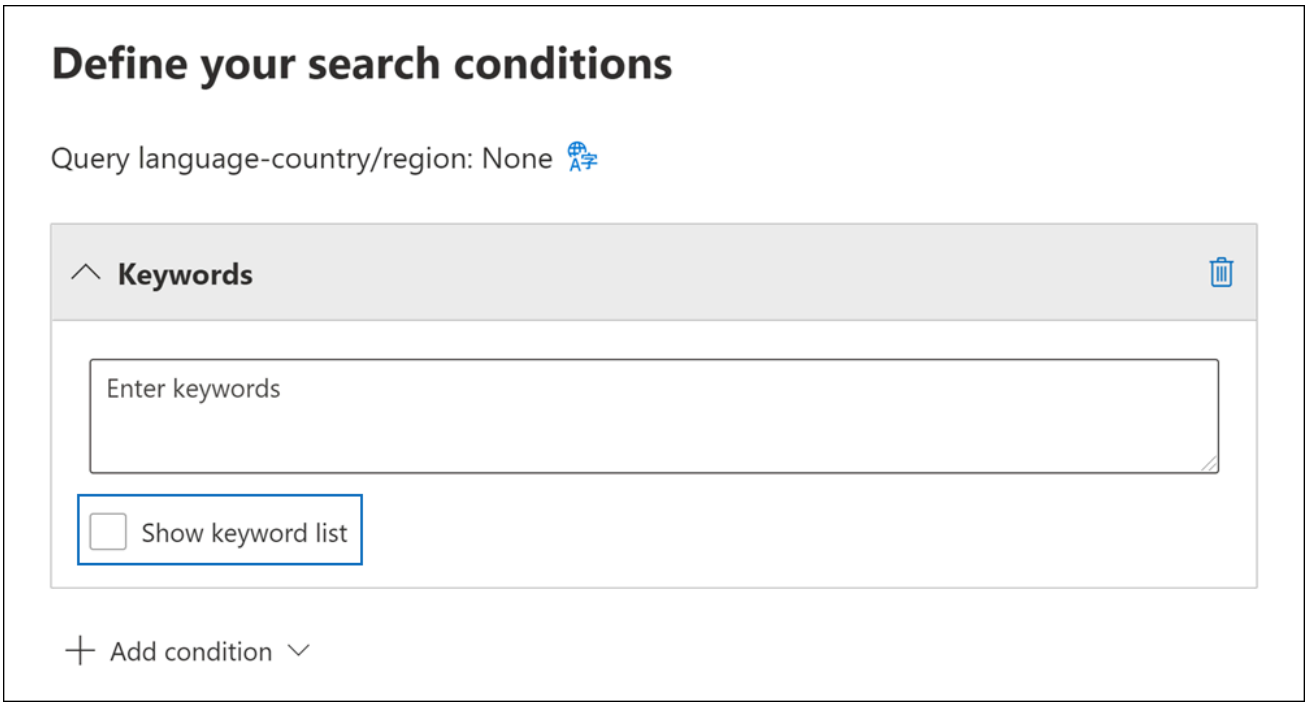
- **Location type**: The type of content location that the query statistics are applicable to. The value of **Exchange** indicates a mailbox location; a value of **SharePoint** indicates a site location.
- **Part**: The part of the search query the statistics are applicable to. **Primary** indicates the entire search query. **Keyword** indicates the statistics in the row are for a specific keyword. If you use a keyword list for search query, statistics for each component of the query are included in this table. For more information, see Get keyword statistics for searches.
- **Condition**: The actual component (keyword or condition) of the search query that returned the statistics displayed in the corresponding row.
- **Locations with hits**: The number of the content locations (specified by the **Location type** column) that contain items that match the primary or keyword query listed in the **Condition** column.

- **Items**: The number of items (from the specified content location) that match the query listed in the **Condition** column. As previously explained, if an item contains multiple instances of a keyword that is being searched for, it's only counted once in this column.
- **Size (MB)**: The total size of all items that were found (in the specified content location) that match the search query in the **Condition** column.

Top locations

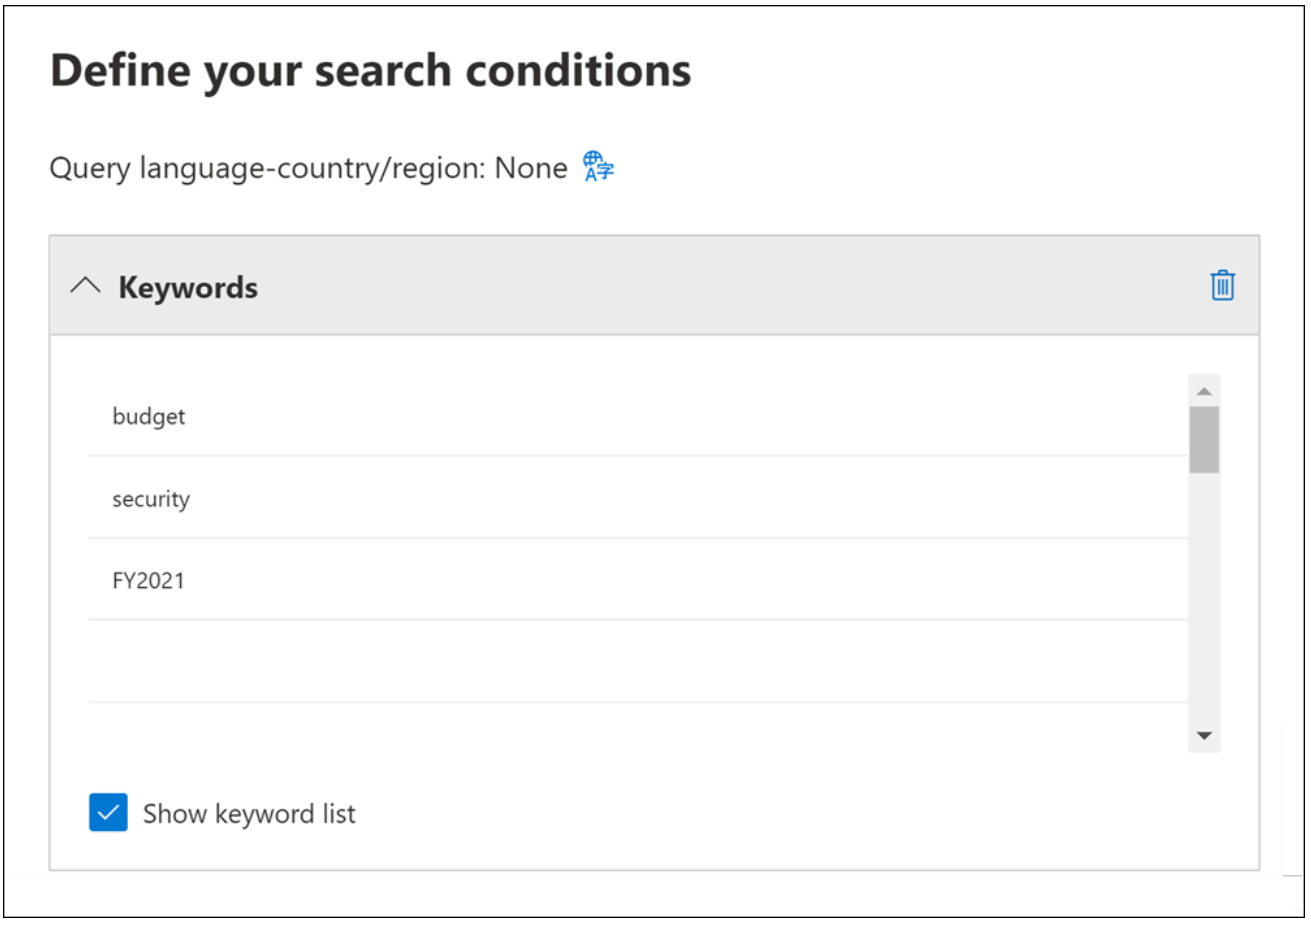
This section displays statistics about the specific content locations with the most items returned by the search. The top 1,000 locations are displayed. You can also download a copy of this report in CSV format.

- The name of the location name (the email address of mailboxes and the URL for sites).
- Location type (a mailbox or site).
- Estimated number of items in the content location returned by the search.
- The total size of estimated items in each content location.



Get keyword statistics for searches

The **Condition report** section shows the search query and the number (and size) of items that match the query. If you use a keyword list when you create or edit a search query, you can get enhanced statistics that show how many items match each keyword or keyword phrase. This can help you quickly identify which parts of the query are the most (and least) effective. For example, if a keyword returns a large number of items, you might choose to refine the keyword query to narrow the search results.

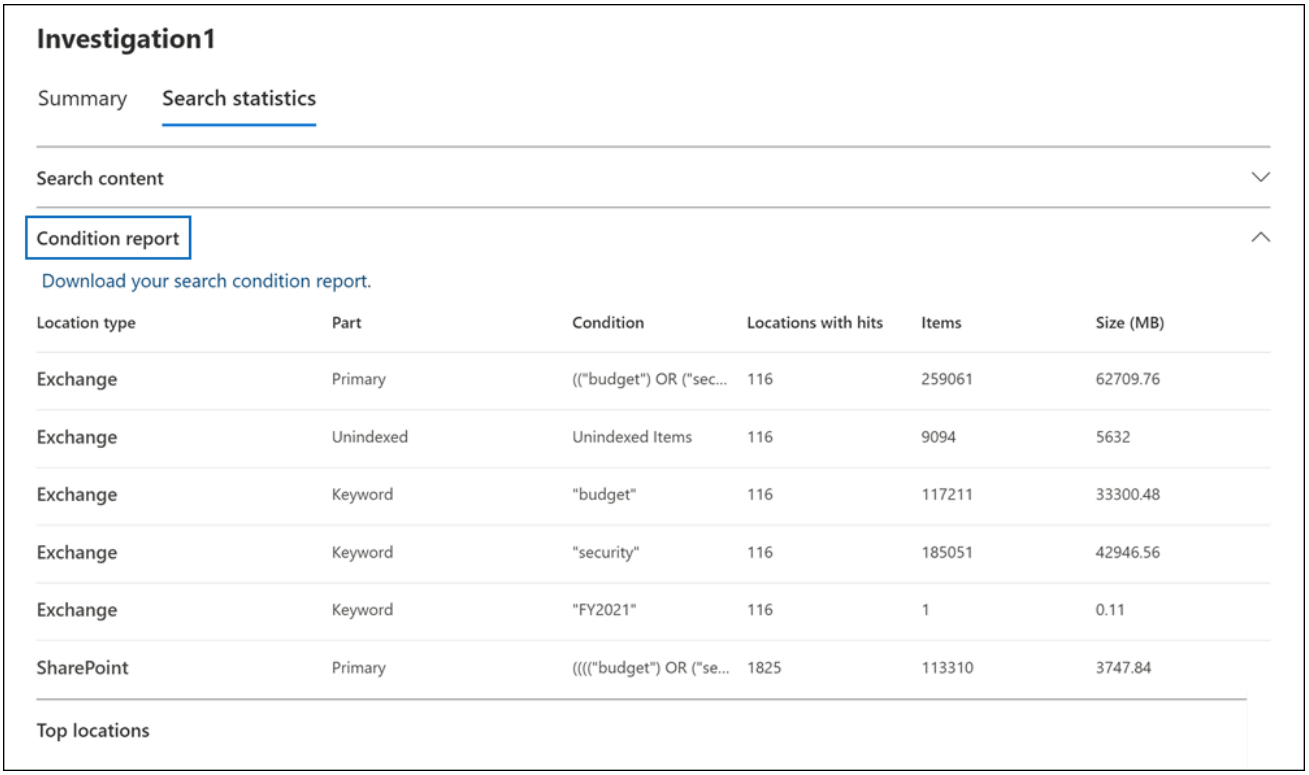


To create a keyword list and view keyword statistics for a search:

1. In the Microsoft Purview portal, create a new Content search or a search associated with an eDiscovery (Standard) case.

2. On the **Conditions** page of the search workflow. select the **Show keyword list** checkbox.

3. Type a keyword or keyword phase in a row in the keywords table. For example, type **budget** in the first row, type **security** in the second row, and type **FY2021** in the third row.



> **Note**

To help reduce issues caused by large keyword lists, you're limited to a maximum of 20 rows in the keyword list of a search query.

4. After adding the keywords to the list that you want to search and get statistics for, run the search.

5. When the search is completed, select it to display the flyout page.

6. On the **Search statistics** tab, select the **Condition report** to display the keyword statistics for the search.

As shown in the previous screenshot, the statistics for each keyword are displayed; this includes:

- The keyword statistics for each type of content location included in the search.
- The number of unindexed mailbox items.
- The actual search query and results for each keyword (identified as **Keyword** in the **Part** column), which includes any conditions from the search query.
- The complete search query (identified as **Primary** in the **Part** column) and the statistics for the complete query for each location type. Note these are the same statistics displayed on the **Summary** tab.

Last updated on 11/21/2025

Export Content search results

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After a Content search is successfully run, you can export the search results to a local computer. When you export email results, they're downloaded to your computer as PST files. When you export content from SharePoint and OneDrive for Business sites, copies of native Office documents are exported. There are other documents and reports included with the exported search results.

Exporting the results of a Content search involves preparing the results, and then downloading them to a local computer. These steps for exporting search results also apply to exporting the results of a search that's associated with Microsoft Purview eDiscovery (Standard) cases.

Before you export search results

> **Important**
>
> The eDiscovery Export tool was permanently **retired on August 31, 2025**, this functionality isn't available in the new eDiscovery experience.

- To export search results, you have to be assigned the Export management role in Microsoft Purview portal. This role is assigned to the built-in eDiscovery Manager role group. It isn't assigned by default to the Organization Management role group. For more information, see Assign eDiscovery permissions.
- The computer you use to export the search results has to meet the following system requirements:

    - Latest version of Windows (32-bit or 64-bit)
    - Microsoft .NET Framework 4.7 or higher

- You have to use Microsoft Edge[1] to run the eDiscovery Export Tool. Using Internet Explorer 11 to export search results is no longer supported[2].

  > **Note**
  >
  > [1] As a result of recent changes to Microsoft Edge, SelectOnce support is no longer enabled by default. Also, Microsoft doesn't manufacture third-party extensions or add-ons for SelectOnce applications. Exporting search results using an unsupported browser with third-party extensions or add-ons isn't supported.
  >
  > [2] Beginning August 2021, Microsoft 365 apps and services will no longer support Internet Explorer 11 (IE11) and users may have a degraded experience or be unable to connect to those apps and services. These apps and services will phase out over the upcoming weeks and months to ensure a smooth end of support. Each app and service are being phased out on independent schedules. For more information, see this **blog post**.

- The eDiscovery Export Tool that you use in Step 2 to download search results doesn't support automation (by using a script or running cmdlets). We highly recommended that you don't automate the download process in Step 2. If you automate this processes, Microsoft Support won't provide assistance if you run into issues.

- We recommend downloading search results to a local computer. To eliminate your company's firewall or proxy infrastructure from causing issues when downloading search results, you might consider downloading search results to a virtual desktop outside of your network. This may decrease timeouts that occur in Azure data connections when exporting a large number of files. For more information about virtual desktops, see Windows Virtual Desktop.

- To improve performance when downloading search results, consider dividing searches that return a large set of results into smaller searches. For example, you can use date ranges in search queries to return a smaller set of results that can be downloaded faster.

- When you export search results, the data is temporarily stored in a Microsoft-provided Azure Storage location in the Microsoft cloud before it's downloaded to your local computer. Be sure that your organization can connect to the endpoint in Azure, which is

***.blob.core.windows.net** (the wildcard represents a unique identifier for your export). The search results data is deleted from the Azure Storage location two weeks after it's created.

- If your organization uses a proxy server to communicate with the Internet, you need to define the proxy server settings on the computer that you use to export the search results (so the export tool can be authenticated by your proxy server). To do this, open the *machine.config* file in the location that matches your version of Windows.

  - **32-bit:** `%windir%\Microsoft.NET\Framework\[version]\Config\machine.config`
  - **64-bit:** `%windir%\Microsoft.NET\Framework64\[version]\Config\machine.config`

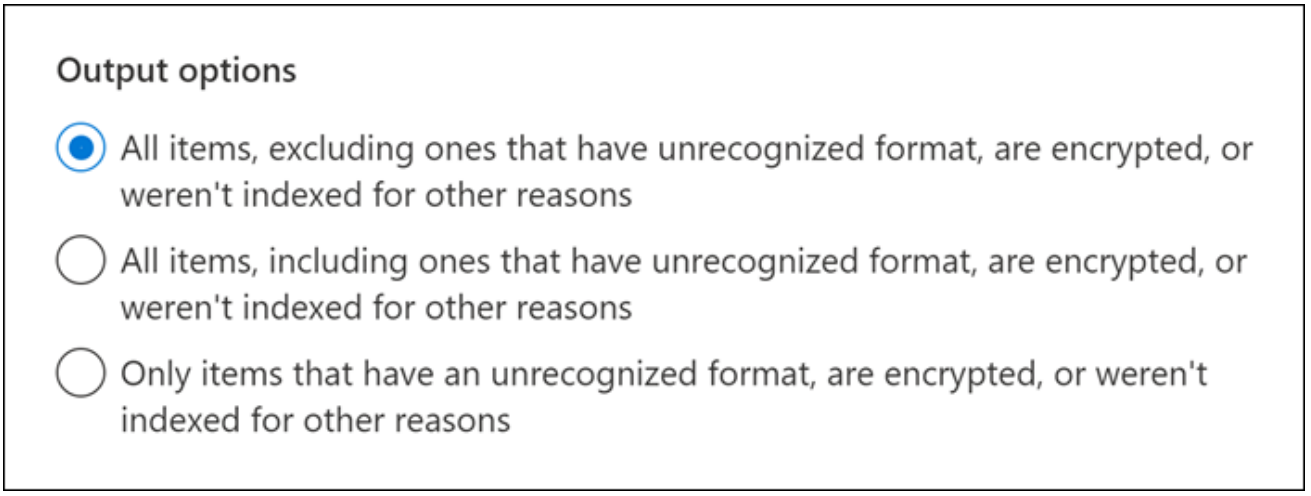
    Add the following lines to the *machine.config* file somewhere between the `<configuration>` and `</configuration>` tags. Be sure to replace `ProxyServer` and `Port` with the correct values for your organization; for example, `proxy01.contoso.com:80`.

    XML

    ```
    <system.net>
       <defaultProxy enabled="true" useDefaultCredentials="true">
         <proxy proxyaddress="https://ProxyServer :Port "
                usesystemdefault="False"
                bypassonlocal="True"
                autoDetect="False" />
       </defaultProxy>
    </system.net>
    ```

- If the results of a search are older than 7 days and you submit an export job, an error message is displayed prompting you to rerun the search to update the search results. If this happens, cancel the export, rerun the search, and then start the export again.

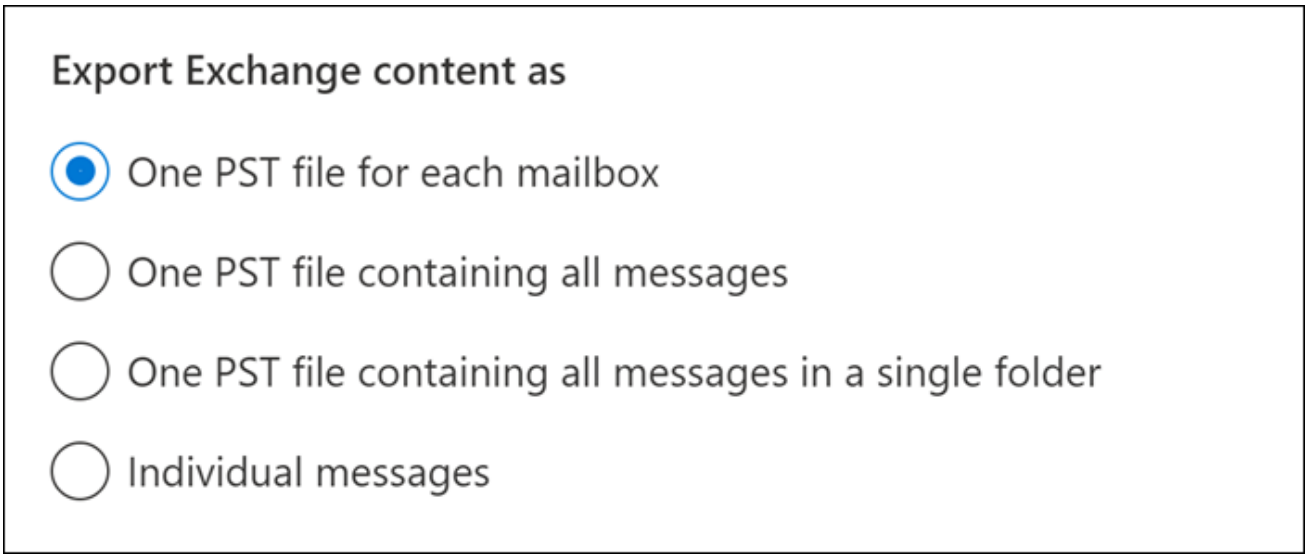
Step 1: Prepare search results for export



The first step is to prepare the search results for exporting. When you prepare results, they're uploaded to a Microsoft-provided Azure Storage location in the Microsoft cloud. Content from mailboxes and sites is uploaded at a maximum rate of 2 GB per hour.

1. In the Microsoft Purview portal, select the content search that you want to export results from.
2. On the **Actions** menu at the bottom of the flyout page, select **Export results**.

The **Export results** flyout page is displayed. The export options available to export content depend on whether search results are located in mailboxes or sites or a combination of both.



3. Under **Output options**, choose one of the following options:

- **All items, excluding ones that have unrecognized format, are encrypted, or weren't indexed for other reasons**. This option exports only indexed items.
- **All items, including ones that have unrecognized format, are encrypted, or weren't indexed for other reasons**. This option exports indexed and unindexed items.
- **Only items that have an unrecognized format, are encrypted, or weren't indexed for other reasons**. This option exports only unindexed items.

  See the More information section for a description about how partially indexed items are exported. For more information about partially indexed items, see Partially indexed items in Content search.

4. Under **Export Exchange content as**, choose one of the following options:

- **One PST file for each mailbox**: Exports one PST file for each user mailbox that contains search results. Any results from the user's archive mailbox are included in the same PST file. This option reproduces the mailbox folder structure from the source mailbox.
- **One PST file containing all messages**: Exports a single PST file (named *Exchange.pst*) that contains the search results from all source mailboxes included in the search. This option reproduces the mailbox folder structure for each message.
- **One PST file containing all messages in a single folder**: Exports search results to a single PST file where all messages are located in a single, top-level folder. This option lets reviewers review items in chronological order (items are sorted by sent date) without having to navigate the original mailbox folder structure for each item.
- **Individual messages**: Exports search results as individual email messages, using the .msg format. If you select this option, email search results are exported to a folder in the file system. The folder path for individual messages is the same as the one used if you exported the results to a PST file.

5. Configure the following additional options:

a. Select the **Enable de-duplication for Exchange content** checkbox to exclude duplicate messages.

   If you select this option, only one copy of a message will be exported even if multiple copies of the same message are found in the mailboxes that were searched. The export results report (which is a file named Results.csv) will contain a row for every copy of a duplicate message so that you can identify the mailboxes (or public folders) that contain a copy of the duplicate message.

b. Select the **Include versions for SharePoint files** checkbox to export all versions of SharePoint documents. This option appears only if the content sources of the search include SharePoint or OneDrive for Business sites.

c. Select the **Export files in a compressed (zipped) folder. Includes only individual messages and SharePoint documents** checkbox to export search results to compressed folders. This option appears only when you choose to export Exchange items as individual messages and when the search results include SharePoint or OneDrive documents. This option is primarily used to work around the 260 character limit in Windows file path names when items are exported. See the "Filenames of exported items" in the More information section.

> ⓘ **Important**
>
> Exporting files in a compressed (zipped) folder will increase export times.

6. Select **Export** to start the export process. The search results are prepared for downloading, which means they're collected from the original content locations and then uploaded to an Azure Storage location in the Microsoft cloud. This may take several minutes.

See the next section for instructions to download the exported search results.

Step 2: Download the search results

The next step is to download the search results from the Azure Storage location to your local computer.

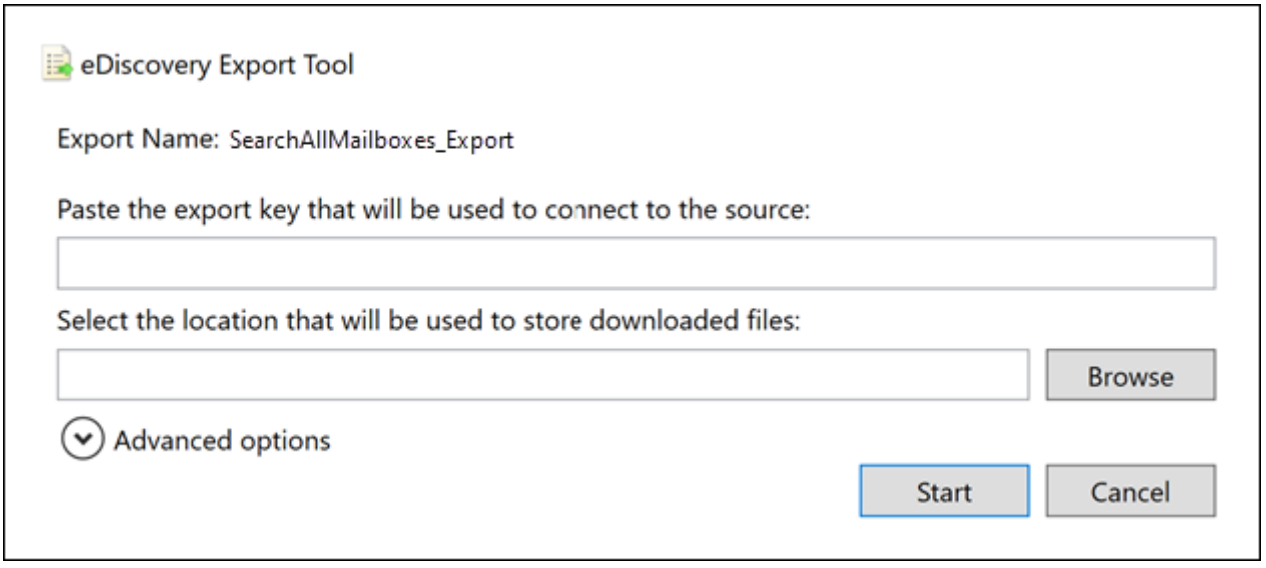
> ⓘ **Important**

The exported search results must be downloaded within 14 days after you created the export job in Step 1.

1. On the **Content search** page in the Microsoft Purview portal, select the **Exports** tab

   You may have to select **Refresh** to update the list of export jobs so that it shows the export job you created. Export jobs have the same name as the corresponding search with **_Export** appended to the search name.

2. Select the export job that you created in Step 1.



3. On the flyout page under **Export key**, select **Copy to clipboard**. You use this key in step 6 to download the search results.

   > **ⓘ Important**
   >
   > Because anyone can install and start the eDiscovery Export tool, and then use this key to download the search results, be sure to take precautions to protect this key just like you would protect passwords or other security-related information.

4. At the top of the flyout page, select **Download results**.

5. If you're prompted to install the **eDiscovery Export Tool**, select **Install**.

6. In the **eDiscovery Export Tool**, do the following:

   a. Paste the export key that you copied in Step 3 in the appropriate box.

   b. Select **Browse** to specify the location where you want to download the search result files.

> **ⓘ Important**
>
> Due to high network activity during download, you should download search results only to a location on an internal drive on your local computer. For the best download experience, follow these guidelines:
>
> - Don't download search results to a UNC path, a mapped network drive, an external USB drive, or a synched OneDrive for Business account.
> - Disable anti-virus scanning for the folder that you download the search result to.
> - Download search results to different folders for concurrent download jobs.

7. Select **Start** to download the search results to your computer.

   The **eDiscovery Export Tool** displays status information about the export process, including an estimate of the number (and size) of the remaining items to be downloaded. When the export process is complete, you can access the files in the location where they were downloaded.

More information

Here's more information about exporting search results.

- Export reports
- Exporting partially indexed items
- Exporting individual messages or PST files
- Decrypting RMS-protected email messages and encrypted file attachments
- Filenames of exported items
- Miscellaneous

Export reports

- When you export search results, the following reports are included in addition to the search results.
  - **Export Summary** An Excel document that contains a summary of the export. This includes information such as the number of content sources that were searched, the estimated and downloaded sizes of the search results, and the estimated and downloaded number of items that were exported.

- **Manifest** A manifest file (in XML format) that contains information about each item included in the search results.
- **Results** An Excel document that contains information about each item that is download as a search result. For email, the result log contains information about each message, including:
  - The location of the message in the source mailbox (including whether the message is in the primary or archive mailbox).
  - The date the message was sent or received.
  - The Subject line from the message.
  - The sender and recipients of the message.
  - Whether the message is a duplicate message if you enabled the de-duplication option when exporting the search results. Duplicate messages have a value in the **Duplicate to Item** column that identifies the message as a duplicate. The value in the **Duplicate to Item** column contains the item identity of the message that was exported.

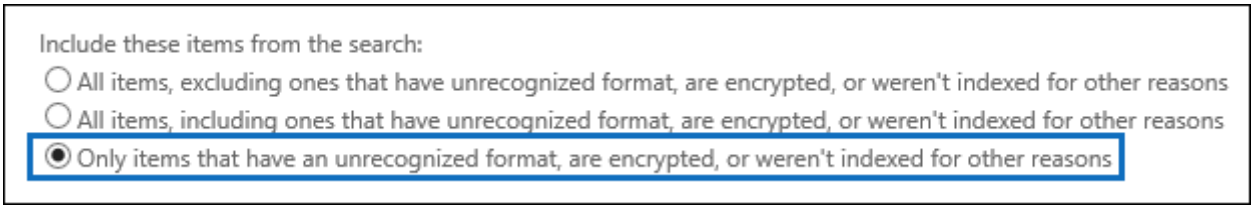
    For documents from SharePoint and OneDrive for Business sites, the result log contains information about each document, including:
    - The URL for the document.
    - The URL for the site collection where the document is located.
    - The date that the document was last modified.
    - The name of the document (which is located in the Subject column in the result log).
- **Unindexed Items** An Excel document that contains information about any partially indexed items that would be included in the search results. If you don't include partially indexed items when you generate the search results report, this report will still be downloaded, but will be empty.
- **Errors and Warnings** Contains errors and warnings for files encountered during export. See the Error Details column for information specific to each individual error or warning.
- **Skipped Items** When you export search results from SharePoint and OneDrive for Business sites, the export will usually include a skipped items report (SkippedItems.csv). The items cited in this report are typically items that won't be downloaded, such as a folder or a document set. Not exporting these types of items is by design. For other

items that were skipped, the 'Error Type' and 'Error Details' field in the skipped items report show the reason the item was skipped and wasn't downloaded with the other search results.

- **Trace.log** Contains detailed logging information about the export process and can help uncover issues during export. If you open a ticket with Microsoft Support about an issue related to exporting search results, you may be asked to provide this trace log.

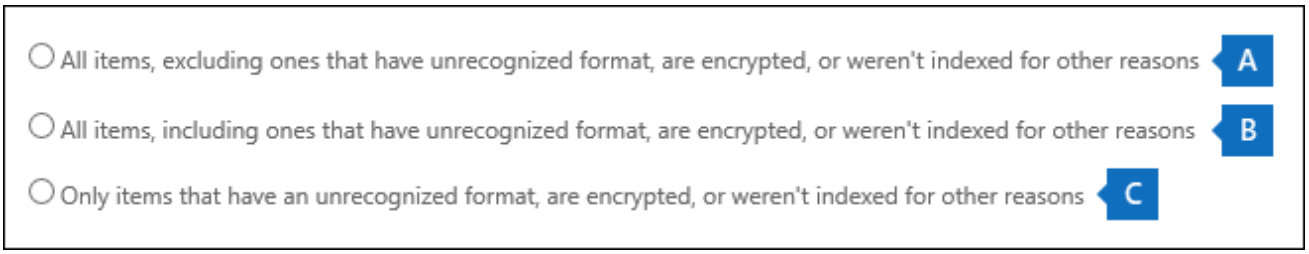
  > ⓘ **Note**
  >
  > You can just export these documents without having to export the actual search results.

Exporting partially indexed items



- If you're exporting mailbox items from a content search that returns all mailbox items in the search results (because no keywords where included in the search query), partially indexed items won't be copied to the PST file that contains the unindexed items. This is because all items, including any partially indexed items, are automatically included in the regular search results. This means that partially indexed items will be included in a PST file (or as individual messages) that contains the other, indexed items.

  If you export both the indexed and partially indexed items or if you export only the indexed items from a content search that returns all items, the same number of items will be downloaded. This happens even though the estimated search results for the content search (displayed in the search statistics in the Microsoft Purview portal) will still include a separate estimate for the number of partially indexed items. For example, let's say that the estimate for a search that includes all items (no keywords in the search query) shows that 1,000 items were found and that 200 partially indexed items were also found. In this case, the 1,000 items include the partially indexed items because the search returns all items. In other words, there are 1,000 total items returned by the search, and not 1,200 items (as you might expect). If you export the results of this search and choose to export indexed and partially indexed items (or export only partially indexed items), then 1,000 items are downloaded. Again, that's because partially indexed items are included with the regular (indexed) results when you use a blank search query to return all items. In this same example, if you choose to export only partially indexed items, then only the 200 unindexed items would be downloaded.



Also note that in the previous example (when you export indexed and partially indexed items or you export only indexed items), the **Export Summary** report included with the exported search results would list 1,000 items estimated items and 1,000 downloaded items for the same reasons as previously described.

- If the search that you're exporting results from was a search of specific content locations or all content locations in your organization, only the partial items from content locations that contain items that match the search criteria will be exported. In other words, if no search results are found in a mailbox or site, then any partially indexed items in that mailbox or site won't be exported. The reason for this is that exporting partially indexed items from lots of locations in the organization might increase the likelihood of export errors and increase the time it takes to export and download the search results.

  To export partially indexed items from all content locations for a search, configure the search to return all items (by removing any keywords from the search query) and then export only partially indexed items when you export the search results.

- When exporting search results from SharePoint or OneDrive for Business sites, the ability to export unindexed items also depends on the export option that you select and whether a site that was searched contains an indexed item that matches the search criteria. For example, if you search specific SharePoint or OneDrive for Business sites and no search results are found, then no unindexed items from those sites will be exported if you choose the second export option to export both indexed and unindexed items. If an indexed item from a site does match the search criteria, then all unindexed items from that site will be exported when exporting both indexed and unindexed items. The following illustration describes the export options based on whether a site contains an indexed item that matches the search criteria.

a. Only indexed items that match the search criteria are exported. No partially indexed items are exported.

b. If no indexed items from a site match the search criteria, then partially indexed items from that same site aren't exported. If indexed items from a site are returned in the search results, then the partially indexed items from that site are exported. In other words, only the partially indexed items from sites that contain items that match the search criteria are exported.

c. All partially indexed items from all sites in the search are exported, regardless of whether a site contains items that match the search criteria.

If you choose to export partially indexed items, partially indexed mailbox items are exported in a separate PST file regardless of the option that you choose under **Export Exchange content as**.

- If partially indexed items are returned in the search results (because other properties of partially indexed items matched the search criteria), then those partially indexed are exported with the regular search results. So, if you choose to export both indexed items and partially indexed items (by selecting the **All items, including ones that have unrecognized format, are encrypted, or weren't indexed for other reasons** export option), the partially indexed items exported with the regular results will be listed in the Results.csv report. They won't be listed in the Unindexed items.csv report.

Exporting individual messages or PST files

- If the file path name of a message exceeds the maximum character limit for Windows, the file path name is truncated. But the original file path name will be listed in the Manifest and ResultsLog.
- As previously explained, email search results are exported to a folder in the file system. The folder path for individual messages would replicate the folder path in the user's mailbox. For example, for a search named "ContosoCase101" messages in a user's inbox would be located in the folder path `~ContosoCase101\\<date of export\Exchange\user@contoso.com (Primary)\Top of Information Store\Inbox`.
- If you choose to export email messages in one PST file containing all messages in a single folder, a **Deleted Items** folder and a **Search Folders** folder are included in the top level of the PST folder. These folders are empty.
- As previously stated, you must export email search results as individual messages to decrypt RMS-protected messages when they're exported. Encrypted messages remain encrypted if

you export email search results as a PST file.

Decrypting RMS-protected email messages and encrypted file attachments

Any rights-protected (RMS-protected) email messages included in the results of a Content search will be decrypted when you export them. Additionally, any file that's encrypted with a Microsoft encryption technology and is attached to an email message that's included in the search results will also be decrypted when it's exported. This decryption capability is enabled by default for members of the eDiscovery Manager role group. This is because the RMS Decrypt management role is assigned to this role group by default. Keep the following things in mind when exporting encrypted email messages and attachments:

- As previously explained, to decrypt RMS-protected messages when you export them, you have to export the search results as individual messages. If you export search results to a PST file, RMS-protected messages remain encrypted.
- Messages that are decrypted are identified in the **ResultsLog** report. This report contains a column named **Decode Status**, and a value of **Decoded** in this column identifies the messages that were decrypted.
- In addition to decrypting file attachments when exporting search results, you can also preview the decrypted file when previewing search results. You can only view the rights-protected email message after you export it.
- At this time, the decryption capability when exporting search results doesn't include encrypted content from SharePoint and OneDrive for Business sites. However, support is coming soon for documents encrypted with Microsoft encryption technologies and stored in SharePoint Online and OneDrive for Business.
- If you need to prevent someone from decrypting RMS-protect messages and encrypted file attachments, you have to create a custom role group (by copying the built-in eDiscovery Manager role group) and then remove the RMS Decrypt management role from the custom role group. Then add the person who you don't want to decrypt messages as a member of the custom role group.

Filenames of exported items

- There's a 260-character limit (imposed by the operating system) for the full path name for email messages and site documents exported to your local computer. The full path name for exported items includes the item's original location and the folder location on the local computer where the search results are downloaded to. For example, if you specify to

download the search results to `C:\Users\Admin\Desktop\SearchResults` in the eDiscovery Export tool, then the full pathname for a downloaded email item would be `C:\Users\Admin\Desktop\SearchResults\ContentSearch1\03.15.2017-1242PM\Exchange\sarad@contoso.com (Primary)\Top of Information Store\Inbox\Insider trading investigation.msg`.

- If the 260-character limit is exceeded, the full path name for an item will be truncated, based on the following:

  - If the full path name is longer than 260 characters, the file name is shortened to get under the limit; note that the truncated filename (excluding the file extension) won't be fewer than eight characters.

  - If the full path name is still too long after shortening the file name, the item is moved from its current location to the parent folder. If the pathname is still too long, then the process is repeated: shorten the filename, and if necessary move again to the parent folder. This process is repeated until the full pathname is under the 260-character limit.

  - If a truncated full path name already exists, a version number is added to the end of the filename; for example, `statusmessage(2).msg`.

    To help mitigate this issue, consider downloading search results to a location with a short path name; for example, downloading search results to a folder named `C:\Results` would add fewer characters to the path names of exported items than downloading them to a folder named `C:\Users\Admin\Desktop\Results`.

- When you export site documents, it's also possible that the original file name of a document will be modified. This happens specifically for documents that have been deleted from a SharePoint or OneDrive for Business site that's been placed on hold. After a document that's on a site that's on hold is deleted, the deleted document is automatically moved to the Preservation Hold library for the site (which was created when the site was placed on hold). When the deleted document is moved to the Preservation Hold library, a randomly generated and unique ID is appended to the original filename of the document. For example, if the filename for a document is `FY2017Budget.xlsx` and that document is later deleted and moved to the Preservation Hold library, the filename of the document that is moved to the Preservation Hold library is modified to something like `FY2017Budget_DEAF727D-0478-4A7F-87DE-5487F033C81A2000-07-05T10-37-55.xlsx`. If a document in the Preservation Hold library matches the query of a Content search and you export the results of that search, the exported file has the modified filename; in this

example, the filename of the exported document would be `FY2017Budget_DEAF727D-0478-4A7F-87DE-5487F033C81A2000-07-05T10-37-55.xlsx`.

When a document on a site that's on hold is modified (and versioning for the document library in the site has been enabled), a copy of the file is automatically created in the Preservation Hold library. In this case, a randomly generated and unique ID is also appended to the filename of the document that's copied to the Preservation Hold library.

The reason why filenames of documents that are moved or copied to the Preservation Hold library is to prevent conflicting filenames. For more information about placing a hold on sites and the Preservation Hold library, see Overview of in-place hold in SharePoint Server 2016.

Miscellaneous

- When downloading search results using the eDiscovery Export Tool, it's possible you might receive the following error: `System.Net.WebException: The remote server returned an error: (412) The condition specified using HTTP conditional header(s) is not met.` This is transient error, which typically occurs in the Azure Storage location. To resolve this issue, retry downloading the search results, which will restart the eDiscovery Export Tool.
- All search results and the export reports are included in a folder that has the same name as the Content search. The email messages that were exported are located in a folder named **Exchange**. Documents are located in a folder named **SharePoint**.
- The file system metadata for documents on SharePoint and OneDrive for Business sites is maintained when documents are exported to your local computer. That means document properties, such as created and last modified dates, aren't changed when documents are exported.
- If your search results include a list item from SharePoint that matches the search query, all rows in the list will be exported in addition to the item that matches the search query and any attachments in the list. The reason for this behavior is to provide a context for list items that are returned in the search results. The other list items and attachments may cause the count of exported items to be different than the original estimate of search results.

Last updated on 10/31/2024

Search for and delete email messages

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

> **Tip**
>
> You can also use the purge feature in Data Security Investigations to search for and permanently delete Exchange mailbox and Microsoft Teams items in your organization. Data Security Investigations provides a built-in search and purge workflow with a purge queue dashboard to help you manage and track purge queries. For more information, see Purge in Data Security Investigations.

You can use the Content search feature to search for and delete email messages from all mailboxes in your organization. This can help you find and remove potentially harmful or high-risk email, such as:

- Messages that contain dangerous attachments or viruses
- Phishing messages
- Messages that contain sensitive data

> **Tip**
>
> If your organization has a Defender for Office 365 Plan 2 subscription, we recommend using the procedure detailed in Remediate malicious email delivered in Office 365, rather than following the procedure described in this article.

Before you begin

- The search and purge workflow described in this article doesn't delete chat messages or other content from Microsoft Teams. If the Content search that you create in Step 2 returns items from Microsoft Teams, those items won't be deleted when you purge items in Step 3. To search for and delete chat messages, see Search and purge chat messages in Teams.

- To create and run a Content search, you have to be a member of the *eDiscovery Manager* role group or be assigned the *Compliance Search* role in the Microsoft Purview portal. To delete messages, you have to be a member of the *Organization Management* role group or be assigned the *Search And Purge* role in the Microsoft Purview portal For information about adding users to a role group, see Assign eDiscovery permissions.

  > ⓘ **Note**
  >
  > The *Organization Management* role group exists in both Exchange Online and in the Microsoft Purview portal. These are separate role groups that give different permissions. Being a member of *Organization Management* in Exchange Online does not grant the required permissions to delete email messages. If you aren't assigned the *Search And Purge* role in the Microsoft Purview portal (either directly or through a role group such as *Organization Management*), you'll receive an error in Step 3 when you run the *New-ComplianceSearchAction* cmdlet with the message "A parameter cannot be found that matches parameter name 'Purge'".

- You have to use Security & Compliance PowerShell to delete messages. See Step 1: Connect to Security & Compliance PowerShell for instructions about how to connect.

- A maximum of 10 items per mailbox can be removed at one time. Because the capability to search for and remove messages is intended to be an incident-response tool, this limit helps ensure that messages are quickly removed from mailboxes. This feature isn't intended to clean up user mailboxes.

  > ⓘ **Note**
  >
  > This option isn't supported if a mailbox has a litigation hold or in-place hold. Only 10 items are removed from view of the user. These 10 items aren't permanently deleted, so these 10 items are the only ones processed.

- The maximum number of mailboxes in a content search that you can use to delete items by doing a search and purge action is 50,000. If the search (that you create in Step 2 searches

more than 50,000 mailboxes, the purge action (that you create in Step 3) will fail. Searching more than 50,000 mailbox in a single search might typically happen when you configure the search to include all mailboxes in your organization. This restriction still applies even when less than 50,000 mailboxes contain items that match the search query. See the More information section for guidance about using search permissions filters to search for and purge items from more than 50,000 mailboxes.

- The procedure in this article can only be used to delete items in Exchange Online mailboxes and public folders. You can't use it to delete content from SharePoint or OneDrive for Business sites.

- Email items in a review set in an eDiscovery (Premium) case can't be deleted by using the procedures in this article. That's because items in a review set are stored in an Azure Storage location, and not in the live service. This means they won't be returned by the content search that you create in Step 1. To delete items in a review set, you have to delete the eDiscovery (Premium) case that contains the review set. For more information, see Close or delete an eDiscovery (Premium) case.

Step 1: Connect to Security & Compliance PowerShell

The first step is to connect to Security & Compliance PowerShell for your organization. For step-by-step instructions, see Connect to Security & Compliance PowerShell.

Step 2: Create a Content Search to find the message to delete

The second step is to create and run a Content search to find the message that you want to remove from mailboxes in your organization. You can create the search by using the Microsoft Purview portal or by running the **New-ComplianceSearch** and **Start-ComplianceSearch** cmdlets in Security & Compliance PowerShell. The messages that match the query for this search will be deleted by running the **New-ComplianceSearchAction -Purge** command in Step 3. For information about creating a Content search and configuring search queries, see the following articles:

- Content search in Office 365
- Keyword queries for Content search
- New-ComplianceSearch
- Start-ComplianceSearch

> **Note**
>
> The content locations that are searched in the Content search that you create in this step can't include SharePoint or OneDrive for Business sites. You can include only mailboxes and public folders in a Content search that will be used to email messages. If the Content search includes sites, you'll receive an error in Step 3 when you run the **New-ComplianceSearchAction** cmdlet.

Tips for finding messages to remove

The goal of the search query is to narrow the results of the search to only the message or messages that you want to remove. Here are some tips:

- If you know the exact text or phrase used in the subject line of the message, use the **Subject** property in the search query.
- If you know that exact date (or date range) of the message, include the **Received** property in the search query.
- If you know who sent the message, include the **From** property in the search query.
- Preview the search results to verify that the search returned only the message (or messages) that you want to delete.
- Use the search estimate statistics (displayed in the details pane of the search in the Microsoft Purview portal or by using the Get-ComplianceSearch cmdlet) to get a count of the total number of results.

Here are two examples of queries to find suspicious email messages.

- This query returns messages that were received by users between April 13, 2016 and April 14, 2016 and that contain the words "action" and "required" in the subject line.

  PowerShell

  ```
  (Received:4/13/2016..4/14/2016) AND (Subject:'Action required')
  ```

- This query returns messages that were sent by user@contoso.com and that contain the exact phrase "Update your account information" in the subject line.

  PowerShell

  ```
  (From:user@contoso.com) AND (Subject:"Update your account information")
  ```

Here's an example of using a query to create and start a search by running the **New-ComplianceSearch** and **Start-ComplianceSearch** cmdlets to search all mailboxes in the organization:

PowerShell

```
$Search=New-ComplianceSearch -Name "Remove Phishing Message" -ExchangeLocation All -ContentMatchQuery '(Received:4/13/2016..4/14/2016) AND (Subject:"Action required")'
Start-ComplianceSearch -Identity $Search.Identity
```

Step 3: Delete the message

After you've created and refined a Content search to return the messages that you want to remove, the final step is to run the **New-ComplianceSearchAction -Purge** command in Security & Compliance PowerShell to delete the message.

You can soft- or hard-delete the message. A soft-deleted message is moved to a user's Recoverable Items folder and retained until the deleted item retention period expires. Hard-deleted messages are marked for permanent removal from the mailbox and will be permanently removed the next time the mailbox is processed by the Managed Folder Assistant. If single item recovery is enabled for the mailbox, hard-deleted items will be permanently removed after the deleted item retention period expires. If a mailbox is placed on hold, deleted messages are preserved until the hold duration for the item expires or until the hold is removed from the mailbox.

> ⓘ **Note**
>
> As previously stated, items from Microsoft Teams that are returned by Content search are not deleted when you run the **New-ComplianceSearchAction -Purge** command.

To run the following commands to delete messages, be sure that you're connected to Security & Compliance PowerShell.

Soft-delete messages

In the following example, the command soft-deletes the search results returned by a Content search named "Remove Phishing Message".

PowerShell

```
New-ComplianceSearchAction -SearchName "Remove Phishing Message" -Purge -PurgeType
SoftDelete
```

Hard-delete messages

To hard-delete the items returned by the "Remove Phishing Message" content search, you would run this command:

PowerShell

```
New-ComplianceSearchAction -SearchName "Remove Phishing Message" -Purge -PurgeType
HardDelete
```

When you run the previous commands to soft- or hard-delete messages, the search specified by the *SearchName* parameter is the Content search that you created in Step 1.

For more information, see New-ComplianceSearchAction.

More information

- **How do you get status on the search and remove operation?**

  Run the **Get-ComplianceSearchAction** to get the status on the delete operation. The object that is created when you run the **New-ComplianceSearchAction** cmdlet is named using this format: `<name of Content Search>_Purge`.

- **What happens after you delete a message?**

  A message that's deleted with the `New-ComplianceSearchAction -Purge -PurgeType HardDelete` command is moved to the Purges folder and can't be accessed by the user. After the message is moved to the Purges folder, the message is retained for the duration of the deleted item retention period if single item recovery is enabled for the mailbox. (In Microsoft 365, single item recovery is enabled by default when a new mailbox is created.) After the deleted item retention period expires, the message is marked for permanent deletion and will be purged from Microsoft 365 the next time the mailbox is processed by the Managed Folder assistant.

  If you use the `New-ComplianceSearchAction -Purge -PurgeType SoftDelete` command, messages are moved to the Deletions folder in the user's Recoverable Items folder. It isn't immediately purged from Microsoft 365. The user can recover messages in the Deleted Items folder for the duration based on the deleted item retention period configured for the

mailbox. After this retention period expires (or if user purges the message before it expires), the message is moved to the Purges folder and can no longer be accessed by the user. Once in the Purges folder, the message is retained for the duration based on the deleted item retention period configured for the mailbox if single items recovery is enabled for the mailbox. (In Microsoft 365, single item recovery is enabled by default when a new mailbox is created.) After the deleted item retention period expires, the message is marked for permanent deletion and will be purged from Microsoft 365 the next time that the mailbox is processed by the Managed Folder assistant.

- **What if you have to delete a message from more than 50,000 mailboxes?**

  As previously stated, you can perform a search and purge operation on a maximum of 50,000 mailboxes (even if less than 50,000 contain items that match the search query). If you have to do a search and purge operation on more than 50,000 mailboxes, consider creating temporary search permissions filters that reduce the number of mailboxes that would be searched to less than 50,000 mailboxes. For example, if your organization contains mailboxes in different departments, states, or countries/regions, you can create a mailbox search permissions filter based on one of those mailbox properties to search a subset of mailboxes in your organization. After you create the search permissions filter, you would create the search (described in Step 1) and then delete the message (described in Step 3). Then you can edit the filter to search for and purge messages in a different set of mailboxes. For more information about creating search permissions filters, see Configure permissions filtering for Content Search.

- **Will unindexed items included in the search results be deleted?**

  No, the `New-ComplianceSearchAction -Purge command doesn't delete unindexed items.

- **What happens if a message is deleted from a mailbox that has been placed on In-Place Hold or Litigation Hold or is assigned to an Microsoft 365 retention policy?**

  After the message is purged and moved to the Purges folder, the message is retained until the hold duration expires. If the hold duration is unlimited, then items are retained until the hold is removed or the hold duration is changed.

- **Why is the search and remove workflow divided among different Microsoft Purview portal role groups?**

  As previously explained, a person has to be a member of the eDiscovery Manager role group or be assigned the Compliance Search management role to search mailboxes. To

delete messages, a person has to be a member of the Organization Management role group or be assigned the Search And Purge management role. This makes it possible to control who can search mailboxes in the organization and who can delete messages.

Last updated on 12/01/2025

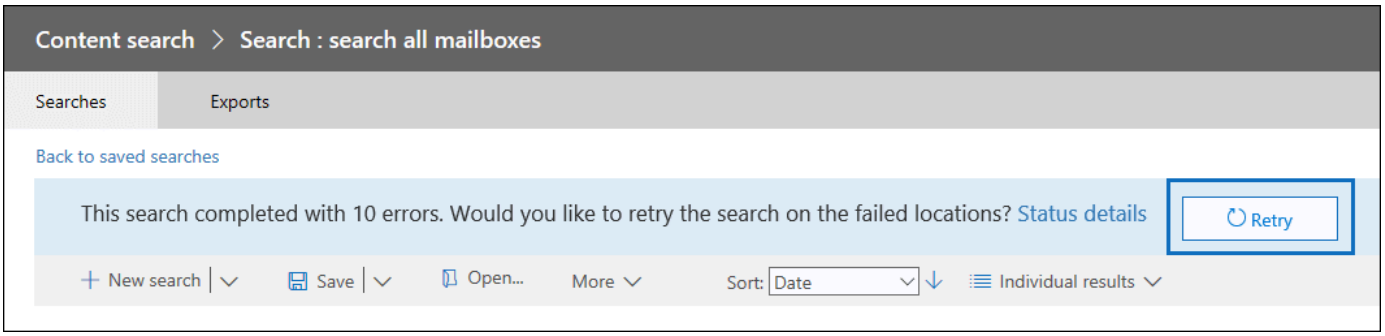
Retry a Content Search to resolve a content location error

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When you use Content Search in the Microsoft Purview portal to search a large number of mailboxes, you may get search errors that are similar to the error:

```text
Error

The search on the following locations failed:
User1@contoso.com: Problem in processing the request. Please try again later. If you keep getting this error, contact your admin. (CS008-009)
User2@contoso.com: Application error occurred. Please try again later. (CS012-002)
```



These errors (with error codes of CS001-002, CS003-002, CS008-009, CS012-002, and other errors of the form CS0XX-0XX) indicate that Content Search failed to search specific content locations. In this example, two mailboxes weren't searched. These errors are displayed on the status details flyout page of the Content Search.

Cause of content location errors

When searching a large number of mailboxes, the search is distributed across thousands of servers in a Microsoft datacenter. At any one time, specific servers could be in reboot state or in the process of failing over to redundant copies. In either of these cases, the Content Search's request to retrieve data will time out. In the previous example, the errors for the mailboxes that failed were the result of the search timing out.

Resolving content location errors

Restarting the search will often result in similar errors on different servers. Instead of restarting the search, select **Retry** at the top of the search results page.

This will result in the retrying the search only for the mailboxes that failed. When you retry the search, the other results that were successfully returned are retained.

Tips to avoid content location errors

Here are some additional causes of content location errors and some tips to help you avoid them when searching large numbers of mailboxes.

- The mailbox being searched might be busy due to user activity. In this case, the search service might throttle itself to prevent the mailbox from becoming unavailable. To avoid this, try running searches during non-business hours.
- The search query might be retrieving too much content from the mailbox. If possible, try to narrow the scope of the search by using keywords, date ranges, and search conditions.
- Too many keywords or keyword phrases when you create a search query using the keywords list. When you run a search query that uses the keywords list, the service essentially runs a separate search for each row in the keyword list so that statistics can be generated. If you're using the keywords list in search queries, minimize the number of rows in the keyword list or divide the number keywords into smaller lists and create a different search for each keyword list.

  > **Note**
  >
  > To help reduce issues caused by large keyword lists, you're now limited to a maximum of 20 rows in the keyword list of a search query.

- Too many searches are being performed on the same mailbox at the same time. If possible, try to run one search at a time on any one mailbox.
- Searching too many mailboxes in a single search. The probability of content location errors increases when searching a large number of mailboxes. If possible, try to run multiple searches so that each search includes a subset of mailboxes in your organization.
- Required maintenance is being performed on the mailbox. Though this cause probably occurs infrequently, wait a little while after receiving the content location error and then retry the search.

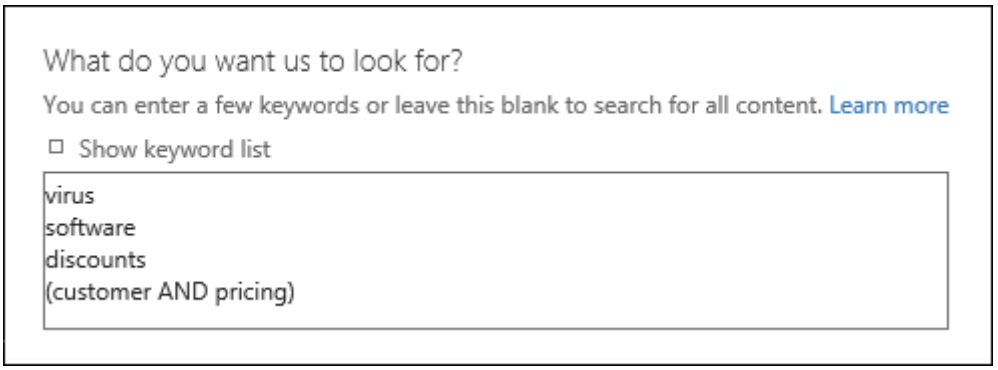
Feature reference for Content search

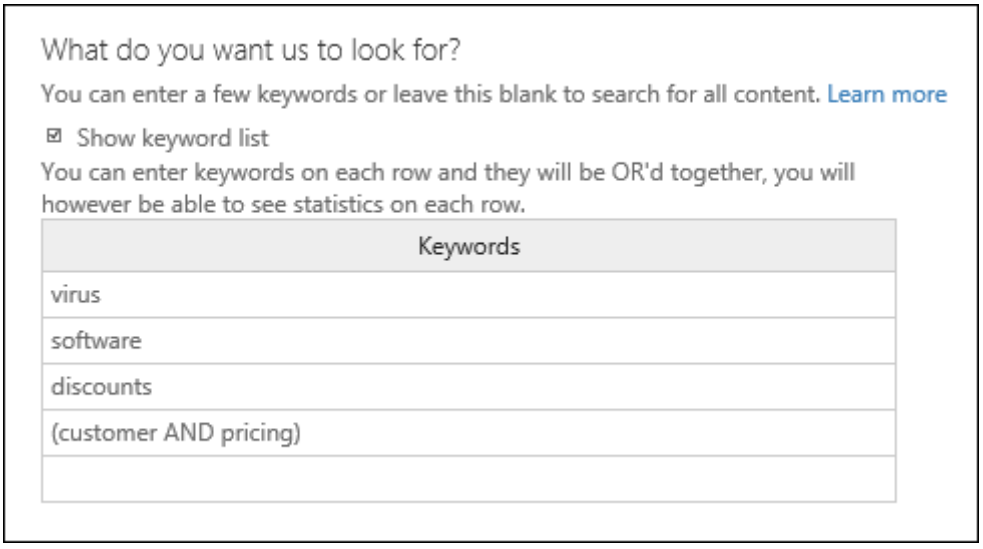
> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article describes features and functionality of Content search. To use the Content search eDiscovery tool in the Microsoft Purview portal to search for in-place content, see Get started with Content search.



Building a search query

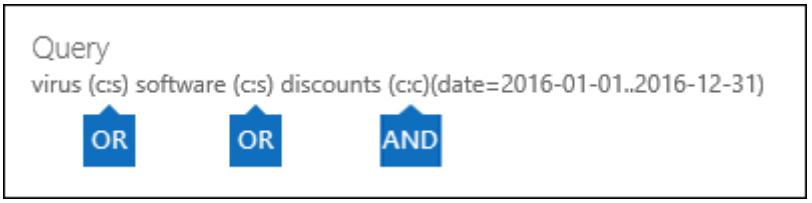
For detailed information about creating a search query, using Boolean search operators and search conditions, and searching for sensitive information types and content shared with users outside your organization, see Keyword queries and search conditions for Content Search.



Keep the following things in mind when using the keyword list to create a search query.

- You have to select the **Show keyword list** checkbox and then type each keyword in a separate row to create a search query where the keywords (or keyword phrases) in each row are connected by the **OR** operator. If you paste a list of keywords in the keyword box or press the **Enter** key after typing a keyword, they won't be connected by the **OR** operator. Here are incorrect and correct examples of how to add a list of keywords.

  Incorrect



Correct

- You can also prepare a list of keywords or keyword phrases in an Excel file or a plain text file, and then copy and paste your list into the keyword list. To do this, you have to select the **Show keyword list** check box. Then, select the first row in the keyword list and paste your list. Each line from the Excel or text file is pasted into separate row in the keyword list.

- After you create a query using the keyword list, it's a good idea to verify the search query syntax to make the search query is what you intended. In the search query that's displayed under **Query** in the details pane, the keywords are separated by the text **(c:s)**. This indicates that the keywords are connected by a logical operator similar in functionality to the **OR** operator. Similarly, if your search query includes conditions, the keywords and the conditions are separated by the text **(c:c)**. This indicates that the keywords are connected to the conditions with a logical operator similar in functionality to the **AND** operator. Here's an example of the search query (displayed in the Details pane) that results when using the keyword list and a condition.

- When you run a content search, Microsoft 365 automatically checks your search query for unsupported characters and for Boolean operators that may not be capitalized. Unsupported characters are often hidden and typically cause a search error or return unintended results. For more information about the unsupported characters that are checked, see Check your Content Search query for errors.

- If you have a search query that contains keywords for non-English characters (such as Chinese characters), you can select **Query language-country/region** and select a language-country/region culture code value for the search. The default language/region is neutral. How can you tell if you need to change the language setting for a content search? If you're certain content locations contain the non-English characters you're searching for, but the search returns no results, the language setting may be the cause.

Partially indexed items

- Partially indexed items in mailboxes are included in the estimated search results. Partially indexed items from SharePoint and OneDrive aren't included in the estimated search results. For more information, see Partially indexed items in eDiscovery.

Searching OneDrive accounts

- To collect a list of the URLs for the OneDrive sites in your organization, see Create a list of all OneDrive locations in your organization. This script in this article creates a text file that contains a list of all OneDrive sites. To run this script, you have to install and use the SharePoint Online Management Shell. Be sure to append the URL for your organization's MySite domain to each OneDrive site that you want to search. This is the domain that contains all your OneDrive; for example, `https://contoso-my.sharepoint.com`. Here's an example of a URL for a user's OneDrive site: `https://contoso-my.sharepoint.com/personal/sarad_contoso_onmicrosoft.com`.

  In the rare case of a person's user principal name (UPN) being changed, the URL for their OneDrive location is changed to incorporate the new UPN. If this happens, you have to modify a content search by adding the user's new OneDrive URL and removing the old one. For more information, see How UPN changes affect the OneDrive URL.

Searching Microsoft Teams and Microsoft 365 Groups

You can search the mailbox that's associated with a Microsoft Team or Microsoft 365 Group. Because Microsoft Teams is built on Microsoft 365 Groups, searching them is similar. In both

cases, only the group or team mailbox is searched. The mailboxes of the group or team members aren't searched. To search them, you've to specifically add them to the search.

Keep the following things in mind when searching for content in Microsoft Teams and Microsoft 365 Groups.

- To search for content located in Teams and Microsoft 365 Groups, you have to specify the mailbox and SharePoint site that are associated with a team or group.
- Content from private channels is stored in each user's mailbox, not the team mailbox. To search for content in private channels, see eDiscovery of private and shared channels.
- Run the **Get-UnifiedGroup** cmdlet in Exchange Online to view properties for a team or a Microsoft 365 Group. This is a good way to get the URL for the site that's associated with a team or a group. For example, the following command displays selected properties for a Microsoft 365 Group named Senior Leadership Team:

  ```text
  Get-UnifiedGroup "Senior Leadership Team" | FL
  DisplayName,Alias,PrimarySmtpAddress,SharePointSiteUrl
  DisplayName            : Senior Leadership Team
  Alias                  : seniorleadershipteam
  PrimarySmtpAddress     : seniorleadershipteam@contoso.onmicrosoft.com
  SharePointSiteUrl      :
  https://contoso.sharepoint.com/sites/seniorleadershipteam
  ```

  > **Note**
  >
  > To run the **Get-UnifiedGroup** cmdlet, you have to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- When a user's mailbox is searched, any team or Microsoft 365 Group that the user is a member of won't be searched. Similarly, when you search a team or a Microsoft 365 Group, only the group mailbox and group site that you specify is searched. The mailboxes and OneDrive for Business accounts of group members aren't searched unless you explicitly add them to the search.
- To get a list of the members of a team or a Microsoft 365 Group, you can view the properties on the **Home** > **Groups** page in the Microsoft 365 admin center. Alternatively, you can run the following command in Exchange Online PowerShell:

PowerShell

```
Get-UnifiedGroupLinks <group or team name> -LinkType Members | FL
DisplayName,PrimarySmtpAddress
```

> ⓘ Note
>
> To run the **Get-UnifiedGroupLinks** cmdlet, you have to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- Conversations that are part of a Teams channel are stored in the mailbox that's associated with the team. Similarly, files that team members share in a channel are stored on the team's SharePoint site. Therefore, you have to add the team mailbox and SharePoint site as a content location to search conversations and files in a channel.

- Alternatively, conversations that are part of the Chat list in Teams are stored in the Exchange Online mailbox of the users who participate in the chat. And files that a user shares in Chat conversations are stored in the OneDrive for Business account of the user who shares the file. Therefore, you have to add the individual user mailboxes and OneDrive for Business accounts as content locations to search conversations and files in the Chat list.

  > ⓘ Note
  >
  > In an Exchange hybrid deployment, users with an on-premises mailbox might participate in conversations that are part of the Chat list in Teams. In this case, content from these conversations is also searchable because it's saved to a cloud-based storage area (called a *cloud-based mailbox for on-premises users*) for users who have an on-premises mailbox. For more information, see Search for Teams chat data for on-premises users.

- Every team or team channel contains a Wiki for note-taking and collaboration. The Wiki content is automatically saved to a file with a .mht format. This file is stored in the Teams Wiki Data document library on the team's SharePoint site. You can use the Content Search tool to search the Wiki by specifying the team's SharePoint site as the content location to search.

  > ⓘ Note

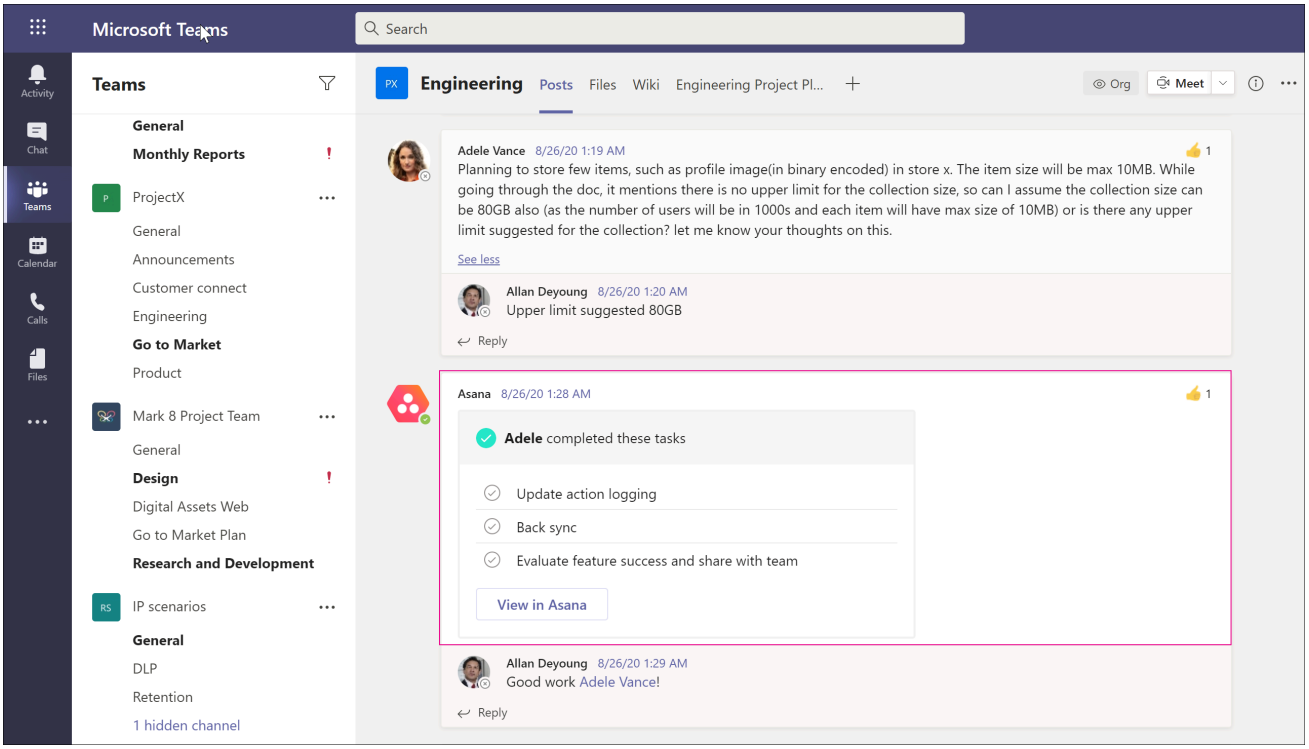
> The capability to search the Wiki for a team or channel (when you search the team's SharePoint site) was released on June 22, 2017. Wiki pages that were saved or updated on that date or after are available to be searched. Wiki pages last saved or updated before that date aren't available for search.

- Summary information for meetings and calls in a Teams channel are also stored in the mailboxes of users who dialed into the meeting or call. This means you can use Content Search to search these summary records. Summary information includes:
  - Date, start time, end time, and duration of a meeting or call
  - The date and time when each participant joined or left the meeting or call
  - Calls sent to voice mail
  - Missed or unanswered calls
  - Call transfers, which are represented as two separate calls

  It can take up to 8 hours for meeting and call summary records to be available to be searched.

  In the search results, meeting summaries are identified as **Meeting** in the **Type field**, and call summaries are identified as **Call**. Also, conversations that are part of a Teams channel and 1xN chats are identified as **IM** in the **Type** field.

For more information, see Microsoft Teams launches eDiscovery for calls and meetings.



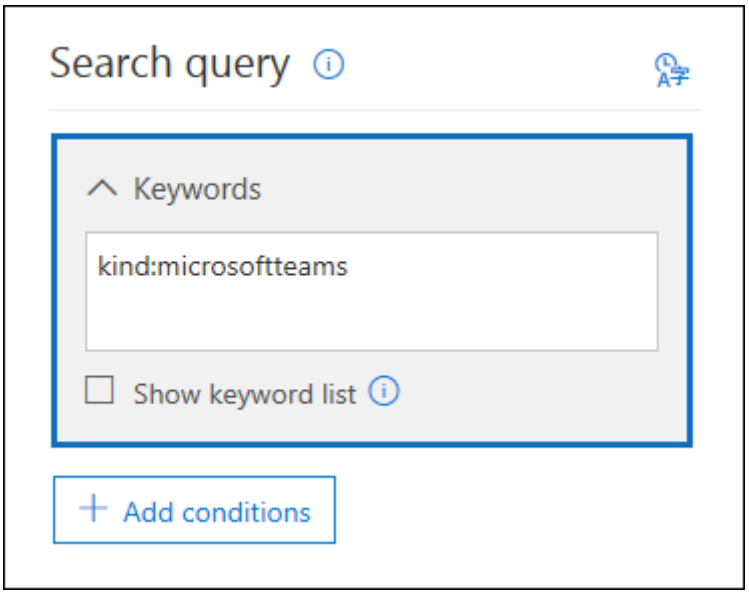
- Card content generated by apps in Teams channels, 1:1 chats, and 1xN chats are stored in mailboxes and can be searched. A *card* is a UI container for short pieces of content. Cards can have multiple properties and attachments, and can include items that trigger card actions. For more information, see Cards

  Like other Teams content, where card content is stored is based on where the card was used. Content for cards used in a Teams channel is stored in the Teams group mailbox. Card content for 1:1 and 1xN chats are stored in the mailboxes of the chat participants.

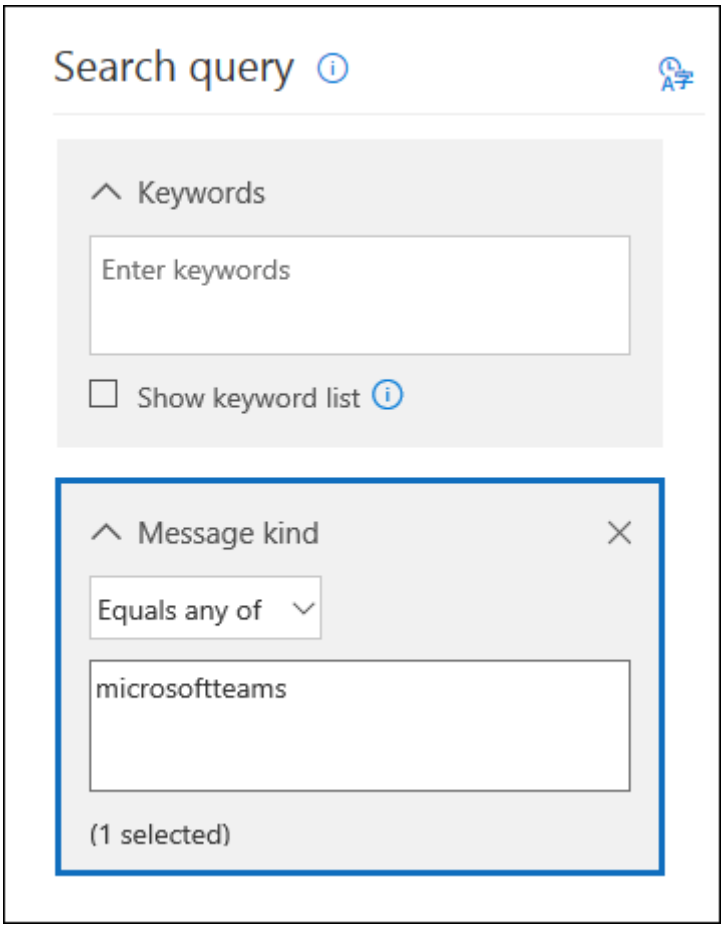
  To search for card content, you can use the `kind:microsoftteams` or `itemclass:IPM.SkypeTeams.Message` search conditions. When reviewing search results, card content generated by bots in a Teams channel has the **Sender/Author** email property as `<appname>@teams.microsoft.com`, where `appname` is the name of the app that generated the card content. If card content was generated by a user, the value of **Sender/Author** identifies the user.

  When viewing card content in Content search results, the content appears as an attachment to the message. The attachment is named `appname.html`, where `appname` is the name of the app that generated the card content. The following screenshots show how card content (for an app named Asana) appears in Teams and in the results of a search.

Card content in Teams



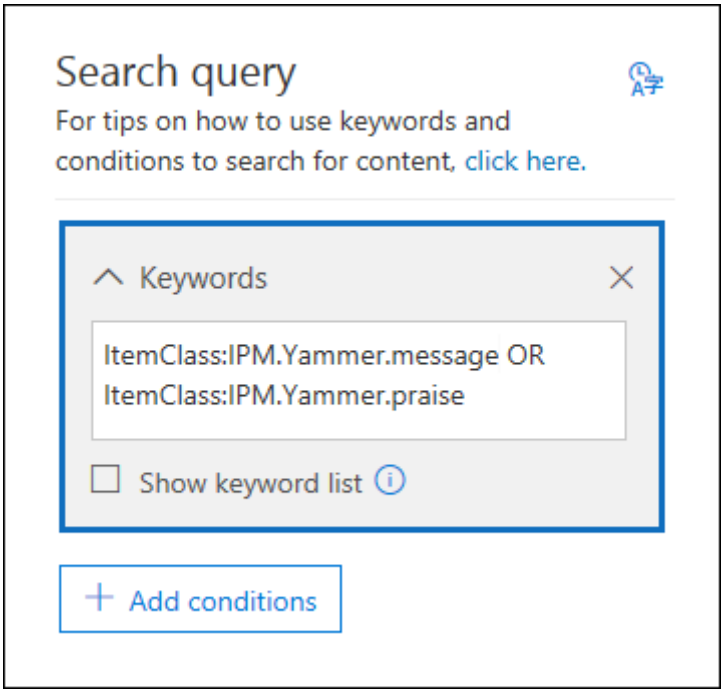
Card content in search results



> **Note**
>
> To display images from card content in search results at this time (such as the checkmarks in the previous screenshot), you have to be signed into Teams (at https://teams.microsoft.com) in a different tab in the same browser session that you use to view the search results. Otherwise, image placeholders are displayed.

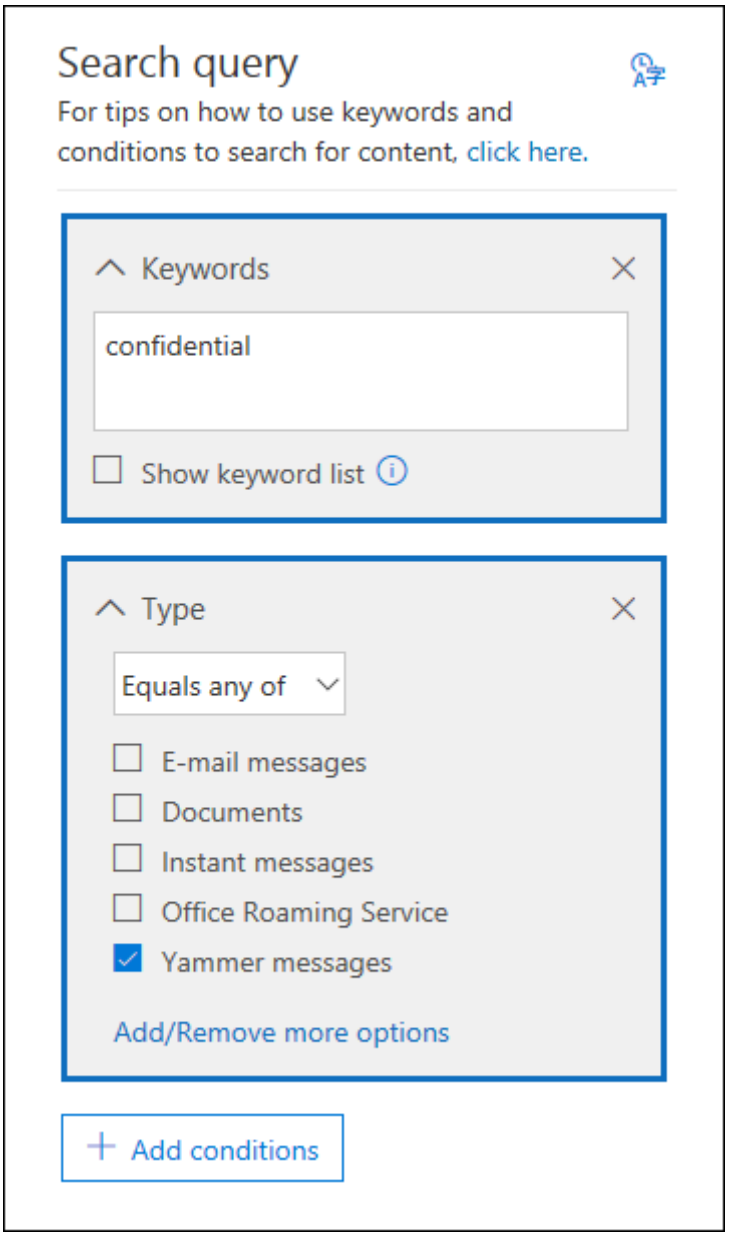
- You can use the **Kind** email property or the **Message kind** search condition to search specifically for content in Teams.
    - To use the **Kind** property as part of the keyword search query, in the **Keywords** box of a search query, type `kind:microsoftteams`.

- To use a search condition, add the **Message kind** condition and use the value `microsoftteams`.



Conditions are logically connected to the keyword query by the **AND** operator. That means an item must match both the keyword query and the search condition to be returned in the search results. For more information, see the "Guidelines for using conditions" section in Keyword queries and search conditions for Content Search.

Searching Viva Engage Groups



You can use the **ItemClass** email property or the **Type** search condition to search specifically for conversation items in Viva Engage Groups.

- To use the **ItemClass** property as part of the keyword search query, in the **Keywords** box of a search query, you can type one (or all) of the following property:value pairs:
  - ItemClass:IPM.Yammer.message
  - ItemClass:IPM.Yammer.poll
  - ItemClass:IPM.Yammer.praise
  - ItemClass:IPM.Yammer.question

  For example, you can use the following search query to return Viva Engage messages and Viva Engage praise items:

- Alternatively, you can use the **Type** email condition and select **Viva Engage messages** to return Viva Engage items. For example, the following search query returns all Viva Engage conversation items that contain the keyword "confidential".

Searching inactive mailboxes

You can search inactive mailboxes in a content search. To get a list of the inactive mailboxes in your organization, run the command `Get-Mailbox -InactiveMailboxOnly` in Exchange Online PowerShell. Alternatively, you can go to **Data lifecycle management** > **Microsoft 365** > **Retention** in the Microsoft Purview portal, and then select **More**••• > **Inactive mailboxes**.

Here are a few things to keep in mind when searching inactive mailboxes.

- If an existing content search includes a user mailbox and that mailbox is made inactive, the content search will continue to search the inactive mailbox when you rerun the search after it becomes inactive.
- Sometimes a user may have an active mailbox and an inactive mailbox that have different SMTP addresses. In this case, only the specific mailbox that you select as a location for a

content search is searched. In other words, if you add a user's mailbox to a search, you can't assume that both their active and inactive mailboxes are searched. Only the mailbox that you explicitly add to the search is searched.

- You can use Security & Compliance PowerShell to create a content search to search an inactive mailbox. To do this, you have to pre-append a period (.) to the email address of the inactive mailbox. For example, the following command creates a content search that searches an inactive mailbox with the email address pavelb@contoso.onmicrosoft.com:

  PowerShell

  ```
  New-ComplianceSearch -Name InactiveMailboxSearch -ExchangeLocation
  .pavelb@contoso.onmicrosoft.com -AllowNotFoundExchangeLocationsEnabled $true
  ```

- We strongly recommend that you avoid having an active mailbox and inactive mailbox with the same SMTP address. If you need to reuse the SMTP address that is assigned to an inactive mailbox, we recommend that you recover the inactive mailbox or restore the contents of an inactive mailbox to an active mailbox (or the archive of an active mailbox), and then delete the inactive mailbox. For more information, see one of the following articles:
  - Recover an inactive mailbox in Office 365
  - Restore an inactive mailbox in Office 365
  - Delete an inactive mailbox in Office 365

Searching disconnected or de-licensed mailboxes

If the Exchange Online license (or the entire Microsoft 365 license) is removed from a user account or in Microsoft Entra ID, the user's mailbox becomes a *disconnected* mailbox. This means that the mailbox is no longer associated with the user account. Here's what happens when searching disconnected mailboxes:

- If the license is removed from a mailbox, the mailbox is no longer searchable.
- If an existing content search includes a mailbox in which the license is removed, no search results from the disconnected mailbox will be returned if you rerun the content search.
- If you use the **New-ComplianceSearch** cmdlet to create a content search and specify a disconnected mailbox as the Exchange content location to search, the content search won't return any search results from the disconnected mailbox.

If you need to preserve the data in a disconnected mailbox so that it's searchable, you must place a hold on the mailbox before removing the license. This preserves the data and keeps the

disconnected mailbox searchable until the hold is removed. For more information about holds, see How to identify the type of hold placed on an Exchange Online mailbox.

Searching for content in a SharePoint multi-geo environment

If it's necessary for an eDiscovery manager to search for content in SharePoint and OneDrive in different regions in a SharePoint multi-geo environment, then you need to do the following things to make that happen:

1. Create a separate user account for each satellite geo location that the eDiscovery manager needs to search. To search for content in sites in that geo location, the eDiscovery manager must sign in to the account you created for that location, and then run a content search.

2. Create a search permissions filter for each satellite geo location (and corresponding user account) the eDiscovery manager needs to search. Each of these search permissions filters limits the scope of the content search to a specific geo location when the eDiscovery manager is signed in to the user account associated with that location.

> **Tip**
>
> You don't have to use this strategy when using the search tool in **eDiscovery (Premium)**. That's because all datacenters are searched when you search SharePoint sites and OneDrive accounts in Microsoft Purview eDiscovery (Premium). You have to use this strategy of region-specific user accounts and search permissions filters only when using the Content Search tool and running searches associated with **eDiscovery cases**.

For example, let's say that an eDiscovery manager needs to search for SharePoint and OneDrive content in satellite locations in North American, Europe, and Asia Pacific. The first step is to create three users accounts, one for each location. The next step is to create three search permissions filters, one for each location *and* corresponding user account. Here are examples of the three search permissions filters for this scenario. In each of these examples, the **Region** specifies the SharePoint datacenter location for that geo and the **Users** parameter specifies the corresponding user account.

North America

PowerShell

```
New-ComplianceSecurityFilter -FilterName "SPMultiGeo-NAM" -Users ediscovery-
nam@contoso.com -Region NAM -Action ALL
```

Europe

PowerShell

```
New-ComplianceSecurityFilter -FilterName "SPMultiGeo-EUR" -Users ediscovery-
eur@contoso.com -Region EUR -Action ALL
```

Asia Pacific

PowerShell

```
New-ComplianceSecurityFilter -FilterName "SPMultiGeo-APC" -Users ediscovery-
apc@contoso.com -Region APC -Action ALL
```

Keep the following things in mind when using search permissions filters to search for content in multi-geo environments:

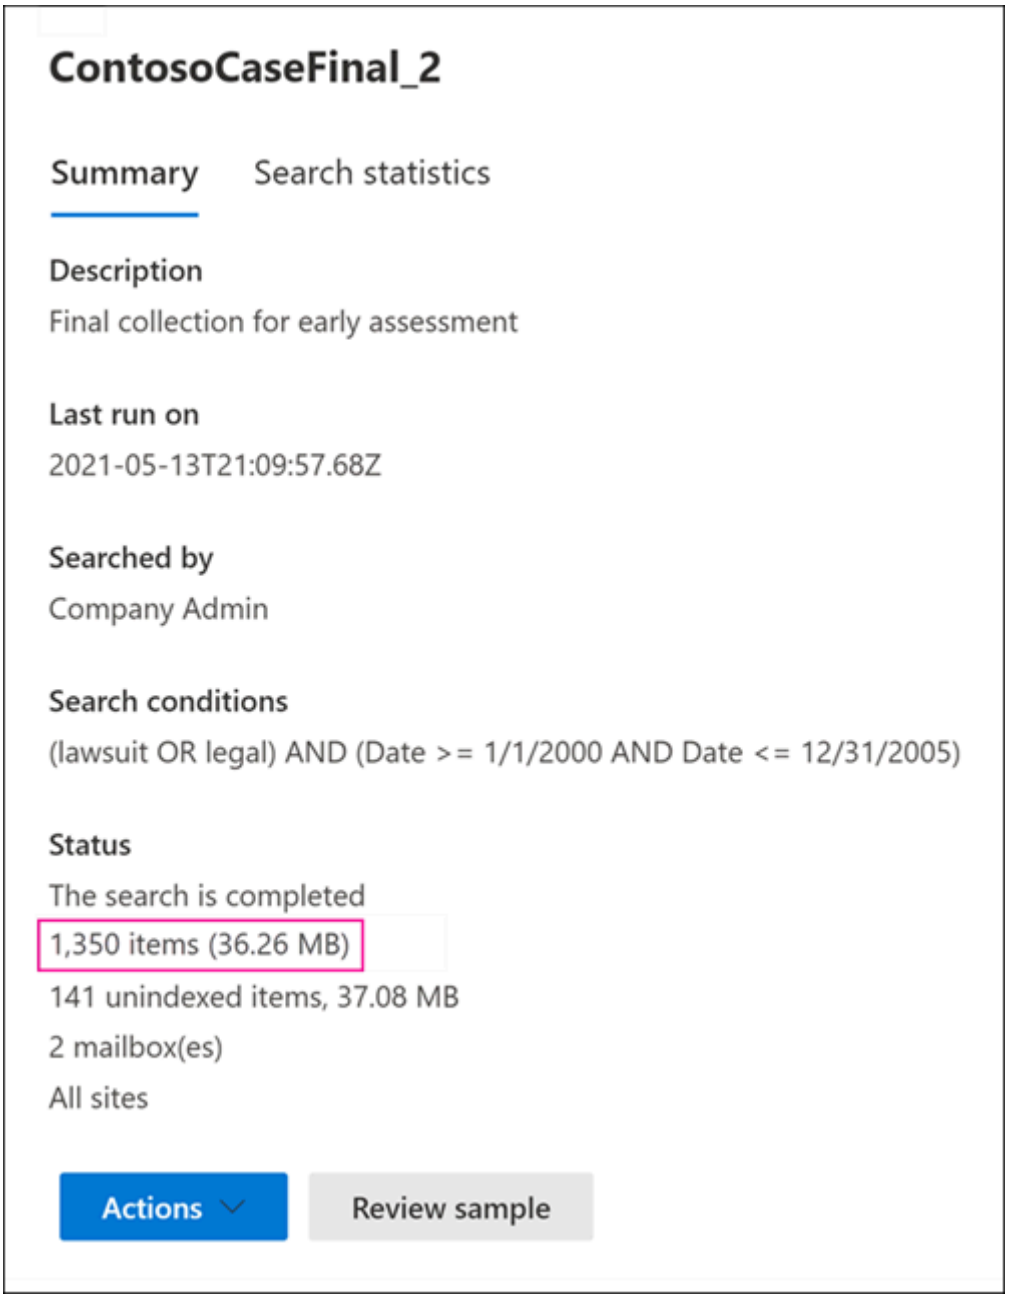
- The **Region** parameter directs searches to the specified satellite location. If an eDiscovery manager only searches SharePoint and OneDrive sites outside of the region specified in the search permissions filter, no search results are returned.
- The **Region** parameter doesn't control searches of Exchange mailboxes. All datacenters are searched when you search mailboxes.

For more information about using search permissions filters in a multi-geo environment, see the "Searching and exporting content in Multi-Geo environments" section in Set up compliance boundaries for eDiscovery investigations.

Need help with eDiscovery issues?

Check out the Resolve common eDiscovery issues article for basic troubleshooting steps that you can take to identify and resolve issues that you might encounter during an eDiscovery search or elsewhere in the eDiscovery process.

Last updated on 10/31/2024

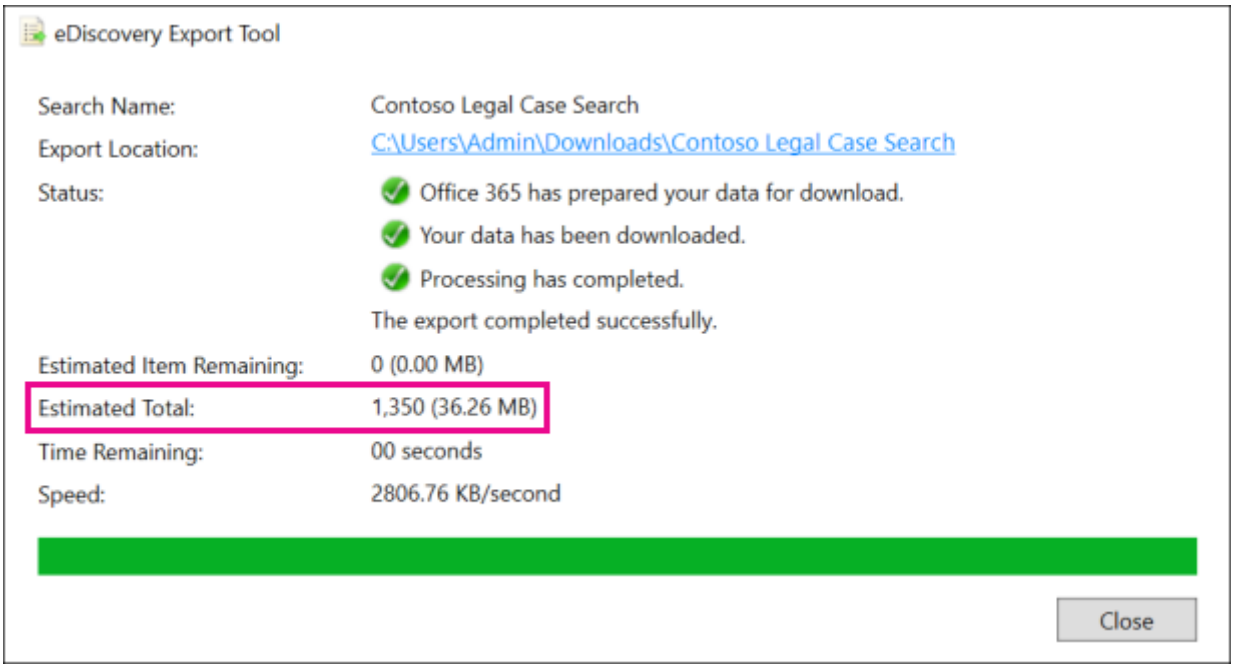


Differences between estimated and actual eDiscovery search results

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

This article applies to searches that you can run using one of the following Microsoft Purview eDiscovery tools:

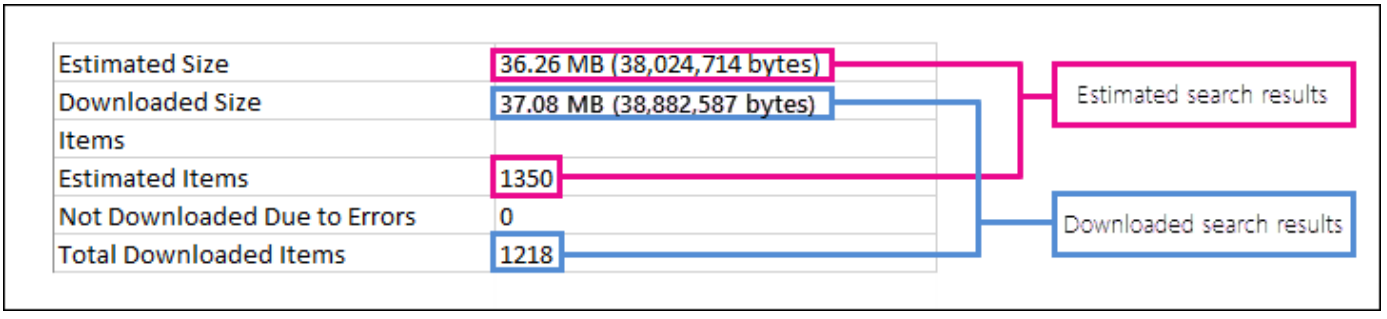
- Content search
- eDiscovery (Standard)



When you run an eDiscovery search, the tool you're using will return an estimate of the number of items (and their total size) that match the search criteria. For example, when you run a search in the Microsoft Purview portal, the estimated search results are displayed on the flyout page for the selected search.

This is the same estimate of total size and number of items that is displayed in the eDiscovery Export Tool when you export results to a local computer and in the Export Summary report that's downloaded with the search results.

> **Important**
>
> The eDiscovery Export tool was permanently **retired on August 31, 2025**, this functionality isn't available in the new eDiscovery experience.



Estimated results in the eDiscovery Export tool

Estimated results in Export Summary report

1	Application launched from	
2	Export Name	Contoso Legal Case Search
3	Download Started	1/8/2016 14:43
4	Download Completed	1/8/2016 14:46
5	Status	The export completed successfully.
6	Locations	
7	Total Locations	22
8	Succeeded Locations	22
9	Failed Locations	0
10	Size	
11	Estimated Size	36.26 MB (38,024,714 bytes)
12	Downloaded Size	37.08 MB (38,882,587 bytes)
13	Items	
14	Estimated Items	1350
15	Not Downloaded Due to Errors	0
16	Total Downloaded Items	1218

However, as you'll notice in the previous screenshot of the Export Summary report, the size and number of actual search results that are downloaded are different than the size and number of estimated search results.

Here are some reasons for these differences:

- **The way results are estimated**. An estimate of the search results is just that, an estimate (and not an actual count) of the items that meet the search query criteria. To compile the estimate of Exchange items, a list of the message IDs that meet the search criteria is requested from the Exchange database by the eDiscovery tool you're using. But when you export the search results, the search is rerun and the actual messages are retrieved from the Exchange database. So these differences might result because of how the estimated number of items and the actual number of items are determined.

- **Changes that happen between the time when estimating and exporting search results**. When you export search results, the search is restarted to collect that most recent items in the search index that meet the search criteria. It's possible there are additional items were created, sent, or received that meet the search criteria in the time between when the estimated search results were collected and when the search results were exported. It's also possible that items that were in the search index when the search results were estimated are no longer there because they were purged from the content location before the search results are exported. One way to mitigate this issue is to specify a date range for an eDiscovery search. Another way is to place a hold on content locations so that items are preserved and can't be purged.

  Here are other issues that can result is differences between estimated and exported search results:
  - In increase in items when using a date query. This is typically cause by the following two things:
    - Hold versioning in SharePoint. If a document is deleted from a site that's on hold and document versioning is enabled, all versions of the deleted document will be preserved.
    - Calendar items. Accept and reject messages and recurring meetings will automatically continue creating new items in the background with old dates.
  - With holds, there can be cases where the same item is preserved in a user's primary mailbox and in their archive mailbox. This can happen when a user manually moves an item to their archive.
  - Although rare, even in the case when a hold is applied, maintenance of built-in calendar items (which aren't editable by the user, but are included in many search results) may be removed from time to time. This periodic removal of calendar items will result in fewer items that are exported.

- **Unindexed items**. Items that are unindexed for search can cause differences between estimated and actual search results. You can include unindexed items when you export the

search results. If you include unindexed items when exporting search results, there might be more items that are exported. This will cause a difference between the estimated and exported search results.

When using the Content search tool, you have the option to include unindexed items when you export search results. The number of unindexed items returned by the search is listed on the flyout page together with the other estimated search results. Any unindexed items would also be included in the total size of the estimated search results. When you export search results, you have the option to include or not include unindexed items. How you configure these options might result in differences between estimated and the actual search results that are downloaded.

- **Exporting the results of a Content search that includes all content locations**. If the search that you're exporting results from was a search of all content locations in your organization, then only the unindexed items from content locations that contain items that match the search criteria will be exported. In other words, if no search results are found in a mailbox or site, then any unindexed items in that mailbox or site won't be exported. However, unindexed items from all content locations (even those that don't contain items that match the search query) will be included in the estimated search results.

  Alternatively, if the search that you're exporting results from included specific content locations, then unindexed items (that aren't excluded by the search criteria) from all the content locations specified in the search will be exported. In this case, the estimated number of unindexed items and the number of unindexed items that are exported should be the same.

  The reason for not exporting unindexed items from every location in the organization is because it might increase the likelihood of export errors and increase the time it takes to export and download the search results.

- **Unindexed items in SharePoint and OneDrive not included in the search estimates**. Unindexed items from SharePoint sites and OneDrive for Business accounts aren't included in the estimated search results. This is because the SharePoint index doesn't contain data for unindexed items. Only unindexed items from mailboxes are included in the search estimates. However, if you include unindexed items when exporting search results, unindexed items in SharePoint and OneDrive are included, which will increase the number of items that are actually exported. This will result in differences between the estimated results (which don't include unindexed items in SharePoint and OneDrive sites) and the actual items that are downloaded. The rule about exporting unindexed items only from

content locations that contain items that match the search criteria still applies in this situation.

- **Document versions in SharePoint and OneDrive**. When searching SharePoint sites and OneDrive accounts, multiple versions of a document aren't included in the count of estimated search results. But you have the option to include all document versions when you export the search results. If you include document versions when exporting search results, the actual number (and total size) of the exported items will be increased.

- **SharePoint folders**. If folders in SharePoint match a search query, for example, searching by date, the search estimate will include a count of those folders with the last modified date range (but not the items in those folders). When you export the search results, the items in folder are exported but the actual folder isn't exported. The result is that the number of exported items will be more than the number of estimated search results. If a folder is empty, then the number of actual search results exported will be reduced by one item, because the actual folder isn't exported.

  > ⓘ **Note**
  >
  > When running a query-based search, you can exclude SharePoint folders by adding the following condition to the query: `NOT(ContentType:folder)`.

- **SharePoint lists**. If the name of a SharePoint list matches a search query, the search estimate will include a count of all the items in the list. When you export the search results, the list (and the list items) is exported as a single CSV file. This will reduce the actual number of items actually exported. If the list contains attachments, the attachments will be exported as separate documents, which will also increase the number of items exported.

  > ⓘ **Note**
  >
  > When running a query-based search, you can exclude SharePoint lists by adding the following condition to the query: `NOT(ContentType:list)`.

- **Raw file formats versus exported file formats**. For Exchange items, the estimated size of the search results is calculated by using the raw Exchange message sizes. However, email messages are exported in a PST file or as individual messages (which are formatted as EML files). Both of these export options use a different file format than raw Exchange messages, which results in the total exported file size being different than the estimated file size.

- **De-duplication of Exchange items during export**. For Exchange items, de-duplication reduces the number of items that are exported. You have the option to de-duplicate the search results when you export them. For Exchange messages, this means that only a single instance of a message is exported, even though that message might be found in multiple mailboxes. The estimated search results include every instance of a message. So if you choose the de-duplication option when exporting search results, the actual number of items that are exported might be considerably less than the estimated number of items.

The search results report (Results.csv file) contains an entry for each duplicate message and identifies the source mailbox where a duplicate message is located. This helps you identify all mailboxes that contain a duplicate message.

> **Note**
>
> If you don't select the **Include items that are encrypted or have an unrecognized format** option when you export search results or just download the reports, the index error reports are downloaded but they don't have any entries. This doesn't mean there aren't any indexing errors. It just means that unindexed items weren't included in the export.

Partially indexed items in Content search

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

A Content search that you run from the Microsoft Purview portal automatically includes partially indexed items in the estimated search results when you run a search. Partially indexed items are Exchange mailbox items and documents on SharePoint and OneDrive for Business sites that for some reason weren't completely indexed for search. In Exchange, a partially indexed item typically contains a file (of a file type that can't be indexed) that is attached to an email message. Here are some other reasons why items can't be indexed for search and are returned as partially indexed items when you run an eDiscovery search:

- The file type is unrecognized or unsupported for indexing.
- Messages have an attached file that can't be opened; this is the most common cause of partially indexed email items.
- The file type is supported for indexing but an indexing error occurred for a specific file.
- Too many files attached to an email message.
- A file attached to an email message is too large.
- A file is encrypted with non-Microsoft technologies.
- A file is password-protected.

> **Note**
>
> Most organizations have less than 1% of content by volume and less than 12% by size that is partially indexed. The reason for the difference between volume and size is that larger files have a higher probability of containing content that can't be completely indexed.

For legal investigations, your organization may be required to review partially indexed items. You can also specify whether to include partially indexed items when you export search results to a local computer or when you prepare the results for analysis with eDiscovery (Premium). For more information, see Investigating partially indexed items in eDiscovery.

File types not indexed for search

Certain types of files, such as Bitmap (.bmp) or MP3 (.mp3) files, don't contain content that can be indexed. As a result, the search indexing servers in Exchange and SharePoint don't perform full-text indexing on these types of files. These types of files are considered to be unsupported file types. There are also file types for which full-text indexing has been disabled, either by default or by an administrator. Unsupported and disabled file types are labeled as unindexed items in Content Searches. As previously stated, partially indexed items can be included in the set of search results when you run a search, export the search results to a local computer, or prepare search results for eDiscovery (Premium).

For a list of supported and disabled file formats, see the following articles:

- **Exchange** - File formats indexed by Exchange Search
- **Exchange** - Get-SearchDocumentFormat
- **SharePoint** - Default crawled file name extensions and parsed file types in SharePoint

Messages and documents with partially indexed file types can be returned in search results

Not every email message with a partially indexed file attachment or every partially indexed SharePoint document is automatically returned as a partially indexed item. That's because other message or document properties, such as the **Subject** property in email messages and the **Title** or **Author** properties for documents are indexed and available to be searched. For example, a keyword search for "financial" will return items with a partially indexed file attachment if that keyword appears in the subject of an email message or in the file name or title of a document. However, if the keyword appears only in the body of the file, the message or document would be returned as a partially indexed item.

Similarly, messages with partially indexed file attachments and documents of a partially indexed file type are included in search results when other message or document properties, which are indexed and searchable, match the search criteria. Message properties that are indexed for search include sent and received dates, sender and recipient, the file name of an attachment, and text in the message body. Document properties indexed for search include created and modified dates.

So even though a message attachment may be a partially indexed item, the message will be included in the regular search results if the value of other message or document properties matches the search criteria.

For a list of email and document properties that you can search for by using eDiscovery tools in the Microsoft Purview portal, see Keyword queries and search conditions for eDiscovery.

> **Note**
>
> If a mailbox item is moved from a folder that is indexed to a folder that is not indexed, a flag is set to unindex the item and the item is removed from the index and will not be searchable. Later, if that same item is moved back to a folder that is indexed, the flag is not reset. That means the item will remain unindexed, and not searchable.

Partially indexed items included in the search results

Your organization might be required to identify and perform additional analysis on partially indexed items to determine what they are, what they contain, and whether they're relevant to a specific investigation. As previously explained, the partially indexed items in the content locations that are searched are automatically included with the estimated search results. You have the option to include these partially indexed items when you export search results or prepare the search results for eDiscovery (Premium).

Keep the following in mind about partially indexed items:

- When you run an eDiscovery search, the total number and size of partially indexed Exchange items (returned by the search query) are displayed in the search statistics on the flyout page, and labeled as **unindexed items**. Statistics about partially indexed items displayed on the flyout page don't include partially indexed items in SharePoint sites or OneDrive accounts.

- If the search that you're exporting results from was a search of specific content locations or all content locations in your organization, only the unindexed items from content locations that contain items that match the search criteria will be exported. In other words, if no search results are found in a mailbox or site, then any unindexed items in that mailbox or site won't be exported. The reason for this is that exporting partially indexed items from lots of locations in the organization might increase the likelihood of export errors and increase the time it takes to export and download the search results.

To export partially indexed items from all content locations for a search, configure the search to return all items (by removing any keywords from the search query) and then export only partially indexed items when you export the search results (by selecting **Only items that have an unrecognized format, are encrypted, or weren't indexed for other reasons** under **Output options**).

- If you choose to include all mailbox items in the search results, or if a search query doesn't specify any keywords or only specifies a date range, partially indexed items might not be copied to the PST file that contains the partially indexed items. This is because all items, including any partially indexed items, will be automatically included in the regular search results.

- Partially indexed items aren't available to be previewed. You have to export the search results to view partially indexed items returned by the search.

  Additionally, when you export search results and include partially indexed items in the export, partially indexed items from SharePoint items are exported to a folder named **Uncrawlable**. When you export partially indexed Exchange items, they're exported differently depending if the partially indexed items matched the search query and the configuration of the export settings.

- The following table shows the export behavior of indexed and partially indexed items and whether or not each is included for the different export configuration settings.

Expand table

Export configuration	Indexed items that match search query	Partially indexed items that match search query	Partially indexed items that don't match search query
Export only indexed items	Exported	Exported (included with the indexed items exported)	Not exported
Export only partially indexed items	Not exported	Exported (as partially indexed items)	Exported (as partially indexed items)
Export indexed and partially indexed items	Exported	Exported (included with the indexed items exported)	Exported (as partially indexed items)

Date ranges and excluding partially indexed items

In Content search and Microsoft Purview eDiscovery, you can't use a date range to exclude partially indexed items from being returned by a search query. In other words, partially indexed items that fall outside of a date range are still included as partially indexed items in the search statistics and when you export partially indexed items. In eDiscovery (Premium), partially indexed items can be collected and then filtered in a review set prior to export.

Indexing limits for messages

The following table describes the indexing limits that might result in an email message being returned as a partially indexed item in an eDiscovery search in Microsoft 365.

For a list of indexing limits for SharePoint documents, see Search limits for SharePoint Online.

Expand table

Indexing limit	Maximum value	Description
Maximum attachment size (excluding Excel files)	150 MB	The maximum size of an email attachment that will parse for indexing. Any attachment that's larger than this limit won't be parsed for indexing, and the message with the attachment will be marked as partially indexed. **Note:** Parsing is the process where the indexing service extracts text from the attachment, removes unnecessary characters like punctuation and spaces, and then divides the text into words (in a process called tokenization), that are then stored in the index.
Maximum size of Excel files	4 MB	The maximum size of an Excel file located on a site or attached to an email message that will be parsed for indexing. Any Excel file that's larger than this limit won't be parsed, and the file or the email the message with the file attachment will be marked as unindexed.
Maximum number of attachments	250	The maximum number of files attached to an email message that will be parsed for indexing. If a message has more than 250 attachments, the first 250 attachments are parsed and indexed, and the message is marked as partially indexed because it had additional attachments that weren't parsed.
Maximum attachment depth	30	The maximum number of nested attachments that are parsed. For example, if an email message has another message attached to it and the attached message has an attached Word document, the Word document and the attached message will be indexed. This behavior will continue for up to 30 nested attachments.
Maximum number of attached images	0	An image that's attached to an email message is skipped by the parser and isn't indexed.

Indexing limit	Maximum value	Description
Maximum time spent parsing an item	30 seconds	A maximum of 30 seconds is spent parsing an item for indexing. If the parsing time exceeds 30 seconds, the item is marked as partially indexed.
Maximum parser output	2 million characters	The maximum amount of text output from the parser that's indexed. For example, if the parser extracted 8 million characters from a document, only the first 2 million characters are indexed.
Maximum annotation tokens	2 million	When an email message is indexed, each word is annotated with different processing instructions that specify how that word should be indexed. Each set of processing instructions is called an annotation token. To maintain the quality of service in Office 365, there's a limit of 2 million annotation tokens for an email message.
Maximum body size in index	67 million characters	The total number of characters in the body of an email message and all its attachments. When an email message is indexed, all text in the body of the message and in all attachments is concatenated into a single string. The maximum size of this string that is indexed is 67 million characters.
Maximum unique tokens in body	1 million	As previously explained, tokens are the result of extracting text from content, removing punctuation and spaces, and then dividing it into words (called tokens) that are stored in the index. For example, the phrase `"cat, mouse, bird, dog, dog"` contains 5 tokens. But only 4 of these are unique tokens. There's a limit of 1 million unique tokens per email message, which helps prevent the index from getting too large with random tokens.

More information about partially indexed items

- As previously stated, because message and document properties and their metadata are indexed, a keyword search might return results if that keyword appears in the indexed metadata. However, that same keyword search might not return the same item if the keyword only appears in the content of an item with an unsupported file type. In this case, the item would be returned as a partially indexed item.
- If a partially indexed item is included in the search results because it matched the search query criteria, it isn't included with partially indexed items when you export search results.
- Although a file type is supported for indexing and is indexed, there can be indexing or search errors that will cause a file to be returned as a partially indexed item. For example, searching a large Excel file might be partially successful (because the first 4 MB are indexed), but then fails because the file size limit is exceeded. In this case, it's possible that the same file is returned with the search results and as a partially indexed item.

- Files that are encrypted with Microsoft encryption technologies and are attached to an email message that matches the criteria of a search can be previewed and will be decrypted when exported. At this time, files that are encrypted with Microsoft encryption technologies (and stored in SharePoint or OneDrive for Business) are partially indexed.
- Email messages encrypted with S/MIME are partially indexed. This includes encrypted messages with or without file attachments.
- Email messages protected using Azure Rights Management are indexed and will be included in the search results if they match the search query. Rights-protected email messages are decrypted and can be previewed and exported. This functionality requires that you're assigned the RMS Decrypt role, which is assigned by default to the eDiscover Manager role group.
- If you create a query-based hold that's associated with an eDiscovery case, all partially indexed items are placed on hold. This includes partially indexed items that don't match the search query criteria for the hold. For more information about creating query-based eDiscovery holds, see Create an eDiscovery hold.

Investigating partially indexed items in eDiscovery

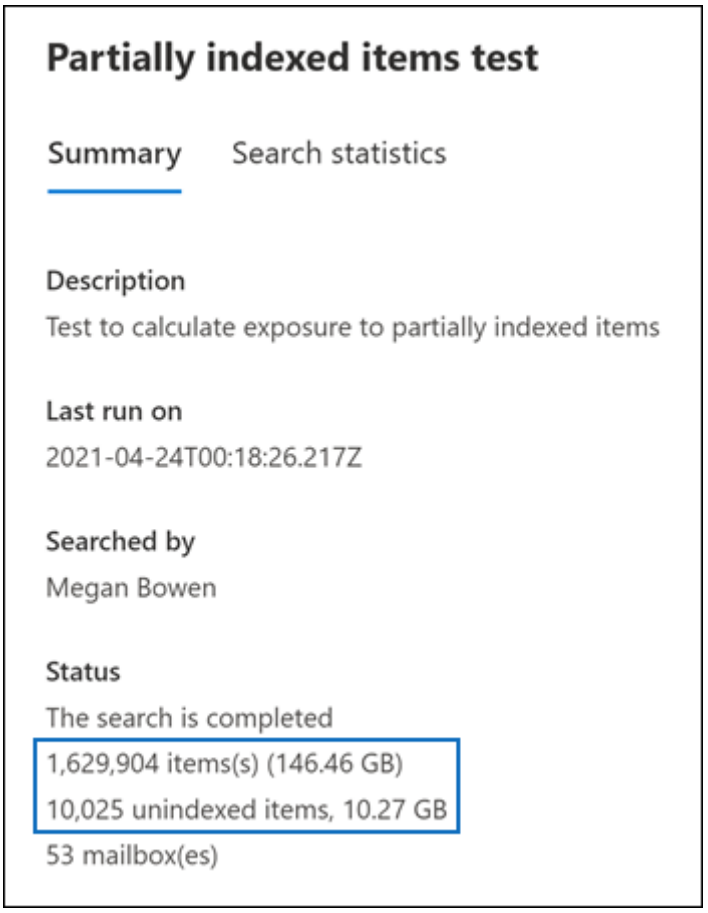
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

An eDiscovery search that you run from the Microsoft Purview portal automatically includes partially indexed items in the estimated search results when you run a search. Partially indexed items are Exchange mailbox items and documents on SharePoint and OneDrive for Business sites that for some reason weren't completely indexed for search. Most email messages and site documents are successfully indexed because they fall within the indexing limits for email messages. However, some items may exceed these indexing limits, and will be partially indexed. Here are other reasons why items can't be indexed for search and are returned as partially indexed items when you run an eDiscovery search:

- Email messages have an attached file that can't be opened; this is the most common cause of partially indexed email items.
- Too many files attached to an email message.
- A file attached to an email message is too large.
- The file type is supported for indexing but an indexing error occurred for a specific file.

Although it varies, most organizations customers have less than 1% of content by volume and less than 12% of content by size that is partially indexed. The reason for the difference between the volume versus size is that larger files have a higher probability of containing content that can't be completely indexed.

For more information about partially index items in Content search, see Investigating partially indexed items in Content search.



Why does the partially indexed item count change for a search?

After you run an eDiscovery search, the total number and size of partially indexed items in the locations that were searched are listed in the search result statistics that are displayed in the detailed statistics for the search. Note these are called *unindexed items* in the search statistics. Here are a few things that will affect the number of partially indexed items that are returned in the search results:

- If an item is partially indexed and matches the search query, it's included in both the count (and size) of search result items and partially indexed items. However, when the results of that same search are exported, the item is included only with set of search results; it's not included as a partially indexed item.
- Partially indexed items located in SharePoint and OneDrive sites *aren't* included in the estimate of partially indexed items that's displayed in the detailed statistics for the search. However, partially indexed items can be exported when you export the results of an eDiscovery search. For example, if you only search sites, the estimated number partially indexed items will be zero.

Calculating the ratio of partially indexed items in your organization

To understand your organization's exposure to partially indexed items, you can run a search for all content in all mailboxes (by using a blank keyword query). In the following example, there are 1,629,904 (146.46 GB) fully indexed items and 10,025 (10.27 GB) partially indexed items.

You can determine the percentage of partially indexed items by using the following calculations.

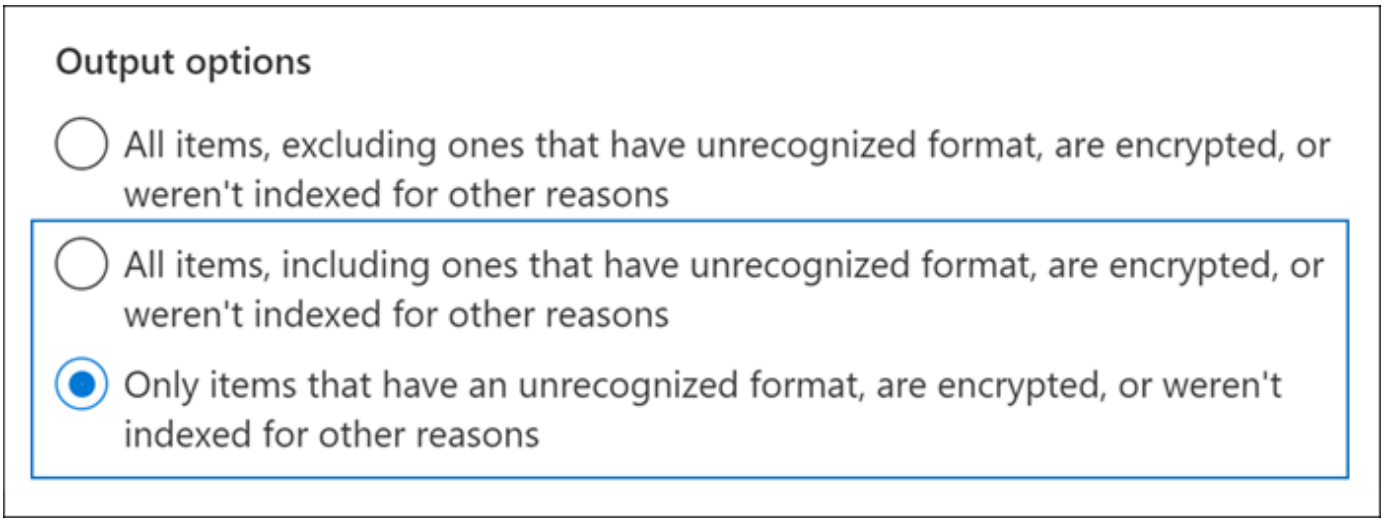
To calculate the ratio of partially indexed items in your organization:

```
(Total number of partially indexed items/Total number of items) x 100
```

```
(10025/1629904) x 100 = 0.62%
```

By using the search results from the previous example, 0.62% of all mailboxes items are partially indexed.

To calculate the percentage of the size of partially indexed items in your organization:



```
(Size of all partially indexed items/Size of all items) x 100
```

```
(10.27 GB/146.46 GB) x 100 = 7.0%
```

So in the previous example, 7% of the total size of mailbox items are from partially indexed items. As previously stated, most organizations customers have less than 1% of content by volume and less than 12% of content by size that is partially indexed.

Working with partially indexed items

In cases when you need to examine partially indexed items to validate that they don't contain relevant information, you can export a content search report that contains information about partially indexed items. When you export a content search report, be sure to choose one of the export options that includes partially indexed items.

When you export eDiscovery search results or a search report using one of these options, the export includes a report named Unindexed Items.csv. This report includes most of the same information as the ResultsLog.csv file; however, the Unindexed Items.csv file also includes two fields related to partially indexed items: **Error Tags** and **Error Properties**. These fields contain information about the indexing error for each partially indexed item. Using the information in these two fields can help you determine whether or not the indexing error for a particular impacts your investigation.

> ⓘ **Note**
>
> The Unindexed Items.csv file also contains fields named **Error Type** and **Error Message**. These are legacy fields that contain information that is similar to the information in the **Error Tags** and **Error Properties** fields, but with less detailed information. You can safely ignore these legacy fields.

Errors related to partially indexed items

Error tags are made up of two pieces of information, the error and the file type. For example, in this error/file-type pair:

```text
parseroutputsize_xls
```

`parseroutputsize` is the error and `xls` is the file type of the file the error occurred on. In cases where the file type wasn't recognized or the file type didn't apply to the error, you will see the value `noformat` in place of the file type.

The following is a list of indexing errors and a description of the possible cause of the error.

Expand table

Error tag	Description
`attachmentcount`	An email message had too many attachments, and some of these attachments weren't processed.
`attachmentdepth`	The content retriever and document parser found too many levels of attachments nested inside other attachments. Some of these attachments weren't processed.
`attachmentrms`	An attachment failed decoding because it was RMS-protected.
`attachmentsize`	A file attached to an email message was too large and couldn't be processed.
`indexingtruncated`	When writing the processed email message to the index, one of the indexable properties was too large and was truncated. The truncated properties are listed in Error Properties field.
`invalidunicode`	An email message contained text that couldn't be processed as valid Unicode. Indexing for this item may be incomplete.
`parserencrypted`	The content of attachment or email message is encrypted, and Microsoft 365 couldn't decode the content.
`parsererror`	An unknown error occurred during parsing. This typically results from a software bug or a service crash.
`parserinputsize`	An attachment was too large for the parser to handle, and the parsing of that attachment didn't happen or wasn't completed.
`parsermalformed`	An attachment was malformed and couldn't be handled by the parser. This result can be due to old file formats, files created by incompatible software, or viruses pretending to be something other than claimed.
`parseroutputsize`	The output from the parsing of an attachment was too large and had to be truncated.
`parserunknowntype`	An attachment had a file type that Microsoft 365 couldn't detect.
`parserunsupportedtype`	An attachment had a file type that Office 365 could detect, but parsing that file type isn't supported.
`propertytoobig`	The value of an email property in Exchange Store was too large to be retrieved and the message couldn't be processed. This typically only happens to the body

Error tag	Description
	property of an email message.
`retrieverrms`	The content retriever failed to decode an RMS-protected message.
`wordbreakertruncated`	Too many words were identified in the document during indexing. Processing of the property stopped when reaching the limit, and the property is truncated.

Error fields describe which fields are affected by the processing error listed in the Error Tags field. If you're searching a property such as `subject` or `participants`, errors in the body of the message won't impact the results of your search. This can be useful when determining exactly which partially indexed items you might need to further investigate.

Disable reports when you export Content Search results

> **Important**
>
> The eDiscovery Export tool was permanently **retired on August 31, 2025**, this functionality isn't available in the new eDiscovery experience.

When you use the eDiscovery Export tool to export the results of a Content Search in the Microsoft Purview portal, the tool automatically creates and exports two reports that contain additional information about the exported content. These reports are the Results.csv file and the Manifest.xml file (see the Frequently asked questions about disabling export reports section in this article for detailed descriptions of these reports). Because these files can be very large, you can speed up the download time and save disk space by preventing these files from being exported. You can do this by changing the Windows Registry on the computer that you use to export the search results. If you want to include the reports at a later time, you can edit the registry setting.

Create registry settings to disable the export reports

Perform the following procedure on the computer that you'll use to export the results a content search.

1. Close the eDiscovery Export tool if it's open.
2. Perform one or both of the following steps, depending on which export report you want to disable.

   - **Results.csv**

     Save the following text to a Windows registry file by using a filename suffix of .reg; for example, DisableResultsCsv.reg.

     text

     ```
     Windows Registry Editor Version 5.00
     reg add HKLM\SOFTWARE\Microsoft\Exchange\Client\eDiscovery\ExportTool /v
     ResultCsvEnabled /t REG_SZ /d False
     ```

- **Manifest.xml**

  Save the following text to a Windows registry file by using a filename suffix of .reg; for example, DisableManifestXml.reg.

  ```text
  Windows Registry Editor Version 5.00
  reg add HKLM\SOFTWARE\Microsoft\Exchange\Client\eDiscovery\ExportTool /v
  ResultEdrmEnabled /t REG_SZ /d False
  ```

3. In Windows Explorer, select or double-click the .reg file that you created in the previous steps.
4. In the User Access Control window, select **Yes** to let the Registry Editor make the change.
5. When prompted to continue, select **Yes**.

   The Registry Editor displays a message saying that the setting was successfully added to the registry.

Edit registry settings to re-enable the export reports

If you disabled the Results.csv and Manifest.xml reports by creating the .reg files in the previous procedure, you can edit those files to re-enable a report so that it's exported with the search results. Again, perform the following procedure on the computer that you'll use to export the results a content search.

1. Close the eDiscovery Export tool if it's open.
2. Edit one or both of the .reg edit files that you created in the previous procedure.

   - **Results.csv**

     Open the DisableResultsCsv.reg file in Notepad, change the value `False` to `True`, and then save the file. For example, after you edit the file, it looks like this:

     ```text
     Windows Registry Editor Version 5.00
     reg add HKLM\SOFTWARE\Microsoft\Exchange\Client\eDiscovery\ExportTool /v
     ResultCsvEnabled /t REG_SZ /d True
     ```

   - **Manifest.xml**

Open the DisableManifestXml.reg file in Notepad, change the value `False` to `True`, and then save the file. For example, after you edit the file, it looks like this:

```text
Windows Registry Editor Version 5.00
reg add HKLM\SOFTWARE\Microsoft\Exchange\Client\eDiscovery\ExportTool /v
ResultEdrmEnabled /t REG_SZ /d True
```

3. In Windows Explorer, select or double-click a .reg file that you edited in the previous step.
4. In the User Access Control window, select **Yes** to let the Registry Editor make the change.
5. When prompted to continue, select **Yes**.

   The Registry Editor displays a message saying that the setting was successfully added to the registry.

Frequently asked questions about disabling export reports

What are the Results.csv and Manifest.xml reports?

The Results.csv and Manifest.xml files contain additional information about the content that was exported.

- **Results.csv** An Excel document that contains information about each item that is download as a search result. For email, the result log contains information about each message, including:
  - The location of the message in the source mailbox (including whether the message is in the primary or archive mailbox).
  - The date the message was sent or received.
  - The Subject line from the message.
  - The sender and recipients of the message.
  - Whether the message is a duplicate message if you enabled de-duplication when exporting the search results. Duplicate messages will have a value in the **Parent ItemId** column that identifies the message as a duplicate. The value in the **Parent ItemId** column is the same as the value in the **Item DocumentId** column of the message that was exported.

For documents from SharePoint and OneDrive for Business sites, the result log contains information about each document, including:
    - The URL for the document.
    - The URL for the site collection where the document is located.
    - The date that the document was last modified.
    - The name of the document (which is located in the Subject column in the result log).

- **Manifest.xml** A manifest file (in XML format) that contains information about each item included in the search results. The information in this report is the same as the Results.csv report, but it's in the format specified by the Electronic Discovery Reference Model (EDRM). For more information about EDRM, go to https://www.edrm.net .

When should I disable exporting these reports?

It depends on your specific needs. Many organizations don't require additional information about search results, and don't need these reports.

What computer do I have to do this on?

You have to change the registry setting on any local computer that you run the eDiscovery Export tool on.

After I change this setting, do I have to restart the computer?

No, you don't have to restart the computer. But if the eDiscovery Export tool is running, you have to close it and then restart it after you change the registry setting.

Does an existing registry key get edited or does a new key get created?

A new registry key is created the first time you run the .reg file that you created in the procedure in this article. Then the setting is edited each time you change and rerun the .reg edit file.

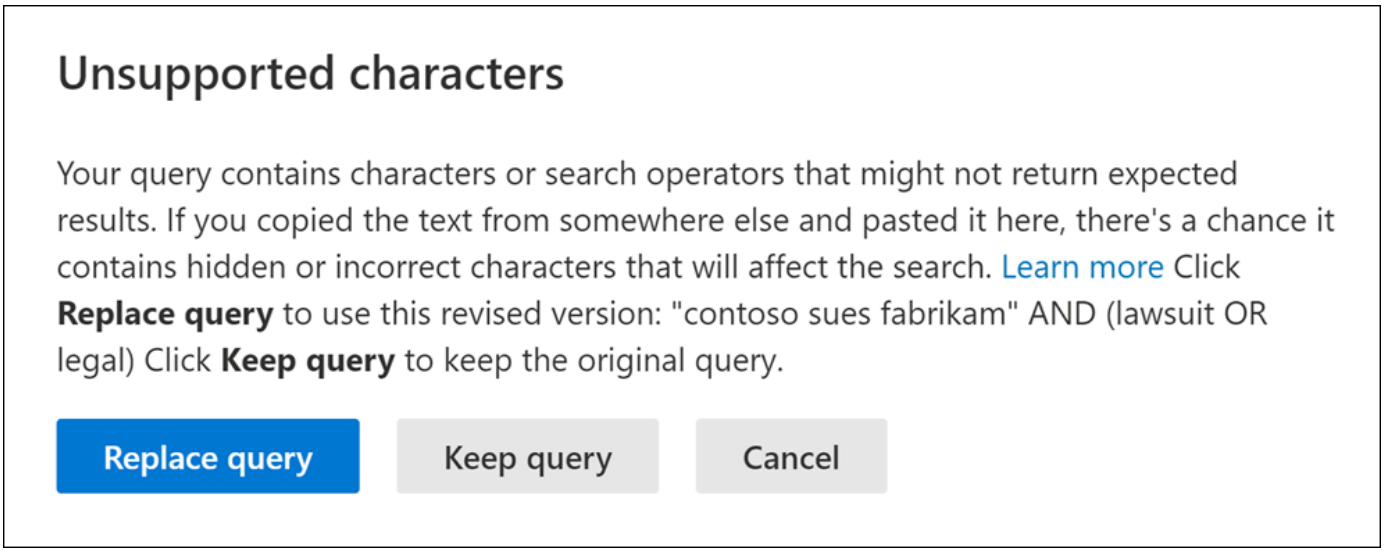
Check your search query for errors

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.



Here's a list of the unsupported characters that we check for in search queries for Content search and Microsoft Purview eDiscovery (Standard). Unsupported characters are often hidden, and they typically cause a search error or return unintended results.

- **Smart quotation marks** - Smart single and double quotation marks (also called curly quotes) aren't supported. Only straight quotation marks can be used in a search query.
- **Non-printable and control characters** - Non-printable and control characters don't represent a written symbol, such as an alpha-numeric character. Examples of non-printable and control characters include characters that format text or separate lines of text.
- **Left-to-right and right-to-left marks** - These marks are control characters used to indicate text direction for left-to-right languages (such as English and Spanish) and right-to-left languages (such as Arabic and Hebrew).
- **Lowercase Boolean operators** - If you use a Boolean operator, such as **AND**, **OR**, and **NOT** in a search query, it must be uppercase. When we check a query for typos, the query syntax will often indicate that a Boolean operator is being used even though lowercase operators might be used; for example, `(WordA or WordB) and (WordC or WordD)`.

What happens if a query has an unsupported character?

If unsupported characters are found in your query, a warning message is displayed that says unsupported characters were found and suggests an alternative. You then have the option keep the original query or replace it with the suggested revised query.

Here's an example of the warning message that's displayed after you select **Check query for typos** for the search query in the previous screenshot. Note the original query used smart quotes and lowercase Boolean operators.

How to prevent unsupported characters in your search queries

Unsupported characters are typically added to a query when you copy the query or parts of the query from other applications (such as Microsoft Word or Microsoft Excel) and paste them in the keyword box on the query page of a Content Search. The best way to prevent unsupported characters is to just type the query in the keyword box. Or you can copy a query from Word or Excel, and then paste it in a plain text editor, such as Microsoft Notepad. Save the text file and select **ANSI** in the **Encoding** drop-down list. This will remove any formatting and unsupported characters. Then you can copy and paste the query from the text file to the keyword query box.

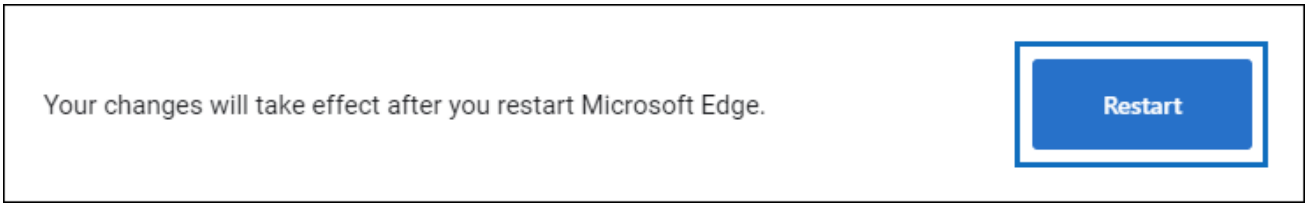
Use the eDiscovery Export Tool in Microsoft Edge

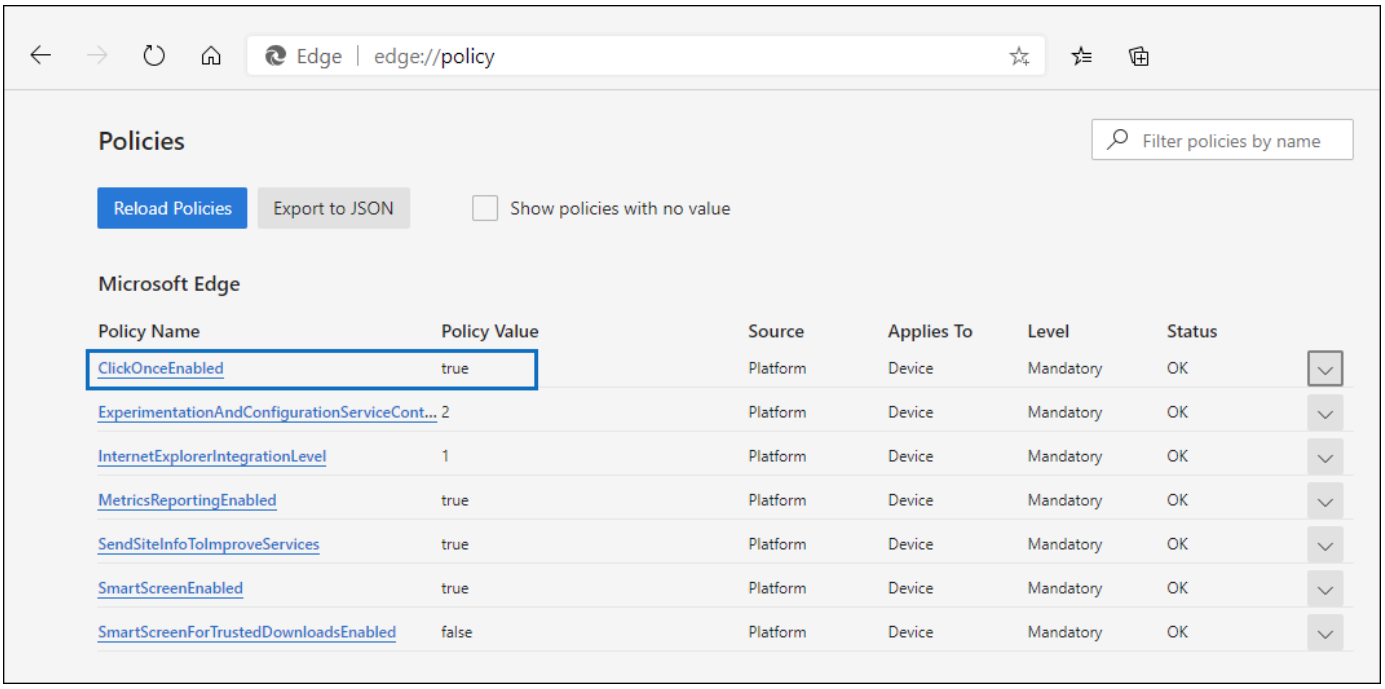
> **Important**
>
> The eDiscovery Export tool was permanently **retired on August 31, 2025**, this functionality isn't available in the new eDiscovery experience.



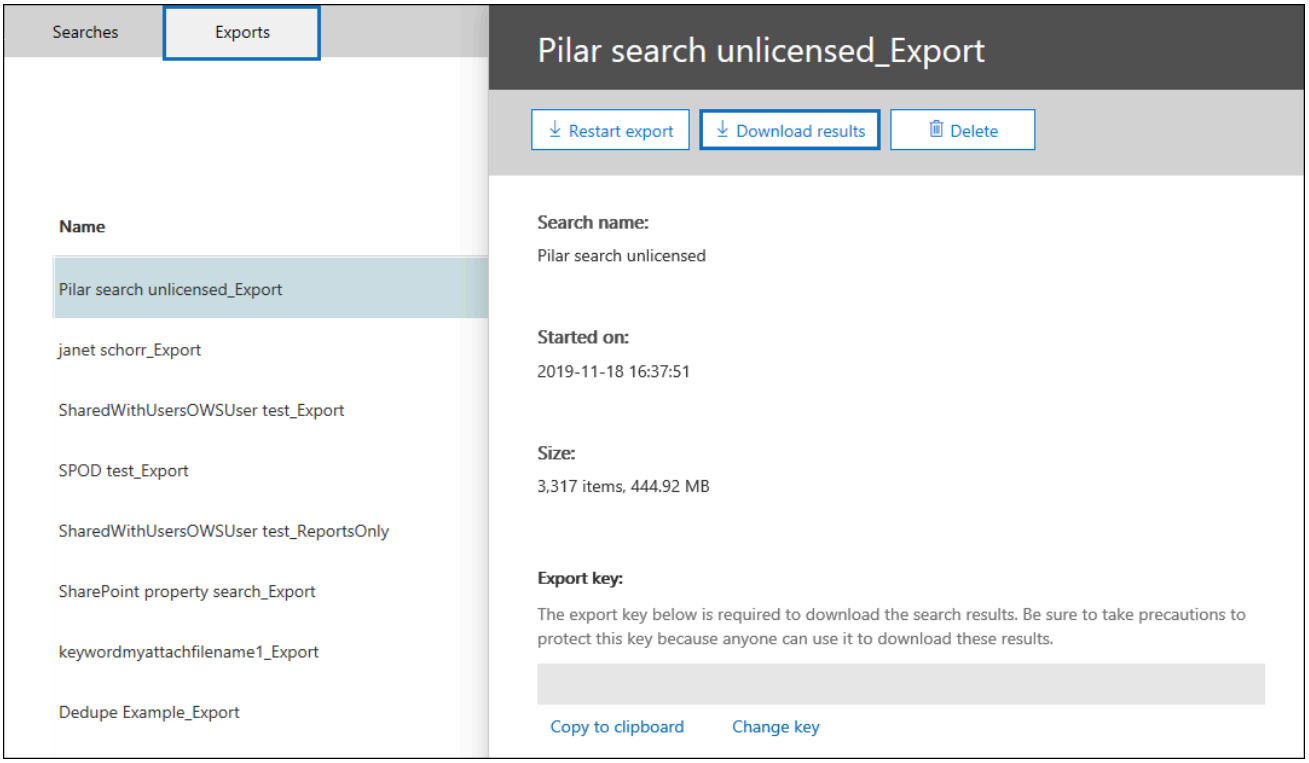
As a result of recent changes to the newest version of Microsoft Edge, ClickOnce support is no longer enabled by default. To continue using the eDiscovery Export Tool to download Content Search or eDiscovery search results, you either need to use Microsoft Internet Explorer or enable ClickOnce support in the newest version of Microsoft Edge.

Enable ClickOnce support in Microsoft Edge

1. In Microsoft Edge, go to **edge://flags/#edge-click-once**.
2. If the existing value is set to **Default** or **Disabled** in the dropdown list, change it to **Enabled**.

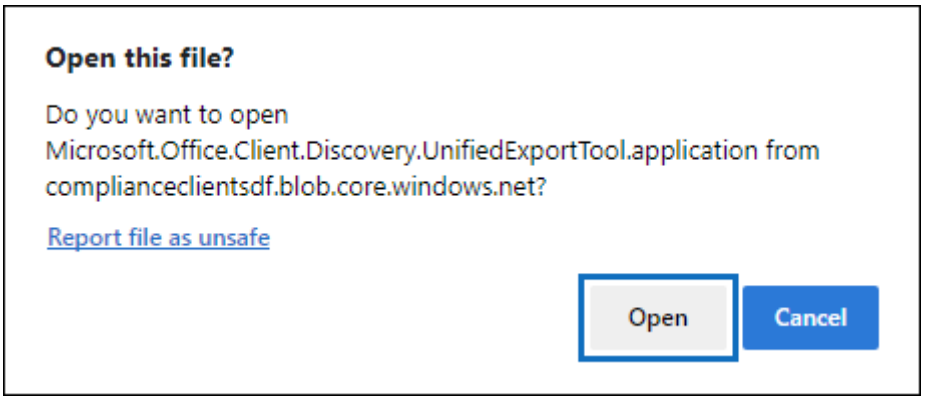


3. Scroll down to the bottom of the browser window and select **Restart** to restart Microsoft Edge.



> **Note**

Organizations can use Group Policy to disable ClickOnce support. To check if there's an organizational policy for ClickOnce support, go to **edge://policy**. The following screenshot shows that ClickOnce is enabled across the entire organization. If this policy value is set to **false**, you'll need to contact an admin in your organization.



Install and run the eDiscovery Export Tool

1. Select **Download results** on the flyout page of an export in Content Search or an eDiscovery case.

2. You'll be prompted with a confirmation to launch the tool, select **Open**. If the eDiscovery Export Tool isn't installed, you'll be prompted with a Security Warning.

3. Select **Install**. After it's installed, the export tool will launch automatically.

For more information, see the following articles:

- Export Content Search results
- How to enable experiment flags in Microsoft Edge

Use Content Search to search the mailbox and OneDrive site for a list of users

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Security & Compliance PowerShell provides numerous cmdlets that let you automate time-consuming eDiscovery-related tasks. Currently, creating a Content search in the Microsoft Purview portal to search a large number of custodian content locations takes time and preparation. Before you create a search, you have to collect the URL for each OneDrive site and then add each mailbox and OneDrive site to the search. This script prompts you for the name of your organization's MySite domain (for example, **contoso** in the URL `https://contoso-my.sharepoint.com`), a list of user email addresses, the name of the new Content Search, and the search query to use. The script gets the OneDrive URL for each user in the list, and then it creates and starts a Content Search that searches the mailbox and OneDrive site for each user in the list, using the search query that you provide.

Permissions and script information

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

- You have to be a member of the eDiscovery Manager role group in the Microsoft Purview portal or the Microsoft Purview portal and a SharePoint global administrator to run the script in Step 3.

- Be sure to save the list of users that you create in Step 2 and the script in Step 3 to the same folder. This makes it easier to run the script.
- The script includes minimal error handling. Its primary purpose is to quickly and easily search the mailbox and OneDrive site of each user.
- The sample scripts provided in this article aren't supported under any Microsoft standard support program or service. The sample scripts are provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample scripts and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Install the SharePoint Management Shell

The first step is to install the SharePoint Management Shell. You don't have to use the shell in this procedure, but you have to install it because it contains prerequisites required by the script that you run in Step 3. These prerequisites allow the script to communicate with SharePoint to get the URLs for the OneDrive sites.

Go to Set up the SharePoint Management Shell environment and perform Step 1 and Step 2 to install the SharePoint Management Shell.

Step 2: Generate a list of users

The script in Step 3 will create a Content Search to search the mailboxes and OneDrive accounts for a list of users. You can just type the email addresses in a text file, or you can run a command in PowerShell to get a list of email addresses and save them to a file (located in same folder that you'll save the script to in Step 3).

Here's an Exchange Online PowerShell command that you can run to get a list of email addresses for all users in your organization and save it to a text file named `Users.txt`.

PowerShell

```
Get-Mailbox -ResultSize unlimited -Filter { RecipientTypeDetails -eq 'UserMailbox'} |
```

```
Select-Object PrimarySmtpAddress > Users.txt
```

After you run this command, be sure to open the file and remove the header that contains the property name, `PrimarySmtpAddress`. The text file should just contain a list of email addresses, and nothing else. Make sure there are no blank rows before or after the list of email addresses.

Step 3: Run the script to create and start the search

When you run the script in this step, it prompts you for the following information. Be sure to have this information ready before you run the script.

- **Your user credentials** - The script uses your credentials to access SharePoint to get the OneDrive URLs and to connect to Security & Compliance PowerShell.
- **Name of your MySite domain** - The MySite domain is the domain that contains all the OneDrive sites in your organization. For example, if the URL for your MySite domain is `https://contoso-my.sharepoint.com`, then you would enter `contoso` when the script prompts you for the name of your MySite domain.
- **Pathname of the text file from Step 2** - The pathname of the text file that you created in Step 2. If the text file and the script are located in the same folder, then enter the name of the text file. Otherwise, enter the complete pathname for the text file.
- **Name of the Content Search** - The name of the Content Search that will be created by the script.
- **Search query** - The search query that is used with the Content Search is created and run. For more information about search queries, see Keyword queries and search conditions for eDiscovery.

To run the script:

1. Save the following text to a Windows PowerShell script file by using a filename suffix of .ps1; for example, `SearchEXOOD4B.ps1`. Save the file to the same folder where you saved the list of users in Step 2.

   PowerShell

   ```
   # This PowerShell script will prompt you for the following information:
   #    * Your user credentials
   #    * The name of your organization's MySite domain
   #    * The pathname for the text file that contains a list of user email
   addresses
   ```

```
#    * The name of the Content Search created
#    * The search query string
# The script will then:
#    * Find the OneDrive site for each user in the text file
#    * Create and start a Content Search using the previous information
# Get user credentials
if (!$credentials)
{
    $credentials = Get-Credential
}
# Get the user's MySite domain name.  We use this to create the admin URL and
root URL for OneDrive
$mySiteDomain = Read-Host "What is your organization's MySite domain?  For
example,  'contoso' for 'https://contoso-my.sharepoint.com'"
$AdminUrl = "https://$mySiteDomain-admin.sharepoint.com"
$mySiteUrlRoot = "https://$mySiteDomain-my.sharepoint.com"
# Get other required information
$inputfile = read-host "Enter the file name of the text file that contains the
email addresses for the users you want to search"
$searchName = Read-Host "Enter the name for the new search"
$searchQuery = Read-Host "Enter the search query you want to use"
$emailAddresses = Get-Content $inputfile | where {$_ -ne ""}  | foreach{
$_.Trim() }
# Connect to Security & Compliance PowerShell
if (!$s -or !$a)
{
    Import-Module ExchangeOnlineManagement
    Connect-IPPSSession
}

# Load the SharePoint assemblies from the SharePoint Management Shell
# To install, go to https://go.microsoft.com/fwlink/p/?LinkId=255251
if (!$SharePointClient -or !$SPRuntime -or !$SPUserProfile)
{
    $SharePointClient =
[System.Reflection.Assembly]::LoadWithPartialName("Microsoft.SharePoint.Client")
    $SPRuntime =
[System.Reflection.Assembly]::LoadWithPartialName("Microsoft.SharePoint.Client.Ru
ntime")
    $SPUserProfile =
[System.Reflection.Assembly]::LoadWithPartialName("Microsoft.SharePoint.Client.Us
erProfiles")
    if (!$SharePointClient)
    {
        Write-Error "SharePoint Management Shell isn't installed, please install
from: https://go.microsoft.com/fwlink/p/?LinkId=255251 and then run this script
again"
        return;
    }
}
if (!$spCreds)
{
    $spCreds = New-Object
Microsoft.SharePoint.Client.SharePointOnlineCredentials($credentials.UserName,
$credentials.Password)
```

```
}
# Add the path of the User Profile Service to the SPO admin URL, then create a
new webservice proxy to access it
$proxyaddr = "$AdminUrl/_vti_bin/UserProfileService.asmx?wsdl"
$UserProfileService= New-WebServiceProxy -Uri $proxyaddr -UseDefaultCredential
False
$UserProfileService.Credentials = $credentials
# Take care of auth cookies
$strAuthCookie = $spCreds.GetAuthenticationCookie($AdminUrl)
$uri = New-Object System.Uri($AdminUrl)
$container = New-Object System.Net.CookieContainer
$container.SetCookies($uri, $strAuthCookie)
$UserProfileService.CookieContainer = $container
Write-Host "Getting each user's OneDrive URL"
$urls = @()
foreach($emailAddress in $emailAddresses)
{
    try
    {
        $prop =
$UserProfileService.GetUserProfileByName("i:0#.f|membership|$emailAddress") |
Where-Object { $_.Name -eq "PersonalSpace" }
        $url = $prop.values[0].value
        $furl = $mySiteUrlRoot + $url
        $urls += $furl
        Write-Host "-$emailAddress => $furl"
    }
    catch
    {
        Write-Warning "Could not locate OneDrive for $emailAddress"
    }
}
Write-Host "Creating and starting the search"
$search = New-ComplianceSearch -Name $searchName -ExchangeLocation
$emailAddresses -SharePointLocation $urls -ContentMatchQuery $searchQuery
# Finally, start the search and then display the status
if($search)
{
    Start-ComplianceSearch $search.Name
    Get-ComplianceSearch $search.Name
}
```

2. Open Windows PowerShell and go to the folder where you saved the script and the list of users from Step 2.

3. Start the script; for example:

PowerShell

```
.\SearchEXOOD4B.ps1
```

4. When prompted for your credentials, enter your email address and password, and then select **OK**.

5. Enter following information when prompted by the script. Type each piece of information and then press **Enter**.

    - The name of your MySite domain.
    - The pathname of the text file that contains the list of users.
    - A name for the Content Search.
    - The search query (leave this blank to return all items in the content locations).

    The script gets the URLs for each OneDrive site and then creates and starts the search. You can either run the **Get-ComplianceSearch** cmdlet in Security & Compliance PowerShell to display the search statistics and results, or you can go to the **Content search** page in the Microsoft Purview portal to view information about the search.

Create, report on, and delete multiple Content Searches

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Quickly creating and reporting discovery searches is often an important step in eDiscovery and investigations when you're trying to learn about the underlying data, and the richness and quality of your searches. To help you do this, Security & Compliance PowerShell offers a set of cmdlets to automate time-consuming Content Search tasks. These scripts provide a quick and easy way to create many searches, and then run reports of the estimated search results that can help you determine the quantity of data in question. You can also use the scripts to create different versions of searches to compare the results each one produces. These scripts can help you to quickly and efficiently identify and cull your data.

Before you create a Content Search

- You have to be a member of the eDiscovery Manager role group in the Microsoft Purview portal to run the scripts that are described in this article.
- To collect a list of the URLs for the OneDrive for Business sites in your organization that you can add to the CSV file in Step 1, see Create a list of all OneDrive locations in your organization.
- Be sure to save all the files that you create in this article to the same folder. That makes it easier to run the scripts.
- The scripts include minimal error handling. Their primary purpose is to quickly create, report on, and delete multiple Content Searches.
- The sample scripts provided in this article aren't supported under any Microsoft standard support program or service. The sample scripts are provided AS IS without warranty of any

kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample scripts and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Create a CSV file that contains information about the searches you want to run

The comma separated value (CSV) file that you create in this step contains a row for each user that you want to search. You can search the user's Exchange Online mailbox (which includes the archive mailbox, if it's enabled) and their OneDrive site. Or you can search just the mailbox or the OneDrive site. You can also search any site in your SharePoint Online organization. The script that you run in Step 3 will create a separate search for each row in the CSV file.

1. Copy and paste the following text into a .txt file using NotePad. Save this file to a folder on your local computer. You save the other scripts to this folder as well.

   text

   ```
   ExchangeLocation,SharePointLocation,ContentMatchQuery,StartDate,EndDate
   sarad@contoso.onmicrosoft.com,https://contoso-
   my.sharepoint.com/personal/sarad_contoso_onmicrosoft_com,(lawsuit OR
   legal),1/1/2000,12/31/2005
   sarad@contoso.onmicrosoft.com,https://contoso-
   my.sharepoint.com/personal/sarad_contoso_onmicrosoft_com,(lawsuit OR
   legal),1/1/2006,12/31/2010
   sarad@contoso.onmicrosoft.com,https://contoso-
   my.sharepoint.com/personal/sarad_contoso_onmicrosoft_com,(lawsuit OR
   legal),1/1/2011,3/21/2016
   ,https://contoso.sharepoint.com/sites/contoso,,,3/21/2016
   ,https://contoso-
   my.sharepoint.com/personal/davidl_contoso_onmicrosoft_com,,1/1/2015,
   ,https://contoso-
   my.sharepoint.com/personal/janets_contoso_onmicrosoft_com,,1/1/2015,
   ```

   The first row, or header row, of the file lists the parameters that will be used by **New-ComplianceSearch** cmdlet (in the script in Step 3) to create a new Content Searches. Each parameter name is separated by a comma. Make sure there aren't any spaces in the header

row. Each row under the header row represents the parameter values for each search. Be sure to replace the placeholder data in the CSV file with your actual data.

2. Open the .txt file in Excel, and then use the information in the following table to edit the file with information for each search.

Expand table

Parameter	Description
`ExchangeLocation`	The SMTP address of the user's mailbox.
`SharePointLocation`	The URL for the user's OneDrive for Business site or the URL for any site in your organization. For the URL for OneDrive for Business sites, use this format: `https://<your organization>-my.sharepoint.com/personal/<user alias>_<your organization>_onmicrosoft_com`. For example, `https://contoso-my.sharepoint.com/personal/sarad_contoso_onmicrosoft_com`.
`ContentMatchQuery`	The search query for the search. For more information about creating a search query, see Keyword queries and search conditions for Content Search.
`StartDate`	For email, the date on or after a message was received by a recipient or sent by the sender. For documents on SharePoint or OneDrive for Business sites, the date on or after a document was last modified.
`EndDate`	For email, the date on or before a message was sent by a sent by the user. For documents on SharePoint or OneDrive for Business sites, the date on or before a document was last modified.

3. Save the Excel file as a CSV file to a folder on your local computer. The script that you create in Step 3 will use the information in this CSV file to create the searches.

Step 2: Connect to Security & Compliance PowerShell

The next step is to connect to Security & Compliance PowerShell for your organization. For step-by-step instructions, see Connect to Security & Compliance PowerShell.

Step 3: Run the script to create and start the searches

The script in this step creates a separate Content Search for each row in the CSV file that you created in Step 1. When you run this script, you're prompted for two values:

- **Search Group ID** - This name provides an easy way to organize the searches that are created from the CSV file. Each search that's created is named with the Search Group ID, and then a number is appended to the search name. For example, if you enter **ContosoCase** for the Search Group ID, then the searches are named **ContosoCase_1**, **ContosoCase_2**, **ContosoCase_3**, and so on. The name you type is case sensitive. When you use the Search Group ID in Step 4 and Step 5, you have to use the same case as you did when you created it.

- **CSV file** - The name of the CSV file that you created in Step 1. Be sure to include the use the full filename and include the .csv file extension; for example, `ContosoCase.csv`.

To run the script:

1. Save the following text to a Windows PowerShell script file by using a filename suffix of .ps1; for example, `CreateSearches.ps1`. Save the file to the same folder where you saved the other files.

Powershell

```
# Get the Search Group ID and the location of the CSV input file
$searchGroup = Read-Host 'Search Group ID'
$csvFile = Read-Host 'Source CSV file'

# Do a quick check to make sure our group name will not collide with other
searches
$searchCounter = 1
import-csv $csvFile |
  ForEach-Object{

 $searchName = $searchGroup +'_' + $searchCounter
 $search = Get-ComplianceSearch $searchName -EA SilentlyContinue
 if ($search)
 {
    Write-Error "The Search Group ID conflicts with existing searches.  Please
choose a search group name and restart the script."
    return
 }
 $searchCounter++
}

$searchCounter = 1
import-csv $csvFile |
  ForEach-Object{

 # Create the query
 $query = $_.ContentMatchQuery
 if(($_.StartDate -or $_.EndDate))
 {
       # Add the appropriate date restrictions.  NOTE: Using the Date condition
```

```
property here because it works across Exchange, SharePoint, and OneDrive for
Business.
       # For Exchange, the Date condition property maps to the Sent and Received
dates; for SharePoint and OneDrive for Business, it maps to Created and Modified
dates.
       if($query)
       {
           $query += " AND"
       }
       $query += " ("
       if($_.StartDate)
       {
           $query += "Date >= " + $_.StartDate
       }
       if($_.EndDate)
       {
           if($_.StartDate)
           {
               $query += " AND "
           }
           $query += "Date <= " + $_.EndDate
       }
       $query += ")"
 }

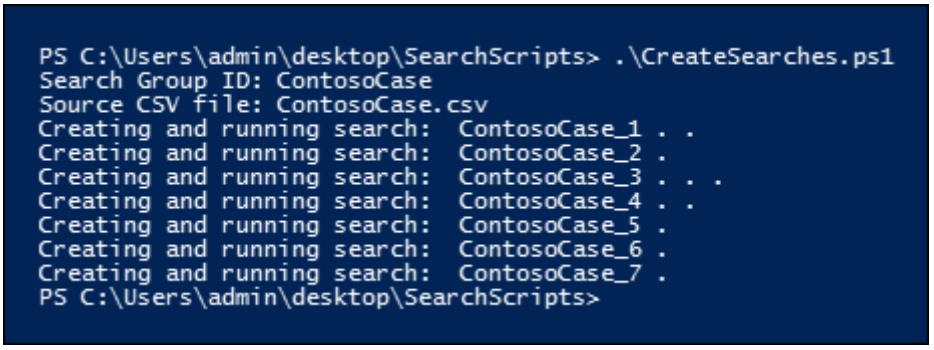
  # -ExchangeLocation can't be set to an empty string, set to null if there's no
location.
  $exchangeLocation = $null
  if ( $_.ExchangeLocation)
  {
        $exchangeLocation = $_.ExchangeLocation
  }

 # Create and run the search
 $searchName = $searchGroup +'_' + $searchCounter
 Write-Host "Creating and running search: " $searchName -NoNewline
 $search = New-ComplianceSearch -Name $searchName -ExchangeLocation
$exchangeLocation -SharePointLocation $_.SharePointLocation -ContentMatchQuery
$query

 # Start and wait for each search to complete
 Start-ComplianceSearch $search.Name
 while ((Get-ComplianceSearch $search.Name).Status -ne "Completed")
 {
    Write-Host " ." -NoNewline
    Start-Sleep -s 3
 }
 Write-Host ""

 $searchCounter++
}
```

2. In Windows PowerShell, go to the folder where you saved the script in the previous step, and then run the script; for example:



```
Powershell
.\CreateSearches.ps1
```

3. At the **Search Group ID** prompt, type a search group name, and then press **Enter**; for example, `ContosoCase`. Remember that this name is case sensitive, so you have to type it the same way in the subsequent steps.

4. At the **Source CSV file** prompt, type the name of the CSV file, including the .csv file extension; for example, `ContosoCase.csv`.

5. Press **Enter** to continue running the script.

   The script displays the progress of creating and running the searches. When the script is complete, it returns to the prompt.

Step 4: Run the script to report the search estimates

After you create the searches, the next step is to run a script that displays a simple report of the number of search hits for each search that was created in Step 3. The report also includes the size of results for each search, and the total number of hits and total size of all searches. When you run the reporting script, you are prompted for the Search Group ID, and a CSV filename if you want to save the report to a CSV file.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of .ps1; for example, `SearchReport.ps1`. Save the file to the same folder where you saved the other files.

```
Powershell
```

```
$searchGroup = Read-Host 'Search Group ID'
$outputFile = Read-Host 'Enter a file name or file path to save the report to a
.csv file. Leave blank to only display the report'
$searches = Get-ComplianceSearch | ?{$_.Name -clike $searchGroup + "_*"}
$allSearchStats = @()
foreach ($partialObj in $searches)
{
   $search = Get-ComplianceSearch $partialObj.Name
   $sizeMB = [System.Math]::Round($search.Size / 1MB, 2)
   $searchStatus = $search.Status
   if($search.Errors)
   {
       $searchStatus = "Failed"
   }elseif($search.NumFailedSources -gt 0)
   {
       $searchStatus = "Failed Sources"
   }
   $searchStats = New-Object PSObject
   Add-Member -InputObject $searchStats -MemberType NoteProperty -Name Name -
Value $search.Name
   Add-Member -InputObject $searchStats -MemberType NoteProperty -Name

   Add-Member -InputObject $searchStats -MemberType NoteProperty -Name "Size(MB)"
-Value $sizeMB
   $allSearchStats += $searchStats
}
# Calculate the totals
$allItems = ($allSearchStats | Measure-Object Items -Sum).Sum
# Convert the total size to MB and round to the nearst 100th
$allSize = ($allSearchStats | Measure-Object 'Size' -Sum).Sum
$allSizeMB = [System.Math]::Round($allSize  / 1MB, 2)
# Get the total successful searches and total of all searches
$allSuccessCount = ($allSearchStats |?{$_.Status -eq "Completed"}).Count
$allCount = $allSearchStats.Count
$allStatus = [string]$allSuccessCount + " of " + [string]$allCount
# Totals Row
$totalSearchStats = New-Object PSObject
Add-Member -InputObject $totalSearchStats -MemberType NoteProperty -Name Name -
Value "Total"
Add-Member -InputObject $totalSearchStats -MemberType NoteProperty -Name Status -
Value $allStatus
Add-Member -InputObject $totalSearchStats -MemberType NoteProperty -Name Items -
Value $allItems
Add-Member -InputObject $totalSearchStats -MemberType NoteProperty -Name
"Size(MB)" -Value $allSizeMB
$allSearchStats += $totalSearchStats
# Just get the columns we're interested in showing
$allSearchStatsPrime = $allSearchStats | Select-Object Name, Status, Items,
```

```
"Size(MB)", ContentMatchQuery
# Print the results to the screen
$allSearchStatsPrime |ft -AutoSize -Wrap
# Save the results to a CSV file
if ($outputFile)
{
   $allSearchStatsPrime | Export-Csv -Path $outputFile -NoTypeInformation
}
```

2. In Windows PowerShell, go to the folder where you saved the script in the previous step, and then run the script; for example:

Powershell

```
.\SearchReport.ps1
```

3. At the **Search Group ID** prompt, type a search group name, and then press **Enter**; for example `ContosoCase`. Remember that this name is case sensitive, so you have to type it the same way you did when you ran the script in Step 3.

4. At the **File path to save the report to a CSV file (leave blank to just display the report)** prompt, type a file name of complete filename path (including the .csv file extension) if you want to save the report to a CSV file. name of the CSV file, including the .csv file extension. For example, you could type `ContosoCaseReport.csv` to save it to the current directory or you could type `C:\Users\admin\OneDrive for Business\ContosoCase\ContosoCaseReport.csv` to save it to a different folder. You can also leave the prompt blank to display the report but not save it to a file.

5. Press **Enter**.

   The script displays the progress of creating and running the searches. When the script is complete, the report is displayed.

```
PS C:\Users\admin\desktop\SearchScripts> .\SearchReport.ps1
Search Group ID: ContosoCase
Enter a file name or file path to save the report to a .csv file. Leave blank to only display the report:

Name          Status       Items  Size (MB)    ContentMatchQuery
----          ------       -----  ---------    -----------------
ContosoCase_1 Completed      865      23.24    (lawsuit OR legal) AND (Date >= 1/1/2000 AND Date <= 12/31/2005)
ContosoCase_2 Completed      229       8.81    (lawsuit OR legal) AND (Date >= 1/1/2006 AND Date <= 12/31/2010)
ContosoCase_3 Completed      249       9.86    (lawsuit OR legal) AND (Date >= 1/1/2011 AND Date <= 12/31/2015)
ContosoCase_4 Completed     1600     663.43    (Date <= 12/31/2015)
ContosoCase_5 Completed      160      62.70    (Date >= 1/1/2015)
ContosoCase_6 Completed      140      65.20    (Date >= 1/1/2015)
ContosoCase_7 Completed       90       2.60    (Date >= 1/1/2015)
Total         7 of 7        3333     835.84

PS C:\Users\admin\desktop\SearchScripts>
```

> **Note**

If the same mailbox or site is specified as a content location in more than one search in a search group, the total results estimate in the report (for both the number of items and the total size) might include results for the same items. That's because the same email message or document will be counted more than once if it matches the query for different searches in the search group.

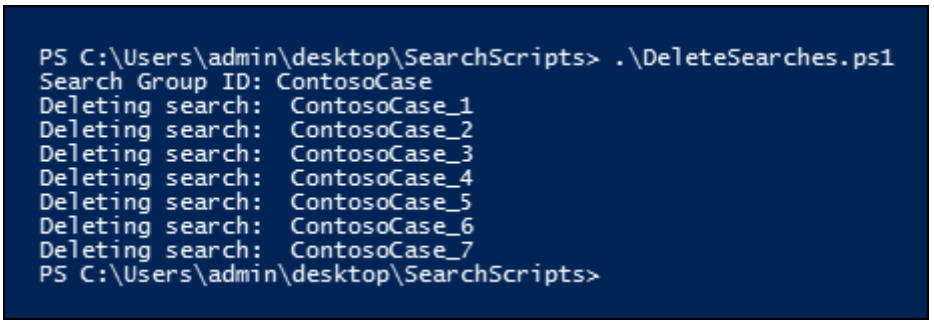
Step 5: Run the script to delete the searches

Because you might be creating numerous searches, this last script just makes it easy to quickly delete the searches you created in Step 3. Like the other scripts, this one also prompts you for the Search Group ID. All searches with the Search Group ID in the search name will be deleted when you run this script.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of .ps1; for example, `DeleteSearches.ps1`. Save the file to the same folder where you saved the other files.

   Powershell

   ```
   # Delete all searches in a search group
   $searchGroup = Read-Host 'Search Group ID'
   Get-ComplianceSearch |
      ForEach-Object{
      # If the name matches the search group name pattern (case sensitive), delete
   the search
      if ($_.Name -cmatch $searchGroup + "_\d+")
      {
          Write-Host "Deleting search: " $_.Name
          Remove-ComplianceSearch $_.Name -Confirm:$false
      }
   }
   ```



2. In Windows PowerShell, go to the folder where you saved the script in the previous step, and then run the script; for example:

   Powershell

   ```
   .\DeleteSearches.ps1
   ```

3. At the **Search Group ID** prompt, type a search group name for the searches that you want to delete, and then press **Enter**; for example, `ContosoCase`. Remember that this name is case sensitive, so you have to type it the same way you did when you ran the script in Step 3.

The script displays the name of each search that's deleted.

Clone a Content Search

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Creating a Content Search in the Microsoft Purview portal in Microsoft 365 that searches many mailboxes or SharePoint and OneDrive for Business sites can take a while. Specifying the sites to search can also be prone to errors if you mistype a URL. To avoid these issues, you can use the Windows PowerShell script in this article to quickly clone an existing Content Search. When you clone a search, a new search (with a different name) is created that contains the same properties (such as the content locations and the search query) as the original search. Then you can edit the new search by changing the keyword query or the date range, and run it.

Why clone Content Searches?

- To compare the results of different keyword search queries run on the same content locations.
- To save you from having to reenter a large number of content locations when you create a new search.
- To decrease the size of the search results. For example, if you have a search that returns too many results to export, you can clone the search and then add a search condition based on a date range to reduce the number of search results.

Script information

- You need to install the Exchange Online PowerShell module. For instructions, see Install and maintain the Exchange Online PowerShell module.

- You have to be a member of the eDiscovery Manager role group in the Microsoft Purview portal to run the script described in this topic.
- The script includes minimal error handling. The primary purpose of the script is to quickly clone a content search.
- The script creates a new Content Search, but doesn't start it.
- This script takes into account whether the Content Search that you're cloning is associated with an eDiscovery case. If the search is associated with a case, the new search will also be associated with the same case. If the existing search isn't associated with a case, the new search will be listed on the **Content search** page in the Microsoft Purview portal.
- The sample script provided in this topic isn't supported under any Microsoft standard support program or service. The sample script is provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample script and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Run the script to clone a search

The script in this step will create a new Content Search by cloning an existing one. When you run this script, you'll be prompted for the following information:

- **Your user credentials** - The script will use your credentials to connect to Security & Compliance PowerShell. As previously stated, you have to be a member of the eDiscovery Manager role group in the Microsoft Purview portal to run the script.
- **The name of the existing search** - This is the Content Search that you want to clone.
- **The name of the new search that will be created** - If you leave this value blank, the script will create a name for the new search that is based on the name of the search that you're cloning.

To clone a search:

1. Save the following text to a Windows PowerShell script file by using a filename suffix of .ps1; for example, `CloneSearch.ps1`.

PowerShell

```
# This PowerShell script clones an existing content search in Microsoft Purview
compliance.

# Ask for the name of the search you want to clone
$searchName = Read-Host 'Enter the name of the search that you want to clone'
# Ask for the name of the new search
$newSearchName = Read-Host 'Enter a name for the new search [leave blank to
automatically generate a name]'
$originalSearch = Get-ComplianceSearch $searchName -EA SilentlyContinue
# Make sure we have a valid search before continuing
if(!$originalSearch)
{
    Write-Error "Couldn't find search: $searchName"
    return
}
$searchNameCounter = 1
# Find a suitable name for the new search
while(!$newSearchName)
{
    $newSearchName = $originalSearch.Name + "_" + $searchNameCounter
    $tempSearch = Get-ComplianceSearch $newSearchName -EA SilentlyContinue
    if ($tempSearch)
    {
        $newSearchName = $null
        $searchNameCounter++
    }
}
$caseName
# Determine if the search is part of a case; if so get the case name
if ($originalSearch.CaseId)
{
    $searchCase = Get-ComplianceCase $originalSearch.CaseId
    $caseName = $searchCase.Name
}
# Need to cast this value as a Boolean the old fashion way
$allowNotFoundExchangeLocationsEnabled = $false
if ($originalSearch.AllowNotFoundExchangeLocationsEnabled)
{
    $allowNotFoundExchangeLocationsEnabled = $true
}
$newSearch = New-ComplianceSearch -Name $newSearchName -
AllowNotFoundExchangeLocationsEnabled $allowNotFoundExchangeLocationsEnabled -
Case $caseName -ContentMatchQuery $originalSearch.ContentMatchQuery -Description
$originalSearch.Description -ExchangeLocation $originalSearch.ExchangeLocation -
ExchangeLocationExclusion $originalSearch.ExchangeLocationExclusion -Language
$originalSearch.Language -SharePointLocation $originalSearch.SharePointLocation -
SharePointLocationExclusion $originalSearch.SharePointLocationExclusion -
PublicFolderLocation $originalSearch.PublicFolderLocation
```

```
if ($newSearch)
{
    Write-Host $newSearch.Name "was successfully created" -ForegroundColor Yellow
}
```

2. Connect to Security & Compliance PowerShell. In the same PowerShell window, go to the folder where you saved the script.

3. Run the script; for example:

   PowerShell

   ```
   .\CloneSearch.ps1
   ```

4. Enter following information when prompted by the script. Type each piece of information and then press **Enter**.

   - The name of the existing search.
   - The name of the new search.

   The script creates the new Content Search, but doesn't start it. This gives you a chance to edit and run the search in the next step. You can view the properties of the new search by running the **Get-ComplianceSearch** cmdlet or by going to the **Content search** or **eDiscovery** page in the Microsoft Purview portal, depending on whether the new search is associated with a case.

Step 2: Edit and run the cloned search in the Microsoft Purview portal

After you run the script to clone an existing Content Search, the next step is to go to the Microsoft Purview portal to edit and run the new search. As previously stated, you can edit a search by changing the keyword search query and adding or removing search conditions. For more information, see:

- Content Search in Office 365
- Keyword queries and search conditions for Content Search
- eDiscovery cases

Last updated on 11/21/2025

Get started with eDiscovery (Standard)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Microsoft Purview eDiscovery (Standard) in Microsoft Purview provides a basic eDiscovery tool that organizations can use to search and export content in Microsoft 365 and Office 365. You can also use eDiscovery (Standard) to place an eDiscovery hold on content locations, such as Exchange mailboxes, SharePoint sites, OneDrive accounts, and Microsoft Teams. Nothing is needed to deploy eDiscovery (Standard), but there are some prerequisite tasks that an IT admin and eDiscovery manager have to complete before your organization can start using eDiscovery (Standard) to search, export, and preserve content.

This article discusses the steps necessary to set up eDiscovery (Standard). This includes ensuring the proper licensing required to access eDiscovery (Standard) and place an eDiscovery hold on content locations, as well as assigning permissions to your IT, legal, and investigation team so they can access and manage cases. This article also provides a high-level overview of using cases to search for and export content.

Step 1: Verify and assign appropriate licenses

Microsoft Purview eDiscovery capabilities are included with Microsoft Purview. The licensing requirements may vary even within capabilities, depending on configuration options. For licensing requirements, guidance, and options, see the Microsoft 365 guidance for security & compliance.

For information about how to assign licenses, see Assign licenses to users.

Step 2: Verify that required eDiscovery apps are enabled

eDiscovery (Standard) requires the following Enterprise apps to be enabled in your Microsoft 365 or Office 365 organization. If these apps aren't enabled, you won't be able to access eDiscovery (Standard) view, filter, and search features.

Expand table

App	App ID
Built-in security add-on for on-premises mailboxes (formerly Exchange Online Protection)	00000007-0000-0ff1-ce00-000000000000
ComplianceWorkbenchApp	92876b03-76a3-4da8-ad6a-0511ffdf8647
Office365Zoom	0d38933a-0bbd-41ca-9ebd-28c4b5ba7cb7

For more information about how to view and enable apps, see:

- Quickstart: View enterprise applications
- Quickstart: Add an enterprise application

Step 3: Assign eDiscovery permissions

To access eDiscovery (Standard) or be added as a member of an eDiscovery (Standard) case, a user must be assigned the appropriate permissions. Specifically, a user must be added as a member of the eDiscovery Manager role group in the Microsoft Purview portal. Members of this role group can create and manage eDiscovery (Standard) cases. They can add and remove members, place an eDiscovery hold on users, create and edit searches, and export content from an eDiscovery (Standard) case.

For step-by-step guidance to configure permissions for eDiscovery, see Assign eDiscovery permissions.

Step 4: Create an eDiscovery (Standard) case

The next step is to create a case and start using eDiscovery (Standard). Complete the following steps to create a case and add members. The user who creates the case is automatically added as a member.

1. Go to Microsoft Purview portal and sign in using the credentials for a user account that has been assigned the appropriate eDiscovery permissions. Members of the Organization Management role group can also create eDiscovery (Standard) cases.
2. In the left navigation pane of the Microsoft Purview portal, select **Show all**, and then select **eDiscovery (Standard)**.
3. On the **eDiscovery (Standard)** page, select **Create a case**.
4. On the **New case** flyout page, give the case a name (required) and then type an optional description. The case name must be unique in your organization.
5. Select **Save** to create the case.

The new case is created and displayed on the eDiscovery (Standard) page. You may have to select **Refresh** to display the new case.

Step 5 (optional): Add members to an eDiscovery (Standard) case

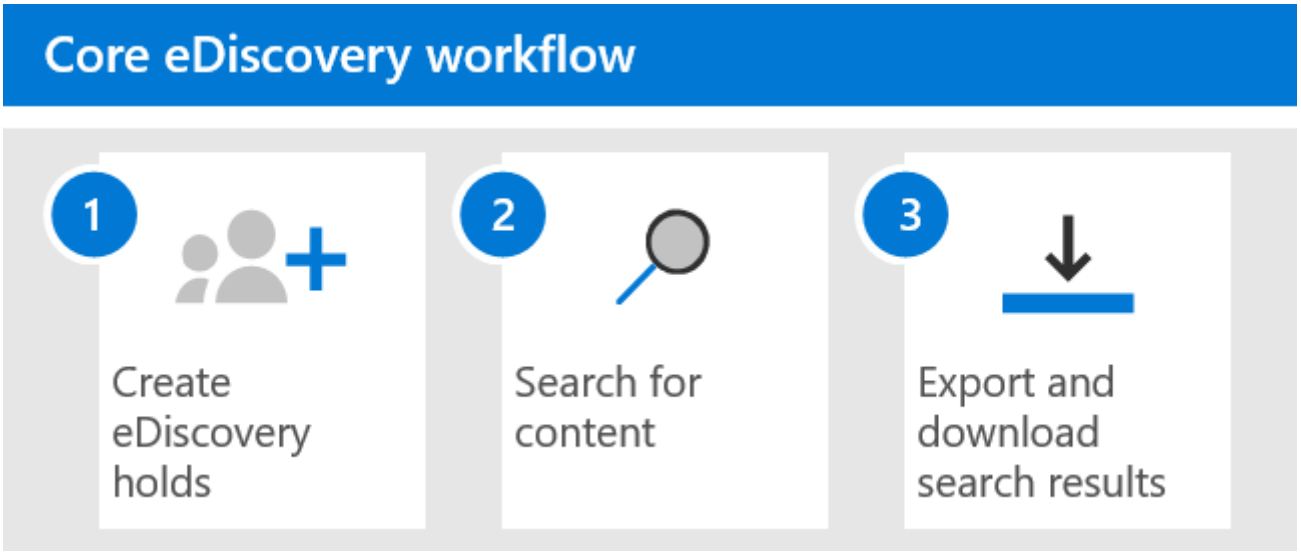
If you create a case in Step 3 and you're the only person who will use the case, then you don't have to perform this step. You can start using the case to create eDiscovery holds, search for content, and export search results. Perform this step if you want to give other users (or roles group) access to the case.

1. On the **eDiscovery (Standard)** page in the Microsoft Purview portal, select the name of the case that you want to add members to.

2. On the case home page, select the **Settings** tab, and then select **Access & permissions**.

3. On the **Access & permissions** flyout page, under **Members**, select **Add** to add members to the case.

   You can also choose to add role groups as members of a case. Under **Role groups**, select **Add**. You can only assign the role groups that you're a member of to a case. That's because role groups control who can assign members to an eDiscovery case.



4. In the list of people or role groups that can be added as members of the case, select to the left of the name of the people (or role groups) that you want to add. If you have a large list of people or role groups who can be added as members, use the **Search** box to search for a specific person or role group in the list.

5. After you select the people or role groups to add as members of the case, select **Save** to save the new members or role groups.

> **Important**
>
> - If a role is added or removed from a role group that you've added as a member of a case, then the role group will be automatically removed as a member of the case (or any case the role group is a member of). The reason for this is to protect your organization from inadvertently providing additional permissions to members of a case. Similarly, if a role group is deleted, it will be removed from all cases it was a member of. For more information, see Assign eDiscovery permissions.
> - Only an eDiscovery Administrator can remove members from a case. Users who are members of the eDiscovery Manager subgroup can't remove members from a case, even if the user created the case.

Explore the eDiscovery (Standard) workflow

To get you started using eDiscovery (Standard), here's a simple workflow of creating eDiscovery holds for people of interest, searching for content that relevant to your investigation, and then exporting that data for further review. In each of these steps, we'll also highlight some extended eDiscovery (Standard) functionality that you can explore.

1. Create an eDiscovery hold. The first step after creating a case is placing a hold (also called an *eDiscovery hold*) on the content locations of the people of interest in your investigation. Content locations include Exchange mailboxes, SharePoint sites, OneDrive accounts, and the mailboxes and sites associated with Microsoft Teams and Microsoft 365 Groups. While this step is optional, creating an eDiscovery hold preserves content that may be relevant to the case during the investigation. When you create an eDiscovery hold you can preserve all content in specific content locations or you can create a query-based hold to preserve only

the content that matches a hold query. In addition to preserving content, another good reason to create eDiscovery holds is to quickly search the content locations on hold (instead of having to select each location to search) when you create and run searches in the next step. After you complete your investigation, you can release any hold that you created.

2. **Search for content**. After you create eDiscovery holds, use the built-in search tool to search the content locations on hold. You can also search other content locations for data that may be relevant to the case. You can create and run different searches that are associated with the case. You use keywords, properties, and conditions to build search queries that return search results with the data that's most likely relevant to the case. You can also:

    - View search statistics that may help you refine a search query to narrow the results.
    - Preview the search results to quickly verify whether the relevant data is being found.
    - Revise a query and rerun the search.

3. **Export and download search results**. After you search for and find data that's relevant to your investigation, you can export it out of Office 365 for review by people outside of the investigation team. Exporting data is a two-step process. The first step is to export the results of a search in the case out of Office 365. This is accomplished by copying the results of a search to a Microsoft-provided Azure Storage location. The next step is to use the eDiscovery Export tool to download the content to a local computer. In addition to the exported data files, the export package contains an export report, a summary report, and an error report.

> **Important**
>
> The eDiscovery Export tool was permanently **retired on August 31, 2025**, this functionality isn't available in the new **eDiscovery experience**.

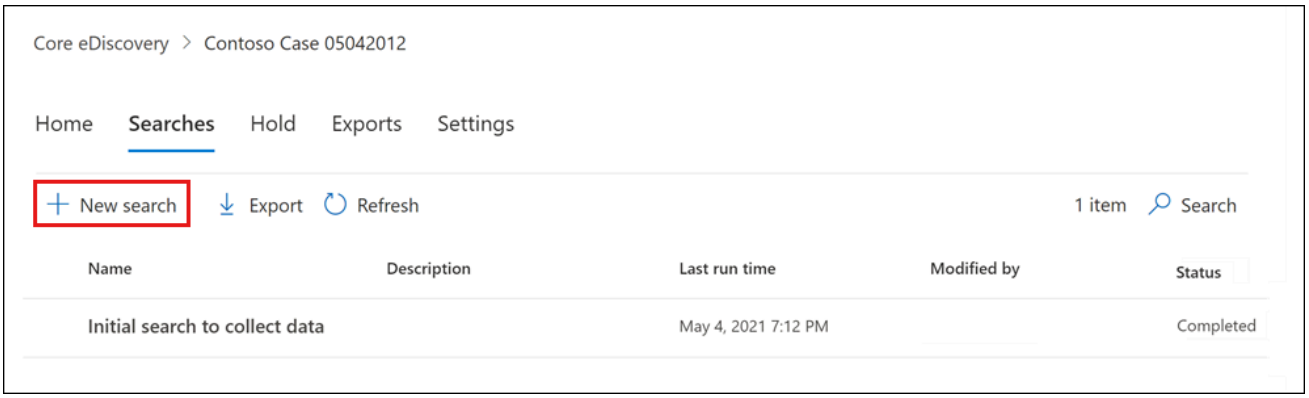
Search for content in an eDiscovery (Standard) case

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After a Microsoft Purview eDiscovery (Standard) case is created and people of interest in the case are placed on hold, you can create and run one or more searches for content relevant to the case. Searches associated with an eDiscovery (Standard) case aren't listed on the **Content search** page in the Microsoft Purview portal. These searches are listed on the **Searches** page of the eDiscovery (Standard) case the searches are associated with. This also means that searches associated with a case can only be accessed by case members.

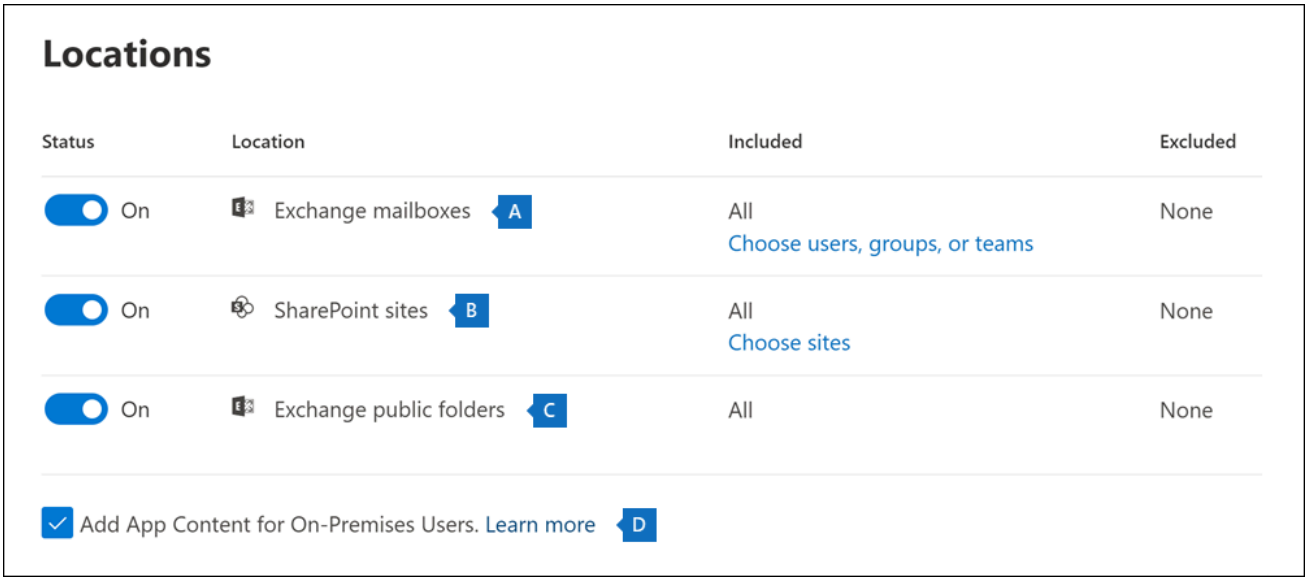
For organizations that have EU General Data Protection Regulation (GDPR) requirements to protect and enable individuals' privacy rights inside the European Union (EU), you can also manage investigations in response to a Data Subject Requests (DSRs) submitted by a person in your organization. The User Data Search case tool has been retired, and its functionality has merged with eDiscovery (Standard). You can now use content to search for content to support DSRs all locations supported by eDiscovery (Standard) searches.



To create an eDiscovery (Standard) search:

1. Go to https://compliance.microsoft.com and sign in using the credentials for user account that has been assigned the appropriate eDiscovery permissions and is a member of the case.

2. In the left navigation pane of the Microsoft Purview portal, select **Show all**, and then select **eDiscovery (Standard)**.



3. On the **eDiscovery (Standard)** page, select the case that you want to create an associated search, and then select **Open case**.

4. On the **Home** page for the case, select the **Searches** tab, and then select **New search**.

5. In the **New search** workflow, type a name for the search, and an optional description that helps identify the search. The name of the search must be unique in your organization.

6. On the **Locations** page, choose the content locations that you want to search. You can search mailboxes, sites, and public folders.

   a. **Exchange mailboxes**: Set the toggle to **On** and then select **Choose users, groups, or teams** to specify the mailboxes to place on hold. Use the search box to find user mailboxes and distribution groups (to place a hold on the mailboxes of group members) to place on hold. You can also search the mailbox associated with a Microsoft Team (for channel messages), Office 365 Group, and Viva Engage Group. All Copilot activity data (user prompts and Copilot responses) generated in supported Microsoft 365 apps and services is stored in custodian mailboxes. For more information about the application data stored in mailboxes, see Content stored in mailboxes for eDiscovery.

b. **SharePoint sites**: Set the toggle to **On** and then select **Choose sites** to specify SharePoint sites and OneDrive accounts to place on hold. Type the URL for each site that you want to place on hold. You can also add the URL for the SharePoint site for a Microsoft Team, Office 365 Group, or Viva Engage Group. The Recycle Bin in SharePoint sites isn't indexed and therefore unavailable for searching. As a result, eDiscovery searches can't find any Recycle Bin content to place holds.

c. **Exchange public folders**: Set the toggle to **On** to put all public folders in your Exchange Online organization on hold. You can't choose specific public folders to put on hold. Leave the toggle switch off if you don't want to put a hold on public folders.

d. Keep this checkbox selected to search for Teams content for on-premises users. For example, if you search all Exchange mailboxes in the organization and this checkbox is selected, the cloud-based storage used to store Teams chat data for on-premises users is included in the scope of the search. For more information, see Search for Teams chat data for on-premises users.

7. On the **Define your search conditions** page, type a keyword query and add conditions to the search query if necessary.

a. Specify keywords, message properties such as sent and received dates, or document properties such as file names or the date that a document was last changed. You can use more complex queries that use a Boolean operator, such as **AND**, **OR**, **NOT**, and **NEAR**. If you leave the keyword box empty, all content located in the specified content locations is

included in the search results. For more information, see Keyword queries and search conditions for eDiscovery.

b. Alternatively, you can select the **Show keyword list** checkbox and the type a keyword in each row. If you do this, the keywords on each row are connected by a logical operator (**c:s**) that is similar in functionality to the **OR** operator in the search query that's created.

   Why use the keyword list? You can get statistics that show how many items match each keyword. This can help you quickly identify which keywords are the most (and least) effective. You can also use a keyword phrase (surrounded by parentheses) in a row. For more information about the keyword list and search statistics, see Get keyword statistics for searches.

   > **Note**
   >
   > To help reduce issues caused by large keyword lists, you're limited to a maximum of 20 rows in the keyword list.

c. You can add search conditions to narrow a search and return a more refined set of results. Each condition adds a clause to the search query that is created and run when you start the search. A condition is logically connected to the keyword query (specified in the keyword box) by a logical operator (**c:c**) that is similar in functionality to the **AND** operator. That means that items have to satisfy both the keyword query and one or more conditions to be included in the results. This is how conditions help to narrow your results. For a list and description of conditions that you can use in a search query, see Search conditions.

8. Review the search settings (and edit if necessary), and then submit the search to start it.

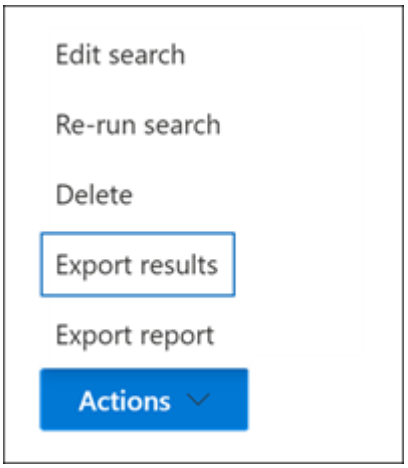
After the search is completed, you can preview the search results. If necessary, select **Refresh** on the **Searches** page to display the search you created.

More information about searching content locations

- When you select **Choose users, groups, or teams** to specify mailboxes to search, the mailbox picker that's displayed is empty. This is by design to enhance performance. To add recipients to this list, select **Choose users, groups, or teams**, type a name (a minimum of three characters) in the search box, select the check box next to the name, and then select **Choose**.

- You can add inactive mailboxes, Microsoft Teams, Viva Engage Groups, Office 365 Groups, and distribution groups to the list of mailboxes to search. Dynamic distribution groups aren't supported. If you add Microsoft Teams, Viva Engage Groups, or Office 365 Groups, the group or team mailbox is searched; the mailboxes of the group members aren't searched.
- To add sites to the search, turn on the toggle and then select **Choose sites**. Type the URL for each site that you want to search. You can also add the URL for the SharePoint site for a Microsoft Team, a Viva Engage Group, or an Office 365 Group.

Last updated on 09/02/2025



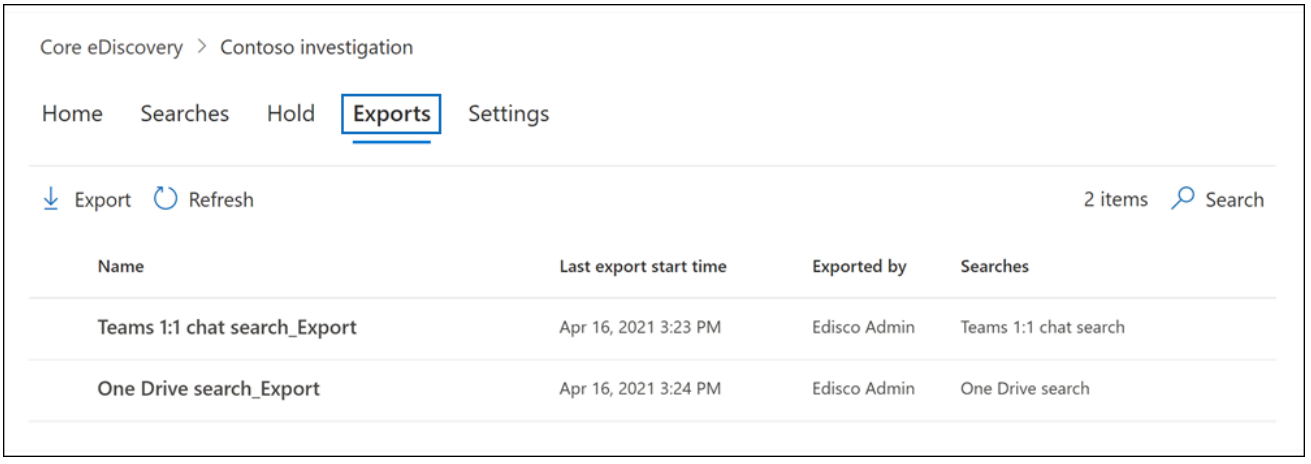
Export content from an eDiscovery (Standard) case

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After a search associated with a Microsoft Purview eDiscovery (Standard) case is successfully run, you can export the search results. When you export search results, mailbox items are downloaded in PST files or as individual messages. When you export content from SharePoint and OneDrive sites, copies of native Office documents and other documents are exported. A Results.csv file that contains information about every item that's exported and a manifest file (in XML format) that contains information about every search result is also exported.

Export search results

1. Go to the Microsoft Purview portal and sign in using the credentials for user account that has been assigned the appropriate eDiscovery permissions.
2. In the left navigation pane of the Microsoft Purview portal, select **Show all**, and then select **eDiscovery** > **eDiscovery (Standard)**.
3. On the **eDiscovery (Standard)** page, select the name of the case that you want to create the hold in.
4. On the **Home** page for the case, select the **Searches** tab.
5. On the **Actions** menu at the bottom of the flyout page, select **Export results**.



The workflow to export the results of a search associated with an eDiscovery (Standard) case is that same as exporting the search results for a search on the **Content search** page. For step-by-step instructions, see Export content search results.

> **Note**
>
> When you export search results, you have the option to enable deduplication so that only one copy of an email message is exported even though multiple instances of the same message might have been found in the mailboxes that were searched.

After you start the export, the search results are prepared for downloading, which means they're transferred to a Microsoft-provided Azure Storage location in the Microsoft cloud.

6. Select the **Exports** tab in the case to display the list of export jobs.

You may have to select **Refresh** to update the list of export jobs so that it shows the export job you created. Export jobs have the same name as the corresponding search with **_Export** appended to the search name.

7. Select the export job you created to display status information on the flyout page. This information includes the percentage of items that have been transferred to the Azure Storage location.

8. After all items have been transferred, select **Download results** to download the search results to your local computer. For more information downloading search results, see Step 2 in Export content search results

> **Note**
>
> The exported search results must be downloaded within 14 days after you created the export job.

More information about exporting searches from a case

- If you restart the export, any changes to the queries of the searches that make up the export job won't affect the search results that are retrieved. When you restart an export, the same combined search query job that was run when the export job was created will be run again.
- Also, if you restart an export, the search results that are copied to the Azure Storage location overwrites the previous results. The previous results that were copied won't be available to be downloaded.

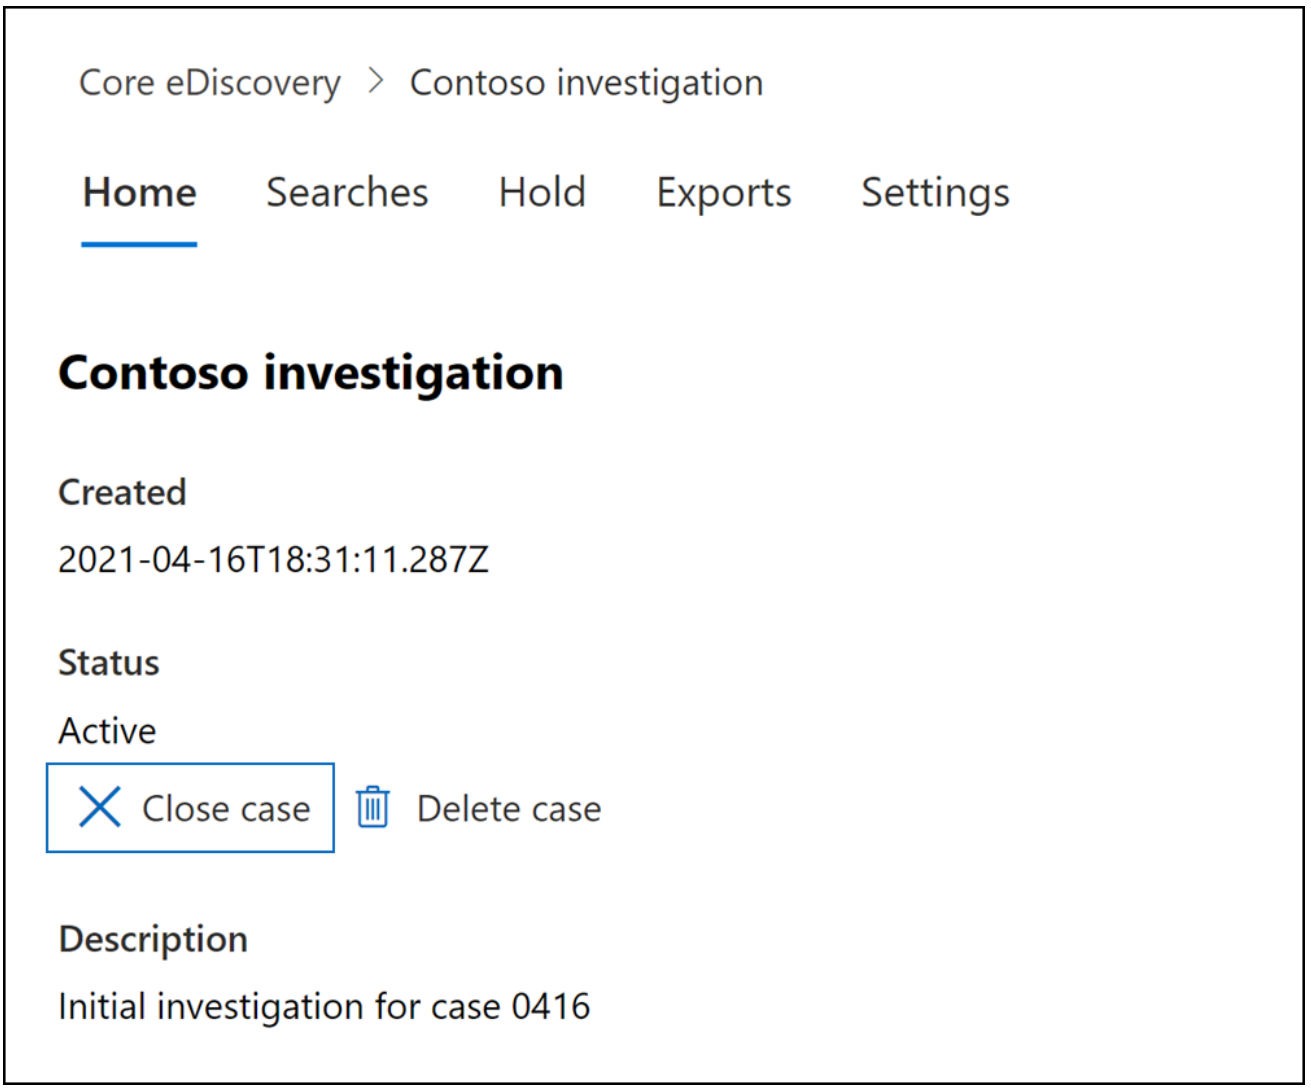
Close, reopen, or delete eDiscovery (Standard) cases

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

This article describes how to close, reopen, delete, or upgrade a Microsoft Purview eDiscovery (Standard) cases in Microsoft Purview.



Close a case

When the legal case or investigation supported by an eDiscovery (Standard) case is completed, you can close the case. Here's what happens when you close a case:

- If the case contains any eDiscovery holds, they'll be turned off. After the hold is turned off, a 30-day grace period (called a *delay hold*) is applied to content locations that were on hold. This helps prevent content from being immediately deleted and provides admins the opportunity to search for and restore content before it may be permanently deleted after the delay hold period expires. For more information, see Removing content locations from an eDiscovery hold.
- Closing a case only turns off the holds that are associated with that case. If other holds are placed on a content location (such as a Litigation Hold, a retention policy, or a hold from a different eDiscovery (Standard) case) those holds will still be maintained.
- The case is still listed on the eDiscovery (Standard) page in the Microsoft Purview portal. The details, holds, searches, and members of a closed case are retained.
- You can edit a case after it's closed. For example, you can add or remove members, create searches, and export search results. The primary difference between active and closed cases is that eDiscovery holds are turned off when a case is closed.

To close a case:

1. In the Microsoft Purview portal, select **eDiscovery** > **eDiscovery (Standard)** to display the list of eDiscovery (Standard) cases in your organization.
2. Select the name of the case that you want to close.

3. On the home page, under **Status**, select **Close case**.

   A warning is displayed saying that the holds associated with the case will be turned off.

4. Select **Yes** to close the case.

   The status on the case home page is changed from **Active** to **Closing**.

5. On the **eDiscovery (Standard)** page, select **Refresh** to update the status of the closed case. It might take up to 60 minutes for the closing process to complete.

   When the process is complete, the status of the case is changed to **Closed** on the **eDiscovery (Standard)** page.

Reopen a closed case

When you reopen a case, any eDiscovery holds that were in place when the case was closed won't be automatically reinstated. After the case is reopened, you'll have to go to the **Holds** page and turn on the previous holds. To turn on a hold, select it to display the flyout page, and then set the **Status** toggle to **On**.

1. In the Microsoft Purview portal, select **eDiscovery (Standard)** to display the list of eDiscovery (Standard) cases in your organization.

2. Select the name of the case that you want to reopen.

3. On the home page, under **Status**, select **Reopen case**.

   A warning is displayed saying that the holds that were associated with the case when it was closed won't be turned on automatically.

4. Select **Yes** to reopen the case.

The status on the case home page flyout page is changed from **Closed** to **Active**.

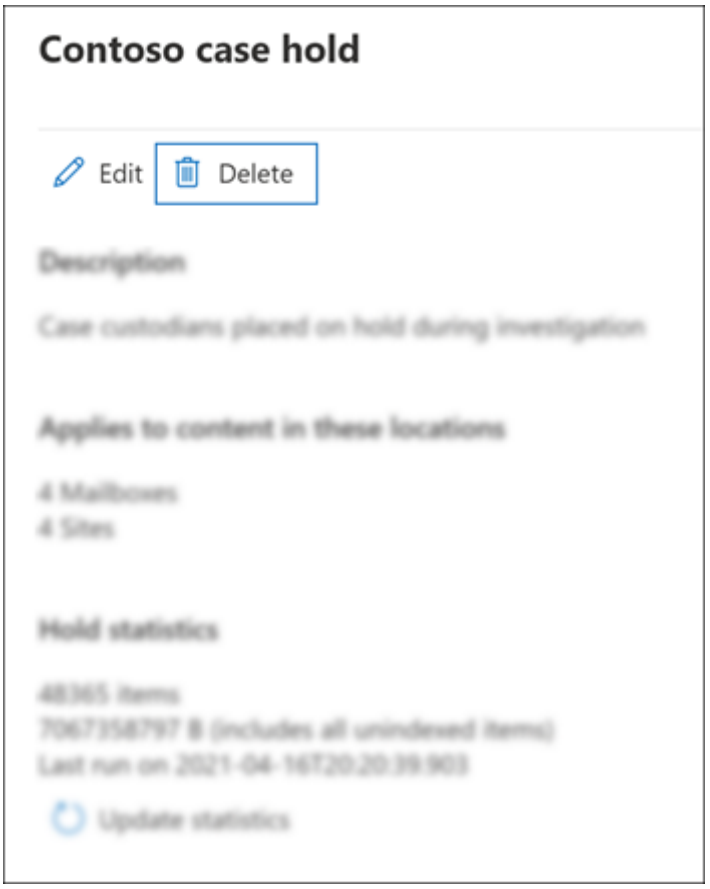
5. On the **eDiscovery (Standard)** page, select **Refresh** to update the status of the reopened case. It might take up to 60 minutes for the reopening process to complete.

   When the process is complete, the status of the case is changed to **Active** on the **eDiscovery (Standard)** page.

6. (Optional) To turn on any holds associated with the reopened case, go to **Holds** tab, select a hold, and then select the checkbox under **Status** on the hold flyout page.

Delete a case

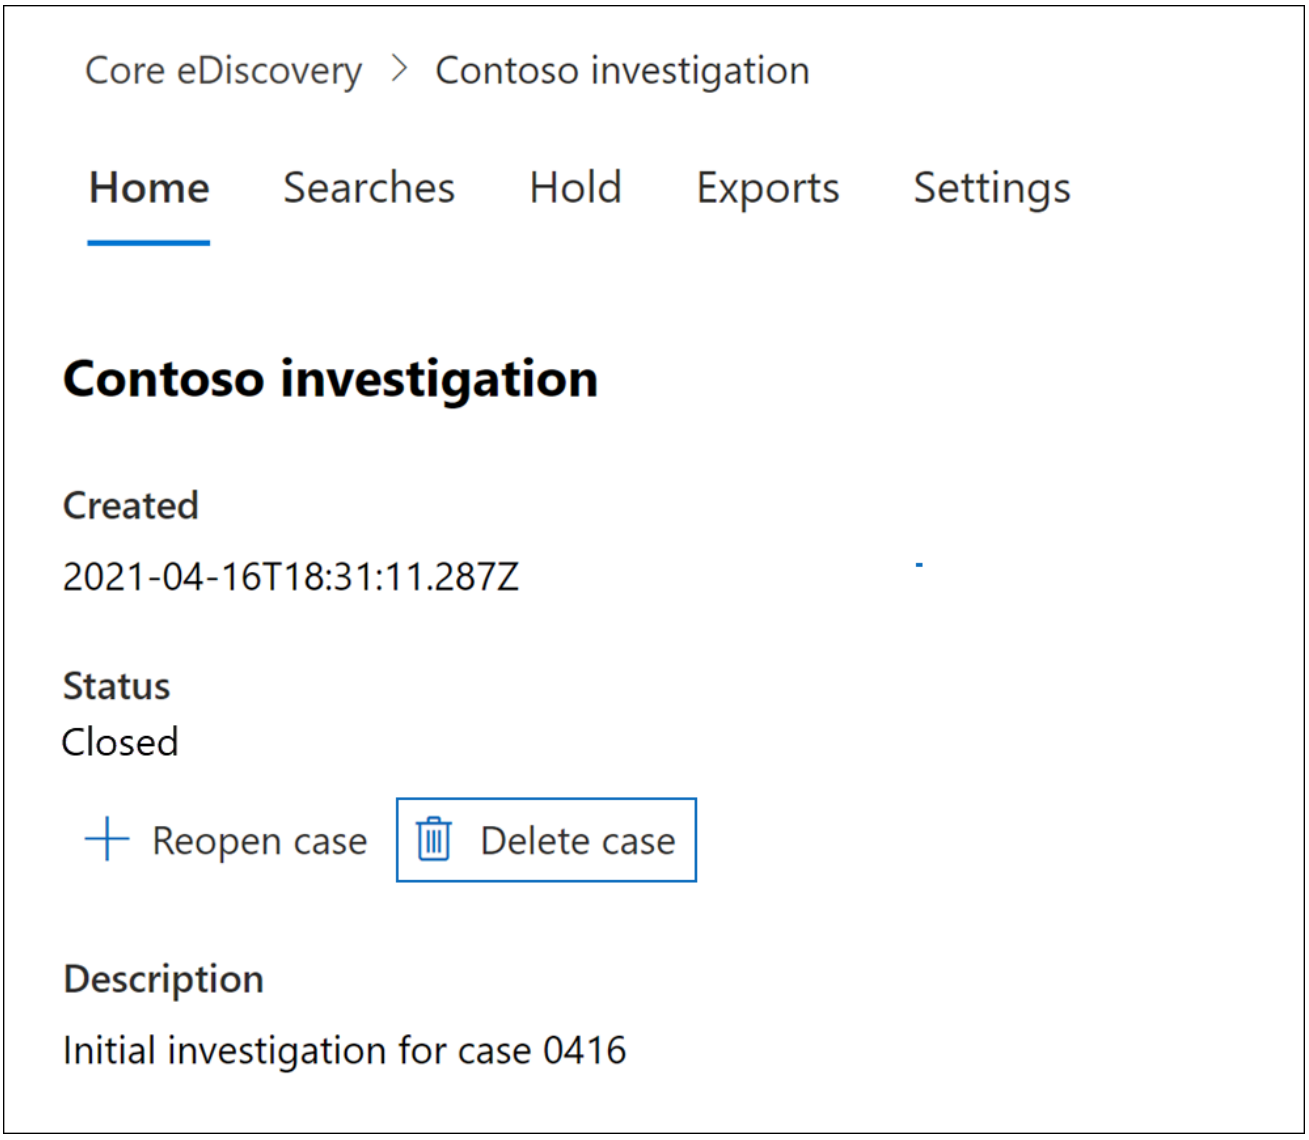
You can also delete active and closed eDiscovery (Standard) cases. When you delete a case, all searches and exports in the case are deleted, and the case is removed from the list of cases on the **eDiscovery (Standard)** page in the Microsoft Purview portal. You can't reopen a deleted case.



Before you can delete a case (whether it's active or closed), you must first delete *all* eDiscovery holds associated with the case. That includes deleting holds with a status of **Off**.

To delete an eDiscovery hold:

1. Go to the **Holds** tab in the case that you want to delete.



2. Select the hold that you want to delete.

3. On the flyout page, select **Delete**.

To delete a case:

1. In the Microsoft Purview portal, select **eDiscovery** > **eDiscovery (Standard)** to display the list of eDiscovery (Standard) cases in your organization.
2. Select the name of the case that you want to delete.
3. On the case home page, under **Status**, select **Delete case**.

If the case you're trying to delete still contains eDiscovery holds, you'll receive an error message. You'll have to delete all holds associated with the case and then try again to delete the case.

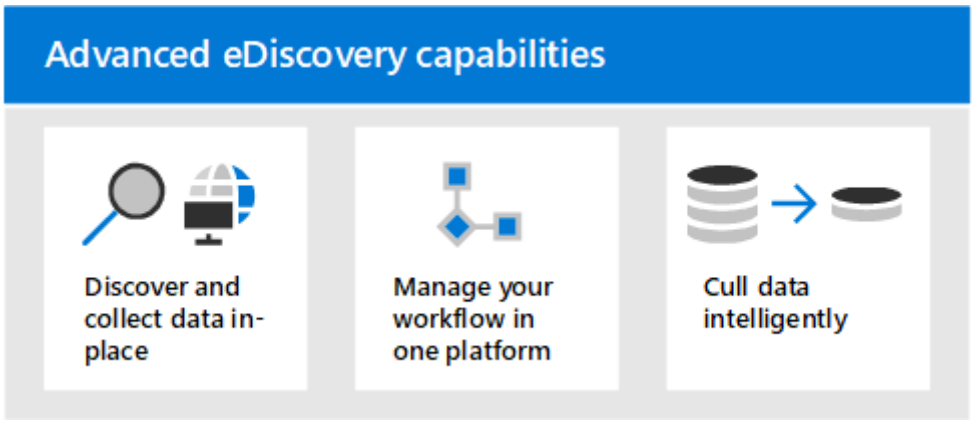
Overview of Microsoft Purview eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.



The Microsoft Purview eDiscovery (Premium) solution builds on the existing Microsoft eDiscovery (Standard) and analytics capabilities. eDiscovery (Premium) provides an end-to-end workflow to preserve, collect, analyze, review, and export content that's responsive to your organization's internal and external investigations across Microsoft 365 and Office 365.

You can also use eDiscovery (Premium) to place an eDiscovery hold on content locations, such as Exchange mailboxes, SharePoint sites, OneDrive accounts, and Microsoft Teams. It also lets legal teams manage the entire legal hold notification workflow to communicate with custodians involved in a case.

eDiscovery (Premium) capabilities

eDiscovery (Premium) can help your organization respond to legal matters or internal investigations by discovering data where it lives. You can seamlessly manage eDiscovery workflows by identifying persons of interest and their data sources, seamlessly apply holds to preserve data, and then manage the legal hold communication process. By collecting data from the source, you can search the live Microsoft 365 platform to quickly find what you need. Intelligent, machine learning capabilities such as deep indexing, email threading, and near duplicate detection also help you reduce large volumes of data to a relevant data set.

The following sections describe how these eDiscovery (Premium) capabilities can help your organization.

Discover and collect data in-place

Traditionally, organizations that rely on multiple third-party eDiscovery solutions require copying large volumes of data out of Microsoft 365 to process and having to host duplicate data. This necessity increases the time to find relevant data and the risk, cost, and complexity of managing multiple solutions.

eDiscovery (Premium) in Microsoft 365 lets you discover data at the source and staying within your Microsoft 365 security and compliance boundary. By collecting data in-place from the live system, eDiscovery (Premium) reduces the friction of going back to the source and reduces unnecessary work of having to find missing content, which often happens when journaling lags in traditional eDiscovery solutions.

Native search and collection capabilities for data in Teams, Viva Engage, SharePoint Online, OneDrive for Business, and Exchange Online further enhances data discovery. For example, eDiscovery (Premium):

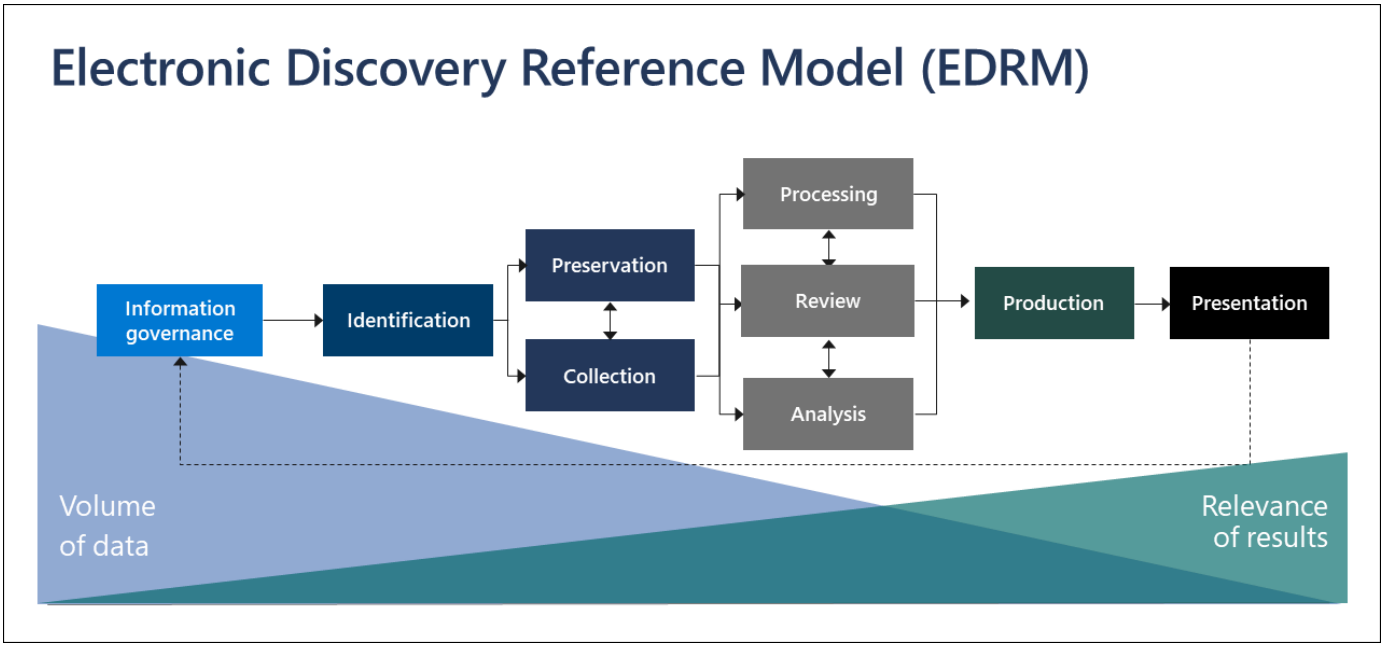
- Reconstructs Teams conversations (instead of returning individual messages from conversations).
- Collects cloud-based content shared with users by use of links or modern attachments in email message and Teams chats.
- Has built-in support for hundreds of non-Microsoft 365 file types.
- Collects data from third-party sources (such as Bloomberg, Facebook, Slack, and Zoom Meetings) that's imported and archived in Microsoft 365 by data connectors.

Manage eDiscovery workflow in one platform

eDiscovery (Premium) can help you reduce the number of eDiscovery solutions you need to rely on. It provides a streamlined, end-to-end workflow, all which occurs within Microsoft 365. eDiscovery (Premium) helps reduce the friction of identifying and collecting potential sources of relevant information by automatically mapping unique and shared data sources to the person of

interest (known as a *custodian*), and by providing reporting and analytics on potentially relevant data prior to collecting it for analysis and review.

Additionally, Microsoft Graph APIs can help you automate the eDiscovery workflow and extend eDiscovery (Premium) for custom solutions.



Cull data intelligently

Intelligent, machine learning capabilities in eDiscovery (Premium) help you reduce the amount of data to review. These intelligent capabilities help you reduce and cull large volumes of data to a relevant set. For example, a built-in review set query helps filter only for unique content by identifying near duplicates. This capability can substantially reduce the amount of data to review.

Additional machine learning capabilities can further refine and identify relevant data using smart tags and technology assisted review tools like the Relevance modules.

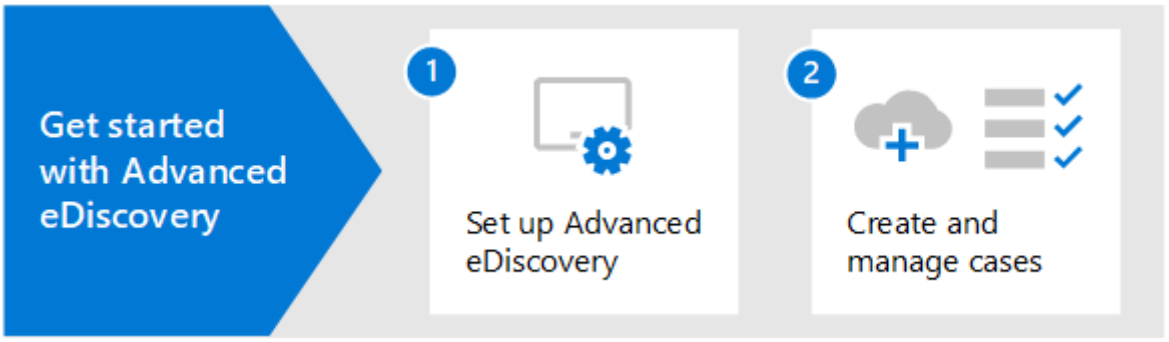
eDiscovery (Premium) alignment with the Electronic Discovery Reference Model

The built-in workflow of eDiscovery (Premium) in Microsoft 365 aligns with the eDiscovery process outlined by the Electronic Discovery Reference Model (EDRM).

(Image based on the EDRM model on edrm.net)

At a high level, here's how eDiscovery (Premium) supports the EDRM workflow:

- **Identification.** After you identify potential persons of interest in an investigation, you can add them as custodians (also called *data custodians*, because they may possess information that's relevant to the investigation) to an eDiscovery (Premium) case. After users are added as custodians, it's easy to preserve, collect, and review custodian documents.
- **Preservation.** To preserve and protect data that's relevant to an investigation, eDiscovery (Premium) lets you place a legal hold on the data sources associated with the custodians in a case. You can also place non-custodial data on hold. eDiscovery (Premium) also has a built-in communications workflow so you can send legal hold notifications to custodians and track their acknowledgments.
- **Collection.** After you identified (and preserved) the data sources relevant to the investigation, you can use the built-in search tool in eDiscovery (Premium) search for and collect live data from the custodial data sources (and non-custodial data sources, if applicable) that may be relevant to the case.
- **Processing.** After you've collected all data relevant to the case, the next step is process it for further review and analysis. In eDiscovery (Premium), the in-place data that you identified in the collection phase is copied to an Azure Storage location (called a *review set*), which provides you with a static view of the case data.
- **Review.** After data has been added to a review set, you can view specific documents and run additional queries to reduce the data to what is most relevant to the case. Also, can annotate and tag specific documents.
- **Analysis.** eDiscovery (Premium) provides integrated analytics tool that helps you further cull data from the review set that you determine isn't relevant to the investigation. In addition to reducing the volume of relevant data, Advance eDiscovery also helps you save legal review costs by letting you organize content to make the review process easier and more efficient.
- **Production** and **Presentation.** When you're ready, you can export documents from a review set for legal review. You can export documents in their native format or in an EDRM-specified format so they can be imported into third-party review applications.



Subscriptions and licensing

Microsoft Purview eDiscovery capabilities are included with Microsoft Purview. The licensing requirements may vary even within capabilities, depending on configuration options. For licensing requirements, guidance, and options, see the subscription requirements for eDiscovery (Standard) and eDiscovery (Premium).

For information about how to assign licenses, see Assign licenses to users.

Get started with eDiscovery (Premium)

There are two quick and easy steps to get started with eDiscovery (Premium).

Expand table

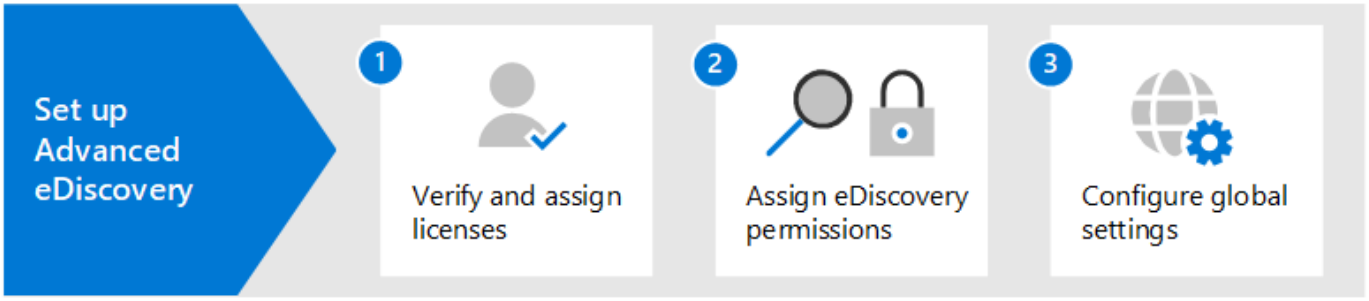
Steps	Description
Set up eDiscovery (Premium)	After verifying the subscription and licensing requirements, you can assign permissions and configure organization-wide settings to get started using eDiscovery (Premium).
Create and manage cases	Create cases to manage the eDiscovery (Premium) workflow for all legal and other types of investigations in your organization.

Integration with Insider Risk Management

Cases in Microsoft Purview Insider Risk Management can be quickly escalated to new cases in Microsoft Purview eDiscovery (Premium) when additional legal review is needed for potentially risky user activity. The tight integration between these solutions can help your risk and legal teams work more efficiently and can help provide a complete end-to-end view of user activities under review. Check out how to get started with Insider Risk Management and how to easily escalate an Insider Risk Management case to an eDiscovery (Premium) case.

Training

Training your IT administrators, eDiscovery managers, and compliance investigation teams in the basics for eDiscovery (Premium) can help your organization get started more quickly using Microsoft 365 eDiscovery tools. Microsoft 365 provides the following resource to help these users in your organization getting started with eDiscovery: Describe the eDiscovery and audit capabilities of Microsoft 365.



Last updated on 11/21/2025

Get started with eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Microsoft Purview eDiscovery (Premium) provides an end-to-end workflow to preserve, collect, review, analyze, and export data that's responsive to your organization's internal and external investigations. Nothing is needed to deploy eDiscovery (Premium), but there are some prerequisite tasks that an IT admin and eDiscovery manager have to complete before your organization can start to create and use eDiscovery (Premium) cases to manage your investigations.

This article discusses the following steps necessary to set up eDiscovery (Premium).

This includes ensuring the proper licensing required to access eDiscovery (Premium) and add custodians to cases, and assigning permissions to your legal and investigation team so they can access and manage cases.

Step 1: Verify and assign appropriate licenses

Microsoft Purview eDiscovery capabilities are included with Microsoft Purview. The licensing requirements may vary even within capabilities, depending on configuration options. For licensing requirements, guidance, and options, see the subscription requirements for eDiscovery (Premium).

Step 2: Assign eDiscovery permissions

To access eDiscovery (Premium) or added as a member of an eDiscovery (Premium) case, a user must be assigned the appropriate permissions. Specifically, a user must be added as a member of the eDiscovery Manager role group in the Microsoft Purview portal. Members of this role group can create and manage eDiscovery (Premium) cases. They can add and remove members, place custodians and content locations on hold, manage legal hold notifications, create and edit searches associated in a case, add search results to a review set, analyze data in a review set, and export and download from an eDiscovery (Premium) case.

For step-by-step guidance to configure permissions for eDiscovery, see Assign eDiscovery permissions.

Step 3: Configure global settings for eDiscovery (Premium)

The last step to complete before people in your organization start to create and use cases is to configure global settings that apply to all cases in your organization. At this time, the only global setting is *attorney-client privilege detection* (more global settings will be available in the future). This setting enables the attorney-client privilege model to run when you analyze data in a review set. The model uses machine learning to determine the likelihood that a document contains content that is legal in nature. It also compares the participants of documents with an attorney list (that you submit when setting up the model) to determine if a document has at least one participant who is an attorney.

For more information about setting up and using the attorney-client privilege detection model, see Set up attorney-client privilege detection in eDiscovery (Premium).

> **Note**
>
> This is an optional step that you can perform anytime. Not implementing the attorney-client privilege detection model doesn't prevent you from creating and using eDiscovery (Premium) cases.

Step 4: Verify that required eDiscovery apps are enabled

eDiscovery (Premium) requires the following Enterprise apps to be enabled in your Microsoft 365 or Office 365 organization. If these apps aren't enabled, you won't be able to access all eDiscovery (Premium) view, filter, and search features.

Expand table

App	App ID
Built-in security add-on for on-premises mailboxes (formerly Exchange Online Protection)	00000007-0000-0ff1-ce00-000000000000
ComplianceWorkbenchApp	92876b03-76a3-4da8-ad6a-0511ffdf8647
MicrosoftPurviewEDiscovery	b26e684c-5068-4120-a679-64a5d2c909d9
Office365Zoom	0d38933a-0bbd-41ca-9ebd-28c4b5ba7cb7

> **Note**
>
> The *MicrosoftPurviewEDiscovery* app provides support for exporting data via scripts in eDiscovery (Premium). For more information about exporting data via scripts, see Get caseOperation.

For more information about how to view and enable apps, see:

- Quickstart: View enterprise applications
- Quickstart: Add an enterprise application

Next steps

After you set up eDiscovery (Premium), you're ready to create a case.

Last updated on 02/18/2026

eDiscovery (Premium) workflow for content in Microsoft Teams

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article provides a comprehensive set of procedures, guidelines, and best practices for using Microsoft Purview eDiscovery (Premium) to preserve, collect, review, and export content from Microsoft Teams. The goal of this article is to help you optimize your eDiscovery workflow for Teams content.

There are seven categories of Teams content that you can collect and process using eDiscovery (Premium):

- **Teams 1:1 chats**. Chat messages, posts, and attachments shared in a Teams conversation between two people. Teams 1:1 chats are also called *conversations*.
- **Teams group chats**. Chat messages, posts, and attachments shared in a Teams conversation between three or more people. Also called *1:N* chats or *group conversations*.
- **Teams reactions**. Reactions applied to chat messages, posts, and attachments in a Teams conversation.
- **Teams channels**. Chat messages, posts, replies, and attachments shared in a standard Teams channel.
- **Teams meetings**. Audio and transcripts from recorded Teams meetings.
- **Private channels**. Message posts, replies, and attachments shared in a private Teams channel.
- **Shared channels**. Message posts, replies, and attachments shared in a shared Teams channel.

Where Teams content is stored

A prerequisite to managing Teams content in eDiscovery (Premium) is to understand the type of Teams content that you can collect, process, and review in eDiscovery (Premium) and where that content is stored in Microsoft 365.

Teams data is stored in Azure Cosmos DB. Teams compliance records captured by the substrate are in Exchange Online and are available for ediscovery.

The following table lists Teams content type and where each is stored for compliance purposes. The data stored in Exchange online is hidden from clients. eDiscovery never operates against the real Teams message data, which remains in Azure Cosmos DB.

Expand table

Teams category	Location of chat messages/posts	Location of files/attachments	Location of meeting recordings
Teams 1:1 chats	Messages in 1:1 chats are stored in the Exchange Online mailbox of all chat participants.	Files shared in a 1:1 chat are stored in the OneDrive for Business account of the person who shared the file.	N/A
Teams group chats	Messages in group chats are stored in the Exchange Online mailbox of all chat participants.	Files shared in group chats are stored in the OneDrive for Business account of the person who shared the file.	N/A
Teams reactions	Messages in group chats are stored in the Exchange Online mailbox of all chat participants.	Files shared in group chats are stored in the OneDrive for Business account of the person who shared the file.	N/A
Teams channels	All channel messages and posts are stored in the Exchange Online mailbox associated with the team.	Files shared in a channel are stored in the SharePoint Online site associated with the team.	N/A
Teams meetings	Chats in recorded meetings are stored in the OneDrive for Business account for the user recording the Teams meeting.	Files and attachments shared in recorded meetings are stored in the OneDrive for Business account for the user recording the Teams meeting.	Meeting recordings are stored in the OneDrive for Business account for the user recording the Teams meeting.
Private channels	Messages sent in a private channel are stored in the Exchange Online mailboxes of all members of the private channel.	Files shared in a private channel are stored in a dedicated SharePoint Online site associated with the private channel.	N/A

Teams category	Location of chat messages/posts	Location of files/attachments	Location of meeting recordings
Shared channels	Messages sent in a shared channel are stored in a system mailbox associated with the shared channel.[1]	Files shared in a shared channel are stored in a dedicated SharePoint Online site associated with the shared channel.	N/A

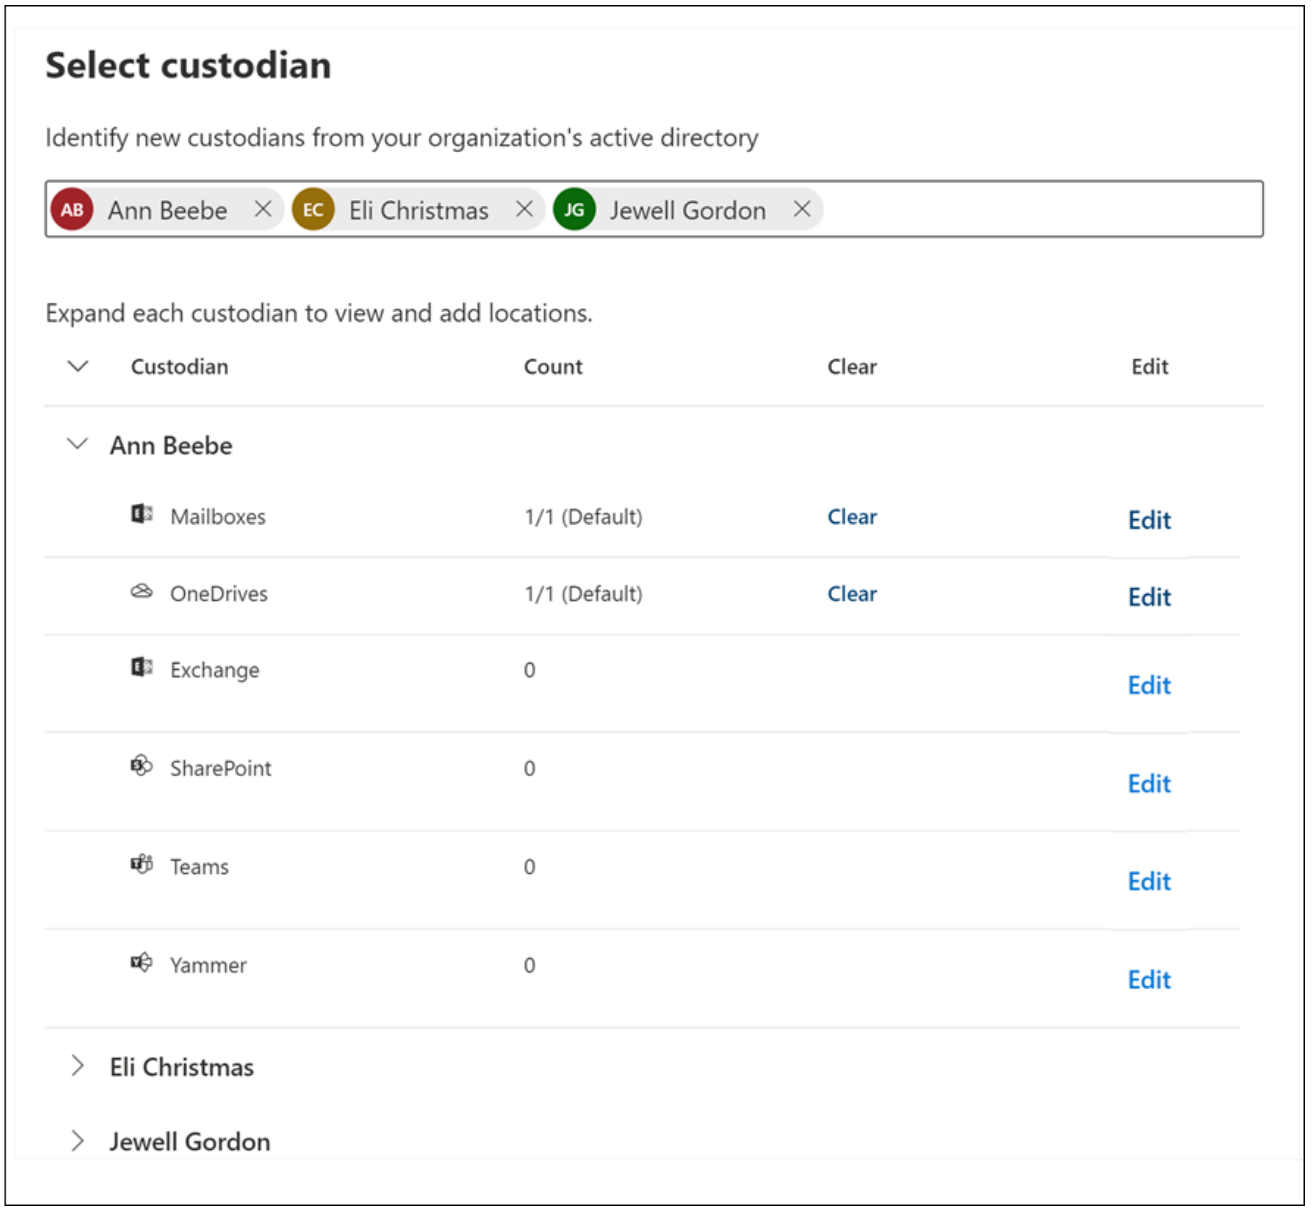
> **Note**
>
> [1] To search for (and preserve) messages sent in a shared channel, you have to search or specify the Exchange Online mailbox for the parent Team.

Create a case for Teams content

The first step to managing Teams content in eDiscovery (Premium) is to create a case using the new case format that's optimized for managing Teams content. The new case format helps accommodate significant increases in case size, both for total data volume and the total number of items in cases.

For step-by-step guidance on how to create a case, see Create and manage an eDiscovery (Premium) case.

Add Teams custodial data sources and preserve Teams content



The next step is to identify the users who are the data custodians in your investigation and add them and their content locations as custodians to the case you created in the previous section. When you add custodians, you can specify their mailbox and OneDrive account as custodial data sources. You can also specify Teams content locations as custodian data sources to quickly place these locations on legal hold to preserve content during your investigation. It also makes it easy to collect content and add it to a review set.

To add custodians to a case and preserve custodial data sources:

1. Go to the eDiscovery (Premium) case that you created in the previous section, and then select **Data sources**.
2. On the **Data sources** page, select **Add data source** > **Add new custodians**.

3. In the **New custodian** workflow, add one or more users as custodians to the case by typing the first part of the user's name or alias. After you find the correct person, select their name to add them to the list.

4. Expand each custodian to view the primary data sources that have been automatically associated to the custodian, and to select other locations to associate to the custodian.

5. Follow these guidelines to add custodial data sources for Teams content. Select **Edit** to add a data location.

   - **Mailboxes**. The custodian's mailbox is selected by default. Keep this selected to add (and preserve) 1:1 chats, group chats, and private channel chats as custodial data.
   - **OneDrives**. The custodian's OneDrive account is selected by default. Keep this selected to add (and preserve) files shared in 1:1 chats, group chats, and Teams meetings as custodial data.

- **SharePoint**. Add the SharePoint site associated with any private or shared channel the custodian is a member of to add (and preserve) as custodial data the files shared in a channel. Select **Edit** and then add the URL for the SharePoint site associated with a private or shared channel. To learn how to locate the private and shared channels a user is a member of, see eDiscovery of private and shared channels.
- **Teams**. Add the teams that the custodian is a member of to add (and preserve) as custodial data all channel messages and all files shared to a Teams channel. This recommendation includes adding the mailbox for the parent team of a shared channel the custodian is a member of. When you select **Edit**, the mailbox and site associated with each team the custodian is a member of are displayed in a list. Select the teams that you want to associate to the custodian. You have to select both the corresponding mailbox and site for each team.

> ⓘ **Note**
>
> You can also add the mailbox and site of Teams that custodians aren't members of as a custodian data location. You do this by clicking **Edit** next to **Exchange** and **SharePoint** and then adding the mailbox and site associated with the team.

6. After you add custodians and configure the custodial data sources, select **Next** to display the **Hold settings** page. A list of the custodians is displayed and the checkbox in the **Hold** column is selected by default. This checkbox indicates that a hold will be placed on the data sources that you associated with each custodian. Leave these checkboxes selected to preserve this data.

7. On the **Hold settings** page, select **Next** to review the custodians settings. Select **Submit** to add the custodians to the case.

For more information about adding and preserving data sources in eDiscovery (Premium) cases, see:

- Add custodians to an eDiscovery (Premium) case
- Add non-custodial data sources to an eDiscovery (Premium) case

Collect Teams content and add to review set

After adding custodians to the case and preserving content in custodian data sources, the next step in the workflow is to search for Teams content that's relevant to your investigation and add it to a review set for further review and analysis. Though it's typical to collect Teams content

together with content from other Microsoft 365 services such as email in Exchange and documents in SharePoint, this section will specifically focus on collecting Teams content in a collection. You can create additional collections that collect non-Teams content to add to a review set.

When you collect Teams content for a case, there are two steps in the workflow:

1. **Create a collection estimate**. The first step is to create a *collection estimate*, which is an estimate of the items that match your search criteria. You can view information about the results that matched the search query, such as the total number and size of items found, the different data sources where they were found, and statistics about the search query. You can also preview a sample of items returned by the collection. Using these statistics, you can change the search query and rerun the collection estimate as many times as is necessary to narrow the results until you're satisfied you're collecting the content relevant to your case.
2. **Commit a collection estimate to a review set**. Once you're satisfied with the results of a collection estimate, you can commit the collection to a review set. When you commit a collection estimate, the items returned by the collection are added to a review set for review, analysis, and export.

You also have the option of not running a collection estimate and adding the collection results directly to a review set when you create and run the collection.

To create a collection of Teams content:

1. Go to the eDiscovery (Premium) case that you added the custodians to in the previous section, and then select **Collections**.

2. On the **Collections** page, select **New collection**.

3. On the **Name and description** page, enter a name (required) and description (optional) for the collection. Select **Next**.

4. On the **Custodial data sources** page, select **Select custodians** to select the custodians that you added to the case. The list of the case custodians is displayed on the **Select custodians** flyout page.

5. Select one or more custodians and then select **Add**. After you add specific custodians to the collection, a list of specific data sources for each custodian is displayed. These data sources are the ones that you configured when you added the custodian to the case. All custodian data sources are selected by default. This includes any Teams or channels that you associated with a custodian.

We recommend doing the following things when collecting Teams content:

- Remove custodians' OneDrive accounts from the collection scope (by unselecting the checkbox in the **Custodian's OneDrive** column for each custodian). This prevents the collection of duplicate files that were attached to 1:1 chats and group chats. Cloud attachments are automatically collected from each conversation found in the collection when you commit the collection estimate to the review set. By using this method (instead of searching OneDrive accounts as part of the collection), files attached to 1:1 and group chats are grouped in the conversation they were shared in.
- Unselect the checkbox in the **Additional site** column to remove the SharePoint sites containing files shared in private or shared channels. Doing this eliminates collecting duplicate files that were attached to private or shared channel conversations because these cloud attachments are automatically added to the review set when you commit the collection estimate and grouped in the conversations they were shared in.

6. If you previously followed the steps to add Teams content as custodian data sources, you can skip this step and select **Next**. Otherwise, on the **Non-custodial data sources** page, you can choose non-custodial data sources that contain Teams content that you may have added to the case to search in the collection.

7. If you previously followed the steps to add Teams content as custodian data sources, you can skip this step and select **Next**. Otherwise, on the **Additional locations** page, you can add other data sources to search in the collection. For example, you could add the mailbox and site for a team that wasn't added as a custodial or non-custodial data source. You can also select the **Shared Teams channels** option to include shared channels during tenant-wide searches. Otherwise, select **Next** and skip this step.

8. On the **Conditions** page, configure the search query to collect Teams content from the data sources that you specified on the previous pages. You can use various keywords and search conditions to narrow the scope of the collection. For more information, see Build search queries for collections.

    - To help ensure the most comprehensive collection of Teams chat conversations (including 1:1, group, and channel chats) use the **Type** filter condition and select the **Instant messages** option.
    - To help ensure you add recorded Teams meeting information to the collection, use the **File type** filter condition and include *.mp4* as contained value.
    - We also recommend including a date range or several keywords to narrow the scope of the collection to items relevant to your investigation.

9. On the **Review your collection** page, review the collection settings and select **Submit** to create a collection estimate or **Save and close** to save the collection settings to complete later.

When the process of adding the collection to the review set is completed, the **Status** value for the collection on the **Collections** tab is set to **Estimated**.

Commit a collection estimate to a review set

When you're satisfied with the items you've collected in a collection estimate and are ready to analyze, tag, and review them, you can commit a collection to a review set in the case.

For step-by-step guidance on how to commit a collection, see Commit a collection estimate to a review set in eDiscovery (Premium).

Review Teams content in a review set

After you add collections of Teams content to a review set, the next step is to review the content for its relevance to your investigation and cull it if necessary. An important prerequisite to reviewing Teams content is understanding how eDiscovery (Premium) processes Teams meeting, chat conversations, and attachments when adding them to a review set. This processing of Teams content results in the following three things:

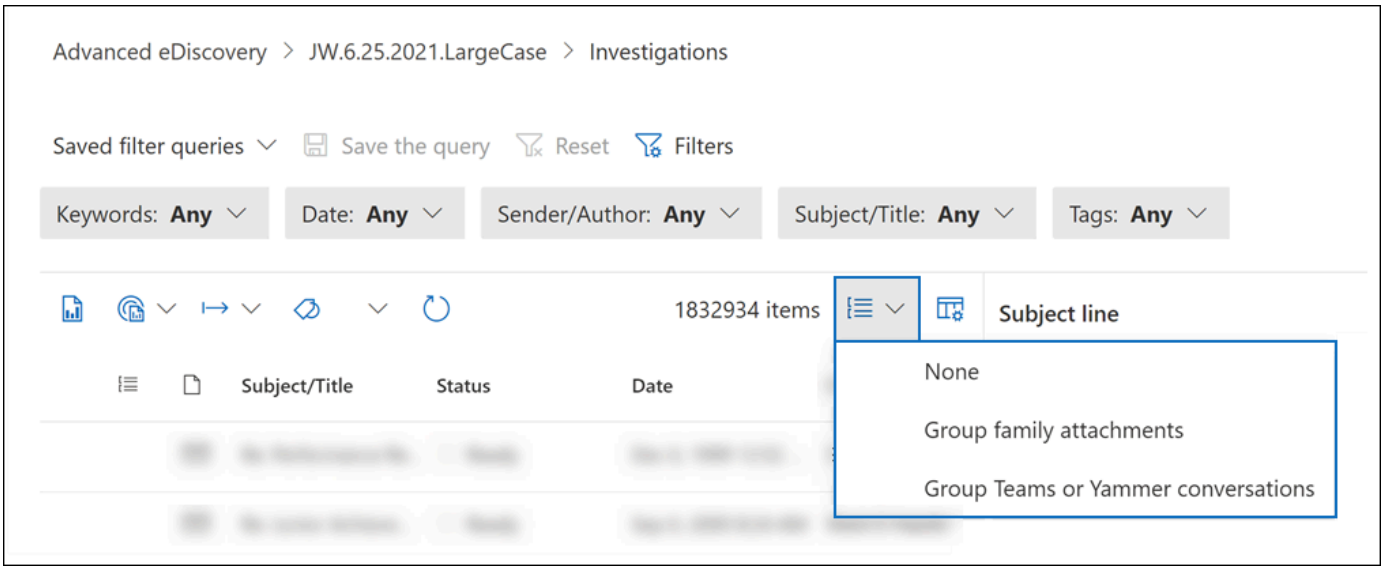
- **Grouping**. How messages, posts, and replies Teams conversations are grouped together and presented in the review set. This also includes attachments in chat conversations are extracted and group within the conversation.
- **Conversation transcript threading**. How eDiscovery (Premium) determines what additional content from a conversation to collect to provide context around items that matched the collection criteria.
- **Deduplication**. How eDiscovery (Premium) handles duplicate Teams content.
- **Metadata**. Metadata properties that eDiscovery (Premium) adds to Teams content after it's collected and added to a review set.

> ⓘ **Note**
>
> The date and time for all conversations in Teams are shown in Coordinated Universal Time (UTC).

Understand grouping, conversation threading, deduplication, and Teams metadata will help you optimize the review and analysis of Teams content. This section also has tips for viewing Teams content in a review set.

Grouping

When content from Teams chat conversations is added to a review set, messages, posts, and replies from conversations are aggregated in HTML transcript files. A single chat conversation can have multiple transcript files. An important function of these transcript files is to present Teams content as continuous conversations and not as individual (or separate) messages. This helps provides context for items that matched the search criteria of your collections in the previous step and reduce the number of items collected into the review set. Transcripts and associated items can be grouped by either *family* or *conversation*. Items in the same family will have the same value for the **FamilyId** metadata property. Items in the same conversation will have the same value for the **ConversationId** metadata property.



The following table describes how the different types of Teams content are grouped by family and conversation.

Expand table

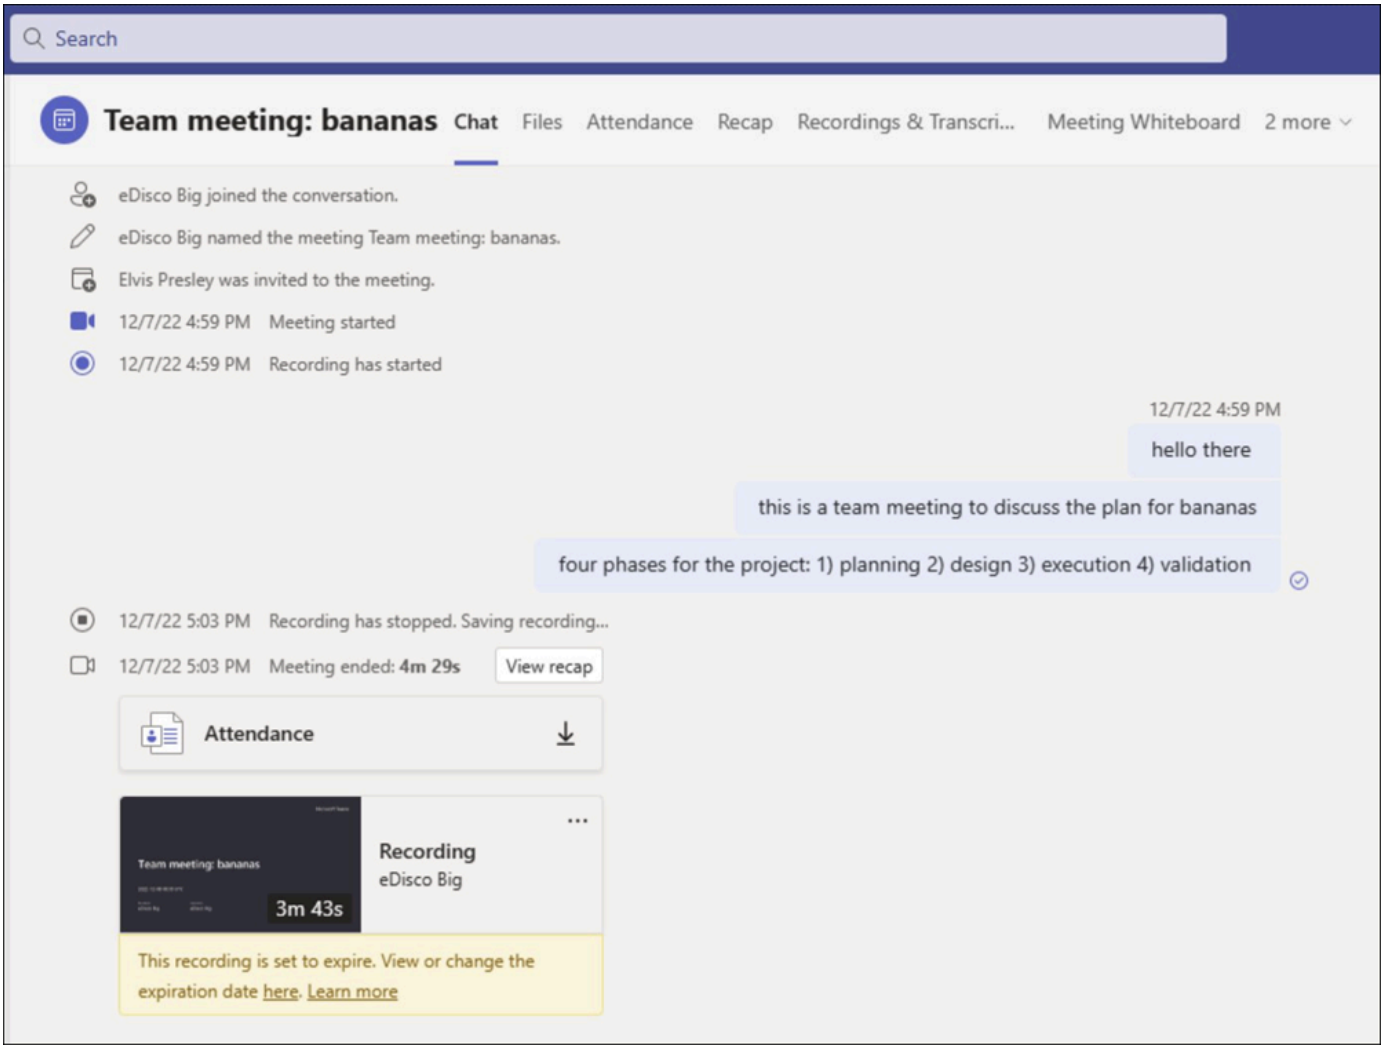
Teams content type	Group by family	Group by conversation
Teams 1:1 and group chats	A transcript and all of its attachments and extracted items share the same **FamilyId**. Each transcript has a unique **FamilyId**.	All transcript files and their family items within the same conversation share the same **ConversationId**. This includes the following items: • All extracted items and attachments of all transcripts that share the same **ConversationId**. • All transcripts for the same chat conversation • All custodian copies of each transcript • Transcripts from subsequent collections from the same chat conversation For Teams 1:1 and group chat conversations, you might have multiple transcript files, each one corresponding to a different time frame within the conversation. Because these transcript files are from the same conversation with the same participants, they share the same **ConversationId**.
Standard, private, and	Each post and all replies and attachments are saved to its	Each post and its attachments and extracted items have a unique **ConversationId**. If there are subsequent

Teams content type	Group by family	Group by conversation
shared channel chats	own transcript. This transcript and all of its attachments and extracted items share the same **FamilyId**.	collections or new replies from the same post, the delta transcripts resulting from those collections will also have the same **ConversationId**.
Teams meetings	Each meeting	

Use the **Group** control in the command bar of a review set to view Teams content grouped by family or conversation.

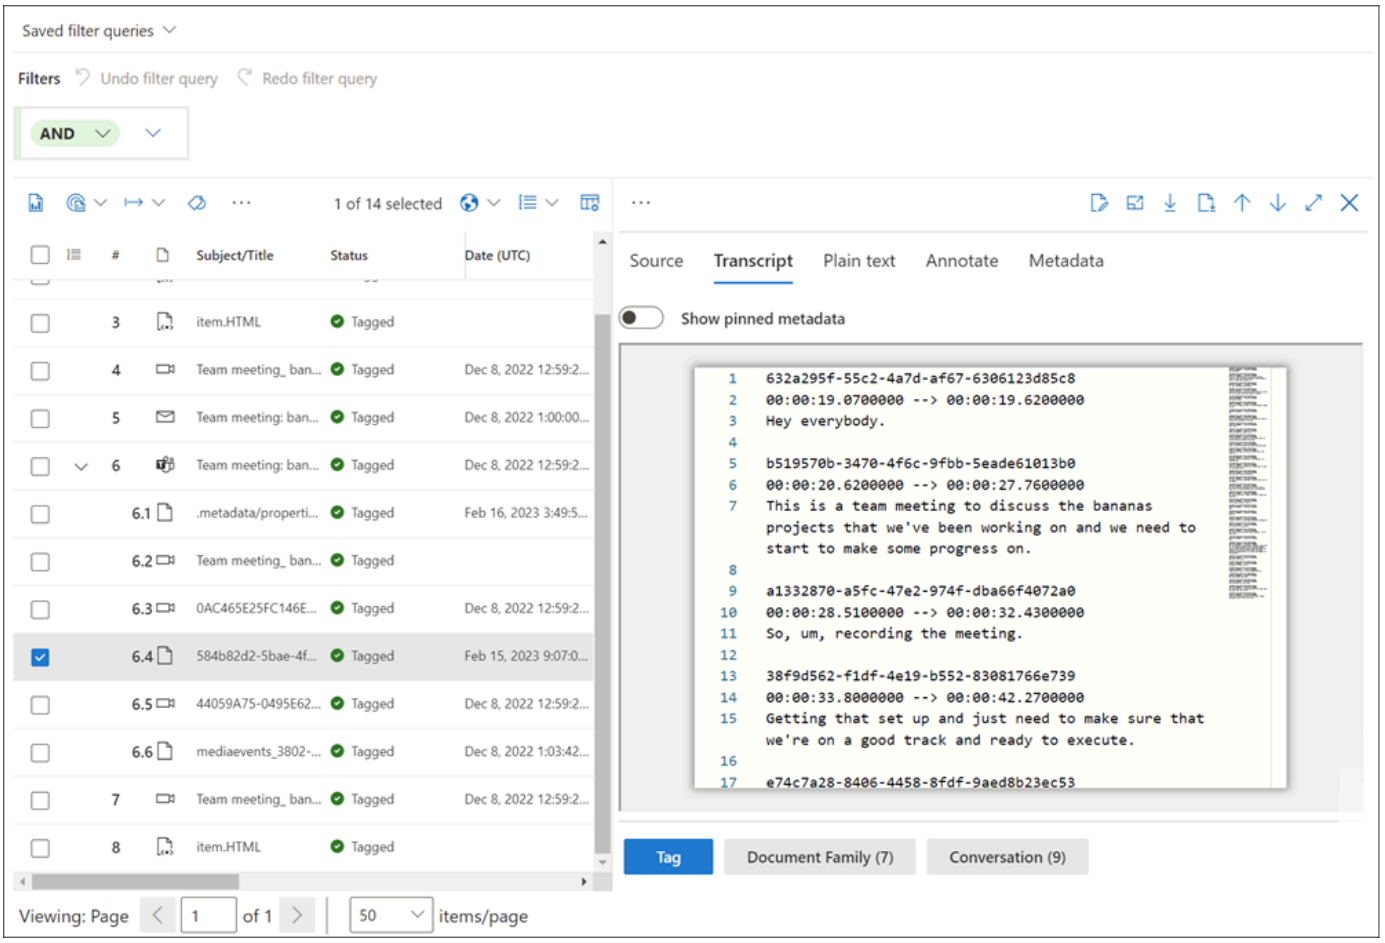
- Select **Group family attachments** to view Teams content grouped by family. Each transcript file is displayed on a line in the list of review set items. Attachments are nested under the item.
- Select **Group Teams or Viva Engage conversations** to view Teams content grouped by conversation. Each conversation is displayed on a line in the list of review set items. Transcript files and attachments are nested under the top-level conversation.

> **Note**
>
> Cloud attachments are grouped with the conversations they appear in. This grouping is accomplished by assigning the same **FamilyId** as the transcript file of the message the file was attached to and the same **ConversationId** as the conversation the message appeared in. This means multiple copies of cloud attachments may be added to the review set if they were attached to different conversations.



Viewing recorded meeting transcripts

The transcript of audio of the recorded meeting is captured as a separate file and indexed automatically for search. Recorded meetings in a review set are stored as a .zip file that contains the following files:

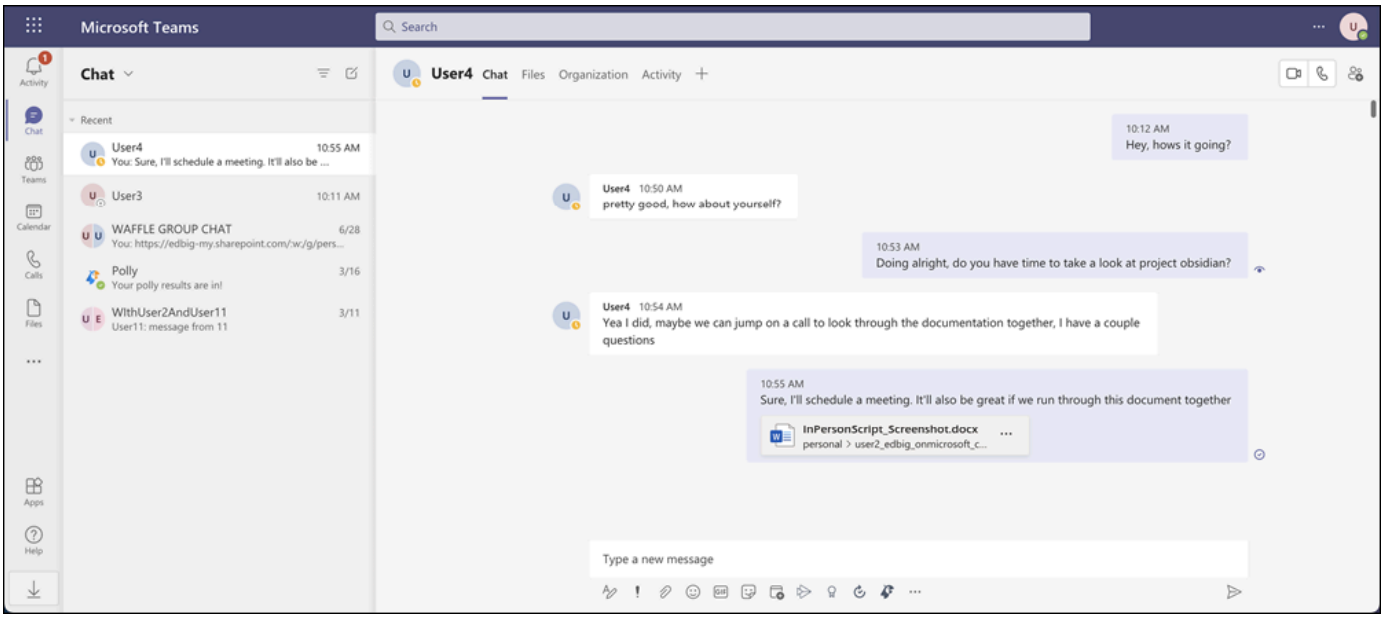


- The transcript of the meeting audio in .txt format
- The video recording of the meeting in .mp4 format
- The thumbnail image of the meeting in .jpg format
- Meeting metadata and meeting chapters (as applicable) in .json format

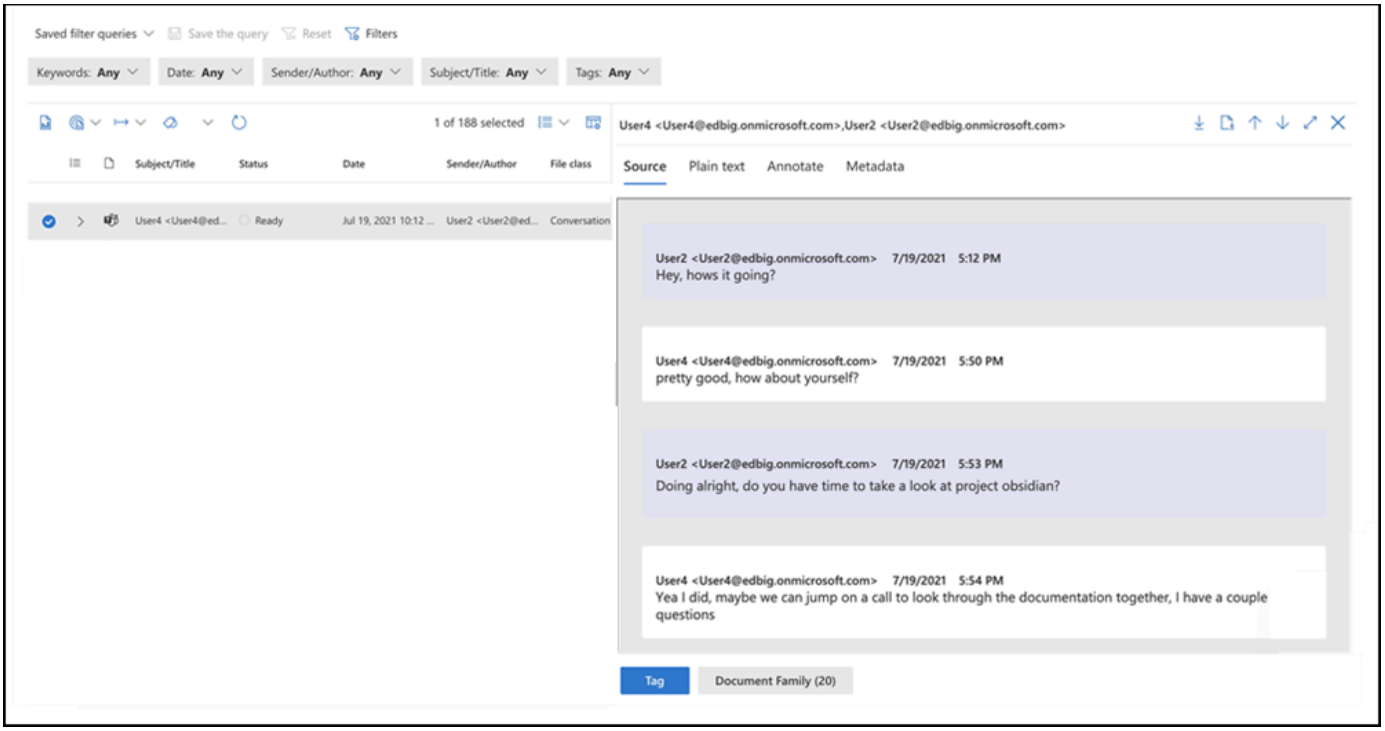
To view meeting audio transcript files in a review set, you'll select the meeting and the **Transcript** viewer on the meeting details pane. The following screenshots show an example of a meeting in the Teams client and the meeting transcript file of the same meeting in the review set.

Meeting in Teams client

Meeting transcript file in review set



Viewing conversation transcript files



When viewing transcript files in a review set, some of the messages are highlighted in purple. The messages that are highlighted depend on which custodian copy of the transcript you're viewing. For example, in a 1:1 chat between User4 and User2, the messages posted by User4 are highlighted in purple when you view the transcript collected from User4's mailbox. When you view User2's transcript of the same conversation, messages posted by User2 are highlighted in purple. This highlighting behavior is based on the same Teams client experience, where a user's posts are highlighted in purple in the Teams client.

The following screenshots show an example of conversation in the Teams client and the transcript file of the same conversation in the review set. The purple highlighting in the transcript file indicates that the transcript was collected from User2's mailbox.

Conversation in Teams client

Conversation in transcript file

Conversation transcript threading

Conversation threading functionality in the new case format in eDiscovery (Premium) helps you identify contextual content related to items that may be relevant to your investigation. This feature produces distinct conversation views that include chat messages that precede and follow the items match the search query during collection. This capability allows you to efficiently and rapidly review complete chat conversations (called *threaded conversations*) in Microsoft Teams. As previous explained, chat conversations are reconstructed in HTML transcript files when eDiscovery (Premium) adds Teams content to a review set.

Here's the logic used by eDiscovery (Premium) to include additional messages and replies transcript files that provide context around the items match the collection query (called *responsive items*) you used when collecting Teams content. Different threading behaviors are based on the types of chats and the search query used to collect the responsive items. There are two common collection scenarios:

- Queries that use search parameters, such as keywords and property:value pairs
- Queries that only use date ranges

Expand table

Teams content type	Queries with search parameters	Queries with date ranges
Teams 1:1 and group chats	Messages that were posted 12 hours before and 12 hours after responsive items are grouped with the responsive item in a single transcript file.	Messages in a 24-hour window are grouped in a single transcript file.
Standard, private, and shared Teams channel chats	Each post that contains responsive items and all corresponding replies are grouped in a single transcript file.	Each post that contains responsive items and all corresponding replies are grouped in a single transcript file.

Deduplication of Teams content

The following list describes the deduplication (and duplication) behavior when collecting Teams content into a review set.

- Each transcript file added to a review set should be a one-to-one mapping to content stored in data locations. That means eDiscovery (Premium) doesn't collect any Teams content that has already been added to the review set. If a chat message is already collected in a review set, eDiscovery (Premium) doesn't add the same message from the same data location to the review set in subsequent collections.

- For 1:1 and group chats, copies of messages are stored in the mailbox of each conversation participant. Copies of the same conversation that exist in different participants' mailboxes are collected with different metadata. As a result, each instance of the conversation is treated as unique and brought into the review set in separate transcript files. So if all participants of a 1:1 or group chat are added as custodians in a case and included in the scope of a collection, then copies of each transcript (for the same conservation) are added to the review set and will be grouped together with the same **ConversationId**. Each of these

copies is associated with a corresponding custodian. **Tip**: The **Custodian** column in the review set list identifies the custodian for the corresponding transcript file.

- In subsequent collections of items from the same conversation, only the delta content that wasn't previously collected previously is added to the review set and grouped (by sharing the same **ConversationId**) with the previously collected transcripts from the same conversation. Here's an example of this behavior:

    1. Collection A collects messages in a conversation between User1 and User2 and adds to review set.
    2. Collection B collects messages from the same conversation, but there are new messages between User1 and User2 since Collection A was run.
    3. Only the new messages in Collection B are added to the review set. These messages are added to a separate transcript file, but the new transcript is grouped with the transcripts from Collection A by the same **ConversationId**.

    This behavior applies to all the types of Teams chats.

Metadata for Teams content

In large review sets with thousands or millions of items, it can be difficult to narrow the scope of your review to Teams content. To help you focus your review on Teams content, there are metadata properties that are specific to Teams content. You can use these properties to organize the columns in the review list and configure filters and queries to optimize the review of Teams content. These metadata properties are also included when you export Teams content from eDiscovery (Premium), to help you organize and view content post-export or in third-party eDiscovery tools.

The following table describes metadata properties for Teams content.

Expand table

Metadata property	Description
ContainsEditedMessage	Indicates whether a transcript file contains an edited message. Edited messages are identified when viewing the transcript file.
ConversationId	A GUID that identifies the conversation that the item is associated with. Transcript files and attachments from the same conversation have the same value for this property.
Conversation name	The name of the conversation the transcript file or attachment is associated with. For Teams 1:1 and group chats, the value of this property is the UPN of all

Metadata property	Description
	participants of the conversation are concatenated. For example, `User3 <User3@contoso.onmicrosoft.com>,User4 <User4@contoso.onmicrosoft.com>,User2 <User2@contoso.onmicrosoft.com>`. Teams channel (standard, private, and shared) chats use the following format for conversation name: `<Team name>,<Channel name>`. For example, `eDiscovery vNext, General`.
ConversationType	Indicates the type of Team chat. For Teams 1:1 and group chats, the value for this property is `Group`. For standard, private, and shared channel chats, the value is `Channel`.
Date	The time stamp of the first message in the transcript file in UTC.
FamilyId	A GUID that identifies the transcript file for a chat conversation. Attachments will have the same value for this property as the transcript file that contains the message the file was attached to.
FileClass	Indicates that type of content. Items from Teams chats have the value `Conversation`. In contrast, Exchange email messages have the value `Email`.
MessageKind	The message kind property. Teams content has the value `microsoftteams , im`.
Recipients	A list of all users who received a message within the transcript conversation.
TeamsChannelName	The Teams channel name of the transcript.

For descriptions of other eDiscovery (Premium) metadata properties, see Document metadata fields in eDiscovery (Premium).

Export Teams content

After you have reviewed and culled Teams content in a review set, you can export the transcript files that contain content that's responsive to your investigation. There aren't any specific export settings for Teams content. Each transcript file is exported as an HTML message file. The metadata properties discussed in the previous section are included when Teams content is exported.

Each transcript file is referenced in the load file and can be located using the relative path in the Export_native_path field in the load file. Transcript files are located in the Conversations folder in the root export folder.

Tips for viewing Teams content in a review set

Here are some tips and best practices for viewing Teams content in a review set.

- Use the **Customize columns** control in the command bar to add and organize columns to optimize the review of Teams content. You can add and remove columns that are useful for Teams content. You can also sequence the order of columns by dragging and dropping them in the **Edit column** flyout page. You can also sort on columns to group Teams content with similar values for the column you sort on.
- Useful columns that to help you review Teams content include **Custodian**, **Recipients**, and **File type** or **Message kind**.
- Use filters for Teams-related properties to quickly display Teams content. There are filters for most of the metadata properties described in the previous section.

Deleting Teams chat messages

You can use eDiscovery (Premium) and the Microsoft Graph Explorer to respond to data spillage incidents, when content containing confidential or malicious information is released through Teams chat messages. Admins in your organization can search for and delete chat messages in Microsoft Teams. This feature can help you remove sensitive information or inappropriate content in Teams chat messages. For more information, see Search and purge chat messages in Teams.

Last updated on 10/31/2024

Conduct an eDiscovery investigation of content in Microsoft Teams

Applies to: Microsoft Teams

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

Large enterprises are often exposed to high penalty legal proceedings that demand submission of all Electronically Stored Information (ESI). Microsoft Teams content can be searched and used during eDiscovery investigations.

Overview

All Microsoft Teams 1:1 or group chats are journaled through to the respective users' mailboxes. All standard channel messages are journaled through to the group mailbox representing the team. Files uploaded in standard channels are covered under the eDiscovery functionality for SharePoint Online and OneDrive for Business.

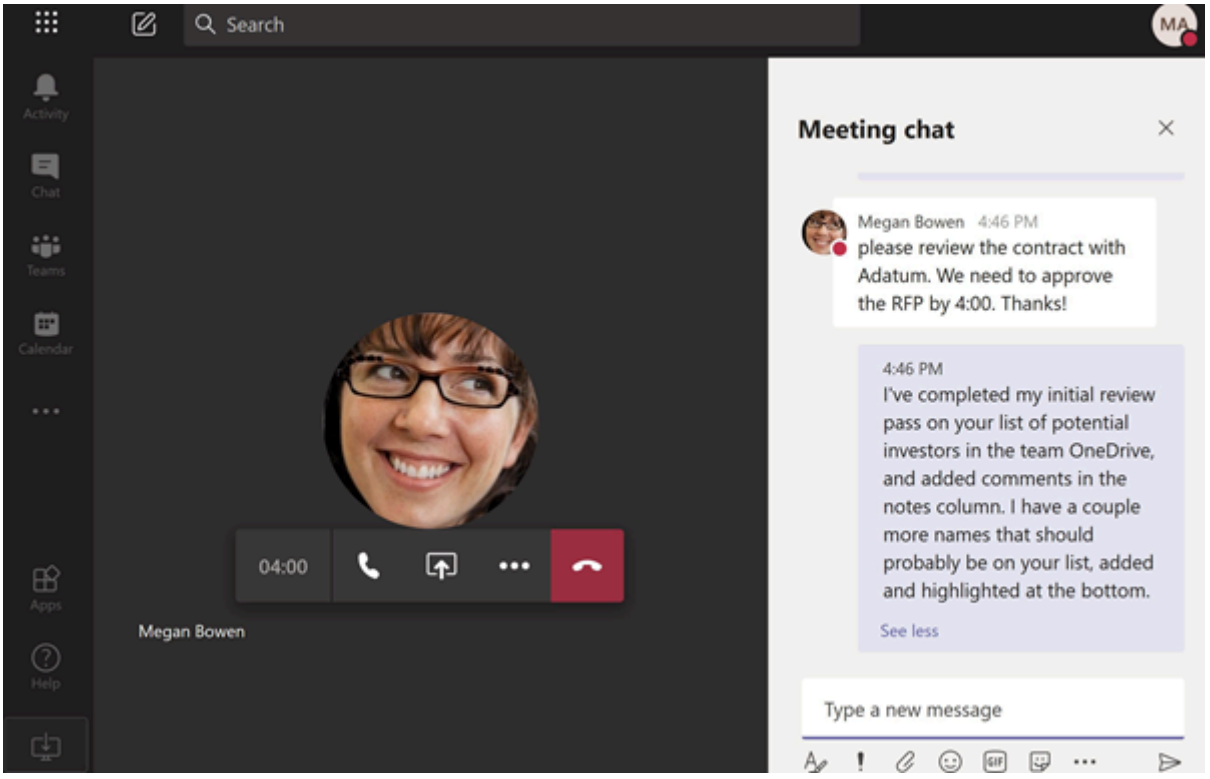
eDiscovery of messages and files in private channels works differently than in standard channels. To learn more, see eDiscovery of private channels.

Recorded Teams meetings are stored in the OneDrive for Business account of the meeting organizer or initiator, depending on the *MeetingRecordingOwnership* configuration. Attendee identification information when using the **Hide Attendee Names** functionality for Teams meetings is stored in the user mailbox of the meeting organizer. To learn more, see eDiscovery (Premium) workflow for content in Microsoft Teams.

Not all Teams content is eDiscoverable. The following table shows the Teams content types that you can search for using Microsoft eDiscovery tools:

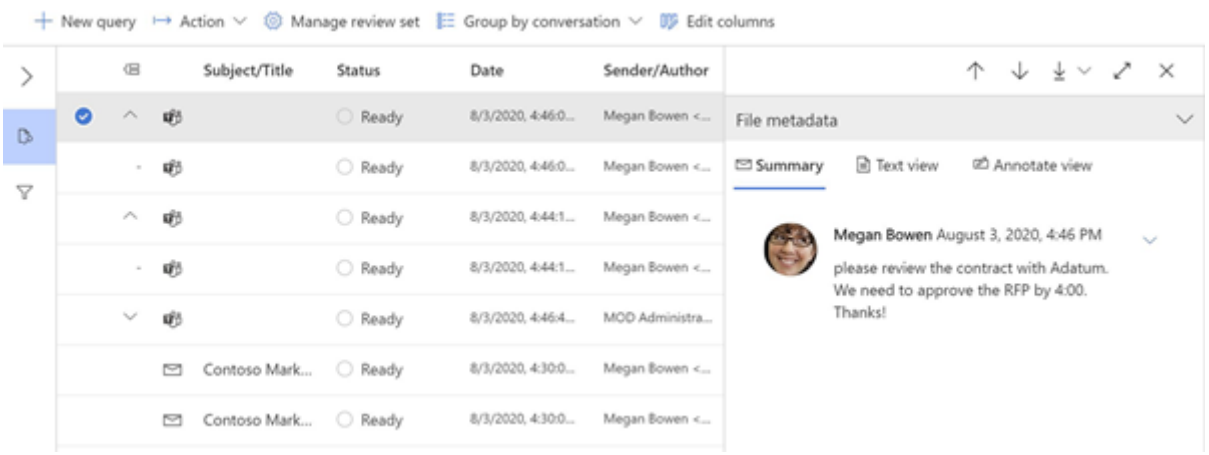
Expand table

Content type	Notes
Audio recordings	Audio calls between Teams user and external contacts
Card content	See Search for card content for more information.
Chat links	
Chat messages	This includes content in standard Teams channels, 1:1 chats, 1:N group chats, chats with yourself, and chats with guests.
Code snippets	
Edited messages	If the user is on hold, previous versions of edited messages are also preserved.
Emojis, GIFs, and stickers	
Inline images	
Loop components	Content in a loop component is saved in a .fluid file that's stored in the OneDrive for Business account of the user who sends the loop component. That means you have to include OneDrive as a data source when searching for content in loop components.
Meeting IM conversations	
Meeting metadata[1]	
Meeting recordings and transcripts	Transcripts of the meeting audio are extracted and provided as a separate file. Maximum supported recorded meeting .mp4 file size is 350 MB. If the recorded meeting file size is greater than 350 MB, a processing error occurs and the file is available for download.
Name of channel	
Quotes	Quoted content is searchable. However, search results don't indicate that the content was quoted.
Reactions (such as likes, hearts, and other reactions)	Reactions are supported for all commercial customers after June 1, 2022. Reactions before this date aren't available for eDiscovery. Expanded reactions are now supported. To understand reaction history, the content must be on legal hold.
Subject	
Tables	
Teams Video Clip (TVC)	Search TVC with "Video-Clip" keyword and "save as" a .mp4 file for each TVC attachment by right-clicking the preview.



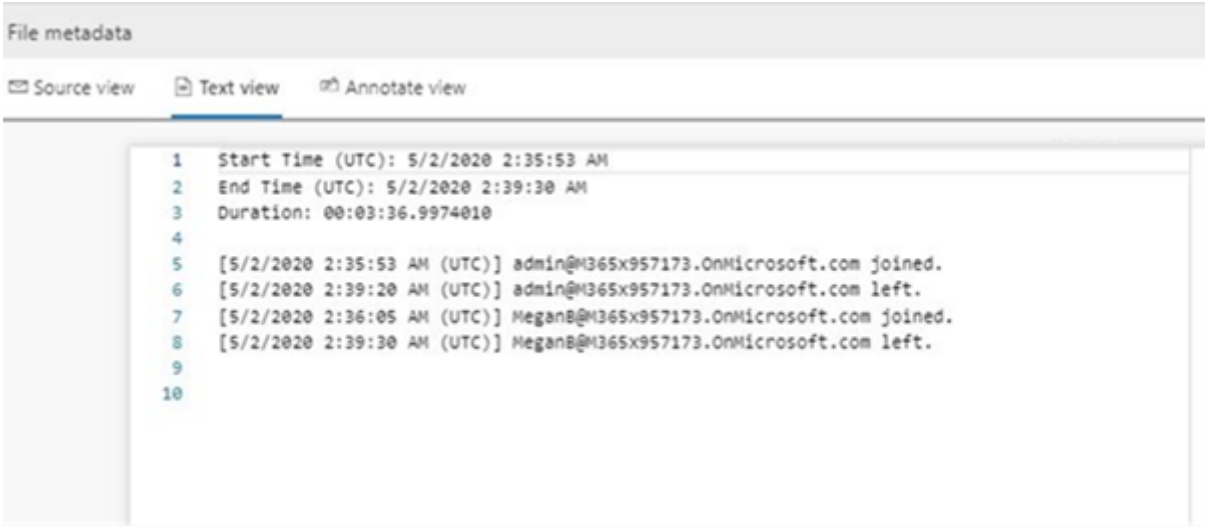
Content type	Notes
	TVCs are collected as Teams conversation attachments (if smaller than 200 MB) and separate .mp4 files. TVC file data is discoverable in eDiscovery review sets and can be exported. Preview of video clips isn't currently supported.

[1] Meeting (and call) metadata includes the following:



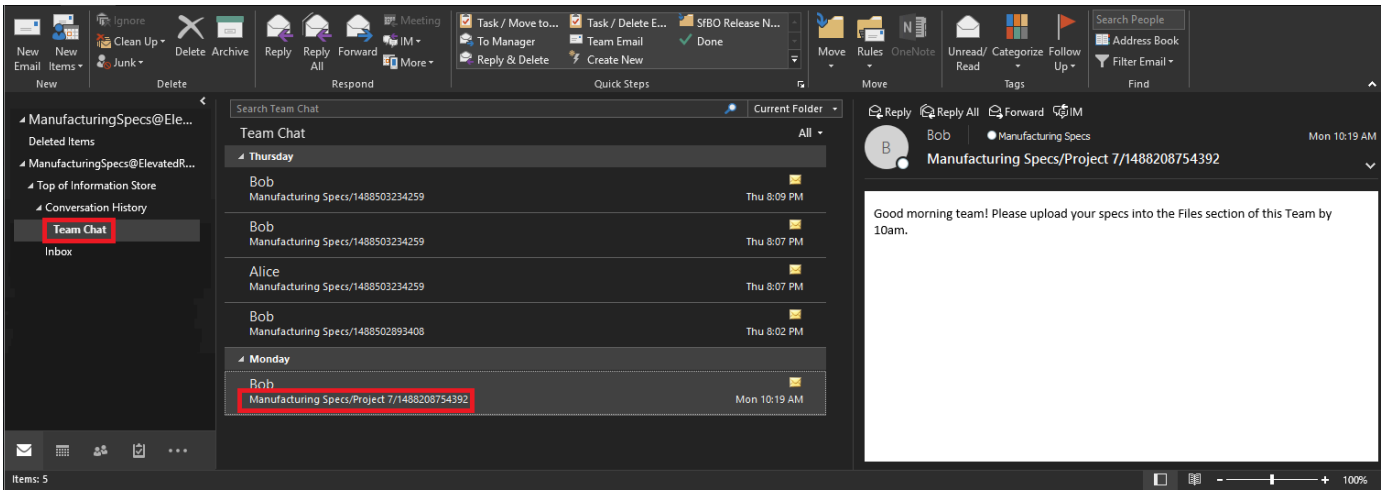
- Meeting start and end time, and duration
- Meeting join and leave events for each participant
- VOIP joins/calls
- Federated user joins
- Guest joins

> **ⓘ Important**
>
> Anonymous users joining meetings and calls aren't currently supported in eDiscovery search queries.



Here's an example of a chat conversation between participants during a meeting.

Here's an example of the compliance copy of the same chat conversation viewed in an eDiscovery tool.



Here's an example of the meeting metadata.

For more information about conducting an eDiscovery investigation, see Get started with eDiscovery (Standard).

Microsoft Teams data appears as IM or Conversations in the Excel eDiscovery export output. You can open the `.pst` file in Outlook to view those messages after you export them.

When viewing the .pst file for the team, all conversations are located in the Team Chat folder under Conversation History. The title of the message contains the team name and channel name. For example, the image below shows a message from Bob who messaged the Project 7 standard channel of the Manufacturing Specs team.

Private chats in a user's mailbox are stored in the Team Chat folder under Conversation History.

eDiscovery of private and shared channels

Compliance copies of messages in private and shared channels are sent to different mailboxes depending on the channel type. That means you have to search different mailbox locations based on the type of channel a user is a member of.

- **Private channels**. Compliance copies are sent to the mailbox of all members of the private channel members. That means you have to search the user mailbox when searching for content in private channel messages.
- **Shared channels**. Compliance copies are sent to a system mailbox that's associated with the parent team. Because Teams doesn't support an eDiscovery search of a single system mailbox for a shared channel, you have to search the mailbox for the parent team (by selecting the name of the Team mailbox) when searching for message content in shared channels.

Each private and shared channel has its own SharePoint site that's separate from the parent team site. That means files in private and shared channels are stored in its own site and managed independently of the parent team. This means you must identify and search the specific site associated with a channel when searching for content in files and channel message attachments.

Use the following sections to help identify the private or shared channel to include in your eDiscovery search.

Identifying the members of a private channel

Use the procedure in this section to identify members of a private channel so that you can use eDiscovery tools to search the member's mailbox for content in private channel messages.

Before you perform these steps, make sure you have the latest version of the Teams PowerShell module installed.

1. Run the following command to get the group ID of the team that contains the shared channels you want to search.

   PowerShell

   ```
   Get-Team -DisplayName <display name of the the parent team>
   ```

   > **Tip**
   >
   > Run the **Get-Team** cmdlet without any parameters to display a list of all Teams in your organization. The list contains the group Id and DisplayName for every team.

2. Run the following command to get a list of private channels in the parent team. Use the group ID for the team that you obtained in step 1.

   PowerShell

   ```
   Get-TeamChannel -GroupId <parent team GroupId> -MembershipType Private
   ```

3. Run the following command to get a list of private channel owners and members for a specific private channel.

   PowerShell

   ```
   Get-TeamChannelUser -GroupId <parent team GroupId> -DisplayName "Partner Shared Channel"
   ```

4. Include the mailboxes of owners and members of a private channel as part of your eDiscovery search query in eDiscovery (Standard) or when identifying and collecting custodian content in eDiscovery (Premium).

Identifying the SharePoint site for private and shared channels

As previously explained, files shared in private and shared channels (and files attached to channel messages) are stored in the site collection associated with the channel. Use the procedure in this section to identify the URL for the site associated with a specific private or shared channel. Then you can use eDiscovery tools to search for content in the site.

Before you perform these steps, install the SharePoint Online Management Shell and connect to SharePoint Online.

1. Optionally, run the following to get a list of all SharePoint site collections associated with shared channels in the parent team.

   PowerShell

   ```
   Get-SPOSite
   ```

   > **Tip**
   >
   > The naming convention of the URL for a site that's associated with private and shared channels is `[SharePoint domain]/sites/[Name of parent team]-[Name of private or shared channel]`. For example, the URL for the shared channel named "Partner Collaboration", which is located in the "Engineer Team" parent team in the Contoso organization is `https://contoso.sharepoint.com/sites/EngineeringTeam-PartnerCollaboration`.

2. Run the following PowerShell commands to display the URL for all SharePoint sites associated with the private and shared channels in your organization. The output of the script also includes the group ID of the parent team, which you need to run the commands in step 3.

   PowerShell

   ```
   $sites = Get-SPOSite -Template "TEAMCHANNEL#1"
   foreach ($site in $sites) {$x= Get-SPOSite -Identity $site.url -Detail;
   $x.relatedgroupID; $x.url}
   ```

   > **Note**
   >
   > SharePoint sites for private channels created before June 28, 2021 use the value `"TEAMCHANNEL#0"` for the custom template ID. To displays private channels created after this date, use the value `"TEAMCHANNEL#1"` when running the previous two scripts. Shared channels only use the value of `"TEAMCHANNEL#1"`.

3. For each parent team, run the following PowerShell commands to identify the private and shared channel sites, where `$groupID` is the group ID of the parent team.

PowerShell

```
$sites = Get-SPOSite -Template "TEAMCHANNEL#1"
$groupID = "<group ID of parent team)"
foreach ($site in $sites) {$x= Get-SpoSite -Identity $site.url -Detail; if
($x.RelatedGroupId -eq $groupID) {$x.RelatedGroupId;$x.url}}
```

4. Include the site associated with a private or shared channel as part of your eDiscovery search query in eDiscovery (Standard) or when identifying and collecting custodian content in eDiscovery (Premium).

Search for content for guests

You can use eDiscovery tools to search for Teams content related to guests in your organization. Teams chat content that's associated with a guest is preserved in a cloud-based storage location and can be searched for using eDiscovery. This includes searching for content in 1:1 and 1:N chat conversations in which a guest is a participant with other users in your organization. You can also search for private channel messages in which a guest is a participant and search for content in *guest:guest* chat conversations where the only participants are guests.

To search for content for guests:

1. Connect to Microsoft Graph PowerShell. For more information, see the Microsoft Graph PowerShell overview. Be sure to complete Step 1 and Step 2 in the previous article.

2. After you successfully connect to Microsoft Graph PowerShell, run the following command to display the user principal name (UPN) for all guests in your organization. You have to use the UPN of the guest when you create the search in step 4.

   PowerShell

   ```
   Get-MgUser -Filter "userType eq 'Guest'" -All $true | FL UserPrincipalName
   ```

   > **Tip**
   >
   > Instead of displaying a list of user principal names on the computer screen, you can redirect the output of the command to a text file. You can do this by appending `> filename.txt` to the previous command. The text file with the user principal names will be saved to the current folder.

3. In a different Windows PowerShell window, connect to Security & Compliance PowerShell. For instructions, see Connect to Security & Compliance PowerShell. You can connect with or without using multi-factor authentication.

4. Create a content search that searches for all content (such as chat messages and email messages) in which the specified guest was a participant by running the following command.

   PowerShell

   ```
   New-ComplianceSearch <search name> -ExchangeLocation <guest UPN>  -
   AllowNotFoundExchangeLocationsEnabled $true -IncludeUserAppContent $true
   ```

   For example, to search for content associated with the guest Sara Davis, you would run the following command.

   PowerShell

   ```
   New-ComplianceSearch "Sara Davis Guest" -ExchangeLocation
   "sara.davis_hotmail.com#EXT#@contoso.onmicrosoft.com" -
   AllowNotFoundExchangeLocationsEnabled $true -IncludeUserAppContent $true
   ```

   For more information about using PowerShell to create content searches, see New-ComplianceSearch.

5. Run the following command to start the content search that you created in step 4:

   PowerShell

   ```
   Start-ComplianceSearch <search name>
   ```

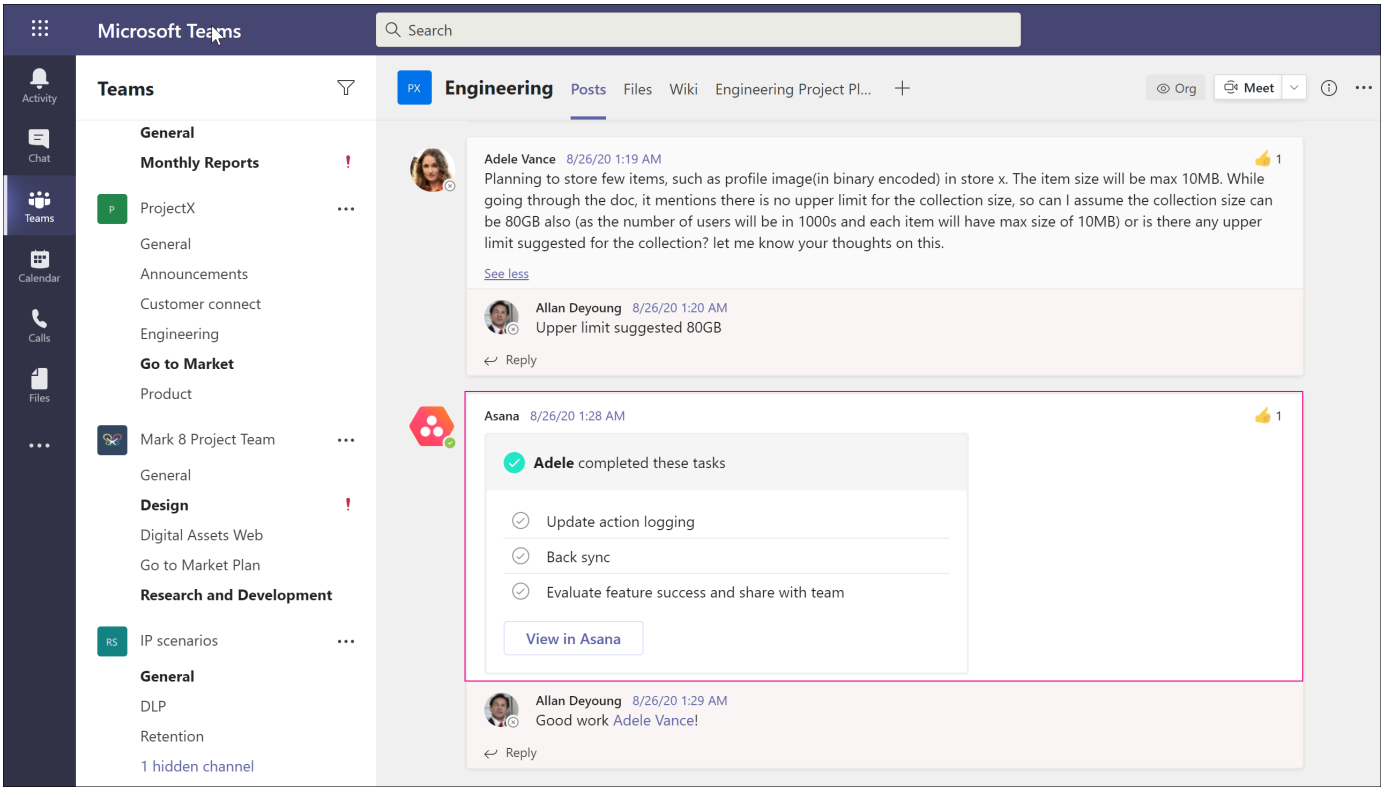
6. Go to https://compliance.microsoft.com and then select **Show all** > **Content search**.

7. In the list of searches, select the search that you created in step 4 to display the flyout page.

8. On the flyout page, you can do the following things:

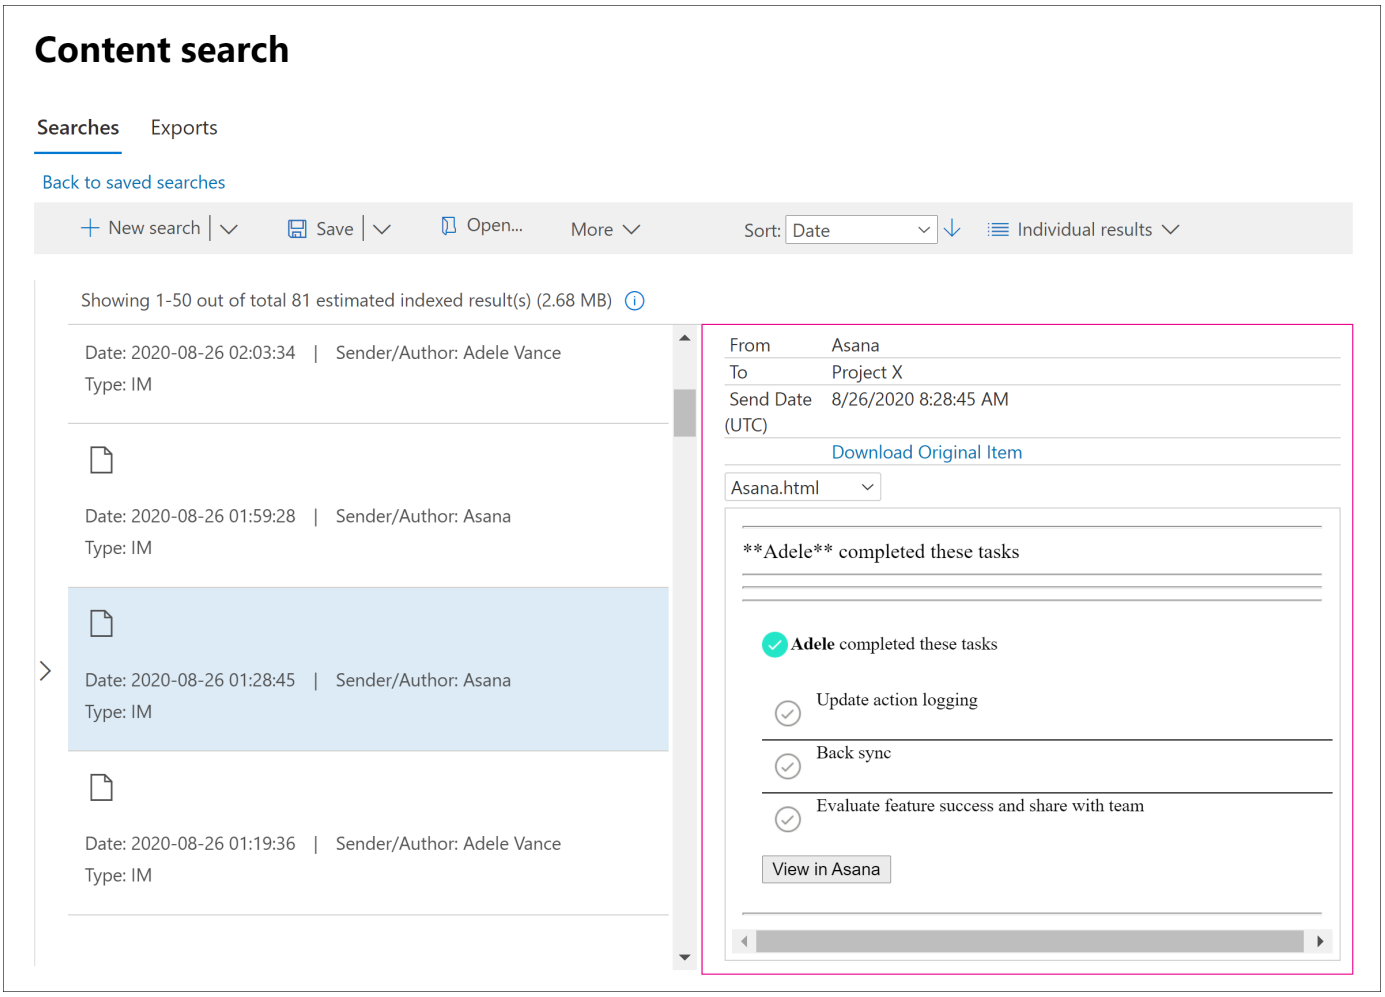
   - Select **View results** to view the search results and preview the content.
   - Next to the **Query** field, select **Edit** to edit and then rerun the search. For example, you can add a search query to narrow the results.
   - Select **Export results** to export and download the search results.

Search for card content



Card content generated by apps in Teams channels, 1:1 chats, and 1xN chats are stored in mailboxes and can be searched. A *card* is a UI container for short pieces of content. Cards can have multiple properties and attachments, and can include items that can trigger card actions. For more information, see Cards

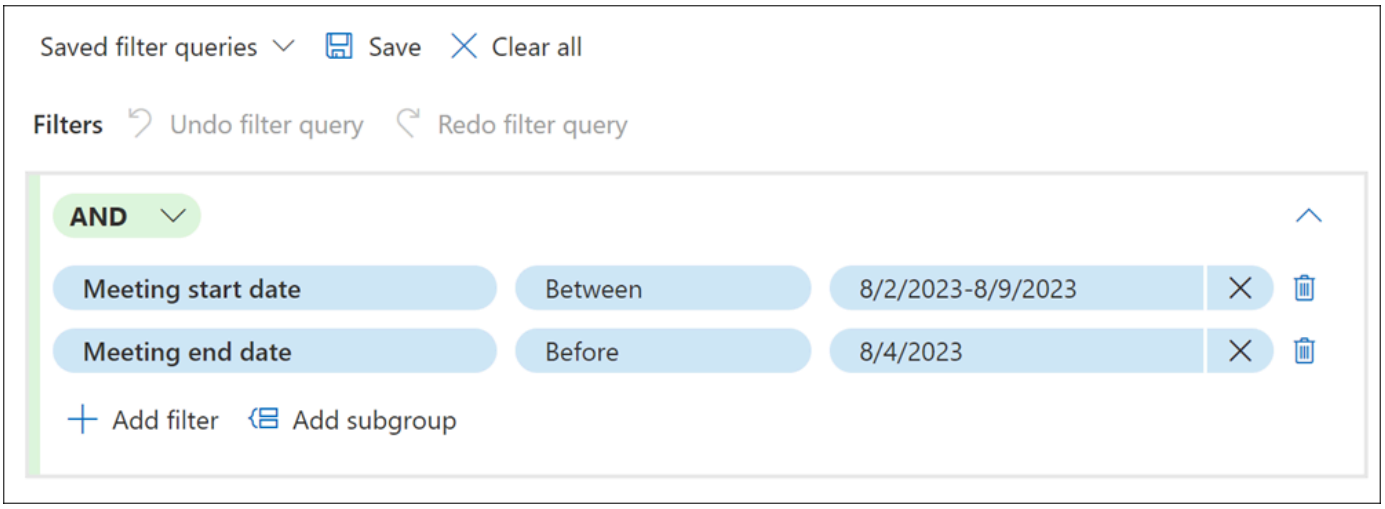
Like other Teams content, where card content is stored is based on where the card was used. Content for cards used in a Teams channel is stored in the Teams group mailbox. Card content for 1:1 and 1xN chats are stored in the mailboxes of the chat participants.



To search for card content, you can use the `kind:microsoftteams` or `itemclass:IPM.SkypeTeams.Message` search conditions. When reviewing search results, card content generated by bots in a Teams channel has the **Sender/Author** email property as `<appname>@teams.microsoft.com`, where `appname` is the name of the app that generated the card content. If card content was generated by a user, the value of **Sender/Author** identifies the user.

When viewing card content in Content search results, the content appears as an attachment to the message. The attachment is named `appname.html`, where `appname` is the name of the app that generated the card content. The following screenshots show how card content (for an app named Asana) appears in Teams and in the results of a search.

Card content in Teams



Card content in search results

> **Note**
>
> To display images from card content in search results at this time (such as the checkmarks in the previous screenshot), you have to be signed into Teams (at https://teams.microsoft.com) in a different tab in the same browser session that you use to view the search results. Otherwise, image placeholders are displayed.

Search for Teams meetings by date

Admins can search for Teams meeting content based on the meeting start or end dates. To filter review set items by specific Teams meeting dates, you can use the *Meeting start date* and *Meeting end date* properties in the advanced filtering options in eDiscovery (Premium).

Search for hidden attendees in Teams meetings

The **Hide Attendee Names** feature in Microsoft Teams hides the name of attendees from other attendees so only organizers can see attendees names. This feature may be used for meetings or events with external businesses, vendors, confidential meetings, or other meetings where personal privacy between attendees is important. When this feature is enabled, the names of attendees are hidden in the meeting roster, meeting chat, and meeting recordings.

To search for the names of attendees in Teams meetings where the **Hide Attendee Names** feature was enabled, you must include the organizer's mailbox in the scope for the search. Hidden attendee names are only available in the organizer's mailbox.

eDiscovery in external access and guest environments

Admins can use eDiscovery to search for content in chats messages in a Teams meeting in external access and guest access environments based on the following restrictions:

- **External access**: In a Teams meeting with users from your organization and users from an external organization where external attendees are using external access, admins in both organizations can search for content in chat messages from the meeting.
- **Guest**: In a Teams meeting with users from your organization and guests, only admins in the organization who hosts the Teams meeting can search for content in chat messages from the meeting.

Last updated on 10/31/2024

Search for and delete chat messages in Teams

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use eDiscovery (Premium) and the Microsoft Graph Explorer to search for and delete chat messages in Microsoft Teams. This feature can help you find and remove sensitive information or inappropriate content. This search and delete workflow will also help you respond to a data spillage incident, when content containing confidential or malicious information is released through Teams chat messages.

> **Tip**
>
> You can also use the purge feature in Data Security Investigations to search for and permanently delete Microsoft Teams items in your organization. Data Security Investigations provides a built-in search and purge workflow with a purge queue dashboard to help you manage and track purge queries. For more information, see Purge in Data Security Investigations.

Before you search and delete chat messages

- To create an eDiscovery (Premium) case and use collections to search for chat messages, you have to be a member of the *eDiscovery Manager* role group in the Microsoft Purview portal. To delete chat messages, you have to be assigned the *Search And Purge* role. This role is assigned to the *Data Investigator* and *Organization Management* role groups by default. For more information, see Assign eDiscovery permissions.

- Search and purge are supported for most conversations within your tenant. Search and purge for Teams Connect Chat (External Access or Federation) conversations isn't supported.

  > **Important**
  >
  > Chats with yourself (or chats by users with themselves) aren't supported for search and delete.

- A maximum of 100 items per mailbox can be removed at one time. Because the capability to search for and remove chat messages is intended to be an incident-response tool, this limit helps ensure that chat messages are quickly removed.

- Deleting chat messages in federated environments isn't supported.

Search and delete workflow

Here's the process to search for and delete Teams chat messages:

Step 1: Create a case in eDiscovery (Premium)

The first step is to create a case in eDiscovery (Premium) to manage the search and delete process. For information about creating a case, see Use the new case format.

Step 2: Create a collection estimate

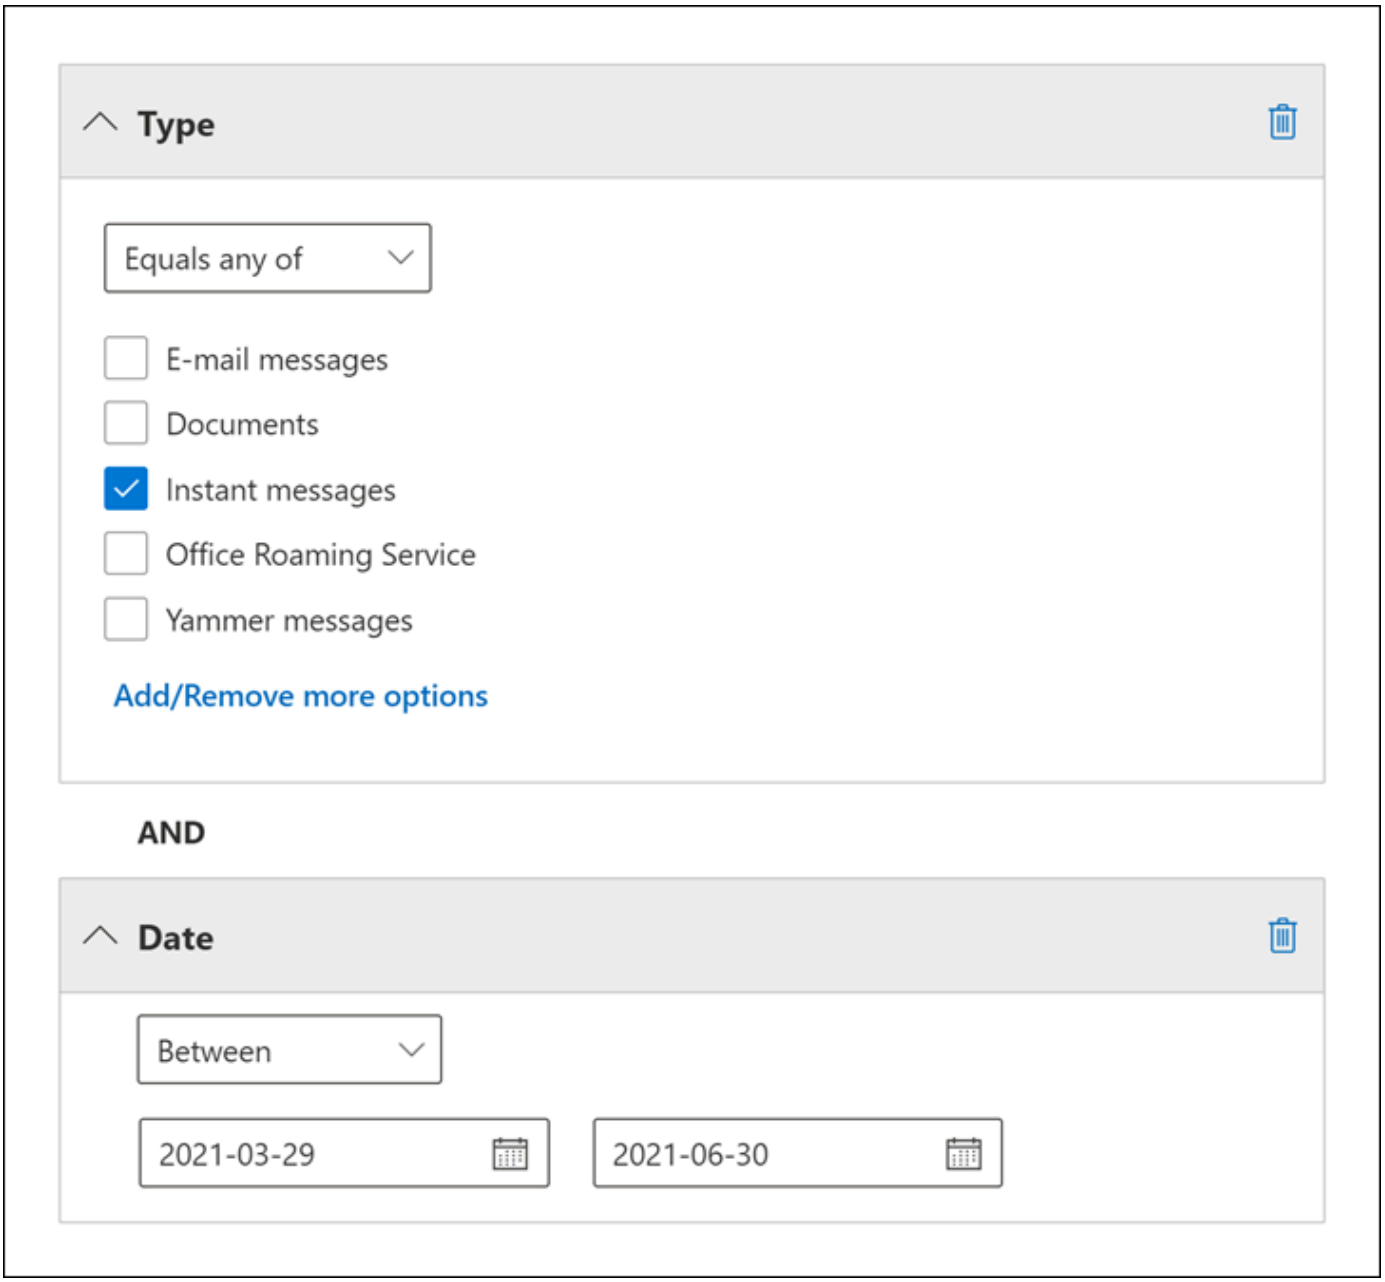
After you create a case, the next step is to create a collection estimate to search for the Teams chat messages that you want to delete. The delete process you perform is Step 5 deletes all items that are found in the collection estimate (within the 10 item per location limit).

In eDiscovery (Premium), a *collection* is an eDiscovery search of the Teams content locations that contain the chat messages that you want to delete. Create the collection estimate in the case that you created in the previous step. For more information, see Create a collection estimate.

Data sources for chat messages

Use the following table to determine which data sources to search depending on the type of chat message you need to delete.

Expand table



For this type of chat...	Search this data source...
Teams 1:1 chats	The mailbox of chat participants.
Teams group chats	The mailboxes of chat participants.
Teams channels (standard and shared)	The mailbox associated with the parent team.
Teams private channels	The mailbox of the private channel members.

> **Note**
>
> In Step 4, you also have to identify and remove any holds and retention policies assigned to the mailbox that contains the type of chat messages that you want to delete.

Tips for searching for chat messages

To help ensure the most comprehensive collection of Teams chat conversations (including 1:1 and group chats, and chats from standard, shared, and private chats) use the **Type** condition and select the **Instant messages** option when you build the search query for the collection estimate. We also recommend including a date range or several keywords to narrow the scope of the collection to items relevant to your search a delete investigation.

Here's an example of a sample query using the **Type** and **Date** options:

For more information, see Build search queries for collections.

Step 3: Review and verify chat messages to delete

The deletion process in Step 5 deletes the items returned by the collection. It's important that you review the collection estimate results to ensure that the collection only returns the items that you want to delete. To review a sample of items in a collection estimate, see the "Next steps after a collection estimate is complete" section in Create a collection estimate.

Additionally, you can use the collection statistics (specifically the Top Locations statistics) to generate a list of the data sources that contain items returned by the collection. Use this list in the next step to remove hold and retention policies from the data sources that contain search results. For more information, see Collection statistics and reports.

Step 4: Remove all holds and retention policies from data sources

Before you can delete chat messages from a mailbox, you have to remove all organization-wide holds, site holds, or retention policy holds that are assigned to a target mailbox. If not, the chat you're trying to delete is retained.

Use the list of mailboxes that contain the chat messages that you want to delete and determine if there's a hold or retention policy assigned to those mailboxes, and then remove the hold or retention policy. Be sure to identify the hold or retention policy that you remove so that you can reassign to the mailboxes in Step 7.

For instructions about how to identify and remove holds and retention policies, see "Step 3: Remove all holds from the mailbox" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold.

Step 5: Delete chat messages from Teams

> **Note**
>
> Because Microsoft Graph Explorer is not available in some US Government clouds (GCC High and DOD), you must use PowerShell to accomplish these tasks. See the **Delete chat messages with PowerShell** for details.

Now you're ready to actually delete chat messages from Teams. Use the Microsoft Graph Explorer to perform the following three tasks:

1. Get the ID of the eDiscovery (Premium) case that you created in Step 1. This is the case that contains the collection created in Step 2.
2. Get the ID of the collection that you created in Step 2 and verified the search results in Step 3. The search query in this collection returns the chat messages that will be deleted.
3. Delete the chat messages returned by the collection.

For information about using Graph Explorer, see Use Graph Explorer to try Microsoft Graph APIs.

> **Important**
>
> To perform these three tasks in Graph Explorer, you may have to consent to the eDiscovery.Read.All and eDiscovery.ReadWrite.All permissions. For more information, see the

"Consent to permissions" section in Working with Graph Explorer.

Get the case ID

1. Go to https://developer.microsoft.com/graph/graph-explorer and sign in to the Graph Explorer with an account that's assigned the *Search And Purge* role in the Microsoft Purview portal.

2. Run the following GET request to retrieve the ID for the eDiscovery (Premium) case. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases` in the address bar of the request query. Be sure to select **v1.0** in the API version dropdown list.

   This request returns information about all cases in your organization on the **Response preview** tab.

3. Scroll through the response to locate the eDiscovery (Premium) case. Use the **displayName** property to identify the case.

4. Copy the corresponding ID (or copy and paste it to a text file). You'll use this ID in the next task to get the collection ID.

> **Tip**
>
> Instead of using the previous procedure to obtain the case Id, you can open the case in the Microsoft Purview portal and copy the case Id from the URL.

Get the eDiscoverySearchID

1. In Graph Explorer, run the following GET request to retrieve the ID for the collection that you created in Step 2, and contains the items you want to delete. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches` in the address bar of the request query, where *{ediscoveryCaseID}* is the CaseID that you obtained in the previous procedure.

2. Scroll through the response to locate the collection that contains the items that you want to delete. Use the *displayName* property to identify the collection that you created in Step 3.

   In the response, the search query from the collection is displayed in the *contentQuery* property. Items returned by this query is deleted in the next task.

3. Copy the corresponding ID (or copy and paste it to a text file). You'll use this ID in the next task to delete the chat messages.

> **Tip**
>
> Instead of using the previous procedure to obtain the search Id, you can open the case in the Microsoft Purview portal. Open the case and navigate to the Jobs tab. Select the relevant collection and under Support information, find the job ID (the job ID displayed here is the same as the collection ID).

Delete the chat messages

1. In Graph Explorer, run the following POST request to delete the items returned by the collection that you created in Step 2. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches/{ediscoverySearchID}/purgeData` in the address bar of the request query, where *{ediscoveryCaseID}* and *{ediscoverySearchID}* are the IDs that you obtained in the previous procedures.

   If the POST request is successful, an HTTP response code is displayed in a green banner stating that the request was accepted.

For more information on purgeData, see sourceCollection: purgeData.

Delete chat messages with PowerShell

You can also delete chat messages using PowerShell. For example, to delete messages in the US Government cloud you could use a command similar to:

```
Connect-MgGraph -Scopes "ediscovery.ReadWrite.All" -Environment USGov
```

```
Invoke-MgGraphRequest -Method POST -Uri
'/v1.0/security/cases/ediscoveryCases/<ediscoverySearchID>/searches/<search ID>/purgeData'
```

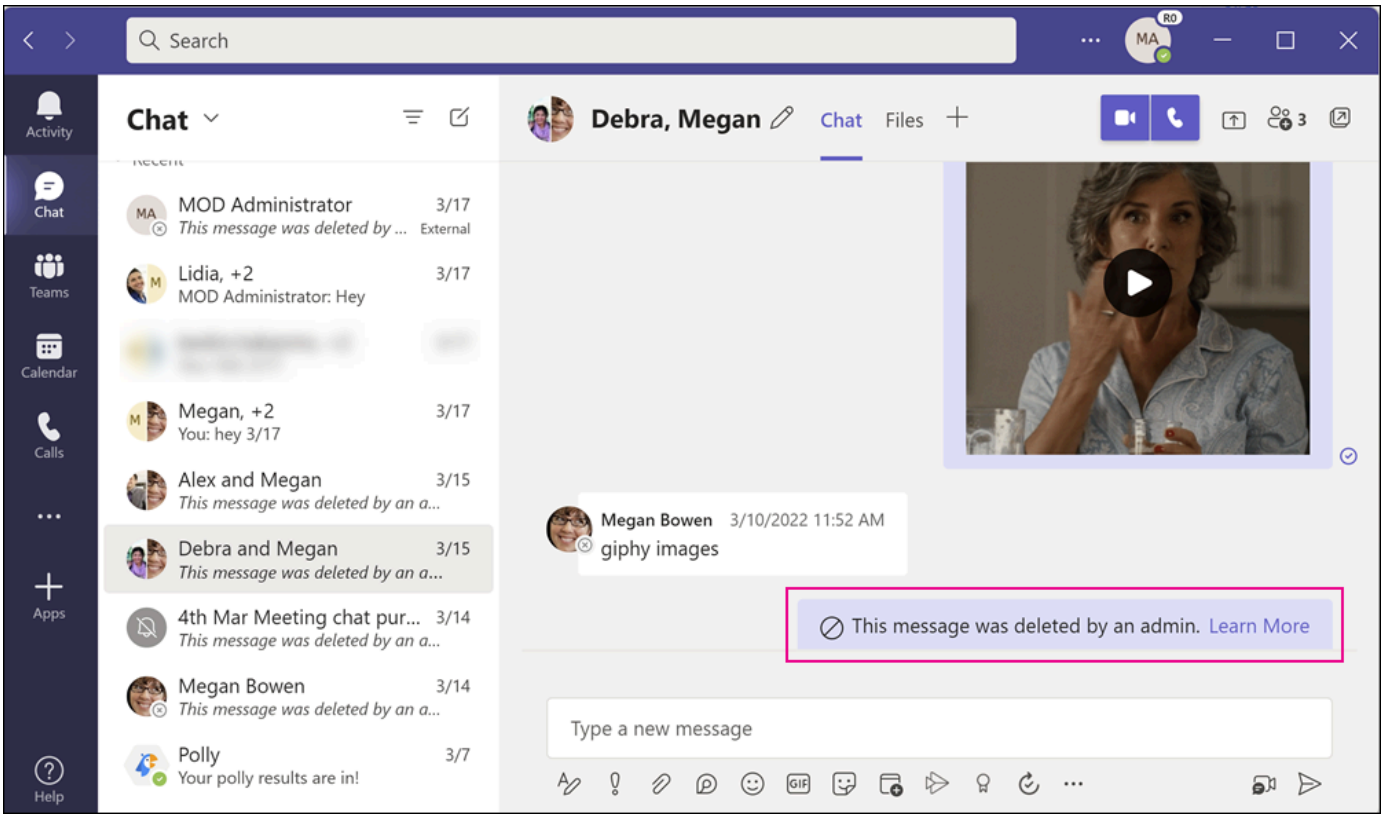
For more information on using PowerShell to delete chat messages, see ediscoverySearch: purgeData.

Step 6: Verify chat messages are deleted

After you run the POST request to delete chat messages, these messages are removed from the Teams client and replaced with an automatically generated stating that an admin has removed the message. For an example of this message, see the End-user experience section in this article.

If you need to confirm a chat message has been removed and don't have access to the end-user message in Teams, re-run the search and verify if any matching messages are found. If there aren't any results for the message, the message has been removed.

Deleted chat messages are moved to the *SubstrateHolds* folder, which is a hidden mailbox folder. Deleted chat messages are stored there for at least 1 day, and then are permanently deleted the next time the timer job runs (typically between 1-7 days). For more information, see Learn about retention for Microsoft Teams.



> **Note**
>
> Because Microsoft Graph Explorer is not available in the US Government cloud (GCC, GCC High, and DOD), you must use PowerShell to accomplish these tasks.

Step 7: Reapply holds and retention policies to data sources

After you verify that chat messages are deleted and removed from the Teams client, you can reapply the holds and retention policies that you removed in Step 4.

End-user experience

For deleted chat messages, users see an automatically generated message stating "This message was deleted by an admin".

The message in the previous screenshot replaces the chat message that was deleted.

> **Note**
>
> If you're an end-user and a chat message was deleted, contact your admin for more information.

Create and manage an eDiscovery (Premium) case

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After setting up Microsoft Purview eDiscovery (Premium) and assigning permissions to eDiscovery managers in your organization that will manage cases, the next step is to create and manage a case.

This article also provides a high-level overview of using cases to manage the eDiscovery (Premium) workflow for a legal case or other types of investigations.

Create a case

Complete the following steps to create a case and configure case settings. The user who creates the case is automatically added as a member. Members of the case can access the case in the Microsoft Purview portal and perform eDiscovery (Premium) tasks.

1. Go to the Microsoft Purview portal and sign in using the credentials for user account that has been assigned eDiscovery permissions. Members of the *Organization Management* role group can also create eDiscovery (Premium) cases.
2. In the left navigation pane of the Microsoft Purview portal, select **Show all**, and then select **eDiscovery** > **Premium**, and then select the **Cases** tab.
3. Select **Create a case**.
4. On the **Name and description** page, complete the following fields:

- **Name**: give the case a name (required). The case name must be unique in your organization
- **Description**: Add an optional description to help others understand this case.
- **Number**: Enter an optional docket number or other numeric identifier.
- **Case format**: The **New (recommended)** option is automatically selected.

> ⓘ Note
>
> The legacy **Classic** format is no longer available when creating new cases. This format is now retired for all new cases.

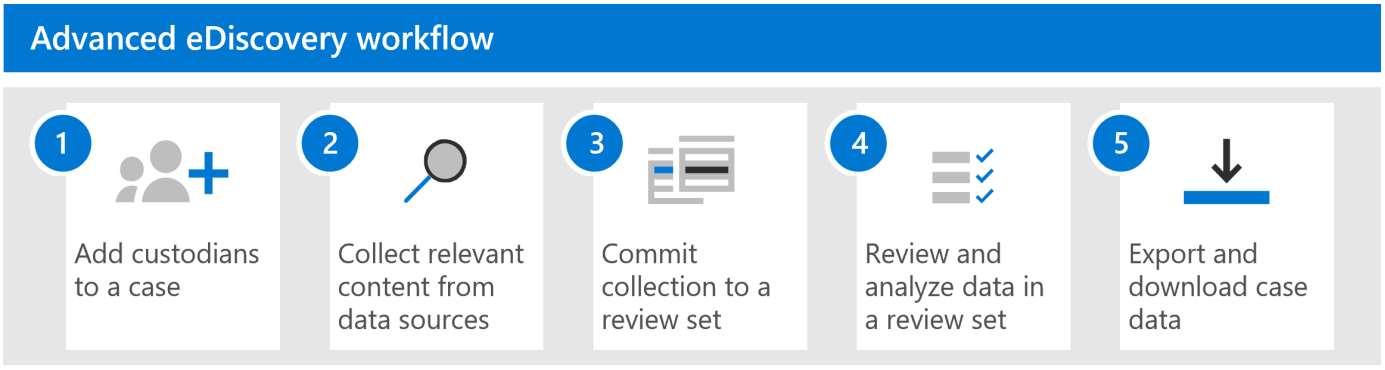
5. Select **Next**.

6. On the **Members and settings** page, complete the following fields as applicable:

   - **Team members**: Select users and groups that should be assigned to the case. Make sure that users and groups assigned here have been assigned the appropriate eDiscovery permissions.
   - **Search and analytics**: Select the options to configure the case. You can skip this section and configure these settings after the case is created if needed.
   - **Text to ignore**: Add text or regex expressions to define text to ignore in the case. You can apply this to *Near-duplicates*, *Email threads*, or *Themes* modules.
   - **Optical character recognition (OCR)**: Configure the option and settings for finding text contained in images during advanced indexing.

7. Select **Next**.

8. On the **Summary** page, review the settings for the case and edit the settings if needed. Select **Submit** to create the new case and start your investigation.



Mark a case as a favorite

You can mark an eDiscovery (Premium) case as a favorite for quicker access to cases you want to prioritize. Cases marked as favorites can be accessed quickly via the eDiscovery (Premium) **Overview** page or can be sorted to be shown at the top of the **Cases** tab for ease of access. You can mark a case as a favorite in the case list on the **Cases** tab or on the top right of the case **Overview** tab for each case. The **Recent favorite cases** card on the **Overview** tab displays all the cases marked as favorites in your organization.

Manage the workflow

To get you started using eDiscovery (Premium), here's a basic workflow that aligns with common eDiscovery practices. In each of these steps, we'll also highlight some extended eDiscovery (Premium) functionality that you can explore. ediscovery-overview

1. **Add custodians and non-custodial data sources to the case**. The first step after creating a case is to add custodians. A *custodian* is a person having administrative control of a document or electronic file that may be relevant to the case. Additionally, you can add data sources that aren't associated with a specific user but may be relevant to the case. These are *non-custodial data sources*.

   Here are some things that happen (or that you can do) when you add custodians to a case:

   - Data in the custodian's Exchange mailbox, OneDrive account, and any Microsoft Teams or Viva Engage groups that the custodian is a member of can be "marked" as custodial data in the case.
   - Custodian (and non-custodial) data is reindexed (by a process called *Advanced indexing*). This helps optimize searching for it in the next step.
   - You can place a hold on custodian and non-custodial data. This hold preserves data that may be relevant to the case during the investigation. To learn more about managing holds, see Manage holds in eDiscovery (Premium).

- You can associate other data sources with a custodian (for example, you can associate a SharePoint site or Microsoft 365 Group with a custodian) so this data can be reindexed, placed on hold, and searched, just like the data in the custodian's mailbox or OneDrive account.

- You can use the communications workflow in eDiscovery (Premium) to send a legal hold notification to custodians.

2. **Collect relevant content from data sources**. After you add custodians and non-custodial data sources to a case, use the built-in collections tool to search these data sources for content that may be relevant to the case. You use keywords, properties, and conditions to build search queries that return search results with the data that's most likely relevant to the case. You can also:

   - View collection statistics that may help you refine a collection to narrow the results.
   - Preview a sample of the collection to quickly verify whether the relevant data is being found.
   - Revise a query and rerun the collection.

3. **Commit collection to a review set**. Once you've configured and verified that a search returns the desired data, the next step is to add the search results to a review set. When you add data to a review set, items are copied from their original location to a secure Azure Storage location. The data is reindexed again to optimize it for thorough and fast searches when reviewing and analyzing items in the review set. Additionally, you can also add non-Office 365 data into a review set.

   There's also a special kind of review set that you can add data to, called a *conversation review set*. These types of reviews sets provide conversation reconstruction capabilities to reconstruct, review, and export threaded conversations like those in Microsoft Teams. For more information, see Review conversations in eDiscovery (Premium).

4. **Review and analyze data in a review set**. Now that data is in a review set, you can use a wide-variety of tools and capabilities to view and analyze the case data with the goal of reducing the data set to what is most relevant to the case you're investigating. Here's a list of some tools and capabilities that you can use during this process.

   - Group and view documents. This includes selecting the group options for review sets in your cases, viewing the metadata for each document in a review set, and viewing the document in its native version or text version.

- Create queries and filters. You create search queries using various search criteria (including the ability to search all file metadata properties to further refine and cull the case data to what is most relevant to the case. You can also use review set filters to quickly apply other conditions to the results of a search query to further refine those results.
- Create and use tags. You can apply tags to documents in a review set to identify which are responsive (or non-responsive to the case) and then use those tags when creating search queries to include or exclude the tagged documents. You can also tagging to determine which documents to export.
- Annotate and redact documents. You can use the annotation tool in a review to annotate documents and redact content in documents as work product. We generate a PDF version of an annotated or redacted document during review to reduce the risk of exporting the unredacted native version of the document.
- Analyze case data. The analytics functionality in eDiscovery (Premium) is powerful. After you run analytics on the data in review set, we perform analysis such as near duplicate detection, email threading, and themes that can help reduce the volume of documents that you have to review. We also generate an Analytics reports that summarize the result of running analytics. As previously explained, running analytics also runs the attorney-client privilege detection model.

5. **Export and download case data**. A final step after collecting, reviewing, and analyzing case data is to export it out of eDiscovery (Premium) for external review or for review by people outside of the investigation team. Exporting data is a two-step process. The first step is to export data out of the review set and copy it to a different Azure Storage location (one provided by Microsoft or one managed by your organization). Then you use Azure Storage Explorer to download the data to a local computer. In addition to the exported data files, the contains of the export package also contains an export report, a summary report, and an error report.

eDiscovery (Premium) architecture

Here's an architecture diagram that shows the eDiscovery (Premium) end-to-end workflow in a single-geo environment and in a multi-geo environment, and the end-to-end data flow that's aligned with the Electronic Discovery Reference Model.

Use the new case format in eDiscovery (Premium)

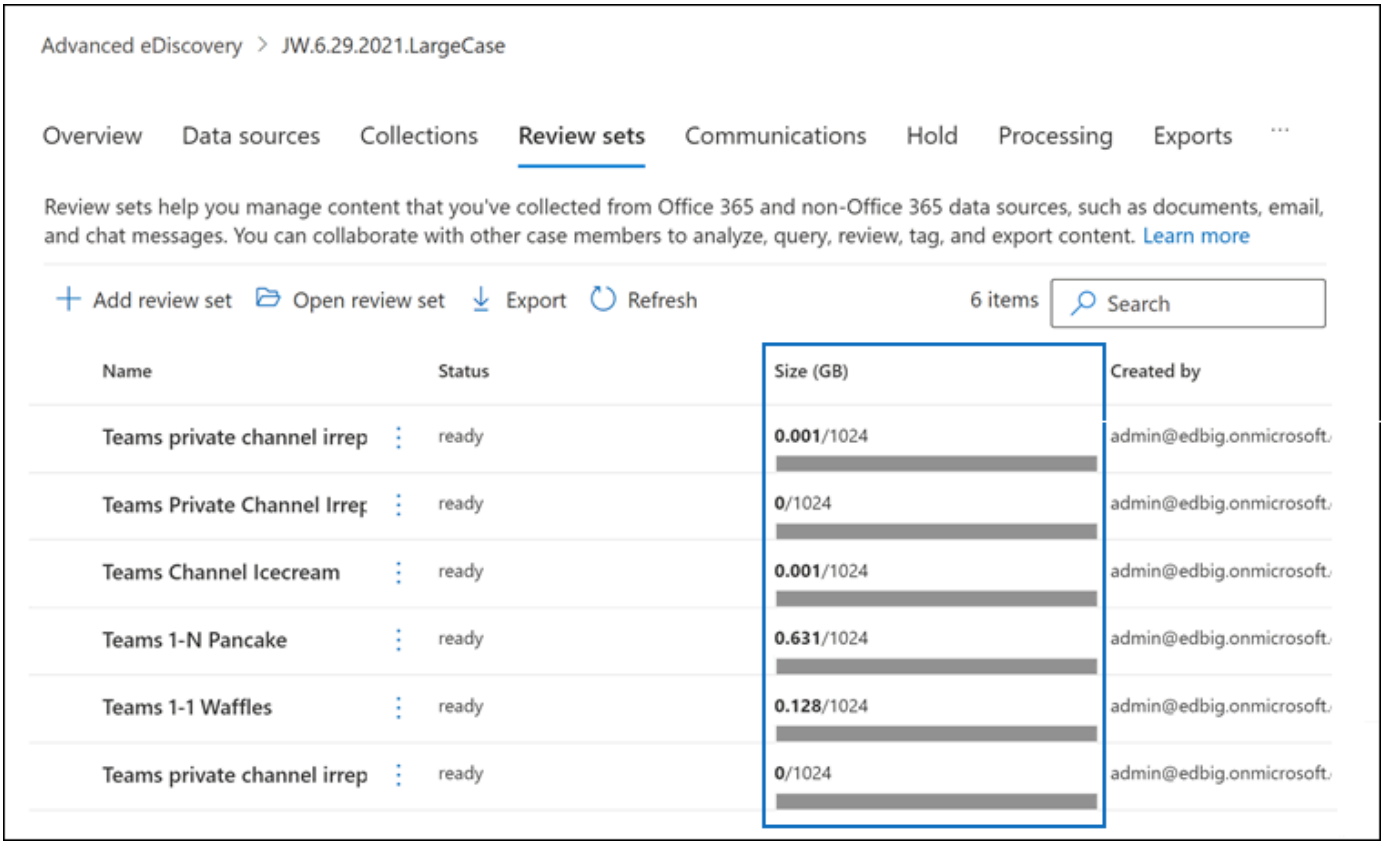
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

More organizations are using the eDiscovery (Premium) solution in Microsoft Purview for critical eDiscovery processes. This includes responding to regulatory requests, investigations, and litigation. As usage of eDiscovery (Premium) increases, a common customer requirement is to expand the total amount of content that can be managed in a single eDiscovery (Premium) case. To help accommodate significant increases in case size, both for total data volume and the total number of items, you can choose the new case format when you create an eDiscovery (Premium) case.

Benefits of the new case format

The new case format allows you to manage cases that contain over 40 million items. This capability helps you effectively manage large volumes of case data through the entire eDiscovery workflow.

Here's a list of other benefits of large cases in eDiscovery (Premium) workflow.



- **Collection**: In the new case format, you can collect up to 1 TB of data for a single collection.

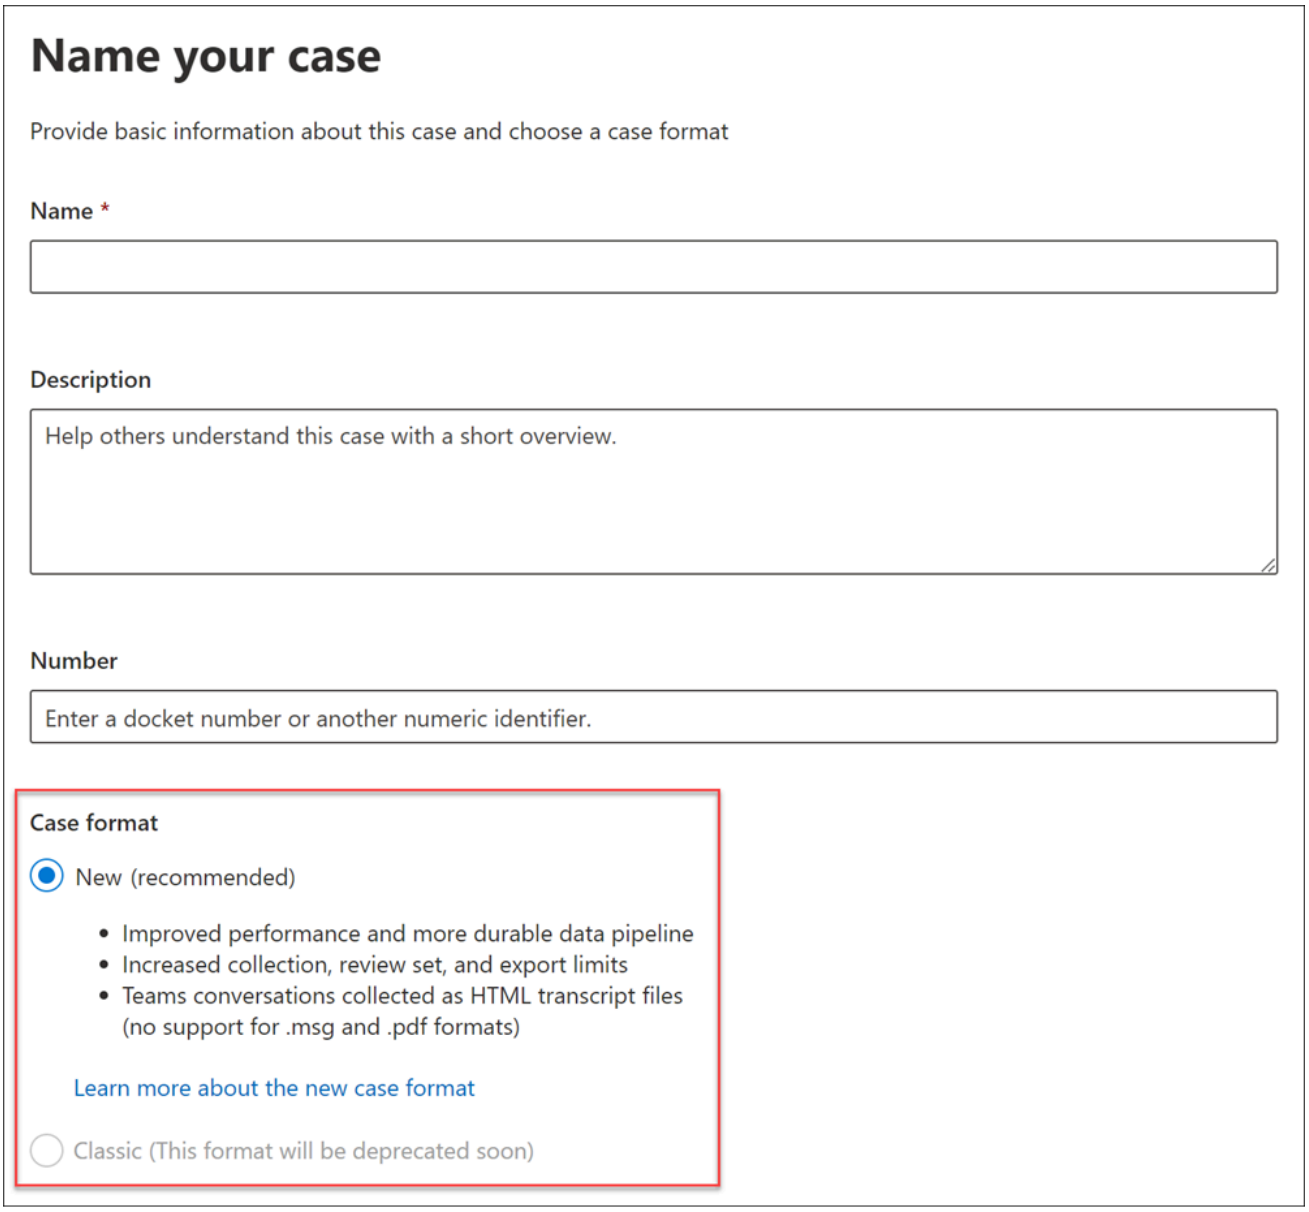
  For each case, the collection settings will default to collect cloud Attachments and contextual Teams and Viva Engage content. These settings help to collect the full picture of digital communications within an investigation. For Teams and Viva Engage contextual conversations, the new case format will convert time-based snapshots of 1:1, 1: N and Channel conversations into HTML transcripts to help provide context of conversations and reduce the total number of items produced by chat-based content.

- **Review**: Each review set will support up to 1 TB of pre-expansion content. Additional metadata will be available for filters and queries including Team name, channel name and conversation name for Teams content. Each transcript will include time-based content for before and after the responsive item. For Channel conversations, the root post and all replies will be collected for responsive content. For more information, see eDiscovery (Premium) workflow for content in Microsoft Teams

- **Export**: You can export large sets of content in a single export job. The new case format lets you can export 5 million documents or 500 GB, whichever is smaller in an export job.

Additionally, the new case format includes an updated user interface that displays the total size of each review set in the case. Review set sizes are displayed in a column on the **Review sets** tab.

Create a case in the new format



To create an eDiscovery (Premium) case using the new case format, complete the following steps:

1. Go to https://compliance.microsoft.com and sign in.

2. In the left navigation pane of the Microsoft Purview portal, select **eDiscovery** > **Premium**.

3. On the **eDiscovery (Premium)** page, select the **Cases** tab, and then select **Create a case**.

The **New eDiscovery case** flyout page is displayed. The **Case format** section on the **Name and description** page provides the option to create a case using the *New (recommended)* or *Classic* format.

4. After naming the case, select the **New (recommended)** option, and then select **Next** to continue in the new case workflow to finish creating your case.

After you've created your case, the case format information is displayed on the **Case format** card on the case **Overview** tab and in the **Case format** section on the case settings page for each case.

Frequently asked questions

If I attempt to collect over 1 TB in a single collection, will it work?

The performance will be negatively impacted and may cause instability in some instances.

If cloud attachments are included by default in the large case format; how can I remove that content from my review experience?

Use review set filters to filter by message kind or to exclude cloud attachments by using the HasAttachment filter. For more information, see Query and filter content in a review set.

When exporting chat conversation transcripts, will the load file contain all of the expanded metadata and a single item for each transcript?

All metadata for a conversation is embedded in the HTML transcript file. Many of the common fields are available in the load file. For more information about exported metadata, see Document metadata fields in eDiscovery (Premium).

Work with custodians and non-custodial data sources in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

When an organization responds to a legal investigation, the workflow around identifying, preserving, and collecting potentially relevant content is based on the people in the organization who are the custodians of relevant data. In eDiscovery, these individuals are called *data custodians* (or just *custodians*) and are defined as "persons having administrative control of a document or electronic file." For example, the custodian of an email message could be the owner of the mailbox that contains the relevant message.

Additionally, there might be content located in mailboxes and sites that aren't associated with a custodian but that's relevant to the case. Content locations where case custodians don't have administrative control but might be owners of relevant data, are known as *non-custodial data sources*.

In an eDiscovery (Premium) case, legal teams can add individuals in their organization as custodians, and identify and preserve custodial data sources such as Exchange mailboxes, OneDrive accounts, and SharePoint and Teams sites. They can also identify and preserve non-custodial data sources. By using the built-in custodian and data source management tool in eDiscovery (Premium), organizations can secure electronically stored information from inadvertent (or intentional) deletion. This tool lets you eliminate the time-consuming and error-prone process of manually having to perform the legal hold processes.

For more information about working with custodians, see the following articles:

- Add custodians to a case
- Bulk-add custodians to a case

- Manage custodians in a case
- View custodian activity
- Add non-custodial data sources to a case

Last updated on 04/01/2026

Add custodians to an eDiscovery (Premium) case

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Use the built-in custodian management tool in Microsoft Purview eDiscovery (Premium) to coordinate your workflows around managing custodians and identifying relevant, custodial data sources associated with a case. When you add a custodian, the system can automatically identify and place a hold on their Exchange mailbox and OneDrive for Business account. During the discovery process of your investigation, you might also identify other data sources (such as mailboxes, sites, or Teams) that a custodian accessed or contributed to. In this situation, you can use the custodian management tool to associate those data sources will a specific custodian. After you add custodians to a case and associate other data source with them, you can quickly preserve data and search the custodial data.

You can add and manage custodians in eDiscovery (Premium) cases in four steps:

1. Identify the custodians.
2. Choose custodian data locations.
3. Configure hold settings.
4. Review the custodians and complete the process.

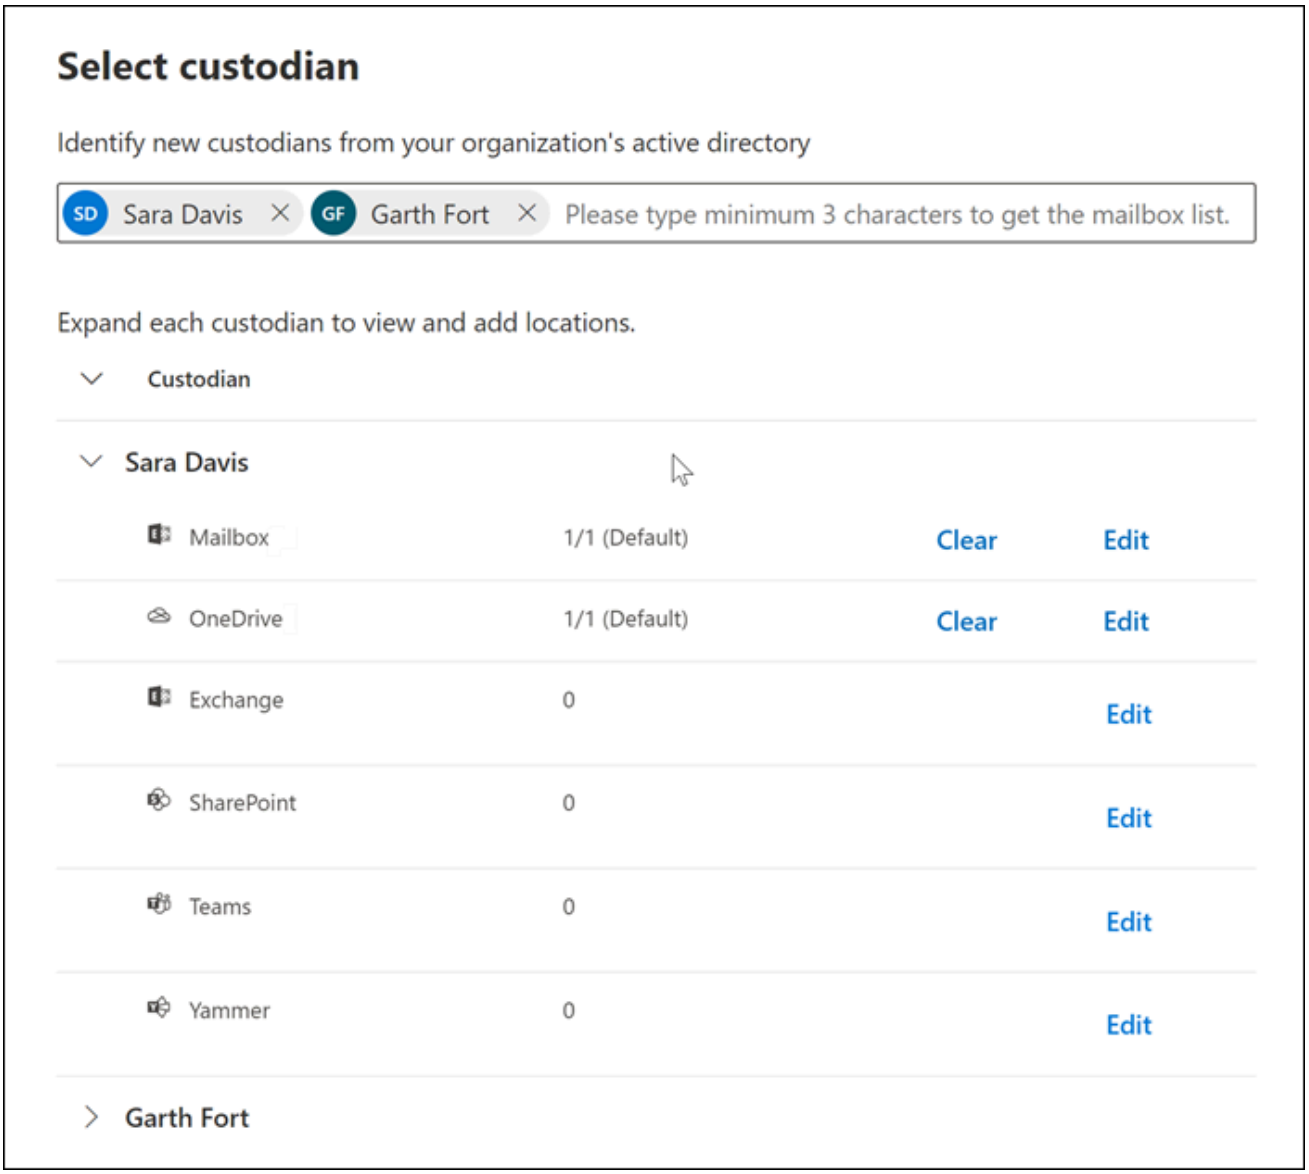
Make sure you have the necessary permissions

To add custodians to a case, you must be a member of the eDiscovery Manager role group. This provides you with the necessary permissions to add custodians to a case and place a hold on the custodial data sources. For more information, see Assign eDiscovery permissions.

Step 1: Identify custodians

1. Go to https://compliance.microsoft.com and sign in with a user account that has been assigned the appropriate eDiscovery permissions.
2. In the left navigation pane, select **eDiscovery** > **eDiscovery (Premium)**, and select the **Cases** tab.
3. Select the case that you want to add custodians to.
4. Select the **Data sources** tab, and then select **Add data source** > **Add new custodians**.
5. Add one or more users in your organization as custodians to the case by typing the first part of a person's name or alias. Both active and inactive users are searched. After you find the correct person, select their name to add them to the list.

Step 2: Choose custodian data locations



After you select custodians, the system automatically attempts to identify and verify these users and their data sources. After adding custodians to the list, the tool automatically includes the primary mailbox and OneDrive account for each active user that has been added as a custodian. If the user is inactive, the tool will only identify the primary mailbox. You can choose not to include these data sources when adding custodians to the case.

In addition to a custodian's mailbox and OneDrive account, you can also associate other data locations to a custodian, such as SharePoint site or a Microsoft Team the custodian is a member of. This allows you to preserve, collect, analyze, and review content in other data sources associated with the custodians of the case.

To deselect the primary mailbox and OneDrive account for a custodian:

1. Expand the custodian to view the primary data locations that have been automatically associated to each custodian.

2. Select **Clear** next to **Mailbox** or **OneDrive** to remove a custodian's mailbox or OneDrive account from being associated as a data location for this custodian.

To associate other mailboxes, sites, Teams, or Viva Engage groups to a specific custodian:

1. Expand a custodian to display the following services to associate data locations with the custodian. Select **Edit** next to a service to add a data location.

    - **Exchange**: Use to associate other mailboxes to the custodian. Type into the search box the name or alias (a minimum of three characters) of user mailboxes or distribution groups. Select the mailboxes to assign to the custodian and then select **Add**.
    - **SharePoint**: Use to associate SharePoint sites to the custodian. Select a site in the list or search for a site by typing a URL in the search box. Select the sites to assign to the custodian and then select **Add**. If a user is inactive, their OneDrive site will need to be added as an additional SharePoint location here.
    - **Teams**: Use to assign the Microsoft Teams the custodian is currently a member of. Select the teams to assign to the custodian and then select **Add**. After you add a team, the system automatically identifies and locates the SharePoint site and group mailbox associated to that team and assigns them to the custodian.

- **Viva Engage**: Use to assign the Viva Engage groups the custodian is currently a member of. Select the groups to assign to the custodian and then select **Add**. After you add a team, the system automatically identifies and locates the SharePoint site and group mailbox associated to that group and assigns them to the custodian.

> ⓘ Note
>
> You can use the **Exchange** and **SharePoint** location pickers to associate any mailbox or site in your organization to a custodian. , This includes associating the mailbox and site for a Microsoft Team or Viva Engage group that a custodian is not a member of. To do this, you have to add both the mailbox and site associated with each team or Viva Engage group.

2. You can view the total number of mailboxes, sites, Teams, and Viva Engage groups assigned to each custodian by expanding each custodian in the table. When you've finalized the assigned data locations for each custodian, these associations will be maintained and used during the collection, processing, and review stages in the eDiscovery (Premium) workflow.

3. After adding custodians and configuring their data locations, select **Next** to go to the **Hold settings** page.

Step 3: Configure hold settings

After you've finalized the custodians and their data locations, you can place some or all of the custodians on hold. When you place a custodian on hold, all content in all content locations that are associated with the custodian is preserved until you remove the hold or release the custodian from the hold. In some cases, you may want to add custodians to a case without placing them on hold. For more information about managing holds, see Manage holds in eDiscovery (Premium).

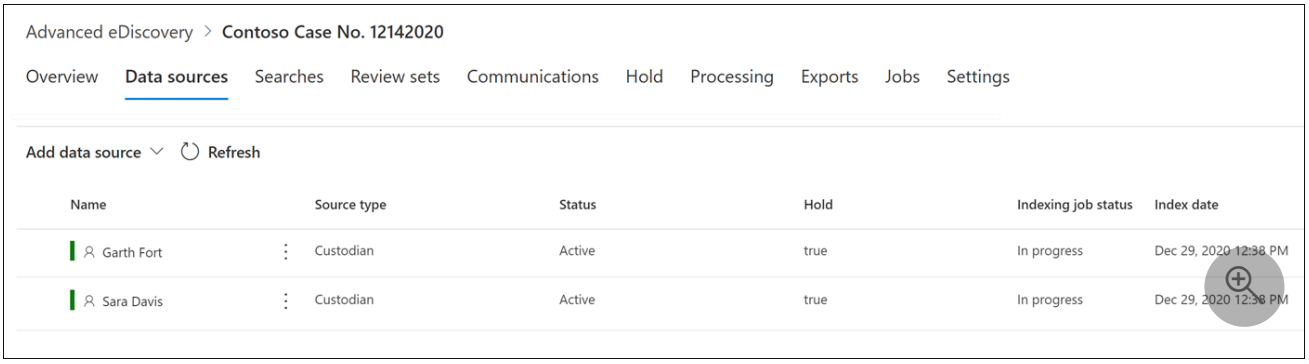
To place the custodians and data sources on hold:

1. On the **Hold settings** page, you can apply a hold to individual custodians by selecting the checkbox under the **Hold** column. Alternatively, you can place all custodians on hold by selecting the **Hold** checkbox at the top of the column.

2. Verify the custodian hold selections and then select **Next**.

> ⓘ Note

If you don't place a hold on a custodian, the custodian and their associated data sources will be added to the case but the content in those data sources won't preserved by the hold that associated with the case.



Step 4: Review the custodians and complete the process

Before you actually add the custodians to the case, you can review the list of custodians, the data locations assigned to them, and the hold settings.

1. Verify and review all the data sources count and the hold setting associated with each custodian in the table. If necessary, go back to the **Identify custodian** or **Hold settings** pages to make any changes.

2. Select **Submit** to add custodians and their data locations to the case and apply all custodial hold settings.

   The new custodians are added to the case and displayed on the **Data sources** tab.

Retry hold action

Once a custodian is placed on hold, you can validate the status in the **Hold** column of the list page. If the hold status isn't equal to *True* (when hold is enabled) or *False* (when hold is disabled), you can multi-select the relevant custodians and select *Retry hold action* at the top of the page. *Retry hold action* is only available for custodial sources and when multiple custodians are selected. If *Retry hold action* is performed for data sources successfully placed or released from hold, no action is triggered.

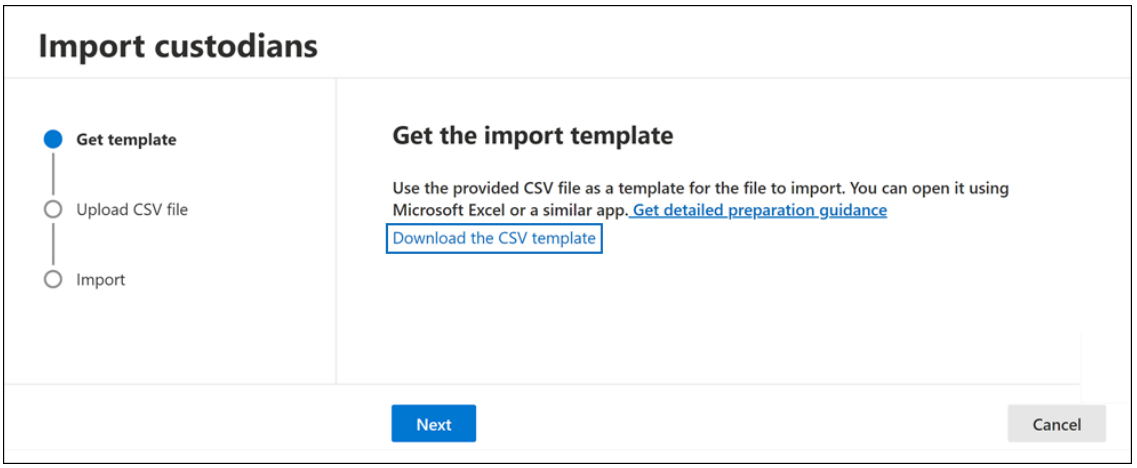
Import custodians to an eDiscovery (Premium) case

> ⊗ **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.



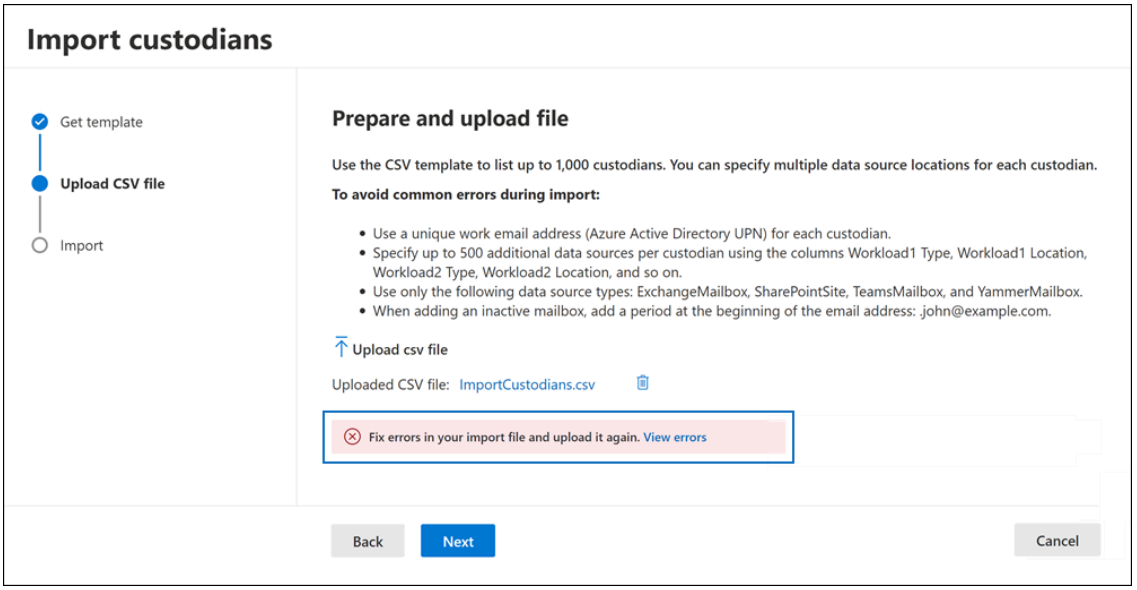
For Microsoft Purview eDiscovery (Premium) cases that involve many custodians, you can import multiple custodians at once by using a CSV file that contains the information necessary to add them to a case. The import custodians tool will also validate the CSV file before the import job is created. This means you can fix any errors in the CSV file instead of having to wait until the import job is complete before learning there are errors that prevent a custodian from being added to the case.

Before you import custodians

- You can import a maximum of 1,000 custodians (rows) per CSV file. Note that importing 1,000 custodians at the same time might result in timeout errors and some custodians might fail the import. To remediate this, repeat the import and the failed custodians should be imported. To avoid timeouts we recommend importing 200 custodians at a time.
- You can associate up to 500 data sources for each custodian.
- You can only import custodians that are part of your organization's Microsoft Entra ID.
- Each custodian must have a unique email address.
- To import an inactive mailbox as a custodian or to associate an inactive mailbox with another custodian, add a "." prefix to the email address of the inactive mailbox (for example, .sarad@contoso.onmmicrosoft.com).

Import custodians

1. Open the eDiscovery (Premium) case and select the **Data sources** tab.
2. Select **Add data source** > **Import custodians**.
3. On the **Get template** workflow page, select **Download the CSV template** to download a custodian template CSV file.



4. Add the custodial information to the CSV file and save it to your local computer. See the Custodian CSV file section for detailed information about the required properties in the CSV file.

5. After you've prepared the CSV file with the custodian information, go back to the **Data sources** tab, and select **Add data source** > **Import custodians** again.

6. On the **Upload CSV file** workflow page, select **Upload csv file** and then upload the CSV file that contains the custodian information.

   After you upload the CSV file, the import workflow validates the CSV file. If any validation errors exist, the workflow displays an error banner with a link to view the errors.

   The error information identifies the row and column of the cell that contains the error, and suggests a remediation action. You have to fix any validation error and then reupload the fixed CSV file. The CSV file must be successfully validated before you can create the import custodian job.

7. Once the CSV file has been successfully validated, select **Next** and then select **Import** to start the import job.

After you start the import job, eDiscovery (Premium) does the following things:

- Creates a job named *Import custodians* on the **Jobs** tab of the case. You can select the *Import custodians* job on the **Jobs** tab to view the status and details of the import custodian job under the **Support information** section. For more information, see Manage jobs.
- Performs Advanced indexing of all data sources for each custodian.
- Places all custodian data sources on hold (if the **Is OnHold** property in the CSV file is set to TRUE)

When the import custodian job is complete, the custodians and their associated data sources are added to the **Data sources** page of the case.

Custodian CSV file

After you download the CSV custodian template, you can add custodians and their data sources in each row. Be sure not to change the column names in the header row. Use the workload type and workload location columns to associate other data sources to a custodian.

Expand table

Column name	Description
Custodian contactEmail	The custodian's UPN email address. For example, sarad@contoso.onmicrosoft.com.
Exchange Enabled	TRUE/FALSE value to include or not include the custodian's mailbox.
OneDrive Enabled	TRUE/FALSE value to include or not include the custodian's OneDrive for Business account.
Is OnHold	TRUE/FALSE value to indicate whether to place the custodian data sources on hold. [1]
Workload1 Type	String value indicating the type of data source to associate with the custodian. Possible values include: - ExchangeMailbox - SharePointSite - TeamsMailbox[2] - Viva EngageMailbox[2]. The previous values for these workload types are case sensitive. The CSV file contains columns for three workload types and their corresponding workload locations. You can add a total of 500 workload types and locations.
Workload1 Location	Depending on your workload type, this would be the location of the data source. For example, the email address for an Exchange mailbox or the URL for a SharePoint site.

> **Note**
>
> [1] If you put more than 1,000 mailboxes or 100 sites on hold in a case, the system will automatically scale the eDiscovery hold as needed. This means the system automatically adds data locations to multiple hold policies, instead of adding them to a single policy. However, the limit of 10,000 case hold policies per organization still applies. For more information about hold limits, see Limits in eDiscovery (Premium).

[2] When you include TeamsMailbox and Viva EngageMailbox workloads in the CSV file, the group site (TeamSite and Viva EngageSite) are automatically added by default. You don't need to specify TeamsSite and Viva EngageSite separately in the CSV file.

Here's an example of a CSV file with custodian information:

Expand table

Custodian contactEmail	Exchange Enabled	OneDrive Enabled	Is OnHold	Workload1 Type	Workload1 Location
robinc@contoso.onmicrosoft.com	TRUE	TRUE	TRUE	SharePointSite	`https://contoso.sharepoint.c`
pillarp@contoso.onmicrosoft.com	TRUE	TRUE	TRUE		
johnj@contoso.onmicrosoft.com	TRUE	TRUE	TRUE		
sarad@contoso.onmicrosoft.com	TRUE	TRUE	TRUE	ExchangeMailbox	.saradavis@contoso.onmicros

Note

As previously explained, add a "." prefix to the UPN address of an inactive mailbox to import an inactive mailbox as a custodian or to associate an inactive mailbox with another custodian.

Retry hold action

Once a custodian is placed on hold, you can validate the status in the **Hold** column of the list page. If the hold status isn't equal to *True* (when hold is enabled) or *False* (when hold is disabled), you can multi-select the relevant custodians and select *Retry hold action* at the top of the page. *Retry hold action* is only available for custodial sources and when multiple custodians are selected. If *Retry hold action* is performed for data sources succesfully placed or released from hold, no action is triggered. For more information about managing holds, see Manage holds in eDiscovery (Premium).

Last updated on 04/22/2026

Manage custodians in an eDiscovery (Premium) case

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The **Data sources** tab in a Microsoft Purview eDiscovery (Premium) case contains a list of all custodians that have been added to the case. After you add custodians to a case, details about each custodian are automatically collected from Microsoft Entra ID and are viewable in eDiscovery (Premium).

View custodian details

The **Data Sources** list view can be filtered by *Source name*, *Source type* (custodian/data location), *Locations*, *Source status*, *Indexing status*, *Hold status*, and *Index date*. The list view can also be grouped by *Data source*, *Source type*, *Source status*, *Hold status*, and *Indexing status*.

To view the details about a custodian, select the custodian from the list on the **Data sources** tab. A flyout page is displayed with the following tabs and information:

- Summary tab
  - Employee information
  - Statuses
- Locations tab
- Import errors

Additionally, the command bar for the custodian flyout page enables the following actions for the custodian:

- **Edit source**: Opens the **Edit custodian** page where you can add or remove data sources associated with the custodian.
- **Update index**: Updates the index for the custodian's data sources. This action is useful when you want to reindex the custodian's data sources to address partially indexed items.
- **Release**: Releases the custodian from the case. This action releases any holds placed on the custodian's data sources through the default hold policies for custodian/non-custodian sources. Any holds placed on the custodian's data sources in other cases or through manual policies (Query base holds) still apply.
- **View activity**: Opens the **View activity** page where you can search for specific activity for the custodian in the audit log.
- **Retry hold action**: Retries the hold for the selected custodians and locations. If the hold option was selected while adding/editing the source, the hold is applied again. If the hold option was not selected while adding/editing the source, the hold is removed.

Summary tab

The **Summary** tab shows the following sections and information about the custodian:

Employee information

- **Title**: The custodian's job title.
- **User principal name**: The user principal name (UPN) for the custodian. For example, user1@contoso.onmicrosoft.com.
- **Manager**: The custodian's manager. The designated manager receives any escalation communications for this custodian.
- **Mailbox**: The custodian's primary mailbox.
- **Location**. The office location in the custodian's place of business.
- **City**: The city in which the custodian works.
- **State**: The state in which the custodian works.
- **Country**: The country/region in which the custodian works.
- **Department**: The name for the department in which the custodian works.

> **Important**
>
> If the UPN of a custodian changes after the custodian is added to a case, the custodian information (Title, Manager, Location, etc.) isn't retained and is displayed in the custodian

summary pane as *No data to show*.

Statuses

- **Hold status**: The hold status of the locations added to the custodian. The hold statuses include:
  - *On hold*: Indicates the custodian and associated locations is successfully placed on hold.
  - *Not on hold*: Indicates the custodian and associated data locations are either not placed on hold or successfully released from hold.
  - *Applying hold*: Indicates the application of hold to the custodian and associated data locations is in progress. Wait until the hold job completes and verify that the hold is placed successfully.
  - *Releasing hold*: Indicates that the release of hold from the custodian and associated data locations is in progress. Wait until the hold job completes and verify if the hold is released successfully.
  - *Partial hold*: Indicates errors for some locations associated with the custodian couldn't be placed on hold.
  - *Partial hold released*: Indicates some locations associated with the custodian weren't released from hold.
  - *Hold failed*: Indicates the hold couldn't be placed on the custodian and any of the associated locations.
  - *Release failed*: Indicates the hold couldn't be released from the custodian and any of the associated locations.

    If the hold couldn't be placed or released successfully, the total count of failed locations with associated error categories and their resolution are displayed in the **Summary** tab. Select **Show locations** to view the full list of failed locations or select **Export list** to download a list of the failed locations by error type. For more information about data source errors, see Manage hold status and errors.

    > ⓘ **Note**

> The improved hold error details and resolution are available only for newly added custodians. A generic error message is displayed for older custodial locations that had previously failed. Users can get the improved error messaging and resolution information for these custodians by selecting **Retry hold action**. This retries the hold and generates the improved error messaging and resolution if the error persists.

- **Indexing status**: Indicates the indexing state, including the last updated date and time (UTC).

Locations tab

This tab shows the count and type of data sources (mailboxes, sites, and Teams) and the hold status for each location associated with the custodian and are part of the case.

- Each data location shows its hold status.
- If you don't see a hold status for a data source, check the status of the custodian hold that's listed on the **Hold** tab for the case. The custodian hold identifies the specific data sources place on hold.

Import errors tab

This tab shows the count and list of locations associated with the custodian that errored during the import custodian process and allows user to remove invalid locations from the sources.

Edit a custodian

As your case progresses, you may discover that there may be additional data sources relevant to a specific custodian and the case. In other scenarios, you may want to remove certain data sources that have been reviewed and deemed as not relevant.

To update the data sources that are associated with a custodian:

1. Go to **eDiscovery** > **eDiscovery (Premium)** and open the case.
2. Select the **Data Sources** tab.
3. Select a custodian from the list, and then select **Edit source** on the flyout page command bar.
4. To add or remove the primary mailbox and OneDrive account for the custodian:

- Expand the custodian to view the primary data locations that have been previously associated with the custodian.
- Select **Edit** next to **Mailboxes** or **OneDrive** to add the custodian's mailbox or OneDrive location.
- Select **Clear** next to **Mailboxes** or **OneDrive** to remove the custodian's mailbox or OneDrive account from being associated as a data location for this custodian.

5. To add or remove other mailboxes, sites, Teams, or Viva Engage groups to a specific custodian, select **Edit** next to the service to add a data location.

   - **Exchange**: Use to associate other mailboxes to the custodian. Type into the search box the name or alias (a minimum of three characters) of user mailboxes or distribution groups. Select the mailboxes to assign to the custodian and then select **Add**.
   - **SharePoint**: Use to associate SharePoint sites to the custodian. Select a site in the list or search for a site by typing a URL in the search box. Select the sites to assign to the custodian and then select **Add**.
   - **Teams**: Use to assign the Microsoft Teams the custodian is currently a member of. Select the teams to assign to the custodian and then select **Add**. After you add a team, the system automatically identifies and locates the SharePoint site and group mailbox associated to that team and assigns them to the custodian.
   - **Viva Engage**: Use to assign the Viva Engage groups the custodian is currently a member of. Select the groups to assign to the custodian and then select **Add**. After you add a team, the system automatically identifies and locates the SharePoint site and group mailbox associated to that group and assigns them to the custodian.

   > ⓘ **Note**
   >
   > You can use the **Exchange** and **SharePoint** location pickers to associate any mailbox or site in your organization, including teams or Viva Engage groups that a custodian is not a member of, to a custodian. To do this, you have to add both the mailbox and site associated with each team or Viva Engage group.

6. After editing the data locations for the custodian, select **Next** to go to the **Hold settings** page.

7. On the **Hold settings** page, update the hold settings for the custodian. Select **Next**.

8. On the **Review** page, review the changes and select **Submit** to save the changes.

Reindex custodian data

In most eDiscovery workflows for legal investigations, a subset of a custodian's data is searched after the custodian is added to a legal case. Because of large file sizes or possible data corruption, some items in the data sources associated with a custodian may be partially indexed. Using the Advanced indexing capability in the eDiscovery (Premium), most partially indexed items can be automatically remediated by reindexing these items on demand.

When a custodian is added to a case, the data located in the data sources associated with the custodian is automatically reindexed (by the Advanced indexing process). This means you can leave the data in-place instead of having to download and remediate it and then search it offline. However, during the lifecycle of a legal case new data sources might be associated with a custodian. In this case, you can reindex the custodian's data by rerunning the Advanced indexing process to remediate any partially indexed items and update the index for the custodian's data.

To trigger the reindexing process to address partially indexed items:

1. Go to **eDiscovery** > **eDiscovery (Premium)** and open the case.
2. Select the **Data sources** tab.
3. On the **Data sources** page, select a custodian whose data must be reindexed.
4. On the flyout page, select **Update index**.A dialog is displayed to confirm the index update, select **Yes** to continue.

Reindexing custodian data is a long-running process; the corresponding job that's created is named **Re-indexing custodian data**. You can track the progress on the **Jobs** tab or on the **Custodians** tab by monitoring the status in the **Indexing job status** column.

For more information, see:

- Work with processing errors
- Manage jobs

Release a custodian from a case

A custodian is released in situations where a case is closed, the custodian is no longer under obligation to preserve content for a case, or when the custodian is deemed to no longer be relevant to the case.

If you release a custodian after a hold notice was published, a release notice will be sent to the custodian. Additionally, any holds placed on data sources that were associated with the custodian

are removed. If the custodian was placed on a *silent hold*, where they weren't issued any legal hold notifications, a release notice won't be sent but any holds placed on data sources that were associated with that custodian are removed.

To release a custodian:

1. Go to **eDiscovery** > **eDiscovery (Premium)** and open the case.
2. Select the **Data sources** tab.
3. On the **Data sources** page, and then select the custodian who is being released from the case.
4. On the flyout page, select **Release**.

   A warning page is displayed explaining that if a hold is placed on a data source associated with the custodian, the hold is removed, and that any other hold associated with a different eDiscovery (Premium) case still apply. That includes other types of preservation and retention features (such as a Microsoft 365 retention policy).
5. Select **Yes** to confirm that you want to release the custodian.

   The status for this user on the **Custodians** tab is set to **Released** and the **Hold status** on the flyout page is changed to **False**.

> **Note**
>
> A custodian may be simultaneously involved in several legal cases. When a custodian is released from a specific case, the holds and notifications across other cases won't be impacted.

Last updated on 09/02/2025

View custodian audit activity

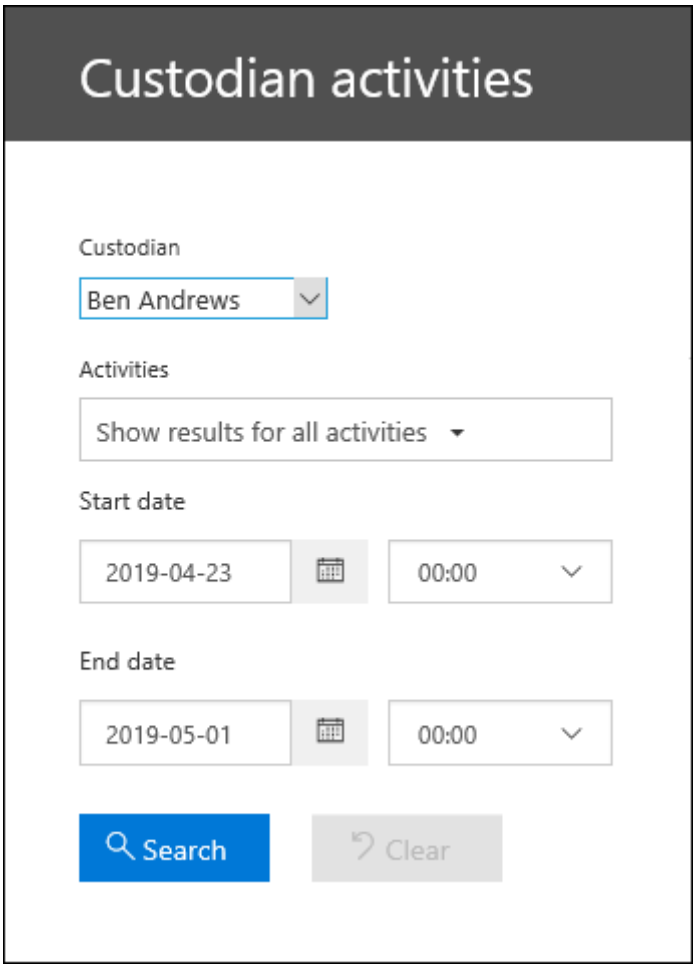
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Need to find if a user viewed a specific document or purged an item from their mailbox? Microsoft Purview eDiscovery (Premium) is now integrated with the existing audit log search tool in the Microsoft Purview portal. Using this embedded experience, you can use the eDiscovery (Premium) Custodian Management tool to facilitate your investigation by easily accessing and searching the activity for custodians within your case.

Get permissions

You have to be assigned the *View-Only Audit Logs* or *Audit Logs* role in Exchange Online to search or export the audit log. By default, these roles are assigned to the *Compliance Management* and *Organization Management* role groups on the **Permissions** page in the Exchange admin center. To give a user the ability to search the eDiscovery (Premium) audit log with the minimum level of privileges, you can create a custom role group in Exchange Online, add the *View-Only Audit Logs* or *Audit Logs* role, and then add the user as a member of the new role group. For more information, see Manage role groups in Exchange Online.

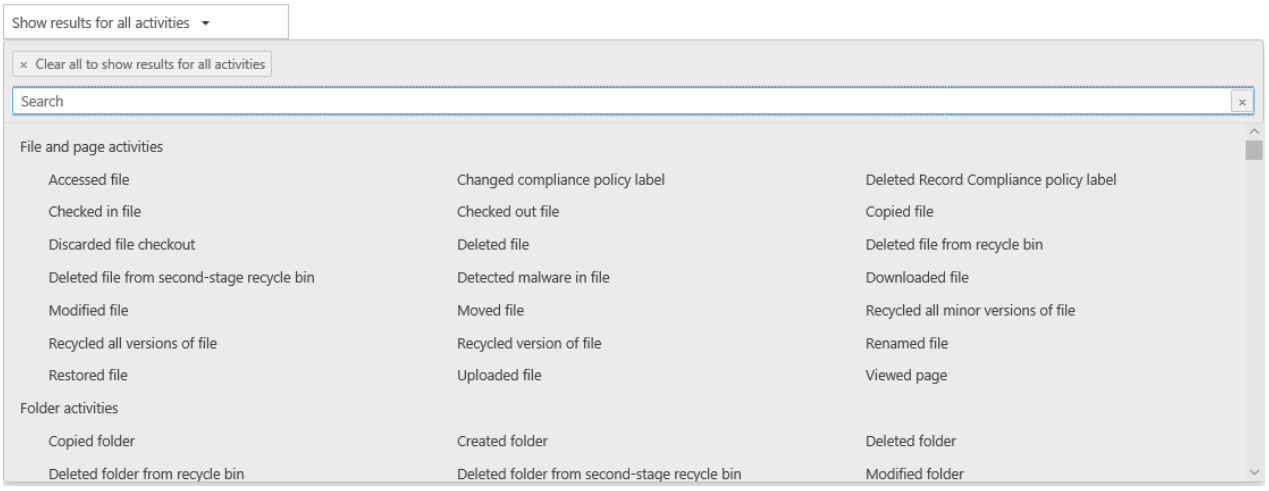
> **Important**
>
> If you assign a user the *View-Only Audit Logs* or *Audit Logs* role on the Permissions page in the Microsoft Purview portal, they won't be able to search or export the audit log. You have to assign the permissions in Exchange Online. This is because the underlying cmdlet used to search the audit log is an Exchange Online cmdlet.



Step 1: Search the audit log for activities performed by a custodian

1. Go to **eDiscovery** > **eDiscovery (Premium)** and open the case.

2. Select the **Sources** tab.



3. On the **Custodians** page, select a custodian from the list, and then select **View custodian activity** on the flyout page.

   The Custodian activities search page is displayed. Note the custodian you selected in the previous step is displayed in the **Custodian** drop-down box. You can select different custodians in the drop-down box, but you can only search for activities for one custodian at a time.

4. Configure the following search criteria:

   a. **Activities** - Select the drop-down list to display the activities that you can search for. After you run the search, only the audit records for the selected activities are displayed. Selecting **Show results for all activities** will display results for all activities performed by the custodian that match the other search criteria.

b. **Start date and End date** - Select a date and time range to display the events that occurred within that period. The last seven days are selected by default. The date and time are presented in Coordinated Universal Time (UTC) format. The maximum date range that you can specify is one year.

c. **Custodians** - Select in this box and then select a specific custodian to display search results for. Audit records for the selected activity performed by the users you select in this box are displayed in the list of results.

5. Select 

to run the search using your search criteria. The search results are loaded, and after a few moments they are displayed under Results on the Custodian Activities search page.

Step 2: View the audit log search results

The results of an audit log search are displayed under Results on the Custodian Audit log page. A maximum of 5,000 (newest) events are displayed in increments of 150 events. To display more events you can use the scroll bar in the Results pane, or you can press Shift + End to display the next 150 events.

The results contain the following information about each event returned by the search.

- **Date**: The date and time (in UTC format) when the event occurred.
- **IP address**: The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format.
- **User**: The user (or service account) who performed the action that triggered the event.
- **Activity**: The activity performed by the user. This value corresponds to the activities that you selected in the Activities drop down list. For an event from the Exchange admin audit log, the value in this column is an Exchange cmdlet.

- **Item**: The object that was created or modified as a result of the corresponding activity. For example, the file that was viewed or modified or the user account that was updated. Not all activities have a value in this column.
- **Detail**: Additional detail about an activity. Again, not all activities will have a value.

Step 3: Filter the search results

In addition to sorting, you can also filter the results of an audit log search. This can help you quickly filter the results for a specific user or activity.

To filter the results:

1. Create and run an audit log search.
2. When the results are displayed, select **Filter results**.
3. Keyword boxes are displayed under each column header.
4. Select one of the boxes under a column header and type a word or phrase, depending on the column you're filtering on. The results will dynamically readjust to display the events that match your filter.
5. To clear a filter, select the **X** in the filter box or just select **Hide filtering**.

Export the search results to a file

You can export the results of an audit log search to a comma separated value (CSV) file on your local computer. You can open this file in Microsoft Excel and use features such as search, sorting, filtering, and splitting a single column (that contains multi-value cells) into multiple columns.

1. Run an audit log search, and then revise the search criteria until you have the desired results.
2. Select Export results and select one of the following options:
    - **Save loaded results:** Choose this option to export only the entries that are displayed under **Results** on the **Custodian Audit log search** page. The CSV file that is downloaded contains the same columns (and data) displayed on the page (Date, User, Activity, Item, and Details). An additional column (titled **More**) is included in the CSV file that contains more information from the audit log entry. Because you're exporting

the same results that are loaded (and viewable) on the Audit log search page, a maximum of 5,000 entries are exported.

- **Download all results:** Choose this option to export all entries from the audit log that meet the search criteria. For a large set of search results, choose this option to download all entries from the audit log in addition to the 5,000 results that can be displayed on the **Custodian Audit log** search page. This option will download the raw data from the audit log to a CSV file, and contains additional information from the audit log entry in a column named AuditData. It may take longer to download the file if you choose this export option because the file may be much larger than the one that's downloaded if you choose the other option.

  > **Important**
  >
  > You can download a maximum of 50,000 entries to a CSV file from a single audit log search. If 50,000 entries are downloaded to the CSV file, you can probably assume there are more than 50,000 events that met the search criteria. To export more than this limit, try using a date range to reduce the number of audit log entries. You might have to run multiple searches with smaller date ranges to export more than 50,000 entries.

3. After you select an export option, a message is displayed at the bottom of the window that prompts you to open the CSV file, save it to the Downloads folder, or save it to a specific folder

For more information about viewing, filtering, or exporting audit log search results, see Search the audit log.

Add non-custodial data sources to an eDiscovery (Premium) case

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

In Microsoft Purview eDiscovery (Premium) cases, it doesn't always meet your needs to associate a Microsoft 365 data source with a custodian in the case. But you may still need to associate that data with a case so that you can search it, add it to a review set, and analyze and review it.

Non-custodial data sources in eDiscovery (Premium) let you add data to a case without having to associate it to a custodian. It also applies the same eDiscovery (Premium) functionality to non-custodial data that's available for data associated with custodian. Two of the most useful things that you can apply to non-custodial data is placing it on hold and processing it using Advanced indexing.

Add a non-custodial data source

Complete the following steps to add and manage non-custodial data sources in an eDiscovery (Premium) case.

1. In the Microsoft Purview portal, select **eDiscovery** > **Premium**.
2. Select the **Cases** tab and select the case that you want to add the data to.
3. Select the **Data sources** tab and then select **Add data source** > **Add data locations**.
4. On the **New non-custodial data locations** flyout page, choose the data sources that you want to add to the case. Select one or more of the following data source locations:

- **SharePoint**: Expand this section and select **Edit** to add SharePoint sites. Complete the following steps to add sites and configure holds:
  a. Select a site in the list or you can search for a site by typing the URL of the site in the search bar. Select the sites that you want to add as non-custodian data sources and select **Add**.
  b. After you add non-custodial data sources, you can place those locations on hold or not. Select or unselect the **Hold** checkbox next to the data source to place it on hold.
  c. Select **Add** at the bottom of the **New non-custodial data locations** flyout page to add the data sources to the case.

- **Exchange**: Expand this section and select **Edit** to add one or more Exchange mailboxes. Complete the following steps to add mailboxes and configure holds:
  a. Type a name or alias (a minimum of three characters) in the search box for mailboxes or distribution groups. Select the mailboxes that you want to add as non-custodian data sources and select **Add**.
  b. After you add non-custodial data sources, you can place those locations on hold or not. Select or unselect the **Hold** checkbox next to the data source to place it on hold.
  c. Select **Add** at the bottom of the **New non-custodial data locations** flyout page to add the data sources to the case.

  > **Note**
  >
  > You can use the **SharePoint** and **Exchange** sections to add sites and mailboxes associated with a Team or Viva Engage group as non-custodial data sources. You have to separately add the mailbox and site associated with a Team or Viva Engage group.
  >
  > Also, adding a root site URL (such as `https://contoso-my.sharepoint.com/personal/` or `https://contoso-my.sharepoint.com/`) as a SharePoint data source isn't supported. You have to add specific sites.

- **Teams**: Expand this section and select **Add Teams locations** to add one or more Microsoft Teams channels. Complete the following steps to add channels and configure holds:
  a. On the **Channels** page, enter a team name and select from the channels associated with the team. You can add up to 10 teams at one time and all the associated

private, standard, and shared channels. Select **Next**. This automatically selects the [storage locations] (/purview/ediscovery-teams-workflow#where-teams-content-is-stored) where the channel messages and files are stored.

b. On the **Configure holds** page, select the locations associated with each Team and channel to place on a hold. Select **Next**.

c. On the summary page, review the selected channel locations and hold configuration. Select **Add channels** to add the channels and configure holds.

d. The **Status** page confirms if the locations were added successfully or if the location already exists in the case. Select **Done**.

Each non-custodial data source that you added is listed on the **Data sources** page. Non-custodial data sources are identified by the *Data location* value in the **Source type** column.

After you add non-custodial data sources to the case, a job named *Reindexing non-custodial data* is created and displayed on the **Jobs** tab of the case. After the job is created, the Advanced indexing process in initiated and the data sources are reindexed. For more information about managing holds, see Manage holds in eDiscovery (Premium).

Release a hold for non-custodial data sources

After you place a hold on a non-custodial data source, a hold policy that contains the non-custodial data sources for the case is automatically created. When you place other non-custodial data sources on hold, they're added to this hold policy.

To release a hold on a non-custodial data source, complete the following steps:

1. In the Microsoft Purview portal, select **eDiscovery** > **Premium**.
2. Select the **Cases** tab and select the case that you want to add the data to.
3. Select the **Data sources** tab and the locations to release from hold.
4. Select **Release**.
5. Select **Yes** to release the hold for the location. Any holds placed on the data sources in other cases still apply.

Last updated on 11/21/2025

Work with communications in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Microsoft Purview eDiscovery (Premium) allows legal departments to simplify their processes around tracking and distributing legal hold notifications. The custodian communications tool enables legal departments to manage and automate the entire legal hold process, from initial notifications, to reminders, and to escalations, all in one location.

What is a legal hold notification?

A legal hold (also known as a *litigation hold*) notice is a notification sent from an organization's legal department to employees, contingent staff, or custodians of data that may be relevant to a legal investigation. These notifications instruct custodians to preserve electronically stored information and any content that may be relevant to an active or impending legal matter. Legal teams must know that each custodian has received, read, understood, and has agreed to comply with the given instructions.

The legal hold notification process

An organization has a duty to preserve relevant information when it learns about an impending litigation or regulatory investigation. To comply with the preservation requirements of an investigation, the organization should immediately inform potential custodians about their duty to preserve relevant information.

With eDiscovery (Premium), legal teams can create and customize their legal hold notification workflow. The custodian communications tool lets legal teams configure the following notices

and workflows:

1. **Issuance notice:** A legal hold notice is issued (or initiated) by a notification from the legal department to custodians who may have relevant information about the case matter. This notice instructs the custodians to preserve any information that may be needed for discovery.

2. **Re-Issuance notice:** During a case, custodians may be required to preserve more content (or less content) than was previously requested. For this scenario, you can update the existing hold notice and reissue it to custodians.

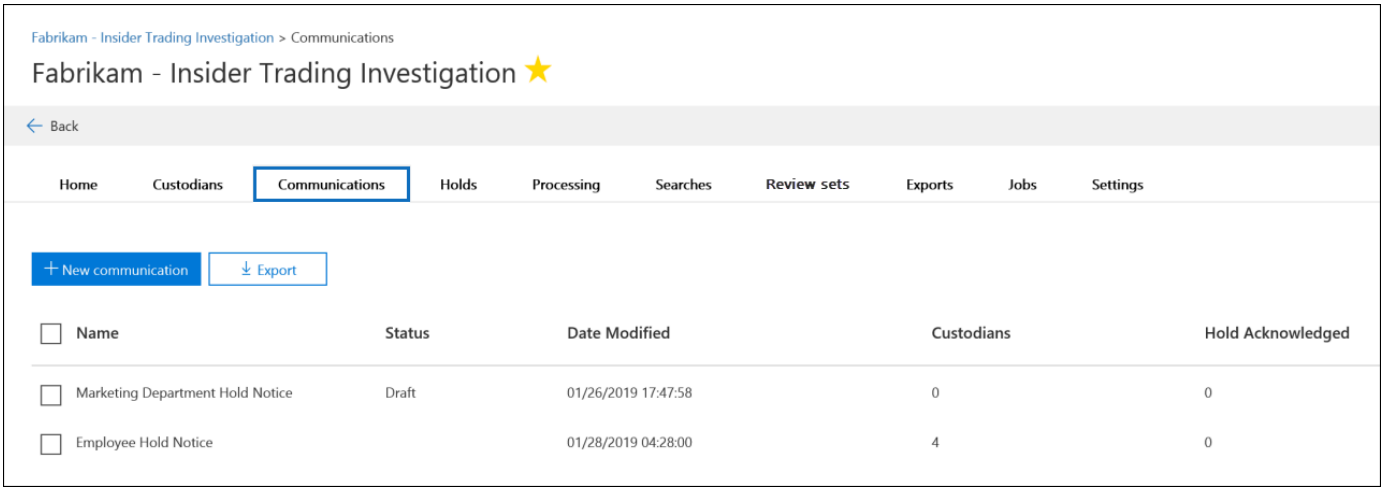
3. **Release notice:** Once a matter is resolved and the custodian is no longer subject to a preservation requirement, the custodian can be released from the case. Additionally, you can notify the custodian that they're no longer required to preserve content, and provide instructions about how to resume their normal work activity and their data.

4. **Reminders and escalations:** In some instances, just issuing a notice isn't enough to satisfy legal discovery requirements. With each notification, legal teams can schedule a set of reminder and escalation workflows to automatically follow up with unresponsive custodians.

    - **Reminders:** After a legal hold notice has been issued or reissued to a set of custodians, an organization can set up reminders to alert unresponsive custodians.

    - **Escalations:** In some cases, if a custodian remains unresponsive even after a set of reminders over a period of time, the legal team can set up an escalation workflow to notify unresponsive custodians and their manager.

For more information about managing the custodian communication process, see the following:

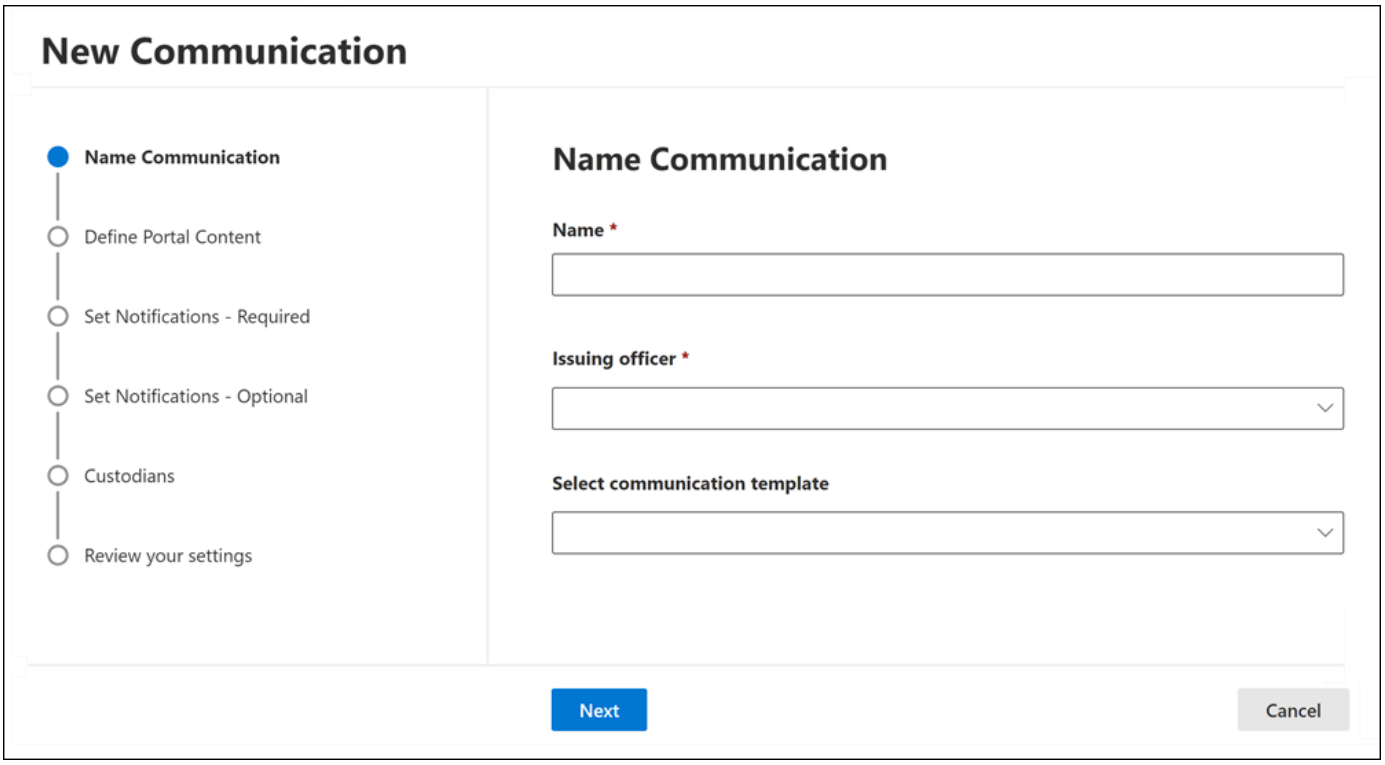


- Create a legal hold notice
- Use the communications editor
- Manage hold notifications
- Acknowledge a hold notification

Last updated on 11/21/2025

Create a legal hold notice

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.



Using eDiscovery (Premium) custodian communications, organizations can manage their workflow around communicating with custodians. Through the Communications tool, legal teams can systematically send, collect, and track legal hold notifications. The flexible creation process also allows teams to customize the hold notification workflow and the content in the notices sent to custodians.

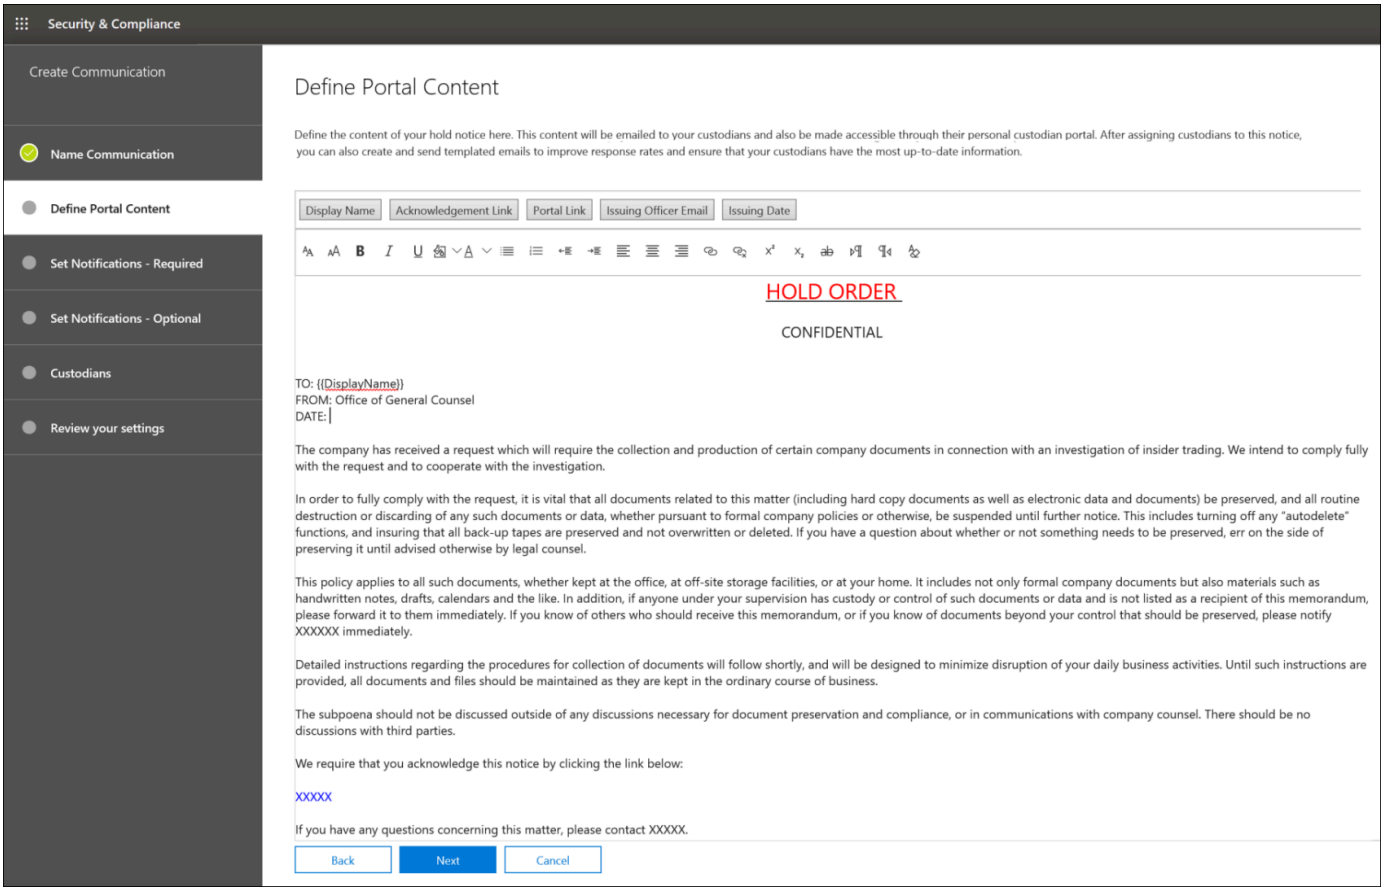
The article outlines the steps in the hold notification workflow.

Step 1: Specify communication details

The first step is to specify the appropriate details for legal hold notices or other custodian communications.

1. In the Microsoft Purview portal, go to **eDiscovery** > **Premium** to display the list of cases in your organization.

2. Select a case, select the **Communications** tab, and then select **New communication**.



3. On the **Name communication** page, specify the following communication settings.

    - **Name**: This is the name for the communication.
    - **Issuing officer**: The drop-down list displays users in your organization who can be selected as the issuing officer for the communication. Each communication sent to custodians will be sent on behalf of the selected issuing officer. The list of users in the drop-down consists of the members of the case and the organization-wide issuing officers. These issuing officers are added by an eDiscovery Administrator, and are available in all eDiscovery (Premium) cases in your organization. For more information, see Manage issuing officers.
    - **Select communication template**: The drop-down list displays the templates from the Communications library on the eDiscovery (Premium) settings page. If you select a template, it will be displayed on the **Define portal content** as a starting point for the text of the notification that you're creating. If you don't select a template, then you'll have to create the notice yourself from scratch. For more information about communication templates, see Manage custodian communications templates.

4. Select **Next**.

Step 2: Define the portal content

Next, you can create and add the content of the hold notice. On the **Define portal content** page in the **Create communication** workflow, specify the contents of the hold notice. This content will be automatically appended to the Issuance, Re-Issue, Reminder, and Escalation notices. Additionally, this content will appear in the custodian's Microsoft Purview portal. If you selected a template from the Communications library, it will be displayed and provide a starting point for the notice you're creating.

To create the portal content:

1. Type (or cut and paste from another document) your hold notice in the textbox for the portal content. If you selected a communications template on the previous workflow page, the template is displayed. You can edit the template content as necessary.
2. Insert merge variables into your notice to customize the notice and share the Custodian in the Microsoft Purview portal.
3. Select **Next**.

> **Tip**

To learn more about how to can customize the content and format of the portal content, see **Use the Communications Editor**.

Step 3: Set the required notifications

After you've defined the contents of the hold notice, you can set up the workflows around sending and managing the notification process. Notifications are email messages that are sent to notify and follow up with custodians. Every custodian added to the communication will receive the same notification.

To set up and send a hold notice, you must include Issuance, Re-Issuance, and Release notifications.

Issuance notification

After the communication is created, the **Issuance Notification** is initiated by the specified Issuing Officer. The Issuance notification is the first communication sent to the custodian to inform them about their preservation obligations.

To create an issuance notification:

1. In the **Issuance** tile, select **Edit**.
2. If necessary, add additional case members or staff to the **Cc** and **Bcc** fields. To add multiple users to these fields, separate email addresses with a semi-colon and without spaces between the addresses. For example, *user1@contoso.com;user2@contoso.com;user3@contoso.com*.
3. Specify the **Subject** for the notice (required).
4. Specify the contents or additional instructions that you would like to provide to the custodian (required). The portal content you defined in Step 2 is added to the end of the issuance notice.
5. Select **Save**.

Re-Issuance notification

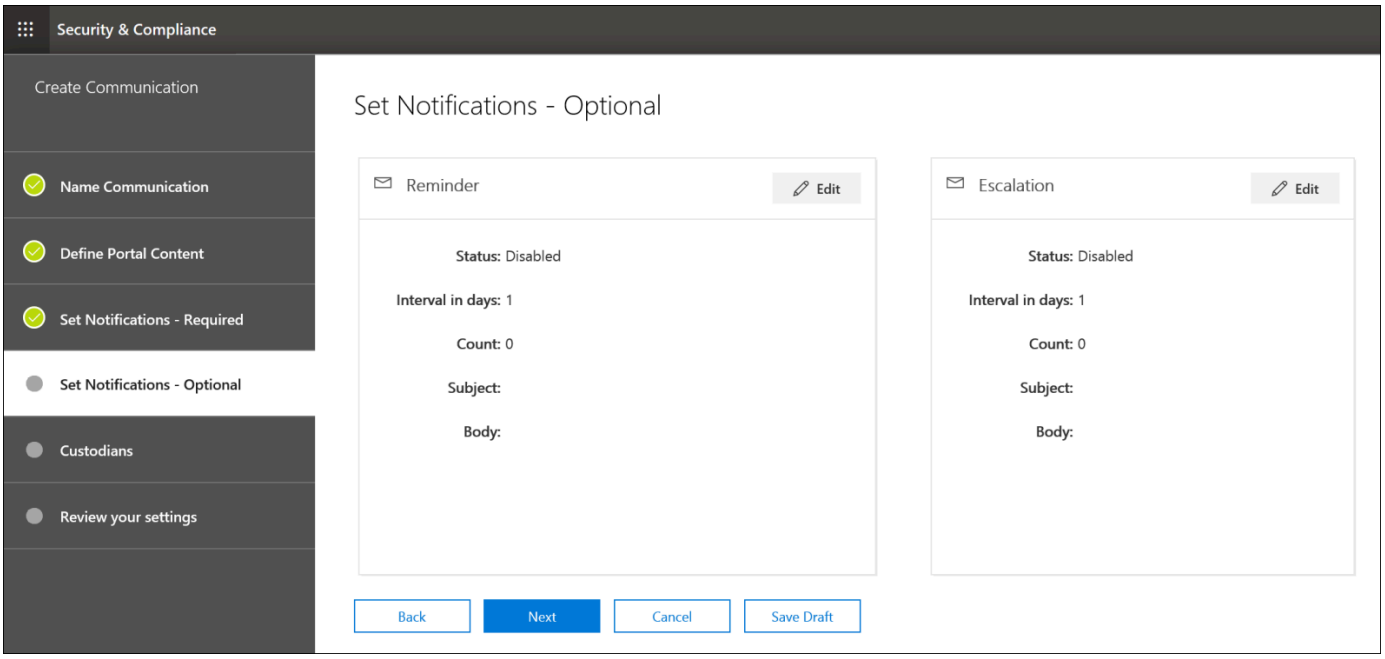
As the case progresses, custodians may be required to preserve additional or less data than was previously instructed. After you update the portal content, the reissuance notification is sent and alerts custodians about any changes to their preservation obligations.

To create a reissuance notification:

1. In the **Reissue** tile, select **Edit**.
2. If necessary, add additional case members or staff to the **Cc** and **Bcc** fields. To add multiple users to these fields, separate email addresses with a semi-colon and without spaces between the addresses. For example, *user1@contoso.com;user2@contoso.com;user3@contoso.com*.
3. Specify the **Subject** for the notice (required).
4. Specify the contents or additional instructions that you would like to provide to the custodian (required). The portal content you defined in Step 2 is added to the end of the reissuance notice.
5. Select **Save**.

> **Note**
>
> If the portal content is modified (on the **Define Portal Content** page in the **Edit communication** workflow), the re-issuance notification will be automatically sent to all custodians assigned to the notice. After the notification is sent, custodians will be asked to re-acknowledge their hold notice. If you have set up any reminder or escalation workflows, these will also re-start. For more information about what other case management events trigger communications, see Events that trigger notifications.

Release notification



After a matter is resolved or if a custodian is no longer subject to preserve content, you can release the custodian from a case. If the custodian was previously issued a hold notice, the release notification can be used to alert custodians that they've been released from their obligation.

To create a release notification:

1. In the **Release** tile, select **Edit**.
2. If necessary, add additional case members or staff to the **Cc** and **Bcc** fields. To add multiple users to these fields, separate email addresses with a semi-colon and without spaces between the addresses. For example, *user1@contoso.com;user2@contoso.com;user3@contoso.com*.
3. Specify the **Subject** for the notice (required).
4. Specify the contents or additional instructions that you would like to provide to the custodian (required).
5. Select **Save** and go to the next step.

(Optional) Step 4: Set the optional notifications

Optionally, you can simplify the workflow for following up with unresponsive custodians by creating and scheduling automated reminder and escalation notifications.

Reminders

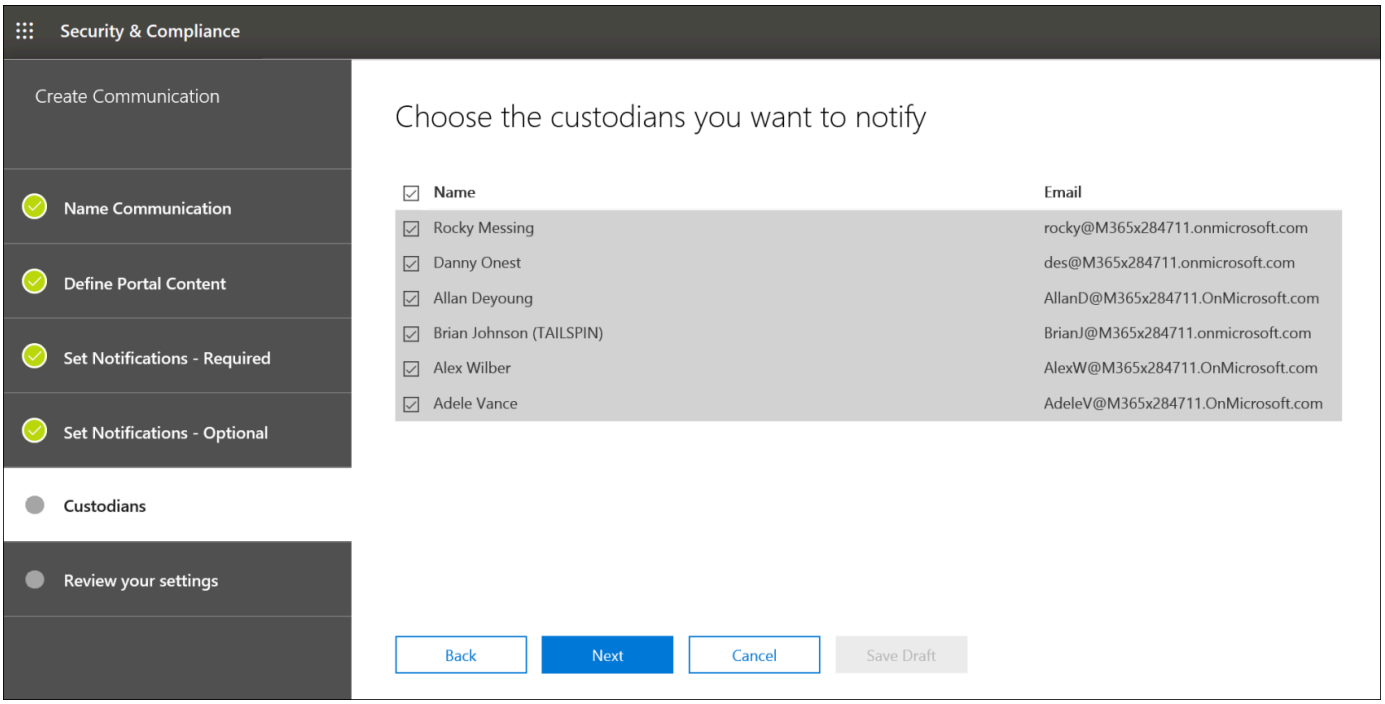
After you've sent a hold notification, you can follow up with unresponsive custodians by defining a reminder workflow.

To schedule reminders:

1. In the **Reminder** tile, select **Edit**.
2. Enable the **Reminder** workflow by turning on the **Status** toggle (required).
3. Specify the **Reminder interval (in days)** (required). This is the number of days to wait before sending the first and follow-up reminder notifications. For example, if you set the reminder interval to seven days, then the first reminder would be sent seven days after the hold notification was initially issued. All subsequent reminders would also be sent every seven days.
4. Specify the **Number of reminders** (required). This field specifies how many reminders to send to unresponsive custodians. For example, if you set the number of reminders to 3, then a custodian would receive a maximum of three reminders. After a custodian acknowledges the hold notification, reminders will no longer be sent to that user.
5. Specify the **Subject** for the notice (required).
6. Specify the contents or additional instructions that you would like to provide to the custodian (required). The portal content you defined in Step 2 is added to the end of the

reminder notice.
7. Select **Save** and go the next step.

Escalations



In some situations, you may need additional ways to follow up with unresponsive custodians. If a custodian doesn't acknowledge a hold notification after receiving the specified number of reminders, the legal team can specify a workflow to automatically send an escalation notice to the custodian and their manager.

To schedule escalations:

1. In the **Escalation** tile, select **Edit**.
2. Enable the **Escalation** workflow by turning on the **Status** toggle.
3. Specify the **Escalation interval (in days)** (required).
4. Specify the **Number of escalations** (required). This field specifies how many escalations to send to unresponsive custodians. For example, if you set the number of escalations to 3, then an escalation notice would be sent to the custodian and their manager a maximum of three times. After a custodian acknowledges the hold notification, escalations will no longer be sent.
5. Specify the **Subject** for the notice (required).
6. Specify the contents or additional instructions that you would like to provide to the custodian (required). The portal content you defined in Step 2 is added to the end of the escalation notice.
7. Select **Save** and go the next step.

Step 5: Assign custodians to receive notifications

After you've finalized the content for notifications, select the custodians that you would like to send notifications to.

To add custodians:

1. Assign custodians to the communication by selecting the checkbox next to their name.

   After the communication is created, the notification workflow will automatically apply to the selected custodians.

2. Select **Next** to review the communication settings and details.

> **Note**
>
> You can only add custodians who have been added to the case and haven't been sent another notification within the case. If the custodian is inactive or released, they can't be added to any new communications.

Step 6: Review settings

After you review the settings and select **Send** to complete the communication, the system will automatically start the communication workflow by sending the issuance notice.

Events that trigger notifications

The following table describes events in the case management process that trigger when the different types of notifications are sent to custodians.

Expand table

Type of communication	Trigger
Issuance notices	The initial creation of the notification. You can also manually resend a hold notification.
Reissuance notices	Updating the portal content on the **Define Portal Content** page in the **Edit communication** workflow.
Release notices	The custodian is released from the case.
Reminders	The interval and number of reminders configured for the reminder.
Escalations	The interval and number of reminders configured for the escalation.

Use the communications editor

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

As you define the content of your portal content, legal hold notifications, and related reminders/escalations, you can use the Communications Editor to format and dynamically customize your content.

Rich text editor

The Communications Editor allows user to customize the text using the editor options. For example, users can change font types, create bulleted lists, highlight content, and more.

Merge field variables

You can use email merge variables from the Communications Editor to embed customized custodian attributes into a communication's body text. When sent to the custodian, the merge field will be populated with the corresponding field. For example, when sent to custodian John Smith, the merge field [Custodian Name] would be translated with the corresponding name.

You can use email merge fields by selecting the **Merge field** icons on the top of the rich-text editor control. The placeholder will be added based off the location of the users' cursor.

List of merge field variables

Expand table

Field name	Field details
Display Name	The custodian's first and last name.
Acknowledgment Link	A customized link to record each custodian's acknowledgment.
Portal Link	A customized link for the custodian's Microsoft Purview portal.
Issuing Officer	The email address of the specified issuing officer.
Issuing Date	The date that the notice was issued (UTC).

Manage hold notifications

> **Important**
>
> Legal hold communications with custodians was permanently **retired on August 31, 2025**, this functionality isn't available in the new eDiscovery experience.

After you've initiated your legal hold notification workflow, you can use the communications workflow in Microsoft Purview eDiscovery (Premium) to track the status of your communications. The Communications tab contains a list of all notifications within your eDiscovery (Premium) case. You can see details such as the number of custodians that have been assigned or have acknowledged the notice.

Monitor acknowledgments

After you select a communication from the **Communications** tab, you can view a list of custodians that have acknowledged a hold notice.

1. In the Microsoft Purview portal, go to **eDiscovery** > **eDiscovery (Premium)**.
2. Select a case and then select the **Communications** tab.
3. Select a communication to display the **Custodian communication** flyout page.

A list of custodians associated with the selected communication is displayed on the communication flyout page. This page also displays insights and about how many acknowledgments were received and how many are outstanding. The page also shows which custodians have sent an acknowledgment that they received the hold notification.

Resend a hold notice

Occasionally, custodians lose track of email messages in their day-to-day work. Or for a long-running litigation case, a custodian may contact you or others and request that you resend a notice. As you manage the communications workflow for legal hold notices, you may need to resend a notice to bring it back to the "top of a user's mailbox".

To resend a hold notice to a custodian:

1. In eDiscovery (Premium), select a case and then select the **Communications** tab.

2. Select a communication to display the **Custodian communication** flyout page.
3. Select **More** > **Re-send hold notice**.
4. On the **Re-send hold notice** flyout page, select the custodians that you what to resend the notice and type an optional reason.
5. Select **Re-send** to send the notice to the selected custodians.

If a custodian hasn't acknowledged the hold notification, the reminder and escalation workflow is restarted. If a custodian has acknowledged the hold notice, the custodian will receive a copy of the original hold notice.

> ⓘ **Note**
>
> You can only resend a legal hold notification to custodians that are assigned to the communication.

Update preservation requirements

As the case progresses, custodians may be required to preserve additional or less data than was previously instructed. In eDiscovery terms, you need to reissue the hold notice with updated content.

To update the contents of the initial hold notice:

1. In eDiscovery (Premium), select a case and then select the **Communications** tab.
2. Select the hold notice that you want to update and select **Edit** on the **Custodian communication** flyout page.
3. In the **Edit Communication** workflow, select **Define Portal Content** in the left pane of the workflow, and update the contents of the notice.
4. Select **Save**.

The reissuance notice will be sent to all the custodians assigned to the legal hold notification. In addition, if the Reminder or Escalation notice is enabled, then the workflows for those types of notices will restart.

Update legal hold notifications and settings

When you update the content or settings of the Issuance, Release, Reissue, Reminder, or Escalation notice, these changes will apply to all future communications generated by the workflow.

More information

- Add custodians to a case
- Create a legal hold notice
- Acknowledge a hold notification

Last updated on 09/02/2025

Acknowledge a hold notification

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When responding to a regulatory request or investigation, you might need to inform custodians of their obligation to preserve electronically stored information (ESI) and any material that might be relevant to an active or imminent legal matter. After you send the notification, legal teams need to know that each custodian receives, reads, understands, and agrees to follow the given instructions.

To help reduce the time, cost, and effort of following up with your custodians, eDiscovery (Premium) enables you to send and follow up on legal hold notifications through email. In addition to email notices, each custodian can access an individualized Microsoft Purview portal, so custodians stay informed of changes to their obligation status.

Email notifications

After you issue a Legal Hold Notification, each custodian receives a unique and personalized email containing your defined legal hold notice and added instructions.

> **Tip**
>
> To allow your custodians to acknowledge their notice or access their Microsoft Purview portal directly from their email, see how you can use the built-in Communication Editor.

Based on the configuration of your legal hold notification, your custodians might receive the following notices:

- **Issuance notice:** The first notice you send to your custodian. This notice contains your issuance instructions and the hold notice appended to the end of your message.
- **Reminder notice:** If you enable this notice, your custodians receive a reminder notice based on the specified frequency and interval. The reminders continue to be sent either until the custodian acknowledges their notice or until the number of reminders is exhausted.
- **Escalation notice:** If you enable this notice, your custodian and their manager receive an escalation notice after the reminder notices are exhausted. The system automatically sends escalation notices until the specified number of escalations is completed or until the custodian acknowledges their hold notification.
- **Reissue notice:** During an investigation, if you update the contents of the hold notice, the updated notice is automatically sent to the custodian.
- **Release notice:** When you release a custodian from the case, you send the release notice to the custodian.

Microsoft Purview portal

In addition to the email notifications, each custodian can access a unique Microsoft Purview portal. Through the Microsoft Purview portal, each custodian can view, access, and acknowledge their active hold notifications.

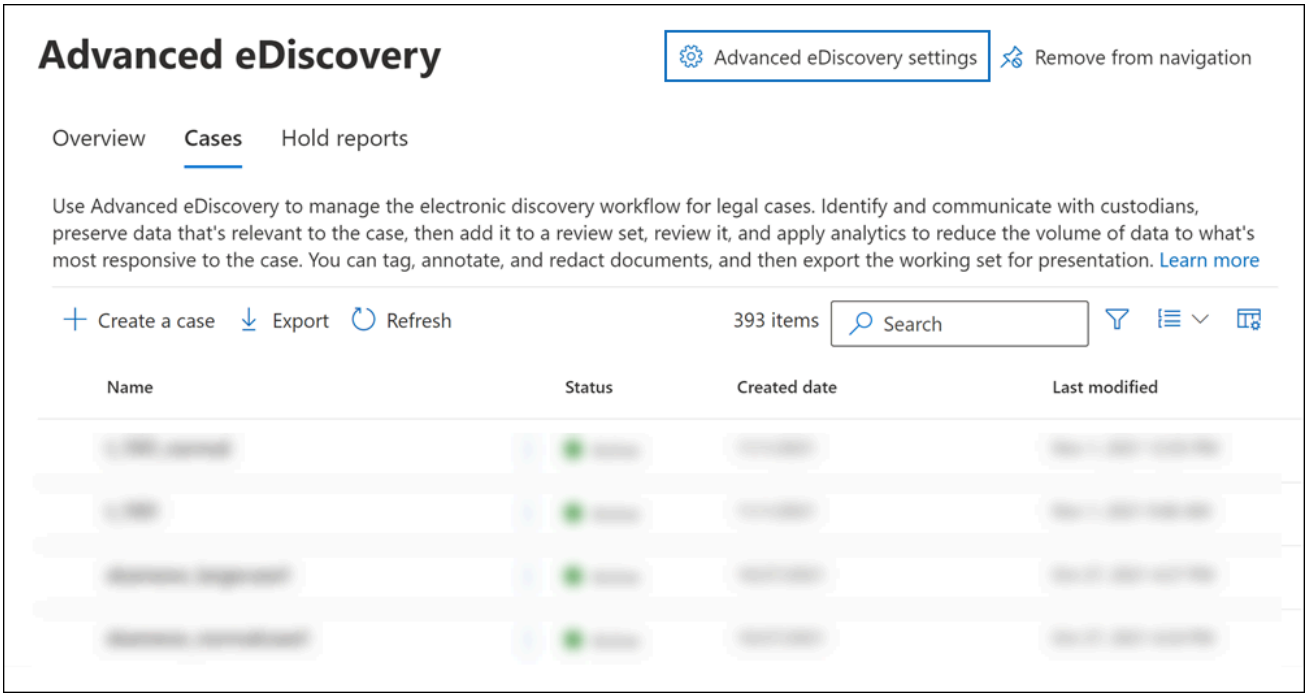
Manage issuing officers in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When you or others create a hold notification or other type of communication that is sent to a user who is a custodian in case, you have to specify an issuing officer. The notification is sent to the custodian on behalf of the specified issuing officer. For example, a paralegal in your organization might be responsible for creating and sending hold notifications to custodians in a case. In this scenario, the paralegal can specify an attorney in the organization as the issuing officer. Who can be specified as an issuing officer? There are two types of users who can be selected as an issuing officer for a custodian communication:

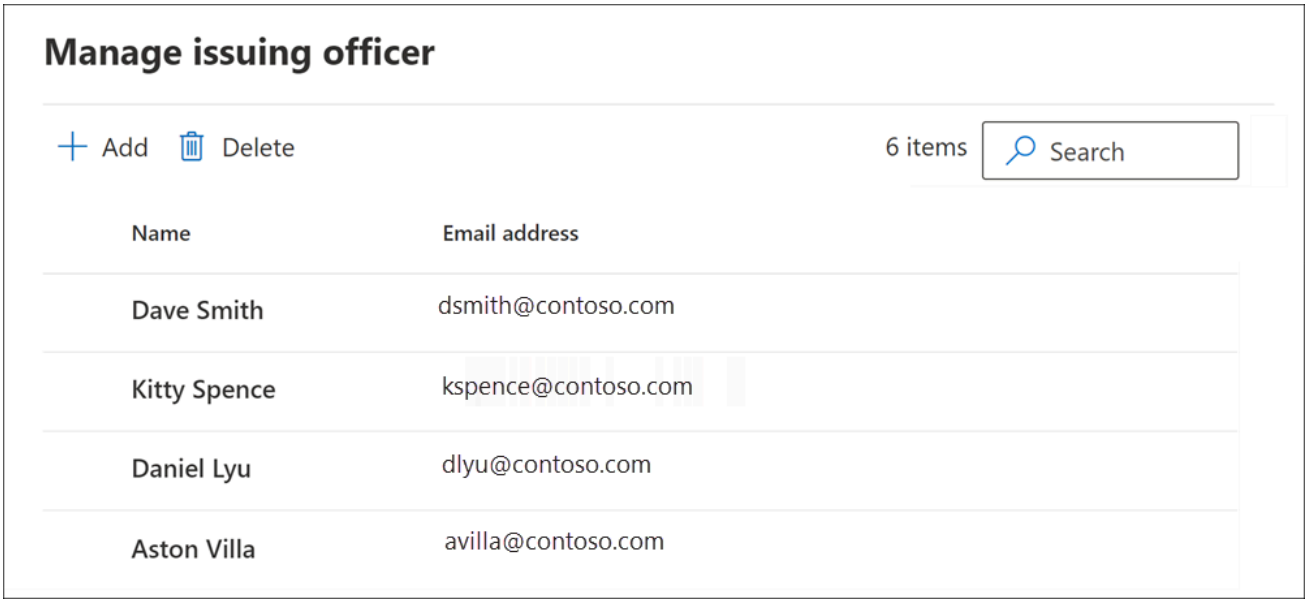
- Any member of the specific case the communication is being sent in behalf of.
- Any user who is added to a list of organization-wide issuing officers. Users from this list can be added an issuing officer to any case in your organization.

This article explains how to add and remove users to the list of organization-wide issuing officers.



Before you add an issuing officer

- You must be an eDiscovery Administrator in your organization to add or remove issuing officers. For more information, see Assign eDiscovery permissions in the Microsoft Purview portal
- The user who is added as an issuing officer must have an active mailbox in your Microsoft 365 organization.
- Your organization can have a maximum of 15 issuing officers. Members of a case who can be specified as an issuing officer aren't counted toward this limit. This limit only applies to



the number of users that can be added to the **Issuing officers** page in eDiscovery (Premium).

Add an issuing officer

1. In the Microsoft Purview portal, go to eDiscovery (Premium), and then select **eDiscovery (Premium) settings**.

2. On the **Settings** page, select the **Issuing officers** tab to display the **Manage issuing officers** page.

3. Select **Add** and then search for and add one or more users to the list of issuing officers.

After you add users as issuing officers, you or other users will be able to specify these users as an issuing officer for custodian communications for any case in your organization. For more information about creating custodian communications, see Create a legal hold notice.

Remove an issuing officer

1. In the Microsoft Purview portal, go to eDiscovery (Premium), and then select **eDiscovery (Premium) settings**.
2. On the **Settings** page, select the **Issuing officers** tab.
3. Select one or more users in the issuing officers list, and then select **Delete**.

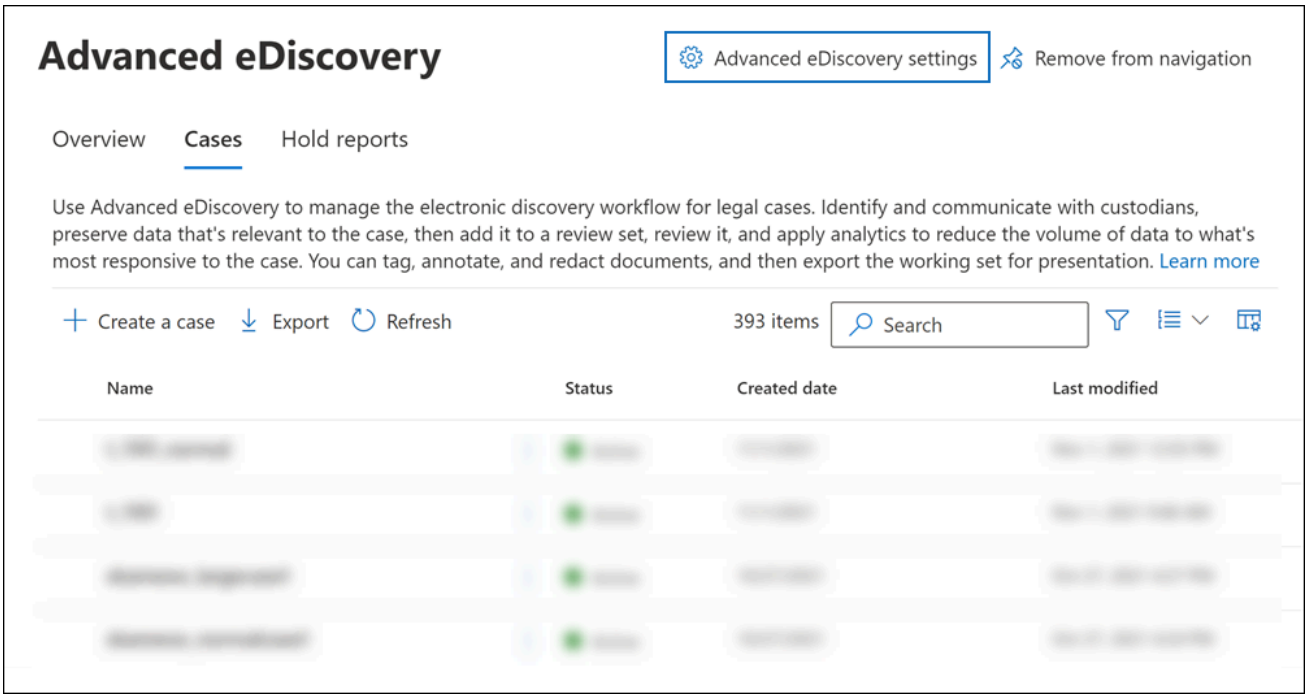
After you delete users from the list of issuing officers, those users can no longer be specified as an issuing officer in new custodian communications, unless the user is a member of the specific case the communication is being issued from. Also, removing an issuing officer won't affect any communications that were sent before the user was removed as an issuing officer.

Last updated on 11/21/2025

Manage custodian communications templates in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When you or other users create a hold notification or other types of custodian communications, you had to create the communication document from scratch by using the communications editor on the **Communications** tab in an eDiscovery (Premium) case. Now, we've released a new feature that lets you create communications templates that can be used to create communications in any case in your organization. After communication templates are created, they're available to be used in a case. This means that paralegals or other users who create custodian communications don't have to start from scratch to build a notification. Instead, they can select a template to build the notification that is sent to a custodian.



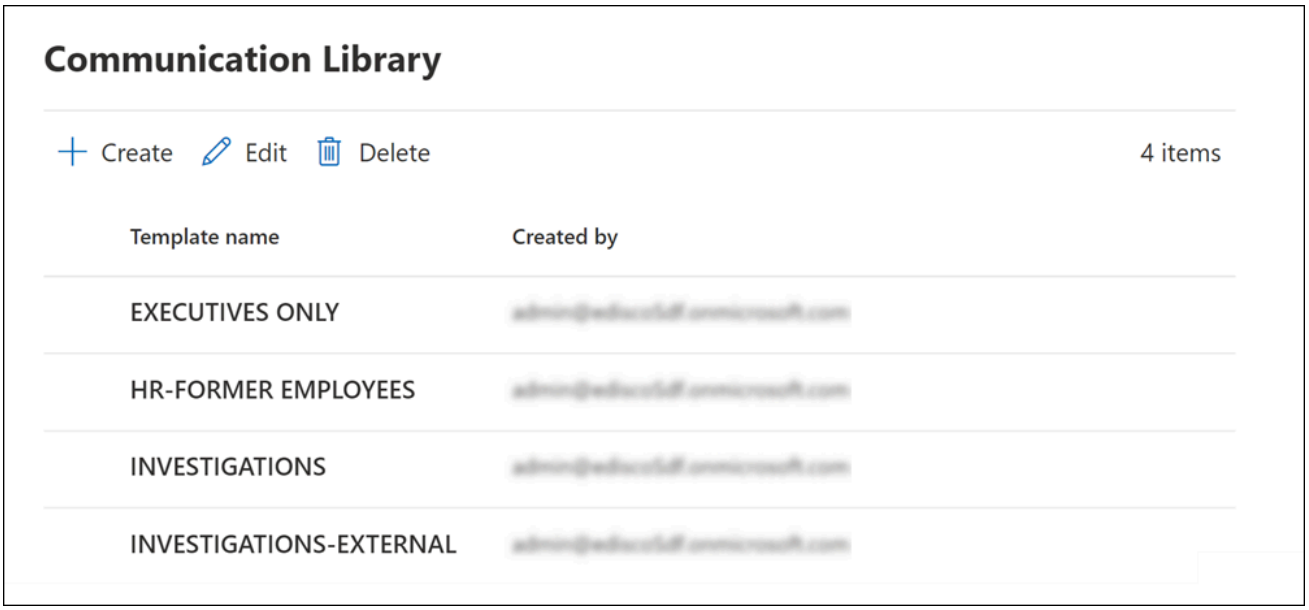
This article explains how to create organization-wide communications templates and select them when creating a new custodian notification for a specific eDiscovery (Premium) case.

Before you create templates in the Communications library

- You must be an eDiscovery Administrator in your organization to add or remove templates in the Communications library in eDiscovery (Premium). For more information, see Assign eDiscovery permissions in the Microsoft Purview portal
- Your organization can have a maximum of 50 templates in the Communications library.

Create a communications template

1. In the Microsoft Purview portal, go to eDiscovery (Premium), and then select **eDiscovery (Premium) settings**.



2. On the **Settings** page, select the **Communications library** tab.

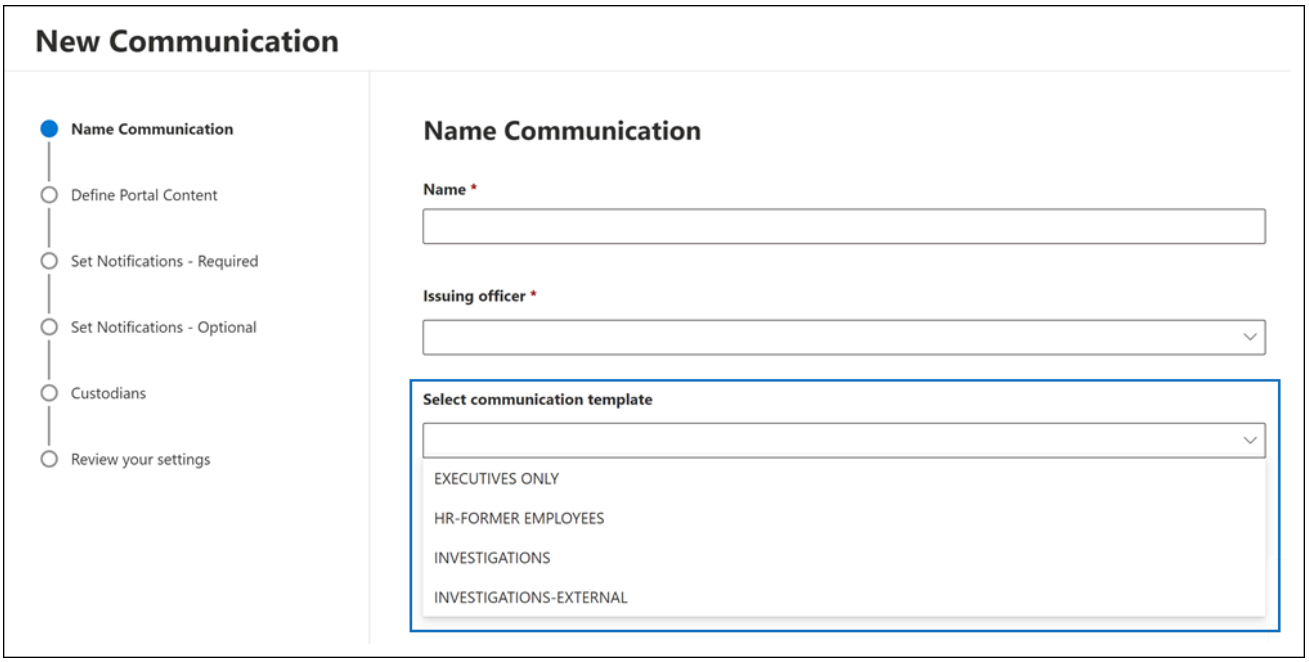
3. On the **Communications library** page, select **Create**.

4. Follow the procedure to create a custodian communication. For step-by-step instructions, see Create a legal hold notification.

> **Note**
>
> The steps to create a communications template are the same as the workflow to create a notification within a case. The only difference is that when you create a template, you don't specify an issuing officer and you don't assign custodians. Specifying an issuing officer and assigning custodians is done when you use a communications template to create a custodian notification for a case.

5. After you create a template, it's displayed on the **Communications library** page.

You or other eDiscovery Administrators can edit a communications template. Any changes that you make to a template don't affect or modify any notifications that were previously created using that template. These changes will only apply to new notifications that created using the updated template.



Use a communications template to create a custodian notification

After one or more communications templates are created in the Communications library, these templates can be selected to create a custodian notification in a case.

To select a template:

1. In the Microsoft Purview portal, go to **eDiscovery** > **Premium** to display the list of cases in your organization.
2. Select a case, select the **Communications** tab, and then select **New communication**.
3. On the **Name communication** page, use the **Select communication template** drop-down list to select a communications template to use to create the custodian notification.

   The list of templates in your organization's Communication library is displayed in the drop-down list.

Last updated on 11/21/2025

Manage holds in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use a Microsoft Purview eDiscovery (Premium) case to create holds to preserve content that might be relevant to your case. Using the eDiscovery (Premium) hold capabilities, you can place holds on custodians and their data sources. Additionally, you can place a noncustodial hold on mailboxes and OneDrive for Business sites. You can also place a hold on the group mailbox, SharePoint site, and OneDrive for Business site for a Microsoft 365 group. Similarly, you can place a hold on the mailbox and site that are associated with Microsoft Teams. When you place content locations on hold, content is held until you release the custodian, remove a specific data location, or delete the hold policy entirely. After you create an eDiscovery hold, it may take up to 24 hours for the hold to be applied.

> **Important**
>
> For long term data retention not related to eDiscovery investigations, it is strongly advised to use retention policies and retention labels. For more information, see Learn about retention policies and retention labels.

View custodian-based holds

In some cases, you may have a set of custodians that you've identified and decided to preserve their data during the case. In eDiscovery (Premium), when these custodians are placed on hold, the user and their selected data sources are automatically added to a custodian hold policy.

Points to remember about hold policies:

- The best policy status is fetched when a location is viewed in a data source
- If the existing applied policy is deleted or released, the system replaces the hold policy status and name with next best applied or active policy.
- Only 1 policy per location is reported. However, there can be more than 1 policy impacting the location within the case. View the hold report to determine all applicable policies.
- The status for a location is fetched only from the policies applicable to the case. A policy from another case won't be referred to highlight the Hold status of the location.
- The hold status of a location is displayed in the *Hold status* column in the hold report.

To view the custodian hold policy:

1. In the Microsoft Purview portal, select **eDiscovery** > **Premium** to display the list of cases in your organization.
2. Go to the **Sources** tab to add custodians within your case. To learn how you can add and place custodians on hold within an eDiscovery (Premium) case, see Add Custodians to a case. If you have already added custodians and placed them on hold, go to step 3.
3. Go to the **Holds** tab and select **CustodianHold(HoldId)** and ensure the hold is placed successfully.

The hold status shown for a custodian in the data source tab is the most restrictive status for all holds in the underlying locations within the custodian or noncustodial data source. For example, if a custodian is added and includes their mailbox, OneDrive, and several Teams channels, all these data sources are placed on hold. However, if the hold for OneDrive returns an error but hold on all other data sources is successful, the hold status for the custodian is *Not on Hold* because the most restrictive status also applies to all of the underlying holds.

For an individual location within a data source, the hold status of that location is determined using all the hold policies applied on that location and the distribution status. The hold status of any successfully applied hold is applied. For example, a location is part of three hold policies and two policies have a *Failed/error* hold status. If the third policy has a hold successfully applied, then the hold status of the location would be *On Hold* based on the success of the hold on the third policy.

View noncustodial holds

In some cases, you may have a set of data that isn't tied to a specific custodian, but you need to identify the data as relevant to the case and preserve it. When these noncustodial sources are placed on hold in eDiscovery (Premium), the selected data sources are automatically added to a noncustodial hold policy.

To view a noncustodial hold for an eDiscovery (Premium) case:

1. In the Microsoft Purview portal, select **eDiscovery** > **Premium** to display the list of cases in your organization.
2. Select the **Sources** tab to add noncustodial locations within your case. To learn how you can add and place noncustodial data on hold within an eDiscovery (Premium) case, see Add noncustodial data sources to an eDiscovery (Premium) case. If you've already added noncustodial location and placed them on hold, go to step 3.
3. Select the **Holds** tab and select **NCDSHold(HoldId)** and ensure hold is placed successfully.

The source policy for the noncustodial location is shown below the hold status. The hold status of that location is determined using all the hold policies applied to the location and the distribution status. The least restrictive hold status of all the statuses is applied.

Placing custodial and noncustodial locations on hold

Placing custodial and noncustodial locations on hold preserves all the content in the locations. For steps to place query-based hold in eDiscovery (Premium), see Create eDiscovery holds in an eDiscovery case.

> **Note**
>
> When you create a query-based hold, all content from selected locations is initially placed on hold. After the timer job in either Exchange or SharePoint runs, any content that doesn't match the specified query is cleared from the hold. After the character count across all queries on a single location exceeds 10,000 characters, the entire location is placed on hold.

> **Note**
>
> If the SMTP address of the user changes after you place the user's mailbox on hold, the mailbox remains on hold. To use the new SMTP address to place hold, create a new hold.

Place a hold on Microsoft Teams and Microsoft 365 groups

Microsoft Teams is built on Microsoft 365 groups. Therefore, placing them on hold in eDiscovery (Premium) is similar. Keep the following things in mind when placing Microsoft 365 groups and Microsoft Teams on hold:

- To place content located in Microsoft 365 groups and Microsoft Teams on hold, you have to specify the mailbox and SharePoint site that associated with a group or team.

- Run the **Get-UnifiedGroup** cmdlet in Exchange Online to view properties for a Microsoft 365 group or Microsoft Team. This method is a good way to get the URL for the site that's associated with a Microsoft 365 group or a Microsoft Team. For example, the following command displays selected properties for a Microsoft 365 group named Senior Leadership Team:

  Console

  ```
  Get-UnifiedGroup "Senior Leadership Team" | FL
  DisplayName,Alias,PrimarySmtpAddress,SharePointSiteUrl
  DisplayName            : Senior Leadership Team
  Alias                  : seniorleadershipteam
  PrimarySmtpAddress     : seniorleadershipteam@contoso.onmicrosoft.com
  SharePointSiteUrl      :
  https://contoso.sharepoint.com/sites/seniorleadershipteam
  ```

  > **Note**
  >
  > To run the Get-UnifiedGroup cmdlet, you have to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- When a user's mailbox is searched, any Microsoft 365 group or Microsoft Team that the user is a member of isn't searched. Similarly, when you place a Microsoft 365 group or Microsoft Team hold, only the group mailbox and group site are placed on hold; the mailboxes and OneDrive sites of group members aren't placed on hold unless you explicitly add them as custodians or place their data sources hold. Therefore, if you need to place a Microsoft 365 group or Microsoft Team on hold for a specific custodian, consider mapping the group site and group mailbox to the custodian (See Managing Custodians in eDiscovery (Premium)). If the Microsoft 365 group or Microsoft Team isn't attributable to a single custodian, consider adding the source to a noncustodial hold.

- To get a list of the members of a Microsoft 365 group or Microsoft Team, you can view the properties on the **Home** > **Groups** page in the Microsoft 365 admin center. Alternatively, you can run the following command in Exchange Online PowerShell:

  PowerShell

```
Get-UnifiedGroupLinks <group or team name> -LinkType Members | FL
DisplayName,PrimarySmtpAddress
```

> **Note**
>
> To run the **Get-UnifiedGroupLinks** cmdlet, you have to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- Channel conversations that are part of a Microsoft Teams channel are stored in the mailbox that's associated with the Team. Similarly, files that team members share in a channel are stored on the team's SharePoint site. Therefore, you have to place the Microsoft Team mailbox and SharePoint site on hold to retain conversations and files in a channel.

- Alternatively, conversations that are part of the Chat list in Microsoft Teams are stored in the mailbox of the user's who participate in the chat. Files that a user shares in Chat conversations are stored in the OneDrive site of the user who shares the file. Therefore, you have to place the individual user mailboxes and OneDrive sites on hold to retain conversations and files in the Chat list.

- Every Microsoft Team or team channel contains a Wiki for note-taking and collaboration. The Wiki content is automatically saved as a .mht file. This file is stored in the Teams Wiki Data document library on the team's SharePoint site. You can place the content in the Wiki on hold by placing the team's SharePoint site on hold.

  > **Note**
  >
  > The capability to retain Wiki content for a Microsoft Team or team channel (when you place the team's SharePoint site on hold) was released on June 22, 2017. If a team site is on hold, the Wiki content will be retained starting on that date. However, if a team site is on hold and the Wiki content was deleted before June 22, 2017, the Wiki content was not retained.

Hold status

The following table lists the status of holds for items:

Expand table

Hold Status	Definition
Applied	A hold is applied on the location. Content is preserved based on the hold policy conditions.
Apply Failed	The hold policy trying to apply Hold on the location has failed. Check the distribution errors in the hold policy.
Applying	A hold is being applied on the location. The hold job is in progress.
Not on Hold	A hold isn't applied on the location. Content preservation isn't force.
Released	A hold is released on the location. Content preservation is disabled.
Release failed	The hold policy releasing a hold on the location failed. Check the distribution errors in the hold policy.
Releasing	A hold release for the location is in progress.
Unknown	The hold status is unknown for the location. Check hold policies, distribution status, and the hold report. This status may appear in cases where the system isn't able to map a hold policy to the location, indicating there isn't a hold present or applied on the location.

Manage hold status errors

You may encounter errors while placing a hold on custodial or noncustodial data sources. The following table lists the errors that you may encounter and the recommended resolution.

Expand table

Hold error types	Description	Resolution
Policy deployment interrupted	A system error indicating a problem was encountered while applying the hold.	Select **Retry hold action** on the custodial/non-custodial data source flyout page command bar to retry the hold application.
Site inaccessible	Indicates the SharePoint location associated with the requested hold request isn't accessible and may be read only.	Contact your SharePoint site administrator to configure the site as writable and retry the hold with **Retry hold action** on the custodial/non-custodial data source flyout page command bar.
Site not found.	Indicates the SharePoint location associated with the requested hold may have been	Check the site URL and confirm if the SharePoint site exists. Once confirmed,

Hold error types	Description	Resolution
	moved, deleted, or the site URL may not exist.	edit the custodial/non-custodial data source for the site and retry the hold action.
Mailbox not found	Indicates the mailbox associated with the requested hold isn't a valid mailbox.	Verify the email address and check that it's a valid Exchange Online mailbox. Once confirmed, edit the custodial/non-custodial data source for the mailbox and then retry the hold action.
Distribution group has too many members	Indicates the distribution group associated with the requested hold has more than 1,000 email addresses. Currently, a distribution group having more than 1,000 email addresses can't be expanded to be placed on hold.	Add the individual email addresses as custodial or noncustodial data sources or split the distribution group into groups with less than 1,000 email addresses and retry the hold action.
Invalid email address or URL	Indicates the location associated with the requested hold has an invalid email address or site URL.	Specify a valid email address or URL that exists within your organization.

Create eDiscovery holds in an eDiscovery case

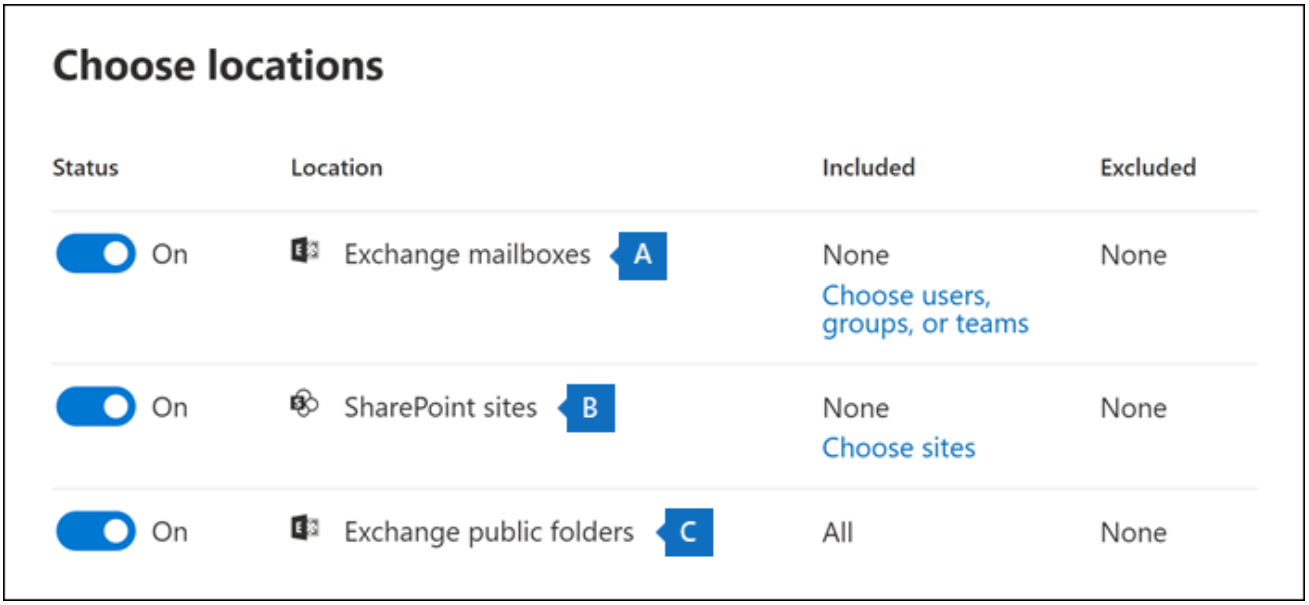
> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use a Microsoft Purview eDiscovery (Premium) or (Standard) case to create holds to preserve content that might be relevant to the case. You can place a hold on the Exchange mailboxes and OneDrive for Business accounts of people you're investigating in the case. You can also place a hold on the mailboxes and sites that are associated with Microsoft Teams, Microsoft 365 groups, and Viva Engage Groups. When you place content locations on hold, content is preserved until you remove the content location from the hold or until you delete the hold.

> **ⓘ Important**
>
> For long term data retention not related to eDiscovery investigations, it is strongly advised to use retention policies and retention labels. For more information, see Learn about retention policies and retention labels.

After you create an eDiscovery hold, it may take up to 24 hours for the hold to take effect.

When you create a hold, you have the following options to scope the content that's preserved in the specified content locations:



- Create an infinite hold where all content in the specified locations is placed on hold. Alternatively, you can create a query-based hold where only the content in the specified locations that matches a search query is placed on hold.
- Specify a date range to preserve only the content that was sent, received, or created within that date range. Alternatively, you can hold all content in specified locations regardless of

when sent, received, or created.

How to create an eDiscovery hold

To create an eDiscovery hold that's associated with an eDiscovery (Premium) or (Standard) case:

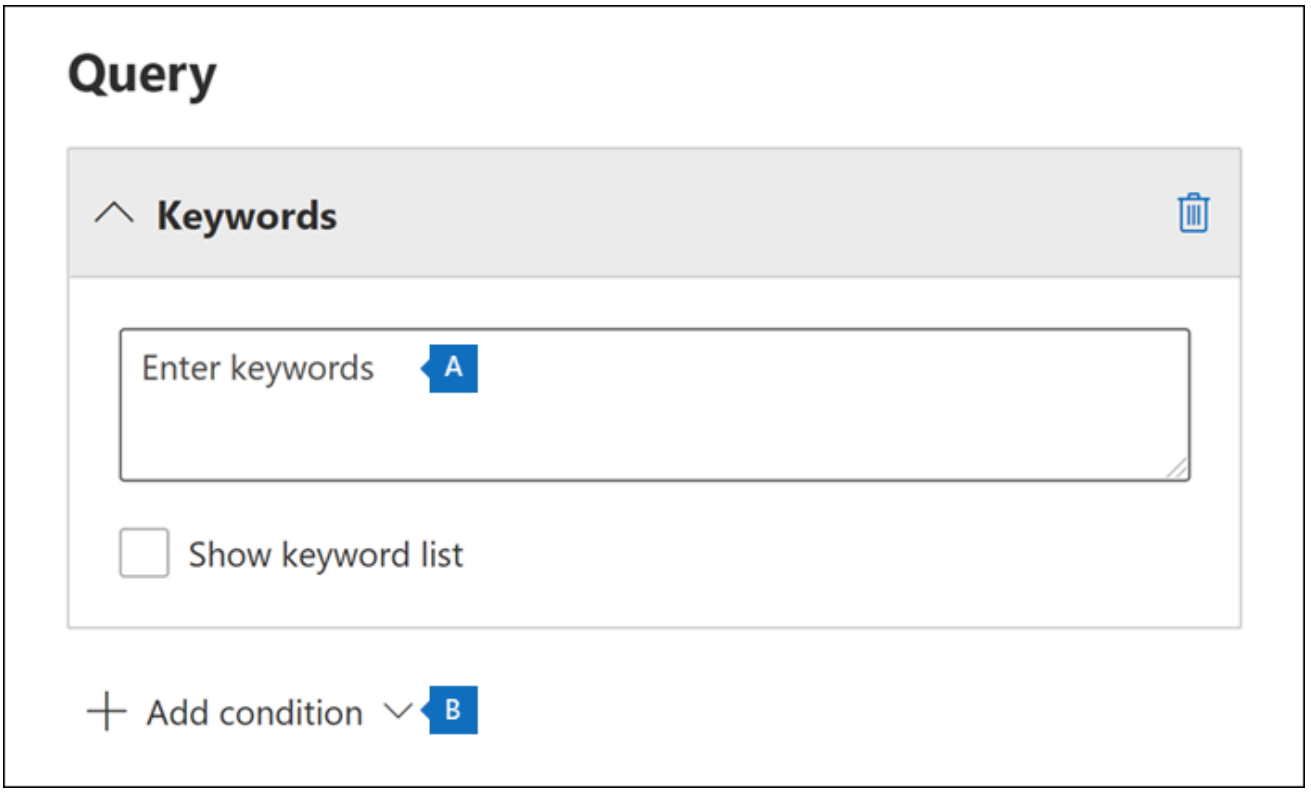
1. Go to Microsoft Purview portal and sign in using the credentials for user account with the appropriate eDiscovery permissions.
2. In the left navigation pane, select **Show all**, and then select **eDiscovery** > **Premium** or **eDiscovery** > **Standard**.
3. On the **eDiscovery** > **Premium** or **eDiscovery (Standard)** page, select the name of the case that you want to create the hold in.
4. On the **Home** page for the case, select the **Hold** tab.
5. On the **Hold** page, select **Create**.
6. On the **Name your hold** workflow page, give the hold a name and add an optional description, and then select **Next**. The name of the hold must be unique in your organization.
7. On the **Choose locations** workflow page, choose the content locations that you want to place on hold. You can place mailboxes, sites, and public folders on hold.

   a. **Exchange mailboxes**: Set the toggle to **On** and then select **Choose users, groups, or teams** to specify the mailboxes to place on hold. Use the search box to find user mailboxes and distribution groups (to place a hold on the mailboxes of group members) to place on hold. You can also place a hold on the associated mailbox for a Microsoft

Team, Microsoft 365 group, and Viva Engage Group. For more information about the application data that is preserved when a mailbox is placed on hold, see Content stored in mailboxes for eDiscovery.

> **Important**
>
> When you select a distribution list to be placed on hold, the hold is placed on each of the member mailboxes in the distribution list when the policy is created. Subsequent changes in the distribution list do not change or update the holds or the policy.

b. **SharePoint sites**: Set the toggle to **On** and then select **Choose sites** to specify SharePoint sites and OneDrive accounts to place on hold. Type the URL for each site that you want to place on hold. You can also add the URL for the SharePoint site for a Microsoft Team, Microsoft 365 group or a Yammer Group.



> **Important**
>
> To create a hold for a subsite related to a SharePoint Online site, you must use the *Path* property in a query filter to select a specific subsite.

c. **Exchange public folders**: Set the toggle to **On** to put all public folders in your Exchange Online organization on hold. You can't choose specific public folders to put on hold. Leave the toggle switch off if you don't want to put a hold on public folders.

> **Important**
>
> When adding Exchange mailboxes or SharePoint sites to a hold, you must explicitly add at least one content location to the hold. In other words, if you set the toggle to **On** for mailboxes or sites, you must select specific mailboxes or sites to add to the hold. Otherwise, the eDiscovery hold will be created but no mailboxes or sites will be added to the hold.

8. When finished adding locations to the hold, select **Next**.

9. To create a query-based hold using keywords or conditions, complete the following steps. To preserve all content in the specified content locations, select **Next**.

a. In the box under **Keywords**, type a query to preserve only the content that matches the query criteria. You can specify keywords, email message properties, or site properties, such as file names. You can also use more complex queries that use a Boolean operator, such as **AND**, **OR**, or **NOT**.
b. Select **Add condition** to add one or more conditions to narrow the query for the hold. Each condition adds a clause to the KeyQL search query that is created and run when you create the hold. For example, you can specify a date range so that email or site documents that were created within the date ranged are preserved. A condition is logically connected to the keyword query (specified in the **Keywords** box) and other conditions by the **AND** operator. That means items have to satisfy both the keyword query and the condition to be preserved.

For more information about creating a search query and using conditions, see Keyword queries and search conditions for eDiscovery.

10. After configuring a query-based hold, select **Next**.

11. Review your settings (and edit them if necessary), and then select **Submit**.

After creating a hold, check that the hold is applied successfully by navigating to the **Hold** tab in the case and selecting the hold policy. For more information about troubleshooting holds with errors, see Resolve eDiscovery hold errors.

> ⓘ Note

When you create a query-based hold, all content from selected locations is initially placed on hold. Subsequently, any content that doesn't match the specified query is cleared from the hold every seven to 14 days. However, a query-based hold won't clear content if more than five holds of any type are applied to a content location, or if any item has indexing issues.

Query-based holds placed on sites

Keep the following things in mind when you place a query-based eDiscovery hold on documents located in SharePoint sites:

- A query-based hold initially preserves all documents in a site for a short period of time after they're deleted. That means when a document is deleted, it is moved to the Preservation Hold library even if it doesn't match the criteria of the query-based hold. However, deleted documents that don't match a query-based hold will be removed by a timer job that processes the Preservation Hold library. The timer job runs periodically and compares all documents in the Preservation Hold library to your query-based eDiscovery holds (and other types of holds and retention policies). The timer job deletes the documents that don't match a query-based hold and preserves the documents that do.
- Query-based holds shouldn't be used to perform targeted preservation, like preserving documents in a specific folder or site or by using other location-based hold criteria. Doing so may have unintended results. We recommend using non-location based hold criteria such as keywords, date ranges, or other document properties to preserve site documents.

Search locations on eDiscovery hold

When you search for content in an eDiscovery (Standard) case, you can quickly configure the search to only search the content locations that have been placed on a hold associated with the case.

Select the **Locations on hold** option to search all the content locations that have been placed on hold. If the case contains multiple eDiscovery holds, the content locations from all holds are searched when you select this option. Additionally, if a content location was placed on a query-based hold, only the items that match the hold query are searched when you run the search. In other words, only the content that matches both the hold criteria and the search criteria is returned with the search results. For example, if a user was placed on query-based case hold that preserves items that were sent or created before a specific date, only those items would be

searched. This is accomplished by connecting the case hold query and the search query by an **AND** operator.

Here are some other things to keep in mind when searching locations on eDiscovery hold:

- If a content location is part of multiple holds within the same case, the hold queries are combined by **OR** operators when you search that content location using the all case content option. Similarly, if a content location is part of two different holds, where one is query-based and the other is an infinite hold (where all content is placed on hold), then all content is search because of the infinite hold.
- If a search is configured it to search locations on hold and then you change an eDiscovery hold in the case (by adding or removing a location or changing a hold query), the search configuration is updated with those changes. However, you have to rerun the search after the hold is changed to update the search results.
- If multiple eDiscovery holds are placed on a single location in an eDiscovery case and you select to search locations on hold, the maximum number of keywords for that search query is 500. That's because the search combines all the query-based holds by using the **OR** operator. If there are more than 500 keywords in the combined hold queries and the search query, then all content in the mailbox is searched, not just that content that matches the query-based case holds.
- If an eDiscovery hold has a status of **On (Pending)**, you can still search the locations on hold while the hold is being turned on.

Preserve content in Microsoft Teams

Conversations that are part of a Microsoft Teams channel are stored in the mailbox that's associated with the Microsoft Team. Similarly, files that team members share in a channel are stored on the team's SharePoint site. Therefore, you have to place the Team mailbox and SharePoint site on eDiscovery hold to preserve conversations and files in a channel.

Alternatively, conversations that are part of the Chat list in Teams (called *1:1 chats* or *1:N group chats*) are stored in the mailboxes of the users who participate in the chat. And files that users share in chat conversations are stored in the OneDrive account of the user who shares the file. Therefore, you have to add the individual user mailboxes and OneDrive accounts to an eDiscovery hold to preserve conversations and files in the chat list. It's a good idea to place a hold on the mailboxes of members of a Microsoft Team in addition to placing the team mailbox and site on hold.

> **Note**
>
> If your organization has an Exchange hybrid deployment (or your organization synchronizes an on-premises Exchange organization with Office 365) and has enabled Microsoft Teams, on-premises users can use the Teams chat application and participate in 1:1 chats and 1:N group chats. These conversations are stored in cloud-based storage that's associated with an on-premises user. If an on-premises user is placed on an eDiscovery hold, the Teams chat content in the cloud-based storage will be preserved. For more information, see **Search for Teams chat data for on-premises users**.

For more information about preserving Teams content, see Place a Microsoft Teams user or team on legal hold.

Preserve card content

Similarly, card content generated by apps in Teams channels, 1:1 chats, and 1:N group chats are stored in mailboxes and is preserved when a mailbox is placed on an eDiscovery hold. A *card* is a UI container for short pieces of content. Cards can have multiple properties and attachments, and can include items that trigger card actions. For more information, see Cards. Like other Teams content, where card content is stored is based on where the card was used. Content for cards used in a Teams channel is stored in the Teams group mailbox. Card content for 1:1 and 1xN chats are stored in the mailboxes of the chat participants.

Preserve meeting and call information

Summary information for meetings and calls in a Teams channel is also stored in the mailboxes of users who dialed into the meeting or call. This content is also preserved when an eDiscovery hold is placed on user mailboxes.

Preserve content in private channels

Starting in February 2020, we also turned on the ability to preserve content in private channels. Because private channel chats are stored in the mailboxes of the chat participants, placing a user mailbox on eDiscovery hold preserves private channel chats. Also, if a user mailbox was placed on an eDiscovery hold prior to February 2020, the hold will now automatically apply to private channel messages stored in that mailbox. Preserving files shared in private channels is also supported.

Preserve wiki content

Every Team or team channel also contains a Wiki for note taking and collaboration. The Wiki content is automatically saved to a file with a .mht format. This file is stored in the Teams Wiki Data document library on the team's SharePoint site. You can preserve the wiki content by adding the team's SharePoint site to an eDiscovery hold.

> **Note**
>
> The capability to preserve Wiki content for a Team or team channel (when you place the team's SharePoint site on hold) was released on June 22, 2017. If a team site is on hold, the Wiki content will be retained starting on that date. However, if a team site is on hold and the Wiki content was deleted before June 22, 2017, the Wiki content was not preserved.

Microsoft 365 groups

Teams is built on Microsoft 365 groups. Therefore, placing Microsoft 365 groups on eDiscovery hold is similar placing Teams content on hold.

Keep the following things in mind when placing both Teams and Microsoft 365 groups on an eDiscovery hold:

- As previously explained, to place content located in Teams and Microsoft 365 groups on hold, you have to specify the mailbox and SharePoint site that associated with a group or team.
- Run the **Get-UnifiedGroup** cmdlet in Exchange Online PowerShell to view properties for Teams and Microsoft 365 groups. This is a good way to get the URL for the site that's associated with a Team or Microsoft 365 group. For example, the following command displays selected properties for a Microsoft 365 group named Senior Leadership Team:

  text

  ```
  Get-UnifiedGroup "Senior Leadership Team" | FL
  DisplayName,Alias,PrimarySmtpAddress,SharePointSiteUrl

  DisplayName            : Senior Leadership Team
  Alias                  : seniorleadershipteam
  PrimarySmtpAddress     : seniorleadershipteam@contoso.onmicrosoft.com
  SharePointSiteUrl      :
  https://contoso.sharepoint.com/sites/seniorleadershipteam
  ```

> **Note**
>
> To run the **Get-UnifiedGroup** cmdlet, you have to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

- When a user's mailbox is searched, any Team or Microsoft 365 group that the user is a member of won't be searched. Similarly, when you place a Team or Microsoft 365 group on eDiscovery hold, only the group mailbox and group site are placed on hold. The mailboxes and OneDrive for Business sites of group members aren't placed on hold unless you explicitly add them to the eDiscovery hold. So if you have to place a Team or Microsoft 365 group on hold for a legal reason, consider adding the mailboxes and OneDrive accounts of team or group members on the same hold.

- To get a list of the members of a Team or Microsoft 365 group, you can view the properties on the **Groups** page in the Microsoft 365 admin center. Alternatively, you can run the following command in Exchange Online PowerShell:

  PowerShell

  ```
  Get-UnifiedGroupLinks <group or team name> -LinkType Members | FL DisplayName,PrimarySmtpAddress
  ```

  > **Note**
  >
  > To run the **Get-UnifiedGroupLinks** cmdlet, you have to be assigned the View-Only Recipients role in Exchange Online or be a member of a role group that's assigned the View-Only Recipients role.

Preserve content in OneDrive accounts

> **Important**
>
> The retention period for deleted OneDrive accounts is different from the retention period for mailboxes. For more information about the retention period for deleted OneDrive accounts, see OneDrive retention and deletion.

To collect a list of the URLs for the OneDrive for Business sites in your organization so you can add them to a hold or search associated with an eDiscovery case, see Create a list of all OneDrive locations in your organization. The script in this article creates a text file that contains a list of all OneDrive sites in your organization. To run this script, you have to install and use the SharePoint Online Management Shell. Be sure to append the URL for your organization's MySite domain to each OneDrive site that you want to search. This is the domain that contains all your OneDrive; for example, `https://contoso-my.sharepoint.com`. Here's an example of a URL for a user's OneDrive site: `https://contoso-my.sharepoint.com/personal/sarad_contoso_onmicrosoft.com`.

> **Important**
>
> The URL for a user's OneDrive account includes their user principal name (UPN) (for example, `https://alpinehouse-my.sharepoint.com/personal/sarad_alpinehouse_onmicrosoft_com`). In the rare case that a person's UPN is changed, their OneDrive URL will also change to incorporate the new UPN. If a user's OneDrive account is part of an eDiscovery hold, and their UPN is changed, you need to update the hold by adding the user's new OneDrive URL and removing the old one. If the URL for the OneDrive site changes, previously placed holds on the site remain effective and content is preserved. For more information, see **How UPN changes affect the OneDrive URL**.

Removing content locations from an eDiscovery hold

After a mailbox, SharePoint site, or OneDrive account is removed from an eDiscovery hold, a *delay hold* is applied. This means that the actual removal of the hold is delayed for 30 days to prevent data from being permanently deleted (purged) from a content location. This gives admins an opportunity to search for or recover content that will be purged after an eDiscovery hold is removed. The details of how the delay hold works for mailboxes and sites are different.

- **Mailboxes:** A delay hold is placed on a mailbox the next time the Managed Folder Assistant processes the mailbox and detects that an eDiscovery hold was removed. Specifically, a delay hold is applied to a mailbox when the Managed Folder Assistant sets one of the following mailbox properties to **True**:
  - **DelayHoldApplied:** This property applies to email-related content (generated by people using Outlook and Outlook on the web) that's stored in a user's mailbox.
  - **DelayReleaseHoldApplied:** This property applies to cloud-based content (generated by non-Outlook apps such as Microsoft Teams, Microsoft Forms, and Microsoft Viva Engage)

that's stored in a user's mailbox. Cloud data generated by a Microsoft app is typically stored in a hidden folder in a user's mailbox.

When a delay hold is placed on the mailbox (when either of the previous properties is set to **True**), the mailbox is still considered to be on hold for an unlimited hold duration, as if the mailbox was on Litigation Hold. After 30 days, the delay hold expires, and Microsoft 365 will automatically attempt to remove the delay hold (by setting the DelayHoldApplied or DelayReleaseHoldApplied property to **False**) so that the hold is removed. After either of these properties are set to **False**, the corresponding items that are marked for removal are purged the next time the mailbox is processed by the Managed Folder Assistant.

For more information, see Managing mailboxes on delay hold.

- **SharePoint and OneDrive sites:** Any SharePoint or OneDrive content that's being retained in the Preservation Hold library isn't deleted during the 30-day delay hold period after a site is removed from an eDiscovery hold. This is similar to what happens when a site is released from a retention policy. Additionally, you can't manually delete this content in the Preservation Hold library during the 30-day delay hold period. To release a site from the 30-day delay hold/grace period hold, see the Can't delete a site because of an invalid retention policy or eDiscovery hold troubleshooting article.

  For more information, see Releasing a policy for retention.

A delay hold is also applied to content locations on hold when you close an eDiscovery (Standard) case because holds are turned off when a case is closed. For more information about closing a case, see Close, reopen, and delete an eDiscovery (Standard) case.

eDiscovery hold limits

The following table lists the limits for eDiscovery cases and case holds.

Expand table

Description of limit	Limit
Maximum number of cases for an organization.	No limit
Maximum number of eDiscovery hold policies for an organization. This limit includes the combined total of hold policies in eDiscovery (Standard) and eDiscovery (Premium) cases.	10,000[1]
Maximum number of mailboxes in a single eDiscovery hold. This limit includes the combined total of user mailboxes, and the mailboxes associated with Microsoft 365	1,000

Description of limit	Limit
groups, Microsoft Teams, and Viva Engage Groups.	
Maximum number of sites in a single eDiscovery hold. This limit includes the combined total of OneDrive for Business sites, SharePoint sites, and the sites associated with Microsoft 365 groups, Microsoft Teams, and Viva Engage Groups. <br/	100
Maximum number of cases displayed on the eDiscovery home page, and the maximum number of items displayed on the Holds, Searches, and Export tabs within a case.	1,000[1]
Hold limits for SharePoint sites and OneDrive	For details, see SharePoint limits.

Note

[1] To view a list of more than 1,000 cases, holds, searches, or exports, you can use the corresponding Security & Compliance PowerShell cmdlet:

- Get-ComplianceCase
- Get-CaseHoldPolicy
- Get-ComplianceSearch
- Get-ComplianceSearchAction

Last updated on 02/21/2025

Hold report in eDiscovery (Premium) (preview)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

The hold report in eDiscovery (Premium) lets users with *eDiscovery Administrator* or *eDiscovery Manager (preview)* permissions access a built-in report with information on all holds associated with eDiscovery cases in the Microsoft Purview portal. This report includes eDiscovery holds associated with eDiscovery (Standard) and eDiscovery (Premium) cases. The hold report currently doesn't show custodian association for each data source, but will show the location.

The hold report is a report on all hold policies within the tenant and lists all locations that are part of those hold policies (whether enabled or disabled). Holds from eDiscovery (Standard) cases are identified by the **Standard** value in the **Case type** column. You can use the **Case type** group option to group the eDiscovery holds from eDiscovery (Standard) cases.

Step 1: Verify your subscription and permissions

- Your organization must have an organization subscription that supports eDiscovery (Premium) to generate and access the hold report.
- Users accessing the hold report must be assigned the *eDiscovery Administrator* or *eDiscovery Manager (preview)* role. All eDiscovery Administrators and eDiscovery Managers in your organization can access it on the **Hold report (preview)** tab in **Reports** section of eDiscovery (Premium). eDiscovery Managers (preview) can only view hold reports which are related to the cases they are a member of. For more information about eDiscovery permissions and the eDiscovery Administrator and eDiscovery Manager roles, see Assign eDiscovery permissions.

Step 2: View the hold report

1. Go to **eDiscovery** > **Premium** > **Reports** > **Hold report (preview)** to view your hold report.
2. Sort, filter, group by, and customize columns to customize your hold report.
3. Download the hold report to CSV file for further analysis. The entire report is downloaded regardless of any filtering or grouping option applied to the report.

The item count at the top of the hold report is total count of locations within the hold policies in the tenant. If the same location is placed on hold under different policies, then the same location is displayed multiple times in the report under the respective case and hold policy and contribute to multiple item counts.

When you search the report, only the **Case name** and **Location** columns are searched. For example, if you search for the keyword *Test*, the search only returns items that are associated with a case or location that contains the word Test.

Default hold report columns

- **Case Name**: Name of the case that the hold policy is associated with. If the case name changed and a hold policy associated with the case is also updated, the case name change for the associated row is immediately reflected in the report. When a full sync of the report occurs (currently every 3 to 7 days), the case name is also updated.
- **Hold name**: Name of the Hold Policy that contains the associated locations.
- **Last modified**: The date when the eDiscovery hold policy was last updated.
- **Location**: The exchange mailbox or SharePoint site in the hold policy. If this field displays *None*, it indicates that the hold policy has no active locations within it. Any previous locations that were part of the policy are released from hold and removed from the policy.
- **Location error**: Displays the error message associated with the location within the hold policy. If this field displays *None*, it indicates that associated location doesn't have errors, even if it's part of a *Partially Applied/Released* policy.
- **Location type**: Indicates if the location is a SharePoint site or Exchange mailbox.
- **Policy status**: The following policy status values are available:
    - *Applied successfully*: Indicates the location of the hold policy is turned on (enabled), a rule is enabled for the policy and the policy is applied successfully. This status means the

location is placed on hold.

- *Applying*: Indicates that the hold policy that the location is part of is set to be turned on (enabled) and is in progress to apply holds to the locations in it. This job is an asynchronous job, which means some locations may have been placed on hold while others may still be in progress. Wait for the hold job to complete checking the final status.

- *Applied Partially*: – Indicates that the hold policy that the location is part of is set to be turned on (enabled) and has some locations where the hold may haven't applied. Check the 'Location error' column. If the associated result is 'None' then the location is placed on hold. If there's an associated error, then the location isn't placed on hold and the error message is displayed here. Check the hold policy for more details to remediate and retry the hold.

- *Released successfully*: Indicates that the hold policy that the location is part of is set to be turned off (disabled) and has completed successfully. This status means the associated location is successfully released from hold.

- *Releasing*: Indicates that the hold policy that the location is part of is set to be turned off (disabled) and is in progress to release holds from the locations in it. This job is an asynchronous job, which means some locations may have been removed from hold while others may still be in progress. Wait for the hold job to complete checking the final status.

  > ⓘ **Note**
  >
  > System default policies (Custodian/NCDS) can only turned off by closing the case. The locations within these policies can still be removed from hold in an active case by releasing them from the data source.

- *Released partially*: Indicates that the hold policy that the location is part of is set to be turned off (disabled) and has some locations where the hold may haven't released. Check the 'Location error' column. If the associated result is 'None' then the location is successfully released from hold. If there's an associated error, then the location isn't removed from hold and the error message is displayed here. Check the hold policy for more details to remediate and retry the action.

- *Policy failed*: Indicates that the policy is set up incorrectly. The policy doesn't have a rule or was set up with rule set as disabled. These policies won't be enforced even if the policy status is successful. To ensure these policies are enforced, create a rule and resync the policy. For more information, see New-CaseHoldRule.

Other available hold report columns

- **Case type**: Indicates if the case is an eDiscovery (Standard) or eDiscovery (Premium case).
- **Case status**: Shows the status of case. Values are *Active*, *Closing*, *Closed with error*, *Pending delete*, or *Closed*. If the case status changed and a hold policy associated with the case is also updated, the case status change for the associated row is immediately reflected in the report. When a full sync of the report occurs (currently every 3 to 7 days), all case status changes are also updated.
- **Policy created by**: Shows the user that created the initial hold policy.
- **Policy last modified by**: Shows the user that last modified the hold policy.
- **Policy last modified**: Shows the last date that the policy was updated on. This date is the policy update date and doesn't necessarily match the date the location was placed on/released from hold.
- **Report last fetched**: Displays the date and time stamp of the latest fetch of policy status and location information by the report for the specific policy.
- **Policy created date**: Shows the first date that the policy was created on. This date is the policy creation date and doesn't necessarily match the date the location was placed on/released from hold.
- **Hold ID**: The unique ID of the hold policy.
- **Case ID**: The unique ID of the case associated with the hold policy.
- **Rule query**: This displays any content match query that is applied to the policy. If there's no content match query applied to the policy, this field is empty.
- **Rule ID**: The unique ID for the rule associated with the hold policy. This status is useful for sending information to Microsoft when reporting any hold errors. If there's no rule associated with the policy, *Rule not available* is displayed in this field. Policies where a rule isn't available aren't set up correctly and not enforced. Create rules and resync the policy. For more information, see New-CaseHoldRule.

Use a script to create a report on holds in eDiscovery cases

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The script in this article lets eDiscovery administrators and eDiscovery managers generate a report that contains information about all holds that are associated with eDiscovery (Standard) and eDiscovery (Premium) cases in the Microsoft Purview portal. The report contains information such as the name of the case a hold is associated with, the content locations that are placed on hold, and whether the hold is query-based. If there are cases that don't have any holds, the script creates an additional report with a list of cases without holds.

See the More information section for a detailed description of the information included in the report.

Admin requirements and script information

- To generate a report on all eDiscovery cases in your organization, you have to be an eDiscovery Administrator in your organization. If you're an eDiscovery Manager, the report will only include information about the cases that you can access. For more information about eDiscovery permissions, see Assign eDiscovery permissions.
- The script in this article has minimal error handling. The primary purpose is to quickly create report about the holds that are associated with the eDiscovery cases in your organization.
- The sample scripts provided in this article aren't supported under any Microsoft standard support program or service. The sample scripts are provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample scripts and documentation remains

with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Connect to Security & Compliance PowerShell

The first step is to connect to Security & Compliance PowerShell for your organization. For step-by-step instructions, see Connect to Security & Compliance PowerShell.

Step 2: Run the script to report on holds associated with eDiscovery cases

After you've connected to Security & Compliance PowerShell, the next step is to create and run the script that collects information about the eDiscovery cases in your organization.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of .ps1; for example, CaseHoldsReport.ps1.

PowerShell

```
 #script begin
 " "
 write-host "**********************************************"
 write-host "Security & Compliance Center   " -foregroundColor yellow -
backgroundcolor darkgreen
 write-host "eDiscovery cases - Holds report         " -foregroundColor yellow -
backgroundcolor darkgreen
 write-host "**********************************************"
 " "

 #prompt users to specify a path to store the output files
 $time = get-date -Format dd-MM-yyyy_hh.mm
 $Path = Read-Host 'Enter a folder path to save the report to a .csv file
(filename is created automatically)'
 $outputpath = $Path + '\' + 'CaseHoldsReport' + ' ' + $time + '.csv'
 $noholdsfilepath = $Path + '\' + 'CaseswithNoHolds' + $time + '.csv'

 #add case details to the csv file
 function add-tocasereport {
     Param([string]$casename,
         [String]$casetype,
         [String]$casestatus,
         [datetime]$casecreatedtime,
```

```
          [string]$casemembers,
          [datetime]$caseClosedDateTime,
          [string]$caseclosedby,
          [string]$holdname,
          [String]$Holdenabled,
          [string]$holdcreatedby,
          [string]$holdlastmodifiedby,
          [string]$ExchangeLocation,
          [string]$sharePointlocation,
          [string]$ContentMatchQuery,
          [datetime]$holdcreatedtime,
          [datetime]$holdchangedtime,
          [string]$holdstatus,
          [string]$holderror
     )

     $addRow = New-Object PSObject
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case name" -
Value $casename
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case type" -
Value $casetype
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case status"
-Value $casestatus
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case
members" -Value $casemembers
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case created
time" -Value $casecreatedtime
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case closed
time" -Value $caseClosedDateTime
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Case closed
by" -Value $caseclosedby
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold name" -
Value $holdname
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold
enabled" -Value $Holdenabled
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold created
by" -Value $holdcreatedby
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold last
changed by" -Value $holdlastmodifiedby
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Exchange
locations" -Value  $ExchangeLocation
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "SharePoint
locations" -Value $sharePointlocation
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold query"
-Value $ContentMatchQuery
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold created
time (UTC)" -Value $holdcreatedtime
     Add-Member -InputObject $addRow -MemberType NoteProperty -Name "Hold changed
time (UTC)" -Value $holdchangedtime
     Add-Member -InputObject $addrow -MemberType NoteProperty -Name "Hold Status"
-Value $holdstatus
     Add-Member -InputObject $addrow -MemberType NoteProperty -Name "Hold Error"
-Value $holderror

     $allholdreport = $addRow | Select-Object "Case name", "Case type", "Case
```

```
status", "Hold name", "Hold enabled", "Case members", "Case created time", "Case
closed time", "Case closed by", "Exchange locations", "SharePoint locations",
"Hold query", "Hold created by", "Hold created time (UTC)", "Hold last changed
by", "Hold changed time (UTC)", "Hold Status", "Hold Error"
     $allholdreport | export-csv -path $outputPath -notypeinfo -append -Encoding
ascii
 }

 #get information on the cases and pass values to the case report function

             [string]$cc.name | out-file -filepath $noholdsfilepath -append
         }
     }
 }

 " "
 Write-host "Script complete! Report files saved to this folder: '$Path'"
 " "
 #script end
```

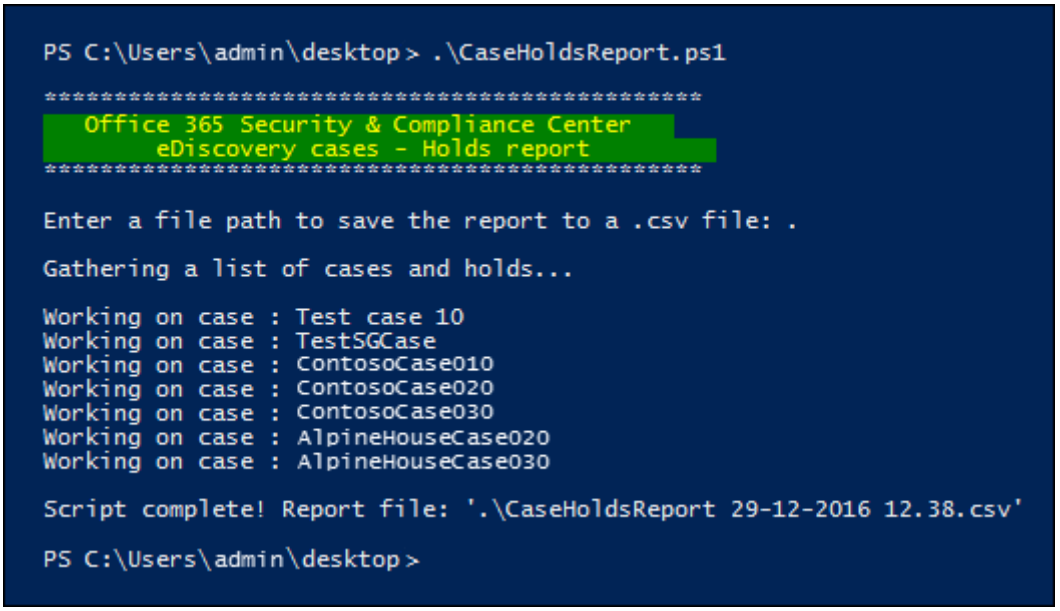
2. In the Windows PowerShell session that opened in Step 1, go to the folder where you saved the script.

3. Run the script; for example:

PowerShell

```
.\CaseHoldsReport.ps1
```

The script prompts for a target folder to save the report to.



4. Type the full path name of the folder to save the report to, and then press **Enter**.

> **Tip**
>
> To save the report in the same folder that the script is located in, type a period (".") when prompted for a target folder. To save the report in a subfolder in the folder where the script is located, just type the name of the subfolder.

The script starts to collect information about all the eDiscovery cases in your organization. Don't access the report file while the script is running. After the script is complete, a confirmation message is displayed in the Windows PowerShell session. After this message is displayed, you can access the report in the folder that you specified in Step 4. The file name for the report is `CaseHoldsReport<DateTimeStamp>.csv`.

Additionally, the script also creates a report with a list of cases that don't have any holds. The file name for this report is `CaseswithNoHolds<DateTimeStamp>.csv`.

Here's an example of running the CaseHoldsReport.ps1 script.

More information

The case holds report that's created when you run the script in this article contains the following information about each hold. As previously explained, you have to be an eDiscovery Administrator to return information for all holds in your organization. For more information about case holds, see eDiscovery cases.

- The name of the hold and the name of the eDiscovery case that the hold is associated with.
- Whether the hold is associated with an eDiscovery (Standard) or eDiscovery (Premium) case.
- Whether or not the eDiscovery case is active or closed.
- Whether or not the hold is enabled or disabled.
- The members of the eDiscovery case that the hold is associated with. Case members can view or manage a case, depending on the eDiscovery permissions they've been assigned.
- The time and date the case was created.
- If a case is closed, the person who closed it and the time and date it was closed.
- The Exchange mailboxes and SharePoint sites locations that are on hold.
- If the hold is query-based, the query syntax.
- The time and date the hold was created and the person who created it.
- The time and date the hold was last changed and the person who changed it.

Place a Microsoft Teams user or team on legal hold

Applies to: Microsoft Teams

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When a reasonable expectation of litigation exists, organizations are required to preserve electronically stored information (ESI), including Teams chat messages that are relevant to the case. Organizations may need to preserve all messages related to a specific investigation or for a specific person. This article will discuss using a legal hold to preserve content in Microsoft Teams. To preserve content in other services in Microsoft 365, see Create an eDiscovery hold.

> **ⓘ Note**
>
> Private channel chats are stored in user mailboxes, while standard channel chats are stored in the mailbox associated with the parent team. If there is already a legal hold in place for a user mailbox, the hold policy will now automatically apply to private channel messages stored in that mailbox. There is no further action needed for an admin to turn this on. Legal hold of files shared in private channels is also supported.

Within Microsoft Teams, an entire team or select users can be put on legal hold. Doing that will make sure that all messages that were exchanged in those teams (including private and shared channels) or messages exchanged by those individuals are discoverable by the organization's compliance managers or Teams Admins.

> **ⓘ Note**

Placing a user on hold does not automatically place a group on hold or vice-versa. Notifications sent in activity feeds can't be placed on hold.

To put a user or a team on legal hold, use the following guidance:

- Create a hold in eDiscovery (Standard)
- Create and manage a hold in eDiscover (Premium)

Important

When a user or group is placed on hold, all compliance copies of messages are preserved. For example, if a user posts a message in a channel and then modifies the message, both copies of the message are preserved. Without the hold, only the latest message is preserved.

Content locations to place on hold to preserve Teams content

As a helpful guide, use the following table to understand what content locations (such as a mailbox or a site) to place on hold to preserve different types of Teams content.

Expand table

Scenario	Content location
Chat messages for a user (for example, 1:1 chats, 1:N group chats, and private channel conversations)	User mailbox
Chat messages in standard and shared channels	Mailbox associated with the parent team
Files in standard channels (for example, Wiki content and files)	SharePoint site associated with the parent team
Files in private and shared channels	Dedicated SharePoint site associated with the channel
User's private content	The user's OneDrive for Business account
Card content in chats	User mailbox for 1:1 chats, 1:N group chats, and private channel conversations; the parent team mailbox for card content in standard

Scenario	Content location
	and shared channel messages. For more information, see the "Preserve card content" section in Create an eDiscovery hold.

> **Note**
>
> To retain message content in private channels, you need to put the user mailboxes (of the members of a private channel) on hold. and when using eDiscovery tool to search private channel messages, you have to search the user's mailbox. As was stated earlier, private channel chats are stored in user mailboxes, not in the group mailbox associated with the parent team.

Use a script to add users to a hold in an eDiscovery (Standard) case

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Security & Compliance PowerShell provides cmdlets that let you automate time-consuming tasks related to creating and managing eDiscovery cases. Currently, using the Microsoft Purview eDiscovery (Standard) case in the Microsoft Purview portal to place a large number of custodian content locations on hold takes time and preparation. For example, before you create a hold, you have to collect the URL for each OneDrive for Business site that you want to place on hold. Then for each user you want to place on hold, you have to add their mailbox and their OneDrive for Business site to the hold. You can use the script in this article to automate this process.

The script prompts you for the name of your organization's My Site domain (for example, `contoso` in the URL `https://contoso-my.sharepoint.com`), the name of an existing eDiscovery case, the name of the new hold that associated with the case, a list of email addresses of the users you want to put on hold, and a search query to use if you want to create a query-based hold. The script then gets the URL for the OneDrive for Business site for each user in the list, creates the new hold, and then adds the mailbox and OneDrive for Business site for each user in the list to the hold. The script also generates log files that contain information about the new hold.

Here are the steps to make this happen:

Step 1: Install the SharePoint Online Management Shell Step 2: Generate a list of users Step 3: Run the script to create a hold and add users

Before you add users to a hold

- You have to be a member of the eDiscovery Manager role group in the Microsoft Purview portal and a SharePoint Online administrator to run the script in Step 3. For more information, see Assign eDiscovery permissions in the Microsoft Purview portal.
- A maximum of 1,000 mailboxes and 100 sites can be added to a hold that's associated with an eDiscovery case in the Microsoft Purview portal. Assuming that every user that you want to place on hold has a OneDrive for Business site, you can add a maximum of 100 users to a hold using the script in this article.
- Be sure to save the list of users that you create in Step 2 and the script in Step 3 to the same folder. That will make it easier to run the script.
- The script adds the list of users to a new hold that is associated with an existing case. Be sure the case that you want to associate the hold with is created before you run the script.
- The script in this article supports modern authentication when connecting to Security & Compliance PowerShell and SharePoint Online Management Shell. You can use the script as-is if you are a Microsoft 365 or a Microsoft 365 GCC organization. If you are an Office 365 Germany organization, a Microsoft 365 GCC High organization, or a Microsoft 365 DoD organization, you will have to edit the script to successfully run it. Specifically, you have to edit the line `Connect-IPPSSession` and use the *ConnectionUri* and *AzureADAuthorizationEndpointUri* parameters (and the appropriate values for your organization type) to connect to Security & Compliance PowerShell. For more information, see the examples in Connect to Security & Compliance PowerShell.
- The script automatically disconnects from Security & Compliance PowerShell and SharePoint Online Management Shell.
- The script includes minimal error handling. Its primary purpose is to quickly and easily place the mailbox and OneDrive for Business site of each user on hold.
- The sample scripts provided in this topic aren't supported under any Microsoft standard support program or service. The sample scripts are provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample scripts and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Install the SharePoint Online Management Shell

The first step is to install the SharePoint Online Management Shell if it's not already installed on your local computer. You don't have to use the shell in this procedure, but you have to install it because it contains pre-requisites required by the script that you run in Step 3. These prerequisites allow the script to communicate with SharePoint Online to get the URLs for the OneDrive for Business sites.

Go to Set up the SharePoint Online Management Shell environment and perform Step 1 and Step 2 to install the SharePoint Online Management Shell on your local computer.

Step 2: Generate a list of users

The script in Step 3 will create a hold that's associated with an eDiscovery case, and the add the mailboxes and OneDrive for Business sites of a list of users to the hold. You can just type the email addresses in a text file, or you can run a command in PowerShell to get a list of email addresses and save them to a file (located in same folder that you'll save the script to in Step 3).

Here's an Exchange Online PowerShell command to get a list of email addresses for all users in your organization and save it to a text file named HoldUsers.txt.

PowerShell

```
Get-Mailbox -ResultSize unlimited -Filter { RecipientTypeDetails -eq 'UserMailbox'} |
Select-Object PrimarySmtpAddress > HoldUsers.txt
```

After you run this command, open the text file and remove the header that contains the property name, `PrimarySmtpAddress`. Then remove all email addresses except the ones for the users that you want to add to the hold that you'll create in Step 3. Make sure there are no blank rows before or after the list of email addresses.

Step 3: Run the script to create a hold and add users

When you run the script in this step, it will prompt you for the following information. Be sure to have this information ready before you run the script.

- **Your user credentials:** The script will use your credentials to connect to Security & Compliance PowerShell. It will also use these credentials to access SharePoint Online to get the OneDrive for Business URLs for the list of users.
- **Name of your SharePoint domain:** The script prompts you to enter this name so it can connect to the SharePoint admin center. It also uses the domain name for the OneDrive URLs in your organization. For example, if the URL for your admin center is

`https://contoso-admin.sharepoint.com` and the URL for OneDrive is `https://contoso-my.sharepoint.com`, then you would enter `contoso` when the script prompts you for your domain name.

- **Name of the case:** The name of an existing case. The script will create a new hold that is associated with this case.
- **Name of the hold:** The name of the hold the script will create and associate with the specified case.
- **Search query for a query-based hold:** You can create a query-based hold so that only the content that meets the specified search criteria is placed on hold. To place all content on hold, just press **Enter** when you're prompted for a search query.
- **Turning on the hold or not:** You can have the script turn on the hold after it's created or you can have the script create the hold without enabling it. If you don't have the script turn on the hold, you can turn it on later in the Microsoft Purview portal or by running the following PowerShell commands:

```
PowerShell
Set-CaseHoldPolicy -Identity <name of the hold> -Enabled $true
```

```
PowerShell
Set-CaseHoldRule -Identity <name of the hold> -Disabled $false
```

- **Name of the text file with the list of users** - The name of the text file from Step 2 that contains the list of users to add to the hold. If this file is located in the same folder as the script, just type the name of the file (for example, HoldUsers.txt). If the text file is in another folder, type the full pathname of the file.

After you've collected the information that the script will prompt you for, the final step is to run the script to create the new hold and add users to it.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of `.ps1`. For example, `AddUsersToHold.ps1`.

```
PowerShell
#script begin
" "
```

```
write-host "*********************************************"
write-host "   Security & Compliance PowerShell  " -foregroundColor yellow -
backgroundcolor darkgreen
write-host "   eDiscovery (Standard) cases - Add users to a hold   " -
foregroundColor yellow -backgroundcolor darkgreen
write-host "*********************************************"
" "
# Connect to Security & Compliance PowerShell using modern authentication
if (!$SccSession)
{
  Import-Module ExchangeOnlineManagement
  Connect-IPPSSession

Yellow
Get-PSSession | Remove-PSSession
Disconnect-PnPOnline

Write-host "Script complete!" -foregroundColor Yellow
""
#script end
```

2. On your local computer, open Windows PowerShell and go to the folder where you saved the script.

3. Run the script; for example:

   PowerShell

   ```
   .\AddUsersToHold.ps1
   ```

4. Enter the information that the script prompts you for.

   The script connects to Security & Compliance PowerShell, and then creates the new hold in the eDiscovery case and adds the mailboxes and OneDrive for Business for the users in the list. You can go to the case on the **eDiscovery** page in the Microsoft Purview portal to view the new hold.

After the script is finished running, it creates the following log files, and saves them to the folder where the script is located.

- **LocationsOnHold.txt:** Contains a list of mailboxes and OneDrive for Business sites that the script successfully placed on hold.
- **LocationsNotOnHold.txt:** Contains a list of mailboxes and OneDrive for Business sites that the script did not place on hold. If a user has a mailbox, but not a OneDrive for Business site, the user would be included in the list of OneDrive for Business sites that weren't placed on hold.
- **GetCaseHoldPolicy.txt:** Contains the output of the **Get-CaseHoldPolicy** cmdlet for the new hold, which the script ran after creating the new hold. The information returned by this cmdlet includes a list of users whose mailboxes and OneDrive for Business sites were placed on hold and whether the hold is enabled or disabled.
- **GetCaseHoldRule.txt:** Contains the output of the **Get-CaseHoldRule** cmdlet for the new hold, which the script ran after creating the new hold. The information returned by this cmdlet includes the search query if you used the script to create a query-based hold.

How to identify the type of hold placed on an Exchange Online mailbox

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article explains how to identify holds placed on Exchange Online mailboxes in Microsoft Purview and Microsoft 365.

Microsoft Purview offers several ways that your organization can prevent mailbox content from being permanently deleted. This allows your organization to retain content to meet compliance regulations or during legal and other types of investigations. Here's a list of the retention features (also called *holds*) in Microsoft Purview and Microsoft 365:

- **Litigation Hold**: Holds that are applied to user mailboxes in Exchange Online.
- **eDiscovery hold**: Holds that are associated with a Microsoft Purview eDiscovery (Standard) case in the Microsoft Purview portal. eDiscovery holds can be applied to user mailboxes and to the corresponding mailbox for Microsoft 365 Groups and Microsoft Teams.
- **In-Place Hold**: Holds that are applied to user mailboxes by using the In-Place eDiscovery & Hold tool in the Exchange admin center in Exchange Online.

  > **Note**
  >
  > In-Place Holds have been retired and you can no longer create In-Place Holds or apply them to mailboxes. However, In-Place Holds might still be applied to mailboxes in your organization, which is why they are included in this article. For more information, see Retirement of legacy eDiscovery tools.

- **Microsoft Purview retention policies:** Can be configured to retain (or retain and then delete) content in user mailboxes in Exchange Online and in the corresponding mailbox for Microsoft 365 Groups and Microsoft Teams. You can also create a retention policy to retain Skype for Business Conversations, which are stored in user mailboxes.

  There are two types of Microsoft Purview retention policies that can be assigned to mailboxes.
  - **Specific location retention policies:** These are policies that are assigned to the content locations of specific users. You use the **Get-Mailbox** cmdlet in Exchange Online PowerShell to get information about retention policies assigned to specific mailboxes. For more information about this type of retention policy, see the section A policy with specific inclusions or exclusions from the retention policy documentation.
  - **Organization-wide retention policies:** These are policies that are assigned to all content locations in your organization. You use the **Get-OrganizationConfig** cmdlet in Exchange Online PowerShell to get information about organization-wide retention policies. For more information about this type of retention policy, see the section A policy that applies to entire locations from the retention policy documentation.

- **Microsoft Purview retention labels:** If a user applies a Microsoft Purview retention label (one that's configured to retain content or retain and then delete content) to *any* folder or item in their mailbox, a hold is placed on the mailbox as if the mailbox was placed on Litigation Hold or assigned to a Microsoft Purview retention policy. For more information, see the Identifying mailboxes on hold because a retention label has been applied to a folder or item section in this article.

To manage mailboxes on hold, you may have to identify the type of hold that's placed on a mailbox so that you can perform tasks such as changing the hold duration, temporarily or permanently removing the hold, or excluding a mailbox from a Microsoft Purview retention policy. In these cases, the first step is to identify the type of hold placed on the mailbox. And because multiple holds (and different types of holds) can be placed on a single mailbox, you have to identify all holds placed on a mailbox if you want to remove or change a hold.

Step 1: Obtain the GUID for holds placed on a mailbox

You can run the following two cmdlets in Exchange Online PowerShell to get the GUID of the holds that are placed on a mailbox. After you obtain a GUID, you use it to identify the specific hold in Step 2. A Litigation Hold isn't identified by a GUID. Litigation Holds are either enabled or disabled for a mailbox.

- **Get-Mailbox:** Use this cmdlet to determine whether Litigation Hold is enabled for a mailbox and to get the GUIDs for eDiscovery holds, In-Place Holds, and Microsoft Purview retention policies that are assigned to a mailbox. The output of this cmdlet will also indicate if a mailbox has been explicitly excluded from an organization-wide retention policy.
- **Get-OrganizationConfig:** Use this cmdlet to get the GUIDs for organization-wide retention policies.

To connect to Exchange Online PowerShell, see Connect to Exchange Online PowerShell.

Get-Mailbox

Run the following command to get information about the holds and Microsoft Purview retention policies applied to a mailbox.

PowerShell

```
Get-Mailbox <username> | FL LitigationHoldEnabled,InPlaceHolds
```

> **Tip**
>
> If there are too many values in the InPlaceHolds property and not all of them are displayed, you can run the `Get-Mailbox <username> | Select-Object -ExpandProperty InPlaceHolds` command to display each GUID on a separate line.

The following table describes how to identify different types of holds based on the values in the *InPlaceHolds* property when you run the **Get-Mailbox** cmdlet.

Expand table

Hold type	Example value	How to identify the hold
Litigation Hold	`True`	Litigation Hold is enabled for a mailbox when the *LitigationHoldEnabled* property is set to `True`.
eDiscovery hold	`UniH7d895d48-7e23-4a8d-8346-533c3beac15d`	The *InPlaceHolds property* contains the GUID of any hold associated with an eDiscovery case in the Microsoft Purview portal. You can tell this is an eDiscovery hold because the GUID starts with the `UniH` prefix (which denotes a Unified Hold).

Hold type	Example value	How to identify the hold
In-Place Hold	`c0ba3ce811b6432a8751430937152491` or `cld9c0a984ca74b457fbe4504bf7d3e00de`	The *InPlaceHolds* property contains the GUID of the In-Place Hold that's placed on the mailbox. You can tell this is an In-Place Hold because the GUID either doesn't start with a prefix or it starts with the `cld` prefix.
Microsoft Purview retention policy applied to the mailbox	`mbxcdbbb86ce60342489bff371876e7f224:1` or `skp127d7cf1076947929bf136b7a2a8c36f:3`	The *InPlaceHolds* property contains GUIDs of any specific location retention policy that's applied to the mailbox. You can identify retention policies because the GUID starts with the `mbx` or the `skp` prefix. The `skp` prefix indicates that the retention policy is applied to Skype for Business conversations in the user's mailbox.
Excluded from an organization-wide Microsoft Purview retention policy	`-mbxe9b52bf7ab3b46a286308ecb29624696`	If a mailbox is excluded from an organization-wide Microsoft Purview retention policy, the GUID for the retention policy that the mailbox is excluded from is displayed in the *InPlaceHolds* property and is identified by the `-mbx` prefix.

Get-OrganizationConfig

If the *InPlaceHolds* property is empty when you run the **Get-Mailbox** cmdlet, there still may be one or more organization-wide Microsoft Purview retention policies applied to the mailbox. Run the following command in Exchange Online PowerShell to get a list of GUIDs for organization-wide Microsoft Purview retention policies.

PowerShell

```
Get-OrganizationConfig | FL InPlaceHolds
```

> **Tip**
>
> If there are too many values in the InPlaceHolds property and not all of them are displayed, you can run the `Get-OrganizationConfig | Select-Object -ExpandProperty InPlaceHolds` command to display each GUID on a separate line.

The following table describes the different types of organization-wide holds and how to identify each type based on the GUIDs contained in *InPlaceHolds* property when you run the **Get-**

OrganizationConfig cmdlet.

Expand table

Hold type	Example value	Description
Microsoft Purview retention policies applied to Exchange mailboxes, Exchange public folders, and Teams chats	`mbx7cfb30345d454ac0a989ab3041051209:2`	Organization-wide retention policies applied to Exchange mailboxes, Exchange public folders, and 1xN chats in Microsoft Teams are identified by GUIDs that start with the `mbx` prefix. Note 1xN chats are stored in the mailbox of the individual chat participants.
Microsoft Purview retention policy applied to Microsoft 365 Groups and Teams channel messages	`grp1a0a132ee8944501a4bb6a452ec31171:3`	Organization-wide retention policies applied to Microsoft 365 groups and channel messages in Microsoft Teams are identified by GUIDs that start with the `grp` prefix. Note channel messages are stored in the group mailbox that is associated with a Microsoft Team.

For more information about retention policies applied to Microsoft Teams, see Learn about retention policies for Microsoft Teams.

Understanding the format of the InPlaceHolds value for retention policies

In addition to the prefix (mbx, skp, or grp) that identifies an item in the InPlaceHolds property as a Microsoft Purview retention policy, the value also contains a suffix that identifies the type of retention action that's configured for the policy. For example, the action suffix is highlighted in bold type in the following examples:

`skp127d7cf1076947929bf136b7a2a8c36f`:1

`mbx7cfb30345d454ac0a989ab3041051209`:2

`grp1a0a132ee8944501a4bb6a452ec31171`:3

The following table defines the three possible retention actions:

Expand table

Value	Description
1	Indicates that the retention policy is configured to delete items or the retention policy is used to publish retention labels. If policy is publishing retention labels, retention configuration for each published label have to be checked.
2	Indicates that the retention policy is configured to hold items. The policy doesn't delete items after the retention period expires.
3	Indicates that the retention policy is configured to hold items and then delete them after the retention period expires.

> **Note**
>
> Because retention label policies publish or auto-apply labels that apply item-level actions, they will always show an action value of 1 within the InPlaceHolds property of the mailbox.
>
> To identify whether a hold has been applied to a folder or item within the mailbox, refer to Identifying mailboxes on hold because a retention label has been applied to a folder or item.

For more information about retention actions, see the Retaining content for a specific period of time section.

Step 2: Use the GUID to identify the hold

After you obtain the GUID for a hold that is applied to a mailbox, the next step is to use that GUID to identify the hold. The following sections show how to identify the name of the hold (and other information) by using the hold GUID.

eDiscovery holds

Run the following commands in Security & Compliance PowerShell to identify an eDiscovery hold that's applied to the mailbox. Use the GUID (not including the UniH prefix) for the eDiscovery hold that you identified in Step 1.

To connect to Security & Compliance PowerShell, see Connect to Security & Compliance PowerShell.

The first command creates a variable that contains information about the hold. This variable is used in the other commands. The second command displays the name of the eDiscovery case the

hold is associated with. The third command displays the name of the hold and a list of the mailboxes the hold applies to.

PowerShell

```
$CaseHold = Get-CaseHoldPolicy <hold GUID without prefix>
```

PowerShell

```
Get-ComplianceCase $CaseHold.CaseId | FL Name
```

PowerShell

```
$CaseHold | FL Name,ExchangeLocation
```

In-Place Holds

Run the following command in Exchange Online PowerShell to identify the In-Place Hold that's applied to the mailbox. Use the GUID for the In-Place Hold that you identified in Step 1. The command displays the name of the hold and a list of the mailboxes the hold applies to.

PowerShell

```
Get-ComplianceSearch -Identity <hold GUID> | FL Name,SourceMailboxes
```

If the GUID for the In-Place Hold starts with the `cld` prefix, be sure to include the prefix when running the previous command.

> **ⓘ Important**
>
> As we continue to invest in different ways to preserve mailbox content, we're announcing the retirement of In-Place Holds in the Exchange admin center (EAC). Starting July 1, 2020 you won't be able to create new In-Place Holds in Exchange Online. But you'll still be able to manage In-Place Holds in the EAC or by using the **Set-MailboxSearch** cmdlet in Exchange Online PowerShell. However, starting October 1, 2020, you won't be able to manage In-Place Holds. You'll only be remove them in the EAC or by using the **Remove-MailboxSearch** cmdlet. For more information about the retirement of In-Place Holds, see Retirement of legacy eDiscovery tools.

Microsoft Purview retention policies

Connect to Security & Compliance PowerShell and run the following command to identity the Microsoft Purview retention policy (organization-wide or specific location) that's applied to the mailbox. Use the GUID (not including the mbx, skp, or grp prefix or the action suffix) that you identified in Step 1.

PowerShell

```
Get-RetentionCompliancePolicy <hold GUID without prefix or suffix> -DistributionDetail
| FL Name,*Location
```

New retention policies that apply to the following locations don't stamp directly on organization configuration or Exchange Online objects:

- Enterprise AI apps
- Microsoft Copilot experiences
- Teams chats
- Teams private channel messages
- Viva Engage community messages
- Viva Engage user messages
- Other AI apps

To determine whether these retention compliance policies apply to a mailbox during an investigation, use Policy Lookup or Retention cmdlets for newer locations.

PowerShell

```
Get-AppRetentionCompliancePolicy <hold GUID without prefix or suffix> -
DistributionDetail  | FL Name, Applications, *Location
```

Identifying mailboxes on hold because a retention label has been applied to a folder or item

Whenever a user applies a retention label that's configured to *retain* or *retain and then delete* content to any folder or item in their mailbox, the *ComplianceTagHoldApplied* mailbox property is set to **True**. When this happens, the mailbox is treated similarly to if it was placed on hold, such as when assigned to a Microsoft Purview retention policy or placed on Litigation Hold, however with some caveats. When the *ComplianceTagHoldApplied* property is set to **True**, the following things occur:

- If the mailbox or the user's Microsoft 365 account is deleted, the mailbox becomes an inactive mailbox.
- You aren't able to disable the mailbox (either the primary mailbox or the archive mailbox, if it's enabled).
- Items that have been deleted from the mailbox will follow one of two paths depending on if they're labeled or not:
  - **Unlabeled items** will follow the same path deleted items take when no holds apply to the mailbox. The time that it takes for these items to be permanently deleted is determined by the deleted item retention configuration and whether single item recovery is enabled for the mailbox or not.
  - **Labeled items** will be retained within the recoverable items folder in the same way they would be if a Microsoft Purview retention policy applied, but at the individual item level. If multiple items have different labels that are configured to *retain* or *retain and then delete* content at different intervals, each item will be retained based on the configuration of the applied label.
- Other holds, such as Microsoft Purview retention policies, eDiscovery holds or litigation hold can extend how long labeled items are retained based on the principles of retention.

To view the value of the *ComplianceTagHoldApplied* property for a single mailbox, run the following command in Exchange Online PowerShell:

PowerShell

```
Get-Mailbox <username> | FL ComplianceTagHoldApplied
```

For more information about retention labels, see retention labels.

Managing mailboxes on delay hold

After any type of hold is removed from a mailbox, a *delay hold* is applied. This means that the actual removal of the hold is delayed for 30 days to prevent data from being permanently deleted (purged) from the mailbox. This gives admins an opportunity to search for or recover mailbox items that will be purged after a hold is removed. A delay hold is placed on a mailbox the next time the Managed Folder Assistant processes the mailbox and detects that a hold was removed. Specifically, a delay hold is applied to a mailbox when the Managed Folder Assistant sets one of the following mailbox properties to **True**:

- **DelayHoldApplied:** This property applies to email-related content (generated by people using Outlook and Outlook on the web) that's stored in a user's mailbox.

- **DelayReleaseHoldApplied:** This property applies to cloud-based content (generated by non-Outlook apps such as Microsoft Teams, Microsoft Forms, and Microsoft Viva Engage) that's stored in a user's mailbox. Cloud data generated by a Microsoft app is typically stored in a hidden folder in a user's mailbox.

When a delay hold is placed on the mailbox (when either of the previous properties is set to **True**), the mailbox is still considered to be on hold for an unlimited hold duration, as if the mailbox was on Litigation Hold. After 30 days, the delay hold expires, and Microsoft 365 will automatically attempt to remove the delay hold (by setting the *DelayHoldApplied* or *DelayReleaseHoldApplied* property to **False**) so that the hold is removed. After either of these properties are set to **False**, the corresponding items that are marked for removal are purged the next time the mailbox is processed by the Managed Folder Assistant.

> ⓘ **Note**
>
> If the user account for the mailbox is disabled, the mailbox isn't processed by the Managed Folder Assistant and the delay hold remains after the 30 days have expired. For more information, see Delay hold considerations.

To view the values for the DelayHoldApplied and DelayReleaseHoldApplied properties for a mailbox, run the following command in Exchange Online PowerShell.

PowerShell

```
Get-Mailbox <username> | FL *HoldApplied*
```

To remove the delay hold before it expires, you can run one (or both) the following commands in Exchange Online PowerShell, depending on which property you want to change:

PowerShell

```
Set-Mailbox <username> -RemoveDelayHoldApplied
```

Or

PowerShell

```
Set-Mailbox <username> -RemoveDelayReleaseHoldApplied
```

You must be assigned the Legal Hold role in Exchange Online to use the *RemoveDelayHoldApplied* or *RemoveDelayReleaseHoldApplied* parameters.

To remove the delay hold on an inactive mailbox, run one of the following commands in Exchange Online PowerShell:

PowerShell

```
Set-Mailbox <DN or Exchange GUID> -InactiveMailbox -RemoveDelayHoldApplied
```

Or

PowerShell

```
Set-Mailbox <DN or Exchange GUID> -InactiveMailbox -RemoveDelayReleaseHoldApplied
```

> **Tip**
>
> The best way to specify an inactive mailbox in the previous command is to use its Distinguished Name or Exchange GUID value. Using one of these values helps prevent accidentally specifying the wrong mailbox.

For more information about using these parameters for managing delay holds, see Set-Mailbox.

Delay hold considerations

Keep the following things in mind when managing a mailbox on delay hold:

- If either the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True** and a mailbox (or the corresponding user account) is deleted, the mailbox becomes an inactive mailbox. That's because a mailbox is considered to be on hold if either property is set to **True**, and deleting a mailbox on hold results in an inactive mailbox. To delete a mailbox and not make it an inactive mailbox, you have to set both properties to **False**.
- A mailbox is considered to be on hold for an unlimited hold duration if either the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True**. However, that doesn't mean that *all* content in the mailbox is preserved. It depends on the value that's set to each property. For example, let's say both properties are set to **True** because holds are removed from the mailbox. Then you remove only the delay hold that's applied to non-Outlook cloud data (by using the *RemoveDelayReleaseHoldApplied* parameter). The next time the Managed Folder Assistant processes the mailbox, the non-Outlook items marked for removal are

purged. Any Outlook items marked for removal won't be purged because the DelayHoldApplied property is still set to **True**. The opposite would also be true: if *DelayHoldApplied* is set to **False** and *DelayReleaseHoldApplied* is set to **True**, then only Outlook items marked for removal would be purged.

How to confirm that an organization-wide retention policy is applied to a mailbox

When an organization-wide retention policy is applied or removed to a mailbox, exporting the mailbox diagnostics logs can help you be certain that Exchange Online has applied or removed the retention policy to the mailbox. To view this information, you first need to validate a few things using Exchange Online PowerShell.

Obtain the GUIDs for any retention policies explicitly applied to a mailbox

PowerShell

```
Get-Mailbox <username> | Select-Object -ExpandProperty InPlaceHolds
```

Obtain the GUIDs for any organization-wide retention policies applied to mailboxes

PowerShell

```
Get-OrganizationConfig | Select-Object -ExpandProperty InPlaceHolds
```

Get the Mailbox Diagnostics for HoldTracking

The Hold Tracking Mailbox Diagnostics logs maintain a history of the holds applied to a user mailbox. If the object is inactive, include `-IncludeInactiveMailboxes` parameter.

PowerShell

```
$ht = Export-MailboxDiagnosticLogs <username> -ComponentName HoldTracking
$ht.MailboxLog | Convertfrom-Json
```

Get the Mailbox Diagnostics for Substrate HoldTracking

The Substrate Hold Tracking Mailbox Diagnostics logs maintain a history of the holds applied to a user mailbox. If the object is inactive, include `-IncludeInactiveMailboxes` parameter.

PowerShell

```
$sht = Export-MailboxDiagnosticLogs <username> -ComponentName SubstrateHoldTracking
$sht.MailboxLog | Convertfrom-Json
```

Review the results of the Mailbox Diagnostics logs

If you gather data from the previous step, the resulting data may look something like this:

> **ed** `: 0001-01-01T00:00:00.0000000` **hid** `: mbx7cfb30345d454ac0a989ab3041051209:1` **ht** `: 4`
> **lsd** `: 2020-03-23T18:24:37.1884606Z` **osd** `: 2020-03-23T18:24:37.1884606Z`

Use the following table to help you understand each of the previous values listed in the diagnostics log.

Expand table

Value	Description
ed	Indicates the End date, which is the date the retention policy was disabled. MinValue means the policy is still assigned to the mailbox.
hid	Indicates the GUID for the retention policy. This value will correlate to the GUIDs that you collected for the explicit or organization-wide retention policies assigned to the mailbox.
ht	Indicates the hold type. Values are *0* for LitigationHold, *1* for InPlaceHold, *2* for ComplianceTagHold, *3* for DelayReleaseHold, *4* for OrganizationRetention, *5* for CompliancePolicy, *6* for SubstrateAppPolicy, and *7* for SharepointPolicy.
lsd	Indicates the Last start date, which is the date the retention policy was assigned to the mailbox.
osd	Indicates the Original start date, which is the date that Exchange first recorded information about the retention policy.

When a retention policy is no longer applied to a mailbox, we'll place a temporary delay hold on the user to prevent purging content. A delay hold can be disabled by running the `Set-Mailbox -RemoveDelayHoldApplied` command.

Next steps

After you identify the holds that are applied to a mailbox, you can perform tasks such as changing the duration of the hold, temporarily or permanently removing the hold, or excluding an inactive mailbox from a Microsoft Purview retention policy. For more information about performing tasks related to holds, see one of the following articles:

- Run the Set-RetentionCompliancePolicy -Identity <Policy Name> -AddExchangeLocationException <user mailbox> command in Security & Compliance PowerShell to exclude a mailbox from an organization-wide Microsoft Purview retention policy. This command can only be used for retention policies where the value for the *ExchangeLocation* property equals `All`.
- Run the Set-AppRetentionCompliancePolicy -Identity <Policy Name> -AddExchangeLocationException <user mailbox> command in Security & Compliance PowerShell to exclude a mailbox from a Teams private channel messages, Viva Engage user messages, Viva Engage community messages, Teams chats, Microsoft Copilot experiences, Enterprise AI apps, and other AI apps. You can only use this command for retention policies where the value for the *ExchangeLocation* property equals `All`.
- Run the Set-Mailbox <\DN or Exchange GUID> -RemoveDelayHoldApplied if needed to remove DelayHoldApplied if that's True. If the object is inactive, include the `-InactiveMailbox` parameter.
- Run the Set-Mailbox <\DN or Exchange GUID> -RemoveDelayReleaseHoldApplied if needed to remove DelayReleaseHoldApplied if that's True. If the object is inactive, include the `-InactiveMailbox` parameter.
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveDelayHoldApplied if needed to remove DelayReleaseHoldApplied if that's True.
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveDelayReleaseHoldApplied if needed to remove DelayReleaseHoldApplied if that's True.
- Run the Set-Mailbox <\DN or Exchange GUID> -LitigationHoldEnabled $False if needed to remove LitigationHold. If the object is inactive, include the `-InactiveMailbox` parameter.
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveLitigationHoldEnabled if needed to remove LitigationHold.
- Run the Set-Mailbox <\DN or Exchange GUID> -InactiveMailbox -RemoveComplianceTagHoldApplied if needed to remove ComplianceTagHoldApplied from inactive mailbox. If the object is active, include the `-ProvideConsent` parameter Set-Mailbox <\DN or Exchange GUID> -RemoveComplianceTagHoldApplied -ProvideConsent
- Run the Set-MailUser <\DN or Exchange GUID> -RemoveComplianceTagHoldApplied if needed to remove ComplianceTagHoldApplied from inactive mailuser.

- Run the Set-Mailbox <\DN or Exchange GUID> -ExcludeFromAllHolds if needed to remove holds from inactive mailbox. Check the Set-Mailbox | ExcludeFromAllHolds to understand which holds this parameter can remove and which it cannot.
- Run the Set-MailUser <\DN or Exchange GUID> -ExcludeFromAllHolds if needed to remove holds from inactive mailuser. Check the Set-MailUser | ExcludeFromAllHolds to understand which holds this parameter can remove and which it cannot.
- Change the hold duration for an inactive mailbox
- Delete an inactive mailbox
- Delete items in the Recoverable Items folder of cloud-based mailboxes on hold

---

Last updated on 02/18/2026

Delete items in the Recoverable Items folder of cloud-based mailboxes on hold

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The Recoverable Items folder for an Exchange Online mailbox exists to protect from accidental or malicious deletions. It's also used to store items that are retained and accessed by compliance features, such as holds and eDiscovery searches. However, in some situations organizations might have data that's been unintentionally retained in the Recoverable Items folder that they must delete. For example, a user might unknowingly send or forward an email message that contains sensitive information or information that may have serious business consequences. Even if the message is permanently deleted, it might be retained indefinitely because a legal hold has been placed on the mailbox. This scenario is known as *data spillage* because data has been unintentionally *spilled* into Office 365. In these situations, you can delete items in a user's Recoverable Items folder for an Exchange Online mailbox, even if that mailbox is placed on hold with one of the different hold features in Office 365. These types of holds include Litigation Holds, In-Place Holds, eDiscovery holds, and retention policies created in the Microsoft Purview portal.

> **Tip**
>
> You can also use the purge feature in Data Security Investigations to search for and permanently delete Exchange mailbox and Microsoft Teams items in your organization. Data Security Investigations provides a streamlined search and purge workflow that doesn't require you to manually remove holds before deleting items. For more information, see Purge in Data Security Investigations.

This article explains how admins can delete items from the Recoverable Items folder for cloud-based mailboxes that are on hold. This procedure involves disabling access to the mailbox and disabling single item recovery, disabling the Managed Folder Assistant from processing the mailbox, temporarily removing the hold, deleting items from the Recoverable Items folder, and then reverting the mailbox to its previous configuration. Here's the process:

Step 1: Collect information about the mailbox

Step 2: Prepare the mailbox

Step 3: Remove all holds from the mailbox

Step 4: Remove the delay hold from the mailbox

Step 5: Delete items in the Recoverable Items folder

Step 6: Revert the mailbox to its previous state

> ⊗ **Caution**
>
> The procedures outlined in this article will result in data being permanently deleted (purged) from an Exchange Online mailbox. That means messages that you delete from the Recoverable Items folder can't be recovered and won't be available for legal discovery or other compliance purposes. If you want to delete messages from a mailbox that's placed on hold as part of a Litigation Hold, In-Place Hold, eDiscovery hold, or retention policy created in the Microsoft Purview portal, check with your records management or legal departments before removing the hold. Your organization might have a policy that defines whether a mailbox on hold or a data spillage incident takes priority.

Before you delete items

- To create and run a Content Search, you have to be a member of the eDiscovery Manager role group or be assigned the Compliance Search management role. To delete messages, you have to be a member of the Organization Management role group or be assigned the Search And Purge management role. For information about adding users to a role group, see Assign eDiscovery permissions.
- If a mailbox is assigned to an organization-wide retention policy, you have to exclude the mailbox from the policy before you can delete items from the Recoverable Items folder. It may take up to 24 hours to synchronize the policy change, and remove the mailbox from

the policy. For more information, see "Organization-wide retention policies" in the Remove all holds from the mailbox section in this article.

- You can't perform this procedure for a mailbox that has been assigned retention settings with a retention policy that's locked by using Preservation Lock. That's because this lock prevents you from removing or excluding the mailbox from the policy and from disabling the Managed Folder Assistant on the mailbox. For more information about locking policies for retention,see Use Preservation Lock to restrict changes to retention policies and retention label policies.
- The procedure described in this article isn't supported for inactive mailboxes. That's because you can't reapply a hold (or retention policy) to an inactive mailbox after you remove it. When you remove a hold from an inactive mailbox, it's changed to a normal soft-deleted mailbox and will be permanently deleted from your organization after it's processed by the Managed Folder Assistant.
- If a mailbox isn't placed on hold (or doesn't have single item recovery enabled), you can delete the items from the Recoverable Items folder. For more information about how to do this, see Search for and delete email messages in your organization.

Step 1: Collect information about the mailbox

This first step is to collect selected properties from the target mailbox that will affect this procedure. Be sure to write down these settings or save them to a text file because you'll change some of these properties and then revert back to the original values in Step 6, after you delete items from the Recoverable Items folder. Here's a list of the mailbox properties you need to collect.

- *SingleItemRecoveryEnabled* and *RetainDeletedItemsFor*. If necessary, you'll disable single recovery and increase the deleted items retention period in Step 3.
- *LitigationHoldEnabled* and *InPlaceHolds*. You need to identify all the holds placed on the mailbox so that you can temporarily remove them in Step 3. See the More information section for tips about how to identify the type hold that might be placed on a mailbox.

Additionally, you need to get the mailbox client access settings so you can temporarily disable them so the owner (or other users) can't access the mailbox during this procedure. Finally, you can get the current size and number of items in the Recoverable Items folder. After you delete items in the Recoverable Items folder in Step 5, you'll use this information to verify that items were removed.

1. Connect to Exchange Online PowerShell. Be sure to use a user name and password for an administrator account that's been assigned the appropriate management roles in Exchange

Online.

2. Run the following command to get information about single item recovery and the deleted item retention period.

```
PowerShell
Get-Mailbox <username> | FL SingleItemRecoveryEnabled,RetainDeletedItemsFor
```

If single item recovery is enabled, you'll have to disable it in Step 2. If the deleted item retention period isn't set for 30 days (the maximum value in Exchange Online), then you can increase it in Step 2.

3. Run the following command to get the mailbox access settings for the mailbox.

```
PowerShell
Get-CASMailbox <username> | FL
EwsEnabled,ActiveSyncEnabled,MAPIEnabled,OWAEnabled,ImapEnabled,PopEnabled
```

You'll disable all of these access methods in Step 2.

4. Run the following command to get information about the holds and retention policies applied to the mailbox.

```
PowerShell
Get-Mailbox <username> | FL LitigationHoldEnabled,InPlaceHolds
```

> **Tip**
>
> If there are too many values in the *InPlaceHolds* property and not all of them are displayed, you can run the `Get-Mailbox <username> | Select-Object -ExpandProperty InPlaceHolds` command to display each value on a separate line.

5. Run the following command to get information about any organization-wide retention policies.

```
PowerShell
Get-OrganizationConfig | FL InPlaceHolds
```

If your organization has any organization-wide retention policies, you'll have to exclude the mailbox from these policies in Step 3. It may take up to 24 hours to replicate the change.

> **Tip**
>
> If there are too many values in the *InPlaceHolds* property and not all of them are displayed, you can run the `Get-OrganizationConfig | Select-Object -ExpandProperty InPlaceHolds` command to display each value on a separate line.

6. Run the following command to determine if a delay hold is applied to the mailbox.

```
PowerShell
Get-Mailbox <username> | FL DelayHoldApplied,DelayReleaseHoldApplied
```

If the value of the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True**, a delay hold is applied to the mailbox and must be removed. For more information about delay holds, see Step 4: Remove the delay hold from the mailbox.

If the value of either properties is set to **False**, a delay hold isn't applied to the mailbox, and you can skip Step 4.

7. Run the following command to get the current size and total number of items in folders and subfolders in the Recoverable Items folder in the user's primary mailbox.

```
PowerShell
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems | FL
Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

If the user's archive mailbox is enabled, run the following command to get the size and total number of items in folders and subfolders in the Recoverable Items folder in their archive mailbox.

```
PowerShell
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems -Archive |
FL Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

When you delete items in Step 5, you can choose to delete or not delete items in the Recoverable Items folder in the user's primary archive mailbox. If auto-expanding archiving

is enabled for the mailbox, items in an auxiliary archive mailbox won't be deleted.

Step 2: Prepare the mailbox

After collecting and saving information about the mailbox, the next step is to prepare the mailbox by performing the following tasks:

- **Disable client access to mailbox** so that the mailbox owner can't access their mailbox and make any changes to the mailbox data during this procedure.
- **Increase the deleted item retention period** to 30 days (the maximum value in Exchange Online) so that items aren't purged from the Recoverable Items folder before you can delete them in Step 5.
- **Disable single Item recovery** so that items won't be retained (for the duration of the deleted item retention period) after you delete them from the Recoverable Items folder in Step 5.
- **Disable the Managed Folder Assistant** so that it doesn't process the mailbox and retain the items that you delete in Step 5.

Perform the following steps in Exchange Online PowerShell.

1. Run the following command to disable all client access to the mailbox. The command syntax assumes that all client access methods were enabled on the mailbox.

   PowerShell

   ```
   Set-CASMailbox <username> -EwsEnabled $false -ActiveSyncEnabled $false -
   MAPIEnabled $false -OWAEnabled $false -ImapEnabled $false -PopEnabled $false
   ```

   > **Note**
   >
   > It might take up to 60 minutes to disable all client access methods to the mailbox. Note that disabling these access methods won't disconnect the mailbox owner if they are currently signed in. If the owner isn't signed in, they won't be able to access their mailbox after these access methods are disabled.

2. Run the following command to increase the deleted item retention period the maximum of 30 days. This assumes that the current setting is less than 30 days.

   PowerShell

```
Set-Mailbox <username> -RetainDeletedItemsFor 30
```

3. Run the following command to disable single item recovery.

```
PowerShell
Set-Mailbox <username> -SingleItemRecoveryEnabled $false
```

> ⓘ Note
>
> It might take up to 240 minutes to disable single item recovery. Don't delete items in the Recoverable Items folder until this period has elapsed.

4. Run the following command to prevent the Managed Folder Assistant from processing the mailbox. As previously explained, you can disable the Managed Folder Assistant only if a retention policy with a Preservation Lock isn't applied to the mailbox.

```
PowerShell
Set-Mailbox <username> -ElcProcessingDisabled $true
```

Step 3: Remove all holds from the mailbox

The last step before you can delete items from the Recoverable Items folder is to remove all holds (that you identified in Step 1) placed on the mailbox. All holds must be removed so that items won't be retained after you delete them from the Recoverable Items folder. The following sections contain information about removing different types of holds on a mailbox. See the More information section for tips about how to identify the type hold that might be placed on a mailbox. For more information, see How to identify the type of hold placed on an Exchange Online mailbox.

> ⊗ Caution
>
> As previously stated, check with your records management or legal departments before removing a hold from a mailbox.

Litigation Hold

Run the following command in Exchange Online PowerShell to remove a Litigation Hold from the mailbox.

```
PowerShell
Set-Mailbox <username> -LitigationHoldEnabled $false
```

> **Note**
>
> Similar to disabling single item recovery, it might take up to 240 minutes to remove the Litigation Hold. Don't delete items from the Recoverable Items folder until this period has elapsed.

In-Place Hold

Run the following command in Exchange Online PowerShell to identify the In-Place Hold that's placed on the mailbox. Use the GUID for the In-Place Hold that you identified in Step 1.

```
PowerShell
Get-ComplianceSearch -Identity <hold GUID> | FL Name
```

After you identify the In-Place Hold, you can use the Exchange admin center (EAC) or Exchange Online PowerShell to remove the mailbox from the hold. For more information, see Create or remove an In-Place Hold.

Retention policies applied to specific mailboxes

Run the following command in Security & Compliance PowerShell to identify the retention policy that is applied to the mailbox. This command will also return any Teams conversation retention policies applied to a mailbox. Use the GUID (not including the `mbx` or `skp` prefix) for the retention policy that you identified in Step 1.

```
PowerShell
Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name
```

After you identify the retention policy, go to the **Data lifecycle management** > **Microsoft 365** > **Retention** page in the Microsoft Purview portal, edit the retention policy that you identified in the

previous step, and remove the mailbox from the list of recipients that are included in the retention policy.

Organization-wide retention policies

Organization-wide, Exchange-wide, and Teams-wide retention policies are applied to every mailbox in the organization. They're applied at the organization level (not the mailbox level) and are returned when you run the **Get-OrganizationConfig** cmdlet in Step 1. Run the following command in Security & Compliance PowerShell to identify the organization-wide retention policies. Use the GUID (not including the `mbx` prefix) for the organization-wide retention policies that you identified in Step 1.

PowerShell

```
Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name
```

After you identify the organization-wide retention policies, go to the **Data lifecycle management** > **Microsoft 365** > **Retention** page in the Microsoft Purview portal, edit each organization-wide retention policy that you identified in the previous step, and add the mailbox to the list of excluded recipients. Doing this removes the user's mailbox from the retention policy.

Organization-wide Viva Engage and private channel retention policies

Organization-wide Yammer/Private Channel retention policies apply to mailboxes that match the workload type of the hold. You can check these policies in your organization with the following cmdlet:

PowerShell

```
Get-AppRetentionCompliancePolicy | fl name,guid,mode,enabled
```

A mailbox needs to be excluded from all organization-wide retention policies, regardless of type (Microsoft Teams, Viva Engage, Exchange) or scope (keeping data, deleting data).

If the mailbox isn't soft deleted or inactive, you can exclude the mailbox from the retention policy in PowerShell by adding an Exchange location exception. For more information, see the AddExchangeLocationException parameter. You can't exclude inactive or soft deleted mailboxes or mail users from these retention policies. To exclude inactive or soft deleted mailboxes or mail users from these retention policies, contact the Microsoft Support team.

> **Important**
>
> After you exclude a mailbox from an organization-wide retention policy, it can take up to 24 hours to synchronize this change and remove the mailbox from the policy.

Retention labels

Whenever a user applies a label that's configured to retain content or retain and then delete content to any folder or item in their mailbox, the *ComplianceTagHoldApplied* mailbox property is set to **True**. When this happens, the mailbox is considered to be on hold, as if it was placed on Litigation Hold or assigned to a retention policy.

To view the value of the *ComplianceTagHoldApplied* property, run the following command in Exchange Online PowerShell:

```
PowerShell
Get-Mailbox <username> |FL ComplianceTagHoldApplied
```

After you've identified that a mailbox is on hold because a retention label is applied to a folder or item, you can use the Content search tool in the Microsoft Purview portal to search for labeled items by using the **Retention label** condition. For more information, see:

- The "Using Content Search to find all content with a specific retention label" section in Learn about retention policies and retention labels
- The "Search conditions" section in Keyword queries and search conditions for Content Search.

For more information about labels, see Learn about retention policies and retention labels.

eDiscovery holds

Run the following commands in Security & Compliance PowerShell to identify the hold associated with an eDiscovery case (called *eDiscovery holds*) that's applied to the mailbox. Use the GUID (not including the `UniH` prefix) for the eDiscovery hold that you identified in Step 1. The second command displays the name of the eDiscovery case the hold is associated with; the third command displays the name of the hold.

```
PowerShell
```

```
$CaseHold = Get-CaseHoldPolicy <hold GUID without prefix>
```

PowerShell

```
Get-ComplianceCase $CaseHold.CaseId | FL Name
```

PowerShell

```
$CaseHold.Name
```

After you've identified the name of the eDiscovery case and the hold, go to the **eDiscovery** > **eDiscovery** page in the Microsoft Purview portal, open the case, and remove the mailbox from the hold. For more information about identifying eDiscovery holds, see the "eDiscovery holds" section in How to identify the type of hold placed on an Exchange Online mailbox.

Step 4: Remove the delay hold from the mailbox

After any type of hold is removed from a mailbox, the value of the *DelayHoldApplied* or *DelayReleaseHoldApplied* mailbox property is set to **True**. This occurs the next time the Managed Folder Assistant processes the mailbox and detects that a hold has been removed. This is called a *delay hold* and means the actual removal of the hold is delayed for 30 days to prevent data from being permanently deleted from the mailbox. (The purpose of a delay hold is to give admins an opportunity to search for or recover mailbox items that will be purged after a hold is removed.) When a delay hold is placed on the mailbox, the mailbox is still considered to be on hold for an unlimited duration, as if the mailbox was on Litigation Hold. After 30 days, the delay hold expires, and Microsoft 365 will automatically attempt to remove the delay hold (by setting the *DelayHoldApplied* or *DelayReleaseHoldApplied* property to **False**) so that the hold is removed. For more information about a delay hold, see the "Managing mailboxes on delay hold" section in How to identify the type of hold placed on an Exchange Online mailbox.

If the value of the *DelayHoldApplied* or *DelayReleaseHoldApplied* property is set to **True**, run one of the following commands to remove the delay hold:

PowerShell

```
Set-Mailbox <username> -RemoveDelayHoldApplied
```

Or

```
```

PowerShell

```
Set-Mailbox <username> -RemoveDelayReleaseHoldApplied
```

You must be assigned the Legal Hold role in Exchange Online to use the *RemoveDelayHoldApplied* or *RemoveDelayReleaseHoldApplied* parameter.

Step 5: Delete items in the Recoverable Items folder

Now you're ready to actually delete items in the Recoverable Items folder by using the New-ComplianceSearch and New-ComplianceSearchAction cmdlets in Security & Compliance PowerShell.

> **Note**
>
> If the mailbox quota is met and the user mailbox is declining emails, you may receive a 554 5.2.0 error when deleting recoverable items. For more information, see "554 5.2.0 STOREDRV.Deliver.Exception" when sending emails in Exchange Online.

Here's an overview of the process to search for and delete items in a user's Recoverable Items folder:

1. Copy the folder IDs for all subfolders in the Recoverable Items folder. Alternatively, you can redirect the output of the script to a text file.

   Here's a list and description of the subfolders in the Recoverable Items folder that you can search and delete items from:

   - **Deletions**: Contains soft-deleted items whose deleted item retention period hasn't expired. Users can recover soft-deleted items from this subfolder using the Recover Deleted Items tool in Outlook.
   - **DiscoveryHolds**: Contains hard-deleted items that have been preserved by an eDiscovery hold or a retention policy. This subfolder isn't visible to end users.
   - **SubstrateHolds**: Contains hard-deleted items from Teams and other cloud-based apps that have been preserved by a retention policy or other type of hold. This subfolder isn't visible to end users.

2. Use the **New-ComplianceSearch** cmdlet (in Security & Compliance PowerShell) or use the Content search tool in the Microsoft Purview portal to create a content search that returns items from the target user's Recoverable Items folder. You can do this by including the

FolderId in the search query for all subfolders that you want to search. For example, the following query returns all messages in the Deletions and eDiscoveryHolds subfolders:

```text
folderid:<folder ID of Deletions subfolder> OR folderid:<folder ID of
DiscoveryHolds subfolder>
```

> ⓘ Note
>
> If you use the **New-ComplianceSearch** cmdlet to search the Recoverable Items folder, be sure to use **Start-ComplianceSearch** cmdlet to run the search.

3. After you've created a content search and validated that it returns the items that you want to delete, use the `New-ComplianceSearchAction -Purge -PurgeType HardDelete` command (in Security & Compliance PowerShell) to permanently delete the items returned by the content search that you created in the previous step. For example, you can run a command similar to the following command:

```PowerShell
New-ComplianceSearchAction -SearchName "RecoverableItems" -Purge -PurgeType
HardDelete
```

4. A maximum of 10 items per mailbox are deleted when you run the previous command. That means you may have to run the `New-ComplianceSearchAction -Purge` command multiple times to delete all the items that you want to delete in the Recoverable Items folder. To delete additional items, you first have to remove the previous compliance search purge action. You do this by running the `Remove-ComplianceSearchAction` cmdlet. For example, to delete the purge action that was run in the previous step, run the following command:

```PowerShell
Remove-ComplianceSearchAction "RecoverableItems_Purge"
```

After you do this, you can create a new compliance search purge action to delete more items. You'll have to delete each purge action before creating a new one.

To get a list of the compliance search actions, you can run the `Get-ComplianceSearchAction` cmdlet. Purge actions are identified by `_Purge` appended to the search name.

Verify that items were deleted

To verify that you've successfully deleted items from the Recoverable Items folder of a mailbox, use **Get-MailboxFolderStatistics** cmdlet in Exchange Online PowerShell to check the size and number of items in Recoverable Items folder. You can compare these statistics with the ones you collected in Step 1.

Run the following command in to get the current size and total number of items in folders and subfolders in the Recoverable Items folder in the user's primary mailbox.

PowerShell

```
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems | FL
Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

Run the following command to get the size and total number of items in folders and subfolders in the Recoverable Items folder in the user's archive mailbox.

PowerShell

```
Get-MailboxFolderStatistics <username> -FolderScope RecoverableItems -Archive | FL
Name,FolderAndSubfolderSize,ItemsInFolderAndSubfolders
```

Step 6: Revert the mailbox to its previous state

The final step is to revert the mailbox back to its previous configuration. This means resetting the properties that you changed in Step 2 and reapplying the holds that you removed in Step 3. This includes:

- Changing the deleted item retention period back to its previous value. Alternatively, you can just leave this set to 30 days, the maximum value in Exchange Online.
- Re-enabling single Item recovery.
- Re-enabling the client access methods so that the owner can access their mailbox.
- Reapplying the holds and retention policies that you removed.
- Re-enabling the Managed Folder Assistant to process the mailbox.

> ⓘ **Important**

> We recommend that you wait 24 hours after re-applying a hold or retention policy (and verifying that it's in place) before you re-enable the Managed Folder Assistant to process the mailbox.

Perform the following steps (in the specified sequence) in Exchange Online PowerShell.

1. Run the following command to change the deleted item retention period back to its original value. This assumes that the previous setting is less than 30 days; for example, 14 days.

   ```
   PowerShell
   Set-Mailbox <username> -RetainDeletedItemsFor 14
   ```

2. Run the following command to re-enable single item recovery.

   ```
   PowerShell
   Set-Mailbox <username> -SingleItemRecoveryEnabled $true
   ```

3. Run the following command to re-enable all client access methods to the mailbox.

   ```
   PowerShell
   Set-CASMailbox <username> -EwsEnabled $true -ActiveSyncEnabled $true -MAPIEnabled $true -OWAEnabled $true -ImapEnabled $true -PopEnabled $true
   ```

4. Reapply the holds that you removed in Step 3. Depending on the type of hold, use one of the following procedures.

   Litigation Hold

   Run the following command to re-enable a Litigation Hold for the mailbox.

   ```
   PowerShell
   Set-Mailbox <username> -LitigationHoldEnabled $true
   ```

   In-Place Hold

   Use the EAC (or Exchange Online PowerShell) to add the mailbox back to the In-Place Hold.

   Retention policies applied to specific mailboxes

Use the Microsoft Purview portal to add the mailbox back to the retention policy. Go to the **Data lifecycle management** > **Microsoft 365** > **Retention** page in the Microsoft Purview portal, edit the retention policy, and add the mailbox back to the list of recipients that the retention policy is applied to.

Organization-wide retention policies

If you removed an organization-wide or Exchange-wide retention policy by excluding it from the policy, then use the Microsoft Purview portal to remove the mailbox from the list of excluded users. Go to the **Data lifecycle management** > **Microsoft 365** > **Retention** page in the Microsoft Purview portal, edit the organization-wide retention policy, and remove the mailbox from the list of excluded recipients. Doing this reapplies the retention policy to the user's mailbox.

eDiscovery case holds

Use the Microsoft Purview portal to add the mailbox back the hold that's associated with an eDiscovery case. Go to the **eDiscovery (Standard)** page, open the case, and add the mailbox back to the hold.

5. Run the following command to allow the Managed Folder Assistant to process the mailbox again. As previously stated, we recommend that you wait 24 hours after reapplying a hold or retention policy (and verifying that it's in place) before you re-enable the Managed Folder Assistant.

```
PowerShell
Set-Mailbox <username> -ElcProcessingDisabled $false
```

6. To verify that the mailbox has been reverted back to its previous configuration, you can run the following commands and then compare the settings to the ones that you collected in Step 1.

```
PowerShell
Get-Mailbox <username> | FL
ElcProcessingDisabled,InPlaceHolds,LitigationHoldEnabled,RetainDeletedItemsFor,Si
ngleItemRecoveryEnabled
```

```
PowerShell
```

```
Get-CASMailbox <username> | FL
EwsEnabled,ActiveSyncEnabled,MAPIEnabled,OWAEnabled,ImapEnabled,PopEnabled
```

More information

Here's a table that describes how to identify different types of holds based on the values in the *InPlaceHolds* property when you run the **Get-Mailbox** or **Get-OrganizationConfig** cmdlets. For more detailed information, see How to identify the type of hold placed on an Exchange Online mailbox.

As previously explained, you have to remove all holds and retention policies from a mailbox before you can successfully delete items in the Recoverable Items folder.

Expand table

Hold type	Example value	How to identify the hold
Litigation Hold	`True`	The *LitigationHoldEnabled* property is set to `True`.
In-Place Hold	`c0ba3ce811b6432a8751430937152491`	The *InPlaceHolds* property contains the GUID of the In-Place Hold that's placed on the mailbox. You can tell this is an In-Place Hold because the GUID doesn't start with a prefix. You can use the Get-ComplianceSearch cmdlet in Exchange Online PowerShell to get information about the In-Place Hold on the mailbox.
Retention policies in the Microsoft Purview portal applied to specific mailboxes	`mbxcdbbb86ce60342489bff371876e7f224` or `skp127d7cf1076947929bf136b7a2a8c36f`	When you run the **Get-Mailbox** cmdlet, the *InPlaceHolds* property also contains GUIDs of retention policies applied to the mailbox. You can identify retention policies because the GUID starts with the `mbx` prefix. If the GUID of the retention policy starts with the `skp` prefix, that indicates that the retention policy is applied to Skype for Business conversations. To identity the retention policy that's applied to the mailbox, run the following command in Security & Compliance PowerShell: `Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name` Be sure to remove the `mbx` or `skp` prefix when you run this command.

Hold type	Example value	How to identify the hold
Organization-wide retention policies in the Microsoft Purview portal	No value or `-mbxe9b52bf7ab3b46a286308ecb29624696` (indicates that the mailbox is excluded from an organization-wide policy)	Even if the *InPlaceHolds* property is empty when you run the **Get-Mailbox** cmdlet, there still might be one or more organization-wide retention policies applied to the mailbox. To verify this, you can run the `Get-OrganizationConfig | FL InPlaceHolds` command in Exchange Online PowerShell to get a list of the GUIDs for organization-wide retention policies. The GUID for organization-wide retention policies applied to Exchange mailboxes starts with the `mbx` prefix; for example, `mbxa3056bb15562480fadb46ce523ff7b02`. To identity the organization-wide retention policy that's applied to the mailbox, run the following command in Security & Compliance PowerShell: `Get-RetentionCompliancePolicy <retention policy GUID without prefix> | FL Name` If a mailbox is excluded from an organization-wide retention policy, the GUID for the retention policy is displayed in the *InPlaceHolds* property of the user's mailbox when you run the **Get-Mailbox** cmdlet; it's identified by the prefix `-mbx`; for example, `-mbxe9b52bf7ab3b46a286308ecb29624696`
eDiscovery case hold in the Microsoft Purview portal	`UniH7d895d48-7e23-4a8d-8346-533c3beac15d`	The *InPlaceHolds* property also contains the GUID of any hold associated with an eDiscovery case in the Microsoft Purview portal that might be placed on the mailbox. You can tell this is an eDiscovery case hold because the GUID starts with the `UniH` prefix. You can use the `Get-CaseHoldPolicy` cmdlet in Security & Compliance PowerShell to get information about the eDiscovery case that the hold on the mailbox is associated with. For example, you can run the command `Get-CaseHoldPolicy <hold GUID without prefix> | FL Name` to display the name of the case hold that's on the mailbox. Be sure to remove the `UniH` prefix when you run this command. To identity the eDiscovery case that the hold on the mailbox is associated with, run the following commands:

Hold type	Example value	How to identify the hold

		`$CaseHold = Get-CaseHoldPolicy <hold GUID without prefix>`
		
		`Get-ComplianceCase $CaseHold.CaseId | FL Name`

Last updated on 10/31/2024

Increase the Recoverable Items quota for mailboxes on hold

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The default Exchange retention policy—named *Default MRM Policy*—that is automatically applied to new mailboxes in Exchange Online contains a retention tag named Recoverable Items 14 days move to archive. This retention tag moves items from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in the user's archive mailbox after the 14-day retention period expires for an item. Emails in Deletions folder will retain based on **RetainDeletedItemsFor** parameter and move to other folders in recoverable deleted items and then to archive mailbox. For this to happen, the user's archive mailbox must be enabled. If the archive mailbox isn't enabled, no action is taken, which means that items in the Recoverable Items folder for a mailbox on hold aren't moved to the archive mailbox after the 14-day retention period expires. Because nothing is deleted from a mailbox on hold, it's possible that the storage quota for the Recoverable Items folder might be exceeded, especially if the user's archive mailbox isn't enabled.

To help reduce the chance of exceeding this limit, the storage quota for the Recoverable Items folder is automatically increased from 30 GB to 100 GB when a hold is placed on a mailbox in Exchange Online. If the archive mailbox is enabled, the storage quota for the Recoverable Items folder in the archive mailbox is also increased from 30 GB to 100 GB. If archive is enabled on a mailbox that is on hold with auto-expanding archive disabled, the storage quota of the Recoverable Items folder quota is increased from 100 GB to 105 GB. If the auto-expanding archiving feature in Exchange Online is enabled, the total storage quota for the user's archive mailbox, including the Recoverable Items folder, is 1.5 TB.

The following table summarizes the storage quota for the Recoverable Items folder.

Expand table

Location of Recoverable Items folder	Mailboxes not on hold	Mailboxes on hold
Primary mailbox	30 GB	100 GB
Archive mailbox, including Recoverable Items folder *	1.5 TB	1.5 TB

> **Note**
>
> * The initial storage quota for the archive mailbox is 100 GB for users with an Exchange Online (Plan 2) license. However, when auto-expanding archiving is turned on for mailboxes on hold, the storage quota for both the archive mailbox and the Recoverable Items folder is increased to 110 GB. Additional archive storage space (which includes the Recoverable Items folder) up to 1.5 TB will be provisioned when necessary. For more information about auto-expanding archiving, see Learn about auto-expanding archiving.

> **Note**
>
> When archiving is enabled for a specific user whose mailbox is on hold or assigned to a retention policy, the storage quota for the user's primary mailbox's Recoverable Items folder is raised from 100 GB to 105 GB and Recoverable items warning quota is raised from 90 GB to 95 GB. This additional space supports an efficient archiving experience for users, even if auto-expanding archive isn't enabled.

When the storage quota for the Recoverable Items folder in the primary mailbox of a mailbox on hold is close to reaching its limit, you can do the following things:

- **Enable the archive mailbox and turn on auto-expanding archiving.** You can enable an additional storage capacity for the Recoverable Items folder simply by enabling the archive mailbox and then turning on the auto-expanding archiving feature in Exchange Online. This results in 110 GB for the Recoverable Items folder in the primary mailbox and up to 1.5 TB of combined storage capacity for the archive and Recoverable Items folder. For more information, see Enable archive mailboxes and Enable auto-expanding archiving.

  > **Note**
  >
  > After you enable the archive for a mailbox that's close to exceeding the storage quota for the Recoverable Items folder, you might want to run the Managed Folder Assistant

to manually trigger the assistant to process the mailbox so that expired items are moved to the Recoverable Items folder in the archive mailbox. See Step 4 for instructions. Note that other items in the user's mailbox might be moved to the new archive mailbox. Consider telling the user that this may happen after you enable the archive mailbox.

- **Create a custom Exchange retention policy for mailboxes on hold.** In addition to enabling the archive mailbox and auto-expanding archiving for mailboxes on Litigation Hold or In-Place Hold, you might also want to create a custom Exchange retention policy for mailboxes on hold. This lets you apply a retention policy to mailboxes on hold that's different from the Default MRM Policy that's applied to mailboxes that aren't on hold, and lets you apply retention tags that are designed for mailboxes on hold. This includes creating a new retention tag for the Recoverable Items folder.

The remainder of this topic describes the step-by-step procedures to create a custom Exchange retention policy for mailboxes on hold.

Step 1: Create a custom retention tag for the Recoverable Items folder

Step 2: Create a new Exchange retention policy for mailboxes on hold

Step 3: Apply the new Exchange retention policy to mailboxes on hold

(Optional) Step 4: Run the Managed Folder Assistant to apply the new retention settings

Step 1: Create a custom retention tag for the Recoverable Items folder

The first step is to create a custom retention tag (called a retention policy tag or RPT) for the Recoverable Items folder. As previously explained, this RPT moves items from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in the user's archive mailbox. You have to use PowerShell to create an RPT for the Recoverable Items folder. You can't use the Exchange admin center (EAC).

1. Connect to Exchange Online PowerShell

2. Run the following command to create a new RPT for the Recoverable Items folder:

```
PowerShell
```

```
New-RetentionPolicyTag -Name <Name of RPT> -Type RecoverableItems -
AgeLimitForRetention <Number of days> -RetentionAction MoveToArchive
```

For example, the following command creates an RPT for the Recoverable Items folder named "Recoverable Items 30 days for mailboxes on hold", with a retention period of 30 days. This means that after an item has been in the Recoverable Items folder for 30 days, it will be moved to the Recoverable Items folder in the user's archive mailbox.

PowerShell

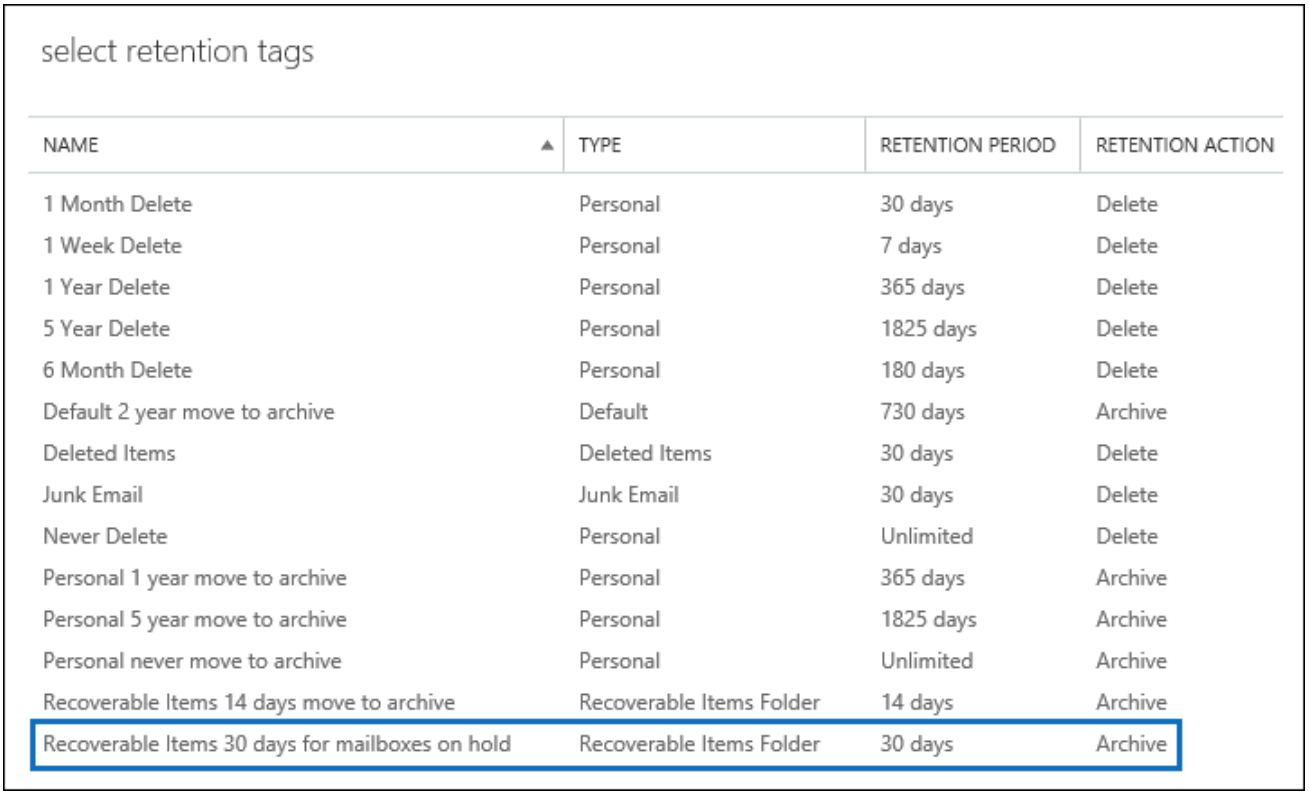
```
New-RetentionPolicyTag -Name "Recoverable Items 30 days for mailboxes on hold" -
Type RecoverableItems -AgeLimitForRetention 30 -RetentionAction MoveToArchive
```

> **Tip**
>
> We recommend that the retention period (defined by the *AgeLimitForRetention* parameter) for the Recoverable Items RPT is the same as the deleted item retention period for the mailboxes that the RPT will be applied to. This allows a user the entire deleted item retention period to recover deleted items before they are moved to the archive mailbox. In the previous example, the retention period was set to 30 days based on the assumption that the deleted item retention period for mailboxes is also 30 days. An Exchange Online mailbox is configured to retain deleted items for 14 days, by default. But you can change this setting to a maximum of 30 days. For more information, see **Change the deleted item retention period for a mailbox in Exchange Online**.

Step 2: Create a new Exchange retention policy for mailboxes on hold

The next step is to create a new retention policy and add retention tags to it, including the Recoverable Items RPT that you created in Step 1. This new policy will be applied to mailboxes on hold in the next step.

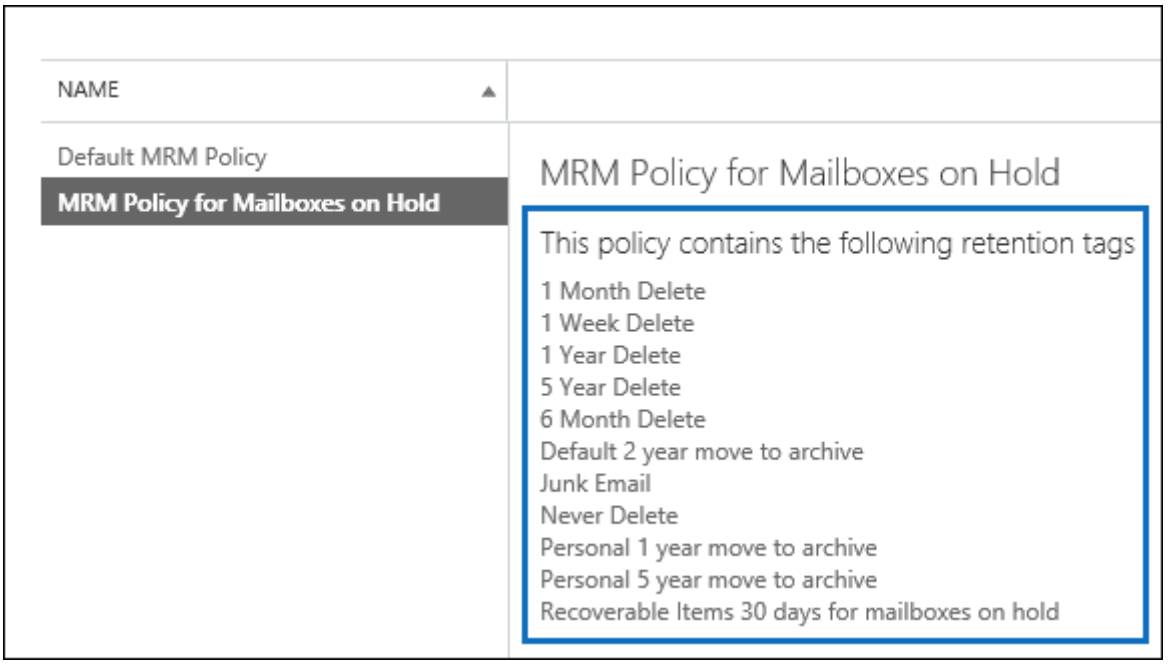
Before you create the new retention policy, determine the additional retention tags that you want to add. For a list of the retention tags that are added to the Default MRM Policy and for information about creating new retention tags, see the following:



- Default Retention Policy in Exchange Online

- Default folders that support Retention Policy Tags
- The "Create a retention tag" section in the Create a Retention Policy topic.

You can use the EAC or Exchange Online PowerShell to create a retention policy.



Use the EAC to create a retention policy

1. In the EAC, go to **Compliance management** > **Retention policies**, and then select **Add +**.
2. On the **New retention policy** page, under **Name**, type a name that describes the purpose of the retention policy; for example, **MRM Policy for Mailboxes on Hold**.
3. Under **Retention tags**, select **Add +**.
4. In the list of retention tags, select the Recoverable Items RPT that you created in Step 1, and then select **Add**.

5. Select additional retention tags to add to the retention policy. For example, you might want to add the same tags that are included in the Default MRM Policy.
6. When you're finished adding retention tags, select **OK**.
7. Select **Save** to create the new retention policy.

   Notice that the retention tags linked to the retention policy are displayed in the details pane.

Use Exchange Online PowerShell to create a retention policy

Run the following command to create new retention policy for mailboxes on hold.

PowerShell

```
New-RetentionPolicy <Name of retention policy>  -RetentionPolicyTagLinks <list of retention tags>
```

For example, the following command creates the retention policy and linked retention tags that are displayed in the previous illustration.

PowerShell

```
New-RetentionPolicy "MRM Policy for Mailboxes on Hold"  -RetentionPolicyTagLinks "Recoverable Items 30 days for mailboxes on hold","1 Month Delete","1 Week Delete","1 Year Delete","5 Year Delete","6 Month Delete","Default 2 year move to archive","Junk Email","Never Delete","Personal 1 year move to archive","Personal 5 year move to archive"
```

Step 3: Apply the new Exchange retention policy to mailboxes on hold

The last step is to apply the new retention policy that you created in Step 2 to mailboxes on hold in your organization. You can use the EAC or Exchange Online PowerShell to apply the retention policy to a single mailbox or to multiple mailboxes.

Use the EAC to apply the new retention policy

1. Go to **Recipients** > **Mailboxes**.
2. In the list view, select the mailbox you want to apply the retention policy to, and then select **Edit** ✎.
3. On the **User Mailbox** page, select **Mailbox features**.
4. Under **Retention policy**, select the retention policy that you created in Step 2, and then select **Save**.

You can also use the EAC to apply the retention policy to multiple mailboxes.

1. Go to **Recipients** > **Mailboxes**.
2. In the list view, use the Shift or Ctrl keys to select multiple mailboxes.
3. In the details pane, select **More options**.
4. Under **Retention Policy**, select **Update**.
5. On the **Bulk assign retention policy** page, select the retention policy that you created in Step 2, and then select **Save**.

Use Exchange Online PowerShell to apply the new retention policy

You can use Exchange Online PowerShell to apply a new retention policy to a single mailbox. But the real power of PowerShell is that you can use it to quickly identify all the mailboxes in your organization that are on either Litigation Hold or In-Place Hold, and then apply the new retention policy to all mailboxes on hold in a single command. Here are some examples of using Exchange PowerShell to apply a retention policy to one or more mailboxes. All of the examples apply the retention policy that was created in Step 2.

This example applies the new retention policy to Pilar Pinilla's mailbox.

PowerShell

```
Set-Mailbox "Pilar Pinilla" -RetentionPolicy "MRM Policy for Mailboxes on Hold"
```

This example applies the new retention policy to all mailboxes in the organization that are on Litigation Hold.

PowerShell

```
$LitigationHolds = Get-Mailbox -ResultSize unlimited | Where-Object
{$_.LitigationHoldEnabled -eq 'True'}
```

PowerShell

```
$LitigationHolds.DistinguishedName | Set-Mailbox -RetentionPolicy "MRM Policy for
Mailboxes on Hold"
```

This example applies the new retention policy to all mailboxes in the organization that are on In-Place Hold.

PowerShell

```
$InPlaceHolds = Get-Mailbox -ResultSize unlimited | Where-Object {$_.InPlaceHolds -ne
$null}
```

PowerShell

```
$InPlaceHolds.DistinguishedName | Set-Mailbox -RetentionPolicy "MRM Policy for
Mailboxes on Hold"
```

You can use the **Get-Mailbox** cmdlet to verify that the new retention policy was applied.

Here are some examples to verify that the commands in the previous examples applied the "MRM Policy for Mailboxes on Hold" retention policy to mailboxes on Litigation Hold and mailboxes on In-Place Hold.

PowerShell

```
Get-Mailbox "Pilar Pinilla" | Select RetentionPolicy
```

PowerShell

```
Get-Mailbox -ResultSize unlimited | Where-Object {$_.LitigationHoldEnabled -eq
'True'} | FT DisplayName,RetentionPolicy -Auto
```

PowerShell

```
Get-Mailbox -ResultSize unlimited | Where-Object {$_.InPlaceHolds -ne $null} | FT
DisplayName,RetentionPolicy -Auto
```

(Optional) Step 4: Run the Managed Folder Assistant to apply the new retention settings

After you apply the new Exchange retention policy to mailboxes on hold, it can take up to 7 days in Exchange Online for the Managed Folder Assistant to process these mailboxes using the settings in the new retention policy. Instead of waiting for the Managed Folder Assistant to run, you can use the **Start-ManagedFolderAssistant** cmdlet to manually trigger the assistant to process the mailboxes that you applied the new retention policy to.

Run the following command to start the Managed Folder Assistant for Pilar Pinilla's mailbox.

PowerShell

```
Start-ManagedFolderAssistant "Pilar Pinilla"
```

Run the following commands to start the Managed Folder Assistant for all mailboxes on hold.

PowerShell

```
$MailboxesOnHold = Get-Mailbox -ResultSize unlimited | Where-Object {($_.InPlaceHolds
-ne $null) -or ($_.LitigationHoldEnabled -eq "True")}
```

PowerShell

```
$MailboxesOnHold.DistinguishedName | Start-ManagedFolderAssistant
```

More information

- After you enable a user's archive mailbox, consider telling the user that other items in their mailbox (not just items in the Recoverable Items folder) might be moved to the archive mailbox. This is because the Default MRM Policy that's assigned to Exchange Online mailboxes contains a retention tag (named Default 2 years move to archive) that moves items to the archive mailbox two years after the date the item was delivered to the mailbox or created by the user. For more information, see Default Retention Policy in Exchange Online
- After you enable a user's archive mailbox, you might also tell the user that they can recover deleted items in the Recoverable Items folder in their archive mailbox. They can do this in Outlook by selecting the **Deleted Items** folder in the archive mailbox, and then selecting **Recover Deleted Items from Server** on the **Home** tab. For more information about recovering deleted items, see Recover deleted items in Outlook for Windows.

Place a mailbox on Litigation Hold

Article • 04/30/2025

APPLIES TO: 2016 2019 Subscription Edition

Place a mailbox on Litigation Hold to preserve all mailbox content, including deleted items and original versions of modified items. When you place a mailbox on Litigation Hold, the user's archive mailbox (if it's enabled) is also placed on hold. Deleted and modified items are preserved for a specified period or until you remove the mailbox from Litigation Hold. All such mailbox items are returned in an In-Place eDiscovery in Exchange Server search.

Before you begin

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place Hold" entry in the Messaging policy and compliance permissions in Exchange Server topic.
- The Litigation Hold setting may take up to 60 minutes to take effect.
- Litigation Hold preserves items in the Recoverable Items folder in the user's mailbox. The default size for this folder is 30 GB. Depending on number and size of items deleted or modified, the size of the Recoverable Items folder of the mailbox may increase quickly. The Recoverable Items folder is configured with a high quota by default. We recommend that you monitor mailboxes that are placed on Litigation Hold on a weekly basis to ensure they don't reach the limits of the Recoverable Items quotas.
- As previously explained, when you place a user's mailbox on Litigation Hold, the user's archive mailbox is also placed on hold.
- Litigation Hold preserves deleted items and also preserves original versions of modified items until the hold is removed. You can optionally specify a hold duration, which preserves a mailbox item for the specified duration period. If you specify a hold duration period, it's calculated from the date a message is received or a mailbox item is created.
- See the More information section for a description of the Litigation Hold workflow process.

Use the EAC to place a mailbox on Litigation Hold

1. Go to **Recipients** > **Mailboxes**.

2. In the list of user mailboxes, click the mailbox that you want to place on Litigation Hold, and then click **Edit** .

3. On the mailbox properties page, click **Mailbox features**.

4. Under **Litigation hold: Disabled**, click **Enable** to place the mailbox on Litigation Hold.

5. On the **Litigation Hold** page, enter the following optional information:

    - **Litigation hold duration (days)**: Use this box to specify how long mailbox items are held when the mailbox is placed on Litigation Hold. The duration is calculated from the date a mailbox item is received or created. If you leave this box blank, items are held indefinitely or until the hold is removed. Use days to specify the duration.

    - **Note***: Use this box to inform the user their mailbox is on Litigation Hold. The note will appear on the **File** tab in Outlook 2010 or later.

    - **URL***: Use this box to direct the user to a website for more information about Litigation Hold. This URL appears on the **File** tab Outlook 2010 or later.

    *If you leave the **Note** and **URL** values blank, the user isn't notified that you placed a litigation hold on their mailbox.

6. Click **Save** on the **Litigation Hold** page, and then click **Save** on the mailbox properties page.

Use the Exchange Management Shell to place a mailbox on Litigation Hold indefinitely

This example places the mailbox bsuneja@contoso.com on Litigation Hold. Items in the mailbox are held indefinitely or until the hold is removed.

PowerShell

```
Set-Mailbox bsuneja@contoso.com -LitigationHoldEnabled $true
```

> **Note**
>
> When you place a mailbox on Litigation Hold indefinitely (by not specifying a duration period), the value for the *LitigationHoldDuration* property mailbox is set to `Unlimited`.

Use the Exchange Management Shell to place a mailbox on Litigation Hold and preserve items for a specified duration

This example places the mailbox bsuneja@contoso.com on Litigation Hold and preserves items for 2555 days (approximately 7 years).

PowerShell

```
Set-Mailbox bsuneja@contoso.com -LitigationHoldEnabled $true -
LitigationHoldDuration 2555
```

Use the Exchange Management Shell to place all mailboxes on Litigation Hold

Your organization may require that all mailbox data be preserved.

This example places all user mailboxes in the organization on Litigation Hold and sets the hold duration for one year (365 days).

PowerShell

```
Get-Mailbox -ResultSize Unlimited -Filter "RecipientTypeDetails -eq 'UserMailbox'"
| Set-Mailbox -LitigationHoldEnabled $true -LitigationHoldDuration 365
```

The example uses the Get-Mailbox cmdlet to retrieve all mailboxes in the organization, specifies a recipient filter to include all user mailboxes, and then pipes the list of mailboxes to the Set-Mailbox cmdlet to enable the Litigation Hold and set the hold duration.

To place all user mailboxes on an indefinite hold, run the previous command but don't include the *LitigationHoldDuration* parameter.

See the More information section for examples of using other recipient properties in a filter to include or exclude one or more mailboxes.

Use the Exchange Management Shell to remove a mailbox from Litigation Hold

This example removes the mailbox bsuneja@contoso.com from Litigation Hold.

PowerShell

```
Set-Mailbox bsuneja@contoso.com -LitigationHoldEnabled $false
```

How do you know this worked?

To verify that you have successfully placed a mailbox on Litigation Hold, do the one of the following:

- In the EAC:

    1. Go to **Recipients** > **Mailboxes**.
    2. In the list of user mailboxes, click the mailbox that you want to verify Litigation Hold settings for, and then click **Edit** ✎.
    3. On the mailbox properties page, click **Mailbox features**.
    4. Under **Litigation hold**, verify that hold is enabled.
    5. Click **View details** to verify when the mailbox was placed on Litigation Hold and by whom. You can also verify or change the values in the optional **Litigation hold duration (days)**, **Note**, and **URL** boxes.

- In the Exchange Management Shell, run one of the following commands:

    PowerShell

    ```
    Get-Mailbox <name of mailbox> | Format-List LitigationHold*
    ```

    or

    PowerShell

    ```
    Get-Mailbox -ResultSize Unlimited -Filter "RecipientTypeDetails -eq
    'UserMailbox'" | Format-List Name,LitigationHold*
    ```

    If a mailbox is placed on Litigation Hold indefinitely, the value for the *LitigationHoldDuration* property mailbox is set to `Unlimited`.

More information

- **How does Litigation Hold work?** In the normal deleted item workflow, a mailbox item is moved to the Deletions subfolder in the Recoverable Items folder when a user permanently deletes it (Shift + Delete) or deletes it from the Deleted Items folder. A deletion policy (which is a retention tag configured with a Delete retention action) also moves items to the Deletions subfolder when the retention period expires. When a user purges an item in the Recoverable Items folder or when the deleted item retention period expires for an item, it's moved to the Purges subfolder in the Recoverable Items folder and marked for permanent deletion. It will be purged from Exchange the next time the mailbox is processed by the Managed Folder Assistant (MFA).

  When a mailbox is placed on Litigation Hold, items in the Purges subfolder are preserved for the hold duration specified by the Litigation Hold. The hold duration is calculated from the original date an item was received or created, and defines how long items in the Purges subfolder are held. When the hold duration expires for an item in the Purges subfolder, the item is marked for permanent deletion and will be purged from Exchange the next time the mailbox is processed by the MFA. If an indefinite hold is placed on a mailbox, items will never be purged from the Purges subfolder.

  The following illustration shows the subfolders in the Recoverable Items folders and the hold workflow process.

> **Note**
>
> If an In-Place Hold is placed on a mailbox, purged items are moved from the Deletions subfolder to the DiscoveryHolds subfolder and are preserved for the hold duration for the In-Place Hold.

- If your organization requires that all mailbox data has to preserved for a specific period of time, consider the following before you place all mailboxes in an organization on Litigation Hold.

  - When you use the previous command to place a hold on all mailboxes in an organization (or a subset of mailboxes matching a specified recipient filter) only mailboxes that exist at the time that you run the command are placed on hold. If you create new mailboxes later, you have to run the command again to place the new mailboxes on hold. If you create new mailboxes often, you can run the command as a scheduled task as frequently as required.

  - Placing all mailboxes on Litigation Hold can significantly impact mailbox sizes. In an Exchange 2016 or Exchange 2019 organization, plan for adequate storage to meet your organization's preservation requirements.

  - The Recoverable Items folder has its own storage limit, so items in the folder don't count towards the mailbox storage limit. As previously explained, preserving mailbox data for a long period of time will result in growth of the Recoverable Items folder in a user's mailbox and archive. We recommend that you periodically monitor the size of this folder by using the **Get-MailboxFolderStatistics** cmdlet to ensure it doesn't reach the limit. For more information, see:

    - Get-MailboxFolderStatistics

    - Clean up or delete items from the Recoverable Items folder.

- The previous command to place a hold on all mailboxes uses a recipient filter that returns all user mailboxes. You can use other recipient properties to return a list of specific mailboxes that you can then pipe to the **Set-Mailbox** cmdlet to place a Litigation Hold on those mailboxes.

  Here are some examples of using the **Get-Mailbox** and **Get-Recipient** cmdlets to return a subset of mailboxes based on common user or mailbox properties. These examples assume that relevant mailbox properties (such as *CustomAttributeN* or *Department*) have been populated.

  PowerShell

  ```
  Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize unlimited -Filter
  'CustomAttribute15 -eq "OneYearLitigationHold"'
  ```

  PowerShell

```
Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize unlimited -Filter
'Department -eq "HR"'
```

PowerShell

```
Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize unlimited -Filter
'PostalCode -eq "98052"'
```

PowerShell

```
Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize unlimited -Filter
'StateOrProvince -eq "WA"'
```

PowerShell

```
Get-Mailbox -ResultSize Unlimited -Filter "RecipientTypeDetails -ne
'DiscoveryMailbox'"
```

You can use other user mailbox properties in a filter to include or exclude mailboxes. For details, see Filterable Properties for the -Filter Parameter.

Preserve Bcc and expanded distribution group recipients for classic eDiscovery

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Litigation holds, eDiscovery holds, and Microsoft 365 retention policies created in the Microsoft Purview portal allow you to preserve mailbox content to meet regulatory compliance and eDiscovery requirements. Information about recipients directly addressed in the To and Cc fields of a message is included in all messages by default. But your organization may require the ability to search for and reproduce details about all recipients of a message. This includes:

- **Recipients addressed using the Bcc field of a message:** Bcc recipients are stored in the message in the sender's mailbox, but not included in headers of the message delivered to recipients.
- **Expanded distribution group recipients:** Recipients who receive the message because they're members of a distribution group to which the message was addressed, either in the To, Cc or Bcc fields.

Exchange Online and Exchange Server 2013 (Cumulative Update 7 and later versions) retain information about Bcc and expanded distribution group recipients. You can search for this information by using an eDiscovery tool in the Microsoft Purview portal.

How Bcc recipients and expanded distribution group recipients are preserved

> **Important**

Only the sender's mailbox's sent items will contain distribution group expansion

Information about Bcc'ed recipients is stored with the message in the sender's mailbox. This information is indexed and available to eDiscovery searches and holds.

Information about expanded distribution group recipients is stored with the message after you place a mailbox on In-Place Hold or Litigation Hold. In Microsoft 365, this information is also stored when a Microsoft Purview retention policy is applied to a mailbox. Distribution group membership is determined at the time the message is sent. The expanded recipients list stored with the message isn't impacted by changes to membership of the group after the message is sent.

Expand table

Information about...	Is stored in...	Is stored by default?	Is accessible to...
To: and Cc: recipients	Message properties in the sender and recipients' mailboxes.	Yes	Sender, recipients, and compliance officers
Bcc: recipients	Message property in the sender's mailbox.	Yes	Sender and compliance officers
Expanded distribution group recipients	Message properties in the sender's mailbox.	No. Expanded distribution group recipient information is stored after a mailbox is placed on In-Place Hold or Litigation Hold, or assigned to a Microsoft Purview retention policy.	Compliance officers

Searching for messages with expanded distribution group recipients

When searching for messages sent to a recipient, eDiscovery search results now include messages sent to a distribution group that the recipient is a member of but only in the sender mailbox and if the sender is on hold.

Important

Distribution group expansion details are only available in the sender's mailbox under Sent Items. If you search the recipient's mailbox, messages sent to distribution groups will not show the expanded list of group members.

Scenario: John is a member of the US-Sales distribution group. This table shows eDiscovery search results when Bob sends a message to John directly or indirectly via a distribution group.

Expand table

When you search Bob's mailbox for messages sent...	And the message is sent with...	Results include message?
To: John	John on To:	Yes
To: John	US-Sales on To:	Yes
To: US-Sales	US-Sales on To:	Yes
Cc: John	John on Cc:	Yes
Cc: John	US-Sales on Cc:	Yes
Cc: US-Sales	US-Sales on Cc:	Yes
When you search John's mailbox for message...		
To/Cc	US-Sales on To/Cc:	No. Only sender mailbox can be searched.

Searching for messages with Bcc

Scenario: Bob sends an email to John (To/Cc) and Jack (Bcc directly, or indirectly via a distribution group). The tables below show eDiscovery search results.

Important

Distribution group expansion detail will only be available if the sender is on hold.

Expand table

When you search Bob's mailbox...	For messages sent...	Results include message?	Notes
Bob's mailbox	To:/Cc: John	Yes	Presents an indication that Jack was Bcc'ed.
Bob's mailbox	Bcc: Jack	Yes	Presents an indication that Jack was Bcc'ed.
Bob's mailbox	Bcc: Jack (via distribution group)	Yes	List of members of the Bcc'ed distribution group, expanded when the message was sent, is visible in eDiscovery search preview, export, and logs.
When you search John's mailbox...			
John's mailbox	To:/Cc: John	Yes	No indication of Bcc recipients.
John's mailbox	Bcc: Jack (directly or via distribution group)	No	Bcc: information isn't stored in the message delivered to recipients. You must search the **sender's mailbox**.
When you search Jack's mailbox...			
Jack's mailbox	To:/Cc: John (directly or via distribution group)	Yes	To:/Cc: information is included in message delivered to all recipients.
Jack's mailbox	Bcc: Jack (directly or via distribution group)	No	Bcc: information isn't stored in the message delivered to recipients. You must search the **sender's mailbox**.

Frequently asked questions

When and where is Bcc recipient information stored?

Bcc recipient information is preserved by default in the original message in sender's mailbox. If the Bcc recipient is a distribution group, distribution group membership is only expanded if the sender's mailbox is on hold or assigned to a Microsoft 365 retention policy.

When and where is the list of expanded distribution group recipients stored?

Group membership is expanded at the time the message is sent. The list of expanded distribution group members is stored in the original message in the sender's mailbox. The sender's mailbox must be on In-Place Hold, Litigation Hold, or assigned to a Microsoft 365 retention policy.

Can the To/Cc recipients see which recipients were Bcc'ed?

No. This information isn't included in message headers, and isn't visible to To/Cc recipients. The sender can see the Bcc field stored in the original message stored in their mailbox. Compliance officers can see this information when searching the sender's mailbox.

How can I ensure that expanded distribution group recipients are always preserved?

To ensure that expanded distribution group members are always preserved with a message, Place all mailboxes on hold or create an organization-wide Microsoft 365 retention policy.

Which types of groups are supported?

Distribution groups, mail-enabled security groups, and dynamic distribution groups are supported.

Is there a limit on the number of distribution group recipients that are expanded and stored in the message?

Up to 10,000 members of a distribution group is preserved.

Are nested distribution groups supported?

Yes, 25 levels of nested distribution groups are expanded.

Where is the Bcc and expanded distribution group recipient information visible?

Bcc and expanded distribution group recipients information is visible to Compliance officers when performing an eDiscovery search. Bcc and expanded distribution group recipients are included in search results copied to a Discovery mailbox or exported to a PST file and in the eDiscovery log included in search results. Bcc recipient information is also available in search preview.

What happens if a member of a distribution group is hidden from the organization's global address list (GAL)?

There's no impact. If recipients are hidden from the GAL, they're still included in the list of recipients for the expanded distribution group.

Work with processing errors in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Processing is the process of file identification, expansion of embedded documents and attachments, text extraction, and Optical Character Recognition (OCR) of image files and the subsequent indexing of that content.

When you add custodians and non-custodian data sources to a case on the **Sources** tab, all partially indexed items from Microsoft 365 are processed to make them fully searchable. Likewise, when content is added to a review set from both Microsoft 365 and non-Microsoft 365 data sources, this content is also processed.

The **Processing** tab in eDiscovery (Premium) provides insight into the status of Advanced indexing for different processing scenarios.

For more information, see the following articles:

- Advanced indexing of custodian data
- Error remediation when processing data
- Single item error remediation

Last updated on 11/21/2025

Advanced indexing of custodian and noncustodial data sources

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When a custodian or noncustodial data source is added to an eDiscovery (Premium) case, any content that was deemed as partially indexed or had indexing errors is reindexed. The reindexing process is called *Advanced indexing*. There are many reasons that content is partially indexed or has indexing errors. This includes image files or the presence of images in a file, unsupported file types, or file sized indexing limits.

For SharePoint files, Advanced indexing only runs on items marked as partially indexed or items with indexing errors. In Exchange, email messages with image attachments aren't marked as partially indexed or with indexing errors. This means that those files won't be reindexed by the Advanced indexing process.

To learn more about processing support and partially indexed items, see:

- Supported file types in eDiscovery (Premium)
- Partially indexed items in eDiscovery
- File formats indexed by Exchange Search
- Default crawled file name extensions and parsed file types in SharePoint Server

Viewing Advanced indexing results

After the Advanced indexing process is completed, you can get an understanding of the effectiveness of reprocessing. In the Advanced indexing results view on the **Processing** tab for a case, the graph lists the number of items added to the *hybrid index*. The hybrid index is where eDiscovery (Premium) stores the reprocessed content.

This view also includes the number of items that require remediation and another graph of errors by file type. For more information, see:

- Error remediation when processing data
- Single item error remediation

Updating the Advanced index

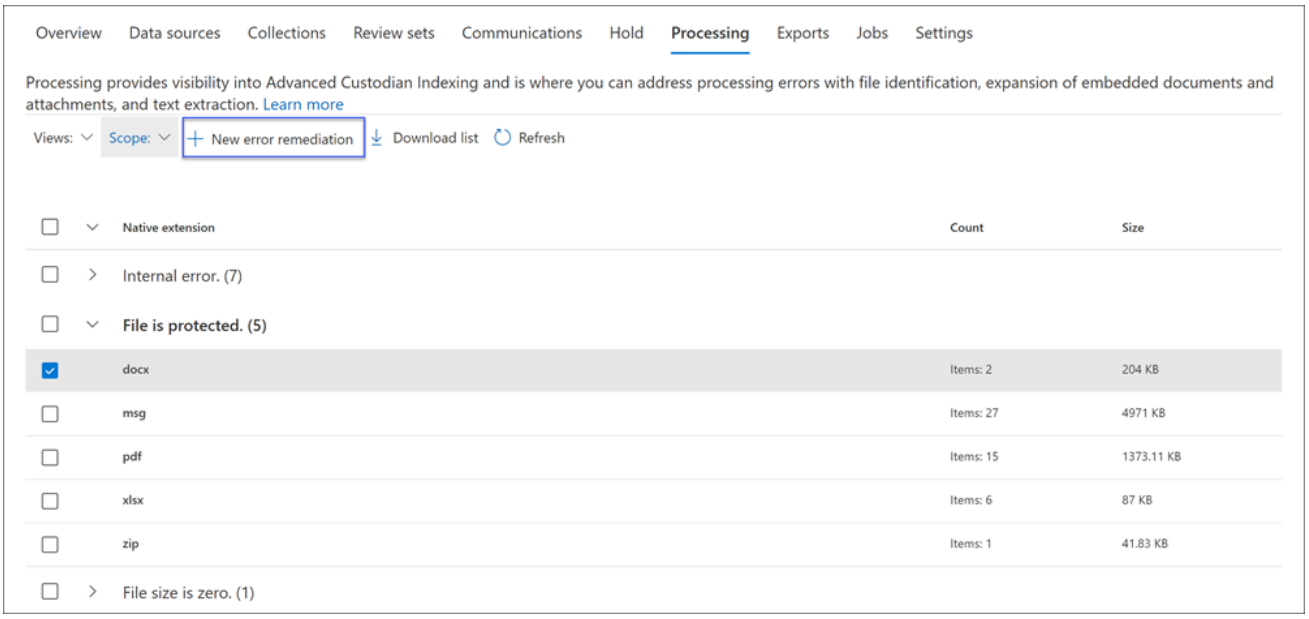
When a custodian or noncustodial data source is added to an eDiscovery (Premium) case, all partially indexed items are reprocessed. However, as time passes, more partially indexed items may be added to a user's mailbox or OneDrive account. If necessary, you can update the index for specific custodian or noncustodial data source. For more information, see Manage custodians in an eDiscovery (Premium) case. You can also update the index for all custodians and noncustodial data sources in a case by selecting the **Update index** on the **Processing** tab.

> **Note**
>
> Updating custodian and noncustodial indexes is a long running process. It's recommended that you don't update indexes more than once a day in a case.

Last updated on 11/21/2025

Error remediation when processing data

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

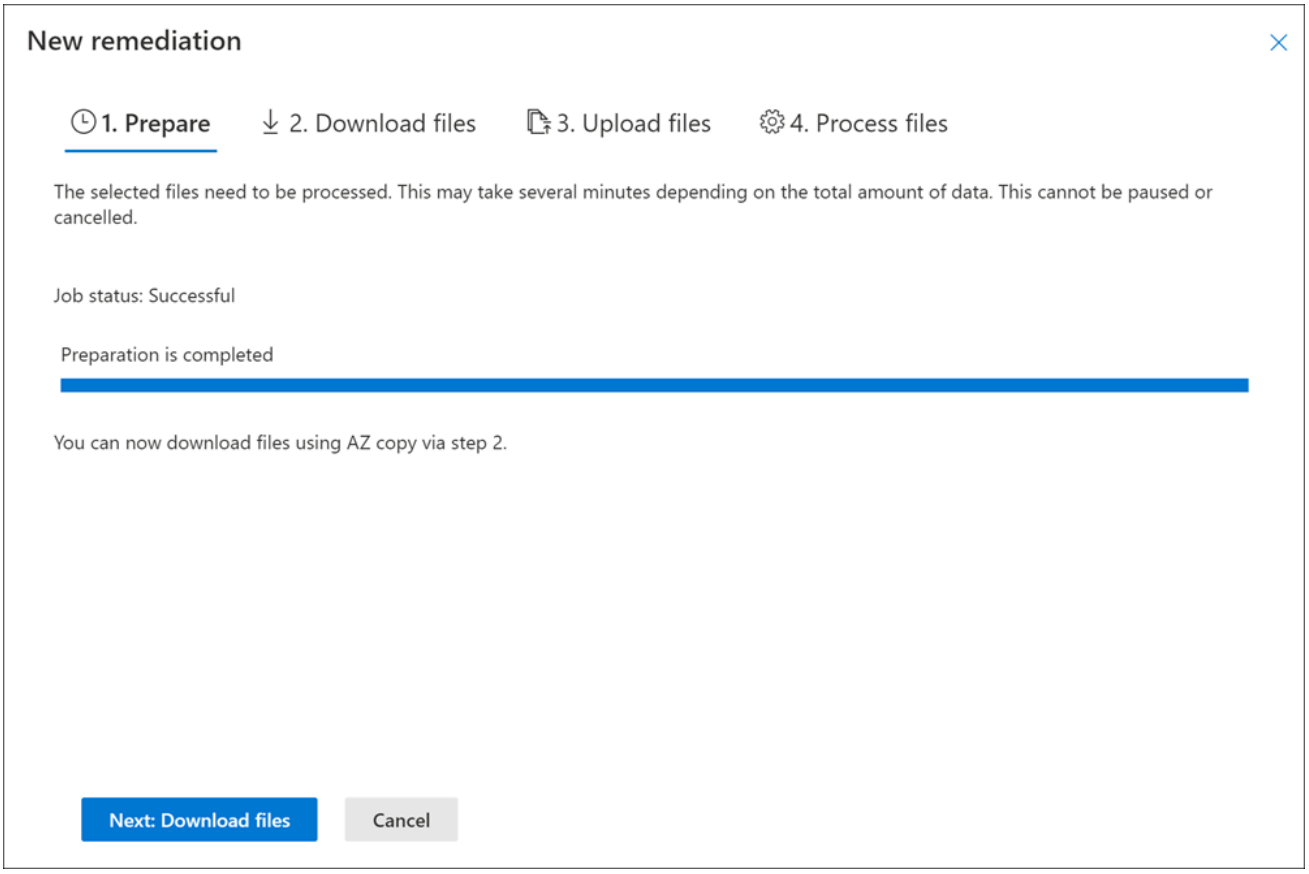


Error remediation allows eDiscovery administrators the ability to rectify data issues that prevent Microsoft Purview eDiscovery (Premium) from properly processing the content. For example, files that are password protected can't be processed since the files are locked or encrypted. Using error remediation, eDiscovery administrators can download files with such errors, remove the password protection, and then upload the remediated files.

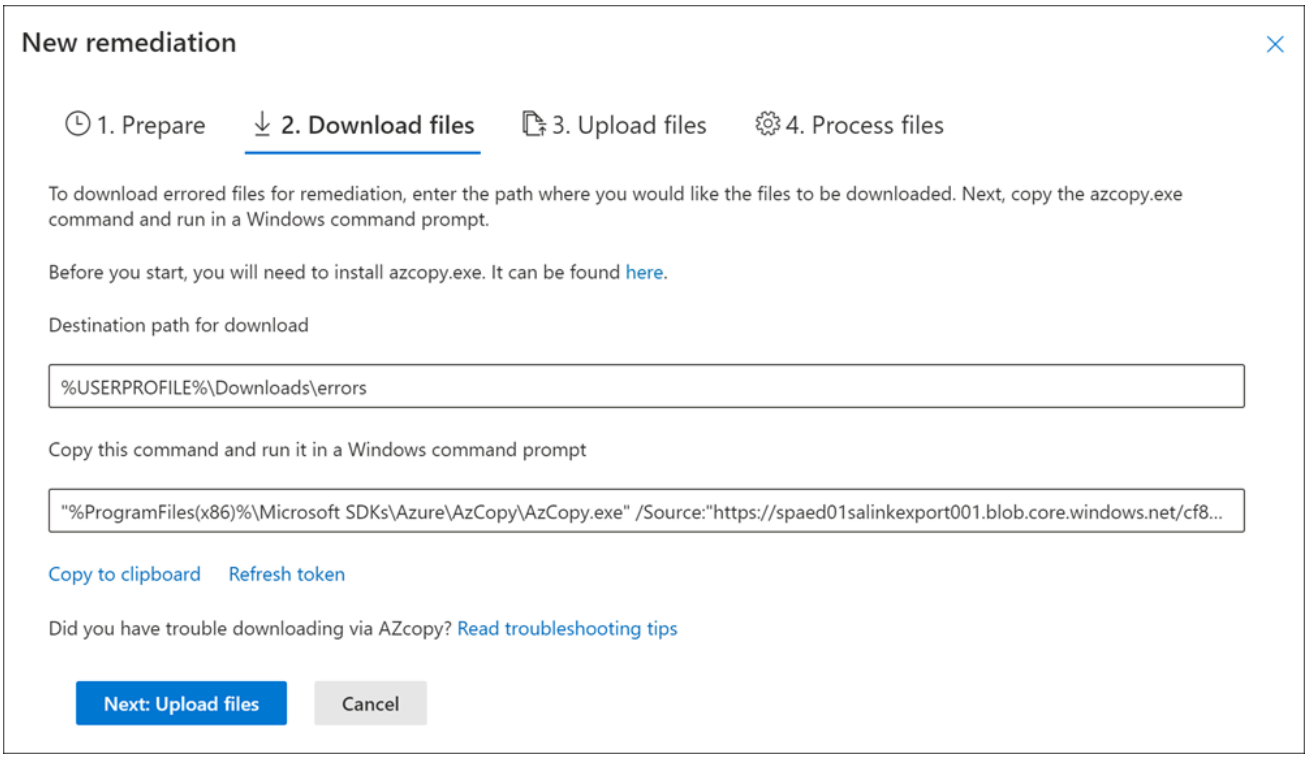
Use the following workflow to remediate files with errors in eDiscovery (Premium) cases.

Create an error remediation session to remediate files with processing errors

> **Note**
>
> If the error remediation workflow is closed at any time during the following procedure, you can return to the error remediation session from the **Processing** tab by selecting **Remediations** in the **View** drop-down menu.



1. On the **Processing** tab in the eDiscovery (Premium) case, select **Errors** in the **View** drop-down menu and then select a review set in the **Scope** drop-down menu. You must select a review set in the scope to start the remediation of any errors. After you've selected the scope, this section displays errors from the specific review set.



2. Select the errors you want to remediate by selecting either the error type or file type option. In the following example, we're remediating a password protected file.

3. Select **New error remediation**.

   The error remediation workflow starts with a preparation stage where the files with errors are copied to a Microsoft-provided Azure Storage location so that you can download them to your local computer to remediate.

4. After the preparation is complete, select **Next: Download files** to proceed with download.

5. To download files, specify the **Destination path for download**. This is a path to the parent folder on your local computer where the file will be downloaded. The default path, %USERPROFILE%\Downloads\errors, points to the logged-in user's downloads folder. You can change this path if desired. If you do change it, we recommend that you use a local file path for the best performance. Don't use a remote network path. For example, you could use the path **C:\Remediation**.

   The path to the parent folder is automatically added to AzCopy command (as the value of the **/Dest** parameter).

6. Copy the predefined command by selecting **Copy to clipboard**. Open a Windows Command Prompt, paste the AzCopy command, and then press **Enter**.

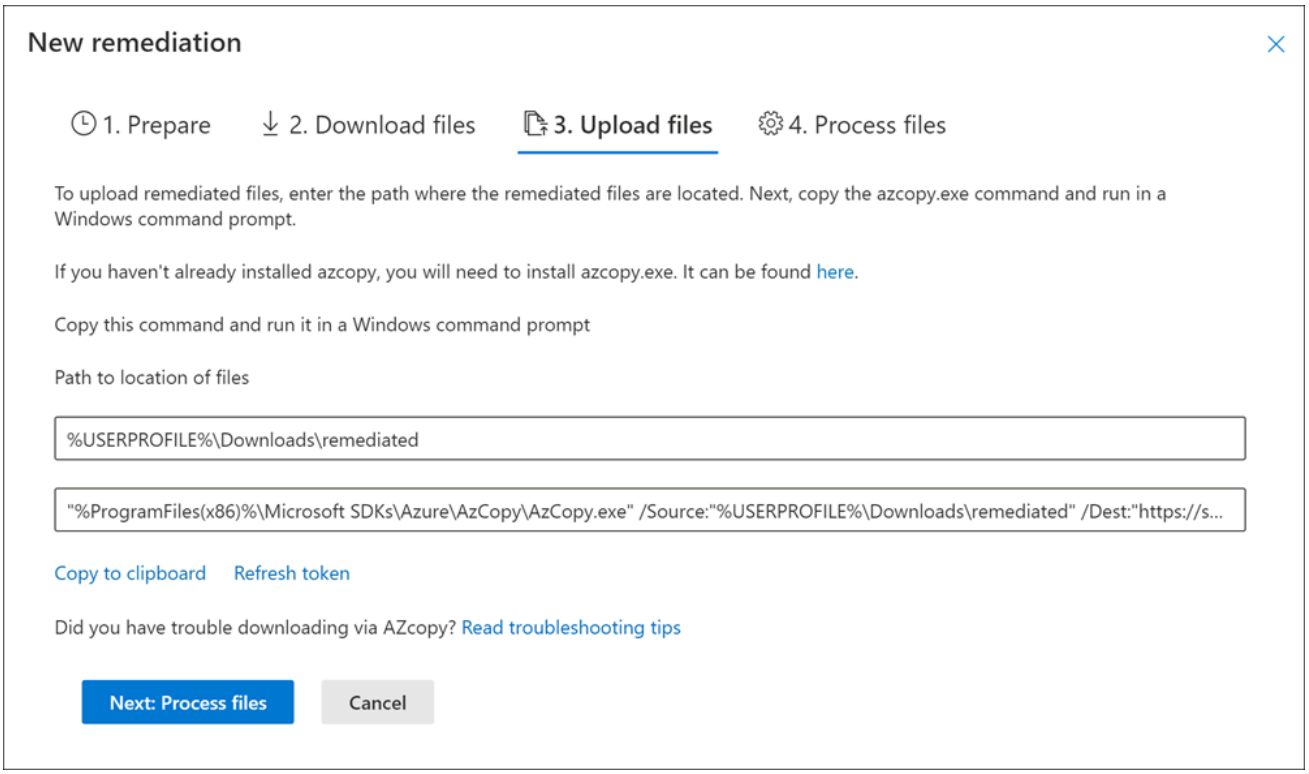
   > **Note**
   >
   > You should use the latest version of AzCopy to successfully use the command that's provided on the **Download files** page. You also must use AzCopy to upload the files in step 10. To install the latest version of AzCopy, see Get started with AzCopy. If the supplied AzCopy command fails, see Troubleshoot AzCopy in eDiscovery (Premium).

   The files that you selected are downloaded to the location that you specified in step 5. In the parent folder (for example, **C:\Remediation**), the following subfolder structure is automatically created:

`<Parent folder>\Subfolder 1\Subfolder 2\<file>`

- *Subfolder 1* is named with the ID for the case or the review set, depending on the scope that you selected in step 1.
- *Subfolder 2* is named with the file ID of the downloaded file
- The downloaded file is located in *Subfolder 2* and is also named with the file ID.

Here's an example of the folder path and error file name that's created when items are downloaded to the **C:\Remediation** parent folder:



`C:\Remediation\232f8b7e-089c-4781-88c6-210da0615d32\d1459499146268a096ea20202cd029857d64087706e6d6ca2a224970ae3b8938\d1459499146268a096ea20202cd029857d64087706e6d6ca2a224970ae3b8938.docx`

If multiple files are downloaded, each one is downloaded to a subfolder that's named with the file ID.

> **ⓘ Important**
>
> When you upload files in step 9 and step 10, the remediated files must have that same filename and be located in the same subfolder structure. The subfolder and file names are used to associated the remediated file with the original error file. If the folder structure or file names are changed, you'll receive the following error: `Cannot apply Error Remediation to the current Workingset`. To prevent any issues, we recommend that keep the remediated files in the same parent folder and subfolder structure.

7. After downloading the files, you can remediate them with an appropriate tool. For password-protected files, there are several password cracking tools you can use. If you know the passwords for the files, you can open them and remove the password protection.

8. Return to eDiscovery (Premium) and the error remediation workflow and then select **Next: Upload files**. This moves to the next page where you can now upload the files.

9. Specify the parent folder where the remediated files are located in the **Path to location of files** text box. Again, the parent folder must have the same subfolder structure that was created when you downloaded the files.

   The path to the parent folder is automatically added to AzCopy command (as the value of the **/Source** parameter).

10. Copy the predefined command by selecting **Copy to clipboard**. Open a Windows Command Prompt, paste the AzCopy command, and then press **Enter**. upload the files.

11. After you run the AzCopy command, select **Next: Process files**.

    When processing is complete, you can go to review set and view the remediated files.

Remediating errors in container files

In situations when the contents of a container file (such as a .zip file) can't be extracted by eDiscovery (Premium), the containers can be downloaded and the contents expanded into the same folder in which the original container resides. The expanded files will be attributed to the parent container as if it was originally expanded by eDiscovery (Premium). The process works as described previously except for uploading a single file as the replacement file. When you upload remediated files, don't include the original container file.

Remediating errors by uploading the extracted text

Sometimes it's not possible to remediate a file to native format that eDiscovery (Premium) can interpret. But you can replace the original file with a text file that contains the original text of the native file (in a process called *text overlay*). To do this, follow the steps described in this article but instead of remediating the original file in the native format, you would create a text file that contains the extracted text from the original file, and then upload the text file using the original filename appended with a .txt suffix.

For example, you download a file during error remediation with the filename 335850cc-6602-4af0-acfa-1d14d9128ca2.abc. You open the file in the native application, copy the text, and then paste it into a new file named 335850cc-6602-4af0-acfa-1d14d9128ca2.abc.txt. When you do this, be sure to remove the original file in the native format from the remediated file location on your local computer before uploading the remediated text file to eDiscovery (Premium).

> **Note**
>
> The number of files used in error remediation upload must match the number of files downloaded from the review set. If the number of uploaded files doesn't match the number of downloaded files, the matching process will fail (even if AzCopy reports that the upload was successful).

What happens when files are remediated

When remediated files are uploaded, the original metadata is preserved except for the following fields:

- ExtractedTextSize
- HasText
- IsErrorRemediate
- LoadId
- ProcessingErrorMessage
- ProcessingStatus
- Text
- WordCount
- WorkingsetId

For a definition of all metadata fields in eDiscovery (Premium), see Document metadata fields.

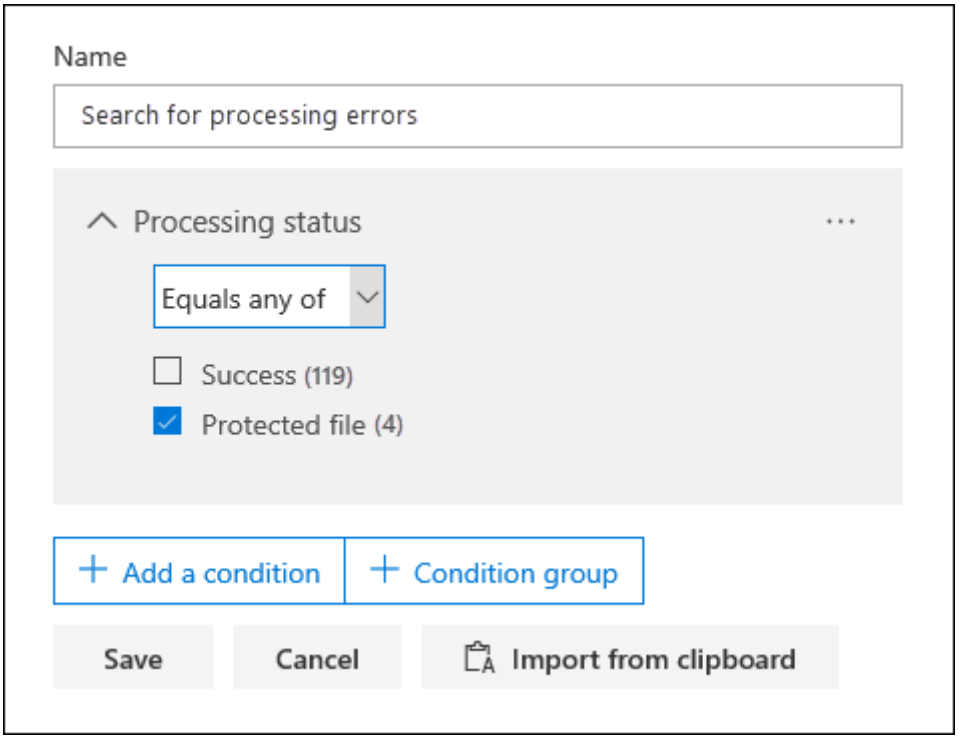
Single item error remediation in eDiscovery (Premium)

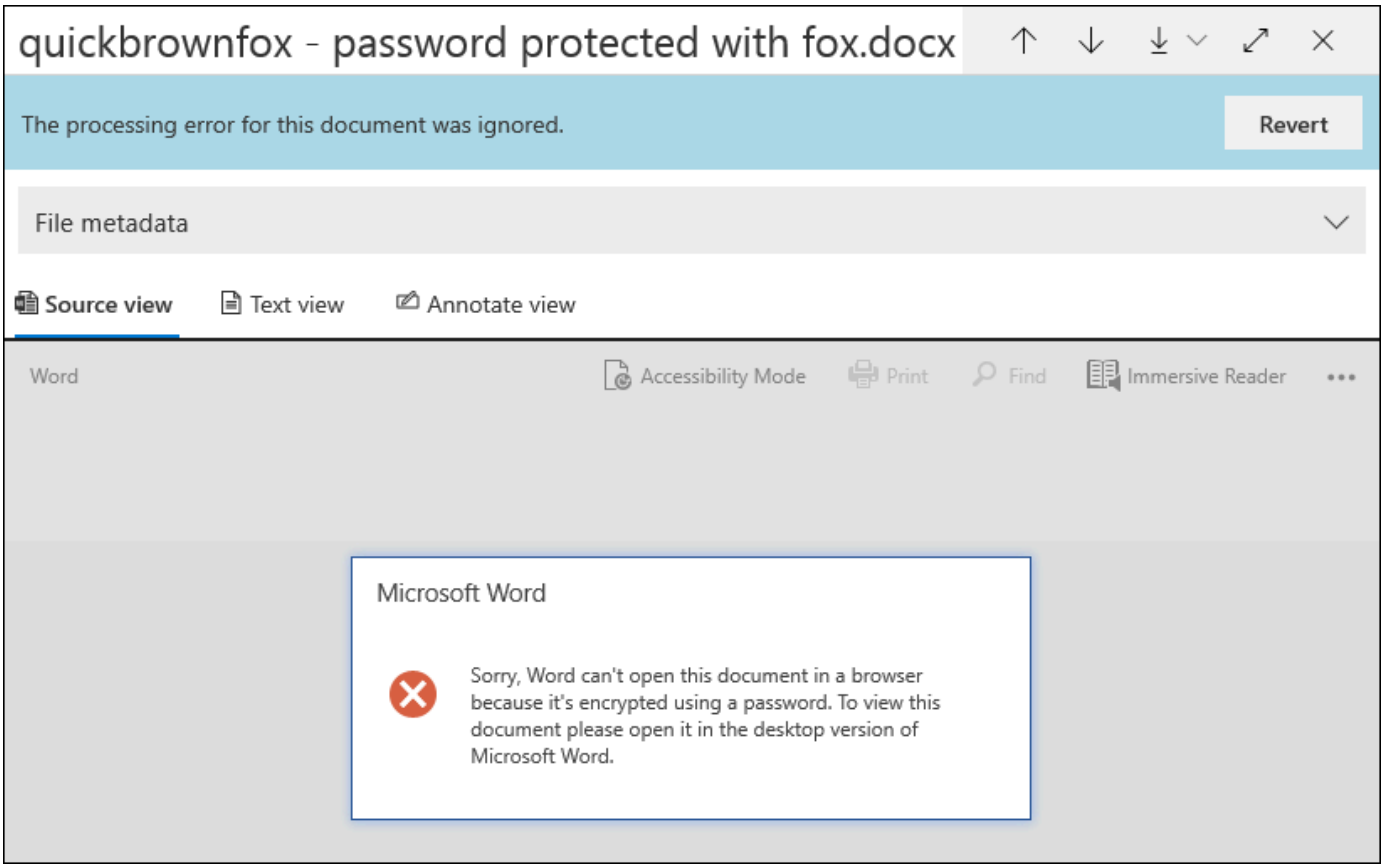
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.



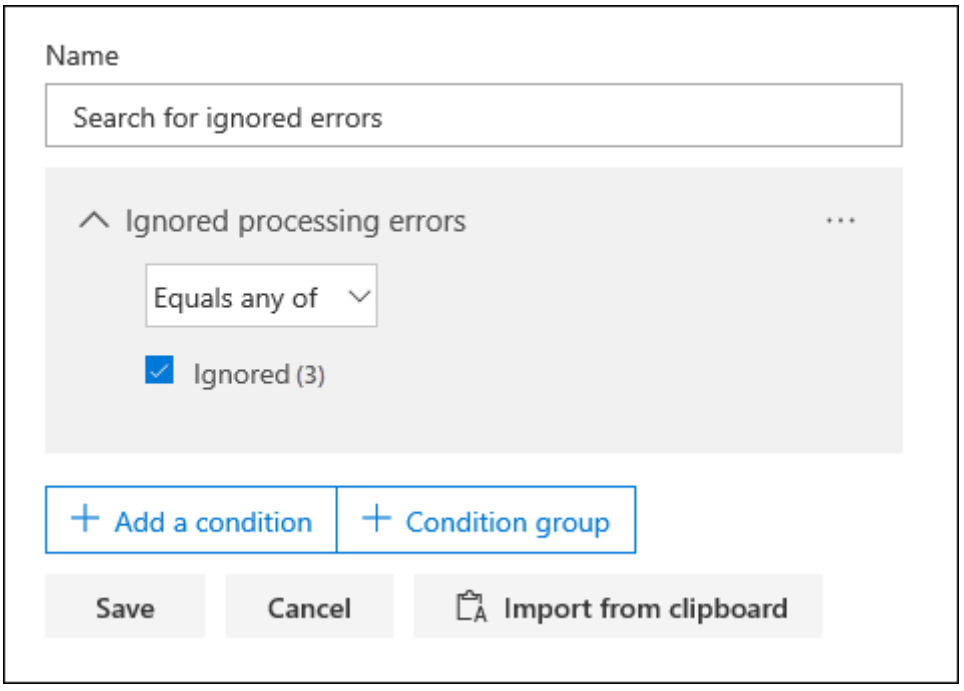
Error remediation gives Microsoft Purview eDiscovery (Premium) users the ability to rectify data issues that prevent eDiscovery (Premium) from properly processing the content. For example, files that are password protected can't be processed because those files are locked or encrypted. Previously, you could only remediate errors in bulk by using this workflow. But sometimes, it doesn't make sense to remediate errors in multiple files when you're unsure if any of those files are responsive to the case you're investigating. It also might not make sense to remediate errors before you've had a chance to review the file metadata (such as file location or who had access) to help you make up-front decisions about responsiveness. A new feature called *single item error remediation* gives eDiscovery managers the ability to view the metadata of files with a processing error and if necessary remediate the error directly in the review set. The article discusses how to identify, ignore, and remediate files with processing errors in a review set.

Identify documents with errors

Documents with processing errors in a review set are now identified (with a banner). You can remediate or ignore the error. The following screenshot shows the processing error banner for a Word document in a review set that is password-protected. Also notice that you can view the file metadata of documents with processing errors.



You can also search for documents that have processing errors by using the **Processing status** condition when querying the documents in a review set.

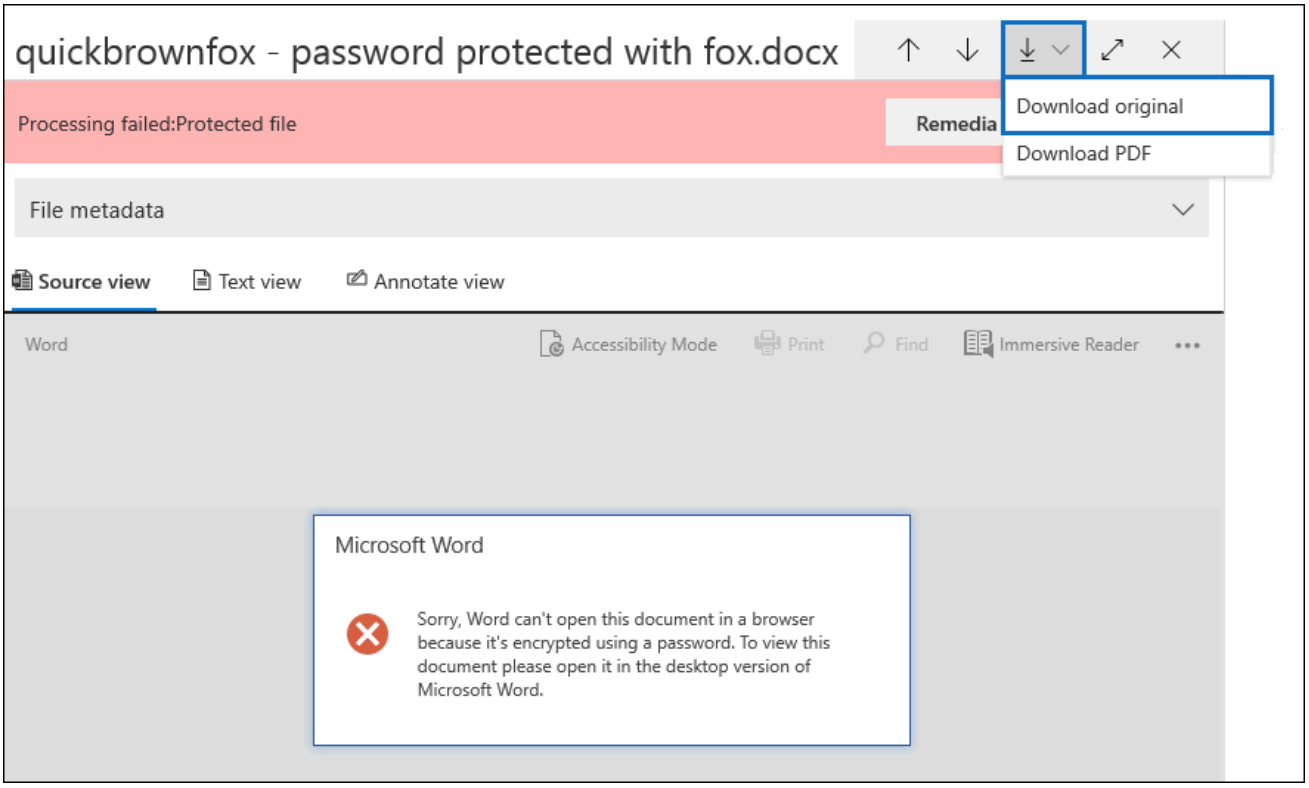


Ignore errors

You can ignore a processing error by selecting **Ignore** in the processing error banner. When you ignore an error, the document is removed from the bulk error remediation workflow. After an

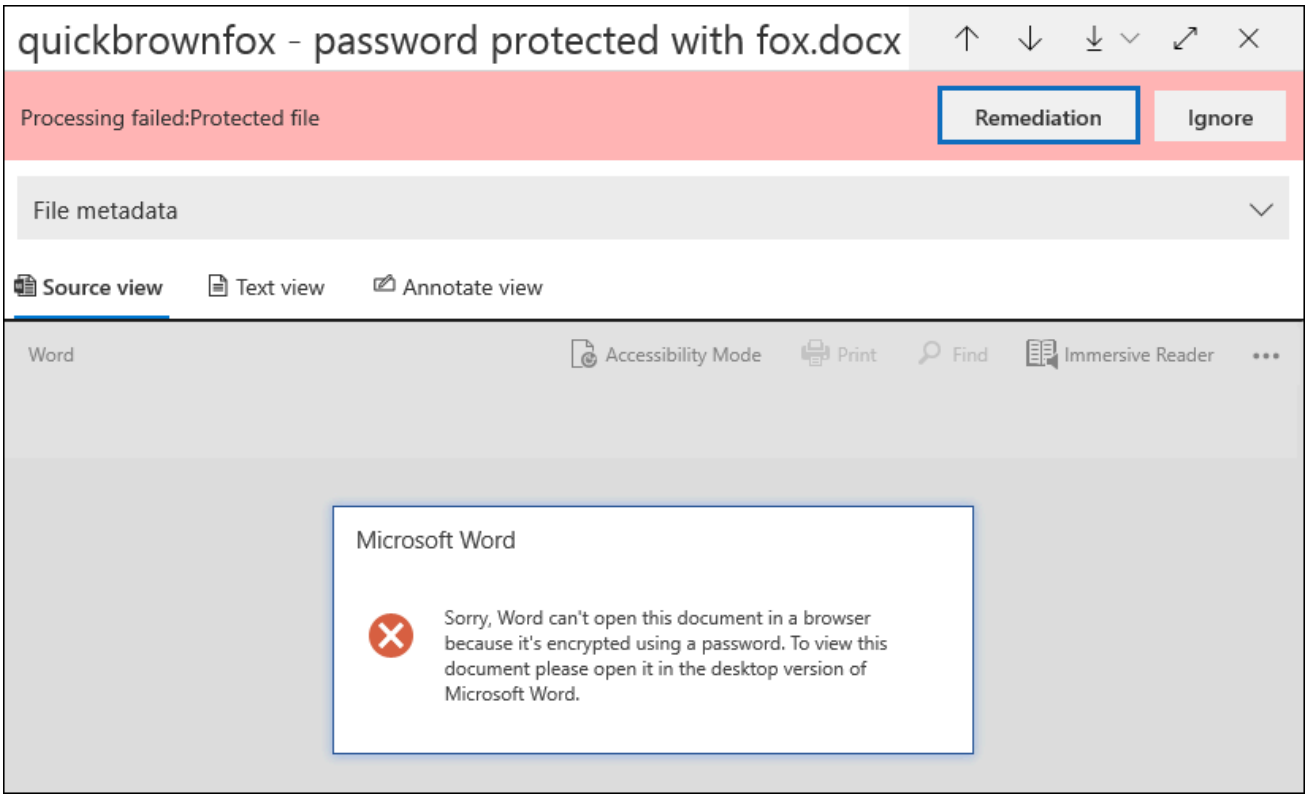
error is ignored, the document banner changes color and indicates that the processing error was ignored. At any time, you can revert the decision to ignore the error by selecting **Revert**.

You can also search for all documents that had a processing error that was ignored by using the *Ignored processing errors* condition when querying documents in a review set.



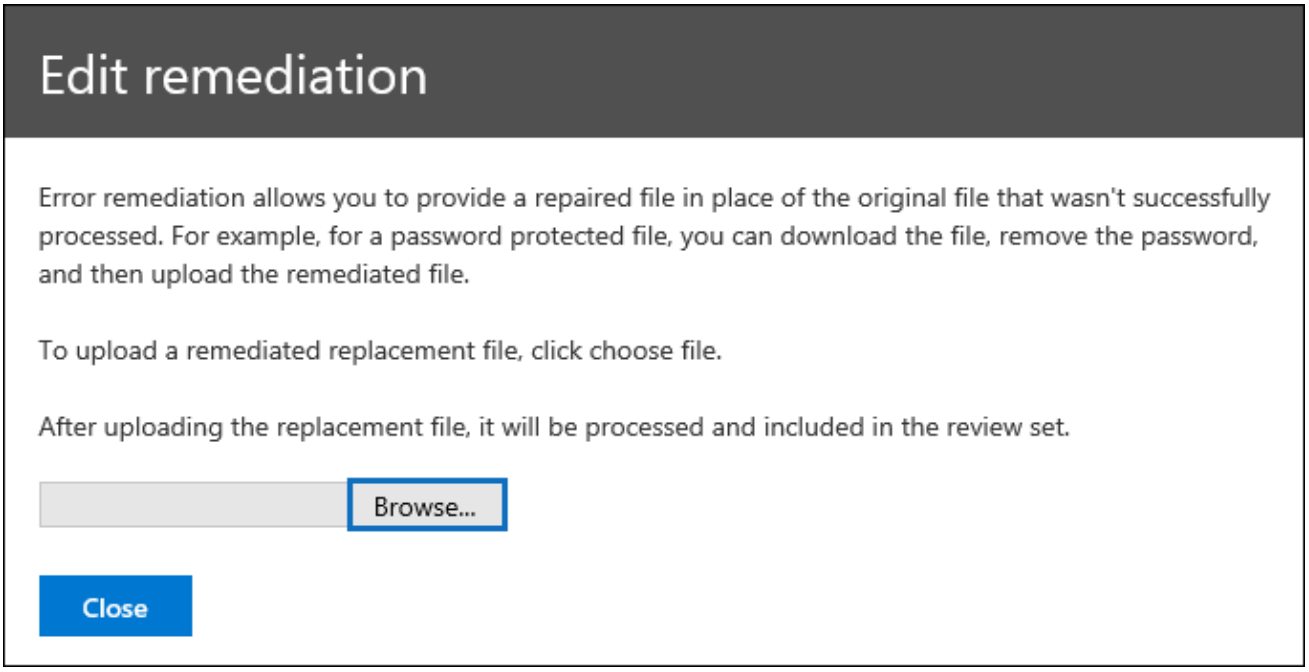
Remediate a document with errors

Sometimes you may be required to remediate a processing error in documents (by removing a password, decrypting an encrypted file, or recovering a corrupted document) and then add the remediated document to the review set. This allows you to review and export the error document together with the other documents in the review set.

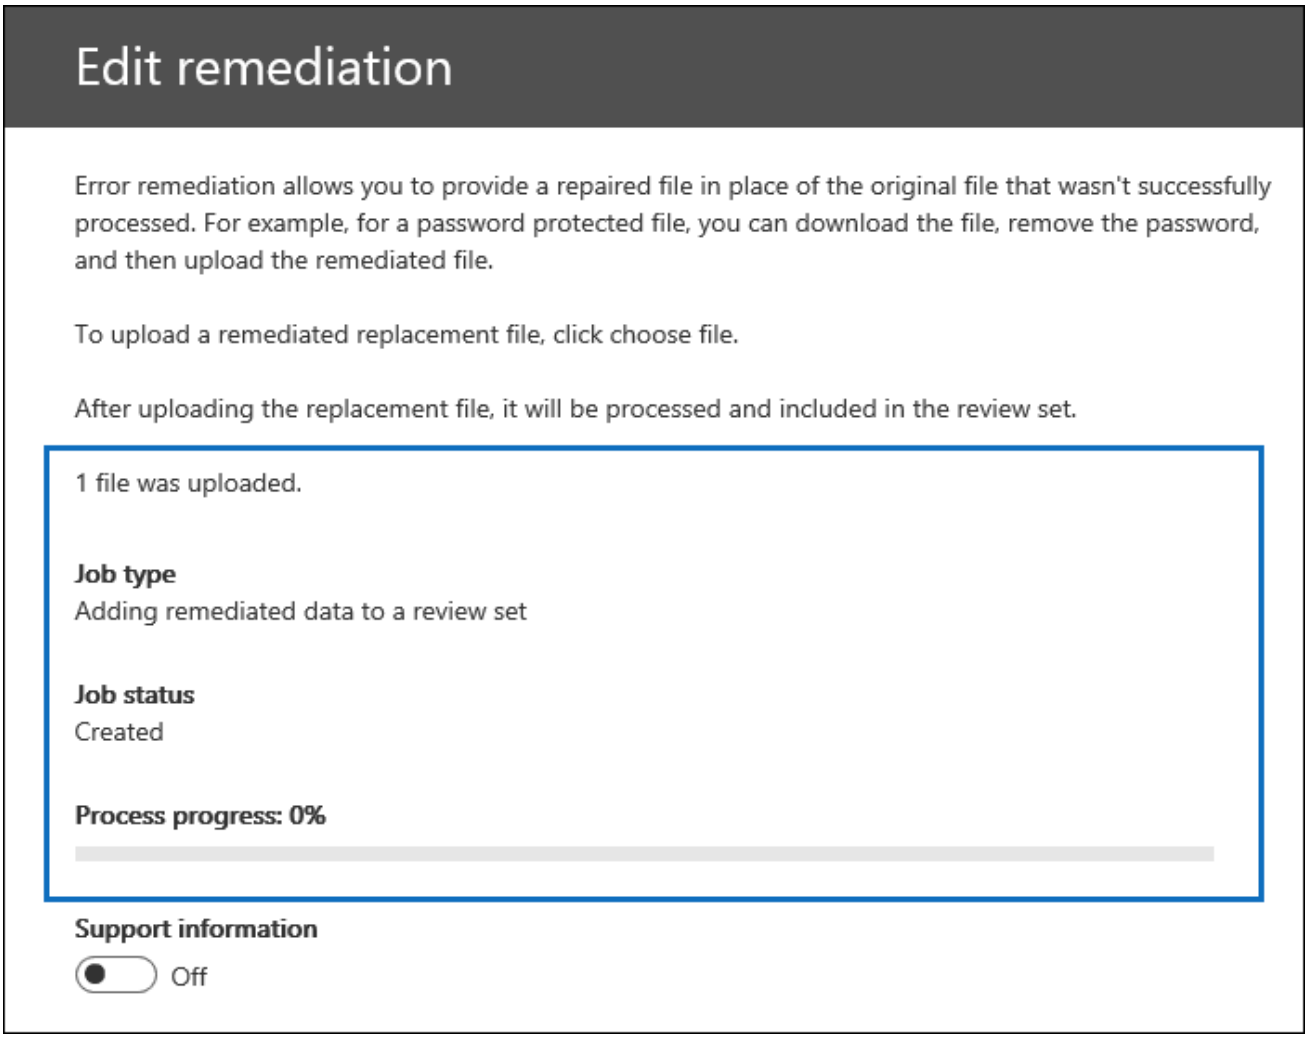


To remediate a single document, follow these steps:

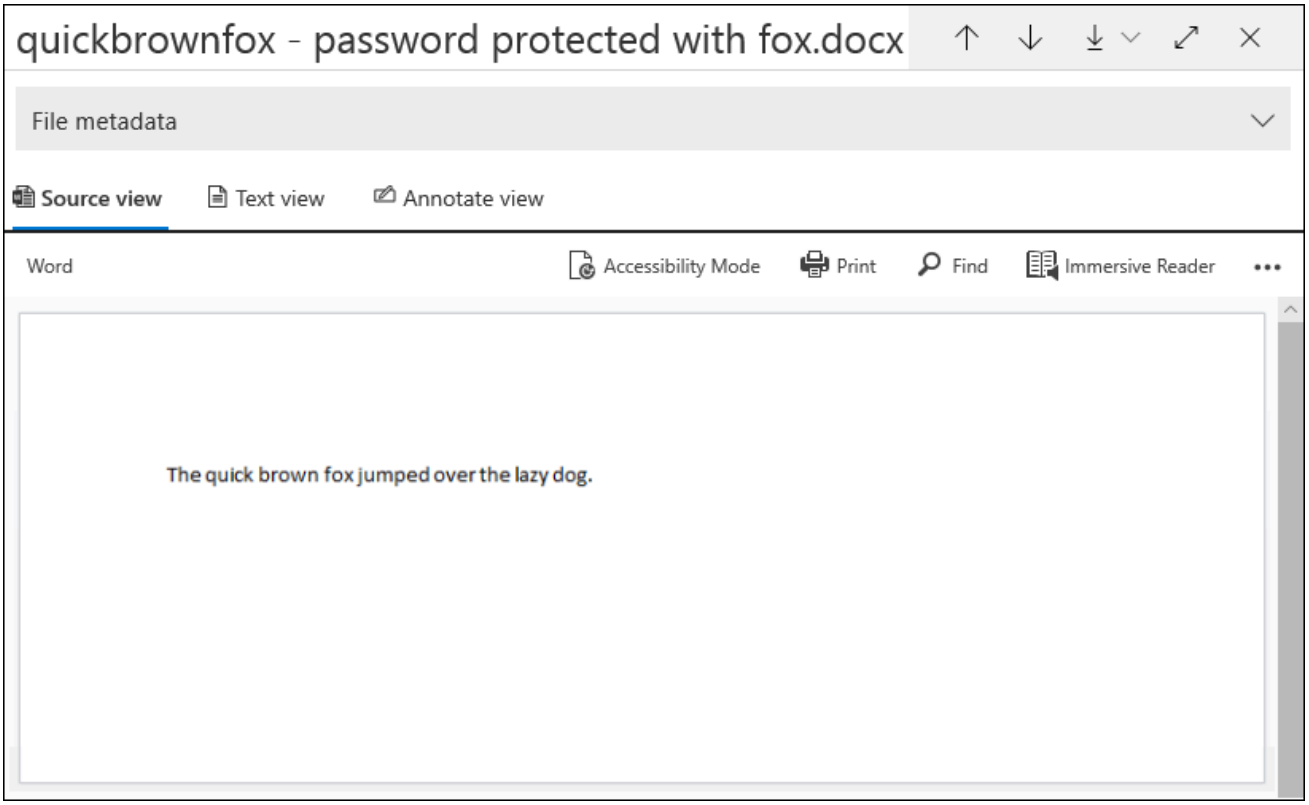
1. Select **Download** > **Download original** to download a copy of the file to a local computer.



2. Remediate the error in the file offline. For encrypted files, that would require decryption software, to remove password protection, either provide the password and save the file or use a password cracker. After you remediate the file, go to the next step.



3. In the review set, select the file with the processing error that you remediated, and then select **Remediation**.



4. Select **Browse**, go to the location of the remediated file on your local computer, and then select the file.

After selecting the remediated file, it is automatically uploaded to the review set. You can track the processing status of the file.

After processing is completed, you can view the remediated document.

For more information about what happens when a document is remediated, see What happens when files are remediated.

Search for remediated documents

You can search for all documents in a review set that were remediated by using the **Keywords** condition and specifying the following property:value pair: **IsFromErrorRemediation:true**. This property is also available in the export load file when you export documents from a review set.

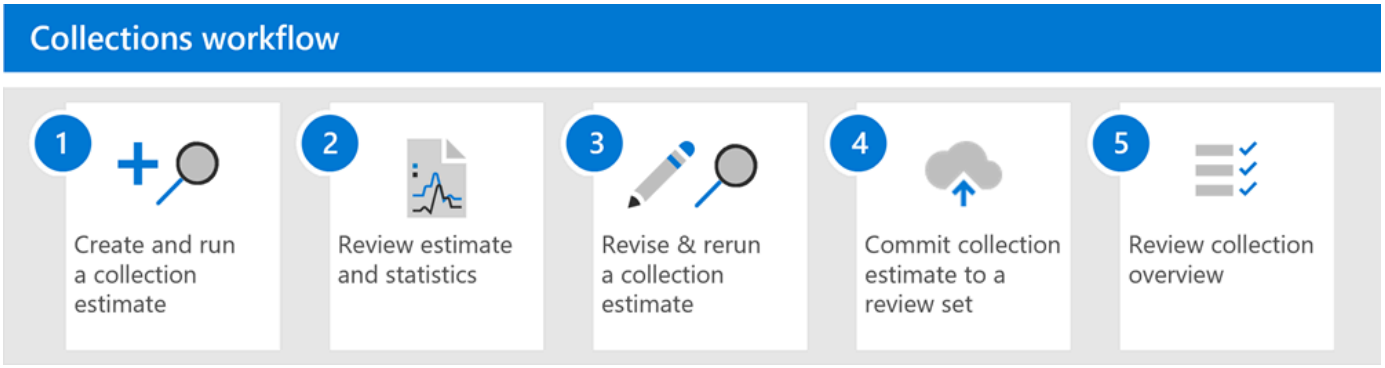
Last updated on 11/21/2025

Learn about collections in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When organizations are faced with gathering the communications and content that may be relevant to an investigation or potential litigation, they face a significant challenge under the best of circumstances. In today's modern workplace, the volume, variety, and velocity of content is enabling innovation and remote work, while also expanding the requirements and process for managing collections for eDiscovery investigations.

Collections in eDiscovery (Premium) help eDiscovery managers quickly scope a search for content across email, documents, Teams reactions, and other content in Microsoft 365. Collections provide managers with an estimate of the content that may be relevant to the case. This estimate allows managers to make quick, informed decisions about the size and scope of content relevant to a case. eDiscovery managers can create a collection to search custodial data sources (such as mailboxes and SharePoint sites), non-custodial data sources (such as SharePoint sites, Group mailboxes, and Microsoft Teams), and by using specific search criteria (such as keywords and date ranges) to quickly define the scope of their collection.



After the collection is defined, eDiscovery managers must first submit the collection to create an estimate. The estimate includes estimates for data volume, the content locations that contain results, and the number of hits for search query condition, and more. These insights can help to inform if the collection should be revised to narrow or expand the scope of the collection before moving on the review and analyze stages in the eDiscovery workflow.

When the manager is satisfied with the scope of the collection and the estimated amount of content that's likely to be responsive, the manager can add or *commit* the content to a review set.

When committing a collection to a review set, that manager also has the options to include chat conversations, cloud attachments, partially indexed items, and document versions. The content in the collection also goes through another level of processing during ingestion into the review set. and the collection will be updated with the final collection summary. After content is added to the review set, eDiscovery managers can continue to query, group, and refine the content in to help with minimization and review. Additionally, the collection is updated with information and statistics about the content committed to the review set. This information provides a historical reference about the content in the collection.

Collections workflow

To get started using collections in eDiscovery (Premium), here's a basic workflow and descriptions of each step in the process.

1. **Create and run a collection estimate**. The first step is to create a collection estimate and define the custodial and non-custodial data sources to search. You can also search other data sources that haven't been added to the case. After you add the data sources, you configure the search query to search the data sources for content relevant to the case. You can use keywords, properties, and conditions to build search queries that return content that's likely most relevant to the case. For more information, see Create a collection estimate.

2. **Review estimate and statistics**. After you create a collection estimate and run it, the next step is to view collection statistics to help you verify whether relevant content is being found and the content locations with the most hits. You can also review a sample of the search results to further help you determine if the content is within scope of your investigation. For more information, see Search statistics for collection estimates.

3. **Revise & rerun a collection estimate**. Based on the estimates and statistics returned by the collection, you can edit the collection estimate by changing the data sources that are searched and the search query to expand or narrow the collection. You can update and

rerun the collection estimate until you're confident that collection contains the content that's most relevant to your case.

4. **Commit a collection estimate to a review set**. When you're satisfied that the collection returns the type content that is relevant to the case, you can commit the collection to the review set. When you commit a collection, you have the option to add conversation threads, cloud attachments, and document versions to the review set, all of which might be relevant to the case.

   When you commit a collection, child items such as email signatures and images are extracted from a parent item (such as an email message, chat message, or document) and then processed by Optical Character Recognition (OCR) to extract any text from the child item. Text extracted from child items is then added to its parent item so you can view it in the review set. By not adding child items to the review set as a separate file, eDiscovery (Premium) helps limit the number of potentially immaterial items added to the review set. For more information about how child items are handled, see Collection statistics and reports.

   For more information, see Commit a collection estimate to a review set.

5. **Review collection overview**. After you commit a collection to a review set, information about the collection is retained, such as statistics about extracted items, deep indexing, the search query used for the collection, and the content locations that items were collected from. Also, committed collections can't be edited or rerun. You can only copy or delete them. Preserving collections provides a historical record of the collected items that were added to a review set. For more information, see Statistics and reports for committed collections.

Last updated on 09/02/2025

Create a collection estimate in eDiscovery (Premium)

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After you've identified custodians and any non-custodian data sources for the case, you're ready to identify and locate a set of documents that are relevant by using the **Collections** tool to search data sources for relevant content. You can create a collection that searches specified data sources for content that matches your search criteria. You must create a *collection estimate*, which is an estimate of the items found.

When you create a collection estimate, you can view information about the estimated results that matched the search query, such as the total number and size of items found, the different data sources for the found items, and statistics about the search query. You can also review a sample of items that were returned by the collection. Using these statistics, you can change the search query and rerun the collection estimate to narrow your results. Once you're satisfied with the collection results, you can commit the collection to a review set. When you commit a collection estimate, the items returned by the collection are added to a review set for review, analysis, and export.

Recommendations when creating collection estimates

- Consider adding custodians and non-custodial data sources to the case before you create a collection estimate. Adding these sources allows you to quickly select the data sources when you create a collection estimate in the workflow. If you choose to skip adding custodians or non-custodial data sources, you can search for these sources and any additional data sources (ones that haven't been added to the case as custodial or non-custodial locations) in a collection estimate for content that may be relevant to the case.

These data sources might include mailboxes, SharePoint sites, and Teams. If this situation is applicable to your case, use additional locations to add these sources to your collection.

- Verify that you have permissions to create a collection estimate for a case.
- When configuring a new collection, you can save your progress in the workflow as a draft collection and complete it later if needed. Just select **Save and close** on any page in the collection workflow to save your progress as a draft. The collection is added to the collection list with a status of *Draft*. To resume working on the collection, select the draft collection, select **Actions**, then select **Edit collection**.

Create a collection estimate

1. In the Microsoft Purview portal, navigate to **eDiscovery** > **Premium**.
2. Select the **Cases** tab and open an eDiscovery (Premium) case, and then select the **Collections** tab.
3. On the **Collections** page, select **New collection**.
4. On the **Name and description** page, enter a name (required) and description (optional) for the collection. After the collection is created, you can't change the name, but you can modify the description.
5. On the **Custodial data sources** page, select one of the following options to identify the custodial data sources to collect content from:
    - Select **Select custodians** to search specific custodians that were added to the case. If you use this option, a list of the case custodians is displayed. Select one or more custodians. After you select and add the custodians, you can also select the specific data sources to search for each custodian. Data sources that are displayed are specified when the custodian is added to the case.
    - Select the **Select all** toggle to search all custodians that were added to the case. When you select this option, all data sources for all custodians are searched.
6. On the **Non-custodial data sources** page, select one of the following options to identify the non-custodial data sources to collect content from:
    - Select **Select non-custodial data sources** to select specific non-custodial data sources that were added to the case. If you use this option, a list of data sources displayed. Select one or more of these data sources.

- Select the **Select all** toggle to select all non-custodial data sources that were added to the case.

7. On the **Additional locations** page, you can select other mailboxes and sites to search as part of the collection. You can also choose additional search options for additional search locations (defined in eDiscovery settings) to include in the collection.

   Use the **Additional locations** options to choose the types of data sources weren't added as custodial or non-custodial data locations in the case. You also have two options when searching additional data sources:

   - To search all content locations for a specific service (Exchange mailboxes, SharePoint and OneDrive sites, or Exchange public folders), select the corresponding **Select all** toggle in the **Status** column. This option will search all content locations in the selected service.

8. On the **Search query** page, you can create the search query that is used to collect items from the data sources that you've identified in the previous workflow pages. You can search for keywords, property:value pairs, or use a keyword list. You can also add various search conditions to narrow the scope of the collection or user the query builder to define query operators, filters, and conditions. For more information, see:

   - Build search queries using keywords and conditions for collections
   - Use the KeyQL editor to build search queries
   - Use the query builder to build search queries
   - Use the Natural Language Query builder to build search queries (preview)

   Use the **Additional search options** options to include other search locations. The options available here are set by your admin in eDiscovery global settings. Search options that aren't defined by your eDiscovery admin aren't selectable or available. Search options enabled by your eDiscovery admin can be selected and included in the collection as applicable. You have two choices for additional search options:

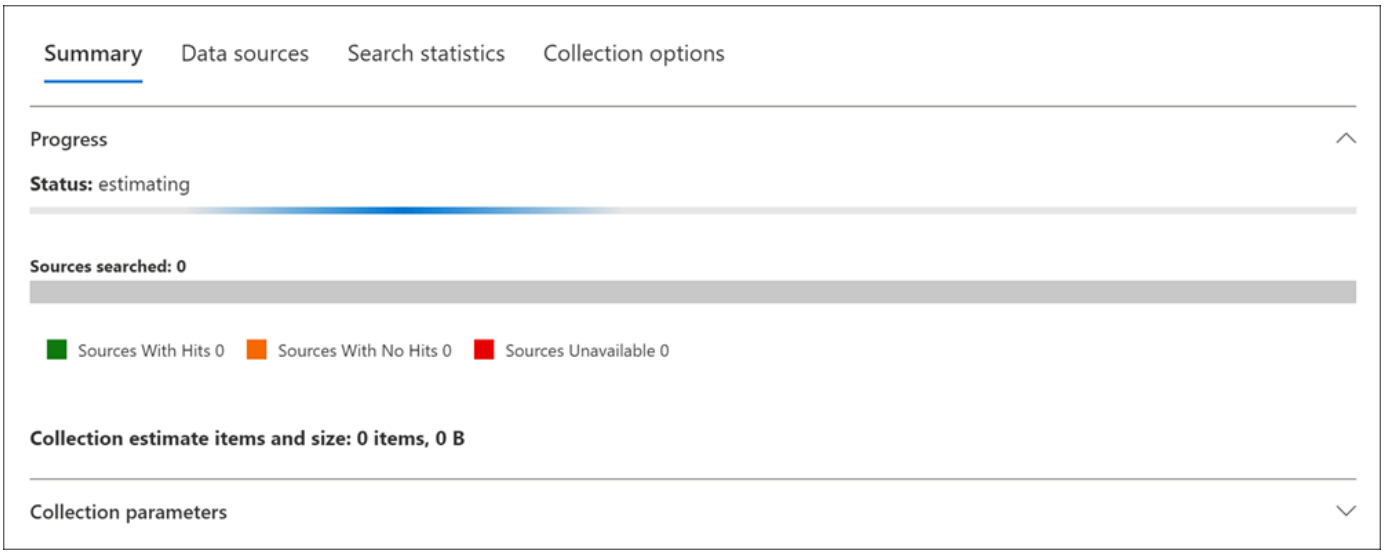
   - **Guest mailboxes**: Select to include guest mailboxes during tenant-wide searches.
   - **Shared Teams channels**: Select to include shared channels during tenant-wide searches.

9. On the **Conditions** page, you can create the search query that is used to collect items from the data sources that you've identified in the previous workflow pages. You can search for keywords, property-value pairs, or use a keyword list. You can also add various search

conditions to narrow the scope of the collection. For more information, see Build search queries for collections.

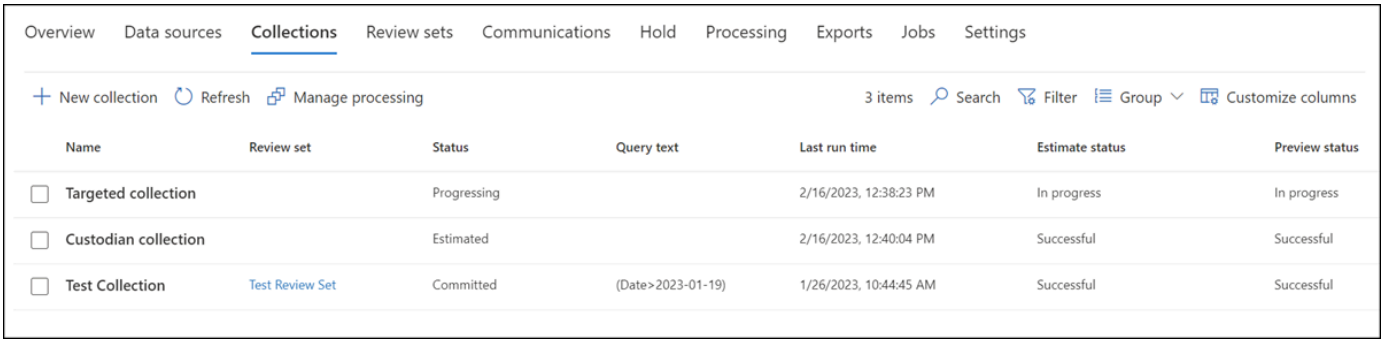
10. On the **Review your collection and get estimates** page, you'll see a summary of the collection estimate process. The collection estimate is saved for further review and refinement, but the results won't be automatically committed to a review set. You'll need to decide to commit to a review set later.

11. On the **Review your collection** page, you can review and update the collection selection, data sources, and conditions that you configured on the previous pages. Select **Edit** for any of the selections and update if needed.



12. Select **Submit** to create the collection estimate. A page is displayed confirming that the collection was created.

What happens after you create a collection estimate



After you create a collection estimate, it listed on the **Collections** page in the case and the status shows that it's in progress. A job named **Preparing search preview and estimates** is also created and displayed on the **Jobs** page in the case. During the collection estimate process, eDiscovery (Premium) performs a search estimate using the search criteria and data sources that you specified in the collection. eDiscovery (Premium) also prepares a sampling of items that you can preview.

Additionally, you can now monitor the progress of the estimate that shows how many sources and items have been completed when building the estimate. As part of the estimate progress, you can see statistics for the following areas:

- **Status**: The status of the estimate. Values are *In progress*, *Successful*, or *UNSUCCESSFUL VALUE?*
- **Sources searched**: The number of sources searched in the estimate.
  - **Sources with Hits**: Sources in the estimate that meet the conditions configured for the collection.
  - **Sources with No Hits**: Sources in the estimate that don't have any items that meet the conditions configured for the collection.
  - **Sources Unavailable**: Sources that were unavailable during the period that the estimate was in progress.
- **Collection estimate items and size**: The number of items and size of the collection estimate.

When the collection is complete, the following columns and corresponding values on the **Collection** page are updated:

- **Status**: Indicates the status and type of collection. A value of **Estimated** indicates that a collection estimate is complete. This same value also indicates that the collection is a collection estimate, and that it hasn't been added to a review set. A value of **Committed** in the **Status** column indicates that the collection has been added to a review set.
- **Estimate status**: Indicates the status of the estimated search results and whether or not the search estimates and statistics are ready for review. A value of **Successful** indicates the results of the collection estimate are ready for review. After you first submit a collection estimate, a value of **In progress** is displayed to indicate the collection is still running
- **Preview status**: Indicates the status of the sample items that you can preview. A value of **Successful** indicates the items are ready for preview. After you first submit a collection estimate, a value of **In progress** is displayed to indicate that the collection estimate is still running.

Next steps after a collection estimate is complete

After the collection estimate is successfully completed, you can perform various tasks. To perform most of these tasks, go the **Collections** tab and select the name of the collection estimate to

display the flyout page.

Summary | Data sources | Search statistics | Collection options

Collection overview (preview)

Understand how the items were found, retrieved, and processed as part of this collection.

Locations with hits

We **searched 7,238 locations,** and found **5,815 locations with hits.**

7,309 mailboxes and 0 sites were searched.

1 locations failed to be searched during estimate.

Retry failed locations

Pre-collection estimates

2,549,828 items (~378.26 GB) had search hits.

11,600 items were partially indexed and weren't fully searched. You can add these items to a review set for inspection.

Estimate

2,549,828 item(s) (378.26 GB)

11,600 unindexed item(s), 6.29 GB

5,815 mailboxes

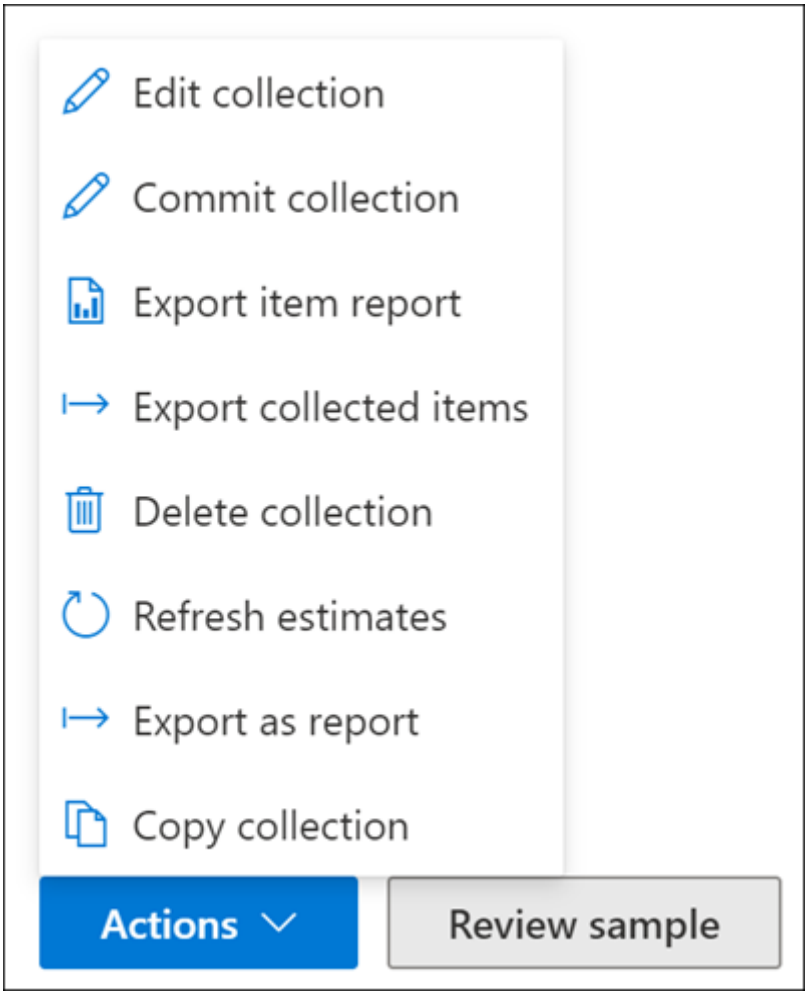
0 sites

> **Note**
>
> You may see differences between the number of *locations with hits* and the total number of Exchange mailboxes, SharePoint and OneDrive sites, or Exchange public folders searched. Empty archived mailboxes are searched, but aren't included in the *location with hits* total.

Here's a list of things you can do from the collection flyout page:

- Select the **Summary** tab to view summary information about the collection and the estimated search results returned by the collection. This includes:
  - **Collection overview** section: This section includes the **Locations with hits** subsection that provides data on the total number of locations searched and the number of locations that contained items resulting in hits. For example, a collection scoped to Exchange Online mailboxes and SharePoint sites may summarize results by the number of mailboxes and sites searched, and the combined number of mailboxes and sites that had hits. This section also includes the **Pre-collection estimate** subsection that displays the total number of items and size of the estimated search results. You have the option to add these items to the review set for inspection.
  - **Collection parameters** section: This section includes information about additional locations, when the collection was created and modified, and a summary of the estimate items, size, and any unindexed items and size.

- Select the **Data sources** tab to view a list of custodians and non-custodial data sources) that were searched in the collection. Any additional content locations that were search are listed under **Locations** on the **Summary** tab.



- Select the **Search statistics** tab to view statistics about the collection. This includes the total number and size of items found in each service (for example, Exchange mailboxes or SharePoint sites) and a condition report that displays statistics about the number of items returned by different components of the search query used by the collection. For more information, see Collection statistics and reports.

- Select the **Collection options** tab to view information about the included collection options. This includes a summary of the additional locations and retrieval options chosen in the collection workflow.

- Select **Review sample** (located at the bottom of the flyout page) to preview a sample of the items returned by the collection.
- Take actions on the collection estimate by selecting choices in the **Actions** menu. For more information, see the following section about the available management options.

Manage a collection estimate

You can use the options in the **Actions** menu on the flyout page of a collection estimate to perform various management tasks.

Here's the descriptions of the pre-collection estimate management options.

- **Edit collection**: Change the settings of the collection estimate. After you make changes, you can rerun the collection and update the search estimates and statistics. As previously explained, you use this option to commit a collection estimate to a review set.
- **Commit collection**: Commit a collection to a review set. This means that you rerun the collection (using the current settings) and add the items returned by the collection to a review set. As previously explained, you can also configure additional settings (such as conversation threading and cloud-based attachments) when you add the collection to a

review set. For more information and step-by-step instructions, see Commit a collection estimate to a review set.

- **Export item report**: Similar to the exporting items in Content search, you can choose this option to export the results of the report that is based on the actual items that can be retrieved from the source. After selecting, you have the following export options for collected items:

  - **Types of collected items to include in the export**: Choose to export collected items with search hits, items with search hits and partially indexed items without hits, or only partially indexed items without search hits. You can also choose to one or more of the following options for collected items:
    - Include Microsoft Teams and Viva Engage conversations
    - Include cloud attachments
    - Include all existing versions of Microsoft 365 documents on SharePoint
    - Include subfolder contents (insider subfolders of a matched folder)
    - Include files in SharePoint lists (and their child items)

- **Export collected items**: Export the collected items without adding the items to the review set. This option is useful in scenarios where data residency requirements associated with data storage may be prohibitive and you need collected data as a download. After selecting, you have the following export options for collected items:

  - **Types of collected items to include in the export**: Choose to export collected items with search hits, items with search hits and partially indexed items without hits, or only partially indexed items without search hits. You can also choose to one or more of the following options for collected items:
    - Include Microsoft Teams and Viva Engage conversations
    - Include cloud attachments
    - Include all existing versions of Microsoft 365 documents on SharePoint
    - Include subfolder contents (inside subfolders of a matched folder)
    - Include files in SharePoint lists (and their child items)

    To export Teams messages as individual messages when exporting collected items, unselect **Teams and Viva Engage conversations**. This exports conversations as individual messages and not as conversation threads.

    > ⓘ **Note**

The **Teams and Viva Engage conversations** setting is selected by default. If selected, exported items contain Teams conversation threads related to the matched search.

  - **How to format emails**: Choose an option of how collected emails should be formatted:
    - Individual .pst files for each mailbox
    - Individual .msg files for each message
    - Individual .eml files for each message

- **Delete collection**: Delete a collection estimate. After you commit a collection estimate to a review set, it can't be deleted.

- **Refresh estimates**: Rerun the query (against the data sources) specified in the collection estimate to update the search estimates and statistics.

- **Export as report**: Exports information about the collection estimate to a CSV file that you can download to your local computer. The export report contains the following information:
  - The identity of each content location that contains items that match the search query in the collection estimate. These locations are typically mailboxes or sites.
  - The total number of items in each content location.
  - The total size (in bytes) of the items in each content location.
  - The service (such as Exchange or SharePoint) in which the content location is located.

  For more information about the limits for **Export as report**, see Collection limits.

- **Copy collection**: Create a new collection estimate by copying the settings from an existing collection. You have to use a different name for the new collection. You also have the option to modify the settings before you submit the new collection. After you submit it, the search query runs and new estimates and statistics are generated. This is a good way to quickly create additional collection estimate and then modify selected settings as necessary while still preserving information in the original collection. This also lets you easily compare the results of two similar collections.

> **Note**
>
> After a collection estimate is committed to a review set, you can only select **Copy collection** and **Export as report**.

Commit a collection estimate to a review set in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When you're satisfied with the items you've collected in a collection estimate and are ready to analyze, tag, and review them, you can commit a collection to a review set in the case. When you commit a collection estimate to a review set, collected items are copied from their original content location in Microsoft 365 services and added to a review set. A review set is a secure, Microsoft-provided Azure Storage location in the Microsoft cloud.

Commit a collection estimate to a review set

1. In the Microsoft Purview portal, navigate to **eDiscovery** > **Premium**.
2. Select the **Cases** tab and open an eDiscovery (Premium) case, and then select the **Collections** tab.

> **Tip**

A value of `Estimated` in the **Status** column identifies the collection estimates that can be added to a review set. A status of `Committed` indicates that a collection has already been added to a review set.

3. On the **Collections** page, select the collection estimate that you want to commit to a review set.

4. On the bottom of the flyout page, select **Commit collection**.

5. Configure the following settings:

   a. Decide whether to **Add to a new review set** (which is created after you submit the collection) or **Add to an existing review set**. Complete this section based on your decision.

   b. Configure the **Retrieval** settings:

      A. **Teams and Viva Engage conversations**: Select this option to add conversation threads to the collection that include the chat items returned by the search query in the collection. This means that the chat conversation that contains items that match the search criteria is reconstructed. This lets you review chat items in the context of the back and forth conversation. Collect up to 12 hours of related conversations when a message matches a search. For more information, see Conversation threading in eDiscovery (Premium).

      To export Teams messages as individual messages when committing to review set, unselect **Teams and Viva Engage conversations**. This commits your review set with individual Teams messages. Once the collection is committed, you can export the documents and messages in the review set. The exported results contain the individual messages for Teams and Viva Engage instead of conversation threads.

> ⓘ **Note**
>
> The **Teams and Viva Engage conversations** setting is selected by default. If selected, review sets contain Teams conversation threads related to the matched search.

- **Cloud attachments**: Select this option to include modern attachments or linked files when the collection results are added to the review set. This means the target file of a modern attachment or linked file is added to the review set.

- **All document versions**: Select this option to enable the collection of all versions of a SharePoint document per the version limits and search parameters of the collection. Selecting this option will significantly increase the size of items that are added to the review set.

- **Partially indexed items**: Select this option to add partially indexed items from additional data sources to the review set. If the collection searched additional data sources (as specified on the **Additional locations** page in the collections workflow), there may be partially indexed items from these locations that you want to add to the review set. Custodial and non-custodial data sources typically don't have partially indexed items. That's because the Advanced indexing process reindexes items when custodial and non-custodial data sources are added to a case. Also, Adding partially indexed items will increase the number of items added to the review set.

> ⓘ **Note**
>
> The options to select retrieval options are configured on the global eDiscovery **Settings** > **Collections** page. Retrieval options selected on the **Collections** setting page will be selected as the default retrieval settings for all collections.

- **Subfolder contents**: Collect items inside subfolders of a matched folder. This option applies only to SharePoint and OneDrive data sources.
- **List attachments**: Collect files attached to SharePoint lists and their child items.

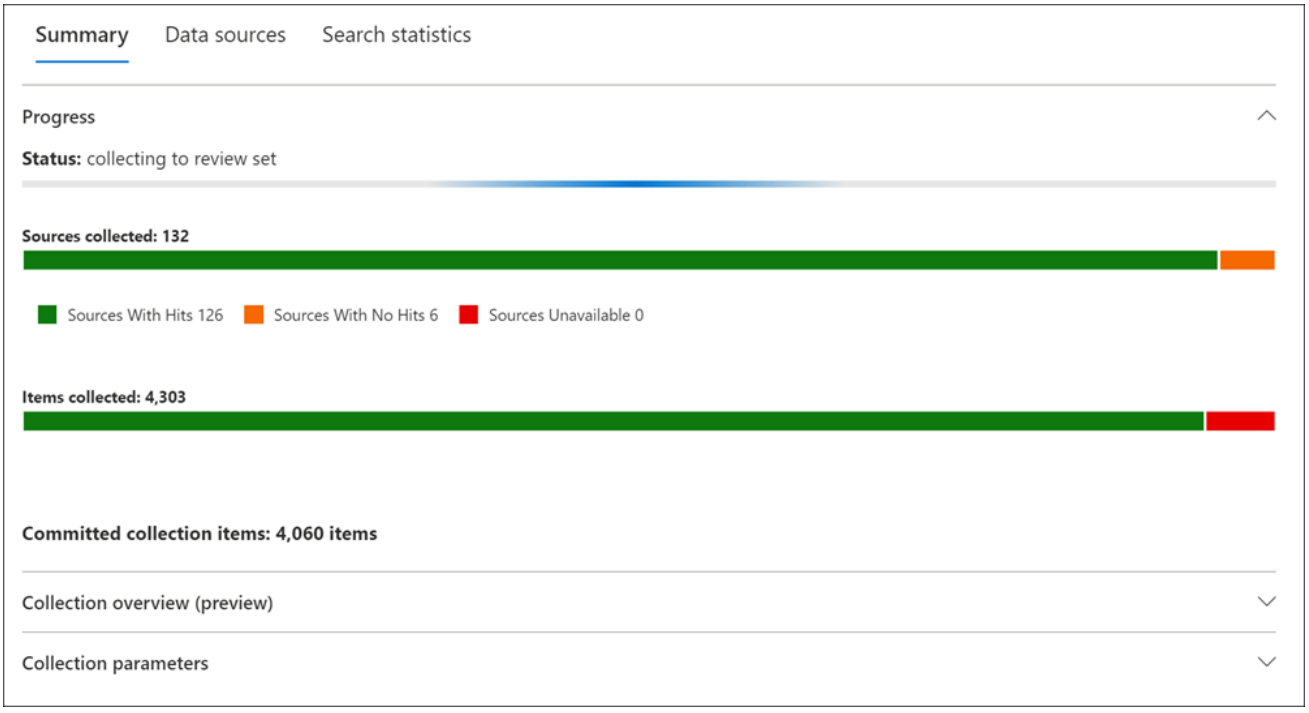
6. Configure settings in the **Collection ingestion scale** section to define the scale of the collection to add to the review set:

   - **Add all of collection to review set**: Select this option to add all the items that match the search criteria of the collection to the review set.

   - **Add only collection sample to review set**: Select this option to add a sample of the collection results to the review set instead of adding all results. If you select this option, select **Edit sample parameters** and choose one of the following options:
     - **Sample based on confidence**: Items from the collection are added to the review set will be determined by the statistical parameters that you set. If you typically use a confidence level and confidence interval when sampling results, specify them in the drop-down boxes. Otherwise, use the default settings.
     - **Randomly sample**: Items from the collection are added to the review set based on a random selection of the specified sample size percentage of the total number of

items returned by the search.

7. Select **Commit** to commit the collection to the review set.



What happens after you commit a collection estimate

When you commit a collection estimate to a review set, the following things happen:

- If you created a new review set to commit the collection to, the review set is created and displayed on the **Review sets** tab in the case. This status value means the review set has been created; it doesn't mean that the collection has been added to the review set. The status of adding items in the collection to the review set is displayed on the **Collections** tab and in the **Summary** tab on the collection flyout page.

- The collection search query is run again. This means the actual search results copied to the review set may be different than the estimated results that were returned when the collection search was last run.

- The progress of the collection commitment is displayed on the collection estimate flyout page. From here, you can monitor the progress and status of the collection, including information about sources and items collected. During the collection process, the status of the collection is shown as *Adding to review set* on the **Collection** tab.

.

- All items in the search results are copied from the original data source in the live service, and copied to a secure Azure Storage location in the Microsoft cloud.

- Encrypted SharePoint and OneDrive documents and encrypted files attached email messages that's returned in the search results are decrypted when you commit the collection to a review set. You can review and query the decrypted files in the review set. For more information, see Decryption in Microsoft 365 eDiscovery tools.

- Optical character recognition (OCR) functionality extracts text from images, and includes the image text with the content that's added to a review set. For more information, see the Optical character recognition section in this article.

- After the commit is successfully completed, the value of the status column of on the **Collections** tab is changed to *Committed* and the **Summary** tab on the collection flyout page is updated with the full results of the committed collection. A link to the review set for the collection is added to the **Review set** column for the collection. Select this link to open the review set results.

Optical character recognition

When you commit a collection to a review set, optical character recognition (OCR) functionality in eDiscovery (Premium) automatically extracts text from images, and includes the image text with the content that's added to a review set. You can view the extracted text in the Text viewer of the selected image file in the review set. This lets you conduct further review and analysis on text in images. OCR supports loose files, email attachments, and embedded images. For a list of OCR-supported image file formats, see Supported file types in eDiscovery (Premium).

You have to enable OCR functionality for each case that you create in eDiscovery (Premium). For more information, see Configure search and analytics settings.

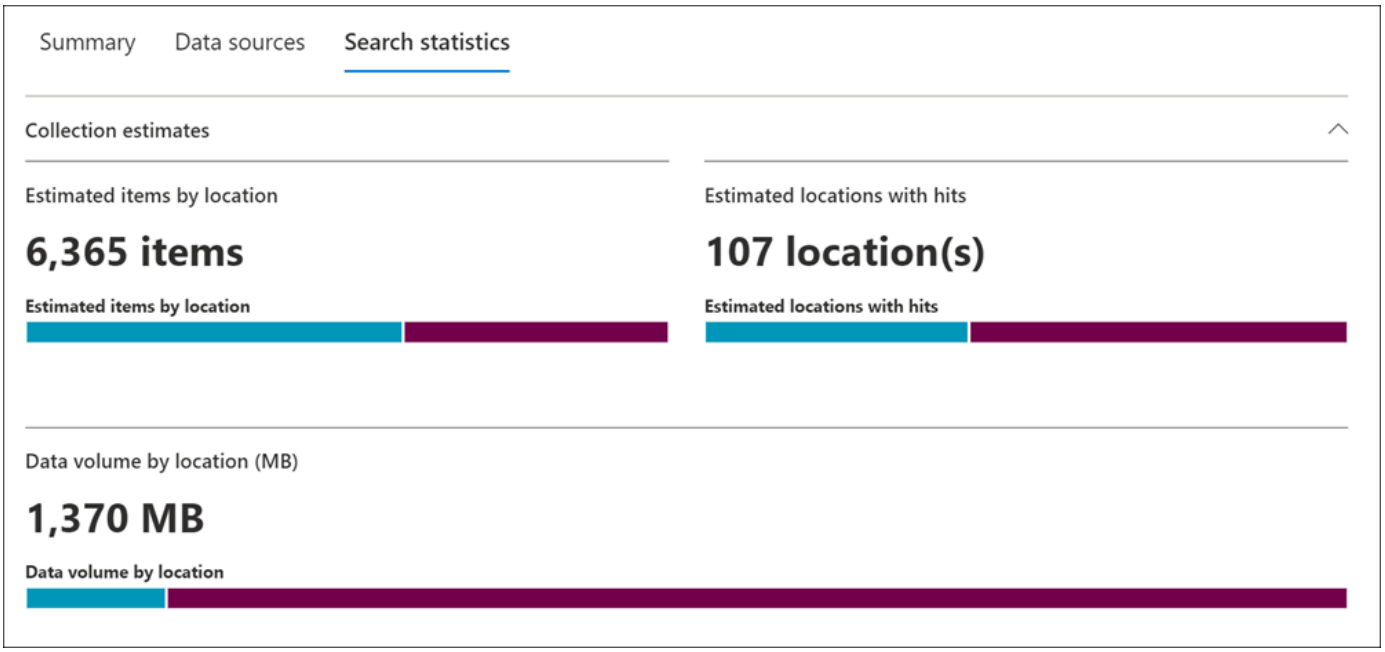
Collection statistics and reports in Microsoft Purview eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After you create a collection estimate, you can view statistics on the retrieved items, such as the content locations that contain the most items that matched the search criteria and the number of items returned by the search query. You can also preview a subset of the results.

When you've identified the set of documents you want to further examine, you can add the search results to a review set to collect and process.

Search statistics for collection estimates



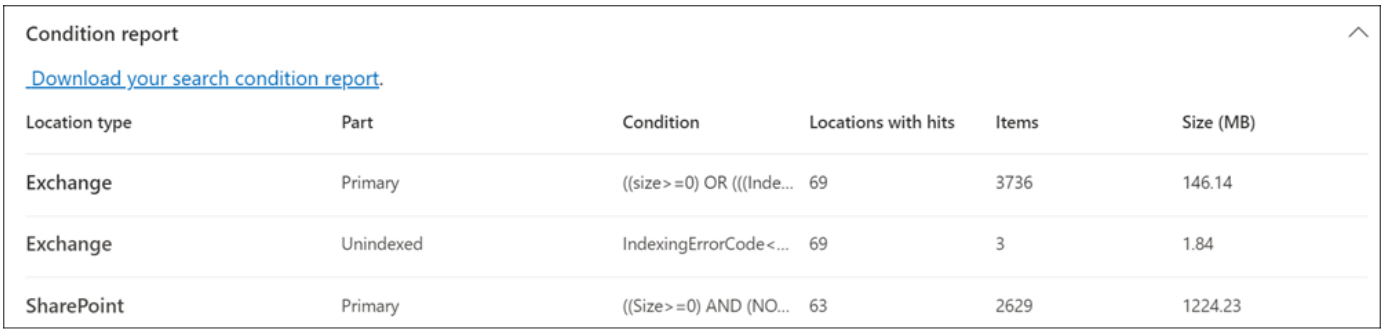
This section describes the statistics that are available for collection estimates. These statistics are available on the **Search statistics** tab on the flyout page of a collection estimate.

Collection estimates

This section displays a graphical summary of the estimated items returned by the collection. This indicates the number of items that match the search criteria of the collection. This information gives you an idea about the estimated number of items returned by the collection.

- **Estimated items by locations**: The total number of estimated items returned by the collection. The specific number of items located in mailboxes and located in sites is also displayed.
- **Estimated locations with hits**: The total number of content locations that contain items returned by the collection. The specific number of mailbox and site locations is also displayed.

- **Data volume by location (in MB)**: The total size of all estimated items returned by the collection. The specific size of mailbox items and site items is also displayed.



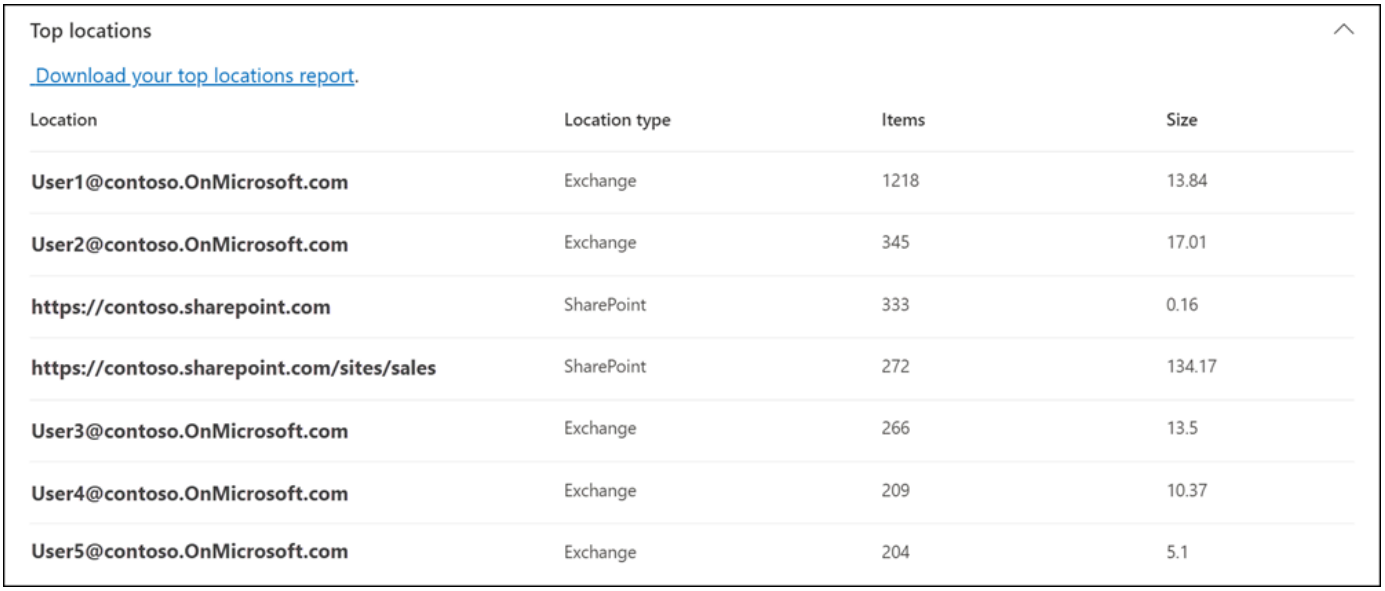
Condition report

This section displays statistics about the collection search query and the number of estimated items that matched different parts of the search query. You can use these statistics to analyze the number of items that match each component of search query. This can help you refine the search criteria for the collection and if necessary narrow the scope of the collection.

- **Location type**: The type of content location that the query statistics are applicable to. The value of **Exchange** indicates a mailbox location; a value of **SharePoint** indicates a site location.
- **Part**: The part of the search query the statistics are applicable to. **Primary** indicates the entire search query. **Keyword** indicates the statistics in the row are for a specific keyword. If you use a keyword list when for the search query in the collection, statistics for each component of the query are included in this table.
- **Condition**: The actual component (keyword or condition) of the search query that was run for the collection estimate that returned the statistics displayed in the corresponding row.
- **Locations with hits**: The number of the content locations (specified by the **Location type** column) that contain items that match the primary or keyword query listed in the **Condition** column.
- **Items**: The number of items (from the specified content location) that match the query listed in the **Condition** column. As previously explained, if an item contains multiple instances of a keyword that is being searched for, it's only counted once in this column.

- **Size (MB)**: The total size of all items that were found (in the specified content location) that match the search query in the **Condition** column.

Condition report



Download your search condition report.

Location type	Part	Condition	Locations with hits	Items	Size (MB)
Exchange	Primary	((size>=0) OR (((Inde...	69	3736	146.14
Exchange	Unindexed	IndexingErrorCode<...	69	3	1.84
SharePoint	Primary	((Size>=0) AND (NO...	63	2629	1224.23

Top locations

This section displays statistics about the specific content locations with the most items returned by the collection.

- **Location**: The name of the location (the email address of mailboxes and the URL for sites).
- **Location type**: A mailbox will have an *Exchange* type and SharePoint sites will have a *SharePoint* type.
- **Items**: Estimated number of items in the content location returned by the collection.
- **Size**: The total size of estimated items in each content location.

Top locations

Download your top locations report.

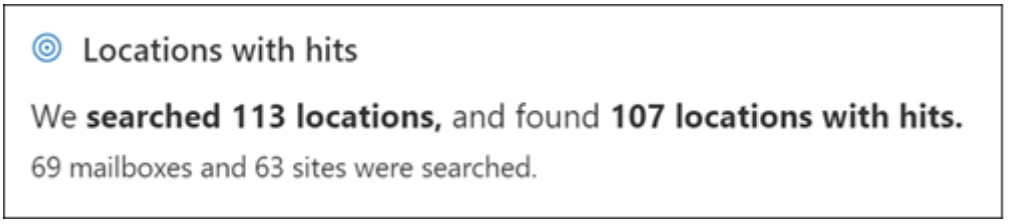
Location	Location type	Items	Size
User1@contoso.OnMicrosoft.com	Exchange	1218	13.84
User2@contoso.OnMicrosoft.com	Exchange	345	17.01
https://contoso.sharepoint.com	SharePoint	333	0.16
https://contoso.sharepoint.com/sites/sales	SharePoint	272	134.17
User3@contoso.OnMicrosoft.com	Exchange	266	13.5
User4@contoso.OnMicrosoft.com	Exchange	209	10.37
User5@contoso.OnMicrosoft.com	Exchange	204	5.1

Statistics and reports for committed collections

This section describes the statistics that are available after you commit a collection to a review set, including the actual number of items added to the review set. These statistics (in addition to load set information) provide historical information about content added to a case.

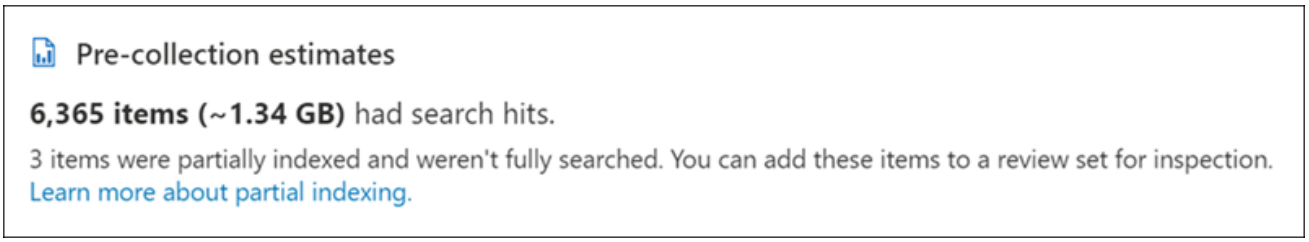
After you commit a collection to a review set, the following tabs are displayed on the flyout page of the committed connection. Each of these tabs contains different types of information about the collection.

Summary tab for collections



The **Summary** tab for committed collections contains several sections that provide information about the collection items, item estimates and locations, indexing, file types, and more.

Collection overview (preview)

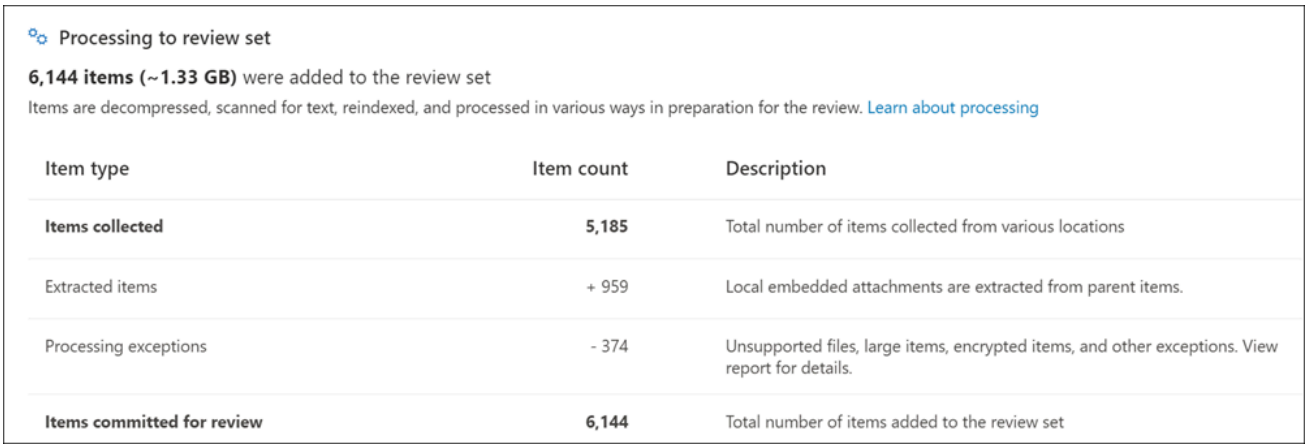


The **Collection overview** section on the **Summary** tab of a committed review set contains information about how items were found, retrieved, and processed as part of the collection. The information in this section is a summary of the information gathered and displayed during the initial collection estimate and includes information gathered and processed during the collection committal to the review set. You can use the information in this section to help improve understanding on how the final collection data evolves from the estimate data during collection committal and processing.

This information is segmented and displayed in the following sub-sections:

- **Locations with hits**: This section summarizes the number of locations searched and the number of location with hits based on the conditions defined in the collection estimate. It also displays the number and type of locations searched.

- **Pre-collection estimates**: This section summarizes number of items and size of the total items calculated for the collection estimate (before the collection is committed). A count of any items that were partially indexed is also displayed.



- **Collection items**: This section displays the type, count, and a description of all items retrieved from locations with hits during the committal of the collection to the review set. During this process, there may be some addition and consolidation of items during processing. Additions and consolidations may include types included in the following table:

Expand table

Item type	Item type description
Items with hits	Estimated number of items found by search.
Review set duplicates	Items that are already in the same review set aren't collected.
Search duplicates	Duplicate instances of the same items aren't collected.
All versions	All versions of items in SharePoint are collected.
Historical versions	Historical versions maintained by SharePoint are collected.
Cloud attachments	Cloud attachments are identified and collected from SharePoint links.
Version as shared	The shared versions of items are collected in addition to their latest versions.
Contextual Teams conversations	Additional chat messages that might be relevant are collected.
Consolidated chat transcripts	Collected chat messages are consolidated into fewer HTML transcripts.
Retrieval exceptions	Access time outs, empty files, and other exceptions.
Total items collected	Total number of items collected from various locations.

- **Processing to review set**: This section displays the type, count, and description of the items that were added to the review set from the collection estimate. Items are decompressed, scanned for text, reindexed, and processed in preparation for the review.

Collection contents

The **Collection contents** section on the **Summary** tab of a committed review set contains statistics and other information about the items that were collected from the data sources in the collection and added to the review set.

- **Total extracted items**. The total number of items added to the review set. This number indicates the sum of parent items and child items added to the review set.

  > **Tip**
  >
  > Hover the cursor over the parent or child item bars to display the total number of parent or child items.

- **Parent items**. The number of items returned by the collection that was used to collect the items that were added to the review set. This number corresponds to (and is equal to) the estimated number of items that is displayed in the **Collection parameters** section. The number of parent items he collection information that was used to collect the items that were added to the review set.

  A parent item might contain multiple child items. For example, an email message is a parent item if it contains an attached file or has a cloud attachment. In this case, the attached file or the target file of the cloud attachment is considered a child item. When you commit a collection, parent items and any corresponding child items (like attached files and cloud attachments) are added to the review set as individual items or files.

- **Child items**. The number of child items added to the review set. Only child items that are file attachments and cloud attachments are added to the review set as individual files. Other types of child items, such as email signatures and images, are extracted from a parent item and then processed by Optical Character Recognition (OCR) to extract any text from the

child item. Text extracted from these types of child items is then added to its parent item so you can view it in the review set. By not adding child items to the review set as a separate file, eDiscovery (Premium) helps streamline the review process by limiting the number of potentially immaterial items in the review set.

- **Unique items**. The number of unique items added to the review set. Unique items are unique to the review set. All items are unique when the first collection is added to a new review set because there were no previous items in the review set.

- **Identified duplicate items**. The number of items from the collection that weren't added to the review set because the same item already exists in the review set. Statistics about duplicate items can help explain the differences between the number of estimated items from a collection estimate and the actual number of items added to the review set.

Indexing

The **Indexing** section on the **Summary** tab of a committed review set contains indexing information about the items added to the review set.

- **New indexed items**. The number of items that were newly indexed before they were added to the review set. Examples of a newly indexed item are child items extracted from a parent item and then indexed before they're added to the review set. Also, items that aren't located in custodial data sources and non-custodial content locations listed on the **Data sources** tab in the case are indexed before they're added to the review. For example, newly indexed items would include items collected from additional locations.

- **Updated indexed items**. The number of partially indexed items that were successfully indexed and added to the review set. This statistic indicates the partially indexed items from custodial and non-custodial content locations **Data sources** tab that were successfully indexed when the collection was committed to the review set.

- **Indexing errors**. The number of partially indexed items that couldn't be indexed before they were added to the review set. These items might require error remediation.

Collection file types

The **Collection file types** section on the **Summary** tab of a committed review set displays the item count for each file type included in the collection. File types include email, image, document, audio, video file types and more. For a complete list of the supported file types, see Supported file types in eDiscovery (Premium).

Errors

The **Errors** section on the **Summary** tab of a committed review set displays the type and number of errors encountered during the collection committal. Errors may include files with a zero size, protected files, malformed files, internal errors, and more. An error report in .csv format can be downloaded by selecting **Download your errors report** in this section.

Collection parameters

The **Collection parameters** section on the **Summary** tab of a committed review set displays the collection information that was used to collect the items that were added to the review set. This tab displays information that is similar to the information on the **Search statistics** tab. This section provides a quick snap shot of the search query used by the collection, the content locations that were searched, and the estimated collection results. As previously explained, the number of estimated items in this section would be equal to the number of parent items shown in the **Collection contents** section.

Data sources tab for collections

The **Data sources** tab contains information about custodial and non-custodial data sources. The **Custodial data sources** section displays the all custodial data sources for each custodian included in the collection. The **Non-custodial data sources** section displays the all non-custodial data sources for the collection. The data source information displayed is also available on the main **Data sources** tab for each case.

Search statistics tab for collections

The statistics displayed on the **Search statistics** tab are the same statistics from the last time that a collection estimate was run. This includes collection estimates, condition report, and top locations. This information is preserved from the collection estimate for historical reference, and can be compared to the actual collection that was committed to the review set.

Differences between collection estimates and the actual committed collection

When you run a collection estimate, an estimate of the number of items (and their total size) that meet the collection criteria is displayed on the **Summary** tab and in **Collection estimates** section of the **Search statistics** tab. After you commit a collection estimate to a review set, the actual number of items (and their total size) added the review set are often different from the estimates.

In most cases, more items are added to the review set than were estimated from the collection estimate. The following list describes the most common reasons for these differences and tips for identifying them:

- **Child items**. Child items (such as files attachments and cloud attachments) that are extracted from their parent items and added as individual files. The number of child items may increase the number of items that are added to the review set. In general, the number of parent items identified in the **Collection contents** section on the **Summary** tab of a committed collection should be equal to the number of estimated items from the collection estimate.

- **Duplicate items**. Items from the collection estimate that have already been added to the review set in a previous collection won't be added. As previously explained, the number of duplicate items in the collection is displayed in the **Collection contents** section on the **Summary** tab.

- **Collection configuration options**. When you commit a collection estimate to a review set, you have to option to include conversation threads, cloud attachments, and document versions. Any of these items that are added to the review set aren't included in the estimates of the collection estimate. They're identified and collected only when you commit the collection. Selecting these options will most likely increase the number of items added to the review set.

  For example, multiple versions of SharePoint documents aren't included in the estimate for the collection estimate. But if you select the option to include all document versions when you commit a collection estimate, the actual number (and total size) of items added to the review set will increase.

  For more information about these options, see Commit a collection estimate to a review set.

Here are other reasons why the estimated results from a collection estimate can be different that the actual committed results.

- **The way results are estimated for collection estimates**. An estimate of the search results returned by a collection estimate is just that, an estimate (and not an actual count) of the items that meet the collection query criteria. To compile the estimate of email items, a list of the message IDs that meet the search criteria is requested from the Exchange database. But when you commit the collection to a review set, the collection is rerun and the actual messages are retrieved from the Exchange database. So differences might result because of how the estimated number of items and the actual number of items are determined.

- **Changes that happen between the time when estimating and committing collection estimates**. When you commit a collection estimate to a review set, the search is rerun to collect that most recent items in the search index that meet the search criteria. It's possible that additional items were created, sent, or deleted that meet the search criteria in the time between when the collection estimate was last run and when the collection estimate is committed to a review set. It's also possible that items that were in the search index when the collection estimate results were estimated are no longer there because they were purged from a data source before committing the collection. One way to mitigate this issue is to specify a date range for a collection. Another way is to place a hold on content locations so that items are preserved and can't be purged.

- **Unindexed items**. If the collection estimate included searching all Exchange mailboxes or all SharePoint sites, then only unindexed items from content locations that contain items that match the collection criteria will be added to the review set. In other words, if no results are found in a mailbox or site, then any unindexed items in that mailbox or site won't be added to the review set. However, unindexed items from all content locations (even those that don't contain items that match the collection query) will be included in the estimated collection results.

- **Partially indexed items**: Selection of this option adds partially indexed items from additional data sources to the review set. If the collection searched additional data sources (as specified on the **Additional locations** page in the collections workflow), there may be partially indexed items from these locations that you want to add to the review set. Custodial and non-custodial data sources typically don't have partially indexed items. That's because the Advanced indexing process reindexes items when custodial and non-custodial data sources are added to a case. Also, Adding partially indexed items will increase the number of items added to the review set.

  After partially indexed items are added to the review set, you can apply a filter to specifically view these items. For more information, see Scenario example: Filter partially indexed items

  Alternatively, if the collection estimate included specific content locations (which means that specific mailboxes or sites where specified on the **Additional locations** page in the collection estimate workflow), then unindexed items (that aren't excluded by the collection criteria) from the content locations specified in the search will be exported. In this case, the estimated number of unindexed items and the number of unindexed items that are added to the review set should be the same.

Build search queries for collections

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When configuring the search query when creating a collection in an eDiscovery (Premium) case, you can use keywords to find specific content and conditions to narrow the scope of the search to return items that are most relevant to your legal investigation.

If you prefer to build a search query with the Keyword Query Language (KeyQL) editor, Query builder, or the Natural Language Query tools, see:

- Use the KeyQL editor to build search queries
- Use the query builder to build search queries
- Use the Natural Language Query builder to build search queries (preview)

Keyword searches

Type a keyword query in the **Keywords** box in the search query. You can specify keywords, email message properties, such as sent and received dates, or document properties, such as file names or the date that a document was last changed. You can use more complex queries that use a Boolean operator, such as **AND**, **OR**, **NOT**, and **NEAR**. You can also search for sensitive information (such as social security numbers) in documents in SharePoint and OneDrive (not in email messages), or search for documents that have been shared externally. If you leave the **Keywords** box empty, all content located in the specified content locations is in the search results.

Keyword list

Alternatively, you can select the **Show keyword list** check box and the type a keyword or keyword phrase in each row. The keywords in each row are connected by a logical operator (which is represented as *c:s* in the search query syntax) that is similar in functionality to the **OR** operator in the search query that's created. This means items that contain any keyword in any row are in the search results. You can add up to 180 rows in the keyword list in eDiscovery (Premium) search queries.

Why use the keyword list? You can get statistics that show how many items match each keyword in the keyword list. This can help you quickly identify the keywords that are the most (and least) effective. You can also use a keyword phrase (surrounded by parentheses) in a row in the keywords list. For more information about search statistics, see Collection statistics and reports

Conditions

You can add search conditions to narrow the scope of a search and return a more refined set of results by selecting **Add condition**.

Each condition adds a clause to the search query that is created and run when you start the search. A condition is logically connected to the keyword query specified in the keyword box by a logical operator (which is represented as *c:c* in the search query syntax) that is similar in functionality to the **AND** operator. That means items have to satisfy both the keyword query and one or more conditions to be included in the search results. This is how conditions help to narrow your results.

For a list and description of conditions that you can use in a search query, see the "Search conditions" section in Keyword queries and search conditions.

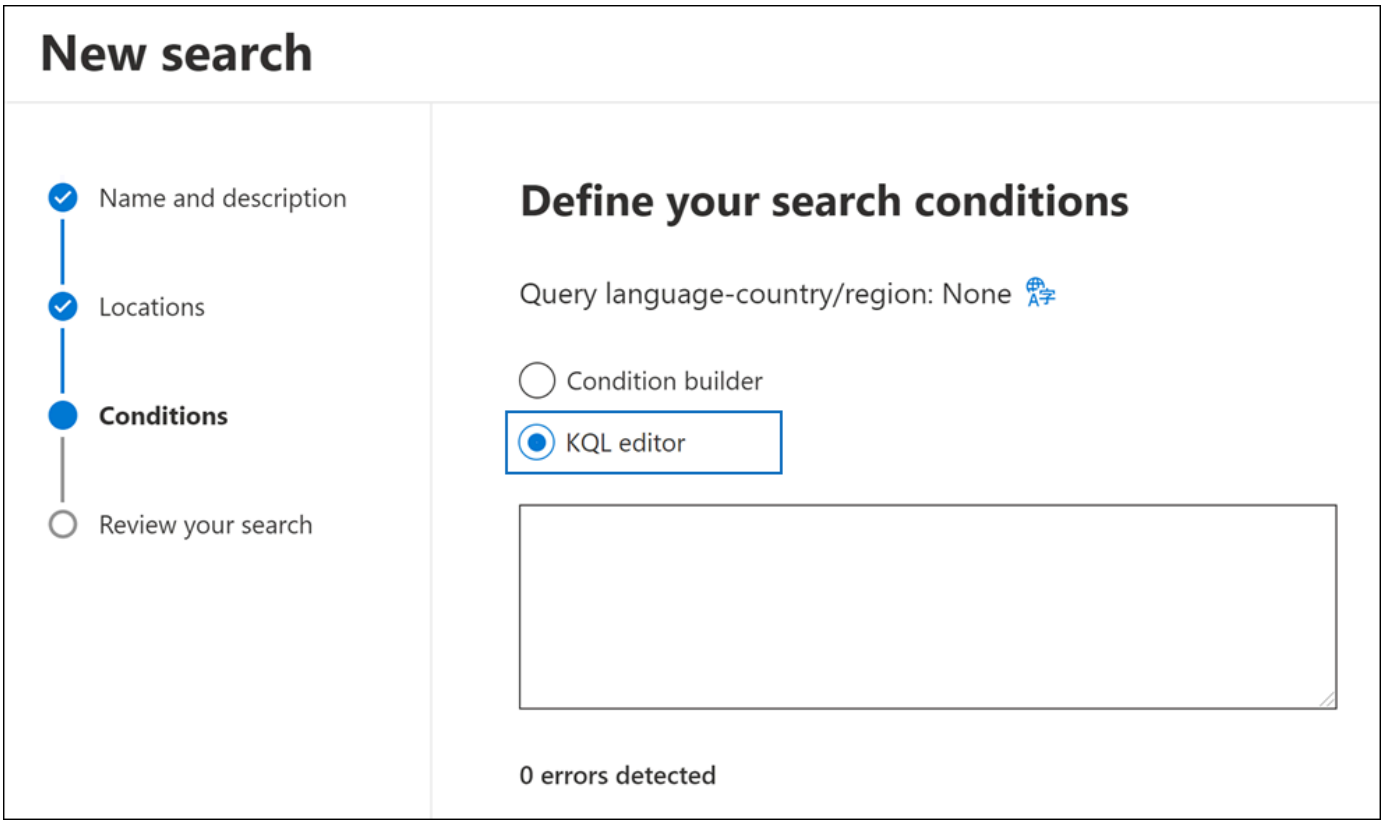
Use the KeyQL editor to build search queries

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

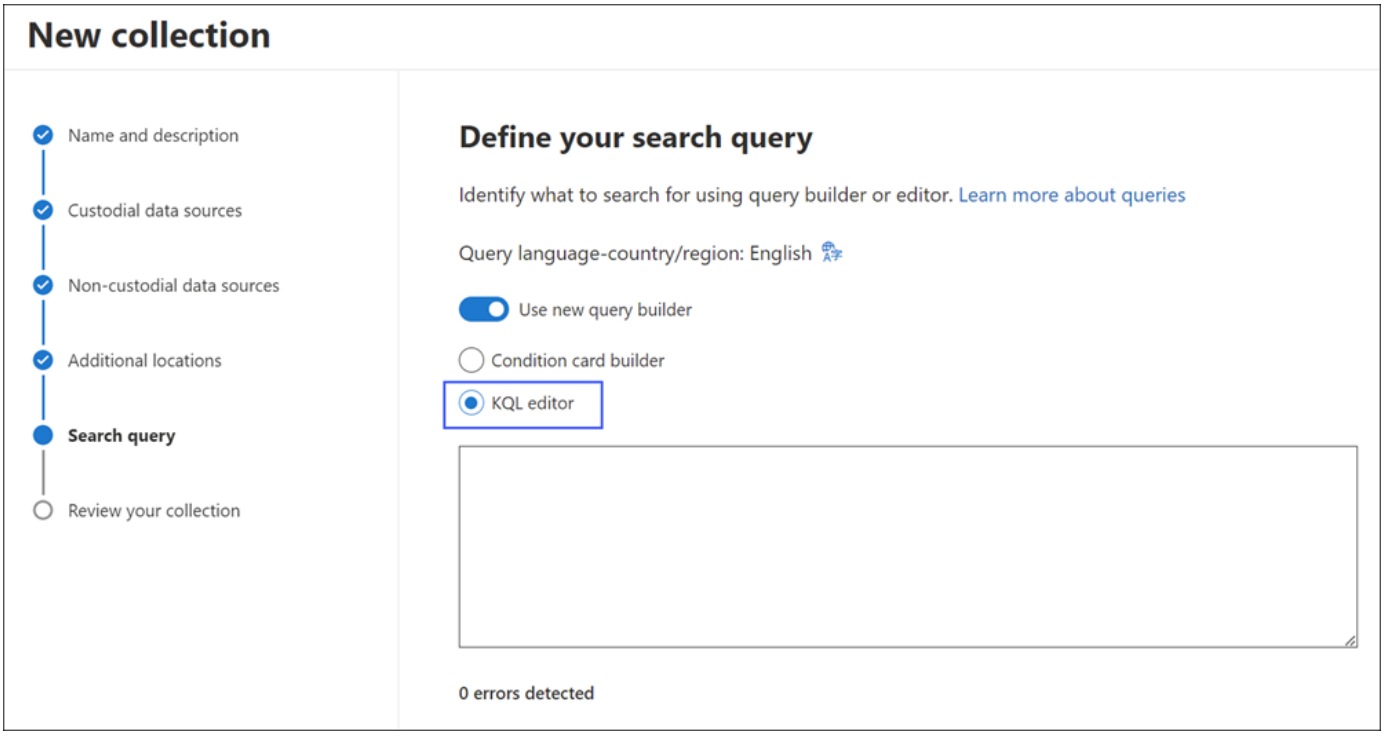
The Keyword Query Language (KeyQL) query option in Microsoft Purview eDiscovery tools search provides feedback and guidance when you build search queries in Content search, Microsoft Purview eDiscovery (Standard), and eDiscovery (Premium). When you enter queries in the editor, it provides autocompletion for supported searchable properties and conditions and provides lists of supported values for standard properties and conditions. For example, if you specify the `kind` email property in your query, the editor will present a list of supported values that you can select. The KeyQL editor also displays potential query errors in real time that you can fix before you run the search. Best of all, you can paste complex queries directly into the editor without having to manually build queries using the keywords and conditions cards in the standard condition builder.

Here are the key benefits to using the KeyQL editor:



- Provides guidance and helps you build search queries from scratch.
- Lets you quickly paste long, complex queries directly into the editor. For example, if you receive a complex query from opposing counsel, you can paste that into the KeyQL editor instead of having to use the condition builder.
- Quickly identifies potential errors and displays hints about how to resolve issues.

The KeyQL editor is also available when you create query-based holds in eDiscovery (Standard) and eDiscovery (Premium).

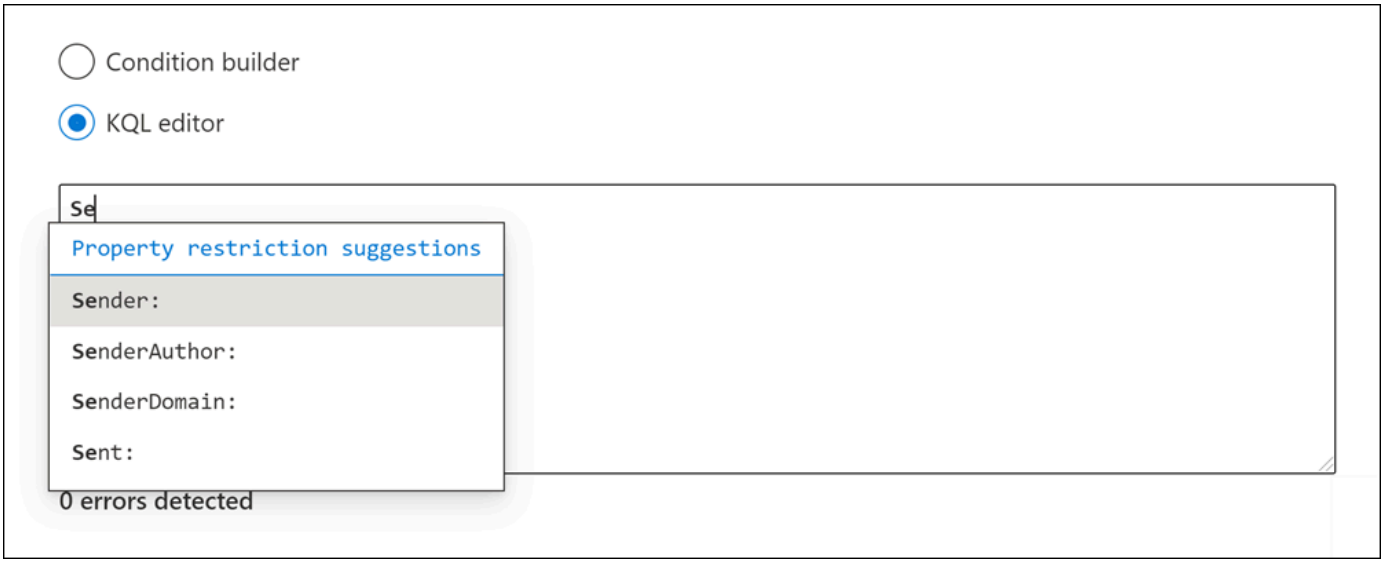


Displaying the KeyQL editor

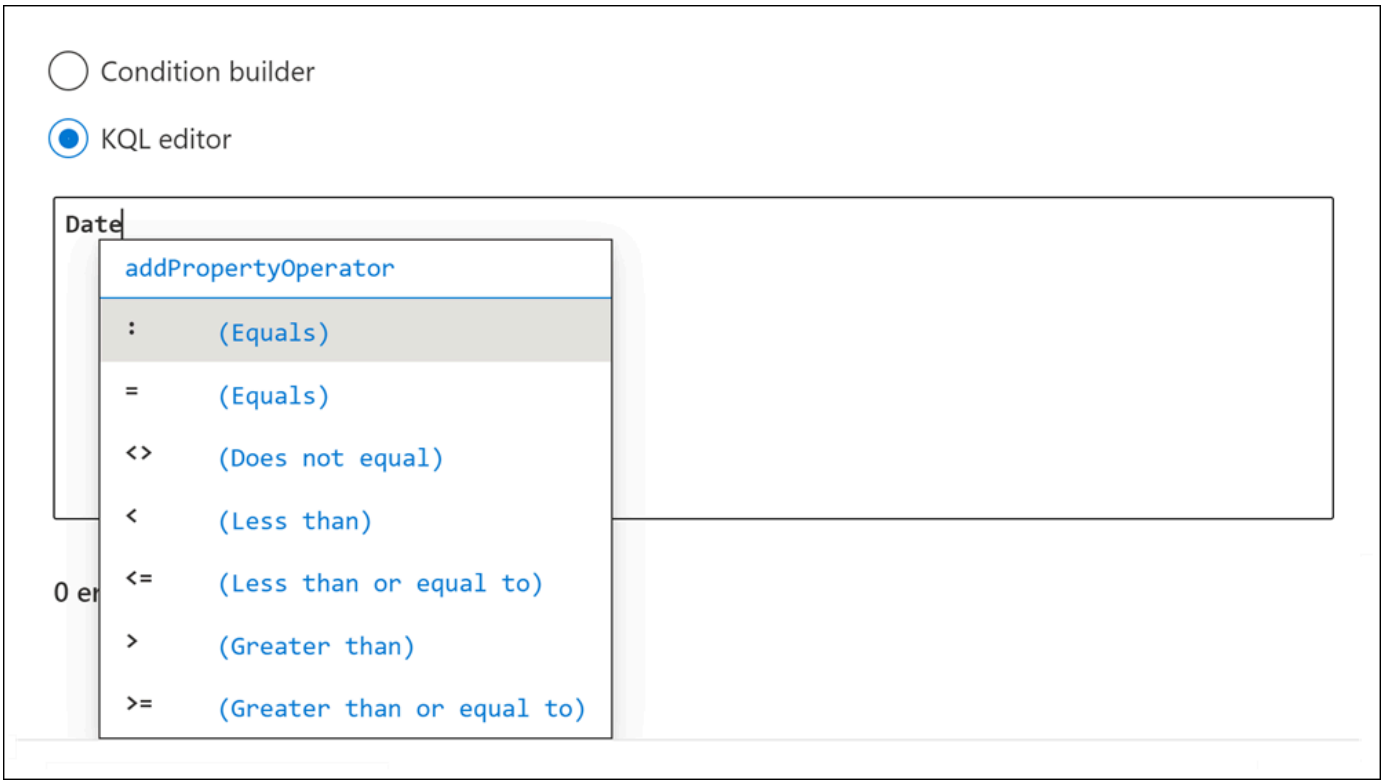
When you create or edit an eDiscovery search, the option to display and use the KeyQL editor is located on the **Conditions** page in the search or collections workflow.

KeyQL editor in Content search and eDiscovery (Standard)

KeyQL editor in eDiscovery (Premium)



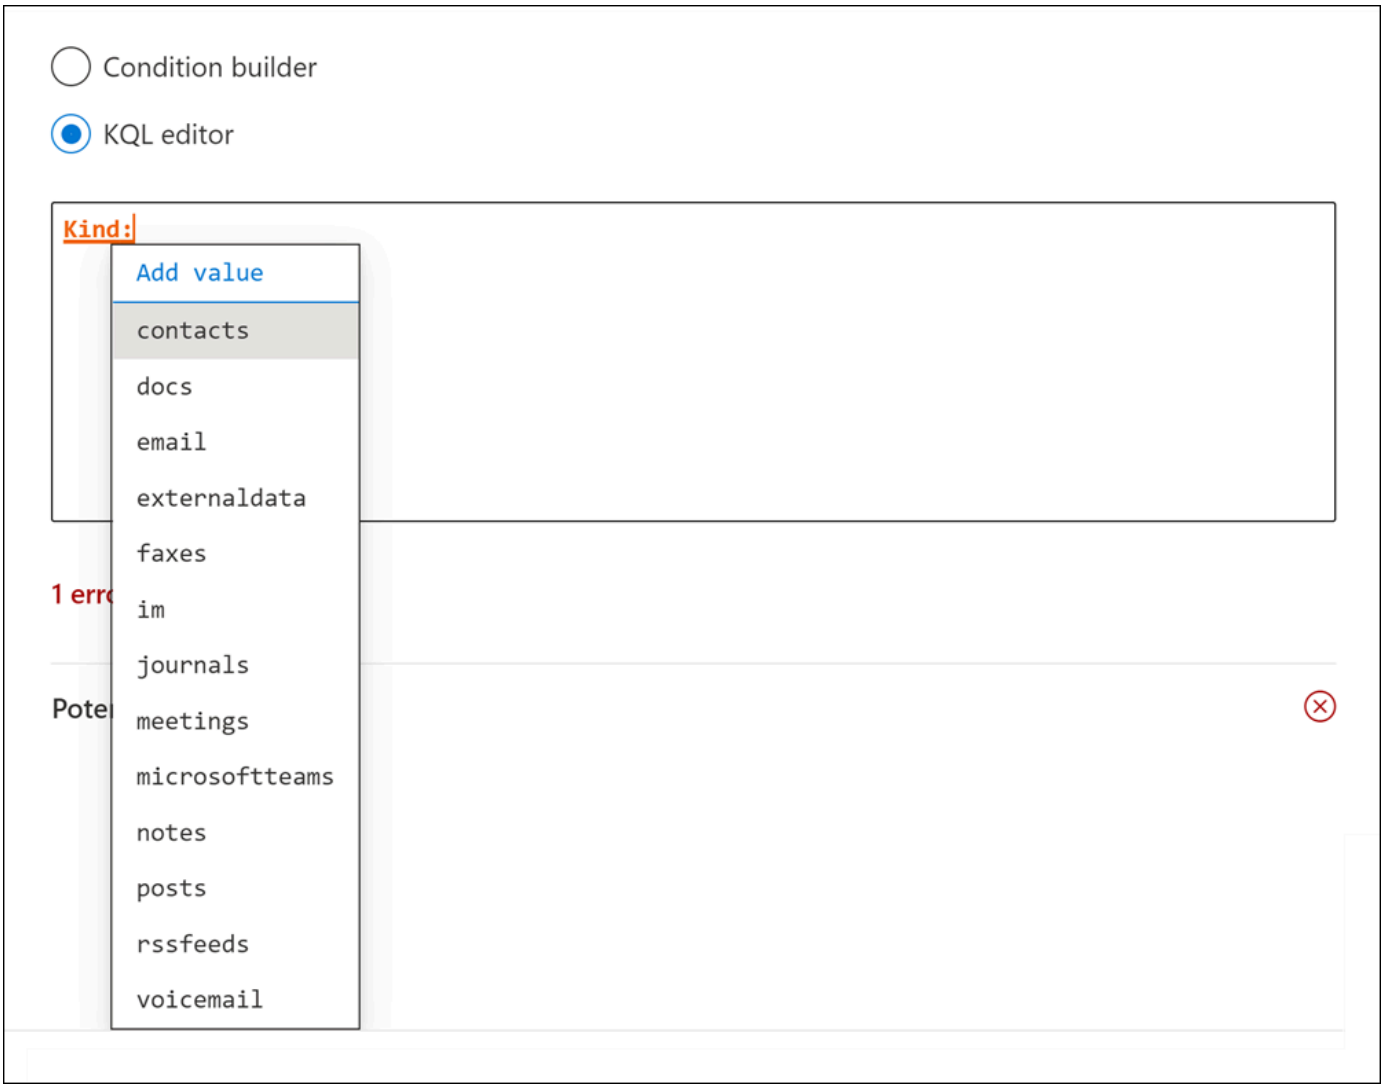
Using the KeyQL editor



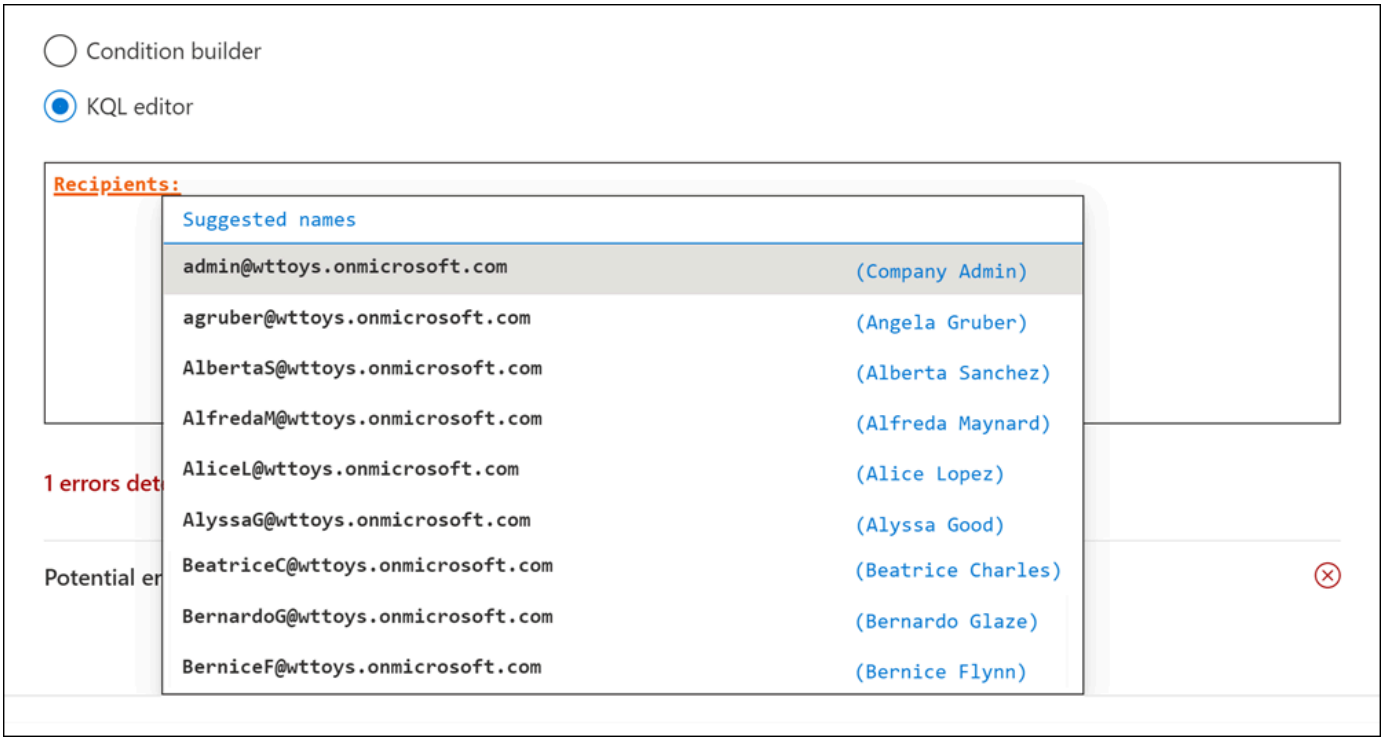
The following sections show examples of how the KeyQL editor provides suggestions and detects potential errors.

Autocompletion of search properties and operators

When you start to enter a search query in the KeyQL editor, the editor displays suggested autocompletion of supported search properties (also called *property restrictions*) that you can select. You have to type a minimum of two characters to display a list of supported properties that begin with those two characters. For example, the following screenshot shows the suggested search properties that begin with `Se`.



Additionally, the editor also suggests provides a list of supported operators (such as `:`, `=` and `<>`) when you type in a complete property name. For example, the following screenshot shows the suggested operators for the `Date` property.

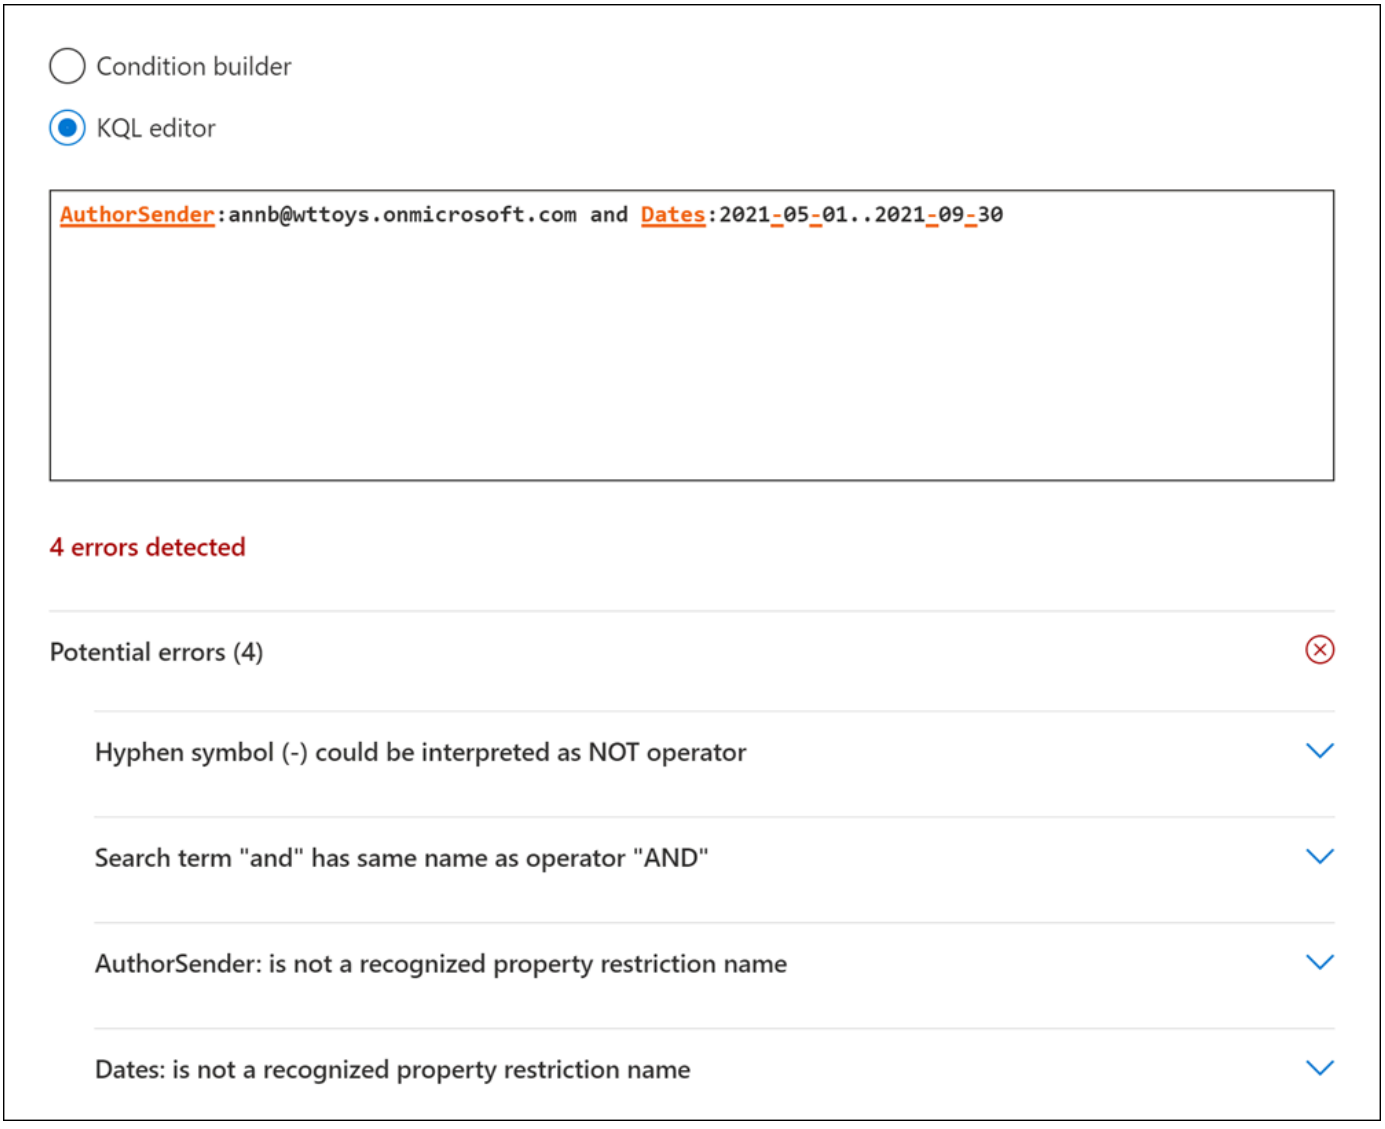


For more information about the supported search properties and operators, see Keyword queries and search conditions for eDiscovery.

Property value suggestions

The KeyQL editor provides suggestions for possible values of some properties. For example, the following screenshot shows the suggested values for the `Kind` property.

The editor also suggests a list of users (in UPN format) when you type email recipient properties, such as `From`, `To`, `Recipients` and `Participants`.



Detection of potential errors

The KeyQL editor detects potential errors in search queries, and provides a hint of what is causing the error to help you resolve the error. The editor also indicates a potential error when a property doesn't have a corresponding operation or value. Potential errors in the query are highlighted in red text, and explanations and possible fixes for the error are displayed in the **Potential errors** drop-down section.

> **Important**
>
> Nested quotation marks aren't supported in the KeyQL editor.

For example, if you pasted the following query into the KeyQL editor, four potential errors would be detected.

In this case, you can use the potential error hints to troubleshoot and fix the query.

More information

- You can toggle between the condition builder and the KeyQL editor. For example, if you use the condition builder to configure a query using the Keywords box and multiple condition cards, you can display the resulting query in the KeyQL editor. However, if you create a complex query (with keywords and conditions) in the KeyQL editor, the resulting query is displayed only in the Keywords box when you view it in the condition builder.
- If you paste a complex query into the KeyQL editor, the editor detects potential errors and suggests possible solutions to resolve errors.

Use the query builder to create search queries

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

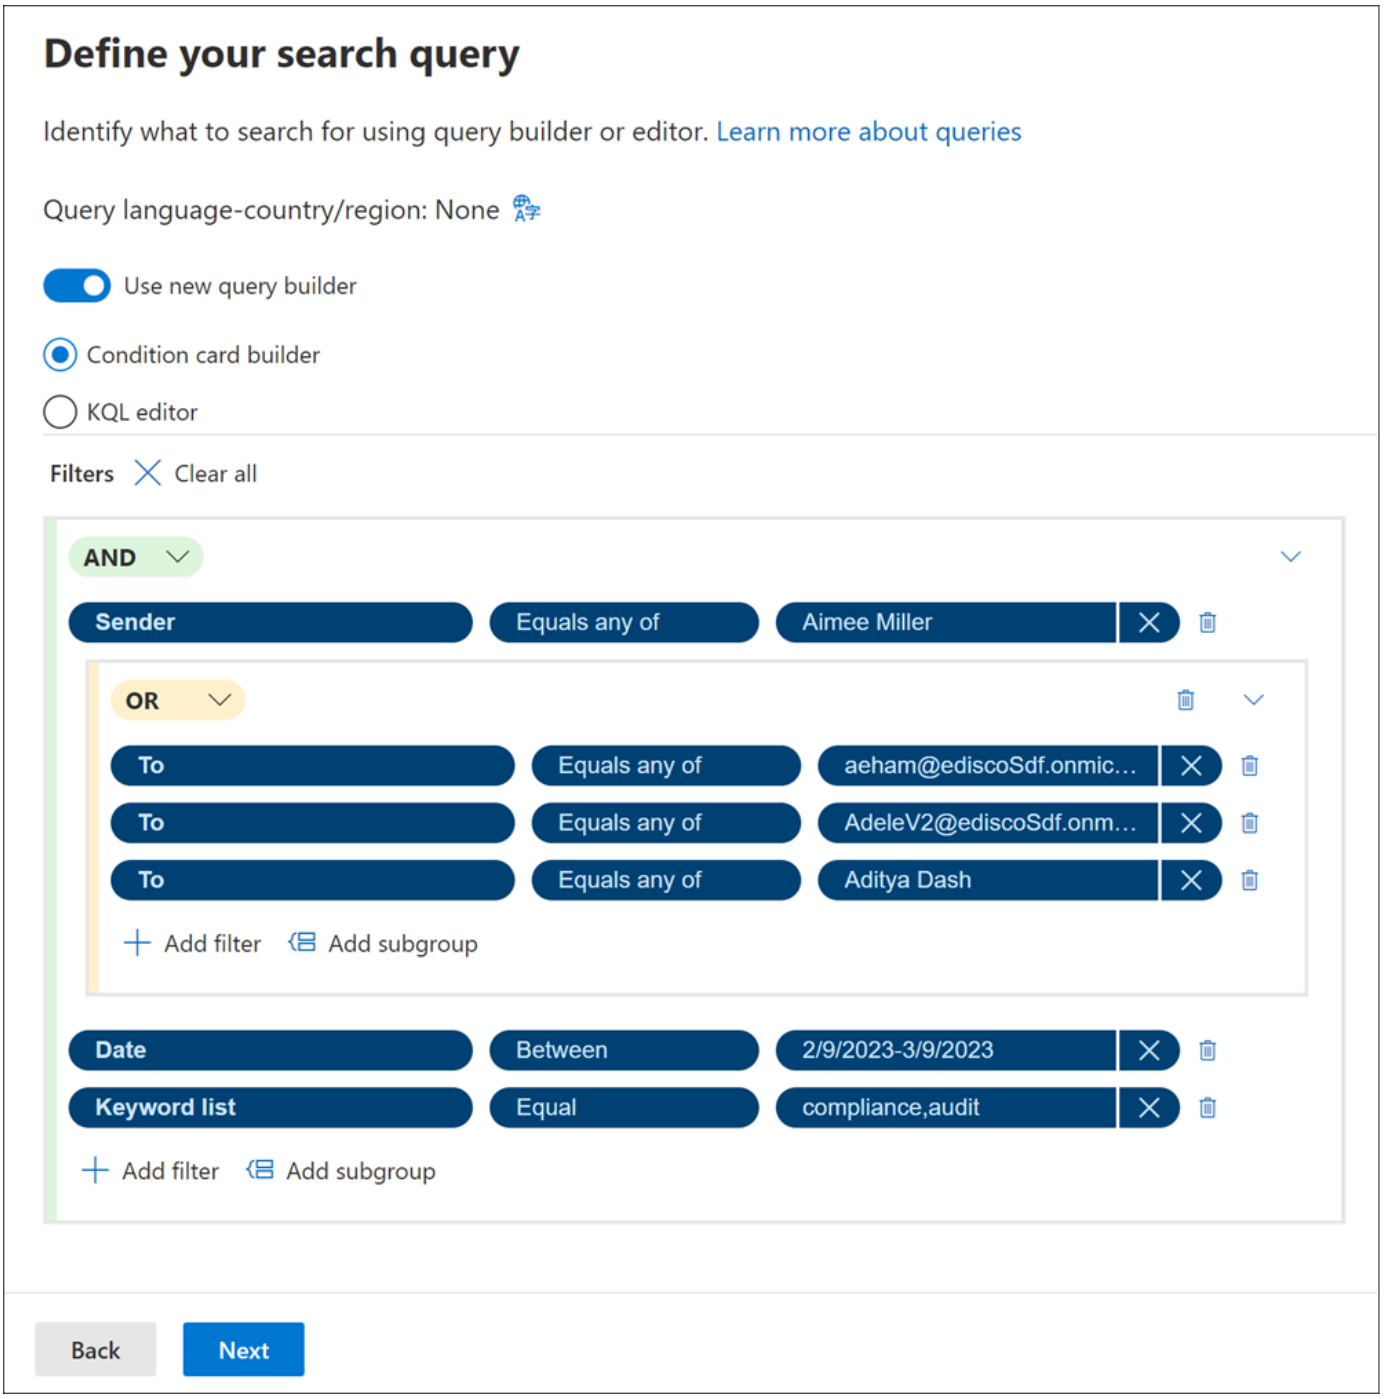
The query builder option in collection search tool provides a visual filtering experience when you build search queries in Microsoft Purview eDiscovery (Premium). Use the new query builder to construct complex queries with additional functionality, including AND, OR, and grouping of conditions. These features in the query builder help you build queries more effectively, provide a visual interface for grouping sub-queries, and provide additional space for complex keyword queries to be constructed and reviewed.

Displaying the query builder

When you create or edit an eDiscovery search for a collection in eDiscovery (Premium), the option to display and use the query builder is located on the **Search query** page in the collections workflow. Select **Use new query builder** to display and use the query builder.

Using the query builder

After you've selected **Use new query builder**, you're ready to get started. To create a query and custom filtering for your search, use the following controls:



- **AND/OR**: These conditional logical operators allow you to select the query condition that applies to specific filters and filter subgroups. These operators allow you to use multiple filters or subgroups connected to a single filter in your query.
- **Select a filter**: Allows you to select filters for the specific data sources and location content selected for the collection.

- **Add filter**: Allows you to add multiple filters to your query. Is available after you've defined at least one query filter.
- **Select an operator**: Depending on the selected filter, the operators compatible for the filter are available to select. For example, if the *Date* filter is selected, the available operators are *Before*, *After*, and *Between*. If the *Size (in bytes)* filter is selected, the available operators are *Greater than*, *Greater or equal*, *Less than*, *Less or equal*, *Between*, and *Equal*.
- **Value**: Depending on the selected filter, the values compatible for the filter are available. Additionally, some filters support multiple values and some filters support one specific value. For example, if the *Date* filter is selected, select date values. If the *Size (in bytes)* filter is selected, select a value for bytes.
- **Add subgroup**: After you've defined a filter, you can add a subgroup to refine the results returned by the filter. You can also add a subgroup to a subgroup for multi-layered query refinement.
- **Remove a filter condition**: To remove an individual filter or subgroup, select the remove icon to the right of each filter line or subgroup.
- **Clear all**: To clear the entire query of all filters and subgroups, select **Clear all**.

Scenario example

The eDiscovery administrator needs to create a query to find emails sent from Aimee Miller to Adam Eham, Adele Vance, or Aditya Dash that were sent between February 9, 2023 and March 9, 2023 that contains the keywords *compliance* and *audit*. For this example, the administrator creates the following query using the new query builder:

1. For the first filter, the administrator selects *Sender*, then selects the *Equals any of* operator, then selects *Aimee Miller* from the list of users available in the **Value** control.
2. Next, the administrator selects **Add subgroup** and the **OR** operator to define the other users that Aimee may have sent an email to about the compliance audit.
3. In the subgroup, the administrator selects the *To* filter, the *Equals any of* operator, and the *Value (user)* for each of the other users that Aimee may have sent email to about the compliance audit. In this example, the administrator creates a filter in the subgroup for Adam Eham, Adele Vance, and Aditya Dash.
4. To define the date range, the administrator selects **Add filter** and selects the *Date* filter, the *Between* operator, and start and ending dates for the *Value*.
5. Finally, the administrator selects the *Keyword list* filter, the *Equal* operator, and *compliance, audit* as the keyword *Value*.

Use the Natural Language Query builder to create search queries (preview)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

The Natural Language Query (preview) builder option in collection search tool allows you to use natural language and Microsoft Security Copilot to quickly generate a Keyword Query Language (KeyQL) statement when you build search queries in Microsoft Purview eDiscovery (Premium).

Use the Natural Language Query (preview) builder to construct complex queries with additional functionality, including AND, OR, and grouping of conditions, all while using natural language prompts. This feature helps you build queries more easily using predefined prompts for example scenarios and allows you to refine and enhance custom prompts for more accurate search queries.

Prerequisites to use the Natural Language Query (preview) builder

You must have Microsoft Security Copilot to use the Natural Language Query (preview) builder. For Security Copilot guidance, see the following:

- Microsoft Security Copilot in Microsoft Purview
- Get started with Microsoft Security Copilot

Microsoft Purview eDiscovery capabilities are included with Microsoft Purview. For more information, see Subscriptions and licensing.

For information about permissions you need to use the Natural Language Query (preview) builder, see Understand authentication in Microsoft Security Copilot.

Displaying the Natural Language Query (preview) builder

When you create or edit an eDiscovery search for a collection in eDiscovery (Premium), the option to display and use the Natural Language Query builder is located on the **Search query** page in the collections workflow. Select **Natural Language Query** to display and use the query builder.

Using the Natural Language Query (preview) builder

After you've selected data sources for a search query, you can create a customized KeyQL search query from a natural language prompt using Security Copilot. You can also choose to use prompt suggestions as a starting point to create and refine KeyQL queries for common or custom search scenarios.

After you've selected data sources for a search query, you can create a customized KeyQL search query from a natural language prompt using Microsoft Security Copilot. You can also choose to use prompt suggestions as a starting point to create and refine KeyQL queries for common or custom search scenarios.

1. In the **Natural language prompt** pane, choose one of the following options:

    - Enter your search query question. You can include user, data source, and other content details as applicable.
    - Select **View prompts** to select one of the following prompt suggestions:
        - *Find all emails containing the words budget and finance and have attachments*
        - *Search all chats in the month of January 2020 that contain the word 'financial year'*
        - *Search for files of type .docx that contain the words confidential and budget*

2. Review the natural language prompt. To refine the prompt with Copilot, select **Refine**.
3. When the prompt is finalized, select **Generate KeyQL**.
4. Review the KeyQL query in the **Keyword Query Language (KeyQL) result** pane. If you need to refine the KeyQL query results, you can update the prompt in the **Natural language prompt** pane and select **Generate KeyQL** again. 1. When the KeyQL results are finalized, select **Copy KeyQL**.
5. Paste the KeyQL results in the query field on the **Keyword query language (KeyQL)** tab. You can close **Draft a query with Copilot**.
6. Select **Next**.

7. On the **Review your collection** page, you can review and update the collection selection, data sources, and conditions that you configured on the previous pages. Select **Edit** for any of the selections and update if needed.
8. Select **Submit** to create the collection estimate. A page is displayed confirming that the collection was created.

Last updated on 11/21/2025

Keyword queries and search conditions for eDiscovery

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article describes the properties available to help find content across email and chat in Exchange Online and documents and files stored on SharePoint and OneDrive using the eDiscovery search tools in the Microsoft Purview portal.

This includes Content search, Microsoft Purview eDiscovery (Standard), and Microsoft Purview eDiscovery (Premium) (eDiscovery searches in eDiscovery (Premium) are called *collections*). You can also use the ***-ComplianceSearch** cmdlets in Security & Compliance PowerShell to search for these properties.

This article also describes:

- Using Boolean search operators, search conditions, and other search query techniques to refine your search results.
- Searching for communications of various types related to specific users and projects during a specific time frame.
- Searching for site content that is related to a specific project, users and/or subjects during a specific time period.

For step-by-step instructions on how to create different eDiscovery searches, see:

- Content search
- Search for content in eDiscovery (Standard)
- Create a collection estimate in eDiscovery (Premium)

> **Note**
>
> eDiscovery searches in the Microsoft Purview portal and the corresponding ***-ComplianceSearch** cmdlets in Security & Compliance PowerShell use the Keyword Query Language (KeyQL). For more detailed information, see Keyword Query Language syntax reference.

Search tips and tricks

- The time zone for all searches is Coordinated Universal Time (UTC). Changing time zones for your organization isn't currently supported. Time zone display settings in the search view are only for applicable for values in *Data* column and don't affect time stamps on collected items.
- Keyword searches aren't case-sensitive. For example, **cat** and **CAT** return the same results.
- The Boolean operators **AND**, **OR**, **NOT**, and **NEAR** must be uppercase.

- Using quotes stops wild cards and any operations inside the quotes.
- A space between two keywords or two `property:value` expressions is the same as using **OR**. For example, `from:"Sara Davis" subject:reorganization` returns all messages sent by Sara Davis or messages that contain the word reorganization in the subject line. However, using a mix of spaces and **OR** conditionals in a single query might lead to unexpected results. We recommend using either spaces or **OR** in a single query.
- Use syntax that matches the `property:value` format. Values aren't case-sensitive, and they can't have a space after the operator. If there's a space, your intended value is a full-text search. For example `to: pilarp` searches for "pilarp" as a keyword, rather than for messages sent to pilarp.
- When searching a recipient property, such as To, From, Cc, or Recipients, you can use an SMTP address, alias, or display name to denote a recipient. For example, you can use pilarp@contoso.com, pilarp, or "Pilar Pinilla."
- You can use only prefix searches; for example, **cat*** or **set***. Suffix searches (***cat**), infix searches (**c*t**), and substring searches (***cat***) aren't supported.
- When searching a property, use double quotation marks (" ") if the search value consists of multiple words or special characters. For example, `subject:budget Q1` returns messages that contain **budget** in the subject line and that contain **Q1** anywhere in the message or in any of the message properties. Using `subject:"budget Q1"` returns all messages that contain **budget Q1** anywhere in the subject line.
- To exclude content marked with a certain property value from your search results, place a minus sign (-) before the name of the property. For example, `-from:"Sara Davis"` excludes any messages sent by Sara Davis.
- You can export items based on message type. For example, to export Skype conversations and chats in Microsoft Teams, use the syntax `kind:im`. To return only email messages, you would use `kind:email`. To return chats, meetings, and calls in Microsoft Teams, use `kind:microsoftteams`.
- When searching sites, you have to add the trailing `/` to the end of the URL when using the `path` property to return only items in a specified site. If you don't include the trailing `/`, items from a site with a similar path name are also returned. For example, if you use `path:sites/HelloWorld` then items from sites named `sites/HelloWorld_East` or `sites/HelloWorld_West` would also be returned. To return items only from the HelloWorld site, you have to use `path:sites/HelloWorld/`.
- The **Query language-country/region** must be defined in your search query prior to collecting content.
- When searching the **Sent** folders for emails, using the SMTP address for the sender isn't supported. Items in the **Sent** folder contain only display names.

Finding content in Exchange Online

Admins are often charged with finding out who knew what when in the most efficient and effective way possible to respond to requests concerning ongoing or potential litigation, internal investigations, and other scenarios. These requests are often urgent, involve multiple stakeholder teams, and have significant impact if not completed in a timely manner. Knowing how to find the right information is critical for admins to complete searches successfully and help their organizations to manage the risk and cost associated with eDiscovery requirements.

When an eDiscovery request is submitted, often there's only partial information available for the admin to start to collect content that might be related to a particular investigation. The request might include employee names, project titles, rough date ranges when the project was active, and not much more. From this information, the admin needs to create queries to find relevant content across Microsoft 365 services to determine the information needed for a particular

project or subject. Understanding how information is stored and managed for these services help admins more efficiently find what they need quickly and in an effective manner.

Email, chat, meeting, and Microsoft 365 Copilot and Microsoft 365 Copilot Chat activity data (user prompts and Copilot responses) are all stored in Exchange Online. Many communication properties are available for searching items included in Exchange Online. Some properties such as *From*, *Sent*, *Subject*, and *To* are unique to certain items and aren't relevant when searching for files or documents in SharePoint and OneDrive for Business. Including these types of properties when searching across workloads can sometimes lead to unexpected results.

For example, to find content related to specific employees (*User 1* and *User 2*), associated with a project called *Tradewinds*, and during January 2020 through January 2022, you might use a query with the following properties:

- Add User 1 and User 2's Exchange Online locations as data sources to the case
- Select User 1 and User 2's Exchange Online locations as collection locations
- For **Keyword**, use *Tradewinds*
- For **Date Range**, use the *January 1, 2020* to *January 31, 2022* range

> **Important**
>
> For emails, when a keyword is used, we search subject, body, and many properties related to the participants. However, due to recipient expansion, search might not return expected results when using the alias or part of the alias. Therefore we recommend using the full UPN.

Searchable email properties

The following table lists the email message properties that can be searched by using the eDiscovery search tools in the Microsoft Purview portal or by using the **New-ComplianceSearch** or the **Set-ComplianceSearch** cmdlet.

> **Important**
>
> While email messages might have other properties supported in other Microsoft 365 services, only the email properties listed in this table are supported in eDiscovery search tools. Attempting to include other email messages properties in searches isn't supported.

The table includes an example of the *property:value* syntax for each property and a description of the search results returned by the examples. You can enter these `property:value` pairs in the keywords box for an eDiscovery search.

> **Note**
>
> When searching email properties, it's not possible to search for message headers. Header information isn't indexed for collections. Additionally, items in which the specified property is empty or blank aren't searchable. For example, using the *property:value* pair of **subject:""** to search for email messages with an empty subject line return zero results. This also applies when searching site and contact properties.

Expand table

Property	Property description	Examples	Search results returned by the examples

AttachmentNames	The names of files attached to an email message.	`attachmentnames:annualreport.ppt`
		
		`attachmentnames:annual*`
			Messages that have an attached file named *annualreport.ppt*. In the second example, using the wildcard character (*) returns messages with the word *annual* in the file name of an attachment.[1]

Bcc	The Bcc field of an email message.[1]	`bcc:pilarp@contoso.com`
		
		`bcc:pilarp`
		
		`bcc:"Pilar Pinilla"`
			All examples return messages with *Pilar Pinilla* included in the Bcc field. (See Recipient Expansion)

Category	The categories to search. Categories can be defined by users by using Outlook or Outlook on the web (formerly known as Outlook Web App). The possible values are: • blue • green • orange • purple • red • yellow	`category:"Red Category"`	Messages that have been assigned the *red* category in the source mailboxes.

Cc	The Cc field of an email message.[1]	`cc:pilarp@contoso.com`
		
		`cc:"Pilar Pinilla"`
			In both examples, messages with *Pilar Pinilla* specified in the Cc field. (See Recipient Expansion)

Folderid	The folder ID (GUID) of a specific mailbox folder in 48-character format. If you use this property, be sure to search the mailbox that the specified folder is located in. Only the specified folder is searched. Any subfolders in the folder won't be searched. To search subfolders, you need to use the *Folderid* property for the subfolder you want to search.	`folderid:4D6DD7F943C29041A65787E30F02AD1F00000000013A0000`
		
		`folderid:2370FB455F82FC44BE31397F47B632A70000000001160000 AND participants:garthf@contoso.com`
			The first example returns all items in the specified mailbo folder. The second example returns all items in the specifie mailbox folder that were sent or receive by *garthf@contoso.com*

From	The sender of an email message.[1]	`from:pilarp@contoso.com`	Messages sent by th specified user. (See Recipient Expansion)
HasAttachment	Indicates whether a message has an attachment. Use the values **true** or **false**.	`from:pilar@contoso.com AND hasattachment:true`	Messages sent by th specified user that have attachments.

Importance	The importance of an email message, which a sender can specify when sending a	`importance:high`
		
		`importance:medium`
			Messages that are marked as high importance, mediun

Property	Property description	Examples	Search results returned by the examples
	message. By default, messages are sent with normal importance, unless the sender sets the importance as **high** or **low**.	`importance:low`	importance, or low importance.

IsRead	Indicates whether messages have been read. Use the values **true** or **false**.	`isread:true`
		
		`isread:false`
			The first example returns messages with the IsRead property set to **True**. The second example returns messages with the IsRead property set to **False**

ItemClass	Use this property to search specific third-party data types that your organization imported to Office 365. Use the following syntax for this property: `itemclass:ipm.externaldata.<third-party data type>*`	`itemclass:ipm.externaldata.Facebook* AND subject:contoso`
		
		`itemclass:ipm.externaldata.Twitter* AND from:"Ann Beebe" AND "Northwind Traders"`
			The first example returns Facebook items that contain the word "contoso" in the Subject property. The second example returns Twitter items that were posted by Ann Beebe and that contain the keyword phrase "Northwind Traders".
			For a complete list of values to use for third-party data types for the ItemClass property, see Use Content search to search third-party data that was imported to Office 365.

Kind	The type of email message to search for. Possible values:
	contacts
	
	docs
	
	email
	
	externaldata
	
	faxes
	
	im
	
	journals
	
	meetings
	
	microsoftteams (returns items from chats, meetings, and calls in Microsoft Teams)
	
	notes
	
	posts
	
	rssfeeds
	
	tasks
		`kind:email`
		
		`kind:email OR kind:im OR kind:voicemail`
		
		`kind:externaldata`
			The first example returns email messages that meet the search criteria. The second example returns email messages, instant messaging conversations (including Skype for Business conversations and chats in Microsoft Teams), and voice messages that meet the search criteria. The third example returns items that were imported to mailboxes in Microsoft 365 from third-party data sources, such as Twitter, Facebook, and Cisco Jabber that meet the search criteria. For more information, see

Property	Property description	Examples	Search results returned by the examples
	voicemail		Archiving third-party data in Office 365 .
Participants	All the people fields in an email message. These fields are From, To, Cc, and Bcc.[1]	`participants:garthf@contoso.com` `participants:contoso.com`	Messages sent by or sent to garthf@contoso.com The second example returns all messages sent by or sent to a user in the contoso.com domain. (See Recipient Expansion)
Received	The date that an email message was received by a recipient.	`received:2021-04-15` `received>=2021-01-01 AND received<=2021-03-31`	Messages that were received on April 15, 2021. The second example returns all messages received between January 1, 2021 and March 31, 2021.
Recipients	All recipient fields in an email message. These fields are To, Cc, and Bcc.[1]	`recipients:garthf@contoso.com` `recipients:contoso.com`	Messages sent to garthf@contoso.com The second example returns messages sent to any recipient in the contoso.com domain. (See Recipient Expansion)
Sent	The date that an email message was sent by the sender.	`sent:2021-07-01` `sent>=2021-06-01 AND sent<=2021-07-01`	Messages that were sent on the specifiec date or sent within the specified date range.
Size	The size of an item, in bytes.	`size>26214400` `size:1..1048567`	Messages larger tha 25 MB. The second example returns messages from 1 through 1,048,567 bytes (1 MB) in size.
Subject	The text in the subject line of an email message. **Note:** When you use the Subject property in a query, the search returns all messages in which the subject line contains the text you're searching for. In other words, the query doesn't return only those messages that have an exact match. For example, if you search for `subject:"Quarterly Financials"`, your results include messages with the subject "Quarterly Financials 2018".	`subject:"Quarterly Financials"` `subject:northwind`	Messages that contain the phrase "Quarterly Financials anywhere in the text of the subject line. The second example returns all messages that contain the word northwind in the subject line.
To	The To field of an email message.[1]	`to:annb@contoso.com`	All examples return messages where Anr

Property	Property description	Examples	Search results returned by the examples
		`to:annb` `to:"Ann Beebe"`	Beebe is specified in the To: line.

> **Note**
>
> [1] For the value of a recipient property, you can use email address (also called *user principal name* or UPN), display name, or alias to specify a user. For example, you can use annb@contoso.com, annb, or "Ann Beebe" to specify the user Ann Beebe.

Recipient expansion

> **Tip**
>
> Use the new **eDiscovery** experience and condition builder to use common mailbox and site **properties** like *MessageIDs* and *ChatThreadIds* when searching for specific recipients or messages.

When searching any of the recipient properties (From, To, Cc, Bcc, Participants, and Recipients), Microsoft 365 attempts to expand the identity of each user by looking them up in Microsoft Entra ID. If the user is found in Microsoft Entra ID, the query is expanded to include the user's email address (or UPN), alias, display name, and LegacyExchangeDN. For example, a query such as `participants:ronnie@contoso.com` expands to `participants:ronnie@contoso.com OR participants:ronnie OR participants:"Ronald Nelson" OR participants:"<LegacyExchangeDN>"`.

To prevent recipient expansion, add a wild card character (asterisk) to the end of the email address and use a reduced domain name; for example, `participants:"ronnie@contoso*"` Be sure to surround the email address with double quotation marks.

However, be aware that preventing recipient expansion in the search query might result in relevant items not being returned in the search results. Email messages in Exchange can be saved with different text formats in the recipient fields. Recipient expansion is intended to help mitigate this fact by returning messages that might contain different text formats. So preventing recipient expansion might result in the search query not returning all items that might be relevant to your investigation.

> **Note**
>
> If you need to review or reduce the items returned by a search query due to recipient expansion, consider using eDiscovery (Premium). You can search for messages (taking advantage of recipient expansion), add them to a review set, and then use review set queries or filters to review or narrow the results. For more information, see Collect data for a case and Query the data in a review set.

Finding content in SharePoint and OneDrive

> **Tip**
>
> Use the new **eDiscovery** experience and search **export options** to download all list attachments for SharePoint sites.

When searching for documents and files located in SharePoint or OneDrive for Business, it might make sense to adjust the query approach based on the metadata for the documents and files of interest. Files and documents have relevant properties like *Author*, *Created*, *CreatedBy*, *FileName*, *LastModifiedTime*, and *Title*. Most of these proprieties aren't relevant when searching for communications content in Exchange Online, and using these properties might lead to unexpected results if used across both documents and communications. Additionally, *FileName* and *Title* of a document might not be the same and using one or the other to try to find a file with specific content might lead to different or inaccurate results. Keep these properties in mind when searching for specific document and file content in SharePoint and OneDrive for Business.

For example, to find content related to documents created by User 1, for a project called *Tradewinds*, for specific files named *Financials*, and from January 2020 to January 2022, you might use a query with the following properties:

- Add User 1's OneDrive for Business site as a data sources to the case
- Select User 1's OneDrive for Business site as a collection location
- Add additional SharePoint site locations related to the project as collection locations
- For **FileName**, use *Financials*
- For **Keyword**, use *Tradewinds*
- For **Date Range**, use the *January 1, 2020* to *January 31, 2022* range

Searchable site properties

The following table lists the SharePoint and OneDrive for Business properties that can be searched by using the eDiscovery search tools in the Microsoft Purview portal or by using the **New-ComplianceSearch** or the **Set-ComplianceSearch** cmdlet.

> **Important**
>
> While documents and files stored on SharePoint and OneDrive for Business might have other properties supported in other Microsoft 365 services, only the document and file properties listed in this table are supported in eDiscovery search tools. Attempting to include other document or file properties in searches isn't supported.

The table includes an example of the *property:value* syntax for each property and a description of the search results returned by the examples.

Expand table

Property	Property description	Example
Author	The author field from Office documents, which persists if a document is copied. For example, if a user creates a document and the emails it to someone else who then uploads it to SharePoint, the document will still retain the original author. Be sure to use the user's display name for this property.	`author:"Garth Fort"`
ContentType	The SharePoint content type of an item, such as Item, Document, or Video.	`contenttype:document`
Created	The date that an item is created.	`created>=2021-06-01`

Property	Property description	Example
CreatedBy	The person that created or uploaded an item. Be sure to use the user's display name for this property.	`createdby:"Garth Fort"`
DetectedLanguage	The language of an item.	`detectedlanguage:english`

DocumentLink	The path (URL) of a specific folder on a SharePoint or OneDrive for Business site. If you use this property, be sure to search the site that the specified folder is located in. We recommend using this property instead of the *Site* and *Path* properties.
	
	To return items located in subfolders of the folder that you specify for the documentlink property, you have to add /* to the URL of the specified folder; for example, `documentlink: "https://contoso.sharepoint.com/Shared Documents/*"`
		`documentlink:"https://contoso-my.sharepoint.com/personal/garthf_contoso_com/Documents/Priva`
		
		`documentlink:"https://contoso-my.sharepoint.com/personal/garthf_contoso_com/Documents/Share with Everyone/*" AND filename:confidential`

FileExtension	The extension of a file; for example, docx, one, pptx, or xlsx.	`fileextension:xlsx`

FileName	The name of a file.	`filename:"marketing plan"`
		
		`filename:estimate`

LastModifiedTime	The date that an item was last changed.	`lastmodifiedtime>=2021-05-01`
		
		`lastmodifiedtime>=2021-05-01 AND lastmodifiedtime<=2021-06-01`

ModifiedBy	The person who last changed an item. Be sure to use the user's display name for this property.	`modifiedby:"Garth Fort"`

SharedWithUsersOWSUser	Documents that have been shared with the specified user and displayed on the **Shared with me** page in the user's OneDrive for Business site. These are documents that have been explicitly shared with the specified user by other	`sharedwithusersowsuser:garthf`
		
		`sharedwithusersowsuser:"garthf@contoso.com"`

Property	Property description	Example
	people in your organization. When you export documents that match a search query that uses the SharedWithUsersOWSUser property, the documents are exported from the original content location of the person who shared the document with the specified user. For more information, see Searching for site content shared within your organization.	
Size	The size of an item, in bytes.	`size>=1` `size:1..10000`
Title	The title of the document. The Title property is metadata that's specified in Microsoft Office documents. It's different from the file name of the document.	`title:"communication plan"`

Searchable contact properties

The following table lists the contact properties that are indexed and that you can search for using eDiscovery search tools. These are the properties that are available for users to configure for the contacts (also called personal contacts) that are located in the personal address book of a user's mailbox. To search for contacts, you can select the mailboxes to search and then use one or more contact properties in the keyword query.

> **Tip**
>
> To search for values that contain spaces or special characters, use double quotation marks (" ") to contain the phrase; for example, `businessaddress:"123 Main Street"`.

Expand table

Property	Property description
BusinessAddress	The address in the **Business Address** property. The property is also called the **Work** address on the contact properties page.
BusinessPhone	The phone number in any of the **Business Phone** number properties.
CompanyName	The name in the **Company** property.
Department	The name in the **Department** property.
DisplayName	The display name of the contact. This is the name in the **Full Name** property of the contact.
EmailAddress	The address for any email address property for the contact. Users can add multiple email addresses for a contact. Using this property would return contacts that match any of the

Property	Property description
	contact's email addresses.
FileAs	The **File as** property. This property is used to specify how the contact is listed in the user's contact list. For example, a contact could be listed as *FirstName,LastName* or *LastName,FirstName*.
GivenName	The name in the **First Name** property.
HomeAddress	The address in any of the **Home** address properties.
HomePhone	The phone number in any of the **Home** phone number properties.
IMAddress	The IM address property, which is typically an email address used for instant messaging.
MiddleName	The name in the **Middle** name property.
MobilePhone	The phone number in the **Mobile** phone number property.
Nickname	The name in the **Nickname** property.
OfficeLocation	The value in **Office** or **Office location** property.
OtherAddress	The value for the **Other** address property.
Surname	The name in the **Last** name property.
Title	The title in the **Job title** property.

Search operators

Boolean search operators, such as **AND**, **OR**, and **NOT**, help you define more-precise searches by including or excluding specific words in the search query. Other techniques, such as using property operators (such as `>=` or `..`), quotation marks, parentheses, and wildcards, help you refine a search query. The following table lists the operators that you can use to narrow or broaden search results.

Expand table

Operator	Usage	Description
AND	keyword1 AND keyword2	Returns items that include all of the specified keywords or `property:value` expressions. For example, `from:"Ann Beebe" AND subject:northwind` would return all messages sent by Ann Beebe that contained the word northwind in the subject line. [2]
+	keyword1 + keyword2 + keyword3	Returns items that contain *either* `keyword2` or `keyword3` *and* that also contain `keyword1`. Therefore, this example is equivalent to the query `(keyword2 OR keyword3) AND keyword1`. The query `keyword1 + keyword2` (with a space after the + symbol) isn't the same as using the **AND** operator. This query would be equivalent to `"keyword1 + keyword2"` and return items with the exact phase `"keyword1 + keyword2"`.
OR	keyword1 OR keyword2	Returns items that include one or more of the specified keywords or `property:value` expressions. [2]
NOT	keyword1 NOT keyword2 NOT from:"Ann Beebe" NOT kind:im	Excludes items specified by a keyword or a `property:value` expression. In the second example excludes messages sent by Ann Beebe. The third example excludes any instant messaging conversations, such as Skype for Business conversations that are saved to the Conversation History mailbox folder. [2]
NEAR	keyword1 NEAR(n) keyword2	Returns items with words that are near each other. In the *keyword1 NEAR(n) keyword2* syntax, *n* equals the number of words exclusive of *keyword1* and *keyword2*. For example, to identify instances where the term *best* is within 3 words of *worst* (example sentence, 'Best is opposite of worst.'), you would use **best NEAR(3) worst**. This returns

Operator	Usage	Description
		any items where there are 3 or fewer words between *best* (keyword1) and *worst* (keyword2). If no number is specified, the default *n* value is 8. [2]
:	property:value	The colon (:) in the `property:value` syntax specifies that the value of the property being searched for contains the specified value. For example, `recipients:garthf@contoso.com` returns any message sent to garthf@contoso.com.
=	property=value	The same as the `:` operator.
<	property<value	Denotes that the property being searched is less than the specified value. [1]
>	property>value	Denotes that the property being searched is greater than the specified value.[1]
<=	property<=value	Denotes that the property being searched is less than or equal to a specific value.[1]
>=	property>=value	Denotes that the property being searched is greater than or equal to a specific value.[1]
..	property:value1..value2	Denotes that the property being searched is greater than or equal to value1 and less than or equal to value2.[1]
" "	"fair value" subject:"Quarterly Financials"	In a keyword query (where you type the `property:value` pair in the **Keyword** box), use double quotation marks (" ") to search for an exact phrase or term. However, if you use the **Subject** or **Subject/Title** search condition condition, don't add double quotation marks to the value because quotation marks are automatically added when using these search conditions. If you do add quotation marks to the value, two pairs of double quotations are added to the condition value, and the search query will return an error.
*	cat* subject:set*	Prefix searches (also called *prefix matching*) where a wildcard character (*) is placed at the end of a word in keywords or `property:value` queries. In prefix searches, the search returns results with terms that contain the word followed by zero or more characters. For example, `title:set*` returns documents that contain the word "set", "setup", and "setting" (and other words that start with "set") in the document title. **Note:** You can use only prefix searches; for example, **cat*** or **set***. Suffix searches (***cat**), infix searches (**c*t**), and substring searches (***cat***) aren't supported. Also, adding a period (.) to a prefix search changes the results that are returned. That's because a period is treated as a stop word. For example, searching for **cat*** and searching for **cat.*** will return different results. We recommend not using a period in a prefix search.
( )	(fair OR free) AND (from:contoso.com) (IPO OR initial) AND (stock OR shares) (quarterly financials)	Parentheses group together Boolean phrases, `property:value` items, and keywords. For example, `(quarterly financials)` returns items that contain the words quarterly and financials.

> **Note**
>
> [1] Use this operator for properties that have date or numeric values.
> [2] Boolean search operators must be uppercase; for example, **AND**. If you use a lowercase operator, such as **and**, it is treated as a keyword in the search query.

Search conditions

You can add conditions to a search query to narrow a search and return a more refined set of results. Each condition adds a clause to the KeyQL search query that is created and run when you start the search.

- Conditions for common properties
- Conditions for mail properties
- Conditions for document properties
- Operators used with conditions
- Guidelines for using conditions
- Examples of using conditions in search queries

Conditions for common properties

Create a condition using common properties when searching mailboxes and sites in the same search. The following table lists the available properties to use when adding a condition.

Expand table

Condition	Description
Date	For email, the date a message was created or imported from a PST file. For documents, the date a document was last modified. If you're searching for email messages for a specific time period, you should use the message *Received* and *Sent* conditions if you're unsure if the email messages might have been imported instead of natively created in Exchange.
Sender/Author	For email, the person who sent a message. For documents, the person cited in the author field from Office documents. You can type more than one name, separated by commas. Two or more values are logically connected by the **OR** operator. (See Recipient Expansion)
Size (in bytes)	For both email and documents, the size of the item (in bytes).
Subject/Title	For email, the text in the subject line of a message. For documents, the title of the document. As previously explained, the Title property is metadata specified in Microsoft Office documents. You can type the name of more than one subject/title values, separated by commas. Two or more values are logically connected by the **OR** operator. **Note**: Don't include double quotation marks to the values for this condition because quotation marks are automatically added when using this search condition. If you add quotation marks to the value, two pairs of double quotations are added to the condition value, and the search query will return an error.
Retention label	For both email and documents, retention labels that can be automatically or manually applied to messages and documents. Retention labels can be used to declare records and help you manage the data lifecycle of content by enforcing retention and deletion rules specified by the label. You can type part of the retention label name and use a wildcard or type the complete label name. For more information about retention labels, see Learn about retention policies and retention labels.

Conditions for mail properties

Create a condition using mail properties when searching mailboxes or public folders in Exchange Online. The following table lists the email properties that you can use for a condition. These properties are a subset of the email properties that were previously described. These descriptions are repeated for your convenience.

Expand table

Condition	Description
Message kind	The message type to search. This is the same property as the Kind email property. Possible values:

Condition	Description
	• contacts • docs • email • externaldata • fax • im • journals • meetings • microsoftteams • notes • posts • rssfeeds • tasks • voicemail
Participants	All the people fields in an email message. These fields are From, To, Cc, and Bcc. (See Recipient Expansion)
Type	The message class property for an email item. This is the same property as the ItemClass email property. It's also a multi-value condition. So to select multiple message classes, hold the **CTRL** key and then select two or more message classes in the drop-down list that you want to add to the condition. Each message class that you select in the list is logically connected by the **OR** operator in the corresponding search query. For a list of the message classes (and their corresponding message class ID) that are used by Exchange and that you can select in the **Message class** list, see Item Types and Message Classes.
Received	The date that an email message was received by a recipient. This is the same property as the Received email property.
Recipients	All recipient fields in an email message. These fields are To, Cc, and Bcc. (See Recipient Expansion)
Sent	The date that an email message was sent by the sender. This is the same property as the Sent email property.
Subject	The text in the subject line of an email message. **Note**: Don't include double quotation marks to the values for this condition because quotation marks are automatically added when using this search condition. If you add quotation marks to the value, two pairs of double quotations are added to the condition value, and the search query will return an error.
To	The recipient of an email message in the To field.

Conditions for document properties

Create a condition using document properties when searching for documents on SharePoint and OneDrive for Business sites. The following table lists the document properties that you can use for a condition. These properties are a subset of the site properties that were previously described. These descriptions are repeated for your convenience.

Expand table

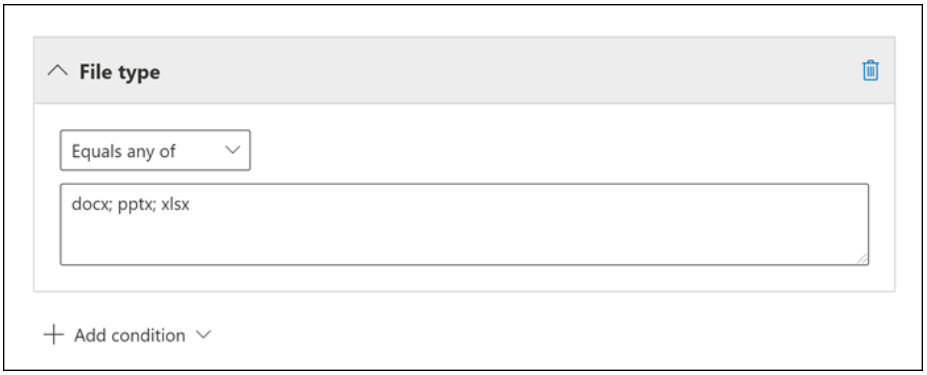
Condition	Description
Author	The author field from Office documents, which persists if a document is copied. For example, if a user creates a document and the emails it to someone else who then uploads it to SharePoint, the document will still retain the original author.
Title	The title of the document. The Title property is metadata that's specified in Office documents. It's different than the file name of the document.
Created	The date that a document is created.
Last modified	The date that a document was last changed.

Condition	Description
File type	The extension of a file; for example, docx, one, pptx, or xlsx. This is the same property as the FileExtension site property. **Note:** If you include a File type condition using the **Equals** or **Equals any of** operator in a search query, you can't use a prefix search (by including the wildcard character (*) at the end of the file type) to return all versions of a file type. If you do, the wildcard is ignored. For example if you include the condition `Equals any of doc*`, only files with an extension of `.doc` are returned. Files with an extension of `.docx` won't be returned. To return all versions of a file type, used the *property:value* pair in a keyword query; for example, `filetype:doc*`.

Operators used with conditions

When you add a condition, you can select an operator that is relevant to type of property for the condition. The following table describes the operators that are used with conditions and lists the equivalent that is used in the search query.

Expand table



Operator	Query equivalent	Description
After	`property>date`	Used with date conditions. Returns items that were sent, received, or modified after the specified date.
Before	`property<date`	Used with date conditions. Returns items that were sent, received, or modified before the specified date.
Between	`date..date`	Use with date and size conditions. When used with a date condition, returns items there were sent, received, or modified within the specified date range. When used with a size condition, returns items whose size is within the specified range.
Contains any of	`(property:value) OR (property:value)`	Used with conditions for properties that specify a string value. Returns items that contain any part of one or more specified string values.
Doesn't contain any of	`-property:value` `NOT property:value`	Used with conditions for properties that specify a string value. Returns items that don't contain any part of the specified string value.
Doesn't equal any of	`-property=value` `NOT property=value`	Used with conditions for properties that specify a string value. Returns items that don't contain the specific string.
Equals	`size=value`	Returns items that are equal to the specified size.[1]
Equals any of	`(property=value) OR (property=value)`	Used with conditions for properties that specify a string value. Returns items that are a match of one or more specified string values.
Greater	`size>value`	Returns items where the specified property is greater than the specified value.[1]
Greater or equal	`size>=value`	Returns items where the specified property is greater than or equal to the specified value.[1]
Less	`size<value`	Returns items that are greater than or equal to the specific value.[1]
Less or equal	`size<=value`	Returns items that are greater than or equal to the specific value.[1]
Not equal	`size<>value`	Returns items that don't equal the specified size.[1]

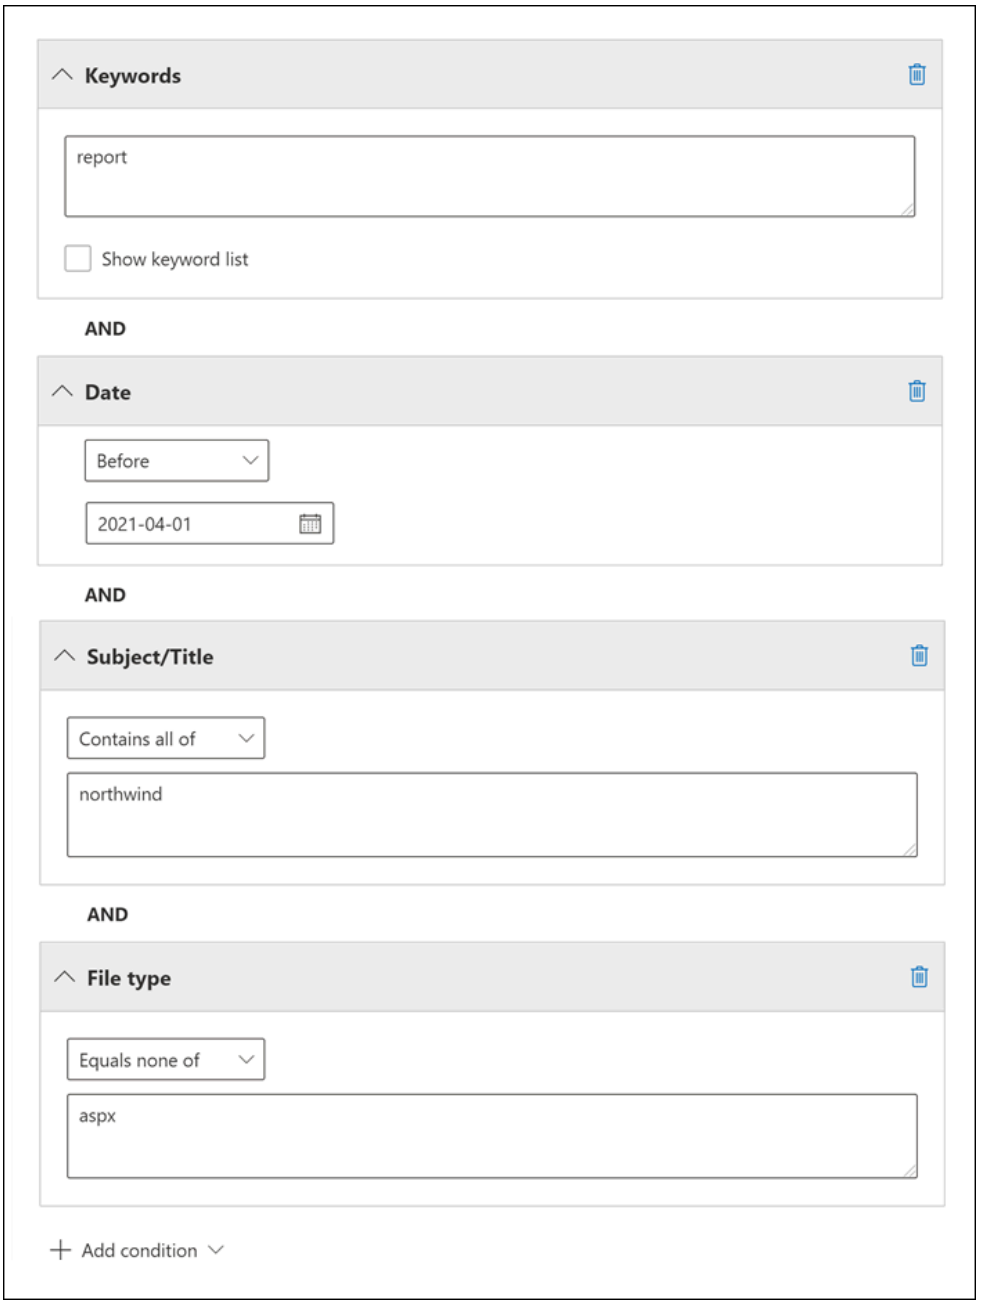
> **Note**
>
> [1] This operator is available only for conditions that use the Size property.

Guidelines for using conditions

Keep the following in mind when using search conditions.

- A condition is logically connected to the keyword query (specified in the keyword box) by the **AND** operator. That means that items have to satisfy both the keyword query and the condition to be included in the results. This is how conditions help to narrow your results.
- If you add two or more unique conditions to a search query (conditions that specify different properties), those conditions are logically connected by the **AND** operator. That means only items that satisfy all the conditions (in addition to any keyword query) are returned.
- If you add more than one condition for the same property, those conditions are logically connected by the **OR** operator. That means items that satisfy the keyword query and any one of the conditions are returned. So, groups of the same conditions are connected to each other by the **OR** operator and then sets of unique conditions are connected by the **AND** operator.
- If you add multiple values (separated by commas or semi-colons) to a single condition, those values are connected by the **OR** operator. That means items are returned if they contain any of the specified values for the property in the condition.
- Any condition that uses an operator with **Contains** and **Equals** logic will return similar search results for simple string searches. A simple string search is a string in the condition that doesn't include a wildcard). For example, a condition that uses **Equals any of** will return the same items as a condition that uses **Contains any of**.
- The search query that is created by using the keywords box and conditions is displayed on the **Search** page, in the details pane for the selected search. In a query, everything to the right of the notation `(c:c)` indicates conditions that are added to the query. `(c:c)` shouldn't be used in manually entered queries and isn't equal to **AND** or **OR**.
- Conditions only add properties to the search query; they don't add operators. This is why the query displayed in the detail pane doesn't show operators to the right of the `(c:c)` notation. KeyQL adds the logical operators (according to the previously explained rules) when the executing the query.
- You can use the drag and drop control to resequence the order of conditions. Select the control for a condition and move it up or down.
- As previously explained, some condition properties allow you to type multiple values (separated by semi-colons). Each value is logically connected by the **OR** operator, and results in the query `(filetype=docx) OR (filetype=pptx) OR (filetype=xlsx)`. The following illustration shows an example of a condition with multiple values.

> **Note**
>
> You can't add multiple conditions (by selecting **Add condition** for the same property). Instead, you have to provide multiple values for the condition (separated by semi-colons), as shown in the previous example.



Examples of using conditions in search queries

The following examples show the GUI-based version of a search query with conditions, the search query syntax that is displayed in the details pane of the selected search (which is also returned by the **Get-ComplianceSearch** cmdlet), and the logic of the corresponding KeyQL query.

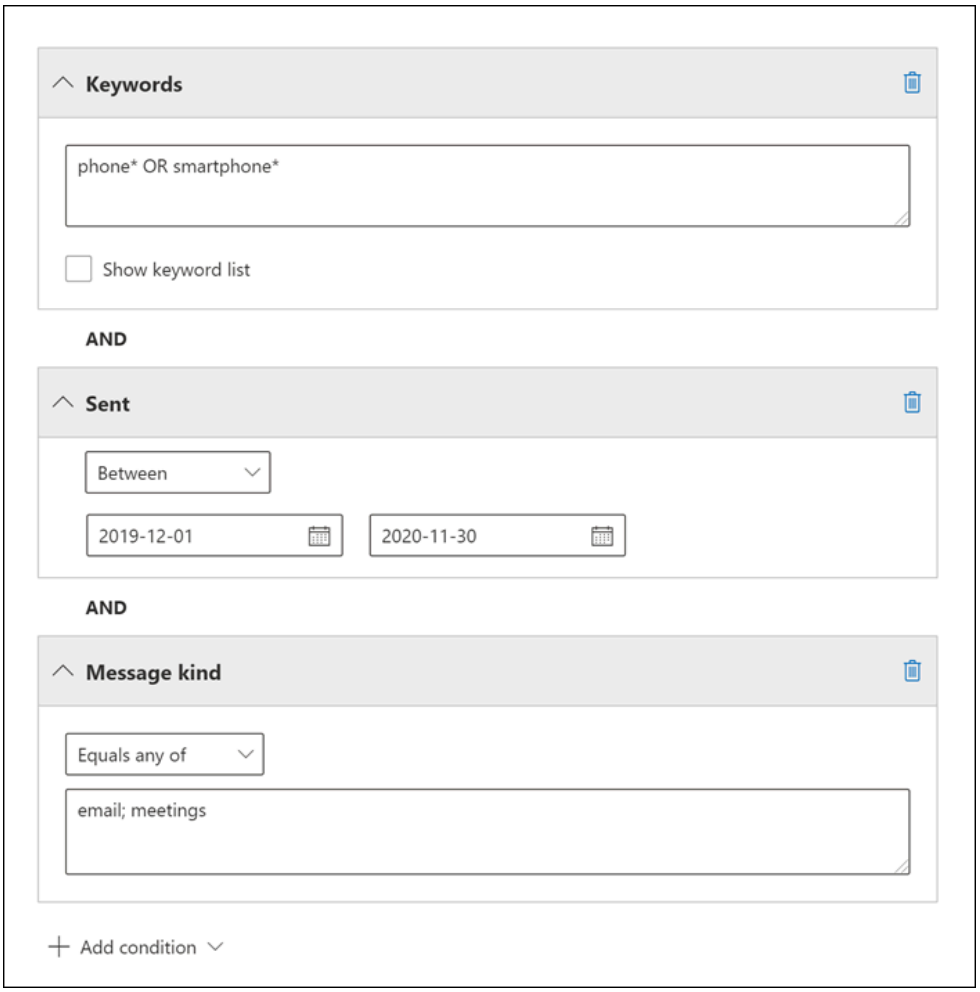
Example 1

This example returns email items or documents that contain the keyword "report", that were sent or created before April 1, 2021, and that contain the word "northwind" in the subject field of email messages or in the title property of documents. The query excludes Web pages that meet the other search criteria.

GUI:

Search query syntax:

```
report(c:c)(date<2021-04-01)(subjecttitle:"northwind")(-filetype:aspx)
```



Search query logic:

```
report AND (date<2021-04-01) AND (subjecttitle:"northwind") NOT (filetype:aspx)
```

Example 2

This example returns email messages or calendar meetings that were sent between December 1, 2019 and November 30, 2020 and that contain words that start with "phone" or "smartphone".

GUI:

Search query syntax:

```
phone* OR smartphone*(c:c)(sent=2019-12-01..2020-11-30)(kind="email")(kind="meetings")
```

Search query logic:

```
phone* OR smartphone* AND (sent=2019-12-01..2020-11-30) AND ((kind="email") OR (kind="meetings"))
```

Special characters

Some special characters aren't included in the search index and therefore aren't searchable. This also includes the special characters that represent search operators in the search query. Here's a list of special characters that are either replaced by a blank space in the actual search query or cause a search error.

```
+ - = : ! @ # % ^ & ; _ / ? ( ) [ ] { }
```

Searchable sensitive data types

You can use eDiscovery search tools in the Microsoft Purview portal to search for sensitive data, such as credit card numbers or social security numbers, that is stored in documents on SharePoint and OneDrive for Business sites. You can do this by using the `SensitiveType` property and the name (or ID) of a sensitive information type in a keyword query. For example, the query `SensitiveType:"Credit Card Number"` returns documents that contain a credit card number. The query `SensitiveType:"U.S. Social Security Number (SSN)"` returns documents that contain a U.S. social security number.

To see a list of the sensitive information types that you can search for, go to **Data classifications** > **Sensitive info types** in the Microsoft Purview portal. Or you can use the **Get-DlpSensitiveInformationType** cmdlet in Security & Compliance PowerShell to display a list of sensitive information types.

Limitations for searching sensitive data types

- To search for custom sensitive information types, you have to specify the ID of the sensitive information type in the `SensitiveType` property. Using the name of a custom sensitive information type (as shown in the example for built-in sensitive information types in the previous section) will return no results. Use the **Publisher** column on the **Sensitive info types** page in the Microsoft Purview portal (or the **Publisher** property in PowerShell) to differentiate between built-in and custom sensitive information types. Built-in sensitive data types have a value of `Microsoft Corporation` for the **Publisher** property.

  To display the name and ID for the custom sensitive data types in your organization, run the following command in Security & Compliance PowerShell:

  ```
  PowerShell
  ```

  ```
  Get-DlpSensitiveInformationType | Where-Object {$_.Publisher -ne "Microsoft Corporation"} | FT Name,Id
  ```

  Then you can use the ID in the `SensitiveType` search property to return documents that contain the custom sensitive data type; for example, `SensitiveType:7e13277e-6b04-3b68-94ed-1aeb9d47de37`

- You can't use sensitive information types and the `SensitiveType` search property to search for sensitive data at-rest in Exchange Online mailboxes. This includes 1:1 chat messages, 1:N group chat messages, and team channel conversations in Microsoft Teams because all of this content is stored in mailboxes. However, you can use data loss prevention (DLP) policies to protect sensitive email data in transit. For more information, see Learn about data loss prevention and Search for and find personal data.

Searching for site content shared with external users

You can also use eDiscovery search tools in the Microsoft Purview portal to search for documents stored on SharePoint and OneDrive for Business sites that have been shared with people outside of your organization. This can help you identify sensitive or proprietary information that's being shared outside your organization. You can do this by using the `ViewableByExternalUsers` property in a keyword query. This property returns documents or sites that have been shared with external users by using one of the following sharing methods:

- A sharing invitation that requires users to sign in to your organization as an authenticated user.
- An anonymous guest link, which allows anyone with this link to access the resource without having to be authenticated.

Here are some examples:

- The query `ViewableByExternalUsers:true AND SensitiveType:"Credit Card Number"` returns all items that have been shared with people outside your organization and contain a credit card number.
- The query `ViewableByExternalUsers:true AND ContentType:document AND site:"https://contoso.sharepoint.com/Sites/Teams"` returns a list of documents on all team

sites in the organization that have been shared with external users.

> **Tip**
>
> A search query such as `ViewableByExternalUsers:true AND ContentType:document` might return numerous .aspx files in the search results. To eliminate these (or other types of files), you can use the `FileExtension` property to exclude specific file types; for example `ViewableByExternalUsers:true AND ContentType:document NOT FileExtension:aspx`.

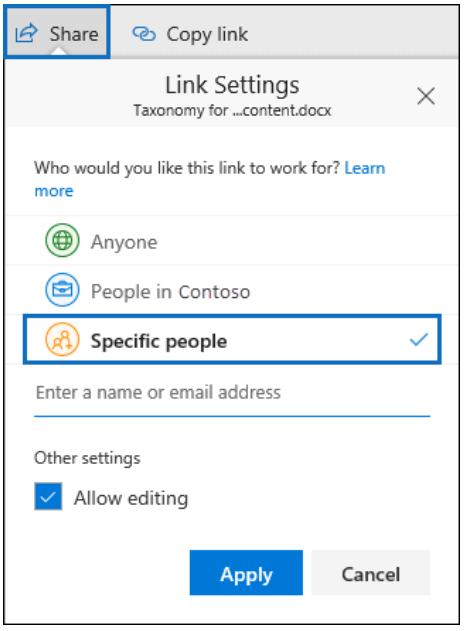
What is considered content that is shared with people outside your organization? Documents in your organization's SharePoint and OneDrive for Business sites that are shared by sending a sharing invitation or that are shared in public locations. For example, the following user activities result in content that is viewable by external users:

- A user shares a file or folder with a person outside your organization.
- A user creates and sends a link to a shared file to a person outside your organization. This link allows the external user to view (or edit) the file.
- A user sends a sharing invitation or a guest link to a person outside your organization to view (or edit) a shared file.

Issues using the ViewableByExternalUsers property

While the `ViewableByExternalUsers` property represents the status of whether a document or site is shared with external users, there are some caveats to what this property does and doesn't reflect. In the following scenarios, the value of the `ViewableByExternalUsers` property won't be updated, and the results of a search query that uses this property might be inaccurate.

- Changes to sharing policy, such as turning off external sharing for a site or for the organization. The property will still show previously shared documents as being externally accessible even though external access might have been revoked.
- Changes to group membership, such as adding or removing external users to Microsoft 365 Groups or Microsoft 365 security groups. The property won't automatically be updated for items the group has access to.
- Sending sharing invitations to external users where the recipient hasn't accepted the invitation, and therefore doesn't yet have access to the content.



In these scenarios, the `ViewableByExternalUsers` property won't reflect the current sharing status until the site or document library is recrawled and reindexed.

Searching for site content shared within your organization

As previously explained, you can use the `SharedWithUsersOWSUser` property so search for documents that have been shared between people in your organization. When a person shares a file (or folder) with another user inside your organization, a link to the shared file appears on the **Shared with me** page in the OneDrive for Business account of the person who the file was shared with. For example, to search for the documents that have been shared with Sara Davis, you can use the query `SharedWithUsersOWSUser:"sarad@contoso.com"`. If you export the results of this search, the original documents (located in the content location of the person who shared the documents with Sara) are downloaded.

Documents must be explicitly shared with a specific user to be returned in search results when using the `SharedWithUsersOWSUser` property. For example, when a person shares a document in their OneDrive account, they have the option to share it with anyone (inside or outside the

organization), share it only with people inside the organization, or share it with a specific person. Here's a screenshot of the **Share** window in OneDrive that shows the three sharing options.

Only documents that are shared by using the third option (shared with **Specific people**) are returned by a search query that uses the `SharedWithUsersOWSUser` property.

Searching for Skype for Business conversations

You can use the following keyword query to specifically search for content in Skype for Business conversations:

PowerShell

```
kind:im
```

The previous search query also returns chats from Microsoft Teams. To prevent this, you can narrow the search results to include only Skype for Business conversations by using the following keyword query:

PowerShell

```
kind:im AND subject:conversation
```

The previous keyword query excludes chats in Microsoft Teams because Skype for Business conversations are saved as email messages with a Subject line that starts with the word "Conversation".

To search for Skype for Business conversations that occurred within a specific date range, use the following keyword query:

PowerShell

```
kind:im AND subject:conversation AND (received=startdate..enddate)
```

Character limits for searches

There's a 4,000 character limit for search queries when searching for content in SharePoint sites and OneDrive accounts. Here's how the total number of characters in the search query are calculated:

- The characters in keyword search query (including both user and filter fields) count against this limit.
- The characters in any location property (such as the URLs for all the SharePoint sites or OneDrive locations being searched) count against this limit.
- The characters in all the search permissions filters that are applied to the user running the search count against the limit.

> **Note**
>
> The 4,000 character limit applies to Content search, eDiscovery (Standard), and eDiscovery (Premium).

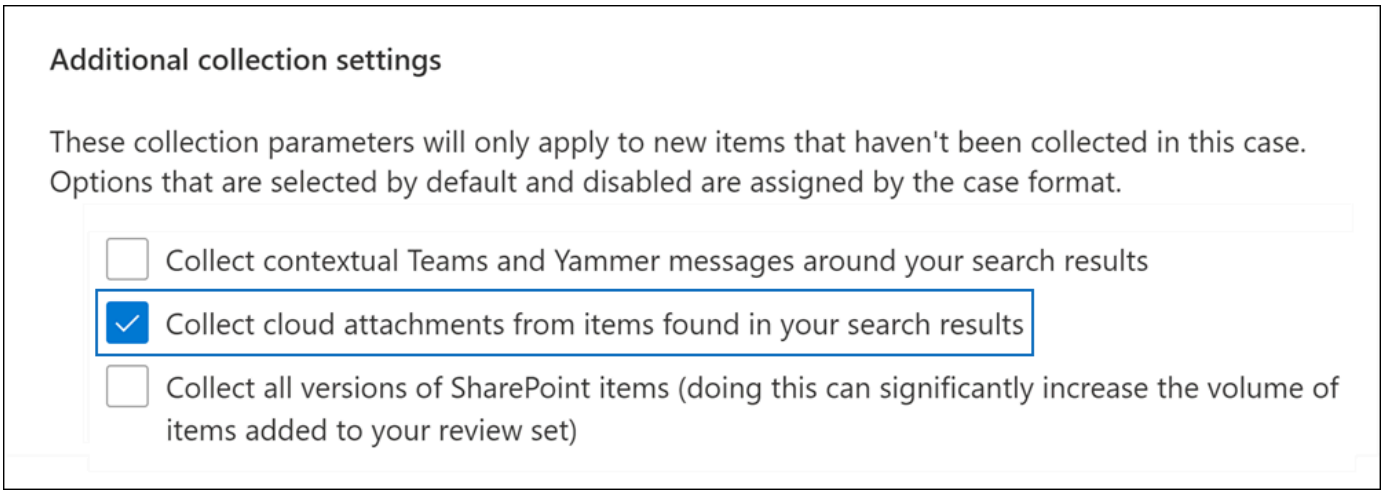
Collect cloud attachments in Microsoft Purview eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.



Cloud attachments are links to documents that are typically stored in SharePoint site and OneDrive. So instead of attaching an actual copy of a document in an email message or a Teams chat conversation, you have the option of sharing a link to the file. Cloud attachments are an effective way to share documents and collaborate with other people in your organization. But cloud attachments present challenges during the eDiscovery workflow because only the cloud attachment link and not the actual content in the shared document are returned in an eDiscovery search. To address this challenge, eDiscovery (Premium) provides two solutions for collecting cloud attachments:

- Collecting the live version of a document that is linked to in a cloud attachment.
- Collecting the version of the document at the time it was shared in a cloud attachment.

Collecting cloud attachments

When you create a collection estimate and the search results contain items that include cloud attachments, you have to the option of collecting the target of the cloud attachment when you commit the collection estimate to a review set. When you select this option, eDiscovery (Premium) adds the documents that are linked to in the cloud attachment to the review set. This option allows you to review the target documents and determine if the document is relevant to your case or investigation.

The following screenshot shows the option to include the targets of cloud attachments when you commit a collection to a review set.

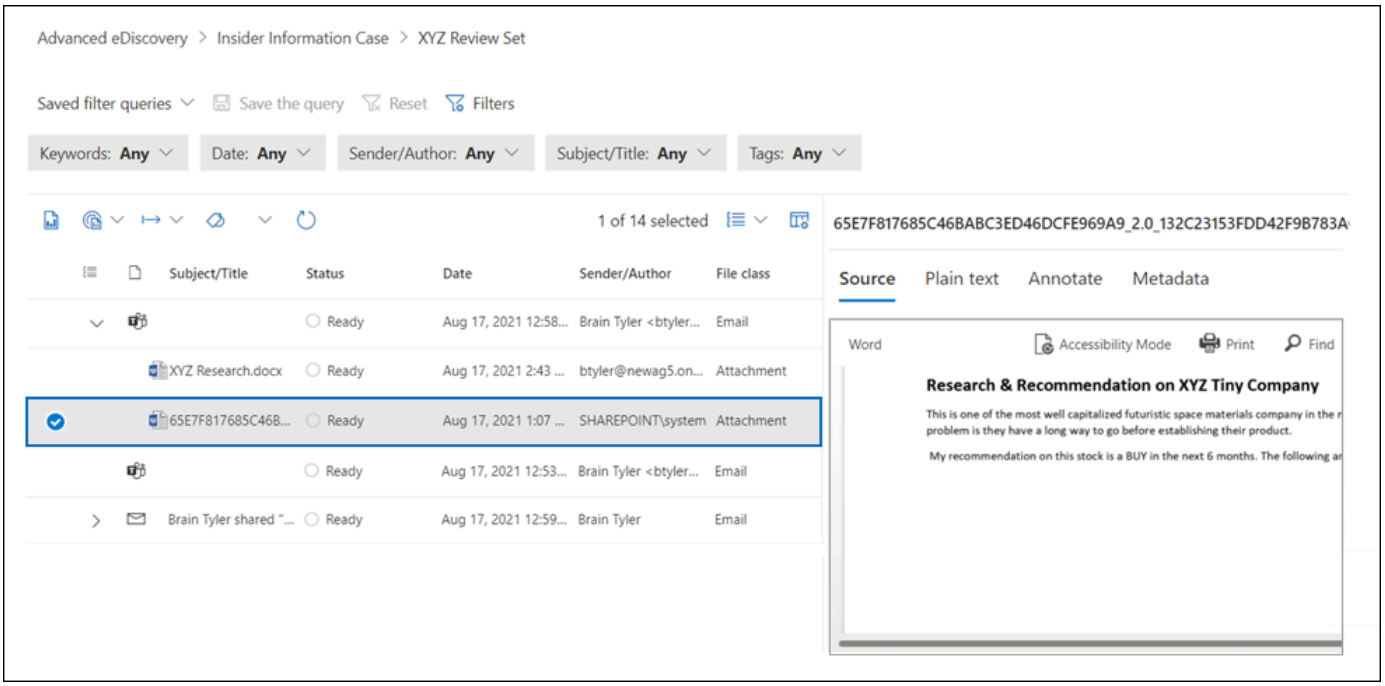
> **Note**
>
> You have the option to include all versions (in addition to the version that was shared) of cloud attachments in the review set.

When working with collections and cloud attachments, the following applies:

- Cloud attachments aren't represented or included in collection estimates. Only direct hits are included in a collection.
- If cloud attachments are moved or no longer available at the location from where it was shared, it isn't included in a collection.
- If the cloud attachment is under retention of legal hold policy, the cloud attachment is included in collections even if deleted by a user.
- For cloud attachments that have been renamed or moved to a different container, it may or may not be included in a collection depending on how it was shared. If the cloud attachment was shared via a link and the link is still active, it's retrieved and included in the collection. If the sharing link to the location for the cloud attachment isn't available, the cloud attachment isn't retrieved or included in the collection.
- For cloud attachments with parent items placed on hold, the hold applies to cloud attachment in certain situations. This depends on the source location of the cloud attachment and the hold policy applied to that location. The policies applicable to the cloud attachment recipient won't necessarily apply to the location of the shared cloud attachment.

For instructions committing a collection to a review set, see Commit a collection estimate to a review set.

Collecting the version shared in a cloud attachment (preview)



The eDiscovery (Premium) workflow for collecting cloud attachments only includes adding the most current version of a cloud attachment to a review set. This means the version that's collected and added to a review set could be different than the version that was originally shared in the cloud attachment. So it's possible that content that was present in the cloud attachment at the time it was shared might have been removed and doesn't exist in the current version that's added to the review set.

Organizations can use Microsoft Purview retention labels to preserve the version of a document at the time when it was shared as a cloud attachment. To do this, your organization can create a retention label, choose the option apply the label to cloud attachments, and then automatically apply the label to documents stored in SharePoint and OneDrive. After you set up this configuration, a copy of a document is created at the time when the file is shared. Also, if the document is modified and shared again as a cloud attachment, the modified version is also preserved. If the file is modified and shared again, a new copy of the file as a new version is preserved.

Preserving the shared versions of cloud attachments can help your organization scope the preservation and collection of potentially relevant content to the specific version of the document that was shared rather than the current live version. After you implement this retention solution, both the current live version of a cloud attachment and the version that was shared in the cloud attachment are collected and added to a review set.

For instructions on setting up a retention label and automatically applying it to cloud attachments, see Auto-apply labels to cloud attachments.

The following screenshot shows a cloud attachment document, named *XYZ Research.docx*, that was added to a review set. The document was shared as a cloud attachment in a Teams chat conversation. The review set also contains the version that was originally shared in the cloud attachment. Notice the name of this version of the cloud attachment is generated by the system and the author is identified as **SharePoint**.

Additionally, the current live version and the version that was shared have the same **FamilyId** property value, which is the same as the **FamilyId** for the parent object (such as an email message or a Teams chat conversation). This lets you group cloud attachments with the item in which they were shared.

After you've implemented the retention label and auto-apply the label to SharePoint documents, you still select the option to collect cloud attachments when committing a collection estimate to a review set. When the cloud attachments are collected, both the current live version and the version that was originally shared are added to the review set.

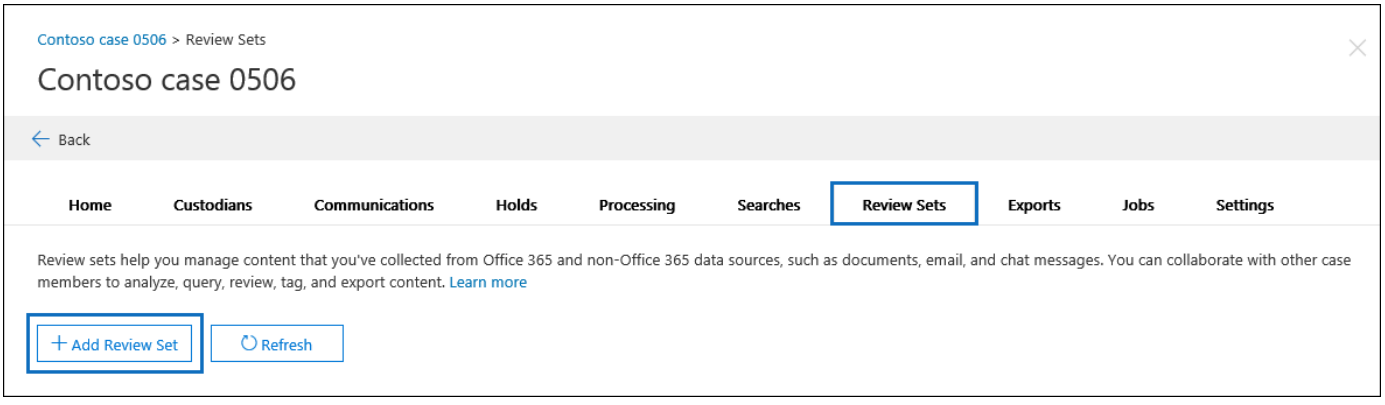
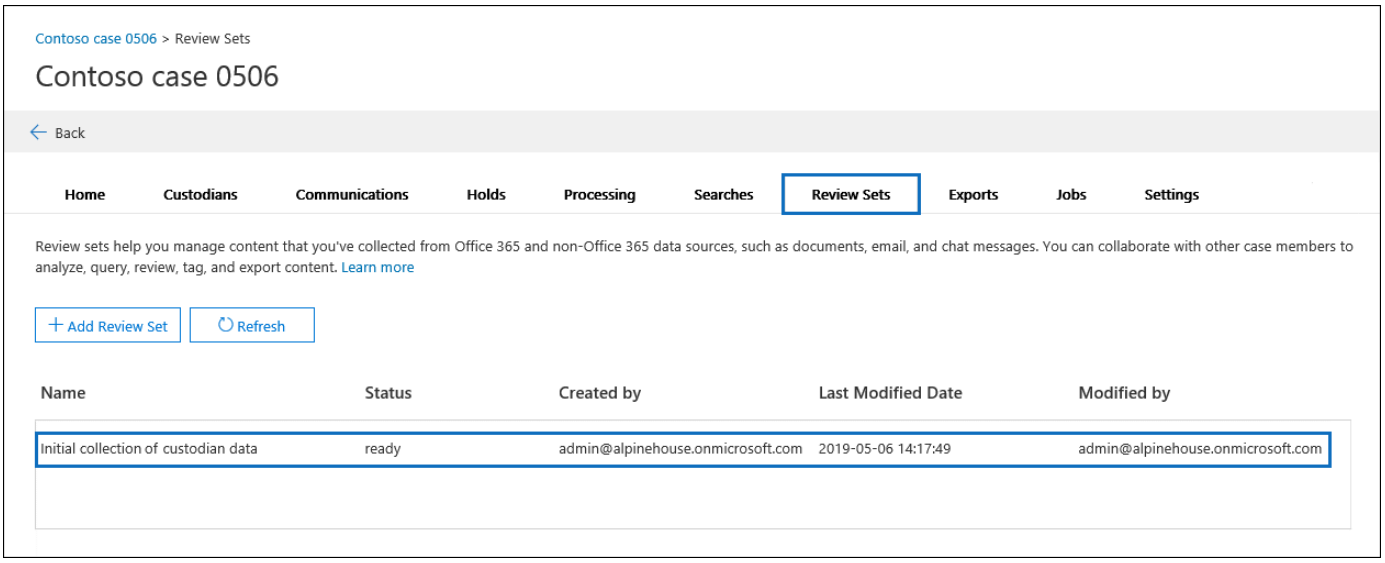
Manage review sets in eDiscovery (Premium)



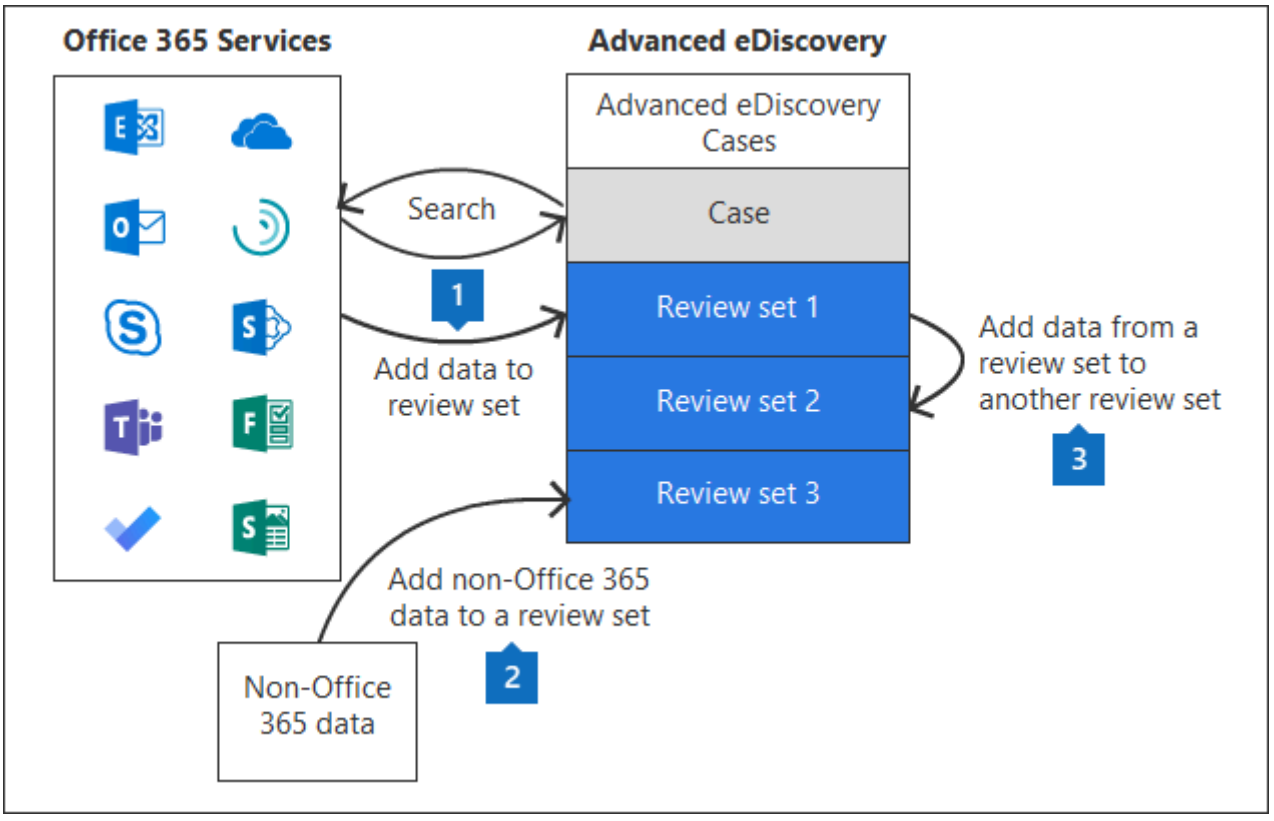
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Review sets are a static set of documents where you can analyze, query, view, tag, and export data in a case. For more information about performing these tasks, see:



- Analyze data in a review set
- Query the data in a review set
- View documents in a review set
- Tag documents in a review set
- Export case data

Create a review set



Review sets can be created on the **Review sets** tab by selecting **+ Add review set**.

On the **Add review set** flyout page, type a name for the review set and then select **Save**. The new review set is displayed in the list on the **Review sets** tab.

There are three different ways to add data to a review set in an eDiscovery (Premium) case.

1. Add search results to a review set
2. Load non-Microsoft 365 data into a review set
3. Add data to a review set from another review set

> **Note**
>
> You can't delete items from a review set and you can't delete review sets from a case. To delete a review set (and delete the data in it), you have to delete the eDiscovery (Premium)

case the review set is located in. For more information, see Close or delete an eDiscovery (Premium) case.

Last updated on 11/21/2025

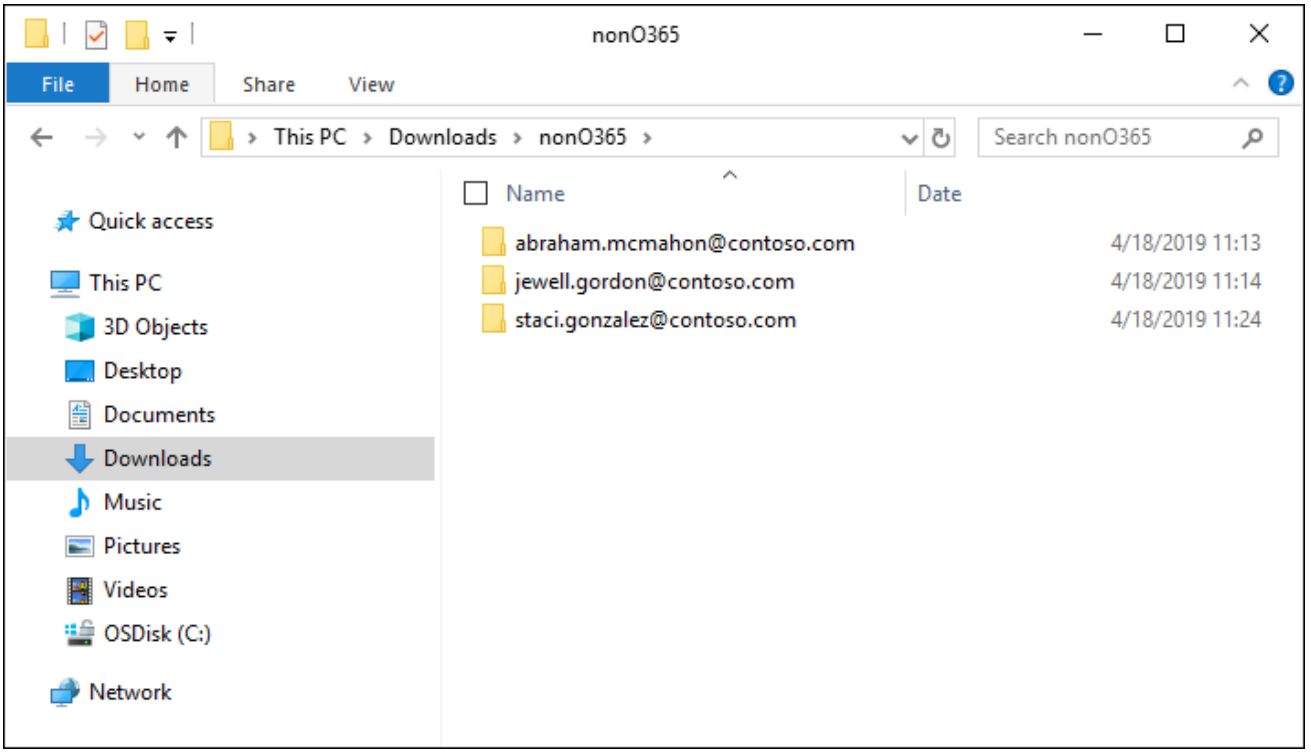
Load non-Microsoft 365 data into a review set

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Not all documents that you need to analyze in Microsoft Purview eDiscovery (Premium) are in Microsoft 365. With the non-Microsoft 365 data import feature in eDiscovery (Premium), you can upload documents that aren't in Microsoft 365 to a review set. This article shows you how to bring your non-Microsoft 365 documents into eDiscovery (Premium) for analysis.

Requirements to upload non-Office 365 content

Using the upload non-Microsoft 365 feature described in this article requires that you've the following:



- All custodians that you want to associate non-Microsoft 365 content to must have the appropriate license. For more information, see Get started with eDiscovery (Premium).
- An existing eDiscovery (Premium) case.
- Custodians must be added to the case before you can upload and associate the non-Microsoft 365 data to them.
- Non-Microsoft 365 data must be a file type that's supported by eDiscovery (Premium). For more information, see Supported file types in eDiscovery (Premium).
- All files that are uploaded to a review set must be located in folders, where each folder is associated with a specific custodian. The names for these folders must use the following naming format: *alias@domainname*. The alias@domainname must be the user's Microsoft

365 alias and domain. You can collect all the alias@domainname folders in a root folder. The root folder can only contain the alias@domainname folders. Loose files in the root folder aren't supported.

The folder structure for the non-Microsoft 365 data that you want to upload would be similar to the following example:

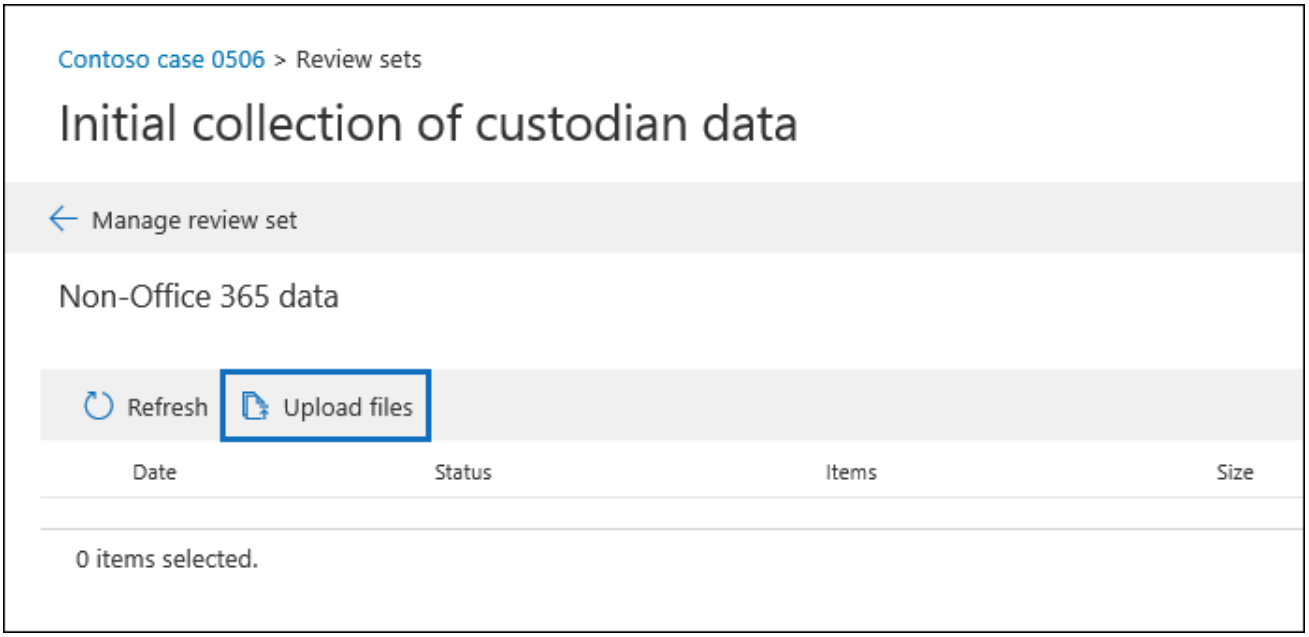
- c:\nonO365\abraham.mcmahon@contoso.com
- c:\nonO365\jewell.gordon@contoso.com
- c:\nonO365\staci.gonzalez@contoso.com

Where abraham.mcmahon@contoso.com, jewell.gordon@contoso.com, and staci.gonzalez@contoso.com are the SMTP addresses of custodians in the case.

- An account that is assigned to the eDiscovery Manager role group (and added as eDiscovery Administrator).

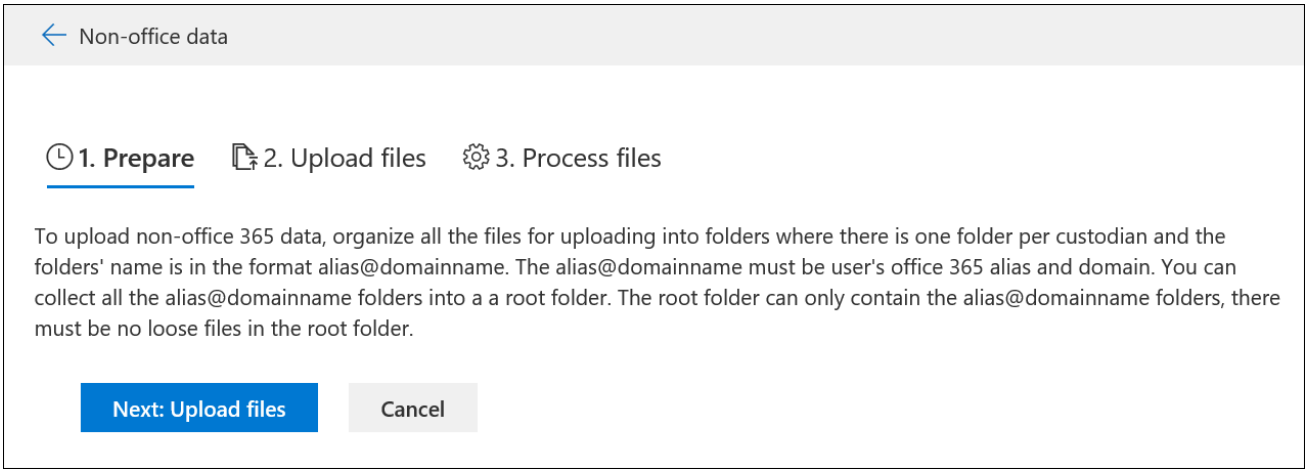
- The AzCopy tool installed on a computer that has access to the non-Microsoft 365 content folder structure. To install AzCopy, see Get started with AzCopy. Be sure to install AzCopy in the default location, which is **%ProgramFiles(x86)%\Microsoft SDKs\Azure\AzCopy**. You should use the latest version of AzCopy. Other versions of AzCopy may not work when loading non-Microsoft 365 data in eDiscovery (Premium).

Upload non-Microsoft 365 content into eDiscovery (Premium)



1. As an eDiscovery Manager or eDiscovery Administrator, open eDiscovery (Premium), and go to the case that the non-Microsoft 365 data will be uploaded to.

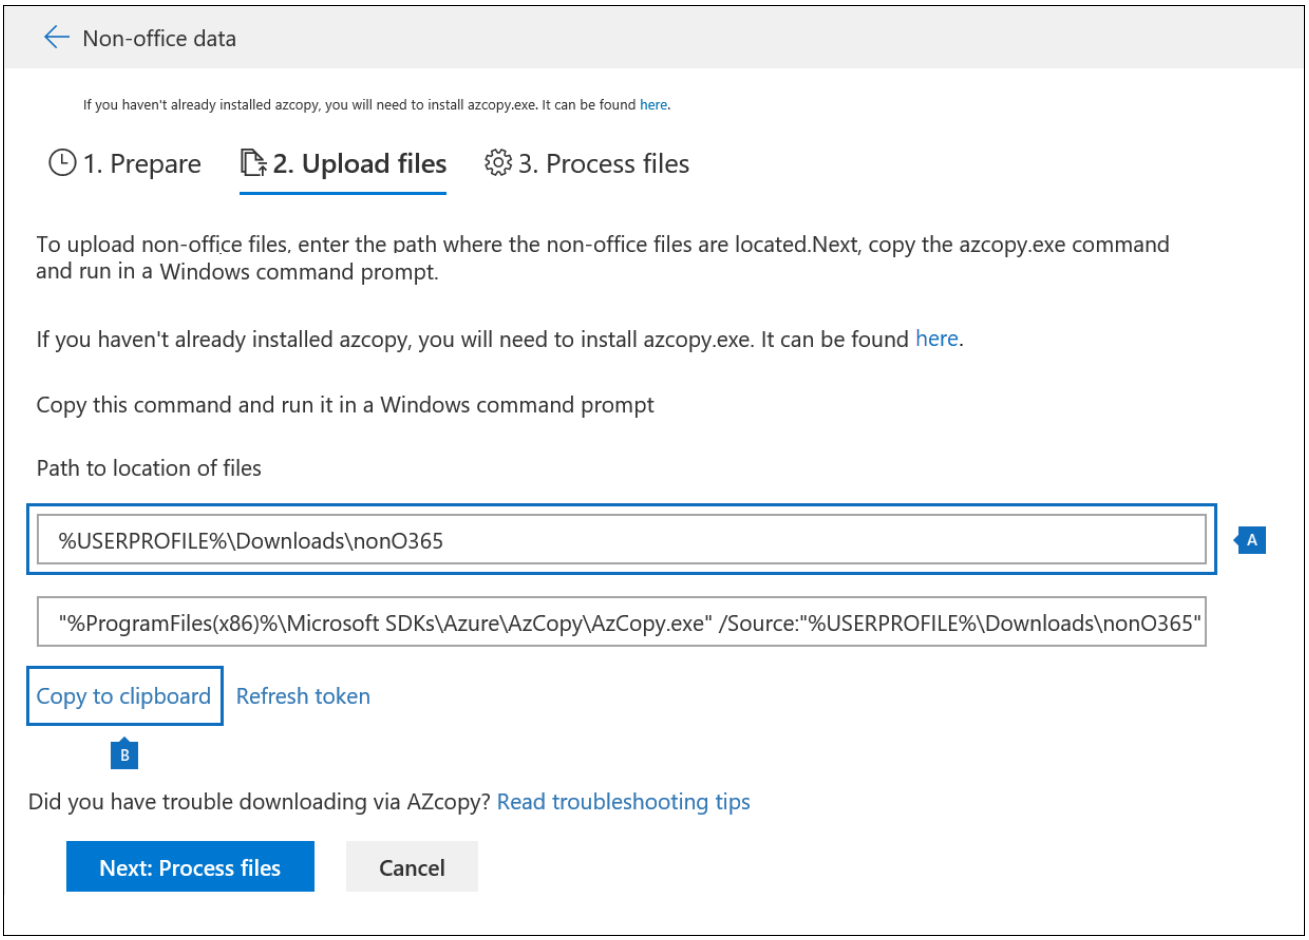
2. Select **Review sets**, and then select the review set to upload the non-Microsoft 365 data to. If you don't have a review set, you can create one.



3. Open the review set by either selecting on it or selecting it and selecting **Open review set**.

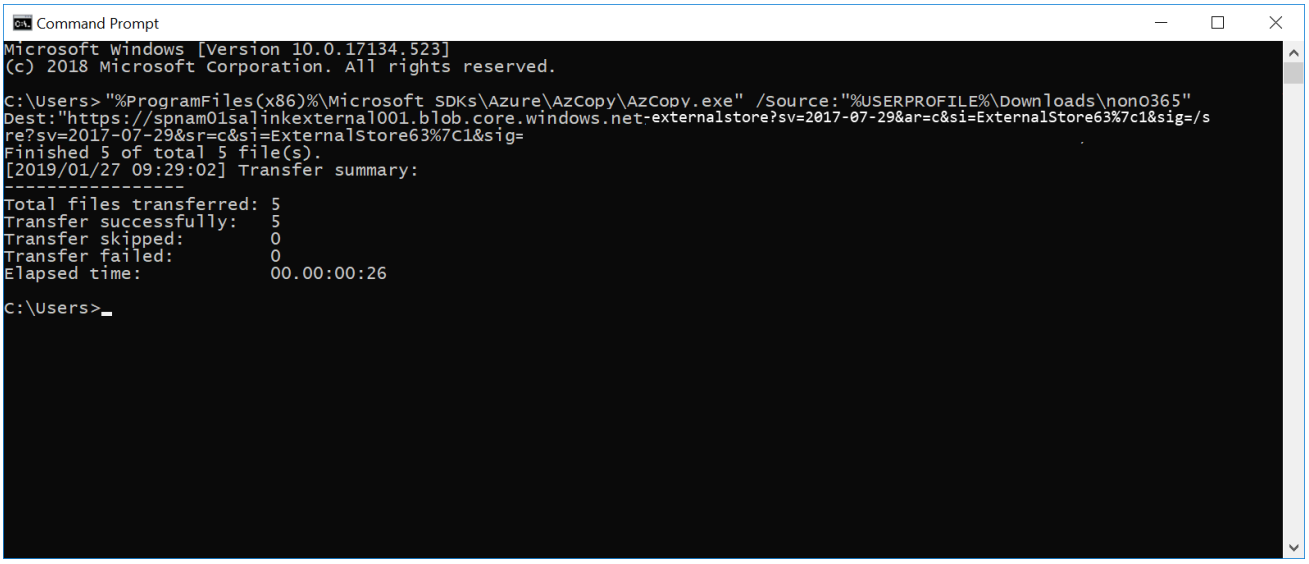
4. In the review set, select **Manage review set** (the down arrow just after the **Actions** option), and then select the **Non-Office 365 data** option.

5. Select **Upload files** to start the data import workflow.



The first step in the workflow prepares a secure Microsoft-provided Azure Storage location to upload the files to. When the preparation is completed, **Next: Upload files** becomes active.

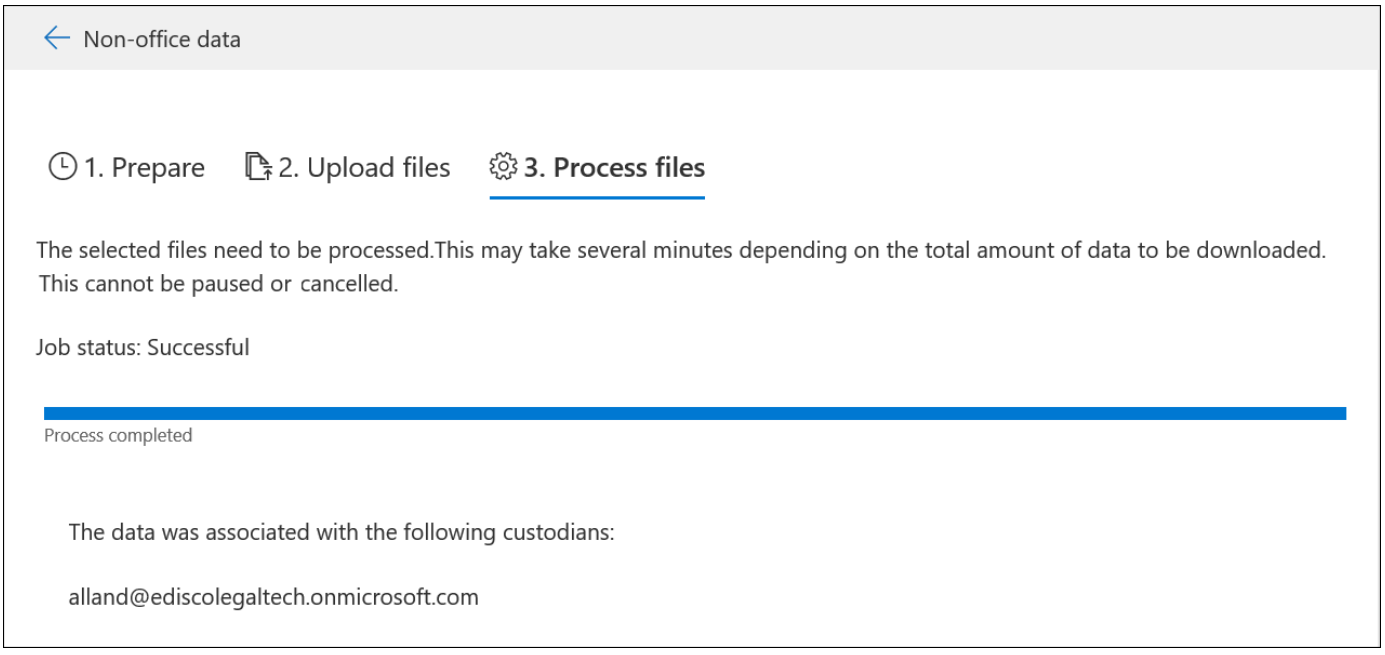
6. Select **Next: Upload files**.



7. On the **Upload files** page, do the following:

a. In the **Path to location of files** box, verify or type the location of the root folder where you've stored the non-Microsoft 365 data you want to upload. For example, for the location of the example files shown in the **Before you begin section**, you would type **%USERPROFILE\Downloads\nonO365**. Providing the correct location ensures the AzCopy command displayed in box under the path is properly updated.

b. Select **Copy to clipboard** to copy the command that is displayed in the box.



8. Start a Windows command prompt, paste the command that you copied in the previous step, and then press **Enter** to start the AzCopy command. After you start the command, the non-Microsoft 365 files will be uploaded to the Azure Storage location that was prepared in step 4.

> **Note**
>
> You should use the latest version of AzCopy to successfully use the command that's provided on the **Upload files** page. If the supplied AzCopy command fails, see Troubleshoot AzCopy in eDiscovery (Premium).

9. Go back to the Microsoft Purview portal, and select **Next: Process files** in the workflow. This initiates processing, text extraction, and indexing of the non-Microsoft 365 files that were uploaded to the Azure Storage location.

10. Track the progress of processing the files on the **Process files** page or on the **Jobs** tab by viewing a job named **Adding non-Microsoft 365 data to a review set**. After the job is finished, the new files will be available in the review set.

11. After the processing is finished, you can close the workflow.

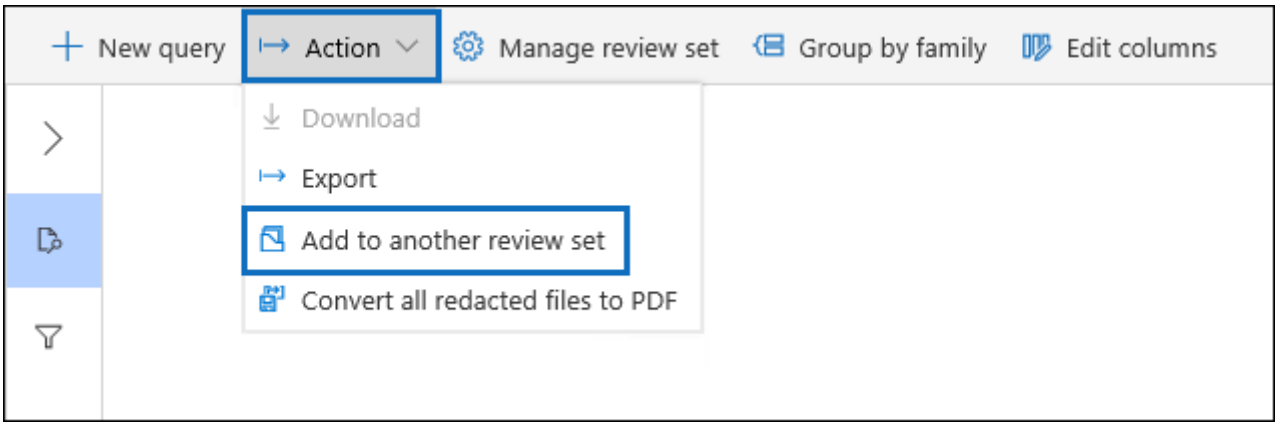
Add data to a review set from another review set

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

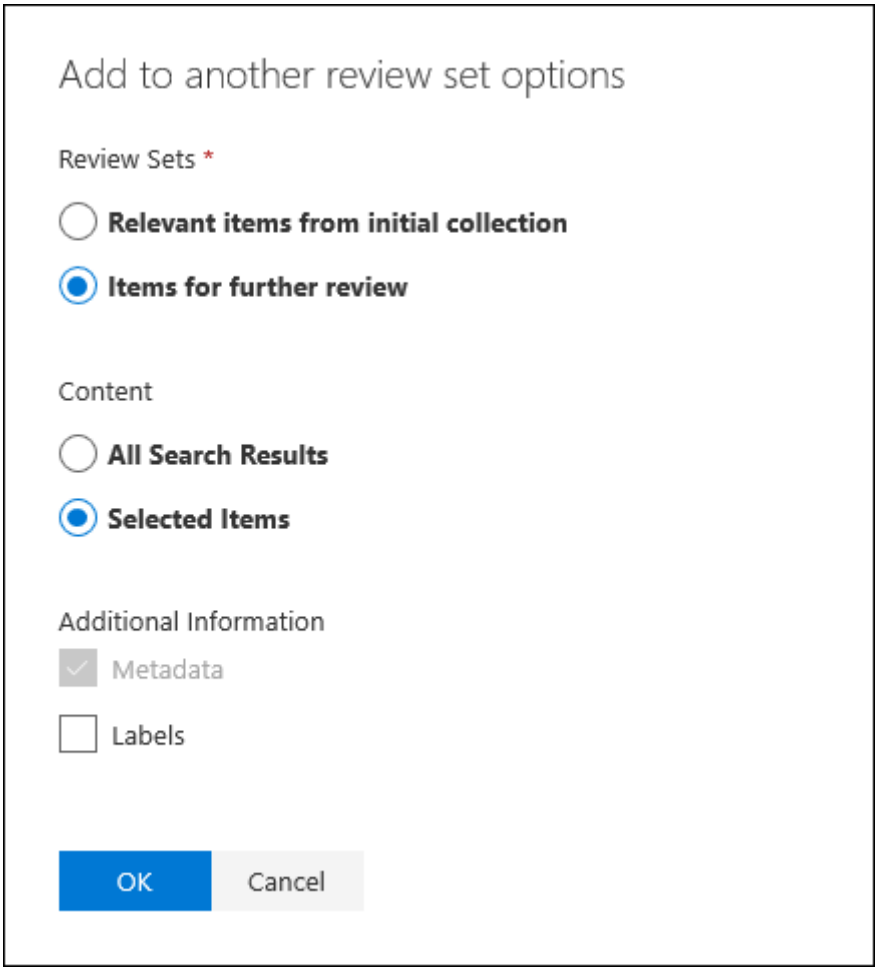
In some cases, it may be necessary to select documents from one review set and work with them individually in another review set. This is especially useful if you've culled content in a review set and want to run analytics on the subset of data.



Follow the workflow in this article to add content from one review set to another.

Create a review set

Before you start, you'll need to create a review set to add the data to. A new review set can be added on the **Review sets** tab of the case. For more information, see Create a review set.



Step 1: Identify content to add to another review set

You can add content from one review set to another one by selecting specific documents in the source review set or by selecting all items returned by review set query. If you're adding selected items, select the items, select **Action**, and then select **Add to another review set**.

Step 2: Specify options for adding to another review set

In the **Add to another review set options** flyout page, choose the review set you want to add the items to. Choose whether to add **All search results** or **Selected items**. **Additional information** provides options to include all metadata from the items and whether to include the tags (by selecting the **Labels** check box) from the source review set when the documents are added to the new review set.

After you select **Ok**, a new job (named **Adding data to another review set**) is created to add the content to another review set. You can go to the **Jobs** tab and monitor the progress of this job. For more information, see Manage jobs.

Configure review set grouping settings for eDiscovery (Premium) cases

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can configure grouping settings for each Microsoft Purview eDiscovery (Premium) case to control how the data in a review set is grouped and displayed. Turning on the **Enable group** setting is only available for review sets in cases created in your organization after March 15, 2023.

Depending when the case is created, items in a review set can be grouped in two ways:

- **Group review set items by Group ID and Thread ID**: When enabled, review set items are grouped by *Group ID* and *Thread ID*. This setting is the default for all cases created after March 15, 2023.
- **Group review set items by Family ID and Conversation ID**: When disabled, review set items are grouped by *Family ID* and *Conversation ID*. This setting is the default for all cases created before March 15, 2023.

For more information about review set grouping, see Group and view documents in a review set.

Configure review set grouping settings for a case

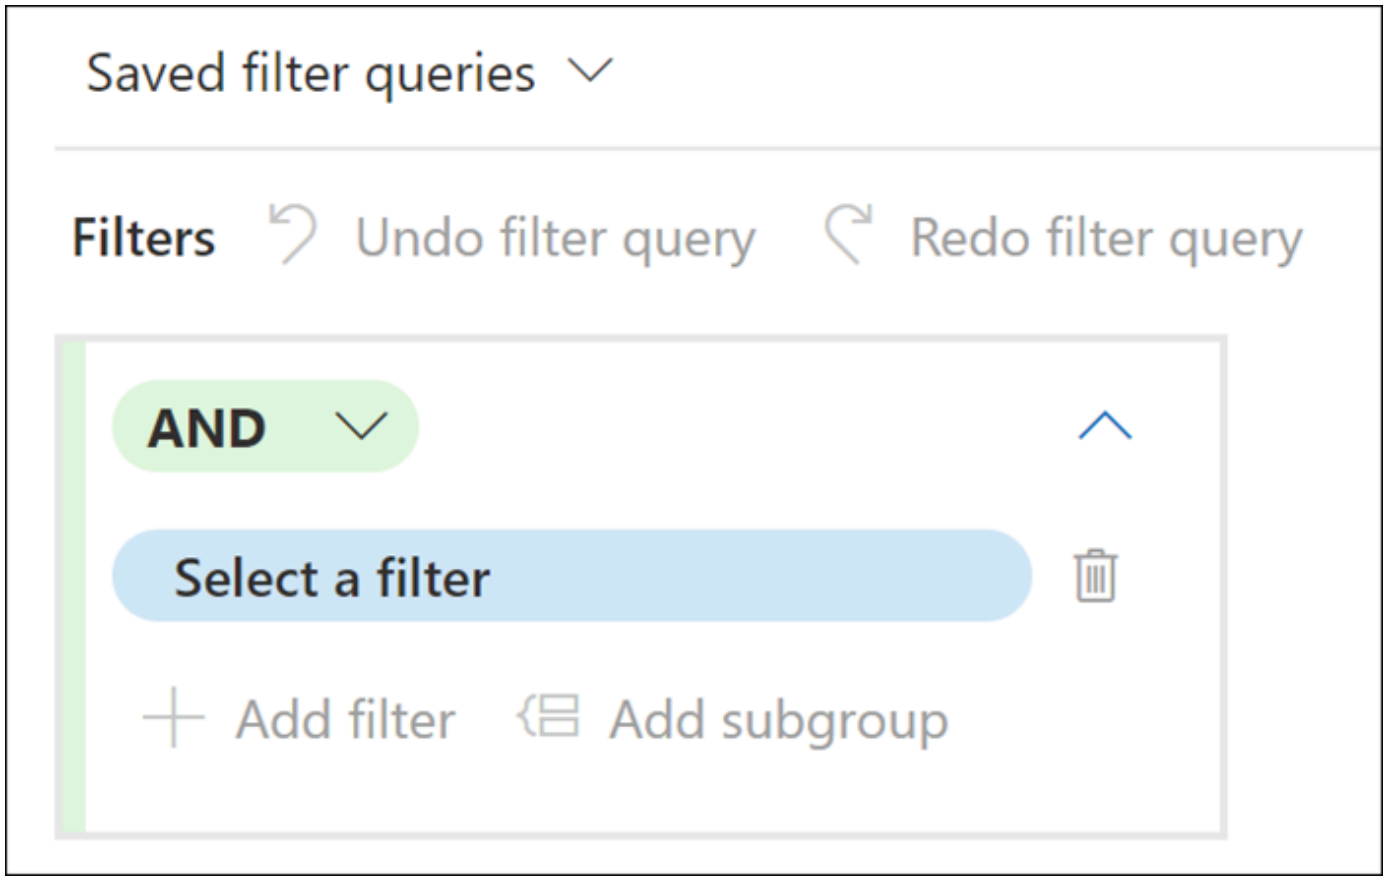
To configure review set grouping settings for a case:

1. On the **eDiscovery (Premium)** page, select the case.
2. On the **Settings** tab, under **Review sets**, choose **Select**.
3. On the **Review sets** page, select the **Enable group** toggle to enable grouping review set items by *Group ID* and *Thread ID*.

> **Note**
>
> For cases created before March 15, 2023, the **Enable group** toggle is disabled. Item grouping in review sets for these cases is based on *Family ID* and *Conversation ID*.

Last updated on 11/21/2025

Query and filter content in a review set



> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

In most cases, it's useful to dig deeper into the content in a review set and organize it to facilitate a more efficient review. Using filters and queries in a review set helps you focus on a subset of documents that meet the criteria of your review. For more information about available search conditions, see Keyword queries and search conditions for eDiscovery.

Advanced filters (preview)

Improving on the default filters in previous versions, eDiscovery (Premium) now provides advanced filters that let you build more flexible and advanced filters for review sets. Similar to the collection query builder experience, the advanced filtering capability enables you to:

- Quickly search for filter conditions.
- Create complex filters using subgroups, *AND*, or *OR* conditions.
- Easily change your queries with **Undo filter query** and **Redo filter query** controls.
- Manage saved filters without having to navigate to another area.
- Use *Is empty* and *Is not empty* conditions for each filter.

> **Important**
>
> A review set displays a maximum of 1,000 items per page and up to 10 pages (for a total of 10,000 items displayed per review set). Use default or custom filters to adjust the displayed items as needed. Matched item counts are estimates.

Advanced filter controls (preview)

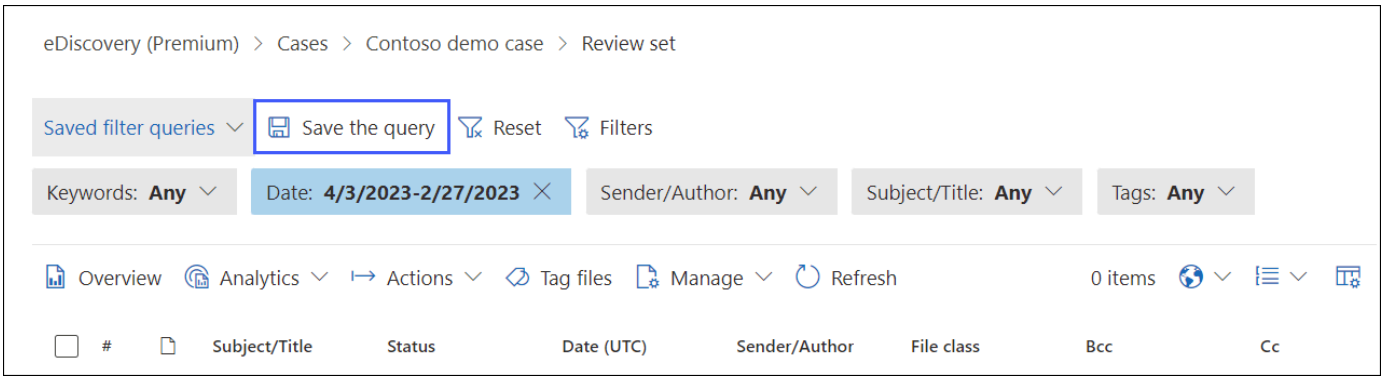
To create and custom filtering for your review set, use the following controls:

- **AND/OR**: These conditional logical operators allow you to select the query condition that applies to specific filters and filter subgroups. These operators allow you to use multiple filters or subgroups connected to a single filter in your query.
- **Select a filter**: Allows you to select filters for the specific data sources and location content selected for the collection.
- **Add filter**: Allows you to add multiple filters to your query. Is available after you've defined at least one query filter.
- **Select an operator**: Depending on the selected filter, the operators compatible for the filter are available to select. For example, if the *Date* filter is selected, the available operators are *Before*, *After*, and *Between*. If the *Size (in bytes)* filter is selected, the available operators are *Greater than*, *Greater or equal*, *Less than*, *Less or equal*, *Between*, and *Equal*.

- **Value**: Depending on the selected filter, the values compatible for the filter are available. Additionally, some filters support multiple values and some filters support one specific value. For example, if the *Date* filter is selected, select date values. If the *Size (in bytes)* filter is selected, select a value for bytes.
- **Add subgroup**: After you've defined a filter, you can add a subgroup to refine the results returned by the filter. You can also add a subgroup to a subgroup for multi-layered query refinement.
- **Remove a filter condition**: To remove an individual filter or subgroup, select the remove icon to the right of each filter line or subgroup.
- **Clear all**: To clear the entire query of all filters and subgroups, select **Clear all**.

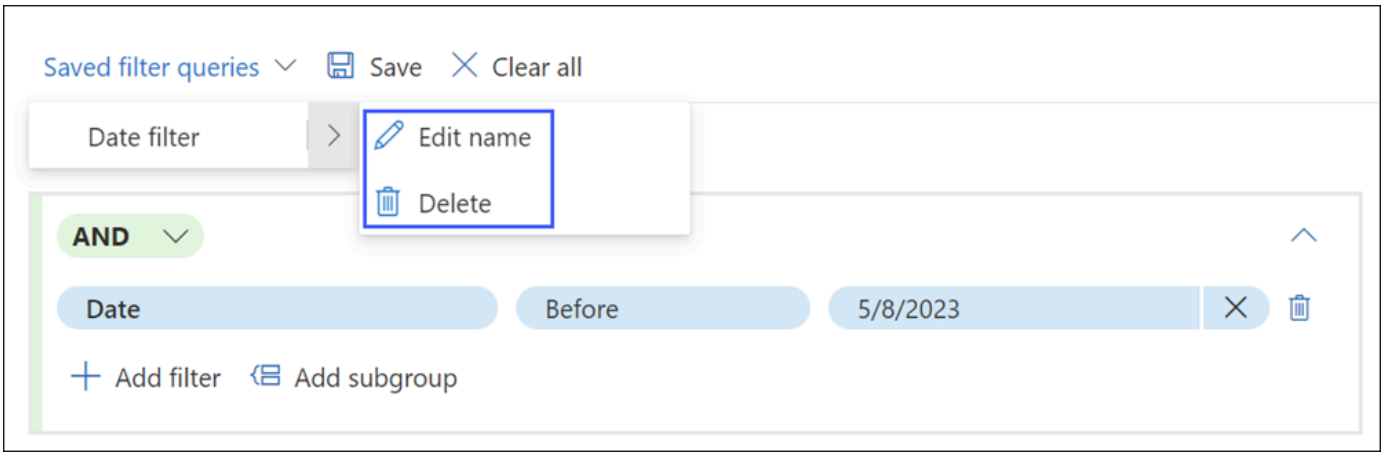
Filter types

Every searchable field in a review set has a corresponding filter that you can use for filter items based on a specific field.



There are multiple types of filters:

- **Freetext**: A freetext filter is applied to text fields such as *Subject*. You can list multiple search terms by separating them with a comma.
- **Date**: A date filter is used for date fields such as *Last modified date*.
- **Search options**: A search options filter provides a list of possible values (each value is displayed with a checkbox that you can select) for particular fields in the review. This filter is used for fields, such as *Sender*, where there's a finite number of possible values in the review set.
- **Keyword**: A keyword condition is a specific instance of freetext condition that you can use to search for terms. You can also use KeyQL-like query language in this type of filter. For more information, see the Query language and Advanced query builder sections in this article. Keyword searching in a review set only applies to document/email content and does not extend to metadata fields (such as *Filename*).



Save and manage filter queries

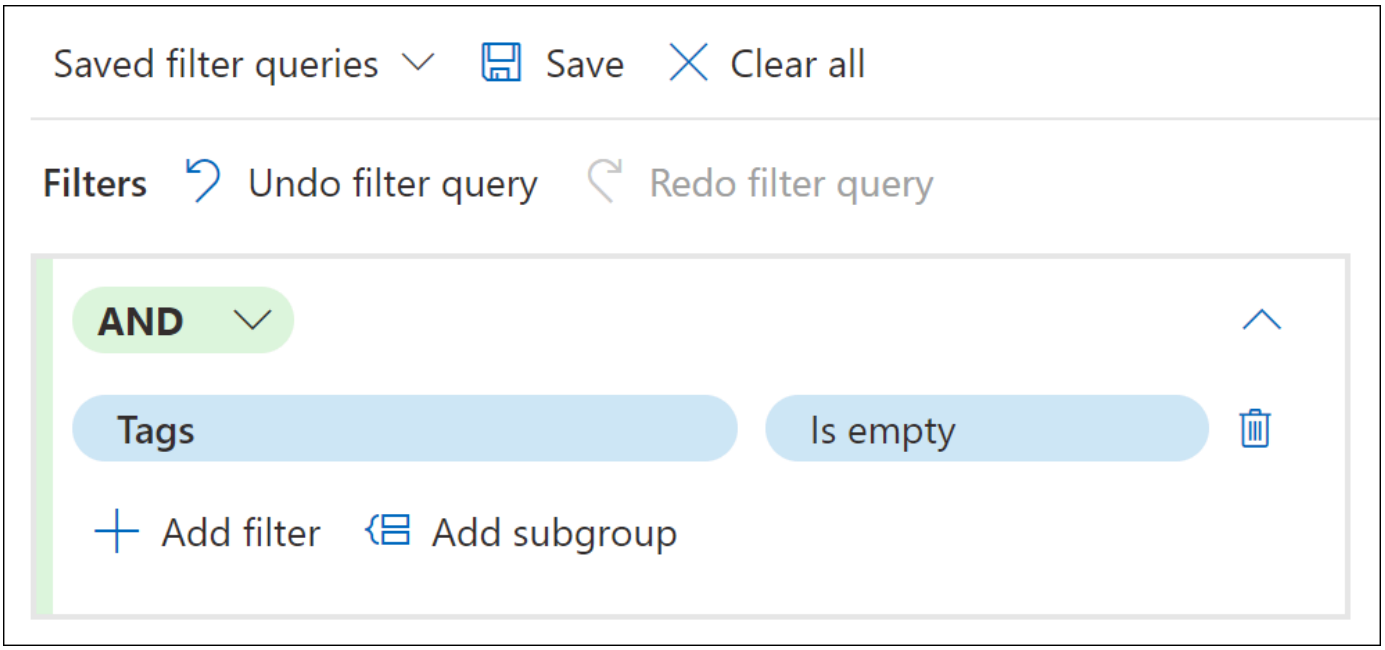
After you're satisfied with your filters, you can save the filter combination as a filter query. This saved filter query lets you apply the filter in the future review sessions.

To save a filter, select **Save** on the **Save filter queries** command bar and name it. You or other reviewers can run previously saved filter queries by selecting the **Saved filter queries** dropdown and selecting a filter query to apply to review set documents.

To edit or delete a saved filter query, select **Saved filter queries** and expand the filter properties to display the **Edit** and **Delete** options for the saved filter query.

Use query language support for KeyQL and Keyword filters

When using the *KeyQL* or *Keyword* filters, you can use a KeyQL-like query language to build your review set search query. The query language for these two filters supports standard Boolean operators, such as **AND**, **OR**, **NOT**, and **NEAR**. It also supports a single-character wildcard (?) and a multi-character wildcard (*).



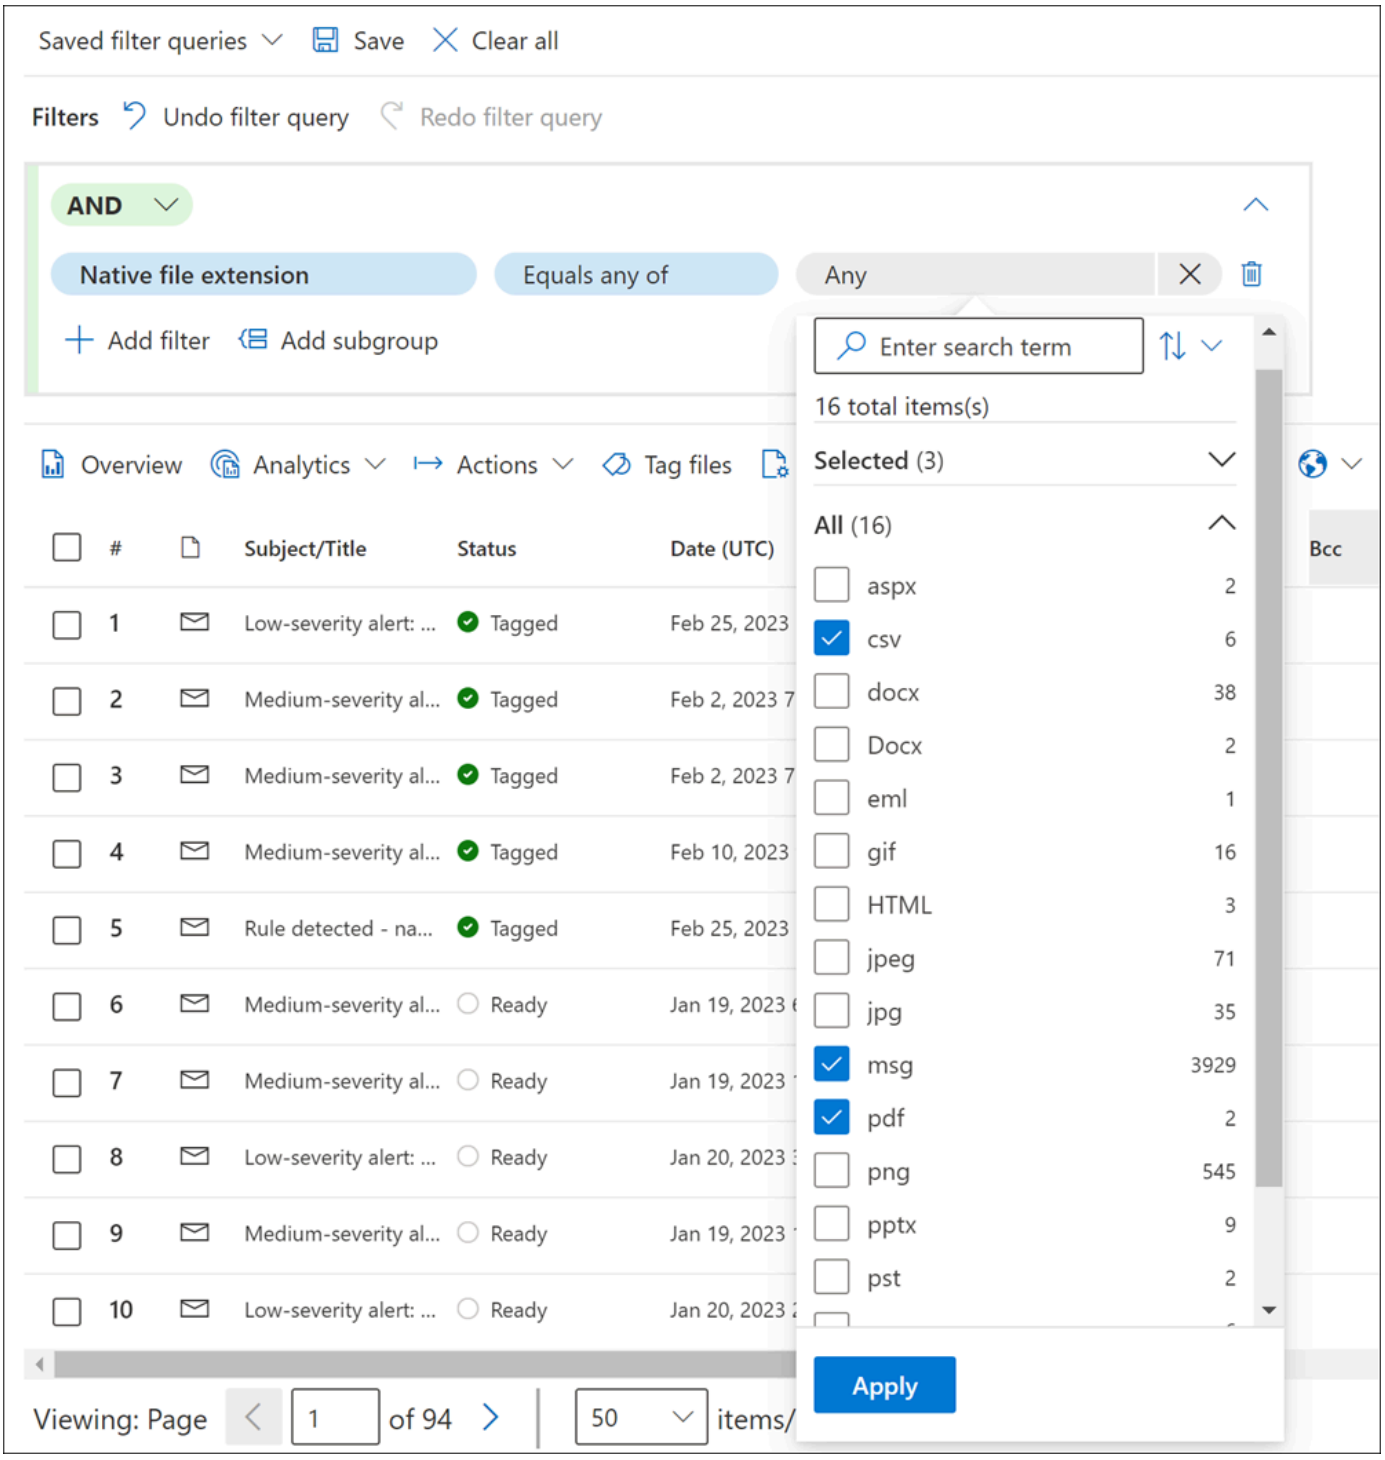
> **Note**
>
> Review filters only support wildcards (? or *) on a single term. Using wildcards in searches on phrases that consist of multiple terms aren't supported.

Scenario example: Filter for untagged items in a review set

An eDiscovery administrator needs to create a query to find all items in the review set that haven't had any tagging applied. For this example, the administrator creates the following review set filter query:

1. For the first filter, the administrator selects the filter and types *tag* in filter search. The filter *Tags* is displayed as a matching option, and the administrator selects it.
2. The administrator then selects **Select an operator** and selects the *Is empty* operator. This operator returns all items that don't have any tags applied.

The review set is immediately updated and the only the items that aren't tagged are displayed.



Scenario example: Filter for native file type items in a review set

An eDiscovery administrator needs to create a query to find all items in the review set that are a certain type, such as .csv, .msg, or .pdf. For this example, the administrator creates the following review set filter query:

1. For the first filter, the administrator selects the filter and types *file* in filter search. The filter *Native file extension* is one of the filter options displayed in the search results, and the administrator selects it.
2. The administrator then selects **Select an operator** and selects the *Equals any of* operator. The administrator selects the *Any* field and selects the checkboxes for the file types to include in the filter query.

The review set is immediately updated and the only the items that match the selected file types are displayed.

Scenario example: Filter partially indexed items

If you selected the option to add partially indexed items from additional data sources when you committed the collection estimate to a review set. You'll probably want to identify and view those items to determine if an item might be relevant to your investigation and whether you need to remediate the error that resulted in the item being partially indexed.

At this time, there isn't a filter option in a review set to display partially indexed items. But we're working on it. Until then, here's a way you can filter and display the partially indexed items that you added to a review set.

1. Create a collection and commit it to a new review set *without* adding partially indexed items from the additional data sources.
2. Create a new collection by copying the collection from step 1.
3. Commit the new collection to the same review set. But this time, add the partially indexed items from the additional data sources. Because items from the collection you created in step 1 have already been added to the review set, only the partially indexed items from the second collection are added to the review set.
4. After both collections are added to the review set, select the review set, and select **Load sets**.
5. Copy or make note of the **Load Id** for the second collection (the one you created in step 2). The collection name is identified in the **Source info** column.
6. Back in the review set, select **Filter**, expand the **IDs** section, and then select the **Load Id** checkbox.
7. Expand the **Load Id** filter, and then select the checkbox for the load ID that corresponds to the second collection to display the partially indexed items.

Last updated on 09/02/2025

Tag documents in a review set in eDiscovery (Premium)

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

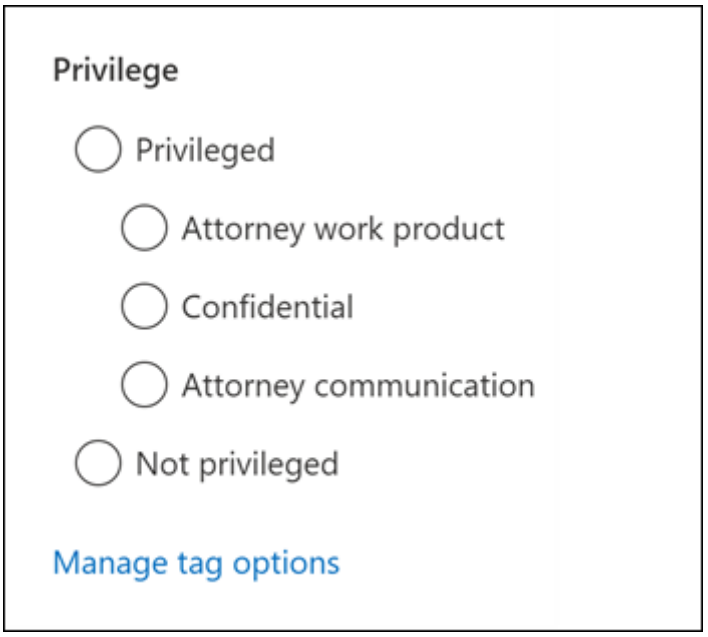
Organizing content in a review set is important to complete various workflows in the eDiscovery process. This workflow includes:

- Culling unnecessary content
- Identifying relevant content
- Identifying content that must be reviewed by an expert or attorney

When experts, attorneys, or other users review content in a review set, their opinions related to the content can be captured by using tags. For example, if the intent is to cull unnecessary content, a user can tag documents with a tag such as "non-responsive". After content has been reviewed and tagged, a review set search can be created to exclude any content tagged as "non-responsive". This process eliminates the non-responsive content from the next steps in the eDiscovery workflow.

You can use *tag templates* to define tags and review workflow across all cases and review sets in your organization. This method is the recommeded approach and helps provide structure and standardization for tagging to ensure searches identify similar content across your organization. You can also use the tagging panel in an individual review set to customized tags for each case when tag templates don't meet your needs, but tags created here are specifically for the individual case and review set.

Tag types



eDiscovery (Premium) provides two types of tags:

- **Single-select tags**: Restricts reviewers to selecting a single tag within a tag group. These types of tags can be useful to ensure that reviewers don't select conflicting tags such as "responsive" and "non-responsive". Single choice tags appear as radio buttons.
- **Multi-select tags**: Allow reviews to select multiple tags within a tag group. These types of tags appear as checkboxes.

Tag groups

In addition to the tag types, the structure of how tags groups are organized in the tag panel can be used to make tagging documents more intuitive. Tags are organized in tag groups. Review set search supports the ability to search by tag and by tag groups. This means you can create a review set search to retrieve documents tagged with any tag in a group or the group itself.

For example, if you need to identify and tag privileged content, grouping can be used to make it clear that a reviewer can tag a document as *Privileged* (the tag group) and select *Attorney work product* (specific tag) as the type of privilege within the tag group.

Tag templates (preview)

Tag templates are used to define and standardize tags and the review workflow across all cases and review sets in your organization. Each tag template contains tag groups where you can create a grouping structure for individual tags. You can create tag templates in the **Tag templates** section in **eDiscovery (Premium) settings**.

Create tag templates

To create a new tag template, complete the following steps:

1. In the Microsoft Purview portal, select **eDiscovery** > **Premium** and then select **eDiscovery (Premium) settings**.
2. Select **Tag templates**.
3. On the **Manage tag templates** page, select **Create**.
4. On the **New tag template** page, enter a name and description for the tag template.
5. In the initial tag group, enter a tag group name and use the dropdown to define if this as a **Multi-select** or **Single-elect** tag group.
6. Enter at least one tag name in the tag group. Select **Add tag** to add additional tags to the tag group.
7. If needed, select **Add tag group** to add additional tag groups and tags to the tag template.
8. Preview the tag template group and tag structure in the **Preview** pane on the right side of the **New tag template** page.
9. When complete, select **Save**.

The tag template is now available for use in all cases and review sets in your organization.

Manage tag templates

After you create a tag template, you can edit or delete it. You can also view information about the tag template, including the dates when it was created or last modified.

To edit a tag template, select the tag template name on the **Manage tag templates** page and select **Edit**. On the **Edit tag template** page, you can edit the tag template name, description, and tag groups and tags. When you're done, select **Save**.

To delete a tag template, select the tag template name on the **Manage tag templates** page and select **Delete**. Select **Yes** to confirm the deletion or **No** to cancel the deletion.

Apply tag templates to a case and review sets

After you've created a tag template, you can apply it to a review set. You can apply a tag template when you create a new review set or when you edit an existing review set.

To apply a tag template to a new review set, complete the following steps:

1. In the Microsoft Purview portal, select **eDiscovery** > **Premium**.
2. Select the **Cases** tab and select a case.
3. In the case, select **Review sets**, select a review set, and then select **Open review set**.

4. On the review set command bar, select **Manage** > **Tags**.
5. On the **Manage tags** page, delete the blank tag group then select **Import tag templates**.
6. On the **Import tag templates** flyout page, select the tag template that you want to apply to the review set and then select **Import**.
7. If needed, you can edit the tag template as it applies to the case and review set.
8. Select **Save** to apply the tag templates to the case and review set.

The applied tag template is now available for use in the case and all included review sets.

Create tags for a specific case or review set

If you choose not to use tag templates for a specific case or review set, you can create tags directly in the review set. This is useful when you need to create tags that are specific to a case or review set. However, these tags are unique to the case or review set and can't be used in other cases or review sets.

Before applying tags to items in a review set, you need to create a tag structure.

1. Open a review set and on the review set command bar, select **Manage** > **Tags**.
2. On the **Manage tags** flyout page, enter a *Tag group name* and select either **Multi-select** or **Single-select** for the tag group.
3. Enter one or more tags in the tag group. Select **Add tag** to add additional tags to the tag group.
4. Select **Add tag group** if more tag groups and tags are needed.
5. Preview the tag template group and tag structure in the **Preview** pane on the right side of the **New tag template** page.
6. Select **Save** to apply the tag group and tags to the case and review set.

Apply tags

With the tag structure from tag templates or custom tagging in place, reviewers can apply tags to items in a review set by configuring tagging settings.

1. In the review set command bar, select **Tag files** to display the **Tag files** flyout page (also called the *tagging panel*).

2. On the **Tag files** flyout page, you can set the following options to configure how to tag items displayed in the review set. The filters or filter queries currently applied to the review set determine which items are displayed and therefore the items that you can apply tags to. For more information, see Query and filter content in a review set.

- **Choose selection**. Choose one the following options to determine the scope of items to apply tags to.
  - **Tag selected items**: This option applies tags to the items that you select. You can select items before or after launching the tagging panel. This option displays (in real time) the number of selected items that are tagged.
  - **Tag all items in list**: This option applies tags to all items displayed in the review set. This option displays the total number of items that are tagged.

- **Expand selection**: Use the following options to tag additional items that are related to tagged items in the review set. Depending on the **Enable group** option enabled in the case settings, you'll see the following options:

  With *Enable group* in settings disabled:
  - **None**: This option doesn't apply tags to associated family items or associated conversation items. It only applies tags to the items that are selected or to all items in the review set list.
  - **Include family groups**: This option applies the same tag to the associated family items of items that are tagged. *Family items* are items that share the same **FamilyId** metadata property value. For example, a document that's attached to an email message shares the same **FamilyId** as the email message. So if this option is selected for this example, the email message and the document are tagged, even though the document might not be included in the list of review set items.
  - **Include conversation groups**: This option applies the same tag to all items that are in the same Teams or Viva Engage conversation as the items that are tagged. *Conversation items* are items that share the same **ConversationId** metadata property value. All messages, posts, and corresponding transcript file of a conversation share the same **ConversationId**. If this option is selected, then all items in the same conversation (and transcript file) are tagged, even though some of those conversation items might not be included in the list of review set items. For more information about conversation items, see the "Grouping" section in eDiscovery (Premium) workflow for content in Microsoft Teams.

  > ⓘ **Note**
  >
  > Including family or conversation groups doesn't change the count of items shown in the **Tag selected items** or **Tag all items in list** options. In other words, the number of grouped items that are tagged is not displayed.

With *Enable group* in settings enabled:

- **None**: This option doesn't apply tags to family group items or conversation group items. It only applies tags to the items that are selected or to all items in the review set list.
- **Include family groups**: This option applies the same tag to the associated family items of items that are tagged. *Family group* items are items that share the same **GroupId** metadata property value. For example, a document that's attached to an PowerPoint file shares the same **GroupId** as the document. So if this option is selected for this example, the document and the PowerPoint file are both tagged. Both are grouped together in the list of review set items.
- **Include conversation groups**: This option applies the same tag to all items that are in the same email, Teams, or Viva Engage conversation as the items that are tagged. *Conversation group* items are items that share the same **ThreadId** metadata property value. All messages, posts, and corresponding transcript files of a conversation share the same **ThreadId**. If this option is selected, then all items in the same conversation (and transcript file) are tagged. All items are grouped together in the list of review set items.

- **Assign tags**: This section displays the tags (organized by tag groups) that you can apply to documents. These are either the tag groups and tags assigned using tag templates or custom tag groups and tags that you've created for this case. You can only apply one single-choice tag (identified by a radio button) per tag group. However, you can apply multiple multi-choice tags (identified by a checkbox).

3. Select **Apply tags** to apply the tags based on your settings.

   The **Applying tags** status message is displayed for each tag group on the tagging panel to indicate a tagging job has been started. Tags for each tag group in the **Assign tags** section are greyed out until the job is completed.

> **Tip**
>
> If you're in the process of configuring the settings on the tagging panel, but want to start over, select **Reset tag assignment** to clear the current setting. This control doesn't apply to items that are already tagged, and it doesn't change or remove tags from previously tagged items.

Monitor tagging jobs

When you tag a large number of items (or select the **Tag all items in list**) option, a **Tagging documents** job is created. You view the status of this job on the **Jobs** tab in the case. This view helps you track large tagging jobs that may take a long time to complete. In some cases, a tagging job might be complete, but the **Applying tags** status message in the tagging panel is still displayed. To update the status of tagging jobs, select **Refresh** in the review set command bar.

Removing tags

You can remove tags from items in a review set. However, you can't remove a single-choice tag that's been applied to a review set item. You can only change a single-choice tag to another single-choice tag within the same tag group.

To remove a tag:

1. Select the items that you want to remove the tag from.
2. Select **Tag files** to display the tagging panel.
3. Under **Assign tags**, unselect the tag, and then select **Apply tags**.

You can also use the previous procedure to change the tag applied to selected items. After unselecting the current tag, you can select a different one.

Group and view documents in a review set in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

eDiscovery (Premium) review sets display content using different grouping options and include specialized viewers that you can use to examine details about individual items.

Grouping

Use the **Group** control in the command bar of a review set to view review content grouped by the following options:

Option 1: Group items with Group ID and Thread ID

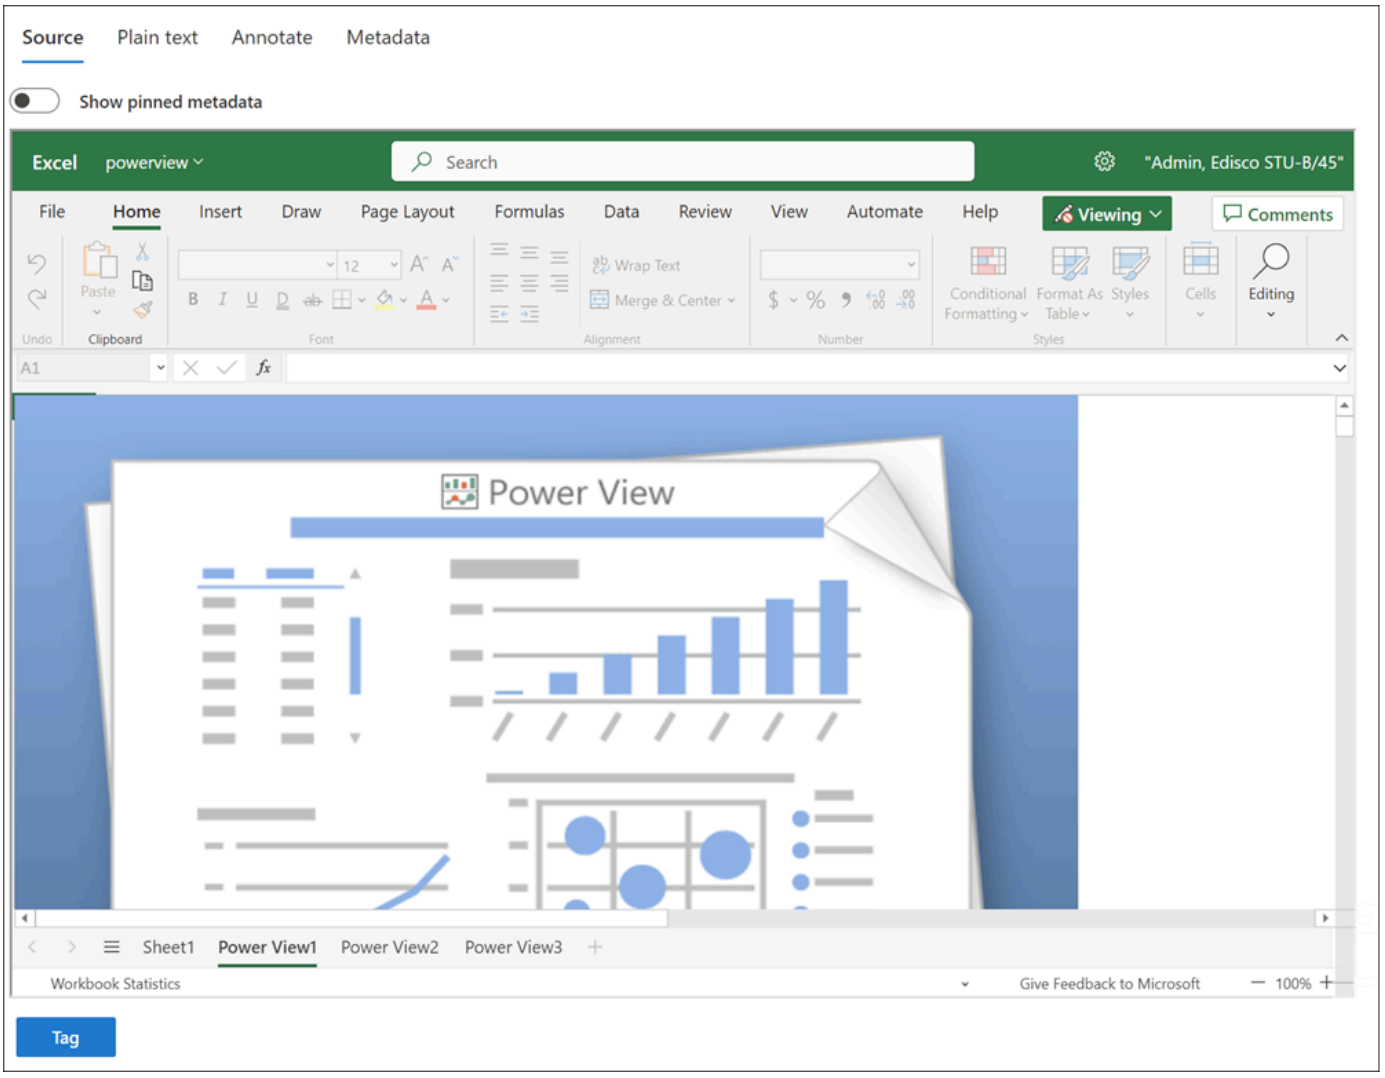
If you're new to eDiscovery or are an existing eDiscovery customer with a steady stream of new cases, grouping review set items using Group IDs and Thread IDs is the recommended option. This grouping option makes it easier to find and review related items in a review set by grouping them together in the list view. With the **Enable group** option enabled in the case settings, you'll see the following grouping options on the **Group** control in the command bar of a review set:

- **Group by families**: All items related to a specific file are grouped together using the same Group ID. For example, if you have a PowerPoint file in the review set that includes imbedded images or .zip files, these images and files are grouped with the PowerPoint file and shown as nested items with the file in the item list view. Microsoft 365 Copilot and Microsoft 365 Copilot Chat user prompts and responses are also grouped together using the same Group ID when there are multiple prompts and responses associated with a file.

- **Group by conversations**: All email messages, Teams conversations, and Viva Engage conversations are grouped using the same Thread ID and appear as nested items. Additionally, all associated content for these messages and conversations is also grouped together. For example, if you have an email conversation that includes several email messages, some of which include attachments and some that include embedded images, all of the email messages, attachments, and images are grouped together in the review set list view under an applicable item.

> ⓘ Note
>
> For cases created before March 15, 2023, the **Enable group** toggle is disabled and these grouping options aren't available. Item grouping in review sets for these cases is based on *Family ID* and *Conversation ID* described in Option 2.

Option 2: Group items with Family ID and Conversation ID

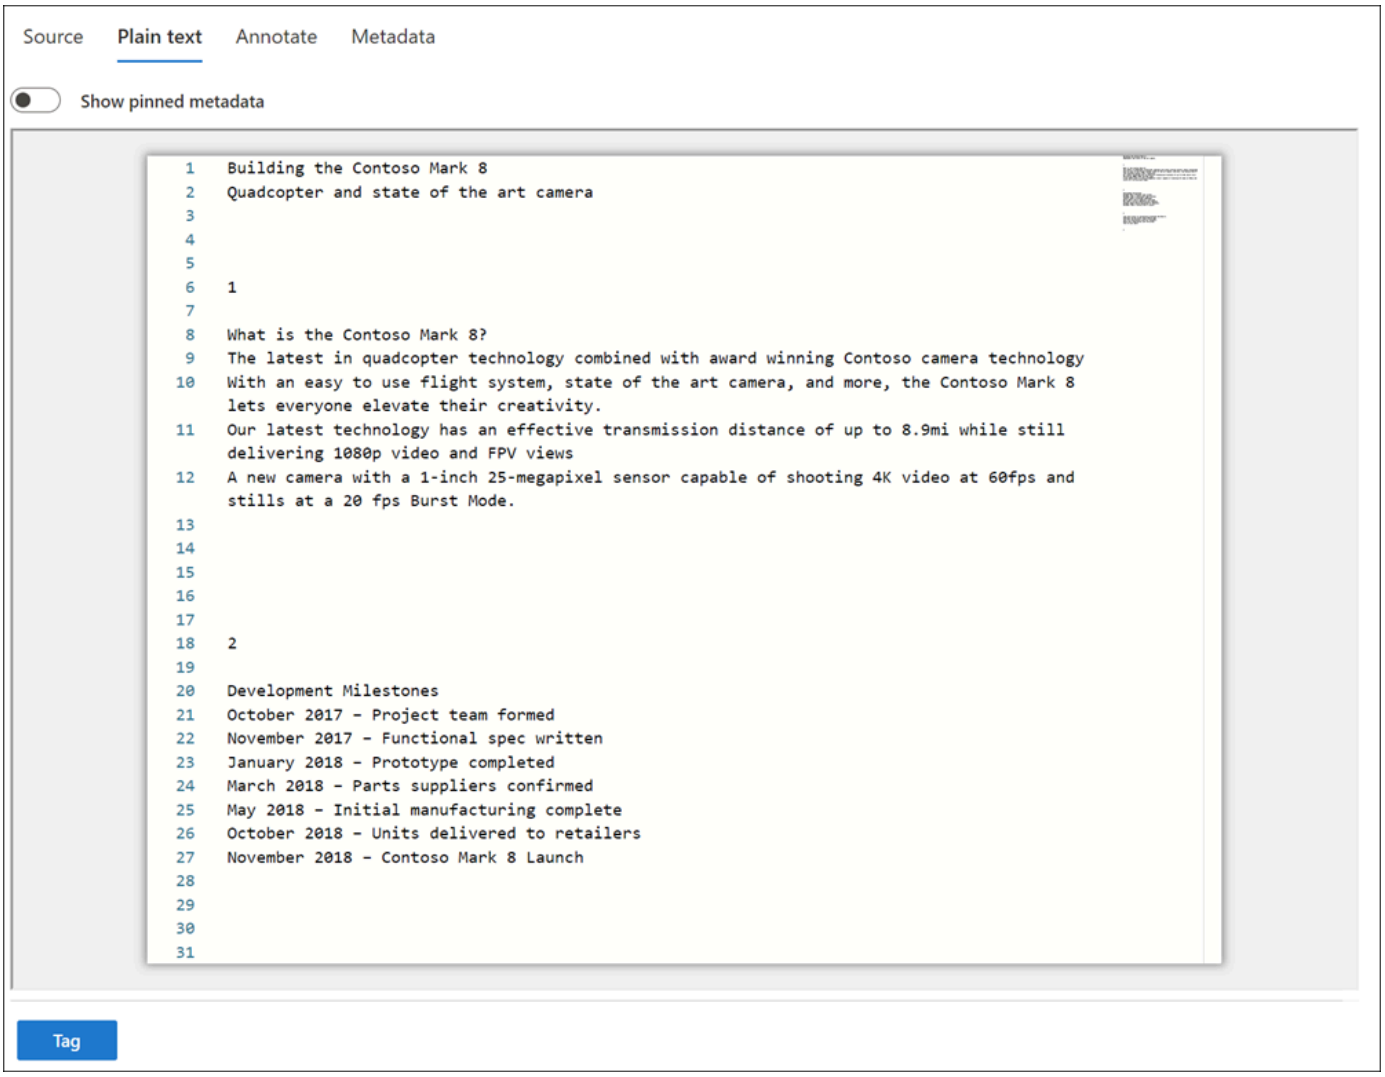


If you're an existing eDiscovery with a large number of existing cases or use existing internal or third-party automation to help process review set items, you may want to continue to group review set items with Family IDs and Conversation IDs. With the **Enable group** option disabled in the case settings, you'll see the following grouping options on the **Group** control in the command bar of a review set:

- **Group family attachments**: View review set content grouped by family. Each transcript file is displayed on a line in the list of review set items. Attachments are nested under the item.
- **Group Teams or Viva Engage conversations**: View Teams and Viva Engage content grouped by conversation. Each conversation is displayed on a line in the list of review set items. Transcript files and attachments are nested under the top-level conversation.

> ⓘ Note
>
> Cloud attachments are grouped with the conversations they appear in. This grouping is accomplished by assigning the same **FamilyId** as the transcript file of the message the file was attached to and the same **ConversationId** as the conversation the message appeared in. This means multiple copies of cloud attachments may be added to the review set if they were attached to different conversations.

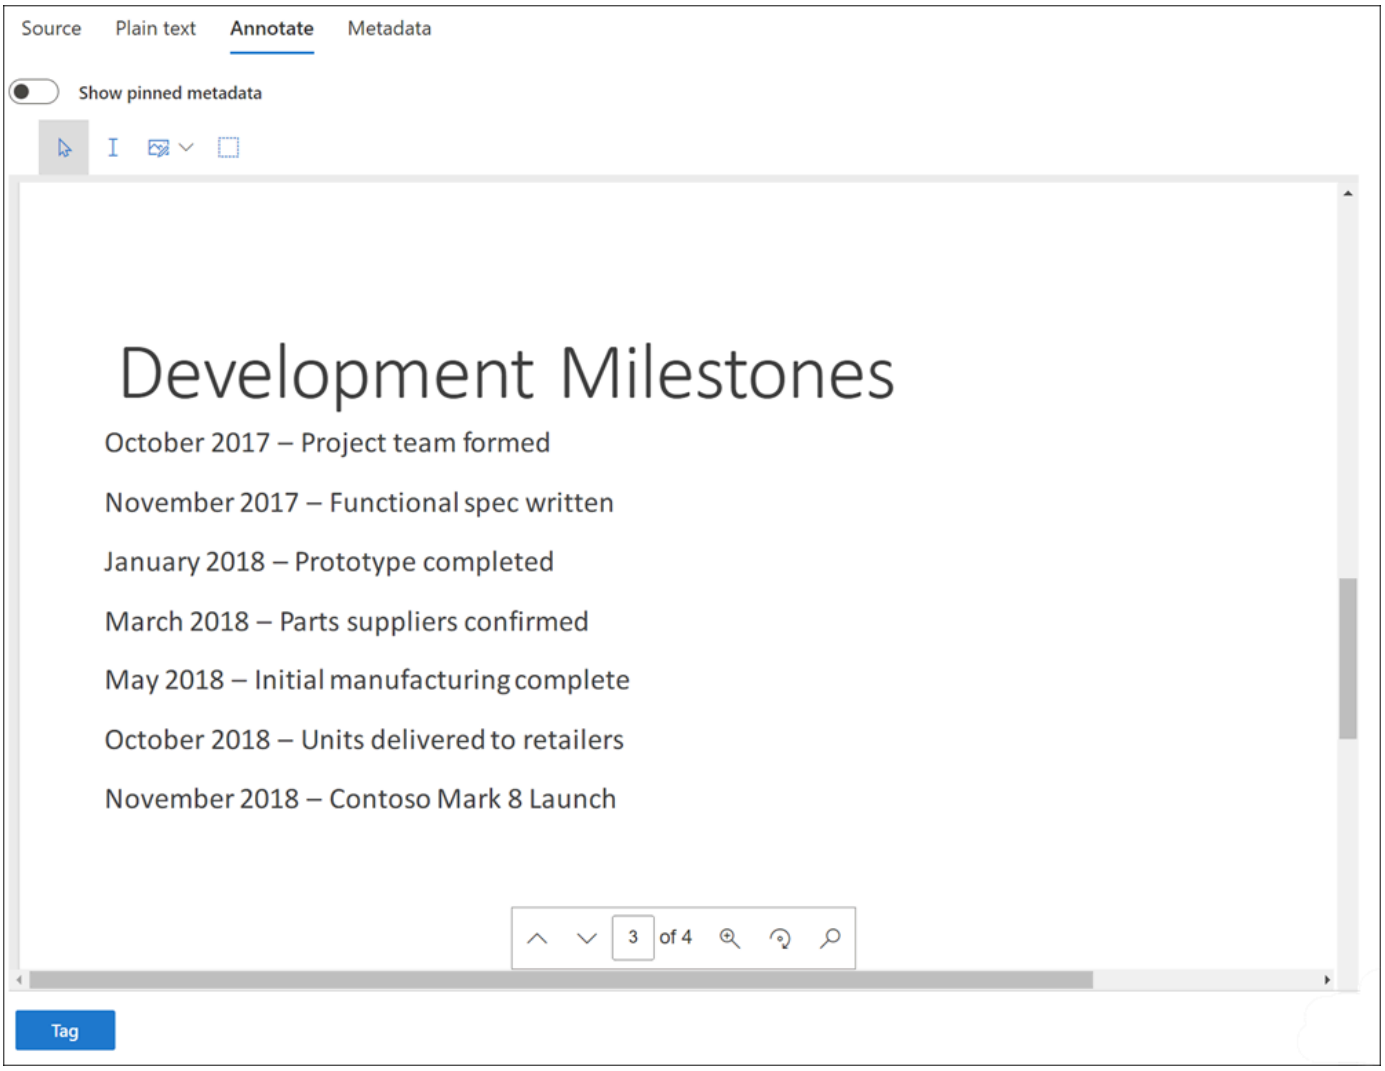
Source view



The **Source** viewer displays the richest view of a selected document. It supports hundreds of file types and is meant to display the truest to native experience possible. For Microsoft Office files, the viewer uses the web version of Office apps to display content such as document comments, Microsoft Teams chats, Excel formulas, hidden rows/columns, and PowerPoint notes.

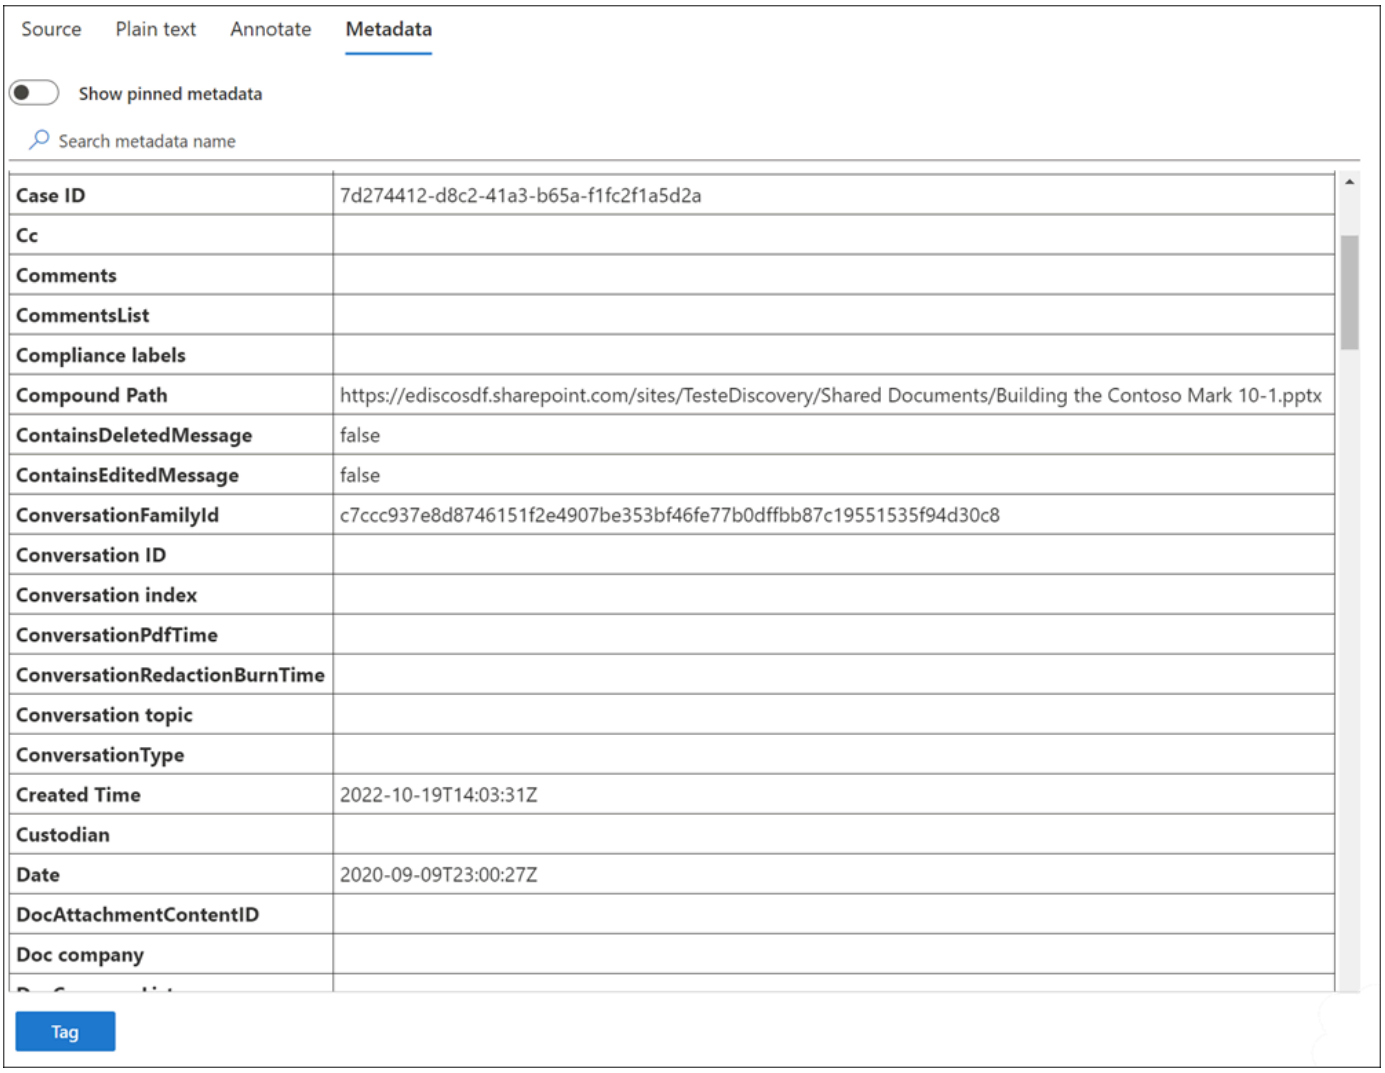
Plain text view

The **Plain text** viewer provides a view of the extracted text of a selected file. It ignores any embedded images and formatting but is useful if you're trying to understand the content quickly. Text view also includes these features:



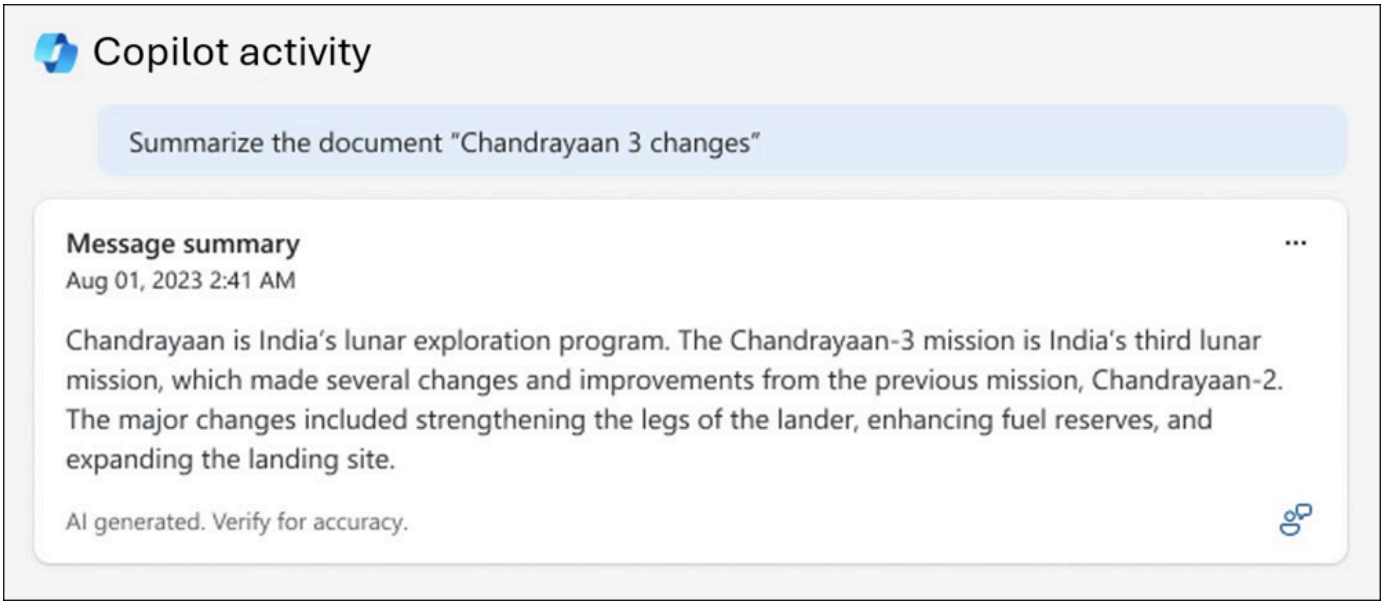
- Line counter makes it easier to reference specific portions of a document
- Search hit highlighting that highlights terms within the document and in the scrollbar

Annotate view



The **Annotate** view provides features that allow users to apply markup on a selected document including:

- **Select annotations**: Select annotations on a document to delete.
- **Select text**: Select text on the document to delete.
- **Area redactions**: Draw a box on the document to hide sensitive content.
- **Pencil**: Free-hand draw in selectable colors on a document in order to bring attention to certain portions of a document.
- **Toggle annotation transparency**: Make annotations semi-transparent in order to view the content behind the annotation.
- **Previous page**: Navigates to previous page.
- **Next page**: Navigates to the next page.
- **Go to page**: Enter a specific page number to navigate to.
- **Zoom**: Set the zoom level for annotate view.
- **Rotate**: Rotate the document clockwise.



Metadata view

The panel in the **Metadata** view can be toggled on/off to display various metadata associated with the selected document. Although the search results grid can be customized to display specific metadata, there are instances where scrolling horizontally can be difficult while reviewing data. The File metadata panel allows a user to toggle on a view within the viewer.

Copilot activity view

The **Copilot activity** view displays the Microsoft 365 Copilot and Microsoft 365 Copilot Chat activity associated with the selected item. User prompts and Copilot responses are displayed in the order they were generated.

Summarize an item by using Microsoft Security Copilot

You can use Security Copilot in Microsoft Purview to provide a contextual summary of most items in a review set. The summary provided is in the context of text included in a selected item. This summary can save time for reviewers by quickly identifying information helpful when tagging or exporting items.

Security Copilot summarizes the entire item, including any documents, meetings transcripts, or attachments. Most all of the common document file types are supported.

Limitations

- The *Plain text* view must be available for an item for Security Copilot availability. For more information on which file types support plain text views, see Supported file types in eDiscovery (Premium).
- The item content must be at least 100 words and fewer than 15,000 words. If the item content is fewer than 100 words or more than 15,000 words, Security Copilot doesn't summarize it.
- Currently, only English language messages are supported for summarization.
- Currently, only individual Teams messages can be summarized. For example. if you summarize an individual Teams message, Copilot doesn't pull in the surrounding conversation (family or conversation groups).

For more information about Microsoft Security Copilot and Microsoft's artificial intelligence (AI) responsibilities, see Responsible AI FAQ.

Prerequisites for using Security Copilot

To summarize an item in a review set in eDiscovery using Security Copilot, you must have:

- Specific licenses and you must onboard your organization to Security Copilot. For more information, see Learn more about Security Copilot licensing requirements and onboarding.
- Your admin assigned at least one of the required roles to access the Security Copilot portal. For more information about these required roles, see Understand authentication in Security Copilot.

> **Note**

Currently, eDiscovery only supports Security Copilot in the embedded experience (not the stand-alone experience).

Summarize an item in a review set

1. In eDiscovery, open a review set and filter the items as needed.
2. Select an item in the list. You can select a parent item or a child item.
3. In an item in any item view, then select **Summarize**. This opens the **Copilot** panel on the right side of the screen and displays a summary of the item.

   > **Note**
   >
   > If the plain text view isn't available for an item, **Summarize** won't be available to select.

4. To use Copilot to create the summary, select one of the suggested prompts at the bottom of the panel. For example, if the item is a legal contract in the Microsoft Word format, select the *Identify key participants*, *Identify key topics*, or *Identify action items* prompt.

   You can also enter an open-ended question in the *Ask questions and get insights about this item* field. Copilot responses are generated without using information from prior messages. For more information about prompts and promptbooks, see Microsoft Copilot in Microsoft Purview prompts and promptbooks.

   > **Note**
   >
   > Only item content is summarized. If you ask a question relevant to the item content, Copilot provides a result. If the question isn't relevant to the item content, Copilot instructs you to ask a different question.

5. If you want to provide feedback on the summarized content, select the drop-down arrow in the lower-right corner below the summary, and then enter your feedback.
6. After reviewing the summary, you can take other eDiscovery actions connected with review set items.

Viewer and management tools

For selected content, there are additional view and management tools to help you work with documents.

You can select the following actions for selected content:

- **View or update notes**: Opens the **Notes** pane where you can view or add notes to the selected document. You can display the notes for the document in a column in the dashboard list by customizing your displayed columns.
- **Show in a new window**: Displays the selected document in a new browser window/tab.
- **Download PDF**: Downloads the selected document as a .pdf file.
- **Move up**: Selects the previous review set item and displays the item in the viewer.
- **Move down**: Selects the next review set item and displays the item in the viewer.
- **Maximize/Minimize**: Maximizes the viewer pane to full screen and minimizes the viewer pane.
- **Close**: Closes the selected item from the viewers.

> **Important**
>
> To download a PDF containing items from a review set, you must be assigned the *Export* role or be assigned to a role group that includes the *Export* role. For more information about eDiscovery permissions, see Assign eDiscovery permissions in the Microsoft Purview portal.

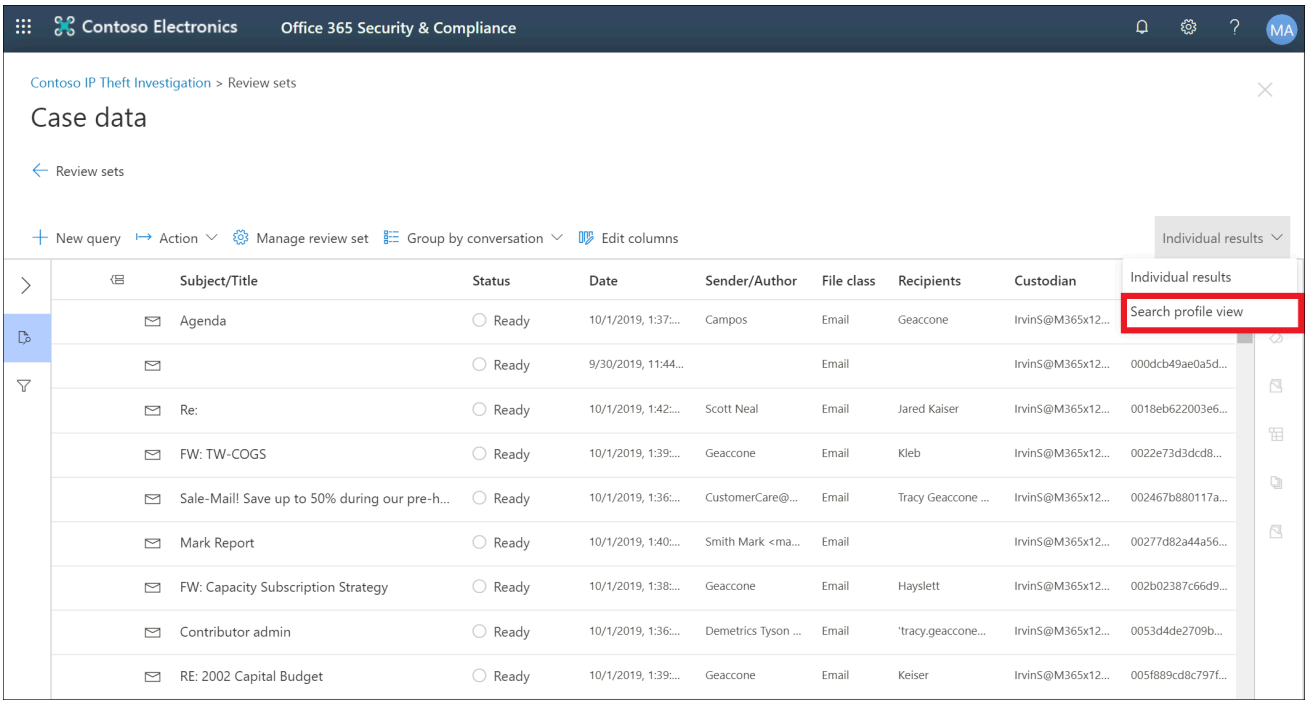
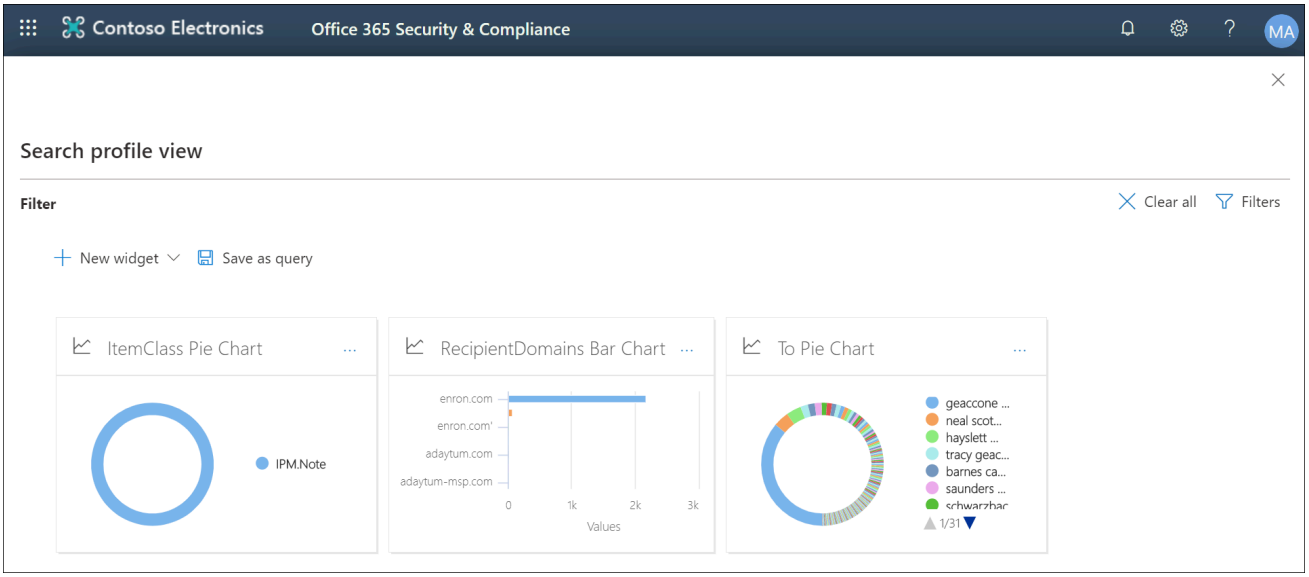
eDiscovery (Premium) dashboard for review sets



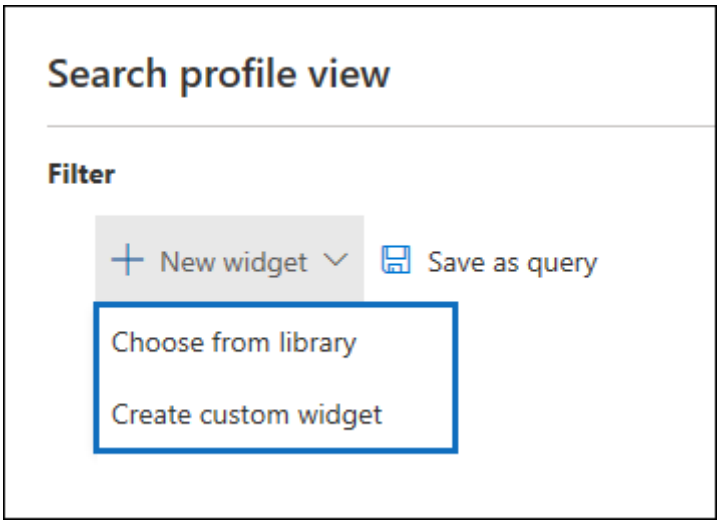
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

> **Important**
>
> Search profile view has been retired as of March 31, 2024 and is not available in new eDiscovery cases.



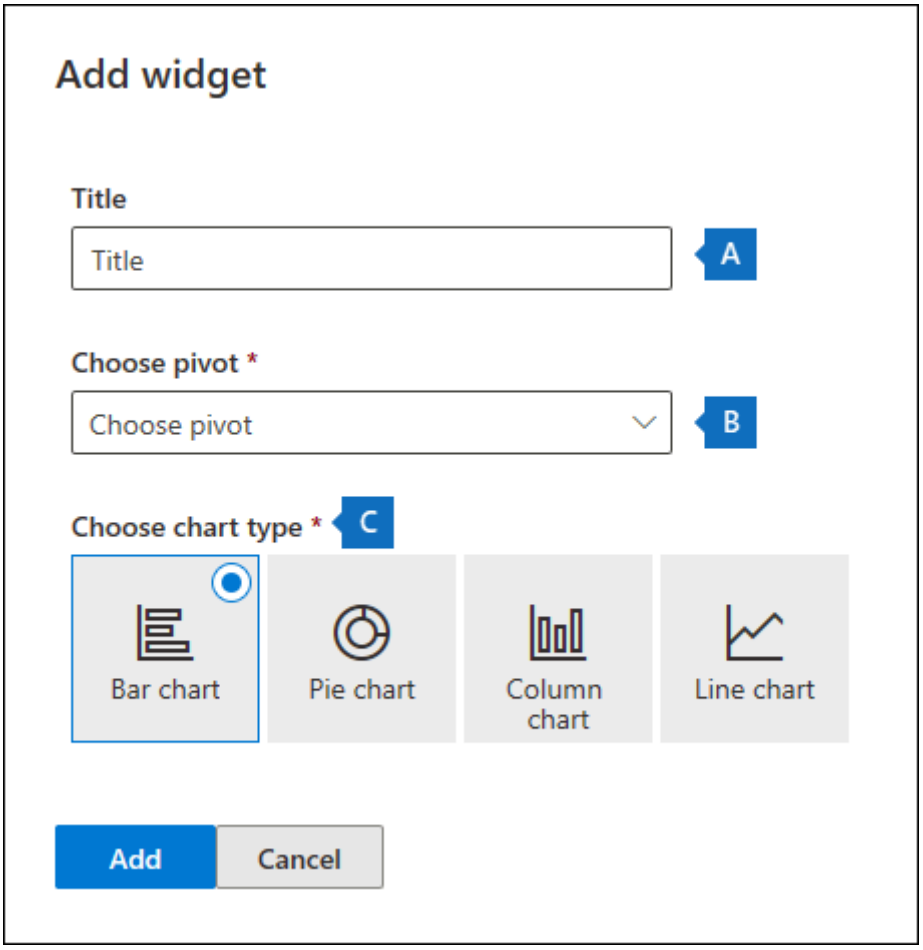
For some cases in Microsoft Purview eDiscovery (Premium), you may have a large volume of documents and email messages that need to be reviewed. Before you start the review process, you may want to quickly analyze your corpus to identify trends or key statistics that will help you develop your review strategy. To do this, you can use the eDiscovery (Premium) dashboard for review sets to quickly analyze your corpus.

Step 1: Create a widget on the review set dashboard



1. In the Microsoft Purview portal, go to **eDiscovery** > **eDiscovery (Premium)** to display the list of cases in your organization.
2. Select an existing case.
3. Select the **Review Set** tab, and then select a review set.
4. In the **Individual results** dropdown list, select **Search profile view**.

The **Search profile view** page is displayed; the first time you display this page, three default widgets are displayed.

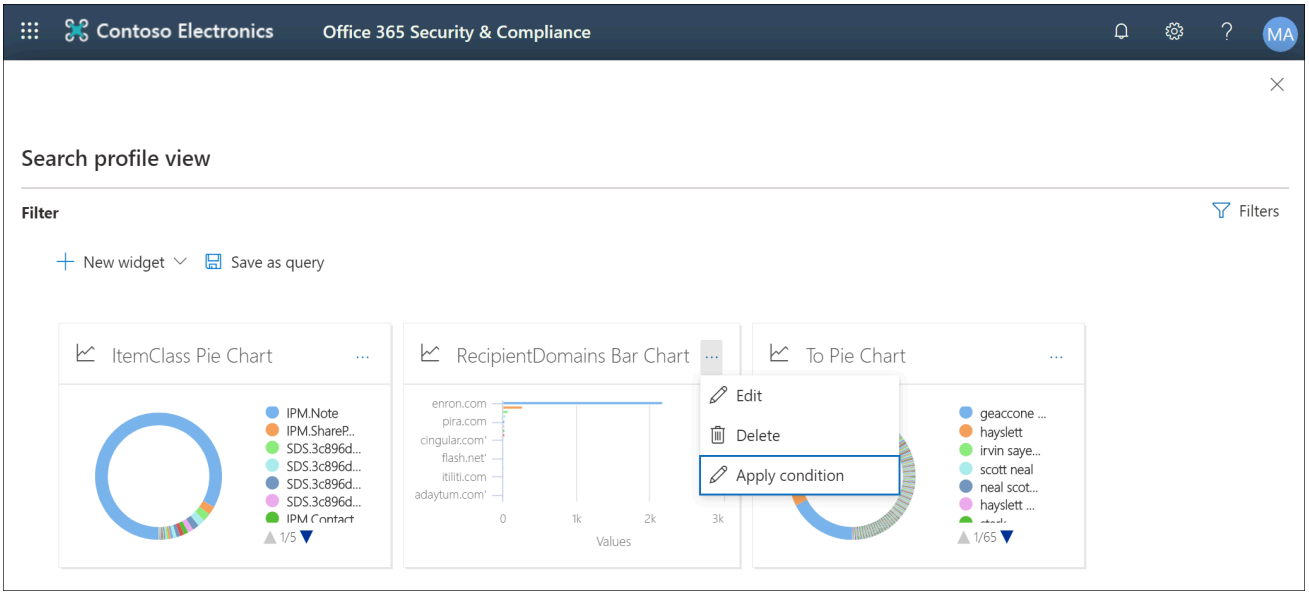


5. Select the **New widget** and then select one of the following items:

- **Choose from library:** Displays a default library of widgets. You select a widget and then select **Add** to add it to the widgets on the **Search profile view** page.
- **Create custom widget:** Displays a flyout page that you can use to set up a custom widget.

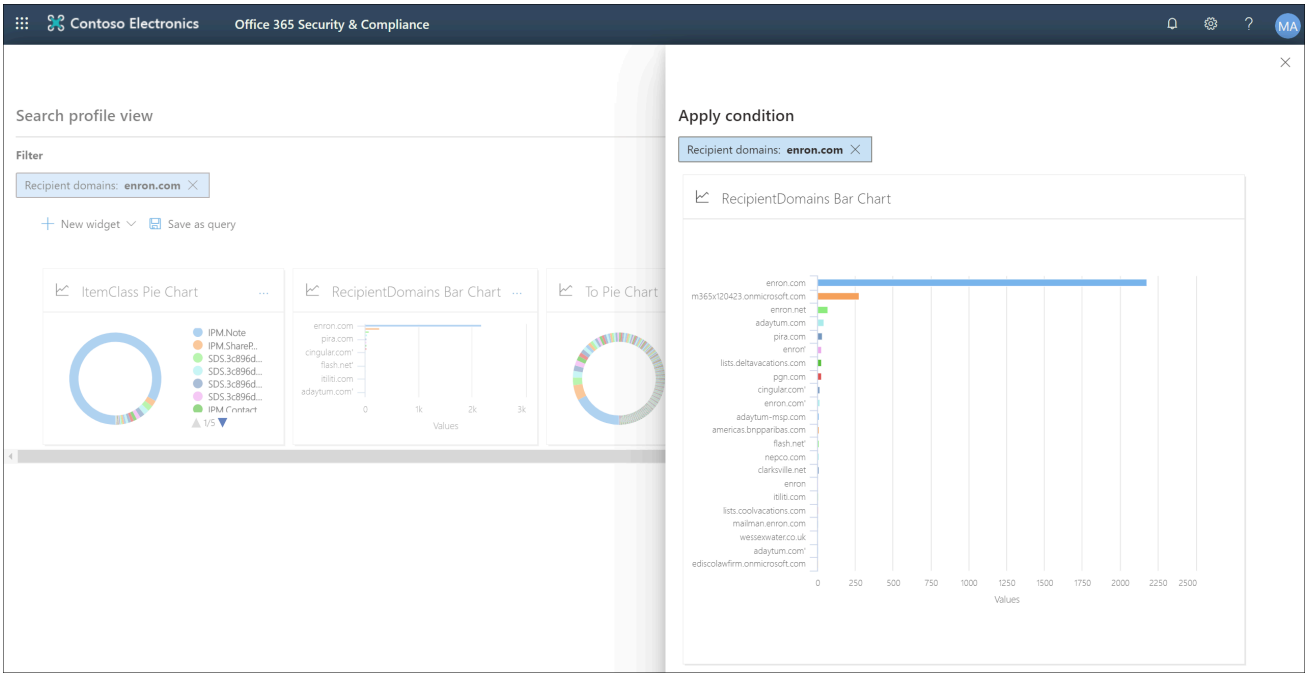
6. To create a custom widget, do the following on the **Add widget** flyout page:

a. Type a name for the widget, which is displayed in the widget title bar. Naming a widget is required, but it's helpful to identify the widget data.



b. Select a property in the **Choose pivot** dropdown list that will be used for the widget data. The items in this list are the searchable properties for the items in the review set. For a description of these properties, see Document metadata fields in eDiscovery (Premium). The pivot options for the widget are listed in the **Searchable field name** column in this topic.

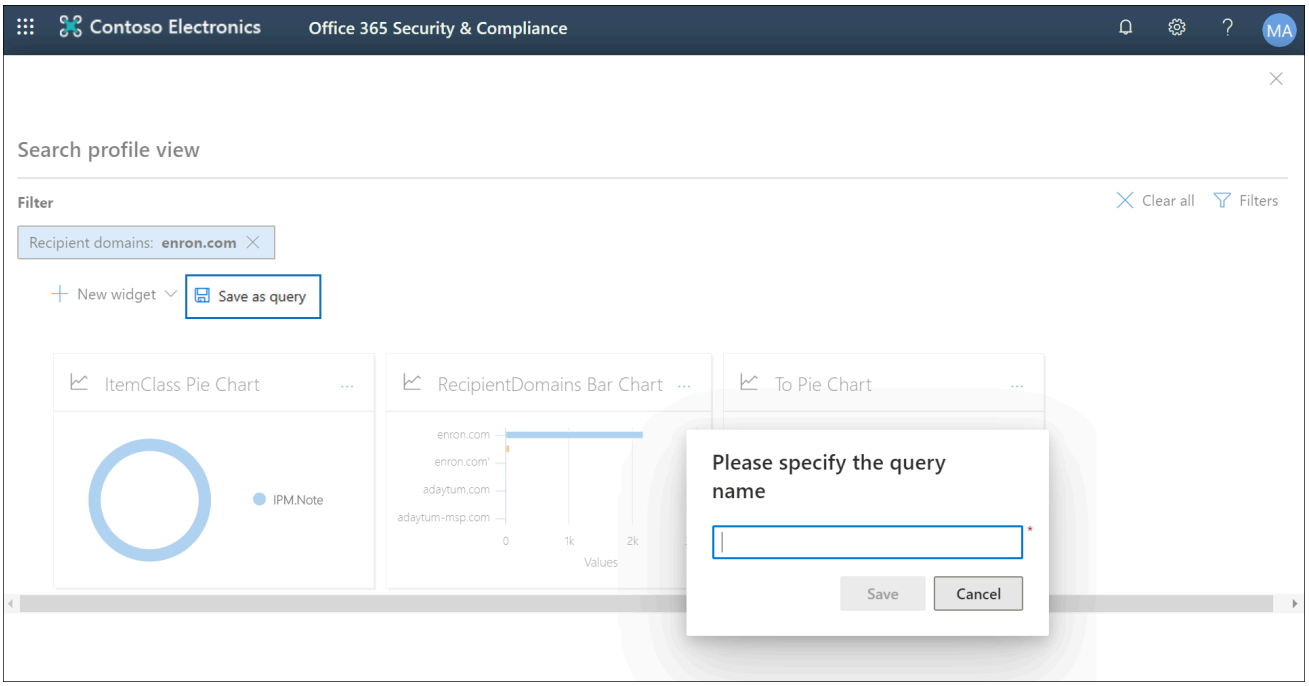
c. Select a chart type to display the data from the selected pivot property.



7. Select **Add** to create the custom widget and display it on the **Search profile view** page.

Step 2: Create a review set search query

1. Select **...** in the widget title bar, and then select **Apply condition**.



2. On the flyout page, select an element on the widget key or widget chart to create a filter.

3. Repeat steps 1-2 for other widgets multiple widgets.

4. When you're done, select **Save as query** to save your conditions as a new search query for the review set.

5. Close the **Search profile view** to return to the search results view.

   If you have created any visual filters, the resulting query is applied to the search results that are displayed, and the search query that you saved in step 4 is displayed under **Saved queries**. For more information about review set queries, see Query the data in a review set.

Last updated on 11/21/2025

Guest access in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

With guest access, you can provide access to an eDiscovery Premium case to people outside your organization. You can invite guests users to eDiscovery (Premium) cases just like you can invite guests into your Teams environment.

A guest is someone who doesn't have a work or school account with your organization. For example, guests may include external partners, vendors, suppliers, or consultants. Anyone who isn't part of your organization can be added as guest for an eDiscovery (Premium) case. This access means that anyone with a Microsoft Entra account or personal email account (Outlook, Gmail, or others) can participate as a guest in eDiscovery and have access to specific eDiscovery (Premium) cases.

Guest access in eDiscovery uses Azure B2B technology, which depends on an organization-wide Azure collaboration setting. When you invite a guest to eDiscovery, a guest account is created for them in Microsoft Entra ID. They're covered by the same compliance and auditing protection as other Microsoft 365 users. Guest access is subject to Microsoft Entra ID and Microsoft 365 service limits.

> **Note**
>
> eDiscovery guests are currently limited to *Reviewer* role group permission only. For more information about the reviewer role, see Assign eDiscovery permissions in the Microsoft Purview portal.

Set up guest access

Setting up guest access in eDiscovery requires configuring other settings in Microsoft Entra ID. To enable access to invite guests to eDiscovery cases, complete the following steps:

1. Check the B2B external collaboration settings to ensure that collaboration with guests isn't blocked. If the **Guest invite settings** is set to *No one in the organization can invite guest users including admins* then inviting guest into eDiscovery won't work. Contact your system administrator to ensure this setting is properly configured. You can view and update the collaboration setting using the *Authorization Policy* API.

2. Depending on the specific configuration in Step 1, eDiscovery administrators may or may not need additional roles to approval a guest access request submitted from the eDiscovery user.

    - If the *Anyone in the organization can invite guest users including guests and non-admins (most inclusive)* or *Member users and users assigned to specific admin roles can invite guest users including guests with member permission* options are selected, then eDiscovery administrators can approve invitation requests without additional roles.
    - If *Only users assigned to specific admin roles can invite guest users* is selected, then the eDiscovery administrator who would approve the invitation request requires the *Invite guest* role to approve and trigger the invitation email to the guest. See the Assign Microsoft Entra roles to users article for guidance on how to add the *Guest Inviter* role to users. If you prefer to use PowerShell to add this role, see Assign the Guest Inviter role to a user.

3. To enable collaboration with guest reviewers from other Microsoft 365 cloud environments, including if you're a Microsoft Azure Government organization, both your organization and the guest user's organization must enable specific connection settings. For detailed configuration guidance, see Collaborate with guests from other Microsoft 365 cloud environments.

Enable guest access in eDiscovery (Premium)

eDiscovery admins must enable guest access in eDiscovery (Premium) before they can invite users as guests.

To enable guest access for guests in eDiscovery (Premium), complete the following steps:

1. In the Microsoft Purview portal, navigate to **eDiscovery** > **Premium** > **eDiscovery (Premium) settings** > **Guest users**.
2. Toggle **Guest access** to *On*.

Now eDiscovery managers and admins can initiate the guest invitation process within any eDiscovery (Premium) case.

Invite guests to an eDiscovery (Premium) case

To invite guests to an eDiscovery (Premium) case, complete the following steps:

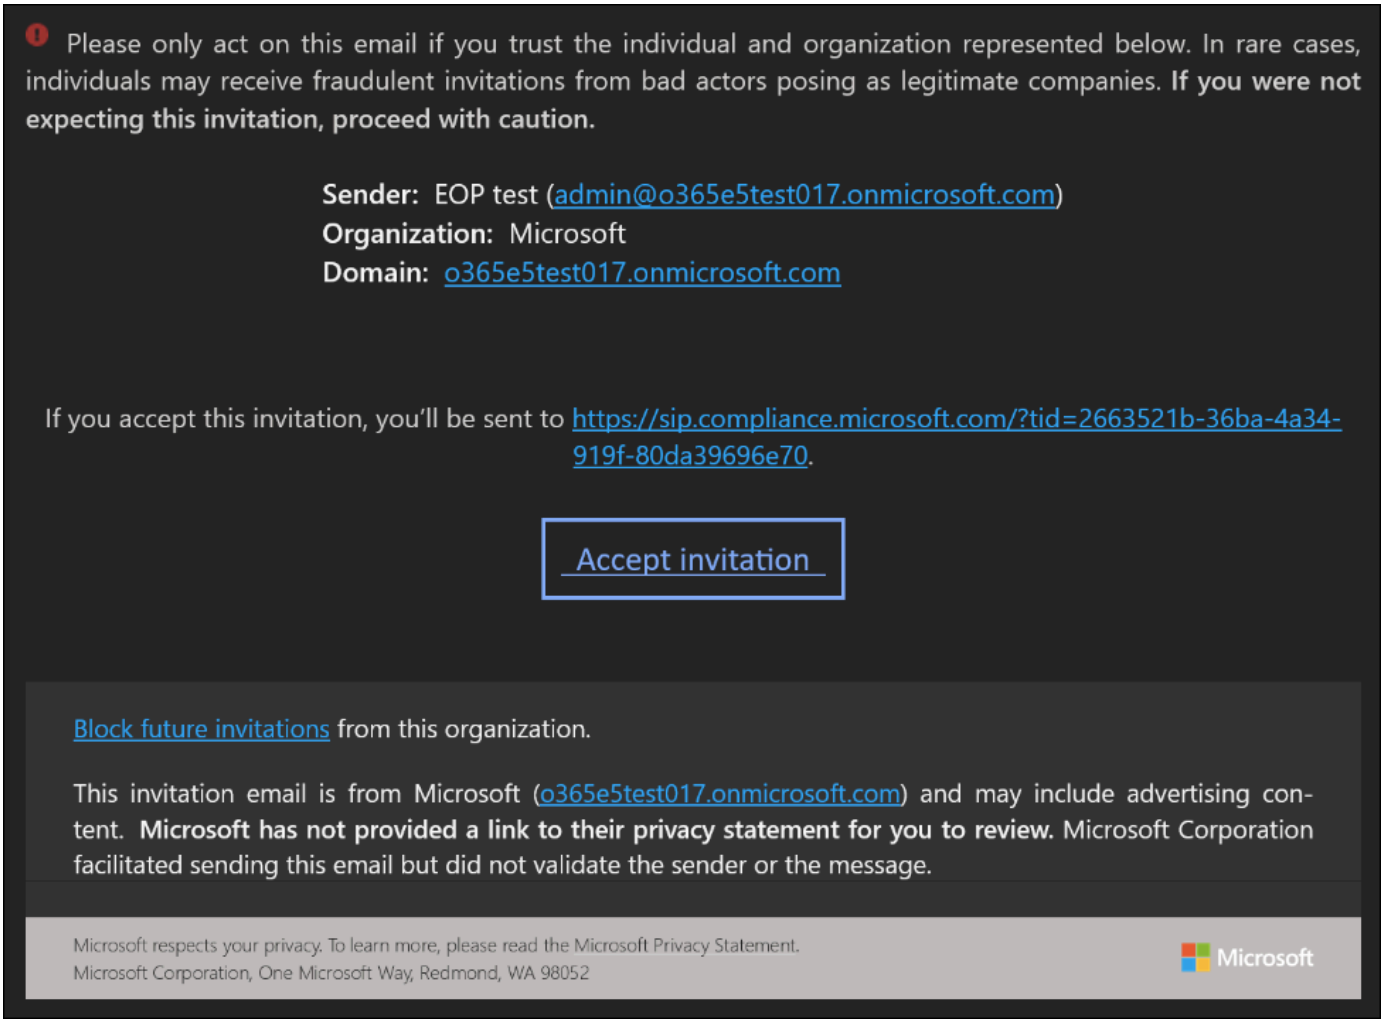
1. In the Microsoft Purview portal, navigate to **eDiscovery** > **Premium** > **eDiscovery (Premium) cases** and select the case you want to invite guests to.
2. In the selected case, select the **Settings** tab and then select **Access & permissions**.
3. In the **Guest users** section, select **Add**.
4. On the **Invite guest** flyout pane, complete the following fields:
    - **Full name**: Enter the full name of the guest you want to invite.
    - **Email address**: Enter the email address of the guest you want to invite.
    - **Organization**: Enter the organization of the guest you want to invite.
    - **Guest role**: Select the role you want to assign to the guest. The guest is currently limited to *Reviewer* role group permission only.
    - **Justification**: Explain why this person needs access to the case.
5. Select **Invite** to submit the invitation request for review and approval by an eDiscovery admin.

Approve guest access requests

After guest invitations are submitted, eDiscovery admins must approve the requests before the guest can access the case. eDiscovery admins must have the *Role Management* role assigned to approve guest access requests.

To approve guest access requests, eDiscovery managers must complete the following steps:

1. eDiscovery managers are notified of pending invitation requests on the **Overview** tab in eDiscovery (Premium).
2. To review and approve or deny the request, navigate to **eDiscovery** > **Premium** > **eDsicovery (Premium) settings** > **Guest users**. Select the guest request and select **Create account** or **Deny**.
3. If the guest is being added to the tenant for the first time, eDiscovery admins need to perform a two-step approval process. They first need to approve creation of an account,



which may take up to 24 hours. After 24 hours, eDiscovery admins can approve guest access to the case. For future access requests for access to other cases for the same guest, only one-step approval is required.

In you encounter an error when approving the guest access to a case, check the following:

- The guest's email isn't disabled, blocked or deleted by the tenant admin.
- If there are any members in the *Reviewer* role group whose Microsoft Entra account has been deleted. Currently, an error occurs when adding a new member to a role group that has any deleted users. If the *Reviewer* role group has any deleted users, remove them from the role group and retry the guest approval.

Accepting guest invitations

After the request is approved by the eDiscovery admin, the guest receives a welcome email from *Microsoft Invitations*. This email contains information about the eDiscovery invitation and a link where the guest can accept the invite and sign in. The guest must select the unique link provided in the email or copy/paste the link in a browser to log into the specific eDiscovery organization.

Guests that have a work or school account in Microsoft Entra ID can accept the invitation and authenticate immediately. Other users are sent a one-time passcode to validate their identity. You must ensure that the one-time passcode setting is enabled in your organization.

> **Note**
>
> If the guest is logged into another eDiscovery organization in their browser, they need to sign out from the organization and clear their browser cache before selecting the link in the invitation email.

After accepting the invitation and authenticating, the guest can participate in the eDiscovery case like an internal reviewer of the case and perform review activities such as querying, filtering, tagging, redaction, downloading single items for review, and more.

Removing guest access

An eDiscovery admin can remove a guest's access to a case from eDiscovery Premium settings page. To remove guest access for a user, eDiscovery admins must complete the following steps:

1. To review and approve or deny the request, navigate to **eDiscovery** > **Premium** > **eDsicovery (Premium) settings** > **Guest users**.
2. Select the guest and select **Remove** from the flyout pane.

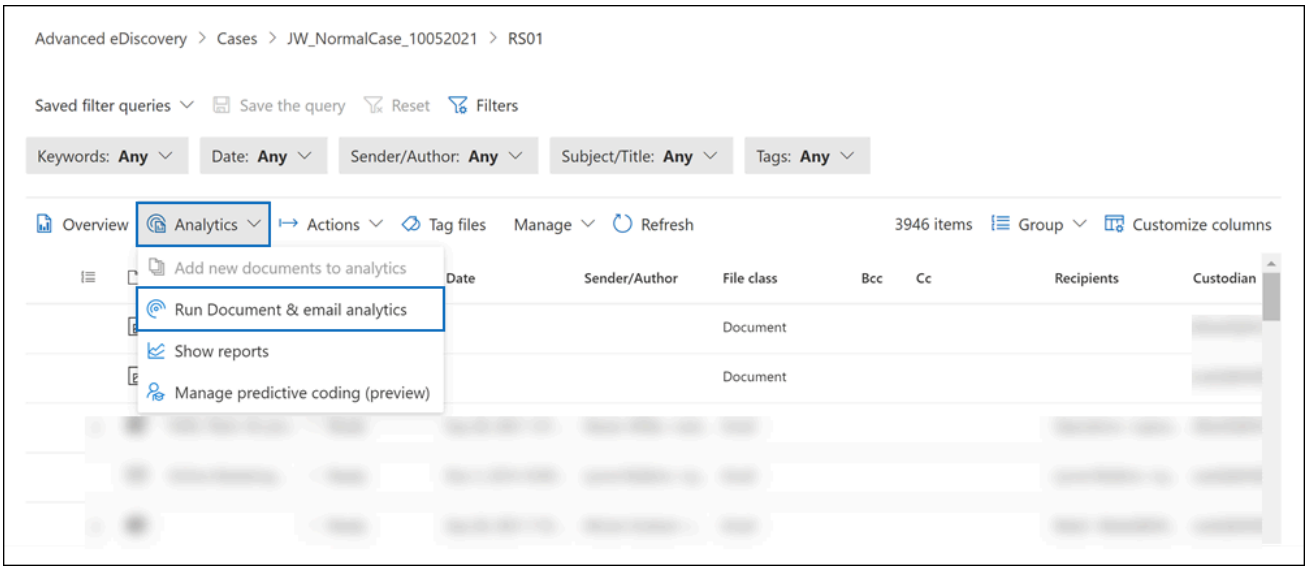
The guest continues to have access to other cases that they have been added to. When a guest is removed from the last case they have access to, they're removed from the *Reviewer* role group and won't have access to any cases in eDiscovery (Premium).

The guest continues to have a Microsoft Entra guest account in the organization. A regular review and clean-up of guest accounts from Microsoft Entra ID is recommended.

Last updated on 09/02/2025

Analyze data in a review set in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.



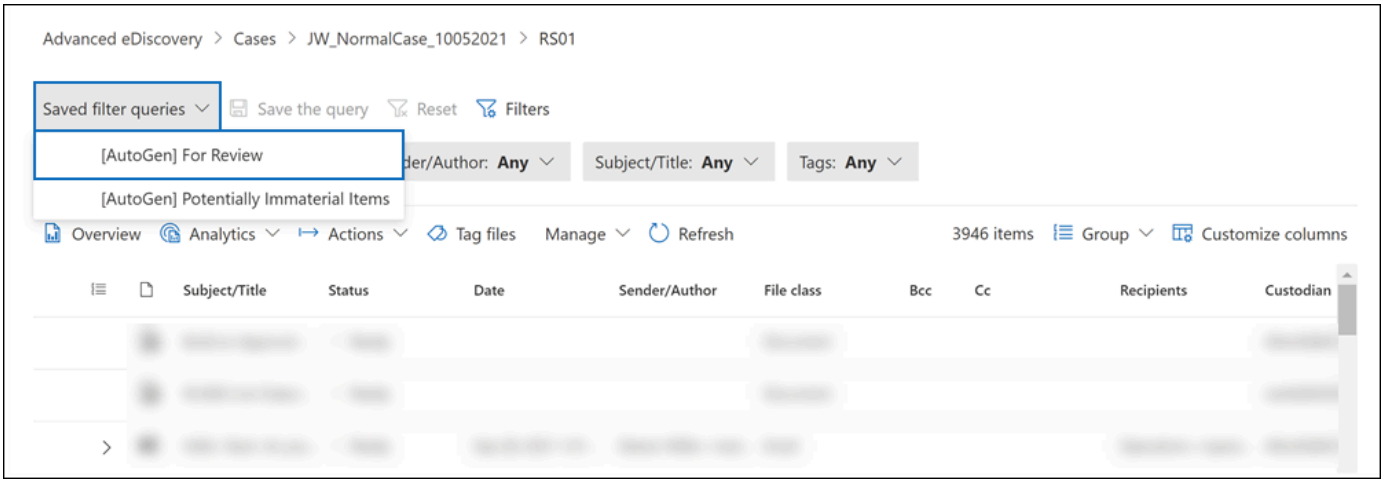
When the number of collected documents is large, it can be difficult to review them all. Microsoft Purview eDiscovery (Premium) provides a number of tools to analyze the documents to reduce the volume of documents to be reviewed without any loss in information, and to help you organize the documents in a coherent manner. To learn more about these capabilities, see:

- Near duplicate detection
- Email threading
- Themes

Run analytics for a review set

To analyze data in a review set:

1. Configure analytics settings for your case. For more information, see Configure search and analytics settings.
2. Open the review set you want to analyze.
3. Select **Analytics** > **Run document & email analytics**.



You can check the progress of analysis on the **Jobs** tab of the case.

After analysis is completed, you can view the analytics report, run queries within your review set on outputs of the analysis (see Query within your review set, and see related documents of a given document (see Reviewing data in review set.

Using the For Review filter query

After running analytics for the review set, you can use an automatically generated filter query (called *For Review*) that filters your review to exclude immaterial, duplicate, or non-inclusive items. This leaves you with only the items that are representative, unique, and inclusive in the review set.

To apply the **For Review** filter query to a review set, select the **Saved filter queries** dropdown list, and then select **[AutoGen] For Review**.

Here's the syntax for the **For Review** filter query:

```
(((FileClass="Email") AND (IsInclusive="True") AND (MarkAsRepresentative="Unique")) OR ((FileClass="Attachment") AND (MarkAsRepresentative="Unique")) OR ((FileClass="Document")
```

```
AND (MarkAsRepresentative="Unique")) OR ((FileClass="Conversation") AND
(MarkAsRepresentative="Unique")) OR ((FileClass="Attachment" OR FileClass="Conversation" OR
FileClass="Document" OR FileClass="Email") AND NOT (Exists:MarkAsRepresentative)))
```

The following list describes the result of the filter query in terms of what content is displayed after you apply it to the review set.

- **Email**: Displays items that are marked as both **Inclusive** and **Representative**. An email is marked as IsInclusive True when it contains all the unique content from a thread, including all previous replies. It ensures that only the most comprehensive email in a thread is reviewed, which is essential for understanding the full context of the conversation without having to review each individual reply. An email is MarkedAsRepresentative Unique when it is the single representative copy among duplicates.
- **Attachments**: Filters out duplicate attachments in the review set. Only attachments that are unique in the review set are displayed.
- **Documents**: Filters out duplicate documents. Only documents that are unique in the review set are displayed.
- **Teams conversations**: Filter out duplicate Teams (and Viva Engage) conversations. Only conversations that are unique in the review set are displayed.
- **Other**: Any emails, attachments, documents and conversations in the review set where MarkedAsRepresentative field contains no value. This means analytics was not able to generate a value for it, so the reviewer should review them and assess themselves.

For more information about inclusive types and document uniqueness, see Email threading in eDiscovery (Premium).

Analytics report

To view the analytics report for a review set:

1. Open the review set.
2. Select **Analytics** > **Show reports**.

The **Analytics** report has seven components from the analysis:

- **Target population:** The number of email messages, attachments, and loose documents found in the review set.

- **Documents (excluding attachments):** The number of loose documents that are pivots, unique near duplicates of a pivot, or an exact duplicate of another document.
- **Emails:** The number of email messages that are marked as *inclusive* vs not.
- **Attachments:** The number of email attachments that are unique or duplicates of another email attachment in the review set.
- **Number documents by file type:** The number of files, identified by file extension.
- **Documents by source:** A summary of content by its original data source.
- **Documents aggregated by process:** A summary of content by review set processes.

Near duplicate detection in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Consider a set of documents to be reviewed in which a subset is based on the same template and has mostly the same boilerplate language, with a few differences here and there. If a reviewer could identify this subset, review one of them thoroughly, and review the differences for the rest, they would not have missed any unique information while taking only a fraction of time that would have taken them to read all documents cover to cover. Near duplicate detection groups textually similar documents together to help you make your review process more efficient.

How does it work?

When near duplicate detection is run, the system parses every document with text. Then, it compares every document against each other to determine whether their similarity is greater than the set threshold. If it is, the documents are grouped together. Once all documents have been compared and grouped, a document from each group is marked as the "pivot"; in reviewing your documents, you can review a pivot first and review the other documents in the same near duplicate set, focusing on the difference between the pivot and the document that is in review.

Email threading in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Consider an email conversation that has been going on for a while. In most cases, the last message in the email thread includes the contents of all the preceding messages. Therefore, reviewing the last message gives a complete context of the conversation that happened in the thread. Email threading identifies such messages so that reviewers can review a fraction of collected documents without losing any context.

What does email threading do?

Email threading in eDiscovery refers to the process of organizing a sequence of related emails that are part of the same conversation. This includes the initial email and all subsequent replies and forwards linked to that original email. By grouping these emails into threads, reviewers can see the entire context of a conversation, making it easier to understand the flow of communication. This approach helps identify relevant information more efficiently, as it eliminates the need to review each email individually. Email messages post analytics process can have the following metadata populated:

- **Is Inclusive**: This field identifies whether an email contains all the unique content from a thread, including all previous replies. It ensures that only the most comprehensive email in a thread is reviewed, which is essential for understanding the full context of the conversation without having to review each individual reply.
- **Has Unique Attachments**: This field marks emails that contain attachments not found in other emails within the same thread. Even if the email content is duplicated, unique attachments are flagged to ensure that all relevant documents are reviewed. This is

important in the legal review process to ensure that no unique evidence is overlooked, even if the email body itself is not unique.

How is it different from conversations in Outlook?

At a glance, this sounds similar to conversation groupings in Outlook. However, there are some important distinctions. Consider an email conversation that got forked into two conversations; for instance, someone responded to an email that isn't the latest in the conversation so the last two emails in the conversation both have unique content.

Outlook would still group the emails into a single conversation; reading only the last email would mean missing the context of the second-to-last email, which also contains unique content. Because email threading parses out each email into individual components and compares them, email threading would mark both of the last two emails as inclusive, ensuring that you won't miss any context as long as you read all emails marked as inclusive.

Let's also consider an email thread with multiple replies, where some replies include inline responses that modify the quoted content. If an inline reply alters part of the previous email, the latest reply doesn't fully encompass the content of the earlier email. Both the latest reply and the earlier email with unique content are marked as inclusive. This approach ensures that any unique information from the inline reply is preserved and not overlooked.

Themes in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When you create a new document, you generally start with one or more ideas that you want to convey in the document, and then compose the document using words that align with these ideas. The more prevalent an idea is, the more frequent the words that are related to that idea tend to be. This method also aligns to how readers consume documents. The important things to understand from reading a document are the main ideas that the document is trying to convey. This also includes which ideas appear where and what the relationships between the ideas are.

This process can be extended to how an eDiscovery reviewer wants to consume a set of documents in a case. They want to see which ideas are present in the review sets and which documents are talking about those ideas. If they find a particular document of interest, they want to be able to see documents that discuss similar ideas.

The **Themes** functionality in eDiscovery (Premium) attempts to mimic how humans reason about documents, by analyzing the *themes* that are discussed in a review set and assigning a theme to documents in the review set. In eDiscovery (Premium), Themes goes one step further and identifies the *dominant theme* in each review set and document. The *dominant theme* is the one that appears the most often in a document.

How does themes work?

The **Themes** functionality analyzes documents with text in a review set to parse out common themes that appear across all the documents in the review set. eDiscovery (Premium) assigns those themes to the documents in which they appear. It also labels each theme with the words used in the documents that are representative of the theme. Because a document can contain various types of subject matter, eDiscovery (Premium) often assigns multiple themes to review

sets and documents. This is referred to as the *Themes list*. The theme that appears most prominently in a review set or document is designated as its *dominant theme*.

Configuring Themes

Themes are supported for cases and apply to all the review sets within them. You can configure the settings for themes when you create a new case or you can update the theme settings for an existing case.

Configure Themes when creating a new case

To configure themes when you create a new case, complete the following steps:

1. In the Microsoft Purview portal, navigate to **eDiscovery** > **Premium**.
2. Select the **Cases** tab and open an eDiscovery (Premium) case, and then select **Create a case**.
3. On the **Name and description** page, name the case and complete the **Description**, **Number**, and **Case format** options as applicable. Select **Next** to continue.
4. On the **Members and settings** page, select **Group items by theme**. Select the following theme options as applicable:

    - **Maximum number of themes:** Specifies the maximum number of themes that can be generated when you run analytics on the data in review sets included in a case. For more information on limits, see Limits in eDiscovery (Premium).
    - **Add numeric identifiers to themes:** Numbers (that identify a theme) are included when generating themes.
    - **Automatically set maximum number of themes:** In certain situations, there may not be enough documents in a review set to produce the desired number of themes for the case. When this setting is enabled, eDiscovery (Premium) adjusts the maximum number of themes dynamically rather than attempting to enforce the maximum number of themes.

5. If you need to exclude keywords associated with themes, enter the text or regular expression needed in the **Text to ignore** field. In the **Apply to** field, select **Themes** to apply the text or regular expression to all themes.
6. Complete the other field on the **Members and settings** page as applicable, then select **Next**.
7. On the **Summary** page, review the case settings, then select **Submit** to create the case.

After a new case is created, analytics are automatically run on the data when the review sets are added to the case. Themes for the review sets are generated as part of the analytics processing.

Configure Themes for an existing case

To configure themes for an existing case, complete the following steps:

1. In the Microsoft Purview portal, navigate to **eDiscovery** > **Premium**.
2. Select the **Cases** tab and open an eDiscovery (Premium) case.
3. Select the **Settings** tab, and then choose **Select** on the **Search & analytics** card.
4. On the **Search & analytics** page, select the **Themes** checkbox and configure the following options as applicable:

    - **Max number of themes:** Specifies the maximum number of themes that can be generated when you run analytics on the data in review sets included in a case. For more information on limits, see Limits in eDiscovery (Premium).
    - **Include numbers themes:** Numbers (that identify a theme) are included when generating themes.
    - **Adjust maximum number of themes dynamically:** In certain situations, there may not be enough documents in a review set to produce the desired number of themes for the case. When this setting is enabled, eDiscovery (Premium) adjusts the maximum number of themes dynamically rather than attempting to enforce the maximum number of themes.

5. If you need to exclude keywords associated with themes, select **Edit** in the **Ignore text** section. Enter the text or regular expression needed in the **Text (Regular expressions are supported)** field. In the **Apply to** field, select **Themes** to apply the text or regular expression to all themes.
6. Select **Save** to save the theme settings.
7. Navigate to the review set in the case that you want to apply the new theme settings to, and select **Analytics** > **Run Document & email analytics**.
8. Select **Yes** to confirm that you want to run analytics on the review set.

After the analytics job completes, you can view the themes that were generated for the review set by filtering the documents in the review set by theme.

Filtering documents by Theme

Filtering documents by theme can significantly save time when reviewing documents. For example, if you're looking for documents that discuss a particular topic, you can filter the documents by the dominant theme that is related to that topic. You can also filter documents by other themes in the theme list to find documents that are similar to a document that you're interested in. To display the themes for a document as a column in the document list for the review set, select **Customize columns** and select **Dominant theme** and **Themes list**.

To filter documents by theme, complete the following steps:

1. In a review set, choose **Filters** and expand the options for **Analytics & predictive coding**.
2. Select **Dominant theme** and **Themes list**, and then select **Done** to add these filters to the review set.
3. Use the conditional controls as needed to filter the documents by specific themes for each of these filters.

To filter documents by theme using advanced filters (preview), complete the following steps:

1. In a review set, choose **Select a filter** and select **Dominant theme**.
2. Select an operator to use with the **Dominant theme** and define the value to use with the operator.
3. Use an addition **Themes list** filter and the operator and values to applicable to this filter. You can configure the **AND** and **OR** operators to filter documents by a combination of the **Dominant theme** and **Themes list** values.

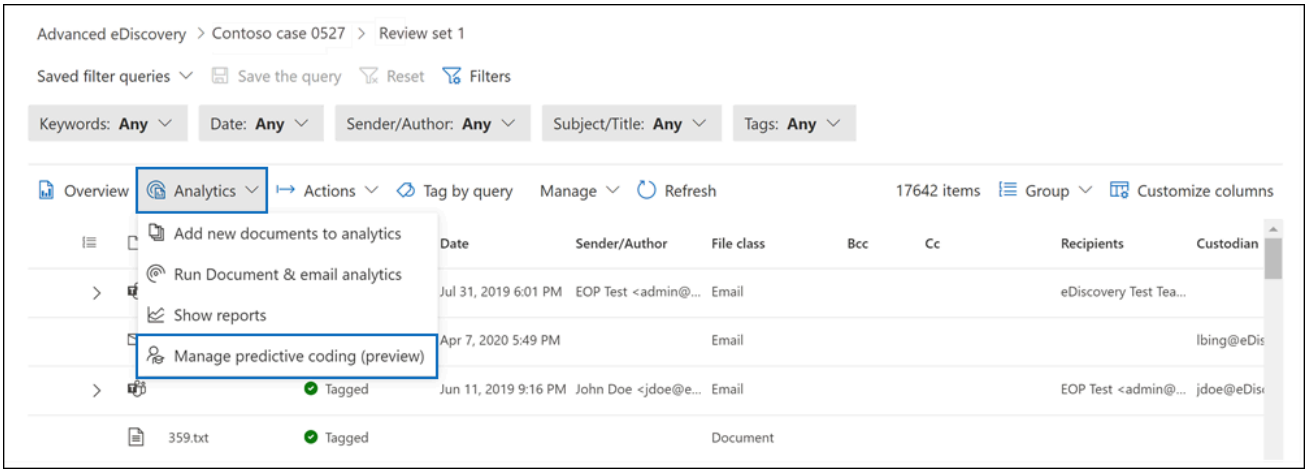
Quick start: Predictive coding in eDiscovery (Premium) (preview)

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article presents a quick start for using predictive coding in Microsoft Purview eDiscovery (Premium). The predictive coding module uses intelligent, machine learning capabilities to help you cull large volumes of case content that's not relevant to your investigation. This is accomplished by creating and training your own predictive coding models that help you prioritize the most relevant items for review.

Here's an a quick overview of the predictive coding process:



To get started, you create a model, label as few as 50 items as relevant or not relevant. The system then uses this training to apply prediction scores to every item in the review set. This lets you filter items based on the prediction score, which allows you to review the most relevant (or non-relevant) items first. If you want to train models with higher accuracies and recall rates, you can continue labeling items in subsequent training rounds until the model stabilizes. Once the model is stabilized, you can apply the final prediction filter to prioritize items to review.

For a detailed overview of predictive coding, see Learn about predictive coding in eDiscovery (Premium).

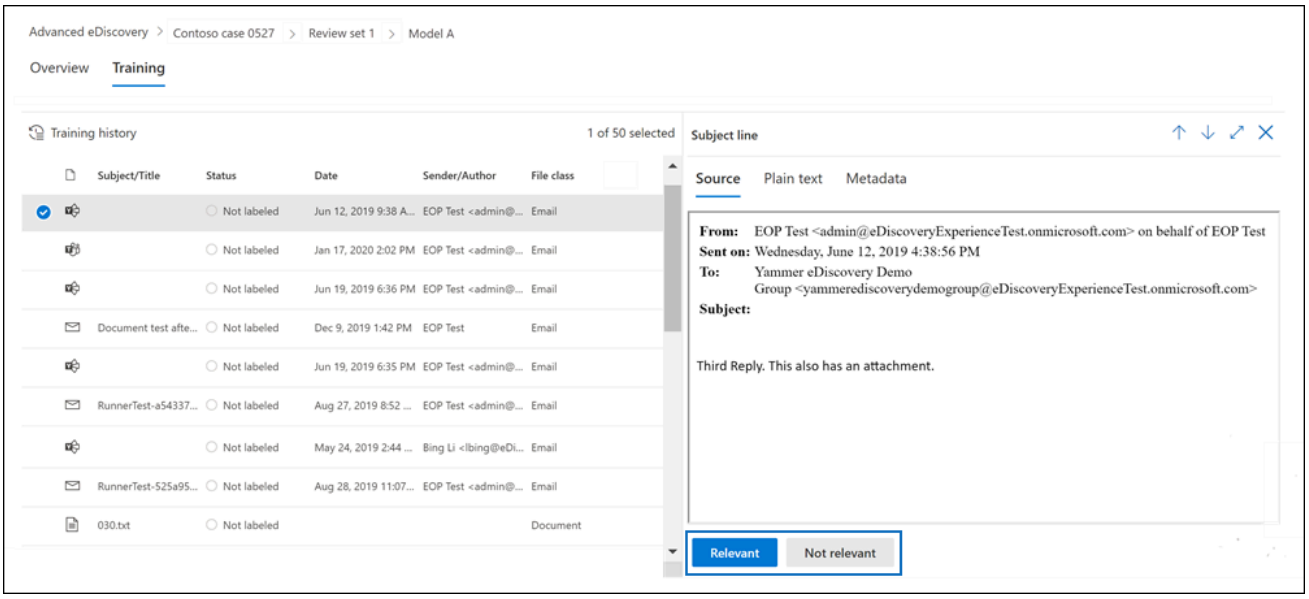
Step 1: Create a new predictive coding model

The first step is to create a new predictive coding model in the review set:

1. In the Microsoft Purview portal, open an eDiscovery (Premium) case and then select the **Review sets** tab.
2. Open a review set and then select **Analytics** > **Manage predictive coding (preview)**.

3. On the **Predictive coding models (preview)** page, select **New model**.
4. On the flyout page, type a name for the model and an optional description.
5. Select **Save** to create the model.

   It will take a couple minutes for the system to prepare your model. After it's ready, you can perform the first round of training.



For more detailed instructions, see Create a predictive coding model.

Step 2: Perform the first training round

After you create the model, the next step is to complete the first training round by labeling items as relevant or not relevant.

1. Open the review set and then select **Analytics** > **Manage predictive coding (preview)**.
2. On the **Predictive coding models (preview)** page, select the model that you want to train.
3. On the **Overview** tab, under **Round 1**, select **Start next training round**.

   The **Training** tab is displayed and contains 50 items for you to label.
4. Review each document and then select **Relevant** or **Not relevant** at the bottom of the reading pane to label it.

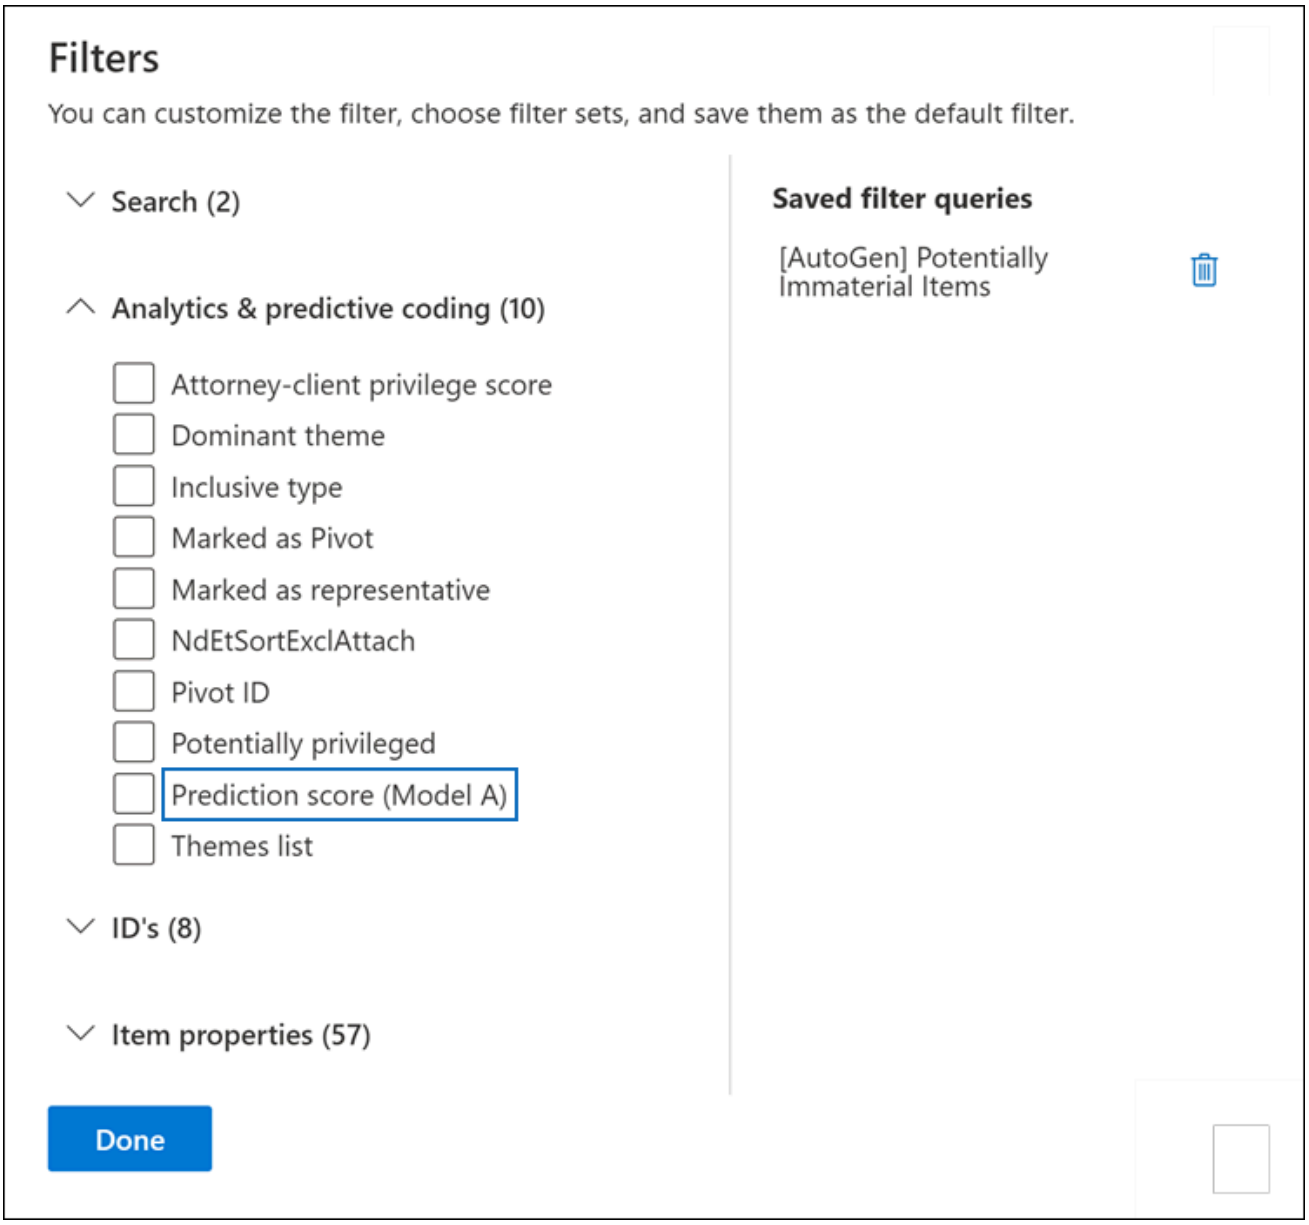
5. After you've labeled all 50 items, select **Finish**.

   It will take a couple minutes for the system to "learn" from your labeling and update the model. When this process is complete, a status of **Ready** is displayed for the model on the **Predictive coding models (preview)** page.

For more detailed instructions, see Train a predictive coding model.

Step 3: Apply the prediction score filter to items in review set

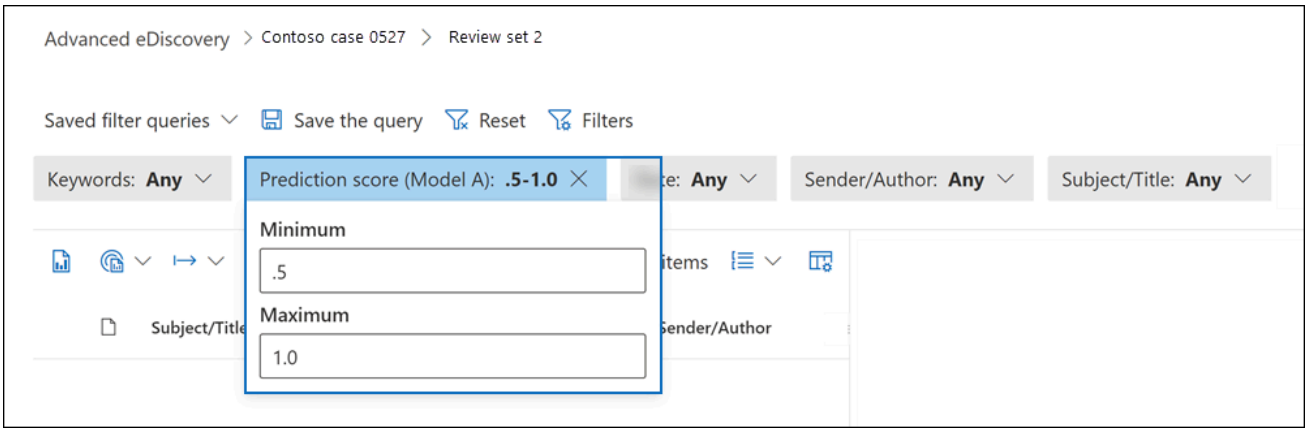
After you perform at lease one training round, you can apply the prediction score filter to items in review set. This lets you review the items the model has predicted as relevant or not relevant.



1. Open the review set.

   The pre-loaded default filters are displayed at the top of the review set page. You can leave these set to **Any**.

2. Select **Filters** to display the **Filters** flyout page.



3. Expand the **Analytics & predictive coding** section to display a set of filters.

The naming convention for prediction score filters is **Prediction score (model name)**. For example, the prediction score filter name for a model named **Model A** is **Prediction score (Model A)**.

4. Select the prediction score filter that you want to use and then select **Done**.

5. On the review set page, select the dropdown for the prediction score filter and type minimum and maximum values for the prediction score range. For example, the following screenshot shows a prediction score range between **.5** and **1.0**.

6. Select outside the filter to automatically apply the filter to the review set.

A list of documents with a prediction score within the range you specified is displayed on the review set page.

For more detailed instructions, see Apply a prediction filter to a review set.

Step 4: Perform more training rounds

More than likely, you'll have to perform more training rounds to train the module to better predict relevant and non-relevant items in the review set. In general, you'll train the model enough times until it stabilizes enough to meet your requirements.

For more information, see Perform additional training rounds

Step 5: Apply the final prediction score filter to prioritize review

Repeat the instructions in Step 3 to apply the final prediction score to the review set to prioritize the review of relevant and non-relevant items after you complete all the training rounds and stabilize the model.

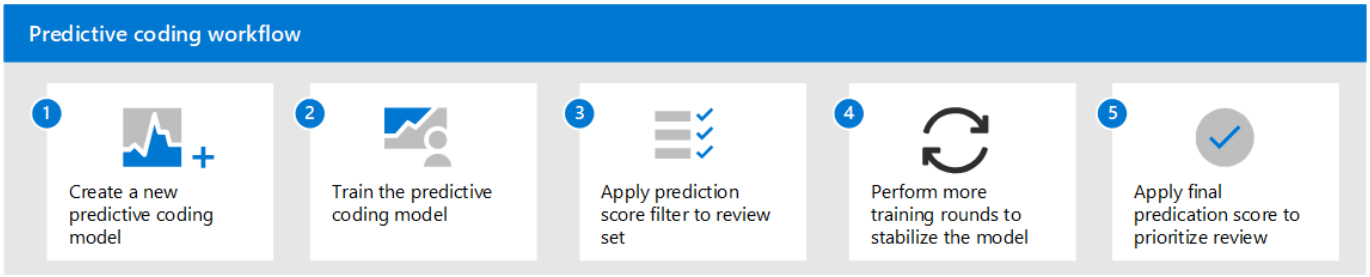
Learn about predictive coding in eDiscovery (Premium) (preview)



> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The predictive coding module in eDiscovery (Premium) uses the intelligent, machine learning capabilities to help you reduce the amount of content to review. Predictive coding helps you reduce and cull large volumes of case content to a relevant set of items that you can prioritize for review. This is accomplished by creating and training your own predictive coding models that help you prioritize the review of the most relevant items in a review set.

The predictive coding module is designed to streamline the complexity of managing a model within a review set and provide an iterative approach to training your model so you can get started faster with the machine learning capabilities in eDiscovery (Premium). To get started, you can create a model, label as few as 50 items as relevant or not relevant. The system uses this training to apply prediction scores to every item in the review set. This lets you filter items based on the prediction score, which allows you to review the most relevant (or non-relevant) items first. If you want to train models with higher accuracies and recall rates, you can continue labeling items in subsequent training rounds until the model stabilizes.

The predictive coding workflow

Here's an overview and description of each step predictive coding workflow. For a more detailed description of the concepts and terminology of the predictive coding process, see Predictive coding reference.

1. **Create a new predictive coding model in the review set**. The first step is to create a new predictive coding model in the review set. You must have at least 2,000 items in the review set to create a model. After you create a model, the system will determine the number of items to use as a *control set*. The control set is used during the training process to evaluate the prediction scores that the model assigns to items with the labeling that you perform during training rounds. The size of the control set is based on the number of items in the review set and the confidence level and margin of error values that are set when creating the model. Items in the control set never change and aren't identifiable to users.

   For more information, see Create a predictive coding model.

2. **Complete the first training round by labeling items as relevant or not relevant**. The next step is to train the model by starting the first round of training. When you start a training round, the model randomly selects additional items from the review set, which is called the *training set*. These items (both from the control set and the training set) are presented to you so that you can label each one as either "relevant" or "not relevant". Relevancy is based on the content in the item and not any of the document metadata. After you complete the labeling process in the training round, the model will "learn" based on how you labeled the items in the training set. Based on this training, the model will process the items in the review set and apply a prediction score to each one.

   For more information, see Train a predictive coding model.

3. **Apply the prediction score filter to items in review set**. After the previous training step is completed, the next step is to apply the prediction score filter to the items in the review to display the items that the model has determined are "most relevant" (alternatively, you could also use a prediction filter to display items that are "not relevant"). When you apply the prediction filter, you specify a range of prediction scores to filter. The range of prediction scores fall between **0** and **1**, with **0** being "not-relevant" and **1** being relevant. In general, items with prediction scores between **0** and **0.5** are considered "not-relevant" and items with prediction scores between **0.5** and **1** are considered relevant.

   For more information, see Apply a prediction filter to a review set.

4. **Perform more training rounds until the model stabilizes**. You can perform additional rounds of training if you want to create a model with a higher accuracy of prediction and increased recall rates. *Recall rate* measures the proportion of items the model predicted were relevant among items that are actually relevant (the ones you marked as relevant during training). The recall rate score ranges from **0** to **1**. A score closer to **1** indicates the model will identify more relevant items. In a new training round, you label additional items in a new training set. After you complete that training round, the model is updated based on new learning from your most recent round of labeling items in the training set. The model will process the items in the review set again, and apply new prediction scores. You can continue performing training rounds until your model stabilizes. A model is considered stabilized when the churn rate after the latest round of training is less than 5%. *Churn rate* is defined as percentage of items in a review set where the prediction score changed between training rounds. The predictive coding dashboard displays information and statistics that help you assess the stability of a model.

5. **Apply the "final" prediction score filter to review set items to prioritize review**. After you complete all the training rounds and stabilize the model, the last step is to apply the final prediction score to the review set to prioritize the review of relevant and non-relevant items. This is the same task that you performed in step 3, but at this point the model is stable and you don't plan on running any more training rounds.

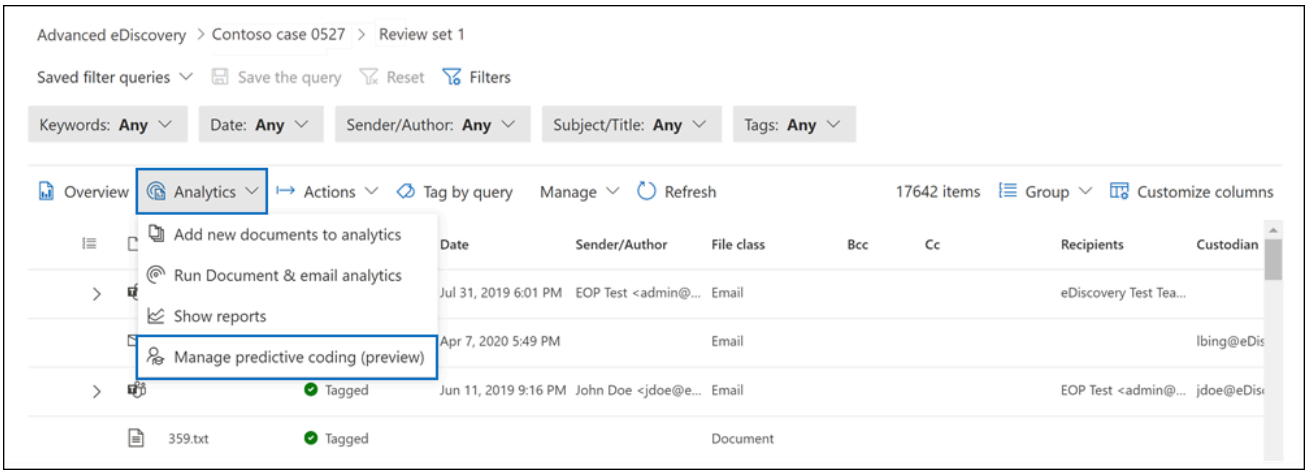
Last updated on 09/02/2025

Create a predictive coding model (preview)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The first step in using the machine learning capabilities of predictive coding in eDiscovery (Premium) is to create a predictive coding model. After you create a model, you can train it identify the relevant and non-relevant content in a review set.

To review the predictive coding workflow, see Learn about predictive coding in eDiscovery (Premium)



Before you create a model

- There must be a minimum of 2,000 items in a review set to create a predictive coding model.
- Be sure to commit all collections to the review set before you create a model. Items added to a review set after the model is created won't be processed and assigned a prediction score that generated by the model.
- Any item in the review set that doesn't contain text would won't be processed by the model or assigned a prediction score. Items with text will be included in the control set or a training set.

Create a model

1. In the Microsoft Purview portal, open an eDiscovery (Premium) case and then select the **Review sets** tab.

2. Open a review set and then select **Analytics** > **Manage predictive coding (preview)**.

3. On the **Predictive coding models (preview)** page, select **New model**.

4. On the flyout page, type a name for the model and an optional description.

5. Optionally, you can configure advanced settings (by selecting **Advanced options** on the flyout page) related to the confidence level and margin of error. These settings affect the number of items included in the control set. The *control set* is used during the training process to evaluate the prediction scores that the model assigns to items with the labeling that you perform during the training rounds. If your organization has guidelines about confidence level and margin of error for document review, specify them in the appropriate boxes. Otherwise, use the default settings.

6. Select **Save** to create the model.

   It takes a couple minutes for the system to prepare your model. After it's ready, you can perform the first round of training.

What happens after you create a model

After you create a model, the following things occur in the background during the creation and preparation of the model:

- The system calculates the number of items for the control set. This size is based on the number of items in the review set and the settings for the confidence level and the margin of error. Items for the control set are randomly selected and designated as control set items. The system includes 10 items from the control set in the first round of training.
- The system randomly selects 40 items from the review set to be included in the training set for the first round of training. Therefore, the first round of training includes 50 items for labeling: 40 items from the training set and 10 items from the control set.

Next steps

After you create a model for a review set, the next step is performing training rounds to "teach" the model to identify content that is relevant to your investigation. For more information, see Train a predictive coding model.

Last updated on 11/21/2025

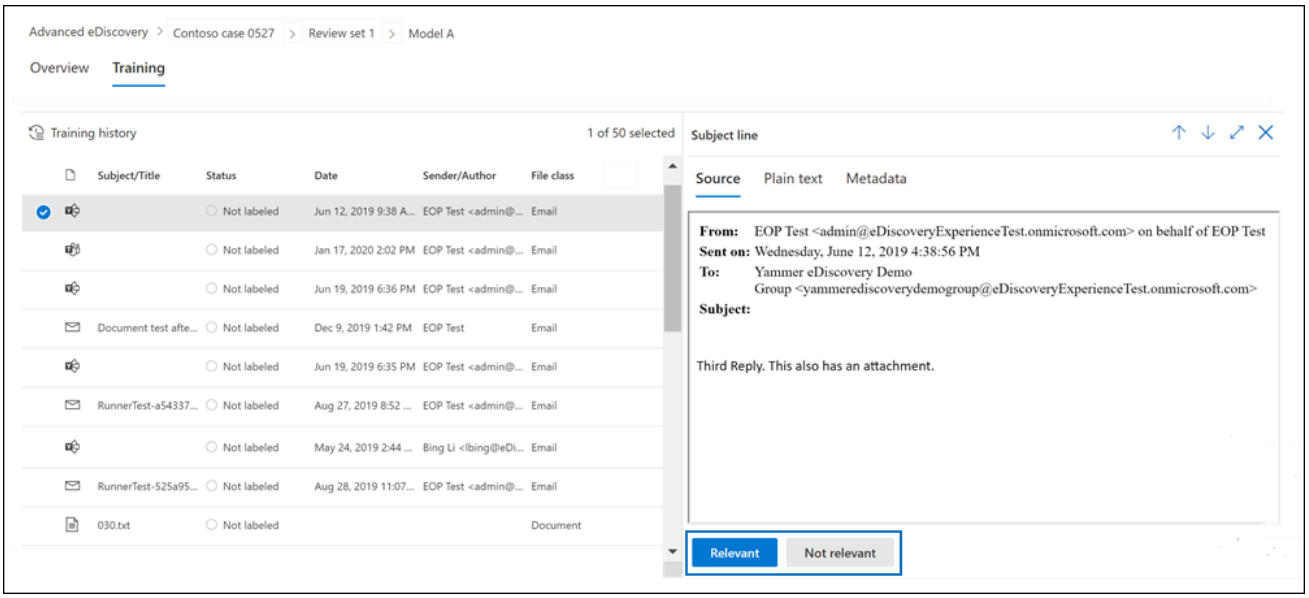
Train a predictive coding model (preview)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After you create a predictive coding model in Microsoft Purview eDiscovery (Premium), the next step is to performing the first training round to train the model on what is relevant and non-relevant content in your review set. After you complete the first round of training, you can perform subsequent training rounds to improve the model's ability to predict relevant and non-relevant content.

To review the predictive coding workflow, see Learn about predictive coding in eDiscovery (Premium)

Before you train a model



- During a training round, label items as **Relevant** or **Not relevant** based on the relevancy of the content in the document. Don't base your decision on the values in the metadata fields. For example, for email messages or Teams conversations, don't base your labeling decision on the message participants.

Train a model for the first time

1. In the Microsoft Purview portal, open an eDiscovery (Premium) case and then select the **Review sets** tab.
2. Open a review set and then select **Analytics** > **Manage predictive coding (preview)**.
3. On the **Predictive coding models (preview)** page, select the model that you want to train.
4. On the **Overview** tab, under **Round 1**, select **Start next training round**.

The **Training** tab is displayed and contains 50 items for you to label.

5. Review each document and then select **Relevant** or **Not relevant** at the bottom of the reading pane to label it.

6. After you've labeled all 50 items, select **Finish**.

   It will take a couple minutes for the system to "learn" from your labeling and update the model. When this process is complete, a status of **Ready** is displayed for the model on the **Predictive coding models (preview)** page.

Perform additional training rounds

After you perform the first round of training, you can perform subsequent training rounds by following the steps in the previous section. The only difference is the number of the training round will be updated on the model **Overview** tab. For example, after performing the first training round, you can select **Start next training round** to start the second round of training. And so on.

Each round of training (both those in progress and those that are complete) is displayed on the **Training** tab for the model. When you select a training round, a flyout page with information and metrics for the round is displayed.

What happens after you perform a training round

After you perform the first training round, a job is started that does the following things:

- Based on how you labeled the 40 items in the training set, the model learns from your labeling and updates itself to become more accurate.
- The model then processes each item in the entire review set and assigns a prediction score between **0** (not relevant) and **1** (relevant).
- The model assigns a prediction score to the 10 items in the control set that you labeled during the training round. The model compares the prediction score of these 10 items with the actual label that you assigned to the item during the training round. Based on this comparison, the model identifies the following classification (called the *Control set confusion matrix*) to assess the model's prediction performance:

Expand table

Label	Model predicts item is relevant	Model predicts item is not relevant
Reviewer labels item as relevant	True positive	False positive
Reviewer labels item as not relevant	False negative	True negative

Based on these comparisons, the model derives values for the F-score, precision, and recall metrics and the margin of error for each one. Scores for these model performance metrics are displayed on a flyout page for the training round. For a description of these metrics, see Predictive coding reference.

- Finally, the model determines the next 50 items that will be used for the next training round. This time, the model might select 20 items from the control set and 30 new items from the review set and designate them as the training set for the next round. The sampling for the next training round is not uniformly sampled. The model will optimize the sampling selection of items from the review set to select items where the prediction is ambiguous, which means the prediction score is in the 0.5 range. This process is known as *biased selection*.

What happens after you perform subsequent training rounds

After you perform subsequent training rounds (after the first training round), the model does the following things:

- The model is updated based on the labels that you applied to the training set in that round of training.
- The system evaluates the model's prediction score on the items in the control set and check whether the score aligns with how you labeled items in the control set. The evaluation is performed on all labeled items from control set for all training rounds. The results of this evaluation are incorporated in the dashboard on the **Overview** tab for the model.
- The updated model reprocesses every item in the review set and assign each item an updated prediction score.

Next steps

After you perform the first training round, you can perform more training rounds or apply the model's prediction score filter to the review set to view the items the model has predicted as relevant or not relevant. For more information, see Apply a prediction score filter to a review set.

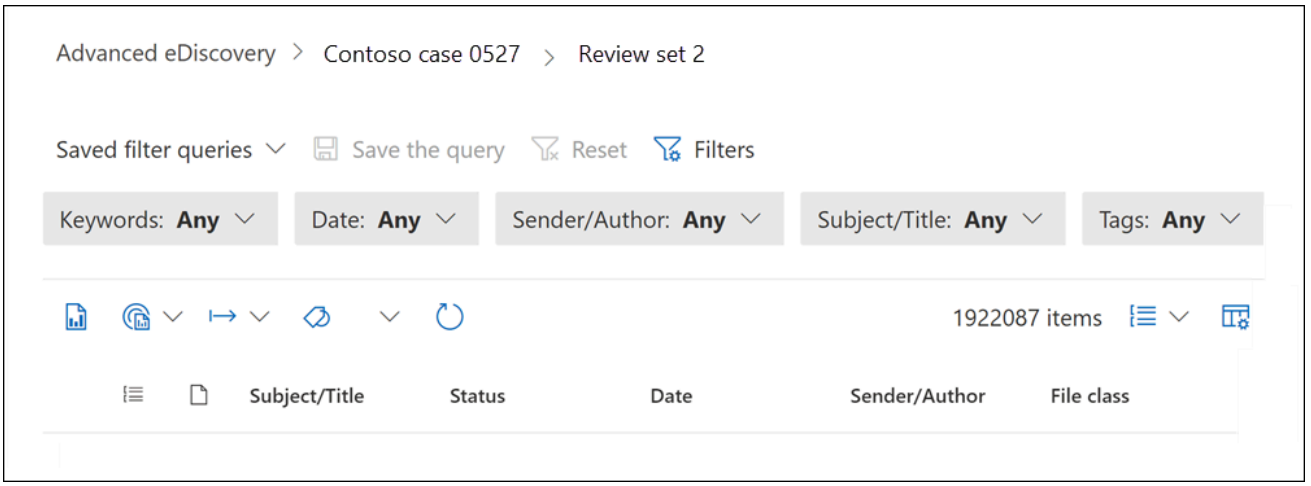
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

After you create a predictive coding model in Microsoft Purview eDiscovery (Premium) and train it to the point where it's stable, you can apply the prediction score filter to display review set items that the model has determined are relevant (or not relevant). When you create a model, a corresponding prediction score filter is also created. You can use this filter to display items assigned a prediction score within a specified range. In general, prediction scores between **0** and **.5** are assigned to items that model has predicted are not relevant. Items assigned prediction scores between **.5** and **1.0** are items the model has predicted are relevant.

Here are two ways you can use the prediction score filter:

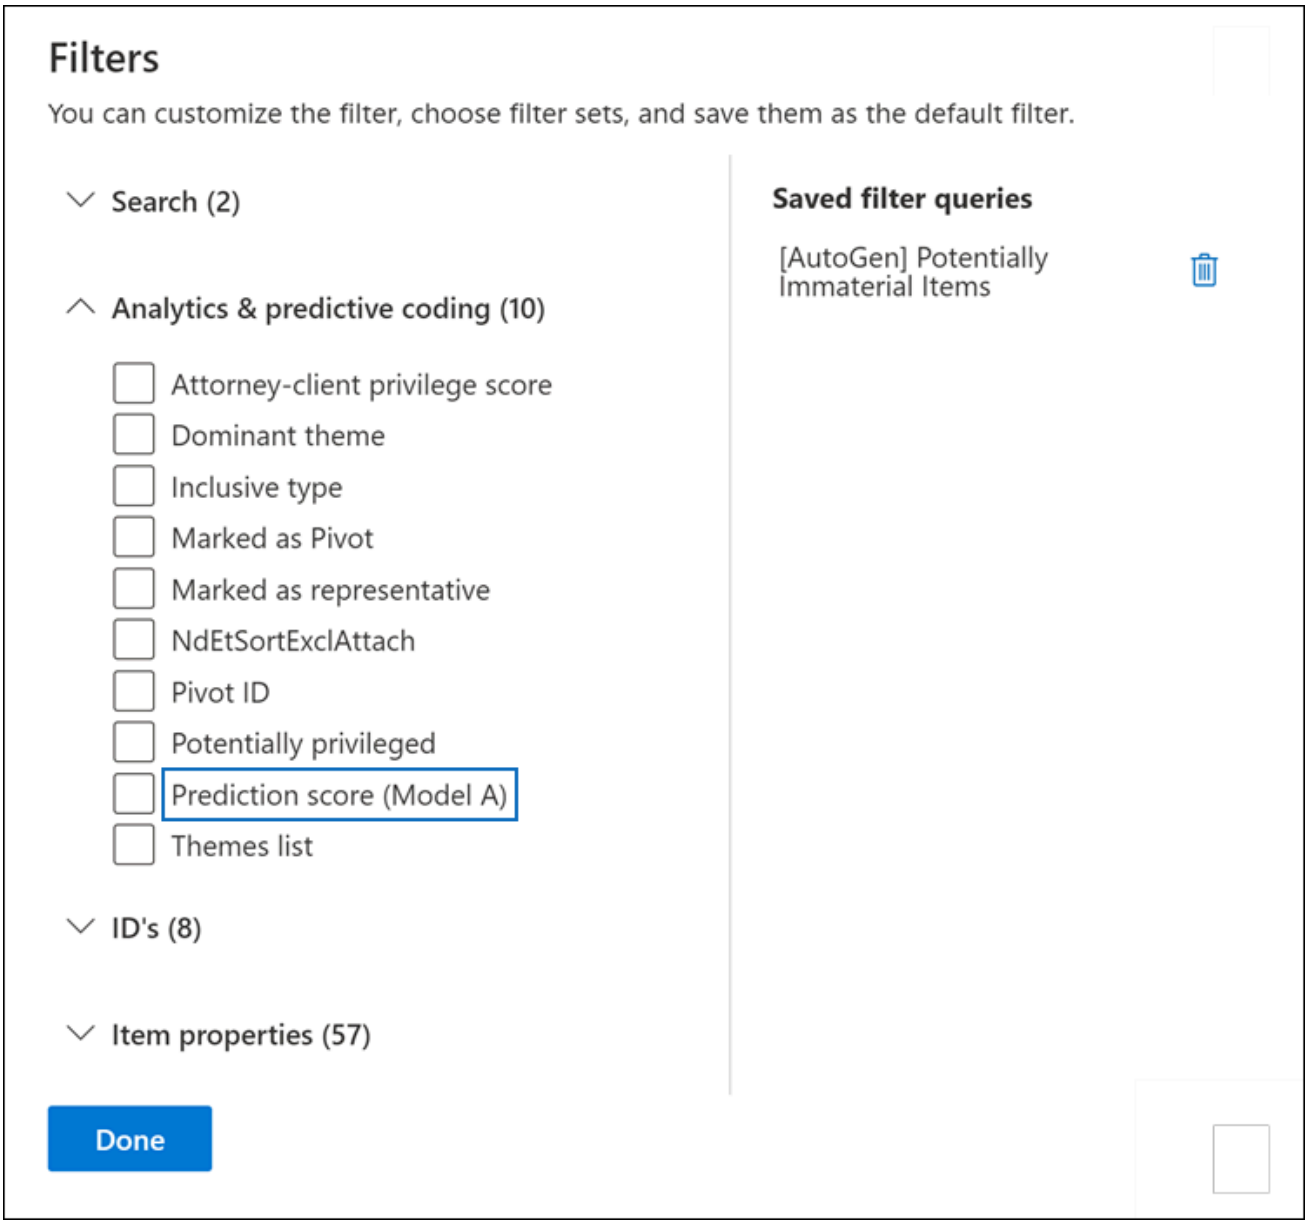


- Prioritize the review of items in a review set that the model has predicted are relevant.
- Cull items from the review set that the model has predicted aren't relevant. Alternative, you can use the prediction score filter to deprioritize the review of nonrelevant items.

Before you apply a prediction score filter

- Create a predictive coding model so that a corresponding prediction score filter is created.
- You can apply a prediction score filter after any of the training rounds. But you may want to wait after performing several rounds or until the model is stable before using the prediction score filter.

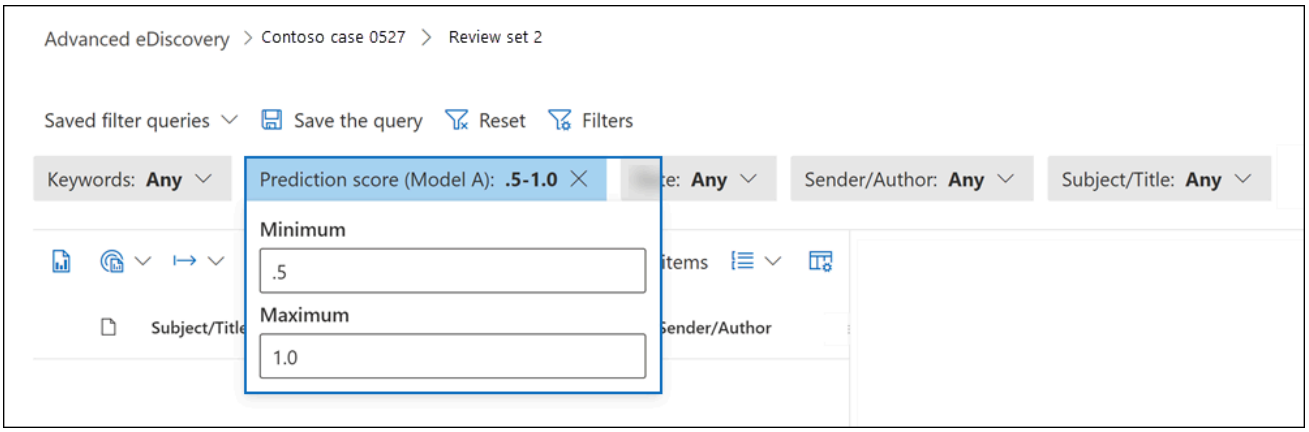
Apply a prediction score filter



1. In the Microsoft Purview portal, open the eDiscovery (Premium) case, select the **Review sets** tab, and then open the review set.

   The preloaded default filters are displayed at the top of the review set page. You can leave these set to **Any**.

2. Select **Filters** to display the **Filters** flyout page.



3. Expand the **Analytics & predictive coding** section to display a set of filters.

The naming convention for prediction score filters is **Prediction score (model name)**. For example, the prediction score filter name for a model named **Model A** is **Prediction score (Model A)**.

4. Select the prediction score filter that you want to use and then select **Done**.

5. On the review set page, select the dropdown for the prediction score filter and type minimum and maximum values for the prediction score range. For example, the following screenshot shows a prediction score range between **.5** and **1.0**.

6. Select outside the filter to automatically apply the filter to the review set.

A list of documents with a prediction score within the range you specified is displayed on the review set page.

> **Tip**
>
> To view the actual prediction score assign to a document, you can select the **Metadata** tab in the reading pane. The prediction scores for all models in the review set are displayed in the **RelevanceScores** metadata property.

More information

- For more information about using filters, see Query and filter content in a review set.

Predictive coding reference (preview)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article describes the key concepts and metrics of the predictive coding tool in Microsoft Purview eDiscovery (Premium). The sections in the article are listed in alphabetical order.

Confidence level

The confidence level is an advanced setting when you create a predictive coding model. It defines that the model's performance metrics (for example, richness, precision, and recall) fall within a specified range (that's determined the margin of error defined for the model) that's representative of the true values of the prediction scores the model assigns to items in the review set. The values for the confidence level and margin of error also help determine how many items are included in the control set. The default value for the confidence level is 0.95% or 95%.

Control set

A control set is used during the training process of a predictive coding model. The control set is to evaluate the prediction scores that the model assigns to items with the labeling that you perform during training rounds. The size of the control set is based on the number of items in the review set and the confidence level and margin of error values that are set when creating the model. Items in the control set never change and aren't identifiable to users. The total number of items in the control set is displayed on the flyout page for a training round.

Control set confusion matrix

After you complete a training round, the model assigns a prediction score to the 10 items in the control set that you labeled during the training round. The model compares the prediction score of these 10 items with the actual label that you assigned to the item during the training round. Based on this comparison, the model identifies the following classifications to assess the model's prediction performance:

Expand table

Label	Model predicts item is relevant	Model predicts item isn't relevant
Reviewer labels item as relevant	True positive	False positive
Reviewer labels item as not relevant	False negative	True negative

Based on these comparisons, the model derives values for the F-score, precision, and recall metrics and the margin of error for each one. The number of each of the confusion types from the matrix is displayed on the flyout page for a training round.

F-score

The F-score is a weighted average of the scores for the precision and recall metrics. The range of scores for this metric is from **0** to **1**. A score closer to **1** indicates the model will more accurately detect relevant items. The F-score metric is displayed on the model dashboard and on the flyout page for each training round.

Margin of error

The margin of error is an advanced setting when you create a predictive coding mode. It specifies the degree of error in performance metrics (for example, richness, precision, and recall) that's derived from the random sampling of items in your control set. A lower margin of error requires a larger control set to ensure that the model's performance metrics fall within a smaller range. The values for the margin of error and confidence level also help determine how many items are included in the control set. The default value for the margin of error is 0.05% or 5%.

Model stability

Model stability indicates the model's ability to accurately predict whether a document in a review set is relevant or not relevant. When a model is unstable, more training rounds may need to be performed to include the model's stability. When the model is stable, no more training rounds may need to be performed. The model dashboard indicates the current state of the model's stability. When a model is stable, the performance metrics have reached a level that matches the settings for the confidence level and margin of error.

Overturn rate

The overturn rate is the percentage of items in the review set where the prediction score changed between training rounds. A model is considered stable when the overturn rate is less than 5%. The overturn rate metric is displayed on the model dashboard and on the flyout page for each training round. The overturn rate for the first training round is zero because there isn't a previous prediction score to overturn.

Precision

The precision metric measures the proportion of items that are relevant among the items the model predicted were relevant. This means that items in the control set where label as relevant by the reviewer and predicted as relevant by the model. The range of scores for this metric is from **0** to **1**. A score closer to **1** indicates the model will identify fewer non-relevant items. The precision metric is displayed on the model dashboard and on the flyout page for each training round.

Prediction score

This is the score that a model assigns to each document in a review set. The score is based on the document's relevance compared to model's learning from the training rounds. In general, items with prediction scores between **0** and **0.5** are considered not relevant and items with prediction scores between **0.5** and **1** are considered relevant. The prediction score is contained in a document metadata field. You can use a prediction filter to display the items in a review set that fall within a specified prediction range.

Recall

The recall metric measures the proportion of items the model predicted were relevant among items that are relevant. This means that relevant items in the control set that the model predicted were also labeled as relevant by the reviewer. The range of scores for this metric is from **0** to **1**. A

score closer to **1** indicates the model will identify a larger portion of relevant items. The recall metric is displayed on the model dashboard and on the flyout page for each training round.

Review set

A review set provides the scope of a predictive coding model. When you create a new model for the review set, items for the control set and training sets are selected from the review set. When the model assigns prediction scores, it assigns those scores the items in the review. You have to add all items to the review set before you create a predictive coding model. If you add items after you create a model, those items won't be assigned a prediction score.

Richness

The richness metric measures the percentage of review set items the model predicts as relevant. The range of scores for this metric is from **0** to **1**. The richness metric is displayed on the model dashboard.

Sampled items

The term *sampled items* is a reference to random sample of items in a review set (that contains text) that are selected and associated with the control set when you create a predictive coding model. A random sample of items is also selected for each training round. Items selected for the control set of a model are never included in a training set for that same model. The reverse is also true: training set items are never included in the control set.

Training set

The model randomly selects items from the review set and adds them to a training set. During a training round, items from the training set (in addition to items from the control set) are presented to you so that you can label each one as either "relevant" or "not relevant". This labeling or "training" process helps the model learn how to predict which items in the review are relevant or not relevant. Each time you perform a training round, the model selects more items from the review and adds them to the training set for that training round. Items from the control set are never selected for a training set.

Export case data in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

There are three ways to export data from a review set:

Download: Download (by using a browser) a small set of native files. This is the quickest way to export a small set of data. This method preserves the native file names. For more information, see Download documents from a review set.

Export: Customize what data is exported. This includes exporting file metadata, native files, text files, and redacted documents that have been saved to a PDF file. Once the exported data is prepared, you can download the data from the **Export** tab to a local computer. For more information, see Export documents from a review set

Add to another review set: Copy data from one review set to a different review set. For more information, see Add data from one review set to another review set.

> **Note**
>
> In Microsoft 365, data is hashed and those hashes are provided in the output file for verification purposes. This is supplemented by audit logs and reporting functionality, such as collection statistics, load set reports, and export reports (including the export load file).

Last updated on 11/21/2025

Download selected documents from a review set

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Download offers a simple way to download content from a review set in native format. The download tool in eDiscovery (Premium) uses the browser's data transfer features. A browser prompt appears when a download is ready.

Files downloaded using this method are zipped in a container file, and this file contains item-level files. It means that if you select to download an attachment, you receive the email message with the attachment included. Similarly, if you export an Excel spreadsheet that is embedded in a Word document, the Word document and the embedded Excel spreadsheet are included in the download.

When you download items, the *Last Modified Data* property is preserved and can be viewed as a file property.

> **Important**
>
> Downloading an item from a review set does not preserve the item metadata. Item metadata is only preserved when exporting items from a review set.

To download a review set item from a review set in an eDiscovery (Premium) case, start by selecting the item you want to download and select **Download original** from the item menu.

> **Important**

To download original items from a review set, you must be assigned the *Export* role or be assigned to a role group that includes the *Export* role. For more information about eDiscovery permissions, see **Assign eDiscovery permissions in the Microsoft Purview portal**.

To download multiple items from a review set at the same time, select the items you want to download then export the selected documents from the review set.

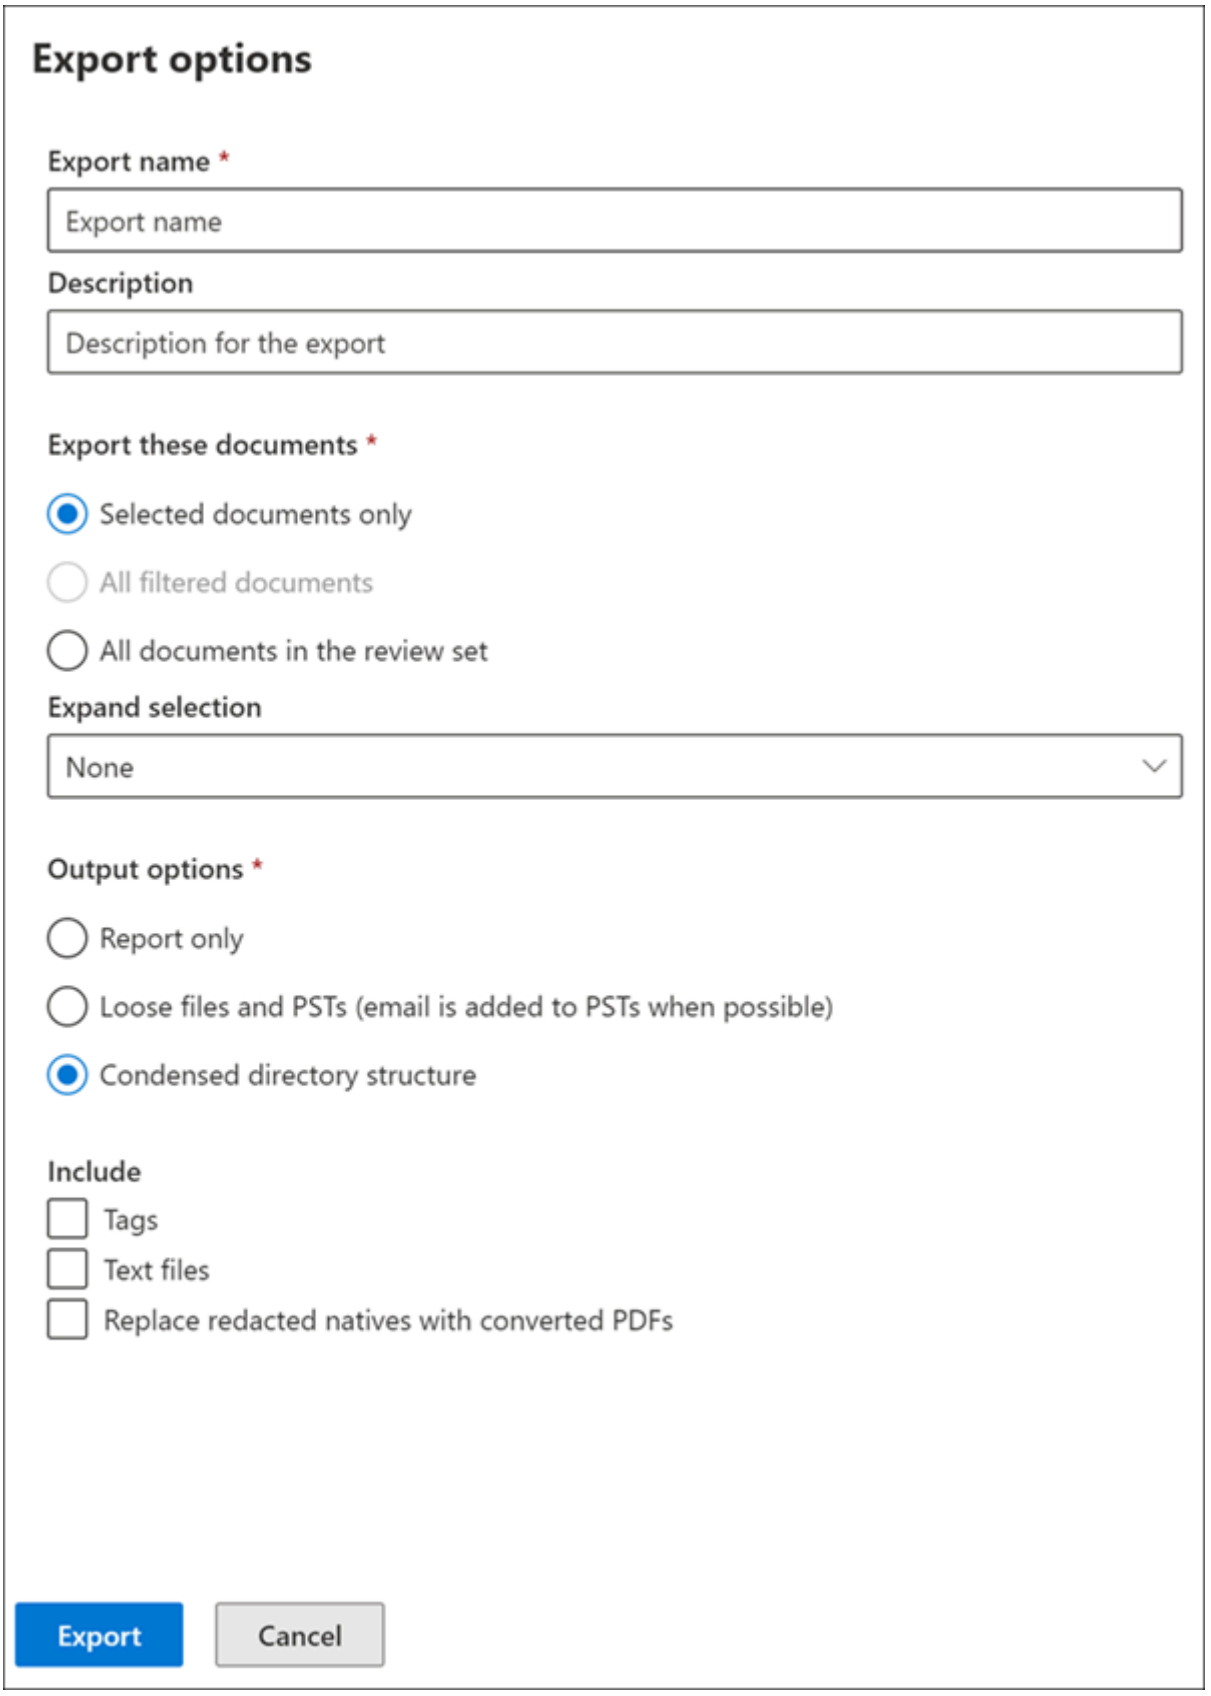
Export documents from a review set in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.



Export allows users to customize the content that is included in the download package when you export document from a review set in eDiscovery (Premium).

To export documents from a review set:

> **Important**
>
> Exporting documents to your Azure Storage locations in eDiscovery was permanently **retired on August 31, 2025**, this functionality isn't available in the new eDiscovery experience.

1. In the Microsoft Purview portal, open the eDiscovery (Premium) case, select the **Review sets** tab, and then select the review set that you want to export.
2. In the review set, select the items to export.
3. Select **Action** > **Export**.

   The Export tool displays the flyout page with the settings to configure the export. Some options are selected by default, but you can change these. See the following section for descriptions of the export options that you can configure.

4. After you configure the export options, select **Export** to start the export process. Depending on the option that you selected in **Output options** section, you can access the export files by direct download or in your organization's Azure Storage account.

> ⓘ **Note**

Export jobs are retained for the life of the case. However, you must download the content from an export job within 30 days after the export job is complete.

Export options

Use the following options to configure the export. Not all options are allowed for some output options, most notably, the export of text files and redacted PDFs aren't allowed when exporting to the PST format.

- **Export name**: Name of the export job. This is used to name the ZIP files that will be downloaded.
- **Description**: Free-text field for you to add a description.
- **Export these documents**
  - *Selected documents only*: This option exports only the documents that are currently selected. This option is only available when items are selected in a review set.
  - *All filtered documents*: This option exports the documents in an active filter. This option is only available when a filter is applied to the review set.
  - *All documents in the review set*: This option exports all documents in the review set.
- **Expand selection**: Use the following options to export additional items that are related to filtered/selected items in the review set:
  - *None*: This option doesn't export the family items or conversation items. It only exports the items that are selected or to all items in the review set list.
  - *Include associated family items*: This option includes associated family items. Family items are items that share the same *FamilyId* metadata property value. For example, a document that's attached to an email message shares the same *FamilyId* as the email message. If this option is selected, the email message and the document are exported in this example, even though the document might not be included in the list of review set items.
  - *Include associated conversation items*: This option includes associated items that are in the same Teams or Viva Engage conversation. Conversation items are items that share the same *ConversationId* metadata property value. All messages, posts, and corresponding transcript file of a conversation share the same *ConversationId*.

  If any option other than *None* is selected, all items that share the same association ID are exported, even though some of those items might not be in the results of the current review

set query. For more information about conversation items, see eDiscovery (Premium) workflow for content in Microsoft Teams.

- **Output options**: Exported content is either available for download directly through a web browser or can be sent to an Azure Storage account. The first two options enable direct download.
  - *Reports only*: Only the summary and load file are created.
  - *Loose files and PSTs (email is added to PSTs when possible)*: Files are exported in a format that resembles the original directory structure seen by users in their native applications. For more information, see the Loose files and PST export structure section.
  - *Condensed directory structure*: Files are exported and included in the download.
  - *Condensed directory structure exported to your Azure Storage account*: Files are exported to your organization's Azure Storage account. For this option, you have to provide the URL for the container in your Azure Storage account to export the files to. You also have to provide the shared access signature (SAS) token for your Azure Storage account. For more information, see Export documents in a review set to an Azure Storage account.

    > **Note**
    >
    > Condensed output options include all extracted items. The item count for condensed output is always more than the *Loose files and PSTs* option because email and attachments are counted differently. For example, for an email with two attachments, the condensed output results in 3 items (1 item for the email and 1 item for each attachment) while the *Loose files and PSTs* option would result in 1 item for the email and all attachments.

- **Include**
  - *Tags*: When selected, tagging information is included in the load file.
  - *Text files*: This option includes the extracted text versions of native files in the export.
  - *Replace redacted natives with converted PDFs*: If redacted PDF files are generated during review, these files are available for export. You can choose to export only the native files that were redacted (by not selecting this option) or you can select this option to export the PDF files that contain the actual redactions.

The following sections describe the folder structure for loose files and condensed directory structure options. Exports are partitioned into ZIP files with a maximum size of uncompressed

content of 75 GB. If the export size is less than 75 GB, the export consists of a summary file and a single ZIP file. For exports larger than 75 GB of uncompressed data, multiple ZIP files are created. Once downloaded, the ZIP files can be uncompressed into a single location to recreate the full export.

Loose files and PST export structure

If you select this export option, the exported content is organized in the following structure:

- **Summary.csv**: Includes a summary of the content exported from the review set. This file is structured with the following columns:
  - *Total*: The number of the items found in the review set.
  - *Actual*: he number of items fetched in the package for the export.
  - *Errors*: The number of errors and warnings. More information can be found in the errors and warnings file. The warning and error file contains important information about the items that weren't exported. Check this file to make sure you understand which files have issues.
  - *Skipped Processing*: The number of items skipped for processing.

    > ⓘ **Note**
    >
    > Skipped processing also contains the number of extracted child items for PST format. For example, a review set has two items, one corresponding to an email and one corresponding to an attachment. When the file is converted to the PST, it is mappped to one item only (the mail item). This results in skipping the child attachment.

  - *Export Containers*: This contains the list of .zip and .pst files created for the export.
- Root folder: This folder in named [Export Name] x of z.zip and is repeated for each .zip file partition. The root folder contains the following:
  - *Export_load_file_x of z.csv*: The metadata file.
  - *Warnings and errors x of z.csv*: This file includes information about errors encountered when trying to export from the review set.
- **Exchange**: This folder contains all content from Exchange stored in PST files. Redacted PDF files can't be included with this option. If an attachment is selected in the review set, the parent email message is exported with the attachment attached.

  The Exchange folder may also contain a subfolder named mailboxname_loosefiles.zip, which contains the following items:

- Information Rights Management (IRM) protected messages that have been decoded.
- Error-remediated messages.
- Modern attachments or links referenced in messages.
- Encrypted items (which aren't included in the PST files in the Exchange folder).

- **SharePoint**: This folder contains all native content from SharePoint in a native file format. Redacted PDF files can't be included with this option.

> ⓘ **Note**
>
> The *Group* option selected in the review set determines which items are included in the content exported from the review set. If *None* is selected, the exported content only includes the selected or filtered items. If *Group by family* is selected, the exported content includes all items in the family.

Condensed directory structure

- **Summary.csv**: Includes a summary of the content exported from the review set. This file is structured with the following columns:
  - *Total*: The number of the items found in the review set.
  - *Actual*: he number of items fetched in the package for the export.
  - *Errors*: The number of errors and warnings. More information can be found in the errors and warnings file.
  - *Skipped Processing*: The number of items skipped for processing.

    > ⓘ **Note**
    >
    > Skipped processing also contains the number of extracted child items for PST format. For example, a review set has two items, one corresponding to an email and one corresponding to an attachment. When the file is converted to the PST, it is mappped to one item only (the mail item). This results in skipping the child attachment.

  - *Export Containers*: This contains the list of .zip and .pst files created for the export.

- **Root folder**: This folder in named [Export Name] x of z.zip and will be repeated for each ZIP file partition.
  - *Export_load_file_x of z.csv*: The metadata file and also includes the location of each file that is stored in the ZIP file

- *Warnings and errors x of z.csv*: This file includes information about errors encountered when trying to export from the review set.
- *NativeFiles*: This folder contains all the native files that were exported. Natives files are replaced with redacted PDFs if you selected the *Replace redacted natives with converted PDFs* option.
- *Error_files*: This folder contains files that had either extraction or other processing error. The files are placed into separate folders, either ExtractionError or ProcessingError. These files are listed in the load file.
- *Extracted_text_files*: This folder contains all of the extracted text files that were generated at processing.

Condensed directory structure exported to your Azure Storage Account

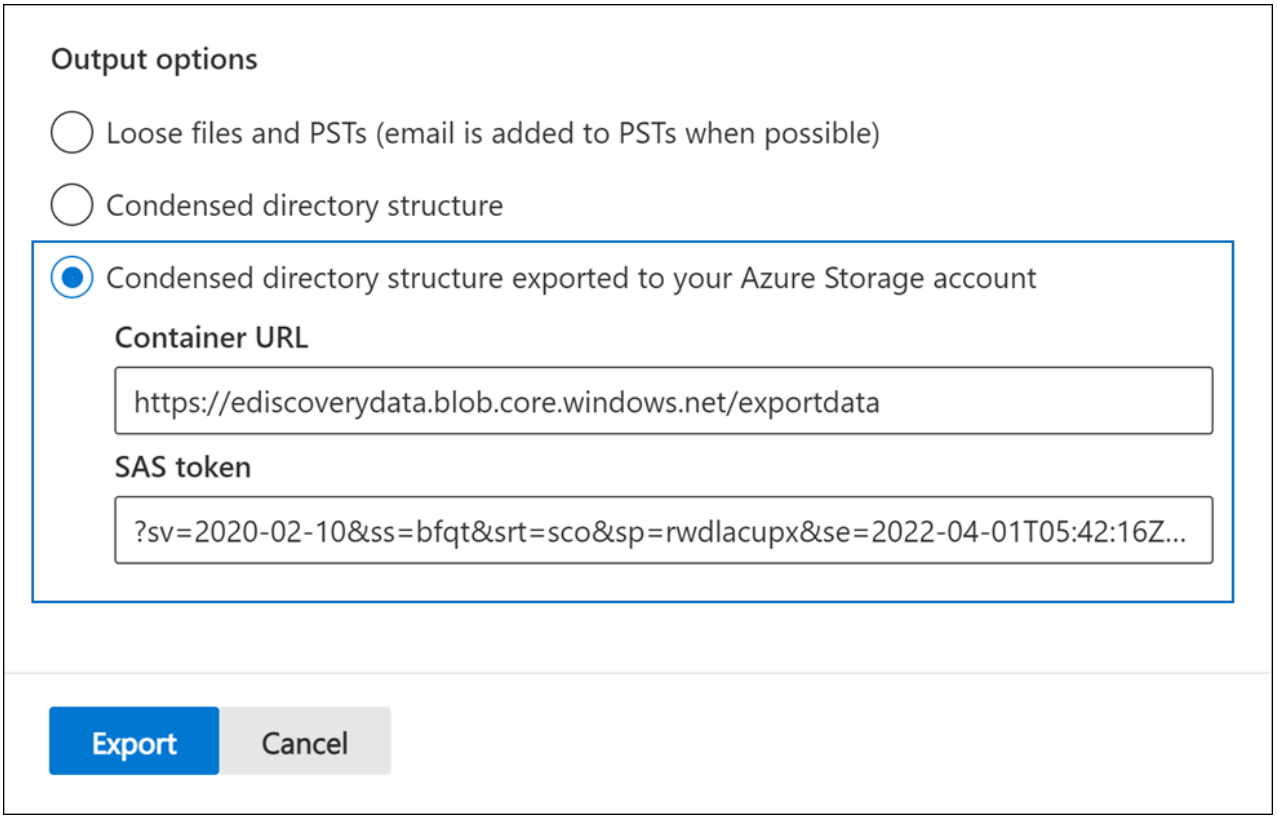
This option uses the same general structure as the *Condensed directory structure*, the contents are zipped and the data is saved to your Azure Storage account. This option is used when working with a third-party eDiscovery provider. For details about how to use this option, see Export documents in a review set to an Azure Storage account.

Last updated on 09/02/2025

Export documents in a review set to an Azure Storage account

When you export documents from a review set in an eDiscovery (Premium) case, you have the option to export them to an Azure Storage account managed by your organization. If you use this option, the documents are uploaded to your Azure Storage location. After they're exported, you can access the documents (and download them to a local computer or other location) by using the Azure Storage Explorer.

This article provides instructions for how to export documents to your Azure Storage account and the use the Azure Storage Explorer to connect to an Azure Storage location to download the exported documents. For more information about Azure Storage Explorer, see Use Azure Storage Explorer.



Before you export documents from a review set

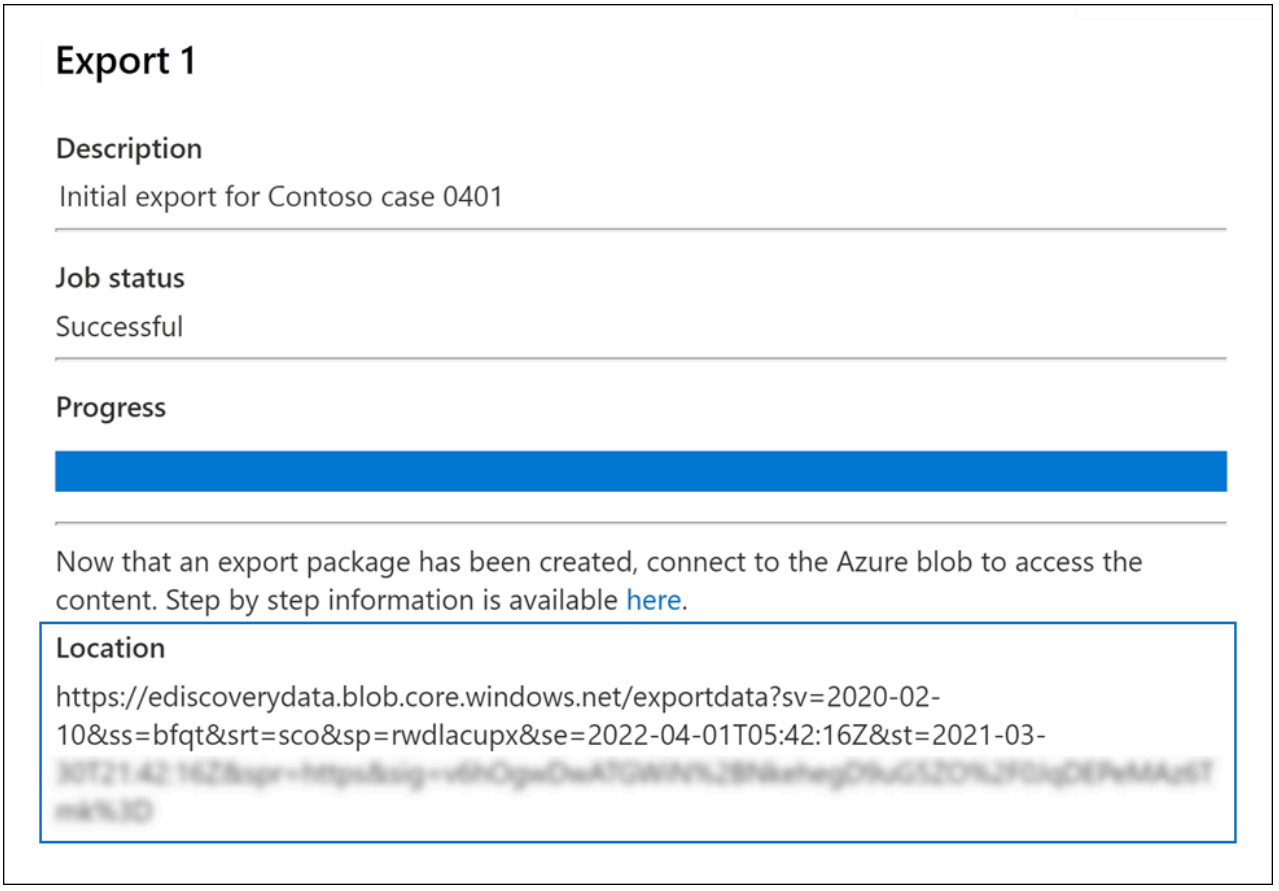
- You need to provide a shared access signature (SAS) token for your Azure Storage account and the URL for a specific container in the storage account to export documents from a review set. Be sure to have these at hand (for example, copied to a text file) when you perform Step 2.
    - **SAS token**: Be sure to get the SAS token for your Azure Storage account (and not for the container). You can generate an SAS token for your account in Azure Storage. To do this, go to the Azure Storage account, and select **Share access signature** under the **Settings** settings in the storage account blade. Make sure you've configured *Add*, *Create*, *Delete*, *Read*, and *Write* permissions and allow all resource types when you generate the SAS token.
    - **Container URL**: You need to create a container to upload the review set documents to, and then get a copy of the URL for the container; for example, `https://ediscoverydata.blob.core.windows.net/exportdata`. To get the URL, go to the container in Azure Storage, and select **Properties** under the **Settings** section in the container blade.
- Download and install the Azure Storage Explorer. For instructions, see Azure Storage Explorer tool. You use this tool to connect to the container in your Azure Storage account and download the documents that you exported in Step 1.

Step 1: Export the documents from a review set

The first step is to create an export job to export documents out of a review set. For more detailed instructions about all the export options, see Export documents from a review set. The following procedure highlights the settings to export documents to your organization's Azure Storage account.

1. In the Microsoft Purview portal, open the eDiscovery (Premium) case, select the **Review sets** tab, and then select the review set that you want to export.
2. In the review set, select **Action** > **Export**.
3. On the **Export options** flyout page, type a name (required) and description (optional) for the export.
4. Configure the settings in the documents, metadata, content, and options sections. For more information about these settings, see Export documents from a review set.
5. In the **Output options** section, select the **Condensed directory structure exported to your Azure Storage account** option.
6. Paste the container URL and the SAS token for your storage account in the corresponding fields.

> **Important**
>
> If the container URL contains unsupported or invalid characters, you'll receive an error when creating the export job. For more information about these characters, see



Keyword queries and search conditions for eDiscovery.

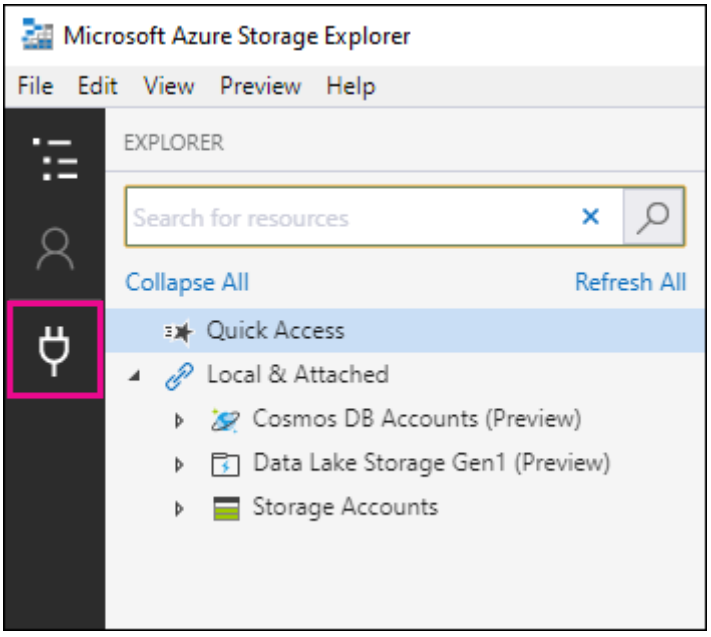
7. Select **Export** to create the export job.

Step 2: Obtain the SAS URL from the export job

The next step is to obtain the SAS URL that's generated after you create the export job in Step 1. You use the SAS URL to connect to the container in your Azure Storage account that you exported the review set documents to.

1. On the **eDiscovery (Premium)** page, go to the case, and then select the **Exports** tab.
2. On the **Exports** tab, select the export job that you want to download. This is the export job that you created in Step 1.
3. On the flyout page, under **Locations**, copy the SAS URL that's displayed. If necessary, you can save it to a text file so you can access it in Step 3.

Tip

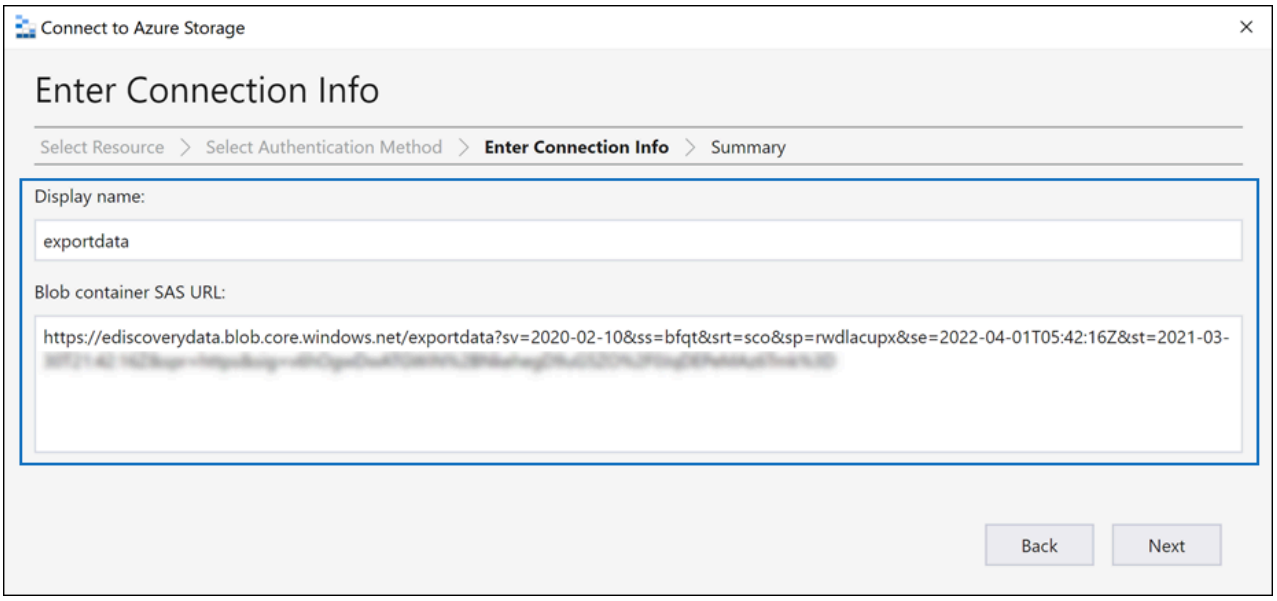


> The SAS URL that's displayed in the export job is a concatenation of the container URL and the SAS token for your Azure Storage account. You can copy it from the export job or create it yourself by combining the URL and the SAS token.

Step 3: Connect to the Azure Storage container

The final step is to use the Azure Storage Explorer and the SAS URL to connect to the container in your Azure Storage account and download the exported documents to a local computer.

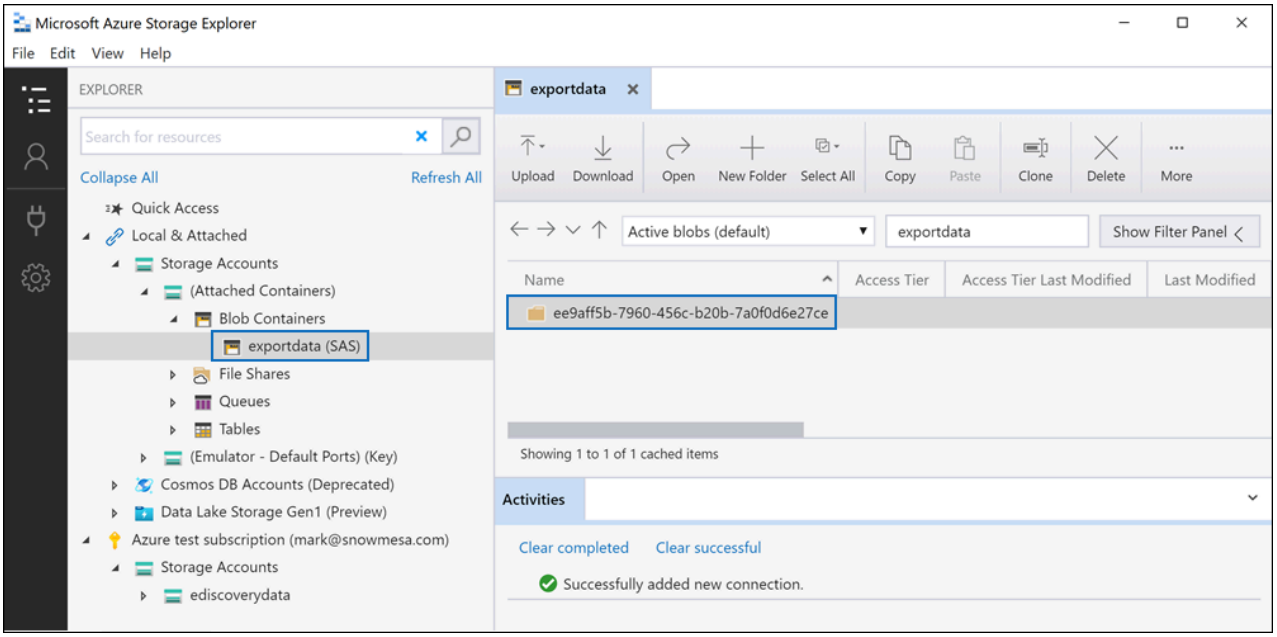
1. Start the Azure Storage Explorer that you downloaded and installed.



2. Select the **Open Connect Dialog** icon.

3. On the **Connect to Azure Storage** page, select **Blob container**.

4. On the **Select Authentication Method** page, select the **Shared access signature (SAS)** option, and then select **Next**.



5. On the **Enter Connection Info** page, paste the SAS URL (that you obtained in the export job in Step 2) in the **Blob Container SAS URL** box.

Notice that the container name is displayed in the **Display name** box. You can edit this name.

6. Select **Next** to display the **summary** page and then select **Connect**.

   The **Blob containers** node (under **Storage Accounts** > **(Attached Containers)** > is opened.

It contains a container named with the display name from Step 5. This container contains a folder for each export job that you've downloaded to the container in your Azure Storage account. These folders are named with an ID that corresponds to the ID of the export job. You can find these export IDs (and the name of the export) under **Support information** on the flyout page for each **Preparing data for export** job listed on the **Jobs** tab in the eDiscovery (Premium) case.

7. Double-click the export job folder to open it.

A list of folders and export reports is displayed.

8. To export all contents from the export job, select the **Up** arrow to go back to the export job folder, and then select **Download**.

9. Specify the location where you want to download the exported files, and then select **Select folder**.

   The Azure Storage Explorer starts the download process. The status of the downloading the exported items is displayed in the **Activities** pane. A message is displayed when the download is complete.

> ⓘ **Note**
>
> Instead of downloading the entire export job in Azure Storage Explorer, you can select specific items to download and view.

More information

- The export job folder contains the following items. The actual items in the export folder are determined by the export options configured when the export job was created. For more information about these options, see Export documents from a review set.
  - Export_load_file.csv: This CSV file is a detail export report that contains information about each exported document. The file consists of a column for each metadata property for a document. For a list and description of the metadata that's included in this report, see the **Exported field name** column in the table in Document metadata fields in eDiscovery (Premium).

- Summary.txt: A text file that contains a summary of the export including export statistics.
- Extracted_text_files: This folder contains a text file version of each exported document.
- NativeFiles: This folder contains a native file version of each exported document.
- Error_files: This folder includes the following items when the export job contains any error files:
  - ExtractionError.csv: This CSV file contains the available metadata for files that weren't properly extracted from their parent item.
  - ProcessingError: This folder contains documents with processing errors. This content is at an item level, which means if an attachment had a processing error, the document that contains the attachment will also be included in this folder.

Last updated on 03/24/2026

Manage jobs in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Jobs report

eDiscovery (Premium) includes a jobs report that lists all jobs that count towards case jobs concurrency and daily limits in eDiscovery for a defined time period. *eDiscovery administrators* and *eDiscovery Managers* (preview) can access this report on the **Reports** > **Jobs report** tab and can use this report to see the job activities across Content Search activities and eDiscovery (Standard and Premium) cases. *eDiscovery Managers* (preview) can view the jobs usage cards at the top of the report, but the jobs list is limited to the cases to which they're assigned.

> **Important**
>
> Jobs listed on the report can't be deleted or removed. Long-running jobs automatically time out after 7 days.

The job report summarizes the following key information for jobs up to the last 30 days:

- All jobs that are in progress or completed (successfully or with error) in a specified time range across eDiscovery Standard and Premium.
- Insights into how far away your organization is from reaching job-related organization-wide limits.
- Creates a .csv report for the list of jobs.
- Filters for job types, statuses, and for hours/days.
- Quick access to case/job pages by selecting case name links.

The following eDiscovery (Premium) job types currently don't count towards the concurrency/daily limits and aren't shown in the report:

- Prepare for export
- Run analytics
- Tag Items
- Compare load sets
- Convert redacted items to PDF
- Relevance train and Relevance load
- Prepare remediation

> **Note**
>
> Any jobs included in the list view of the report and that have run for more than 24 hours do not contribute towards the concurrency/daily limits for your organization.

The following eDiscovery (Premium) jobs started in classic cases don't contribute to throttling limits and aren't reflected in the report. However, these jobs started for cases in the New case format are included in the report:

- Adding non-Microsoft 365 data to a review set
- Adding remediated data to a review set
- Re-indexing custodian data
- Adding data to a review set
- Adding data to another review set

Job types and descriptions

Long-running processes are associated with specific jobs that support cases, collections, and reporting in Microsoft Purview eDiscovery (Premium). These jobs are triggered by user actions when using and managing cases and collections.

Expand table

Job type	Description
Add external data	A user uploads non-Microsoft 365 data to a review set. The data is also indexed during this process. For example, files from an on-premises file server or a client computer are uploaded to a review set. For more information, see Load non-Microsoft 365 data into a review set.

Job type	Description
Add items to another review set	A user adds documents from one review set to a different review set in the same case. For more information, see Add data to a review set from another review set.
Add items to review set	A user adds a collection to a review set. This job consists of two sub jobs: - **Export** - A list of items in the collection is generated. - **Ingestion & Indexing** - The items in the collection that match the search query are copied to an Azure Storage location (in a process called *ingestion*) and then those items in the Azure Storage location are reindexed. This new index is used when querying and analyzing items in the data set. For more information, see Add search results to a review set.
Adding remediated items to a review set	Data with processing errors is remediated and loaded back into a review set. For more information, see: • Error remediation when processing data • Single item error remediation
Apply holds	A user adds custodial and non-custodial sources on the Data sources page and places them on hold. This triggers an Apply holds job. For more information, see, Work with custodians in eDiscovery (Premium).
Compare load sets	A user looks at the differences between different load sets in a review set. A load set is an instance of adding data to a review set. For example, if you add the results of two different searches to the same review set, each would represent a load set.
Converting redacted items to PDF	After a user annotates a document in a review set and redacts a portion of it, they can choose to convert the redacted document to a PDF file. This ensures that the redacted portion won't be visible if the document is exported for presentation. For more information, see View documents in a review set.
Create conversation PDFs	When a user adds the results of a search to a conversation review set, instant message conversations (also called threaded conversations) in services like Microsoft Teams are reconstructed in a PDF file. This job is also triggered when a user selects **Action** > **Create conversation PDFs in a review set**. For more information, see Review conversations in eDiscovery (Premium).
Prepare search estimates	After a user creates and runs or reruns a collection estimate, the search tool searches the index for items that match the search query and prepares an estimate that includes the number and total size of all items by the search, and the number of data sources searched. For more information, see Collect data for a case.
Import custodians	User imports multiple custodians at once by uploading a CSV file that contains the information necessary to add them to a case. For more information, see Import custodians to an eDiscovery (Premium) case.
Preparing for export	A user exports documents from a review set. When the export process is complete, they can download the exported data to a local computer. For more information, see Export

Job type	Description
	case data.
Prepare remediation	When a user selects a file and creates a new error remediation in the Error view on the Processing tab of a case, the first step in the process is to upload the file that has the processing error to an Azure Storage location in the Microsoft cloud. This job tracks the progress of the upload process. For more information about the error remediation workflow, see Error remediation when processing data.
Prepare search preview	After a user creates and runs a new collection estimate (or reruns an existing collection estimate), the search tool prepares a sample subset of items (that match the search query) that can be previewed. Previewing search results help you determine the effectiveness of the search. For more information, see Learn about collections in eDiscovery.
Purge data	Use eDiscovery (Premium) and the Microsoft Graph Explorer to search for and delete chat messages in Microsoft Teams. This feature can help you find and remove sensitive information or inappropriate content. This search and purge workflow will also help you respond to a data spillage incident, when content containing confidential or malicious information is released through Teams chat messages.
Reindex data sources	When you add custodial or non-custodial data sources to a case, all partially indexed items in the selected data source locations are reindexed by a process called *Advanced indexing*. This job is also triggered when you select **Update index** on the **Processing** tab of a case, and when you update the index for a specific data source on the properties flyout page. For more information, see Advanced indexing of custodian data.
Relevance load	This job is triggered when user starts a "new model" - Review set > Manage predictive coding models (preview). It sets up the machine learning model. After you create a model, the following things occur in the background during the creation and preparation of the model: - The system calculates the number of items for the control set. This size is based on the number of items in the review set and the settings for the confidence level and the margin of error. Items for the control set are randomly selected and designated as control set items. The system includes 10 items from the control set in the first round of training. - The system randomly selects 40 items from the review set to be included in the training set for the first round of training. Therefore, the first round of training includes 50 items for labeling: 40 items from the training set and 10 items from the control set.
Run analytics	A user analyzes data in a review set by running eDiscovery (Premium) analytics tools such as near duplicate detection, email threading analysis, and themes analysis. For more information, see Analyze data in a review set.
Tag items	This job is triggered when a user selects **Start tagging job** in the **Tagging panel** when reviewing documents in a review set. A user can start this job after tagging documents in a review set and then bulk-selecting them in the view document panel. For more information, see Tag documents in a review set.

Job status

The following table describes the different status states for jobs:

Expand table

Status	Description
Submitted	A new job was created. The date and time that the job was submitted is displayed in the **Created** column on the **Jobs** tab.
Submission failed	The job submission failed. You should attempt to rerun the action that triggered the job.
In progress	The job is in progress, you can monitor the progress of the job in the **Jobs** tab.
Successful/Completed	The job was successfully completed. The date and time that the job completed is displayed in the **Completed** column on the **Jobs** tab.
Partially successful	The job was successful. This status is typically returned when the job didn't find any partially indexed data (also called *unindexed data*) in some of the custodian data sources.
Failed/Completed with errors	The job failed. You should attempt to rerun the action that triggered the job. If the job fails a second time, we recommend that you contact Microsoft Support and provide the support information from the job.

Close or delete an eDiscovery (Premium) case

> ⊗ **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic **Content Search**, classic **eDiscovery (Standard)**, and classic **eDiscovery (Premium)**.
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the **new eDiscovery experience** in the **Microsoft Purview portal**.

When the legal case or investigation supported by a Microsoft Purview eDiscovery (Premium) case is completed, you can close or delete a case. You can also reopen a closed case.

Close a case

Here's what happens when you close an eDiscovery (Premium) case:

- If the case contains any content locations on hold, these holds are turned off. After the hold is turned off, a 30-day grace period (called a *delay hold*) is applied to content locations that were on hold. This helps prevent content from being immediately deleted and gives admins an opportunity to search for or recover content that will be permanently deleted after the delay hold period expires. For more information, see Removing content locations from an eDiscovery hold.
- Closing a case only turns off the holds that are associated with that case. If other holds are place on a content location (such as a Litigation Hold, Microsoft Purview eDiscovery (Standard) hold, or a hold from a different eDiscovery (Premium) case) those holds will still be maintained.
- The case is still listed on the eDiscovery page in the Microsoft Purview portal. The details, holds, searches, and members of a closed case are retained.
- You can edit a case after it's closed. For example, you can add or removing members, create searches, export search results, and prepare search results for analysis in eDiscovery (Premium). The primary difference between active and closed cases is that holds are turned off when a case is closed.

> **Important**
>
> If a case has more than 100 hold policies, you must manually remove the policies using PowerShell. For more information, see Remove-CaseHoldPolicy.

To close a case:

1. On the **eDiscovery (Premium)** page, select the case that you want to close.
2. On the **Settings** tab, under **Case Information**, choose **Select**.
3. At the bottom of the **Case Information** flyout page, select **Actions**, and then select **Close case**. It may take up to 60 minutes for the closing process to complete.

When closing a case, you'll see the status of the case changing as the case is processed for closing. The following table describes the case status messages that you'll see when closing a case:

Expand table

Status	Description
Active	The case is active.
Closed	The case is closed without errors and the case can be reopened.
Closed with Errors	The case is closed, but there are errors. Errors are most likely associated with holds that were not released during closing. To resolve, check policies with errors, resolve the errors, and redistribute the policies.
Closing	The case is being closed. This status is usually seen only for case with active holds. Cases without holds are immediately closed.
Pending delete	The case likely has a hold in the pending deletion state. Check the hold policy and redistribute to resolve the error. Afterwards, cases without any holds should be deleted successfully.

Reopen a closed case

When you reopen an eDiscovery (Premium) case, any holds that were in place when the case was closed won't be automatically reinstated. After the case is reopened, you'll have to go to the **Holds** tab and turn on the previous holds. To turn on a hold, select it to display the flyout page, and then set the **Status** toggle to **On**.

To reopen a closed case:

1. On the **eDiscovery (Premium)** page, select the case that you want to reopen.
2. On the **Settings** tab, under **Case Information**, select **Select**.
3. At the bottom of the **Case Information** flyout page, select **Actions**, and then select **Reopen case**.

It might take up to 60 minutes for the reopening process to complete.

Delete a case

You can delete both active and closed eDiscovery (Premium) cases. When you delete a case, all components associated with the case, such as the list of custodians, communications, searches, review sets, and export job are deleted. The case is removed from the list of cases on the **eDiscovery (Premium)** page in the Microsoft Purview portal. You can't recover or reopen a deleted case.

> **Note**
>
> In data spillage scenarios, the only way to remove items in a review set is to delete the eDiscovery (Premium) case. Other "search and purge" methods don't remove items from a review set.

Before you can delete a case, you must first delete *all* holds listed on the holds page of the case. That includes deleting holds with a status of **Off**. Default hold policies can only be deleted when the hold is turned off. You must close an active case to turn off any default hold policies in the case. Once the holds are turned off for default hold policies, they can be deleted.

To delete holds associated with a case:

1. Go the **Holds** tab in the eDiscovery (Premium) case that you want to delete.
2. Select the hold that you want to delete.
3. On the flyout page, select **Delete**. Ensure that the hold is turned off.

To delete a case:

1. On the **eDiscovery (Premium)** page, select the case that you want to delete.
2. On the **Settings** tab, under **Case Information**, choose **Select**.
3. At the bottom of the **Case Information** flyout page, select **Actions**, and then select **Delete case**.

Last updated on 09/02/2025

Add or remove members from an eDiscovery (Premium) case

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can add or remove members to manage who can access the case. However, before a member can access an eDiscovery (Premium) case (and perform tasks in the case), you must add the user to the eDiscovery Manager role group on the **Permissions** page in the Microsoft Purview portal. For more information, see Assign eDiscovery permissions.

1. On the **eDiscovery (Premium)** page, go to the case that you want to add a member to.
2. Select the **Settings** tab and then choose **Select** in the **Access & permissions** tile.
3. Under **Manage members**, select **Add** to add members to the case. You can also choose to add a role group to the case by selecting **Add** under **Manage role groups**.
4. In the list of people or role groups that can be added as members of the case, select the check box next to the names of the people or role groups that you want to add.

   > **ⓘ Note**
   >
   > When adding a role group to a case, you can only add the role groups that you are a member of.

5. After you've selected the people or role groups to add as members of the case, select **Add**.
6. In the **Manage this case** flyout page, select **Save** to save the new list of case members.

> **Important**
>
> If a role is added or removed from a role group that you've added as a member of a case, then the role group will be automatically removed as a member of the case (or any case the role group is a member of). The reason for this is to protect your organization from inadvertently providing additional permissions to members of a case. Similarly, if a role group is deleted, it will be removed from all cases it was a member of. For more information, see Assign eDiscovery permissions.

Removing members from a case

Only an eDiscovery Administrator can remove members from a case. Even if you're assigned to the eDiscovery Manager role group or initially created the case, you won't be able to remove yourself or other members from a case unless you're also an eDiscovery Administrator. To remove yourself or other members from a case, contact an eDiscovery Administrator in your organization.

Configure search and analytics settings for eDiscovery (Premium) cases

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can configure settings for each Microsoft Purview eDiscovery (Premium) case to control the following functionality:

- Near duplicates and email threading
- Themes
- Autogenerated review set query
- Ignore text
- Optical character recognition

Configure analytics settings for a case

To configure search and analytics settings for a case:

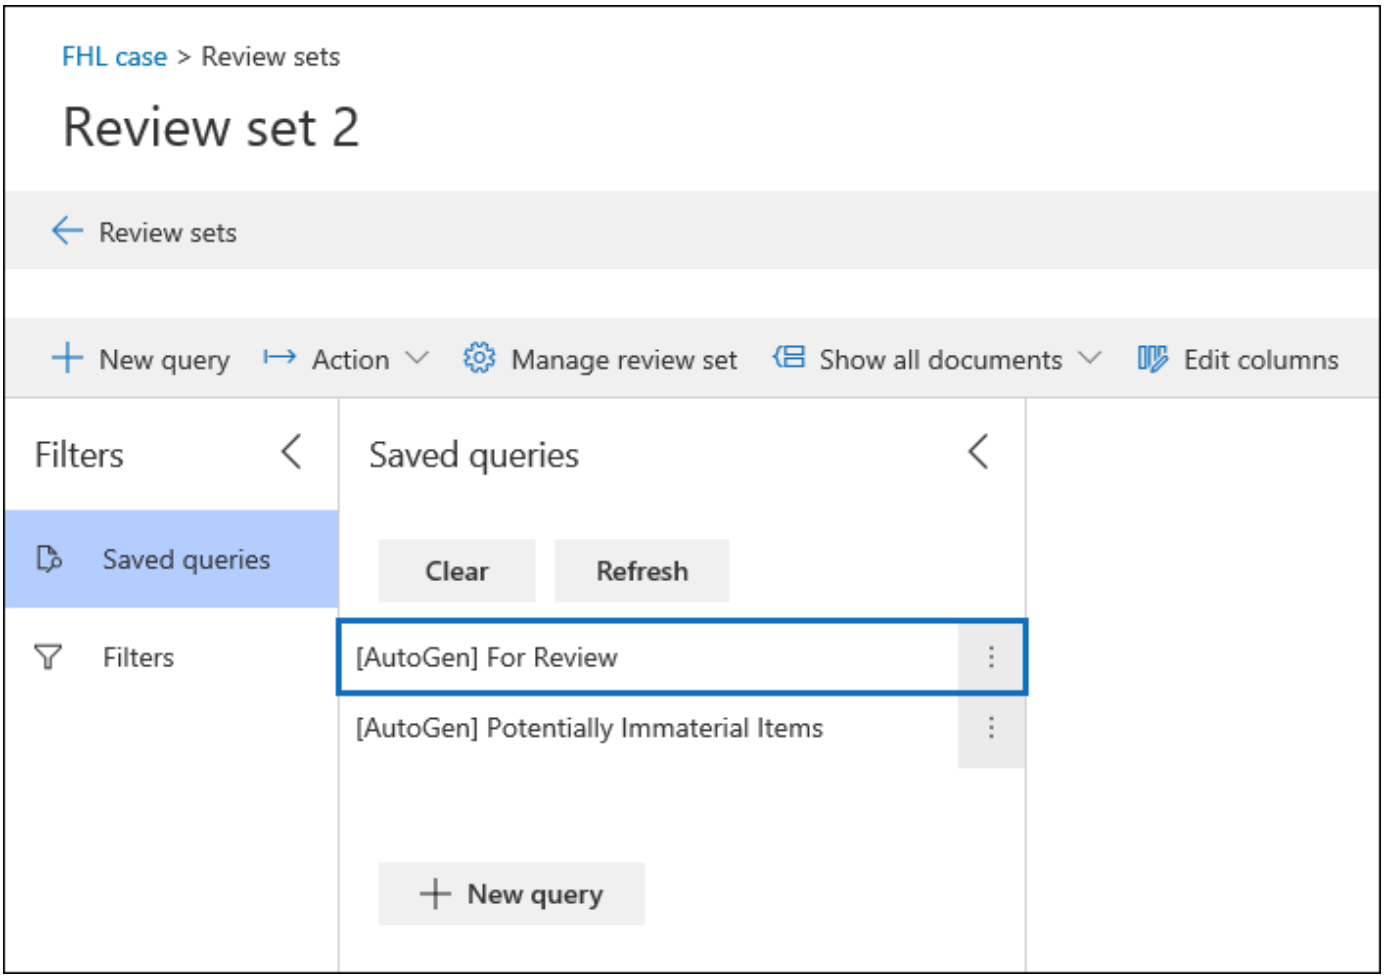
1. On the **eDiscovery (Premium)** page, select the case.
2. On the **Settings** tab, under **Search & analytics**, choose **Select**. The case settings page is displayed. These settings are applied to all review sets in a case.

The following sections in this article describe the analytics settings that you can configure for a case.

Near duplicates and email threading

In this section, you can set parameters for duplicate detection, near duplicate detection, and email threading. For more information, see Near duplicate detection and Email threading.

- **Near duplicates/email threading:** When turned on, duplicate detection, near duplicate detection, and email threading are included as part of the workflow when you run analytics on the data in a review set.
- **Document and email similarity threshold:** If the similarity level for two documents is over the threshold, both documents are put in the same near duplicate set.
- **Minimum/maximum number of words:** These settings specify that near duplicates and email threading analysis are performed only on documents that have at least the minimum number of words and at most the maximum number of words.



Themes

In this section, you can set parameters for themes. For more information, see Themes.

- **Themes:** When turned on, themes clustering is performed as part of the workflow when you run analytics on the data in a review set.
- **Maximum number of themes:** Specifies the maximum number of themes that can be generated when you run analytics on the data in a review set.
- **Include numbers in themes:** When turned on, numbers (that identifies a theme) are included when generating themes.
- **Adjust maximum number of themes dynamically:** In certain situations, there may not be enough documents in a review set to produce the desired number of themes. When this setting is enabled, eDiscovery (Premium) adjusts the maximum number of themes dynamically rather than attempting to enforce the maximum number of themes.

Review set query

If you select the **Automatically create a For Review saved search after analytics** checkbox, eDiscovery (Premium) autogenerates review set query named **For Review.**

This query basically filters out duplicate items from the review set. This lets you review the unique items in the review set. This query is created only when you run analytics for a review set in the case. For more information, about review set queries, see Query the data in a review set.

Ignore text

There are situations where certain text will diminish the quality of analytics, such as lengthy disclaimers that get added to email messages regardless of the content of the email. If you know of text that should be ignored, you can exclude it from analytics by specifying the text string and the analytics functionality (Near-duplicates, Email threading, Themes, and Relevance) that the text should be excluded for. Using regular expressions (RegEx) as ignored text is also supported.

Optical character recognition (OCR)

When this setting is turned on, OCR processing will be run on image files. OCR processing is run in the following situations:

- When custodians and non-custodial data sources are added to a case. When OCR is applied to image files, the text in those files will be searchable during a collection. OCR processing is performed during the Advanced indexing process. OCR is only run on items that are

processed during Advanced indexing. For example, if a large PDF file that is partially indexed or had other indexing errors is processed during Advanced indexing, the file will also have OCR applied. In other words, OCR processing only occurs on files that are reindexed during the Advanced indexing process.

This means there may be situations where custodians are added to a case but some email attachments won't be processed for OCR because those files aren't processed during Advanced indexing.

- When content from other data sources(that aren't associated with a custodian and added to the case in a non-custodial data source) is added to a review set.
- KeyQL search (collection estimates) don't run OCR on an item unless an item had indexing errors and these items must be Advanced indexed.

After data is added to a review set, image text can be reviewed, searched, tagged, and analyzed. You can view the extracted text in the Text viewer of the selected image file in the review set. For more information, see:

- Advanced indexing of custodian data
- Add search results to a review set
- Supported image file types

Limits in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

This article describes the limits in the Microsoft Purview eDiscovery (Premium) solution in Microsoft Purview.

Case and review set limits

The following table lists the limits for cases and review sets in eDiscovery (Premium).

Expand table

Description of limit	Classic Case Limit	New Case Limit
Total number of documents that can be added to a case (for all review sets in a case).	3 million	40 million
Total file size per load set. This includes loading non-Office 365 into a review set.	300 GB	1 TB
Maximum number of custodians per case	Not applicable	1000
Maximum number of load sets per case.	200	200
Maximum number of review sets per case.	20	20
Maximum number of tag groups per case.	1,000	1,000
Maximum number of unique tags per case.	1,000[1]	1,000[1]

Collection limits

Expand table

Description of limit	Limit
Maximum number of locations for a single collection. This limit includes the combined total of user mailboxes, and the mailboxes associated with Microsoft 365 Groups, Microsoft Teams, and Viva Engage Groups.	1000

The limits for the **Export as report** and the export results are as follows:

Expand table

Description of limit	Limit
Total items	1 million
Total locations	500,000
Exported results (items)	500,000
Exported results (locations)	100,000

Export limits

The limits described in this section are related to exporting documents out of a review set.

Expand table

Description of limit	Limit
Maximum size of a single export.	5 million documents or 500 GB, whichever is smaller

Hold limits

The following table lists the limits for holds associated with an eDiscovery (Premium) case.

Expand table

Description of limit	Limit
Maximum number of hold policies for an organization. This limit includes the combined total of hold policies in Microsoft Purview eDiscovery (Standard) and Microsoft Purview eDiscovery (Premium) cases.	10,000[2]
Maximum number of mailboxes in a single case hold. This limit includes the combined total of user mailboxes, and the mailboxes associated with Microsoft 365 Groups, Microsoft Teams, and	2,000

Description of limit	Limit
Viva Engage Groups.	
Maximum number of sites in a single case hold. This limit includes the combined total of OneDrive sites, SharePoint sites, and the sites associated with Microsoft 365 Groups, Microsoft Teams, and Viva Engage Groups.	2,000

> **Note**
>
> If your license is downgraded or if the **Case** setting is changed to *Standard*, existing holds aren't removed but the policy is now subject to the *Standard* case limits (1,000 locations). For example, if a *Premium* case has a hold policy with 1,500 mailboxes and 1,500 sites and the case setting is changed to *Standard*, you can't add additional locations to the hold policy because it's now based on the *Standard* limits. However, you can remove locations from the hold policy.

Indexing limits

The following table lists the indexing limits in eDiscovery (Premium).

Expand table

Description of limit	Limit
Maximum number of characters extracted from a single file.	10 million[3]
Maximum size of a single file.	150 MB[3]
Maximum depth of embedded items in a document.	25[3]
Maximum size of files processed by Optical Character Recognition (OCR).	24 MB[3]
Maximum Advanced indexing throughput	2 GB per hour

Jobs limits

Expand table

Description of limit	Limit
Maximum number of concurrent jobs in your organization.	100
Maximum number of concurrent jobs that a single user can start at one time.	50

Description of limit	Limit
Maximum number of concurrent tenant-wide jobs (for example, tenant-wide searches) in your organization.	50
Maximum number of concurrent tenant-wide jobs (for example, tenant-wide searches) that a single user can start at one time.	25

Review set download limits

Expand table

Description of limit	Limit
Total file size or maximum number of documents downloaded from a review set.	3 MB or 50 documents[6]

Review set viewer limits

Expand table

Description of limit	Limit
Maximum number of items displayed per page in a review set.	1,000

> **Note**
>
> Use default or custom filters to adjust the displayed items in a review set as needed.

Search limits

The limits described in this section are related to using the search tool on the **Searches** tab to collect data for a case. For more information, see Collect data for a case in eDiscovery (Premium).

Expand table

Description of limit	Limit
Maximum number of mailboxes or sites that can be searched in a single search.	No limit
Maximum number of searches that can run at the same time.	No limit
Maximum number of characters for a search query (including operators and conditions).	10,000[4]

Description of limit	Limit
Maximum number of characters for a search query for SharePoint and OneDrive for Business sites (including operators and conditions).	10,000 4,000 with Wildcards[4]
Minimum number of alpha characters for prefix wildcards; for example, **one*** or **set***.	3
Maximum variants returned when using prefix wildcard to search for an exact phrase or when using a prefix wildcard and the **NEAR** Boolean operator.	10,000[5]
Maximum number of items per user mailbox that are displayed on preview page for searches. The newest items are displayed.	100
Maximum number of items from all mailboxes displayed on preview page for searches.	1,000
Maximum number of mailboxes that can be previewed for search results. If there are more than 1,000 mailboxes that contain items that match the search query, only the top 1,000 mailboxes with the most results are available for preview.	1,000
Maximum number of items from SharePoint and OneDrive for Business sites displayed on preview page for searches. The newest items are displayed.	200
Maximum number of SharePoint and OneDrive for Business sites that can be previewed for search results. If there are more than 200 sites that contain items that match the search query, only the top 200 sites with the most results are available for preview.	200
Maximum number of items per public folder mailbox displayed on preview page for searches.	100
Maximum number of items found in all public folder mailbox items displayed on preview page for searches.	200
Maximum number of public folder mailboxes that can be previewed for search results. If there are more than 500 public folder mailboxes that contain items that match the search query, only the top 500 mailboxes with the most results are available for preview.	500
The maximum size of an item that can be viewed on the sample page of a collection estimate.	10,000,000 bytes (approximately 9.5 MB)

Search times

Microsoft collects performance information for searches run by all organizations. While the complexity of the search query can impact search times, the biggest factor that affects how long searches take is the number of mailboxes searched. Although Microsoft doesn't provide a Service

Level Agreement for search times, the following table lists average search times for collection searches based on the number of mailboxes included in the search.

Expand table

Number of mailboxes	Average search time
100	30 seconds
1,000	45 seconds
10,000	4 minutes
25,000	10 minutes
50,000	20 minutes
100,000	25 minutes

Themes limits

The limits described in this section are related to manually defining the maximum number of themes in settings for a case.

Expand table

Description of limit	Limit
Minimum number of the maximum number of defined themes.	3
Maximum number of defined themes.	10,000

Viewer limits

Expand table

Description of limit	Limit
Maximum size of Excel file that can be viewed in the native viewer.	4 MB

Need help with eDiscovery issues?

Check out the Resolve common eDiscovery issues article for basic troubleshooting steps that you can take to identify and resolve issues that you might encounter during an eDiscovery search or

elsewhere in the eDiscovery process.

Reference notes

[1] This is the maximum number of tags that you can create in a case. This limit isn't related to the number of documents that can be tagged.

[2] When you put more than 1,000 mailboxes or 100 sites on hold in a single hold policy, the system will automatically scale the hold as needed. This means the system will automatically add data locations to multiple hold policies, instead of adding them to a single hold policy. However, the limit of 10,000 case hold policies per organization still applies.

[3] Any item that exceeds a single file limit shows up as a processing error.

[4] When searching SharePoint and OneDrive for Business locations, the characters in the URLs of the sites being searched count against this limit. The total number of characters consists of:

- All characters in both the Users and Filters fields.
  - All search permissions filters that apply to the user.
  - The characters from any location properties in the search, including ExchangeLocation, PublicFolderLocation, SharPointLocation, ExchangeLocationExclusion, PublicFolderLocationExclusion, SharePointLocationExclusion, and OneDriveLocationExclusion. For example, including all SharePoint sites and OneDrive accounts in the search counts as six characters, as the word "ALL" will appear for both the SharePointLocation and OneDriveLocation field.

[5] For non-phrase queries (a keyword value that doesn't use double quotation marks) we use a special prefix index. This tells us that a word occurs in a document, but not where it occurs in the document. To do a phrase query (a keyword value with double quotation marks), we need to compare the position within the document for the words in the phrase. This means that we can't use the prefix index for phrase queries. In this case, we internally expand the query with all possible words that the prefix expands to; for example, **time*** can expand to "**time OR timer OR times OR timex OR time boxed OR ...**". The limit of 10,000 is the maximum number of variants the word can expand to, not the number of documents matching the query. There's no upper limit for non-phrase terms.

[6] This limit applies to downloading selected documents from a review set. It doesn't apply to exporting documents from a review set. For more information about downloading and exporting documents, see Export case data in eDiscovery (Premium).

Last updated on 09/02/2025

Supported file types in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Microsoft Purview eDiscovery (Premium) supports many file types at many different levels. The following tables in this article list the currently supported files types.

These tables indicate if a file type is supported for text extraction (and Optical Character Recognition or OCR text extraction for image files), viewable in the native viewer, and also supported in the Annotate viewer in eDiscovery (Premium).

Archive / Container

Expand table

Mime type	File identification	Metadata extraction	Container extraction	Possible Extensions
application/x-7z-compressed	Yes	Yes	Yes	.7z
application/x-rar-compressed	Yes	Yes	Yes	.rar[1]

Document metadata fields in eDiscovery (Premium)

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The following table lists the metadata fields for documents in a review set in a case in Microsoft Purview eDiscovery (Premium). For more information about searchable properties when searching Microsoft 365 content locations when you're collecting data for an eDiscovery (Premium) case, see Keyword queries and search conditions for Content Search.

This table provides the following information:

- **Field name** and **Display field name:** The name of the metadata field and the name of the field that's displayed when viewing the file metadata of a selected document in a review set. Some metadata fields aren't included when viewing the file metadata of a document. These fields are highlighted with an asterisk (*).
- **Searchable field name:** The name of the property that you can search for when running a review set query.
- **Exported field name:** The name of the metadata field that included when documents are exported.
- **Description:** A description of the metadata field.

> **ⓘ Note**
>
> The **Keywords** field in review set search uses Keyword Query Language (KeyQL). The fields listed in the **Searchable field name** column can be used in the **Keywords** field in a review set search to form complex queries without you having to use the query builder. For more information about KeyQL, see Keyword Query Language syntax reference.

Expand table

Field name and Display field name	Searchable field name	Exported field name	Description
Attachment Content ID	AttachmentContentId	*Not exported*	Attachment content ID the item.
Attorney client privilege score	AttorneyClientPrivilegeScore	*Not exported*	Attorney-client privileg model content score.
Author	Author	Doc_authors	Author from the docun metadata.
BCC	Bcc	Email_bcc	Bcc field for message t The format is *DisplayN* *<SMTPAddress>*.
CC	Cc	Email_cc	Cc field for message ty The format is *DisplayN* *<SMTPAddress>*.

Duplicate subset	*Not searchable*	Duplicate_subset	Group ID for exact

Field name and Display field name	Searchable field name	Exported field name	Description
			duplicates.
EmailAction*	*Not searchable*	Email_action	Values are *None*, *Reply*, *Forward*; based on the subject line of a messa
Email Delivery Receipt Requested	*Not searchable*	Email_delivery_receipt	Email address supplied Internet Headers for de receipt.
Importance	EmailImportance	Email_importance	Importance of the mes *0* - Low; *1* - Normal; *2* -
Ignored processing errors	ErrorIgnored	Error_Ignored	Error was ignored and remediated.
EmailInternetHeaders	EmailInternetHeaders	Email_internet_headers	The full set of email he from the email messag
EmailLevel*	*Not searchable*	Email_level	Indicates a message's l within the email thread belongs to; attachment inherit its parent messa value.
Email Message ID	*Not searchable*	Email_message_ID	Internet message ID fro the message.
EmailReadReceiptRequested	*Not searchable*	Email_read_receipt	Email address supplied Internet Headers for re receipt.
Email Security	EmailSecurity	Email_security	Security setting of the message: *0* - None; *1* - Signed; *2* - Encrypted; . Encrypted and signed.
Email Sensitivity	EmailSensitivity	email_sensitivity	Sensitivity setting of th message: *0* - None; *1* Personal; *2* - Private; *3* CompanyConfidential.
Email set	EmailSet	Email_set	Group ID for all messag the same email set.
EmailThread*	*Not searchable*	Email_thread	Position of the messag within the email set; co of node IDs from the ro the current message ar separated by periods (.
N/A	*N/A*	Export_native_path	The path of the exporte file.
Extracted content type	*Not searchable*	Native_type	Extracted content type, the form of mime type;

Field name and Display field name	Searchable field name	Exported field name	Description
			example, *image/jpeg*
N/A	*N/A*	Extracted_text_path	The path to the extract text file in the export.
ExtractedTextLength*	*Not searchable*	Extracted_text_length	Number of characters i extracted text.
FamilyDuplicateSet*	*Not searchable*	Family_duplicate_set	Numeric identifier for families that are exact duplicates of each othe (same content and all t same attachments).
Family ID	FamilyId	Family_ID	Groups together attachments and extrac items from email and c with its parent item. Th includes the chat or em and all attachments an extracted items.
Family Size	*Not searchable*	Family_size	Number of documents the family.
File class	FileClass	File_class	For content from Share and OneDrive: *Docume* For content from Excha *Email* or *Attachment*. For content from Team Viva Engage: *Conversat*
File ID	FileId	File_ID	Document identifier un within the case.
File system date created	*Not searchable*	File_system_date_created	Created date from file system (only applies to Office 365 data).
File system date modified	*Not searchable*	File_system_date_modified	Modified date from file system (only applies to Office 365 data).
File Type	FileType	*Not exported*	File type of the item ba on file extension.
Group ID	GroupId	Group_ID	Groups together all ite email and documents. email, this includes the message and all attach and extracted items. Fo documents, this includ document and any embedded items.

Field name and Display field name	Searchable field name	Exported field name	Description
Has attachment	EmailHasAttachment	Email_has_attachment	Indicates whether or nc message has attachme
Has attorney	HasAttorney	*Not exported*	*True* when at least one the participants is foun the attorney list; otherv the value is *False*.
HasText*	*Not searchable*	Has_text	Indicates whether or nc item has text; possible values are *True* and *Fal*
Immutable ID	*Not searchable*	Immutable_ID	This ID is used to uniqu identify a document wi review set. This field ca used in a review set sea and the ID can't be use access a document in i native location.
Inclusive type	InclusiveType	Inclusive_type	Inclusive type calculate analytics: *0* - not inclus - inclusive; *2* - inclusive minus; *3* - inclusive cop
In Reply To ID	*Not searchable*	In_reply_to_ID	In reply to ID from the message.
InputFileExtension	*Not searchable*	Original_file_extension	The original file extensi the file.
InputFileID	*Not searchable*	Input_file_ID	The file ID of the top le item in the review set. I attachment, this ID will the ID of the parent. Th be used to group famil together.
Is modern attachment	IsModernAttachment	*Not exported*	This file is a modern attachment or linked fi
Is from document version	IsFromDocumentVersion	*Not exported*	Current document is fr different version of anc document.
Is email attachment	IsEmailAttachment	*Not exported*	This item is from an em attachment that shows an attached item to the message.
Is inline attachment	IsInlineAttachment	*Not exported*	This was attached inlin shows up in the body c message.

Field name and Display field name	Searchable field name	Exported field name	Description
Is Representative	IsRepresentative	Is_representative	One document in every of exact duplicates is m as representative.
Item class	ItemClass	Item_class	Item class supplied by exchange server; for example, *IPM.Note*
Last modified date	LastModifiedDate	Doc_date_modified	Last modified date fror document metadata.
Load ID	LoadId	Load_ID	The ID of the load set i which the item was adc a review set.
Location	Location	Location	String that indicates th of location that docum were sourced from. **Imported Data** - Non- 365 data **Teams** - Microsoft Tear **Exchange** - Exchange mailboxes **SharePoint** - SharePoir sites **OneDrive** - OneDrive accounts
Location name	LocationName	Location_name	String that identifies th source of the item. For exchange, this will be t SMTP address of the mailbox; for SharePoint OneDrive, the URL for t site collection.
N/A	*N/A*	Marked_as_pivot	This file is the pivot in a duplicate set.
Marked as representative	MarkAsRepresentative	*Not exported*	One document from ea set of exact duplicates marked as representati
Meeting End Date	MeetingEndDate	Meeting_end_date	Meeting end date for meetings.
Meeting Start Date	MeetingStartDate	Meeting_start_date	Meeting start date for meetings.
Message kind	MessageKind	Message_kind	The type of message tc search for. Possible valu *contacts* *docs* *email*

Field name and Display field name	Searchable field name	Exported field name	Description
			externaldata *faxes* *im* *journals* *meetings* *microsoftteams* (returns items from chats, meet and calls in Microsoft T *notes* *posts* *rssfeeds* *tasks* *voicemail*
Modern Attachment Parent ID	*Not searchable*	ModernAttachment_ParentId	The Immutable ID of th document's parent.
Native Extension	NativeExtension	Native_extension	Native extension of the
Native file name	NativeFileName	Native_file_name	Native file name of the
Native file size	Size	Native_size	Number of bytes of the native item.
NativeMD5	*Not searchable*	Native_MD5	MD5 hash (128-bit has value) of the file stream
NativeSHA256	*Not searchable*	Native_SHA_256	SHA256 hash (256-bit l value) of the file stream
ND/ET Sort: Excluding attachments	NdEtSortExclAttach	ND_ET_sort_excl_attach	Concatenation of the e thread (ET) set and Nea duplicate (ND) set. This is used for efficient sor at review time. A *D* is prefixed to ND sets and is prefixed to ET sets.
ND/ET Sort: Including attachments	NdEtSortInclAttach	ND_ET_sort_incl_attach	Concatenation of an er thread (ET) set and nea duplicate (ND) set. This is used for efficient sor at review time. A *D* is prefixed to ND sets and is prefixed to ET sets. E email item in an ET set followed by its appropr attachments.
Near Duplicate Set	*Not searchable*	ND_set	Items that are similar to pivot document share t same ND_set.
O365 authors	*Not searchable*	O365_authors	Author from SharePoin

Field name and Display field name	Searchable field name	Exported field name	Description
O365 created by	*Not searchable*	O365_created_by	Created by from Sharel
O365 date created	*Not searchable*	O365_date_created	Created date from SharePoint.
O365ModifiedDate	*Not searchable*	O365_date_modified	The date a document (document version) coll from SharePoint or On for Business was modif This is the same modifi date as the one display the version history in th SharePoint and OneDri user experience.
O365 modified by	*Not searchable*	O365_modified_by	Modified by from Shar or OneDrive.
Other custodians	DedupedCustodians	Deduped_custodians	List of custodians of documents that are exa duplicates (for email, b on content; for docume based on hash).
Other file IDs	DedupedFileIds	Deduped_file_IDs	List of file IDs of docum that are exact duplicate email, based on conter documents, based on h
Other paths	Dedupedcompoundpath	Deduped_compound_path	List of compound path documents that are exa duplicates (email: base content, documents: ba on hash).
Parent ID	ParentId	Parent_ID	ID of the item's parent.
ParentNode	*Not searchable*	Parent_node	The closest preceding e message in the email th
Participant domains	ParticipantDomains	Email_participant_domains	List of all domains of participants of a messa
Participants	Participants	Email_participants	List of all participants c message; for example, *Sender*, *To*, *Cc*, *Bcc*.
Pivot ID	PivotId	Pivot_ID	The ID of a pivot.
Potentially privileged	PotentiallyPrivileged	Potentially_privileged	True if attorney-client privilege detection mo considers the documer potentially privileged

Field name and Display field name	Searchable field name	Exported field name	Description
Processing status	ProcessingStatus	Error_code	Processing status after item was added to a re set.
Read percentile	ReadPercentile	*Not exported*	Read percentile for the document based on Relevance.
Received	Received	Email_date_received	The date and time the was received in UTC.
Recipient Count	*Not searchable*	Recipient_count	Number of recipients i message.
Recipient domains	RecipientDomains	Email_recipient_domains	List of all domains of recipients of a message
Recipients	Recipients	Email_recipients	List of all recipients of message (To, Cc, Bcc).
N/A	*N/A*	Redacted_file_path	The path of the redacte replacement file in the export.
N/A	*N/A*	Redacted_text_path	The path of the redacte text file replacement in export. For internal Microsoft use only.
Relevance tag Case issue 1	*Not searchable*	Relevance_tag_case_issue_1	Relevance tag Case issu from Relevance.
Relevance score	RelevanceScore	*Not exported*	Relevance score of a document based on Relevance.
Relevance tag	RelevanceTag	*Not exported*	Relevance score of a document based on Relevance.
Representative ID	RepresentativeId	*Not exported*	Numeric identifier of e set of exact duplicates.
N/A	*N/A*	Row_number	The row number of the in the load file.
Sender	Sender	Email_sender	Sender (From) field for message types. The for *DisplayName <SmtpAddress>*.
Sender/Author	SenderAuthor	*Not exported*	Calculated field compri of the sender or autho the item.

Field name and Display field name	Searchable field name	Exported field name	Description
Sender domain	SenderDomain	Email_sender_domain	Domain of the sender.
Sent	Sent	Email_date_sent	Sent date of the messa Chats: Beginning date the transcript
Set ID	*Not searchable*	Set_ID	Documents of similar content (ND_set) or em within the same email (Email_set) share the sa Set_ID.
Set Order: Inclusive First	SetOrderInclusivesFirst	Set_order_inclusives_first	Sorting field - email an attachments: counter- chronological; docume pivot first then by descending similarity s
SimilarityPercent	*Not searchable*	Similarity_percent	Indicates how similar a document is to the piv the near duplicate set.
Subject	Subject	Email_subject	Subject of the message
Subject/Title	SubjectTitle	*Not searchable*	Calculated field compri of the subject or title o item.
Tags	Tags	Tags	Tags applied in a reviev
Team Name	TeamName	TeamName	**Teams:** Name of team **Viva Engage:** Commun name
Themes list	ThemesList	Themes_list	Themes list as calculate analytics.
Thread ID	ThreadId	Thread_ID	The Thread ID from em messages, Teams conversations, and Viva Engage conversations. email messages, all rep messages and attachm share the same Thread For Teams 1:1 and grou chats, all transcript files their associated items the same conversation the same Thread ID. Fo more information, see documents in a review
Title	Title	Doc_title	Title from the documer metadata. Title from th document metadata. F

Field name and Display field name	Searchable field name	Exported field name	Description
			Teams and Viva Engage content, this is the valu from the ConversationI property.
To	To	Email_to	To field for message ty The format is *DisplayName<SmtpAd*
Unique in email set	UniqueInEmailSet	*Not exported*	*False* if there's a duplic the attachment in its e set.
Version Group ID	*Not searchable*	Version_Group_Id	Groups together the different versions of th same document.
VersionNumber	*Not searchable*	Version_Number	The version number of document collected fro SharePoint or OneDrive Business. This is the sa version number as the displayed in the versio history in the SharePoi OneDrive user experie
Was Remediated	WasRemediated	Was_Remediated	*True* if the item was remediated, otherwise
Word count	WordCount	Word_count	Number of words in th item.

Search for and delete Copilot data

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use eDiscovery (Premium) and the Microsoft Graph Explorer to search for and delete user prompts and Microsoft 365 Copilot and Microsoft 365 Copilot Chat responses in supported applications and services. This feature can help you find and remove sensitive information or inappropriate content included in Copilot activities. This search and deletion workflow can also help you respond to a data spillage incident, when content containing confidential or malicious information is released through Copilot-related activity.

Before you search and delete Copilot data

- To create an eDiscovery (Premium) case and use collections to search for Copilot activity data, you have to be a member of the *eDiscovery Manager* role group in the Microsoft Purview portal. To delete Copilot data, you have to be assigned the *Search And Purge* role. This role is assigned to the *Data Investigator* and *Organization Management* role groups by default. For more information, see Assign eDiscovery permissions.
- A maximum of 100 items per mailbox can be removed at one time. Because the capability to search for and remove Copilot data is intended to be an incident-response tool, this limit helps ensure that this data is quickly removed.

Step 1: Create a case in eDiscovery (Premium)

The first step is to create a case in eDiscovery (Premium) to manage the search and deletion process. For information about creating a case, see Use the new case format.

Step 2: Create a collection estimate

After you create a case, the next step is to create a collection estimate to search for the Copilot data that you want to delete. The deletion process you perform is Step 5 deletes all Copilot-related items that are found in the collection estimate (within the 10 item per location limit).

In eDiscovery (Premium), a *collection* is an eDiscovery search of the content locations that contain Copilot data that you want to delete. Create the collection estimate in the case that you created in the previous step. For more information, see Create a collection estimate.

Data sources for Copilot data

The following table lists the applications and services that are sources for Copilot data. All user prompts to Copilot and responses from Copilot are stored in a user's mailbox.

WebChat	IPM.SkypeTeams.Message.Copilot.WebChat

For this type of Microsoft Copilot data...	Search this item class...
Whiteboard	IPM.SkypeTeams.Message.Copilot.Whiteboard
Word	IPM.SkypeTeams.Message.Copilot.Word

> **Note**
>
> In Step 4, you also have to identify and remove any holds and retention policies assigned to the mailbox that contains the type of Copilot data that you want to delete.

Tips for searching for Copilot data

To help ensure the most comprehensive collection of Copilot data, use the **Type** condition and select the **Copilot activity** option when you build the search query for the collection estimate. We also recommend including a date range or several keywords to narrow the scope of the collection to items relevant to your search and delete investigation.

For more information, see Build search queries for collections.

Identifying web queries in Microsoft 365 Copilot usage

With the web search enabled for Microsoft 365 Copilot or Microsoft Copilot to include the latest data from the web, the web search queries sent to Microsoft Bing are searchable in eDiscovery. For more information about web search, see Data, privacy, and security for web search in Microsoft 365 Copilot and Microsoft 365 Copilot Chat.

Complete the following steps for finding these web queries:

1. Using the Condition builder in eDiscovery, search for Copilot activity using the filter *Type*, *Equals any of*, and *Copilot activity*.
2. In the query results, download any single item.
3. Open up the downloaded item in a text editor.
4. Look for *WebSearchQuery*
5. If the Copilot activity is involved in a Bing search query, *WebSearchQuery* is present in the downloaded file. It's followed by the specific query sent in the Microsoft Bing search query.

Step 3: Review and verify Copilot data to delete

The deletion process in Step 5 will delete the items returned by the collection. It's important that you review the collection estimate results to ensure that the collection only returns the items that you want to delete. To review a sample of items in a collection estimate, see the **Next steps after a collection estimate is complete** section in Create a collection estimate.

Additionally, you can use the collection statistics (specifically the *Top Locations* statistics) to generate a list of the data sources that contain items returned by the collection. Use this list in the next step to remove hold and retention policies from the user mailboxes that contain search results. For more information, see Collection statistics and reports.

Step 4: Remove holds and retention policies from data sources

Before you can delete Copilot data from a mailbox, you have to remove any hold or retention policy that is assigned to a target mailbox. If not, then the data you're trying to delete is retained.

Use the list of mailboxes that contain the Copilot data that you want to delete and determine if there's a hold or retention policy assigned to those mailboxes, and then remove the hold or retention policy. Be sure to identify the hold or retention policy that you remove so that you can reassign to the mailboxes in Step 7.

For instructions about how to identify and remove holds and retention policies, see **Step 3: Remove all holds from the mailbox** in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold.

Step 5: Delete Copilot data

> **Note**
>
> Because Microsoft Graph Explorer is not available in some US Government clouds (GCC High and DOD), you must use PowerShell to accomplish these tasks. See the **Delete Copilot data with PowerShell** for details.

Now you're ready to delete Copilot data from user mailboexes. Use the Microsoft Graph Explorer to perform the following three tasks:

1. Get the ID of the eDiscovery (Premium) case that you created in Step 1. This is the case that contains the collection created in Step 2.

2. Get the ID of the collection that you created in Step 2 and verified the search results in Step 3. The search query in this collection returns the Copilot data to be deleted.
3. Delete the Copilot data returned by the collection.

For information about using Graph Explorer, see Use Graph Explorer to try Microsoft Graph APIs.

> **Important**
>
> To perform these three tasks in Graph Explorer, you may have to consent to the eDiscovery.Read.All and eDiscovery.ReadWrite.All permissions. For more information, see the "Consent to permissions" section in **Working with Graph Explorer**.

Get the case ID

1. Go to https://developer.microsoft.com/graph/graph-explorer and sign in to the Graph Explorer with an account that's assigned the *Search And Purge* role in the Microsoft Purview portal.

2. Run the following GET request to retrieve the ID for the eDiscovery (Premium) case. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases` in the address bar of the request query. Be sure to select **v1.0** in the API version dropdown list.

   This request returns information about all cases in your organization on the **Response preview** tab.

3. Scroll through the response to locate the eDiscovery (Premium) case. Use the **displayName** property to identify the case.

4. Copy the corresponding ID (or copy and paste it to a text file). You'll use this ID in the next task to get the collection ID.

> **Tip**
>
> Instead of using the previous procedure to obtain the case Id, you can open the case in the Microsoft Purview portal and copy the case Id from the URL.

Get the eDiscoverySearchID

1. In Graph Explorer, run the following GET request to retrieve the ID for the collection that you created in Step 2, and contains the items you want to delete. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches` in the address bar of the request query, where *{ediscoveryCaseID}* is the CaseID that you obtained in the previous procedure.

2. Scroll through the response to locate the collection that contains the items that you want to delete. Use the *displayName* property to identify the collection that you created in Step 3.

   In the response, the search query from the collection is displayed in the *contentQuery* property. Items returned by this query are deleted in the next task.

3. Copy the corresponding ID (or copy and paste it to a text file). You'll use this ID in the next task to delete Copilot data.

> **Tip**
>
> Instead of using the previous procedure to obtain the search Id, you can open the case in the Microsoft Purview portal. Open the case and navigate to the Jobs tab. Select the relevant collection and under Support information, find the job ID (the job ID displayed here is the same as the collection ID).

Delete Copilot data

1. In Graph Explorer, run the following POST request to delete the items returned by the collection that you created in Step 2. Use the value `https://graph.microsoft.com/v1.0/security/cases/ediscoveryCases/{ediscoveryCaseID}/searches/{ediscoverySearchID}/purgeData` in the address bar of the request query, where *{ediscoveryCaseID}* and *{ediscoverySearchID}* are the IDs that you obtained in the previous procedures.

   If the POST request is successful, an HTTP response code is displayed in a green banner stating that the request was accepted.

For more information on purgeData, see sourceCollection: purgeData.

Delete Copilot data with PowerShell

> **Note**

Because Microsoft Graph Explorer is not available in the US Government cloud (GCC, GCC High, and DOD), you must use PowerShell to accomplish these tasks.

You can also delete Copilot data using PowerShell. For example, to delete Copilot data in the US Government cloud you could use a command similar to:

```
Connect-MgGraph -Scopes "ediscovery.ReadWrite.All" -Environment USGov
```

```
Invoke-MgGraphRequest -Method POST -Uri
'/v1.0/security/cases/ediscoveryCases/<ediscoverySearchID>/searches/<search ID>/purgeData'
```

For more information on using PowerShell to delete Copilot data, see ediscoverySearch: purgeData.

Step 6: Verify Copilot data is deleted

After you run the POST request to delete Copilot data, this data is removed from the user's mailbox. There isn't any visible notification or confirmation for the user that the data has been deleted.

Deleted Copilot data is moved to the *SubstrateHolds* folder, which is a hidden mailbox folder. Deleted Copilot data is stored there for at least 1 day and then are permanently deleted the next time the timer job runs (typically between 1-7 days).

Step 7: Reapply holds and retention policies to user mailboxes

After you verify that the Copilot data is deleted, you can reapply the holds and retention policies to user mailboxes that you removed in Step 4.

Find sensitive data stored on sites with eDiscovery

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Users often store sensitive data, such as credit card numbers, social security numbers, or personal, on their sites, and over time this can expose an organization to significant risk of data loss. Documents stored on sites—including OneDrive for Business sites—could be shared with people outside the organization who shouldn't have access to the information.

With Microsoft Purview eDiscovery, you can discover documents that contain sensitive data throughout your tenant. After discovering the documents, you can work with the document owners to protect the data. This article can help you form a query to search for sensitive data.

Forming a basic query

There are three parts that make up a basic query: SensitiveType, count range, and confidence range. For example, **SensitiveType:"<type>"** is required, and both **|<count range>** and **|<confidence range>** are optional.

Sensitive type - required

Queries typically begin with the property `SensitiveType:"` and an information type name from the sensitive information types inventory, and end with a `"`. To search for custom sensitive information types, you have to specify the ID of the sensitive information type in the `SensitiveType` property. Using the name of a custom sensitive information type won't return any results.

Ranges - optional

Both of the next two parts are ranges, so let's quickly examine what a range looks like. In SharePoint queries, a basic range is represented by two numbers separated by two periods, which looks like this: `[number]..[number]`. For instance, if `10..20` is used, that range would capture numbers from 10 through 20. There are many different range combinations and several are covered in this article.

Let's add a count range to the query. You can use count range to define the number of occurrences of sensitive information a document needs to contain before it's included in the query results. For example, if you want your query to return only documents that contain exactly five credit card numbers, use this: `SensitiveType:"Credit Card Number|5"`. Count range can also help you identify documents that pose high degrees of risk. For example, your organization might consider documents with five or more credit card numbers a high risk. To find documents fitting this criterion, you would use this query: `SensitiveType:"Credit Card Number|5.."`. Alternatively, you can find documents with five or fewer credit card numbers by using this query: `SensitiveType:"Credit Card Number|..5"`.

Confidence range

Finally, confidence range is the level of confidence that the detected sensitive type is actually a match. The values for confidence range work similarly to count range. You can form a query without including a count range. For example, to search for documents with any number of credit card numbers—as long as the confidence range is 85 percent or higher—you would use this query: `SensitiveType:"Credit Card Number|*|85.."`.

> **Important**
>
> The asterisk (`*`) is a wildcard character that means any value works. You can use the wildcard character (`*`) either in the count range or in the confidence range, but not in a sensitive type.

Additional query properties and search operators available in the eDiscovery Center

Queries in SharePoint also contains the LastSensitiveContentScan property, which can help you search for files scanned within a specific timeframe. For query examples with the `LastSensitiveContentScan` property, see the Examples of complex queries in the next section.

You can use SharePoint eDiscovery search properties such as `Author` or `FileExtension`. You can use operators to build complex queries. For the list of available properties and operators, see the Using Search Properties and Operators with eDiscovery blog post.

Examples of complex queries

The following examples use different sensitive types, properties, and operators to illustrate how you can refine your queries to find exactly what you're looking for.

Expand table

Query	Explanation
`SensitiveType:"International Banking Account Number (IBAN)"`	The name might seem strange because it's so long, but it's the correct name for that sensitive type. Make sure to use exact names from the sensitive information types inventory. You can also use the name of a custom sensitive information type that you created for your organization.
`SensitiveType:"Credit Card Number|1..4294967295|1..100"`	This returns documents with at least one match to the sensitive type "Credit Card Number." The values for each range are the respective minimum and maximum values. A simpler way to write this query is `SensitiveType:"Credit Card Number"`, but where's the fun in that?
`SensitiveType:"Credit Card Number|5..25" AND LastSensitiveContentScan:"8/11/2018..8/13/2018"`	This returns documents with 5-25 credit card numbers that were scanned from August 11, 2018 through August 13, 2018.
`SensitiveType:"Credit Card Number|5..25" AND LastSensitiveContentScan:"8/11/2018..8/13/2018" NOT FileExtension:XLSX`	This returns documents with 5-25 credit card numbers that were scanned from August 11, 2018 through August 13, 2018. Files with an XLSX extension aren't included in the query results. `FileExtension` is one of many properties that you can include in a query. For more information, see Using Search Properties and Operators with eDiscovery.
`SensitiveType:"Credit Card Number" OR SensitiveType:"U.S. Social Security Number (SSN)"`	This returns documents that contain either a credit card number or a social security number.

Examples of queries to avoid

Not all queries are created equal. The following table gives examples of queries that don't work in SharePoint and describes why.

Expand table

Unsupported query	Reason
`SensitiveType:"Credit Card Number|.."`	You must add at least one number.
`SensitiveType:"NotARule"`	"NotARule" isn't a valid sensitive type name. Only names in the sensitive information types inventory work in eDiscovery queries.
`SensitiveType:"Credit Card Number|0"`	Zero isn't valid as either the minimum value or the maximum value in a range.
`SensitiveType:"Credit Card Number"`	It's might be difficult to see, but there's extra white space between "Credit" and "Card" that makes the query invalid. Use exact sensitive type names from the sensitive information types inventory.
`SensitiveType:"Credit Card Number|1. .3"`	The two-period portion shouldn't be separated by a space.
`SensitiveType:"Credit Card Number| |1..|80.."`	There are too many pipe delimiters (|). Follow this format instead: `SensitiveType: "Credit Card Number|1..|80.."`
`SensitiveType:"Credit Card Number|1..|80..101"`	Because confidence values represent a percentage, they can't exceed 100. Choose a number from 1 through 100 instead.

Set up historical versions in eDiscovery (Premium) (preview)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The historical versions feature in eDiscovery (Premium) lets eDiscovery managers in your organization search for and collect content from all versions of documents stored in SharePoint Online and OneDrive for Business. Then you can add that content to a review set for analysis and review. This helps you find and review content from a specific version of a document that may be relevant to a case or investigation, even if the latest version of the same document doesn't contain the relevant information.

To support the historical versions capability in eDiscovery (Premium), SharePoint administrators must enable versioning for sites in their organization. Then, when users modify documents in SharePoint or OneDrive, implicit regular versions are created when document is saved (or autosaved). SharePoint versioning allows for tracking of the activity performed on SharePoint items (including documents, events, and tasks). This versioning capability leaves an audit trail that can provide evidence in legal investigations. These older versions of a document are available to the organization, who may be required to share such versions that have sensitive or relevant content during court discovery in a legal matter.

After an eDiscovery administrator turns on historical versions for the organization and then activates it for specific SharePoint sites, the SharePoint content push service crawls all major and minor versions of documents on the activated sites and then sends those versions for indexing. After the crawling and indexing process is complete, documents and their versions are available for eDiscovery search. As long as a specific version can be accessed (by version history), then that version will be discoverable in an eDiscovery (Premium) collection search.

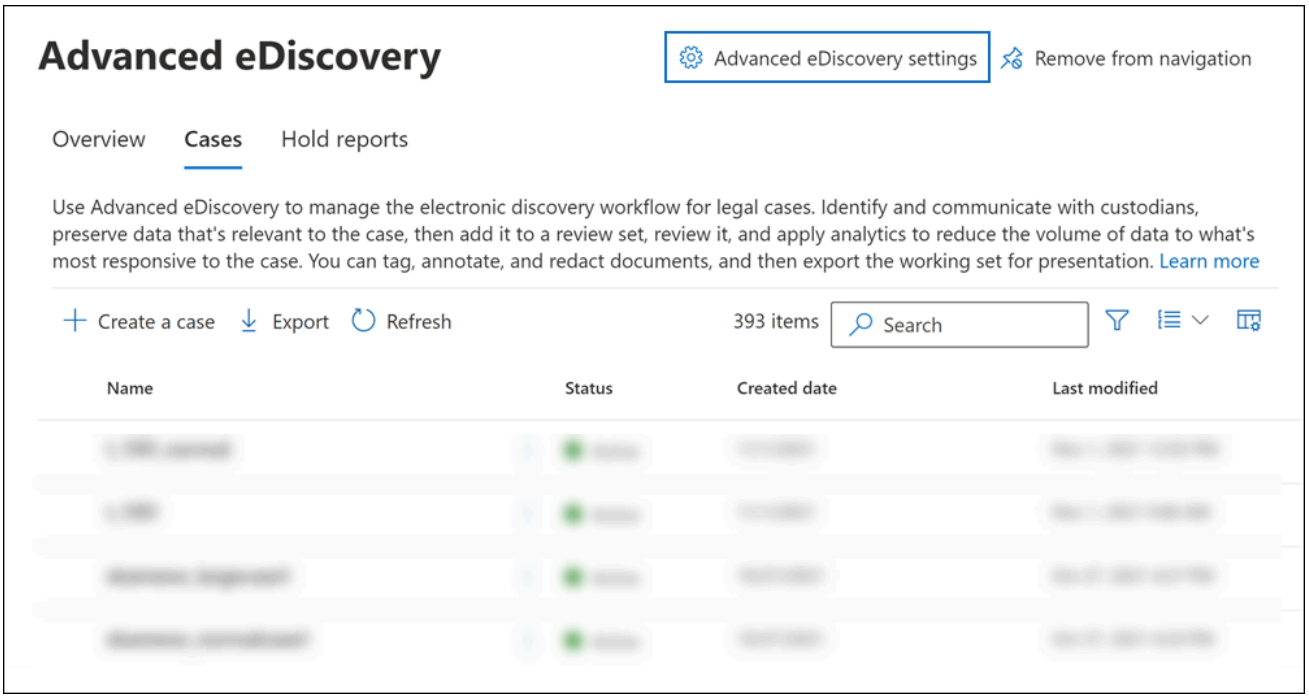
Set up historical versions

To enable historical versions in eDiscovery (Premium), your organization has to turn it on and then activate specific sites so that all versions of documents stored on those sites are indexed for search. Before you set up eDiscovery (Premium) for historical versions, you have to enable versioning support in SharePoint.

Step 1: Turn on versioning in SharePoint

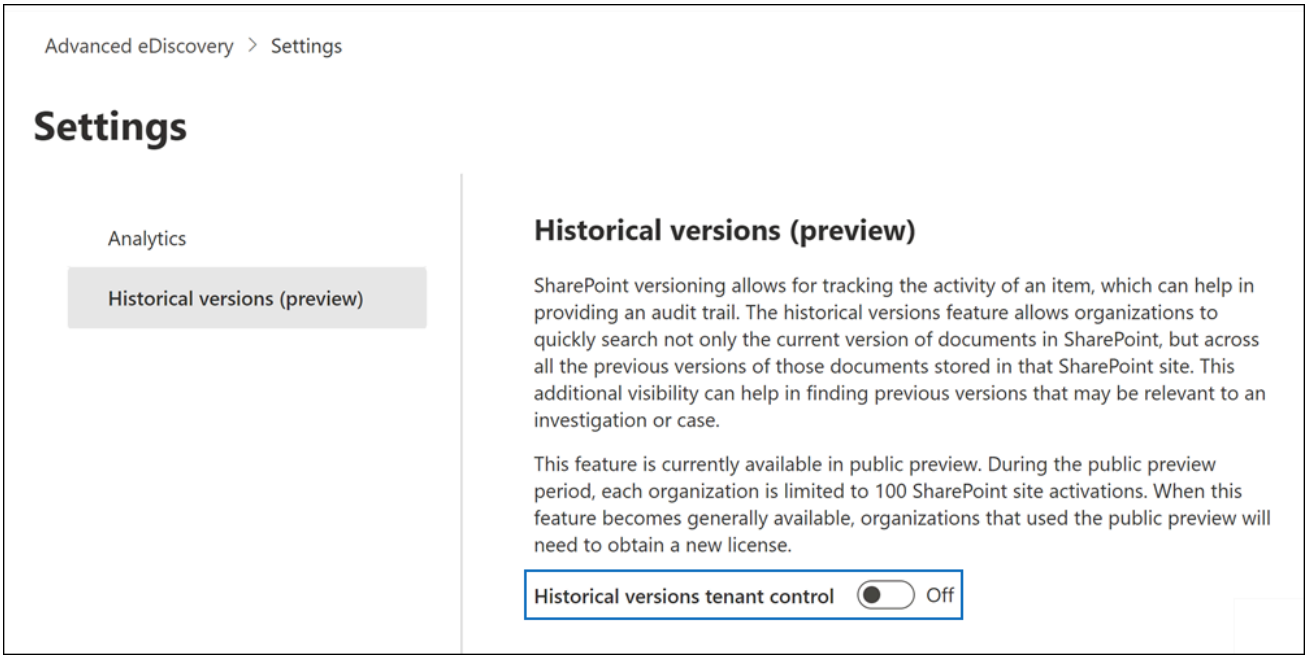
The first step is to turn on versioning in SharePoint Online so that all versions of a document are preserved. For instructions, see Versioning in SharePoint.

> **Important**
>
> Adding SharePoint sites to historical versions isn't currently supported in multi-geo environments. Only the primary domain of your organization is enabled for historical versions.



Step 2: Turn on historical versions

The next step is to turn on historical versions in eDiscovery (Premium). To turn on historical versions for your organization, a person must be a global administrator or an eDiscovery Administrator (a member of the eDiscovery Administrator subgroup in the eDiscovery Manager role group). After historical versions is turned on, it will apply to your entire organization.



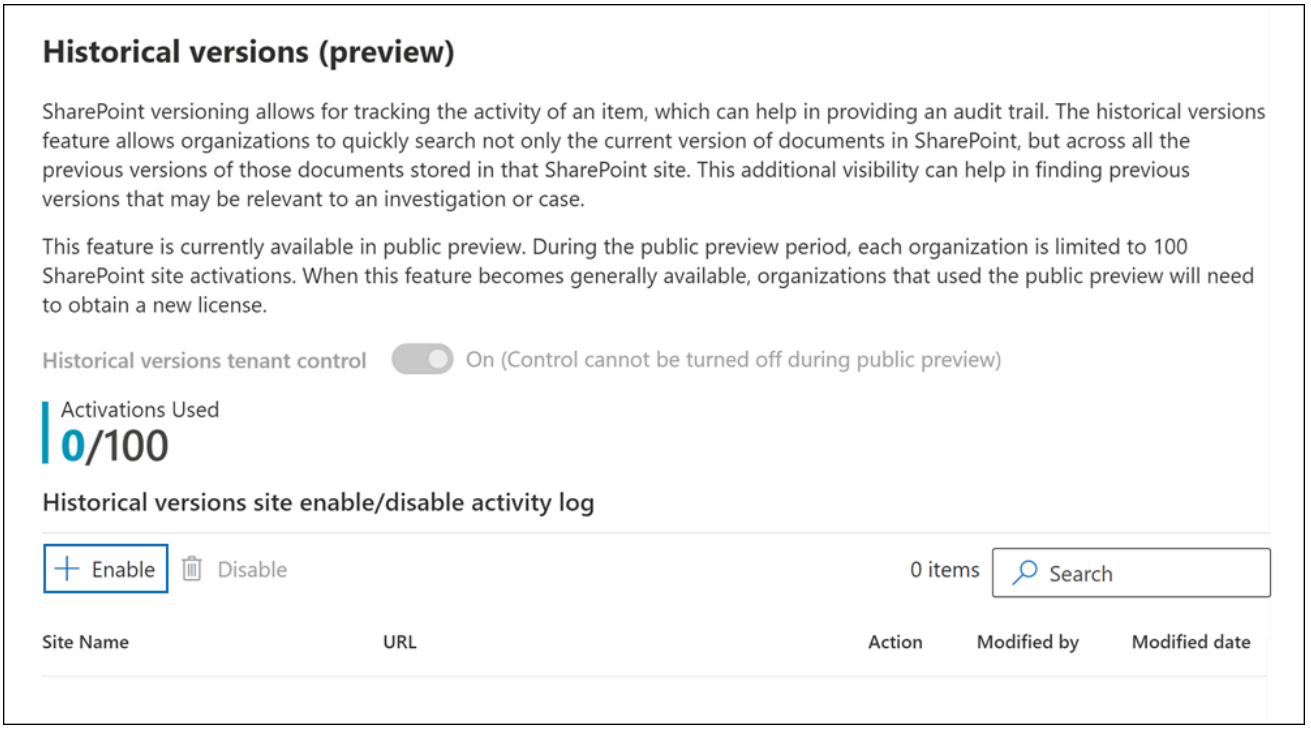
> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

> **Important**
>
> After you turn on historical versions, you won't be able to turn it off during the public preview. You will be able to turn it off after historical versions is released for general availability.

1. In the Microsoft Purview portal, go to eDiscovery (Premium), and then select **eDiscovery (Premium) settings**.

2. On the **Settings** page, select the **Historical versions (preview)** tab, and then switch the **Historical versions tenant control** toggle to on.

   A warning is displayed that says you won't be able to turn off historical versions. As previously stated, you won't be able to turn off historical versions until the feature is released for general availability.



3. Select **Yes** to turn on historical versions.

Step 3: Activate SharePoint sites

After you turn on historical versions for your organization, the last step is to activate SharePoint sites to support historical versions. When you activate a site (by adding it to a list of sites on the **Historical versions** tab), the site is recrawled and all versions of documents stored on that site are indexed for search.

> **Note**
>
> There is a limit of 100 site activations per organization during the public preview of historical versions. An activation is counted against this limit whenever you enable or disable a site for historical versions. If you enable multiple sites, each site is counted as a single activation. The total number of activations is displayed on the **Historical versions** tab.

1. On the **Historical versions** tab on the eDiscovery (Premium) **Settings** page, select **Enable** to activate sites for historical versions.

   A flyout out page is displayed that contains a list of all SharePoint sites in your organization.

2. Select a site to activate, and then select **Enable** to activate it for historical versions. You can use the search box to search for a specific site.

   A warning is displayed that says document versions on the site will be indexed and this indexing process will take some time before the versions will be ready to be searched. The warning also states that you won't be able to disable historical versions for the selected site for 30 days.

3. Select **Yes** to activate the site for historical versions.

The site is added to the list of activated sites. The counter showing the number of site activations is also updated.

4. Repeat the previous steps for each site that you want to activate for historical versions.

Frequently asked questions

How are historical versions different that the option to "collect all versions" when you commit a collection estimate to a review set?

Currently, only the latest version of documents is indexed for search. That means when you run a collection estimate, only the latest versions of documents are searched. If a document matches the keyword query for the collection, it is returned in the collection results. However, if the latest version of a document doesn't match a search query, the document won't be returned event if older versions of the document contain the keyword. To help mitigate this situation, eDiscovery (Premium) gives you the ability to collect all versions of the document when you commit a collection to a review set. That means any older version that may contain the keyword will be added to the review set.

Historical versions are different and more efficient than "collecting all versions" because when you activate a site, all versions of a document (and not just the last version) are indexed for search. The result is that if an older version of a document contains a keyword that matches the search query, it will be returned by the collection.

When historical versions is enabled for a site, does it impact the performance of the site?

No. Once historical versions is enabled for a site, the performance for the site will the same as it was before the site was enabled. The crawling and indexing processes that are performed on the

site after it's enabled will occur at a slower rate and be performed during off-peak hours. Enabling historical versions for a site will kick off a backfill process, which finds all the versions of documents on the site and then sends those versions to the index. Depending on the number of document versions for site, this backfill process might impact service health. We have mitigated this potential impact in the following ways:

- We make the best effort to process these versions during off-peak hours.
- We process document versions in our lowest priority queues, which allows most service resources to be delegated to user changes.

How long do I have to wait after a site is activated until all historical versions of documents on that site are all indexed and available for eDiscovery search?

Based on the number of documents for a site and the average number of versions per document, we try to estimate the total number of files per site. Based on this, an estimate of how long it may take to index is as follows:

`Number of versions / (Processing rate of 100,000 files per day ) + .5 days = Total number of days to process a site`

The half-day is added as a buffer since indexing of versions on site is optimized to run during off-peak hours.

For example, if the total number of documents and all versions for a site is 150,000 then it will take at least two days to process the site for historical versions:

`150,000 files/100,000 files per day + .5 days = 2 days`

Why is it not recommended to frequently activate or deactivate sites for historical versions?

When you deactivate a previously activated site, a clean-up process is triggered. This process will take time to complete. If that same site is activated again, the backfill process of reindexing the site has to be rerun. Both the clean-up and backfill processes are time- and resource-intensive. Therefore we recommended that you carefully consider and plan which sites you want to activate for historical version so you can avoid repeatedly activating and deactivating historical versions for a site.

Set up attorney-client privilege detection in eDiscovery (Premium)

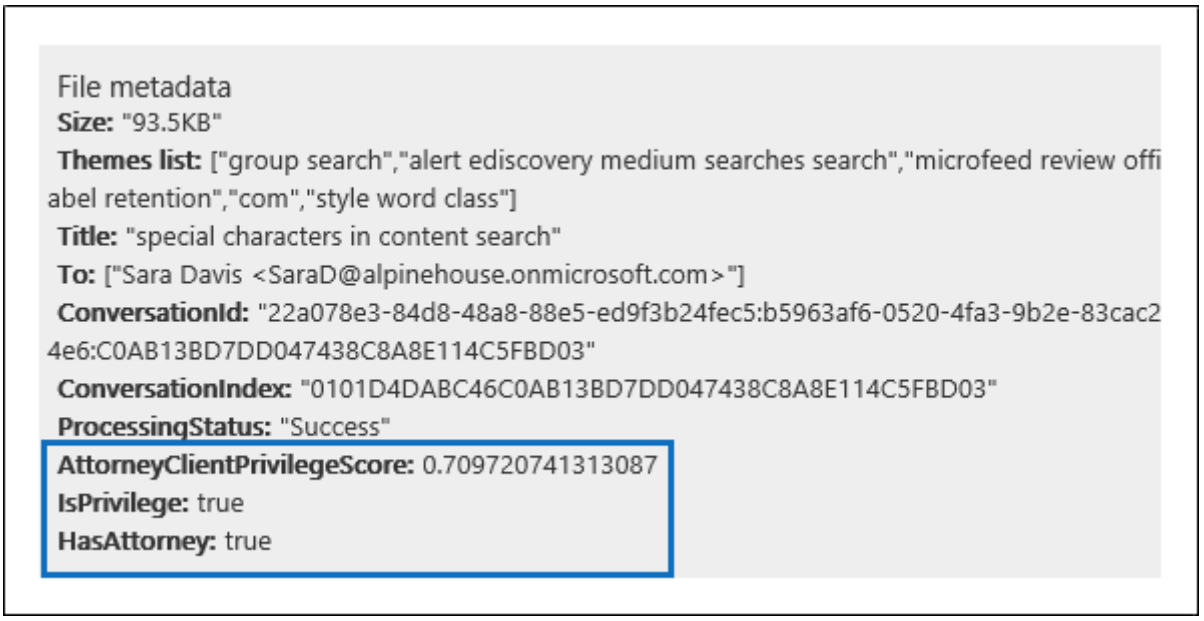
> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

A major and costly aspect of the review phase of any eDiscovery process is reviewing documents for privileged content. Microsoft Purview eDiscovery (Premium) provides machine learning-based detection of privileged content to make this process more efficient. This feature is called *attorney-client privilege detection*.

How does it work?

When attorney-client privilege detection is enabled, all documents in a review set will be processed by the attorney-client privilege detection model when you analyze the data in the review set. The model looks for two things:

- **Privileged content**: The model uses machine learning to determine the likelihood that the document contains content that is legal in nature.
- **Participants**: As part of setting up attorney-client privilege detection, you have to submit a list of attorneys for your organization. The model then compares the participants of the document with the attorney list to determine if a document has at least one attorney participant.



The model produces the following three properties for every document:

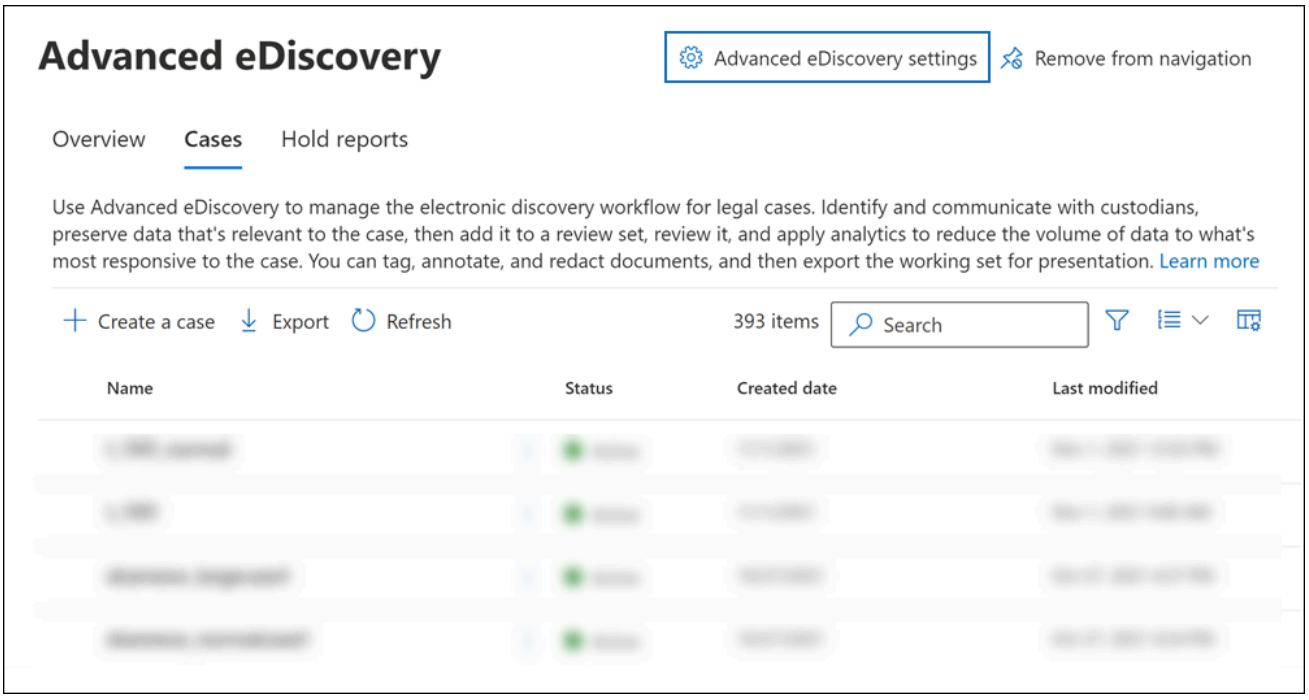
- **AttorneyClientPrivilegeScore:** The likelihood the document is legal in nature; the values for the score are between **0** and **1**.
- **HasAttorney:** This property is set to **true** if one of the document participants is listed in the attorney list; otherwise the value is **false**. The value is also set to **false** if your organization

didn't upload an attorney list.

- **IsPrivilege:** This property is set to **true** if the value for **AttorneyClientPrivilegeScore** is over the threshold *or* if the document has an attorney participant; otherwise the value is set to **false**.

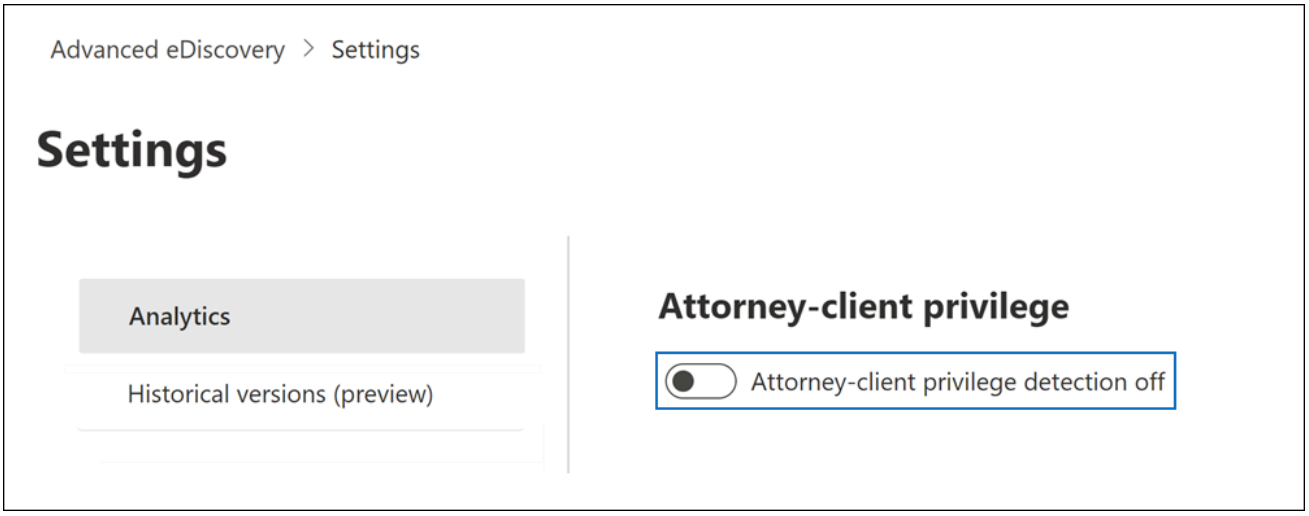
These properties (and their corresponding values) are added to the file metadata of the documents in a review set, as shown in the following screenshot:

These three properties are also searchable within a review set. For more information, see Query the data in a review set.



Set up the attorney-client privilege detection model

To enable the attorney-client privilege detection model, your organization has to turn it on and then upload an attorney list.



Step 1: Turn on attorney-client privilege detection

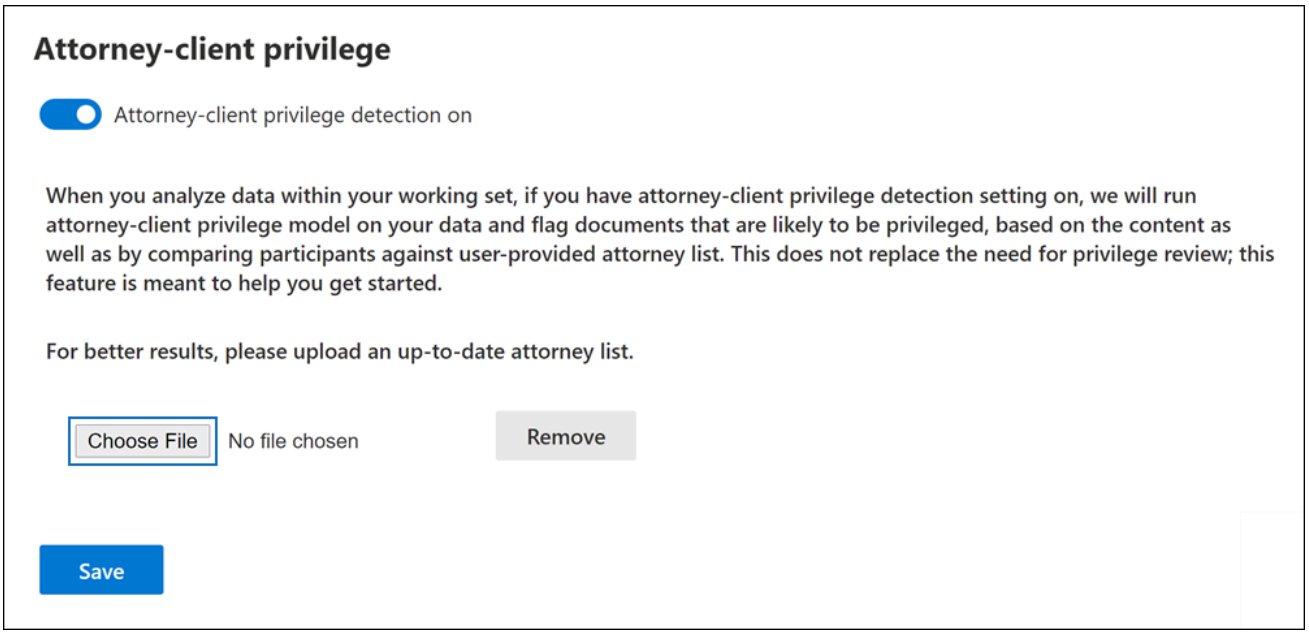
A person who is an eDiscovery Administrator in your organization (a member of the eDiscovery Administrator subgroup in the eDiscovery Manager role group) must make the model available in your eDiscovery (Premium) cases.

1. In the Microsoft Purview portal, go to eDiscovery (Premium), and then select **eDiscovery (Premium) settings**.

2. On the **Settings** page, select the **Analytics** tab, and then switch the **Attorney-client privilege detection** toggle to on.

3. Select **Save** to save the change.

Step 2: Upload a list of attorneys (optional)



To take full advantage of the attorney-client privilege detection model and use the results of the **Has Attorney** or **Potentially Privileged** detection that was previously described, we recommend that you upload a list of email addresses for the lawyers and legal personnel who work for your organization.

To upload an attorney list for use by the attorney-client privilege detection model:

1. Create a .csv file (without a header row) and add the email address for each appropriate person on a separate line. Save this file to your local computer.

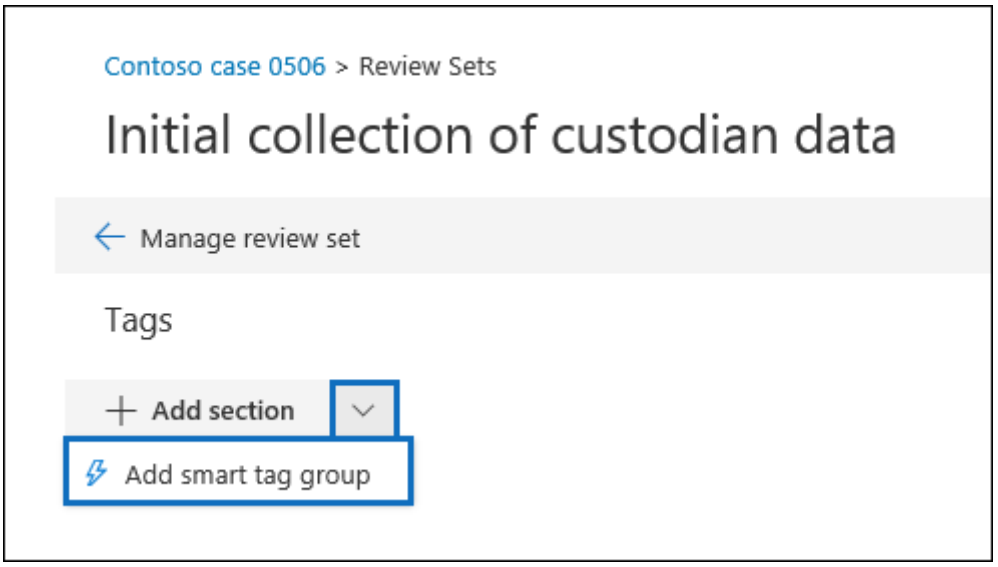
2. On the eDiscovery (Premium) **Settings** page, select the **Analytics** tab.

   The **Attorney-client privilege** page is displayed, and the **Attorney-client privilege detection** toggle is turned on.

3. Select **Choose file** and then find and select the .csv file that you created in step 1.

4. Select **Save** to upload the attorney list.

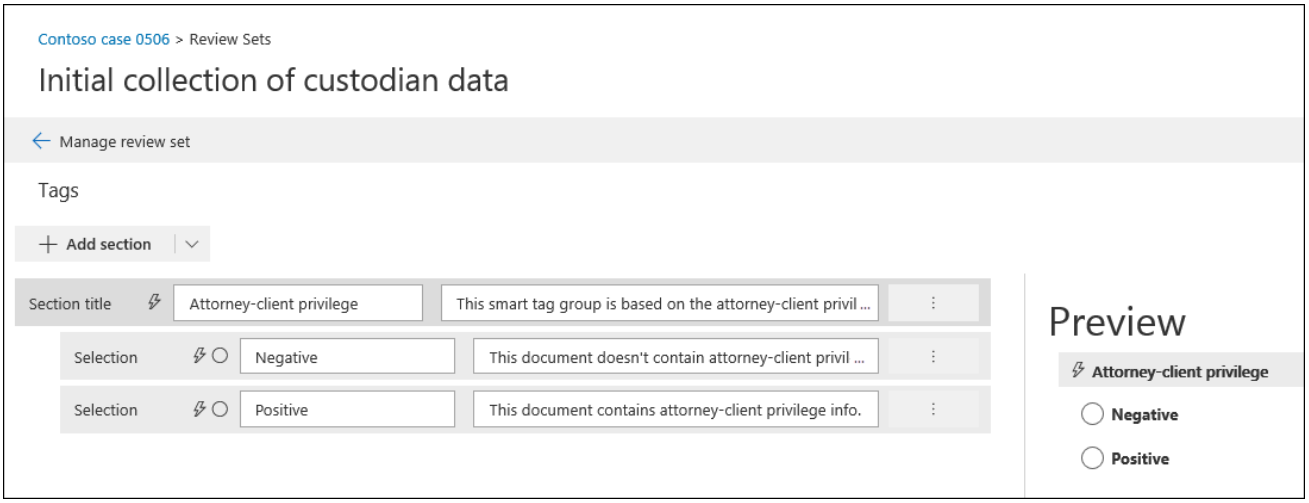
Use the attorney-client privilege detection model



Follow the steps in this section to use attorney-client privilege detection for documents in a review set.

Step 1: Create a smart tag group with attorney-client privilege detection model

One of the primary ways to see the results of attorney-client privilege detection in your review process is by using a smart tag group. A smart tag group indicates the results of the attorney-client privilege detection and shows the results in-line next to the tags in a smart tag group. This lets you quickly identify potentially privileged documents during document review. Additionally, you can also use the tags in the smart tag group to tag documents as privileged or non-privileged. For more information about smart tags, see Set up smart tags in eDiscovery (Premium).



1. In the review set that contains the documents that you analyzed in Step 1, select **Manage review set** and then select **Manage tags**.

2. Under **Tags**, select the pull-down next to **Add group** and then select **Add smart tag group**.

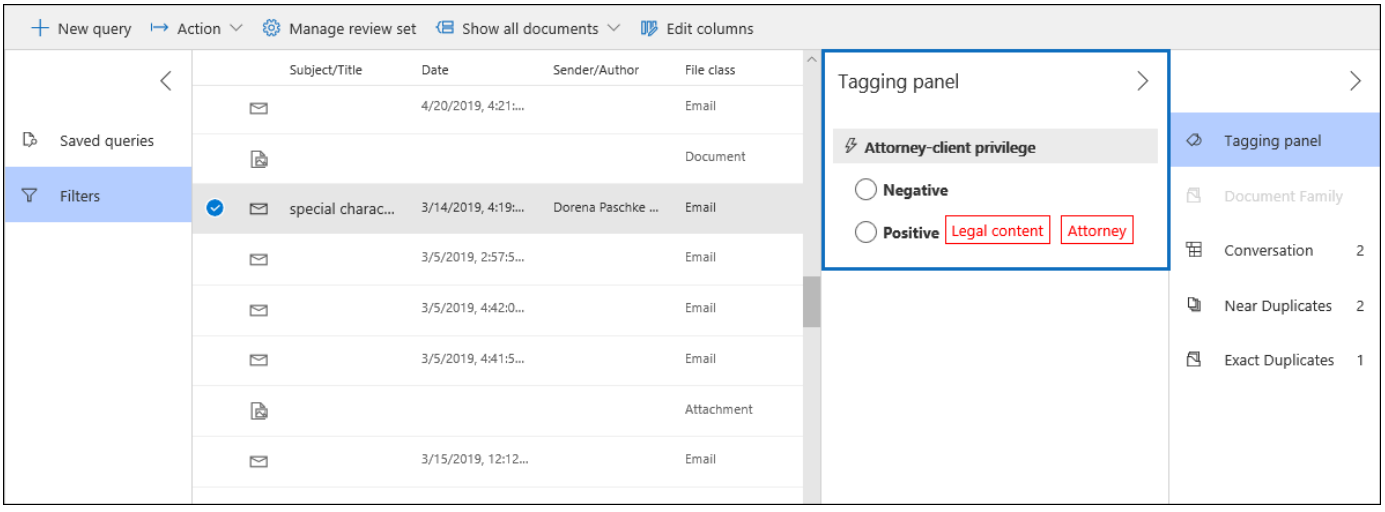
3. On the **Choose a model for your smart tag** page, choose **Select** next to **Attorney-client privilege**.

   A tag group named **Attorney-client privilege** is displayed. It contains two child tags named **Positive** and **Negative**, which correspond to the possible results produced by the model.

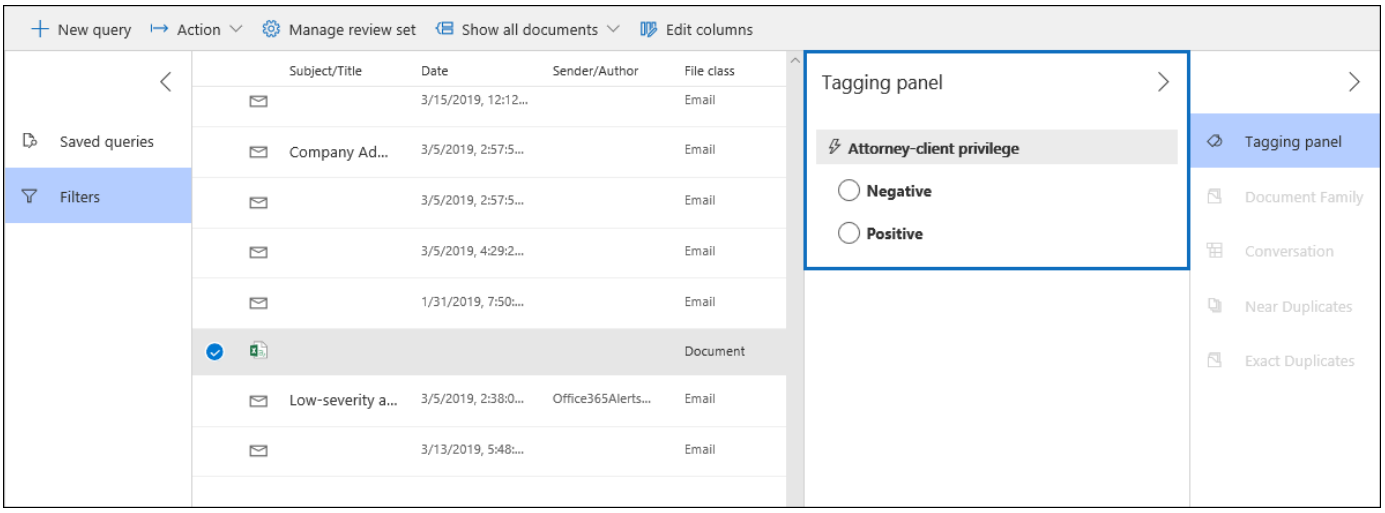
4. Rename the tag group and tags as appropriate for your review. For example, you can rename **Positive** to **Privileged** and **Negative** to **Not privileged**.

Step 2: Analyze a review set

When you analyze the documents in a review set, the attorney-client privilege detection model will also run and the corresponding properties (described in How does it work?) will be added to every document in the review set. For more information about analyzing data in review set, see Analyze data in a review set in eDiscovery (Premium).



Step 3: Use the smart tag group for review of privileged content



After analyzing the review set and setting up smart tags, the next step is to review the documents. If the model has determined the document is potentially privileged, the corresponding smart tag in the **Tagging panel** will indicate the following results produced by the attorney-client privilege detection:

- If the document has content that may be legal in nature, the label **Legal content** is displayed next to the corresponding smart tag (which in this case is the default **Positive** tag).
- If the document has a participant who is found in your organization's attorney list, the label **Attorney** is displayed next to the corresponding smart tag (which in this case is also the default **Positive** tag).
- If the document has content that may be legal in nature *and* has a participant found in the attorney list, both the **Legal content** and **Attorney** labels are displayed.

If the model determines that a document doesn't contain content that is legal in nature or doesn't contain a participant from the attorney list, then neither label is displayed in the tagging panel.

For example, the following screenshots show two documents. The first one contains content that is legal in nature and has a participant found in the list of attorneys. The second contains neither and therefore doesn't display any labels.

After you review a document to see if it contains privileged content, you can tag the document with the appropriate tag.

Assign eDiscovery permissions in the Microsoft Purview portal

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

To use any of the eDiscovery-related tools in the Microsoft Purview portal, assign the appropriate permissions. The easiest way to assign roles is to add the person to the appropriate role group on the **Permissions** page in the Purview portal. This article describes the permissions required to perform these tasks.

> **Tip**
>
> You can view your own permissions on the eDiscovery (Premium) overview page in the Purview portal. You must have at least one role assigned for your permissions to be displayed.

The primary eDiscovery-related role group in Purview portal is called **eDiscovery Manager**. Two subgroups exist within this role group:

- **eDiscovery Manager** - An eDiscovery Manager can use eDiscovery search tools to search content locations in the organization, and perform various search-related actions such as preview and export search results. Members can also create and manage cases in Microsoft Purview eDiscovery (Premium), add and remove members to a case, create case holds, run searches associated with a case, and access case data. eDiscovery Managers can only access and manage the cases they create. They can't access or manage cases created by other eDiscovery Managers.

- **eDiscovery Administrator** - An eDiscovery Administrator is a member of the eDiscovery Manager role group, and can perform the same content search and case management-related tasks that an eDiscovery Manager can perform. An eDiscovery Administrator can also:
  - Access all cases that are listed on the **eDiscovery (Premium)** page in the Purview portal.
  - Access case data in eDiscovery (Premium) for any case in the organization.
  - Manage any eDiscovery case after they add themselves as a member of the case.
  - Remove members from an eDiscovery case. Only an eDiscovery Administrator can remove members from a case. Users who are members of the eDiscovery Manager subgroup can't remove members from a case, even if the user created the case.

  For reasons why you might want eDiscovery Administrators in your organization, see eDiscovery Administrator considerations.

> **Note**
>
> eDiscovery (Premium) licensing requirements:
>
> - The custodian of the data must be assigned an Office 365 E5 or Microsoft 365 E5 license.
> - Users with an Office 365 E1 or an Office 365 or Microsoft 365 E3 license can be assigned a Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance) or Microsoft 365 eDiscovery and Audit add-on license.
> - Administrators, compliance officers, or legal personnel who are assigned to cases as members and use eDiscovery (Premium) to collect, view, and analyze data don't need an E5 license.
>
> For more information about eDiscovery (Premium) licensing, see **Subscriptions and licensing in eDiscovery (Premium)**.

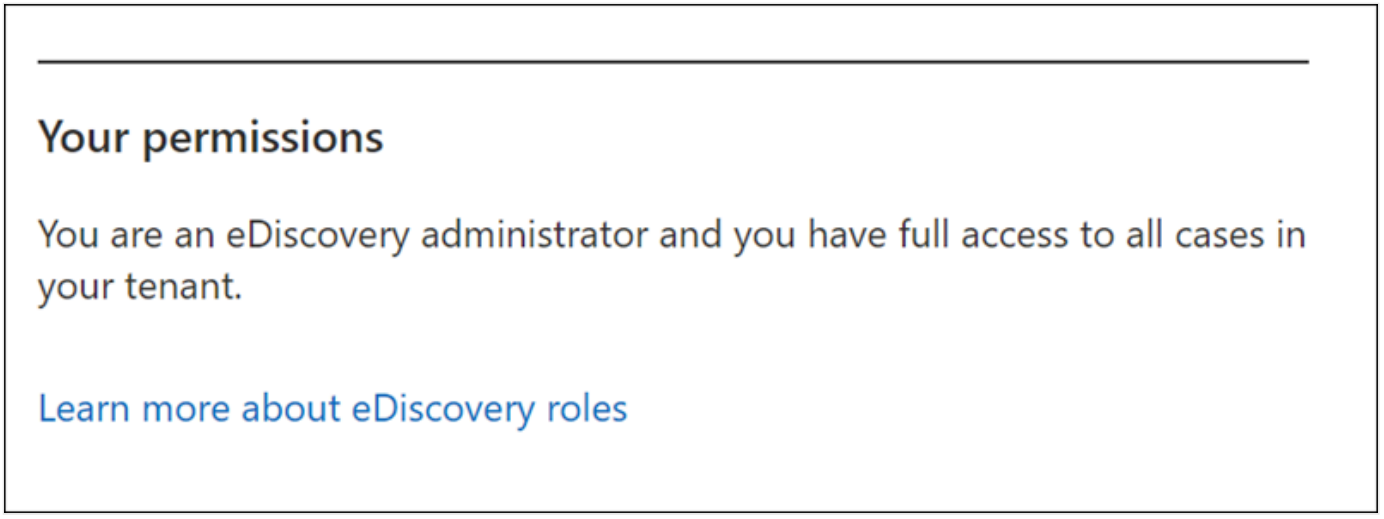
Prerequisites

- You must be a member of the *Organization Management* role group or be assigned the *Role Management* role to assign eDiscovery permissions in the Purview portal.
- You can use the Add-RoleGroupMember cmdlet in Security & Compliance PowerShell to add a mail-enabled security group as a member of the *eDiscovery Managers* subgroup in the *eDiscovery Manager* role group. However, you can't add a mail-enabled security group

to the *eDiscovery Administrators* subgroup. For details, see eDiscovery Administrator considerations.

Assign eDiscovery permissions

To assign eDiscovery permissions to users in the Microsoft Purview portal, follow these steps:



1. Go to the Purview portal and sign in with an account that can assign permissions.
2. In the left pane, select **Roles & scopes** > **Permissions**.
3. On **Permissions**, under **Microsoft Purview solutions**, select **Roles**.
4. On **Role groups for Microsoft Purview solutions**, select **eDiscovery Manager**.
5. On the **eDiscovery Manager** flyout, choose one of the following options based on the eDiscovery permissions that you want to assign.
   a. Select **Edit**.
   b. On **Manage eDiscovery Manager**, select **Choose users**.
   c. Search for and select the users you want to add as *eDiscovery Manager*, then select **Select**.
   d. Select **Next**.
   e. To assign users to the *eDiscovery Administrator* role group, select **Choose users**.
   f. Search for and select the users you want to add as *eDiscovery Administrator*, then select **Select**.
   g. Select **Next**.
   h. On **Review the role group and finish**, review the role group changes. Select **Save** to save the changes to the eDiscovery role groups.

> **Note**
>
> You can also use the **Add-eDiscoveryCaseAdmin** cmdlet to make a user an eDiscovery Administrator. However, you must assign the *Case Management* role to the user before you can use this cmdlet to make them an eDiscovery Administrator. For more information, see Add-eDiscoveryCaseAdmin.

On **Permissions** in the Microsoft Purview portal, you can also assign users eDiscovery-related permissions by adding them to the *Compliance Administrator*, *Organization Management*, and *Reviewer* role groups. For a description of the eDiscovery-related role-based access control roles assigned to each of these role groups, see Role-based access control roles related to eDiscovery.

View assigned permissions

When eDiscovery users sign in to Discovery in the Microsoft Purview portal, the **Your permissions** card on the eDiscovery **Overview** tab displays their assigned permissions. This card outlines the user's access and roles, including any limitations to eDiscovery cases.

RBAC roles related to eDiscovery

The following table lists the eDiscovery-related role-based access control roles in the Microsoft Purview portal, and shows the built-in role groups that each role belongs to by default.

Expand table

Role	Compliance Administrator	eDiscovery Manager & Administrator	Organization Management	Reviewer
Case Management	✓	✓	✓	
Communication		✓		
Compliance Search	✓	✓	✓	
Custodian		✓		
Export		✓		
Hold	✓	✓	✓	
Manage review set tags		✓		
Preview		✓		

Role	Compliance Administrator	eDiscovery Manager & Administrator	Organization Management	Reviewer
Review		✓		✓
RMS Decrypt		✓		
Search And Purge			✓	

> **Note**
>
> To view the list of eDiscovery cases, a user must have at least one of the roles listed in the previous table. For users who aren't eDiscovery Administrators, the cases shown are limited to those where the user is a member.

Run the following diagnostic test to check if the *Export*, *Preview*, or *Search* roles are assigned to the designated admin account.

1. Select the **Help** control in the top right of the Microsoft Purview portal. Enter *Diag:edisRBACdiag* in search (or select the eDiscovery RBAC Check diagnostic) to run the **eDiscovery RBAC Check** test.
2. In the **Run diagnostics** section, enter the UPN or email address of the user trying to run an export, preview, or search task.
3. Select **Run Tests**. If the user doesn't have the necessary eDiscovery roles, assign the roles to perform the desired task.

The following sections describe each of the eDiscovery-related role-based access control roles listed in the previous table.

Case Management role

This role lets users create, edit, delete, and control access to eDiscovery (Premium) cases in the Microsoft Purview portal. You must assign the *Case Management* role before you can use the **Add-eDiscoveryCaseAdmin** cmdlet to make a user an eDiscovery Administrator.

For more information, see Get started with eDiscovery (Premium).

Communication role

This role lets users manage all communications with the custodians identified in an eDiscovery (Premium) case. This management includes creating hold notifications, hold reminders, and

escalations to management. The user can also track custodian acknowledgment of hold notifications and manage access to the custodian portal that each custodian uses to track communications for the cases where they were identified as a custodian.

For more information, see Work with communications in eDiscovery (Premium).

Compliance Search role

This role lets users run the Content Search tool in the Microsoft Purview portal to search mailboxes and public folders, SharePoint Online sites, OneDrive for Business sites, Skype for Business conversations, Microsoft 365 groups, Microsoft Teams, and Viva Engage groups. This role allows a user to get an estimate of the search results and create export reports, but other roles are needed to initiate content search actions such as previewing, exporting, or deleting search results.

In Content search and eDiscovery (Standard), users who are assigned the *Compliance Search* role but don't have the *Preview* role can preview the results of a search when a user assigned the *Preview* role initiates the preview action. The user without the *Preview* role can preview results for up to two weeks after the initial preview action was created.

Similarly, users in Content search and eDiscovery (Standard) who are assigned the *Compliance Search* role but don't have the *Export* role can download the results of a search when a user assigned the *Export* role initiates the export action. The user without the *Export* role can download the results of a search for up to two weeks after the initial export action was created. After that, they can't download the results unless someone with the *Export* role restarts the export.

The two-week grace period for previewing and exporting search results (without the corresponding search and export roles) doesn't apply to eDiscovery (Premium). Users must be assigned the *Preview* and *Export* roles to preview and export content in eDiscovery (Premium).

Custodian role

This role lets users identify and manage custodians for eDiscovery (Premium) cases and use the information from Microsoft Entra ID and other sources to find data sources associated with custodians. The user can associate other data sources such as mailboxes, SharePoint sites, and Teams with custodians in a case. The user can also place a legal hold on the data sources associated with custodians to preserve content in the context of a case.

For more information, see Work with custodians in eDiscovery (Premium).

Export role

This role lets users export the results of a Content Search to a local computer. It also lets them prepare search results for analysis in eDiscovery (Premium).

For more information about exporting search results, see Export search results from Microsoft Purview portal.

Hold role

This role lets users place content on hold in mailboxes, public folders, sites, Skype for Business conversations, and Microsoft 365 groups. When content is on hold, content owners can still modify or delete the original content, but the content is preserved until the hold is removed or until the hold duration expires.

For more information about holds, see:

- Create a hold in eDiscovery (Standard)
- Create a hold in eDiscovery (Premium)

Manage review set tags role

This role lets users create, edit, and delete review set tags for cases they can access. Users need to at least have the *Review* role and this role to manage tags during reviews.

Preview role

This role lets users view a list of items that a Content Search returns. They can also open and view each item from the list to view its contents.

Review role

This role lets users access review sets in eDiscovery (Premium). Users who are assigned this role can see and open the list of cases on the **eDiscovery** > **Premium** page in the Microsoft Purview portal that they're members of. After the user accesses an eDiscovery (Premium) case, they can select **Review sets** to access case data. This role doesn't allow the user to preview the results of a collection search that's associated with the case or do other search or case management tasks. Users with this role can only access the data in a review set.

RMS Decrypt role

This role lets users view rights-protected email messages when previewing search results and export decrypted rights-protected email messages. This role also lets users view and export a file that's encrypted with a Microsoft encryption technology when the encrypted file is attached to an email message that's included in the results of an eDiscovery search. Additionally, this role lets users review and query encrypted email attachments that are added to a review set in eDiscovery (Premium). For more information about decryption in eDiscovery, see Decryption in Microsoft 365 eDiscovery tools.

Search And Purge role

This role lets users perform bulk removal of data matching the criteria of a content search. For more information, see Search for and delete email messages in your organization.

Add role groups as members of eDiscovery cases

You can add role groups as members of eDiscovery (Standard) and eDiscovery (Premium) cases so that members of the role groups can access and perform tasks in the assigned cases. The roles assigned to the role group define what members of the role group can do. Adding a role group as a member of the case lets members access and perform those tasks in a specific case. For more information about adding role groups as members of cases, see:

- Get started with eDiscovery (Standard)
- Add or remove members from an eDiscovery (Premium) case

If you add or remove a role from a role group, the role group is automatically removed as a member of any case it belongs to. This behavior protects your organization from inadvertently providing extra permissions to members of a case. Similarly, if you delete a role group, you remove it from all cases it was a member of.

Before you add or remove roles to a role group that might be a member of an eDiscovery case, run the following commands in Security & Compliance PowerShell to get a list of cases the role group is a member of. After you update the role group, add the role group back as a member of those cases.

Get a list of eDiscovery (Standard) cases a role group is assigned to

PowerShell

```
Get-ComplianceCase -RoleGroup "Name of role group"
```

Get a list of eDiscovery (Premium) cases a role group is assigned to

PowerShell

```
Get-ComplianceCase -RoleGroup "Name of role group" -CaseType AdvancedEdiscovery
```

eDiscovery Administrator considerations

- **Why create an eDiscovery Administrator?** An eDiscovery Administrator is a member of the *eDiscovery Manager* role group who can view and access all eDiscovery cases in your organization. This ability to access all the eDiscovery cases has two important purposes:
  - If a person who is the only member of an eDiscovery case leaves your organization, no one (including members of the *Organization Management* role group or another member of the *eDiscovery Manager* role group) can access that eDiscovery case because they aren't a member of a case. In this situation, there's no way to access the data in the case. But because an eDiscovery Administrator can access all eDiscovery cases in the organization, they can view the case and add themselves or another eDiscovery manager as a member of the case.
  - Because an eDiscovery Administrator can view and access all eDiscovery (Standard) and eDiscovery (Premium) cases, they can audit and oversee all cases and associated compliance searches. This functionality can help to prevent any misuse of compliance searches or eDiscovery cases. And because eDiscovery Administrators can access potentially sensitive information in the results of a compliance search, you should limit the number of people who are eDiscovery Administrators.

- **Can I add a group as a member of the eDiscovery Manager role group?** As described in the Prerequisites section, you can add a mail-enabled security group as a member of the eDiscovery Managers subgroup in the *eDiscovery Manager* role group by using the **Add-RoleGroupMember** cmdlet in Security & Compliance PowerShell. For example, you can run the following command to add a mail-enabled security group to the *eDiscovery Manager* role group.

  PowerShell

  ```
  Add-RoleGroupMember "eDiscoveryManager" -Member <name of security group>
  ```

  Exchange distribution groups and Microsoft 365 Groups aren't supported. You must use a mail-enabled security group, which you can create in Exchange Online PowerShell by

running `New-DistributionGroup -Type Security`. You can also create a mail-enabled security group (and add members) in the Exchange admin center or in the Microsoft 365 admin center. It might take up to 60 minutes after you create it for a new mail-enabled security group to be available to add to the eDiscovery Managers role group.

You can't make a mail-enabled security group an eDiscovery Administrator by using the **Add-eDiscoveryCaseAdmin** cmdlet in Security & Compliance PowerShell. You can only add individual users as eDiscovery Administrators.

You also can't add a mail-enabled security group as a member of a case.

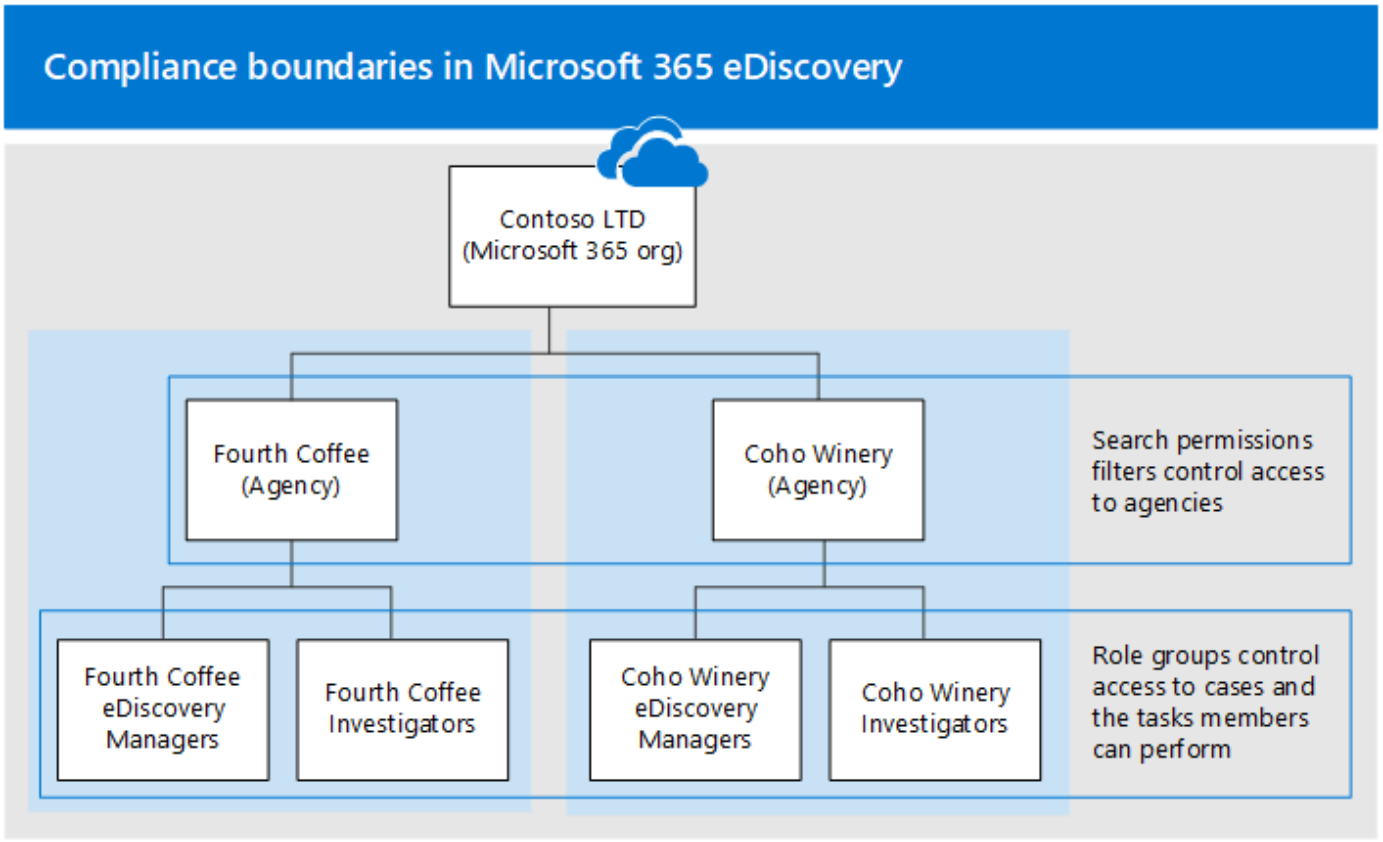
Set up compliance boundaries for eDiscovery investigations



> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

The guidance in this article can be applied when using either Microsoft Purview eDiscovery (Standard) or Microsoft Purview eDiscovery (Premium) to manage investigations.

Compliance boundaries create logical boundaries within an organization that control the user content locations (such as mailboxes, OneDrive accounts, and SharePoint sites) that eDiscovery managers can search. Compliance boundaries also control who can access eDiscovery cases used to manage the legal, human resources, or other investigations within your organization.

The need for compliance boundaries is often necessary for multi-national corporations that have to respect geographical boarders and regulations and for governments, which are often divided into different agencies. In Microsoft 365, compliance boundaries help you meet these requirements when performing content searches and managing investigations with eDiscovery cases.

We'll use the example in the following illustration to explain how compliance boundaries work.

In this example, Contoso LTD is an organization that consists of two subsidiaries, Fourth Coffee and Coho Winery. The business requires that eDiscovery managers and investigators can only search the Exchange mailboxes, OneDrive accounts, and SharePoint sites in their agency. Also, eDiscovery managers and investigators can only see eDiscovery cases in their agency, and they can only access the cases that they're a member of. Additionally in this scenario, investigators can't place content locations on hold or export content from a case. Here's how compliance boundaries meet these requirements.

- The search permissions filtering functionality for eDiscovery controls the content locations that eDiscovery managers and investigators can search. This control means eDiscovery managers and investigators in the Fourth Coffee agency can only search content locations in the Fourth Coffee subsidiary. The same restriction applies to the Coho Winery subsidiary.

- Role groups provide the following functions for compliance boundaries:
  - Control who can see the eDiscovery cases in the Microsoft Purview portal. This control means that eDiscovery managers and investigators can only see the eDiscovery cases in their agency.
  - Control who can assign members to an eDiscovery case. This control means eDiscovery managers and investigators can only assign members to cases that they themselves are a member of.
  - Control the eDiscovery-related tasks that members can perform by adding or removing roles that assign specific permissions.

- When a search permissions filter is applied to a role group, members of the role group can perform the following search-related actions as long as the permissions to perform an action is assigned to the role group:
  - Search for content
  - Preview search results
  - Export search results
  - Purge items returned by a search

Before you set up compliance boundaries

- Users must be assigned an Exchange Online license. To verify assignments, use the Get-User cmdlet in Exchange Online PowerShell.

Setting up compliance boundaries

Here's the steps for setting up compliance boundaries:

- Step 1: Identify a user attribute to define your agencies
- Step 2: Create a role group for each agency
- Step 3: Create a search permissions filter to enforce the compliance boundary
- Step 4: Create an eDiscovery case for an intra-agency investigations

Step 1: Identify a user attribute to define your agencies

The first step is to choose an attribute to use that will define your agencies. This attribute is used to create the search permissions filter that limits an eDiscovery manager to search only the content locations of users who are assigned a specific value for this attribute. For example, let's say Contoso decides to use the **Department** attribute. The value for this attribute for users in the Fourth Coffee subsidiary would be `FourthCoffee` and the value for users in Coho Winery subsidiary would be `CohoWinery`. In Step 3, you use this `attribute:value` pair (for example, *Department:FourthCoffee*) to limit the user content locations that eDiscovery managers can search.

Here are some examples of user attributes that you can use for compliance boundaries:

- Company
- CustomAttribute1 - CustomAttribute15
- Department
- Office

- CountryOrRegion (Two-letter country code)

Step 2: Create a role group for each agency

The next step is to create the role groups in the Microsoft Purview portal that will align with your agencies.

To create the role groups, go to the **Permissions** page in the Microsoft Purview portal and create a role group for each team in each agency that will use compliance boundaries and eDiscovery cases to manage investigations.

We recommend that the role groups created for the compliance boundary don't have any roles attached to it. This role group should only be used to assign users to the role group. Separate built-in (eDiscovery Manager) or custom role groups should be used to assign roles to members. For more information about eDiscovery-related roles, see Assign eDiscovery permissions.

> **Note**
>
> To ceate and update role groups with empty roles, you must use PowerShell cmdlets. For details, see New-RoleGroup and Add-RoleGroupMember.

Using the Contoso compliance boundaries scenario, four role groups need to be created and the appropriate members added to each one.

- Fourth Coffee eDiscovery Managers
- Fourth Coffee Investigators
- Coho Winery eDiscovery Managers
- Coho Winery Investigators

> **Important**
>
> If a role is added or removed from a role group that you've added as a member of a case, then the role group is automatically removed as a member of the case (or any case the role group is a member of). The reason for this is to protect your organization from inadvertently providing additional permissions to members of a case. If a role group is deleted, it is removed from all cases it was a member of. We recommend that the role groups created for compliance boundaries don't have any roles assigned to them. Use separate built-in/custom role groups to assign roles to members.

Step 3: Create a search permissions filter to enforce the compliance boundary

After you've created role groups for each agency, the next step is to create the search permissions filters that associate each role group to its specific agency and defines the compliance boundary itself. You need to create one search permissions filter for each agency. For more information about creating security permissions filters, see Configure permissions filtering for Content Search.

Here's the syntax that's used to create a search permissions filter used for compliance boundaries for the scenario in this article.

PowerShell

```
New-ComplianceSecurityFilter -FilterName <name of filter> -Users <role groups> -
Filters "Mailbox_<MailboxPropertyName>  -eq '<Value> '", "SiteContent_Path -like
'<SharePointURL>' -or SiteContent_Path -like '<OneDriveURL>'"
```

Here's a description of each parameter in the command:

- `FilterName`: Specifies the name of the filter. Use a name that describes or identifies the agency that the filter is used in.
- `Users`: Specifies the users or groups who get this filter applied to the search actions they perform. For compliance boundaries, this parameter specifies the role groups (that you created in Step 2) in the agency that you're creating the filter for. This parameter is a multi-value parameter so you can include one or more role groups, separated by commas.
- `Filters`: Specifies the search criteria for the filter. For compliance boundaries, you define the following filters. Each one applies to different content locations.
  - `Mailbox`: Specifies the mailboxes or OneDrive accounts that the role groups defined in the `Users` parameter can search. This filter allows members of the role group to search only the mailboxes or OneDrive accounts in a specific agency; for example, `"Mailbox_Department -eq 'FourthCoffee'"`.
  - `SiteContent`: This filter includes two separate filters. The first `SiteContent_Path` specifies the SharePoint sites in the agency that the role groups defined in the `Users` parameter can search. For example, `SiteContent_Path -like 'https://contoso.sharepoint.com/sites/FourthCoffee*'`. The second `SiteContent_Path` filter (connected to the first `SiteContent_Path` filter by the `or` operator) specifies the

agency's OneDrive domain (also called the *MySite* domain). For example, `SiteContent_Path -like 'https://contoso-my.sharepoint.com/personal*'`. You can also use the `Site_Path` filter in place of the `SiteContent` filter. The `Site` and `SiteContent` filters are interchangeable, and don't affect search permissions filters described in this article.

> **Important**
>
> Why is the `SiteContent` filter for OneDrive included in the previous search permissions filter? Although the `Mailbox` filter applies to *both* mailboxes and OneDrive accounts, the inclusion of the SharePoint filter would exclude OneDrive accounts if you didn't also include the OneDrive `Site` filter. If the search permissions filter didn't include a SharePoint filter, then you wouldn't have to include a separate OneDrive filter because the Mailbox filter would include OneDrive accounts in the scope of the compliance boundary. In other words, a search permissions filter with only the `Mailbox` filter would include both mailboxes and OneDrive accounts.

Here are examples of the two search permissions filters that would be created to support the Contoso compliance boundaries scenario. Both of these examples include a comma-separated filters list, in which the mailbox and site filters are included in the same search permissions filter and are separated by a comma.

Fourth Coffee

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Fourth Coffee Security Filter" -Users
"Fourth Coffee eDiscovery Managers", "Fourth Coffee Investigators" -Filters
"Mailbox_Department -eq 'FourthCoffee'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/FourthCoffee*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'"
```

Coho Winery

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Security Filter" -Users "Coho
Winery eDiscovery Managers", "Coho Winery Investigators" -Filters "Mailbox_Department
-eq 'CohoWinery'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/CohoWinery*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'"
```

> **Note**
>
> The syntax for the `Filters` parameters in the previous examples includes a *filters list*. A filters list is a filter that includes a mailbox filter and a site path filter separated by a comma. In the previous example, notice that a comma separates `Mailbox` and `SiteContent` filters: `-Filters "Mailbox_<MailboxPropertyName> -eq '<Value> '", "SiteContent_Path -like '<SharePointURL>' -or SiteContent_Path -like '<OneDriveURL>'"`. When this filter is processed during the running of an eDiscovery search, two search permissions filters are created from the filters list: one mailbox filter and one SharePoint/OneDrive filter. An alternative to using a filters list would be to create two separate search permissions filters for each agency: one search permissions filter for the mailbox attribute and one filter for the SharePoint and OneDrive site attributes. In either case, the results will be the same. Using a filters list or creating separate search permissions filters is a matter of preference.

How do the search permissions filters work in this scenario?

Here's how the search permission filters are applied for each agency in this scenario.

1. The `Mailbox` filter is first applied to define the content locations that eDiscovery managers can search. In this case, Coho Winery eDiscovery managers can only search the mailboxes and OneDrive accounts of users whose *Department* mailbox property has a value of **FourthCoffee**; Coho Winery eDiscovery managers can only search the mailboxes and OneDrive accounts of users whose *Department* mailbox property has a value of **CohoWinery**. The `Mailbox` filter is a *content location filter*, because it specifies the content locations that eDiscovery managers can search. In both filters, eDiscovery managers can only search content locations with a specific mailbox property value.

2. After the content locations that can be searched are defined, the next part of the filter defines the content that eDiscovery managers can search. The first `SiteContent` filter lets Fourth Coffee eDiscovery managers only search for documents that have a site path property that contains (or starts with) `https://contoso.sharepoint.com/sites/FourthCoffee`; Coho Winery eDiscovery managers can only search documents that have a site path property that contains (or starts with) `https://contoso.sharepoint.com/sites/CohoWinery`. Therefore, the two `SiteContent` filters are *content filters* because they define the content that can be searched for. In both filters, eDiscovery managers can only search for documents with a specific document property value. All SharePoint-related filters are content filters because searchable site properties are stamped on all documents. For more information, see Configure permissions filtering for eDiscovery.

> **Note**
>
> Although the scenario in this article doesn't use them, you can also use mailbox content filters to specify the content that eDiscovery managers can search for. The syntax for mailbox content filters is `"MailboxContent_<property> -<comparison operator> '<value>'"`. You can create content filters based on date ranges, recipients, and domains or any searchable email property. For example, this filter would allow eDiscovery managers to only search for mail items sent or received by users in the contoso.com domain: `"MailboxContent_Participants -like 'contoso.com'"`. For more information about mailbox content filters, see Configure search permissions filtering.

3. The search permissions filter is joined to the search query by the **AND** Boolean operator. That means when an eDiscovery manager in one of the agencies runs an eDiscovery search, the items returned by the search must match the search query and the conditions defined in the search permissions filter.

Step 4: Create an eDiscovery case for intra-agency investigations

The final step is to create an eDiscovery (Standard) case or eDiscovery (Premium) case in the Microsoft Purview portal and then add the role group that you created in Step 2 as a member of the case. This results in two important characteristics of using compliance boundaries:

- Only members of the role group added to the case will be able to see and access the case in the Microsoft Purview portal. For example, if the Fourth Coffee Investigators role group is the only member of a case, then members of the Fourth Coffee eDiscovery Managers role group (or members of any other role group) won't be able to see or access the case.
- When a member of the role group assigned to a case runs a search associated with the case, they'll only be able to search the content locations within their agency (which is defined by the search permissions filter that you created in Step 3.)

To create a case and assign members:

1. Go to the **eDiscovery (Standard)** or **eDiscovery (Premium)** page in the Microsoft Purview portal and create a case.
2. In the list of cases, select the name of the case you created.

3. Add role groups as members to the case. For instructions, see the one of the following articles:

    - Add members to an eDiscovery (Standard) case
    - Add members to an eDiscovery (Premium) case

> **Note**
>
> When adding a role group to a case, you can only add the role groups that you are a member of.

Searching and exporting content in multi-geo environments

Search permissions filters also let you control where content is routed for export and which datacenter can be searched when searching content locations in a SharePoint Multi-Geo environment.

- **Export search results:** You can export the search results from Exchange mailboxes, SharePoint sites, and OneDrive accounts from a specific datacenter. This means that you can specify the datacenter location that search results are exported from.

  Use the *Region* parameter for **New-ComplianceSecurityFilter** or **Set-ComplianceSecurityFilter** cmdlets to create or change which datacenter the export is routed through.

  Expand table

Parameter value	Datacenter location
NAM	North American (datacenters are in the US)
EUR	Europe
APC	Asia Pacific
CAN	Canada

- **Route content searches:** You can route the content searches of SharePoint sites and OneDrive accounts to a satellite datacenter. This means you can specify the datacenter location where searches are run.

Use one of the following values for the *Region* parameter to control the datacenter location that searches will run in when searching SharePoint sites and OneDrive accounts.

Expand table

Parameter value	Datacenter routing locations for SharePoint
NAM	US
EUR	Europe
APC	Asia Pacific
CAN	US
AUS	Asia Pacific
KOR	The organization's default datacenter
GBR	Europe
JPN	Asia Pacific
IND	Asia Pacific
LAM	US
NOR	Europe
BRA	North American datacenters

If you don't specify the *Region* parameter for a search permissions filter, the organization's primary SharePoint region is searched. Search results are exported to the closest datacenter.

To simplify the concept, the *Region* parameter controls the datacenter that is used to search for content in SharePoint and OneDrive. This doesn't apply to searching for content in Exchange because Exchange content searches aren't bound by the geographic location of datacenters. Also, the same *Region* parameter value may also dictate the datacenter that exports are routed through. This is often necessary to control the movement of data across geographic boarders.

Note

If you're using eDiscovery (Premium), the *Region* parameter doesn't control the region that data is exported from. Data is exported from the organization's central location. Also, searching for content in SharePoint and OneDrive isn't bound by the geographic location of

datacenters. All datacenters are searched. For more information about eDiscovery (Premium), see Overview of the eDiscovery (Premium) solution in Microsoft 365.

Here are examples of using the *Region* parameter when creating search permission filters for compliance boundaries. This assumes that the Fourth Coffee subsidiary is located in North America and that Coho Winery is in Europe.

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Fourth Coffee Security Filter" -Users
"Fourth Coffee eDiscovery Managers", "Fourth Coffee Investigators" -Filters
"Mailbox_Department -eq 'FourthCoffee'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/FourthCoffee*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'" -Region NAM
```

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Security Filter" -Users "Coho
Winery eDiscovery Managers", "Coho Winery Investigators" -Filters "Mailbox_Department
-eq 'CohoWinery'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/CohoWinery*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'" -Region EUR
```

Keep the following things in mind when searching and exporting content in multi-geo environments.

- The *Region* parameter doesn't control searches of Exchange mailboxes. All datacenters will be searched when you search mailboxes. To limit the scope of which Exchange mailboxes are searched, use the *Filters* parameter when creating or changing a search permissions filter.
- If it's necessary for an eDiscovery Manager to search across multiple SharePoint regions, you need to create a different user account for that eDiscovery manager to use in the search permissions filter to specify the region where the SharePoint sites or OneDrive accounts are located. For more information about setting this up, see the "Searching for content in a SharePoint Multi-Geo environment" section in Content Search.
- When searching for content in SharePoint and OneDrive, the *Region* parameter directs searches to either the primary or satellite location where the eDiscovery manager will conduct eDiscovery investigations. If an eDiscovery manager searches SharePoint and OneDrive sites outside of the region that's specified in the search permissions filter, no search results are returned.

- When exporting search results from eDiscovery (Standard), content from all content locations (including Exchange, Skype for Business, SharePoint, OneDrive, and other services that you can search by using the Content Search tool) are uploaded to the Azure Storage location in the datacenter that's specified by the *Region* parameter. This helps organizations stay within compliance by not allowing content to be exported across controlled borders. If no region is specified in the search permissions filter, content is uploaded to the organization's primary datacenter.

  When exporting content from eDiscovery (Premium), you can't control where content is uploaded by using the *Region* parameter. Content is uploaded to an Azure Storage location in a datacenter in your organization's central location. For a list of geo locations based on your central location, see Microsoft 365 Multi-Geo eDiscovery configuration.

- You can edit an existing search permissions filter to add or change the region by running the following command:

  PowerShell

  ```
  Set-ComplianceSecurityFilter -FilterName <Filter name>  -Region <Region>
  ```

Using compliance boundaries for SharePoint hub sites

SharePoint hub sites often align with the same geographical or agency boundaries that eDiscovery compliance boundaries follow. That means you can use the site ID property of the hub site to create a compliance boundary. To do this, use the Get-SPOHubSite cmdlet in SharePoint Online PowerShell to obtain the SiteId for the hub site, and then use this value for the department ID property to create a search permissions filter.

Use the following syntax to create a search permissions filter for a SharePoint hub site:

PowerShell

```
New-ComplianceSecurityFilter -FilterName <Filter Name> -Users <User or Group> -Filters
"Site_Departmentid -eq '{SiteId of hub site}'"
```

Here's an example of creating a search permissions filter for a hub site for the Coho Winery agency:

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Hub Site Security Filter" -Users
"Coho Winery eDiscovery Managers", "Coho Winery Investigators" -Filters
"Site_Departmentid -eq '44252d09-62c4-4913-9eb0-a2a8b8d7f863'"
```

Compliance boundary limitations

Keep the following limitations in mind when managing eDiscovery cases and investigations that use of compliance boundaries.

- When creating and running a search, you can select content locations that are outside of your agency. However, because of the search permissions filter, content from those locations isn't included in the search results.
- Compliance boundaries don't apply to holds in eDiscovery cases. That means an eDiscovery manager in one agency can place a user in a different agency on hold. However, the compliance boundary will be enforced if the eDiscovery manager searches the content locations of the user who was placed on hold. That means the eDiscovery manager won't be able search the user's content locations, even though they were able to place the user on hold.
- If you're assigned a search permissions filter (either a mailbox or a site filter) and you try to export unindexed items for a search that includes all SharePoint sites in your organization, you'll receive the following error message: `Unable to execute the task. Reason: The scope options UnindexedItemsOnly or BothIndexedandUnindexedItems are not allowed when the executing user has a compliance security filter applied`. If you're assigned a search permissions filter and you want to export unindexed items from SharePoint, you'll have to rerun the search and include specific SharePoint sites to search. Otherwise, you'll only be able to export indexed items from a search that includes all SharePoint sites. For more information about the options when you export search results, see Export Content search results.
- Search permissions filters aren't applied to Exchange public folders.
- Supported search filters include `-and`, `-or`, `-like`, `-not`, `-eq`, and `-ne`. We don't recommend using other exclusion filters (such as using `-notlike)`, `inotlike`, etc. in a search permissions filter) for a content-based compliance boundary. Using these exclusion filters can have unexpected results if content with recently updated attributes hasn't been indexed.
- Respect for compliance boundaries for OneDrive sites in searches may be impacted when:

- The sites (or associated mailboxes) are moved or re-homed
- OneDrive ownership is re-assigned, or more than one owner is added
- The OneDrive site is renamed/re-issued

Moving a OneDrive site can change the ownership of the content and may include creating an arbitration mailbox. When these resources are moved, there's a chance that content search results may be available across compliance boundaries. When a OneDrive site is re-assigned, re-named or assigned to more than one owner, it's possible that the content from these sites may be available across compliance boundaries.

- Compliance boundaries for mailboxes may be impacted when:
- The mailbox isn't associated with a licensed user (includes disabled or deleted users)
  - A mailbox isn't managed or synced from Microsoft Entra ID

    Additionally, there are several types of mailboxes that may produce content during search, regardless of their compliance boundaries. These mailbox types include:
    - EquipmentMailbox
    - GuestMailUser
    - LinkedMailbox
    - RoomList
    - RoomMailbox
    - SchedulingMailbox
    - SharedMailbox
    - SystemMailbox
    - TeamMailbox

  To make sure that the search respects the compliance boundaries as expected, users can set attributes on shared mailboxes, equipment mailboxes, and other mailboxes using the Set-Mailbox cmdlet or by using Invoke-ComplianceSecurityFilterAction to ensure the attribute is set correctly. If the attribute is properly configured and aligned with the compliance boundary attribute, the mailbox respects the compliance boundary.

More information

- If a mailbox is de-licensed or soft-deleted, the user will no longer be considered within the compliance boundary. If a hold was placed on the mailbox when it was deleted, the content preserved in the mailbox is still subject to a compliance boundary or search permissions filter.

- If compliance boundaries and search permissions filters are implemented for a user, then we recommend that you don't delete a user's mailbox and not their OneDrive account. In other words, if you delete a user's mailbox, you should also remove the user's OneDrive account since mailbox_RecipientFilter is used to enforce search permission filter for OneDrive.
- Compliance boundaries and search permissions filters depend on attributes being stamped on content in Exchange, OneDrive, and SharePoint and the subsequent indexing of this stamped content.

Frequently asked questions

Who can create and manage search permissions filters (using New-ComplianceSecurityFilter and Set-ComplianceSecurityFilter cmdlets)?

To create, view, and modify search permissions filters, you have to be a member of the Organization Management role group in the Microsoft Purview portal.

If an eDiscovery manager is assigned to more than one role group that spans multiple agencies, how do they search for content in one agency or the other?

The eDiscovery manager can add parameters to their search query that restrict the search to a specific agency. For example, if an organization has specified the **CustomAttribute10** property to differentiate agencies, they can append the following to their search query to search mailboxes and OneDrive accounts in a specific agency: `CustomAttribute10:<value>`.

What happens if the value of the attribute that's used as the compliance attribute in a search permissions filter is changed?

It takes up to three days for a search permissions filter to enforce the compliance boundary if the value of the attribute that's used in the filter is changed. For example, in the Contoso scenario let's say that a user in the Fourth Coffee agency is transferred to the Coho Winery agency. As a result, the value of the **Department** attribute on the user object is changed from *FourthCoffee* to *CohoWinery*. In this situation, Fourth Coffee eDiscovery and investors will get search results for that user for up three days after the attribute is changed. Similarly, it takes up to three days before Coho Winery eDiscovery managers and investigators get search results for the user.

Can an eDiscovery manager see content from two separate compliance boundaries?

Yes, this can be done when searching Exchange mailboxes by adding the eDiscovery manager to role groups that have visibility to both agencies. However when searching SharePoint sites and OneDrive accounts, an eDiscovery manager can search for content in different compliance

boundaries only if the agencies are in the same region or geo location. **Note:** This limitation for sites doesn't apply in eDiscovery (Premium) because searching for content in SharePoint and OneDrive isn't bound by geographic location.

Do search permissions filters work for eDiscovery case holds, Microsoft 365 retention policies, or DLP?

No, not at this time.

If I specify a region to control where content is exported, but I don't have a SharePoint organization in that region, can I still search SharePoint?

If the region specified in the search permissions filter doesn't exist in your organization, the default region is searched.

What is the maximum number of search permissions filters that can be created in an organization?

There's no limit to the number of search permissions filters that can be created in an organization. However, a search query can have a maximum of 100 conditions. In this case, a condition is defined as something that's connected to the query by a Boolean operator (such as **AND**, **OR**, and **NEAR**). The limit of the number of conditions includes the search query itself plus all search permissions filters that are applied to the user who runs the search. Therefore, the more search permissions filters you have (especially if these filters are applied to the same user or group of users), the better the chance of exceeding the maximum number of conditions for a search.

To understand how this limit works, you need to understand that a search permissions filter is appended to the search query when a search is run. A search permissions filter is joined to the search query by the **AND** Boolean operator. The query logic for the search query and a single search permissions filter would look like this:

```text
<SearchQuery> AND <PermissionsFilter>
```

Multiple search permissions filters are combined together by the **OR** Boolean operator, and then those conditions are connected to the search query by the **AND** operator.

The query logic for the search query and multiple search permissions filters would look like this:

text

```
<SearchQuery> AND (<PermissionsFilter1> OR <PermissionsFilter2> OR
<PermissionsFilter3>...)
```

It's possible the search query itself may consist of multiple conditions connected by Boolean operators. Each condition in the search query would also count against the 100-condition limit.

Also, the number of search permissions filters appended to a query depends on the user who is running the search. When a specific user runs a search, the search permissions filters that are applied to the user (which is defined by the *Users* parameter in the filter) are appended to the query. Your organization could have hundreds of search permissions filters, but if more than 100 filters are applied to the same users, then it's likely the 100-condition limit will be exceeded when those users run searches.

There's one more thing to keep in mind about the condition limit. The number of specific SharePoint sites that are included in the search query or search permissions filters also count against this limit.

To prevent your organization from reaching the conditions limit, keep the number of search permissions filters in your organization to few as possible to meet your business requirements.

Configure permissions filtering for eDiscovery

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use search permissions filtering to let an eDiscovery manager search only a subset of mailboxes and sites in your organization. You can also use permissions filtering to let that same eDiscovery manager search only for mailbox or site content that meets a specific search criteria.

For example, you might want an eDiscovery manager to search only the mailboxes of users in a specific location or department. You do this by creating a filter that uses a supported recipient filter to limit which mailboxes a specific user or group of users can search. You can also create a filter that specifies what mailbox content a user can search for. This is done by creating a filter that uses a searchable message property. Similarly, you can let an eDiscovery manager search only specific SharePoint sites in your organization. You do this by creating a filter that limits which site can be searched. You can also create a filter that specifies what site content can be searched. This is done by creating a filter that uses a searchable site property.

Search permissions filters are applied when you search for content using Content search, Microsoft Purview eDiscovery (Standard), and Microsoft Purview eDiscovery (Premium) in the Microsoft Purview portal. When a search permissions filter is applied to a specific user, that user can perform the following search-related actions:

- Search for content
- Preview search results
- Export search results
- Purge items returned by a search

You can also use search permissions filtering to create logical boundaries (called *compliance boundaries*) within an organization that control the user content locations (such as mailboxes, SharePoint sites, and OneDrive accounts) that specific eDiscovery managers can search. For more information, see Set up compliance boundaries for eDiscovery investigations.

The following four cmdlets in Security & Compliance PowerShell let you configure and manage search permissions filters:

- New-ComplianceSecurityFilter
- Get-ComplianceSecurityFilter
- Set-ComplianceSecurityFilter
- Remove-ComplianceSecurityFilter

Requirements to configure permissions filtering

- To run the compliance security filter cmdlets, you have to be a member of the *Organization Management* role group in the Microsoft Purview portal. For more information, see Permissions in the Security & Compliance Center.
- You have to connect to both Exchange Online and Security & Compliance PowerShell to use the compliance security filter cmdlets. This is necessary because these cmdlets require access to mailbox properties, which is why you have to connect to Exchange Online PowerShell. See the steps in the next section.
- See the More information section for additional information about search permissions filters.
- Search permissions filtering is applicable to inactive mailboxes, which means you can use mailbox and mailbox content filtering to limit who can search an inactive mailbox. See the More information section for additional information about permissions filtering and inactive mailboxes.
- Search permissions filtering can't be used to limit who can search public folders in Exchange.
- There's no limit to the number of search permissions filters that can be created in an organization. However, a search query can have a maximum of 100 conditions. In this case, a condition is defined as something that's connected to the query by a Boolean operator (such as **AND**, **OR**, and **NEAR**). The limit for the number of conditions includes the search query itself plus all search permissions filters that are applied to the user who runs the search. Therefore, the more search permissions filters you have (especially if these filters are applied to the same user or group of users), the better the chance of exceeding the maximum number of conditions for a search. To prevent your organization from reaching

the conditions limit, keep the number of search permissions filters in your organization to few as possible to meet your business requirements. For more information, see Set up compliance boundaries for eDiscovery investigations.

Connect to Exchange Online and Security & Compliance PowerShell in a single session

Before you can successfully run the script in this section, you have to download and install the Exchange Online PowerShell module. For information, see Install and maintain the Exchange Online PowerShell module.

1. Save the following text to a Windows PowerShell script file by using a filename suffix of **.ps1**. For example, you could save it to a file named **ConnectEXO-SCC.ps1**.

   PowerShell

   ```
   Import-Module ExchangeOnlineManagement
   $UserCredential = Get-Credential
   Connect-ExchangeOnline -Credential $UserCredential -ShowBanner:$false
   Connect-IPPSSession -Credential $UserCredential
   $Host.UI.RawUI.WindowTitle = $UserCredential.UserName + " (Exchange Online + Security & Compliance)"
   ```

2. On your local computer, open Windows PowerShell, go to the folder where the script that you created in the previous step is located, and then run the script; for example:

   PowerShell

   ```
   .\ConnectEXO-SCC.ps1
   ```

How do you know if this worked? After you run the script, cmdlets from Exchange Online PowerShell and Security & Compliance PowerShell are available. If you don't receive any errors, you connected successfully. A quick test is to run Exchange Online PowerShell and Security & Compliance PowerShell cmdlets. For example, you can run and **Get-Mailbox** and **Get-ComplianceSearch**.

For troubleshooting PowerShell connection errors, see:

- Connect to Exchange Online PowerShell
- Connect to Security & Compliance PowerShell

New-ComplianceSecurityFilter

The **New-ComplianceSecurityFilter** cmdlet is used to create a search permissions filter. Here's the basic syntax for this cmdlet:

```
PowerShell
New-ComplianceSecurityFilter -FilterName <name of filter> -Users <user or role group>
-Filters <filter>
```

The following sections describe the parameters for this cmdlet. All parameters are required to create a search permissions filter.

FilterName

The *FilterName* parameter specifies the name of the permissions filter. This name is used to identity a filter when using the **Get-ComplianceSecurityFilter**, **Set-ComplianceSecurityFilter,** and **Remove-ComplianceSecurityFilter** cmdlets.

Filters

The *Filters* parameter specifies the search criteria for the compliance security filter. You can create three different types of filters:

- **Mailbox or OneDrive filtering:** This type of filter specifies the mailboxes and OneDrive accounts the assigned users (specified by the *Users* parameter) can search. This type of filter is called a *content location* filter because it defines the content locations that a user can search. The syntax for this type of filter is **Mailbox_** *MailboxPropertyName*, where *MailboxPropertyName* specifies a mailbox property used to scope the mailboxes and OneDrive accounts that can be searched. For example, the mailbox filter `"Mailbox_CustomAttribute10 -eq 'OttawaUsers'"` would allow the user assigned this filter to search only the mailboxes and OneDrive accounts that have the value "OttawaUsers" in the CustomAttribute10 property.

  Any supported filterable recipient property can be used for the *MailboxPropertyName* property in a mailbox or OneDrive filter. The following table list four commonly used recipient properties used to create a mailbox or OneDrive filter. The table also includes an example of using the property in a filter.

Expand table

Property name	Example
Alias	`"Mailbox_Alias -like 'v-'"`
Company	`"Mailbox_Company -eq 'Contoso'"`
CountryOrRegion	`"Mailbox_CountryOrRegion -eq 'United States'"`
Department	`"Mailbox_Department -eq 'Finance'"`

> **Note**
>
> The Mailbox filter applies to both user and group mailboxes. The associated OneDrive site for the user mailbox and SharePoint sites associated to the group mailbox satisfying the mailbox_ filter are allowed.

- **Mailbox content filtering:** This type of filter is applied on the content that can be searched. This type of filter is called a *content filter* because it specifies the mailbox content or searchable email properties the assigned users can search for. The syntax for this type of filter is **MailboxContent**_*SearchablePropertyName*, where *SearchablePropertyName* specifies a Keyword Query Language (KeyQL) property that can be specified in a search. For example, the mailbox content filter `"MailboxContent_Recipients -like 'contoso.com'"` would allow the user assigned this filter to only search for messages sent to recipients in the contoso.com domain. For a list of searchable email properties, see Keyword queries and search conditions for eDiscovery.

  > **Important**
  >
  > A single search filter can't contain a mailbox filter and a mailbox content filter. To combine these in a single filter, you have to use a filters list. But a filter can contain a more complex query of the same type. For example, `"Mailbox_CustomAttribute10 -eq 'FTE' -and Mailbox_MemberOfGroup -eq '$($DG.DistinguishedName)'"`

- **Site and site content filtering:** There are two SharePoint- and OneDrive-related filters that you can use to specify what site or site content the assigned users can search.
  - **Site**_*QueryableSiteProperty*
  - **SiteContent**_*QueryableSiteProperty*

  These two filters are interchangeable. For example, `"Site_Path -like 'https://contoso.sharepoint.com/sites/doctors'"` and `"SiteContent_Path -like`

`'https://contoso.sharepoint.com/sites/doctors'"` return the same results. For a list of searchable site properties, see Keyword queries and search conditions for eDiscovery For a more complete list, see Overview of crawled and managed properties in SharePoint. Properties marked with a **Yes** in the **Queryable** column can be used to create a site or site content filter.

> **ⓘ Important**
>
> Setting up a site filter with one of the supported properties doesn't mean the site property in the filter will propagate to all documents on that site. This means the user is still responsible for populating the specific property fields associated with the documents on that site in order for the site filter to work and capture the right content. For example, if the user has a security filter "Site_RefineableString00 -eq 'abc'" applied and then the user runs a search using keyword query "xyz". The security filter gets appended to the query and the actual query running would be "xyz **AND RefineableString0:'abc'**". The user needs to ensure that documents on the site indeed have values in the RefineableString00 field as"abc". If not, the search query won't return any results.

Keep the following considerations in mind when configuring the *Filters* parameter for search permissions filters:

- Unlike mailboxes, there isn't a content location filter for sites even though the *Site* filter looks like a location filter. All filters for SharePoint and OneDrive are content filters (which is also why *Site_* and *SiteContent_* filters are interchangeable) because site-related properties like *Path* are stamped directly on the documents. Why is this? It's a result of the way that SharePoint is designed. In SharePoint, there isn't a "site object" with properties, like there is with Exchange mailboxes. Therefore, the *Path* property is stamped on the document and contains the URL of the site where the document is located. This is why a *Site* filter is considered a content filter and not a content location filter.
- You have to create a search permissions filter to explicitly prevent users from searching content locations in a specific service (such as preventing a user from searching any Exchange mailbox or any SharePoint site). In other words, creating a search permissions filter that allows a user to search all SharePoint sites in the organization doesn't prevent that user from searching mailboxes. For example, to allow SharePoint admins to only search SharePoint sites, you have to create a filter that prevents them from searching mailboxes. Similarly, to allow Exchange admins to only search mailboxes, you have to create a filter that prevents them from searching sites.

Users

The *Users* parameter specifies the users who get this filter applied to their searches. Identify users by their alias or primary SMTP address. You can specify multiple values separated by commas, or you can assign the filter to all users by using the value **All**.

You can also use the *Users* parameter to specify a Microsoft Purview portal role group. This lets you create a custom role group and then assign that role group a search permissions filter. For example, let's say you have a custom role group for eDiscovery managers for the U.S. subsidiary of a multi-national corporation. You can use the *Users* parameter to specify this role group (by using the Name property of the role group) and then use the *Filter* parameter to allow only mailboxes in the U.S. to be searched. You can't specify distribution groups with this parameter.

Using a filters list to combine filter types

A *filters list* is a filter that includes a mailbox filter and a site filter separated by a comma. This comma also functions as an **OR** operator. Using a filters list is the only supported method for combining different types of filters. In the following example, notice that a comma separates the **Mailbox** and **Site** filters:

PowerShell

```
-Filters "Mailbox_CustomAttribute10 -eq 'OttawaUsers'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/doctors'"
```

When a filter that contains a filters list is processed during the running of a search, two search permissions filters are created from the filters list: One for each filter that's separated by a comma. So in the previous example, one mailbox search permissions filter and one site search permissions filter would be created. These filters are connected by the **OR** operator.

An alternative to using a filters list would be to create two separate search permissions filters. So in the previous example, you'd create one filter for the mailbox attribute and one filter for the site attribute. In either case, the results are the same. Using a filters list or creating separate search permissions filters is a matter of preference.

> ⓘ **Note**
>
> For OneDrive sites, the comma works as AND. For SharePoint sites, the comma works as OR.

Keep the following things in mind about using a filters list:

- You have to use a filters list to create a filter that includes a **Mailbox** filter and a **MailboxContent** filter.
- Each component of a filters list can contain a complex filter syntax. For example, the mailbox and site filters can contain multiple filters separated by an **-or** operator:

```
PowerShell
-Filters "Mailbox_Department -eq 'CohoWinery' -or Mailbox_CustomAttribute10 -eq
'CohoUsers'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/CohoWinery*'"
```

Examples of creating search permissions filters

Here are examples of using the **New-ComplianceSecurityFilter** cmdlet to create a search permissions filter.

This example allows members of the "US Discovery Managers" role group to search only the mailboxes and OneDrive accounts in the United States.

```
PowerShell
New-ComplianceSecurityFilter -FilterName USDiscoveryManagers  -Users "US Discovery
Managers" -Filters "Mailbox_CountryOrRegion  -eq 'United States'"
```

This example allows the user annb@contoso.com to perform search actions only for mailboxes and OneDrive accounts in Canada. This filter contains the three-digit numeric country code for Canada from ISO 3166-1.

```
PowerShell
New-ComplianceSecurityFilter -FilterName CountryFilter  -Users annb@contoso.com -
Filters "Mailbox_CountryCode  -eq '124'"
```

This example allows the users *donh* and *suzanf* to search only the mailboxes and OneDrive accounts that have the value 'Marketing' for the CustomAttribute1 mailbox property.

```
PowerShell
New-ComplianceSecurityFilter -FilterName MarketingFilter  -Users donh,suzanf -Filters
"Mailbox_CustomAttribute1  -eq 'Marketing'"
```

This example allows members of the "Fourth Coffee eDiscovery Managers" role group to search only the mailboxes and OneDrive accounts that have the value 'FourthCoffee' for the Department mailbox property. The filter also allows the role group members to search for documents in the Fourth Coffee SharePoint site.

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Fourth Coffee Security Filter" -Users
"Fourth Coffee eDiscovery Managers", "Fourth Coffee Investigators" -Filters
"Mailbox_Department -eq 'FourthCoffee'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/FourthCoffee*' -or SiteContent_Path -like
'https://contoso-my.sharepoint.com/personal*'"
```

> **Note**
>
> In the previous example, an additional site content filter (`SiteContent_Path -like 'https://contoso-my.sharepoint.com/personal*'`) has to be included so that role group members can search for documents in OneDrive accounts. If this filter isn't included, the filter would only allow role group members to search for documents located in `https://contoso.sharepoint.com/sites/FourthCoffee`.

This example allows members of the eDiscovery Manager role group to search only the mailboxes and OneDrive accounts of members of the Ottawa Users distribution group. The Get-DistributionGroup cmdlet in Exchange Online PowerShell is used to find the members of the Ottawa Users group.

PowerShell

```
$DG = Get-DistributionGroup "Ottawa Users"
```

PowerShell

```
New-ComplianceSecurityFilter -FilterName DGFilter  -Users eDiscoveryManager -Filters
"Mailbox_MemberOfGroup -eq '$($DG.DistinguishedName)'"
```

This example prevents any user from performing search actions on the mailboxes and OneDrive accounts of members of the Executive Team distribution group. That means users can delete content from these mailboxes. The Get-DistributionGroup cmdlet in Exchange Online PowerShell is used to find the members of the Executive Team group.

PowerShell

```
$DG = Get-DistributionGroup "Executive Team"
```

PowerShell

```
New-ComplianceSecurityFilter -FilterName NoExecutivesPreview  -Users All -Filters
"Mailbox_MemberOfGroup -ne '$($DG.DistinguishedName)'"
```

This example allows members of the OneDrive eDiscovery Managers custom role group to only search for content in OneDrive accounts in the organization.

PowerShell

```
New-ComplianceSecurityFilter -FilterName OneDriveOnly  -Users "OneDrive eDiscovery
Managers" -Filters "SiteContent_Path -like 'https://contoso-
my.sharepoint.com/personal*'"
```

This example restricts the user to performing search actions only on email messages sent during the calendar year 2015.

PowerShell

```
New-ComplianceSecurityFilter -FilterName EmailDateRestrictionFilter -Users
donh@contoso.com -Filters "MailboxContent_Received -ge '01-01-2015' -and
MailboxContent_Received -le '12-31-2015'"
```

Similar to the previous example, this example restricts the user to performing search actions only on documents that were last changed sometime in the calendar year 2015.

PowerShell

```
New-ComplianceSecurityFilter -FilterName DocumentDateRestrictionFilter -Users
donh@contoso.com -Filters "SiteContent_LastModifiedTime -ge '01-01-2015' -and
SiteContent_LastModifiedTime -le '12-31-2015'"
```

This example prevents members of the "OneDrive Discovery Managers" role group from performing search actions on any mailbox in the organization.

PowerShell

```
New-ComplianceSecurityFilter -FilterName NoEXO -Users "OneDrive Discovery Managers" -
Filters "Mailbox_Alias -notlike '*'"
```

This example prevents anyone in the organization from performing search actions on email messages that were sent or received by janets or sarad.

PowerShell

```
New-ComplianceSecurityFilter -FilterName NoSaraJanet -Users All -Filters
"MailboxContent_Participants -notlike 'janets@contoso.onmicrosoft.com' -and
MailboxContent_Participants -notlike 'sarad@contoso.onmicrosoft.com'"
```

This example uses a filters list to combine mailbox and site filters. In this example, the mailbox filter is a content location filter and the site filter is a content filter.

PowerShell

```
New-ComplianceSecurityFilter -FilterName "Coho Winery Security Filter" -Users "Coho
Winery eDiscovery Managers", "Coho Winery Investigators" -Filters "Mailbox_Department
-eq 'CohoWinery'", "SiteContent_Path -like
'https://contoso.sharepoint.com/sites/CohoWinery*'"
```

Get-ComplianceSecurityFilter

The **Get-ComplianceSecurityFilter** is used to return a list of search permissions filters. Use the *FilterName* parameter to return information for a specific search filter.

Set-ComplianceSecurityFilter

The **Set-ComplianceSecurityFilter** is used to modify an existing search permissions filter. The following sections describe the parameters for this cmdlet. The only required parameter is *FilterName*.

FilterName

The *FilterName* parameter specifies the name of the permissions filter.

Users

The *Users* parameter specifies the users who get this filter applied to their searches. Because this is a multi-value property, specifying a user or group of users with this parameter overwrite the existing list of users. See the following examples for the syntax to add and remove selected users.

You can also use the *Users* parameter to specify a Microsoft Purview portal role group. This lets you create a custom role group and then assign that role group a search permissions filter. For

example, let's say you have a custom role group for eDiscovery managers for the U.S. subsidiary of a multi-national corporation. You can use the *Users* parameter to specify this role group (by using the Name property of the role group) and then use the *Filter* parameter to allow only mailboxes in the U.S. to be searched. You can't specify distribution groups with this parameter.

Filters

The *Filters* parameter specifies the search criteria for the compliance security filter. You can create three different types of filters:

- **Mailbox and OneDrive filtering:** This type of filter specifies the mailboxes and OneDrive accounts the assigned users (specified by the *Users* parameter) can search. The syntax for this type of filter is **Mailbox**_ *MailboxPropertyName*, where *MailboxPropertyName* specifies a mailbox property used to scope the mailboxes that can be searched. For example, the mailbox filter `"Mailbox_CustomAttribute10 -eq 'OttawaUsers'"` would allow the user assigned this filter to search only the mailboxes that have the value "OttawaUsers" in the CustomAttribute10 property. Any supported filterable recipient property can be used for the *MailboxPropertyName* property. For a list of supported properties, see Filterable properties for the -RecipientFilter parameter.

- **Mailbox content filtering:** This type of filter is applied on the content that can be searched. It specifies the mailbox content the assigned users can search for. The syntax for this type of filter is **MailboxContent**_*SearchablePropertyName*, where *SearchablePropertyName* specifies a Keyword Query Language (KeyQL) property that can be specified in a search. For example, the mailbox content filter `"MailboxContent_Recipients -like 'contoso.com'"` would allow the user assigned this filter to only search for messages sent to recipients in the contoso.com domain. For a list of searchable email properties, see Keyword queries and search conditions for eDiscovery.

- **Site and site content filtering:** There are two SharePoint and OneDrive for Business site-related filters that you can use to specify what site or site content the assigned users can search:
  - **Site**_ *SearchableSiteProperty*
  - **SiteContent**_*SearchableSiteProperty*

  These two filters are interchangeable. For example, `"Site_Path -like 'https://contoso.spoppe.com/sites/doctors*'"` and `"SiteContent_Path -like 'https://contoso.spoppe.com/sites/doctors*'"` return the same results. For a list of searchable site properties, see Overview of crawled and managed properties in SharePoint.

Properties marked with a **Yes** in the **Queryable** column can be used to create a site or site content filter.

Examples of changing search permissions filters

These examples show how to use the **Get-ComplianceSecurityFilter** and **Set-ComplianceSecurityFilter** cmdlets to add or remove a user to the existing list of users that the filter is assigned to. When you add or remove users from a filter, specify the user by using their SMTP address.

This example adds a user to the filter.

PowerShell

```
$filterusers = Get-ComplianceSecurityFilter -FilterName OttawaUsersFilter
```

PowerShell

```
$filterusers.users.add("pilarp@contoso.com")
```

PowerShell

```
Set-ComplianceSecurityFilter -FilterName OttawaUsersFilter -Users $filterusers.users
```

This example removes a user from the filter.

PowerShell

```
$filterusers = Get-ComplianceSecurityFilter -FilterName OttawaUsersFilter
```

PowerShell

```
$filterusers.users.remove("annb@contoso.com")
```

PowerShell

```
Set-ComplianceSecurityFilter -FilterName OttawaUsersFilter -Users $filterusers.users
```

Remove-ComplianceSecurityFilter

The **Remove-ComplianceSecurityFilter** is used to delete a search filter. Use the *FilterName* parameter to specify the filter you want to delete.

More information

How does search permissions filtering work? The permissions filter is appended to the search query when a search is run. The permissions filter is joined to the search query by the **AND** Boolean operator. The query logic for the search query and the permissions filter would look like this:

```text
<SearchQuery> AND <PermissionsFilter>
```

For example, you have a permissions filter that allows Bob to perform all search actions on the mailboxes of members of the Workers distribution group. Then Bob runs a search on all mailboxes in the organization with the search query `sender:jerry@adatum.com`. Because the permissions filter and the search query are logically combined by an **AND** operator, the search returns any message sent by jerry@adatum.com to any member of the Workers distribution group.

What happens if you have multiple search permissions filters? In a search query, multiple permissions filters are combined by **OR** Boolean operators. So results will be returned if any of the filters are true. In a search, all filters (combined by **OR** operators) are then combined with the search query by the **AND** operator.

```text
<SearchQuery> AND  (<PermissionsFilter1> OR <PermissionsFilter2> OR
<PermissionsFilter3>)
```

Let's take the previous example, where a search filter allows Bob to search only the mailboxes of the members of the Workers distribution group. Then we create another filter that prevents Bob from searching Phil's mailbox ("Mailbox_Alias -ne 'Phil'"). And let's also assume that Phil is a member of the Workers group. When Bob runs a search (from the previous example) on all mailboxes in the organization, search results are returned for Phil's mailbox even though you applied filter to prevent Bob from searching Phil's mailbox. This is because the first filter, which allows Bob to search the Workers group, is true. And because Phil is a member of the Workers group, Bob can search Phil's mailbox.

Does search permissions filtering work for inactive mailboxes? Yes, you can use mailbox and mailbox content filters to limit who can search inactive mailboxes in your organization. Like a regular mailbox, an inactive mailbox has to be configured with the recipient property that's used to create a permissions filter. If necessary, you can use the **Get-Mailbox -InactiveMailboxOnly** command to display the properties of inactive mailboxes. For more information, see Create and manage inactive mailboxes.

Does search permissions filtering work for public folders? No. As previously explained, search permissions filtering can't be used to limit who can search public folders in Exchange. For example, items in public folder locations can't be excluded from the search results by a permissions filter.

Does allowing a user to search all content locations in a specific service also prevent them from searching content locations in a different service? No. As previously explained, you have to create a search permissions filter to explicitly prevent users from searching content locations in a specific service (such as preventing a user from searching any Exchange mailbox or any SharePoint site). In other words, creating a search permissions filter that allows a user to search all SharePoint sites in the organization doesn't prevent that user from searching mailboxes. For example, to allow SharePoint admins to only search SharePoint sites, you have to create a filter that prevents them from searching mailboxes. Similarly, to allow Exchange admins to only search mailboxes, you have to create a filter that prevents them from searching sites.

Do search permissions filters count against search query character limits? Yes. Search permissions filters count against the character limit for search queries. For more information, see Limits in eDiscovery (Premium).

What is the maximum number of search permissions filters that can be created in an organization?

There's no limit to the number of search permissions filters that can be created in an organization. However, a search query can have a maximum of 100 conditions. In this case, a condition is defined as something that's connected to the query by a Boolean operator (such as **AND**, **OR**, and **NEAR**). The limit of the number of conditions includes the search query itself plus all search permissions filters that are applied to the user who runs the search. Therefore, the more search permissions filters you have (especially if these filters are applied to the same user or group of users), the better the chance of exceeding the maximum number of conditions for a search.

To understand how this limit works, you need to understand that a search permissions filter is appended to the search query when a search is run. A search permissions filter is joined to the

search query by the **AND** Boolean operator. The query logic for the search query and a single search permissions filter would look like this:

```text
<SearchQuery> AND <PermissionsFilter>
```

Multiple search permissions filters are combined together by the **OR** Boolean operator, and then those conditions are connected to the search query by the **AND** operator.

The query logic for the search query and multiple search permissions filters would look like this:

```text
<SearchQuery> AND (<PermissionsFilter1> OR <PermissionsFilter2> OR
<PermissionsFilter3>...)
```

It's possible the search query itself may consist of multiple conditions connected by Boolean operators. Each condition in the search query would also count against the 100-condition limit.

Also, the number of search permissions filters appended to a query depends on the user who is running the search. When a specific user runs a search, the search permissions filters that are applied to the user (which is defined by the *Users* parameter in the filter) are appended to the query. Your organization could have hundreds of search permissions filters, but if more than 100 filters are applied to the same users, then it's likely the 100-condition limit will be exceeded when those users run searches.

There's one more thing to keep in mind about the condition limit. The number of specific SharePoint sites that are included in the search query or search permissions filters also count against this limit.

To prevent your organization from reaching the conditions limit, keep the number of search permissions filters in your organization to few as possible to meet your business requirements.

Last updated on 10/31/2024

Content stored in Exchange Online mailboxes for eDiscovery

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

A mailbox in Exchange Online is primarily used to store email-related items such as messages, calendar items, tasks, and notes. But that's changing as more cloud-based apps also store their data in a user's mailbox. One advantage of storing data in a mailbox is that you can use the search tools in content search, Microsoft Purview eDiscovery (Standard), and Microsoft Purview eDiscovery (Premium) to find, view, and export the data from these cloud-based apps.

The data from some of these apps is stored in hidden folders located in a non-interpersonal message (non-IPM) subtree in the mailbox. Data from other cloud-based apps might not be stored *in* the mailbox, but it's *associated with* the mailbox, and is returned in searches (if that data matches the search query). Regardless of whether cloud-based data is stored in or associated with a user mailbox, the data is typically not visible in an email client when a user opens their mailbox.

The following table lists the apps that either stores or associates data with a cloud-based mailbox. The table also describes the type of content that each app produces.

Expand table

Microsoft 365 app	Description
Forms*	Forms and responses to a form are stored in files that are attached to email messages and stored in a hidden folder in the mailbox of the user who created the form. Forms created before April 2020 are stored as a PDF file. Forms created after 2020 are stored as a JSON file. Responses to a form are stored in a CSV file. When you export content from Forms in a PST file, this data is located in the

Microsoft 365 app	Description
	ApplicationDataRoot folder in a subfolder named with the following globally unique identified (GUID): **c9a559d2-7aab-4f13-a6ed-e7e9c52aec87**.
Microsoft 365 Groups	Email messages, calendar items, contacts (People), notes, and tasks are stored in the mailbox that's associated with a Microsoft 365 group.
Microsoft 365 Copilot and Microsoft 365 Copilot Chat	All Copilot activity data (user prompts and Copilot responses) generated in supported Microsoft 365 apps and services is stored in custodian mailboxes.
Outlook/Exchange Online	Email messages, calendar items, contacts (People), notes, and tasks are stored in a user's mailbox.
People	Contacts in the People app (which are the same contacts as the ones accessible in Outlook) are stored in a user's mailbox.
Class Schedule	Plans created in Class Schedule are stored in the mailbox of the corresponding Microsoft 365 Group that is provisioned when a new plan is created. The alias for the group mailbox is the name of the plan.
Skype for Business	Conversations in Skype for Business are stored in the Conversation History folder in a user's mailbox. If the mailbox of a participant of a Skype meeting is placed on Litigation Hold or assigned to a retention policy, files attached to a meeting are retained in the participants mailbox.
Sway*	Sways are stored as an HTML file that is attached to an email message and stored in a hidden folder in the mailbox of the user who created the sway. When you export content from Sway in a PST file, this data is located in the **ApplicationDataRoot** folder in a subfolder named with the following GUID: **905fcf26-4eb7-48a0-9ff0-8dcc7194b5ba**.
Tasks	Tasks in the Tasks app (which are the same tasks as the ones accessible in Outlook) are stored in a user's mailbox.
Teams	Conversations that are part of a Teams channel are associated with the Teams mailbox. Conversations that are part of the Chat list in Teams (also called *1 x N chats*) are associated with the mailbox of the users who participate in the chat. Also, summary information for meetings and calls in a Teams channel are associated with mailboxes of users who dialed into the meeting or call. So when searching for Teams content, you would search the Teams mailbox for content in channel conversations and search user mailboxes for content in 1 x N chats.
To-Do	Tasks (called *to-dos*, which are saved in to-do lists) in the To-Do app are stored in a user's mailbox.
Viva Engage	Conversations and comments within a Viva Engage community are associated with the Microsoft 365 group mailbox, as well as the user mailbox of the author and any named recipients (@ mentioned or Cc'ed users). Private messages sent outside of a

Microsoft 365 app	Description
	Viva Engage community are stored in the mailbox of the users who participate in the private message.

> **Note**
>
> * At this time, if a hold is placed on a mailbox (by using holds in eDiscovery (Standard) or eDiscovery (Premium) cases), content from this app will not be preserved by the hold.

Decryption in Microsoft Purview eDiscovery tools

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Encryption is an important part of your file protection and information protection strategy. Organizations of all types use encryption technology to protect sensitive content within their organization and ensure that only the right people have access to that content.

To run common eDiscovery tasks on encrypted content, eDiscovery managers are required to decrypt email message content when exported from content searches, Microsoft Purview eDiscovery (Standard) cases, and Microsoft Purview eDiscovery (Premium) cases. Content encrypted with Microsoft encryption technologies wasn't available for review until after export.

To make it easier to manage encrypted content in the eDiscovery workflow, Microsoft Purview eDiscovery tools now incorporate the decryption of encrypted files attached to email messages and sent in Exchange Online.[1] Additionally, encrypted documents stored in SharePoint Online and OneDrive for Business are decrypted in eDiscovery (Premium)[2].

Prior to this new capability, only the content of an email message protected by rights management (and not attached files) were decrypted. Encrypted documents in SharePoint and OneDrive couldn't be decrypted during the eDiscovery workflow. Now, files that are encrypted with a Microsoft encryption technology is located on a SharePoint or OneDrive account are searchable and decrypted when the search results are prepared for preview, added to a review set in eDiscovery (Premium), and exported. Additionally, encrypted documents in SharePoint and OneDrive that are attached to an email message (as a copy) are searchable. This decryption capability allows eDiscovery managers to view the content of encrypted email attachments and

site documents when previewing search results, and review them after they've been added to a review set in eDiscovery (Premium).

Requirements for decryption in eDiscovery

- **Permissions**: You have to be assigned the *RMS Decrypt* role to preview, review, and export files encrypted with Microsoft encryption technologies. You also have to be assigned this role to review and query encrypted files that are added to a review set in eDiscovery (Premium). This role is assigned by default to the eDiscovery Manager role group on the **Permissions** page in the Microsoft Purview portal. For more information about the RMS Decrypt role, see Assign eDiscovery permissions.
- **Run the Inbox Repair tool on exported PST files**: After you've exported PST files, we recommend that you run the Inbox Repair tool (ScanPST.exe) to diagnose and repair any errors in the PST files.

Supported encryption technologies

For Exchange, Microsoft Purview eDiscovery tools support items encrypted with Microsoft encryption technologies. These technologies are Azure Rights Management (Azure RMS)[3] and Microsoft Purview Information Protection (specifically sensitivity labels). For more information about Microsoft encryption technologies, see Encryption and the various email encryption options available. Content encrypted by S/MIME or third-party encryption technologies isn't supported. For example, previewing or exporting content encrypted with non-Microsoft technologies isn't supported.

> **Note**
>
> The decryption of email messages sent with an Microsoft Purview Message Encryption custom branding template is not supported by Microsoft eDiscovery tools. When using an OME custom branding template, email messages are delivered to the OME portal instead of the recipient's mailbox. Therefore, you won't be able to use eDiscovery tools to search for encrypted messages because those messages are never received by the recipient's mailbox.

For SharePoint, content labeled with SharePoint online service are decrypted. Items labeled or encrypted in the client before uploading to SharePoint, legacy document library RMS templates or settings and S/MIME or other standards aren't supported[2].

eDiscovery activities that support encrypted items

The following table identifies the supported tasks that can be performed in Microsoft Purview eDiscovery tools on encrypted files attached to email messages and encrypted documents in SharePoint and OneDrive. These supported tasks can be performed on encrypted files that match the criteria of a search. A value of `N/A` indicates the functionality isn't available in the corresponding eDiscovery tool.

Expand table

eDiscovery task	Content search	eDiscovery (Standard)	eDiscovery (Premium)
Search for content in encrypted files in sites and email attachments[1]	No	No	Yes
Preview encrypted files attached to email	No	No	Yes
Preview encrypted documents in SharePoint and OneDrive	No	No	Yes
Review encrypted files in a review set	N/A	N/A	Yes
Export encrypted files attached to email	Yes	Yes	Yes
Export encrypted documents in SharePoint and OneDrive	No	No	Yes

Supported decryption

The following table describes the decryption supported by eDiscovery (Standard) and eDiscovery (Premium) for email, email with attachments, and files hosted by SharePoint.

Expand table

Item type	Task	eDiscovery (Standard)	eDiscovery (Premium)
Encrypted email	Search	Yes	Yes
Encrypted email	Decryption to .pst	No	Yes
Encrypted email	Decryption to file	Yes	Yes
Encrypted mail and attachment	Search	No	Yes (with Advanced indexing)[1]

Item type	Task	eDiscovery (Standard)	eDiscovery (Premium)
Encrypted mail and attachment	Decryption to .pst	No	Yes
Encrypted mail and attachment	Decryption to file	No	Yes
File in SharePoint with MIP label	Search	No	Yes
File in SharePoint with MIP label	Decryption	No	Yes
File in SharePoint with other encryption[2]	Search, Decryption	No	No

> **Important**
>
> eDiscovery (Standard) doesn't support legacy encryption protocols.

Decryption limitations with email and attachments

eDiscovery support for decryption of email messages and attachments is subject to the following limitations:

- Decryption isn't supported when the email or attachment encryption is applied in an external organization. eDiscovery only supports decryption for email and attachments that are encrypted in your organization.
- When decrypting emails or attachments, the owner of the mailbox where the emails and attachments are included in eDiscovery activities must have access to view the encrypted content. Decryption for emails or attachments isn't supported if they're sent or forwarded other recipients that can't view the encrypted content. Changes in the owner's groups or other organization permissions may also affect decryption support.

Decryption limitations with sensitivity labels in SharePoint and OneDrive

eDiscovery doesn't support encrypted files in SharePoint and OneDrive when a sensitivity label that applied the encryption is configured with either of the following settings:

- Users can assign permissions when they manually apply the label to a document. This is sometimes referred to as *user-defined permissions*.

- User access to the document has an expiration setting that is set to a value other than **Never**.

For more information about these settings, see the "Configure encryption settings" section in Restrict access to content by using sensitivity labels to apply encryption.

Documents encrypted with the previous settings can still be returned by an eDiscovery search. This result may happen when a document property (such as the title, author, or modified date) matches the search criteria. Although these documents might be included in search results, they can't be previewed or reviewed. These documents will also remain encrypted when they're exported in eDiscovery (Premium).

> **Important**
>
> Decryption isn't supported for files that are locally encrypted and then uploaded to SharePoint or OneDrive. For example, local files that are encrypted by the Microsoft Purview Information Protection client and then uploaded to Microsoft 365 aren't supported. Only files that are encrypted in the SharePoint or OneDrive service are supported for decryption.

Notes

[1] Encrypted files located on a local computer and copied to an email message aren't decrypted and indexed for eDiscovery. For eDiscovery (Premium), encrypted email and attachments in recipient mailbox needs to be advanced indexed to be decrypted. For more information about Advanced indexing, see Advanced indexing of custodian data.

[2] Only items labeled in SharePoint (or uploaded to SharePoint after integration with sensitivity labels are enabled) and that have labels with admin-defined permissions and no expiration are decrypted. All other encrypted files in SharePoint aren't decrypted. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

Other documents aren't decrypted, including:

- Files encrypted in the client and uploaded before sensitivity labels were integrated with SharePoint Online.
- Documents encrypted with legacy RMS templates and not labeled.
- Documents with user-defined permissions or with expiration settings (SMIME or other standards).

[3] Only content encrypted with RMS keys hosted in Microsoft 365 is transparently decrypted by eDiscovery (Premium). Double Key Encryption (DKE), Hold Your Own Key (HYOK), on-premises RMS, etc. aren't supported. For more information, see Key types for the service.

Last updated on 10/31/2024

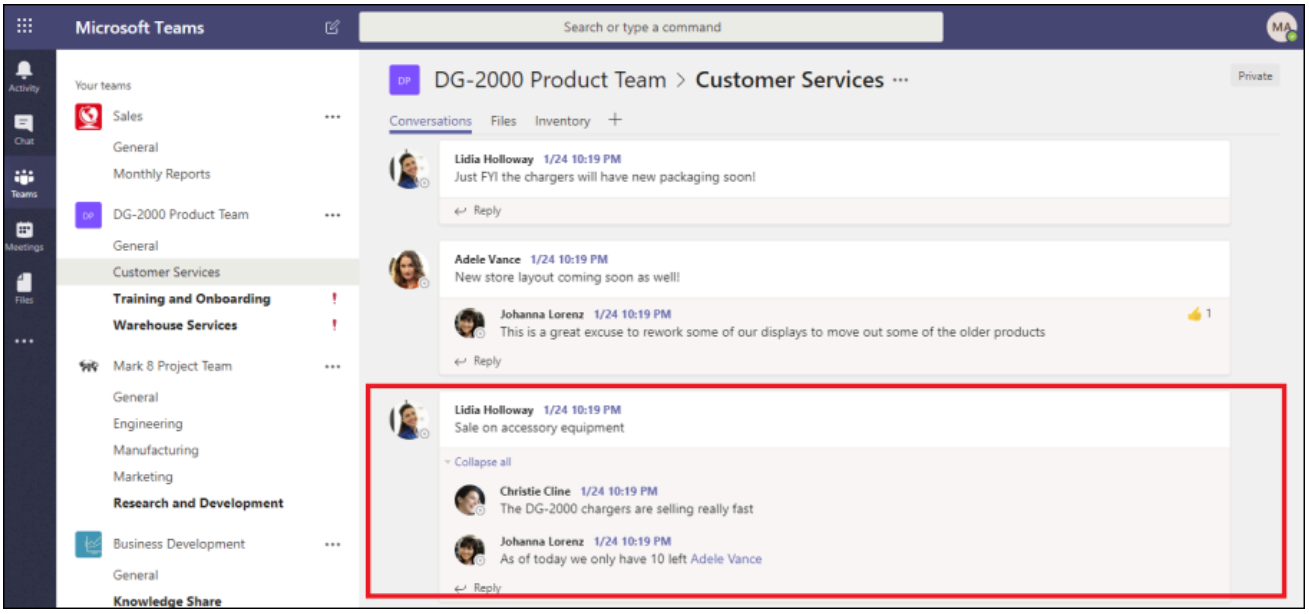
Conversation threading in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Instant messaging is a convenient way to ask questions, share ideas, or quickly communicate across large audiences. As instant messaging platforms, like Microsoft Teams and Viva Engage groups, become core to enterprise collaboration, organizations must evaluate how their eDiscovery workflow addresses these new forms of communication and collaboration.

The conversation reconstruction feature in Microsoft Purview eDiscovery (Premium) is designed to help you identify contextual content and produce distinct conversation views. This capability allows you to efficiently and rapidly review complete instant message conversations (also called *threaded conversations*) that are generated in platforms like Microsoft Teams.

With conversation reconstruction, you can use built-in capabilities to reconstruct, review, and export threaded conversations. Use eDiscovery (Premium) conversation reconstruction to:



- Preserve unique message-level metadata across all messages within a conversation.
- Collect contextual messages around your search results.
- Review, annotate, and redact threaded conversations.
- Export individual messages or threaded conversations

Terminology

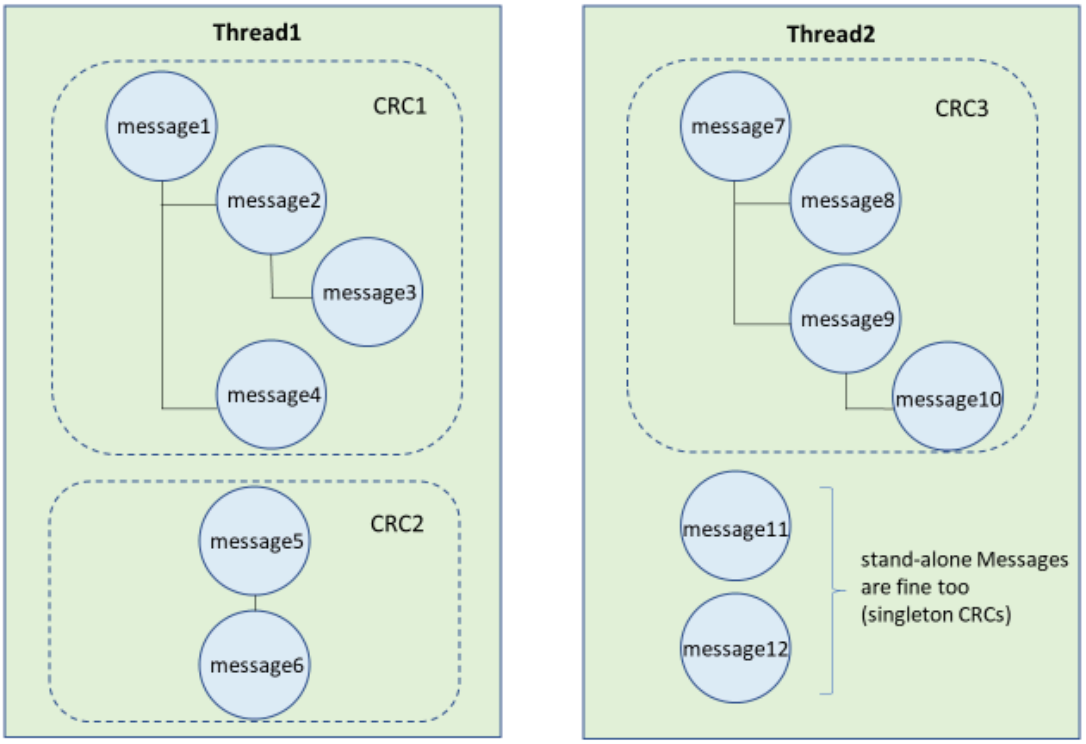
Here are few definitions to help you get start using conversation reconstruction.

- **Messages:** Represent the smallest unit of a conversation. Messages may vary in size, structure, and metadata.

- **Conversation:** Represents a grouping of one or more messages. Across different applications, conversations may be represented in different ways. In some applications, there is an explicit action that results from replying to an existing message. Conversations are formed explicitly as a result of this user action. For example, here is a screenshot of a channel conversation in Microsoft Teams.

  In other apps (such as group chat messages in Teams), there is not a formal reply chain and instead messages appear as a "flat river of messages" within a single thread. In these types apps, conversations are inferred from a group of messages that occur within a certain time. This "soft-grouping" of messages (as opposed to a reply chain) represent the "back and forth" conversation about a specific topic of interest.

Step 1: Create a collection estimate



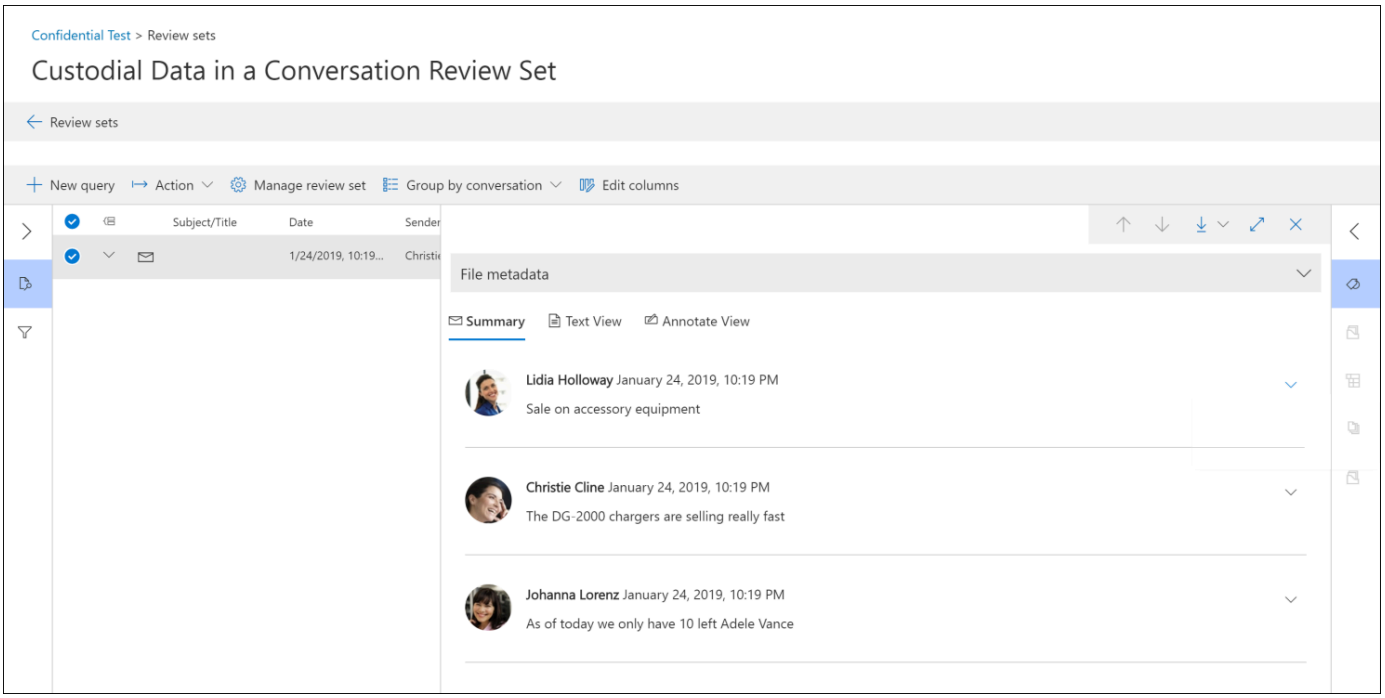
After you have identified relevant custodians and content locations, you can create a search to find potentially relevant content. On the **Collections** tab in the eDiscovery (Premium) case, you can create a collection by selecting **New collection** and following the workflow. For information about how you can create a collection, build a search query, and preview the search results, see Create a collection estimate.

Step 2: Commit a collection estimate to a review set

After you have reviewed and finalized the search query in a collection, you can add the search results to a review set. When you add your search results into a review set, the original data is copied to an Azure Storage area to facilitate the review and analysis process. For more

information about adding search results to a review set, see Commit a collection estimate to a review set.

When you add items from conversations to a review set, you can use the threaded conversations option to collect contextual messages from conversations that contain items that match the search criteria of the collection. After you select the thread conversations option, the following things can happen:



1. Using a keyword and date range query, the search returned a hit on *Message 3*. This message was part of a larger conversation, illustrated by *CRC1*.
2. When you add the data into a review set and enable the conversation retrieval options, eDiscovery (Premium) will go back and collect other items in *CRC1*.
3. After the items have been added to the review set, you can review all the individual messages from *CRC1*.

To enable the threaded conversations option, see Commit a collection estimate to a review set.

Step 3: Review and export threaded conversations

After the content has been processed and added to the review set, you can start reviewing the data in the review set. Individual messages are threaded together and presented as conversations. This lets you review and export contextual conversations.

The following sections describe reviewing and exporting conversations.

Reviewing conversations

In a review set, you can use the following options to facilitate the review process.

- **Group by conversation:** Groups messages within the same conversation together to help users simplify and expedite their review process.
- **Summary view:** Displays the threaded conversation. In this view, you can see the entire conversation and also access the metadata for each individual message.
  - View metadata for individual messages
  - Download individual messages
- **Text view:** Provides the extracted text for the entire conversation.
- **Annotate view:** Lets you markup a threaded view of the conversation. All messages in the conversation share the same annotated document.
- **Tagging:** When viewing conversations in a review set, you can view and apply tags by selecting **Tagging panel** in the Coding panel.
- **Rerun conversation conversion:** When messages are added to a conversation review set, a conversion job is automatically run to create the threaded summary and annotate views. If the Conversation Reconstruction job fails, you can rerun this job by selecting **Action** > **Create conversation PDFs** in the review set.

> **Note**
>
> The date and time for all conversations in Teams are shown in Coordinated Universal Time (UTC).

Exporting conversations

For the options you can select when exporting conversations from a review set, see Export documents from a review set.

Specifically, you can export entire chat conversations in a single PDF file or you can export each chat message in a conversation as an individual file.

More information

To learn more about how to review case data in eDiscovery (Premium), see the following articles:

- Query and filter content in a review set
- Tag documents in a review set
- View case data
- Analyze case data
- Export case data

CJK language support for eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Microsoft Purview eDiscovery (Premium) supports double-byte character set languages (these include Simplified Chinese, Traditional Chinese, Japanese, and Korean, which are collectively known as *CJK* languages) for the following advanced scenarios in a review set:

- When you query the data in a review set.
- When you tag documents in a review set.
- When you analyze case data in a review set by using near duplicate detection, email threading, and themes analytics.

Frequently asked questions

How do I create a search to collect items that contains CJK characters?

You can use CJK characters for keyword searches, keyword queries and search conditions when searching for content in eDiscovery (Premium). Searching for CJK characters is also supported when searching for content in Microsoft Purview eDiscovery (Standard) and Content Search.

We provide CJK support for all search operators and search conditions, including the boolean operators **AND**, **OR**, **NOT**, and **NEAR**.

If you're certain that content locations or items contain CJK characters, but searches aren't returning any results, select the query language-country/region icon and select the corresponding language-country/region culture code value for the search. The default language/region is neutral.

Can I search for multiple languages at once?

It depends on your search scenario.

- When you query data in a review set in eDiscovery (Premium), you can search for multiple languages.
- When you create a search to collect data, create separate collections for each language you're targeting. For example, if you are searching for a document that contains both Chinese and Korean, select Chinese for your first collection and select Korean for your second collection.

I don't see the query language-country/region icon to select a language for queries in a review set. How can I specify a query language in a review set search?

For review set queries, you don't need to specify a document language. eDiscovery (Premium) automatically detects document languages when you add content to a review set. This helps you optimize your query results in a review set.

Can I see detected languages in file metadata?

No, you can't see detected languages in file metadata.

Can I filter by document languages in a review set?

No, you can't filter, sort, or search by document languages in a review set.

Will this CJK release for review set scenarios affect any of my existing searches and review sets?

No, none of your existing searches and review sets will change. You don't need to reindex existing data, and search results for English text will be the same.

How do I change my display language to Chinese, Japanese, or Korean?

For information about how to change display language and time zone, see How to set language and region settings for Office 365.

Limits

- OCR doesn't support CJK characters from image files
- Email files (such as *.eml and *.msg) in Annotate view aren't supported for CJK languages.
- Search hit highlighting in Text view isn't supported for CJK languages.

- The Relevance module used to analyze data doesn't support CJK languages.
- Query-based holds aren't supported for CJK languages.

Collect eDiscovery diagnostic information

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Occasionally Microsoft Support engineers require specific information about your issue when you open a support case related to Microsoft Purview eDiscovery (Standard) or Microsoft Purview eDiscovery (Premium). This article provides guidance on how to collect diagnostic information to help support engineers investigate and resolve issues. Typically, you don't need to collect this information until asked to do so by a Microsoft Support engineer.

> **Important**
>
> The output from the cmdlets and diagnostic information described in this article may include sensitive information about litigation or internal investigations in your organization. Before sending the raw diagnostic information to Microsoft Support, you should review the information and redact any sensitive information (such as names or other information about parties to litigation or investigation) by replacing it with `xxxxxxx`. Using this method will also indicate to the Microsoft Support engineer that information was redacted.

Collect diagnostic information for eDiscovery (Standard)

Collecting diagnostic information for eDiscovery (Standard) is cmdlet-based, so you'll have to use Security & Compliance PowerShell. The following PowerShell examples will run cmdlets and then save the output to a specified text file. In most support cases, you should only have to run one of these commands.

To run the following cmdlets, connect to Security & Compliance PowerShell. After you're connected, run one or more of the following commands and be sure to replace placeholders with the actual object names.

After reviewing the generated text file and redacting sensitive information, send it to the Microsoft Support engineer working on your case.

> **Note**
>
> You can also run the commands in this section to collect diagnostic information for the searches and exports listed on the **Content search** page in the Microsoft Purview portal.

Collect information about searches

The following command collects information that's helpful when investigating issues with a Content search or a search associated with an eDiscovery (Standard) case.

PowerShell

```
Get-ComplianceSearch "<Search name>" | FL > "ComplianceSearch.txt"
```

Collect information about search actions

The following command collects information to investigate problems with previewing, exporting, or purging the results of a Content search or a search associated with an eDiscovery (Standard) case. You can identify the name of the search action by selecting an export that's listed on the **Exports** tab. To identify the names of preview and purge actions, you can run the **Get-ComplianceSearchAction** cmdlet to display a list of all actions. The format for the search action name is constructed by appending `_Preview`, `_Export`, or `_Purge` to the name of the corresponding search.

PowerShell

```
Get-ComplianceSearchAction "<Search action name>" | FL > "ComplianceSearchAction.txt"
```

Collect information about eDiscovery holds

When an eDiscovery hold associated with an eDiscovery (Standard) case isn't functioning as expected, run the following command to collect information about the Case Hold Policy and

associated Case Hold Rule for the eDiscovery hold. The *Case hold policy name* in the following command is the same as the name of the eDiscovery hold. You can identify this name on the **Holds** tabs in the eDiscovery (Standard) case.

PowerShell

```
Get-CaseHoldPolicy "<Case hold policy name>" | %{"--CaseHoldPolicy--";$_|FL;"--
CaseHoldRule--";Get-CaseHoldRule -Policy $_.Name | FL} > "eDiscoveryCaseHold.txt"
```

Collect all case information

Sometimes, it's not apparent what information is required by Microsoft Support to investigate your issue. In this situation, you can collect all of the diagnostics information for an eDiscovery (Standard) case. The *eDiscovery (Standard) case name* in the following command is the same as the name of a case that's displayed on the **eDiscovery (Standard)** page in the Microsoft Purview portal.

PowerShell

```
Get-ComplianceCase "<eDiscovery (Standard) case name>"| %{$_|fl;"`t==Searches==";Get-
ComplianceSearch -Case $_.Name | FL;"`t==Search Actions==";Get-ComplianceSearchAction
-Case $_.Name |FL;"`t==Holds==";Get-CaseHoldPolicy -Case $_.Name | %{$_|FL;"`t`t
==$($_.Name) Rules==";Get-CaseHoldRule -Policy $_.Name | FL}} > "eDiscoveryCase.txt"
```

Collect diagnostic information for eDiscovery (Premium)

Collect case information

The **Settings** tab in an eDiscovery (Premium) case lets you quickly copy the diagnostic information for the case. The diagnostic information is saved to the clipboard so you can paste it to a text file and send to Microsoft Support.

1. Go to the Microsoft Purview portal, and select **eDiscovery** > **Advanced**.
2. Select a case and then select the **Settings** tab.
3. Under **Case Information**, select **Select**.
4. On the flyout page, select **Actions** > **Copy support information** to copy the information to the clipboard.
5. Open a text file (in Notepad) and then paste the information in the text file.

6. Save the text file and name it something like `eDP Diagnostic Info YYYY.MM.DD` (for example, `eDP Diagnostic Info 2020.11.03`).

After reviewing the file and redacting sensitive information, send it to the Microsoft Support engineer working on your case.

Collect job information

1. While in a case, select the **Jobs** tab.
2. Scroll down to the Job that failed and select it to open the job information pane.
3. Select **Copy support information** to copy the job diagnostics information to the clipboard.
4. Open a text file (in Notepad) and then paste the information into the text file.
5. Save the text file and name it something like `eDP Job Diagnostic Info YYYY.MM.DD` (for example, `eDP Diagnostic Info 2020.11.03`).

After reviewing the file and redacting sensitive information, send it to the Microsoft Support engineer working on your case.

Search for eDiscovery (classic) activities in the audit log

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

Content Search and eDiscovery-related activities (for Microsoft Purview eDiscovery (Standard) and Microsoft Purview eDiscovery (Premium)) that are performed in Microsoft Purview portal or by running the corresponding PowerShell cmdlets are logged in the audit log. Events are logged when administrators or eDiscovery managers (or any user assigned eDiscovery permissions) perform the following Content Search and eDiscovery (Standard) tasks in the Microsoft Purview portal:

- Creating and managing eDiscovery (Standard) and eDiscovery (Premium) cases.
- Creating, starting, and editing Content searches.
- Performing search actions, such as previewing, exporting, and deleting search results.
- Managing custodians and review sets in eDiscovery (Premium).
- Configuring permissions filtering for Content search.
- Managing the eDiscovery Administrator role.

For more information about searching the audit log, the permissions that are required, and exporting search results, see Search the audit log.

How to search for and view eDiscovery activities

Currently, you have to do a few specific things to view eDiscovery activities in the audit log. Here's how:

1. Go to the Microsoft Purview portal and sign in using your work or school account.

2. In the left navigation pane of the Microsoft Purview portal, select **Audit**.
3. In the **Activities** drop-down list, under **eDiscovery activities** or **eDiscovery (Premium) activities**, select one or more activities to search for.

   > ⓘ Note
   >
   > The **Activities** drop-down list also includes a group of activities named **eDiscovery cmdlet activities** that will return records from the cmdlet audit log.

4. Select a date and time range to display eDiscovery events that occurred within that period.
5. In the **Users** box, select one or more users to display search results for. Leave this box blank to return entries for all users.
6. Select **Search** to run the search using your search criteria.
7. After the search results are displayed, you can select **Filter results** to filter or sort the resulting activity records. Unfortunately, you can't use filtering to explicitly exclude certain activities.
8. To view details about an activity, select the activity record in the list of search results.

   A **Details** fly out page is displayed that contains the detailed properties from the event record. To display additional details, select **More information**. For a description of these properties, see the Detailed properties for eDiscovery activities section.
9. If desired, you can export the audit log search results to a CSV file, and then use the Excel Power Query feature to format and filter these records. For more information, see Export, configure, and view audit log records.

eDiscovery activities

The following table describes the Content Search and eDiscovery (Standard) activities that are logged when an administrator or eDiscovery manager performs an eDiscovery-related activity using the Microsoft Purview portal. Some activities performed in eDiscovery (Premium) may be returned when you search for activities in this list.

> ⓘ Note

The eDiscovery activities described in this section provide similar information to the eDiscovery cmdlet activities described in the next section. We recommend that you use the eDiscovery activities described in this section because they will appear in the audit log search results within 30 minutes. It may take up to 24 hours for eDiscovery cmdlet activities to appear in audit log search results.

Expand table

Friendly name	Operation	Corresponding cmdlet	Description
Added member to eDiscovery case	CaseMemberAdded	Add-ComplianceCaseMember	A user was added as a member of an eDiscovery case. As a member of a case, a user can perform various case-related tasks depending on whether they've been assigned the necessary permissions.
Changed content search	SearchUpdated	Set-ComplianceSearch	An existing content search was changed. Changes can include adding or removing content locations or editing the search query.
Changed eDiscovery administrator membership	CaseAdminUpdated	Update-eDiscoveryCaseAdmin	The list of eDiscovery Administrators in your organization was changed. This activity is logged when the list of eDiscovery Administrators is replaced with a group of new users. If a single user is added or removed, the CaseAdminAdded operation is logged.
Changed eDiscovery case	CaseUpdated	Set-ComplianceCase	An eDiscovery case was changed. Changes include closing an open case or reopening a closed case.

Friendly name	Operation	Corresponding cmdlet	Description
Changed eDiscovery case membership	CaseMemberUpdated	Update-ComplianceCaseMember	The membership list of an eDiscovery case was changed. This activity is logged when all members are replaced with a group of new users. If a single member is added or removed, CaseMemberAdded or CaseMemberRemoved operation is logged.
Changed search permissions filter	SearchPermissionUpdated	Set-ComplianceSecurityFilter	A search permissions filter was changed.
Changed search query for eDiscovery case hold	HoldUpdated	Set-CaseHoldRule	A query-based hold associated with an eDiscovery case was changed. Possible changes include editing the query or date range for a query-based hold.
Content search preview item downloaded	PreviewItemDownloaded	N/A	A user downloaded an item to their local computer (by selecting the **Download original item** link) when previewing search results.
Content search preview item listed	PreviewItemListed	N/A	A user selected **Preview search results** to display the preview search results page, which lists up to 1,000 items from the results of a search.
Created content search	SearchCreated	New-ComplianceSearch	A new content search was created.
Created eDiscovery administrator	CaseAdminAdded	Add-eDiscoveryCaseAdmin	A user was added as an eDiscovery Administrator in the organization.

Friendly name	Operation	Corresponding cmdlet	Description
Created eDiscovery case	CaseAdded	New-ComplianceCase	An eDiscovery case was created. When a case is created, you only have to give it a name. Other case-related tasks such as adding members, creating holds, and creating content searches associated with the case result in additional events being logged.
Created search permissions filter	SearchPermissionCreated	New-ComplianceSecurityFilter	A search permissions filter was created.
Created search query for eDiscovery case hold	HoldCreated	New-CaseHoldRule	A query-based hold associated with an eDiscovery case was created.
Deleted content search	SearchRemoved	Remove-ComplianceSearch	An existing content search was deleted.
Deleted eDiscovery administrator	CaseAdminRemoved	Remove-eDiscoveryCaseAdmin	An eDiscovery Administrator was deleted from your organization.
Deleted eDiscovery case	CaseRemoved	Remove-ComplianceCase	An eDiscovery case was deleted. Any hold associated with the case has to be removed before the case can be deleted.
Deleted search permissions filter	SearchPermissionRemoved	Remove-ComplianceSecurityFilter	A search permissions filter was deleted.
Deleted search query for eDiscovery case hold	HoldRemoved	Remove-CaseHoldRule	A query-based hold associated with an eDiscovery case was deleted. Removing the query from the hold is often the result of

Friendly name	Operation	Corresponding cmdlet	Description
			deleting a hold. When a hold or a hold query is deleted, the content locations that were on hold are released.
Downloaded export of content search	SearchExportDownloaded	N/A	A user downloaded the results of a content search to their local computer. A **Started export of content search** activity has to be initiated before search results can be downloaded.
Previewed results of content search	SearchPreviewed	N/A	A user previewed the results of a content search.
Purged results of content search	SearchResultsPurged	New-ComplianceSearchAction	A user purged the results of a Content search by running the **New-ComplianceSearchAction -Purge** command.
Removed analysis of content search	RemovedSearchResultsSentToZoom	Remove-ComplianceSearchAction	A content search prepare action (to prepare search results for eDiscovery (Premium)) was deleted. If the preparation action was less than two weeks old, the search results that were prepared for eDiscovery (Premium) were deleted from the Microsoft Azure storage area. If the preparation action was older than 2 weeks, then this event indicates that only the corresponding preparation action was deleted.
Removed export of	RemovedSearchExported	Remove-ComplianceSearchAction	A content search export action was deleted. If the export action was less

Friendly name	Operation	Corresponding cmdlet	Description
content search			than two weeks old, the search results that were uploaded to the Microsoft Azure storage area were deleted. If the export action was older than 2 weeks, then this event indicates that only the corresponding export action was deleted.
Removed member from eDiscovery case	CaseMemberRemoved	Remove-ComplianceCaseMember	A user was removed as a member of an eDiscovery case.
Removed preview results of content search	RemovedSearchPreviewed	Remove-ComplianceSearchAction	A content search preview action was deleted.
Removed purge action performed on content search	RemovedSearchResultsPurged	Remove-ComplianceSearchAction	A content search purge action was deleted.
Removed search report	SearchReportRemoved	Remove-ComplianceSearchAction	A content search export report action was deleted.
Started analysis of content search	SearchResultsSentToZoom	New-ComplianceSearchAction	The results of a content search were prepared for analysis in eDiscovery (Premium).
Started content search	SearchStarted	Start-ComplianceSearch	A content search was started. When you create or change a content search by using the Microsoft Purview portal, the search is automatically started.
Started export of	SearchExported	New-ComplianceSearchAction	A user exported the results of a content search.

Friendly name	Operation	Corresponding cmdlet	Description
content search			
Started export report	SearchReport	New-ComplianceSearchAction	A user exported a content search report.
Stopped content search	SearchStopped	Stop-ComplianceSearch	A user stopped a content search.
(none)	CaseViewed	Get-ComplianceCase	A user viewed an eDiscovery (Standard) case in the Microsoft Purview portal. The audit record for this event includes the name of the case that was viewed.
(none)	SearchViewed	Get-ComplianceSearch	A user viewed a Content search in the Microsoft Purview portal by accessing the search on the **Searches** tab in an eDiscovery (Standard) case or accessing it on the **Content search** page. The audit record for this event includes the identity of the search that was viewed.
(none)	ViewedSearchPreviewed	Get-ComplianceSearchAction -Preview	A user previewed the results of a Content search in the Microsoft Purview portal. This activity is also logged when a user previews the results of a search associated with an eDiscovery (Standard) case.

eDiscovery (Premium) activities

The following table describes the eDiscovery (Premium) activities logged in the audit log. These activities can be used to help you track the progression of activity in an eDiscovery (Premium) case.

Expand table

Friendly name	Operation	Description
Added data to another review set	AddWorkingSetQueryToWorkingSet	User added documents from one review set to a different review set.
Added data to review set	AddQueryToWorkingSet	User added the search results from a content search associated with an eDiscovery (Premium) case to a review set.
Added non-Microsoft 365 data to review set	AddNonOffice365DataToWorkingSet	User added non-Microsoft 365 data to a review set.
Added remediated documents to review set	AddRemediatedData	User uploads documents that had indexing errors that were fixed to a review set.
Analyzed data in review set	RunAlgo	User ran analytics on the documents in a review set.
Annotated document in review set	AnnotateDocument	User annotated a document in a review set. Annotation includes redacting content in a document.
Compared load sets	LoadComparisonJob	User compared two different load sets in a review set. A load set is when data from a content search that associated with the case is added to a review set.
Converted redacted documents to PDF	BurnJob	User converted all the redacted documents in a review set to PDF files.
Created review set	CreateWorkingSet	User created a review set.
Created review set search	CreateWorkingSetSearch	User created a search query that searches the documents in a review set.
Created tag	CreateTag	User created a tag group in a review set. A tag group can contain one or more child tags. These tags are then used to tag documents in the review set.
Deleted review set search	DeleteWorkingSetSearch	User deleted a search query in a review set.

Friendly name	Operation	Description
Deleted tag	DeleteTag	User deleted a tag or a tag group in a review set.
Downloaded document	DownloadDocument	User downloaded a document from a review set.
Edited tag	UpdateTag	User changed a tag in a review set.
Exported documents from review set	ExportJob	User exported documents from a review set.
Modified case setting	UpdateCaseSettings	User modified the settings for a case. Case settings include case information, access permissions, and settings that control search and analytics behavior.
Modified review set search	UpdateWorkingSetSearch	User edited a search query in a review set.
Previewed review set search	PreviewWorkingSetSearch	User previewed the results of a search query in a review set.
Remediated error documents	ErrorRemediationJob	User fixes files that contained indexing errors.
Tagged document	TagFiles	User tags a document in a review set.
Tagged results of a query	TagJob	User tags all of the documents that match the criteria of search query in a review set.
Viewed document in review set	ViewDocument	User viewed a document in a review set.

eDiscovery cmdlet activities

The following table lists the cmdlet audit log records that are logged when an administrator or user performs an eDiscovery-related activity by using the Microsoft Purview portal or by running the corresponding cmdlet in Security & Compliance PowerShell. The detailed information in the audit log record is different for the cmdlet activities listed in this table and the eDiscovery activities described in the previous section.

As previously stated, it may take up to 24 hours for eDiscovery cmdlet activities to appear in the audit log search results.

> **Tip**
>
> The cmdlets in the **Operation** column in the following table are linked to the corresponding cmdlet help topic on TechNet. Go to the cmdlet help topic for a description of the available parameters for each cmdlet. The parameter and the parameter value that were used with a cmdlet are included in the audit log entry for each eDiscovery cmdlet activity that's logged.

Expand table

Friendly name	Operation (cmdlet)	Description
Created hold in eDiscovery case	New-CaseHoldPolicy	A hold was created for an eDiscovery case. A hold can be created with or without specifying a content source. If content sources are specified, they'll be identified in the audit log entry.
Deleted hold from eDiscovery case	Remove-CaseHoldPolicy	A hold that is associated with an eDiscovery case was deleted. Deleting a hold releases all of the content locations from the hold. Deleting the hold also results in deleting the case hold rules associated with the hold (see **Remove-CaseHoldRule** below).
Changed hold in eDiscovery case	Set-CaseHoldPolicy	A hold that is associated with an eDiscovery was changed. Possible changes include adding or removing content locations or turning off (disabling) the hold.
Created search query for eDiscovery case hold	New-CaseHoldRule	A query-based hold associated with an eDiscovery case was created.
Deleted search query for eDiscovery case hold	Remove-CaseHoldRule	A query-based hold associated with an eDiscovery case was deleted. Removing the query from the hold is often the result of deleting a hold. When a hold or a hold query is deleted, the content locations that were on hold are released.
Changed search query for eDiscovery case hold	Set-CaseHoldRule	A query-based hold associated with an eDiscovery case was changed. Possible changes include editing the query or date range for a query-based hold.
Created eDiscovery case	New-ComplianceCase	An eDiscovery case was created. When a case is created, you only have to give it a name. Other case-related tasks such as adding members, creating holds, and creating content searches associated with the case result in additional events being logged.

Friendly name	Operation (cmdlet)	Description
Deleted eDiscovery case	Remove-ComplianceCase	An eDiscovery case was deleted. Any hold associated with the case has to be removed before the case can be deleted.
Changed eDiscovery case	Set-ComplianceCase	An eDiscovery case was changed. Changes include closing an open case or reopening a closed case.
Added member to eDiscovery case	Add-ComplianceCaseMember	A user was added as a member of an eDiscovery case. As a member of a case, a user can perform various case-related tasks depending on whether they've been assigned the necessary permissions.
Removed member from eDiscovery case	Remove-ComplianceCaseMember	A user was removed as a member of an eDiscovery case.
Changed eDiscovery case membership	Update-ComplianceCaseMember	The membership list of an eDiscovery case was changed. This activity is logged when all members are replaced with a group of new users. If a single member is added or removed, the **Add-ComplianceCaseMember** or **Remove-ComplianceCaseMember** operation is logged.
Created content search	New-ComplianceSearch	A new content search was created.
Deleted content search	Remove-ComplianceSearch	An existing content search was deleted.
Changed content search	Set-ComplianceSearch	An existing content search was changed. Changes can include adding or removing content locations that are searched and editing the search query.
Started content search	Start-ComplianceSearch	A content search was started. When you create or change a content search by using the Microsoft Purview portal GUI, the search is automatically started. If you create or change a search by using the **New-ComplianceSearch** or **Set-ComplianceSearch** cmdlet, you have to run the **Start-ComplianceSearch** cmdlet to start the search.
Stopped content search	Stop-ComplianceSearch	A content search that was running was stopped.
Created content search action	New-ComplianceSearchAction	A content search action was created. Content search actions include previewing search results, exporting search results, preparing search results for analysis in eDiscovery (Premium), and permanently deleting items that match the search criteria of a content search.

Friendly name	Operation (cmdlet)	Description
Deleted content search action	Remove-ComplianceSearchAction	A content search action was deleted.
Created search permissions filter	New-ComplianceSecurityFilter	A search permissions filter was created.
Deleted search permissions filter	Remove-ComplianceSecurityFilter	A search permissions filter was deleted.
Changed search permissions filter	Set-ComplianceSecurityFilter	A search permissions filter was changed.
Created eDiscovery administrator	Add-eDiscoveryCaseAdmin	A user was added as an eDiscovery Administrator in your organization.
Deleted eDiscovery administrator	Remove-eDiscoveryCaseAdmin	An eDiscovery Administrator was deleted from your organization.
Changed eDiscovery administrator membership	Update-eDiscoveryCaseAdmin	The list of eDiscovery Administrators in your organization was changed. This activity is logged when the list of eDiscovery Administrators is replaced with a group of new users. If a single user is added or removed, the **Add-eDiscoveryCaseAdmin** or **Remove-eDiscoveryCaseAdmin** operation is logged.
(none)	Get-ComplianceCase	This activity is logged when a user viewed a list of eDiscovery (Standard) or eDiscovery (Premium) cases. This activity is also logged when a user views a specific case in eDiscovery (Standard). When a user views a specific case, the audit record includes the identity of the case that was viewed. If the user only viewed a list of cases, the audit record doesn't contain a case identity.
(none)	Get-ComplianceSearch	This activity is logged when a user viewed a list of Content searches or searches associated with an eDiscovery (Standard) case. This activity is also logged when a user views a specific Content search or views a specific search associated with an eDiscovery (Standard) case. When a user views a specific search, the audit record includes the identity of the search that was viewed. If the user only viewed a list of searches, the audit record doesn't contain a search identity.

Friendly name	Operation (cmdlet)	Description
(none)	Get-ComplianceSearchAction	This activity is logged when a user viewed a list of compliance search actions (such as exports, previews, or purges) or actions associated with an eDiscovery (Standard) case. This activity is also logged when a user views a specific compliance search action (such as an export) or views a specific action associated with an eDiscovery (Standard) case. When a user views a search action, the audit record includes the identity of the search action that was viewed. If the user only viewed a list of actions, the audit record doesn't contain an action identity.

Detailed properties for eDiscovery activities

The following table describes the properties that are included on the flyout page for an eDiscovery activity listed in the search results. These properties are also included in the CSV file when you export the audit log search results. An audit log record for an eDiscovery activity won't include every detailed property listed below.

> **Tip**
>
> When you export the search results, the CSV file contains a column named **AudtiData**, which contains the detailed properties described in the following table in a multi-value property. You can use the Power Query feature in Excel to split this column into multiple columns so that each property will have its own column. This will let you sort and filter on one or more of these properties. For more information, see Search the audit log.

Expand table

Property	Description
Case	The identity (GUID) of the eDiscovery case that was created, changed, or deleted.
ClientApplication	eDiscovery cmdlet activities have a value of **EMC** for this property. This indicates the activity was performed by using the Microsoft Purview portal GUI or running the cmdlet in PowerShell.
ClientIP	The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format.

Property	Description
ClientRequestId	For eDiscovery activities, this property is typically blank.
CmdletVersion	The build number for the version of the Microsoft Purview portal running in your organization.
CreationTime	The date and time in Coordinated Universal Time (UTC) when the eDiscovery activity was completed.
EffectiveOrganization	The name of the Microsoft 365 organization.
ExchangeLocations	The Exchange Online mailboxes that are included in a content search or placed on hold in an eDiscovery case.
Exclusions	Mailbox or site locations that are excluded from a content search or a hold in an eDiscovery case.
ExtendedProperties	Additional properties from a content search, a content search action, or hold in an eDiscovery case, such as the object GUID and the corresponding cmdlet and cmdlet parameters that were used when the activity was performed.
Id	The ID of the report entry. The ID uniquely identifies the audit log entry.
NonPIIParameters	A list of the parameters (without any values) that were used with the cmdlet identified in the Operation property. The parameters listed in this property are the same as those listed in the Parameters property.
ObjectId	The GUID or name of the object (for example, a Content search or an eDiscovery (Standard) case) that was created, accessed, changed, or deleted by the activity listed in the Operation property. This object is also identified in the Item column in the audit log search results.
ObjectType	The type of eDiscovery object that the user created, deleted, or modified; for example, a content search action (preview, export, or purge), an eDiscovery case, or a content search.
Operation	The name of the operation that corresponds to the eDiscovery activity that was performed.
OrganizationId	The GUID for your Microsoft 365 organization.
Parameters	The name and value for the parameters that were used with the corresponding cmdlet.
PublicFolderLocations	The public folder locations in Exchange Online that are included in a content search or placed on hold in an eDiscovery case.
Query	The search query associated with the activity, such as a content search or a query-based hold.

Property	Description
RecordType	The type of operation indicated by the record. The value of **18** indicates an event related to an activity listed in the eDiscovery cmdlet activities section. A value of **24** indicates an event related to an activity listed in the How to search for and view eDiscovery activities section.
ResultStatus	Indicates whether the action (specified in the Operation property) was successful or not.
SecurityComplianceCenterEventType	Indicates that the activity was a Microsoft Purview portal event. All eDiscovery activities will have a value of **0** for this property.
SharepointLocations	The SharePoint Online sites that are included in a content search or placed on hold in an eDiscovery case.
StartTime	The date and time in Coordinated Universal Time (UTC) when the eDiscovery activity was started.
UserId	The user who performed the activity (specified in the Operation property) that resulted in the record being logged. Records for eDiscovery activity performed by system accounts (such as NT AUTHORITY\SYSTEM) are also included in the audit log.
UserKey	An alternative ID for the user identified in the UserId property. For eDiscovery activities, the value for this property is typically the same as the UserId property.
UserServicePlan	The subscription used by your organization. For eDiscovery activities, this property is typically blank.
UserType	The type of user that performed the operation. The following values indicate the user type. 0 A regular user. 2 An administrator in your organization. 3 A Microsoft datacenter administrator or datacenter system account. 4 A system account. 5 An application. 6 A service principal.
Version	Indicates the version number of the activity (identified by the Operation property) that's logged.
Workload	The service where the activity occurred. For eDiscovery activities, the value is **SecurityComplianceCenter**.

eDiscovery solution series: Data spillage scenario - Search and purge

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

What is data spillage and why should you care? Data spillage is when a confidential document is released into an untrusted environment. When a data spillage incident is detected, it's important to quickly assess the size and locations of the spillage, examine user activities around it, and then permanently purge the spilled data from the system.

> **Tip**
>
> You can also use the purge feature in Data Security Investigations to identify and permanently delete Exchange mailbox and Microsoft Teams items associated with data spillage incidents. Data Security Investigations provides a streamlined search and purge workflow with a purge queue dashboard to help you manage and track purge queries across your organization. For more information, see Purge in Data Security Investigations.

Data spillage scenario

You're a lead information security officer at Contoso. You are informed of a data spillage situation where an employee unknowingly shared a highly confidential document with multiple people through email. You want to quickly assess who received this document internally and externally. Once identified, you would like to share case findings with other investigators to review, and then permanently remove the data from Office 365. After the investigation is complete, you want to generate a report with the evidence of permanent removal and other case details for any future reference.

Scope of this article

This document provides a list of instructions on how to permanently remove a message from Microsoft 365 so that it's not accessible or recoverable. To delete a message and make it recoverable until the deleted item retention period expires, see Search for and delete email messages in your organization.

Workflow for managing data spillage incidents

Here's a how to manage a data spillage incident:

Step 1: Manage who can access the case and set compliance boundaries (Optional)
Step 2: Create an eDiscovery case
Step 3: Search for the spilled data
Step 4: Review and validate case findings
Step 5: Use message trace log to check how spilled data was shared
Step 6: Prepare the mailboxes
Step 7: Permanently delete the spilled data
Step 8: Verify, provide a proof of deletion, and audit

Things to know before you start

- The data spillage workflow described in this article doesn't delete chat messages in Microsoft Teams. To search for and delete Teams chat messages, see Search and purge chat messages in Teams.
- When a mailbox is on hold, a deleted message remains in the Recoverable Items folder until the retention period expires or the hold is released. Step 6 describes how to remove hold from the mailboxes. Check with your records management or legal departments before removing the hold. Your organization might have a policy that defines whether a mailbox on hold or a data spillage incident takes priority.
- To control which user mailboxes a data spillage investigator can search and manage who can access the case, you can set up compliance boundaries and create a custom role group, which is described in Step 1. To do this, you have to be a member of the Organization Management role group or be assigned the role management role. If you or an

administrator in your organization has already set compliance boundaries, you can skip Step 1.

- To create a case, you must be a member of the eDiscovery Manager role group or be a member of a custom role group that's assigned the Case Management role. If you're not a member, ask a Microsoft 365 administrator to add you to the eDiscovery manager role group.
- To create and run a Content Search, you have to be a member of the eDiscovery Manager role group or be assigned the Compliance Search management role. To delete messages, you have to be a member of the Organization Management role group or be assigned the Search And Purge management role. For information about adding users to a role group, see Assign eDiscovery permissions.
- To search the audit log eDiscovery activities in Step 8, auditing must be turned on for your organization. You can search for activities that were performed within the last 90 days. To learn more about how to enable and use auditing, see the Auditing the data spillage investigation process section in Step 8.

(Optional) Step 1: Manage who can access the case and set compliance boundaries

Depending on your organizational practice, you need to control who can access the eDiscovery case used to investigate a data spillage incident and set up compliance boundaries. The easiest way to do this is to add investigators as members of an existing role group in the Microsoft Purview portal and then add the role group as a member of the eDiscovery case. For information about the built-in eDiscovery role groups and how to add members to an eDiscovery case, see Assign eDiscovery permissions.

You can also create a new role group that aligns with your organizational needs. For example, you might want a group of data spillage investigators in the organization to access and collaborate on all data spillage cases. You can do this by creating a "Data Spillage Investigator" role group, assigning the appropriate roles (Export, RMS Decrypt, Review, Preview, Compliance Search, and Case Management), adding the data spillage investigators to the role group, and then adding the role group as a member of the data spillage eDiscovery case. See Set up compliance boundaries for eDiscovery investigations in Office 365 for detailed instructions on how to do this.

Step 2: Create an eDiscovery case

An eDiscovery case provides an effective way to manage your data spillage investigation. You can add members to the role group that you created in Step 1, add the role group as a member of

new an eDiscovery case, perform iterative searches to find the spilled data, export a report to share, track the status of the case, and then refer back to the details of the case if needed. Consider establishing a naming convention for eDiscovery cases used for data spillage incidents, and provide as much information as you can in the case name and description so you can locate and refer to in the future if necessary.

To create a new case, you can use eDiscovery in the Microsoft Purview portal. See "Create a new case" in Get started with eDiscovery (Standard).

Step 3: Search for the spilled data

Now that you've created a case and managed access, you can use the case to iteratively search to find the spilled data and identify the mailboxes that contain the spilled data. You will use the same search query that you used to find the email messages to delete those same messages in Step 7.

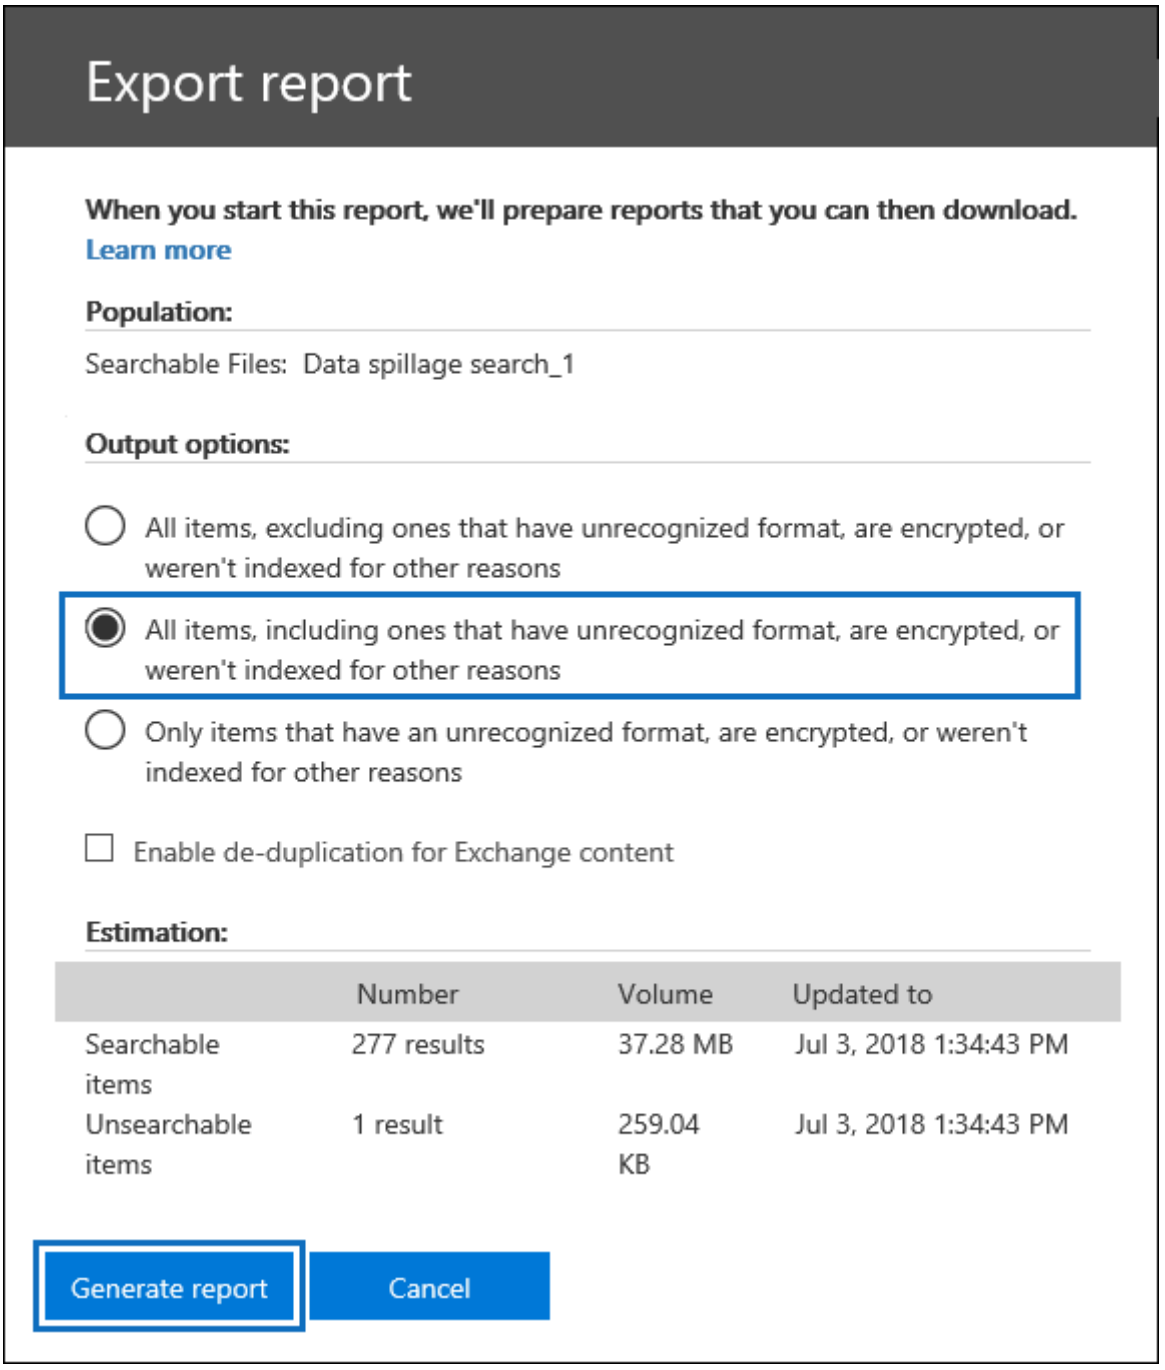
To create a content search associated with an eDiscovery case, see Search for content in an eDiscovery (Standard) case.

> **Important**
>
> The keywords that you use in the search query may contain the actual spilled data that you're searching for. For example, if you searching for documents containing a social security number and you use the it as search keyword, you must delete the query afterwards to avoid further spillage. See **Deleting the search query** in Step 8.

Step 4: Review and validate case findings

After you create a content search, you need to review and validate that the search results and verify that they consist only of the email messages that must be deleted. In a content search, you can preview a random sampling of 1,000 email messages without exporting the search results to avoid further data spillage.

If you have more than 1,000 mailboxes or more than 100 email messages per mailbox to review, you can divide the initial search into multiple searches by using additional keywords or conditions such as date range or sender/recipient and review the results of each search individually. Make sure to note down all search queries to use when you delete messages in Step 7.



When you find an email message that contains spilled data, check the recipients of the message to determine if it was shared externally. To further trace a message, you can collect sender information and date ranges so you can use the message trace logs. This process is described in Step 5.

After you verified the search results, you may want to share your findings with others for a secondary review. People who you assigned to the case in Step 1 can review the case content in both eDiscovery and Microsoft Purview eDiscovery (Premium) and approve case findings. You can also generate a report without exporting the actual content. You can also use this same report as a proof of deletion, which is described in Step 8.

To generate a statistical report:

1. Go to the **Search** page in the eDiscovery case, and select the search that you want to generate a report for.
2. On the flyout page, select **More** > **Export report**.

   The Export report page is displayed.

3. Select **All items, including ones that have unrecognized format, are encrypted, or weren't indexed for other reasons** and then select **Generate report**.

4. In the eDiscovery case, select **Export** to display the list of export jobs. You may have to select **Refresh** to update the list to display the export job you created.

5. Select the export job, and then select **Download** report on the flyout page.

The **Export Summary** report contains the number of locations found with results and the size of the search results. You can use this to compare with the report generated after deletion and provide as a proof of deletion. The **Results** report contains a more detailed summary of the search results, including the subject, sender, recipients, if the email was read, dates, and size of each message. If any of the details in this report contains that actual spilled data, be sure to permanently delete the Results.csv file when the investigation is complete.

Step 5: Use message trace log to check how spilled data was shared

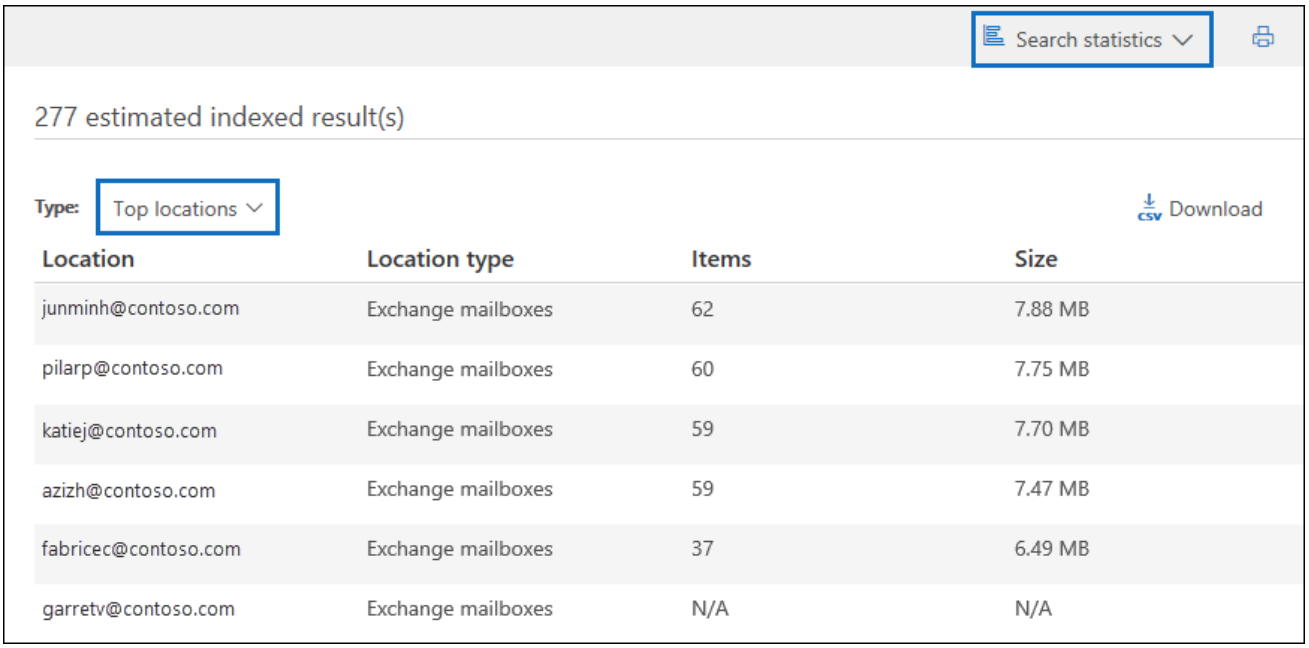
To further investigate if email with spilled data was shared, you can optionally query the message trace logs with the sender information and the date range information that you gathered in Step 4. The retention period for message trace is 30 days for real-time data and 90 days for historical data.

You can use Message trace in the Microsoft Purview portal or use the corresponding cmdlets in Exchange Online PowerShell. It's important to note that message tracing doesn't offer full guarantees on the completeness of data returned. For more information about using Message trace, see:

- Message trace in the Security & Compliance Center
- New Message Trace in Security & Compliance Center

Step 6: Prepare the mailboxes

After you review and validate that the search results contain only the messages that must be deleted, you need to collect a list of the email addresses of the impacted mailboxes to use in Step 7 when you delete the spilled data. You may also have to prepare the mailboxes before you can



permanently delete email messages depending on whether single item recovery is enabled on the mailboxes that contain the spilled data or if any of those mailboxes are on hold.

Get a list of addresses of mailboxes with spilled data

There are two ways to collect a list of email addresses of mailboxes with spilled data.

Option 1: Get a list of addresses of mailboxes with spilled data

1. Open the eDiscovery case, go to the **Search** page and select the appropriate content search.
2. On the flyout page, select **View results**.
3. In the **Individual results** drop down list, select **Search statistics**.
4. In the **Type** drop down list, select **Top locations**.

Location	Location type	Items	Size
junminh@contoso.com	Exchange mailboxes	62	7.88 MB
pilarp@contoso.com	Exchange mailboxes	60	7.75 MB
katiej@contoso.com	Exchange mailboxes	59	7.70 MB
azizh@contoso.com	Exchange mailboxes	59	7.47 MB
fabricec@contoso.com	Exchange mailboxes	37	6.49 MB
garretv@contoso.com	Exchange mailboxes	N/A	N/A

   A list of mailboxes that contain search results is displayed. The number of items in each mailbox that match the search query is also displayed.

5. Copy the information in the list and save it to a file or select **Download** to download the information to a CSV file.

Option 2: Get mailbox locations from the export report

Open the Export Summary report that you downloaded in Step 4. In the first column in the report, the email address of each mailbox is listed under **Locations**.

Prepare the mailboxes so you can delete the spilled data

If single item recovery is enabled or if a mailbox is placed on hold, a permanently deleted (purged) message will be retained in Recoverable Items folder. So before you can purge spilled data, you need to check the existing mailbox configurations and disable single item recovery and remove any hold or retention policy. Keep in mind that you can prepare one mailbox at a time, and then run the same command on different mailboxes or create a PowerShell script to prepare multiple mailboxes at the same time.

- See "Step 1: Collect information about the mailbox" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold for instructions about how to check if single item recovery is enabled or if the mailbox is placed on hold or it's assigned to a retention policy.
- See "Step 2: Prepare the mailbox" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold for instructions about disabling single item recovery.
- See "Step 3: Remove all holds from the mailbox" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold for instructions about how to remove a hold or retention policy from a mailbox.
- See "Step 4: Remove the delay hold from the mailbox" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold for instructions about removing the delay hold that is placed on the mailbox after any type of hold is removed.

> **Important**
>
> Check with your records management or legal departments before removing a hold or retention policy. Your organization may have a policy that defines whether a mailbox on hold or a data spillage incident takes priority.

Be sure to revert the mailbox to previous configurations after you verify that the spilled data has been permanently deleted. See the details in Step 7.

Step 7: Permanently delete the spilled data

Using the mailbox locations that you collected and prepared in Step 6 and the search query that was created and refined in Step 3 to find email messages that contain the spilled data, you can now permanently delete the spilled data. As previously explained, to delete messages, you have to be a member of the Organization Management role group or be assigned the Search And Purge management role. For information about adding users to a role group, see Assign eDiscovery permissions.

To delete the spilled messages, see Search for and delete email messages.

Keep the following limits in mind when deleting spilled data:

- The maximum number of mailboxes in a search that you can use to delete items by doing a search and purge action is 50,000. If the search that you create in Step 3 searches more than 50,000 mailboxes, the purge action will fail. Searching more than 50,000 mailbox in a single search might typically happen when you configure the search to include all mailboxes in your organization. This restriction still applies even when less than 50,000 mailboxes contain items that match the search query.
- A maximum of 10 items per mailbox can be removed at one time. Because the capability to search for and remove messages is intended to be an incident-response tool, this limit helps ensure that messages are quickly removed from mailboxes. This feature isn't intended to clean up user mailboxes.

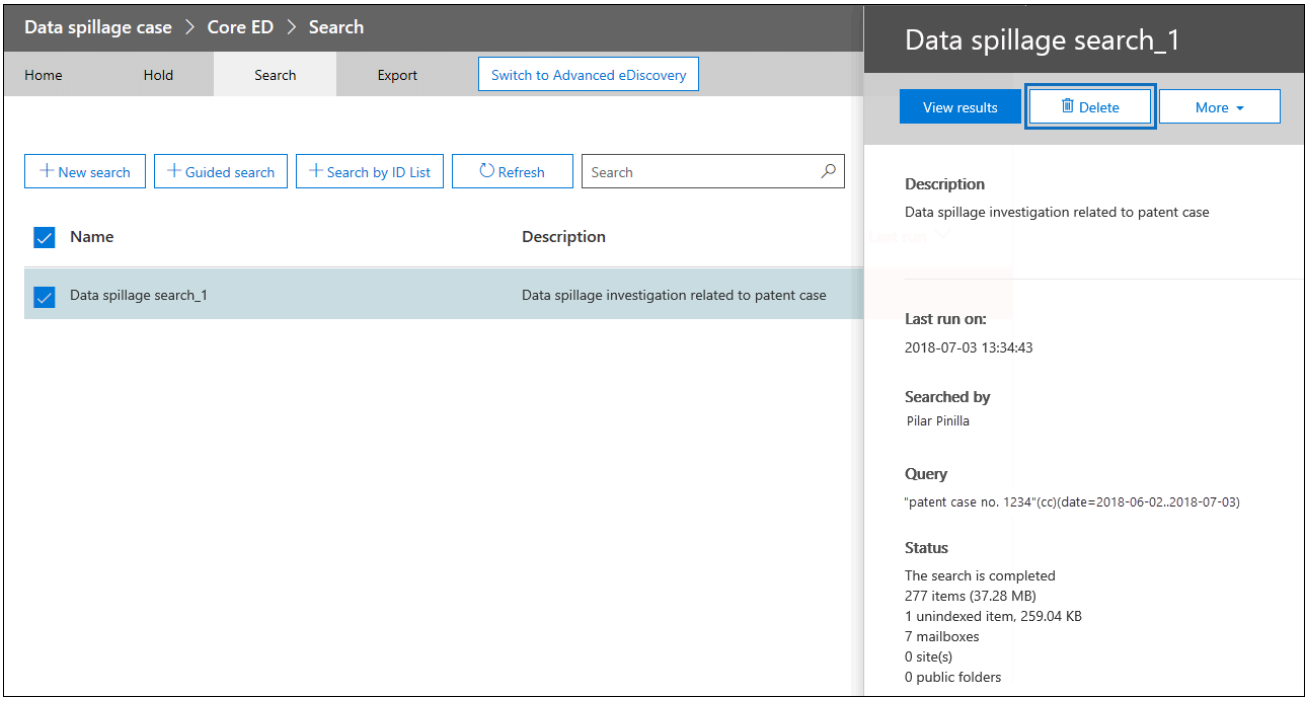
> **Important**
>
> Email items in a review set in an eDiscovery (Premium) case can't be deleted by using the procedures in this article. That's because items in a review set are copies of items in the live service that are copied and stored in an Azure Storage location. This means they won't be returned by a content search that you create in Step 3. To delete items in a review set, you have to delete the eDiscovery (Premium) case that contains the review set. For more information, see Close or delete an eDiscovery (Premium) case.

Step 8: Verify, provide a proof of deletion, and audit

The final step in the workflow to manage a data spillage incident is to verify that the spilled data was permanently removed from the mailbox by going to the eDiscovery case and rerunning the same search query that was used to delete that data to confirm that no results are returned. After you confirm the spilled data has been permanently removed, you can export a report and include it (along with the original report) as a proof of deletion. Then you can close the case which will allow you to reopen it if you have to refer to it in the future. Additionally, you can also revert mailboxes to their previous state, delete the search query used to find the spilled data, and search for auditing records of tasks performed when managing the data spillage incident.

Reverting the mailboxes to their previous state

If you changed any mailbox configuration in Step 6 to prepare the mailboxes before the spilled data was deleted, you will need to revert them to their previous state. See "Step 6: Revert the



mailbox to its previous state" in Delete items in the Recoverable Items folder of cloud-based mailboxes on hold.

Deleting the search query

If the keywords in the search query that you created and used in Step 3 contains some of all of the actual spilled data, you should delete the search query to prevent further data spillage.

1. In the Microsoft Purview portal, open the eDiscovery case, go to the **Search** page, and select the appropriate content search.

2. On the flyout page, select **Delete**.

Auditing the data spillage investigation process

You can search the audit log for the eDiscovery activities that were performed during the investigation. You can also search the audit log to return the audit records for the **New-ComplianceSearchAction -Purge** command that you ran in Step 7 to delete the spilled data. For more information, see:

- Search the audit log
- Search for eDiscovery activities in the audit log

Last updated on 09/02/2025

Troubleshoot AzCopy in eDiscovery (Premium)

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

When loading non-Microsoft 365 data or documents for error remediation in Microsoft Purview eDiscovery (Premium), the user interface supplies an Azure AzCopy command that contains parameters with the location of where the files that you want to upload are stored and the Azure storage location that the files will be uploaded to. To upload your documents, you copy this command and then run it in a Command Prompt on your local computer.

Usually the command that's provided works when you run it. However, there may be cases when the command that's displayed won't run successfully. Here's a few possible reasons.

The supported version of AzCopy isn't installed on the local computer

You should use the latest version of AzCopy to load non-Microsoft 365 data in eDiscovery (Premium). To install the latest version, see Get started with AzCopy.

AzCopy isn't installed on the local computer or it's not installed in the default location

If AzCopy isn't installed or it's installed in a location other than the default install location (which is `%ProgramFiles(x86)%`), you may receive the following error when you run the AzCopy command:

> The system cannot find the path specified.

If AzCopy isn't installed on the local computer, see Get started with AzCopy. Be sure to install it in the default location.

If AzCopy is installed, but it's installed in a location different than the default location, you can copy the command, paste it to a text file, and then change the path to the location where AzCopy is installed. For example, if Azcopy is located in `%ProgramFiles%`, then you can change the first part of the command from `%ProgramFiles(x86)%\Microsoft SDKs\Azure\AzCopy.exe` to `%ProgramFiles%\Microsoft SDKs\Azure\AzCopy`. After you make this change, copy it from the text file, and then run it a Command Prompt.

> **Tip**
>
> If AzCopy is installed in a location other then the default install location, consider uninstalling it and then re-installing it in the default location. This will help prevent this issue in the future.

Retirement of legacy eDiscovery tools

> **Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

> **Important**
>
> The functionality of the legacy eDiscovery tools described in this article has either been removed from the Microsoft 365 service or is still available, but no longer supported. Any functionality that's still available may be removed without notice. If you're still using any of these legacy tools, consider migrating to the eDiscovery tools in the Microsoft Purview portal or one of the alternatives described in this article.

Over the years, Microsoft has provided eDiscovery tools that let you search, preview, and export email content from Exchange Online. However, these tools no longer offer an effective way to search for non-Exchange content in other Microsoft 365 services, such as SharePoint and Microsoft 365 Groups.

To address this, Microsoft offers other eDiscovery tools that help you search for a wide variety of Microsoft 365 content. And we've been working hard to incorporate the most current and powerful eDiscovery functionality in the Microsoft Purview portal. This allows organizations to respond to legal, internal, and other document requests for content across many Microsoft 365 services, including Exchange Online.

As a result of this new and improved eDiscovery functionality in the Microsoft Purview portal, the following eDiscovery-related features and functionality related to searching for email content in Exchange Online and Microsoft 365 are retired:

- In-Place eDiscovery and In-Place Holds in the Exchange admin center.

- The Exchange Online PowerShell cmdlets that support In-Place eDiscovery and In-Place Holds (these cmdlets are collectively identified as **-MailboxSearch* cmdlets). This includes the following cmdlets:
  - New-MailboxSearch
  - Start-MailboxSearch
  - Stop-MailboxSearch
  - Set-MailboxSearch

  > **Note**
  >
  > The **Remove-MailboxSearch** cmdlet will be available after the other ****-MailboxSearch*** cmdlets are retired so that you can use it to help in your transition to other eDiscovery and hold tools. However, after a certain date (cited below) Microsoft Support will no longer supports this cmdlet.

- The Search-Mailbox cmdlet in Exchange Online PowerShell.

- The following operations in the Exchange Web Services API:
  - GetSearchableMailboxes
  - SearchMailboxes
  - SetHoldOnMailboxes
  - GetHoldOnMailboxes

- Microsoft Purview eDiscovery (Premium) v1.0, which is the first version of eDiscovery (Premium) that's accessed through a Microsoft Purview eDiscovery (Standard) case in the Microsoft Purview portal. The retirement of eDiscovery (Premium) v1.0 doesn't impact your ability to create and manage eDiscovery (Standard) cases.

> **Note**
>
> The eDiscovery functionality being retired only applies to cloud-based versions of Microsoft 365 and Office 365. eDiscovery functionality in on-premises versions of Exchange and SharePoint will still be supported until further notice.

The following sections in this article provide guidance about each feature being retired. This information including timelines and alternative tools that you can use instead of the retired tool.

In-Place eDiscovery and In-Place Holds in the Exchange admin center

As per the original announcement on July 1, 2017, the In-Place eDiscovery & Hold functionality in the Exchange admin center (EAC) is being retired. The In-Place eDiscovery & Holds page in the EAC allowed you to search, hold, and export content from Exchange Online. In-Place eDiscovery also let you copy search results to a discovery mailbox so that you or other eDiscovery managers could review content and make it available for legal, regulatory, and public requests.

Because all of these capabilities (except for copying search results to a discovery mailbox) are now available in the content search, eDiscovery and eDiscovery (Premium) tools in the Micrsoft Purview portal (with improved functionality, reliability, and support for a wide range of Microsoft 365 services), we recommend that you start using these tools as soon as possible. To help you in the transition to these other eDiscovery tools, the table below lists the tools you can use instead of In-Place eDiscovery and In-Place Hold.

> **Note**
>
> When migrating mailboxes from on-premises Exchange to Exchange Online, you need to create new holds in the Microsoft Purview portal for mailboxes with holds to preserve the data. Legacy holds in on-premises Exchange organizations aren't migrated.

Scope of affected organizations

- Office 365 and Microsoft 365 Enterprise organizations
- Office 365 and Microsoft 365 Education organizations
- Office 365 and Microsoft 365 Government organizations; this includes GCC, GCC High, and DoD
- Office 365 and Microsoft 365 operated by 21Vianet (China)
- Office 365 and Microsoft 365 Germany

Timeline for retirement

- July 1, 2020: You won't be able to create new searches and holds, but you can still run, edit, and delete existing searches at your own risk. Microsoft Support will no longer In-Place eDiscovery & Holds in the EAC.
- October 1, 2020: The In-Place eDiscovery & Holds functionality in the EAC was placed in a read-only mode. This means you'll only be able to remove existing searches and holds.

Alternative tools

The following table describes other tools that you can use to replace the existing functionality that's being retired.

Expand table

Functionality	Alternative tool	Comments
Search, export, and hold for legal purposes	eDiscovery (Standard) cases in the Microsoft Purview portal	Using the capabilities of eDiscovery (Standard) cases provide the functional parity to In-Place eDiscovery and In-Place Holds. This includes the following: • Search scales to millions of locations • Higher reliability for searching, exporting, and placing content on hold • Searching for content in for Exchange Online, SharePoint, OneDrive, Skype for Business, Microsoft Teams, Viva Engage Groups, Microsoft 365 Groups, and other content stored in Office 365 applications
Hold for retention purposes	Retention policies in the Microsoft Purview portal	You can use Retention policies to retain content and, if desired, delete it after the retention period expires. Other capabilities include: • Applying policies to your entire organization • Applying policies to specific content locations such as Exchange Online, SharePoint, OneDrive, Skype for Business, Microsoft Teams, and Office 365 Groups • Applying policies to specific users For more information, see Learn about retention policies and retention labels.
Copy email search results to a discovery mailbox for review	Review sets in eDiscovery (Premium) v2.0	Reviewing content in Microsoft 365 has never been easier. Review sets have many great capabilities to help reduce the amount of time and data needed to review, including: • Perform fast search queries and filter content in a review set • Analyze content in a review set; this includes email threading, near-duplicate detection, Themes analysis, and Predictive coding • Tag documents in a review set • Tagging suggestions to help identify attorney client privilege content For more information, see Overview of the eDiscovery (Premium) solution in Microsoft 365.

Functionality	Alternative tool	Comments
		Alternatively, you can export search results to PST files and then use Microsoft 365 Import service to import the PSTs to a discovery mailbox. For step-by-step instruction, see Use network upload to import PST files to Office 365.
Copy messages from one mailbox to a different mailbox	Assign permissions to a mailbox	To give a person access to another user's email (such as when an employee leaves your organization and you need to give another person access to the former employee's email), we recommended that you assign that person permissions to access the former employee's mailbox. So instead of copying mailbox items to another user mailbox or a shared mailbox, just assign a user the permissions necessary to access the source mailbox.
Restore items from the Recoverable Items folder	Restore-RecoverableItems	You can restore permanently deleted items (also known as *soft-deleted* items) in mailboxes, as long as the deleted item retention period for an item hasn't expired. For more information, see Recoverable Items folder in Exchange Online.

FAQs about In-Place eDiscovery and In-Place Holds

I use the copy search results functionality of In-Place eDiscovery & Holds in the EAC to copy search results to a discovery mailbox for review by attorneys. What options do I have now?

There are two ways to replicate this functionality today. The first is to use review sets in eDiscovery (Premium) v2.0. Review sets have many of the same capabilities you see in a traditional review tool like fast search of documents, tagging, email threading, near duplicate grouping, themes analysis, and predictive coding. If you still want to use discovery mailboxes for review, the second option is to export search results to PST files and then import the PST files to a discovery mailbox by using the PST import feature in the Microsoft compliance center.

How do I control which content locations (such as mailboxes or sites) that can an eDiscovery manager can search using the new tools?

The Microsoft Purview portal also uses compliance boundaries to control which content locations an eDiscovery Manager can search. Compliance boundaries are useful in government entities that need to stay within agency boundaries or multi-national corporations required to respect geographical boarders.

*-MailboxSearch cmdlets

As per the original notice announced on July 1, 2017 in the Exchange admin center, the In-Place eDiscovery & Hold functionality and the corresponding ***-MailboxSearch** cmdlets are being retired. These cmdlets provide users the ability to search, hold, and export mailbox content for legal, regulatory, and public requests.

Because these capabilities are now available in the Microsoft Purview portal and Office 365 Security & Compliance PowerShell with improved performance and scalability, you should using these improved cmdlets. These cmdlets include *-ComplianceCase, *-ComplianceSearch, *-CaseHoldPolicy, *-CaseHoldRule, and *-ComplianceSearchAction.

Scope of affected organizations

- Office 365 and Microsoft 365 Enterprise organizations
- Office 365 and Microsoft 365 Education organizations
- Office 365 and Microsoft 365 Government organizations; this includes GCC, GCC High, and DoD
- Office 365 and Microsoft 365 operated by 21Vianet (China)
- Office 365 Germany

Timeline

- July 1, 2020: You won't be able to use **New-MailboxSearch** to create new In-Place eDiscovery searches and In-Place Holds, but you can still use cmdlets to run, edit, and delete existing searches and holds at your own risk. Microsoft Support will no longer provide assistance for these types of searches and holds.
- October 1, 2020: The In-Place eDiscovery & Holds functionality in the EAC was placed in a read-only mode. You won't be able to use the **New-MailboxSearch**, **Start-MailboxSearch**, or **Set-MailboxSearch** cmdlets. You'll only be able to get and remove existing searches and holds.

Alternative tools

The following table describes other tools that you can use to replace the existing functionality that's being retired.

Expand table

Functionality	Alternative tools	Comments
Search and export	*-ComplianceSearch *-ComplianceSearchAction *-ComplianceCase	The ComplianceSearch and ComplianceSearchAction cmdlets work together to help you search and export content. You can create a new search and view the search estimate by using the **New-**, **Get-**, and **Start-ComplianceSearch** cmdlets. Then you can use the **New-ComplianceSearchAction** cmdlet to export the search results. You'll still have to use the eDiscovery (Standard) tool in the Microsoft Purview portal to download those search results to your local computer. **Note:** If you use these cmdlets to create searches that aren't associated with an eDiscovery (Standard) case, these searches will be located on the **Content search** page in the Microsoft Purview portal.
Hold content in a mailbox	*-CaseHoldPolicy *-CaseHoldRule *-ComplianceCase	Holds in the Microsoft Purview portal must be associated with a ComplianceCase. First, create the compliance case, and then create a CaseHoldPolicy and a CaseHoldRule. **Note:** Creating a CaseHoldPolicy without a creating CaseHoldRule will render the hold inoperable until the CaseHoldRule is created and associated to the CaseHoldPolicy. See the cmdlet documentation for more information.
Copy search results to a discovery mailbox	None	There's no direct replacement for this functionality because it does not provide access to all Microsoft 365 services. See the following FAQ below for alternative solutions.
Copy messages from one mailbox to a different mailbox	Assign permissions to a mailbox	To give a person access to another user's email (such as when an employee leaves your organization and you need to give another person access to the former employee's email), we recommended that you assign that person permissions to access the former employee's mailbox. So instead of copying mailbox items to another user mailbox or a shared mailbox, just assign a user permissions to access the source mailbox.

FAQs about *-MailboxSearch cmdlets

We use Copy Search to export email messages or instant Messages for purposes other eDiscovery and legal investigations. What other options do we have after these cmdlets are retired?

The Microsoft Graph APIs provide a number of methods for extracting data for analysis and other purposes that are far more resilient and scalable than the using the ***-MailboxSearch** cmdlets.

After the cmdlets are retired, will I still be able to remove or retrieve searches?

Yes, although we're removing the ability to create and modify searches, you'll still be able to use the **Remove-MailboxSearch** until further notice. However, the use of this cmdlet will be at your own risk after the retirement dates and Microsoft Support will no longer be able to provide assistance.

Search-Mailbox cmdlet

The **Search-Mailbox** cmdlet in Exchange Online PowerShell has been retired as originally announced in a warning in the cmdlet output starting back in 2018. The **Search-Mailbox** cmdlet was originally used to search a user's mailbox and purge malicious content. We recommend that you start using the **New-ComplianceSearch** and **New-ComplianceSearchAction** cmdlets in Office 365 Security & Compliance PowerShell to search for and purge content. For a built-in security experience, the <Microsoft 365 security features provide robust threat protection for email and many other Microsoft services.

Scope of affected organizations

- Office 365 and Microsoft 365 Enterprise organizations
- Office 365 and Microsoft 365 Education organizations
- Office 365 and Microsoft 365 Government organizations; this includes GCC, GCC High, and DoD
- Office 365 and Microsoft 365 operated by 21Vianet (China)
- Office 365 Germany

Timeline

April, 2024: The **Search-Mailbox** cmdlet is no longer be available and Microsoft Support will no longer provide assistance.

Alternative tools

The following table describes other tools that you can use to replace the existing functionality that's being retired.

Expand table

Functionality	Alternative tools	Comments
Search a mailbox	*-ComplianceSearch *-ComplianceSearchAction	The ComplianceSearch and ComplianceSearchAction cmdlets work together to help you search content. You can create a new search and view the search estimate by using the **New-**, **Get-**, and **Start-ComplianceSearch** cmdlets.
Delete bulk email from a mailbox	Set up an archive and deletion policy for mailboxes	Admins can create an archiving and deletion policy that automatically moves items to a user's archive mailbox and automatically deletes items from the mailbox.
Copy search results to a discovery mailbox		There's no direct replacement for this functionality because it does not provide access to all Microsoft 365 services. See the FAQs in the ***-MailboxSearch cmdlets** section for alternative solutions.
Copy messages from one mailbox to a different mailbox	Assign permissions to a mailbox	To give a person access to another user's email (such as when an employee leaves your organization and you need to give another person access to the former employee's email), we recommended that you assign that person permissions to access the former employee's mailbox. So instead of copying mailbox items to another user mailbox or a shared mailbox, just assign a user permission to access the source mailbox.
Purge messages from a mailbox	*-ComplianceSearch *-ComplianceSearchAction	The ComplianceSearch and ComplianceSearchAction cmdlets work together to help you search and purge content. You can create and run a search with **New-ComplianceSearch** and **New-ComplianceSearch** cmdlets, and then you can purge the content by using **New-ComplianceSearchAction -Purge -PurgeType** command. For more information, see Search for and delete messages.
Purge messages from a mailbox	Assign permissions to a mailbox	To purge messages from a mailbox, assign an administrator permissions to access the employee's mailbox. Messages can be deleted and recycled as needed taking advantage of the built-in search and viewing capabilities in Outlook.

Exchange Web Services API operations

These operations in the Exchange Web Services API are used by the In-Place eDiscovery & Holds feature in the Exchange admin center and the corresponding ***-MailboxSearch** cmdlets in

Exchange Online PowerShell. They will also be retired as part of retiring the other legacy eDiscovery tools.

Scope of affected organizations

- Office 365 and Microsoft 365 Enterprise organizations
- Office 365 and Microsoft 365 Education organizations
- Office 365 and Microsoft 365 Government organizations; this includes GCC, GCC High, and DoD
- Office 365 Germany

Timeline

July 1, 2020: The GetSearchableMailboxes, SearchMailboxes, SetHoldOnMailboxes, and GetHoldOnMailboxes operations will no longer be available, and Microsoft Support will no longer provide assistance.

eDiscovery (Premium) v1.0

eDiscovery (Premium) v1.0, which is the version of eDiscovery (Premium) available in an eDiscovery (Standard) case by selecting **Switch to eDiscovery (Premium)**, is being retired. Its functionality has been replaced by the new eDiscovery (Premium) solution in the Microsoft Purview portal.

To determine if your organization is using eDiscovery (Premium) v1.0:

1. Go to the Microsoft Purview portal, select **eDiscovery (Standard)**, and open an eDiscovery (Standard) case.

2. If you see **Switch to eDiscovery (Premium)**, selecting it takes you to the 1.0 version of eDiscovery (Premium), which is being retired. The ability to create and manage cases in eDiscovery (Standard) won't be affected. Only the ability to add and analyze case data in eDiscovery (Premium) v1.0 (by selecting **Switch to eDiscovery (Premium)**) is being retired.

The new eDiscovery (Premium) solution in Microsoft 365 (also known as *eDiscovery (Premium) v2.0*) provides all of the capabilities of the original solution, but now includes a custodian-based approach of identifying content in other Microsoft 365 services, collecting that content, and then adding it to a review set where reviewers can take advantage of fast search queries, tagging, and analytics features to help cull relevant documents. eDiscovery (Premium) now includes improved processing and native viewers for both Microsoft and non-Microsoft file types, a full list of file

types is here and supported metadata fields are here. Also, the new eDiscovery (Premium) solution provides a powerful custodian holds management feature that lets you apply holds to content in different services, notify users of the holds, and track custodian responses, all within an eDiscovery (Premium) case.

To access eDiscovery (Premium) v2.0:

Go to the Microsoft Purview portal, select **eDiscovery** > **Advanced**, and open an eDiscovery (Standard) case.

At this time, we recommend that you begin to transition your eDiscovery workflow to the new eDiscovery (Premium) functionality. If necessary, you can archive your eDiscovery (Premium) 1.0 cases by exporting the content and storing it offline. Although you'll still be able to access eDiscovery (Premium) v1.0 in existing cases until December 31, 2020, Microsoft Support won't provide support after October 1, 2020. See the following timeline for more details.

Scope of affected organizations

- Office 365 and Microsoft 365 Enterprise organizations
- Office 365 and Microsoft 365 Education organizations
- Office 365 and Microsoft 365 Government organizations; this includes GCC, GCC High, and DoD
- Office 365 Germany

Timeline

- July 1, 2020: You won't be able to create new eDiscovery (Premium) v1.0 cases.
- October 1, 2020: You won't be able to add new data (Prepare search results for eDiscovery (Premium)) to any cases. You'll be able to continue working with data in existing cases at your own risk. Microsoft Support will no longer provide assistance.
- December 31, 2020: You won't be able to access eDiscovery (Premium) v1.0 cases.

Exchange Online mail encryption with AD RMS

> *Microsoft Purview service description*

To help prevent information leakage, Exchange Online includes Information Rights Management (IRM) functionality that provides online and offline protection of email messages and attachments. You can configure Exchange Online IRM to use on-premises Active Directory Rights Management Service (AD RMS), if needed, to satisfy your organization requirements. This is not common. If you do not have a requirement to use AD RMS, use Microsoft Purview Message Encryption instead.

IRM protection can be applied by users in Microsoft Outlook or Outlook on the web, and it can be applied by administrators using transport protection rules or Outlook protection rules. IRM helps you and your users control who can access, forward, print, or copy sensitive data within an email.

Changes to how IRM works with message encryption and Microsoft Entra ID

As of September 2017, when you set up Microsoft Purview Message Encryption for your organization, you also set up IRM for use with the Azure Rights Management service. You no longer set up IRM with Rights Management service separately. Instead, message encryption and rights management work seamlessly together. For more details about Microsoft Purview Message Encryption, see Message Encryption FAQ. If you're ready to get started using Microsoft Purview Message Encryption within your organization, see Set up Microsoft Purview Message Encryption.

How IRM works with Exchange Online and Active Directory Rights Management Services

Exchange Online IRM uses on-premises Active Directory Rights Management Services (AD RMS), an information protection technology in Windows Server 2008 and later. IRM protection is applied to email by applying an AD RMS rights policy template to an email message. Rights are attached to the message itself so that protection occurs online and offline and inside and outside of your organization's firewall.

Users can apply a template to an email message to control the permissions that recipients have on a message. Actions, such as forwarding, extracting information from a message, saving a message or printing a message can be controlled by applying an AD RMS rights policy to the message.

You can configure IRM to use an AD RMS server running Windows Server 2008 or later. You can use this AD RMS server to manage the AD RMS rights policy templates for your cloud-based organization. Outlook also relies on the AD RMS server to enable users to apply IRM protection to messages they send. For details, see Configure IRM to use an on-premises AD RMS server.

After it's enabled, IRM protection can be applied to messages as follows:

- **Users can manually apply a template using Outlook and Outlook on the web.** Users can apply an AD RMS rights policy template to an email message by selecting the template from the **Set permissions** list. When users send an IRM-protected message, any attached files that use a supported format also receive the same IRM protection as the message. IRM protection is applied to files associated with Word, Excel, and PowerPoint, as well as .xps files and attached email messages.

- **Administrators can use transport protection rules to apply IRM protection automatically to both Outlook and Outlook on the web.** You can create transport protection rules to IRM-protect messages. Configure the transport protection rule action to apply an AD RMS rights policy template to messages that meet the rule condition. After you enable IRM, your organization's AD RMS rights policy templates are available to use with the transport protection rule action called **Apply rights protection to the message with**.

- **Administrators can create Outlook protection rules.** Outlook protection rules automatically apply IRM-protection to messages in Outlook 2010 (not Outlook on the web) based on message conditions that include the sender's department, who the message is sent to, and whether recipients are inside or outside your organization. For details, see Create an Outlook Protection Rule.

Configure IRM to use an on-premises AD RMS server

> *Microsoft Purview service description*

For use with on-premises deployments, Information Rights Management (IRM) in Exchange Online uses Active Directory Rights Management Services (AD RMS), an information protection technology in Windows Server 2008 and later. IRM protection is applied to email by applying an AD RMS rights policy template to an email message. Rights are attached to the message itself so that protection occurs online and offline and inside and outside of your organization's firewall.

This topic shows you how to configure IRM to use an AD RMS server. For information about using Microsoft Purview Message Encryption with Microsoft Entra ID and the Azure Rights Management service, see the Message encryption FAQ.

To learn more about IRM in Exchange Online, see Information Rights Management in Exchange Online.

What do you need to know before you begin?

- Estimated time to complete this task: 30 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Information Rights Management" entry in the Messaging policy and compliance permissions topic.
- The AD RMS server must be running Windows Server 2008 or later. For details about how to deploy AD RMS, see Installing an AD RMS Cluster.
- For details about how to install and configure Windows PowerShell and connect to the service, see Connect to Exchange Online PowerShell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts for the Exchange admin center in Exchange Online.

How do you do this?

Complete the following steps to export the trusted publishing domain, import it into Exchange Online, distribute a rights policy template, and enable IRM.

Step 1: Use the AD RMS console to export a trusted publishing domain (TPD) from an AD RMS server

The first step is to export a trusted publishing domain (TPD) from the on-premises AD RMS server to an XML file. The TPD contains the following settings needed to use RMS features:

- The server licensor certificate (SLC) used for signing and encrypting certificates and licenses
- The URLs used for licensing and publishing
- The AD RMS rights policy templates that were created with the specific SLC for that TPD

When you import the TPD, it's stored and protected in Exchange Online.

1. Open the Active Directory Rights Management Services console, and then expand the AD RMS cluster.
2. In the console tree, expand **Trust Policies**, and then click **Trusted Publishing Domains**.
3. In the results pane, select the certificate for the domain you want to export.
4. In the **Actions** pane, click **Export Trusted Publishing Domain**.
5. In the **Publishing domain file** box, click **Save As** to save the file to a specific location on the local computer. Type a file name, making sure to specify the `.xml` file name extension, and then click **Save**.
6. In the **Password** and **Confirm Password** boxes, type a strong password that will be used to encrypt the trusted publishing domain file. You will have to specify this password when you import the TPD to your cloud-based email organization.

Step 2: Use the Exchange Management Shell to import the TPD to Exchange Online

After the TPD is exported to an XML file, you have to import it to Exchange Online. When a TPD is imported, your organization's AD RMS templates are also imported. When the first TPD is imported, it becomes the default TPD for your cloud-based organization. If you import another TPD, you can use the `-Default` switch on the `Import-RMSTrustedPublishingDomain` cmdlet to make that TPD the default for your organization, so its templates are available to users.

To import the TPD into Exchange Online so the associated AD RMS templates become available to your organization, run the following command in Exchange Online PowerShell:

PowerShell

```
Import-RMSTrustedPublishingDomain -FileData ([System.IO.File]::ReadAllBytes('<path to exported TPD file>')) -Name "<name of TPD>" -ExtranetLicensingUrl <URL> -IntranetLicensingUrl <URL>
```

The following table describes each parameter:

Expand table

Parameter	Value to provide
FileData	The byte content of the exported TPD XML file. Specify the full file path in the `ReadAllBytes` method.
Name	A display name for the TPD in Exchange Online.
ExtranetLicensingUrl	The external licensing URL of the AD RMS cluster.
IntranetLicensingUrl	The internal licensing URL of the AD RMS cluster.

You can obtain the values for the *ExtranetLicensingUrl* and *IntranetLicensingUrl* parameters in the Active Directory Rights Management Services console. Select the AD RMS cluster in the console tree. The licensing URLs are displayed in the results pane. These URLs are used by email clients when content has to be decrypted and when Exchange Online needs to determine which TPD to use.

When you run this command, you'll be prompted for a password. Enter the password that you specified when you exported the TPD from your AD RMS server.

The following example imports an exported TPD file and specifies the internal and external licensing URLs required for AD RMS integration. In this case, the TPD XML file was exported from the AD RMS server and saved to the desktop of the Administrator account. The Name parameter is used to specify a name for the imported TPD.

PowerShell

```
Import-RMSTrustedPublishingDomain -FileData ([System.IO.File]::ReadAllBytes('C:\Users\Administrator\Desktop\ExportTPD.xml')) -Name "Exported TPD" -ExtranetLicensingUrl https://corp.contoso.com/_wmcs/licensing -IntranetLicensingUrl https://rmsserver/_wmcs/licensing
```

For detailed syntax and parameter information, see Import-RMSTrustedPublishingDomain.

How do you know that you successfully imported the TPD?

To verify that you have successfully imported the TPD, run the **Get-RMSTrustedPublishingDomain** cmdlet to retrieve TPDs in your Exchange Online organization. For details, see the examples in Get-RMSTrustedPublishingDomain.

Step 3: Use the Exchange Management Shell to distribute an AD RMS rights policy template

After you import the TPD, you must make sure an AD RMS rights policy template is distributed. A distributed template is visible to Outlook on the web (formerly known as Outlook Web App) users, who can then apply the templates to an email message.

To verify which RMS templates are available in the default TPD after the import, list all templates by running the following command:

PowerShell

```
Get-RMSTemplate -Type All | fl
```

If the value of the *Type* parameter is `Archived`, the template isn't visible to users. Only distributed templates in the default TPD are available in Outlook on the web.

To make a specific RMS template available to users in Outlook on the web, set its type to Distributed by running the following command:

PowerShell

```
Set-RMSTemplate -Identity "<name of the template>" -Type Distributed
```

For example, to distribute the Company Confidential template so that users can apply it to messages, run the following command:

PowerShell

```
Set-RMSTemplate -Identity "Company Confidential" -Type Distributed
```

For detailed syntax and parameter information, see Get-RMSTemplate and Set-RMSTemplate.

The Do Not Forward template

When you import the default TPD from your on-premises organization into Exchange Online, one AD RMS rights policy template named **Do Not Forward** is imported. By default, this template is distributed when you import the default TPD. You can't use the **Set-RMSTemplate** cmdlet to modify the **Do Not Forward** template.

When the **Do Not Forward** template is applied to a message, only the recipients addressed in the message can read the message. Additionally, recipients can't do the following:

- Forward the message to another person.
- Copy content from the message.
- Print the message.

> **Important**
>
> The **Do Not Forward** template can't prevent information in a message from being copied with third-party screen capture programs, cameras, or users manually transcribing the information

You can create additional AD RMS rights policy templates on the AD RMS server in your on-premises organization to meet your IRM protection requirements. If you create additional AD RMS rights policy templates, you have to export the TPD from the on-premises AD RMS server again and refresh the TPD in the cloud-based email organization.

How do you know that you successfully distributed the AD RMS rights policy template?

To verify that you have successfully distributed and AD RMS rights policy template, run the **Get-RMSTemplate** cmdlet to check the template's properties. For details, see the examples in Get-RMSTemplate.

Step 4: Use the Exchange Management Shell to enable IRM

After you import the TPD and distribute an AD RMS rights policy template, enable internal licensing so that Exchange Online can apply and consume IRM-protected content. Run the following command to enable IRM for your cloud-based email organization.

PowerShell

```
Set-IRMConfiguration -InternalLicensingEnabled $true
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

How do you know that you successfully enabled IRM?

To verify that you have successfully enabled IRM, run the Get-IRMConfiguration cmdlet to check IRM configuration in the Exchange Online organization.

Verify that IRM is working

Verify the full IRM configuration

To verify that you have successfully imported the TPD and enabled IRM, do the following:

- Use the **Test-IRMConfiguration** cmdlet to test IRM functionality. For details, see the Test-IRMConfiguration examples.
- Compose a new message in Outlook on the web and IRM-protect it by selecting **Set permissions** option from the extended menu (•••).

Learn about Microsoft Priva

Privacy is top of mind for organizations and consumers today, and concerns about how personal data is handled are steadily increasing. To meet regulatory requirements and build customer trust, organizations need to take a "privacy by default" stance and empower individuals to have control over their data. Robust privacy solutions are essential not only in ensuring regulatory adherence, but also in cultivating a culture of transparency, accountability, and respect for user privacy.

Microsoft Priva supports privacy operations across an organization's data landscape. Priva Privacy Risk Management, located in the Microsoft Priva portal, provides visibility into your organization's data. Customizable and easy-to-create policies help you identify privacy risks in your data estate and enable easy remediation to help reduce risks.

The Microsoft Priva portal

The Microsoft Priva portal is designed to give you streamlined access to all Priva privacy protection and privacy risk management capabilities. Learn more about accessing and navigating the Priva portal.

How and where Priva identifies items with personal data

Personal data is typically personal information that is related to a living person that can be used to identify that person. It may be a data type that can directly identify the individual, such as a name, passport number, social security number, and so on, or combinations of different data types that can be used to identify the individual. The definition of personal data or personal information may vary under applicable law, so make sure you understand the types of data for which you have legal obligations.

Priva utilizes foundational capabilities of Microsoft Purview to help you identify these personal data types based on your settings by using data classifications and sensitive information types (SITs). Organizations that create custom classifications and SITs can use them in Priva.

Priva evaluates your organization's data stored in the following Microsoft 365 services within your Microsoft 365 tenant:

- Exchange Online
- SharePoint Online
- OneDrive for Business
- Microsoft Teams

Priva evaluates data that is only within your organization's Microsoft 365 environment. It doesn't access personal data that isn't part of the organization's Microsoft 365 environment. For example, it doesn't access a user's personal Microsoft 365 account.

Priva also evaluates your organization's data sources that are registered through Microsoft Purview. Learn more about Microsoft Purview solutions for data governance.

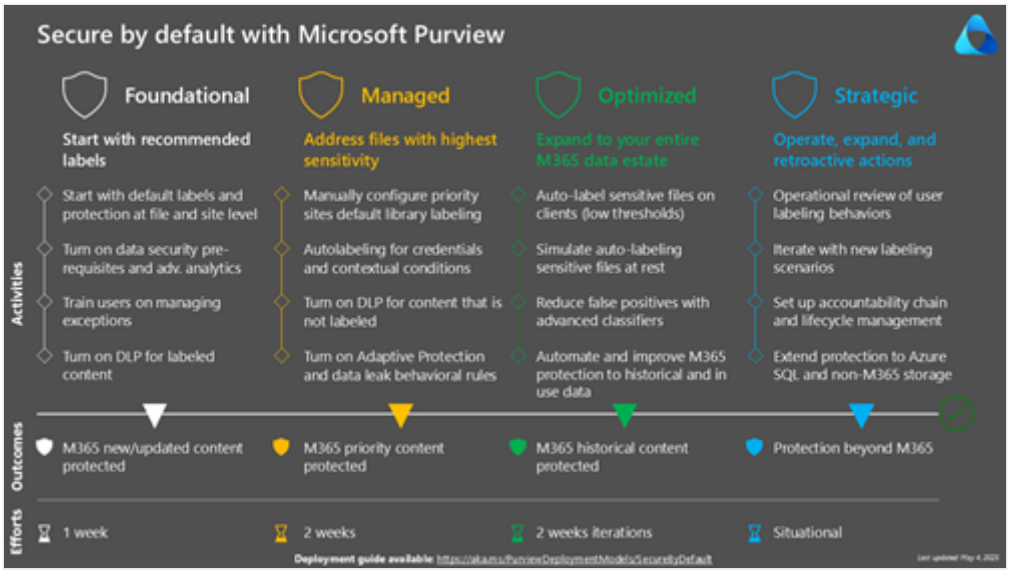
Microsoft Purview deployment models

Microsoft Purview provides integrated solutions and features that complement each other. For new Microsoft Purview administrators, it can be overwhelming to know where to start. But even existing administrators might be unfamiliar with how some Microsoft Purview features can enhance their data security.

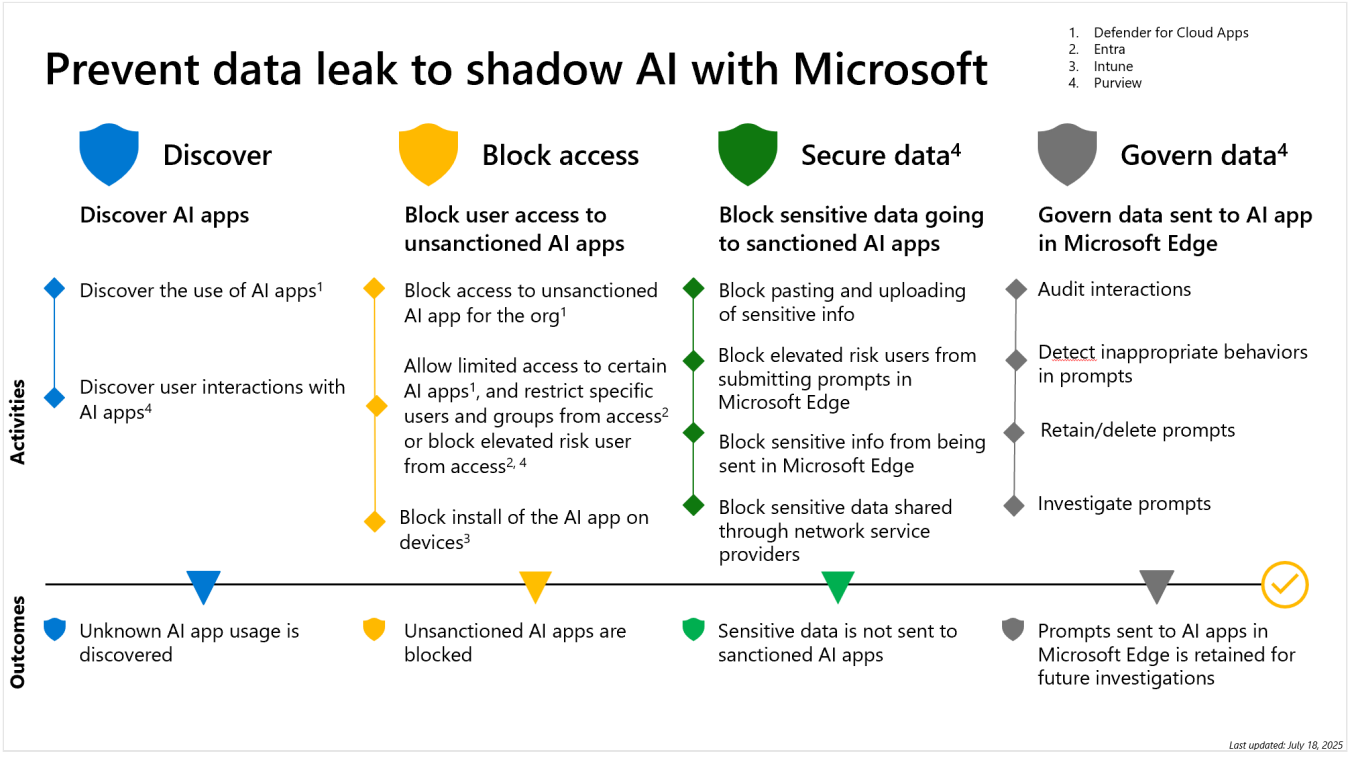


To address the need for shorter, actionable, and prescriptive guidance, the Product Engineering team is releasing a new series: Microsoft Purview Deployment Models. Deployment models are scenario-based and include a comprehensive step-by-step guide to jumpstart your deployment.

Audience

IT professionals, security professionals, and compliance officers who are responsible for deploying and managing Microsoft Purview in their organization. They don't provide detailed technical guidance but rather a high-level overview of the deployment process for a configuration that meets a specific business need. If you're new to Microsoft Purview technologies, concepts, and planning, deployment, and administration, see Learn about Microsoft Purview.

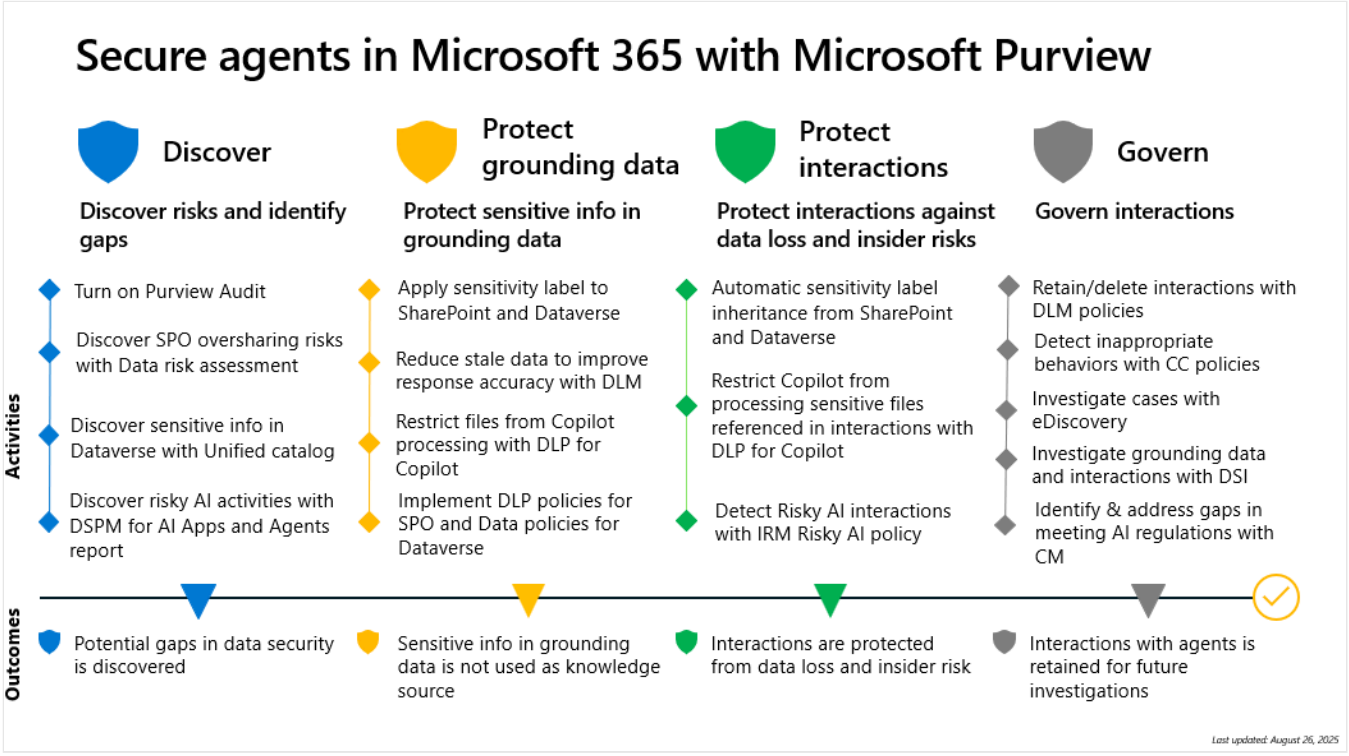
Deployment models come from our engineering teams. They're based on proven deployments with organizations. The objective of deployment models is to enable organizations to accelerate securing content and deploy faster.



Secure by default with Microsoft Purview

Use this deployment model to help rapidly implement a secure by default configuration with Microsoft Purview Information Protection, Data Loss Prevention, and Insider Risk Management.

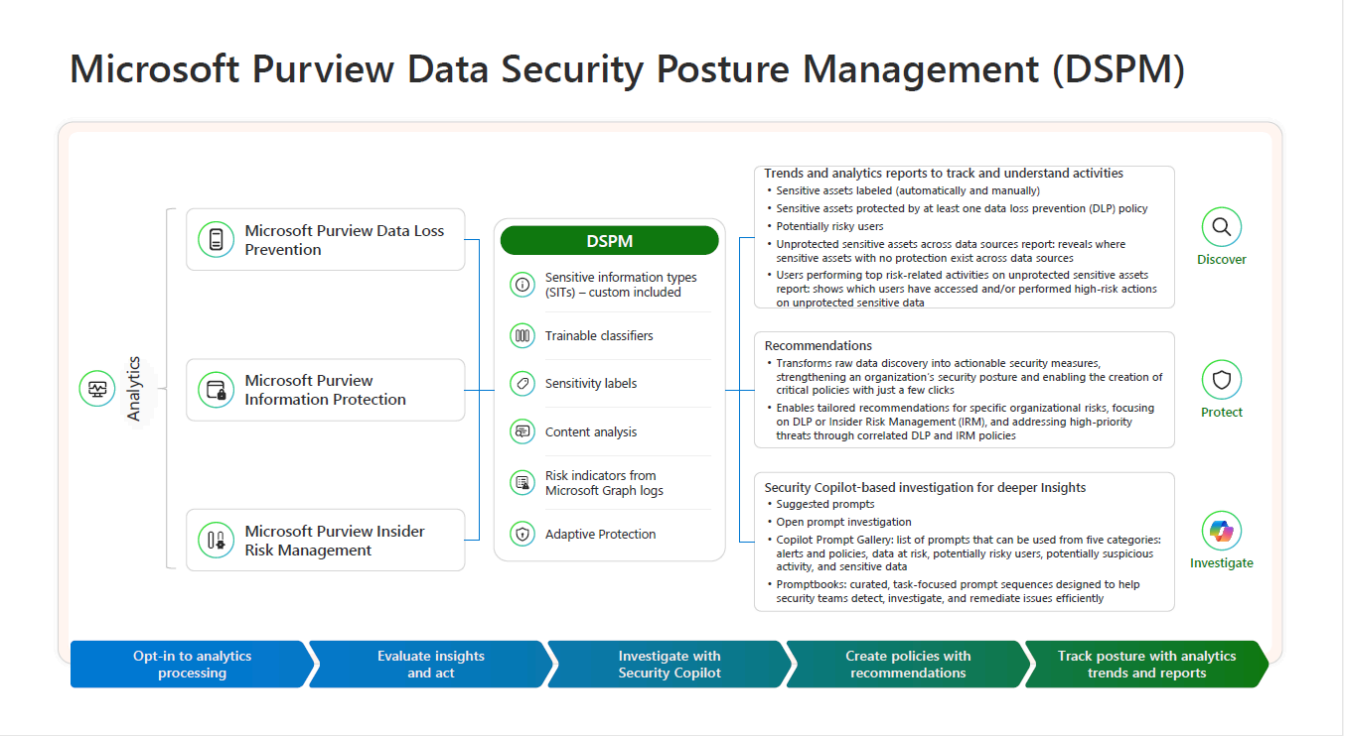
- Introduction
- Step 1: Start with default labeling
- Step 2: Address files with the highest sensitivity
- Step 3: Expand protection to your entire Microsoft 365 data estate
- Step 4: Operate, expand, and retroactive actions



Prevent data leak to shadow AI

Use this deployment model to help your organization identify and prevent data leaks to shadow AI by using Microsoft Purview, Microsoft Defender for Cloud Apps, Microsoft Entra, and Microsoft Intune.

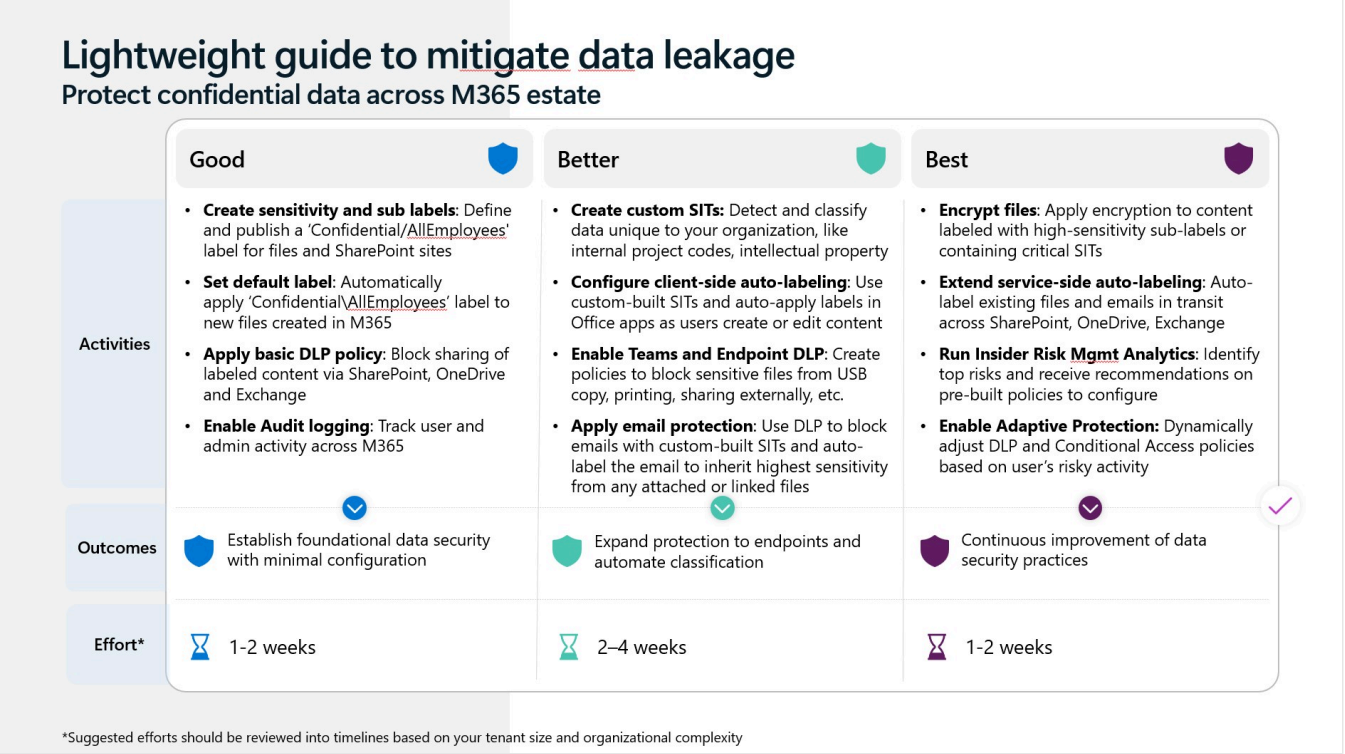
- Introduction
- Step 1: Discover AI apps
- Step 2: Block access to unsanctioned AI apps
- Step 3: Block sensitive data going to sanctioned AI apps
- Step 4: Govern data sent to AI apps



Secure and govern Microsoft 365 Copilot agents

Use this deployment model for Microsoft 365 Copilot agents by securing both the grounding data and interactions with Microsoft Purview.

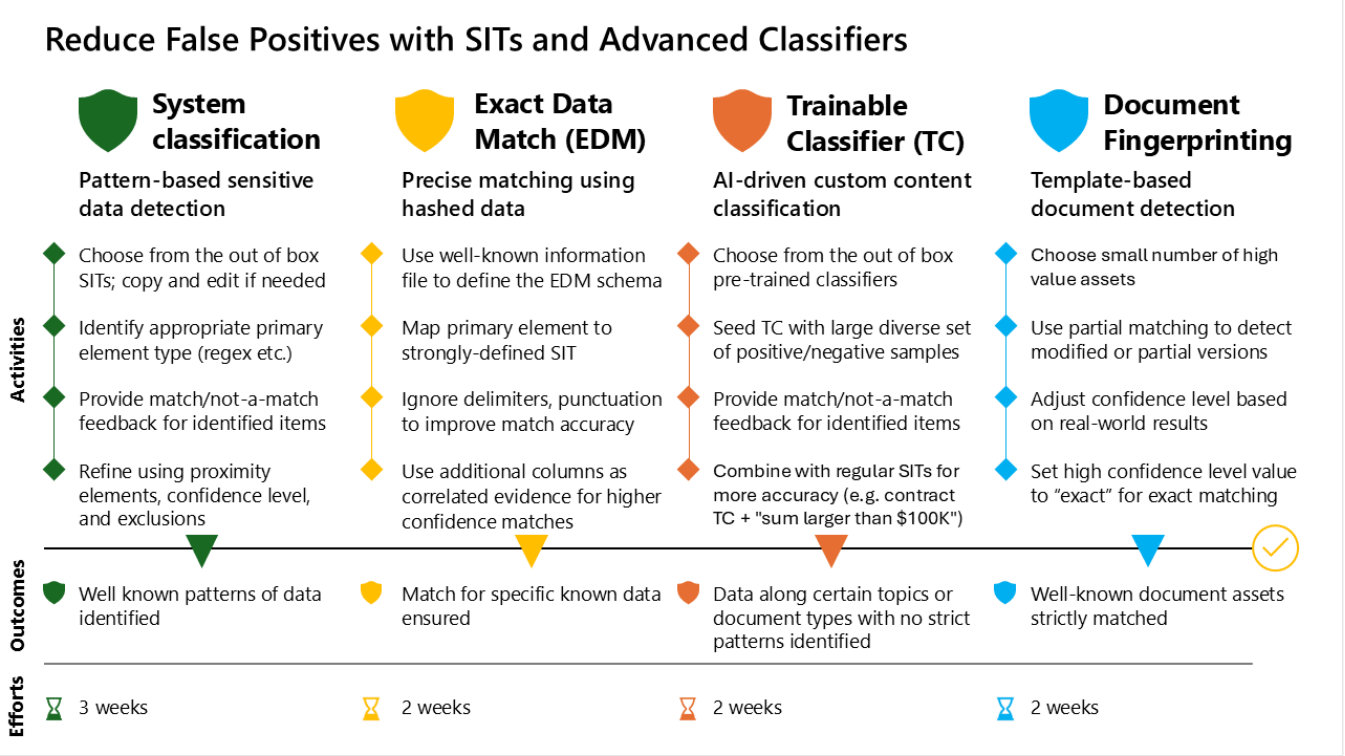
- Introduction
- Step 1: Discover risks and identify gaps
- Step 2: Protect sensitive info in grounding data
- Step 3: Protect interactions
- Step 4: Govern interactions



Deploy and use Data Security Posture Management

Use this deployment model to prepare for a Data Security Posture Management (DSPM) deployment with step-by-step guidance.

- Introduction
- Step 1: Establish foundational elements
- Step 2: Configure access and analytics
- Step 3: Understand data landscape and risks
- Step 4: Take action and investigate with Security Copilot



Lightweight guide to mitigate data leakage

Use this deployment model to enable core data security capabilities with minimal configuration, focusing on essential steps to get started quickly.

- Introduction
- Step 1: Establish foundational data security
- Step 2: Expand protection to endpoints
- Step 3: Continuous improvement

Reduce false positives by using SITs and advanced classifiers

Use this deployment model to minimize false positives by effectively leveraging the classification capabilities of Microsoft Purview.

- Introduction
- Step 1: Configure pattern-based sensitive data detection
- Step 2: Implement Exact Data Match for precise matching
- Step 3: Use trainable classifiers for complex content
- Step 4: Apply document fingerprinting for templates

Privacy in Microsoft Purview

Microsoft is committed to providing the information you need to manage privacy concerns in Microsoft Purview. All aspects of Microsoft Purview adhere to Microsoft's privacy governance model, which includes controls on data minimization, retention and deletion, location and transfer, sharing, and more.

For information about Microsoft's privacy governance model, see Privacy & data management overview - Microsoft Service Assurance.

Data security and privacy

Microsoft Purview processes and stores the following content types:

- Customer data
- End User Identifiable Information (EUII)
- Administrator data
- End User Pseudonymized Identifiers (EUPI)
- Feedback data

These types of data typically come from other Microsoft 365 services, such as Exchange, SharePoint, Microsoft Teams, and Copilot. Microsoft Purview also sources data when tenant admins configure policies and define data classification labels that can be applied to the organization's assets. This data includes emails, files, chats, messages, or Copilot interactions. EUII, administrator data, and EUPI data come from Microsoft Purview tenant administrators or users. Tenant administrators can also bring data from third-party sources so that the solutions offered by Microsoft Purview can extend to these sets of organizational data.

Customer data

You can categorize Microsoft Purview customer data as follows:

- Custom configuration settings.
- Search queries: In e-discovery, administrators can perform search and export results. This action could contain a portion of the data impacted by the user action, and the system retains it until the user deletes it. This category includes all Microsoft 365 user data, such as emails, files, Teams chat, and Copilot & AI interactions.
- Alerts

- Reports
- Tenant data that connectors ingest from third-party data sources.
- Data classification labels.

End User Identifiable Information (EUII)

End User Identifiable Information (EUII) includes a user's email address, User Principal Name (UPN), end user's IP address, address book data, user name, and user display name. Tenant admins choose how to process EUII data and decide which solutions to apply to these end users' data.

Administrator data

Administrator data includes the tenant admin's email address, UPN, IP address, user name, and display name. These types of data are specifically processed around tenant admin's activities when they perform administrative duties, such as:

- Set up policies, configurations, or connectors.
- Assign data classification label or policies to users.
- Put a user's data on legal hold.
- Assign compliance tasks to users.

End user pseudonymized identifier (EUPI)

End User Pseudonymized Identifier (EUPI) data includes UserID, UserKey, and Mailbox GUID. EUPI and EUII are used for user activities, audit logs, eDiscovery search, and service logs.

Feedback data

Feedback data is the feedback about the compliance solutions that a tenant administrator submitted through Unified Feedback Platform within Microsoft Purview.

How are these content types processed?

In the solutions that Microsoft Purview provides, customer data, EUII, administrator data, EUPI, and feedback data are applied to data assets such as emails, files, chats, messages, or Copilot and AI app interactions. For users managed by tenant admins, Microsoft Purview data processing can include monitoring for risky activities, preserving accounts and data, assigning tasks, and more. Microsoft Purview solutions handle these data assets as follows:

Expand table

Data asset	Processing
Exchange emails and calendar items	Microsoft Purview solutions process this data to enable: - Data classification labels - Legal hold - Data Loss Prevention policies - Encryption with customer's own encryption key
SharePoint and OneDrive files	
Messages from Teams, Skype for Business, and Viva Engage	
Copilot and AI app interactions.	
Email subject & metadata	Microsoft Purview solutions process this data for audit that tracks activities of tenant admins, analysts, and users.
Calendar item data	
List, filename, & metadata from SharePoint and OneDrive.	

Retention

Tenant administrators primarily control the retention of these types of data, except for the following cases:

- **eDiscovery:** Tenant administrators retain data that is in scope for eDiscovery case investigation until they delete the case when the legal investigation is complete, and the case is closed. A former employee's data isn't deleted until the investigation case is closed.
- **Audit:** User activity logs are retained for 180 days by default, 365 days for E5 licensed customers, and 10 years if customers purchase an additional license.
- **Communication policy hits:** Tenant administrators retain these as configured. The default policy retention is one year.
- **Configuration and policy data:** Tenant administrators retain this data until they delete configuration settings or policies.
- **Connector data:** Tenant administrators retain all data that is brought into the in-scope Microsoft Purview solutions through connectors until they remove the connectors and purge the data.

- **Administrator data:** Administrator data is retained until the person is no longer a tenant administrator.
- **Feedback data:** Feedback data is retained for 180 days.

When a user or the tenant leaves Microsoft 365 services, their data is retained for 90 days and no longer than 180 days to allow recovery or export of the data, except where specified by policy. For example, for eDiscovery, the data is retained until the tenant admin releases the user's account from legal hold.

Data residency

Customer data is stored based on where customer accounts are provisioned and in accordance with the commitments in the Online Service Terms. For more information, see Where your Microsoft 365 customer data is stored

Data sharing

Microsoft Purview solutions don't share data outside of Microsoft or across Microsoft without customer consent or authorization. Microsoft Purview compliance solutions share data with Microsoft Security Copilot as a plugin to Security Copilot. Microsoft Security Copilot processes the following data to provide the Purview Copilot capability:

- Microsoft 365 audit logs collected through the Microsoft Purview Audit pipeline
- eDiscovery and Communication Compliance data, which could include:
  - Emails
  - Teams conversations
  - Copilot and AI app interactions
  - Microsoft Purview alerts or insights generated by Data Loss Prevention (DLP) and Insider Risk Management (IRM)
  - Underlying data that led to such alerts or insights, such as audit logs and telemetry data collected by Microsoft Defender for Office related to emails and Teams, DLP, or IRM policies

For customers in the Government Community Cloud (GCC), data sharing between government and commercial cloud environments may occur, depending on the location of the service offering.

Data Subject Requests

For information about how to find, access, and act on personal data that resides in Microsoft IT systems, see: Introduction to DSRs.

Data privacy and protection – Respond to incidents and subject requests

Regulatory compliance

As a product, Microsoft Purview provides solutions to help manage risk and compliance for your organization. For more information about these product capabilities, see: Microsoft Purview risk and compliance solutions.

As an online service, Microsoft Purview aligns to the Microsoft Security Policy (MSP). For more information, see: Governance, risk, and compliance overview - Microsoft Service Assurance.

For more information about regulatory compliance in Microsoft Purview, see: Regulatory & industry compliance.
