   a. Run `kubectl` command line and execute this command to confirm the current context:
      - `kubectl config get-contexts`: List all contexts configured on the machine
      - `kubectl config current-context`: Get the current context name
      - `kubectl config use-context <name of context>`
   b. Run DIRCTL and execute `-context` to specify the context in the Kube config.
7. Run the DIRCTL Create command: `./DIRCTL create - -registration-key <registration-key copied from the portal>`. The DIRCTL Create command registers a new data integration runtime with Data Quality and initiates the creation of an application in Kubernetes as a pod specific to the registered data integration runtime. It handles the provisioning of resources and configuration essential for data integration runtime functionality while maintaining compatibility with existing system requirements.

After registration finishes, you can check the status of the data integration runtime on the **Data Integration Runtime** page in **Settings**. The status is displayed as **Online**. You can also check the status of your data integration runtime by running this command: `./DIRCTL describe`.

> **Tip**

These are the public endpoints that data integration runtime connects to that need to be allow listed:

- <purview_account_name>.purview.azure.com
- Mcr.microsoft.com
- *.data.mcr.microsoft.com

Create the namespace

1. Run the following command to create the namespace:

   Bash

   ```
   kubectl create namespace dirctl
   ```

2. Create and apply the `rolebindingv2.yaml` file with the following content:

   YAML

   ```yaml
   apiVersion: rbac.authorization.k8s.io/v1
   kind: RoleBinding
   metadata:
     name: readwrite-mongodb-secret
     namespace: dirctl
   subjects:
   - kind: ServiceAccount
     name: default
     namespace: dirctl
   roleRef:
     kind: Role
     name: secret-manager
     apiGroup: rbac.authorization.k8s.io
   ```

   Apply the file:

   Bash

   ```
   kubectl apply -f rolebindingv2.yaml
   ```

3. Create and apply the `secret-manager-role.yaml` file with the following content:

   YAML

   ```yaml
   apiVersion: rbac.authorization.k8s.io/v1
   kind: Role
   ```

```
metadata:
  namespace: dirctl
  name: secret-manager
rules:
- apiGroups: [""]
  resources: ["secrets"]
  verbs: ["get", "list", "create", "update", "patch", "delete"]
- apiGroups: [""]
  resources: ["configmaps"]
  verbs: ["get", "list", "watch"]
- apiGroups: ["apps"]
  resources: ["deployments"]
  verbs: ["get", "list", "watch","update"]
```

Apply the file:

Bash

```
kubectl apply -f secret-manager-role.yaml
```

Set up on-premises data source connection with data integration runtime

Connect to your Oracle database

Create connections by associating them with a data integration runtime instance.

- In Unified Catalog, go to **Health management** > **Data quality**.
- Select the governance domain where you created your data product with Oracle data asset.
- Select **Manage**, and then select **Connection** to set up connection for your Oracle database.

Add the following information to set up the connection:

- Enter a **Display name** for the connection.
- Enter a **Description**.
- At **Source type**, select **Oracle**.
- Select the **Data integration runtime** that you created as part of the prerequisite.
- Enter the **Host** name.
- Enter the **Port** number.
- Enter the **Service name**.
- Enter the **Schema name**.
- Select an **Authentication method**.
- Enter the **Username**.

- At **Credential**, enter the **Azure subscription**, **Azure Key Vault connection**, **Secret name**, and **Secret version**.
- Select **Submit** to complete the connection setup.

> **Tip**
>
> If you don't have all the required information, select **Save as draft** to continue later when you have the rest of the information to complete the connection setup.

This image illustrates how to create a connection:

Overview

c##testuser

Authentication method *

Basic authentication

Username *

ma

Credential *

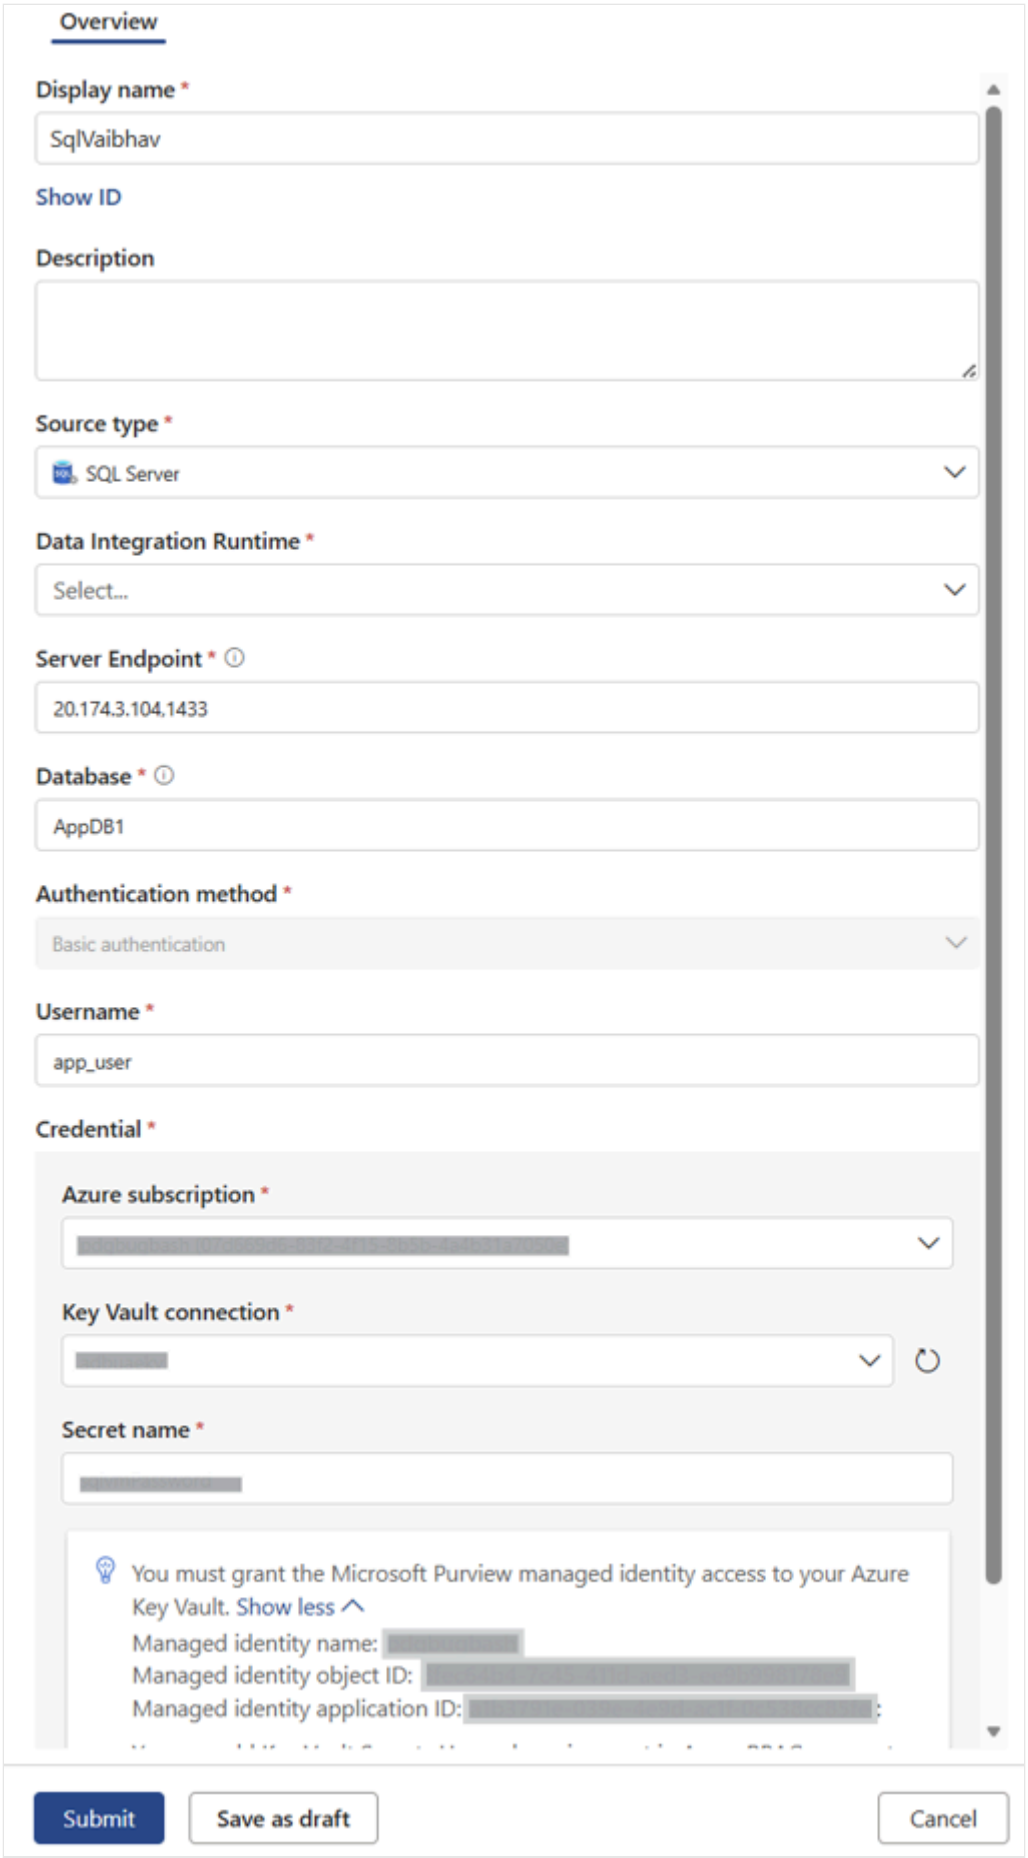
Azure subscription *

[redacted]

Key Vault connection *

Connect to your SQL Server database

Create connections by associating them with a data integration runtime instance, just like you do for Oracle. In SQL Server, a single database can contain tables belonging to multiple schemas, so you can use a single connection to scan all schemas in a single database. A connection accepts only database information but not schema. Create connections for SQL Server just like you do for other data source types.



- In Unified Catalog, go to **Health management** > **Data quality**.
- Select the governance domain where you created your data product with Oracle data asset.
- Select **Manage**, and then select **Connection** to set up connection for your Oracle database.

Add the following information to set up connection successfully:

- Enter a **Display name** for the connection.
- Enter a **Description**.
- At **Source type**, select **SQL Server**.
- Select the **Data integration runtime** that you created as part of the prerequisite.
- Enter the **Server Endpoint**.
- Enter the **Database** name.
- Select an **Authentication method**.
- Enter the **Username**.
- At **Credential**, enter the **Azure subscription**, **Azure Key Vault connection**, and **Secret name**.
- Select **Submit** to complete the connection setup.

> **Tip**
>
> If you don't have all the required information, select **Save as draft** to continue later when you have the rest of the information to complete the connection setup.

This image illustrates how to create a connection:

Data quality scan

After you complete the connection setup, follow data quality profiling and scanning documents to measure and monitor data quality of Oracle and SQL Server on-premises data sources.

- Data quality overview
- Supported data sources
- Set up data source connection
- Data product quality scan
- Data asset quality scan
- Incremental data quality scan

High availability and scalability

Assign multiple nodes in the Kubernetes cluster for high availability by using the node selector during the installation of the Kubernetes supported self-hosted integration runtime. The benefits of having multiple nodes include:

- Higher availability of the self-hosted integration runtime so that it isn't a single point of failure for scans.
- More concurrent scans. Each node can handle many scan runs at the same time. You can manually scale out nodes of the Kubernetes cluster if you need more concurrent scans.
- When scanning some sources like Azure Blob, Azure Data Lake Storage Gen2, and Azure Files, each scan run can use multiple nodes to boost the scan performance. For other sources, scans run on only one of the nodes.

You can update the capabilities of the Kubernetes supported self-hosted integration runtime by manually scaling out or scaling in nodes of the Kubernetes cluster.

> **Note**
>
> You must upload all necessary drivers for scanning on each new node.

Networking requirement

Set up DIRCTL tool for self-hosted integration runtime (preview)

Data integration runtime command line (DIRCTL) is a .NET-based command line interface (CLI) tool that automates data integration runtime management within Kubernetes clusters. It simplifies complex Kubernetes operations with straightforward commands and ensures secure communication with Microsoft Purview for registration and token lifecycle management.

To manage your Microsoft Purview Kubernetes self-hosted data integration runtime locally, you need the DIRCTL command line tool. You can download this tool during the data integration runtime creation process. See the setup instructions below for Windows and Linux operating systems.

Windows setup for DIRCTL CLI

1. Download and install the Kubectl CLI tool.
2. Place the generated kube config file in the user-specific folder according to this path: `C:/Users/<user-folder>/.kube/`. Copy the file and name it **config**.

   > **Note**
   >
   > This config file is required for DIRCTL authentication on Kubernetes clusters.

3. Download the DIRCTL CLI package .zip for Windows.
4. Extract the contents to a preferred directory on your local machine.
5. Open a terminal on Windows.
6. Navigate to the extracted DIRCTL directory.
7. Use the cd command `<path-to-dirctl>` to move into the folder.
8. Run commands using `./`DIRCTL```.

Linux setup for DIRCTL CLI

1. Download and install the kubectl CLI for your Linux distribution.
2. Place the kubeconfig file, for authentication to Kubernetes, in the default kube folder: `~/.kube/`.

3. Copy your generated kubeconfig file to the user-specific directory. Make sure the file is named **config**: `mkdir -p ~/.kube cp /path/to/your/kubeconfig ~/.kube/config`

   > ⓘ **Note**
   >
   > This config file is required for DIRCTL authentication on Kubernetes clusters.

4. Download the DIRCTL CLI package for Windows or Linux.
5. Open a terminal and navigate to the DIRCTL directory: `cd /your/target/directory/DIRCTL`
6. Run commands by using: `./DIRCTL` .

DIRCTL commands

1. **DIRCTL Help**: The Help command provides a comprehensive overview of all the available commands and functionalities within the DIRCTL tool. It ensures you can use the tool effectively by providing guidance and context for your data integration tasks.

2. **DIRCTL Re-register**: `./DIRCTL re-register –registration-key <re-registration-key-value>` Use the Re-register command to re-register an existing data integration runtime resource, if it's inactive for a long time, by using a new registration key.

3. **DIRCTL Delete**: `./DIRCTL delete` When you want to deregister a data integration runtime from the system and release all associated application Kubernetes pods, the Delete command provides a streamlined solution. This command completely removes the DIR from the SQL Server Data Quality Services (DQS), ensuring that no remnants of the runtime or its application pods remain. The command also handles the termination of all running Kubernetes pods associated with the DIR application, freeing up resources within the system.

4. **DIRCTL Upgrade**: `./DIRCTL upgrade –v <image version>` The Upgrade command enables you to seamlessly upgrade the version of a data integration runtime to the latest available version specified by the user. This process ensures that the data integration runtime operates with the most up-to-date features, enhancements, and security patches, maintaining its compatibility and efficiency within the system.

5. **DIRCTL Describe:** `./DIRCTL describe` The Describe command provides detailed insights into the status and performance of the running DIR and DIRCTL applications. It checks the health of application pods, ensuring that any problems or anomalies are promptly identified. By offering visibility into the runtime environment, this functionality supports troubleshooting and proactive system maintenance.

6. **DIRCTL Log**: `./DIRCTL log download -d <relative-destination-folder-path>` Use the Log command to download logs of all active data integration runtime application pods into a specified destination folder path. This functionality is especially vital for debugging, performance monitoring, or audit activities as it ensures you have access to detailed runtime records. By retaining comprehensive logs, you can effectively identify patterns, anomalies, and potential problems, making it a key tool in system maintenance and optimization.
7. **DIRCTL Config**: `./DIRCTL config auto-update-enable <true/false>` Update the configuration for auto-update-enable to false or true.

Troubleshoot data integration runtime and DIRCTL for Unified Catalog (preview)

This article helps you resolve common setup and configuration issues with the data integration runtime and the DIRCTL command-line tool in Microsoft Purview Unified Catalog. For setup instructions, see Set up a Kubernetes self-hosted data integration runtime. Learn how to download, install, and manage DIRCTL.

Verify prerequisites

Before deployment, verify the following prerequisites to avoid setup errors:

- Linux machine with Kubernetes installed
- Hardware requirements. Minimum specs:
  - CPU – eight cores
  - RAM – 32 GB
  - HDD – 80 GB
- Kubernetes tools
  - To access the `K8s` cluster from a Windows machine, install Kubectl.
  - To check the installation, run: `kubectl version --client`
- Permissions: You need the Data Governance Administrator role to run the DIRCTL CLI tool.

Networking: Firewall and ports

Expand table

Domain Name	Outbound Ports	Description
Public cloud: https://<purview_account>.purview.azure.com https://mcr.microsoft.com	443	Required to connect to Microsoft Purview service. If you use Microsoft Purview private endpoints, the account private endpoint covers this endpoint.

Common issues and solutions

Issue 1: Kubernetes setup isn't available

If you don't have a Kubernetes cluster set up, follow these steps to prepare the environment. You can set up Kubernetes in two ways:

1. Install Kubernetes on any Linux-based virtual machine, such as Ubuntu; or
2. Enable Hyper-V on an existing Windows Server, create a Linux-based virtual machine, and install Kubernetes.

Issue 2: Data integration runtime can't reach the database

Cause

Data integration runtime and the database might be running on different machines or networks. As a result, you might see this error message as the failure reason:

`TNS: destination host unreachable.`

Resolution

Ensure that the firewall in the database network allows inbound traffic on the configured database listener port from the IP address of the machine hosting the data integration runtime.

Issue 3: Config file isn't found in host machine

After installing Kubernetes inside the Linux-based machine, it's essential that the Kubernetes configuration file (config) is present in the `.kube` directory on the host machine.

1. Verify that the config file exists in the `.kube` directory.
2. If it's missing, copy the Kubernetes admin config file `~/.kube/config` to the required user location.

This file enables kubectl to connect to the Kubernetes cluster.

Issue 4: DIRCTL connectivity error to Microsoft Purview service endpoint

When you try to register the Kubernetes supported self-hosted data integration runtime, the DIRCTL create command throws errors.

Cause

DIRCTL can't connect to Microsoft Purview service endpoint. This issue is usually caused by network settings or a firewall.

Resolution

- Review the network topology of the DIRCTL host machine.
- Allow port 443 outbound to https://<Accountname>.purview.azure.com

Issue 5: Kubernetes connectivity error with Microsoft Purview service endpoint

When you try to register the Kubernetes supported self-hosted data integration runtime, the DIRCTL create command could run long until it eventually times out. Or, after a successful installation, the self-hosted data integration runtime status shows as unhealthy or offline in the Microsoft Purview portal.

Resolution

Verify network reachability to the Microsoft Purview service endpoint as specified in the documentation. Ensure that outbound traffic on port 443 to the Microsoft Purview service endpoint https://<AccountName>.purview.azure.com is allowed through the firewall.

Issue 6: Kubernetes self-hosted data integration runtime creation timed out error

If the DIRCTL create command doesn't complete all operations successfully within 10 minutes, it throws a timeout error. Check the status of pods under the namespaces mentioned by the kubectl command.

```
Kubectl get pods –n dirctl
```

Resolution

You should reinitiate the process of DIRCTL delete, wait for pods to destroy completely, and then do create command.

Issue 7: Registration key isn't authorized

When you try to register the Kubernetes supported self-hosted data integration runtime, the DIRCTL create command returns this error:

```
[Error] DIR failed for registration.
```

Cause

The registration key might have expired past its 24 hour validity time, or was manually revoked.

Resolution

Regenerate the key from the data integration runtime's page in the Microsoft Purview portal and register again.

Issue 8: Self-hosted data integration runtime isn't functional or has been offline for more than 14 days

The refresh token expires if data integration runtime isn't functional for more than 14 days due to any reason. In that case, reregister the data integration runtime using this command:

```
./DIRCTL create --registration-key <registration-key>
```

Issue 9: Download data integration runtime logs locally for troubleshooting

Each day's data integration runtime log file only persists for 14 days. After 14 days, the log files are deleted. Download logs locally using DIRCTL log download command if necessary:

```
e.g. ./DIRCTL log download –d <relative path>
```

Set up data source connection for data quality in Unified Catalog

Data source connections set up the authentication needed to profile your data for a statistical snapshot, or scan your data for data quality anomalies and scoring.

Setting up data source connections is the **fourth** step in the data quality life cycle for a data asset. Previous steps are:

1. Assign users data quality steward permissions in Unified Catalog to use all data quality features.
2. Register and scan a data source in your Microsoft Purview Data Map.
3. Add data assets to a data product.

Prerequisites

1. To create connections to data assets, your users must be in the data quality steward role.
2. You need at least read access to the data source for which you're setting up the connection.

Supported multicloud data sources

Browse the supported data source document to view the list of supported data sources, including file formats for data profiling and data quality scanning, with and without virtual network support.

Currently, data quality scans can only run by using managed identity as an authentication option for Microsoft native data sources, such as Microsoft Fabric, Azure Data Lake Storage Gen2, Azure SQL, Synapse, and Azure SQL Managed Instance. **For Azure Databricks, Snowflake, and Google BigQuery, a managed identity can't be used as an authentication option**.

Data quality services run on **Apache Spark 3.4** and **Delta Lake 2.4**.

> **Important**
>
> To access these sources, either you need to set your Azure Storage sources to have an open firewall, to Allow Trusted Azure Services, or to use private endpoints follow the guideline documented in the data quality managed virtual network configuration guide.

Microsoft Purview only needs read-level permissions to discover metadata, run profiling, and execute Data Quality scans.

Set up data source connection

Follow these steps to create a new connection for the data products and data assets in a governance domain.

1. In Unified Catalog, select **Health management**, and then select **Data quality**.
2. Select a governance domain from the list.
3. From the **Manage** dropdown list, select **Connections**.
4. On **Connections**, select **New**.
5. On **Create connection**, enter a **Display name** and an optional **Description**.
6. Select a **Source type**.
7. Select one of the data sources: Azure subscription, Data Map, or enter a data source manually. Depending on which data source you choose, enter the required access details. The connection is then tested.
8. If the test connection is successful, select **Submit** to complete the connection setup.

Tip

- You can also create a connection to your resources by using private endpoints and a Microsoft Purview Data Quality managed virtual network. Learn more about setting up managed virtual networks for data quality.
- Connection setup steps vary for native connectors. Check the connection setup steps from native connectors articles to set up connection for Azure Databricks, Snowflake, Google BigQuery, and Azure Synapse connectors.
- To set up Azure Dedicated SQL Pool (formerly SQL DW) connection, select source type as **Azure SQL Database** and add `sqldatawarehouse.database.windows.net` as **endpoint** name.
- The virtual network region is auto populated from the selected source region. Find details on managing virtual network provisioning.
- For Azure SQL Managed Instance, you need to provide the port number for connection. Public endpoint port number is 3342 and private endpoint port number is 1433.

Grant Microsoft Purview permissions on the source

After you create the connection, grant Microsoft Purview managed identity permissions on your data sources to scan them:

- To scan Azure Data Lake Storage Gen2, assign the storage blob data reader role to Microsoft Purview Managed Identity. Follow the steps to assign managed identity permissions.
- To scan an Azure SQL database, assign the db_datareader role to the Microsoft Purview Managed Identity. Follow the steps to assign managed identity permissions.

- Data quality for Fabric shortcut data sources
- Data quality for Azure Synapse serverless and data warehouses
- Data quality for Azure Databricks Unity Catalog
- Data quality for Snowflake data sources
- Data quality for Google BigQuery
- Data quality native support for Iceberg data

Next steps

1. Configure and run data profiling for an asset in your data source.
2. Set up data quality rules based on the profiling results, and apply them to your data asset.
3. Configure and run a data quality scan on a data product to assess the quality of all supported assets in the data product.
4. Review your scan results to evaluate your data product's current data quality.

Set up data quality for Azure Databricks Unity Catalog

This article explains how to configure Microsoft Purview to scan Azure Databricks Unity Catalog metadata and set up a data quality connection for profiling and scanning your Databricks data. It covers prerequisites, supported assets, Data Map scan configuration, and connection setup. Use this guide if you're a data quality steward or admin who manages Azure Databricks data governance in Microsoft Purview.

Prerequisites

Before you begin, enable your Azure Databricks workspace for Unity Catalog. Attach the workspace to a Unity Catalog metastore. Recent workspaces are enabled automatically. For older workspaces, an account admin might need to enable Unity Catalog manually.

After Unity Catalog is enabled, complete these steps:

- Create catalogs and schemas to contain database objects like tables and volumes.
- Create managed storage locations to store the managed tables and volumes in these catalogs and schemas.
- Grant user access to catalogs, schemas, and database objects.

Workspaces that are automatically enabled for Unity Catalog provision a workspace catalog with broad privileges granted to all workspace users. The workspace catalog is a convenient starting point for trying out Unity Catalog.

Before you configure a scan or connection, store your Azure Databricks Access Token in Azure Key Vault and grant the product (service) MSI read (secret) access to the Key Vault. Microsoft Purview only needs read-level permissions to discover metadata, run profiling, and execute data quality scans.

For detailed setup instructions, see Set up and manage Unity Catalog.

Supported Unity Catalog assets

When you scan Azure Databricks Unity Catalog, Microsoft Purview supports the following assets:

- Metastore

- Catalogs
- Schemas
- Tables including the columns
- Views including the columns

When you set up a scan, you can choose to scan the entire Unity Catalog or scope the scan to a subset of catalogs.

Configure a Data Map scan for Databricks Unity Catalog

To catalog your Azure Databricks Unity Catalog data in Microsoft Purview, configure a Data Map scan.

1. Register an Azure Databricks workspace in Microsoft Purview.
2. Create a scan for the registered workspace:
   a. Enter the name of the scan.
   b. Select **Unity Catalog** as the extraction method.
   c. Connect through an integration runtime (Azure Integration runtime, Managed Virtual Network IR, or a Kubernetes-supported self-hosted integration runtime).
   d. Select **Access Token** authentication while creating a credential. For more information, see Credentials for source authentication in Data Map.
   e. Specify the Databricks SQL Warehouse HTTP path that Microsoft Purview uses to perform the scan.
3. On the **Scope your scan** page, select the catalogs you want to scan.
4. Select a scan rule set for classification. You can choose the system default, existing custom rule sets, or create a new rule set inline. For more information, see Data classification in Data Map.
5. For **Scan trigger**, choose whether to set up a schedule or run the scan once.
6. Review your scan and select **Save and run**.
7. View your scans and scan runs to verify that cataloging completed successfully.

After scanning, the scanned Unity Catalog asset is available in Microsoft Purview Unified Catalog search. For more information, see Connect to and manage Azure Databricks Unity Catalog in Microsoft Purview.

> ⓘ **Note**

Data quality scans for Microsoft native data sources (Microsoft Fabric, Azure Data Lake Storage Gen2, Azure SQL, Azure Synapse Analytics, and Azure SQL Managed Instance) use managed identity authentication. For Azure Databricks, Snowflake, and Google BigQuery, managed identity isn't available as an authentication option — use an Access Token stored in Key Vault instead.

Set up a connection for a data quality scan

After the Azure Databricks Unity Catalog scan completes, the scanned asset is ready for cataloging and governance. To run data quality scans, create a data quality connection for your Azure Databricks source and associate it with a data product in a governance domain.

> **Important**
>
> - Data quality stewards need **read only** access to Azure Databricks Unity Catalog to set up a data quality connection.
> - If public access is disabled, select the **Allow trusted Microsoft services** checkbox for Key Vault. This requirement applies only to Key Vault, not to your Azure Databricks workspace.
> - Virtual network support is generally available to all supported Azure regions. It's temporarily included in the Data Governance SKUs to maintain flexibility during this phase. Virtual network pricing isn't yet available to include in billing.

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Health management**, select **Data quality**.
3. Select a governance domain from the list, then select **Connections** from the **Manage** dropdown list.
4. Configure the connection on the **Connections** page:
    - Add connection name and description.
    - Select source type **Azure Databricks**.
    - Select Azure subscription.
    - Select workspace URL.
    - Add Databricks metastore ID.
    - Select Unity catalog as extraction method.

- Select HTTP path.
- Select unity catalog name.
- Select schema name.
- Select table name.
- Select authentication method: **Access Token**.
  - Add Azure subscription.
  - Key Vault connection.
  - Secret name.
  - Secret version.
- Select the **Enable managed V-Net** checkbox if your Databricks is running in a virtual network.
- Region is selected automatically.
- Create a new virtual network if a virtual network storage hasn't yet been created.

5. If your Databricks storage is in a virtual network, you can't test the data quality connection. Otherwise, select **Test connection** to validate your configuration.

> ⓘ **Note**
>
> - The fully qualified domain name (FQDN) for a data asset follows a pattern like `databricks://(metastore-id)/catalogs/(catalog-name)/schemas/(schema-name)/tables/(table-name)`. You can find the FQDN details for your Azure Databricks data asset on the Data Map asset page.
> - If your connection parameters don't match the FQDN, your connection might still work but you see a connection error on the data quality overview page. Ensure that you fill in all corresponding fields correctly.

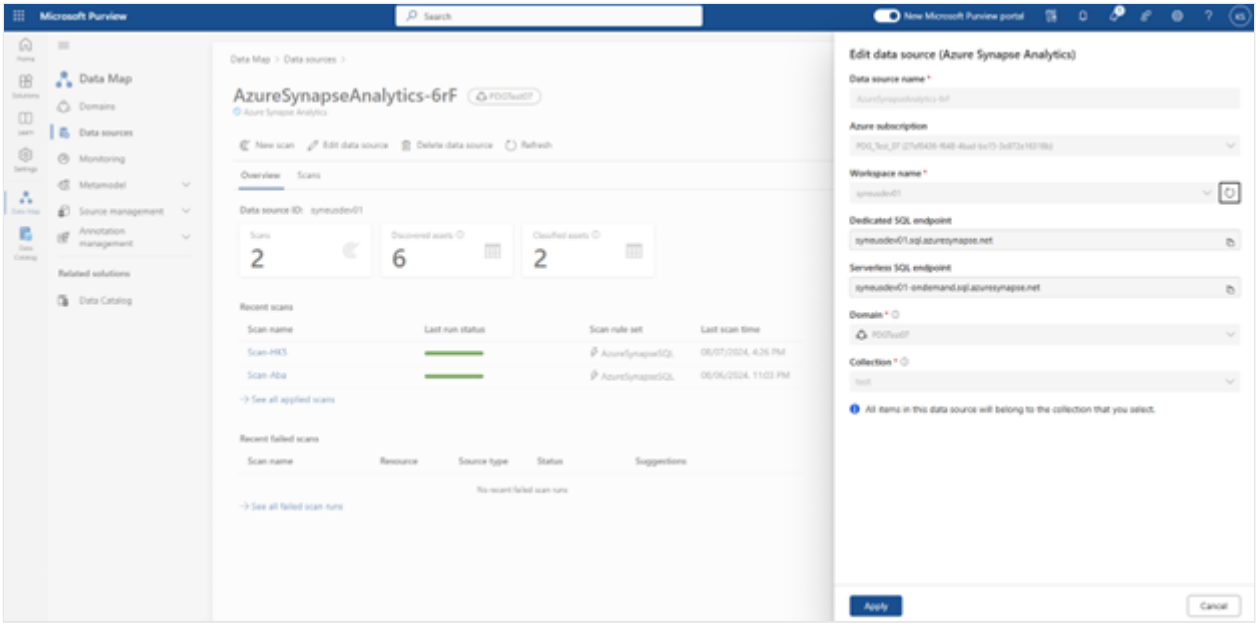
Set up data quality for Microsoft Azure Synapse serverless and data warehouse

This article explains how to configure data quality scans for Azure Synapse Analytics assets in Microsoft Purview Unified Catalog. You'll learn how to set up Data Map scans, create connections, and run data profiling and quality scans for both Synapse dedicated data warehouse and Synapse serverless SQL pools.

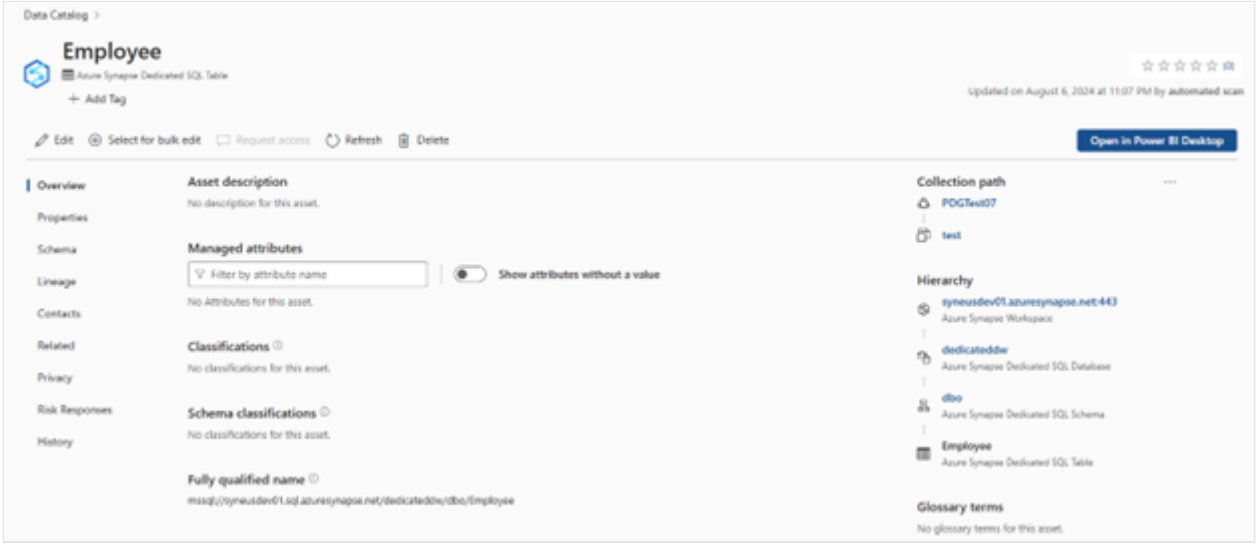
Microsoft Azure Synapse Analytics is an enterprise analytics service that accelerates time to insight across data warehouses and big data systems. For more details, see the Azure Synapse Analytics documentation.

The following example shows a Synapse workspace with a Dedicated Synapse Data Warehouse (DWH) table called **EMPLOYEE** and a Serverless Database (SQL_ON_DEMAND) with a **SynapseSalesDelta** table.



After you scan Azure Synapse assets, the scanned assets appear in Microsoft Purview. The following example shows an Employee table on a Synapse Analytics Dedicated instance.

Set up data quality for Azure Synapse Analytics dedicated SQL pool

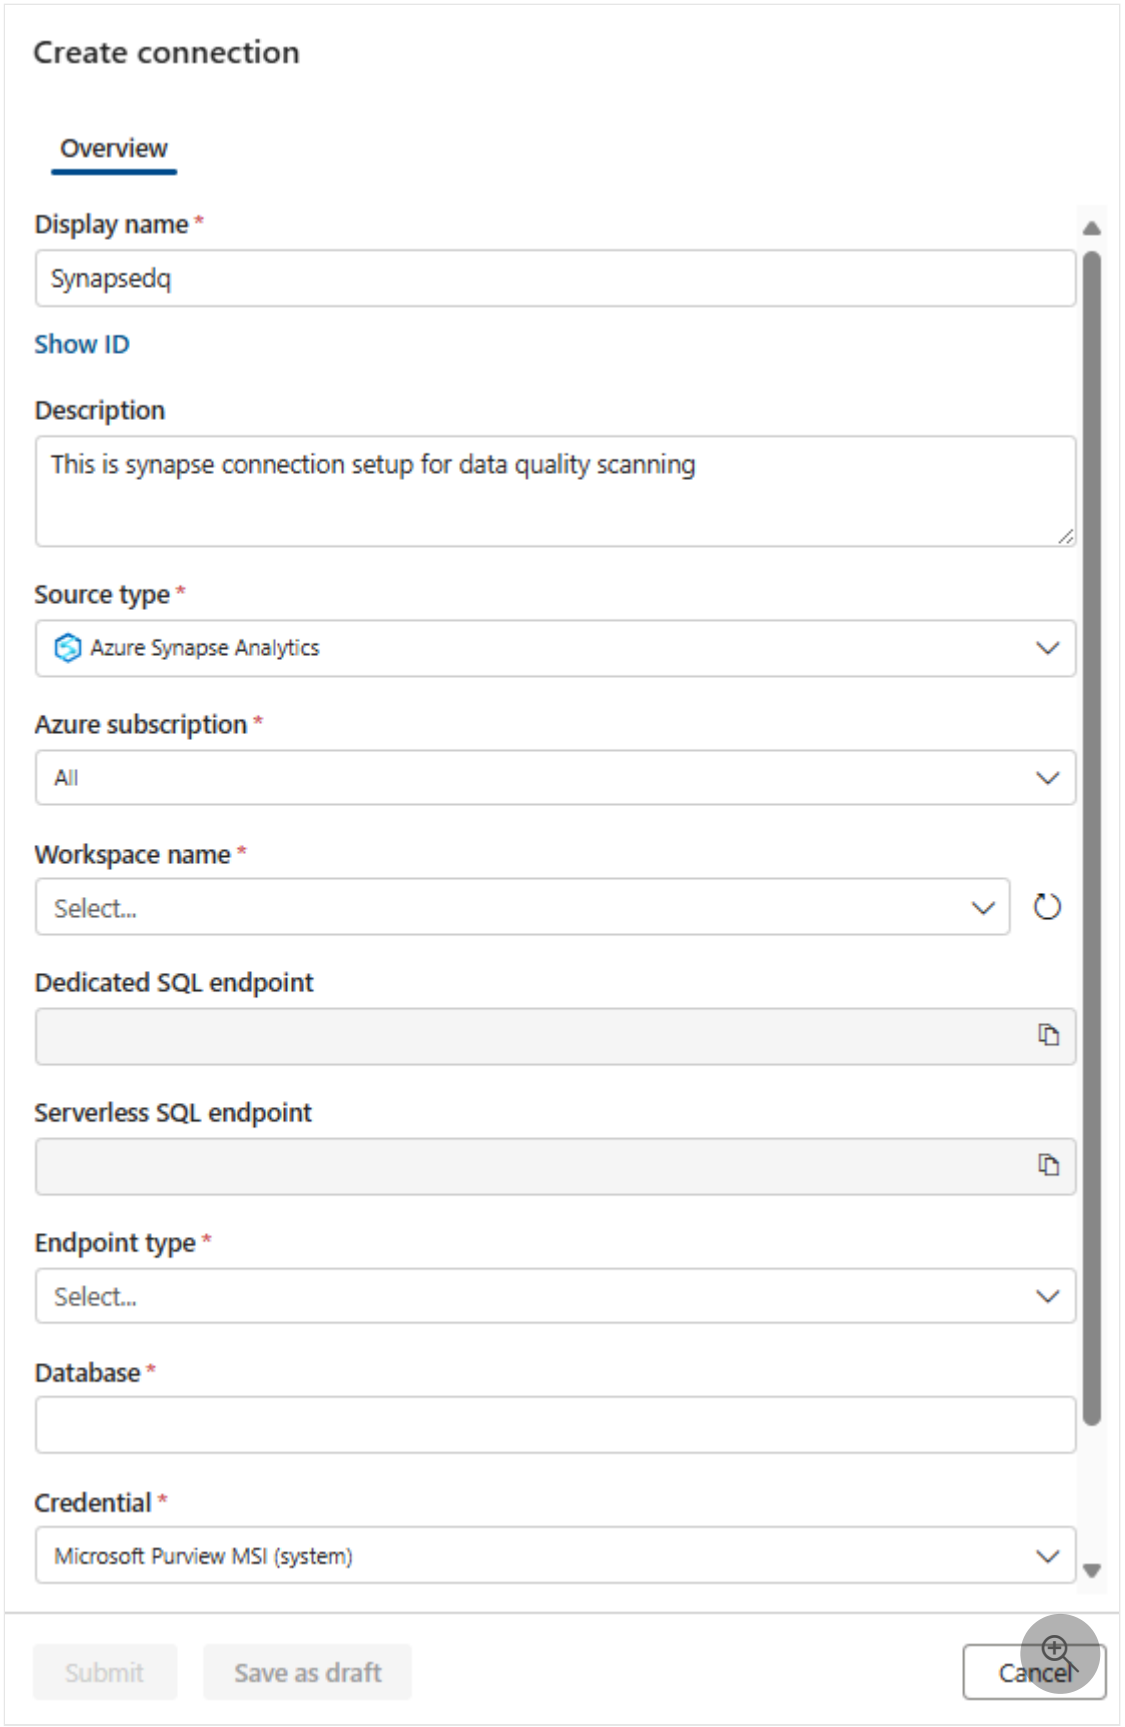


To configure data quality for a Synapse dedicated SQL pool, set up a Data Map scan, create a connection, and then run profiling and data quality scans.

Set up Data Map scan for Synapse dedicated SQL

To scan Azure Synapse Analytics dedicated SQL pool, see Register and scan a Synapse workspace. To grant the necessary managed identity permissions on the dedicated SQL instance, see Use a managed identity for dedicated SQL databases.

After the Data Map scan completes, the Synapse dedicated SQL assets appear in Microsoft Purview Unified Catalog. The following example shows an Employee table on a Synapse Analytics dedicated instance:



Set up connection to your Synapse dedicated data warehouse

After the Data Map scan completes and the dedicated SQL asset appears in Unified Catalog, the asset is ready for cataloging and governance.

> **Important**
>
> - Data Quality stewards need read-only access to the Synapse dedicated data warehouse to set up the data quality connection.
> - If your Synapse data source is behind a private endpoint, you must first enable managed virtual networks. See Set up managed virtual networks. In managed virtual network setups, you can't test the connection.

Associate the scanned asset to the data product in a governance domain. At the Data Quality tab, add a new Azure SQL Database connection and enter the database name manually.

1. In Unified Catalog, go to **Health management** > **Data quality** and select a governance domain.
2. On the governance domain's details page, select **Manage**, then select **Connections**.
3. On the **Connections** page, select **New** and configure connection with the following information, as seen in the example below:
    - Add connection name and description.
    - Select source type **Azure Synapse Analytics**.
    - Select **Azure subscription**.
    - Select **Workspace name**.
    - Select **Dedicated SQL endpoint**.
    - Select **serverless SQL endpoint**.
    - Select **Endpoint type**.
    - Select **Database**.
    - Add MSI as Credential.

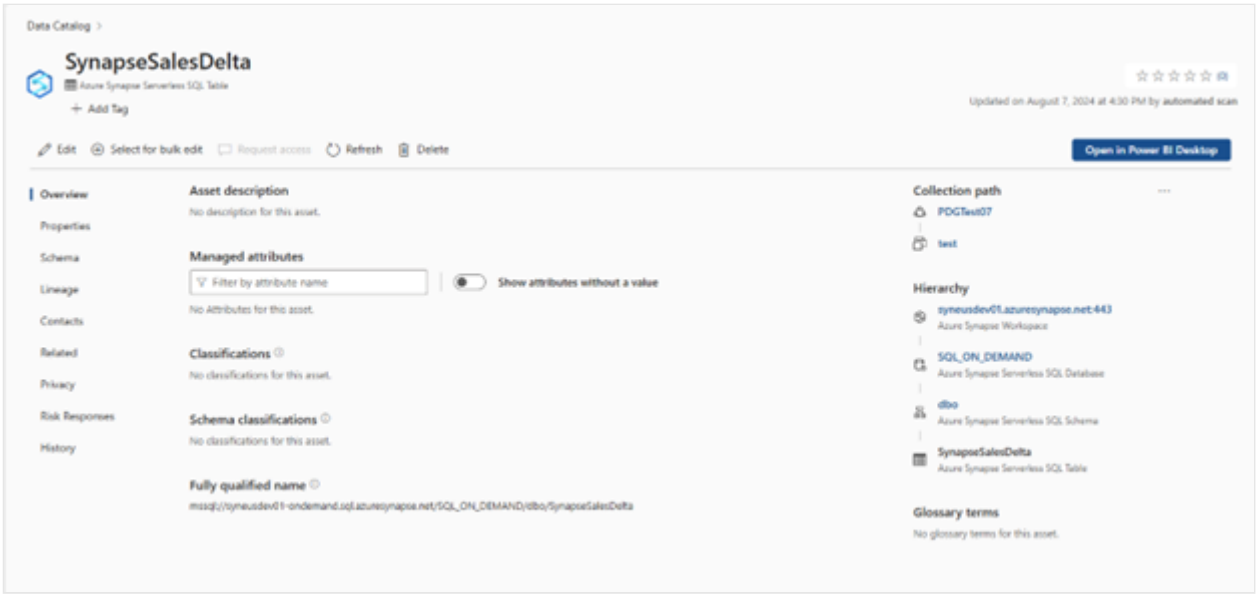
4. Test the connection. After configuring the data source connection and successfully testing it, you can proceed to configure and run data profiling and data quality scans.

Profiling and data quality scanning for data in Synapse dedicated data warehouse

After you set up the connection, you can profile your data, create and apply rules, and run a data quality scan for your data in Synapse dedicated data warehouse.

> **Important**
>
> Before you run profiling or data quality scans, verify that your dedicated SQL pool configuration and concurrency limits can support these jobs. Data quality assessment jobs open connections on the dedicated SQL pool and might fail if the instance is underprovisioned or exceeds concurrency limits. Concurrency limits might lead to job termination. Higher DW limits (such as DWU 1000) provide the capacity to run the queries. For more information, see **Memory and concurrency limits**.

Use the following articles for step-by-step guidance:



- How to configure and run data profiling of your data
- How to configure and run data quality scan

Set up data quality for Azure Synapse Analytics serverless SQL pool

To configure data quality for a Synapse serverless SQL pool, set up a Data Map scan, create a connection, and then run profiling and data quality scans.

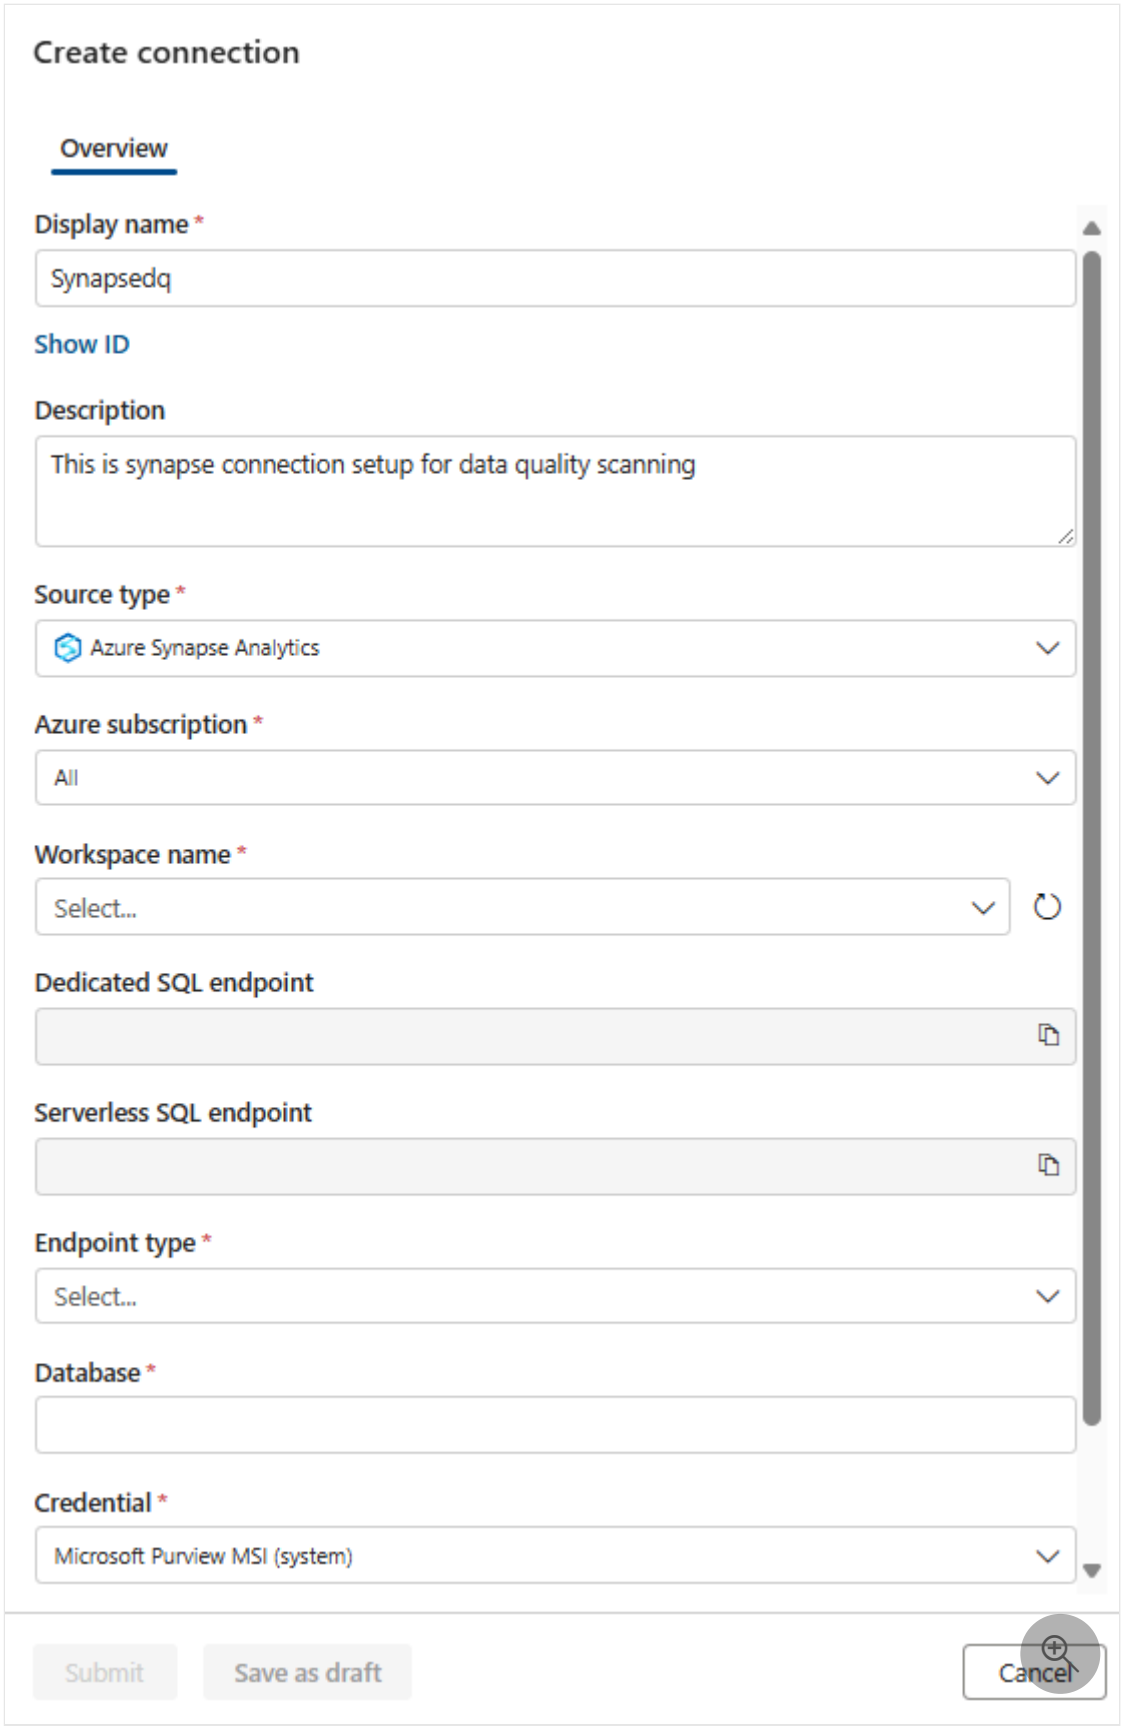
Set up Data Map scan for Synapse serverless SQL

To scan Azure Synapse Analytics serverless SQL pool, see Register and scan a Synapse workspace. To grant the necessary managed identity permissions, see Use a managed identity for dedicated SQL databases. After the Data Map scan completes, the serverless assets appear in Unified Catalog.

Set up connection to your Synapse serverless SQL pool

After the Data Map scan completes and the serverless SQL asset appears in Unified Catalog, the asset is ready for cataloging and governance.

> **ⓘ Important**
>
> - Data Quality stewards need read-only access to the Synapse dedicated data warehouse to set up the data quality connection.
> - If your Synapse data source is behind a private endpoint, you must first enable managed virtual networks. See Set up managed virtual networks.
> - In Synapse serverless setup, the external table points to Delta formatted data stored in ADLS Gen2.
> - The Synapse connector only detects and supports **sql.azuresynapse.net**. If the Fully Qualified Name (FQN) generated by your Data Map scan contains **database.windows.net**, the Synapse connection for data quality scan will fail.



Associate the scanned asset to the data product in a governance domain. In **Data Quality**, add a new SQL Database connection and enter the database name manually.

1. In Unified Catalog, go to **Health management** > **Data quality** and select a governance domain.

2. On the governance domain's details page, select **Manage**, then select **Connections**.

3. On the **Connections** page, select **New** and configure connection with the following information, as seen in the example below

- Add connection name and description.
- Select source type **Azure Synapse Analytics**.
- Select **Azure subscription**.
- Select **Workspace name**.
- Select **Dedicated SQL endpoint**.
- Select **serverless SQL endpoint**.
- Select **Endpoint type**.
- Select **Database**.
- Add MSI as Credential.

4. Test the connection. After configuring the data source connection and successfully testing it, you can proceed to configure and run data profiling and data quality scans.

Profiling and data quality scanning for data in Synapse serverless

After you set up the connection, you can profile your data, create and apply rules, and run a data quality scan for your data in Synapse serverless SQL pool.

> **Important**
>
> Data quality assessments and profiling run on Spark in the background, where each Spark node opens a connection. For Azure Synapse serverless SQL, no concurrency limits apply. Performance depends on the Delta Parquet optimizations on your ADLS Gen2 instance. The engine works with external lakehouse sources such as Delta format tables.

Use the following articles for step-by-step guidance:

- How to configure and run data profiling of your data
- How to configure and run data quality scan

Performance and connection reference for Synapse serverless

Use the following references for serverless performance and connection details:

- Memory and concurrency limits for Azure Synapse Analytics
- Set up data source connection for data quality

Set up data quality for Fabric Lakehouse data

This article explains how to register, scan, and run data quality assessments on Fabric Lakehouse data using Microsoft Purview. Before you begin, review the prerequisites.

Overview of Fabric OneLake

Fabric OneLake is a single, unified, logical data lake for your whole organization. A data lake processes large volumes of data from various sources. Like Microsoft OneDrive, OneLake comes automatically with every Microsoft Fabric tenant and is designed to be the single place for all your analytics data. OneLake brings customers:

- One data lake for the entire organization
- One copy of data for use with multiple analytical engines

OneLake aims to give you the most value possible out of a single copy of data without data movement or duplication. You no longer need to copy data just to use it with another engine or to break down silos so you can analyze the data with data from other sources. You can use Microsoft Purview to catalog fabric data estate and measure data quality to govern and drive improvement action.

You can use shortcut for referencing to data that is stored in other file locations. These file locations can be within the same workspace or across different workspaces, within OneLake or external to OneLake in Azure Data Lake Storage (ADLS), Amazon Web Services (AWS) S3, or Dataverse with more target locations coming soon. Data source location doesn't matter that much, OneLake shortcuts make files and folders appear as if they are stored locally. When teams work independently in separate workspaces, shortcuts enable you to combine data across different business groups and domains into a virtual data product to fit a user's specific needs.

You can use mirroring to bring data from various sources together into Fabric. Mirroring in Fabric is a low-cost and low-latency solution to bring data from various systems together into a single analytics platform. You can continuously replicate your existing data estate directly into Fabric's OneLake, including data from Azure SQL Database, Azure Cosmos DB, and Snowflake. With the most up-to-date data in a queriable format in OneLake, you can now use all the different services in Fabric. For example, running analytics with Spark, executing notebooks, data engineering,

visualizing through Power BI Reports, and more. The Delta tables created from mirrored data can then be used throughout Fabric, allowing users to accelerate their journey into Fabric.

Register Fabric OneLake as a data source

To configure Data Map scan, you need to first register data source that you want to scan. To scan a Fabric workspace, there are no changes to the existing experience to register a Fabric tenant as a data source. To register a new data source, follow these steps:

- In the Microsoft Purview portal, go to **Data Map**.
- Select **Register**.
- On **Register** sources, select **Fabric**.

For setup instructions, see same-tenant Fabric scan setup and cross-tenant Fabric scan setup.

Set up a Data Map scan for Fabric Lakehouse

To scan Lakehouse subartifacts, you don't need to change your existing experience in Data Map to set up a scan. A viewer role is sufficient to scan metadata and item-level lineage.

Currently, only service principal is supported as an authentication method. Managed identity (MSI) support is still in the backlog.

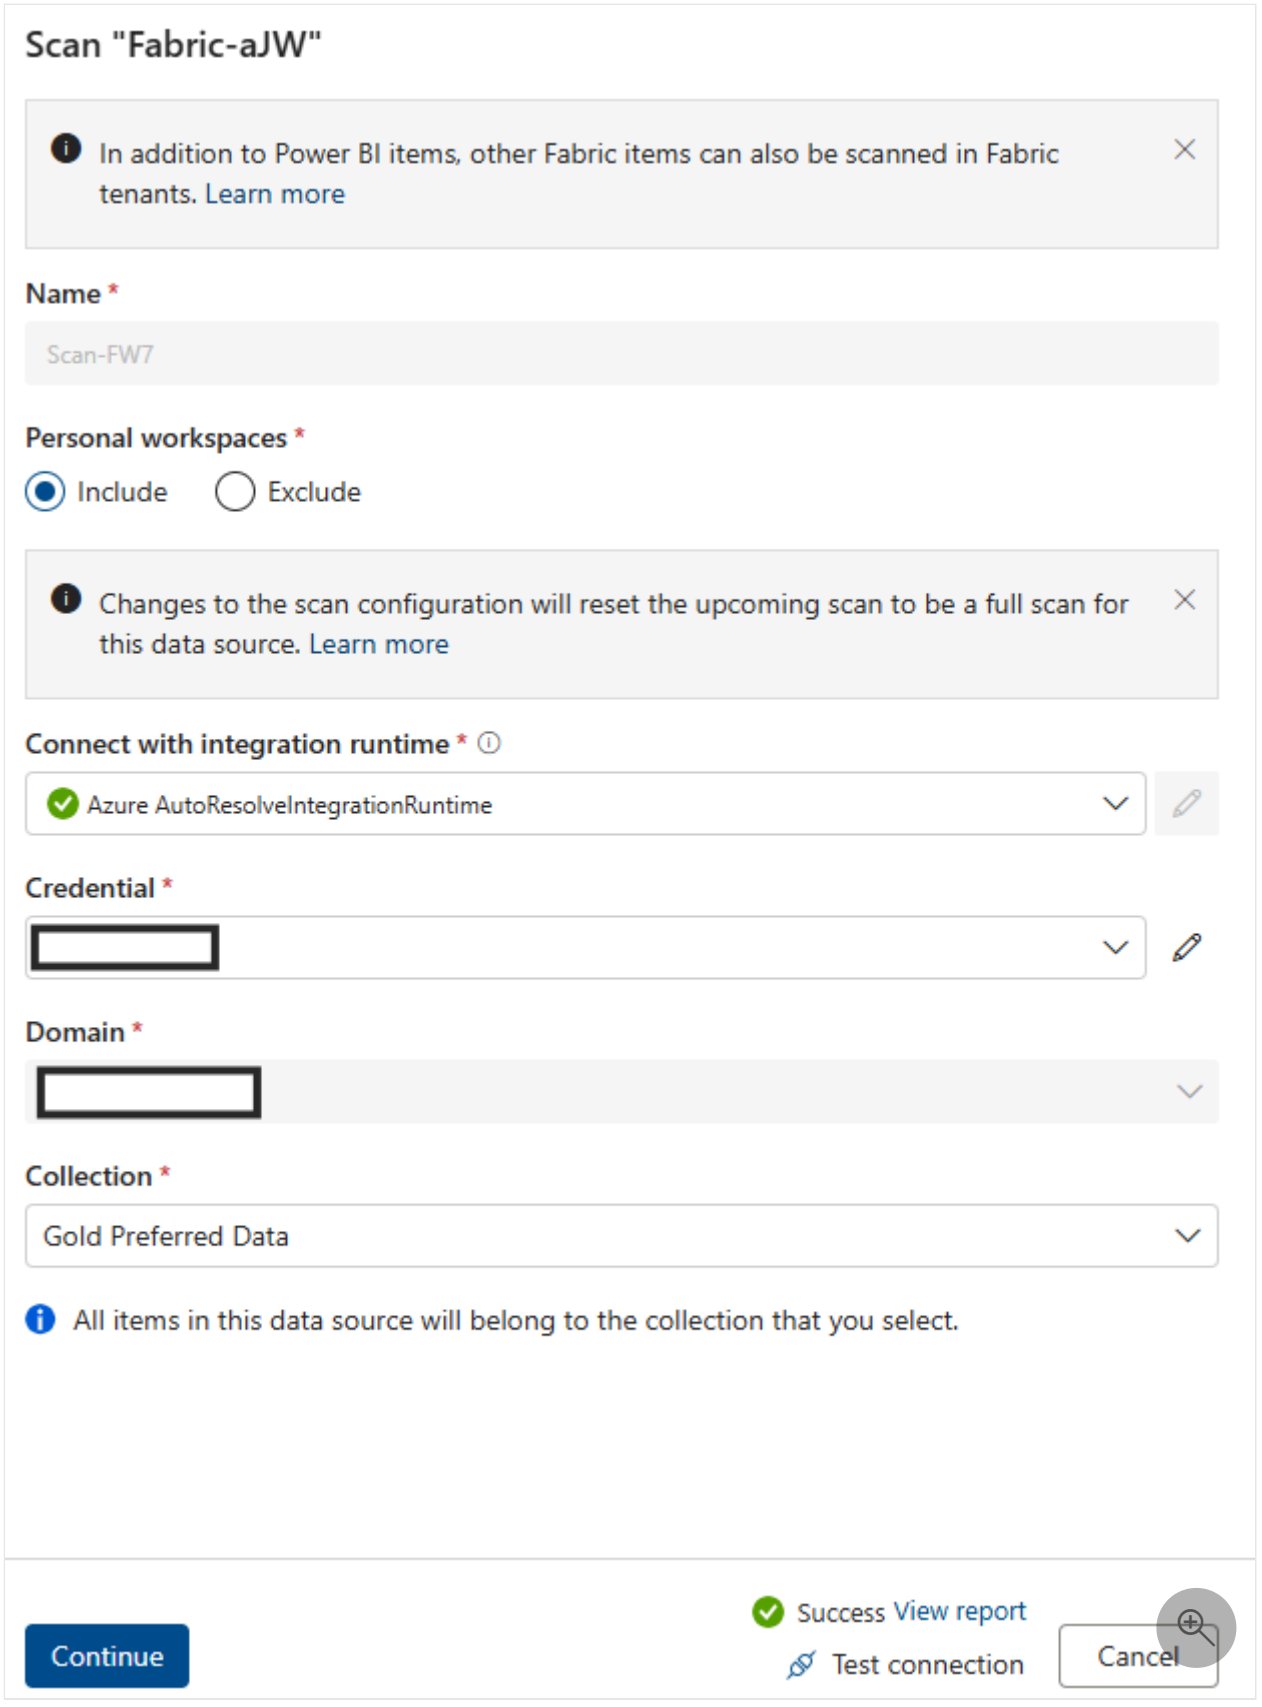
For setup instructions, see same-tenant Fabric scan setup and cross-tenant Fabric scan setup.

Set up connection for Fabric Lakehouse scan

After you register Fabric Lakehouse as a source, you can select Fabric from the list of your registered data sources in Data Map and select **New scan**. Add a **Data source ID**, then follow these steps:

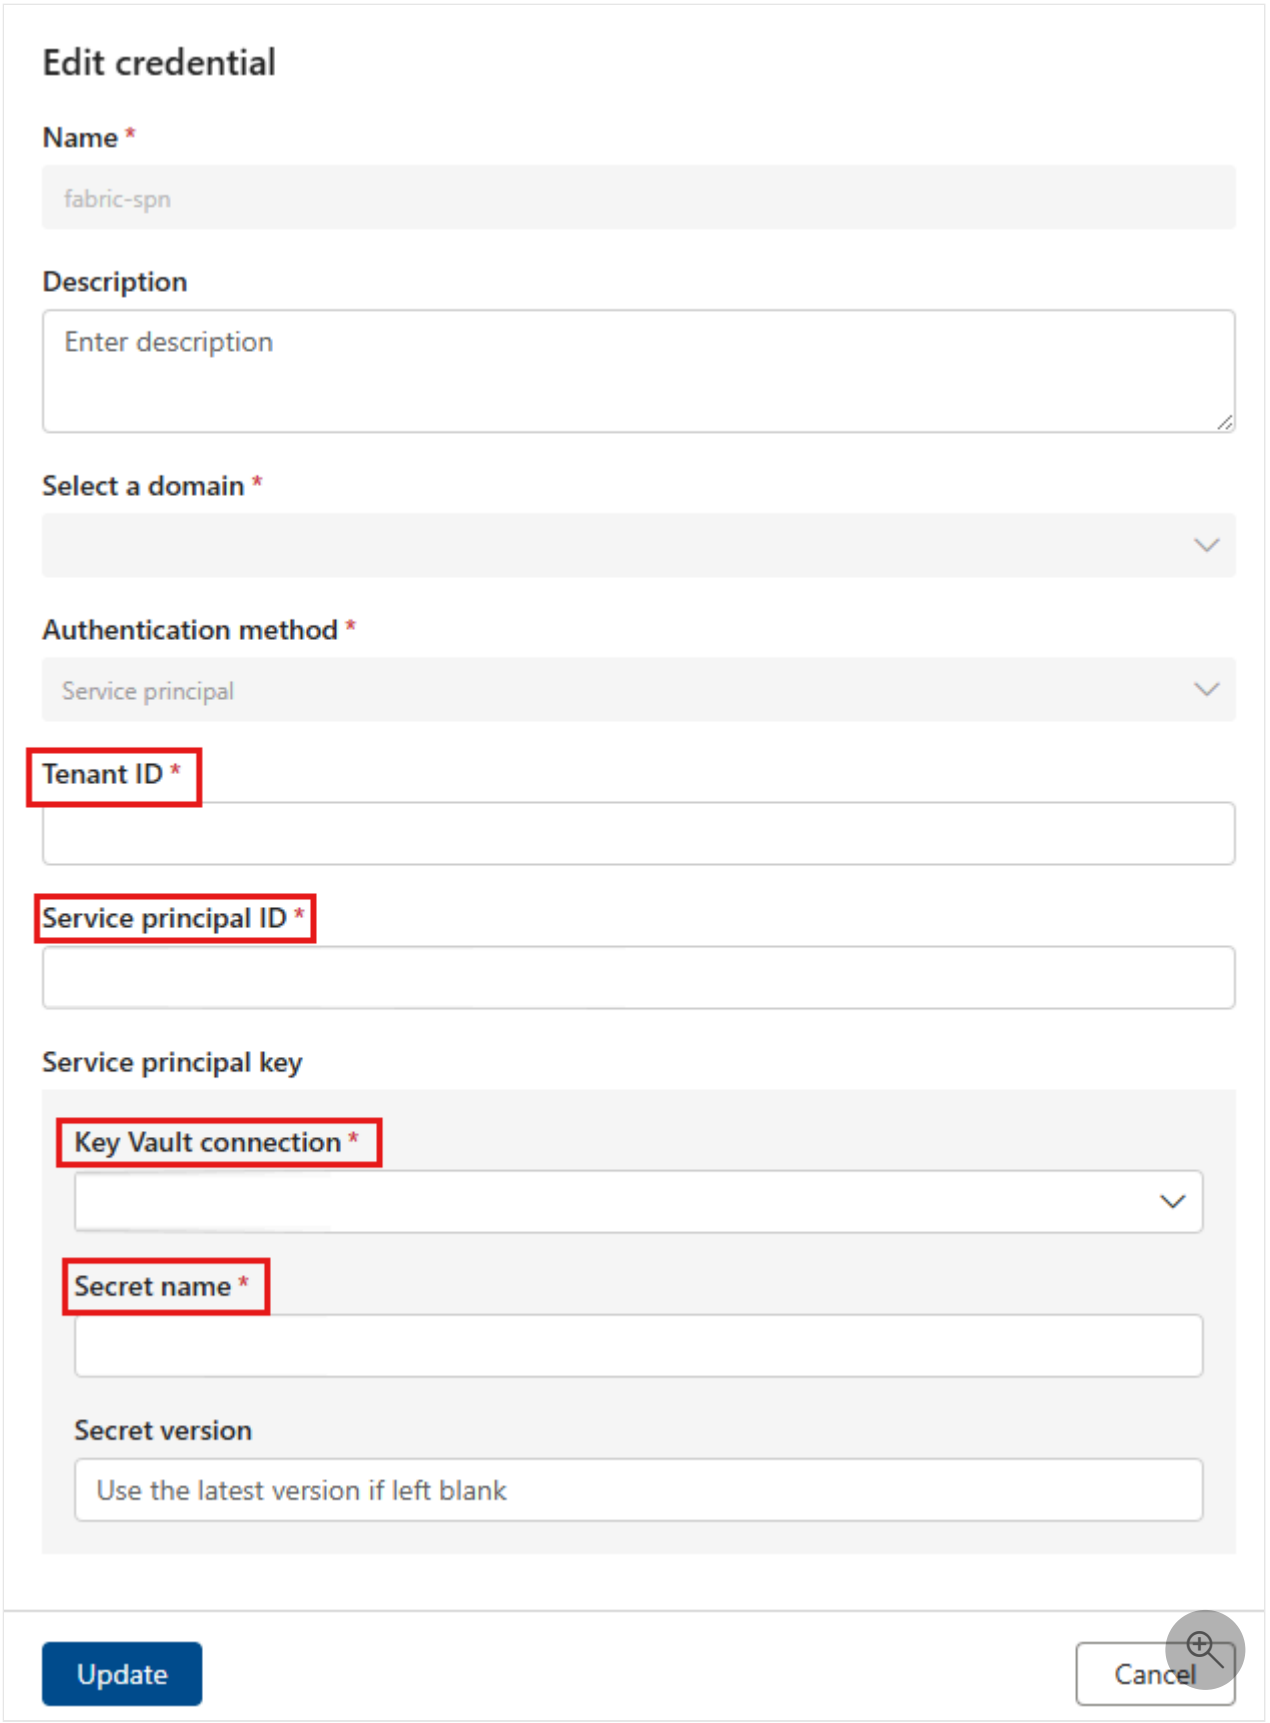
1. Create a security group and a service principal.

2. Add both this service principal and the Purview Managed Identity to this security group, then specify that security group in the Fabric tenant Admin API settings.



3. Associate the security group with Fabric tenant.
   a. Sign in to the Fabric admin portal.
   b. Select the Tenant settings page. **You need to be a Fabric Admin to see the tenant settings page.**
   c. Select Admin API settings > Allow service principals to use read-only admin APIs.

d. Select Specific security groups.
e. Select Admin API settings > Enhance admin APIs responses with detailed metadata and Enhance admin APIs responses with DAX and mashup expressions > Enable the toggle to allow Data Map to automatically discover the detailed metadata of Fabric datasets as part of its scans. **After you update the Admin API settings on your Fabric tenant, wait about 15 minutes before registering a scan and test connection.**



4. Provide Admin API settings read-only API permission to the security group that contains the service principal and Purview Managed Identity.

5. Add **SPN** into **Credential** field.

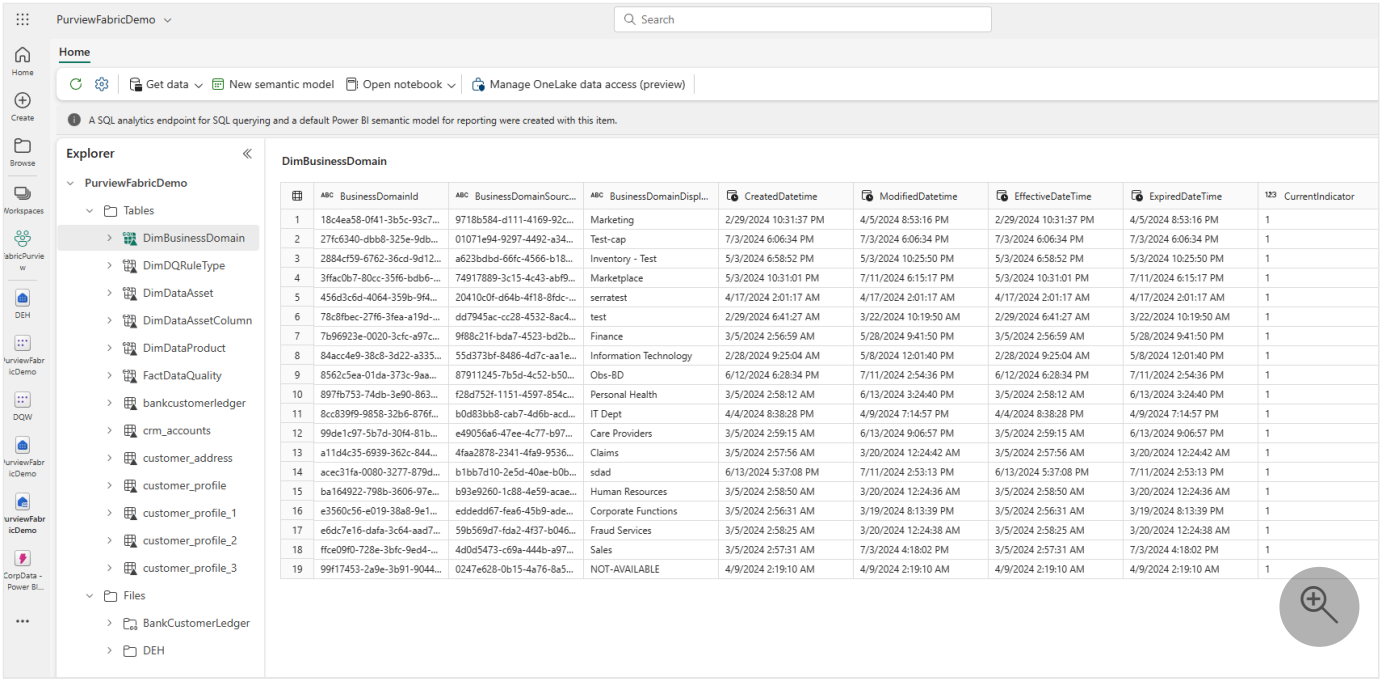
6. Add Azure resource name.

7. Add **Tenant ID**.
8. Add **Service Principle ID**.
9. Add **Key Vault connection**.
10. Add **Secret name**.

After you finish the Data Map scan, locate a Lakehouse instance in Unified Catalog.

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Select **Discovery**, then **Data assets**.
3. On the **Data assets** page, select **Microsoft Fabric**.
4. Select **Fabric workspaces**, then select a workspace from the list.

5. On the workspace's page, find the Lakehouse instance under **Item name**.

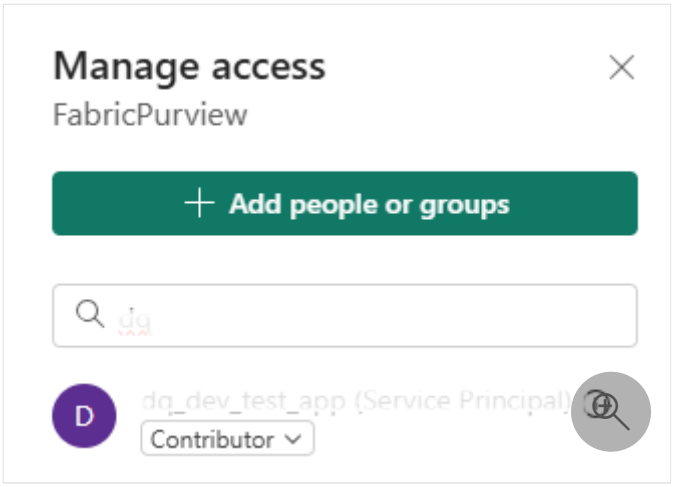


To browse Lakehouse tables:

1. On a workspace page, select the item name **Tables**.
2. Select a Lakehouse table asset listed under **Item name**.
3. View the asset's details page to find metadata such as schema, lineage, and properties.

Review Fabric Lakehouse data quality scan prerequisites

Before you run a data quality scan on Fabric Lakehouse data, complete the following prerequisites:



1. Shortcut, mirror, or load your data to Fabric Lakehouse in delta format.

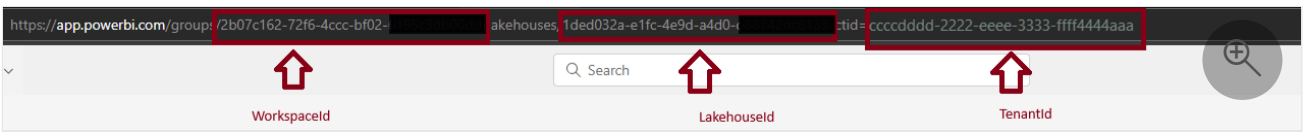
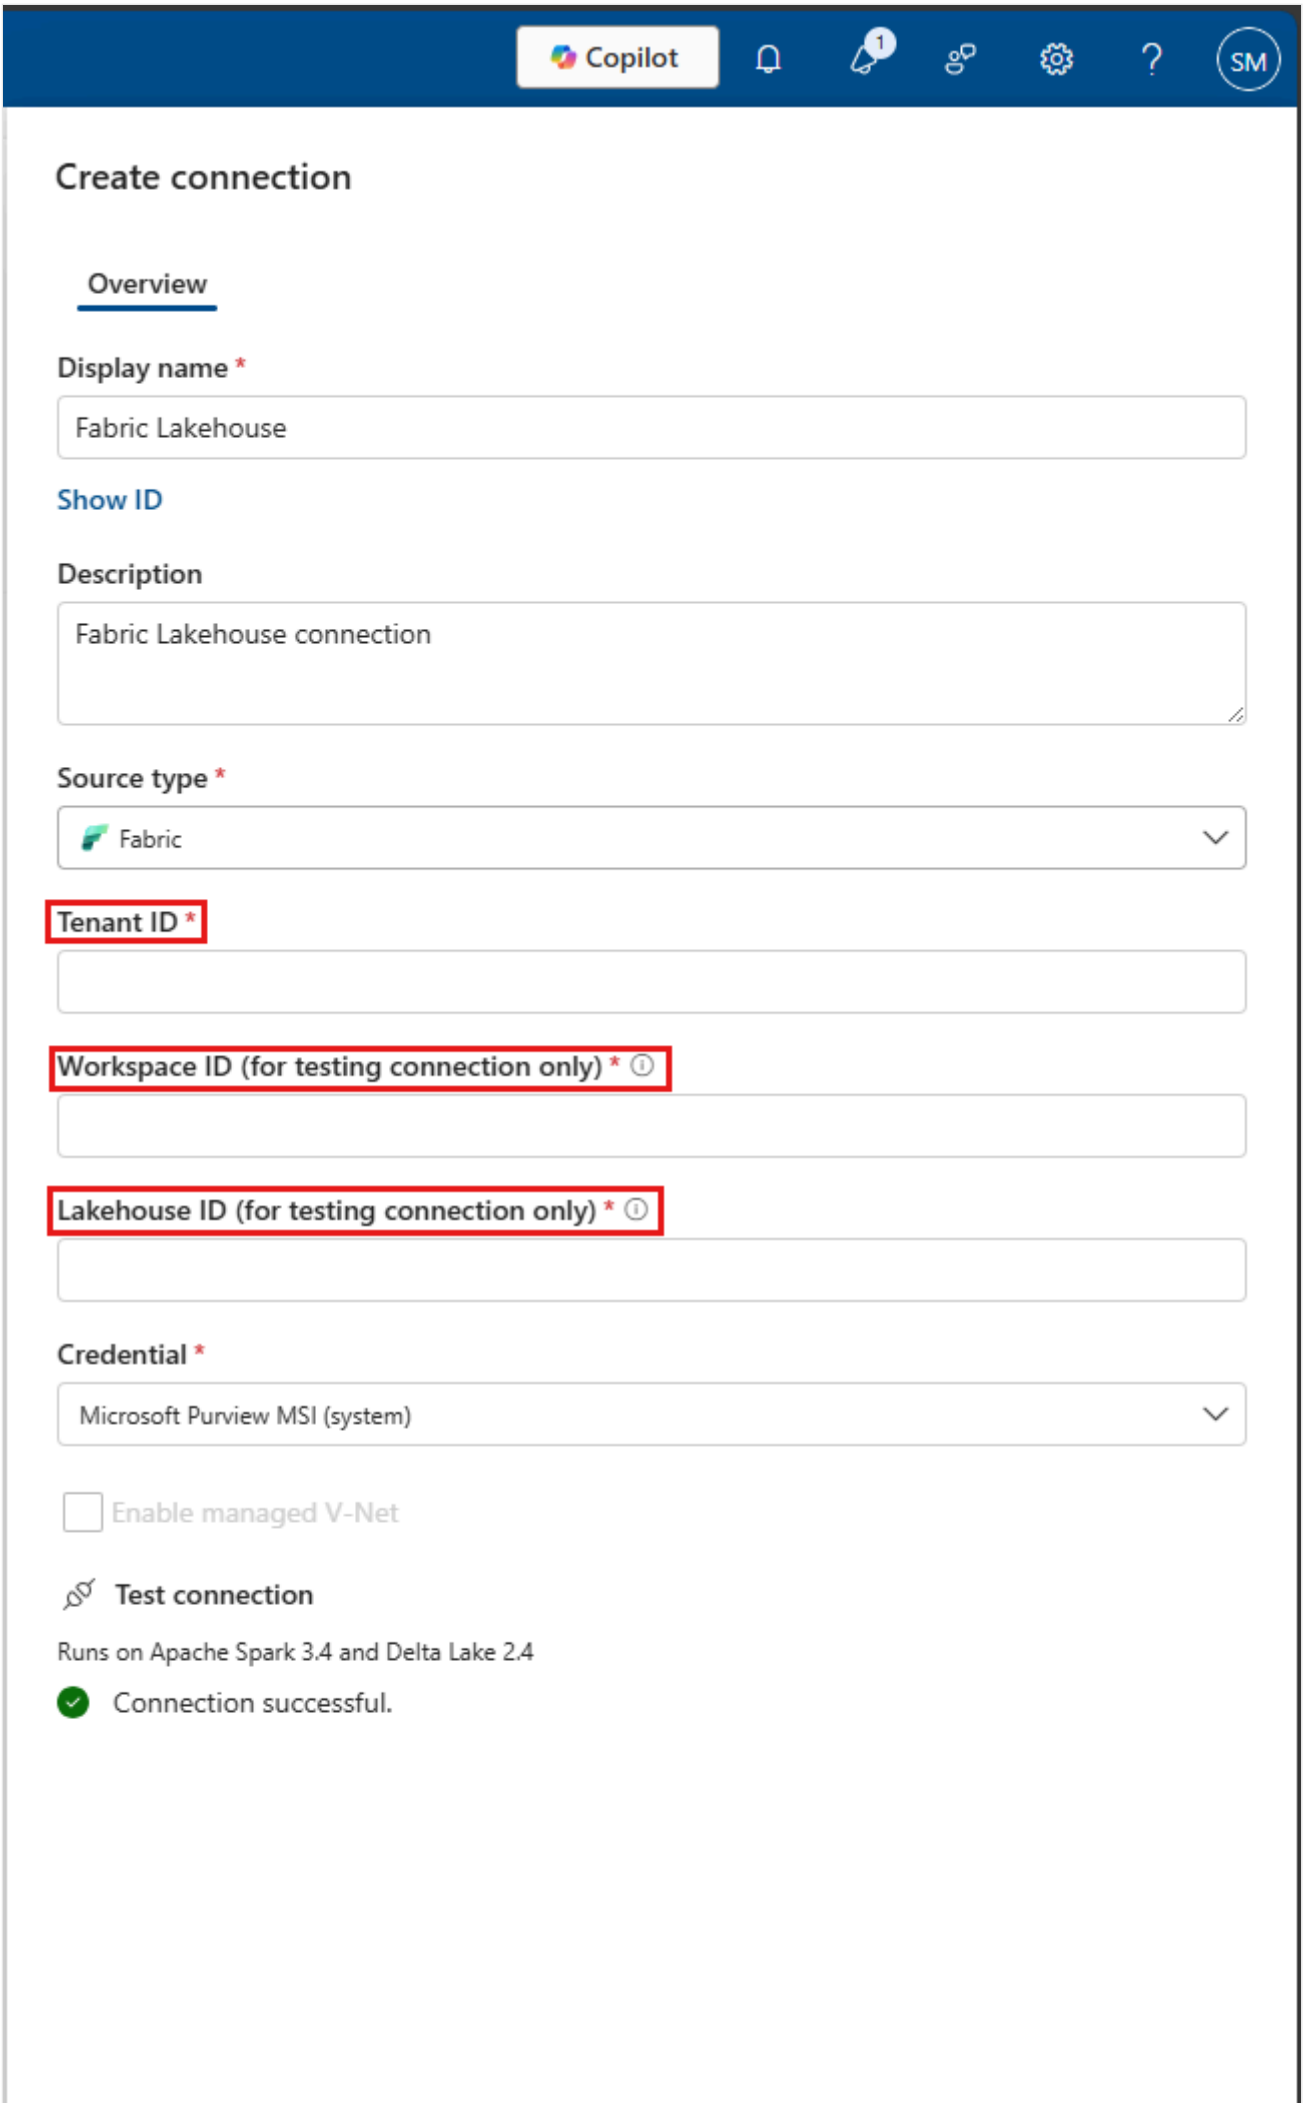
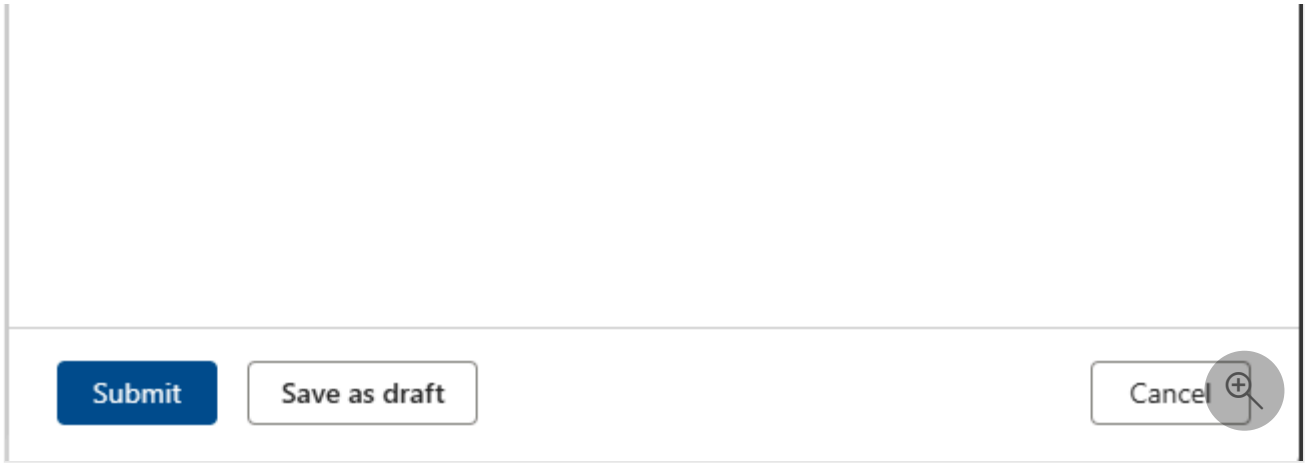
> **Important**
>
> If you add new tables, files, or new sets of data to Fabric Lakehouse through mirroring or shortcut, run a Data Map scope scan to catalog those new sets of data before adding those data assets to a data product for data quality assessment.



2. Grant Contributor right to your workspace for Purview MSI



3. Add scanned data asset from Lakehouse to the data products of the governance domain. On a data product's page in Unified Catalog, locate the data assets and select **Add data assets**. You can only perform data profiling and data quality scanning for the data assets associated with the data products under the governance domain.



For data profiling and data quality scanning, you need to create a separate data source connection. Data Map uses a service principal scan connection, while Unified Catalog data quality uses a Fabric connection with Microsoft Purview MSI. To set up the data quality connection:

1. In Unified Catalog, select **Health management**, then select **Data quality**.
2. Select a governance domain, and from the **Manage** dropdown list, select **Connections**.
3. Select **New** to open connection configuration page.
4. Add connection display name and a description.
5. Add Source type **Fabric**.
6. Add **Tenant ID**.
7. Add **Workspace ID**.
8. Add **Lakehouse ID**.
9. Add **Credential** - **Microsoft Purview MSI**.

10. Test connection to make sure that the configured connection is successful.

Copilot
SM

Microsoft Purview MSI (system)
Enable managed V-Net
Test connection
Runs on Apache Spark 3.4 and Delta Lake 2.4
Connection successful.

If your Fabric tenant is configured to run on Virtual Network or in Private Link, check the Virtual Network checkbox in the connection screen. Then select the Azure region where your Fabric and Microsoft Purview are running; for example, UAE North, West Europe, or Canada Central.

In addition to Azure region, you need to add the **Private Link Resource ID**. The following example shows the format:

```
/subscriptions/07d669d6-83f2-4f15-8b5b-4a4b31a7050e/resourceGroups/pdgbugbashfabricvnet/providers/Microsoft.PowerBI/privateLinkServicesForPowerBI/fabricvnetpl.
```

To set up compute for virtual networks, refer to Set up data quality for managed virtual networks. And get details on how to set up and use private link for your Fabric tenant. You need to set up the private link for the Fabric tenant before configuring data quality virtual network connection and compute allocation.

> **Important**
>
> - For a data quality scan, Microsoft Purview MSI must have contributor access to Fabric workspace to connect Fabric workspace. To grant contributor access, open your Fabric workspace, select three dots (...), select **Workspace access**, then **Add people or group**, then add Purview MSI as **Contributor**.
> - Fabric tables must be in Delta format or Iceberg format.

Profiling and data quality scanning for data in Fabric Lakehouse

After completed connection setup successfully, you can profile, create and apply rules, and run a data quality (DQ) scan of your data in Fabric Lakehouse. Follow these steps:

1. Associate a Lakehouse table to a data product for curation, discovery, and subscription. Learn how to create and manage data products.

2. Profile Fabric Lakehouse table. Learn how to configure and run data profiling for a data asset.

3. Configure and run data quality scan to measure data quality of a Fabric Lakehouse table. Learn how to configure and run a data quality scan.

> **Important**
>
> - Make sure that your data are in Delta format or Iceberg format.
> - Make sure the Data Map scan ran successfully. If it didn't, then rerun the scan.

Limitations

Data Quality for Parquet file is designed to support:

- A directory with Parquet Part File. For example: *./Sales/{Parquet Part Files}*. The Fully Qualified Name must follow `https://(storage account).dfs.core.windows.net/(container)/path/path2/{SparkPartitions}`. Make sure there are no {n} patterns in directory/sub-directory structure; it must rather be a direct FQN leading to {SparkPartitions}.
- A directory with Partitioned Parquet Files, partitioned by columns within the dataset like sales data partitioned by year and month. For example: *./Sales/{Year=2018}/{Month=Dec}/{Parquet Part Files}*.

Both supported Parquet directory patterns present a consistent Parquet dataset schema. Limitation: It isn't designed to or won't support N arbitrary Hierarchies of Directories with Parquet Files. We advise the customer to present data in (1) or (2) constructed structure. So recommending customer to follow the supported parquet standard or migrate their data to **ACID** compliant delta format.

Tips for initial setup

Use the following tips when setting up data quality scanning for Fabric Lakehouse data for the first time.

For Data Map:

- Ensure the service principal (SPN) has workspace permissions.
- Ensure scan connection uses the service principal.
- Running a full scan is suggested if you're setting up a Lakehouse scan for the first time.
- Check that the ingested assets have been updated or refreshed.

For Unified Catalog:

- The data quality connection needs to use MSI credentials.
- Ideally, create a new data product for first-time testing of Lakehouse data quality scans.
- Add the ingested data assets, and check that the data assets are updated.
- Try running a profile first. If successful, try running a data quality rule. If not successful, try refreshing the asset schema (**Schema** > **Schema management** > **Import schema**).
- Some users also had to create a new Lakehouse and sample data to verify everything works from scratch. In some cases, working with assets that were previously ingested in the Data Map, the experience isn't consistent.

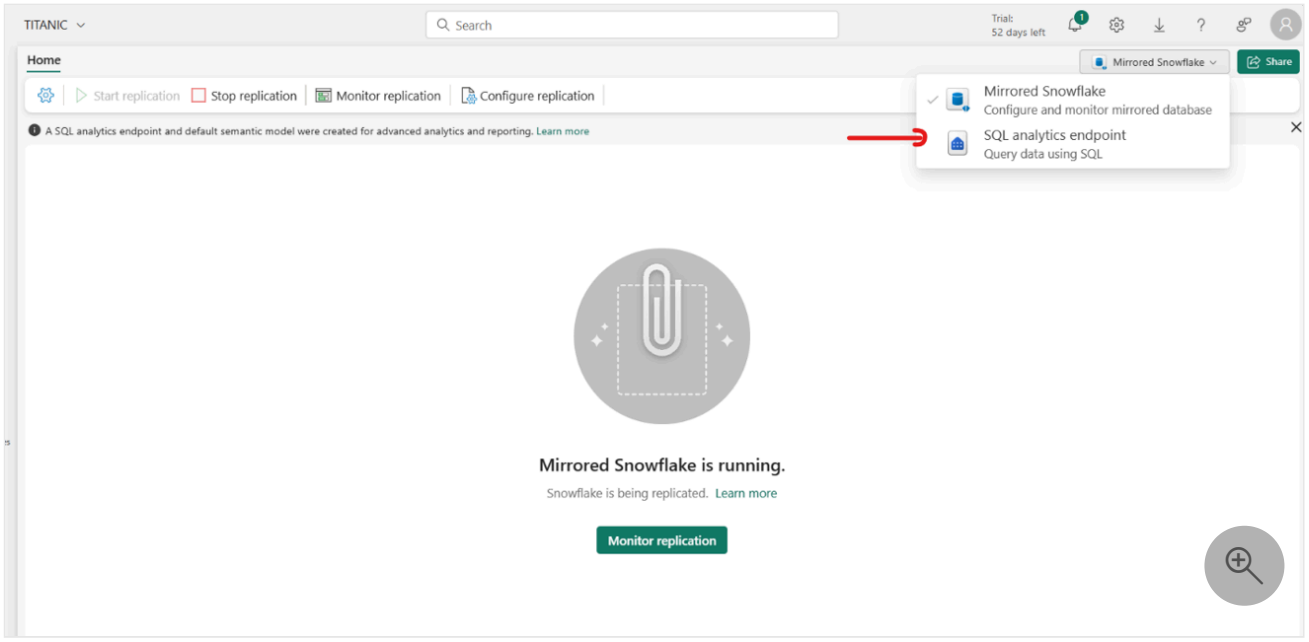
Last updated on 05/27/2026

Set up data quality for Fabric mirrored databases

This article explains how to configure data quality scans in Microsoft Purview for data assets that are mirrored from external sources into Microsoft Fabric.

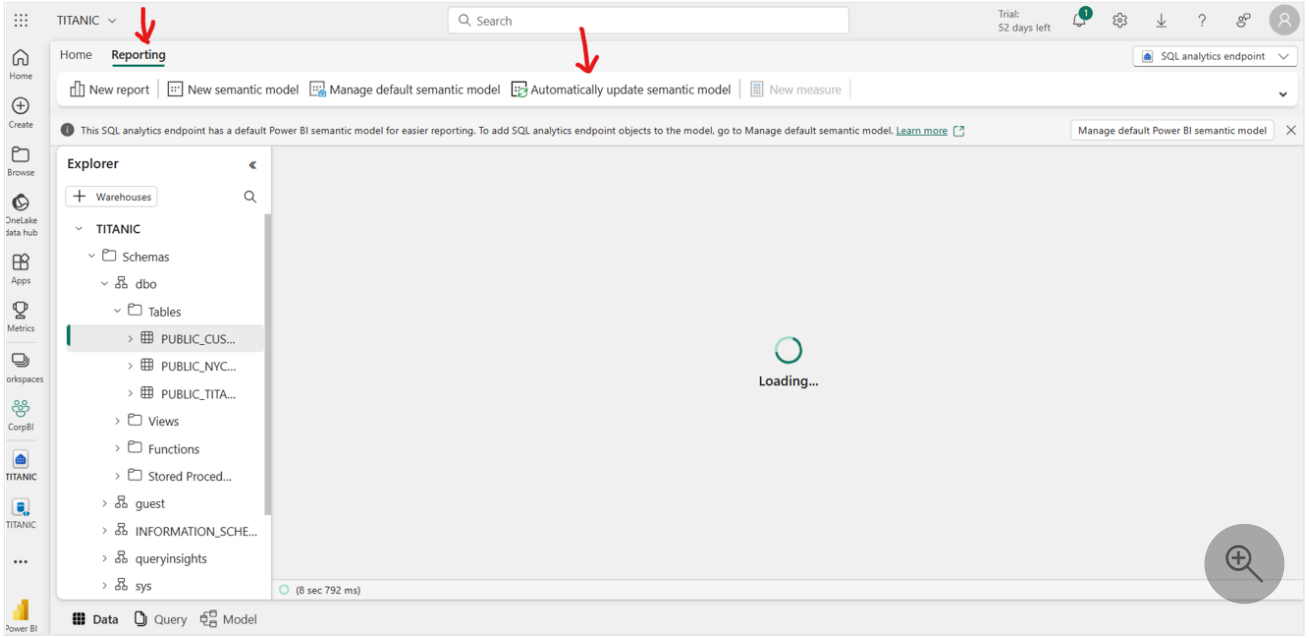
Mirroring in Fabric is a low-cost, low-latency solution that replicates data from sources like Azure SQL Database, Azure Cosmos DB, and Snowflake into Fabric's OneLake. For more information, see the Fabric mirroring documentation.

Configure data quality for a Fabric mirrored database



To set up data quality for a Fabric mirrored database, complete the following steps:

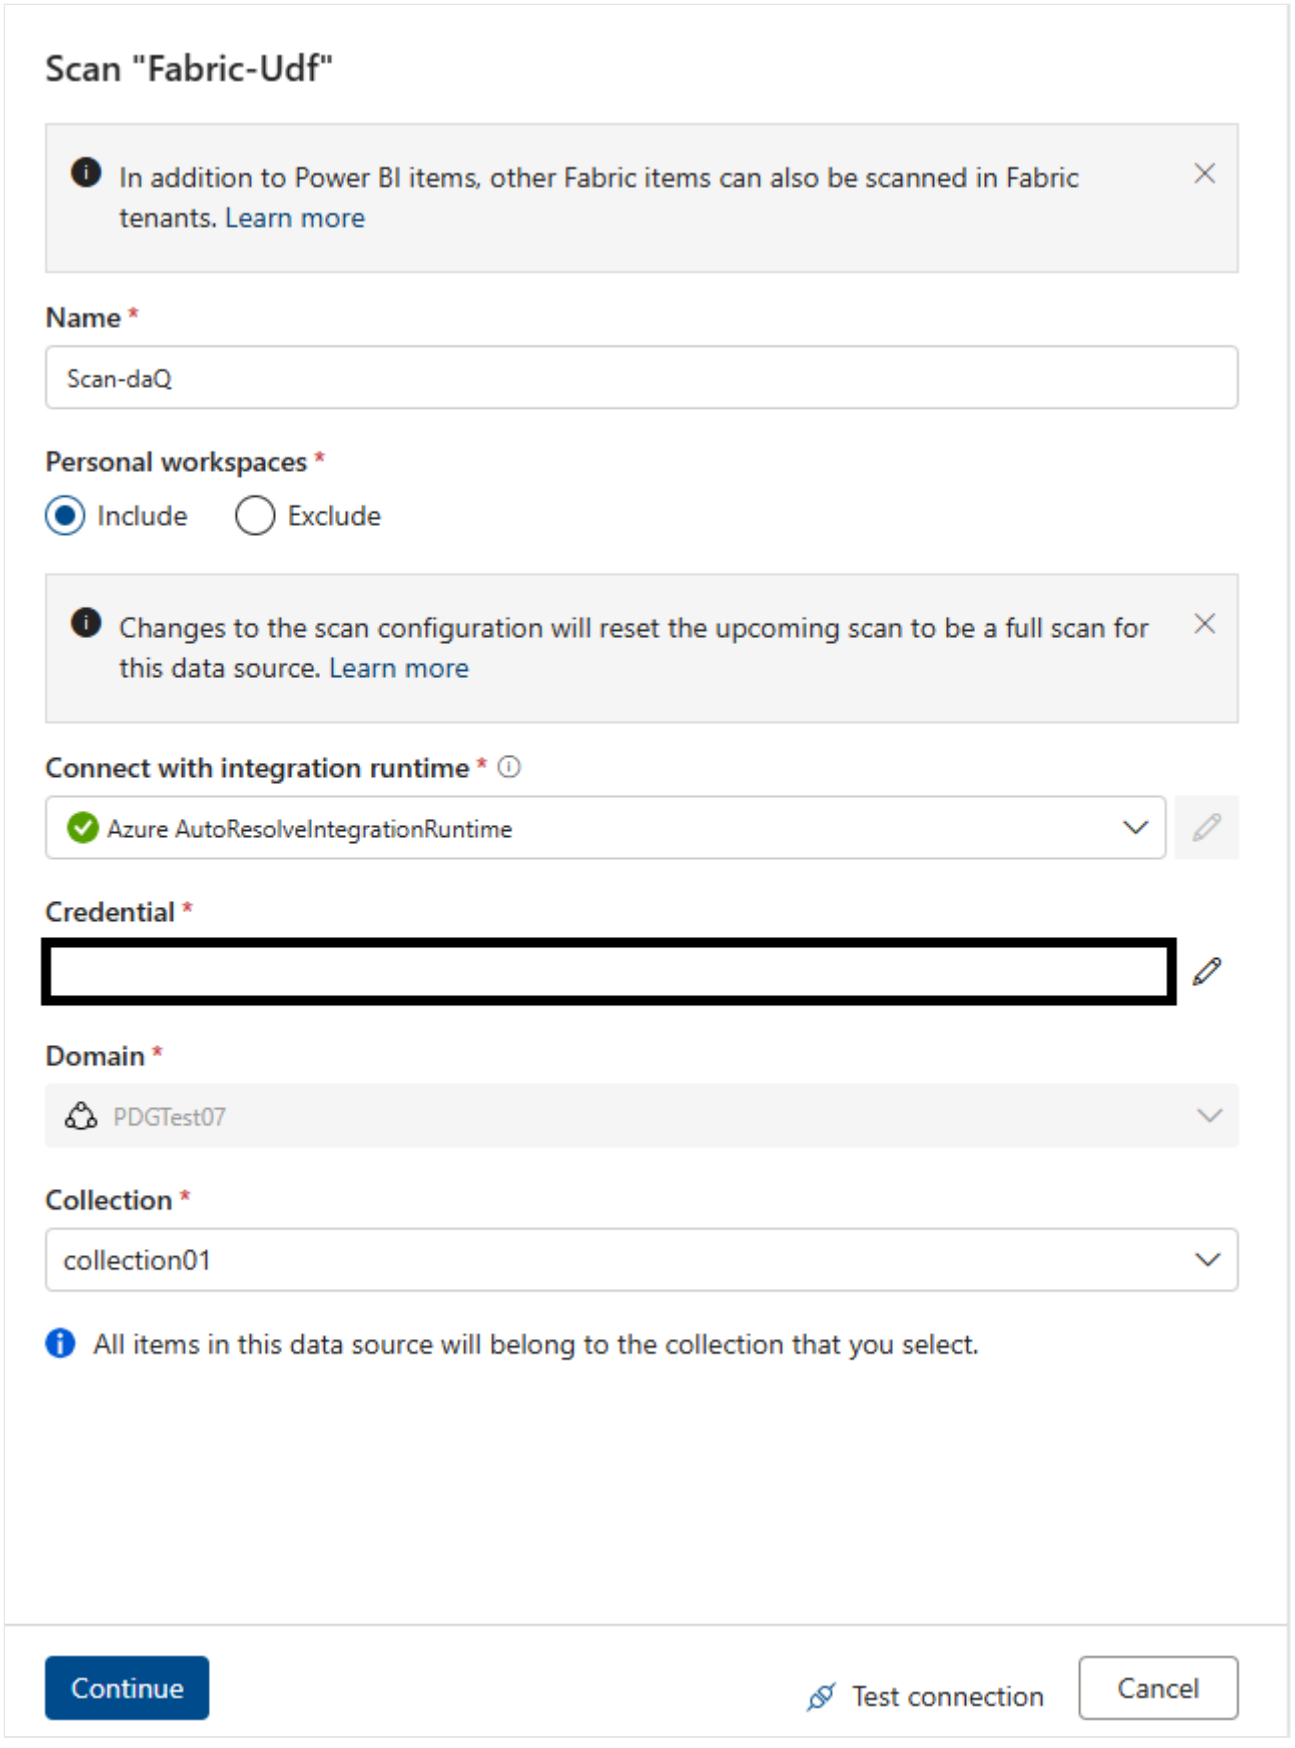
> **Note**
>
> Before you begin, make sure you have:
>
> - A Microsoft Fabric workspace with mirroring enabled.
> - A Lakehouse in your Fabric workspace (or permissions to create one).
> - Access to Microsoft Purview Data Map with service principal authentication configured.



1. Enable mirroring in your Fabric tenant. A Power BI administrator can enable mirroring for the entire organization or for specific security groups in the Power BI admin portal. You can replicate an entire database or individual tables.

2. After enabling mirroring and initiating replication, confirm that replication completes successfully.

3. Open the SQL analytics endpoint.



4. On the **Reporting** tab, select **Automatically update semantic model**.

5. Create a Lakehouse in your Fabric workspace if you don't have one created.

6. Create a Fabric shortcut from your mirrored database to the lakehouse.

7. Go to Microsoft Purview Data Map and run a Data Map scan on the lakehouse you created in the previous step. Use service principal authentication.

8. When the scan is completed, associate the discovered Lakehouse table assets with a data product. Make sure to select the **Lakehouse tables** to associate to your data product.

9. After associating the Lakehouse tables with your target data product in Unified Catalog, you can profile and measure the data quality of all mirrored tables as Lakehouse tables in Microsoft Purview.

10. In the **Data quality** area of **Health management** in Unified Catalog, run a data quality scan or profile your data as usual.

> **Important**
>
> - Use service principal for Data Map scans, and use a managed identity for data quality scans.
> - Select the mirrored database instead of individual tables.
> - Update the semantic model every time when you add new table to the mirrored database.
> - If your mirrored database tables aren't available in the Fabric Lakehouse, contact Fabric support.
> - Data quality scanning is supported only for Lakehouse Delta, Iceberg, and Parquet file formats.

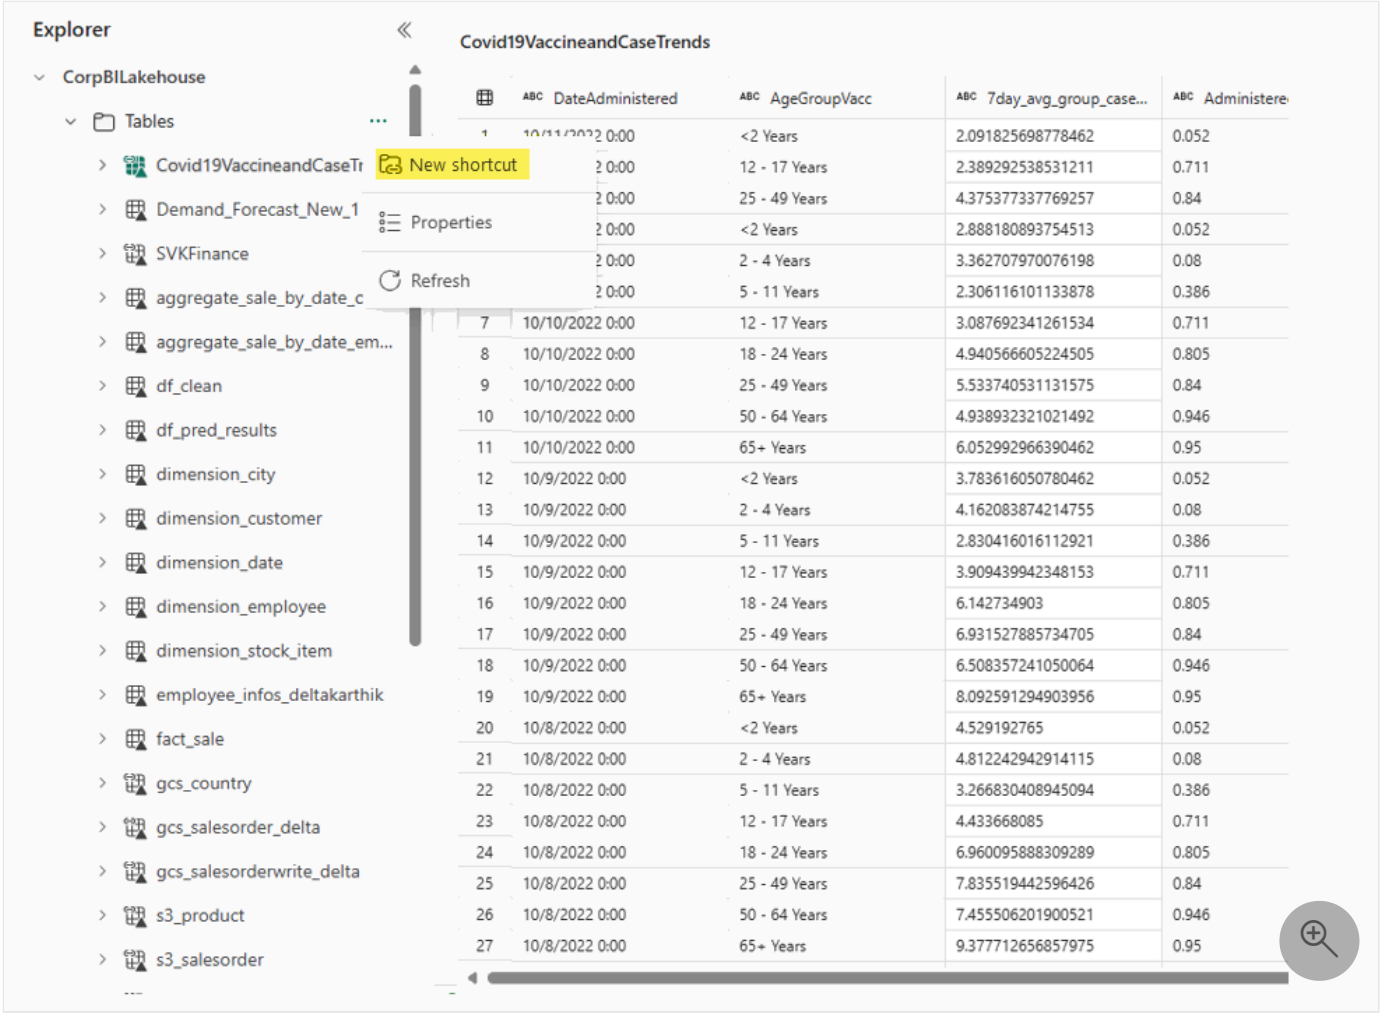
Set up data quality for Fabric shortcut databases

Shortcuts are objects in Microsoft OneLake that point to other storage locations. The location can be internal or external to OneLake. The shortcut target path is the location the shortcut points to. The shortcut path is where the shortcut appears. Shortcuts appear as folders in OneLake, and any workload or service with access to OneLake can use them.

This article explains how to create Fabric shortcuts for external data sources and configure data quality scans for the shortcut-based assets in Microsoft Purview Unified Catalog.

With OneLake shortcuts, you can unify your data across domains, clouds, and accounts in a single virtual data lake. All Microsoft Fabric analytical engines connect directly to data sources like Azure, Amazon Web Services (AWS), and OneLake through a unified namespace. OneLake manages permissions and credentials, so you don't need to configure each Fabric workload separately.

For more information about Fabric shortcuts, see the OneLake shortcuts documentation.



Prerequisites

Before you can run data quality scans on shortcut databases, create a shortcut for your external data source. After you create the shortcut, run a Data Map scan to register the asset in Unified Catalog, then run a data quality scan.

> **ⓘ Important**
>
> - Use a service principal or managed identity for Data Map scans, and managed identity for data quality scans.
> - Any data sourced through a shortcut is processed in the same region as the Fabric workspace.
> - The Fabric team needs to differentiate shortcut items from native items in the Microsoft OneLake SDK for Lakehouse subartifacts. For now, all shortcut items (tables and files) are considered as native items during Data Map scanning.

Sign in to your Microsoft Fabric workspace. Select the ellipsis button under **Tables**, and select **New Shortcut**. On the **New shortcut** page, you can create shortcuts for several external sources. This article covers the following:

- Azure Data Lake Gen2 shortcuts
- Amazon S3 shortcuts
- Google Cloud Storage shortcuts

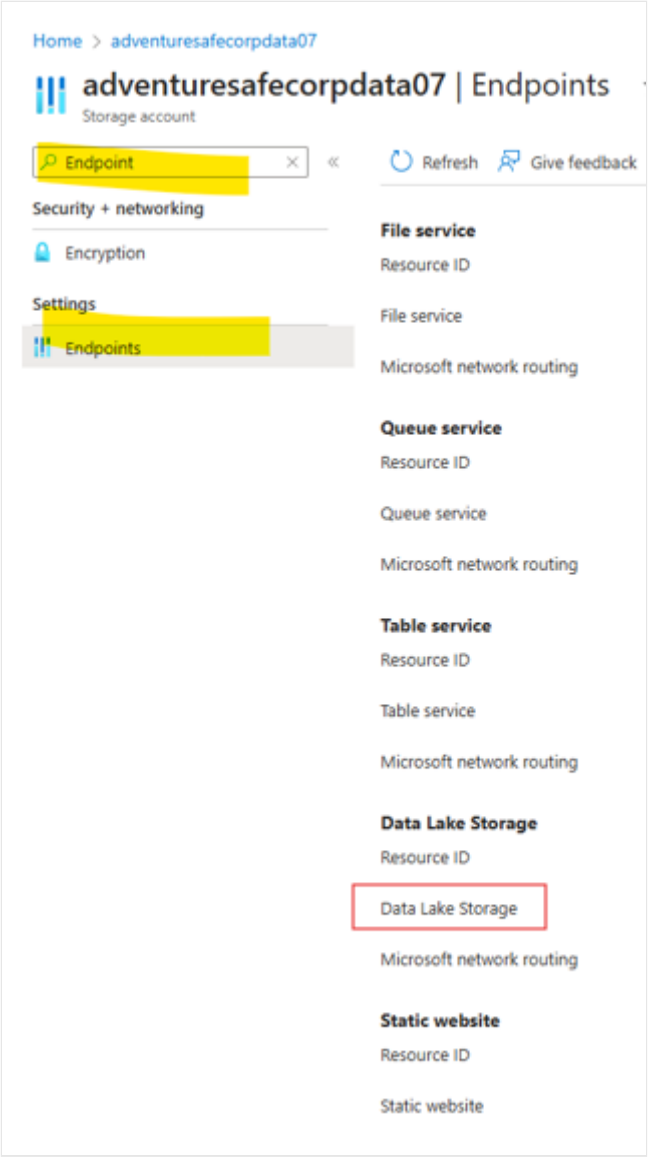
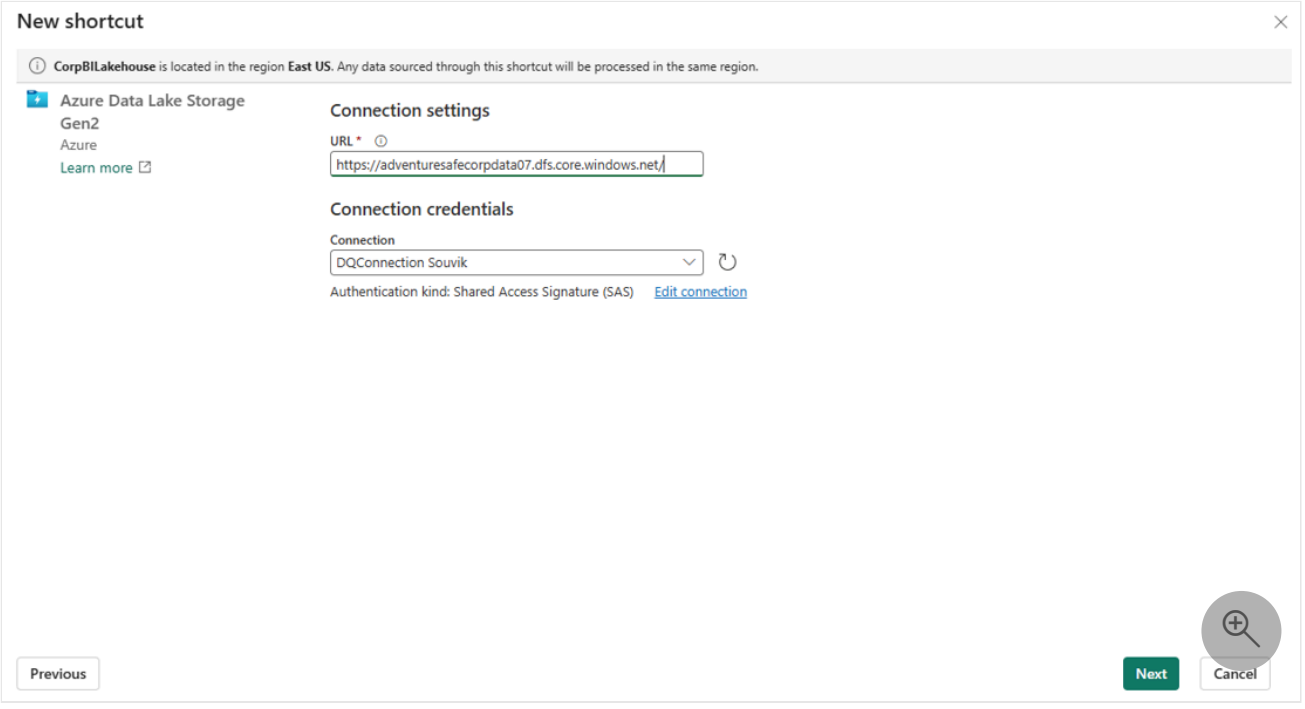
Set up an Azure Data Lake Gen2 shortcut

To create an Azure Data Lake Gen2 shortcut and scan it for data quality, complete the following steps:

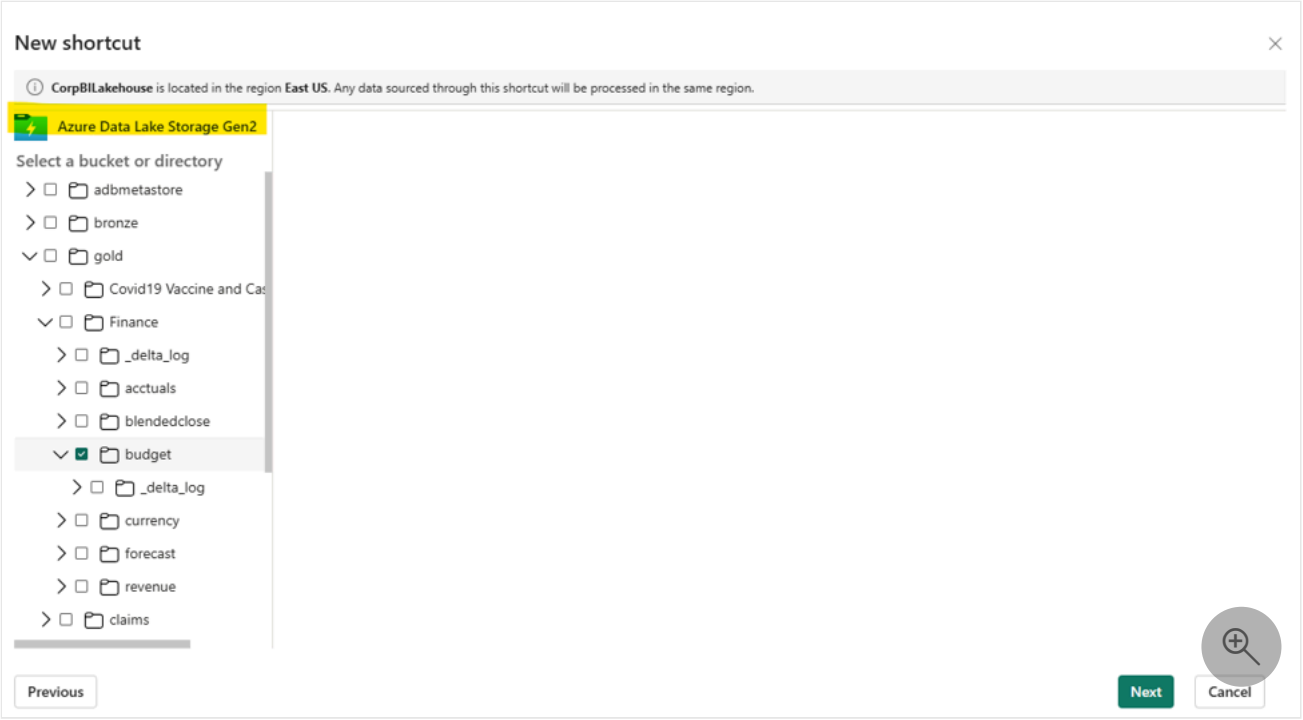
1. Select **Azure Data Lake Storage Gen2** on the Fabric workspace **New shortcut** page.



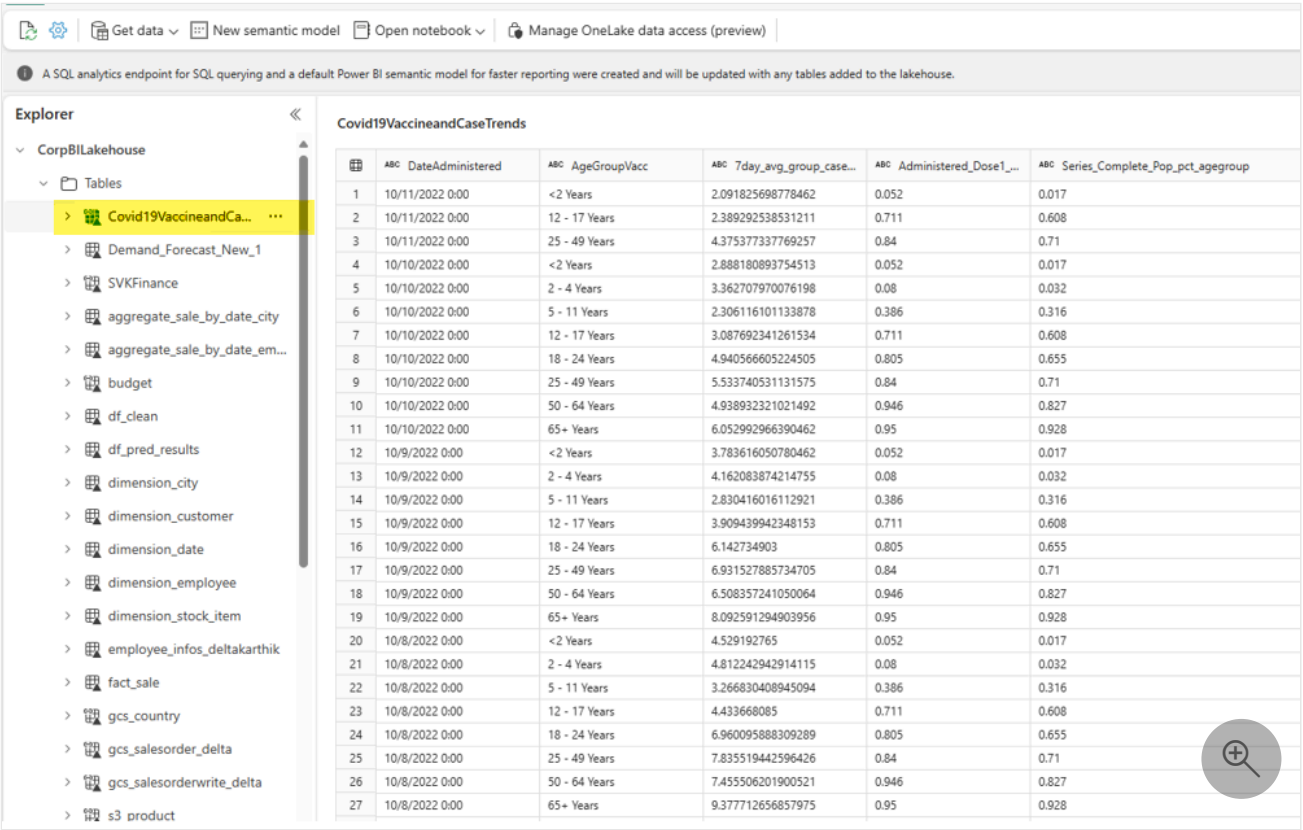
2. Select ADLS Gen2 SAS authentication.



3. In the Azure portal, generate a shared access signature (SAS) and connection string for your ADLS Gen2 resource.

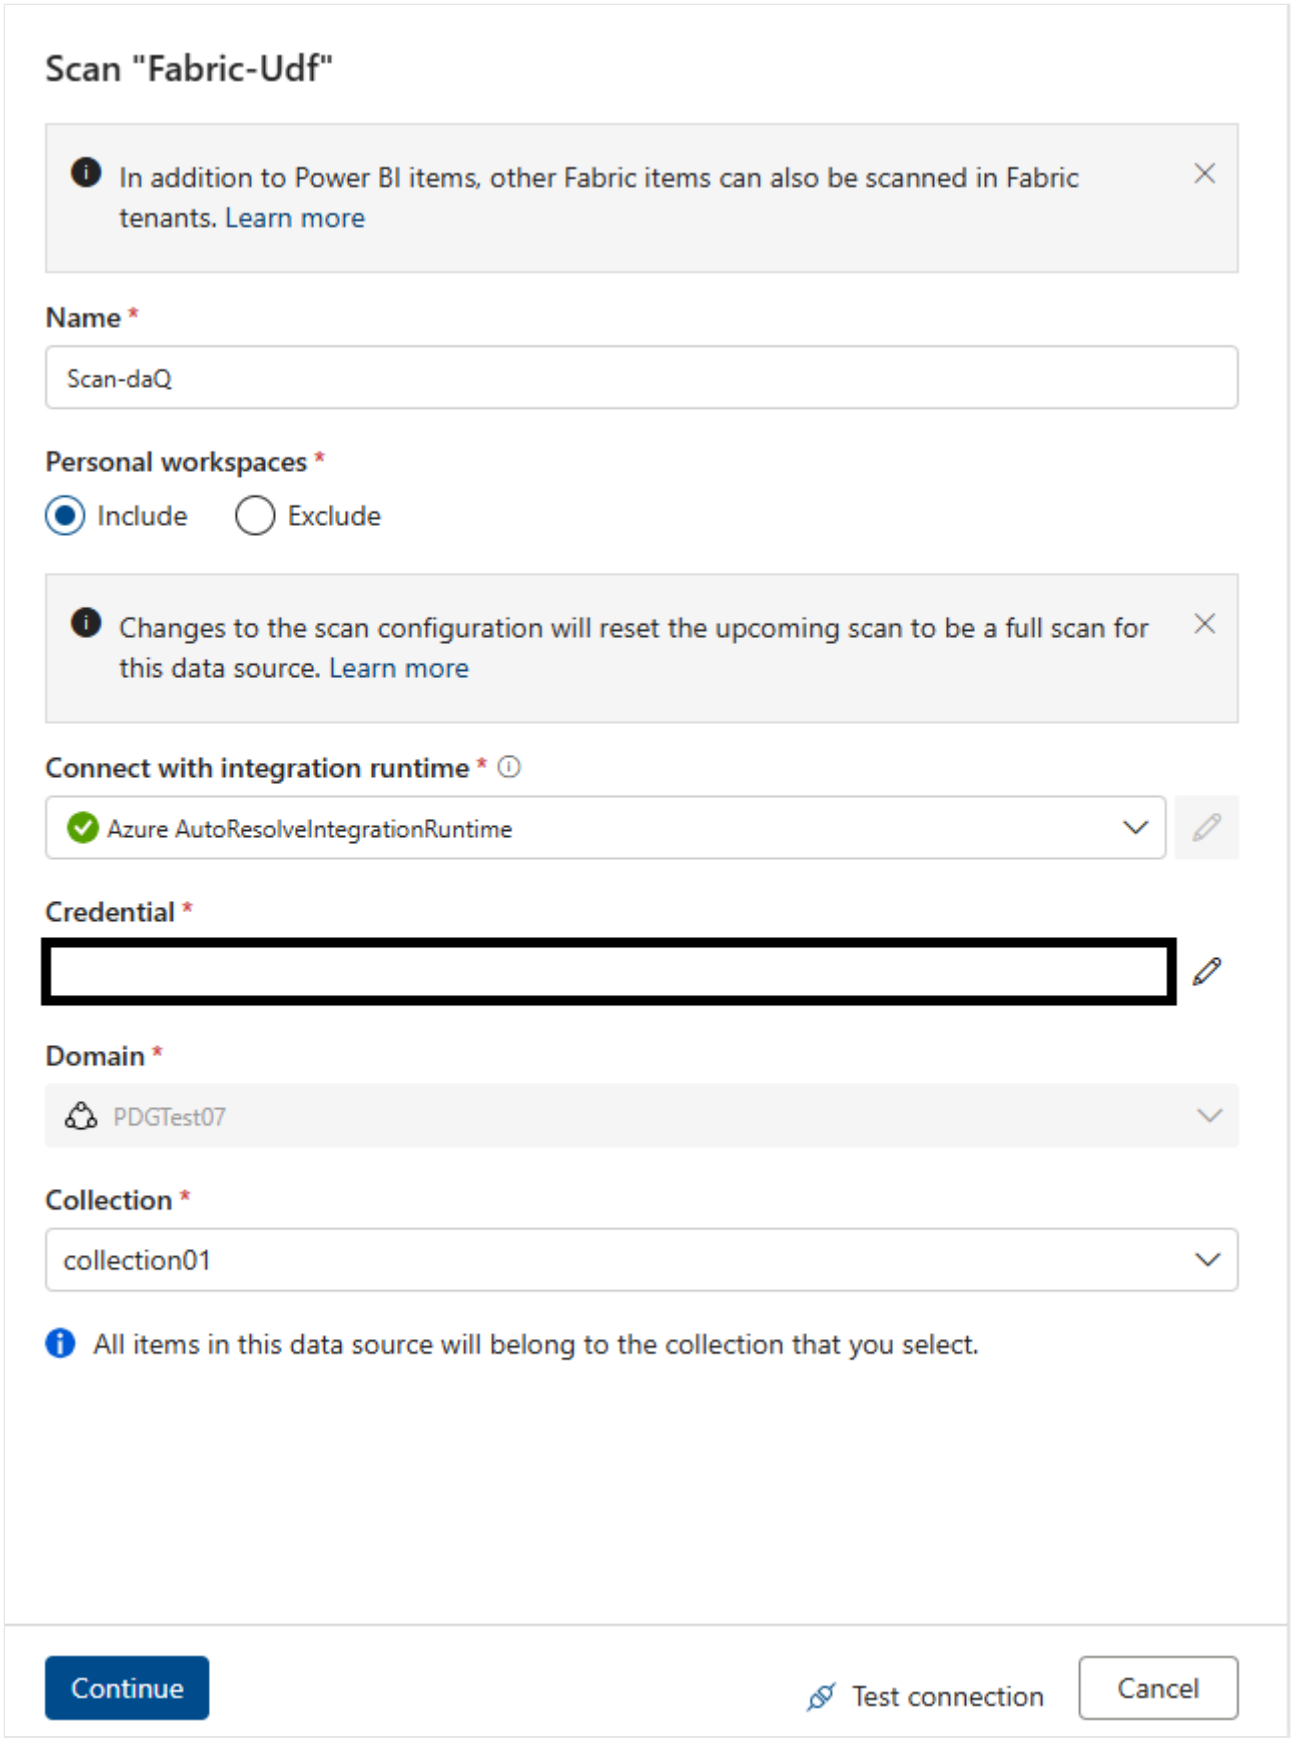


4. **Copy** the endpoint of the data lake.



5. Add storage details for the shortcut storage.

6. Navigate to and choose the correct delta folder.



7. Preview the shortcut delta table in your Fabric workspace.

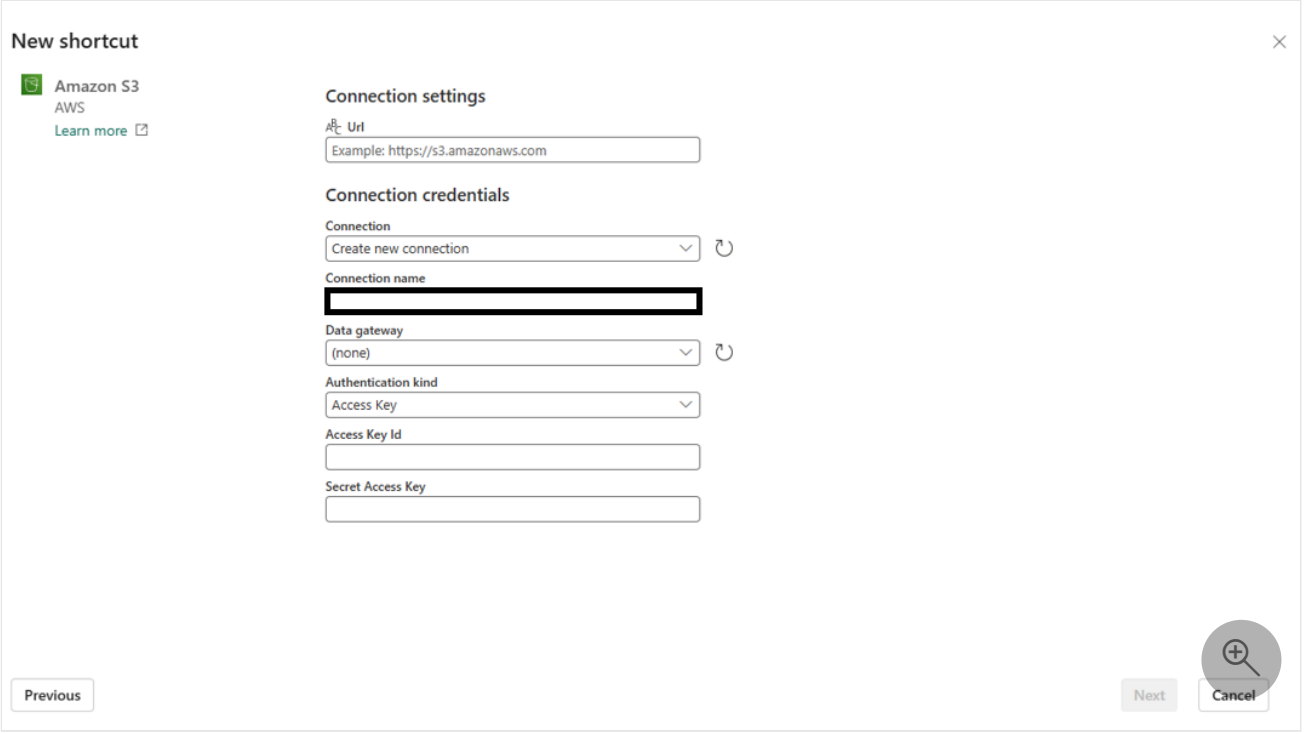
8. Start a Data Map scan of your Azure Data Lake Gen2 resource. Use service principal or managed identity authentication.

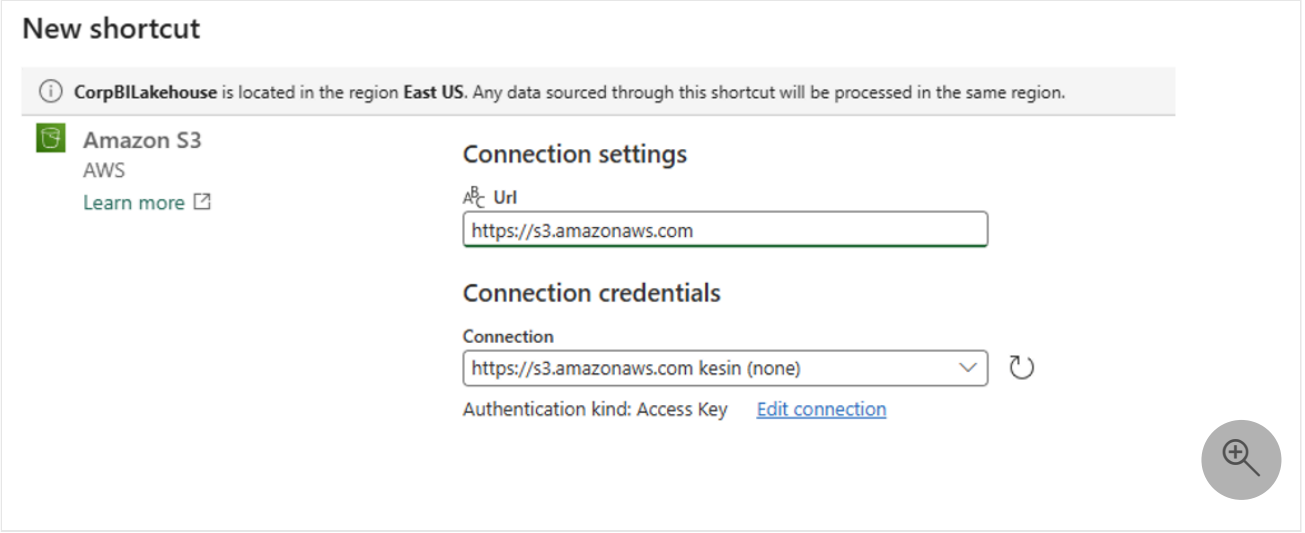
9. When the Data Map scan finishes, your asset appears in Unified Catalog as a Fabric Lakehouse table.

10. Associate the asset with a data product for curation and data quality assessment.



11. In Unified Catalog, configure and run a data quality scan or run data profiling as usual.

Set up an Amazon S3 shortcut



To create an Amazon S3 shortcut and scan it for data quality, you need the S3 bucket URL, access key ID, and secret access key. Complete the following steps:

1. Select **New shortcut** in the Microsoft Fabric workspace.

2. Select **Amazon S3** and add the URL, access key ID, and secret access key.

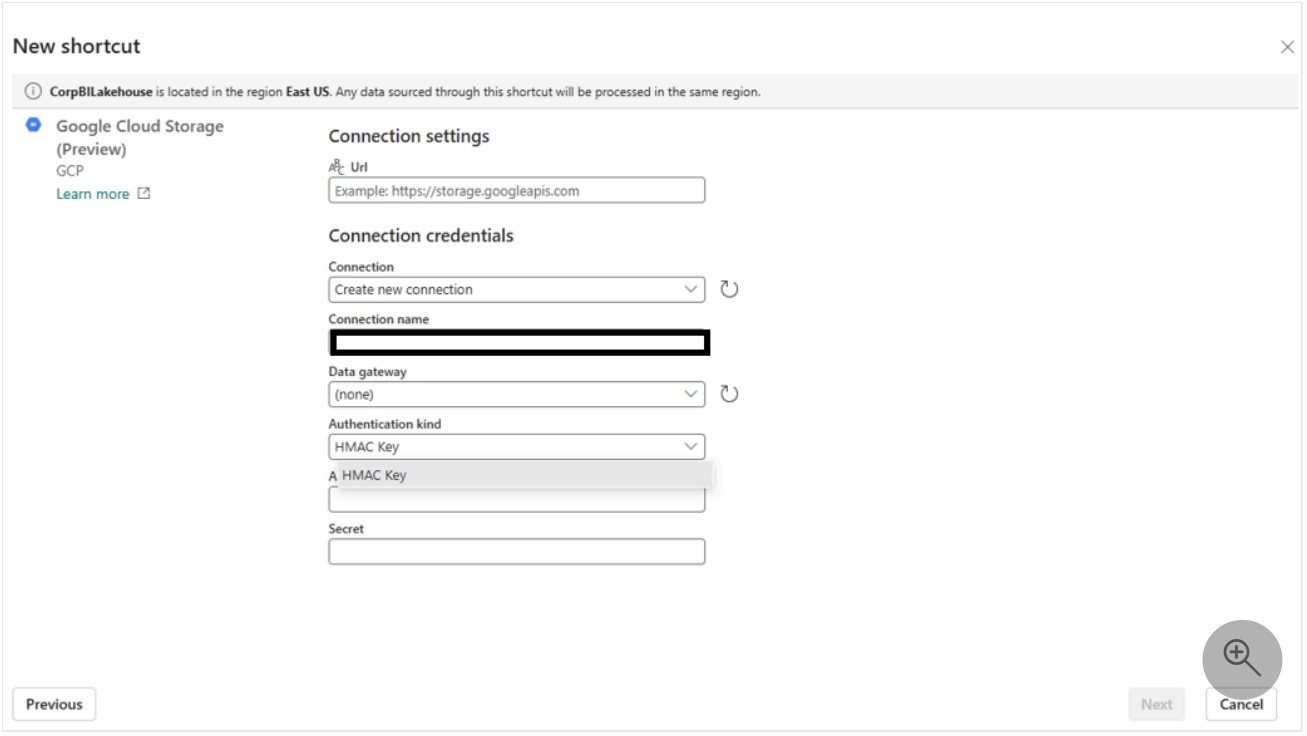
3. Add the connection URL and storage details.

4. Preview the shortcut in your Fabric workspace.

5. Start a Data Map scan of your Amazon S3 resource. Use service principal or managed identity authentication.

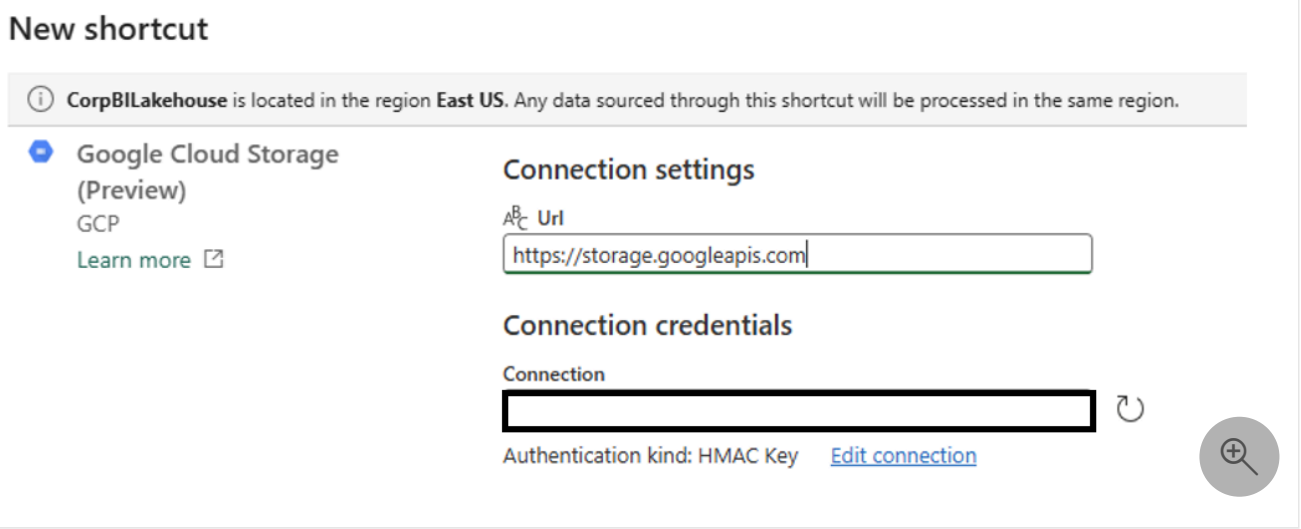
6. When the Data Map scan finishes, your data asset appears in Unified Catalog.

7. Associate the asset with a data product for curation and data quality assessment.



8. In Unified Catalog, configure and run a data quality scan or run data profiling as usual.

Set up a Google Cloud Storage (GCS) shortcut



To create a Google Cloud Storage shortcut and scan it for data quality, you need the storage URL and HMAC access key credentials. Complete the following steps:

1. Select **New shortcut** in the Fabric workspace.

2. Select **Google Cloud Storage** and add the URL, access key ID, and access key shortcut.

3. Add the connection URL and storage details.

4. Preview the shortcut in your Fabric workspace.

5. Start a Data Map scan of your Google Cloud Storage resource. Use service principal or managed identity authentication.

6. When the Data Map scan finishes, your data asset appears in Unified Catalog.

7. Associate the asset with a data product for curation and data quality assessment.

8. In Unified Catalog, configure and run a data quality scan or run data profiling as usual.

Set up data quality for Google BigQuery (preview)

This article provides step-by-step guidance to register, scan, and configure data quality for Google BigQuery sources in Microsoft Purview Unified Catalog.

Supported capabilities

When scanning a Google BigQuery source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Projects and datasets.
  - Tables including the columns.
  - Views including the columns.
- Fetching static lineage on assets relationships among tables and views.

When setting up a scan, you can choose to scan an entire Google BigQuery project. You can also scope the scan to a subset of datasets matching the given names or name patterns.

Known limitations

Be aware of the following limitations when scanning Google BigQuery sources:

- Microsoft Purview only supports scanning Google BigQuery datasets in a US multiregional location. If a dataset is in another location (for example, "us-east1" or "EU"), the scan completes but no assets appear in Microsoft Purview.

- When you delete an object from the data source, the subsequent scan doesn't automatically remove the corresponding asset in Microsoft Purview.

Configure Data Map scan to catalog Google BigQuery data in Microsoft Purview

Register a Google BigQuery project

To register a Google BigQuery project in Microsoft Purview, complete the following steps:

1. In the Microsoft Purview portal, select **Data Map**, then select **Register**.

2. At **Register sources**, select **Google BigQuery**, then select **Continue**.
3. Enter a **Name** for the data source that appears in the catalog.
4. Enter the **ProjectID**. The ProjectID should be a fully qualified project ID. For example, `mydomain.com: myProject`.
5. Select a collection from the list.
6. Select **Register**.

Set up a Data Map scan for Google BigQuery project

To configure a Data Map scan for the registered Google BigQuery project, follow these steps:

1. Make sure a self-hosted integration runtime is set up. If the runtime isn't set up, use the steps in Google BigQuery connection prerequisites.

2. Navigate to **Sources**.

3. Select the registered BigQuery project.

4. Select **New scan**.

5. Enter these details:

    - **Name**: The name of the scan.
    - **Connect via integration runtime**: Select the configured self-hosted integration runtime.
    - **Credential**: While configuring BigQuery credential, make sure to:
        - Select **Basic Authentication** as the authentication method.
        - Provide the email ID of the service account in the **User name** field. For example, `xyz\@developer.gserviceaccount.com`.
        - Store the service account private key as a Key Vault secret (see the following steps).
    - **JDBC driver location**: Specify the path to the JDBC (Java Database Connectivity) driver on the machine where the self-hosted integration runtime is running. For example: `D:\Drivers\GoogleBigQuery`.
    - **Datasets to import**: Specify a list of BigQuery datasets to import. For example, `dataset1`; `dataset2`. When the list is empty, all available datasets are imported.
    - **Maximum memory (in GB)**: The required memory value depends on the size of the Google BigQuery project being scanned.

    Create a service account private key:

a. In the Google Cloud console navigation menu, select **IAM & Admin** > **Service Accounts**, then select a project.
b. Select the email address of the service account that you want to create a key for.
c. Select the **Keys** tab.
d. Select **Add key** > **Create new key**.
e. Choose JSON format.
f. Copy the entire JSON key file and store it as the value of a Key Vault secret.

6. Select **Test connection**.

7. Select **Continue**.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

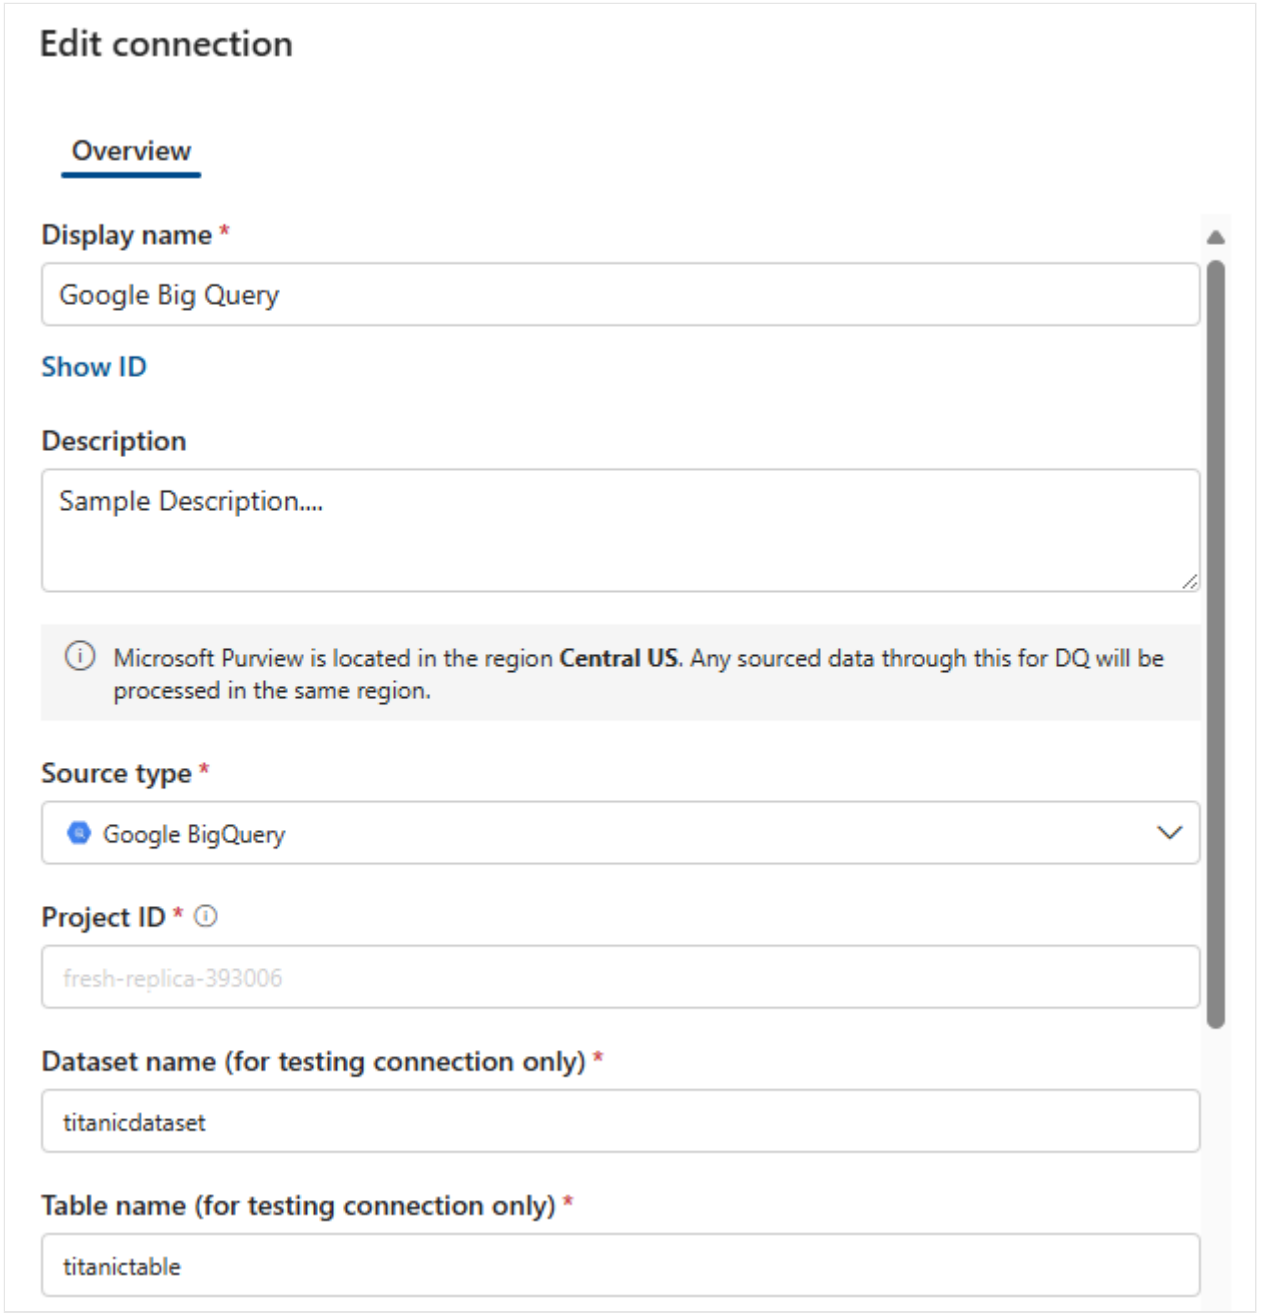
9. Review your scan and select **Save and Run**.

Once scanned, the data assets in Google BigQuery project are available in the Unified Catalog search. For more information, see how to connect and manage Google BigQuery in Microsoft Purview.

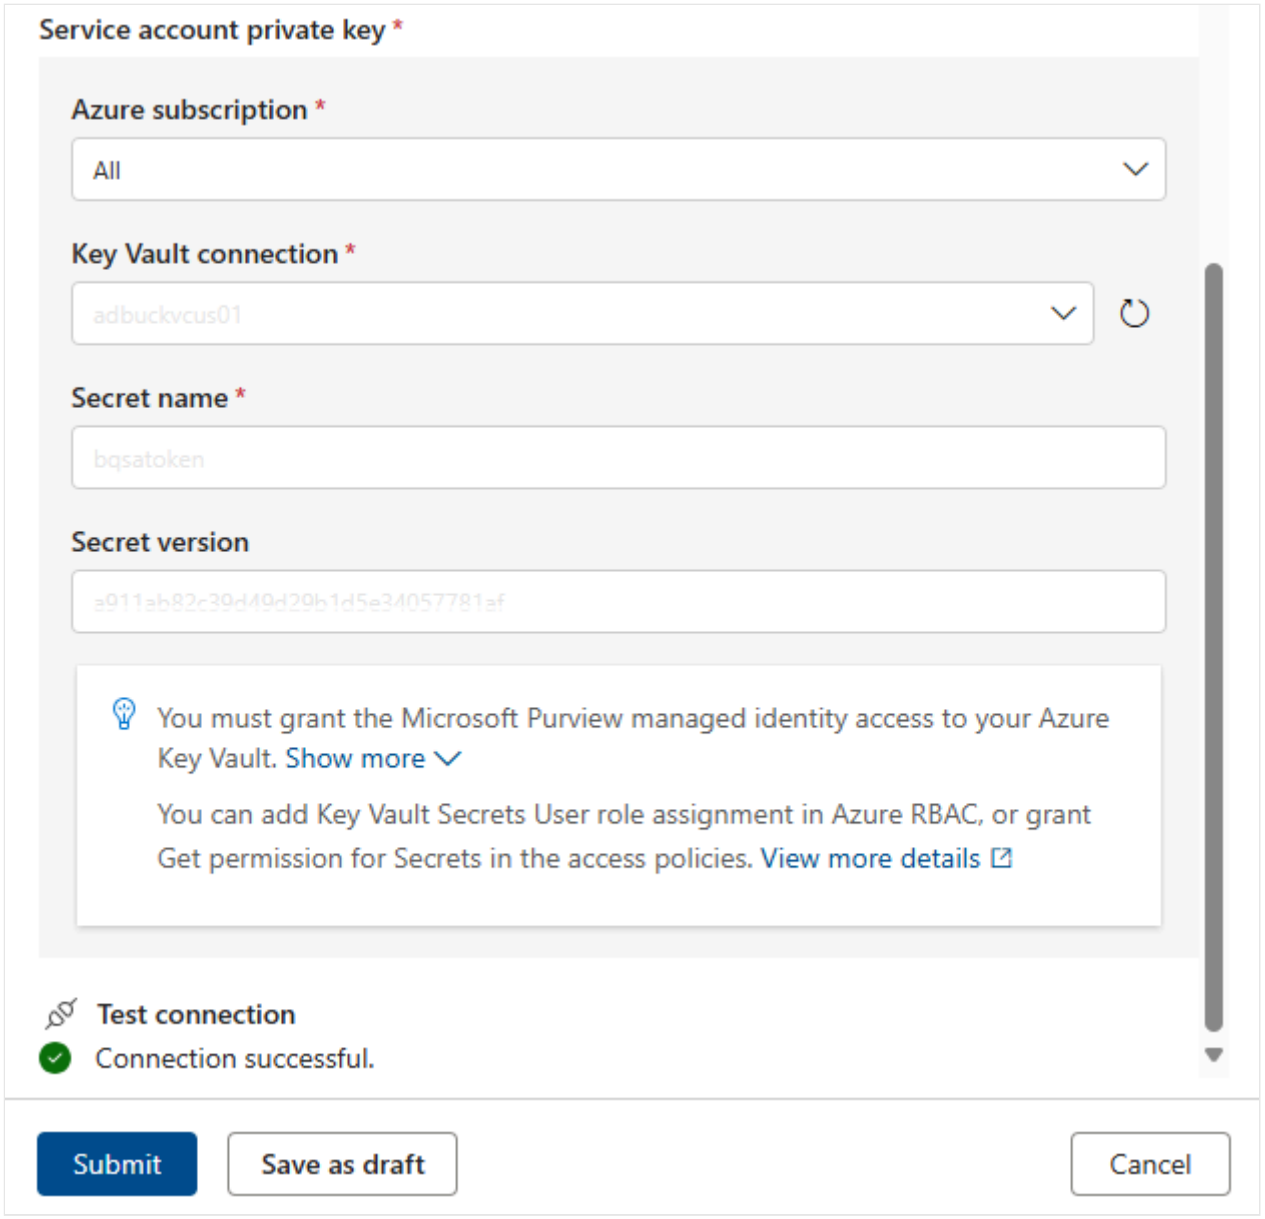
> ⓘ **Important**
>
> Deleting your scan doesn't delete catalog assets created from previous scans.

Set up connection to Google BigQuery project for data quality scan

The scanned assets are now ready for cataloging and governance. Associate the scanned assets to the data products in a governance domain to set up a data quality scan.



> ⓘ **Important**
>
> Data quality stewards need **read only** access to Google BigQuery to set up a data quality connection. Virtual network and private endpoint aren't supported for Google BigQuery data source yet for data quality scanning service.



1. In Unified Catalog, go to **Health management** > **Data quality**. Select a governance domain to open its details page, then select **Manage** to create a connection.

2. Set up the connection:

- Add connection name and description.
- Select source type **Google BigQuery**.
- Add **Project ID**, **Dataset name**, and **Table name**.
- Enter details at **Service account private key**:
  - Add the Microsoft Azure subscription.
  - Add the Microsoft Azure Key Vault connection.
  - Enter the **Secret name**.
  - Enter the **Secret version**.

3. Test the connection to make sure the data source connection is successfully configured.

Profiling and data quality scanning for data in Google BigQuery

After you set up the connection, you can profile your data, create and apply rules, and run a data quality scan for your data in Google BigQuery. Follow the step-by-step guidelines in the following articles:

- How to configure and run data profiling of your data
- How to configure and run data quality scan

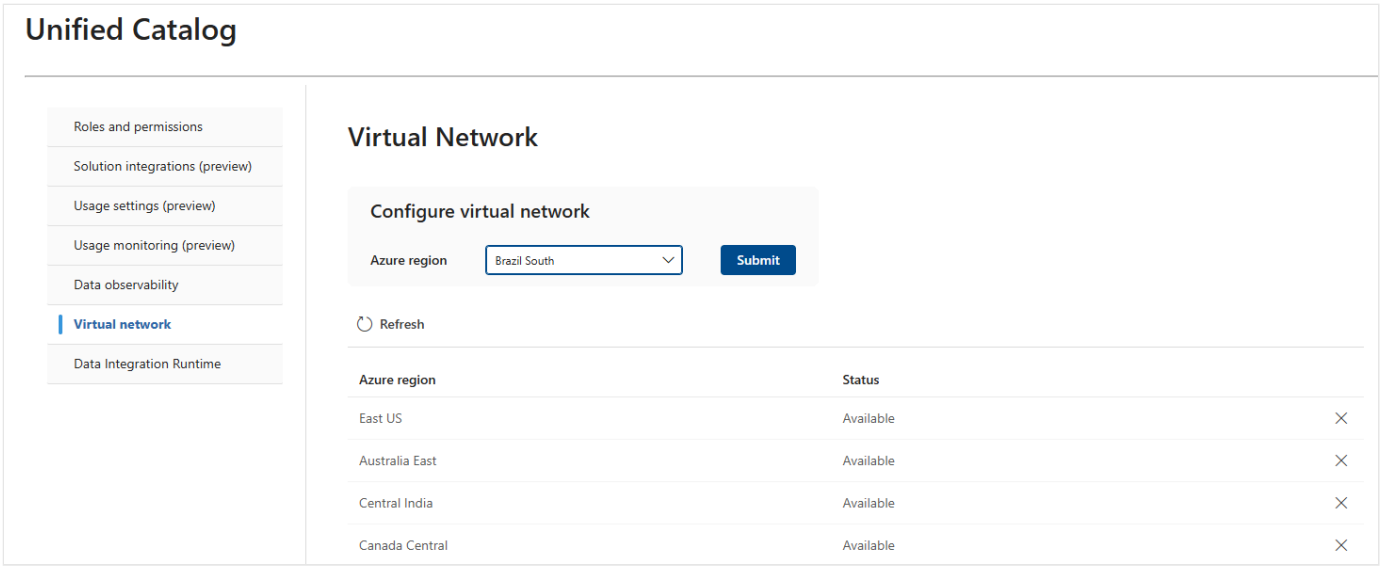
Set up managed virtual networks for data quality scans in virtual network storage

This article outlines the steps to create protected data source connections for data profiling and data quality scans in Microsoft Purview.

Virtual networks and private endpoints enhance the security and isolation of Azure resources. Virtual network protected endpoints let you access Azure services while keeping traffic on the Azure backbone network. Private endpoints go further by assigning a private IP address in your virtual network, so all traffic stays within the network and doesn't use the public internet. Virtual network protected endpoints and private endpoints are essential when security and network isolation are critical, because they minimize exposure to threats from the public internet.

Review user permission requirements



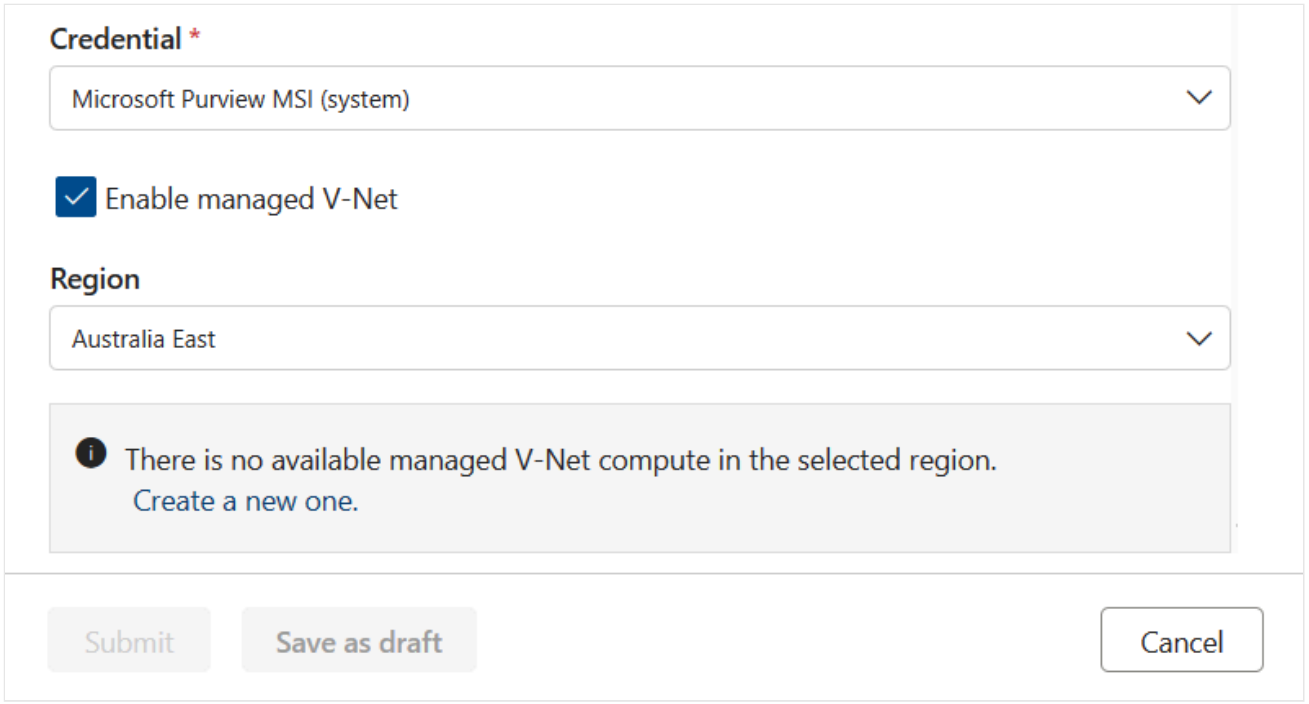
You need the following permissions to set up managed virtual networks for data quality:

- Compute provision – Governance Domain Owner
- Managed private endpoint creation - Governance Domain Owner
- Private endpoint approval – Owner of the Azure storage source

> **⊗ Caution**
>
> Compute and managed private endpoint connections are shared across all governance domains in the same Purview account. These connections are shared per region and data source.

Manage virtual network provisioning

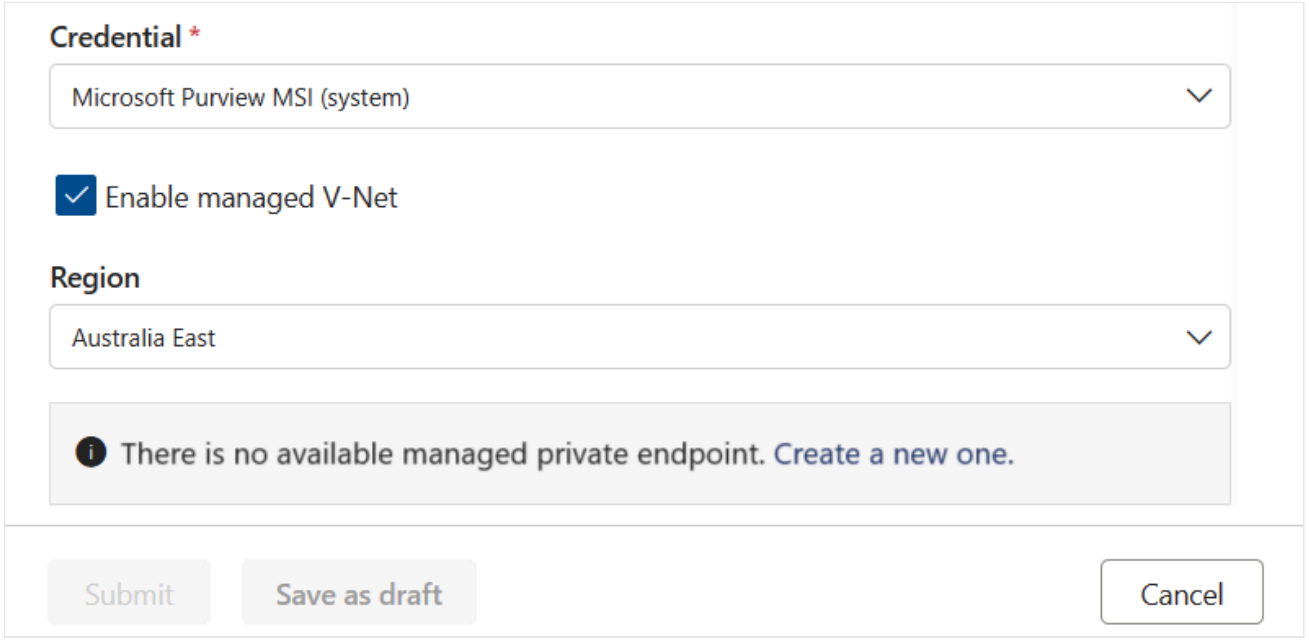
Data Governance Administrators can provision a virtual network compute location in supported Azure regions. To provision a compute location, go to **Settings** > **Unified Catalog** > **Virtual network** in the Unified Catalog Admin page. Select a region from the **Region** dropdown. Regions that are already set up are greyed out.



Deleting a configured region removes all associated data quality connections linked to that region's virtual network across business domains. To delete a region, select **X** on the region's row. You can't delete a region while it's being provisioned. Provisioning has three stages: Provisioning, Completed, and Available.

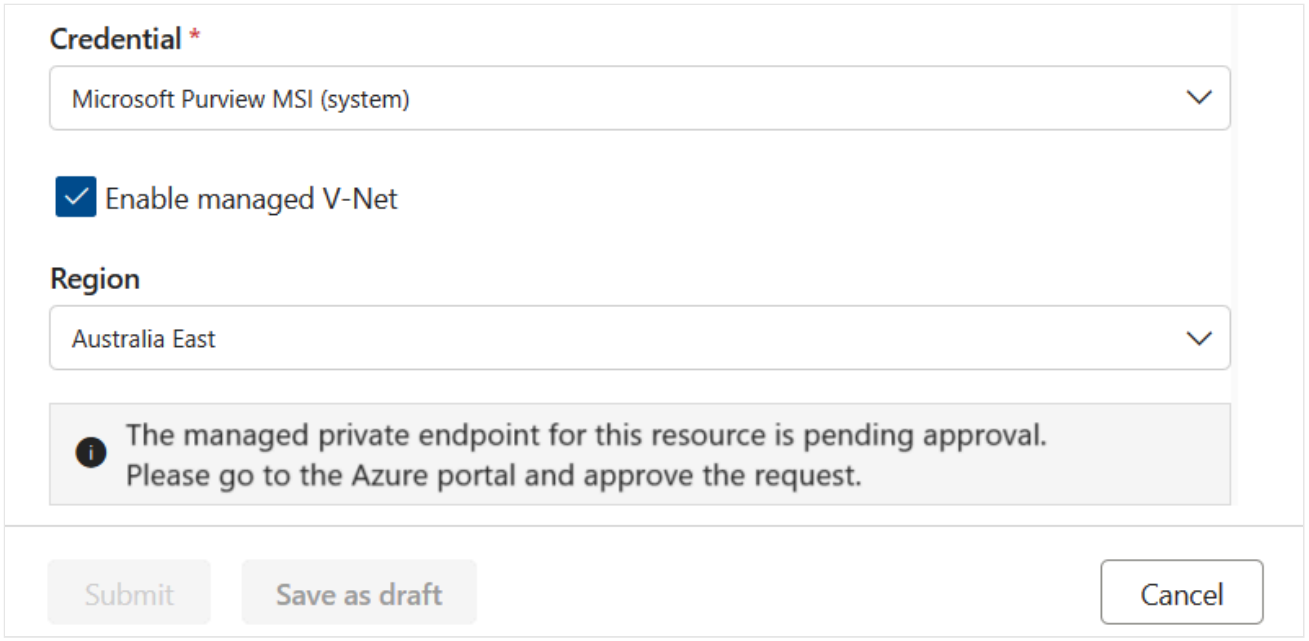
Configure a data quality managed virtual network

Configure a data quality managed virtual network by creating a connection to a protected data source.

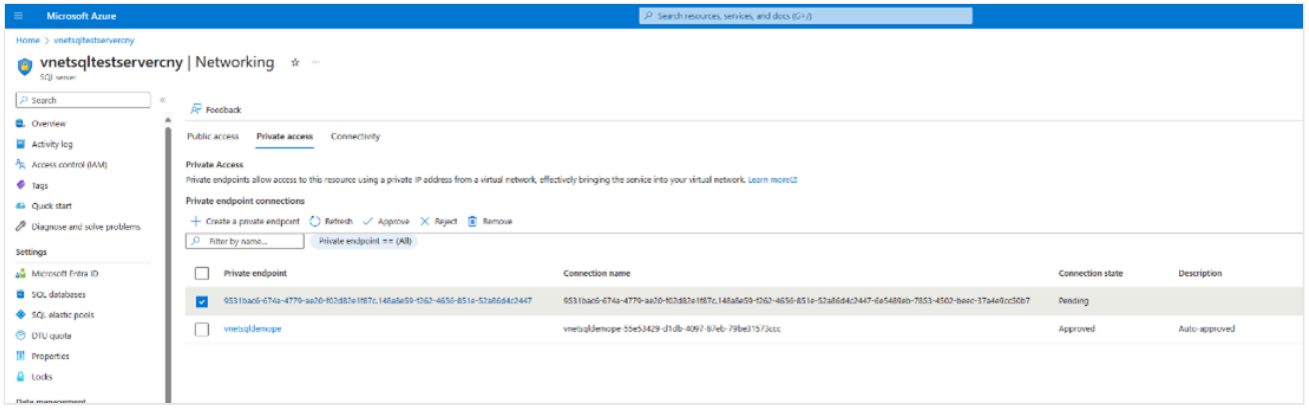


1. In the Microsoft Purview Unified Catalog, select **Health Management**, and then select **Data quality**.
2. Select a governance domain from the list.
3. From the **Manage** dropdown list, select **Connections** to open the connections page.
4. Select the **New** tab to create a new connection for the data products and data assets in your governance domain.
5. In the connection page, add a display name and description, and select the data source type.
6. Add other data source details like **Subscription** and **Storage Account** name or **Server Name** and **database name**, depending on the source.
7. Select the **Enable managed V-Net** checkbox.
8. Select the region where the data source is housed.

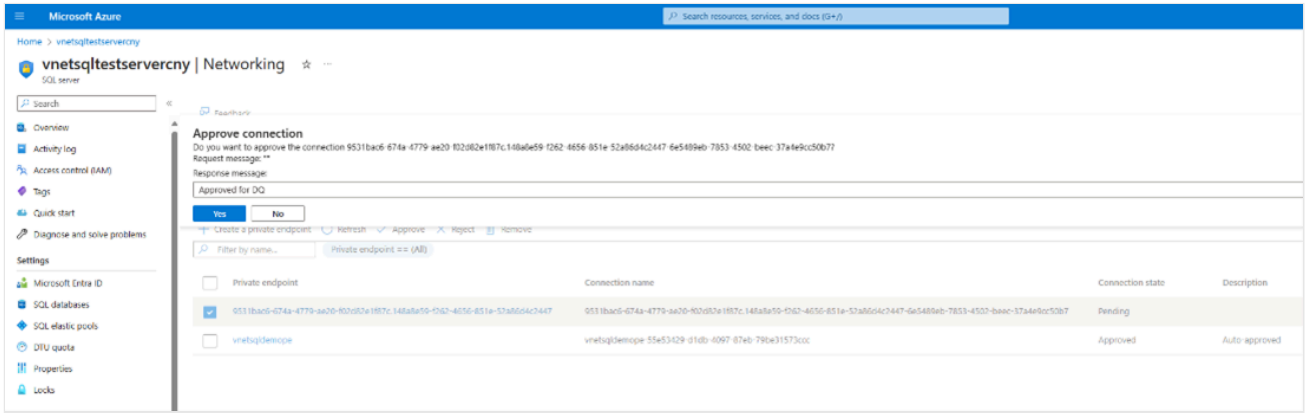
9. Purview Data Quality checks if a compute infrastructure already exists for the account in that region. If not, you're prompted to create a new **virtual network dedicated compute**.



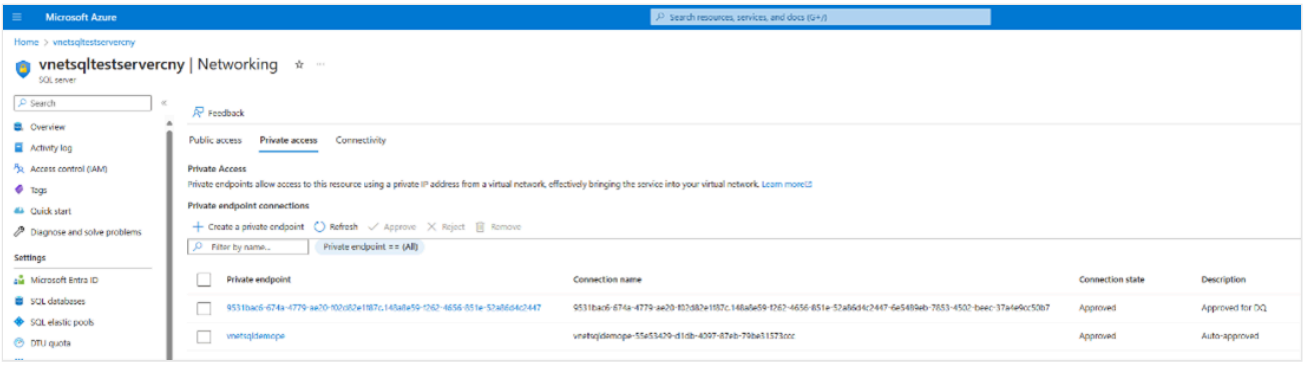
> **Tip**
>
> Provisioning compute can take up to 10 minutes. After requesting compute provisioning, you can save the connection creation request in draft mode and edit it later.



10. After the compute is provisioned, data quality checks if a **private endpoint** connection to the asset already exists. If not, you're prompted to create a private endpoint connection.

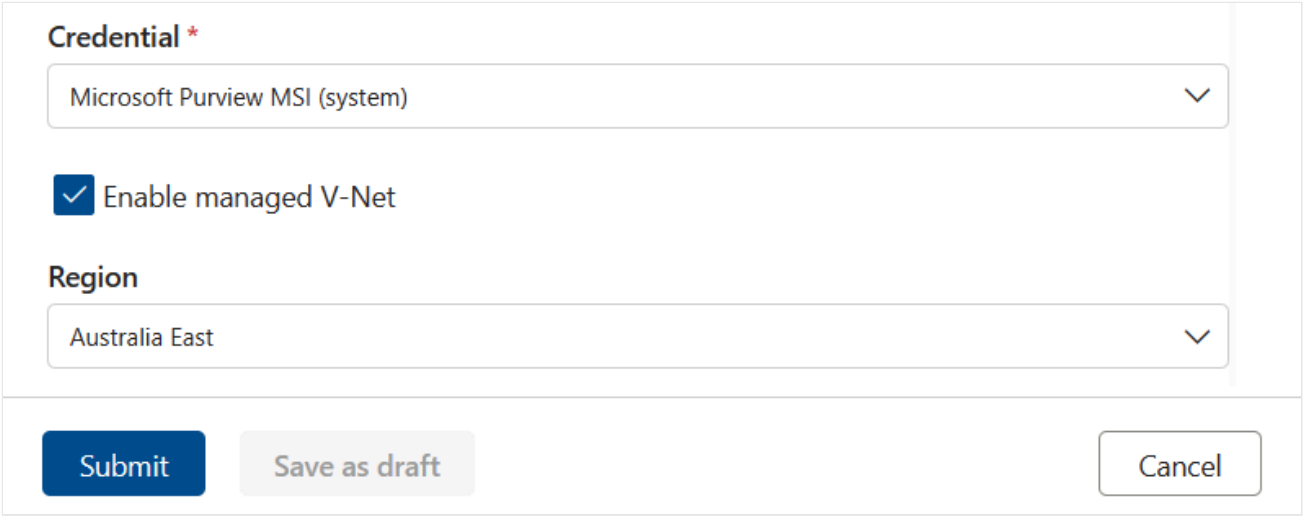


11. After the private endpoint is created, or if a private endpoint already exists but wasn't approved, you're prompted to approve the private endpoint connection request.



12. To approve this request, go to the Networking tab in Storage Account or SQL Server. Select the **Private access** tab, select a pending connection, and select **Approve**.

13. Select **Yes** to approve the connection.



14. The request now shows as **Approved**.

> **Tip**
>
> After you request the private endpoint connection, you can save the connection as a draft and resume after the request is approved.

15. After the private endpoint connection is created and approved, submit the connection.

> **Caution**
>
> Test connection isn't currently supported for virtual network protected assets.

16. After the connection is completed, you can run data quality jobs as usual against the virtual network protected assets.

> **Note**
>
> Virtual Network currently supports only these data sources:
>
> - **Azure Data Lake storage**
> - **Azure SQL**

- **Synapse serverless and Synapse Data Warehouse**
- **Azure Databricks**
- **Snowflake**
- **Microsoft Fabric OneLake (in tenant level)**
- **Azure SQL Managed Instance (SQL MI)**

Set up data source-specific connections

To set up virtual network connections for specific data sources, see the following resources:

- Data quality for Azure Databricks UC
- Data quality for Azure Synapse serverless and data warehouse
- Data quality for Snowflake data
- Data quality for Fabric Lakehouse

For Azure SQL and Data Lake storage, follow the steps in Configure a data quality managed virtual network.

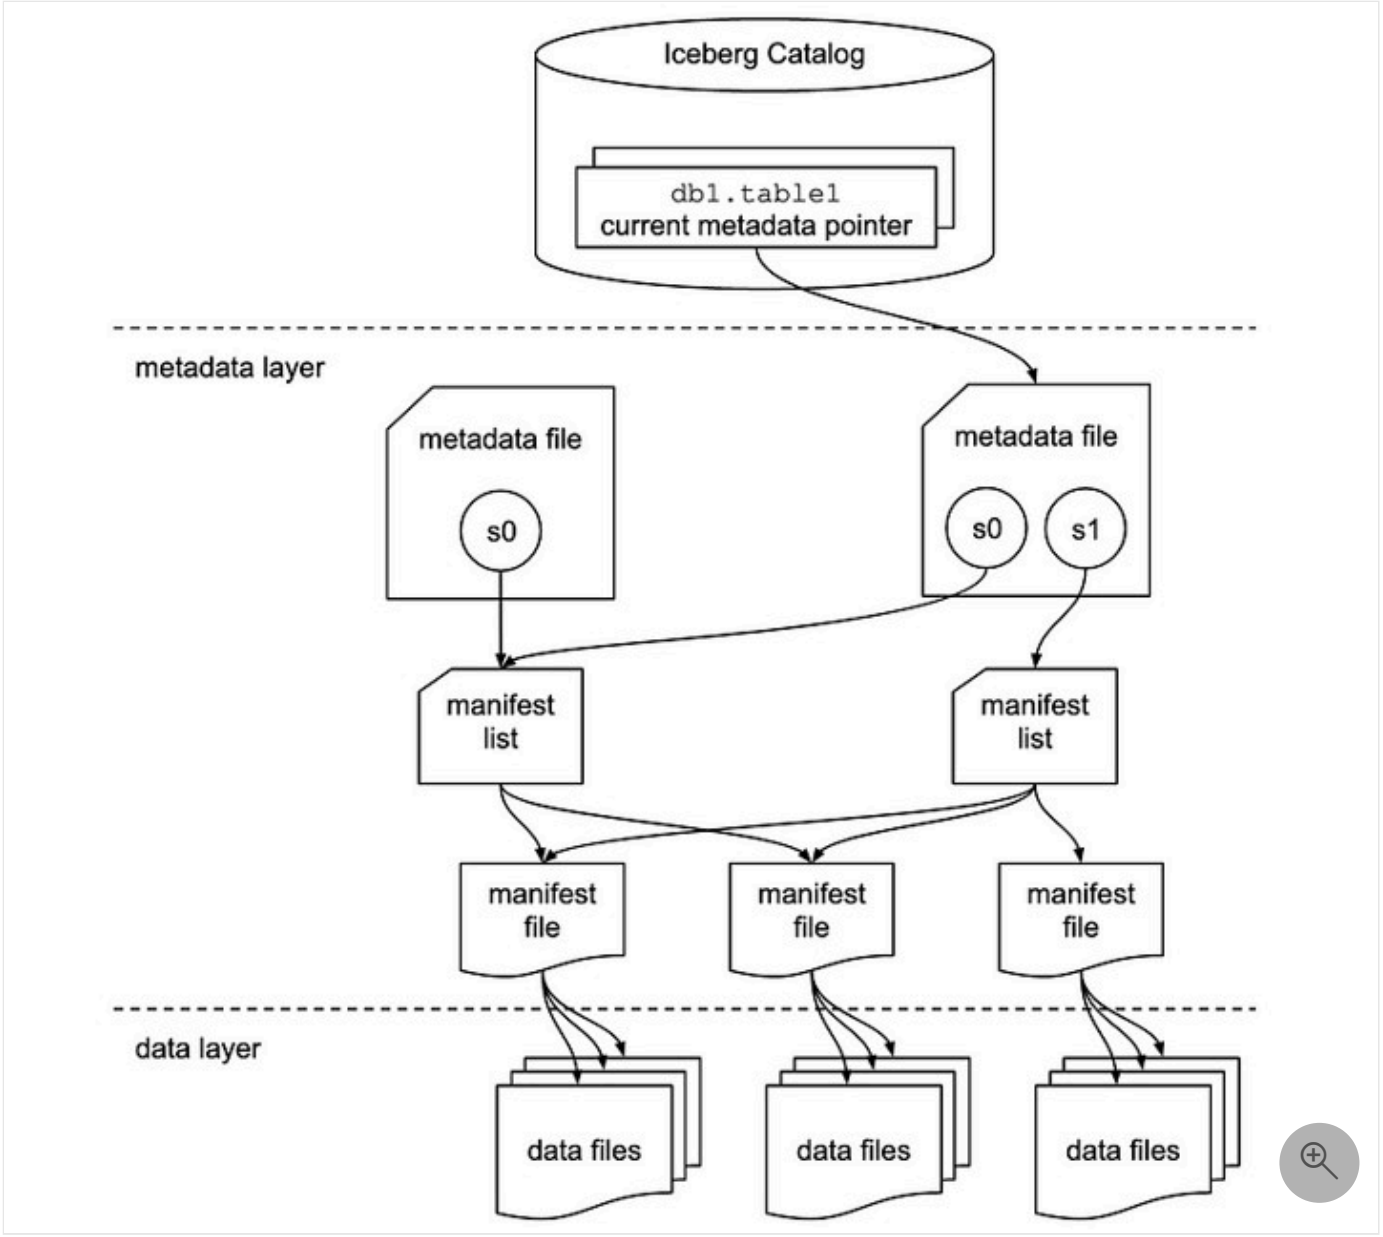
Import a schema for data quality

If the data type in a schema is undefined, incorrectly defined, or changed in the source, your data quality job might fail. If the job fails, re-import the schema by using the schema import capability. You can import schemas for data sources on both public networks and those behind private endpoints. For supported data sources, see Configure a data quality managed virtual network. To import a schema from your data sources, follow these steps:

- In Unified Catalog, under **Health Management**, select **Data quality**.
- Select a business domain, then select a data product, then select a data asset from that data product. You arrive at the data quality overview page.
- Select **Schema**, then select the **Schema management** toggle.
- Select **Import schema** to import the schema.

Last updated on 06/05/2026

Data quality native support for Iceberg format (preview)



Microsoft Purview supports data quality assessment on Apache Iceberg data assets. You can curate, govern, and scan Iceberg data on these storage sources:

- Azure Data Lake Storage Gen2
- Microsoft Fabric Lakehouse
- Amazon Web Services (AWS) S3
- Google Cloud Platform (GCP) Cloud Storage (GCS)

This article explains the Iceberg file structure, shows how to set up data quality scans, and lists tips for each catalog and storage type.

Iceberg file structure

An Iceberg table is more than just a collection of data files. It includes various metadata files that track the state of the table and facilitate operations like reads, writes, and schema evolution. An Iceberg table includes a catalog, a metadata layer, and a data layer. The data files in an Iceberg table are typically stored in columnar formats like Apache Parquet, Apache Avro, or Apache Optimized Row Columnar (ORC). These files contain the actual data that users interact with during queries.

Catalog layer overview

The Iceberg catalog sits at the top of the hierarchy. It stores the current metadata pointer for each table. The catalog enables tracking the most recent state of a table by referencing the current metadata file.

Metadata layer overview

The metadata layer is central to Iceberg's functionality. It includes these key elements:

- **Metadata file:** Contains information about the table's schema, partitioning, and snapshots. In the diagram, s0 refers to a snapshot, a record of the table's state at a given point in time. If multiple snapshots exist (such as s0 and s1), the metadata file tracks both.
- **Manifest list:** Points to one or more manifest files. A manifest list acts as a container of references to these manifests. It helps Iceberg manage which data files should be read or

written during different operations. Each snapshot might have its own manifest list.

Data layer overview

In the data layer, the manifest files act as an intermediary between the metadata and the actual data files. Each manifest file points to a collection of data files, providing a map of the physical files stored in the data lake.

- **Manifest files**: Store the metadata for a group of data files, including row counts, partition information, and file paths. They allow Iceberg to prune and access specific files quickly.
- **Data files**: Contain the actual data, stored in formats like Parquet, ORC, or Avro. Iceberg organizes data files based on partitions, which minimizes unnecessary data scans during query execution.

How Iceberg components work together

When you query or update data, Iceberg looks up the table's metadata file via the catalog. The metadata file references the current snapshot (or multiple snapshots). Each snapshot points to a manifest list, which references manifest files. The manifest files list the data files. This layered lookup lets Iceberg manage large datasets while keeping reads and writes consistent. Readers and writers always see a coherent table state. The snapshot-based design also enables time travel (querying earlier table states) and schema evolution.

The same layered approach boosts performance for batch and streaming operations. Only the needed data files are read, and updates use snapshots without changing the full dataset.

Iceberg data in OneLake

> **Important**
>
> Iceberg data in AWS S3 and GCS also needs to be auto synced as Delta to curate, govern, and to measure and monitor data quality.

You can seamlessly consume Iceberg-formatted data across Microsoft Fabric with no data movement or duplication. Use OneLake shortcuts to directly point to a data layer.

Iceberg data is stored in OneLake and written using Snowflake or another Iceberg writer. OneLake virtualizes the table as a Delta Lake table, which ensures broad compatibility across Fabric engines. For example, you can create a volume in Snowflake and point it directly to the

Fabric Lakehouse. Once the Iceberg table is created in OneLake, autosync reflects data updates in real time. Get further details in Configure an Iceberg external volume for Azure in the Snowflake documentation.

Data quality for Iceberg data

For all users natively hydrating data in Iceberg on Parquet, ORC, or Avro on Data Lake Storage Gen2 or Fabric Lakehouse, configure a scan pointing to the location of the directory hosting the data and metadata Iceberg directories. To configure Iceberg data quality support, complete these steps:

1. Configure and run a scan in Microsoft Purview Data Map.
2. Configure the directory hosting data and metadata as a data asset and associate it to a data product. Associating the directory as a data asset and linking it to a data product forms the Iceberg dataset. Learn to associate data assets to a data product.
3. In Unified Catalog, under **Health management** select **Data quality** view to find your Iceberg files (data asset) and to set up data source connection.
   a. To set up a Data Lake Storage Gen2 connection, follow the steps in Set up data source connection for data quality.
   b. To set up a Fabric OneLake connection, follow the steps in Set up data quality for Fabric Lakehouse data.
4. On the **Schema** page of the selected Iceberg file (data asset), select **Import schema** to import the schema from the data source.
5. On the Iceberg file's **Overview** page, at the **Data asset** dropdown menu, select **Iceberg**.
6. Apply data quality rules, and run data quality scans for column- and table-level data quality scoring.

Profiling and data quality scanning

> **Important**
>
> Before you run data profiling or data quality scans, you need to retrieve and set the schema from the Data Quality Schema page. Consumers don't see the schema in the data asset view because Data Map doesn't yet support the Iceberg open table format. Data Quality stewards can import the schema from the Data Quality schema page.

After you finish the connection setup and data asset file format selection, you can profile your data, create and apply rules, and run a data quality scan of your data in Iceberg open format files.

For step-by-step guidance, see the following articles:

- Configure and run data profiling for a data asset
- Configure and run a data quality scan

> **Important**
>
> Support for the Iceberg open format in catalog discovery, curation, data profiling, and data quality scanning features is in **preview**.

Current limitations for Iceberg data quality

The current preview release of Microsoft Purview supports data created in Iceberg format with **Apache Hadoop** catalog (a file-based catalog implementation) only. Snowflake catalog scenarios are supported only through Delta virtualization using OneLake shortcuts.

Lakehouse Path and Data Lake Storage Gen2 Path

- Iceberg Metadata stores the complete path for the data and metadata. Ensure you use the complete path for Data Lake Storage Gen2 and Fabric Lakehouse. Additionally for Fabric Lakehouse path during the write, ensure operating (WRITES, UPSERTS) with the ID paths. The following example shows the required ABFSS path format. Replace `<filesystem-ID>` and `<lakehouse-ID>` with your actual GUIDs:

  ```text
  abfss://<filesystem-ID>@onelake.dfs.fabric.microsoft.com/<lakehouse-ID>/Files/CustomerData
  ```

- Filesystem as ID and Lakehouse as ID. Absolute and not relative paths are necessary for Microsoft Purview to perform data quality on Iceberg. To validate, ensure you check the snapshots path to point as complete Fully Qualified Name (FQN) paths.

Schema detection

- Data Map can't detect the Iceberg schema. When curating the Iceberg directories on Fabric Lakehouse or Data Lake Storage Gen2, you can't review the schema. However, the data quality fetch schema can pull up the schema for the curated asset.

Recommendations for Iceberg data quality configuration

Choose the approach that matches your catalog and storage:

Expand table

Source/Catalog	Storage	Approach	Supported formats
Snowflake Catalog	Data Lake Storage Gen2, AWS S3, or GCP GCS (VOLUME)	Use a Fabric OneLake Table shortcut. Run data quality as a Delta table.	Parquet only
Hadoop catalog	Data Lake Storage Gen2	Scan the directory directly. Use the Iceberg engine for data quality.	Parquet, ORC, Avro
Snowflake	Fabric Lakehouse (VOLUME pointed to Lakehouse)	Use OneLake Table to create a Delta-compatible version.	Parquet only
Hadoop catalog	Fabric Lakehouse	Scan the Lakehouse directory directly. Use the Iceberg engine for data quality.	Parquet, ORC, Avro

Set up data quality for Snowflake data

This article walks you through how to register a Snowflake source, run a Data Map scan, and configure a data quality connection in Microsoft Purview Unified Catalog. After you complete these steps, you can profile your Snowflake data and run data quality scans.

Supported Snowflake metadata

When you scan Snowflake data sources, Microsoft Purview extracts technical metadata. The scan captures the following objects:

- Servers, databases, schemas, and tables
- Views, foreign keys, and unique constraints
- Stored procedures and their parameters
- Functions and their parameters
- Pipes, stages, and streams
- Tasks and sequences

Register a Snowflake source in Data Map

To register a new Snowflake source in Microsoft Purview Unified Catalog, follow these steps:

1. Sign in to the Microsoft Purview portal.
2. Select the **Data Map** solution card. If the **Data Map** solution card isn't displayed, select **View all solutions** and then select **Data Map** from the **Core** section.
3. Select **Register**.
4. On **Register sources**, select **Snowflake**.

Set up a Data Map scan

To set up a scan for your registered Snowflake source, follow these steps:

1. Select the registered Snowflake source.
2. Select **New scan**.
3. Provide the following details:

    - Name: The name of the scan.

- Connect via integration runtime: Select the autoresolved integration runtime, Managed Virtual Network IR, or SHIR for your scenario.
- Host for connection: Select the server URL or another host you configured in the data source.
- Credential: Select the credential for your data source. Use Basic Authentication, provide the Snowflake user name, and store the password in the secret key.
- Warehouse: Specify the warehouse name in uppercase. The credential's default role must have USAGE rights on this warehouse.
- Databases: Specify one or more database names in uppercase, separated by semicolons (for example, `DB1;DB2`). The credential's default role must have rights on these database objects.
- Schema: List the schemas to import, separated by semicolons.

4. Select **Test connection** to validate the settings (available when using Azure Integration Runtime).
5. Select **Continue**.
6. Select a scan rule set for classification. You can choose between the system default, existing custom rule sets, or create a new rule set inline.
7. Review your scan and select **Save and Run**.

After the scan finishes, the data asset in Snowflake is available on the Unified Catalog search. For more information about how to connect and manage Snowflake in Microsoft Purview, see Connect to and manage Snowflake in Microsoft Purview.

> ⓘ **Important**
>
> When you delete the object from the data source, the subsequent scan doesn't automatically remove the corresponding asset in Microsoft Purview.

Set up a Snowflake data quality connection

After the scan completes, the scanned asset is ready for cataloging and governance. To run data quality scans on the asset, set up a Snowflake connection in Microsoft Purview.

> ⓘ **Important**
>
> - Data quality stewards need **read only** access to Snowflake to set up the data quality connection.

- The Snowflake connector doesn't accept **https://**. Remove **https://** when you add the server name to configure the data source connection.
- If you disable public access, you need to select **Allow trusted Microsoft services** for Key Vault. This requirement applies only to Key Vault, not to your Snowflake workspace.

1. In the Microsoft Purview portal, open **Unified Catalog**.

2. Under **Health management**, select **Data quality**.

3. Select a governance domain from the list, then select **Connections** from the **Manage** dropdown list.

4. Configure the connection on the **Connections** page:

    - Add a connection name and description.
    - Select source type **Snowflake**.
    - Add the server name, warehouse name, database name, schema name, and table name.
    - Select an authentication method: **Basic**, **Private key (preview)**, or **OAuth (preview)**.
    - Add the user name.
    - Add credentials: Azure subscription, Key Vault connection, secret name, and secret version.
    - Select **Enable managed VNet** if your Snowflake instance runs on Azure Virtual Network, then add the Azure region, Private Link Resources ID, and Fully Qualified Domain Name.

5. Test the connection to make sure it works. If you're using Virtual Network, the test connection feature isn't supported.

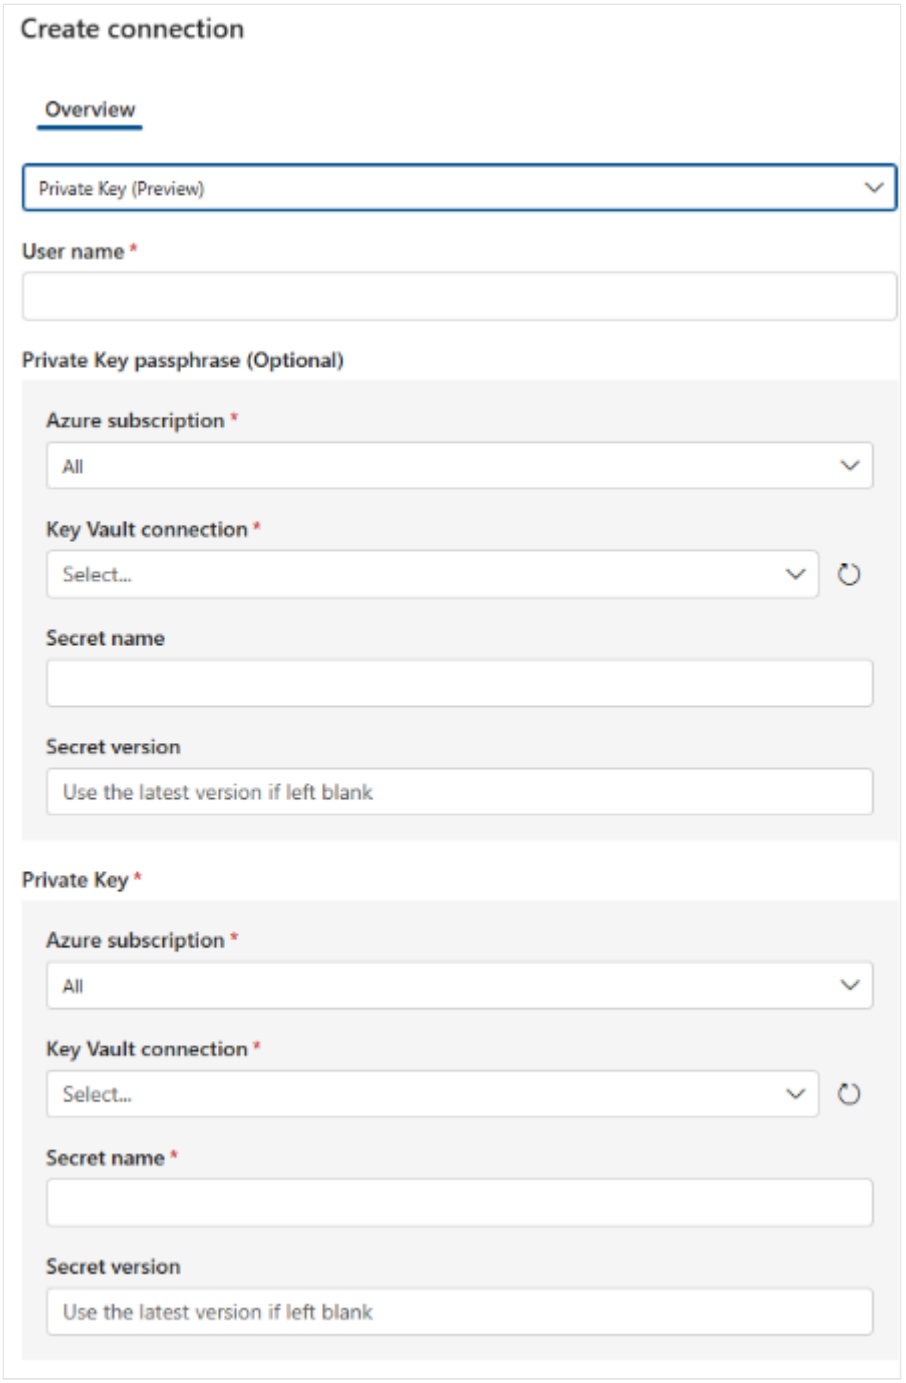
The resource ID for the target Snowflake private link has the following format: `/subscriptions/(subscription_id)/resourcegroups/az(region)-privatelink/providers/microsoft.network/privatelinkservices/sf-pvlinksvc-az(region)`.

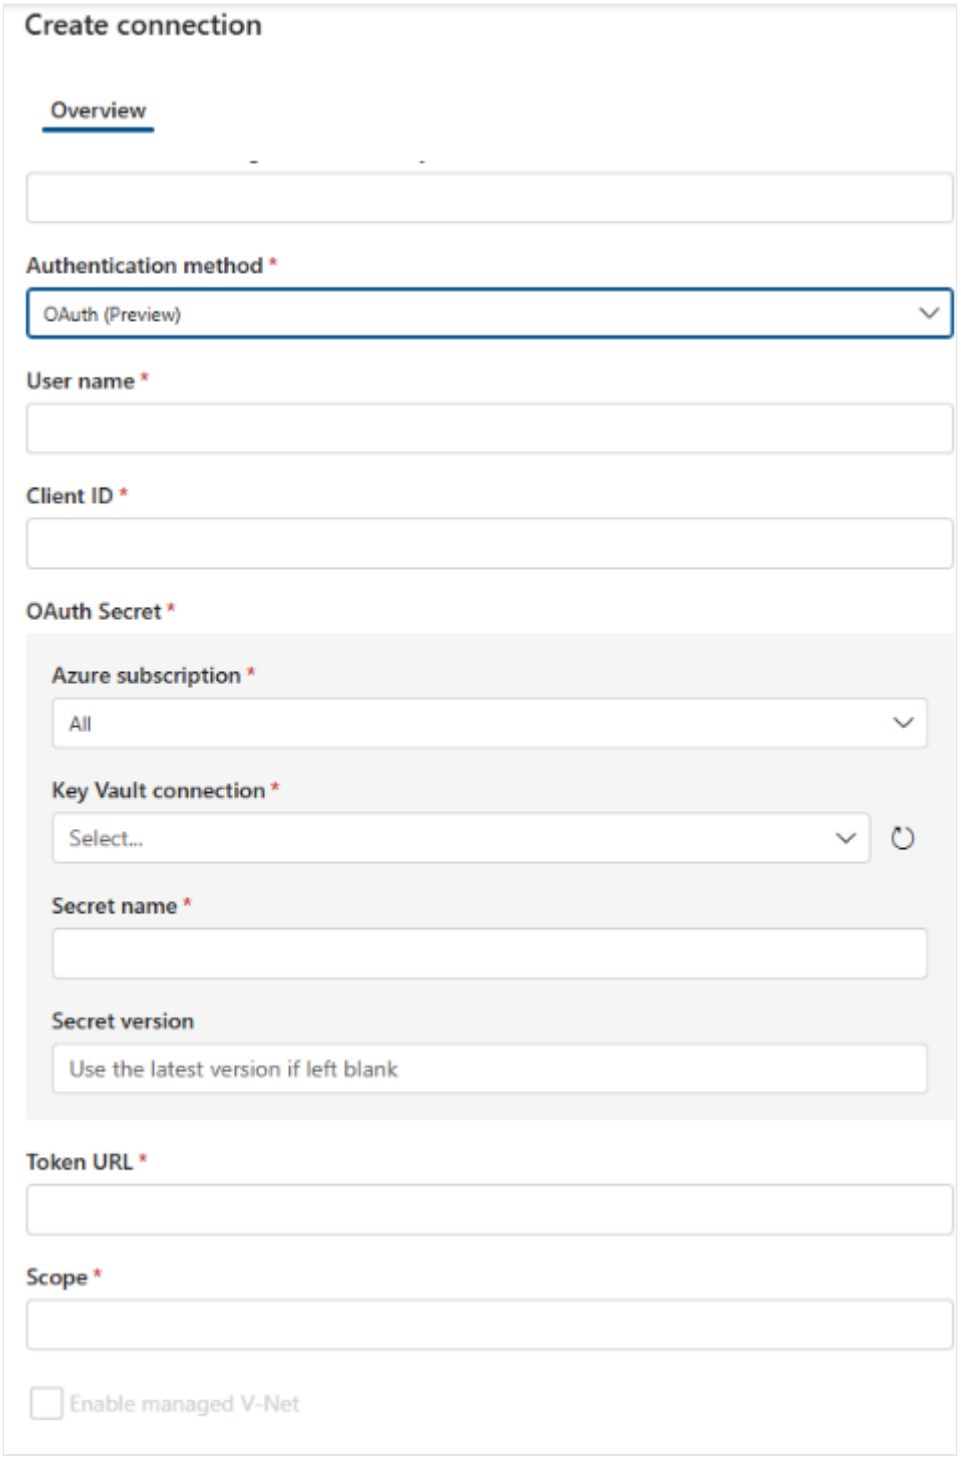


- To obtain region-ID and fully qualified name, run `SYSTEM_WHITE_LIST` and `SYSTEM_WHITE_LIST_PRIVATELINK` to get the `SNOWFLAKE_DEPLOYMENT`, `SNOWFLAKE_DEPLOYMENT_REGIONLESS`, and `OCSP_CACHE` values for public and allow list hosts.
- To obtain Subscription ID, run `SYSTEM$GET_SNOWFLAKE_PLATFORM_INFO()` as `ACCOUNTADMIN` to obtain the **snowflake-vnet-subnet-ids** values. The Subscription ID for the Private Link of the Snowflake Azure tenant is obtained from the **snowflake-vnet-subnet-ids** output.

Private key authentication (preview)

You can create private keys with or without a passphrase by using OpenSSL, a command-line tool for generating cryptographic keys. If you generate a private key with a passphrase, configure both the key and passphrase with the connection as shown in the following screenshot. If you don't provide a passphrase during key generation, omit it in the connection.

The private key generated through the **openssl** command contains `headers/footers` that indicate the beginning and ending of the `key/encrypted` key. Save the entire contents of the file, including headers and new lines, as-is in the Key Vault as the secret value. You can use a command-line tool such as Azure CLI to do this. Without the private key file headers, footers, and original newline formatting, authentication with Snowflake fails.



For security, rotate your keys regularly. When you rotate a key, update it in Key Vault and in the Microsoft Purview connection. New jobs use the updated key. Keep the older key active until any in-progress jobs complete.

OAuth authentication (preview)

You can configure an OAuth-based connection by using Microsoft Entra ID as the OAuth provider. OAuth access tokens are typically short-lived. But data quality assessment jobs can run for a long time, depending on data volume. Set the OAuth access token lifetime to at least six hours, which is the average maximum job duration. Jobs fail if the access token expires before the job completes.

If you can't increase the access token lifetime, or if your policy doesn't allow it, use key-pair-based authentication because key-pair auth doesn't have token lifetime constraints.

Sample values for the OAuth connection parameters:

- User name: DB41C9CD-96E7-47B0-ADB6-0A4D080229A0 (Value of `login_name` property of Snowflake)
- Client ID: 632ce887-41bb-4975-b6a9-ae798bf41956 (Client ID from Azure portal)
- Token URL: `https://login.microsoftonline.com/ddfd8861-7cbd-43df-ad13-4f9e958cf53b/oauth2/v2.0/token (Token URL from Azure app)`
- Scope: `api://d682fa4a-d784-4d28-93e2-7156ff129ae0/.default (Scope as registered with the Azure app)`

Understand connection selection

You don't explicitly choose connections when you start assessments or configure schedules. The system selects a connection automatically based on the following rules:

- If only user-password connections exist, the system selects the first one created.
- If key-pair or OAuth connections exist, the system ignores all user-password connections and selects the first key-pair or OAuth connection created.

The following illustration shows how the system selects a connection based on type and creation order.

Suppose there are only user-password-based connections:

- SnowflakeConnectionBob (User-password)
- SnowflakeConnectionAlice (User-password)
- SnowflakeConnectionEve (User-password)

The system selects the **SnowflakeConnectionBob** connection.

Suppose all types of connections exist and you created them in the following order:

- SnowflakeConnectionBob (User-password)
- SnowflakeConnectionAlice (Key-pair)
- SnowflakeConnectionCharlie (OAuth)
- SnowflakeConnectionEve (User-password)

In this case, the system ignores **SnowflakeConnectionBob** and **SnowflakeConnectionEve**. The system considers only the following connections for selection:

- SnowflakeConnectionAlice (Key-pair)
- SnowflakeConnectionCharlie (OAuth)

Typically, the system selects **SnowflakeConnectionAlice** for assessment and scheduled runs.

> **Important**
>
> After you create the request for a private endpoint connection, raise a support ticket with Snowflake support to approve the private endpoint connection. Provide the details of the managed private endpoint resource ID in this support ticket for the Snowflake team to approve.

> **Note**

Open Authorization (OAuth) and key pair authentication for Snowflake database connections will come. With these options, you can create multiple connections that each use a different authentication method. When multiple connections use different authentication mechanisms, the system picks the last created connection. For example, if you first create a key pair-based connection followed by an OAuth connection, the system picks the OAuth connection. If you want the key pair connection to be picked, you need to delete the OAuth connection. Contact your Microsoft account representative to preview the new Snowflake authentication model for Microsoft Purview data quality scans.

Next steps

After you set up the connection, you can profile your data, create and apply rules, and run a data quality scan. For step-by-step guidance, see the data profiling and data quality scan articles:

- Configure and run data profiling
- Configure and run a data quality scan

Configure and run data profiling for a data asset

Data profiling is the process of examining the data available in different data sources and collecting statistics and information about this data. Data profiling helps you assess the quality level of the data according to a defined set of goals. If data is of poor quality, or managed in structures that can't be integrated to meet the needs of the organization, business processes and decision making suffer. Data profiling allows you to understand the trustworthiness and quality of your data, which is a prerequisite for making data-driven decisions that boost revenue and foster growth.

Prerequisites

- To run and schedule data quality assessment scans, your users must be in the data quality steward role.
- Currently, you can set the Microsoft Purview account to allow public access or managed virtual network access so data quality scans can run.

Data quality life cycle

Data profiling is the **fifth** step in the data quality life cycle for a data asset. The previous steps are:

1. Assign users(s) data quality steward permissions in Unified Catalog to use all data quality features.
2. Register and scan a data source in your Purview Data Map.
3. Add your data asset to a data product.
4. Set up a data source connection to prepare your source for data quality assessment.

Supported multicloud data sources

Browse the supported data source document to view the list of supported data sources, including file formats for data profiling and data quality scanning, with and without virtual network support.

> **Important**

Data quality for Parquet file is designed to support:

1. A directory with Parquet Part File. For example: **./Sales/{Parquet Part Files}**. The Fully Qualified Name must follow `https://(storage account).dfs.core.windows.net/(container)/path/path2/{SparkPartitions}`. Make sure not to have {n} patterns in directory or subdirectory structure; it must be a direct FQN leading to {SparkPartitions}.
2. A directory with Partitioned Parquet Files, partitioned by columns within the dataset like sales data partitioned by year and month. For example: **./Sales/{Year=2018}/{Month=Dec}/{Parquet Part Files}.**

Both of these essential scenarios, which present a consistent Parquet dataset schema, are supported. **Limitation:** It isn't designed to or won't support N arbitrary hierarchies of directories with Parquet files. **We recommend presenting data in (1) or (2) constructed structure.**

Supported authentication methods

Currently, Microsoft Purview can only run data quality scans by using Managed Identity as authentication option. Data quality services run on **Apache Spark 3.5** and **Delta Lake 3.2.1**. For more information about supported regions, see the data quality overview.

ⓘ Important

- If you update the schema on the data source, you need to import schema from data quality overview page by using **schema import feature** before running data profiling.
- Virtual network isn't supported for Google BigQuery.
- In the current version, you can profile 50 columns per batch. If your data asset has more than 50 columns, you can profile extra columns in more batches.
- Profiling is using random sample from the selected data asset, the sample size is 1 million records.
- If a column contains distinct value, don't profile that column. A column with distinct values can't create a normal distribution.

Steps to configure data profiling job

1. Configure a data source connection to the assets you're scanning for data quality if you haven't already done so.
2. From Microsoft Purview Unified Catalog, select **Health Management**, then select **Data quality**.
3. Select a **governance domain** from the list.
4. Select a **data product** to profile a **data asset** linked to that product.
5. Select a data asset to navigate into data quality **Overview** page for profiling.
6. Select **Profile** button to run profiling job for the selected data asset.
7. The AI recommendation engine suggests potentially important columns to run data profiling against. You can deselect recommended columns and/or select more columns to be profiled.
8. Once you've selected the relevant columns, select **Run Profile**.
9. While the job is running, you can track its progress from the data quality monitoring page in the governance domain.
10. When the job is complete, select the **Profile** tab from left menu of the asset's data quality page to list browse the profiling result and statistical snapshot. There could be several profile result pages depending on how many columns your data assets have.
11. Browse the profiling results and statistical measures for each column.

Understanding profiling results

- **Minimum**: Minimum length of the characters in the column.
- **Maximum**: Maximum length of the characters in the column.
- **Distribution**: Normal distribution of your data.
- **Unique values**: Values that don't repeat; they're unique.
- **Duplicate values**: Values that repeat more than once.
- **Empty/blank values**: The column is blank or empty.
- **Null**: Null values in the column.
- **Average**: Mid value or arithmetic average.
- **Standard deviation**: A statistical measure that quantifies the amount of variation or dispersion in a set of values.

- Data quality for Fabric Mirrored data sources
- Data quality for Fabric shortcut data sources
- Data quality for Azure Synapse serverless and data warehouses
- Data quality for Azure Databricks Unity Catalog
- Data quality for Snowflake data sources
- Data quality for Google BigQuery

Next steps

1. Set up data quality rules based on the profiling results, and apply them to your data asset.
2. Configure and run a data quality scan on a data product to assess the quality of all supported assets in the data product.
3. Review your scan results to evaluate your data product's current data quality.

Create data quality rules

Data quality measures the integrity of data in an organization. You assess data quality by using data quality scores. Microsoft Purview Unified Catalog generates scores based on the assessment of the data against rules that you define.

Data quality rules are essential guidelines that organizations establish to ensure the accuracy, consistency, and completeness of their data. These rules help maintain data integrity and reliability.

Here are some key aspects of data quality rules:

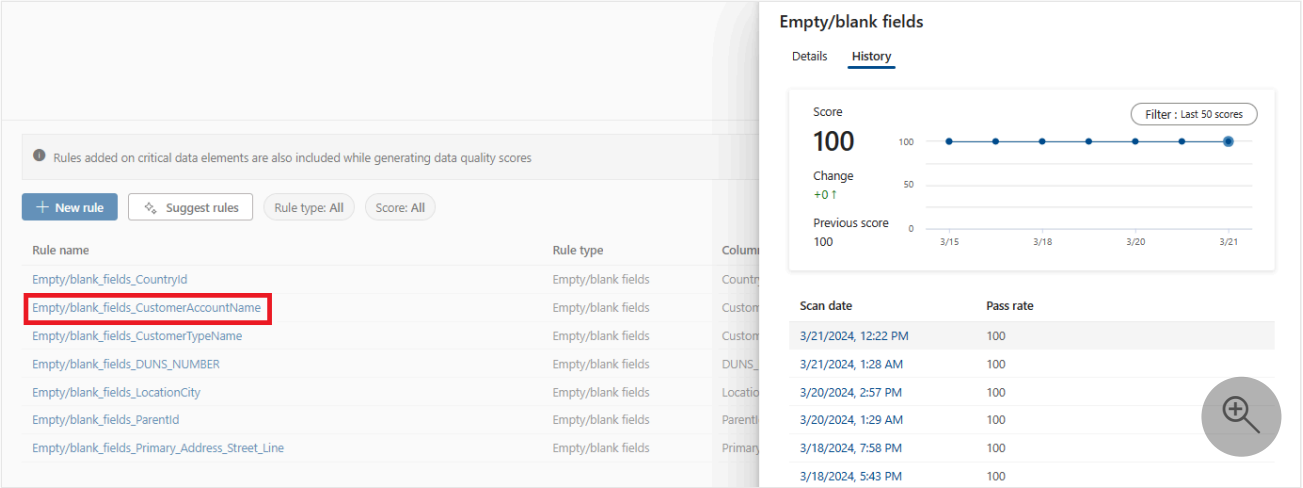
- **Accuracy**: Data should accurately represent real-world entities. Context matters! For example, if you're storing customer addresses, ensure they match the actual locations.
- **Completeness**: This rule identifies empty, null, or missing data. It validates that all values are present, though not necessarily correct.
- **Conformity**: This rule ensures that the data follows data formatting standards such as representation of dates, addresses, and allowed values.
- **Consistency**: This rule checks that different values of the same record conform to a given rule and that there are no contradictions. Data consistency ensures that the same information is represented uniformly across different records. For instance, if you have a product catalog, consistent product names and descriptions are crucial.
- **Timeliness**: This rule aims to ensure that the data is accessible in as short a time as possible. It ensures that the data is up to date.
- **Uniqueness**: This rule checks that values aren't duplicated. For example, if there's supposed to be only one record per customer, then there aren't multiple records for the same customer. Each customer, product, or transaction should have a unique identifier.

Data quality life cycle

Creating data quality rules is the **sixth** step in the data quality lifecycle. The previous steps are:

1. Assign users data quality steward permissions in Unified Catalog to use all data quality features.
2. Register and scan a data source in Microsoft Purview Data Map.

3. Add your data asset to a data product.
4. Set up a data source connection to prepare your source for data quality assessment.
5. Configure and run data profiling for an asset in your data source.



Required roles

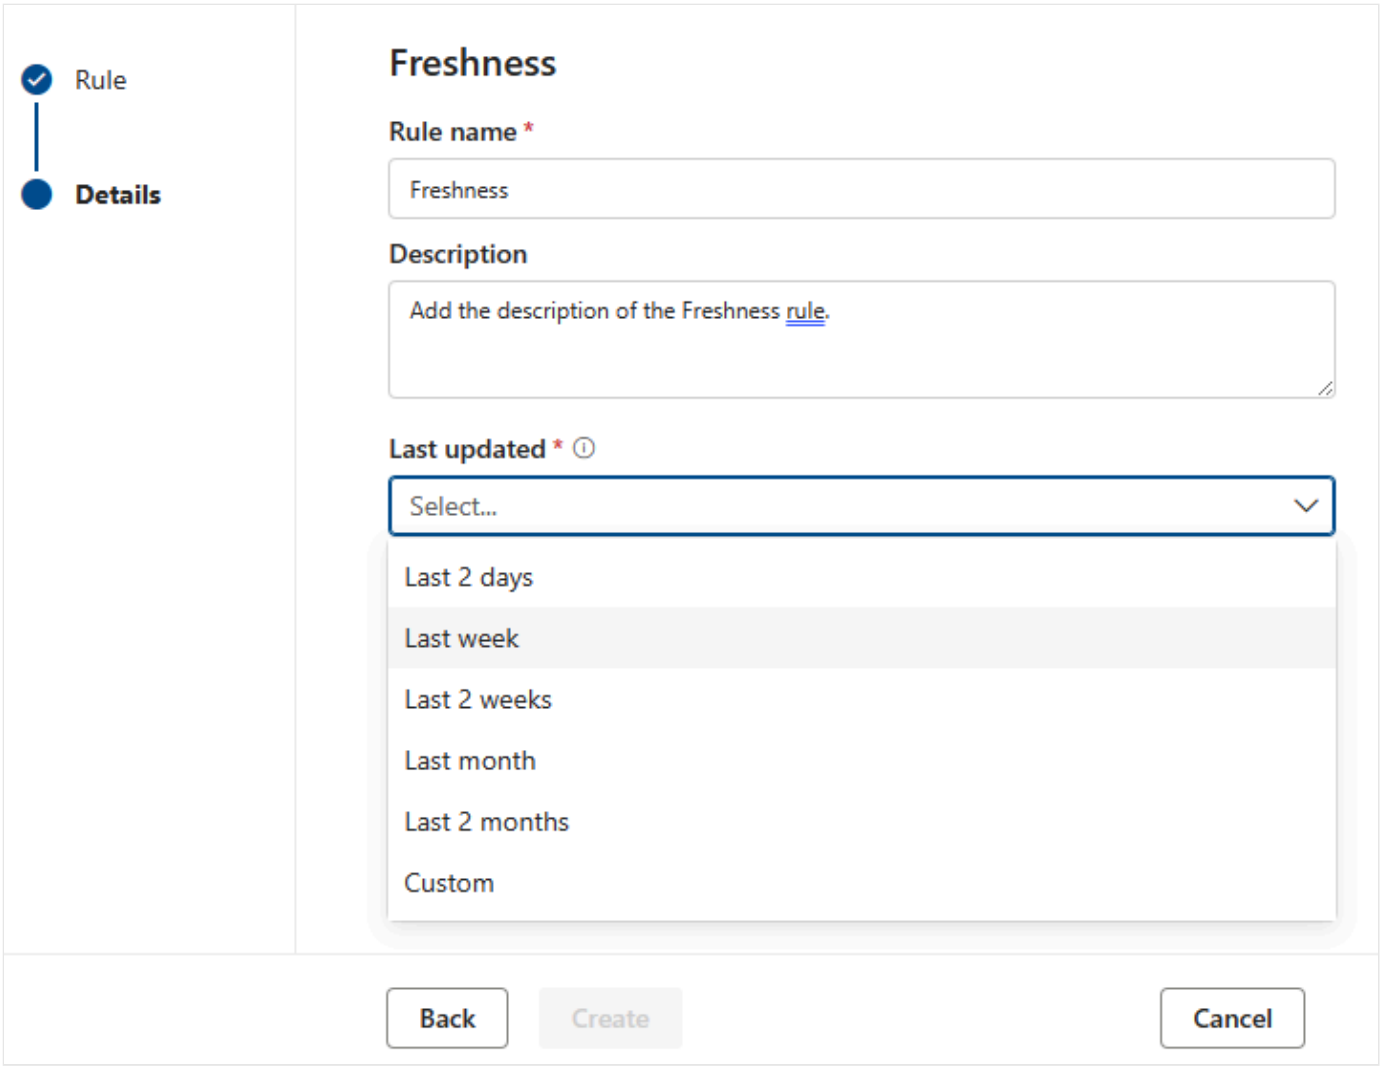
- To create and manage data quality rules, users need the data quality steward role.
- To view existing quality rules, users need the data quality reader role.

> **Note**
>
> When you create a rule through the API, first create the associated asset metadata. Rule creation depends on this metadata. If the asset metadata doesn't exist, the rule creation request fails. For a successful workflow:
>
> 1. Create the asset metadata.
> 2. Verify that the asset is successfully registered.
> 3. Create the data quality rule and associate it with the asset.

View existing data quality rules

1. In Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a **governance domain**, then select a data product.
3. Select a data asset from the **Data assets** list.
4. Select the **Rules** tab to see the existing rules applied to the asset.
5. Select a rule to browse the performance history of the applied rule to the selected data asset.

Available data quality rules

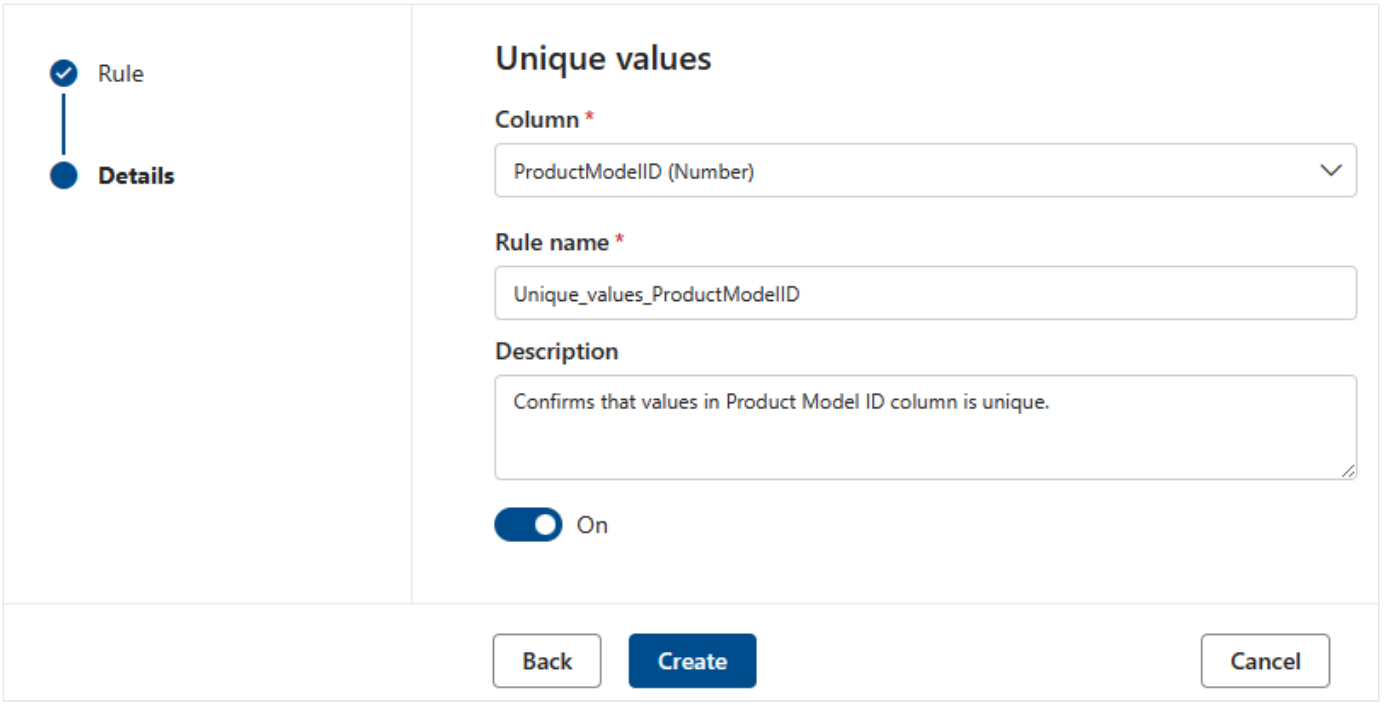


Microsoft Purview Data Quality enables configuration of the following rules. These rules are available out of the box and offer a low-code to no-code way to measure the quality of your data.

Expand table

Rule	Definition
Freshness	Confirms that all values are up to date.
Unique values	Confirms that the values in a column are unique.
String format match	Confirms that the values in a column match a specific format or other criteria.
Data type match	Confirms that the values in a column match their data type requirements.
Duplicate rows	Checks for duplicate rows with the same values across two or more columns.
Empty/blank fields	Looks for blank and empty fields in a column where there should be values.
Table lookup	Confirms that a value in one table can be found in the specific column of another table.
Custom	Create a custom rule with the visual expression builder.

Freshness

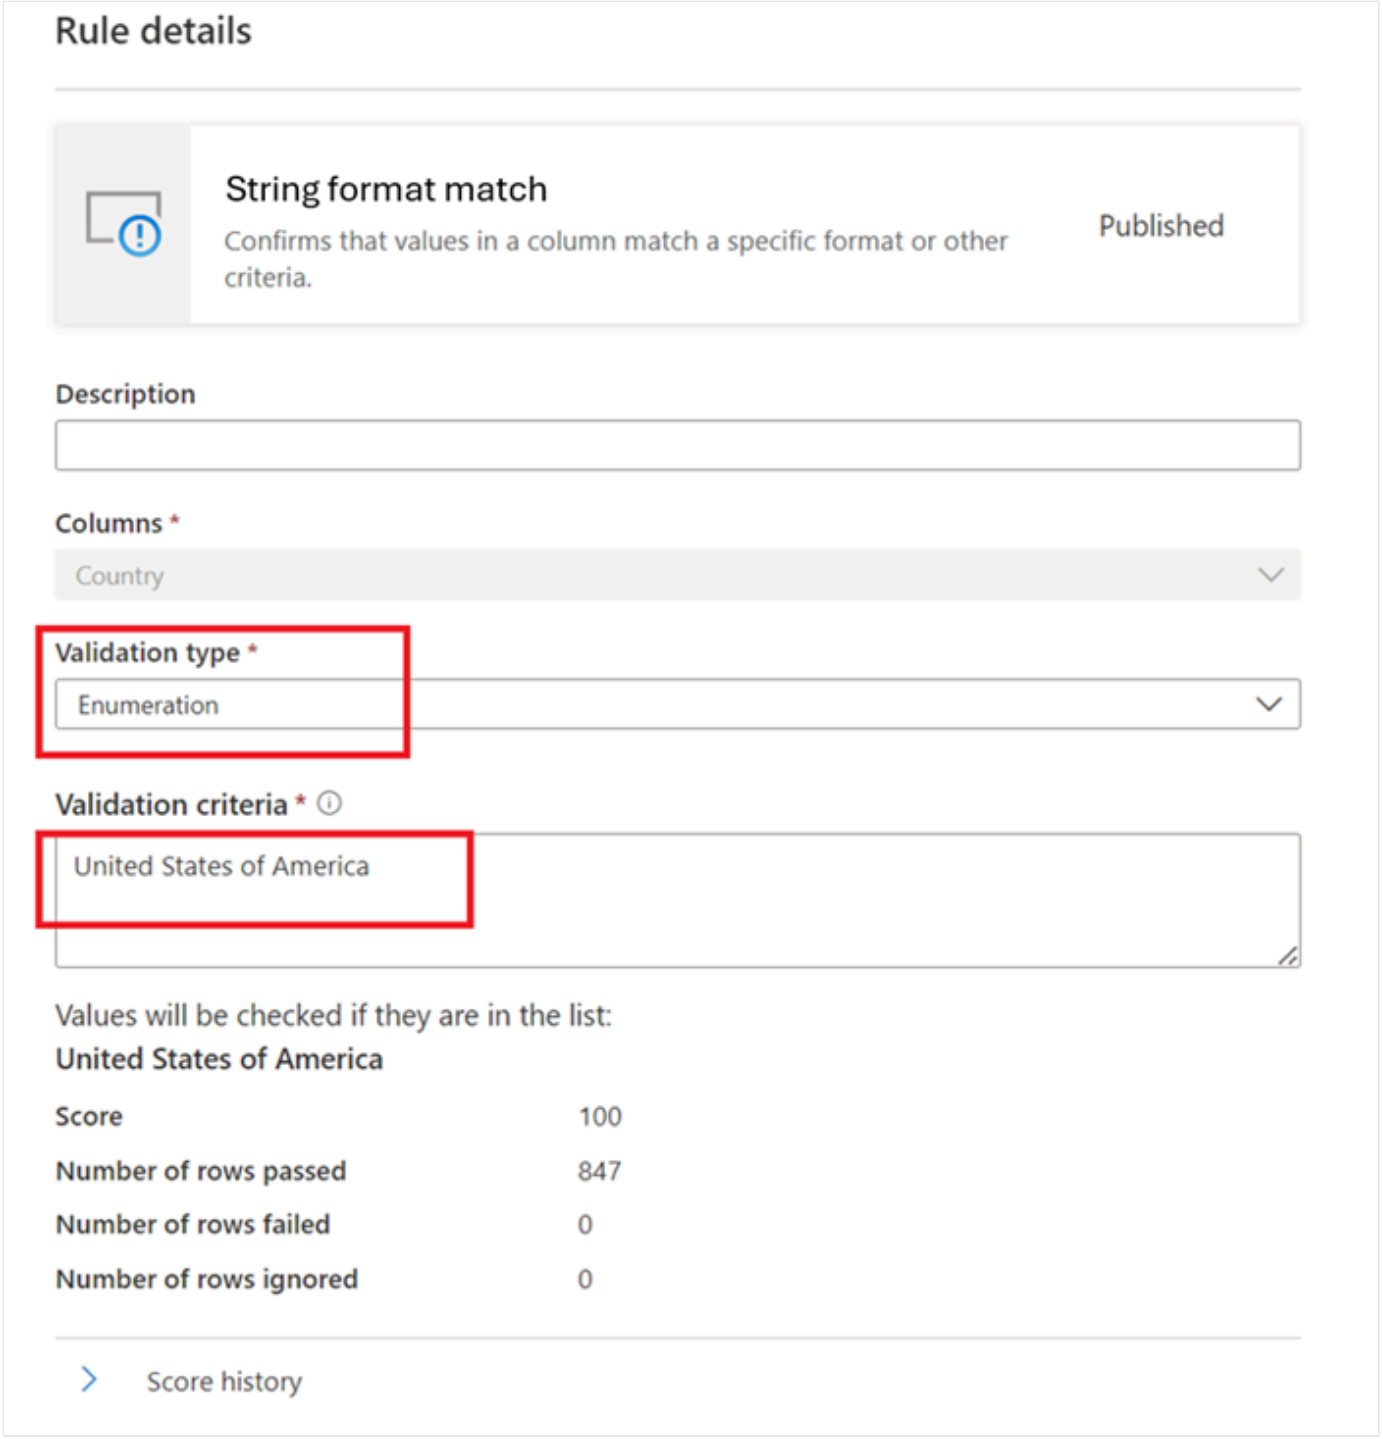


The **freshness rule** checks if the asset is updated within the expected time. Freshness is determined by the selection of *last modified dates*.

> **Note**
>
> The freshness rule score is either 100 (pass) or 0 (fail). The freshness rule isn't supported for Snowflake, Azure Databricks Unity Catalog, Google BigQuery, Synapse, and Microsoft Azure SQL.

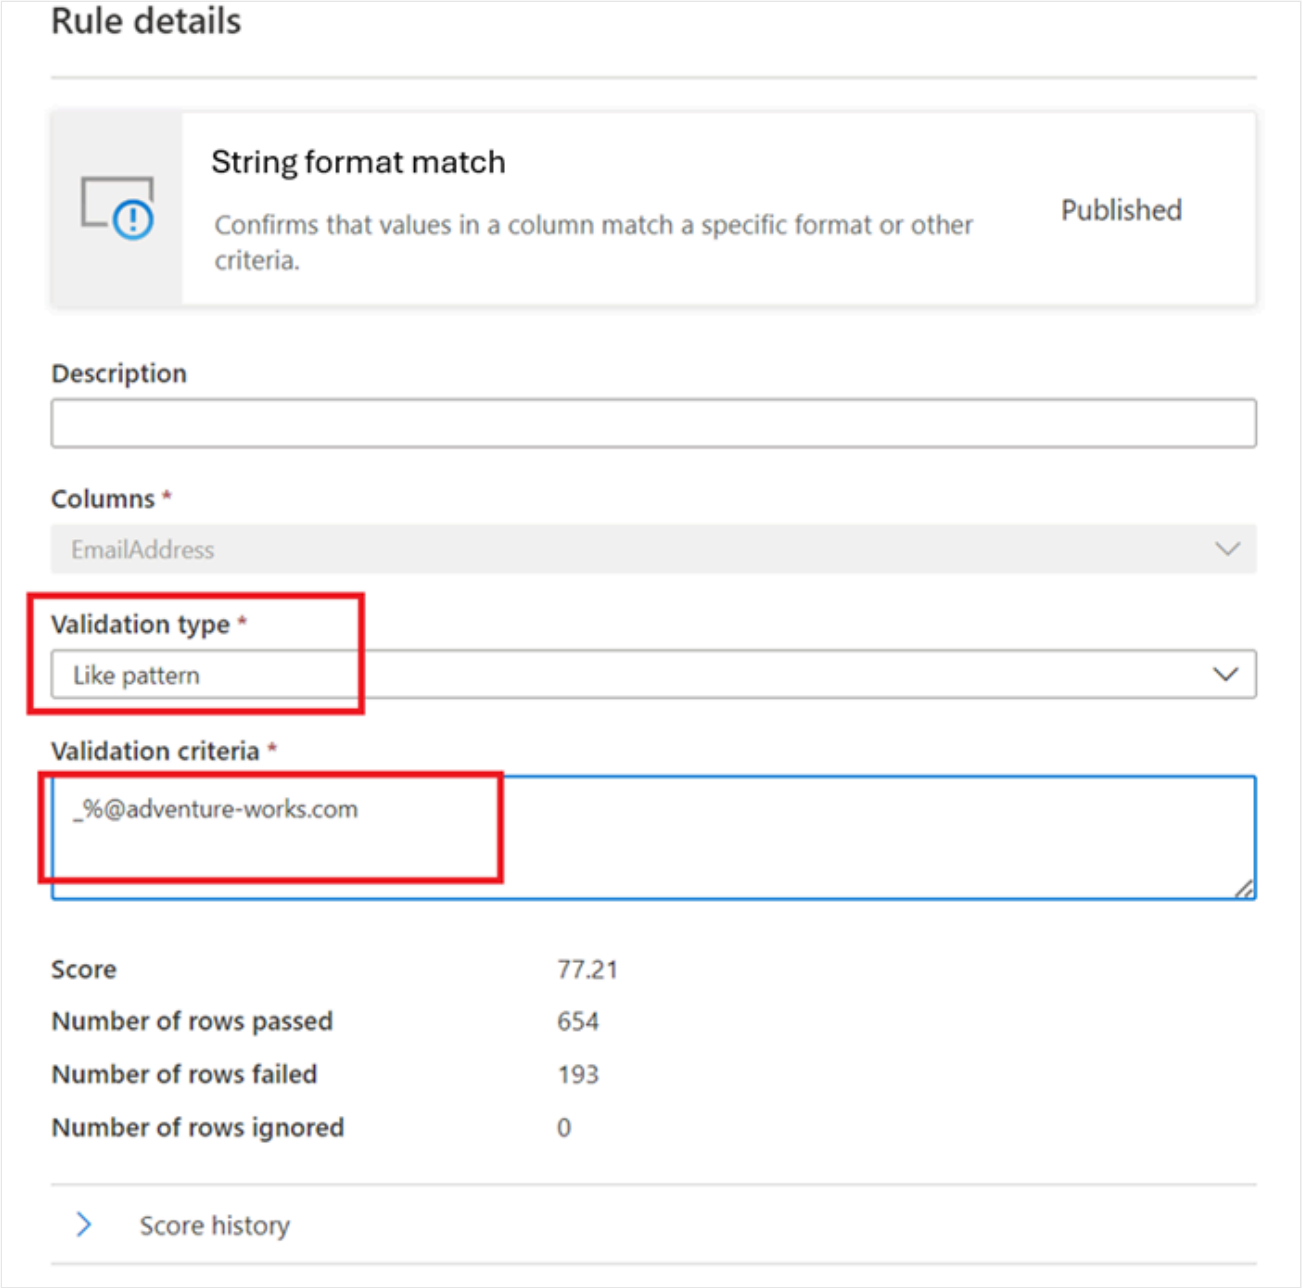
Unique values

The **Unique values** rule states that all the values in the specified column must be unique. All values that are unique are treated as pass, and values that aren't unique are treated as fail. If the **Empty/blank fields** rule isn't defined on the column, then null or empty values are ignored for the purposes of this rule.



String format match

The **Format match** rule checks if all the values in the column are valid. If you don't define the **Empty/blank fields** rule on a column, the rule ignores null or empty values.



This rule can validate each value in the column by using three different approaches:

1. **Enumeration**: This approach uses a comma-separated list of values. If the value you evaluate doesn't match one of the listed values, it fails the check. You can escape commas and backslashes by using a backslash (`\`). So, `a \, b, c` contains two values: the first is `a , b` and the second is `c`.

1. **Like Pattern**: `like(<i><string></i> : string, <i><pattern match></i> : string) => boolean` The pattern is a string that the rule matches literally. The exceptions are the following special symbols: _ matches any one character in the input (similar to `.` in `posix` regular expressions) % matches zero or more characters in the input (similar to `.` in `posix` regular expressions). The escape character is `.` If an escape character precedes a special symbol or another escape character, the following character is matched literally. It's invalid to escape any other character.

    - `like('icecream', 'ice%') -> true`

2. **Regular Expression**: `regexMatch(<i><string></i> : string, <i><regex to match></i> : string) => boolean`

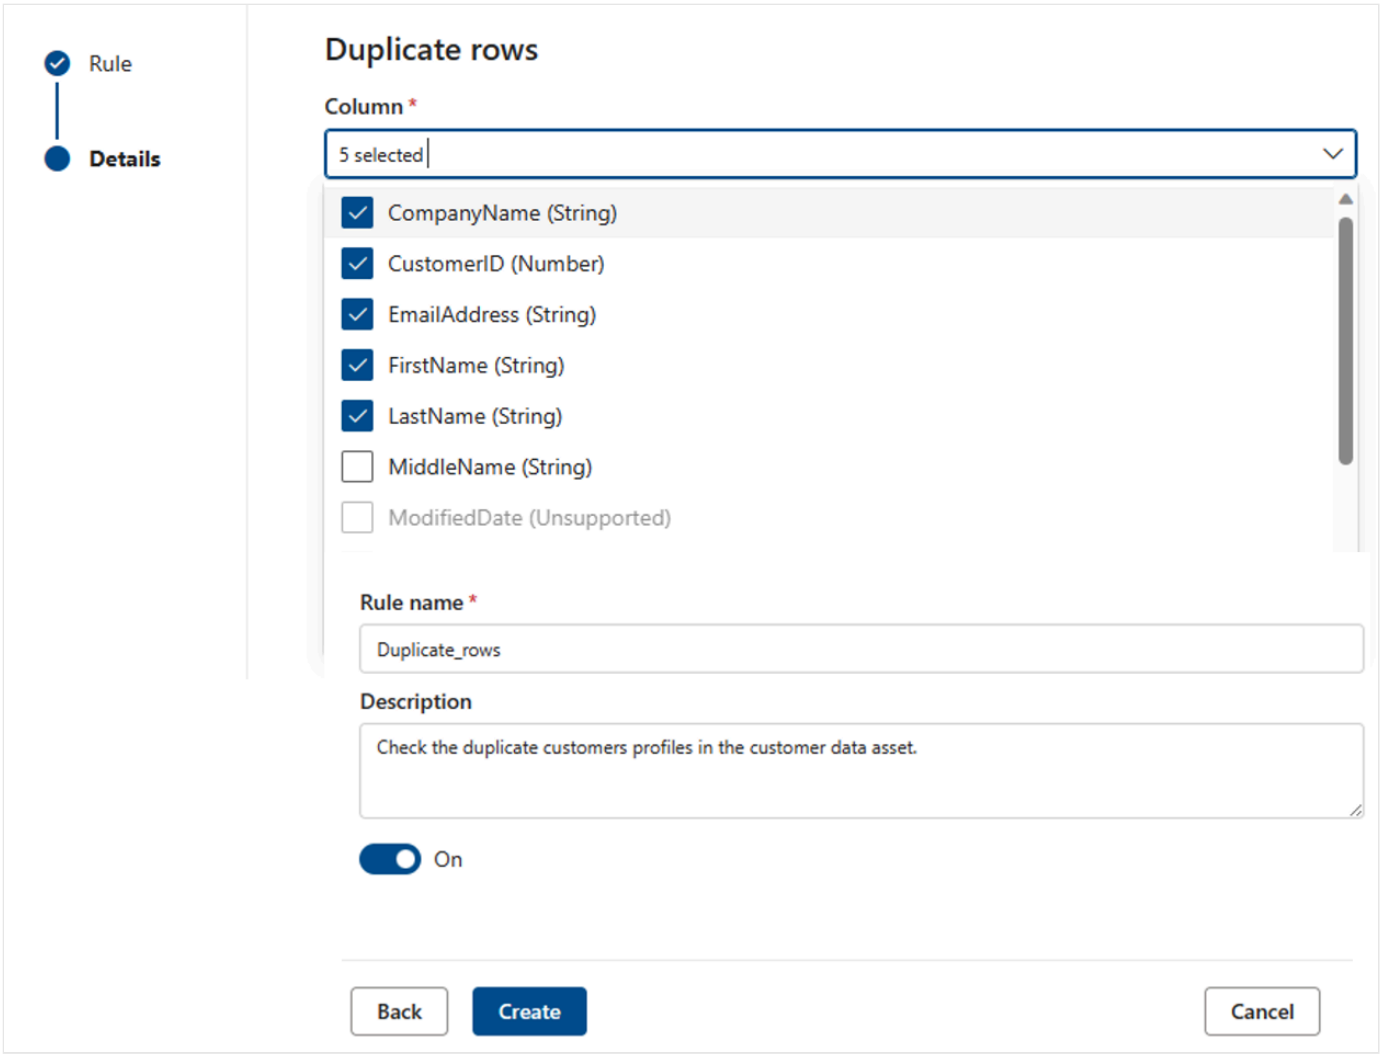
   Checks if the string matches the given regex pattern. Use `<regex>` (back quote) to match a string without escaping.

   - `regexMatch('200.50', '(\\d+).(\\d+)') -> true`
   - `regexMatch('200.50', `(\d+).(\d+)`) -> true`

Data type match

The **Data type match** rule specifies the expected data type for the associated column. Since the rule engine runs across many different data sources, it can't use native types like BIGINT or VARCHAR. Instead, it uses its own type system and translates native types into this system. This rule tells the quality scan engine which of its built-in types to use for the native type. The data type system comes from the Microsoft Azure Data Flow type system used in Azure Data Factory.

During a quality scan, the engine tests all native types against the data type match type. If it can't translate the native type into the data type match type, it treats that row as an error.



Duplicate rows

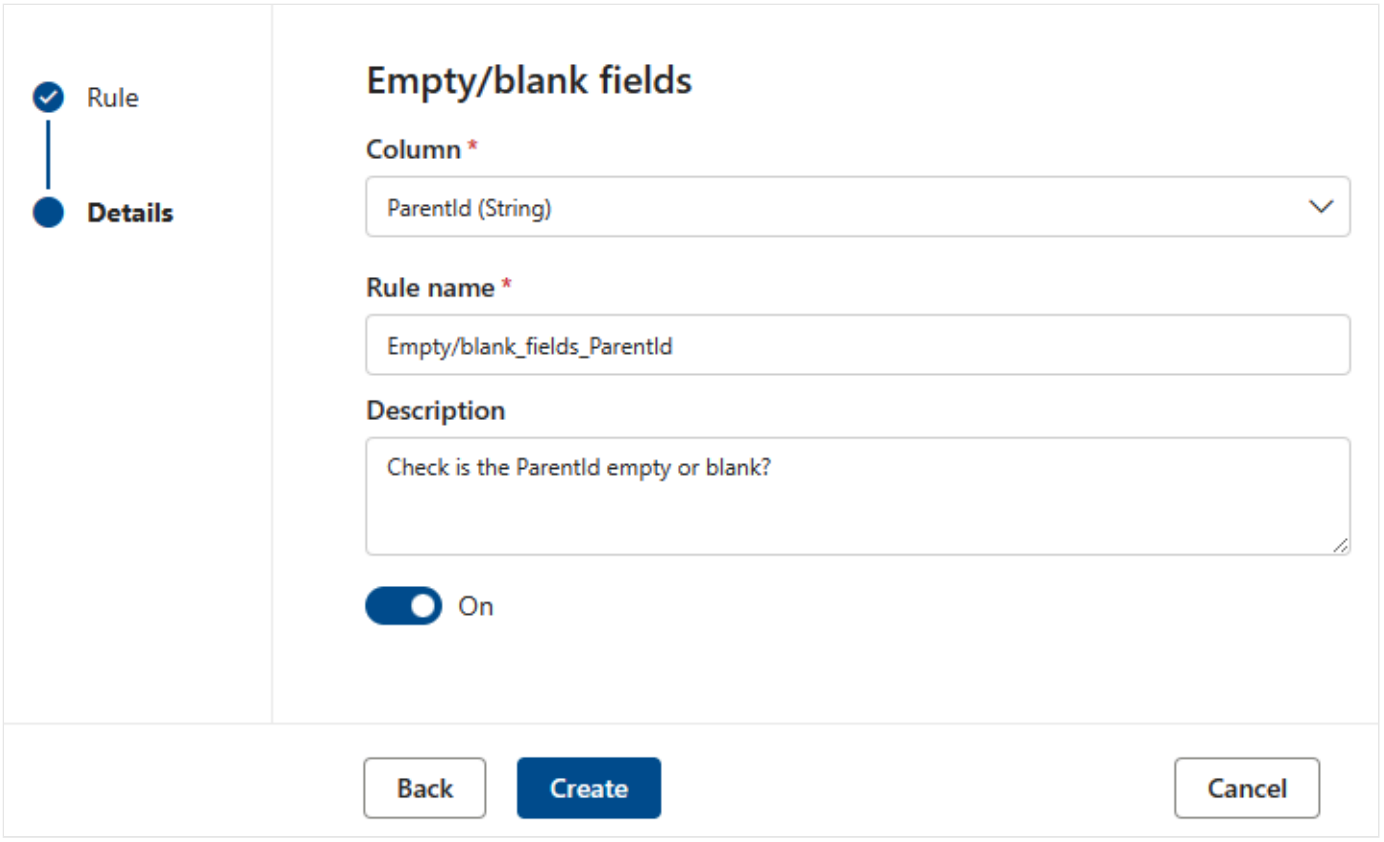
The **Duplicate rows** rule checks if the combination of the values in the column is unique for every row in the table.

In the following example, the expectation is that the concatenation of *CompanyName*, *CustomerID*, *EmailAddress*, *FirstName*, and *LastName* produces a value that's unique for all the rows in the table.

Each asset can have zero or one instance of this rule.

Empty/blank fields

The **Empty/blank fields** rule asserts that the identified columns shouldn't contain any null values. For strings, the rule also disallows empty or whitespace-only values. During a data quality scan, the engine treats any value in this column that isn't null as correct. This rule affects other rules such as the **Unique values** or **Format match** rules. If you don't define this rule on a column, those rules automatically ignore any null values when they run on that column. If you define this rule on a column, those rules examine null or empty values on that column and consider them for score purposes.



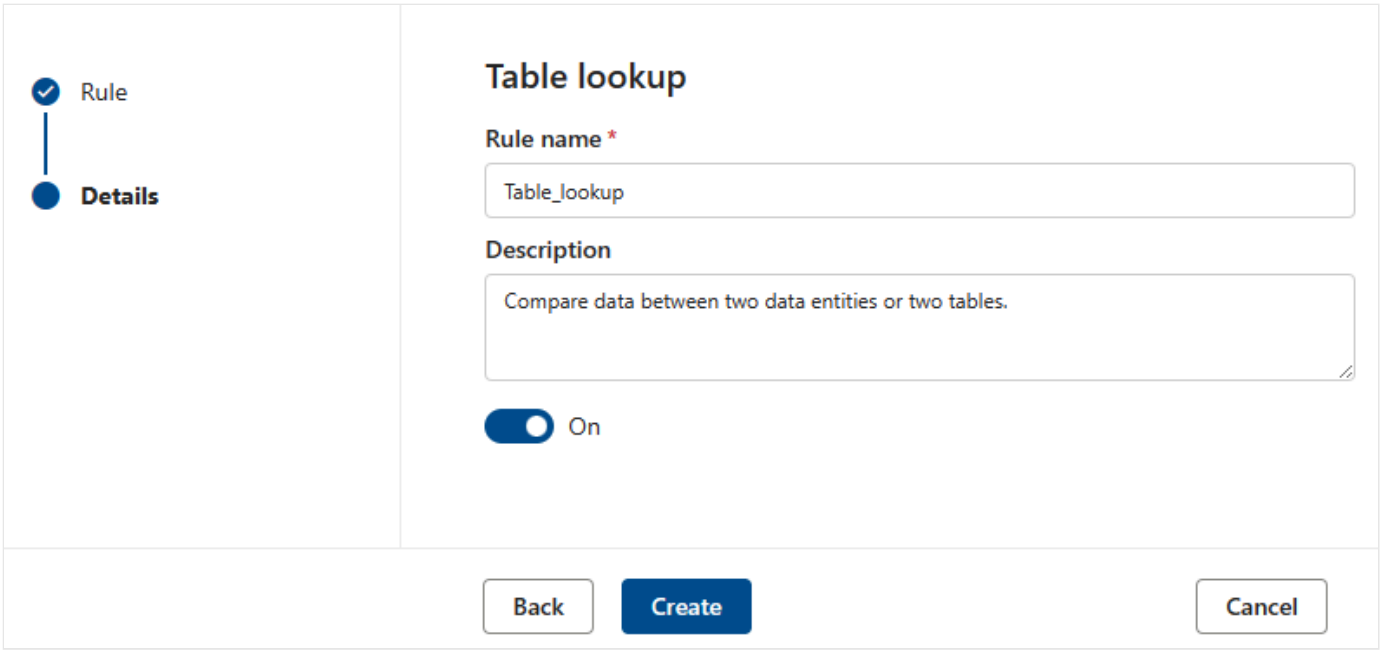


Table lookup

The **Table lookup** rule examines each value in the column where you define the rule and compares it to a reference table. For example, a primary table has a column called "location" that contains cities, states, and zip codes in the form "city, state zip". A reference table called "citystate" contains all the legal combinations of cities, states, and zip codes supported in the United States. The goal is to compare all the locations in the current column against that reference list to make sure that only legal combinations are used.

To set up this rule, enter the "citystatezip" name into the search assets dialog. Then select the desired asset and the column you want to compare against.

> **Note**
>
> The reference table or data asset must belong to the same governance domain. You can't compare a data asset across different governance domains.

Custom rules

The **Custom** rule enables you to specify rules that validate rows based on one or more values in that row. You can use regular expression language, Azure Data Factory expression, and SQL expression language to create custom rules.

A custom rule has three parts:

1. **Row expression**: This Boolean expression applies to each row that the filter expression approves. If this expression returns true, the row passes. If it returns false, the row fails.

2. **Filter expression**: This optional condition narrows down the dataset on which the row condition is evaluated. You activate it by selecting the **Use filter expression** checkbox. This expression returns a Boolean value. The filter expression applies to a row and if it returns true, then that row is considered for the rule. If the filter expression returns false for that row, then it means that row is ignored for the purposes of this rule. The default behavior of the filter expression is to pass all rows, so if you don't specify a filter expression, all rows are considered.

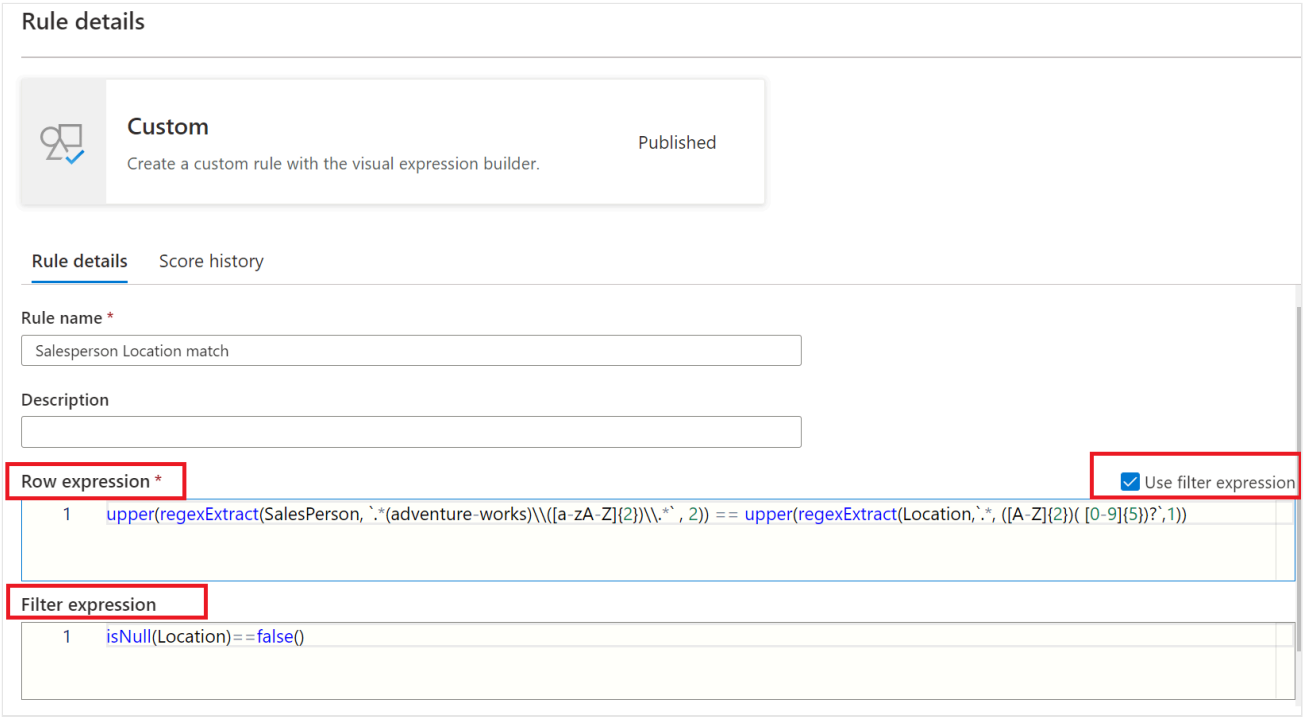
3. **Null expression**: Checks how NULL values should be handled. This expression returns a Boolean that handles cases where data is missing. If the expression returns true, the row

expression isn't applied.

Each part of the rule works similarly to existing Microsoft Purview Data Quality conditions. A rule only passes if the row expression evaluates to TRUE for the dataset that matches the filter expression and handles missing values as specified in the null expression.

Example: A rule to ensure "fareAmount" is positive and "tripDistance" is valid:

- Row expression: tripDistance > 0 AND fareAmount > 0
- Filter expression: paymentType = 'CRD'
- Null expression: tripDistance IS NULL



Create a custom rule

1. In Unified Catalog, go to **Health management** > **Data quality**.
2. Select a governance domain, select a data product, then select a data asset.
3. On the **Rules** tab, select **New rule**.

Create a custom rule using Azure Data Factory (ADF) expression

1. To create the rule by using regular expression or ADF expression, select **Custom** from the rule list of options, then select **Next**.

2. Add **Rule name** and **Description**, then select **Create**.

Examples of custom rules

Expand table

Scenario	Expressions
Validate if *state_id* is equal to California, and *aba_Routing_Number* matches a certain regex pattern, and date of birth falls in a certain range	`state_id=='California' && regexMatch(toString(aba_Routing_Number), '^((0[0-9])|(1[0-2])|(2[1-9])|(3[0-2])|(6[1-9])|(7[0-2])|80)([0-9]{7})$') && between(dateOfBirth,toDate('1968-12-13'),toDate('2020-12-13'))==true()`
Verify if *VendorID* is equal to 124	`{VendorID}=='124'`
Check if *fare_amount* is equal or greater than 100	`{fare_amount} >= "100"`
Validate if *fare_amount* is greater than 100 and *tolls_amount* isn't equal to 100	`{fare_amount} >= "100"||{tolls_amount} != "400"`
Check if *Rating* is less than 5	`Rating < 5`
Verify if number of digits in *year* is 4	`length(toString(year)) == 4`
Compare two columns *bbToLoanRatio* and *bankBalance* to check if their values are equal	`compare(variance(toLong(bbToLoanRatio)),variance(toLong(bankBalance)))<0`
Check if trimmed and concatenated number of characters in *firstName*, *lastName*, *LoanID*, *uuid* is greater than 20	`length(trim(concat(firstName,lastName,LoanID,uuid())))>20`
Verify if *aba_Routing_Number* matches certain regex pattern, and initial transaction date is greater than 2022-11-12, and *Disallow-Listed* is false, and average *bankBalance* is greater	`regexMatch(toString(aba_Routing_Number), '^((0[0-9])|(1[0-2])|(2[1-9])|(3[0-2])|(6[1-9])|(7[0-2])|80)([0-9]{7})$') && toDate(addDays(toTimestamp(initialTransaction, 'yyyy-MM-dd\'T\'HH:mm:ss'),15))>toDate('2022-11-12') && ({Disallow-Listed}=='false') && avg(toLong(bankBalance))>50000 && (state_id=='Massachusetts' || state_id=='Tennessee ' || state_id=='North Dakota' || state_id=='Alabama')`

Scenario	Expressions
than 50000, and *state_id* is equal to 'Massachusetts', 'Tennessee', 'North Dakota' or 'Alabama'	
Validate if *aba_Routing_Number* matches certain regex pattern, and *dateOfBirth* is between 1968-12-13 and 2020-12-13	`regexMatch(toString(aba_Routing_Number), '^((0[0-9])|(1[0-2])|(2[1-9])|(3[0-2])|(6[1-9])|(7[0-2])|80)([0-9]{7})$') && between(dateOfBirth,toDate('1968-12-13'),toDate('2020-12-13'))==true()`
Check if number of unique values in *aba_Routing_Number* is equal to 1,000,000, and number of unique values in *EMAIL_ADDR* is equal to 1,000,000	`approxDistinctCount({aba_Routing_Number})==1000000 && approxDistinctCount({EMAIL_ADDR})==1000000`

Both the filter expression and row expression are defined using the Azure Data Factory expression language, with the language defined here. However, not all the functions defined for the generic ADF expression language are available. The full list of available functions is in the Functions list available in the expression dialog. The following functions defined in here aren't supported: isDelete, isError, isIgnore, isInsert, isMatch, isUpdate, isUpsert, partitionId, cached lookup, and Window functions.

> **Note**
>
> `<regex>` (back quote) can be used in regular expressions included in custom rules to match string without escaping special characters. The regular expression language is based on Java. Learn about regular expressions and Java and understand the characters that need to be escaped.

Create a custom rule using SQL expression

Custom SQL rules in Microsoft Purview Data Quality provide a flexible way to define data quality checks using Spark SQL predicates. This feature allows users to author rules directly in Spark SQL for advanced validation scenarios. Only a row expression is required; filter and null expressions are optional for further customization. Use Custom SQL rules to address complex business

requirements and enhance data quality, using the full capabilities of Spark SQL. Custom SQL rules enable complex data validation that might not be possible with ADF expressions alone. By writing Spark SQL predicates, you can meet unique business needs and maintain high data quality standards.

1. To create the rule by using SQL expression language, select **Custom (SQL)** from the rule list of options, then select **Next**.

2. Add **Rule name** and **Description**, then select **Create**.

Expand table

Scenario	Expressions

Validates correct string patterns (for example, rateCodeId starting with '1' and numeric) and filters by valid payment types.	`Row: rateCodeId RLIKE '^1[0-9]+$'`
	`Filter: paymentType IN ('CRD', 'CSH')`
	`Null: rateCodeId IS NULL`

Ensures correct column comparisons between puLocationId and doLocationId, and fare compared to trip distance.	`Row: puLocationId > doLocationId AND fareAmount > tripDistance * 10'`
	`Filter: paymentType <> 'CSH''`
	`Null: tripDistance IS NULL`

Checks if the paymentType is in a given list (Card, Cash), filtering rows based on fare amounts.	`Row: paymentType IN ('CRD', 'CSH')'`
	`Filter: fareAmount >= 50`
	`Null: paymentType IS NULL`

Ensures distance is within an inclusive range (5-10 miles) while handling NULL and filtering for valid payment types.	`Row: tripDistance BETWEEN 5 AND 10`
	`Filter: paymentType <> 'CRD'`
	`Null: tripDistance IS NULL`

Ensures that the dataset doesn't exceed a 20% NULL value for fareAmount.	`Row: (SELECT avg(CASE WHEN fareAmount IS NULL THEN 1 ELSE 0 END) FROM nycyellowtaxidelta1BillionPartitioned) < 0.20'` `Filter: vendorID IN ('VTS', 'CMT')`
Verifies that there are at least 2 distinct paymentType values in the dataset.	`Row: (SELECT count(DISTINCT paymentType) FROM nycyellowtaxidelta1BillionPartitioned) >= 2` `Filter: vendorID IN ('1', '2')`
Ensures that the dataset's average fare amount falls within a specified range (80 <= avg <= 140).	`Row: (SELECT avg(fareAmount) FROM nycyellowtaxidelta1BillionPartitioned) BETWEEN 80 AND 140 '` `Filter: paymentType IN ('CRD', 'CSH')`

Scenario	Expressions
Ensures the maximum tripDistance in the dataset is <= 10 miles.	`Row: (SELECT max(tripDistance) FROM nycyellowtaxidelta1BillionPartitioned) <= 10.0` `Filter: vendorID IN ('VTS', 'CMT')`
Ensures that the standard deviation of fareAmount is below a certain threshold (< 30).	`Row: (SELECT stddev_samp(fareAmount) FROM nycyellowtaxidelta1BillionPartitioned) < 30.0` `Filter: vendorID IN ('VTS', 'CMT')`
Ensures that the dataset's median fare amount is within the specified threshold (<= 15).	`Row: (SELECT percentile_approx(fareAmount, 0.5) FROM nycyellowtaxidelta1BillionPartitioned) <= 15.0` `Filter: vendorID IN ('VTS', 'CMT')`
Ensures that vendorId is unique in the dataset within specific paymentType.	`Row: COUNT(1) OVER (PARTITION BY vendorID) = 1` `Filter: paymentType IN ('CRD', 'CSH','1', '2')` `Null: vendorID IS NULL`
Ensures that the combination of puLocationId and doLocationId is unique within the dataset.	`Row: COUNT(1) OVER (PARTITION BY puLocationId, doLocationId) = 1` `Filter: paymentType IN ('CRD', 'CSH')` `Null: puLocationId IS NULL OR doLocationId IS NULL`
Ensures that vendorId is unique per paymentType.	`Row: COUNT(1) OVER (PARTITION BY paymentType, vendorID) = 1 ,Filter: rateCodeId < 25, Null: vendorID IS NULL`
Ensures that the row's tpepPickupDateTime is greater than a given cutoff timestamp.	`Row: tpepPickupDateTime >= TIMESTAMP '2014-01-03 00:00:00'` `Filter: paymentType IN ('CRD', 'CSG', '1', '2')` `Null: tpepPickupDateTime IS NULL`
Each trip must be completed within 1 hour	`Row: (unix_timestamp(tpepDropoffDateTime) - unix_timestamp(tpepPickupDateTime)) <= 3600` `Filter: paymentType IN ('CRD', 'CSH', '1', '2')` `Null: tpepPickupDateTime IS NULL OR tpepDropoffDateTime IS NULL`
Keeps only highest fare trip per pickup location.	`Row: row_number() OVER (PARTITION BY puLocationId ORDER BY fareAmount DESC) = 1, Filter: paymentType IN ('CRD', 'CSH','1','2') AND tripDistance > 0, Null: fareAmount IS NULL OR puLocationId IS NULL`
All tied highest fares per pickup location pass (not just first by row_number).	`Row: rank() OVER (PARTITION BY puLocationId ORDER BY fareAmount DESC) = 1` `Filter: paymentType IN ('CRD', 'CSH','1','2') AND tripDistance > 0` `Null: fareAmount IS NULL OR puLocationId IS NULL`

Scenario	Expressions
Fare must not decrease over time for each payment type.	`Row: fareAmount >= lag(fareAmount) OVER (PARTITION BY paymentType ORDER BY tpepPickupDateTime)` `Null: tpepPickupDateTime IS NULL OR fareAmount IS NULL`

Each row's fare within 10 of group average by payment type.	`Row: abs(fareAmount - avg(fareAmount) OVER (PARTITION BY paymentType)) <= 10`
	`Filter: paymentType IN ('CRD', 'CSH','1','2')`
	`Null: fareAmount IS NULL`

Running total of trip distances must not exceed 20 miles.	`Row: sum(tripDistance) OVER (ORDER BY tpepPickupDateTime ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) <= 20`
	`Filter: paymentType = '1'`
	`Null: tripDistance IS NULL`

Checks if each trip's fare is above the global average for eligible vendors.	`Row: fareAmount > (SELECT avg(fareAmount) FROM nycyellowtaxidelta1BillionPartitioned)`
	`Filter: vendorID IN ('VTS', 'CMT')`
	`Null: fareAmount IS NULL`

Checks if each row's tripDistance is greater than the minimum for its paymentType (Card/Cash).	`Row: tripDistance > (SELECT min(u.tripDistance) FROM (SELECT tripDistance, paymentType AS pt FROM nycyellowtaxidelta1BillionPartitioned) u WHERE u.pt = paymentType)`
	`Filter: paymentType IN ('CRD', 'CSH')`
	`Null: tripDistance IS NULL`

For each trip, checks if the fare is above the average for its payment type	`Row: fareAmount > (SELECT avg(u.fareAmount) FROM (SELECT fareAmount, paymentType AS pt FROM nycyellowtaxidelta1BillionPartitioned) u WHERE u.pt = paymentType)`
	`Filter: paymentType IN ('CRD','CSH','1','2') AND vendorID IN ('VTS','CMT')`
	`Null: fareAmount IS NULL`

Validates if the fareAmount column (numeric) can be correctly represented as a string matching the numeric pattern (positive numbers with optional decimal). This uses casting as fareAmount is a numeric column.	`Row: CAST(fareAmount AS STRING) RLIKE '^[0-9]+(\.[0-9]+)?$'`
	`Filter: paymentType IN ('CRD', 'CSH')`
	`Null: fareAmount IS NULL`

Ensures that the tpepPickupDateTime is a valid timestamp in yyyy-MM-dd HH:mm:ss format. This column is already in DATETIME format	`Row: to_timestamp(tpepPickupDateTime, 'yyyy-MM-dd HH:mm:ss') IS NOT NULL`
	`Filter: paymentType IN ('CRD', 'CSH')`
	`Null: tpepPickupDateTime IS NULL`

Scenario	Expressions
Ensures that paymentType values are normalized to lowercase and have no leading or trailing spaces.	`Row: lower(trim(paymentType)) IN ('card','cash') AND length(trim(paymentType)) > 0` `Null: paymentType IS NULL OR trim(paymentType) = ''`
Safely calculates the ratio of fareAmount to tripDistance, ensuring that division by zero doesn't occur by first checking if tripDistance > 0.	`Row: CASE WHEN tripDistance > 0 THEN fareAmount / tripDistance ELSE NULL END >= 10` `Filter: tripDistance > 0 AND vendorID IN ('VTS', 'CMT')`
Demonstrates how coalesce can replace null values with default values (for example, 0.0), and ensures only valid rows are returned.	`Row: coalesce(fareAmount, 0.0) >= 5` `Filter: paymentType IN ('CRD','CSH')`

Best practices for writing custom SQL rules

- Keep expressions simple. Aim to write clear, straightforward expressions that are easy to maintain.
- Use built-in Spark SQL functions. Use Spark SQL's rich library of functions for string manipulation, date handling, and numeric operations to minimize errors and improve performance.
- Test with a small dataset first. Validate rules on a small dataset before applying them at scale to identify potential issues early.

Known limitations and considerations for SQL expressions rules

Ambiguous column references and column shadowing

- Problem: When a column appears in both the outer query and subquery (or across different parts of the query) with the same name, Spark SQL might not be able to resolve which column to use. This issue results in logical errors or incorrect query execution. This problem can arise in nested queries, subqueries, or joins, leading to ambiguity or shadowing.

- Ambiguity: Occurs when a column name is present in both the outer query and the subquery without clear qualification, causing Spark SQL to be uncertain about which column to reference.

- Shadowing: Refers to when a column in the outer query is "overridden" or "shadowed" by the same column in the subquery, causing the outer reference to be ignored.

  Example Expression:

SQL

```
distance_km >
(
SELECT min(distance_km)
FROM Tripdata t
WHERE t.payment_type = payment_type -- ambiguous outer reference
)
```

- Issue: Unqualified payment_type is resolved to the nearest scope that has a column of that name, that is, the inner t.payment_type - not the outer row's payment_type. That turns the predicate into t.payment_type = t.payment_type (always TRUE), so your subquery becomes a global min instead of a group min.
- Solution: To resolve this ambiguity and avoid column shadowing, rename the inner column in the subquery, ensuring that the outer query's payment_type remains unambiguous.

Corrected Expression:

SQL

```
distance_km >
(
SELECT min(u.distance_km)
FROM (
SELECT distance_km, payment_type AS pt
FROM Tripdata
) u
 WHERE u.pt = payment_type   -- this `payment_type` now binds to OUTER row
)
```

- In the subquery, the column payment_type is aliased as pt (that is, payment_type AS pt), and u.pt is used in the condition.
- In the outer query, the original payment_type can now be clearly referenced, and Spark SQL correctly resolves it as the outer payment_type.

Window operations (performance consideration)

- Window operations such as ROW_NUMBER() and RANK() can be expensive, especially for large datasets. Use them judiciously and test performance on smaller datasets before applying them at scale. Consider using PARTITION BY to reduce the data scope.

Column name escaping in Spark SQL

- If column names contain special characters (such as spaces, hyphens, or other non-alphanumeric characters), they must be escaped using backticks.
- Example if the column name is order-id and the rule needs to be that it should be greater than 10.
- Incorrect expression: order-id > 10
- Correct expression: `` `order-id` `` > 10

Data asset name referencing in expressions

When referencing your data asset in SQL expressions, you need to follow specific sanitization rules. The original data asset name doesn't need to be updated, but the data asset name referenced in SQL expressions must be sanitized to meet the following criteria:

Expand table

Rule	Description	Example- Original Name	Example- Sanitized Name
Allowable Characters	Only letters (A-Z, a-z), numbers (0-9), and underscores (_) are allowed. Special characters (spaces, hyphens, periods, etc.) must be removed.	my-dataset_v1+2023	mydataset_v12023
Trim Underscores	Underscores at the beginning or end of the name must be removed.	my_dataset_	my_dataset
Character Limit	The final, sanitized name must not exceed 64 characters.	[A long name exceeding 64 characters]	[The first 64 characters of the sanitized name]

If your data asset name already follows these guidelines (that is, it doesn't contain any special characters, leading/trailing underscores, and is within the 64-character limit), it can be used as-is in your SQL expressions without any modification.

How to sanitize a dataset name

Follow these steps to ensure your dataset name is valid for SQL expressions:

1. Remove special characters: Strip out all characters except letters, numbers, and underscores.
2. Trim underscores: Remove any leading or trailing underscores.
3. Truncate: If the resulting name exceeds 64 characters, truncate it to fit within the 64-character limit.

Example: Data asset name f07d724d-82c9-4c75-97c4-c5baf2cd12a4.parquet

1. Remove special characters: f07d724d82c94c7597c4c5baf2cd12a4parquet
2. Trim underscores: (N/A in this case, as there are no leading or trailing underscores.)
3. Truncate: The resulting name is 54 characters long, which is under the 64-character limit.

Final SQL reference name: f07d724d82c94c7597c4c5baf2cd12a4parquet

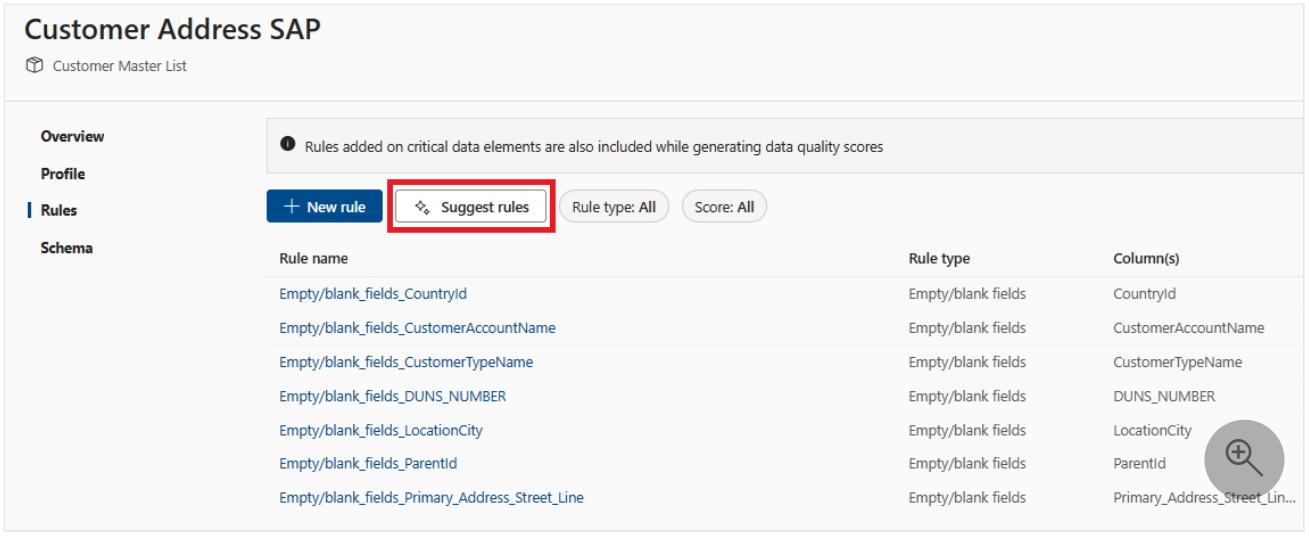
> ⓘ **Note**
>
> The original data asset name remains unchanged. Only the data asset name used in the SQL expressions needs to follow these rules. For column names that contain special characters, such as spaces or hyphens, you can escape them using back quotes in SQL expressions.

Joins aren't supported

Custom SQL rules in Microsoft Purview Data Quality don't support joins. The rules must operate on a single dataset. You can't join multiple tables or datasets when writing these custom rules.

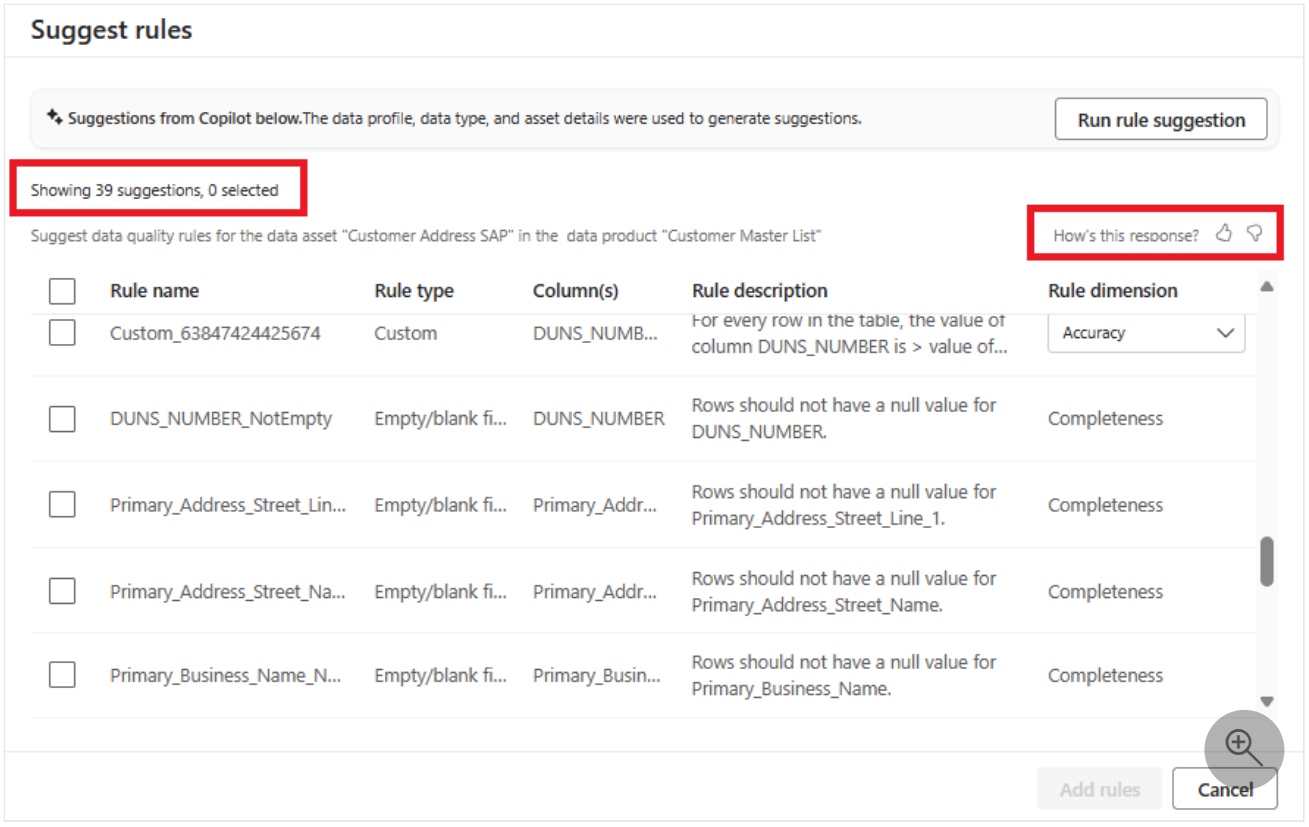
Unsupported SQL operations (DML, DCL, and harmful SQL)

Custom SQL rules don't support Data Manipulation Language (DML) or Data Control Language (DCL) operations such as INSERT, UPDATE, DELETE, GRANT, and other harmful SQL operations like TRUNCATE, DROP, and ALTER. These operations aren't supported because they modify the data or the database's state.



AI-assisted autogenerated rules

AI-assisted automated rule generation for data quality measurement uses artificial intelligence (AI) techniques to automatically create rules for assessing and improving the quality of data. Autogenerated rules are content specific. Most of the common rules are generated automatically so that you don't need to put much effort into creating custom rules.



To browse and apply autogenerated rules:

1. On the **Rules** tab of a data asset, select **Suggest rules**.

2. Browse the list of suggested rules.

3. Select rules from the suggested rule list to apply to the data asset.

Limitation

You can apply a maximum of 200 data quality rules per data asset for a data quality scan. The scan fails if more than 200 rules are active for a single asset. If you need to define more than 200 rules for a data asset, they can do so, but only up to 200 rules can be in an active (ON) state at any given time.

To work around this limit:

- Add the same data asset to multiple data products to distribute rules across them.

- Activate and deactivate rules as needed to ensure no more than 200 rules are active at once.

Next steps

1. Configure and run a data quality scan on a data product to assess the quality of all supported assets in the data product.
2. Review your scan results to evaluate your data product's current data quality.

Data quality thresholds

A data quality threshold is a predefined limit that determines whether data meets an acceptable level of quality. In simple terms, it answers the question: How good is good enough?

For example, if you run a completeness rule on a column:

- Total records: 1,000
- Records with values: 920
- Completeness score: 92%

If your threshold is 90%, the data meets the expectation.

If your threshold is 95%, the data doesn't meet the expectation.

The threshold is the cutoff point that defines whether the data meets the expectation for specific use cases.

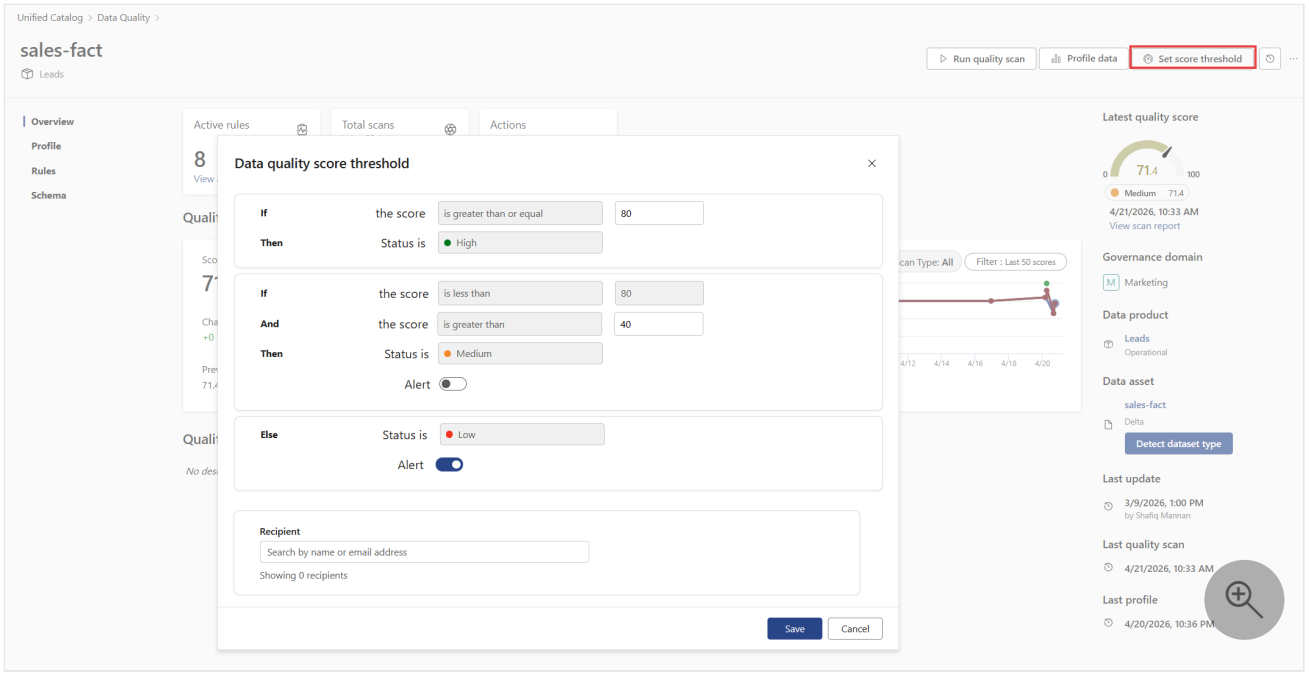
Why thresholds matter

Different types of data require different quality expectations. For example:

- Email address column: Might require 99–100% completeness.
- Description column: Perhaps 80–90% is acceptable.
- Financial transactions: Might require 100% accuracy.

Using one fixed threshold, such as 80% for everything, can be misleading, especially for critical or regulated data.

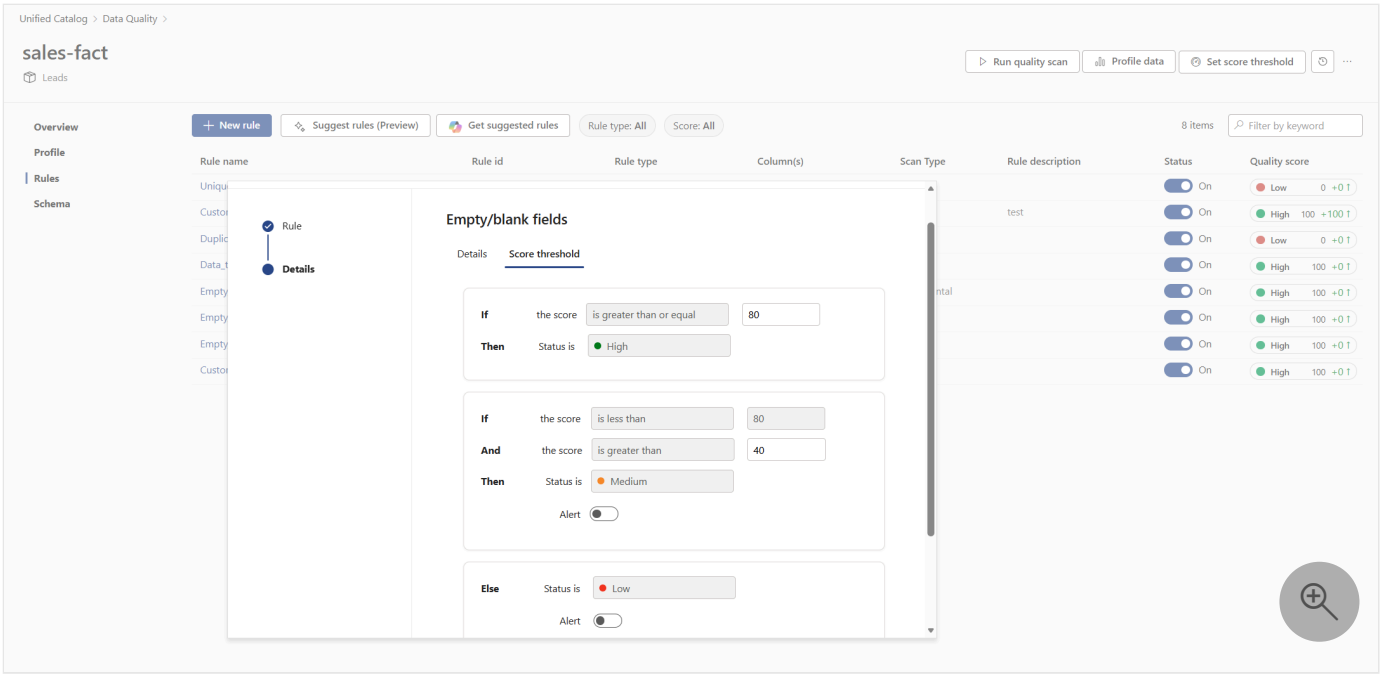
Types of thresholds



- Rule-level threshold: Set for each rule (for example, completeness must be ≥ 95%).
- Data asset level threshold: Different expectations for different columns.
- Data product level threshold: Overall score requirement.

Configurable data quality thresholds

You can configure Data Quality thresholds to set minimum acceptable quality scores at the rule and data asset levels. Define the threshold to align quality evaluation with business criticality.

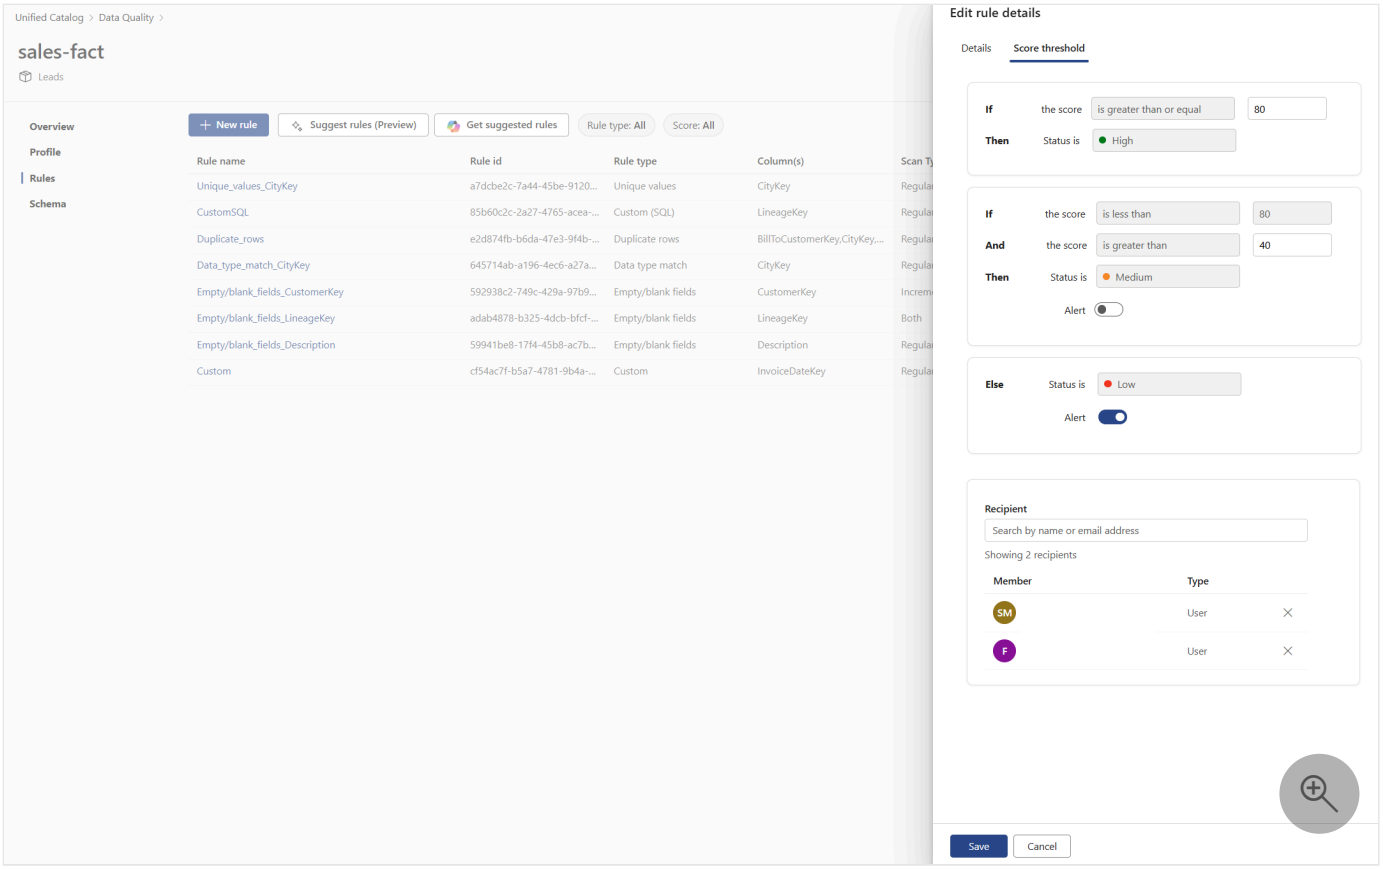


Configure or edit the default threshold for a data asset

1. In Microsoft Purview Unified Catalog, select **Health management**, and then select **Data quality**.
2. Select a governance domain, select a data product, and then select a data asset.
3. On the **Overview** page, select **Set score threshold**.
4. Change the default threshold.
5. Select **Save**.

Configure the threshold for a data quality rule

1. In Unified Catalog, select **Health management**, and then select **Data quality**.
2. Select a governance domain, select a data product, and then select a data asset.
3. On the **Rules** page, select **New rule**.
4. Select the out-of-the-box rule or the custom rule, and select **Next**.
5. Select **Score threshold** and change the default threshold value.
6. Select **Save**.



Edit a data quality rule threshold

1. On the **Rules** page of a data asset, select the edit icon for a rule.
2. From the overview, select **Score threshold**.
3. Edit the threshold value.
4. Select **Save**.

Configure alerts

Set an alert to notify you when the data quality score of a data asset or rule falls below a defined threshold. When you set up or edit a rule threshold, follow these steps:

- Set the **Alert** toggle to on.
- At **Recipient**, add one or more users.
- Select **Save**.

> **Note**
>
> If you don't configure a threshold, the default threshold values and colors are used. The default threshold score values are:
>
> - **Low (red)**: 0-40
> - **Medium (orange)**: 40-80
> - **High (green)**: 80-100

> **Important**
>
> Threshold metadata doesn't publish to Azure Data Lake Storage Gen2 or Fabric Lakehouse for self-serve analytics.

The benefits that an organization gets from the configurable data quality threshold feature are:

- Enables the enterprise to align their organization with quality governance.
- Improves trust in the data quality scores produced by Microsoft Purview Data Quality, enabling teams across the enterprise to confidently determine whether data is fit for their specific use cases.

- Helps organizations move beyond generic quality checks and toward business-driven data quality management.
- Supports regulatory and decision-critical use cases.
- Reduces user or organizational confusion caused by uniform threshold evaluation.

Setting rule-level thresholds creates a clear standard for what "good" looks like. Alerts ensure you act the moment data drifts below that standard. This has several practical benefits:

- **Early detection of issues**: Catch things like missing, inconsistent, or incorrect data before they impact reports, pipelines, or models.
- **Reduced business risk**: Prevents bad data from driving incorrect decisions, financial errors, or compliance issues.
- **Faster remediation**: Alerts enable teams to respond immediately instead of discovering issues days or weeks later.
- **Accountability and governance**: Clear thresholds define ownership and expectations for data quality.
- **Operational efficiency**: Eliminates manual monitoring and reduces reliance on ad hoc checks.
- **Trust in data**: Consistent enforcement of quality standards increases confidence in analytics and AI outputs.

In short, **thresholds** define acceptable quality, and alerts make that standard actionable.

Next steps

- Data quality scan

Configure a data quality scan for a data product

Data quality scans review your data assets based on their applied data quality rules and produce a score. Your data stewards can use that score to assess the data health and address any issues that might be lowering the quality of your data.

> **Note**
>
> There are two other types of data quality scans you can run:
>
> - Data quality scan for a standalone data asset (preview).
> - Incremental data quality scan (preview) using a time-based filter.

Prerequisites

- To run and schedule data quality assessment scans, users need the data quality steward role.
- Currently, you can set the Microsoft Purview account to allow public access or managed virtual network access so that data quality scans can run.

Data quality life cycle

Data quality scanning is the **seventh** step in the data quality life cycle for a data asset. The previous steps are:

1. Assign users data quality steward permissions in Microsoft Purview Unified Catalog so they can use all data quality features.
2. Register and scan a data source in Microsoft Purview Data Map.
3. Add your data asset to a data product.
4. Set up a data source connection to prepare your source for data quality assessment.
5. Configure and run data profiling for an asset in your data source. When profiling is complete, browse the results for each column in the data asset to understand your data's current structure and state.
6. Set up data quality rules based on the profiling results, and apply them to your data asset.

Supported multicloud data sources

Browse the supported data source document to view the list of supported data sources, including file formats for data profiling and data quality scanning, with and without virtual network support.

> **Important**
>
> Data quality for Parquet file is designed to support:
>
> 1. A directory with Parquet Part File. For example: **./Sales/{Parquet Part Files}**. The Fully Qualified Name must follow `https://(storage account).dfs.core.windows.net/(container)/path/path2/{SparkPartitions}`. Make sure there are no {n} patterns in directory/sub-directory structure. It must be a direct FQN leading to {SparkPartitions}.
> 2. A directory with Partitioned Parquet Files, partitioned by Columns within the dataset like sales data partitioned by year and month. For example: **./Sales/{Year=2018}/{Month=Dec}/{Parquet Part Files}.**
>
> Both of these essential scenarios, which present a consistent parquet dataset schema, are supported. **Limitation:** It isn't designed to or won't support N arbitrary Hierarchies of Directories with Parquet Files. **We recommend presenting data in (1) or (2) constructed structure.**

Supported authentication methods

Currently, Microsoft Purview can only run data quality scans by using Managed Identity as authentication option. Data quality services run on **Apache Spark 3.5** and **Delta Lake 3.2.1**. For more information about supported regions, see data quality overview.

> **Important**
>
> - If you update the schema on the data source, you need to import schema from data quality overview page by using **schema import feature** before running a data quality scan.
> - Virtual network isn't supported for Google BigQuery.

Run a data quality scan

1. Configure a data source connection to the assets you're scanning for data quality if you haven't already done so.
2. In Unified Catalog, select **Health Management**, then select **Data quality**.
3. Select a **governance domain** from the list.
4. Select a **data product** to assess the data quality of the **data assets** linked to that product.
5. Select the name of a data asset, which takes you to the data quality **Overview** page.
6. Browse the existing data quality rules and add new rules by selecting **Rules**. Browse the schema of the data asset by selecting **Schema**. Toggle on or off the rules you added.
7. Run the quality scan by selecting **Run quality scan** on the overview page.
8. While the scan is running, you can track its progress from the data quality monitoring page in the governance domain.

Schedule data quality scans

Although you can run data quality scans on an ad-hoc basis by selecting **Run quality scan**, in production scenarios the source data is likely to be constantly updated. You should regularly monitor data quality to detect any issues. Automating the scanning process helps you manage regular updates of quality scans.

1. In Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a **governance domain** from the list.
3. Select **Manage**, then select **Scheduled scans**.
4. Fill out the form on the **Create scheduled scan** page. Add a **name** and **description** for the source you're setting up the schedule.
5. Select **Continue**.
6. On the **Scope** tab, select individual data product and assets or all data products and data assets of the entire governance domain.
7. Select **Continue**.
8. Set a schedule based on your preferences and select **Continue**.

9. On the **Review** tab, select **Save** (or **Save and run** to test immediately) to complete scheduling the data quality assessment scan.

You can monitor scheduled scans on the data quality job monitoring page under the **Scans** tab.

> ⓘ Note
>
> - You can't add more than 30 assets across all data products in a single schedule. Create multiple schedules for 30 assets per batch. You can configure to run multiple schedules in the same time window.
> - Auto-scheduling to run a weekly scan is enabled at the asset level by default. If you want to disable auto-scheduling for a data asset, go to **Health management** > **Data quality** > **Run quality scan**, and then select the option to disable the scheduled scan.
> - When you manually run a data quality scan, a notification appears on the Data Quality page prompting you to configure alerts. Ignore this notification if you don't want to configure alerts.

Delete previous data quality scans and history

When you remove a data asset from a data product, if that data asset has a data quality score, you need to delete the data quality score first, then remove the data asset from the data product.

When you delete data quality history data, it removes the profile history, the data quality scan history, and data quality rules, but data quality actions aren't deleted.

Follow the steps below to delete previous data quality scans of a data asset:

1. In Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a **governance domain** from the list.
3. Select the **data product** from the list.
4. Select the **data asset** from the list to navigate the Data quality overview page.
5. Select the ellipsis (...) at the top right of the Data quality overview page.
6. Select **Delete data quality data** to delete the history of data quality runs.

> ⓘ Note
>
> - Use **Delete data quality data** for test runs, errored data quality runs, or if you're removing a data asset from a data product.

- The system stores up to 50 snapshots of data quality profiling and data quality assessment history. If you want to delete a specific snapshot, select the desired history run and select the delete icon.

Import schema

If the data type in a schema is undefined, incorrectly defined, or changed in the source, your data quality job might fail. If it fails, reimport the schema by using the schema import capability. Schema import is supported for data sources on both public networks and behind private endpoints. The supported data sources are listed at Data sources and file formats supported for data quality. To import a schema from your data sources, follow these steps:

- Select **Data quality** from **Health Management**.
- Select a business domain, then select a data product, then select a data asset from that data product. You arrive at the data quality overview page.
- Select **Schema**, then select the **Schema management** toggle.
- Select **Import schema** to import the schema.

Configure a data quality scan for a data asset

A standalone data asset is a data asset that isn't associated with a data product in Microsoft Purview Unified Catalog. When you manage data quality for standalone data assets, you can measure, monitor, and improve the quality of these assets independently, without requiring a data product association.

Benefits of running data quality on a data asset

- **Helps you assess and improve the quality of your data before linking it to a data product**. Microsoft Purview Data Quality users can profile and evaluate the quality of their data before associating it with a data product. Users can standardize, clean, and resolve issues upfront.
- **Helps you decide which assets should be part of a data product**. By understanding the quality of standalone assets, organizations can make informed decisions about which assets are suitable for curation and governance within a data product.
- **Supports broader use cases beyond analytics.** Many organizations associate data products only with analytics use cases. Standalone data assets might serve other purposes such as:
  - Data monetization
  - AI grounding data
  - Operational workloads
- **Provides unified data quality tooling across all data**. Organizations can use a single Microsoft Purview Data Quality solution to assess both standalone data assets and data product–associated assets, including issue remediation.
- **Helps optimize data storage and reduce costs**. If standalone assets are low quality, incomplete, or unusable, organizations can archive them to lower-cost storage or apply data minimalism principles, which reduces unnecessary data retention and improving return on investment.
- **Accelerates data governance maturity**. Organizations can begin measuring and improving data quality immediately, without waiting for data product definitions or use cases. This significantly speeds up governance adoption.

Data quality scans review your data assets based on their applied data quality rules and produce a score. Your data stewards can use that score to assess the data health and address any issues that might be lowering the quality of your data. Here's an example of how data asset scores appear in a governance domain:

Prerequisites

- To run and schedule data quality assessment scans, you need the data quality steward role.
- Currently, you can set the Microsoft Purview account to allow public access or managed virtual network access so that data quality scans can run.
- Configure the data source connection if it isn't created yet for the data asset's source system.
- Configure the data quality error records storage if you want to store data quality failed records for review and correction.

Data quality life cycle for data assets

Data quality scanning is the **seventh** step in the data quality life cycle for a data asset. The previous steps are:

1. Register and scan a data source in Microsoft Purview Data Map.
2. Assign users data quality steward permissions in Unified Catalog so they can use all data quality features.
3. Set up a data source connection to prepare your source for data quality assessment.
4. Add your data asset from Data Map to a governance domain.

5. Configure a storage to store data quality error records if you want to store data quality error record for review and remediation.
6. Configure and run data profiling for an asset in your data source.. When profiling is complete, browse the results for each column in the data asset to understand your data's current structure and state to identify what rules need to be created to measure and monitor data quality of your data continuously.
7. Set up data quality rules based on the profiling results, and apply them to your data asset.
8. Review data quality error records and correct those failed records to improve data quality of your data.

Supported multicloud data sources

To see the list of supported data sources, including file formats for data profiling and data quality scanning with and without virtual network support, see the supported data sources.

> **Important**
>
> Data quality for Parquet file supports:
>
> 1. A directory with Parquet Part File. For example: **./Sales/{Parquet Part Files}**. The fully qualified name (FQN) must follow `https://(storage account).dfs.core.windows.net/(container)/path/path2/{SparkPartitions}`. Make sure there are no {n} patterns in directory or subdirectory structure. It must be a direct FQN leading to {SparkPartitions}.
> 2. A directory with Partitioned Parquet Files, partitioned by columns within the dataset like sales data partitioned by year and month. For example: **./Sales/{Year=2018}/{Month=Dec}/{Parquet Part Files}.**
>
> Both of these essential scenarios, which present a consistent parquet dataset schema, are supported. **Limitation:** The feature doesn't support N arbitrary hierarchies of directories with Parquet files. **Present data in (1) or (2) constructed structure.**

Supported authentication methods

Currently, Microsoft Purview can only run data quality scans by using Managed Identity as authentication option. Data quality services run on **Apache Spark 3.4** and **Delta Lake 2.4**. For more information about supported regions, see data quality overview.

> **Important**
>
> - If you update the schema on the data source, import the schema from the Data Quality overview page by using **schema import feature** before running a data quality scan.
> - Virtual network isn't supported for Google BigQuery.

Run a data quality scan for standalone data asset

1. In Unified Catalog, select **Health Management**, and then select **Data quality**.
2. Select a governance domain from the list.
3. Configure a data source connection to the assets you're scanning for data quality if you haven't already done so.
4. Select a **Data asset** and select **Add data assets** to add data assets from Data Map for a data quality assessment. Select the data assets you want from the Data Map assets list to add them to the governance domain to begin measuring their data quality.
5. Select the name of a data asset, which takes you to the data quality **Overview** page.
6. Profile the selected data asset if you want to know the distribution, min, max, uniqueness, completeness, standard deviation, and other statistical measures of your data assets.
7. To set up the scan, browse the existing data quality rules and add new rules by selecting **Rules**. Browse the schema of the data asset by selecting **Schema**. Toggle on or off the rules you added. If you toggle off a rule, that rule isn't included in the data quality scan.
8. Run the quality scan by selecting **Run quality scan** on the overview page.
9. While the scan is running, you can track its progress from the data quality monitoring page in the governance domain.
10. If you configured data quality error records in the governance domain level or data asset level, check the error records in the configured storage.

Add a data asset with a quality score to another governance domain

After a data asset has a data quality score, you can add it to another governance domain by cloning it. You can clone and associate the same data asset with any governance domain as

needed.

- Select a data asset with data quality score.
- Select **Add to another domain**, and then select the domain from the drop-down list.
- Select the domain to add the selected data asset.

Associate asset with a quality score to a data product

You can associate a data asset with its latest data quality score to a data product in a different governance domain.

- Select a data asset with data quality score.
- Select **Add to data product**, and then select the **Governance domain** and **Data product** from the drop-down list.
- Select the domain and data product to add the selected data asset.

When the same data asset is associated with multiple data products, the meaning and expectations of data quality for that asset can differ depending on the business context.

For example, a customer profile data asset might be associated with a Marketing data product for campaign use cases and a Finance data product for billing scenarios. In this case, billing address quality is critical for Finance but less important for Marketing, while customer contact email quality is critical for Marketing but less relevant for Finance.

Because data quality expectations vary by data product, you need to run data quality scans locally on the cloned or associated asset within each target data product to ensure that data quality is evaluated based on the specific use case.

> ⓘ **Note**
>
> - When you clone or associate a data asset with an existing data quality score from the Data Quality > Data Asset page to another domain or data product, you must run the data quality scan locally in the target domain or data product where the asset is cloned or associated.
> - For example, if you clone a data asset named Budget with an existing data quality score from the Marketing domain to the Sales domain, you will need to run a data quality scan for the Budget asset within the Sales domain to view the updated data quality score in that domain.

- A similar process must be followed for any asset cloned or associated with a data product.

Important

- Threshold and alert metadata don't publish to Azure Data Lake Storage Gen2 or Fabric Lakehouse for self-serve analytics.
- Standalone data assets and associated metadata, for example data quality score and data quality rules, don't publish to Azure Data Lake Storage Gen2 or Fabric Lakehouse for self-serve analytics. If a standalone data asset is associated with a data product, then the associated metadata is available for self-serve analytics with the data product association.

Roles and permissions

- You can't associate a standalone data asset with a data quality score to a data product that is in a published state. The data product must be in draft state.
- If you're not the data product owner, you can't add a standalone data asset to a data product.
- If you don't have permissions for a business domain, you can't clone a standalone data asset into that domain.
- A data product owner must have a local or global Domain Reader role or a Data Quality Reader role to browse the standalone data asset data quality page and to associate a data asset (with data quality scores and rules) to a data product.
- A data steward must have a local or global Domain Owner role to browse the standalone data asset data quality page.

Note

If you delete a data asset from the Data Map, it appears in read-only mode and you identify it by its GUID instead of the asset name. When you hover over the asset GUID, a tooltip message is displayed. You can't run data quality scans on deleted assets, so you can remove the asset from the list.

Schedule data quality scans

Although you can run data quality scans on an ad-hoc basis by selecting **Run quality scan**, in production scenarios, the source data is likely to be constantly updated. You should regularly monitor data quality to detect any issues. Automating the scanning process helps you manage regular updates of quality scans.

1. In Unified Catalog, select **Health Management**, and then select **Data quality**.
2. Select a **governance domain** from the list.
3. Select **Manage**, then select **Scheduled scans**.
4. Fill out the form on the **Create scheduled scan** page. Add a **name** and **description** for the source you're setting up the schedule.
5. Select **Continue**.
6. On the **Scope** tab, select data assets you want to set up schedule to run data quality as per configured schedule.
7. Select **Continue**.
8. Set a schedule based on your preferences and select **Continue**.
9. On the **Review** tab, select **Save** (or **Save and run** to test immediately) to complete scheduling the data quality assessment scan.

You can monitor scheduled scans on the data quality job monitoring page under the **Scans** tab.

> **Note**
>
> - You can't add more than 30 assets across all data products in a single schedule. Create multiple schedules for 30 assets per batch. You can configure to run multiple schedules in the same time window.
> - Auto-scheduling to run a weekly scan is enabled at the asset level by default. If you want to disable auto-scheduling for a data asset, go to **Health management** > **Data quality** > **Run quality scan**, and then select the option to disable the scheduled scan.
> - When you manually run a data quality scan, a notification appears on the Data Quality page prompting you to configure alerts. Ignore this notification if you don't want to configure alerts.

Delete previous data quality scans and history

To remove a data asset from the data asset list on the data quality page, first delete the data quality score if the data asset has one. Then, remove the data asset from the data quality data asset list.

When you delete data quality history data, you remove the profile history, the data quality scan history, and data quality rules. Data quality actions aren't deleted.

To delete previous data quality scans for a data asset, follow these steps:

1. In Unified Catalog, select **Health Management**, and then select **Data quality**.
2. Select a **governance domain** from the list.
3. Select the **data asset** from the list to go to the Data quality overview page.
4. Select the ellipsis (...) at the upper right of the Data quality overview page.
5. Select **Delete data quality data** to delete the history of data quality runs.

> ⓘ **Note**
>
> - Use **Delete data quality data** for test runs, errored data quality runs, or if you're removing a data asset from the data quality data asset list.
> - The system stores up to 50 snapshots of data quality profiling and data quality assessment history. To delete a specific snapshot, select the desired history run and select the delete icon.

Import schema

If the data type in a schema is undefined, incorrectly defined, or changed in the source, your data quality job might fail. If it fails, reimport the schema by using the schema import capability. You can import schemas for data sources on both public networks and behind private endpoints. For a list of supported data sources, see Data sources and file formats supported for data quality. To import a schema from your data sources, follow these steps:

- Select **Data quality** from **Health Management**.
- Select a governance domain, and then select a data asset from the list to go to the Data Quality overview page.
- Select **Schema**, and then select the **Schema management** toggle.
- Select **Import schema** to import the schema.

Data quality for on-premises data sources (preview)

On-premises data source data quality refers to the ability to assess, monitor, score, and improve the quality of data that resides inside enterprise-owned infrastructure such as on-premises SQL Server and on-premises Oracle. These datasets are stored within a customer's private network environment rather than in cloud platforms.

Prerequisites

On-premises databases are scanned in on-premises infrastructure to ensure that data doesn't move beyond the customer premises. You need to set up a Kubernetes cluster to host the runtime that scans these databases. Before you use Microsoft Purview Data Quality for on-premises data sources:

1. Create a Kubernetes cluster.
2. Download the data integration runtime.
3. Register it with Microsoft Purview.

For prerequisites, installation, and set up, see:

- Set up DIRCTL tool for self-hosted integration runtime (preview)
- Kubernetes supported self-hosted data integration runtime for on-premises data sources (preview)

Before you run a data quality scan, you must scan the assets through a Data Map scan. The Data Map scan requires you to install and configure a self-hosted integration runtime.

Set up a connection to your on-premises databases

Create connections for on-premises data sources the same way you create connections for other data source types. In Unified Catalog, select **Health management**, then select **Data quality**. Select the governance domain where you created your data product with the on-premises data asset. Select **Manage** and select **Connection** to set up a connection for your on-premises databases. Supported on-premises data sources are:

- Oracle
- SQL Server

Create connections by associating them with a data integration runtime instance. In SQL Server, a single database can contain tables belonging to multiple schemas. So, you can use a single connection to scan all schemas in a single database. Therefore, a connection accepts only database information but not schema. For an Oracle database, you can create the connection at the schema level or the database level. If you want to restrict the connection to the schema level, add the schema name in the connection configuration page.

> **Note**
>
> - One Oracle database should have only one database level connection, but it can have many schema level connections for schema 1, schema 2, and schema 3.
> - Each schema level connection is used as a separate connection because they're separate schemas.
> - If an Oracle database has both schema level and database level connections, the system uses only the schema level connection.
> - If an Oracle database has two database level connections, the system uses only the first connection.

Data quality scan

After you complete the connection setup, follow the data quality scanning documentation to measure and monitor data quality of Oracle and SQL Server on-premises data sources.

- Data quality overview
- Supported data sources
- Set up data source connection
- Data product quality scan
- Data asset quality scan
- Incremental data quality scan

Limitations

- Profiling on-premises data sources isn't supported.
- Table lookup rules aren't supported if you don't publish the tables as data assets, or if the databases of the reference tables aren't running or hosting on the same server.
- Freshness rule isn't supported for SQL Server database.

- Custom expressions that are supported for cloud sources aren't supported for SQL Server database, but Custom SQL is supported.
- Regex rules aren't supported, but LIKE is supported.

Resolve common errors

- **Error**: *Value cannot be null. (Parameter 'Password property is missing')*. This error occurs when the key vault secret isn't found. The actual error message in the Kubernetes log is: "A secret with `(name/id)` KVSecretsOfficers-purview was not found in this key vault."

Configure an incremental data quality scan

Microsoft Purview Data Quality supports incremental data quality scans by using time-based filtering. By using incremental scans, you can choose between full scans, incremental scans, or both when you run data quality rules on data assets.

While certain rules, such as duplicate detection, require a full scan of the entire dataset, you can efficiently evaluate many data quality checks on newly created or updated data. By using incremental scans, you can run these rules on a defined schedule, such as daily or weekly, which improves performance and reduces scan costs.

By using incremental data quality scans, you can:

- Create rules that run on full scans, incremental scans, or both.
- Flexibly assign existing rules to incremental or full scan execution.
- Configure schedules for data assets to run incremental scans at defined intervals.

Data quality scores are calculated across all rules and data assets, regardless of whether the scan is incremental or full. Microsoft Purview Data Quality computes a cumulative data quality score to help you understand overall data quality trends over time.

Benefits of running incremental scans

Data offices and data practitioners don't always need to assess data quality across the entire historical dataset, such as five to 10 years of data, on a frequent basis. You can evaluate historical data periodically, such as monthly or quarterly, while newly created or updated data often requires more frequent monitoring.

By using incremental scans, you can enable continuous data quality monitoring on recent data so that you can identify and address problems quickly, before they affect downstream systems and analytics.

Configure and run a data quality scan

Data quality scans review your data assets based on their applied data quality rules and produce a score. Your data stewards can use that score to assess the data health and address any problems that might lower the quality of your data.

Prerequisites

- To run and schedule data quality assessment scans, users need the data quality steward role.
- Currently, you can set the Microsoft Purview account to allow public access or managed virtual network access so that data quality scans can run.

Data quality life cycle

Data quality scanning is the **seventh** step in the data quality life cycle for a data asset. The previous steps are:

1. Register and scan a data source in Microsoft Purview Data Map.
2. Assign users data quality steward permissions in Unified Catalog so they can use all data quality features.
3. Add your data asset to a data product. This step is needed only if you want to run data quality for data assets associated to a data product to calculate data product data quality score.
4. If you want to measure data quality for a standalone data asset, add a data asset from the Data Map to a domain to run data quality scan for the asset without association to a data product.
5. Set up a data source connection to prepare your source for data quality assessment.
6. Configure a container or storage to store data quality error records for review and correct the failed records.
7. Configure and run data profiling for an asset in your data source.. When profiling is complete, browse the results for each column in the data asset to understand your data's current structure and state.
8. Set up data quality rules based on the profiling results, and apply them to your data asset.
9. Run data quality scan to understand and improve the quality of your data.

Supported multicloud data sources

Browse the supported data source document to view the list of supported data sources, including file formats for data profiling and data quality scanning, with and without virtual network support.

> **Important**
>
> Data quality for Parquet file is designed to support:

1. A directory with Parquet Part File. For example: **./Sales/{Parquet Part Files}**. The Fully Qualified Name must follow `https://(storage account).dfs.core.windows.net/(container)/path/path2/{SparkPartitions}`. Make sure there are no {n} patterns in directory/sub-directory structure. It must be a direct FQN leading to {SparkPartitions}.
2. A directory with Partitioned Parquet Files, partitioned by columns within the dataset like sales data partitioned by year and month. For example: **./Sales/{Year=2018}/{Month=Dec}/{Parquet Part Files}.**

Both of these essential scenarios, which present a consistent parquet dataset schema, are supported. **Limitation:** It isn't designed to or won't support N arbitrary hierarchies of directories with Parquet files. **We recommend presenting data in (1) or (2) constructed structure.**

Microsoft Purview Data Quality doesn't currently support specifying data quality rules on maps, lists, and structs in Parquet data structures.

Supported authentication methods

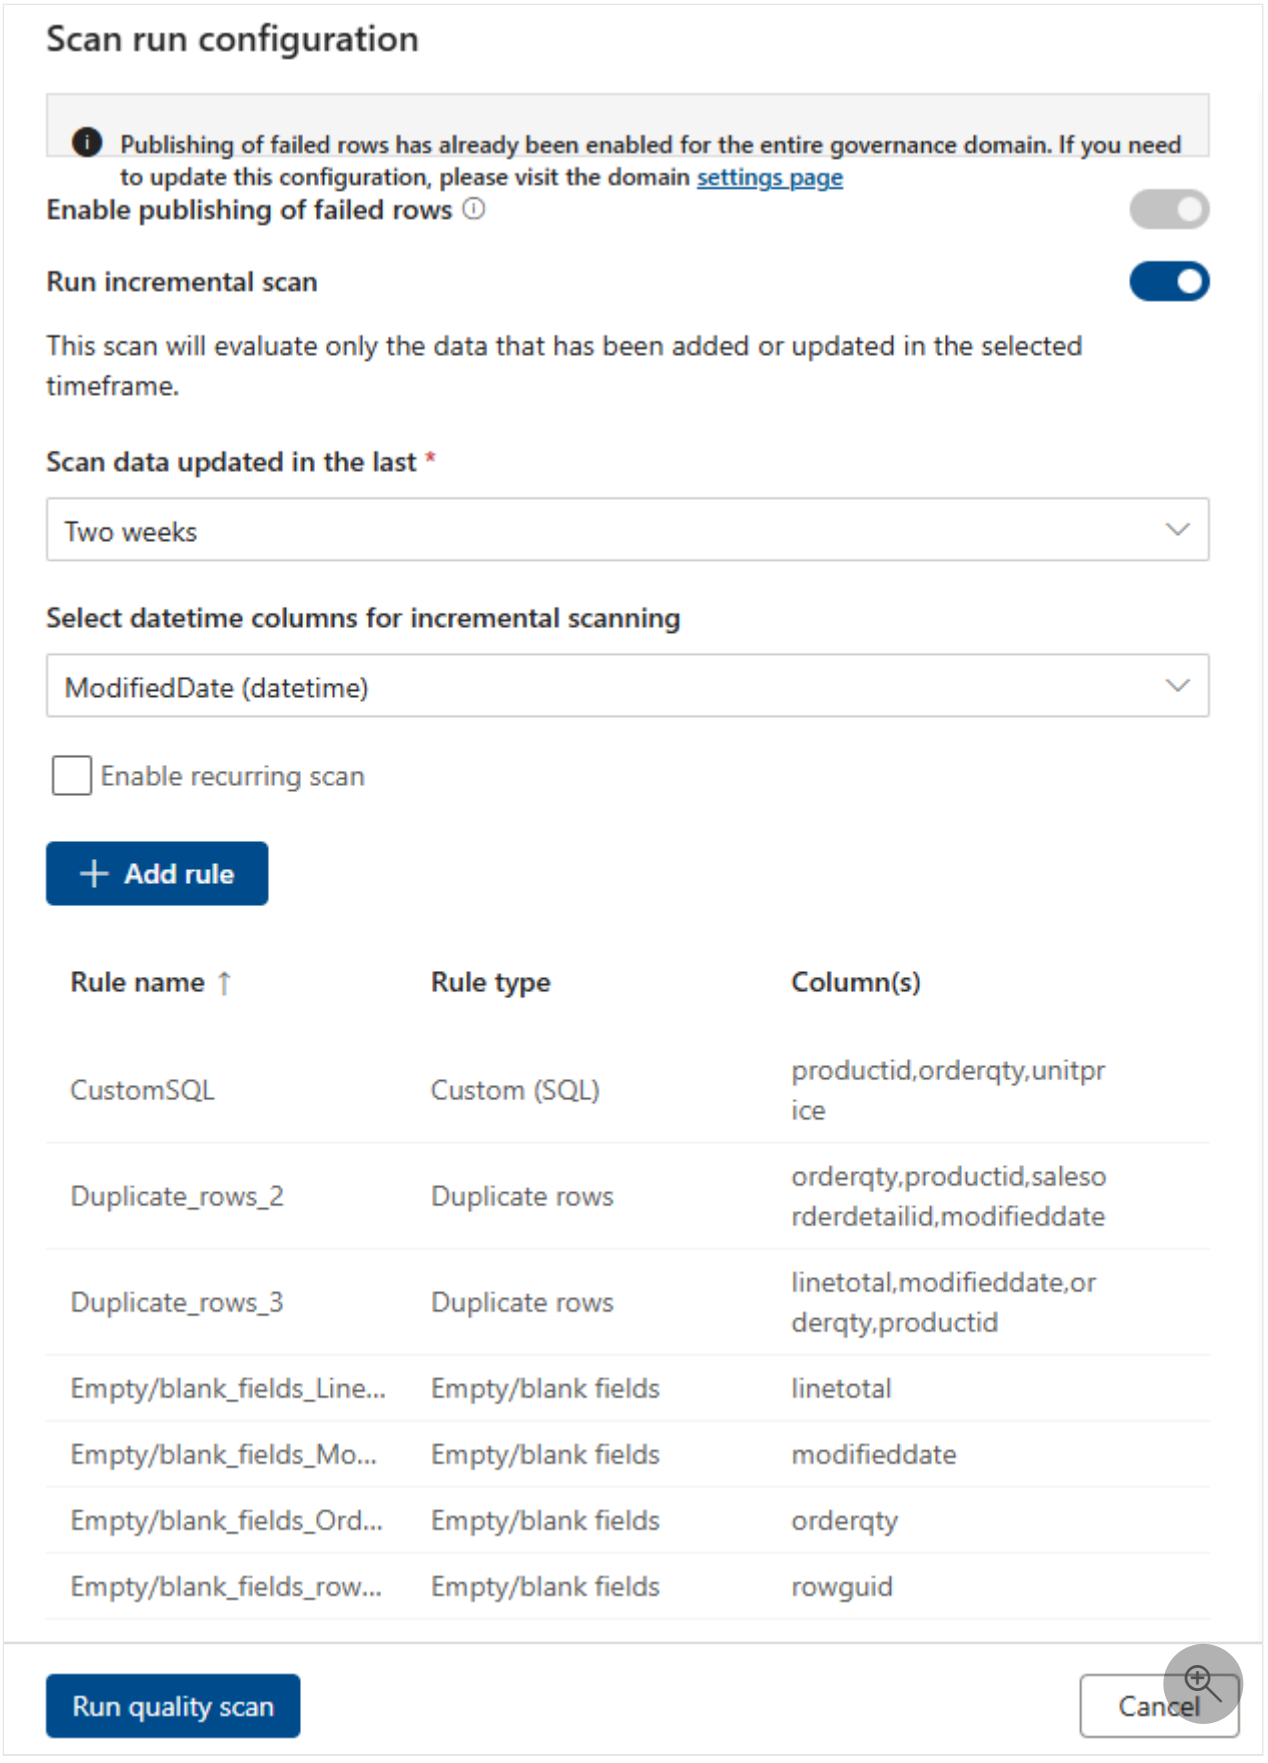
Currently, Microsoft Purview can only run data quality scans by using Managed Identity as authentication option. Data quality services run on **Apache Spark 3.4** and **Delta Lake 2.4**. For more information about supported regions, see data quality overview.

ⓘ Important

- If you update the schema on the data source, you need to import schema from data quality overview page by using **schema import feature** before running a data quality scan.
- Virtual network isn't supported for Google BigQuery.

Configure and run incremental data quality scan

1. In Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a **governance domain** from the list.
3. Configure a data source connection to the assets you're scanning for data quality if you haven't already done so.



4. Select a **data product** to assess the data quality of the **data assets** associated with that product. If you want to scan a data asset without data product association, select **Add assets** to add a data asset to the asset list from Data Map.
5. Select the name of a data asset, which takes you to the data quality **Overview** page.
6. Browse the existing data quality rules and add new rules by selecting **Rules**. Create custom rules using SQL expression or ADF expression language if out of the box rules aren't enough for your use case. Toggle on or off the rules you added if you want to turn off or on any rule.
7. Select the scan recurrence option:

    - Incremental
    - Full
    - Both

8. Select **Run quality scan** from the upper-right corner on the overview page.
9. Enable the Run incremental scan toggle and provide the following details:

    - Choose the time window for updated data: last day, last week, last two weeks, or last month
    - Select the datetime column to use for incremental scanning
    - Use the **Add Rule** tab to select rules from the predefined rule list

10. Select **Run Quality Scan** to execute the incremental scan.
11. Schedule incremental scan. To set up a schedule to run data quality scan, enable scheduled execution by selecting **Enable recurring scan** and setting the desired schedule. If you configure a recurring schedule, the **Run Quality Scan** button is read-only on the Scan Run Configuration page.
12. While the scan is running, you can track its progress from the data quality monitoring page in the governance domain.

> **Note**
>
> - Both **datetime** and **date** columns are supported, but we recommend using a **datetime** column. If the data asset doesn't contain a timestamp column, incremental data quality scans can't be configured for daily scans. A date column prevents the system from

calculating the last 24 hours accurately, which is required to slice one day's data for data quality scans. The datetime data type is also more commonly used for created, updated, and other timestamp columns.

- Filter days: 90 days for three months, 180 days for six months, and 365 days for one year.
- Auto-scheduling to run a weekly scan is enabled at the asset level by default. If you want to disable auto-scheduling for a data asset, go to **Health management** > **Data quality** > **Run quality scan**, and then select the option to disable the scheduled scan.
- When you manually run a data quality scan, a notification appears on the Data Quality page prompting you to configure alerts. Ignore this notification if you don't want to configure alerts.
- Cumulative score is calculated as the average of the incremental scan score and the full (regular) scan score.
- Incremental data quality scan isn't supported for on-premises data sources.

> **Important**
>
> Scan type, incremental data quality score, and cumulative data quality score don't publish to Azure Data Lake Storage Gen2 or Fabric Lakehouse for self-serve analytics.

Delete previous data quality scans and history

When you remove a data asset from a data product, if that data asset has a data quality score, delete the data quality score first, and then remove the data asset from the data product.

When you delete data quality history data, you remove the profile history, the data quality scan history, and data quality rules. Data quality actions aren't deleted.

To delete previous data quality scans of a data asset, follow these steps:

1. In Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a **governance domain** from the list.
3. Select the **data product** from the list. Select the **data asset** from the list to go to the Data quality overview page. If you're using the standalone data asset data quality feature, select the data asset from the data asset list.
4. Select the ellipsis (...) at the upper right of the Data quality overview page.
5. Select **Delete data quality data** to delete the history of data quality runs.

> **Note**
>
> - Use **Delete data quality data** for test runs, errored data quality runs, or if you're removing a data asset from a data product.
> - The system stores up to 50 snapshots of data quality profiling and data quality assessment history. To delete a specific snapshot, select the desired history run and select the delete icon.

Import schema

If the data type in a schema is undefined, incorrectly defined, or changed in the source, your data quality job might fail. If it fails, reimport the schema by using the schema import capability. You can import schemas for data sources on both public networks and behind private endpoints. For a list of supported data sources, see Data sources and file formats supported for data quality. To import a schema from your data sources, follow these steps:

- Select **Data quality** from **Health Management**.
- Select a business domain, and then select a data product. Select a data asset from that data product. You arrive at the data quality overview page.
- Select **Schema**, then select the **Schema management** toggle.
- Select **Import schema** to import the schema.

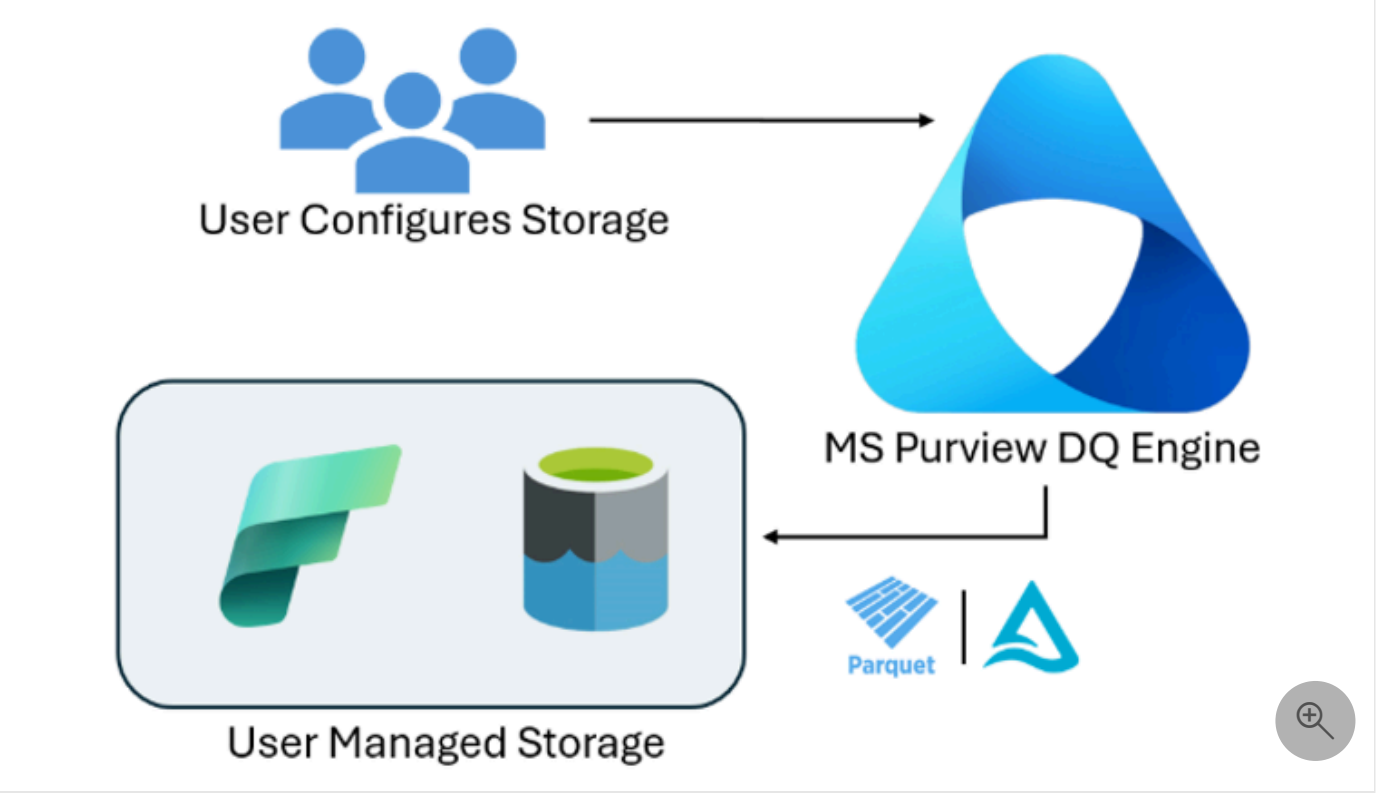
Data quality error records



When you perform data quality checks in Microsoft Purview Unified Catalog, you can configure and publish data quality error records for rule exceptions. By using this setup, you can review and remediate these records directly in your managed storage.

For cloud data sources, you can store and manage data quality error records in Microsoft Fabric Lakehouse or Azure Data Lake Storage Gen2. For on-premises data sources, you can create an error records database in Oracle or SQL Server to store and manage data quality error records.

By using this feature, Microsoft Purview Data Quality users can identify, analyze, and address data quality problems. It helps ensure data accuracy, completeness, consistency, timeliness, and validity across systems and use cases.

Architecture

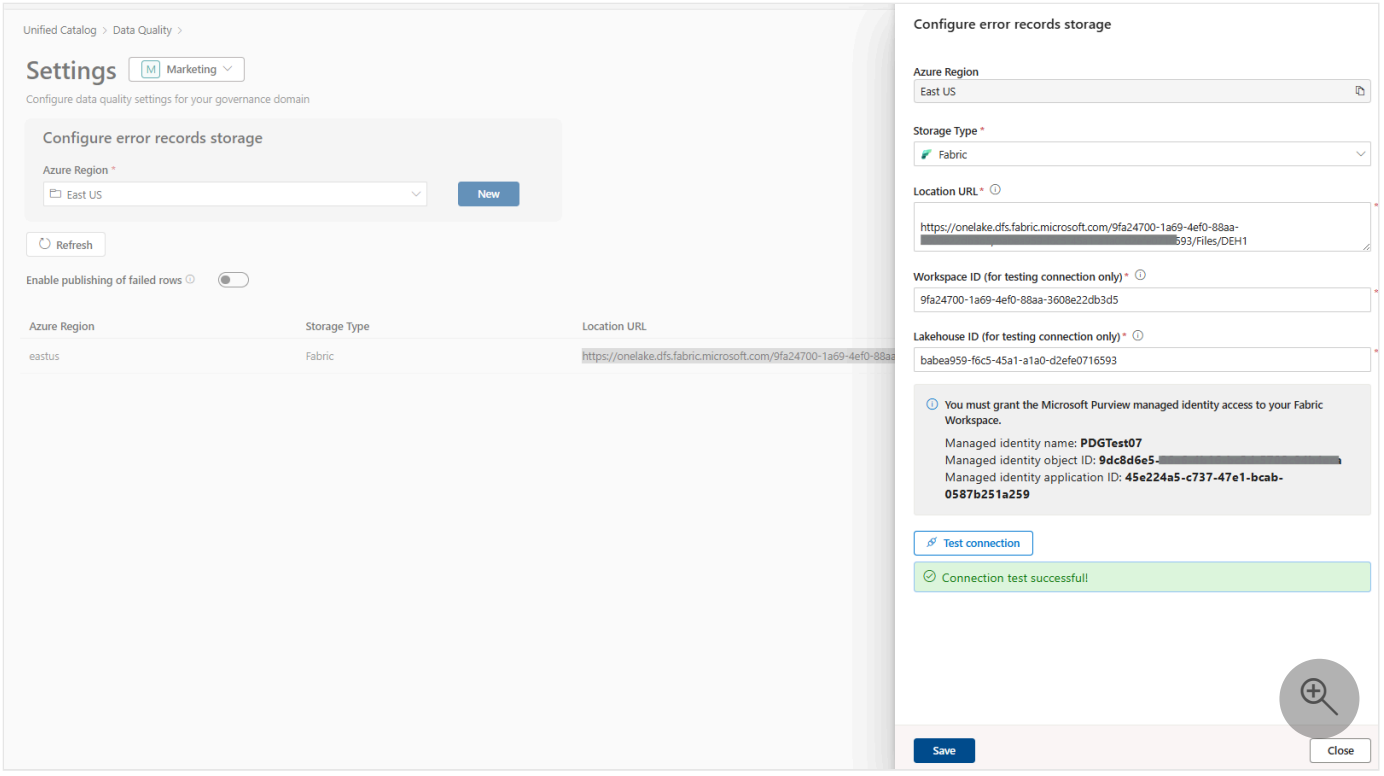
To publish data quality error records for rule exceptions, you need to set up your managed storage in Microsoft Purview. The Data Governance Administrator for your organization is responsible for configuring the storage details on the Microsoft Purview administration page. The Data Quality Steward can enable the toggle either from the Data Quality Manage console or the data quality overview page at **Unified Catalog** > **Health management** > **Data quality**.

Configuration storage location

- In Unified Catalog, go to **Health management** > **Data quality**.
- Select a governance domain from the list to open its details page.
- Select **Manage**, then select **Settings**.
- Select **Azure Region** from the dropdown list of all supported Azure regions.
- After selecting the Azure region, select **New** to configure storage details.
- Select **Storage Type**: Fabric or Data Lake Storage Gen2.
- Enter the **Location URL**.
- If you select **Fabric** as the storage type, enter the **Workspace ID** and **Lakehouse ID**. Grant contributor access to Microsoft Purview Manage Service Identity (MSI) to your Fabric workspace.
- If you select **Azure Data Lake Storage Gen2** as the storage type, enter following details:
  - Add **Azure subscription**. To find your Azure subscription name, go to `portal.azure.com`.
  - Add **Resource**. To find the resource name, select **Home** > select **Resource** from the **Resource list**.
  - Add **Container** name. To find the container name, select **Data Lake Storage** from the overview page in `portal.azure.com`
  - Add **Folder Path**. This is optional information.
  - Grant Storage Blob Data Contributor access to Microsoft Purview Manage Service Identity (MSI) to your Data Lake Storage Gen2 container.
- Test the connection.
- Save the configuration.
- You can **Save as draft** if you don't have all the required information so that you won't lose what you've entered.

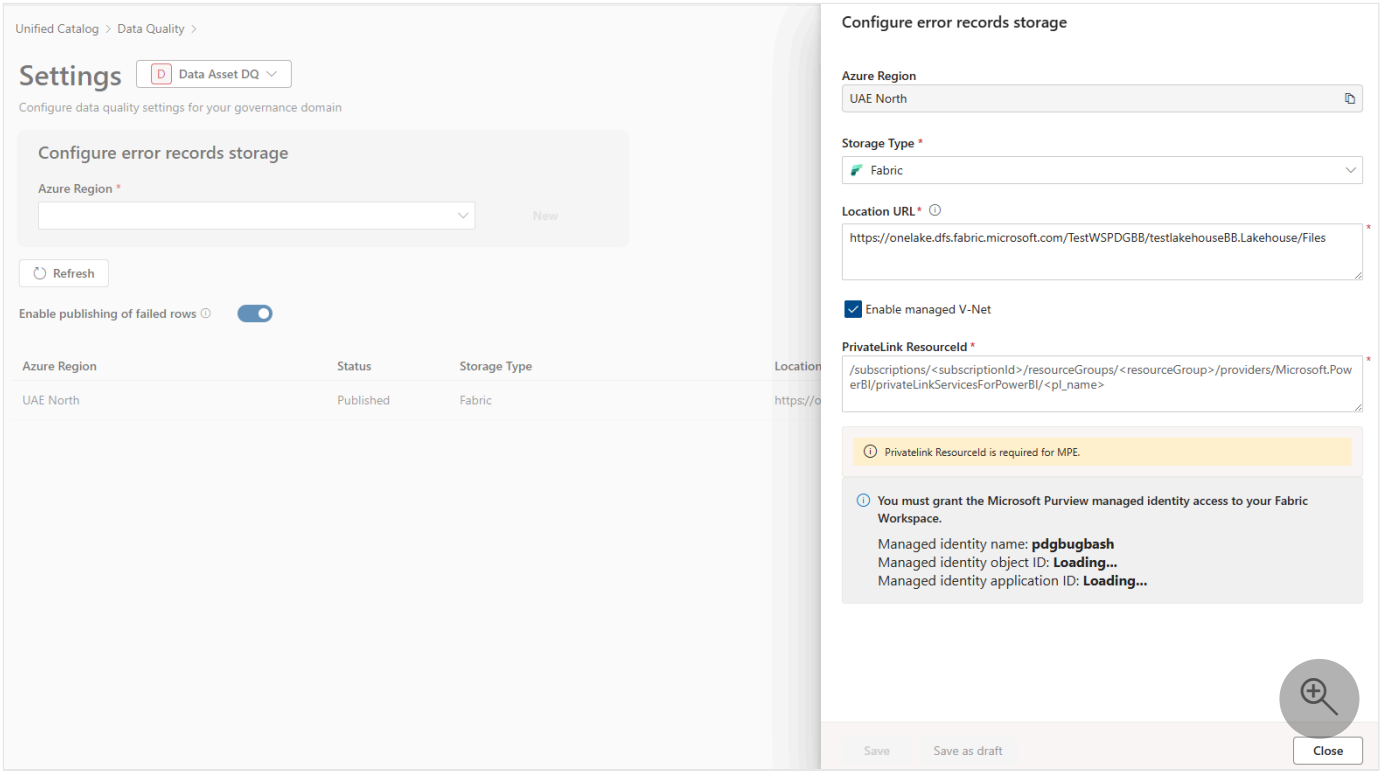
Compute is a prerequisite for private endpoint or virtual network storage setup. For private endpoint approval request, select **Enable managed V-Net** checkbox. An approval request is sent to your Azure portal, which you must approve to enable virtual network access. This process is similar to setting up a Data Quality connection. You must deploy the compute in the same Azure region as the storage account.

If you configure your Fabric tenant to run on a virtual network or in private link, select the **Enable managed V-NET** checkbox on the **Configure Storage** page. Then add the Private Link Resource ID as listed here:



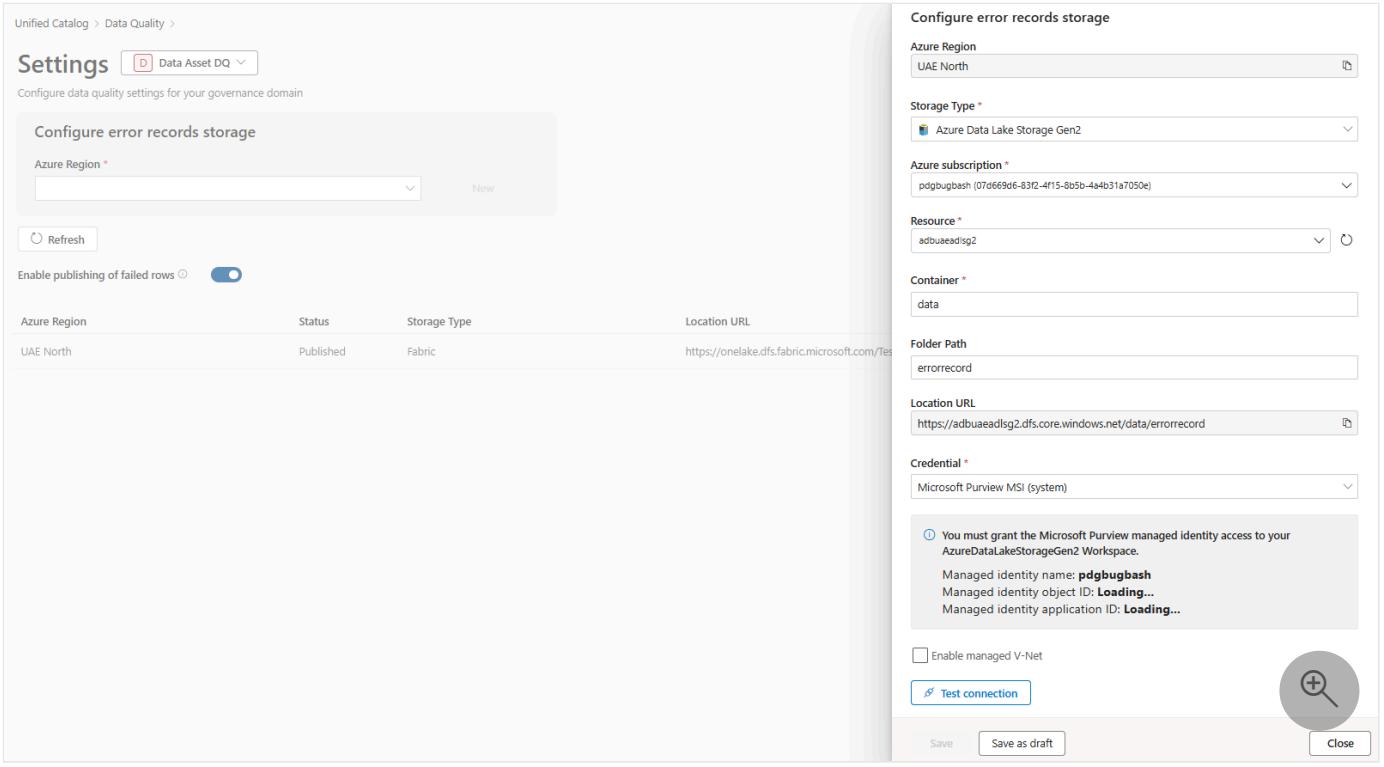
/subscriptions/07d669d6-83f2-4f15-8b5b
4a4b31a7050e/resourceGroups/pdgbugbashfabricvnet/providers/Microsoft.PowerBI/priva

teLinkServicesForPowerBI/fabricvnetpl.

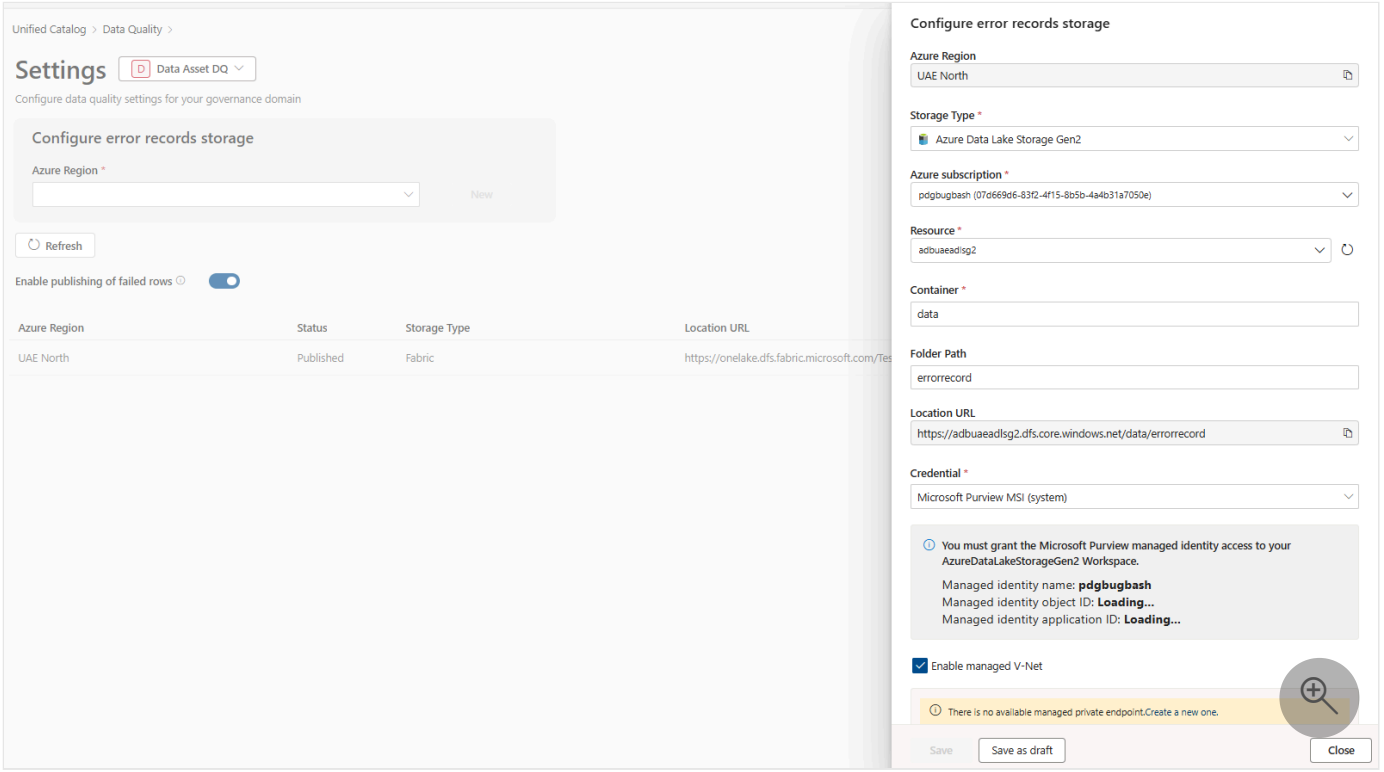


To set up compute for virtual networks, see Set up data quality for managed virtual networks. To set up and use private link for your Fabric tenant, follow the instructions to set up the private link for the Fabric tenant before configuring data quality virtual network connection and compute allocation.

> **Note**
>
> - Supported cloud data sources for Data Quality error records are: Azure SQL, Azure SQL MI, Azure Data Lake Storage G2, Azure Databricks, Microsoft Fabric, Azure Synapse, and Google BigQuery.
> - Supported on-premises data sources for error records are: Oracle and SQL Server.
> - If your data products include assets from multiple Azure regions, you must create a region-specific data quality error records folder for each region to meet data residency requirements. Microsoft Purview Data Quality doesn't copy data between Azure regions.
> - If you already created a storage location without specifying an Azure region, you must update it to include the region. Data quality failed/error records won't publish until a region is provided.
> - If you configure multiple region-specific folders for storing data quality failed/error records, Microsoft Purview Data Quality automatically routes the error records to the correct regional folder during the scan.
> - If you're using virtual networks, you can't test the connection. The **Test Connection** tab is disabled.
> - You can use error sink behind virtual networks only if you're also running the job in a virtual network connection. If not, error row publishing is skipped.
> - For a non-virtual network source connection to Azure Databricks Unity Catalog, Snowflake, Google BigQuery, Azure Synapse Analytics, on-premises Oracle Database, Fabric, and Azure SQL MI database, you need to set up error sink in the Microsoft Purview account region, not the data asset region.
> - For virtual network sources and all other types of non-virtual network sources, the error sink region has to match the asset region.



Data quality error records storage setting for non-virtual network storage - Fabric:



Data quality error records storage setting for virtual storage - Fabric:

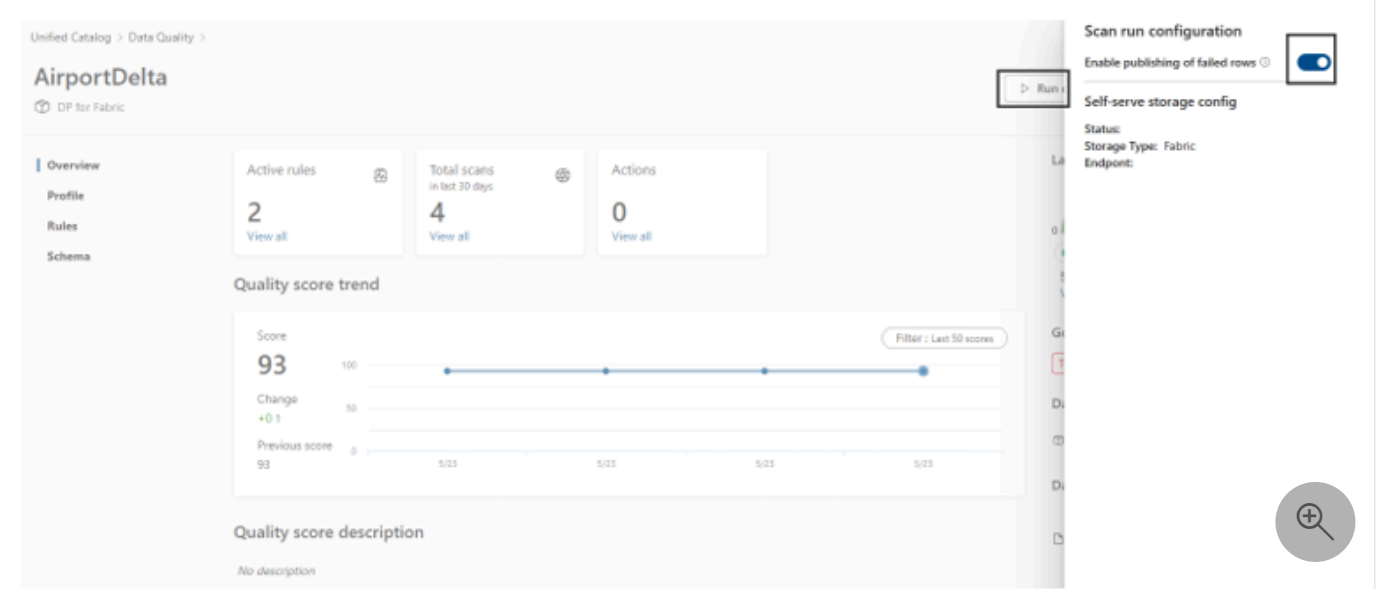
Data quality error records storage setting for non-virtual storage - AdlsG2:

Data quality error records storage setting for virtual network storage - AdlsG2:

⊗ Caution

- If you don't have storage and a connection set up to store data quality error records in the asset region (as mentioned in the preceding section), the data quality scan job still succeeds, but error row publishing is skipped.

- After configuring the storage and connection, you can enable the data quality error record feature either by going to **Health management** > **Data quality** > **Manage** > **Settings** for the selected governance domain, or from the Data Quality overview page for a data asset.
- To analyze the published erroneous records, use the latest versions of Spark (>= 3.xx) on Synapse or Databricks.
- Error sink configurations in a **published** state will only be used for error sink output, *not* in a **draft** state. If the configuration is in a draft state, the system skips error row publishing to the configured storage.



Data quality error detection

To detect data quality errors in your data, configure and set up a data quality scan. Select the data asset and configure rules for the critical columns that need a Data Quality measurement. You can use out-of-the-box rules, create custom rules, or use the rule suggestion feature to recommend rules for a data quality scan. For more information, see data quality rules.

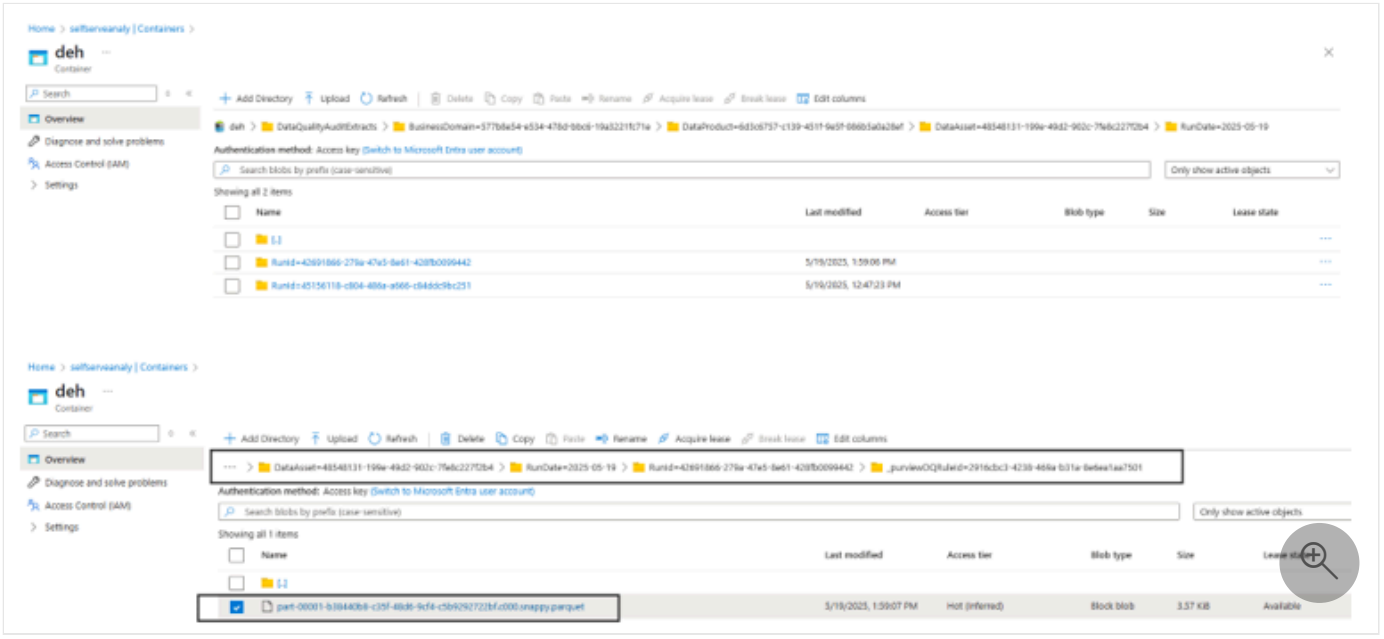
Enable error recording

To get error records, enable the capture and storage of error records for every data quality job run by following these steps:

1. Follow the instructions to start a data quality scan on a data asset.
2. After selecting **Run quality scan** on the data asset's page, turn on the toggle for **Enable publishing of failed rows**.

You can also enable error recording for all data assets with data quality rules associated with data products in a **governance domain** level by following these steps:

- In Unified Catalog, go to **Health management** > **Data quality**.
- Select a governance domain from the list to open its details page.
- Select **Manage**, then select **Settings**.
- Turn on the toggle for **Enable publishing of failed rows**.



Set up schedule to run

Set up the schedule to run your data quality job and publish the error records into the configured storage. For more information, see configure and run data quality scans.

Though you can run data quality scans on an ad-hoc basis by selecting **Run quality scan** on a data asset page, in production scenarios it's likely that the source data is constantly updated. Regularly monitor data quality to detect any problems. Automating the scanning process helps you manage regular updates of quality scans.

Check the error records in the configured storage

1. Find the location of the published error rows from the data quality overview page.
2. Select **View Scan report**, in the top-right corner just below the **Latest quality score**.
3. Go to the path shown in your Data Lake Storage Gen2 or Fabric Lakehouse folder, as seen in the following example:

Data Lake Storage Gen2 folder hierarchy

Data Lake Storage Gen2 container (for example, folder name is DEH):

1. DataQualityAuditExtract
2. Governance domain (BusinessDomain)
3. DataProduct
4. DataAsset
5. RunDate
6. RunId
7. Purview DQRunId
8. Error record file

Read data quality error records from Data Lake Storage Gen2

Use a Synapse or Databricks notebook to read data from Data Lake Storage Gen2 container by using this PySpark script:

Python

```
#For complete error records of all jobs run on the asset
path =
"abfss://TestWSPDGBB@onelake.dfs.fabric.microsoft.com/TestSelfServeLakehouse.Lakehouse
/Files/SelfServeFolder/DataQualityAuditExtracts/BusinessDomain_577b8e54-e534-478d-

display(df)
```

Example dataset:

Read error records from Fabric Lakehouse

1. Go to the path shown in your Lakehouse, and browse all fail records published to Fabric Lakehouse.
2. Create a shortcut from Delta Parquet to Delta Table. Or you can use a Delta Parquet file to create a dashboard of your data quality error records, as seen in this example:

Use a notebook to create a shortcut table of failed data asset records. See the notebook script.

Output data model

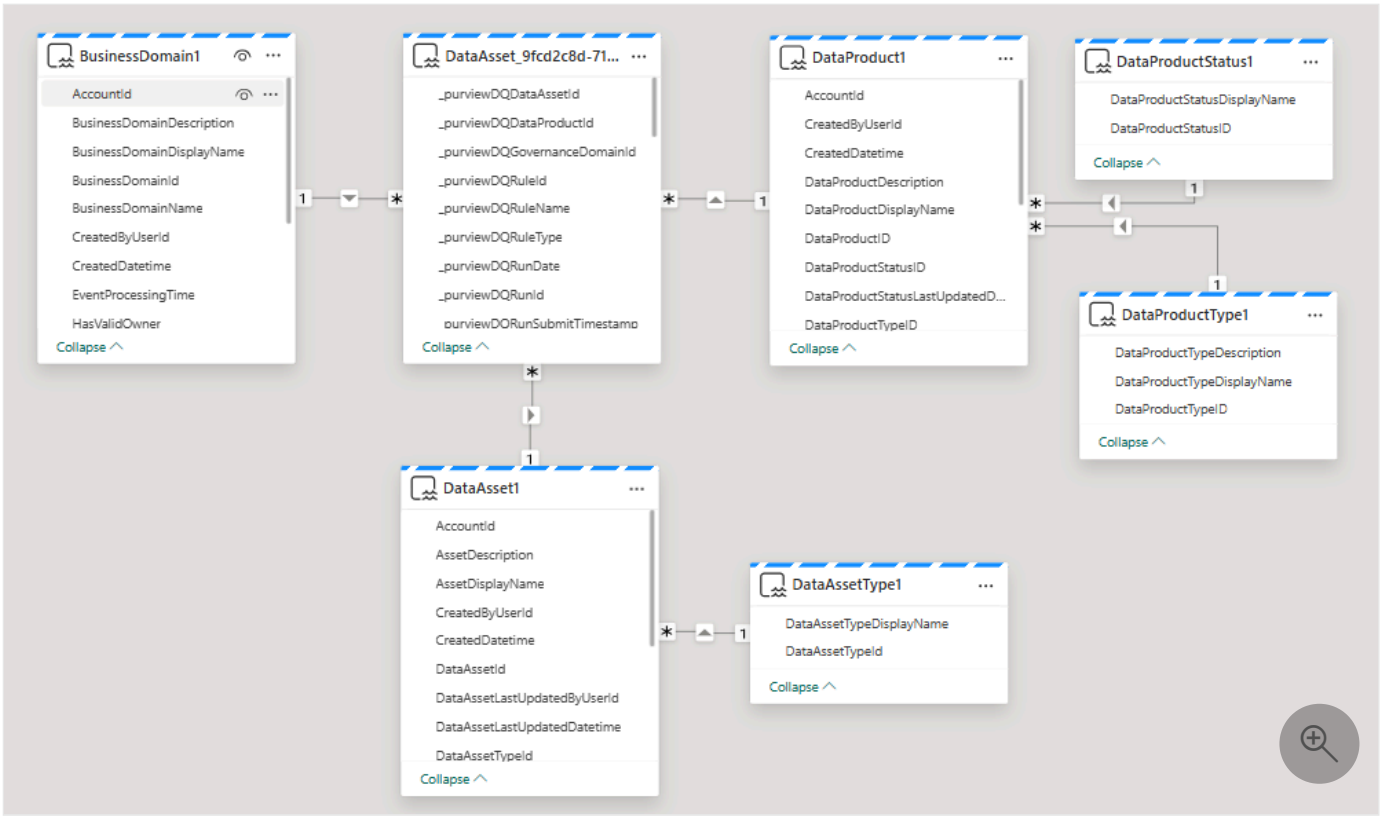
You can view failed records at the level of a governed data asset. For each new assessment run that succeeds on the data asset, the process adds a new set of failed records for each rule evaluation to the failed records table.

Format: Delta

Output schema: Each row of output contains all the columns of an input data asset row that failed a rule evaluation, along with a set of metadata columns that you can use to identify and analyze the failed row.

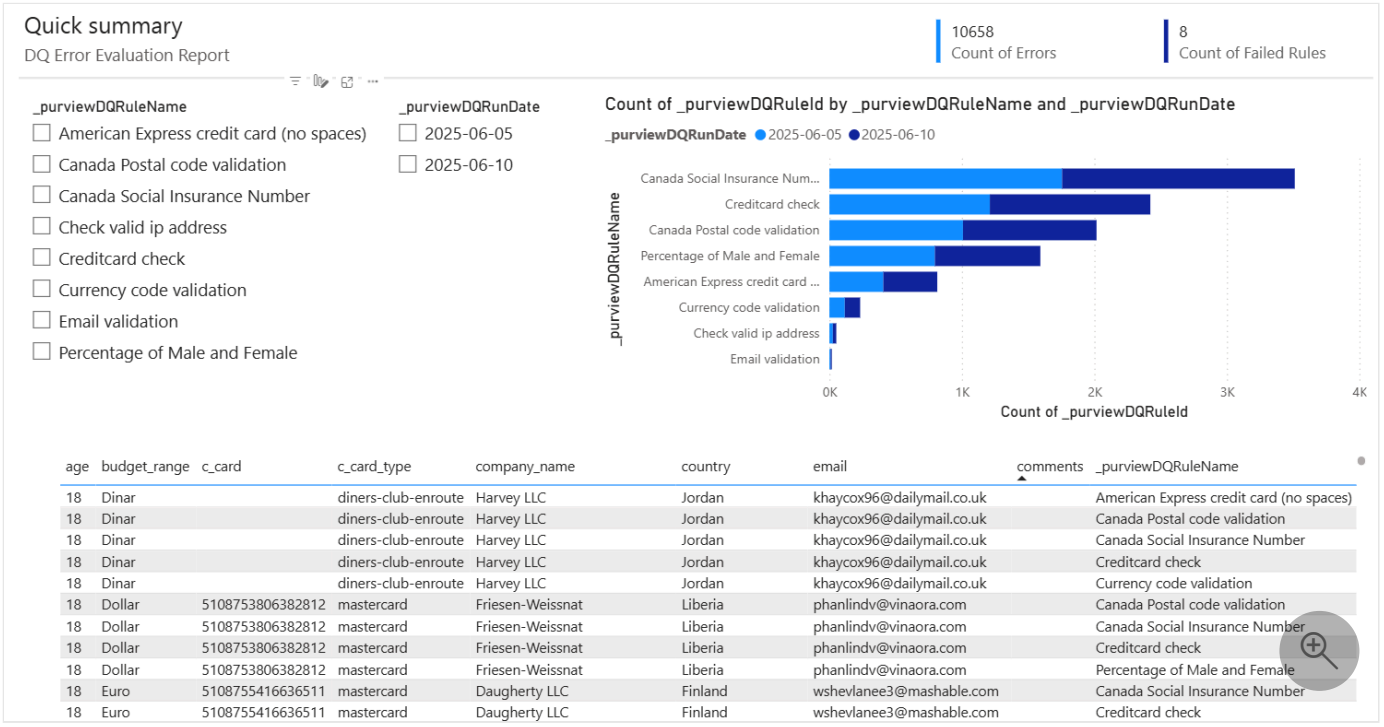
Primary key: Composite key of input data asset columns + _purviewDQRunId + _purviewDQRuleId

Expand table



Metadata columns	Data type	Description
_purviewDQRunId	string	A GUID that represents the Run ID of the assessment scan available to the user at the time of run. Also, a Delta partition-column.
_purviewDQRunDate	string	The run date in YYYY-MM-DD format. Also, a Delta partition-column.
_purviewDQRuleId	string	The quality Rule ID that corresponds to the failed rule. Also, a Delta partition-column.
_purviewDQRuleName	string	The Rule Name at the time of job run.
_purviewDQRuleType	string	The Rule type (for example: UniqueCheck, NotNull, Regex).
_purviewDQGovernanceDomainId	string	The governance domain ID of the data asset that you ran.
_purviewDQDataProductId	string	The data product of the data asset that you ran.
_purviewDQDataAssetId	string	The data asset ID.
_purviewDQRunSubmitTimestamp	string	The exact timestamps of the run submit time in the default UTC time-zone per the ISO format.

Create a Power BI dashboard for your data quality error records



Use the Business Domain ID to link data products and their associated data assets for reporting data quality error records.

- One business domain can link to multiple data products.
- Each data product can link to multiple data assets.
- Each data asset can have multiple rules.
- Each rule can generate multiple error records.

This image illustrates a data model to create a basic report of your data quality error record:

This image illustrates a sample report created with the data model shown in the preceding image:

Limitations

- 100,000 failed records are published per rule for each run.
- Datasets up to 100 million rows with up to 40 rules have been benchmarked.
- As data is stored in organizations' managed storage, the organization owns role-based access control for the data. Microsoft publishes data quality error rows to an organization's

storage based on the organization's consent.

> **Note**
>
> Failed rows can't be accessed by selecting the URL. For security reasons, direct browsing of the error record database through the URL isn't supported.
>
> Example URL: `https://onelake.dfs.fabric.microsoft.com/xxxxxxx-4xxx-88aa-xxxe22db3d5/babea959-fxxxxxxxxx-d2efe0716593/Files/xxxx1/DataQualityAuditExtracts/BusinessDomain_xxxx-xxxx-ccc9-92c2-1554a93dd2af/DataProduct_abc33xxxxyu-28ec-4186-01fg-591c0420e677/DataAsset_xxxxx-583a-49ee-abd6-6543464654e4ss`

Script to create shortcut

You can automate the creation of table shortcuts from data quality audit extracts failed row data by using this script in a Fabric notebook. After creating the shortcut tables, your error records for new job runs on the asset shortcut table automatically refresh in Fabric.

Python

```
# NEW Script to automate the creation of table shortcuts from Data Quality audit extracts failed row data.

# Update these three values for your Fabric Workspace ID, Lakehouse ID and Purview BYOC Self-serve store path
workspaceId = "f28dc1c8-360c-4788-9f46-e69853b1c40d" #Example: f28dc1c8-360c-4788-9f46-e69853b1c40d
lakehouseId = "77d6df6b-64ab-4628-985f-9365591a85a8" #Example: 77d6df6b-64ab-4628-985f-9365591a85a8
dataqualityauditPath = "Files/SelfServeFolder/DataQualityAuditExtracts" #Example: "Files/DEH2/DataQualityAuditExtracts"

#Use for lakehouses with Lakehouse-Schema (Public preview feature)
DestinationShortcutUri = f"abfss://{workspaceId}@onelake.dfs.fabric.microsoft.com/{lakehouseId}/Tables/DataQualityAuditExtracts"

#Use for lakehouses without Lakehouse-Schema
#DestinationShortcutUri = f"abfss://{workspaceId}@onelake.dfs.fabric.microsoft.com/{lakehouseId}/Tables"

```

Error records for on-premises data sources

Data quality error records for on-premises data sources are stored within the corresponding on-premises Oracle or SQL Server databases. Users must define a designated error database where data quality failed records will be stored. For each supported on-premises data source, users are required to create an error database in the same environment. For example, if users are performing data quality assessments on an Oracle database, they must create an Oracle error database to store the resulting failed or error records. Similarly, if users are assessing data quality on a SQL Server database, they must create a SQL Server database to store the corresponding data quality failed records.

Example of Oracle database data quality error records setup

Error record table naming convention

Table Name Format

`PURVIEW_ERRORRECORD_<SCHEMA>_<ASSET_NAME>`

Example

- Schema: ORACLENEW_DATAGOV
- Asset / Table Name: EMPLOYEE_DETAILS_ERRORRECORD

Final table name:

PURVIEW_ERRORRECORD_ORACLENEW_DATAGOV_EMPLOYEE_DETAILS_ERRORRECORD

This convention ensures:

- Clear traceability to the source schema
- Easy identification of error-record tables
- Alignment with Purview data governance standards

Data load scenarios

Scenario 1: First-Time Load (Table Creation)

- Table, columns, and indexes are created during the first execution
- Records inserted: 1,000,000
- Rules applied: 1

Timestamps:

- CreatedAt: 01/28/2026 07:37:55 PM
- LastModifiedAt: 01/28/2026 07:41:34 PM

Scenario 2: Load on existing table

- Table already exists
- Only data insertion occurs
- Records inserted: 1,000,000
- Rules applied: 1

Timestamps:

- CreatedAt: 01/28/2026 07:33:19 PM
- LastModifiedAt: 01/28/2026 07:36:54 PM

Failure recovery and restart logic

- If data insertion fails, the process resumes from the last successfully inserted record.
- Previously inserted records aren't duplicated.

This ensures:

- Idempotent behavior
- No data loss
- Minimal reprocessing

Querying error record tables

Source Table: MANUFACTURERS Error Record Table:
PURVIEW_ERRORRECORD_DBO_MANUFACTURERS

Sample query

```
SELECT TOP 5 *
FROM PURVIEW_ERRORRECORD_DBO_MANUFACTURERS WITH (NOLOCK)
WHERE _PurviewJobId = 'c7f7c92e-9a36-46c5-86bc-bc3c595d5ddd';
```

This query retrieves error records associated with a specific Microsoft Purview job execution.

SQL Server performance metrics

1 Million Record Insert Performance

Execution time:

- CreatedAt: 01/29/2026 04:45:05 PM
- LastModifiedAt: 01/29/2026 04:54:14 PM

Total Time Taken: ~9 minutes

This demonstrates efficient bulk insertion using parallel processing.

> **Note**
>
> - Proper Oracle and SQL Server permissions should be configured for data governance operations.
> - Use standardized naming convention for error record tables.
> - Large-scale inserts should be optimized using parallel batching.
> - Enabling failure recovery ensures safe restart without duplication.

Monitor data quality jobs

Article • 04/21/2025

Data quality job monitoring enables data quality stewards to see the progress of data profiling, data quality rule generation, and data quality scanning jobs. Both manually configured and scheduled jobs' progress can be viewed from the data quality monitoring page.

Browse data quality job status

1. In Microsoft Purview Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a **governance domain**.
3. From the **Manage** dropdown menu, select **Monitoring**.
4. The **Activities** tab shows a summary of all activities. Use the filters to scope your view by submit time, status, activity type, scan type, or scan name. Select the activity for more details.
5. You can switch between governance domains from this menu, using the governance domain tab next to the page title.
6. Select the **Scan** tab to see the progress of scheduled scans.
7. Select and open a completed job for a data asset. Under **Scan details**, you can view the processing units consumed at **PU consumed**. To calculate the cost of the data quality job, multiply the **PU consumed** with SKU cost.

Next steps

- Review your scan results to evaluate your data product's current data quality.
- Configure alerts for data quality scan results.
- Run a data profile.
- Create a data quality scan.

Review data quality scores of data assets

After you create data quality rules and run a data quality scan, your data assets receive a data quality score based on results from your rules. This article explains how scores are calculated so you can better understand your data quality results and develop action items to improve your data's integrity.

Understand data quality scores

Data quality rules describe the state of the data. They show how far the data is from the ideal state described by the rules. Each rule produces a score that describes how close the data is to its desired state. Most rules are straightforward; they divide the total number of rows that pass the assessment by the total number of rows to arrive at the score.

The formula used to calculate the data quality score for a rule against data in a column is:

`[(total number of passed records)/(passed records + failed records + miscast records + empty records)]`

- Numerator = total number of passed records
- Denominator = total number of records (number of passed records + number of failed records + number of miscast records + number of empty records)

> ⓘ Note
>
> - **Passed**: Number of records that passed an applied rule.
> - **Unevaluable**: The columns required to evaluate this rule aren't evaluable.
> - **Failed**: Number of records that failed an applied rule.
> - **Miscast**: The data type of the asset and the type that customer listed it as not matching. It can't be converted to the expressed type.
> - **Empty**: Null or blank records.
> - **Ignored**: Rows didn't participate in the rule evaluation. Users can express rows to ignore; for example, ignore all rows that have email="n/a", or ignore all rows where departmentCode='test' or 'internal'. Ignored records aren't used for score calculation.

Microsoft Purview Data Quality then gives a sense for the state of each column by generating a column score. This score is the average of all the scores of the rules on that column. Once the column scores are calculated, the formula used to calculate average percentage data quality score for data products and governance domains is:

`[(Percentage 1 + Percentage 2) / (Sample size 1 + Sample size 2)] x 100`

The score is multiplied by 100 to make the scores more readable.

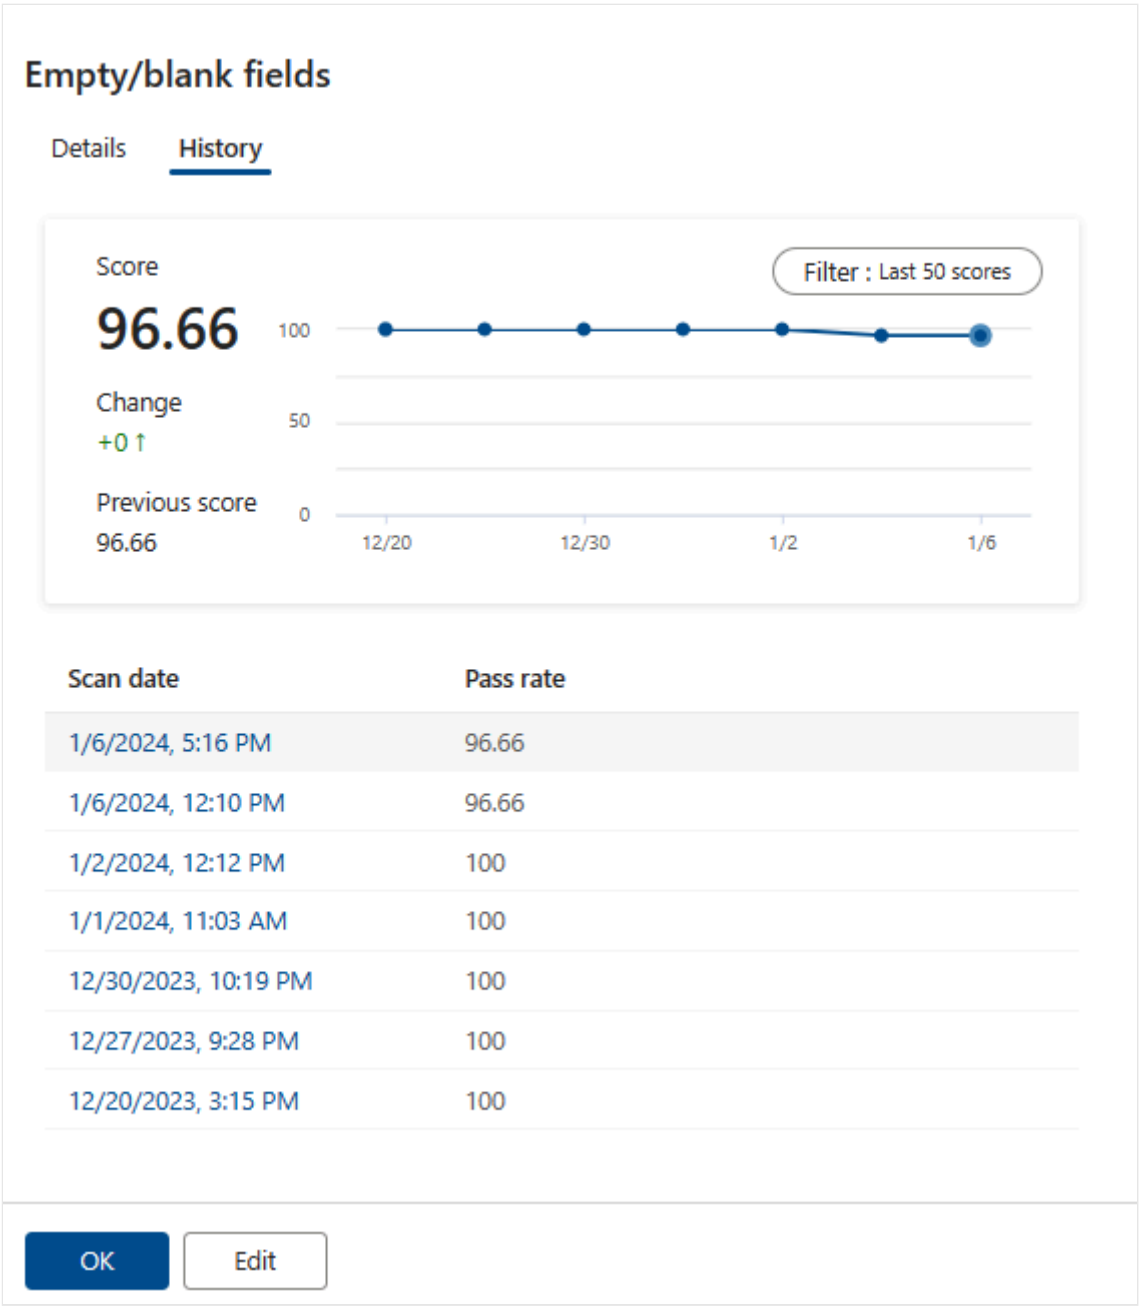
Example calculation

Let's imagine there's a column that doesn't have the **Empty/blank fields** rule defined on it. This implies that null values are allowed for this column. So certain rules, like the **Unique values** rule, will filter out null values in that case.

For example: If the asset has 10,000 rows in a table but 3,000 were null and 500 weren't unique then the score would be: `((10000 - 3000 - 500)/(10000 - 3000) )* 100 = 93`

The null rows are ignored when evaluating the data and determining a score.

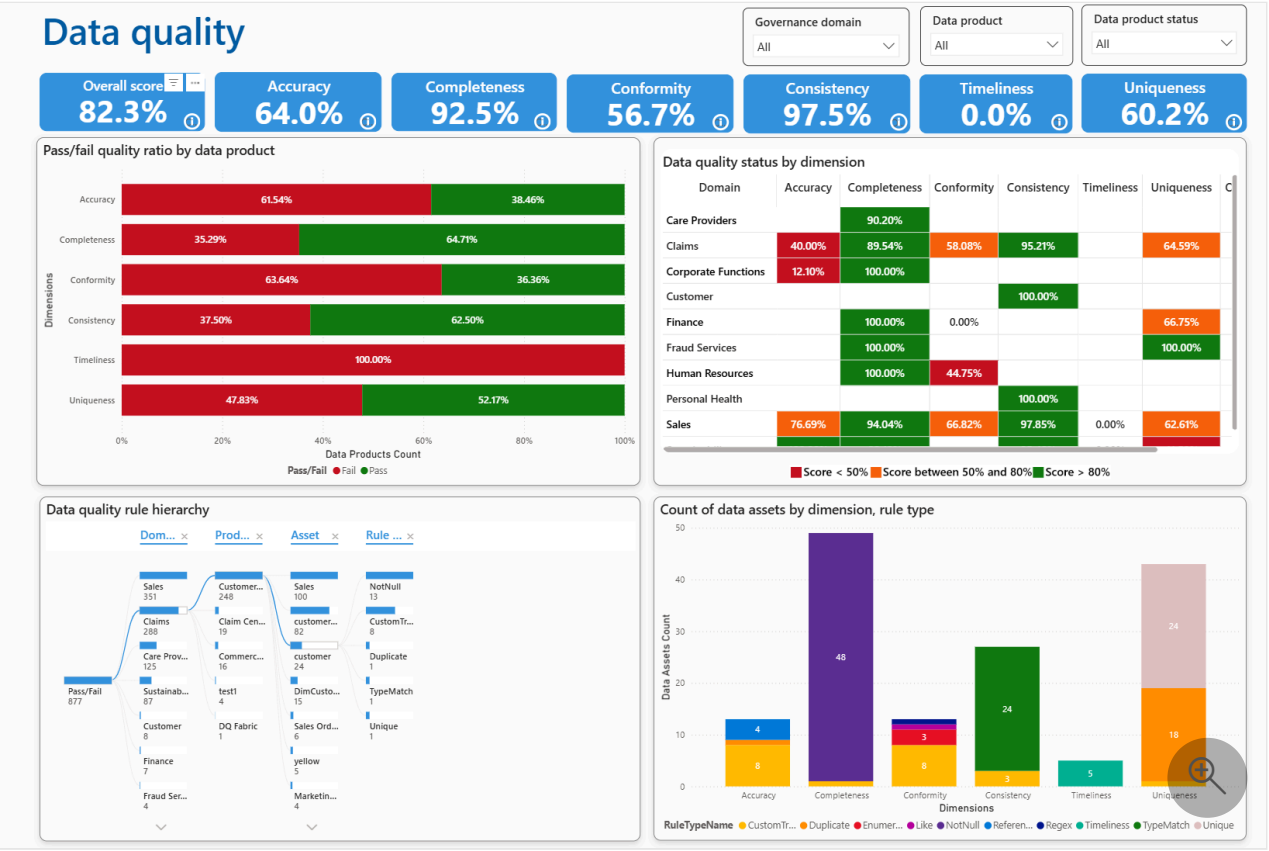
Specific rule scores



For **Custom** rules, there's a capability similar to what you might see for the unique values rule. But in this case, the filter isn't on nulls, but rather the filter expression.

Some rules, like the **Freshness** rule, are either pass or fail, so their scores are either 0 or 100. The Freshness rule is applied at the data asset level, not at the column level.

Rule details and history



You can view the details and history of rule scores by selecting a rule. Selecting a specific rule name and navigating to the rule **History** tab, you see the trend of the different scan runs for the particular rule.

- Rule **Details** provides information on the number of rows passed, failed, and ignored for the various runs for the particular rule. Rules that are in **draft state** (OFF state) won't have their scores contribute to the global score. Rules in a draft state won't be run at all during quality scans and so won't have scores.

- Columns and rules have a many-to-many relationship, the same rule can be applied to many columns, and many rules can be applied to the same column. You can view the trend pattern of each rule by going to the **Schema** tab on the asset's data quality page and viewing the line in the **Trend** column.
- Asset level data quality score trends are available for the last 50 runs. This quality score trend helps data quality stewards to monitor data quality trend and fluctuations month over month. Data quality can also trigger alerts for every data quality scan if the quality score doesn't meet the threshold or business expectation.
- Global score is the average of the production rules defined on the asset. The asset level global score is also rolled up to the data product level and governance domain level. The global score is intended to be the official definition of the state of the data asset, data product, and governance domain in context of quality of data.

- A summary report is created for data quality dimension. This report contains data quality score for each data quality dimension. Global score for the governance domain is published also in this report. You can browse the quality score for each governance domain, data product, and data asset from this Power BI report.

> **Note**
>
> - Data quality dimensions are recognized terms used by data practitioners to describe a feature of data that can be measured or assessed against defined standards in order to quantify the quality level of data used to run a business.
> - The data quality score for an asset is the arithmetic average of the scores of the rules applied to its columns.
> - The data quality score for a data product is the arithmetic average of the data quality scores of the data assets associated with that data product.
> - The data quality score for a governance domain is the arithmetic average of the data quality scores of the data products associated with that domain.

Next steps

- Data quality scan

Data quality improvement actions

The quality of data directly affects the quality of decision making. Good quality data provides business process insights, a better understanding of customers, and faster problem identification. Data quality actions identify problems that you should address to improve data quality in your data estate.

Required roles

- To see data quality actions in your environment, users need the data quality reader role.
- To assign and modify actions, users need the data quality steward role.

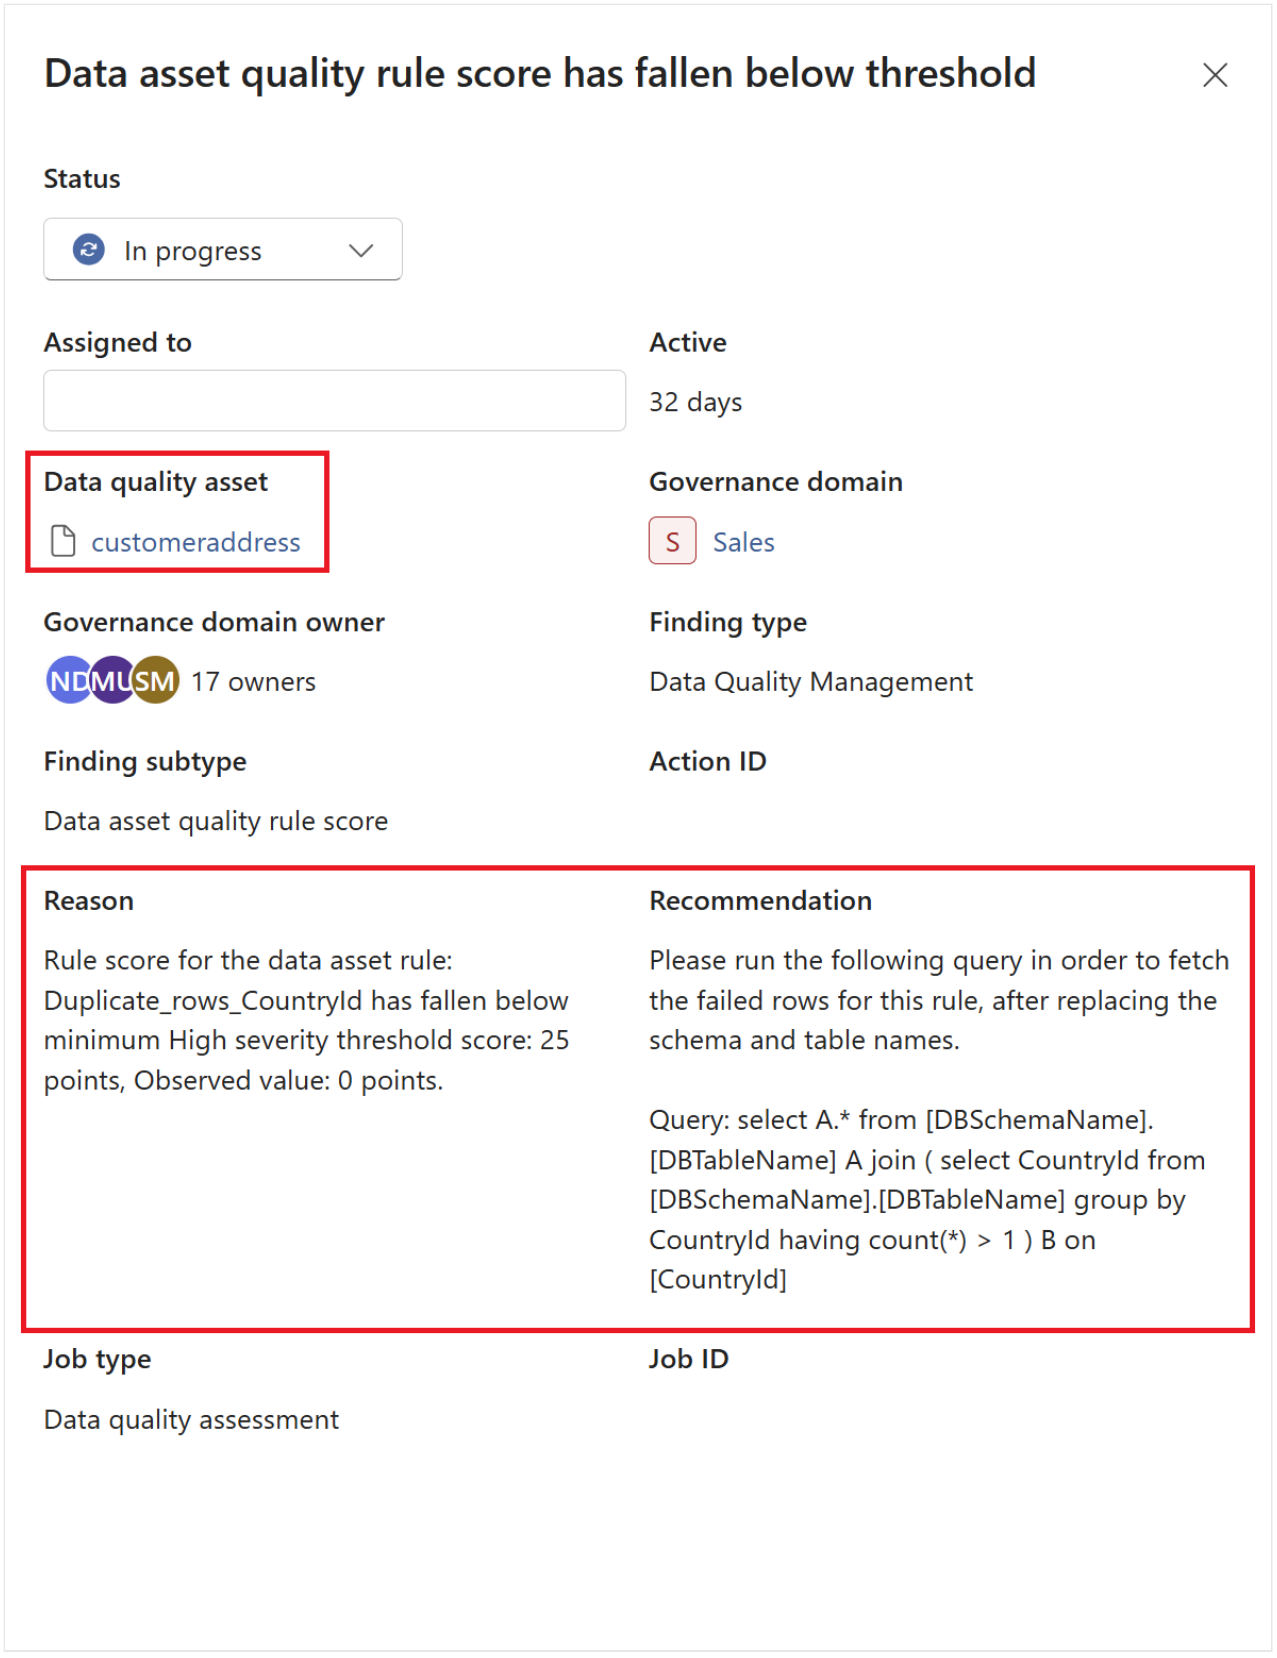
Data quality action types

The types of data quality actions generated are:

- A rule that falls below default thresholds.
- A global data quality score that falls below the threshold.
- A data quality scanning and data quality profiling job that fails.
- A data quality scanning and data quality profiling job that skips due to no changes on data since the last run.
- Outlier presence in profiled columns.
- Too many nulls in the profiled data asset.

Data quality actions severity

Data quality actions have a severity level and color indicator depending on the data quality score:



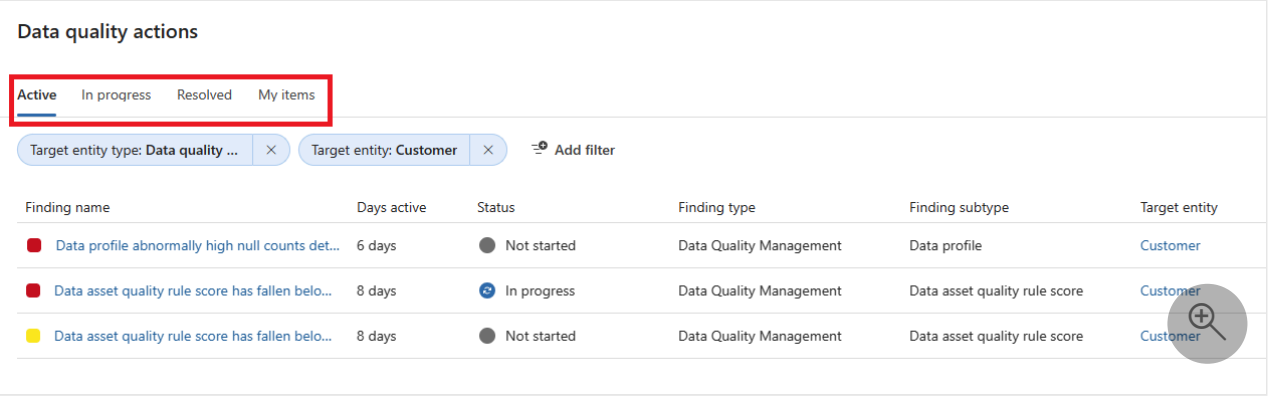
- **High (red)**: Data quality score is less than **25**.
- **Medium (orange)**: Data quality score is less than **50**.
- **Low (yellow)**: Data quality score is less than **75**.

View and manage data quality actions for governance domains

Data quality actions roll up from the data asset level to the governance domain level. To browse actions and assign them to users for further action:

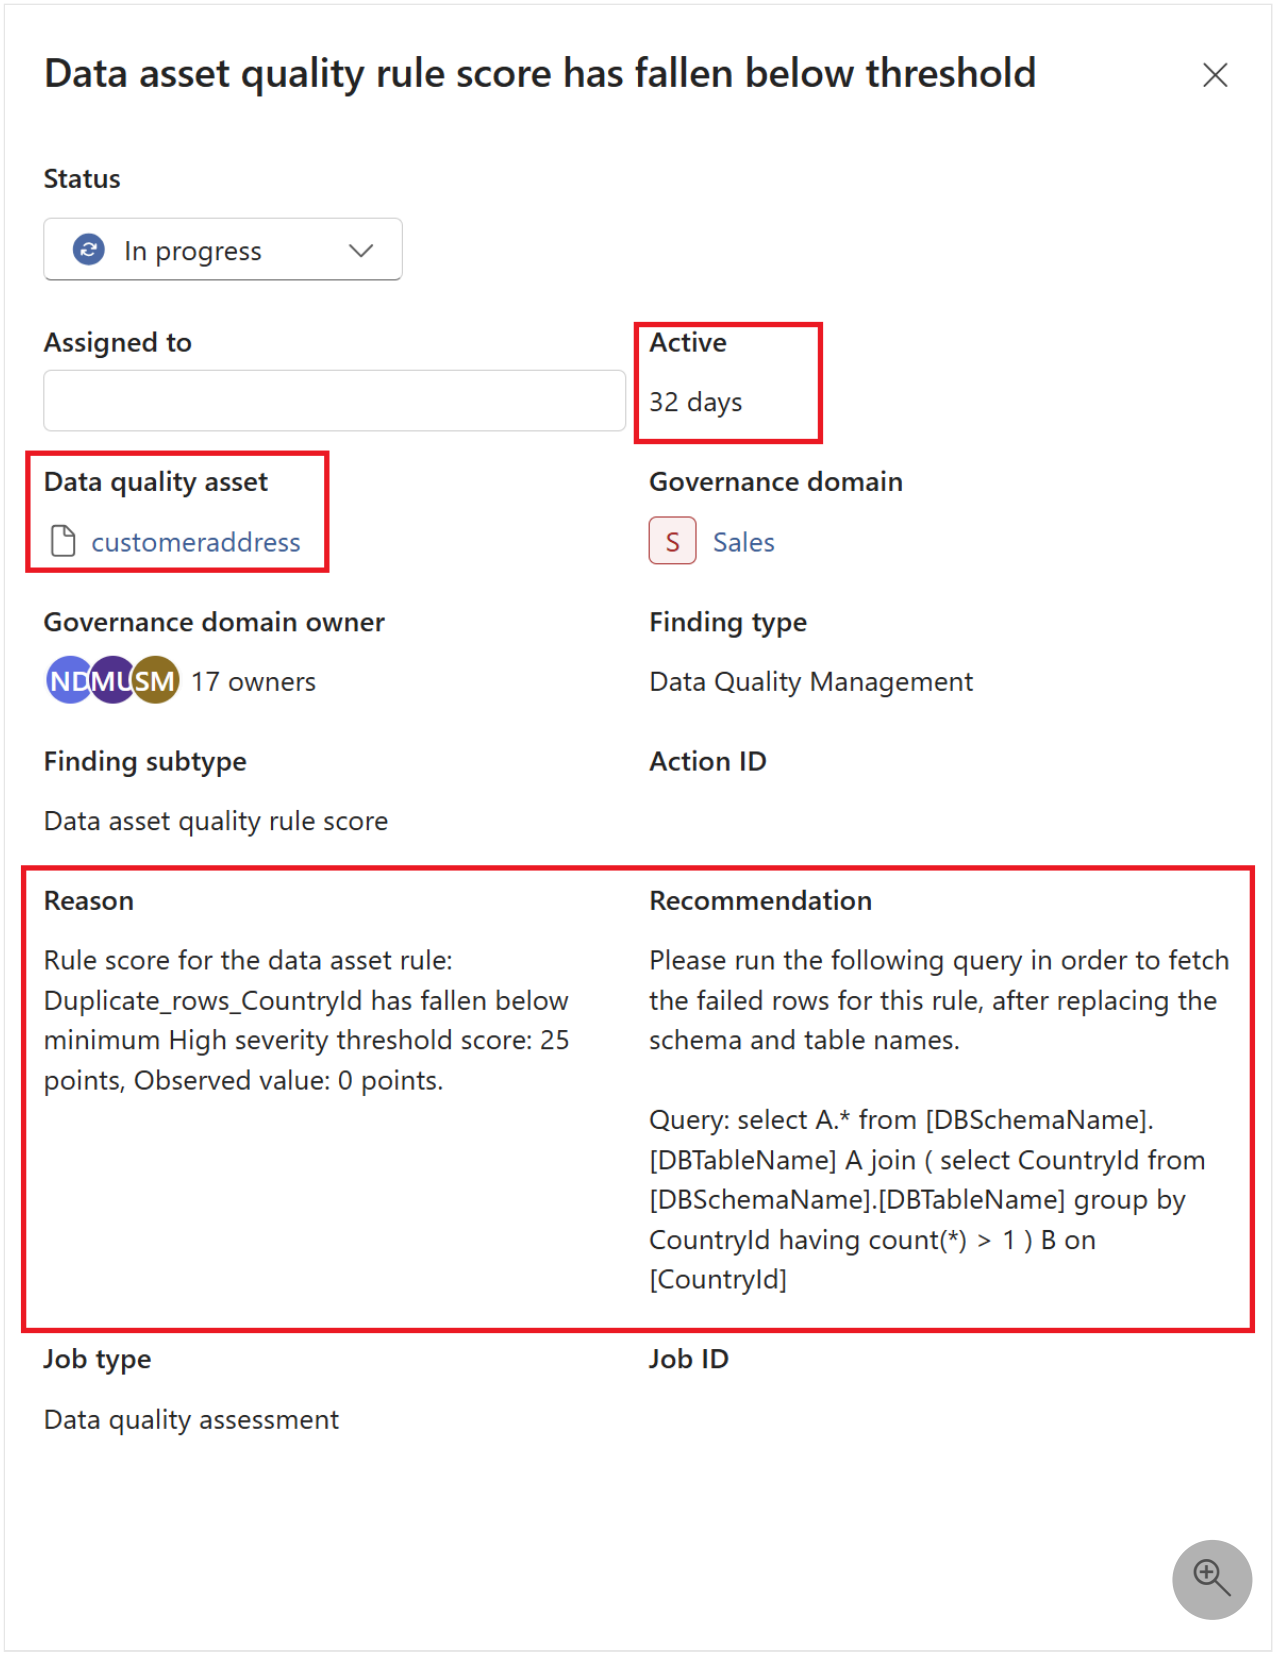
1. In Microsoft Purview Unified Catalog, select **Health Management**, then select **Data quality**.
2. Select a governance domain from the list.
3. The **Action items** button shows the number of action items for the domain. Select **Action items** to view all data quality actions.
4. Select an action from the list of actions to view the action's details page.
5. From here, you can assign the action to a user to investigate and resolve. The **Recommendation** section suggests the action to take and provides queries to find the low quality data.

> **Note**
>
> - Not every action has a SQL query because not all actions are data related or related to a data quality rule. Some actions are system related, such as a failed or skipped data quality job.
> - If a custom rule exception occurs, which means that the data quality score generated from the custom rule doesn't meet the defined threshold, an action is created. However, a SQL query isn't suggested.



6. Update the *Status**, then select **Save**.

View and manage data quality actions for data assets



You can browse data quality actions for a data asset and assign them to users from the data quality overview page:

1. In Microsoft Purview Unified Catalog, select the **Health Management** menu and **Data quality** submenu.
2. Select a governance domain from the list.
3. Select a **data product** from the list, then select a **data asset** from the list of assets.
4. On the data asset's details page, select **View all** on the **Actions** tile to see all actions for the data asset.
5. Browse through the list of **Active**, **In progress**, **Resolved**, and **My items** actions.

6. Select an action to see its details and assign it to a user to investigate and resolve. an individual for remedy. The **Recommendation** section suggests the action to take and provides queries to find the low quality data.

> **Note**
>
> - Not every action has a SQL query because not all actions are data related or related to a data quality rule. Some actions are system related, such as a failed or skipped data quality job.
> - If a custom rule exception occurs, which means the data quality score generated from the custom rule doesn't meet the defined threshold, an action is created. However, a SQL query isn't suggested.

7. Update the **Status**, then select **Save**.

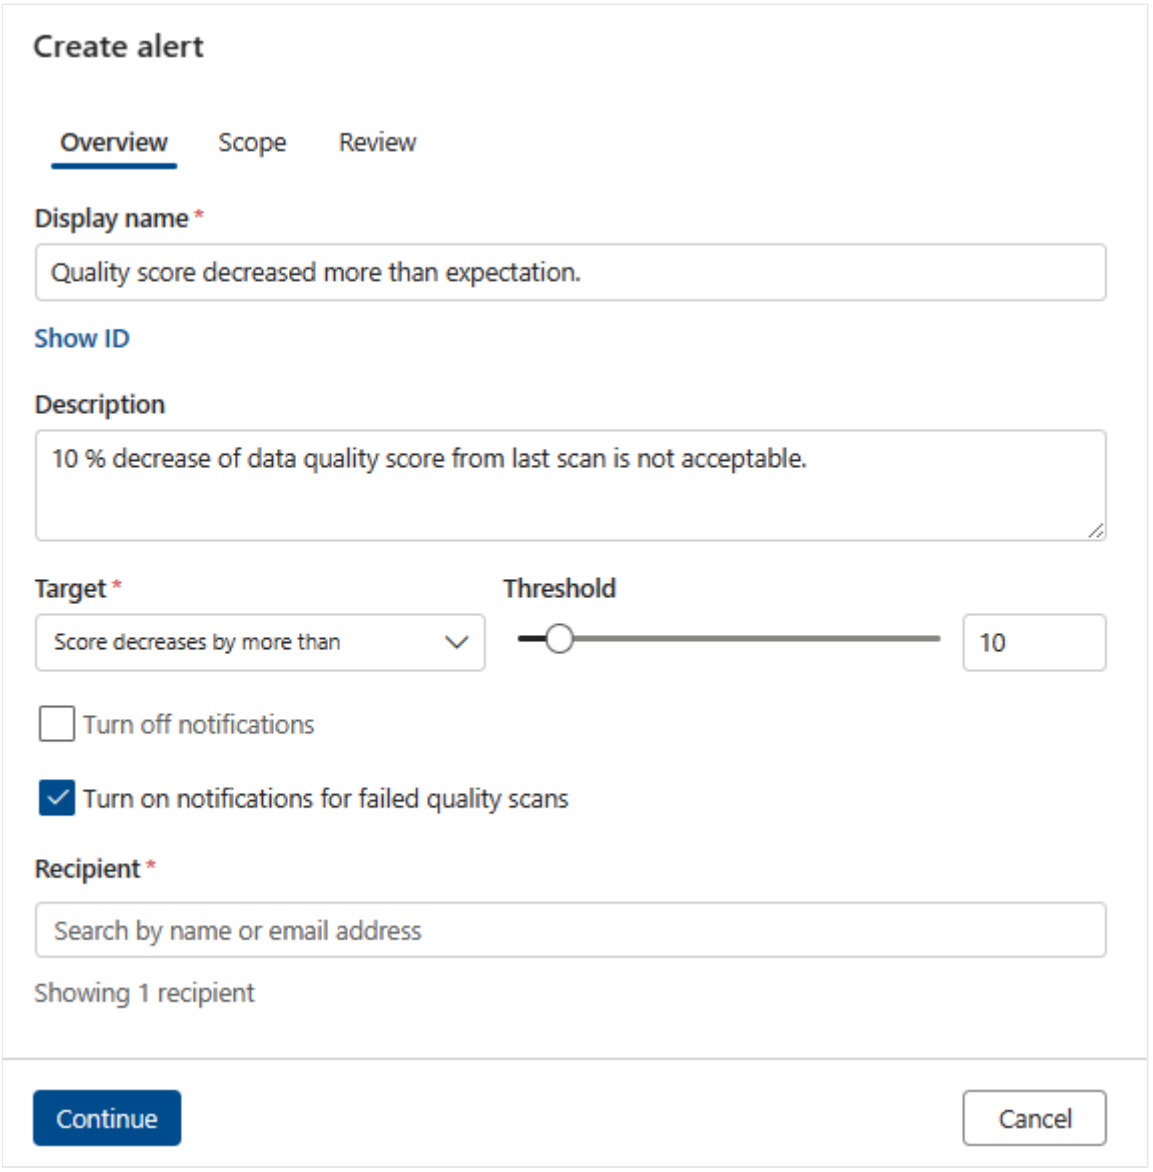
Set up data quality alerts



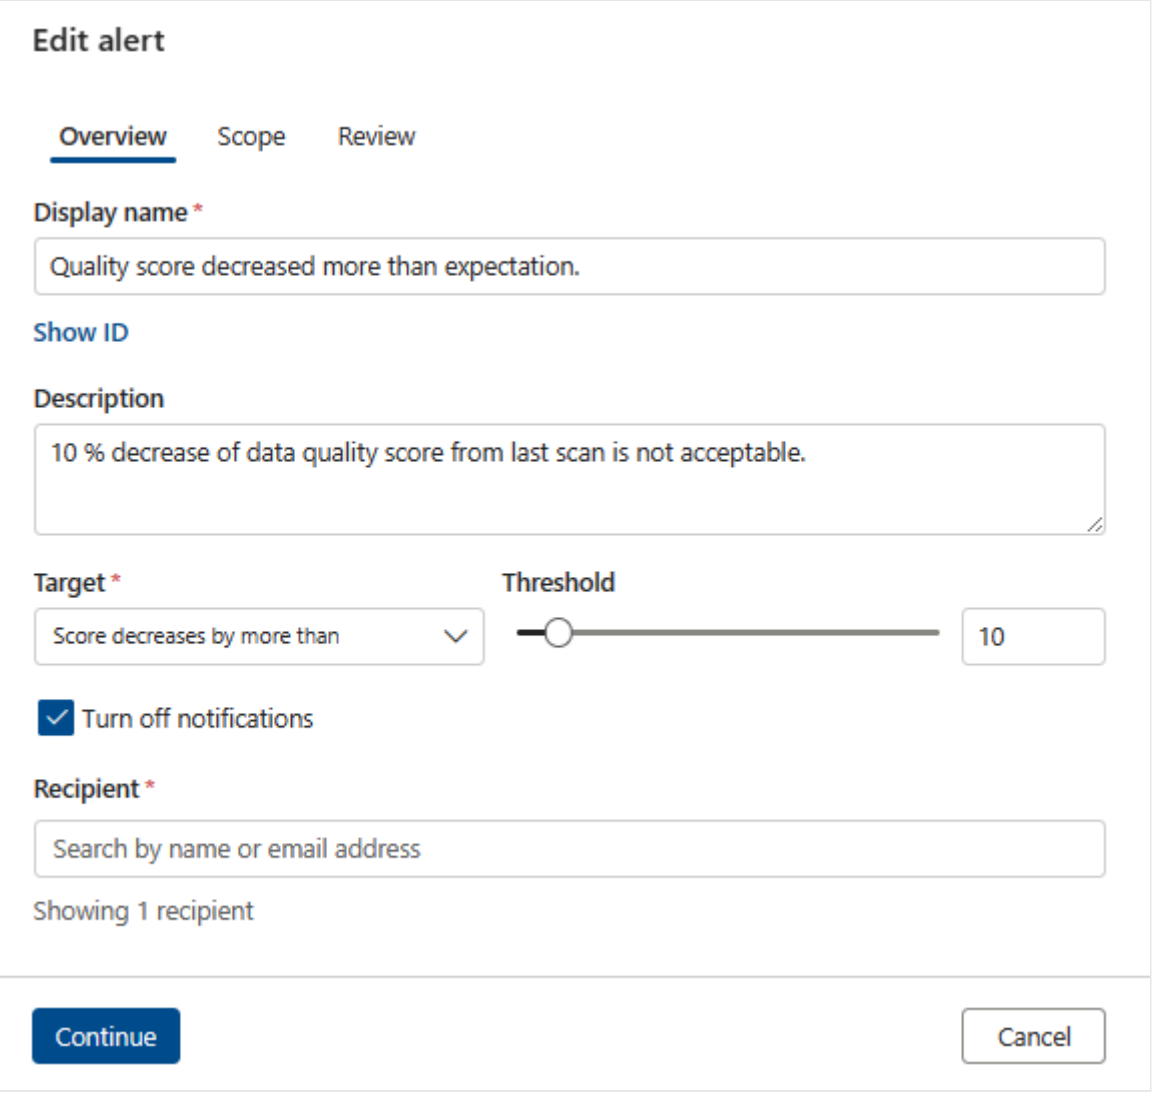
Data quality alerts notify you about important events or unexpected behavior detected around the quality of the data. When you create alerts for data assets, you receive email notifications about data quality scores.

Required roles

To create data quality alerts, you need the data quality steward role.

Set data quality alerts

1. In Microsoft Purview Unified Catalog, select **Health management**, then select **Data quality**.
2. On the **Data Quality** page, select a governance domain from the list.
3. Select **Manage**, then select **Alerts**.
4. Select **New** to set up a new alert for the data products and data assets in your selected governance domain.
5. On the **Overview** tab, enter a **Display name** and a **Description**.
6. For **Target**, select any of the following options:
    - **Score less than**: Alerts you if the assets' data quality score is less than certain percentage.
    - **Score decreased by more than**: Alerts you if the current quality score drops by certain percentage after a new scan is run.
7. Select the threshold that triggers an alert.
8. Select **Turn on notifications** for failed quality scan to enable alert notifications.
9. Add a **Recipient** to send the notification email to the recipient alias.



10. Select **Continue** to define the scope of alerts.
11. On the **Scope** tab, select data products and data assets that the alert will monitor, then select **Save**.
12. Select **Continue** to review.
13. Check alert details on the **Review** tab, then select **Submit** to create the alert.

Disable data quality alerts

Alerts are enabled by default. To disable an alert:

1. In Unified Catalog, select **Health management**, then select **Data quality**.
2. On the **Data Quality** page, select a governance domain from the list.
3. Select **Manage**, then select **Alerts**.

4. Select the **Notifications** toggle next to the alert, or select the alert and select the **Turn off notifications** checkbox.

> **Note**
>
> Disabling an alert stops the sending of notification emails related to the assets within the alert's scope.

Next steps

- Set up data quality rules based on the profiling results, and apply them to your data asset.
- Configure and run a data quality scan on a data product to assess the quality of all supported assets in the data product.
- Review your scan results to evaluate your data product's current data quality.

Last updated on 11/13/2025

Data quality troubleshooting

Summarize this article for me

This article describes common questions and symptoms of errors, along with possible resolutions:

Why do I see an invalid source error from the scanning job?

- You might see this error for two reasons:
  - The delta table doesn't exist in the location.
  - The data in the file aren't in a valid delta format.

I'm setting up data quality scans for my Microsoft Fabric delta tables. I see all data assets in the data quality view, I select one asset and apply rules for data quality scanning, but the scan fails.

- Your data quality scanning might fail for several reasons:
  - The data in tables aren't in the correct delta format. Make sure that your data are in delta format.
    - The Data Map scan didn't run successfully. Rerun the Data Map scan.
    - You need to delete any previous data quality runs for the data asset.

Why do I see the error message, "No connection can be used. Try to create connection first."?

- To profile data or to run data quality scanning, you first need to configure a data source connection. This alert disappears after you create a data source connection.

Why is the total count of profiled data less than the total count in my Microsoft Azure Data Lake Storage Gen2 delta table?

- Microsoft Purview Data Quality uses a **1 million** sample size for profiling. This sample is taken **randomly**. If your delta table has more than 1 million records, the total count doesn't match.

Why do I see an action about data quality score missing for a data product, but I see the score in the data product when I browsed the data product view?

- When you created the action, there wasn't any data quality score for that data product. Data quality scanning ran after you created the action and the score published for the data product. Close the action once the remediation is done to avoid confusion.

Data quality rule creation from "Suggest rules" throws an error about a "date" column when trying to add all 30 suggested rules

- This error occurs because the schema data type is **unsupported** in the data quality schema view. You can change the **data type** to **date** by selecting the **schema management** toggle and saving it. After you change the data type, you should be able to add the rule.

When trying to add all suggested rules, why do I see the error "ObserverId already exists"?

- Most likely, the same or identical rule is already added to a column. When you try to add the same or identical rule to a column, the application throws this error message.

Why is my scheduled job skipping instead of running? I see Skipped for data quality scanning jobs.

- The data quality job checks and runs data quality only if there are changes since the last run. It checks the delta history. **Skipped** means there are no changes in the data since last run, and the spark run for data quality isn't performed. **Skipped** doesn't mean failed.

When I select profile data tab, I see number of columns preselected. Can I change the selected columns?

- Microsoft Purview Data Quality uses an AI assisted profiling solution. The Microsoft Purview Data Profiling AI selects the preselected columns. You can deselect those columns and reselect based on criticality of the columns, and select **Save and run** to run profiling.

Why can't I select some of the data assets from data quality asset list page to profile and scan?

- There are a few reasons:
  - Those data assets are published from unsupported data sources.
  - The file format of those data assets isn't supported.

Why is my profiling job failing for the supported data sources?

- Check the schema to make sure that there's no column name with spaces. The current version doesn't support column names with spaces.

Why can't I run data quality scanning and data profiling for CSV, TSV, and text files?

- Data Quality currently supports the Delta format of Parquet, Delta, Iceberg ORC, and Iceberg AVRO. Purview Data Quality doesn't support CSV, TSV, and text files.

Why don't I see the data quality freshness rule in the rule list?

- Microsoft Azure SQL tables don't support data quality freshness. If your data asset is an Azure SQL table, the freshness rule doesn't appear in the list for selection and application to the data asset.

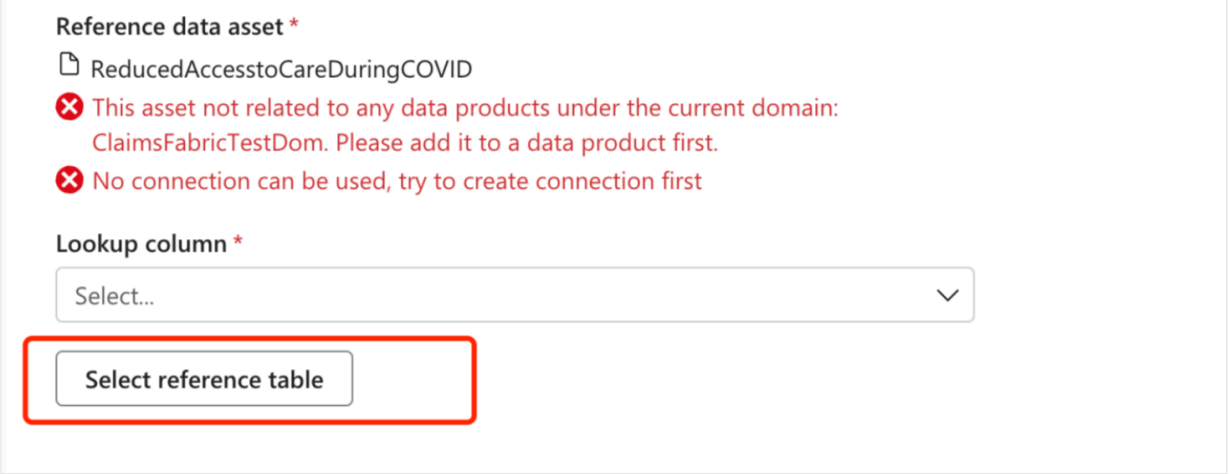
Why do I see datatype Undefined for some columns of a data asset schema in a data quality schema page?

- It seems the data type for all columns isn't identified correctly. You can import the schema to resolve the issue (to update the datatype). Select the schema menu item from the data quality overview page, select the **Schema management** toggle, and select **Import schema**. After importing the schema, select the schema management toggle again to save the updated schema.

- Microsoft Azure SQL tables don't support data quality freshness. If your data asset is an Azure SQL table, the freshness rule doesn't appear in the list for selection and application to the data asset.

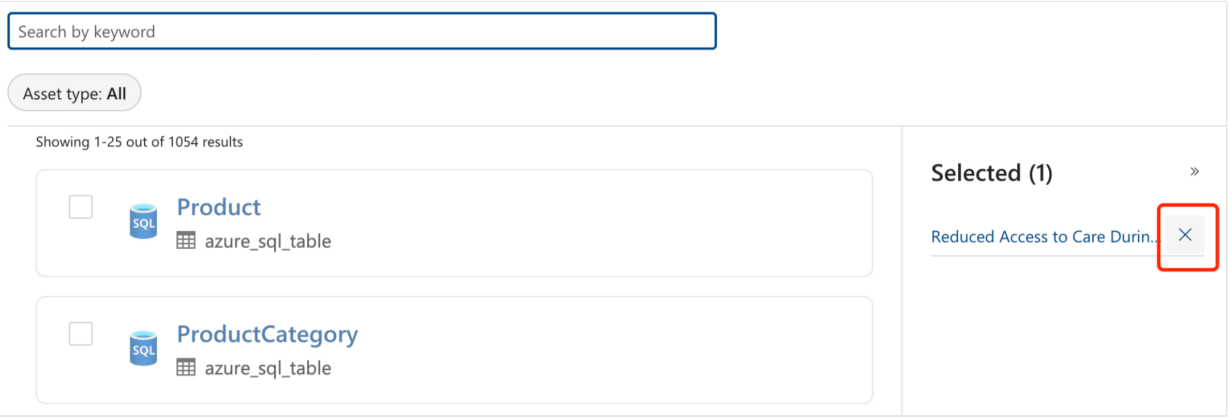
My data quality scan job failed. I see an error message 'Internal service error occurred, please retry, or contact Microsoft support.' What should I do to troubleshoot?

- Many reasons can cause the scan to fail with this error message:
  - You're not authorized to perform the current operation for the workspace that you're trying to access for the data quality scan.
  - Error code 403, meaning access to data sources is forbidden temporarily.
  - Granted access to the data source for your managed identity (MSI) expired.
    - Microsoft Purview managed identity (MSI) needs contributor access to the Fabric workspace. If you don't provide the contributor access for the Microsoft Purview



MSI to the Fabric workspace, the data quality scan fails.

Why am I getting delta format error even though I'm using delta format?



- We support Spark 3.4 Delta 2.4. Make sure that you're using delta lake version 2.4.

Why am I seeing the error when I selected a reference data asset to configure Table lookup rule?

- You selected a data asset that isn't part linked or referred to a data product under the same governance domain. To select the right data asset:
  - Select **select reference table**, as indicated in this image:

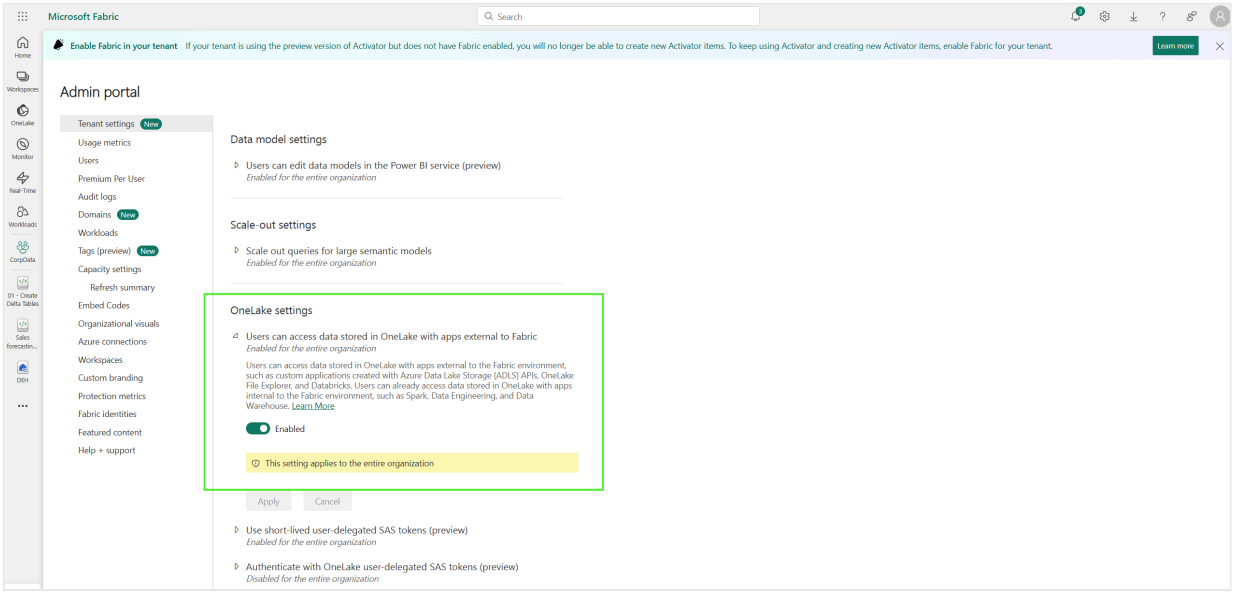
  - Cancel current selection, as shown in the following image:

  - After canceling the current selection, select another asset.

How can I configure access to data source for Microsoft Purview MSI?

- Here's MSI configuration guide. You find the details in this document.

All our data sources are behind the private end point (in virtual network), Can Microsoft Purview access data in virtual network for data quality scanning?



- Yes, Microsoft Purview supports Managed Virtual Network for data quality scanning. See the Microsoft Purview managed virtual network configuration article.

Where can I find documentation about expression function to create custom rules?

- Find information and examples at Create data quality rules.

Why is my data quality scan for Fabric Lakehouse table failing?

- Many reasons can cause the failure:
  - Make sure that your lakehouse tables are discoverable in Data Map with schema.
  - Make sure that you're using SPN for Data Map scan and MSI for data quality scan.
    - Make sure that you configured the data quality connection with MSI.
    - Make sure that Microsoft Purview MSI has contributor access to your Fabric workspace.
    - Enable Microsoft OneLake setting: Users can access data stored in OneLake with apps external to Fabric.

  - Learn how to configure data quality for Fabric Lakehouse.
  - Learn how to configure a Data Map scan setup for Fabric.

Why can't users enable managed virtual network (VNET) for data quality configuration on Microsoft Purview for Databricks or Synapse, or any other supported data sources?

- **Problem**: After selecting the **Enable managed Vnet** checkbox and receiving approval, no changes occur on the Microsoft Purview side. Subsequent attempts to create a connection fail with no request sent to the sources (for example, Azure Databricks, Synpase, Data Lake Storage Gen2) for approval.
- **Resolution**: This problem occurs when you delete the Managed Private Endpoint (MPE) after configuring it. Currently, if you update or delete the MPE directly from the source after initial approval, the Data Quality system can't track the MPE status change. To resolve this problem, contact Microsoft support.

Schema is blank or columns are missing

- Import the schema from the **Data Quality** page to ensure that all columns, including any missing ones, are properly loaded and to resolve the issue. After importing the schema, perform a hard refresh to avoid reloading cached or outdated information.
- Depending on the extent of the schema changes, you might need to remove the asset from the data asset data quality page or the data product page and then re-add it from the Data Map to fully resolve the issue.
- Rule bindings use the technical column name as the key, not just the DisplayName. If the column’s name changed, or the asset’s schema cached in data quality still references the old technical name, subsequent runs fail because the rule can’t find the column.
- Data product assets don’t auto refresh when you update metadata in Data Map (owner, description, lineage, and relevant here, schema). You need to manually refresh the asset inside catalog management so that data quality sees the latest column set.

Last updated on 02/24/2026

Overview of health management reports in Unified Catalog

Data health management reports in Microsoft Purview Unified Catalog enable your users to explore detailed information about your data health management and create customized reports for your organization.

Report types

Classic reports

- Classic assets: An overview of assets by type and collection, and their curation status.
- Classic catalog adoption: Helps you see at a glance how the classic Microsoft Purview Data Catalog is being used.
- Classic classifications: An overview of assets classified and the types of classifications.
- Classic data stewardship: Helps governance and quality focused users, like data stewards and chief data officers, understand governance health gaps like asset curation and asset ownership.
- Classic glossary: An overview of the health and use of glossary terms.
- Classic sensitivity labels: An overview of assets that have sensitivity labels applied and the types of labels applied.

> **Note**
>
> Classic reports refresh weekly. You can't change the schedule. Classic reports don't have any impact to the data governance billing model. When you consent to using Unified Catalog, the billing model starts, but classic reports have no charge.

Data governance reports

- Data governance (preview): Helps you understand your data estate governance and performance of data governance controls.
  - The data governance (preview) report depends on data health controls. If you don't use data health controls, the report isn't refreshed. Make sure that you set up the

schedule to run data health controls and refresh the health controls scores and data governance report.

- Data quality health: Includes assessments of various data quality dimensions, and metrics to help stakeholders understand the accuracy, completeness, consistency, reliability, and freshness of your data estate.
  - The data quality health report depends on data health controls and the Microsoft Purview metadata self-serve analytics model. If you don't use data health controls and don't subscribe Unified Catalog metadata, the data quality health report isn't refreshed. You either need to use data health controls or need to subscribe Unified Catalog metadata for self-serve analytics to refresh the data quality health report.
  - If you don't use the data quality feature, the data quality health report shows as blank because the report is created using data generated from data quality scans.

> **Note**
>
> - Data governance (preview) and Data quality health reports are part of the **data governance billing model**. If you don't want to use these reports, then you need to disable **self-serve analytics metadata subscription**, and you also need to disable the **health controls refresh schedule**. For details, see **self-serve analytics and insights**.

Understand the classic assets report in Unified Catalog

This article describes how to access, view, and filter data asset insight reports for your data.

In this article, you learn how to:

- ✓ View data estate insights from your Microsoft Purview account.
- ✓ Get a bird's eye view of your data.
- ✓ Drill down for more asset count details.

Prerequisites

Before getting started with Microsoft Purview Data Estate Insights, make sure that you've completed the following steps:

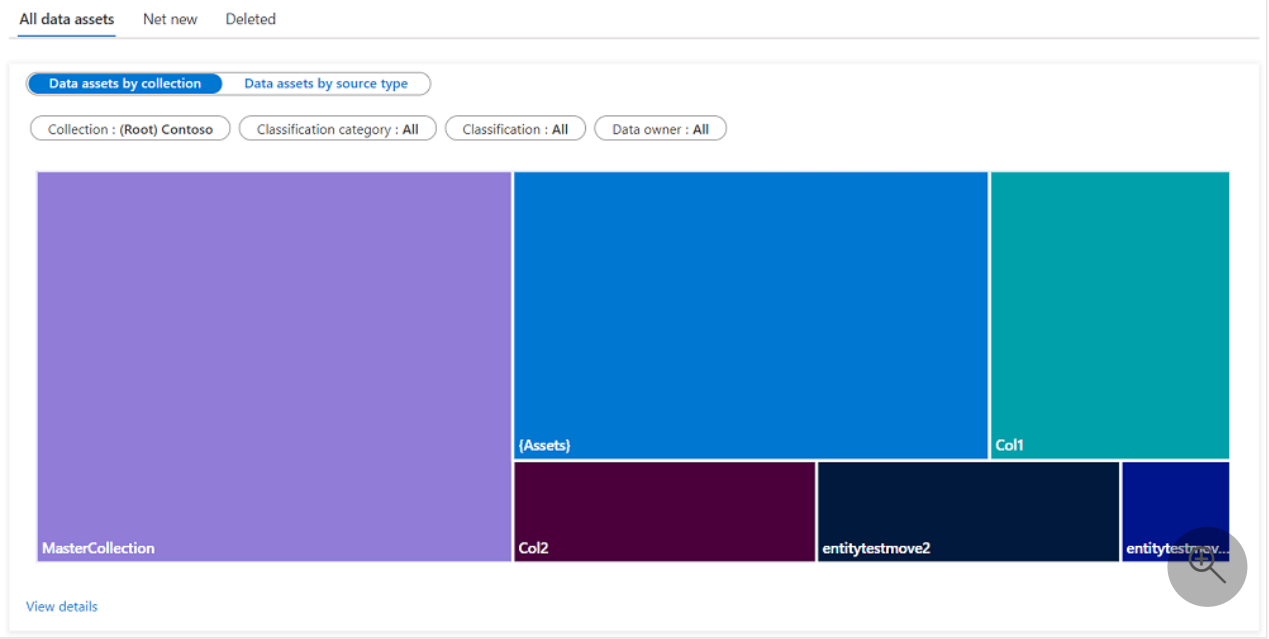
- Set up a storage resource and populated the account with data.
- Set up and completed a scan your storage source. For more information to create and complete a scan, see Manage data sources in Microsoft Purview.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Understand your asset inventory in Data Estate Insights

In Microsoft Purview Data Estate Insights, you can get an overview of the assets that you scanned into the Data Map. You can also view key gaps that governance stakeholders can close for better governance of the data estate.

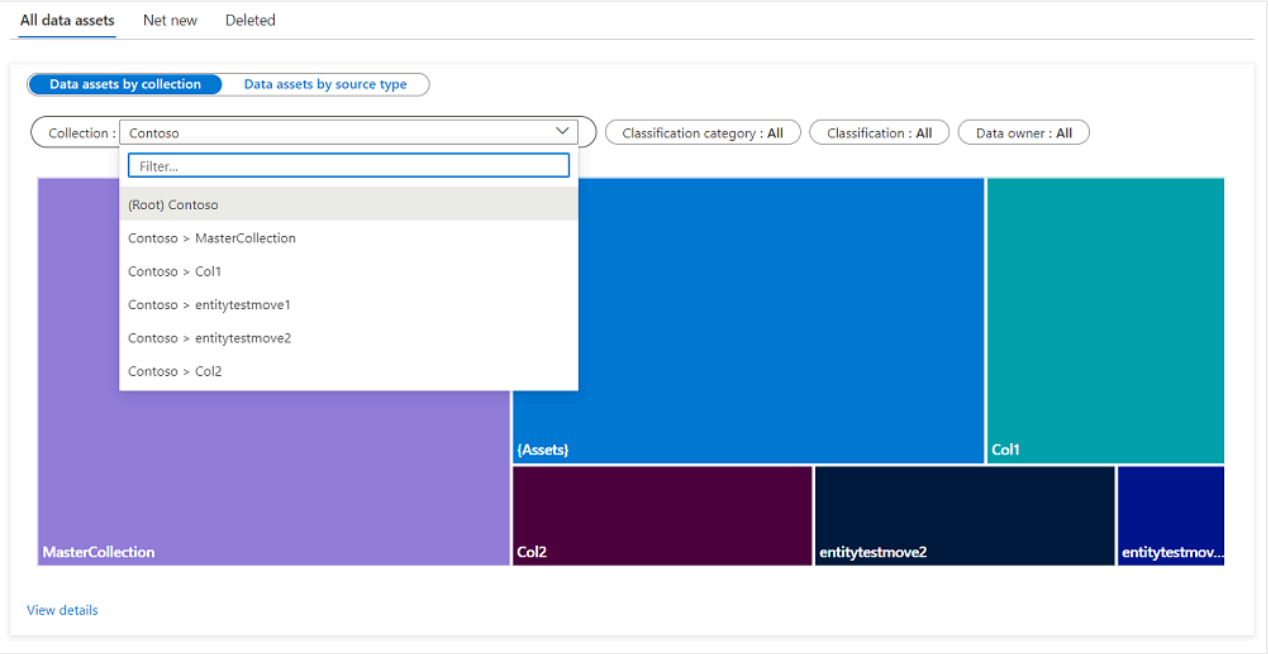
1. Open the Microsoft Purview portal.

2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.



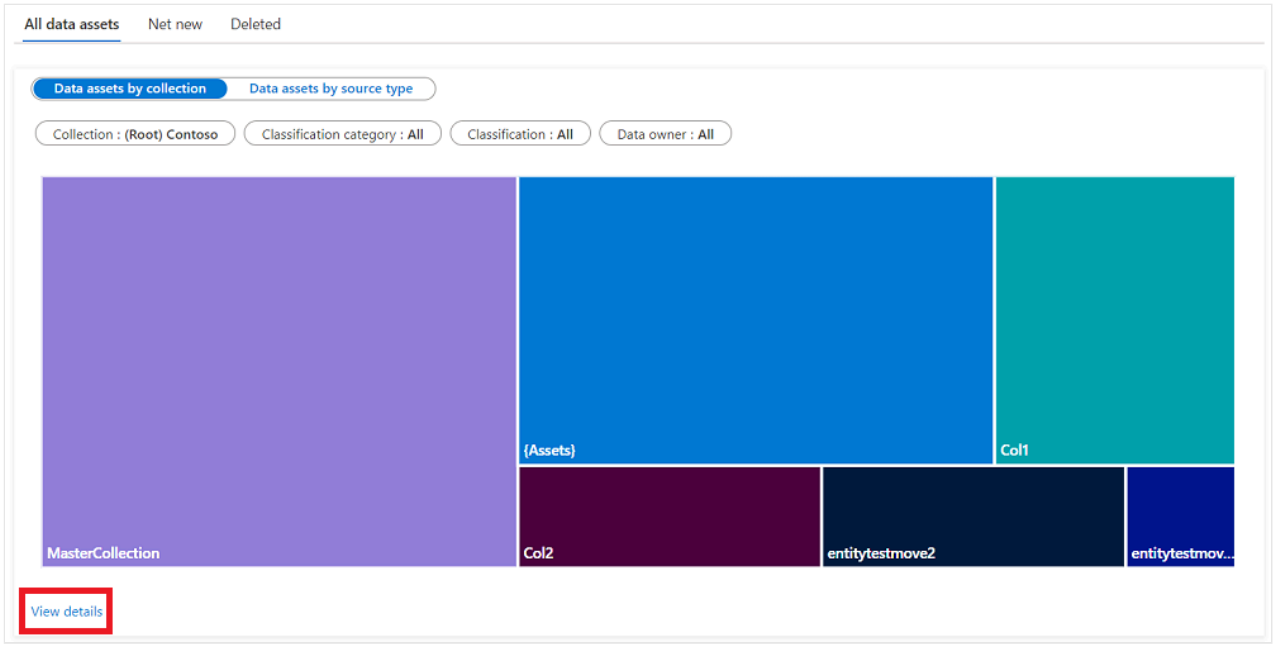
3. Select the **Classic assets** report.

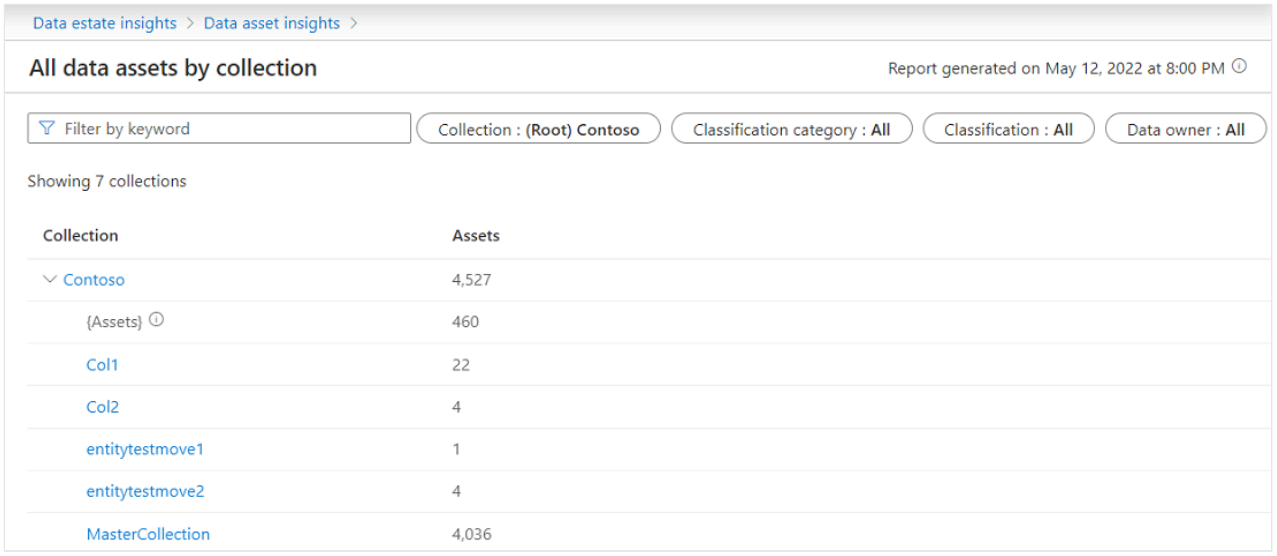
4. The **Assets Summary** report provides several high-level KPIs, with these graphs:



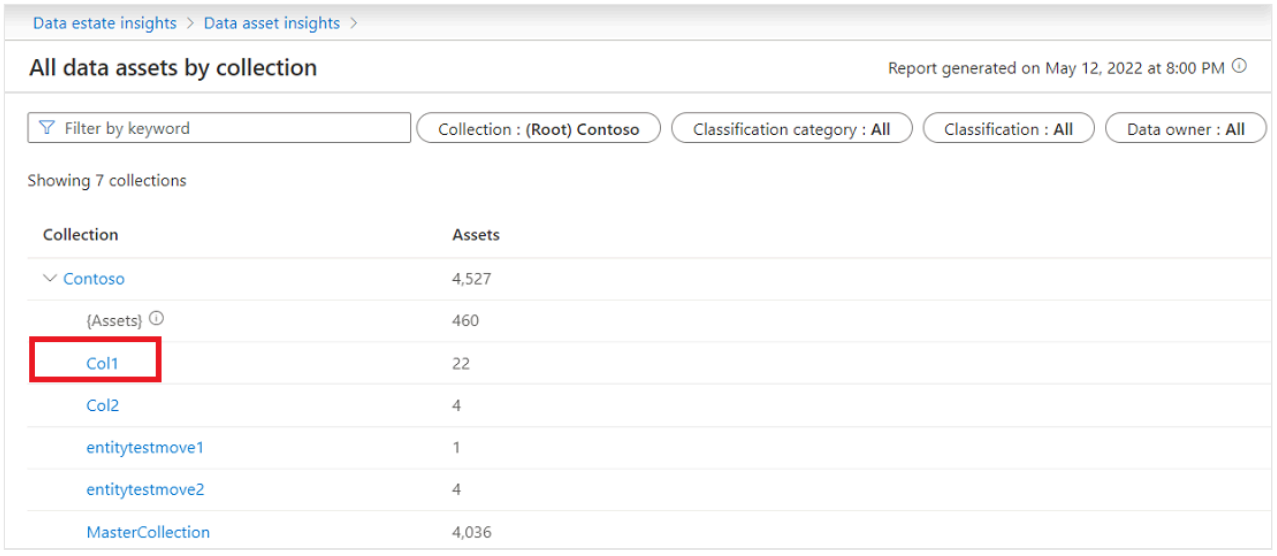
- **Unclassified assets**: Assets with no system or custom classification on the entity or its columns.
- **Unassigned data owner**: Assets that have the owner attribute within "Contacts" tab as blank.
- **Net new assets in last 30 days**: Assets that you added to the Purview account, via data scan or Atlas API pushes.
- **Deleted assets in last 30 days**: Assets that you deleted from the Purview account, as a result of deletion from data sources.

5. Below these KPIs, you can also view your data asset distribution by collection.

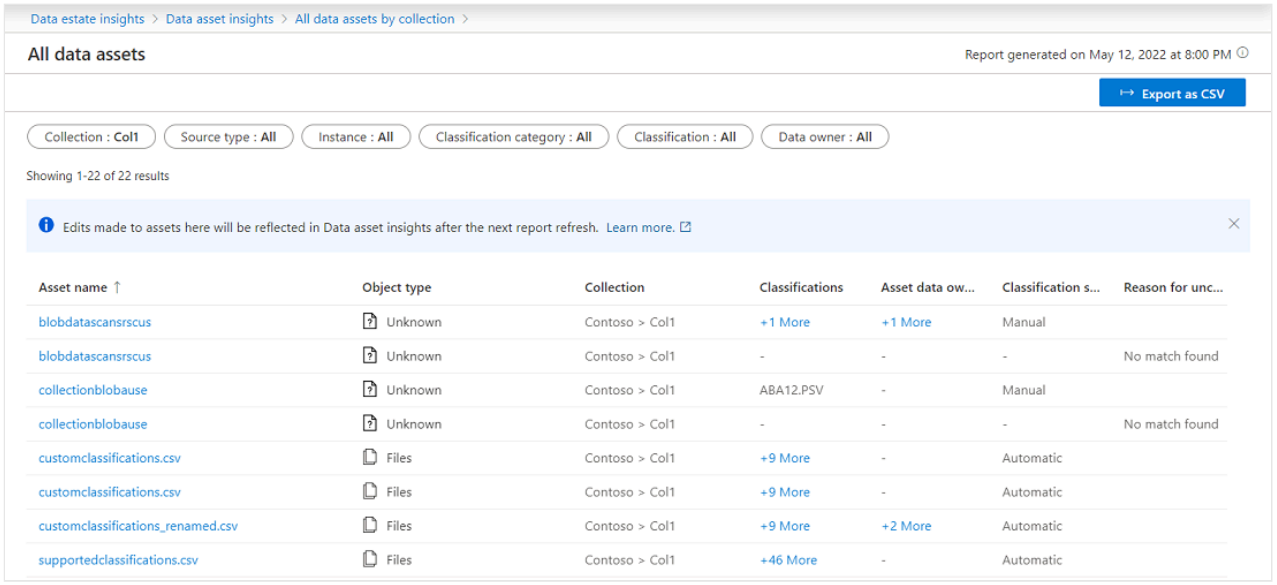




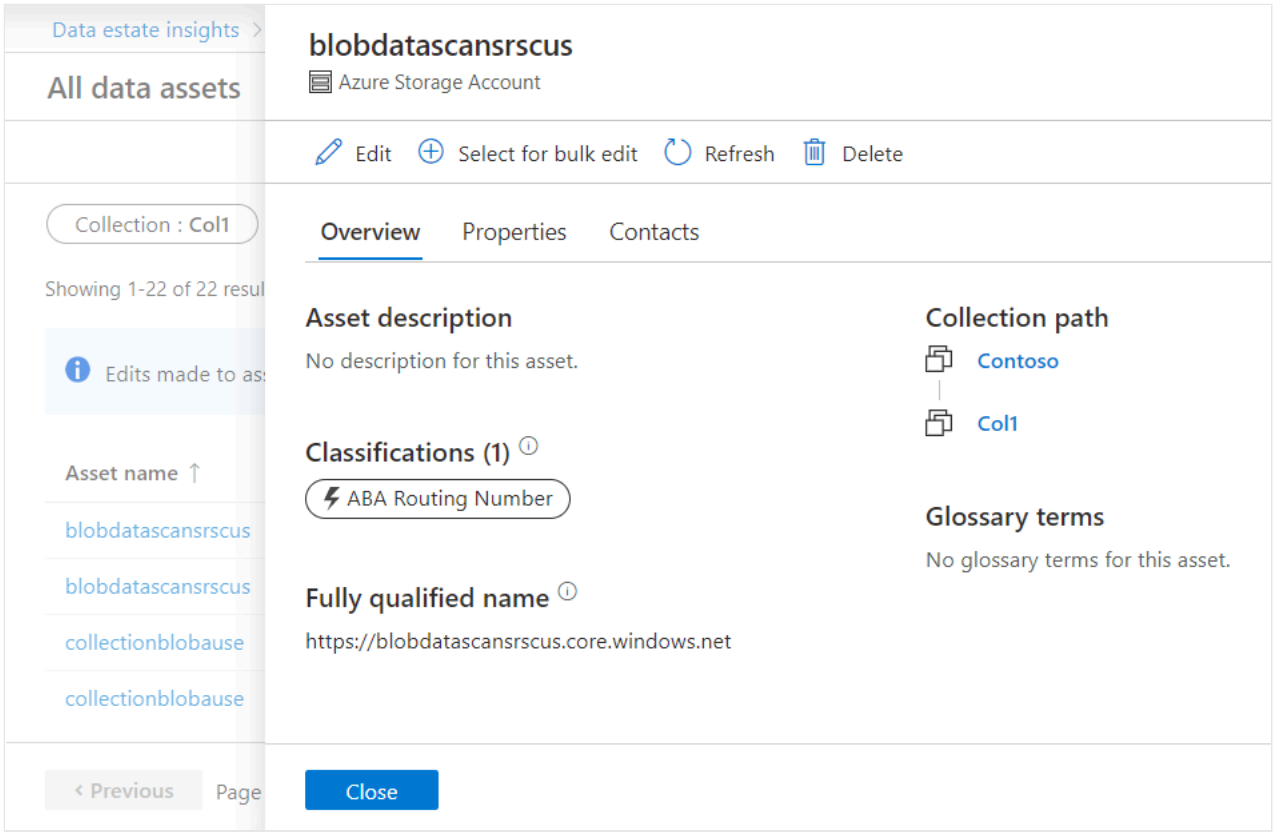
6. Using filters you can drill down to assets within a specific collection or classification category.



> ⓘ Note
>
> ***Each classification filter has some common values:***
>
> - **Applied**: Any filter value is applied
> - **Not Applied**: No filter value is applied. For example, if you pick a classification filter with value as "Not Applied", the graph shows all assets with no classification.
> - **All**: Filter values are cleared. Meaning the graph shows all assets, with or without classification.
> - **Specific**: You pick a specific classification from the filter, and only that classification is shown.



7. To learn more about which specific assets are shown in the graph, select **View details**.



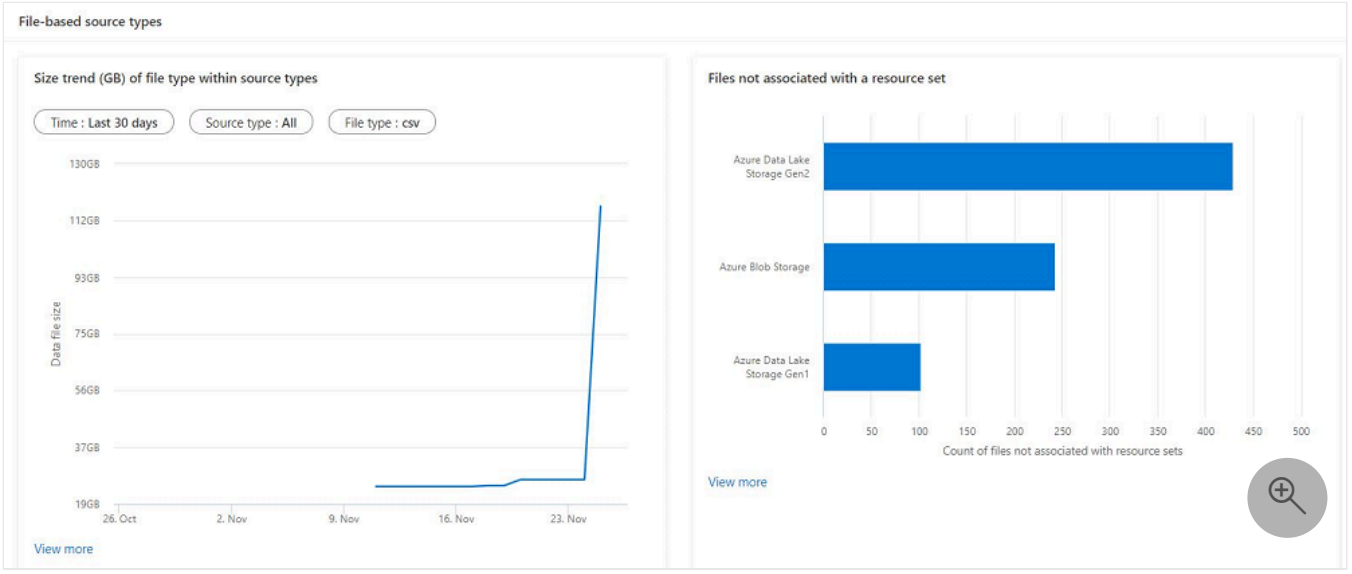
8. You can select any collection to view the collection's asset list.

9. You can also select an asset to edit without leaving the Data Estate Insights App.

File-based source types

The next graphs in asset insights show a distribution of file-based source types. The first graph, **Size trend (GB) of file type within source types**, shows top file type size trends over the last 30 days.

1. Pick your source type to view the file type within the source.



2. Select **View details** to see the current data size, change in size, current asset count, and change in asset count.

> **Note**
>
> If the scan runs only once in the last 30 days, or any catalog change such as classification addition or removal happens only once in 30 days, then the change information appears blank.

3. See the top folders with change top asset counts when you select source type.

4. Select the path to see the asset list.

The second graph in file-based source types is **Files not associated with a resource set**. If you expect that all files should roll up into a resource set, this graph can help you understand which assets aren't rolled up. Missing assets can be an indication of the wrong file-pattern in the folder. You can select **View details** below the graph for more information.

Understand the classic catalog adoption report in Unified Catalog

As described in the insights concepts, the catalog adoption report is part of the "Health" section of classic Microsoft Purview Data Estate Insights. This report offers a one-stop shop experience for administrators to determine if and how the classic Microsoft Purview Data Catalog is being used. It helps answer questions like:

- What are my users searching for?
- How many people used the catalog last month?
- What are the most used data assets?

Prerequisites

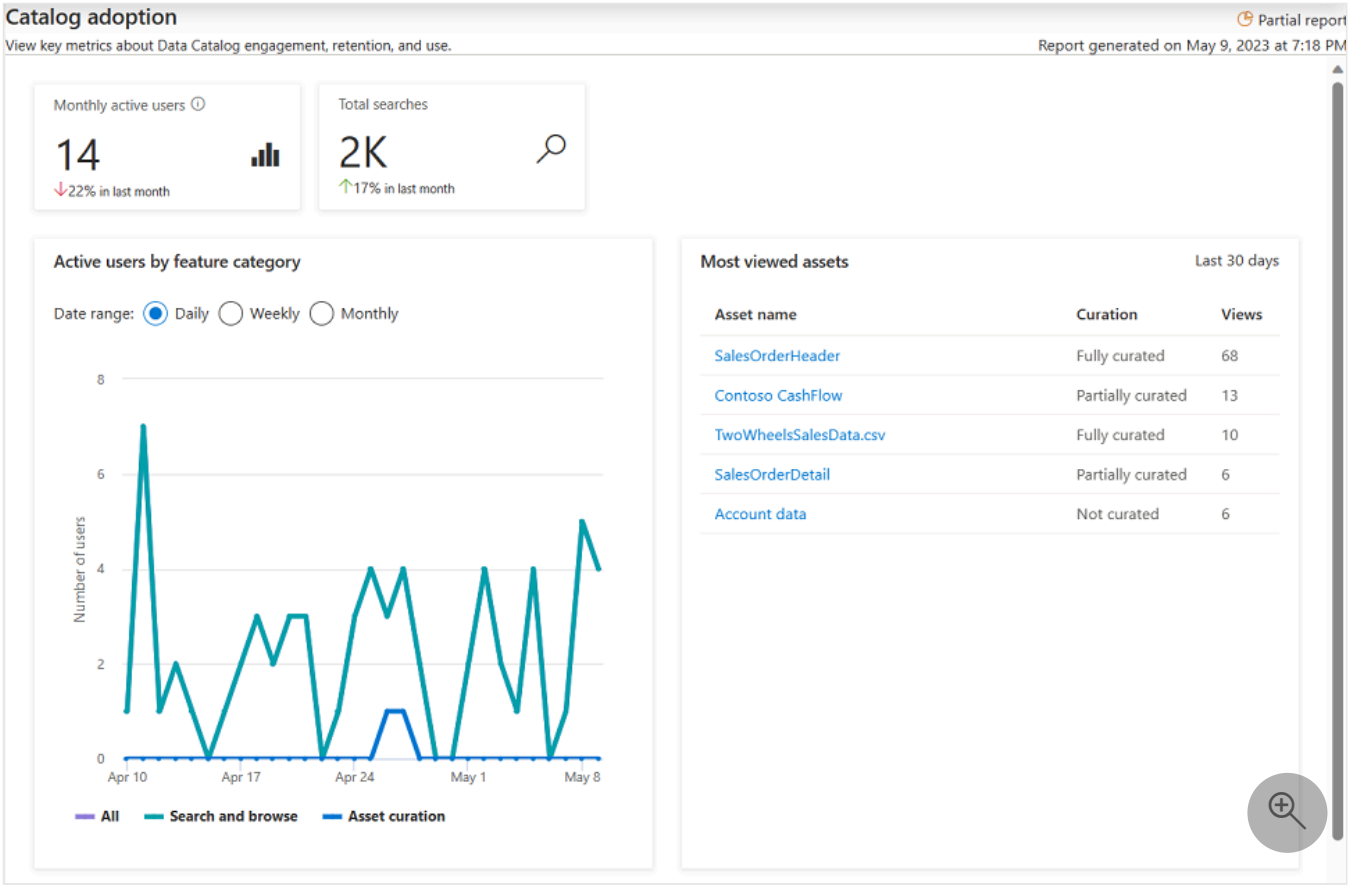
Before getting started with Data Estate Insights, make sure that you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan of your storage source. For more information about creating and completing a scan, see manage data sources in Microsoft Purview.
- Have the right permissions depending on your current experience:
  - If using the classic Microsoft Purview Data Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Understand your data estate and catalog health in Data Estate Insights

In Data Estate Insights, you can get an overview of all assets inventoried in the Data Map, and any key gaps that governance stakeholders can close for better governance of the data estate.

1. Open the Microsoft Purview portal.



2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.

3. Select **Classic catalog adoption**.

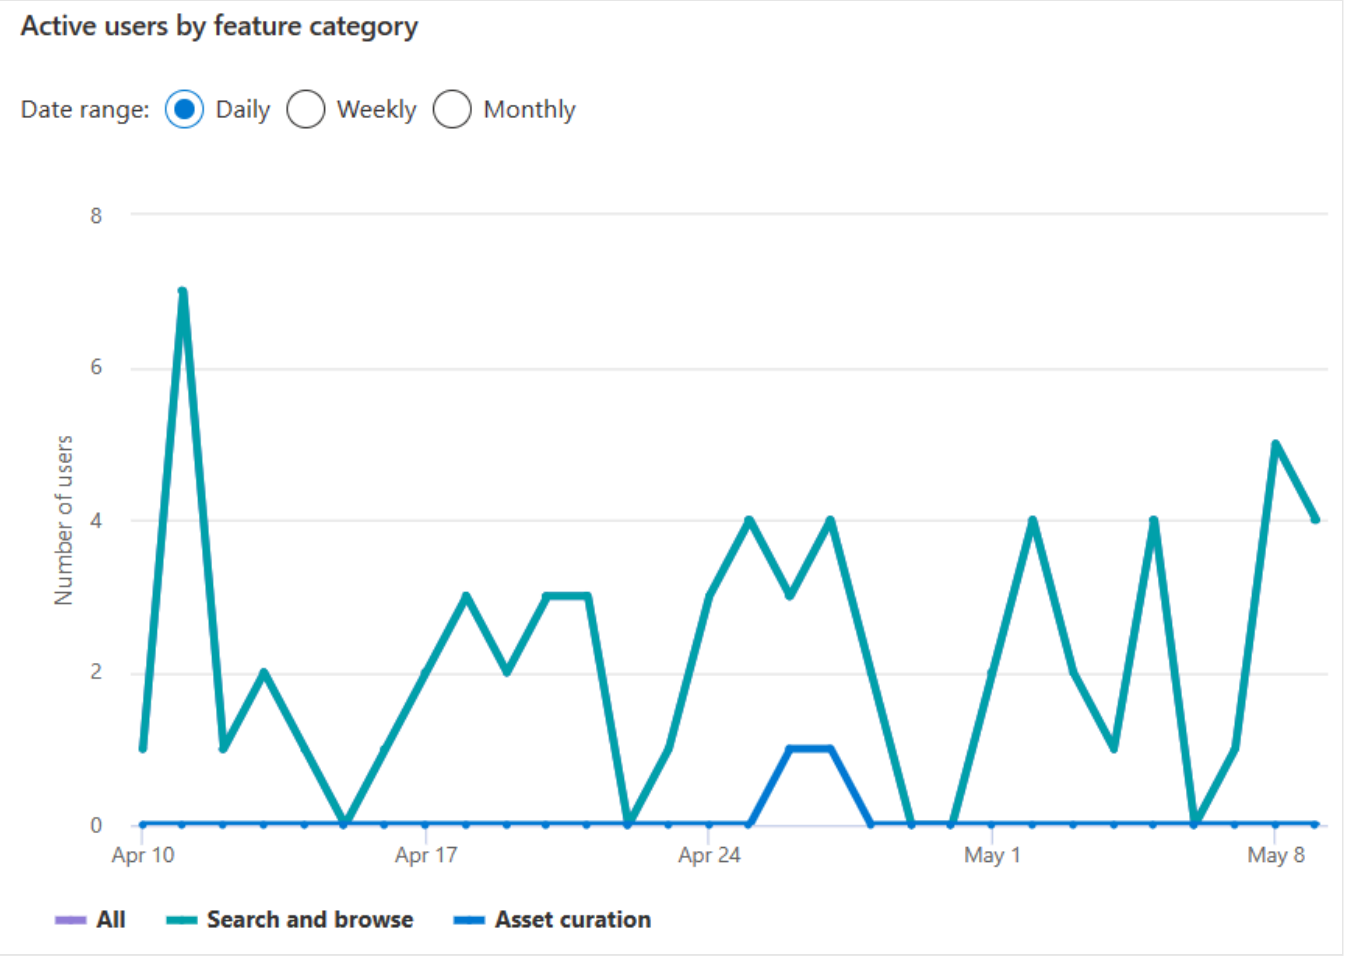
View catalog adoption dashboard

The catalog adoption dashboard has several curated tiles and charts to identify:

- How many active users your catalog had in the last month.
- How many total searches were performed in the last month.
- Which catalog features are being used.
- Most viewed assets.
- Top searched keywords in catalog.

Monthly active users

The **Monthly active users** count is the number of unique users who perform any action, such as search, browse, or curation.



The **Monthly active users** tile shows how many users took at least one action in the catalog in the last 30 days. An action in the catalog includes searching for a term, browsing in the catalog, and updating an asset in the catalog. This tile also includes an indicator of a percentage increase or decrease in users from the previous month.

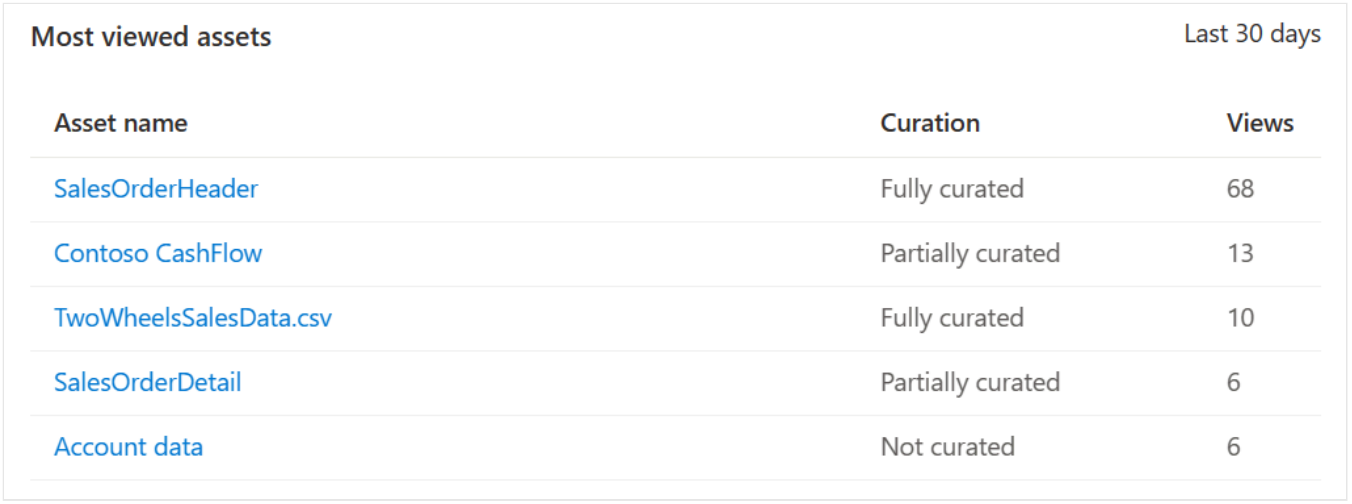
Total searches

The **Total searches** tile shows a count of all searches performed in the catalog over the last 30 days. The tile also shows the percentage increase or decrease in the number of searches from the previous month.

Active users by feature category

The **Active users by feature category** chart helps you monitor user activity trends in the catalog. Here's an example of the chart:

At the top of the chart, select your date range to view user activity on a daily, weekly, or monthly basis.



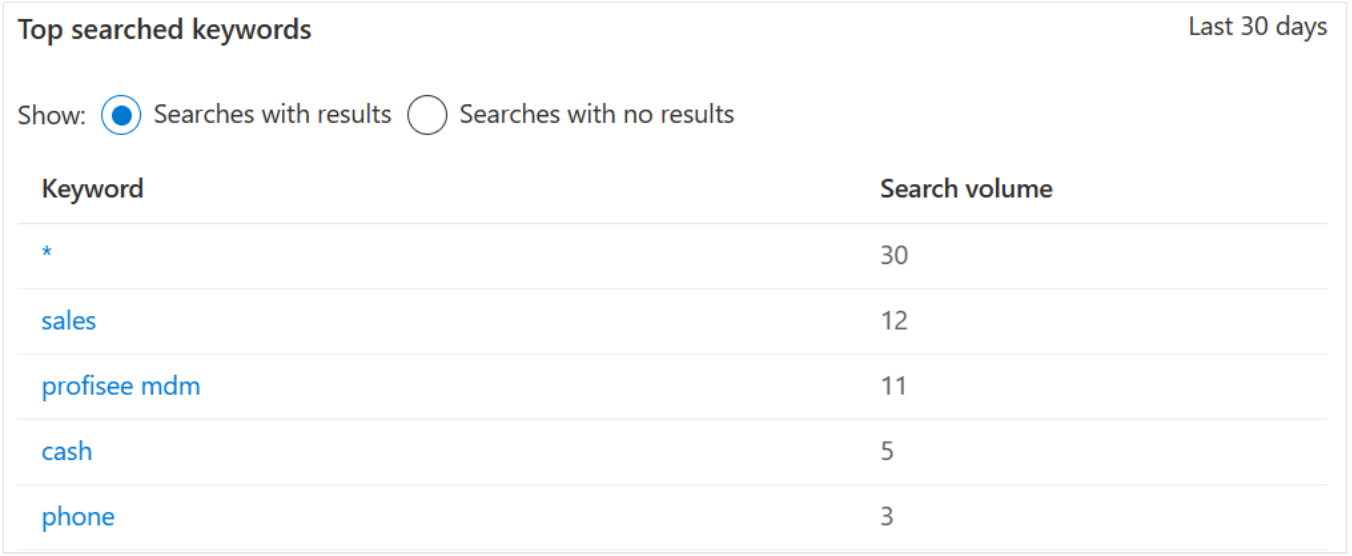
The chart shows the number of users in the date range who perform actions in one of three categories:

- **Search and browse**: The count of users per action category (search or browse). A user may appear in both counts if they perform both actions. For example, if a user performs both search and browse, the same user is counted twice in this number (once under search, once under browse). One user can contribute two counts in Search/Browse, but still counts as one in Monthly Active Users. This is why **Search and browse** can be higher than **Monthly active users**.

- **Asset curation**: The count of users who performed at least any one of these actions on an asset:
  - Added, removed, or updated a rating
  - Added or removed a tag
  - Added or removed a glossary term
  - Added or removed a classification
  - Edited an asset's name or description
  - Added or removed a certification
  - Added or removed a column level classification, glossary term, description, name, or data type
  - Added or removed manual lineage
  - Added or removed a contact
- **All**: The count of users who performed both a search or browse action, *and* at least one asset curation action within the date range.

Most viewed assets

The most viewed assets table shows the top assets in the catalog, by sum of views in the last 30 days.



This table allows you to select through to your most viewed assets for more information, but the table also provides these other details:

- Curation status - There are three possible statuses: **Fully curated**, **Partially curated**, and **Not curated**, based on certain attributes of assets being present. An asset is **Fully curated** if it has at least one classification tag, an assigned Data Owner, and a description. If any of these attributes is missing, but not all, then the asset is categorized as **Partially curated** and if all of them are missing, then it's **Not curated**. For more information about the curation status of your data assets, see the data stewardship dashboard.
- Views - count of the number of views the asset received in the last 30 days.

Top searched keywords

The top searched keywords table shows your top keywords both for searches that produced results, and searches that didn't. That way you can know what users are finding with the catalog, and what they're still looking for.

At the top of the table, you can select one of the two radio buttons to select whether to show keywords for searches with results, or searches without results.

You can select any of the keywords to run the search in the catalog and see the results for yourself as well.

The table also provides search volume, which is the number of times that keyword was searched in the last 30 days.

Report generated timestamp

The timestamp displayed, such as, "Report generated on December 4, 2025 at 11:37 AM", indicates when the page was loaded or refreshed. It doesn't represent the time when the backend actually computed the KPI data. The actual calculation time comes from the backend timePoint field (for example, 2025-11-05T06:59:48) from the API response.

Monthly aggregation behavior for usage metrics

The **Monthly active users** and **Total searches** metrics display data from the previous fully completed month. For example, December views show November data. The KPI is updated during the job run after the month changes, even though the job runs every week.

Last updated on 01/15/2026

Understand the classic classifications report in Unified Catalog

This article describes how to access, view, and filter the classic classifications report for your data.

In this article, you learn how to:

- ✓ Launch your Microsoft Purview account from Microsoft Azure.
- ✓ View classification insights on your data.
- ✓ Drill down for more classification details on your data.

Prerequisites

Before getting started with Data Estate Insights, make sure you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan on the data in each data source. For more information, see Manage data sources in Microsoft Purview and Create a scan rule set.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Use Data Estate Insights for classifications

In Microsoft Purview, classifications are similar to subject tags, and are used to mark and identify data of a specific type that's found within your data estate during scanning.

Microsoft Purview uses the same sensitive information types as Microsoft 365, allowing you to stretch your existing security policies and protection across your entire data estate.

> ⓘ **Note**
>
> After you scan your source types, wait a couple of hours for the classic classifications report to reflect the new assets.

View classification insights

1. Open the Microsoft Purview portal.
2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health management**, then select **Reports**.
3. Select the **Classic classifications** report. The **Classification insights** page displays the following areas:

Expand table

Area	Description
Overview of sources with classifications	Displays tiles that provide: - The number of subscriptions found in your data - The number of unique classifications found in your data - The number of classified sources found - The number of classified files found - The number of classified tables found
Top sources with classified data (last 30 days)	Shows the trend, over the past 30 days, of the number of sources found with classified data.
Top classification categories by sources	Shows the number of sources found by classification category, such as **Financial** or **Government**.
Top classifications for files	Shows the top classifications applied to files in your data, such as credit card numbers or national/regional identification numbers.
Top classifications for tables	Shows the top classifications applied to tables in your data, such as personal identifying information.
Classification activity (files and tables)	Displays separate graphs for files and tables, each showing the number of files or tables classified over the selected timeframe. **Default**: 30 days Select the **Time** filter above the graphs to select a different time frame to display.

Classification insights drilldown

In any of the following **Classification insights** graphs, select the **View details** link to drill down for more details:

- **Top classification categories by sources**
- **Top classifications for files**
- **Top classifications for tables**

- **Classification activity > Classification data**

To learn more, use the following options:

Expand table

Option	Description
Filter your data	Use the filters above the grid to filter the data shown, including the classification name, subscription name, or source type. If you're not sure of the exact classification name, enter part or all of the name in the **Filter by keyword** box.
Sort the grid	Select a column header to sort the grid by that column.
Edit columns	To display more or fewer columns in your grid, select **Edit Columns**, then select the columns you want to view or change the order.
Drill down further	To drill down to a specific classification, select a name in the **Classification** column to view the **Classification by source** report. This report displays data for the selected classification, including the source name, source type, subscription ID, and the numbers of classified files and tables.
Browse assets	To browse through the assets found with a specific classification or source, select a classification or source, depending on the report you're viewing, then select **Browse assets** above the filters. The search results display all of the classified assets found for the selected filter. For more information, see Search the Microsoft Purview Unified Catalog.

Understand the classic data stewardship report in Unified Catalog

As described in the insights concepts, the data stewardship report is part of the "Health" section of Data Estate Insights. This report offers a one-stop shop experience for data, governance, and quality focused users like chief data officers and data stewards to get actionable insights into key areas of gap in their data estate.

In this guide, you learn how to:

- ✓ Navigate and view data stewardship report from your Microsoft Purview account.
- ✓ Drill down for more asset count details.

Prerequisites

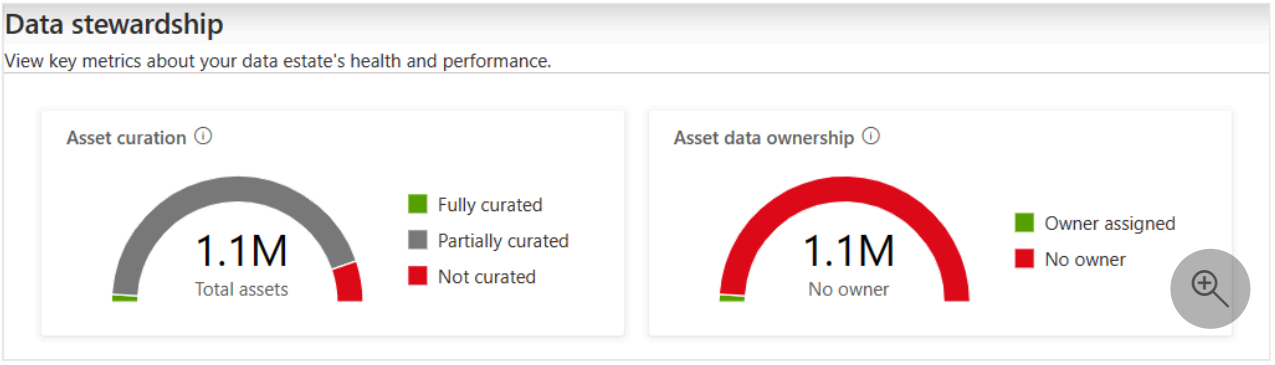
Before getting started with Data Estate Insights, make sure that you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan your storage source. For more information on how to create and complete a scan, see Manage data sources in Microsoft Purview.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Understand your data estate and catalog health in Data Estate Insights

In Data Estate Insights, you can get an overview of all assets inventoried in Data Map, and any key gaps that governance stakeholders can close for better governance of the data estate.

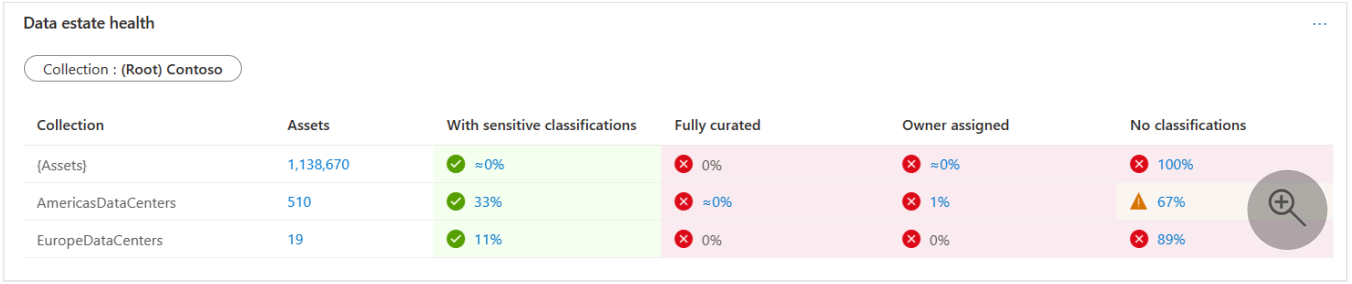
1. Open the Microsoft Purview portal.



2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.

3. Select **Classic data stewardship**.

View data stewardship dashboard

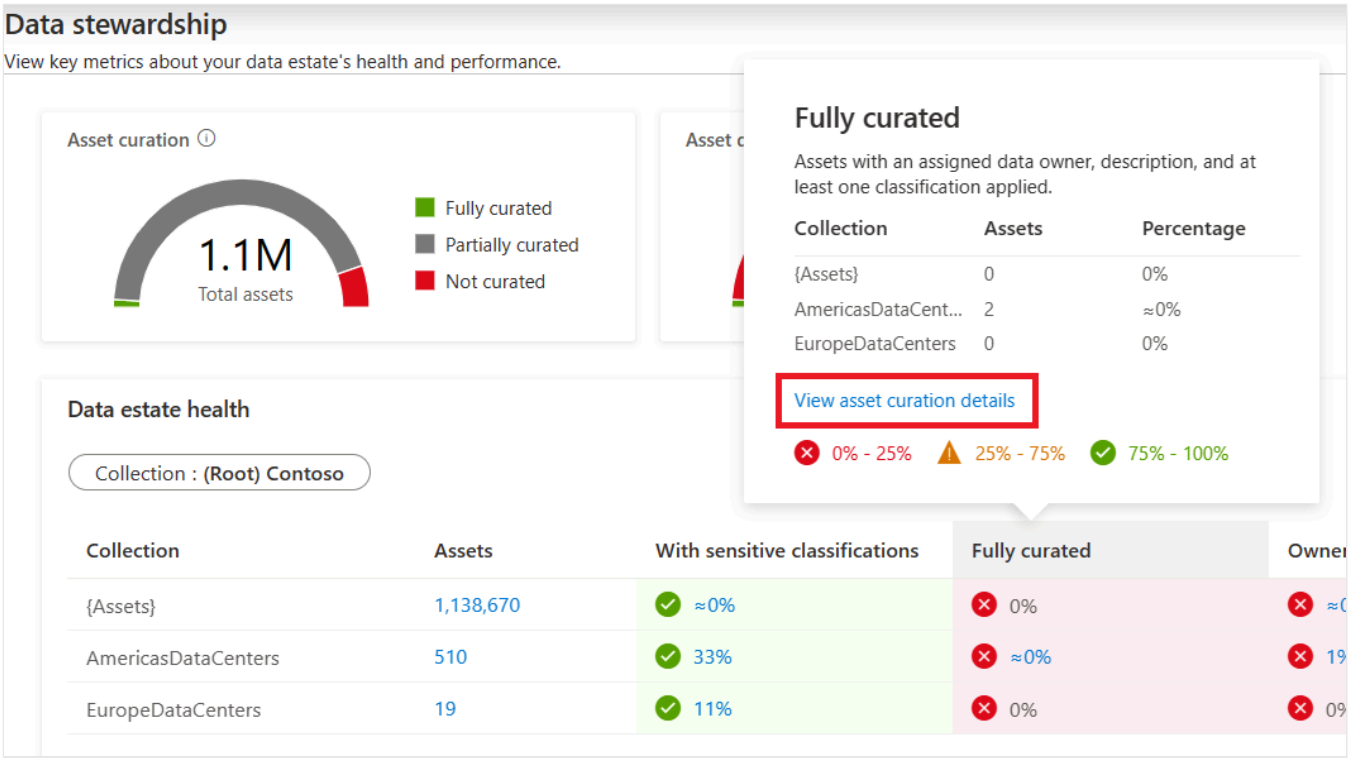


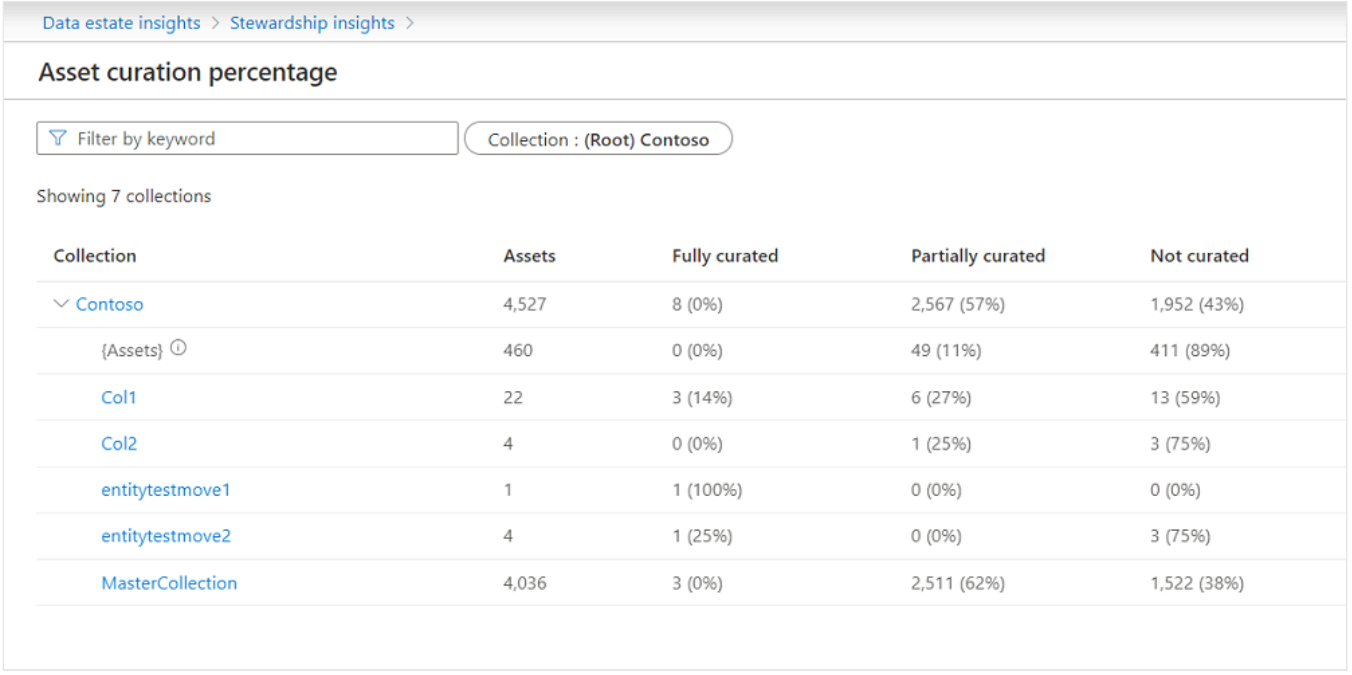
The dashboard is purpose-built for governance and quality-focused users, like data stewards and chief data officers, to understand the health management of their organization. The dashboard shows high-level KPIs that help reduce governance risks:

- **Asset curation**: The dashboard categorizes all data assets into three areas: "Fully curated," "Partially curated," and "Not curated," based on certain attributes of assets being present. An asset is "Fully curated" if it has at least one classification tag, an assigned data owner, and a description. If any of these attributes is missing, but not all, then the asset is categorized as "Partially curated" and if all of them are missing, then it's "Not curated."
- **Asset data ownership**: The dashboard categorizes assets that have the owner attribute within the "Contacts" tab as blank as "No owner". Otherwise, it categorizes them as "Owner assigned".

Health management

Health management is a scorecard view that helps management and governance focused users, like chief data officers, understand critical governance metrics that can be looked at by collection hierarchy.

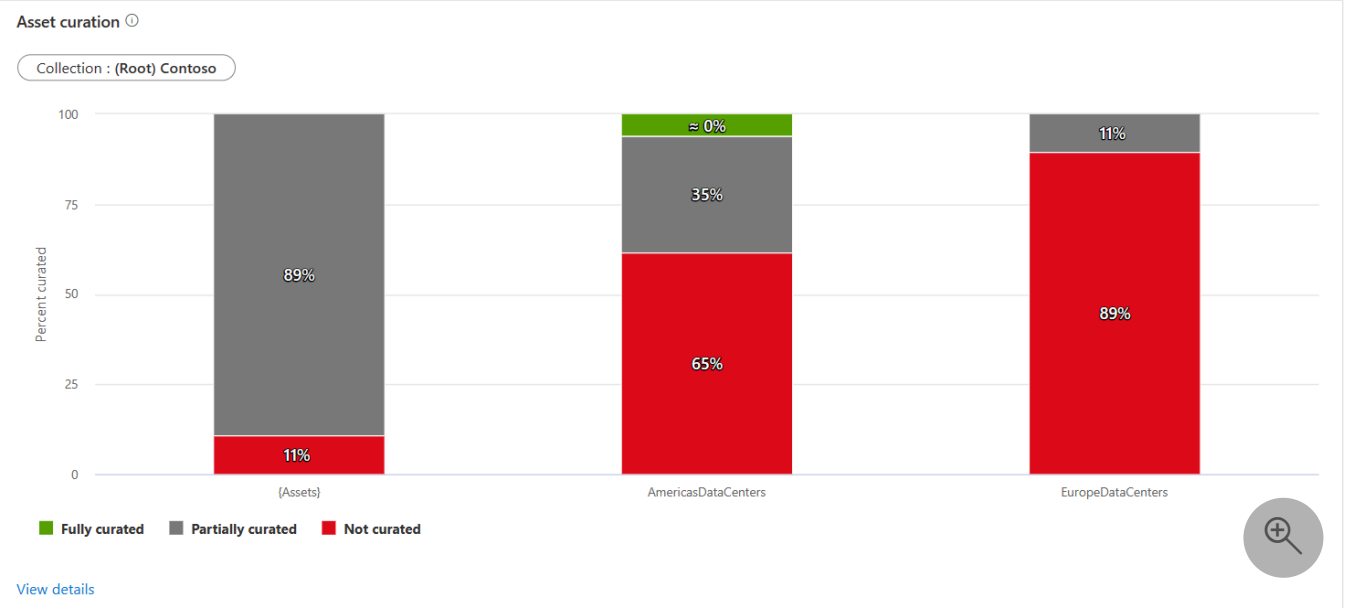




You can view the following metrics:

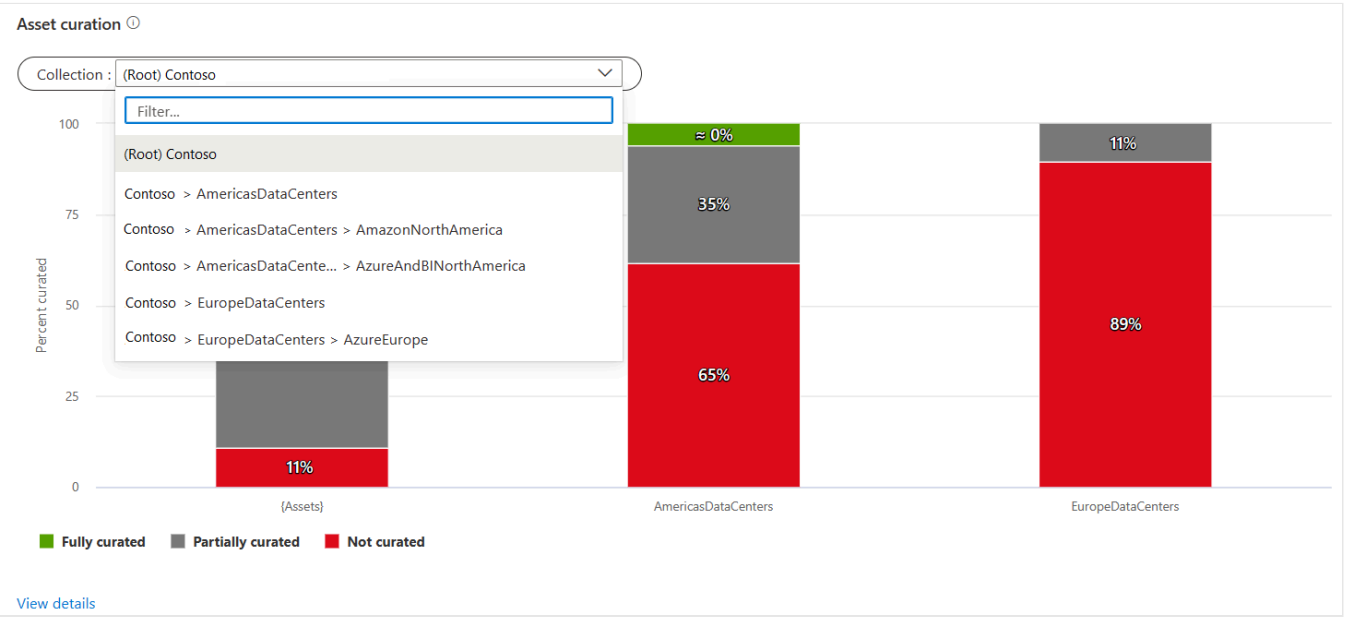
- **Assets**: Count of assets by collection drill-down.
- **With sensitive classifications**: Count of assets with any system classification applied.
- **Fully curated assets**: Count of assets that have a data owner, at least one classification, and a description.

- **Owner assigned**: Count of assets with data owner assigned on them.
- **No classifications**: Count of assets with no classification tag.
- **Out of date**: Percentage of assets that haven't been updated in over 365 days.
- **New**: Count of new assets pushed in the Data Map in the last 30 days.
- **Updated**: Count of assets updated in the Data Map in the last 30 days.
- **Deleted**: Count of deleted assets from the Data Map in the last 30 days.

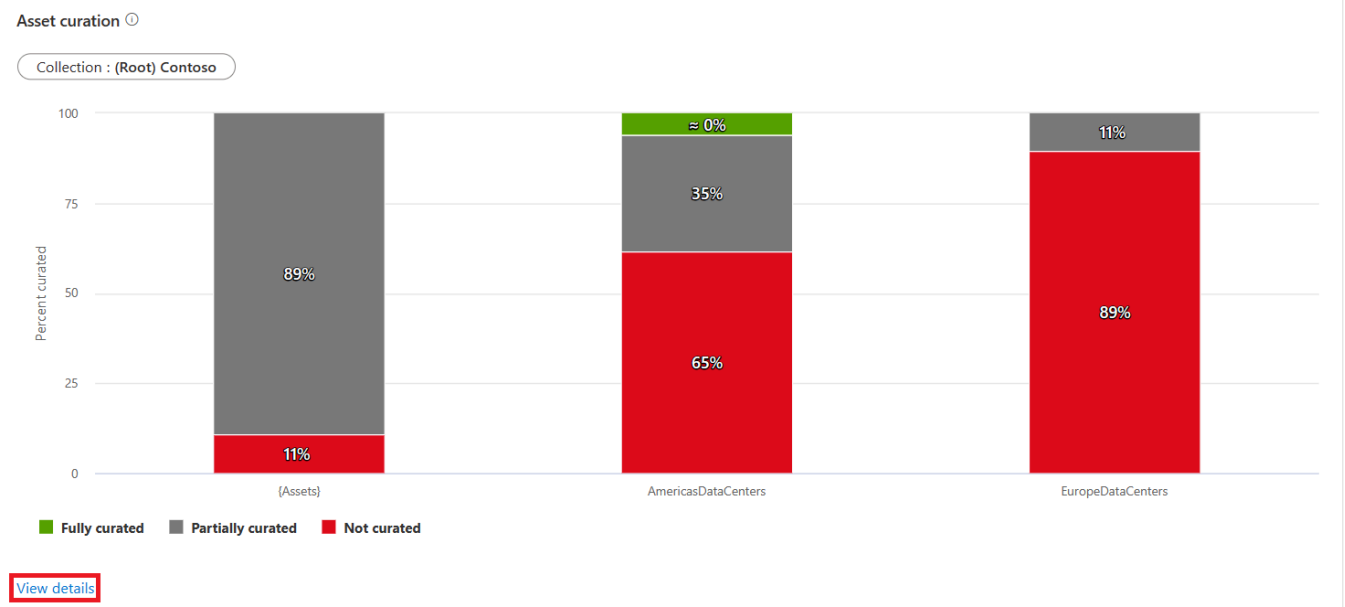


You can also drill down by collection paths. As you hover on each column name, it provides description of the column, provides recommended percentage ranges, and takes you to the detailed graph for further drill-down.

Asset curation

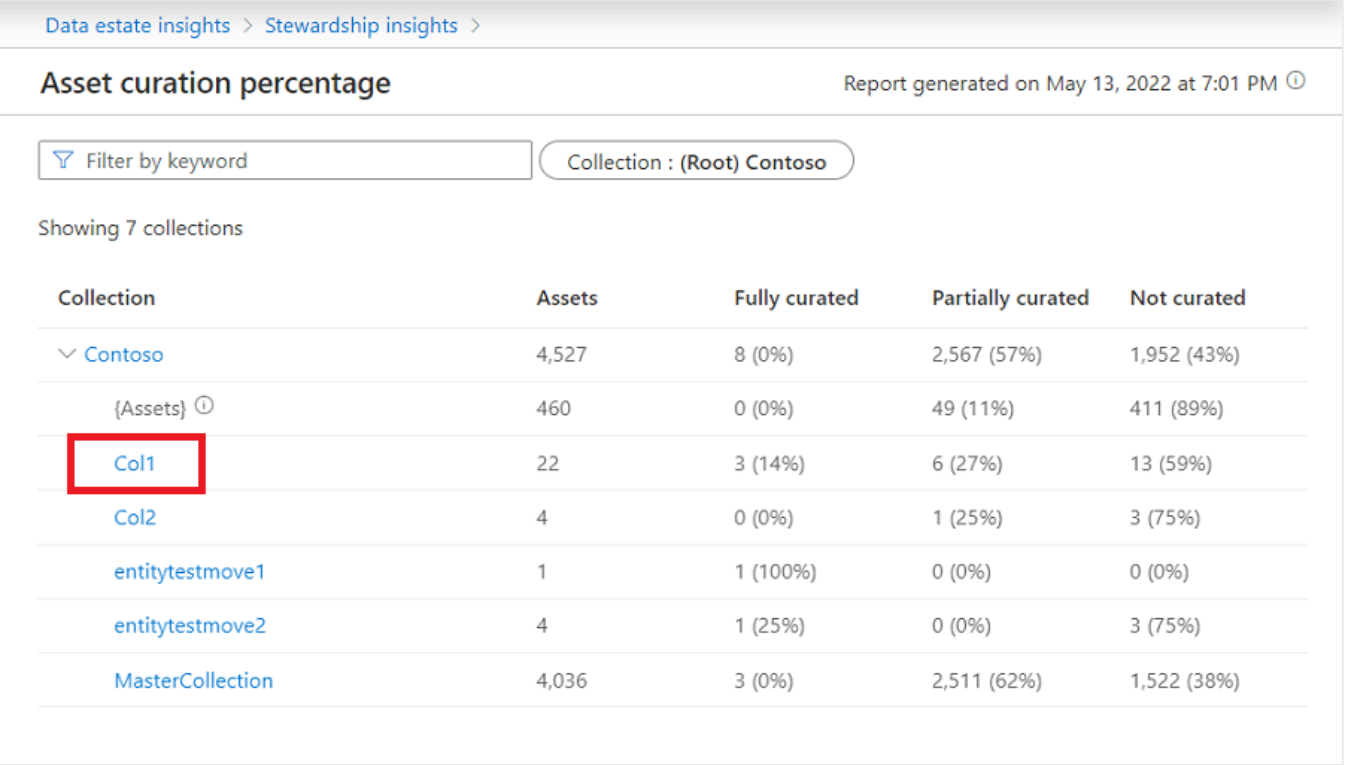


The system categorizes all data assets into three areas: **Fully curated**, **Partially curated**, and **Not curated**, based on whether assets have certain attributes.



An asset is ***Fully curated*** if it has at least one classification tag, an assigned data owner, and a description.

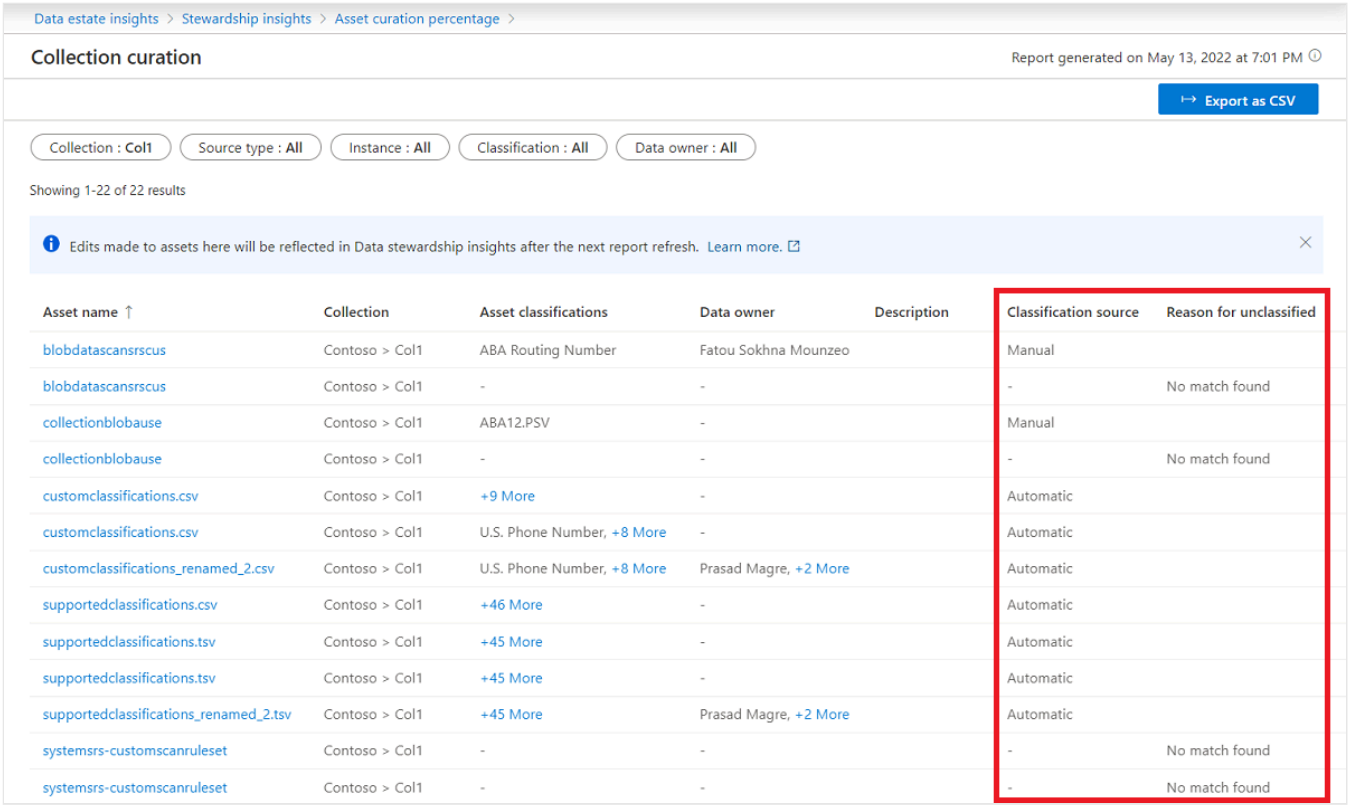
If an asset is missing any of these attributes, but not all, the system categorizes it as **Partially curated**. If an asset is missing all of these attributes, the system lists it as **Not curated**.



You can drill down by collection hierarchy.

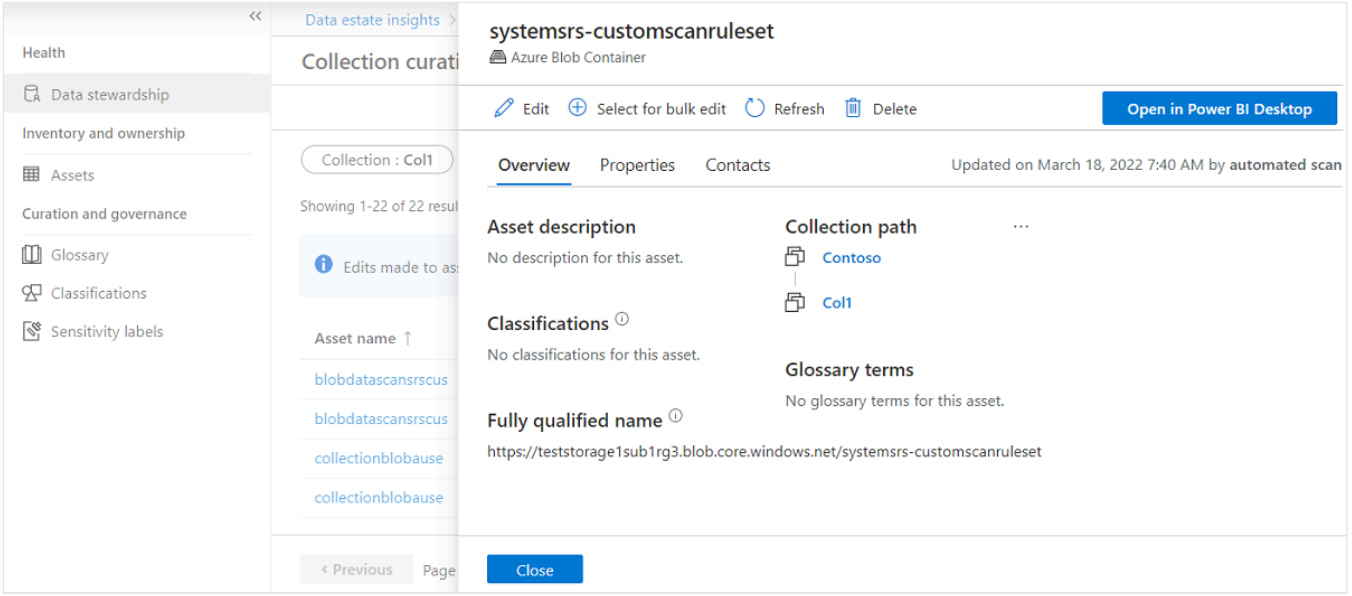
For further information about which assets aren't fully curated, you can select **View details** link that takes you into the deeper view.

In the **View details** page, if you select a specific collection, it lists all assets with attribute values or blanks that make up the ***fully curated*** assets.



The detail page shows two key pieces of information:

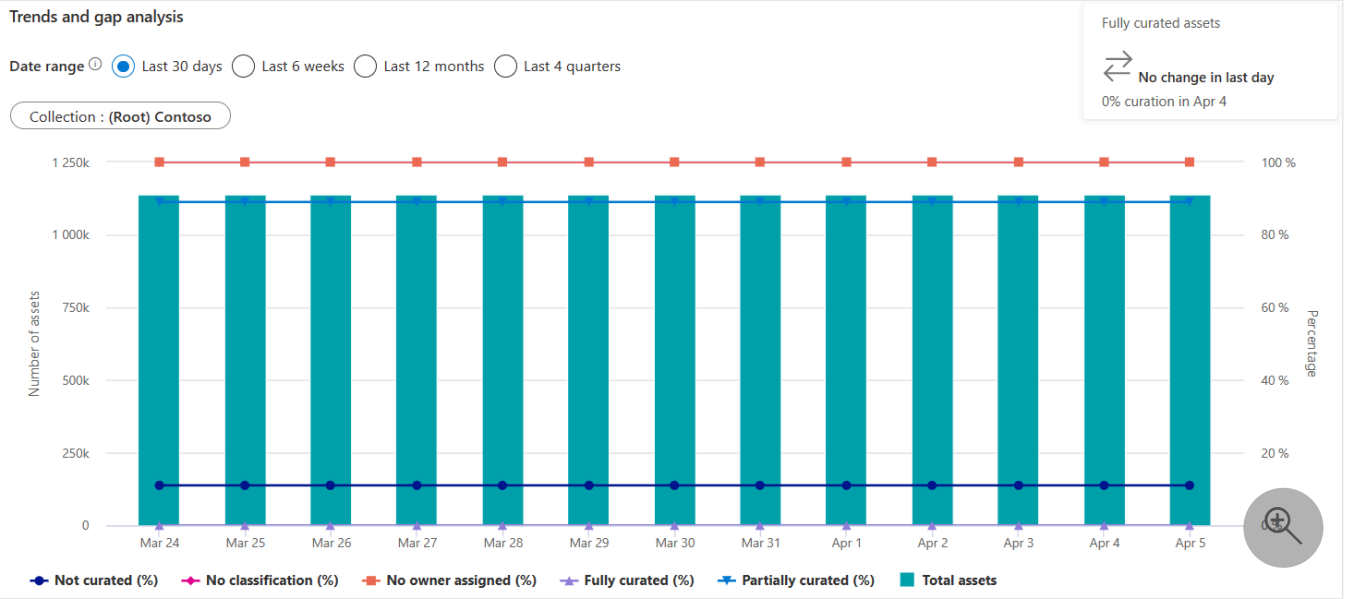
First, it tells you what the ***classification source*** is, if the asset is classified. It's **Manual** if a curator or data owner applies the classification manually. It's **Automatic** if the system classifies the asset during scanning. This page only provides the last applied classification state.



Second, if an asset is unclassified, it tells us why it's not classified, in the column ***Reasons for unclassified***. Currently, Data Estate Insights can provide one of the following reasons:

- No match found

- Low confidence score
- Not applicable



You can select any asset and add missing attributes, without leaving the **Data estate insights** app.

Trends and gap analysis

This graph shows how the assets and key metrics have been trending over different time periods:

- Last 30 days: The graph uses the last run of the day or the recording of the last run across days as a data point.
- Last six weeks: The graph uses the last run of the week, with the week ending on Sunday. If there's no run on Sunday, the graph uses the last recorded run.
- Last 12 months: The graph uses the last run of the month.
- Last four quarters: The graph uses the last run of the calendar quarter.

Understand the classic glossary report in Unified Catalog

This article describes how to access, view, and filter Microsoft Purview glossary insight reports for your data. In this how-to guide, you learn how to:

- ✓ Find Data Estate Insights.
- ✓ Get a bird's eye view of your data.

Prerequisites

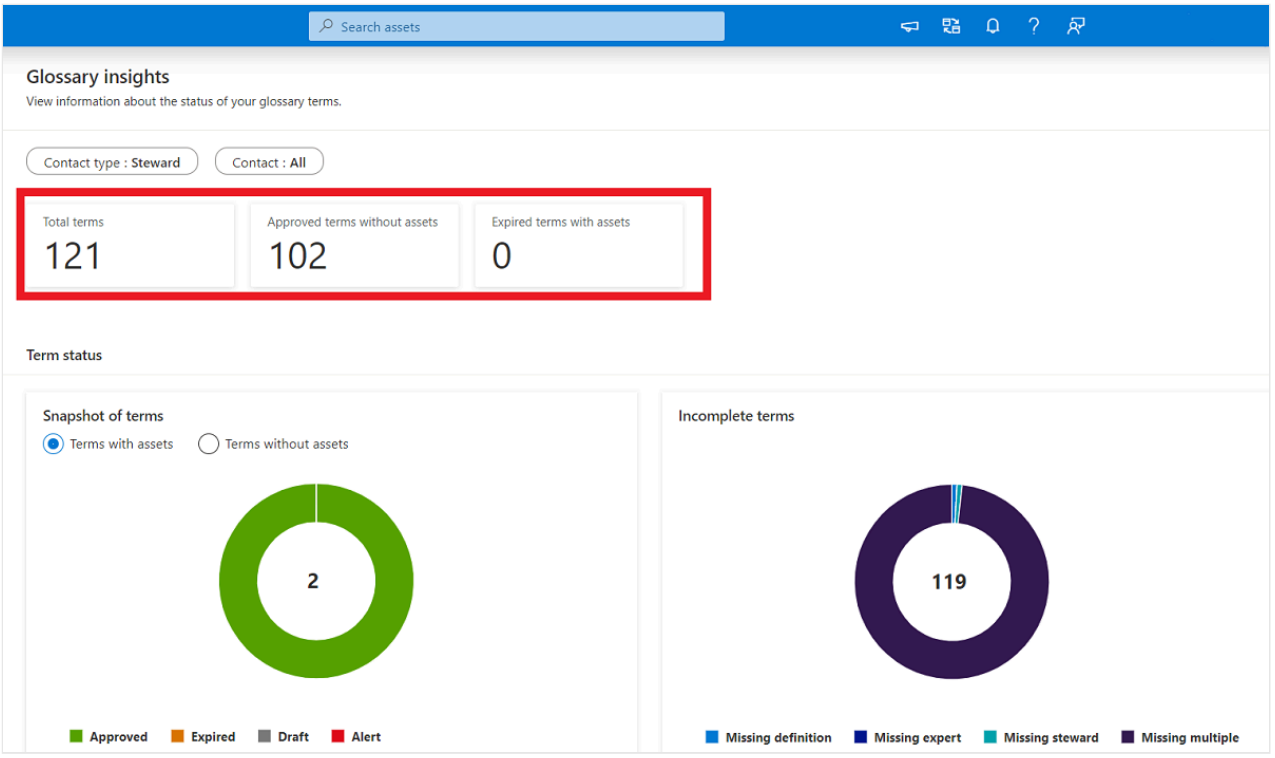
Before getting started with Data Estate Insights glossary insights, make sure that you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan your storage source.
- Set up at least one business glossary term and attach it to an asset.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Use Microsoft Purview glossary insights

In Microsoft Purview, you can create glossary terms and attach them to assets. As you make use of these terms in your data map, you can view the glossary distribution in glossary insights. These insights give you the state of your glossary based on:

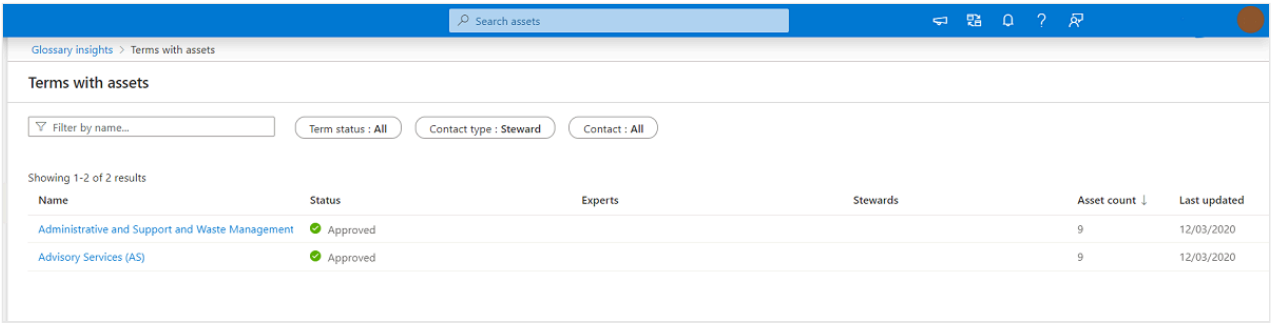
- Number of terms attached to assets.
- Status of terms.
- Distribution of roles by users.



View glossary insights

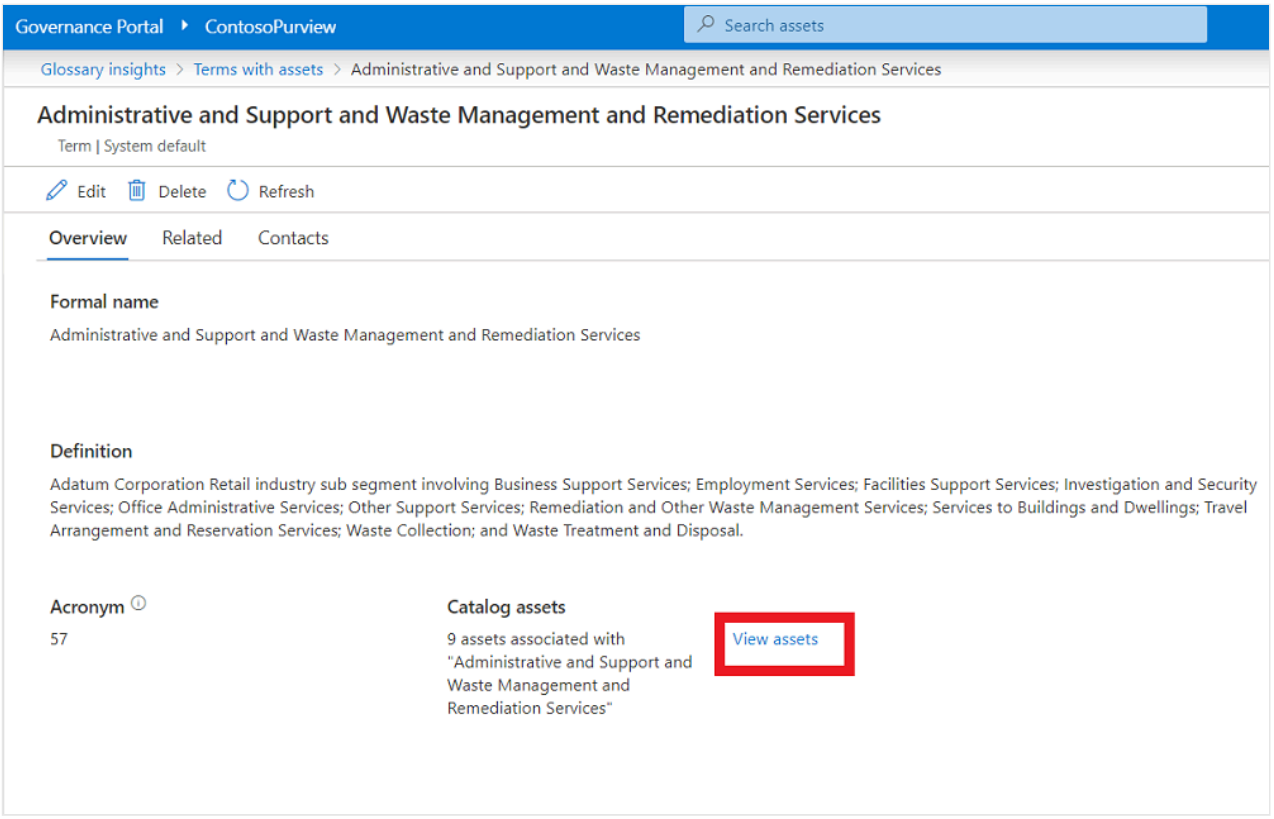
1. Open the Microsoft Purview portal.

2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.



3. Select the **Classic glossary** report.

4. The report starts with **High-level KPIs** that shows ***Total terms*** in your Microsoft Purview account, ***Approved terms without assets***, and ***Expired terms with assets***. Each of these values helps you understand the current health of your Glossary.



5. The **Snapshot of terms** section (displayed above) shows the term status as ***Draft***, ***Approved***, ***Alert***, and ***Expired*** for terms with assets and terms without assets.

6. Select **View details** to see the term names with various status and more details about ***Stewards*** and ***Experts***.

7. When you select "View more" for ***Approved terms with assets***, Data Estate Insights allows you to navigate to the **Glossary** term detail page, from where you can further navigate to the list of assets with the attached terms.

8. In Glossary insights page, view a distribution of **Incomplete terms** by type of information missing. The graph shows count of terms with ***Missing definition***, ***Missing expert***, ***Missing steward***, and ***Missing multiple*** fields.

9. Select ***View more*** from **Incomplete terms**, to view the terms that have missing information. You can navigate to Glossary term detail page to input the missing information and ensure the glossary term is complete.

Understand the classic sensitivity labels report in Unified Catalog

This article describes how to access, view, and filter security insights provided by sensitivity labels applied to your data.

Supported data sources include: Azure Blob Storage, Azure Data Lake Storage (ADLS) GEN 1, Azure Data Lake Storage (ADLS) GEN 2, SQL Server, Azure SQL Database, Azure SQL Managed Instance, Amazon S3 buckets, Amazon RDS databases (public preview), Power BI.

In this article, you learn how to:

- ✓ Launch your Microsoft Purview account from Microsoft Azure.
- ✓ View sensitivity labeling insights on your data.
- ✓ Drill down for more sensitivity labeling details on your data.

Prerequisites

Before getting started with Data Estate Insights, make sure that you complete the following steps:

- Set up your Azure resources and populate the relevant accounts with test data.
- Extended sensitivity labels to assets in Microsoft Purview Data Map, and create or select the labels you want to apply to your data.
- Set up and complete a scan on the test data in each data source. For more information, see Manage data sources in Microsoft Purview and Create a scan rule set.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

For more information, see Manage data sources in Microsoft Purview and Automatically label your data in Microsoft Purview.

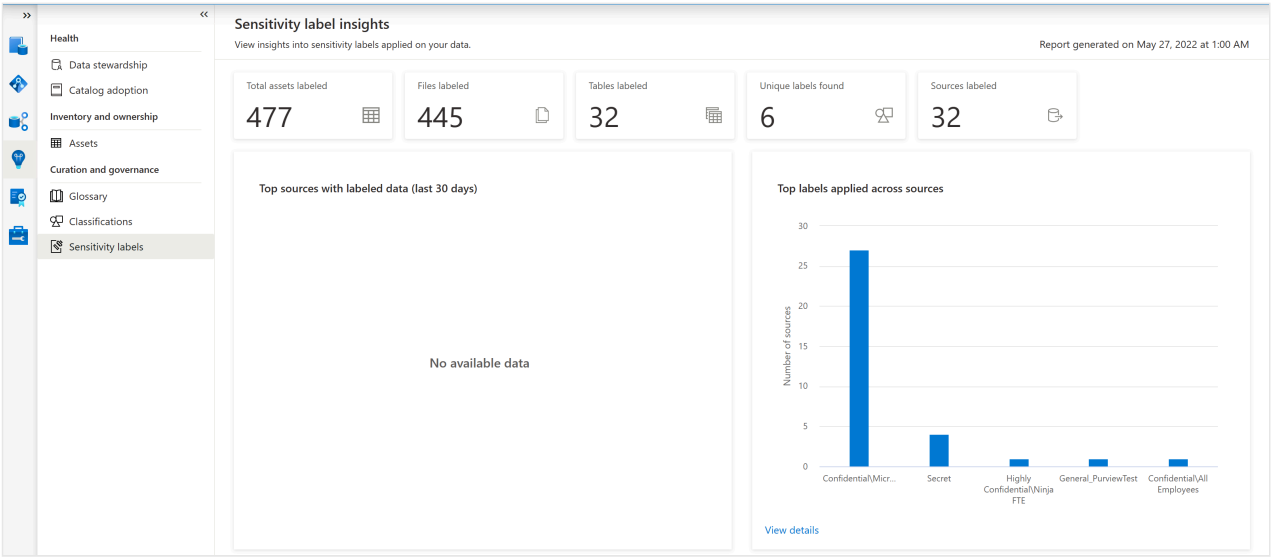
Use Data Estate Insights for sensitivity labels

Classifications are similar to subject tags. Use them to mark and identify data of a specific type that you find within your data estate during scanning.

Sensitivity labels enable you to state how sensitive certain data is in your organization. For example, a specific project name might be highly confidential within your organization, while that same term isn't confidential to other organizations.

Classifications match directly, such as a social security number, which has a classification of **Social Security Number**.

In contrast, sensitivity labels are applied when one or more classifications and conditions are found together. In this context, conditions refer to all the parameters that you can define for unstructured data, such as **proximity to another classification**, and **% confidence**.



Data Estate Insights uses the same classifications, also known as sensitive information types, as those used with Microsoft 365 apps and services. This enables you to extend your existing sensitivity labels to assets in Data Map.

> ⓘ **Note**
>
> After you scan your source types, wait a couple of hours for the **Classic sensitivity labels** report to reflect the new assets.

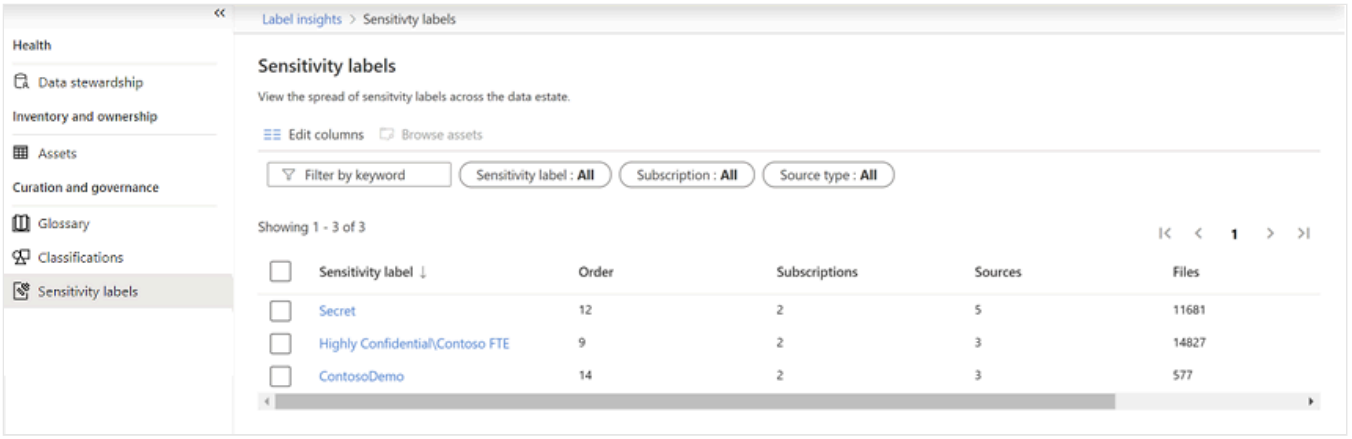
View sensitivity labeling insights

1. Open the Microsoft Purview portal.
2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.
3. Select the **Classic sensitivity labels** report.

   > ⓘ **Note**
   >
   > If this report is empty, you might not have extended your sensitivity labels to Data Map. For more information, see Learn about sensitivity labels in Data Map.

The main **Sensitivity labeling insights** page displays the following areas:

Expand table



Area	Description
Overview of sources with sensitivity labels	Displays tiles that provide: - The number of subscriptions found in your data. - The number of unique sensitivity labels applied on your data - The number of sources with sensitivity labels applied - The number of files and tables found with sensitivity labels applied
Top sources with labeled data (last 30 days)	Shows the trend, over the past 30 days, of the number of sources with sensitivity labels applied.
Top labels applied across sources	Shows the top labels applied across all of your Microsoft Purview data resources.
Top labels applied on files	Shows the top sensitivity labels applied to files in your data.
Top labels applied on tables	Shows the top sensitivity labels applied to database tables in your data.
Labeling activity	Displays separate graphs for files and tables, each showing the number of files or tables labeled over the selected time frame. **Default**: 30 days Select the **Time** filter above the graphs to select a different time frame to display.

Sensitivity labeling insights drilldown

In any of the following **Sensitivity labeling insights** graphs, select the **View more** link to drill down for more details:

- **Top labels applied across sources**
- **Top labels applied on files**
- **Top labels applied on tables**
- **Labeling activity > Labeled data**

For example:

To learn more, use the following options:

Expand table

Option	Description
Filter your data	Use the filters above the grid to filter the data shown, including the label name, subscription name, or source type. If you're not sure of the exact label name, enter part or all of the name in the **Filter by keyword** box.
Sort the grid	Select a column header to sort the grid by that column.
Edit columns	To display more or fewer columns in your grid, select **Edit Columns**, then select the columns you want to view or change the order. Select a column header to sort the grid by that column.
Drill down further	To drill down to a specific label, select a name in the **Sensitivity label** column to view the **Label by source** report. This report displays data for the selected label, including the source name, source type, subscription ID, and the numbers of classified files and tables.
Browse assets	To browse through the assets found with a specific label or source, select one or more labels or sources, depending on the report you're viewing, then select **Browse assets** above the filters.

Option	Description
	The search results display all of the labeled assets found for the selected filter. For more information, see Search the Microsoft Purview Unified Catalog.

Sensitivity label integration with Microsoft Purview Information Protection

Close integration with Microsoft Purview Information Protection means that you have direct ways to extend visibility into your data estate, and classify and label your data. For more information about sensitivity labels, see: Learn about sensitivity labels.

To extend sensitivity labels to your assets in Data Map, you must turn on this capability in the Microsoft Purview portal.

For more information, see Apply sensitivity labels to your data in Data Map.

Next steps

Learn how to use Data Estate Insights with sources below:

- Learn how to use Asset insights.
- Learn how to use Data Stewardship.
- Learn how to use Classification insights.
- Learn how to use Glossary insights.

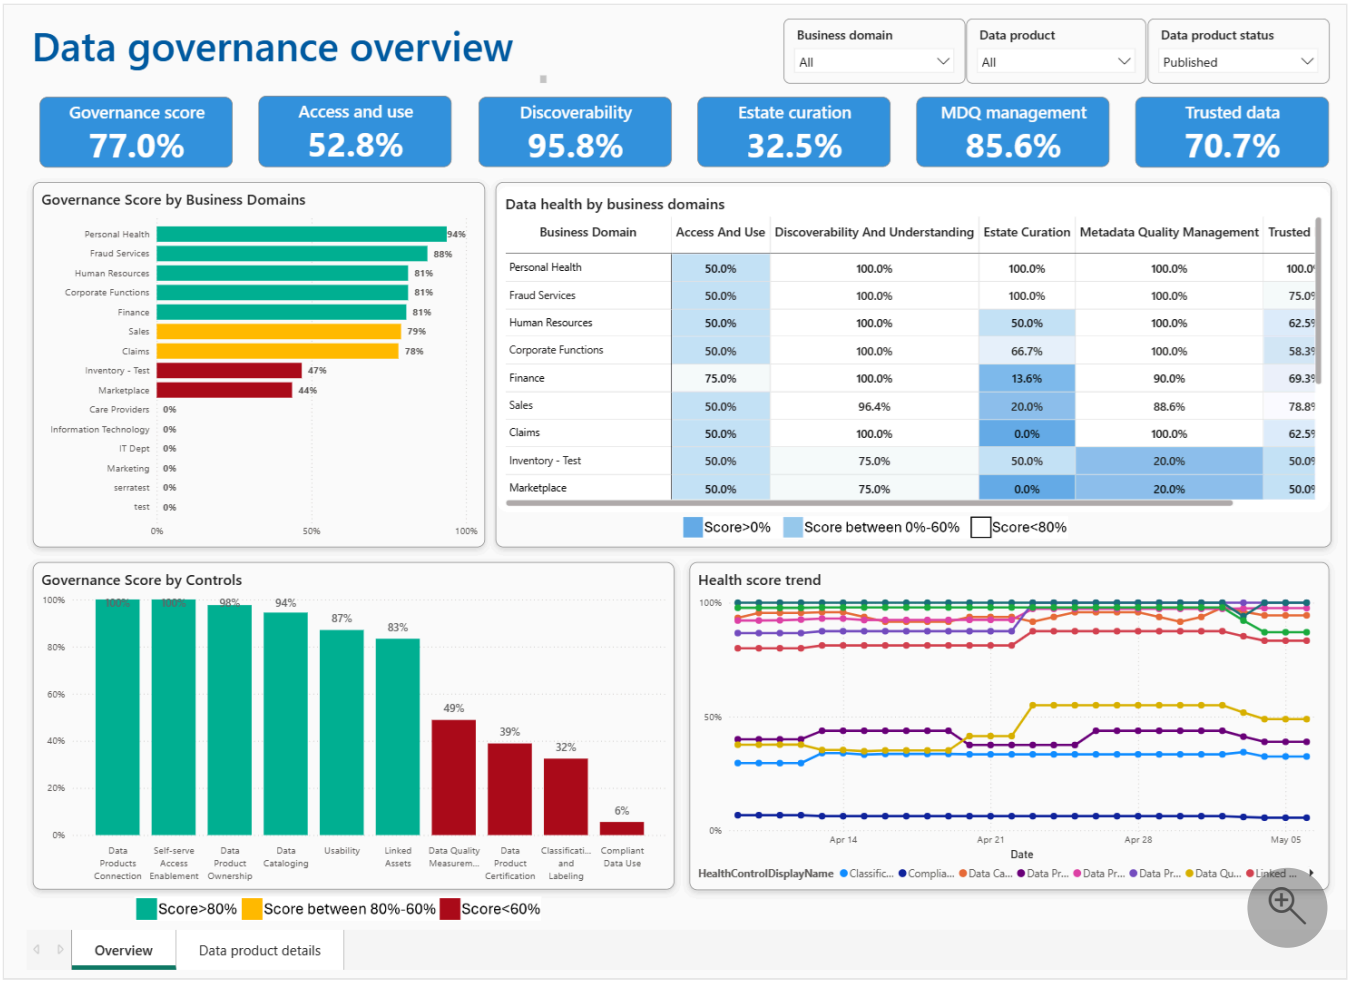
Understand the data governance report in Unified Catalog (preview)

The data governance health report allows your team to track your health progress at a glance, and identify areas that need more work. This article covers how you can access this report and what the provided information means for your data governance health.

> **Note**
>
> If you don't use data health controls, the data governance health report doesn't refresh. Ensure that you set up the schedule to run data health controls for refreshing the health controls scores and the data governance health report.



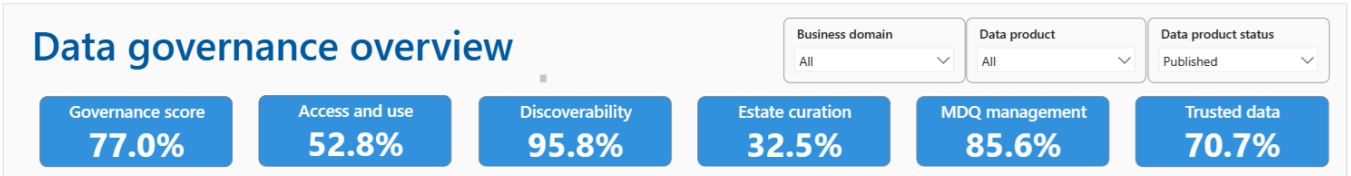
Prerequisites

- You need data health reader permissions to view Data Estate Health information.

View data governance health report

1. Open the Microsoft Purview portal and select **Unified Catalog**.
2. At **Health management**, select **Reports**.
3. Select the **Data governance (preview)** report.

The overview page of the report covers the overall health of your governance domains, and provides details about your data products.



Use the filters to see information for specific governance domains, data products, or data products in a certain status (for example: draft).

Overview

The main overview covers the controls for your governance domains.

Controls and actions

The top controls and actions help you understand your overall governance health at a glance. They cover both controls and actions.

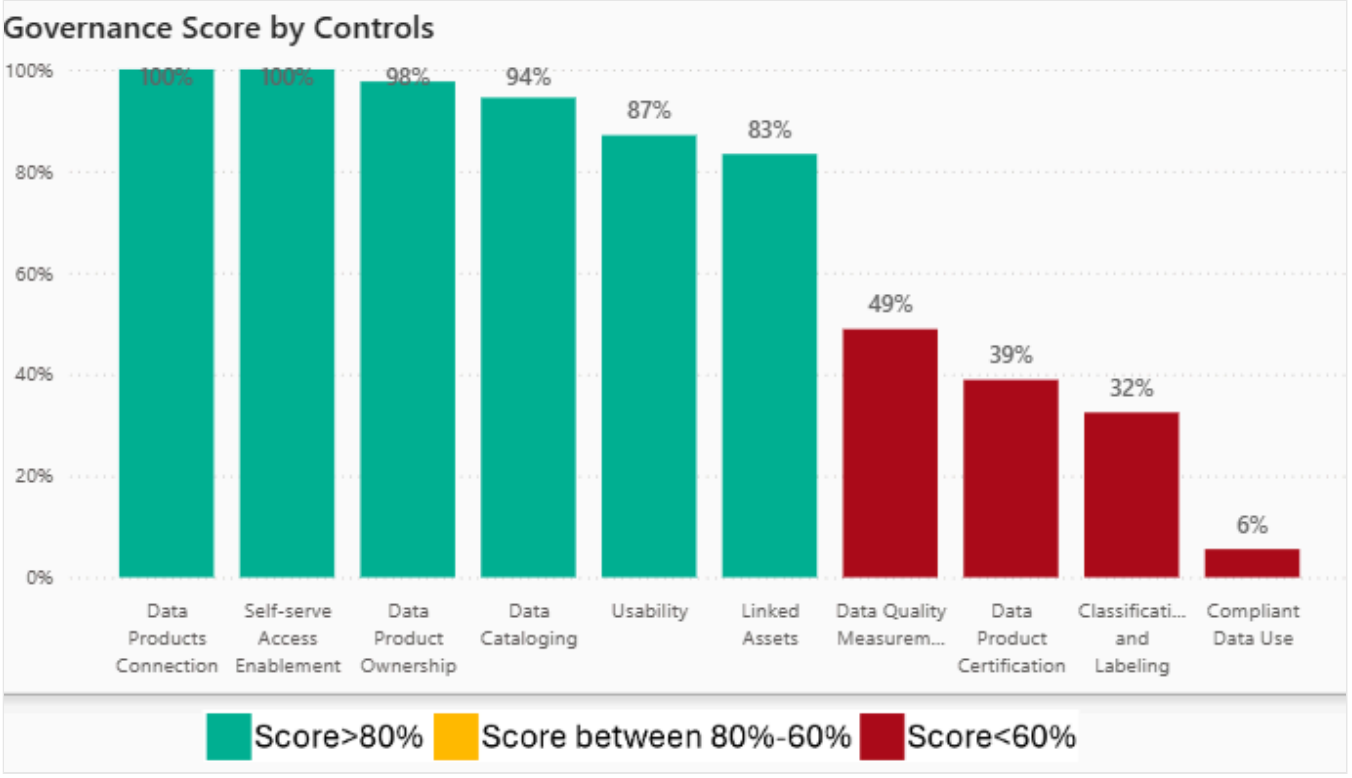
Expand table

Control or action	Description	Example
Governance score	Average of the ownership, cataloging, and classification controls.	
Access and use	Average of the self-service access enablement and compliant data use controls.	(Self-serv score is **100** + Compliaant score is **5.6**) / 2 = **52.8%** is the Access and use score control group score.
Discoverability	Average of these two checks: number of governance domains with Unified Catalogs and the number data products that have data assets mapped.	
Estate curation	Percentage of data assets that have classifications applied.	Estate curation score is **32.5%** because only 32.5% of data assets are classified during scan.
MDQ management	Average of data product useability (products with long descriptions and attached glossary terms), and percentage of data products with linked assets.	(MDQ data product usability is **87.9** + MDQ Linked asset is **83.3**) /2 = **85.6%** is the MDQ management score.
Trusted data	Average of three controls: Percentage of data products with owners, percentage of data products that have data quality scoring enabled, percentage of data products that are certified.	(% of data products with owner is **97.6** + % data product with data quality score is **68.4** + % of data product certified is **46.2**) = **70.7%** is the Trusted data score.

> **Tip**
>
> If you use the filters, these KPIs reflect scores for the governance domains or data products you select.

Data health by governance domain

The data health by governance domain chart gives you individual control scores for your governance domains without needing to use the filters. At a glance, you can see which of your governance domains are healthy and which need more attention.

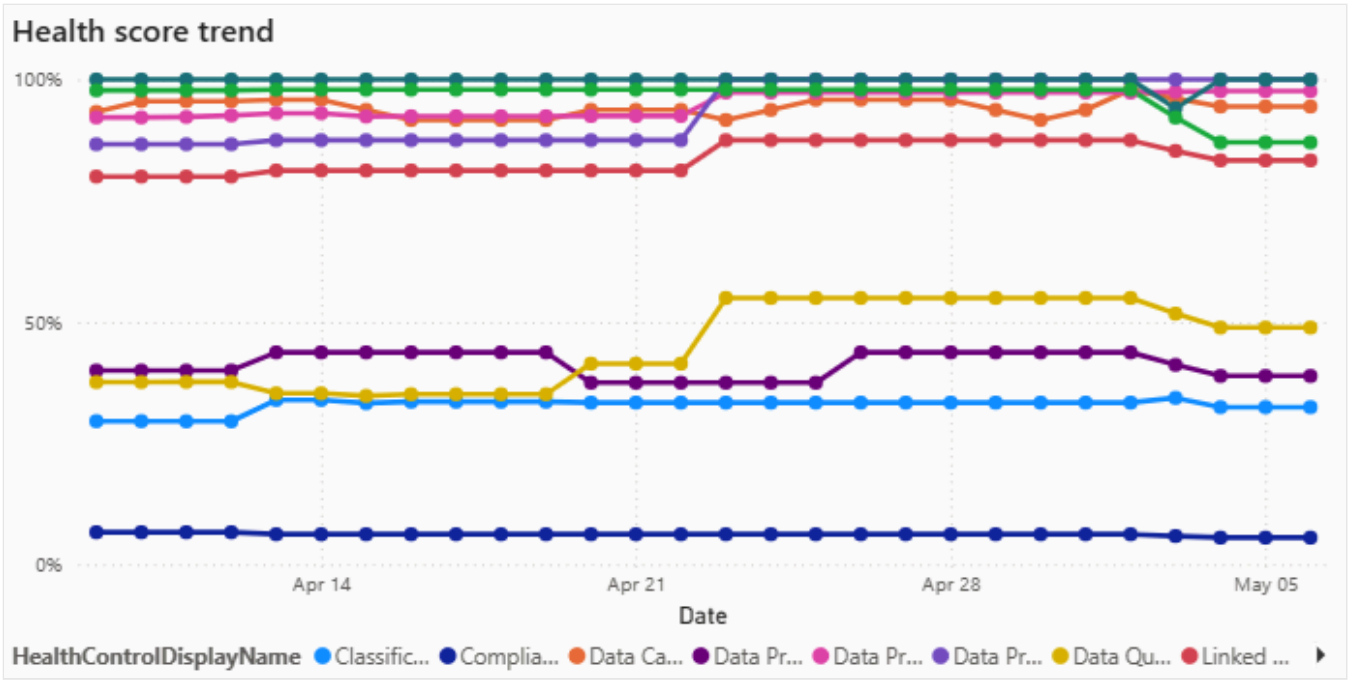


Data health by business domains

Business Domain	Access And Use	Discoverability And Understanding	Estate Curation	Metadata Quality Management	Trusted
Personal Health	50.0%	100.0%	100.0%	100.0%	100.0
Fraud Services	50.0%	100.0%	100.0%	100.0%	75.0
Human Resources	50.0%	100.0%	50.0%	100.0%	62.5
Corporate Functions	50.0%	100.0%	66.7%	100.0%	58.3
Finance	75.0%	100.0%	13.6%	90.0%	69.3
Sales	50.0%	96.4%	20.0%	88.6%	78.8
Claims	50.0%	100.0%	0.0%	100.0%	62.5
Inventory - Test	50.0%	75.0%	50.0%	20.0%	50.0
Marketplace	50.0%	75.0%	0.0%	20.0%	50.0

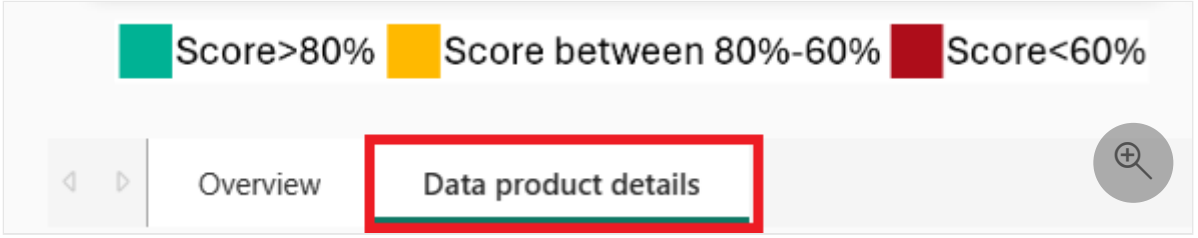
Score>0% Score between 0%-60% Score<80%

Governance score by controls



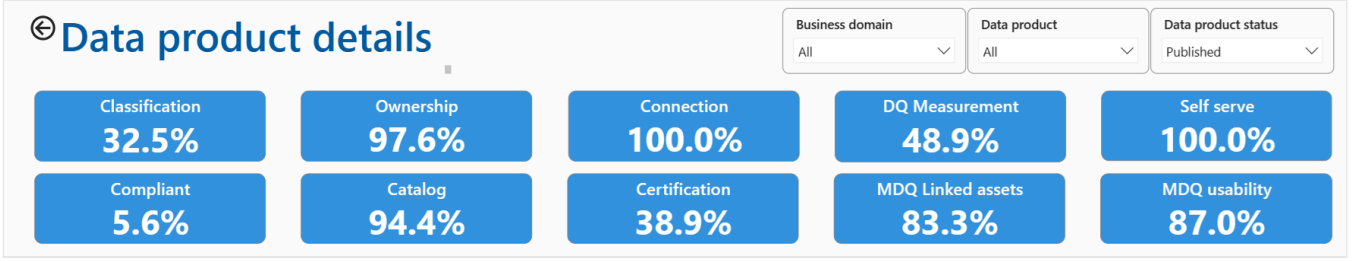
This column chart highlights your governance strengths and weaknesses by showing overall score for each control in Unified Catalog. Prioritize low or flagging scores to increase your data governance coverage across your data estate.

Health score trend



This table shows your daily health progression for all of the main health controls.

Use this table to track how well your team manages your data estate over time and to track your progress toward healthy data governance.

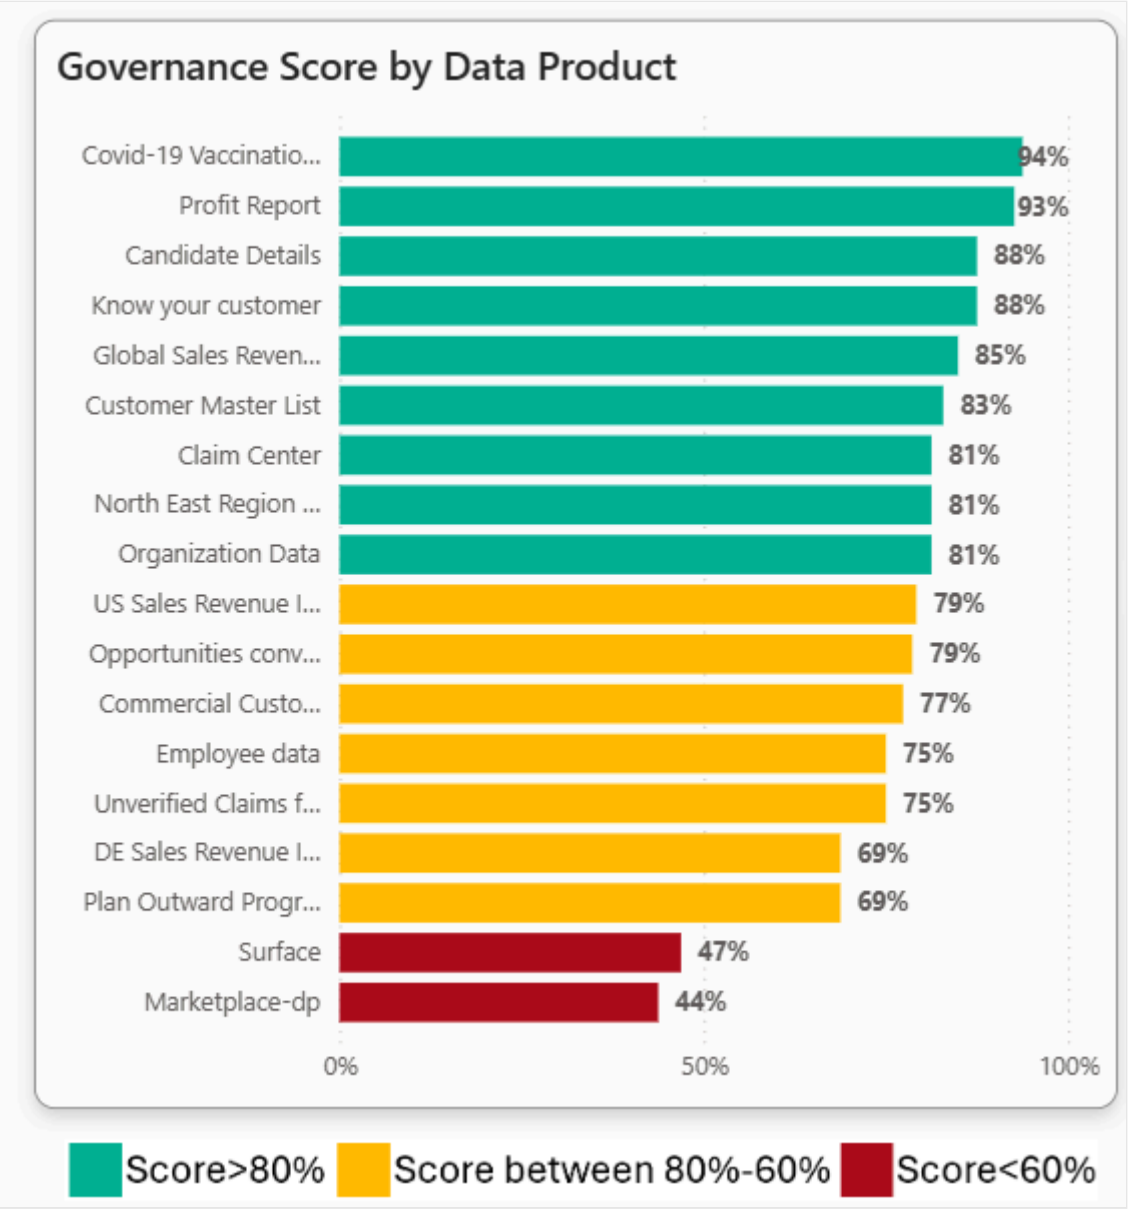


Data product details

Select the **Data product details** tab at the bottom of the page to see action and control information for your data products.

Data product controls and actions

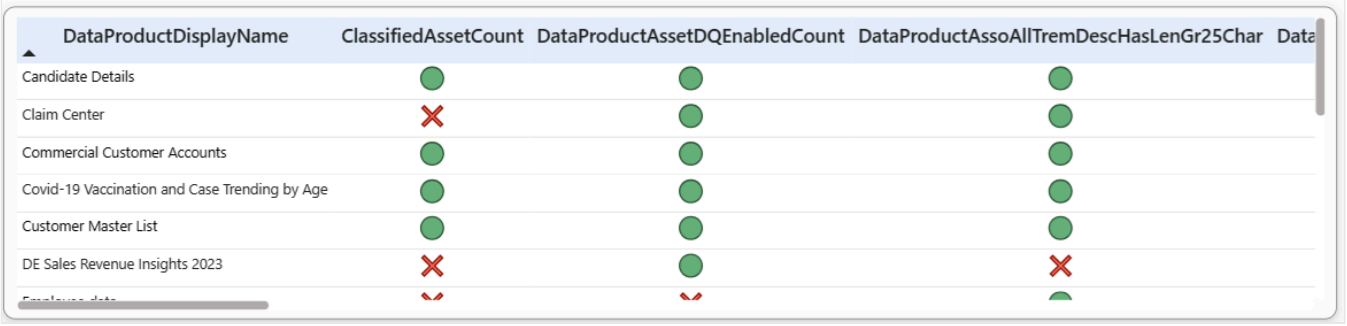
The top controls and actions help you understand your overall governance health at a glance. They cover both controls and actions.



Expand table

Control or action	Description	Example in the image above
Classification	Percentage of data products that have classified assets attached.	**32.5%** of data assets are classified by Data Map scans.
Ownership	Percentage of data products that have an active owner.	**97.6%** of data products have at least one owner.
Connection	Percentage of data products that have at least one asset attached.	**100%** of data products have at least one data asset attached.
DQ measurement	Aggregation of data quality scores across the data products.	**48.9%** of data assets have a data quality score.
Self serve	Percentage of data products with self-service access setup.	**100%** of data products have a self-serve access policy attached.
Compliant	Percentage of data products with the purpose of use policy added.	**5.6%** of data products have a compliant policy attached.
Catalog	Percentage of data products with a description, published glossary terms, and a use case.	**94.4%** of data products have descriptions, use cases, and at least one glossary term associated.
Certification	Percentage of data products that have been verified.	**38.9%** of data products are verified.
MDQ linked assets	Percentage of data products with at least one asset and at least one published glossary term.	**83.3%** of data products have at least one data asset and one glossary term linked.
MDQ usability	Percentage of data products that have a description over 100 characters long, the parent domain has a description 100 characters long, and the associated term has a description 100 characters long.	**87%** of data products have descriptions and use cases that are at least 100 characters long.

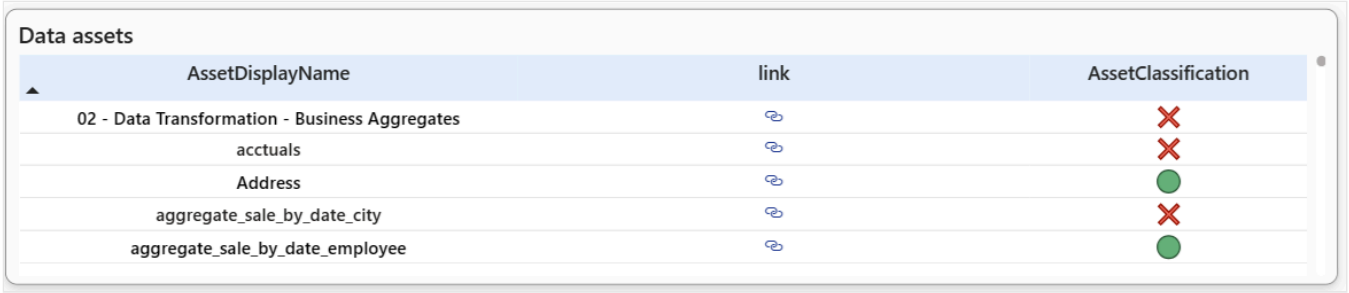
Use the filters to narrow your view to only certain governance domains, data products, or data products with a certain status.



Governance score by data product

This bar chart highlights your strongest and weakest data products by showing the overall governance score for each data product. Prioritize low-scoring but high-use data products to bring the most value to Unified Catalog.

Individual control checks

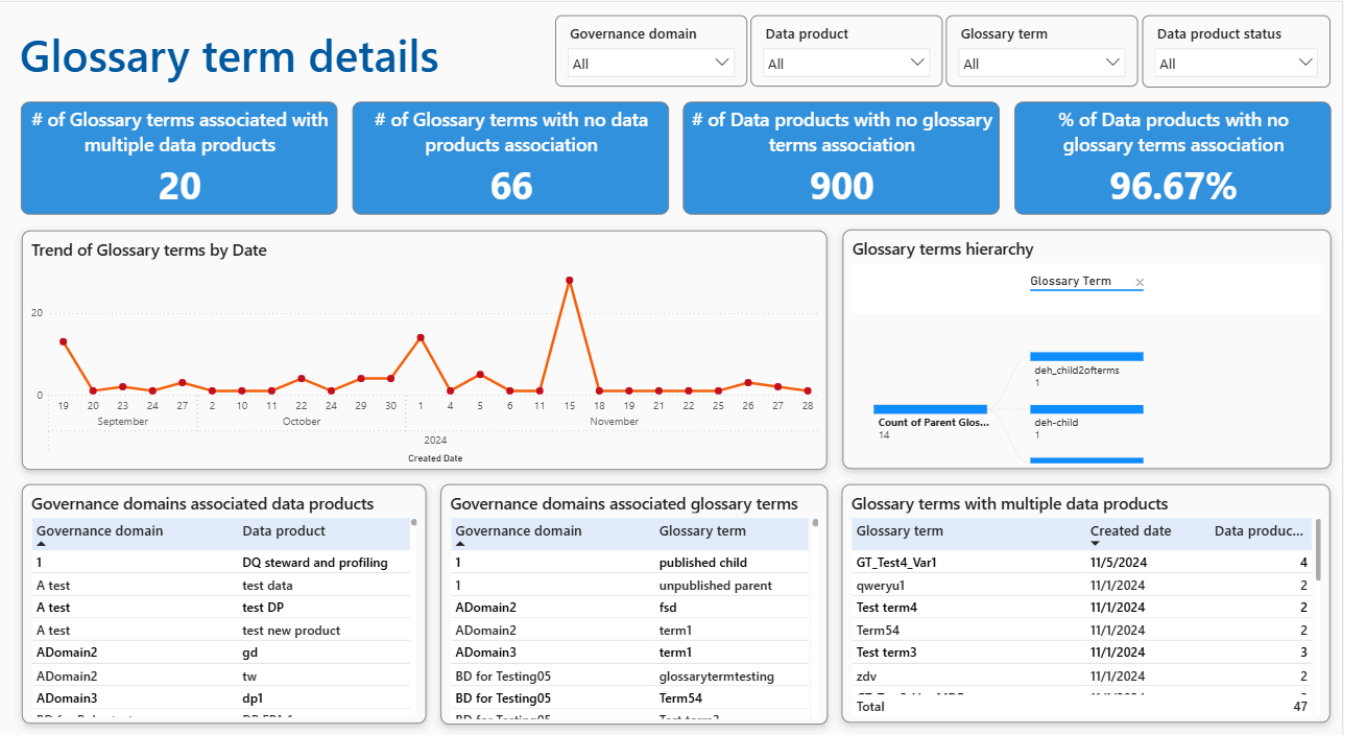


This table shows the pass or fail status for each individual control check available to your data product. You can check controls for low-scoring data products to see which areas need improvement.

DataProductDisplayName	ClassifiedAssetCount	DataProductAssetDQEnabledCount	DataProductAssoAllTremDescHasLenGr25Char	Data
Candidate Details	●	●	●	
Claim Center	✕	●	●	
Commercial Customer Accounts	●	●	●	
Covid-19 Vaccination and Case Trending by Age	●	●	●	
Customer Master List	●	●	●	
DE Sales Revenue Insights 2023	✕	●	✕	

Data assets

This table shows the pass or fail status for individual assets in Unified Catalog. If multiple data products reference a single asset, resolving any outstanding governance issues for that asset raises your score overall.



Data assets

AssetDisplayName	link	AssetClassification

acctuals		✗
Address		●
aggregate_sale_by_date_city		✗
aggregate_sale_by_date_employee		●

Glossary terms report (preview)

Glossary terms provide vocabulary for business users. These terms allow users to discover and work with data in the vocabulary that's familiar to them versus using abstract technical terminology inherited from physical data sources. Terms are created under governance domains to create context specific to each part of your organization. Both sales and marketing might use the same term to mean different things, and your governance domains help your team to differentiate between those meanings. Once created, terms map to data products, to provide context for those data products, and to provide specific data governance based on business context. Terms are an active part of Microsoft Purview that provide data governance by now containing policies. The glossary terms report (preview) helps data stewards to browse:

- Glossary terms trends.
- Glossary terms hierarchy.
- Data product associated with glossary terms.
- Governance domain association with glossary terms.

Understand the quality report in Unified Catalog

The data quality health report evaluates and summarizes the quality of data within an organization or system. It includes assessments of various data quality dimensions and metrics to help stakeholders understand the accuracy, completeness, consistency, reliability, and timeliness of their data. This data quality report allows your team to track your health management progress at a glance and identify areas that need more work to improve the quality of data in your data estate.

This article covers how you can access this report and what the provided data quality measure means for your health management.

Report purposes

- **Monitoring and governance**: To continuously monitor and manage the quality of data, ensuring it meets the organization's standards and regulatory requirements.
- **Decision support**: To provide stakeholders with reliable data for making informed business decisions.
- **Identifying issues**: To detect and document data quality issues, enabling timely remediation.
- **Improving data management**: To enhance data management practices by identifying root causes of data quality issues and implementing corrective measures.
- **Performance measurement**: To measure the effectiveness of data quality initiatives and track improvements over time.
- **Stakeholder communication**: To communicate data quality status and progress to stakeholders, including management, data product owners, data stewards, and IT teams. By providing a clear and comprehensive view of the state of data quality, these reports play a crucial role in maintaining the integrity and usefulness of data within an organization.

Prerequisites

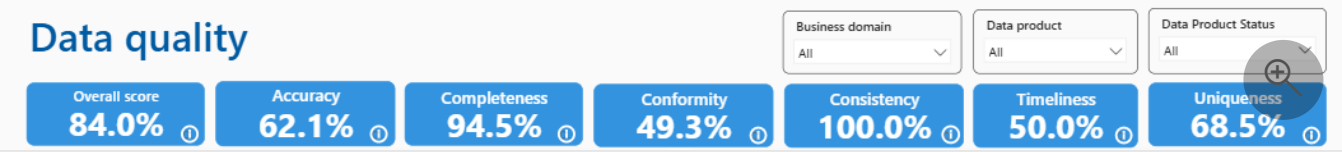
You need the Data Health Reader role to view data health information.

View data quality health report

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Go to **Health management** > **Reports**.
3. Select the **DQ health** report.

Data quality dimension reporting

The overview page of the report shows data quality dimension scores, data quality rule hierarchy, data quality status by dimension, and data quality dimensions and rule types used for different data assets. The top controls help you understand your overall health management at a glance.



Use the filters to see information for specific governance domains, data products, or data products in a certain status (for example: draft).

Expand table

Data Quality Dimension	Description
Accuracy	Data should accurately represent real-world entities. Context matters. For example, if you're storing customer addresses, ensure they match the actual locations.
Completeness	The objective of this rule is to identify the empty, null, or missing data. This rule validates that all values are present (though not necessarily correct).
Conformity	This rule ensures that the data follows data formatting standards such as representation of dates, addresses, and allowed values.
Consistency	This rule checks that different values of the same record conform with a given rule and that there are no contradictions. Data consistency ensures that the same information is represented uniformly across different records. For example, if you have a product catalog, consistent product names and descriptions are crucial.
Timeliness	This rule aims to ensure that the data is accessible in as short a time as possible. It ensures that the data is up to date.
Uniqueness	This rule checks that values aren't duplicated. For example, if there's supposed to be only one record per customer, then there aren't multiple records for the same customer. Each customer, product, or transaction should have a unique identifier.

Data quality overall score and dimension scores help data practitioners and data estate owners understand how complete, accurate, consistent, and trustworthy their data is. These scores also indicate what improvement actions need to be taken to enhance the quality of their data estate.

How the scores are calculated

> **Tip**
>
> If you use the filters, these KPIs show scores for the governance domains or data products you select.

Data quality status by dimensions

Overall score % = Percentage of data quality dimension score of all measured dimensions divided by total number of dimensions with score. **Exception**: If any dimension score is **Blank**,

the calculation excludes the **Blank** score from the overall score; for example:

Expand table

Data Quality Dimension	Score %
Accuracy	100
Completeness	80
Consistency	100
Conformity	Blank
Uniqueness	100
Timeliness	50

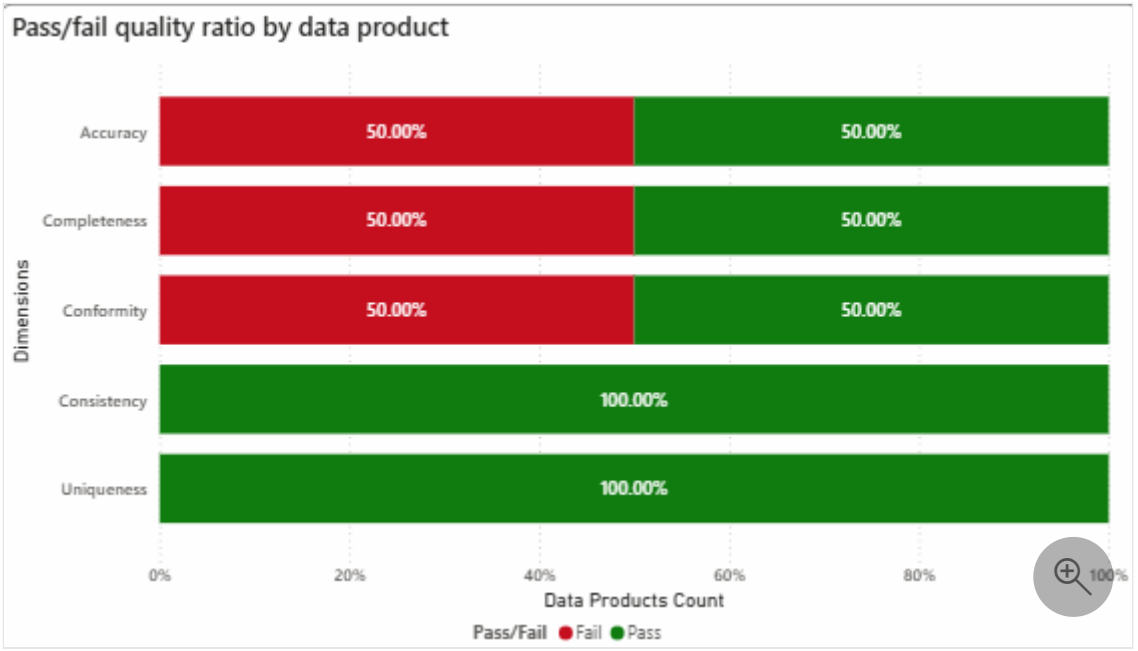
Overall score % = ((100+80+100+100+50)/5)*100 = 86%

As conformity score is **Blank**, the calculation excludes it from the overall score. If the conformity score is zero (0) instead of **Blank**, the calculation includes the zero score. In this scenario, the overall score = ((100+80+100+0+100+50)/6)*100 = 72% (71.66%).

The score for each dimension is calculated as follows:

Data quality score for a dimension (%) = (Total number of records that pass all applied rules for the selected dimension across all data assets of a data product) ÷ (Total number of records of all data assets of the selected data product measured against the selected dimension) × 100

Example:



Total number of assets associated with a data product is 4. Total passed records for asset one are 1,000, for asset two are 200, for asset three are 4,000, and for asset four are 100. Total number of records for all four assets is 6,000. Data quality score (%) for the selected dimension = ((1,000 + 200 + 4,000 + 100) / 6,000) * 100 = 88%.

Data quality dimension scores are calculated for each governance domain. Dimensions are mapped with rules, and the score rolls up from data asset columns to data asset, and from data asset to data product and governance domain level for each industry standard dimension. You can filter dimension level scores per governance domain to investigate more details.

Domain	Accuracy	Completeness	Conformity	Consistency	Timeliness	Uniqueness	Overall Score
Care Providers		90.35%					90.35%
Claims	0.00%	94.75%	14.44%			0.00%	56.96%
Corporate Functions		99.35%				79.38%	86.54%
Finance		98.23%		100.00%		66.72%	93.21%
Fraud Services		100.00%				100.00%	100.00%
Human Resources		84.34%				2.68%	81.34%
Personal Health		100.00%		100.00%			100.00%
Sales	70.95%	92.87%	75.46%	100.00%	50.00%	78.09%	89.43%
Test-cap		89.98%				0.00%	15.00%

Data quality rules pass and fail ratio

The pass and fail ratio of data quality rules is measured for each data quality dimension for data products. This measure helps data owners and data practitioners understand what percentage of data in a data product is inaccurate, inconsistent, incomplete, duplicate, or not fresh enough as expected. This measure also helps to investigate and understand whether the applied rules are incorrect or the data is incorrect.

Example scenario 1

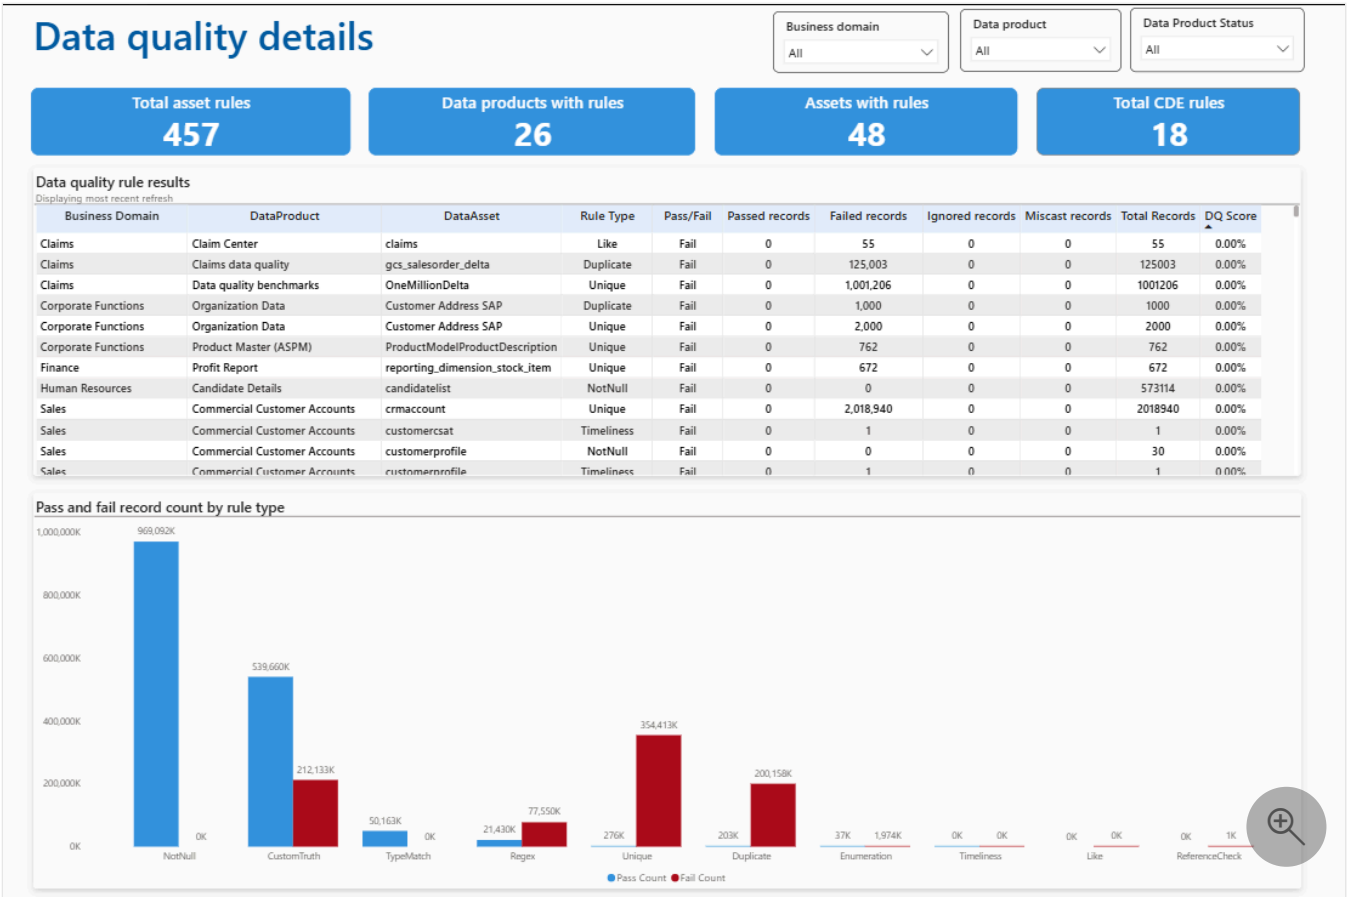
You create rules to measure accuracy and completeness of a data asset. After a data quality scan is completed and the data health report is refreshed, if the Accuracy score is 100% and Completeness score is 16.6%, the report displays one data product count.

- Accuracy as 100%, with a green bar.
- Completeness as 16.6%, which is below the threshold (100%), as Failed with a red bar.

Example scenario 2

You apply two accuracy dimension rules. After a data quality scan, you see one accuracy rule score is 100%, which is visible in the report as Passed, shown with a green bar. Another accuracy rule dimension for same data product has a score of 15.98%, which is visible in the report as Failed, shown with a red bar. The report shows 50% Passed and 50% Failed, because Accuracy has two rule dimensions.

Expand table



Accuracy rule	Score	Result
Rule 1	100%	Passed
Rule 2	15.98%	Failed

Calculation:

- Passed rule = 1
- Failed rule = 1
- Total rules = 2
- Accuracy score pass fail ratio = (1/2) x 100 = 50%, so you see 50% Pass, and 50% Fail.

Data quality details report

In the data quality health report, select the **Details** tab to see how many rules apply to data products, data assets, and critical data elements. These rules help measure and monitor the quality of the entire data estate of your organization. You can drill down to see how many records of a data asset failed for a rule type, which rule type is performing better, and which governance domain and data products are publishing and maintaining trustworthy data. You can filter the measures by governance domain and data product to understand the current state and to plan improvement actions. Here's an example of the details view:

Historical trend

In the data quality health report, select the **Historical Trend** tab to help you understand the historical trend of the data quality of governed data assets. You can filter governance domain and data product level trends for the associated data assets. You can also use the selector to select the top or bottom 10 data assets to browse the data quality trends of each data quality dimension. Here's an example of the historical trend view:

> **Note**
>
> - The data quality health report depends on data health controls and Microsoft Purview metadata self-serve analytics model. If you don't use the data health controls and don't subscribe Unified Catalog metadata, the data quality health report doesn't refresh. You need to use data health controls or subscribe Microsoft Purview metadata for self-serve analytics to refresh the data quality health report.
> - If you don't use the data quality feature, the data quality health report appears blank because the report is created using data generated from the data quality scan feature.

Self-serve analytics and insights

Self-serve analytics and insights refer to data, tools, and platforms that enable business users to access, analyze, and generate insights from data independently. Microsoft Purview data governance publishes a domain model of metadata into Microsoft Fabric OneLake and Microsoft Azure Data Lake Storage Gen2, so you can analyze and generate insights by bringing your own tools and compute. Self-serve analytics of data governance metadata is valuable in driving continuous improvement of your data estate health management and fostering a data-driven culture across your organization by democratizing access to data estate insights and health management.

Key components

- **Data Model:** 3NF Model with domains and dimensions details.
- **Metadata:** Data governance metadata that includes:
  - Governance domains
  - Data products
  - Data assets
  - Glossary terms
  - Subscription request
  - Data quality rules
  - Dimensions
  - Data quality facts (pass and fail counts)
  - Data health actions (including data quality actions)
  - And many more

Benefits

- **Empowerment:** Empowers data practitioners, data product owners, data stewards, and analysts to explore data governance metadata and link metadata from various sources to derive insights.
- **Flexibility and efficiency:** You can create custom reports in addition to out-of-the-box reports in health management.
- **Agility:** Allows your organization to respond more swiftly to health management issues and remediation.

- **Cost-effective:** Reduces the need for setting up platforms and build tools. All data is available in OneLake and you can use available tools (Fabric semantic model, Power BI reporting, data flow, and notebook) in OneLake.

Available reports (out-of-the-box)

Here are the available out-of-the-box reports. You can't customize these reports.

- Classic assets - an overview of assets by type and collection, and their curation status.
- Classic catalog adoption - to understand at a glance how Unified Catalog is being used.
- Classic classifications - an overview of assets classified and the types of classifications.
- Classic data stewardship - an overview of assets classified and the types of classifications.
- Classic glossary - health and use of glossary terms.
- Classic sensitivity labels - an overview of assets that have sensitivity labels applied and the types of labels applied.
- Data governance - The data governance health report allows your team to track your health progress at a glance, and identify areas that need more work.
- Data quality health - Data quality dimensions and data quality rules performance reporting.

Data model for self-serve analytics metadata

The 3NF domain model is part of the normalization process in relational database design. It ensures that the database is free of redundancy and update anomalies. A database schema is in the Third Normal Form if it meets the requirements of the First and Second Normal Forms and all its attributes are functionally dependent only on the primary key.

Use the 3NF domain model to structure data in a way that minimizes duplication and ensures data integrity. It focuses on breaking down data into smaller, related tables where each piece of information is stored only once.

Characteristics:

- Elimination of transitive dependencies: Nonkey attributes shouldn't depend on other nonkey attributes.
- Logical grouping: Data is logically grouped into domains based on its function or meaning.
- Entity-relationship diagrams (ERDs): Commonly used to represent 3NF domain models, showing how entities relate to each other.

Expand table

Table name	What's stored in the table	Relationship keys
Access Policy Provisioning State	Information about provisioning state	ProvisioningStateId
Access Policy Resource Type	Access policy resource information	ResourceTypeId
Access Policy Set	Overall information about access policy, policy use case details, and where the policy is applied	AccessPolicySetId (UniqueId), ResourceTypeId (FK), ProvisioningStateId (FK)
Business Domain	Business domain (called **governance domain** in Unified Catalog) name, description, status, and ownership details	Parent Business Domain ID (FK), Created By User ID (FK), Last Modified By User ID (FK)
Classification	Data asset classification information	ClassificationId
Critical Data Column	Store glossary terms associated to data asset column in this field	Critical Data Column Id, Business Domain Id, Asset Id
Critical Data Element	Critical data elements of the data assets	Critical Data Element Id
Custom Access Use Case	Access use case information	AccessPolicySetId
Data Asset	Data asset name, description, and source information	DataAssetId (UniqueId), DataAssetTypeId (FK), CreatedByUserId (FK), LastModifiedByUserId (FK)
Data Asset Column	Data asset column name, column description, and references	DataAssetId (FK), ColumnId (Unique), DataAssetTypeId (FK), DataTypeId (FK), Created By User Id (FK), Last Modified By User Id (FK)
Data Asset Column Classification Assignment	Data classification assignment related reference keys	DataAssetId (FK), ColumnId (FK), ClassificationId (FK)
Data Asset Column Critical Data Element Assignment	Data asset column associating with critical data element	ColumnId
Data Asset Domain Assignment	Data asset governance domain assignment related information	DataAssetId (FK), BusinessDomainId (FK), AssignedByUserId (FK)
Data Asset Owner	Data asset owner information	DataAssetOwnerId

Table name	What's stored in the table	Relationship keys
Data Asset Owner Assignment	Data asset owner assignment information	DataAssetId, DataAssetOwnerId
Data Asset Type Data Type	Data asset type information	DataTypeId (UniqueId), DataAssetTypeId (FK)
Data Product	Data product name, description, use cases, status, and other relevant information	DataProductId (UniqueId), DataProductTypeId (FK), DataProductStatusId (FK), UpdateFrequencyId (FK), CreatedByUserId (FK), LastUpdatedByUserId (FK)
Data Product Asset Assignment	Data product and data asset assignment information	DataProductId, DataAssetId
Data Product Business Domain Assignment	Data product and governance domain assignment information	DataProductId (FK), BusinessDomainId (FK), AssignedByUserId (FK)
Data Product Critical Data Element Assignment	Critical data element assignment to data product	DataProductId
Data Product Documentation	Data product documentation reference information is stored in this table.	DataProductId, DocumentationId
Data Product OKR Assignment	Assigned objectives and key results to data product	Data Product Id, Objective Id, Key Result Id
Data Product Owner	Data product owner information	DataProductId, DataProductOwnerId
Data Product Status	Data product status (like published or draft) related information	DataProductStatusId
Data Product Terms Of Use	Data product usage terms information	DataProductId, TermOfUsedId, DataAssetId
Data Product Type	The information about data product types, such as master, reference, or operational	DataProductTypeId
Data Product Update Frequency	The information about how often this data product's data are updated	UpdateFrequencyId

Table name	What's stored in the table	Relationship keys
Data Quality Asset Rule Execution	Data quality scanning results, including custom rule column list and rule column IDs.	RuleId (FK), DataAssetId (FK), JobExecutionId (FK), RuleColumnList, RuleColumnIdList
Data Quality Job Execution	Data quality job execution status	JobExecutionId (UniqueId)
Data Quality Rule	Information about data quality rules	RuleId (UniqueId), RuleTypeId (FK), BusinessDomainId (FK), DataProductId (FK), DataAssetId (FK), JobTypeDisplayName (FK), RuleOriginDisplayName (FK), RuleTargetObjectType (FK), CreatedByUserId (FK), LastUpdatedByUserId (FK)
Data Quality Rule Column Execution	Information about data quality rules pass and fail count, data quality score at the column level, and data quality job execution details. Only out-of-the-box rule data are available. For custom rule column list and column ID list, see the Data Quality Asset Rule Execution table.	RuleId (FK), DataAssetId (FK), ColumnId (FK), JobExecutionId (FK)
Data Quality Rule Type	Data quality rule type and associated dimensions	RuleTypeId (UniqueId), DimensionDisplayName (FK)
Data Subscription Request	Information about data subscribers, policies applied, subscription request status, and other relevant information	SubscriberRequestId (UniqueId), SubscriberIdentityTypeDisplayName (FK), RequestorIdentityTypeDisplayName (FK), RequestorStatusDisplayName (FK)
Glossary Term	Information about glossary term, description, and overall status of the glossary term	GlossaryTermId (UniqueId), ParentGlossaryTermId (FK), CreatedByUserId (FK), LastModifiedByUserId (FK)
Glossary Term Business Domain Assignment	Information about glossary term governance domain assignment and statuses	GlossaryTermId (FK), BusinessDomainId (FK), AssignedByUserId (FK), GlossaryTermStatusId (FK), CreatedByUserId (FK), LastUpdatedByUserId (FK)
Glossary Term Critical Data Element Assignment	Associating glossary term with critical data element	GlossaryTermId
Glossary Term Data Product Assignment	Information about glossary term data product assignment	GlossaryTermId (FK), DataProductId (FK), AssignedByUserId (FK), GlossaryTermStatusId (FK), CreatedByUserId (FK), LastUpdatedByUserId (FK)

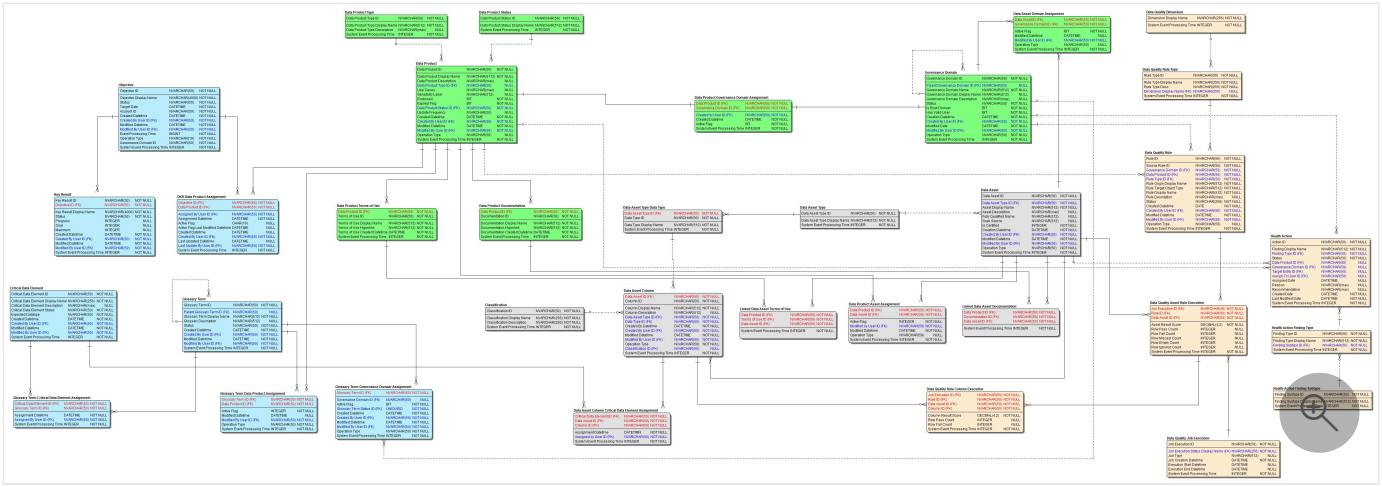

Table name	What's stored in the table	Relationship keys
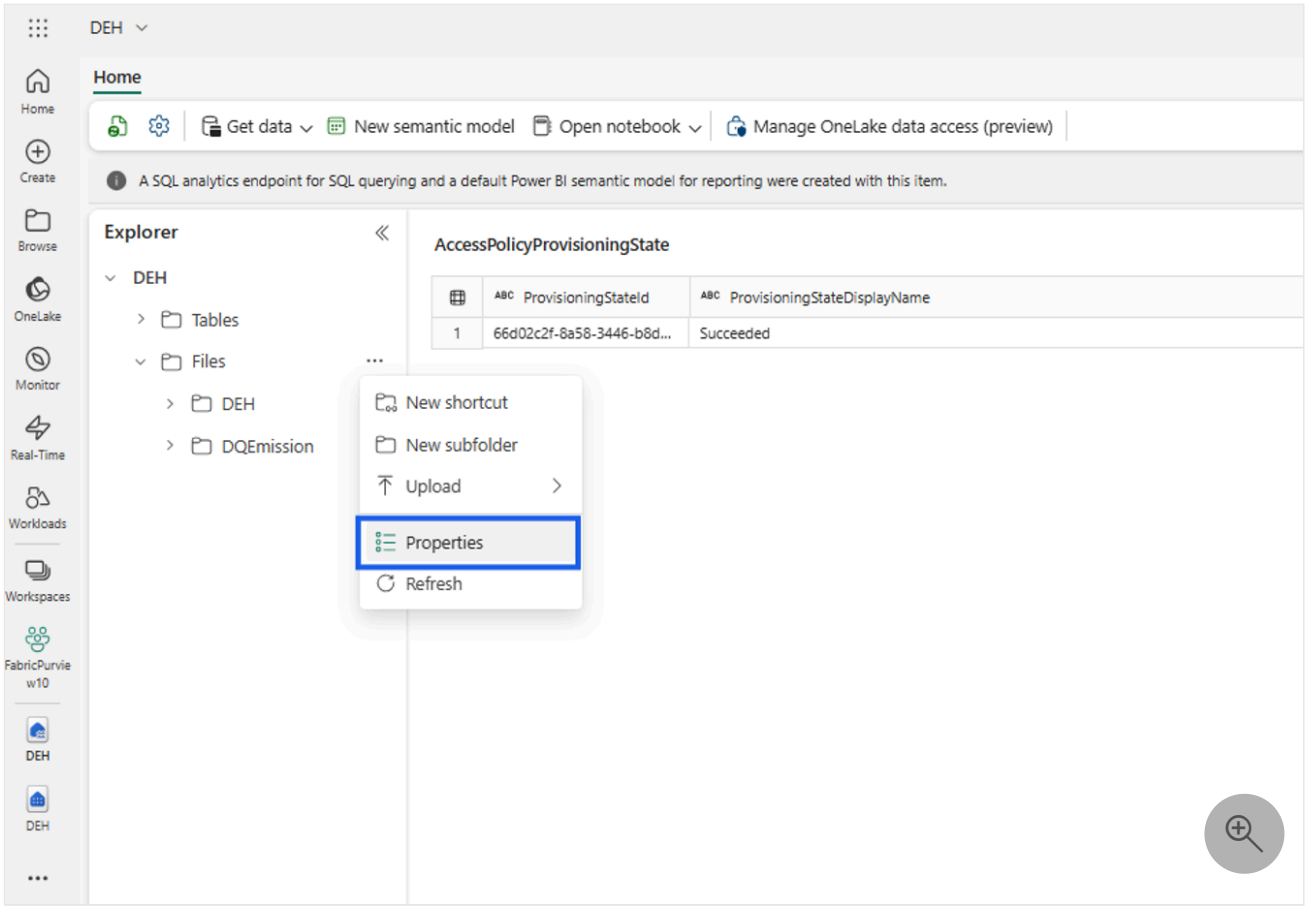
Health Action	Information about data governance and data quality actions	ActionId, TargetEntityId, CreatedByUserId
Health Action Finding Type	Data health actions **Finding Types**	FindingTypeId
Health Action Finding Sub Type	Data health actions **Finding Sub Types**	FindingSubTypeId, FindingTypeId
Health Action User Assignment	Data health actions **User Assignment** information	ActionId, AssignedToUserId
Key Result	Key result of data product objective, including details description	Key Result Id, Objective Id
Objective	Objective of the data product contains objective Id, objective description, and objective status	Objective Id
Policy Set Approver	Policy set and the approver information	SubscriberRequestId (FK), AccessPolicySetId (FK), ApproverUserId (FK)
Relationship	Information about source type and target information. The relationship of glossary terms association with assets and columns is available in this relationship table.	AccountId, SourceId, TargetId

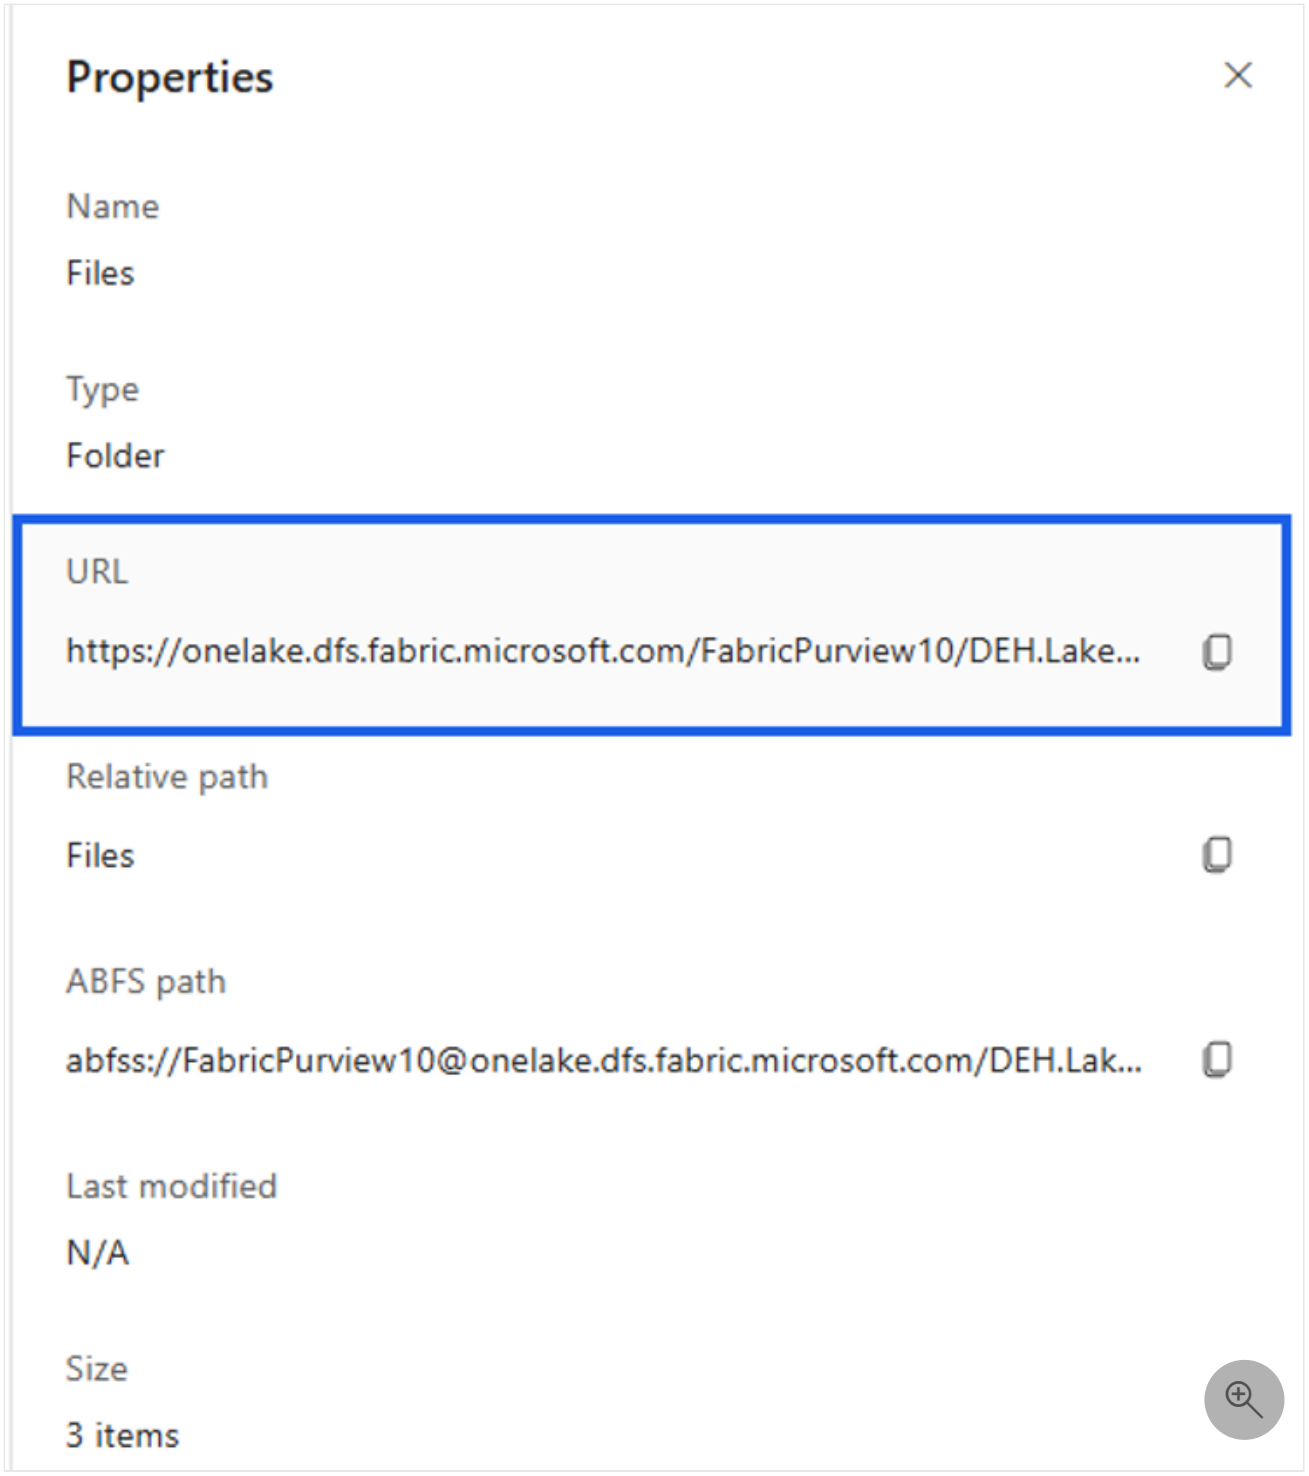
Note

- Business Domain is called **governance domain** in Unified Catalog, but it's still called **Business Domain** in the physical model in the database. The name difference doesn't affect the usage scenario described here for Business Domain.
- When you delete an asset from Data Map and later recreate it with the same name, the asset is treated as new and gets a new ID. As a result, the deleted asset is no longer valid for Data Quality rules column and column ID association. This scenario isn't currently supported. So, the `RuleColumnIdList` in the Data Quality Asset Rule Execution table stays blank for the deleted data asset in Data Map. You must run Data Quality

scans again on the newly created data asset, even if the asset name and schema are identical to the deleted one.



This diagram shows the entity relationship for the domain model described in the data model table:



Subscribe Unified Catalog metadata to Fabric OneLake

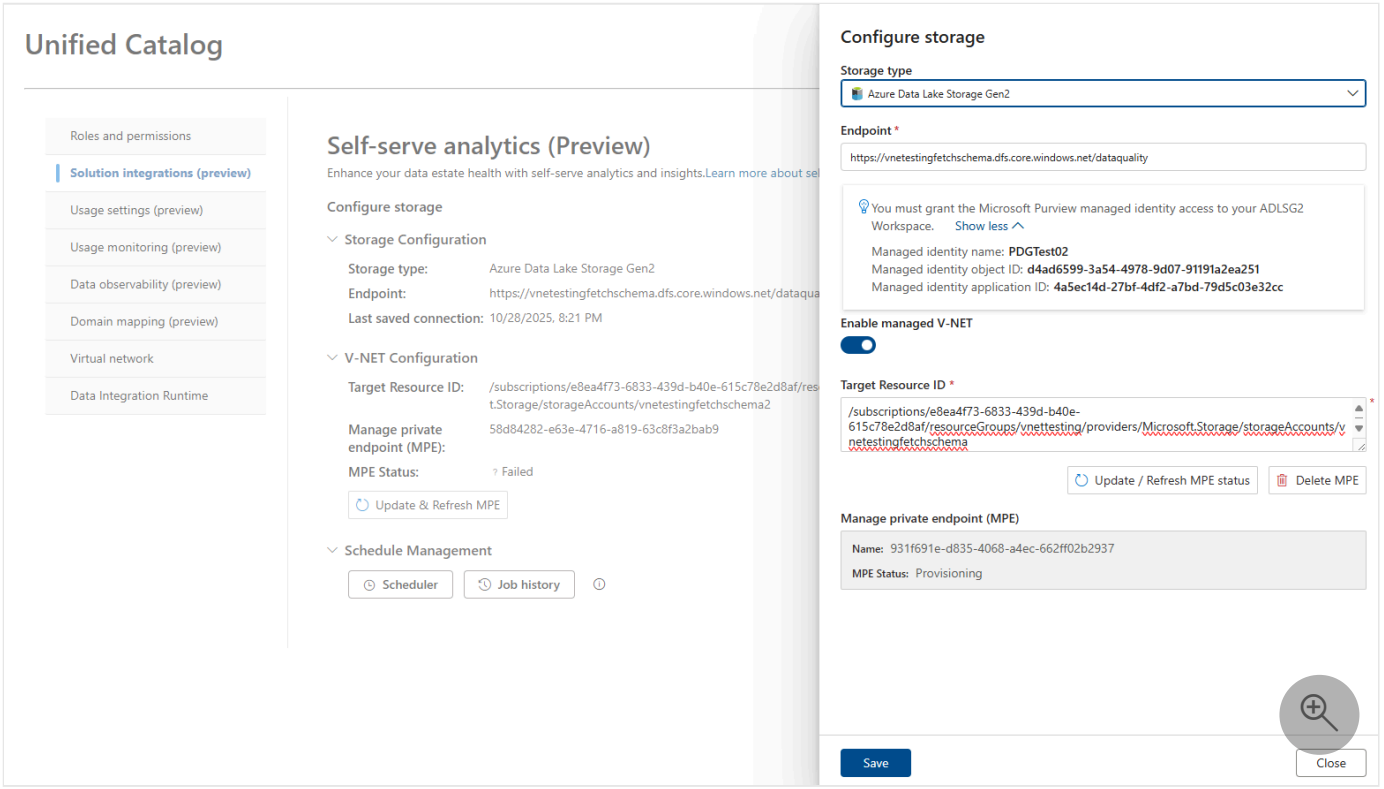
Subscribe to Purview data governance metadata for analytics and get insights by following these steps:

1. In the Purview portal, select **Settings**, then select **Unified Catalog**, then select **Solution integrations (preview)**.
2. Make sure that you have the Data Governance Administrator role (learn more about roles and permissions).
3. Select **Edit**.
4. Add **Storage type** and **Enable** the setup.
5. Add **Location URL** (example: `https://onelake.dfs.fabric.microsoft.com/workspace name/lakehouse name/Files/purviewmetadata`)
6. Select **Properties** to copy the URL.

7. Copy the URL from the **Properties** page.

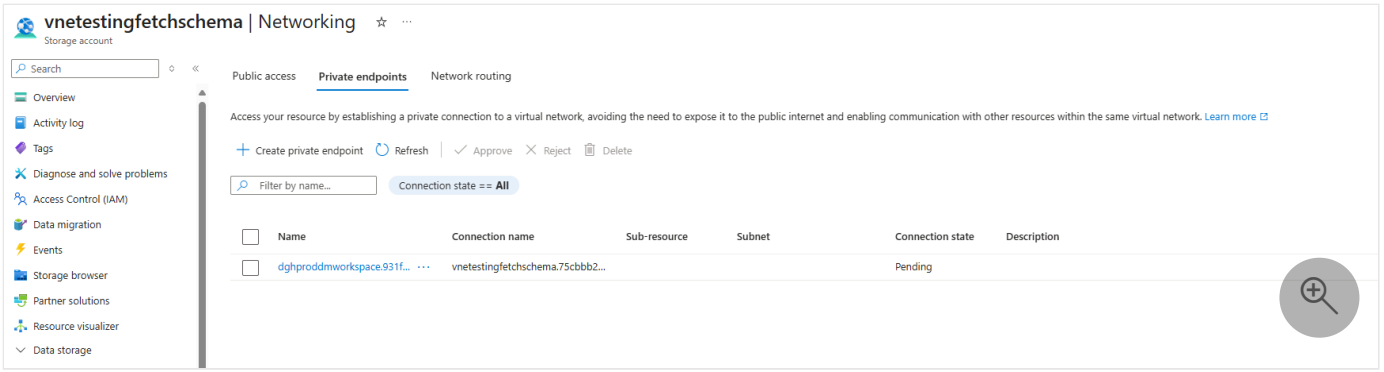
8. Add the folder name at the end of the URL. For example, add `/DEH` to the copied URL, as shown in the previous screenshot.

9. Grant contributor access to Purview Managed Service Identity (MSI) for your Fabric workspace.



10. Test the connection.

11. Select **Save** to save the configuration and publish Purview metadata to your OneLake workspace.



Enable managed V-NET

To enable or disable managed virtual network, follow these steps:

1. In the Purview portal, select **Settings**.
2. Under **Solution settings**, select Unified Catalog, and then select **Solution integrations (preview)**.
3. On **Configure storage**, select the **Enable managed V-NET** toggle to enable managed virtual network for your storage.

1. Enter the **Target Resource ID**. For example, the target resource ID is: `/subscriptions/e2223ea4f73-6833-439d-b40e615c78e2d8af/resourceGroups/vnettesting/providers/`. To copy a resource ID of your storage, select the JSON View of your storage and copy the JSON string.
2. Select **Update/Refresh MPE status** to see the update. The status changes from **Provisioning** to **Pending**.
3. You need to approve the MPE request in the Azure portal to complete the setup. After you approve the request, the MPE status changes from **Pending** to **Approved**.

To disable the virtual network setup, select the **Enable managed V-NET** toggle to turn it off. If you disable it, you need to change non-virtual network storage endpoint.

Remove a configured virtual network

To remove a managed virtual network setup, select **Delete MPE** on **Configure storage**. This action deletes the virtual network configuration and removes it from the **Configure storage** pane. The **Test connection** area reappears, which you can use to test a non-virtual network connection. **Test connection** is only enabled for non-virtual storage setup.

> **Note**
>
> Publishing Unified Catalog metadata to a Fabric workspace isn't supported in Fabric tenants with Managed Private Endpoints enabled. Use a Fabric tenant without Managed Private Endpoints to publish Unified Catalog metadata.

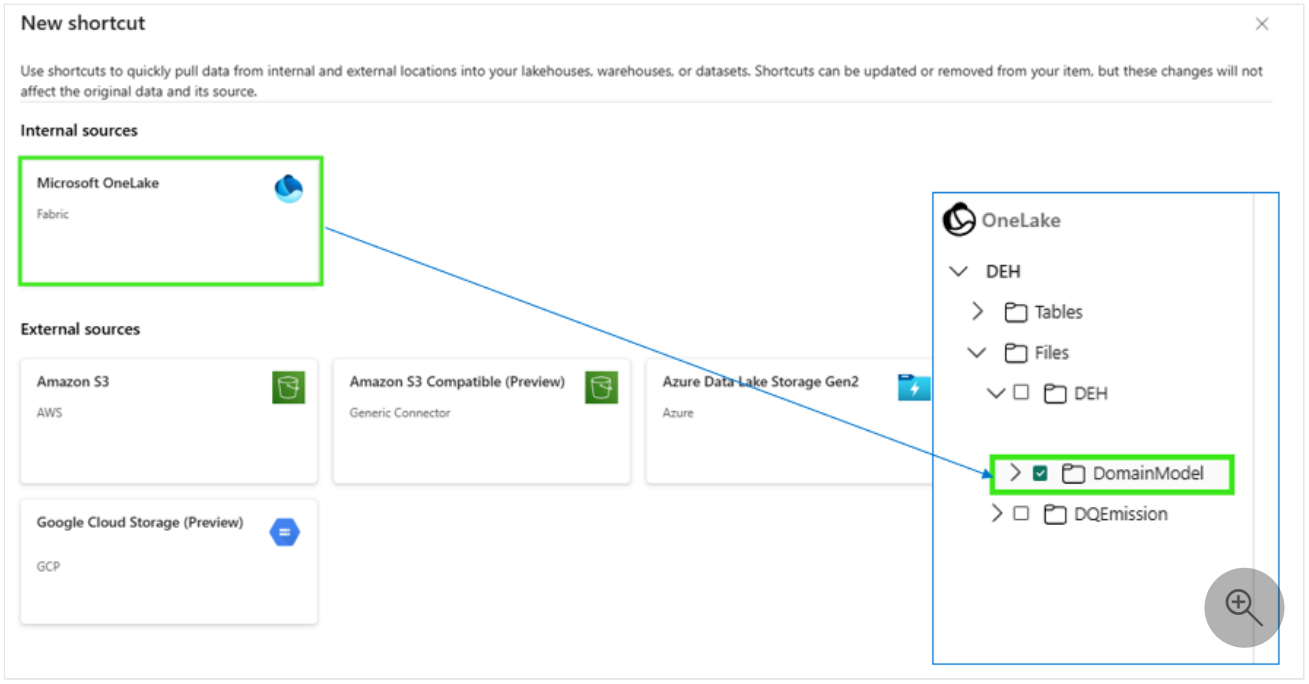
Helpful information about virtual network setup

- Use the Location URL or Endpoint from virtual network storage when you enable managed virtual network to store Purview metadata.
- Use JSON View to copy **Target Resource ID** from your Azure portal to avoid using an incorrect resource group.
- If you deleted the configured virtual network, then make sure that you change the endpoint or Location URL to use non-virtual-network storage and test the connection for non-virtual-network storage.

> **Note**
>
> To store data quality error records, create separate folder locations for each domain. This approach organizes and stores domain-specific data quality error records in dedicated

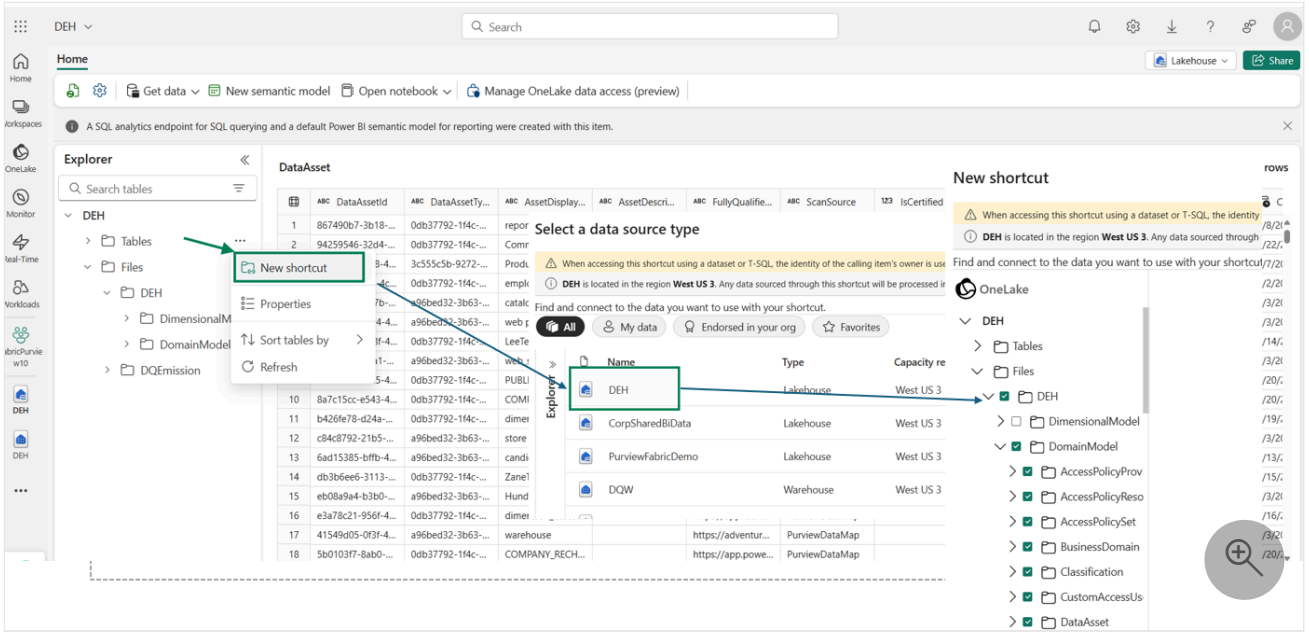
folders. You must configure data quality error records storage separately. To create data quality error record storage, go to **Data Quality** > **Manage** > **Settings**, select an Azure region, and set up the storage connection. You can't use self-serve storage connection setup for data quality error records storage even if you use identical or same storage location.

Create a semantic model in OneLake



In the context of data and analytics, a semantic model is a structured representation of data that defines the meaning, relationships, and rules within a specific domain. It provides a layer of abstraction that helps users understand and interact with complex data by making it more intuitive and accessible, especially in the context of business intelligence (Power BI) and analytics platforms.

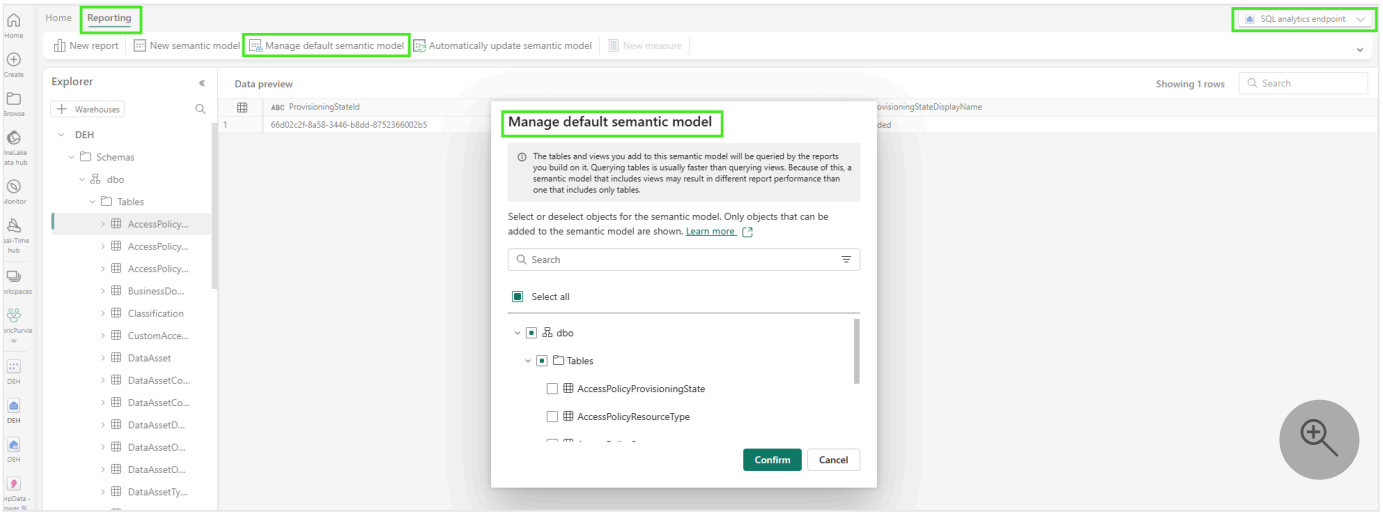
You always need a semantic model before you can build any reports. Within the warehouse, you can add warehouse objects - tables or views - to your default Power BI semantic model. You can also add other semantic modeling properties, such as hierarchies and descriptions. Use these properties to create the Power BI semantic model's tables. You can also remove objects from the default Power BI semantic model.



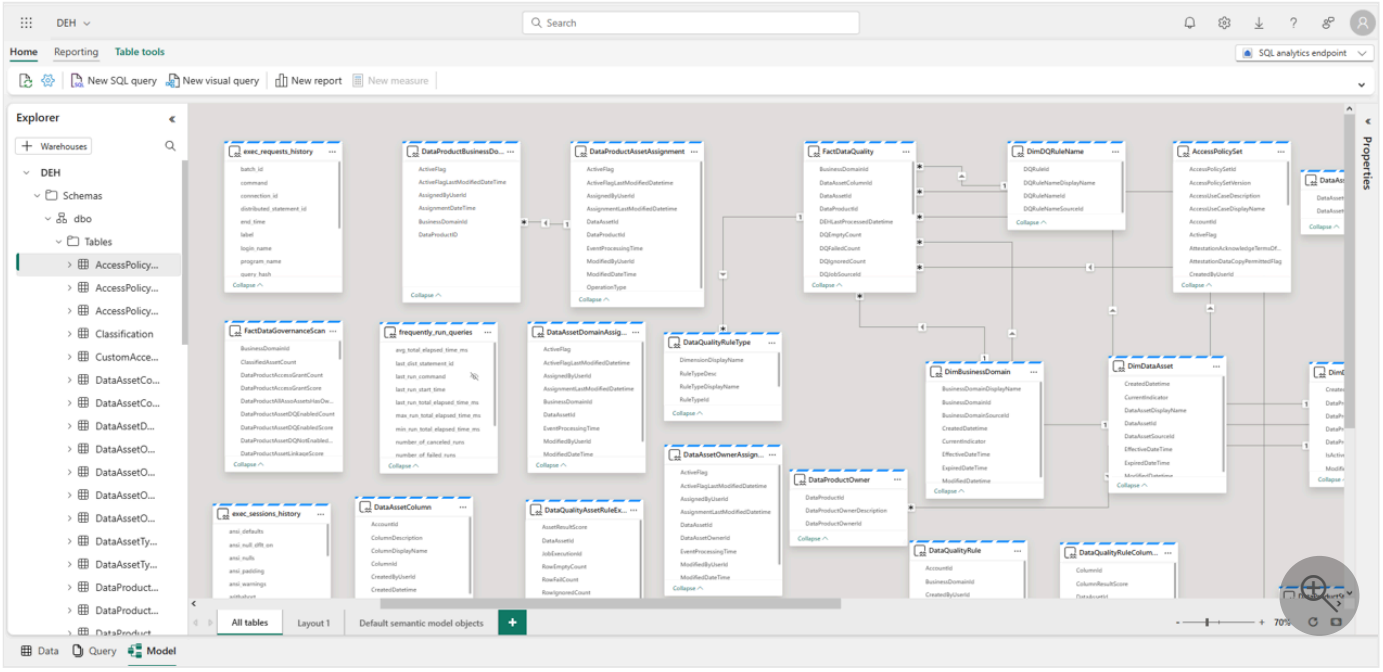
To create a semantic model from the Data Governance metadata domain model:

1. Open the Lakehouse in your Fabric workspace.

2. Use a **shortcut** to create a shortcut of the domain model from OneLake and within OneLake.
   a. Select the **Tables** ellipsis button (...).
   b. Select **New Shortcut** and select OneLake from New Shortcut sources page.
   c. Select the **DomainModel** table to shortcut.



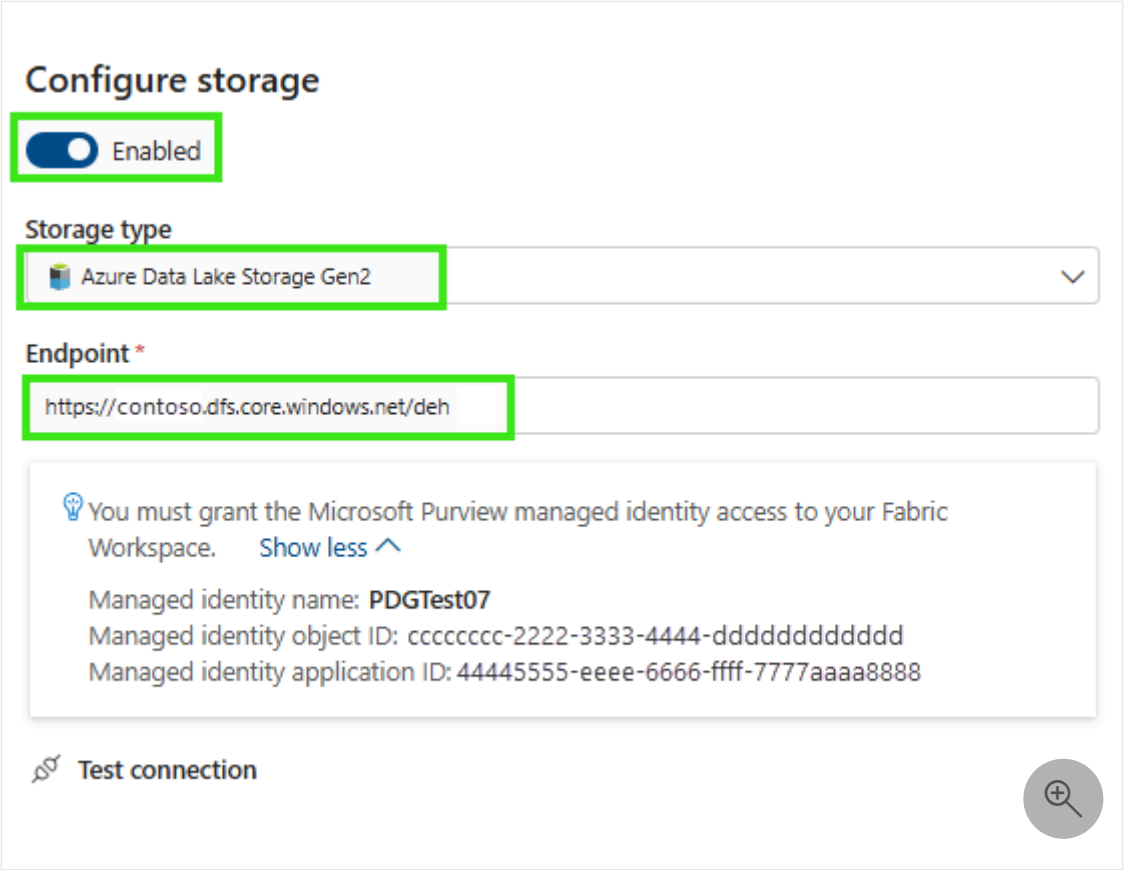
3. Create a shortcut directly at the table level for all files, which eliminates duplicate records.



After you publish all files to delta tables via shortcut, you can add the delta tables to semantic model.

1. Switch to SQL analytics endpoint page from the Lakehouse page.
2. Select **Reporting** from top left corner of the **SQL analytics endpoint** page.
3. Select **Manage default semantic model**.
4. Select the tables from dbo > Tables that you want to add to the semantic model for reporting.

To add objects such as tables or views to the default Power BI semantic model, select **Automatically update semantic model**.

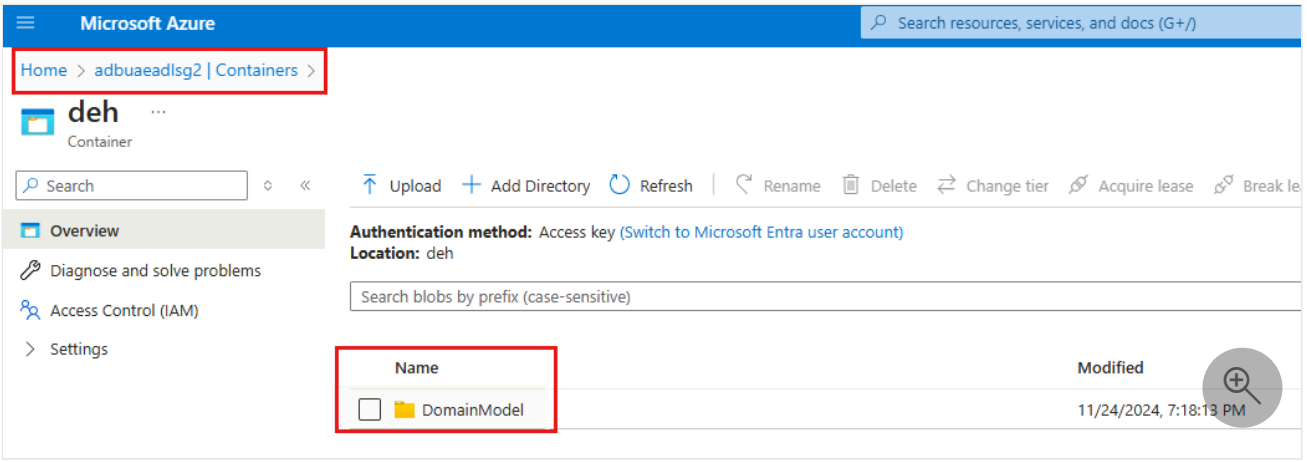


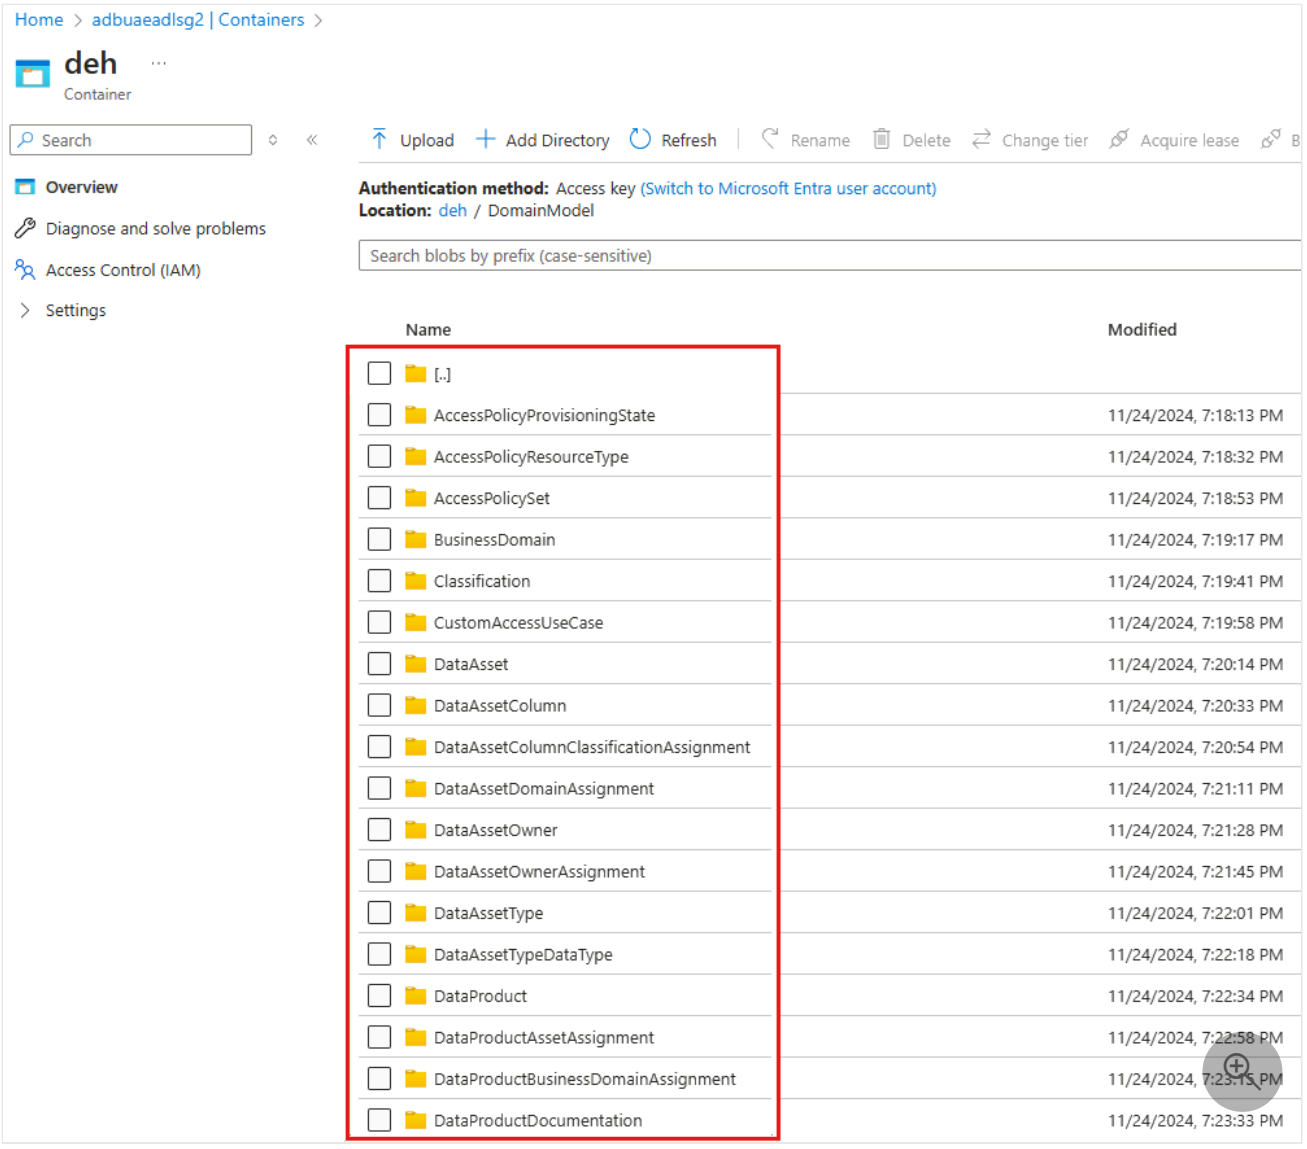
> **Note**
>
> - You can right-click to add related tables to create a relationship.
> - If you prefer not to subscribe Purview metadata for self-serve analytics, you can manually disable self-serve analytics (metadata subscription): go to Solution settings > Unified Catalog > Solution Integrations > Self-serve analytics and select the toggle to disable it. You need the Data Governance Administrator role to enable and disable this feature.

Subscribe to Purview catalog metadata to Data Lake Storage Gen2 storage

To subscribe to Purview's data governance metadata and publish it to your Data Lake Storage Gen2 storage for analytics and insights, follow these steps:

1. In the Purview portal, open **Unified Catalog**.
2. Select **Settings** in the left navigation. Under **Solution settings**, select **Unified Catalog**.
3. Select **Solution integration**, and then select **Edit**.
4. Select **Storage type** and **Enable** the setup.
5. Add **Location URL**. This URL needs to be the Data Lake Storage Gen2 path plus the container name, formatted as Data Lake Storage Gen2 endpoint + "/(container name)".
    a. Go to portal.azure.com.
        i. Select your Data Lake Storage Gen2 storage.
    b. Go to **Settings** > **Endpoints** and select the primary endpoint of your Data Lake Storage Gen2 storage.
6. Grant **Storage Blob Data Contributor** access to Purview Managed Service Identity (MSI) for your Data Lake Storage Gen2 container.
7. Test the connection.





8. Select **Save** to save the configuration and publish the domain model to your Data Lake Storage Gen2 storage.

> **Note**
>
> To store data quality error records, create separate folder locations for each domain. This approach organizes and stores domain-specific data quality error records in dedicated folders.

Review published model and data

1. Open portal.azure.com.
2. Select your Data Lake Storage Gen2 storage.
3. Select the container that you added with the Data Lake Storage Gen2 endpoint in Purview.
4. Browse the list of Delta Parquet files published in the container.
5. Browse published model and metadata (see the following images).

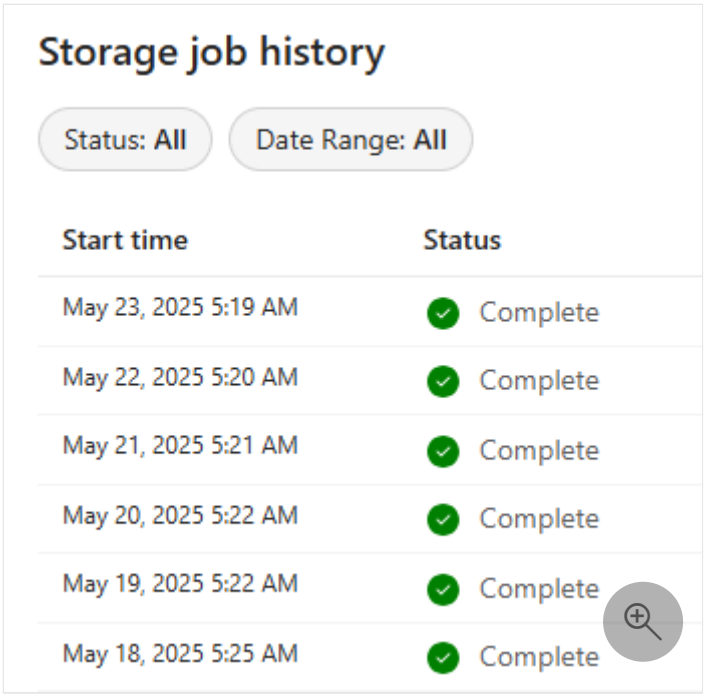
Create a Power BI report

Power BI is natively integrated in the whole Fabric experience. This native integration includes a unique mode, called DirectLake, for accessing the data from the lakehouse to provide the most performant query and reporting experience. DirectLake is a groundbreaking new capability that allows you to analyze large semantic models in Power BI.

With DirectLake, you load parquet-formatted files directly from a data lake without needing to query a data warehouse or lakehouse endpoint, and without needing to import or duplicate data into a Power BI semantic model. DirectLake is a fast path to load the data from the data lake straight into the Power BI engine, ready for analysis.

In traditional DirectQuery mode, the Power BI engine directly queries the data from the source for each query execution, and the query performance depends on the data retrieval speed. DirectQuery eliminates the need to copy data, ensuring that any changes in the source are immediately reflected in query results.

For more information, see how to create a Power BI report in Microsoft Fabric.



Set up the schedule

Data Governance Administrators can set up the self-serve analytics metadata refreshing schedule by following these steps:

1. In the Purview portal, open **Unified Catalog**.
2. Select **Settings** in the left navigation. Under **Solution settings**, select **Unified Catalog**.
3. Select **Solution integration**, then select the scheduler icon.
4. On **Schedule self-serve analytics**, turn on the **Enabled** toggle, and set the start date, frequency, and end date.
5. Select **Save**.

Job history

You can browse **Job history** by selecting the **Job history** icon on the self-serve analytics page. You can filter job status by Complete or Failed for a date range.

ⓘ Important

- Purview MSI needs contributor access to your Fabric workspace if you're subscribing Purview metadata to publish into your Fabric workspace.
- Purview MSI needs **Storage Blob Data Contributor** access to your Data Lake Storage Gen2 if you're subscribing Purview metadata to publish into your Data Lake Storage Gen2 container.
- Standalone data assets with a Data Quality score aren't published for self-serve analytics. If you associate a standalone data asset with a data product and run Data Quality for it, Purview publishes the associated data asset's metadata for self-serve analytics.
- If a user deletes the Data Quality history for a data asset, the deleted history continues to exist in the self-serve analytics storage (Fabric and Data Lake Storage Gen2). Purview doesn't publish a delete indicator or deletion flag to self-serve analytics storage, making it impossible to distinguish deleted Data Quality scan history from active history records. As a result, consumers of the self-serve analytics data might continue to see historical Data Quality records even after they're deleted from the product experience.
- Purview only publishes governed assets data. Data assets associated with a data product are categorized as governed assets. Data Map assets that aren't governed won't appear in the self-serve analytics data asset table.
- The Catalog implements role-based access control (RBAC), ensuring that not all users can view all domains or data products. However, for self-serve analytics, Purview

publishes all data, allowing anyone with access to this data to view the entire catalog. Access control for self-serve metadata depends on where the data is stored - either the Fabric workspace owner or the Data Lake Storage Gen2 storage owner can manage access.

- If you prefer not to subscribe Purview metadata for self-serve analytics, you can manually disable self-serve analytics (metadata subscription): go to Solution settings > Unified Catalog > Solution Integrations > Self-serve analytics and select the toggle to disable it. You need the Data Governance Administrator role to enable and disable this feature.

Disaster recovery for Unified Catalog (manual)

This article provides guidance on backup and recovery strategy when using Microsoft Purview Unified Catalog in production deployment. The scope of this article is to cover manual business continuity and disaster recovery (BCDR) methods that you can set up using APIs.

Features covered

The following areas are covered in this BCDR strategy:

- Unified Catalog foundation: Governance Domains, Glossary Terms, and Data Assets — the foundational catalog that organizes and describes an organization's data estate.
- Data products: Curated, business-ready data sets with ownership, documentation, terms of use, and audience metadata.
- Critical data elements: Regulated or high-value data elements (for example, personal data, financial identifiers) with lifecycle management (Draft → Published → Expired).
- Data quality: Quality rules and asset metadata that track data health and conformance across the estate.
- Data access: Access request workflows, multi-stage approval chains, policy sets, and permitted use-case definitions for governed data sharing.
- Data estate health: CDMC control templates and analytics schedules that continuously measure governance maturity and compliance posture.
- Workflows: Configurable multi-stage approval workflows including manager, privacy, and approver stages for data access governance.

BCDR workflow

Step 1. Create an Enterprise tier account

Create a Purview Data Governance account at the **Enterprise** tier. This serves as the **primary account** with full governance capabilities.

Step 2. Request Classic Purview provisioning in a secondary region

Create a **support ticket** through the Customer Support channel requesting enablement of Classic Purview account provisioning in a **secondary (paired) region** for BCDR purposes.

Step 3. Create a Classic Purview account

After Classic provisioning is enabled in the secondary region, create a **Classic Purview account**. This account serves as the **secondary (backup) account** with limited capabilities.

Step 4. Copy data from the Enterprise account to the Classic account

Using the available BCDR APIs (described in the API details section), copy governance data from the **Enterprise account (primary)** to the **Classic account (secondary)**. This includes:

- Governance domains
- Data products
- Glossary terms
- Critical data elements
- Data assets
- Data Quality metadata
- Data estate health configuration
- Data access workflows and policies

Step 5. Manage GUIDs during backup

You're responsible for **managing and mapping globally unique identifiers (GUIDs)** during the backup process. Because the secondary account generates new identifiers, you must maintain a mapping between primary and secondary GUIDs to ensure data consistency and traceability.

Step 6. Validate the secondary account

Use the **GET APIs** for each feature area to validate that all governance data is replicated to the secondary account:

- `GET /catalog/businessdomains`
- `GET /catalog/dataProducts`
- `GET /catalog/terms`
- `GET /catalog/criticalDataElements`
- `GET /catalog/dataAssets`
- `GET /quality/bulk-asset-metadata`

- `GET /health/analytics/schedule`
- `GET /dataaccess/workflows`

Step 7. Fail over during a disaster recovery (DR) event

When a disaster recovery event occurs, create a **support ticket** requesting:

1. **Promote** the Secondary (Classic) account to **Enterprise** tier
2. **Demote** the Primary (Enterprise) account to **Secondary**

This completes the failover, and the previously secondary account becomes the new primary with full Enterprise capabilities.

API details

1. Account and provisioning

Get current policies

Verify the BCDR account is operational by listing the current user's policies.

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/catalog/policies
```

> ⓘ Note
>
> Account provisioning is performed with **Is BCDR = true**. Acquire tokens by using standard Microsoft Entra ID/OAuth flows for Purview REST APIs.

---

2. Governance domains

Create governance domain

Create a governance domain:

HTTP

```
POST https://<accountName>.purview.azure.com/datagovernance/catalog/businessdomains
```

Request body:

JSON

```
{
  "name": "BCDR - My Business Domain",
  "type": "DataDomain",
  "status": "Draft",
  "description": "Optional description up to 200k chars",
  "isStagingDomain": false,
  "managedAttributes": []
}
```

Response body:

JSON

```
{
  "status": "Draft",
  "type": "DataDomain",
  "name": "BCDR - My Business Domain",
  "description": "Optional description up to 200k chars",
  "isRestricted": false,
  "isStagingDomain": false
}
```

Get governance domains

List the governance domains to confirm replication:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/catalog/businessdomains
```

---

3. Data products

Create data product

Create a data product under a governance domain:

HTTP

```
POST https://<accountName>.purview.azure.com/datagovernance/catalog/dataProducts
```

Request body:

JSON

```
{
  "name": "BCDR - Sales Analytics",
  "domain": "<businessDomainId>",
  "status": "Draft",
  "type": "Analytical",
  "endorsed": false,
  "contacts": {
    "owner": [
      {
        "id": "<guidObjectId>",
        "info": "<email>"
      }
    ]
  },
  "description": "Aggregated sales data across regions",
  "businessUse": "Used for quarterly reporting",
  "audience": [
    "DataAnalyst",
    "BusinessUser"
  ],
  "updateFrequency": "Monthly",
  "termsOfUse": [
    {
      "name": "Data Policy",
      "url": "https://contoso.com/policy"
    }
  ],
  "documentation": [
    {
      "name": "User Guide",
      "url": "https://contoso.com/guide"
    }
  ]
}
```

Response body:

JSON

```
{
  "status": "Draft",
  "type": "Analytical",
  "name": "BCDR - Sales Analytics",
  "description": "Aggregated sales data across regions",
  "businessUse": "Used for quarterly reporting",
```

```
  "updateFrequency": "Monthly",
  "endorsed": false
}
```

Get data products

List the data products:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/catalog/dataProducts
```

---

4. Glossary terms

Create term

Create a glossary term under a governance domain:

HTTP

```
POST https://<accountName>.purview.azure.com/datagovernance/catalog/terms
```

Request body:

JSON

```
{
  "name": "BCDR - Customer Revenue",
  "domain": "<businessDomainId>",
  "status": "Draft",
  "description": "Total revenue attributed to a customer",
  "acronyms": [
    "CR",
    "CustRev"
  ],
  "contacts": {
    "owner": [
      {
        "id": "<guidObjectId>",
        "info": "<email>"
      }
    ],
    "expert": [
      {
        "id": "<guidObjectId>",
        "info": "<email>"
      }
```

```
    ]
  },
  "resources": [
    {
      "name": "Wiki",
      "url": "https://contoso.com/wiki/customer-revenue"
    }
  ]
}
```

Response body:

JSON

```
{
  "status": "Draft",
  "name": "BCDR - Customer Revenue",
  "description": "Total revenue attributed to a customer",
  "contacts": {
    "owner": [],
    "expert": []
  },
  "isMigrated": false
}
```

> **Note**
>
> The API response may return empty `contacts` arrays even when contacts are provided in the request. Contacts are linked asynchronously and will appear on subsequent GET calls.

Get terms

List the glossary terms:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/catalog/terms
```

---

5. Critical data elements (CDE)

Create critical data element

Create a critical data element under a governance domain:

HTTP

```
POST
https://<accountName>.purview.azure.com/datagovernance/catalog/criticalDataElements
```

Request body:

JSON

```
{
  "name": "BCDR - Customer SSN",
  "domain": "<businessDomainId>",
  "status": "Draft",
  "dataType": "DateTime",
  "description": "Social Security Number – regulated PII element",
  "contacts": {
    "owner": [
      {
        "id": "<guidObjectId>",
        "info": "<email>"
      }
    ],
    "expert": [
      {
        "id": "<guidObjectId>",
        "info": "<email>"
      }
    ]
  }
}
```

Response body:

JSON

```
{
  "status": "Draft",
  "dataType": "DateTime",
  "name": "BCDR - Customer SSN",
  "description": "Social Security Number - regulated PII element"
}
```

> **CDE Data Types:** Boolean, DateTime, Number, Text **CDE Status Lifecycle:** Draft → Published → Expired

Get critical data elements

List the critical data elements:

HTTP

```
GET
https://<accountName>.purview.azure.com/datagovernance/catalog/criticalDataElements
```

---

6. Data assets

Create data asset

Create a data asset that references a source:

HTTP

```
POST https://<accountName>.purview.azure.com/datagovernance/catalog/dataAssets
```

Request body:

JSON

```
{
  "name": "gold",
  "type": "ADLSGen2Path",
  "source": {
    "type": "PurviewDataMap",
    "accountName": "BCDRSecondary",
    "assetId": "<assetGuid>",
    "assetType": "azure_datalake_gen2_filesystem",
    "fqn": "https://<storageAccount>.dfs.core.windows.net/gold"
  },
  "typeProperties": {
    "serverEndpoint": "<storageAccount>.dfs.core.windows.net",
    "container": "gold"
  },
  "contacts": {
    "owner": [
      {
        "id": "<guidObjectId>",
        "info": "<email>"
      }
    ]
  }
}
```

Response body:

JSON

```
{
  "name": "gold",
  "status": "ACTIVE",
  "displayText": "gold",
  "source": {
    "type": "PurviewDataMap",
    "assetId": "<assetGuid>"
  }
}
```

Get data assets

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/catalog/dataAssets
```

---

7. Data estate health

CDMC control template

CDMC (Cloud Data Management Capabilities) control templates are **auto-created** when the BCDR account is provisioned. A global analytics schedule is enabled by default (daily frequency).

Create or update analytics schedule

Create or update the schedule that controls how often data estate health is measured:

HTTP

```
PUT https://<accountName>.purview.azure.com/datagovernance/health/analytics/schedule?api-version=2024-02-01-preview
```

Request body:

JSON

```
{
  "frequency": "Hour",
  "interval": 6,
  "startTime": "2026-03-18T00:00:00Z",
  "status": "Enabled",
  "timeZone": "UTC"
}
```

Response body:

JSON

```
{
  "frequency": "Hour",
  "interval": 6,
  "status": "Enabled",
  "timeZone": "UTC"
}
```

Get analytics schedule

Retrieve the current analytics schedule:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/health/analytics/schedule?api-version=2024-02-01-preview
```

---

8. Data access

Get default access request template

Retrieve the default data access request template:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/dataaccess/workflows/templates/dataAccessRequestTemplate
```

Create data access workflow

Create or update a data access workflow:

HTTP

```
PUT https://<accountName>.purview.azure.com/datagovernance/dataaccess/workflows/{workflowId}
```

The workflow request body is a **large JSON directed acyclic graph (DAG)** that defines multi-stage approvals including:

- `DataSubscriptionWebhook`: subscription trigger
- `DataAccessRequestSubmitted`: entry trigger
- **Manager approval** stage
- **Privacy / compliance approval** stage
- **Approver chain** stages
- **Approve / Reject** terminal actions

Apply policy sets to data product

Apply policy sets to a data product to govern access:

HTTP

```
PUT
https://<accountName>.purview.azure.com/datagovernance/dataaccess/dataProducts/{dataProductId}/policySets/applied?api-version=2023-10-01-preview
```

Request body:

JSON

```
{
  "policies": {
    "approvers": [
      {
        "identityType": "User",
        "objectId": "<userObjectId>",
        "tenantId": "<tenantId>"
      }
    ],
    "permittedUseCases": [
      {
        "title": "Assessing Fit",
        "description": "Use to determine if data is useful"
      },
      {
        "title": "Critical Reporting",
        "description": "Use to create high quality reports"
      },
      {
        "title": "Directional Insights",
        "description": "Use to gather directional insights"
      }
    ],
    "managerApprovalRequired": false,
```

```
    "privacyComplianceApprovalRequired": false,
    "dataCopyPermitted": false,
    "attestations": [],
    "skipWorkflow": false,
    "maximumAccessDuration": {
      "durationType": "Years",
      "length": 1
    }
  }
}
```

List workflows

List the data access workflows:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/dataaccess/workflows
```

Get approvals

Retrieve pending data access approvals:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/dataaccess/approvals?
approvalStatus=Pending&api-version=2023-10-01-preview
```

Get workflow runs

Retrieve the data access workflow runs:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/dataaccess/workflowRuns?
ignoreActionStatuses=true&api-version=2023-10-01-preview
```

---

9. Data Quality

Create bulk asset metadata

Create bulk asset metadata for data quality:

```
```

HTTP

```
PUT https://<accountName>.purview.azure.com/datagovernance/quality/bulk-asset-metadata
```

> **Note**
>
> The request body references an external JSON file (`BCDR-DQ-Create Metadata.json`). Contact your support representative for the complete payload.

Get bulk asset metadata

Retrieve the bulk asset metadata:

HTTP

```
GET https://<accountName>.purview.azure.com/datagovernance/quality/bulk-asset-metadata
```

Application card: Microsoft Purview Unified Catalog

What is an Application or Platform Card?

Microsoft's Application and Platform cards are intended to help you understand how our AI technology works, the choices application owners can make that influence application performance and behavior, and the importance of considering the whole application, including the technology, the people, and the environment. Application cards are created for AI applications and platform cards are created for AI platform services. These resources can support the development or deployment of your own applications and can be shared with users or stakeholders impacted by them.

As part of its commitment to responsible AI, Microsoft adheres to six core principles: fairness, reliability and safety, privacy and security, inclusiveness, transparency, and accountability. These principles are embedded in the Responsible AI Standard, which guides teams in designing, building, and testing AI applications. Application and Platform Cards play a key role in operationalizing these principles by offering transparency around capabilities, intended uses, and limitations. For further insight, readers are encouraged to explore Microsoft's Responsible AI Transparency Report and Code of Conduct, which outline how enterprise customers and individuals can engage with AI responsibly.

Overview

Microsoft Purview Unified Catalog is a data governance solution that enables business experts and technical data owners to collaborate and contribute to a shared understanding of data. Unified Catalog enables inventory of metadata and provides a framework for the governance of metadata and the use of the underlying data. Unified Catalog helps organizations create value from data, manage access to data, improve data quality, and monitor data health. Unified Catalog is intended for enterprise customers and their downstream users, including business users, analysts, data scientists, stewards, and governance leaders. Learn about Unified Catalog capabilities and implementation guidance.

AI capabilities are embedded in selected capabilities to improve discovery and curation efficiency. These capabilities include natural language data product search (preview), suggested data asset mapping (preview), and suggested data quality rules (preview).

Key terms

The following list provides a glossary of key terms related to Unified Catalog:

- **Data asset**: A technical data resource indexed in the catalog, such as a table, file, or report. Data assets are the building blocks that can be grouped and governed through higher-level business concepts.
- **Data product**: A curated grouping of related data assets with a defined business use case, ownership, and governance context. Data products are designed to improve discoverability, reuse, and controlled access.
- **Data quality rule**: A configurable rule that evaluates data quality dimensions such as completeness, consistency, conformity, accuracy, freshness, and uniqueness. Rules can be out-of-box, custom, or AI-suggested in supported preview workflows.
- **Governance domain**: A business-aligned boundary used to organize data and governance responsibilities. Domains help scale stewardship and simplify discovery by aligning data with business context.
- **Metadata**: Descriptive information about data, including technical properties, business definitions, lineage, classifications, and usage context. Unified Catalog uses metadata to power search, governance workflows, and health insights.
- **Natural language search (preview)**: An AI-enabled search mode that allows users to describe the data they need in plain language. The feature returns ranked data product results based on metadata and business context.

Key features or capabilities

The key features and capabilities outlined here describe what Unified Catalog is designed to do and how it performs across supported tasks.

- **Business-aligned data organization**: Unified Catalog organizes information through governance domains, data products, glossary terms, and related concepts. This structure helps users understand data in business context rather than only by technical source or schema. It also supports distributed stewardship so teams can manage data where domain expertise exists.
- **Natural language data product discovery (preview)**: Users can search for data products by describing intent in plain language, rather than relying only on exact keywords. The feature currently supports data products in English, French, and Spanish, with corresponding search terms. This improves data discovery for semi-technical users who may not know internal naming conventions.

- **AI-assisted data product curation (preview)**: During data product creation, Unified Catalog can suggest relevant data assets based on metadata such as names, descriptions, and use cases. Suggestions are prioritized so owners can review the most relevant candidates first. The experience accelerates curation while keeping final selection under human control.
- **AI-assisted data quality rule generation (preview)**: Data quality stewards can use AI-generated rule suggestions as a starting point for rule authoring. Suggested rules are informed by profiling metadata and are meant to be reviewed and tested before use. This reduces setup time for quality programs while preserving expert oversight.
- **Integrated access governance workflows**: Data product access policies support configurable approvals and attestations. Policy inheritance from governance domains, glossary terms, and critical data elements helps maintain consistent control at scale. This balances data accessibility with compliance and right-use expectations.
- **Data health and monitoring capabilities**: Unified Catalog provides health management actions, data quality scoring, and reporting to track governance progress. Teams can monitor quality, identify gaps, and prioritize remediation. These controls support continuous improvement instead of one-time governance exercises.

Intended uses

Unified Catalog can be used in multiple scenarios across a variety of industries. Some examples of use cases include:

- **Enterprise analytics readiness in financial services**: A bank can create curated data products for risk, finance, and customer analytics teams so analysts can find trusted data faster. Governance domains and access policies help enforce right-use and approval paths for regulated data. Natural language search can reduce the time it takes to discover relevant data products when users do not know technical table names. The result is quicker analysis with stronger governance controls.
- **Cross-functional reporting in government organizations**: A public sector organization can organize data products by service area, such as benefits, operations, and citizen support. Teams can use Unified Catalog to discover approved datasets, request access through policy workflows, and understand business definitions before use. This improves consistency across departments while preserving accountability and review requirements. It also helps reduce duplicated data preparation effort.
- **Data quality improvement in education systems**: A university can apply data quality rules to critical operational datasets used for enrollment, course planning, and student outcomes reporting. AI-suggested rules can speed up initial setup, while stewards validate and tune

rules for institutional standards. Quality scores and actions provide visibility into where remediation is needed. This supports more reliable reporting and decision making.

- **Consumer goods demand planning and operations**: A retail organization can publish data products for sales, inventory, and supply chain teams with clear ownership and terms of use. Teams can reuse curated data instead of repeatedly rebuilding similar datasets. Governance and quality controls help maintain trust as data is shared across planning, merchandising, and operations functions. The approach supports both day-to-day reporting and longer-term planning.

Models and training data

Unified Catalog leverages a variety of AI models to power the experience that users see. Some examples include Azure OpenAI GPT and embedding models offered by Foundry Models sold by Azure. To learn more about the data used to train the foundation models behind Unified Catalog, refer to the model details in Foundry.

- Foundry Models sold by Azure
- Responsible AI practices at Microsoft

Performance

Unified Catalog is designed to perform reliably in enterprise data governance scenarios where organizations have scanned and curated metadata in Microsoft Purview Data Map and have configured role-based access correctly. In this environment, users can discover data products, review business context, and request access through policy workflows with clear ownership and governance boundaries.

The application's intended input modalities are primarily structured metadata and user-entered text. Structured inputs include data asset metadata, governance domains, glossary mappings, access policy settings, and data quality definitions. Text inputs include keyword search, natural language search prompts (preview), business descriptions, and use-case narratives entered by stewards and owners. Expected outputs include ranked discovery results, suggested data assets and quality rules in supported preview flows, policy workflow states, and governance health indicators such as quality scores and remediation actions.

For multilingual capabilities, natural language data product search (preview) is designed and documented for English, French, and Spanish data products and corresponding search terms. Organizations operating outside these supported language conditions should validate effectiveness for their specific content and user patterns before broad deployment.

Performance also depends on governance maturity and metadata quality. Experiences such as discovery relevance and recommendation usefulness generally improve when data products are well described, business concepts are curated, and ownership is clearly defined. Organizations should expect better outcomes when they apply iterative stewardship practices and maintain up-to-date metadata.

Limitations

Understanding Unified Catalog's limitations is crucial to determine if it is used within safe and effective boundaries. While we encourage customers to leverage Unified Catalog in their innovative solutions or applications, it's important to note that Unified Catalog was not designed for every possible scenario. We encourage users to refer to either the Microsoft Enterprise AI Services Code of Conduct (for organizations) or the Code Conduct section in the Microsoft Services Agreement (for individuals) as well as the following considerations when choosing a use case:

- **Domain scope constraints**: AI features in Unified Catalog are designed for data governance scenarios, not general-purpose knowledge tasks. Using these features outside governance context can reduce response relevance or completeness. Teams should align prompts and workflows to cataloged metadata and business governance objectives. This helps avoid misuse and improves reliability.
- **Language and input constraints**: Natural language data product search (preview) supports data products created in English, French, and Spanish, and search terms in the corresponding languages. Results for unsupported languages or highly ambiguous prompts can be less reliable. Long text inputs might also be difficult for some AI-assisted workflows to process effectively. Users should provide clear, scoped prompts and validate outputs.
- **Human review requirement for AI suggestions**: AI-generated data asset mappings and suggested data quality rules are intended as starting points. They can accelerate setup, but they don't replace expert review and testing. Applying suggestions without validation can introduce quality or governance gaps. Human oversight is required before operational use.

Evaluations

Performance and safety evaluations assess whether AI applications are operating reliably and securely by examining factors like groundedness, relevance, and coherence while identifying the risks of generating harmful content. The following evaluations were conducted with safety components already in place, which are also described in Safety components and mitigations.

Performance and quality evaluations

Performance evaluations for AI applications are essential to improving their reliability in real-world applications. Metrics like groundedness, relevance, and coherence help assess the accuracy and consistency of AI-generated outputs, so that they are factually supported in grounded content scenarios, contextually appropriate, and logically structured. For Unified Catalog, we conducted performance evaluations for the following metrics, which are available through Microsoft Foundry:

- Groundedness
- Coherence
- Fluency
- Similarity

Risk and safety evaluations

Evaluating potential risks associated with AI-generated content is essential for safeguarding against content risks with varying degrees of severity. This includes evaluating an AI application's predisposition towards generating harmful content or testing vulnerabilities to jailbreak attacks. For [application/platform], we conducted risk and safety evaluations for the following metrics available through Microsoft Foundry:

- Hate and unfairness
- Sexual
- Violence
- Self-harm
- Protected material
- Indirect jailbreak
- Direct jailbreak
- Code vulnerability
- Ungrounded attributes

Evaluation data for safety and quality

Our evaluation data is custom-built to assess AI application performance across key areas of **safety** and **quality**, simulating real-world scenarios and risks. We begin by identifying relevant evaluation aspects of concern based on multi-disciplinary research and expert input. These concerns are translated into targeted evaluation objectives and guide formulation of evaluation metrics. For **safety**, we create adversarial prompts to elicit undesirable or edge-case responses,

which are then scored using AI-assisted annotators trained to assess alignment with Microsoft's safety standards. For **quality**, we craft rubric-based prompts relevant to scenarios including evaluating retrieval-augmented generation (RAG) applications and agents. Datasets are curated from diverse sources including synthetic and public datasets to simulate real-world user scenarios. Using the curated datasets, both evaluations undergo iterative refinement and human alignment to improve metric efficacy and reliability. This methodology forms the foundation of repeatable, rigorous assessments that reflect how customers use evaluations to build better and safer AI.

Custom evaluations

AI features in Unified Catalog underwent various testing before release, including red teaming to identify failure modes and off-scope behaviors. These evaluations focus on whether AI-assisted experiences remain aligned to intended data governance uses and whether they avoid generating responses that conflict with Microsoft AI principles. For current documented AI capabilities, the primary evaluated modality is text.

Evaluation methods include scenario-based testing of search and recommendation quality, plus risk-focused testing of edge-case prompts. Ideal outcomes are contextually relevant, governance-aligned outputs that help users complete discovery and curation tasks with clear next steps. Suboptimal outcomes include irrelevant recommendations, incomplete responses, or outputs that require substantial correction.

Safety components and mitigations

- **Human-in-the-loop validation for AI features**: AI-generated suggestions in preview are intended to be reviewed and tested by users before adoption. This mitigation lowers the risk of overreliance on automated recommendations and supports accountable decision making. Stewards and owners remain responsible for final curation and policy decisions.
- **Feedback and issue reporting loops**: Users can provide feedback on AI outputs that are inaccurate, incomplete, or unclear, including unacceptable results. Feedback helps Microsoft improve AI application.

Best practices for deploying and adopting Unified Catalog

Responsible AI is a shared commitment between Microsoft and its customers. While Microsoft builds AI applications with safety, fairness, and transparency at the core, customers play a critical

role in deploying and using these technologies responsibly within their own contexts. To support this partnership, we offer the following best practices for deployers and end users to help customers implement responsible AI effectively.

Deployers and end-users (admins) should:

- **Exercise caution and evaluate outcomes when using Unified Catalog for consequential decisions or in sensitive domains**: Consequential decisions are those that may have a legal or significant impact on a person's access to education, employment, financial platforms, government benefits, healthcare, housing, insurance, legal platforms, or that could result in physical, psychological, or financial harm. Sensitive domains—such as financial platforms, healthcare, and housing—require particular care due to the potential for disproportionate impact on different groups of people. When using AI for decisions in these areas, make sure that impacted stakeholders can understand how decisions are made, appeal decisions, and update any relevant input data.

- **Evaluate legal and regulatory considerations**: Customers need to evaluate potential specific legal and regulatory obligations when using any AI platforms and solutions, which may not be appropriate for use in every industry or scenario. Additionally, AI platforms or solutions are not designed for and may not be used in ways prohibited in applicable terms of service and relevant codes of conduct.

End-users should:

- **Exercise human oversight when appropriate**: Human oversight is an important safeguard when interacting with AI applications. While we continuously improve our AI applications, AI might still make mistakes. The outputs generated may be inaccurate, incomplete, biased, misaligned, or irrelevant to your intended goals. This could happen due to various reasons, such as ambiguity in the inputs or limitations of the underlying models. As such, users should review the responses generated by Unified Catalog and verify that they match their expectations and requirements.

- **Be aware of the risk of overreliance**: Overreliance on AI happens when users accept incorrect or incomplete AI outputs, mainly because mistakes in AI outputs may be hard to detect. For the end-user, overreliance could result in decreased productivity, loss of trust, application abandonment, financial loss, psychological harm, physical harm, among others. (e.g. a doctor accepts an incorrect AI output).

Learn more about Unified Catalog

For additional guidance or to learn more about the responsible use of Unified Catalog, we recommend reviewing the following documentation:

- Unified Catalog overview

Microsoft Purview Data Map overview

Microsoft Purview Data Map is the foundation for data discovery and data governance in Microsoft Purview. It captures metadata about data in analytics, software-as-a-service (SaaS), and operational systems across hybrid, on-premises, and multicloud environments. Built-in scanning and classification keep the Data Map up to date.

This overview helps Microsoft Purview admins plan capacity and monitor Data Map usage and costs. Every Microsoft Purview account has a Data Map that starts at one capacity unit and can scale based on request load and the amount of metadata stored.

Capacity and autoscaling

The Data Map has two capacity components: metadata storage and operation throughput. A capacity unit (CU) represents both components. By default, a Microsoft Purview account starts with one capacity unit and scales based on usage up to a maximum of 10 capacity units. Each capacity unit includes throughput of 25 operations per second and 10 GB of metadata storage.

The Data Map includes the following capabilities:

- **Elastic Data Map with autoscale**: Start with one capacity unit and automatically scale based on load up to 10 capacity units.
- **Enhanced scanning and ingestion**: Track and control how scanning and ingestion populate data assets, classifications, and lineage. This capability affects pricing.

Operation throughput

Operations measure the throughput of Microsoft Purview Data Map. They include create, read, write, update, and delete operations on metadata stored in the Data Map. Examples include:

- Creating an asset in the Data Map.
- Adding a relationship to an asset, such as an owner, steward, parent, or lineage.
- Editing an asset to add business metadata, such as a description or glossary term.
- Running a keyword search that returns results to the search results page.

Metadata storage

Storage includes technical, business, operational, and semantic metadata.

Technical metadata includes schemas, data types, and columns discovered through Microsoft Purview scanning. Business metadata includes automated metadata, such as metadata promoted from Microsoft Power BI datasets or descriptions from SQL tables, and manually added descriptions and glossary terms. Semantic metadata includes collection mappings to data sources or classifications. Operational metadata includes data factory copy and data flow activity run statuses and run times.

Example scenario

Claudia is a Microsoft Azure admin at Contoso who wants to create a Microsoft Purview account from the Azure portal. She doesn't know the Data Map size that the future state of the platform requires. However, she knows that Data Map billing uses capacity units and is affected by storage and operations throughput. She wants to start with the smallest Data Map to keep costs low and grow it elastically based on consumption.

Claudia can create a Microsoft Purview account with the default Data Map size of one capacity unit, which can automatically scale up and down. Autoscaling also allows capacity to adjust for intermittent or planned data bursts during specific periods. Claudia then configures the network settings and completes the account creation.

On the Microsoft Purview account's **Metrics** page in the Azure portal, Claudia can view Data Map storage and operations throughput consumption. She can also create an alert for when storage or operations throughput reaches a specified limit.

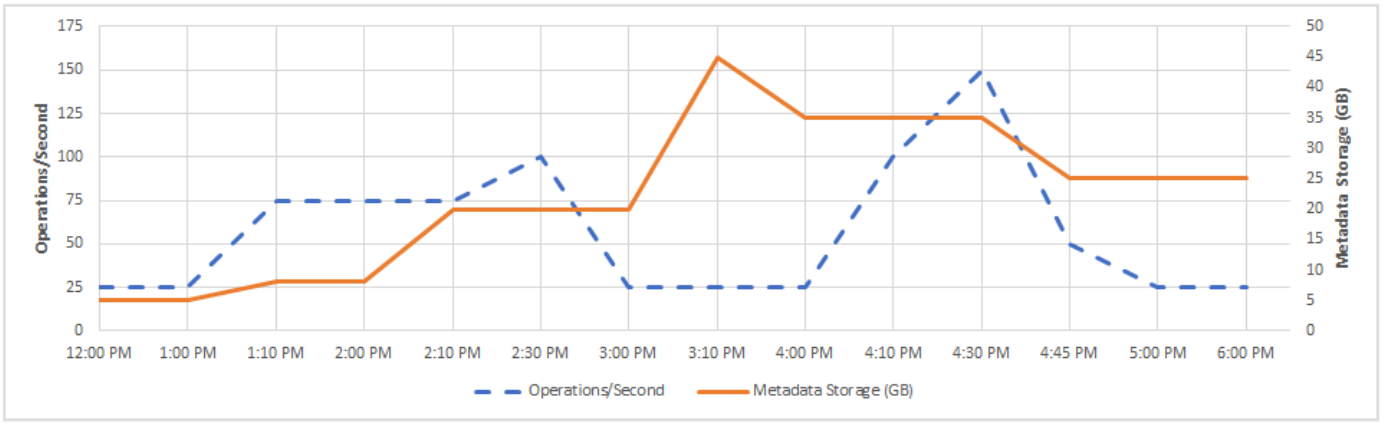
Data Map billing

Billing for classic Microsoft Purview accounts

You pay for one capacity unit, which includes 25 operations per second and 10 GB of metadata storage. Extra billing is based on the consumption of each extra capacity unit, calculated hourly. Data Map operations scale in increments of 25 operations per second, and metadata storage scales in increments of 10 GB. Data Map can automatically scale up and down within the elasticity window. You can increase the elasticity window only for classic Microsoft Purview accounts. To request an increase, review the current limits and create a support request.

Data Map capacity units come with a cap on operations throughput and storage. If storage exceeds the current capacity unit, you pay for the next capacity unit even if you don't use the operations throughput. The following table shows the Data Map capacity unit ranges. Contact support if the Data Map capacity unit goes beyond 10 capacity units.

Expand table



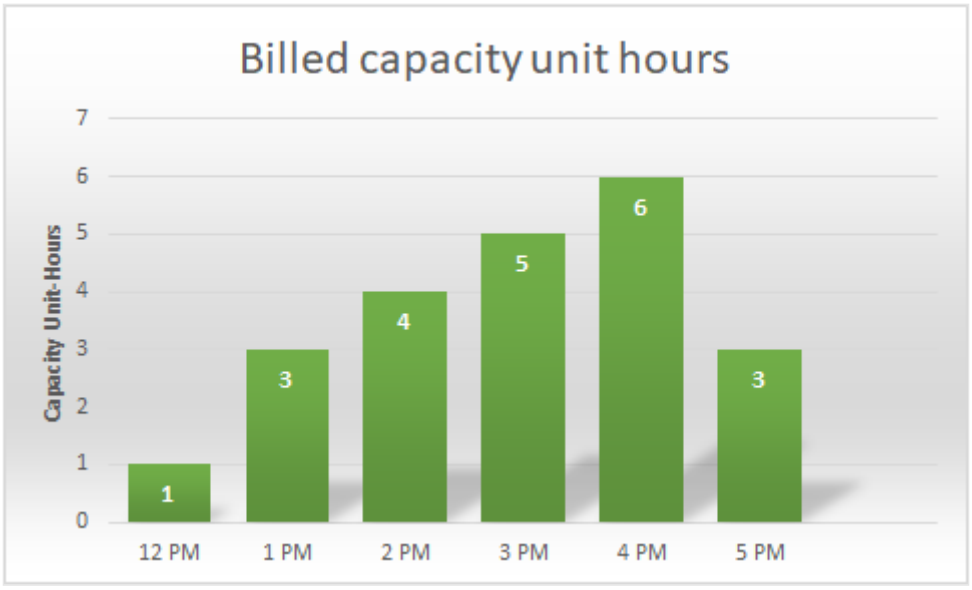
Data Map capacity unit	Operations-per-second throughput	Storage capacity in GB
1	25	10
2	50	20
3	75	30
4	100	40
5	125	50
6	150	60
7	175	70
8	200	80
9	225	90
10	250	100

Billing examples

- The operation throughput for the hour is less than or equal to 25 operations per second, and the storage size is 1 GB. You pay for one capacity unit.
- The operation throughput for the hour is less than or equal to 25 operations per second, and the storage size is 15 GB. You pay for two capacity units.
- The operation throughput for the hour is 50 operations per second, and the storage size is 15 GB. You pay for two capacity units.
- The operation throughput for the hour is 50 operations per second, and the storage size is 25 GB. You pay for three capacity units.
- The operation throughput for the hour is 250 operations per second, and the storage size is 15 GB. You pay for 10 capacity units.

Detailed billing example

The Data Map billing example shows growing metadata storage and variable operations per second over a six-hour window from 12 PM to 6 PM. The dashed line shows operations per second, and the solid line shows metadata storage:



Each Data Map capacity unit supports 25 operations per second and 10 GB of metadata storage. The Data Map is billed hourly. The billing process considers the maximum Data Map capacity units needed within the hour, with a minimum of one capacity unit. At times, you might need more operations per second within the hour, and more operations increase the number of capacity units needed within that hour. At other times, your operations per second usage could be low, but you might still need a large volume of metadata storage. The metadata storage determines how many capacity units you need within the hour.

The table shows the maximum number of operations per second and metadata storage used per hour for this billing example:

Period	1	2	3	4	5	6
Start Time	12 PM	1 PM	2 PM	3 PM	4 PM	5 PM
End Time	1 PM	2 PM	3 PM	4 PM	5 PM	6 PM
Max ops/sec	25	75	100	25	150	25
Max Storage (GB)	5	8	20	45	35	25
Billed CU-hours	1	3	4	5	6	3

Based on the operations-per-second and metadata storage consumption during this period, the Data Map is billed for 22 capacity-unit hours over six hours (1 + 3 + 4 + 5 + 6 + 3):

> **Important**
>
> Data Map can automatically scale up and down within the elasticity window. To increase the elasticity window, review the current limits and create a support request.

Operations throughput limits

The default throughput limit is 10 capacity units. If you're working with a large Microsoft Purview environment and need higher throughput, you can request a larger elasticity window by creating a quota request. Select **Data map capacity unit** as the quota type. Include relevant information about your environment and the extra capacity that you need. You can increase the elasticity window only for classic Microsoft Purview accounts.

> **Important**
>
> There's no default limit for metadata storage. As you add more metadata to Data Map, it elastically increases.

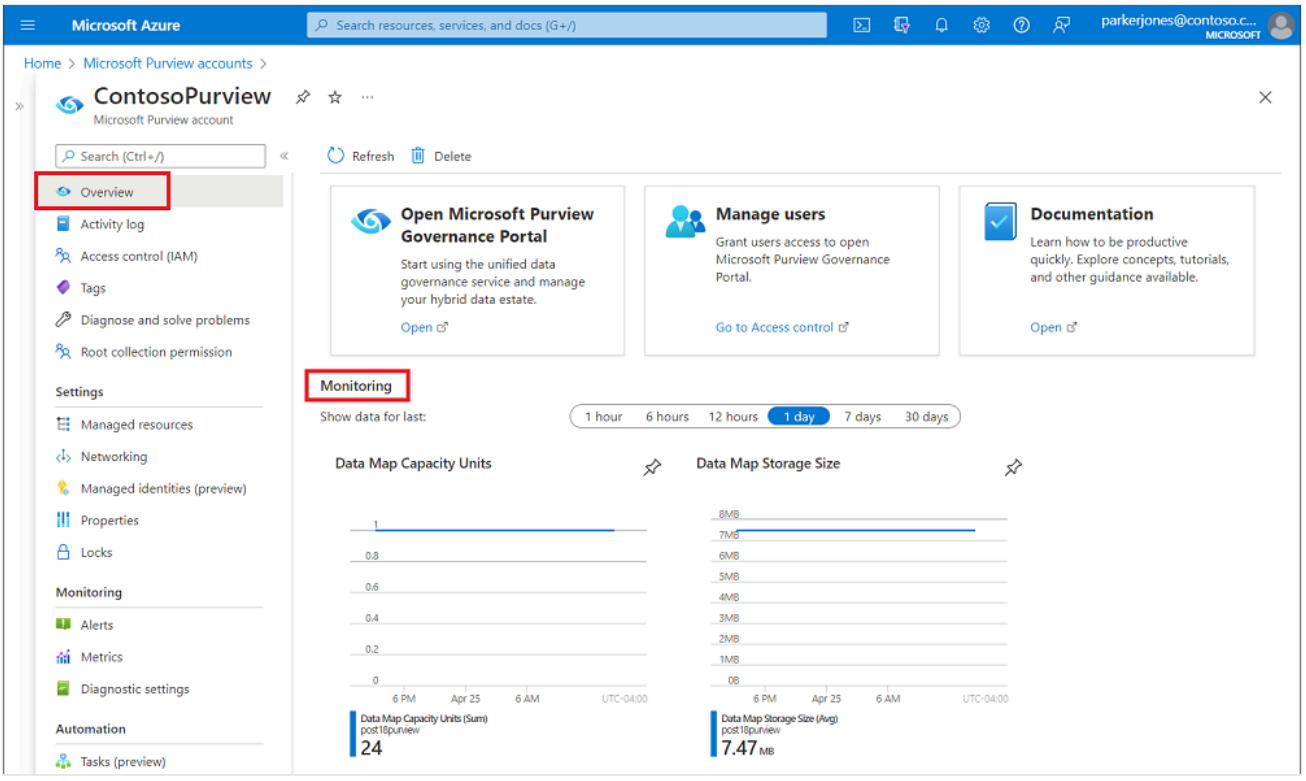
When you increase the operations throughput limit, you also increase the minimum number of capacity units. For example, if you increase the throughput limit to 20, you pay for a minimum of two capacity units. The following table shows the possible throughput options. The number that you enter in the quota request is the minimum number of capacity units on the account.

Expand table

Minimum capacity units	Operations throughput limit
1	10 (default)
2	20
3	30
4	40
5	50
6	60
7	70
8	80
9	90
10	100

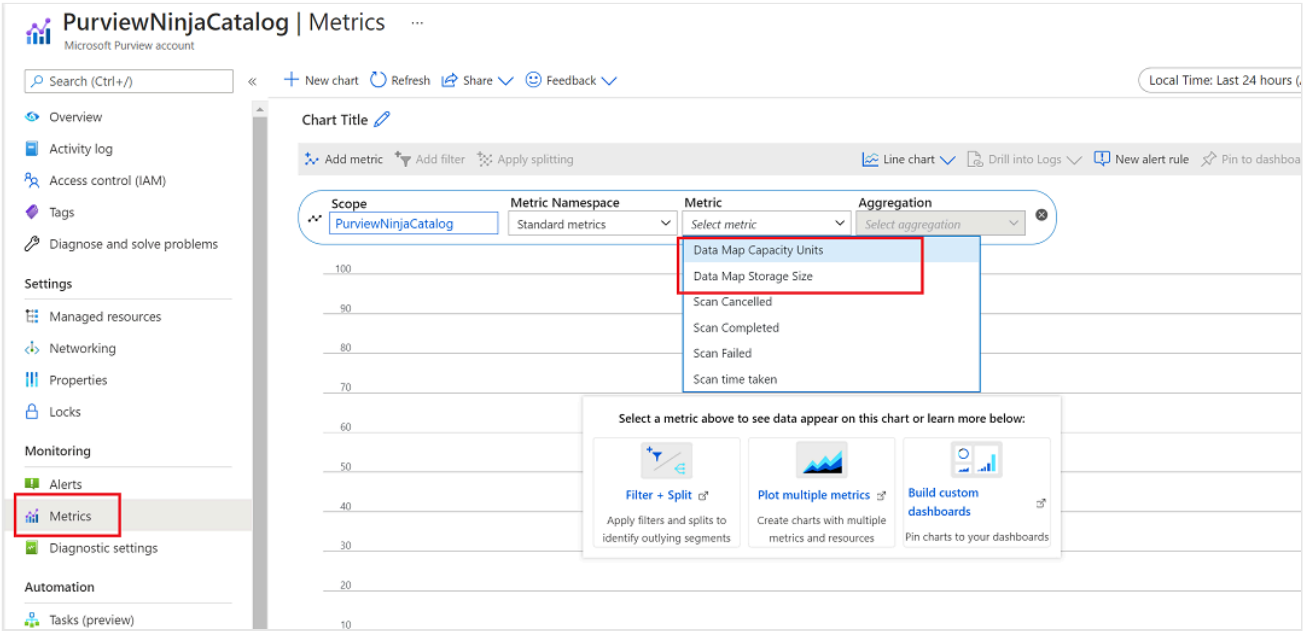
Optimize capacity units and operations throughput

Use these best practices to optimize capacity-unit and operations-throughput usage:



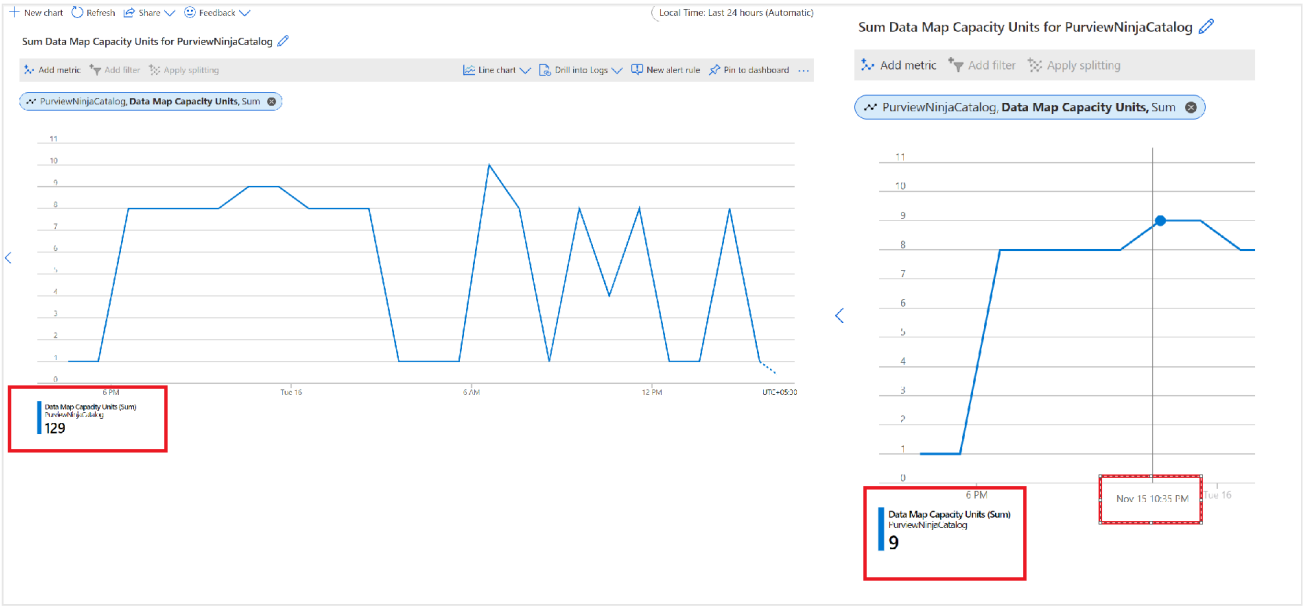
- Use incremental scans after the initial full scan. Incremental scans process only objects changed since the previous scan and typically provide the greatest reduction.
- Limit the scan scope and, where available, use **Advanced mode** to include or exclude specific paths instead of scanning the entire source.
- Stagger scan schedules. Avoid running several scans simultaneously; run them sequentially and outside peak usage periods.
- Reduce scan frequency. For example, change hourly scans to daily scans if the governance freshness requirement allows it.
- Disable lineage extraction if it is not required.
- Use separate, nonoverlapping scans.
- Clean up historical lineage regularly from Microsoft Purview storage.
- Manually remove nonessential or stale data from Microsoft Purview storage.

Monitoring and metrics

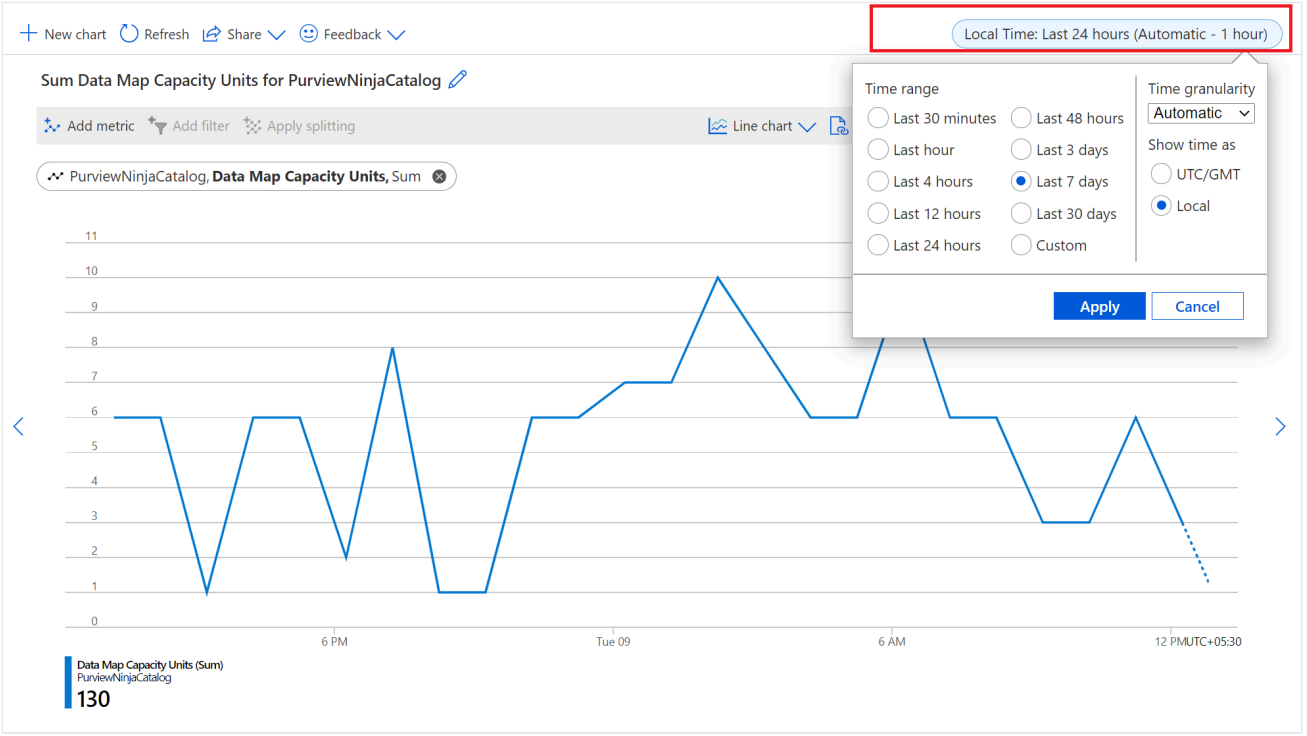


Monitor the **Data Map Capacity Units** and **Data Map Storage Size** metrics to understand the size and billing of your data estate.

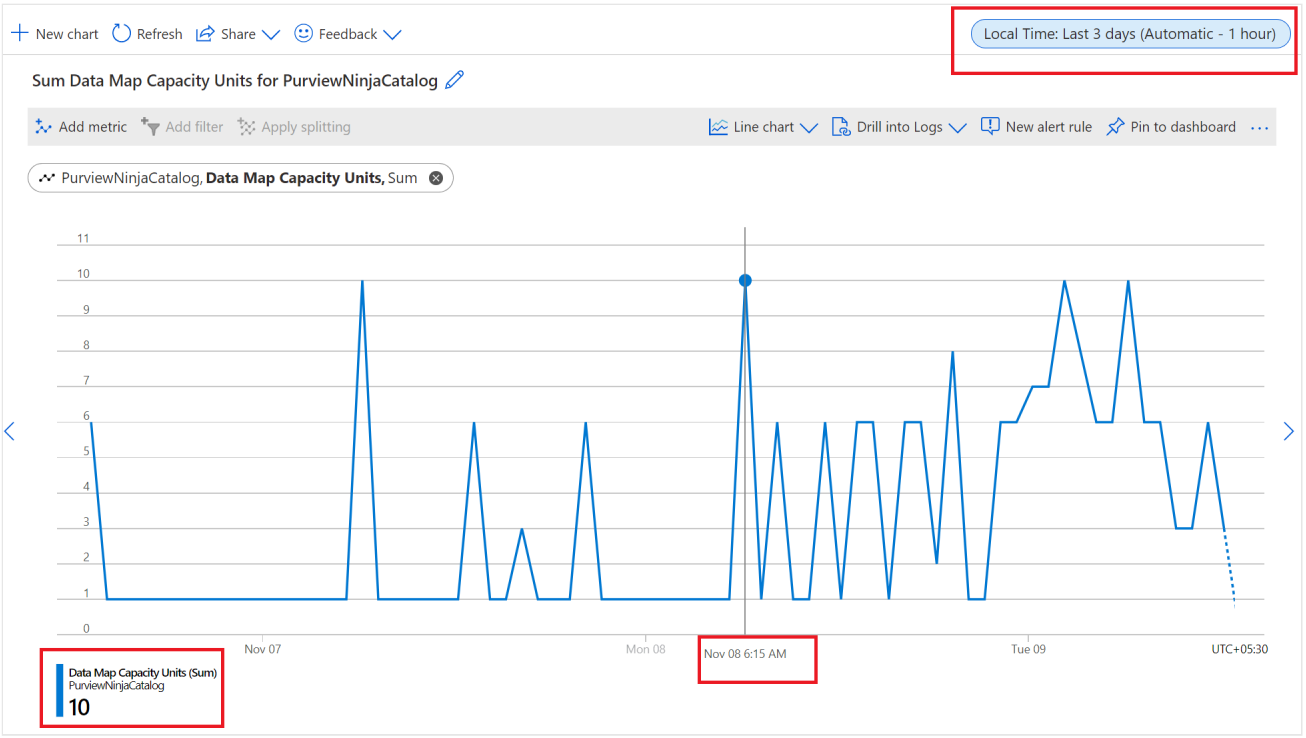
1. In the Azure portal, go to **Microsoft Purview accounts**, and then select your Microsoft Purview account.



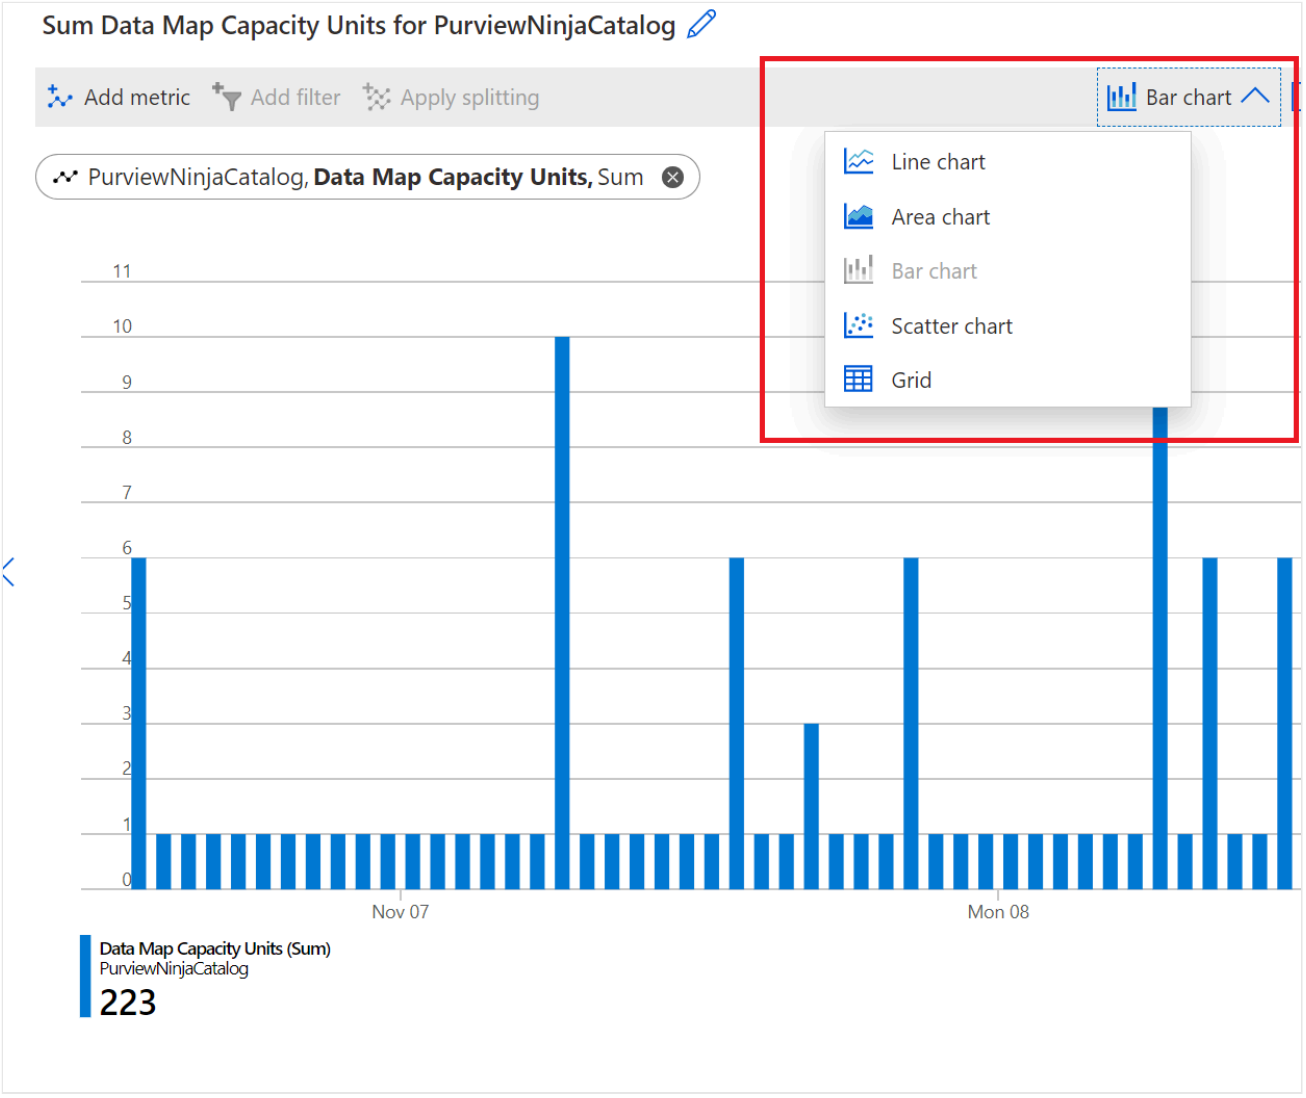
2. On the **Overview** page, scroll to the **Monitoring** section to view the **Data Map Capacity Units** and **Data Map Storage Size** metrics over different time periods.



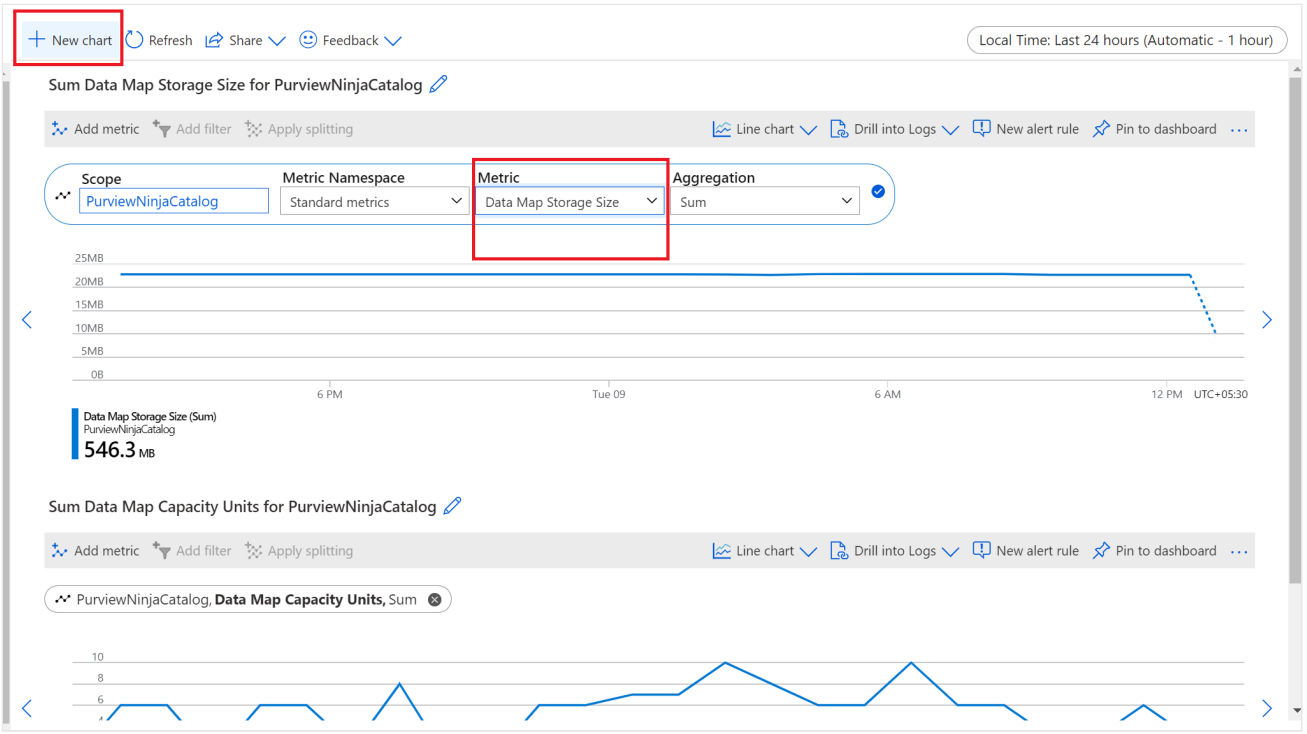
3. For more settings, go to **Monitoring** > **Metrics** to view **Data Map Capacity Units** and **Data Map Storage Size**.



4. Select **Data Map Capacity Units** to view capacity unit usage over the last 24 hours. Hover over the line graph to view the Data Map capacity units consumed at a specific time.



5. At the top of the page, select **Local Time: Last 24 hours (Automatic - 1 hour)** to change the time range displayed in the graph.



6. Select a graph type to customize the visualization.

7. Select **New chart** to add a **Data Map Storage Size** chart.

Next steps

- Create a Microsoft Purview account
- Learn about scans and ingestion in Microsoft Purview Data Map
- Monitor Microsoft Purview with Azure Monitor
- Review Data Map pricing
- Manage and increase quotas for classic data governance resources

Domains in Microsoft Purview Data Map

> **Tip**
>
> This article covers domains in the Microsoft Purview Data Map. For governance domains in Microsoft Purview Unified Catalog, see the governance domains article.

A domain is a construct that you use to distribute organizational responsibility in your instance of Purview Data Map. Domains provide structure in Data Map so that domain administrators can maintain the isolation of collections, data sources, scans, and assigned roles for access control. Previously, only collections filled this role, but we're introducing domains as top-level nodes above the rest of the hierarchy to address a few other scenarios:

- Decentralize and distribute responsibility by assigning roles at the domain level.
- Create the possibility for hard logical separations within your Data Map.
- Replace multiple accounts within a tenant to multiple domains within a single Microsoft Purview resource.

Domains also serve as the container for collections and assets.

> **Note**
>
> Domains are only available to Microsoft Purview accounts using a tenant-level account (https://purview.microsoft.com).

Default domain

Every Microsoft Purview Data Map starts with a default domain.

When an account is upgraded to the new experience, the primary account's root collection becomes the default domain.

If you haven't upgraded to the new experience yet, take these points into consideration when choosing which account to elevate as your default domain:

- **Data Assets**: Choose the account with the most valuable or frequently used data assets, as this will become the default domain after the upgrade.
- **Account Usage**: Evaluate how each account is currently being used and its role within your organization. Accounts that are considered "production" would be most viable to select for this purpose.

- **Permissions and Access Controls**: Consider the existing permissions and access controls for each account, as they'll be carried over to the upgraded environment (as an isolated Domain). The permissions are applied in the new environment exactly as they are in the original environment. No more permissions are granted.

For more information about the new experience, see our guide on governance in the new Microsoft Purview experience.

Custom domains

You can also create up to four more custom domains in your Data Map to better organize and govern your assets in Data Map. Get more information on how to create and manage domains.

Domain level roles

Alongside all the permissions you can assign at a collection level, a new role can be assigned at the domain level to manage domains, collections, and glossaries:

- Domain admin - Can assign permissions within a domain and manage its resources.

For more information, see how to assign permissions in collections and on a domain level.

Data Map structure

Capabilities and responsibilities are distributed between these three new levels in Data Map's structure: tenant/organization level, domain level, and collection level.

- Tenant level - Classifications, search, browse, metamodel, managed attributes, integration runtimes, lineage, workflows, insights, private endpoints.
- Domain level - Credentials, term templates, custom scan rule sets, advanced resource sets, pattern rules, policies, assets.
- Collection level - Data sources, scans, assets.

> **Important**
>
> Data sources and assets can't be duplicated in a tenant.

Domains don't change permissions in Microsoft Purview. Search and browse across a tenant are still managed by the level a user's assigned permissions. In Unified Catalog, a user only has access to metadata if they have data-level access or collection-level access.

For more information, see permissions for Microsoft Purview Data Map and Unified Catalog.

Next steps

Merge secondary accounts into Microsoft Purview as domains.

Last updated on 11/24/2025

Manage domains and collections in Microsoft Purview Data Map

06/25/2025

> **Important**
>
> These features are only available if you're using the Microsoft Purview portal.
>
> If you're using the classic governance experience (https://web.purview.azure.com/), see the classic create and manage collections article instead.

Domains and collections in Microsoft Purview Data Map can be used to organize assets and sources by your business's flow. They're also the tool used to manage access across the Microsoft Purview portal. This guide takes you through the creation and management of domains and collections, as well as cover steps about how to register sources and add assets into your collections.

Find more information about domains and the structure of Data Map.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- Your own Microsoft Entra tenant.
- A Microsoft Purview account using the Microsoft Purview portal experience.
- You need to be a **Microsoft Purview administrator** within the Microsoft Purview portal to manage domains. To check or set these roles, see our permissions documentation.

Permissions to manage domains and collections

To manage domains, and permissions in domains, a user needs to be a Purview administrator or a domain admin.

To manage collections, a user needs to be at least a **Domain Admin** or **Collection Admin** within the Microsoft Purview portal.

To manage collections, a user needs to be at least a **Domain Admin** or **Collection Admin** within the Microsoft Purview portal.

To check these permissions in the Microsoft Purview portal:

1. Open **Data Map**, then select **Domains** to open the domains management page.
2. Select your default domain, which is currently the only available domain.
3. Select the **Role assignments** tab.
4. Search under these roles for your user:
    - Domain admins - to be able to manage the domain or permissions in it.
    - Collection admins - to be able to create or manage collections in the domain.

> **Tip**
>
> If you don't have either of the needed permissions, contact the domain admin to grant you permission.

Default domain

Every Microsoft Purview Data Map starts with a default domain.

When an account is upgraded to the new experience, the primary account's root collection becomes the default domain.

If you haven't upgraded to the new experience yet, take these points into consideration when choosing which account to elevate as your default domain:

- **Data Assets**: Choose the account with the most valuable or frequently used data assets, as this will become the default domain after the upgrade.
- **Account Usage**: Evaluate how each account is currently being used and its role within your organization. Accounts that are considered "production" would be most viable to select for this purpose.
- **Permissions and Access Controls**: Consider the existing permissions and access controls for each account, as they'll be carried over to the upgraded environment (as an isolated Domain). The permissions are applied in the new environment exactly as they are in the original environment. No more permissions are granted.

For more information about the new experience, see our guide on governance in the new Microsoft Purview experience.

Custom domains

You can create up to four custom domains in your Data Map.

Create custom domains

1. In **Data Map**, select **Domains**.
2. Select **+ New domain**.
3. On the **New domain** pane, enter a name for the domain, a description, and assign one or more domain administrators.
4. Select **Create**.

Edit custom domains

You can modify the description or the administrators of your custom domains by editing them.

1. In **Data Map**, select **Domains**.
2. Select the domain you want to edit, and on its details page, select **Edit**.

Delete custom domains

> **Important**
>
> - Before you delete a custom domain, you must remove everything under it first. Including: subcollections, data sources, scans, assets, glossaries, terms, credentials, Azure Key Vaults, etc.
> - Default domains can't be deleted.

To remove a domain, you need to have either Microsoft Purview administrator or domain administrator permissions.

1. Navigate to https://purview.microsoft.com.
2. Open the **Data Map** solution.
3. Select **Domains** from the left pane to open the domains management page.
4. Select the domain you want to delete.
5. Select the **Delete** button and confirm the deletion.

Collection management

Create a collection

You need to be a collection admin or domain admin within a domain order to create a collection. If you aren't sure, see how to check permissions.

1. In **Data Map**, select **Domains**.
2. Use the dropdown next to your default domain to select your default domain, or select an existing collection where you want to make a child collection.
3. Select **+ New collection**. Only domain and collection admins can manage collections.
4. In the new collection window, enter the collection display name and description. If needed, you can also add users or groups as collection admins to the new collection.
5. Select **Create**.
6. The new collection's information reflects in the collection list under your domain, and you're taken to your collection's detail page.

Edit a collection

1. Select **Edit** either from the collection detail page, or from the collection's dropdown list.

2. Make changes, then select **Save**.

View Collections

1. On the **Domains** page in Data Map, select the arrow next to the collection's name to expand or collapse the collection hierarchy. Select the collection name to navigate.
2. Enter a name in the **Filter by name** box to filter collections.
3. Select **Refresh** in collection detail page to reload the single collection.

Delete a collection

You need to be a domain admin or a collection admin in order to delete a collection. If you aren't sure, check permissions. Collections can be deleted only if no child collections, assets, data sources, or scans are associated with it.

1. On the collection's details page, select **Delete**.
2. A confirmation window appears. Select **Confirm** to continue the deletion.
3. Verify deletion of the collection from your Data Map.

> ⓘ **Note**
>
> Collections can be deleted only if no child collections, assets, data sources, or scans are associated with it.

Move registered sources between collections

You can move registered sources from one collection to another you have access to. For steps, see Manage data sources.

Add roles and restrict access

Since permissions are managed through domains and collections in Data Map, it's important to understand the roles and what permissions they give to your users.

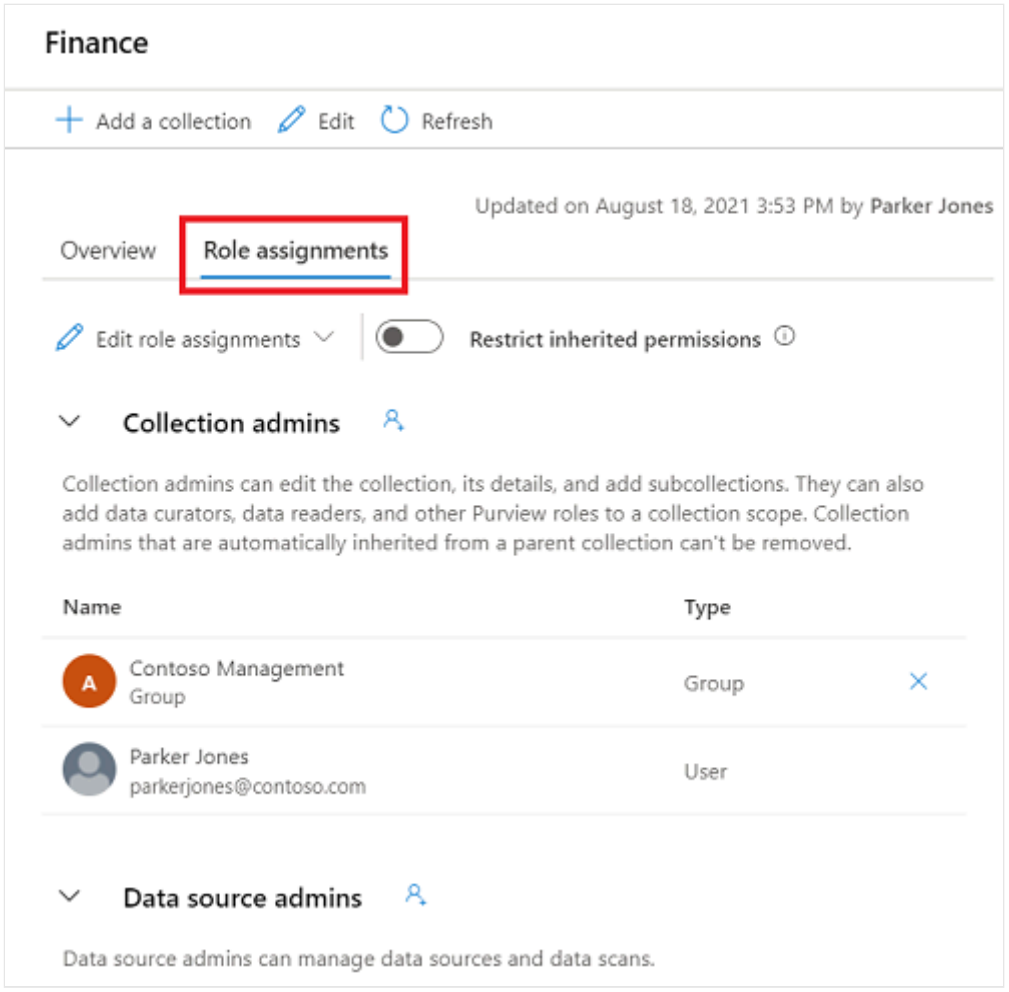
The roles are assigned and inherited in domains and collections the same way. A user granted permissions on a domain or collection will have access to sources and assets associated with that collection, and inherit permissions to its subcollections. Inheritance can be restricted, but is allowed by default.

The following guide discusses the roles, how to manage them, and permissions inheritance.

Roles

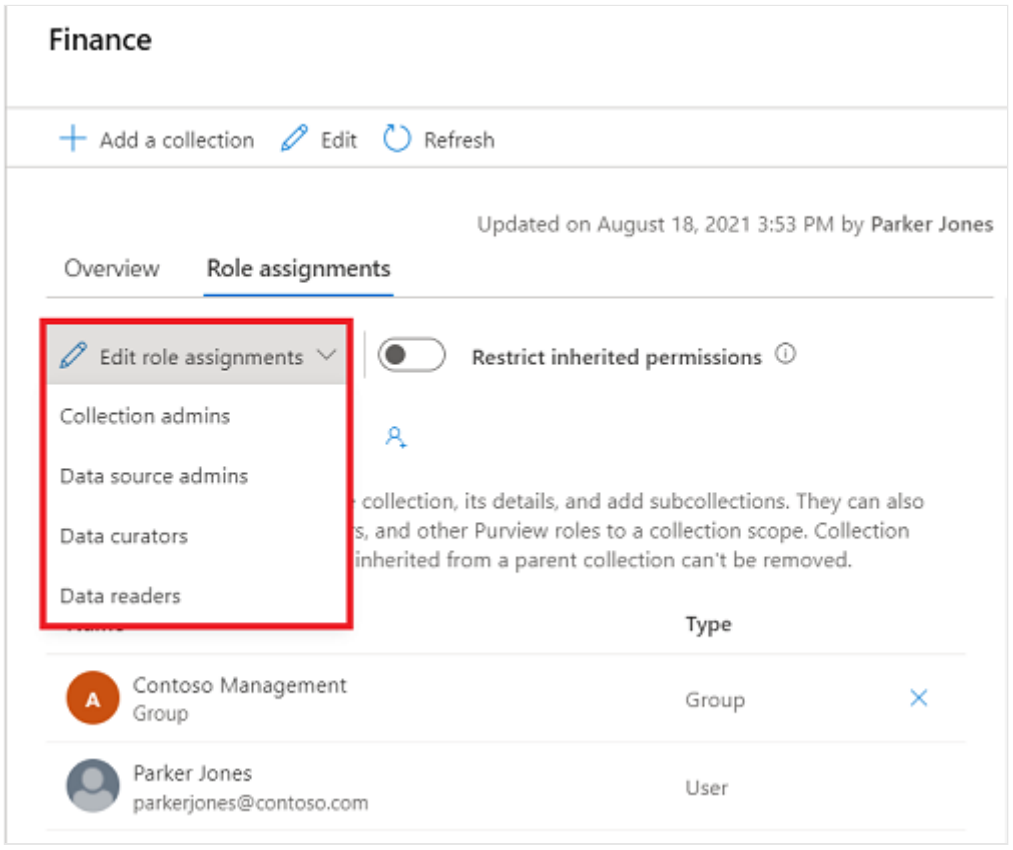
All assigned roles apply to sources, assets, and other objects within the domain or collection where the role is applied.

- **Domain admin** (domain level only) - Can assign permissions within a domain and manage its resources.
- **Collection administrator** - a role for users that will need to assign roles to other users in the Microsoft Purview governance portal or manage collections. Collection admins can add users to roles on collections where they're admins. They can also edit collections, their details, and add subcollections. A collection administrator on the root collection also automatically has permission to the Microsoft Purview governance portal. If your **root collection administrator** ever needs to be changed, you can follow the steps in the section below.
- **Data curators** - a role that provides access to the Microsoft Purview Unified Catalog to manage assets, configure custom classifications, create and manage glossary terms, and view data estate insights. Data curators can create, read, modify, move, and delete assets. They can also apply annotations to assets.
- **Data readers** - a role that provides read-only access to data assets, classifications, classification rules, collections and glossary terms.
- **Data source administrator** - a role that allows a user to manage data sources and scans. If a user is granted only to **Data source admin** role on a given data source, they can run new scans using an existing scan rule. To create new scan rules, the user must be also granted as either **Data reader** or **Data curator** roles.



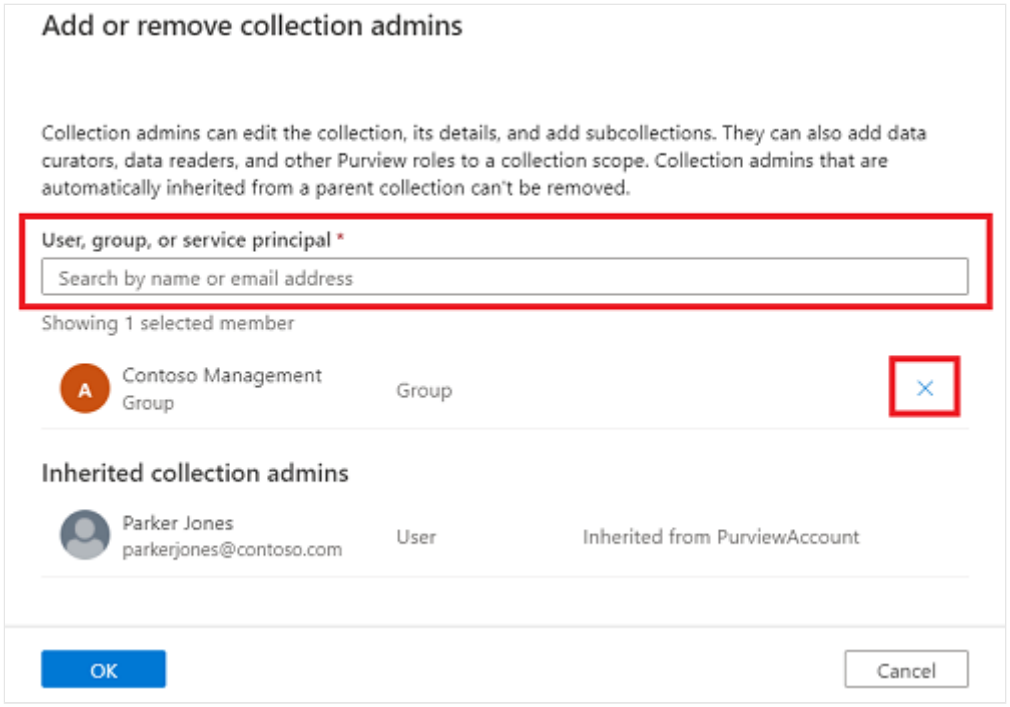
- **Insights reader** - a role that provides read-only access to insights reports for collections where the insights reader also has at least the **Data reader** role. For more information, see insights permissions.
- **Policy author** - a role that allows a user to view, update, and delete Microsoft Purview policies through the Data policy app within Microsoft Purview.
- **Workflow administrator** - a role that allows a user to access the workflow authoring page in the Microsoft Purview governance portal, and publish workflows on collections where they have access permissions. Workflow administrator only has access to authoring, and so will need at least Data reader permission on a collection to be able to access the Purview governance portal.

> **Note**
>
> At this time, Microsoft Purview policy author role is not sufficient to create policies. The Microsoft Purview data source admin role is also required.



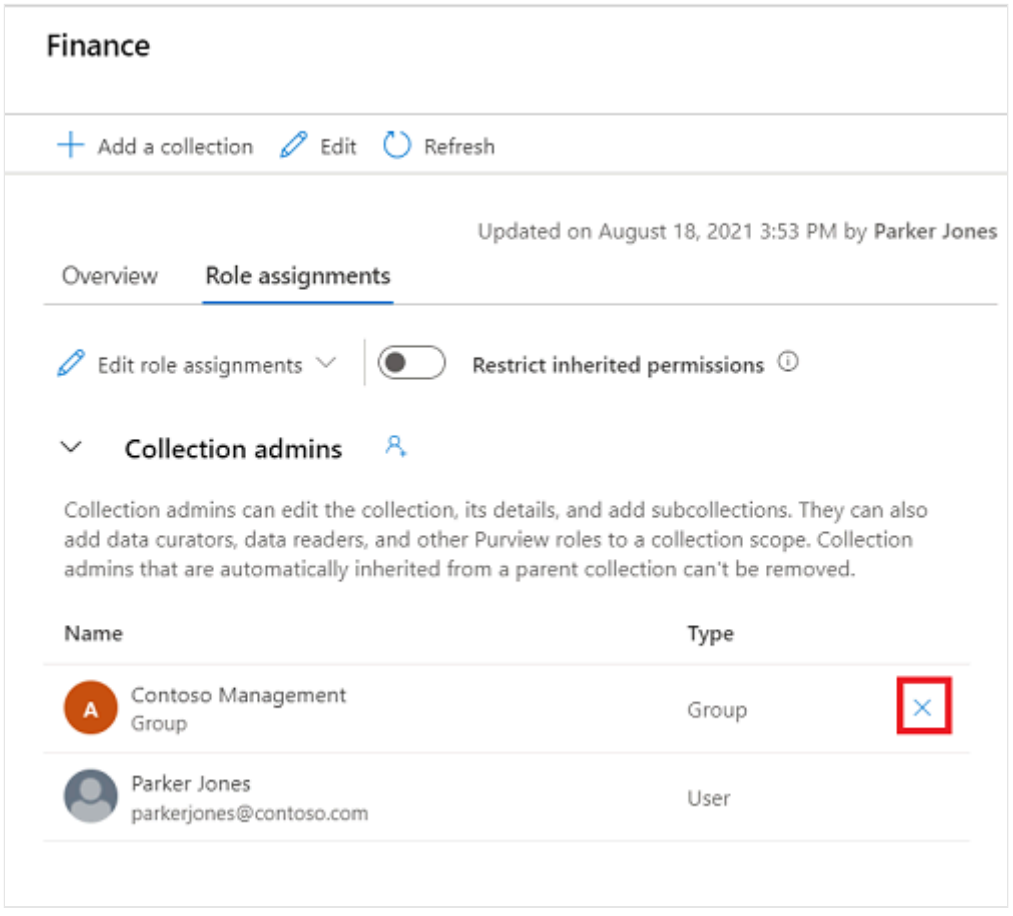
> **Important**
>
> The user that created the account is automatically assigned domain admin on the default domain and collection admin on the root collection.

Add role assignments

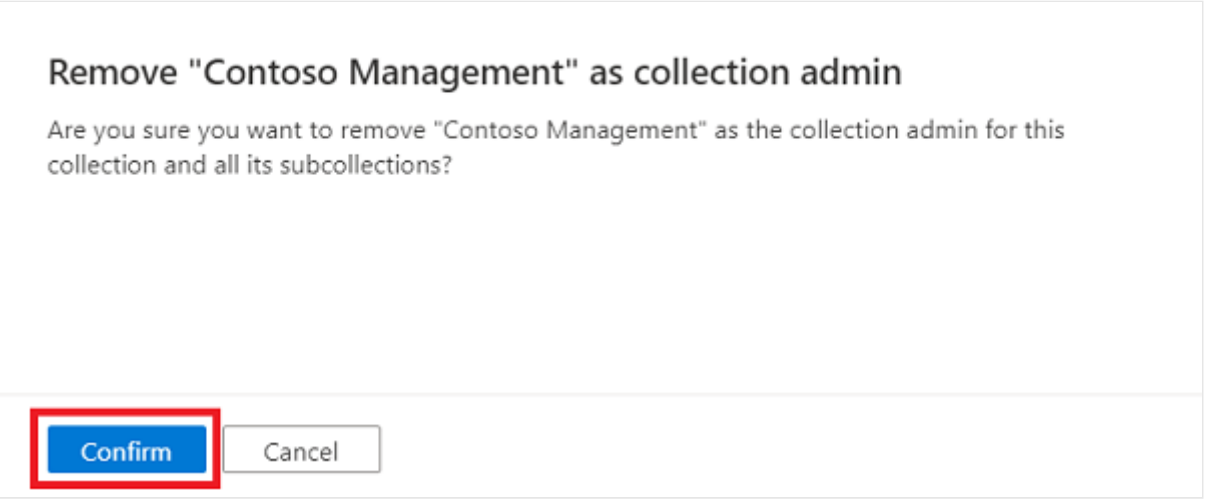


1. Open the Microsoft Purview Data Map.
2. Select the domain or collection where you want to add your role assignment.
3. Select the **Role assignments** tab to see all the roles in a collection or a domain. Only a collection admin or domain admin can manage role assignments.

4. Select **Edit role assignments** or the person icon to edit each role member.



5. Type in the textbox to search for users you want to add to the role member. Select **X** to remove members you don't want to add.



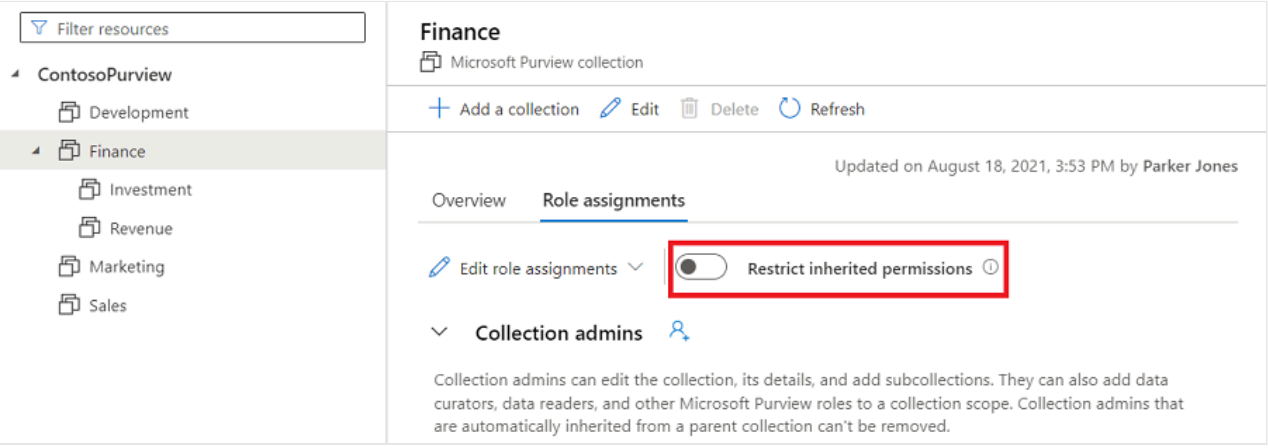
6. Select **OK** to save your changes, and you'll see the new users reflected in the role assignments list.

Remove role assignments

1. Select **X** button next to a user's name to remove a role assignment.

2. Select **Confirm** if you're sure to remove the user.

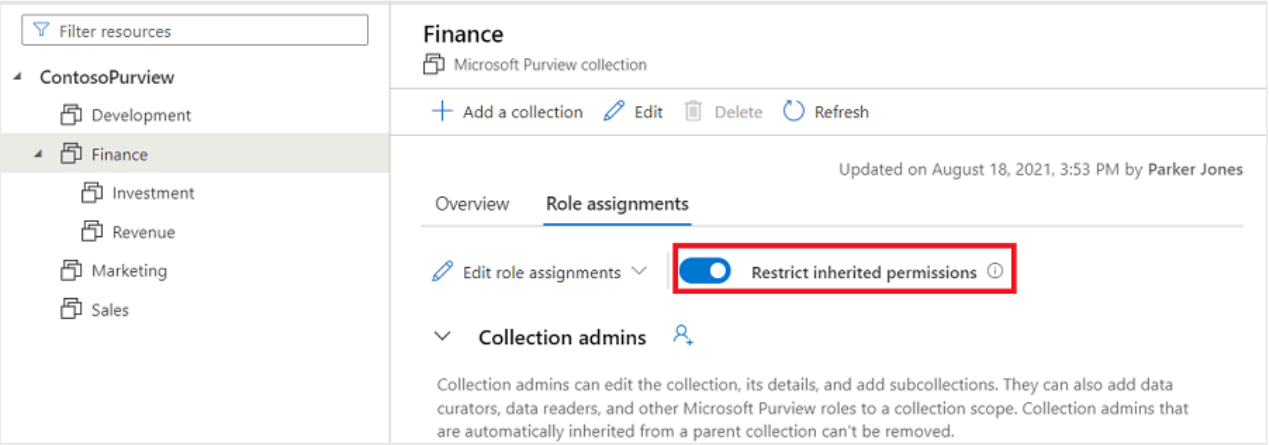
Restrict inheritance



Collection permissions are inherited automatically from the parent collection. You can restrict inheritance from a parent collection at any time, using the restrict inherited permissions option.

> **Note**
>
> Currently permissions from the default domain cannot be restricted. Any permissions assigned at the default domain will be inherited by the domain's direct subcollections.

Once you restrict inheritance, you'll need to add users directly to the restricted collection to grant them access.



1. Navigate to the collection where you want to restrict inheritance and select the **Role assignments** tab.

2. Select **Restrict inherited permissions** and select **Restrict access** in the popup dialog to remove inherited permissions from this collection and any subcollections. Collection admin permissions won't be affected.

3. After restriction, inherited members are removed from the roles expect for collection admin.

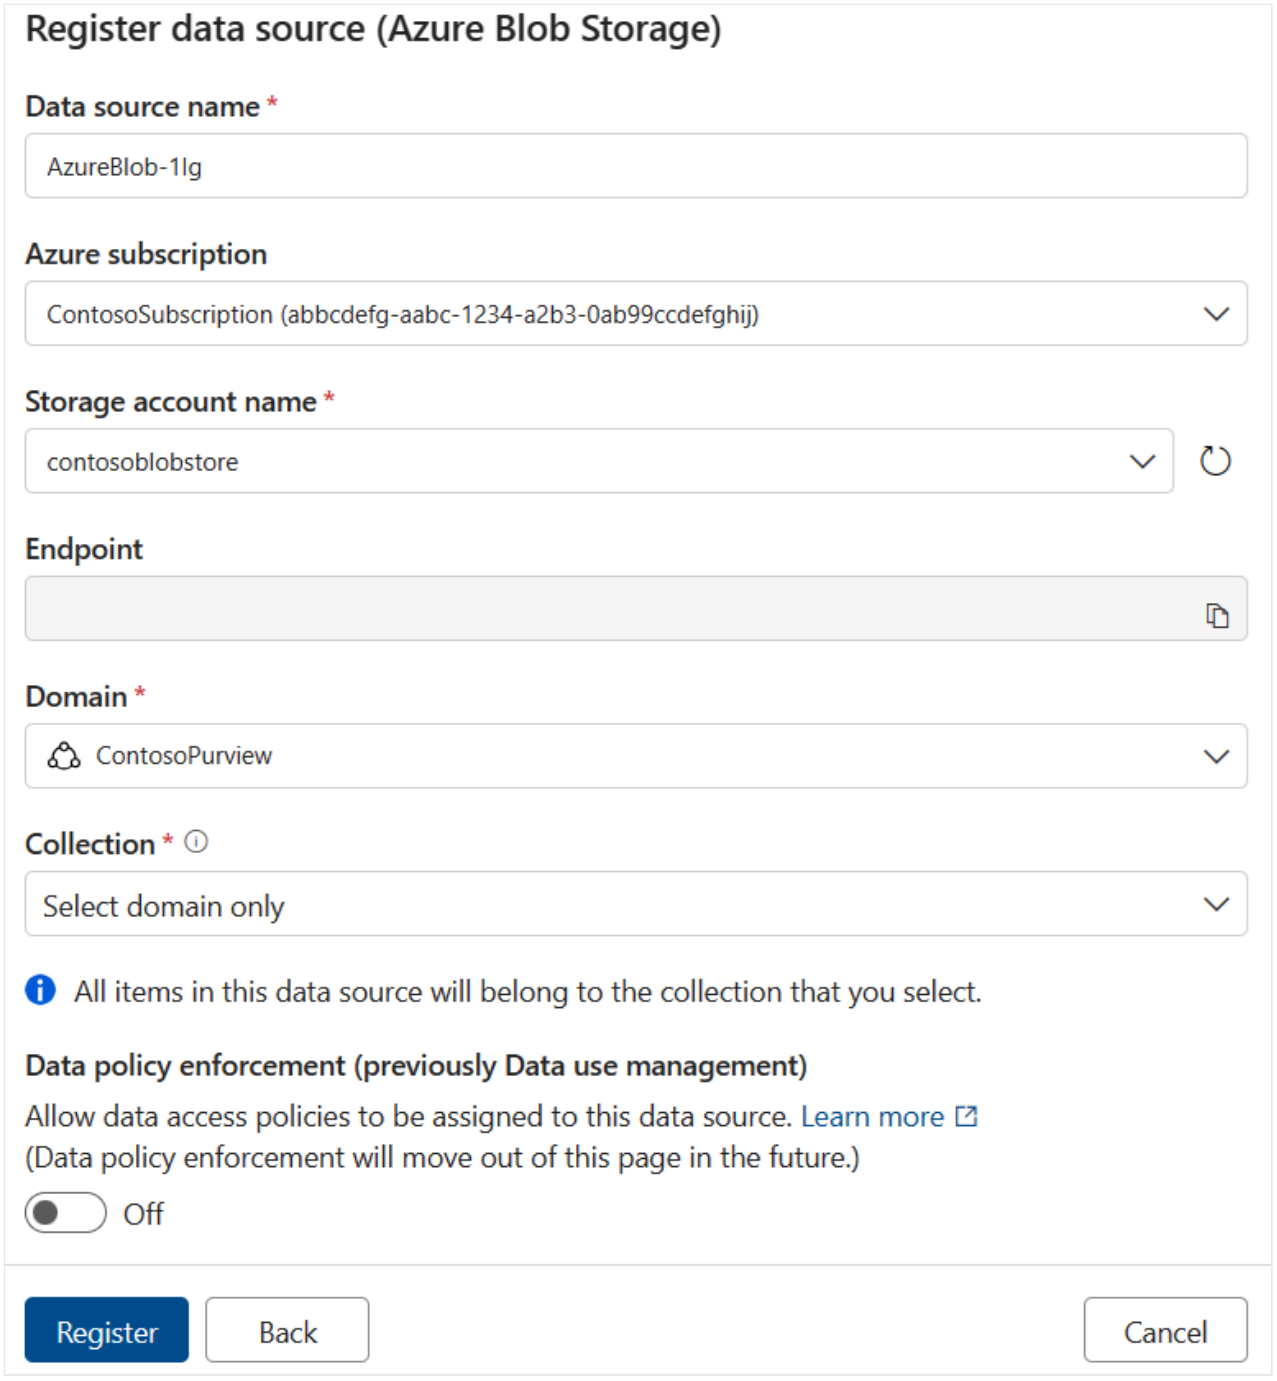
4. Select the **Restrict inherited permissions** toggle button again to revert.

Register and scan source in a domain or collection

> **Important**
>
> Every source has its own prerequisites and information for registration and scanning. Get detailed registration and scanning steps for each data source.

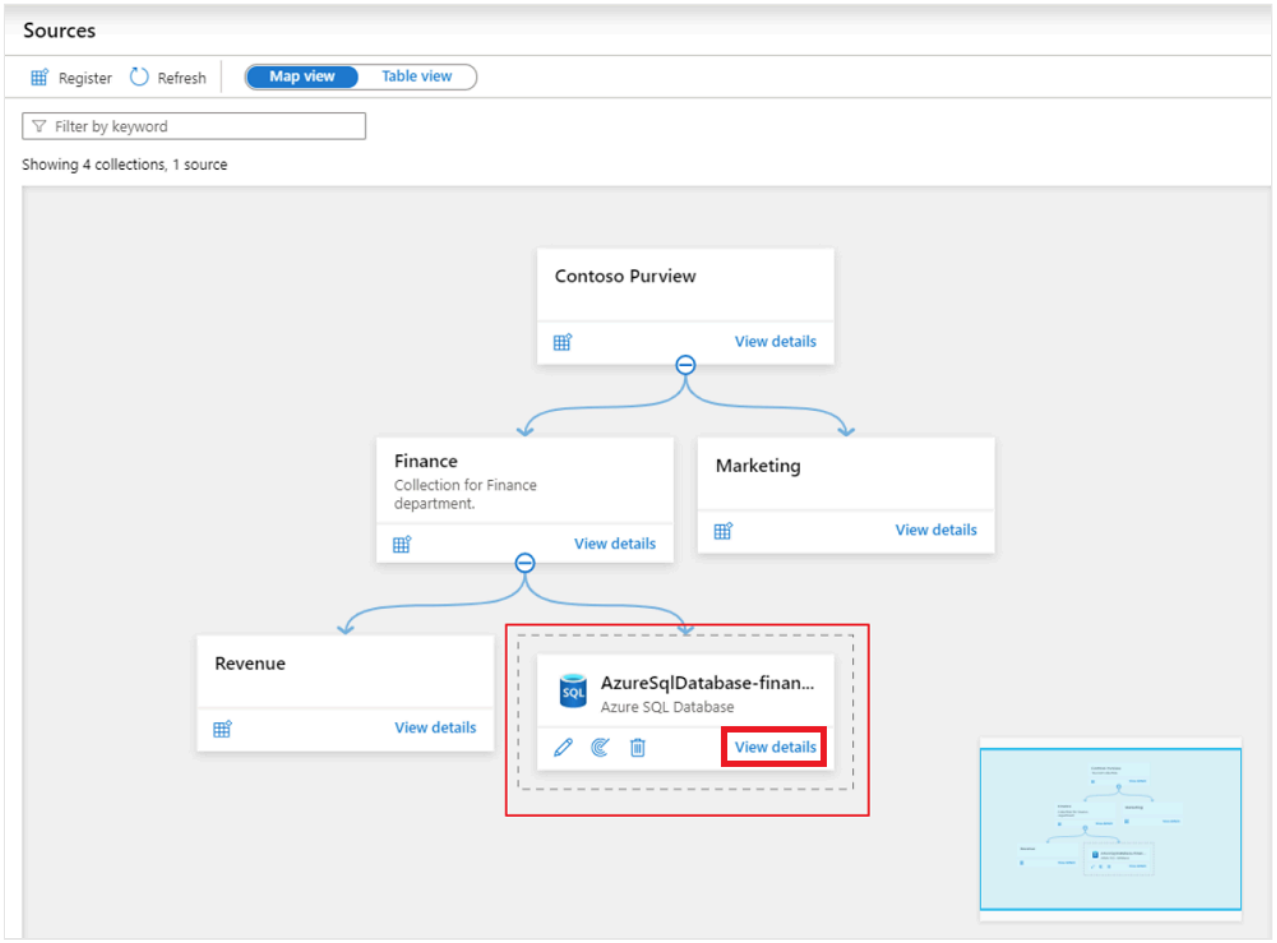
1. Navigate to https://purview.microsoft.com.

2. Open the **Data Map** solution.



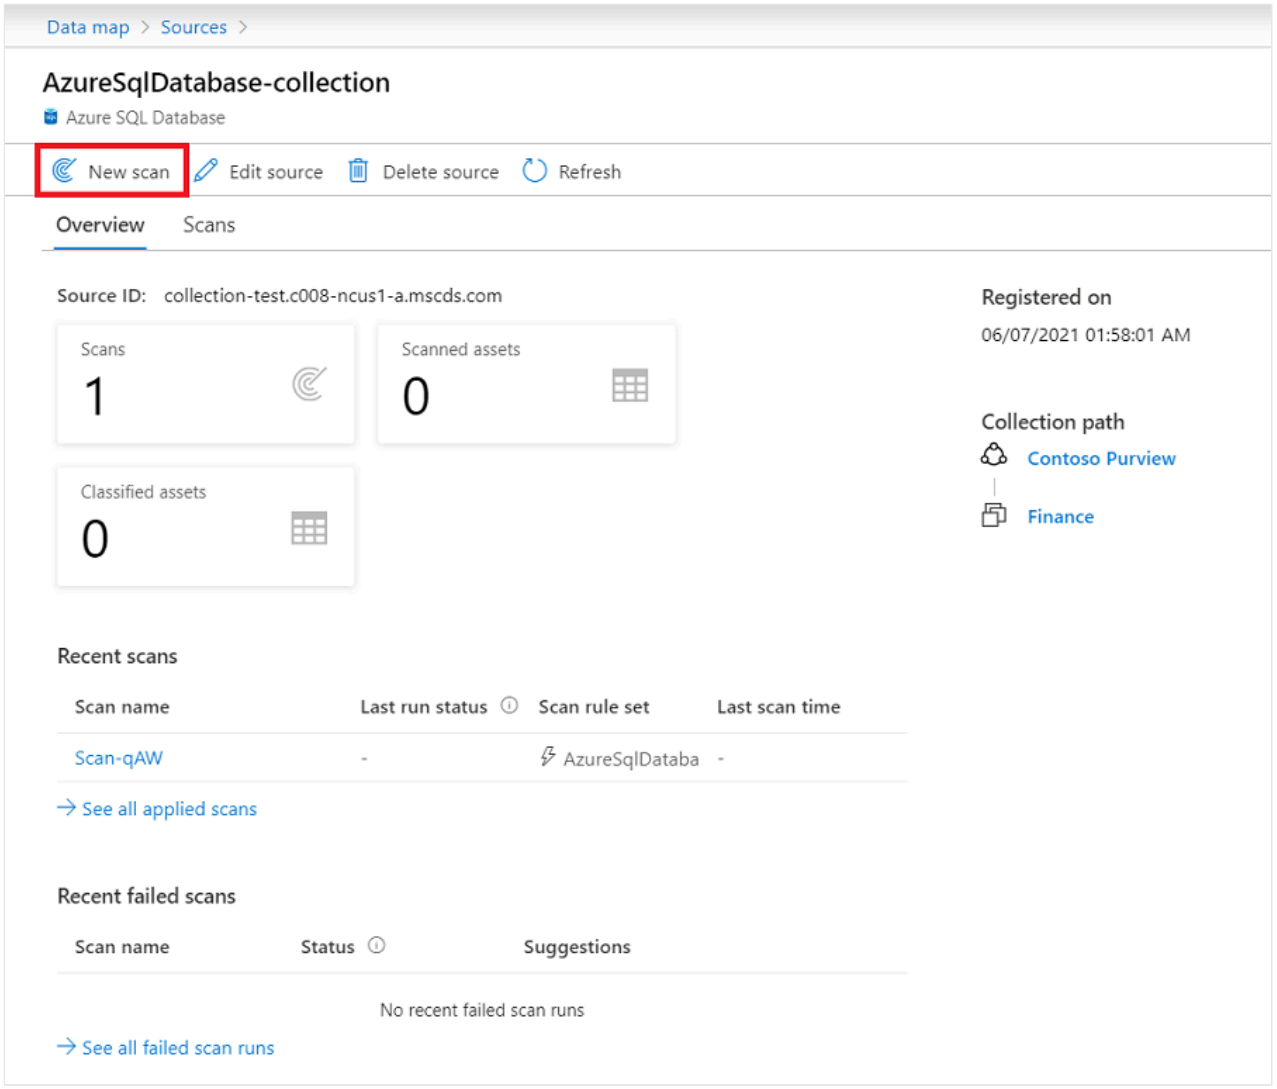
3. Select **Data sources** from the left pane to open the data sources map page.

4. Select **Register** or the register icon on a domain or collection node to register a data source. Only data source admins can register sources.

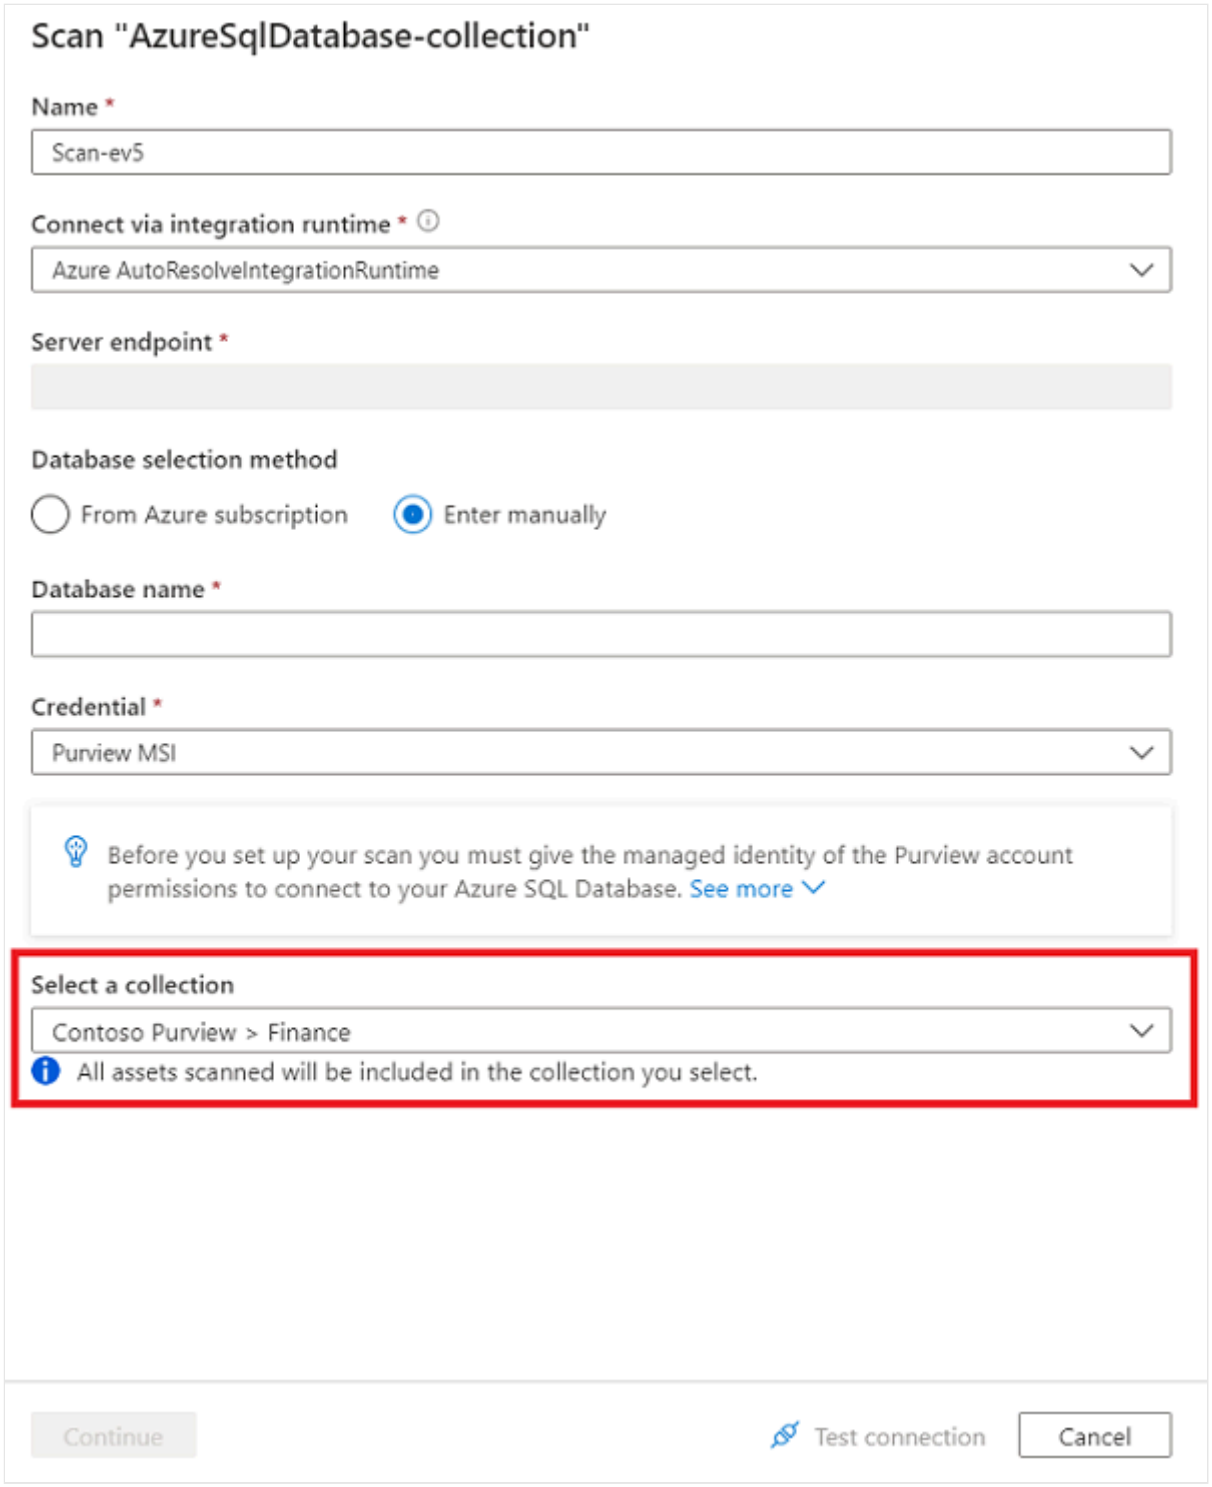


5. Fill in the data source name, and other source information.

6. Select a domain.



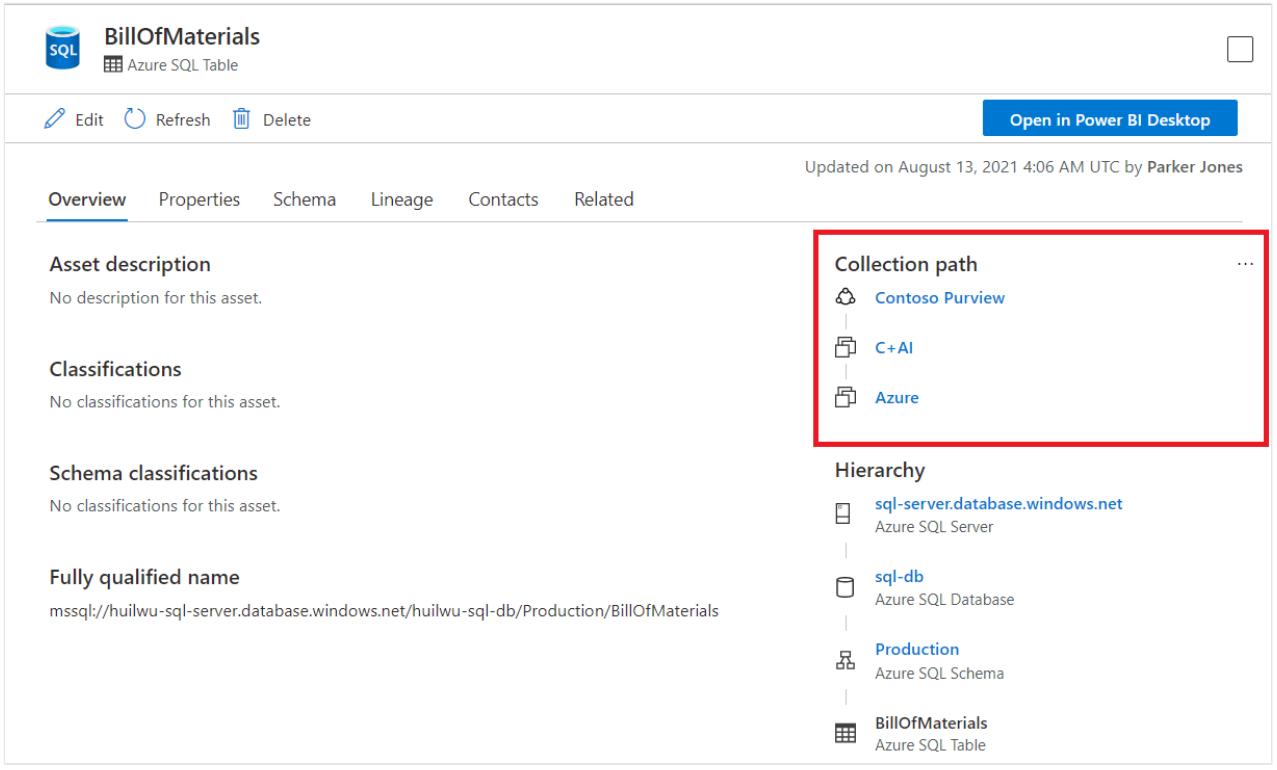
7. Select a collection. To register the resource in the domain, choose the **Select domain only** option. All assets under this source belong to the domain or collection you select.



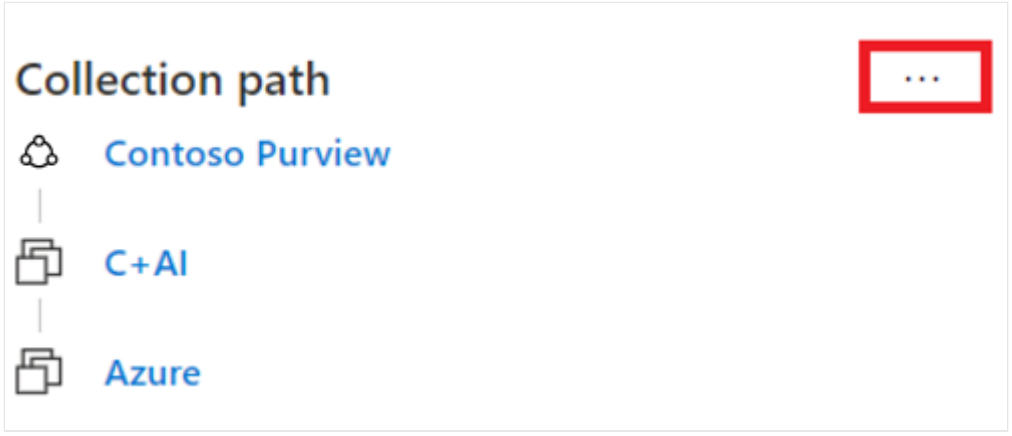
8. The created data source is put under the selected domain or collection. Select **View details** to see the data source.

9. Select **New scan** to create scan under the data source.

10. When creating a scan, you can select a collection and all assets scanned will be included in that collection. Collections listed in a scan are subcollections of the data source collection.



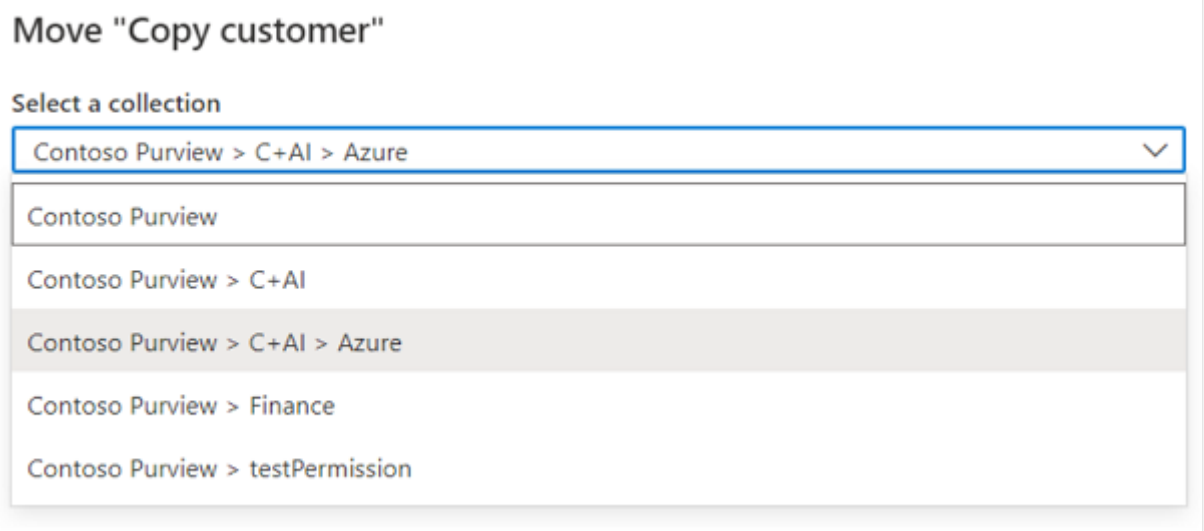
11. After your scan, you'll see the data sources linked to the collection or domain on their data sources card.



Add assets to collection and domains

Assets and sources are also associated with domains and collections. During a scan, if the scan was associated with a domain or collection, the assets are automatically added to that resource, but the assets can also be manually moved to any subcollections (if you have the write permissions on those subcollections.)

1. Check the domain and collection information in asset details. You can find information in the **Collection path** section on right-top corner of the asset details page.



2. Select the ellipsis button on the right-top corner of the **Collection path** section.

3. Select the **Move to another collection** button.

4. In the right side panel, choose the target collection you want move to. You can only see the collections where you have write permissions. The asset can also only be added to the subcollections of the data source collection.

5. Select **Move** button on the bottom of the window to move the asset.

Rename collections

1. In Data Map, navigate to the collection that you want to rename.
2. Select **Edit** either from the collection detail page, or from the collection's dropdown menu.
3. Enter a new friendly name and select **Save**.

Move collections

1. In the Microsoft Purview portal, navigate to the collection that you want to move to a different parent collection.
2. Select the ellipsis button on the right-top corner of collection path section and select **Move to another collection**.
3. From **Select parent collection** dropdown list, select a new parent for the collection and select **OK**.

Best practices

- Domains and collections architecture best practices
- Data Map domains and governance domains best practices

Next steps

Now that you have organized your domains and collections, you can follow these guides below to add resources and scan:

- Manage data sources
- Supported data sources
- Scan and ingestion

Merge a classic Microsoft Purview account to a domain

Article • 05/30/2025

This guide describes how to merge an existing classic Microsoft Purview account into your Microsoft Purview tenant account as a domain. Merge is a one-time process to *copy* the information in your secondary classic Microsoft Purview account into your tenant level account. All the information is incorporated into a new domain. Your existing classic account remains as-is, so you can migrate your managed identity and deactivate and remove the secondary account once you have validated the merge.

Throughout this document, we use the terms **primary account** and **secondary account**:

- **Primary account** - refers to your tenant-level Microsoft Purview instance.
- **Secondary account** - refers to the Microsoft Purview instance you're migrating into your primary account as a domain.

Prerequisites

- Tenant with multiple Microsoft Purview accounts.
- Public network access enabled on your **secondary account** for the merging process.
- A Microsoft Purview account upgraded to the new experience as a primary account.

Limitations

1. Secondary accounts can only be merged once. Any values added to your secondary account after merging will have to be manually added to your primary account. It's recommended you stop using your secondary account after merging and either deactivate or delete the account.
2. Any values or assets added to a secondary account during an active merge aren't guaranteed to be migrated to the primary account. It's recommended you stop update and scanning activities on your secondary account during a merge.

There are also some current limitations that could prevent you from merging your existing Microsoft Purview account as a domain. Review these limitations and the behavior changes to confirm that merging is the correct option for you. The limitations could be updated in the future.

Expand table

Category	Limitation	Potential resolution
	Primary account can only have five domains.	Contact support to provide your business requirement and increase the domain number.
	Either primary account or secondary account has more than 1,000,000 assets.	Remove assets to the allowed limit, choose to filter out the asset category, or contact support to provide your business requirements.
	Secondary account's collection number + primary account's collection number > 400.	Remove or consolidate collections to the allowed limit.
Scan limitations	Secondary account has a user-assigned managed identity (UAMI) scan.	Remove all scheduled UAMI scans from any data sources or filter out the user assigned managed identity category during merge.
	Scan run histories aren't migrated to the primary account.	No resolution.
	Secondary account has private endpoints enabled.	Remove all private endpoints from secondary account or filter out the private endpoint category during merge.
	Secondary account has a self-hosted integration runtimes.	Remove all self-hosted integration runtimes from secondary account or filter out the self-hosted integration runtime category during merge.
	Secondary account has managed virtual networks.	Remove all managed virtual networks from secondary account or filter out the managed virtual networks category during merge.
	Secondary account has "bring your own Event Hubs" configured.	Remove all Kafka configurations from secondary accounts.
	Secondary account has managed Event Hubs enabled and it's actively used in last 30 days.	Disable managed event hub.
	Secondary account has a data factory connection.	Remove data factory connections.
	Secondary account has a data share connection.	Remove all data share connections.
Asset limitations	Secondary account has lineage scans.	Remove all lineage scans from any data sources.
Source limitations	Secondary account has a Website data source registered.	Unregister all Website data sources

Behavior changes

1. Any secondary accounts' scans that use the managed identity (MSI) to scan a data source will keep using the same MSI after migrating to the primary account. So, if the secondary account is deleted after merge, these migrated scans won't work unless you follow the managed identity switchover process after merging.

2. Any secondary accounts' key vault connections that use managed identity (MSI) to connect will keep using the same MSI after migrating to the primary account. So if the secondary account is deleted after merge, these migrated scans won't work unless you follow the managed identity switchover process after merging.

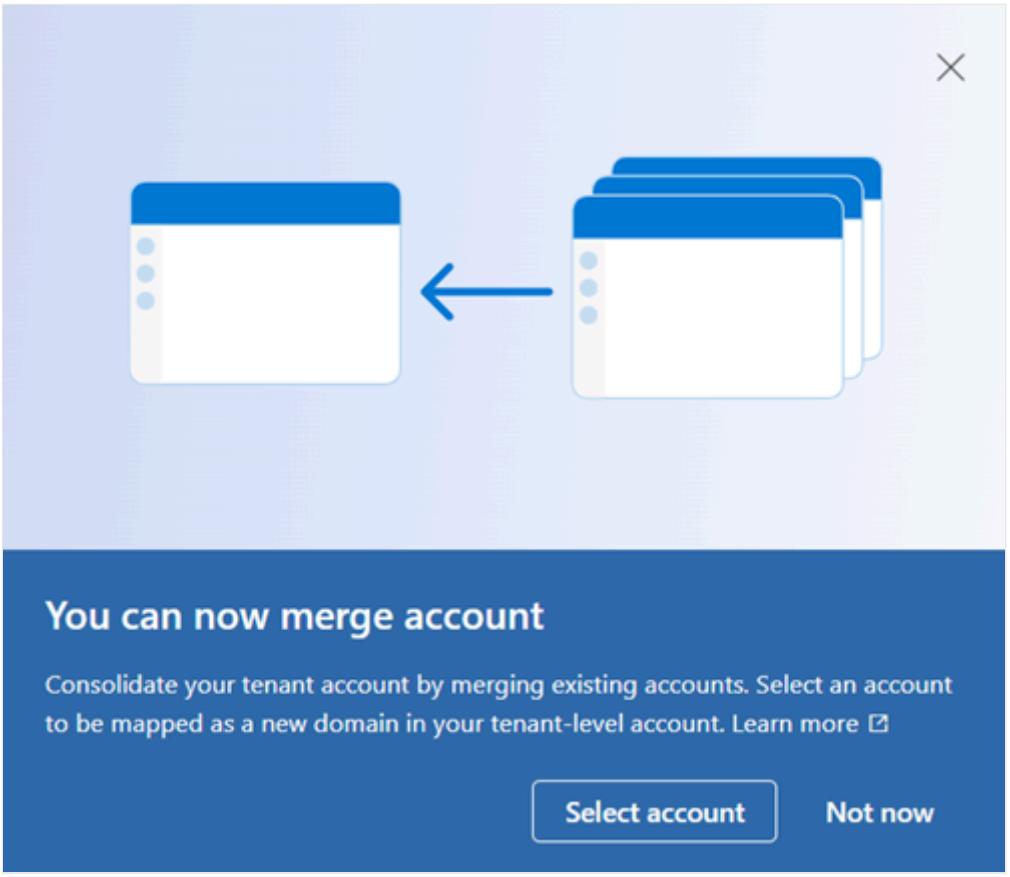
3. If secondary account has a glossary named *Glossary*, the migrated glossary is named *Glossary-{secondary account name}* in the primary account. This behavior could cause glossary conflicts during assessment:

    - Secondary account already has a glossary named *Glossary-{secondary account name}*
    - Primary account has a glossary named *Glossary-{secondary account name}*

4. If the secondary account was created before 7/12/2022 and the primary account was created after this date, after the merge, the scan will populate hierarchical schema types(parquet_schema, json_schema, xml_schema, and delimited_text_schema) rather than tabular_schema.

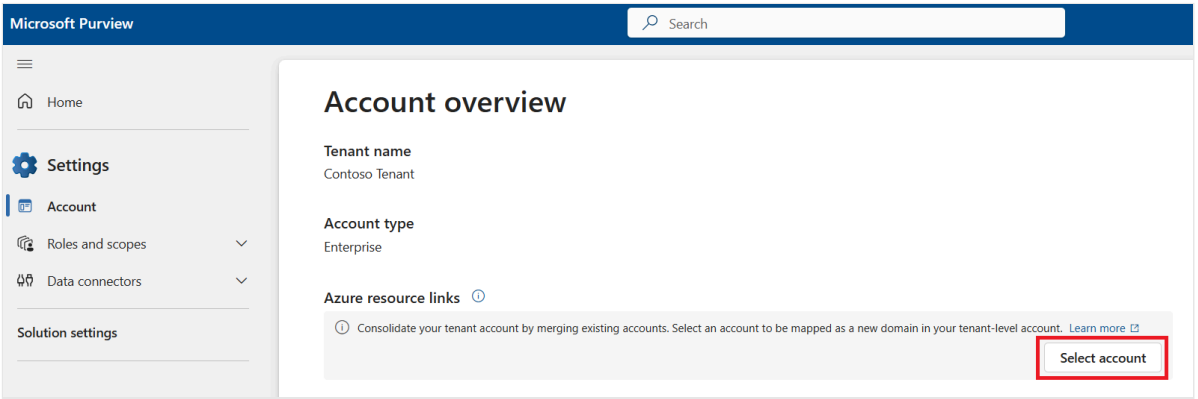
Request account merge

You can request an account merge from your primary account or from the secondary account you want to merge.



> **Tip**
>
> It's recommended to **assess your merge** before requesting a full merge to check for any conflicts or limitations.

Request account merge from the primary account



> **Important**

To request account merge from the primary account, requestors need to be a member of the Purview Administrator role group.

1. Open the Microsoft Purview portal.
2. To select an existing account to be mapped as a new domain in primary account. You can either:
   - Select the **Select account** button in the pop-up.

   - If you're using the classic Microsoft Purview governance portal, open the Management center, navigate to the **Overview** in the General section. If you're using the Microsoft Purview portal, open Settings solution card, select **Account** and then select **Select account** in the alert box.

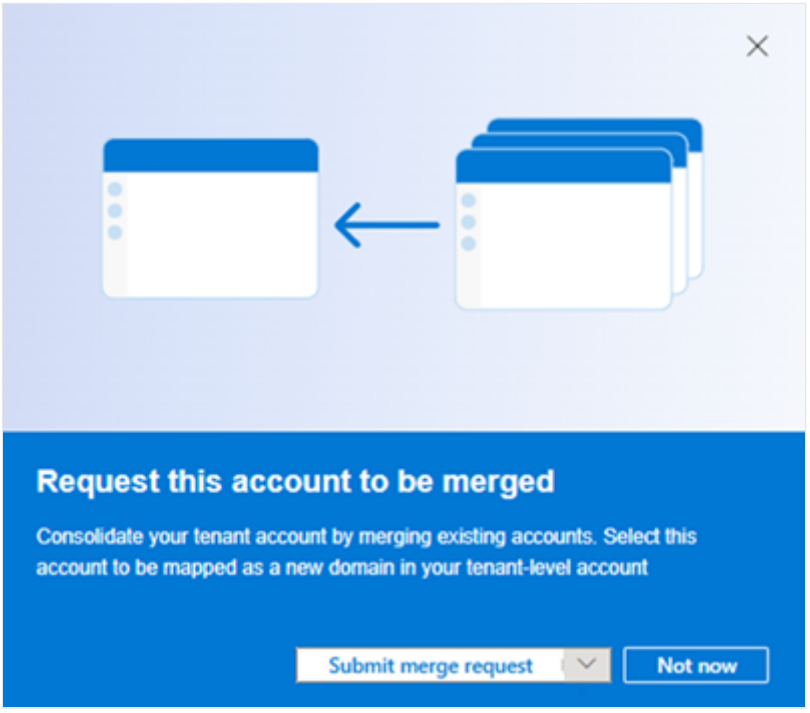
> **Note**
>
> - If a merge is currently in progress within the tenant, then the **Submit request** pop-up and alert box won't appear.
> - If the logged-in user doesn't have the proper permissions to request a merge, the **Submit request** pop-up and alert box won't appear.

3. Select an account to merge. (It's recommended that you perform an assessment before you merge.)

4. Specify categories for the merge filter, and select whether you want to allow auto-resolve for conflicts in that category.

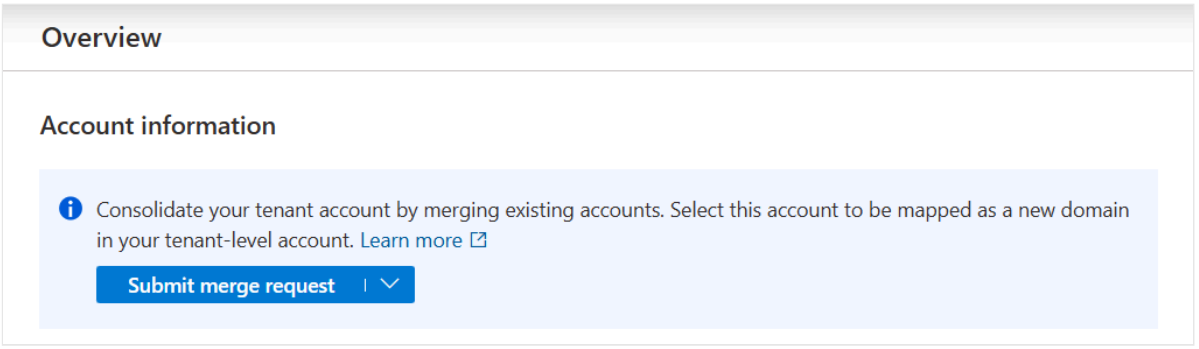
5. Select **Submit**.

6. An assessment runs to confirm if there are any conflicts or limitations, and if the assessment is successful, the merge process begins.



7. You can monitor the merge process from the report page.

> **Important**
>
> Failed merges start the cleanup process to revert everything back to its previous state.



Request account merge from secondary account

> **Important**
>
> To request account merge from the secondary account, requestors need to be either be a Collection Admin on the root collection or an **ARM Resource Owner**, and then they also need to be assigned one of these roles: Compliance Manager Administration, Role Management, Case Management .

1. Open the secondary account's Microsoft Purview portal
2. To select this account to be mapped as a new domain in primary account, you can either:
   - Select **Submit merge request** in the pop-up.

   - Or in the classic Microsoft Purview governance portal, open the Management center, navigate to the **Overview** in the General section, then select the alert box.

> **Note**
>
> - If a merge is currently in progress within the tenant, then the **Submit request** pop-up and alert box won't appear.
> - If the logged-in user doesn't have the proper permissions to request a merge, the **Submit request** pop-up and alert box won't appear.

3. Specify categories for the merge filter, and select whether you want to allow auto-resolve for conflicts in that category.
4. Select **Submit**.
5. The request is sent through an approval process where a Purview Administrator needs to approve the request.
6. After approval, an assessment will run to confirm if there are any conflicts or limitations, and if the assessment is successful, the merge process will begin.
7. You can monitor the merge process from the report page.

> **Important**
>
> Failed merges start the cleanup process to revert everything back to its previous state.

Merge filter

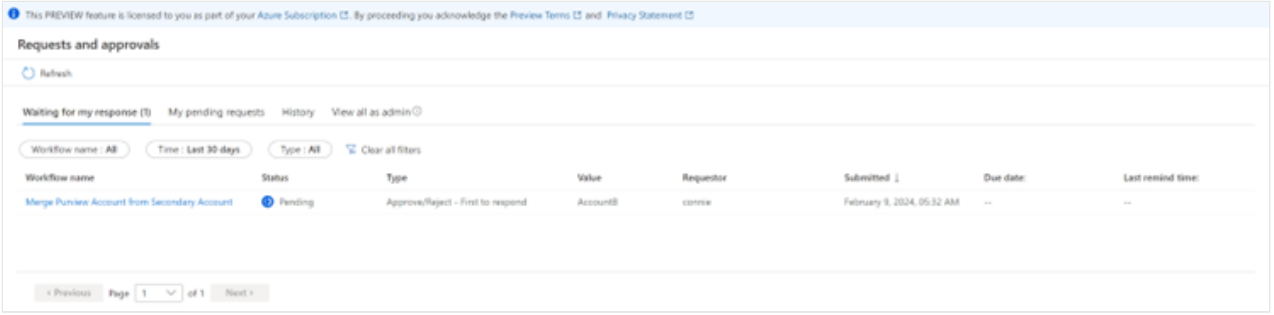
Whenever you merge an account, you can select which objects to migrate and which objects to exclude. In many cases, the filter impacts objects in its own category. However, there are potential behavior changes when you unselect some objects that might apply to associated objects. Some of these categories and the associated behavior changes are listed below:

Expand table

Unselected category	Behavior change
Contact assignment	If unselected, contact assignments configured to glossary terms or assets are removed.
Credential	If unselected, scans that use credentials to scan data sources aren't migrated.
Custom classification rule	If unselected, scans that applied custom classification rules aren't migrated.
Custom scan rule set	If unselected, scans that use applied custom scan rule sets aren't migrated.
Custom type	If unselected: - All custom type assets aren't migrated - All relationships for custom types and affected assets aren't migrated. - All classification instances of custom types attached to glossary terms or assets aren't migrated. - Managed attributes attached to glossary terms or assets are removed.
Glossary	If unselected, workflows applied to glossary or glossary term aren't migrated, and assets won't have associated glossaries.
Key vault connection	If unselected, scans that use key vault credentials to scan data sources aren't migrated.
Managed virtual network	If unselected, scans that use managed virtual network to scan data sources aren't migrated.
Self-hosted integration runtime	If unselected, scans that use a self-hosted integration runtime to scan data sources aren't migrated.
User assigned managed identity	If unselected, scans that use a user assigned managed identity to scan data sources aren't migrated
Resource set rule	If unselected, future assets scanned will have no resource set rule applied util users configure new resource set rules in the primary account.
Contact assignment	If unselected, contact assignments configured to assets and glossary terms are removed.

Approval for account merges

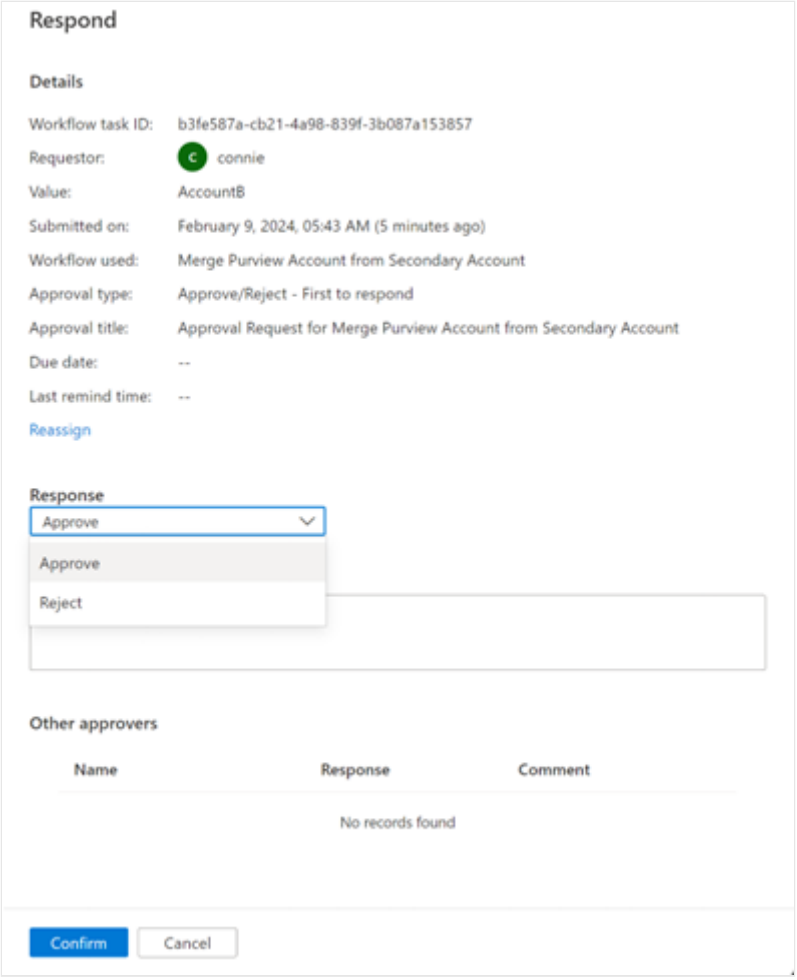
If the merge is requested from the secondary account, it needs to be approved by a Purview Administrator before proceeding with the merge. Purview Administrators receive an email notification to approve the merge request. Alternatively, the merge request can be approved within primary account's Microsoft Purview portal.



> ⓘ **Important**

If the outlook account and Microsoft Purview accounts are in different tenants, approving from the email might fail. In this case, use the Microsoft Purview portal to approve.

1. Open primary account's Microsoft Purview portal.



2. Depending on which portal you're using:

   - If you're using **the Microsoft Purview governance portal**:
     a. Open the Management center
     b. Select **Request and approvals** in the Workflow section.
   - If you're using the **Microsoft Purview portal**:
     a. open Workflows solution card
     b. select **Requests and approvals**.

3. Select the request.

4. Choose your response and select **Confirm**.

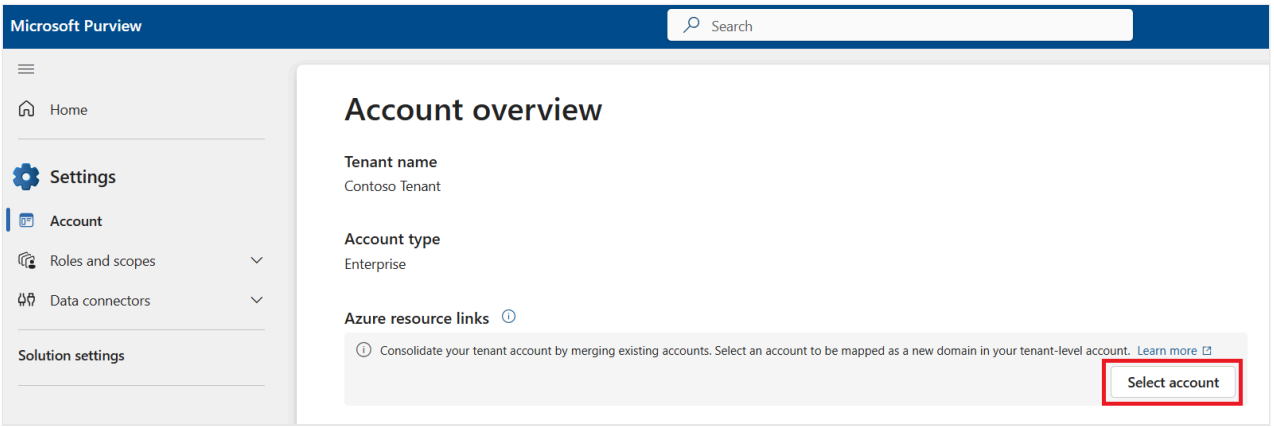
Assess conflicts and limitations

Before you run a merge, Microsoft Purview will assess a secondary account to see if it meets the prerequisites for merging with the primary account. If conflicts/limitations are detected and validation fails, manual intervention is required to proceed with the merge. After assessment, you'll have a report of any conflicts, and you can use our conflicts and resolutions to help resolve them.

Auto-resolve

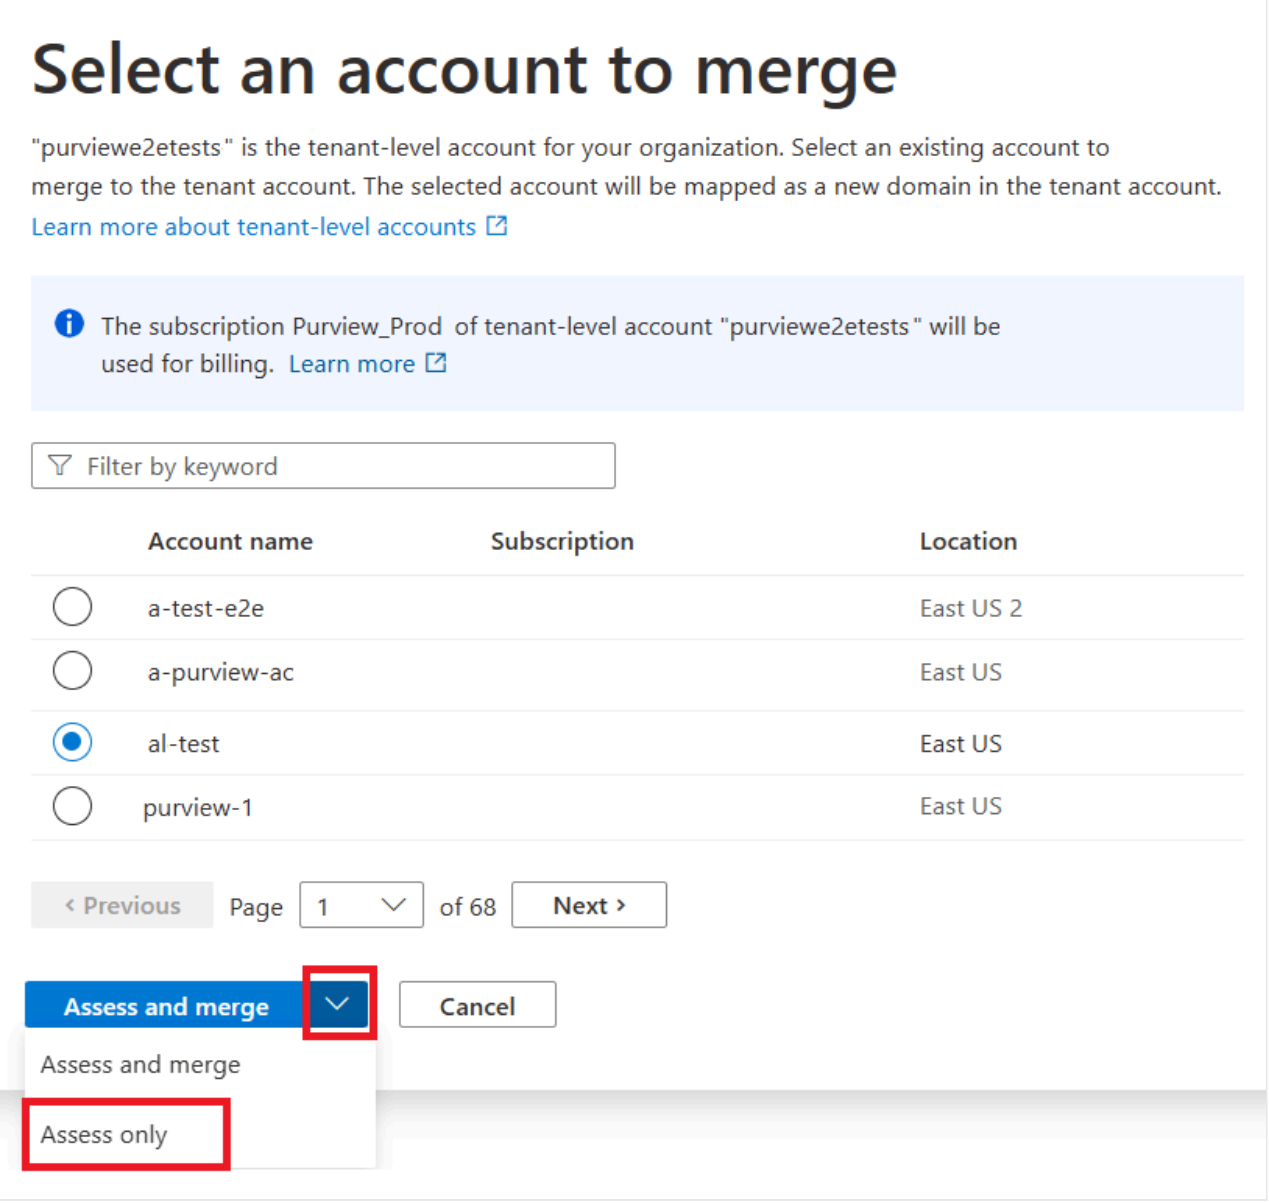
During the Account Merge process, if the auto-resolve rule is set for a category, the system will automatically resolve any conflicts encountered according to the rule. Currently, only the **skip** rule is supported, which means the object causing the conflict is skipped and not moved from the secondary account to the primary account. Any other objects that depend on this object will also be skipped.

For example: If an auto-resolve rule is set for the **Glossary** category, and a Glossary term encounters a conflict, the system will automatically skip the merge of that term, and also skip the merge of any of that term's children.



Any conflicts encountered when auto-resolve is enabled won't be shown as errors in the assessment or merge process, because they'll be automatically resolved according to the rule.

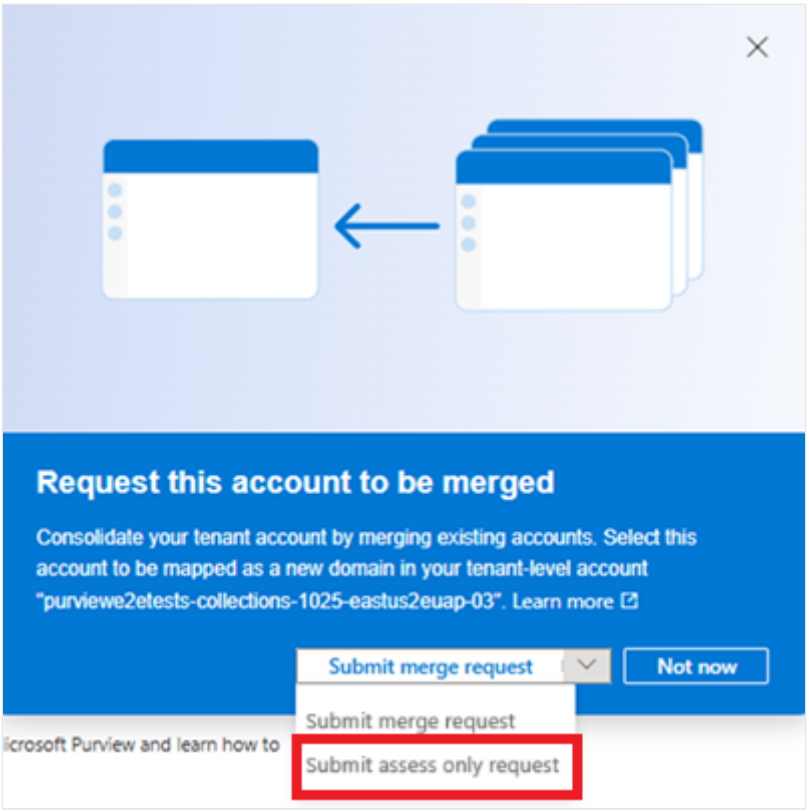
Assessment only



You can submit an account for a merge assessment without merging it, to check for any conflicts.

To run an assessment from your primary account:

1. Open the Microsoft Purview portal.
2. To assess an existing account for merging, if you're using the classic Microsoft Purview governance portal, open the Management center, navigate to the **Overview** in the General section. If you're using the Microsoft Purview portal, open Settings solution card, select **Account** and then select **Select account** in the alert box.



3. Select an account to assess.
4. Select the drop-down on the **Assess and merge** button and select **Assess only**. Only an assessment is run and the merge process won't start afterwards, regardless of the assessment result.

To run an assessment from your secondary account:

1. Select the dropdown in the pop-up and select **Submit assess only request**.

After assessment, you'll have a report of any conflicts, and you can use our conflicts and resolutions to help resolve them.

Conflicts and resolutions

> **Tip**
>
> For many conflicts, three potential options to resolve the issue are:
>
> 1. Remove the conflicting asset from either the primary or secondary account.
> 2. Choose to **filter out** that asset category during merge.
> 3. Select **auto-resolve** to skip migration for conflicting assets.

Here's a table of conflicts and their possible resolutions:

Expand table

Conflict	Potential resolution
Asset with the same qualified name exists in both the primary and secondary accounts.	There are a few options: - Remove the conflicting asset from either primary or secondary account - Choose to filter out the assets category - Select auto-resolve to skip migration when initiating a merge.

Conflict	Potential resolution
Glossary with the same name exists in both the primary and secondary accounts.	Remove the conflict glossary from either the primary or secondary account or filter out the glossary category during merge.
Glossary term with the same qualified name exists in both the primary and secondary accounts.	Remove the conflict glossary term from either the primary or secondary account.
Term template with the same name exists in both the primary and secondary accounts.	Remove the conflict term template from either the primary or secondary account.
Classification rule with the same name exists in both the primary and secondary accounts.	Remove the conflict classification rule from either the primary or secondary account.
Workflow with the same name exists in both the primary and secondary account.	Remove the conflict workflow from either the primary or secondary account.
Key vault connection with the same name exists in both the primary and secondary accounts.	Remove the conflict key vault connection from either the primary or secondary account.
Credential with the same name exists in both the primary and secondary accounts.	Remove the conflict credential from either the primary or secondary account.
Data source with the same data source name registered in both the primary and secondary accounts.	Unregister the conflict data source from either the primary or secondary account.
The same data source registered in both the primary and secondary account.	Unregister the conflict data source from either the primary or secondary account.
Data policy with the same policy name exists in both the primary and secondary accounts.	Remove the conflict policy from either the primary or secondary account: DevOps policy, data owner policy, self-service policy.
Scan rule set with the same name exists in both the primary and secondary accounts.	Remove the conflict scan rule set from either the primary or secondary account.
The same contact assignment exists in both the primary and secondary accounts.	Remove the conflict contact assignment from either the primary or secondary account.
Secondary account has a glossary named 'Glossary' and another glossary named 'Glossary-{secondary account name}'	Remove either 'Glossary' or 'Glossary-{secondary account name}' from the secondary account.
Secondary account has a glossary named 'Glossary' and primary account has a glossary named 'Glossary-{secondary account name}'	Remove 'Glossary' from secondary account or remove 'Glossary-{secondary account name}' from the primary account.
Collections with the same name (not display name) exists in both the primary and secondary accounts.	Remove the conflicting collection from either the secondary account or the primary account.

View merge and assessment reports

You can track the merge progress in real time during the merging process. To view merge report, users need to be a member of Purview Administrator role group.

1. Open the Microsoft Purview portal.
2. Open the Data Map and select **Monitoring**.
3. The merge reports are located on the **Account merging** tab.
4. Select any account name to see full information about its merge or assessment. Select the account name again to collapse its details and see the full account list.

On the report page, you can see the merge statistics summaries:

- Total accounts: Number of accounts that have attempted to merge
- Merging in progress: Accounts currently undergoing merging
- Completed merges: accounts that have successfully merged
- Failed merges: accounts that failed to merge

For any completed assessment, you can rerun an assessment, or rerun an assessment and merge, by selecting **Rerun assessment the assessment details.

Merge and assessment summary

On the account merging page, select an account, and you can view the merge or assessment summary and the detailed progress for that account.

- Assessment: the step that identifies conflicts and limitations between the primary and secondary accounts.

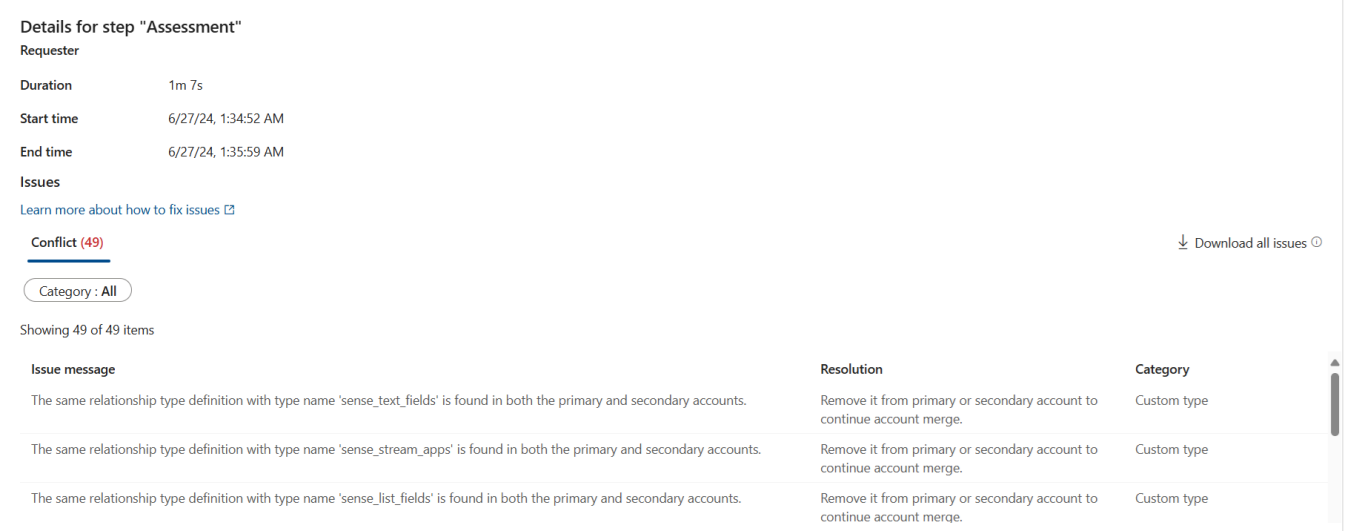
  > **Note**
  >
  > The discovered conflicts and limitations are blocking the merge from proceeding. You must resolve all of them before selecting **Rerun**.

- Migration: the step that copies the objects from the secondary account to the primary account

  > **Note**
  >
  > - Migrated objects in the primary account are invisible, and their associated functions are disabled during this step. For example, scan schedules are disabled

in the primary account during migration and will be enabled before merge complete.

  - Since both the primary and secondary accounts remain operational during the merge, there might be new conflicts and limitations. In such cases, migration will fail and automatic cleanup be triggered to roll back the state of the primary account back to its state before the merge.



- Cleanup: the step that is automatically triggered to clean up migrated objects from the primary account in case the prior step **Migration** fails.
- PostMigration: the step involves preparation work before merge completes.

You can also view detailed merge progress at object category level under a step (Assessment/Migration/PostMigration/Cleanup).

> **Tip**
>
> Objects that were filtered to not be merged will show as **Skipped** in the report.

You can view issues details by selecting **View details**. It lists all conflicts and limitations detected during the assessment, as seen in this example:

Use filters to examine conflicts and limitations within selected categories.

Download report

You can download all conflict details for any failed assessment.

1. Go to **Data Map** -> **Monitoring** -> **Account merging**.
2. Select the secondary account's assessment.
3. Select the link in the **Issues** column.
4. Select **Download all issues** to download the conflict detail report that has **Description**, **Object category**, **Resolution**, and **Type** columns.

> **Tip**
>
> Objects that were **filtered to not be merged** will show as **Skipped** in the report.

After merge completion

After the merge has successfully completed, a new domain will appear in the primary account. It could take a few minutes before the domain appears. Its display name is the root collection's friendly name of the secondary account. This contains all the domain level data migrated from the secondary account.

Next, you should switch over your managed identity connections from your secondary to your primary account using the managed identity switchover process.

After merger completion, the merged account still incurs billing. To prevent billing through the merged account, you can either:

- Delete the account, or

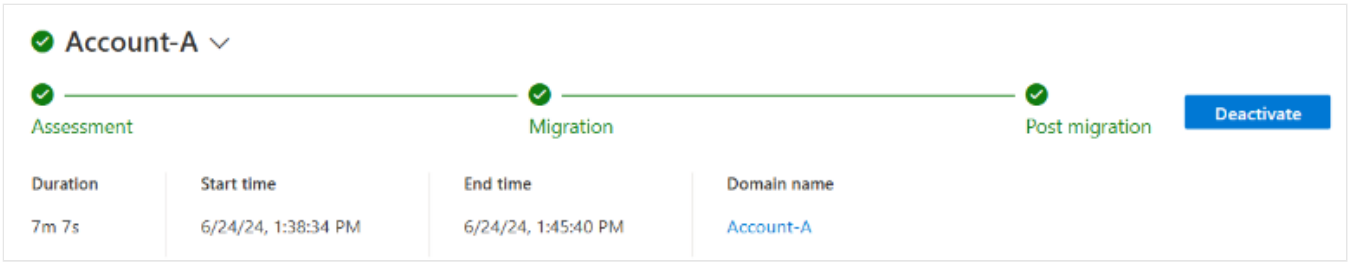
- Deactivate the account.

Hard deletion of merged secondary account

Hard delete the Purview account will also delete System Assigned Managed Identity associated with the secondary account. To ensure your scans and resources will connect after deletion of the secondary account, you can use the managed identity switchover process to migrate your resources to the primary account's managed identity.

1. Open the Azure portal and select your Microsoft Purview account.
2. Select the **Delete** button and confirm the request.
3. Wait for the deletion to successfully complete.

After hard deleting the account:



- Migrated scans that use secondary account's system assigned managed identity to access data source won't work in the Primary account.
- Migrated key vault connections that use secondary account's system assigned managed identity to access key vaults won't work in the Primary account.

Deactivate merged secondary account

If you want to stop billing on your secondary account, or you want to use secondary account's system assigned managed identity to access data sources and key vaults in the primary account, you can choose to deactivate the secondary account after merge complete. After the account is deactivated, the data plane operations for this account will be blocked and billing will stop. To switch your sources and scans to the primary managed identity, use the managed identity switchover process.

> ⊗ **Caution**
>
> Once an account is deactivated, it can't be reactivated.

1. Open secondary account's Microsoft Purview portal.
2. Open Data Map and select **Monitoring**.
3. Select the **Account merging** tab.
4. Select **Deactivate**.

Managed identity switchover

When a secondary account is merged into the tenant-level account, switching your managed identity to the new tenant account is a required step to use the self-hosted integration runtime (SHIR), and is still highly recommended even if you're not. Once the secondary account is deleted, any scans or key vaults that use its managed identity will fail.

To switch your scans and resources from your secondary accounts' managed identity to your primary account's managed identity, follow the steps below. Users must hold the Domain admin role in order to perform these functions.

1. Ensure that your primary/tenant-level Microsoft Purview account's managed identity has access to the migrated sources and connections.
2. You can start the switchover from:
    a. The domain overview in your secondary account
        i. If your secondary account was using its own managed identity, on the domain overview page there's a **Switch managed identity button**. Select it.
        ii. Select **Confirm**
        iii. Once the switchover is completed, you receive a notification.
    b. On the create/edit scan page of your secondary account
        i. Once a merge has been completed, on the secondary account's scan pages there's a notification that asks you to confirm switching your managed identity.
        ii. Select **Confirm**
        iii. Once the switchover is completed, you receive a notification.
    c. On the create/edit key vault connection page in your secondary account
        i. Once a merge has been completed, on the secondary account's key vault connection page there's a notification that asks you to confirm switching your managed identity.
        ii. Select **Confirm**
        iii. Once the switchover is completed, you receive a notification.

Billing

After merge completion, billing for the secondary account will be consolidated with the primary account and will be charged to the primary account's subscription. However, until you deactivate the secondary account, its billing will still be applicable to its subscription.

> **Tip**
>
> Once you've merged your secondary account, **deactivate** and then delete it to reduce billing.

- Manage domains and collections

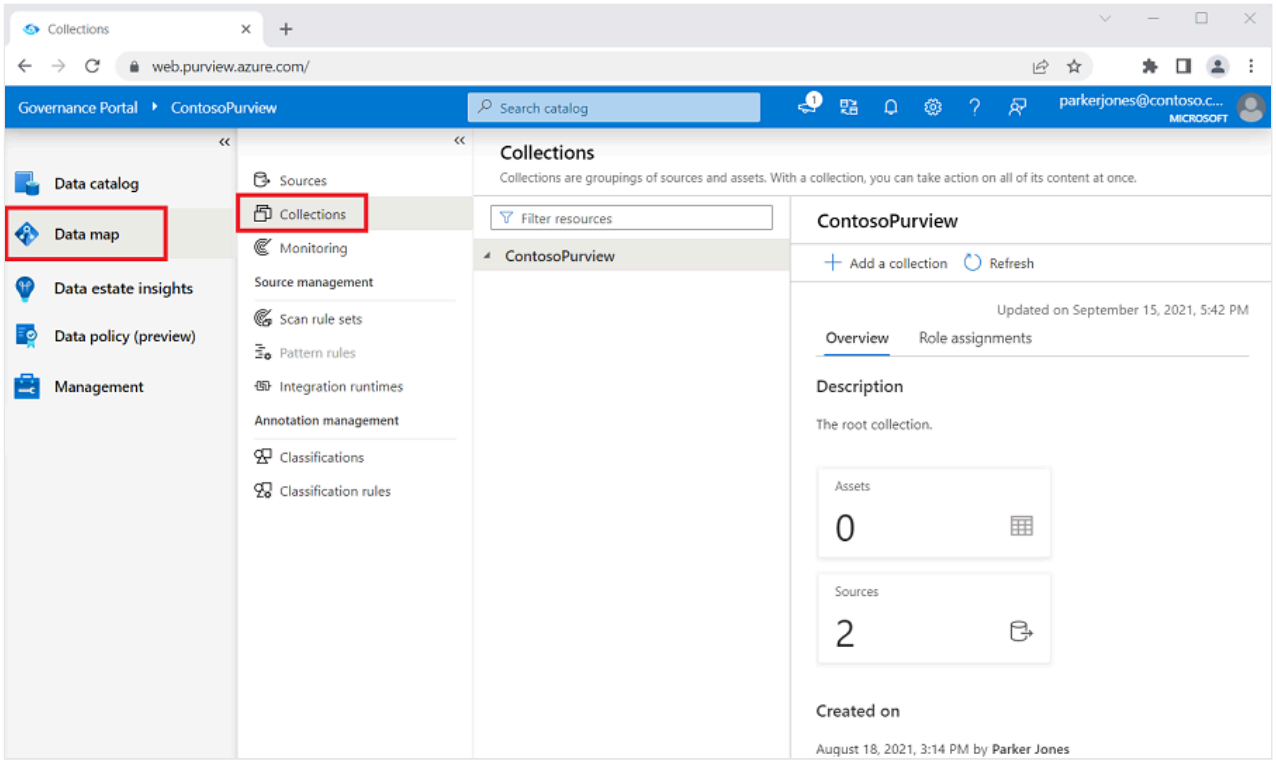
Create and manage collections in Microsoft Purview Data Map (classic)

Article • 05/30/2025

> **Tip**
>
> If you're using the new **Microsoft Purview portal experience**, refer instead to **how to create and manage domains and collections** .

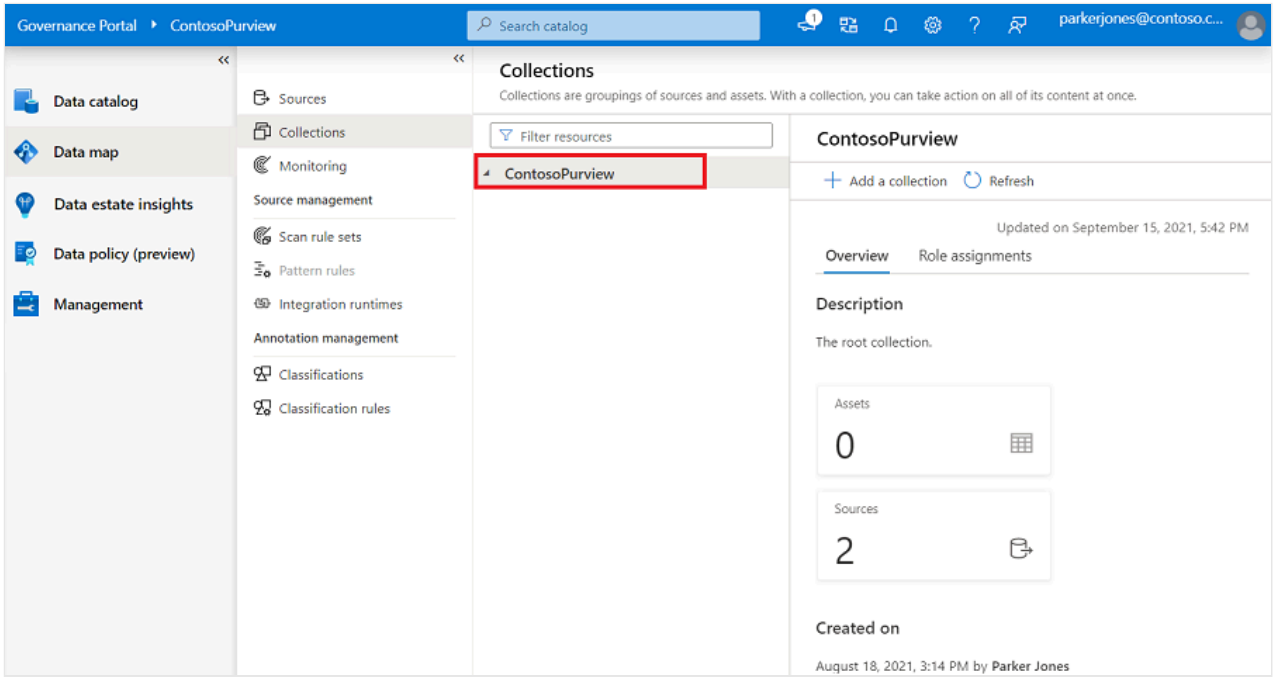
Collections in the Microsoft Purview Data Map can be used to organize assets and sources by your business's flow. They're also the tool used to manage access across the classic Microsoft Purview governance portal. This guide will take you through the creation and management of these collections, as well as cover steps about how to register sources and add assets into your collections.

Prerequisites



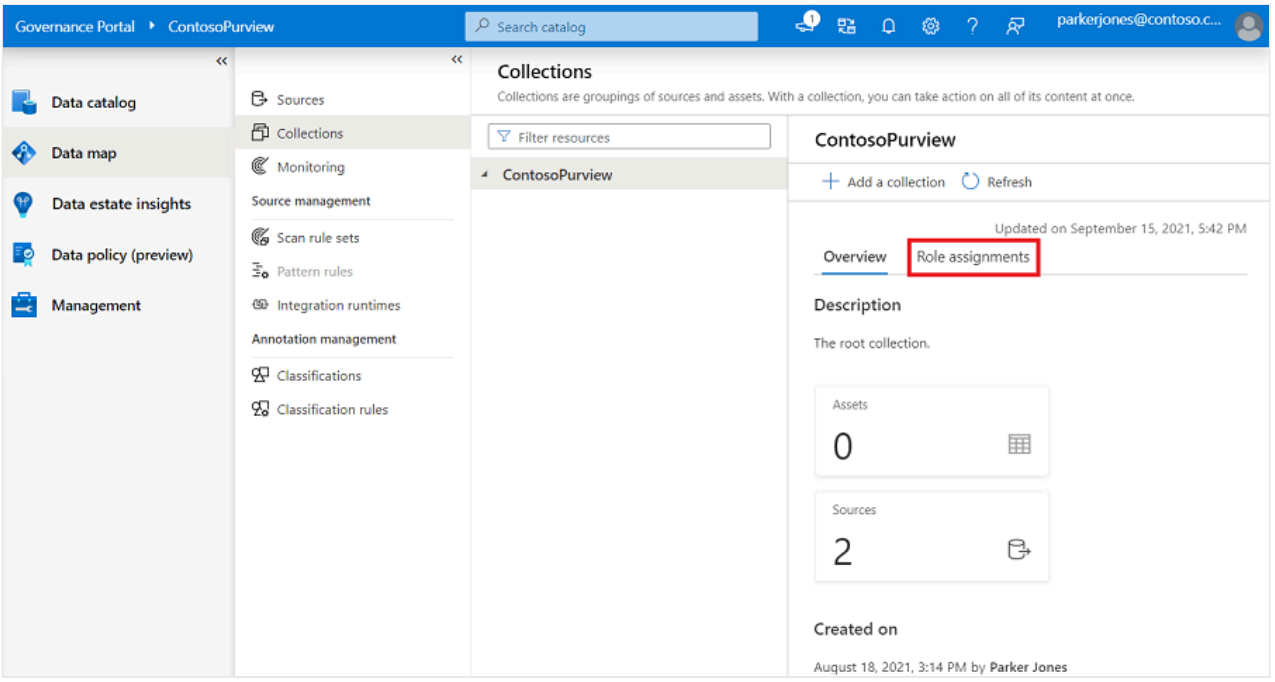
- An Azure account with an active subscription. Create an account for free .
- Your own Microsoft Entra tenant.
- An active Microsoft Purview (formerly Azure Purview) account.

Check permissions

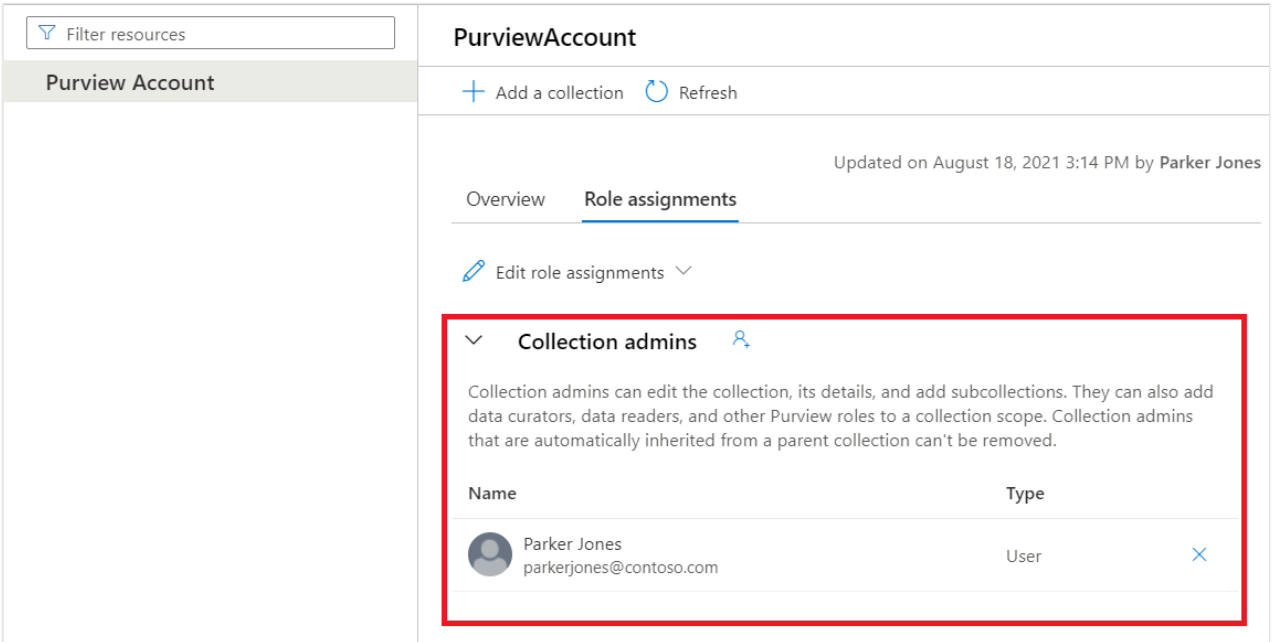


In order to create and manage collections in the Data Map, you'll need to be a **Collection Admin** within the classic Microsoft Purview governance portal. We can check these permissions in the classic Microsoft Purview governance portal . You can find the portal by:

- Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
- Opening the Azure portal , searching for and selecting the Microsoft Purview account. Selecting the **Microsoft Purview governance portal** button.



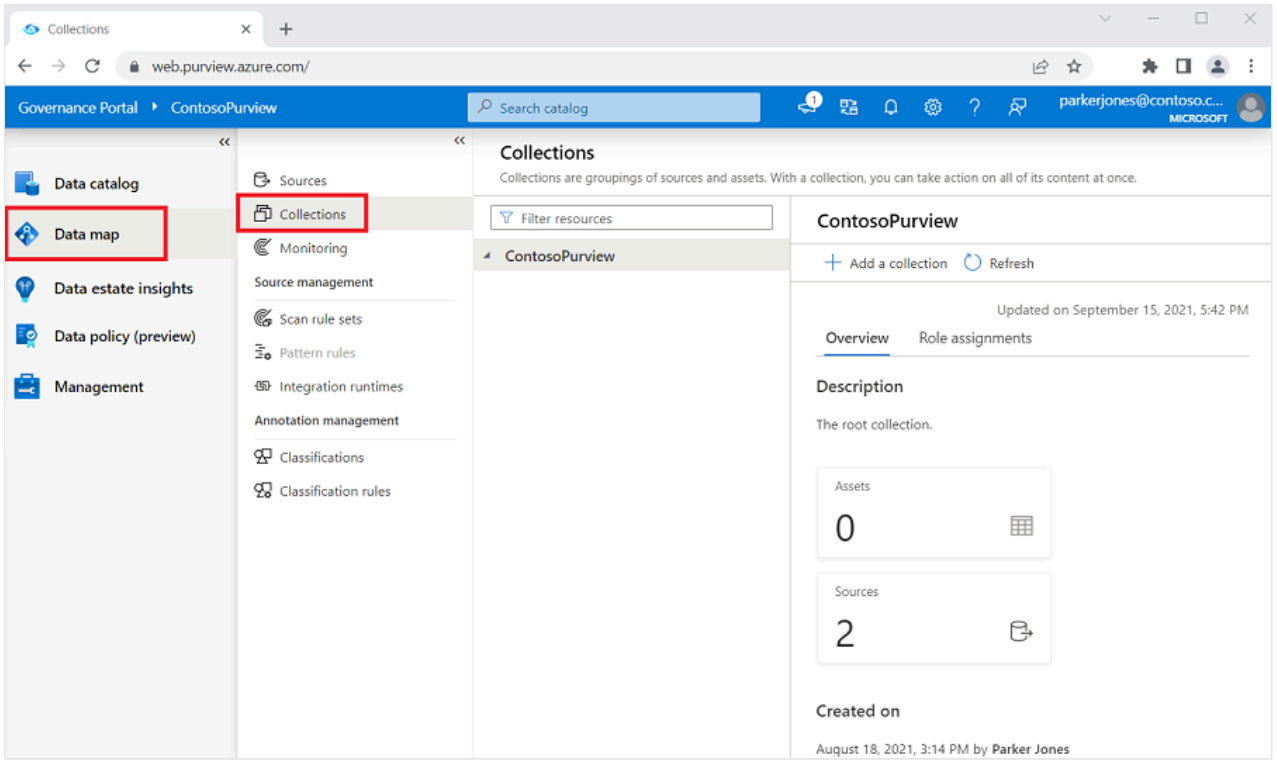
1. Select Data Map > Collections from the left pane to open collection management page.



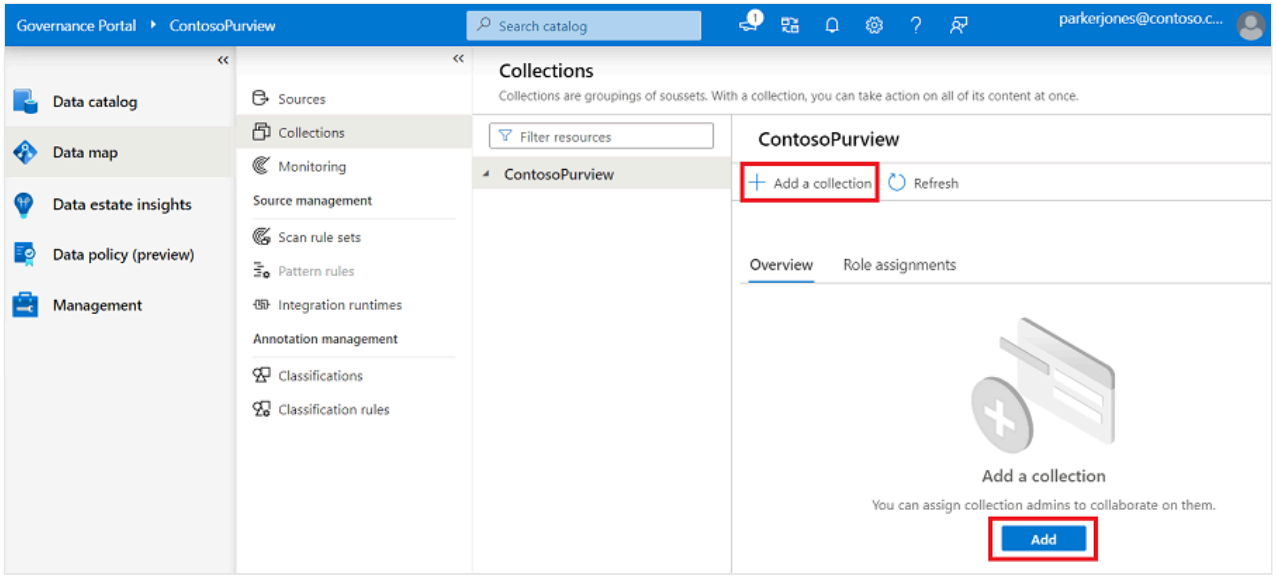
2. Select your root collection. This is the top collection in your collection list and will have the same name as your account. In the following example, it's called Contoso Microsoft Purview. Alternatively, if collections already exist you can select any collection where you want to create a subcollection.

3. Select **Role assignments** in the collection window.

4. To create a collection, you'll need to be in the collection admin list under role assignments. If you created the account, you should be listed as a collection admin under the root collection already. If not, you'll need to contact the collection admin to grant your permission.



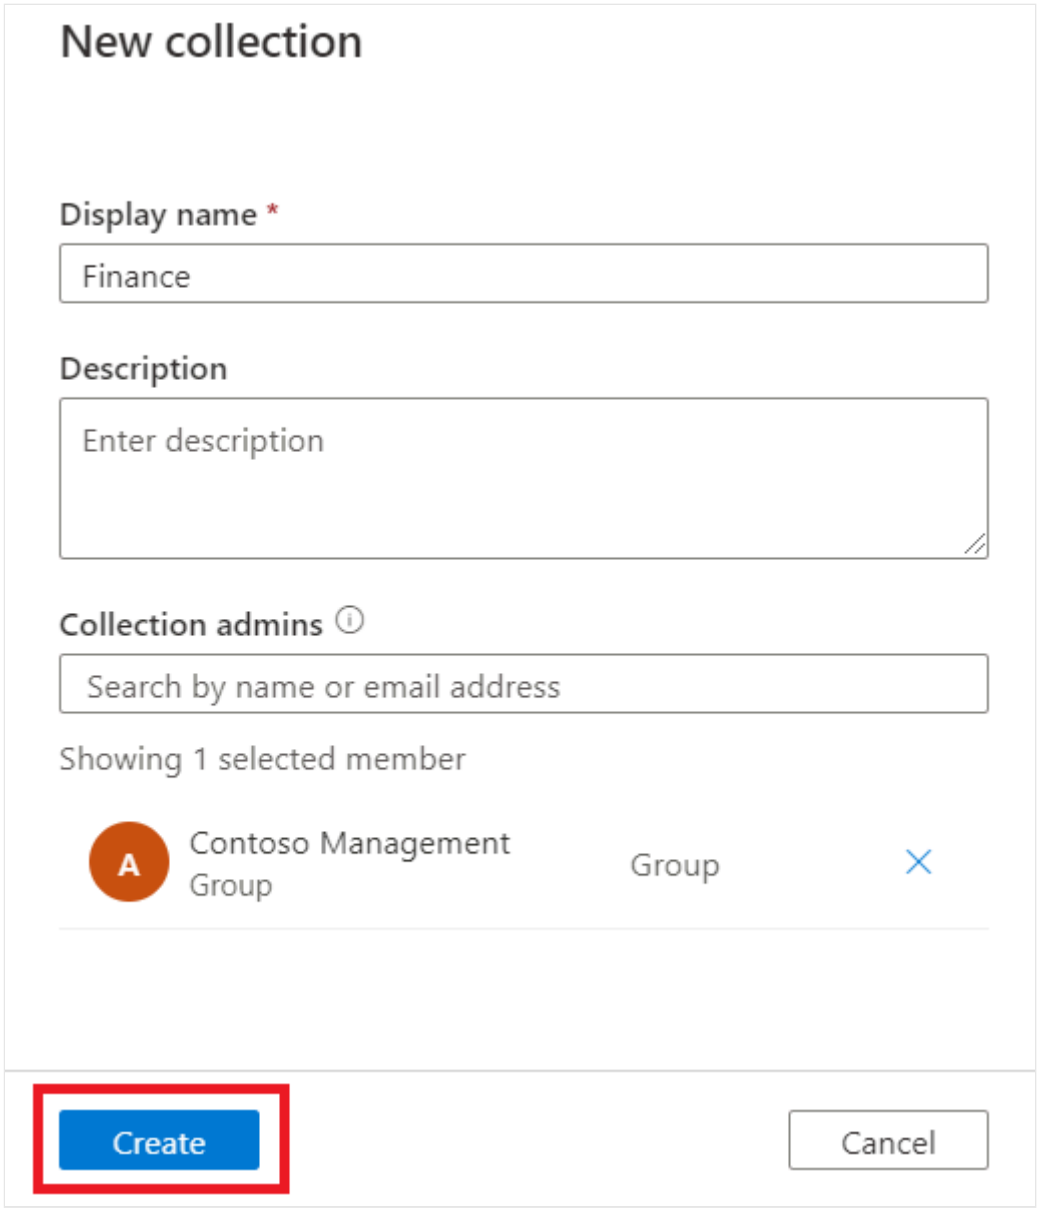
Collection management



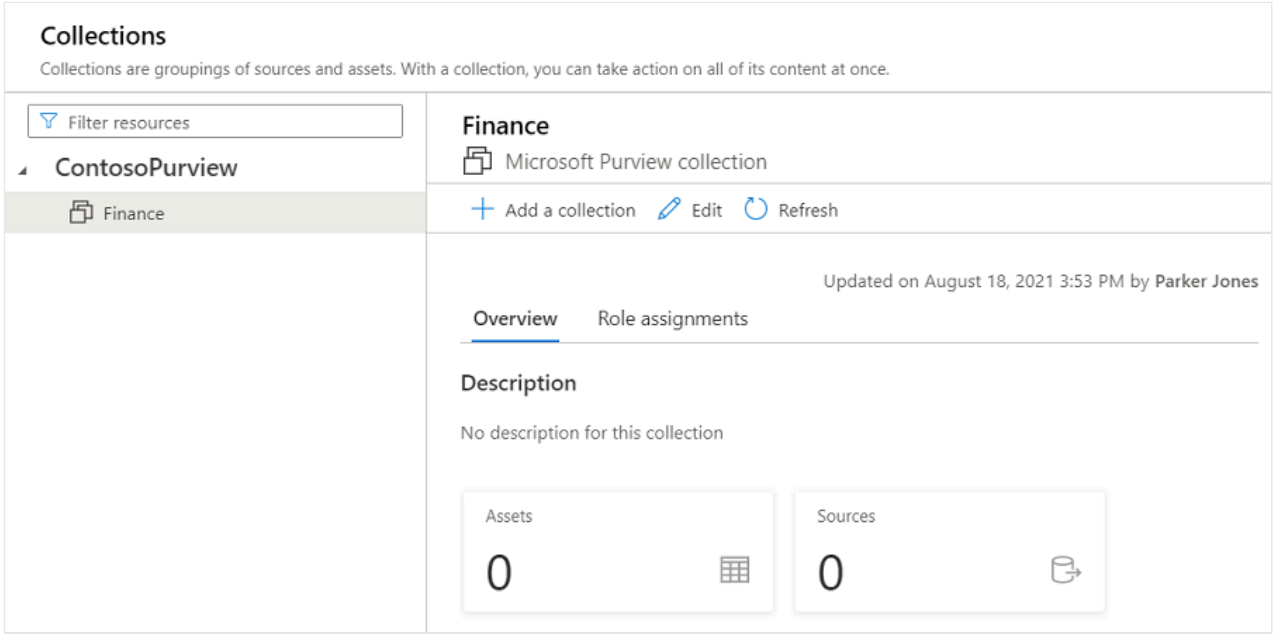
Create a collection

You'll need to be a collection admin in order to create a collection. If you aren't sure, follow the guide above to check permissions.

1. Select Data Map > Collections from the left pane to open collection management page.

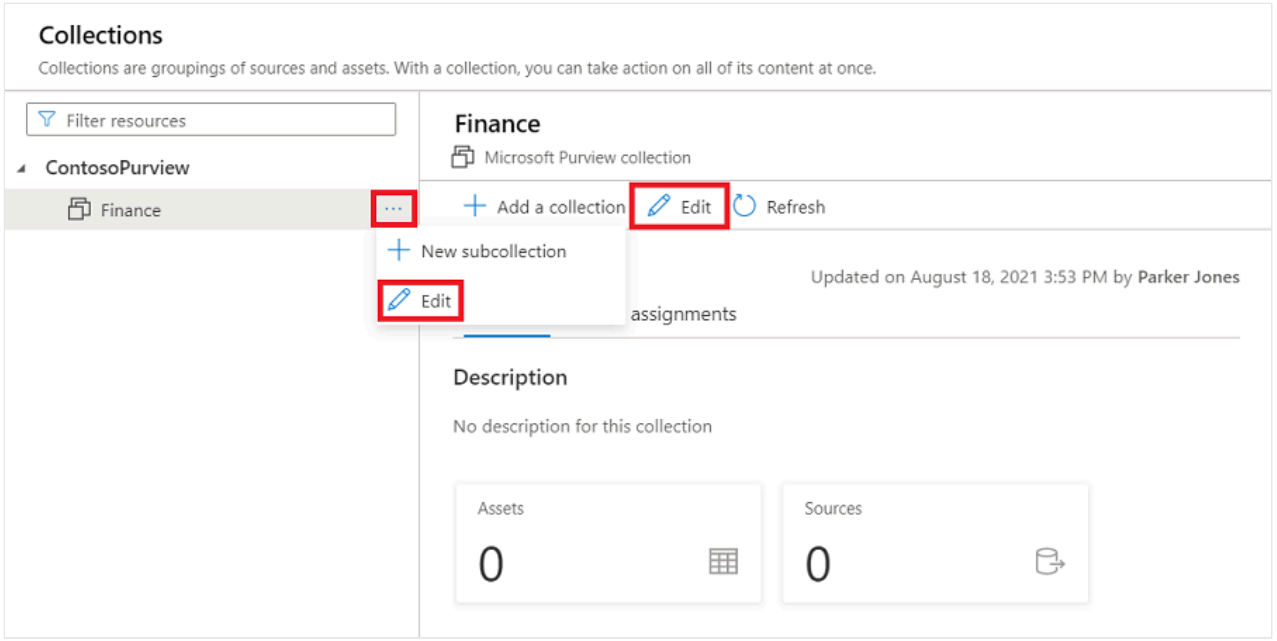


2. Select + **Add a collection**. Again, note that only collection admins can manage collections.

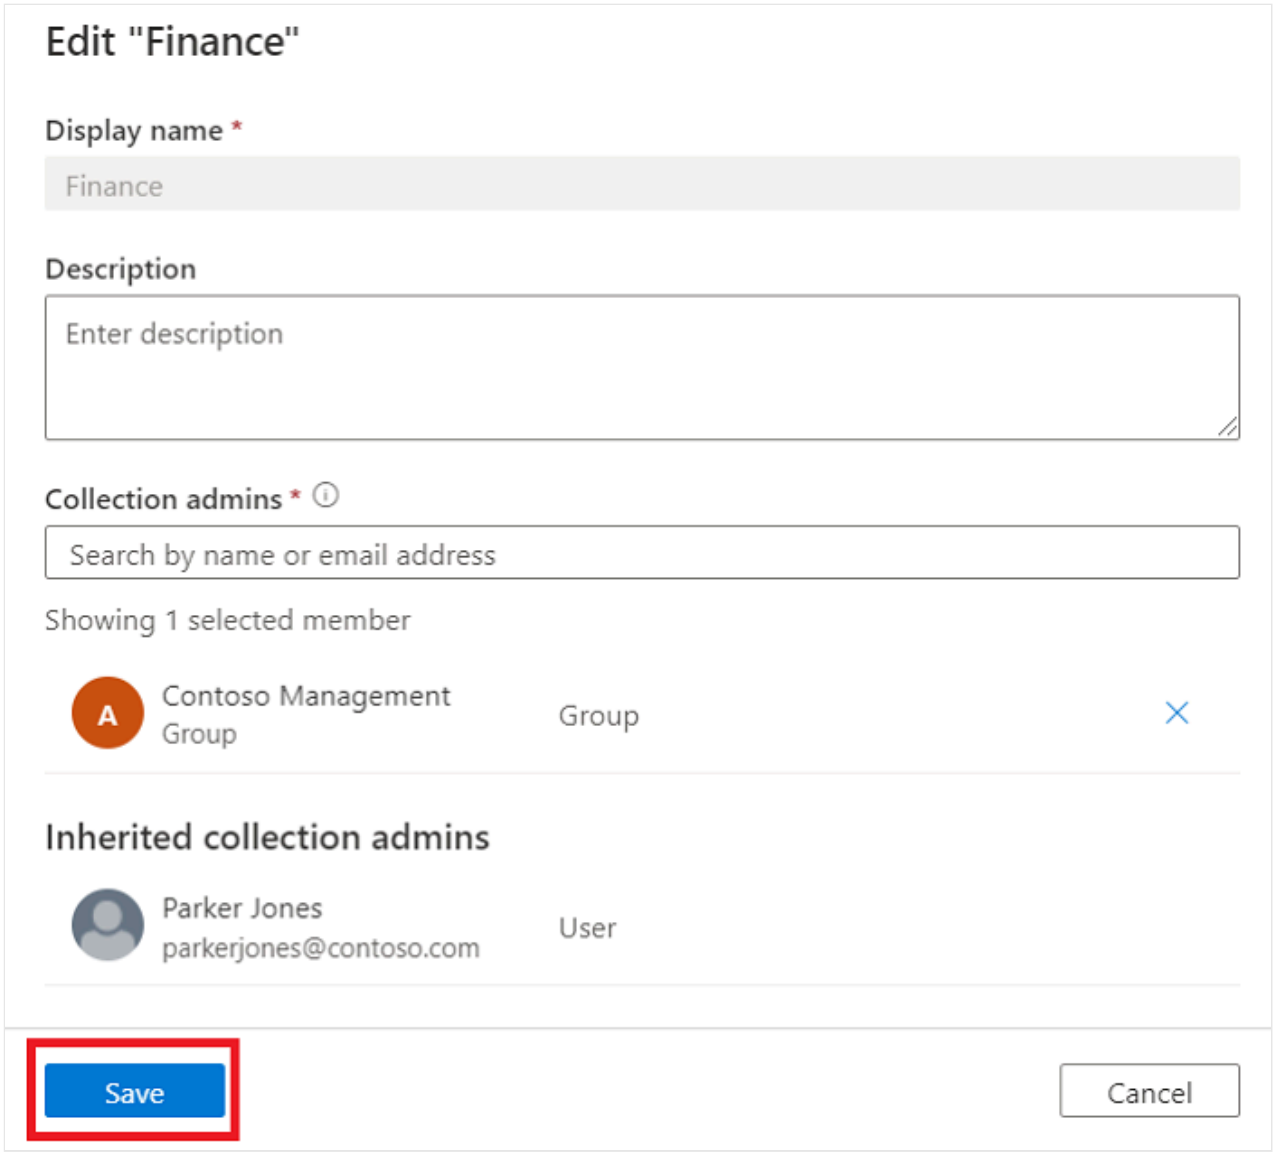


3. In the right panel, enter the collection name and description. If needed you can also add users or groups as collection admins to the new collection.

4. Select **Create**.

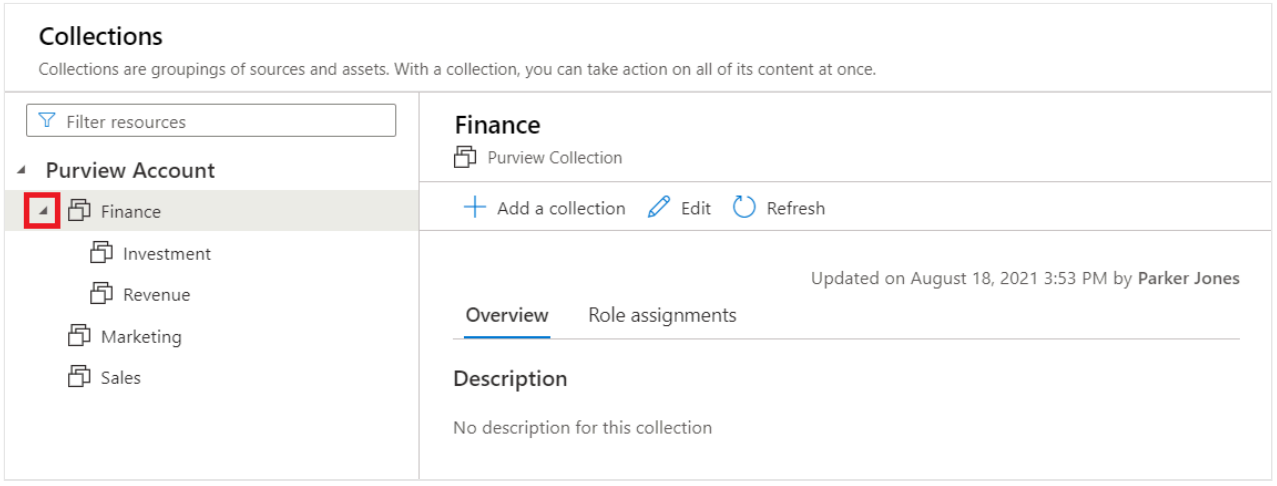


5. The new collection's information will reflect on the page.

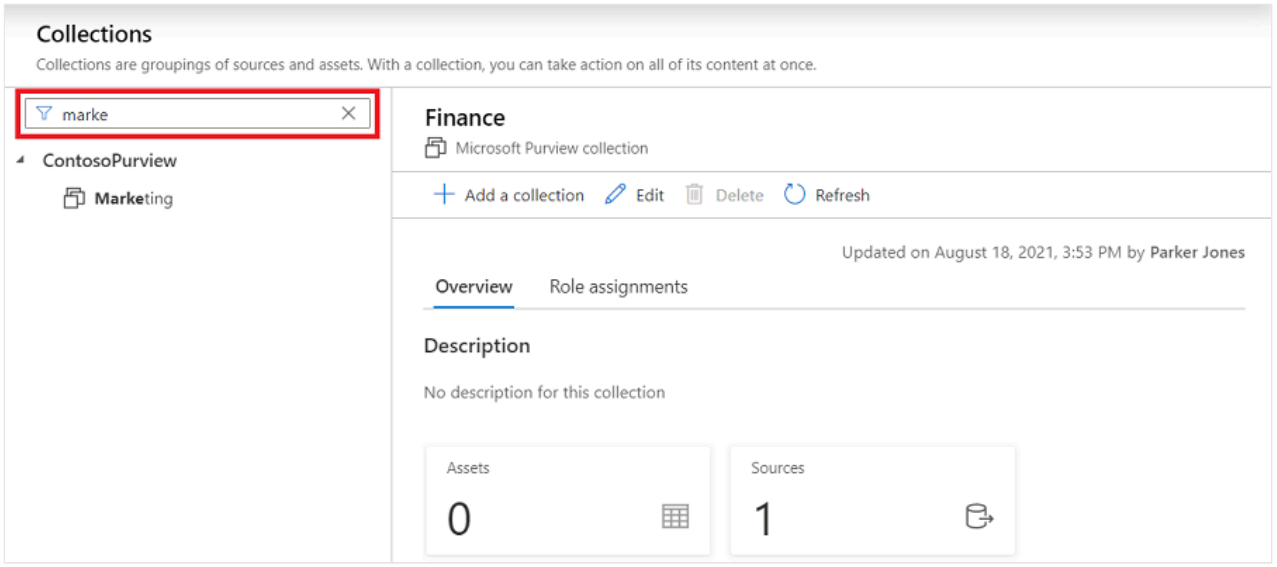


Edit a collection

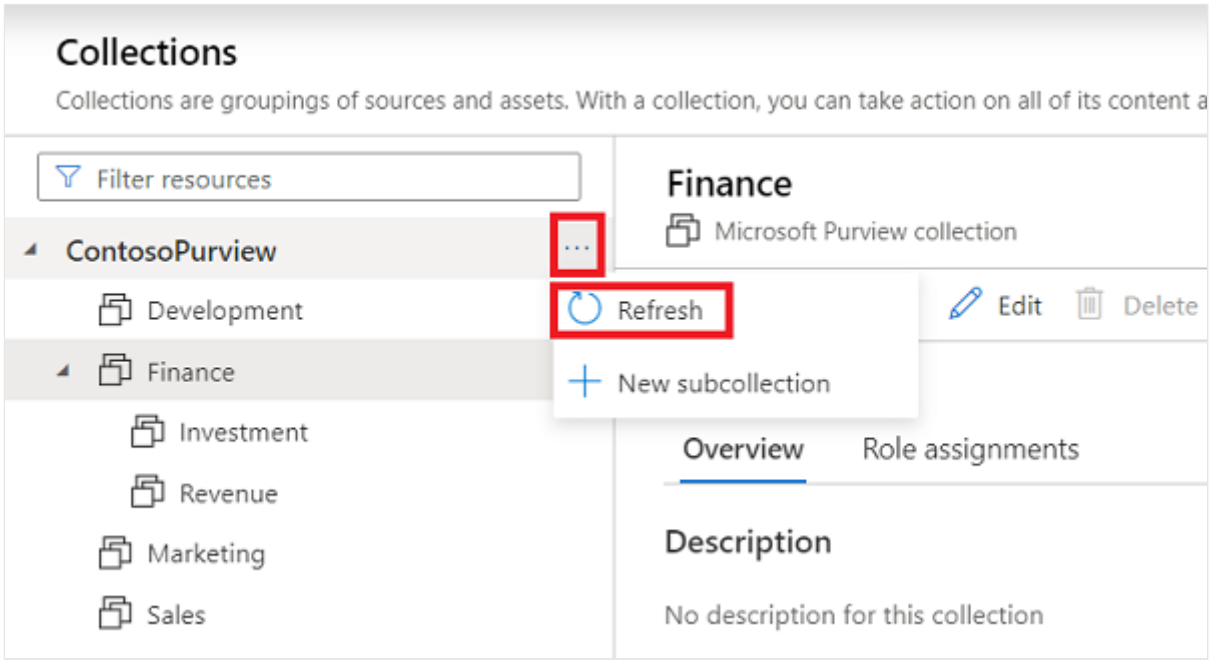
1. Select **Edit** either from the collection detail page, or from the collection's dropdown menu.



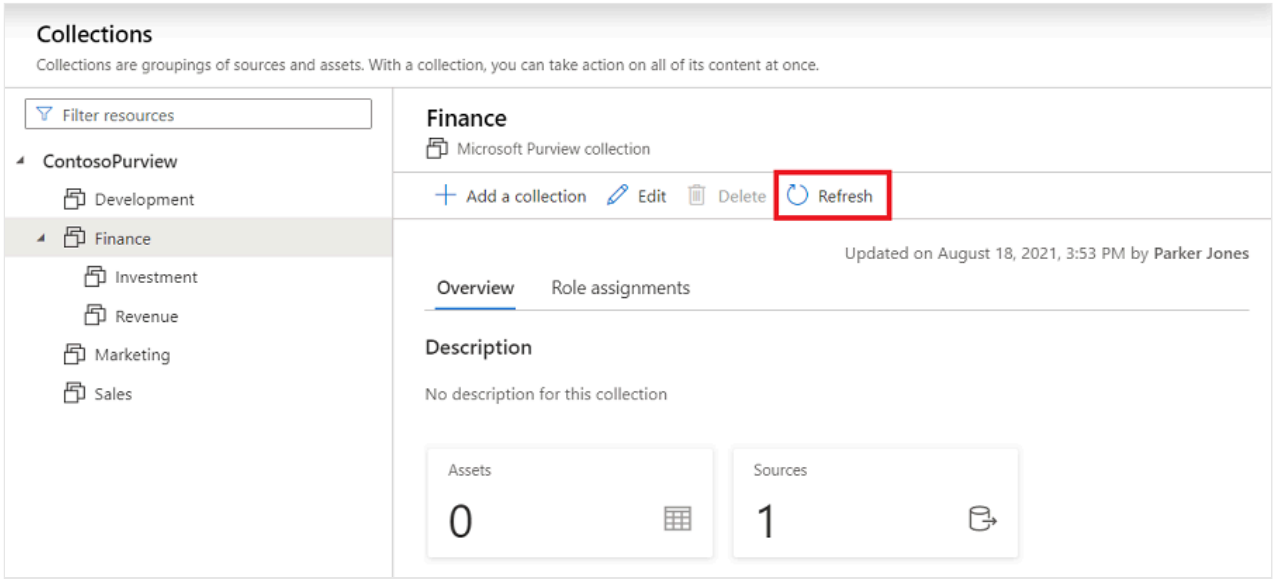
2. Currently collection description and collection admins can be edited. Make any changes, then select **Save** to save your change.



View Collections

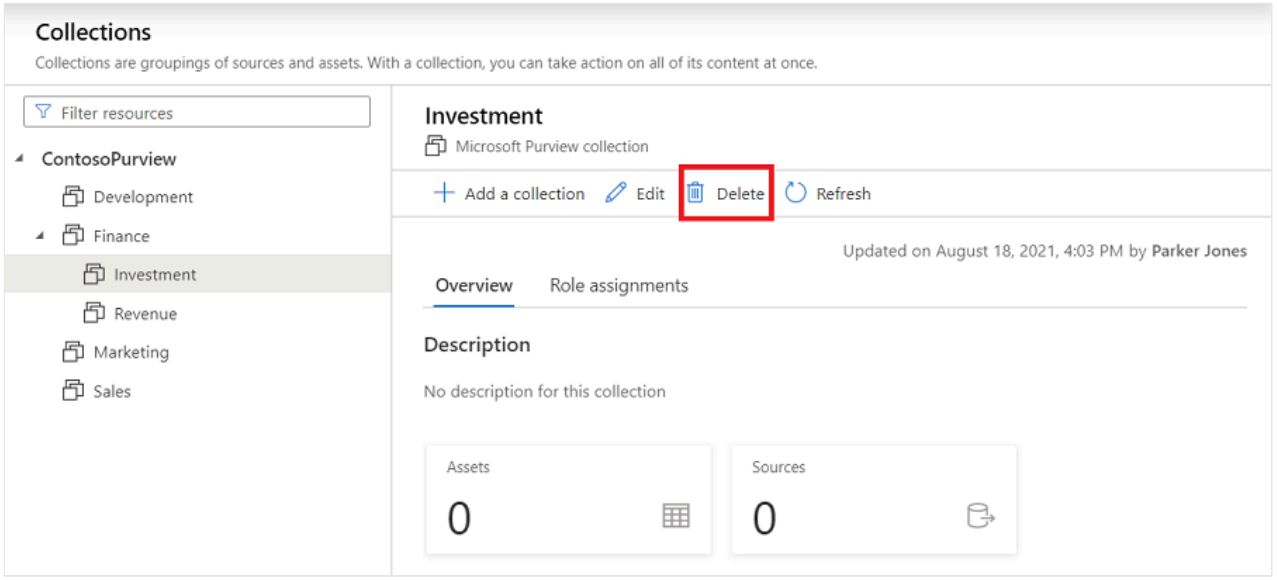


1. Select the triangle icon beside the collection's name to expand or collapse the collection hierarchy. Select the collection names to navigate.

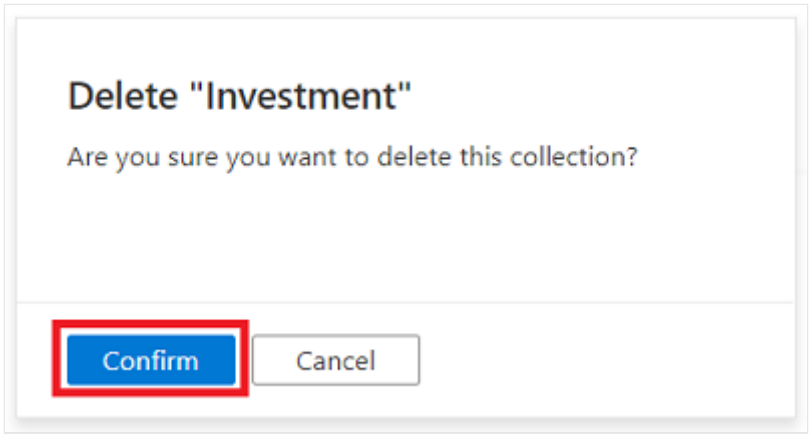


2. Type in the filter box at the top of the list to filter collections.

3. Select **Refresh** in Root collection's contextual menu to reload the collection list.



4. Select **Refresh** in collection detail page to reload the single collection.



Delete a collection

You'll need to be a collection admin in order to delete a collection. If you aren't sure, follow the guide above to check permissions. Collection can be deleted only if no child collections, assets, data sources or scans are associated with it.

1. Select **Delete** from the collection detail page.

2. Select **Confirm** when prompted, **Are you sure you want to delete this collection?**

3. Verify deletion of the collection from your Data Map.

Move registered sources between collections

You can move registered sources from one collection to another you have access to. For steps, see Manage data sources.

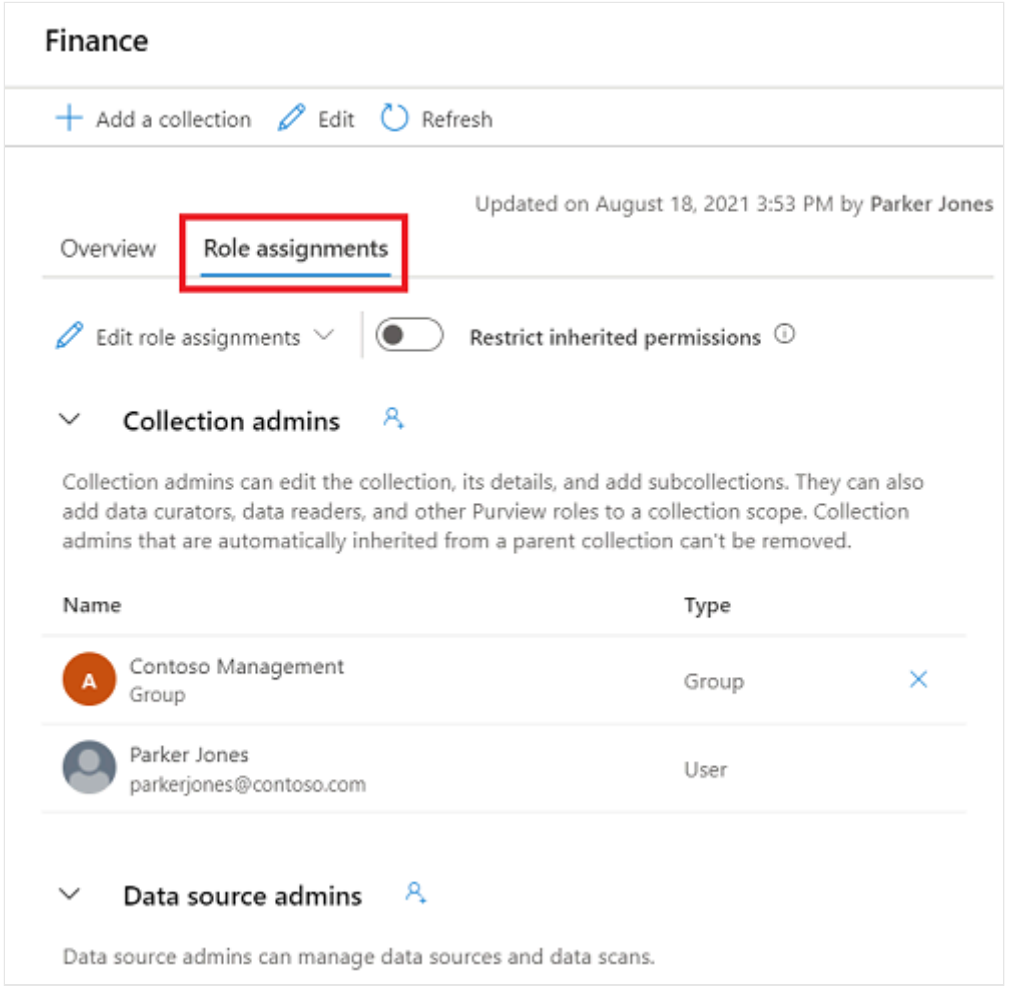
Add roles and restrict access through collections

Since permissions are managed through collections in Data Map, it's important to understand the roles and what permissions they'll give your users. A user granted permissions on a collection will have access to sources and assets associated with that collection, and inherit permissions to subcollections. Inheritance can be restricted, but is allowed by default.

The following guide will discuss the roles, how to manage them, and permissions inheritance.

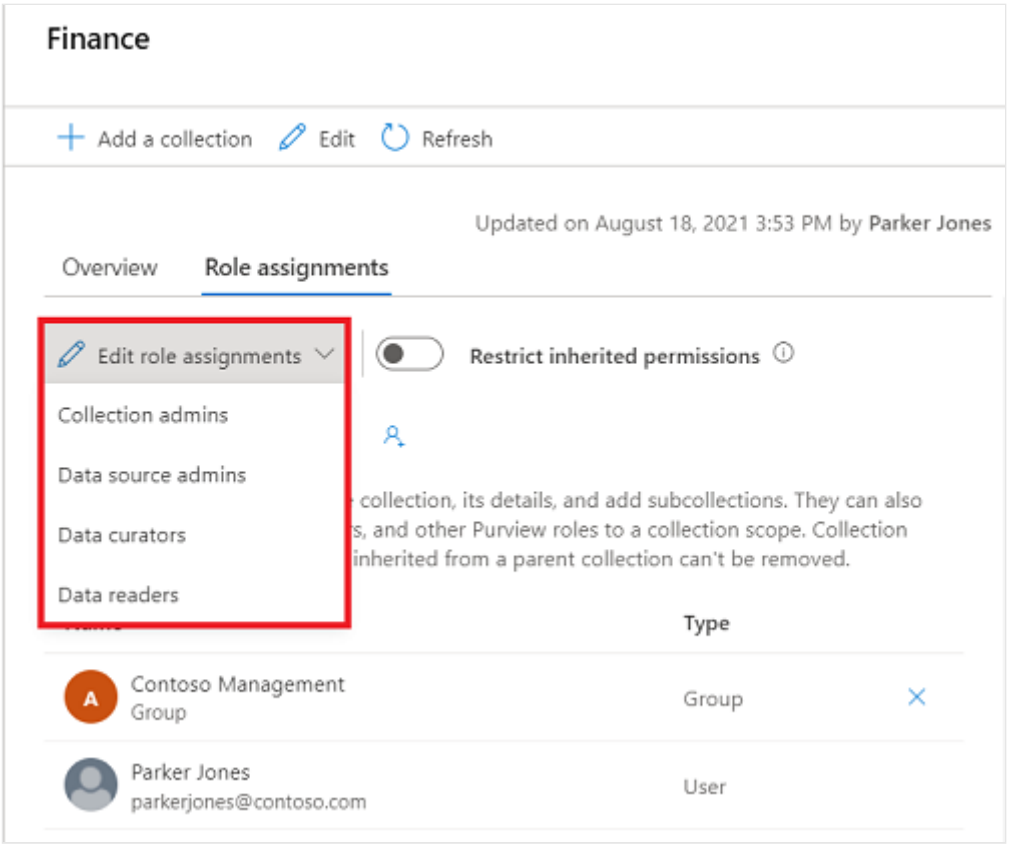
Roles

- **Domain admin** (domain level only) - Can assign permissions within a domain and manage its resources.
- **Collection administrator** - a role for users that will need to assign roles to other users in the Microsoft Purview governance portal or manage collections. Collection admins can add users to roles on collections where they're admins. They can also edit collections, their details, and add subcollections. A collection administrator on the root collection also automatically has permission to the Microsoft Purview governance portal. If your **root collection administrator** ever needs to be changed, you can follow the steps in the section below.
- **Data curators** - a role that provides access to the Microsoft Purview Unified Catalog to manage assets, configure custom classifications, create and manage glossary terms, and view data estate insights. Data curators can create, read, modify, move, and delete assets. They can also apply annotations to assets.
- **Data readers** - a role that provides read-only access to data assets, classifications, classification rules, collections and glossary terms.
- **Data source administrator** - a role that allows a user to manage data sources and scans. If a user is granted only to **Data source admin** role on a given data source, they can run new scans using an existing scan rule. To create new scan rules, the user must be also granted as either **Data reader** or **Data curator** roles.
- **Insights reader** - a role that provides read-only access to insights reports for collections where the insights reader also has at least the **Data reader** role. For more information, see insights permissions.
- **Policy author** - a role that allows a user to view, update, and delete Microsoft Purview policies through the Data policy app within Microsoft Purview.
- **Workflow administrator** - a role that allows a user to access the workflow authoring page in the Microsoft Purview governance portal, and publish workflows on collections where they have access permissions. Workflow administrator only has access to authoring, and so will need at least Data reader permission on a collection to be able to access the Purview governance portal.



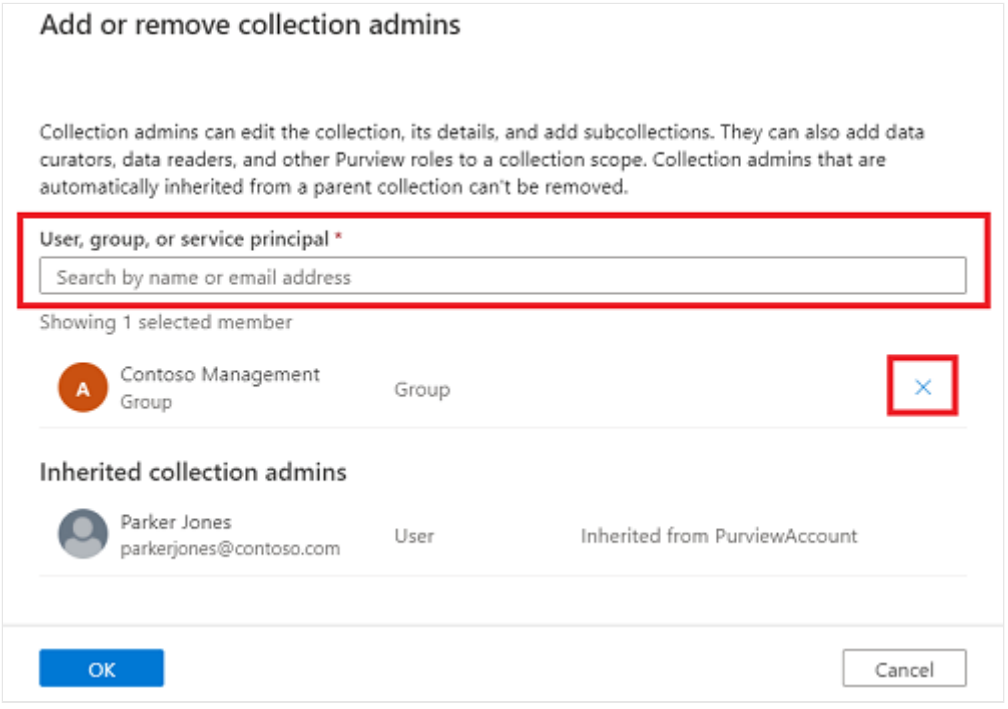
> ⓘ **Note**

At this time, Microsoft Purview policy author role is not sufficient to create policies. The Microsoft Purview data source admin role is also required.



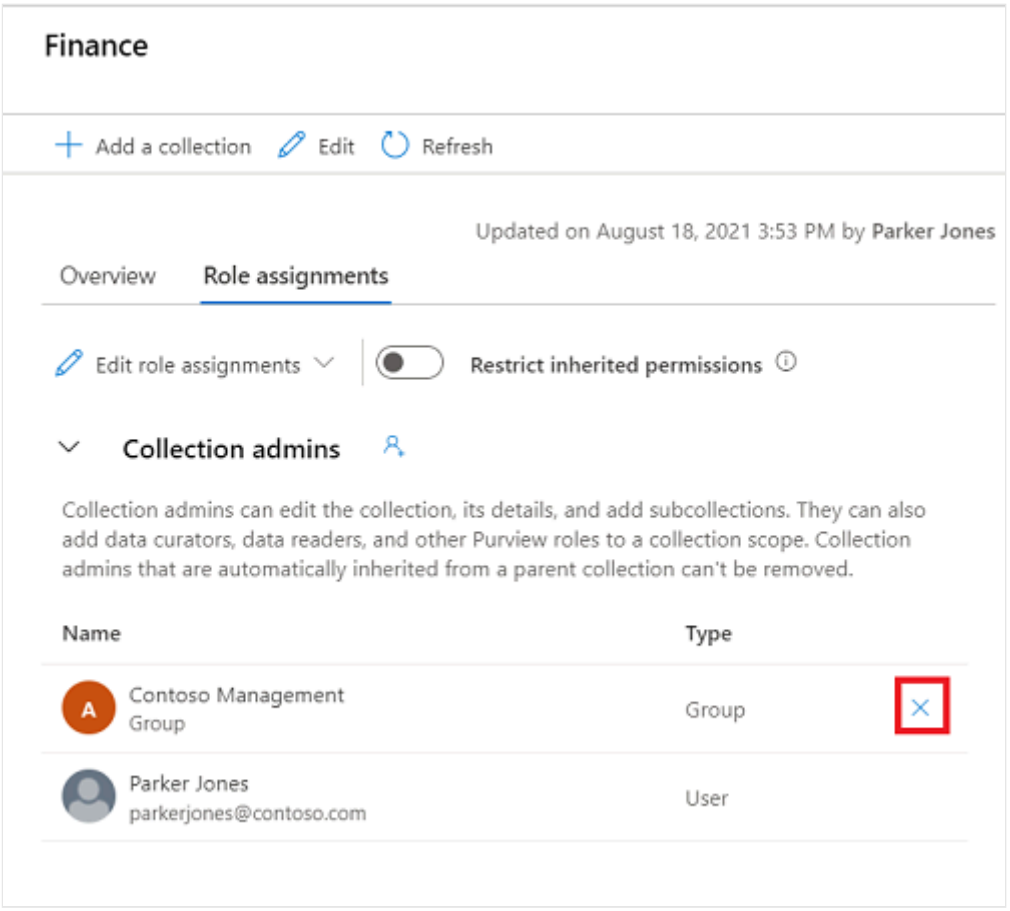
> **Important**
>
> The user that created the account is automatically assigned domain admin on the default domain and collection admin on the root collection.

Add role assignments

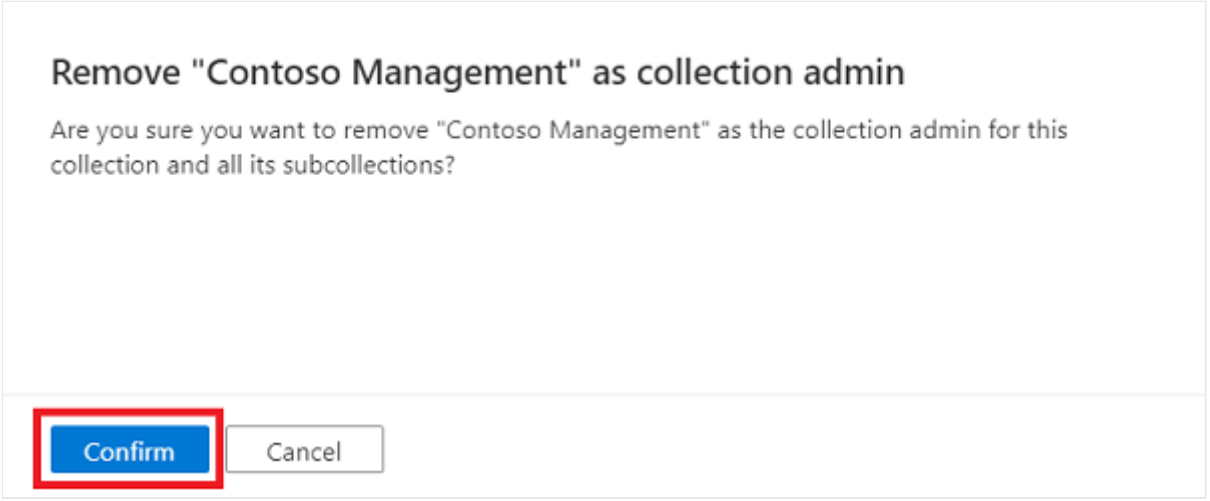


1. Open the Microsoft Purview Data Map.
2. Select the domain or collection where you want to add your role assignment.
3. Select the **Role assignments** tab to see all the roles in a collection or a domain. Only a collection admin or domain admin can manage role assignments.

4. Select **Edit role assignments** or the person icon to edit each role member.



5. Type in the textbox to search for users you want to add to the role member. Select **X** to remove members you don't want to add.



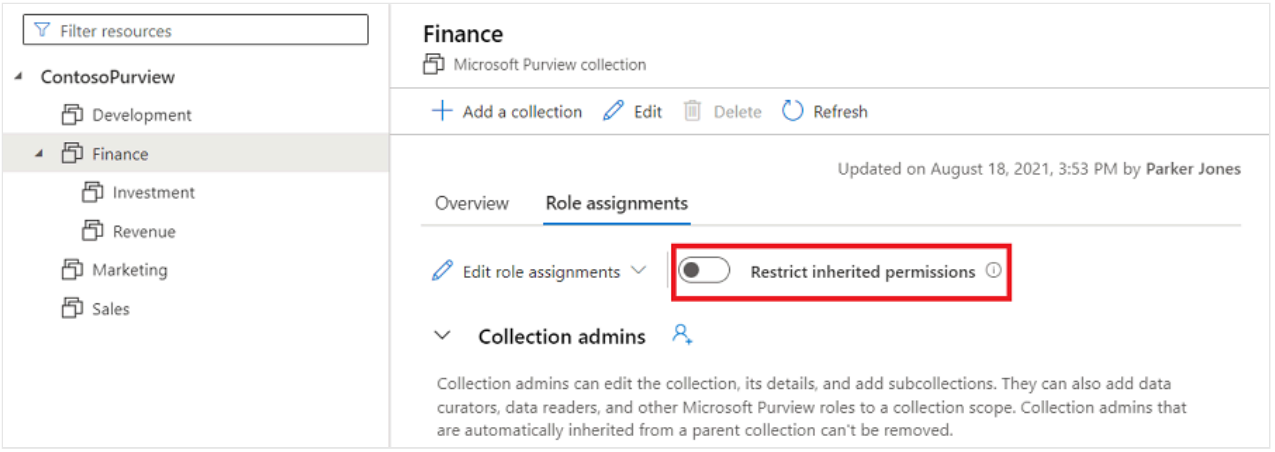
6. Select **OK** to save your changes, and you'll see the new users reflected in the role assignments list.

Remove role assignments

1. Select **X** button next to a user's name to remove a role assignment.

2. Select **Confirm** if you're sure to remove the user.

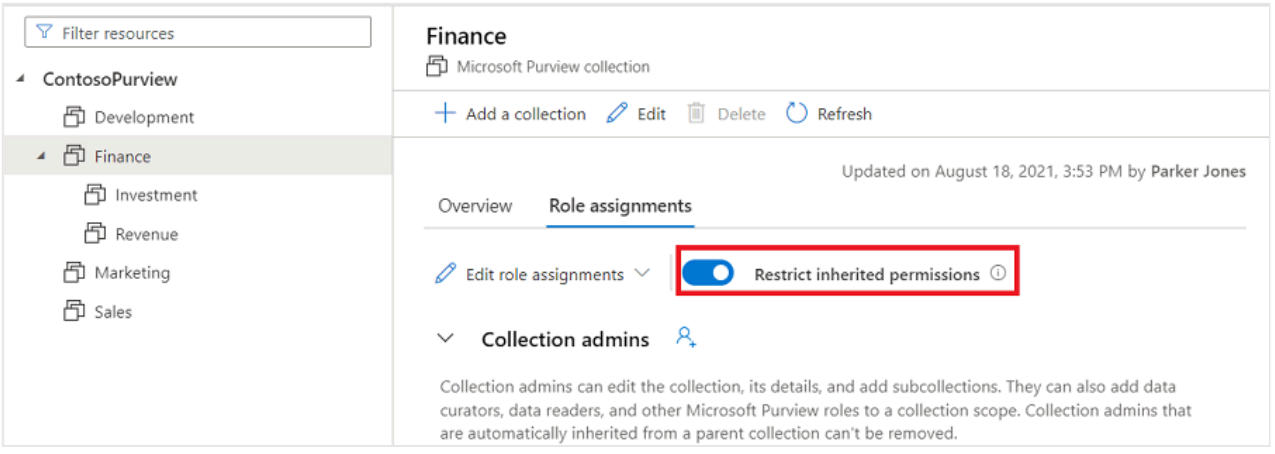
Restrict inheritance



Collection permissions are inherited automatically from the parent collection. You can restrict inheritance from a parent collection at any time, using the restrict inherited permissions option.

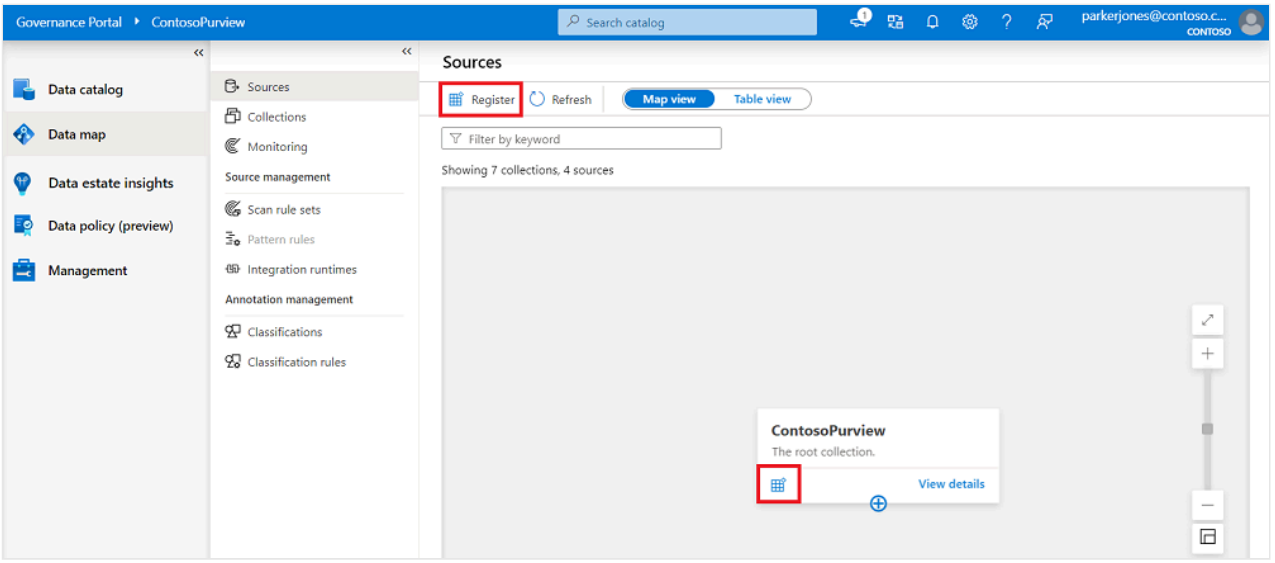
> **Note**
>
> Currently permissions from the default domain cannot be restricted. Any permissions assigned at the default domain will be inherited by the domain's direct subcollections.

Once you restrict inheritance, you'll need to add users directly to the restricted collection to grant them access.



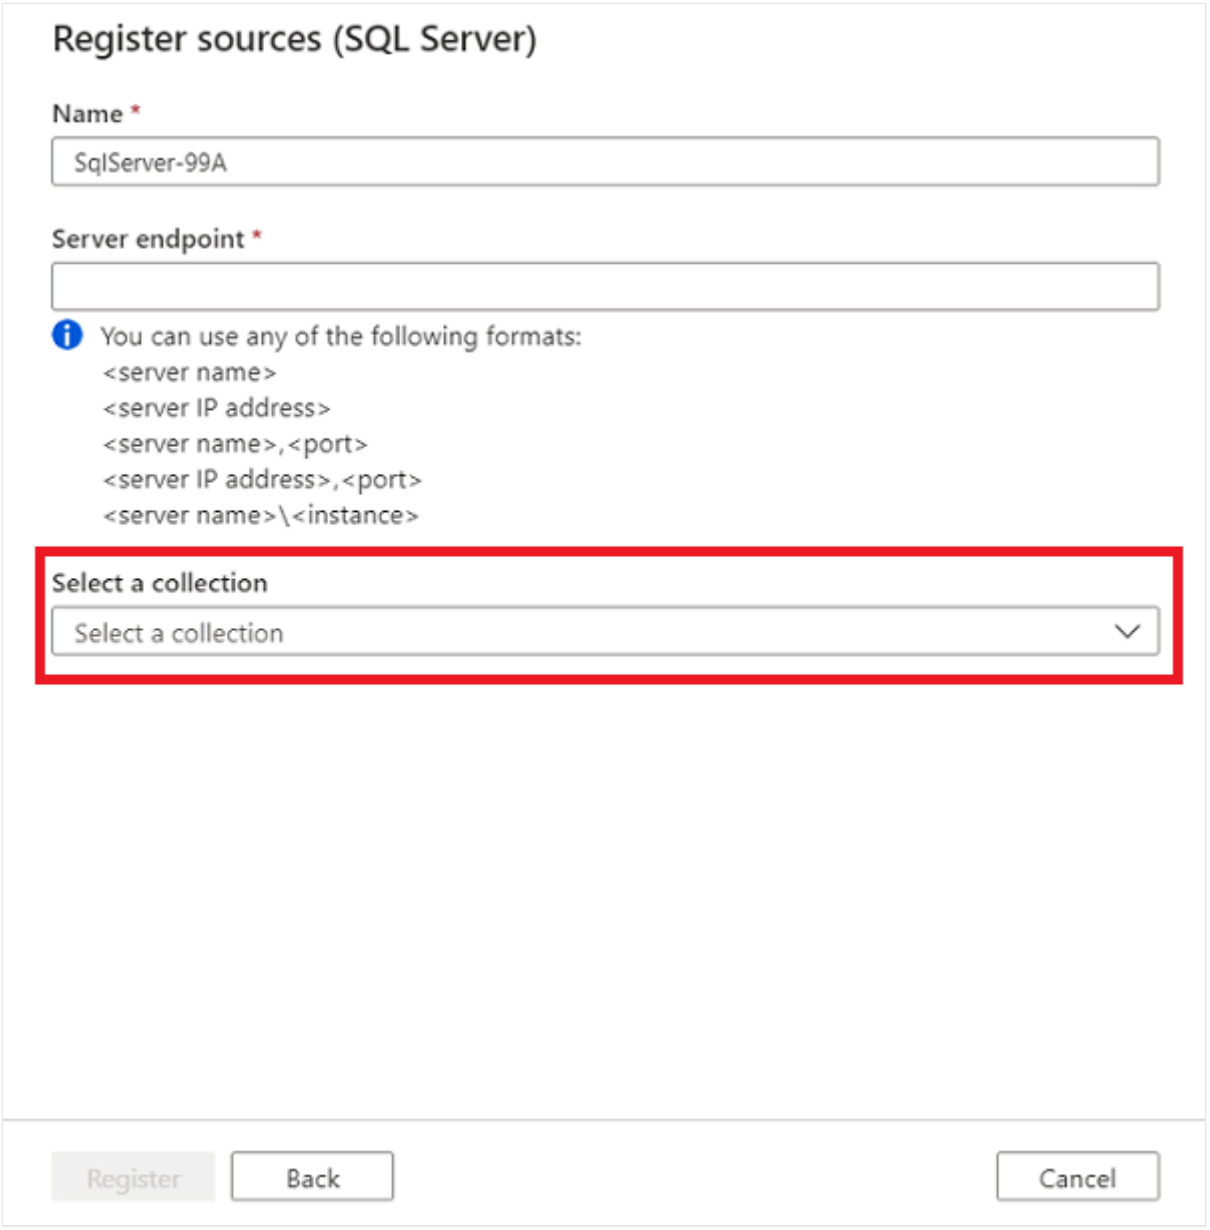
1. Navigate to the collection where you want to restrict inheritance and select the **Role assignments** tab.

2. Select **Restrict inherited permissions** and select **Restrict access** in the popup dialog to remove inherited permissions from this collection and any subcollections. Collection admin permissions won't be affected.

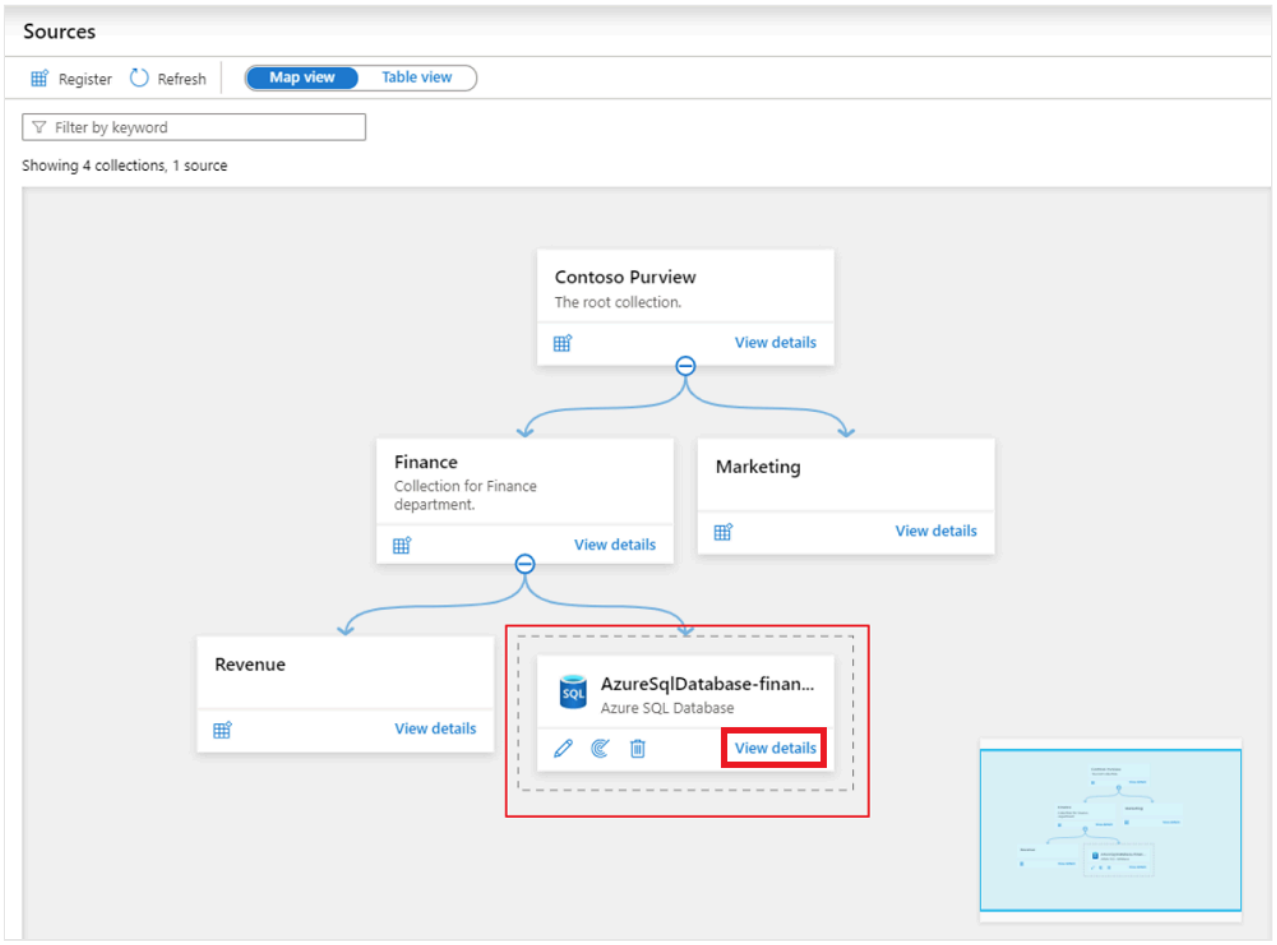


3. After restriction, inherited members are removed from the roles expect for collection admin.

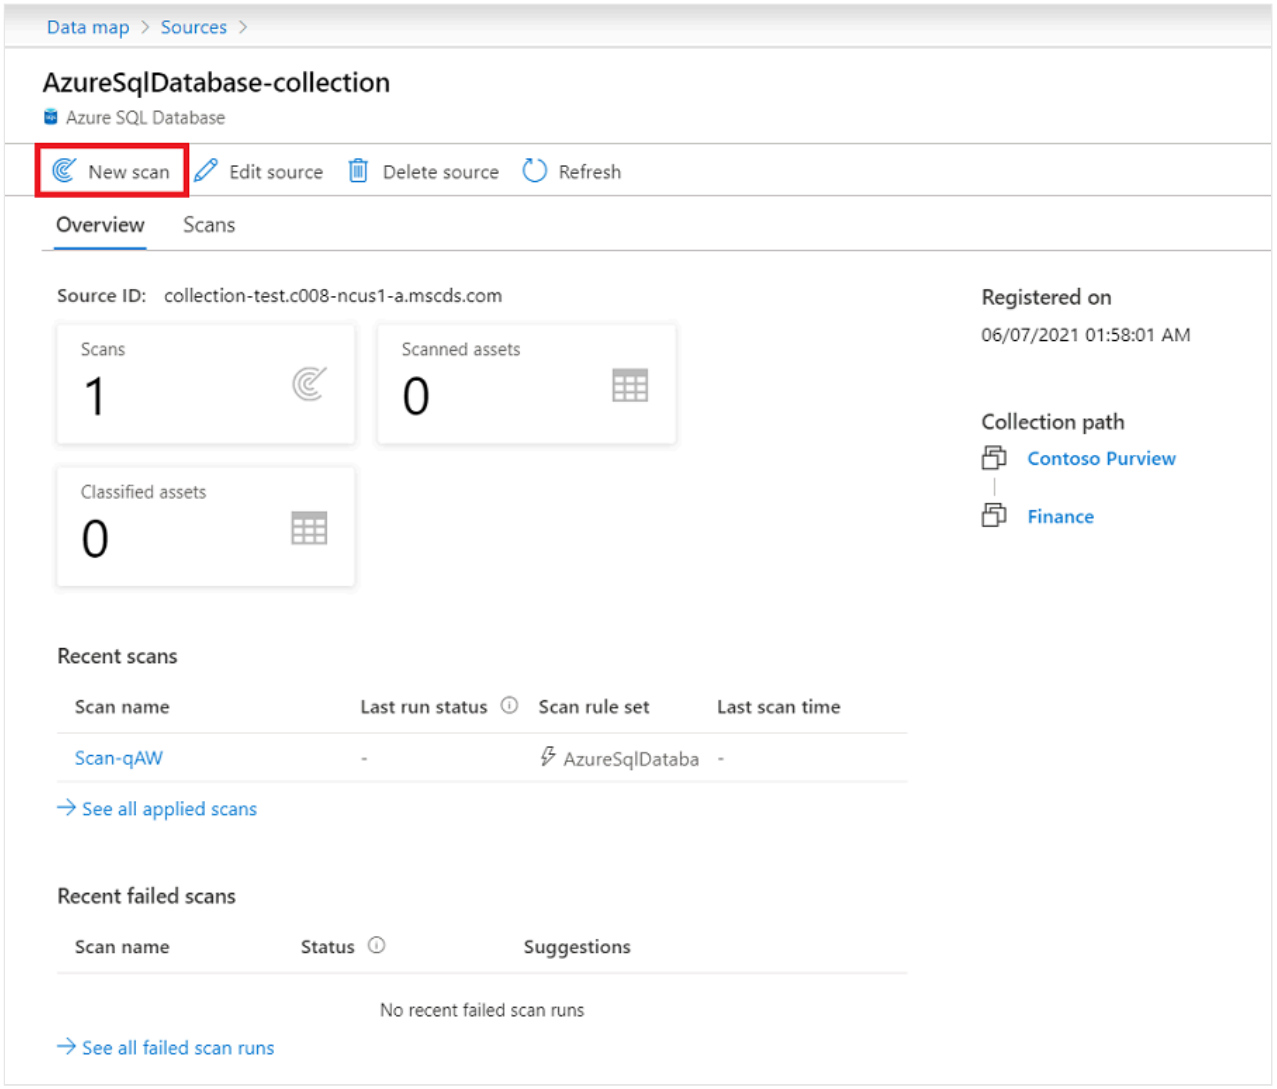
4. Select the **Restrict inherited permissions** toggle button again to revert.



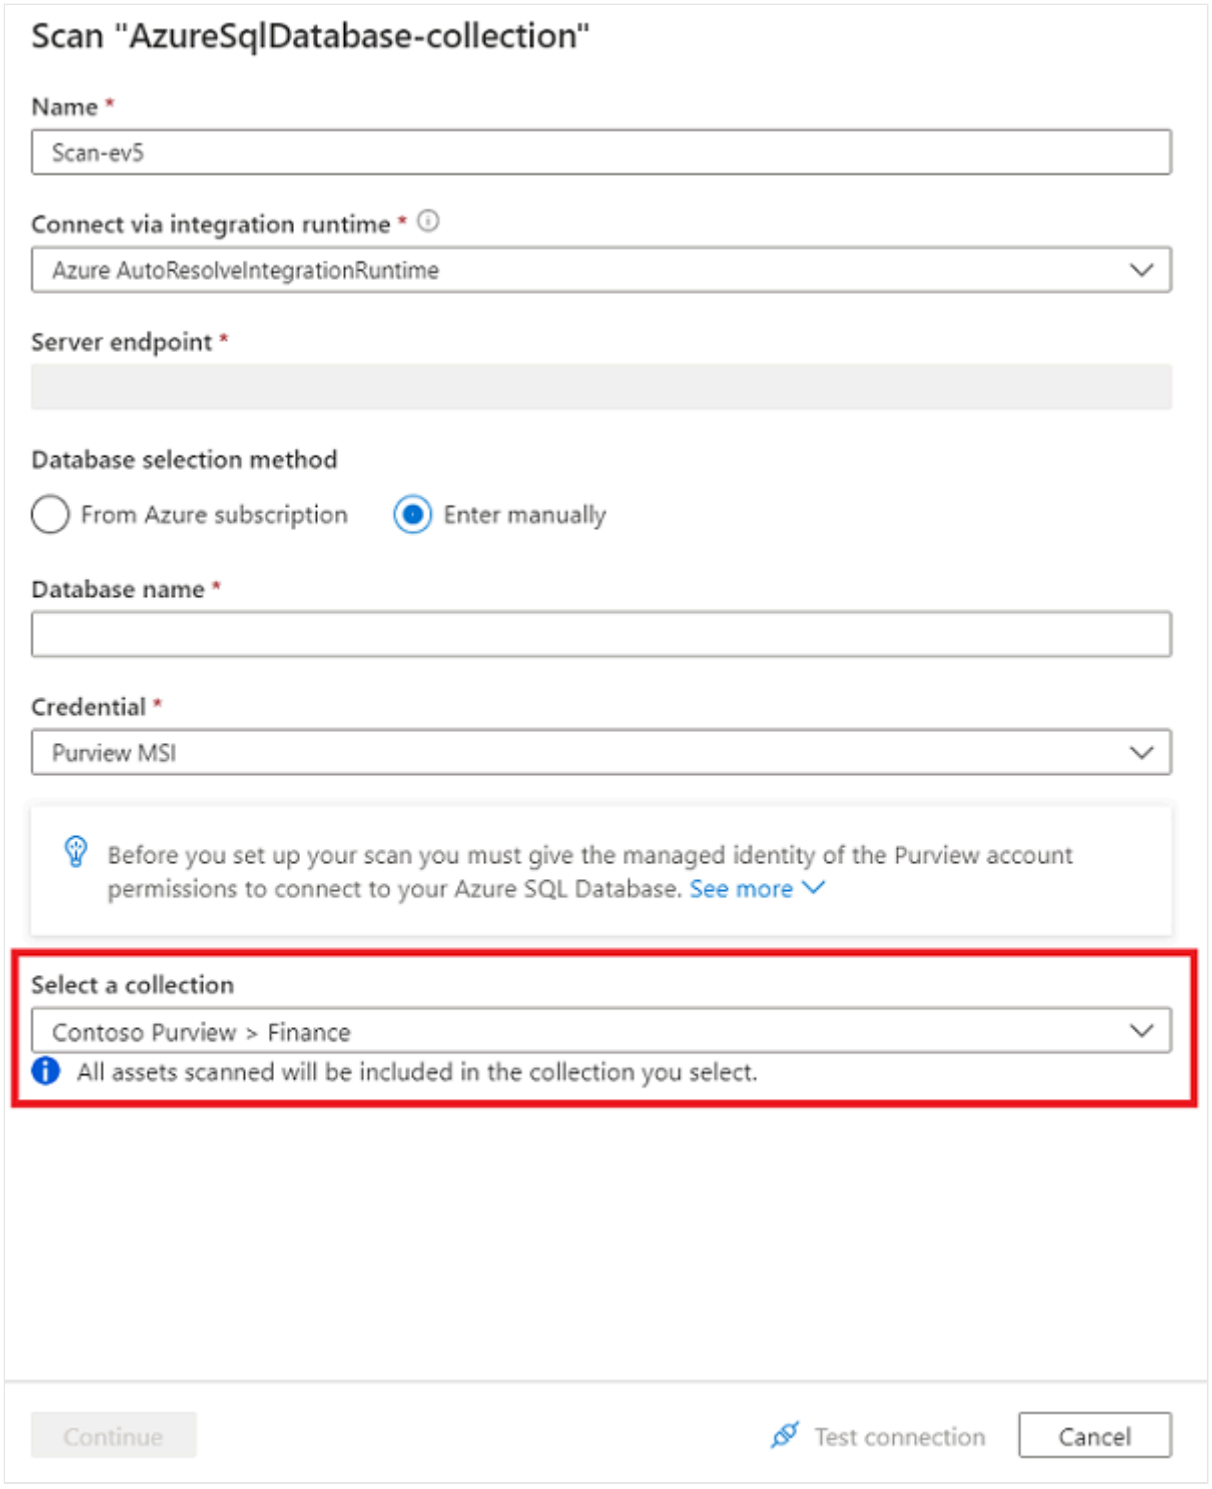
Register source to a collection



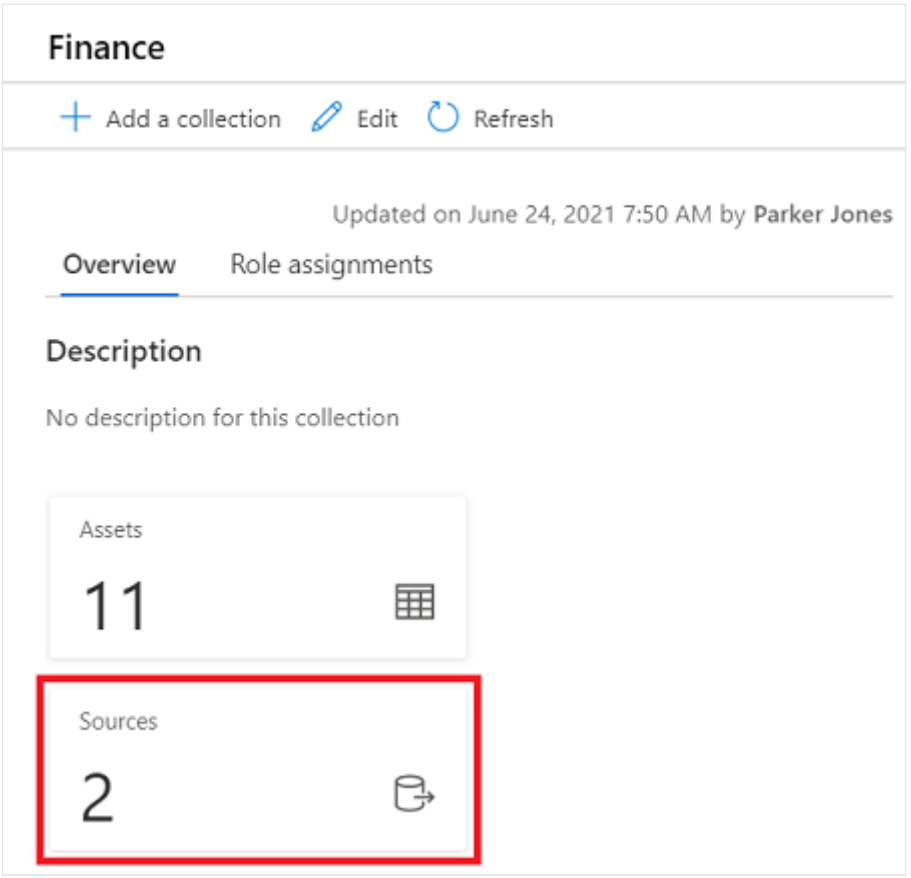
1. Select **Register** or register icon on collection node to register a data source. Only a data source admin can register sources.



2. Fill in the data source name, and other source information. It lists all the collections where you have scan permission on the bottom of the form. You can select one collection. All assets under this source will belong to the collection you select.

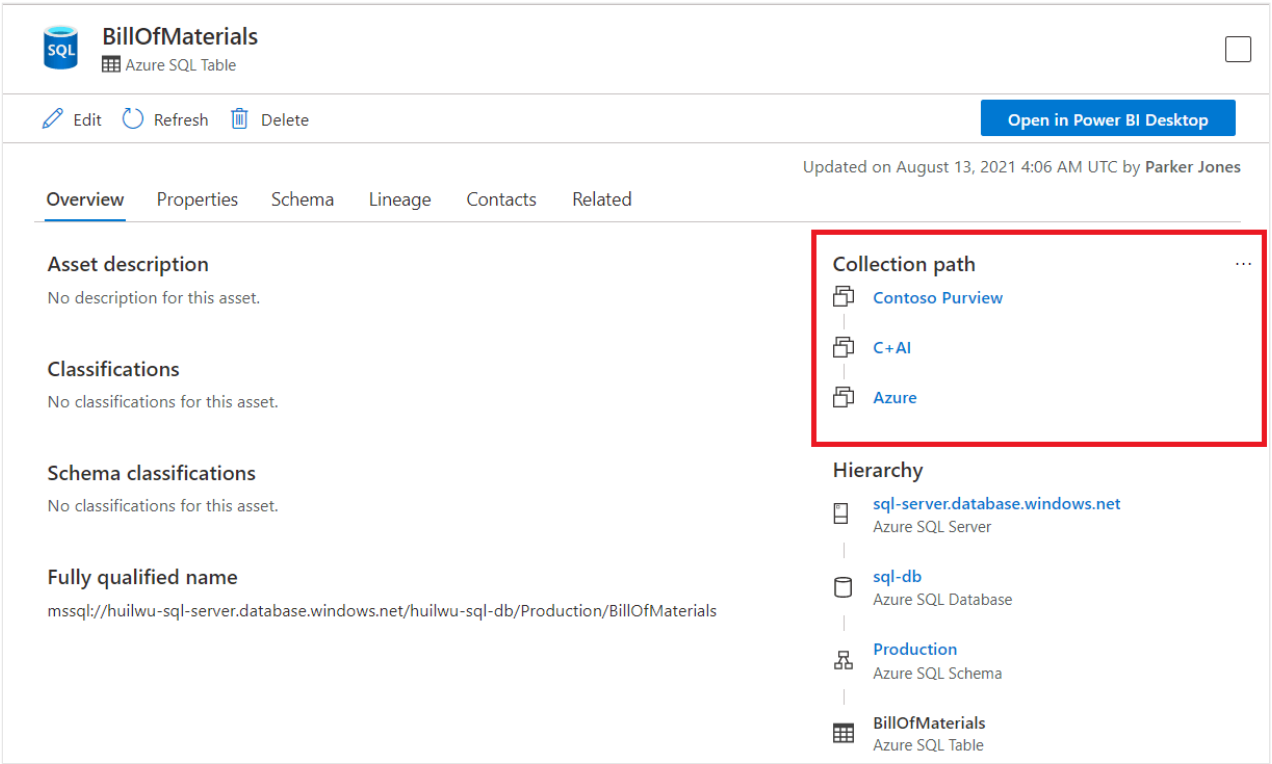


3. The created data source will be put under the selected collection. Select **View details** to see the data source.



4. Select **New scan** to create scan under the data source.

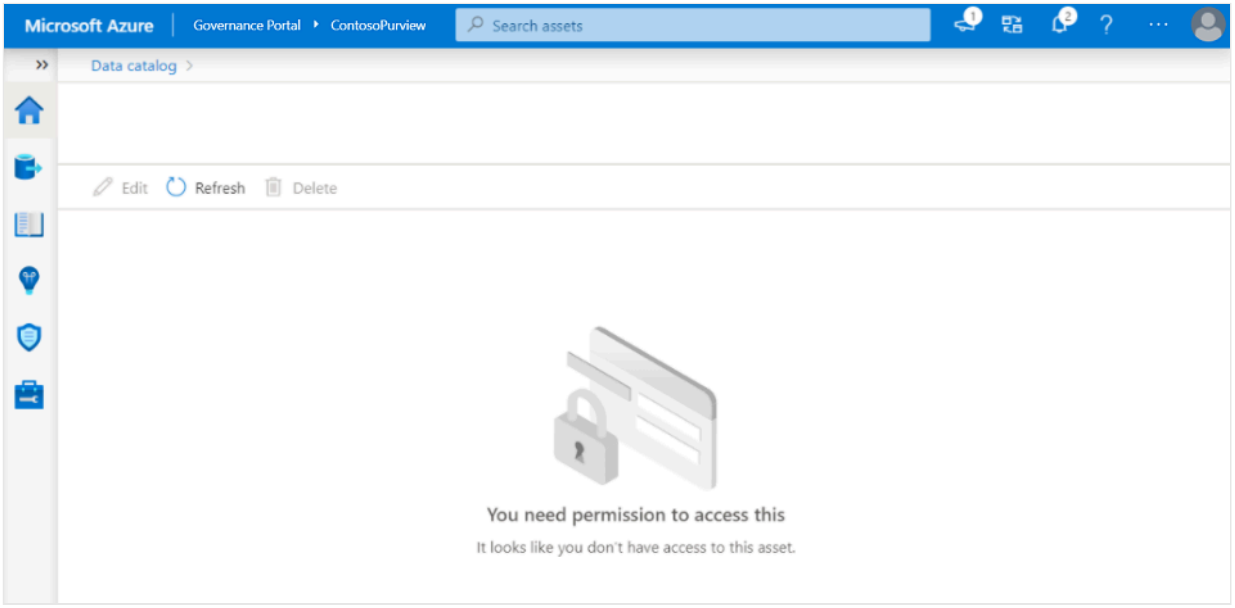
5. Similarly, at the bottom of the form, you can select a collection, and all assets scanned will be included in the collection. The collections listed here are restricted to subcollections of the data source collection.



6. Back in the collection window, you'll see the data sources linked to the collection on the sources card.

Add assets to collections

Assets and sources are also associated with collections. During a scan, if the scan was associated with a collection the assets will be automatically added to that collection, but can also be manually added to any subcollections.



1. Check the collection information in asset details. You can find collection information in the **Collection path** section on right-top corner of the asset details page.

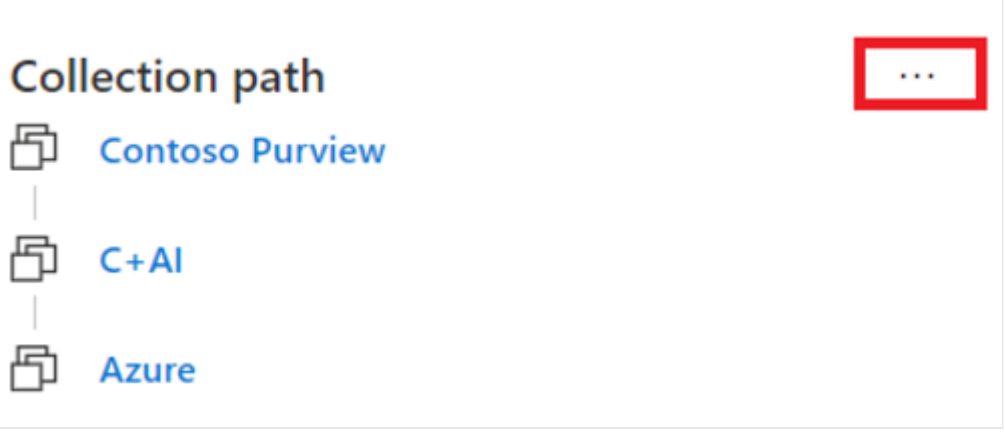
2. Permissions in asset details page:

   a. Check the collection-based permission model by following the add roles and restricting access on collections guide above.

   b. If you don't have read permission on a collection, the assets under that collection won't be listed in search results. If you get the direct URL of one asset and open it, you'll see the no access page. Contact your collection admin to grant you the access. You can select the **Refresh** button to check the permission again.

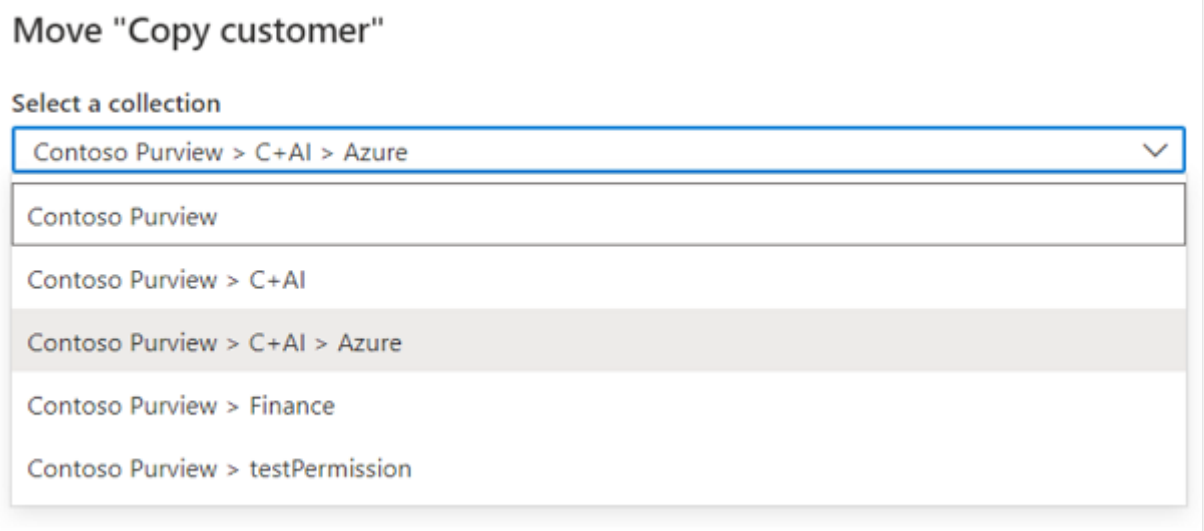
   c. If you have the read permission to one collection but don't have the write permission, you can browse the asset details page, but the following operations are disabled:

      - Edit the asset. The **Edit** button will be disabled.



- Delete the asset. The **Delete** button will be disabled.
- Move asset to another collection. The ellipsis button on the right-top corner of Collection path section will be hidden.

d. The assets in **Hierarchy** section are also affected by permissions. Assets without read permission will be grayed.

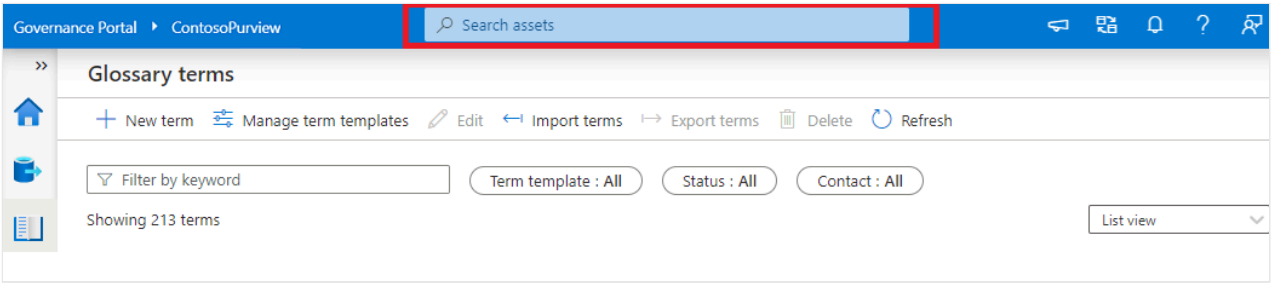


Move asset to another collection

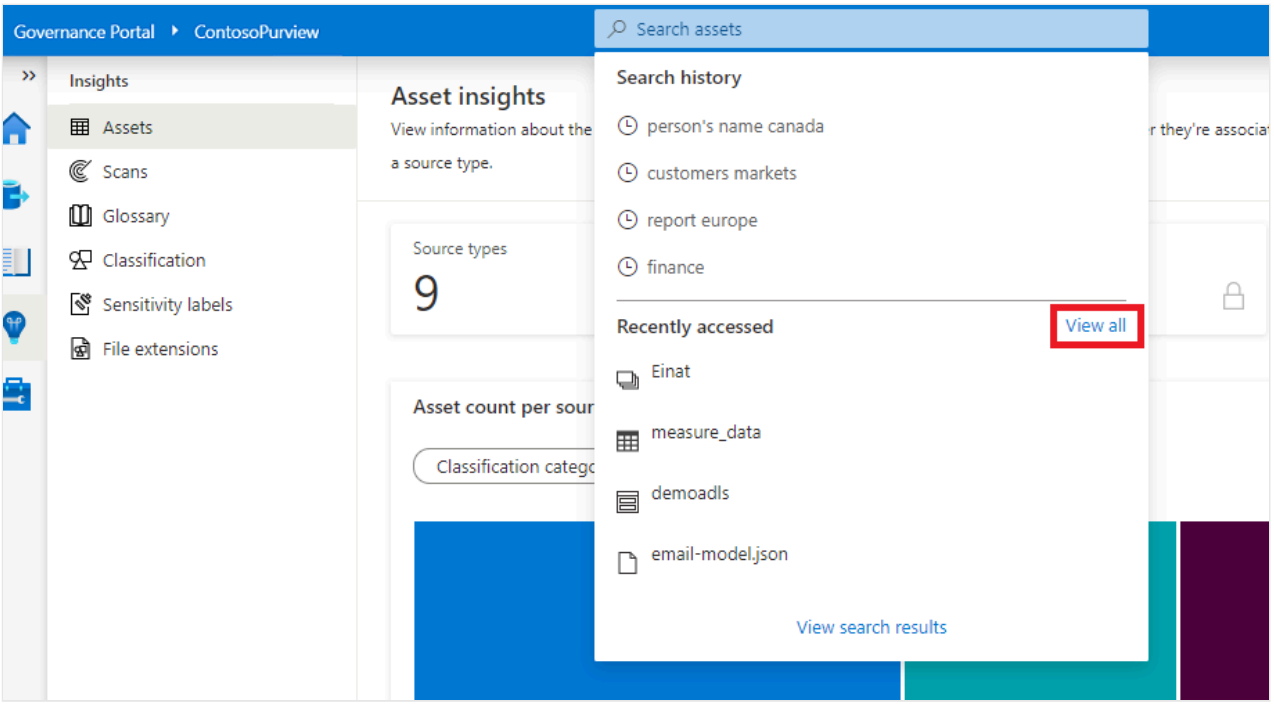
1. Select the ellipsis button on the right-top corner of Collection path section.

2. Select the **Move to another collection** button.

3. In the right side panel, choose the target collection you want move to. You can only see the collections where you have write permissions. The asset can also only be added to the subcollections of the data source collection.

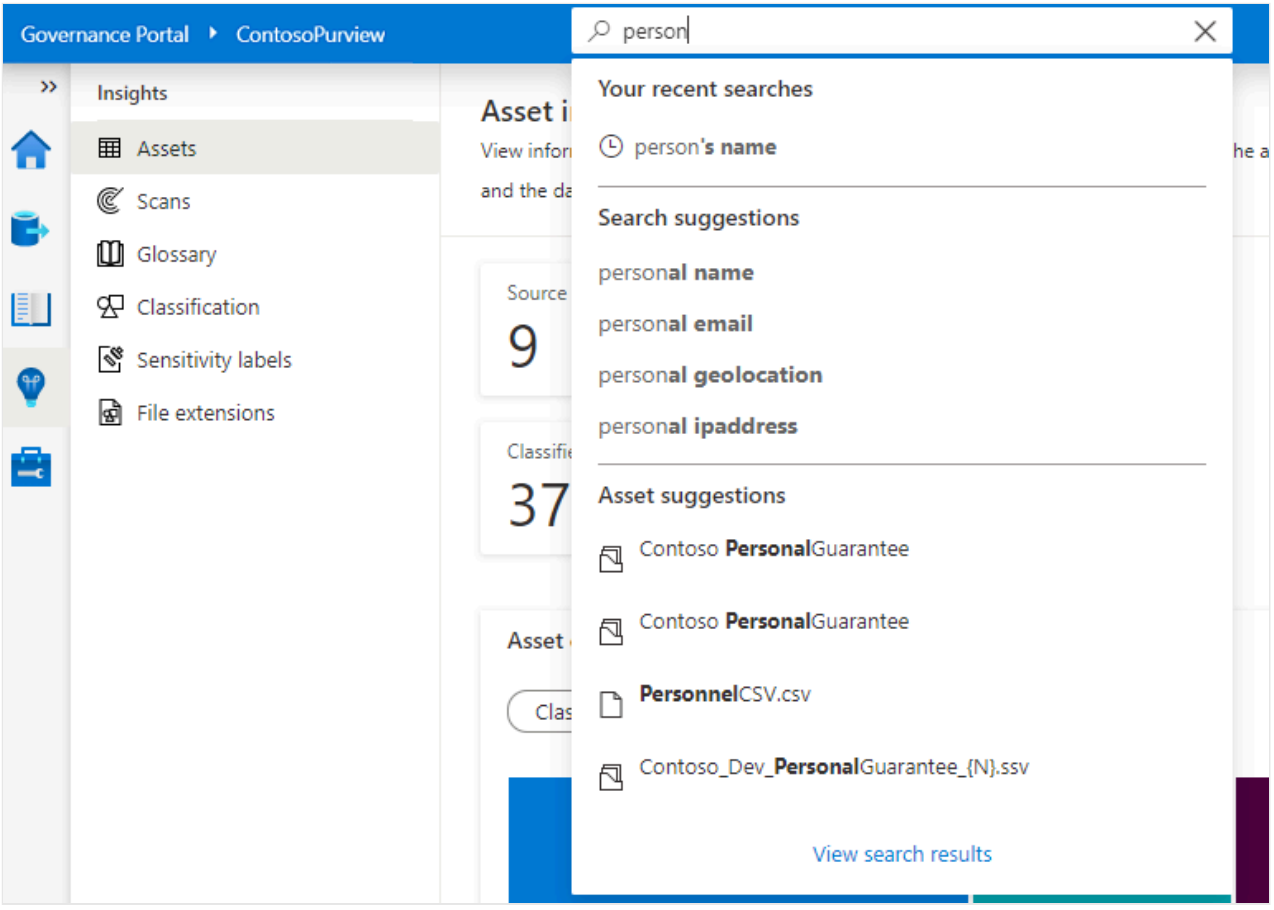


4. Select **Move** button on the bottom of the window to move the asset.



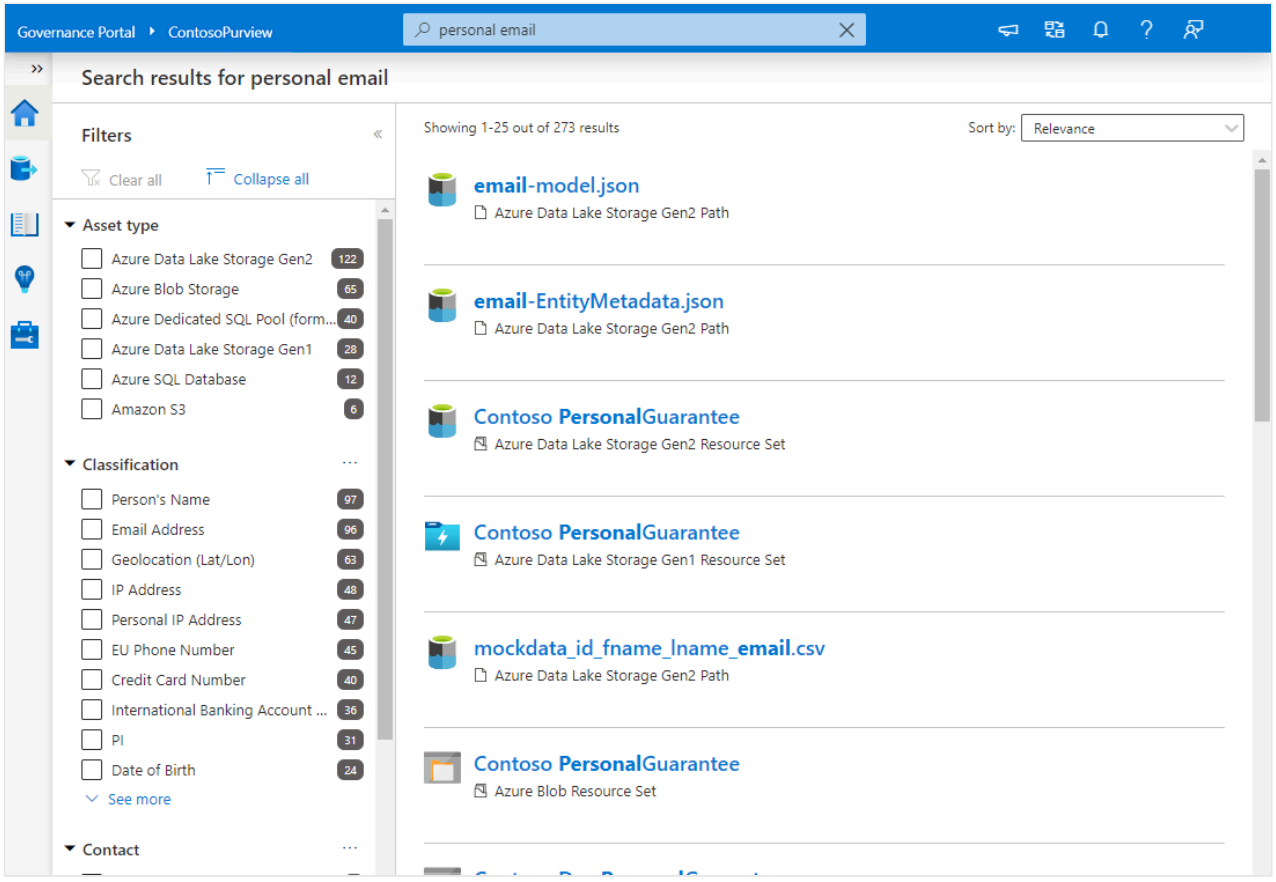
Search and browse by collections

Search by collection

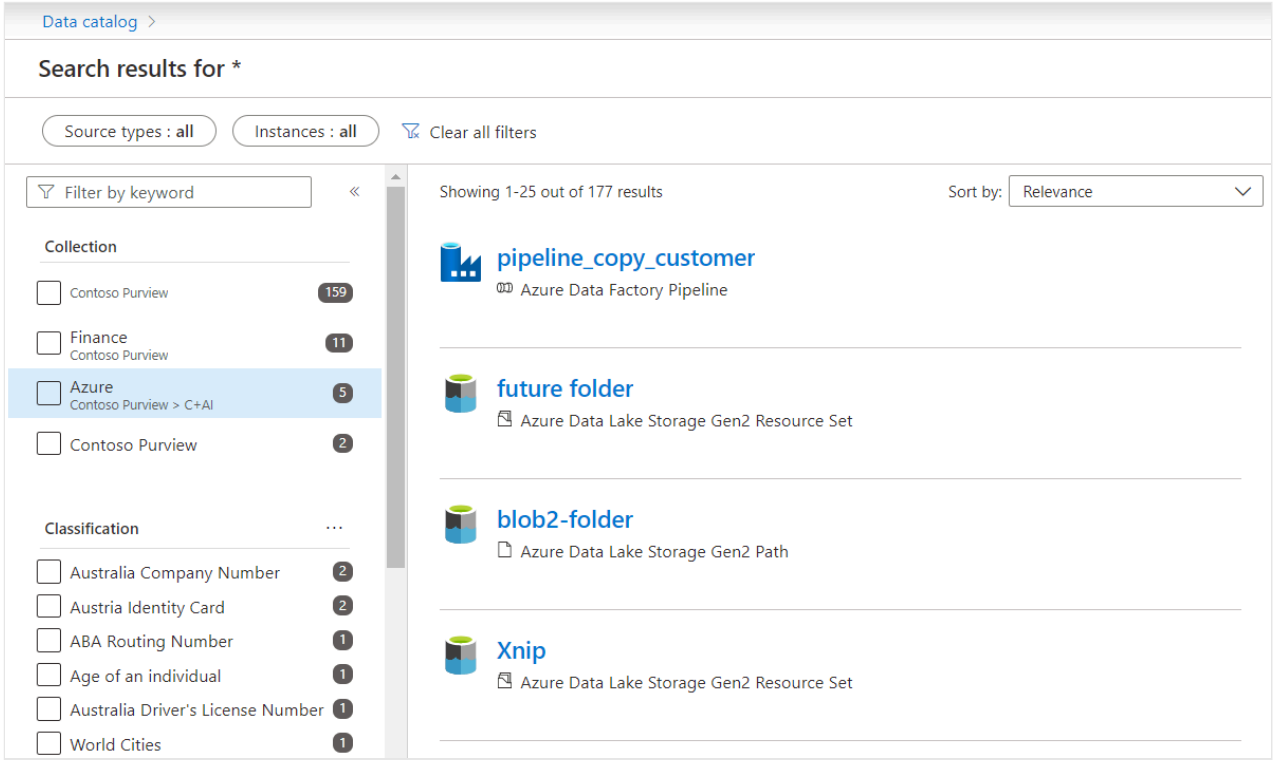


1. In the classic Microsoft Purview governance portal, the search bar is located at the top of the portal window.

2. When you select the search bar, you can see your recent search history and recently accessed assets. Select **View all** to see all of the recently viewed assets.

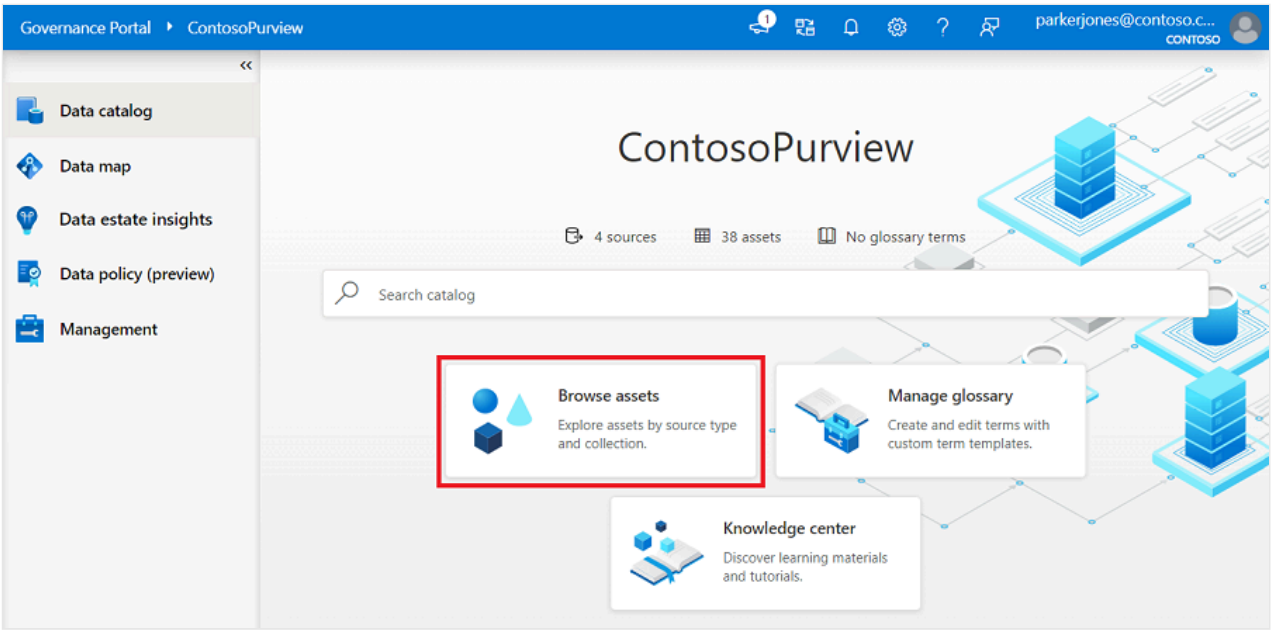


3. Enter in keywords that help identify your asset such as its name, data type, classifications, and glossary terms. As you enter in keywords relating to your desired asset, the classic Microsoft Purview governance portal displays suggestions on what to search and potential asset matches. To complete your search, select **View search results** or press **Enter**.

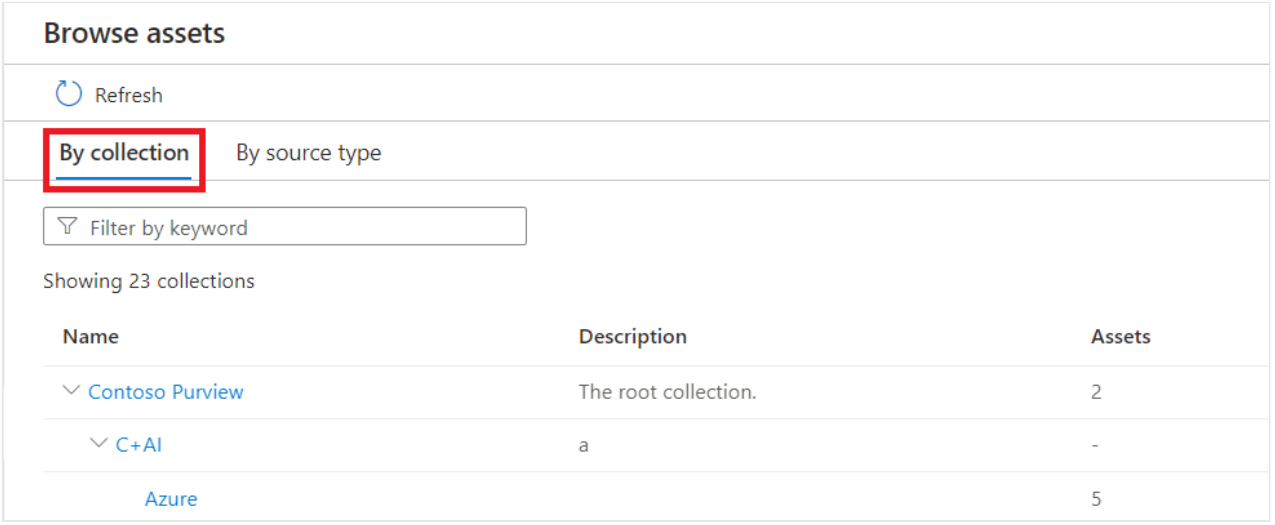


4. The search results page shows a list of assets that match the keywords provided in order of relevance. There are various factors that can affect the relevance score of an asset. You

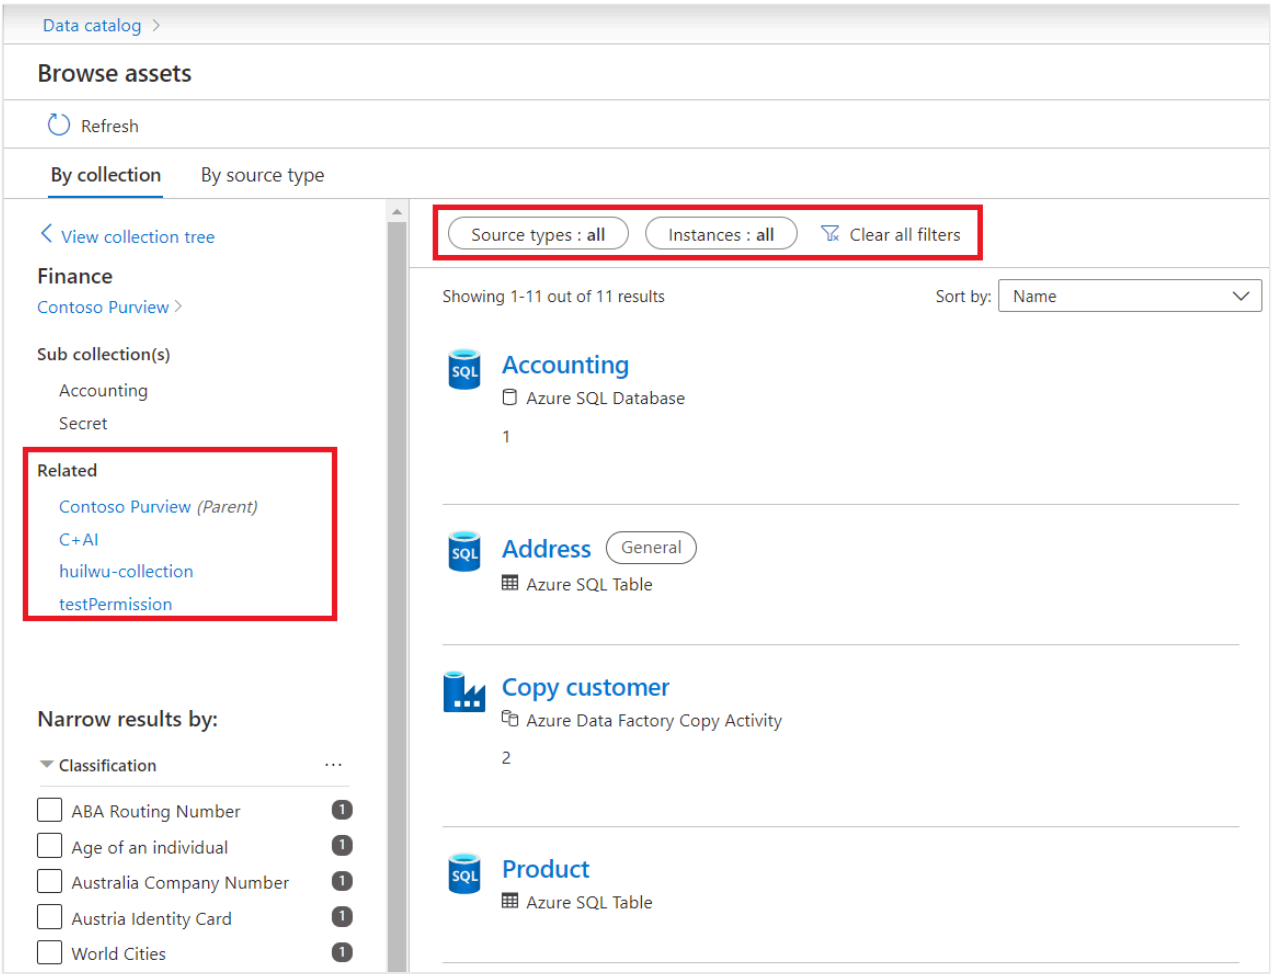
can filter down the list more by selecting specific collections, data stores, classifications, contacts, labels, and glossary terms that apply to the asset you're looking for.



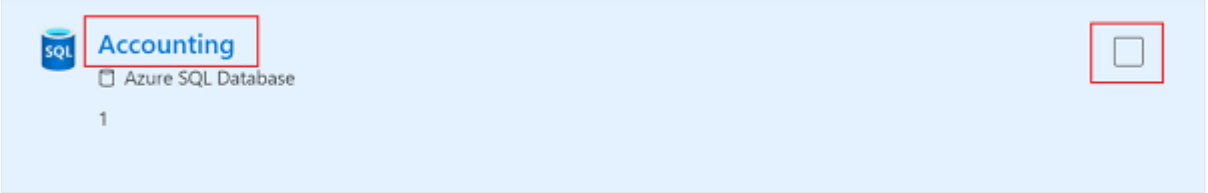
5. Select your desired asset to view the asset details page where you can view properties including schema, lineage, and asset owners.



Browse by collection



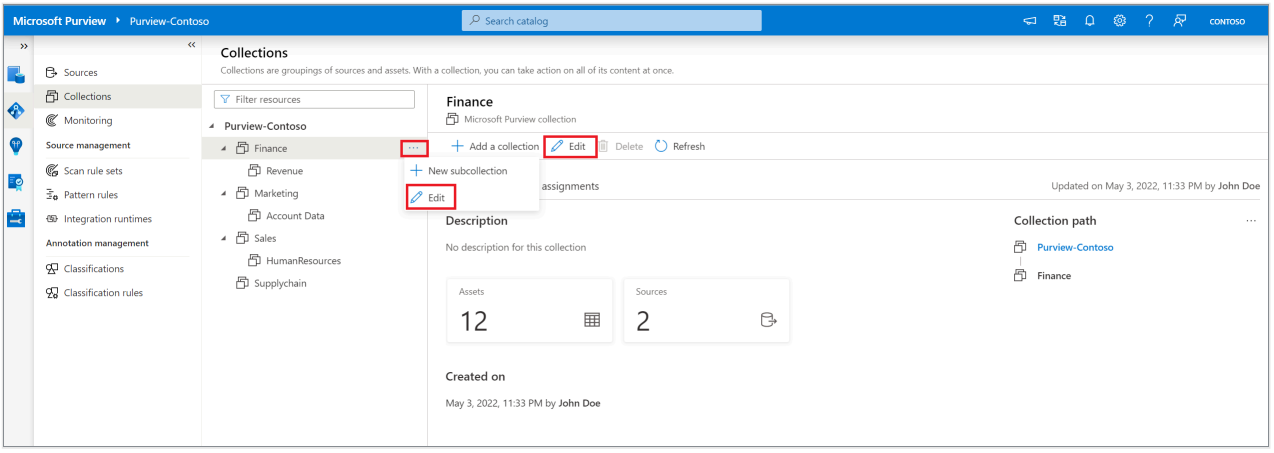
1. You can browse data assets, by selecting the **Browse assets** on the homepage.



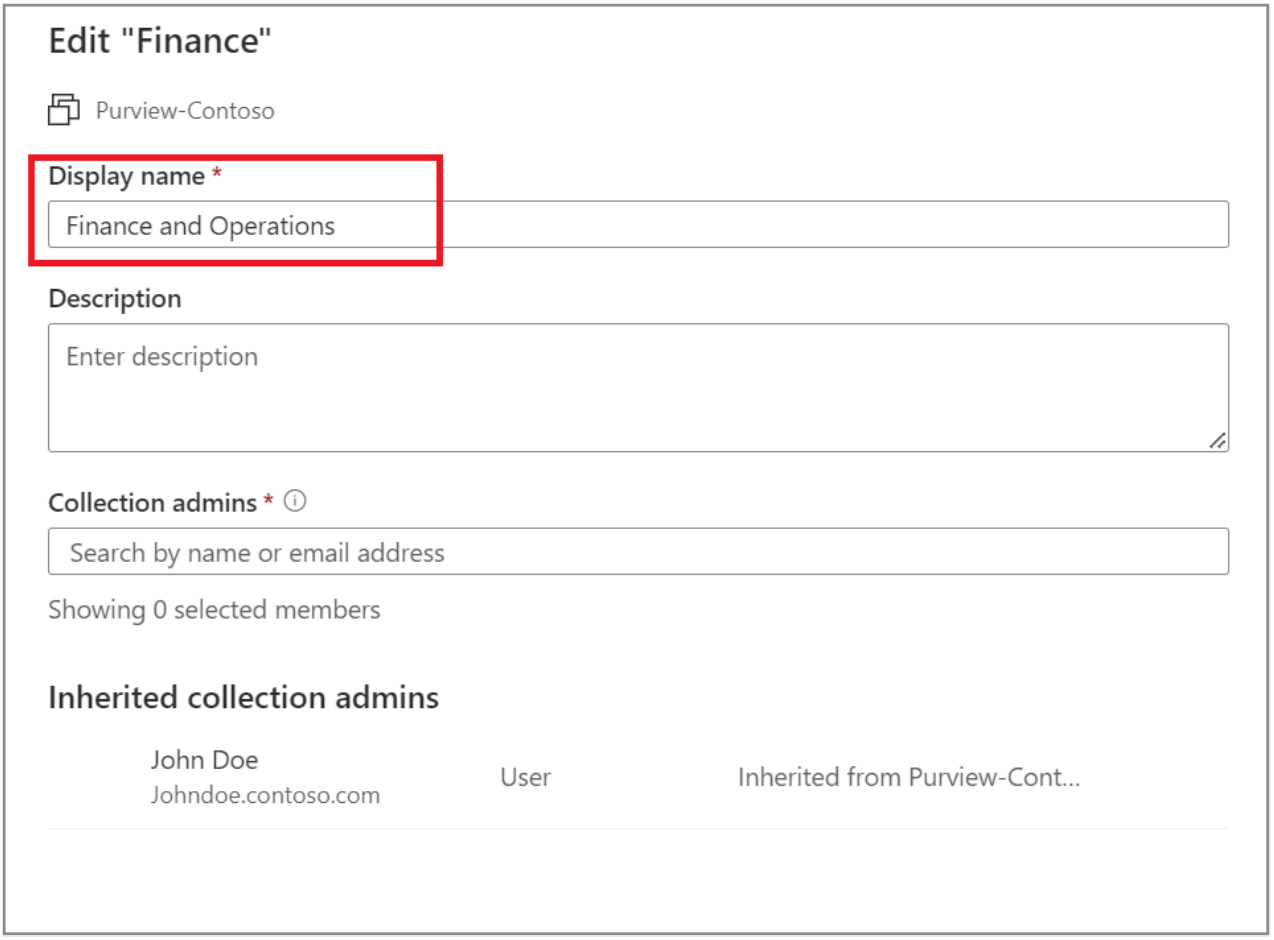
2. On the Browse asset page, select **By collection** pivot. Collections are listed with hierarchical table view. To further explore assets in each collection, select the corresponding collection name.

3. On the next page, the search results of the assets under selected collection will be shown. You can narrow the results by selecting the facet filters. Or you can see the assets under other collections by selecting the sub/related collection names.

4. To view the details of an asset, select the asset name in the search result. Or you can check the assets and bulk edit them.



Rename collections (preview)

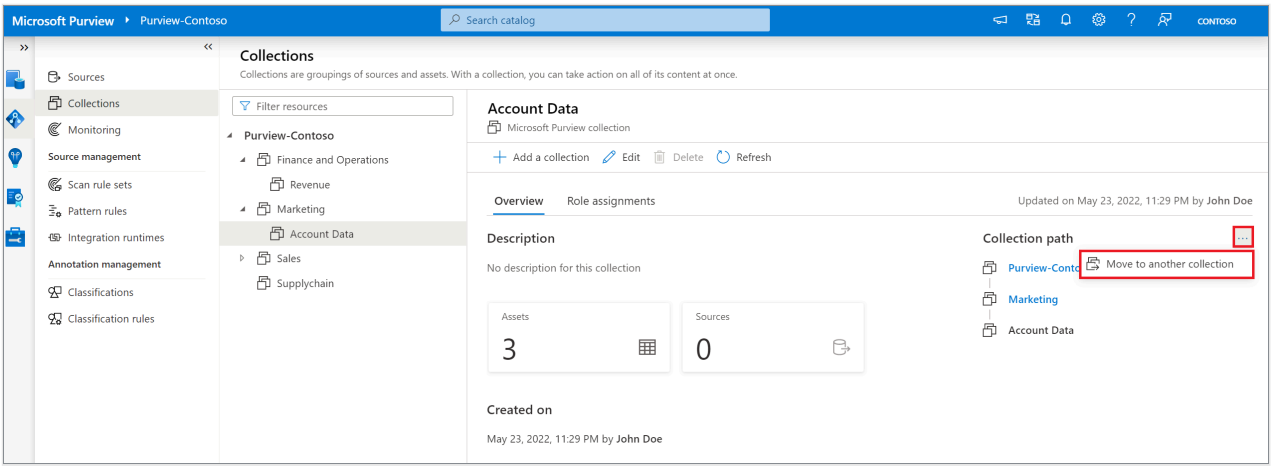


> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

1. In the classic Microsoft Purview governance portal, navigate to the collection that you want to rename.

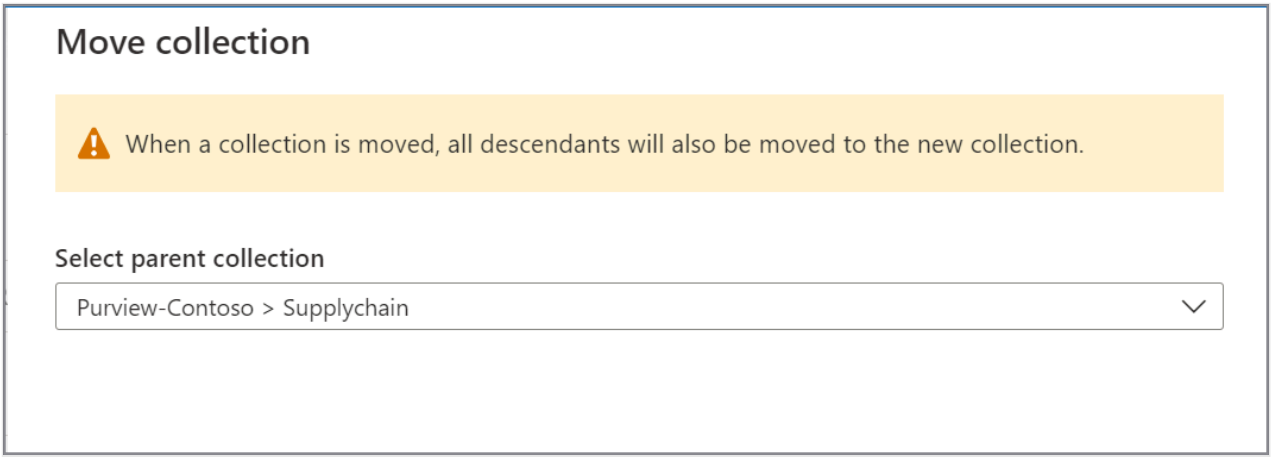
2. Select **Edit** either from the collection detail page, or from the collection's dropdown menu.

3. Provide a new friendly name and select **Save** to save your change.



Move collections (preview)

> **Important**



This feature is currently in preview. The [Supplemental Terms of Use for Microsoft Azure Previews] include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

1. In the classic Microsoft Purview governance portal, navigate to the collection that you want to move to a different parent collection.

2. Select the ellipsis button on the right-top corner of collection path section and select **Move to another collection**.

3. From **Select parent collection** dropdown list, select a new parent for the collection and select **OK**.

Next steps

Now that you have a collection, you can follow these guides below to add resources and scan.

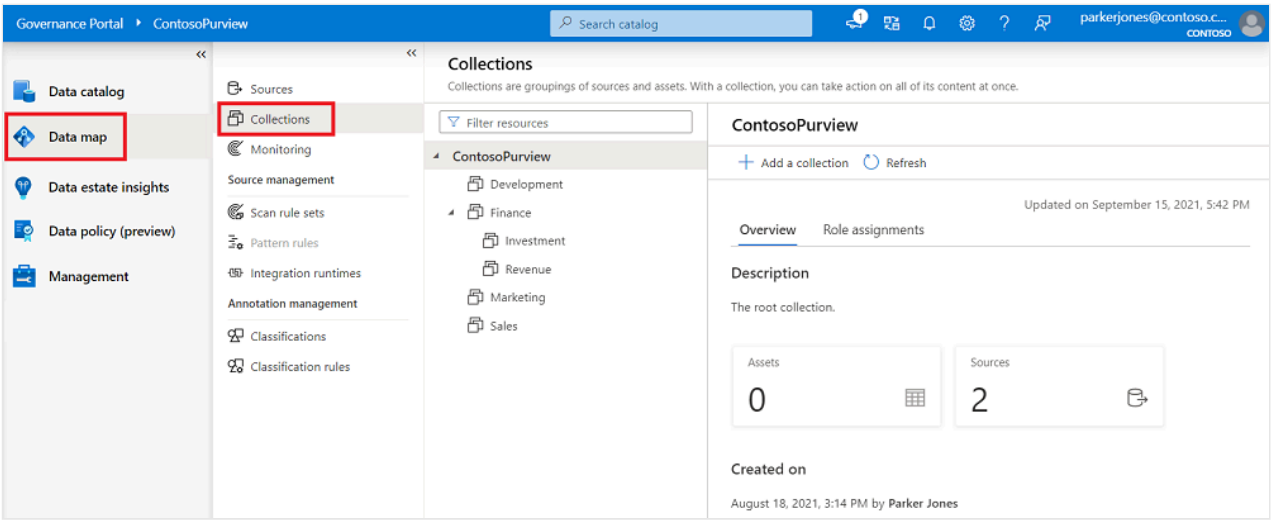
- Manage data sources
- Supported data sources
- Scan and ingestion

Quickstart: Create a collection and assign permissions in Microsoft Purview Data Map (classic)

Article • 05/30/2025

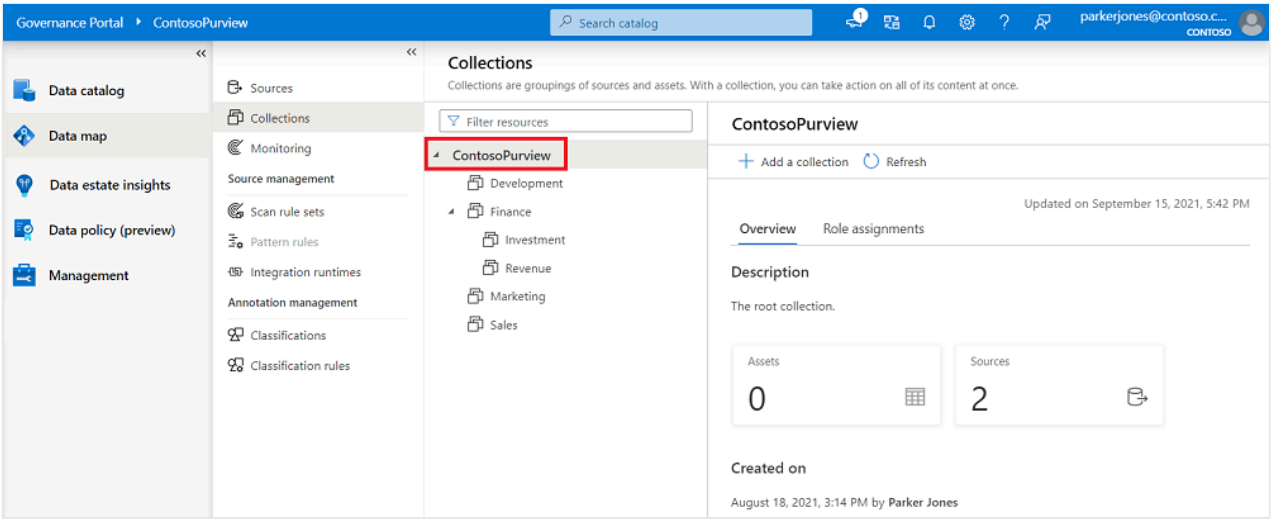
Collections are the Microsoft Purview Data Map's tool to manage ownership and access control across assets, sources, and information. They also organize your sources and assets into categories that are customized to match your management experience with your data. This guide takes you through setting up your first collection and collection admin to prepare your Microsoft Purview environment for your organization.

Prerequisites



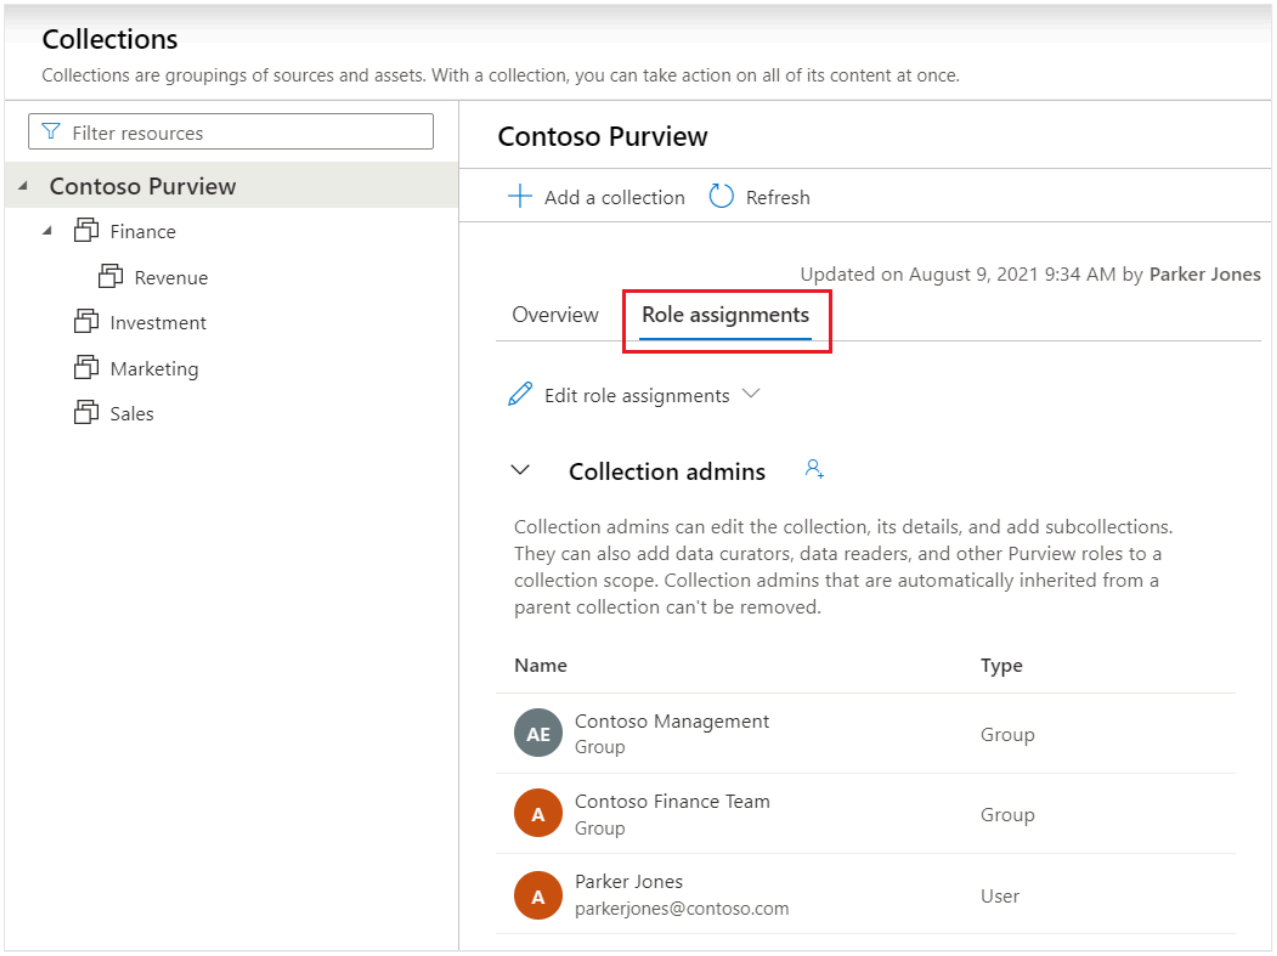
- An Azure account with an active subscription. Create an account for free.
- Your own Microsoft Entra tenant.
- An active Microsoft Purview account.

Check permissions

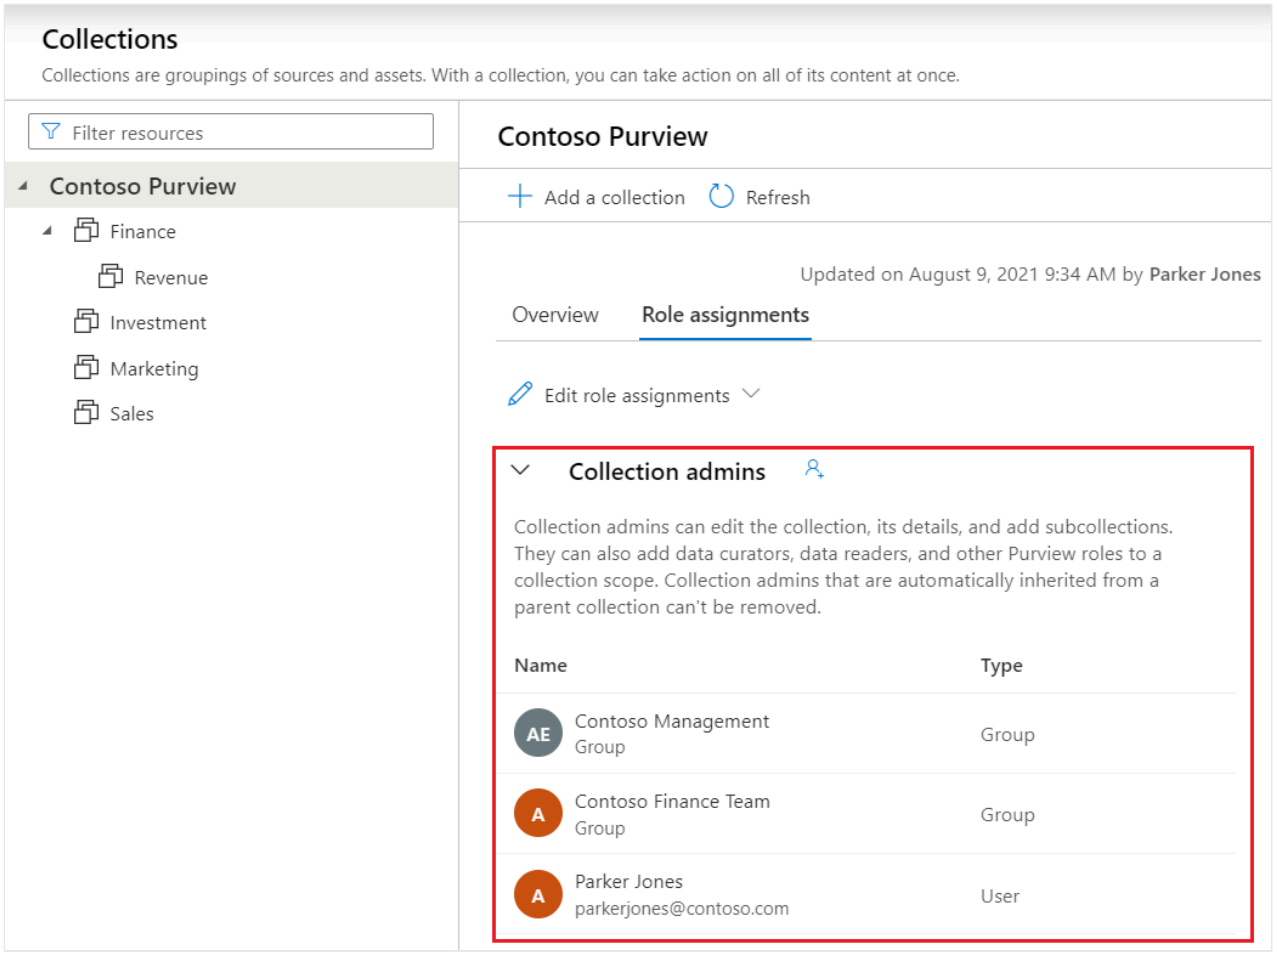


In order to create and manage collections in Data Map, you need to be a **Collection Admin** within the classic Microsoft Purview governance portal. We can check these permissions in the governance portal. You can find the governance portal by:

- Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
- Open the Azure portal, search for and select the Microsoft Purview account you want to use to receive the share. Open the classic Microsoft Purview governance portal.



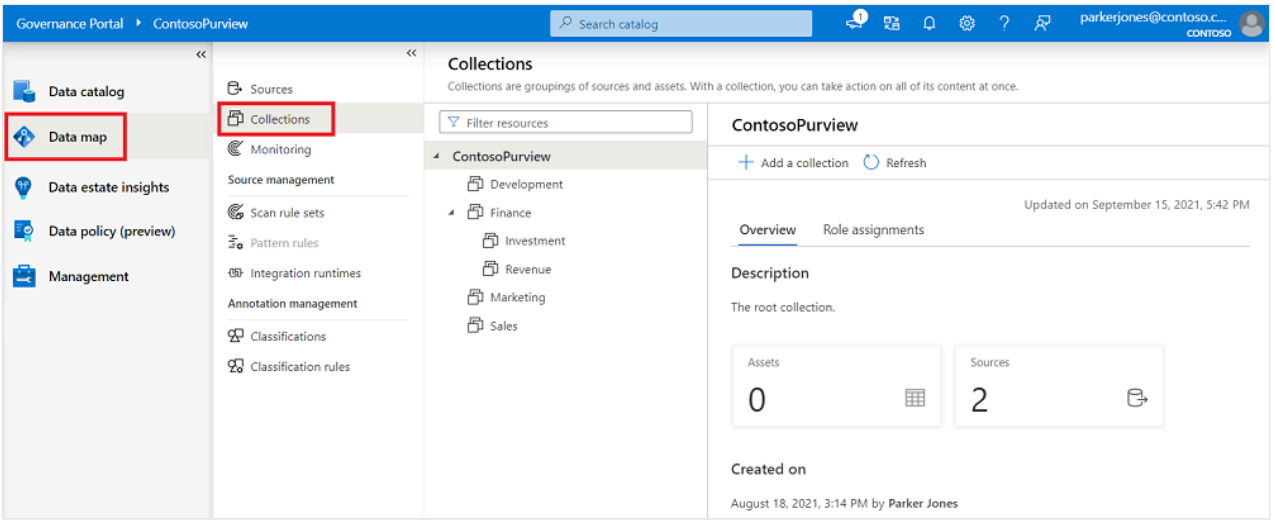
1. Select Data Map > Collections from the left pane to open collection management page.



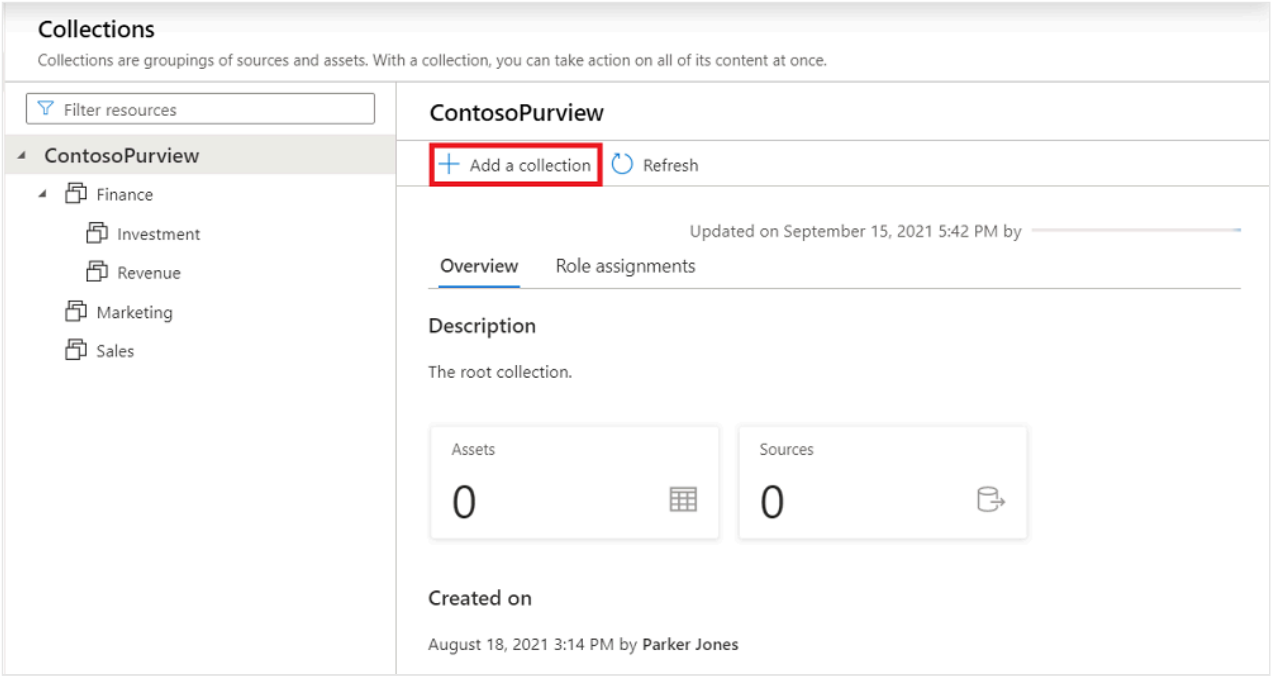
2. Select your root collection. This is the top collection in your collection list and will have the same name as your Microsoft Purview account. In our example below, it's called ContosoPurview.

3. Select role assignments in the collection window.

4. To create a collection, you need to be in the collection admin list under role assignments. If you created the account, you should be listed as a collection admin under the root collection already. If not, you need to contact the collection admin to grant you permission.

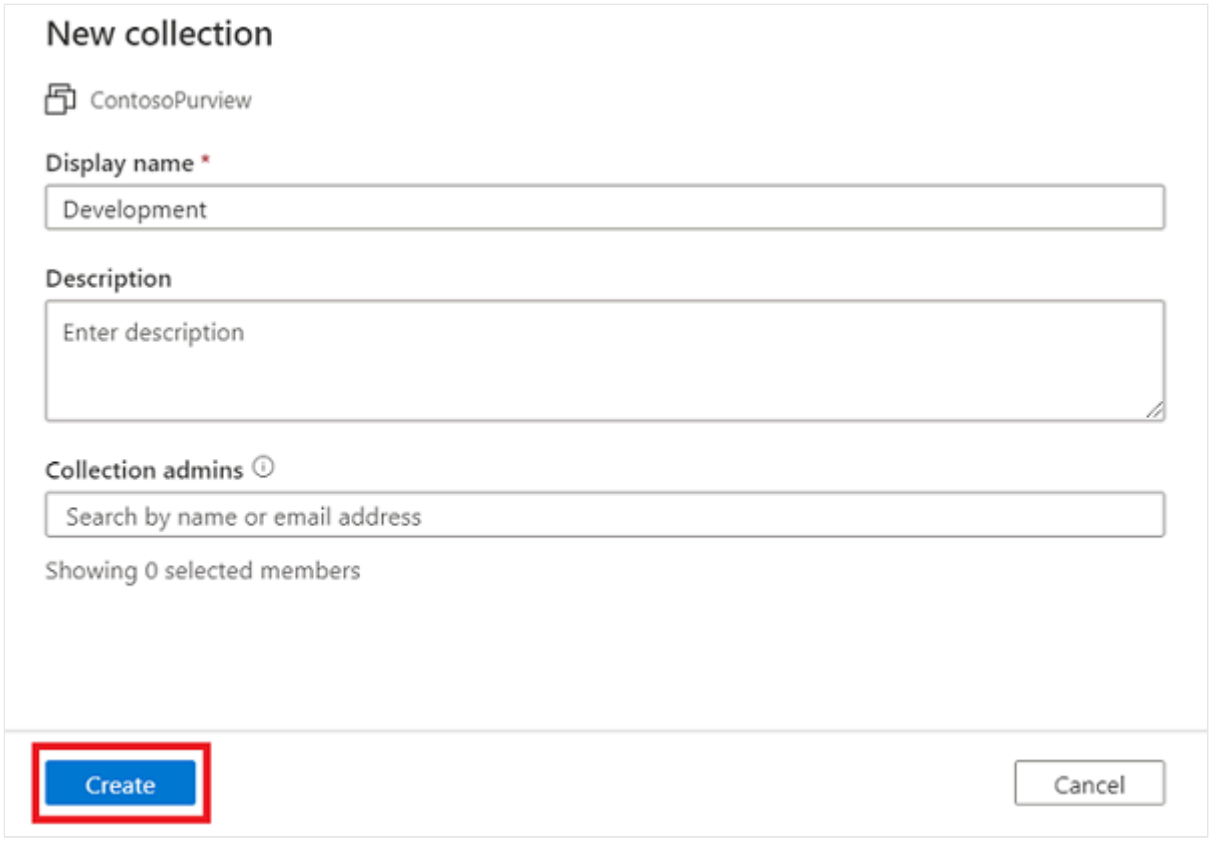


Create a collection in the portal

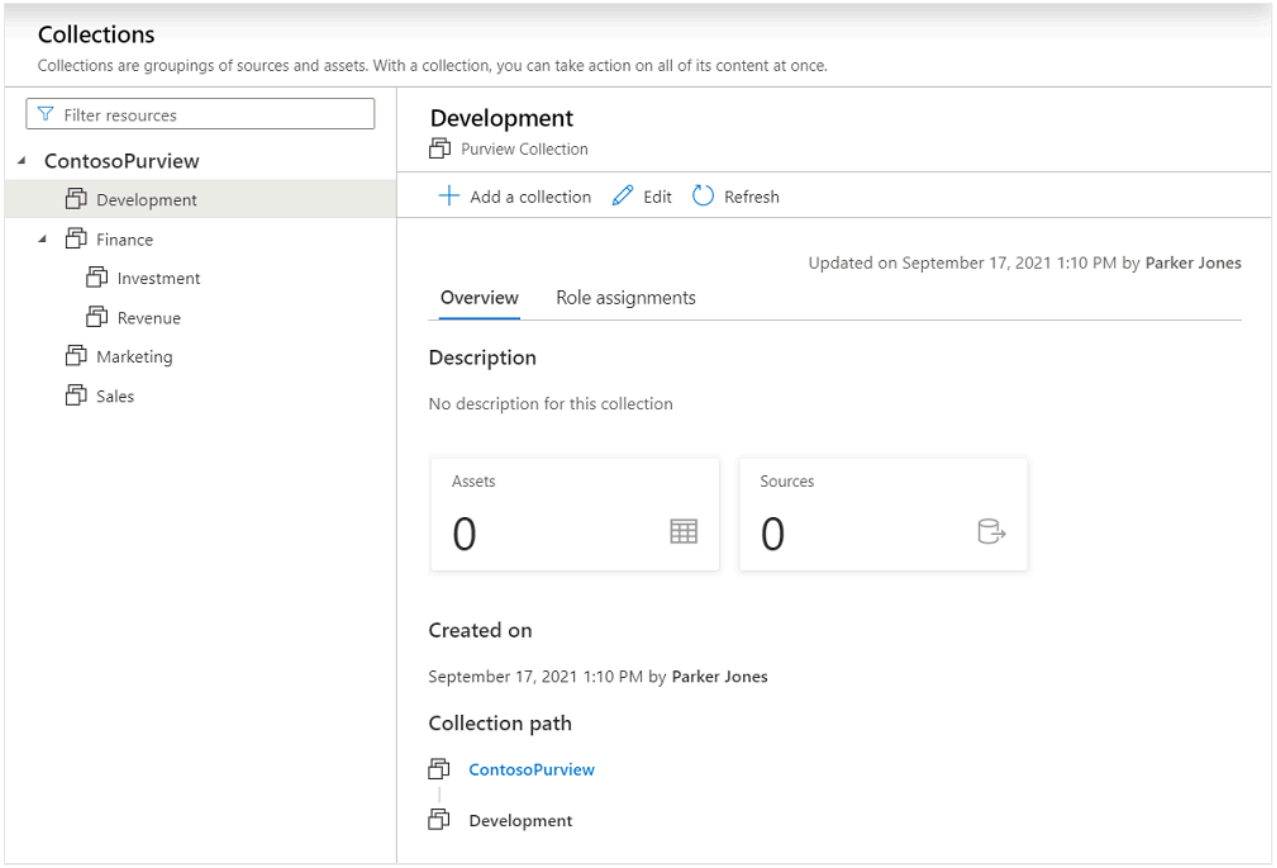


To create your collection, start in the classic Microsoft Purview governance portal. You can find the portal by:

- Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
- Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the classic **Microsoft Purview governance portal** button.



1. Select Data Map > Collections from the left pane to open collection management page.



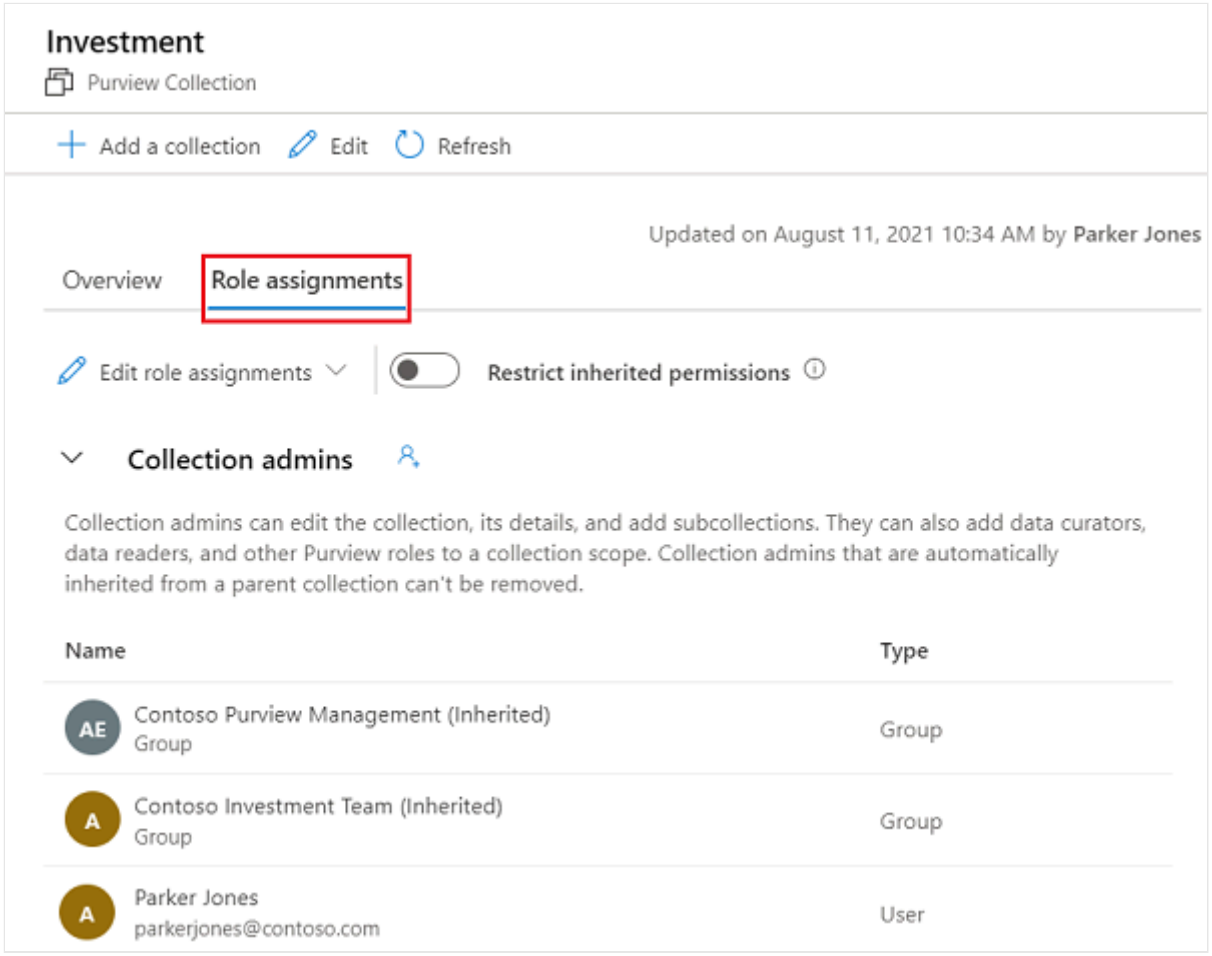
2. Select + **Add a collection**.

3. In the right panel, enter the collection name, description, and search for users to add them as collection admins.

4. Select **Create**. The collection information displays on the page.

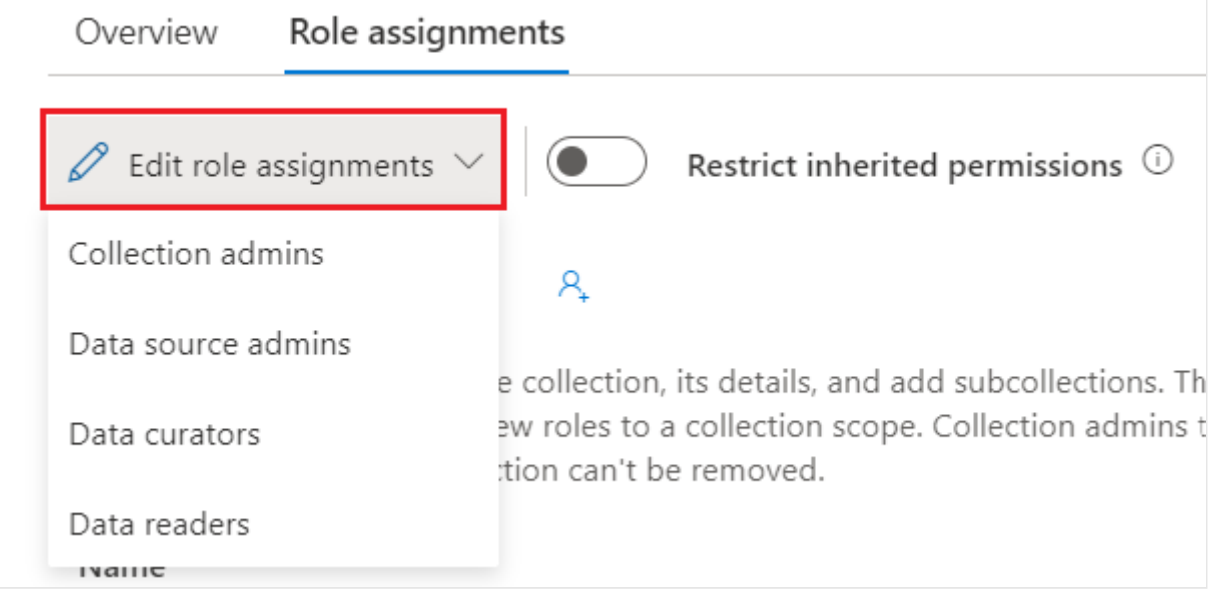
Assign permissions to collection

Now that you have a collection, you can assign permissions to this collection to manage your users access to the classic Microsoft Purview governance portal.



Roles

All assigned roles apply to sources, assets, and other objects within the collection where the role is applied.



- **Collection admins** - can edit a collection, its details, manage access in the collection, and add subcollections.
- **Data source admins** - can manage data sources and data scans.
- **Data curators** - can create, read, modify, and delete actions on catalog data objects.
- **Data readers** - can access but not modify catalog data objects.

Assign permissions

1. Select **Role assignments** tab to see all the roles in a collection.

2. Select **Edit role assignments** or the person icon to edit each role member.

3. Type in the textbox to search for users you want to add to the role member. Select **OK** to save the change.

Next steps

Now that you have a collection, you can follow these guides to add resources, scan, and manage your collections.

- Register source to collection
- Access management through collections

Data sources that connect to Data Map

This article lists the supported data sources, file types, and scanning concepts in Microsoft Purview Data Map.

Data source listing by type

The tables below show all data sources that have technical metadata available in Microsoft Purview Data Map, along with other supported capabilities. Select a data source name in the **Data source** column for instructions on connecting that source to Data Map.

- Microsoft Azure
- Database
- File
- Services and apps

Azure

Azure resources are only available in the same tenant as your Microsoft Purview account, unless noted otherwise on each data source's page.

Expand table

* Besides the lineage on assets within the data source, lineage is also supported if dataset is used as a source/sink in Data Factory or Synapse pipeline.

** Power BI items in a Fabric tenant are available using live view.

> **Note**

Currently, the Microsoft Purview Data Map can't scan an asset that has `/`, `\`, or `#` in its name. To scope your scan and avoid scanning assets that have those characters in the asset name, use the example in Register and scan an Azure SQL Database.

> **Important**
>
> If you plan on using a self-hosted integration runtime, scanning some data sources requires extra setup on the self-hosted integration runtime machine. For example, JDK, Microsoft Visual C++ Redistributable, or specific driver. For your source, refer to each source article for prerequisite details. Any requirements are listed in the **Prerequisites** section.

Data Map scanner regions

The following list shows the Azure data source (data center) regions where the Data Map scanner runs. If your Azure data source is in a region outside of this list, the scanner runs in the region of your Microsoft Purview instance.

- Australia East
- Australia Southeast
- Brazil South
- Canada Central
- Canada East
- Central India
- China North 3
- East Asia
- East US
- East US 2
- France Central
- Germany West Central
- Japan East
- Korea Central
- North Central US
- North Europe
- Qatar Central
- South Africa North
- South Central US
- Southeast Asia

- Switzerland North
- UAE North
- UK South
- USGov Virginia
- West Central US
- West Europe
- West US
- West US 2
- West US 3

File types supported for scanning

The file types listed in the following section support scanning, schema extraction, and classification where applicable. Additionally, Data Map supports custom file extensions and custom parsers.

Structured file formats supported by extension include scanning, schema extraction, and asset and column level classification:

- AVRO
- CSV
- GZIP
- JSON
- ORC
- PARQUET*
- PSV
- SSV
- TSV
- TXT
- XML

*For noncompressed PARQUET files, all Parquet formats are supported. For compressed PARQUET files, only snappy Parquet format is supported.

Document file formats supported by extension include scanning and asset level classification:

- DOC
- DOCM
- DOCX

- DOT
- ODP
- ODS
- ODT
- PDF
- POT
- PPS
- PPSX
- PPT
- PPTM
- PPTX
- XLC
- XLS
- XLSB
- XLSM
- XLSX
- XLT

> ⓘ **Note**
>
> **Known limitations:**
>
> - The Microsoft Purview Data Map scanner only supports schema extraction for the structured file types listed in the previous section.
> - For AVRO, ORC, and PARQUET file types, the scanner doesn't support schema extraction for files that contain complex data types (for example, MAP, LIST, STRUCT).
> - For noncompressed PARQUET files, all Parquet formats are supported. For compressed PARQUET files, only snappy Parquet format is supported for schema extraction and classification.
> - For GZIP file types, the GZIP must be mapped to a single CSV file within. GZIP files are subject to system and custom classification rules. The scanner currently doesn't support scanning a GZIP file mapped to multiple files within, or any file type other than CSV.
> - For Parquet files, if you're using a self-hosted integration runtime, you need to install the **64-bit JRE 11 (Java Runtime Environment) or OpenJDK** on your IR machine. See the Java runtime installation guide.

- The Delta format isn't supported. If you're scanning the Delta format directly from storage data source like Microsoft Azure Data Lake Storage Gen2, the set of Parquet files from the delta format are parsed and handled as resource set as described in Understanding resource sets. The columns used for partitioning aren't recognized as part of the schema for the resource set.

- Unsupported Parquet encodings: Microsoft Purview doesn't support schema extraction for Parquet files that use run-length encoding (RLE) in Microsoft Fabric Lakehouse. Tables containing RLE-encoded columns might fail to extract schema metadata, including tables, columns, and data types. The process still discovers asset-level metadata (L1). To enable full schema extraction, re-create the affected tables by using a supported encoding format, such as dictionary or plain encoding.

For delimited file types (CSV, PSV, SSV, TSV, TXT):

- Delimited files with only one column can't be determined to be CSV files and have no schema.
- Data type detection isn't supported. The data type is listed as "string" for all columns.
- The only supported delimiters are comma(','), semicolon(';'), vertical bar('|'), and tab('\t').
- Delimited files with less than three rows can't be determined to be CSV files if they're using a custom delimiter. For example, files with ~ delimiter and less than three rows can't be determined to be CSV files.
- If a field contains double quotes, the double quotes can only appear at the beginning and end of the field and must be matched. Double quotes that appear in the middle of the field or appear at the beginning and end but aren't matched are recognized as bad data and no schema is parsed from the file. Rows that have different number of columns than the header row are judged as error rows. The numbers of error rows divided by the numbers of rows sampled must be less than 0.1.

Schema extraction

For data sources that support schema extraction during scan, the number of columns doesn't directly truncate the asset schema.

Nested data

Nested data is only supported for JSON content. For all system supported file types, if there's nested JSON content in a column, then the scanner parses the nested JSON data and surfaces it

within the schema tab of the asset.

Nested data, or nested schema parsing, isn't supported in SQL. A column with nested data will be reported and classified as is, and subdata won't be parsed.

Sampling data for classification

In Data Map terminology,

- L1 scan: Extracts basic information and metadata like file name, size, and fully qualified name.
- L2 scan: Extracts schema for structured file types and database tables.
- L3 scan: Extracts schema where applicable and subjects the sampled file to system and custom classification rules.

Learn more about customizing the scan levels.

For all structured file formats, the Microsoft Purview Data Map scanner samples files in the following way:

- For structured file types, it samples the top 128 rows in each column or the first 1 MB, whichever is lower.
- For document file formats, it samples the first 20 MB of each file.
- If a document file is larger than 20 MB, the scanner doesn't perform a deep scan (subject to classification). In that case, Microsoft Purview captures only basic metadata like file name and fully qualified name.
- For **tabular data sources (SQL)**, it samples the top 128 rows.
- For **Azure Cosmos DB for NoSQL**, up to 300 distinct properties from the first 10 documents in a container are collected for the schema. For each property, the scanner samples values from up to 128 documents or the first 1 MB.
- For unstructured data formats, such as DOCX files, there's no requirement to meet a condition of eight distinct values. The presence of a single relevant keyword is sufficient for classification.

Resource set file sampling

If a folder or group of partition files matches a system resource set policy or a customer-defined resource set policy, Data Map detects it as a *resource set*. If the scanner detects a resource set, it samples each folder it contains. For more information about resource sets, see Resource sets in Microsoft Purview Data Map.

File sampling for resource sets by file types:

- **Delimited files (CSV, PSV, SSV, TSV)**: The scanner samples 1 in 100 files (L3 scan) within a folder or group of partition files that are considered as a resource set.
- **Data Lake file types (Parquet, Avro, Orc)**: The scanner samples 1 in 18,446,744,073,709,551,615 (long max) files (L3 scan) within a folder or group of partition files that are considered as a resource set.
- **Other structured file types (JSON, XML, TXT)**: The scanner samples 1 in 100 files (L3 scan) within a folder or group of partition files that are considered as a resource set.
- **SQL objects and Azure Cosmos DB entities**: The scanner L3 scans each file.
- **Document file types**: The scanner L3 scans each file. Resource set patterns don't apply to these file types.

Credentials for source authentication in Microsoft Purview Data Map

10/24/2025

This article describes how you can create credentials in Microsoft Purview Data Map. These saved credentials let you quickly reuse and apply saved authentication information to your data source scans.

Prerequisites

- A Microsoft Azure Key Vault. To learn how to create one, see Quickstart: Create a key vault using the Azure portal.

Introduction

A credential is authentication information that Microsoft Purview can use to authenticate to your registered data sources. A credential object can be created for various types of authentication scenarios, such as Basic Authentication requiring username/password. Credential capture specific information required to authenticate, based on the chosen type of authentication method. Credentials use your existing Key Vault secrets for retrieving sensitive authentication information during the Credential creation process.

In Microsoft Purview, there are few options to use as authentication method to scan data sources such as the following options. Learn from each data source article for its supported authentication.

- Microsoft Purview system-assigned managed identity
- User-assigned managed identity (preview)
- Account Key (using Key Vault)
- SQL Authentication (using Key Vault)
- Service Principal (using Key Vault)
- Consumer Key (using Key Vault)
- And more

Before creating any credentials, consider your data source types and networking requirements to decide which authentication method you need for your scenario.

Use Microsoft Purview system-assigned managed identity to set up scans

If you're using the Microsoft Purview system-assigned managed identity (SAMI) to set up scans, you won't need to create a credential and link your key vault to Microsoft Purview to store them. For detailed instructions on adding the Microsoft Purview SAMI to have access to scan your data sources, refer to the data source-specific authentication sections below:

- Azure Blob Storage
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure SQL Database
- Azure SQL Managed Instance
- Azure Synapse Workspace
- Azure Synapse dedicated SQL pools (formerly SQL DW)

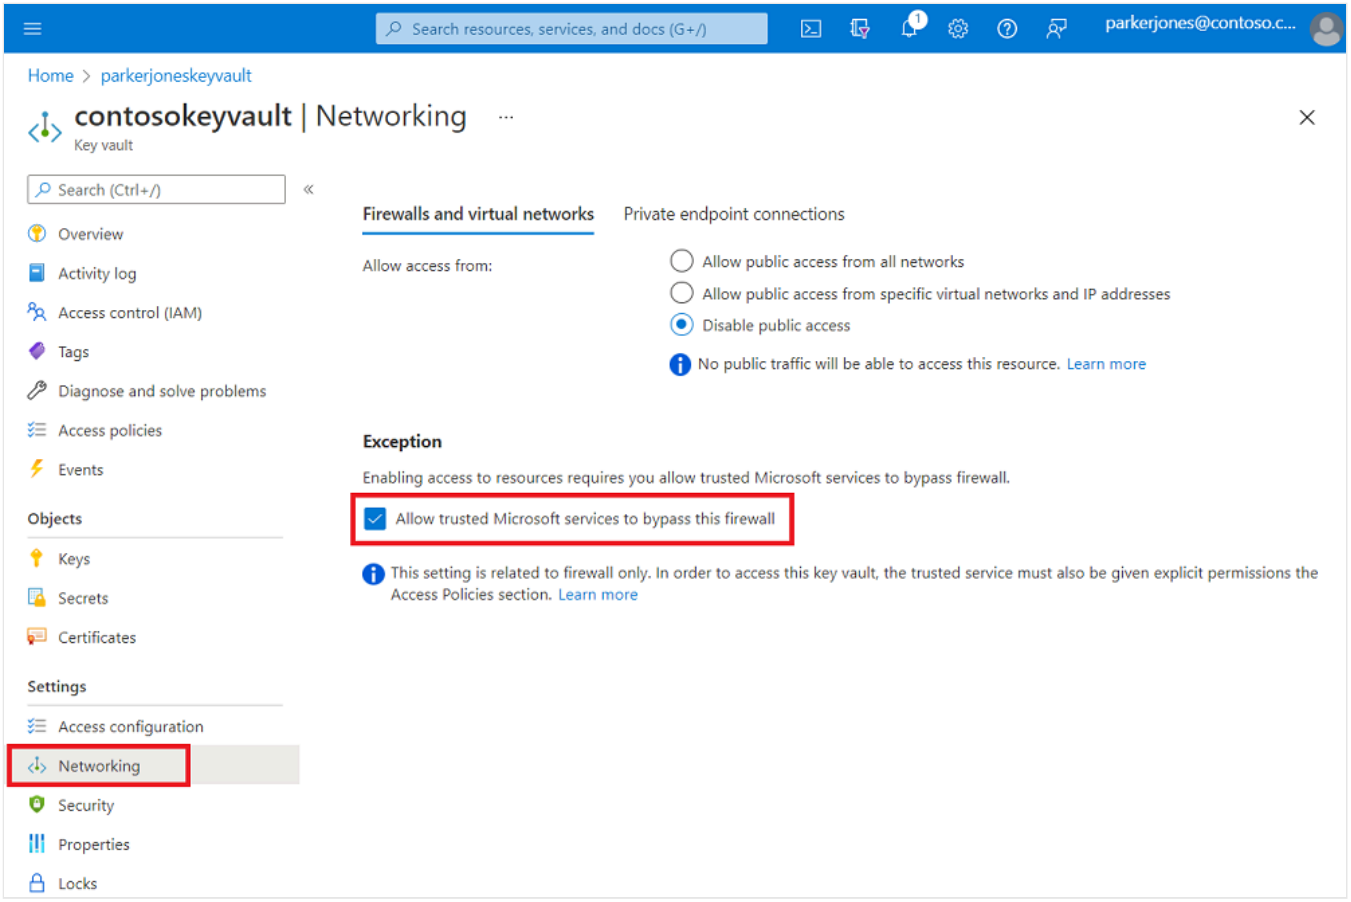
Grant Microsoft Purview access to your Azure Key Vault

To give Microsoft Purview access to your Azure Key Vault, there are two things you need to confirm:

- Firewall access to the Azure Key Vault
- Microsoft Purview permissions on the Azure Key Vault

Firewall access to Azure Key Vault

If your Azure Key Vault has disabled public network access, you have two options to allow access for Microsoft Purview.



- Trusted Microsoft services
- Private endpoint connections

Trusted Microsoft services

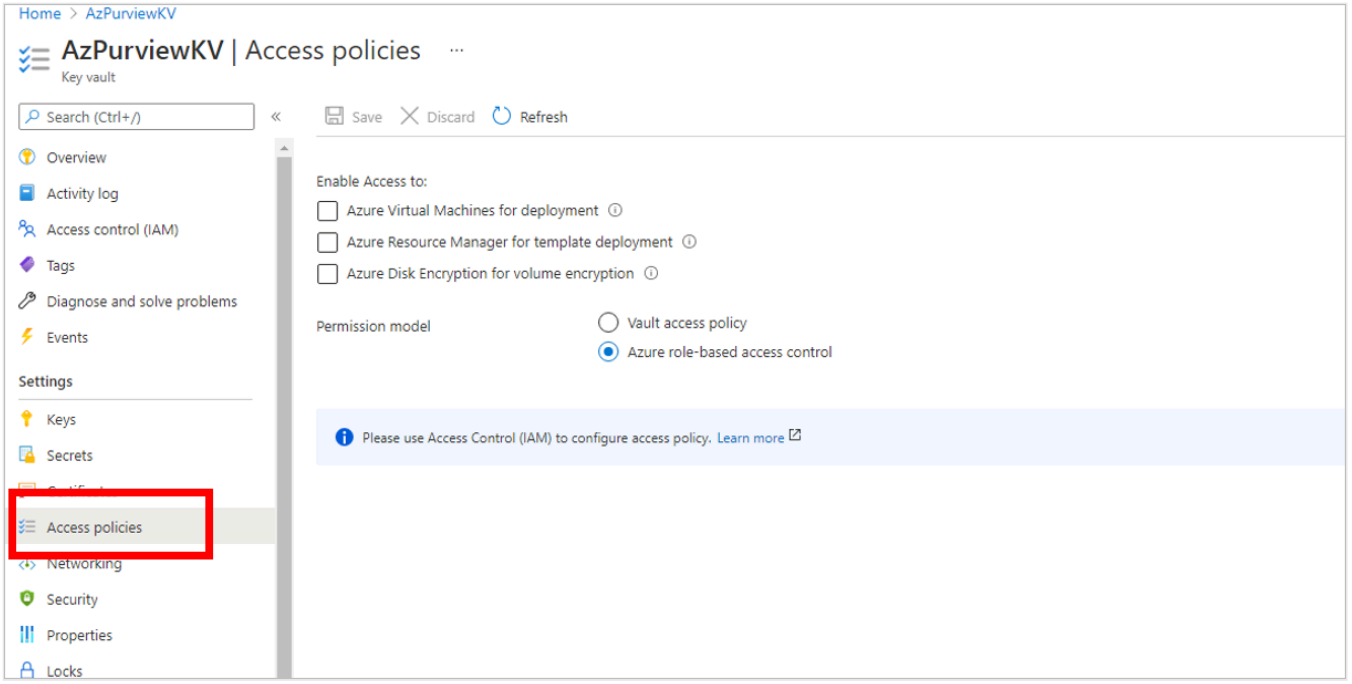
Microsoft Purview is listed as one of Azure Key Vault's trusted services, so if public network access is disabled on your Azure Key Vault you can enable access only to trusted Microsoft services, and Microsoft Purview will be included.

You can enable this setting in your Azure Key Vault under the **Networking** tab.

At the bottom of the page, under Exception, enable the **Allow trusted Microsoft services to bypass this firewall** feature.

Private endpoint connections

To connect to Azure Key Vault with private endpoints, follow Azure Key Vault's private endpoint documentation.



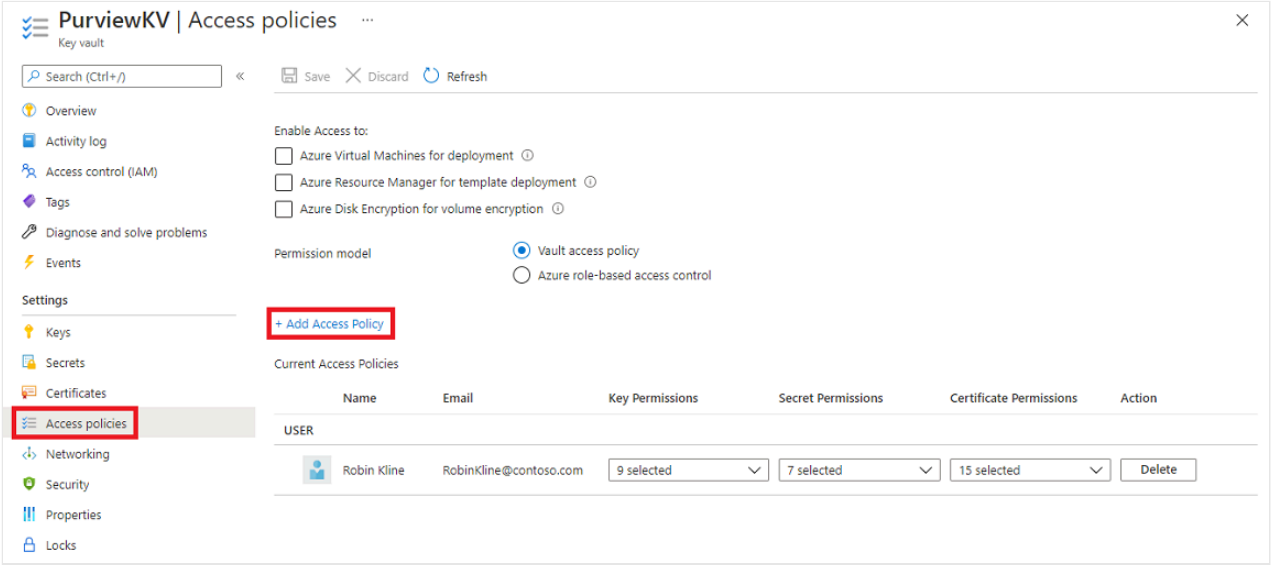
> **Note**
>
> Private endpoint connection option is supported when using Azure integration runtime in managed virtual network to scan the data sources. For self-hosted integration runtime, you need to enable trusted Microsoft services.

Microsoft Purview permissions on the Azure Key Vault

Currently Azure Key Vault supports two permission models:

- Option 1 - Access Policies
- Option 2 - Role-based Access Control

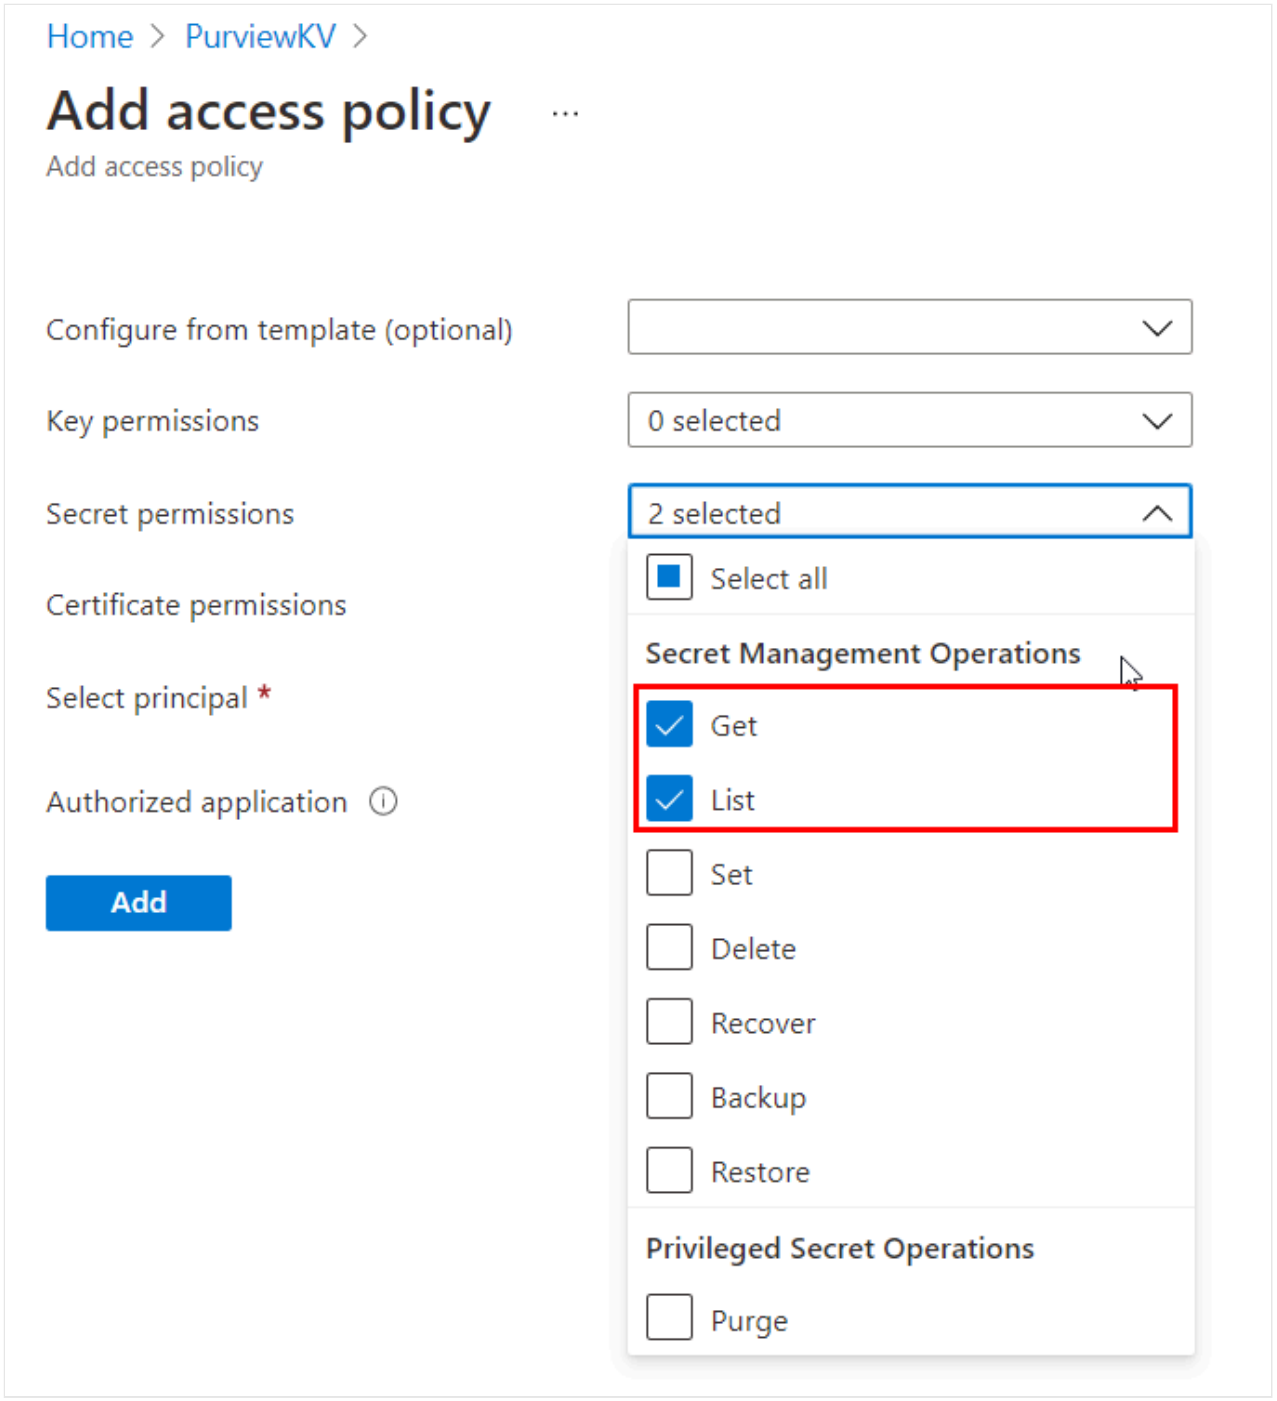
Before assigning access to the Microsoft Purview system-assigned managed identity (SAMI), first identify your Azure Key Vault permission model from Key Vault resource **Access Policies** in the menu. Follow steps below based on relevant the permission model.



Option 1 - Assign access using Key Vault Access Policy

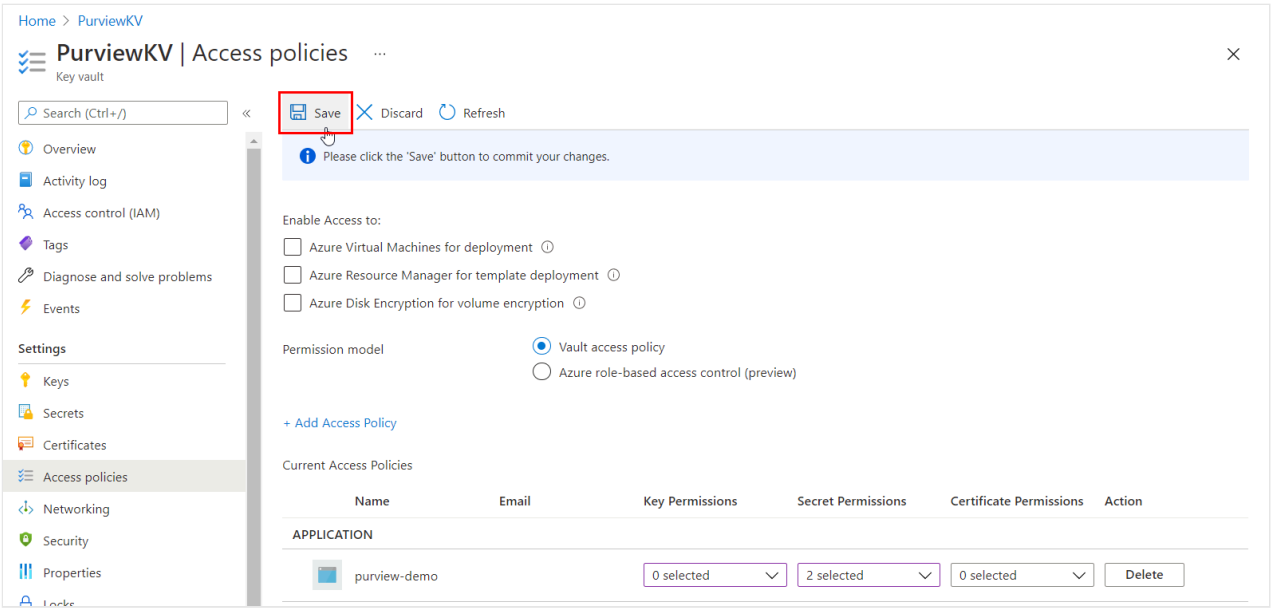
Follow these steps only if permission model in your Azure Key Vault resource is set to **Vault Access Policy**:

1. Navigate to your Azure Key Vault.



2. Select the **Access policies** page.

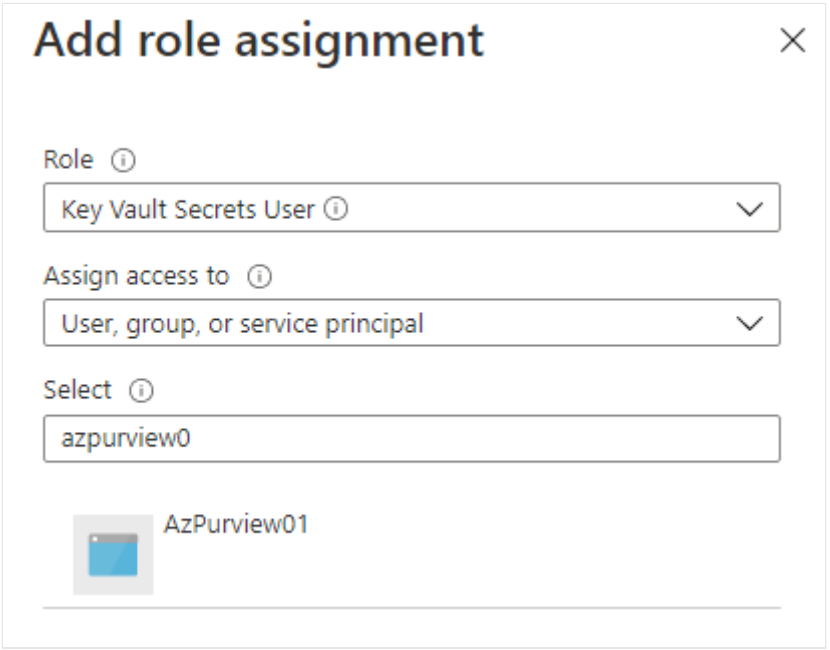
3. Select **Add Access Policy**.



4. In the **Secrets permissions** dropdown, select **Get** and **List** permissions.

5. For **Select principal**, choose the Microsoft Purview system managed identity. You can search for the Microsoft Purview SAMI using either the Microsoft Purview instance name **or** the managed identity application ID. We don't currently support compound identities (managed identity name + application ID).

6. Select **Add**.

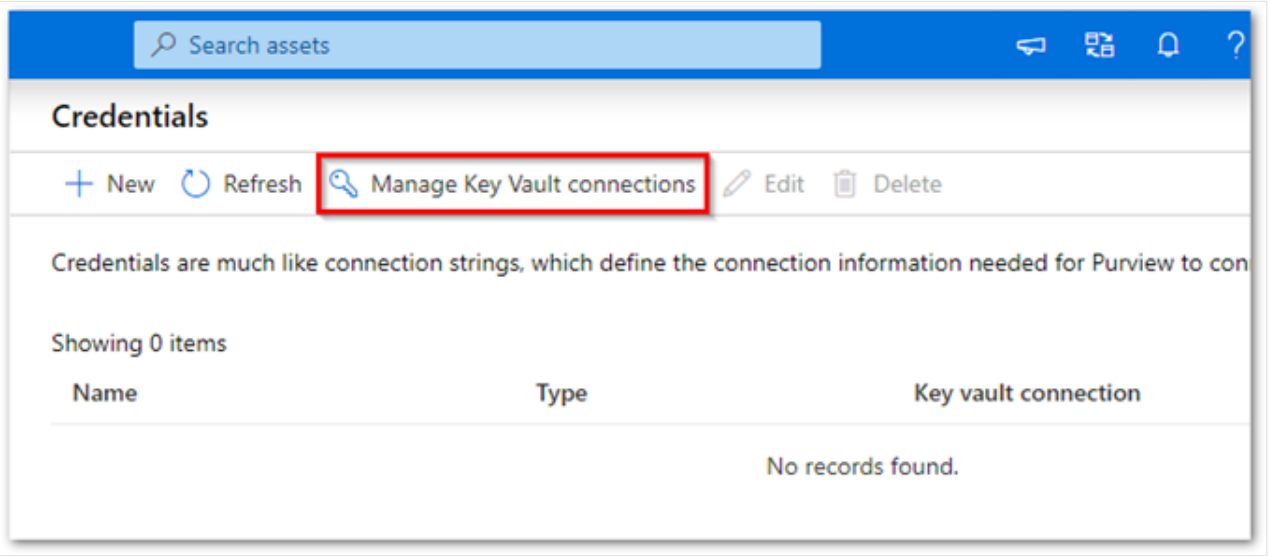


7. Select **Save** to save the Access policy.

Option 2 - Assign access using Key Vault Azure role-based access control

Follow these steps only if permission model in your Azure Key Vault resource is set to **Azure role-based access control**:

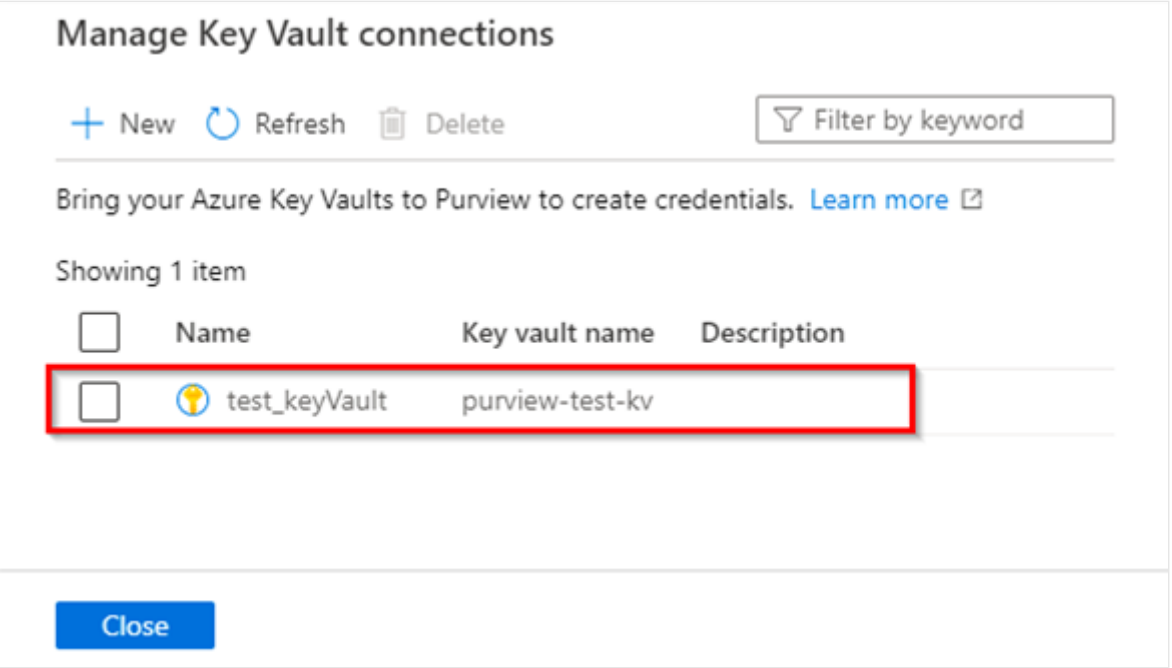
1. Navigate to your Azure Key Vault.
2. Select **Access Control (IAM)** from the left navigation menu.
3. Select **+ Add**.
4. Set the **Role** to **Key Vault Secrets User** and enter your Microsoft Purview account name under **Select** input box. Then, select Save to give this role assignment to your Microsoft Purview account.



Create Azure Key Vaults connections in your Microsoft Purview account

Before you can create a Credential, first associate one or more of your existing Azure Key Vault instances with your Microsoft Purview account.

1. If you're using the classic Microsoft Purview portal, navigate to the **Management Center** in the studio and then navigate to **Credentials**. If you're using the new Microsoft Purview portal, open **Data Map**, select **Source management**, then select **Credentials**.



2. From the **Credentials** page, select **Manage Key Vault connections**.

3. Select + **New** from the Manage Key Vault connections page.

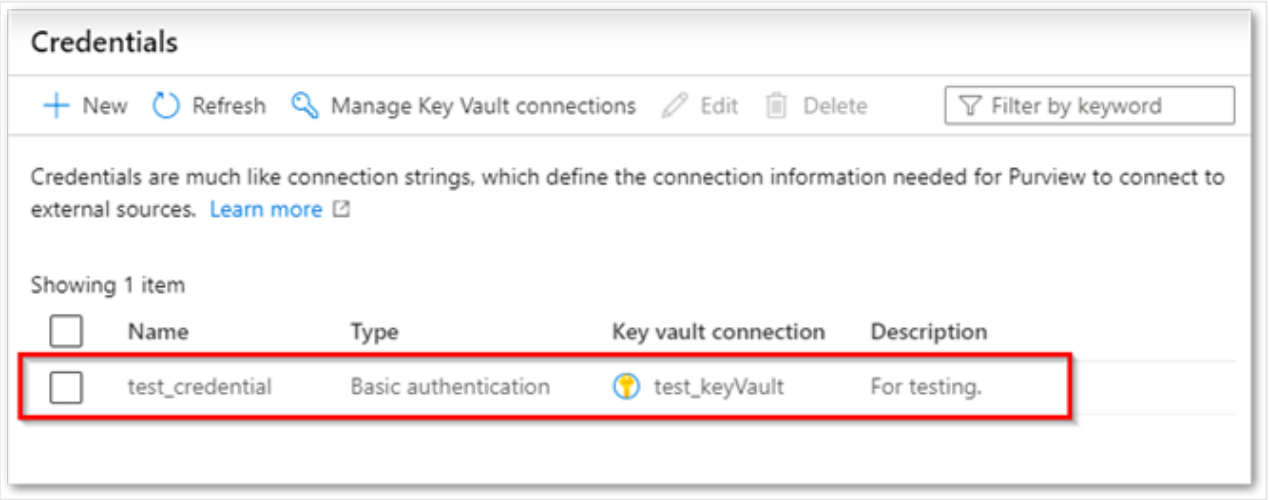
4. Provide the required information, then select **Create**.

5. Confirm that your Key Vault has been successfully associated with your Microsoft Purview account as shown in this example:

Create a new credential

These credential types are supported in Microsoft Purview:

- Basic authentication: You add the **password** as a secret in key vault.
- Service Principal: You add the **service principal key** as a secret in key vault.
- SQL authentication: You add the **password** as a secret in key vault.
- Windows authentication: You add the **password** as a secret in key vault.
- Account Key: You add the **account key** as a secret in key vault.
- Role ARN: For an Amazon S3 data source, add your **role ARN** in AWS.
- Consumer Key: For Salesforce data sources, you can add the **password** and the **consumer secret** in key vault.
- User-assigned managed identity (preview): You can add user-assigned managed identity credentials. For more information, see the create a user-assigned managed identity section below.



For more information, see Add a secret to Key Vault and Create a new AWS role for Microsoft Purview.

After storing your secrets in the key vault:

1. Provide 'Reader access' to the user at the Azure subscription level.
2. In Microsoft Purview, go to the Credentials page.
3. Create your new Credential by selecting + **New**.
4. Provide the required information. Select the **Authentication method** and a **Key Vault connection** from which to select a secret from.

5. Once all the details have been filled in, select **Create**.

6. Verify that your new credential shows up in the list view and is ready to use.

Manage your key vault connections

1. Search for Key Vault connections by entering a name in the search box.

2. Delete one or more Key Vault connections by selecting the checkbox next to the Key Vault's name, then selecting **Delete**.

Manage your credentials

1. Search/find Credentials by name.

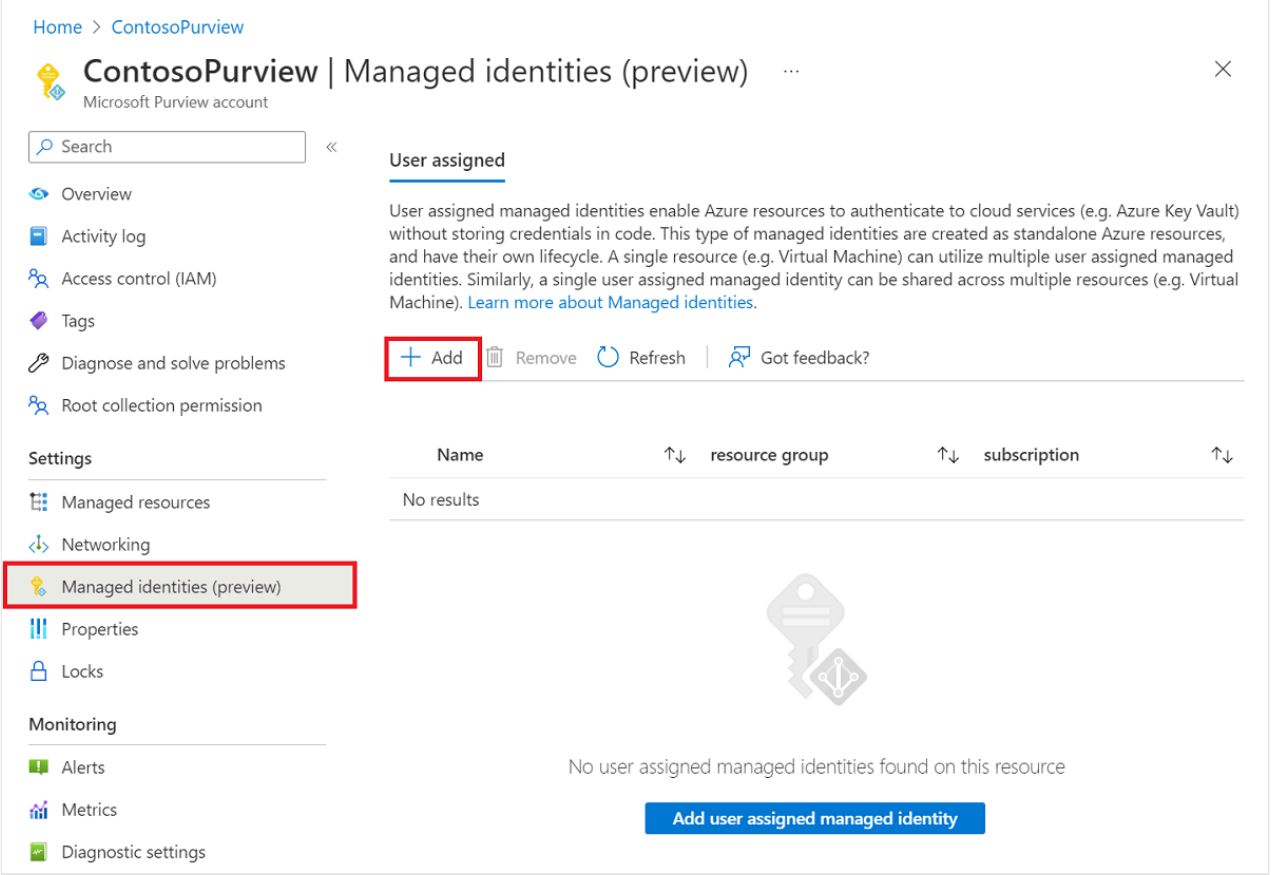
2. Select and make updates to an existing Credential.

3. Delete one or more Credentials.

Create a user-assigned managed identity

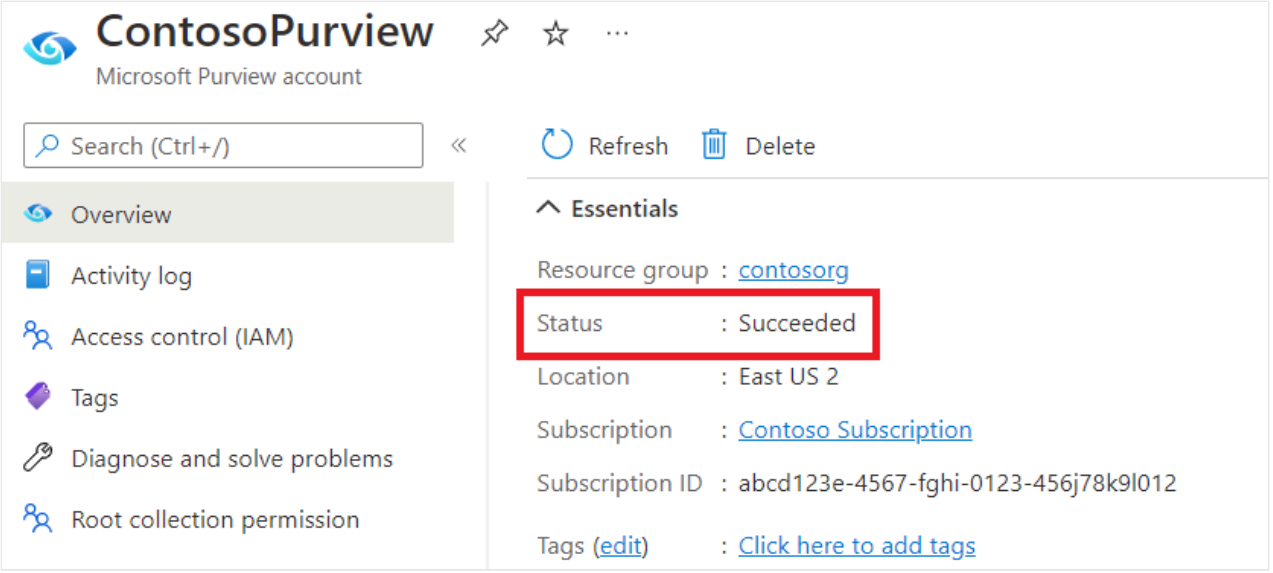
User-assigned managed identities (UAMI) enable Azure resources to authenticate directly with other resources using Microsoft Entra authentication, without the need to manage those credentials. They allow you to authenticate and assign access just like you would with a system assigned managed identity, Microsoft Entra user, Microsoft Entra group, or service principal. User-assigned managed identities are created as their own resource (rather than being connected to a preexisting resource). For more information about managed identities, see the managed identities for Azure resources documentation.

The following steps explain how to create a UAMI for Microsoft Purview to use.



Supported data sources for UAMI

- Azure Data Lake Gen 1
- Azure Data Lake Gen 2
- Azure SQL Database
- Azure SQL Managed Instance
- Azure SQL Dedicated SQL pools
- Azure Blob Storage



Create a user-assigned managed identity

1. In the Azure portal, navigate to your Microsoft Purview account.

2. In the **Managed identities** section on the left menu, select the **+ Add** button to add user assigned managed identities.

3. After finishing the setup, go back to your Microsoft Purview account in the Azure portal. If the managed identity is successfully deployed, you'll see the Microsoft Purview account's status as **Succeeded**.

4. Once the managed identity is successfully deployed, navigate to the classic Microsoft Purview governance portal by selecting **Open Microsoft Purview governance portal**.

5. In the classic Microsoft Purview governance portal, navigate to the Management Center in the studio and then navigate to the Credentials section.

6. Create a user-assigned managed identity by selecting **+New**.

7. Select the Managed identity authentication method from the **Authentication method** dropdown list, and make a selection from the **User assigned managed identities** dropdown list.

   > **Note**
   >
   > If the portal was open during creation of your user assigned managed identity, you need to refresh the Microsoft Purview portal to load the settings finished in the Azure portal.

8. When done filling in all the information, select **Create**.

Delete a user-assigned managed identity

1. In the Azure portal navigate to your Microsoft Purview account.

2. In the **Managed identities** section on the left menu, select the identity you want to delete.

3. Select the **Remove** button.

4. Once the managed identity is successfully removed, navigate to the classic Microsoft Purview governance portal by selecting **Open Microsoft Purview governance portal**.
5. Navigate to the Management Center in the studio and then navigate to the Credentials section.
6. Select the identity you want to delete, and then select the **Delete** button.

> **Note**
>
> If you have deleted a user-assigned managed identity in the Azure portal, you need to delete the original identity and create a new one in the Microsoft Purview portal.

Next steps

Create a scan rule set.

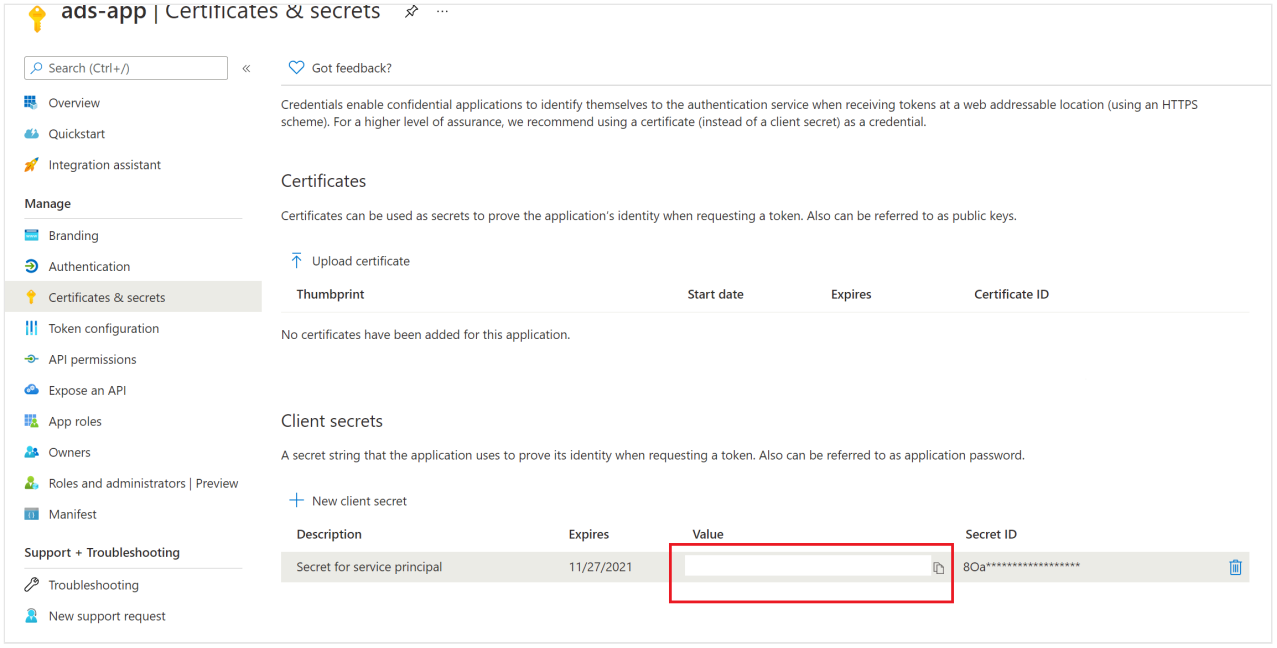
Create a service principal for use with Microsoft Purview

You can create a new or use an existing service principal in your Microsoft Entra tenant to authenticate Microsoft Purview with other services. This article explains how to prepare a service principal for Purview to use to authenticate with other services.

App registration

1. Follow the steps in this linked article section to create a service principal: Register an application with Microsoft Entra ID and create a service principal.

   > **Tip**
   >
   > For the Redirect URL, if you have an authentication endpoint for your organization you want to use, add it. Otherwise, `https://contoso.com/auth` works.

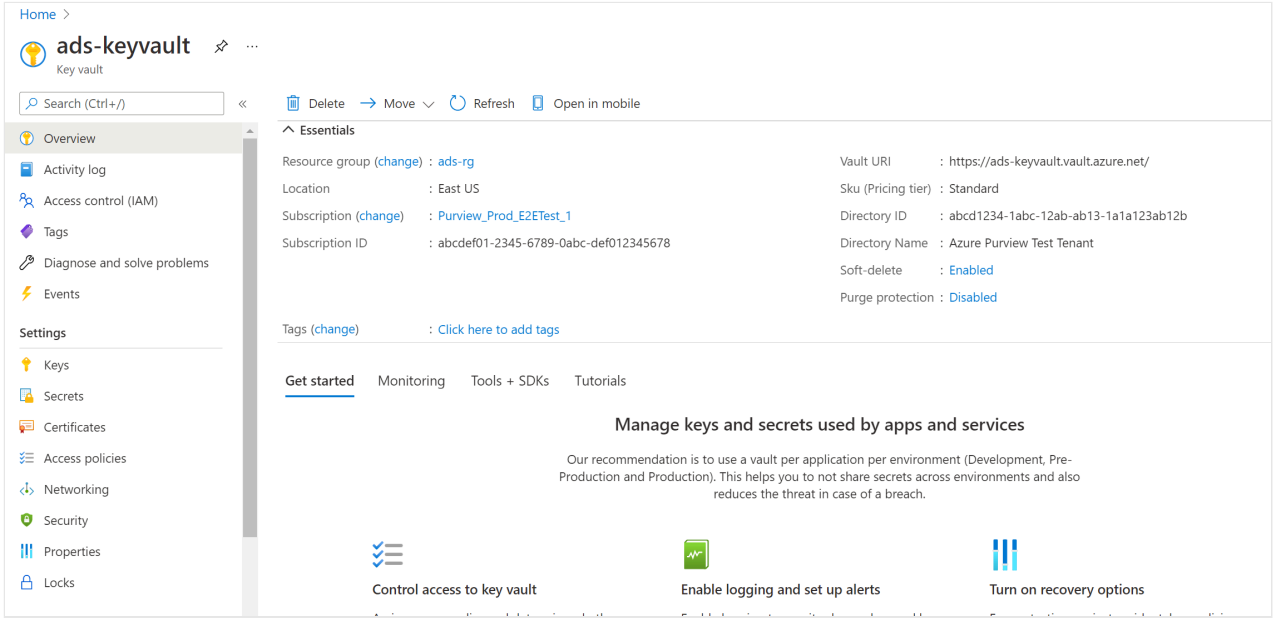


2. Once you register the app, copy the **Application (client) ID** value. Use this value later to create a credential in Microsoft Purview.

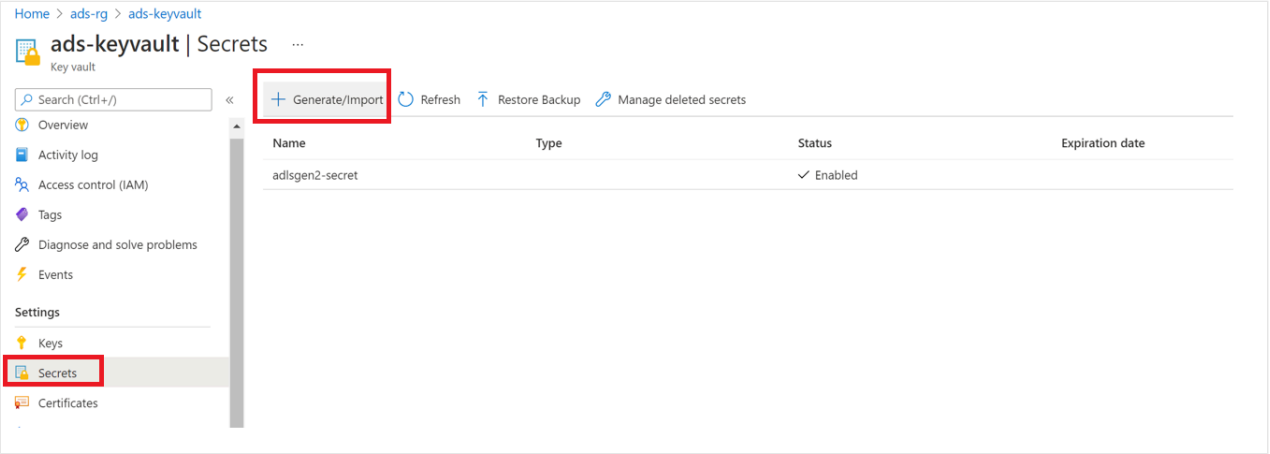
Add a secret to the client credentials

1. Follow the steps in this linked article section to create a new client secret: Create a new client secret.

2. Copy the **Secret value**. Use this value later to create a secret in Azure Key Vault (KV).



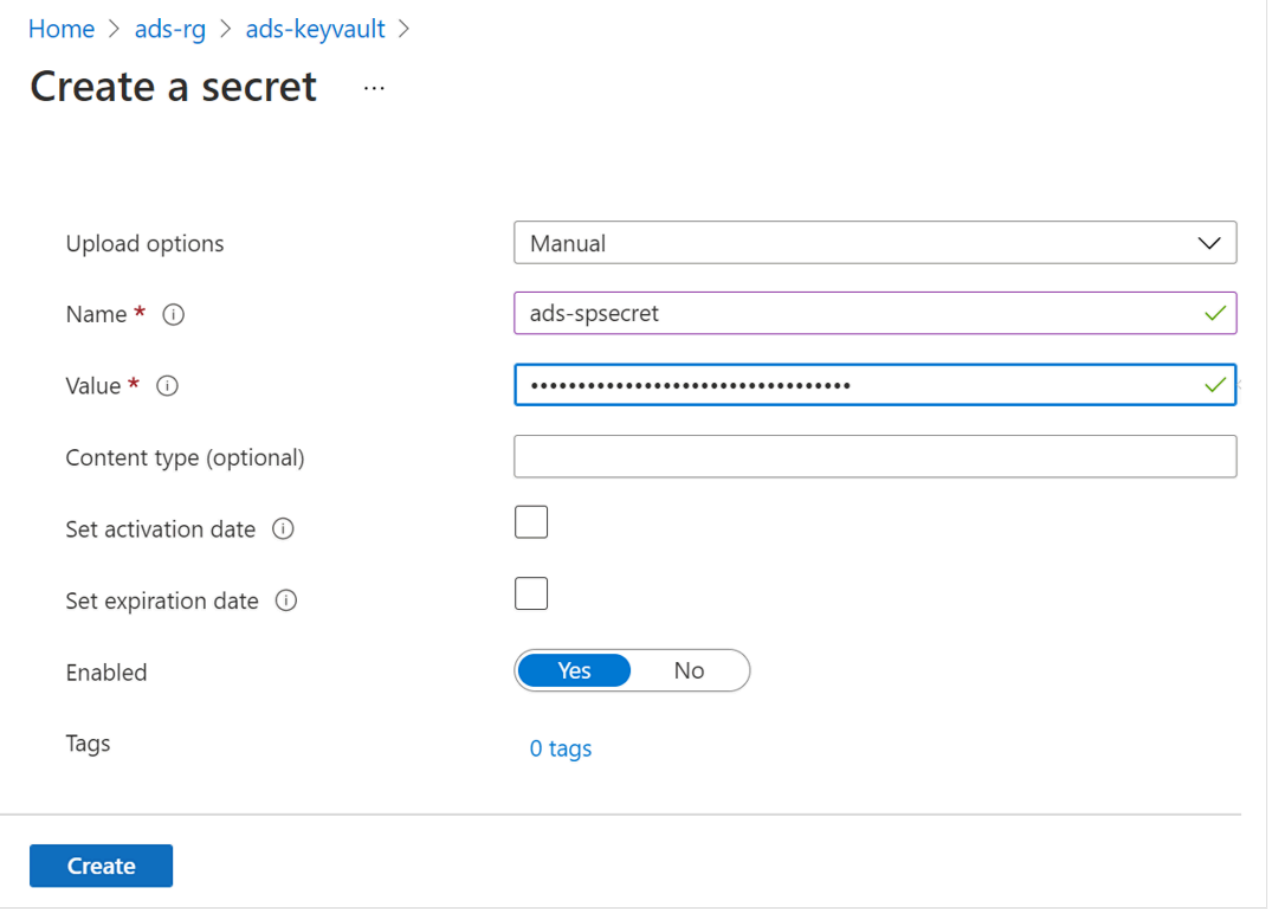
Add the secret to your Azure Key Vault



To allow Microsoft Purview to use this service principal to authenticate with other services, store this credential in Azure Key Vault.

- If you need an Azure Key vault, you can follow these steps to create one.
- To grant your Microsoft Purview account access to the Azure Key Vault, you can follow these steps.

1. Go to your **Key Vault**.



2. Select **Settings** > **Secrets** > **+ Generate/Import**.

3. Enter the **Name** of your choice, and save it to create a credential in Microsoft Purview.

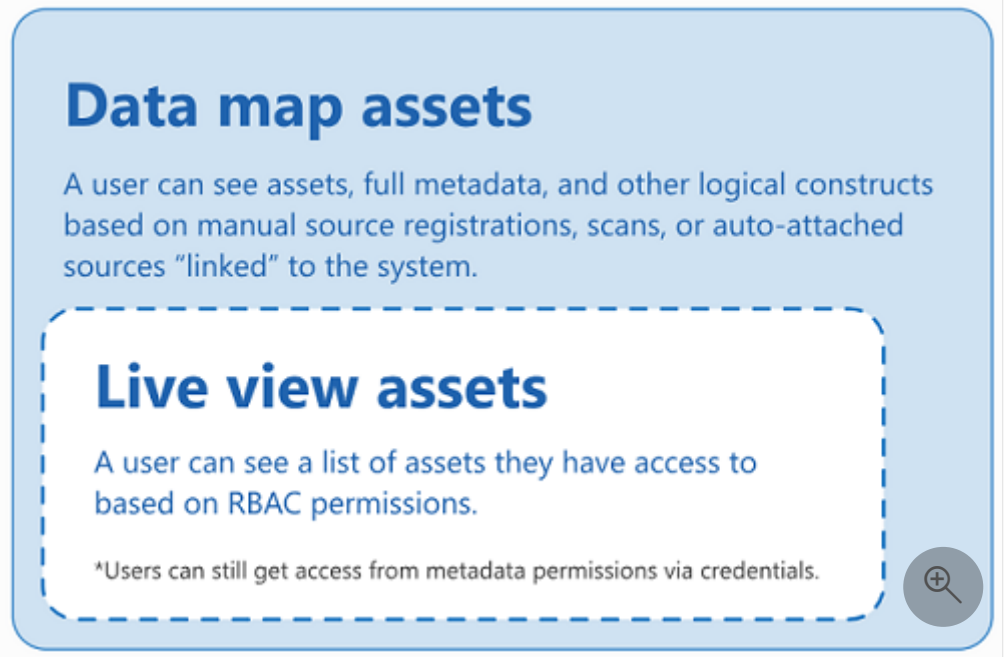
4. Enter the **Value** as the **Secret value** from your Service Principal.

5. Select **Create** to complete.

Create a credential for your secret in Microsoft Purview

To enable Microsoft Purview to use this service principal to authenticate with other services, follow these three steps:

1. Connect your Azure Key Vault to Microsoft Purview
2. Grant your service principal authentication on your source. Every source is different, so select your specific source page from the list of supported sources and follow instructions to assign permissions.
3. Create a new credential in Microsoft Purview - Use the service principal's application (client) ID and the name of the secret you created in your Azure Key Vault.



Last updated on 12/08/2025

Live view in Microsoft Purview (preview)

06/02/2025

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Some Azure resources are available to be seen in live view. Live view means that users with data access permissions can find these resources and their data assets in the catalog without setup or scanning. These resources and their metadata are immediately available when you access the free or enterprise versions of Microsoft Purview, so you can start your governance journey quickly.

In this article we'll cover:

- What resources have live view available
- What metadata is available in live view
- Who has permissions to live view resources
- Next steps to govern live view resources

Limitations

- Live view for Microsoft Fabric limitations:
  - Personal workspaces aren't supported yet in live view.

- Only Microsoft Fabric item level metadata are available in live view.
- Power BI Datasets don't support showing schema in live view if the item hasn't been scanned.
- Dataflow Gen2 (Preview) items are displayed as Dataflow items.

What resources have live view available?

Live view resources in the same tenant as your Microsoft Purview account are automatically accessible for users in your catalog. These resources have live view available:

Expand table

Resource	Level of view available
Azure Blob Storage	Storage account, Azure Blob Service, Container
Azure Data Lake Storage Gen 2	Storage account, Azure Data Lake Storage Gen2 Service, File system
Azure SQL Database	Server, Database, Schema, Tables, Columns
Azure Subscriptions	Live view assets in the subscription
Microsoft Fabric	Workspace, Item

Users with permissions can browse and search for these assets in the catalog without needing to set up a scan.

Metadata available in live view

Resources in live view in the catalog automatically have this metadata available:

- Name
- Properties
- Schema
- Lineage

> **Note**
>
> Live view resources won't automatically have classifications applied. To automatically apply classifications to these resources, you need to upgrade to the enterprise version of Microsoft Purview, register and scan the resource.

Data owners can also update the metadata on live view resources to add more information. Including manually adding description, contacts, etc.

Live view permissions

Users that have permissions on the available resources are automatically able to access these resources in the catalog as either data readers or data owners. No other permissions in Microsoft Purview are required.

Data readers

These are the permissions needed on the resources for a user to be able to see it as a reader in live view in Microsoft Purview.

Expand table

Data source	Reader permission
Azure SQL Database	Reader role in Azure
Azure Blob Storage	Reader role in Azure
Azure Data Lake Storage Gen2	Reader role in Azure
Azure Subscription	Read permission on subscription

Data owners

These are the permissions needed on the resources for a user to be able to see it as an owner and curate its metadata in live view in Microsoft Purview.

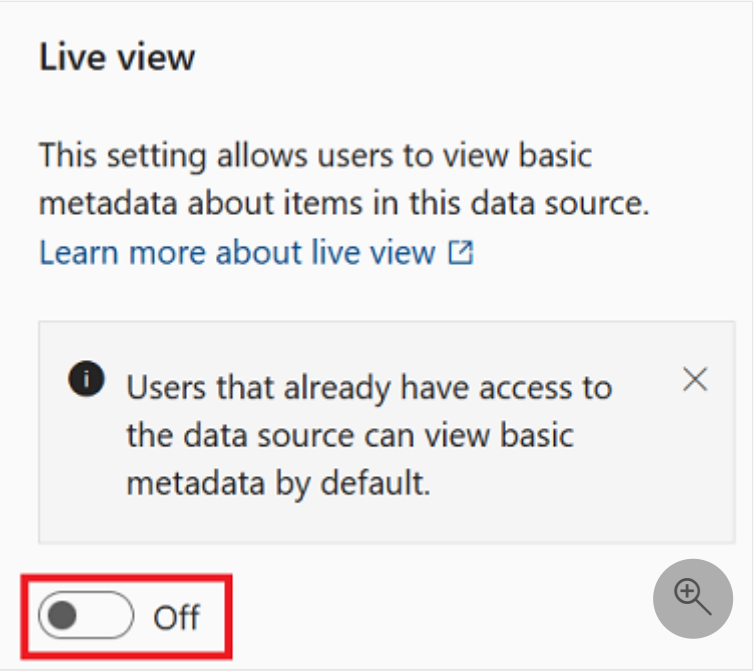
Expand table

Data source	Owner permission
Azure SQL Database	"Microsoft.Sql/servers/write", "Microsoft.Sql/servers/databases/write", "Microsoft.Authorization/roleAssignments/write"
Azure Blob Storage	"Microsoft.Storage/storageAccounts/write", "Microsoft.Authorization/roleAssignments/write"
Azure Data Lake Storage Gen2	"Microsoft.Storage/storageAccounts/write", "Microsoft.Authorization/roleAssignments/write"

Extend live view permissions

You can expand discoverability of these resources to users that don't have permissions already by enabling live view for all users. This can only be enabled with an enterprise version of Microsoft Purview. Extending live view also deepens the level of information available.

Expand table



Resource	Level of view available
Azure Blob Storage	Storage account, Azure Blob Service, Container, Folders, Files
Azure Data Lake Storage Gen 2	Storage account, Azure Data Lake Storage Gen2 Service, File system, Folders, Files
Azure SQL Database	Server, Database, Schema, Tables, Columns, Views, Stored procedures

> **Note**
>
> - For Azure Blob storage and Azure Data Lake Storage Gen 2, file schema is provided for parquet files.
> - You can't extend live view permissions for Microsoft Fabric sources.

To enable these permissions, the user must be a Data Source Administrator and Reader on the collection where they're going to host the resource.

To enable:

1. Browse the catalog for the source where you want to expand live view to users who don't already have data access permissions.
2. Select the data source.
3. Switch the **Live view** toggle under **Source management** to enable it.

4. Add a credential for your resource. Select an existing credential or add a new one. Your available options depend on which resources you're using. For more information about each credential, follow these links:

    - Azure Blob Storage credential
    - Azure Data Lake Gen 2 credential
    - Azure SQL Database credential

5. Select **Test connection** to test your credential. You can only extend live view with a successful connection. Follow this guide to troubleshoot connections.

6. Choose a collection for your resource.

    > **Tip**
    >
    > Follow this link for more information about permissions in collections.

7. Select **Apply** to register your source and extend your permissions.

Preset scan

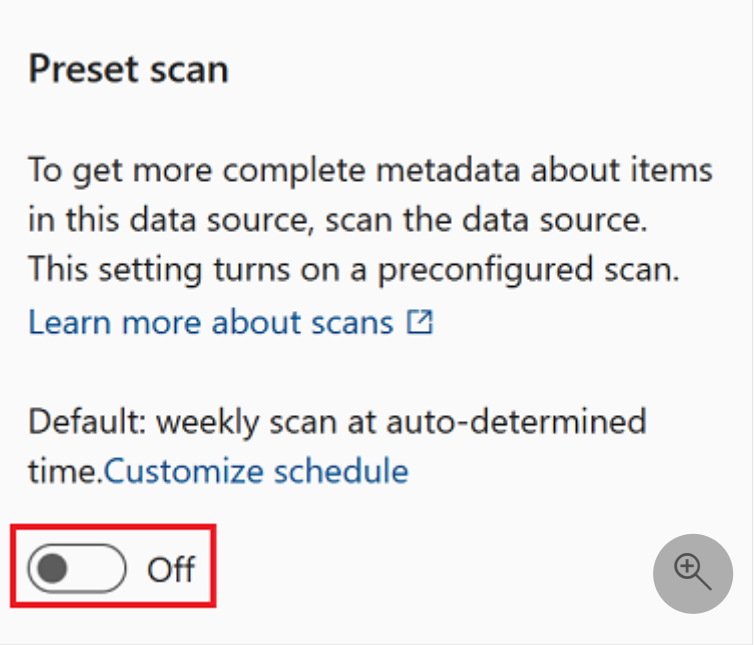
> **Note**
>
> Microsoft Fabric resources don't currently support a preset scan.

Assets with a live view allow data source administrators to perform preset scans. A live view asset has only some of it's metadata automatically available to users. A preset scan gathers the rest of that metadata and makes it available in Microsoft Purview.

A preset scan can only be run in the enterprise version of Microsoft Purview, and runs a scan with these default options:

- Full scan - all data assets are scanned and updated
- Default classifications - Microsoft Purview will check for default classifications for the source
- Scheduled - the scan is scheduled to run weekly by default, but the schedule can be updated.

> **Tip**



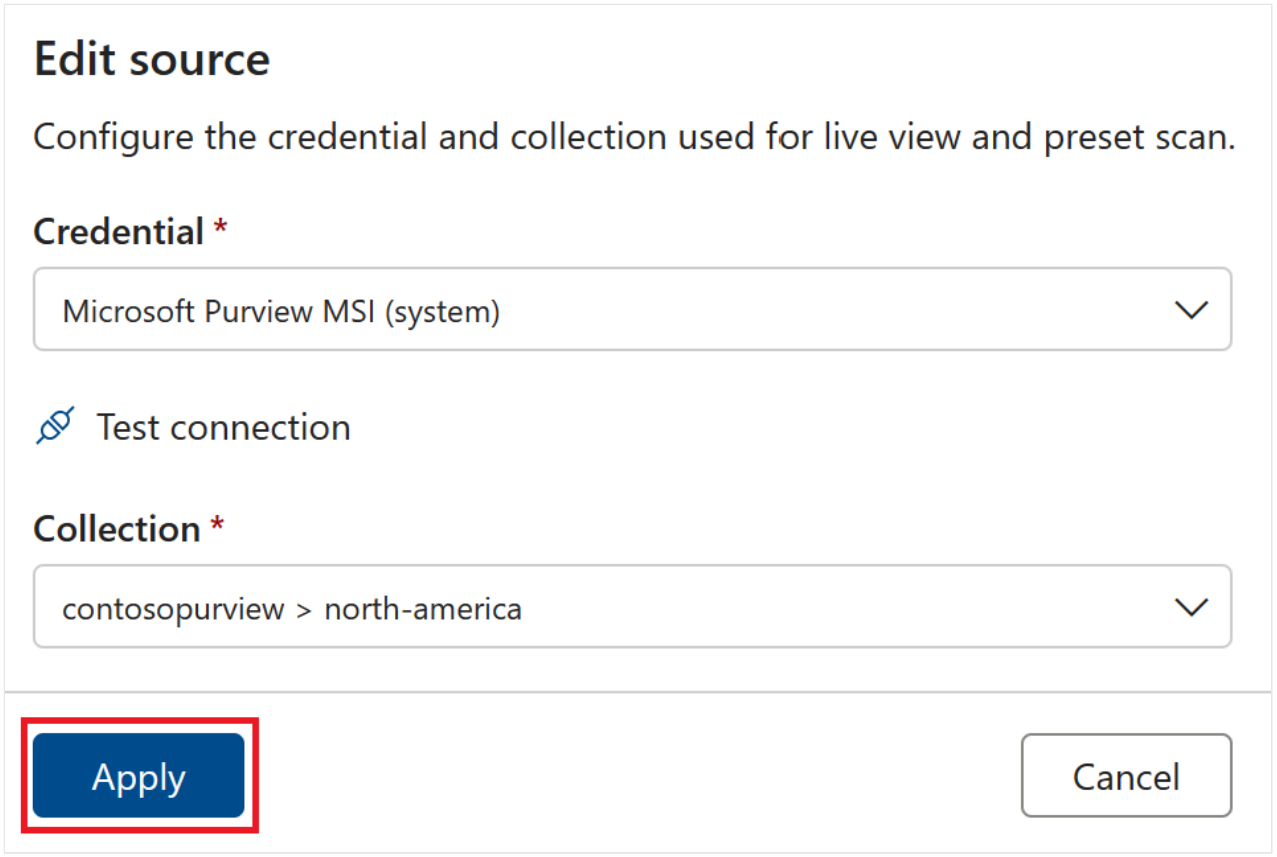
To run a scan with any other options available to your source and organization, like custom classifications, perform a regular scan.

To run a preset scan, a user must be a Data Source Administrator on the collection where they're going to host the resource.

1. Browse the catalog for the source where you want to run a preset scan to enhance the metadata.

2. Select the data source.

3. Select the **Preset scan** toggle under **Source management** to scan.

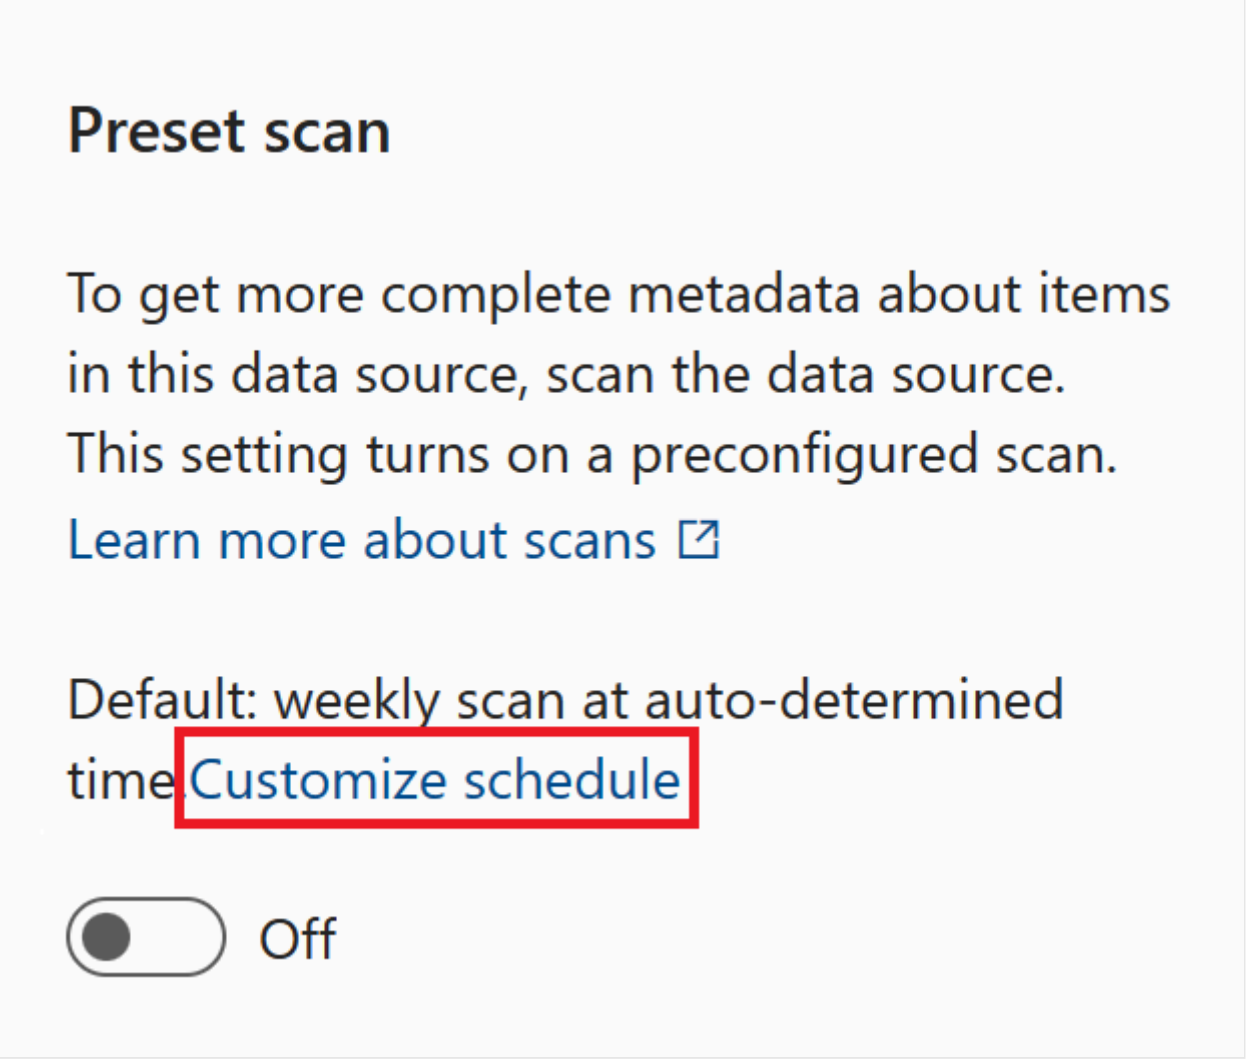


4. If live view permissions have already been extended, the scan starts. If live view hasn't been enabled, you need to submit a credential and select a collection to house the metadata:

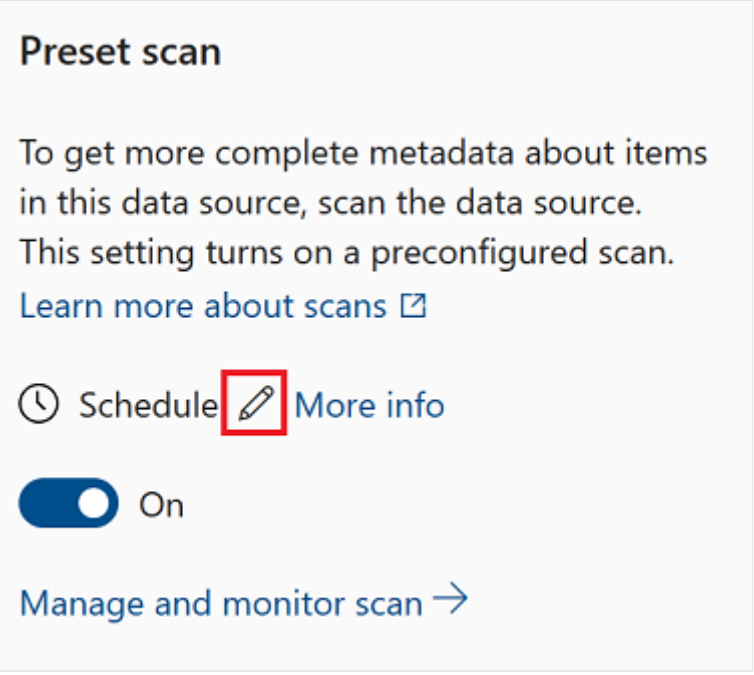
    - Azure Blob Storage credential
    - Azure Data Lake Gen 2 credential
    - Azure SQL Database credential

5. Select **Test connection** to test your credential. You can only scan with a successful connection. Follow this guide to troubleshoot connections.

6. Select **Apply** to run your scan.

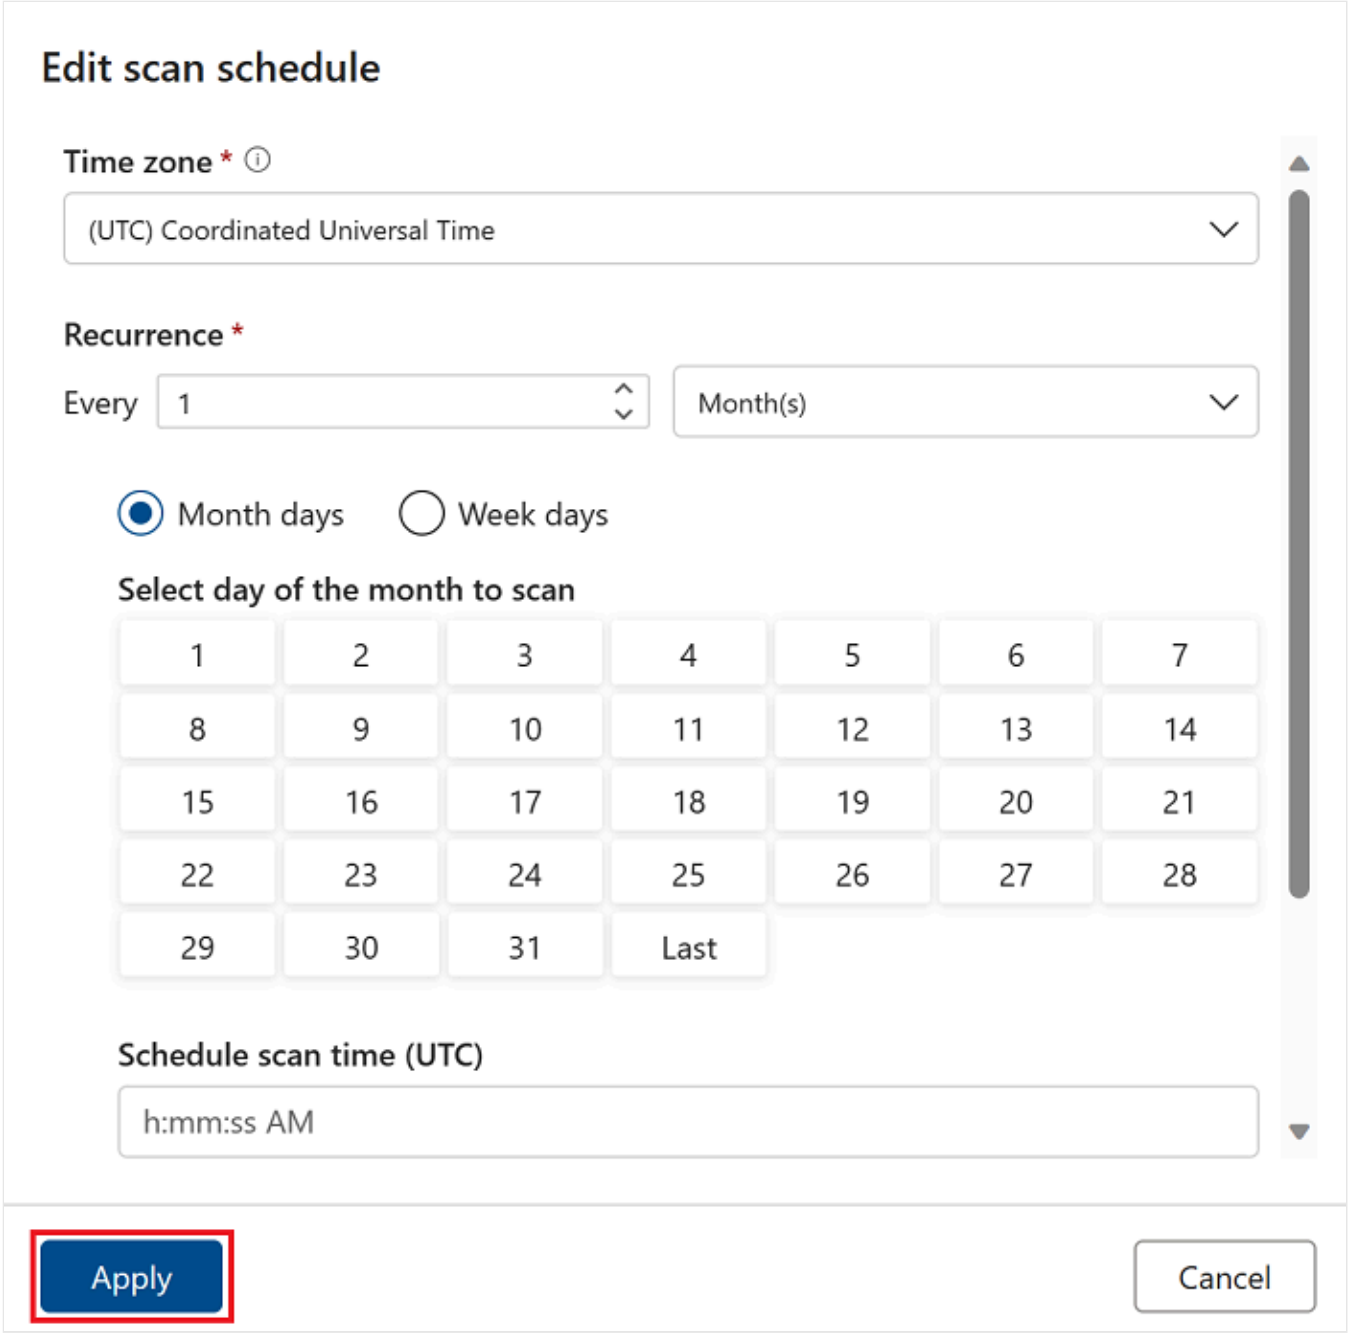


7. To monitor the scan, select **Manage scans** in the **Source management** window.



Update schedule

To update the schedule of a preset scan either:

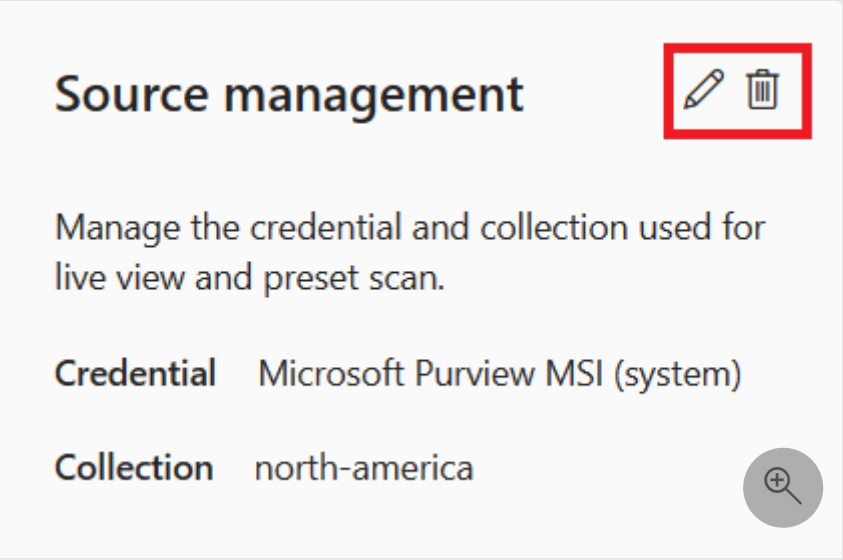


- Select **Customize schedule** before selecting the toggle. You'll set your scan schedule and then the preset scan will be automatically enabled.

- Select the **Edit pencil** next to the schedule label after enabling the preset scan

Then you can set your schedule to run monthly or weekly on specified days. Select **Apply** to apply the schedule to the scan.

Manage live view credentials



If you have extended live view permissions or run a preset scan your live view resource will have credentials that allow Microsoft Purview to access it.

If you need to update or remove those credentials, you can use the **Source management** window.

1. Browse the catalog for the source where you want to run a preset scan to enhance the metadata.

2. Select the data source.

3. Under source management, you can see your credential and collection listed, and the buttons to edit or delete the credentials.

4. Select the **Edit** pencil icon to update the credentials.

> ⓘ **Note**
>
> You can't change the collection the source is mapped to.

5. Select **Delete** to remove the credentials.

> ⓘ **Note**
>
> Deleting credentials will also disable extended live view permissions or preset scans.

Enterprise governance of your data estate

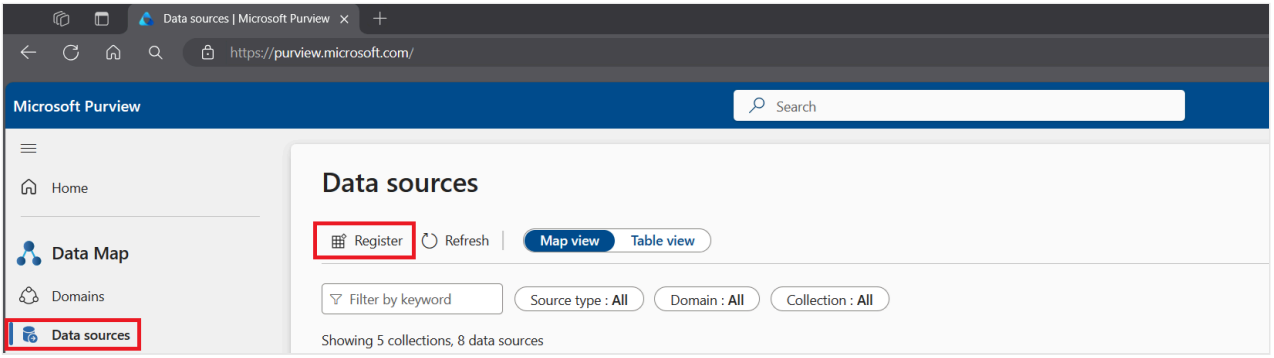
In free version of governance solutions, users can only view live resources and manually update some metadata.

For access to all Microsoft Purview's applications, sources, automation, and to fully govern data assets in Microsoft Purview, upgrade to the enterprise version of Microsoft Purview.

Next steps

- Metadata curation
- Use the new Microsoft Purview portal
- Roles and permissions

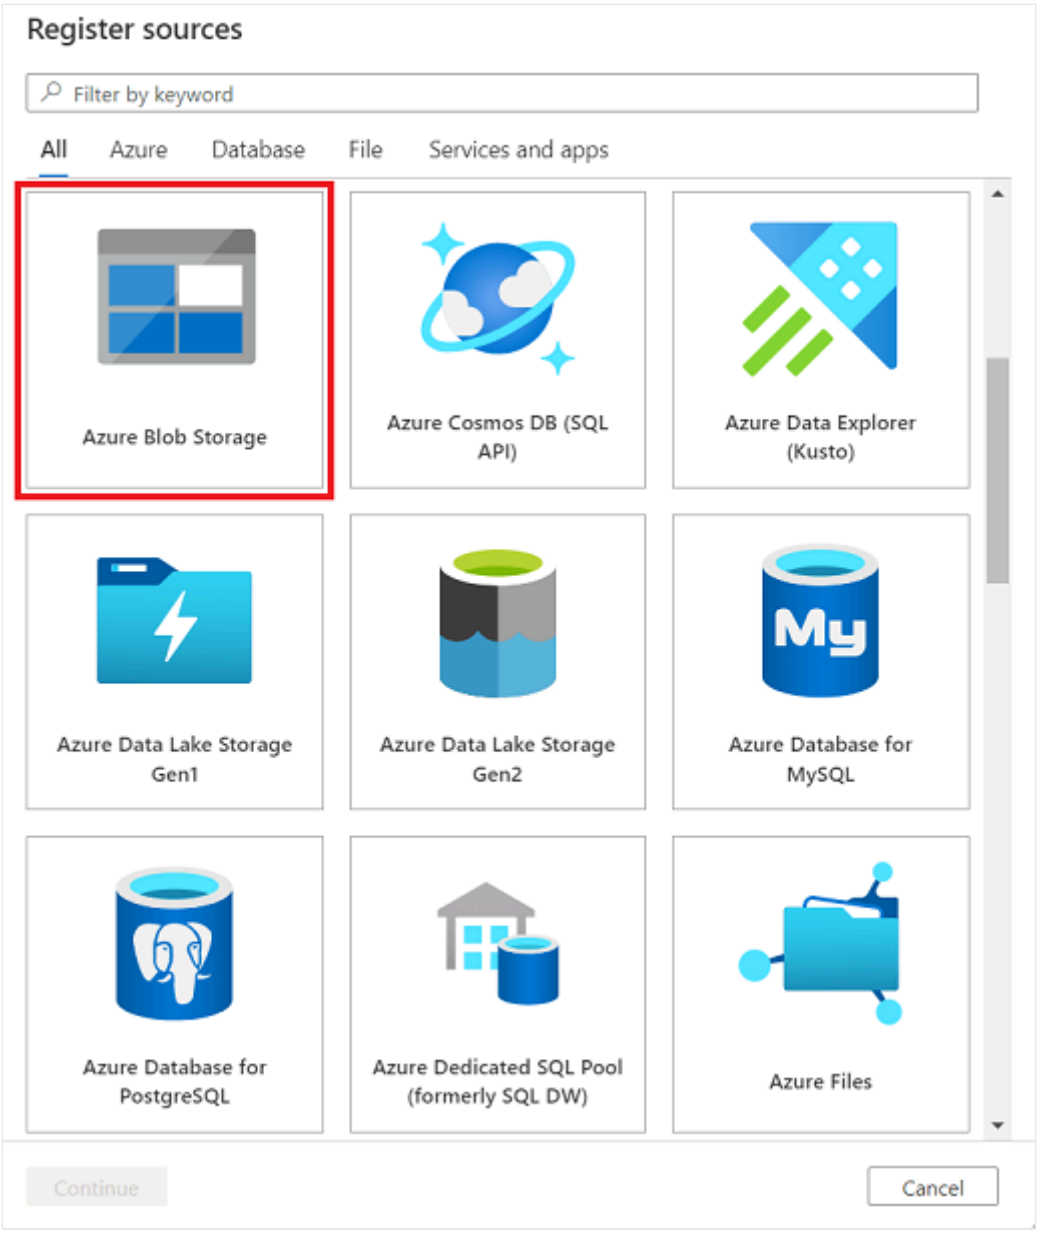
Manage data sources in Microsoft Purview



In this article, you learn how to register new data sources, manage domains and collections of data sources, view sources, and move sources between collections in the Microsoft Purview Data Map.

Register a new source

> **Note**
>
> To register and manage a source in Data Map, you need to be a Data Source Admin and have one of the other Data Map roles, such as Data Reader. For more information, see assigning data governance roles and permissions.



Use the following steps to register a new source:

1. In the Microsoft Purview portal, navigate to **Data Map**, **Data sources**, and select **Register**.

2. If you're using the classic experience, open the classic Microsoft Purview governance portal, go to **Data Map**, **Sources**, and select **Register**.

3. Select a source type. This example uses Azure Blob Storage. Select **Continue**.

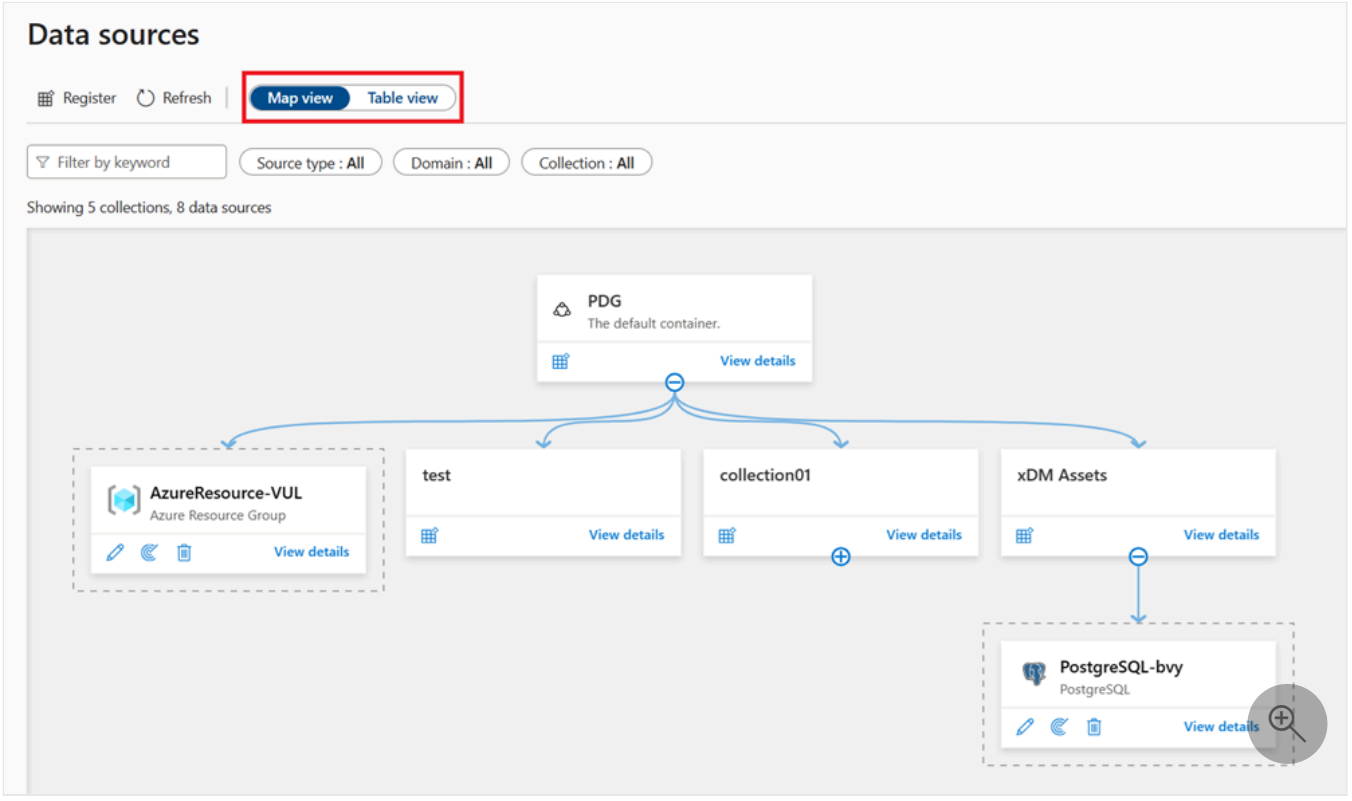
4. Fill out the form on the **Register sources** page. Select a name for your source and enter the relevant information. If you choose **From Azure subscription** as your account selection method, the sources in your subscription appear in a dropdown list.

5. Select **Register**.

> **Important**
>
> Most data sources have prerequisites to register and scan them in Microsoft Purview. For a list of all available sources, and links to source-specific instructions to register and scan, see Data sources that connect to Data Map.

View sources

You can view all registered sources by going to the Microsoft Purview portal > **Data Map** > **Data sources**.



There are two view types:

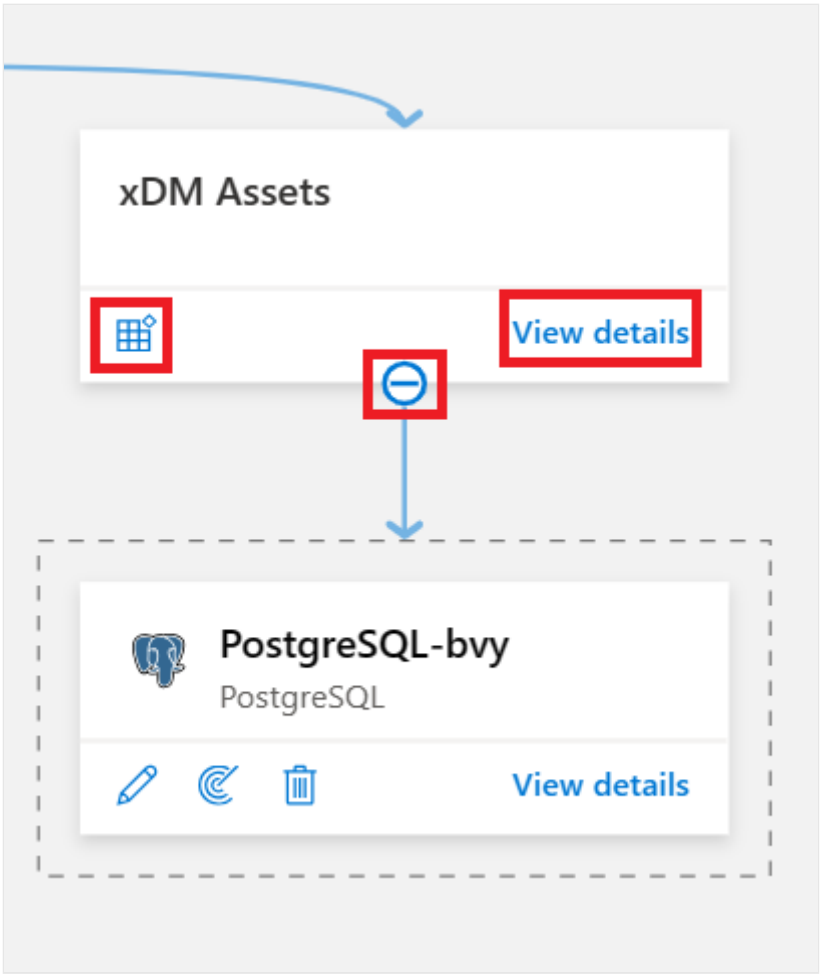
- The map view
- The table view

Map view

To find the map view, open Data Map and select **Data sources**. Make sure the toggle at the top of the page is set to **Map view**.

In **Map view**, you see all of your sources and collections, and you can filter by sources, domains, and collections. In the following screenshot, you see the default domain at the top called PDG. It has three collections: test, collection01, and xDM Assets. The collection xDM Assets has a PostgreSQL source registered to it. An Azure resource group source is also housed under the root domain.

You can open and manage each of the subcollections from the map view by selecting the + button. You can also register a new source by selecting the register source button, or view details by selecting **View details**.



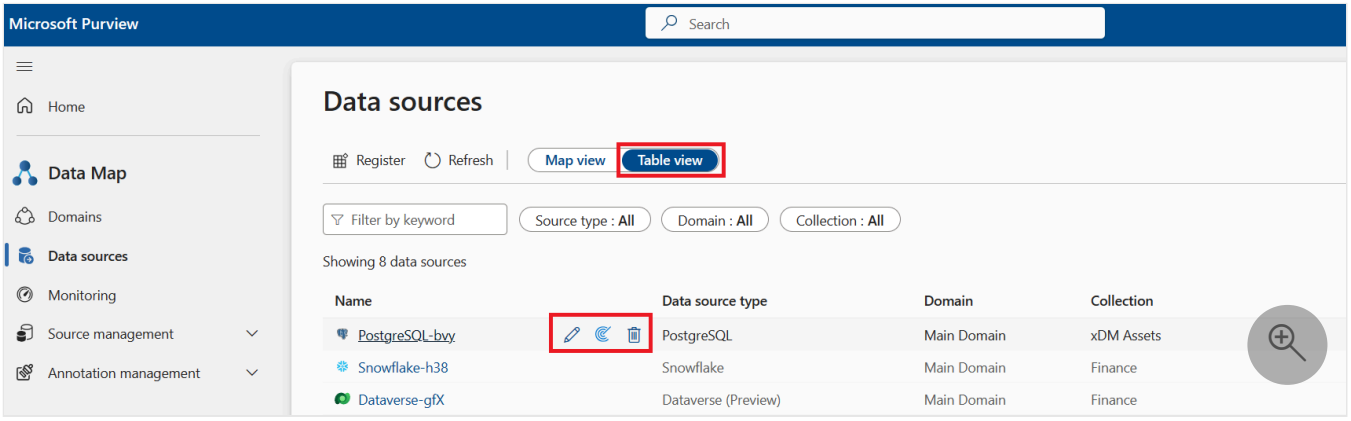


Table view

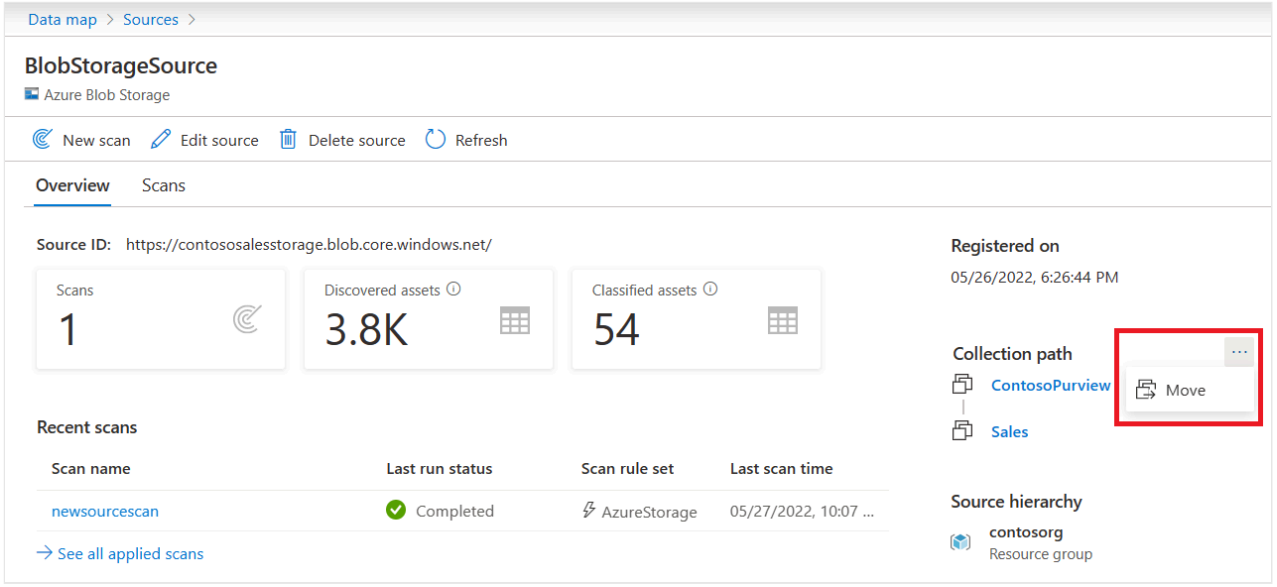
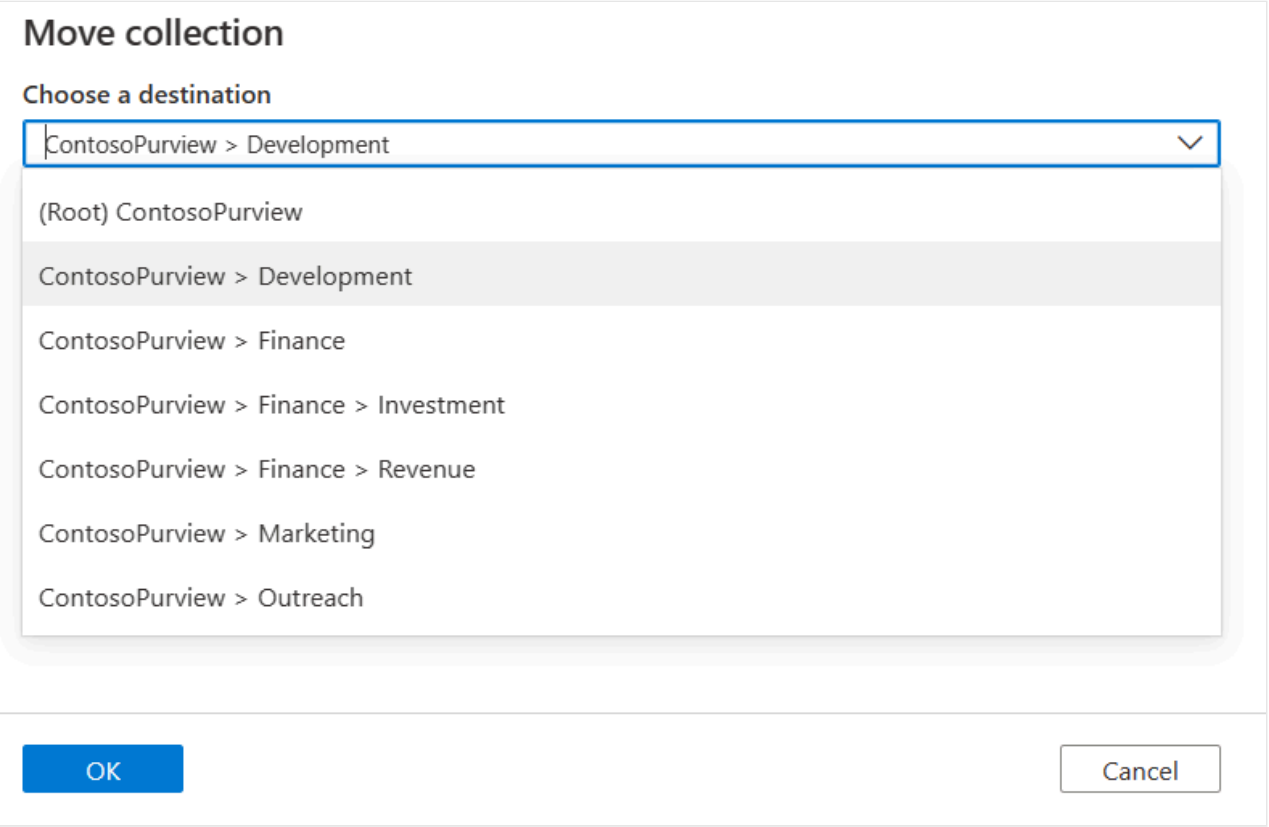
In the table view, you see a sortable list of sources. Hover over the source for options to edit, begin a new scan, or delete.

Manage collections and domains



To manage collections and domains, and assign permissions based on your collections and domains, see Create and manage collections and domains.

Move sources between collections



After you register your source, you can move it to another collection that you have access to within the same domain.

> **Important**
>
> Data source connections that register multiple sources can't be moved between collections:
>
> - Azure (Multiple)
> - AWS account (Multiple)
> - Azure Synapse Analytics (Multiple)

1. Find your source in Data Map and select it.
2. Beside the **Collection Path** list, select the ellipsis (...) button and select **Move**.

3. In the **Move collection** menu that appears, select your collection from the drop-down and then select **Ok**.

4. Your data source has been moved. It can take up to an hour for results to be fully seen across your Microsoft Purview environment. Your scans will move with your resource, but assets will remain in their original collection until your next scan, then they'll move to the new collection.

> **Note**
>
> - When a source moves to a new collection, its scans move with it, but assets don't appear in the new collection until your next scan.
> - If you manually moved any assets from your source to a different collection before migrating the source, the scan doesn't take them to the new collection. They remain in the collection you moved them to.

Next steps

Learn how to discover and govern various data sources:

- Azure Data Lake Storage Gen 2
- Power BI tenant
- Azure SQL Database

Last updated on 12/08/2025

Check Azure data source readiness to register and scan in Microsoft Purview

06/03/2025

To scan data sources, Microsoft Purview requires access to them. It uses credentials to obtain this access. A *credential* is the authentication information that Microsoft Purview can use to authenticate to your registered data sources. There are a few ways to set up the credentials for Microsoft Purview, including:

- The managed identity assigned to the Microsoft Purview account.
- Secrets stored in Azure Key Vault.
- Service principals.

In this two-part tutorial series, we'll help you verify and configure required Azure role assignments and network access for various Azure data sources across your Azure subscriptions at scale. You can then register and scan your Azure data sources in Microsoft Purview.

Run the Microsoft Purview data sources readiness checklist script after you deploy your Microsoft Purview account and before you register and scan your Azure data sources.

In part 1 of this tutorial series, you'll:

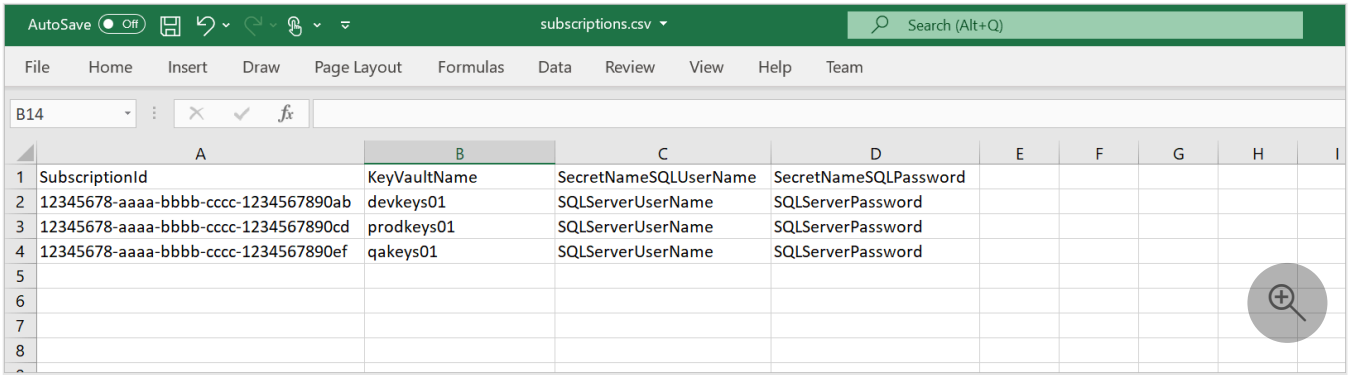
- ✓ Locate your data sources and prepare a list of data source subscriptions.
- ✓ Run the readiness checklist script to find any missing role-based access control (RBAC) or network configurations across your data sources in Azure.
- ✓ In the output report, review missing network configurations and role assignments required by Microsoft Purview Managed Identity (MSI).
- ✓ Share the report with data Azure subscription owners so they can take suggested actions.

Prerequisites

- Azure subscriptions where your data sources are located. If you don't have an Azure subscription, create a free account before you begin.
- A Microsoft Purview account.
- An Azure Key Vault resource in each subscription that has data sources like Azure SQL Database, Azure Synapse Analytics, or Azure SQL Managed Instance.
- The Microsoft Purview data sources readiness checklist script.

> ⓘ **Note**

The Microsoft Purview data sources readiness checklist is available only for Windows. This readiness checklist script is currently supported for Microsoft Purview MSI.



Prepare Azure subscriptions list for data sources

Before running the script, create a .csv file (for example, C:\temp\Subscriptions.csv) with four columns:

Expand table

Column name	Description	Example
`SubscriptionId`	Azure subscription IDs for your data sources.	12345678-aaaa-bbbb-cccc-1234567890ab
`KeyVaultName`	Name of existing key vault that's deployed in the data source subscription.	ContosoDevKeyVault
`SecretNameSQLUserName`	Name of an existing Azure Key Vault secret that contains a Microsoft Entra user name that can sign in to Azure Synapse, Azure SQL Database, or Azure SQL Managed Instance by using Microsoft Entra authentication.	ContosoDevSQLAdmin
`SecretNameSQLPassword`	Name of an existing Azure Key Vault secret that contains a Microsoft Entra user password that can sign in to Azure Synapse, Azure SQL Database, or Azure SQL Managed Instance by using Microsoft Entra authentication.	ContosoDevSQLPassword

Sample .csv file:

> **Note**
>
> You can update the file name and path in the code, if you need to.

Run the script and install the required PowerShell modules

Follow these steps to run the script from your Windows computer:

1. Download the Microsoft Purview data sources readiness checklist script to the location of your choice.
2. On your computer, enter **PowerShell** in the search box on the Windows taskbar. In the search list, select and hold (or right-click) **Windows PowerShell** and then select **Run as administrator**.
3. In the PowerShell window, enter the following command. (Replace `<path-to-script>` with the folder path of the extracted script file.)

   ```PowerShell
   dir -Path <path-to-script> | Unblock-File
   ```

4. Enter the following command to install the Azure cmdlets:

   ```PowerShell
   Install-Module -Name Az -AllowClobber -Scope CurrentUser
   ```

5. If you see the prompt *NuGet provider is required to continue*, enter **Y**, and then select **Enter**.
6. If you see the prompt *Untrusted repository*, enter **A**, and then select **Enter**.
7. Repeat the previous steps to install the `Az.Synapse` and `AzureAD` modules.

It might take up to a minute for PowerShell to install the required modules.

Collect other data needed to run the script

Before you run the PowerShell script to verify the readiness of data source subscriptions, obtain the values of the following arguments to use in the scripts:

- `AzureDataType`: Choose any of the following options as your data-source type to check the readiness for the data type across your subscriptions:
  - `BlobStorage`

- `AzureSQLMI`
- `AzureSQLDB`
- `ADLSGen2`
- `ADLSGen1`
- `Synapse`
- `All`

- `PurviewAccount`: Your existing Microsoft Purview account resource name.
- `PurviewSub`: Subscription ID where the Microsoft Purview account is deployed.

Verify your permissions

Make sure your user has the following roles and permissions:

Expand table

Role or permission	Scope
Global Reader	Microsoft Entra tenant
Reader	Azure subscriptions where your Azure data sources are located
Reader	Subscription where your Microsoft Purview account was created
SQL Admin (Microsoft Entra authentication)	Azure Synapse dedicated pools, Azure SQL Database instances, Azure SQL managed instances
Access to your Azure key vault	Access to get/list key vault's secret or Azure Key Vault secret user

Run the client-side readiness script

Run the script by completing these steps:

1. Use the following command to go to the script's folder. Replace `<path-to-script>` with the folder path of the extracted file.

```
PowerShell

cd <path-to-script>
```

2. Run the following command to set the execution policy for the local computer. Enter **A** for *Yes to All* when you're prompted to change the execution policy.

   ```PowerShell
   Set-ExecutionPolicy -ExecutionPolicy Unrestricted
   ```

3. Run the script with the following parameters. Replace the `DataType`, `PurviewName`, and `SubscriptionID` placeholders.

   ```PowerShell
   .\purview-data-sources-readiness-checklist.ps1 -AzureDataType <DataType> -PurviewAccount <PurviewName> -PurviewSub <SubscriptionID>
   ```

   When you run the command, a pop-up window might appear twice prompting you to sign in to Azure and Microsoft Entra ID by using your Microsoft Entra credentials.

It can take several minutes to create the report, depending on the number of Azure subscriptions and resources in the environment.

After the process completes, review the output report, which demonstrates the detected missing configurations in your Azure subscriptions or resources. The results can appear as *Passed*, *Not Passed*, or *Awareness*. You can share the results with the corresponding subscription admins in your organization so they can configure the required settings.

More information

What data sources are supported by the script?

Currently, the following data sources are supported by the script:

- Azure Blob Storage (BlobStorage)
- Azure Data Lake Storage Gen2 (ADLSGen2)
- Azure Data Lake Storage Gen1 (ADLSGen1)
- Azure SQL Database (AzureSQLDB)
- Azure SQL Managed Instance (AzureSQLMI)
- Azure Synapse (Synapse) dedicated pool

You can choose all or any of these data sources as the input parameter when you run the script.

What checks are included in the results?

Azure Blob Storage (BlobStorage)

- RBAC. Check whether Microsoft Purview MSI is assigned the **Storage Blob Data Reader** role in each of the subscriptions below the selected scope.
- RBAC. Check whether Microsoft Purview MSI is assigned the **Reader** role on the selected scope.
- Service endpoint. Check whether service endpoint is on, and check whether **Allow trusted Microsoft services to access this storage account** is enabled.
- Networking: Check whether private endpoint is created for storage and enabled for Blob Storage.

Azure Data Lake Storage Gen2 (ADLSGen2)

- RBAC. Check whether Microsoft Purview MSI is assigned the **Storage Blob Data Reader** role in each of the subscriptions below the selected scope.
- RBAC. Check whether Microsoft Purview MSI is assigned the **Reader** role on the selected scope.
- Service endpoint. Check whether service endpoint is on, and check whether **Allow trusted Microsoft services to access this storage account** is enabled.
- Networking: Check whether private endpoint is created for storage and enabled for Blob Storage.

Azure Data Lake Storage Gen1 (ADLSGen1)

- Networking. Check whether service endpoint is on, and check whether **Allow all Azure services to access this Data Lake Storage Gen1 account** is enabled.
- Permissions. Check whether Microsoft Purview MSI has Read/Execute permissions.

Azure SQL Database (AzureSQLDB)

- SQL Server instances:
  - Network. Check whether public endpoint or private endpoint is enabled.
  - Firewall. Check whether **Allow Azure services and resources to access this server** is enabled.
  - Microsoft Entra administration. Check whether Azure SQL Server has Microsoft Entra authentication.
  - Microsoft Entra administration. Populate the Azure SQL Server Microsoft Entra admin user or group.

- SQL databases:
  - SQL role. Check whether Microsoft Purview MSI is assigned the **db_datareader** role.

Azure SQL Managed Instance (AzureSQLMI)

- SQL Managed Instance servers:
  - Network. Check whether public endpoint or private endpoint is enabled.
  - ProxyOverride. Check whether Azure SQL Managed Instance is configured as Proxy or Redirect.
  - Networking. Check whether NSG has an inbound rule to allow AzureCloud over required ports:
    - Redirect: 1433 and 11000-11999
      or
    - Proxy: 3342
  - Microsoft Entra administration. Check whether Azure SQL Server has Microsoft Entra authentication.
  - Microsoft Entra administration. Populate the Azure SQL Server Microsoft Entra admin user or group.

- SQL databases:
  - SQL role. Check whether Microsoft Purview MSI is assigned the **db_datareader** role.

Azure Synapse (Synapse) dedicated pool

- RBAC. Check whether Microsoft Purview MSI is assigned the **Storage Blob Data Reader** role in each of the subscriptions below the selected scope.

- RBAC. Check whether Microsoft Purview MSI is assigned the **Reader** role on the selected scope.

- SQL Server instances (dedicated pools):
  - Network: Check whether public endpoint or private endpoint is enabled.
  - Firewall: Check whether **Allow Azure services and resources to access this server** is enabled.
  - Microsoft Entra administration: Check whether Azure SQL Server has Microsoft Entra authentication.
  - Microsoft Entra administration: Populate the Azure SQL Server Microsoft Entra admin user or group.

- SQL databases:
  - SQL role. Check whether Microsoft Purview MSI is assigned the **db_datareader** role.

Next steps

In this tutorial, you learned how to:

- ✓ Run the Microsoft Purview readiness checklist to check, at scale, whether your Azure subscriptions are missing configuration, before you register and scan them in Microsoft Purview.

Go to the next tutorial to learn how to identify the required access and set up required authentication and network rules for Microsoft Purview across Azure data sources:

Configure access to data sources for Microsoft Purview MSI at scale

Configure access to data sources for Microsoft Purview MSI at scale

06/03/2025

To scan data sources, Microsoft Purview requires access to them. This tutorial is intended for Azure subscription owners and Microsoft Purview Data Source Administrators. It will help you identify required access and set up required authentication and network rules for Microsoft Purview across Azure data sources.

In part 2 of this tutorial series, you'll:

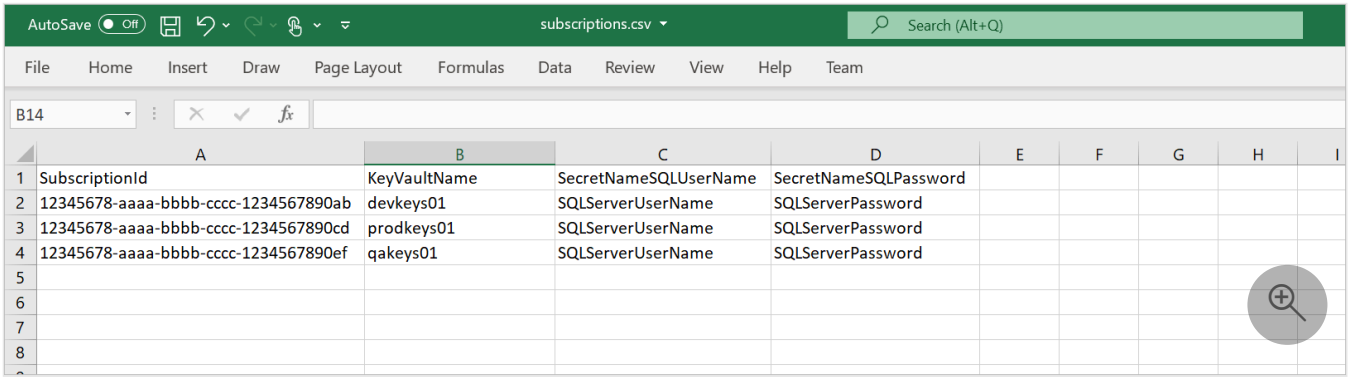
- ✓ Locate your data sources and prepare a list of data source subscriptions.
- ✓ Run a script to configure any missing role-based access control (RBAC) or required network configurations across your data sources in Azure.
- ✓ Review the output report.

Prerequisites

- Azure subscriptions where your data sources are located. If you don't have an Azure subscription, create a free account before you begin.
- An Microsoft Purview account.
- An Azure Key Vault resource in each subscription that has data sources like Azure SQL Database, Azure Synapse Analytics, or Azure SQL Managed Instance.
- The Microsoft Purview MSI Configuration script.

> **Note**
>
> The Microsoft Purview MSI Configuration script is available only for Windows. This script is currently supported for Microsoft Purview Managed Identity (MSI).

> **Important**
>
> We strongly recommend that you test and verify all the changes the script performs in your Azure environment before you deploy it into your production environment.



Prepare Azure subscriptions list for data sources

Before you run the script, create a .csv file (for example, "C:\temp\Subscriptions.csv) with four columns:

Expand table

Column name	Description	Example
`SubscriptionId`	Azure subscription IDs for your data sources.	12345678-aaaa-bbbb-cccc-1234567890ab
`KeyVaultName`	Name of existing key vault that's deployed in the data source subscription.	ContosoDevKeyVault
`SecretNameSQLUserName`	Name of an existing Azure Key Vault secret that contains a Microsoft Entra user name that can sign in to Azure Synapse, Azure SQL Database, or Azure SQL Managed Instance by using Microsoft Entra authentication.	ContosoDevSQLAdmin
`SecretNameSQLPassword`	Name of an existing Azure Key Vault secret that contains a Microsoft Entra user password that can sign in to Azure Synapse, Azure SQL Database, or Azure SQL Managed Instance by using Microsoft Entra authentication.	ContosoDevSQLPassword

Sample .csv file:

> **Note**
>
> You can update the file name and path in the code, if you need to.

Run the script and install the required PowerShell modules

Follow these steps to run the script from your Windows computer:

1. Download Microsoft Purview MSI Configuration script to the location of your choice.
2. On your computer, enter **PowerShell** in the search box on the Windows taskbar. In the search list, select and hold (or right-click) **Windows PowerShell** and then select **Run as administrator**.
3. In the PowerShell window, enter the following command. (Replace `<path-to-script>` with the folder path of the extracted script file.)

   ```PowerShell
   dir -Path <path-to-script> | Unblock-File
   ```

4. Enter the following command to install the Azure cmdlets:

   ```PowerShell
   Install-Module -Name Az -AllowClobber -Scope CurrentUser
   ```

5. If you see the prompt *NuGet provider is required to continue*, enter **Y**, and then select **Enter**.
6. If you see the prompt *Untrusted repository*, enter **A**, and then select **Enter**.
7. Repeat the previous steps to install the `Az.Synapse` and `AzureAD` modules.

It might take up to a minute for PowerShell to install the required modules.

Collect other data needed to run the script

Before you run the PowerShell script to verify the readiness of data source subscriptions, obtain the values of the following arguments to use in the scripts:

- `AzureDataType`: Choose any of the following options as your data-source type to check the readiness for the data type across your subscriptions:
  - `BlobStorage`
  - `AzureSQLMI`
  - `AzureSQLDB`
  - `ADLSGen2`

- `ADLSGen1`
- `Synapse`
- `All`

- `PurviewAccount`: Your existing Microsoft Purview account resource name.
- `PurviewSub`: Subscription ID where the Microsoft Purview account is deployed.

Verify your permissions

Make sure your user has the following roles and permissions:

At a minimum, you need the following permissions to run the script in your Azure environment:

Expand table

Role	Scope	Why is it needed?
Global Reader	Microsoft Entra tenant	To read Azure SQL Admin user group membership and Microsoft Purview MSI
Application Administrator	Microsoft Entra tenant	To assign the **Directory Reader** role to Azure SQL managed instances
Contributor	Subscription or resource group where your Microsoft Purview account is created	To read the Microsoft Purview account resource and create a Key Vault resource and secret
Owner or User Access Administrator	Management group or subscription where your Azure data sources are located	To assign RBAC
Contributor	Management group or subscription where your Azure data sources are located	To set up network configuration
SQL Admin (Microsoft Entra authentication)	Azure SQL Server instances or Azure SQL managed instances	To assign the **db_datareader** role to Microsoft Purview
Access to your Azure key vault	Access to get/list Key Vault secret for Azure SQL Database, Azure SQL Managed Instance, or Azure Synapse authentication	

Run the client-side readiness script

Run the script by completing these steps:

1. Use the following command to go to the script's folder. Replace `<path-to-script>` with the folder path of the extracted file.

   ```
   PowerShell

   cd <path-to-script>
   ```

2. Run the following command to set the execution policy for the local computer. Enter **A** for *Yes to All* when you're prompted to change the execution policy.

   ```
   PowerShell

   Set-ExecutionPolicy -ExecutionPolicy Unrestricted
   ```

3. Run the script with the following parameters. Replace the `DataType`, `PurviewName`, and `SubscriptionID` placeholders.

   ```
   PowerShell

   .\purview-msi-configuration.ps1 -AzureDataType <DataType> -PurviewAccount
   <PurviewName> -PurviewSub <SubscriptionID>
   ```

   When you run the command, a pop-up window might appear twice prompting you to sign in to Azure and Microsoft Entra ID by using your Microsoft Entra credentials.

It can take several minutes to create the report, depending on the number of Azure subscriptions and resources in the environment.

You might be prompted to sign in to your Azure SQL Server instances if the credentials in the key vault don't match. You can provide the credentials or select **Enter** to skip the specific server.

After the process completes, view the output report to review the changes.

More information

What data sources are supported by the script?

Currently, the following data sources are supported by the script:

- Azure Blob Storage (BlobStorage)

- Azure Data Lake Storage Gen2 (ADLSGen2)
- Azure Data Lake Storage Gen1 (ADLSGen1)
- Azure SQL Database (AzureSQLDB)
- Azure SQL Managed Instance (AzureSQLMI)
- Azure Synapse (Synapse) dedicated pool

You can choose all or any of these data sources as input parameter when you run the script.

What configurations are included in the script?

This script can help you automatically complete the following tasks:

Azure Blob Storage (BlobStorage)

- RBAC. Assign the Azure RBAC **Reader** role to Microsoft Purview MSI on the selected scope. Verify the assignment.
- RBAC. Assign the Azure RBAC **Storage Blob Data Reader** role to Microsoft Purview MSI in each of the subscriptions below the selected scope. Verify the assignments.
- Networking. Report whether private endpoint is created for storage and enabled for Blob Storage.
- Service endpoint. If private endpoint is off, check whether service endpoint is on, and enable **Allow trusted Microsoft services to access this storage account**.

Azure Data Lake Storage Gen2 (ADLSGen2)

- RBAC. Assign the Azure RBAC **Reader** role to Microsoft Purview MSI on the selected scope. Verify the assignment.
- RBAC. Assign the Azure RBAC **Storage Blob Data Reader** role to Microsoft Purview MSI in each of the subscriptions below the selected scope. Verify the assignments.
- Networking. Report whether private endpoint is created for storage and enabled for Blob Storage.
- Service endpoint. If private endpoint is off, check whether service endpoint is on, and enable **Allow trusted Microsoft services to access this storage account**.

Azure Data Lake Storage Gen1 (ADLSGen1)

- Networking. Verify that service endpoint is on, and enable **Allow all Azure services to access this Data Lake Storage Gen1 account** on Data Lake Storage.
- Permissions. Assign Read/Execute access to Microsoft Purview MSI. Verify the access.

Azure SQL Database (AzureSQLDB)

- SQL Server instances:
  - Network. Report whether public endpoint or private endpoint is enabled.
  - Firewall. If private endpoint is off, verify firewall rules and enable **Allow Azure services and resources to access this server**.
  - Microsoft Entra administration. Enable Microsoft Entra authentication for Azure SQL Database.

- SQL databases:
  - SQL role. Assign the **db_datareader** role to Microsoft Purview MSI.

Azure SQL Managed Instance (AzureSQLMI)

- SQL Managed Instance servers:

  - Network. Verify that public endpoint or private endpoint is on. Report if public endpoint is off.

  - ProxyOverride. Verify that Azure SQL Managed Instance is configured as Proxy or Redirect.

  - Networking. Update NSG rules to allow AzureCloud inbound access to SQL Server instances over required ports:
    - Redirect: 1433 and 11000-11999

    or
    - Proxy: 3342

    Verify this access.

  - Microsoft Entra administration. Enable Microsoft Entra authentication for Azure SQL Managed Instance.

- SQL databases:
  - SQL role. Assign the **db_datareader** role to Microsoft Purview MSI.

Azure Synapse (Synapse) dedicated pool

- RBAC. Assign the Azure RBAC **Reader** role to Microsoft Purview MSI on the selected scope. Verify the assignment.

- RBAC. Assign the Azure RBAC **Storage Blob Data Reader** role to Microsoft Purview MSI in each of the subscriptions below the selected scope. Verify the assignments.

- SQL Server instances (dedicated pools):
  - Network. Report whether public endpoint or private endpoint is on.
  - Firewall. If private endpoint is off, verify firewall rules and enable **Allow Azure services and resources to access this server**.
  - Microsoft Entra administration. Enable Microsoft Entra authentication for Azure SQL Database.

- SQL databases:
  - SQL role. Assign the **db_datareader** role to Microsoft Purview MSI.

Next steps

In this tutorial, you learned how to:

- ✓ Identify required access and set up required authentication and network rules for Microsoft Purview across Azure data sources.

Go to the next tutorial to learn how to Register and scan multiple sources in Microsoft Purview.

Discover and govern multiple Azure sources in Microsoft Purview

Article • 05/21/2025

This article outlines how to register multiple Azure sources and how to authenticate and interact with them in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

Register

This section describes how to register multiple Azure sources in Microsoft Purview using the Microsoft Purview governance portal.

Prerequisites for registration

Microsoft Purview needs permissions to be able to list resources under a subscription or resource group.

1. Go to the subscription or the resource group in the Azure portal.
2. Select **Access Control (IAM)** from the left menu.
3. Select **+Add**.
4. In the **Select input** box, select the **Reader** role and enter your Microsoft Purview account name (which represents its MSI file name).
5. Select **Save** to finish the role assignment. This will allow Microsoft Purview to list resources under a subscription or resource group.

Authentication for registration

There are two ways to set up authentication for multiple sources in Azure:

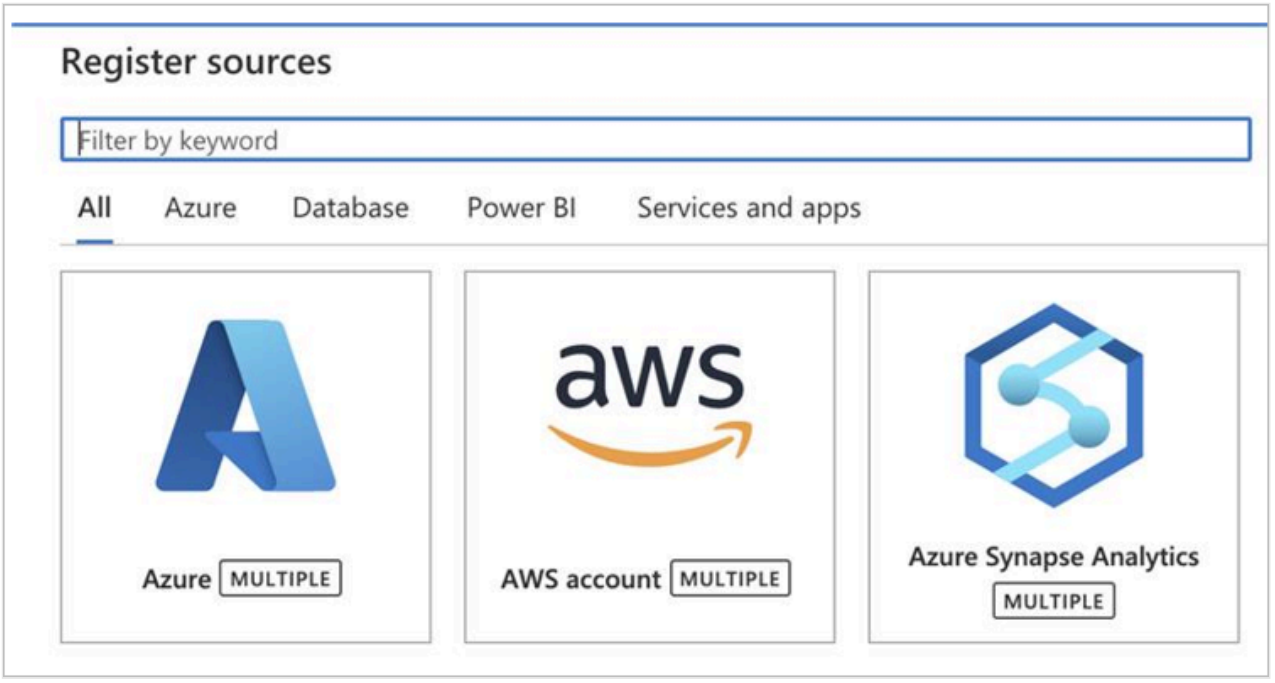
- Managed identity
- Service principal

You must set up authentication on each resource within your subscription or resource group that you want to register and scan. Azure Storage resource types (Azure Blob Storage and Azure Data Lake Storage Gen2) make it easy by allowing you to add the MSI file or service principal at the subscription or resource group level as a storage blob data reader. The permissions then trickle down to each storage account within that subscription or resource group. For all other resource types, you must apply the MSI file or service principal on each resource, or create a script to do so.

To learn how to add permissions on each resource type within a subscription or resource group, see the following resources:

- Azure Blob Storage
- Azure Data Explorer
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure Dedicated SQL pool (formerly SQL DW)
- Azure SQL Database
- Azure SQL Managed Instance
- Azure Synapse Analytics

Steps to register



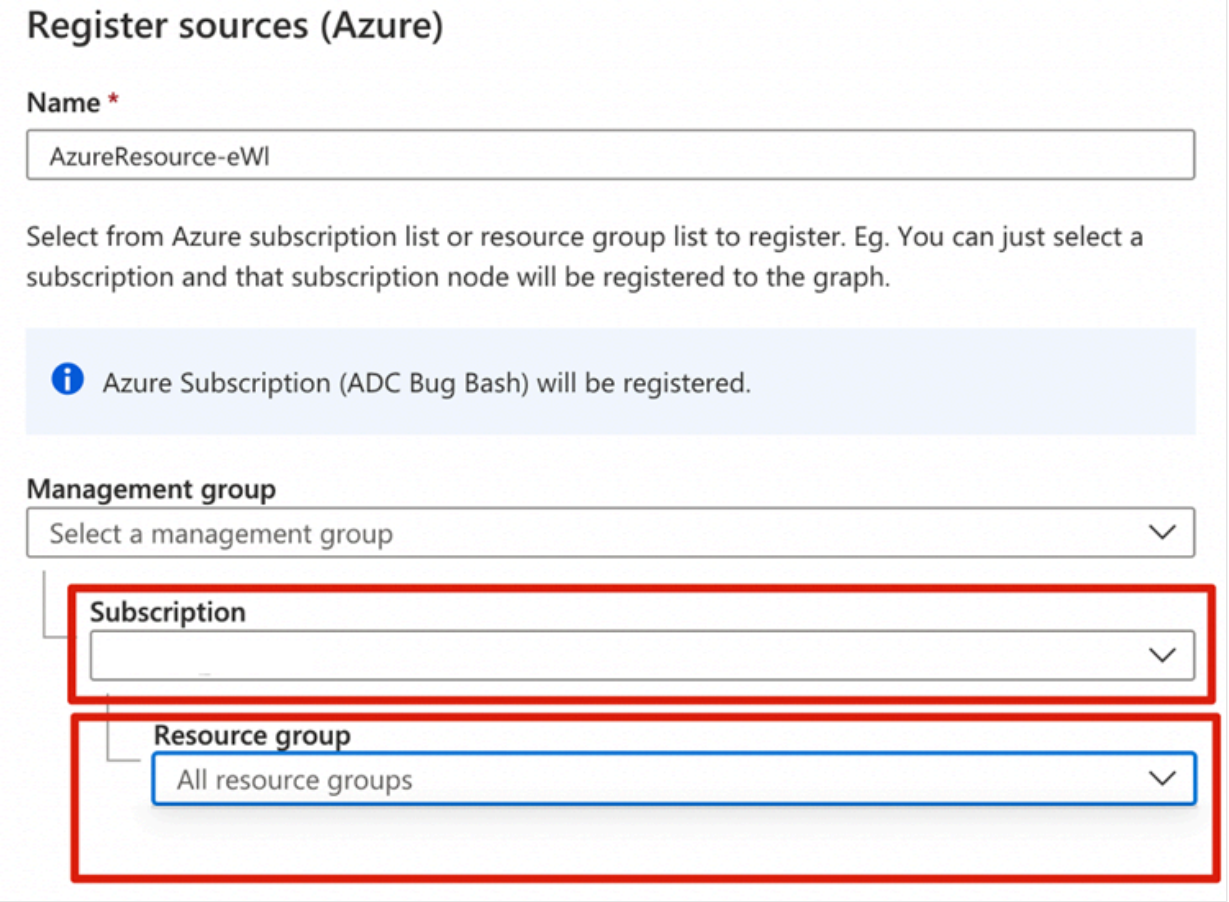
1. Open the Microsoft Purview governance portal by:

- Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
- Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left menu.

3. Select **Register**.

4. On **Register sources**, select **Azure (multiple)**.



5. Select **Continue**.

6. On the **Register sources (Azure)** screen, do the following:

   a. In the **Name** box, enter a name that the data source will be listed with in the catalog.

   b. In the **Management group** box, optionally choose a management group to filter down to.

   c. In the **Subscription** and **Resource group** dropdown list boxes, select a subscription or a specific resource group, respectively. The registration scope will be set to the selected subscription or resource group.

d. Select a collection from the list.

e. Select **Register** to register the data sources.

Scan

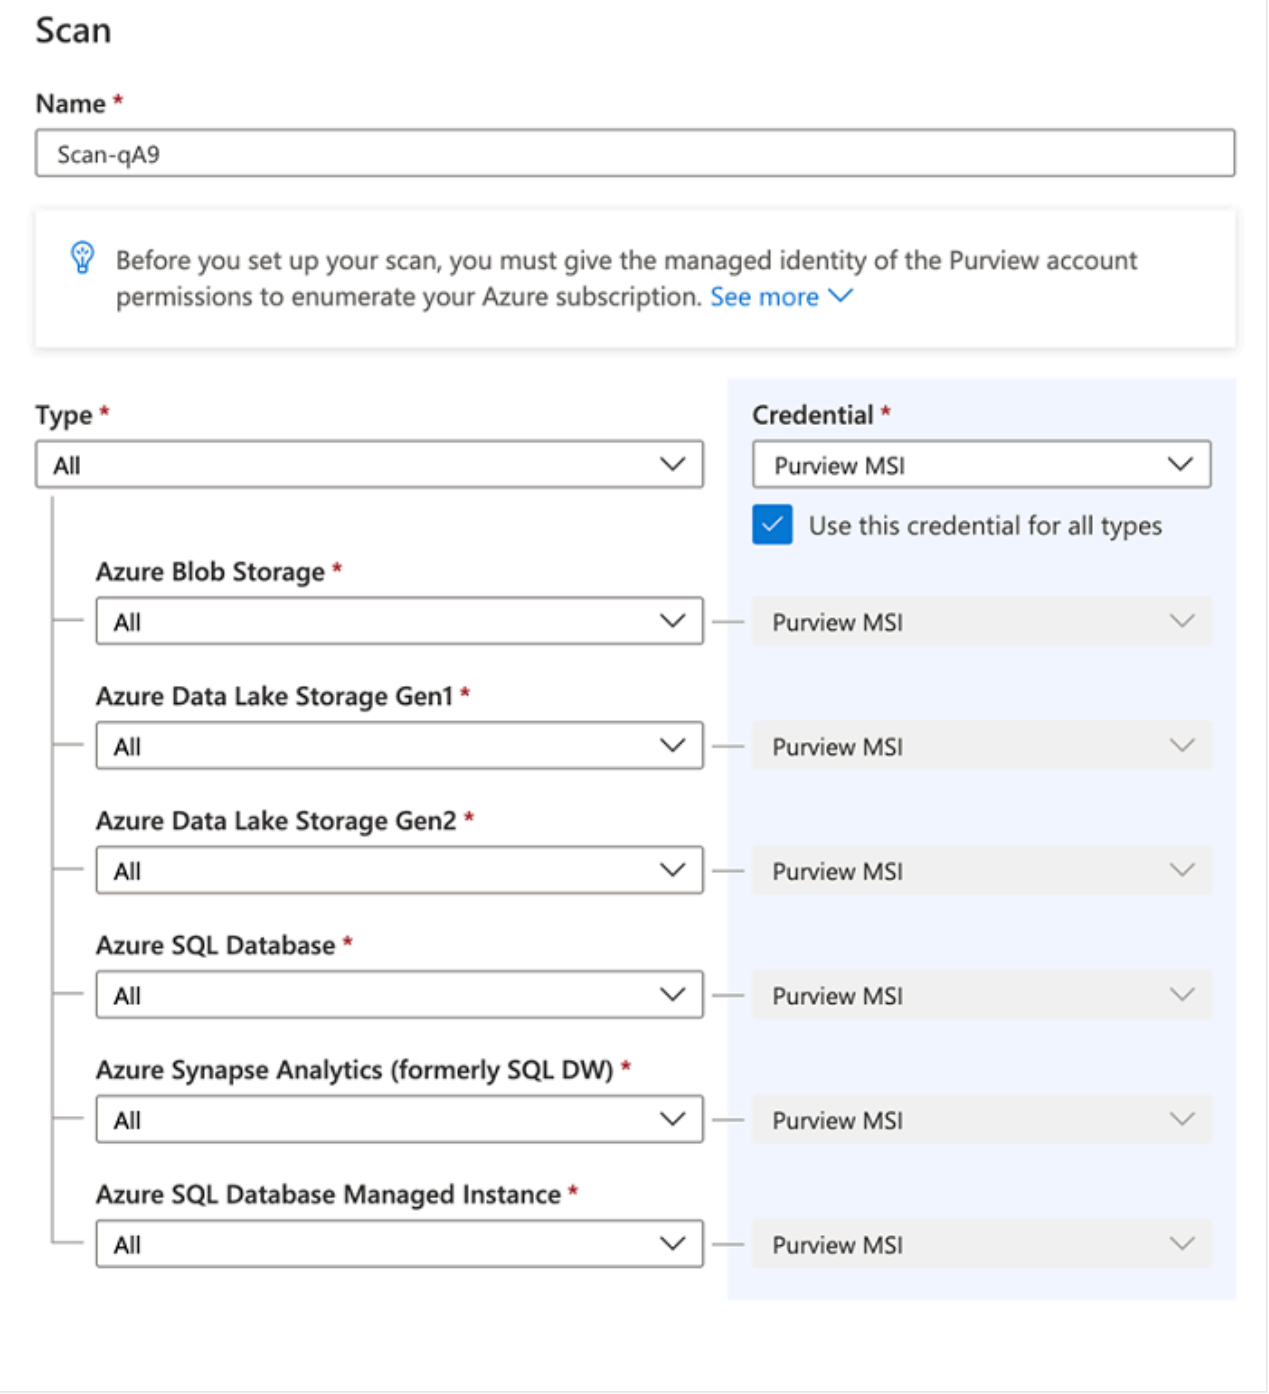
> **Important**
>
> Currently, scanning multiple Azure sources is only supported using Azure integration runtime, therefore, only Microsoft Purview accounts that allow public access on the firewall can use this option.

Follow the steps below to scan multiple Azure sources to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion.

Create and run scan

To create and run a new scan, do the following:

1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.



2. Select the data source that you registered.

3. Select **View details** > **+ New scan**, or use the **Scan** quick-action icon on the source tile.

4. For **Name**, fill in the name.

5. For **Type**, select the types of resources that you want to scan within this source. Choose one of these options:

    - Leave it as **All**. This selection includes future resource types that might not currently exist within that subscription or resource group.
    - Use the boxes to specifically select resource types that you want to scan. If you choose this option, future resource types that might be created within this subscription or resource group won't be included for scans, unless the scan is explicitly edited in the future.

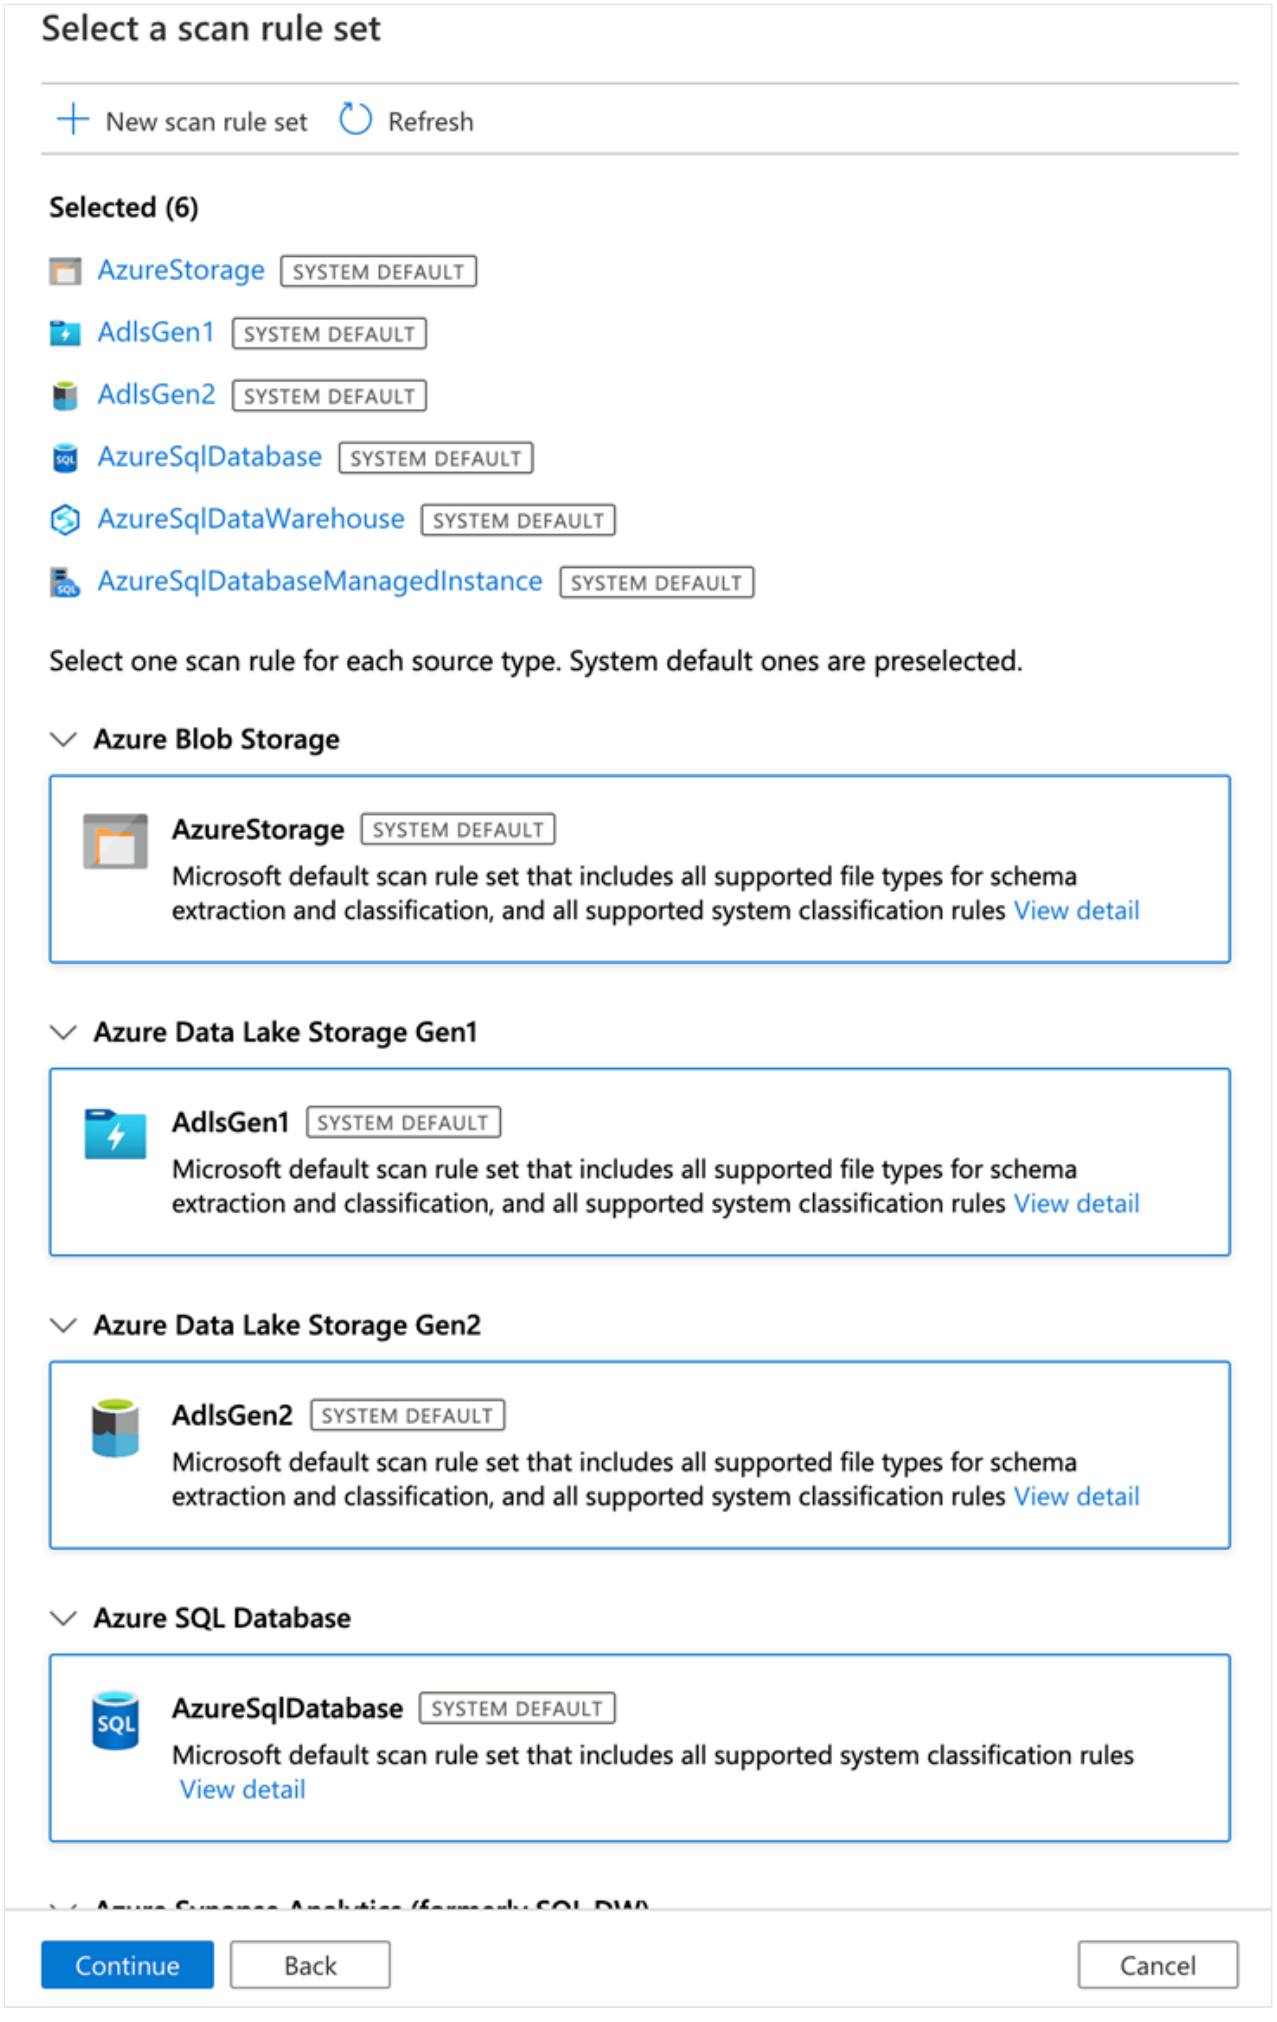
6. Select the credential to connect to the resources within your data source:

    - You can select a credential at the parent level as an MSI file, or you can select a credential for a particular service principal type. You can then use that credential for all the resource types under the subscription or resource group.
    - You can specifically select the resource type and apply a different credential for that resource type.

    Each credential will be considered as the method of authentication for all the resources under a particular type. You must set the chosen credential on the resources in order to successfully scan them, as described earlier in this article.

7. Within each type, you can select to either scan all the resources or scan a subset of them by name:

- If you leave the option as **All**, then future resources of that type will also be scanned in future scan runs.
- If you select specific storage accounts or SQL databases, then future resources of that type created within this subscription or resource group won't be included for scans, unless the scan is explicitly edited in the future.



8. Select **Test connection**. This will first test access to check if you've applied the Microsoft Purview MSI file as a reader on the subscription or resource group. If you get an error message, follow these instructions to resolve it. Then it will test your authentication and connection to each of your selected sources and generate a report. The number of sources selected will impact the time it takes to generate this report. If failed on some resources, hovering over the **X** icon will display the detailed error message.

Scan "XYZ-resource-group"
Name *
Scan-SxS
Before you set up your scan, you must give the managed identity of the Purview account permissions to enumerate your Azure resource group. See more

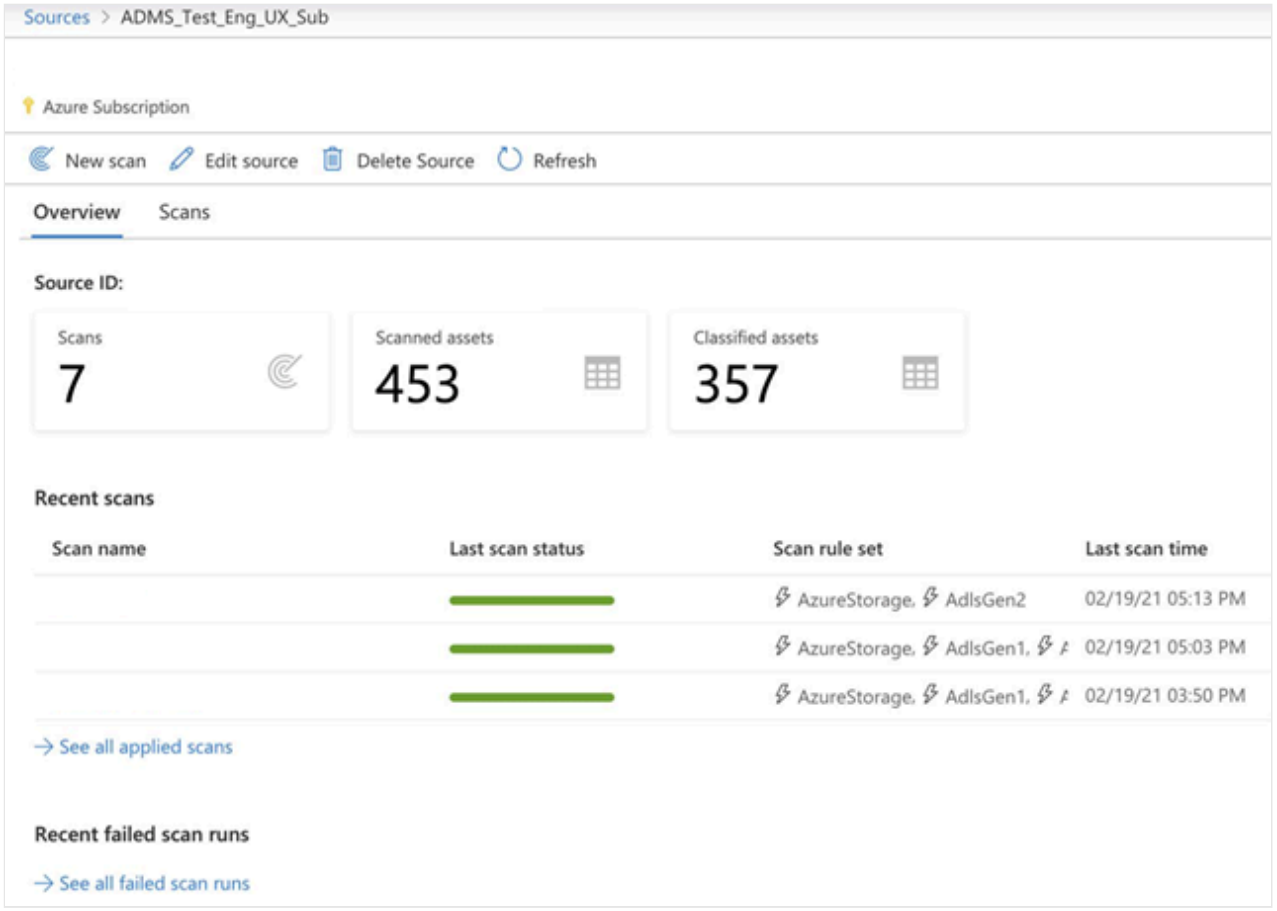
Azure Synapse Analytics *
All
Purview MSI (system)
Select a collection
Purview Account > multiple-resources
All assets scanned will be included in the collection you select.
Continue
Test connection
Cancel

9. After your test connection has passed, select **Continue** to proceed.

10. Select scan rule sets for each resource type that you chose in the previous step. You can also create scan rule sets inline.

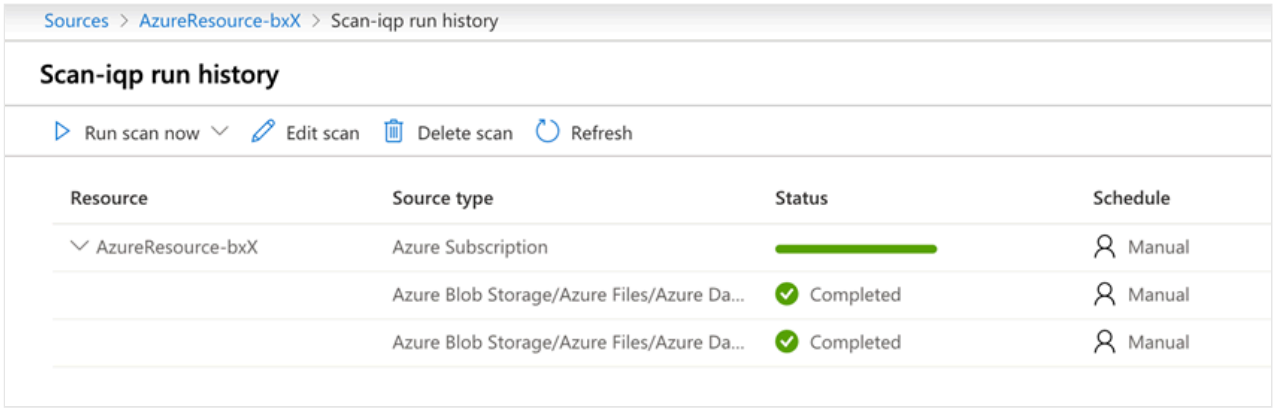


11. Choose your scan trigger. You can set up a schedule or run the scan once.

12. Review your scan and select **Save** to complete setup.

View your scans and scan runs

1. View source details by selecting **View details** on the tile under the **Data Map** section.



2. View scan run details by going to the **Scan details** page.

   The *status bar* is a brief summary of the running status of the child resources. It's displayed on the subscription level or resource group level. The colors have the following meanings:

   - Green: The scan was successful.
   - Red: The scan failed.
   - Gray: The scan is still in progress.

   You can select each scan to view finer details.

3. View a summary of recent failed scan runs at the bottom of the source details. You can also view more granular details about these runs.

Manage your scans: edit, delete, or cancel

To manage a scan, do the following:

1. Go to the management center.
2. Select **Data sources** under the **Sources and scanning** section, and then select the desired data source.
3. Select the scan that you want to manage. Then:
    - You can edit the scan by selecting **Edit**.
    - You can delete the scan by selecting **Delete**.
    - If the scan is running, you can cancel it by selecting **Cancel**.

Policies

The following types of policies are supported on this data resource from Microsoft Purview:

- DevOps policies
- Data owner policies

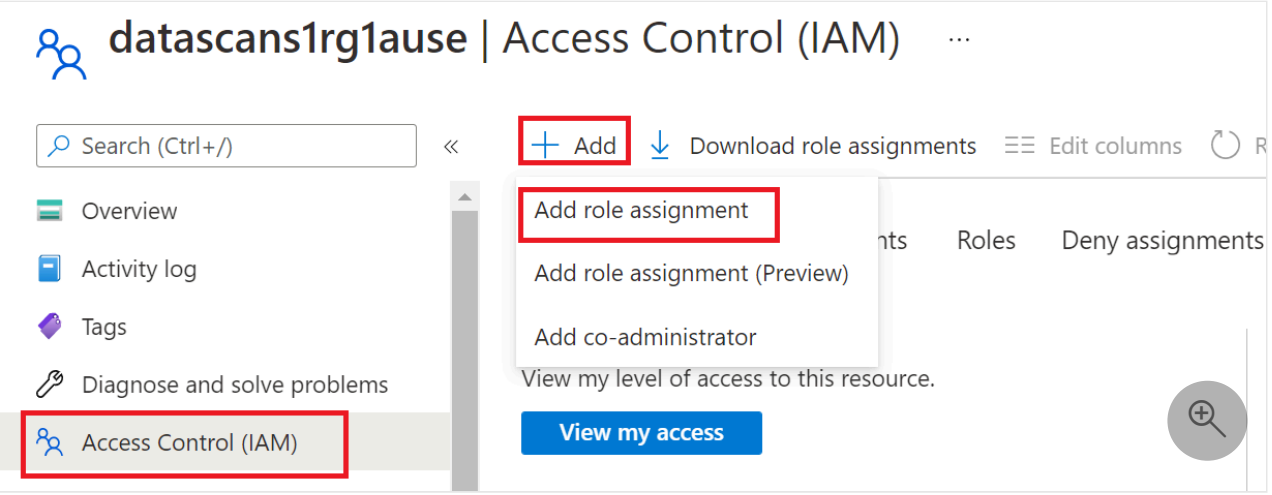
Access policy pre-requisites on Azure Storage accounts

To be able to enforce policies from Microsoft Purview, data sources under a resource group or subscription need to be configured first. Instructions vary based on the data source type. Please review whether they support Microsoft Purview policies, and if so, the specific instructions to enable them, under the Access Policy link in the Microsoft Purview connector document.

Configure the Microsoft Purview account for policies

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

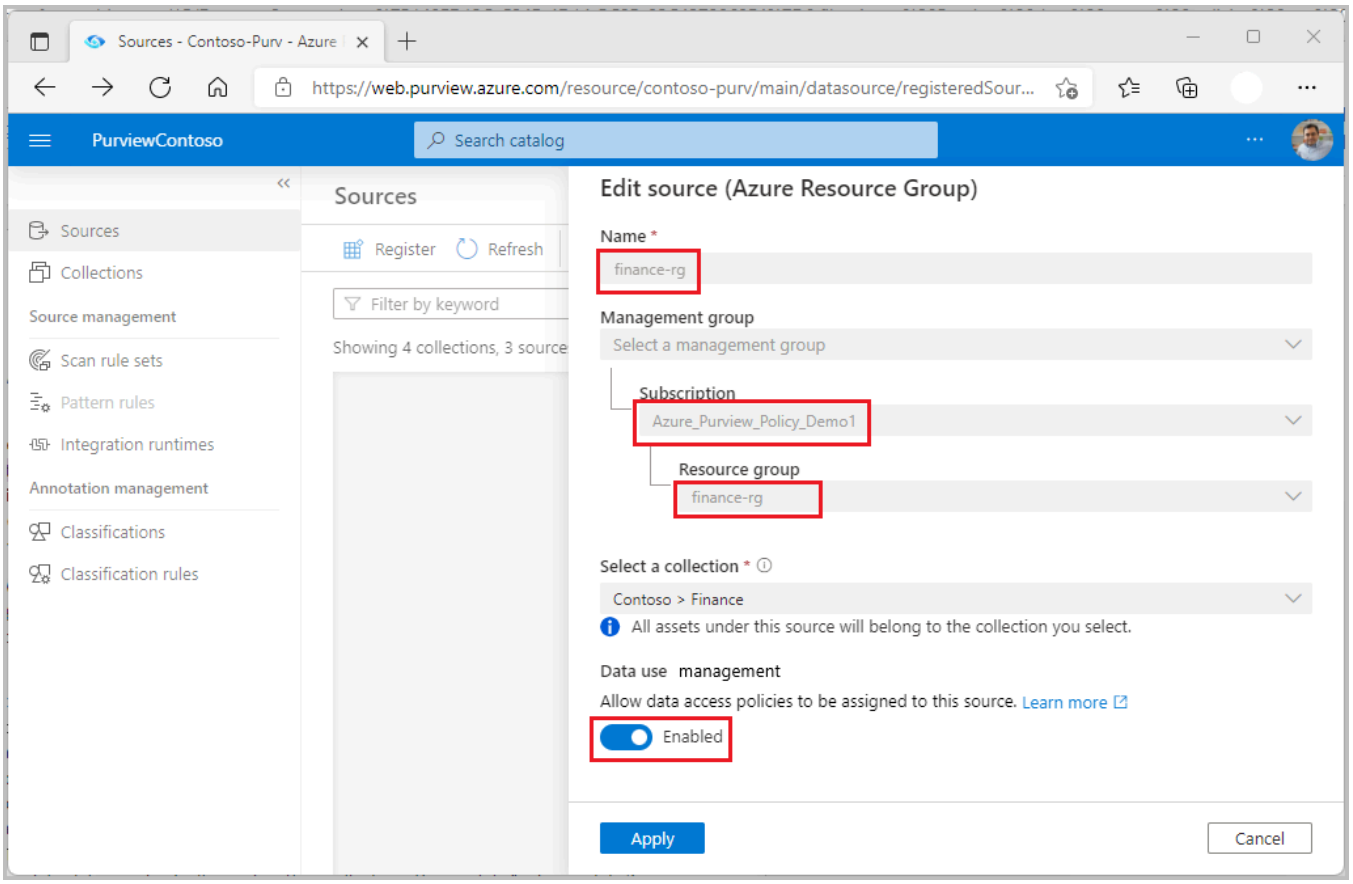
> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the data source in Microsoft Purview for Data Policy Enforcement

The Azure subscription or resource group needs to be registered first with Microsoft Purview before you can create access policies. To register your resource, follow the **Prerequisites** and **Register** sections of this guide:

- Register multiple sources in Microsoft Purview

After you've registered the data resource, you'll need to enable Data Policy Enforcement. This is a pre-requisite before you can create policies on the data resource. Data Policy Enforcement can impact the security of your data, as it delegates to certain Microsoft Purview roles managing access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

Once your data source has the **Data Policy Enforcement** option set to **Enabled**, it will look like this screenshot:

Create a policy

To create an access policy on an entire Azure subscription or resource group, follow these guides:

- DevOps policy covering all sources in a subscription or resource group
- Provision read/modify access to all sources in a subscription or resource group

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Devops policies in Microsoft Purview
- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage Azure Synapse Analytics workspaces in Microsoft Purview

Summarize this article for me

This article outlines how to register Azure Synapse Analytics workspaces. It also describes how to authenticate and interact with Azure Synapse Analytics workspaces in Microsoft Purview. Learn more about Microsoft Purview.

> **Note**
>
> There are dedicated SQL pools (formerly SQL DW) and dedicated SQL pools in Azure Synapse workspace. For the detailed difference between the two, see What is the difference between dedicated SQL pools (SQL DW) and dedicated SQL pools in Azure Synapse workspaces. Currently Microsoft Purview provides separate data sources for dedicated SQL pools (formerly SQL DW) and dedicated SQL pools:
>
> - To register and scan a dedicated SQL pool (formerly SQL DW), see Connect to and manage dedicated SQL pools in Microsoft Purview.
> - To register and scan a dedicated SQL pool (formerly SQL DW) that has enabled Azure Synapse workspace features, as documented in Enable Azure Synapse workspace features for a dedicated SQL pool (formerly SQL DW), see Connect to and manage Azure Synapse Analytics workspaces in Microsoft Purview.
> - To register and scan a dedicated SQL pool or a serverless SQL pool in Azure Synapse workspace, see Connect to and manage Azure Synapse Analytics workspaces in Microsoft Purview.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	No

Azure Synapse Analytics lake databases aren't currently supported. You might observe some inconsistencies in the scanned assets for these databases.

For external tables, Azure Synapse Analytics doesn't currently capture the relationship of those tables to their original files.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- Data source administrator and data reader permissions to register a source and manage it in the Microsoft Purview governance portal. For details, see Access control in the Microsoft Purview governance portal.

Register

The following procedure describes how to register Azure Synapse Analytics workspaces in Microsoft Purview by using the Microsoft Purview governance portal.

To register an Synapse Analytics workspace, you need at least the data reader role on the Synapse Analytics workspace and be a data source administrator in Microsoft Purview.

1. Open the Microsoft Purview governance portal and select your Microsoft Purview account.

   Alternatively, go to the Azure portal, search for and select the Microsoft Purview account, and then select the **Microsoft Purview governance portal** button.

2. On the left pane, select **Sources**.

3. Select **Register**.

4. Under **Register sources**, select **Azure Synapse Analytics (multiple)**.

5. Select **Continue**.

6. On the **Register sources (Azure Synapse Analytics)** page, do the following:

   a. For **Name**, enter a name for the data source to be listed in Microsoft Purview Unified Catalog.

   b. Optionally, for **Azure subscription**, choose a subscription to filter down to.

   c. For **Workspace name**, select the workspace that you're working with.

      The boxes for the SQL endpoints are automatically filled in based on your workspace selection.

   d. Select a collection from the list.

   e. Select **Register** to finish registering the data source.

Scan

Use the following steps to scan Azure Synapse Analytics workspaces to automatically identify assets and classify your data. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

1. Set up authentication for enumerating your dedicated or serverless resources. By setting up authentication, Microsoft Purview can enumerate your workspace assets and perform scans.
2. Apply permissions to scan the contents of the workspace.
3. Confirm that your network is set up to allow access for Microsoft Purview.

Enumeration authentication

Use the following procedures to set up authentication. You must be an owner or a user access administrator to add the specified roles.

Authentication for enumerating dedicated SQL database resources

1. In the Azure portal, go to the Azure Synapse Analytics workspace resource.
2. On the left pane, select **Access Control (IAM)**.
3. Select the **Add** button.
4. Set the **Reader** role and enter your Microsoft Purview account name, which represents its managed service identity (MSI).
5. Select **Save** to finish assigning the role.

If you want to scan a dedicated SQL pool (formerly SQL DW) that has enabled Azure Synapse Analytics workspace features as documented in Enable Azure Synapse workspace features for a dedicated SQL pool (formerly SQL DW), follow these additional configuration steps for the dedicated SQL pool (formerly SQL DW):

1. In the Azure portal, go to the SQL Server resource associated with the dedicated SQL pool (formerly SQL DW).
2. On the left pane, select **Access Control (IAM)**.
3. Select the **Add** button.
4. Set the **Reader** role and enter your Microsoft Purview account name, which represents its managed service identity (MSI).
5. Select **Save** to finish assigning the role.

> **Note**

If you're planning to register and scan multiple Azure Synapse Analytics workspaces in your Microsoft Purview account, you can also assign the role from a higher level, such as a resource group or a subscription.

Authentication for enumerating serverless SQL Database resources

Set authentication in three places to allow Microsoft Purview to enumerate your serverless SQL Database resources.

To set authentication for the Azure Synapse Analytics workspace:

1. In the Azure portal, go to the Azure Synapse Analytics workspace resource.
2. On the left pane, select **Access Control (IAM)**.
3. Select the **Add** button.
4. Set the **Reader** role and enter your Microsoft Purview account name, which represents its MSI.
5. Select **Save** to finish assigning the role.

To set authentication for the storage account:

1. In the Azure portal, go to the resource group or subscription that contains the storage account associated with the Azure Synapse Analytics workspace.
2. On the left pane, select **Access Control (IAM)**.
3. Select the **Add** button.
4. Set the **Storage blob data reader** role and enter your Microsoft Purview account name (which represents its MSI) in the **Select** box.
5. Select **Save** to finish assigning the role.

To set authentication for the Azure Synapse Analytics serverless database:

1. Go to your Azure Synapse Analytics workspace and open Synapse Studio.
2. On the left pane, select **Data**.
3. Select the ellipsis (...) next to one of your databases, and then start a new SQL script.
4. Run the following command in your SQL script to add the Microsoft Purview account MSI (represented by the account name) on the serverless SQL databases:

```SQL
CREATE LOGIN [PurviewAccountName] FROM EXTERNAL PROVIDER;
```

Apply permissions to scan the contents of the workspace

You must set up authentication on each SQL Database that you want to register and scan from your Azure Synapse Analytics workspace. For steps to apply permissions, see the following scenarios.

> **Important**
>
> The following steps for serverless databases *do not* apply to replicated databases. In Azure Synapse Analytics, serverless databases that are replicated from Spark databases are currently read-only. For more information, see Operation isn't allowed for a replicated database.

Managed identity

Use a managed identity for dedicated SQL databases

> **Important**
>
> If you use a self-hosted integration runtime to connect to your resource on a private network, managed identities don't work. You need to use service principal authentication or SQL authentication.

To run the commands in the following procedure, you must be an Azure Synapse administrator on the workspace. For more information about Azure Synapse Analytics permissions, see Set up access control for your Azure Synapse Analytics workspace.

1. Go to your Azure Synapse Analytics workspace.
2. Go to the **Data** section, and then look for one of your dedicated SQL databases.
3. Select the ellipsis (...) next to the database name, and then start a new SQL script.
4. Run the following command in your SQL script to add the Microsoft Purview account MSI (represented by the account name) as `db_datareader` on the dedicated SQL database:

```
SQL

CREATE USER [PurviewAccountName] FROM EXTERNAL PROVIDER
GO
```

```
EXEC sp_addrolemember 'db_datareader', [PurviewAccountName]
GO
```

5. Run the following command in your SQL script to verify the addition of the role:

```
SQL

SELECT p.name AS UserName, r.name AS RoleName
FROM sys.database_principals p
LEFT JOIN sys.database_role_members rm ON p.principal_id =
rm.member_principal_id
LEFT JOIN sys.database_principals r ON rm.role_principal_id =
r.principal_id
WHERE p.authentication_type_desc = 'EXTERNAL'
ORDER BY p.name;
```

Follow the same steps for each database that you want to scan.

Use a managed identity for serverless SQL databases

1. Go to your Azure Synapse Analytics workspace.
2. Go to the **Data** section, and select one of your SQL databases.
3. Select the ellipsis (...) next to the database name, and then start a new SQL script.
4. Run the following command in your SQL script to add the Microsoft Purview account MSI (represented by the account name) as `db_datareader` on the serverless SQL databases:

```
SQL

CREATE USER [PurviewAccountName] FOR LOGIN [PurviewAccountName];
ALTER ROLE db_datareader ADD MEMBER [PurviewAccountName];
```

5. Run the following command in your SQL script to verify the addition of the role:

```
SQL

SELECT p.name AS UserName, r.name AS RoleName
FROM sys.database_principals p
LEFT JOIN sys.database_role_members rm ON p.principal_id =
rm.member_principal_id
LEFT JOIN sys.database_principals r ON rm.role_principal_id =
r.principal_id
```

```
WHERE p.authentication_type_desc = 'EXTERNAL'
ORDER BY p.name;
```

Follow the same steps for each database that you want to scan.

Grant permission to use credentials for external tables

If the Synapse Analytics workspace has any external tables, you must give the Microsoft Purview managed identity References permission on the external table's scoped credentials. By using the References permission, Microsoft Purview can read data from external tables.

1. Run the following command in your SQL script to get the list of database scoped credentials:

   SQL

   ```
   Select name, credential_identity
   from sys.database_scoped_credentials;
   ```

2. To grant access to database scoped credentials, run the following command. Replace `scoped_credential` with the name of the database scoped credential.

   SQL

   ```
   GRANT REFERENCES ON DATABASE SCOPED CREDENTIAL::[scoped_credential] TO
   [PurviewAccountName];
   ```

3. To verify the permission assignment, run the following command in your SQL script:

   SQL

   ```
   SELECT dp.permission_name, dp.grantee_principal_id, p.name AS
   grantee_principal_name
   FROM sys.database_permissions AS dp
   JOIN sys.database_principals AS p ON dp.grantee_principal_id =
   p.principal_id
   JOIN sys.database_scoped_credentials AS c ON dp.major_id =
   c.credential_id;
   ```

Set up firewall access for the Azure Synapse Analytics workspace

1. In the Azure portal, go to the Azure Synapse Analytics workspace.
2. On the left pane, select **Networking**.
3. For **Allow Azure services and resources to access this workspace**, select **ON**.
4. Select **Save**.

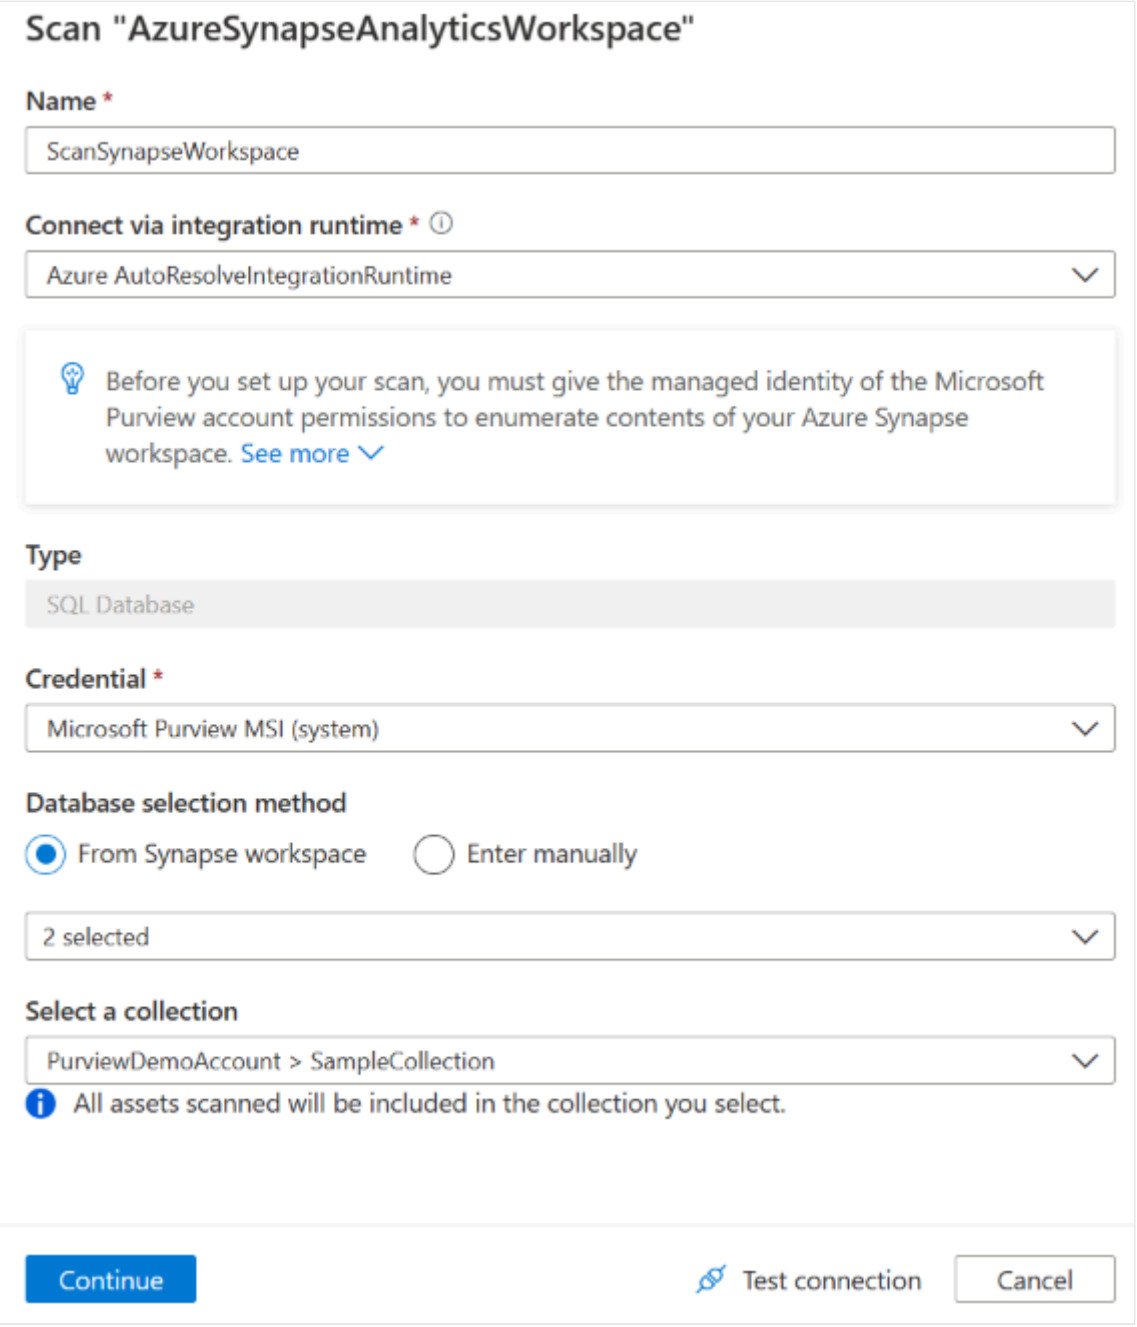
If you want to scan a dedicated SQL pool (formerly SQL DW) that has enabled Azure Synapse Analytics workspace features as documented in Enable Azure Synapse workspace features for a dedicated SQL pool (formerly SQL DW), follow these additional configuration steps for the dedicated SQL pool (formerly SQL DW):

1. In the Azure portal, go to the SQL Server resource associated with the dedicated SQL pool (formerly SQL DW).
2. On the left pane, select **Networking**.
3. For **Allow Azure services and resources to access this server**, select **ON**.
4. Select **Save**.

> **Important**
>
> If you can't enable **Allow Azure services and resources to access this workspace** on your Azure Synapse Analytics workspaces, you'll get a serverless database enumeration failure when you set up a scan in the Microsoft Purview governance portal. In this case, you can choose the **Enter manually** option to specify the database names that you want to scan, and then proceed or **set up a scan using an API**.

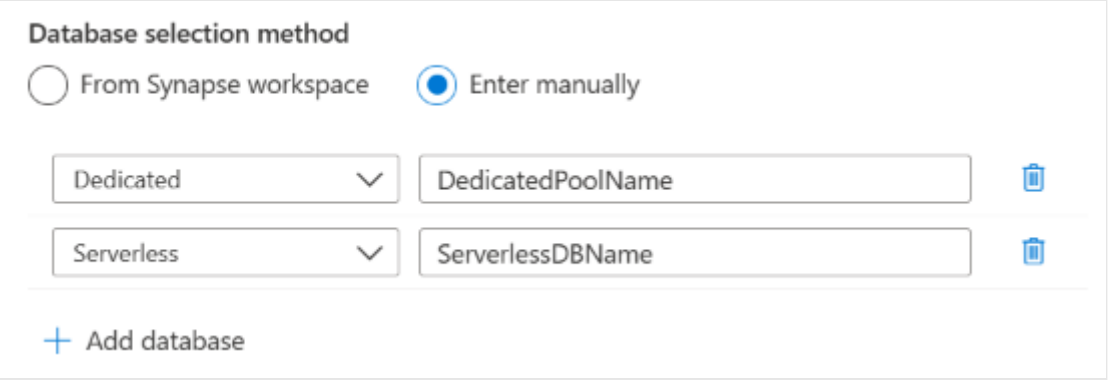
Create and run a scan

1. In the Microsoft Purview governance portal, on the left pane, select **Data Map**.
2. Select the data source that you registered.
3. Select **View details**, and then select **New scan**. Alternatively, you can select the **Scan quick action** icon on the source tile.
4. On the **Scan** details pane, in the **Name** box, enter a name for the scan.



> **Note**

For the integration runtime, if you're using **Managed VNet Runtime**, make sure you create the required Managed Private Endpoints:



- To scan Serverless pools, create a managed private endpoint of *sqlOnDemand* sub-resource type for your Synapse workspace.
- To scan Dedicated pools, create a managed private endpoint of *sql* sub-resource type for your Synapse workspace.
- If you're scanning both Serverless and Dedicated pools, you must create both managed private endpoints and in the wizard select one.

1. In the **Credential** dropdown list, select the credential to connect to the resources within your data source.

2. For **Database selection method**, select **From Synapse workspace** or **Enter manually**. By default, Microsoft Purview tries to enumerate the databases under the workspace, and you can select the ones that you want to scan.

If you get an error that says Microsoft Purview failed to load the serverless databases, you can select **Enter manually** to specify the type of database (dedicated or serverless) and the corresponding database name.

3. Select **Test connection** to validate the settings. If you get any error, on the report page, hover over the connection status to see details.

4. Select **Continue**.
5. Select **Scan rule sets** of type **Azure Synapse SQL**. You can also create scan rule sets inline.
6. Choose your scan trigger. You can set up a schedule or run the scan once.
7. Review your scan, and then select **Save** to complete the setup.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

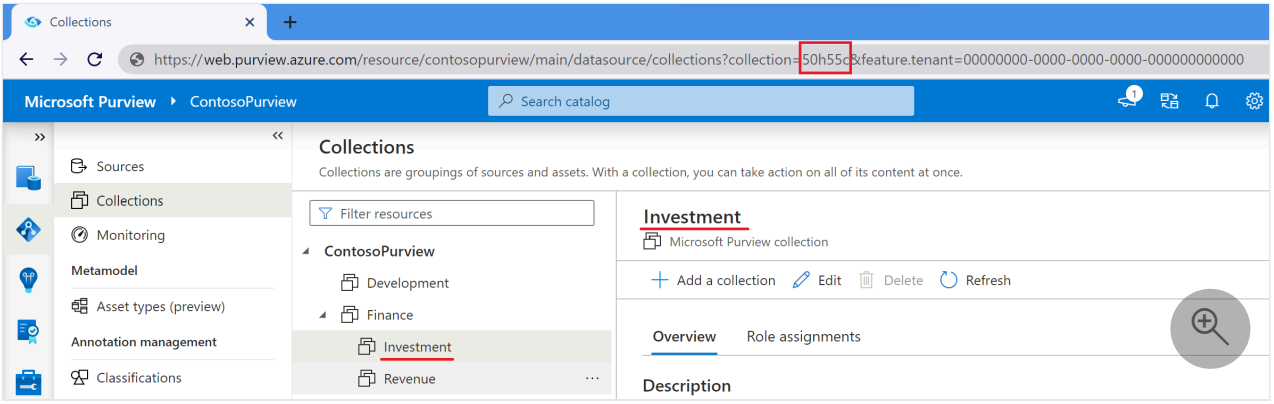
To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Set up a scan by using an API

Here's an example of creating a scan for a serverless database by using the Microsoft Purview REST API. Replace the placeholders in braces (`{}`) with your actual settings. To learn more, see



Scans - Create Or Update.

HTTP

```
PUT
https://{purview_account_name}.purview.azure.com/scan/datasources/<data_source_name
>/scans/{scan_name}?api-version=2022-02-01-preview
```

In the following code, `collection_id` isn't the friendly name for the collection. It's a five-character ID. For the root collection, `collection_id` is the name of the collection. For all subcollections, it's the ID that you can find in one of these places:

- The URL in the Microsoft Purview governance portal. Select the collection, and check the URL to find where it says **collection**=. That's your ID. In the following example, the **Investment** collection has the ID **50h55c**.

- You can list child collection names of the root collection to list the collections, and then use the name instead of the friendly name.

JSON

```
{
    "properties":{
        "resourceTypes":{
            "AzureSynapseServerlessSql":{
                "scanRulesetName":"AzureSynapseSQL",
                "scanRulesetType":"System",
                "resourceNameFilter":{
                    "resources":[ "{serverless_database_name_1}", "
{serverless_database_name_2}", ...]
                }
            }
        },
        "credential":{
            "referenceName":"{credential_name}",
            "credentialType":"SqlAuth | ServicePrincipal | ManagedIdentity (if UAMI
authentication)"
        },
```

```
        "collection":{
            "referenceName":"{collection_id}",
            "type":"CollectionReference"
        },
        "connectedVia":{
            "referenceName":"{integration_runtime_name}",
            "integrationRuntimeType":"SelfHosted (if self-hosted IR) | Managed (if
VNet IR)"
        }
    },
    "kind":"AzureSynapseWorkspaceCredential | AzureSynapseWorkspaceMsi (if system-
assigned managed identity authentication)"
}
```

To schedule the scan, create a trigger for it after scan creation. For more information, see Triggers - Create Trigger.

Troubleshooting

If you have any problems with scanning:

- Confirm that you followed all prerequisites.
- Confirm that you set up enumeration authentication for your resources.
- Confirm that you set up authentication.
- Check the network by confirming firewall settings.
- Review the scan troubleshooting documentation.

Next steps

After you register your source, use the following guides to learn more about Microsoft Purview and your data:

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search the Microsoft Purview Unified Catalog

Last updated on 02/24/2026

Connect to and manage Azure Arc-enabled SQL Server in Microsoft Purview

Article • 03/21/2024

This article shows how to register an Azure Arc-enabled SQL Server instance. It also shows how to authenticate and interact with Azure Arc-enabled SQL Server in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes (preview)	Yes (preview)	Yes (preview)

The supported SQL Server versions are 2012 and later. SQL Server Express LocalDB isn't supported.

When you're scanning Azure Arc-enabled SQL Server, Microsoft Purview supports extracting the following technical metadata:

- Instances
- Databases
- Schemas
- Tables, including the columns
- Views, including the columns

When you're setting up a scan, you can choose to specify the database name to scan one database. You can further scope the scan by selecting tables and views as needed. The whole Azure Arc-enabled SQL Server instance will be scanned if you don't provide a database name.

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. See Access control in the Microsoft Purview governance portal for details.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:** Follow the article to create and configure a self-hosted integration runtime.
  - **To use a kubernetes supported self-hosted integration runtime:** Follow the article to create and configure a kubernetes supported integration runtime. (SQL authentication only.)

Networking

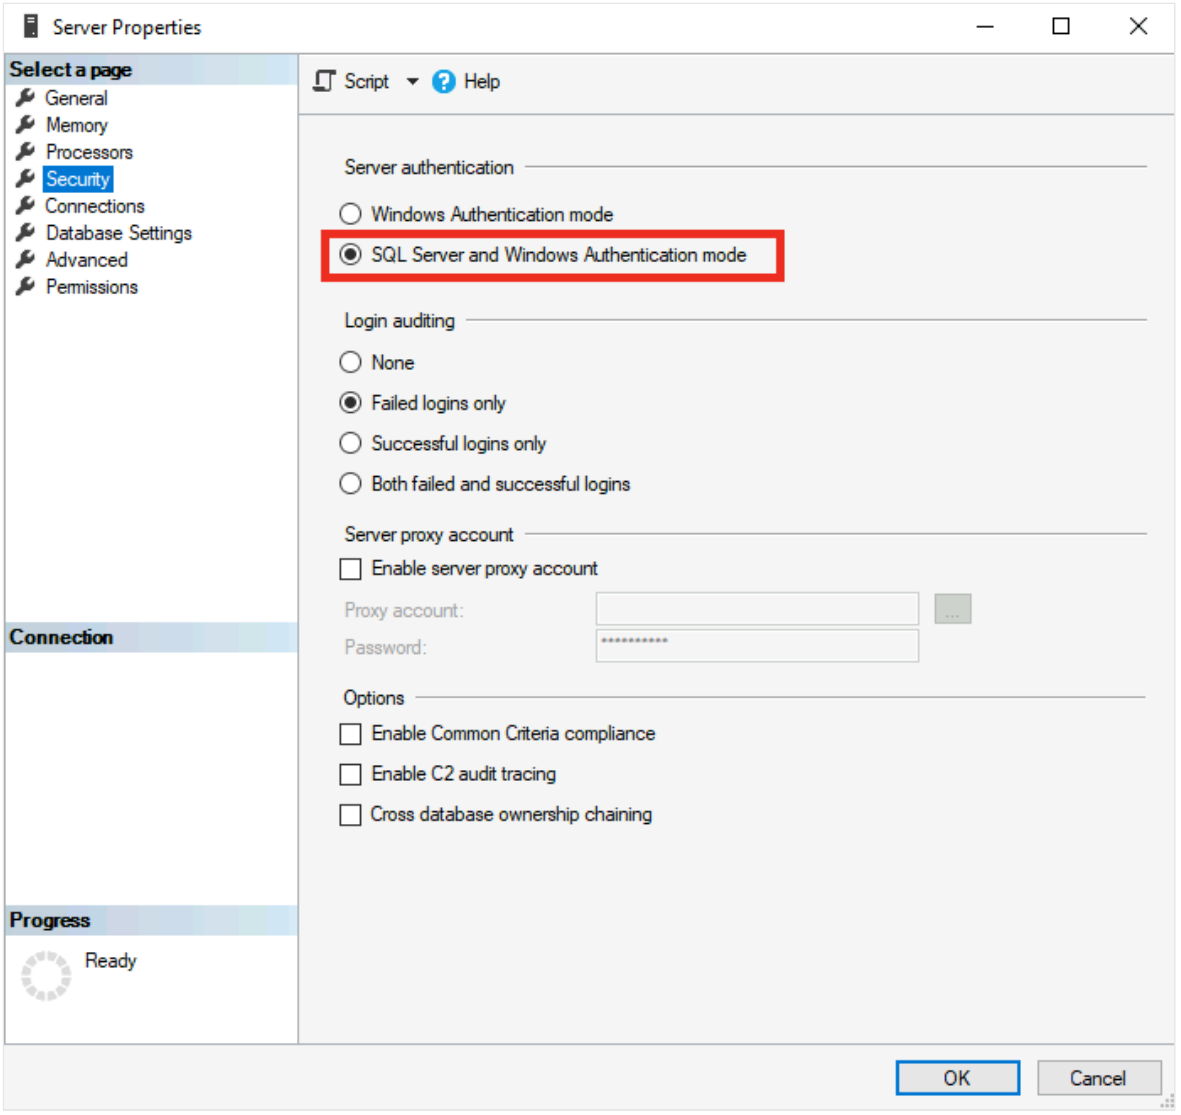
If your Microsoft Purview instance has disabled all public network access, to access your Arc-Enabled SQL Server, the virtual machine must be added to the virtual network that is connected to your Microsoft Purview instance.

Register

This section describes how to register an Azure Arc-enabled SQL Server instance in Microsoft Purview by using the Microsoft Purview governance portal.

Authentication for registration

There are two ways to set up authentication for scanning Azure Arc-enabled SQL Server with a self-hosted integration runtime:



- SQL Server authentication
- Windows authentication - Not supported by a Kubernetes SHIR.

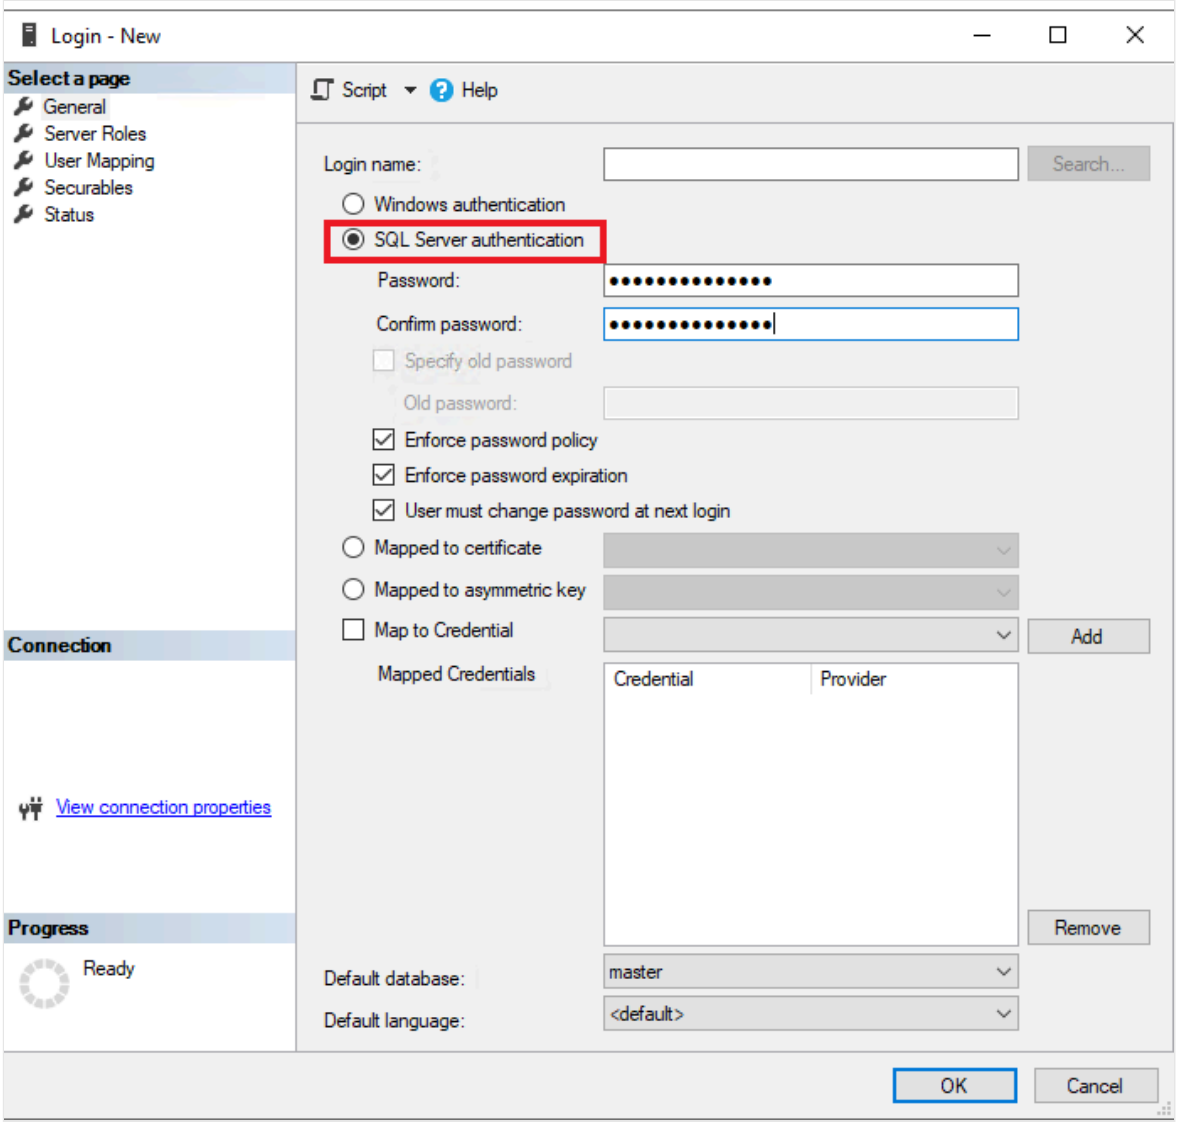
To configure authentication for the SQL Server deployment:

1. In SQL Server Management Studio (SSMS), go to **Server Properties**, and then select **Security** on the left pane.

2. Under **Server authentication**:

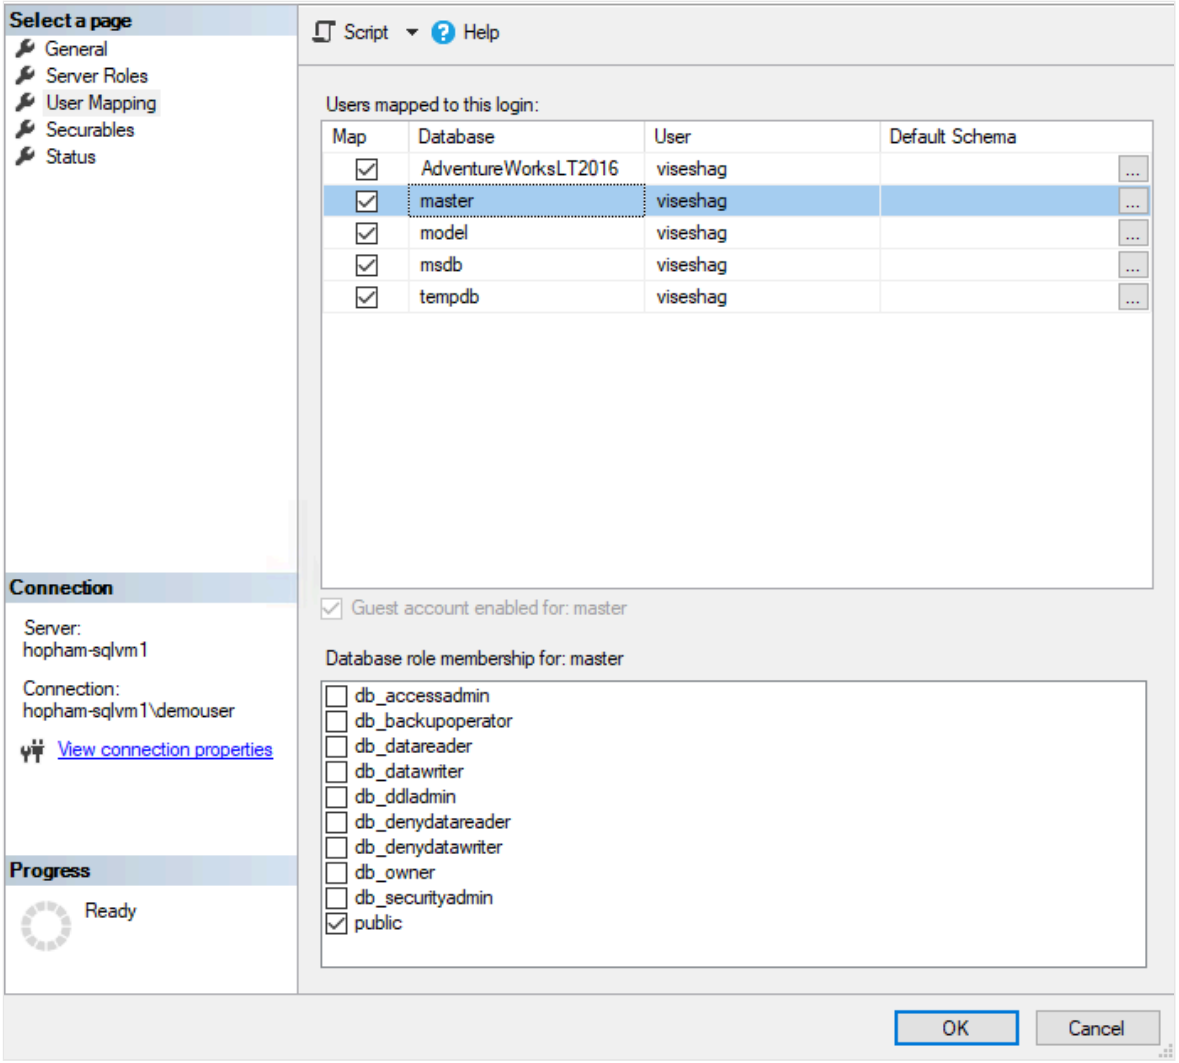
    - For Windows authentication, select either **Windows Authentication mode** or **SQL Server and Windows Authentication mode**.
    - For SQL Server authentication, select **SQL Server and Windows Authentication mode**.

A change to the server authentication requires you to restart the SQL Server instance and SQL Server Agent. In SSMS, go to the SQL Server instance and select **Restart** on the right-click options pane.



Create a new login and user

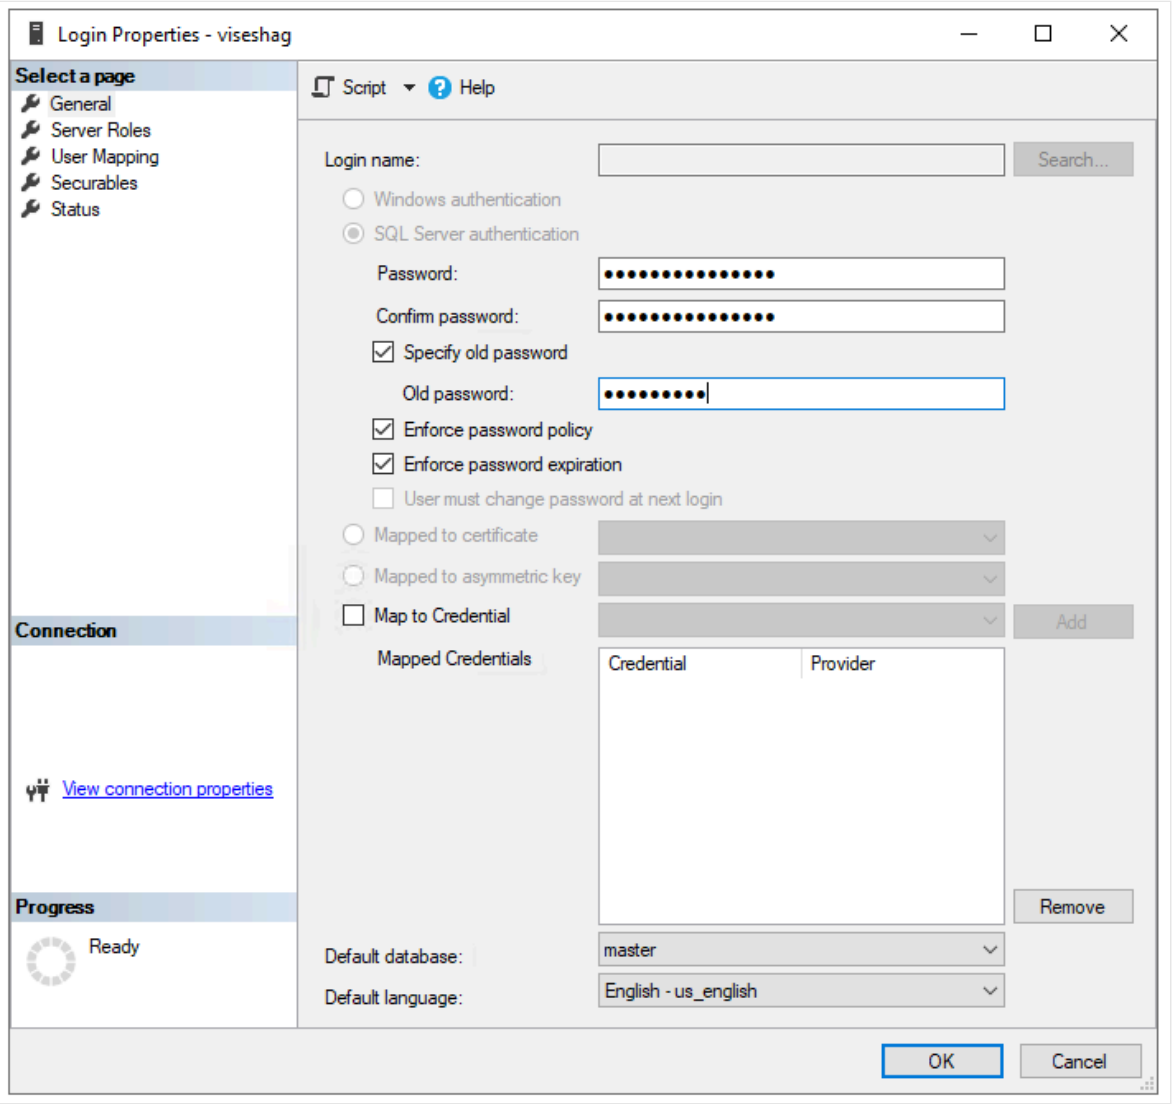
If you want to create a new login and user to scan your SQL Server instance, use the following steps.



The account must have access to the master database, because `sys.databases` is in the master database. The Microsoft Purview scanner needs to enumerate `sys.databases` in order to find all the SQL databases on the server.

> **Note**
>
> You can run all the following steps by using this code.

1. Go to SSMS, connect to the server, and then select **Security** on the left pane.
2. Select and hold (or right-click) **Login**, and then select **New login**. If Windows authentication is applied, select **Windows authentication**. If SQL Server authentication is applied, select **SQL Server authentication**.



3. Select **Server Roles** on the left pane, and ensure that a public role is assigned.
4. Select **User Mapping** on the left pane, select all the databases in the map, and then select the **db_datareader** database role.

5. Select **OK** to save.

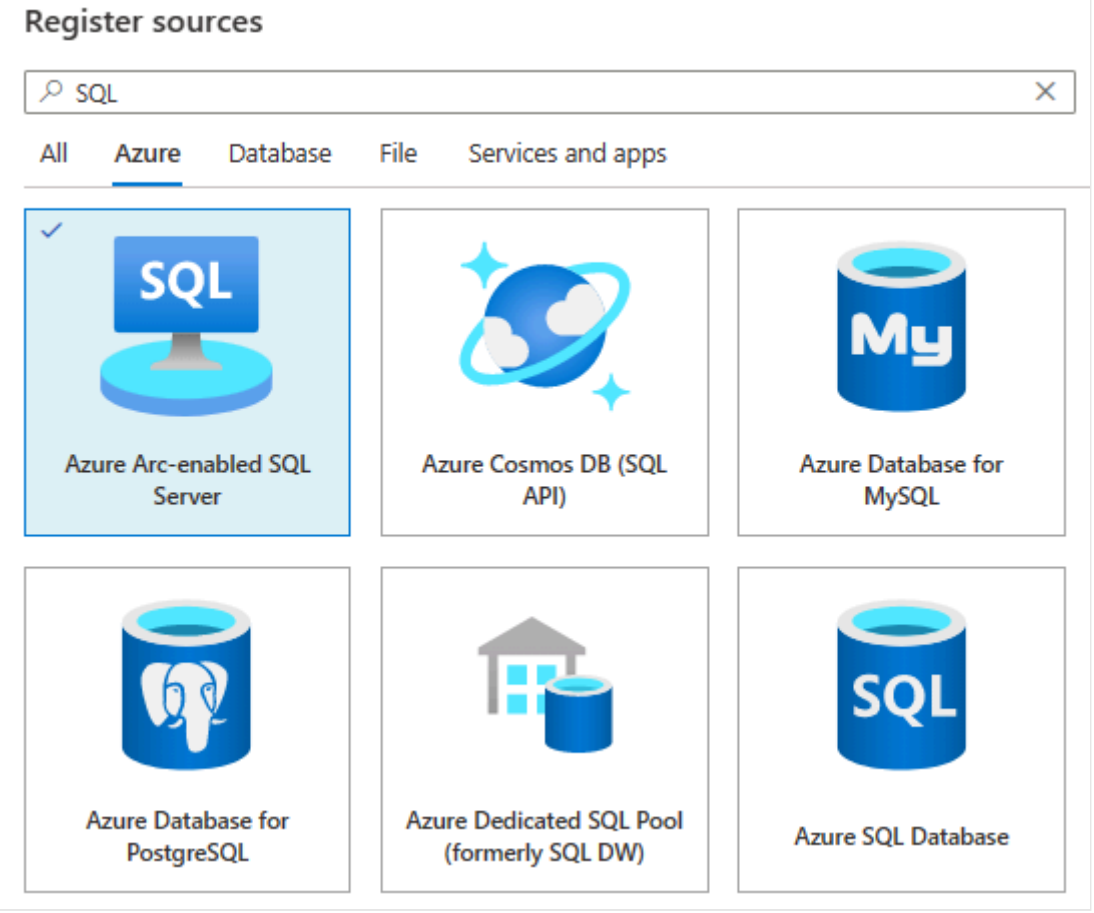
6. If SQL Server authentication is applied, you must change your password as soon as you create a new login:
   a. Select and hold (or right-click) the user that you created, and then select **Properties**.
   b. Enter a new password and confirm it.
   c. Select the **Specify old password** checkbox and enter the old password.
   d. Select **OK**.

Store your SQL Server login password in a key vault and create a credential in Microsoft Purview

1. Go to your key vault in the Azure portal. Select **Settings** > **Secrets**.

2. Select **+ Generate/Import**. For **Name** and **Value**, enter the password from your SQL Server login.

3. Select **Create**.



4. If your key vault isn't connected to Microsoft Purview yet, create a new key vault connection.

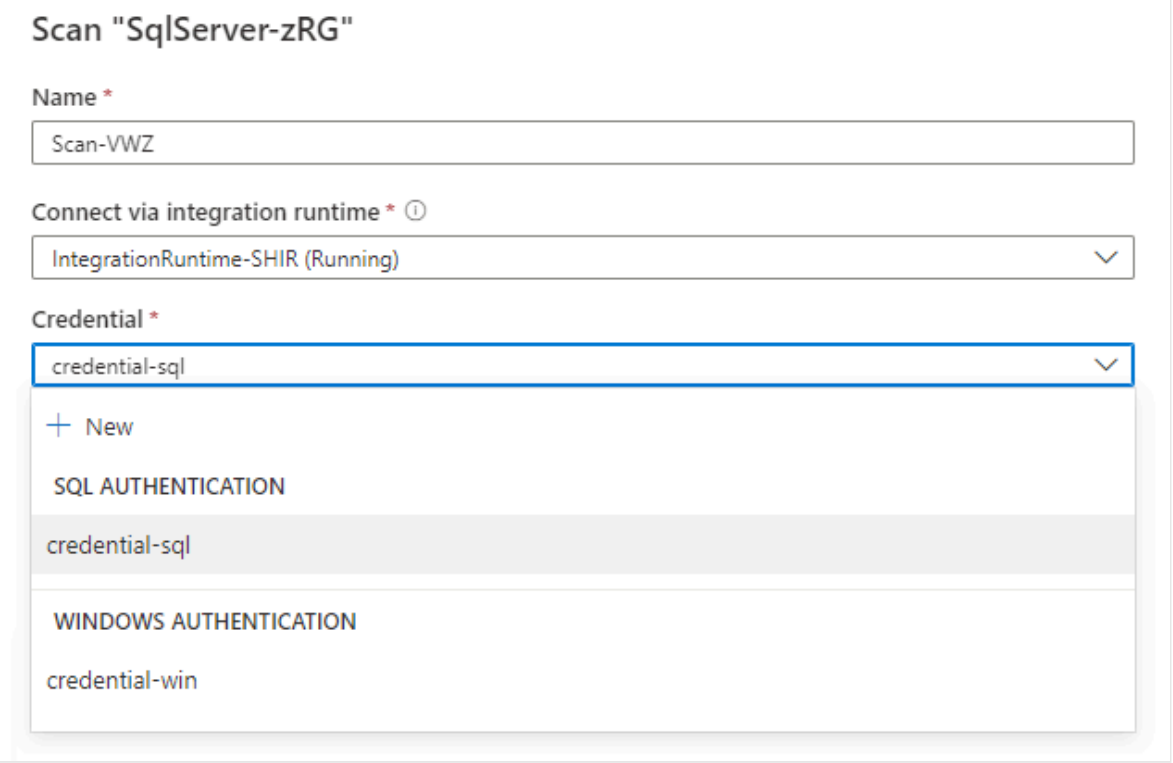
5. Create a new credential by using the username and password to set up your scan.

   Be sure to select the right authentication method when you're creating a new credential. If Windows authentication is applied, select **Windows authentication**. If SQL Server authentication is applied, select **SQL Server authentication**.

Steps to register

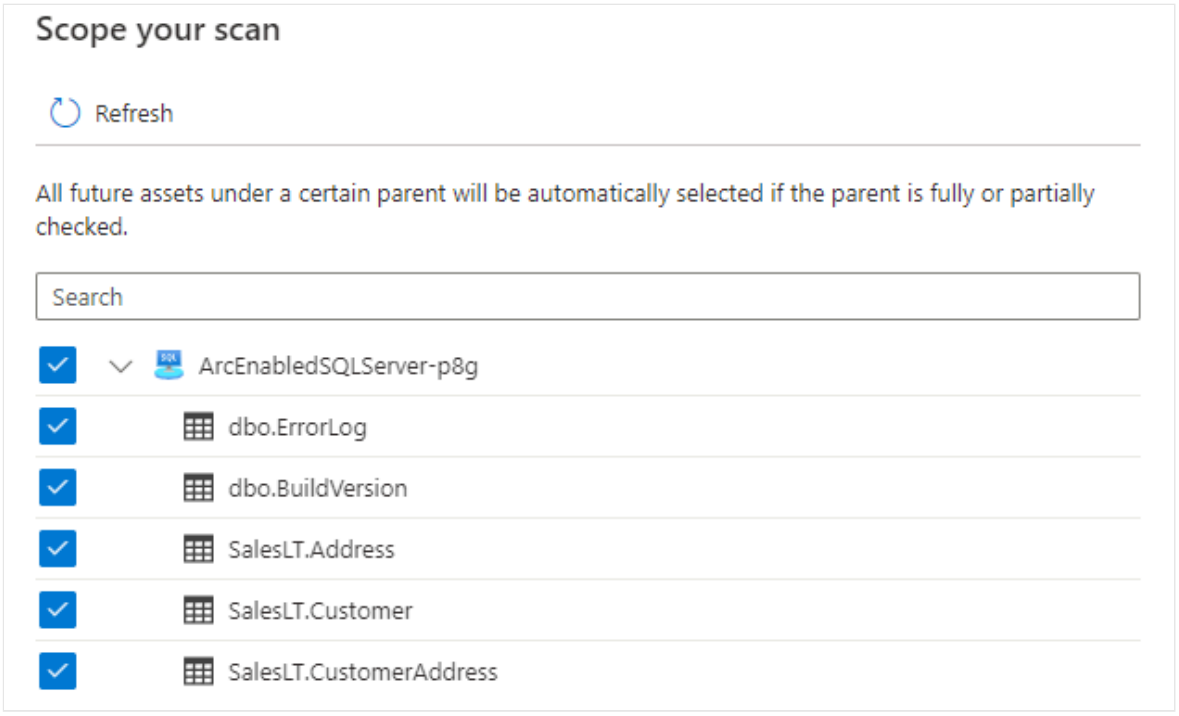
1. Go to your Microsoft Purview account.
2. Under **Sources and scanning** on the left pane, select **Integration runtimes**. Make sure that a self-hosted integration runtime is set up. If it isn't set up, follow the steps to create a self-hosted integration runtime for scanning on an on-premises or Azure virtual machine that has access to your on-premises network.
3. Select **Data Map** on the left pane.
4. Select **Register**.
5. Select **Azure Arc-enabled SQL Server**, and then select **Continue**.

6. Provide a friendly name, which is a short name that you can use to identify your server. Also provide the server endpoint.
7. Select **Finish** to register the data source.



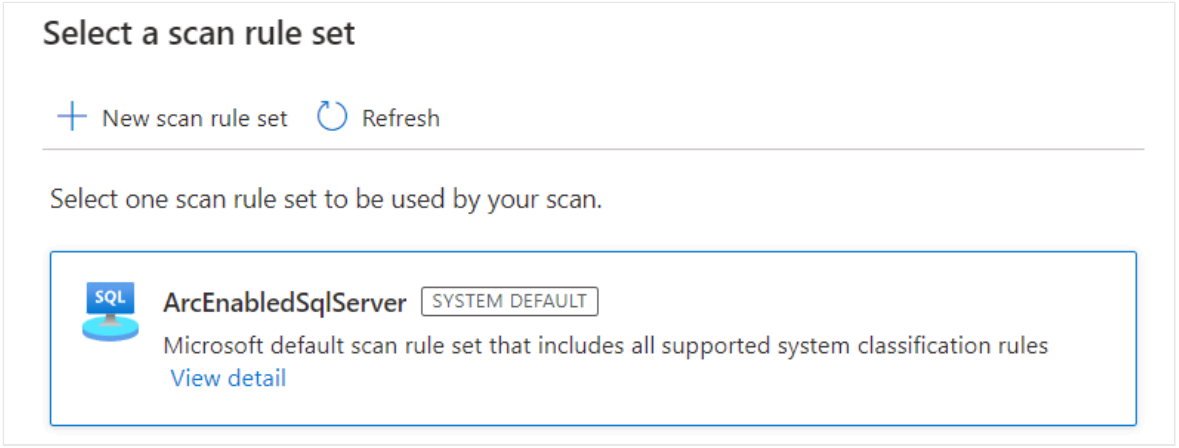
Scan

Use the following steps to scan Azure Arc-enabled SQL Server instances to automatically identify assets and classify your data. For more information about scanning in general,

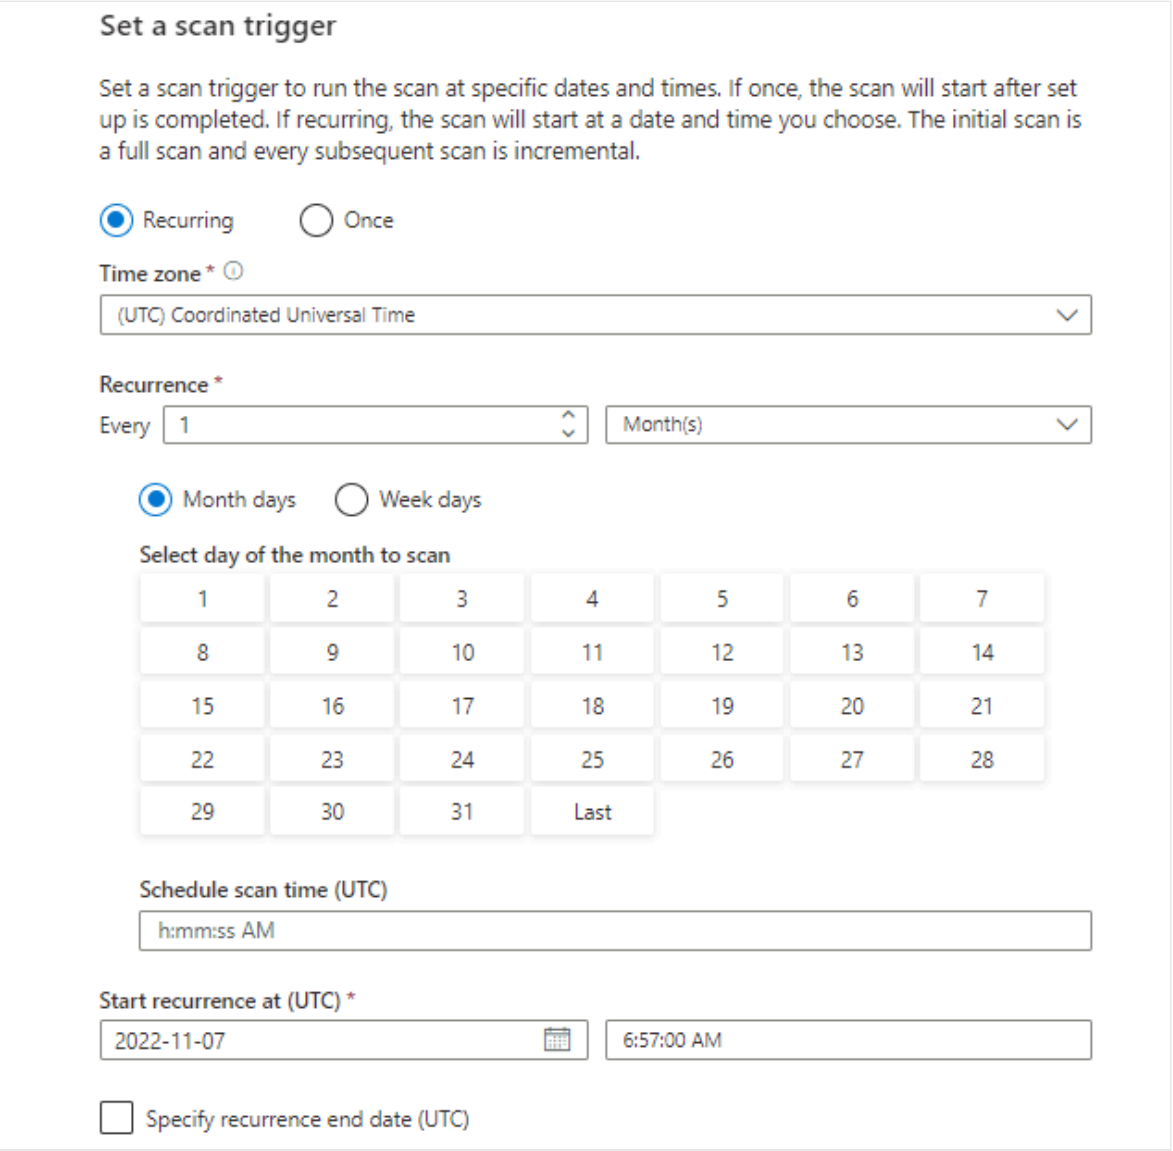


see Scans and ingestion in Microsoft Purview.

To create and run a new scan:



1. In the Microsoft Purview governance portal, select the **Data Map** tab on the left pane.
2. Select the Azure Arc-enabled SQL Server source that you registered.
3. Select **New scan**.
4. Select the credential to connect to your data source. Credentials are grouped and listed under the authentication methods.



5. You can scope your scan to specific tables by choosing the appropriate items in the list.

6. Select a scan rule set. You can choose between the system default, existing custom rule sets, or creation of a new rule set inline.

7. Choose your scan trigger. You can set up a schedule or run the scan once.

8. Review your scan, and then select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Access policy

Supported policies

The following types of policies are supported on this data resource from Microsoft Purview:

- DevOps policies
- Data Owner policies (preview)

Access policy prerequisites on Azure Arc-enabled SQL Server

- Get SQL Server on-premises version 2022 and install it. Versions 2022 or more recent are supported on both Windows and Linux. You can try the free Developer edition.
- Configure your permissions and then register a list of resource providers in the subscription you'll use to onboard the SQL Server instance to Azure Arc.
- Complete prerequisites and onboard the SQL Server instance with Azure Arc. A simple configuration for Windows SQL Server is here. An alternate configuration for Linux SQL Server is here.
- Enable Microsoft Entra authentication in SQL Server. For a simpler setup, complete the prerequisites and process outlined in this article.
- Remember to grant application permissions and grant admin consent
- You need to configure a Microsoft Entra admin for the SQL Server instance, but it isn't necessary to set up other Microsoft Entra logins or users. You'll grant access to

those users by using Microsoft Purview policies.

Region support

Data policy enforcement is available in all Microsoft Purview regions except:

- West US2
- East Asia
- US Gov Virginia
- China North 3

Security considerations for Azure Arc-enabled SQL Server

- The server admin can turn off the Microsoft Purview policy enforcement.
- Azure Arc admin and server admin permissions provide the ability to change the Azure Resource Manager path of the server. Because mappings in Microsoft Purview use Resource Manager paths, it can lead to wrong policy enforcements.
- A SQL Server admin (database admin) can gain the power of a server admin and can tamper with the cached policies from Microsoft Purview.
- The recommended configuration is to create a separate app registration for each SQL server instance. This configuration prevents the second SQL Server instance from reading the policies meant for the first SQL Server instance, in case a rogue admin in the second SQL Server instance tampers with the Resource Manager path.

Verify the prerequisites

1. Sign in to the Azure portal through this link
2. Navigate to **SQL servers** on the left pane. You'll see a list of SQL Server instances on Azure Arc.
3. Select the SQL Server instance that you want to configure.
4. Go to **Microsoft Entra ID** on the left pane.
5. Ensure that Microsoft Entra authentication is configured with an admin login. If not, refer to the access policy prerequisites section in this guide.
6. Ensure that a certificate has been provided to for SQL Server to authenticate to Azure. If not, refer to the access policy prerequisites section in this guide.

7. Ensure that an app registration has been entered to create a trust relationship between SQL Server and Microsoft Entra ID. If not, refer to the access policy prerequisites section in this guide.

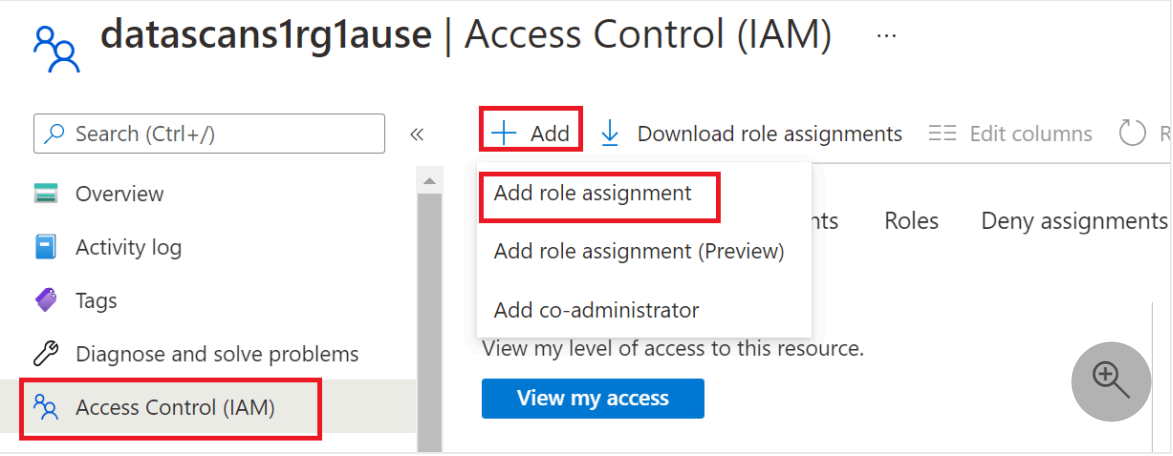
8. If you made any changes, select the **Save** button to save the configuration and wait until the operation completes successfully. This could take a few minutes. The message "*Saved successfully*" will be displayed at the top of the page in green background. You might need to scroll up to see it.

Configure the Microsoft Purview account for policies

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

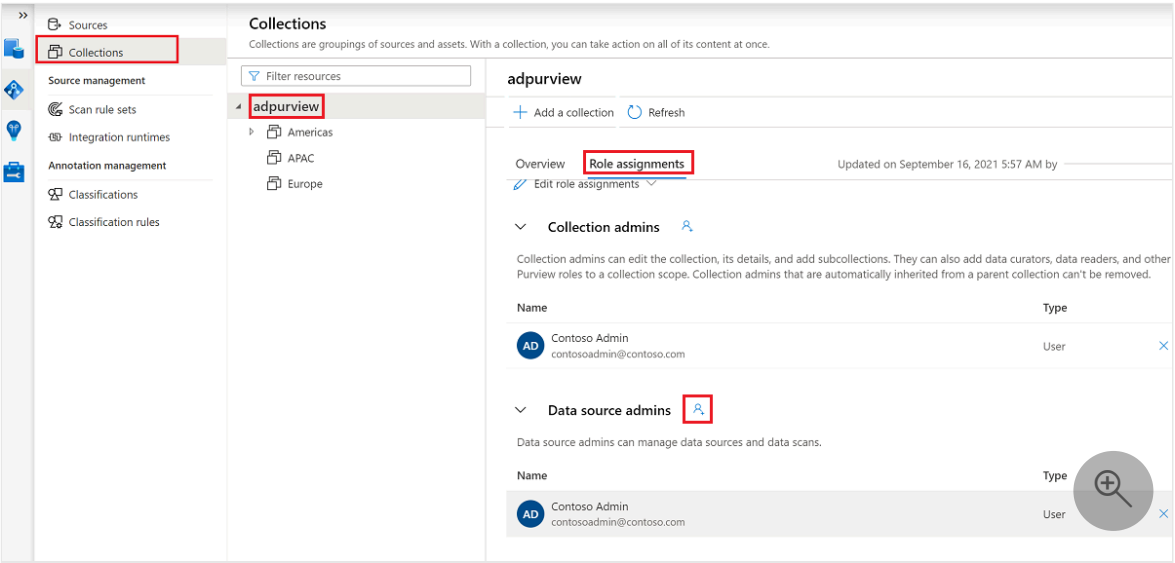


Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the



Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> ⓘ **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

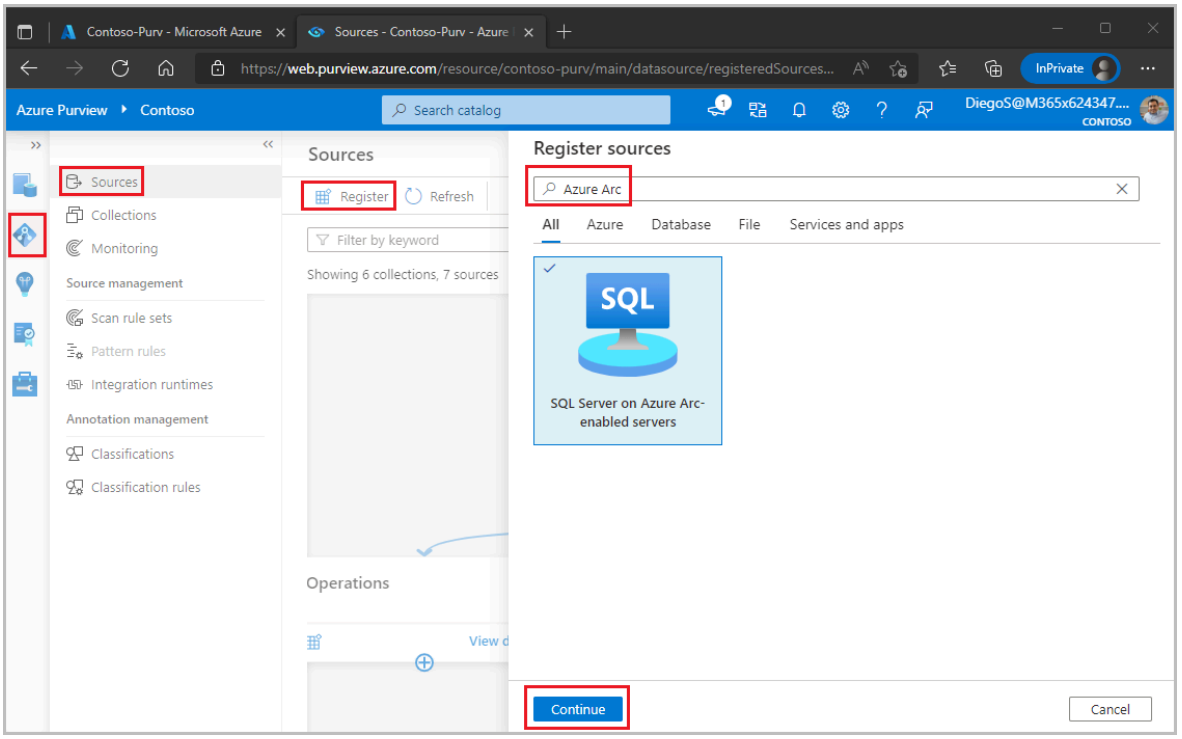
For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.



If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

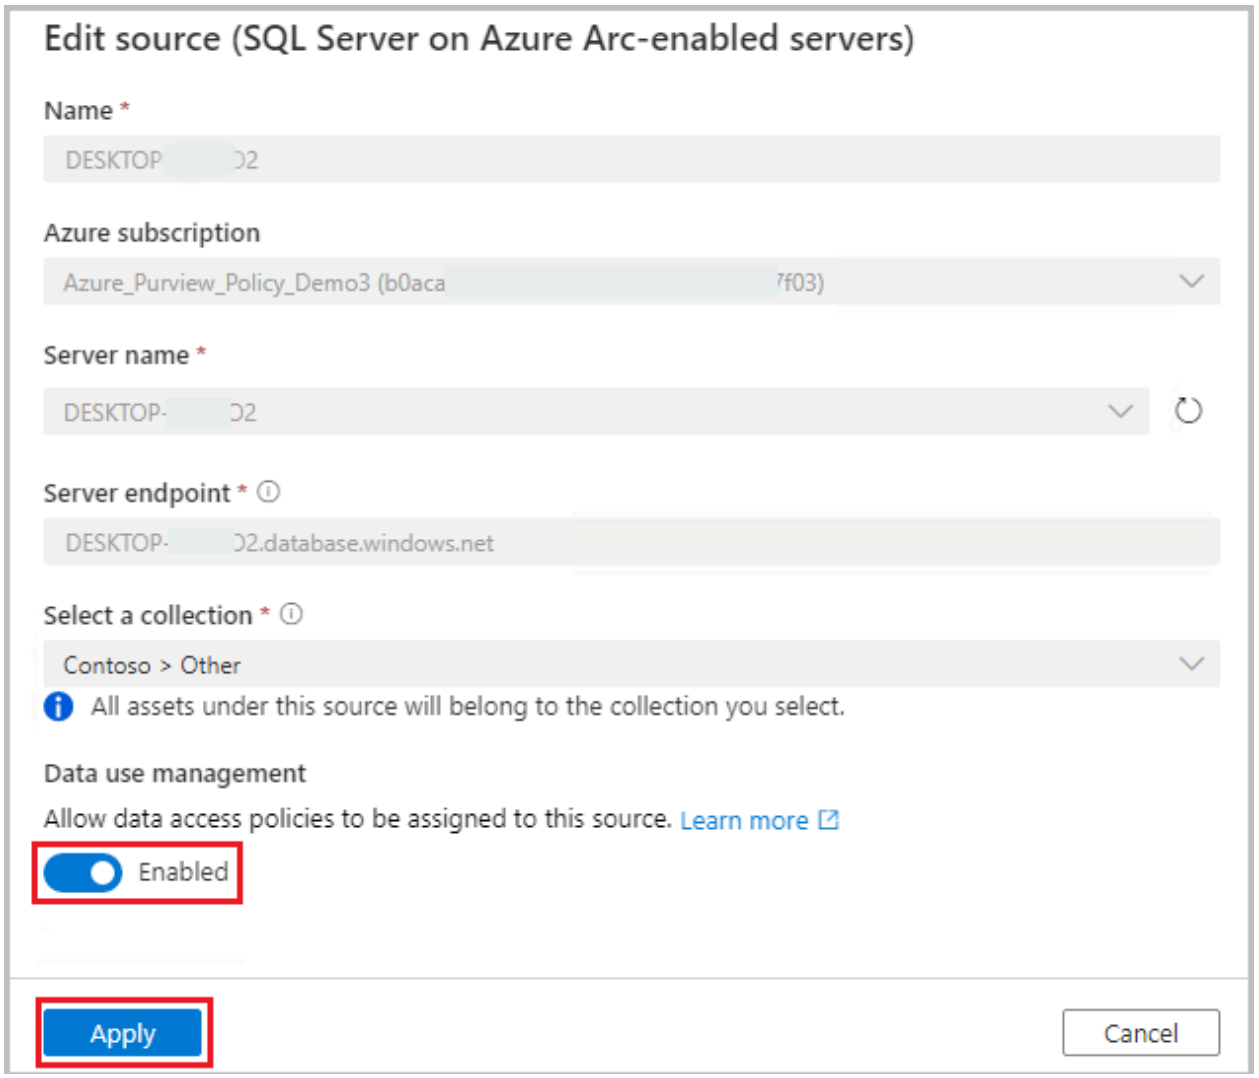
Register the data source and enable Data policy enforcement

Before you can create policies, you must register the Azure Arc-enabled SQL Server data source with Microsoft Purview:

1. Sign in to Microsoft Purview Studio.

2. Go to **Data map** on the left pane, select **Sources**, and then select **Register**. Enter **Azure Arc** in the search box and select **SQL Server on Azure Arc**. Then select **Continue**.

3. For **Name**, enter a name for this registration. It's best practice to make the name of the registration the same as the server name in the next step.

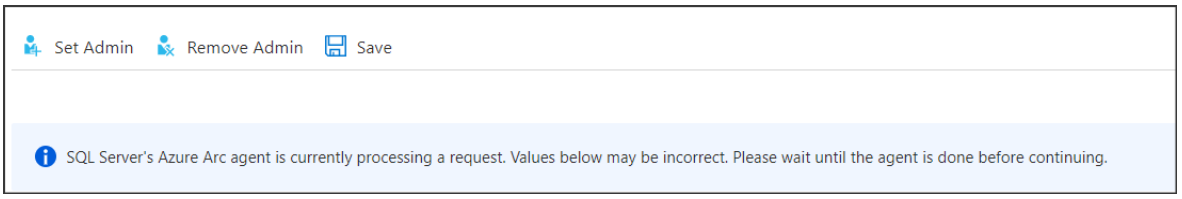


4. Select values for **Azure subscription**, **Server name**, and **Server endpoint**.

5. For **Select a collection**, choose a collection to put this registration in.

6. Enable **Data policy enforcement**. **Data policy enforcement** needs certain permissions and can affect the security of your data, because it delegates to certain Microsoft Purview roles to manage access to the data sources. Go through the secure practices related to **Data policy enforcement** in this guide: Enable Data policy enforcement on your Microsoft Purview sources.

7. Upon enabling Data Policy Enforcement, Microsoft Purview will automatically capture the **Application ID** of the App Registration related to this Azure Arc-enabled SQL Server if one has been configured. Come back to this screen and hit the refresh button on the side of it to refresh, in case the association between the Azure Arc-enabled SQL Server and the App Registration changes in the future.



8. Select **Register** or **Apply**.

Enable policies in Azure Arc-enabled SQL Server

This section describes the steps to configure SQL Server on Azure Arc to use Microsoft Purview. Execute these steps after you enable the *Data policy enforcement* option for this data source in the Microsoft Purview account.

1. Sign in to the Azure portal through this link
2. Navigate to **SQL servers** on the left pane. You'll see a list of SQL Server instances on Azure Arc.
3. Select the SQL Server instance that you want to configure.
4. Go to **Microsoft Entra ID** on the left pane.
5. Scroll down to **Microsoft Purview access policies**.
6. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. While that happens, this message will be displayed at the top of the page. You might need to scroll up to see it.

7. At the bottom of the page, confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it may take up to 30 minutes** for the correct status to be reflected. Continue doing a browser refresh until that happens.

8. Confirm that the Microsoft Purview Endpoint points to the Microsoft Purview account where you registered this data source and enabled the *data policy enforcement*

Create a policy

To create an access policy for Azure Arc-enabled SQL Server, follow these guides:

- Provision access to system health, performance and audit information in SQL Server 2022
- Provision read/modify access on a single SQL Server 2022

To create policies that cover all data sources inside a resource group or Azure subscription, see Discover and govern multiple Azure sources in Microsoft Purview.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Concepts for Microsoft Purview Data owner policies
- Concepts for Microsoft Purview DevOps policies
- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search the Unified Catalog

Feedback

Was this page helpful? Yes No

Connect to Azure Blob storage in Microsoft Purview

This article outlines the process to register and govern Azure Blob Storage accounts in Microsoft Purview including instructions to authenticate and interact with the Azure Blob Storage source

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

For file types such as csv, tsv, psv, ssv, the schema is extracted when the following logics are in place:

- First row values are non-empty
- First row values are unique
- First row values aren't a date or a number

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

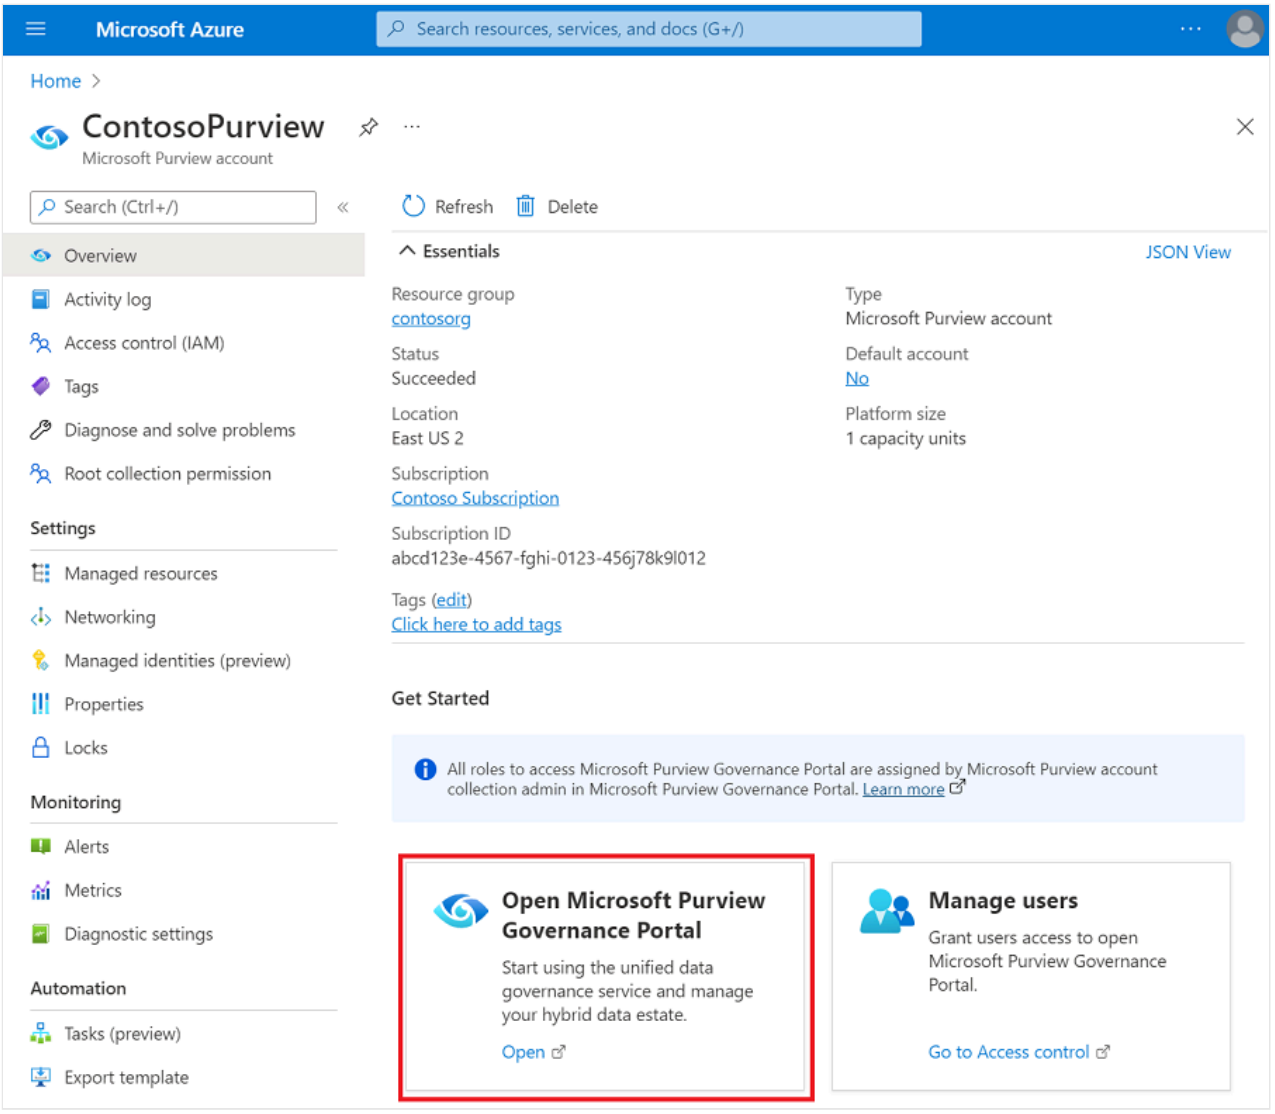
- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

** Lineage is supported if dataset is used as a source/sink in Data Factory Copy activity

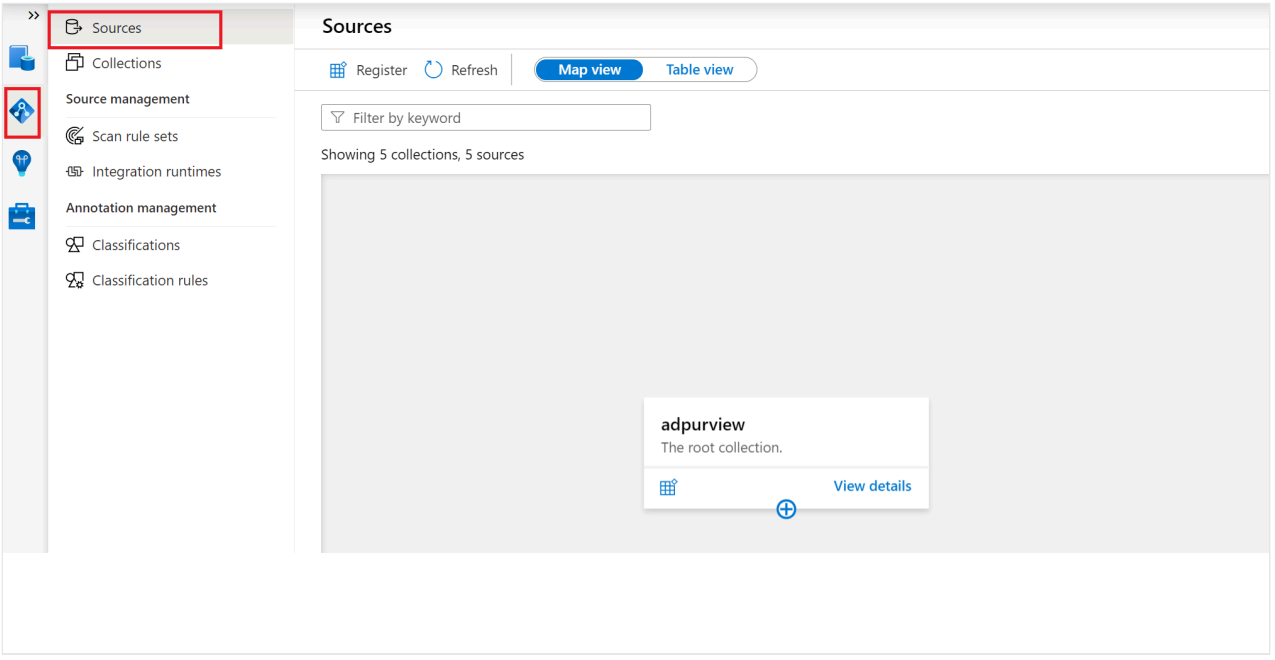
> **Note**
>
> Avoid using an FNS file system design with Blob Storage, as it causes only folders to be ingested as blobs and excludes subfolders and files. Instead, use Microsoft Azure Data Lake Storage Gen2 with hierarchical namespace to ensure complete ingestion of folders and their contents.

Register

This section will enable you to register the Azure Blob storage account for scan and data share in Purview.

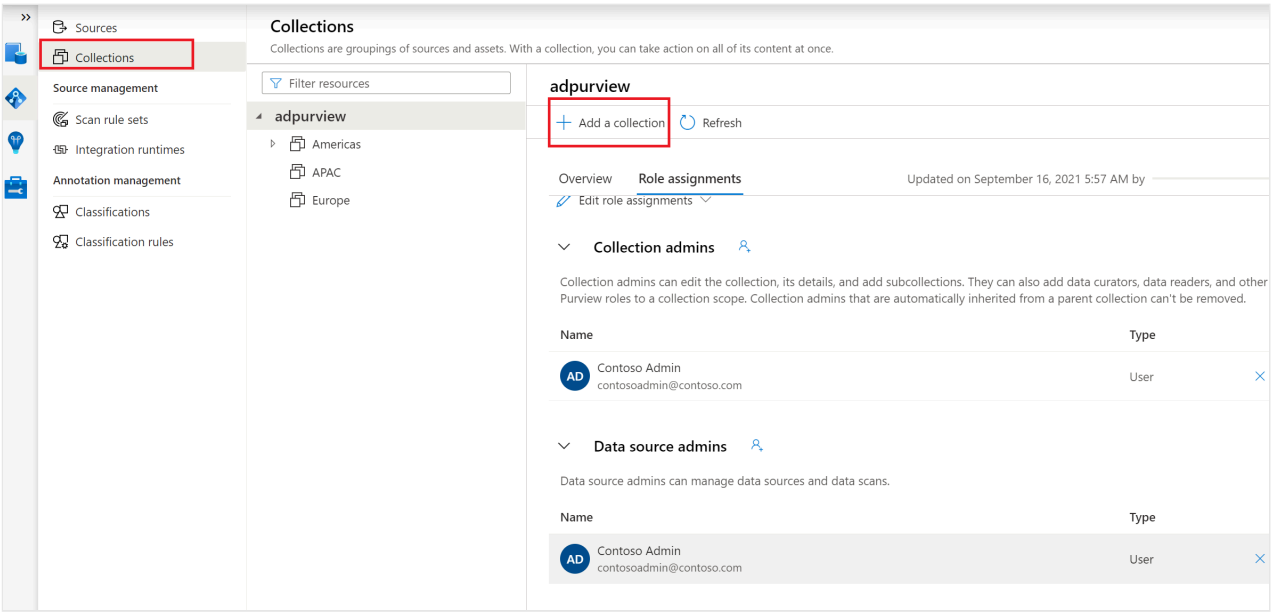


Prerequisites for register



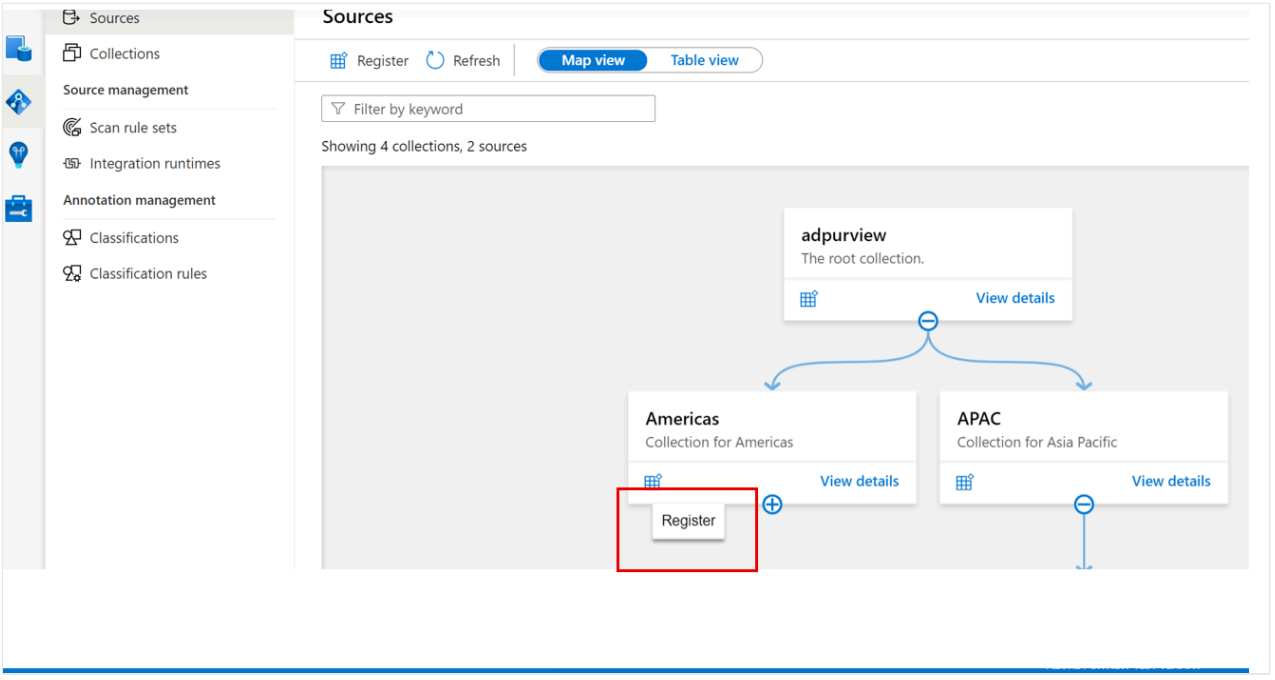
- You'll need to be a Data Source Admin and one of the other Purview roles (for example, Data Reader or Data Share Contributor) to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

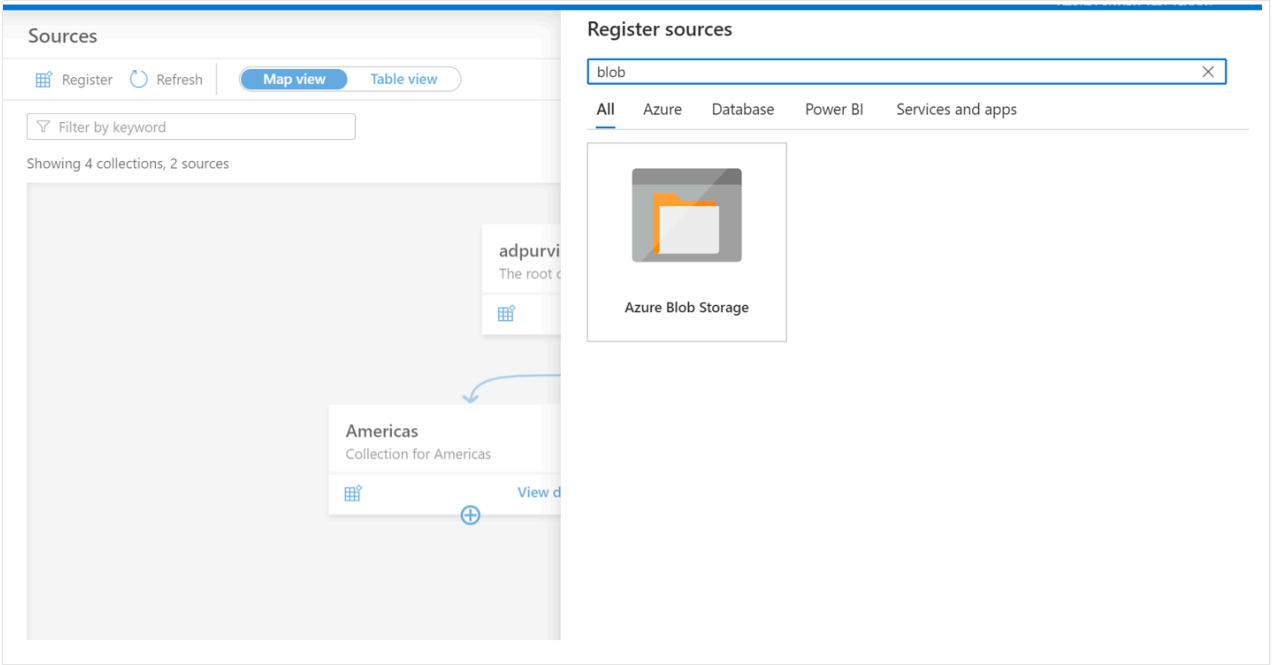
Steps to register



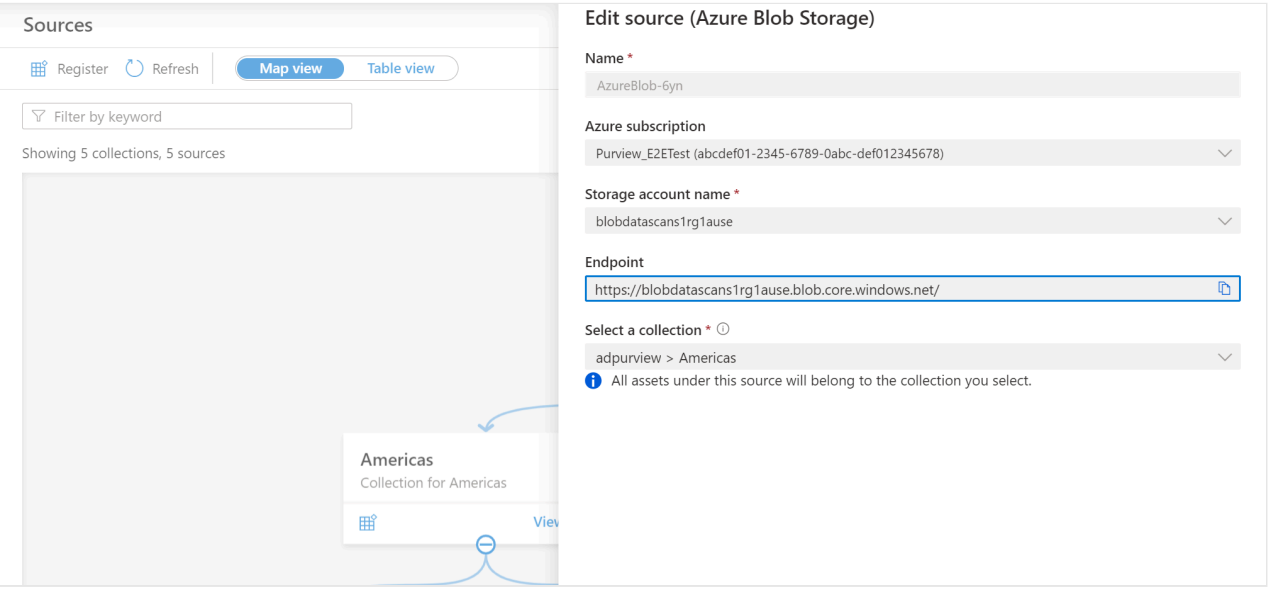
It is important to register the data source in Microsoft Purview prior to setting up a scan for the data source.

1. Go to the Microsoft Purview governance portal by:
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.
2. Navigate to the **Data Map --> Sources**

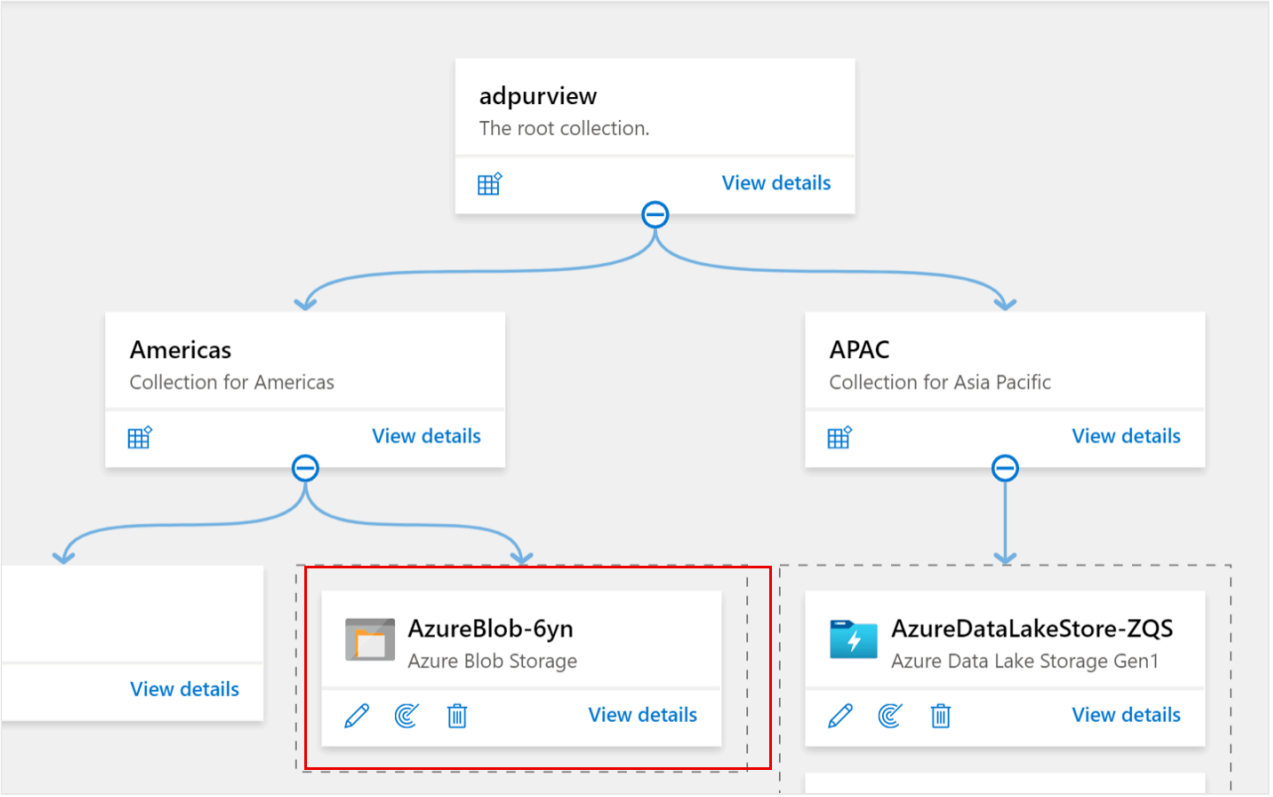




3. Create the Collection hierarchy using the **Collections** menu and assign permissions to individual subcollections, as required



4. Navigate to the appropriate collection under the **Sources** menu and select the **Register** icon to register a new Azure Blob data source



5. Select the **Azure Blob Storage** data source and select **Continue**

6. Provide a suitable **Name** for the data source, select the relevant **Azure subscription**, existing **Azure Blob Storage account name** and the **collection** and select **Apply**. Leave the **Data Policy Enforcement** toggle on the **disabled** position until you have a chance to carefully go over this document.

7. The Azure Blob storage account will be shown under the selected Collection

Scan

For file types such as csv, tsv, psv, ssv, the schema is extracted when the following logics are in place:

- First row values are non-empty
- First row values are unique
- First row values are not a date or a number

Authentication for a scan

Your Azure network may allow for communications between your Azure resources, but if you've set up firewalls, private endpoints, or virtual networks within Azure, you'll need to follow one of these configurations below.

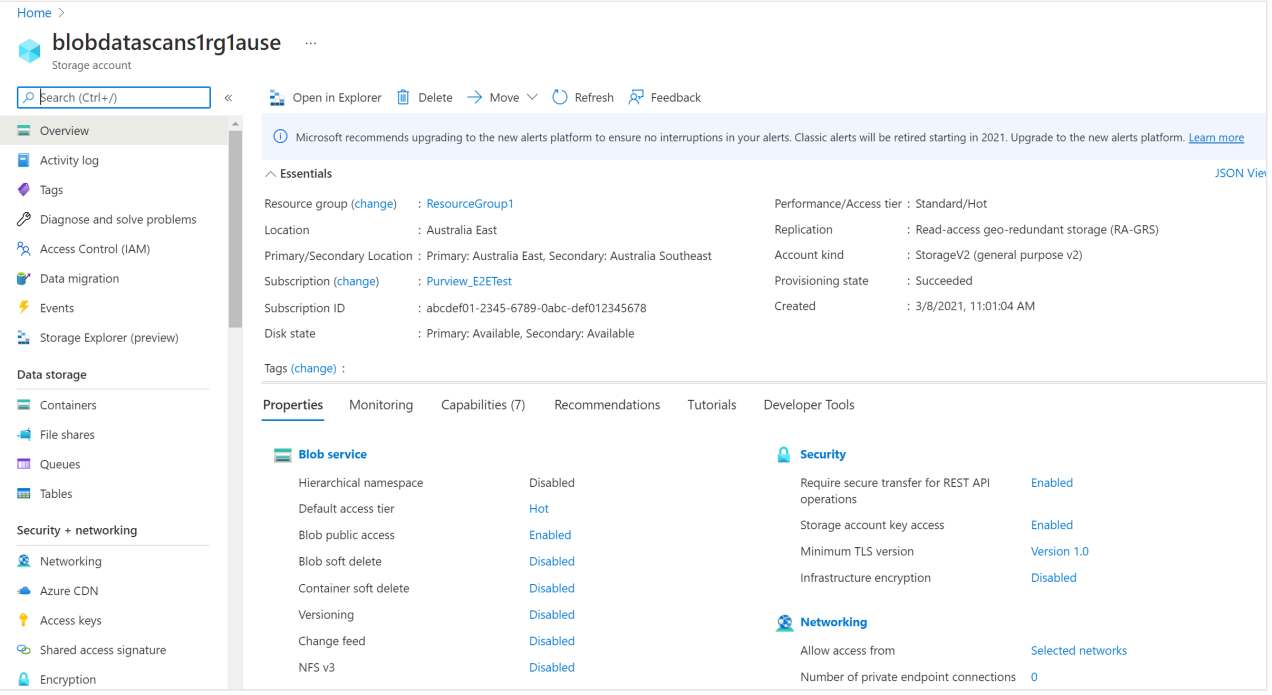
Expand table

Networking constraints	Integration runtime type	Available credential types
No private endpoints or firewalls	Azure IR	Managed identity (Recommended), service principal, or account key
Firewall enabled but no private endpoints	Azure IR	Managed identity

Networking constraints	Integration runtime type	Available credential types
Private endpoints enabled	*Self-Hosted IR	Service principal, account key

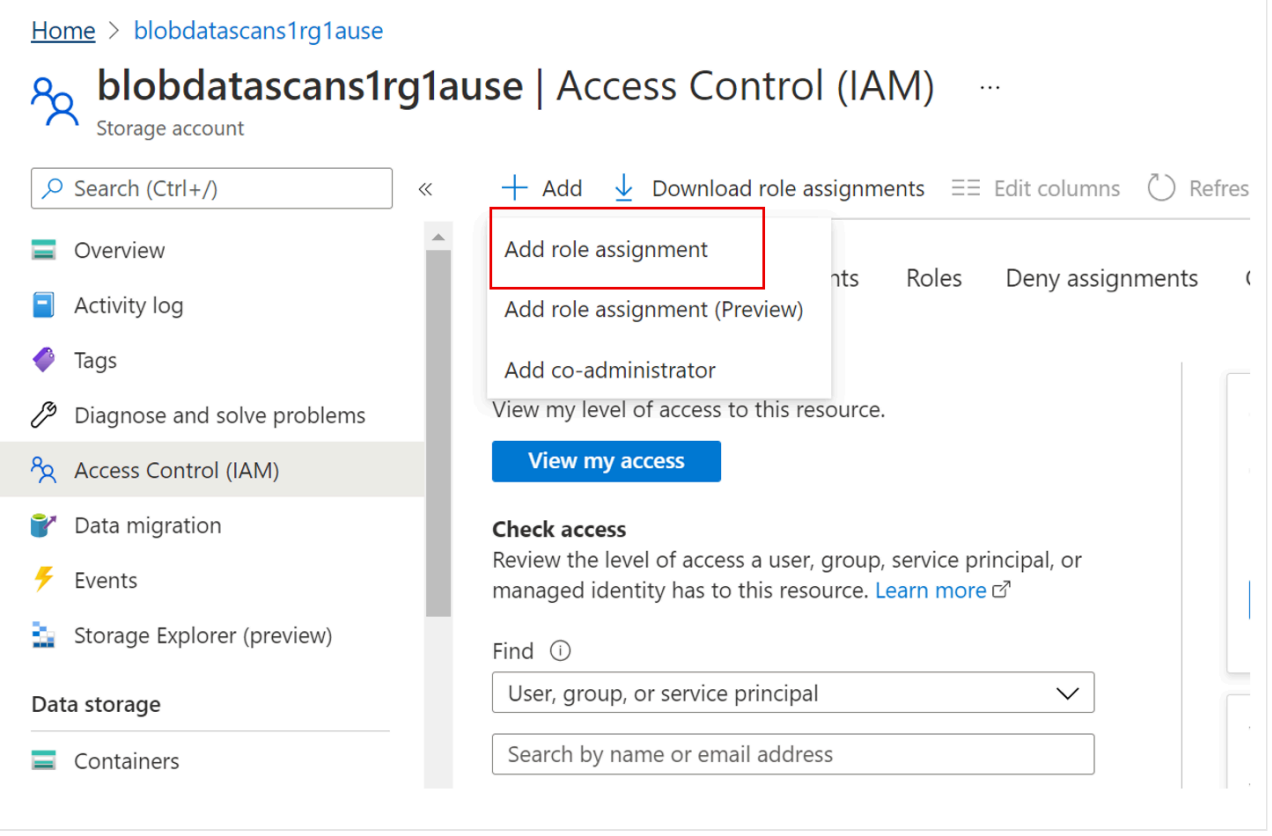
*To use a self-hosted integration runtime, you'll first need to choose the right one for your scenario, create one, and confirm your network settings for Microsoft Purview.

Using a system or user assigned managed identity for scanning



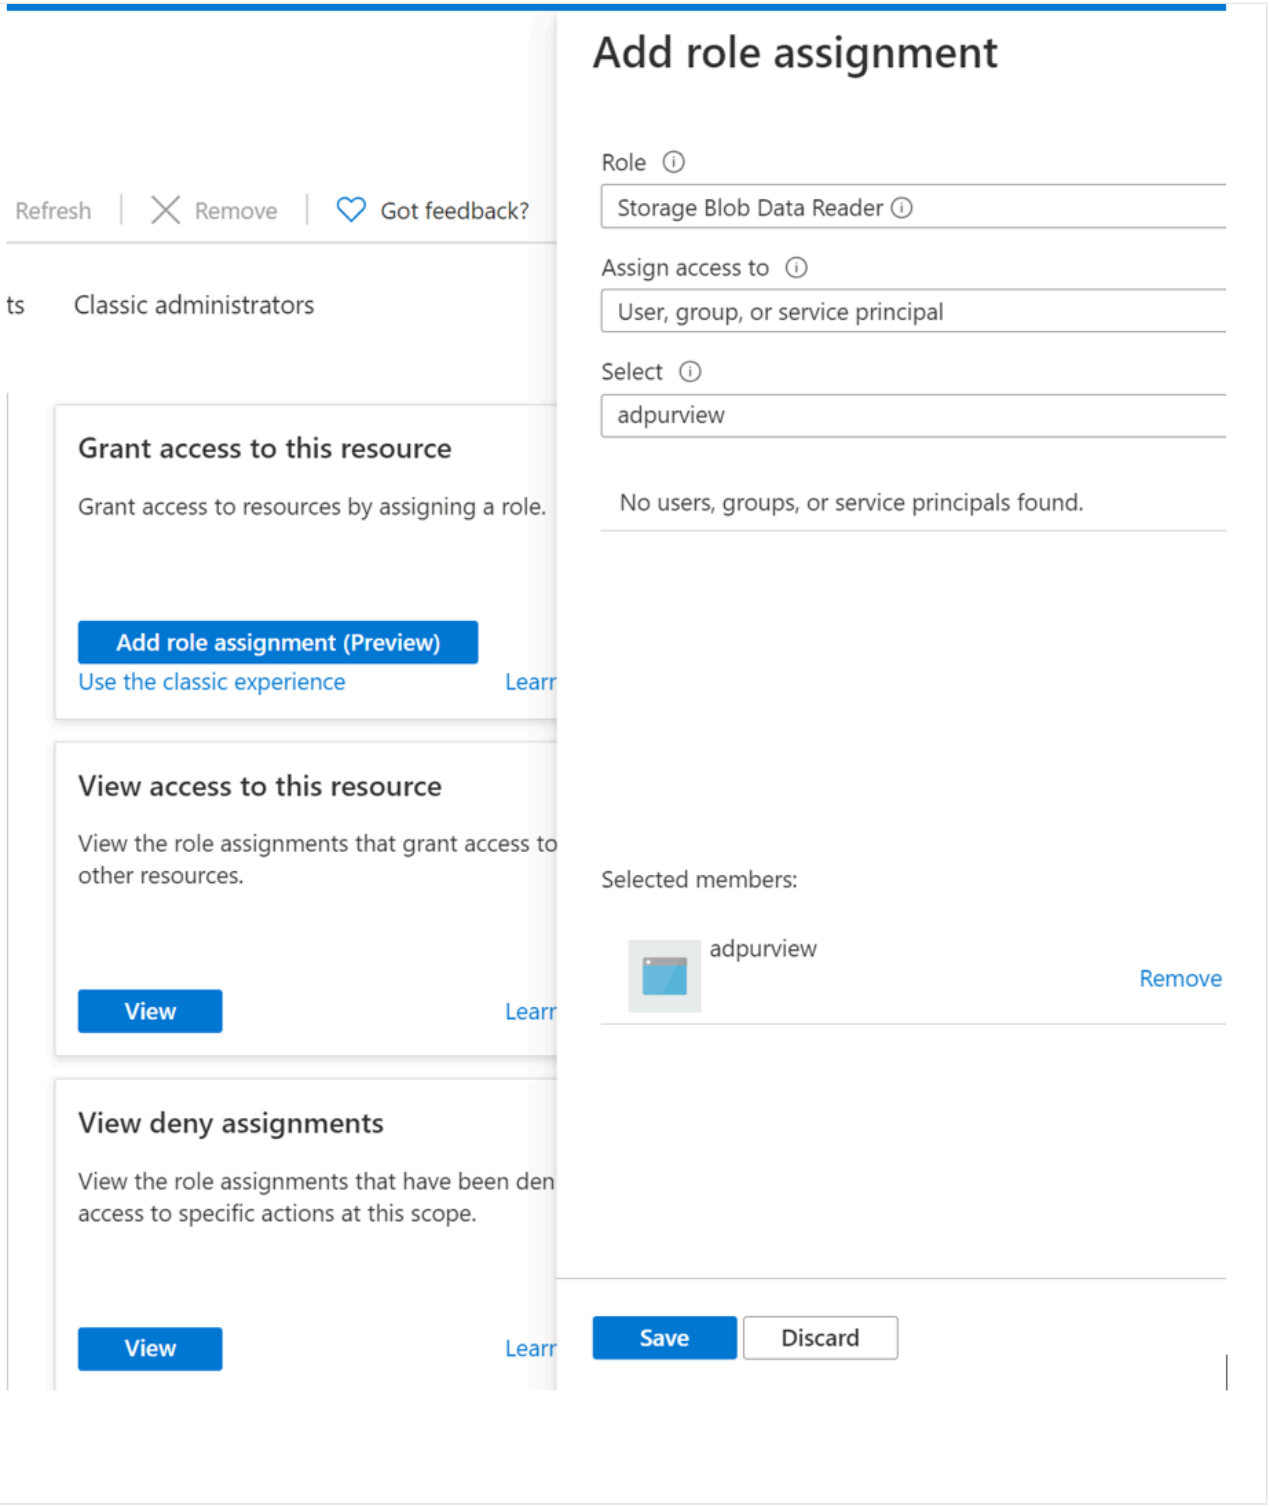
There are two types of managed identity you can use:

- **System-assigned managed identity (Recommended)** - As soon as the Microsoft Purview Account is created, a system-assigned managed identity (SAMI) is created automatically in Microsoft Entra tenant. Depending on the type of resource, specific RBAC role assignments are required for the Microsoft Purview system-assigned managed identity (SAMI) to perform the scans.
- **User-assigned managed identity** (preview) - Similar to a system managed identity, a user-assigned managed identity (UAMI) is a credential resource that can be used to allow Microsoft Purview to authenticate against Microsoft Entra ID. For more information, you can see our User-assigned managed identity guide. It's important to give your Microsoft Purview account the permission to scan the Azure Blob data source. You can add access for the SAMI or UAMI at the Subscription, Resource Group, or Resource level, depending on what level scan permission is needed.



> **Note**
>
> If you have firewall enabled for the storage account, you must use **managed identity** authentication method when setting up a scan.

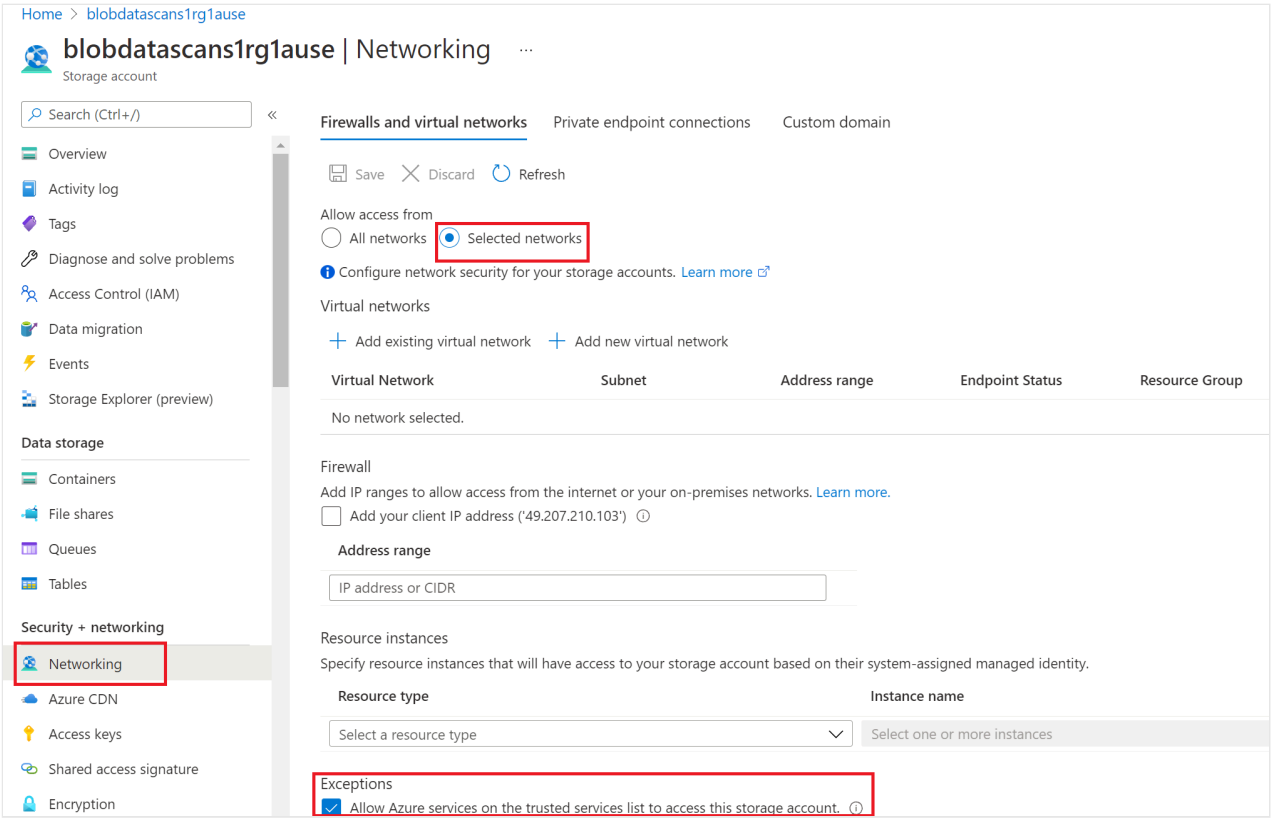
> **Note**
>
> You need to be an owner of the subscription to be able to add a managed identity on an Azure resource.



1. From the Azure portal, find either the subscription, resource group, or resource (for example, an Azure Blob storage account) that you would like to allow the catalog to scan.

2. Select **Access Control (IAM)** in the left navigation and then select **+ Add** --> **Add role assignment**

3. Set the **Role** to **Storage Blob Data Reader** and enter your *Microsoft Purview account name* or *user-assigned managed identity* under **Select** input box. Then, select **Save** to give this role assignment to your Microsoft Purview account.

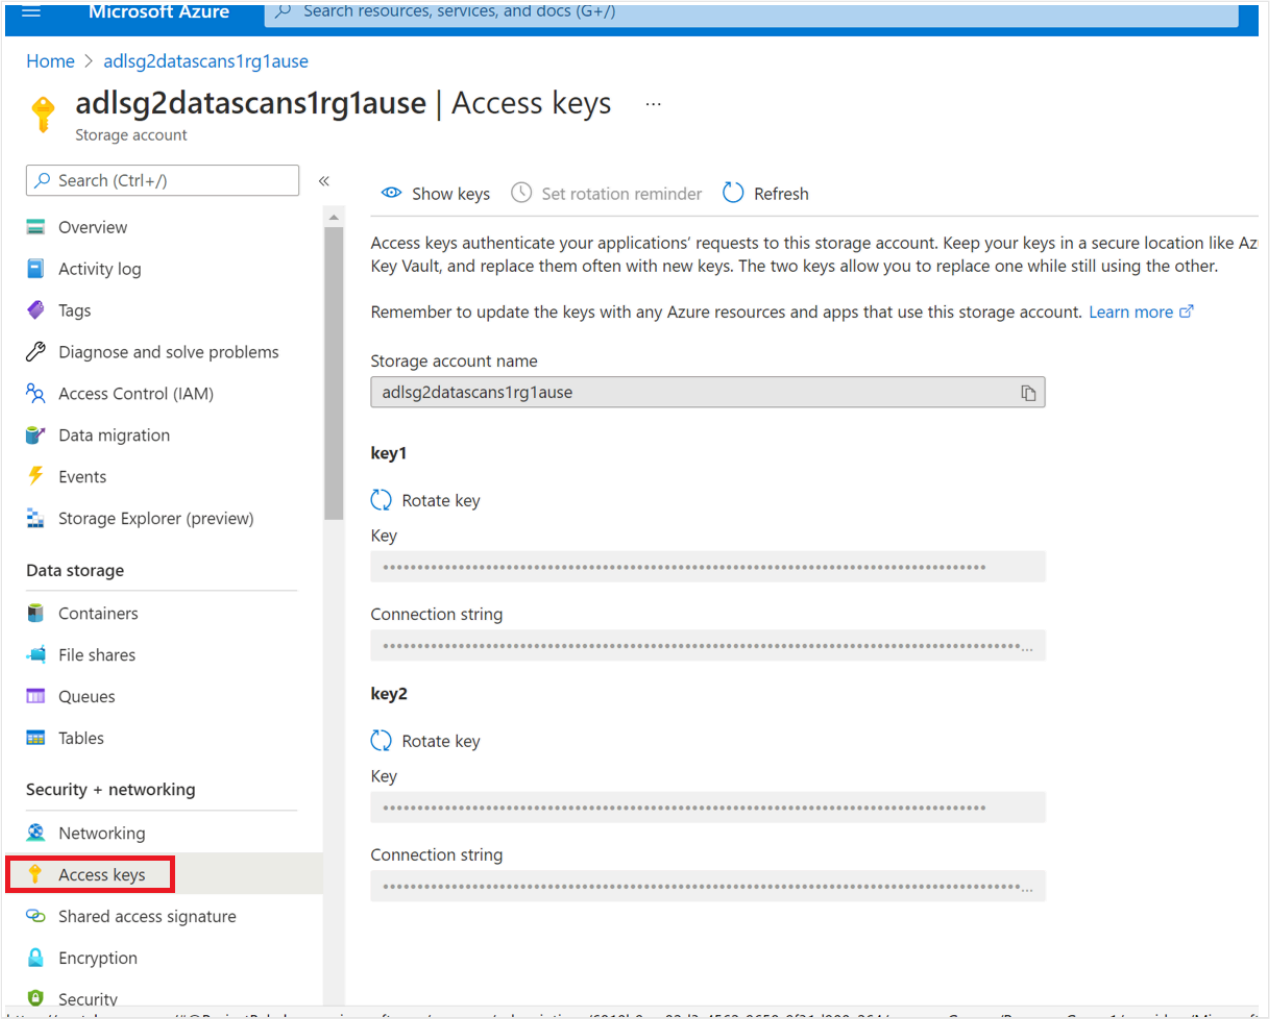


4. Go into your Azure Blob storage account in Azure portal

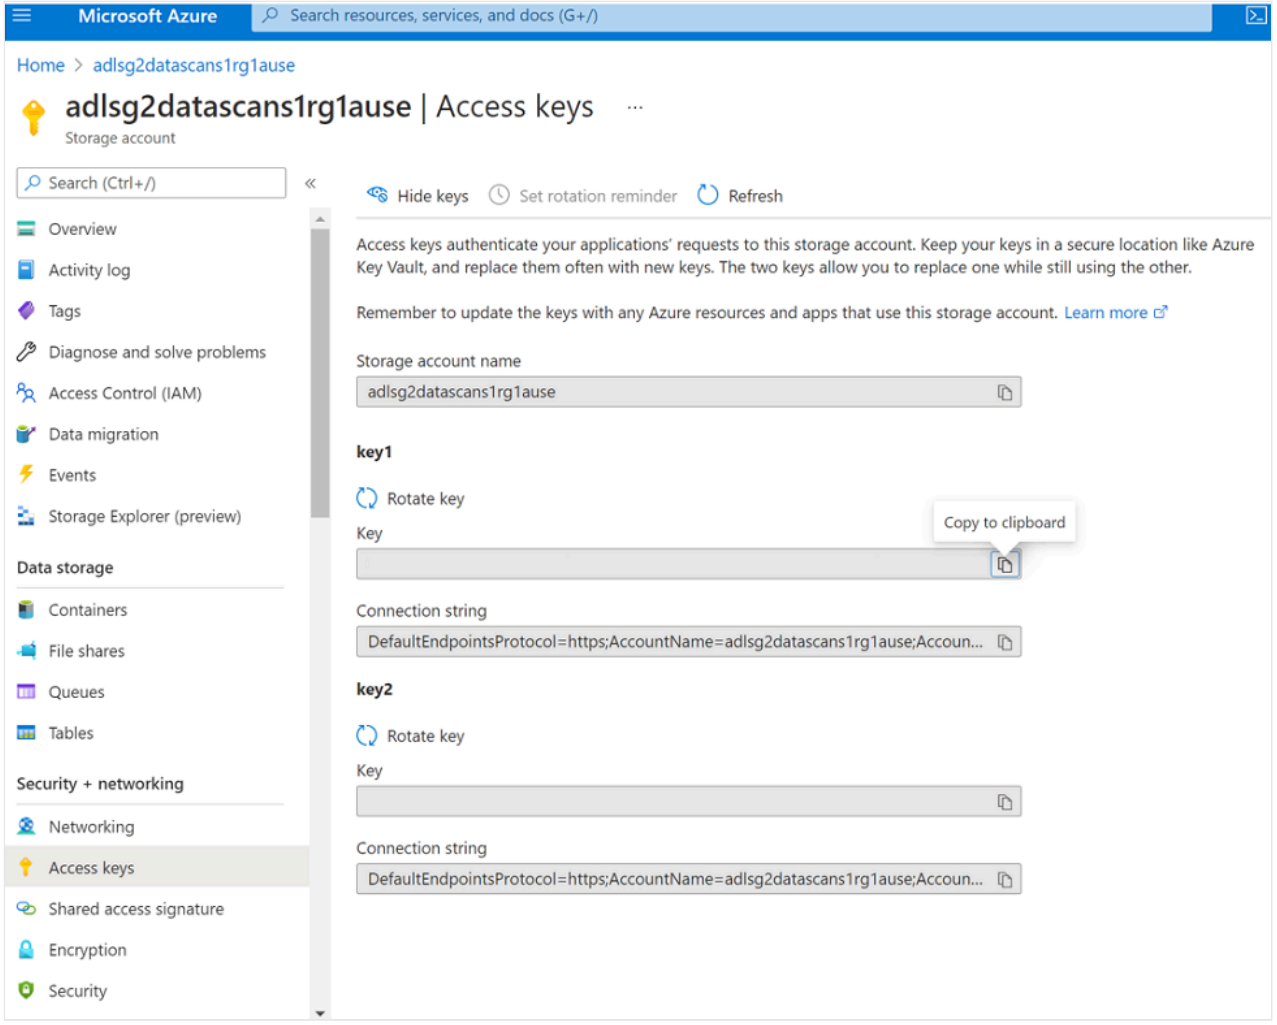
5. Navigate to **Security + networking** > **Networking**

6. Choose **Selected Networks** under **Allow access from**

7. In the **Exceptions** section, select **Allow trusted Microsoft services to access this storage account** and hit **Save**

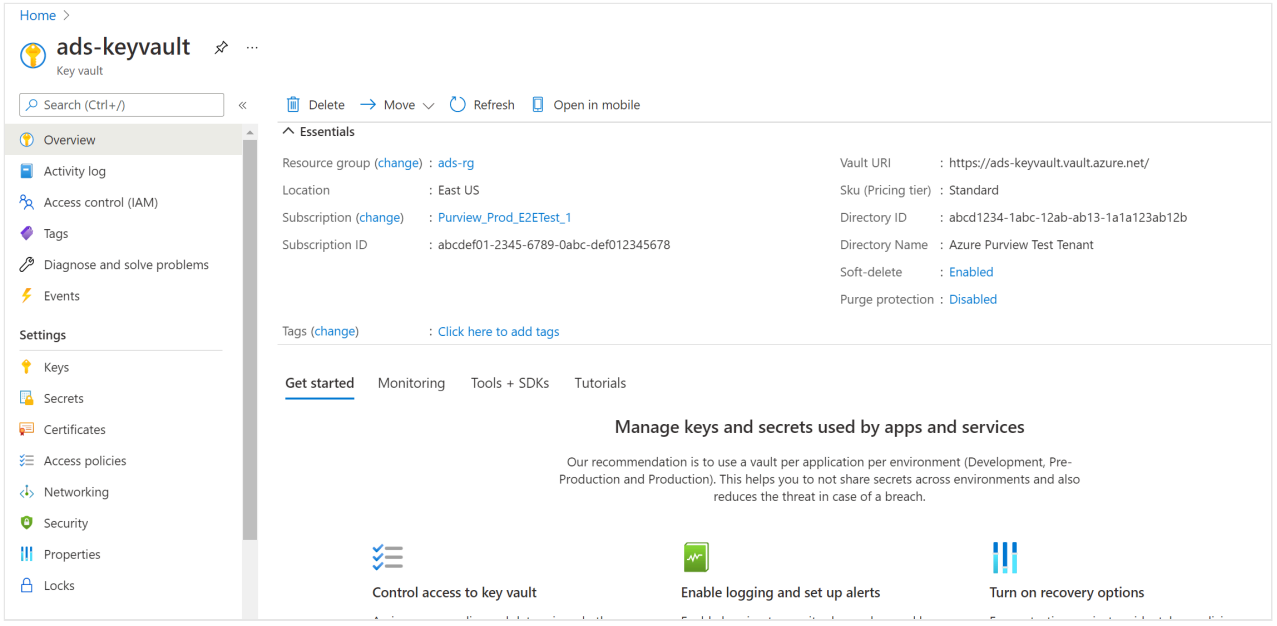


> **Note**
>
> For more details, please see steps in Authorize access to blobs and queues using Microsoft Entra ID

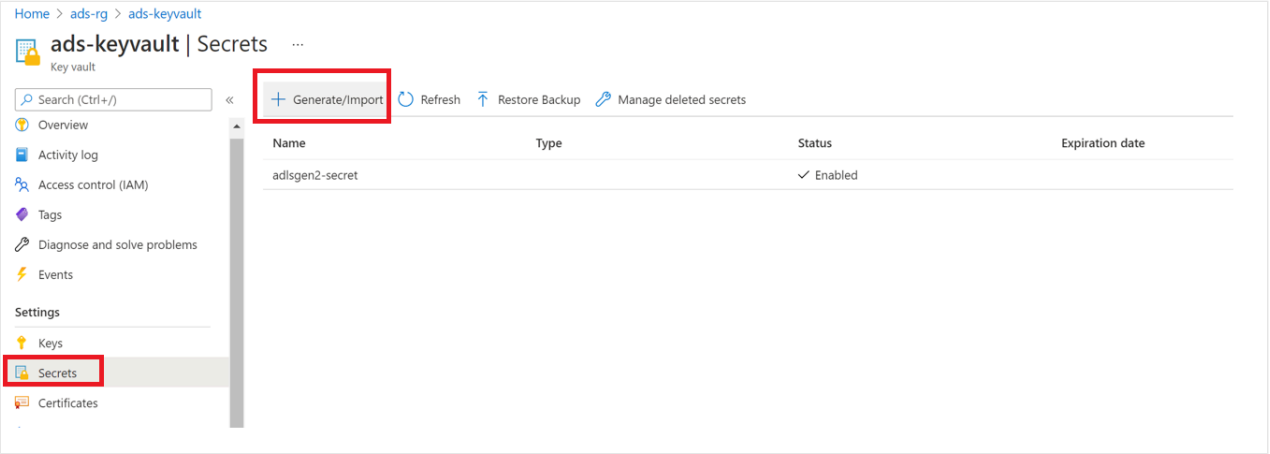


Using Account Key for scanning

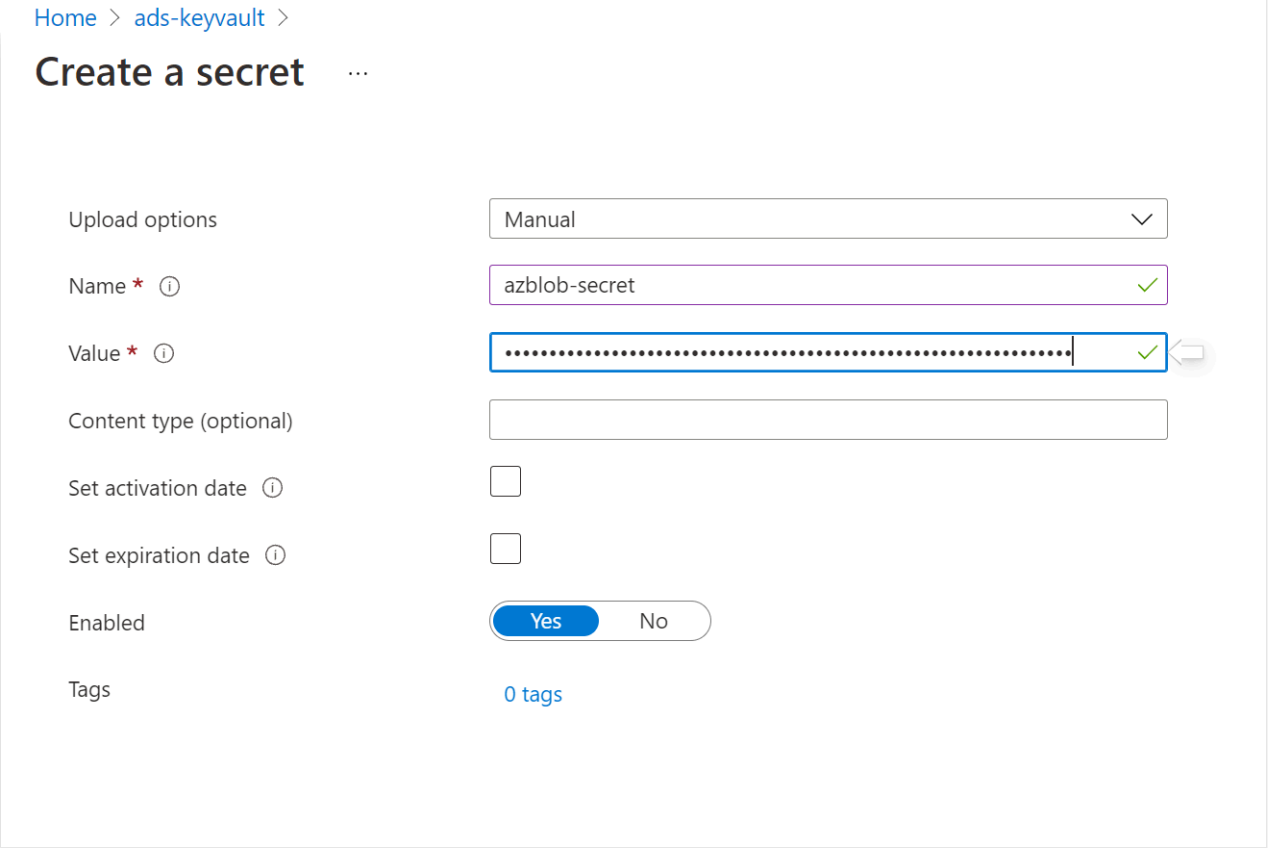
When authentication method selected is **Account Key**, you need to get your access key and store in the key vault:



1. Navigate to your Azure Blob storage account
2. Select **Security + networking** > **Access keys**



3. Copy your *key* and save it separately for the next steps



4. Navigate to your key vault

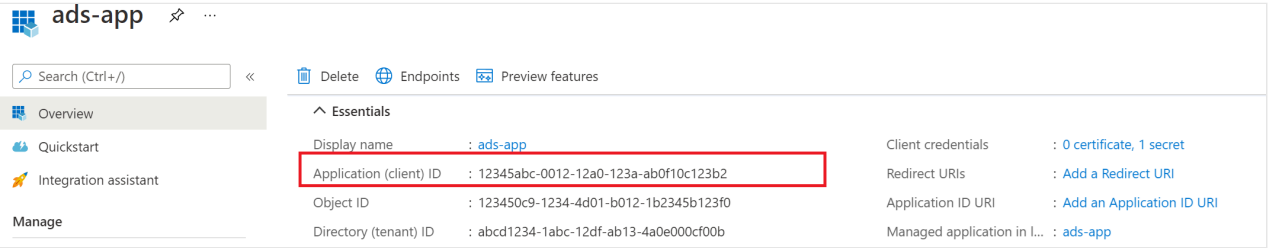
5. Select **Settings** > **Secrets** and select **+ Generate/Import**

6. Enter the **Name** and **Value** as the *key* from your storage account

7. Select **Create** to complete

8. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection

9. Finally, create a new credential using the key to set up your scan



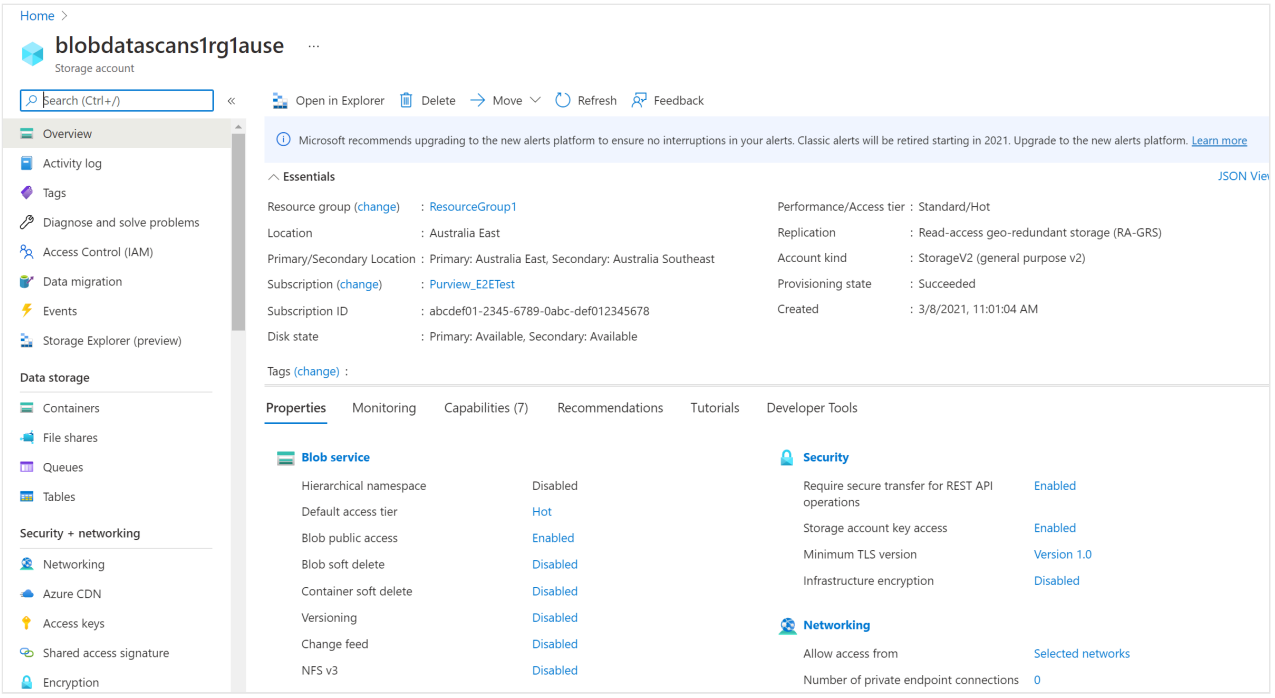
Using Service Principal for scanning

Creating a new service principal

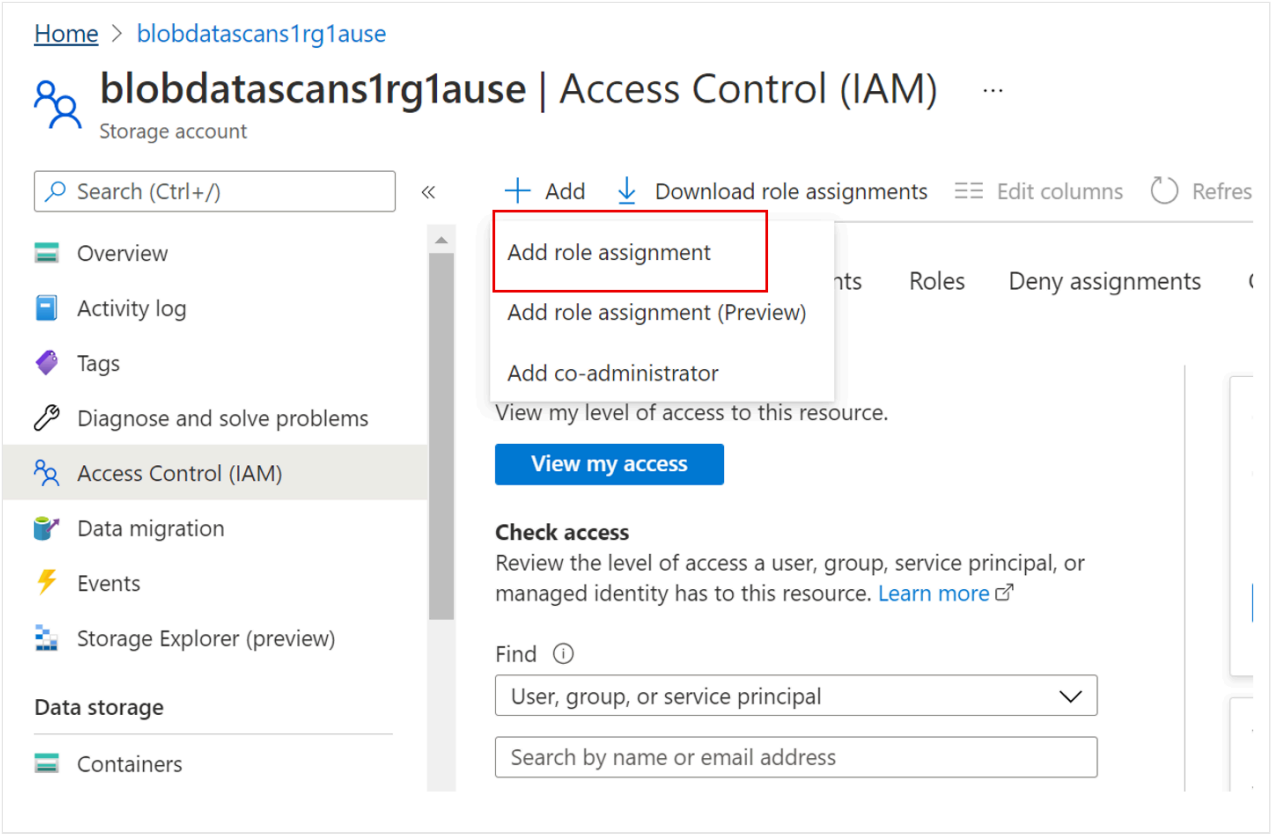
If you need to Create a new service principal, it's required to register an application in your Microsoft Entra tenant and provide access to Service Principal in your data sources. Your Microsoft Entra Application Administrator can perform this operation.

Getting the Service Principal's Application ID

1. Copy the **Application (client) ID** present in the **Overview** of the *Service Principal* already created

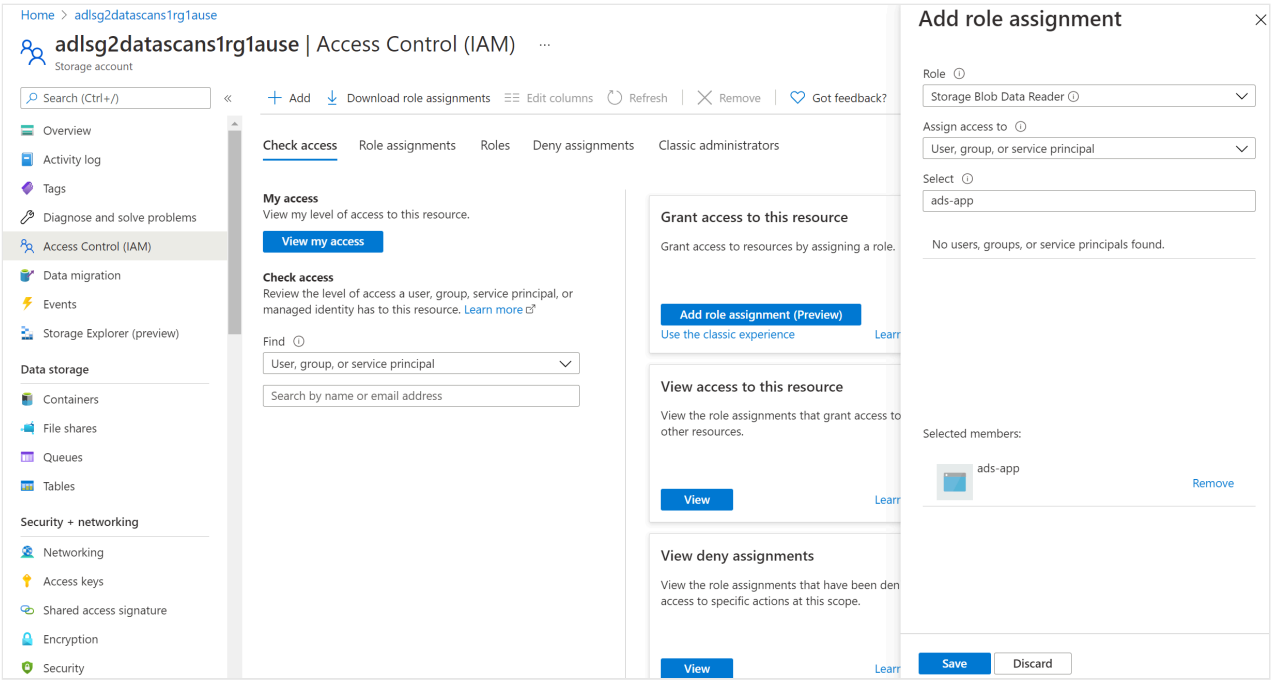


Granting the Service Principal access to your Azure Blob account



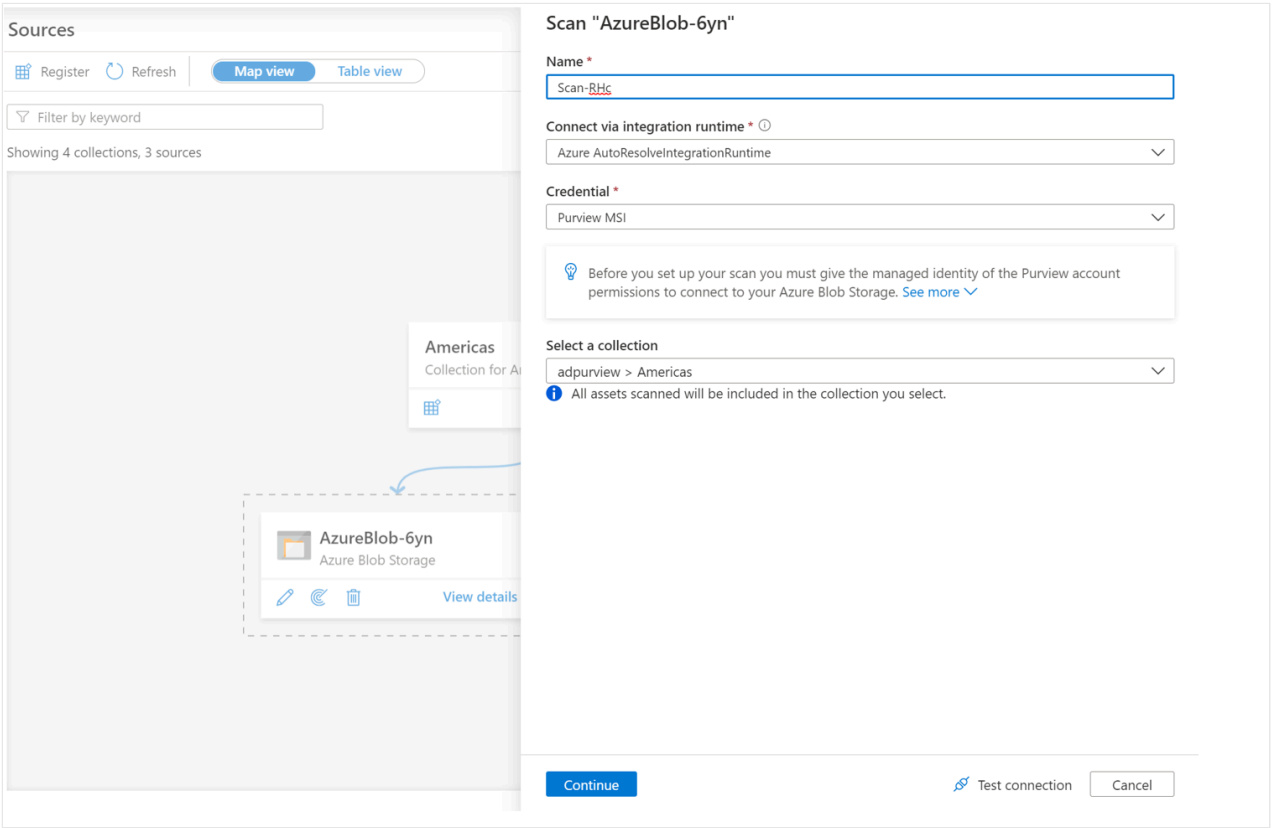
It's important to give your service principal the permission to scan the Azure Blob data source. You can add access for the service principal at the Subscription, Resource Group, or Resource level, depending on what level scan access is needed.

> **Note**
>
> You need to be an owner of the subscription to be able to add a service principal on an Azure resource.



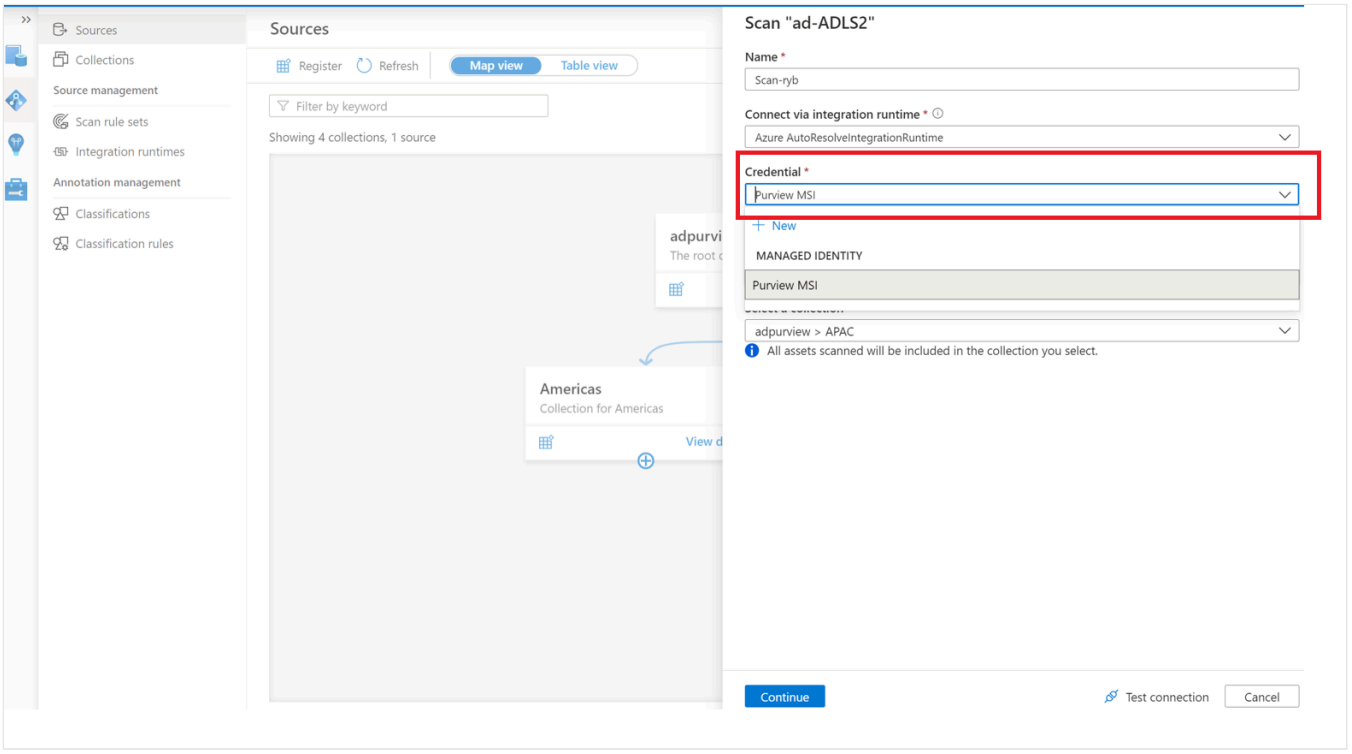
1. From the Azure portal, find either the subscription, resource group, or resource (for example, an Azure Blob Storage storage account) that you would like to allow the catalog to scan.

2. Select **Access Control (IAM)** in the left navigation and then select **+ Add** --> **Add role assignment**



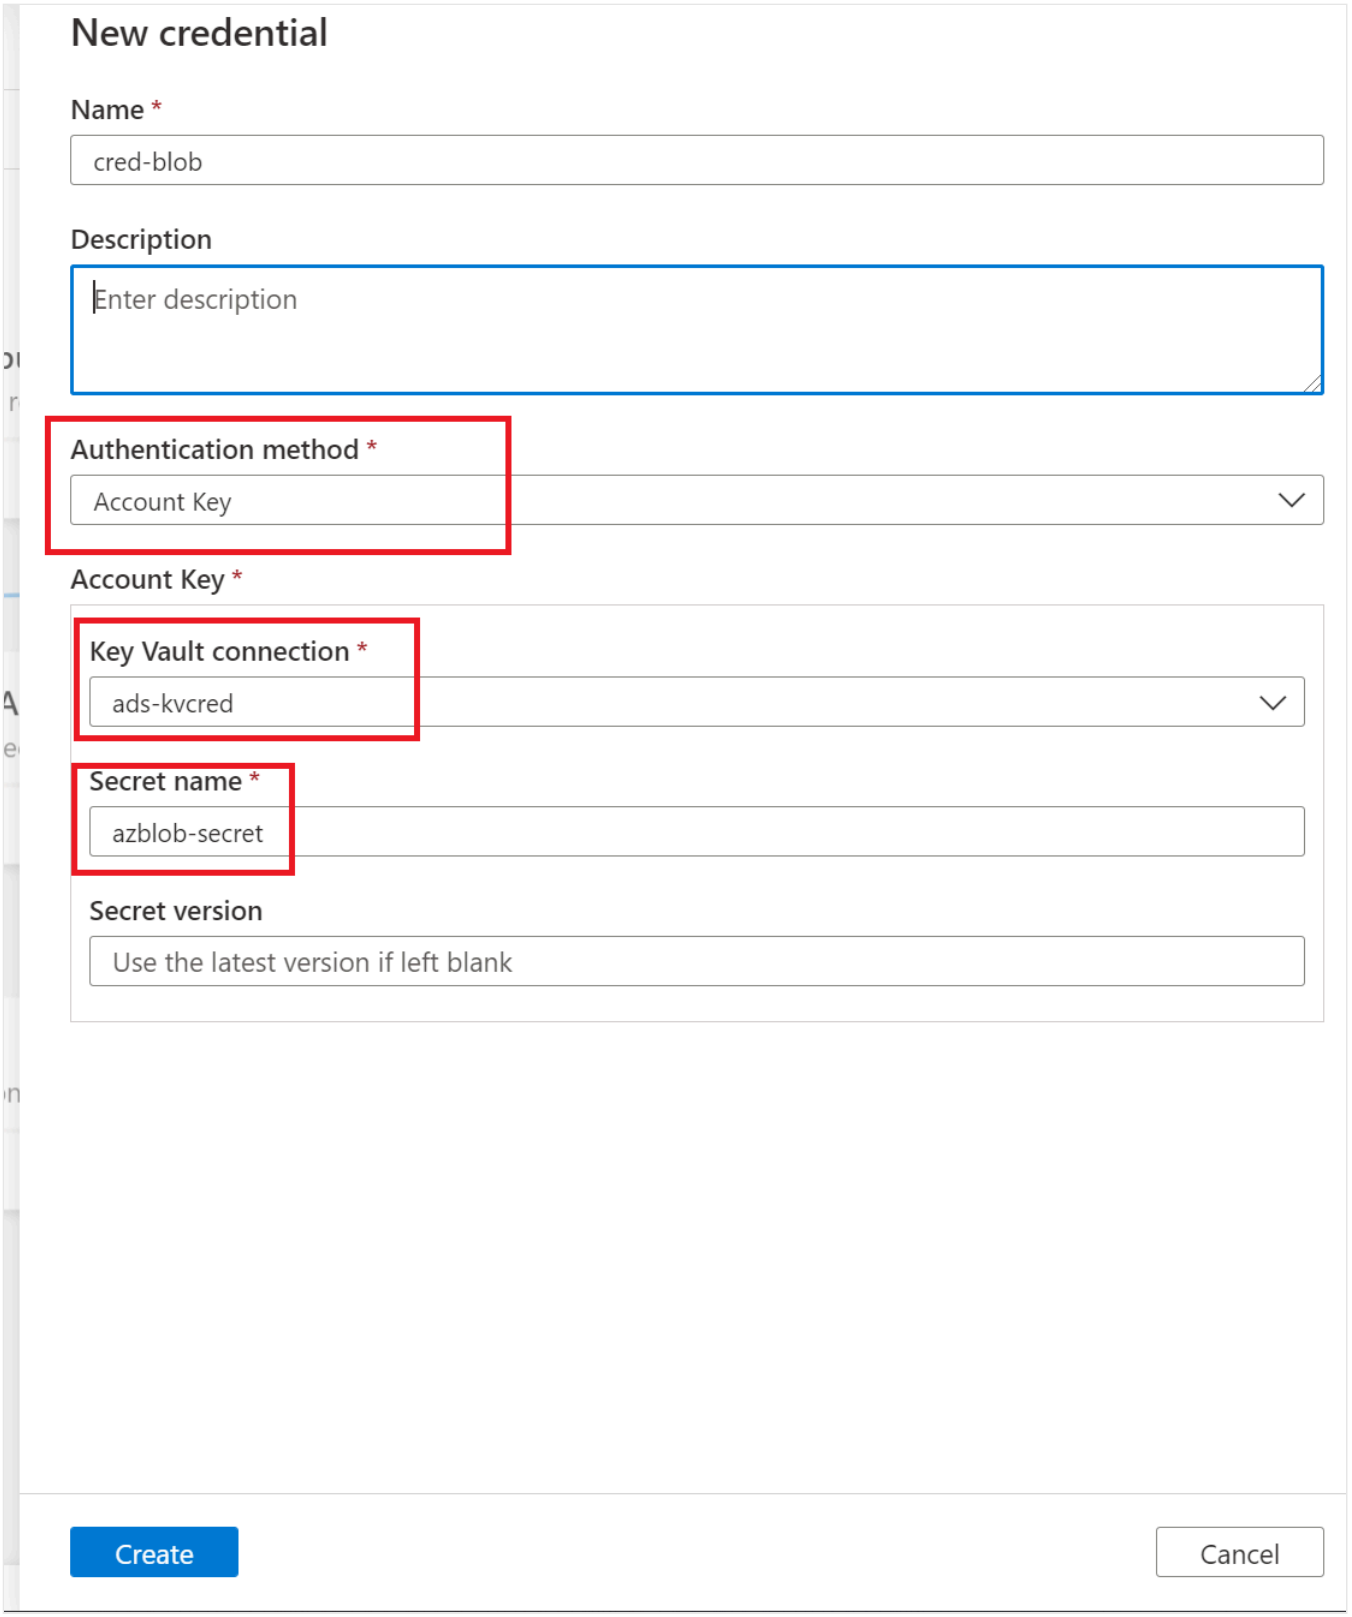
3. Set the **Role** to **Storage Blob Data Reader** and enter your *service principal* under **Select** input box. Then, select **Save** to give this role assignment to your Microsoft Purview account.

Creating the scan



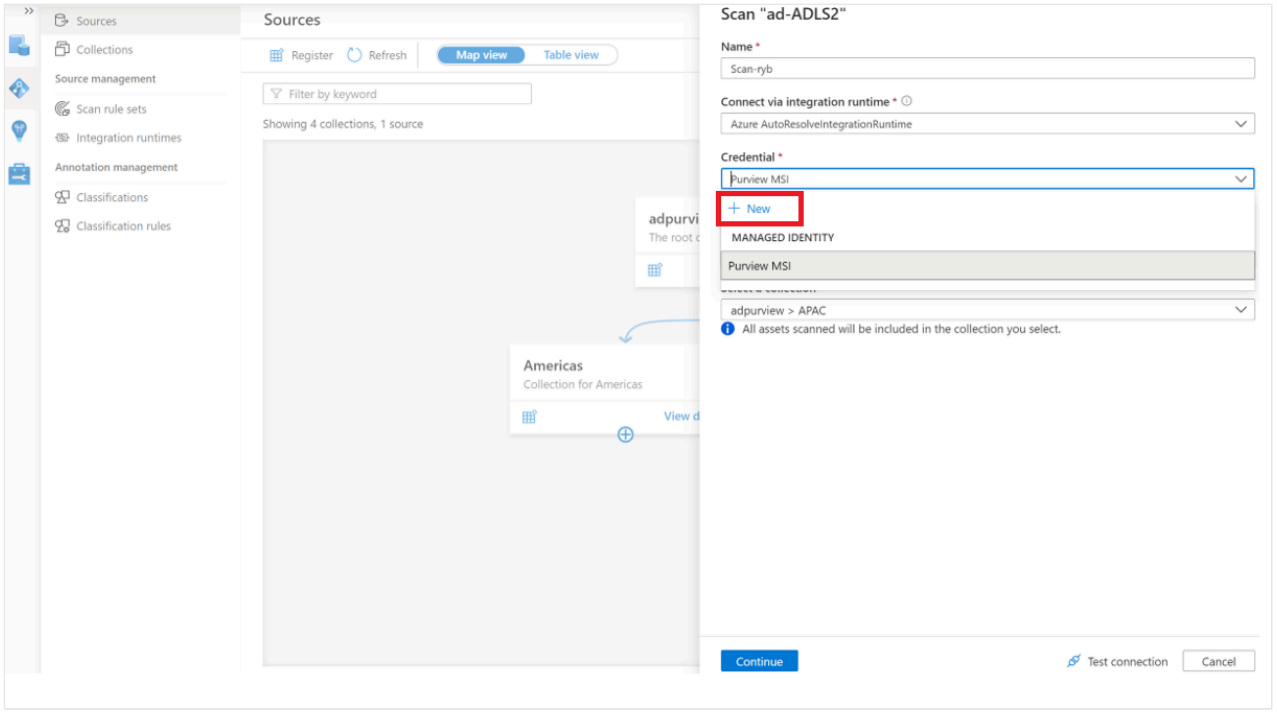
1. Open your **Microsoft Purview account** and select the **Open Microsoft Purview governance portal**
2. Navigate to the **Data map** --> **Sources** to view the collection hierarchy
3. Select the **New Scan** icon under the **Azure Blob data source** registered earlier

4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.



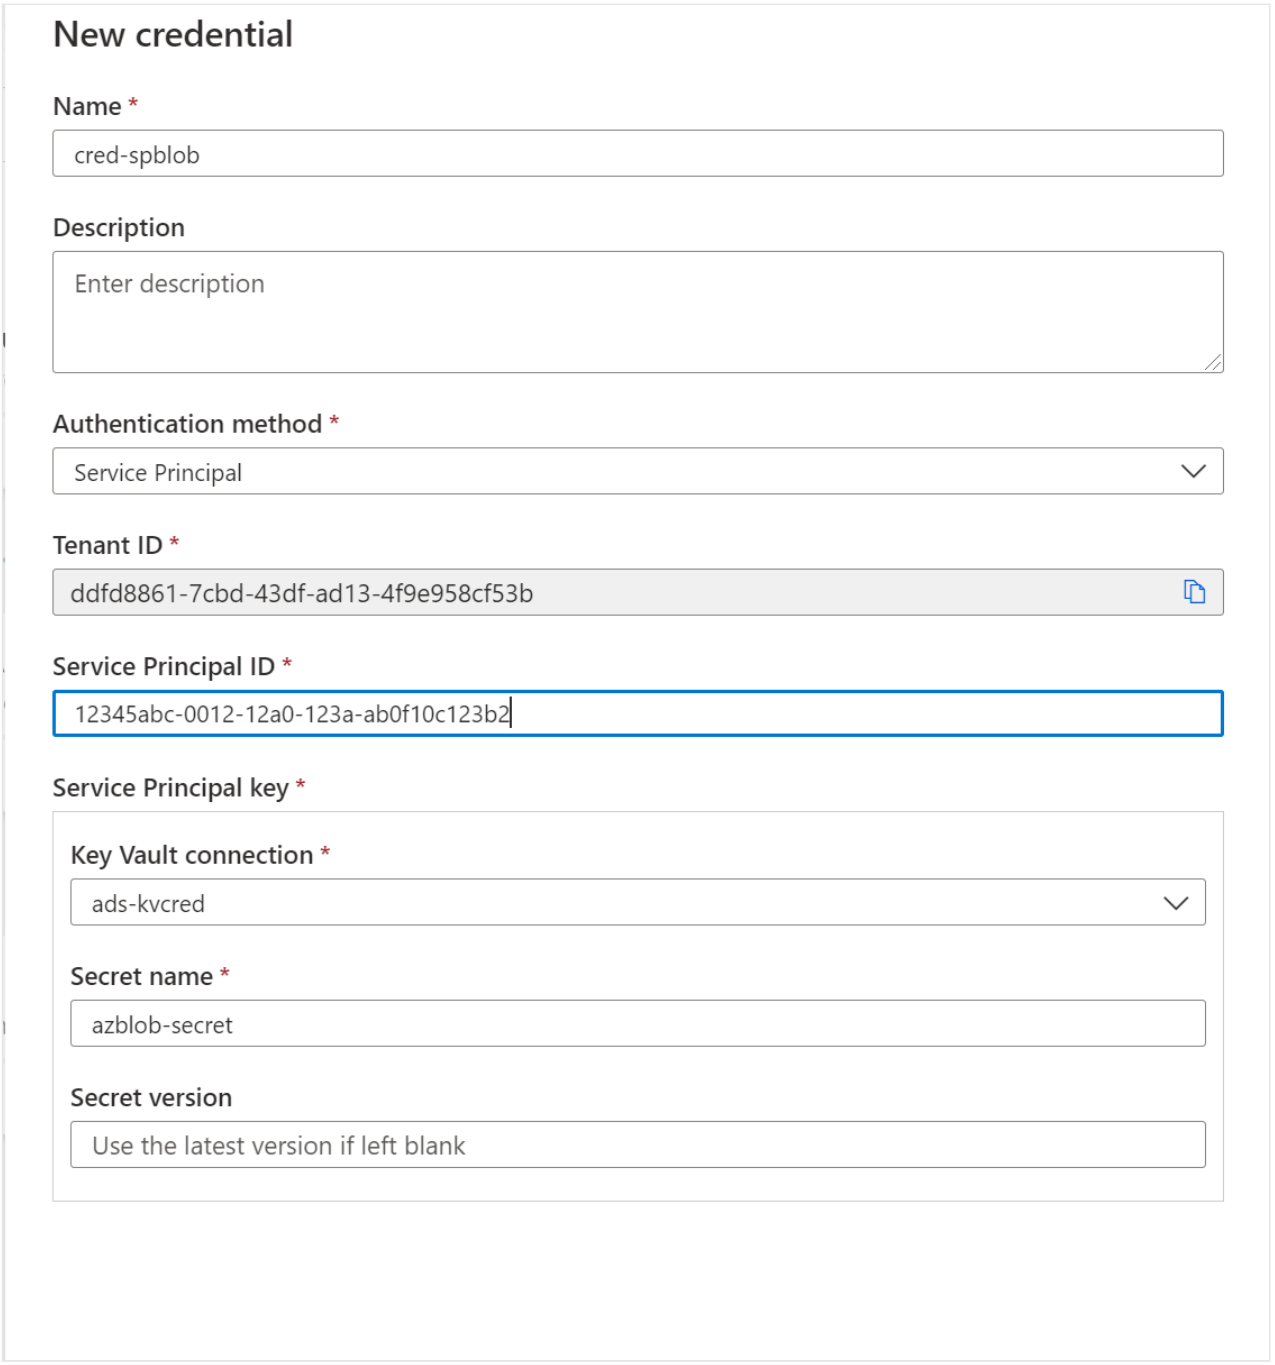
If using a system or user assigned managed identity

Provide a **Name** for the scan, select the Microsoft Purview accounts SAMI or UAMI under **Credential**, choose the appropriate collection for the scan, and select **Test connection**. On a successful connection, select **Continue**



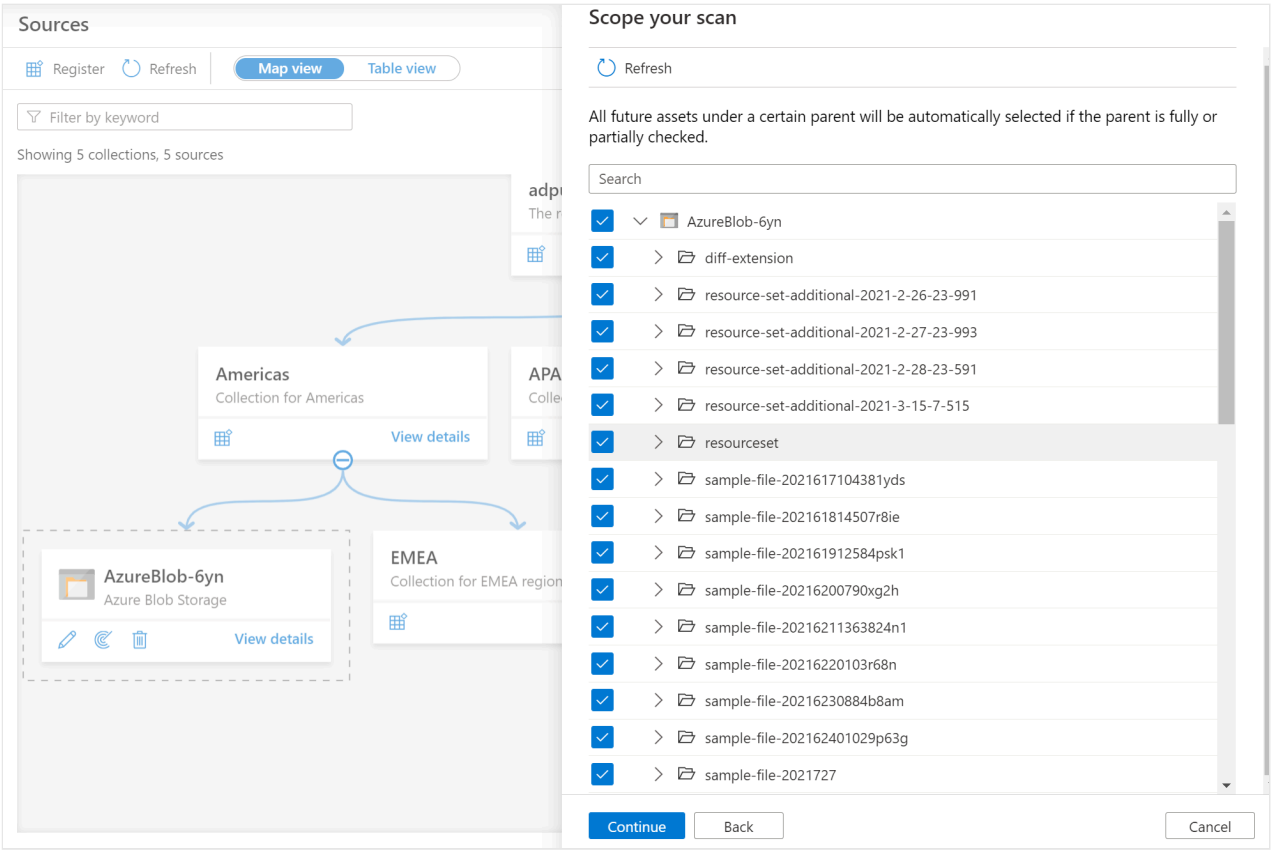
If using Account Key

Provide a **Name** for the scan, select the Azure IR or your Self-Hosted IR depending on your configuration, choose the appropriate collection for the scan, and select **Authentication method** as *Account Key* and select **Create**

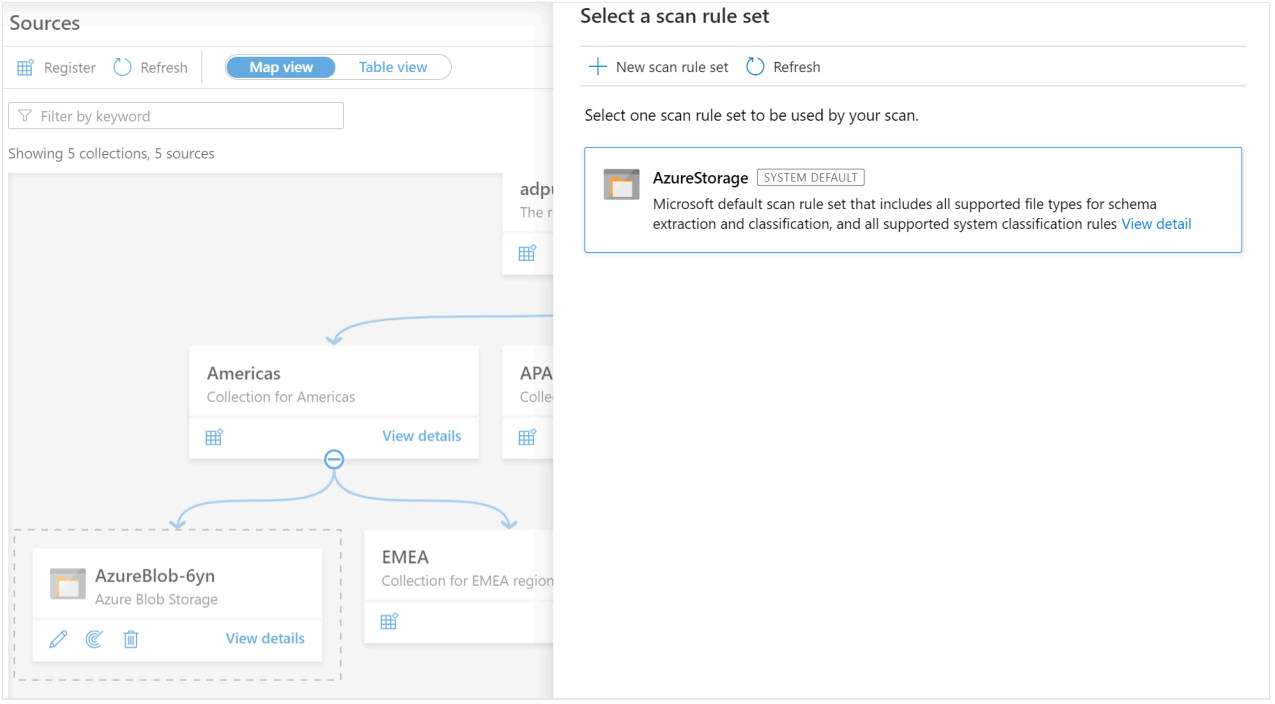


If using Service Principal

1. Provide a **Name** for the scan, select the Azure IR or your Self-Hosted IR depending on your configuration, choose the appropriate collection for the scan, and select the **+ New** under **Credential**

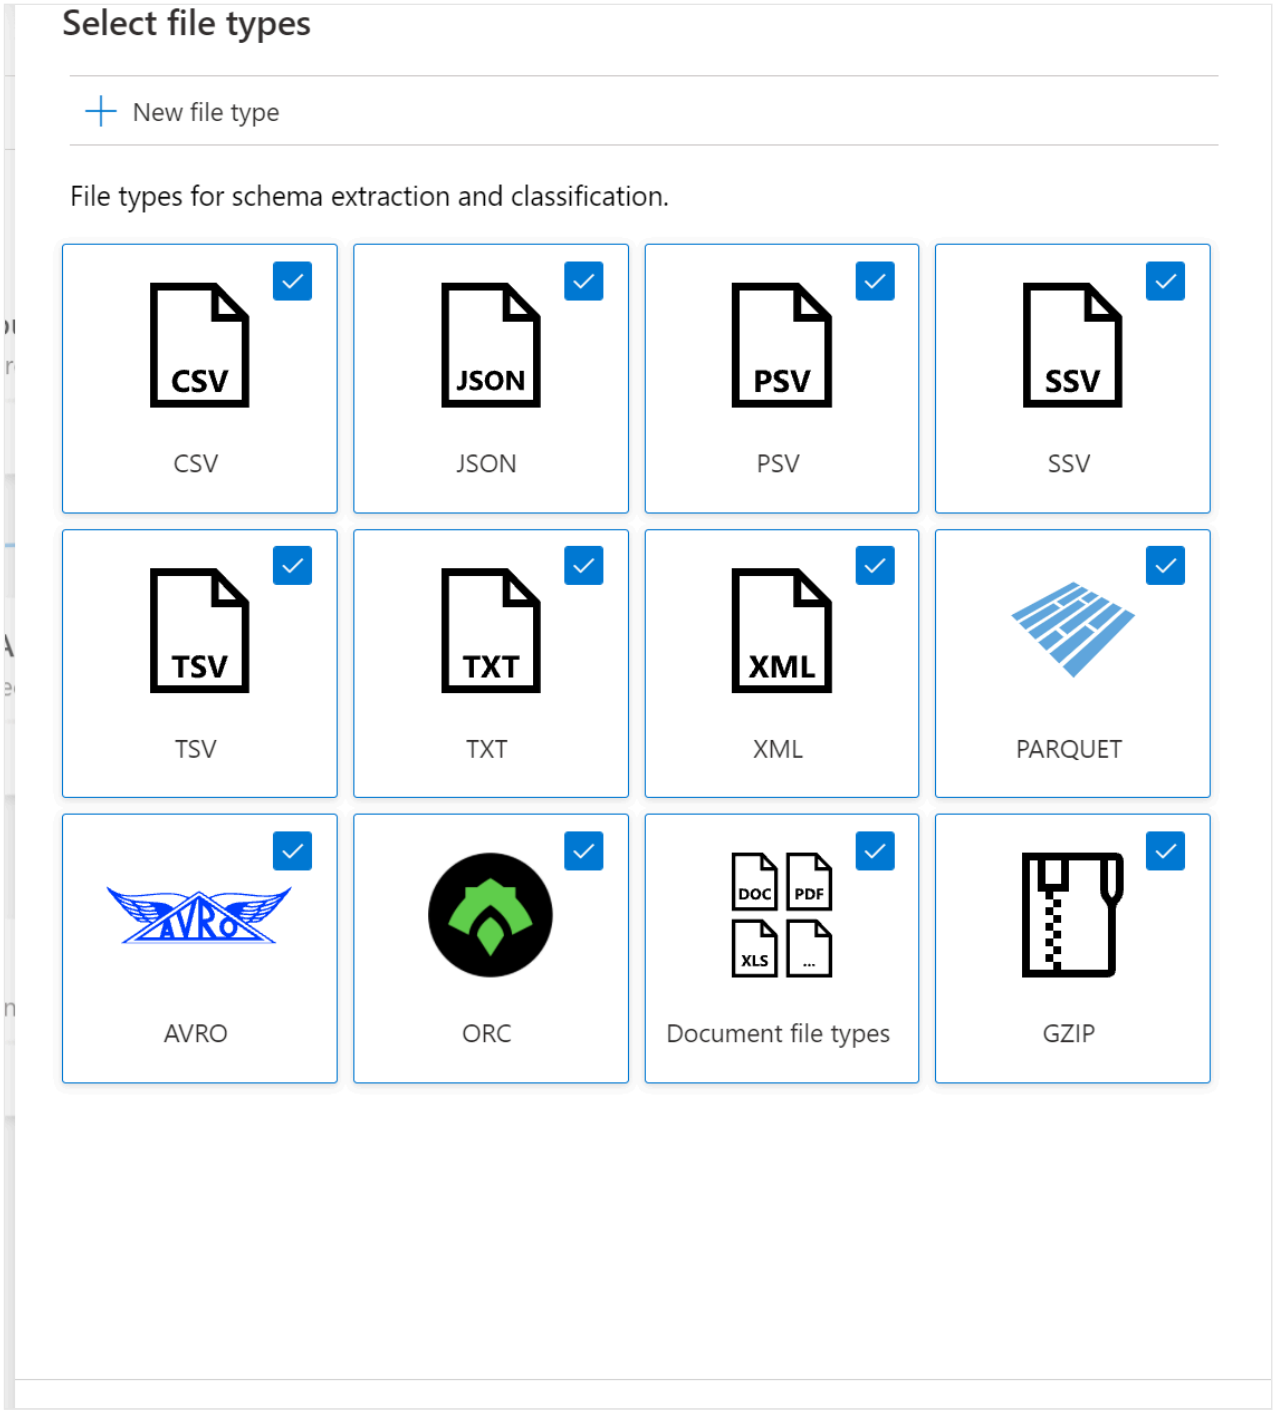


2. Select the appropriate **Key vault connection** and the **Secret name** that was used while creating the *Service Principal*. The **Service Principal ID** is the **Application (client) ID** copied earlier

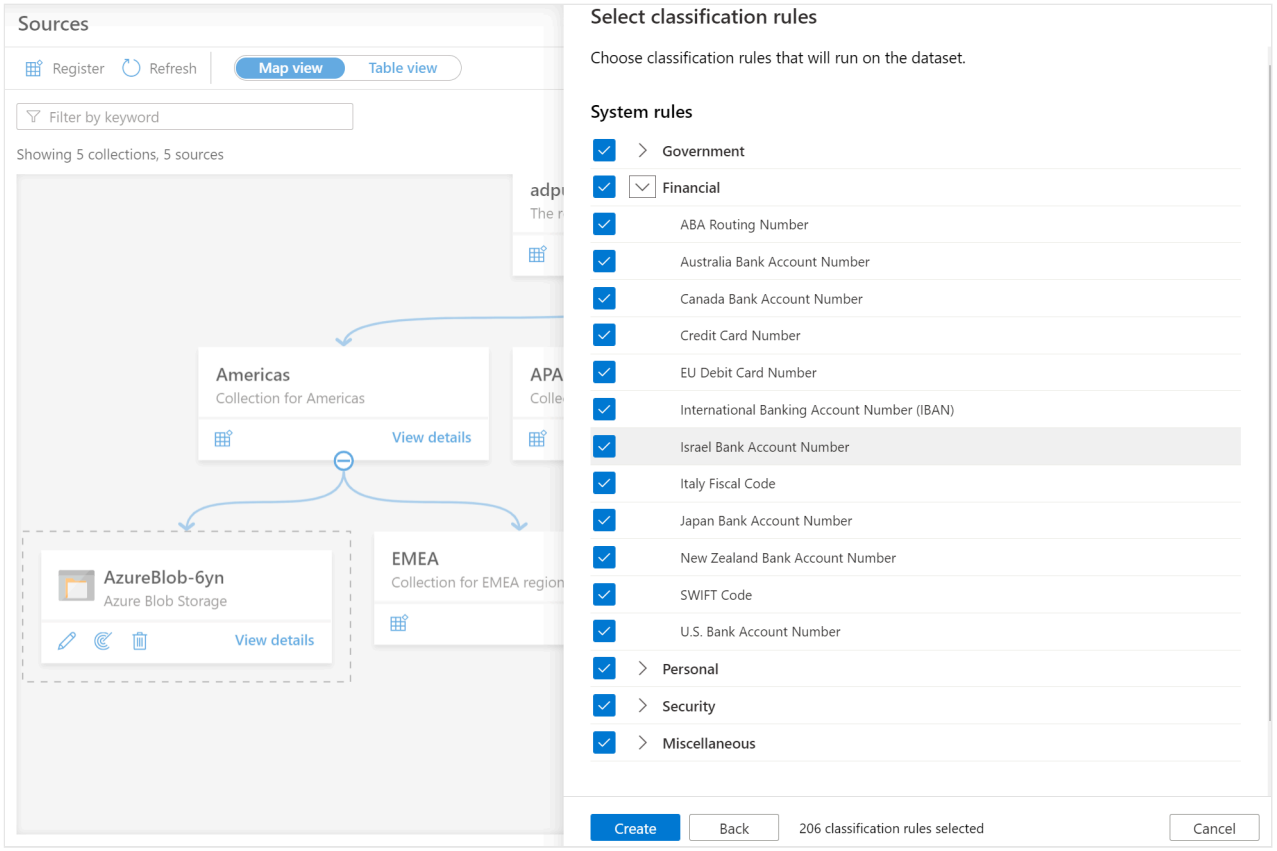


3. Select **Test connection**. On a successful connection, select **Continue**

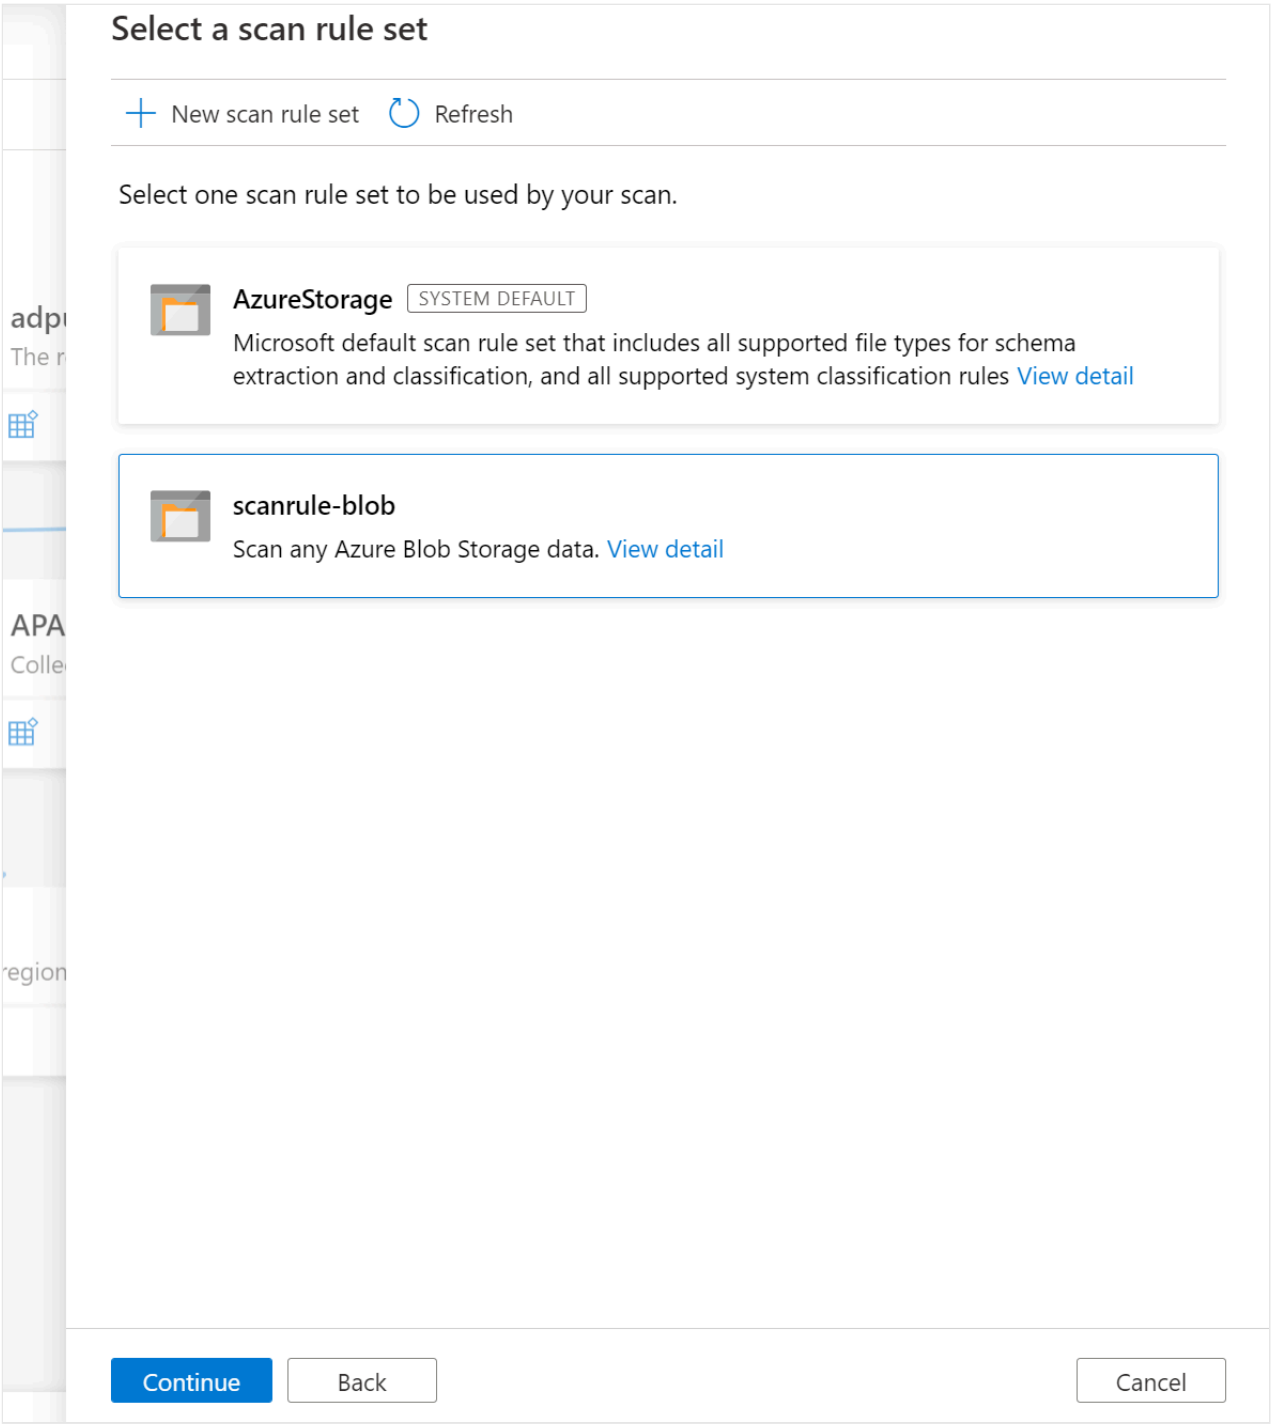
Scoping and running the scan



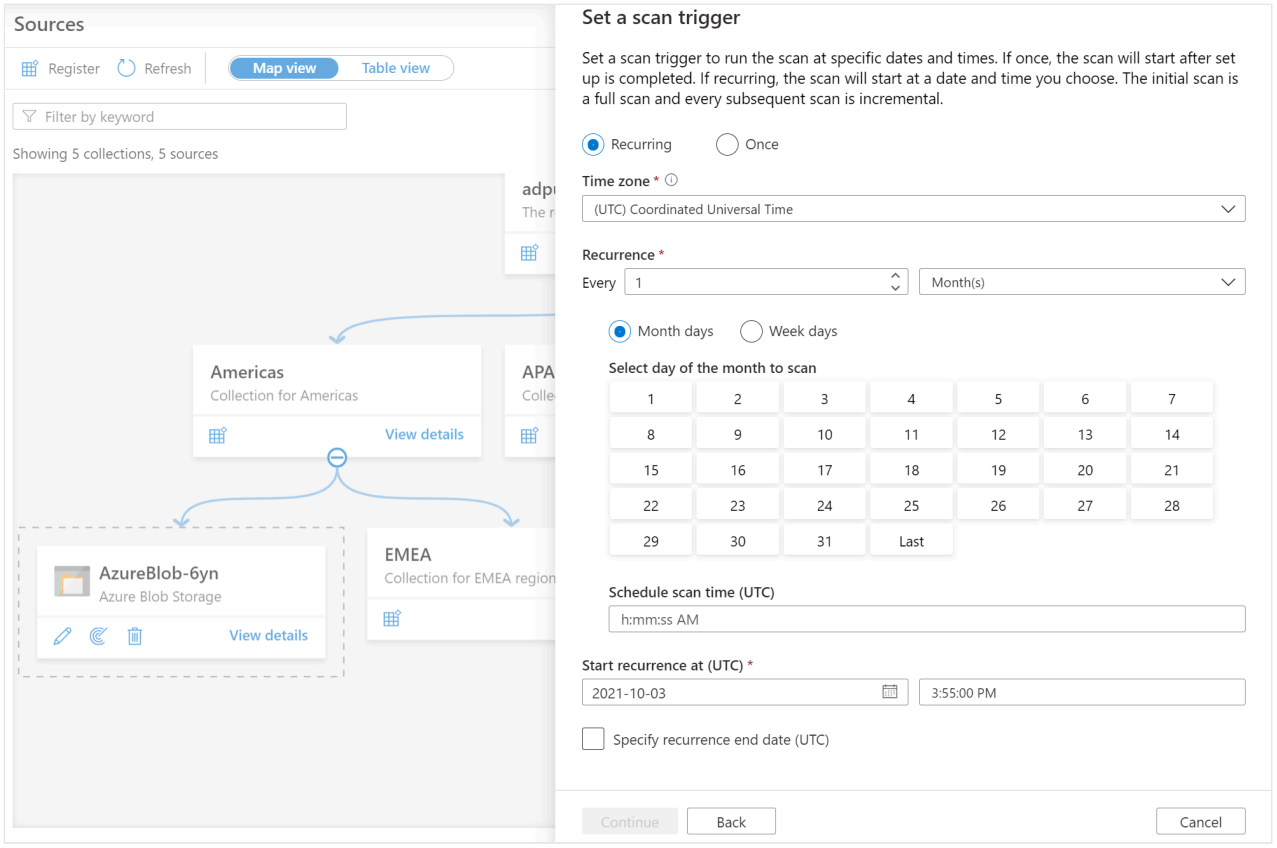
1. You can scope your scan to specific folders and subfolders by choosing the appropriate items in the list.



2. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.



3. If creating a new *scan rule set*, select the **file types** to be included in the scan rule.



4. You can select the **classification rules** to be included in the scan rule

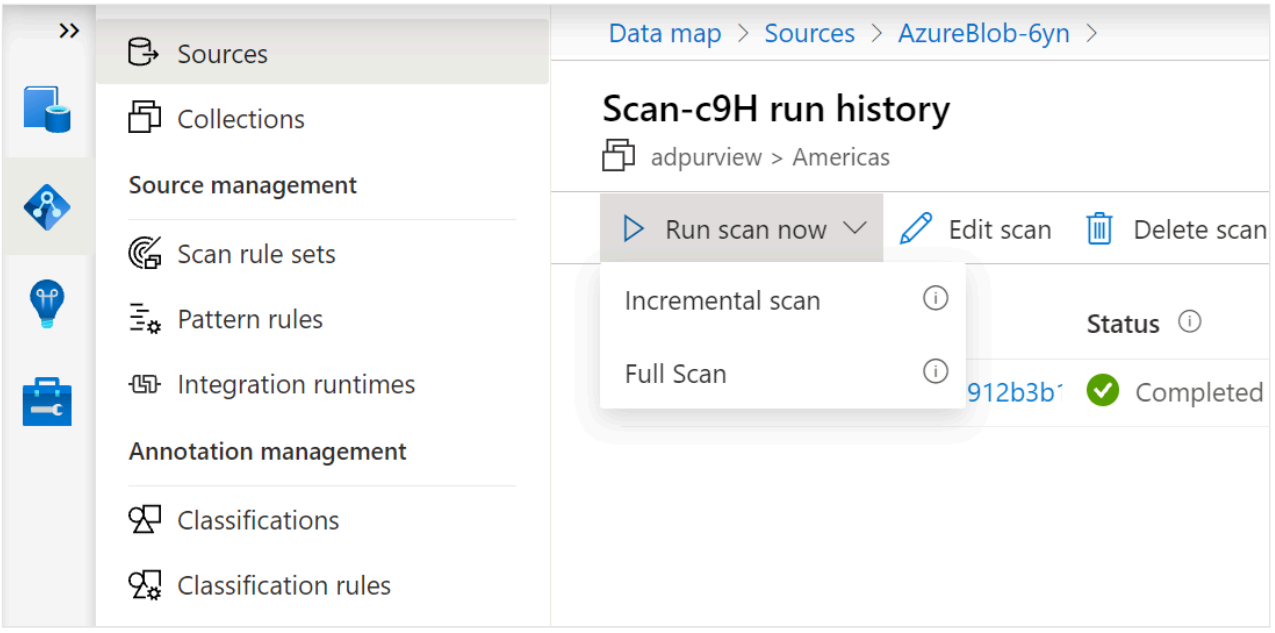
Managing Scan

Scans can be managed or run again on completion



1. Select the **Scan name** to manage the scan

2. You can *run the scan* again, *edit the scan*, *delete the scan*

3. You can *run an incremental scan* or a *full scan* again.

Data sharing

Microsoft Purview Data Sharing (preview) enables sharing of data in-place from Azure Blob storage account to Azure Blob storage account. This section provides details about the specific requirements for sharing and receiving data in-place between Azure Blob storage accounts. Refer to How to share data and How to receive share for step by step guides on how to use data sharing.

Storage accounts supported for in-place data sharing

The following storage accounts are supported for in-place data sharing:

- Regions: Canada Central, Canada East, UK South, UK West, Australia East, Japan East, Korea South, and South Africa North
- Redundancy options: LRS, GRS, RA-GRS
- Tiers: Hot, Cool

Only use storage accounts without production workload for the preview.

> **Note**
>
> Source and target storage accounts must be in the same region as each other. They don't need to be in the same region as the Microsoft Purview account.

Storage account permissions required to share data

To add or update a storage account asset to a share, you need ONE of the following permissions:

- **Microsoft.Authorization/roleAssignments/write** - This permission is available in the *Owner* role.
- **Microsoft.Storage/storageAccounts/blobServices/containers/blobs/modifyPermissions/** - This permission is available in the *Blob Storage Data Owner* role.

Storage account permissions required to receive shared data

To map a storage account asset in a received share, you need ONE of the following permissions:

- **Microsoft.Storage/storageAccounts/write** - This permission is available in the *Contributor* and *Owner* role.
- **Microsoft.Storage/storageAccounts/blobServices/containers/write** - This permission is available in the *Contributor*, *Owner*, *Storage Blob Data Contributor* and *Storage Blob Data Owner* role.

Update shared data in source storage account

Updates you make to shared files or data in the shared folder from source storage account will be made available to recipient in target storage account in near real time. When you delete subfolder or files within the shared folder, they will disappear for recipient. To delete the shared folder, file or parent folders or containers, you need to first revoke access to all your shares from the source storage account.

Access shared data in target storage account

The target storage account enables recipient to access the shared data read-only in near real time. You can connect analytics tools such as Synapse Workspace and Databricks to the shared data to perform analytics. Cost of accessing the shared data is charged to the target storage account.

Service limit

Source storage account can support up to 20 targets, and target storage account can support up to 100 sources. If you require an increase in limit, please contact Support.

Policies

The following types of policies are supported on this data resource from Microsoft Purview:

- Data owner policies - a set of policy statements that allow you to grant users and groups access to data sources.
- Self-service access policies - policy that allows users to request access to data sources registered to Microsoft Purview.
- Protection policies - denies access to data tagged with sensitivity labels to all users except those specified by the policy.

Access policy pre-requisites on Azure Storage accounts

Region support

- All Microsoft Purview regions are supported.
- Storage accounts in the following regions are supported without the need for additional configuration. However, zone-redundant storage (ZRS) accounts are not supported.
  - Australia Central
  - Australia East
  - Australia Southeast
  - Brazil South
  - Canada Central
  - Canada East
  - Central India
  - Central US
  - East Asia
  - East US 2
  - East US
  - France Central
  - Germany West Central
  - Japan East
  - Japan West
  - Korea Central
  - North Central US
  - North Europe
  - Norway East
  - Poland Central
  - Qatar Central
  - South Central US
  - South Africa North
  - Southeast Asia

    - South India
    - Sweden Central
    - Switzerland North
    - West Central US
    - West Europe
    - West US
    - West US 2
    - West US 3
    - UAE North
    - UK South
    - UK West
- Storage accounts in other regions in Public Cloud are supported after setting feature flag *AllowPurviewPolicyEnforcement*, as outlined in the next section. Newly created ZRS Storage accounts are supported, if created after setting the feature flag *AllowPurviewPolicyEnforcement*.

If needed, you can create a new Storage account by following this guide.

Configure the subscription where the Azure Storage account resides for policies from Microsoft Purview

This step is only necessary in certain regions (see prior section). To enable Microsoft Purview to manage policies for one or more Azure Storage accounts, execute the following PowerShell commands in the subscription where you'll deploy your Azure Storage account. These PowerShell commands will enable Microsoft Purview to manage policies on all Azure Storage accounts in that subscription.

If you're executing these commands locally, be sure to run PowerShell as an administrator. Alternatively, you can use the Azure Cloud Shell in the Azure portal: https://shell.azure.com.

PowerShell

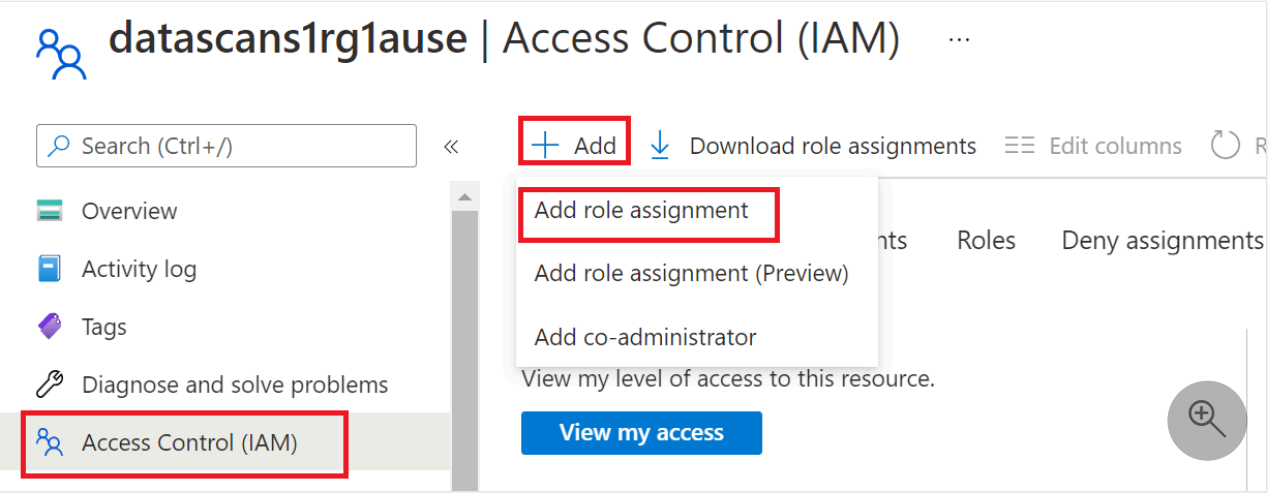
```
# Install the Az module
Install-Module -Name Az -Scope CurrentUser -Repository PSGallery -Force
# Login into the subscription
Connect-AzAccount -Subscription <SubscriptionID>
# Register the feature
Register-AzProviderFeature -FeatureName AllowPurviewPolicyEnforcement -
ProviderNamespace Microsoft.Storage
```

If the output of the last command shows *RegistrationState* as *Registered*, then your subscription is enabled for access policies. If the output is *Registering*, wait at least 10 minutes, and then retry the command. **Do not continue unless the RegistrationState shows as *Registered*.**

Configure the Microsoft Purview account for policies

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

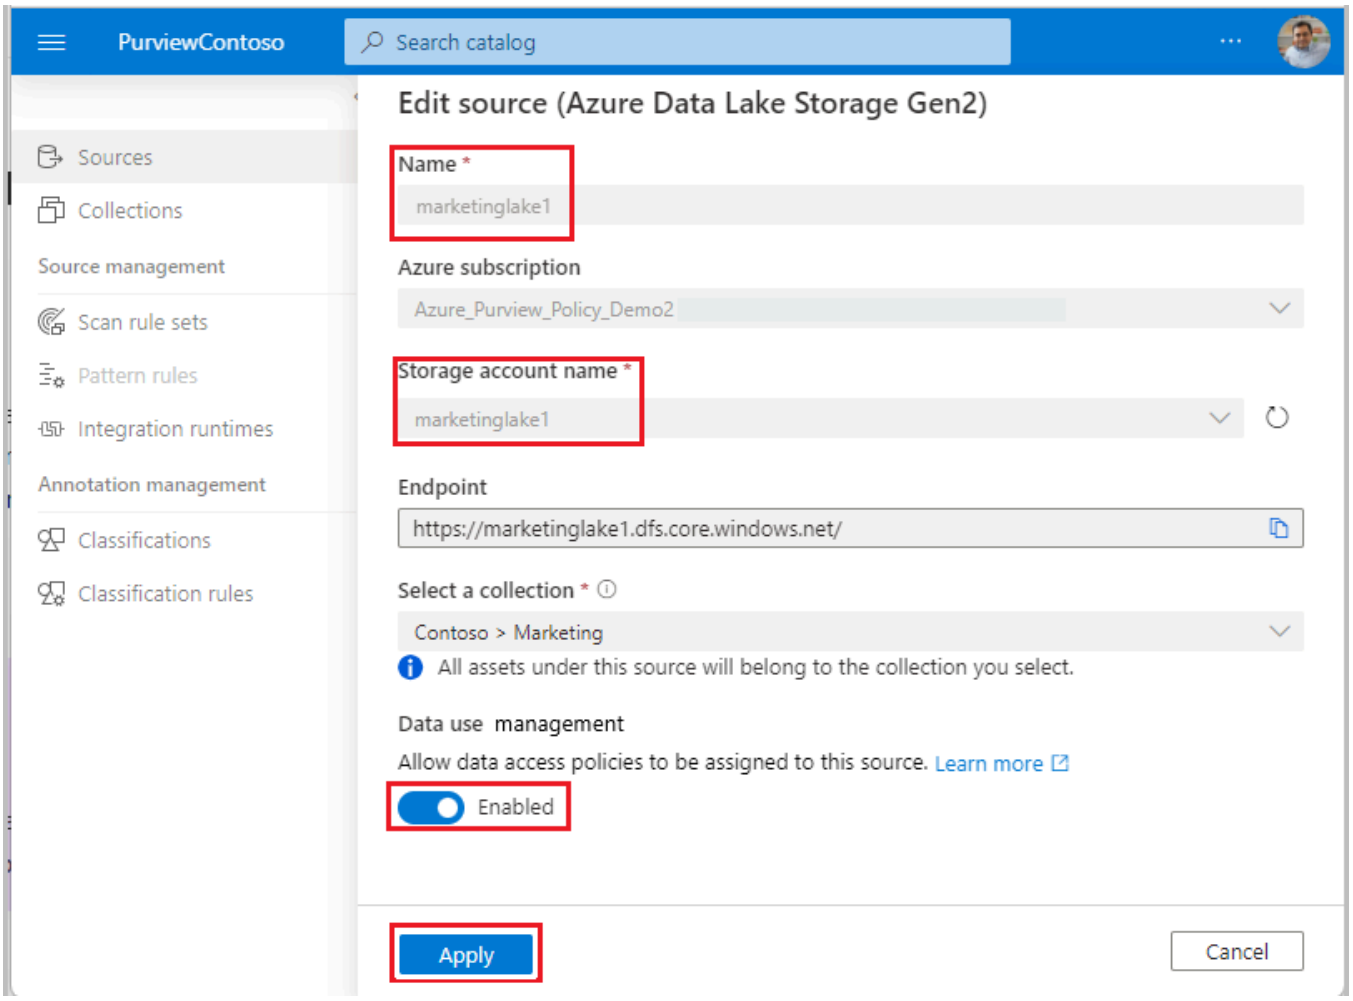
> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the data source in Microsoft Purview for Data Policy Enforcement

The Azure Storage resource needs to be registered first with Microsoft Purview before you can create access policies. To register your resource, follow the **Prerequisites** and **Register** sections of this guide:

- Register Azure Blob Storage in Microsoft Purview

After you've registered the data source, you'll need to enable Data Policy Enforcement. This is a pre-requisite before you can create policies on the data source. Data Policy Enforcement can impact the security of your data, as it delegates to certain Microsoft Purview roles managing access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

Once your data source has the **Data Policy Enforcement** option set to **Enabled**, it will look like this screenshot:

Create a policy

To create an access policy for Azure Blob Storage, follow this guide: Provision read/modify access on a single storage account.

To create policies that cover all data sources inside a resource group or Azure subscription you can refer to this section.

Protection policy

Protection access control policies (protection policies) enable organizations to automatically protect sensitive data across data sources. Microsoft Purview already scans data assets and identifies sensitive data elements, and this new feature allows you to automatically restrict access to that data using sensitivity labels from Microsoft Purview Information Protection.

Follow this documentation to create a protection policy: How to create a Microsoft Purview Information Protection policy.

Connect to and manage Azure Files in Microsoft Purview

Article • 05/21/2025

This article outlines how to register Azure Files, and how to authenticate and interact with Azure Files in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

Azure Files supports full and incremental scans to capture the metadata and classifications, based on system default and custom classification rules.

For file types such as .csv, .tsv, .psv, and .ssv, the schema is extracted when the following logics are in place:

1. First row values are nonempty.
2. First row values are unique.
3. First row values are not a date or a number.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview

Permissions page for details.

Register

This section describes how to register Azure Files in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

Currently there's only one way to set up authentication for Azure file shares:

- Account Key

Account Key to register

When authentication method selected is **Account Key**, you need to get your access key and store in the key vault:

1. Navigate to your storage account
2. Select **Security + networking** > **Access keys**
3. Copy your *key* and save it somewhere for the next steps
4. Navigate to your key vault
5. Select **Objects** > **Secrets**
6. Select **+ Generate/Import** and enter the **Name** and **Value** as the *key* from your storage account
7. Select **Create** to complete
8. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection
9. Finally, create a new credential using the key to set up your scan

Steps to register

To register a new Azure Files account in Microsoft Purview Unified Catalog, follow these steps:

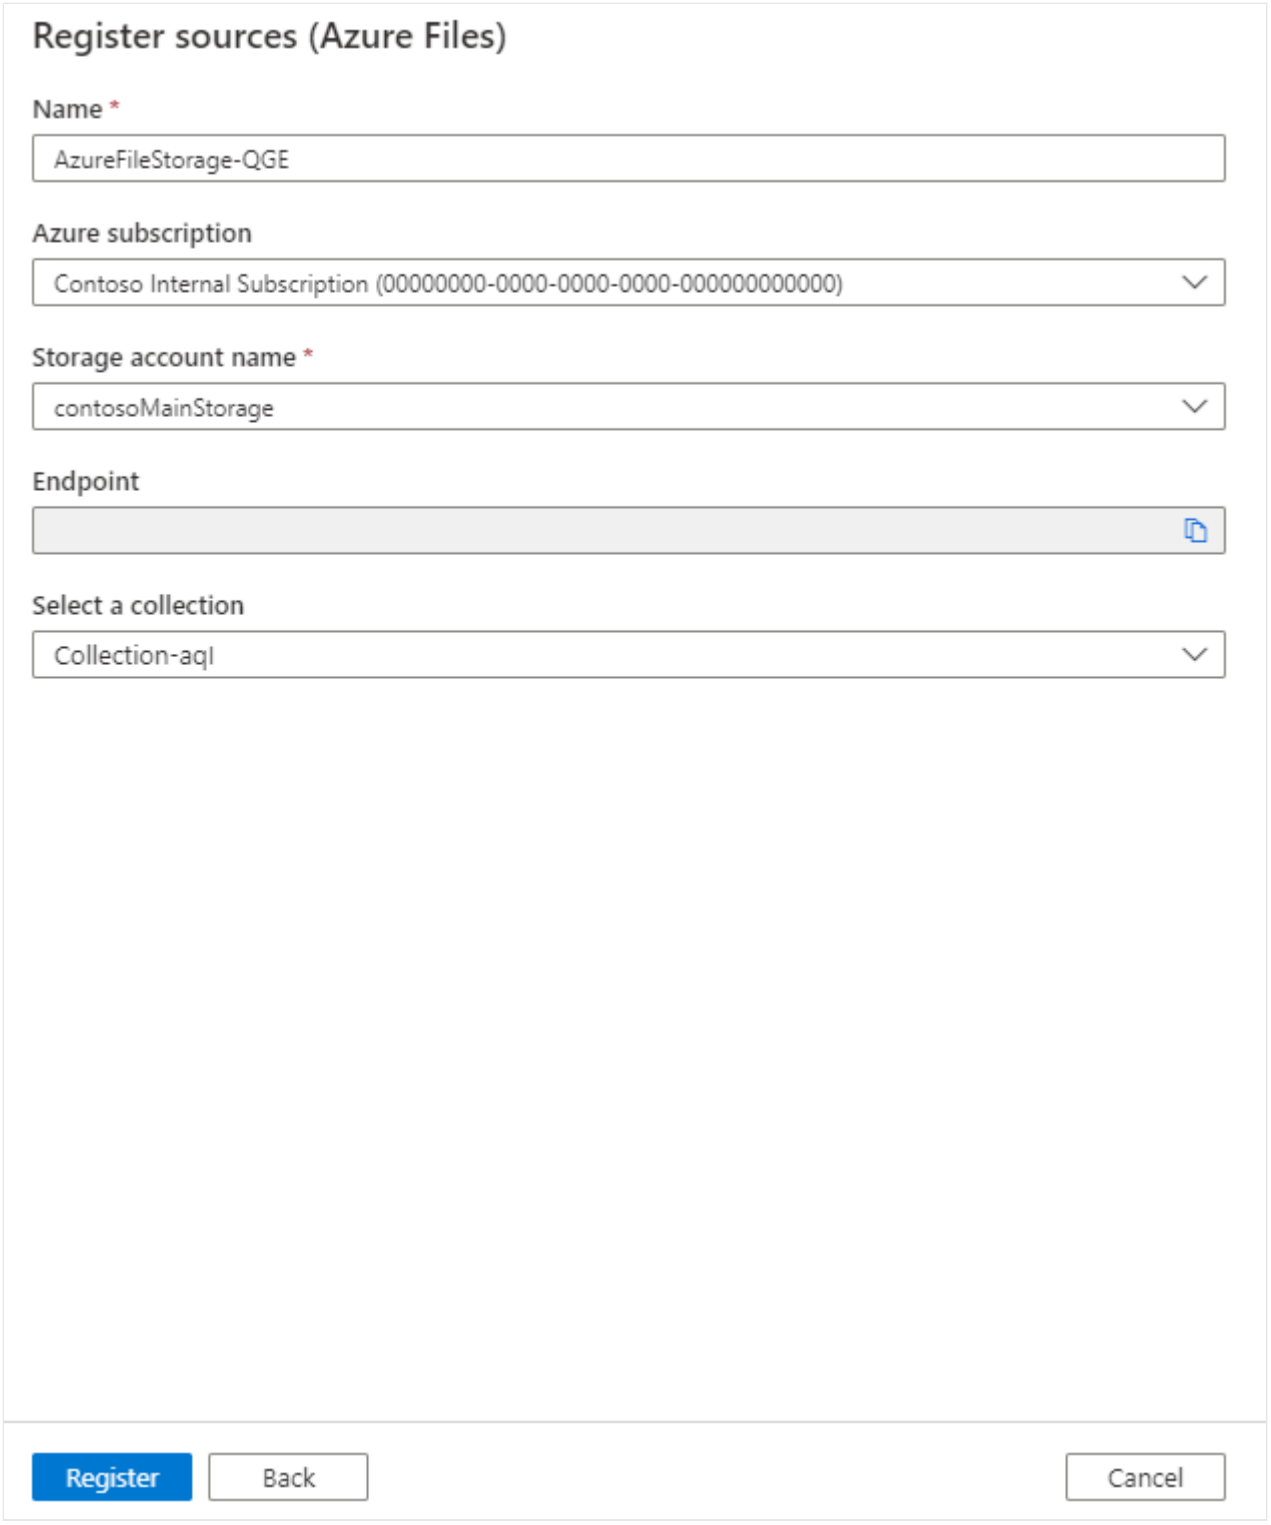
1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.

3. Select **Register**

4. On **Register sources**, select **Azure Files**



5. Select **Continue**

On the **Register sources (Azure Files)** screen, follow these steps:

1. Enter a **Name** that the data source will be listed with in the Catalog.
2. Choose your Azure subscription to filter down Azure Storage Accounts.

3. Select an Azure Storage Account.
4. Select a collection from the list.
5. Select **Register** to register the data source.

Scan

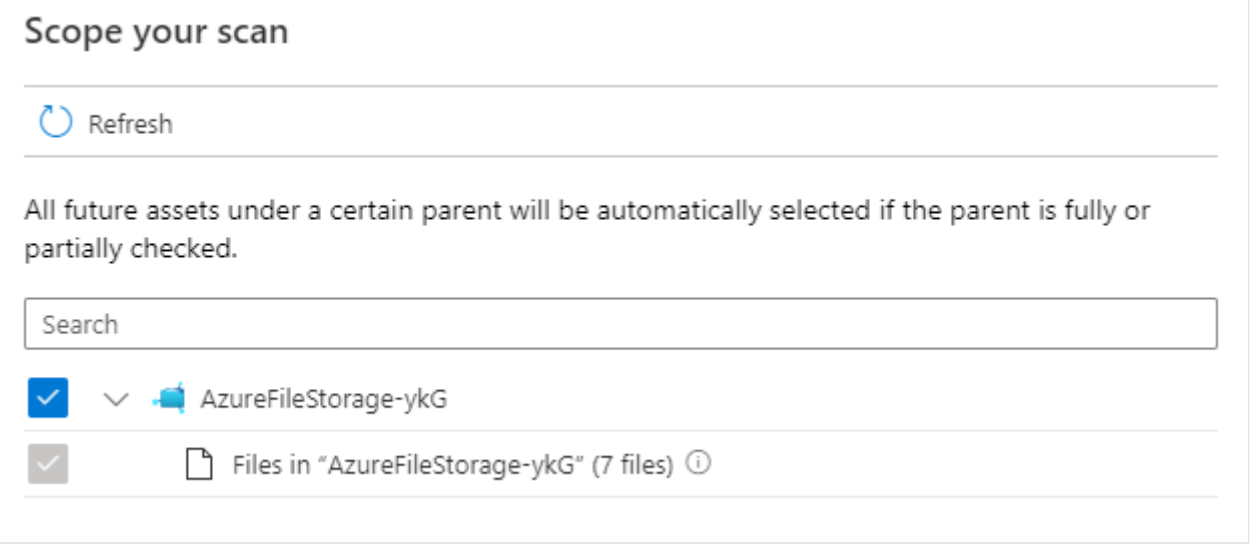
Follow the steps below to scan Azure Files to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion

Create and run scan

To create and run a new scan, follow these steps:

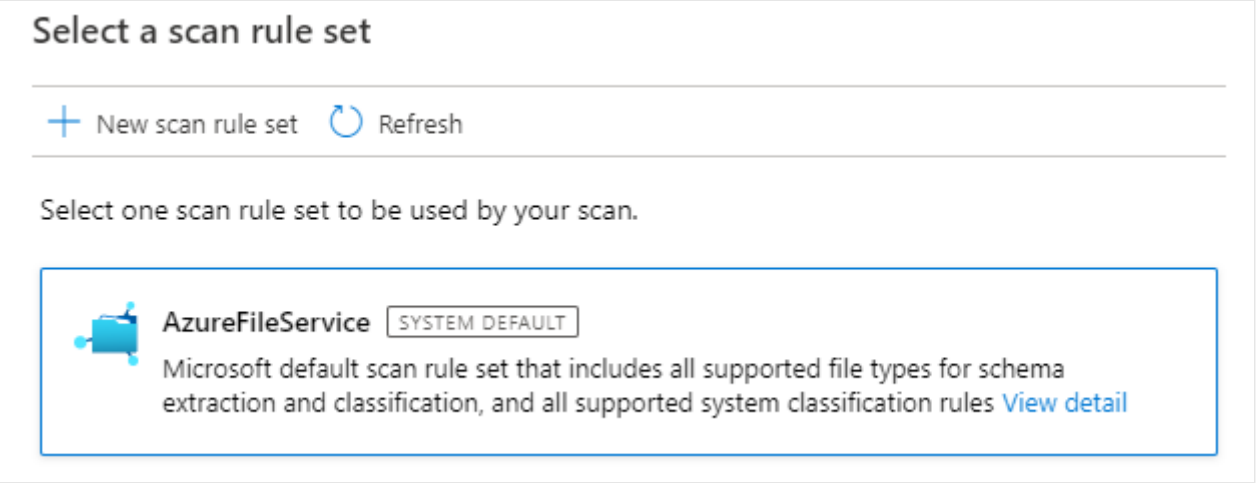
1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.

2. Select the Azure Files source that you registered.

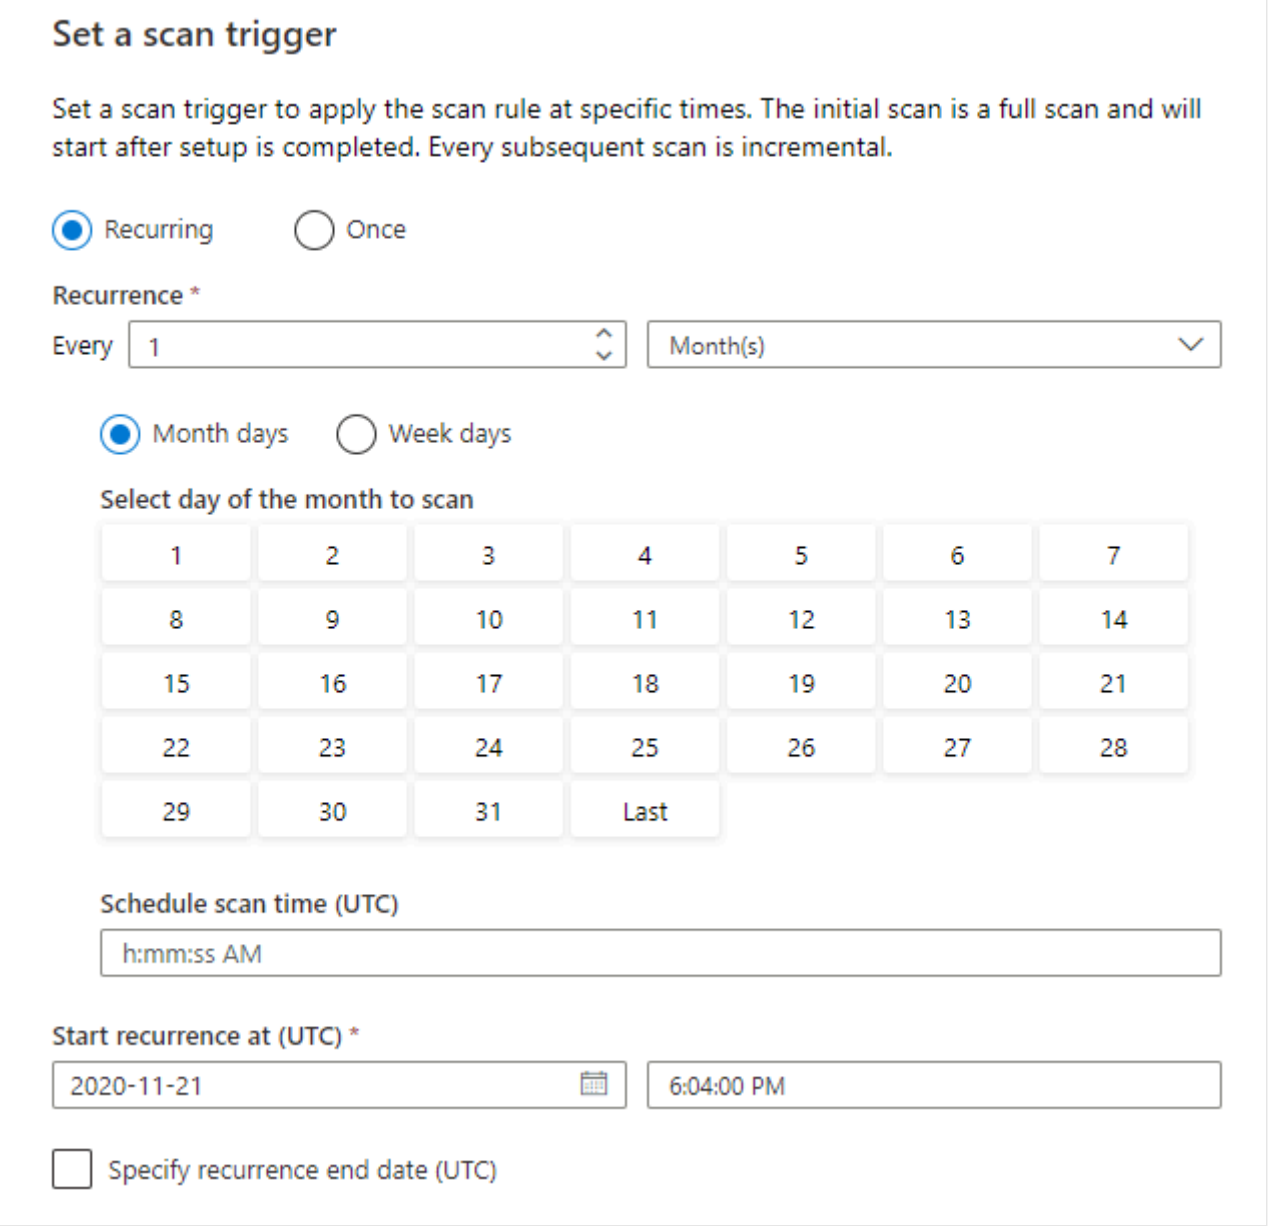


3. Select **New scan**

4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.



5. Select the account key credential to connect to your data source.



6. You can scope your scan to specific databases by choosing the appropriate items in the list.

7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule to reoccur, or run the scan once.

9. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you have registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to Azure Cosmos DB for SQL API in Microsoft Purview

Article • 05/21/2025

This article outlines the process to register and scan Azure Cosmos DB for SQL API instance in Microsoft Purview, including instructions to authenticate and interact with the Azure Cosmos DB database source

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

Other capabilities

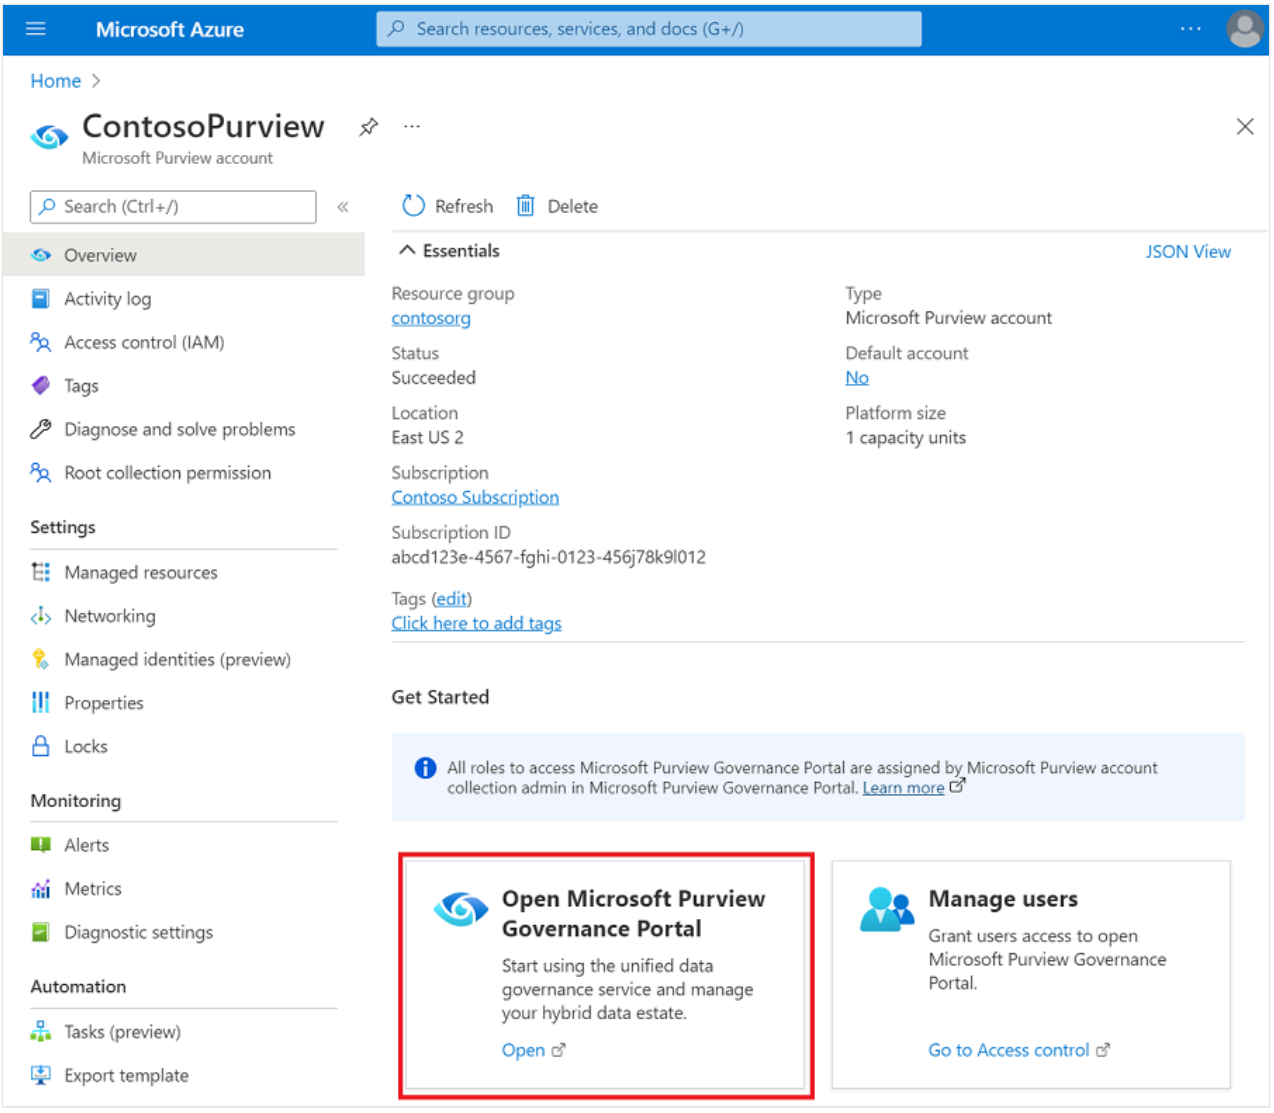
For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You will need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

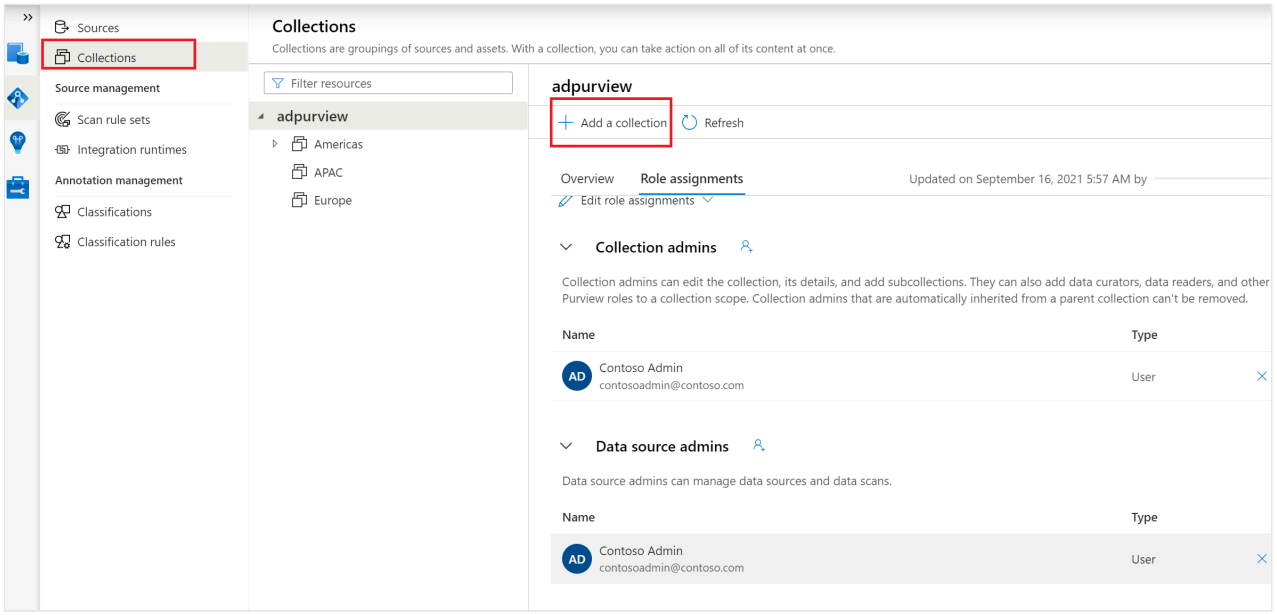
Register

This section will enable you to register the Azure Cosmos DB for SQL API instance and set up an appropriate authentication mechanism to ensure successful scanning of the data source.



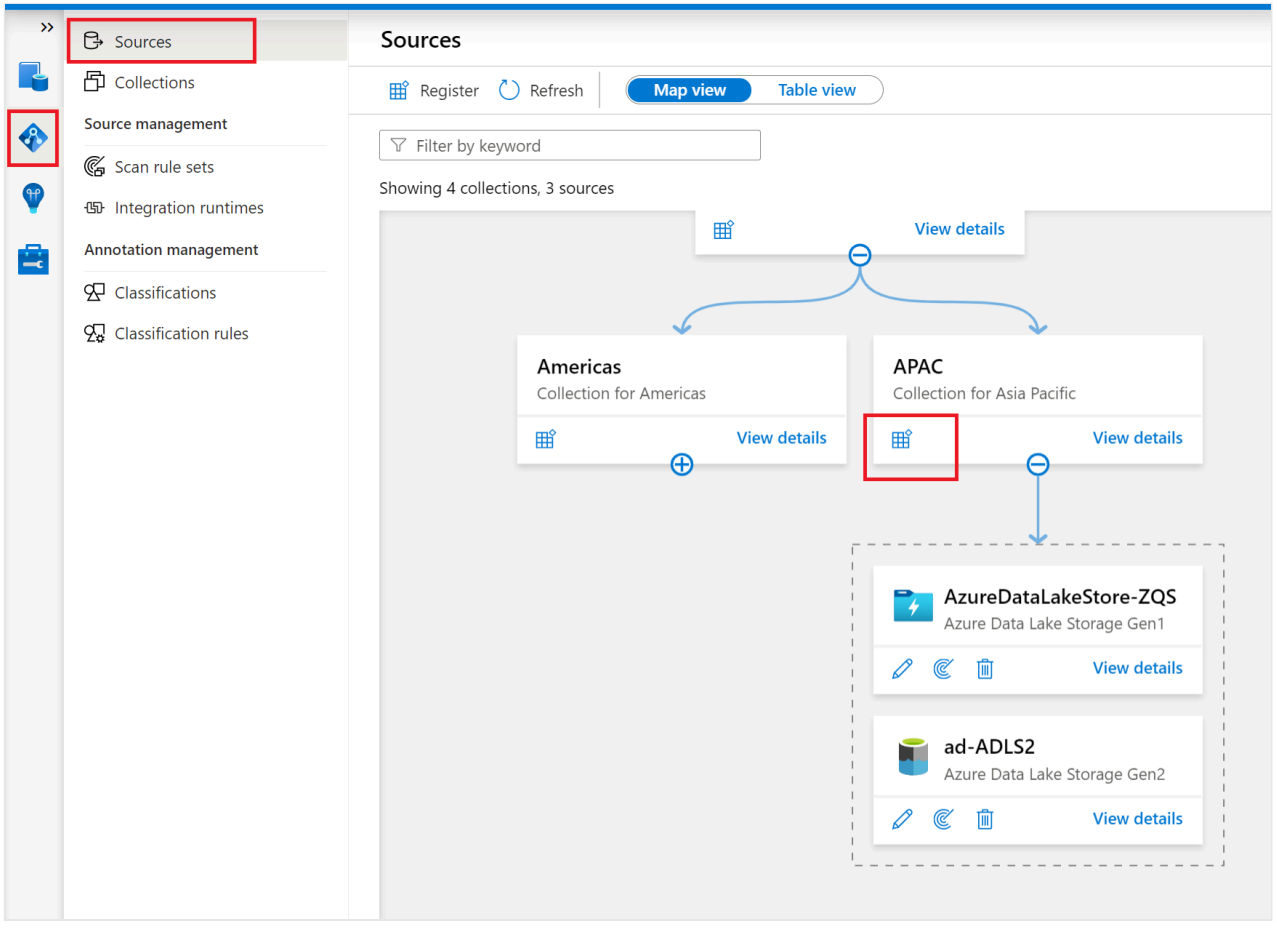
Steps to register

It is important to register the data source in Microsoft Purview prior to setting up a scan for the data source.

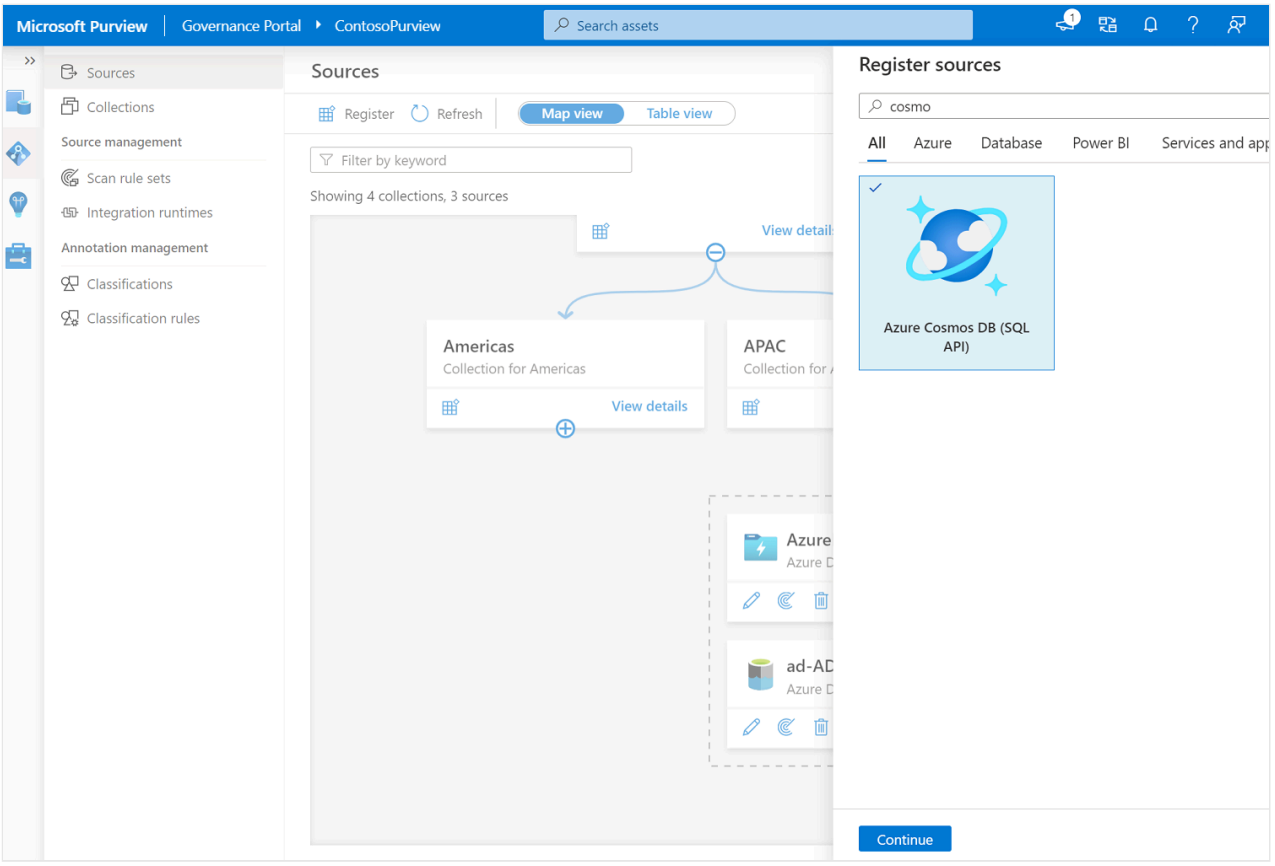


1. Open the Microsoft Purview governance portal by:

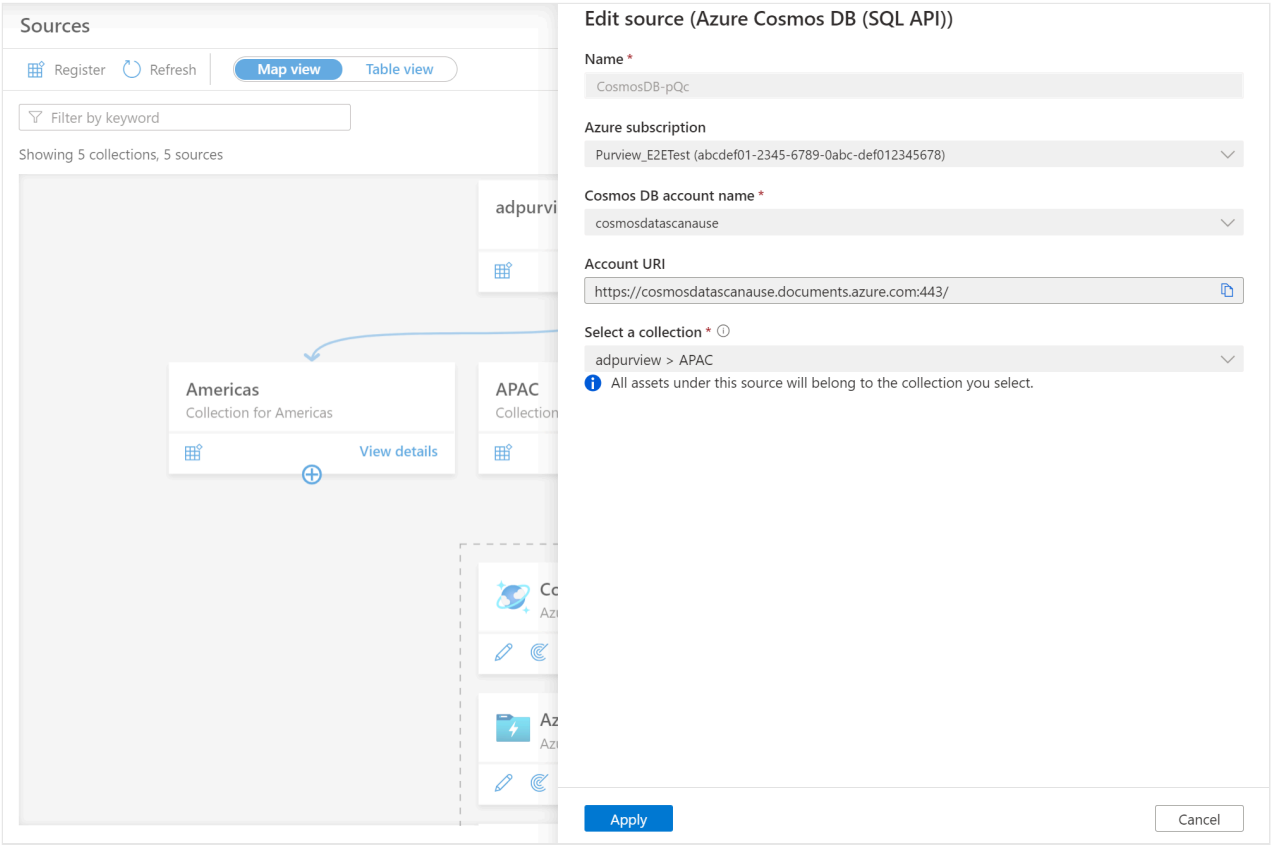
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.



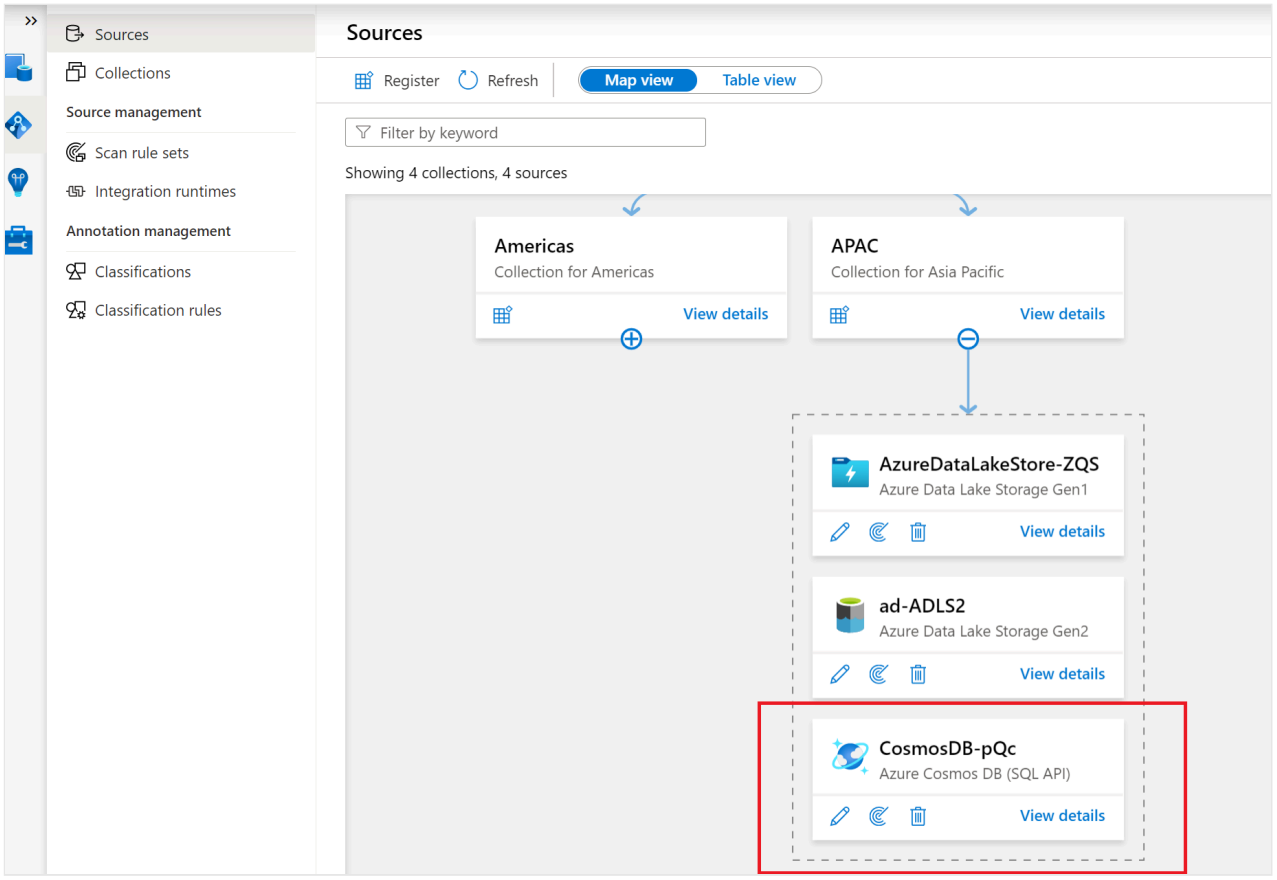
2. Navigate to the **Data Map --> Collections**



3. Create the Collection hierarchy using the **Collections** menu and assign permissions to individual subcollections, as required



4. Navigate to the appropriate collection under the **Sources** menu and select the **Register** icon to register a new Azure Cosmos DB database



5. Select the **Azure Cosmos DB for SQL API** data source and select **Continue**

6. Provide a suitable **Name** for the data source, select the relevant **Azure subscription**, **Cosmos DB account name** and the **collection** and select **Apply**

7. The *Azure Cosmos DB database* storage account will be shown under the selected Collection

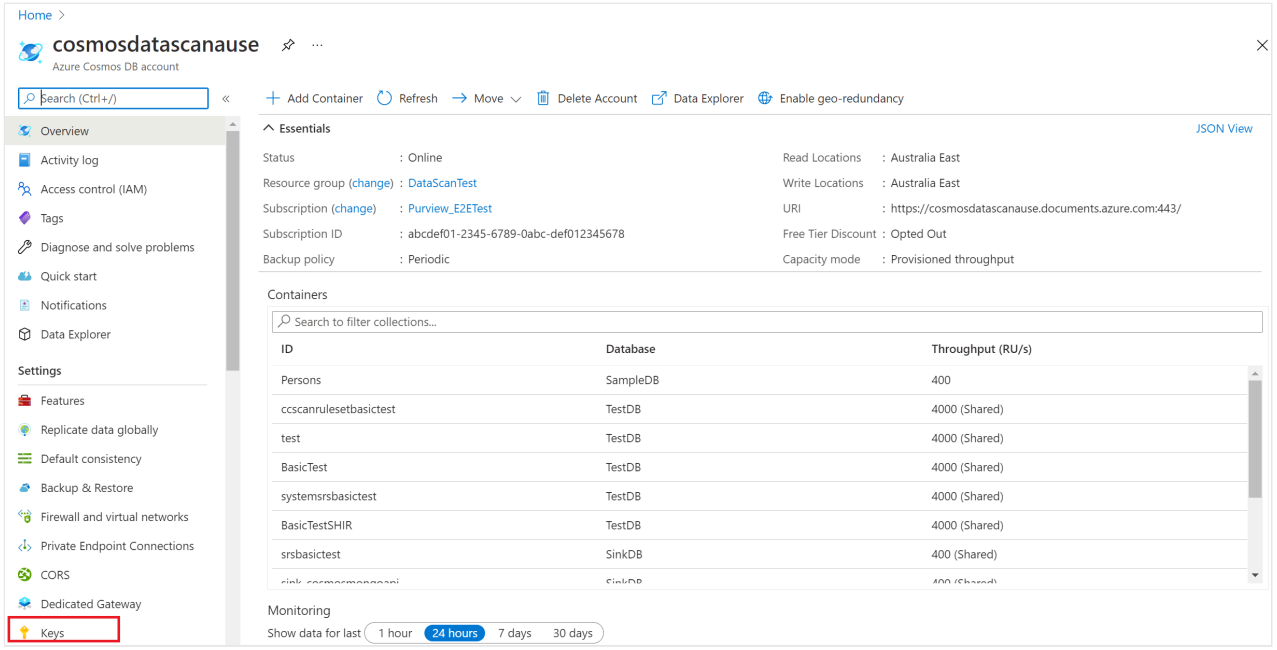
Scan

Authentication for a scan

In order to have access to scan the data source, an authentication method in the Azure Cosmos DB database Storage account needs to be configured.

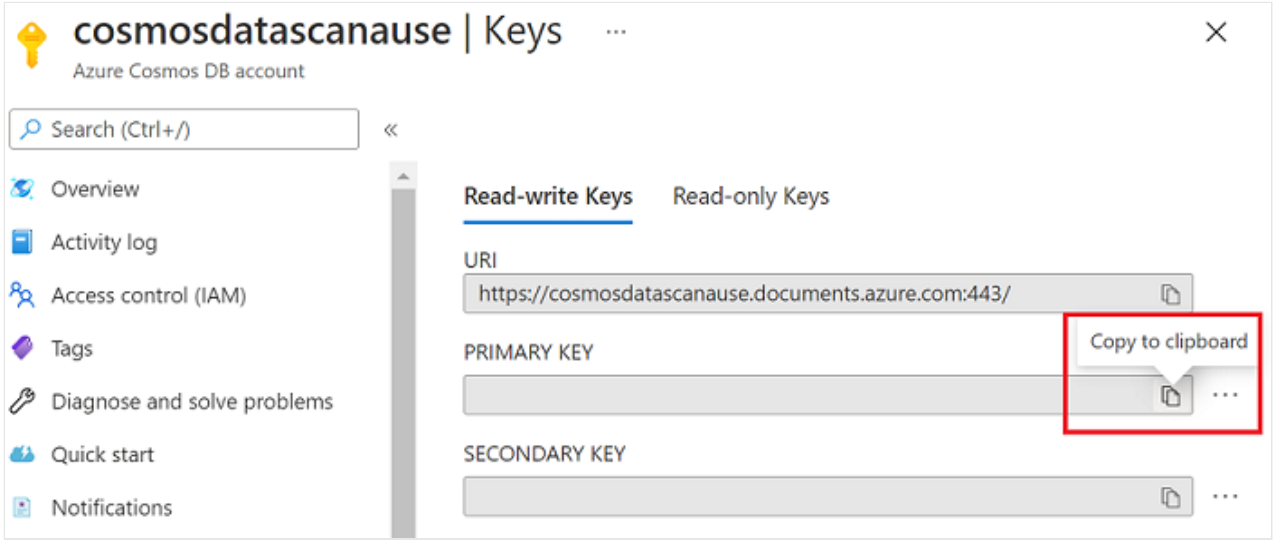
There is only one way to set up authentication for Azure Cosmos DB Database:

Account Key - Secrets can be created inside an Azure Key Vault to store credentials in order to enable access for Microsoft Purview to scan data sources securely using the secrets. A secret can be a storage account key, SQL login password or a password.



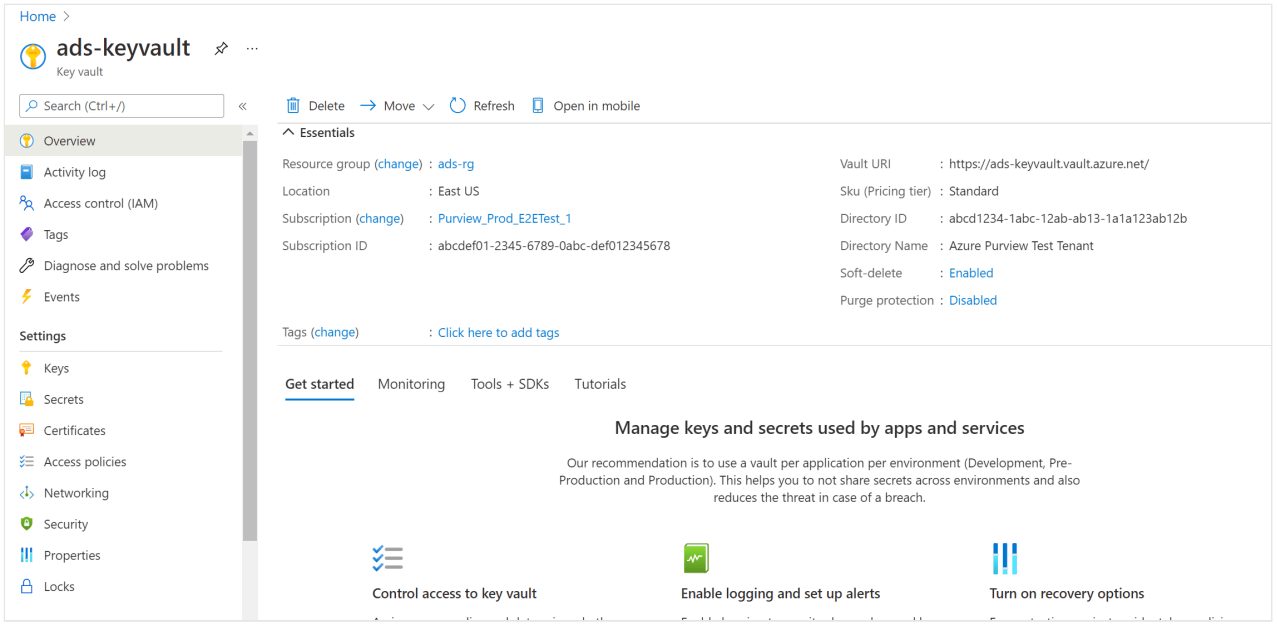
> ⓘ **Note**
>
> You need to deploy an *Azure key vault* resource in your subscription and assign *Microsoft Purview account's* MSI with required access permission to secrets inside *Azure key vault*.

Using Account Key for scanning

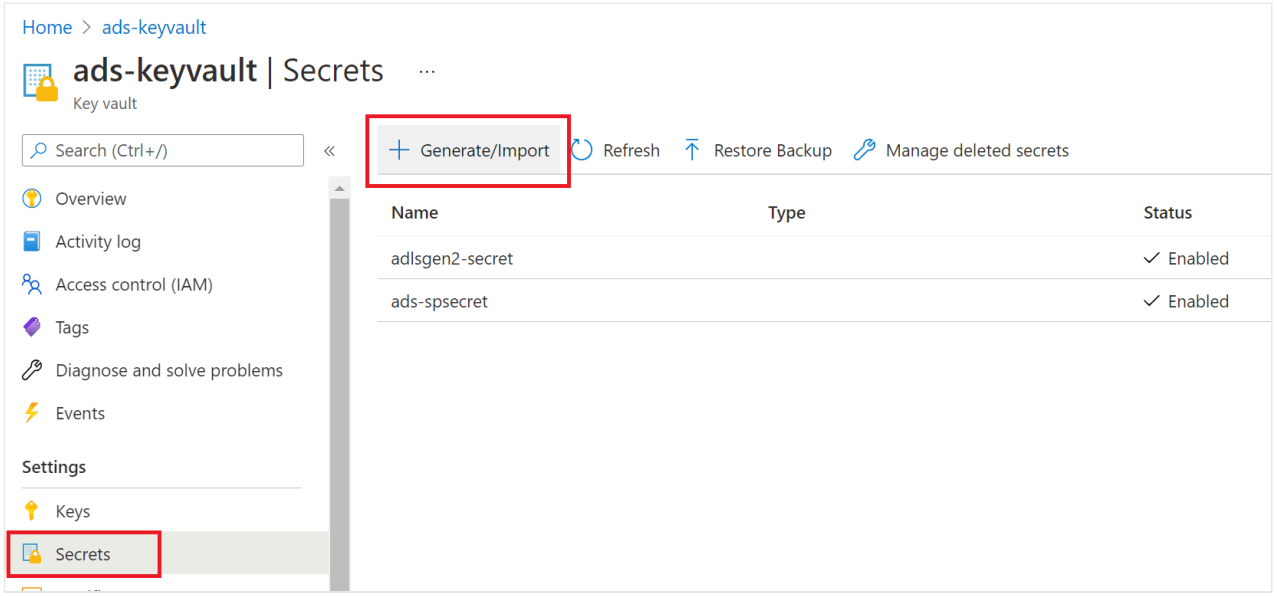


You need to get your access key and store in the key vault:

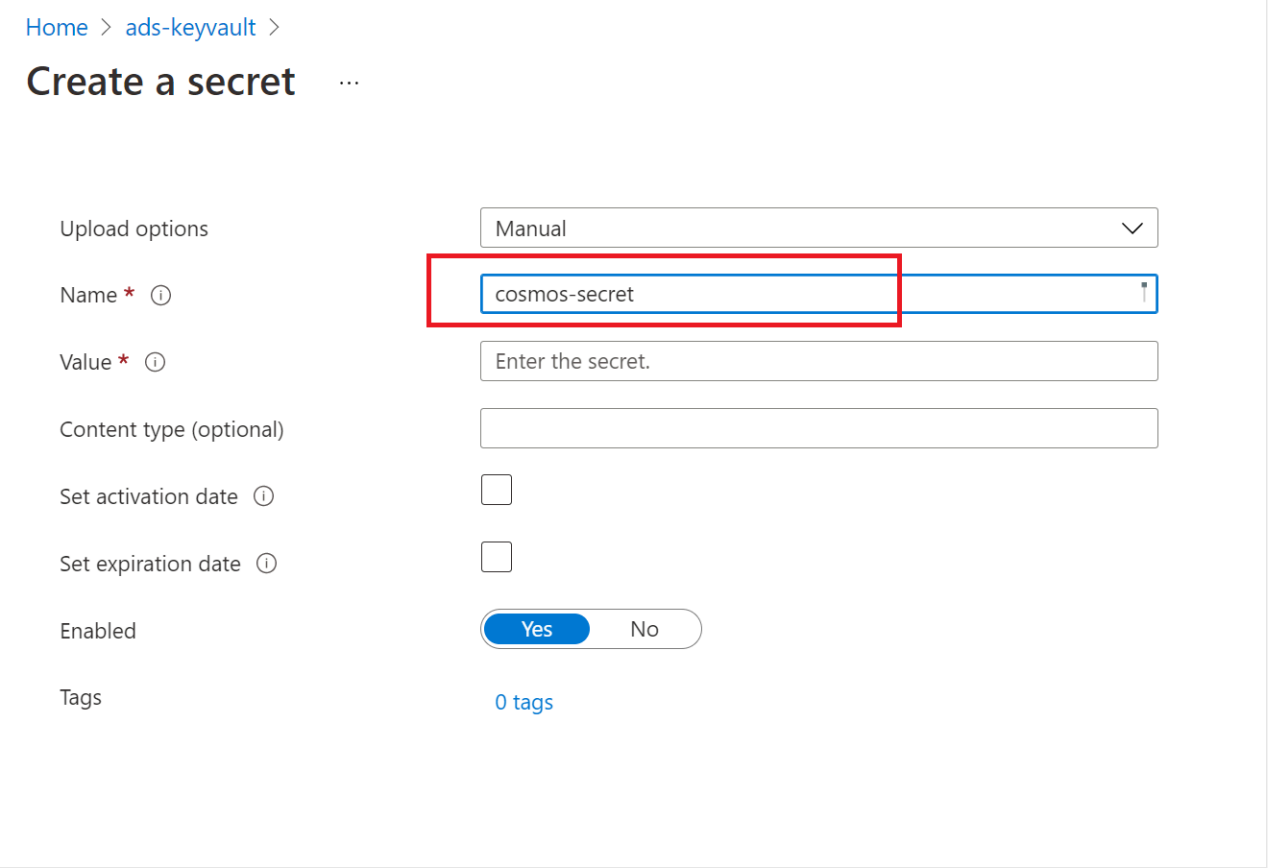
1. Navigate to your Azure Cosmos DB database storage account



2. Select **Settings** > **Keys**



3. Copy your *key* and save it separately for the next steps

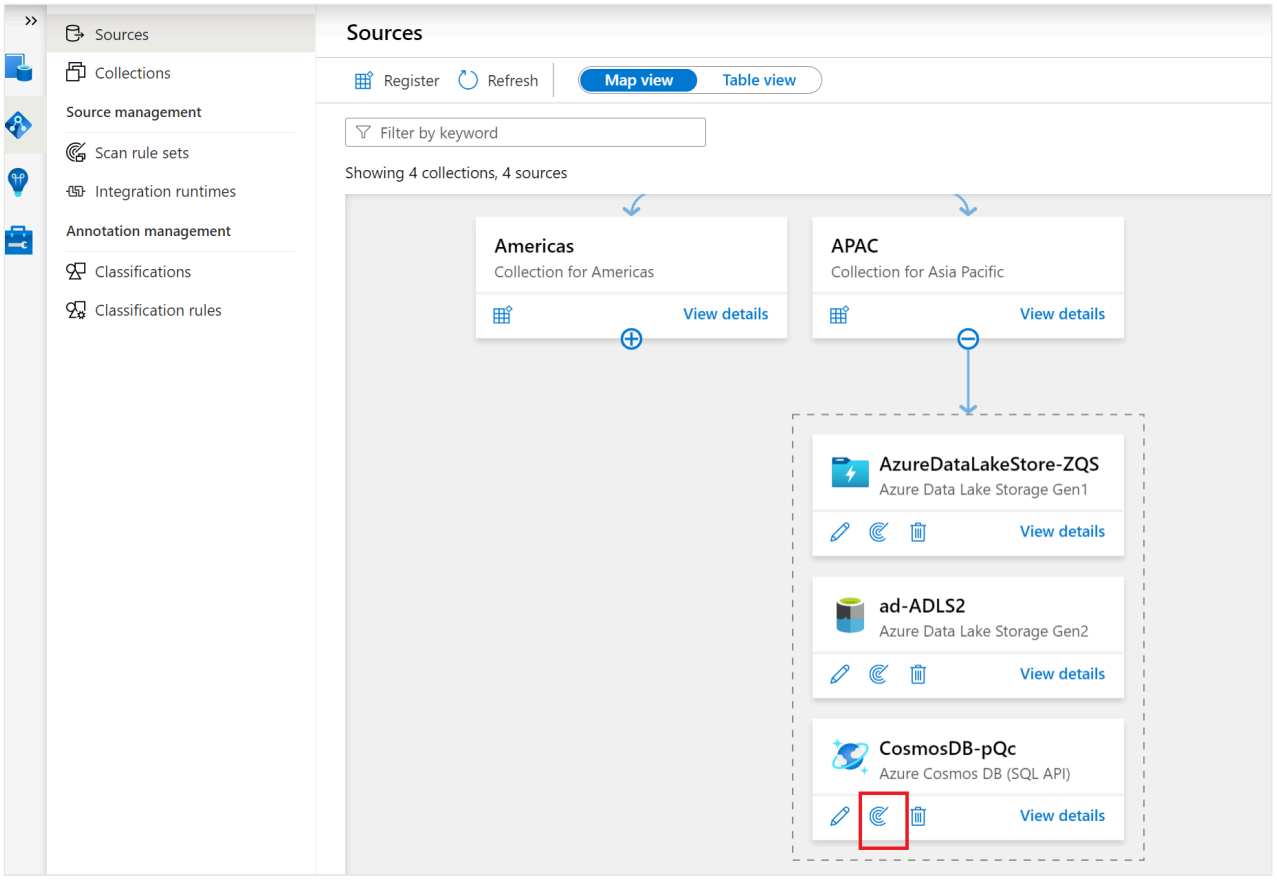


4. Navigate to your key vault

5. Select **Settings** > **Secrets** and select **+ Generate/Import**

6. Enter the **Name** and **Value** as the *key* from your storage account and Select **Create** to complete

7. If your key vault is not connected to Microsoft Purview yet, you will need to create a new key vault connection

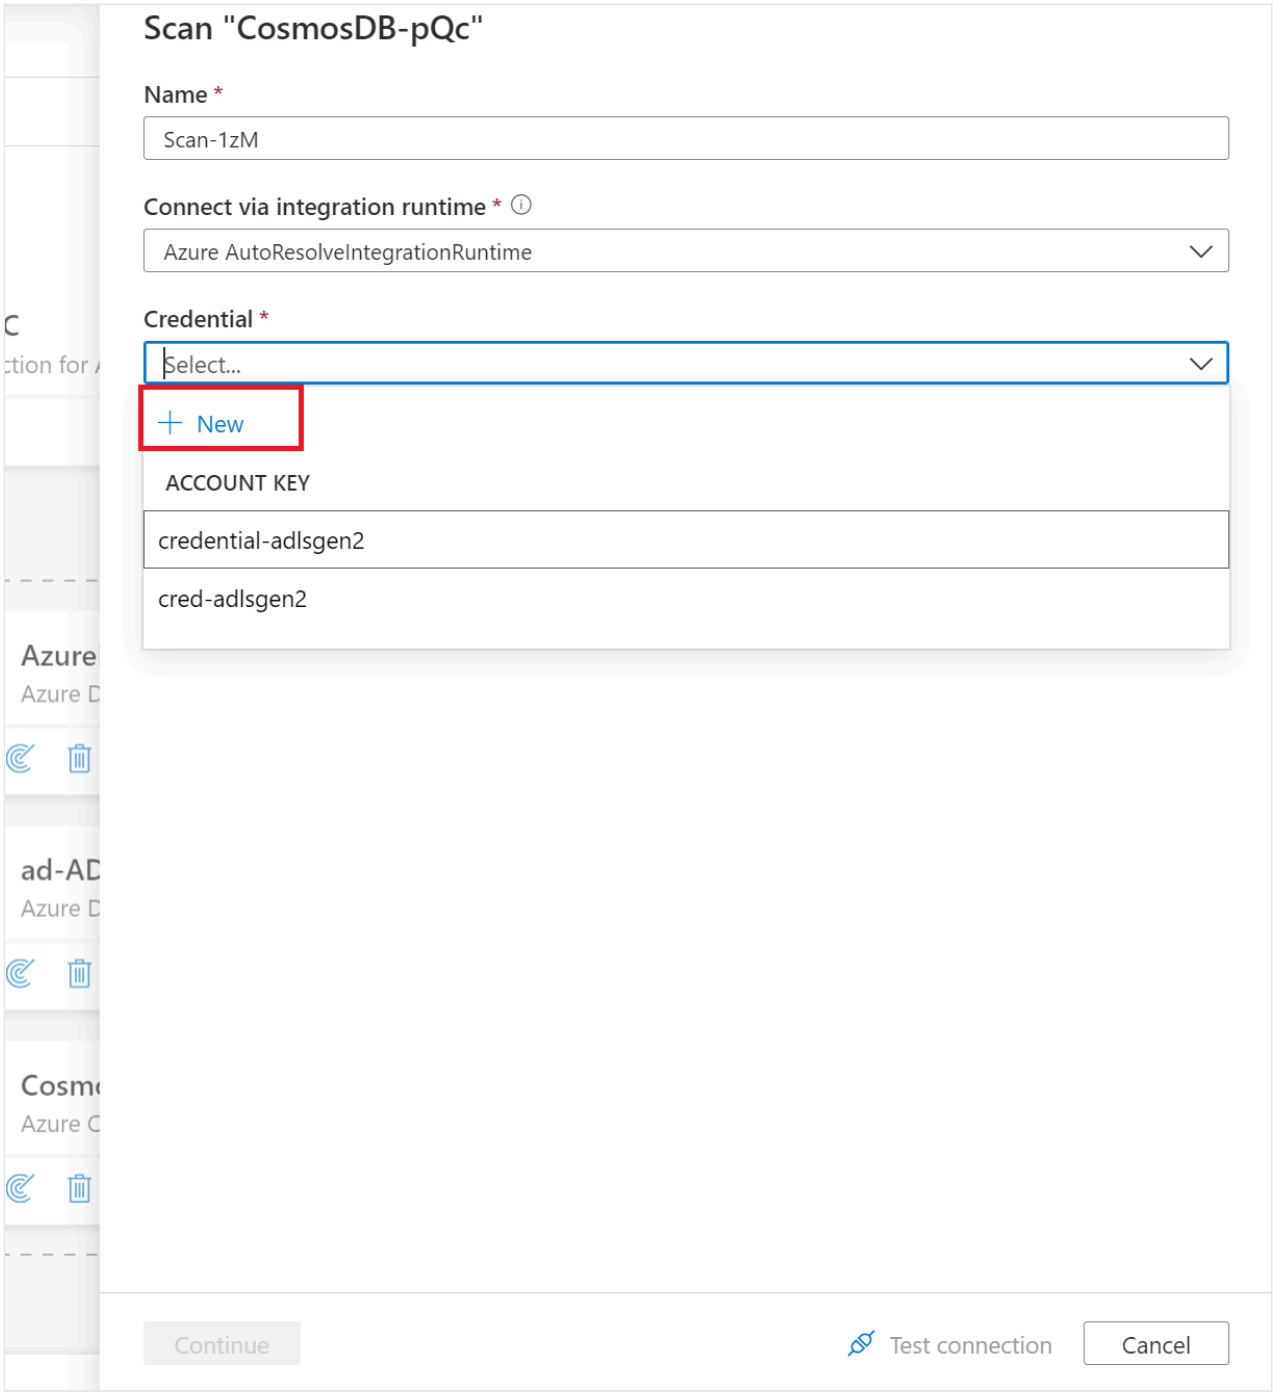


8. Finally, create a new credential using the key to set up your scan.

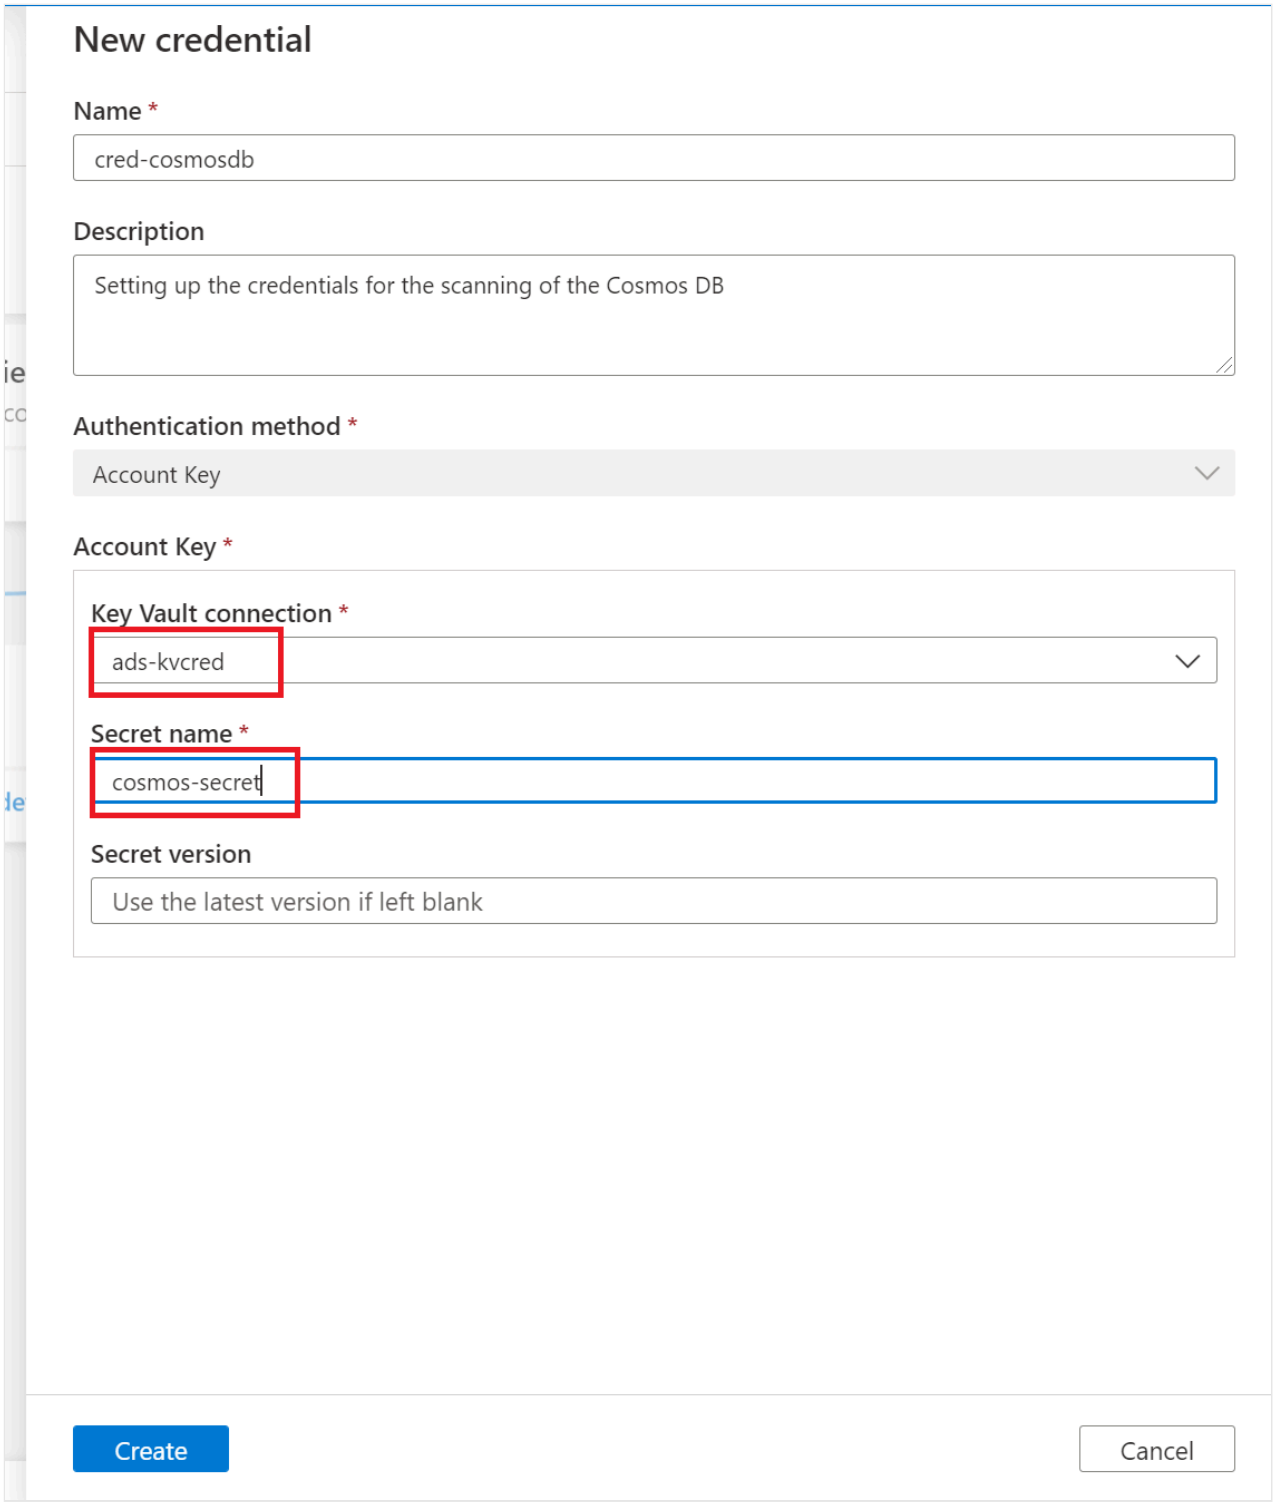
Creating the scan

1. Open your **Microsoft Purview account** and select the **Open Microsoft Purview governance portal**

2. Navigate to the **Data map** --> **Sources** to view the collection hierarchy

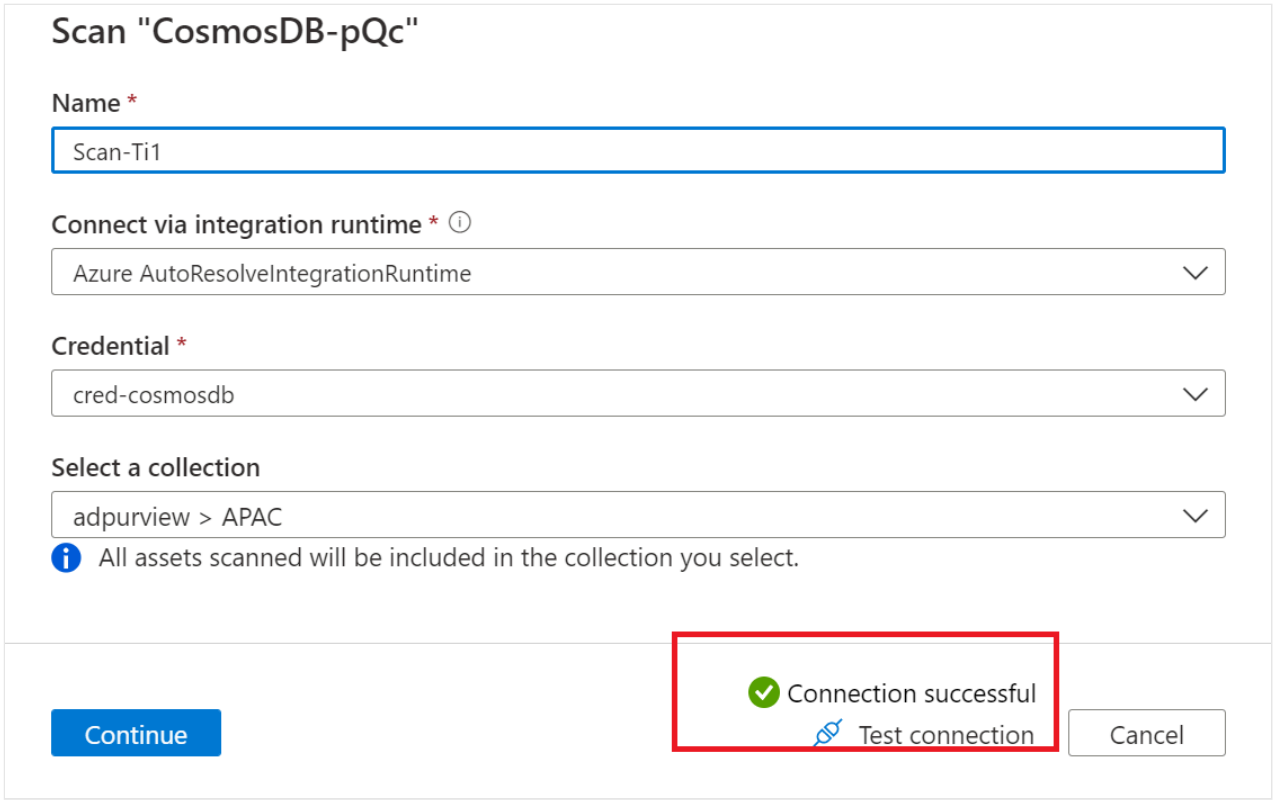


3. Select the **New Scan** icon under the **Azure Cosmos database** registered earlier



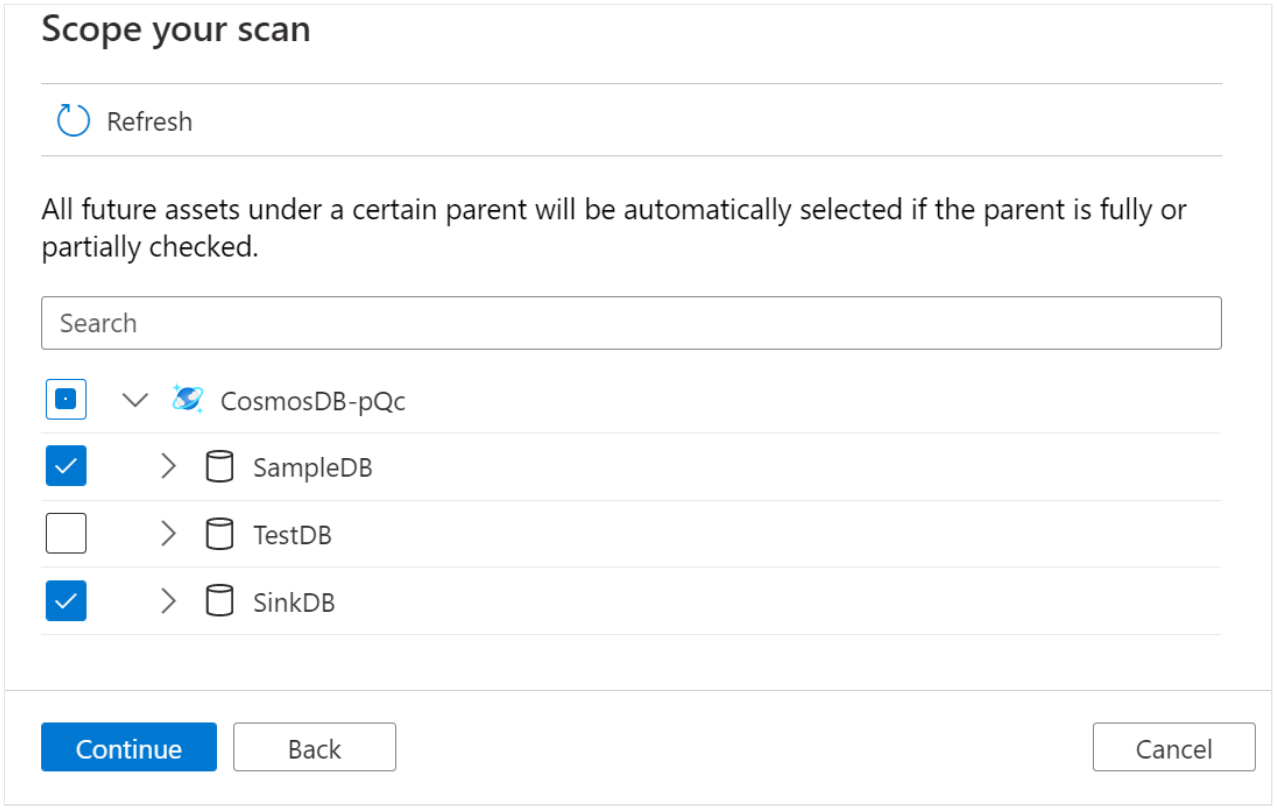
4. Provide a **Name** for the scan.

5. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.

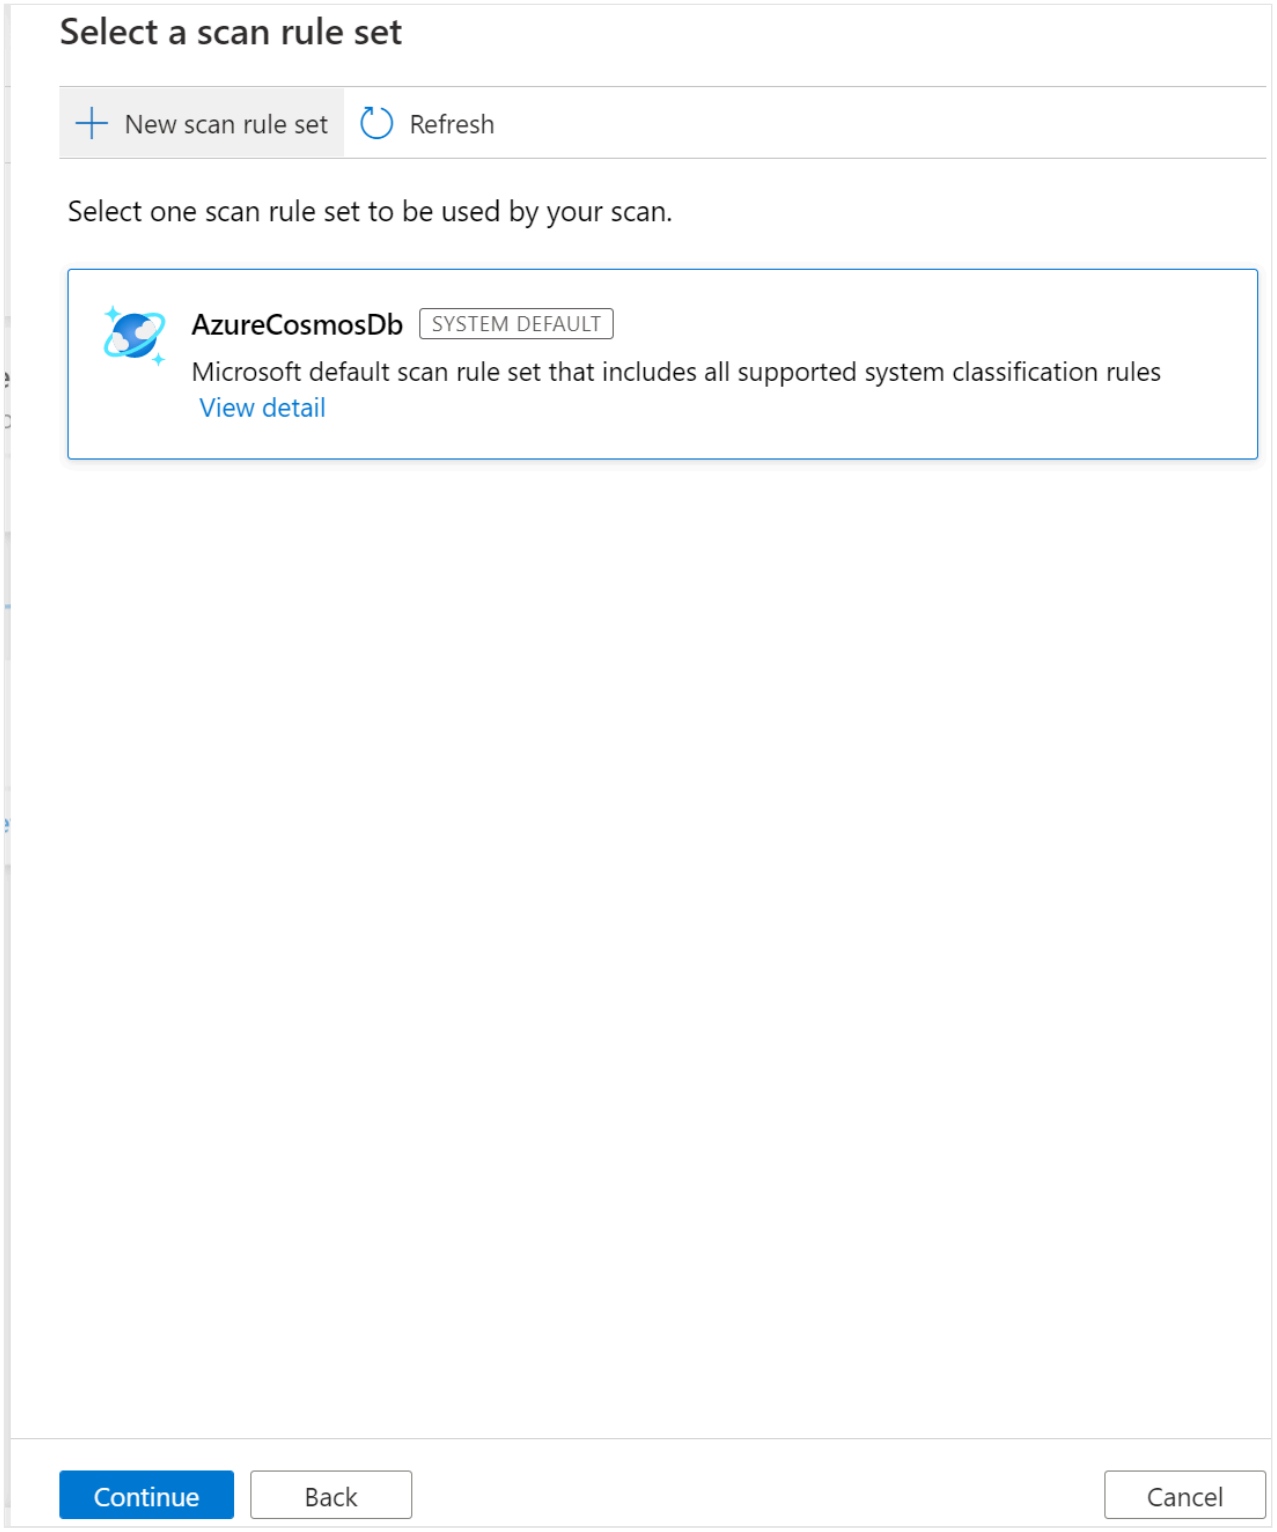


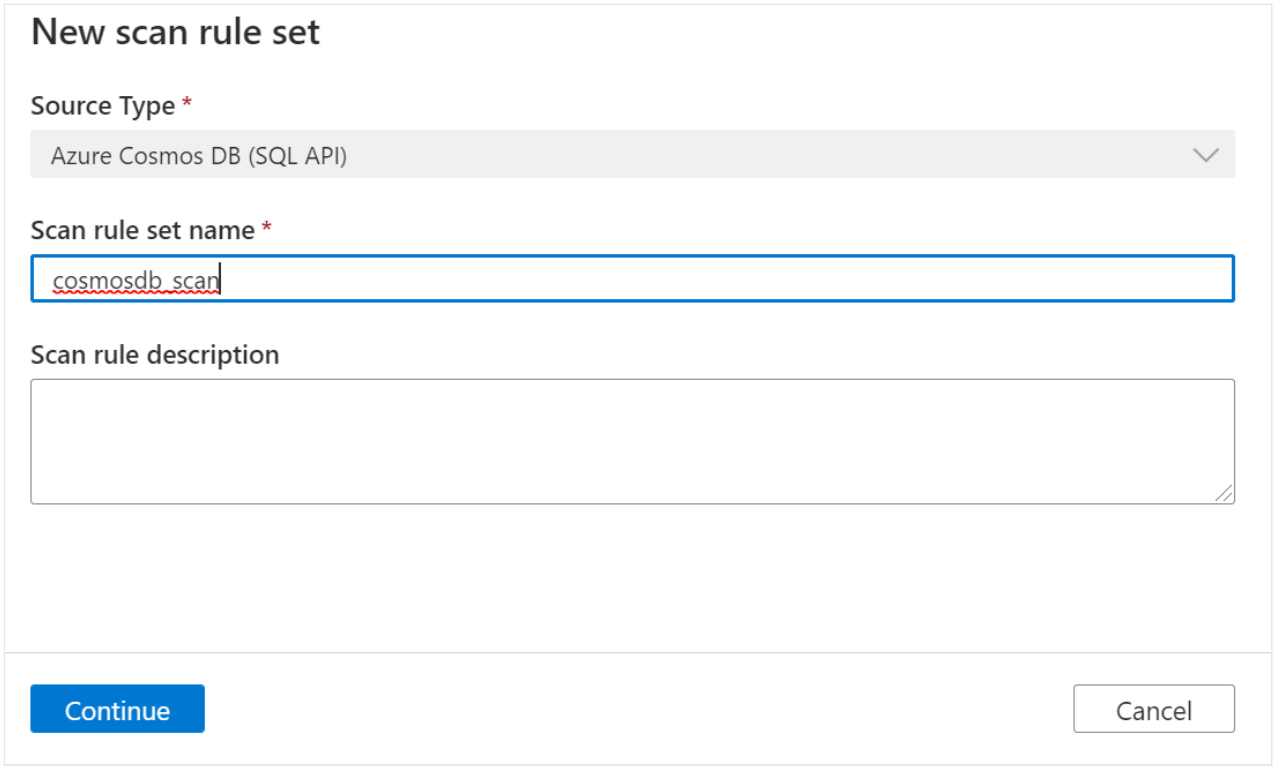
6. Choose the appropriate collection for the scan and select + **New** under **Credential**

7. Select the appropriate **Key vault connection** and the **Secret name** that was used while creating the *Account Key*. Choose **Authentication method** as *Account Key*



8. Select **Test connection**. On a successful connection, select **Continue**





Scoping and running the scan

1. You can scope your scan to specific folders and subfolders by choosing the appropriate items in the list.

2. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

Select a scan rule set
New scan rule set
Refresh
Select one scan rule set to be used by your scan.

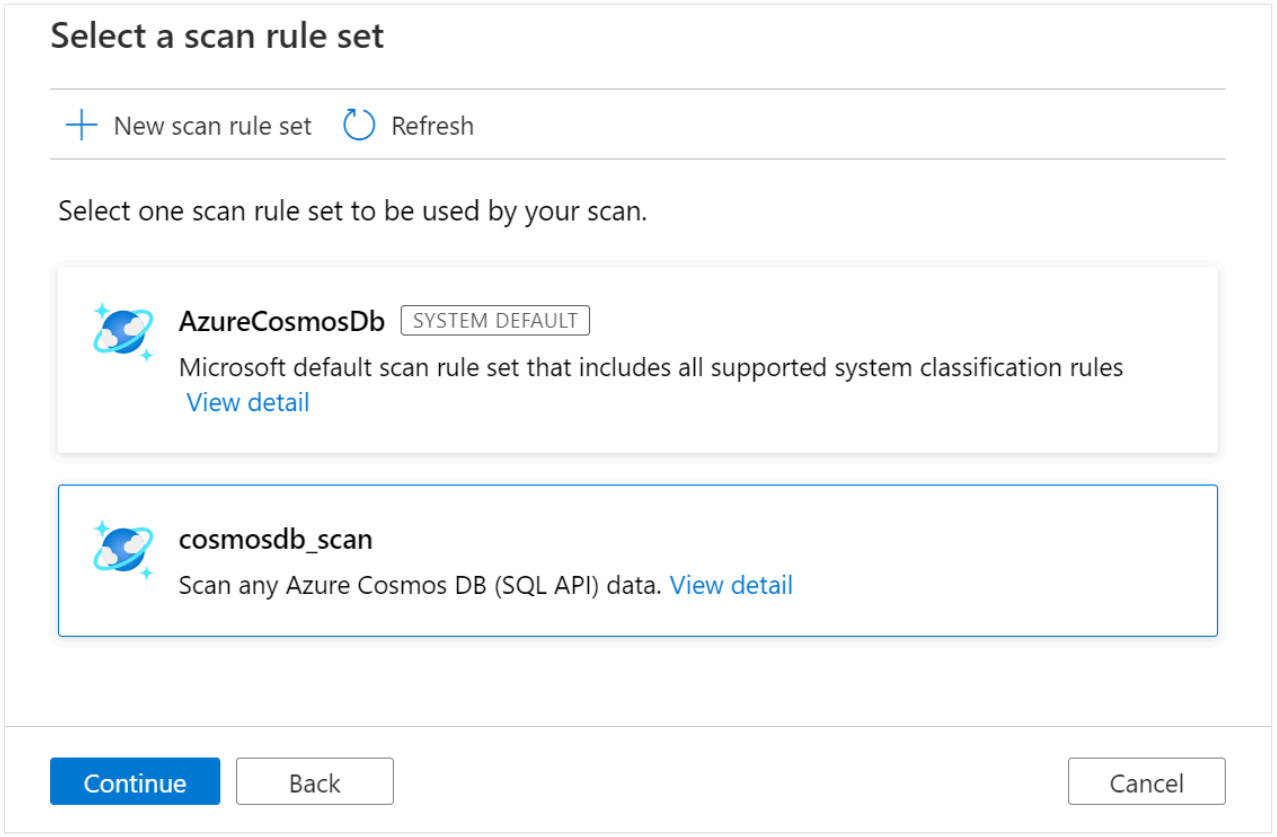
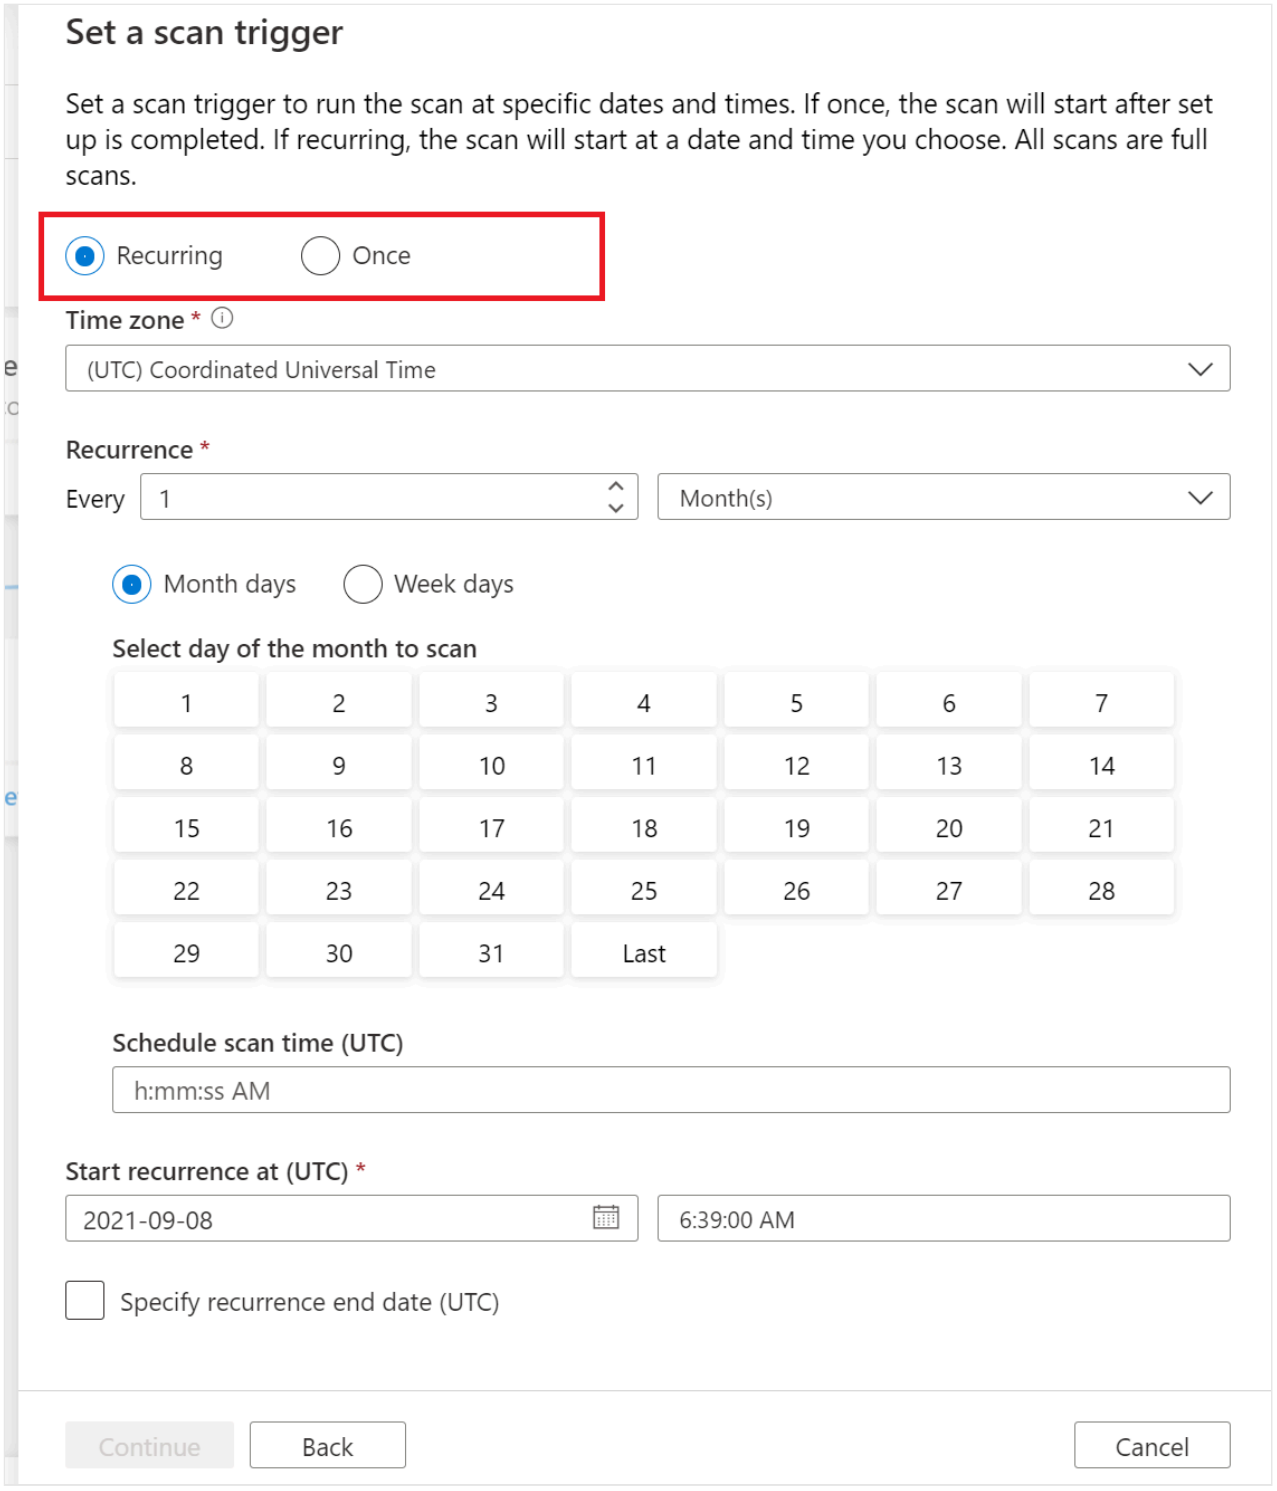
3. You can select the **classification rules** to be included in the scan rule



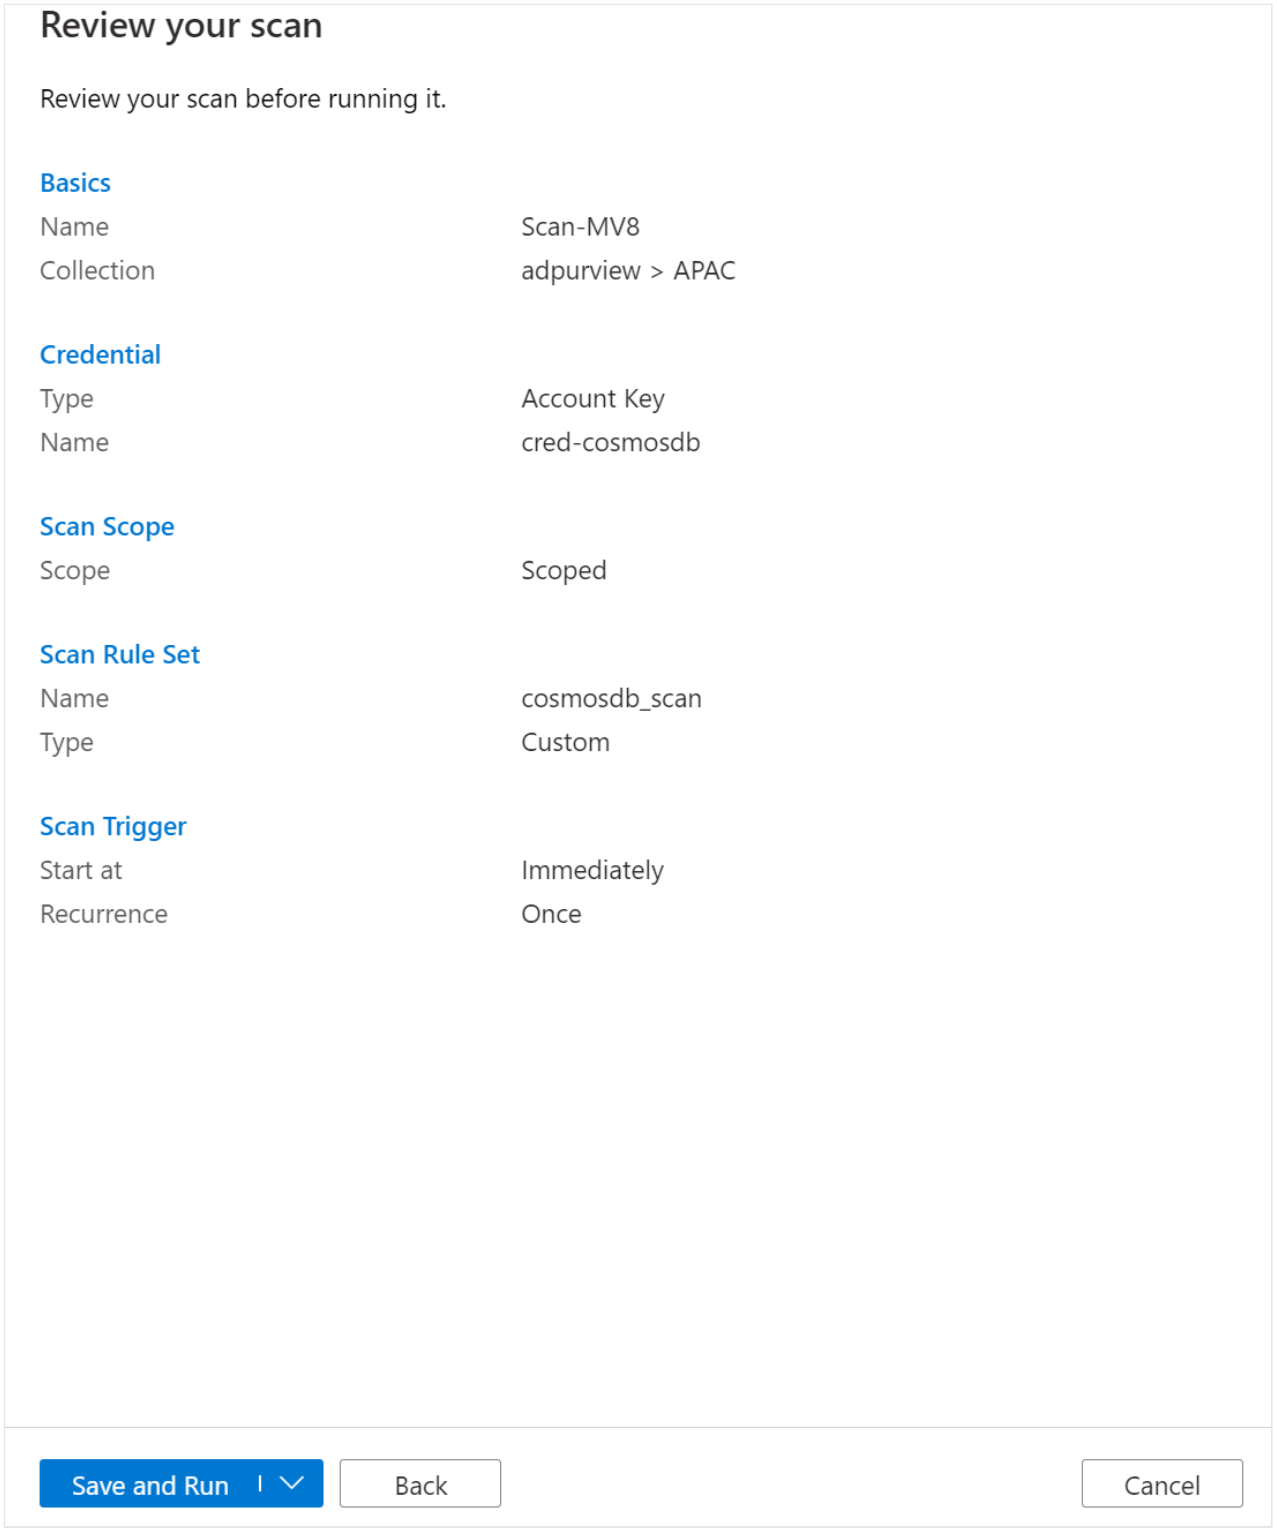
Select classification rules

Choose classification rules that will run on the dataset.



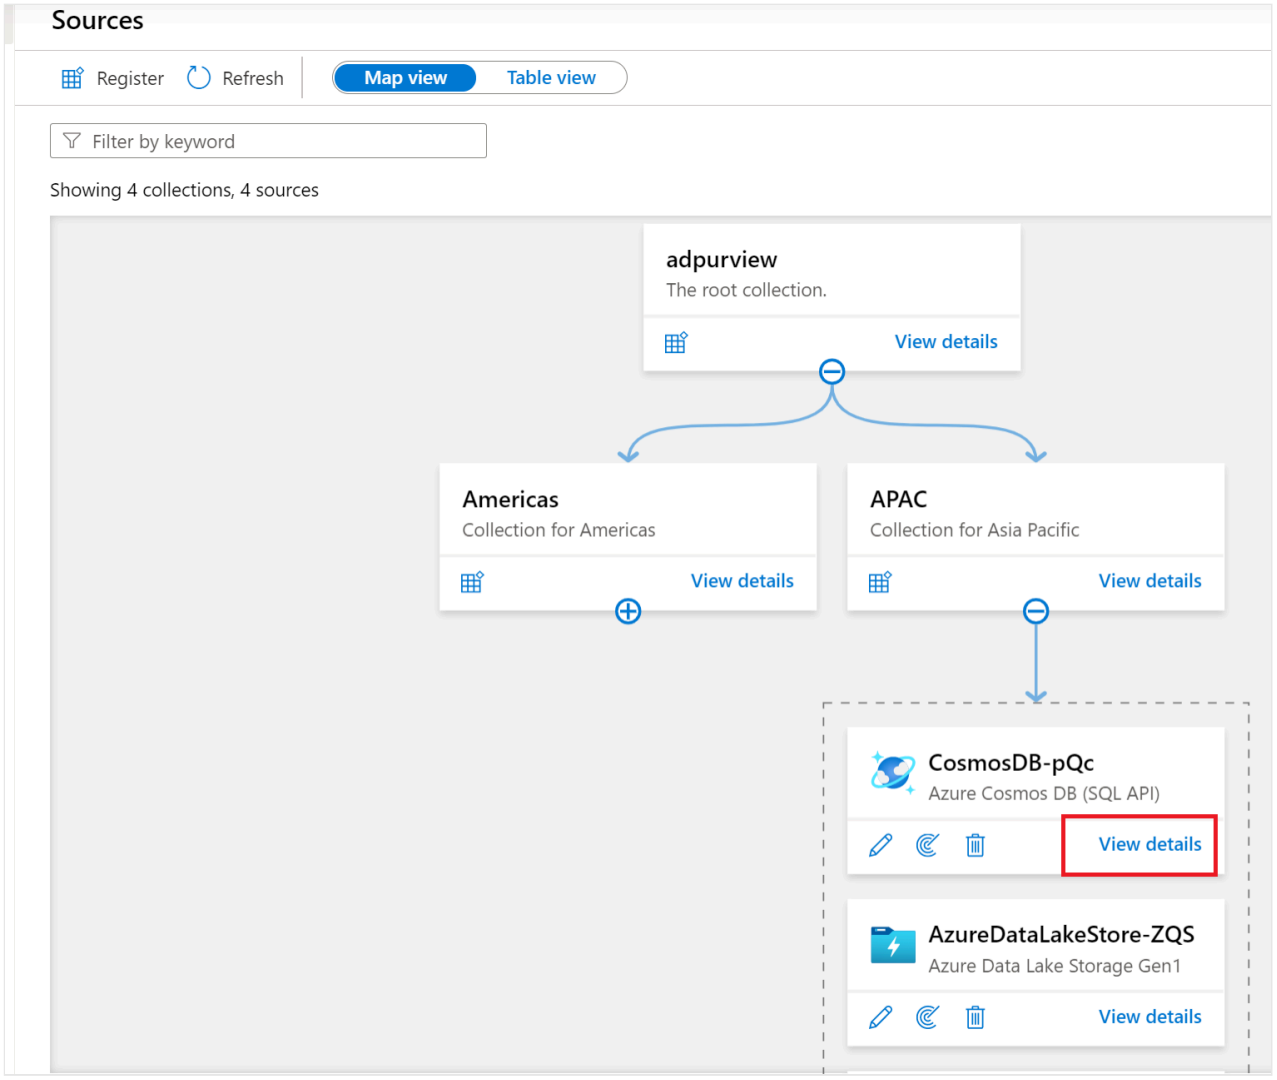
System rules

- [x] Government
- [x] Financial
- [-] Personal
  - [x] Age of an individual
  - [x] Date of Birth
  - [x] Email Address
  - [ ] Ethnic Group
  - [ ] EU GPS Coordinates
  - [ ] EU Mobile Phone Number
  - [ ] EU Phone Number
  - [ ] Geolocation (Lat/Lon)
  - [ ] Japanese My Number – Corporate
  - [ ] Japanese My Number – Personal
  - [ ] Person's Name
  - [x] Personal IP Address
  - [x] U.S. Phone Number
- [x] Security
- [x] Miscellaneous

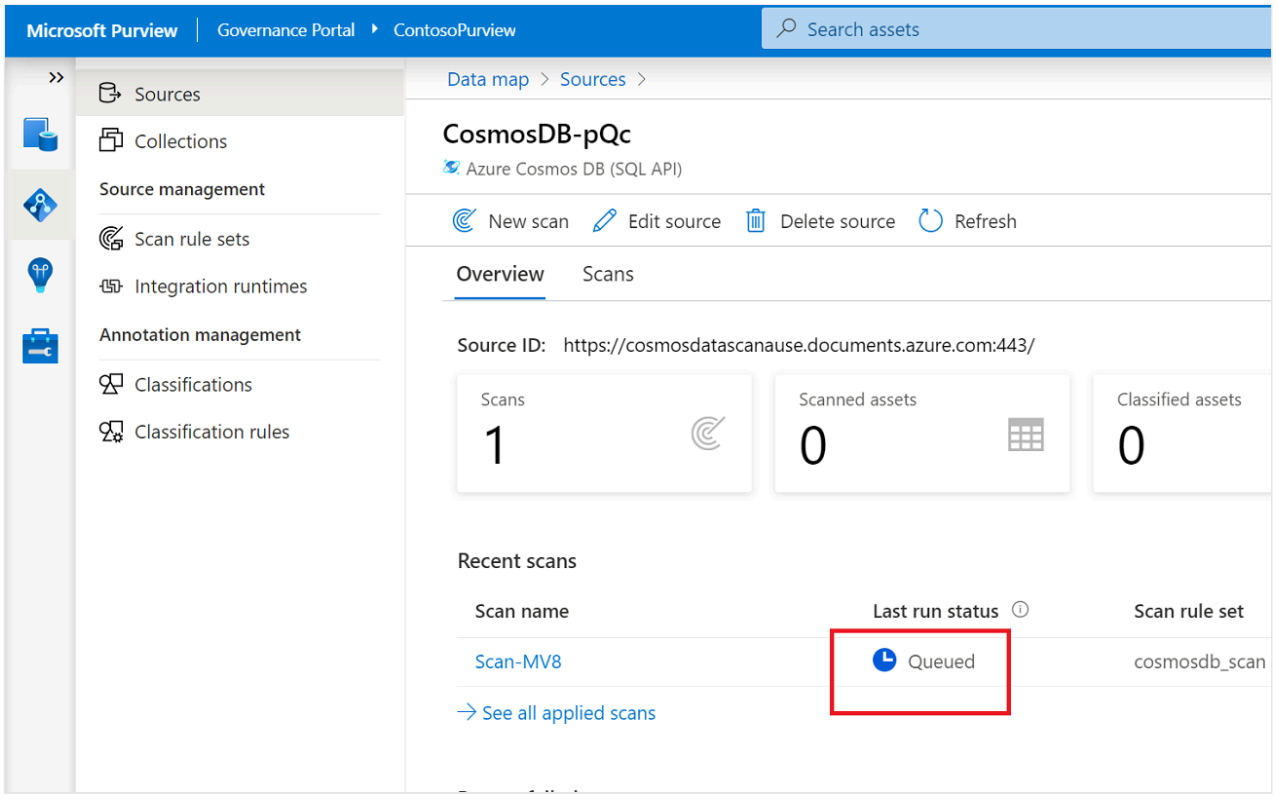


Create | Back | 198 classification rules selected | Cancel

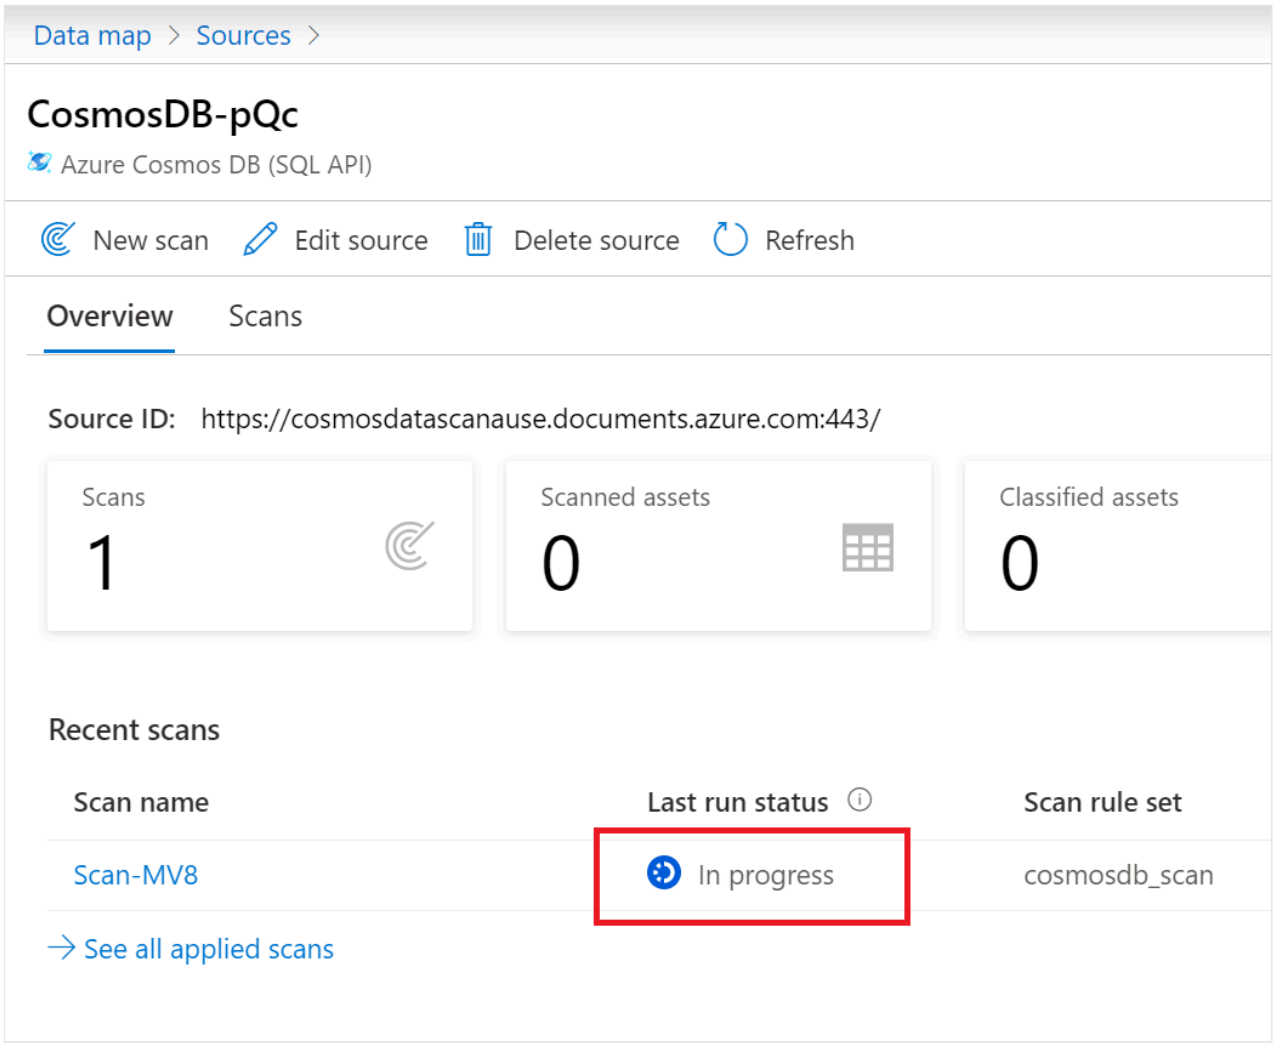
4. Choose your scan trigger. You can set up a schedule or run the scan once.



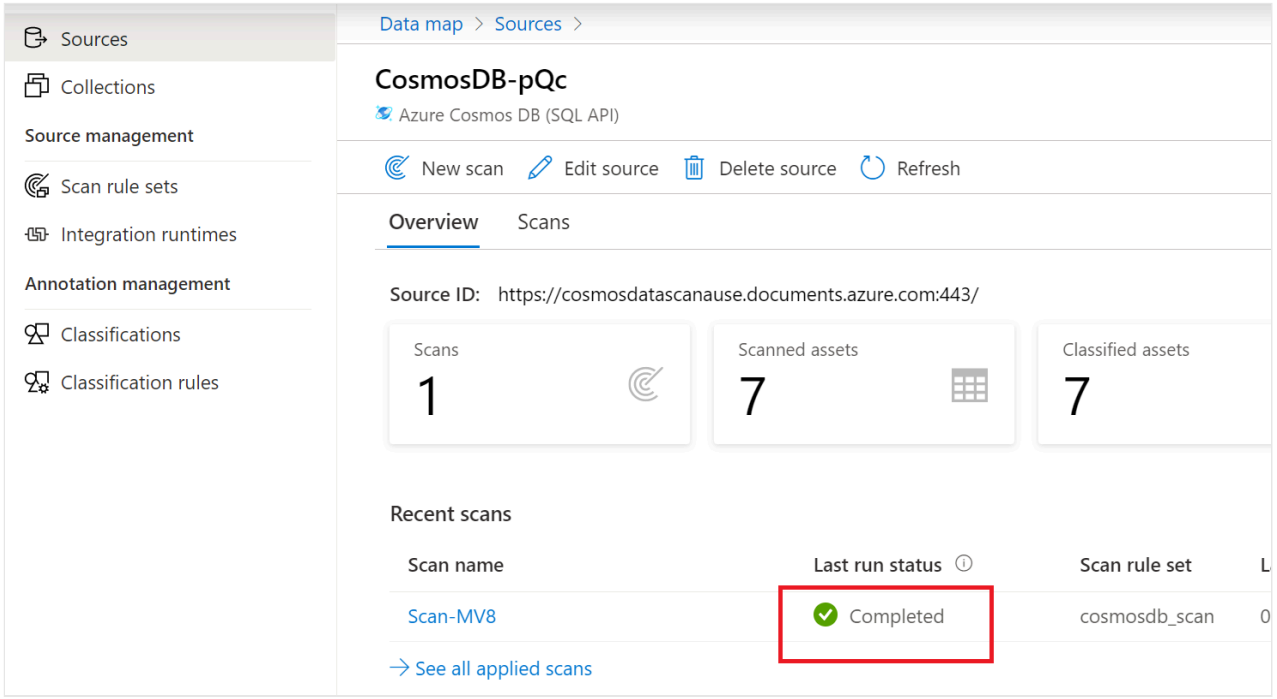
5. Review your scan and select **Save and run**.



Viewing Scan

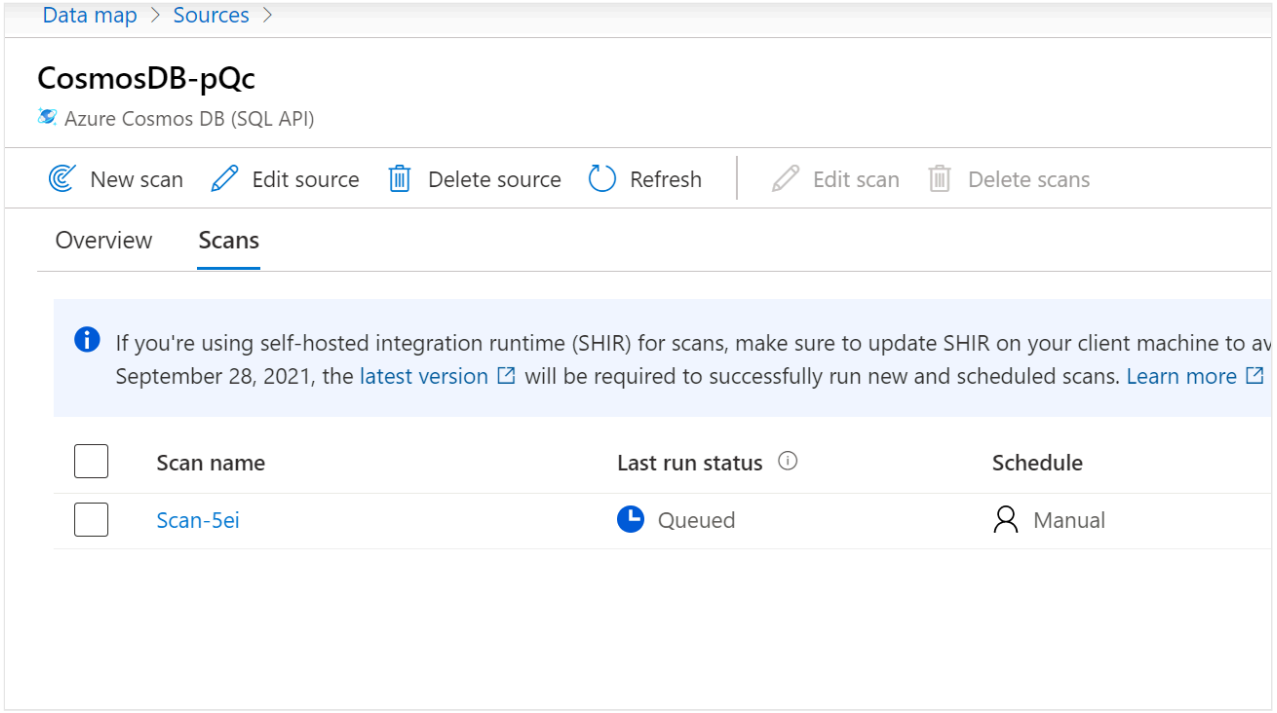


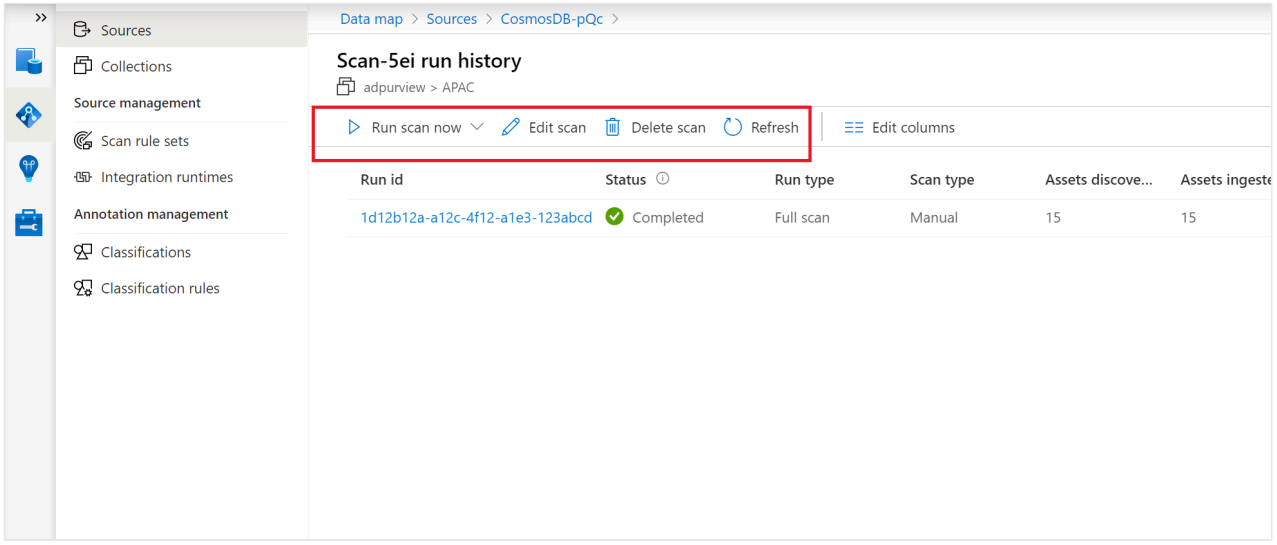
1. Navigate to the *data source* in the *Collection* and select **View Details** to check the status of the scan



2. The scan details indicate the progress of the scan in the **Last run status** and the number of assets *scanned* and *classified*

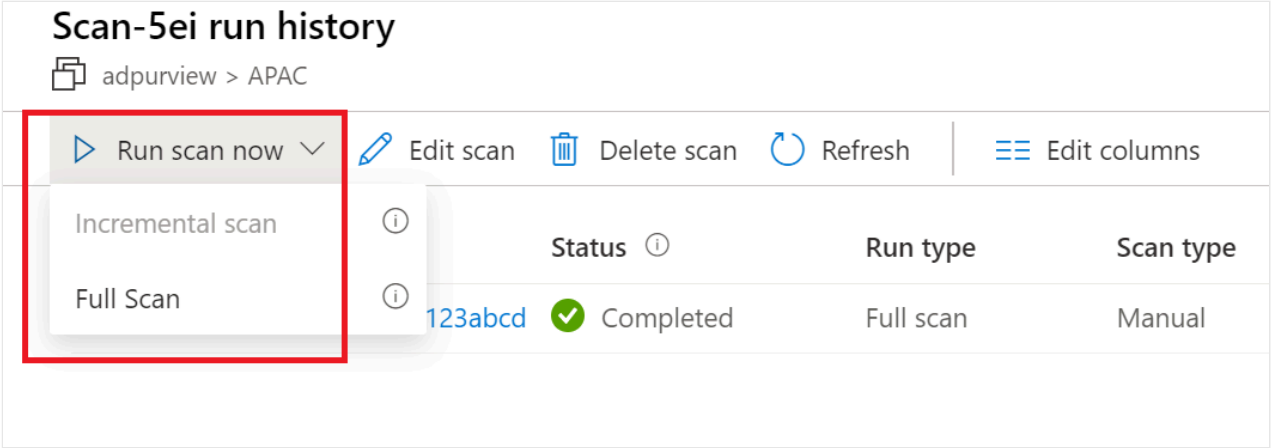
3. The **Last run status** will be updated to **In progress** and then **Completed** once the entire scan has run successfully





Managing Scan

Scans can be managed or run again on completion.



1. Select the **Scan name** to manage the scan

2. You can *run the scan* again, *edit the scan*, *delete the scan*

3. You can run a *Full Scan* again

Next steps

Now that you have registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage Azure Data Explorer in Microsoft Purview

Article • 05/21/2025

This article outlines how to register Azure Data Explorer, and how to authenticate and interact with Azure Data Explorer in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You will need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

Register

This section describes how to register Azure Data Explorer in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

There are several methods available for authentication for Azure Data Explorer:

- Service Principal
- System-assigned managed identity (SAMI)
- User-assigned managed identity (UAMI)

Service Principal to register

To use service principal authentication for scans, you can use an existing one or create a new one.

> **Note**
>
> If you have to create a new Service Principal, please follow these steps:
>
> 1. Navigate to the Azure portal.
> 2. Select **Microsoft Entra ID** from the left-hand side menu.
> 3. Select **App registrations**.
> 4. Select **+ New application registration**.
> 5. Enter a name for the **application** (the service principal name).
> 6. Select **Accounts in this organizational directory only**.
> 7. For Redirect URI select **Web** and enter any URL you want; it doesn't have to be real or work.
> 8. Then select **Register**.

It is required to get the Service Principal's application ID and secret:

1. Navigate to your Service Principal in the Azure portal
2. Copy the values the **Application (client) ID** from **Overview** and **Client secret** from **Certificates & secrets**.
3. Navigate to your key vault
4. Select **Settings** > **Secrets**
5. Select **+ Generate/Import** and enter the **Name** of your choice and **Value** as the **Client secret** from your Service Principal
6. Select **Create** to complete
7. If your key vault is not connected to Microsoft Purview yet, you will need to create a new key vault connection
8. Finally, create a new credential using the Service Principal to set up your scan

Granting the Service Principal access to your Azure data explorer instance

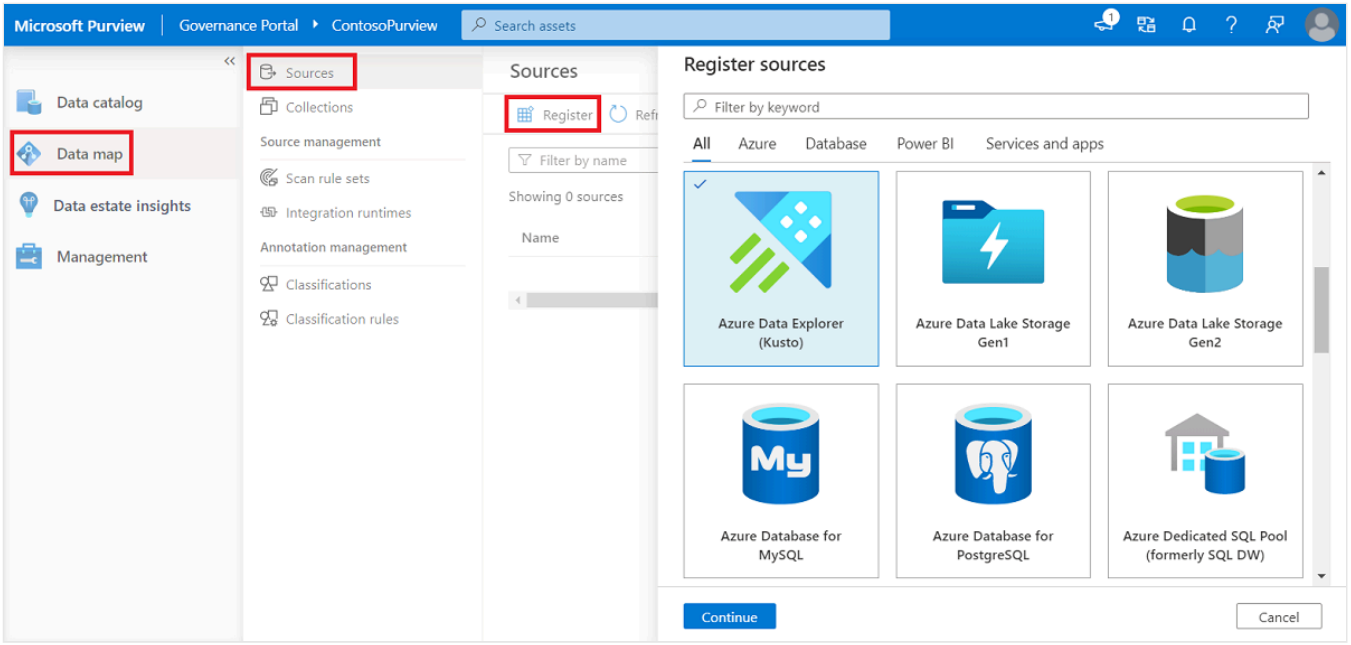
1. Navigate to the Azure portal. Then navigate to your Azure data explorer instance.
2. Add the service principal to the **AllDatabasesViewer** role in the **Permissions** tab.

System or user assigned managed identity to register

- **System-assigned managed identity** - As soon as the Microsoft Purview Account is created, a system-assigned managed identity (SAMI) is created automatically in Microsoft Entra tenant. It has the same name as your Microsoft Purview account.
- **User-assigned managed identity** (preview) - Similar to a system-managed identity, a user-assigned managed identity (UAMI) is a credential resource that can be used to allow Microsoft Purview to authenticate against Microsoft Entra ID. For more information, you can see our User-assigned managed identity guide.

To register using either of these managed identities, follow these steps:

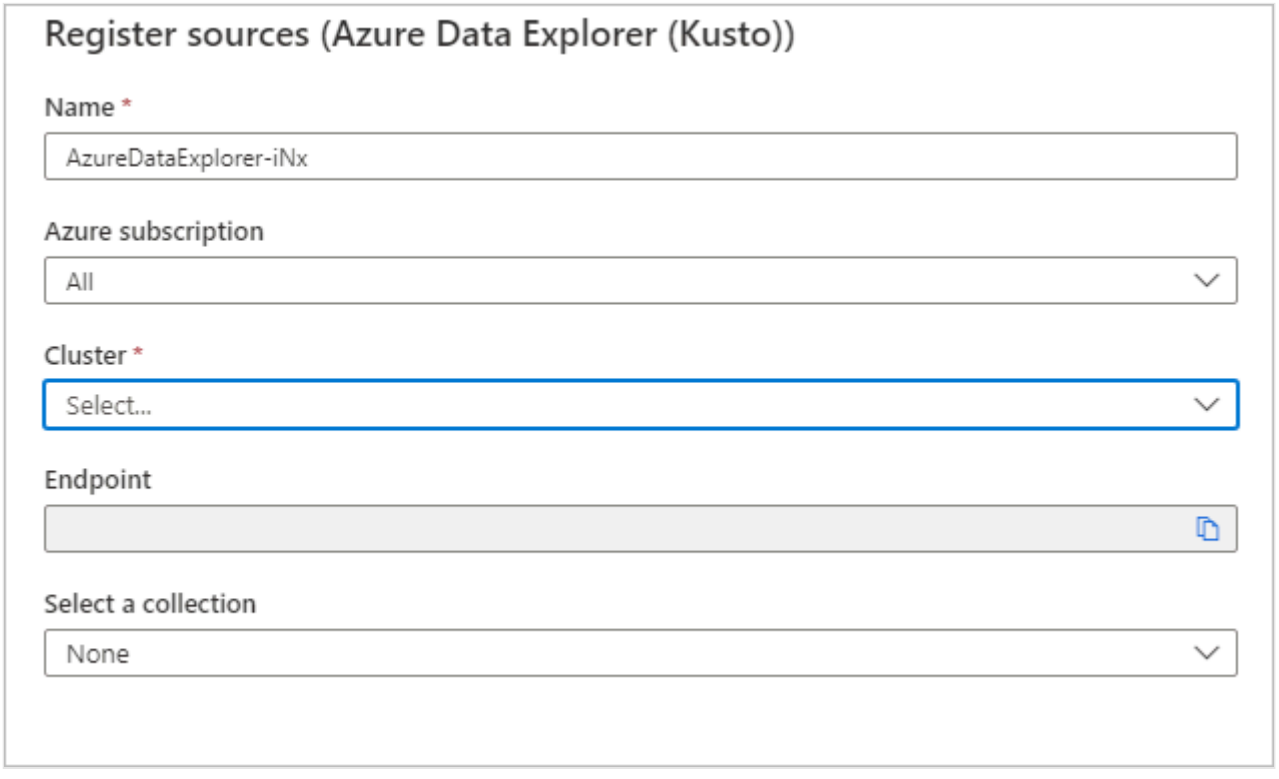
1. If you would like to use a user-assigned managed identity and have not created one, follow the steps to create the identity in the User-assigned managed identity guide.
2. Navigate to the Azure portal. Then navigate to your Azure data explorer instance.
3. Select the **Permissions** tab on the left pane.
4. Add the SAMI or UAMI to the **AllDatabasesViewer** role in the **Permissions** tab.



Steps to register

To register a new Azure Data Explorer (Kusto) account in Microsoft Purview Unified Catalog, follow these steps:

1. Open the Microsoft Purview governance portal by:
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.
2. Select **Data Map** on the left navigation.
3. Select **Register**

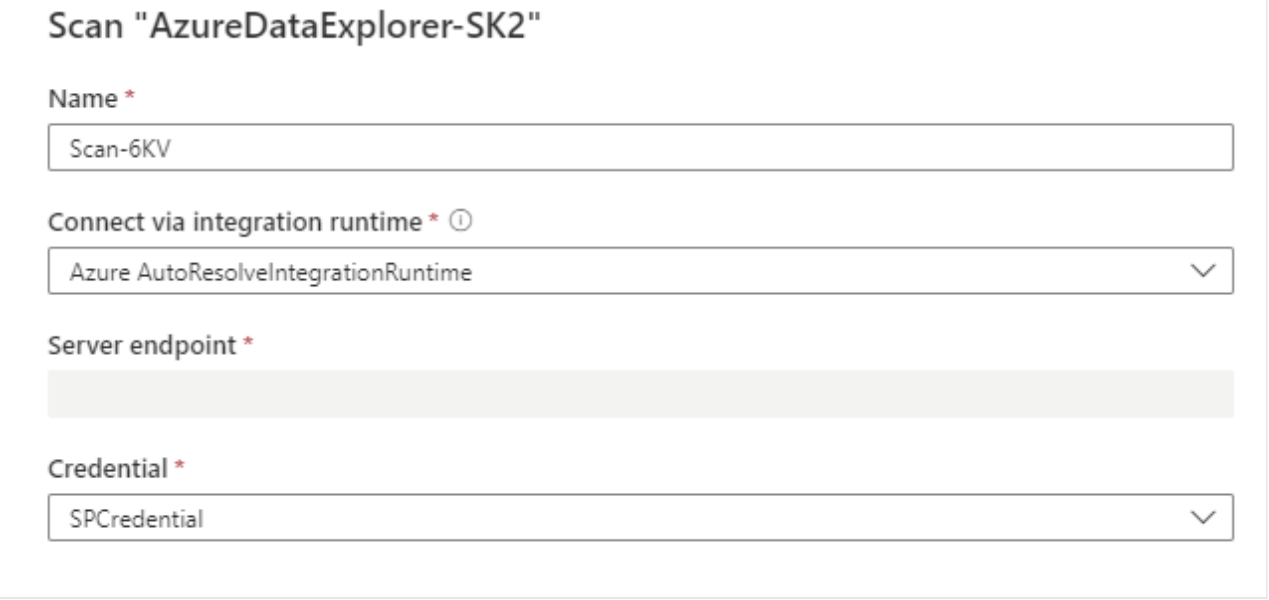


4. On **Register sources**, select **Azure Data Explorer**

5. Select **Continue**

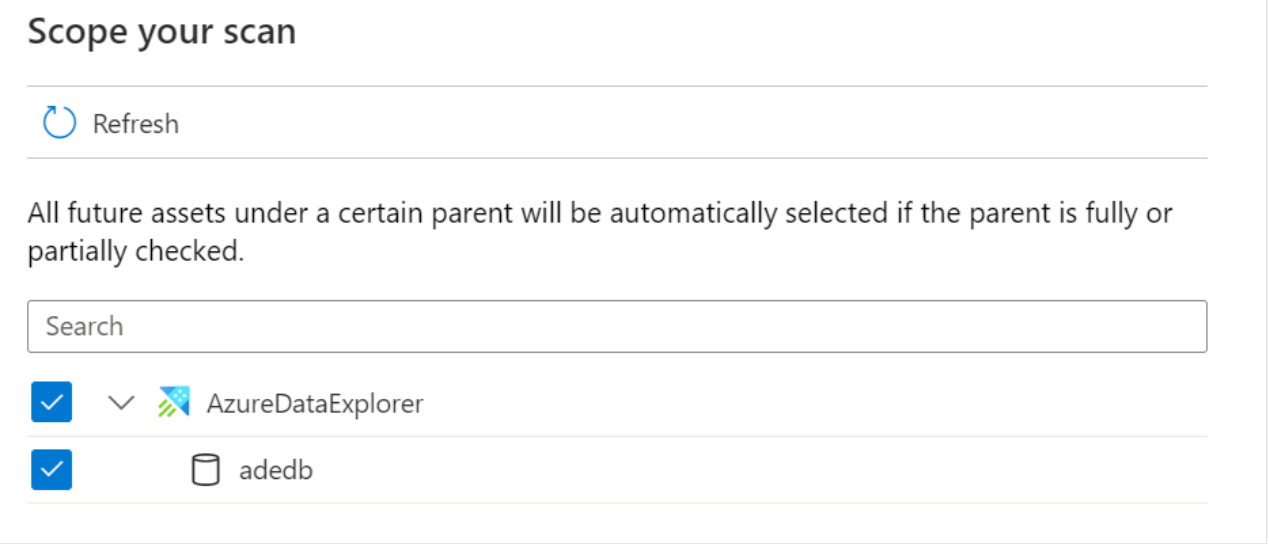
On the **Register sources (Azure Data Explorer (Kusto))** screen, do the following:

1. Enter a **Name** that the data source will be listed with in the Catalog.
2. Choose your Azure subscription to filter down Azure Data Explorer.
3. Select an appropriate cluster.
4. Select a collection from the list.
5. Select **Register** to register the data source.



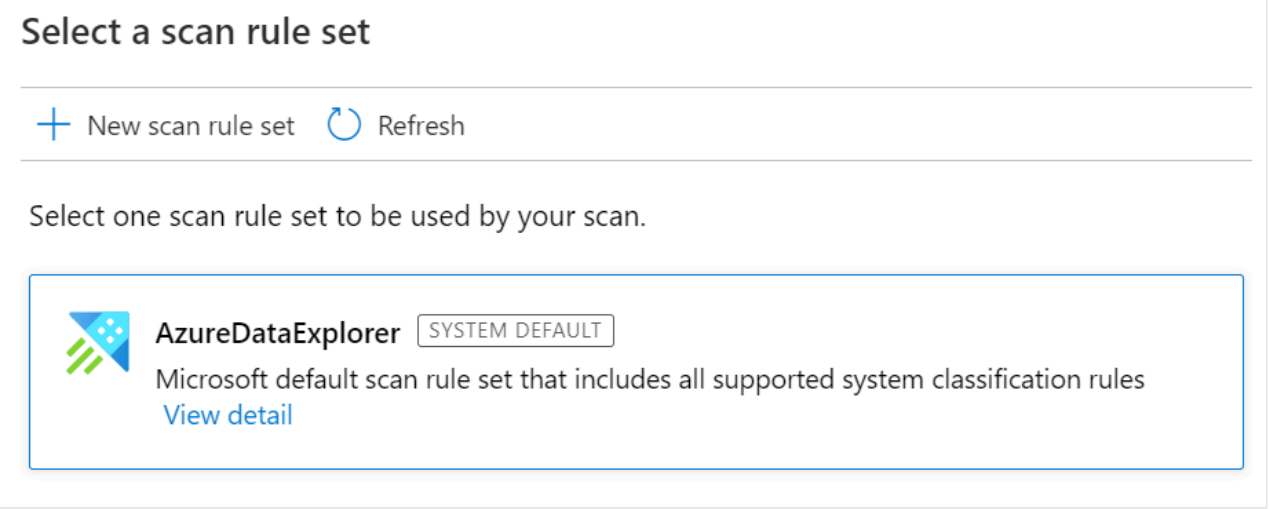
Scan

Follow the steps below to scan Azure Data Explorer to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion.

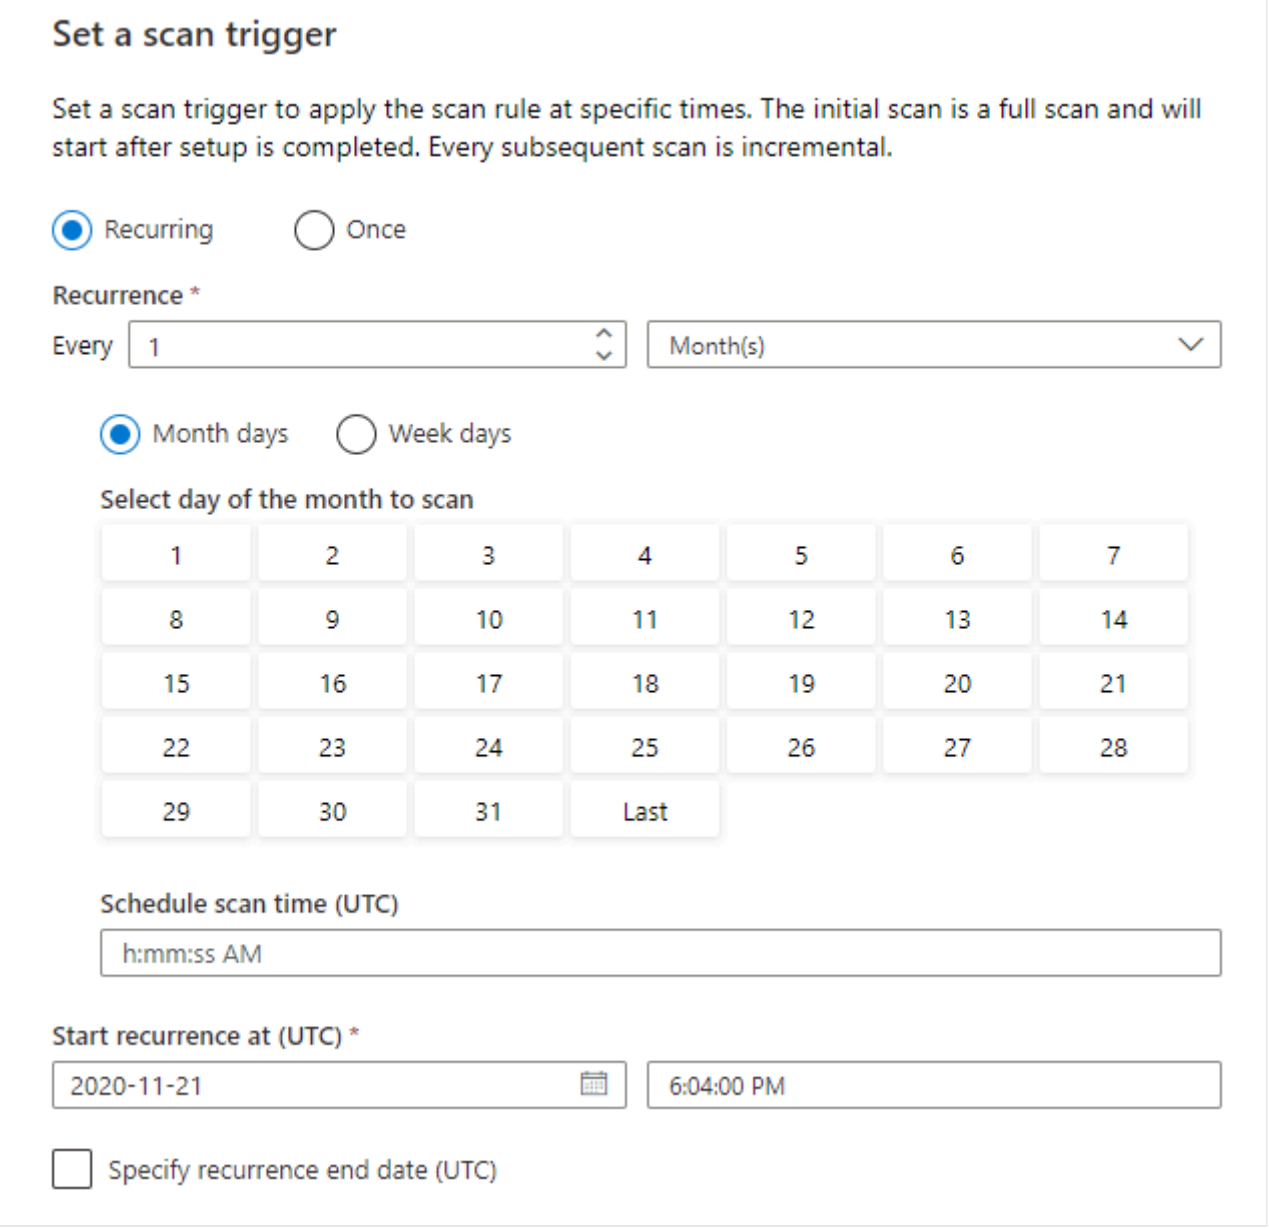


Create and run scan

To create and run a new scan, follow these steps:



1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.
2. Select the Azure Data Explorer source that you registered.
3. Select **New scan**
4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.
5. Select the credential to connect to your data source.



6. You can scope your scan to specific databases by choosing the appropriate items in the list.

7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you have registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to Azure Data Lake Storage in Microsoft Purview

Article • 05/21/2025

This article outlines the process to register and govern an Azure Data Lake Storage (ADLS Gen2) data source in Microsoft Purview, including instructions to authenticate and interact with the ADLS Gen2 source.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

When scanning Azure Data Lake Storage Gen2 source, Microsoft Purview supports extracting technical metadata including:

- Storage account
- Data Lake Storage Gen2 Service
- File system (container)
- Folders
- Files
- Resource sets

When setting up scan, you can choose to scan the entire ADLS Gen2 or selective folders. Learn about the supported file format here.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

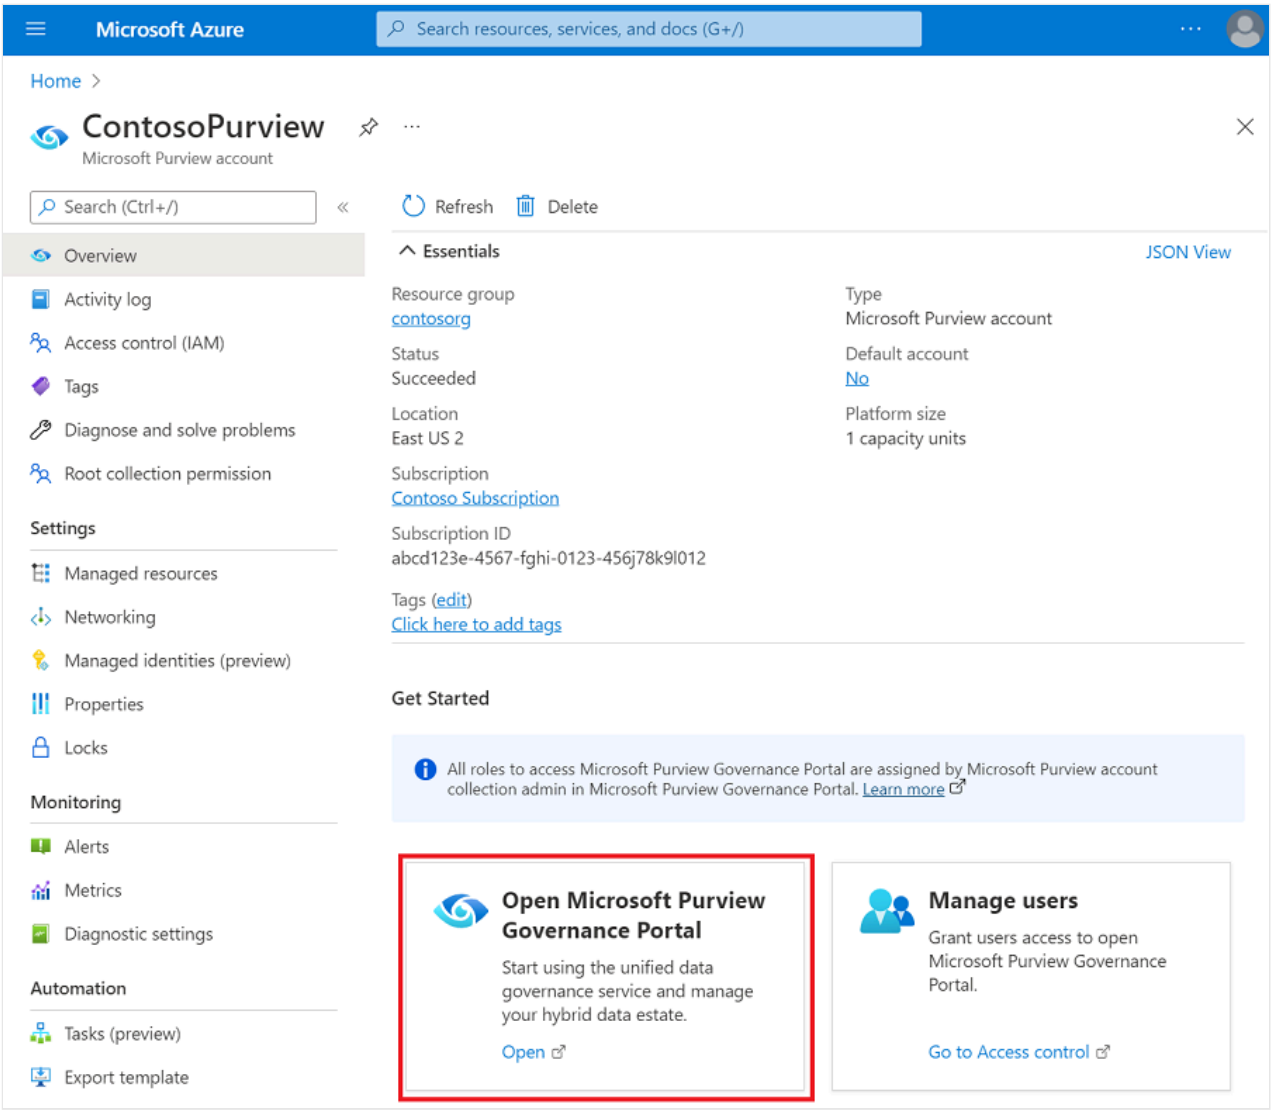
Prerequisites

- An Azure account with an active subscription. Create an account for free.

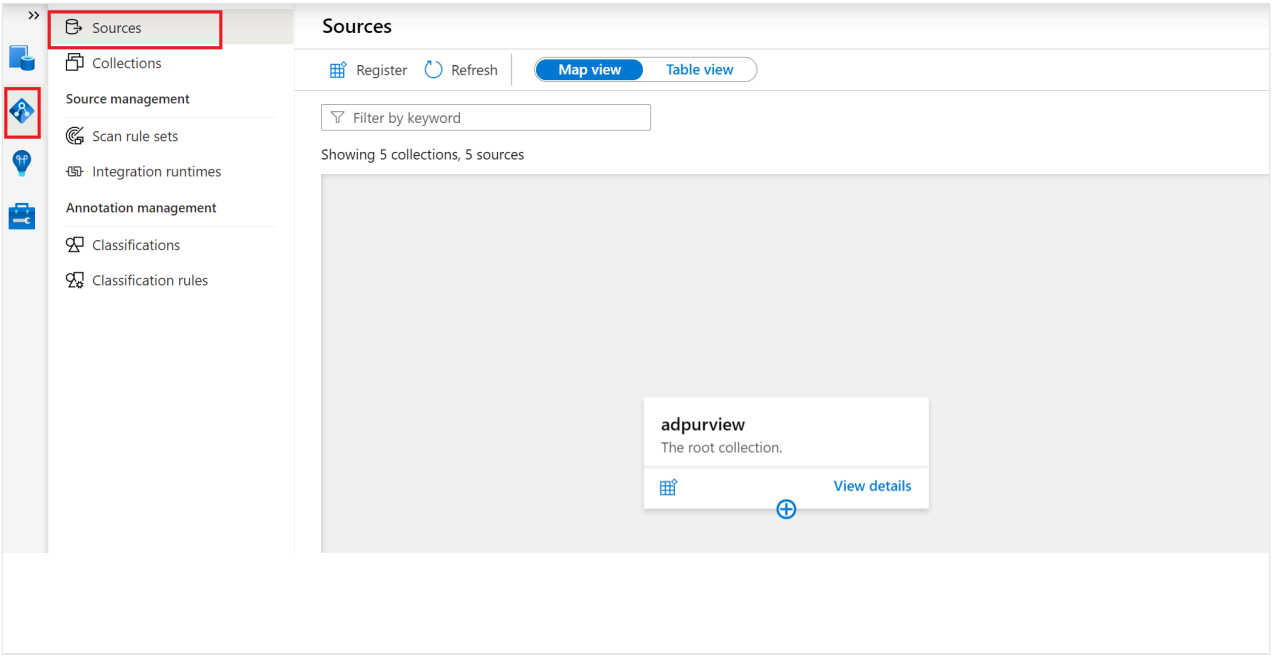
- An active Microsoft Purview account.
- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.
- You need to have at least Reader permission on the ADLS Gen 2 account to be able to register it.

Register

This section will enable you to register the ADLS Gen2 data source for scan and data share in Purview.

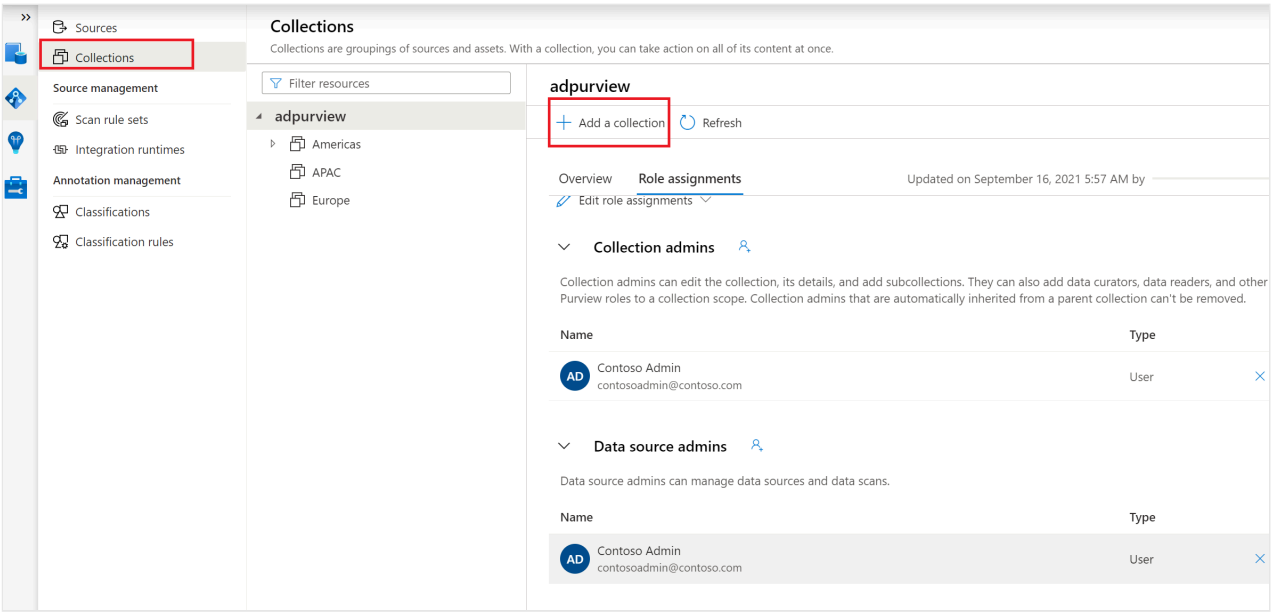


Prerequisites for register



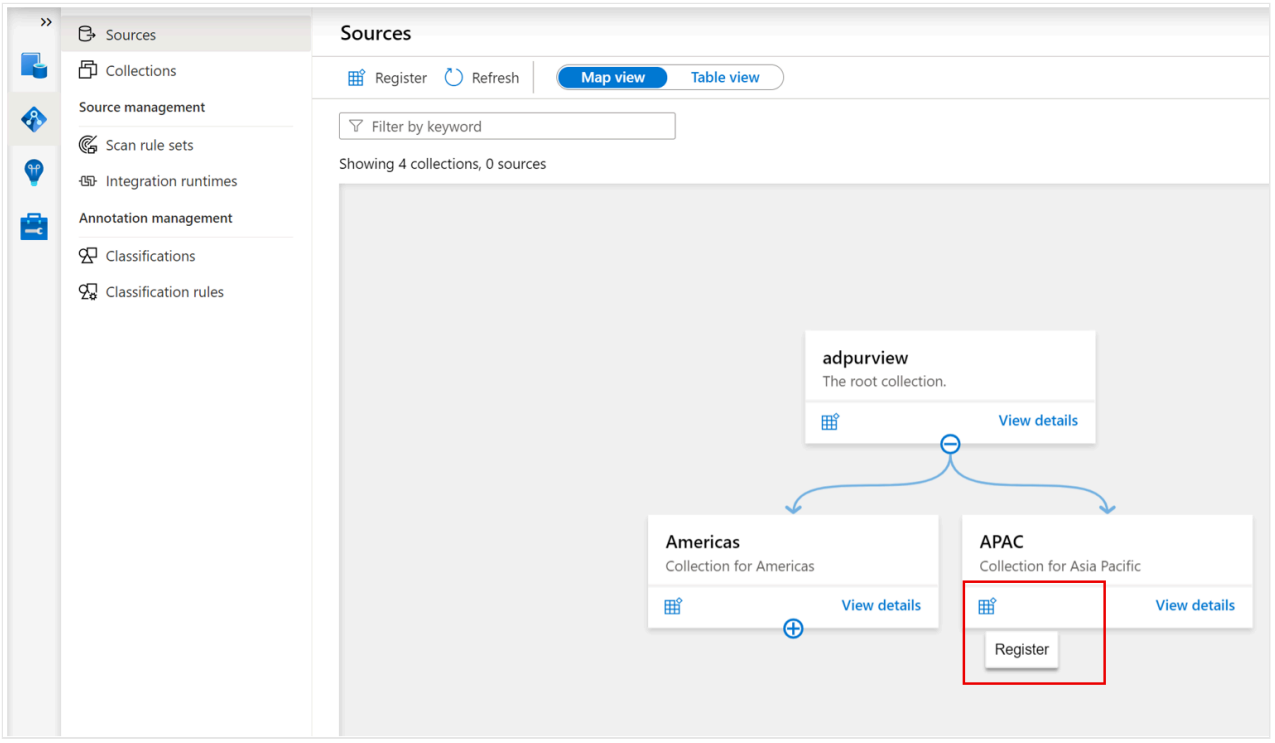
- You'll need to be a Data Source Admin and one of the other Purview roles (for example, Data Reader or Data Share Contributor) to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

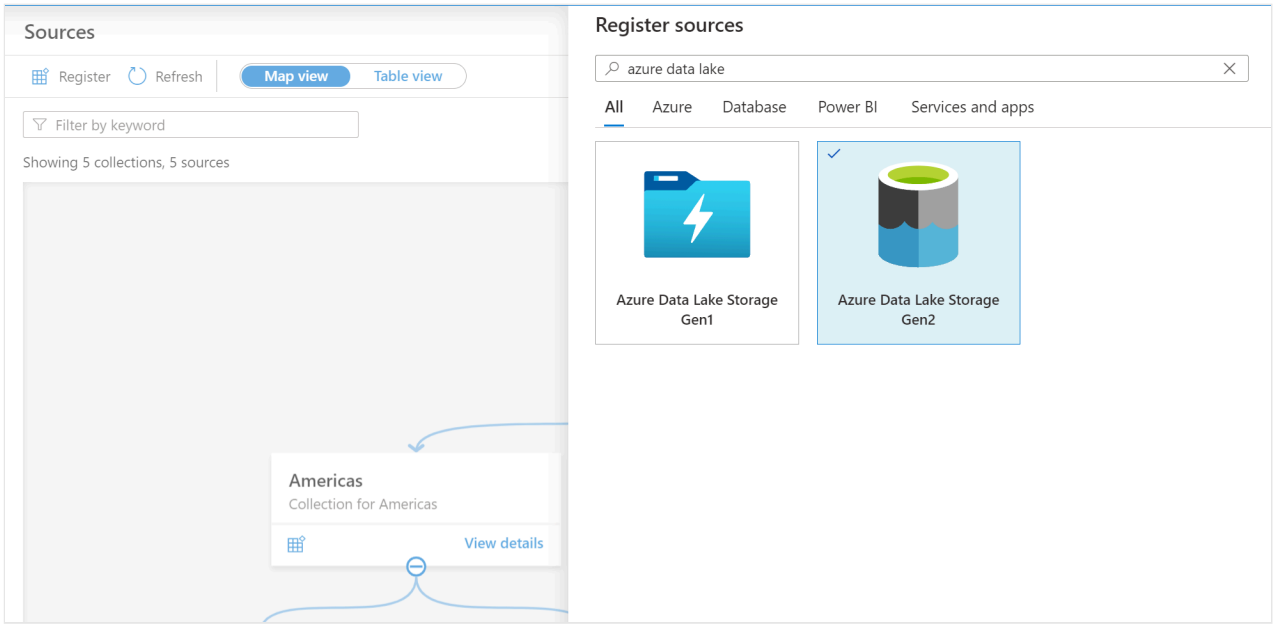
Steps to register



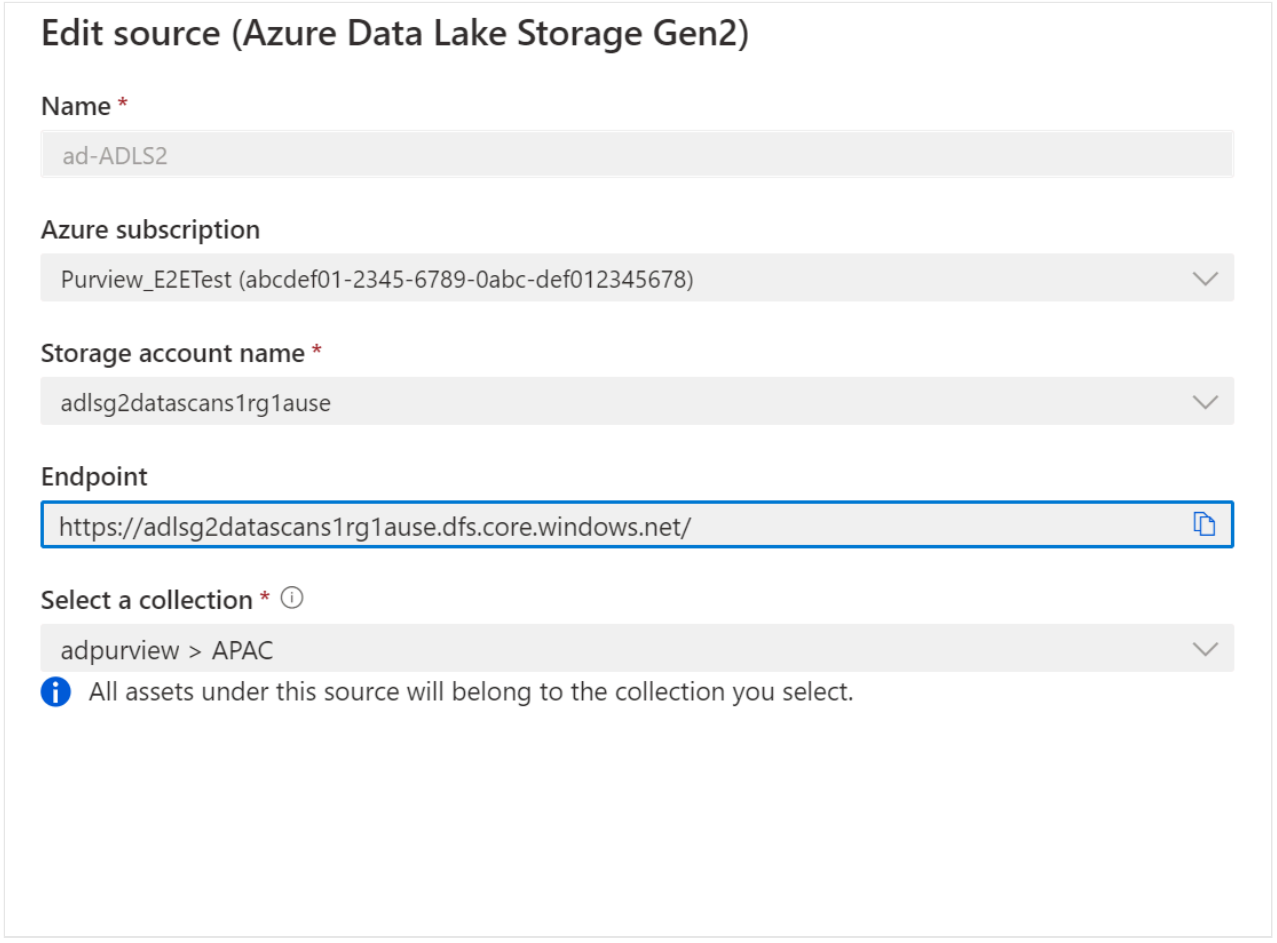
It's important to register the data source in Microsoft Purview prior to setting up a scan for the data source.

1. Go to the Microsoft Purview governance portal by:
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.
2. Navigate to the **Data Map --> Sources**

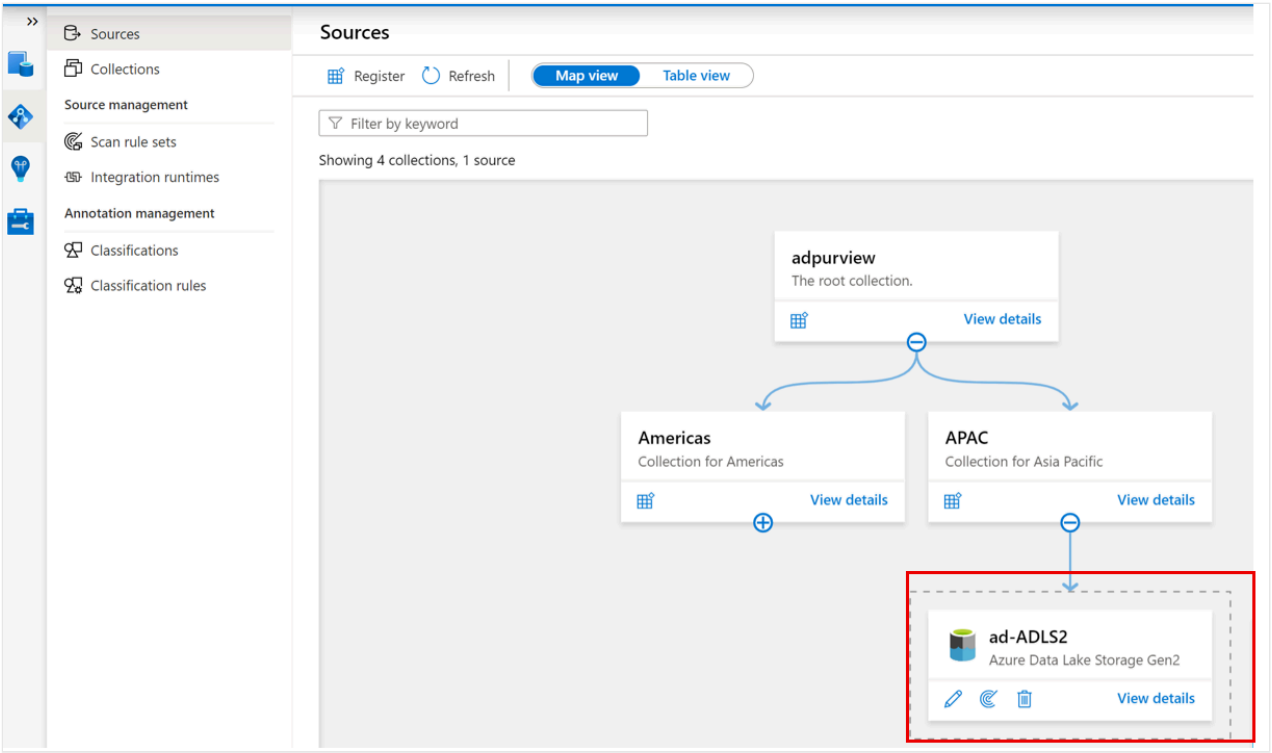




3. Create the Collection hierarchy using the **Collections** menu and assign permissions to individual subcollections, as required



4. Navigate to the appropriate collection under the **Sources** menu and select the **Register** icon to register a new ADLS Gen2 data source



5. Select the **Azure Data Lake Storage Gen2** data source and select **Continue**

6. Provide a suitable **Name** for the data source, select the relevant **Azure subscription**, existing **Data Lake Store account name** and the **collection** and select **Apply**. Leave the **Data Policy Enforcement** toggle on the **disabled** position until you have a chance to carefully go over this document.

7. The ADLS Gen2 storage account will be shown under the selected Collection

Scan

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have properly set up authentication for scanning
> 2. Review our scan troubleshooting documentation.

Authentication for a scan

Your Azure network may allow for communications between your Azure resources, but if you've set up firewalls, private endpoints, or virtual networks within Azure, you'll need to follow one of these configurations below.

Expand table

Networking constraints	Integration runtime type	Available credential types
No private endpoints or firewalls	Azure IR	Managed identity (Recommended), service principal, or account key
Firewall enabled but no private endpoints	Azure IR	Managed identity

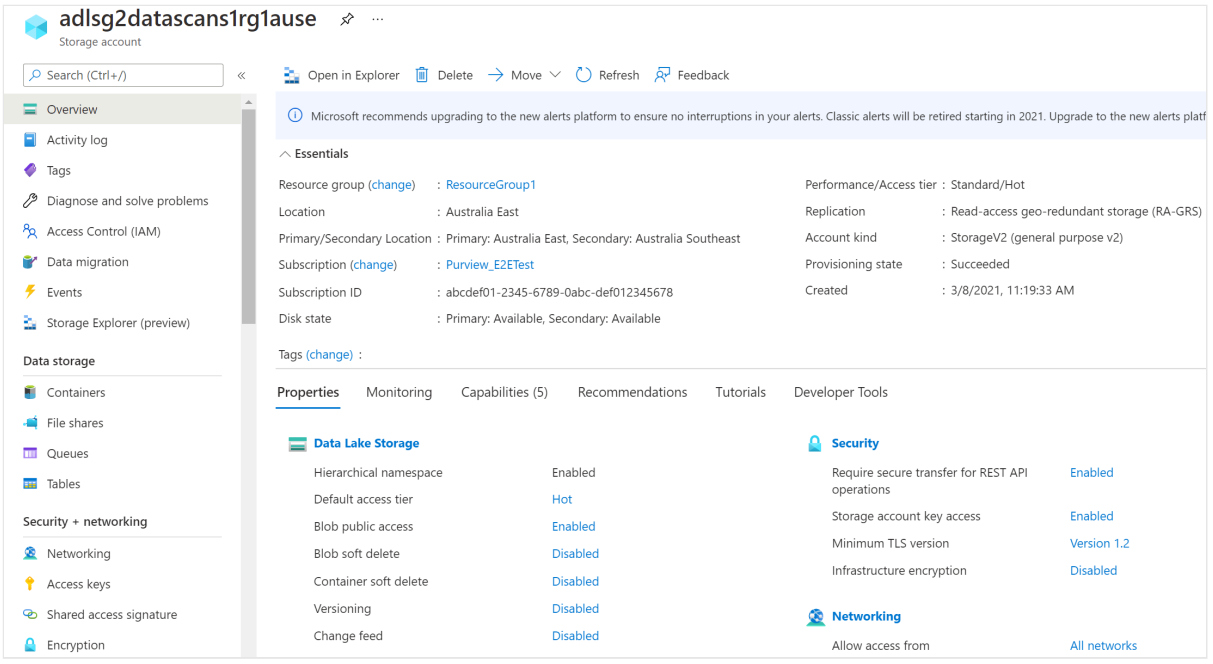
Networking constraints	Integration runtime type	Available credential types
Private endpoints enabled	*Self-Hosted IR	Service principal, account key

> **Important**
>
> 1. *To use a self-hosted integration runtime, you'll first need to choose the right one for your scenario, create one, and confirm your network settings for Microsoft Purview.
> 2. If you use the Self-Hosted Integration runtime to scan parquet files, you need to install the **64-bit JRE 8 (Java Runtime Environment) or OpenJDK** on your IR machine. You can check our Java Runtime Environment installation guide.

System or user assigned managed identity

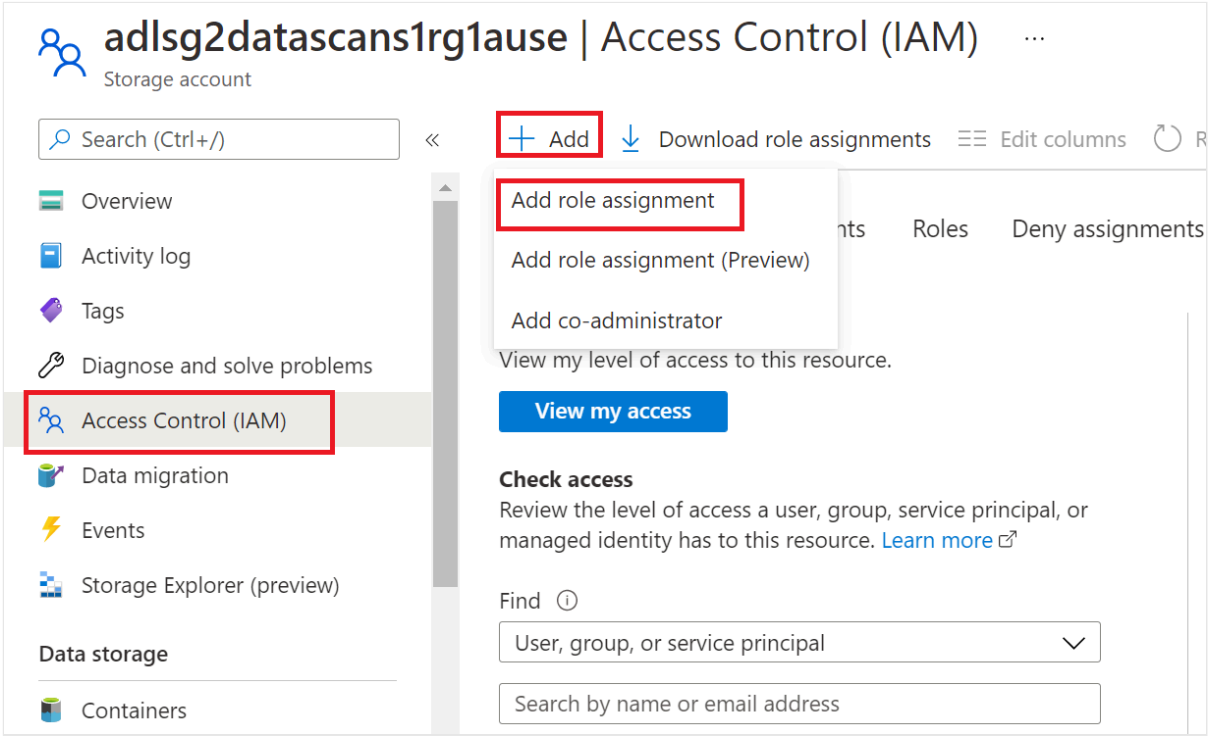
Using a system or user assigned managed identity for scanning

There are two types of managed identity you can use:



- **System-assigned managed identity (Recommended)** - As soon as the Microsoft Purview Account is created, a system-assigned managed identity (SAMI) is created automatically in Microsoft Entra tenant. Depending on the type of resource, specific RBAC role assignments are required for the Microsoft Purview system-assigned managed identity (SAMI) to perform the scans.
- **User-assigned managed identity** (preview) - Similar to a system managed identity, a user-assigned managed identity (UAMI) is a credential resource that can be used to allow Microsoft Purview to authenticate against Microsoft Entra ID. For more information, you can see our User-assigned managed identity guide.

It's important to give your Microsoft Purview account or user-assigned managed identity (UAMI) the permission to scan the ADLS Gen2 data source. You can add your Microsoft Purview account's system-assigned managed identity (which has the same name as your Microsoft Purview account) or UAMI at the Subscription, Resource Group, or Resource level, depending on what level scan permissions are needed.



> **Note**

You need to be an owner of the subscription to be able to add a managed identity on an Azure resource.

1. From the Azure portal, find either the subscription, resource group, or resource (for example, an Azure Data Lake Storage Gen2 storage account) that you would like to allow the catalog to scan.

2. Select **Access Control (IAM)** in the left navigation and then select **+ Add** --> **Add role assignment**

3. Set the **Role** to **Storage Blob Data Reader** and enter your *Microsoft Purview account name* or *user-assigned managed identity* under the **Select** input box. Then, select

Save to give this role assignment to your Microsoft Purview account.

Add role assignment

Role ⓘ

Storage Blob Data Reader ⓘ

Assign access to ⓘ

User, group, or service principal

Select ⓘ

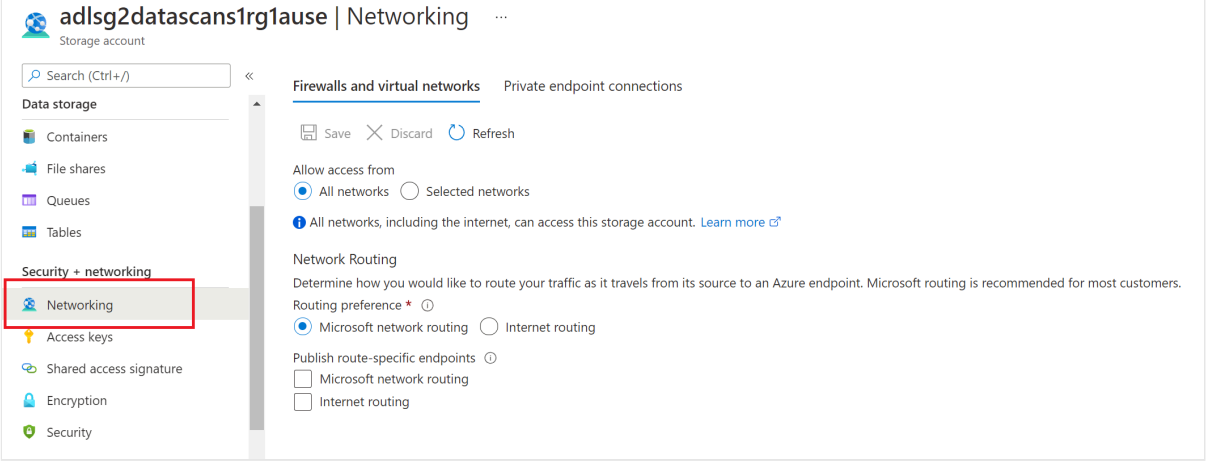
adpurview

No users, groups, or service principals found.

Selected members:

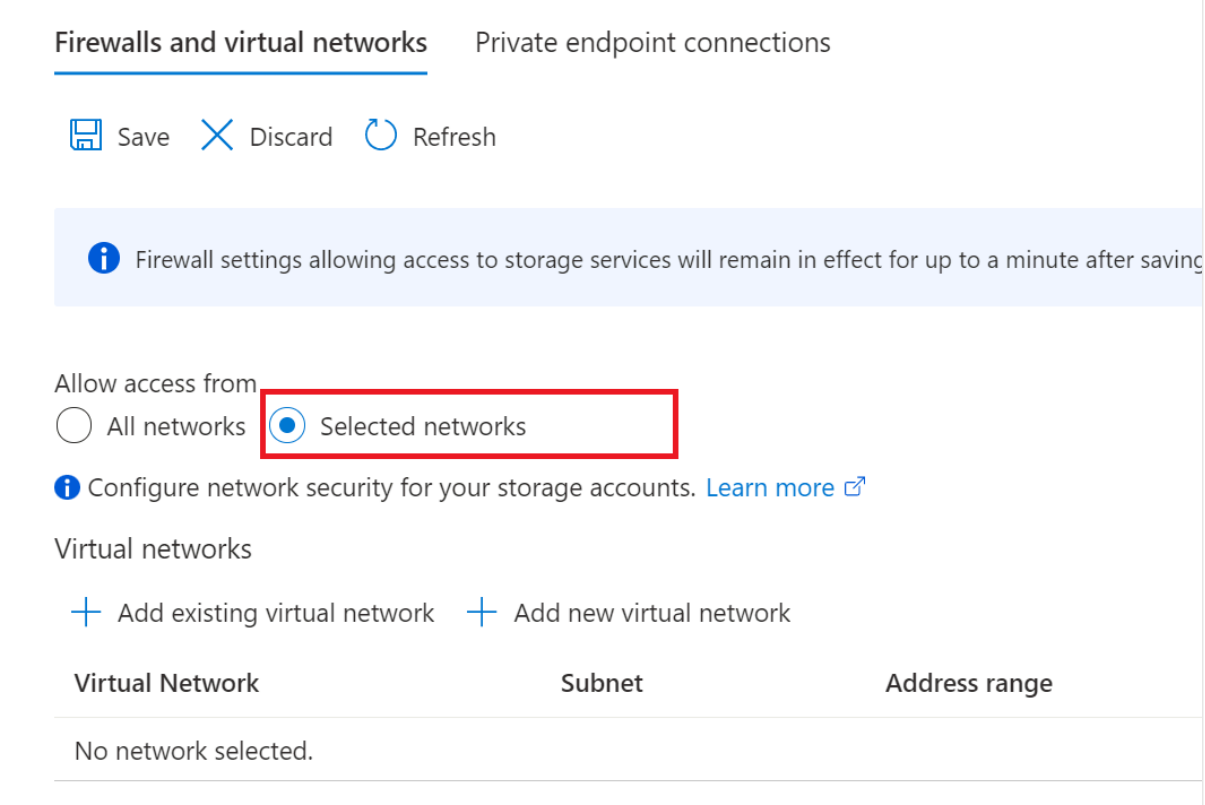
adpurview

Remove



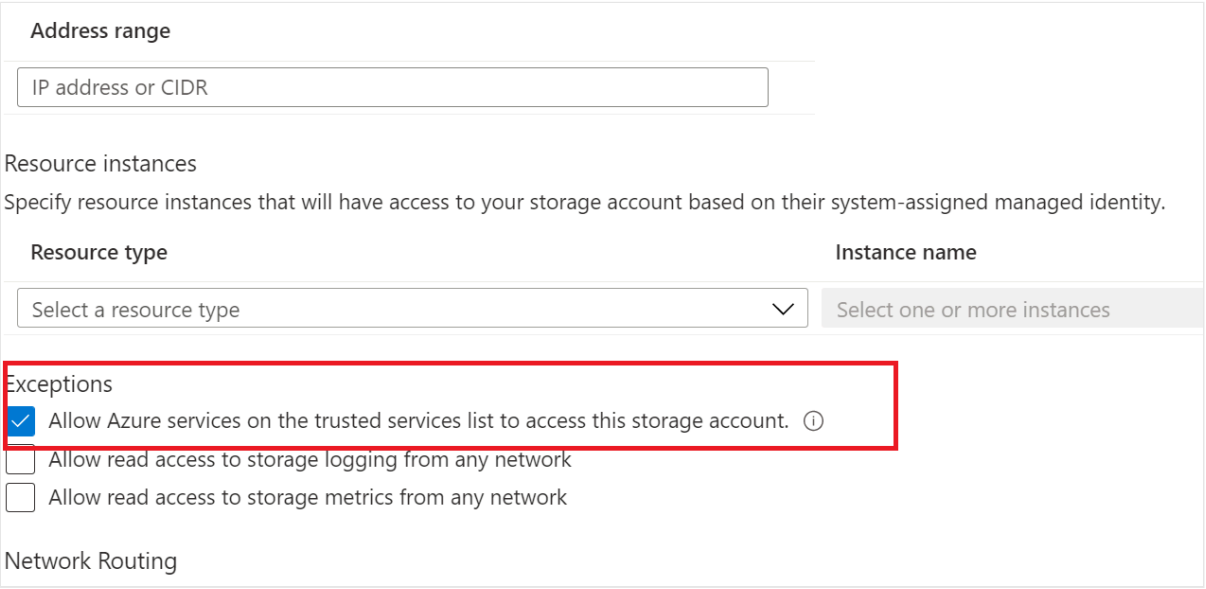
Save Discard

> **Note**
>
> For more details, please see steps in Authorize access to blobs and queues using Microsoft Entra ID



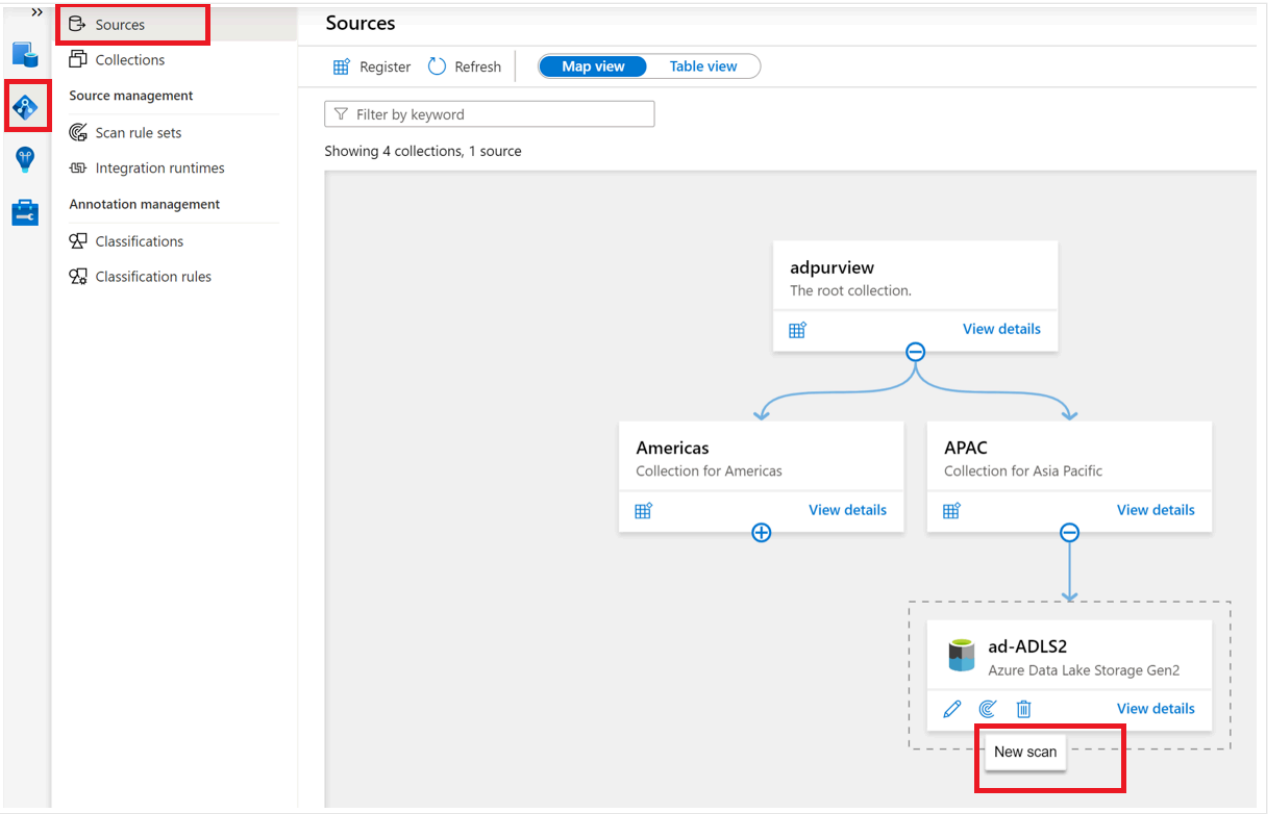
> **Note**
>
> If you have firewall enabled for the storage account, you must use **managed identity** authentication method when setting up a scan.

4. Go into your ADLS Gen2 storage account in Azure portal



5. Navigate to **Security + networking** > **Networking**

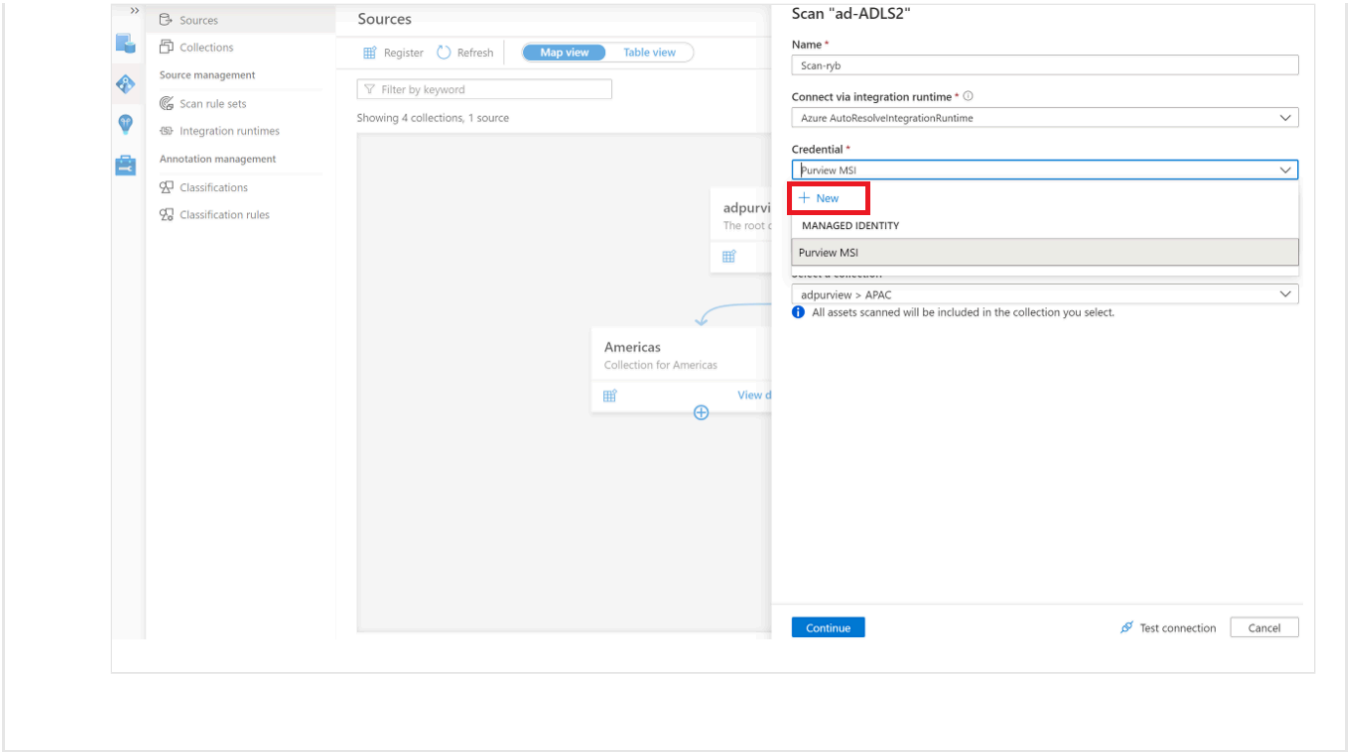
6. Choose **Selected Networks** under **Allow access from**



7. In the **Exceptions** section, select **Allow trusted Microsoft services to access this storage account** and hit **Save**

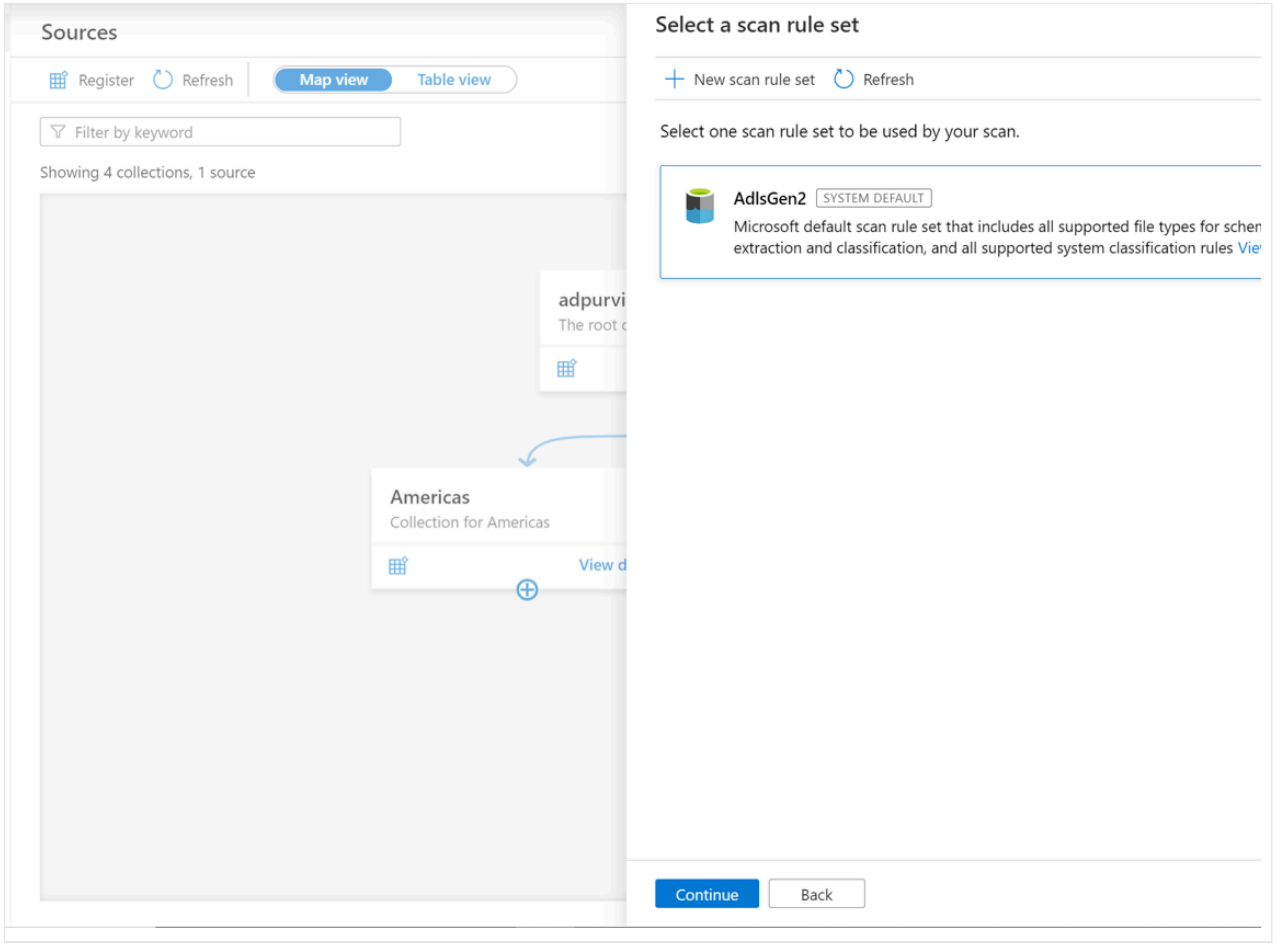
Create the scan

1. Open your **Microsoft Purview account** and select the **Open Microsoft Purview governance portal**
2. Navigate to the **Data map** --> **Sources** to view the collection hierarchy
3. Select the **New Scan** icon under the **ADLS Gen2 data source** registered earlier



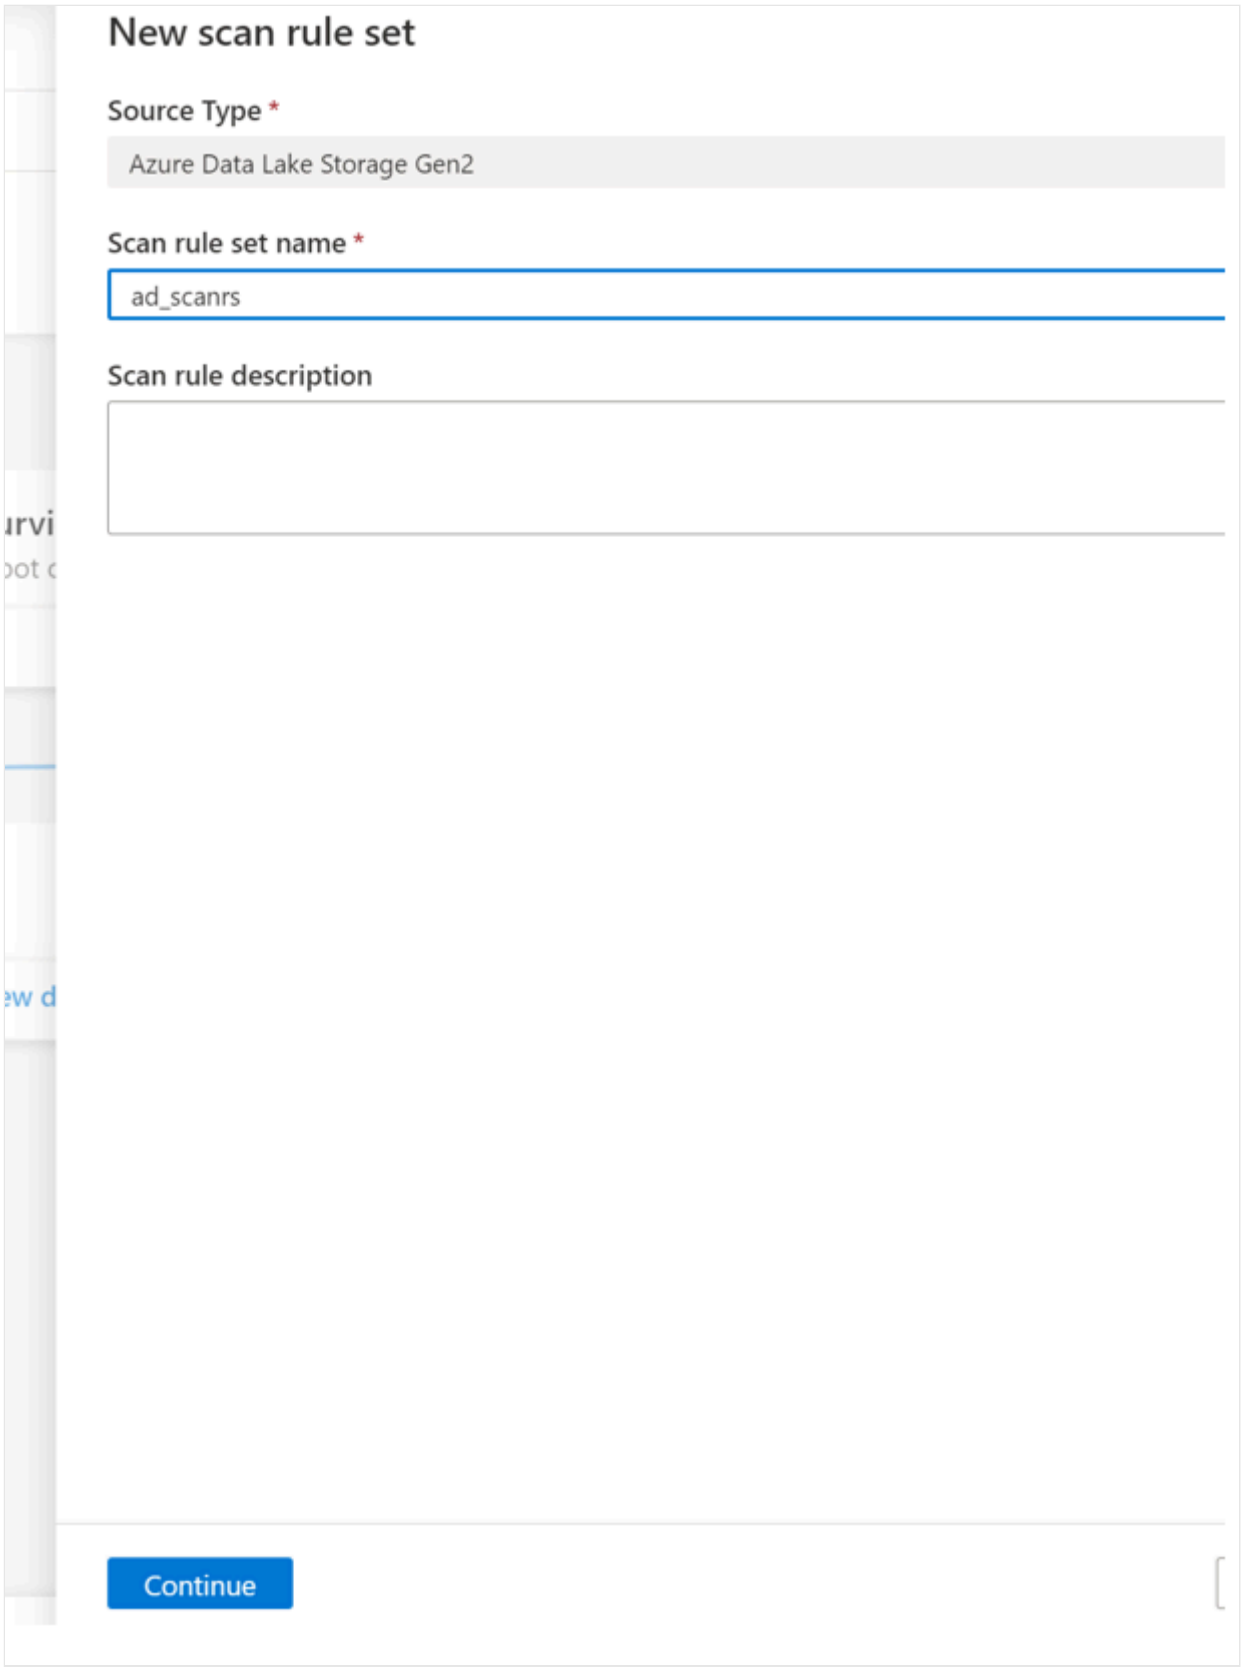
4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.

System or user assigned managed identity

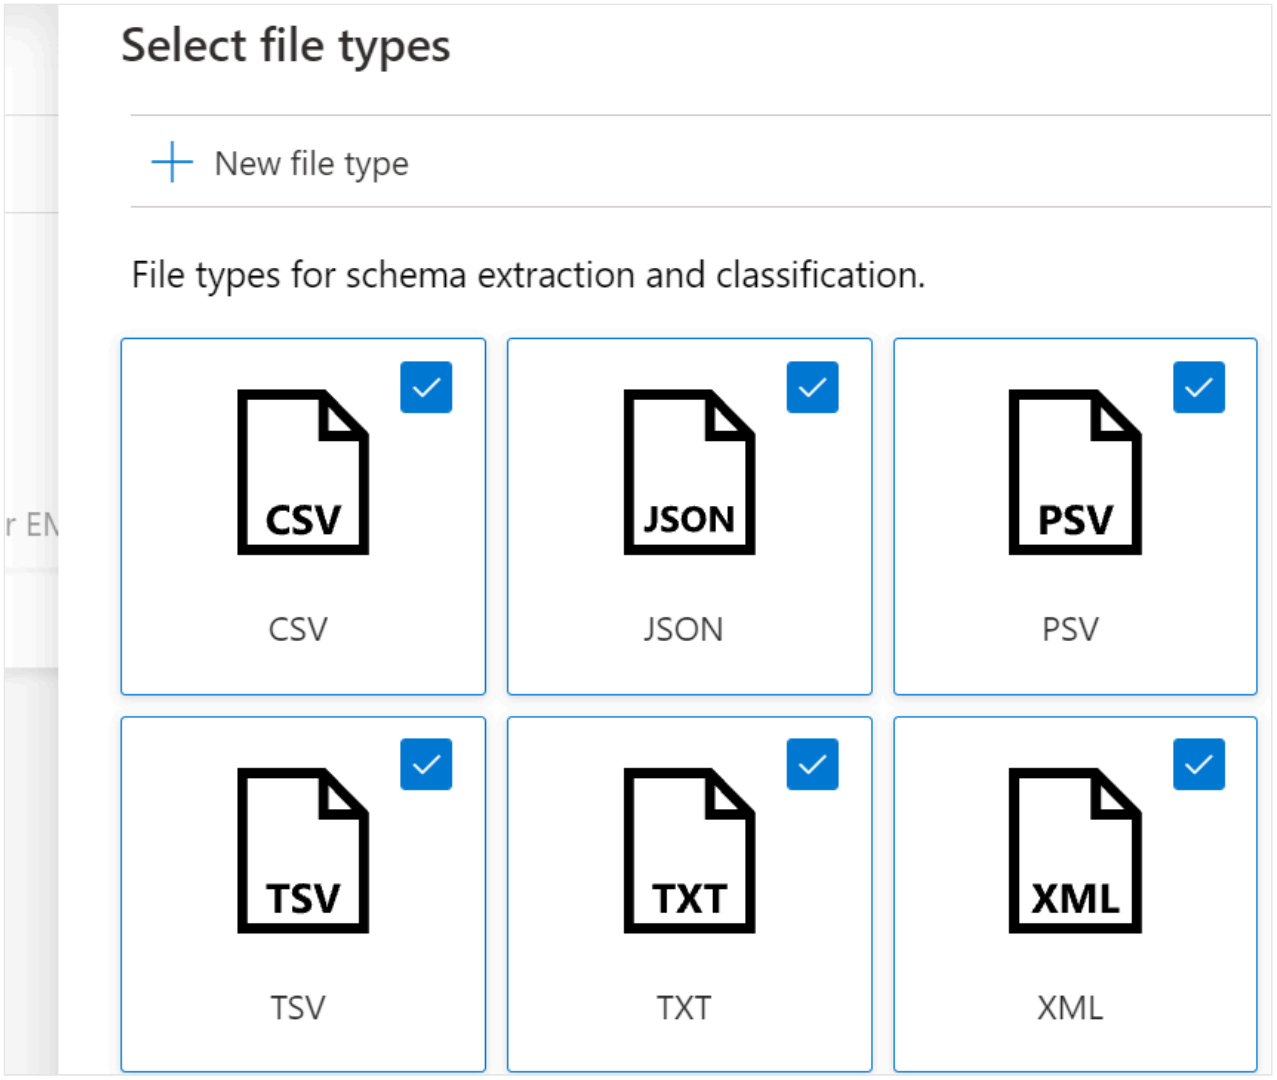


If using a system or user assigned managed identity

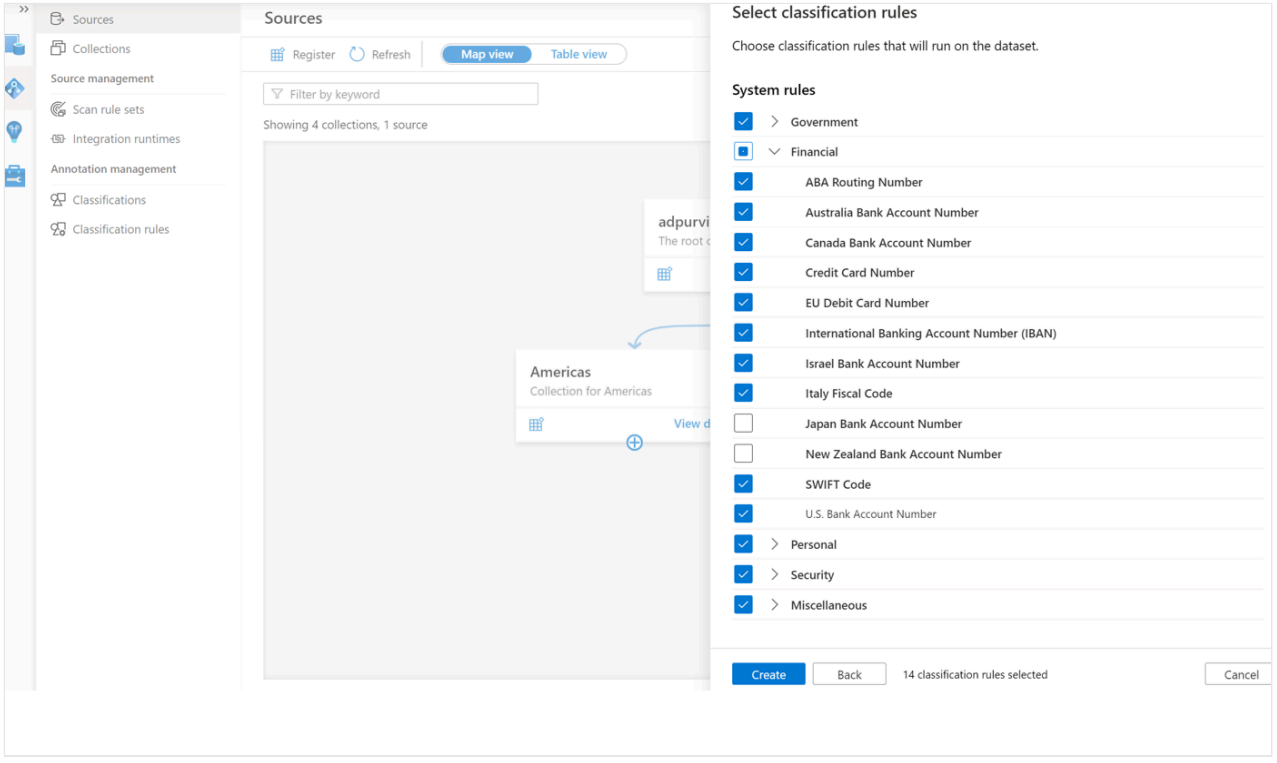
1. Provide a **Name** for the scan, select the system-assigned or user-assigned managed identity under **Credential**, choose the appropriate collection for the scan, and select **Test connection**. On a successful connection, select **Continue**.



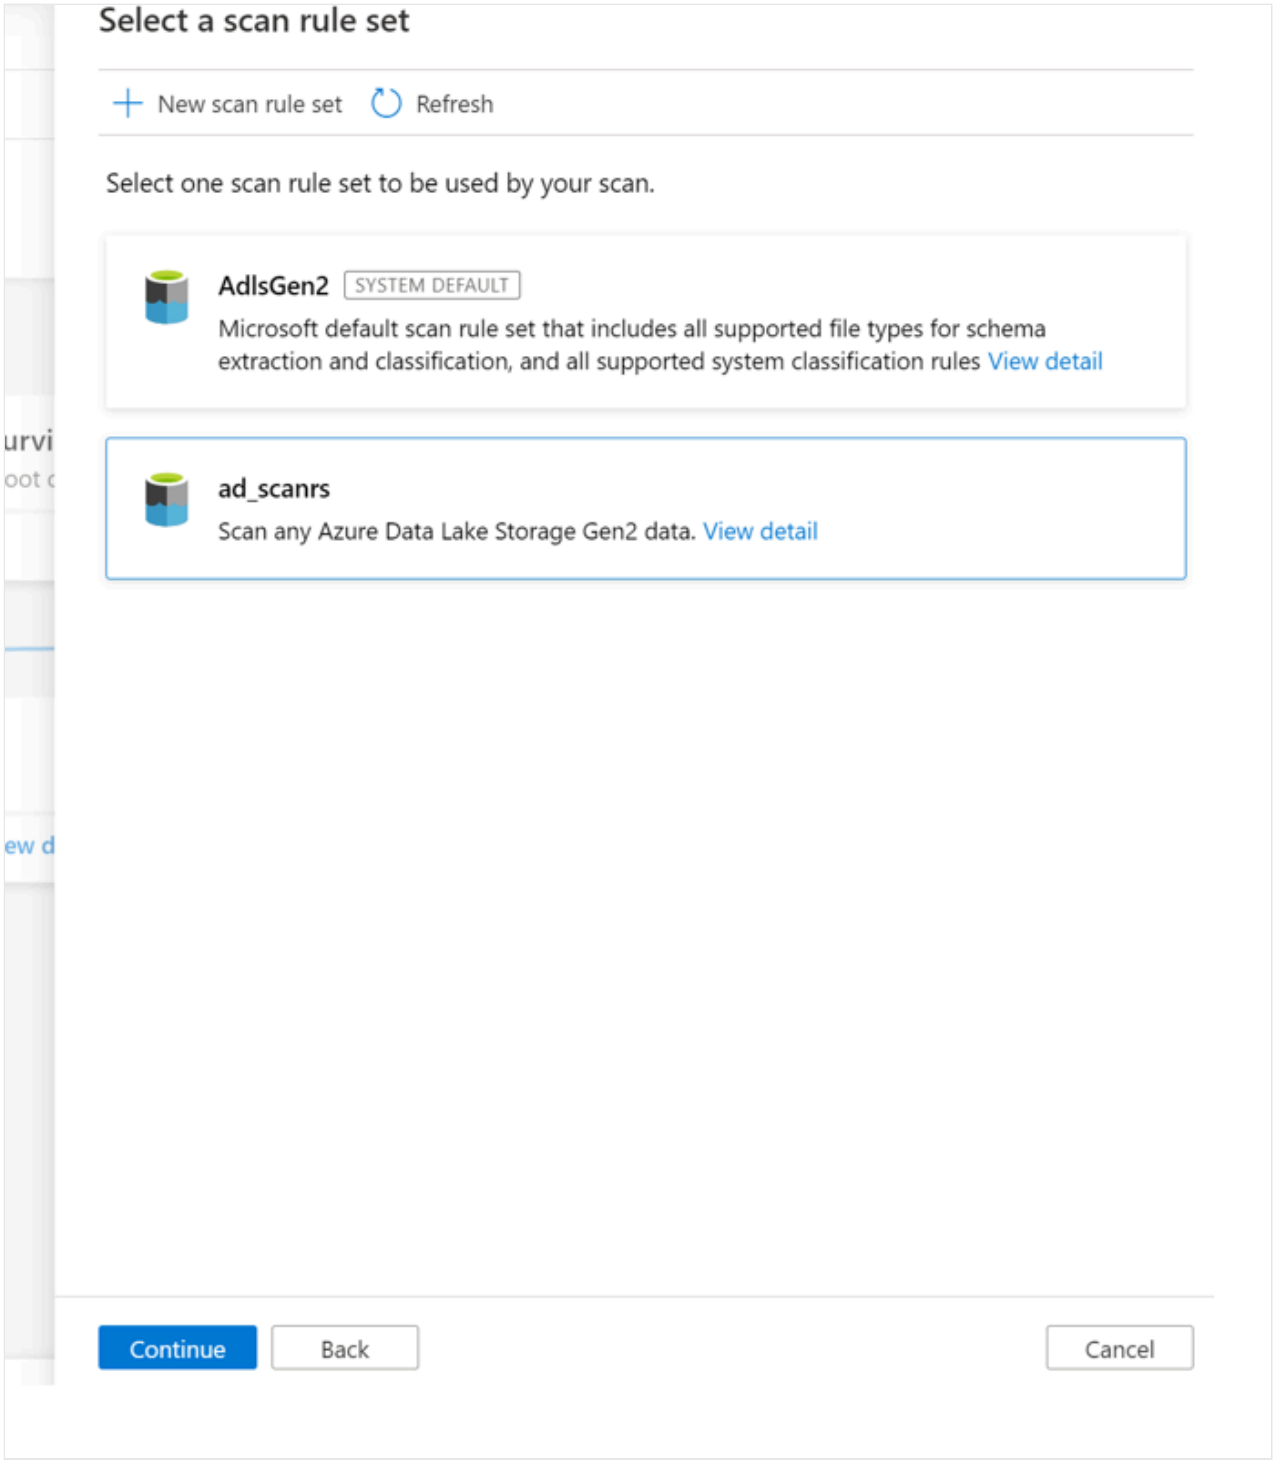
Scope and run the scan



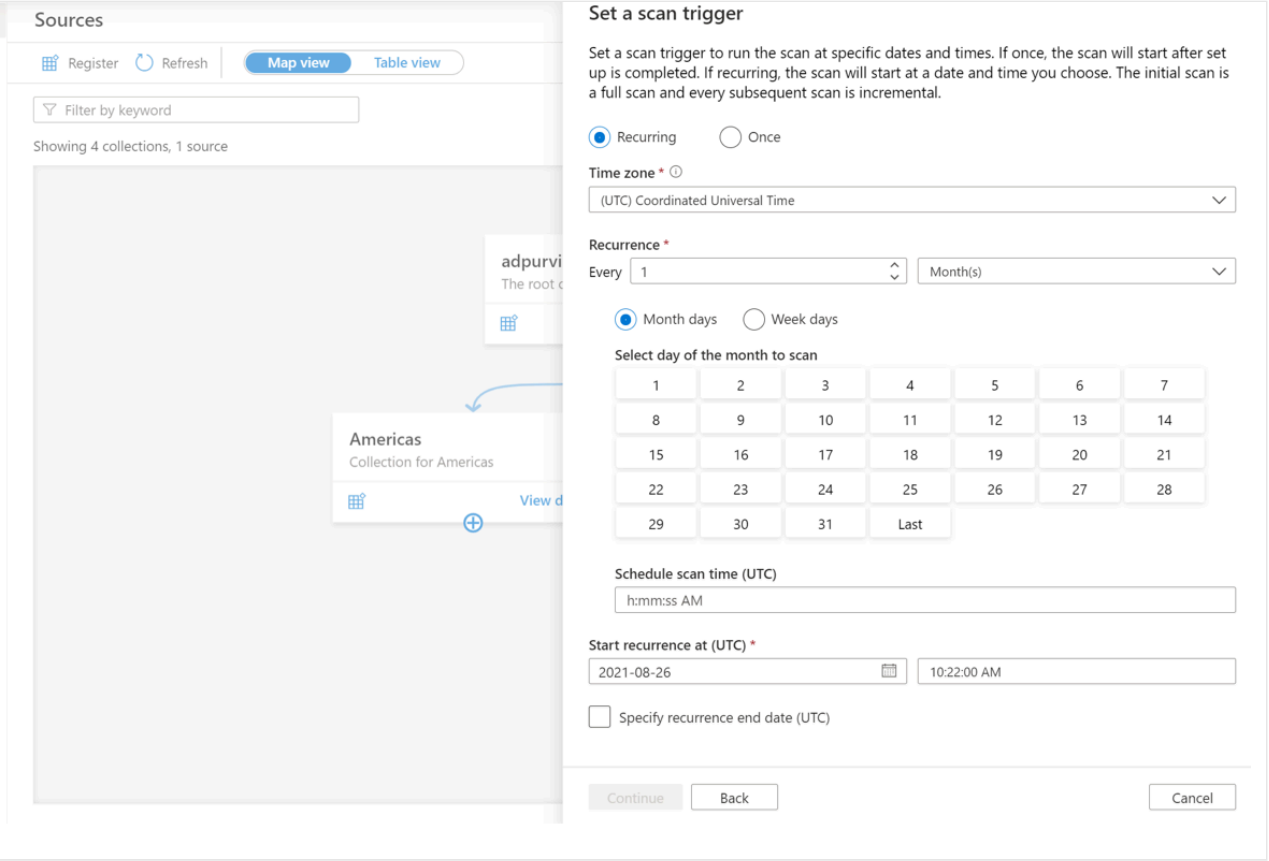
1. You can scope your scan to specific folders and subfolders by choosing the appropriate items in the list.



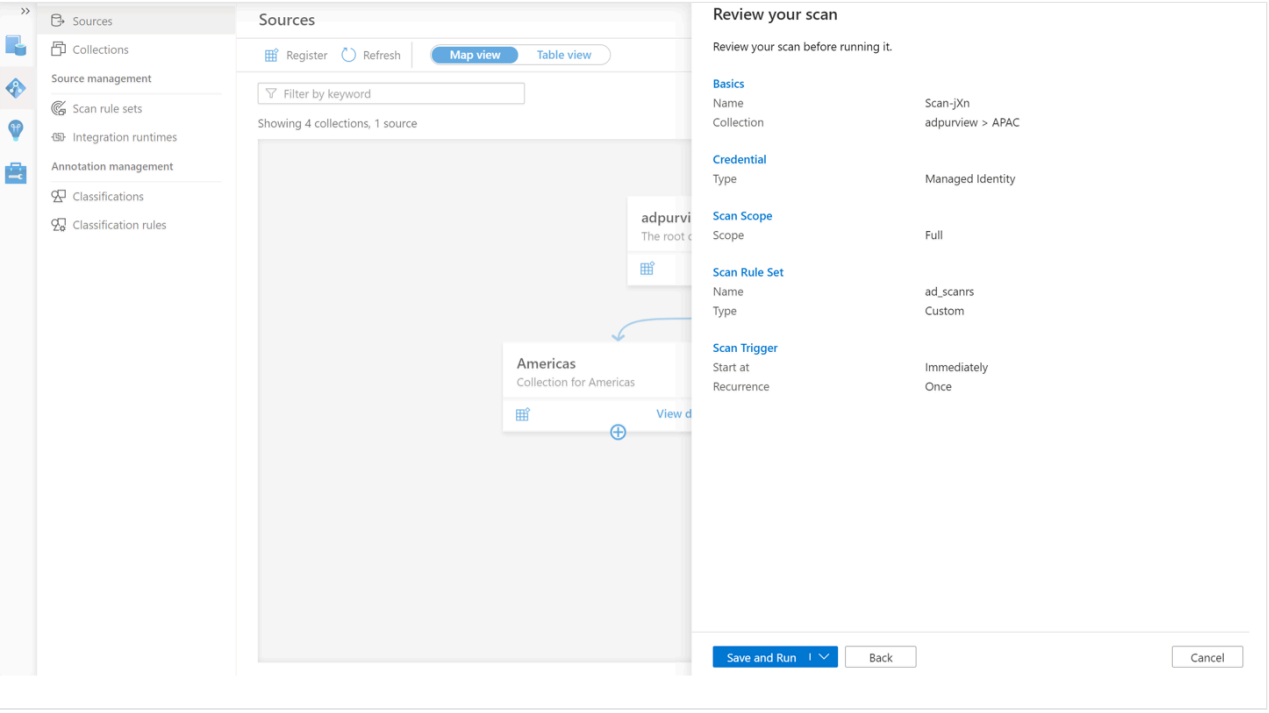
2. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.



3. If creating a new *scan rule set*, select the **file types** to be included in the scan rule.



4. You can select the **classification rules** to be included in the scan rule



5. Choose your scan trigger. You can set up a schedule or run the scan once.

6. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ Note
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Data sharing

Microsoft Purview Data Sharing (preview) enables sharing of data in-place from ADLS Gen2 to ADLS Gen2. This section provides details about the ADLS Gen2 specific requirements for sharing and receiving data in-place. Refer to How to share data and How to receive share for step by step guide on how to use data sharing.

Storage accounts supported for in-place data sharing

The following storage accounts are supported for in-place data sharing:

- Regions: Canada Central, Canada East, UK South, UK West, Australia East, Japan East, Korea South, and South Africa North
- Redundancy options: LRS, GRS, RA-GRS
- Tiers: Hot, Cool

Only use storage accounts without production workload for the preview.

> **Note**
>
> Source and target storage accounts must be in the same region as each other. They don't need to be in the same region as the Microsoft Purview account.

Storage account permissions required to share data

To add or update a storage account asset to a share, you need ONE of the following permissions:

- **Microsoft.Authorization/roleAssignments/write** - This permission is available in the *Owner* role.
- **Microsoft.Storage/storageAccounts/blobServices/containers/blobs/modifyPermissions/** - This permission is available in the *Blob Storage Data Owner* role.

Storage account permissions required to receive shared data

To map a storage account asset in a received share, you need ONE of the following permissions:

- **Microsoft.Storage/storageAccounts/write** - This permission is available in the *Contributor* and *Owner* role.
- **Microsoft.Storage/storageAccounts/blobServices/containers/write** - This permission is available in the *Contributor*, *Owner*, *Storage Blob Data Contributor* and *Storage Blob Data Owner* role.

Update shared data in source storage account

Updates you make to shared files or data in the shared folder from source storage account will be made available to recipient in target storage account in near real time. When you delete subfolder or files within the shared folder, they'll disappear for recipient. To delete the shared folder, file or parent folders or containers, you need to first revoke access to all your shares from the source storage account.

Access shared data in target storage account

The target storage account enables recipient to access the shared data read-only in near real time. You can connect analytics tools such as Synapse Workspace and Databricks to the shared data to perform analytics. Cost of accessing the shared data is charged to the target storage account.

Service limit

Source storage account can support up to 20 targets, and target storage account can support up to 100 sources. If you require an increase in limit, contact Support.

Policies

The following types of policies are supported on this data resource from Microsoft Purview:

- Data owner policies - a set of policy statements that allow you to grant users and groups access to data sources.
- Self-service access policies - policy that allows users to request access to data sources registered to Microsoft Purview.
- Protection policies - denies access to data tagged with sensitivity labels to all users except those specified by the policy.

Access policy pre-requisites on Azure Storage accounts

Region support

- All Microsoft Purview regions are supported.
- Storage accounts in the following regions are supported without the need for additional configuration. However, zone-redundant storage (ZRS) accounts are not supported.
  - Australia Central
  - Australia East
  - Australia Southeast
  - Brazil South
  - Canada Central
  - Canada East
  - Central India
  - Central US
  - East Asia
  - East US 2
  - East US
  - France Central
  - Germany West Central
  - Japan East
  - Japan West
  - Korea Central
  - North Central US

    - North Europe
    - Norway East
    - Poland Central
    - Qatar Central
    - South Central US
    - South Africa North
    - Southeast Asia
    - South India
    - Sweden Central
    - Switzerland North
    - West Central US
    - West Europe
    - West US
    - West US 2
    - West US 3
    - UAE North
    - UK South
    - UK West
- Storage accounts in other regions in Public Cloud are supported after setting feature flag *AllowPurviewPolicyEnforcement*, as outlined in the next section. Newly created ZRS Storage accounts are supported, if created after setting the feature flag *AllowPurviewPolicyEnforcement*.

If needed, you can create a new Storage account by following this guide.

Configure the subscription where the Azure Storage account resides for policies from Microsoft Purview

This step is only necessary in certain regions (see prior section). To enable Microsoft Purview to manage policies for one or more Azure Storage accounts, execute the following PowerShell commands in the subscription where you'll deploy your Azure Storage account. These PowerShell commands will enable Microsoft Purview to manage policies on all Azure Storage accounts in that subscription.

If you're executing these commands locally, be sure to run PowerShell as an administrator. Alternatively, you can use the Azure Cloud Shell in the Azure portal: https://shell.azure.com.

PowerShell

```
# Install the Az module
Install-Module -Name Az -Scope CurrentUser -Repository PSGallery -Force
# Login into the subscription
Connect-AzAccount -Subscription <SubscriptionID>
```

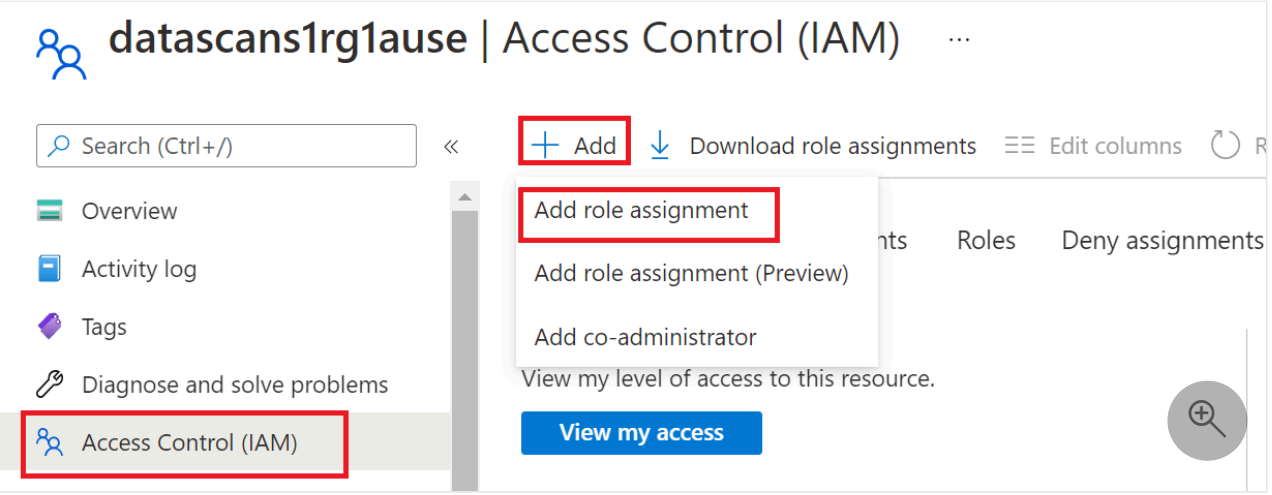
```
# Register the feature
Register-AzProviderFeature -FeatureName AllowPurviewPolicyEnforcement -
ProviderNamespace Microsoft.Storage
```

If the output of the last command shows *RegistrationState* as *Registered*, then your subscription is enabled for access policies. If the output is *Registering*, wait at least 10 minutes, and then retry the command. **Do not continue unless the RegistrationState shows as *Registered***.

Configure the Microsoft Purview account for policies

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

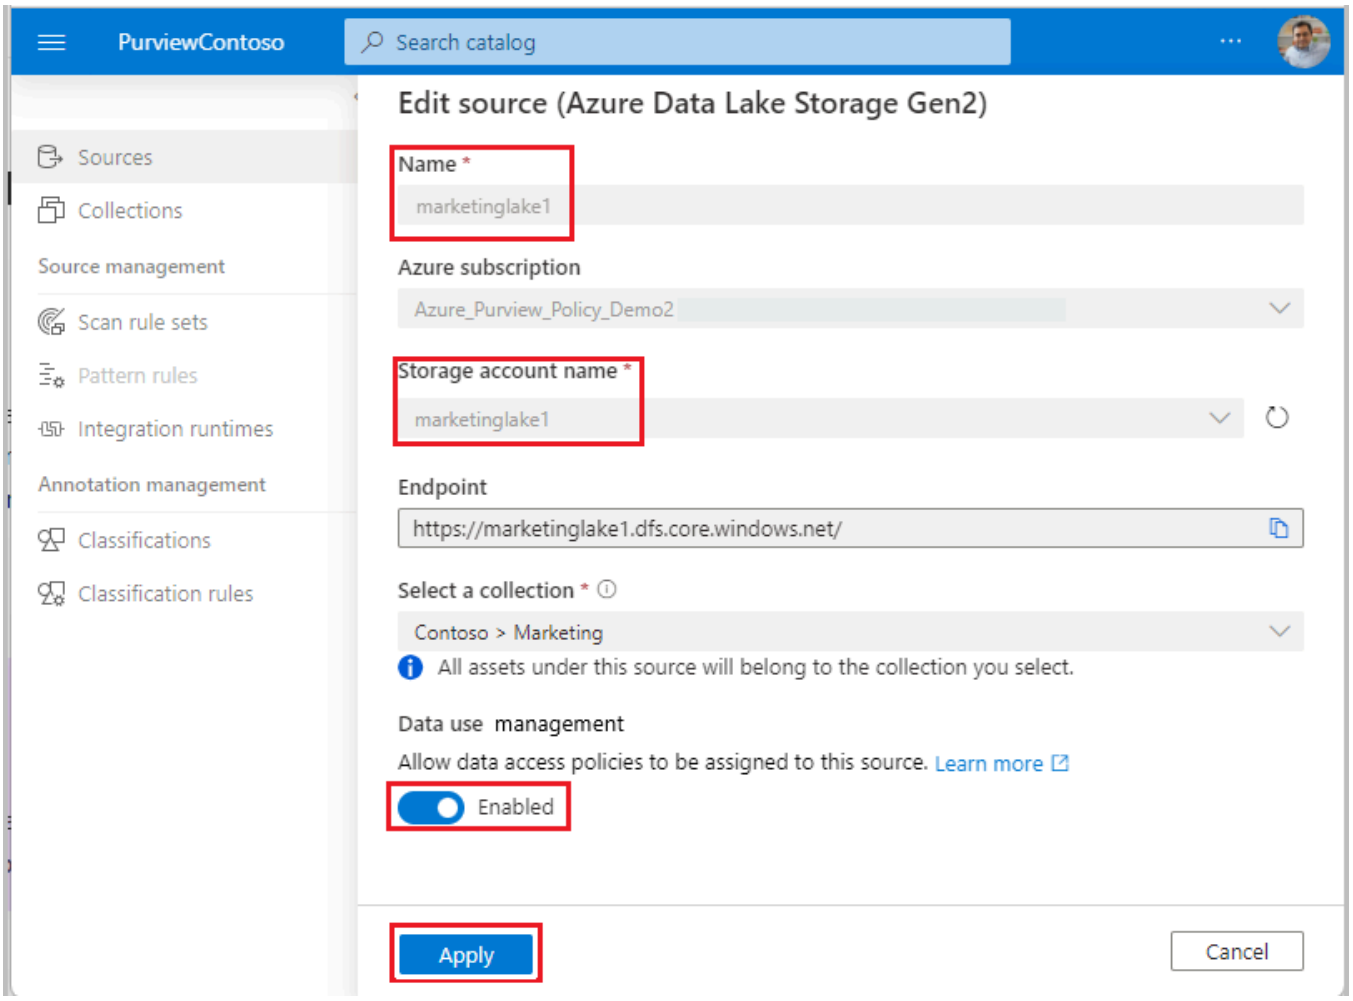
> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the data source in Microsoft Purview for Data Policy Enforcement

The Azure Storage resource needs to be registered first with Microsoft Purview before you can create access policies. To register your resource, follow the **Prerequisites** and **Register** sections of this guide:

- Register Azure Data Lake Storage (ADLS) Gen2 in Microsoft Purview

After you've registered the data source, you'll need to enable Data Policy Enforcement. This is a pre-requisite before you can create policies on the data source. Data Policy Enforcement can impact the security of your data, as it delegates to certain Microsoft Purview roles managing access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

Once your data source has the **Data Policy Enforcement** option set to **Enabled**, it will look like this screenshot:

Create a policy

To create an access policy for Azure Data Lake Storage Gen2, follow this guide:

- Provision read/modify access on a single storage account

To create policies that cover all data sources inside a resource group or Azure subscription you can refer to this section.

Protection policy

Protection access control policies (protection policies) enable organizations to automatically protect sensitive data across data sources. Microsoft Purview already scans data assets and identifies sensitive data elements, and this new feature allows you to automatically restrict access to that data using sensitivity labels from Microsoft Purview Information Protection.

Follow this documentation to create a protection policy: How to create a Microsoft Purview Information Protection policy.

Next steps

Follow the below guides to learn more about Microsoft Purview and your data.

- Data owner policies in Microsoft Purview
- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Data share in Microsoft Purview

Connect to and manage Azure Database for MySQL in Microsoft Purview

Article • 04/01/2025

This article outlines how to register a database in Azure Database for MySQL, and how to authenticate and interact with Azure Database for MySQL in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes*	Yes

* Microsoft Purview relies on UPDATE_TIME metadata from Azure Database for MySQL for incremental scans. In some cases, this field might not persist in the database and a full scan is performed. For more information, see The INFORMATION_SCHEMA TABLES Table for MySQL.

> **Important**
>
> Microsoft Purview only supports single server deployment option for Azure Database for MySQL.

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

Register

This section describes how to register an Azure Database for MySQL in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

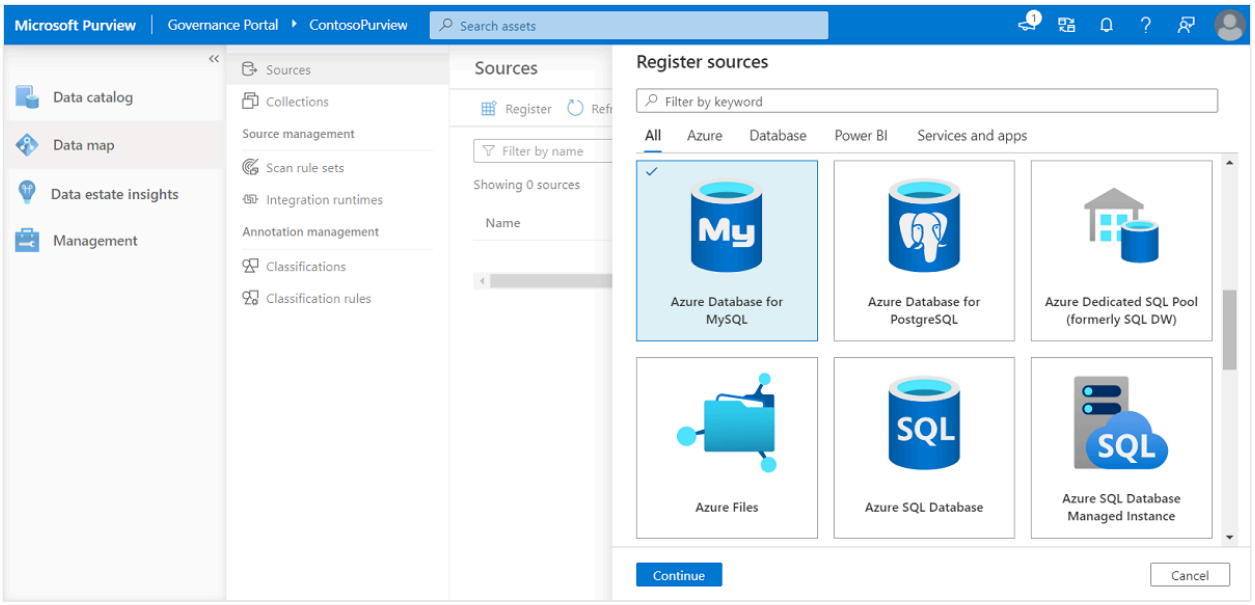
You'll need **username** and **password** for the next steps.

Follow the instructions in CREATE DATABASES AND USERS to create a login for your Azure Database for MySQL.

1. Navigate to your key vault in the Azure portal
2. Select **Settings** > **Secrets**
3. Select + **Generate/Import** and enter the **Name** and **Value** as the *password* from your Azure SQL Database
4. Select **Create** to complete
5. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection
6. Finally, create a new credential of type SQL authentication using the **username** and **password** to set up your scan.

Steps to register

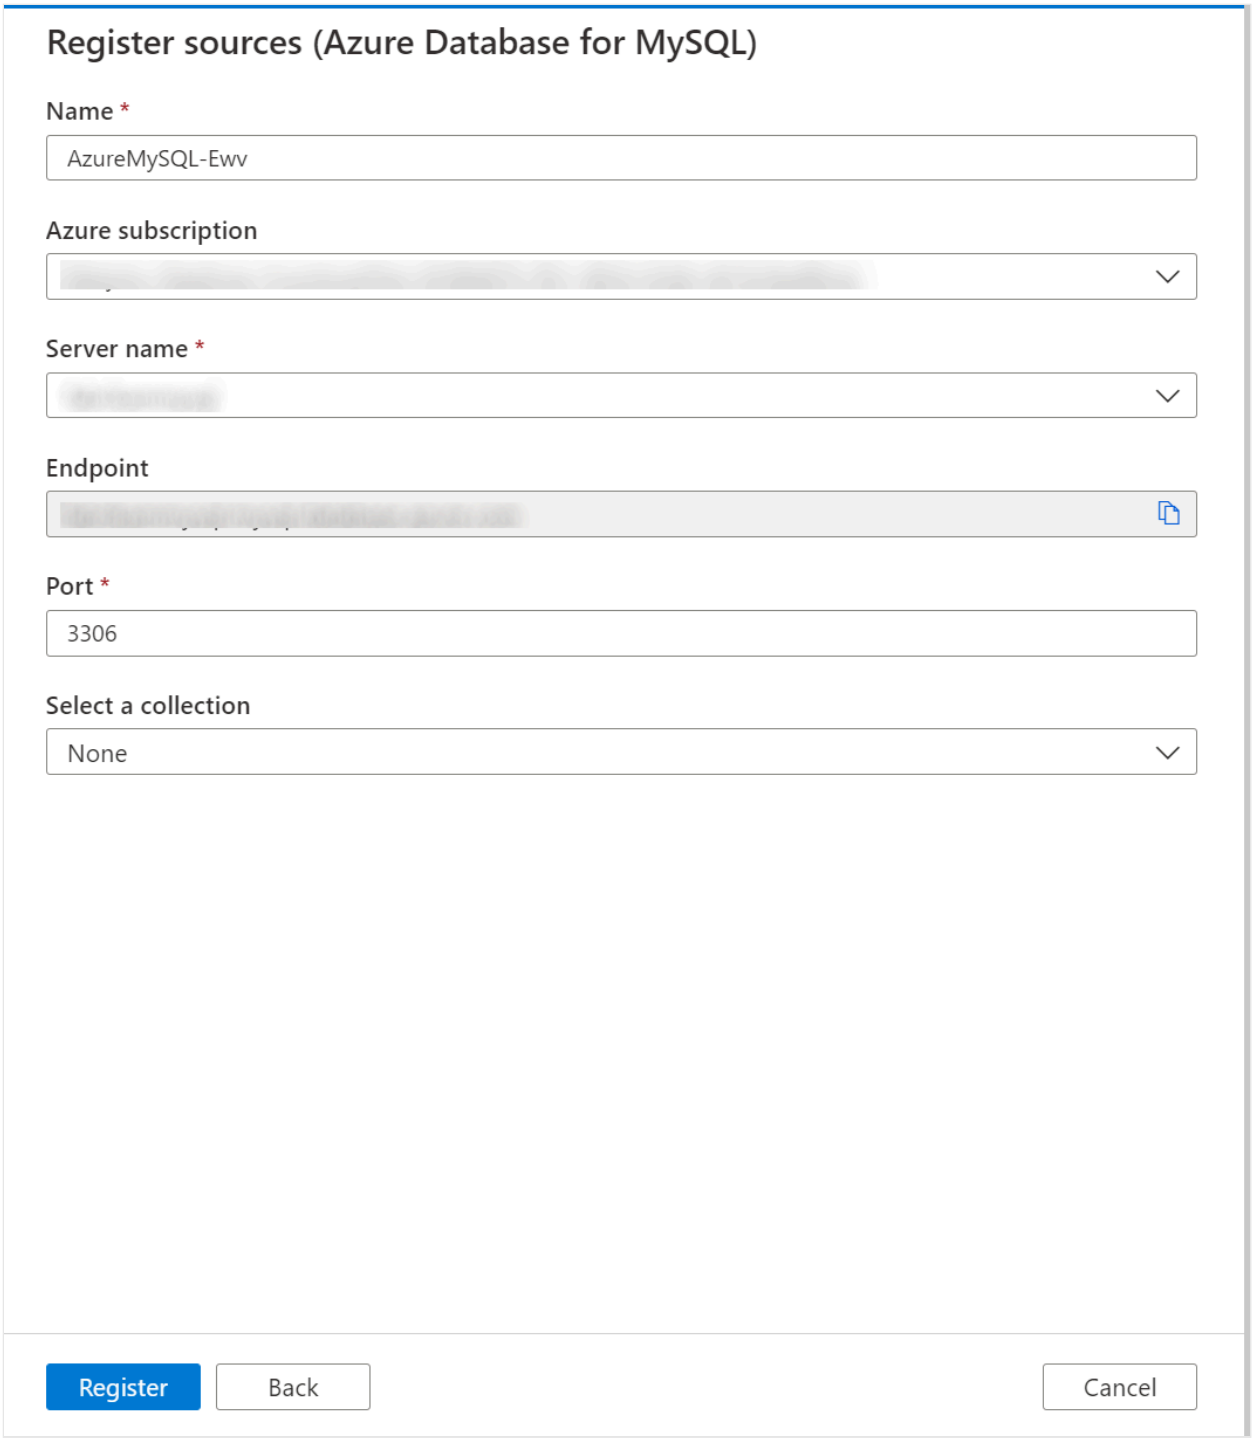
To register a new Azure Database for MySQL in Microsoft Purview Unified Catalog, do the following:



1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.



3. Select **Register**.

4. On **Register sources**, select **Azure Database for MySQL**. Select **Continue**.

On the **Register sources (Azure Database for MySQL)** screen, do the following:

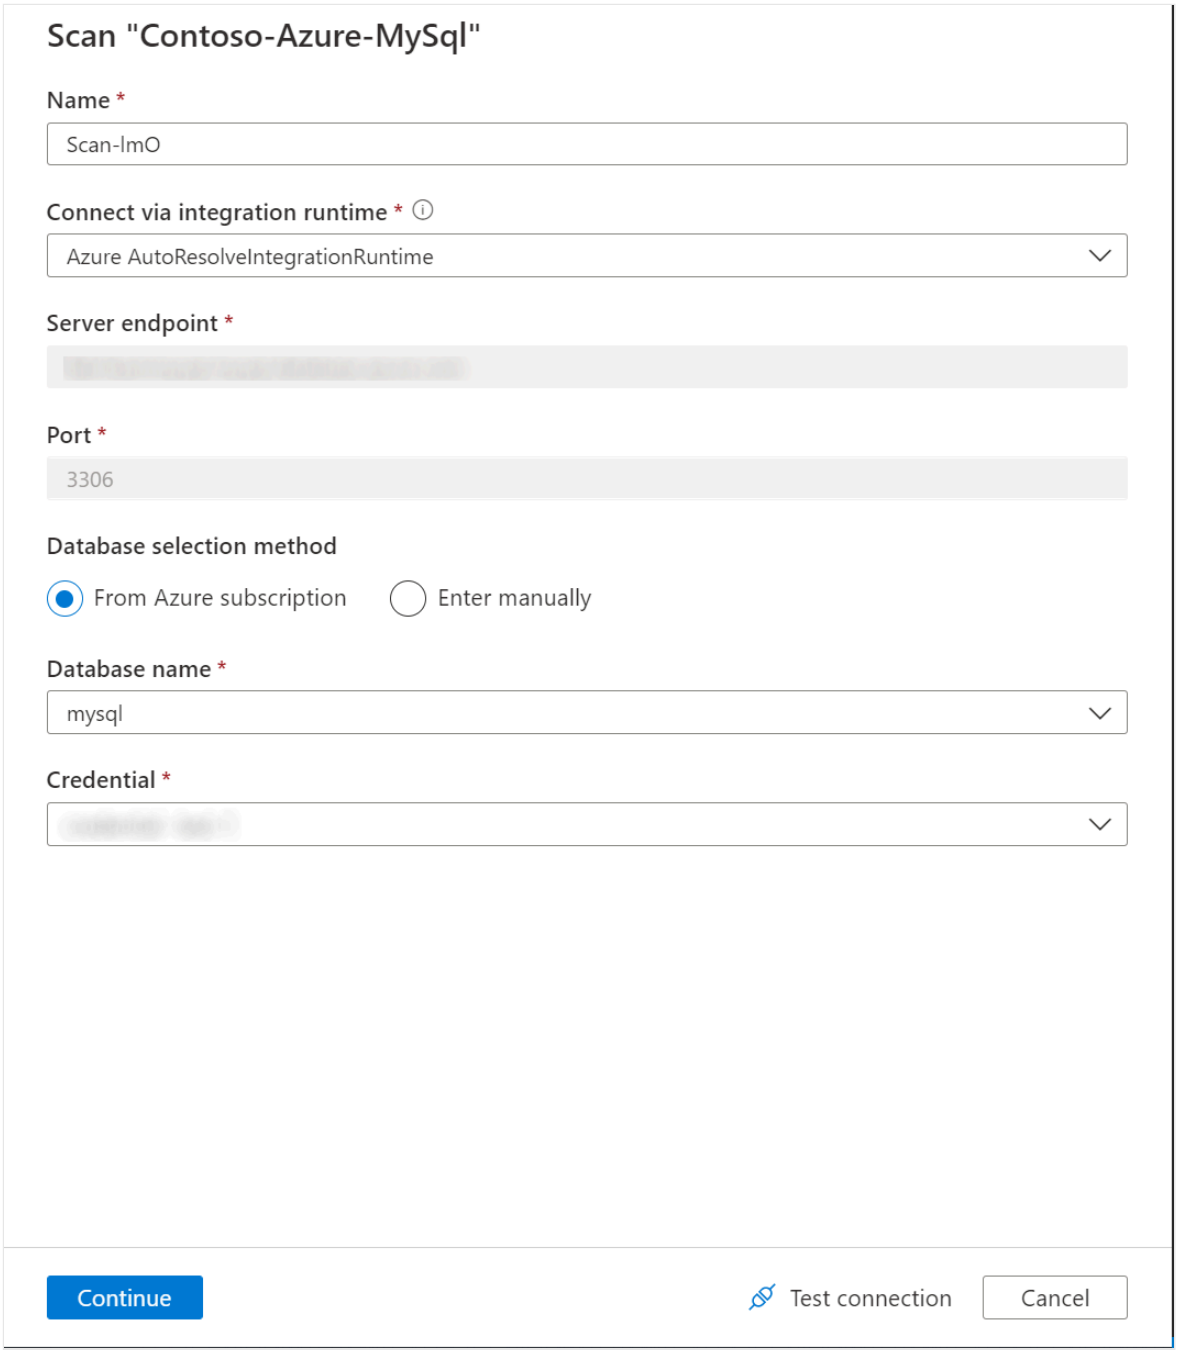
1. Enter a **Name** for your data source. This will be the display name for this data source in your Catalog.
2. Select **From Azure subscription**, select the appropriate subscription from the **Azure subscription** drop-down box and the appropriate server from the **Server name** drop-down box.
3. Select **Register** to register the data source.

Scan

Follow the steps below to scan Azure Database for MySQL to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion

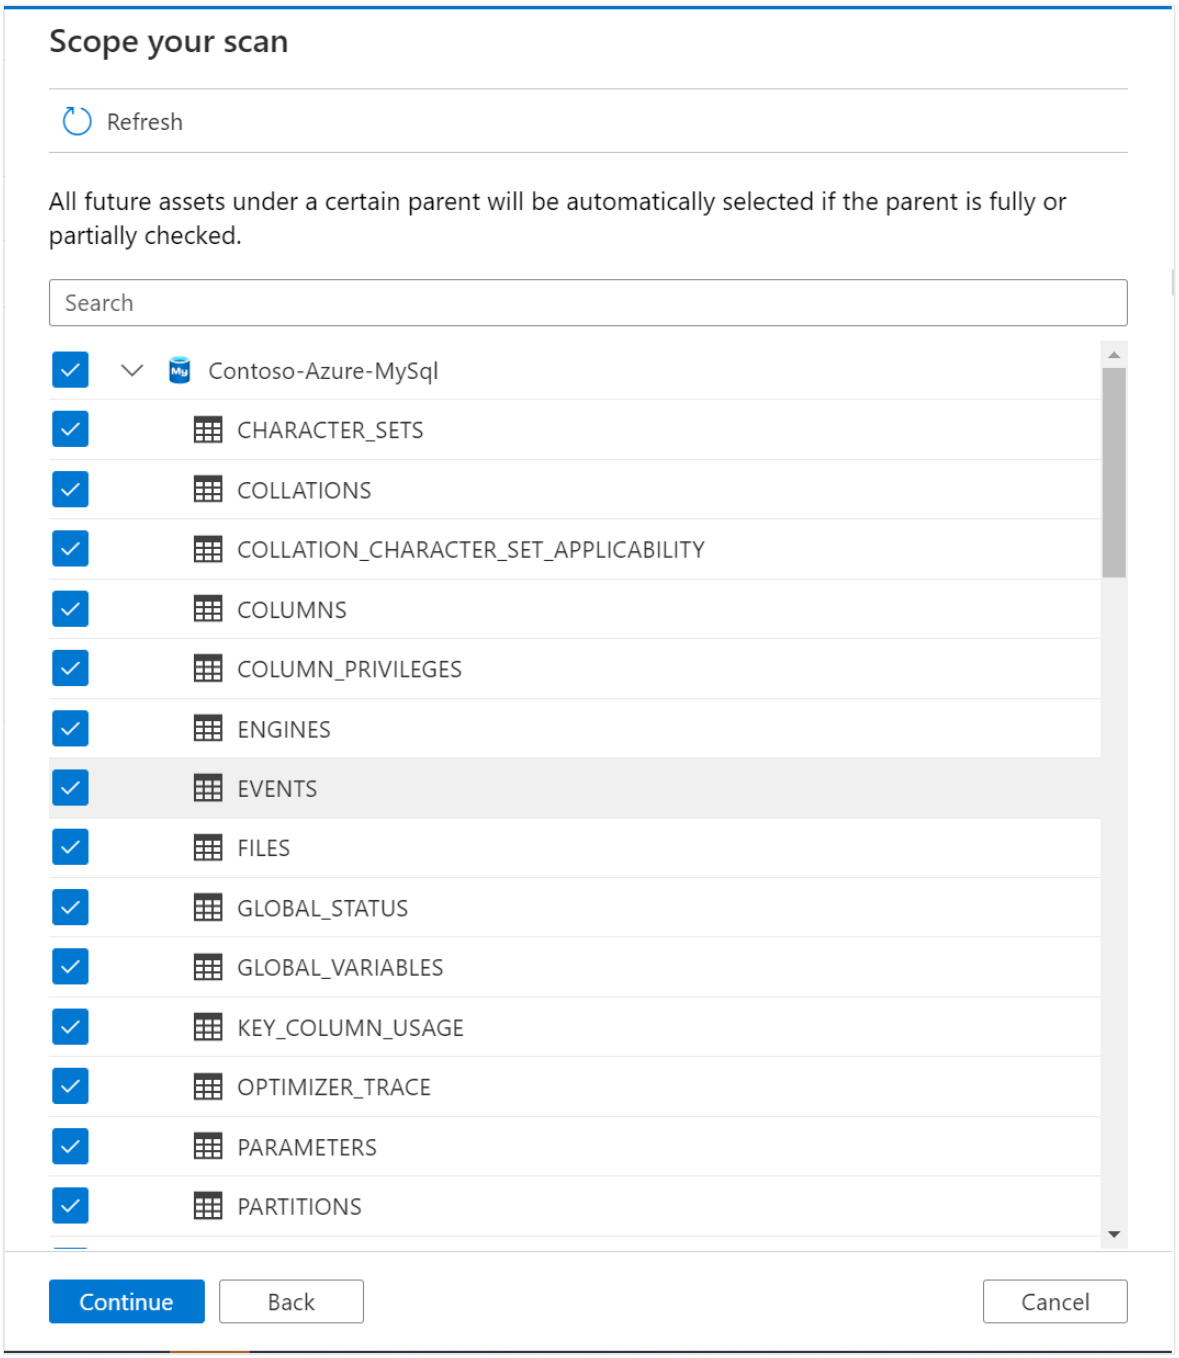
Create and run scan

To create and run a new scan, do the following:



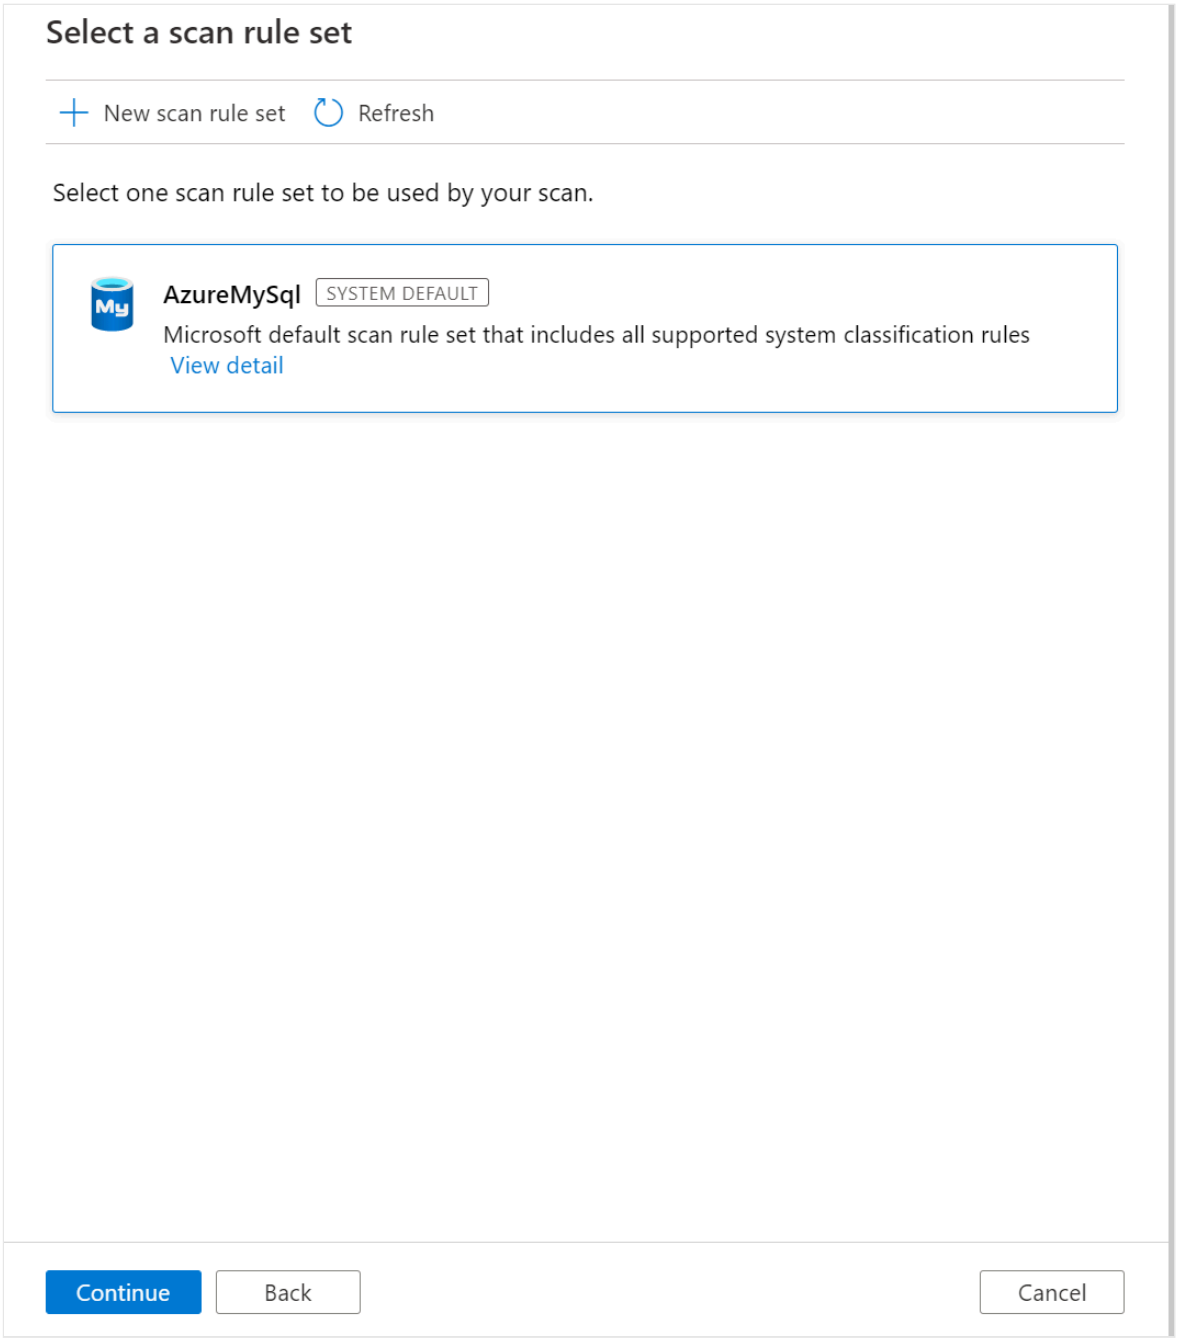
1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.

2. Select the Azure Database for MySQL source that you registered.

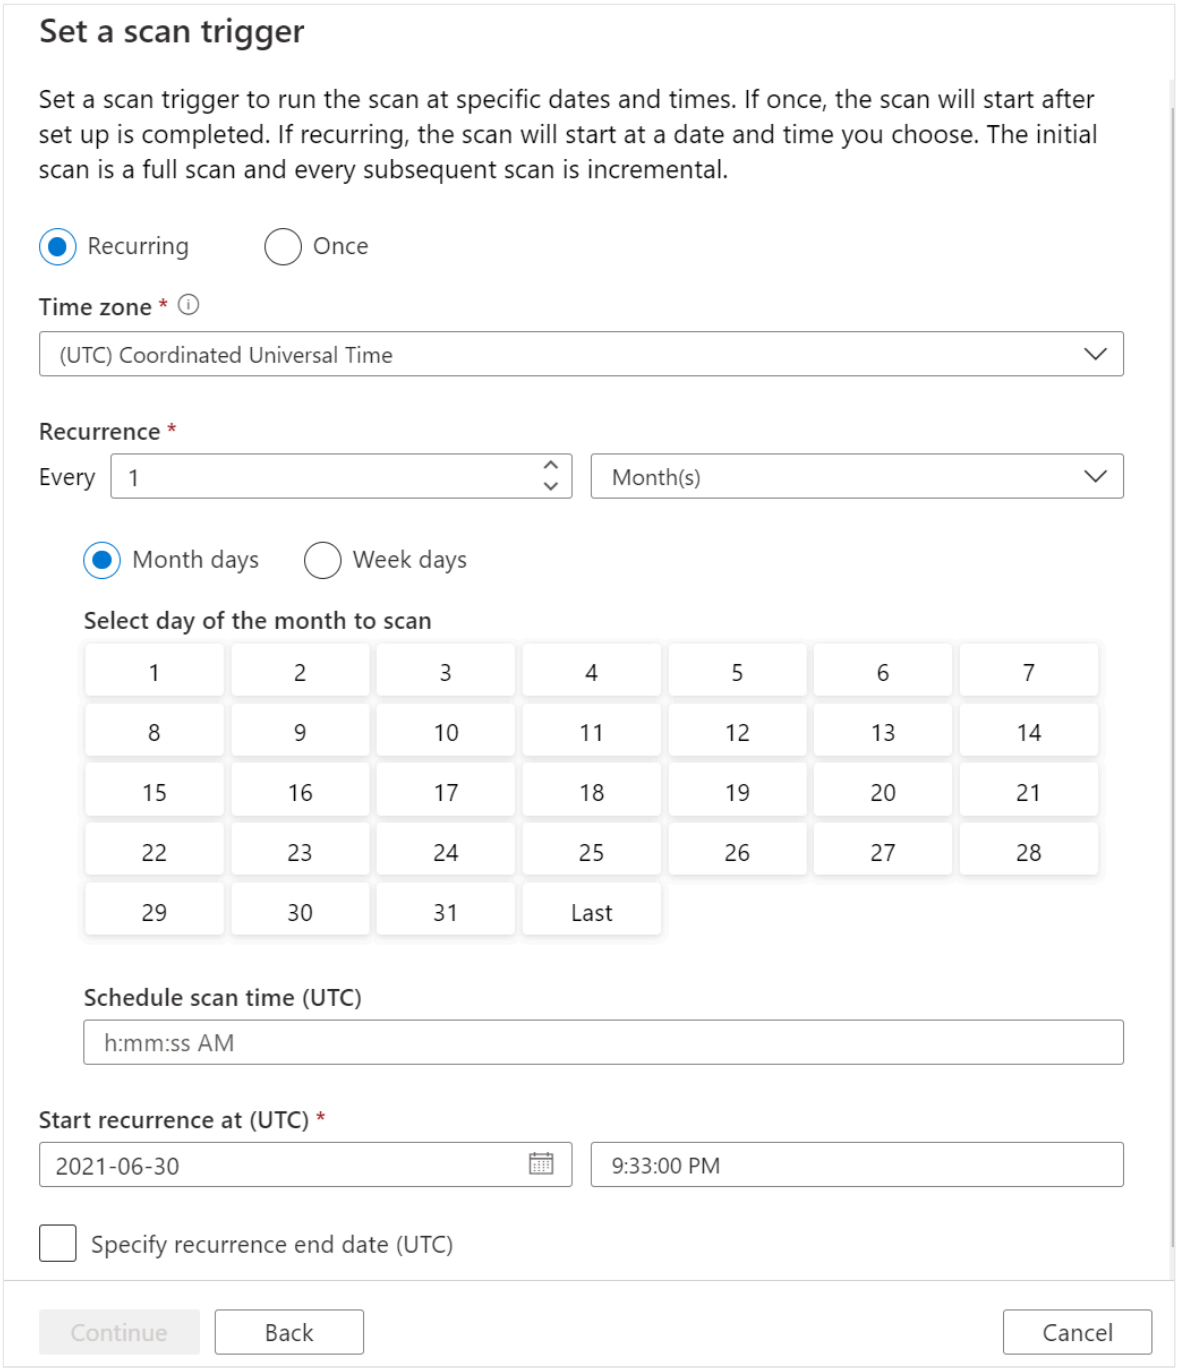


3. Select **New scan**

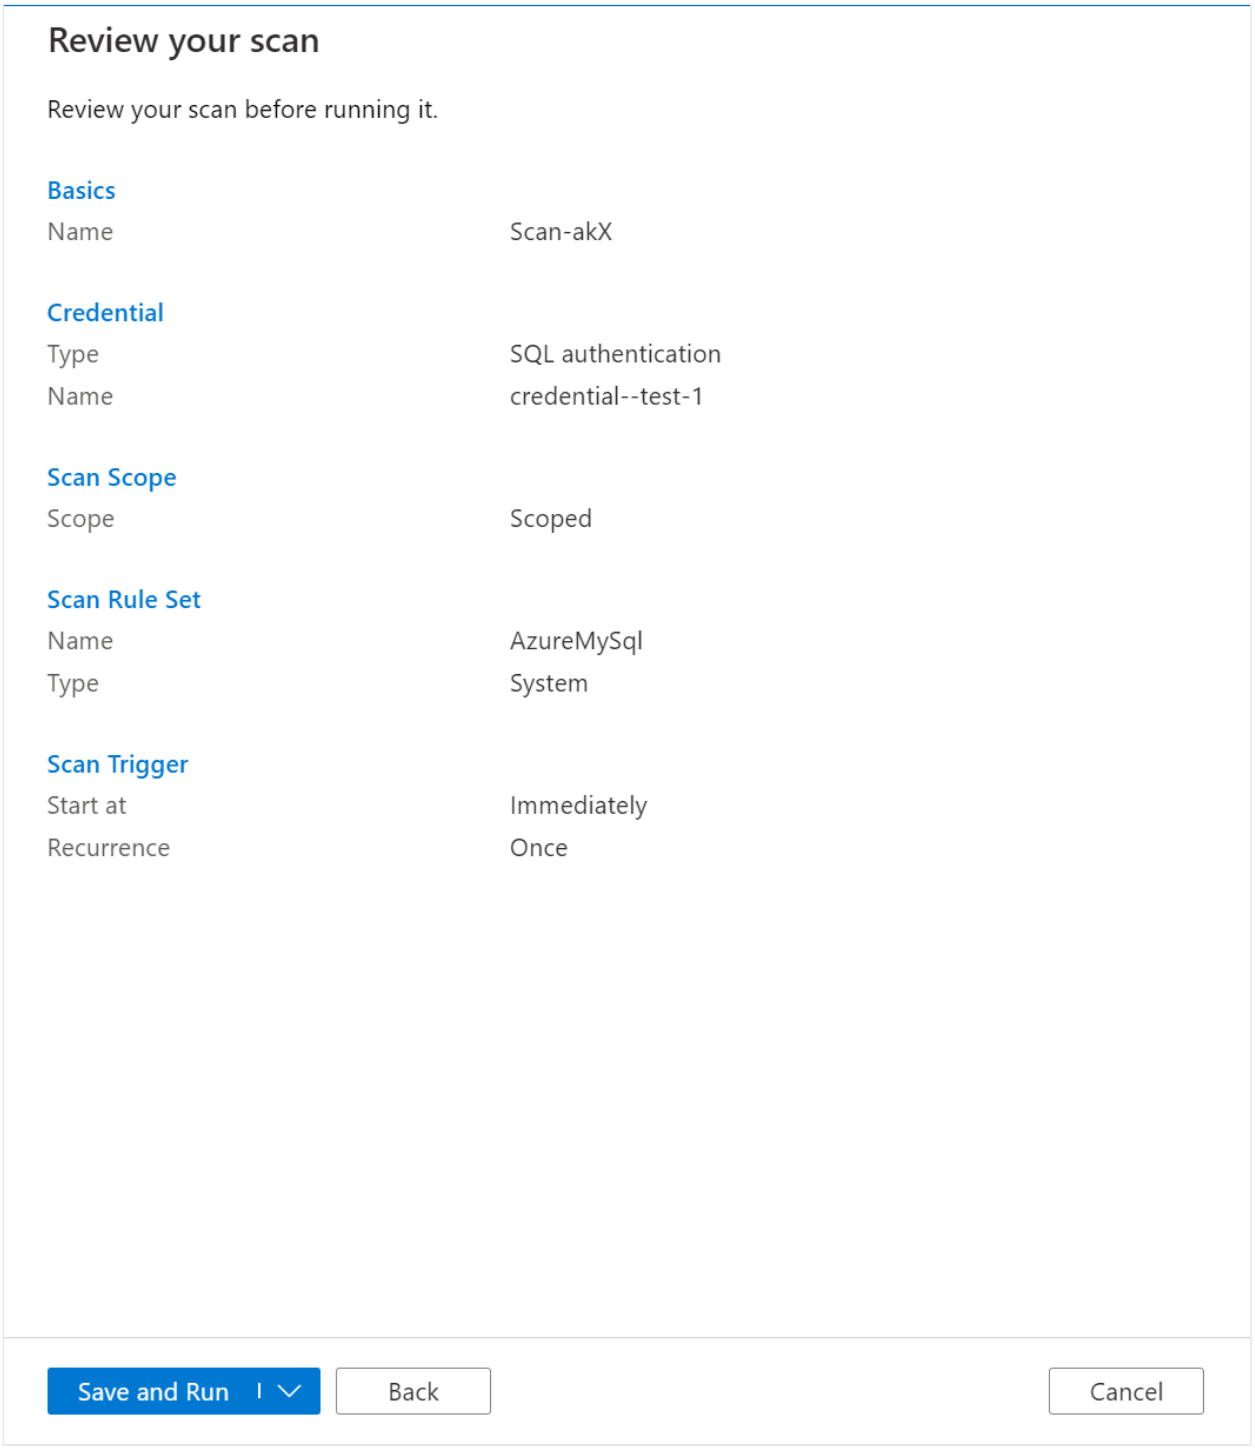
4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.



5. Select the credential to connect to your data source and check your connection to make sure your credential is properly configured.



6. You can scope your scan to specific folders or subfolders by choosing the appropriate items in the list.



7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.-->

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage an Azure Database for PostgreSQL in Microsoft Purview (single server source retired in March 2025)

This article outlines how to register an Azure Database for PostgreSQL deployed with single server deployment option, and how to authenticate and interact with an Azure Database for PostgreSQL in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

Important

Microsoft Purview only supports single server deployment option for Azure Database for PostgreSQL. Versions 8.x to 12.x.

> **Azure Database for PostgreSQL single server retired in March 2025. We are working on bringing support for Azure Database for PostgreSQL Flex server.**

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

Register

This section describes how to register an Azure Database for PostgreSQL in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

Currently, to be able to manage and interact with an Azure Database for PostgreSQL single server, only SQL Authentication is supported.

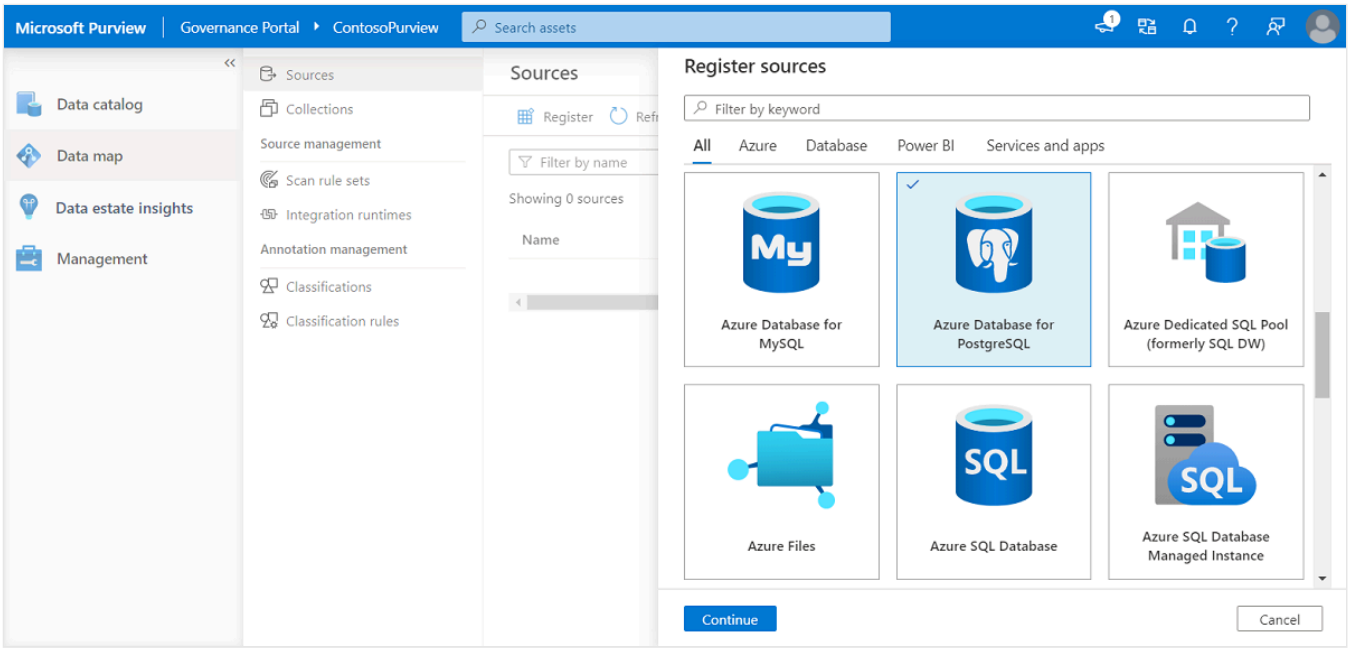
SQL Authentication

Connecting to an Azure Database for PostgreSQL database requires the fully qualified server name and login credentials. You can follow the instructions in CONNECT AND QUERY to create a login for your Azure Database for PostgreSQL if you don't have this available. You'll need **username** and **password** for the next steps.

1. If you don't have an Azure Key vault already, follow this guide to create an Azure Key Vault.
2. Navigate to your key vault in the Azure portal
3. Select **Settings** > **Secrets**
4. Select **+ Generate/Import** and enter the **Name** and **Value** as the *password* from your Azure PostgreSQL Database
5. Select **Create** to complete
6. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection
7. Finally, create a new credential of type SQL authentication using the **username** and **password** to set up your scan

Steps to register

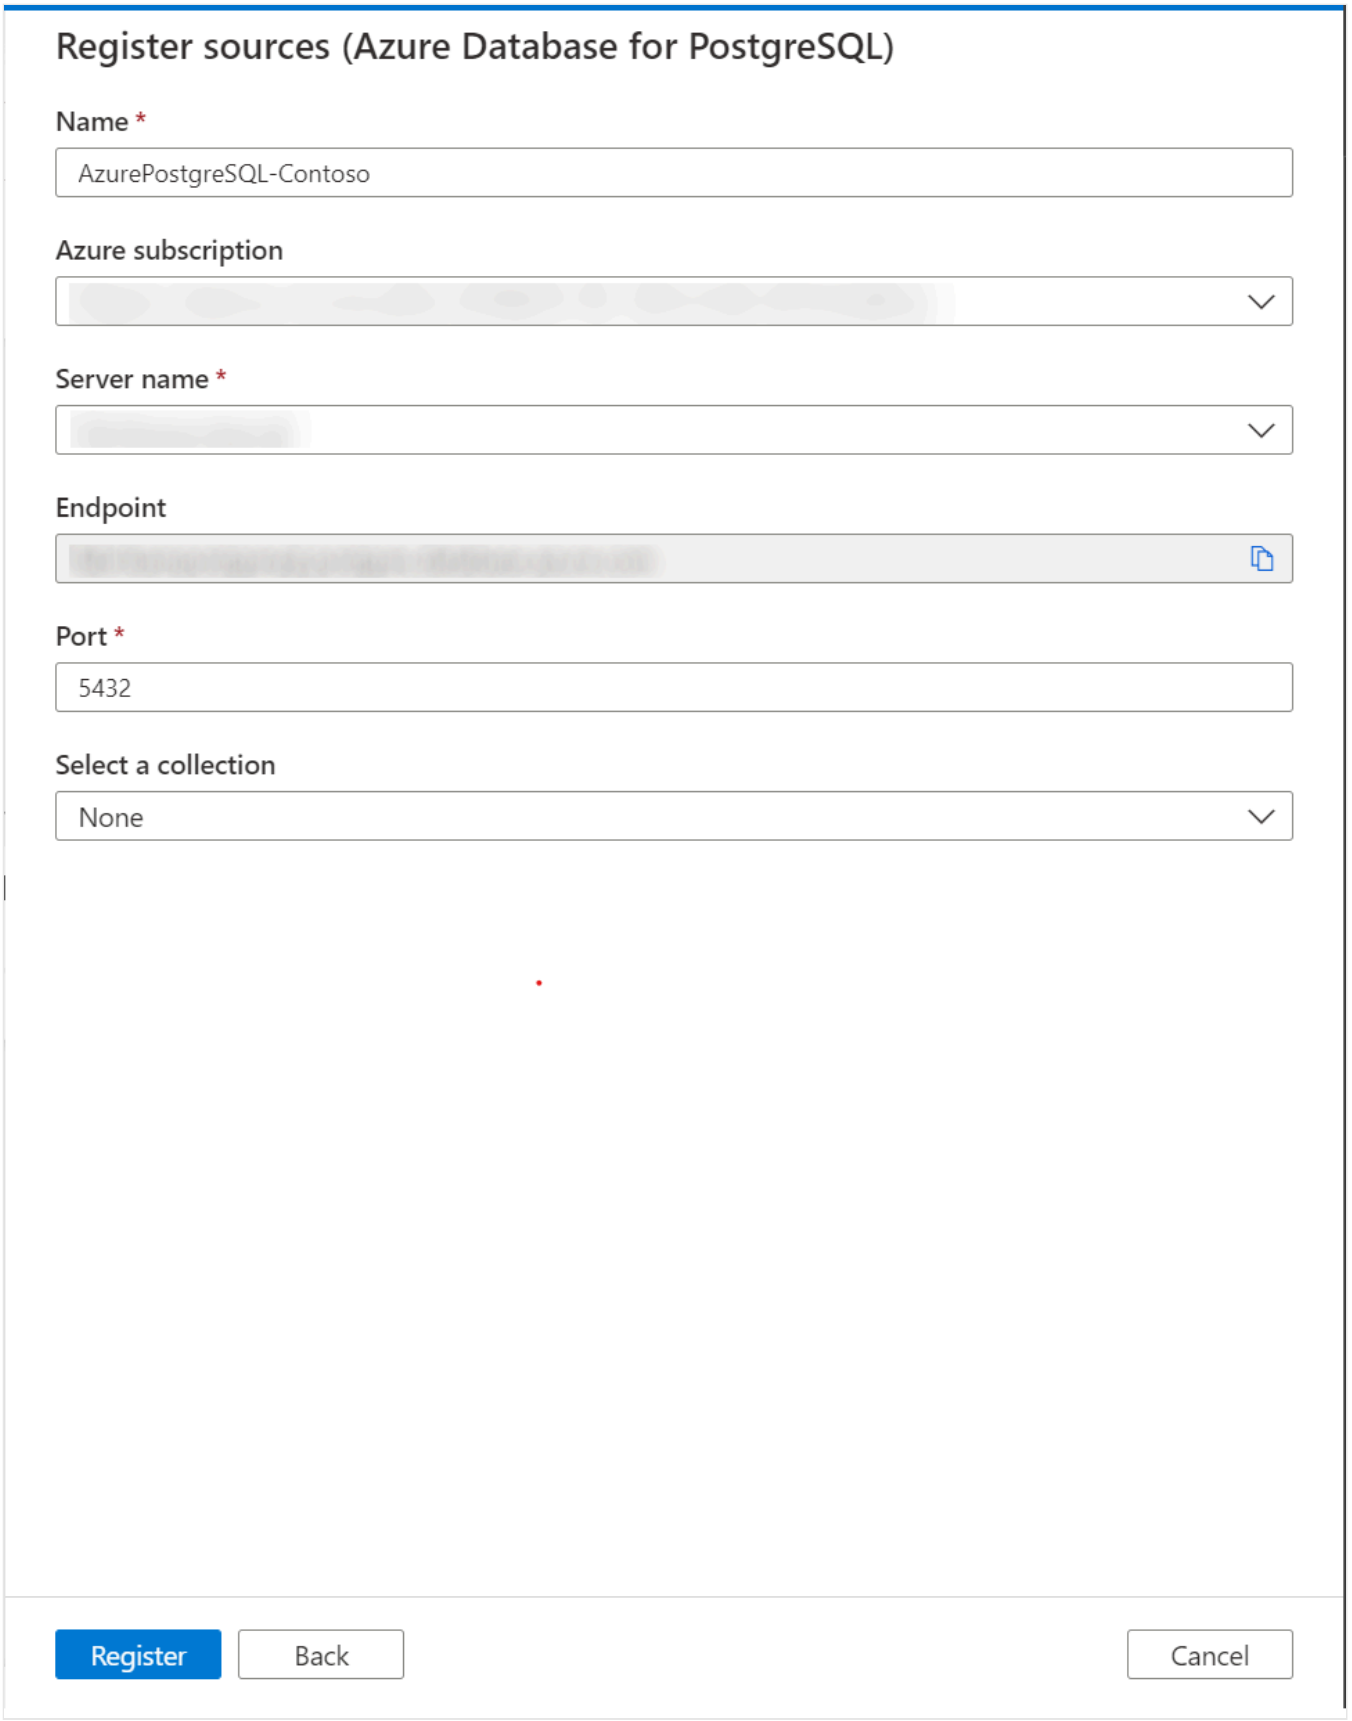
To register a new Azure Database for PostgreSQL in Microsoft Purview Unified Catalog, do the following:



1. Open the Microsoft Purview governance portal by:

- Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
- Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.



3. Select **Register**

4. On **Register sources**, select **Azure Database for PostgreSQL**. Select **Continue**.

On the **Register sources Azure Database for PostgreSQL** screen, do the following:

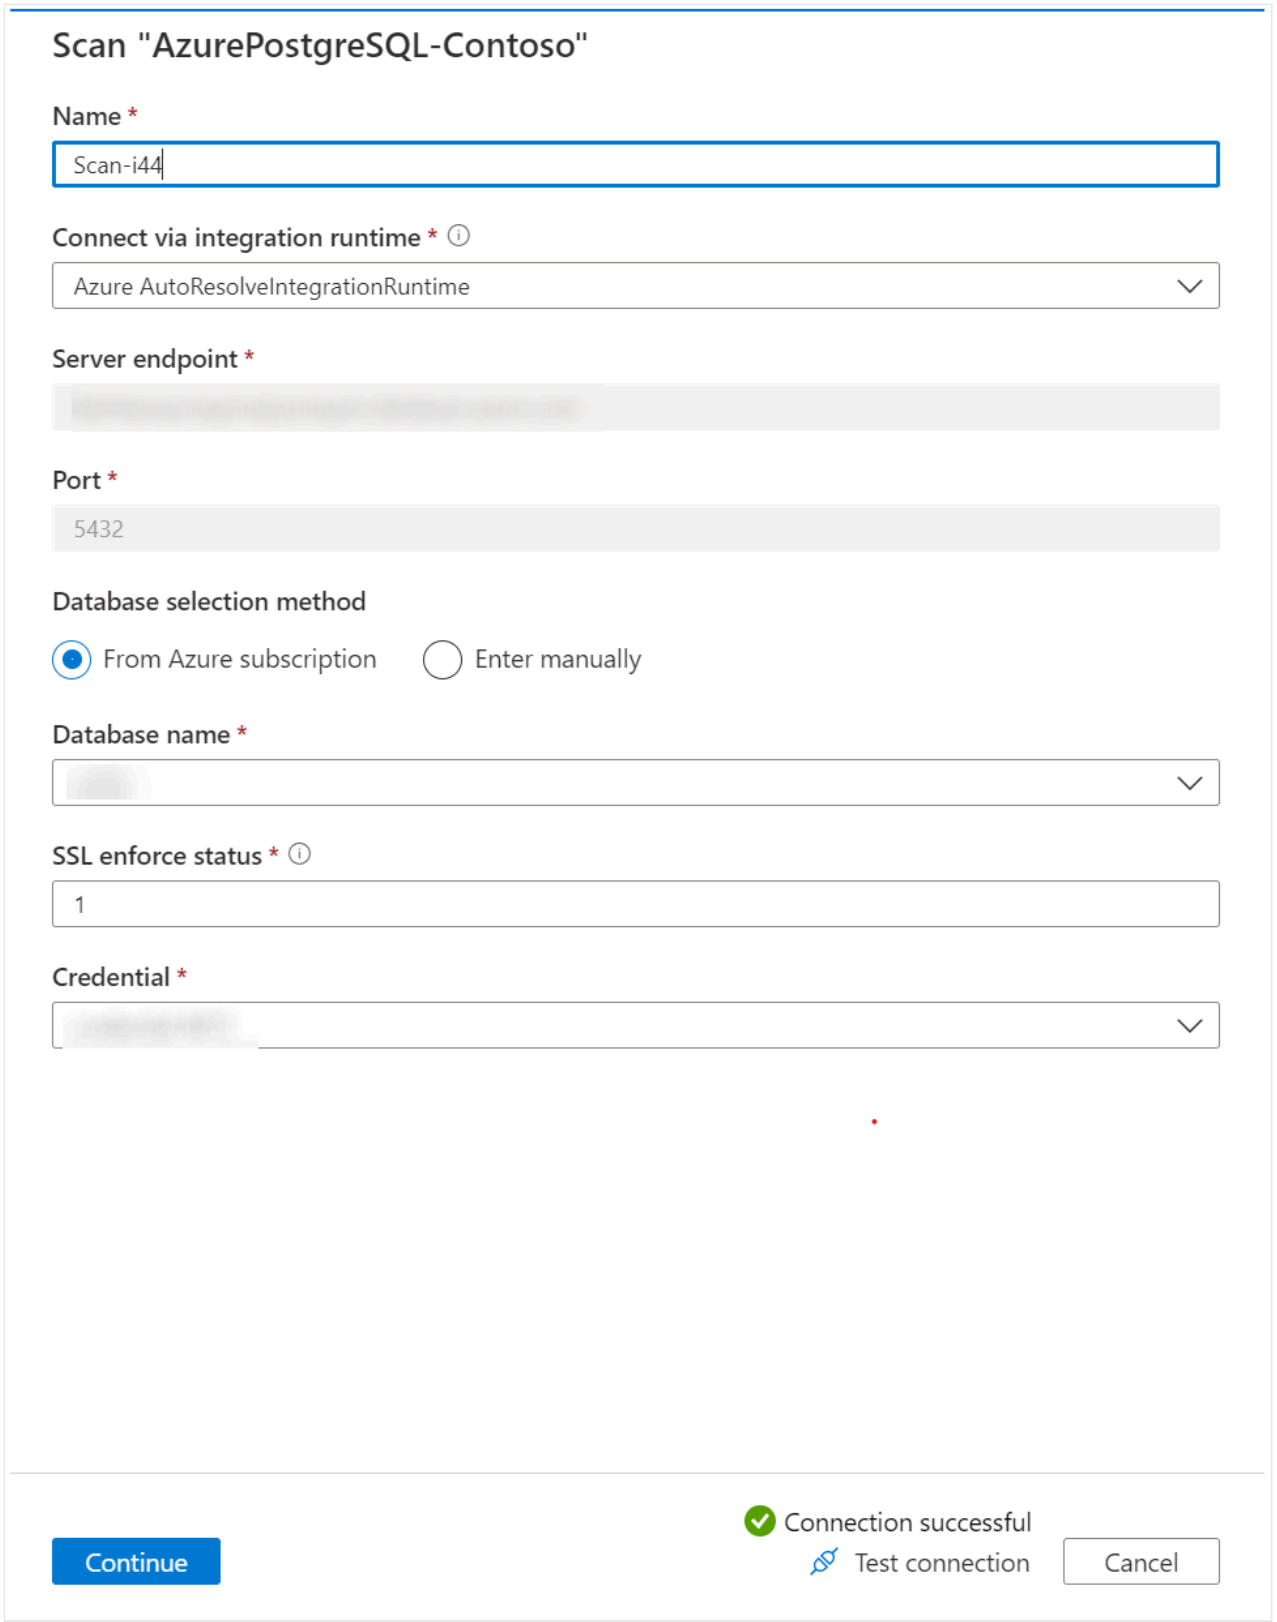
1. Enter a **Name** for your data source. This will be the display name for this data source in your Catalog.
2. Select **From Azure subscription**, select the appropriate subscription from the **Azure subscription** drop-down box and the appropriate server from the **Server name** drop-down box.
3. Select **Register** to register the data source.

Scan

Follow the steps below to scan an Azure Database for PostgreSQL database to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion

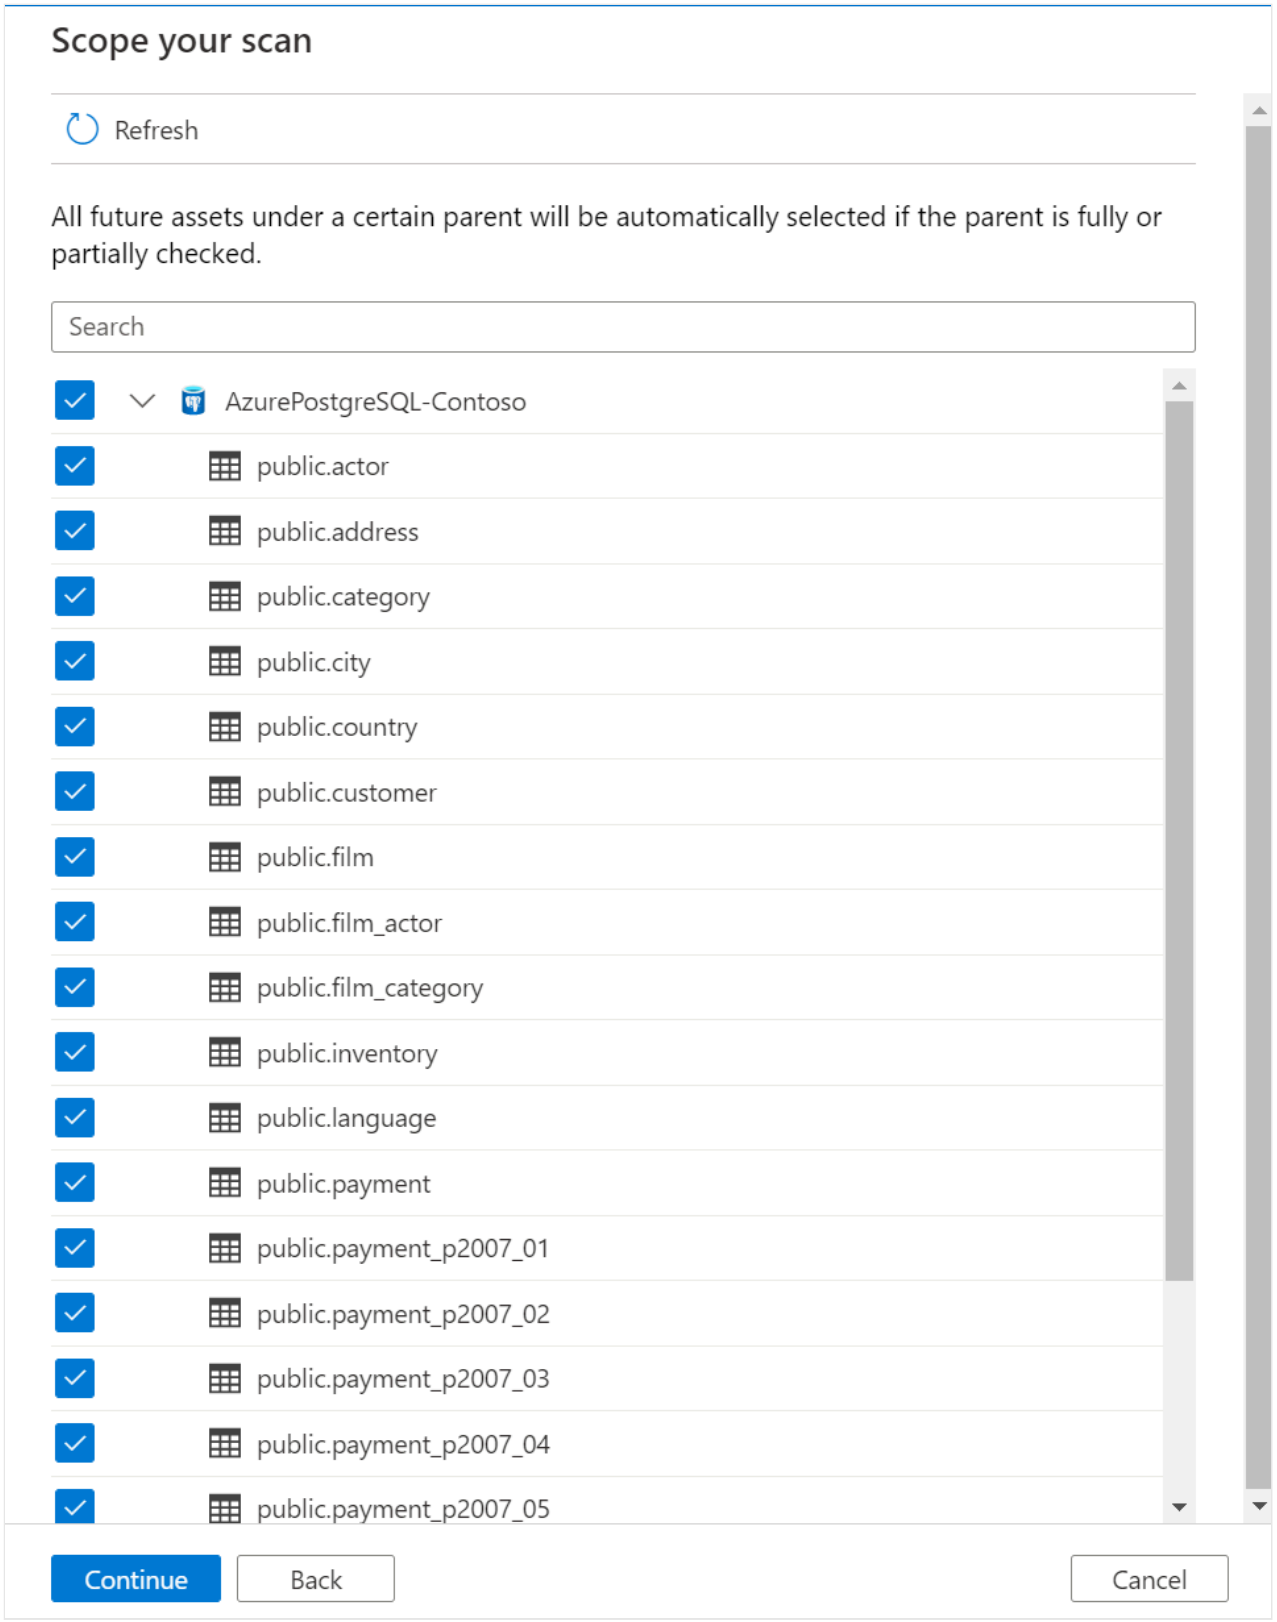
Create and run scan

To create and run a new scan, do the following:



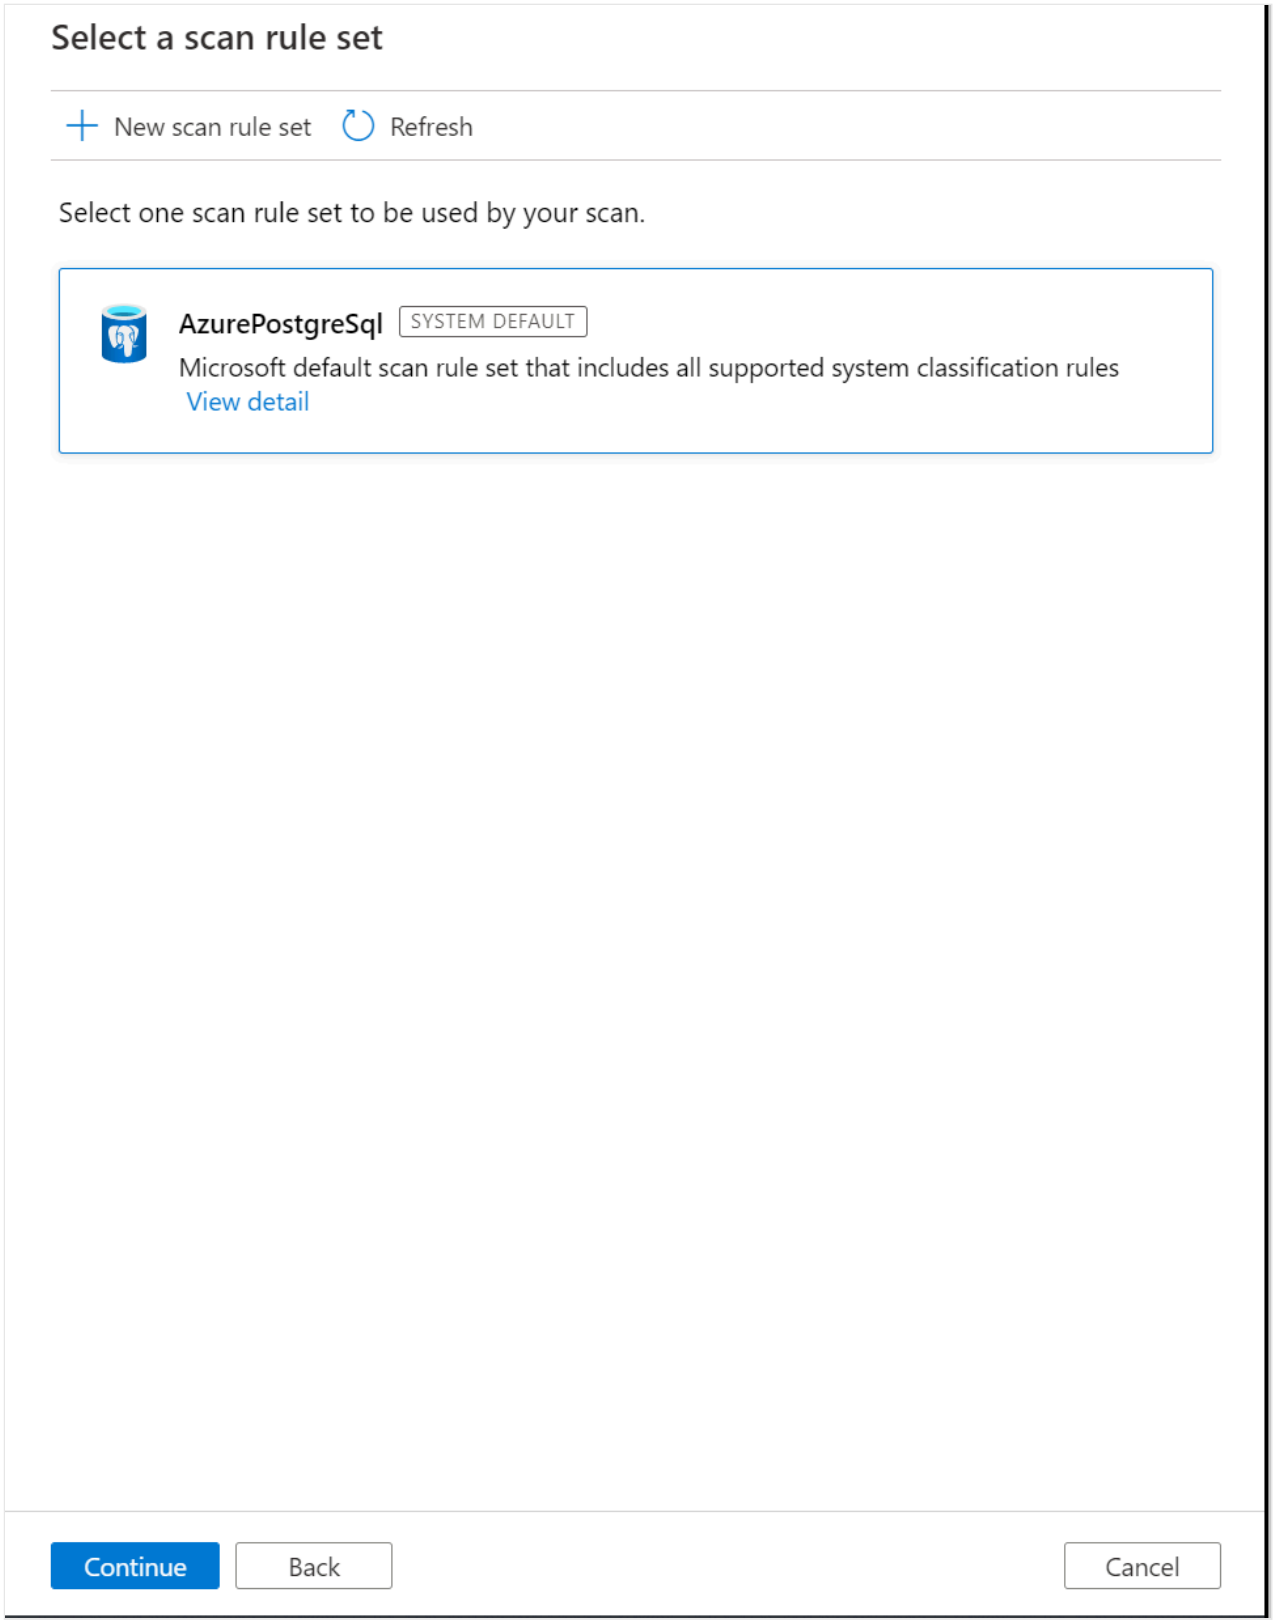
1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.

2. Select the Azure Database for PostgreSQL source that you registered.

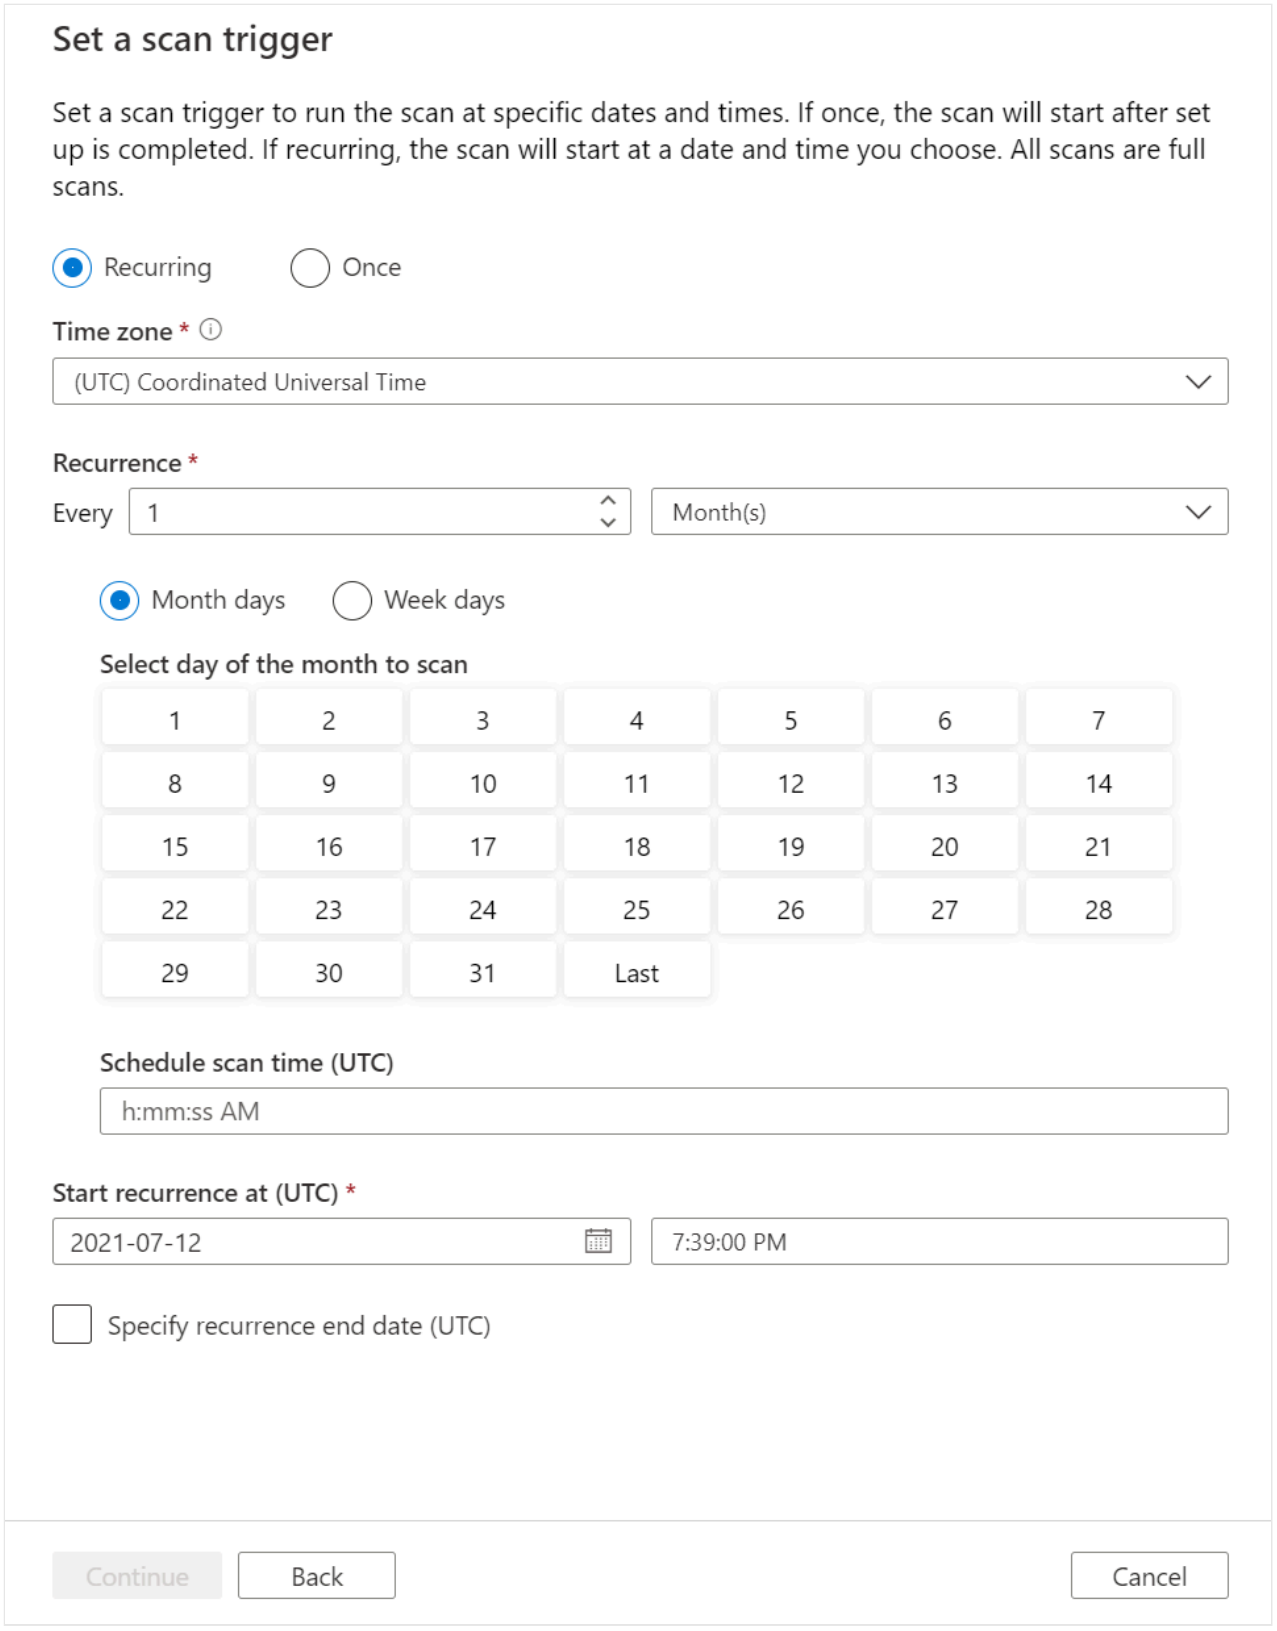


3. Select **New scan**

4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.



5. Select the credential to connect to your data source.



6. You can scope your scan to specific folders or subfolders by choosing the appropriate items in the list.

7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage Azure Databricks in Microsoft Purview

This article outlines how to register Azure Databricks, and how to authenticate and interact with Azure Databricks in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

> **Note**
>
> This connector brings metadata from Azure Databricks workspace-scoped Hive metastore. To scan metadata in Azure Databricks Unity Catalog, refer to Azure Databricks Unity Catalog connector.

When scanning Azure Databricks Hive metastore, Microsoft Purview supports:

- Extracting technical metadata, including:
  - Azure Databricks workspace
  - Hive server
  - Databases
  - Tables including the columns, foreign keys, unique constraints, and storage description
  - Views including the columns and storage description
- Fetching relationship between external tables and Azure Data Lake Storage Gen2/Azure Blob assets (external locations).
- Fetching static lineage between tables and views based on the view definition.

When setting up scan, you can choose to scan the entire Hive metastore, or scope the scan to a subset of schemas.

Compared to scanning via generic Hive Metastore connector if you use it to scan Azure Databricks earlier:

- You can directly set up scan for Azure Databricks workspaces without direct HMS access. It uses Databricks personal access token for authentication and connects to a cluster to perform scan.
- The Databricks workspace info is captured.
- The relationship between tables and storage assets is captured.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

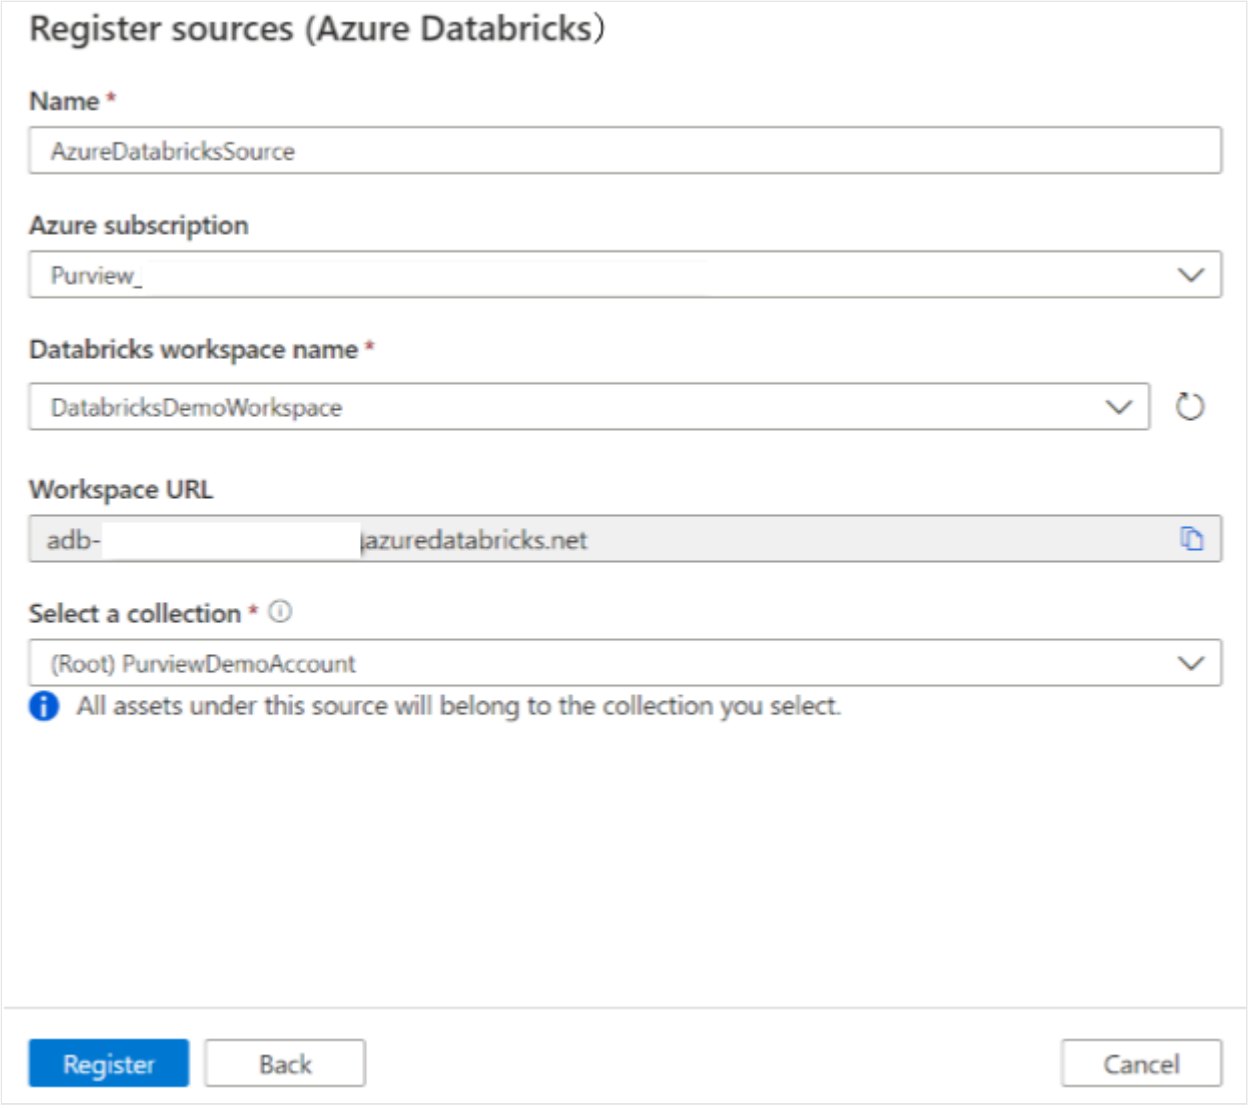
When you delete an object from the data source, the subsequent scan doesn't automatically remove the corresponding asset in Purview.

Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need an Azure Key Vault, and to grant Microsoft Purview permissions to access secrets.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the latest self-hosted integration runtime. For more information, see Create and configure a self-hosted integration runtime. The minimal supported self-hosted Integration Runtime version is 5.20.8227.2.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.

- In your Azure Databricks workspace:
  - Generate a personal access token, and store it as a secret in Azure Key Vault.
  - Create a cluster. Note the cluster ID - you can find it in Azure Databricks workspace -> Compute -> your cluster -> Tags -> Automatically added tags -> `ClusterId`.
  - Make sure the user has the following permissions so as to connect to the Azure Databricks cluster:
    - **Can Attach To** permission to connect to the running cluster.
    - **Can Restart** permission to automatically trigger the cluster to start if its state is terminated when connecting.

Register



This section describes how to register an Azure Databricks workspace in Microsoft Purview by using the Microsoft Purview governance portal.

1. Go to your Microsoft Purview account.
2. Select **Data Map** on the left pane.
3. Select **Register**.
4. In **Register sources**, select **Azure Databricks** > **Continue**.
5. On the **Register sources (Azure Databricks)** screen, complete the following steps:

   a. For **Name**, enter a name that Microsoft Purview lists as the data source.

   b. For **Azure subscription** and **Databricks workspace name**, select the subscription and workspace that you want to scan from the dropdown. The Databricks workspace URL is automatically populated.

   c. Select a collection from the list.

6. Select **Finish**.

Scan

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you followed all prerequisites.
> 2. Review the scan troubleshooting documentation.

Use the following steps to scan Azure Databricks to automatically identify assets. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

1. In the Management Center, select integration runtimes. Make sure that a self-hosted integration runtime is set up. If it isn't set up, use the steps in Create and manage a self-hosted integration runtime.

2. Go to **Sources**.

3. Select the registered Azure Databricks.

4. Select + **New scan**.

5. Provide the following details:

   a. **Name**: Enter a name for the scan.

   b. **Extraction method:** Indicate to extract metadata from Hive Metastore or Unity Catalog. Select **Hive Metastore**.

   c. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

   d. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select **Access Token Authentication** while creating a credential.
      - Provide secret name of the personal access token that you created in Prerequisites in the appropriate box.

      For more information, see Credentials for source authentication in Microsoft Purview.

   e. **Cluster ID**: Specify the cluster ID that Microsoft Purview connects to and powers the scan. You can find it in Azure Databricks workspace -> Compute -> your cluster -> Tags -> Automatically added tags -> `ClusterId`.

      i. **Mount points**: Provide the mount point and Azure Storage source location string when you have external storage manually mounted to Databricks. Use the format `/mnt/<path>=abfss://<container>@<adls_gen2_storage_account>.dfs.core.windows.net/;/mnt/<path>=wasbs://<container>@<blob_storage_account>.blob.core.windows.net`. It's used to capture the relationship between tables and the corresponding storage assets in Microsoft Purview. This setting is optional. If you don't specify it, the relationship isn't retrieved.

   You can get the list of mount points in your Databricks workspace by running the following Python command in a notebook:

   ```
   dbutils.fs.mounts()
   ```

   It prints all the mount points like below:

   ```
   ```

```
[MountInfo(mountPoint='/databricks-datasets', source='databricks-datasets',
encryptionType=''),
MountInfo(mountPoint='/mnt/ADLS2',
source='abfss://samplelocation1@azurestorage1.dfs.core.windows.net/',
encryptionType=''),
MountInfo(mountPoint='/databricks/mlflow-tracking',
source='databricks/mlflow-tracking', encryptionType=''),
MountInfo(mountPoint='/mnt/Blob',
source='wasbs://samplelocation2@azurestorage2.blob.core.windows.net',
encryptionType=''),
MountInfo(mountPoint='/databricks-results', source='databricks-results',
encryptionType=''),
MountInfo(mountPoint='/databricks/mlflow-registry',
source='databricks/mlflow-registry', encryptionType=''),
MountInfo(mountPoint='/', source='DatabricksRoot', encryptionType='')]
```

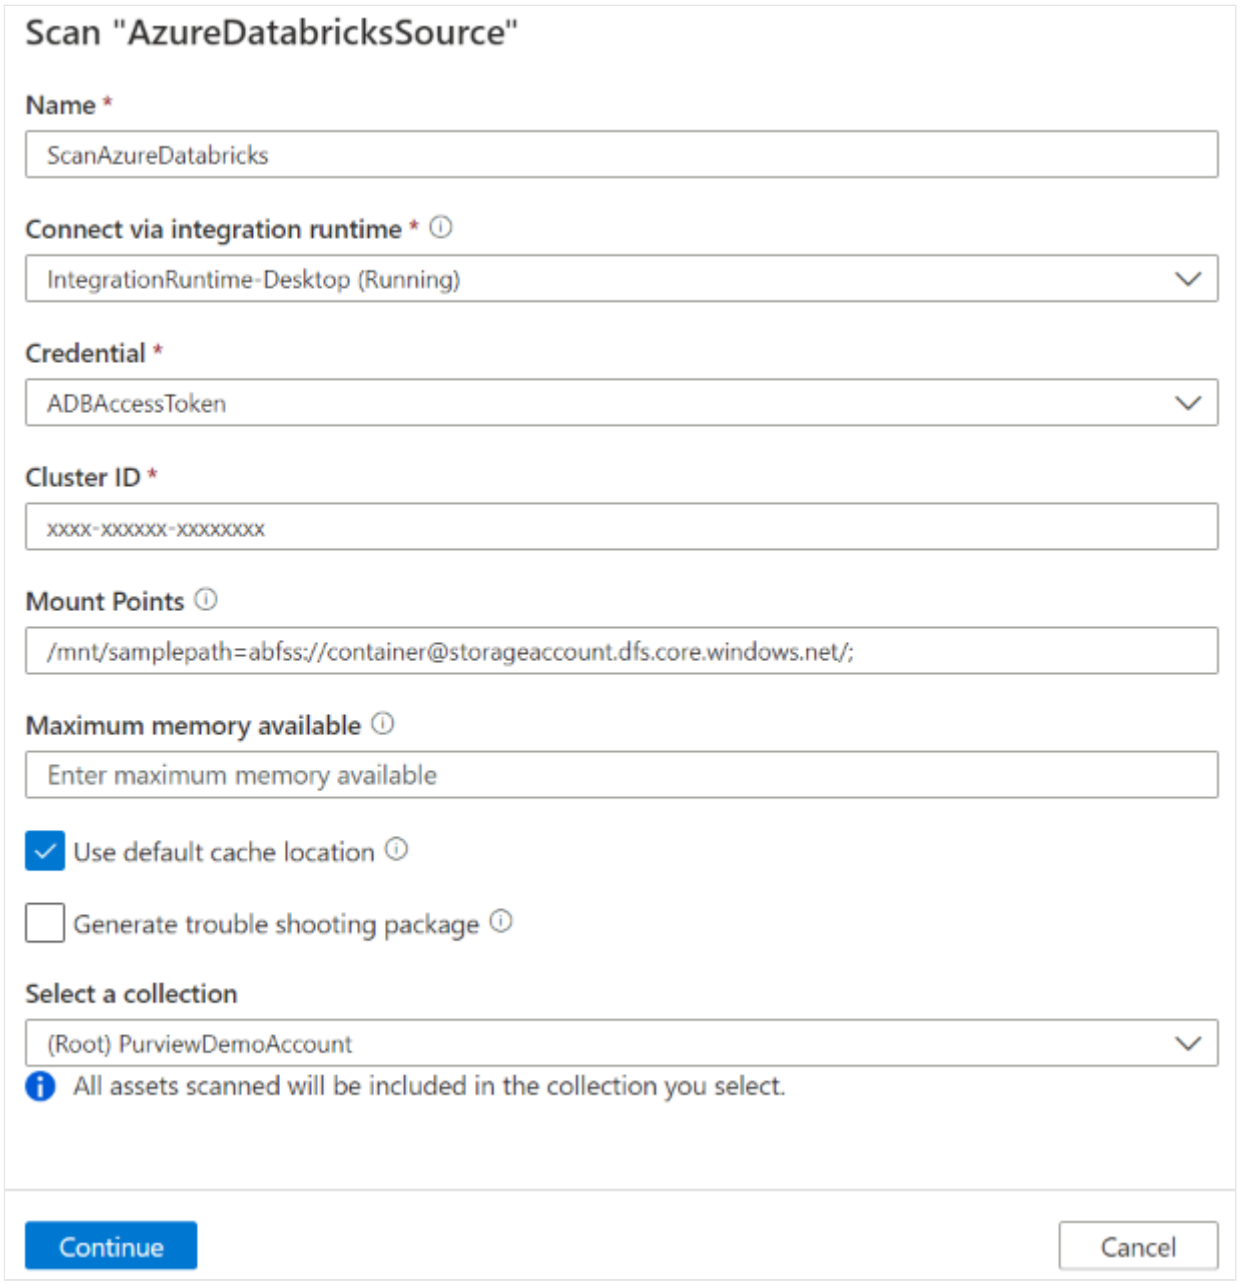
In this example, specify the following as mount points:

`/mnt/ADLS2=abfss://samplelocation1@azurestorage1.dfs.core.windows.net/;/mnt/Blob=wasbs://samplelocation2@azurestorage2.blob.core.windows.net`

f. **Schema**: The subset of schemas to import expressed as a semicolon separated list of schemas. For example, `schema1;schema2`. All user schemas are imported if that list is empty. All system schemas and objects are ignored by default.

Acceptable schema name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`

- Start with A or
- End with B or
- Contain C or
- Equal D



Usage of NOT and special characters aren't acceptable.

> ⓘ **Note**
>
> This schema filter is supported on Self-hosted Integration Runtime version 5.32.8597.1 and above.

g. **Maximum memory available**: Maximum memory (in gigabytes) available on the customer's machine for the scanning processes to use. This value is dependent on the size of Azure Databricks to be scanned.

> ⓘ **Note**

As a thumb rule, please provide 1GB memory for every 1000 tables.

6. Select **Continue**.

7. For **Scan trigger**, choose whether to set up a schedule or run the scan once.

8. Review your scan and select **Save and Run**.

Once the scan successfully completes, see how to browse and search Azure Databricks assets.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

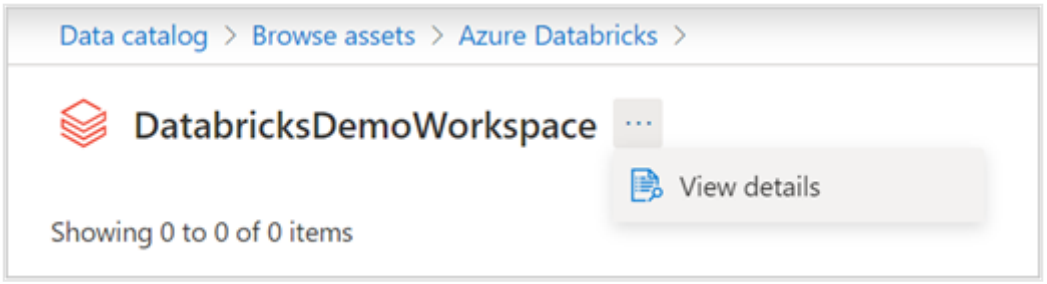
To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

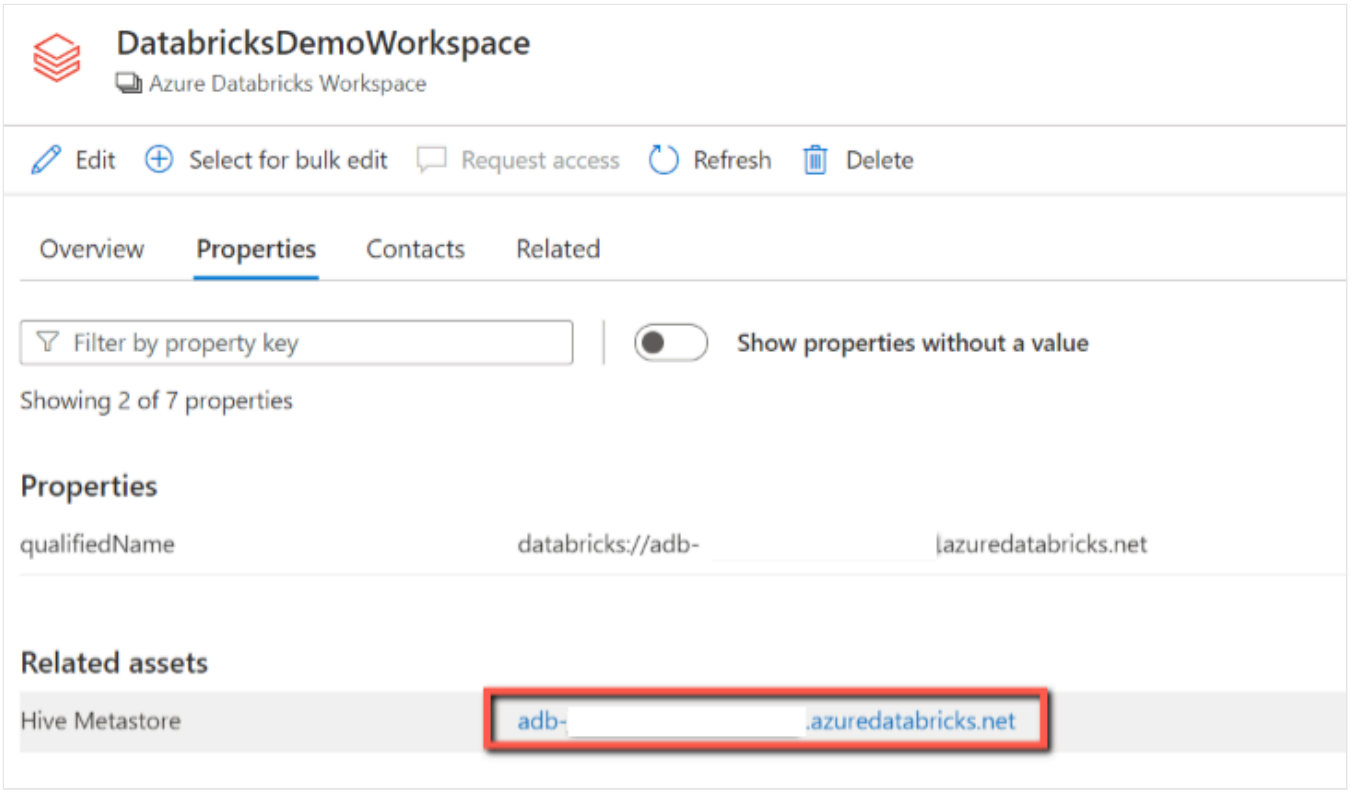
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.



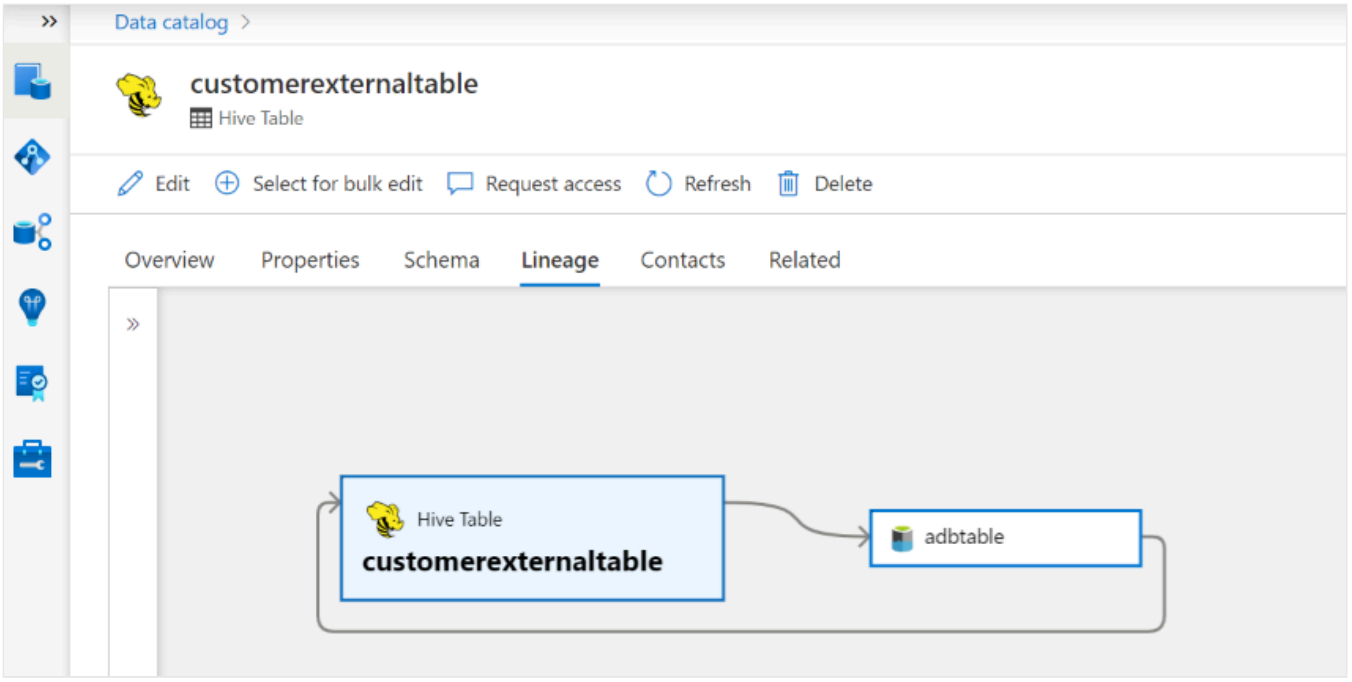
> ⓘ Note
>
> - Deleting your scan does not delete catalog assets created from previous scans.



Browse and search assets

After scanning your Azure Databricks, you can browse Unified Catalog or search Unified Catalog to view the asset details.

From the Databricks workspace asset, you can find the associated Hive Metastore and the tables/views, reversed applies too.



Lineage

Refer to the supported capabilities section on the supported Azure Databricks scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Go to the Hive table/view asset -> lineage tab, you can see the asset relationship when applicable. For relationship between table and external storage assets, you see Hive table asset and the storage asset are directly connected bi-directionally, as they mutually impact each other. If you use mount point in create table statement, you need to provide the mount point information in scan settings to extract such relationship.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search the Unified Catalog

Last updated on 03/31/2026

Connect to and manage Azure Databricks Unity Catalog in Microsoft Purview

This article outlines how to register Azure Databricks, and how to authenticate and interact with Azure Databricks Unity Catalog in Microsoft Purview. For more information about Microsoft Purview, see the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	No

When scanning Azure Databricks Unity Catalog, Microsoft Purview supports:

- Extracting technical metadata, including:
  - Metastore
  - Catalogs
  - Schemas
  - Tables, including the columns. Purview supports external tables metadata, but lineage isn't supported.
  - Views, including the columns
  - Tags from Unity Catalog (tags that represent labels, classification equivalent in Unity Catalog are scanned in Microsoft Purview in properties)
- Fetching lineage on assets relationships between tables, views, and columns during notebook runs.

When setting up a scan, you can choose to scan the entire Unity Catalog, or scope the scan to a subset of catalogs.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

> **Note**
>
> This connector brings metadata from Azure Databricks Unity Catalog. To scan Azure Databricks workspace-scoped metadata, see Azure Databricks Hive Metastore connector.

Known limitations

- In Microsoft Purview, Databricks notebook names appear as numeric IDs instead of readable names. This limitation exists because Databricks doesn't expose notebook names in the Unity Catalog system table.
- You might encounter errors if scan results from Azure Databricks exceed 1 MB and Azure Databricks-managed blob storage denies public network access. To prevent this problem, ensure that Microsoft Purview has access to the internal DBFS storage location of the Azure Databricks workspace being scanned. To learn more, see Cloud fetch in JDBC.
- Incremental scan is available only for the *Azure Databricks Unity Catalog* data source.
- Scoped scan is available only for the Unity Catalog option under *Azure Databricks* data source.
- You can add managed private endpoints only for the Unity Catalog option under *Azure Databricks* data source.
- When you delete an object from the data source, the subsequent scan doesn't automatically remove the corresponding asset in Microsoft Purview.
- Lineage information isn't available in Azure Databricks workspaces in the China region. This limitation exists because Azure Databricks system tables aren't supported in this region. Microsoft Purview uses these tables to extract lineage, so it can't retrieve lineage in this region.
- Set the Databricks table column comment to an empty string if you don't want the column description displayed in Microsoft Purview.
- Scan of external tables or dynamic tables isn't supported.
- Tags aren't currently supported for scans done using a Kubernetes SHIR option.

For more information about other limitations related to native Azure Databricks lineage, see Azure Databricks documentation.

Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need an Azure Key Vault, and to grant Microsoft Purview permissions to access secrets.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the classic Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- To scan Azure Databricks Unity Catalog, Microsoft Purview connects to a SQL Warehouse in your workspace, and uses a Personal Access Token for authentication. You need to have an Azure Databricks workspace that is Unity Catalog enabled and attached to the metastore you want to scan. In your Azure Databricks workspace:
    - Create a SQL Warehouse. You can use the autocreated Starter warehouse as well if applicable.
    - Note down the HTTP path. You can find it in Azure Databricks workspace > SQL Warehouses > your warehouse > Connection details > HTTP path.
    - Make sure the user has the **Can Use** permission so they can connect to the Azure Databricks SQL warehouse. Learn more at SQL warehouse access control.
    - The SQL warehouse in Azure Databricks must be running to establish a connection with Microsoft Purview before setting up the scan in Microsoft Purview.
- To fetch lineage from Azure Databricks using Microsoft Purview, the following prerequisites must be in place:
    - Enable the system schema: The system schema **system.access** must be enabled in your Unity Catalog. This requirement exists because lineage information is stored in system tables, and enabling this schema allows access to those tables. Learn more about monitoring usage with system tables.
    - User privileges:
        - The user account you use for scanning needs to have SELECT privileges on the following system tables:
            - system.access.table_lineage

    - system.access.column_lineage

    These permissions are required because lineage data is read directly from the system tables, and without the necessary access, Microsoft Purview can't retrieve the lineage information.

    The user account you use for scanning also needs to have these permissions:
    - USE CATALOG on system
    - USE SCHEMA on system.access

- If your Azure Databricks workspace doesn't allow access from public network or if your Microsoft Purview account doesn't enable access from all networks, you can use the Managed Virtual Network Integration Runtime or a kubernetes supported self-hosted integration runtime to scan. You can set up a managed private endpoint for Azure Databricks as needed to establish private connectivity.

Data source setup (Azure Databricks vs. Azure Databricks Unity Catalog)

You can set up an Azure Databricks Unity Catalog connection to Microsoft Purview through two sources:

- Azure Databricks (old source)
- Azure Databricks Unity Catalog

Differences in capabilities between data sources

The capabilities of the Azure Databricks Unity Catalog connector differ based on the source used for the connection, as outlined in the following table:

Expand table

Capability	Old source	New source
Source name	Azure Databricks	Azure Databricks Unity Catalog
Source support	Hive & Unity Catalog	Unity Catalog
Authentication: Personal Access Token	Supported	Supported
Authentication: Service Principal	No	Supported

Capability	Old source	New source
Authentication: Managed Identity	No	Supported (system managed identity)
Integration Runtime: Azure IR	Supported	Supported
Integration Runtime: Managed Virtual Network IR	Supported	Yes**
Integration Runtime: Kubernetes Self-Hosted IR	Supported	Supported
Scoped scan	Yes - catalog level	No
Incremental scan	No	Yes
Lineage	Supported	Supported

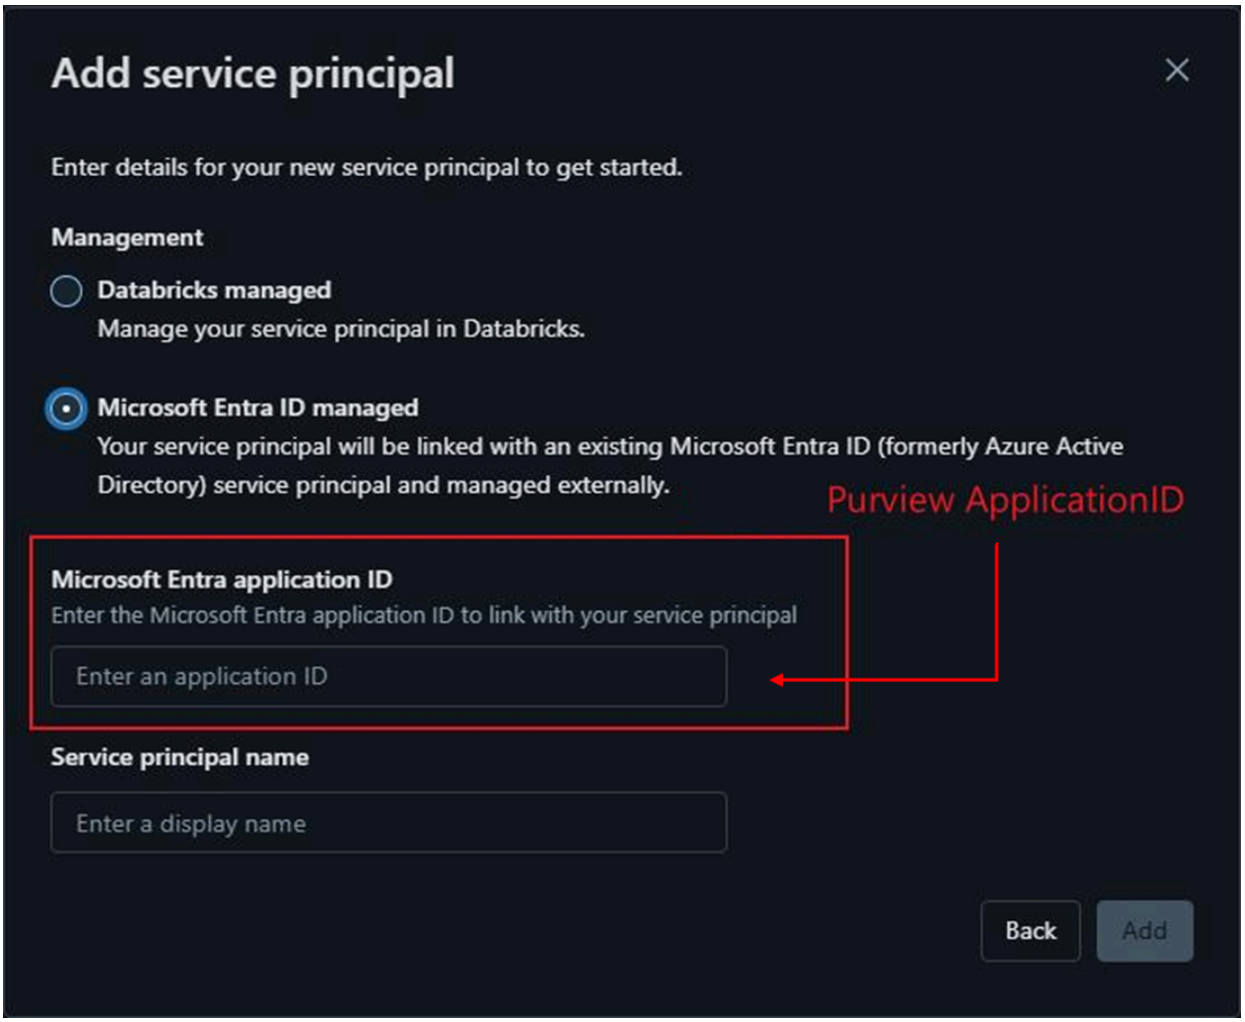
**Scanning Azure Databricks Unity Catalog is supported through Managed Virtual Network Integration Runtime. However, Managed Private Endpoint isn't supported in this case.

Which source should I use?

Choose either source based on your organization's needs, or use both in parallel. Switching between sources or using both simultaneously **doesn't cause asset duplication** in Microsoft Purview. This flexibility allows you to start with the option that best fits your current setup and adjust over time as needed.

Authentication for a scan

To scan Azure Databricks Unity Catalog, use personal access tokens, managed identities, or service principal authentication methods.



System assigned managed identity

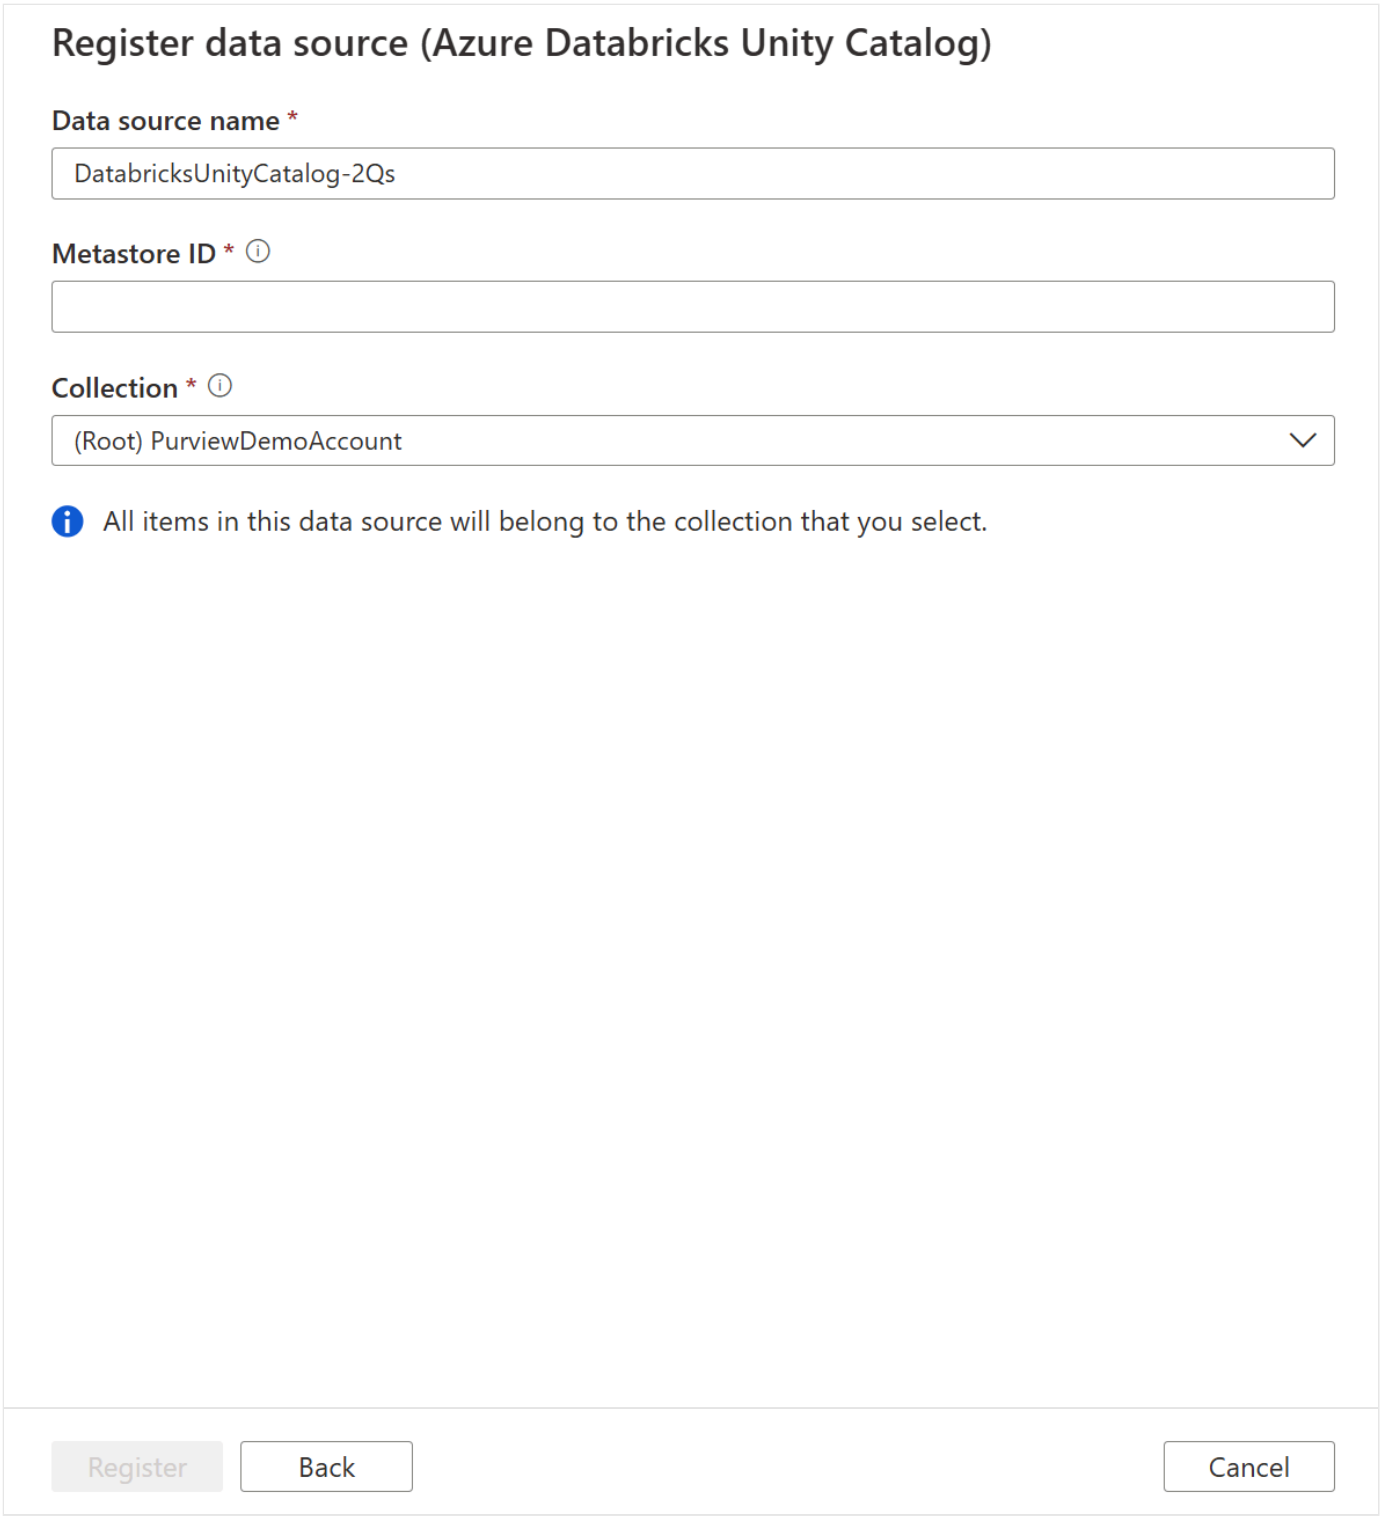
If you use a system assigned managed identity

In Azure Databricks

1. Go to **Settings** > **Workspace admin** > **Identity and access**.
2. Select **Add service principal**.
3. Select **Add new**.

4. Select **Microsoft Entra ID managed**. Enter the **Application ID** for Microsoft Purview. You can find the Application ID under Microsoft Purview account resource details in the Azure portal.

In Microsoft Purview



1. Select the system-assigned managed identity under **Credential**.

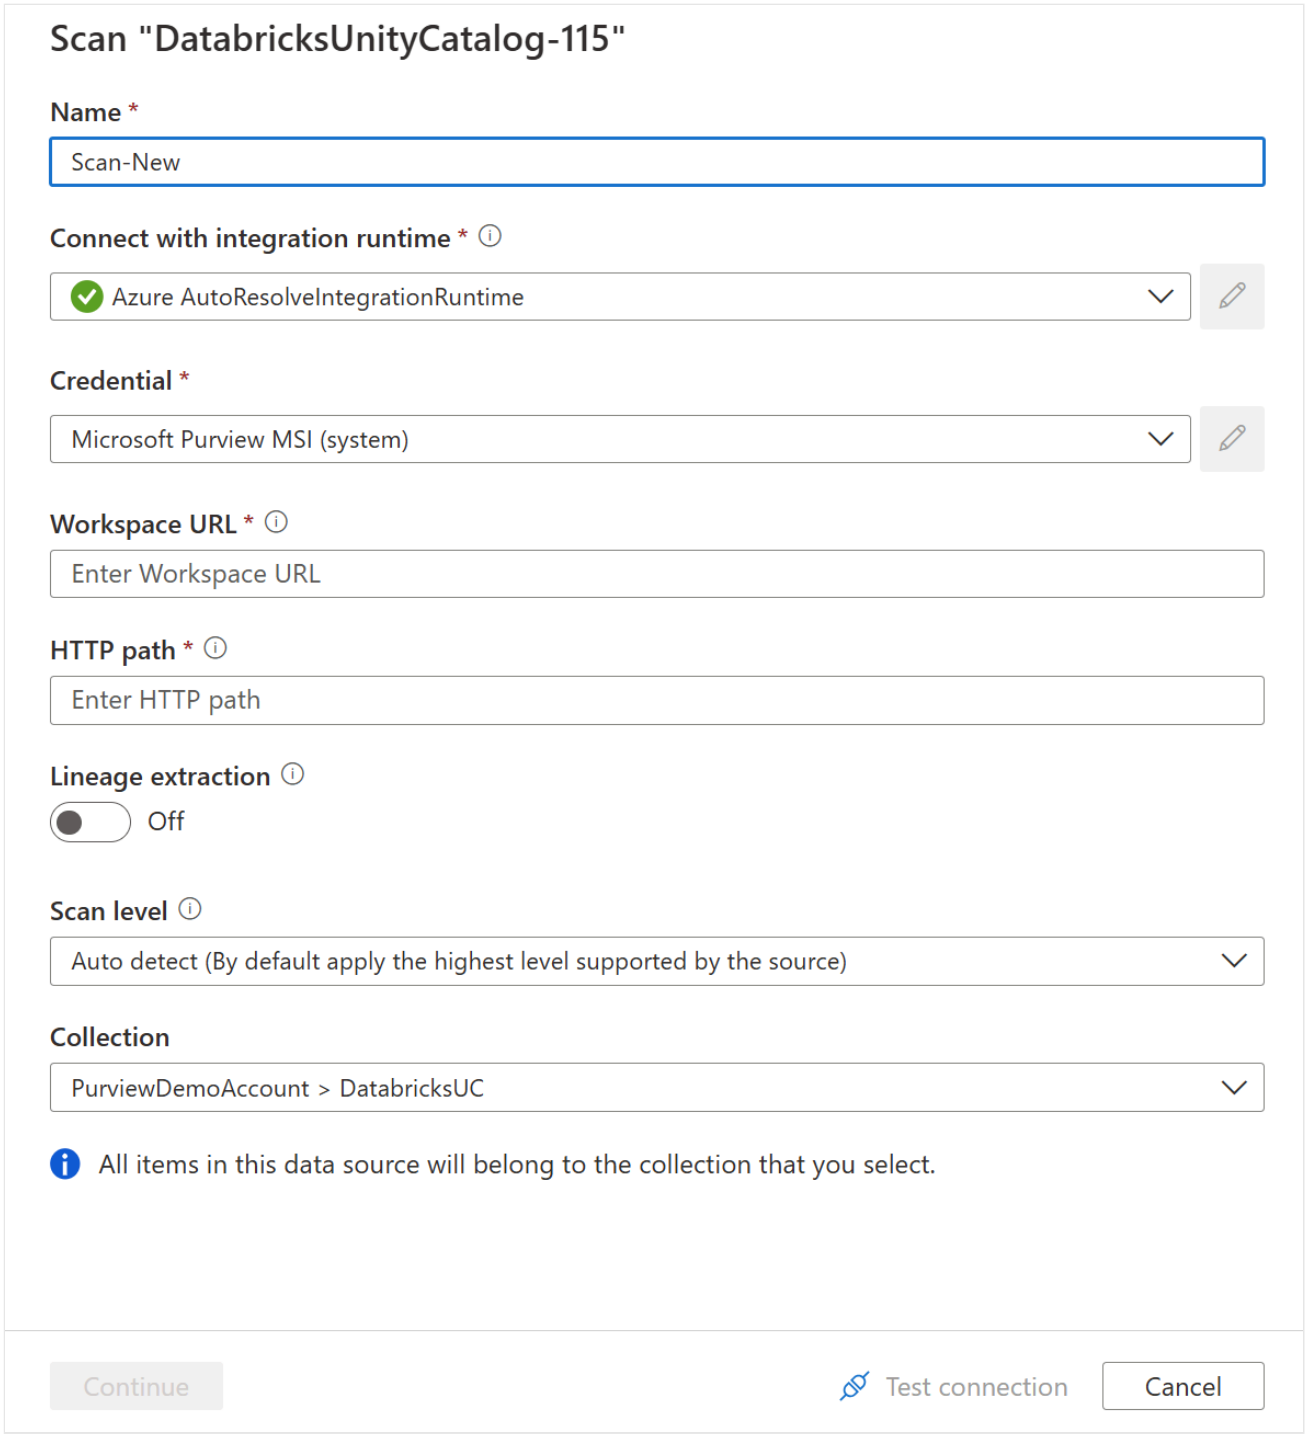
- For all the objects that you want to bring into Microsoft Purview, the user or service principal needs to have at least **SELECT** privilege on tables/views, **USE CATALOG** on the object's catalog, and **USE SCHEMA** on the object's schema.
    - To scan all the objects in a Unity Catalog metastore, use a user or service principal with metastore admin role. For more information, see Manage privileges in Unity Catalog and Unity Catalog privileges and securable objects.
        - For classification, the user also needs to have **SELECT** privilege on the tables/views to retrieve sample data.

Register

This section describes how to register an Azure Databricks workspace in Microsoft Purview by using the classic Microsoft Purview governance portal.

1. Go to your Microsoft Purview account.
2. Select **Data Map** on the left pane.
3. Select **Register**.
4. In **Register sources**, select **Azure Databricks Unity Catalog** > **Continue**.
5. On the **Register sources (Azure Databricks Unity Catalog)** screen, complete the following steps:
6. For **Name**, enter a name that Microsoft Purview will list as the data source.
    a. For **Metastore ID**, enter the metastore ID for the Azure Databricks Unity Catalog metastore that you want to scan.
    b. Select a collection from the list.

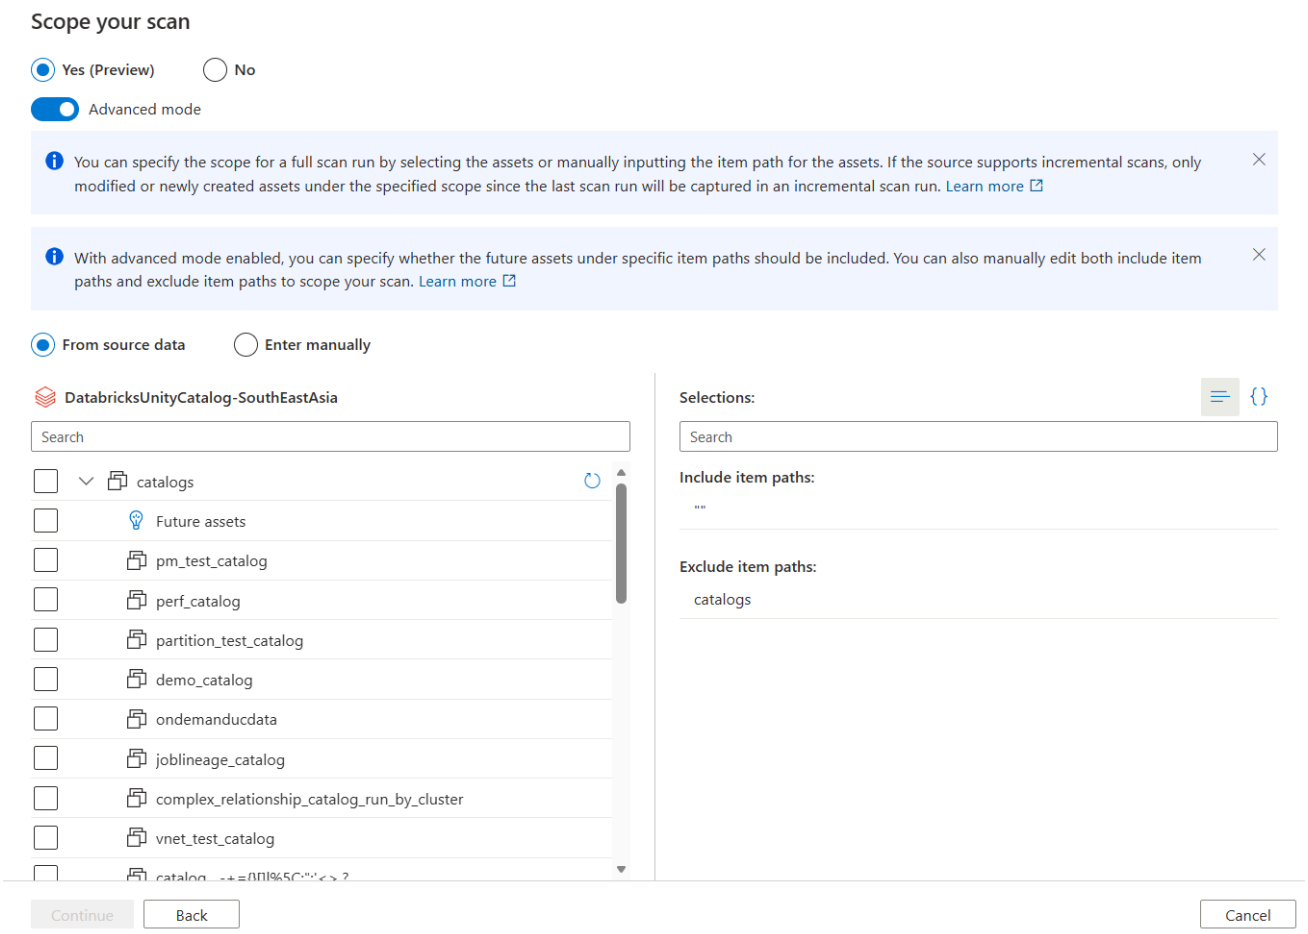
7. Select **Finish**.



Scan

> **Tip**
>
> To troubleshoot any problems with scanning:
>
> 1. Confirm you meet all prerequisites.

2. Review the **scan troubleshooting documentation**.



Use the following steps to scan Azure Databricks and automatically identify assets. For more information about scanning, see Scans and ingestion in Microsoft Purview.

1. Go to **Sources**.
2. Select the registered Azure Databricks.
3. Select **+ New scan**.
4. Provide the following details:
    a. **Name**: Enter a name for the scan.
    b. **Connect via integration runtime**: Choose the default Azure integration runtime, Managed Virtual Network IR, or a Kubernetes supported self-hosted integration runtime you created.
    c. **Credential**: Select the credential to connect to your data source. Make sure to:
        - Select **Access Token**, **Managed Identity**, or **Service Principal**.
        - You can create a new Access Token or Service Principal credential while registering a scan. For more information, see Credentials for source authentication in Microsoft Purview.
    d. **Workspace URL:** Provide the URL for the workspace that you want to scan.
        i. **HTTP path:** Specify the Databricks SQL Warehouse's HTTP path that Microsoft Purview connects to and performs the scan; for example, `/sql/1.0/endpoints/xxxxxxxxxxxxxxxx`. You can find it in Azure Databricks workspace -> SQL Warehouses -> your warehouse -> Connection details -> HTTP path.
    e. **Lineage extraction:** Toggle lineage extraction to **On** to fetch lineage of the scanned assets.
5. Select **Test connection** to validate the settings.

6. Select **Continue**.

7. On the **Scope your scan** page, select one or more catalogs on which you want to limit your scan. Use **Advanced mode** (preview) to select specific item paths to include or exclude from the scan.

8. For **Scan trigger**, choose whether to set up a schedule or run the scan once.

9. Review your scan and select **Save and Run**.

After the scan finishes successfully, see how to browse and search assets.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

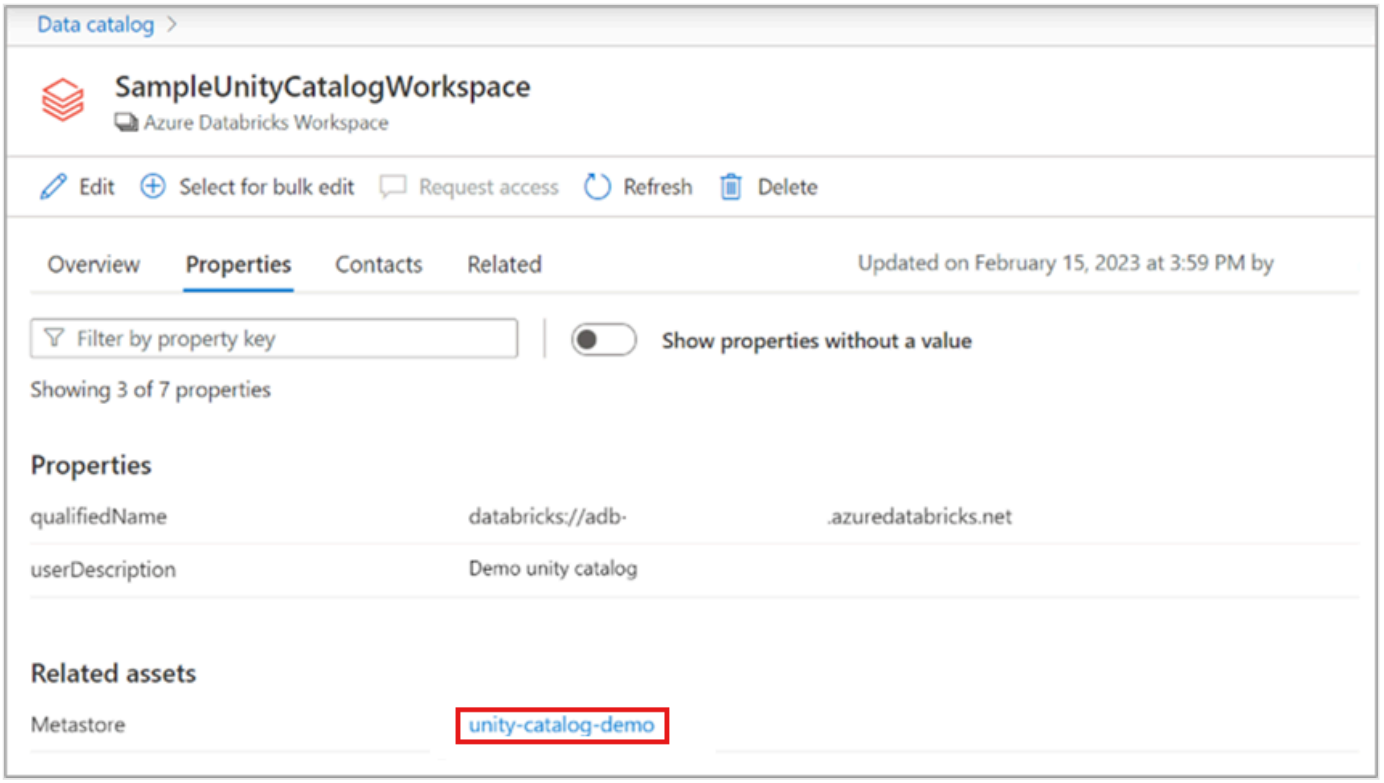
1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

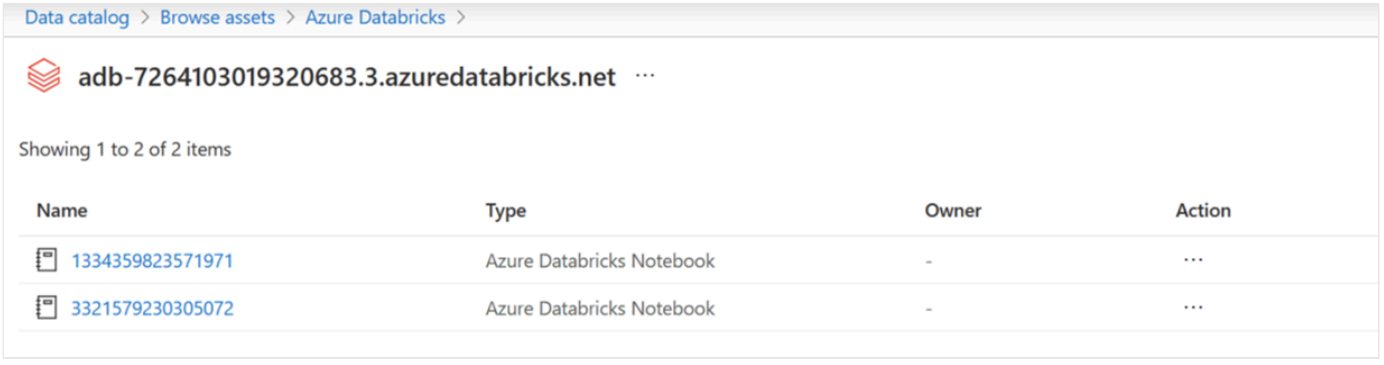
> ⓘ Note
>
> - Deleting your scan does not delete catalog assets created from previous scans.



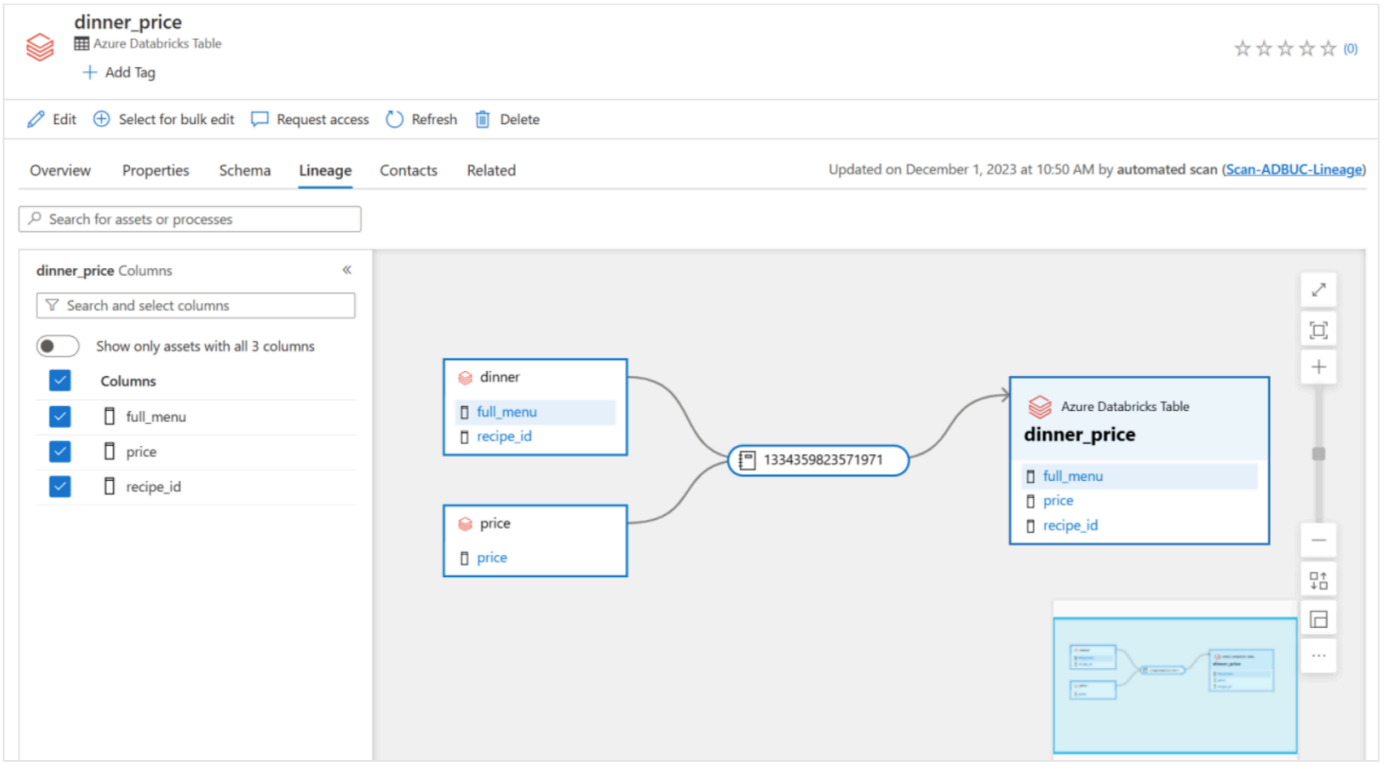
Browse and search assets

After scanning your Azure Databricks, you can browse Unified Catalog or search Unified Catalog to view the asset details and lineage.

When you browse by source types, you see two entries for **Azure Databricks Unity Catalog** and **Azure Databricks**. The **Azure Databricks Unity Catalog** entry contains the Unity Catalog artifacts, including the metastore and its catalogs, schemas, tables, and views. The **Azure Databricks** entry contains the workspace artifacts.



From the Azure Databricks workspace asset, you can find the associated Unity Catalog under the **Properties** tab. The association also works in reverse.



Lineage

When you browse a particular Azure Databricks asset, you can see the notebooks that have captured lineage.

Go to the asset and select the lineage tab. You can see the lineage on the Azure Databricks Notebook asset or table/view asset when applicable.

Supported lineage scenarios

- Lineage is supported for tables and views when they're connected via Databricks notebooks within the Unity Catalog.
- Lineage appears only for objects scanned through Microsoft Purview. All related assets must be scanned to form a complete lineage graph. Ensure all Databricks workspaces with relevant notebooks are included in Microsoft Purview scans.

Lineage limitations

- When you execute notebooks through Databricks jobs, column-level lineage might not be captured.
- Microsoft Purview shows only partial lineage if you don't scan all objects involved in a data flow. For example, if a notebook in Workspace A writes data to a table in Workspace B, but you only scan Workspace A by using Microsoft Purview, the lineage shows the notebook but not the destination table, resulting in incomplete lineage.
- If an external service triggers a notebook (for example, Azure Data Factory [ADF] pipeline calling a Databricks job), the lineage in Microsoft Purview doesn't reflect that dependency.
  - In this case, lineage between ADF datasets and Databricks assets isn't shown.
  - Only lineage built within Databricks notebooks is captured.

Lineage is missing scenario

Lineage extraction is passive; Microsoft Purview only ingests what Unity Catalog system table logs and makes accessible.

- Refer to the preceding sections to ensure that your lineage scenario is supported.
- Validate that Unity Catalog lineage system tables (`system.access.table_lineage`, `system.access.column_lineage`) are populated correctly.
- Raise a support ticket if you still encounter problems.

Refer to the supported capabilities section for supported Databricks Unity Catalog lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Frequently asked questions (FAQ)

Does Microsoft Purview capture column-level lineage from Unity Catalog?

Microsoft Purview captures lineage at both the Unity Catalog table and view level, and at the column level.

Why don't I see column-level lineage?

Column-level lineage appears when you run your notebook from a cluster. SQL warehouses don't generate column-level lineage.

How do I fix a timeout error?

Your scan might not finish if your workspace contains a large number of assets. To fix this problem, scope your scan to a few catalogs at a time. This approach reduces the number of assets in each scan and helps your scans complete.

Why didn't Microsoft Purview fetch the lineage after I ran my notebook?

After you run your notebook, Databricks might take a few minutes to update the lineage information in its system tables. Microsoft Purview can fetch the lineage after the system tables are updated.

Next steps

After you register your source, use the following guides to learn more about Microsoft Purview and your data:

- Search the Unified Catalog
- Data Estate Insights in Microsoft Purview

Connect to and manage dedicated SQL pools in Microsoft Purview

Article • 05/21/2025

This article outlines how to register dedicated SQL pools (formerly SQL DW), and how to authenticate and interact with dedicated SQL pools in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

> **Note**
>
> There are dedicated SQL pools (formerly SQL DW) and dedicated SQL pools in Azure Synapse workspace and you can refer to What is the difference between dedicated SQL pools (SQL DW) and dedicated SQL pools in Azure Synapse workspaces for the detail difference between the two. Currently Microsoft Purview provides separate data sources for dedicated SQL pools (formerly SQL DW) and dedicated SQL pools:
>
> - if you are looking to register and scan a dedicated SQL pool (formerly SQL DW), you can follow instructions in Connect to and manage dedicated SQL pools in Microsoft Purview.
> - if you are looking to register and scan a dedicated SQL pool (formerly SQL DW) which has enabled Azure Synapse workspace features as documented in Enable Azure Synapse workspace features for a dedicated SQL pool (formerly SQL DW), you can also follow instructions in Connect to and manage Azure Synapse Analytics workspaces in Microsoft Purview.
> - if you are looking to register and scan a dedicated SQL pool or a serverless SQL pool in Azure Synapse workspace, you must follow instructions in Connect to and manage Azure Synapse Analytics workspaces in Microsoft Purview.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

When scanning dedicated SQL pool (formerly SQL DW) source, Microsoft Purview supports extracting technical metadata including:

- Server
- Dedicated SQL pools
- Schemas
- Tables including columns
- Views including columns

When setting up the scan, you can further scope it after providing the dedicated SQL pool name by selecting tables and views as needed.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You will need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

Register

This section describes how to register dedicated SQL pools in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

There are three ways to set up authentication:

- System or user assigned managed identity (Recommended)
- Service Principal
- SQL authentication

> **Note**
>
> Only the server-level principal login (created by the provisioning process) or members of the `loginmanager` database role in the master database can create new logins. It takes about 15 minutes after granting permission, the Microsoft Purview account should have the appropriate permissions to be able to scan the resource(s).

System or user assigned managed identity to register

You can use either your Microsoft Purview system-assigned managed identity (SAMI), or a User-assigned managed identity (UAMI) to authenticate. Both options allow you to assign authentication directly to Microsoft Purview, like you would for any other user, group, or service principal. The Microsoft Purview SAMI is created automatically when the account is created. A UAMI is a resource that can be created independently, and to create one you can follow our user-assigned managed identity guide. Create a Microsoft Entra user in the dedicated SQL pool using your managed identity object name by following the prerequisites and tutorial on Create Microsoft Entra users using Microsoft Entra applications.

Example SQL syntax to create user and grant permission:

```SQL
CREATE USER [PurviewManagedIdentity] FROM EXTERNAL PROVIDER
GO

EXEC sp_addrolemember 'db_datareader', [PurviewManagedIdentity]
GO
```

The authentication must have permission to get metadata for the database, schemas, and tables. It must also be able to query the tables to sample for classification. The recommendation is to assign `db_datareader` permission to the identity.

Service Principal to register

To use service principal authentication for scans, you can use an existing one or create a new one.

If you need to create a new Service Principal, follow these steps:

1. Navigate to the Azure portal.
2. Select **Microsoft Entra ID** from the left-hand side menu.
3. a. Select **App registrations**.

4. Select + **New application registration**.
5. Enter a name for the **application** (the service principal name).
6. Select **Accounts in this organizational directory only**.
7. For Redirect URI, select **Web** and enter any URL you want; it doesn't have to be real or work.
8. Then select **Register**.

It is required to get the Service Principal's application ID and secret:

1. Navigate to your Service Principal in the Azure portal
2. Copy the values the **Application (client) ID** from **Overview** and **Client secret** from **Certificates & secrets**.
3. Navigate to your key vault
4. Select **Settings** > **Secrets**
5. Select + **Generate/Import** and enter the **Name** of your choice and **Value** as the **Client secret** from your Service Principal
6. Select **Create** to complete
7. If your key vault is not connected to Microsoft Purview yet, you will need to create a new key vault connection
8. Finally, create a new credential using the Service Principal to set up your scan.

Granting the Service Principal access

In addition, you must also create a Microsoft Entra user in the dedicated pool by following the prerequisites and tutorial on Create Microsoft Entra users using Microsoft Entra applications. Example SQL syntax to create user and grant permission:

```SQL
CREATE USER [ServicePrincipalName] FROM EXTERNAL PROVIDER
GO

ALTER ROLE db_datareader ADD MEMBER [ServicePrincipalName]
GO
```

> **Note**
>
> Microsoft Purview will need the **Application (client) ID** and the **client secret** in order to scan.

SQL authentication to register

You can follow the instructions in CREATE LOGIN to create a login for your dedicated SQL pool (formerly SQL DW) if you don't already have one.

When authentication method selected is **SQL Authentication**, you need to get your password and store in the key vault:

1. Get the password for your SQL login
2. Navigate to your key vault
3. Select **Settings** > **Secrets**
4. Select + **Generate/Import** and enter the **Name** and **Value** as the *password* for your SQL login
5. Select **Create** to complete
6. If your key vault is not connected to Microsoft Purview yet, you will need to create a new key vault connection
7. Finally, create a new credential using the key to set up your scan.

Steps to register

To register a new SQL dedicated pool in Microsoft Purview, complete the following steps:

1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.

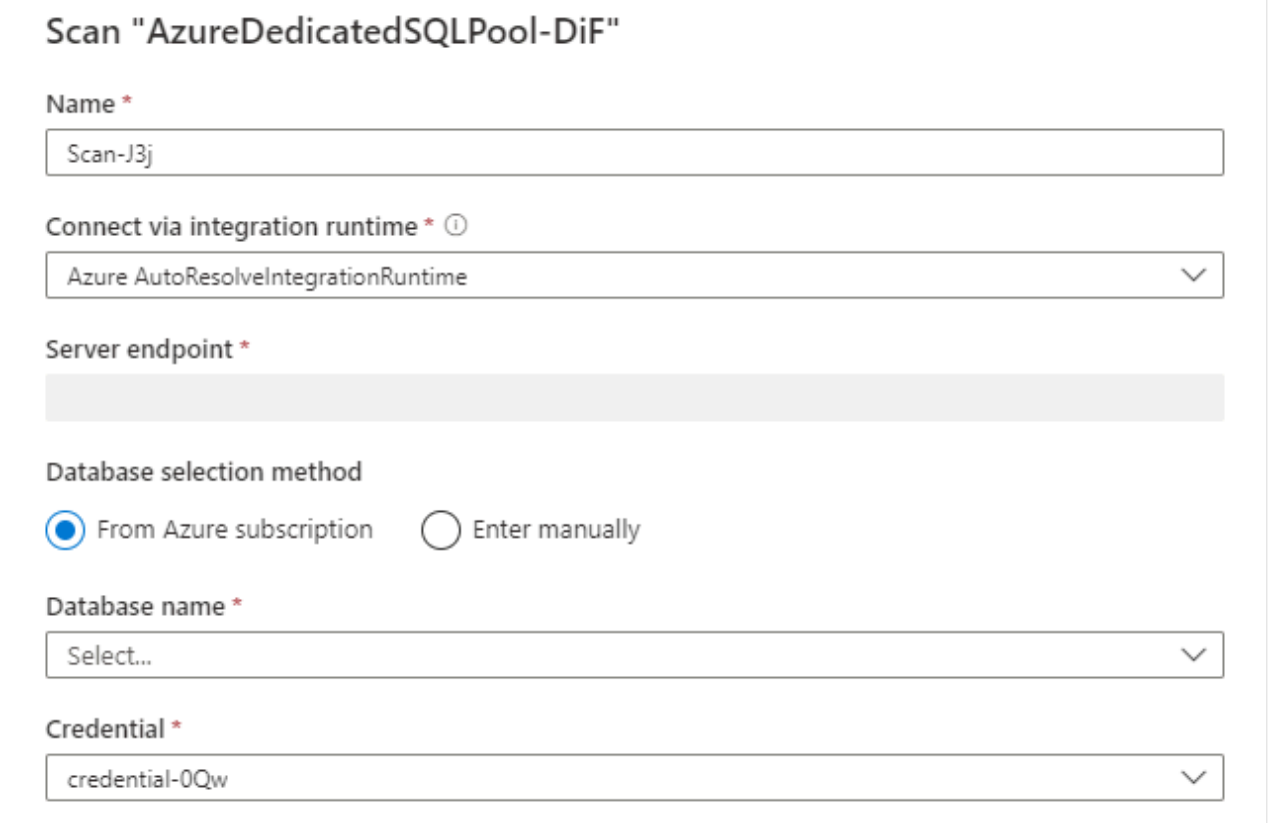
3. Select **Register**

4. On **Register sources**, select **Azure Dedicated SQL Pool (formerly SQL DW)**.

5. Select **Continue**

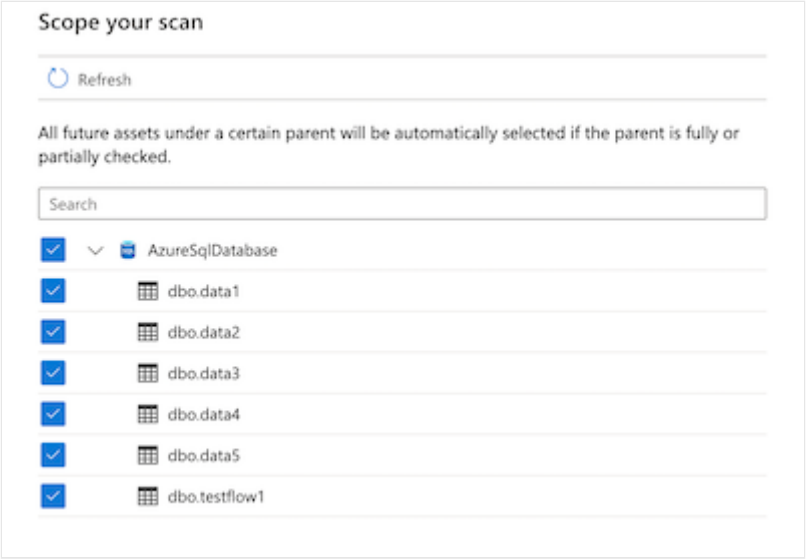
On the **Register sources** screen, complete the following steps:

1. Enter a **Name** that the data source will be listed with in the Catalog.
2. Choose your Azure subscription to filter down dedicated SQL pools.
3. Select your dedicated SQL pool.
4. Select a collection from the list.
5. Select **Register** to register the data source.



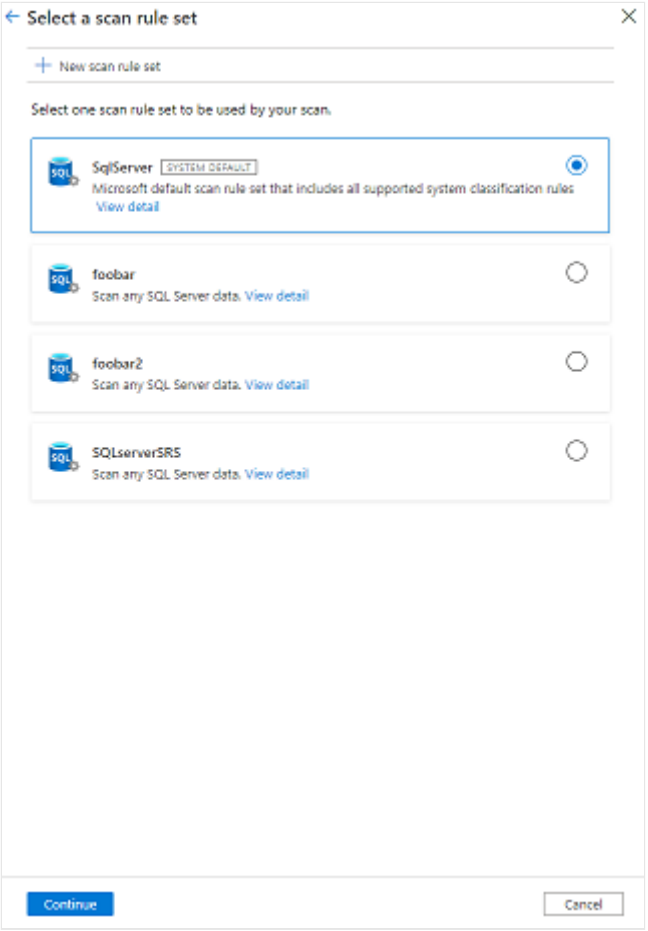
Scan

Follow the steps below to scan dedicated SQL pools to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion

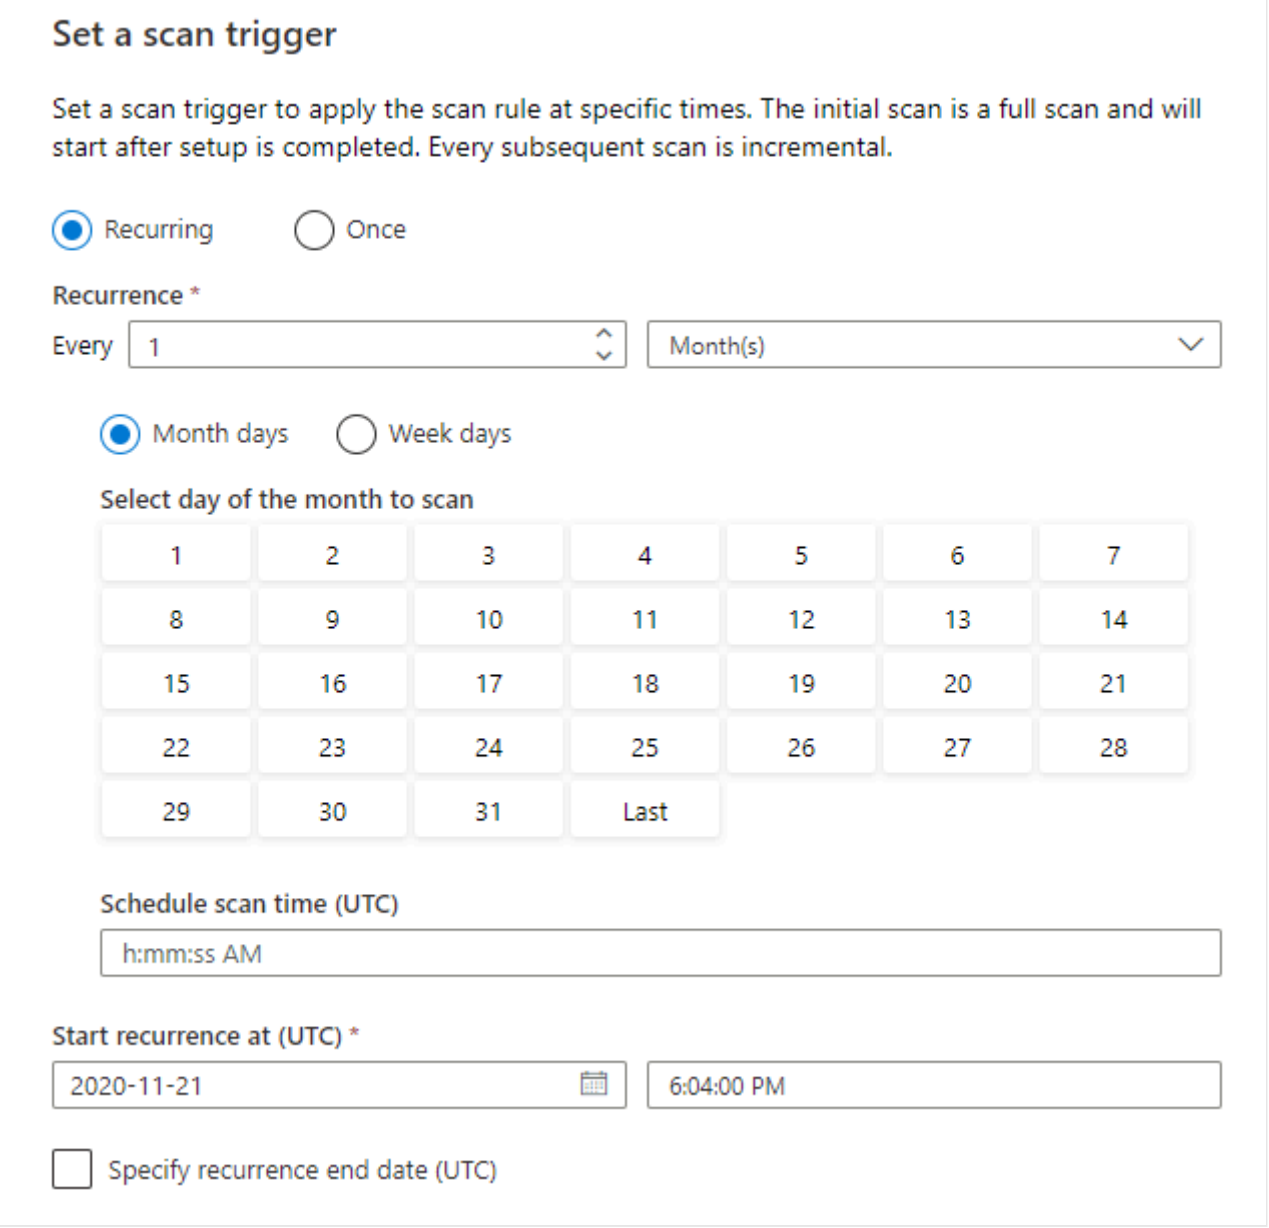


Create and run scan

To create and run a new scan, complete the following steps:



1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.
2. Select the SQL dedicated pool source that you registered.
3. Select **New scan**
4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.
5. Select the credential to connect to your data source.



6. You can scope your scan to specific tables by choosing the appropriate items in the list.

7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you have registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage Azure Machine Learning in Microsoft Purview (preview)

Article • 05/21/2025

This article outlines how to register Azure Machine Learning and how to authenticate and interact with Azure Machine Learning in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

This integration between Azure Machine Learning and Microsoft Purview applies an auto push model that, once the Azure Machine Learning workspace has been registered in Microsoft Purview, the metadata from workspace is pushed to Microsoft Purview automatically on a daily basis. It isn't necessary to manually scan to bring metadata from the workspace into Microsoft Purview.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	No

When scanning the Azure Machine Learning source, Microsoft Purview supports:

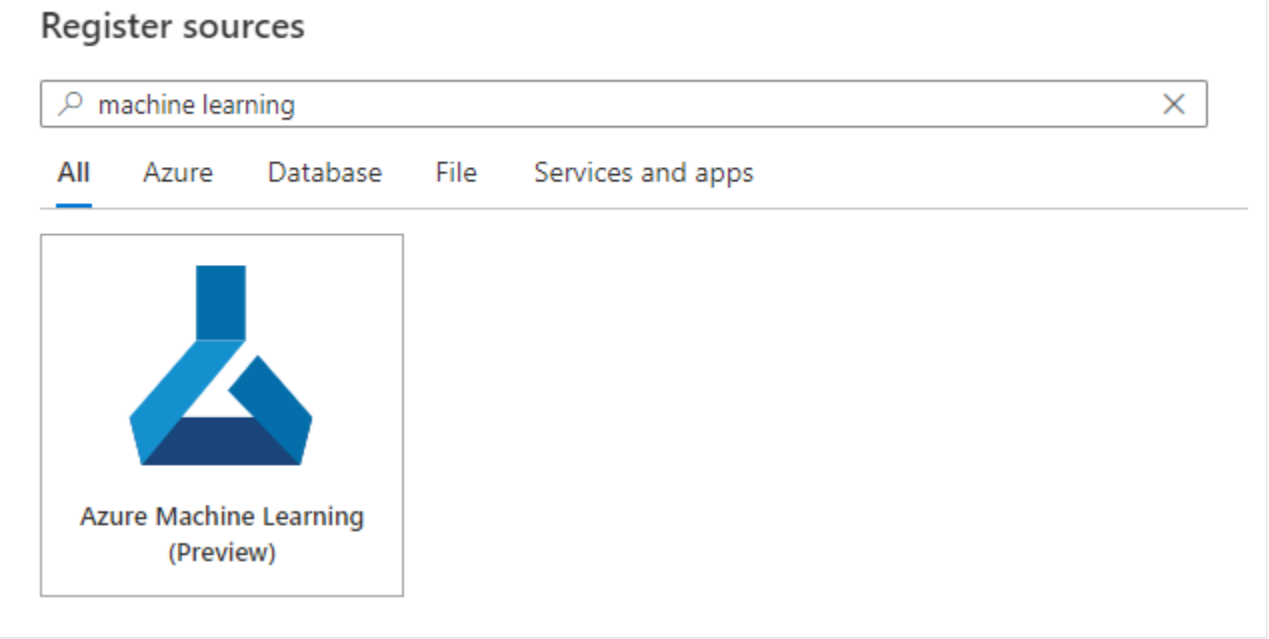
- Extracting technical metadata from Azure Machine Learning, including:
  - Workspace
  - Models
  - Datasets
  - Jobs

> **Note**

1. AML workspaces don't currently support pushing metadata through a private endpoint to Microsoft Purview.
2. You must register assets in your AML workspace for them to appear in Microsoft Purview.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.



Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- An active Azure Machine Learning workspace
- A user needs the Contributor role in the Azure Machine Learning workspace to enable auto push from Azure Machine Learning workspace.

Register

This section describes how to register an Azure Machine Learning workspace in Microsoft Purview by using the Microsoft Purview governance portal.

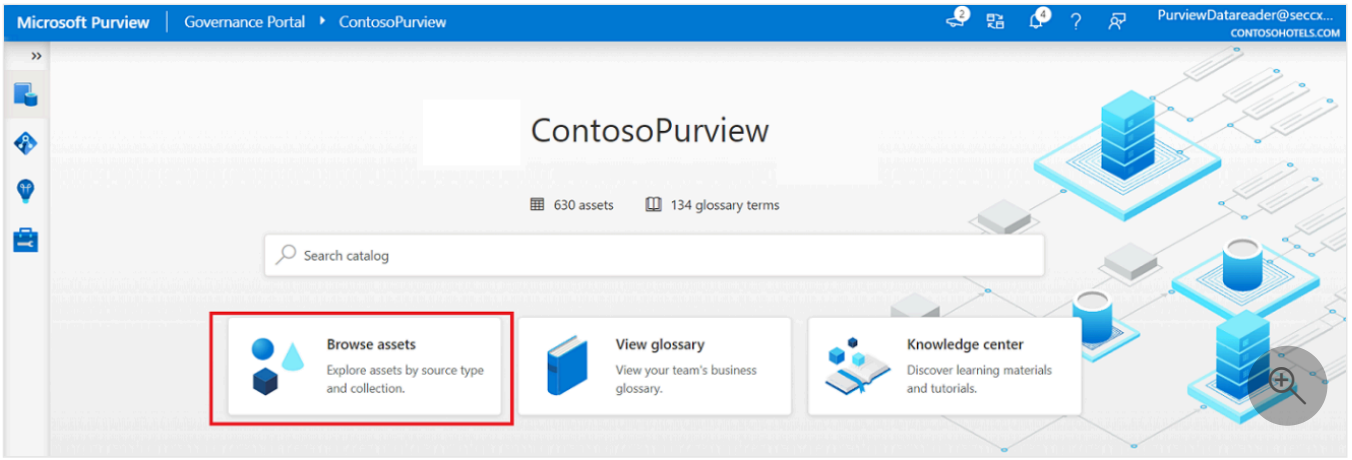
1. Go to your Microsoft Purview account.
2. Select **Data Map** on the left pane.
3. Select **Register**.
4. In **Register sources**, select **Azure Machine Learning (Preview)** > **Continue**.

5. On the **Register sources (Azure Machine Learning)** screen, do the following:

    a. For **Name**, enter a friendly name that Microsoft Purview lists as the data source for the workspace.

    b. For **Azure subscription** and **Workspace name**, select the subscription and workspace that you want to push from the dropdown. The Azure Machine Learning workspace URL is automatically populated.

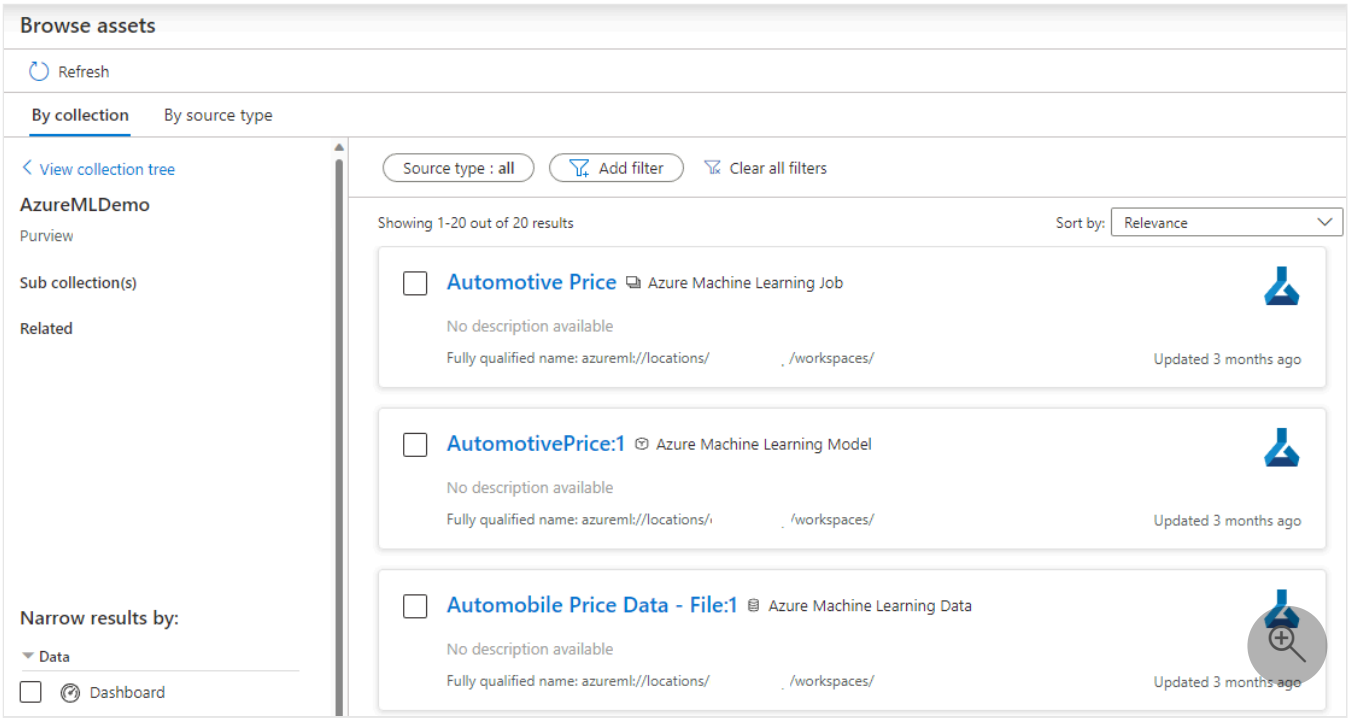
    c. Select a collection from the list.



6. Select **Register** to register the source.

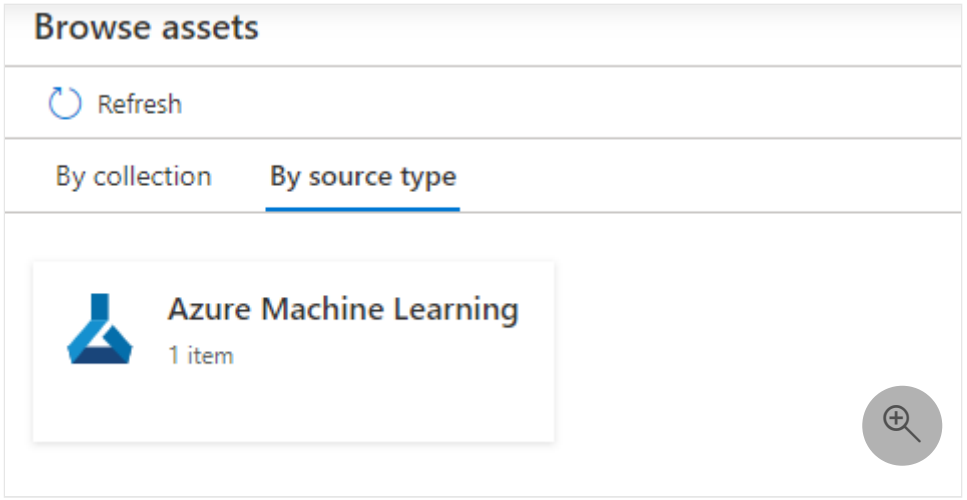
Scan

After you register your Azure Machine Learning workspace, the metadata will be automatically pushed to Microsoft Purview on a daily basis.



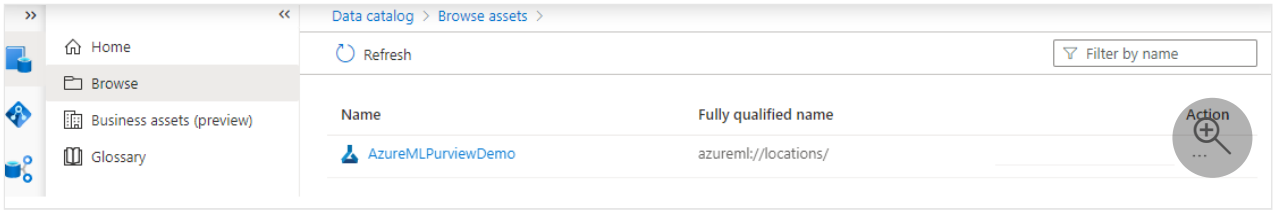
Browse and discover

To access the browse experience for data assets from your Azure Machine Learning workspace, select **Browse Assets**.

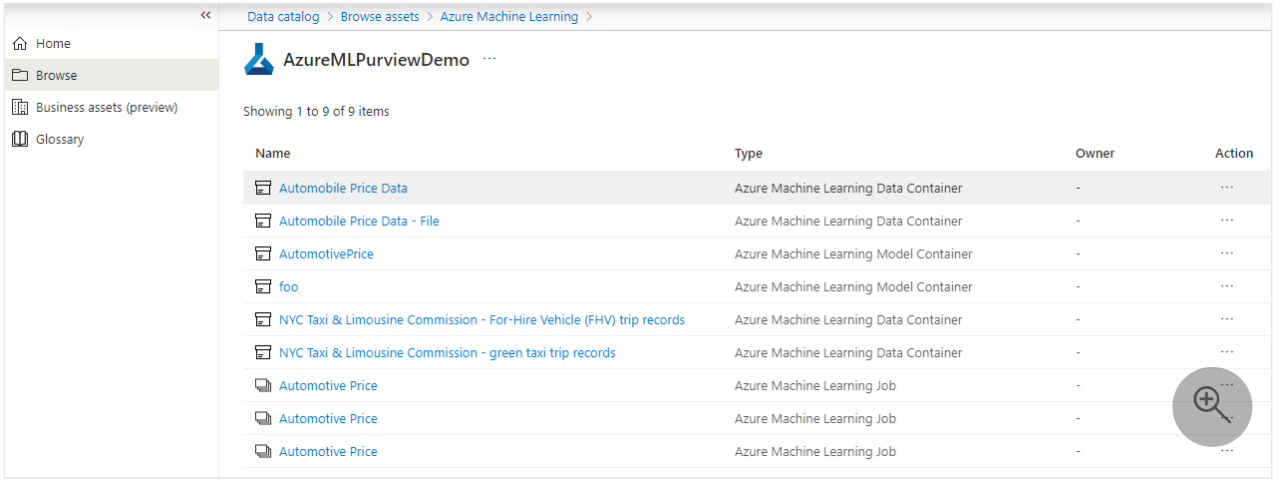


Browse by collection

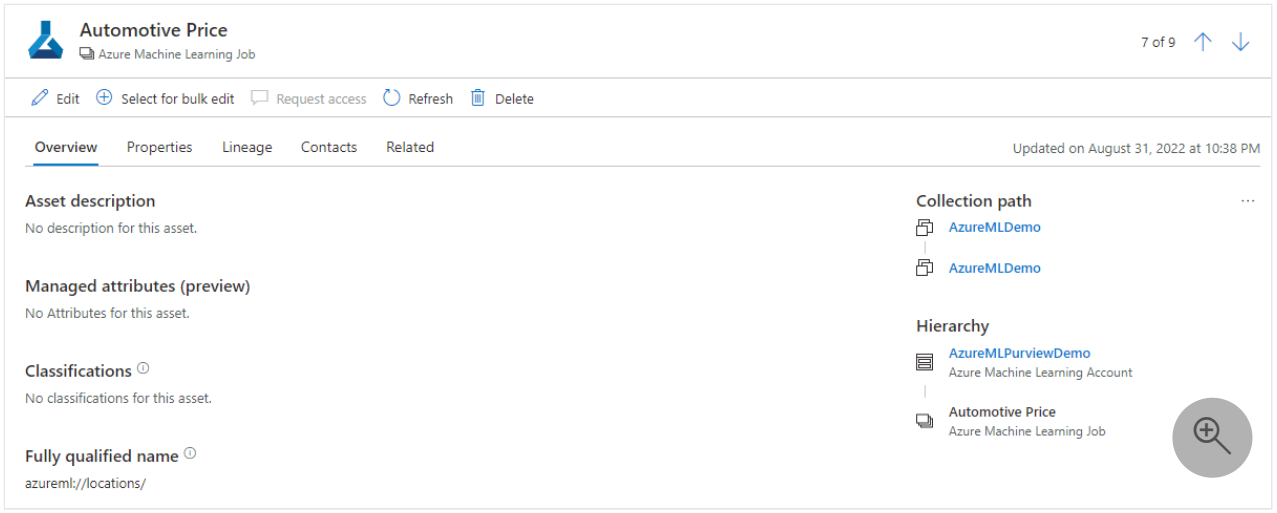
Browse by collection allows you to explore the different collections you're a data reader or curator for.



Browse by source type

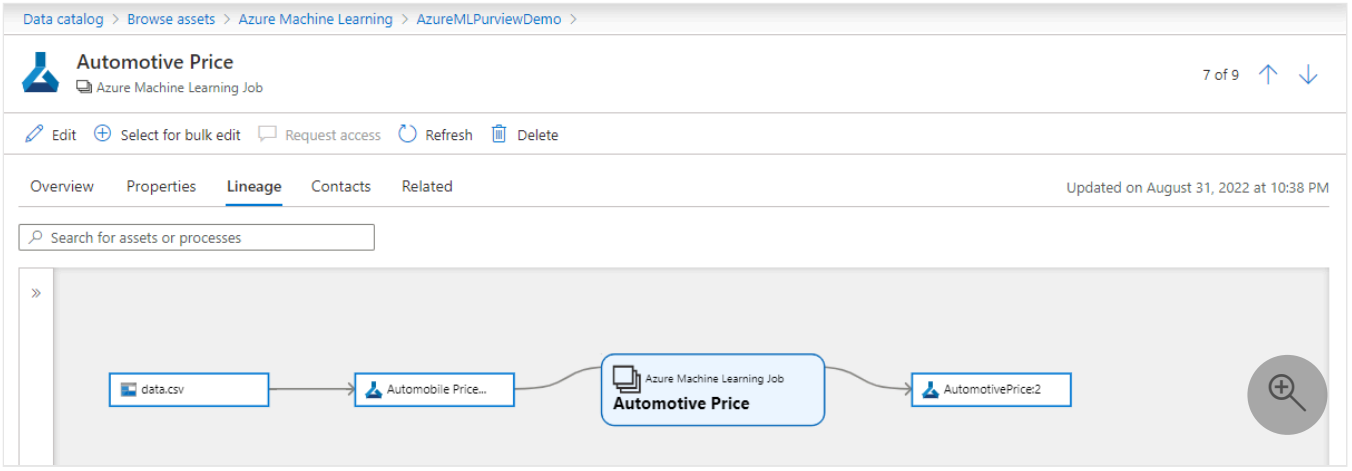


1. On the browse by source types page, select **Azure Machine Learning**.



2. The top-level assets under your selected data type are listed. Pick one of the assets to further explore its contents. For example, after selecting Azure Machine Learning, you'll see a list of workspaces with assets in Unified Catalog.

3. Selecting one of the workspaces displays the child assets.



4. From the list, you can select on any of the asset items to view details. For example, selecting one of the Azure Machine Learning job assets displays the details of the job.

Lineage

To view lineage information, select an asset and then select the **Lineage** tab. From the lineage tab, you can see the asset's relationships when applicable. You can see what source data was used (if registered in Purview), the data asset created in Azure Machine Learning, any jobs, and finally the resulting machine learning model. In more advanced scenarios, you can see:

- If multiple data sources were used
- Multiple stages of training on multiple data assets
- If multiple models were created from the same data sources

For more information on lineage in general, see data lineage and lineage users guide.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview

- Search the Unified Catalog

Discover and govern Azure SQL Database in Microsoft Purview

This article outlines the process to register an Azure SQL database source in Microsoft Purview. It includes instructions to authenticate and interact with the SQL database.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

When you're scanning Azure SQL Database, Microsoft Purview supports extracting technical metadata from these sources:

- Server
- Database
- Schemas
- Tables, including columns
- Views, including columns
- Stored procedures (with lineage extraction enabled)*
- Stored procedure runs (with lineage extraction enabled)*

When you're setting up a scan, you can further scope it after providing the database name by selecting tables and views as needed.

* Stored procedure lineage extraction scan has some limitations. Refer to the Known limitations section on this page for details.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

For stored procedures (SP) lineage extraction:

- SP lineage extraction scan isn't supported if your logical server in Azure disables public access or doesn't allow Azure services to access it.
- SP lineage extraction scan is currently not supported if your stored procedures contain an INSERT or a DROP query.
- SP lineage extraction scan isn't supported if your Microsoft Purview account disables public access.
  - SP lineage extraction scan is scheduled to run every six hours by default. The frequency can't be changed.
  - Lineage is captured only when the stored procedure execution transfers data from one table to another. And it's not supported for temporary tables.
  - Lineage extraction isn't supported for functions or triggers.
  - Due to the following limitations, you could see duplicate assets in the catalog if you have scenarios such as:
    - The object names in assets and fully qualified names follow the case used in stored procedure statements, which might not align with the object case in original data source.
    - When SQL views are referenced in stored procedures, they're currently captured as SQL tables.

For scanned assets:

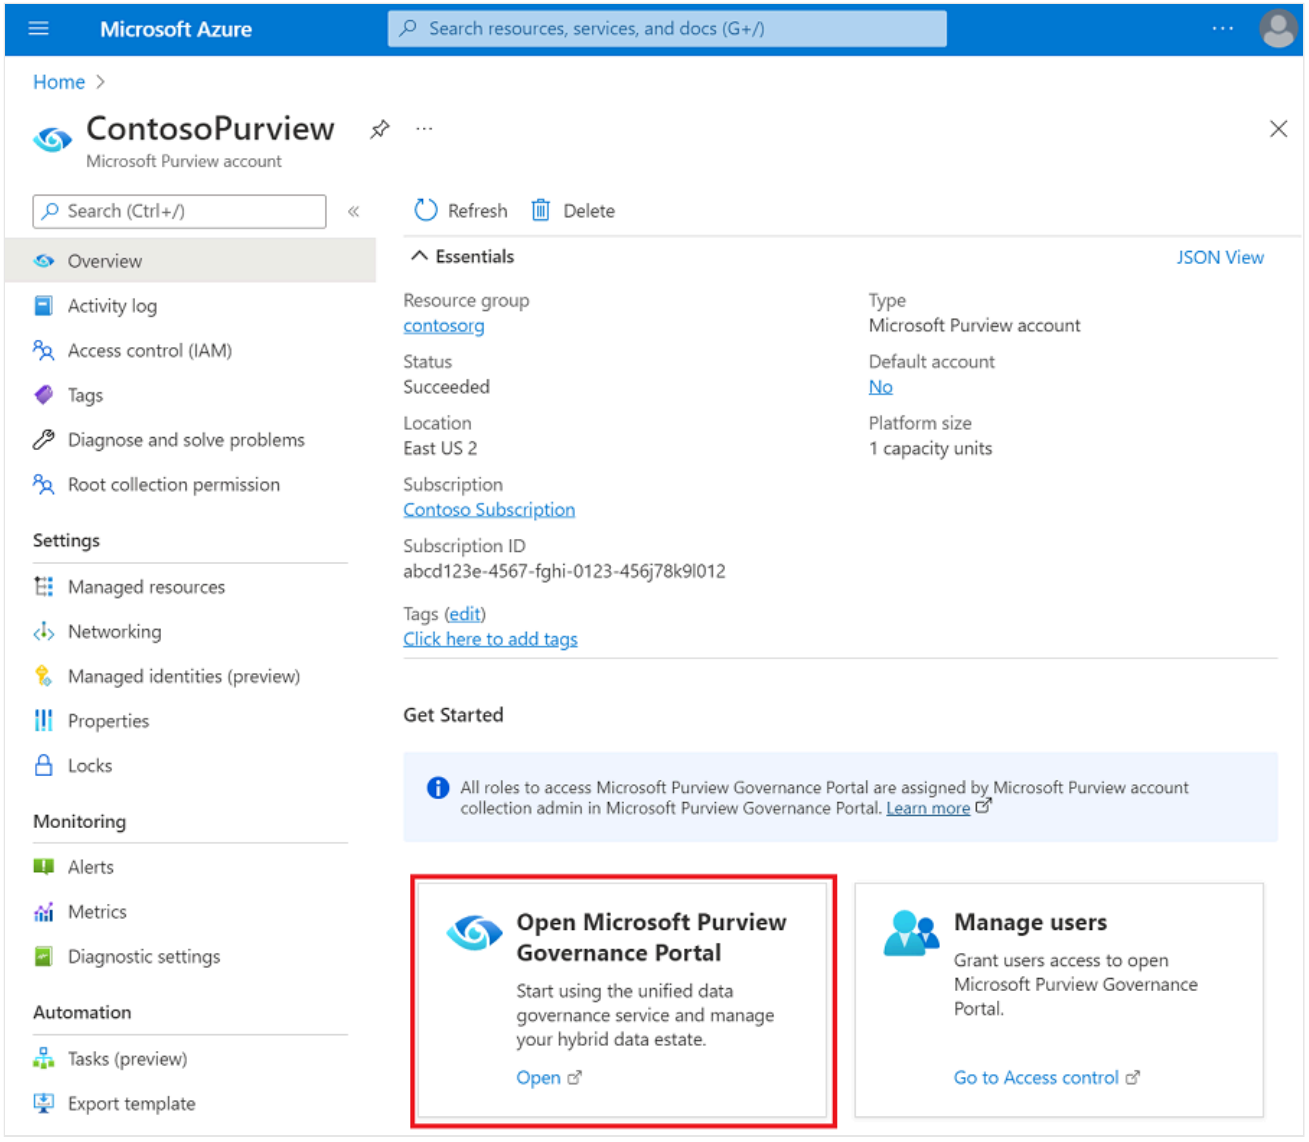
- For a full scan, instead of INT and NUMERIC data type, DECIMAL is displayed as a data type for SQL asset properties. If length of the field is MAX, it is displayed as zero (0).
- For **nchar** data type, column length is displayed in character count.

> **Note**
>
> Lineage is also supported if Azure SQL tables or views are used as a source/sink in Azure Data Factory Copy and Data Flow activities.

Prerequisites

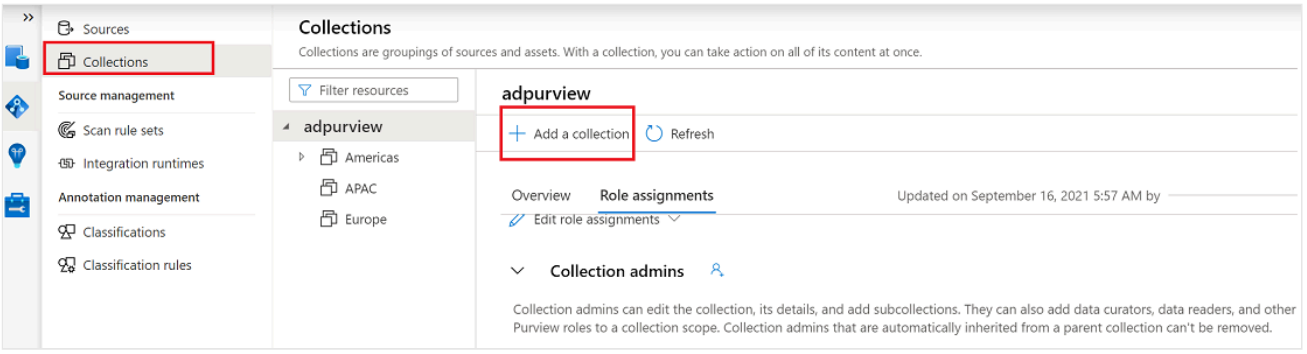
- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

- Data Source Administrator and Data Reader permissions, so you can register a source and manage it in the Microsoft Purview governance portal. For details, see Access control in the Microsoft Purview governance portal.



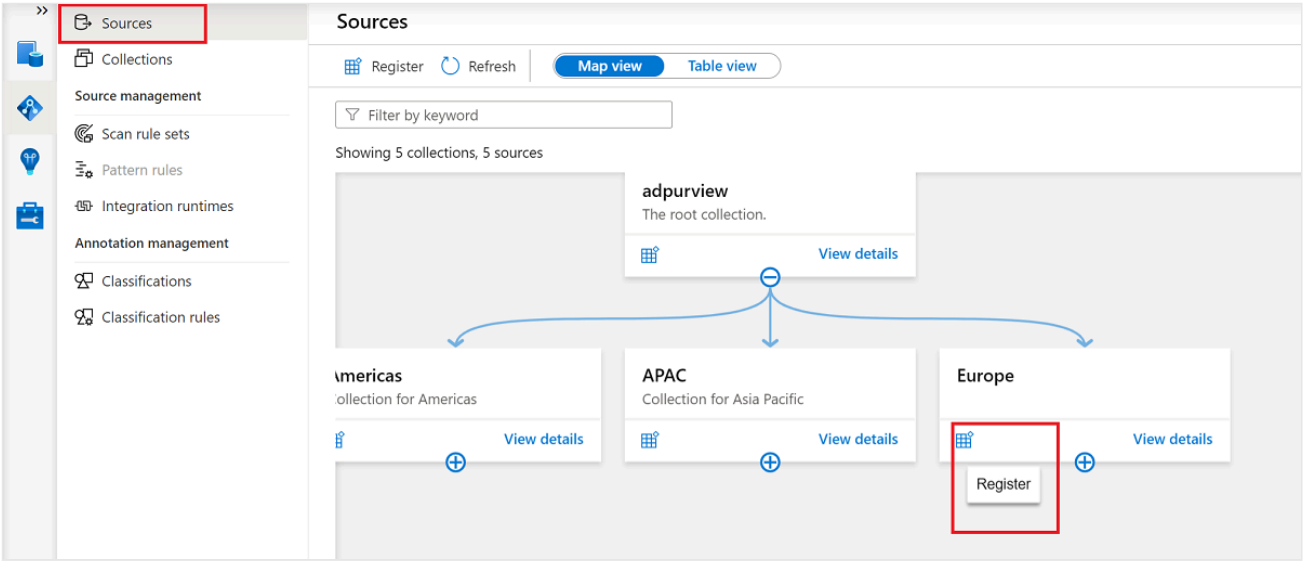
Register the data source

Before you scan, it's important to register the data source in Microsoft Purview:



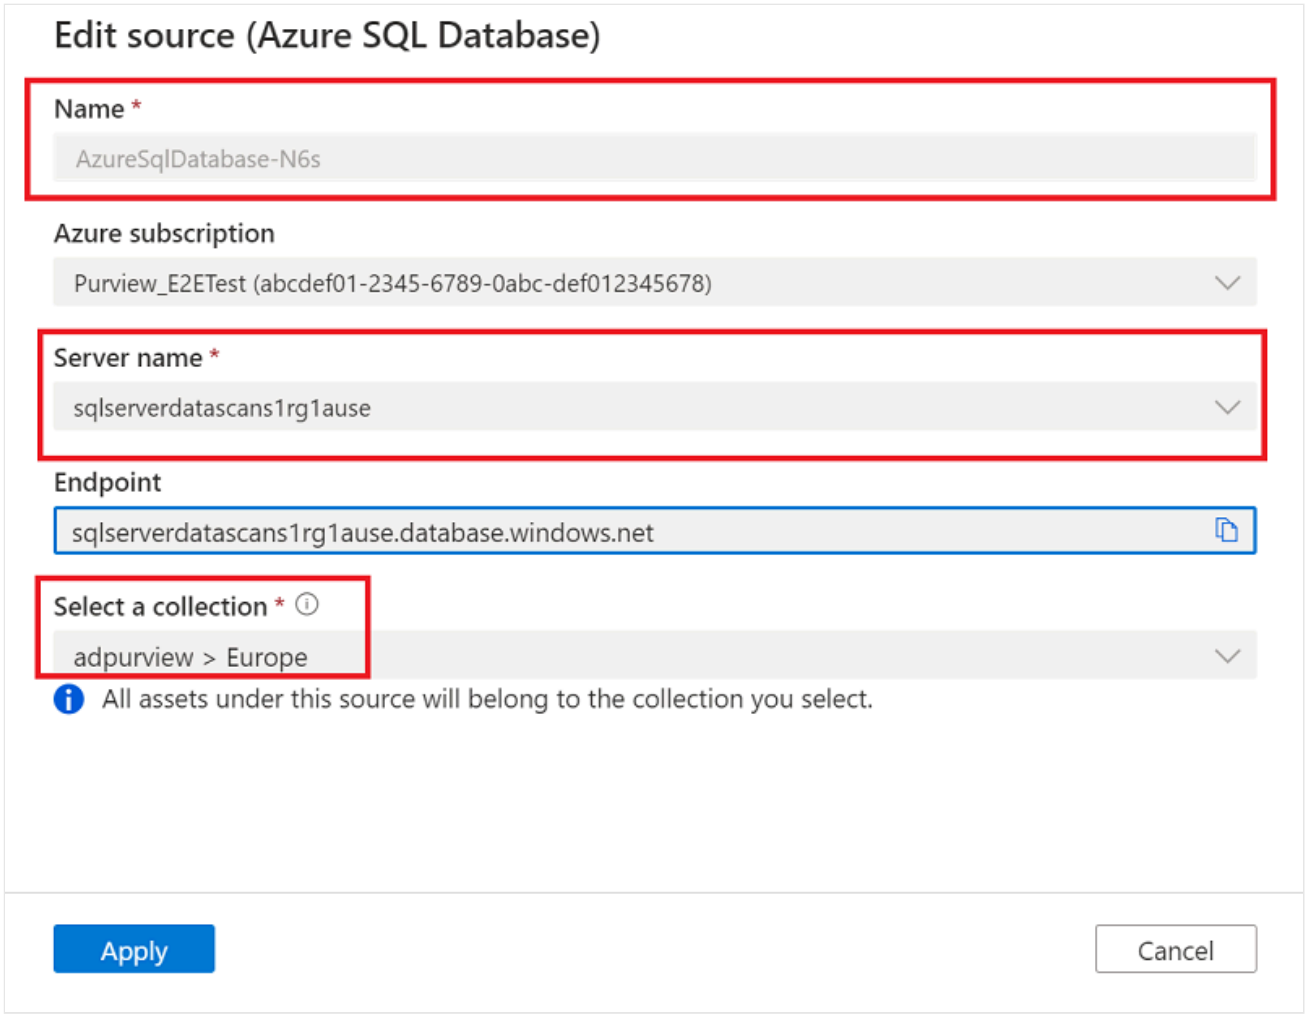
1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.

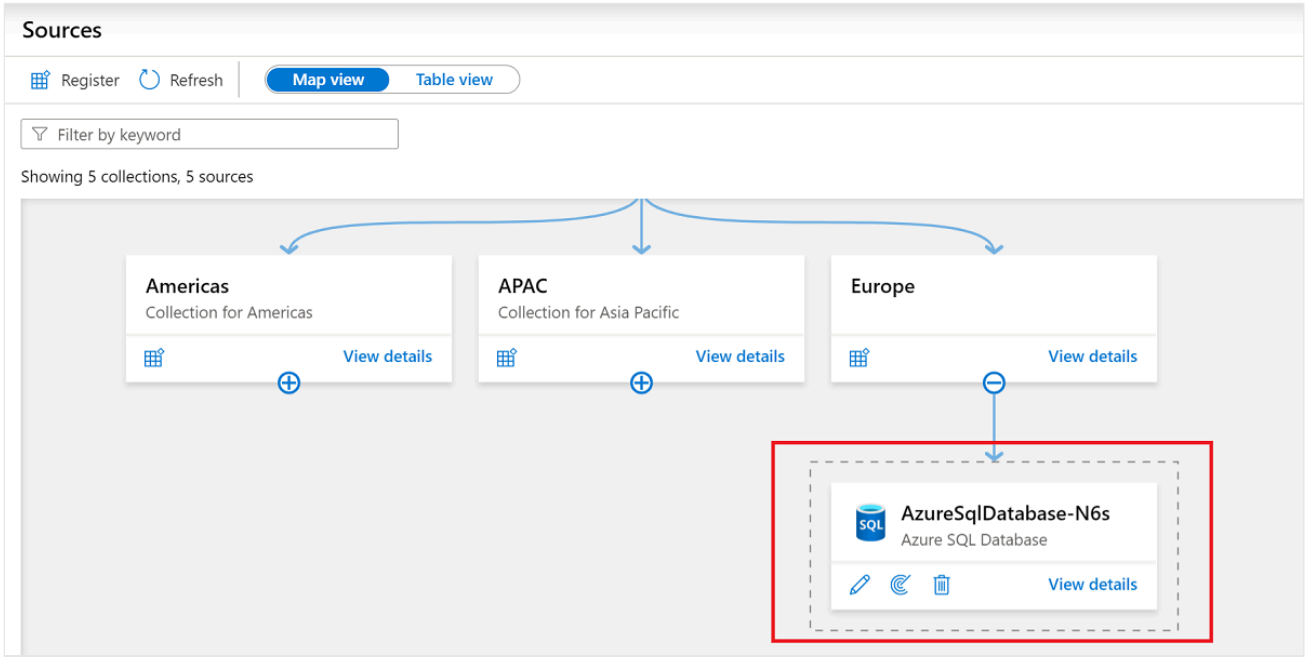


2. Navigate to the **Data Map**.

3. Create the collection hierarchy by going to **Collections** and then selecting **Add a collection**. Assign permissions to individual subcollections as required.



4. Go to the appropriate collection under **Sources**, and then select the **Register** icon to register a new SQL database.



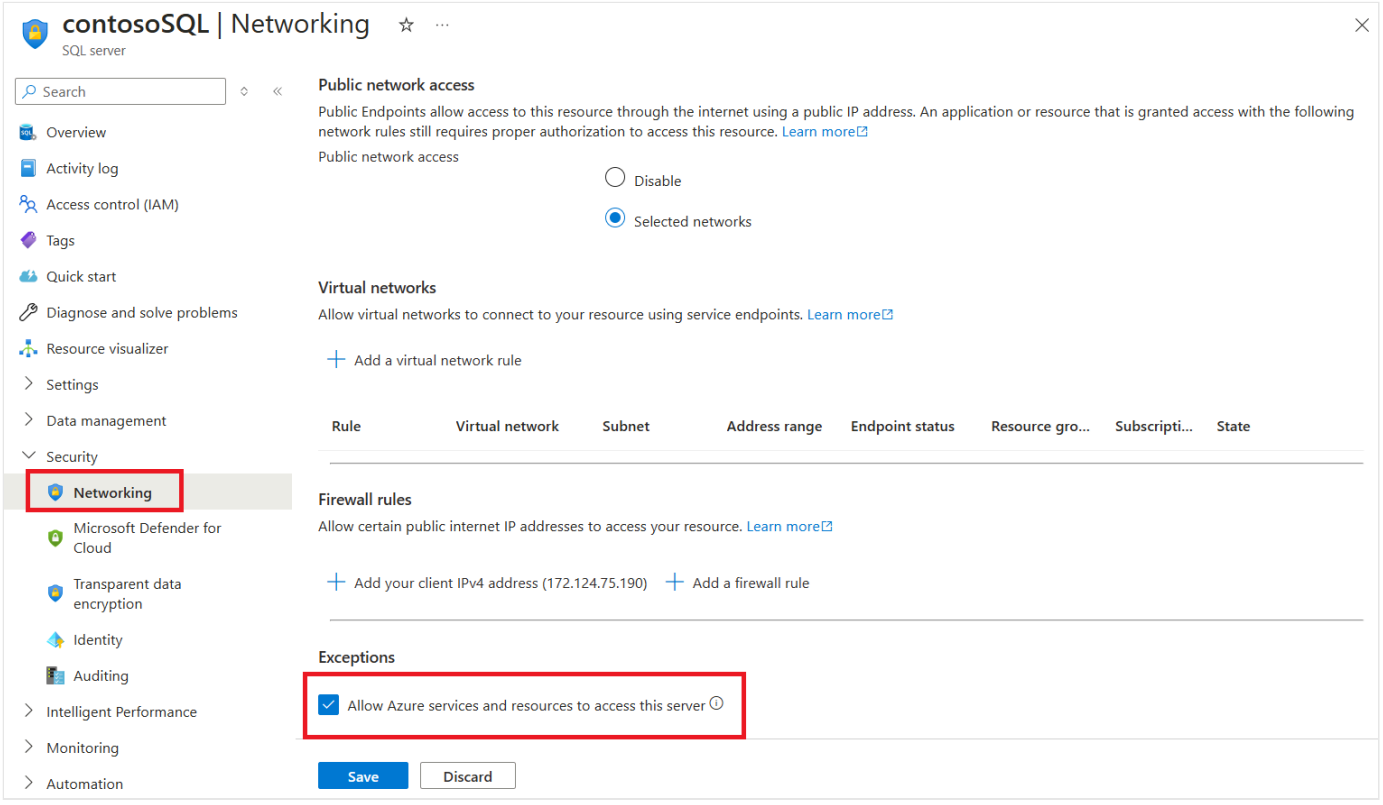
5. Select the **Azure SQL Database** data source, and then select **Continue**.

6. For **Name**, provide a suitable name for the data source. Select relevant names for **Azure subscription**, **Server name**, and **Select a collection**, and then select **Apply**.

7. Confirm that the SQL database appears under the selected collection.

Update firewall settings

If your database server has a firewall enabled, you need to update the firewall to allow access in one of the following ways:



- Allow Azure connections through the firewall. This is a straightforward option to route traffic through Azure networking, without needing to manage virtual machines.
- Install a self-hosted integration runtime on a machine in your network and give it access through the firewall. If you have a private virtual network set up within Azure, or have any other closed network set up, using a self-hosted integration runtime on a machine within that network will allow you to fully manage traffic flow and utilize your existing network.
- Use a managed virtual network. Setting up a managed virtual network with your Microsoft Purview account allows you to connect to Azure SQL by using the Azure integration runtime in a closed network.

For more information about the firewall, see the Azure SQL Database firewall documentation.

Allow Azure connections

Enabling Azure connections allows Microsoft Purview to connect to the server without requiring you to update the firewall itself.

1. Go to your database account.
2. On the **Overview** page, select the server name.
3. Select **Security** > **Networking**.
4. For **Allow Azure services and resources to access this server**, select **Yes**.

For more information about allowing connections from inside Azure, see the how-to guide.

Install a self-hosted integration runtime

You can install a self-hosted integration runtime on a machine to connect with a resource in a private network:

1. Choose the right integration runtime for your scenario
2. Create and install your integration runtime:

    - **To use a self-hosted integration runtime:** Follow the article to create and configure a self-hosted integration runtime.
    - **To use a kubernetes supported self-hosted integration runtime:** Follow the article to create and configure a kubernetes supported integration runtime.

3. Check your database server's networking configuration to confirm that a private endpoint is accessible to the machine that contains the self-hosted integration runtime. Add the IP address of the machine if it doesn't already have access.
4. If your logical server is behind a private endpoint or in a virtual network, you can use an ingestion private endpoint to ensure end-to-end network isolation.

Configure authentication for a scan

To scan your data source, you need to configure an authentication method in Azure SQL Database.

> **Important**
>
> If you're using a **self-hosted integration runtime** to connect to your resource, system-assigned and user-assigned managed identities won't work. You need to use service principal authentication or SQL authentication.

Microsoft Purview supports the following options:

- **System-assigned managed identity (SAMI)** (recommended). This is an identity that is associated directly with your Microsoft Purview account. It allows you to authenticate directly with other Azure resources without needing to manage a go-between user or credential set.

  The SAMI is created when your Microsoft Purview resource is created. The SAMI is managed by Azure and uses your Microsoft Purview account's name. The SAMI can't currently be used with a self-hosted integration runtime for Azure SQL.

For more information, see the managed identity overview.

- **User-assigned managed identity (UAMI)** (preview). Similar to a SAMI, a UAMI is a credential resource that allows Microsoft Purview to authenticate against Microsoft Entra ID.

  The UAMI is managed by users in Azure, rather than by Azure itself, which gives you more control over security. The UAMI can't currently be used with a self-hosted integration runtime for Azure SQL.

  For more information, see the guide for user-assigned managed identities.

- **Service principal**. A service principal is an application that can be assigned permissions like any other group or user, without being associated directly with a person. Authentication for service principals has an expiration date, so it can be useful for temporary projects.

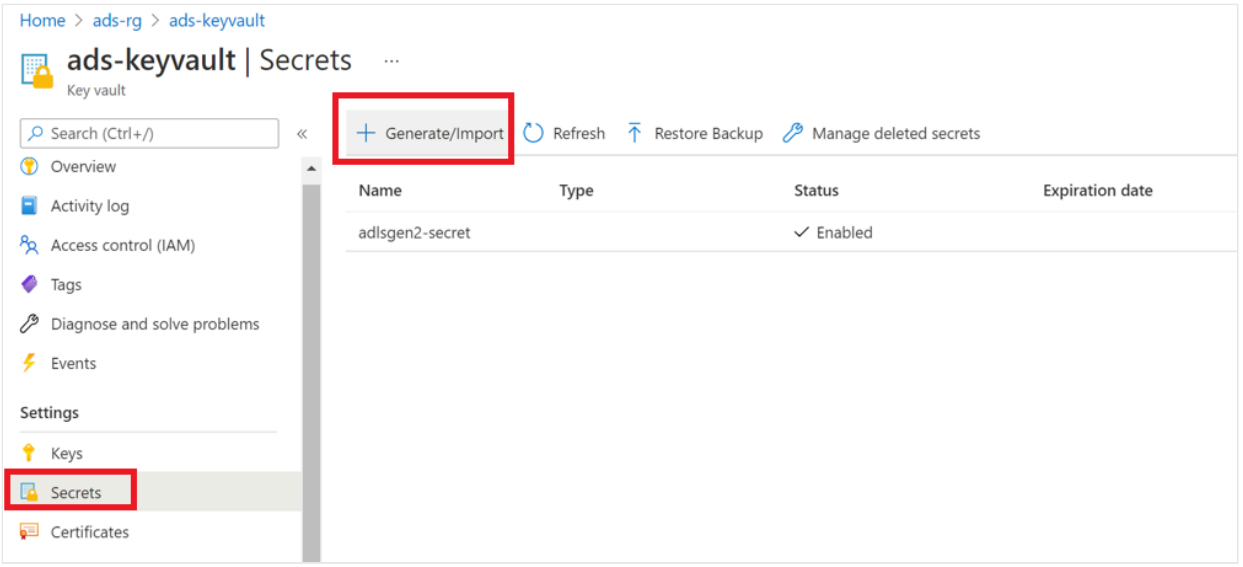
  For more information, see the service principal documentation.

- **SQL authentication**. Connect to the SQL database with a username and password. For more information, see the SQL authentication documentation.

  If you need to create a login, follow this guide to query a SQL database. Use this guide to create a login by using T-SQL.

  > **Note**
  >
  > Be sure to select the **Azure SQL Database** option on the page.

For steps to authenticate with your SQL database, select your chosen method of authentication from the following tabs.



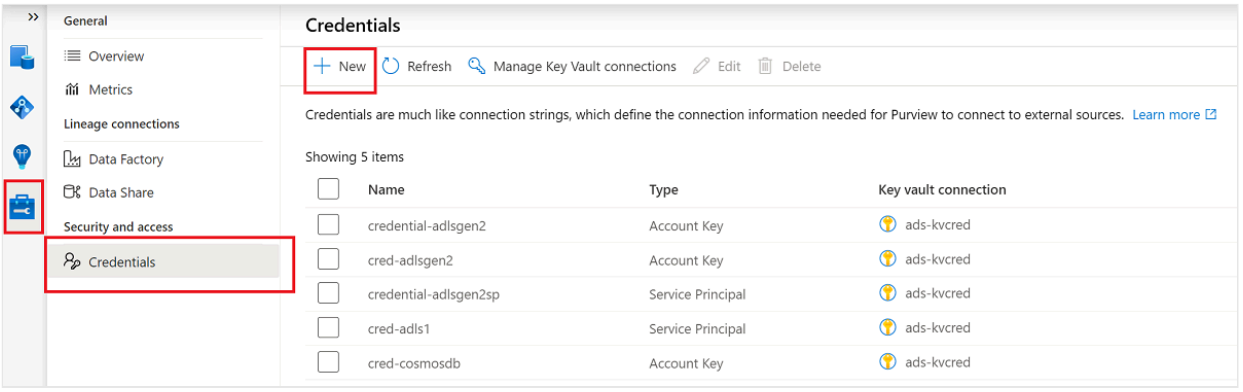
SQL authentication

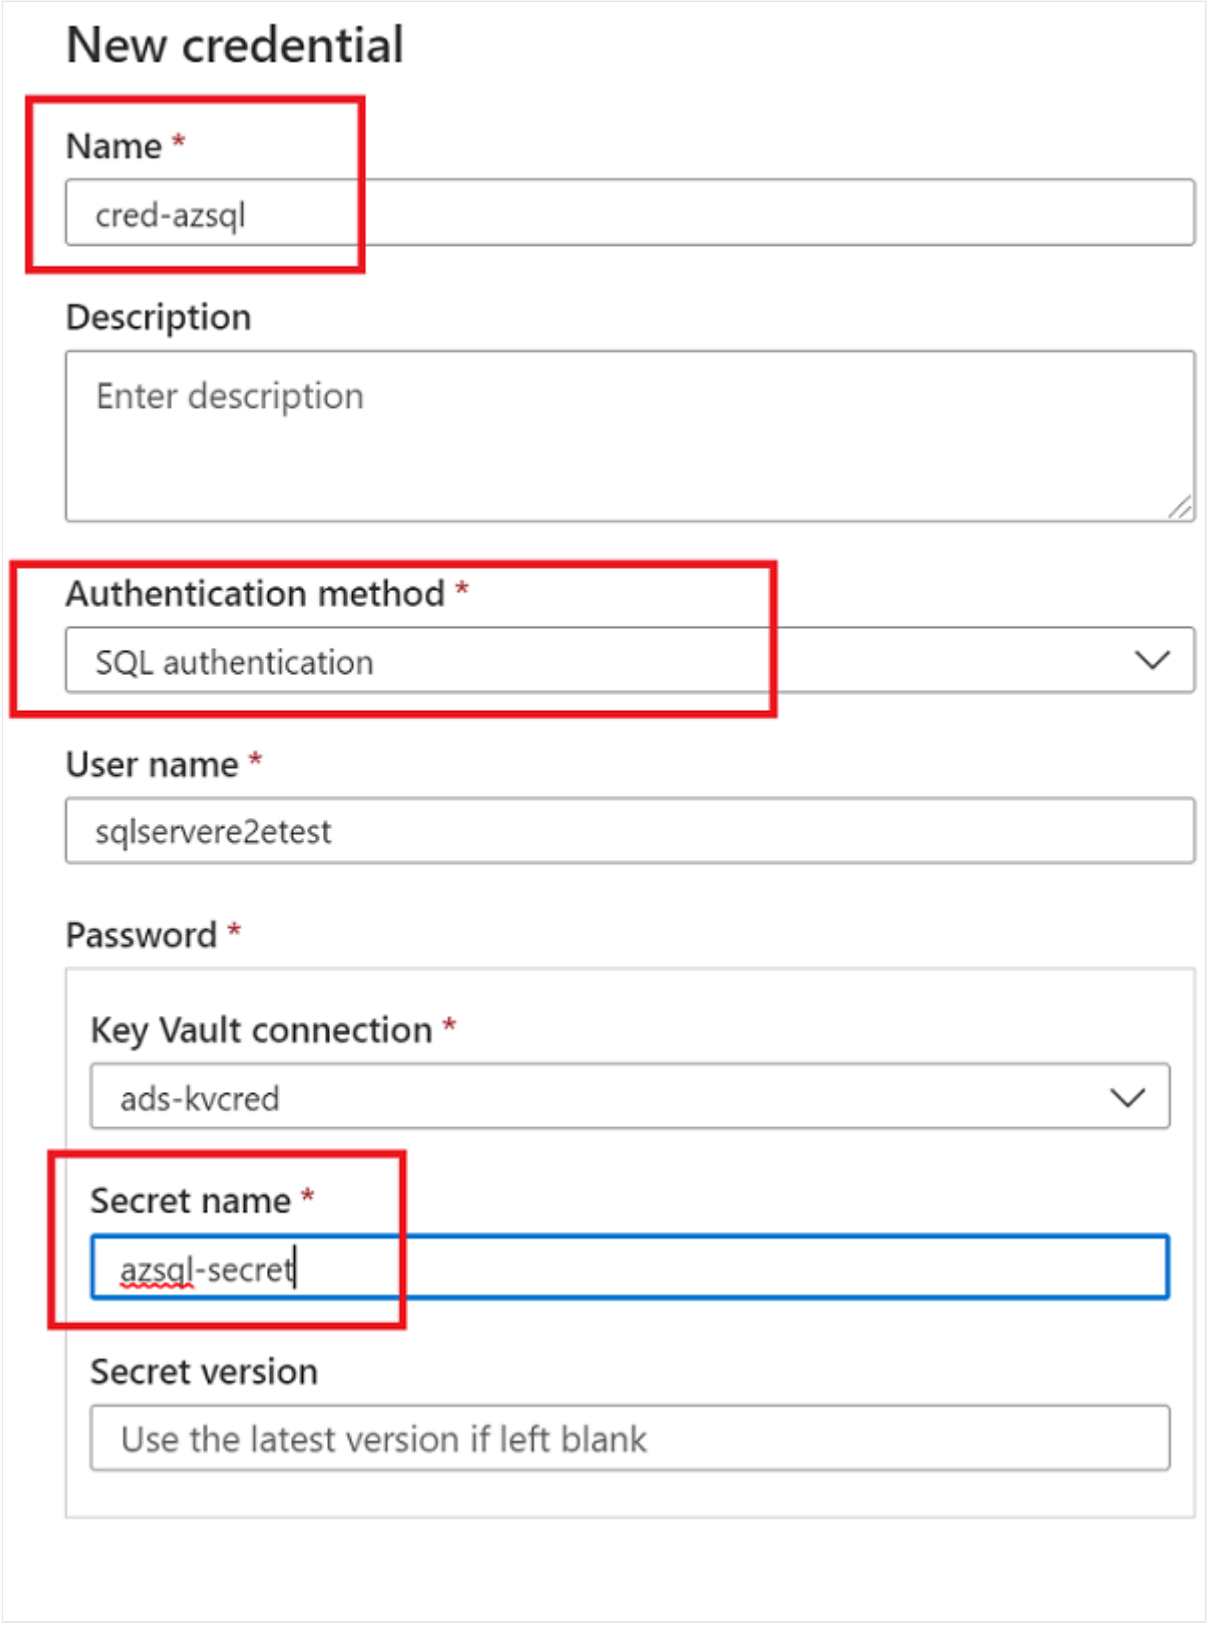
> **Note**
>
> Only the server-level principal login (created by the provisioning process) or members of the `loginmanager` database role in the master database can create new logins. The Microsoft Purview account should be able to scan the resources about 15 minutes after it gets permissions.

1. You need a SQL login with at least `db_datareader` permissions to be able to access the information that Microsoft Purview needs to scan the database. You can follow the instructions in CREATE LOGIN to create a login for Azure SQL Database. Save the username and password for the next steps.

2. Go to your key vault in the Azure portal.

3. Select **Settings** > **Secrets**, and then select + **Generate/Import**.



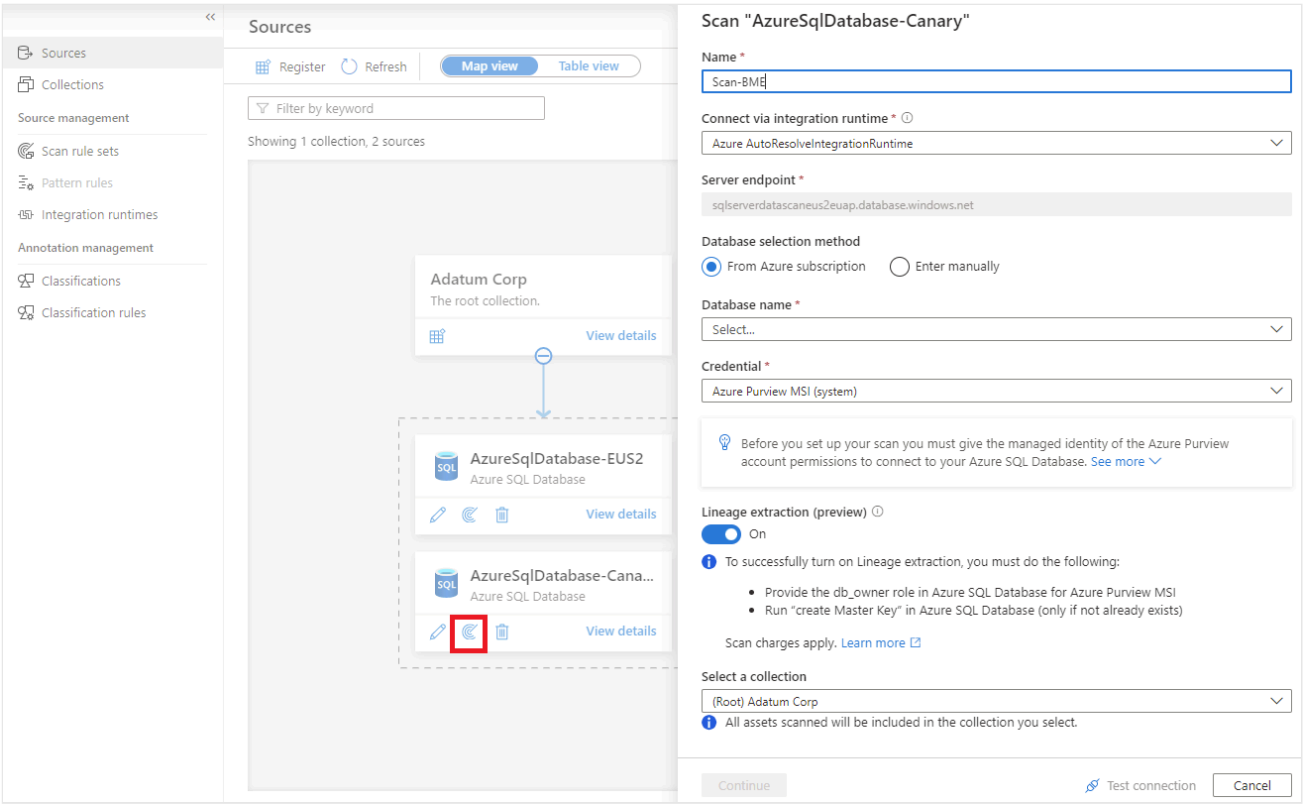


4. For **Name** and **Value**, use the username and password (respectively) from your SQL database.

5. Select **Create**.

6. If your key vault isn't connected to Microsoft Purview yet, create a new key vault connection.

7. Create a new credential by using the key to set up your scan.



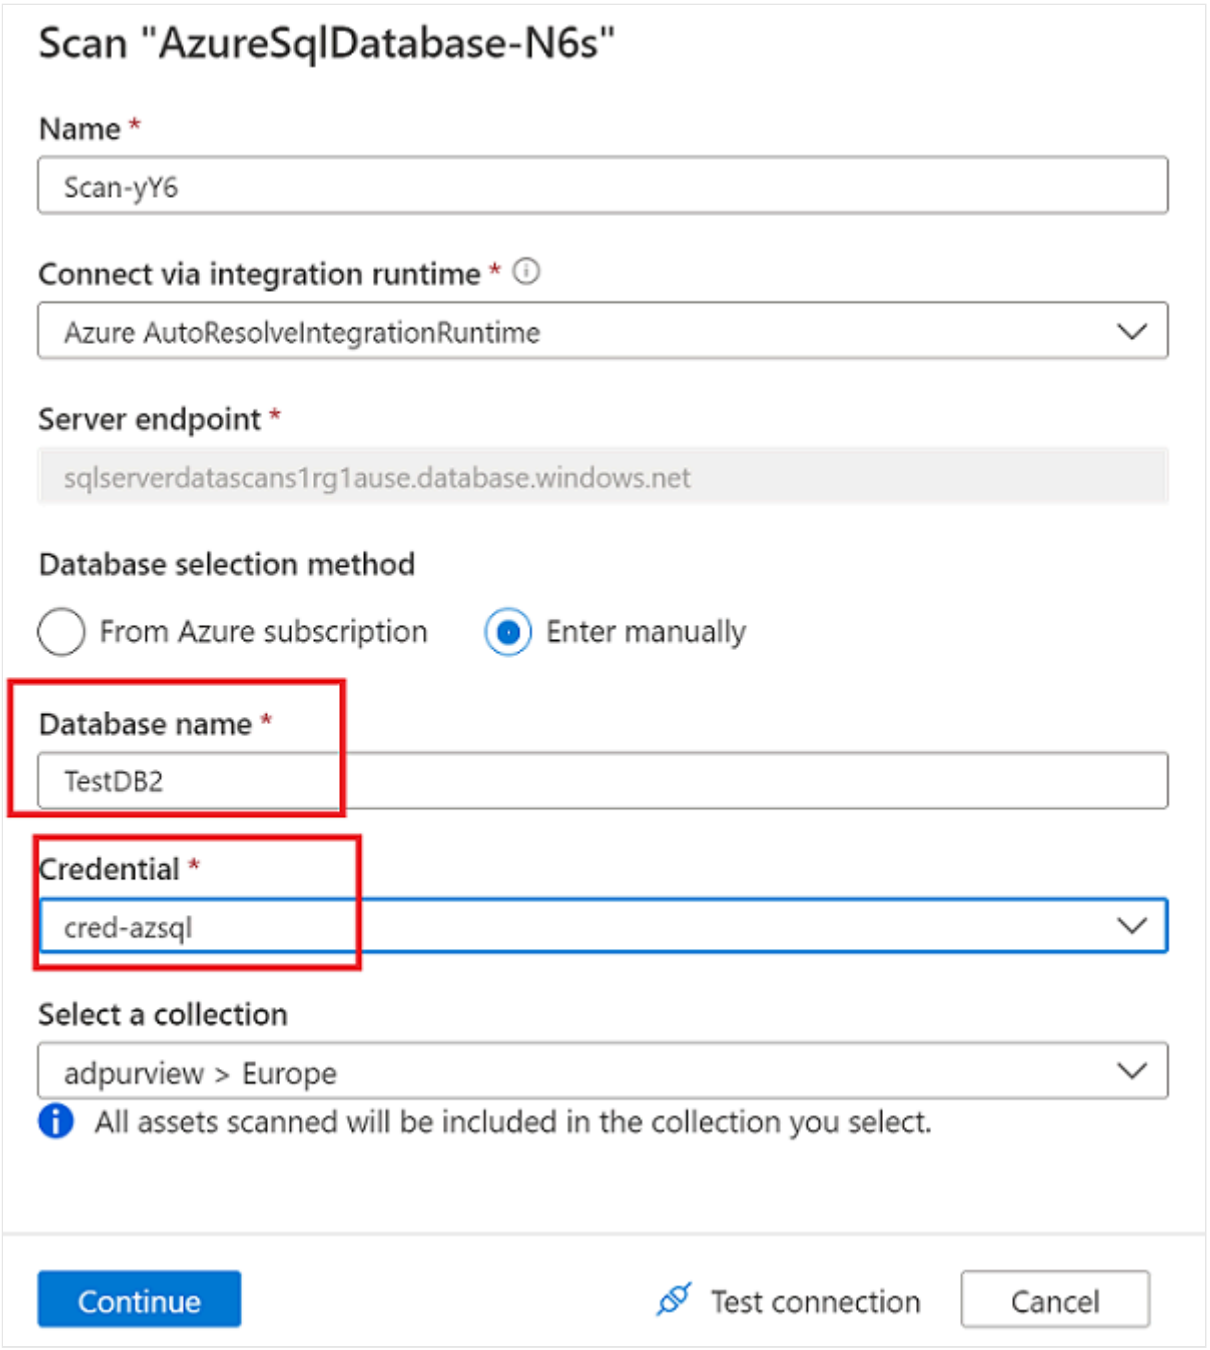
Create the scan

1. Open your Microsoft Purview account and select **Open Microsoft Purview governance portal**.

2. Go to **Data map** > **Sources** to view the collection hierarchy.

3. Select the **New Scan** icon under the SQL database that you registered earlier.

To learn more about stored procedure data lineage in Azure SQL Database, see the Extract lineage (preview) section of this article.



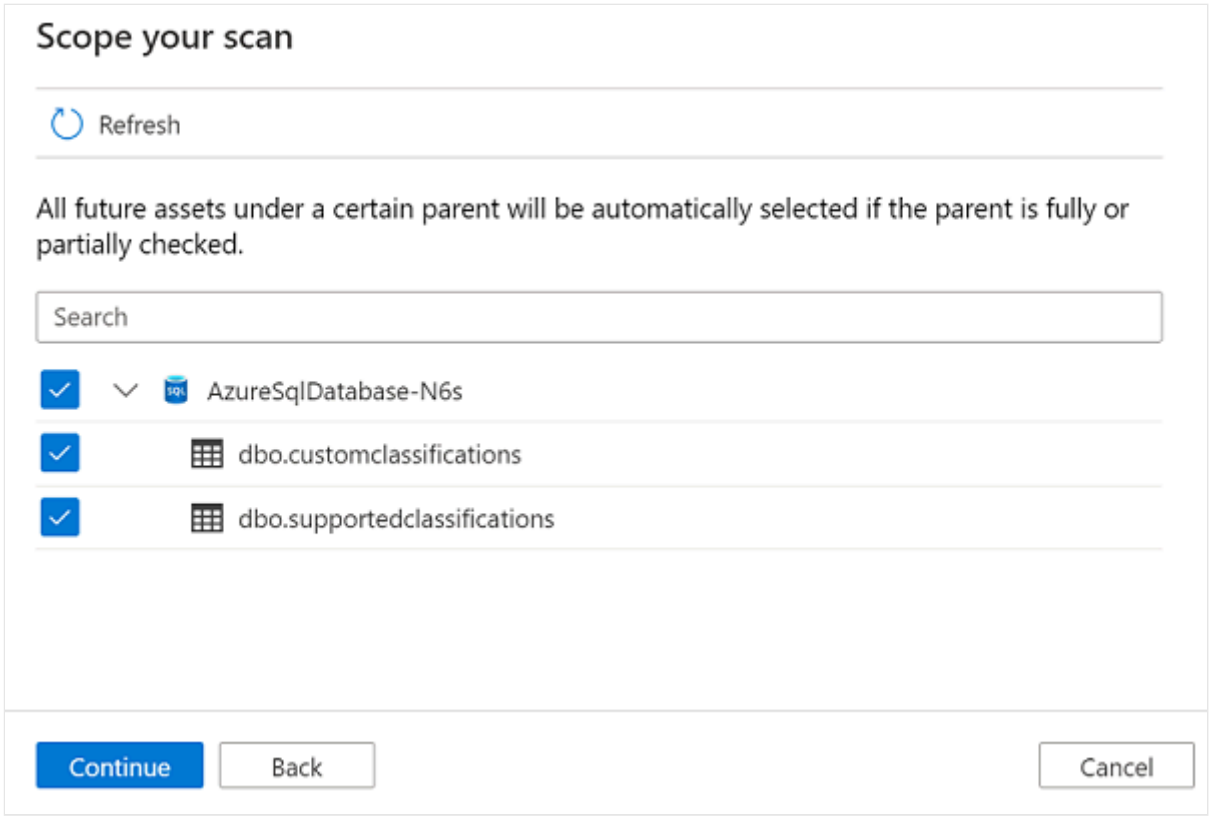
For scanning steps, select your method of authentication from the following tabs.

SQL authentication

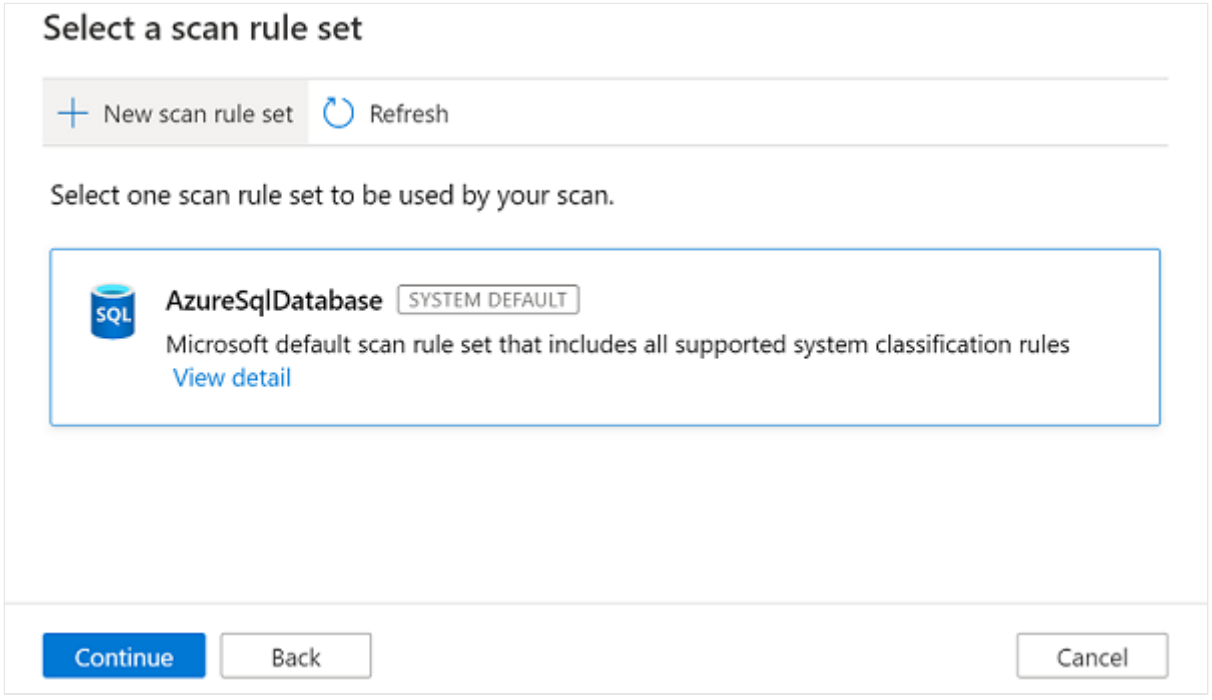
1. For **Name**, provide a name for the scan.

2. For **Database selection method**, select **Enter manually**.

3. For **Database name** and **Credential**, enter the values that you created earlier.

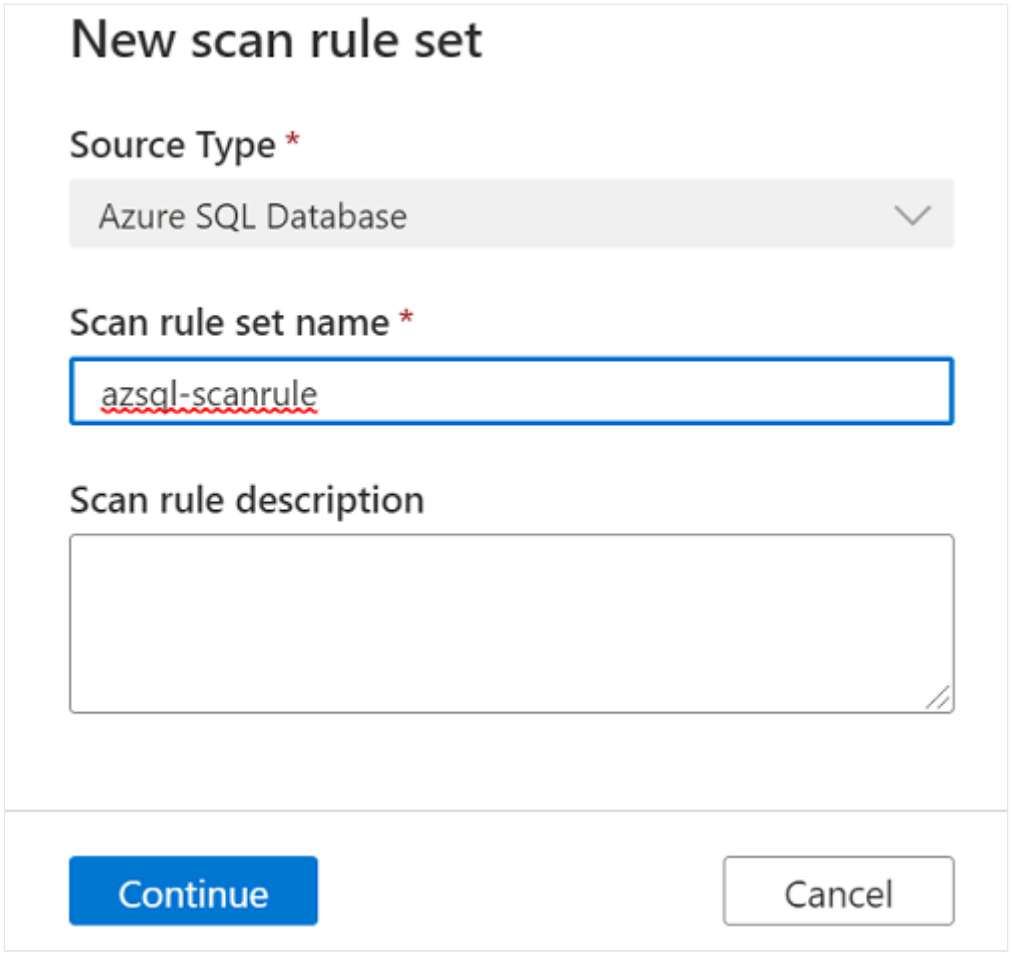


4. For **Select a connection**, choose the appropriate collection for the scan.

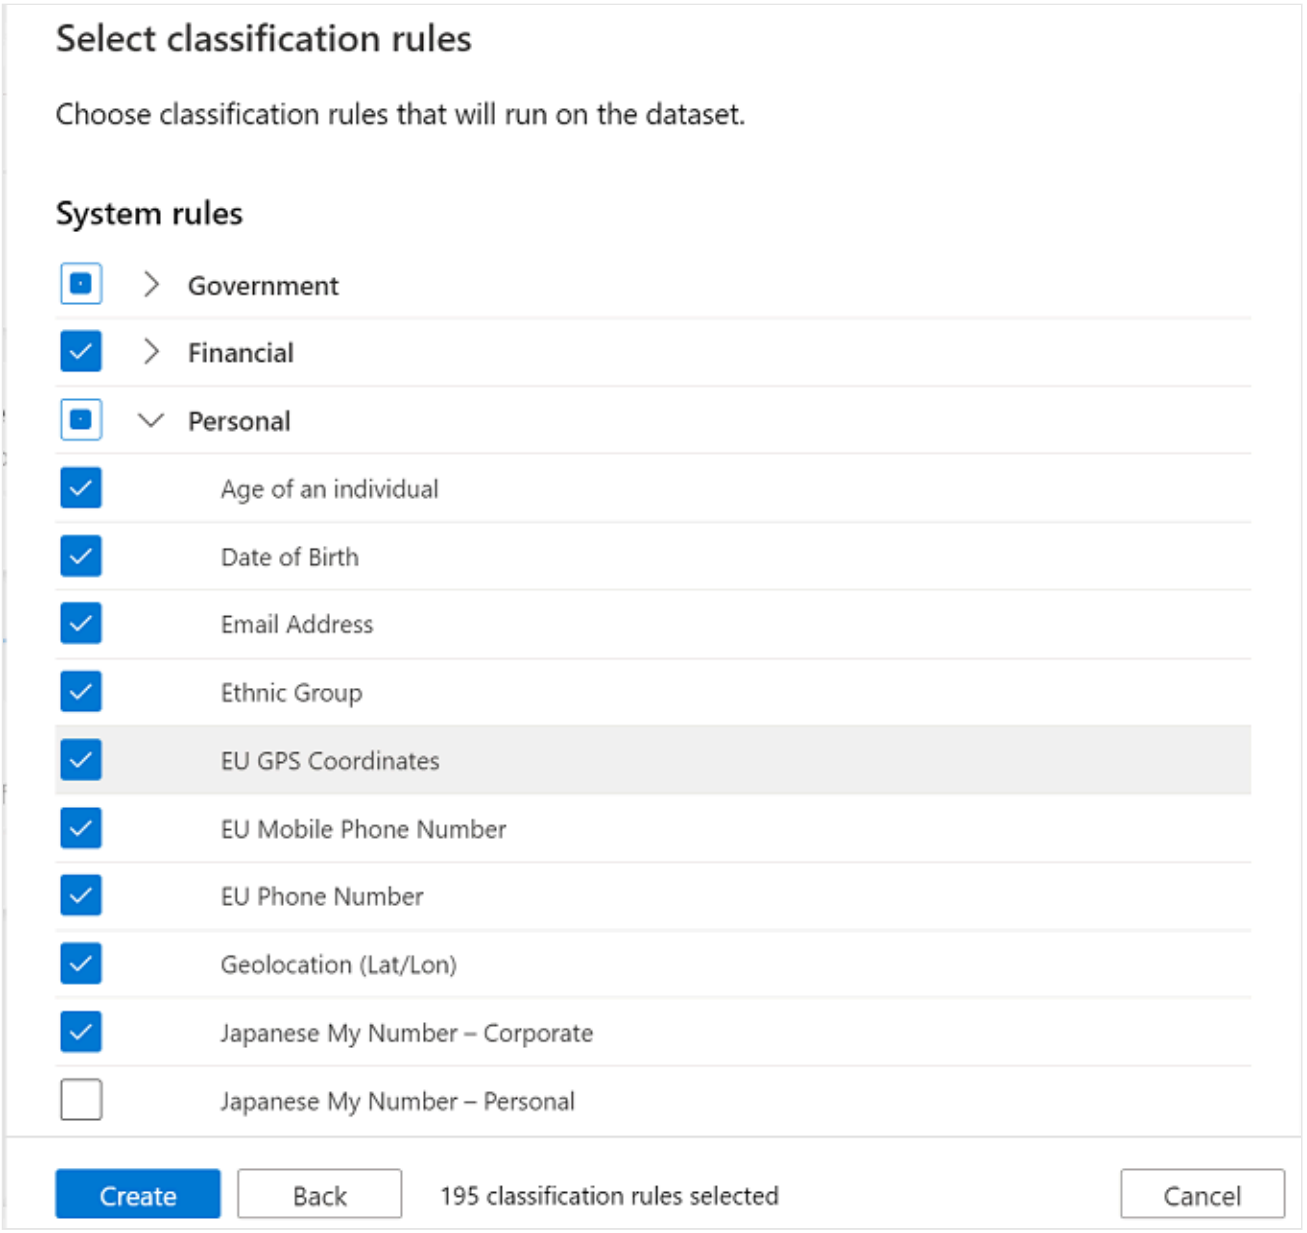


5. Select **Test connection** to validate the connection. After the connection is successful, select **Continue**.

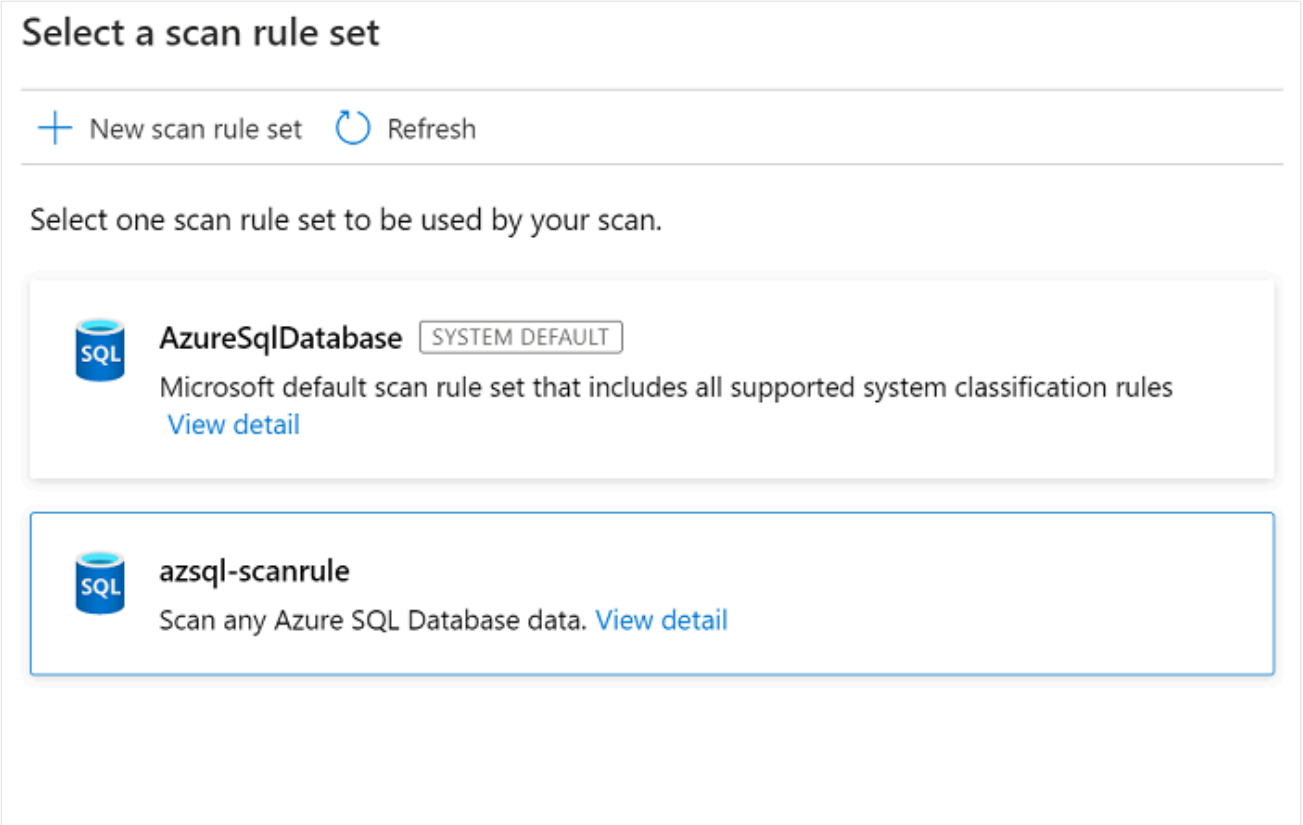
Scope and run the scan



1. You can scope your scan to specific database objects by choosing the appropriate items in the list.



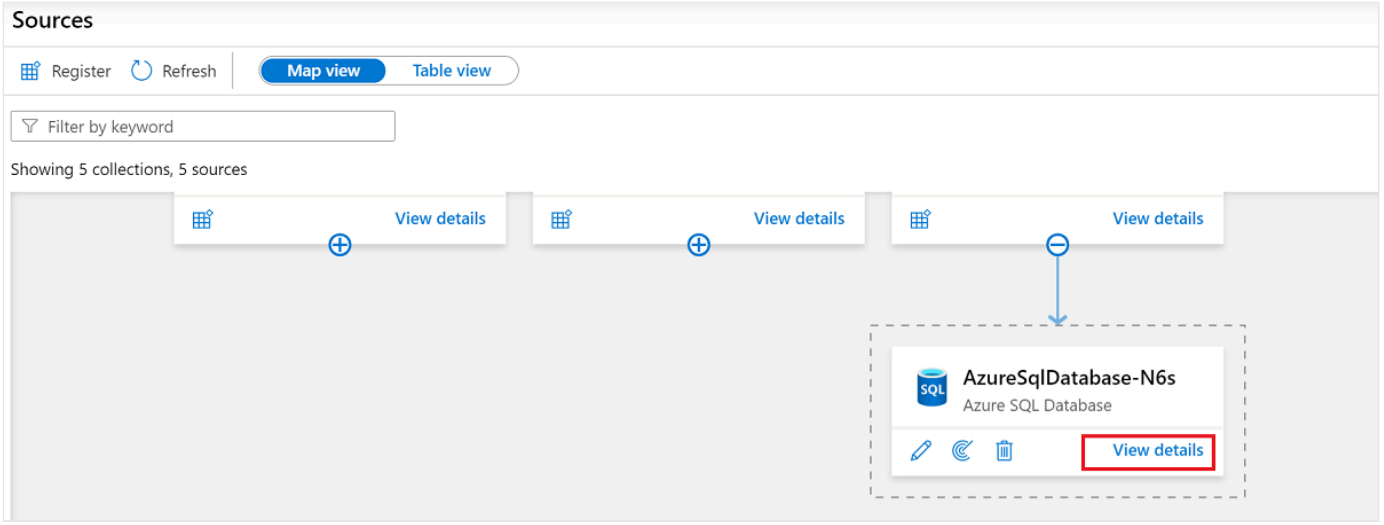
2. Select a scan rule set. You can use the system default, choose from existing custom rule sets, or create a new rule set inline. Select **Continue** when you're finished.



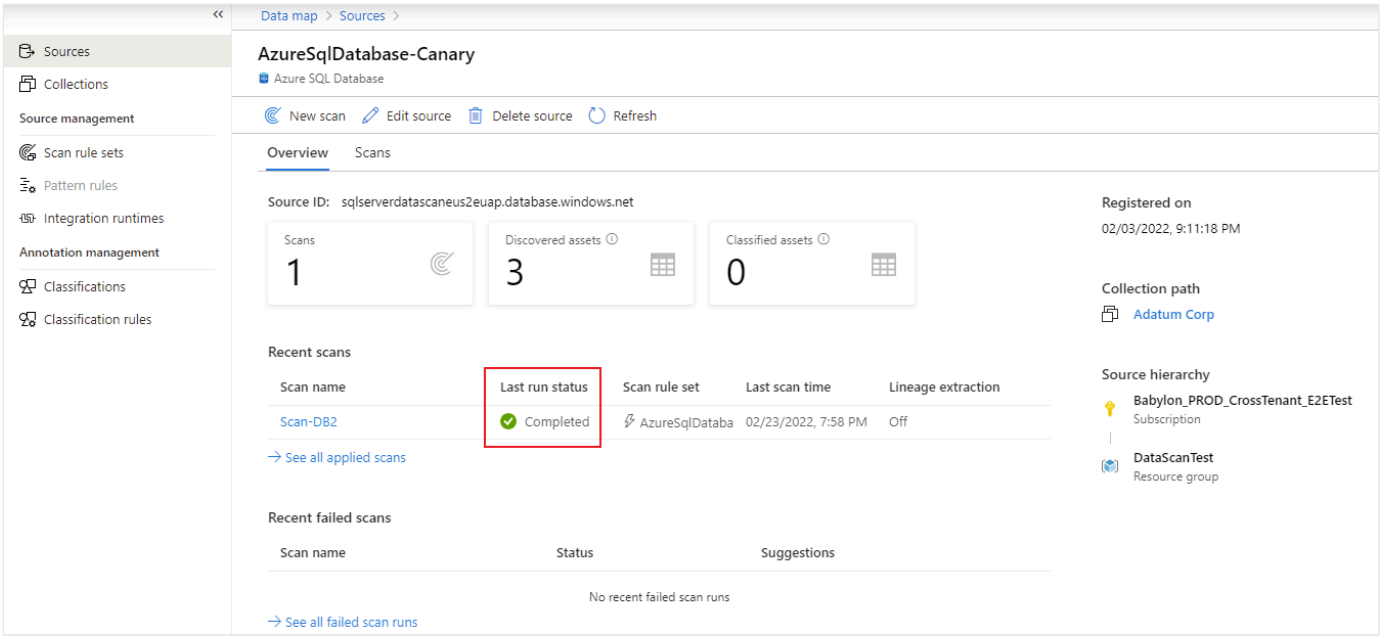
If you select **New scan rule set**, a pane opens so that you can enter the source type, the name of the rule set, and a description. Select **Continue** when you're finished.

For **Select classification rules**, choose the classification rules that you want to include in the scan rule set, and then select **Create**.

The new scan rule set then appears in the list of available rule sets.



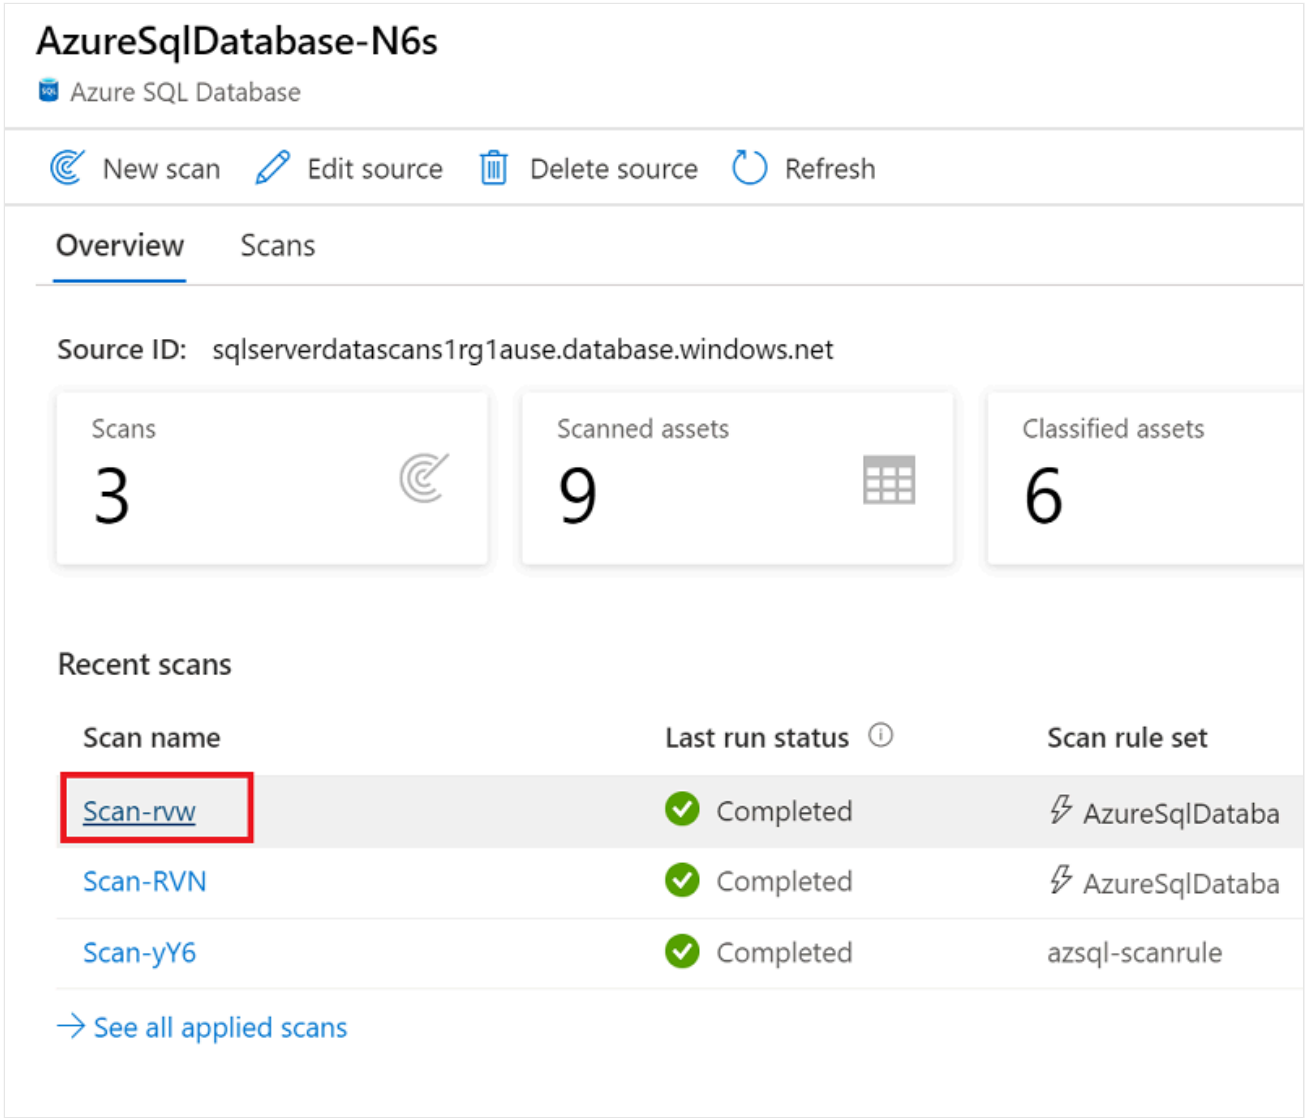
3. Choose your scan trigger. You can set up a schedule or run the scan once.



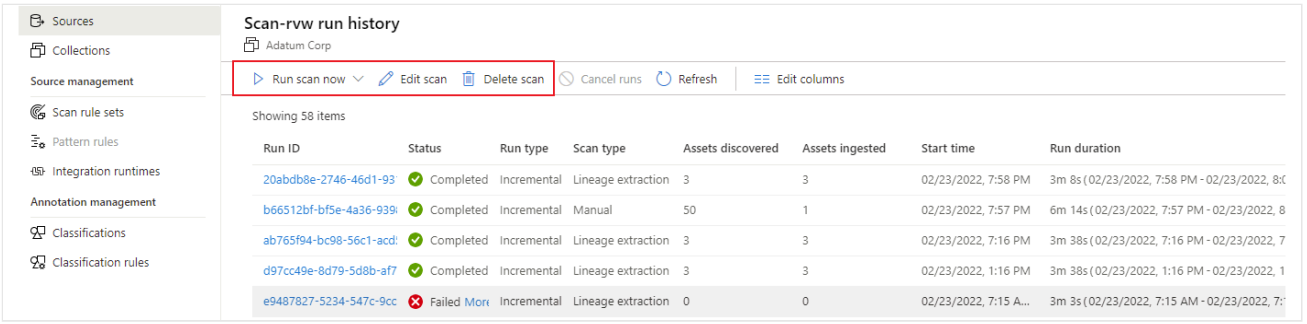
4. Review your scan, and then select **Save and run**.

View a scan

To check the status of a scan, go to the data source in the collection, and then select **View details**.

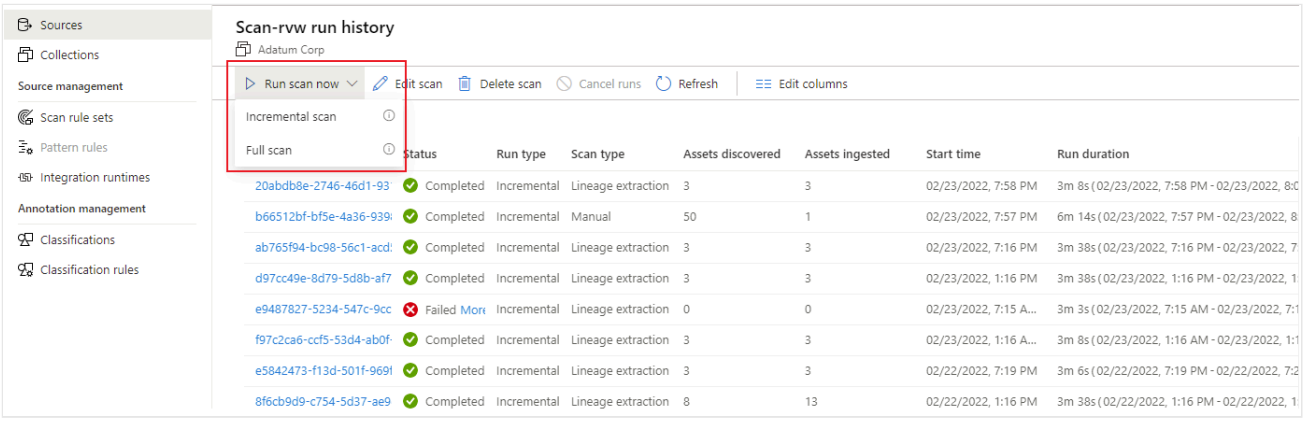


The scan details indicate the progress of the scan in **Last run status**, along with the number of assets scanned and classified. **Last run status** is updated to **In progress** and then **Completed** after the entire scan has run successfully.



Manage a scan

After you run a scan, you can use the run history to manage it:



1. Under **Recent scans**, select a scan.

2. In the run history, you have options for running the scan again, editing it, or deleting it.

If you select **Run scan now** to rerun the scan, you can then choose either **Incremental scan** or **Full scan**.

Troubleshoot scanning

If you have problems with scanning, try these tips:

- Confirm that you followed all prerequisites.
- Check the network by confirming firewall, Azure connections, or integration runtime settings.
- Confirm that authentication is properly set up.

For more information, review Troubleshoot your connections in Microsoft Purview.

Set up policies

The following types of Microsoft Purview policies are supported on this data resource:

- Data owner policies - a set of policy statements that allow you to grant users and groups access to data sources.
- Self-service policies - policy that allows users to request access to data sources registered to Microsoft Purview.

- DevOps policies - grants access to database system metadata across multiple sources. They simplify access provisioning for IT operations and security auditing personnel. They only grant access, and don't deny access.

Access policy prerequisites on Azure SQL Database

- Create a new Azure SQL Database instance, or use an existing one, in one of the currently available regions for this feature. You can follow this guide to create an Azure SQL Database instance.

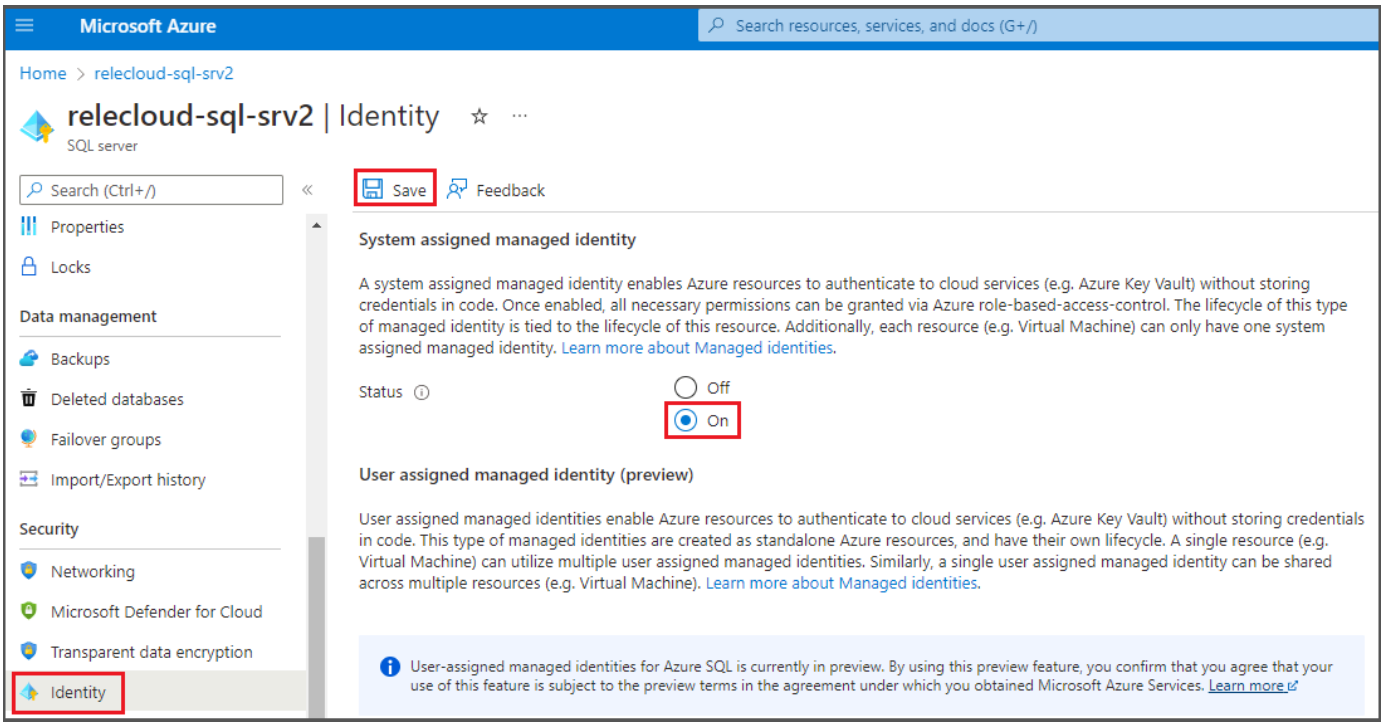
Region support

All Microsoft Purview regions are supported.

Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL Database:

Public cloud:

- East US
- East US2
- South Central US
- West Central US
- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East



Sovereign clouds:

- USGov Virginia
- China North 3

Configure the Azure SQL Database instance for policies from Microsoft Purview

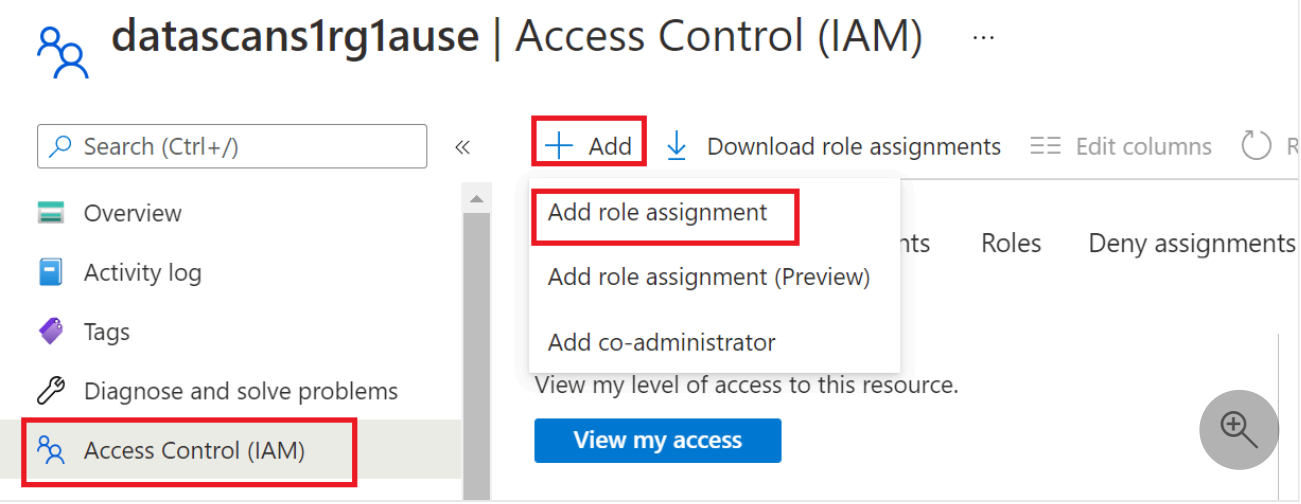
For the logical server associated with Azure SQL Database to honor policies from Microsoft Purview, you need to configure a Microsoft Entra admin. In the Azure portal, go to the logical server that hosts the Azure SQL Database instance. On the side menu, select **Microsoft Entra ID**. Set an admin name to any Microsoft Entra user or group that you prefer, and then select **Save**.

Then, on the side menu, select **Identity**. Under **System assigned managed identity**, turn the status to **On**, and then select **Save**.

Configure the Microsoft Purview account for policies

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

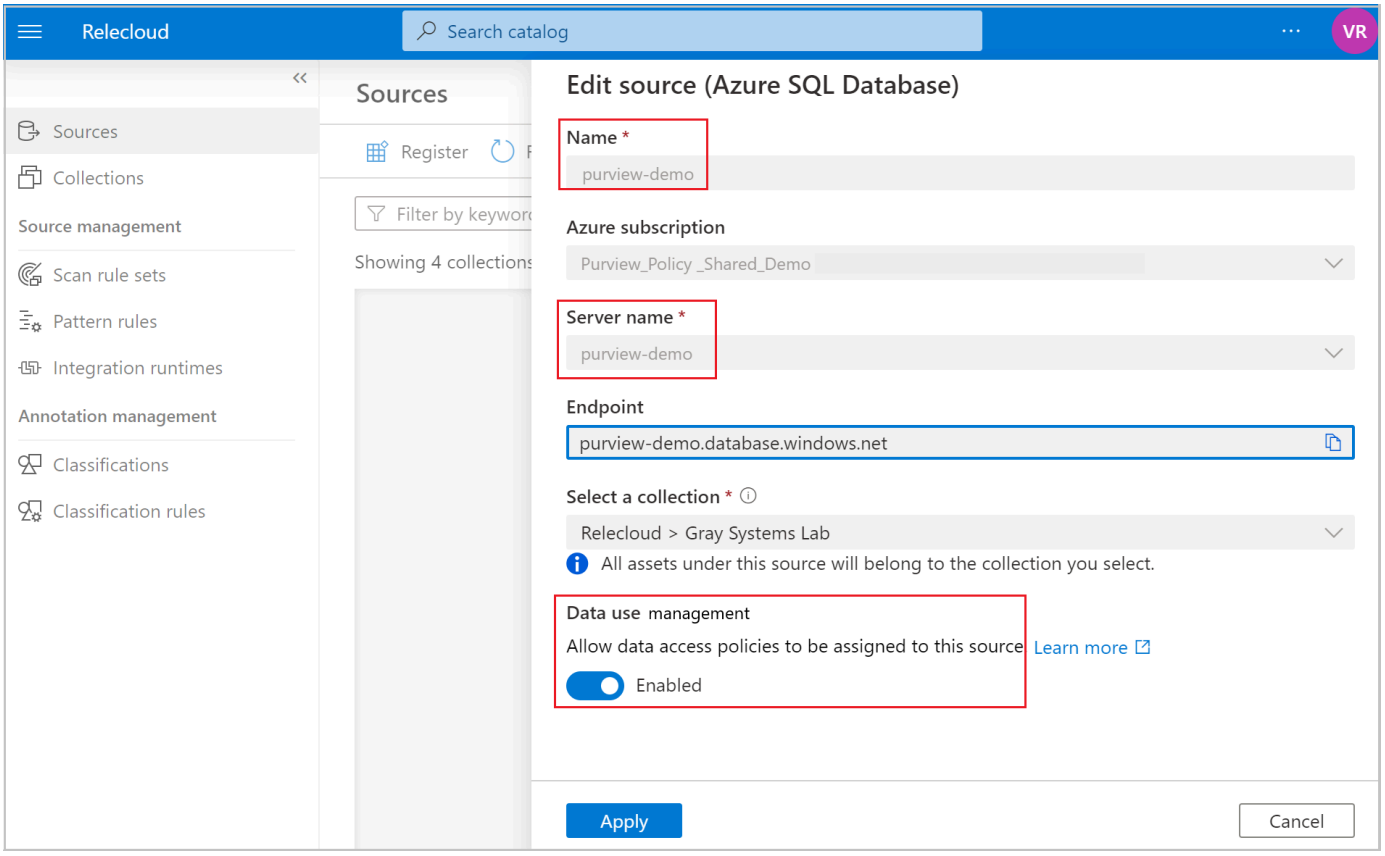
For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.



If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

Register the data source and enable Data policy enforcement

The Azure SQL Database resource needs to be registered with Microsoft Purview before you can create access policies. To register your resources, follow the "Prerequisites" and "Register the data source" sections in Enable Data policy enforcement on your Microsoft Purview sources.

After you register the data source, you need to enable **Data policy enforcement**. This is a prerequisite before you can create policies on the data source. **Data policy enforcement** can affect the security of your data, because it delegates to certain Microsoft Purview roles that manage access to the data sources. Go through the security practices in Enable Data policy enforcement on your Microsoft Purview sources.

After your data source has the **Data policy enforcement** option set to **Enabled**, it will look like this screenshot:

Return to the Azure portal for Azure SQL Database to verify it's now governed by Microsoft Purview:

1. Sign in to the Azure portal through this link.
2. Select the Azure SQL Server that you want to configure.
3. Go to **Microsoft Entra ID** on the left pane.

4. Scroll down to **Microsoft Purview access policies**.

5. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed, which could take a few minutes.

6. Confirm that the Microsoft Purview Governance Status shows **Governed**. Note that **it could take a few minutes** after you enable *Data policy enforcement* in Microsoft Purview for the correct status to be reflected.

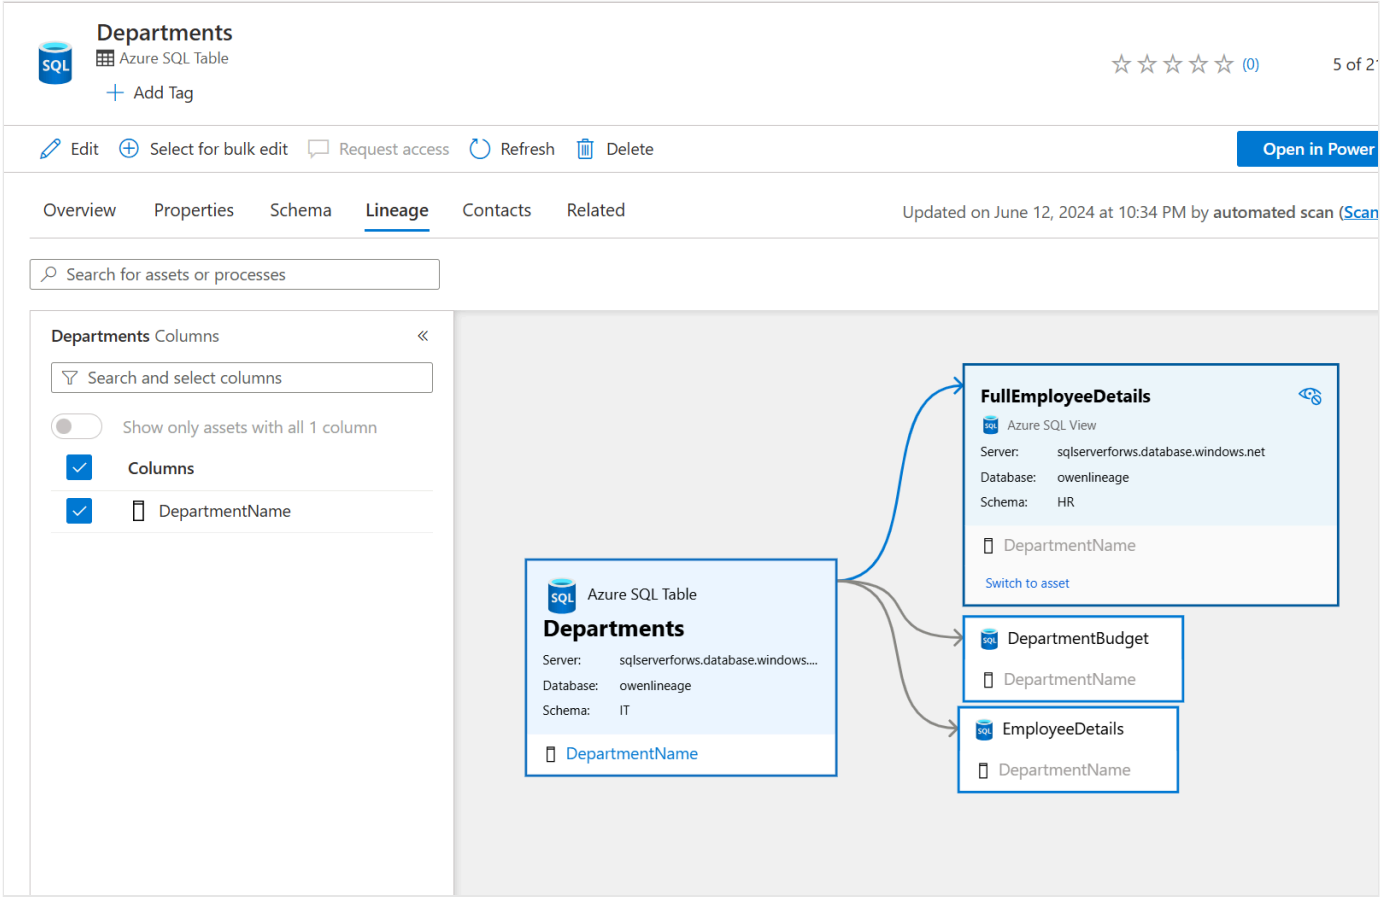
> **Note**
>
> If you disable data policy enforcement for this Azure SQL Database data source in Microsoft Purview, select **Check for Microsoft Purview Governance** for the Microsoft Purview Governance Status to be updated to **Not Governed**. This step must be done for the impacted data source each time data policy enforcement status is changed for an existing or new access policy in Microsoft Purview. Before you enable *Data policy enforcement* for the data source in another Microsoft Purview account, ensure that the Purview Governance Status shows as **Not Governed**. Then repeat the steps above with the new Microsoft Purview account.

Create an access policy

To create an access policy for Azure SQL Database, follow these guides:

- Provision access to system health, performance, and audit information in Azure SQL Database. Use this guide to apply a DevOps policy on a single SQL database.
- Provision read/modify access on a single Azure SQL Database. Use this guide to provision access on a single SQL database account in your subscription.
- Self-service access policies for Azure SQL Database. Use this guide to allow data consumers to request access to data assets by using a self-service workflow.

To create policies that cover all data sources inside a resource group or Azure subscription, see Discover and govern multiple Azure sources in Microsoft Purview.



Extract lineage (preview)

Microsoft Purview supports lineage for views and stored procedures from Azure SQL Database. While lineage for views is supported as part of scanning, you'll need to turn on the **Lineage extraction** toggle to extract stored procedure lineage when you're setting up a scan.

> **Note**
>
> Lineage isn't supported using a self-hosted integration runtime or managed VNET runtime and an Azure SQL private endpoint. You need to enable Azure services to access the server under network settings for your Azure SQL Database, and your Microsoft Purview account needs to allow public access. Learn more about the known limitations in lineage extraction scan.

Lineage for SQL DB views

SQL DB metadata scan includes lineage extraction for views. Only new scans include the view lineage extraction. Lineage is extracted at all scan levels (L1/L2/L3). In case of an incremental scan, whatever metadata is scanned as part of incremental scan, the corresponding static lineage for tables/views will be extracted.

Prerequisites for setting up a scan with SP lineage extraction

1. Follow the steps in the Configure authentication for a scan section of this article to authorize Microsoft Purview to scan your SQL database.

2. Sign in to Azure SQL Database with your Microsoft Entra account, and assign `db_owner` permissions to the Microsoft Purview managed identity.

   > **Note**
   >
   > The 'db_owner' permissions is needed because lineage is based on XEvent sessions. So Microsoft Purview needs the permission to manage the XEvent sessions in SQL.

   Use the following example SQL syntax to create a user and grant permission. Replace `<purview-account>` with your account name.

   ```
   SQL

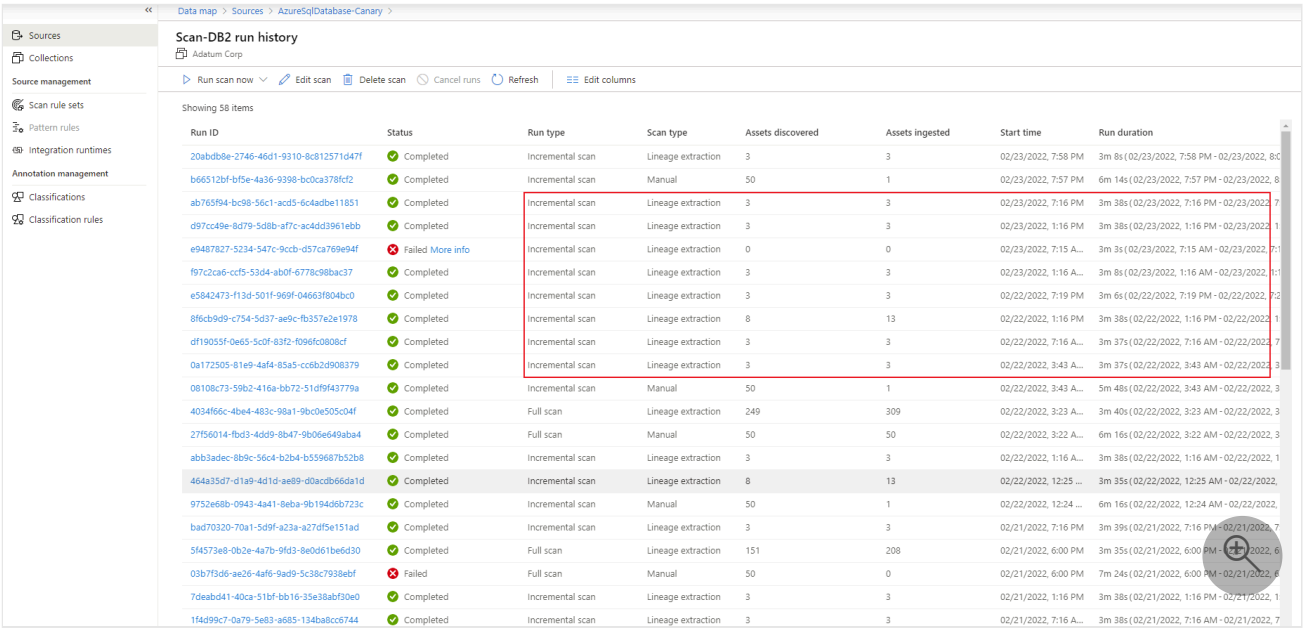
   Create user <purview-account> FROM EXTERNAL PROVIDER
   GO
   EXEC sp_addrolemember 'db_owner', <purview-account>
   GO
   ```

3. Run the following command on your SQL database to create a master key:

   ```
   SQL

   Create master key
   Go
   ```

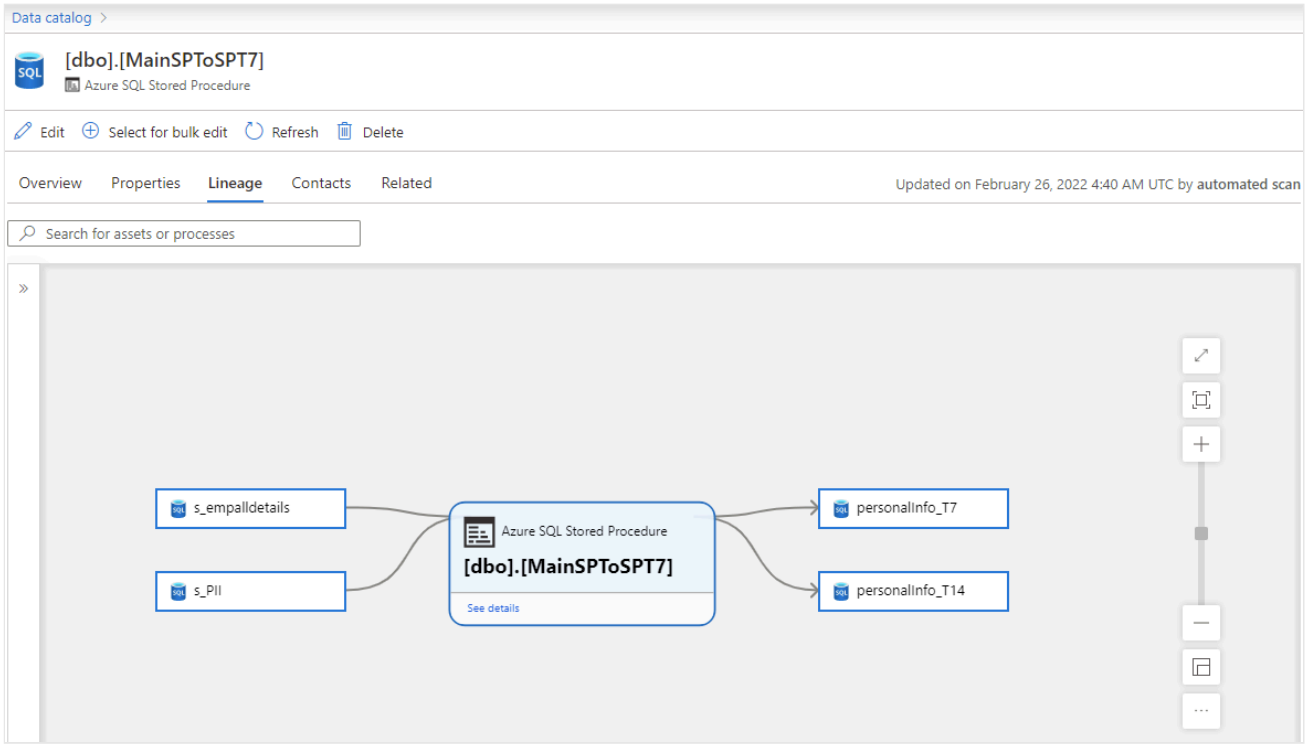
4. Ensure that **Allow Azure services and resources to access this server** is enabled under networking/firewall for your Azure SQL resource.



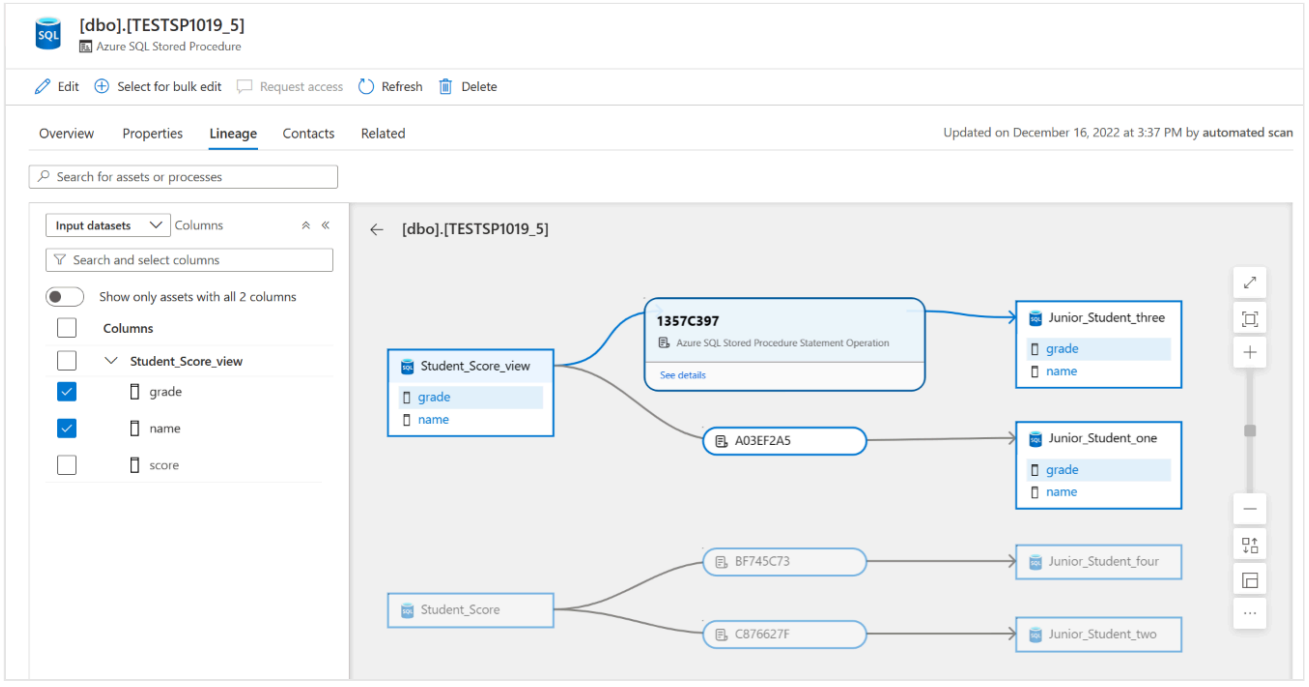
Create a scan with lineage extraction turned on

1. On the pane for setting up a scan, turn on the **Enable lineage extraction** toggle.

2. Select your method of authentication by following the steps in the Create the scan section of this article.



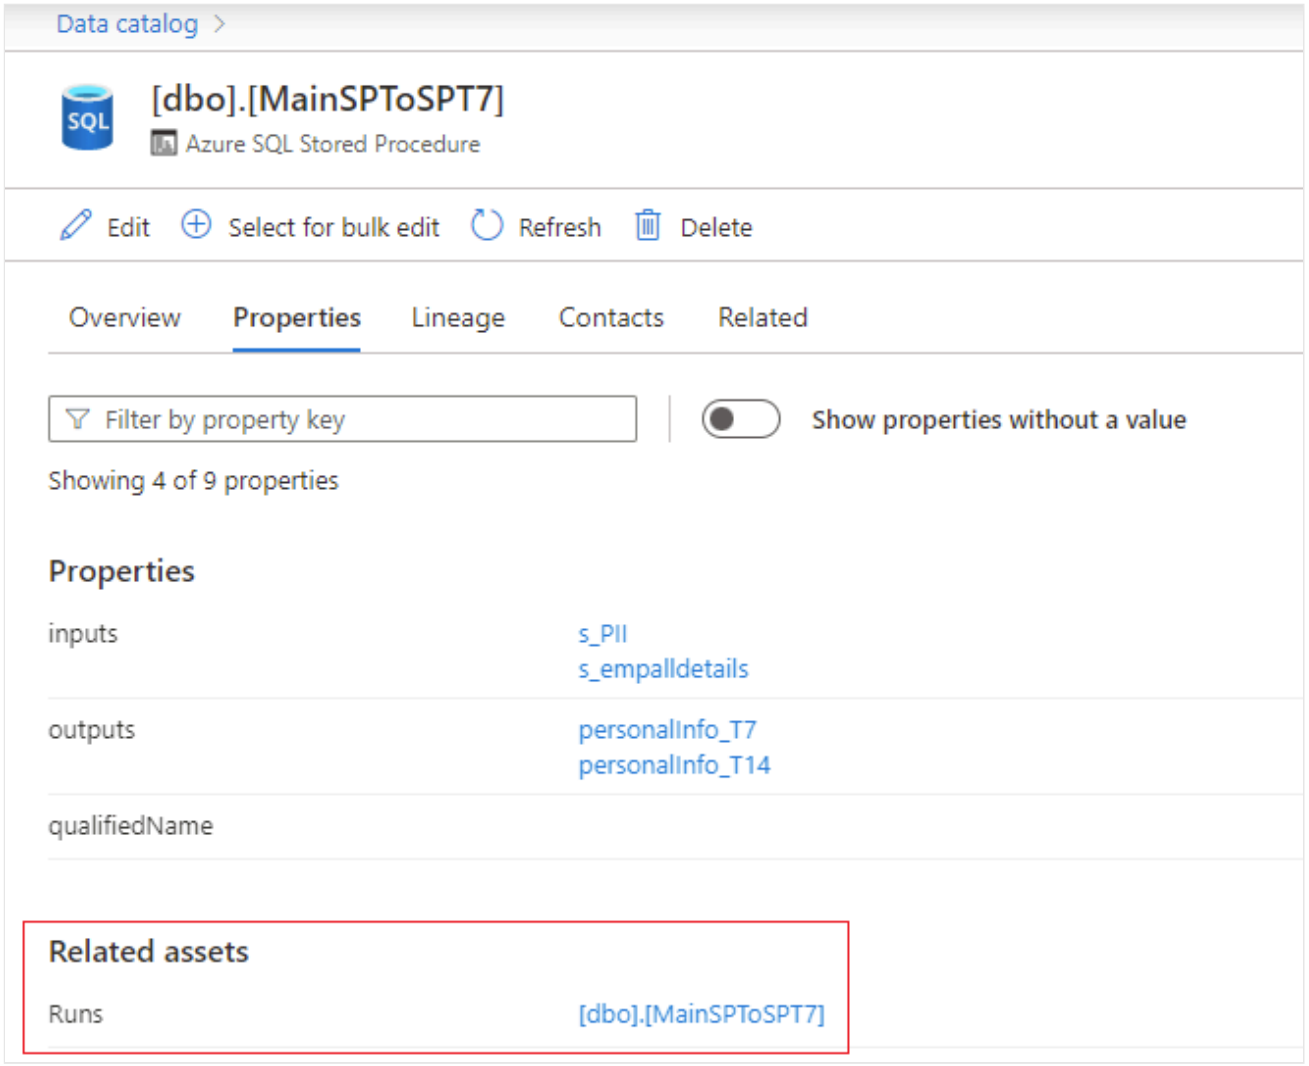
3. After you successfully set up the scan, a new scan type called **Lineage extraction** will run incremental scans **every six hours** to extract lineage from Azure SQL Database. Lineage is extracted based on the stored procedure runs in the SQL database.



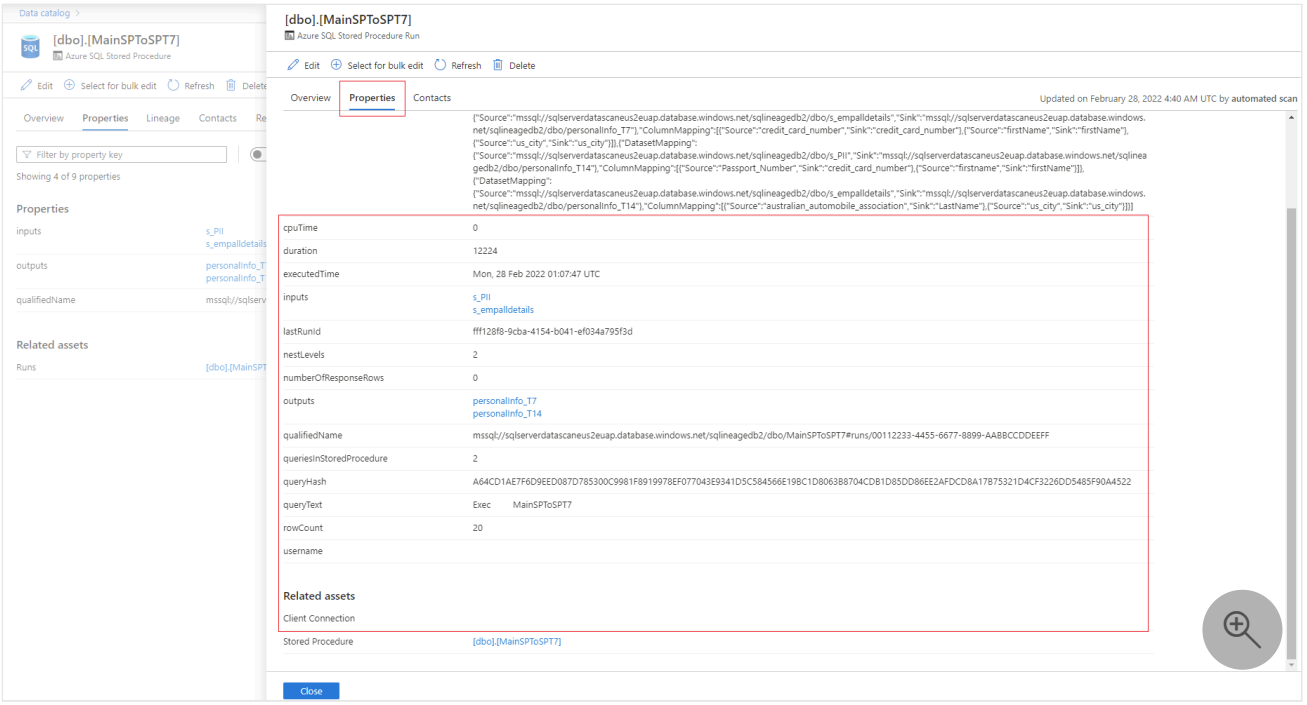
Search Azure SQL Database assets and view runtime lineage

You can browse through the Unified Catalog or search the Unified Catalog to view asset details for Azure SQL Database. The following steps describe how to view runtime lineage details:

1. Go to the **Lineage** tab for the asset. When applicable, the asset lineage appears here.



When applicable, you can further drill down to see the lineage at SQL statement level within a stored procedure, along with column level lineage. When using Self-hosted Integration Runtime for scan, retrieving the lineage drilldown information during scan is supported since version 5.25.8374.1.



For information about supported Azure SQL Database lineage scenarios, refer to the Supported capabilities section of this article. For more information about lineage in general, see Data lineage in Microsoft Purview and Microsoft Purview lineage user guide.

2. Go to the stored procedure asset. On the **Properties** tab, go to **Related assets** to get the latest run details of stored procedures.

3. Select the stored procedure hyperlink next to **Runs** to see the **Azure SQL Stored Procedure Run** overview. Go to the **Properties** tab to see enhanced runtime information from the stored procedure, such as **executedTime**, **rowCount**, and **Client Connection**.

Troubleshoot lineage extraction for Stored Procedures

The following tips can help you solve problems related to lineage:

- If no lineage is captured after a successful **Lineage extraction** run, it's possible that no stored procedures have run at least once since you set up the scan.
- Lineage is captured for stored procedure runs that happen after a successful scan is set up. Lineage from past stored procedure runs isn't captured.
- If your database is processing heavy workloads with lots of stored procedure runs, lineage extraction filters only the most recent runs. Stored procedure runs early in the six-hour window, or the run instances that create heavy query load, won't be extracted. Contact support if you're missing lineage from any stored procedure runs.
- If a stored procedure contains drop or create statements, they aren't currently captured in lineage

Next steps

To learn more about Microsoft Purview and your data, use these guides:

- Concepts for Microsoft Purview Data owner policies
- Concepts for Microsoft Purview DevOps policies
- Understand the Microsoft Purview Data Estate Insights application
- Microsoft Purview lineage user guide
- Search the Microsoft Purview Unified Catalog

Connect to and manage an Azure SQL Managed Instance in Microsoft Purview

Article • 06/06/2024

This article outlines how to register and Azure SQL Managed Instance, as well as how to authenticate and interact with the Azure SQL Managed Instance in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.
- Configure public endpoint in Azure SQL Managed Instance

> **Note**
>
> We now support scanning Azure SQL Managed Instances over the private connection using Microsoft Purview ingestion private endpoints and a self-

hosted integration runtime VM. For more information related to prerequisites, see Connect to your Microsoft Purview and scan data sources privately and securely

Register

This section describes how to register an Azure SQL Managed Instance in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

If you need to create new authentication, you need to authorize database access to SQL Database SQL Managed Instance. There are three authentication methods that Microsoft Purview supports today:

- System or user assigned managed identity
- Service Principal
- SQL authentication

System or user assigned managed identity to register

> **Note**
>
> If you're using Private Endpoints to connect to Microsoft Purview, managed identity isn't supported.

You can use either your Microsoft Purview system-assigned managed identity (SAMI), or a user-assigned managed identity (UAMI) to authenticate. Both options allow you to assign authentication directly to Microsoft Purview, like you would for any other user, group, or service principal. The Microsoft Purview system-assigned managed identity is created automatically when the account is created and has the same name as your Microsoft Purview account. A user-assigned managed identity is a resource that can be created independently. To create one, you can follow our user-assigned managed identity guide.

You can find your managed identity Object ID in the Azure portal by following these steps:

For Microsoft Purview account's system-assigned managed identity:

1. Open the Azure portal, and navigate to your Microsoft Purview account.
2. Select the **Properties** tab on the left side menu.
3. Select the **Managed identity object ID** value and copy it.

For user-assigned managed identity (preview):

1. Open the Azure portal, and navigate to your Microsoft Purview account.
2. Select the Managed identities tab on the left side menu
3. Select the user assigned managed identities, select the intended identity to view the details.
4. The object (principal) ID is displayed in the overview essential section.

Either managed identity will need permission to get metadata for the database, schemas and tables, and to query the tables for classification.

- Create a Microsoft Entra user in Azure SQL Managed Instance by following the prerequisites and tutorial on Create contained users mapped to Microsoft Entra identities
- Assign `db_datareader` permission to the identity.

Service Principal to register

There are several steps to allow Microsoft Purview to use service principal to scan your Azure SQL Managed Instance.

Create or use an existing service principal

To use a service principal, you can use an existing one or create a new one. If you're going to use an existing service principal, skip to the next step. If you have to create a new Service Principal, follow these steps:

1. Navigate to the Azure portal.
2. Select **Microsoft Entra ID** from the left-hand side menu.
3. Select **App registrations**.
4. Select **+ New application registration**.
5. Enter a name for the **application** (the service principal name).
6. Select **Accounts in this organizational directory only**.
7. For Redirect URI, select **Web** and enter any URL you want; it doesn't have to be real or work.
8. Then select **Register**.

Configure Microsoft Entra authentication in the database account

The service principal must have permission to get metadata for the database, schemas, and tables. It must also be able to query the tables to sample for classification.

- Configure and manage Microsoft Entra authentication with Azure SQL
- Create a Microsoft Entra user in Azure SQL Managed Instance by following the prerequisites and tutorial on Create contained users mapped to Microsoft Entra identities
- Assign `db_datareader` permission to the identity.

Add service principal to key vault and Microsoft Purview's credential

It's required to get the service principal's application ID and secret:

1. Navigate to your Service Principal in the Azure portal
2. Copy the values the **Application (client) ID** from **Overview** and **Client secret** from **Certificates & secrets**.
3. Navigate to your key vault
4. Select **Settings** > **Secrets**
5. Select + **Generate/Import** and enter the **Name** of your choice and **Value** as the **Client secret** from your Service Principal
6. Select **Create** to complete
7. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection
8. Finally, create a new credential using the Service Principal to set up your scan.

SQL authentication to register

> **Note**
>
> Only the server-level principal login (created by the provisioning process) or members of the `loginmanager` database role in the master database can create new logins. It takes about **15 minutes** after granting permission, the Microsoft Purview account should have the appropriate permissions to be able to scan the resource(s).

You can follow the instructions in CREATE LOGIN to create a login for Azure SQL Managed Instance if you don't have this login available. You'll need **username** and **password** for the next steps.

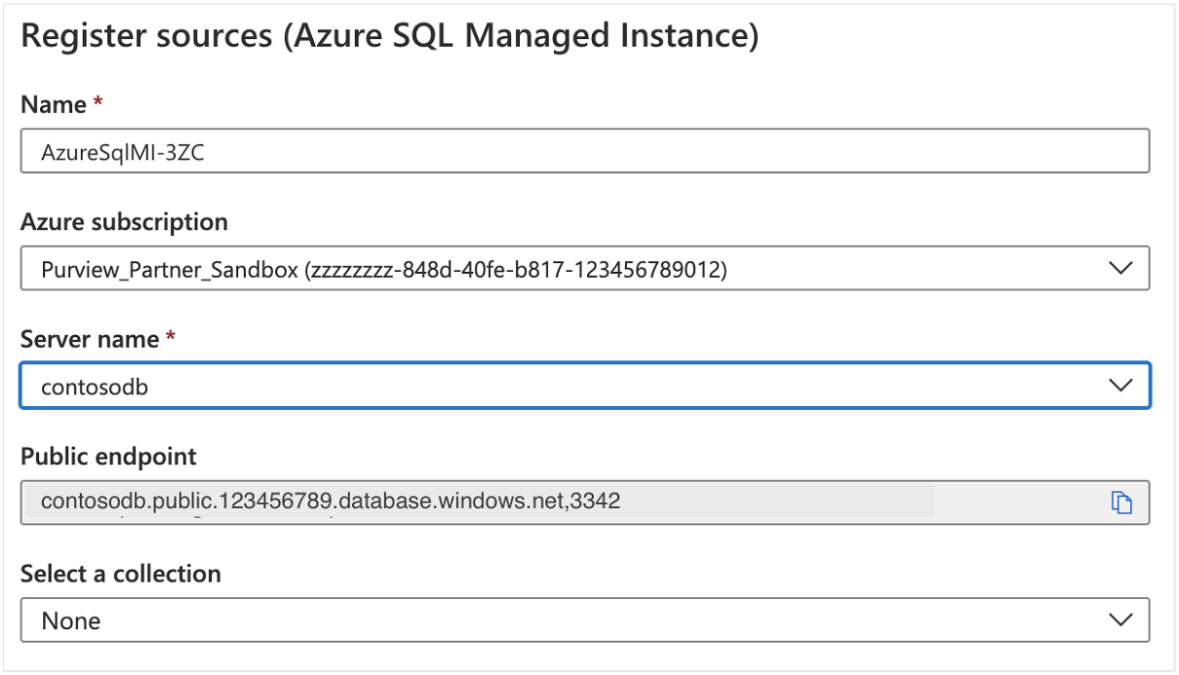
1. Navigate to your key vault in the Azure portal

2. Select **Settings** > **Secrets**
3. Select + **Generate/Import** and enter the **Name** and **Value** as the *password* from your Azure SQL Managed Instance
4. Select **Create** to complete
5. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection
6. Finally, create a new credential using the **username** and **password** to set up your scan.

Steps to register

1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.



2. Navigate to the **Data Map**.

3. Select **Register**

4. Select **Azure SQL Managed Instance** and then **Continue**.

5. Select **From Azure subscription**, select the appropriate subscription from the **Azure subscription** drop-down box and the appropriate server from the **Server name** drop-down box.

6. Provide the **public endpoint fully qualified domain name** and **port number**. Then select **Register** to register the data source.

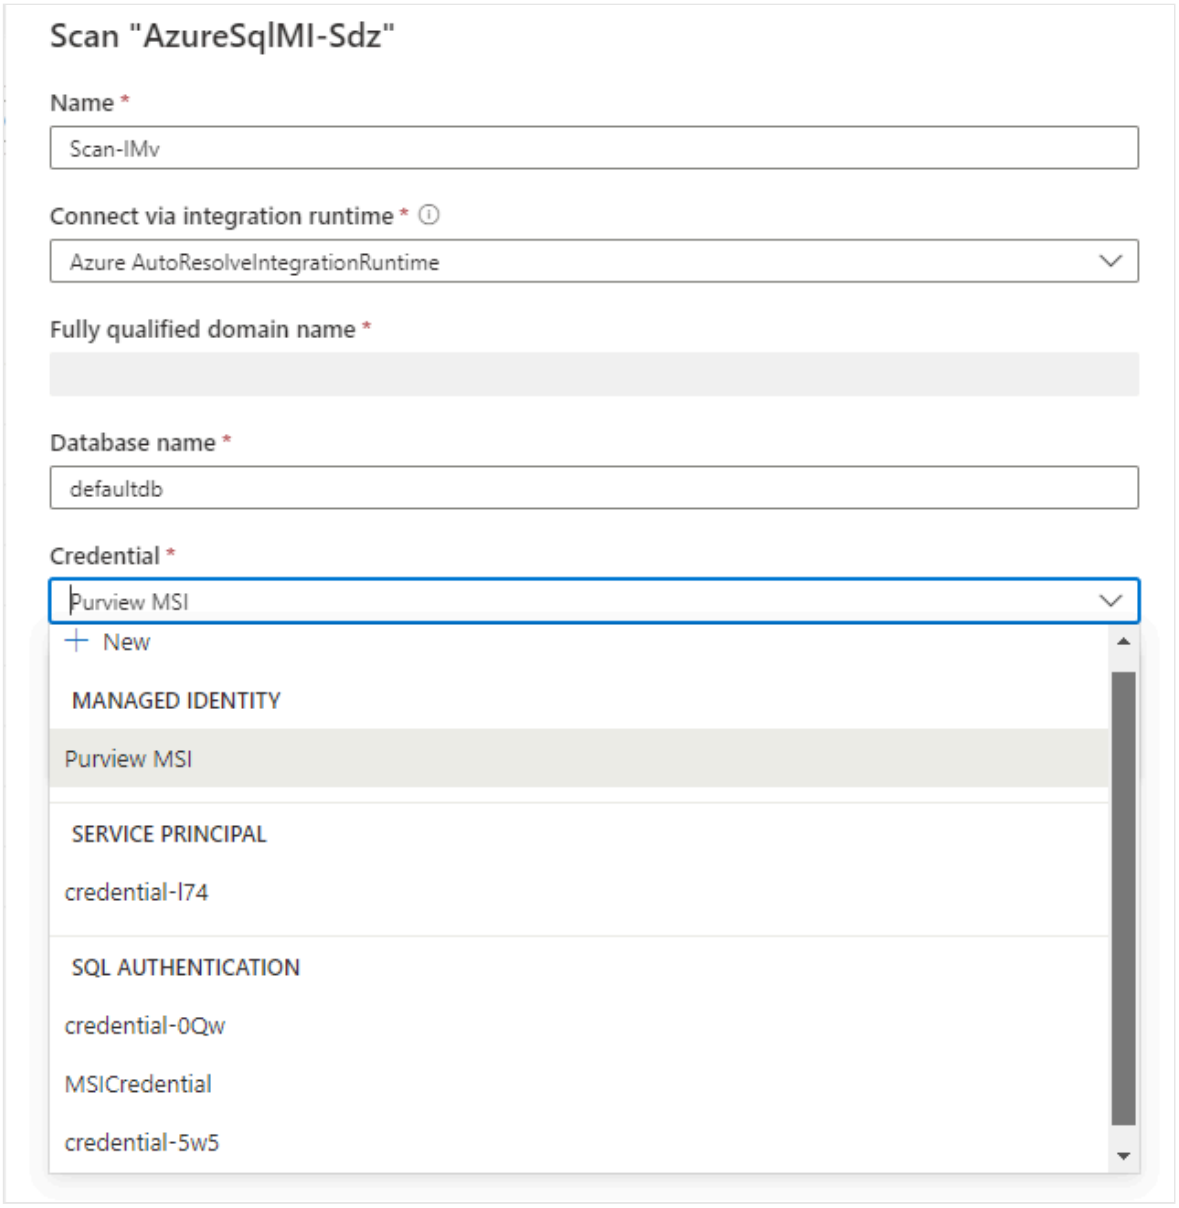
For Example: `foobar.public.123.database.windows.net,3342`

Scan

Follow the steps below to scan an Azure SQL Managed Instance to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion.

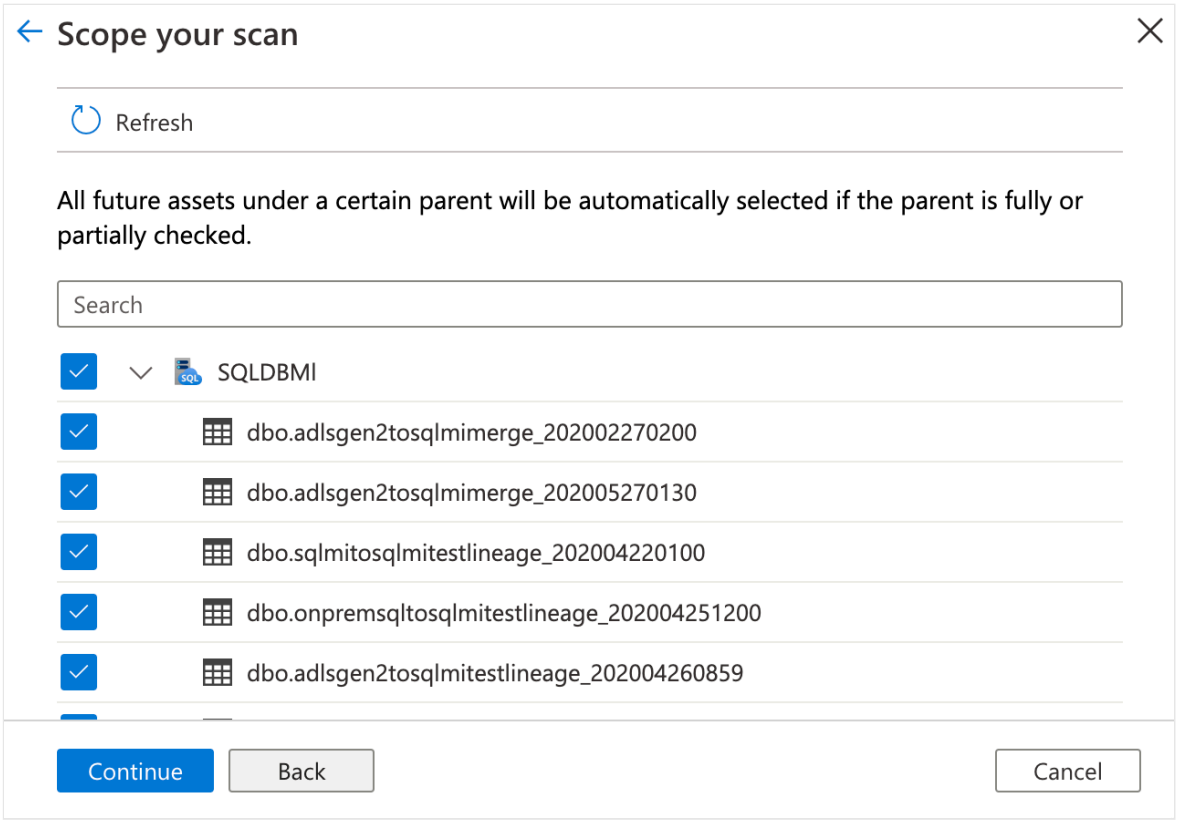
Create and run scan

To create and run a new scan, complete the following steps:



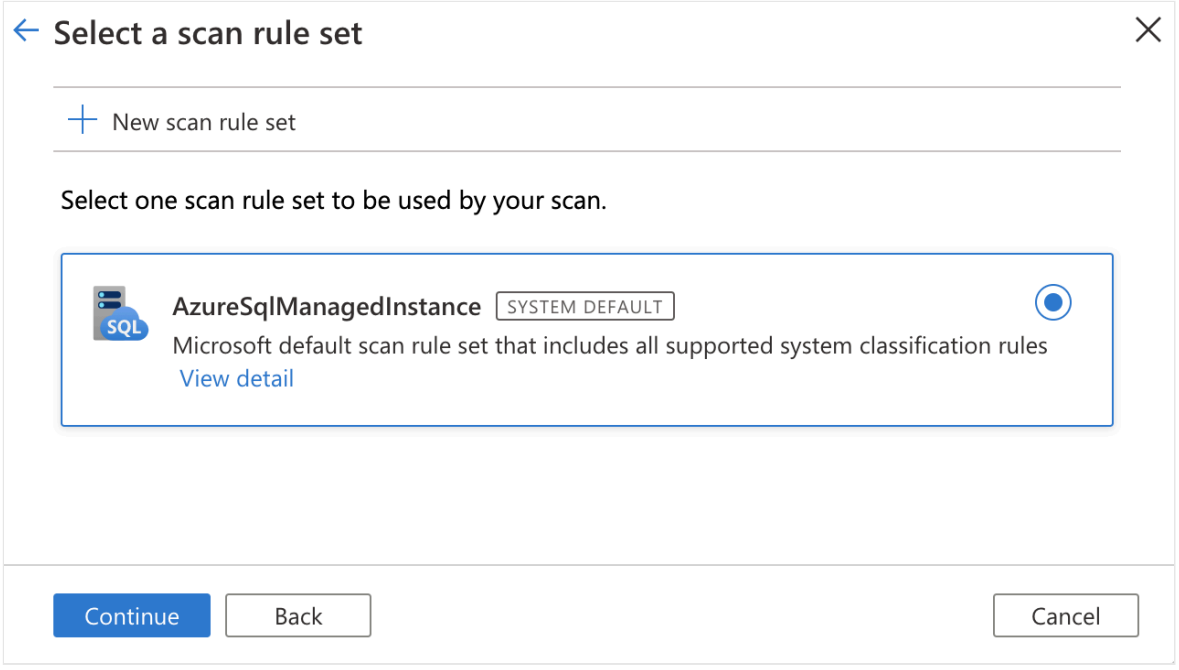
1. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.

2. Select the Azure SQL Managed Instance source that you registered.

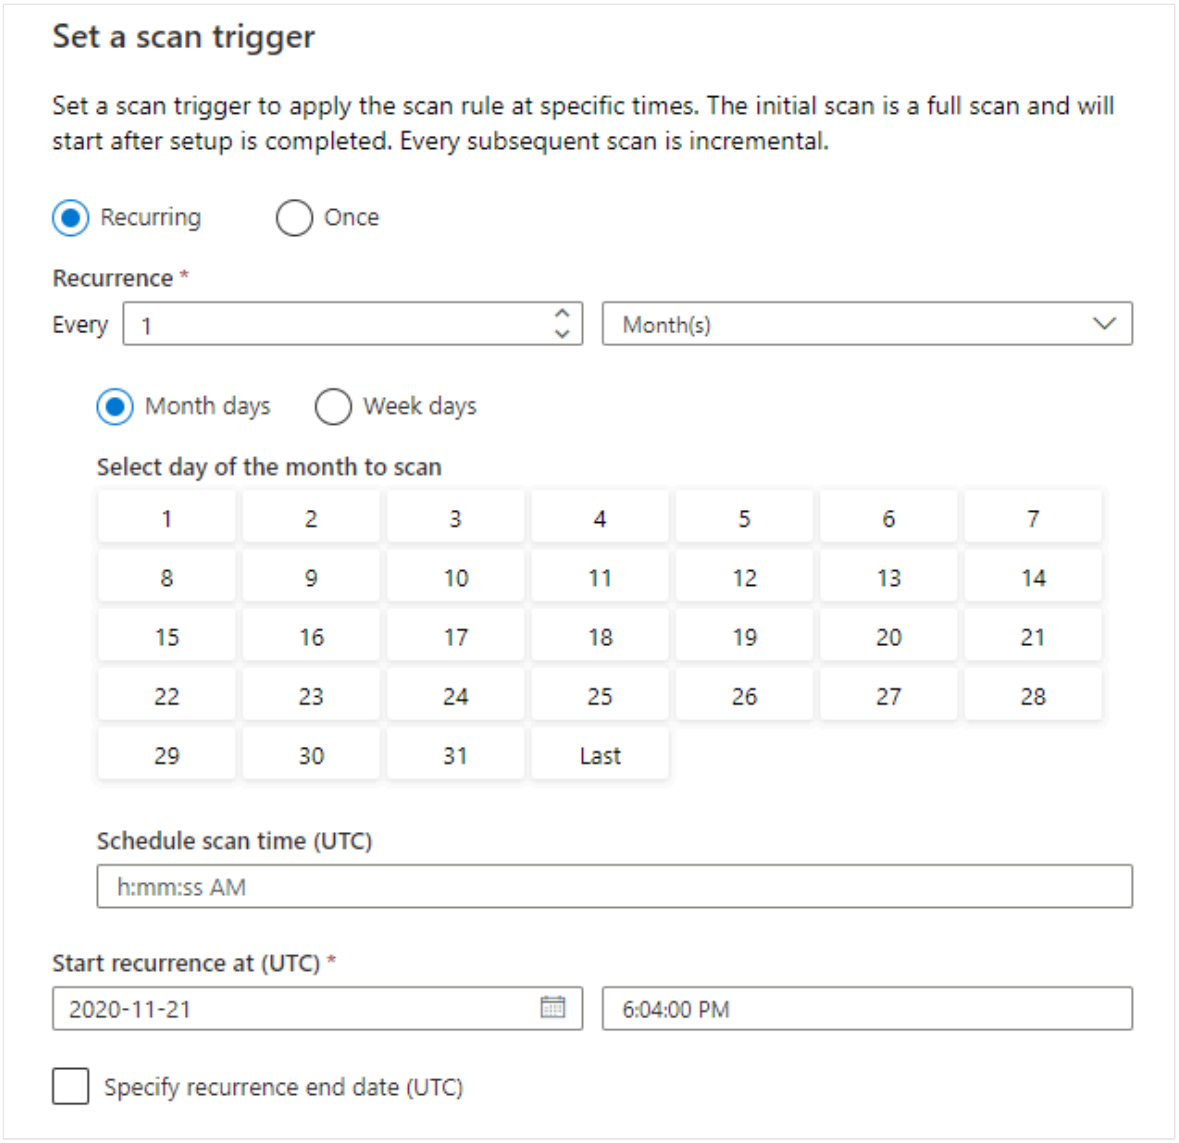


3. Select **New scan**

4. Choose either the Azure integration runtime if your source is publicly accessible, a managed virtual network integration runtime if using a managed virtual network, or a standard or kubernetes supported self-hosted integration runtime if your source is in a private virtual network. For more information about which integration runtime to use, see the choose the right integration runtime configuration article.



5. Select the credential to connect to your data source.



6. You can scope your scan to specific tables by choosing the appropriate items in the list.

7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.

If you're having trouble connecting to your data source, or running your scan, you scan see our troubleshooting guide for scans and connections.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Set up access policies

The following types of Microsoft Purview policies are supported on this data resource:

- DevOps policies

Access policy prerequisites on Azure SQL MI

- Create a new Azure SQL MI or use an existing one in one of the currently available regions for this feature. You can follow this guide to create a new Azure SQL MI.

Region support

All Microsoft Purview regions are supported.

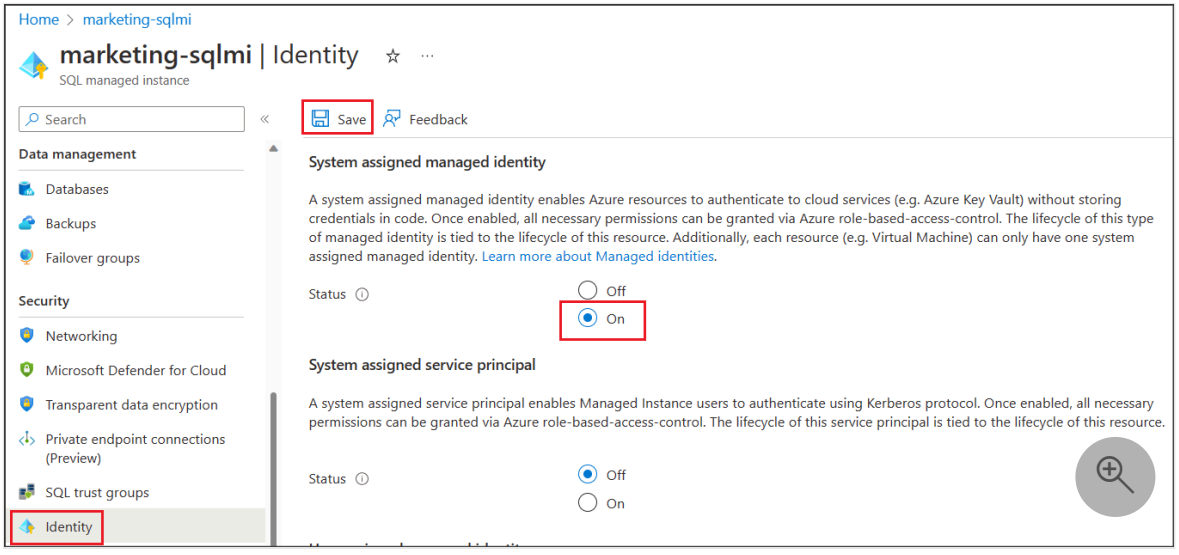
Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL MI:

Public cloud:

- East US
- East US2
- South Central US
- West Central US

- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East

Azure SQL MI configuration

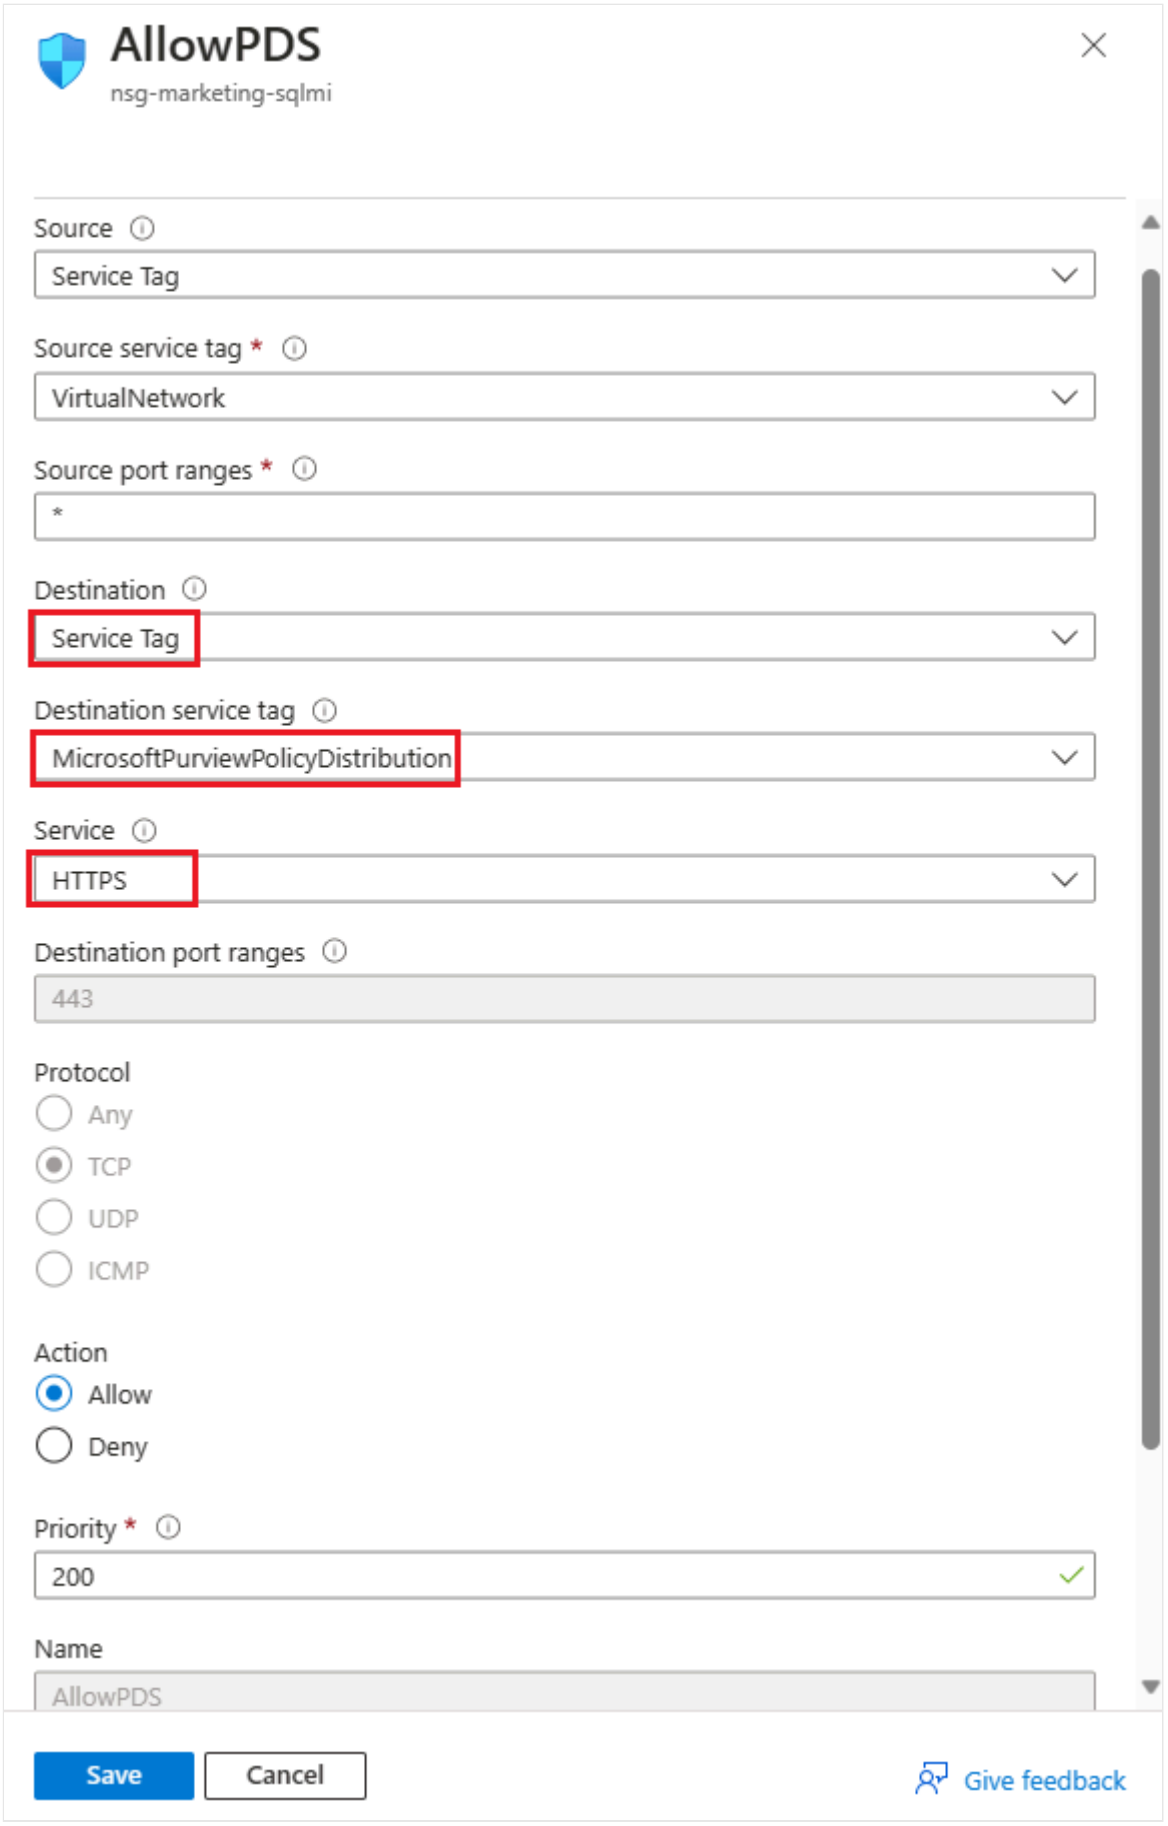


This section explains how you can set up Azure SQL MI to honor policies from Microsoft Purview. Check first whether Azure SQL MI is configured for public or private endpoint. This guide explains how to do so.

Configuration for SQL MI public endpoint

If Azure SQL MI is configured for public endpoint, follow these steps:

- Configure a Microsoft Entra Admin. In Azure portal navigate to the Azure SQL MI then navigate to Microsoft Entra ID on the side menu (formerly called Active Directory admin). Set an Admin name and then select **Save**.



- Then navigate to Identity on the side menu. Under System assigned managed identity check status to *On* and then select **Save**. See screenshot:

Configuration for SQL MI private endpoint

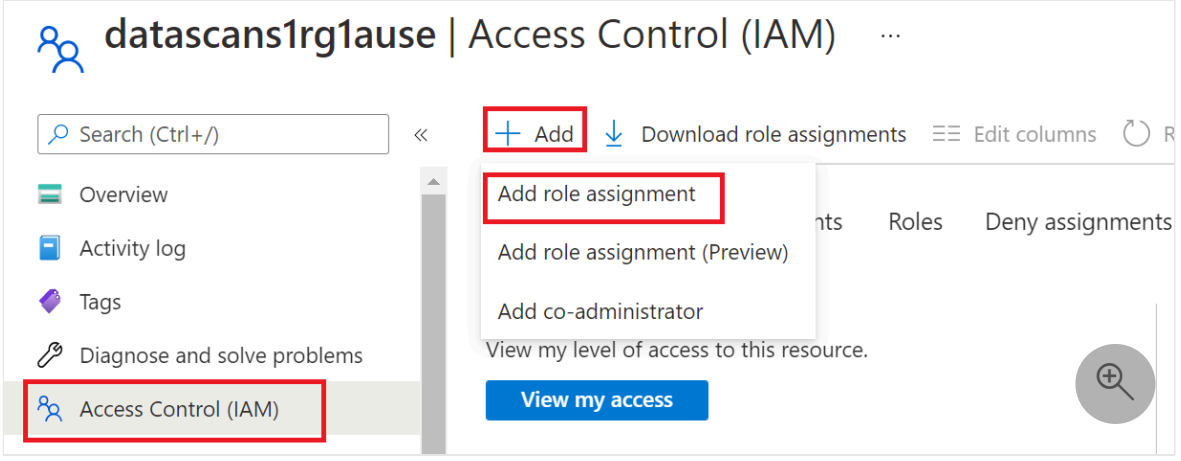
If Azure SQL MI is configured to use private endpoint, execute the same steps outlined in the configuration for public endpoint, and in addition, do the following:

- Navigate to the Network Security Group (NSG) associated to your Azure SQL MI.
- Add an outbound security rule similar to the one in the following screenshot. *Destination = Service Tag, Destination service tag = MicrosoftPurviewPolicyDistribution, Service = HTTPS, Action = Allow.* Ensure also that this rule's priority is lower than the one for the *deny_all_outbound* rule.

Configure the Microsoft Purview account for policies

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



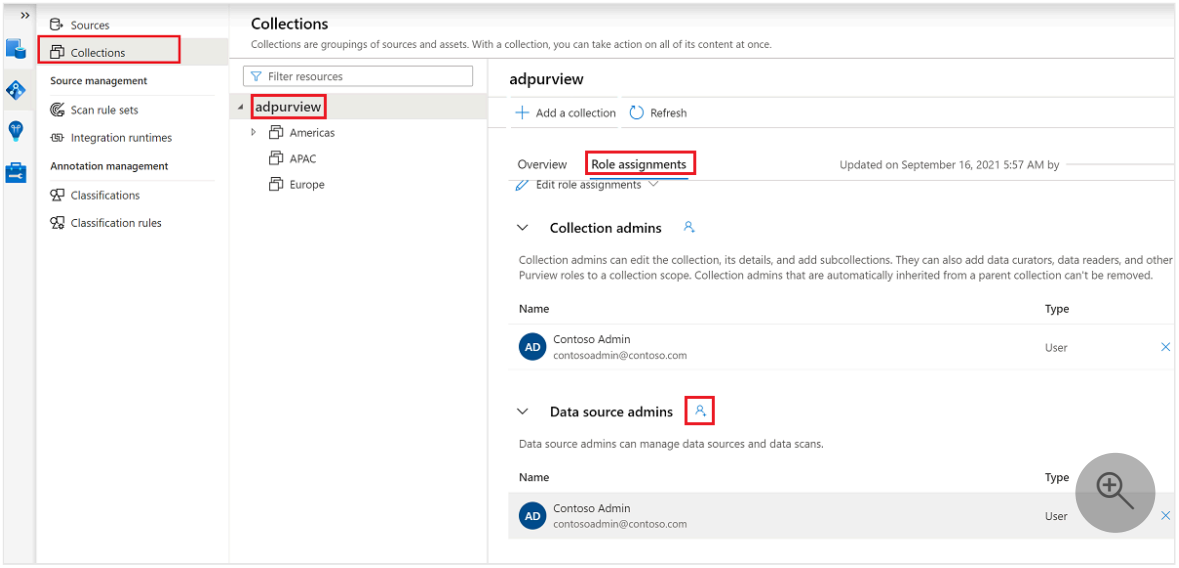
> ⓘ Note
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.



> ⓘ Note

The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

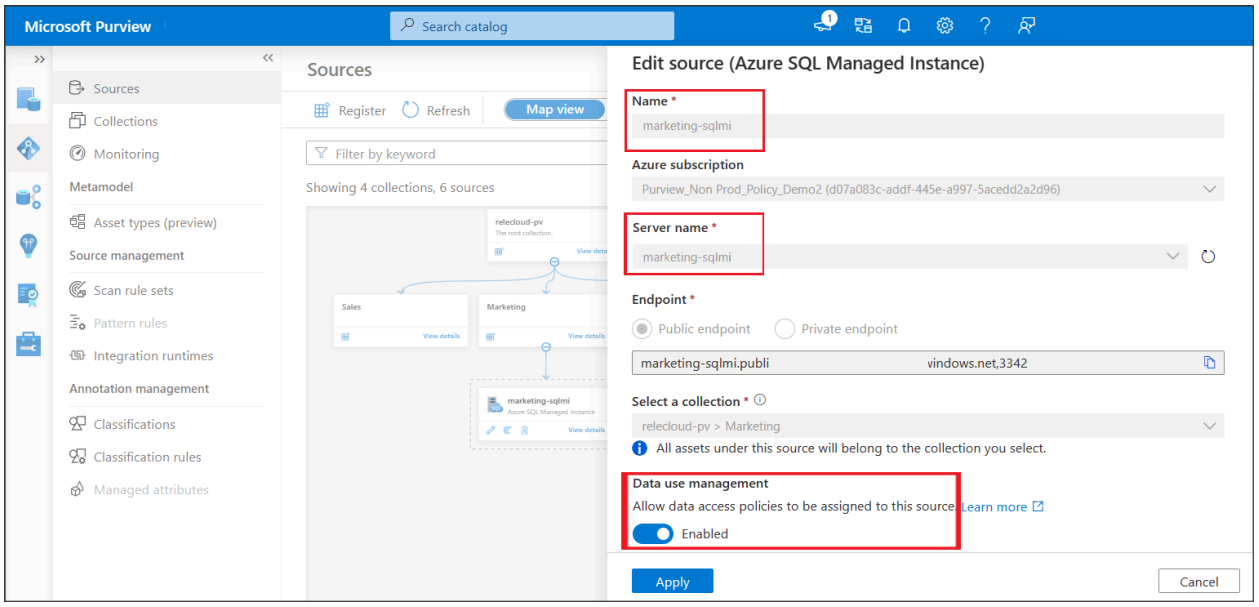
After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin*

role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

Register the data sources in Microsoft Purview



The Azure SQL Managed Instance data source needs to be registered first with Microsoft Purview, before you can create access policies. You can follow the "Prerequisites" and "Register the data source" sections in this guide:

Register and scan Azure SQL MI

After you've registered your resources, you'll need to enable data policy enforcement (formerly Data Use Management). Data policy enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles the ability to manage access to data sources. **Go through the secure practices related to data policy enforcement in this guide**: How to enable data policy enforcement

Once your data source has the **Data policy enforcement** toggle *Enabled*, it will look like this screenshot. This will enable the access policies to be used with the given data

source

Return to the Azure portal for Azure SQL Database to verify it's now governed by Microsoft Purview:

1. Sign in to the Azure portal through this link.
2. Select the Azure SQL Server that you want to configure.
3. Go to **Microsoft Entra ID** on the left pane.
4. Scroll down to **Microsoft Purview access policies**.
5. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed, which could take a few minutes.

6. Confirm that the Microsoft Purview Governance Status shows **Governed**. Note that **it could take a few minutes** after you enable *Data policy enforcement* in Microsoft Purview for the correct status to be reflected.

> **Note**
>
> If you disable data policy enforcement for this Azure SQL Database data source in Microsoft Purview, select **Check for Microsoft Purview Governance** for the Microsoft Purview Governance Status to be updated to **Not Governed**. This step must be done for the impacted data source each time data policy enforcement status is changed for an existing or new access policy in Microsoft Purview. Before

you enable *Data policy enforcement* for the data source in another Microsoft Purview account, ensure that the Purview Governance Status shows as **Not Governed**. Then repeat the steps above with the new Microsoft Purview account.

Create a policy

To create access policies for Azure SQL MI, follow these guides:

- To create a DevOps policy on a single Azure SQL MI see Provision access to system health, performance and audit information in Azure SQL MI.
- To create policies that cover all data sources inside a resource group or Azure subscription, see Discover and govern multiple Azure sources in Microsoft Purview.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Concepts for Microsoft Purview DevOps policies
- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage Cassandra in Microsoft Purview

Article • 06/27/2024

This article outlines how to register Cassandra, and how to authenticate and interact with Cassandra in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported Cassandra server versions are 3.*x* or 4.*x*.

When scanning Cassandra source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Cluster
  - Keyspaces
  - Tables including the columns and indexes
  - Materialized views including the columns
- Fetching static lineage on assets relationships among tables and materialized views.

When setting up scan, you can choose to scan an entire Cassandra instance, or scope the scan to a subset of keyspaces matching the given name(s) or name pattern(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.

> **Note**
>
> **If your data store is not publicly accessible** (if your data store limits access from on-premises network, private network or specific IPs, etc.), **you will need to configure a self hosted integration runtime to connect to it**.

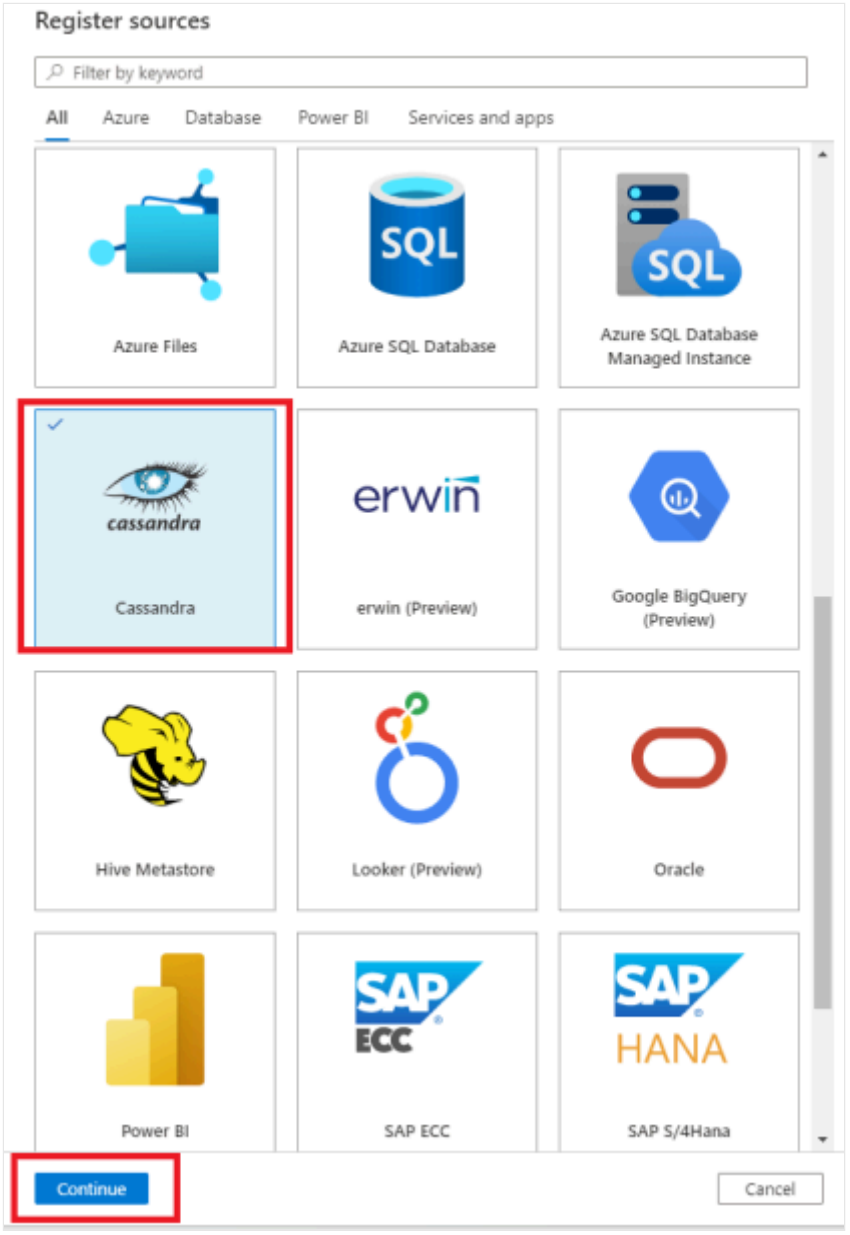
- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - **To use a kubernetes supported self-hosted integration runtime:**
      - Follow the article to create and configure a kubernetes supported integration runtime.

Register

This section describes how to register Cassandra in Microsoft Purview using the Microsoft Purview governance portal.

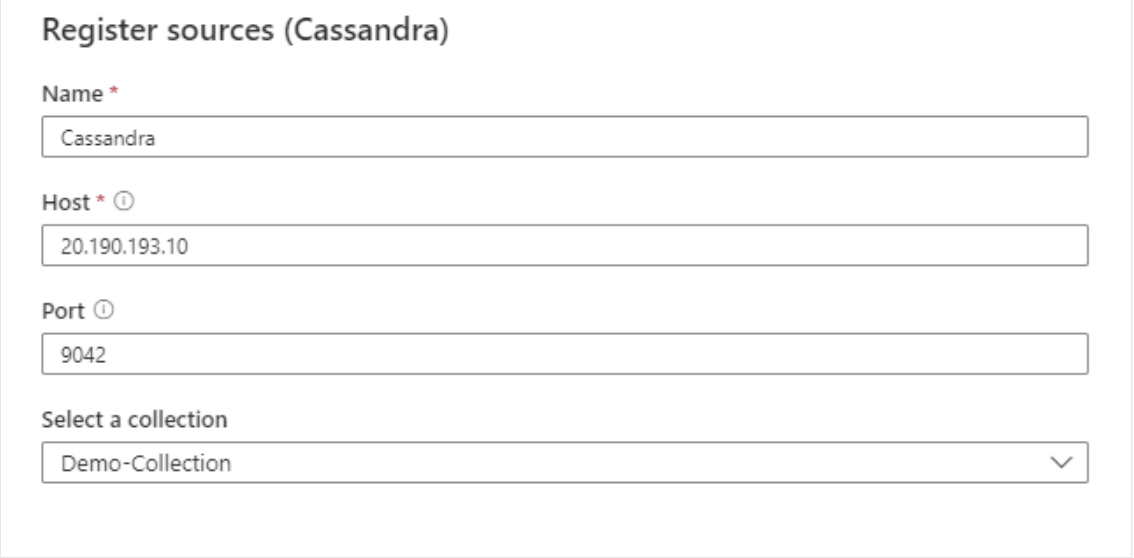
Steps to register

To register a new Cassandra server in Microsoft Purview Unified Catalog:



1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.



2. Select **Data Map** on the left pane.

3. Select **Register**.

4. On the **Register sources** screen, select **Cassandra**, and then select **Continue**:

5. On the **Register sources (Cassandra)** screen:
   a. Enter a **Name**. The data source will use this name in the catalog.
   b. In the **Host** box, enter the server address where the Cassandra server is running. For example, 20.190.193.10.
   c. In the **Port** box, enter the port used by the Cassandra server.
   d. Select a collection from the list.

   e. Select **Register**.

Scan

Follow the steps below to scan Cassandra to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion

Create and run scan

To create and run a new scan:

1. If your server is publicly accessible, skip to step two. Otherwise, you'll need to make sure your self-hosted integration runtime is configured:
   a. In the Microsoft Purview governance portal, got to the Management Center, and select **Integration runtimes**.
   b. Make sure a self-hosted integration runtime is available. If one isn't set up, use the steps mentioned in prerequisites to set up a self-hosted integration runtime.

2. In the Microsoft Purview governance portal, navigate to **Sources**.

3. Select the registered Cassandra server.

4. Select **New scan**.

5. Provide the following details.

a. **Name**: Specify a name for the scan.

b. **Connect via integration runtime**: Select the Azure auto-resolved integration runtime if your server is publicly accessible, or your configured self-hosted integration runtime if it isn't publicly available.

c. **Credential**: When you configure the Cassandra credentials, be sure to:

   - Select **Basic Authentication** as the authentication method.
   - In the **User name** box, provide the name of the user you're making the connection for.
   - In the key vault's secret, save the password of the Cassandra user you're making the connection for.

   For more information, see Credentials for source authentication in Microsoft Purview.

d. **Keyspaces**: Specify a list of Cassandra keyspaces to import. Multiple keyspaces must be separated with semicolons. For example, `keyspace1;keyspace2`. When the list is empty, all available keyspaces are imported.

e. **Use Secure Sockets Layer(SSL)**: Select **True** or **False** to specify whether to use Secure Sockets Layer (SSL) when connecting to the Cassandra server. By default, this option is set to **False**.

f. **Maximum memory available** (applicable when using self-hosted integration runtime): Specify the maximum memory (in GB) available on your VM to be used for scanning processes. This value depends on the size of Cassandra server

to be scanned.

6. Select **Test connection** to validate the settings.

7. Select **Continue**.

8. Select a **scan trigger**. You can set up a schedule or run the scan once.

9. Review your scan, and then select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Cassandra source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Cassandra lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage ChatGPT Enterprise AI interactions in Microsoft Purview (preview)

This article outlines how to register ChatGPT Enterprise workspaces as a data source in Microsoft Purview. This connector allows you to discover and govern interactions with ChatGPT Enterprise AI across your organization. Before you start, ensure you have the required permissions, billing configuration, and a ChatGPT Enterprise plan as described in the Prerequisites section.

> **Important**
>
> Any scans run are subject to the new Microsoft Purview billing model. Be sure to enable pay-as-you-go billing in your organization.

Find more information about how Microsoft Purview solutions support AI interactions with ChatGPT Enterprise.

Supported capabilities

This section summarizes which scan modes and governance features are supported for ChatGPT Enterprise sources.

Choose to scan all user interactions from the current date or pick a specific start date from past when configuring your scan.

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan	Classification	Labeling	Access Policy	Lineage	Data Sharing	Live view
Yes	Yes	Yes	No	Yes	No	No	No	No	No

When scanning ChatGPT Enterprise sources, Microsoft Purview supports:

- Extracting technical metadata, including:
  - Text prompts
  - Text responses

> **Note**
>
> Due to OpenAI's current API limitations, conversations are ingested 24 hours after they occur.

Prerequisites

Make sure you have the following accounts, permissions, and configurations in place:

- An Azure account with an active subscription.
- An active Enterprise Microsoft Purview account.
  - If you create a classic Microsoft Purview instance for the first time in your organization, the instance is automatically upgraded to the enterprise version of Microsoft Purview.
- *Data Source Administrator* and *Data Reader* Microsoft Purview Data Governance classic permissions must be assigned to register a source and manage it in the Microsoft Purview governance portal.
- A ChatGPT Enterprise plan.
- Have pay-as-you-go billing enabled in your organization.
- Have a collection policy allowing for the ingestion of prompts and responses. There are two ways you can set up the policy:
  - Set up a one-click policy to capture interactions for enterprise AI apps.
  - Set up a collection policy for enterprise AI apps in Microsoft Purview Data Loss Prevention.
- At present, scope for API key is not defined while creating the API key on the OpenAI API Platform Portal, but it is a prerequisite for Microsoft Purview to run a scan and fetch metadata. Complete the following steps to define the scope:
  - Send an email to `support@openai.com` with:
    1. The last 4 digits of the API key.
    2. The Key Name.
    3. The Created By Name.
    4. The requested scope (**read**, **delete**, or both). Microsoft Purview needs at least the **read** scope to run a scan.

- The Open AI team will verify the key and grant the requested Compliance API scopes.
- Administrators can now use this key or pass it to a partner for use with the Compliance API.

Add permissions

Add the necessary permissions for other Microsoft Purview solutions used as part of this scanning process:

- Azure Key Vault
- Microsoft Purview AI hub
- Microsoft Purview Communication Compliance
- Microsoft Purview Data Lifecycle Management
- Microsoft Purview Data Map
- Microsoft Purview eDiscovery
- Microsoft Purview Insider Risk Management
- Microsoft Purview Records Management

Microsoft Purview uses the OAuth 2.0 protocol for accessing ChatGPT Enterprise workspaces. To set up the credential, create an API key credential mapped to your Azure Key Vault when you configure the scan. For detailed steps, see the Scan section.

Register a ChatGPT Enterprise workspace

This section describes how to register a ChatGPT Enterprise workspace in Microsoft Purview using the Microsoft Purview governance portal.

Complete the following steps to register:

1. Open the Azure portal and complete the following steps:
   a. Search for *Key Vault* to create/manage the secret to use for this connector.
   b. Create a Key Vault.
   c. Grant role assignments to your Key Vault. Assign Key Vault administrators and Key Vault secret users for the required members. For other roles, check the Key Vault roles in the **Required permissions** section.
   d. Create a secret for your Key Vault.
   e. For your Key Vault, assign access policy.

2. Open the Microsoft Purview governance portal and complete the following steps:

a. Search for Microsoft Purview accounts, select the account you want to use and select **Open Microsoft Purview governance portal**.
b. Select **Data Map** in left navigation and select the *Data source*.
c. Select **Register data source**.
d. On register sources, select **ChatGPT Enterprise** and select **Continue**.

3. Open the ChatGPT Enterprise register source and complete the following steps:
   a. Enter a name for the data source within the catalog.
   b. Enter the WorkspaceID for your Enterprise workspace.
   c. Select a domain and collection.
   d. Select **Register**.

4. Open the Microsoft Purview portal and complete the following steps:
   a. Select **Source management** under **Data Map**, and select **Credentials**.
   b. Select **New**.
   c. Create and manage credentials for scans in Microsoft Purview Data Map
   d. Enter the name, description, and select the domain.
   e. For authentication method, select **API key**.
   f. For Key Vault connection, select the Azure key vault created for *ChatGPT Enterprise*.
   g. Enter the secret name and secret version.

Scan a ChatGPT Enterprise workspace

Complete the following steps to scan a ChatGPT Enterprise workspace to automatically identify messages. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

1. Navigate to **Sources**.
2. Select the registered ChatGPT Enterprise workspace.
3. Select **New scan** and complete the following:
   a. **Name**: The name of the scan.
   b. **Capture data since**: Select if the scan should capture data from the current date of the new scan or choose a specific date from the past.
   c. **Credential**: Select the credential mapping to the correct Key Vault for this connector.
   d. **Domain**: Select a domain from the existing list or choose default domain.
   e. **Collection**: Select a collection from your domain.
4. Select **Test connection** to ensure the connection is established successfully. Select **Continue**.
5. Review your scan and select **Save** and **Run**.

For future scans, we recommend running an incremental scan. Avoid creating a new scan to avoid duplicate ingestion of data.

View scan status and results

To view existing scans, complete the following steps:

1. Open the Microsoft Purview portal and select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scans, along with the status and metrics for each scan.
4. Select the scan ID to check the scan details. During scanning, the organization is considered an asset, but isn't classified. The number of assets classified in the scan details are always one less than the number of assets ingested.
5. Review added data to Microsoft Purview in Data Security Posture Management (DSPM) for AI.
    a. View analytics for AI interactions, sensitive data, and insider risk in DSPM for AI reports.
    b. View the AI interactions for prompts and responses in Activity explorer.
    c. View the sensitive info type data identified in prompts and responses in Activity explorer.
    \

Use other Microsoft Purview solutions with this data:

- Communication Compliance
- Data Lifecycle Management
- eDiscovery
- Insider Risk Management
- Records Management

Connect to and manage Db2 in Microsoft Purview

Article • 05/21/2025

This article outlines how to register Db2, and how to authenticate and interact with Db2 in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported IBM Db2 versions are Db2 for LUW 9.7 to 11.x. Db2 for z/OS (mainframe) and iSeries (AS/400) aren't supported.

When you scan an IBM Db2 source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Databases
  - Schemas
  - Tables including the columns, foreign keys, indexes, and constraints
  - Views including the columns
  - Triggers
- Fetching static lineage on assets relationships among tables and views.

You can scan an entire Db2 database, or scope the scan to a subset matching the given names or name patterns.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - Download the Db2 JDBC driver on the machine where your self-hosted integration runtime is running. Note down the folder path so you can use it to set up the scan.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.
    - Download the Db2 JDBC driver on the machine where your self-hosted integration runtime is running. Note down the folder path so you can use it to set up the scan.

  > **Note**
  >
  > The driver should be accessible by the self-hosted integration runtime. By default, self-hosted integration runtime uses local service account "NT SERVICE\DIAHostService". Make sure it has "Read and execute" and "List folder contents" permission to the driver folder.

- The Db2 user must have the CONNECT permission. Microsoft Purview connects to the syscat tables in IBM Db2 environment when importing metadata.

Register

This section describes how to register Db2 in Microsoft Purview using the Microsoft Purview governance portal.

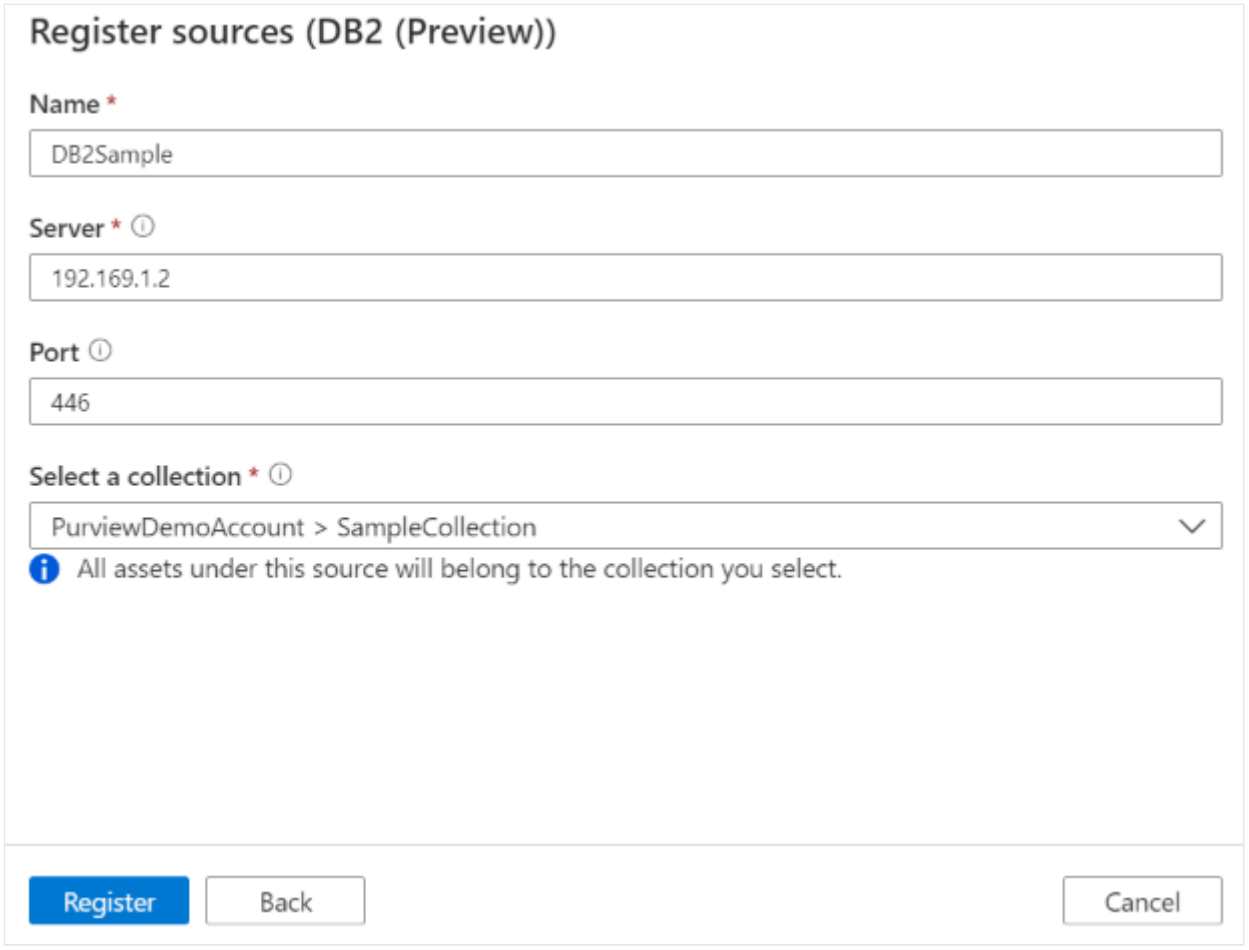
Steps to register

To register a new Db2 source in Microsoft Purview Unified Catalog, do the following steps:

1. Navigate to your Microsoft Purview account in the Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**
4. On Register sources, select **Db2**. Select **Continue**.

On the **Register sources (Db2)** screen, do the following steps:

1. Enter a **Name** that the data source is within the Catalog.



2. Enter the **Server** name to connect to a Db2 source. This name can either be:

    - A host name used to connect to the database server. For example: `MyDatabaseServer.com`
    - An IP address. For example: `192.169.1.2`

3. Enter the **Port** used to connect to the database server (446 by default for Db2).

4. Select a collection from the list.

5. Finish to register the data source.

Scan

Follow the steps to scan Db2 to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Authentication for a scan

The supported authentication type for a Db2 source is **Basic authentication**.

Create and run scan

To create and run a new scan, follow these steps:

1. In the Management Center, select Integration runtimes. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned in prerequisites to create a self-hosted integration runtime.

2. Navigate to **Sources**.

3. Select the registered Db2 source.

4. Select + **New scan**.

5. Provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the configured self-hosted integration runtime

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select **Basic Authentication** while creating a credential.
      - Provide the user name used to connect to the database server in the User name input field.
      - Store the user password used to connect to the database server in the secret key.

   d. **Database**: The name of the database instance to import.

   e. **Schema**: List subset of schemas to import expressed as a semicolon separated list. For example, `schema1;schema2`. All user schemas are imported if that list is empty. All system schemas (for example, SysAdmin) and objects are ignored by default.

      Acceptable schema name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

      Usage of NOT and special characters aren't acceptable.

   f. **Driver location**: Specify the path to the JDBC driver location in your machine where self-host integration runtime is running. For example, `D:\Drivers\Db2`.

      i. For Kubernetes-supported self-hosted integration runtime: `./drivers/Db2`. It's the path to valid JAR folder location. The value must be a valid relative file path. Please refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

   g. **Maximum memory available**: Maximum memory (in GB) available on customer's VM to be used by scanning processes. The memory needed is dependent on the size of Db2 source to be scanned.

      > ⓘ **Note**
      >
      > As a thumb rule, please provide 1GB memory for every 1000 tables

6. Select **Continue**.

7. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.

4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ Note
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Db2 source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Db2 lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage Microsoft Dataverse in Microsoft Purview

This article outlines the process to register and govern a Microsoft Dataverse environment data source in Microsoft Purview including instructions to authenticate and interact with the Microsoft Dataverse source.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

When scanning Dataverse source, Microsoft Purview supports extracting technical metadata including:

- Environment
- Tables, including columns

When setting up a scan, you can choose to scope the scan by selecting tables as needed.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

- When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.
- Dataverse integration with Microsoft Purview Data Map isn't available in sovereign clouds.

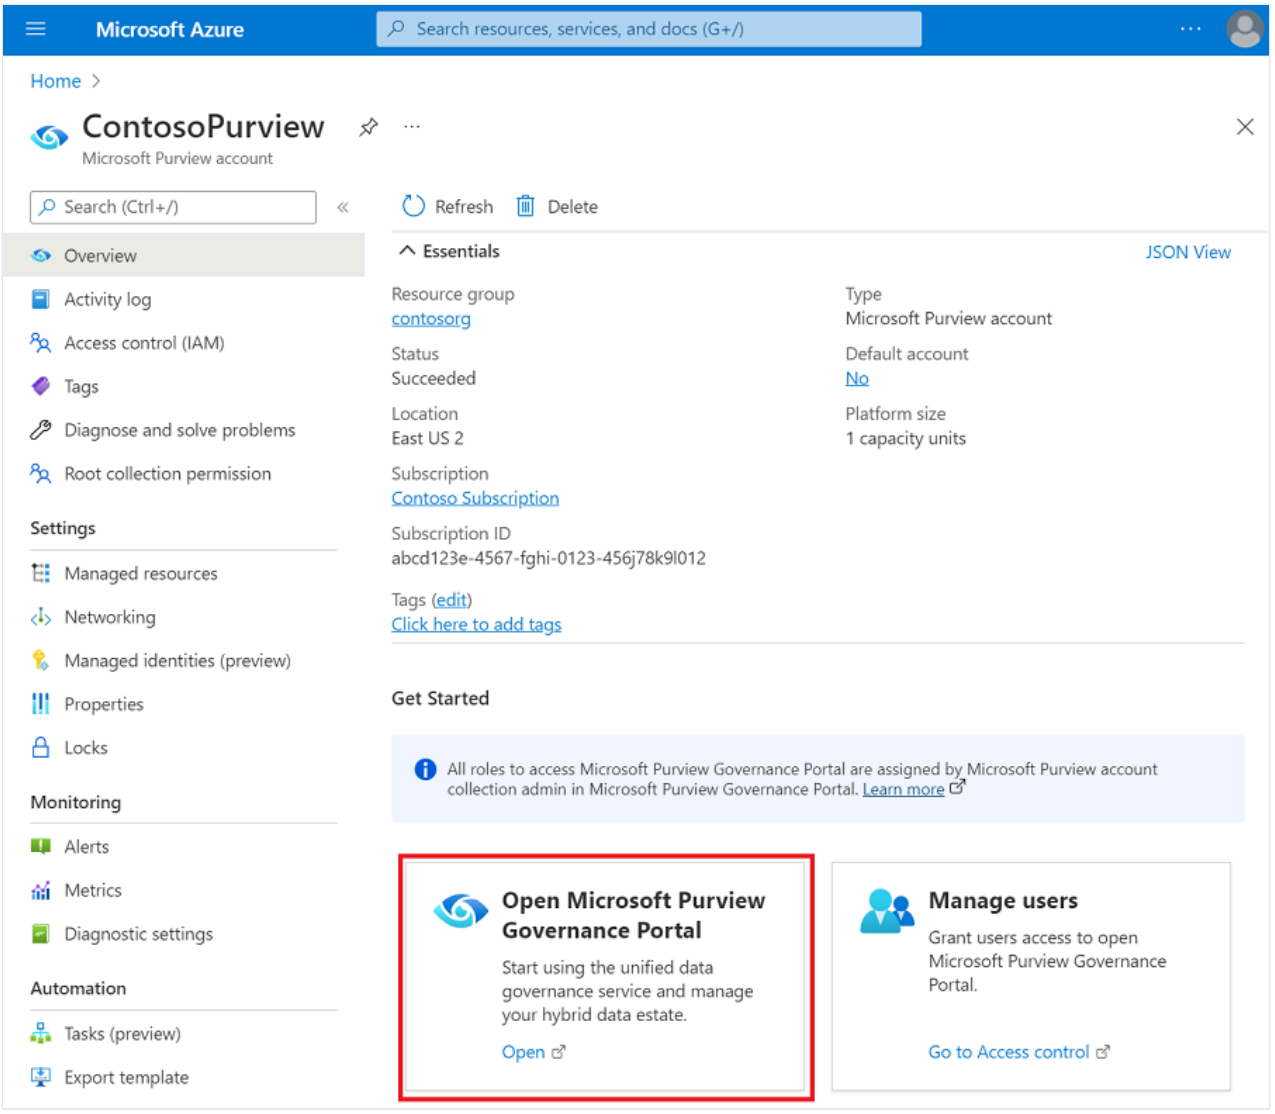
Prerequisites

- An Azure account with an active subscription. Create an account for free.

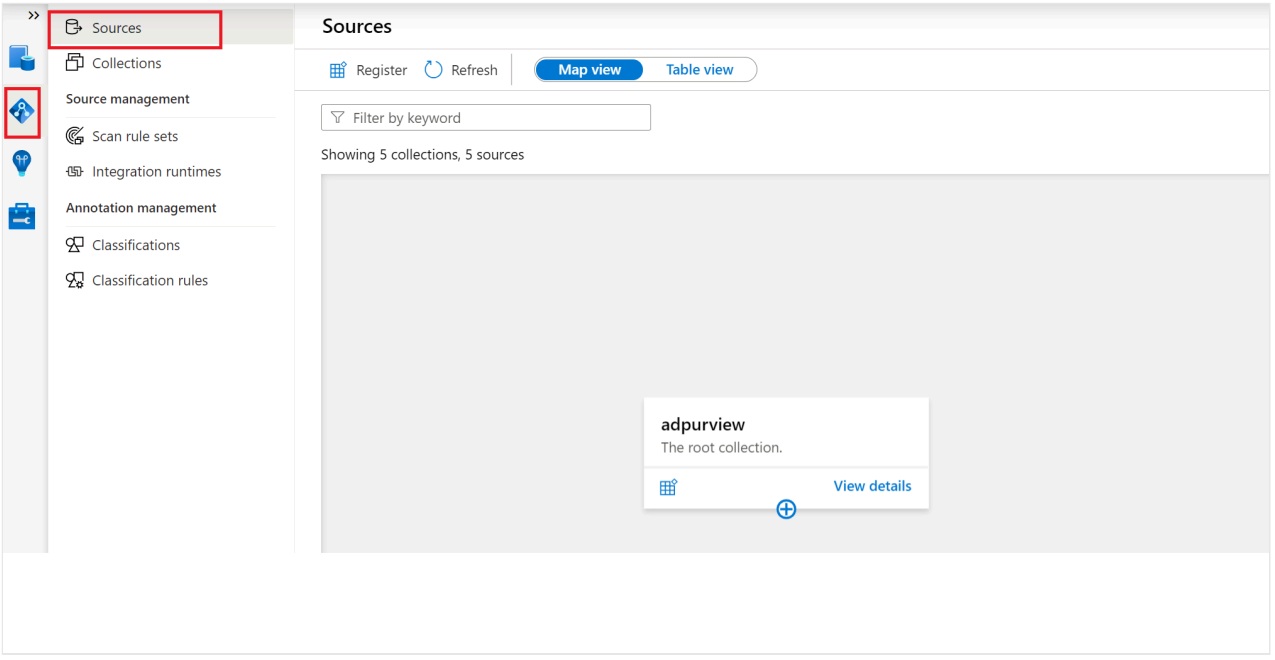
- An active Microsoft Purview account.
- You need to be a Data Source Administrator and Data Reader to register a source and manage it in the classic Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.
- You need to have the permission in your Dataverse environment to create an application user and assign the Service Reader role for the user.

Register

This section describes how to register Dataverse in Microsoft Purview. Before you create a scan, it's necessary to register the data source in Microsoft Purview.

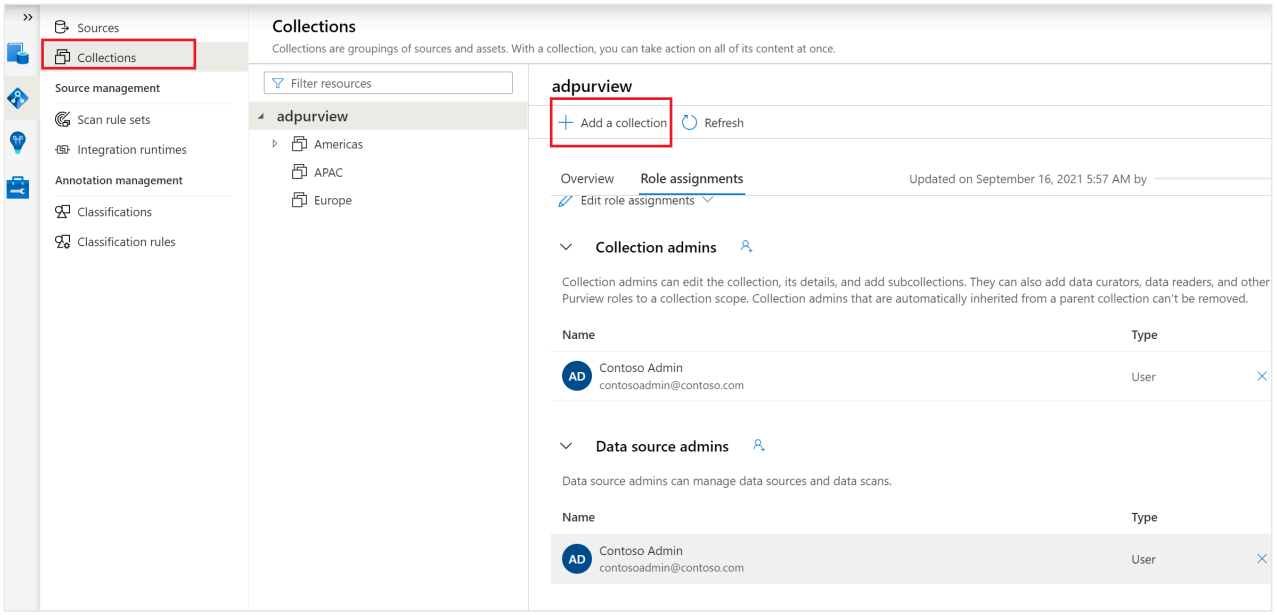


Prerequisites for register



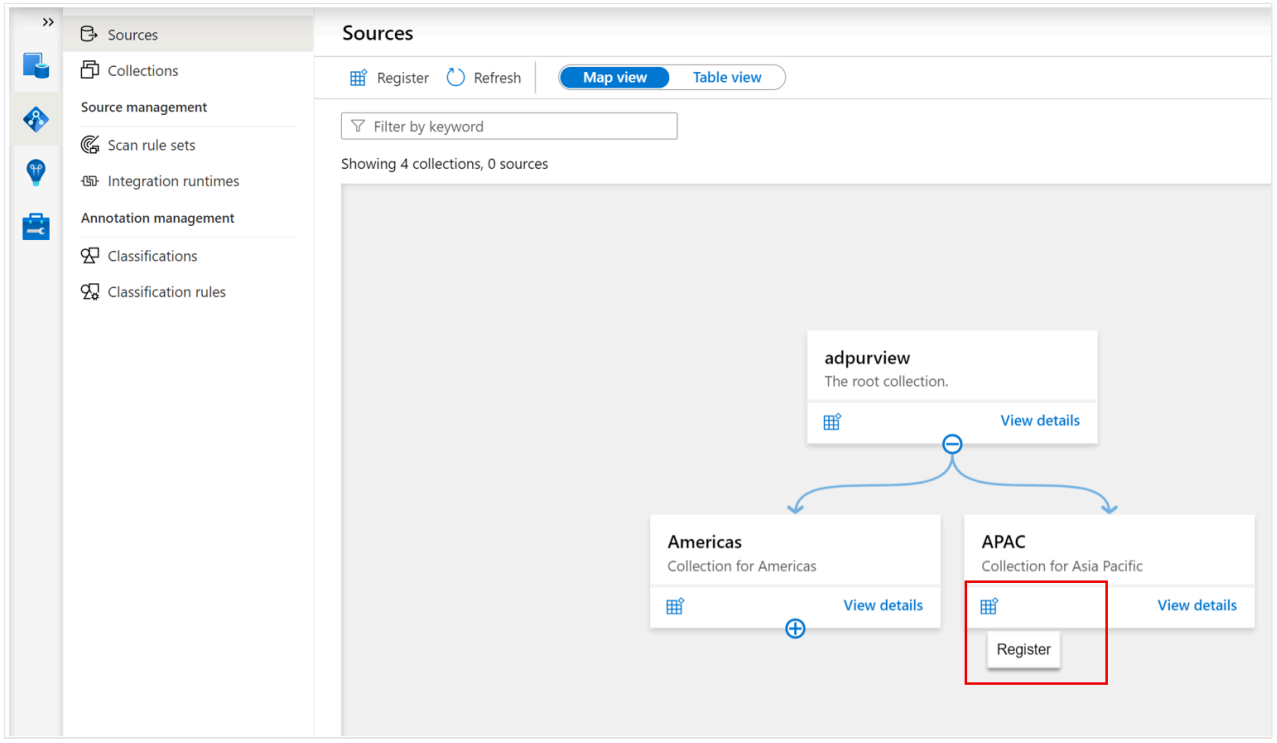
- You need to be a Data Source Admin and one of the other Purview roles (for example, Data Reader or Data Share Contributor) to register a source and manage it in the classic Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.

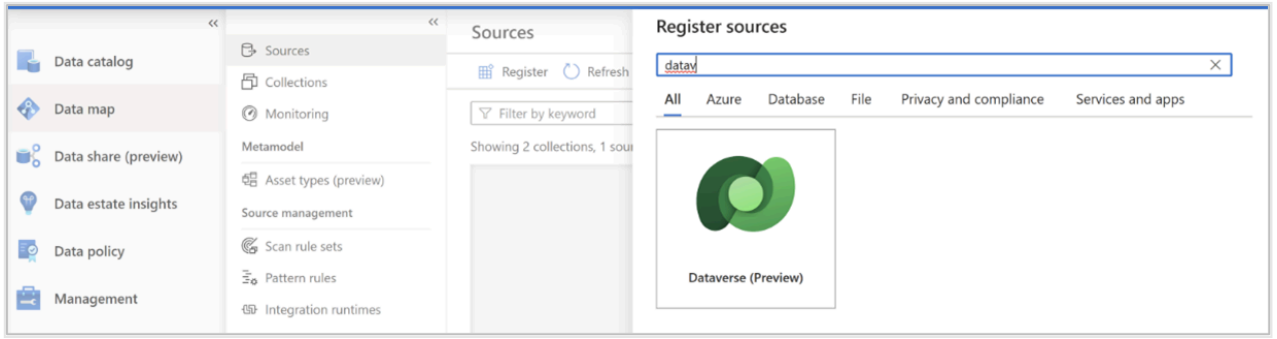
Steps to register



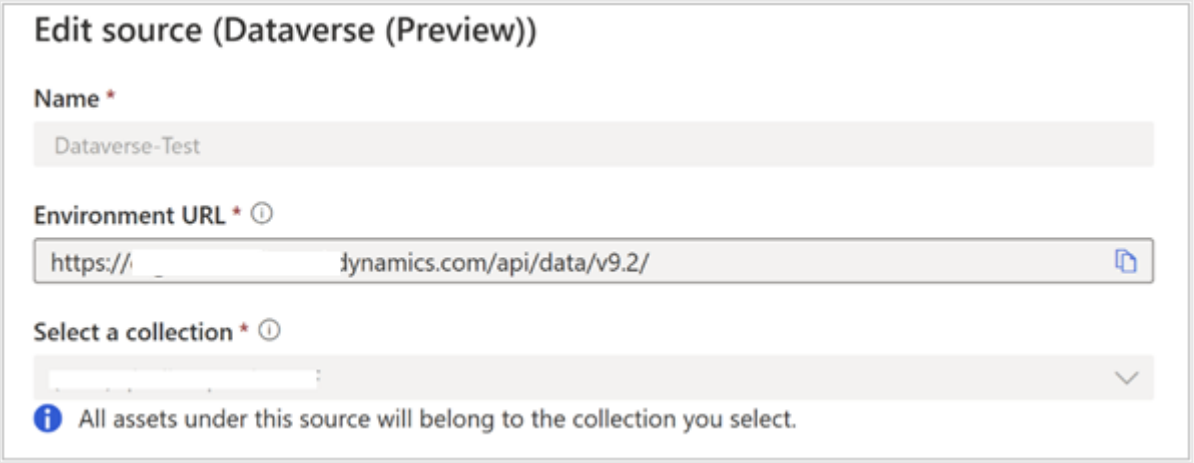
It's important to register the data source in Microsoft Purview prior to setting up a scan for the data source.

1. Go to the classic Microsoft Purview governance portal by:
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the classic **Microsoft Purview governance portal**.
2. Navigate to the **Data Map --> Sources**

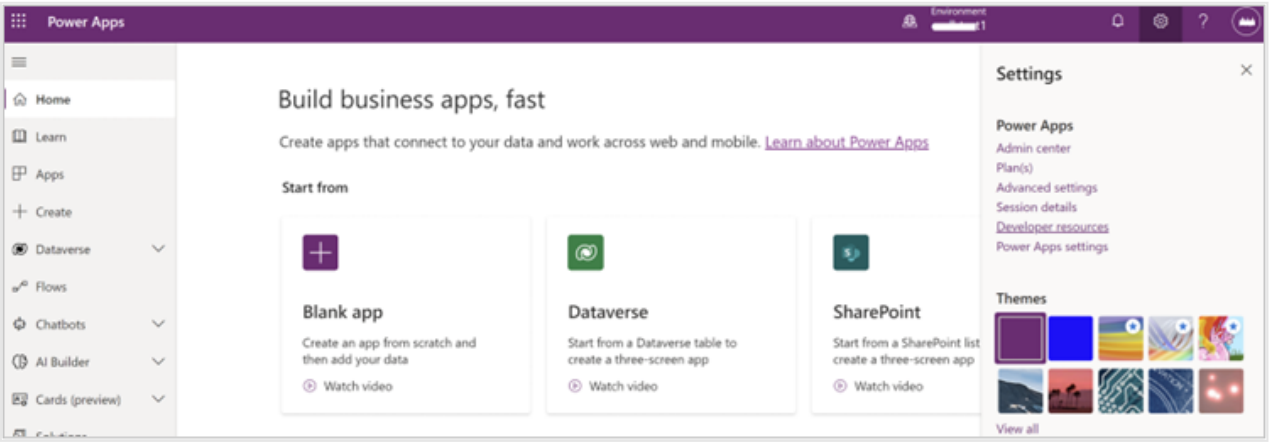




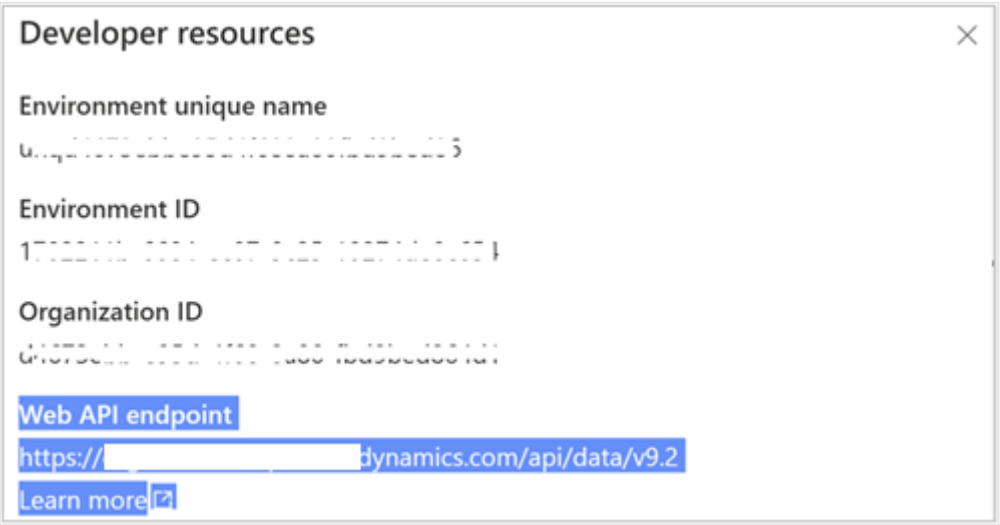
3. Create the Collection hierarchy using the **Collections** menu and assign permissions to individual subcollections, as required



4. Navigate to the appropriate collection under the **Sources** menu and select the **Register** icon to register a new Dataverse data source



5. Select the **Dataverse** data source and select **Continue**



6. Provide a suitable **Name** for the data source. Fill in the Web API endpoint for your Dataverse environment as **Environment URL** and select a **collection** and select **Apply**.

You can get the Web API endpoint from Developer resources from the Microsoft Power Apps maker portal.

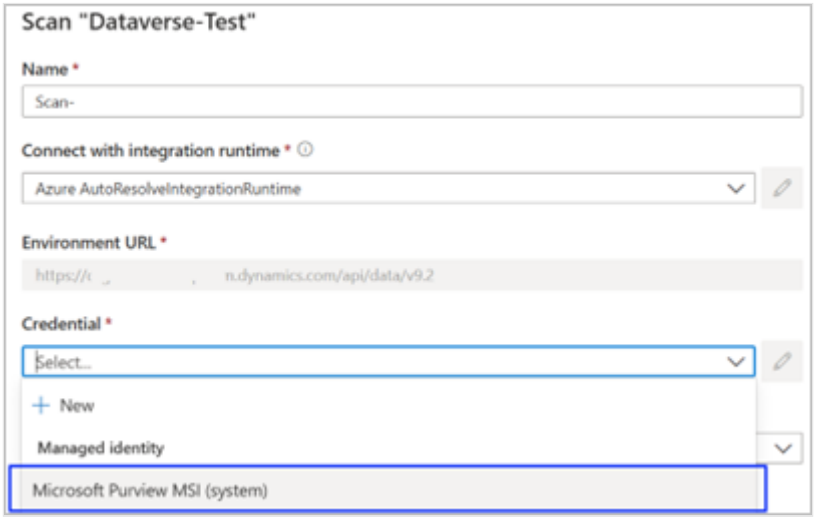
7. The Dataverse source is shown under the selected Collection

Scan

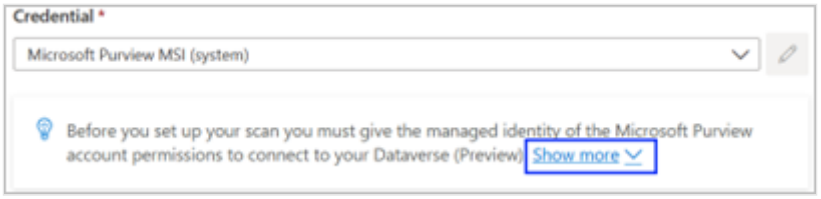
Authentication method

Currently Microsoft Purview supports the following options to scan Dataverse:

- **System assigned managed identity (SAMI)**. This is an identity that's associated directly with your Microsoft Purview account. The SAMI is created when your Microsoft Purview resource is created. It's managed by Azure and uses your Microsoft Purview account's name.
- **Service principal**. A service principal is an application that can be assigned permissions like any other group or user, without being associated directly with a person.

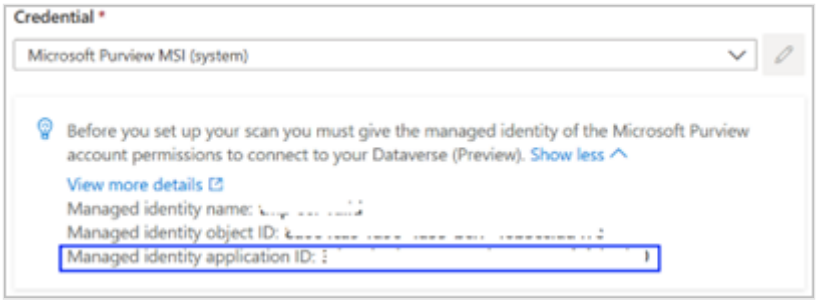


System assigned managed identity



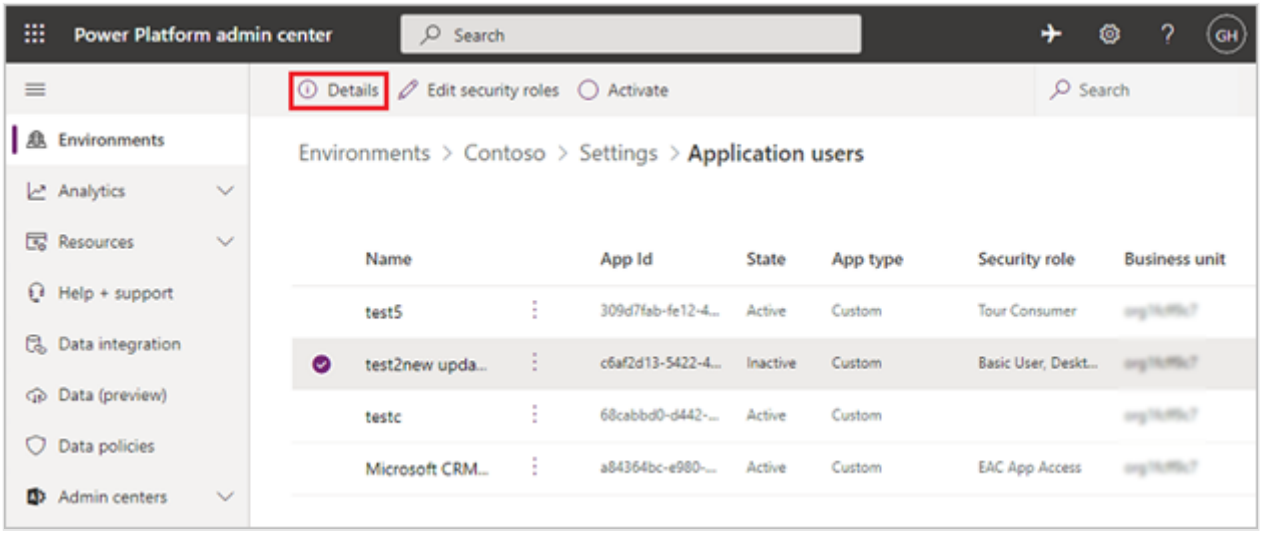
Using a system assigned managed identity for scanning

The system-assigned managed identity needs permission to get metadata from Dataverse environments. It must also be authorized to query the Dataverse tables to sample for classification. There are several steps to allow Microsoft Purview to use system-assigned managed identity to scan your Dataverse environment.



Get the application ID for the system-assigned managed identity

1. Go to **Data Map** > **Sources** to view the collection hierarchy.
2. Select the **New Scan** icon under the Dataverse source that you registered earlier.
3. For **Credential**, select **Microsoft Purview MSI (system)** from the drop-down list then select **Show more** to view details about the system assigned managed identity.



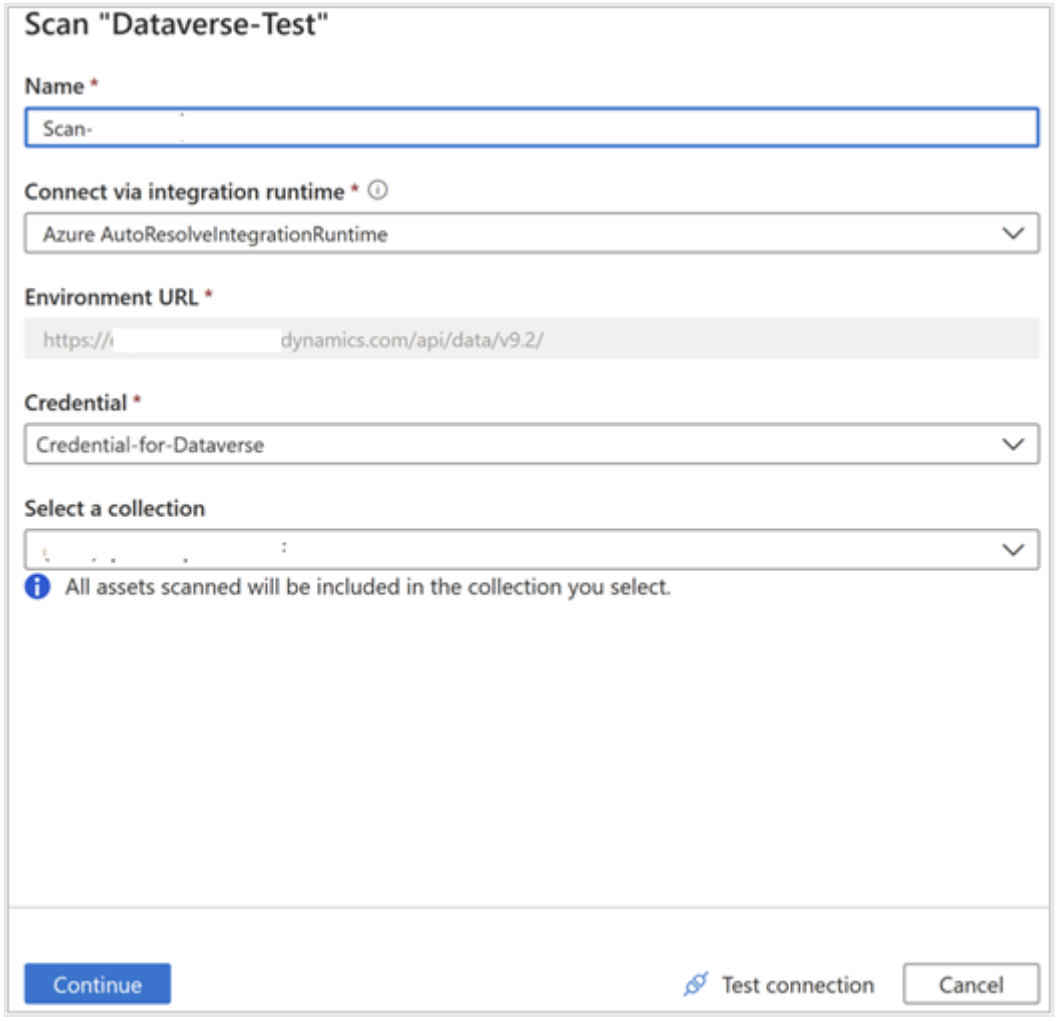
4. Record the managed identity application ID.

Create and enable an application user in Power Platform Admin Center

An application user is needed to be created in the Dataverse environment that you want to scan in Microsoft Purview. Follow the steps in Create An Application User to create the user with the application ID you recorded and assign the security role **Service Reader** to it.

You can check the application user in the Details page. Now the application user is bound with the system assigned managed identity created with your Microsoft Purview resource.

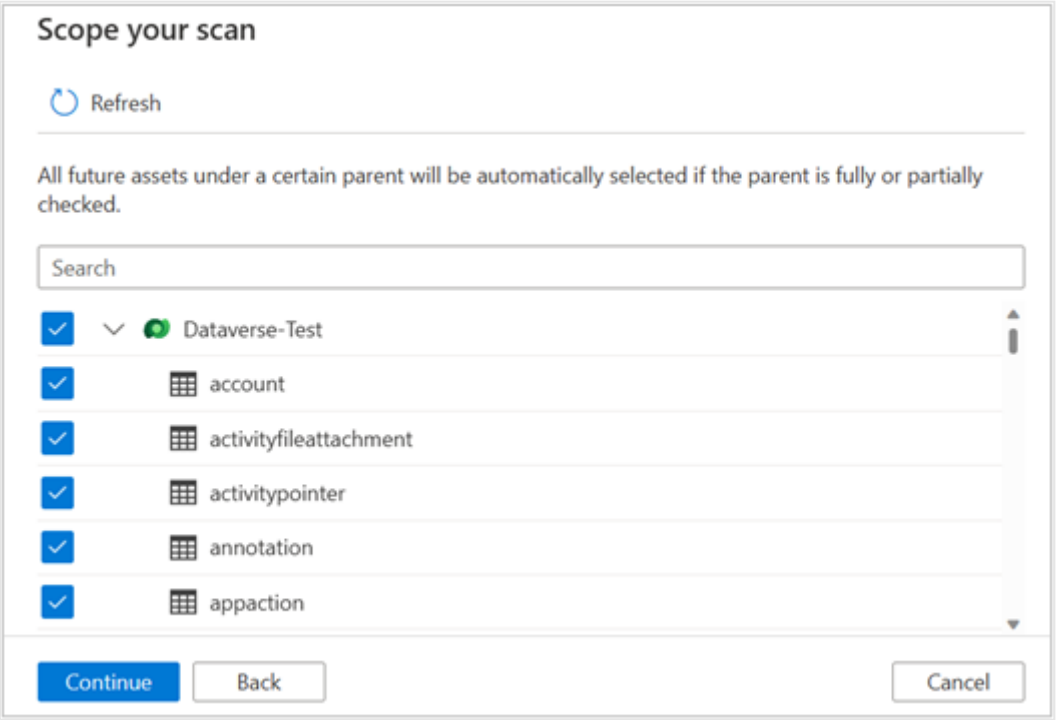
Create the scan



1. Go to **Data Map** > **Sources** to view the collection hierarchy.
2. Select the **New Scan** icon under the Dataverse source that you registered earlier.
3. For **Name**, provide a name for the scan.

4. For **Integration runtime**, see the list of supported data sources for scans to choose right integration runtime according to the scenario.
5. For **Credential**, select the credential you prepared earlier.

- If system-assigned managed identity is configured for authentication, then select **Microsoft Purview MSI (system)** from the drop-down list.
- If service principal is configured for authentication, then select the credential you created before from the drop-down list.



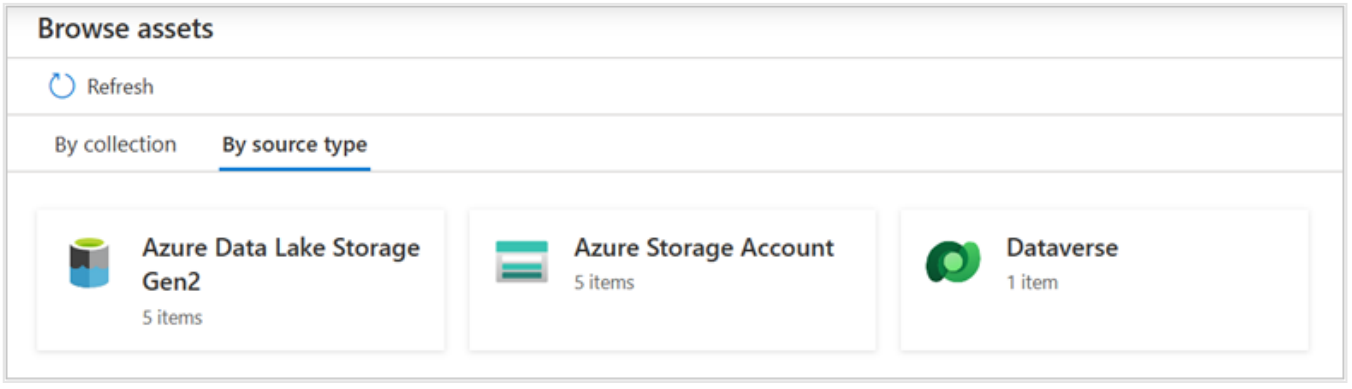
1. For **Select a collection**, choose the appropriate collection for the scan.

2. Select **Test connection** to validate the connection. After the connection is successful, select **Continue**.

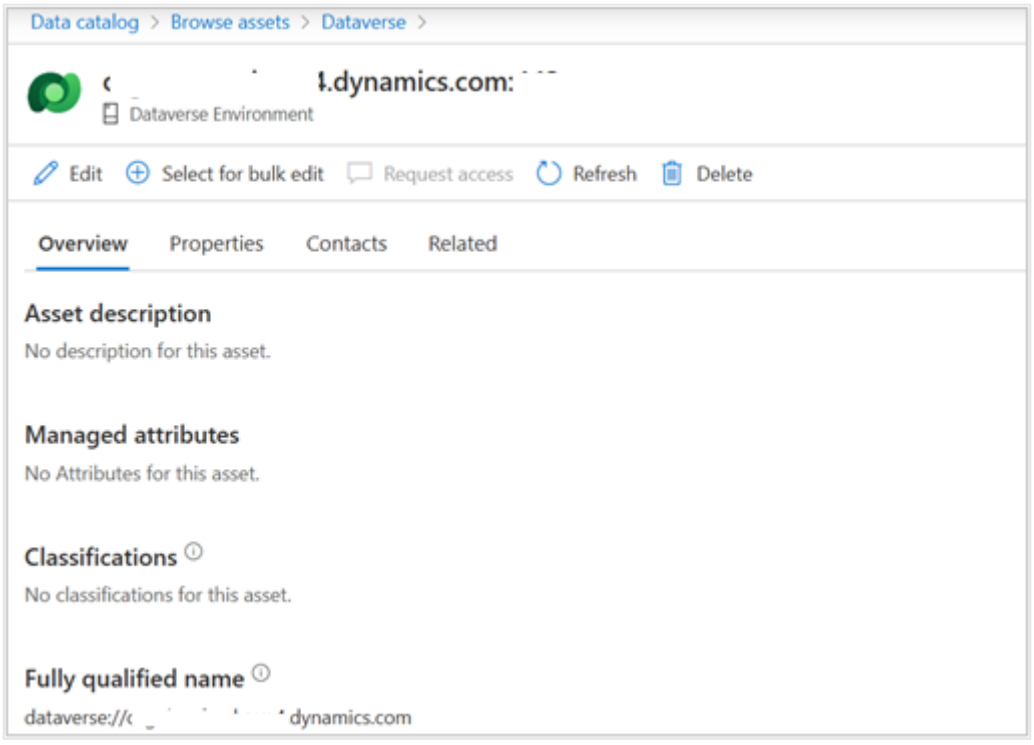
Scope and run the scan

1. You can scope your scan to specific Dataverse tables by choosing the appropriate items in the list.

2. Choose your scan trigger. You can set up a schedule or run the scan once.



3. Review your scan, and then select **Save and run**.



View and manage a scan

To check the status of a scan, go to the data source in the collection, and then select **View details**. The scan details indicate the progress of the scan in **Last run status**, along with the number of assets scanned and classified. **Last run status** is updated to **In progress** and then **Completed** after the entire scan runs successfully. After you run a scan, you can use the run history to manage it. In the run history, you have options for running the scan again, editing it, or deleting it.

Browse, search, and view Dataverse assets

Once the scan is completed, you can go to Microsoft Purview Unified Catalog to browse or search the Dataverse related assets, and view related details.

Connect to and manage erwin Mart servers in Microsoft Purview

Article • 03/28/2025

This article outlines how to register erwin Mart servers, and how to authenticate and interact with erwin Mart Servers in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported erwin Mart versions are 9.x to 2021.

When scanning erwin Mart source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Mart
  - Libraries
  - Models
  - Entities including the attributes, foreign keys, indexes, index members, candidate keys, and triggers
  - Default values
  - Synonyms
  - Sequences
  - Domains
  - Subject areas
  - Relationships
  - Validation rules including the valid values
  - ER diagrams
  - Views including the attributes
  - Stored procedures including the parameters
  - Schemas

    - Subtype relationships
    - View relationship
    - User defined properties

- Fetching static lineage on assets relationships among entities, views and stored procedures.

When setting up scan, you can choose to scan an entire erwin Mart server, or scope the scan to a list of models matching the given name(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

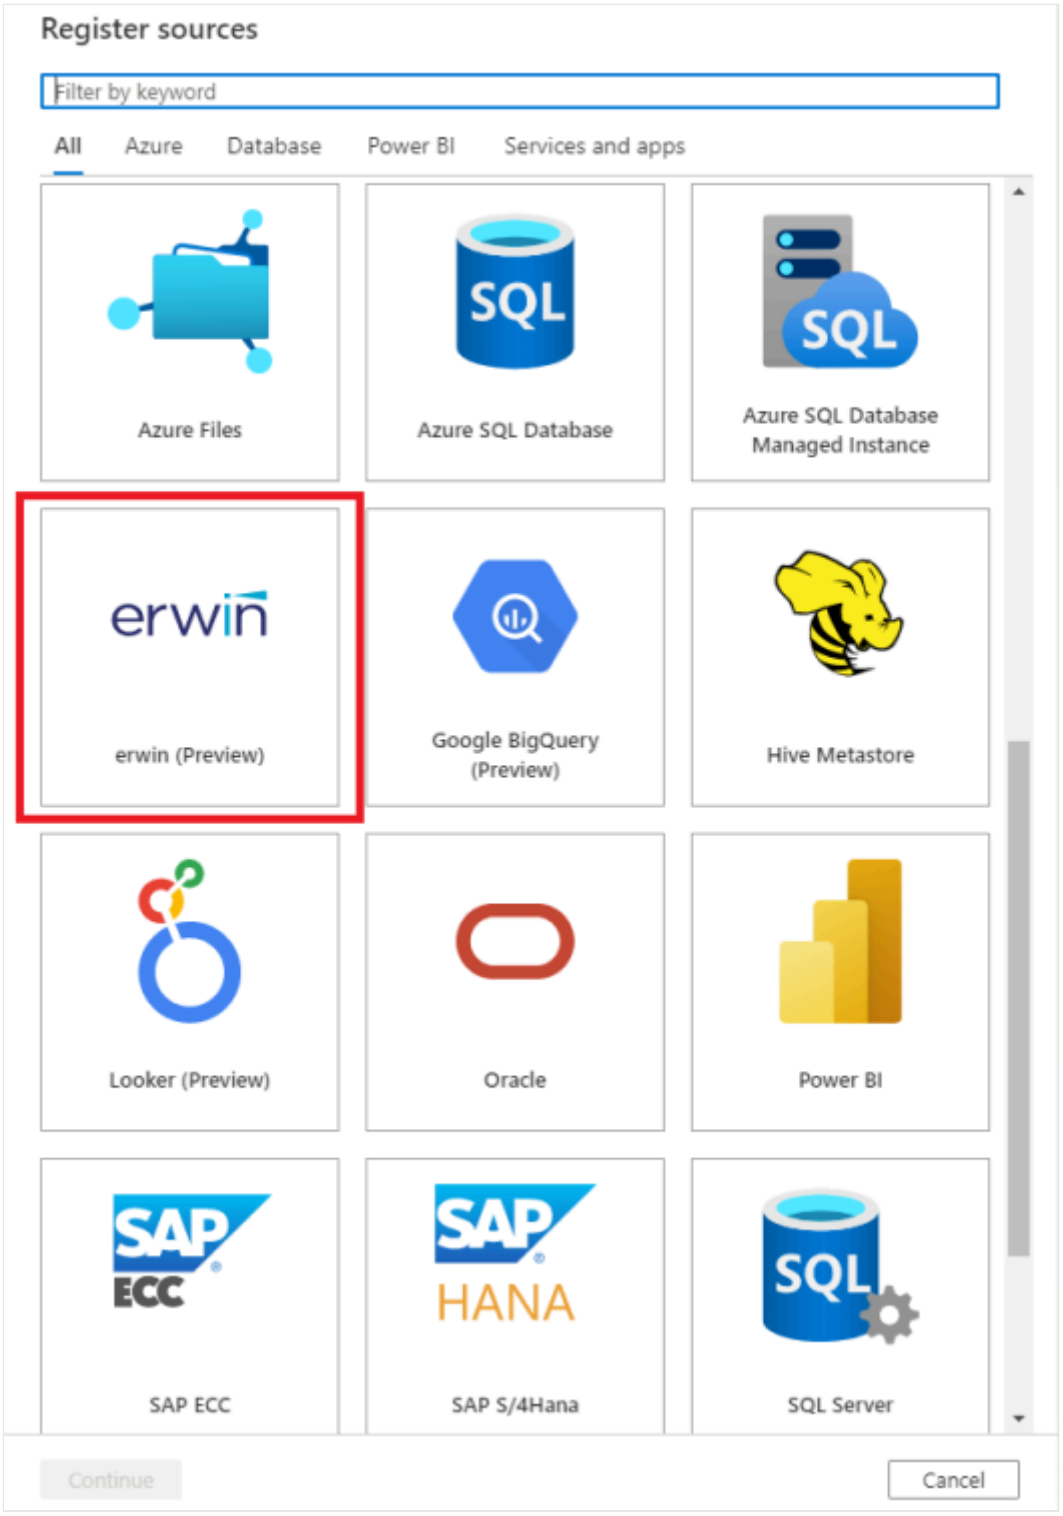
- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the latest self-hosted integration runtime. For more information, see the create and configure a self-hosted integration runtime guide.

  > **Important**
  >
  > Make sure to install the self-hosted integration runtime and the Erwin Data Modeler software on the same machine where erwin Mart instance is running.

    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.

- Ensure Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the self-hosted integration runtime machine. If you don't have this update installed, you can download it here.

Register

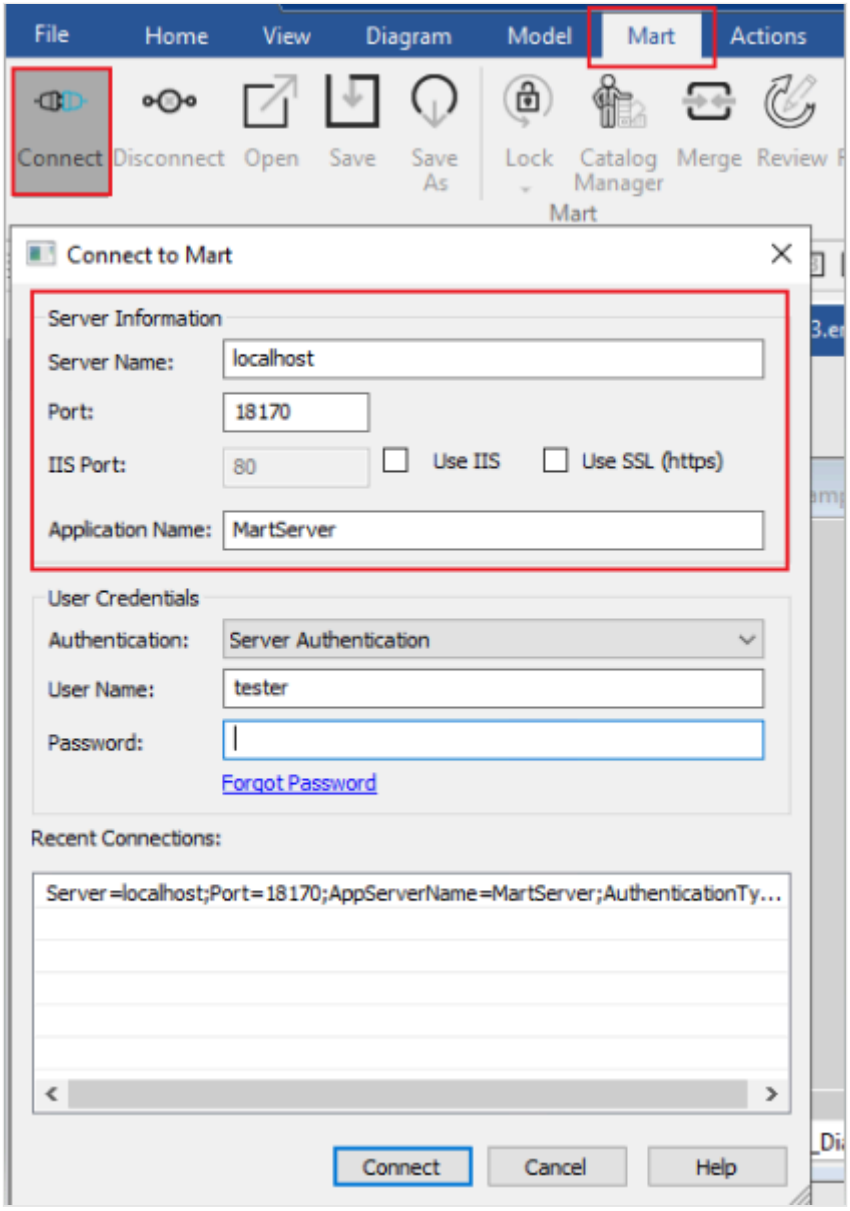


This section describes how to register erwin Mart servers in Microsoft Purview using the Microsoft Purview governance portal.

The only supported authentication for an erwin Mart source is **Server Authentication** in the form of username and password.

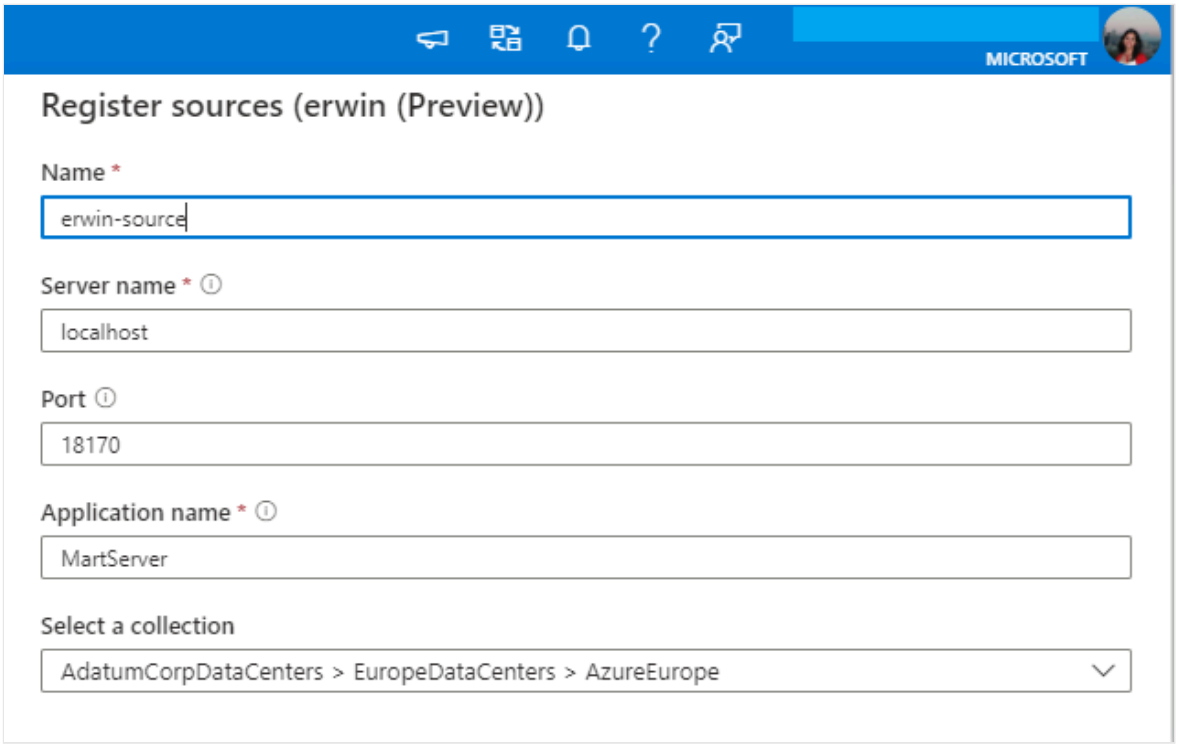
Steps to register

1. Navigate to your Microsoft Purview account in the Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**



4. On Register sources, select **erwin**. Select **Continue.**

On the Register sources (erwin) screen, do the following:



1. Enter a **Name** that the data source will be listed within the Catalog.
2. Enter the erwin Mart **Server name.** This is the network host name used to connect to the erwin Mart server. For example, localhost
3. Enter the **Port** number used when connecting to erwin Mart. By default, this value is 18170.
4. Enter the **Application name**

> ⓘ **Note**
>
> The above details can be found by navigating to your erwin Data Modeler. Select Mart -> Connect to see details related to server name, port and application name.

5. Select a collection from the list.

6. Finish to register the data source.

Scan

Follow the steps below to scan erwin Mart servers to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion

Create and run scan

To create and run a new scan, do the following:

1. In the Management Center, select Integration runtimes. Make sure a self-hosted integration runtime is set up on the VM where erwin Mart instance is running. If it isn't set up, use the steps mentioned here to set up a self-hosted integration runtime.

2. Navigate to **Sources**.

3. Select the registered **erwin** Mart.

4. Select + **New scan**.

5. Provide the below details:

    a. **Name**: The name of the scan

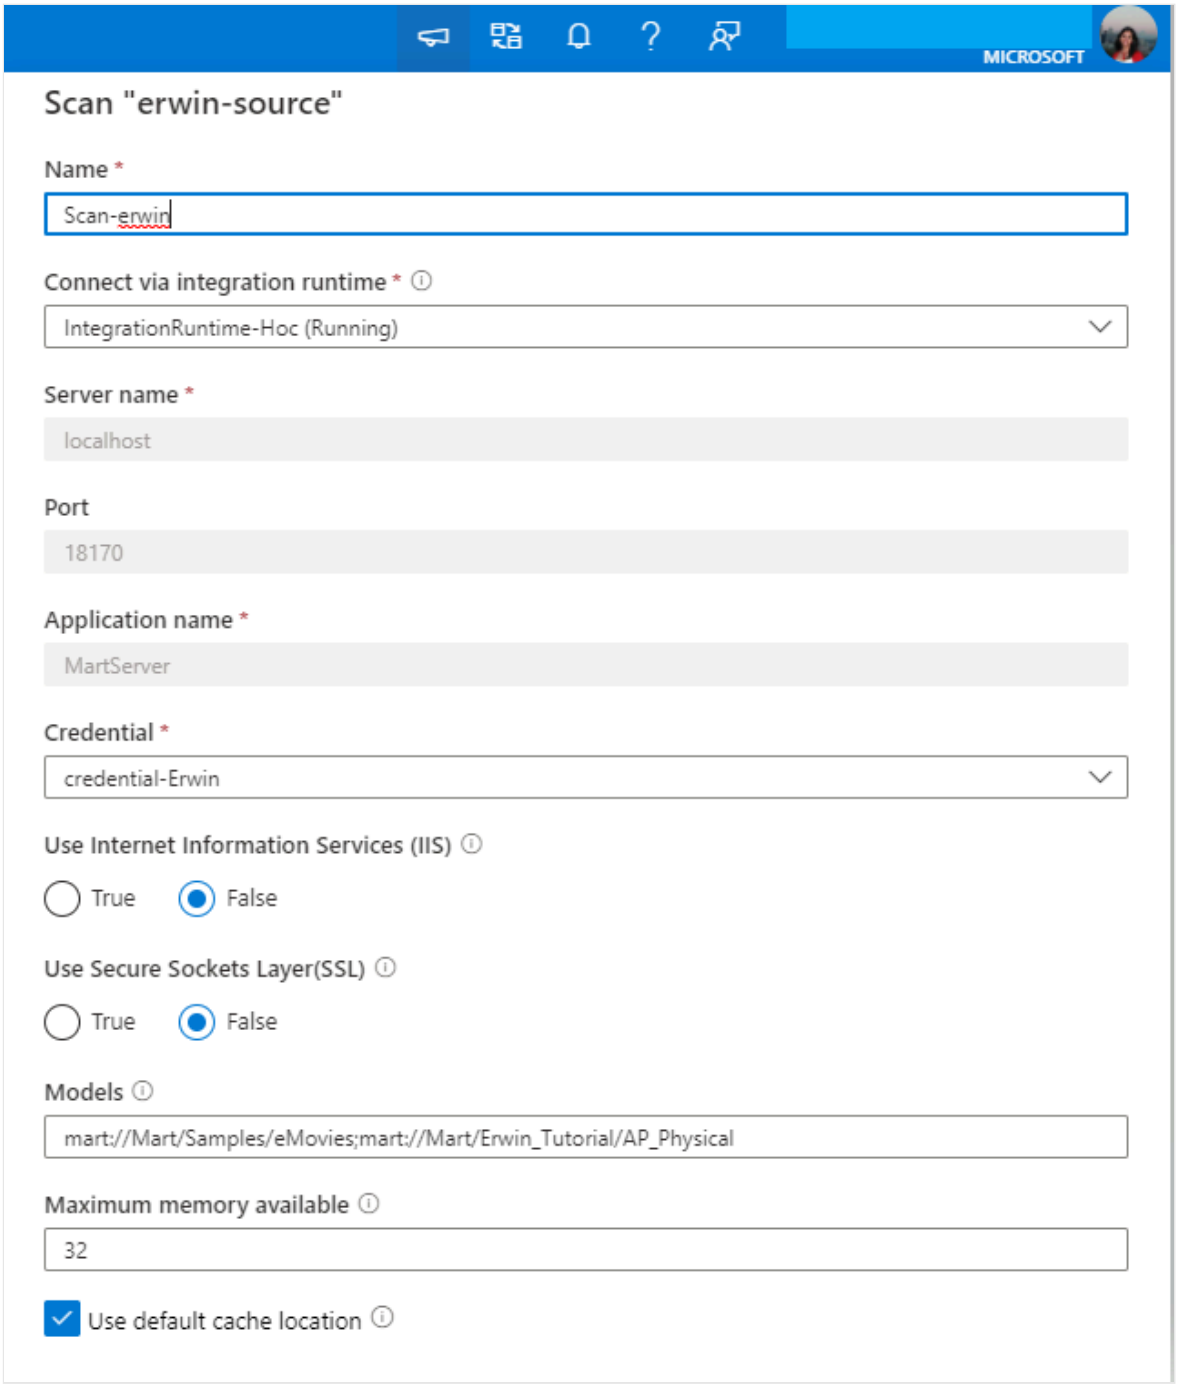
    b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

c. **Server name, Port** and **Application name** are auto populated based on the values entered during registration.

d. **Credential:** Select the credential configured to connect to your erwin Mart server. While creating a credential, make sure to:

   - Select **Basic Authentication** as the Authentication method
   - Provide your erwin Mart server's username in the User name field.
   - Save your user password for server authentication in the key vault's secret.

   To understand more on credentials, refer to the link here.



e. **Use Internet Information Services (IIS)** - Select True or False to notify if Microsoft Internet Information Services (IIS) must be used when connecting to the erwin Mart server. By default this value is set to False.

f. **Use Secure Sockets Layer (SSL)** - Select True or False to Notify if Secure Sockets Layer (SSL) must be used when connecting to the erwin Mart server. By default, this value is set to False.

> ⓘ **Note**
>
> This parameter is only applicable for erwin Mart version 9.1 or later.

g. **Models** - Scope your scan by providing a semicolon separated list of erwin model locator strings. For example, mart://Mart/Samples/eMovies;mart://Mart/Erwin_Tutorial/AP_Physical

h. **Maximum memory available**: Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of erwin Mart to be scanned.

6. Select **Test connection.**

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your erwin source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported erwin lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to your Microsoft Fabric tenant in the same tenant as Microsoft Purview

This article outlines how to register a Microsoft Fabric tenant that's in **the same tenant** as your Microsoft Purview resource, and how to authenticate and interact with the Fabric source in Microsoft Purview. For more information about Microsoft Purview in general, read the introductory article.

> **Note**
>
> Scanning a Fabric tenant brings in metadata and lineage from Fabric items including Power BI. To learn more, see scan a Power BI tenant. The experience of registering a Fabric tenant and setting up a scan is similar to Power BI tenant and shared among all Fabric items.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Expand table

Experiences	Fabric items	Available in scan	Available in live view (same tenant only)
Real-Time Analytics	Kusto Query Language (KQL) Database	Yes	Yes
	KQL Queryset	Yes	Yes

Experiences	Fabric items	Available in scan	Available in live view (same tenant only)
Data Science	Experiment	Yes	Yes
	ML model	Yes	Yes
Data Factory	Data pipeline	Yes	Yes
	Dataflow Gen2	Yes	Yes
Data Engineering	Lakehouse	Yes	Yes
	Notebook	Yes	Yes
	Spark Job Definition	Yes	Yes
	SQL analytics endpoint	Yes	Yes
Data Warehouse	Warehouse	Yes	Yes
Power BI	Dashboard	Yes	Yes
	Dataflow	Yes	Yes
	Datamart	Yes	Yes
	Semantic model (Dataset)	Yes	Yes
	Report	Yes	Yes
	Paginated report	Yes	

Supported scenarios for Fabric scans

Expand table

Scenarios	Microsoft Purview public access allowed/denied	Fabric public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Public access with Azure IR	Allowed	Allowed	Azure Runtime	Managed Identity/ Delegated authentication / Service principal	Review deployment checklist
Public access with	Allowed	Allowed	SHIR or Kubernetes SHIR	Service principal	Review deployment checklist

Scenarios	Microsoft Purview public access allowed/denied	Fabric public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Self-hosted IR					
Private access	Denied	Allowed	Managed Virtual Network IR (v2 only)	Managed Identity / Delegated authentication / Service principal	Review deployment checklist

> **Note**
>
> The supported scenarios above apply for non-Power BI items in Fabric. See the **Power BI documentation** for supported scenarios that apply to Power BI items.
>
> Support for scanning Fabric Lakehouses by using Managed Identity is now available. Hence, you can scan Fabric Lakehouses by using Service Principal or Managed Identity. Previously, only service principal was supported for Fabric Lakehouses. There's no change for other Fabric items.
>
> Support for scanning Fabric Lakehouses by using Managed Virtual Network IR is now available.

Known limitations

- Currently for all Fabric items besides Power BI, only item level metadata and lineage can be scanned. For Lakehouse tables and files, sub-item level metadata scanning is available but sub-item level lineage isn't supported.
- For self-hosted integration runtime, the standard self-hosted integration runtime with minimal version 5.47.9073.1 or Kubernetes supported self-hosted integration runtime is supported.
- Empty workspaces are skipped.
- Microsoft Purview doesn't support Fabric DAX expressions as part of metadata scanning.
- You might get a **Too many requests** error while running multiple Fabric or Power BI scans. If so, reduce the concurrent scans and scatter the scans over different times to help resolve

the error.

- In the incremental scan, you might see a non-zero count of assets ingested and assets discovered, even if there's no change in the data source. This behavior should be ignored. The data catalog and Data Map assets continue to reflect the true state of the data source.
- Fabric with tenant-level or workspace-level private links aren't supported.

> **Note**
>
> For Fabric Lakehouse tables with schema-enabled databases, the schema name and table name are combined into a single segment in the qualified name using `%252F` (double-URL-encoded forward slash) as a separator. For example, a table at the OneLake path `Tables/dbo/my_table` will appear in Data Map with the qualified name `.../tables/dbo%252Fmy_table`, while the entity display name will show only the table name (for example, `my_table`) without the schema prefix.

Prerequisites

Before you start, make sure you have the following prerequisites:

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

Authentication options

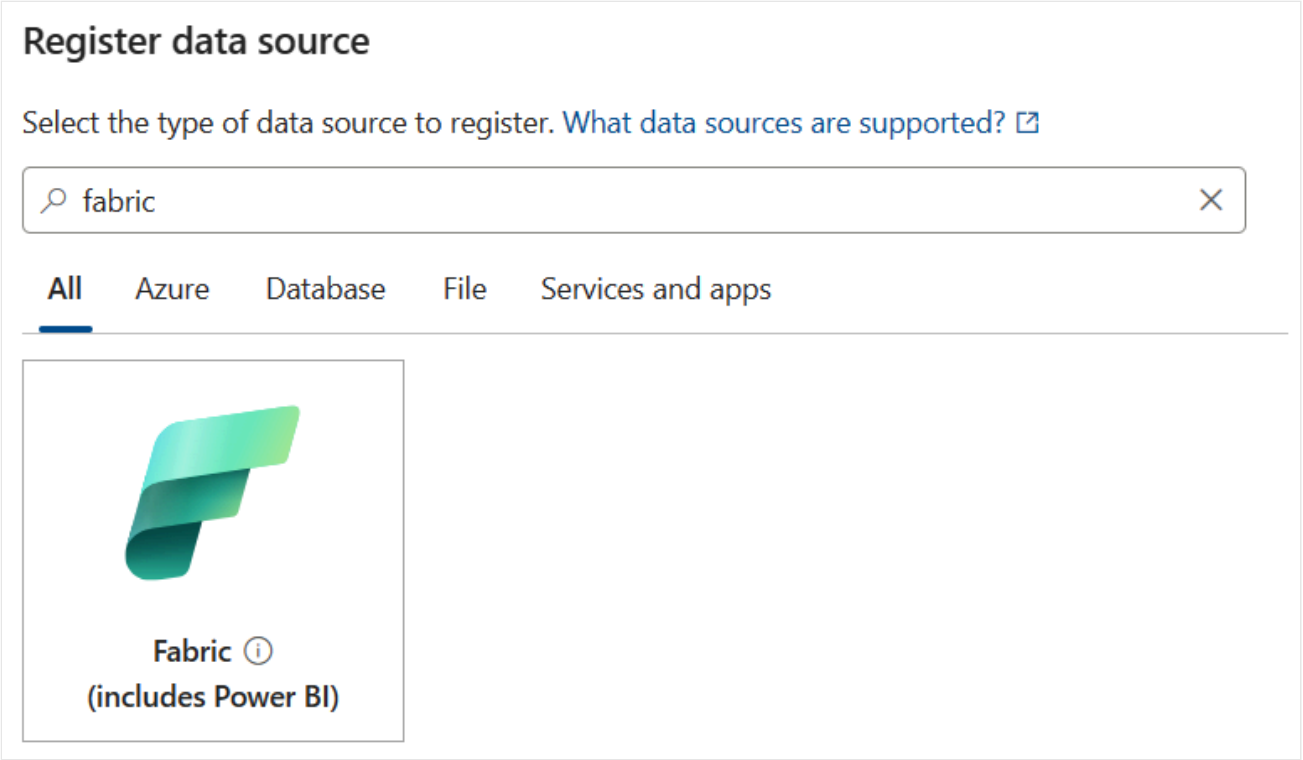
- Managed Identity
- *Service Principal
- Delegated Authentication

Deployment checklist

Use any of the following deployment checklists during the setup or for troubleshooting purposes, based on your scenario:

Public access with Azure IR

Scan same-tenant Fabric using Azure IR and Managed Identity in public network



1. Make sure Fabric and Microsoft Purview accounts are in the same tenant.
2. Make sure you enter the Fabric tenant ID correctly during the registration.
3. Make sure your Fabric Metadata model is up to date by enabling metadata scanning.
4. From Azure portal, validate if Microsoft Purview account Network is set to public access.
5. From Fabric tenant Admin Portal, make sure Fabric tenant is configured to allow public network.
6. In Microsoft Entra tenant, create a security group.
7. From Microsoft Entra tenant, make sure Microsoft Purview account MSI is member of the new security group.
8. On the Fabric Tenant Admin portal, validate if Allow service principals to use read-only admin APIs is enabled for the new security group.
9. On the Fabric Tenant Admin portal, validate if **Tenant Settings** -> **OneLake Settings** -> Users can access data stored in OneLake with apps external to Fabric is enabled.

Register Fabric tenant

This section describes how to register a Fabric tenant in Microsoft Purview for same-tenant scenario.

1. Select the **Data Map** on the left navigation.
2. Select **Register**.

   Select **Fabric** as your data source.

3. Enter a friendly name for your Fabric instance and select a collection.

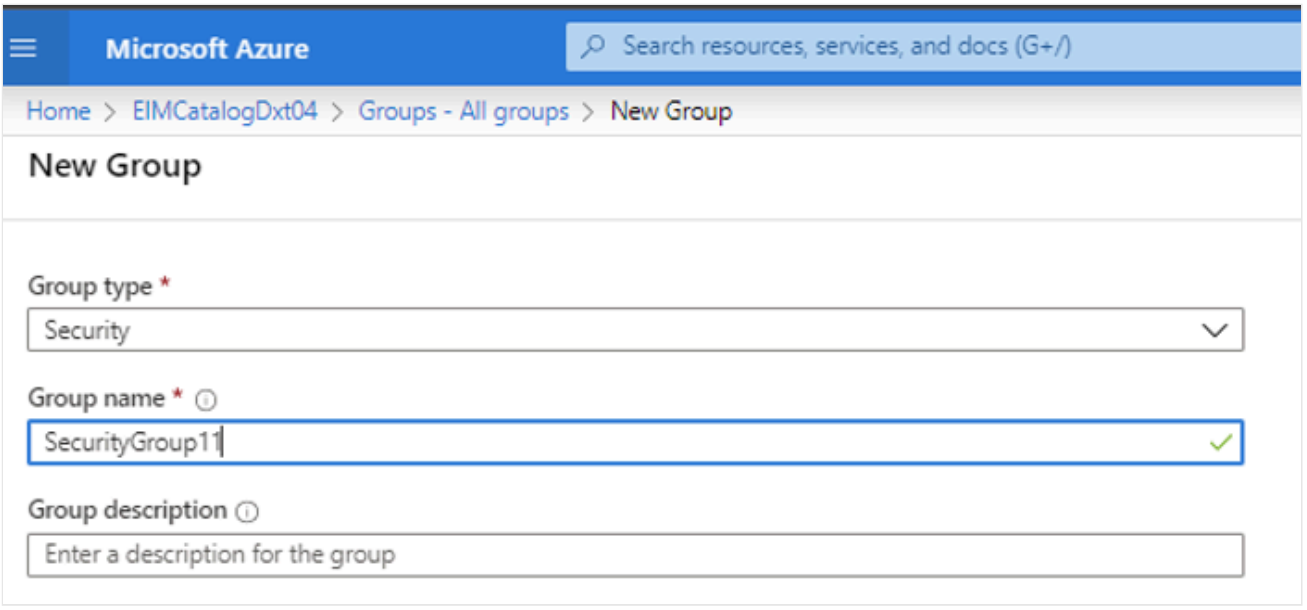
   The name must be between 3-63 characters long and can only contain letters, numbers, underscores, and hyphens. Don't use spaces.

   By default, the system finds the Fabric tenant that exists in the same Microsoft Entra tenant.

Authentication to scan

To scan your Fabric tenant and review its metadata, you first need to create a way to authenticate by using the Fabric tenant. Then, provide Microsoft Purview with the authentication information.

Authenticate to Fabric tenant



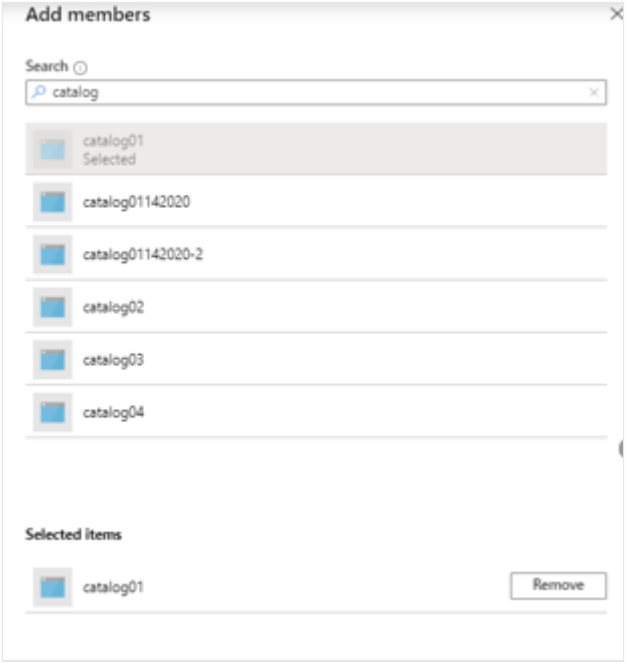
In the Microsoft Entra tenant where the Fabric tenant is located:

1. In the Azure portal, search for **Microsoft Entra ID**.

2. Create a new security group in your Microsoft Entra ID, by following Create a basic group and add members using Microsoft Entra ID.

   > **Tip**
   >
   > You can skip this step if you already have a security group you want to use.

3. Select **Security** as the **Group Type**.



4. Add any relevant users to the security group:

   - If you're using **Managed Identity** as the authentication method, add your Microsoft Purview managed identity to this security group. Select **Members**, and then select **Add members**.

   - If you're using **delegated authentication** or **service principal** as the authentication method, add your **service principal** to this security group. Select **Members**, and then select **Add members**.

5. Search for your Microsoft Purview managed identity or service principal and select it.

You see a success notification that shows you it was added.

Associate the security group with Fabric tenant

1. Sign in to the Fabric admin portal.

2. Select the **Tenant settings** page.

   > **Important**
   >
   > You need to be a Fabric Admin to see the tenant settings page.

3. Select **Admin API settings** > **Allow service principals to use read-only admin APIs**.

4. Select **Specific security groups**.

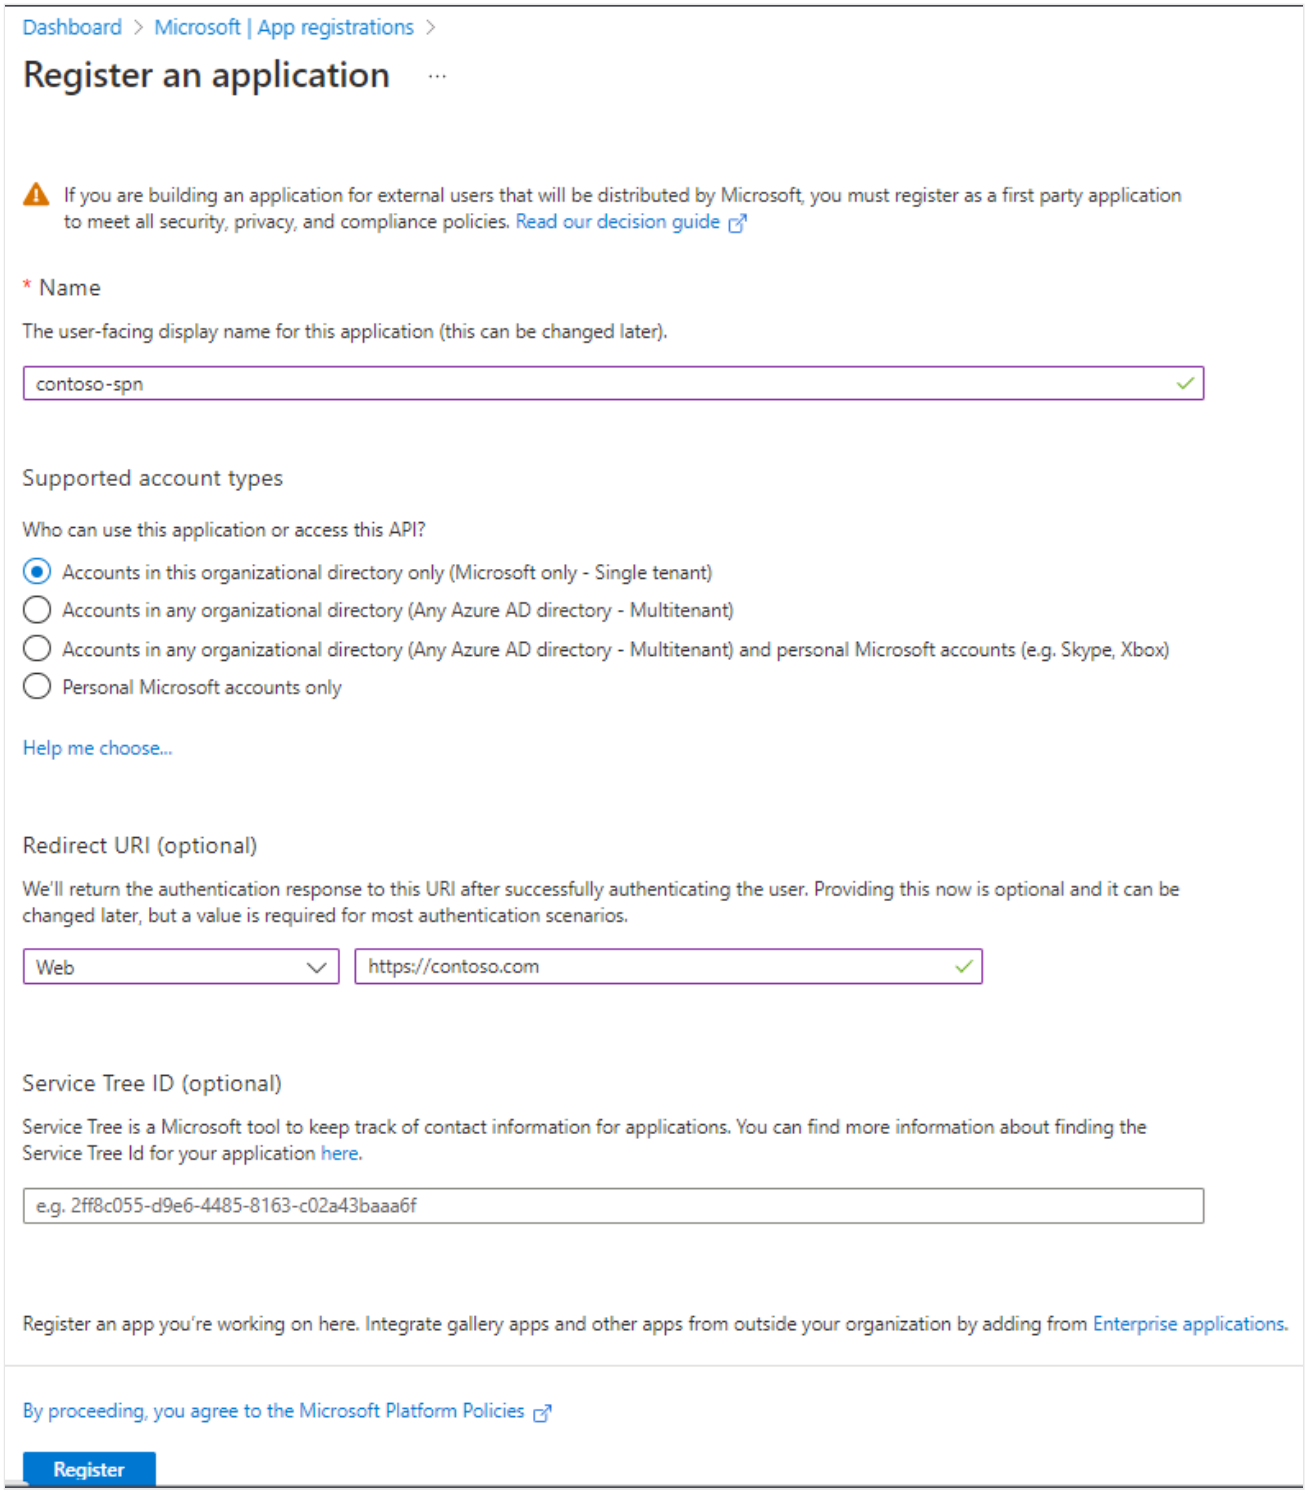
5. Select **Admin API settings** > **Enhance admin APIs responses with detailed metadata** and **Enhance admin APIs responses with DAX and mashup expressions** > Enable the toggle to allow Microsoft Purview Data Map automatically discover the detailed metadata of Fabric datasets as part of its scans.

   > **Important**
   >
   > After you update the Admin API settings on your Fabric tenant, wait about 15 minutes before registering a scan and testing connection.

   > **Caution**
   >
   > When you allow the security group you created (that has your Microsoft Purview managed identity as a member) to use read-only admin APIs, you also allow it to access the metadata (such as dashboard and report names, owners, and descriptions) for all of your Fabric artifacts in this tenant. Once the metadata is pulled into Microsoft

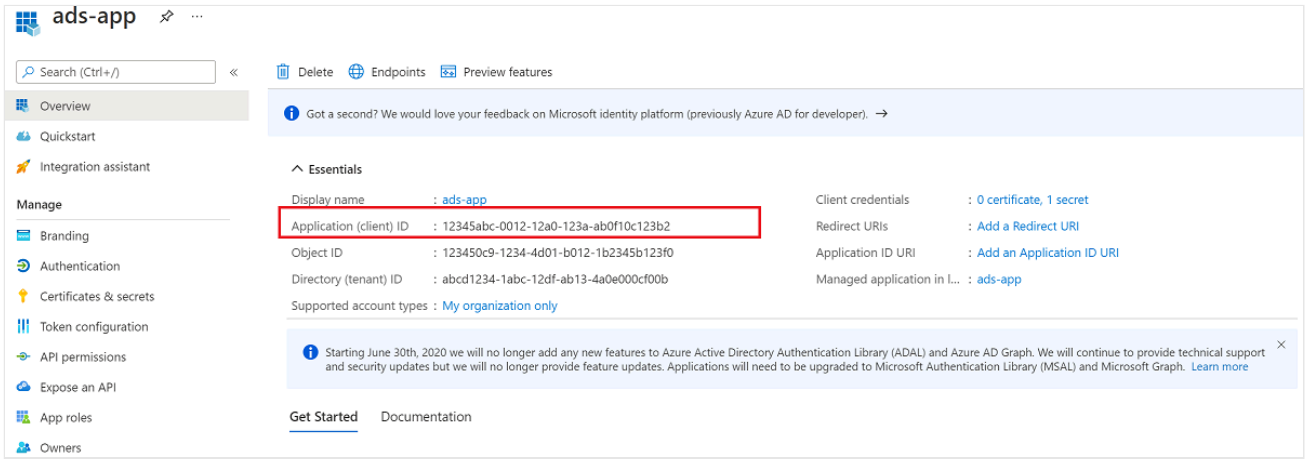
Purview, Microsoft Purview's permissions, not Fabric permissions, determine who can see that metadata.

> **Note**
>
> - You can remove the security group from your developer settings, but the metadata previously extracted won't be removed from the Microsoft Purview account. You can delete it separately if you wish.
> - If your Fabric item (such as lakehouse or mirrored catalog) has OneLake security enabled, then you must create a OneLake security role with **Read** permission assigned to the Microsoft Purview user. See Get started with OneLake Security for step-by-step instructions.



Configure credentials for scans in Microsoft Purview

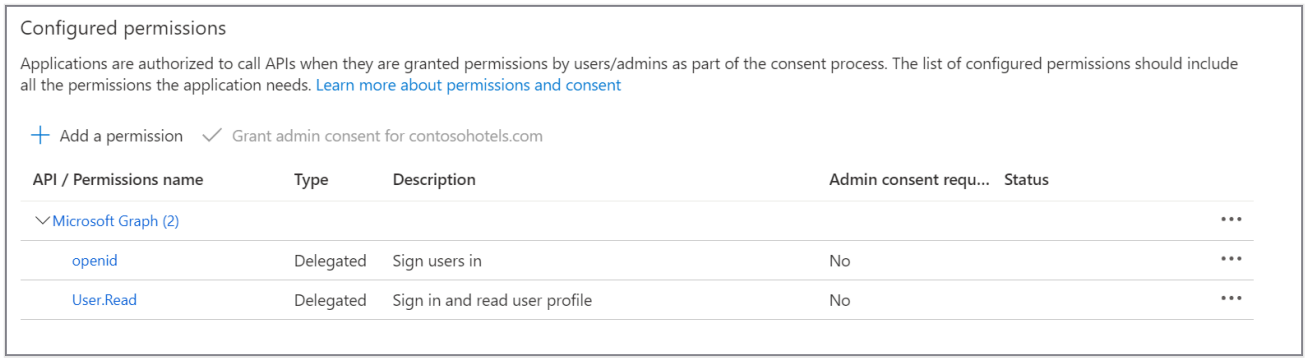
Managed identity



If you follow all the steps in authenticate Microsoft Purview to Fabric, you don't need any other authentication steps for managed identities.

Service principal

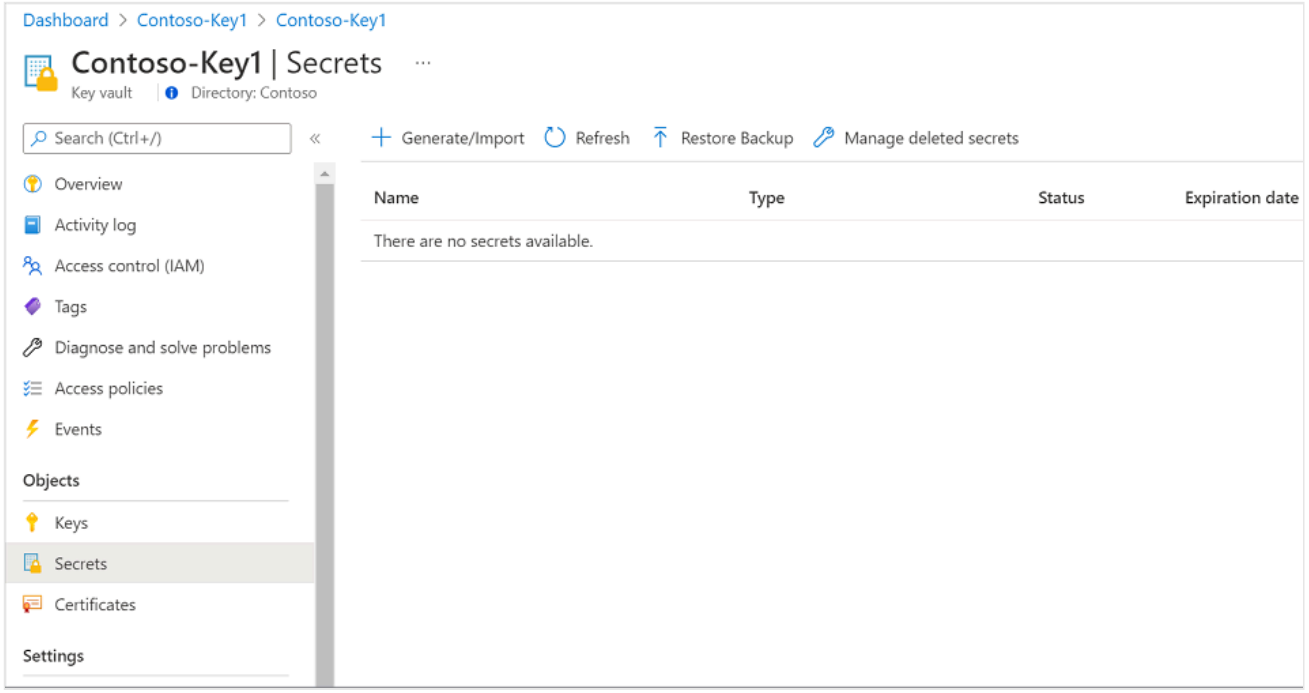
1. In the Azure portal, select **Microsoft Entra ID** and create an App Registration in the tenant. Provide a web URL in the **Redirect URI**. For information about the Redirect URI see this documentation from Microsoft Entra ID.



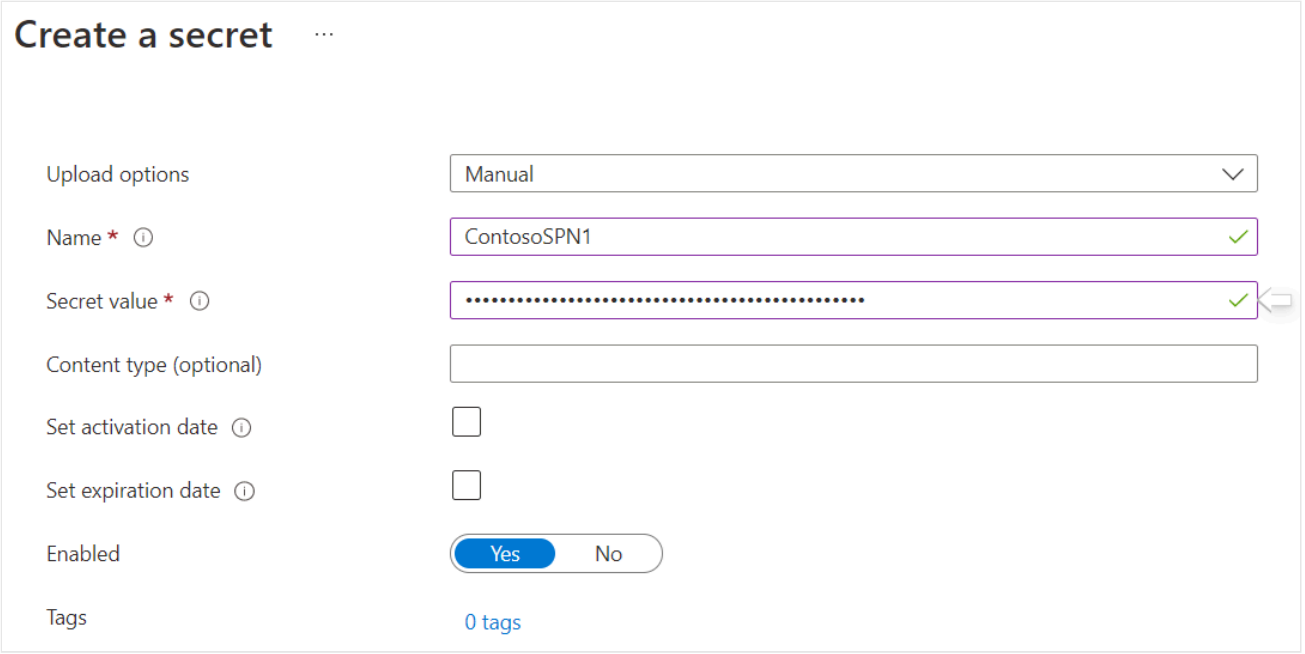
2. Take note of Client ID(App ID).

3. From Microsoft Entra dashboard, select newly created application and then select **App registration**. From **API Permissions**, assign the application the following delegated permissions:

    - Microsoft Graph openid
    - Microsoft Graph User.Read



4. Under **Advanced settings**, enable **Allow Public client flows**.



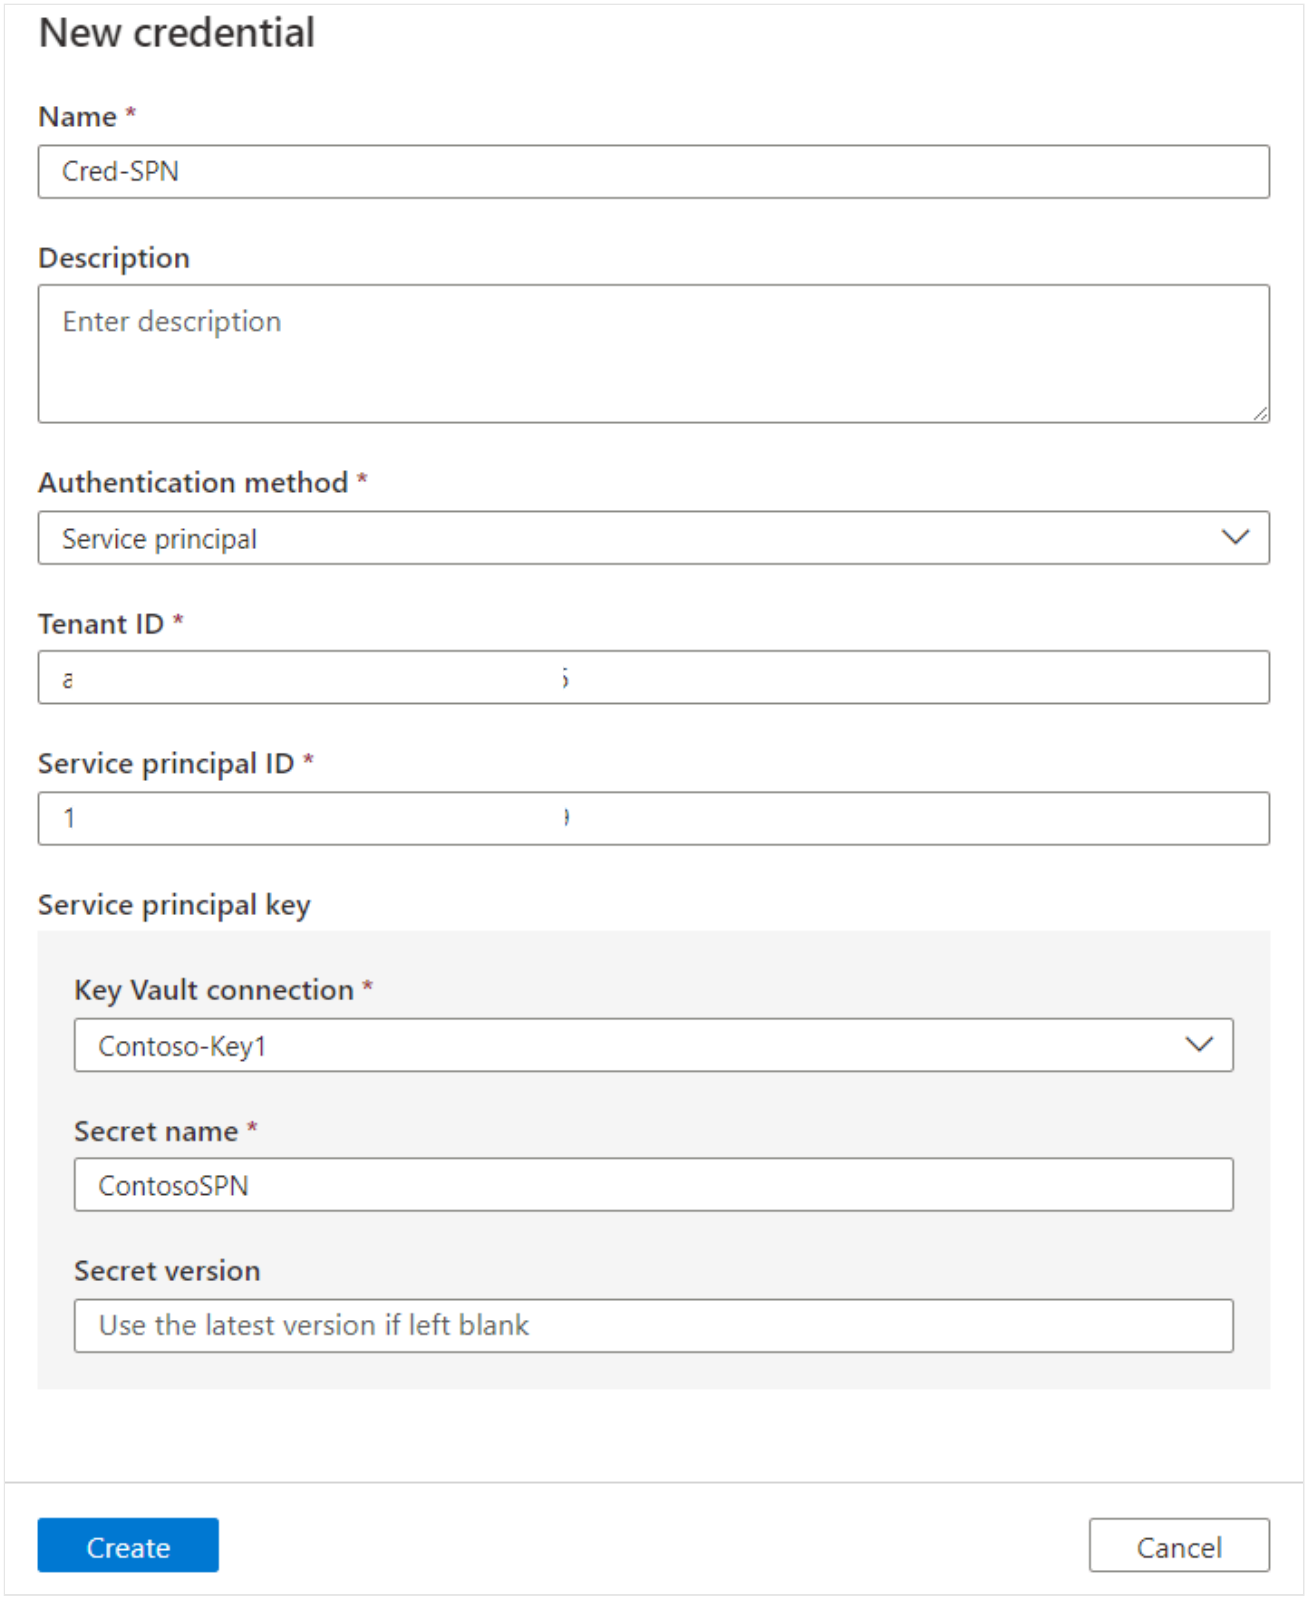
5. Under **Certificates & secrets**, create a new secret and save it securely for next steps.

6. In Azure portal, navigate to your Key Vault.

7. Select **Settings** > **Secrets** and select **+ Generate/Import**.

8. Enter a name for the secret and for **Value**, type the newly created secret for the App registration. Select **Create** to complete.

9. If your key vault isn't connected to Microsoft Purview yet, you need to create a new key vault connection.



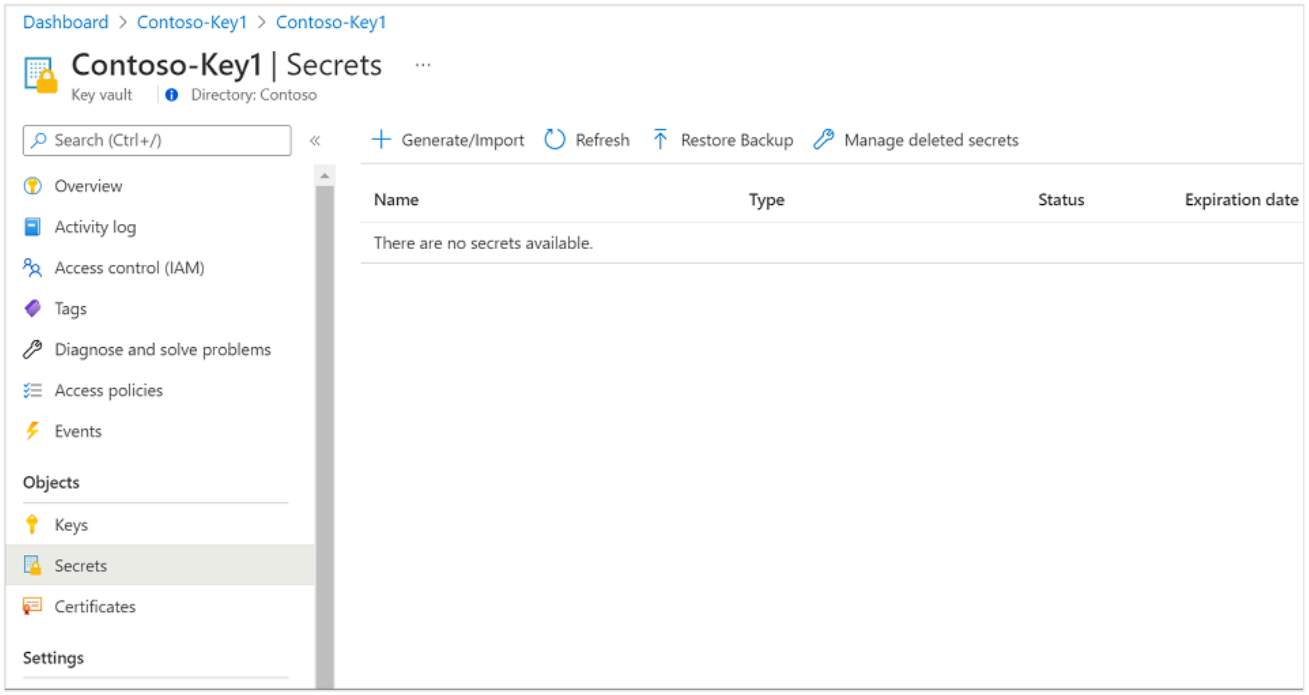
10. Now that you created your secret, in Microsoft Purview, go to the **Credentials** page under **Management**.

    > **Tip**
    >
    > Alternatively, you can create a new credential during the scanning process.

11. Select **New** to create your new credential.

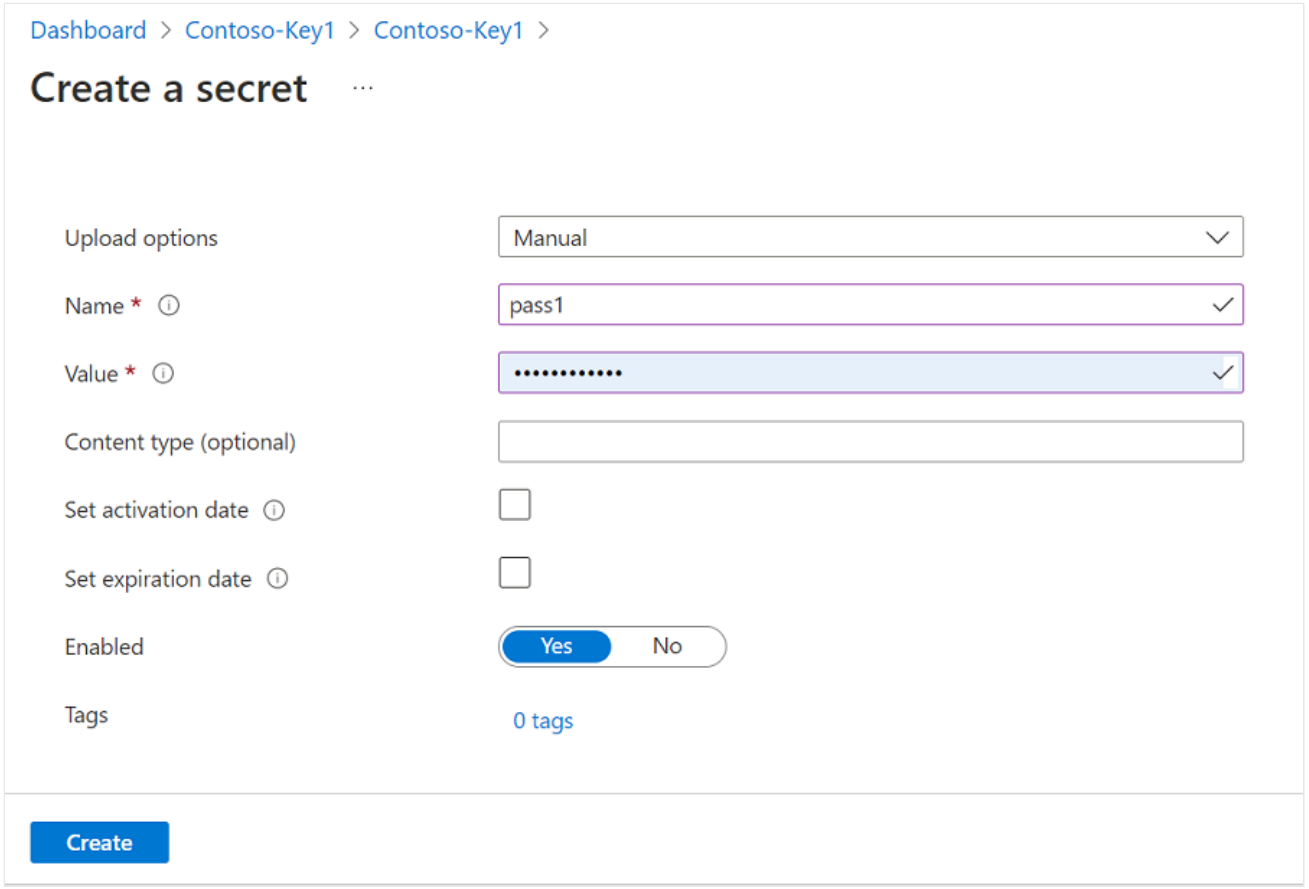
12. Provide the required parameters:

    - **Name**: Provide a unique name for the credential.
    - **Authentication method**: Service principal
    - **Tenant ID**: Your Fabric tenant ID
    - **Client ID**: Use Service Principal Client ID (App ID) you created earlier.
    - **Key Vault Connection**: the Microsoft Purview connection to the Key Vault where you created your secret earlier.
    - **Secret name**: the name of the secret you created earlier.



13. Once you fill in all the details, select **Create**.

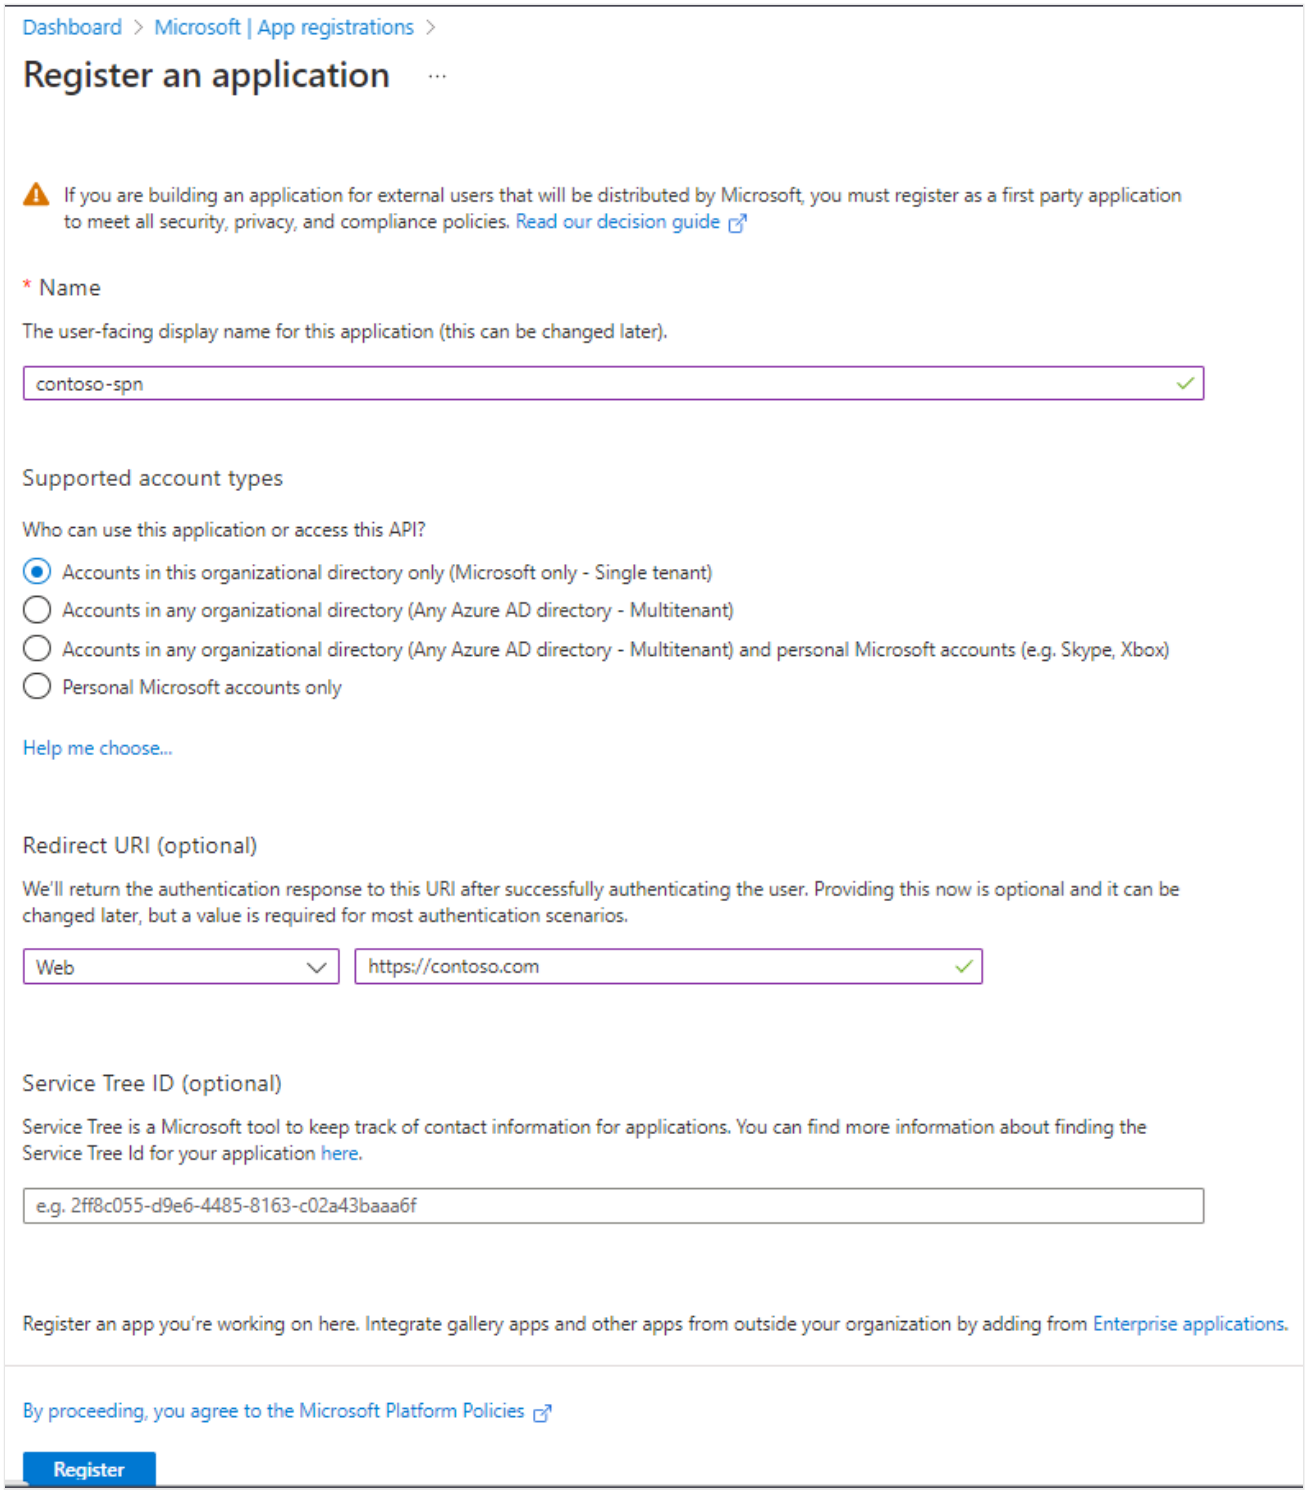
Delegated authentication



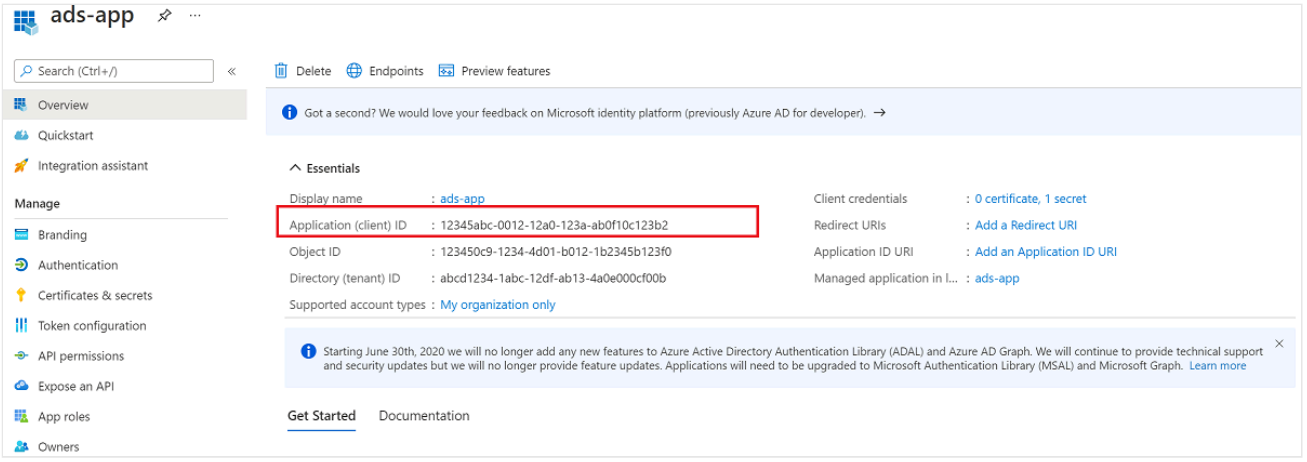
1. Create a user account in Microsoft Entra tenant and assign the user to Microsoft Entra role, **Fabric Administrator**. Take note of username and sign in to change the password.

2. Go to your Key Vault.

3. Select **Settings** > **Secrets** and select **+ Generate/Import**.

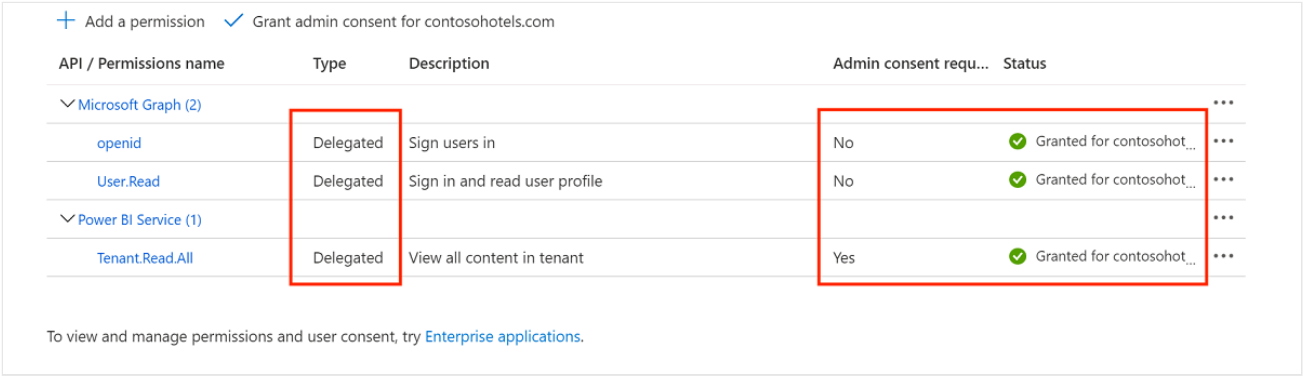


4. Enter a name for the secret and for **Value**, type the newly created password for the Microsoft Entra user. Select **Create** to complete.



5. If your key vault isn't connected to Microsoft Purview yet, you need to create a new key vault connection

6. Create an app registration in your Microsoft Entra tenant. Provide a web URL in the **Redirect URI**.



7. Take note of Client ID(App ID).

8. From Microsoft Entra dashboard, select newly created application and then select **API permissions**. Assign the application the following delegated permissions, and grant admin consent for the tenant:

    - Fabric Service Tenant.Read.All
    - Microsoft Graph openid
    - Microsoft Graph User.Read

9. Under **Advanced settings**, enable **Allow Public client flows**.

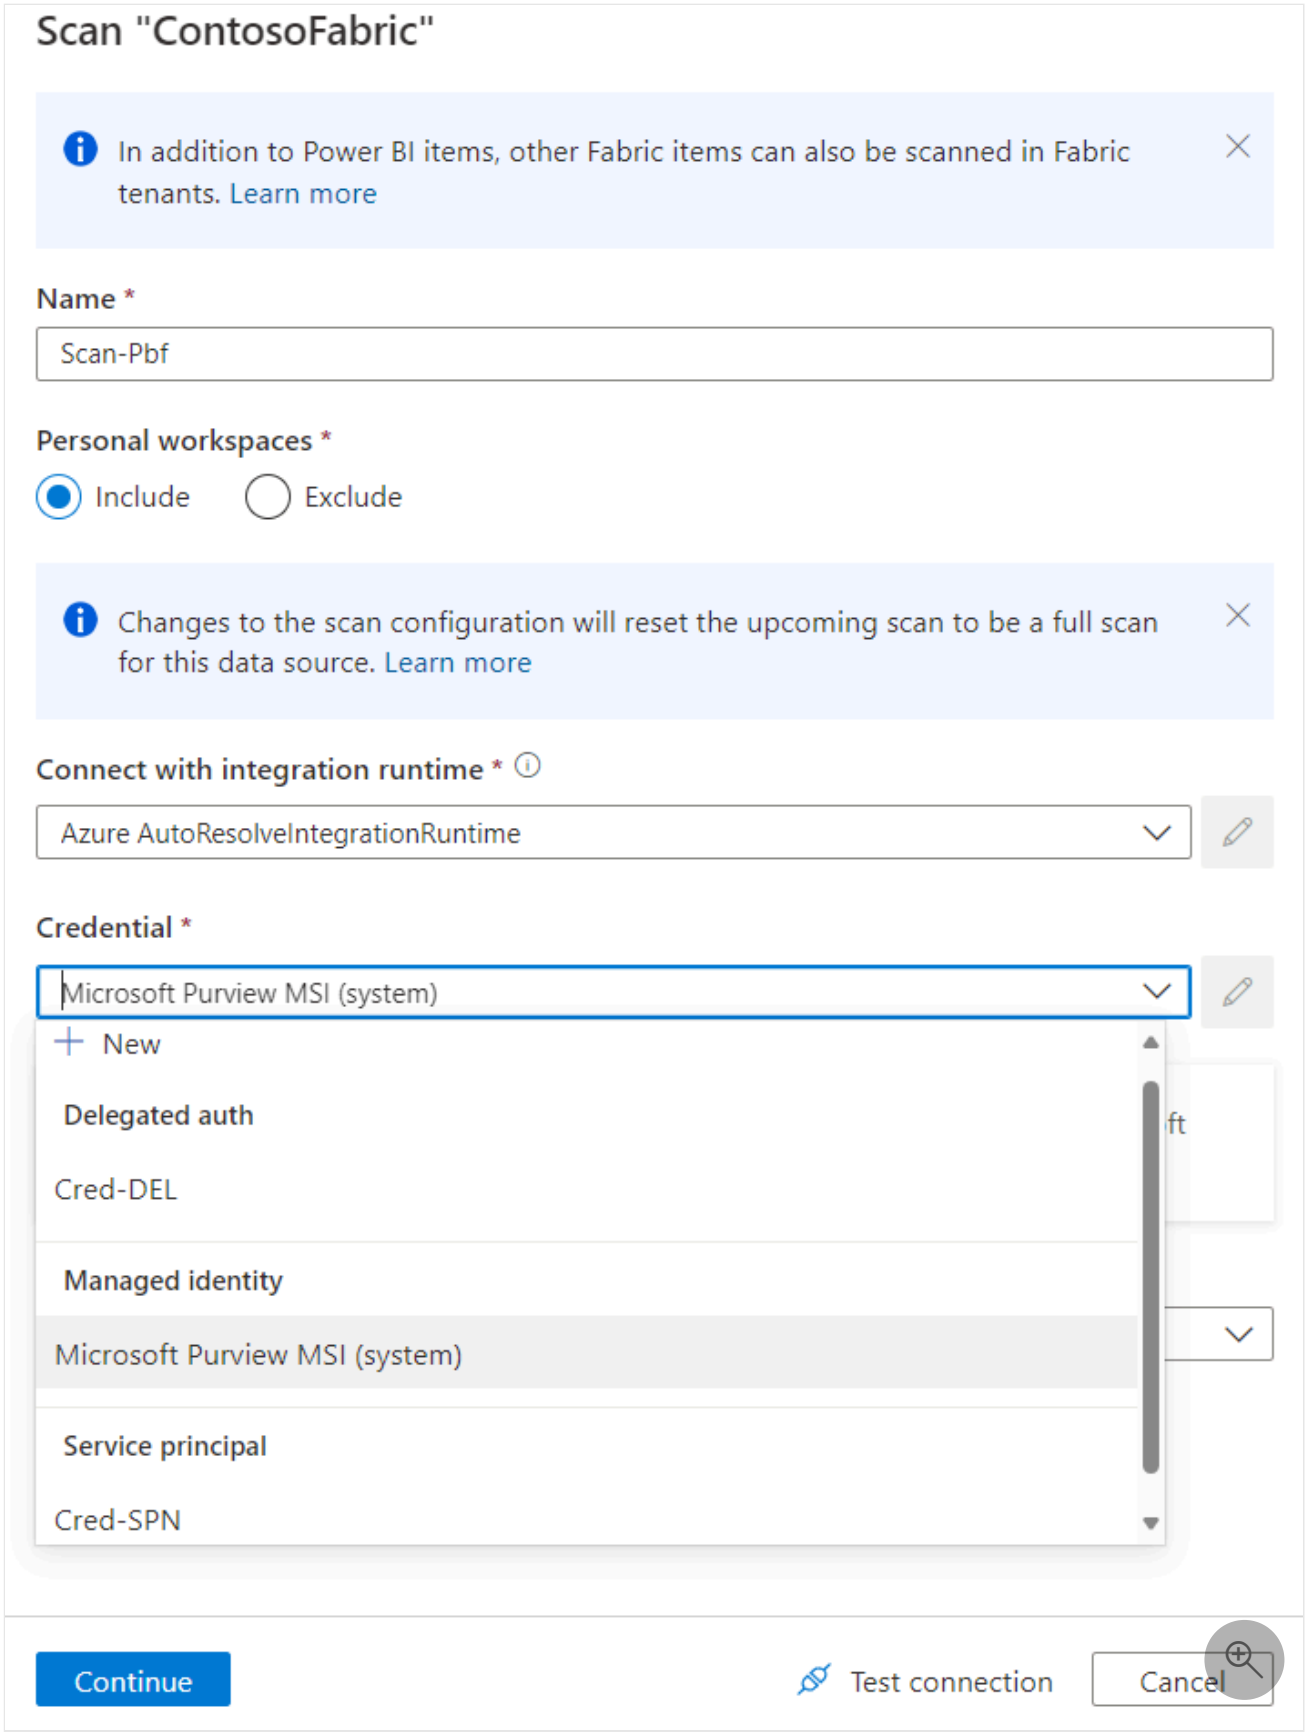
10. Next, in Microsoft Purview, go to the **Credentials** page under **Management** to create a new credential.

    > **Tip**
    >
    > Alternatively, you can create a new credential during the scanning process.

11. Select **New** to create your new credential.

12. Provide the required parameters:

    - **Name**: Provide a unique name for the credential.
    - **Authentication method**: Delegated auth.

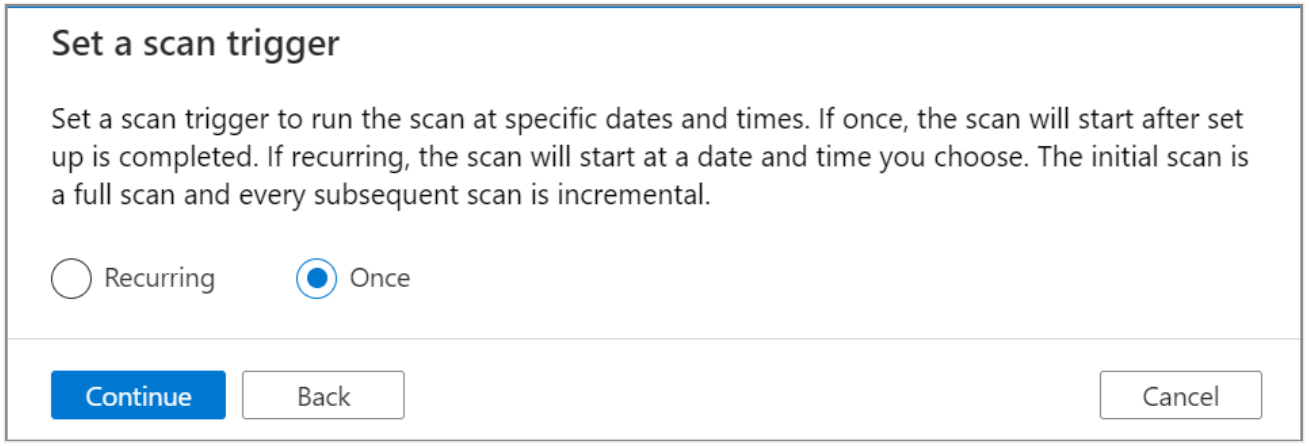


- **Client ID**: Use Service Principal Client ID (App ID) you created earlier.
- **User name**: Provide the username of Fabric Administrator you created earlier.
- **Key Vault Connection**: the Microsoft Purview connection to the Key Vault where you created your secret earlier.
- **Secret name**: the name of the secret you created earlier.

13. Once you fill in all the details, select **Create**.

Create scan

1. In the Microsoft Purview portal, go to **Data Map**.
2. Go to **Sources**.
3. Select the registered Fabric source.
4. Select **+ New scan**.
5. Enter a name for your scan.
6. Select either your managed identity credential or the credential you created for your service principal or delegated authentication.



7. Select **Test Connection** before continuing to next steps. If **Test Connection** fails, select **View Report** to see the detailed status and troubleshoot the problem. 1. Access - Failed status means the user authentication failed. Scans that use managed identity always pass because no user authentication is required. If you use service principal or delegated authentication, make sure your Key Vault credential is set up correctly and that Microsoft Purview has

access to the key vault. 1. Assets (+ lineage) - Failed status means the Microsoft Purview - Fabric authorization failed. Make sure the Microsoft Purview managed identity is added to the security group in the Fabric admin portal.

a. Detailed metadata (Enhanced) - Failed status means the Fabric admin portal is disabled for the following setting - **Enhance admin APIs responses with detailed metadata**

> **Tip**
>
> For more troubleshooting, see the deployment checklist to make sure you covered every step in your scenario.

8. Set up a scan trigger. Your options are **Recurring** and **Once**.

9. On **Review new scan**, select **Save and run** to launch your scan.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ Note
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Glossary

Items and **sub-items** in Microsoft Fabric Lakehouse:

- **Items**: In Fabric, items are top-level workspace artifacts such as Lakehouse, Warehouse, Notebook, Pipeline, and Semantic Model. Each item acts as a single entity for lifecycle operations, including creation, deletion, and CI/CD tracking. A Lakehouse itself is an item. Tables (Delta and non-Delta), files, folders, and sometimes shortcuts within a Lakehouse are considered sub-items.
- **Sub-items**: These elements represent the actual data layer. You can view and query them through Spark and SQL endpoints. However, you can't manage or deploy them independently.

Next steps

Now that you registered your source, follow these guides to learn more about Microsoft Purview and your data.

Expand table

Scenarios	Microsoft Purview public access allowed/denied	Fabric public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Public access with Azure IR	Allowed	Allowed	Azure Runtime	Delegated authentication / Service principal	Review deployment checklist
Public access with Self-hosted IR	Allowed	Allowed	SHIR or Kubernetes SHIR	Service principal	Review deployment checklist
Private access	Denied	Allowed	Managed Virtual Network IR (v2 only)	Delegated authentication / Service principal	Review deployment checklist

> **Note**
>
> The supported scenarios above apply for non-Power BI items in Fabric. See the **Power BI documentation** for supported scenarios applicable for Power BI items.

Known limitations

- Currently for all Fabric items besides Power BI, only item level metadata and lineage will be scanned. For Lakehouse tables and files, sub-item level metadata scanning is available but sub-item level lineage is still not supported.
- For self-hosted integration runtime, the standard self-hosted integration runtime with minimal version 5.40.8836.1 or Kubernetes supported self-hosted integration runtime is supported.
- Empty workspaces are skipped.

> **Note**
>
> For Fabric Lakehouse tables with schema-enabled databases, the schema name and table name are combined into a single segment in the qualified name using `%252F` (double-URL-encoded forward slash) as a separator. For example, a table at the OneLake path `Tables/dbo/my_table` will appear in Data Map with the qualified name `.../tables/dbo%252Fmy_table`, while the entity display name will show only the table name (for example, `my_table`) without the schema prefix.

Prerequisites

Before you start, make sure you have the following:

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

Authentication options

- Service Principal
- Delegated Authentication

Deployment checklist

The deployment checklist is a summary of all the steps you need to take to set up a cross-tenant Fabric source. You can use it during setup or for troubleshooting, to confirm you've followed all the necessary steps to connect.

Public access with Azure IR

Scan cross-tenant Fabric by using delegated authentication in a public network

1. Make sure the Fabric tenant ID is entered correctly during the registration. By default, the Fabric tenant ID that exists in the same Microsoft Entra instance as Microsoft Purview will be populated.

2. Make sure your Fabric metadata model is up to date by enabling metadata scanning.

3. From the Azure portal, validate if the Microsoft Purview account network is set to **public access**.

4. From the Fabric tenant admin portal, make sure the Fabric tenant is configured to allow a public network.

5. Check your instance of Azure Key Vault to make sure:
   a. There are no typos in the password or secret.
   b. Microsoft Purview managed identity has **get** and **list** access to secrets.

6. Review your credential to validate that the:
   a. Client ID matches the *Application (Client) ID* of the app registration.
   b. For **delegated auth**, username includes the user principal name, such as `johndoe@contoso.com`.

7. In the Fabric Microsoft Entra tenant, validate the following Fabric admin user settings:
   a. The user is assigned to the Fabric administrator role.
   b. If the user is recently created, sign in with the user at least once, to make sure that the password is reset successfully, and the user can successfully initiate the session.
   c. There are no multifactor authentication or conditional access policies enforced on the user.

8. In the Fabric Microsoft Entra tenant, validate the following app registration settings:

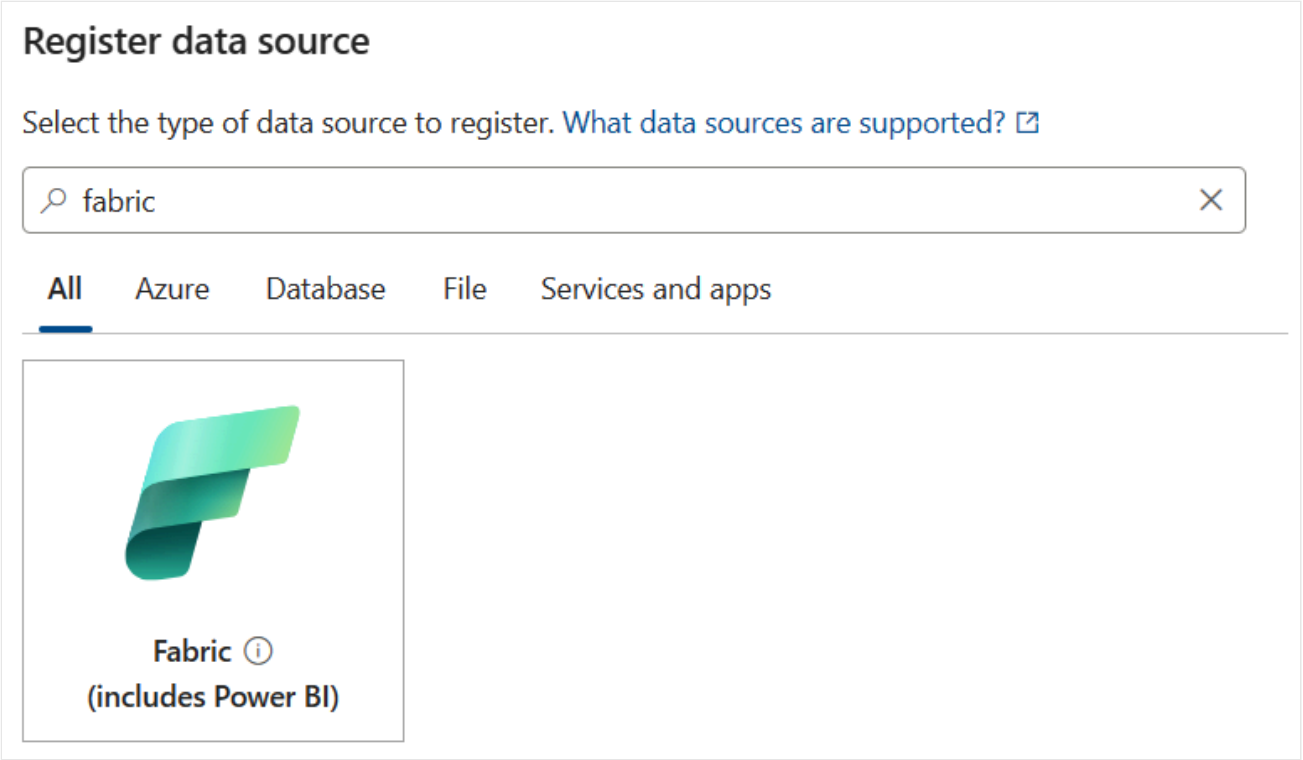
a. The app registration exists in your Microsoft Entra tenant where the Fabric tenant is located.
b. If service principal is used, under **API permissions**, the following **delegated permissions** are assigned with read for the following APIs:

- Microsoft Graph openid
- Microsoft Graph User.Read

c. If delegated authentication is used, under **API permissions**, the following **delegated permissions** and **grant admin consent for the tenant** is set up with read for the following APIs:

- Power BI Service Tenant.Read.All
- Microsoft Graph openid
- Microsoft Graph User.Read

d. Under **Authentication**:
   i. **Supported account types** > **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)** is selected.
   ii. **Implicit grant and hybrid flows** > **ID tokens (used for implicit and hybrid flows)** is selected.
   iii. **Allow public client flows** is enabled.



9. In Fabric tenant, from Microsoft Entra tenant, make sure Service Principal is member of the new security group.

10. On the Fabric Tenant Admin portal, validate if Allow service principals to use read-only admin APIs is enabled for the new security group.

Register the Fabric tenant

1. From the options on the left, select **Data Map**.

2. Select **Register**, and then select **Fabric** as your data source.

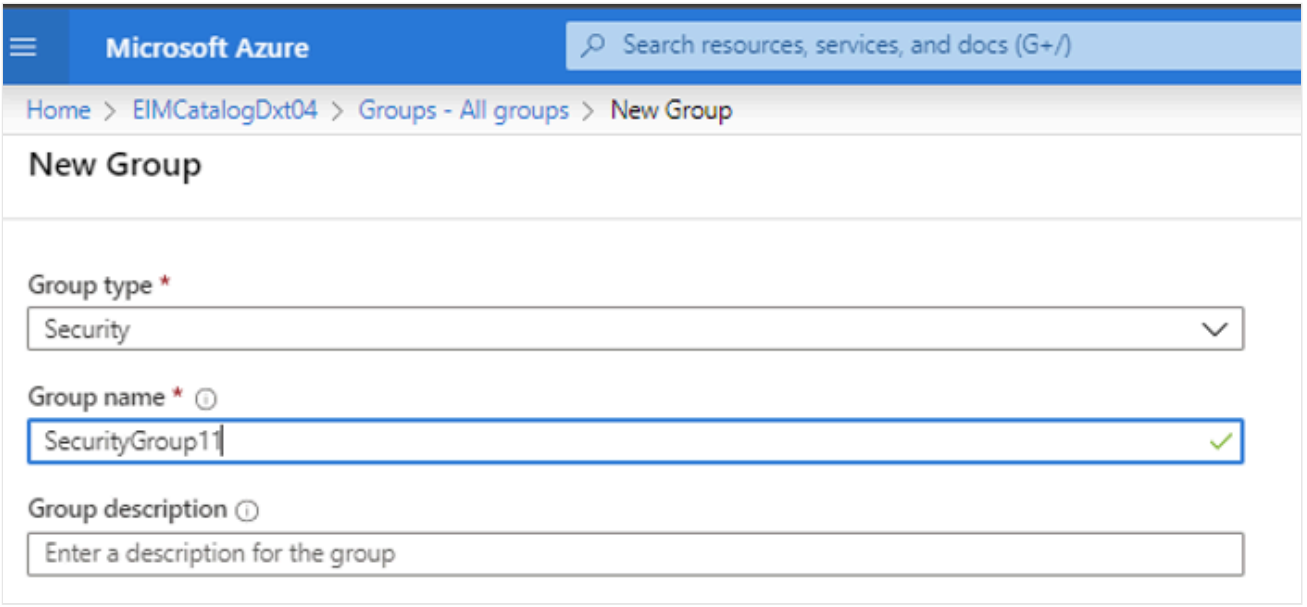
3. Give your Fabric instance a friendly name. The name must be 3 to 63 characters long, and must contain only letters, numbers, underscores, and hyphens. Spaces aren't allowed.

4. Edit the **Tenant ID** field, to replace with the tenant for the cross-tenant Fabric that you want to register and scan. By default, Microsoft Purview's tenant ID is populated.

Authentication to scan

To be able to scan your Microsoft Fabric tenant and review its metadata, you'll first need to create a way to authenticate with the Fabric tenant, and then give Microsoft Purview the authentication information.

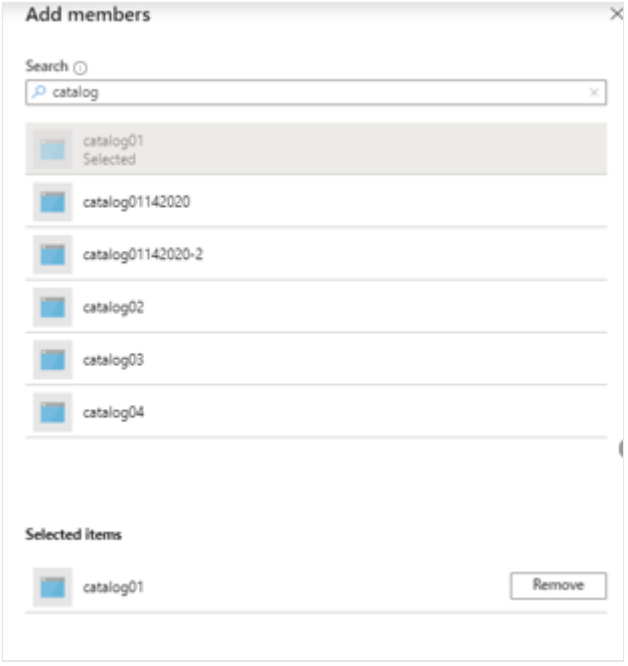
Authenticate to Fabric tenant



In Microsoft Entra tenant, where Fabric tenant is located:

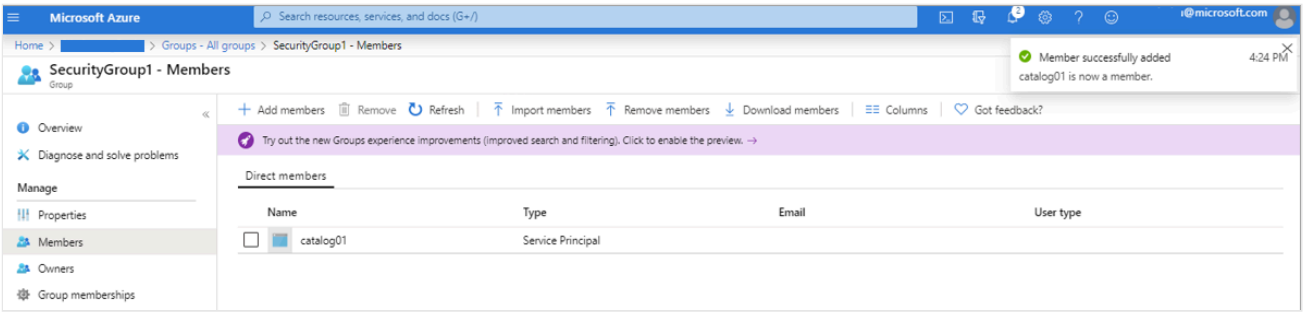
1. In the Azure portal, search for **Microsoft Entra ID**.

2. Create a new security group in your Microsoft Entra ID, by following Create a basic group and add members using Microsoft Entra ID.



> **Tip**
>
> You can skip this step if you already have a security group you want to use.

3. Select **Security** as the **Group Type**.



4. Select **Members**, then select **+ Add members**.

5. Search for your Microsoft Purview managed identity or service principal and select it.

You should see a success notification showing you that it was added.

Associate the security group with Fabric tenant

1. Log into the Fabric admin portal.

2. Select the **Tenant settings** page.

   > **Important**
   >
   > You need to be a Fabric Admin to see the tenant settings page.

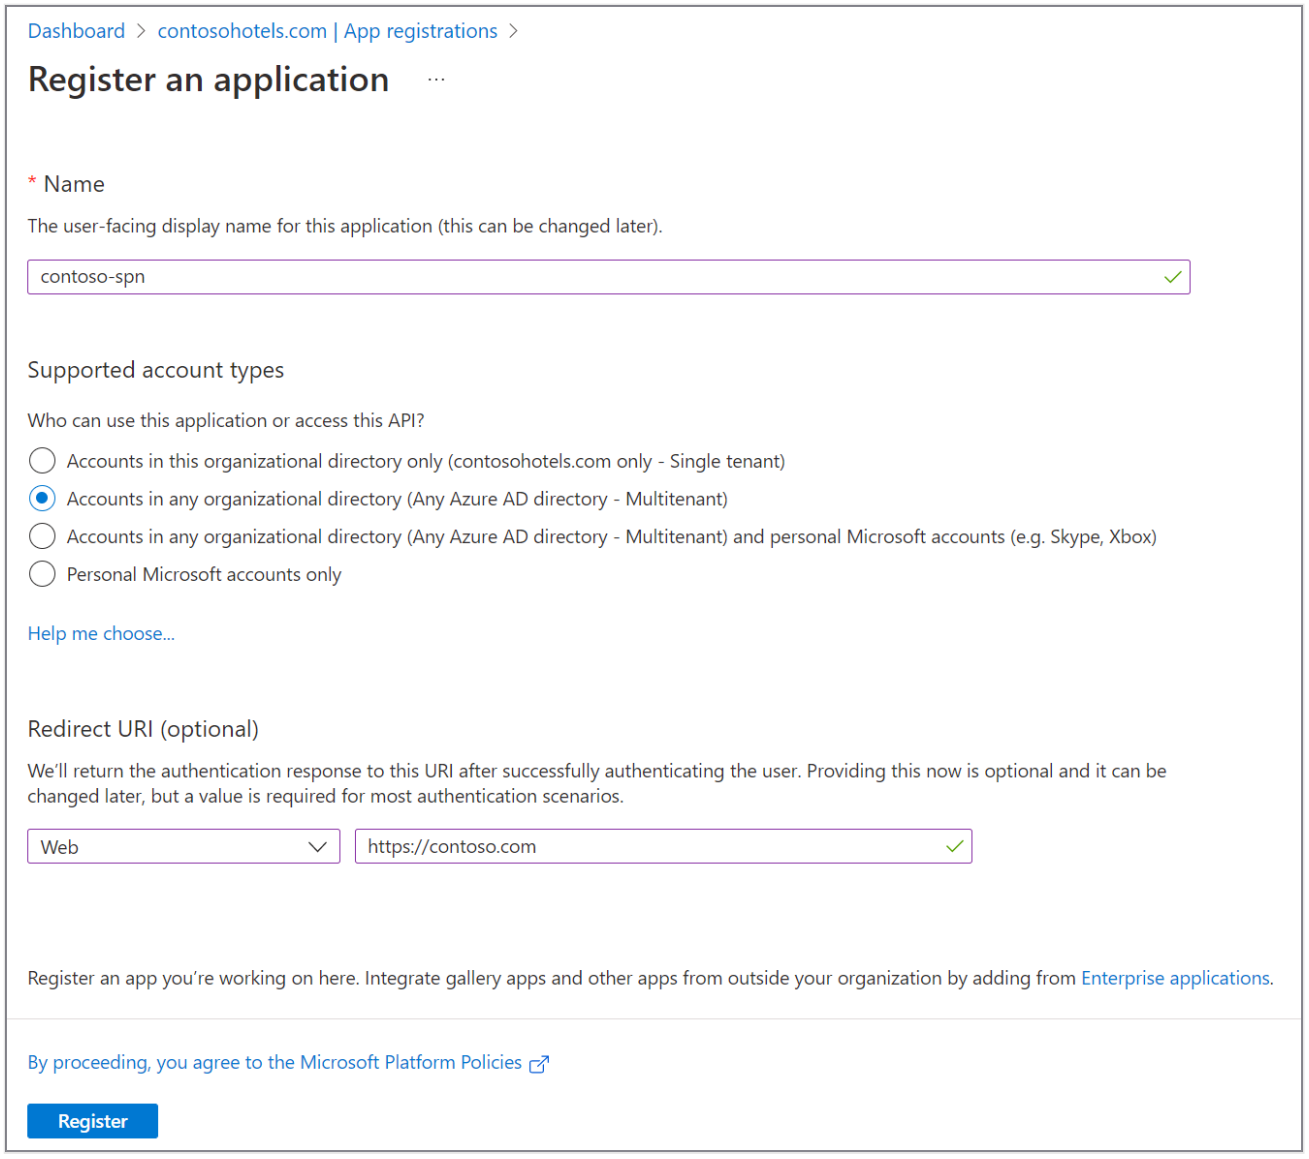
3. Select **Admin API settings** > **Allow service principals to use read-only admin APIs**.

4. Select **Specific security groups**.

5. Select **Admin API settings** > **Enhance admin APIs responses with detailed metadata** and **Enhance admin APIs responses with DAX and mashup expressions** > Enable the toggle to allow Microsoft Purview Data Map automatically discover the detailed metadata of Fabric datasets as part of its scans.

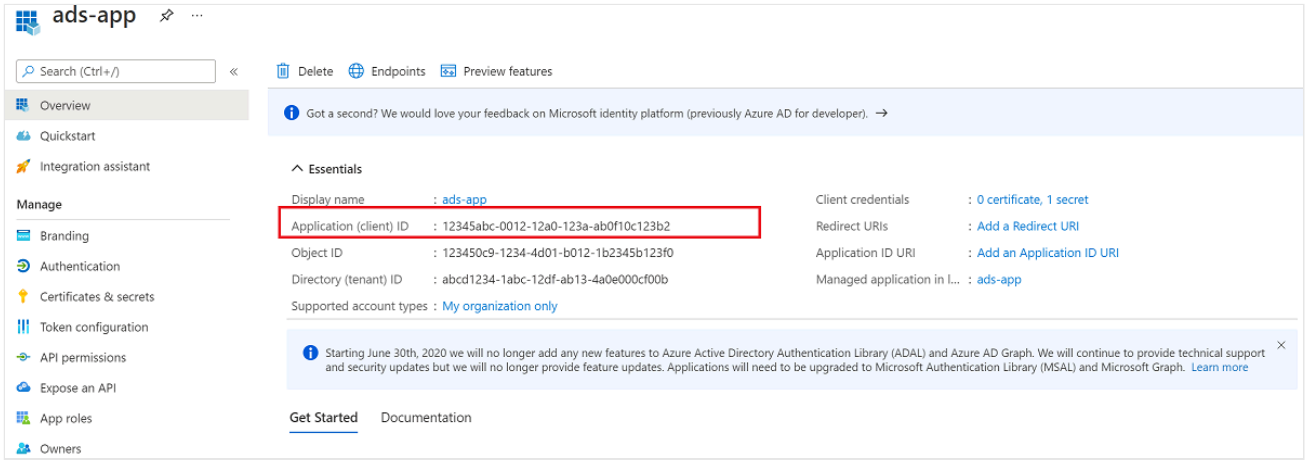
   > **Important**
   >
   > After you update the Admin API settings on your Fabric tenant, wait around 15 minutes before registering a scan and test connection.

   > **Caution**
   >
   > When you allow the security group you created to use read-only admin APIs, you also allow it to access the metadata (such as dashboard and report names, owners, and descriptions) for all of your Fabric artifacts in this tenant. Once the metadata has been



pulled into the Microsoft Purview, Microsoft Purview's permissions, not Fabric permissions, determine who can see that metadata.

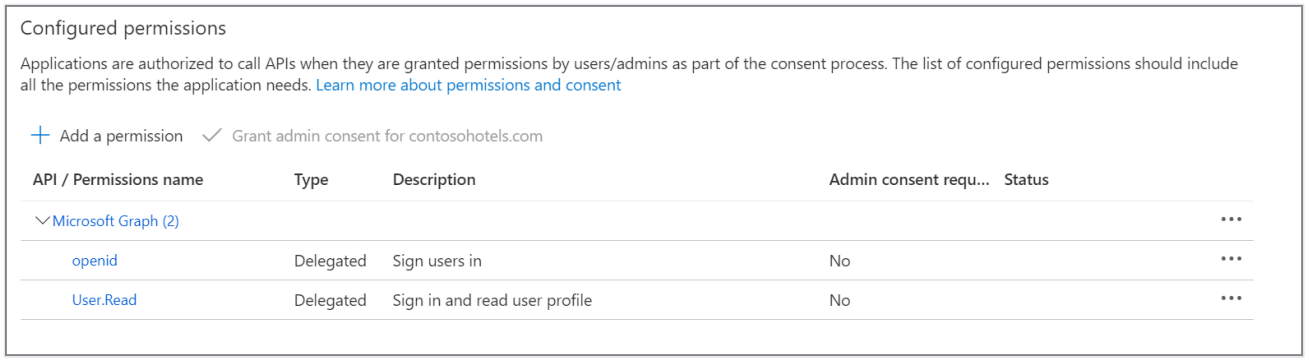
> **Note**
>
> - You can remove the security group from your developer settings, but the metadata previously extracted won't be removed from the Microsoft Purview account. You can delete it separately if you wish.
> - If your Fabric item (such as lakehouse or mirrored catalog) has OneLake security enabled, then you must create a OneLake security role with **Read** permission assigned to the Microsoft Purview user. See Get started with OneLake Security for step-by-step instructions.



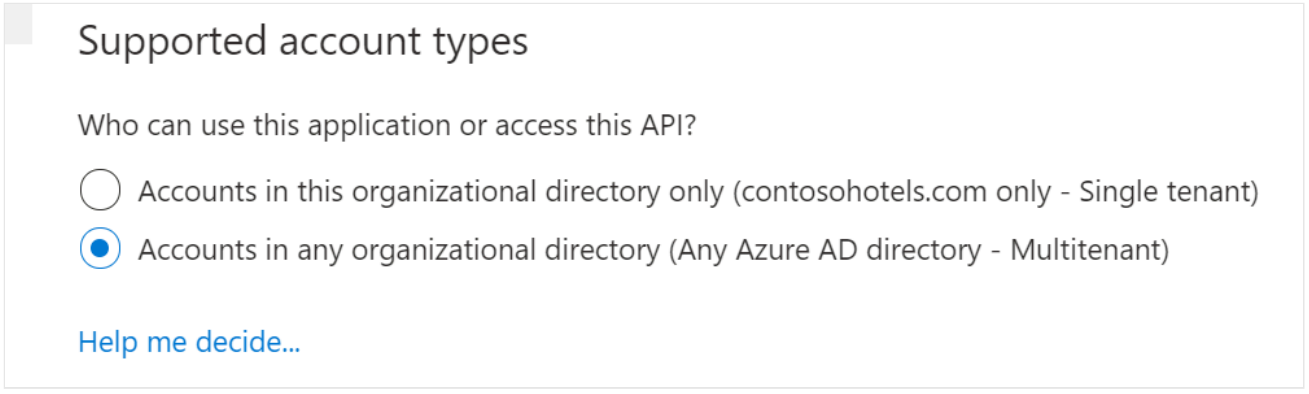
Configure credentials for scans in Microsoft Purview

Service principal

1. Create an app registration in your Microsoft Entra tenant where Fabric is located. Provide a web URL in the **Redirect URI**.



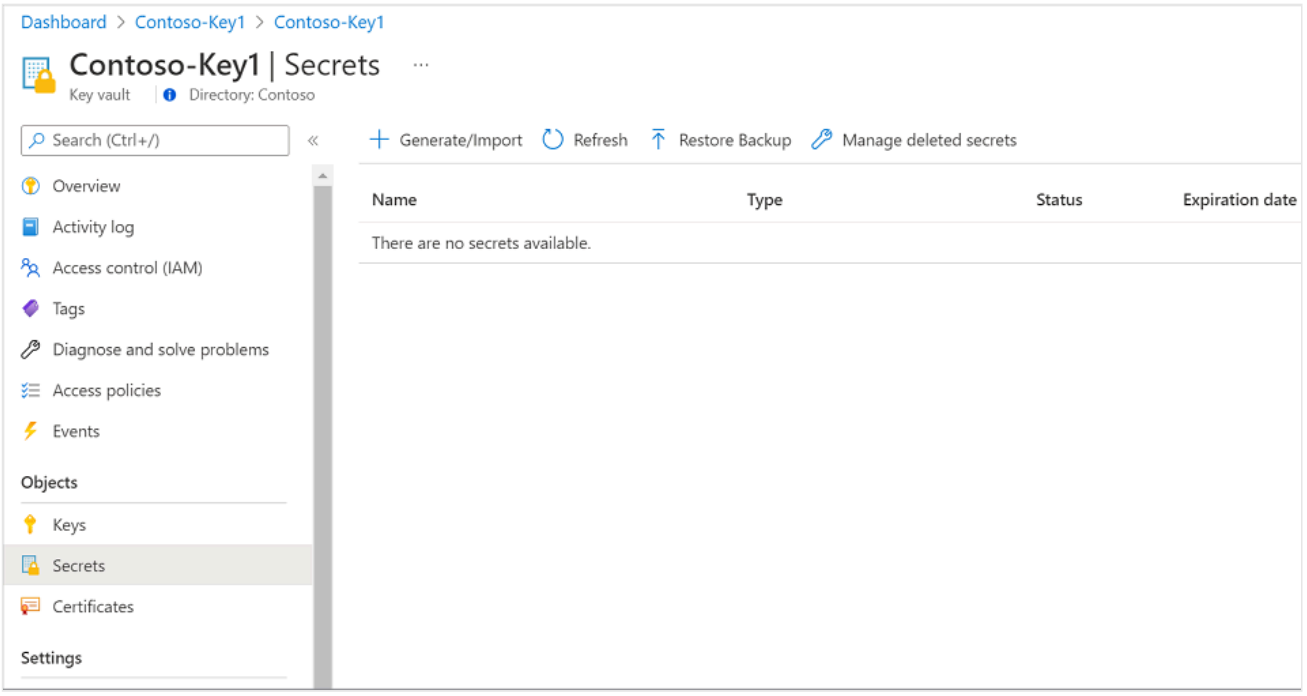
2. Take note of the client ID (app ID).



3. From the Microsoft Entra dashboard, select the newly created application, and then select **App permissions**. Assign the application the following delegated permissions:

   - Microsoft Graph openid
   - Microsoft Graph User.Read

4. From the Microsoft Entra dashboard, select the newly created application, and then select **Authentication**. Under **Supported account types**, select **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)**.

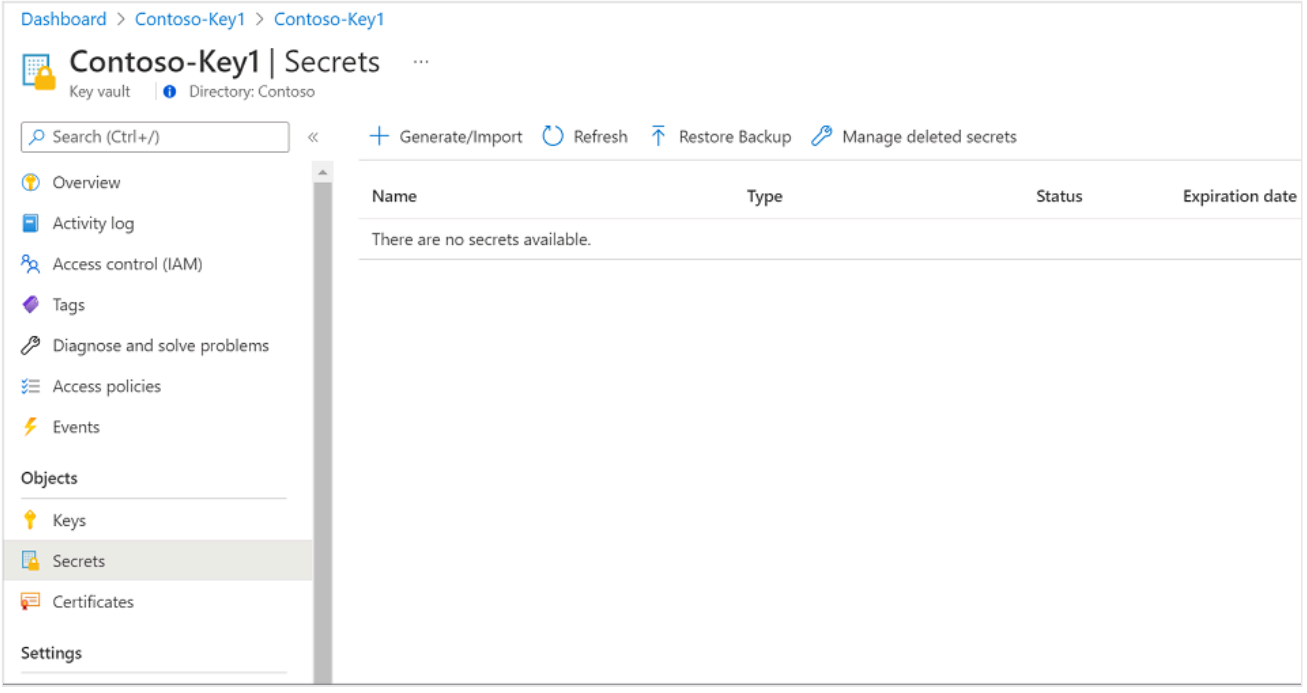


5. Under **Implicit grant and hybrid flows**, select **ID tokens (used for implicit and hybrid flows)**.

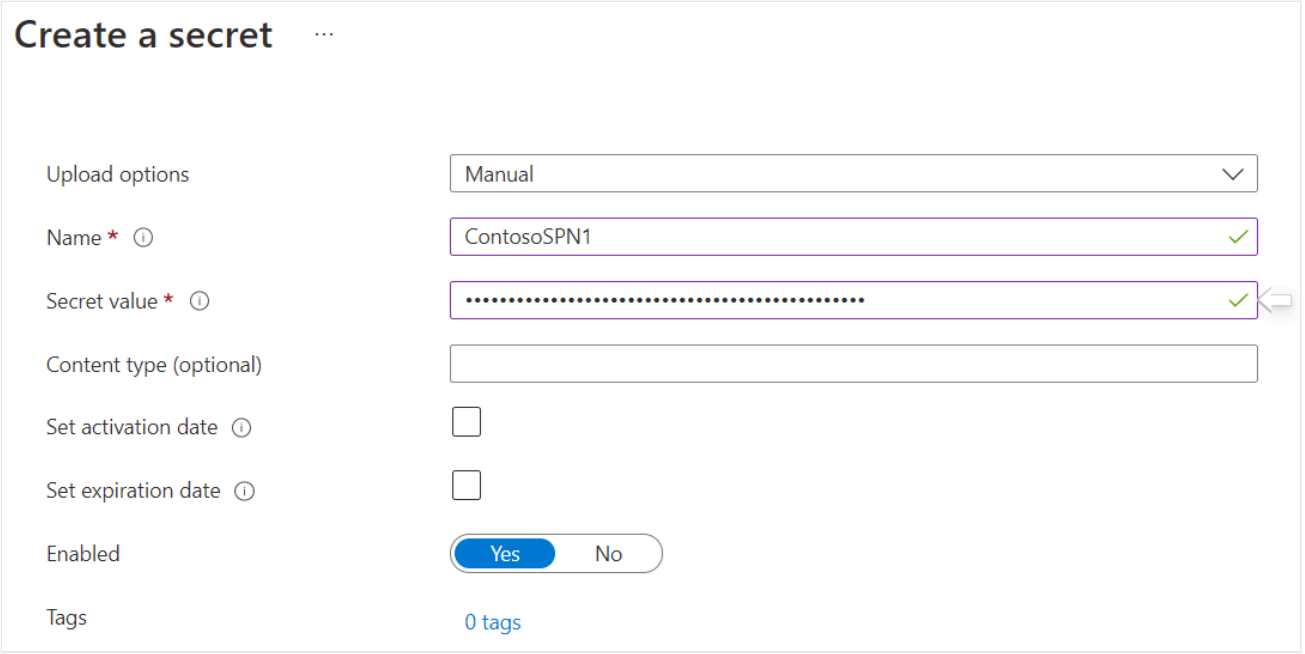
6. Under **Advanced settings**, enable **Allow Public client flows**.

7. In the tenant where Microsoft Purview is created go to the instance of Azure Key Vault.

8. Select **Settings** > **Secrets**, and then select **+ Generate/Import**.



9. Enter a name for the secret. For **Value**, type the newly created secret for the App registration. Select **Create** to complete.



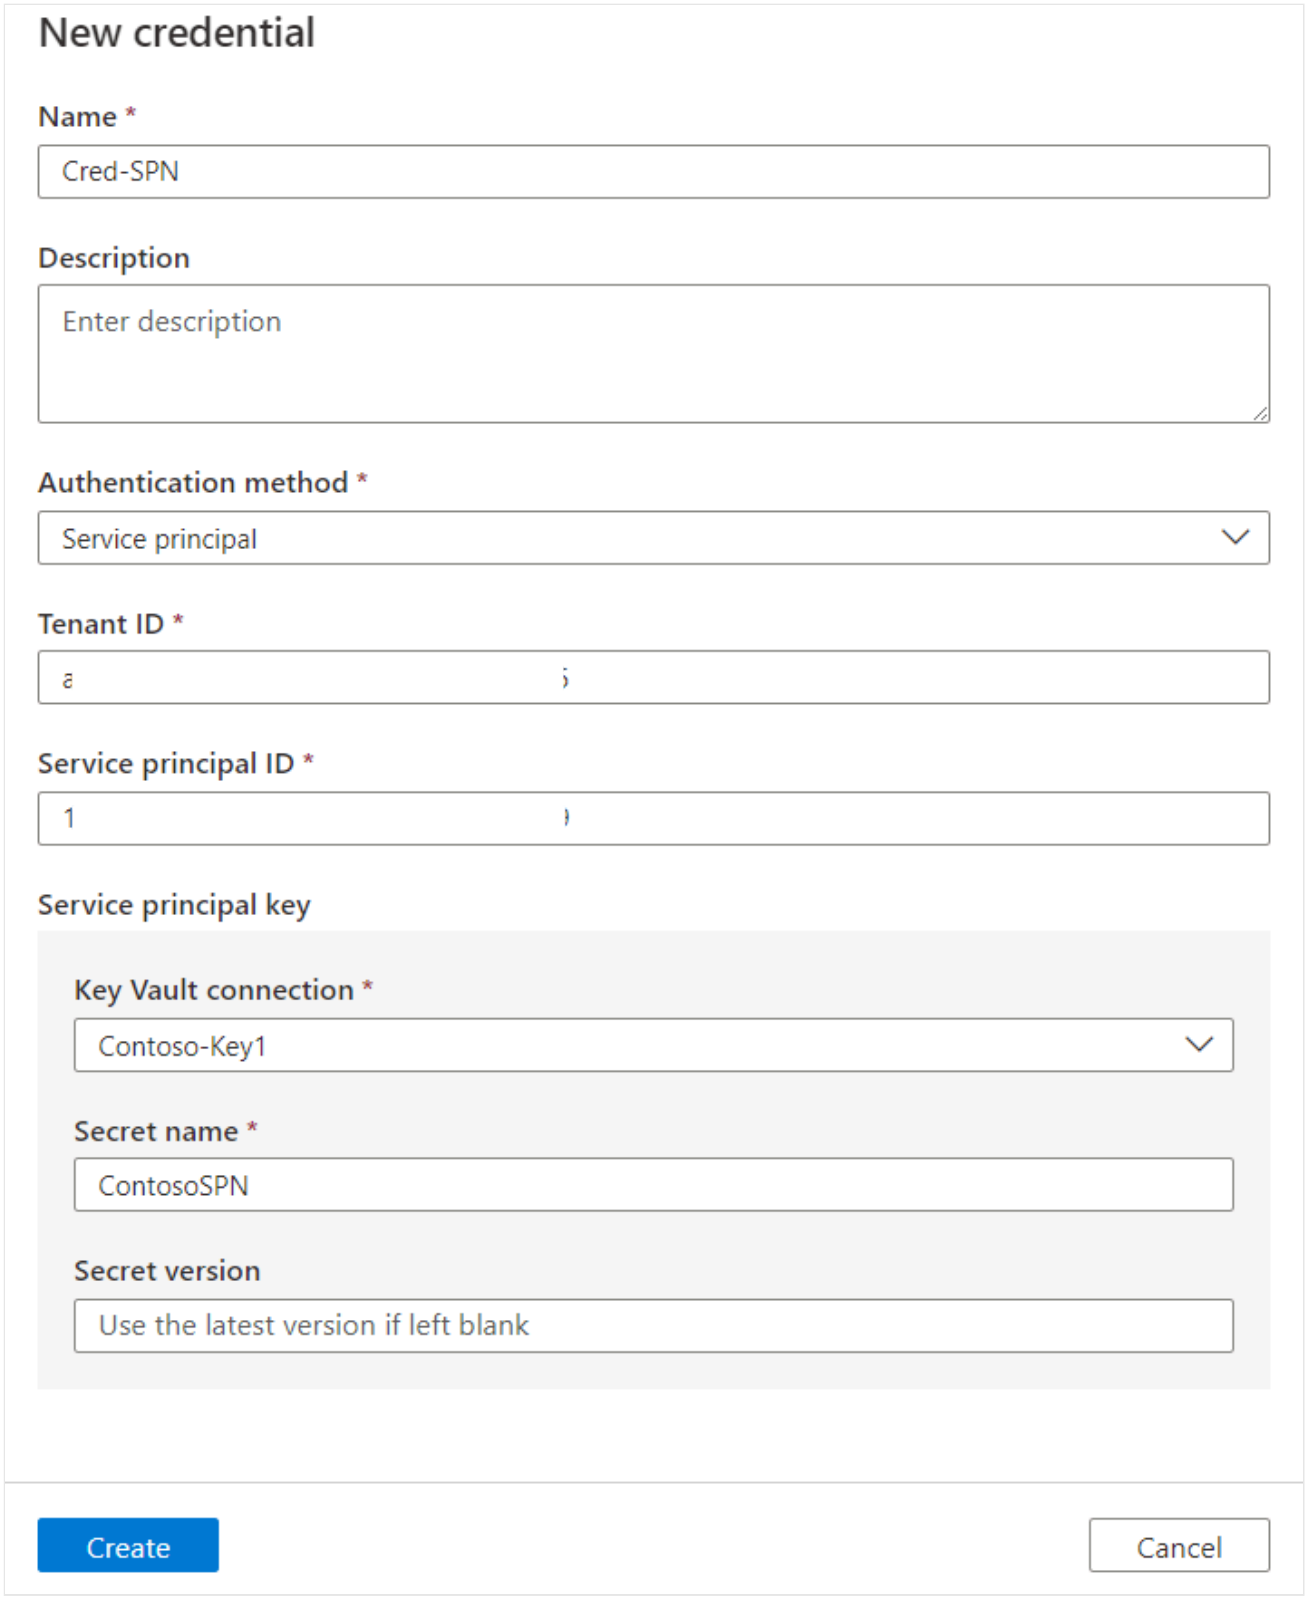
10. Under **Certificates & secrets**, create a new secret and save it securely for next steps.

11. In Azure portal, navigate to your Azure key vault.

12. Select **Settings** > **Secrets** and select **+ Generate/Import**.

13. Enter a name for the secret and for **Value**, type the newly created secret for the App registration. Select **Create** to complete.

14. If your key vault isn't connected to Microsoft Purview yet, you need to create a new key vault connection.



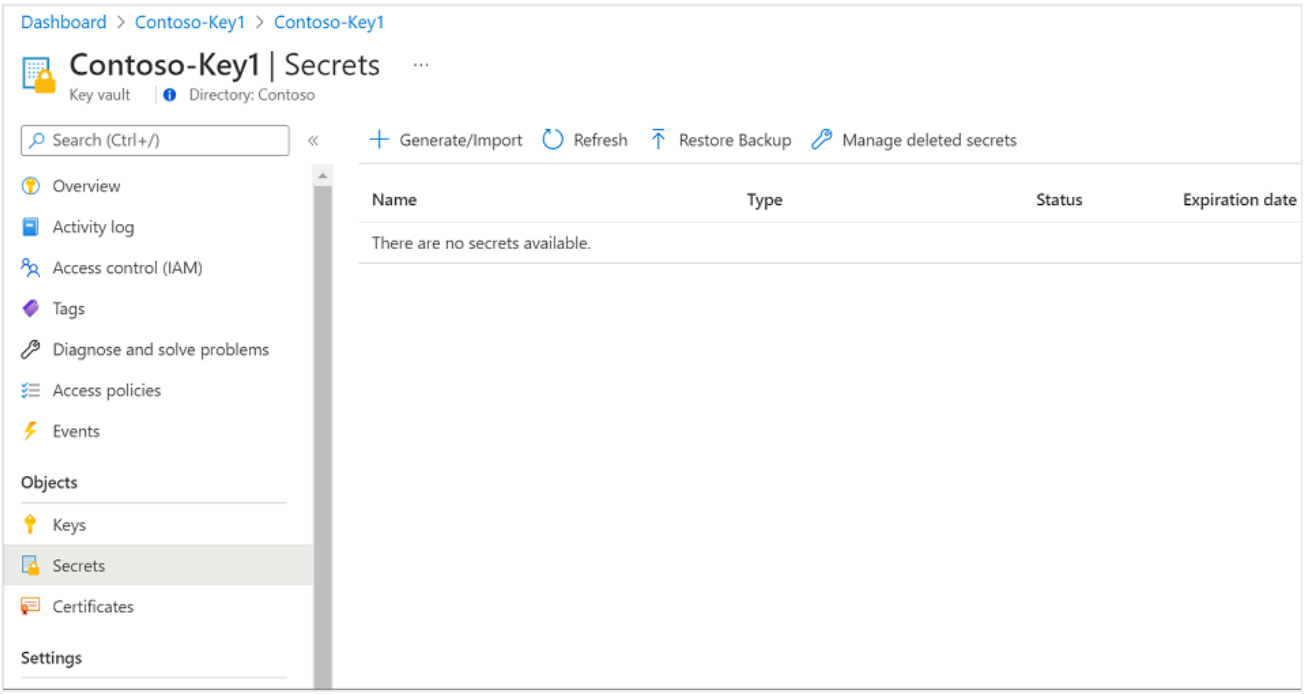
15. Next, in Microsoft Purview, go to the **Credentials** page under **Management** to create a new credential.

> **Tip**
>
> Alternatively, you can create a new credential during the scanning process.

16. Create your new Credential by selecting **+ New**.

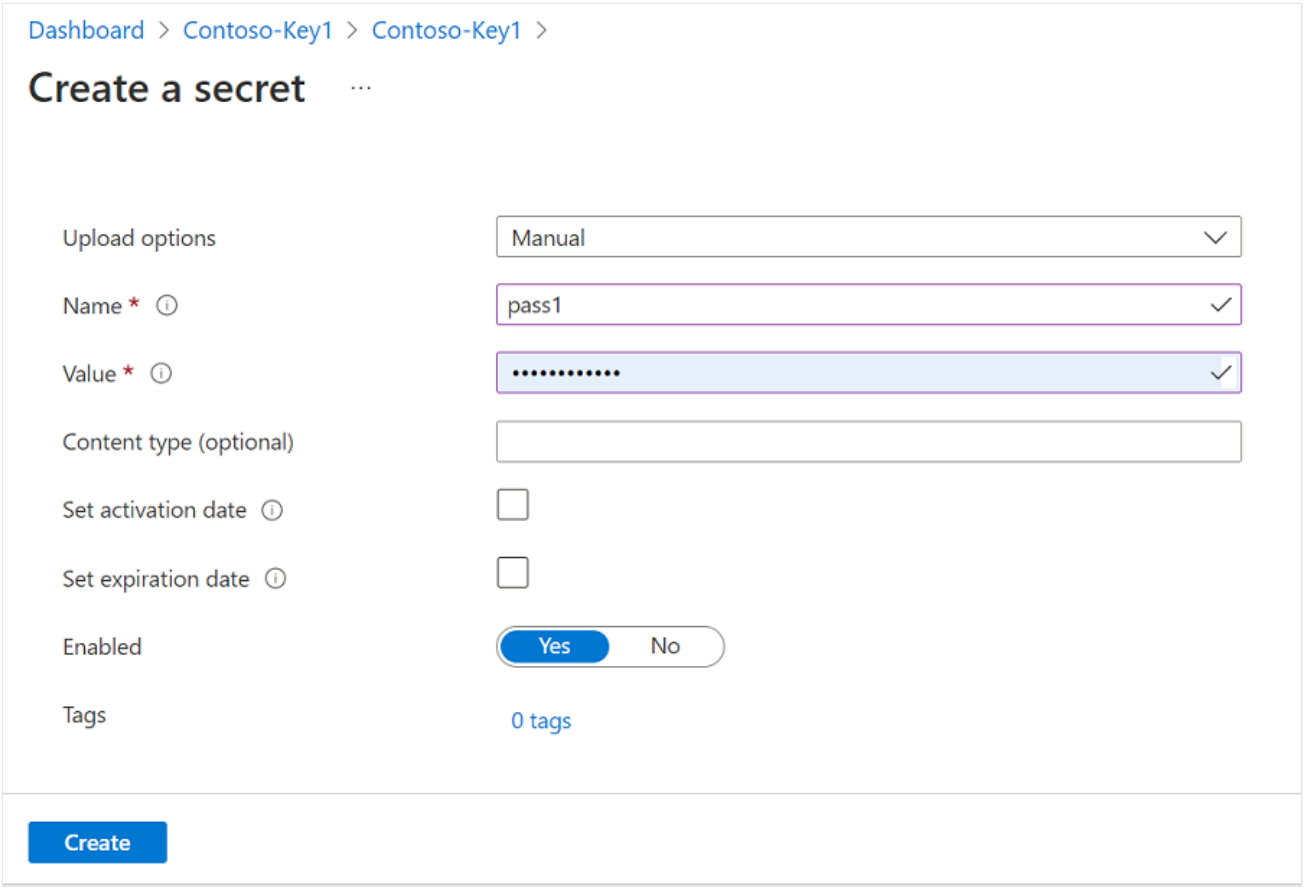
17. Provide required parameters:

    - **Name**: Provide a unique name for credential
    - **Authentication method**: Service principal
    - **Tenant ID**: Your Fabric tenant ID
    - **Client ID**: Use Service Principal Client ID (App ID) you created earlier
    - **Key Vault Connection**: the Microsoft Purview connection to the Key Vault where you created your secret earlier.
    - **Secret name**: the name of the secret you created earlier.



18. Once all the details have been filled in, select **Create**.

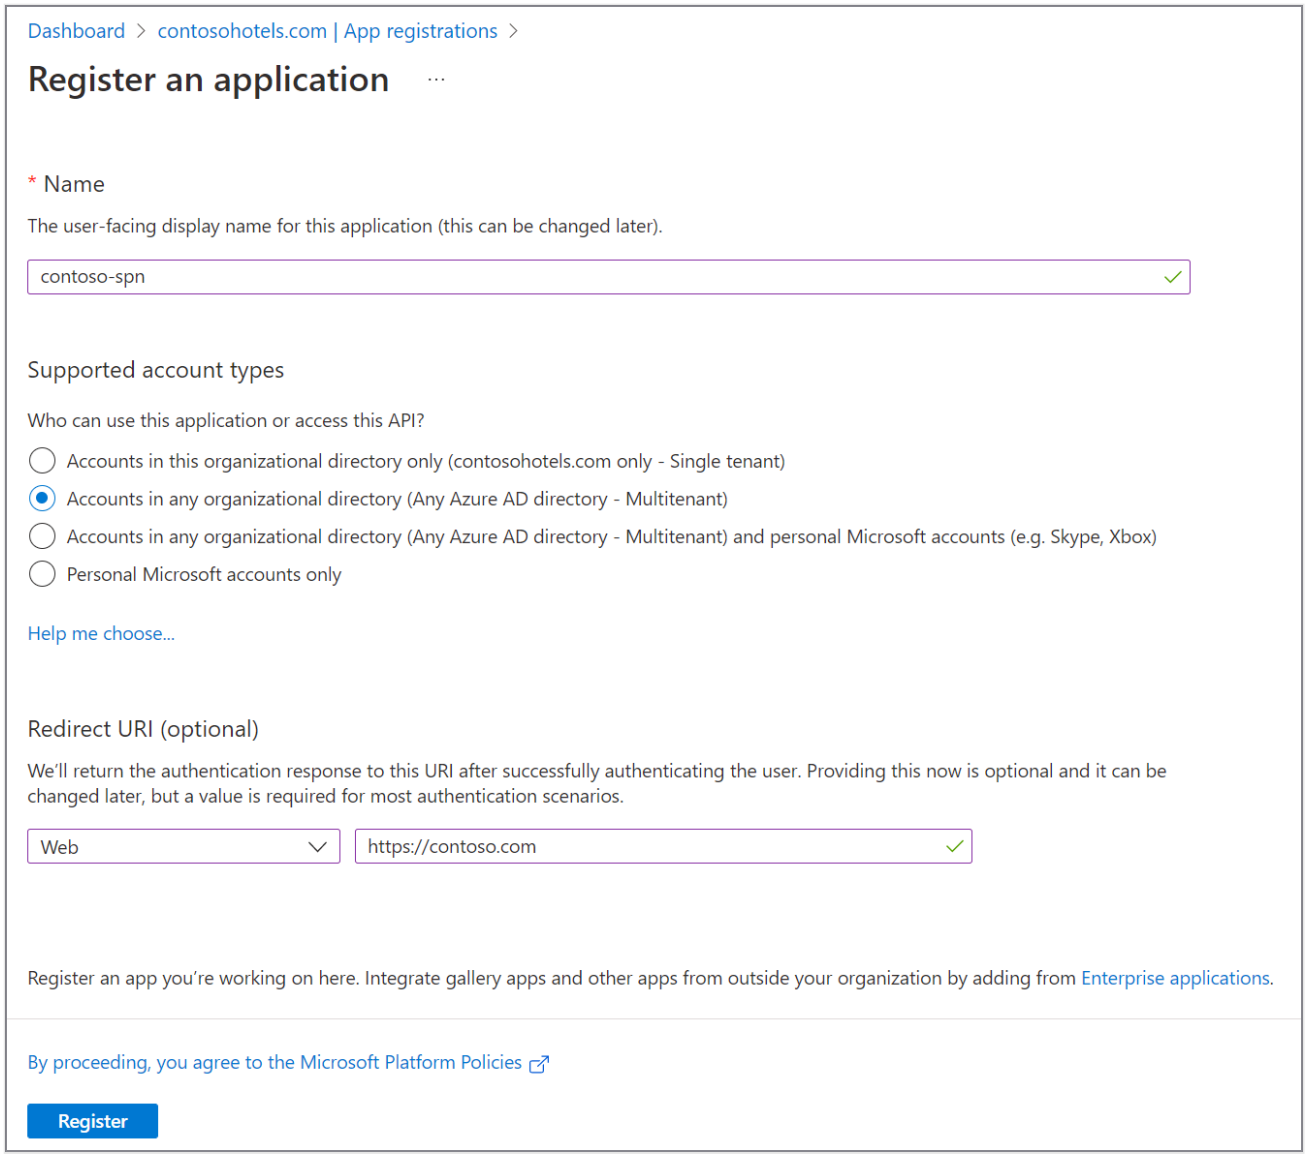
Delegated authentication



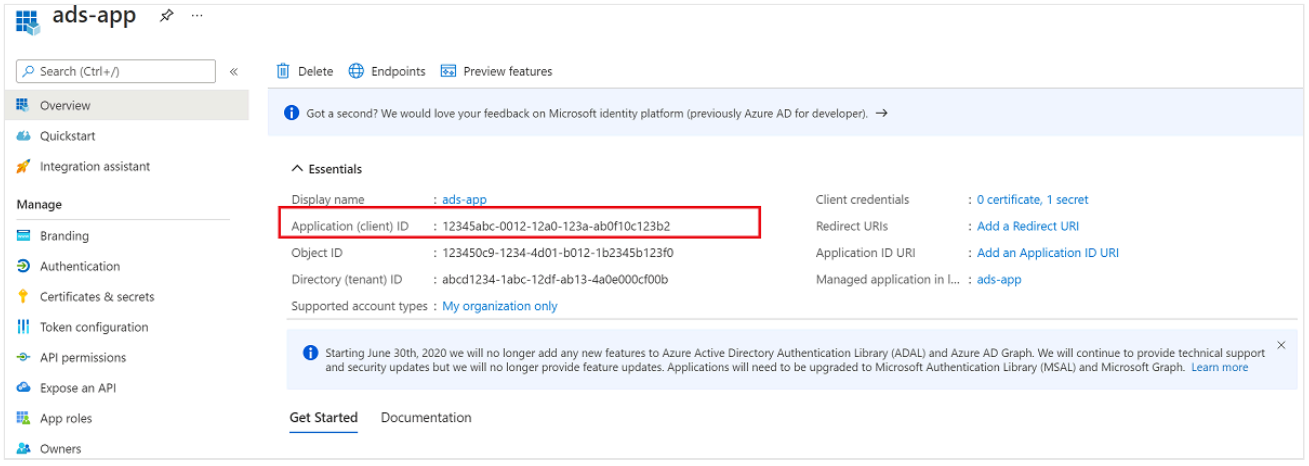
1. Create a user account in the Microsoft Entra tenant where the Fabric tenant is located, and assign the user to this role: **Fabric Administrator**. Take note of the username and sign in to change the password.

2. Go to the instance of Azure Key Vault in the tenant where Microsoft Purview is created.

3. Select **Settings** > **Secrets**, and then select **+ Generate/Import**.

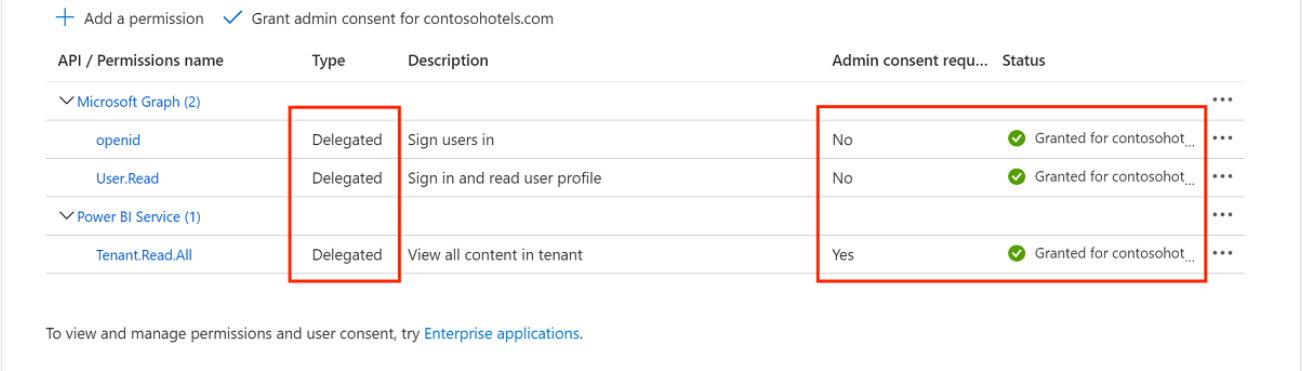


4. Enter a name for the secret. For **Value**, type the newly created password for the Microsoft Entra user. Select **Create** to complete.

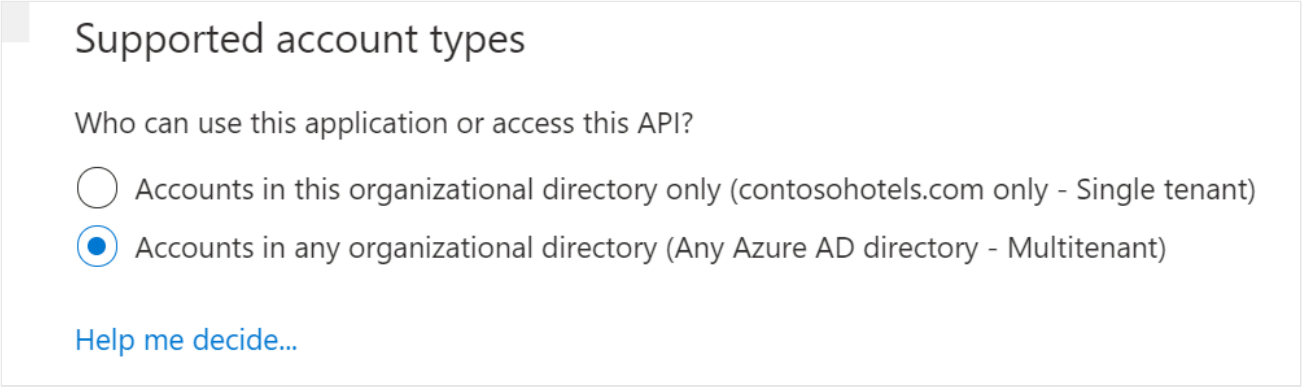


5. If your key vault isn't connected to Microsoft Purview yet, you need to create a new key vault connection.

6. Create an app registration in your Microsoft Entra tenant where Fabric is located. Provide a web URL in the **Redirect URI**.

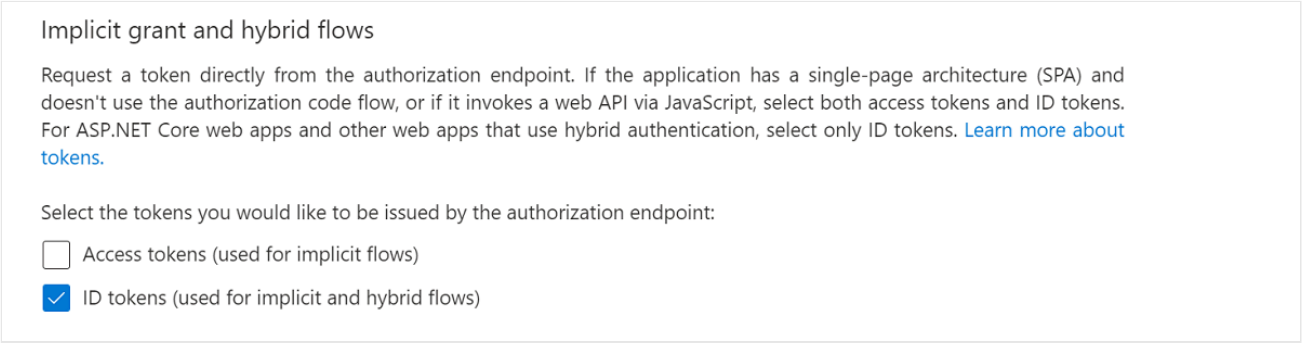


7. Take note of the client ID (app ID).



8. From the Microsoft Entra dashboard, select the newly created application, and then select **App permissions**. Assign the application the following delegated permissions, and grant

admin consent for the tenant:

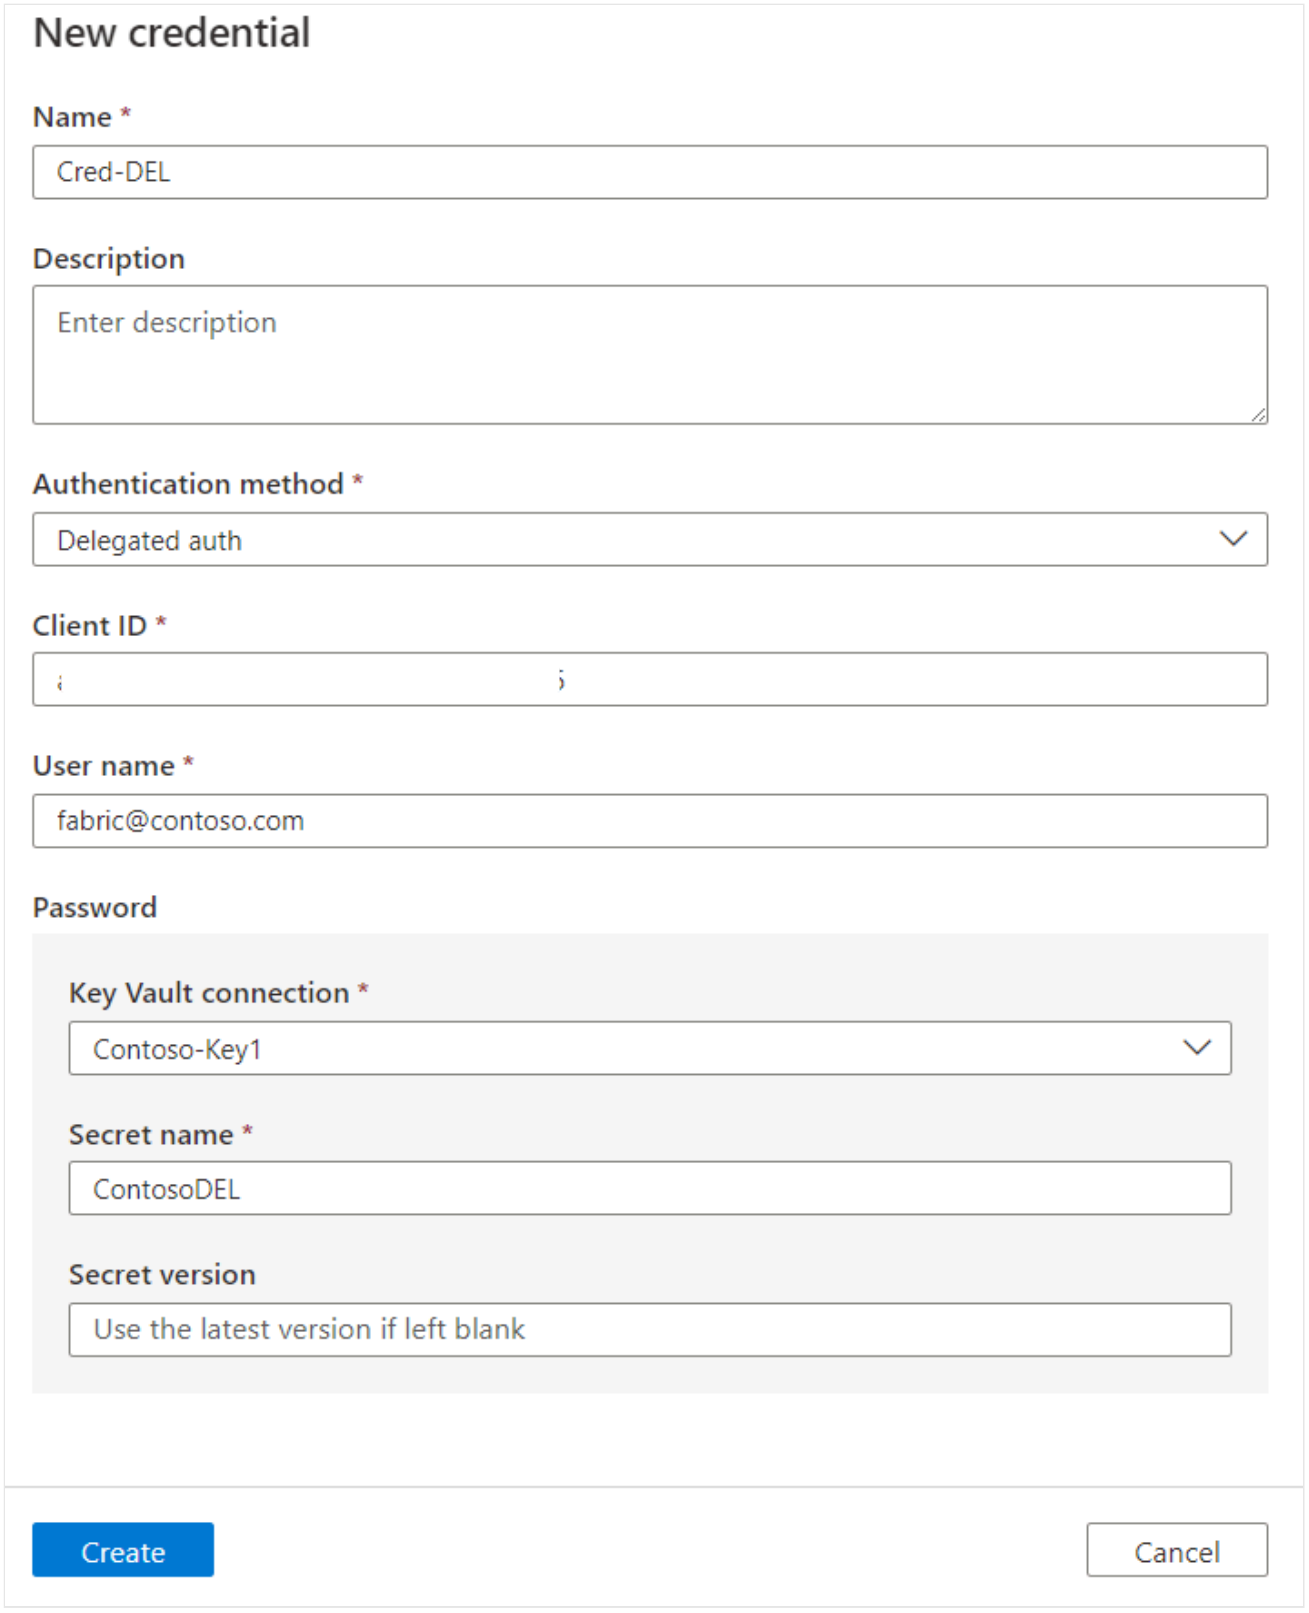


- Fabric Service Tenant.Read.All
- Microsoft Graph openid
- Microsoft Graph User.Read

9. From the Microsoft Entra dashboard, select the newly created application, and then select **Authentication**. Under **Supported account types**, select **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)**.

10. Under **Implicit grant and hybrid flows**, select **ID tokens (used for implicit and hybrid flows)**.

11. Under **Advanced settings**, enable **Allow Public client flows**.



12. Next, in Microsoft Purview, go to the **Credentials** page under **Management** to create a new credential.

> **Tip**
>
> Alternatively, you can create a new credential during the scanning process.

13. Create your new Credential by selecting **+ New**.

14. Provide required parameters:

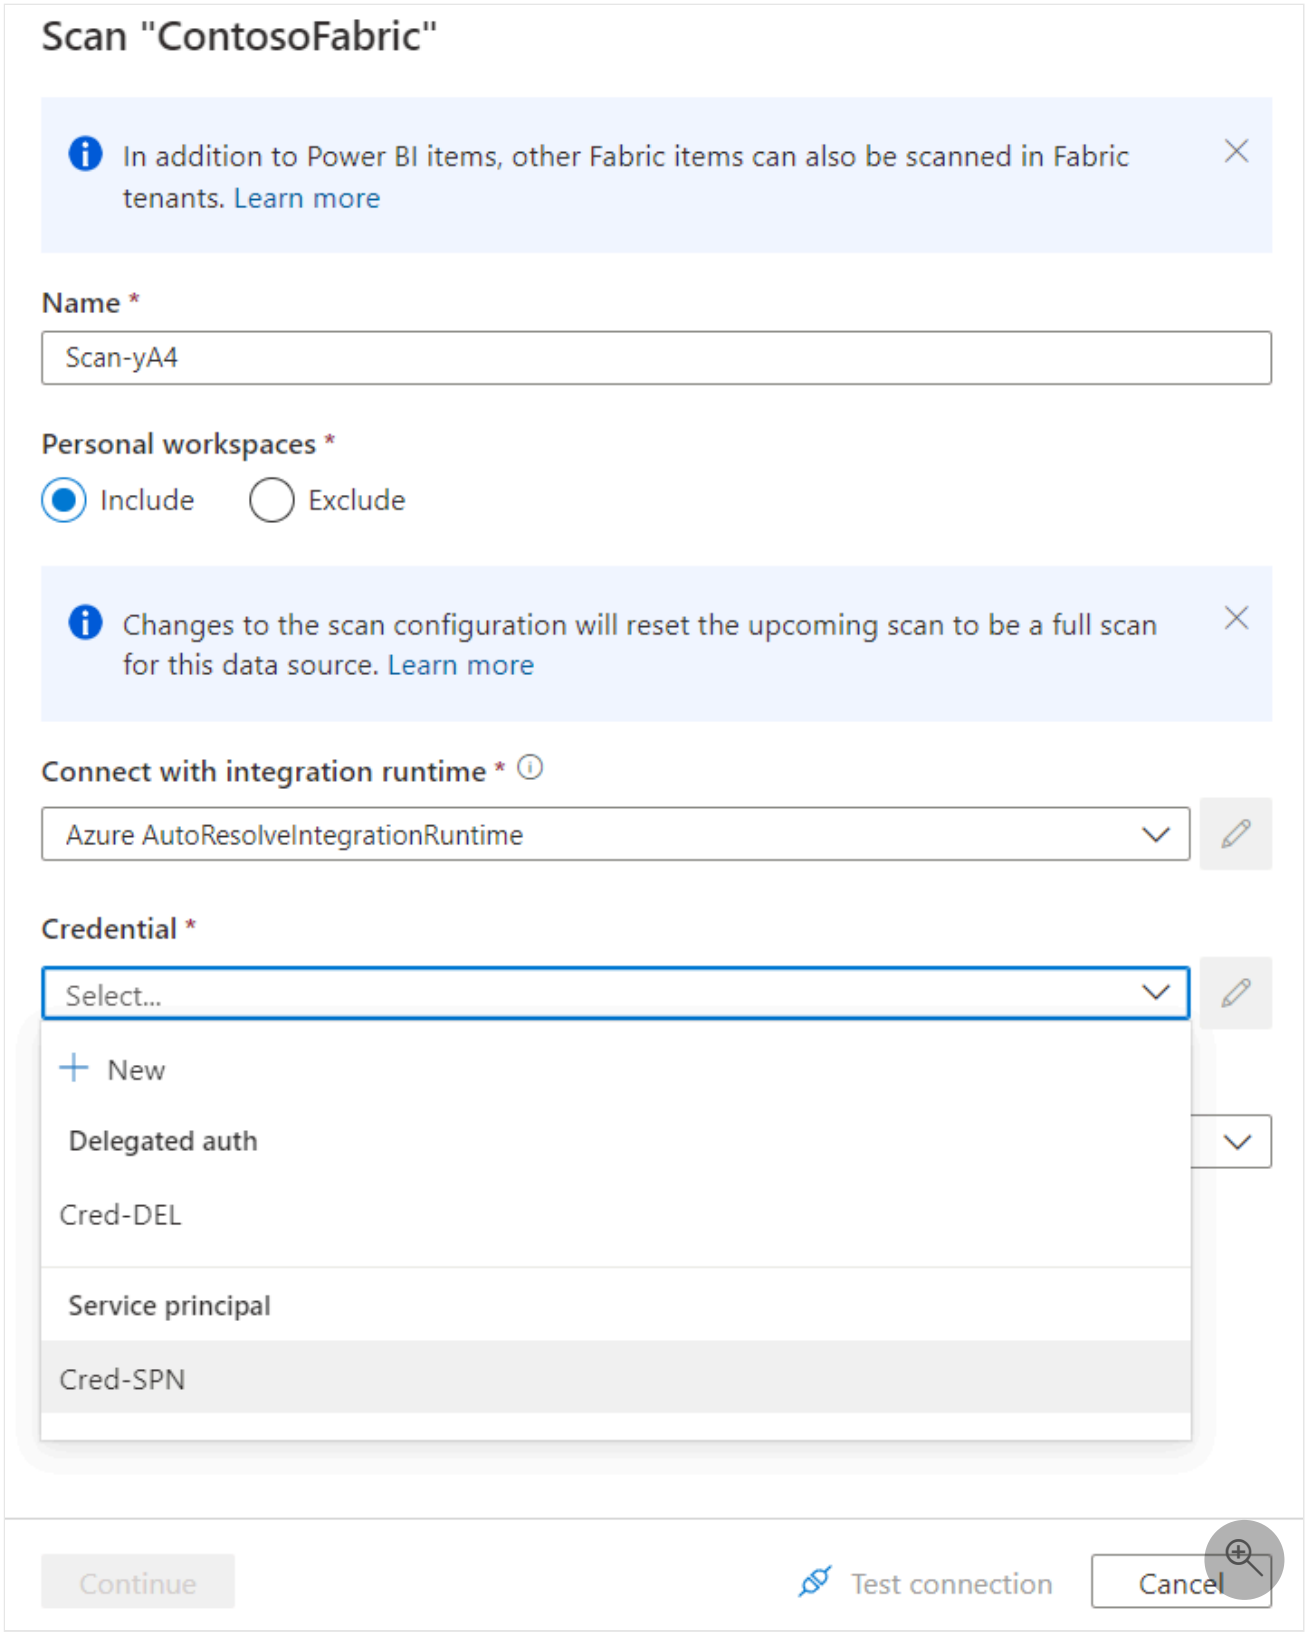
    - **Name**: Provide a unique name for credential
    - **Authentication method**: Delegated auth
    - **Client ID**: Use Service Principal Client ID (App ID) you created earlier
    - **User name**: Provide the username of Fabric Administrator you created earlier
    - **Key Vault Connection**: the Microsoft Purview connection to the Key Vault where you created your secret earlier.
    - **Secret name**: the name of the secret you created earlier.

15. Once all the details have been filled in, select **Create**.

Create scan

1. In the Microsoft Purview Studio, go to the **Data map** in the left menu. Go to **Sources**.

2. Select the registered Fabric source from cross-tenant.



3. Select + **New scan**.

4. Give your scan a name. Then select the option to include or exclude the personal workspaces.

   > **Note**
   >
   > If you switch the configuration of a scan to include or exclude a personal workspace, you trigger a full scan of the Fabric source.

5. Select **Azure AutoResolveIntegrationRuntime** from the dropdown list.

6. For the **Credential**, select the credential you created for your service principal or delegated authentication.

7. Select **Test connection** before continuing to the next steps.

   If the test fails, select **View Report** to see the detailed status and troubleshoot the problem:

   a. *Access - Failed* status means that the user authentication failed. Validate if the username and password are correct. Review if the credential contains the correct client (app) ID from the app registration.

   b. *Assets (+ lineage) - Failed* status means that the authorization between Microsoft Purview and Fabric has failed. Make sure that the user is added to the Fabric administrator role.

c. *Detailed metadata (Enhanced) - Failed* status means that the Fabric admin portal is disabled for the following setting: **Enhance admin APIs responses with detailed metadata**.

> **Tip**
>
> For more troubleshooting, see the deployment checklist to make sure you've covered every step in your scenario.

8. Set up a scan trigger. Your options are **Recurring** or **Once**.

9. On **Review new scan**, select **Save and run** to launch your scan.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ Note
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you registered your source, see these guides to learn more about Microsoft Purview and your data.

- Data estate insights in Microsoft Purview
- Search Unified Catalog

Connect to and manage Google BigQuery projects in Microsoft Purview

Article • 12/12/2024

This article outlines how to register Google BigQuery projects, and how to authenticate and interact with Google BigQuery in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

When scanning Google BigQuery source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Projects
  - Datasets
  - Tables including the columns
  - Views including the columns
- Fetching static lineage on assets relationships among tables and views.

When setting up scan, you can choose to scan an entire Google BigQuery project, or scope the scan to a subset of datasets matching the given name(s) or name pattern(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

- Currently, Microsoft Purview only supports scanning Google BigQuery datasets in US multi-regional location. If the specified dataset is in other location e.g. us-east1

or EU, you will observe scan completes but no assets shown up in Microsoft Purview.
- When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - Download and unzip the BigQuery JDBC driver on the machine where your self-hosted integration runtime is running. Note down the folder path which you will use to set up the scan.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.
    - Download and unzip the BigQuery JDBC driver on the machine where your self-hosted integration runtime is running. Note down the folder path which you will use to set up the scan.

> **Note**
>
> The driver should be accessible by the self-hosted integration runtime. By default, self-hosted integration runtime uses local service account "NT SERVICE\DIAHostService". Make sure it has "Read and execute" and "List folder contents" permission to the driver folder.

Required permissions for scan

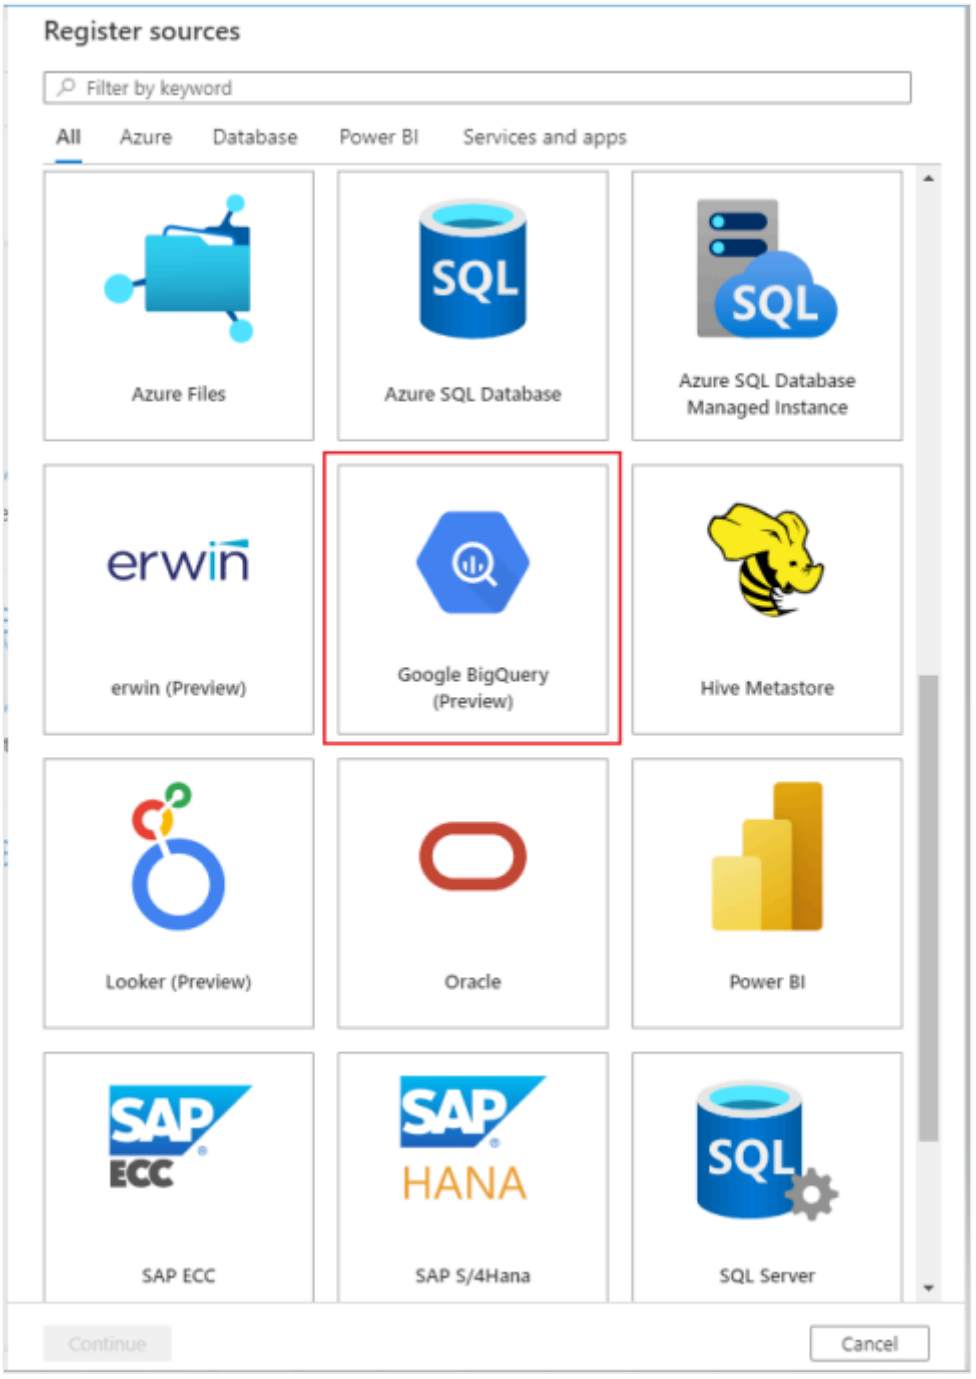
The Google BigQuery service account you use for scan needs to have both BigQuery Metadata Viewer and BigQuery Job User IAM roles on the project(s) you want to scan. These permissions are required because Microsoft Purview extracts the metadata by reading the Google BigQuery database system tables (e.g. INFORMATION_SCHEMA). And the underlying Google BigQuery JDBC driver creates a BigQuery job when it needs to read from these system tables.

Microsoft Purview uses Oauth 2.0 protocol for accessing Google BigQuery service. Set up the credential by following the instruction in Create and run scan section.

Register

This section describes how to register a Google BigQuery project in Microsoft Purview using the Microsoft Purview governance portal.

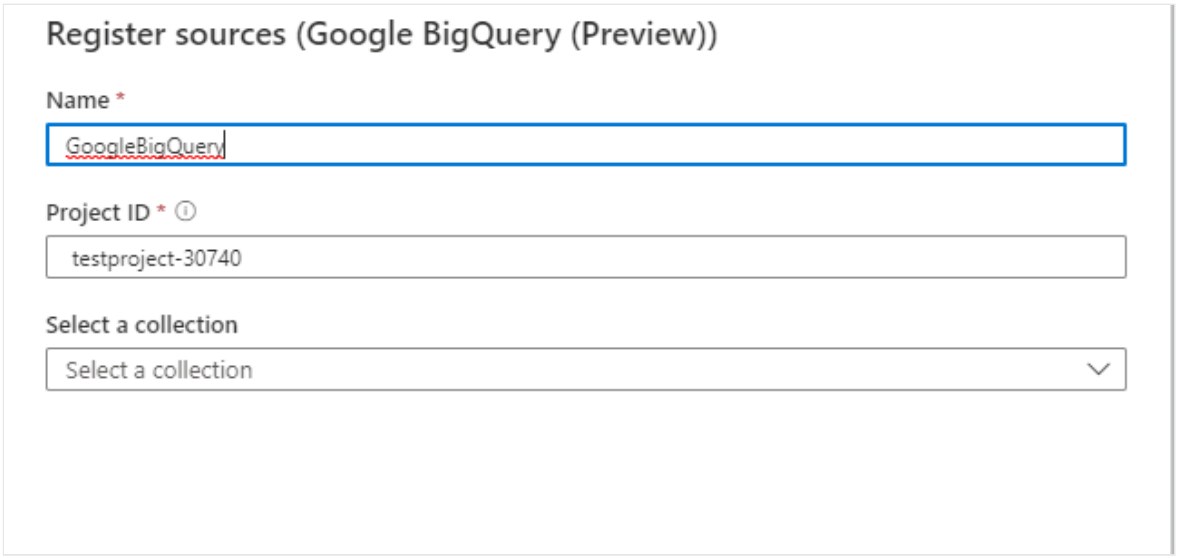
Steps to register



1. Open the Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.



3. Select **Register.**

4. On Register sources, select **Google BigQuery** . Select **Continue.**

On the Register sources (Google BigQuery) screen, do the following:

1. Enter a **Name** that the data source will be listed within the Catalog.
2. Enter the **ProjectID.** This should be a fully qualified project ID. For example, mydomain.com:myProject
3. Select a collection from the list.
4. Select **Register**.

Scan

Follow the steps below to scan a Google BigQuery project to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Create and run scan

1. In the Management Center, select Integration runtimes. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned in prerequisites.

2. Navigate to **Sources**.

3. Select the registered **BigQuery** project.

4. Select **+ New scan**.

5. Provide the below details:

    a. **Name**: The name of the scan

    b. **Connect via integration runtime**: Select the configured self-hosted integration runtime

    c. **Credential**: While configuring BigQuery credential, make sure to:

    - Select **Basic Authentication** as the Authentication method
    - Provide the email ID of the service account in the User name field. For example, `xyz\@developer.gserviceaccount.com`

- Follow below steps to generate the private key, copy the entire JSON key file then store it as the value of a Key Vault secret.

To create a new private key from Google's cloud platform:

i. In the navigation menu, select IAM & Admin -> Service Accounts -> Select a project ->

ii. Select the email address of the service account that you want to create a key for.

iii. Select the **Keys** tab.

iv. Select the **Add key** drop-down menu, then select Create new key.

v. Choose JSON format.

> ⓘ **Note**
>
> The contents of the private key are saved in a temp file on the VM when scanning processes are running. This temp file is deleted after the scans are successfully completed. In the event of a scan failure, the system will continue to retry until success. Please make sure access is appropriately restricted on the VM where SHIR is running.

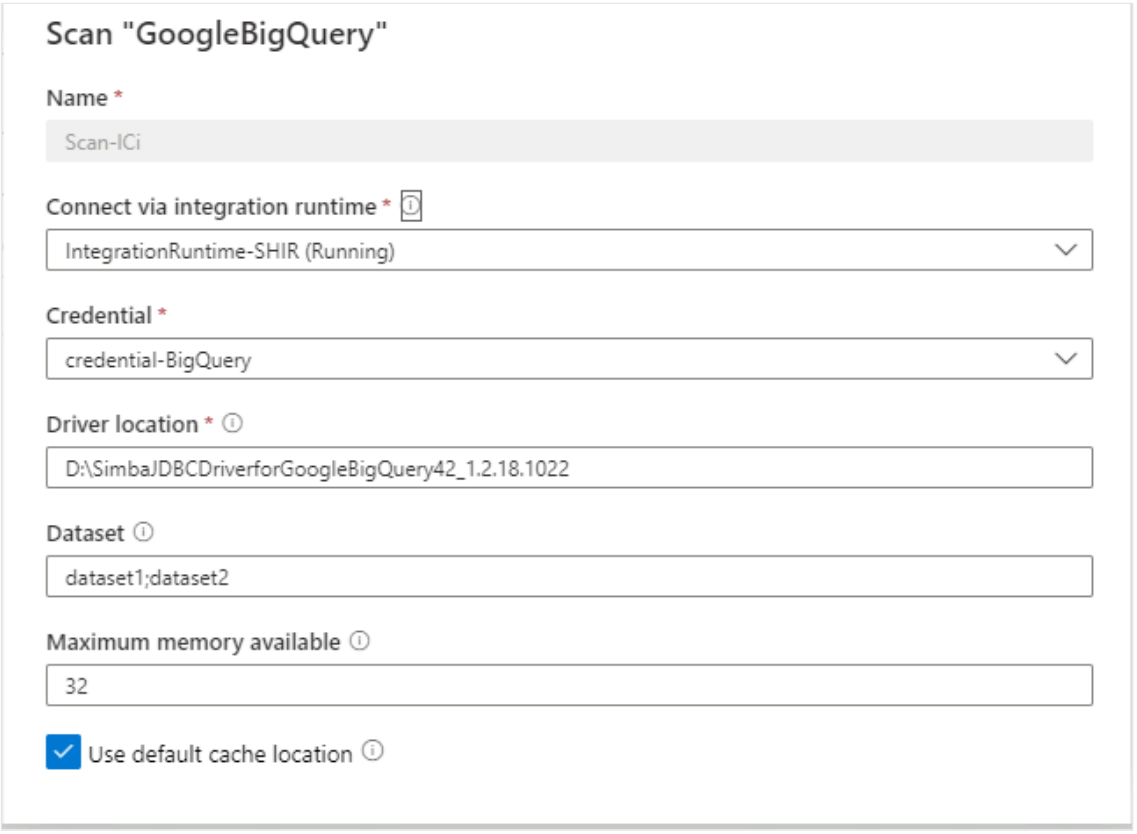
To understand more on credentials, refer to the link here.

d. **Driver location**: Specify the path to the JDBC driver location in your machine where self-host integration runtime is running. For example: `D:\Drivers\GoogleBigQuery`.

i. For self-hosted integration runtime on a local machine: `D:\Drivers\GoogleBigQuery`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime;; learn more from prerequisites section.

ii. For Kubernetes-supported self-hosted integration runtime: `./drivers/GoogleBigQuery`. It's the path to valid JAR folder location. The value must be a valid relative file path. Please refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

e. **Dataset**: Specify a list of BigQuery datasets to import. For example, `dataset1;dataset2`. When the list is empty, all available datasets are imported. Acceptable dataset name patterns can be static names or contain wildcard %.



Example: `A%;%B;%C%;D`

- Start with A or

- end with B or
- contain C or
- equal D

Usage of NOT and special characters aren't acceptable.

f. **Maximum memory available**: Maximum memory (in GB) available on your VM to be used by scanning processes. This is dependent on the size of Google BigQuery project to be scanned.

6. Select **Test connection.**

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Google BigQuery source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Google BigQuery lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage HDFS in Microsoft Purview

Article • 06/27/2024

This article outlines how to register Hadoop Distributed File System (HDFS), and how to authenticate and interact with HDFS in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

When scanning HDFS source, Microsoft Purview supports extracting technical metadata including HDFS:

- Namenode
- Folders
- Files
- Resource sets

When setting up scan, you can choose to scan the entire HDFS or selective folders. Learn about the supported file format here.

The connector uses *webhdfs* protocol to connect to HDFS and retrieve metadata. MapR Hadoop distribution is not supported.

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - To set up your environment to enable Kerberos authentication, see the Use Kerberos authentication for the HDFS connector section.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.
    - To set up your environment to enable Kerberos authentication, see the Use Kerberos authentication for the HDFS connector section.

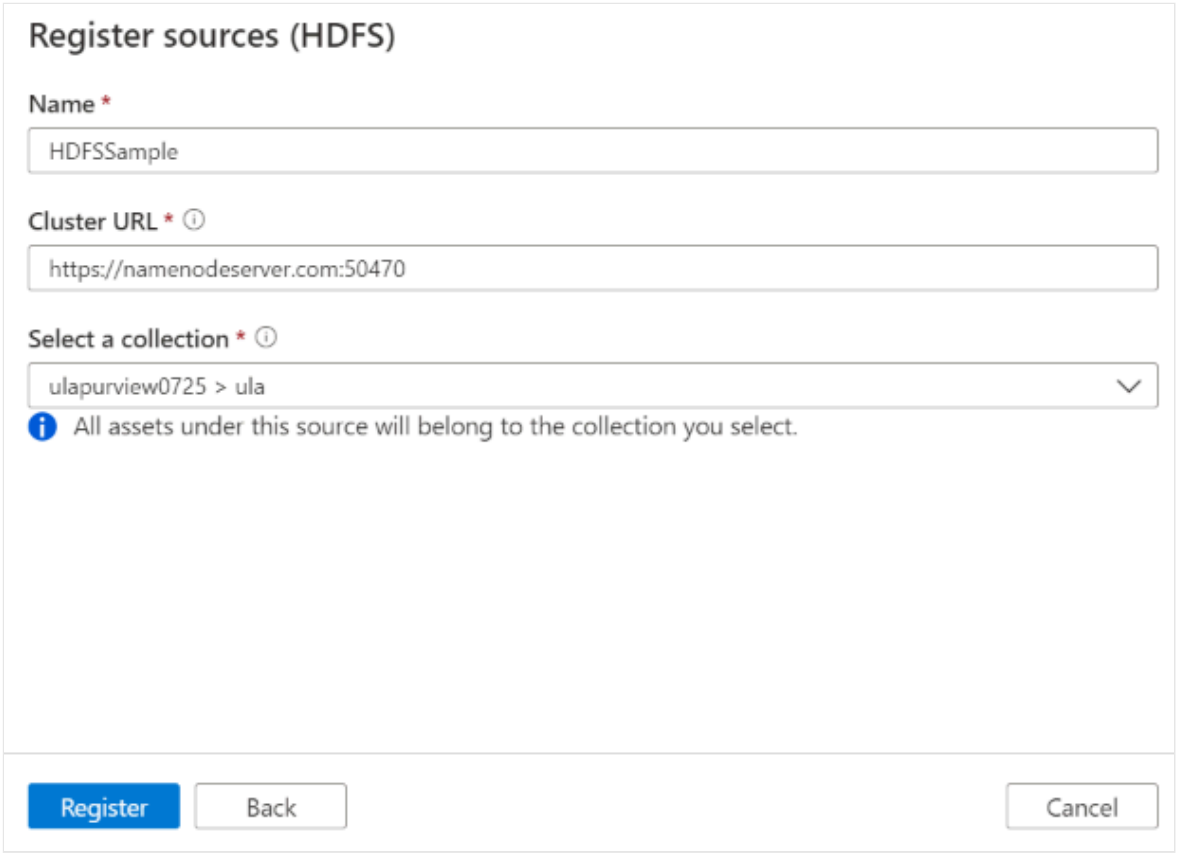
Register

This section describes how to register HDFS in Microsoft Purview using the Microsoft Purview governance portal.

Steps to register

To register a new HDFS source in Microsoft Purview Unified Catalog, follow these steps:

1. Navigate to your Microsoft Purview account in the Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**
4. On Register sources, select **HDFS**. Select **Continue**.



On the **Register sources (HDFS)** screen, follow these steps:

1. Enter a **Name** that the data source will be listed within the Catalog.

2. Enter the **Cluster URL** of the HDFS NameNode in the form of `https://<namenode>:<port>` or `http://<namenode>:<port>`, e.g. `https://namenodeserver.com:50470` or `http://namenodeserver.com:50070`.

3. Select a collection from the list.

4. Finish to register the data source.

Scan

Follow the steps below to scan HDFS to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Authentication for a scan

The supported authentication type for an HDFS source is **Kerberos authentication**.

Create and run scan

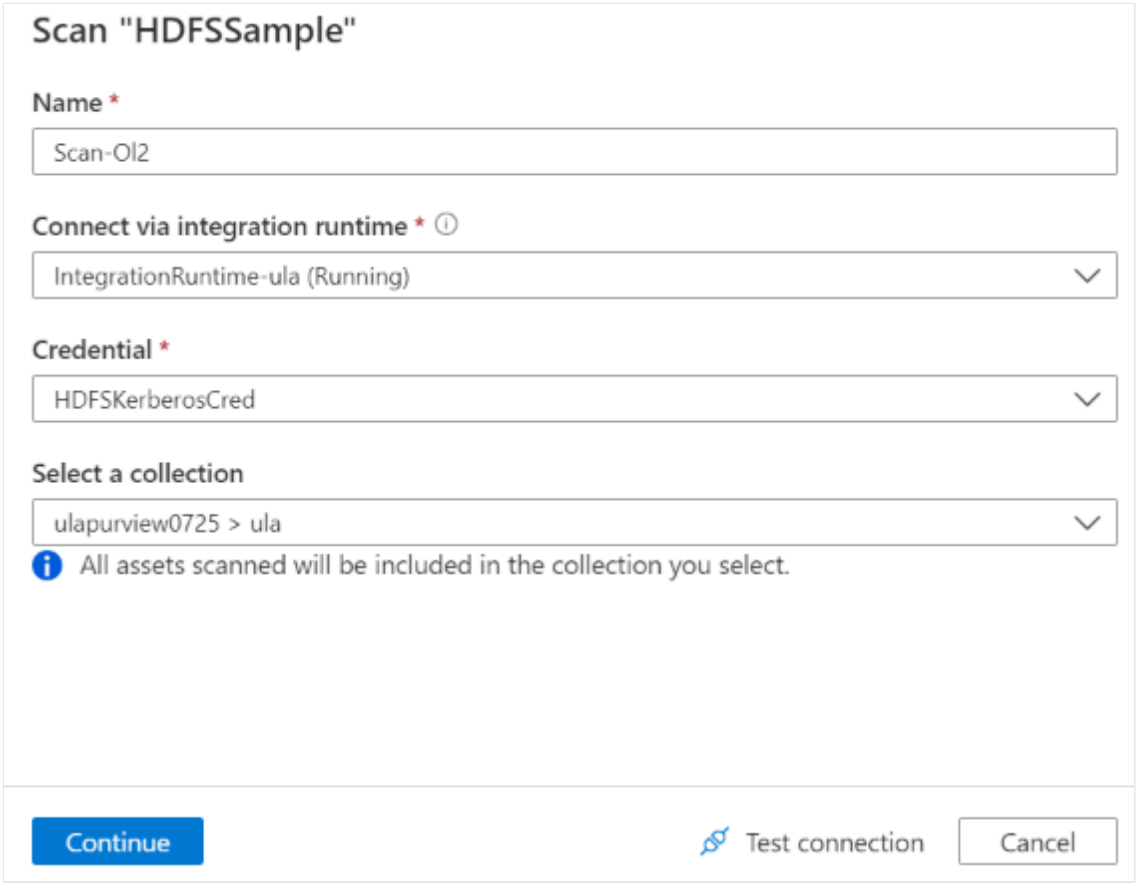
To create and run a new scan, follow these steps:

1. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned in prerequisites to create a self-hosted integration runtime.

2. Navigate to **Sources**.

3. Select the registered HDFS source.

4. Select + **New scan**.



5. On "**Scan *source_name***"" page, provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the configured self-hosted integration runtime. See setup requirements in Prerequisites section.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

   - Select **Kerberos Authentication** while creating a credential.
   - Provide the user name in the format of `<username>@<domain>.com` in the User name input field. Learn more from Use Kerberos authentication for the HDFS connector.
   - Store the user password used to connect to HDFS in the secret key.

6. Select **Test connection**.

7. Select **Continue**.

8. On "**Scope your scan**" page, select the path(s) that you want to scan.

9. On "**Select a scan rule set**" page, select the scan rule set you want to use for schema extraction and classification. You can choose between the system default, existing custom rule sets, or create a new rule set inline. Learn more from Create a scan rule set.

10. On "**Set a scan trigger**" page, choose your **scan trigger**. You can set up a schedule or ran the scan once.

11. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Use Kerberos authentication for the HDFS connector

There are two options for setting up the on-premises environment to use Kerberos authentication for the HDFS connector. You can choose the one that better fits your situation.

- Option 1: Join a self-hosted integration runtime machine in the Kerberos realm
- Option 2: Enable mutual trust between the Windows domain and the Kerberos realm

For either option, make sure you turn on webhdfs for Hadoop cluster:

1. Create the HTTP principal and keytab for webhdfs.

   > **Important**
   >
   > The HTTP Kerberos principal must start with "**HTTP/**" according to Kerberos HTTP SPNEGO specification. Learn more from here.

   Bash

   ```
   Kadmin> addprinc -randkey HTTP/<namenode hostname>@<REALM.COM>
   Kadmin> ktadd -k /etc/security/keytab/spnego.service.keytab
   HTTP/<namenode hostname>@<REALM.COM>
   ```

2. HDFS configuration options: add the following three properties in `hdfs-site.xml`.

   XML

   ```
   <property>
       <name>dfs.webhdfs.enabled</name>
       <value>true</value>
   </property>
   <property>
       <name>dfs.web.authentication.kerberos.principal</name>
       <value>HTTP/_HOST@<REALM.COM></value>
   </property>
   <property>
       <name>dfs.web.authentication.kerberos.keytab</name>
       <value>/etc/security/keytab/spnego.service.keytab</value>
   </property>
   ```

Option 1: Join a self-hosted integration runtime machine in the Kerberos realm

Requirements

- The self-hosted integration runtime machine needs to join the Kerberos realm and can't join any Windows domain.

How to configure

On the KDC server:

Create a principal, and specify the password.

> **Important**
>
> The username should not contain the hostname.

```
Bash

Kadmin> addprinc <username>@<REALM.COM>
```

On the self-hosted integration runtime machine:

1. Run the Ksetup utility to configure the Kerberos Key Distribution Center (KDC) server and realm.

   The machine must be configured as a member of a workgroup, because a Kerberos realm is different from a Windows domain. You can achieve this configuration by setting the Kerberos realm and adding a KDC server by running the following commands. Replace *REALM.COM* with your own realm name.

   ```
   Windows Command Prompt

   C:> Ksetup /setdomain REALM.COM
   C:> Ksetup /addkdc REALM.COM <your_kdc_server_address>
   ```

   After you run these commands, restart the machine.

2. Verify the configuration with the `Ksetup` command. The output should be like:

   ```
   Windows Command Prompt
   ```

```
C:> Ksetup
default realm = REALM.COM (external)
REALM.com:
    kdc = <your_kdc_server_address>
```

In your Purview account:

- Configure a credential with Kerberos authentication type with your Kerberos principal name and password to scan the HDFS. For configuration details, check the credential setting part in Scan section.

Option 2: Enable mutual trust between the Windows domain and the Kerberos realm

Requirements

- The self-hosted integration runtime machine must join a Windows domain.
- You need permission to update the domain controller's settings.

How to configure

> **Note**
>
> Replace REALM.COM and AD.COM in the following tutorial with your own realm name and domain controller.

On the KDC server:

1. Edit the KDC configuration in the *krb5.conf* file to let KDC trust the Windows domain by referring to the following configuration template. By default, the configuration is located at */etc/krb5.conf*.

```
config
```

```
[logging]
 default = FILE:/var/log/krb5libs.log
 kdc = FILE:/var/log/krb5kdc.log
 admin_server = FILE:/var/log/kadmind.log

[libdefaults]
 default_realm = REALM.COM
 dns_lookup_realm = false
 dns_lookup_kdc = false
```

```
 ticket_lifetime = 24h
 renew_lifetime = 7d
 forwardable = true

[realms]
 REALM.COM = {
  kdc = node.REALM.COM
  admin_server = node.REALM.COM
 }
AD.COM = {
 kdc = windc.ad.com
 admin_server = windc.ad.com
}

[domain_realm]
 .REALM.COM = REALM.COM
 REALM.COM = REALM.COM
 .ad.com = AD.COM
 ad.com = AD.COM

[capaths]
 AD.COM = {
  REALM.COM = .
 }
```

After you configure the file, restart the KDC service.

2. Prepare a principal named *krbtgt/REALM.COM@AD.COM* in the KDC server with the following command:

```
Windows Command Prompt

Kadmin> addprinc krbtgt/REALM.COM@AD.COM
```

3. In the *hadoop.security.auth_to_local* HDFS service configuration file, add `RULE:[1:$1@$0](.*\@AD.COM)s/\@.*//`.

On the domain controller:

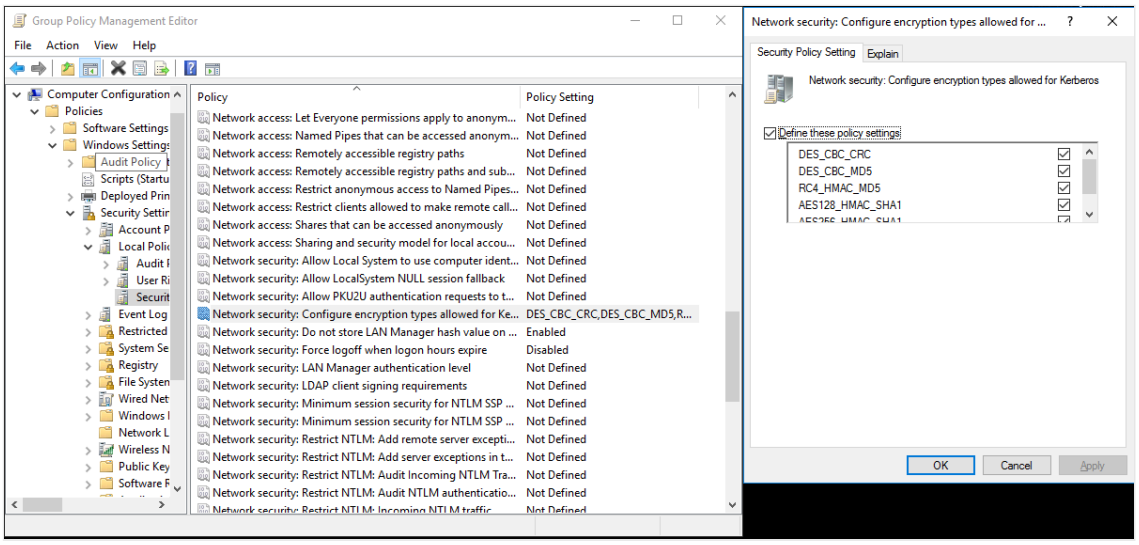
1. Run the following `Ksetup` commands to add a realm entry:

```
Windows Command Prompt

C:> Ksetup /addkdc REALM.COM <your_kdc_server_address>
C:> ksetup /addhosttorealmmap HDFS-service-FQDN REALM.COM
```

2. Establish trust from the Windows domain to the Kerberos realm. [password] is the password for the principal *krbtgt/REALM.COM@AD.COM*.

Windows Command Prompt



```
C:> netdom trust REALM.COM /Domain: AD.COM /add /realm /password:
[password]
```

3. Select the encryption algorithm that's used in Kerberos.

   a. Select **Server Manager** > **Group Policy Management** > **Domain** > **Group Policy Objects** > **Default or Active Domain Policy**, and then select **Edit**.

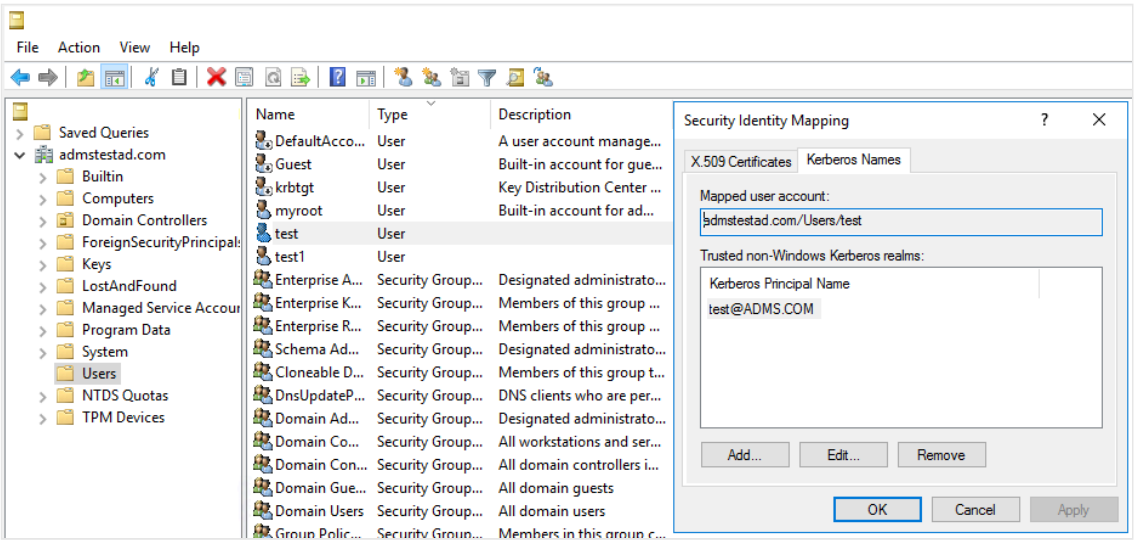
   b. On the **Group Policy Management Editor** pane, select **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Local Policies** > **Security Options**, and then configure **Network security: Configure Encryption types allowed for Kerberos**.

   c. Select the encryption algorithm you want to use when you connect to the KDC server. You can select all the options.

   d. Use the `Ksetup` command to specify the encryption algorithm to be used on the specified realm.

Windows Command Prompt

```
C:> ksetup /SetEncTypeAttr REALM.COM DES-CBC-CRC DES-CBC-MD5 RC4-
HMAC-MD5 AES128-CTS-HMAC-SHA1-96 AES256-CTS-HMAC-SHA1-96
```



4. Create the mapping between the domain account and the Kerberos principal, so that you can use the Kerberos principal in the Windows domain.

   a. Select **Administrative tools** > **Active Directory Users and Computers**.

   b. Configure advanced features by selecting **View** > **Advanced Features**.

c. On the **Advanced Features** pane, right-click the account to which you want to create mappings and, on the **Name Mappings** pane, select the **Kerberos Names** tab.

d. Add a principal from the realm.

On the self-hosted integration runtime machine:

- Run the following `Ksetup` commands to add a realm entry.

```
Windows Command Prompt

C:> Ksetup /addkdc REALM.COM <your_kdc_server_address>
C:> ksetup /addhosttorealmmap HDFS-service-FQDN REALM.COM
```

In your Purview account:

- Configure a credential with Kerberos authentication type with your Kerberos principal name and password to scan the HDFS. For configuration details, check the credential setting part in Scan section.

Known limitations

Currently, HDFS connector doesn't support custom resource set pattern rule for advanced resource set, the built-in resource set patterns will be applied.

Sensitivity label is not yet supported.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

Connect to and manage Hive Metastore databases in Microsoft Purview

Article • 12/12/2024

This article outlines how to register Hive Metastore databases, and how to authenticate and interact with Hive Metastore databases in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported Hive versions are 2.x to 3.x. The supported platforms are Apache Hadoop, Cloudera, and Hortonworks. If you want to scan Azure Databricks, you're suggested to use the Azure Databricks connector, which is more compatible and user friendly.

When scanning Hive metastore source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Databases
  - Tables including the columns, foreign keys, unique constraints, and storage description
  - Views including the columns and storage description
- Fetching static lineage on assets relationships among tables and views.

When setting up scan, you can choose to scan an entire Hive metastore database, or scope the scan to a subset of schemas matching the given name(s) or name pattern(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

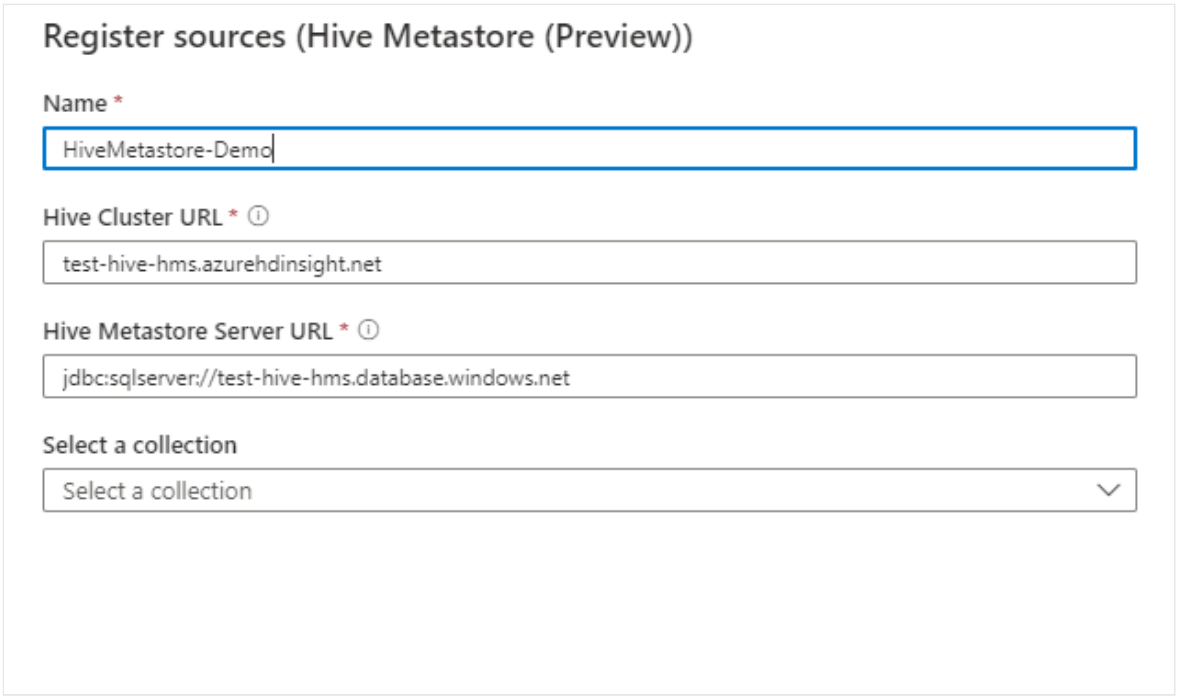
Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
      - Download the Hive Metastore database's JDBC driver on the machine where your self-hosted integration runtime is running. For example, if the database is *mssql*, download Microsoft's JDBC driver for SQL Server. Note down the folder path that you'll use to set up the scan.
    - **To use a kubernetes supported self-hosted integration runtime:**
      - Follow the article to create and configure a kubernetes supported integration runtime.
      - Download the Hive Metastore database's JDBC driver on the machine where your self-hosted integration runtime is running. For example, if the

database is *mssql*, download Microsoft's JDBC driver for SQL Server. Note down the folder path that you'll use to set up the scan.



> **Note**
>
> The JDBC driver should be accessible by the self-hosted integration runtime. By default, self-hosted integration runtime uses local service account "NT SERVICE\DIAHostService". Make sure it has "Read and execute" and "List folder contents" permission to the driver folder.

Register

This section describes how to register a Hive Metastore database in Microsoft Purview by using the Microsoft Purview governance portal.

The only supported authentication for a Hive Metastore database is Basic Authentication.

1. Open the Microsoft Purview governance portal by:
   - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
   - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.
2. Select **Data Map** on the left pane.
3. Select **Register**.
4. In **Register sources**, select **Hive Metastore** > **Continue**.
5. On the **Register sources (Hive Metastore)** screen, do the following:
   a. For **Name**, enter a name that Microsoft Purview will list as the data source.
   b. For **Hive Cluster URL**, enter a value that you get from the Ambari URL. For example, enter **hive.azurehdinsight.net**.
   c. For **Hive Metastore Server URL**, enter a URL for the server. For example, enter **sqlserver://hive.database.windows.net**.
   d. Select a collection from the list.

6. Select **Finish**.

Scan

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have followed all **prerequisites**.
> 2. Review our **scan troubleshooting documentation**.

Use the following steps to scan Hive Metastore databases to automatically identify assets. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

1. In the Management Center, select integration runtimes. Make sure that a self-hosted integration runtime is set up. If it isn't set up, use the steps in prerequisites.

2. Go to **Sources**.

3. Select the registered Hive Metastore database.

4. Select + **New scan**.

5. Provide the following details:

    a. **Name**: Enter a name for the scan.

b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

c. **Credential**: Select the credential to connect to your data source. Make sure to:

- Select Basic Authentication while creating a credential.
- Provide the Metastore username in the appropriate box.
- Store the Metastore password in the secret key.

For more information, see Credentials for source authentication in Microsoft Purview.

d. **Metastore JDBC Driver Location**: Specify the path to the JDBC driver location in your machine where self-host integration runtime is running. For example, `D:\Drivers\HiveMetastore`.

i. For self-hosted integration runtime on a local machine: `D:\Drivers\HiveMetastore`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime;; learn more from prerequisites section.

ii. For Kubernetes-supported self-hosted integration runtime: `./drivers/HiveMetastore`. It's the path to valid JAR folder location. The value must be a valid relative file path. Please refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

e. **Metastore JDBC Driver Class**: Provide the class name for the connection driver. For example, enter **\com.microsoft.sqlserver.jdbc.SQLServerDriver**.

f. **Metastore JDBC URL**: Provide the connection URL value and define the connection to the URL of the Metastore database server. For example: `jdbc:sqlserver://hive.database.windows.net;database=hive;encrypt=true;trustServerCertificate=true;create=false;loginTimeout=300`.

> **Note**
>
> When you copy the URL from *hive-site.xml*, remove `amp;` from the string or the scan will fail.
>
> Download the SSL certificate to the self-hosted integration runtime machine, then update the path to the SSL certificate's location on your machine in the URL.

When you enter local file paths in the scan configuration, change the Windows path separator character from a backslash (`\`) to a forward slash (`/`). For example, if you place the SSL certificate at local file path *D:\Drivers\SSLCert\BaltimoreCyberTrustRoot.crt.pem*, change the `serverSslCert` parameter value to *D:/Drivers/SSLCert/BaltimoreCyberTrustRoot.crt.pem*.

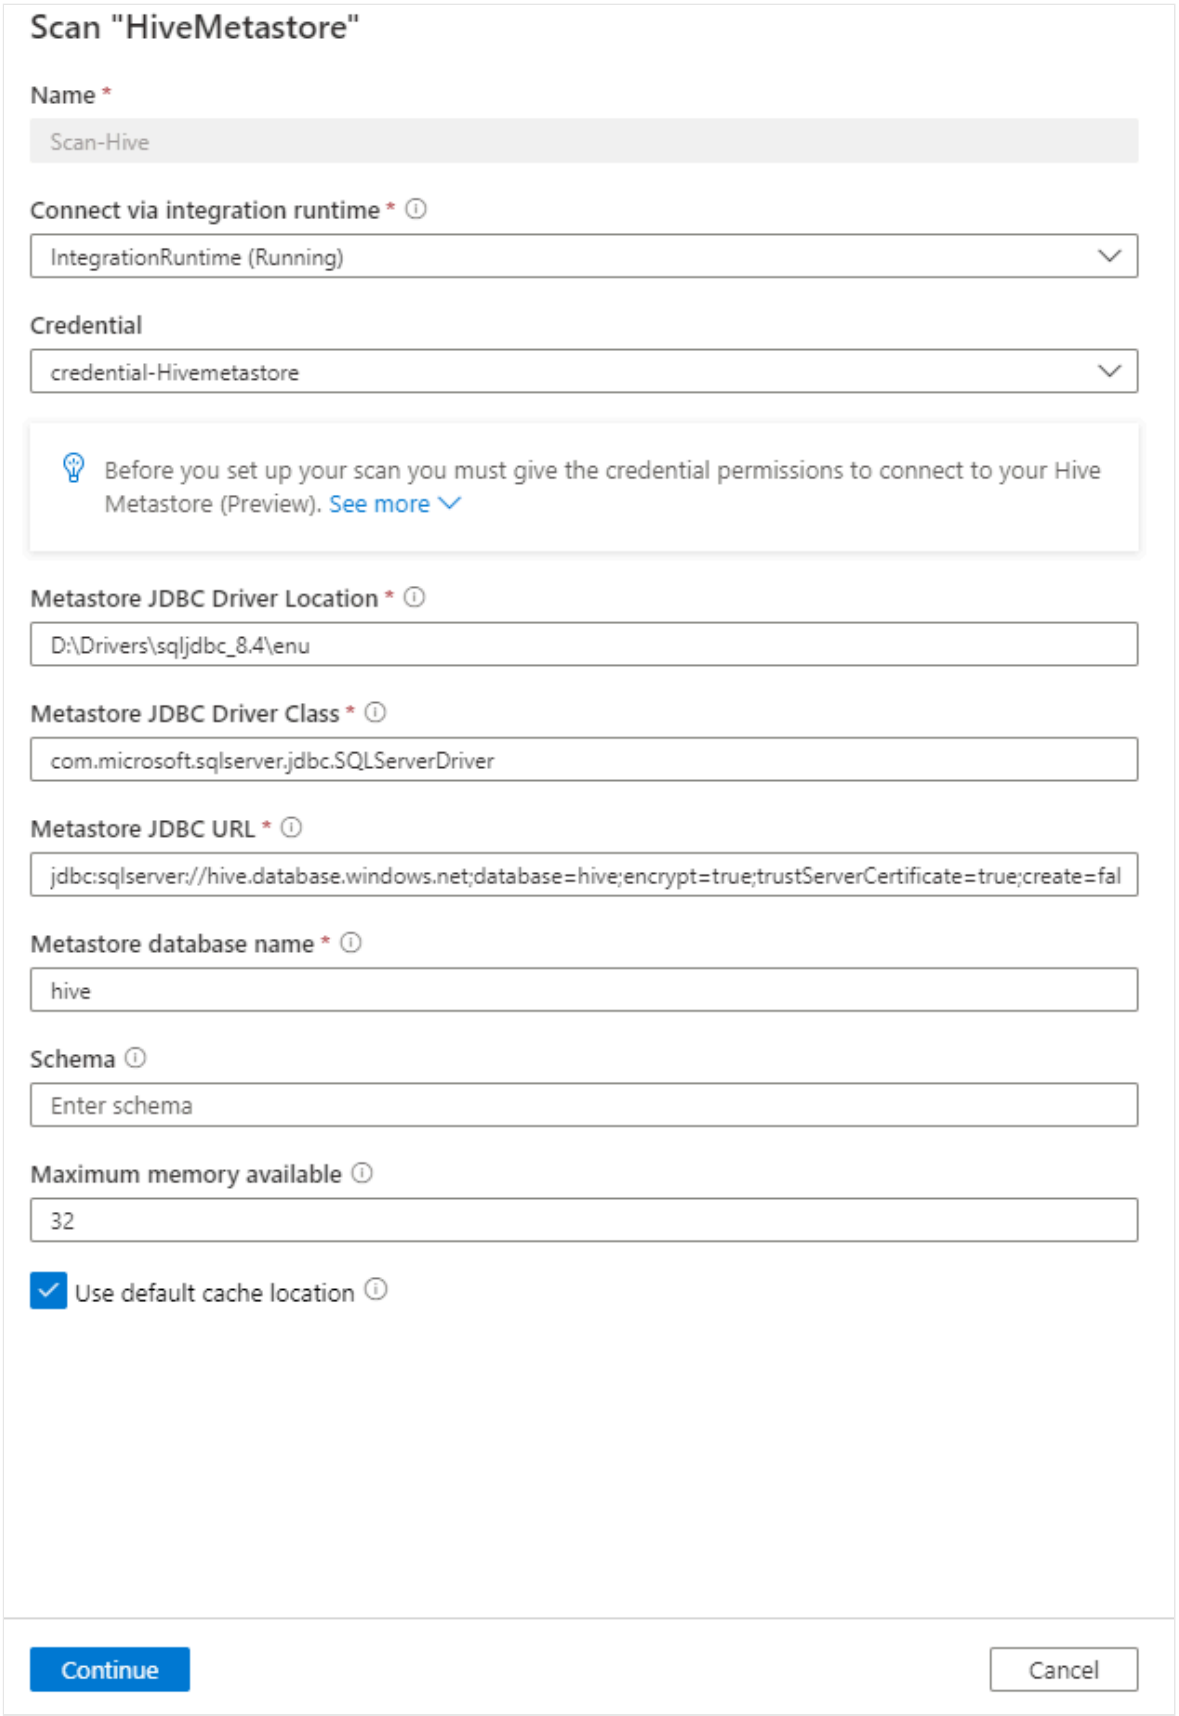
The **Metastore JDBC URL** value will look like this example:

```
jdbc:mariadb://samplehost.mysql.database.azure.com:3306/XXXXXXXXXXXXXXXX?useSSL=true&enabledSslProtocolSuites=TLSv1,TLSv1.1,TLSv1.2&serverSslCert=D:/Drivers/SSLCert/BaltimoreCyberTrustRoot.crt.pem
```

g. **Metastore database name**: Provide the name of the Hive Metastore database.

h. **Schema**: Specify a list of Hive schemas to import. For example: **schema1; schema2**.

All user schemas are imported if that list is empty. All system schemas (for example, SysAdmin) and objects are ignored by default.



Acceptable schema name patterns that use SQL `LIKE` expression syntax include the percent sign (%). For example, `A%; %B; %C%; D` means:

- Start with A or
- End with B or
- Contain C or
- Equal D

Usage of `NOT` and special characters isn't acceptable.

i. **Maximum memory available**: Maximum memory (in gigabytes) available on the customer's machine for the scanning processes to use. This value is dependent on the size of Hive Metastore database to be scanned.

> ⓘ **Note**
>
> As a thumb rule, please provide 1GB memory for every 1000 tables.

6. Select **Continue**.

7. For **Scan trigger**, choose whether to set up a schedule or run the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Hive Metastore source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Hive Metastore lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search the Unified Catalog

Connect to and manage Looker in Microsoft Purview (preview)

Article • 06/27/2024

This article outlines how to register Looker, and how to authenticate and interact with Looker in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported Looker server version is 7.2.

When scanning Looker source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Folders
  - Projects
  - Models
  - Dashboards
  - Looks
  - Explore diagrams including the joins
  - Views including the dimensions, measures, parameters, and filters
  - Layouts including the chart layouts, table layouts, text, and fields

- Fetching static lineage on assets relationships among views and layouts.

When setting up scan, you can choose to scan an entire Looker server, or scope the scan to a subset of Looker projects matching the given name(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.

> **Note**
>
> **If your data store is not publicly accessible** (if your data store limits access from on-premises network, private network or specific IPs, etc.), **you will need to configure a self hosted integration runtime to connect to it**.

- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration

runtime is running. If you don't have this update installed, download it now.

- **To use a kubernetes supported self-hosted integration runtime:**
  - Follow the article to create and configure a kubernetes supported integration runtime.

Register

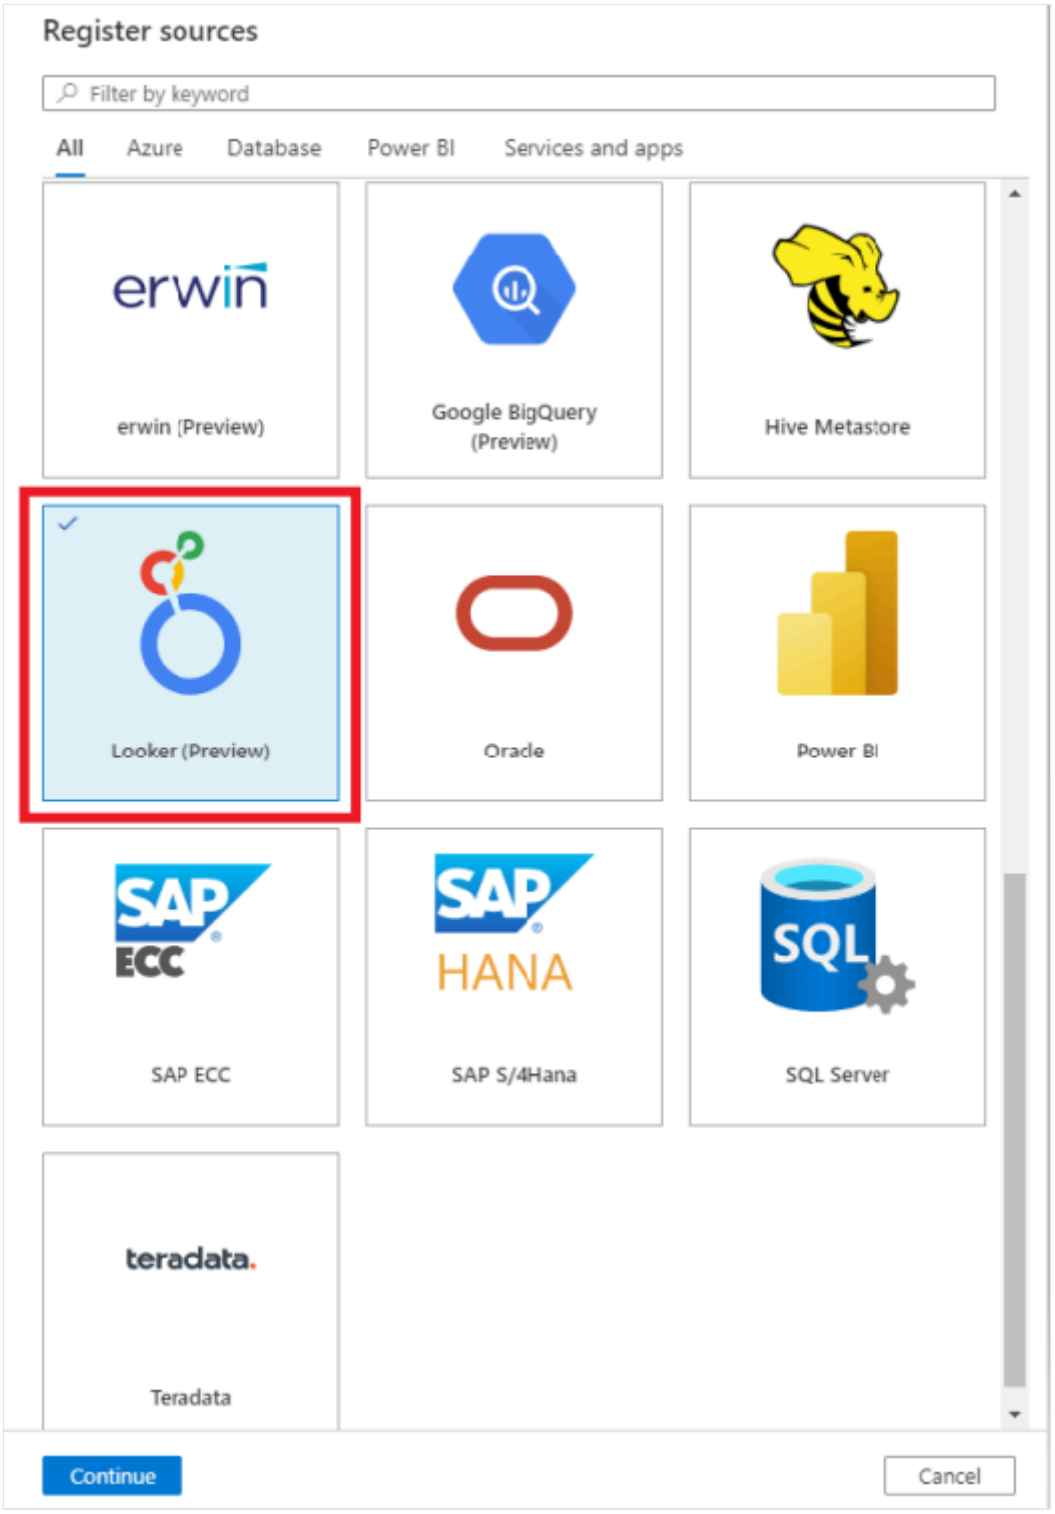
This section describes how to register Looker in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

An API3 key is required to connect to the Looker server. The API3 key consists in a public client_id and a private client_secret and follows an OAuth2 authentication pattern.

Steps to register

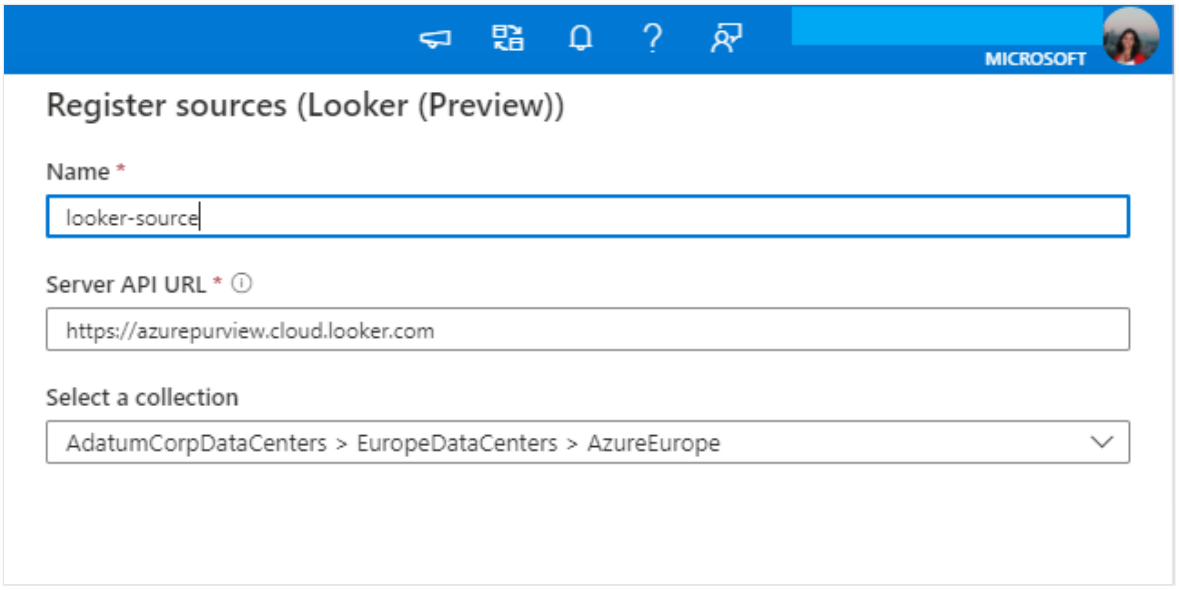
To register a new Looker server in Microsoft Purview Unified Catalog, follow these steps:



1. Open the Microsoft Purview governance portal by:

   - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
   - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.



3. Select **Register.**

4. On Register sources, select **Looker**. Select **Continue.**

On the Register sources (Looker) screen, follow these steps:

1. Enter a **Name** that the data source will be listed within the Catalog.
2. Enter the Looker API URL in the **Server API URL** field. The default port for API requests is port 19999. Also, all Looker API endpoints require an HTTPS connection. For example: 'https://azurepurview.cloud.looker.com'
3. Select a collection from the list.
4. Finish to register the data source.

Scan

Follow the steps below to scan Looker to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion

Create and run scan

To create and run a new scan, follow these steps:

1. If your server is publicly accessible, skip to step two. Otherwise, you'll need to make sure your self-hosted integration runtime is configured:
   a. In the Microsoft Purview governance portal, got to the Management Center, and select **Integration runtimes**.
   b. Make sure a self-hosted integration runtime is available. If one isn't set up, use the steps mentioned in prerequisites to set up a self-hosted integration runtime.

2. In the Microsoft Purview governance portal, navigate to **Sources**.

3. Select the registered **Looker** server.

4. Select + **New scan**.

5. Provide the below details:

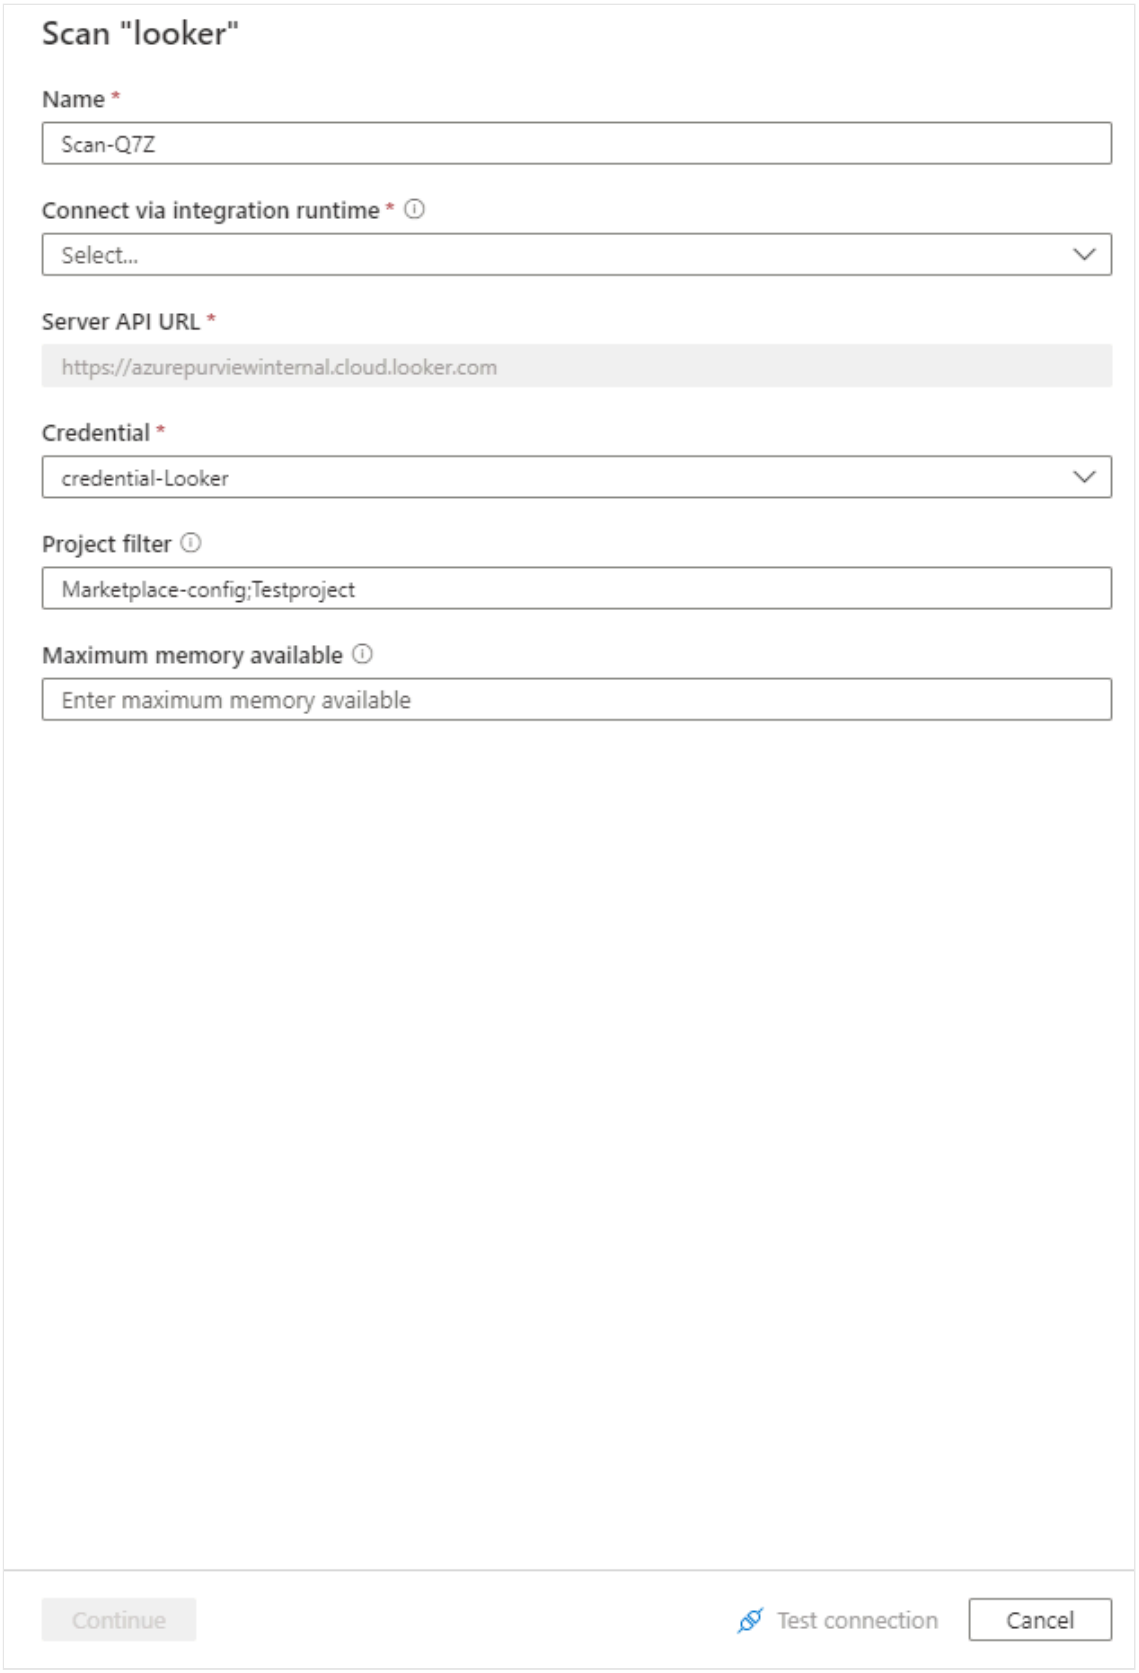
   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the Azure auto-resolved integration runtime if your server is publicly accessible, or your configured self-hosted integration runtime if it isn't publicly available.

c. **Server API URL** is auto populated based on the value entered during registration.

d. **Credential:** While configuring Looker credential, make sure to:

- Select **Basic Authentication** as the Authentication method
- Provide your Looker API3 key's client ID in the User name field
- Save your Looker API3 key's client secret in the key vault's secret.



To access client ID and client secret, navigate to Looker ->Admin -> Users -> Select **Edit** on a user -> Select **EditKeys** -> Use the Client ID and Client Secret or create a new one.

To understand more on credentials, refer to the link here

e. **Model filter** - Scope your scan by providing a semicolon separated list of Looker models. This option is used to select looks and dashboards by their parent model.

f. **Maximum memory available** (applicable when using self-hosted integration runtime): Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of erwin Mart to be scanned.

6. Select **Test connection** to validate the settings.

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select on **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Looker source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Looker lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage MongoDB in Microsoft Purview

This article outlines how to register MongoDB, and how to authenticate and interact with MongoDB in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported MongoDB versions are 3.6 to 7.0. You can use this connector to scan MongoDB Atlas as well.

When scanning MongoDB source, Microsoft Purview supports extracting technical metadata including:

- Server
- Databases
- Collections including the schema
- Views including the schema

During scan, Microsoft Purview retrieves and analyzes sample documents to infer the collection/view schema. The sample size is configurable.

When setting up scan, you can choose to scan one or more MongoDB databases entirely, or further scope the scan to a subset of collections matching the given names or name patterns.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

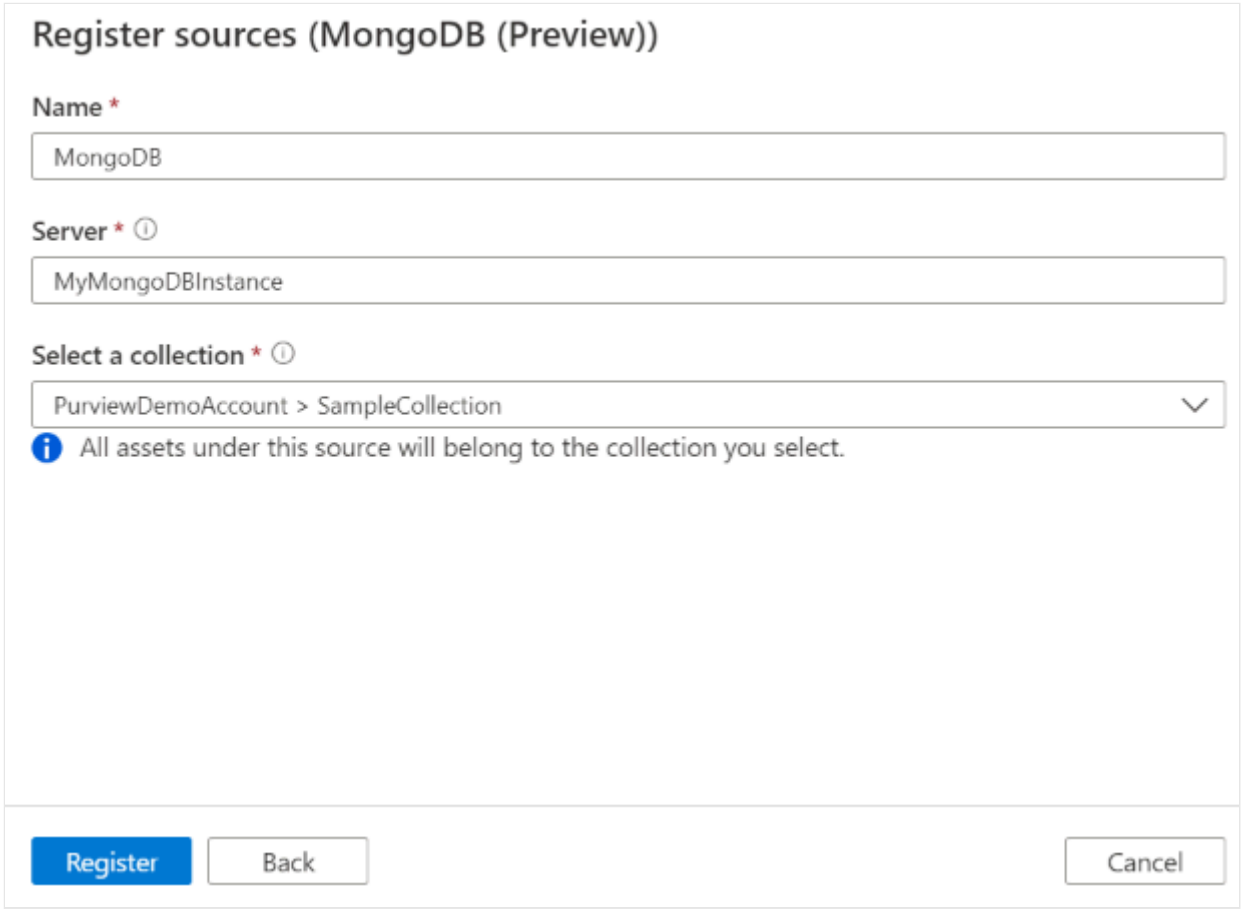
Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - **To use a kubernetes supported self-hosted integration runtime:**
      - Follow the article to create and configure a kubernetes supported integration runtime.

Register

This section describes how to register MongoDB in Microsoft Purview using the classic Microsoft Purview governance portal.

Steps to register



To register a new MongoDB source in Microsoft Purview Unified Catalog, do the following:

1. Navigate to your Microsoft Purview account in the classic Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**

4. On Register sources, select **MongoDB**. Select **Continue**.

On the **Register sources (MongoDB)** screen, do the following:

1. Enter a **Name** that the data source will be listed within the Catalog.
2. Enter the **server** name. Specify a name to uniquely identify your MongoDB instance in your company. For example, `host` for standalone deployment, `MyReplicaSetName` for replica set, `MyClusterName` for sharded cluster. This value is used in asset qualified name and can't be changed.
3. Select a collection from the list.
4. Finish to register the data source.

Scan

Follow the steps below to scan MongoDB to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Authentication for a scan

The supported authentication type for a MongoDB source is **Basic authentication**.

Create and run scan

To create and run a new scan, do the following:

1. In the Management Center, select Integration runtimes. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned in prerequisites to create a self-hosted integration runtime.

2. Navigate to **Sources**.

3. Select the registered MongoDB source.

4. Select + **New scan**.

5. Provide the below details:

    a. **Name**: The name of the scan

    b. **Connect via integration runtime**: Select the self-hosted integration runtime used to perform scan.

    c. **Credential**: Select the credential to connect to your data source. Make sure to:

    - Select **Basic Authentication** while creating a credential.
    - Provide the user name used to connect to MongoDB in the User name input field.
    - Store the user password used to connect to MongoDB in the secret key.

    d. **Connection string**: Specify the MongoDB connection string used to connect to your MongoDB, excluding the username and password. For example, `mongodb://mongodb0.example.com:27017,mongodb1.example.com:27017/?replicaSet=myRepl`, `mongodb+srv://mongodb0.example.com/?authSource=admin&replicaSet=myRepl`.

    e. **Databases**: Specify a list of MongoDB databases to be imported. The list can have one or more database names separated by semicolon (;), for example, `database1;database2`.

    f. **Collections**: The subset of collections to import expressed as a semicolon separated list of collections, for example, `collection1;collection2`. All collections are imported if the list is empty.

    Acceptable collection name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`:

    - Start with A or

- End with B or
- Contain C or
- Equal D

Usage of NOT and special characters aren't acceptable.

g. **Number of sample documents**: Number of sample documents to be analyzed for schema extraction. Default is 10.

h. **Maximum memory available** (applicable when using self-hosted integration runtime): Maximum memory (in GB) available on customer's VM to be used by scanning processes. It's dependent on the size of MongoDB source to be scanned.

6. Select **Test connection** to validate the configurations.

   > ⓘ Note
   >
   > After you select **Test connection**, this message might appear: "The legacy MongoDB connector is deprecated." If you get this message, it doesn't affect the scan. You can skip the test connection and continue scanning Mongo DB in Microsoft Purview.

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

   - Edit the scan by selecting **Edit scan**.
   - Cancel an in-progress scan by selecting **Cancel scan run**.
   - Delete your scan by selecting **Delete scan**.

> ⓘ Note

- Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you've registered your source, visit these articles to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Search Unified Catalog

Connect to and manage MySQL in Microsoft Purview

Article • 03/28/2025

This article outlines how to register MySQL, and how to authenticate and interact with MySQL in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported MySQL server versions are 5.7 to 8.x.

When scanning MySQL source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Databases
  - Tables including the columns
  - Views including the columns
- Fetching static lineage on assets relationships among tables and views.

When setting up scan, you can choose to scan an entire MySQL server, or scope the scan to a subset of databases matching the given name(s) or name pattern(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.

> **Note**
>
> **If your data store is not publicly accessible** (if your data store limits access from on-premises network, private network or specific IPs, etc.), **you will need to configure a self hosted integration runtime to connect to it**.

- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - **To use a kubernetes supported self-hosted integration runtime:**
      - Follow the article to create and configure a kubernetes supported integration runtime.

Required permissions for scan

The MySQL user must have the SELECT, SHOW VIEW and EXECUTE permissions for each target MySQL schema that contains metadata.

Register

This section describes how to register MySQL in Microsoft Purview using the Microsoft Purview governance portal.

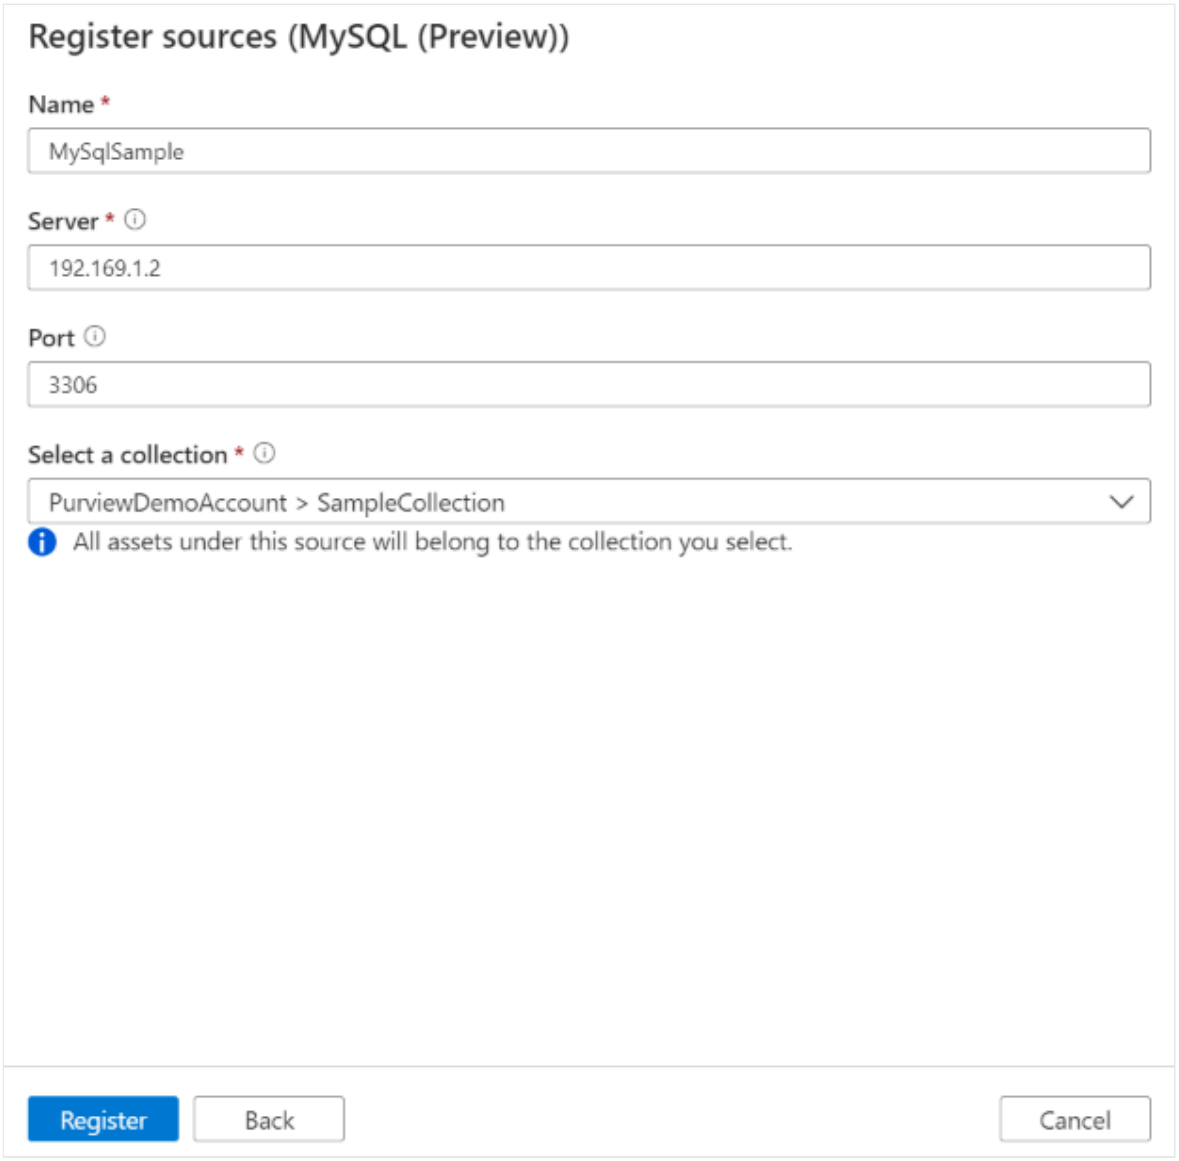
Steps to register

To register a new MySQL source in Microsoft Purview Unified Catalog, follow these steps:

1. Navigate to your Microsoft Purview account in the Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**
4. On Register sources, select **MySQL**. Select **Continue**.

On the **Register sources (MySQL)** screen, follow these steps:

1. Enter a **Name** that the data source will be listed within the Catalog.



2. Enter the **Server** name to connect to a MySQL source. This can either be:

    - A host name used to connect to the database server. For example: `MyDatabaseServer.com`
    - An IP address. For example: `192.169.1.2`

3. Enter the **Port** used to connect to the database server (3306 by default for MySQL).

4. Select a collection from the list.

5. Finish to register the data source.

Scan

Follow the steps below to scan MySQL to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Authentication for a scan

The supported authentication type for a MySQL source is **Basic authentication**.

Create and run scan

To create and run a new scan, follow these steps:

1. If your server is publicly accessible, skip to step two. Otherwise, you'll need to make sure your self-hosted integration runtime is configured:
   a. In the Microsoft Purview governance portal, got to the Management Center, and select **Integration runtimes**.

b. Make sure a self-hosted integration runtime is available. If one isn't set up, use the steps mentioned in prerequisites to set up a self-hosted integration runtime.

2. In the Microsoft Purview governance portal, navigate to **Sources**.

3. Select the registered MySQL source.

4. Select + **New scan**.

5. Provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the Azure auto-resolved integration runtime if your server is publicly accessible, or your configured self-hosted integration runtime if it isn't publicly available.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select **Basic Authentication** while creating a credential.
      - Provide the user name used to connect to the database server in the User name input field.
      - Store the user password used to connect to the database server in the secret key.

   d. **Database**: List subset of databases to import expressed as a semicolon separated list. For example, `database1;database2`. All user databases are imported if the list is empty. All system databases (for example, SysAdmin) are ignored by default.

      Acceptable schema name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

      Usage of NOT and special characters aren't acceptable.

   e. **Maximum memory available** (applicable when using self-hosted integration runtime): Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of MySQL source to be scanned.

> **Note**
>
> As a rule of thumb, please provide 1GB memory for every 1000 tables

6. Select **Test connection** to validate the settings (available when using Azure Integration Runtime).

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your MySQL source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported MySQL lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview

- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage an on-premises SQL server instance in Microsoft Purview

This article outlines how to register on-premises SQL server instances, and how to authenticate and interact with an on-premises SQL server instance in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

The supported SQL Server versions are 2005 and above. SQL Server Express LocalDB isn't supported.

When you scan an on-premises SQL server, Microsoft Purview supports:

- Extracting technical metadata including:
  - Instance
  - Databases
  - Schemas
  - Tables including the columns
  - Views including the columns

When setting up scan, you can choose to specify the database name to scan one database, and you can further scope the scan by selecting tables and views as needed. The whole SQL Server instance will be scanned if database name isn't provided.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Prerequisites

- The enterprise version of Microsoft Purview or an active Microsoft Purview account using the classic governance portal.
- You'll need to be a Data Source Administrator and Data Reader to register a source in the Microsoft Purview Data Map. Get details about domain and collection permissions.
- Set up the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:** Use these instructions to create and configure a self-hosted integration runtime. In this case, classification of SqlBigDecimal isn't supported.
        - **To use a kubernetes supported self-hosted integration runtime:** Follow the article to create and configure a kubernetes supported integration runtime. (SQL authentication only.)

Register

This section describes how to register an on-premises SQL server instance in Microsoft Purview using the Microsoft Purview portal.

1. Accessing the Microsoft Purview Data Map depends on which portal experience you're using.

    - If you're using the Microsoft Purview portal, navigate directly to the portal (https://purview.microsoft.com) and select the **Data Map** solution.
    - If you're using the classic Microsoft Purview governance portal, navigate directly to the portal (https://web.purview.azure.com), select your Microsoft Purview account, and select **Data map** from the left menu.

2. Under **Source management**, select **Integration runtimes**. Make sure a self-hosted integration runtime is set up. If it isn't set up, follow the steps mentioned in prerequisites to create a self-hosted integration runtime for scanning from an on-premises or Azure VM that has access to your on-premises network.

3. Select **Data sources** on the left navigation.

4. Select **Register**.

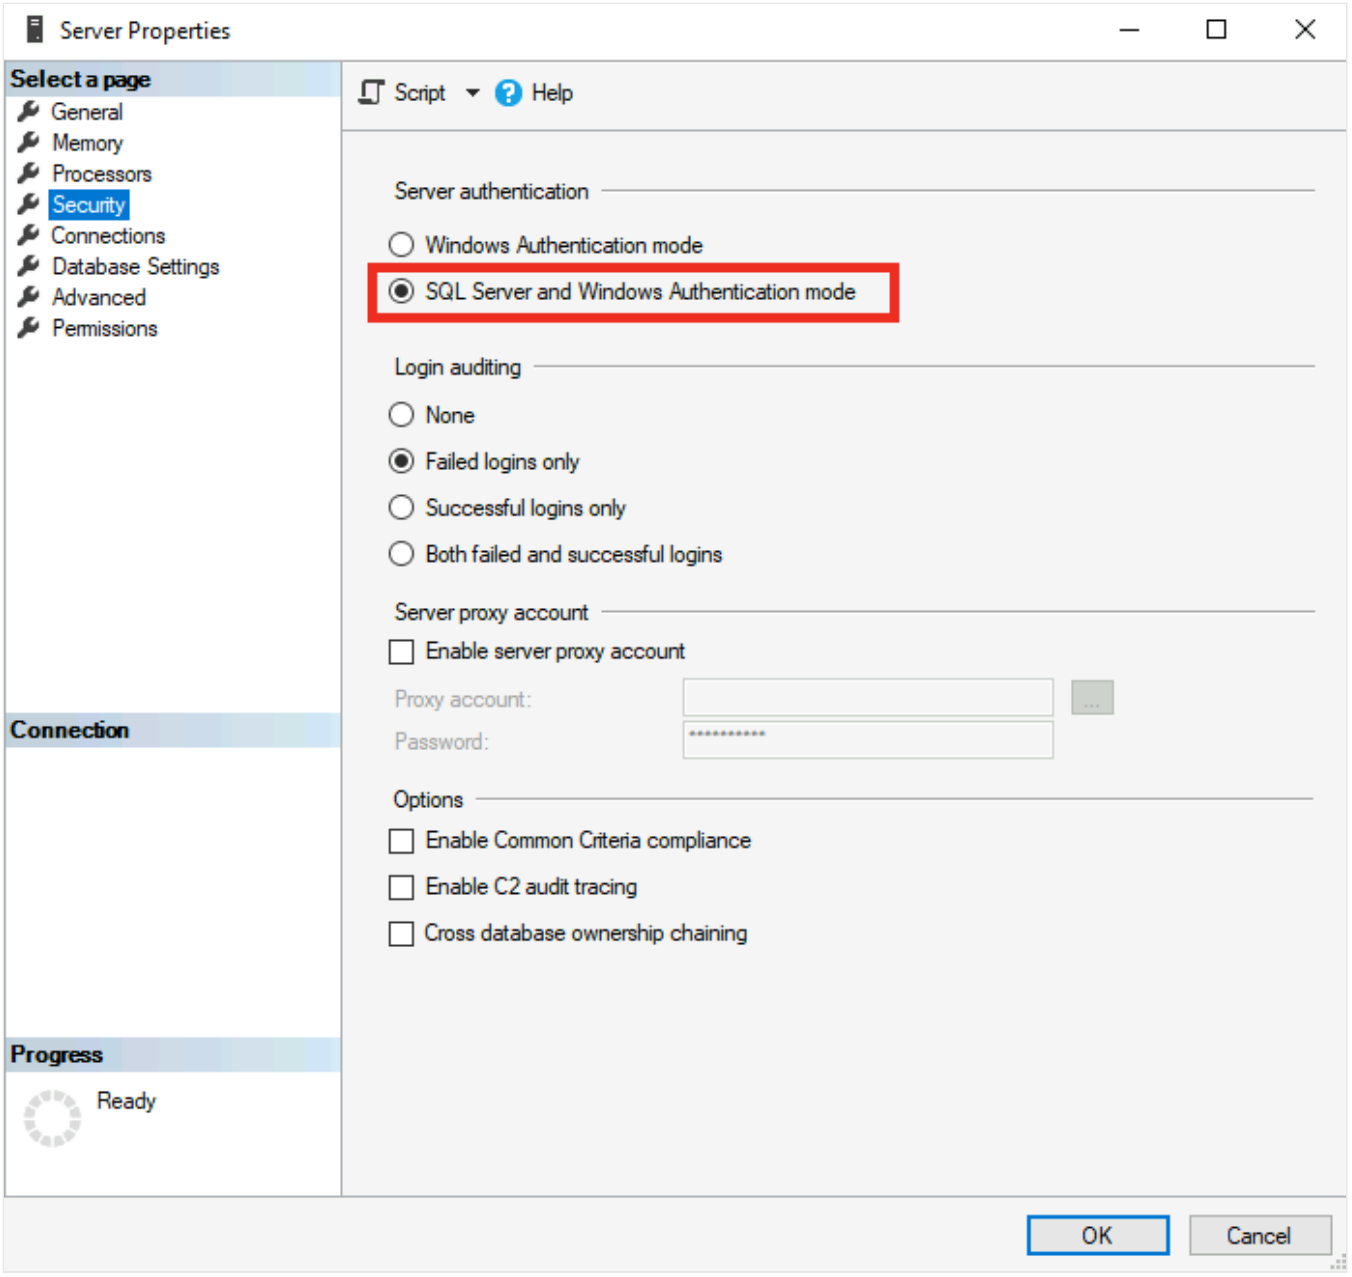
5. Select **SQL Server**, then **Continue9**.

6. Provide a friendly name, which will be a short name you can use to identify your server, and the server endpoint.

7. Select **Finish** to register the data source.

Scan

Follow the steps below to scan on-premises SQL server instances to automatically identify assets and classify your data. For more information about scanning in general, see our introduction to scans and ingestion



Authentication for scanning

There are two authentication methods supported for SQL server on-premises:

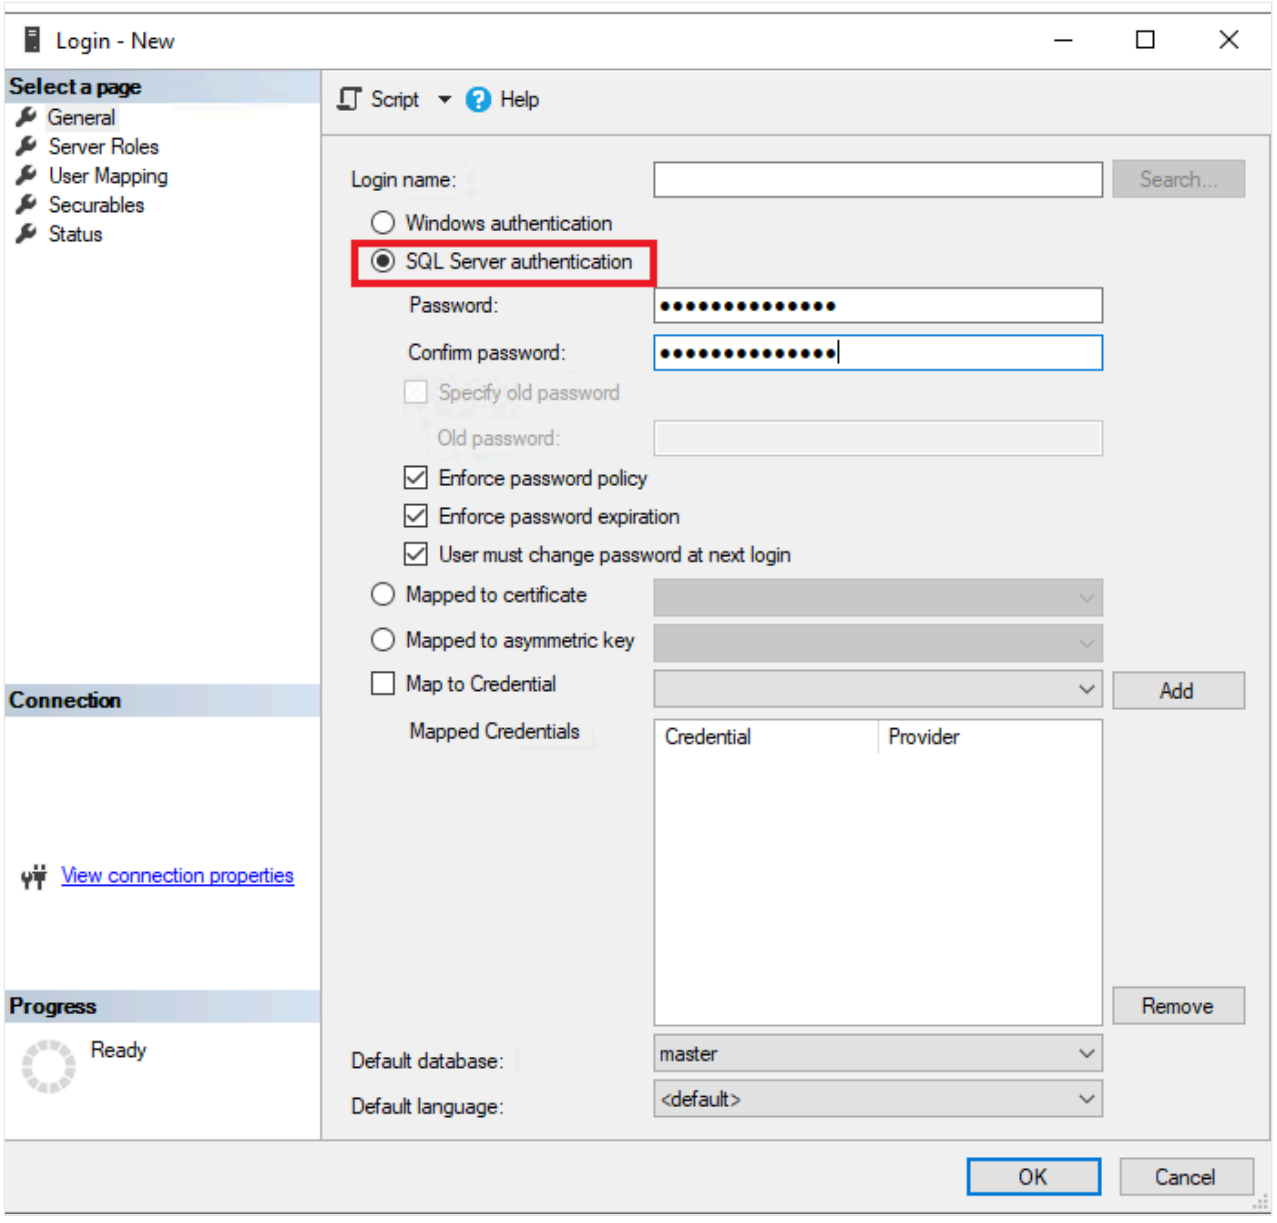
- SQL Authentication
- Windows Authentication - Not supported by a Kubernetes SHIR.

If SQL Authentication is applied, ensure the SQL Server deployment is configured to allow SQL Server and Windows Authentication.

To enable this, within SQL Server Management Studio (SSMS), navigate to **Server Properties** and change from **Windows Authentication Mode** to **SQL Server and Windows Authentication mode**.

If Windows Authentication is applied, configure the SQL Server deployment to use Windows Authentication mode.

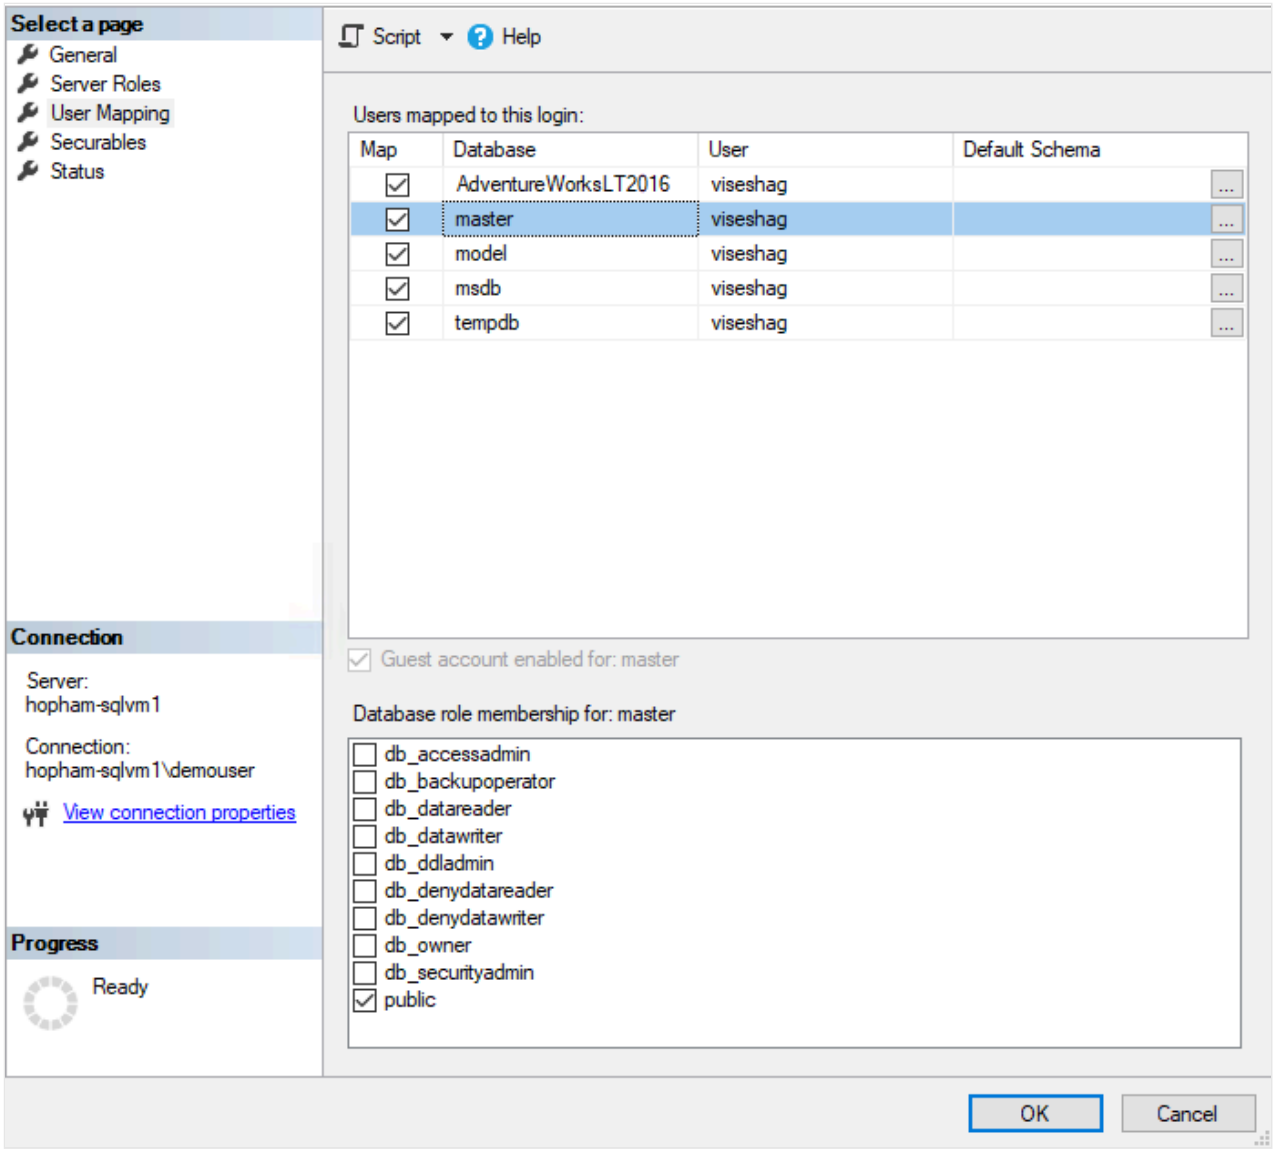
A change to the Server Authentication will require a restart of the SQL Server Instance and SQL Server Agent, this can be triggered within SSMS by navigating to the SQL Server instance and selecting "Restart" within the right-click options pane.



Creating a new login and user

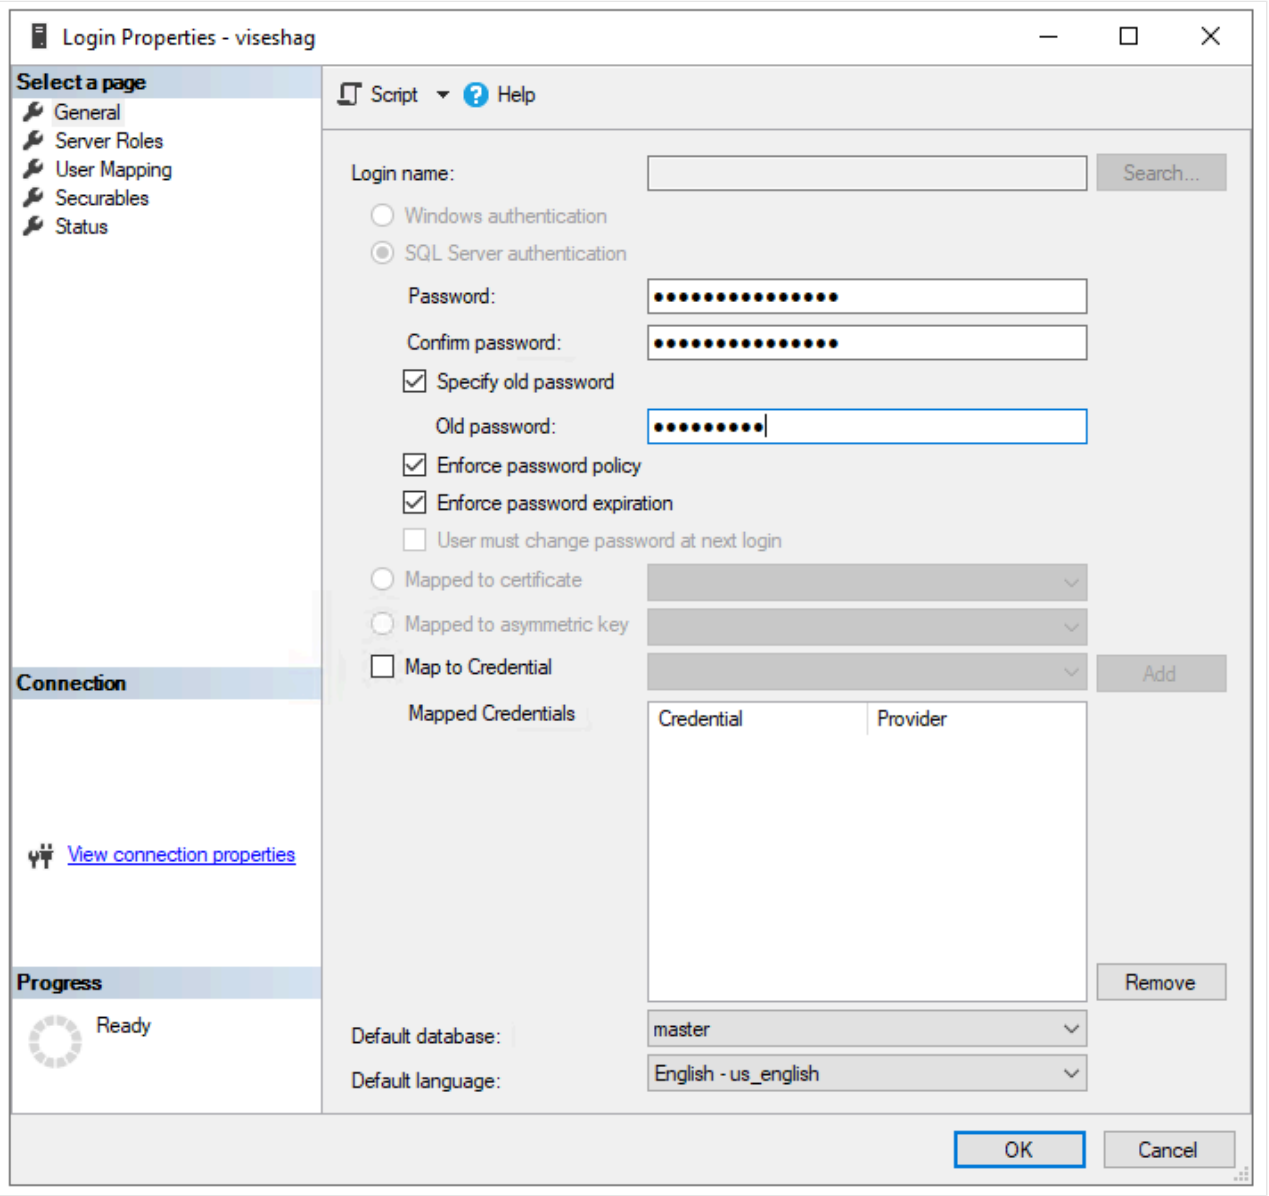
If you would like to create a new login and user to be able to scan your SQL server, follow the steps below:

The account must have access to the **master** database. This is because the `sys.databases` is in the master database. The Microsoft Purview scanner needs to enumerate `sys.databases` in order to find all the SQL databases on the server.



> **Note**
>
> All the steps below can be executed using the code provided here

1. Navigate to SQL Server Management Studio (SSMS), connect to the server, navigate to security, select and hold (or right-click) on login and create New login. If Windows Authentication is applied, select **Windows authentication**. If SQL Authentication is applied, make sure to select **SQL authentication**.



2. Select Server roles on the left navigation and ensure that public role is assigned.

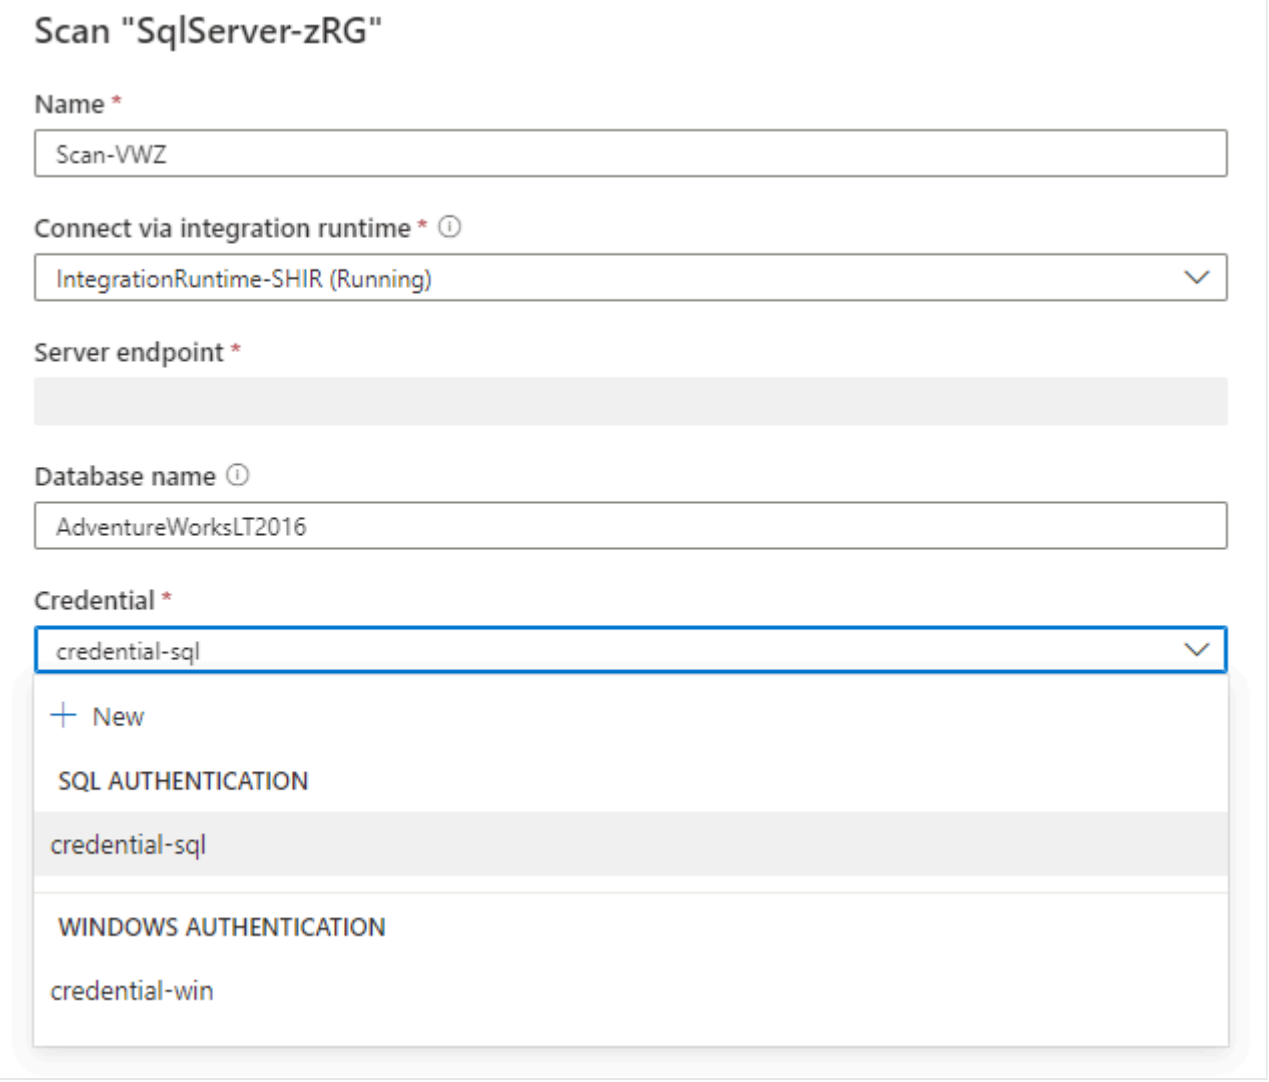
3. Select User mapping on the left navigation, select all the databases in the map and select the Database role: **db_datareader**.

4. Select OK to save.

5. If SQL Authentication is applied, navigate again to the user you created, by selecting and holding (or right-clicking) and selecting **Properties**. Enter a new password and confirm it. Select the 'Specify old password' and enter the old password. **It is required to change your password as soon as you create a new login.**

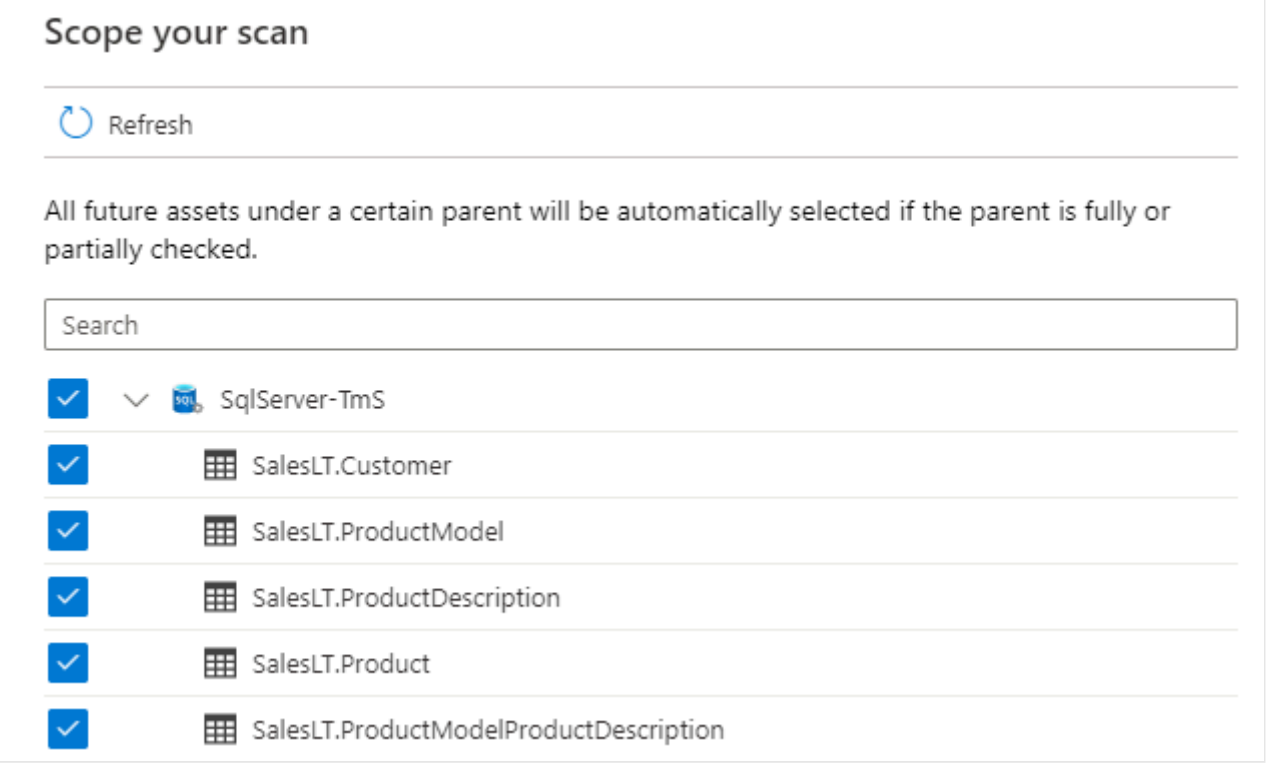
Storing your SQL login password in a key vault and creating a credential in Microsoft Purview

1. Navigate to your key vault in the Azure portal. Select **Settings** > **Secrets**
2. Select **+ Generate/Import** and enter the **Name** and **Value** as the *password* from your SQL server login
3. Select **Create** to complete
4. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection
5. Finally, create a new credential using the **username** and **password** to set up your scan. Make sure the right authentication method is selected when creating a new credential. If SQL Authentication is applied, select "SQL authentication" as the authentication method. If Windows Authentication is applied, then select **Windows authentication**.



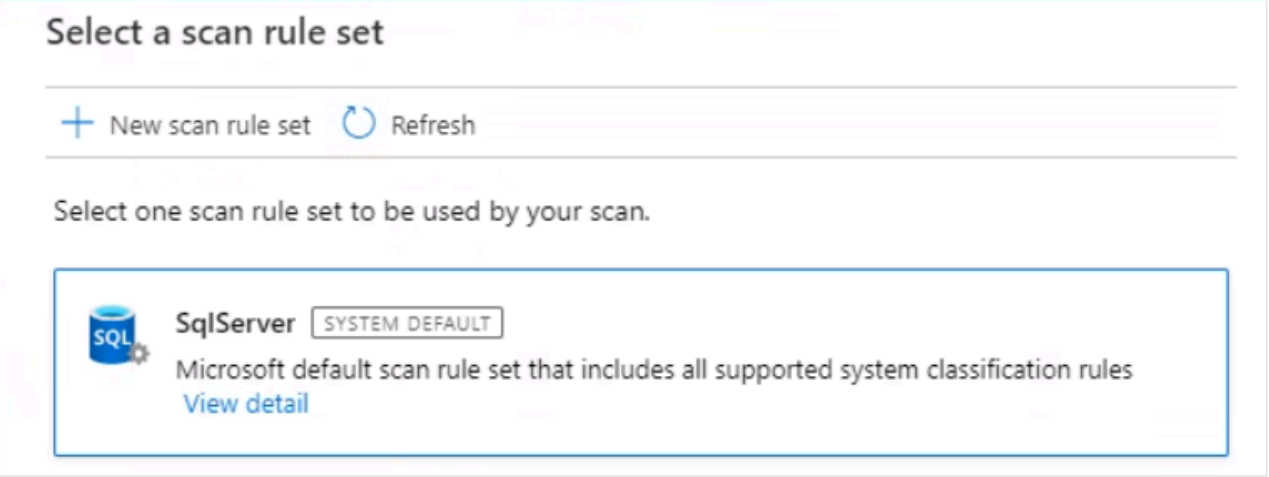
Set up a self-hosted integration runtime

If you haven't already, you need to download and install the latest self-hosted integration runtime. For more information, see the create and configure a self-hosted integration runtime guide.

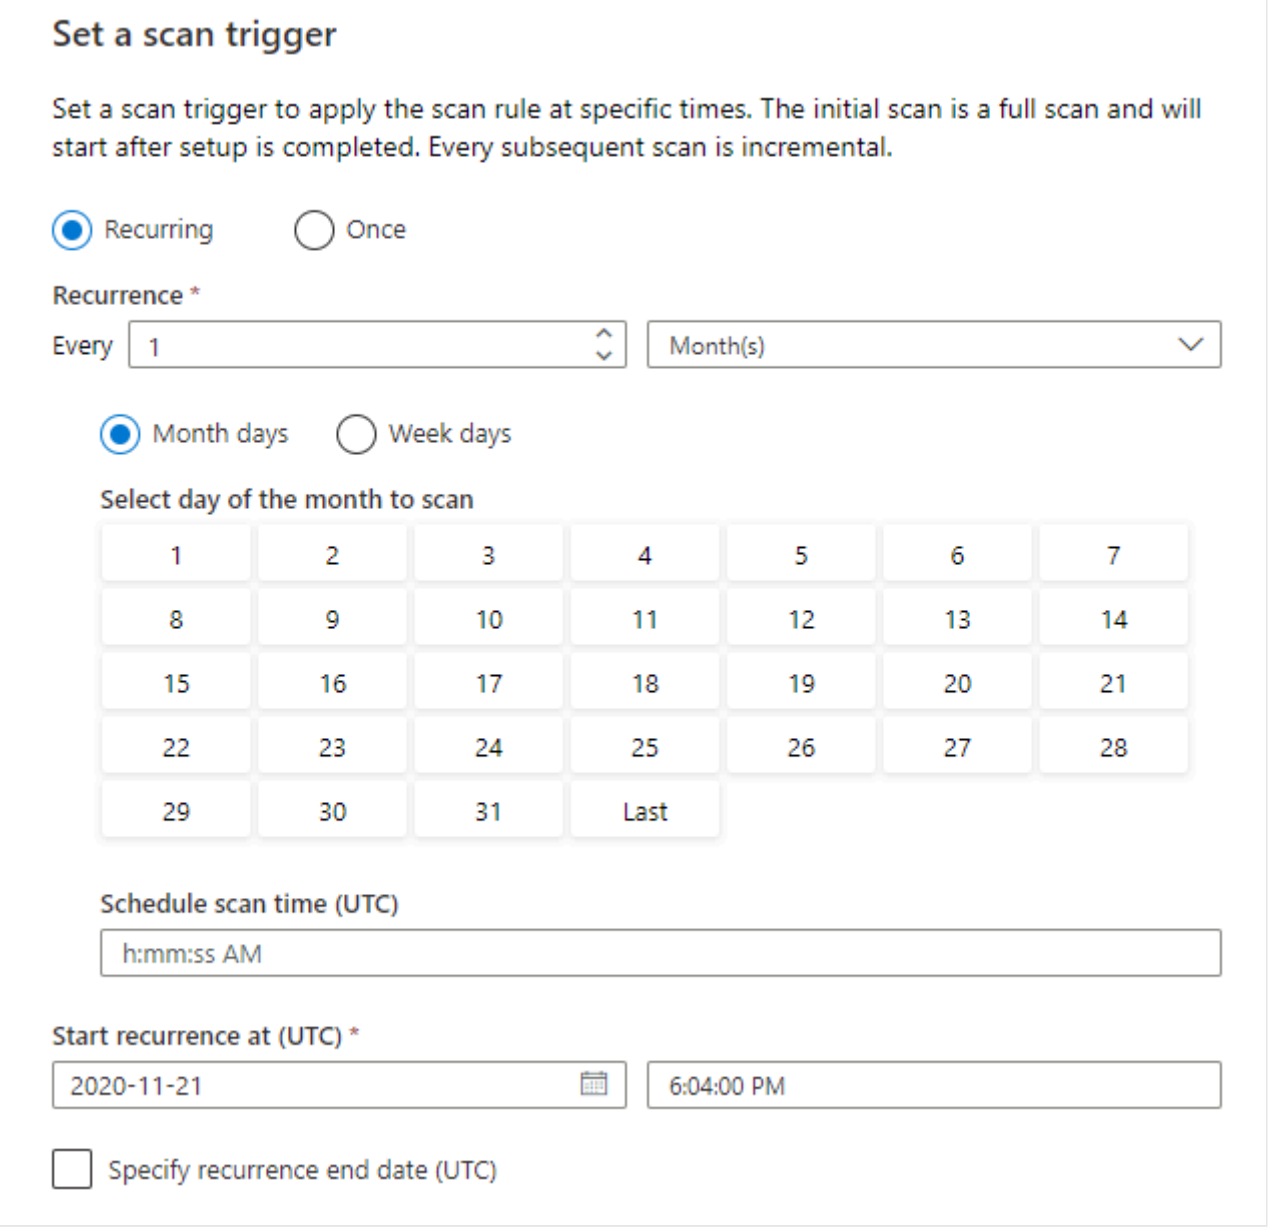


Create and run scan

Now that you've set up authentication and a self-hosted integration



1. Open the Microsoft Purview portal and select the **Data Map**.
2. Select **Data sources**.
3. Select the SQL Server source that you registered.
4. Select **New scan**
5. Select the credential to connect to your data source. The credentials are grouped and listed under different authentication methods.



6. You can scope your scan to specific tables by choosing the appropriate items in the list after enter Database name.

7. Then select a scan rule set. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your scan trigger. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you have registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Last updated on 03/20/2026

Connect to and manage Oracle in Microsoft Purview

This article outlines how to register Oracle, and how to authenticate and interact with Oracle in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported Oracle server versions are 6i to 19c. Oracle proxy server isn't supported when scanning Oracle source.

When scanning Oracle source, Microsoft Purview supports:

- Extracting technical metadata, including:
  - Server
  - Schemas
  - Packages
  - Tables including the columns, foreign keys, indexes, triggers, and unique constraints
  - Views including the columns and triggers
  - Stored procedures including the parameter dataset and result set
  - Functions including the parameter dataset
  - Sequences
  - Synonyms
  - Types including the type attributes
- Fetching static lineage on assets relationships among tables and views.
- Stored procedure lineage.

When setting up scan, you can choose to scan an entire Oracle server, or scope the scan to a subset of schemas matching one or more given names or name patterns.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

- Currently, the Oracle service name isn't captured in the metadata or hierarchy.
- When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.
- Stored procedures directly under a schema or not within a package aren't supported.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- The enterprise version of Microsoft Purview or an active Microsoft Purview account using the classic governance portal.
- You need to be a Data Source Administrator and Data Reader to register a source in the Microsoft Purview Data Map. Get details about domain and collection permissions.
- Set up the latest self-hosted integration runtime. For more information, see the create and configure a self-hosted integration runtime guide.
    - Ensure OpenJDK 8 with OJDBC driver 8 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you install the JDK for it to take effect.
        - Ensure Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the self-hosted integration runtime machine. If you don't have this update installed, you can download it here.
        - Download the Oracle JDBC driver on the machine where your self-hosted integration runtime is running. Note down the folder path that you'll use to set up the scan.

          > **Note**

The driver should be accessible by the self-hosted integration runtime. By default, self-hosted integration runtime uses local service account "NT SERVICE\DIAHostService". Make sure it has "Read and execute" and "List folder contents" permission to the driver folder.

Required permissions for scan

Microsoft Purview supports basic authentication (username and password) for scanning Oracle. The Oracle user must have read access to system tables in order to access advanced metadata and classification.

The user should have permission to create a session and role SELECT_CATALOG_ROLE assigned. Alternatively, the user could have SELECT permission granted for every individual system table that this connector queries metadata from:

SQL

```
grant create session to [user];
grant select on all_users to [user];
grant select on dba_objects to [user];
grant select on dba_tab_comments to [user];
grant select on dba_external_locations to [user];
grant select on dba_directories to [user];
grant select on dba_mviews to [user];
grant select on dba_clu_columns to [user];
grant select on dba_tab_columns to [user];
grant select on dba_col_comments to [user];
grant select on dba_constraints to [user];
grant select on dba_cons_columns to [user];
grant select on dba_indexes to [user];
grant select on dba_ind_columns to [user];
grant select on dba_procedures to [user];
grant select on dba_synonyms to [user];
grant select on dba_views to [user];
grant select on dba_source to [user];
grant select on dba_triggers to [user];
grant select on dba_arguments to [user];
grant select on dba_sequences to [user];
grant select on dba_dependencies to [user];
grant select on dba_type_attrs to [user];
grant select on V_$INSTANCE to [user];
grant select on v_$database to [user];
```

For classification, the user must have reader (SELECT) permissions on the relevant tables.

For Individual Tables Use the following SQL command to grant access to a specific table:

SQL

```
GRANT SELECT ON [table_name] TO [purview_user];
```

For All Tables at Once To grant access across all tables in the database, use:

SQL

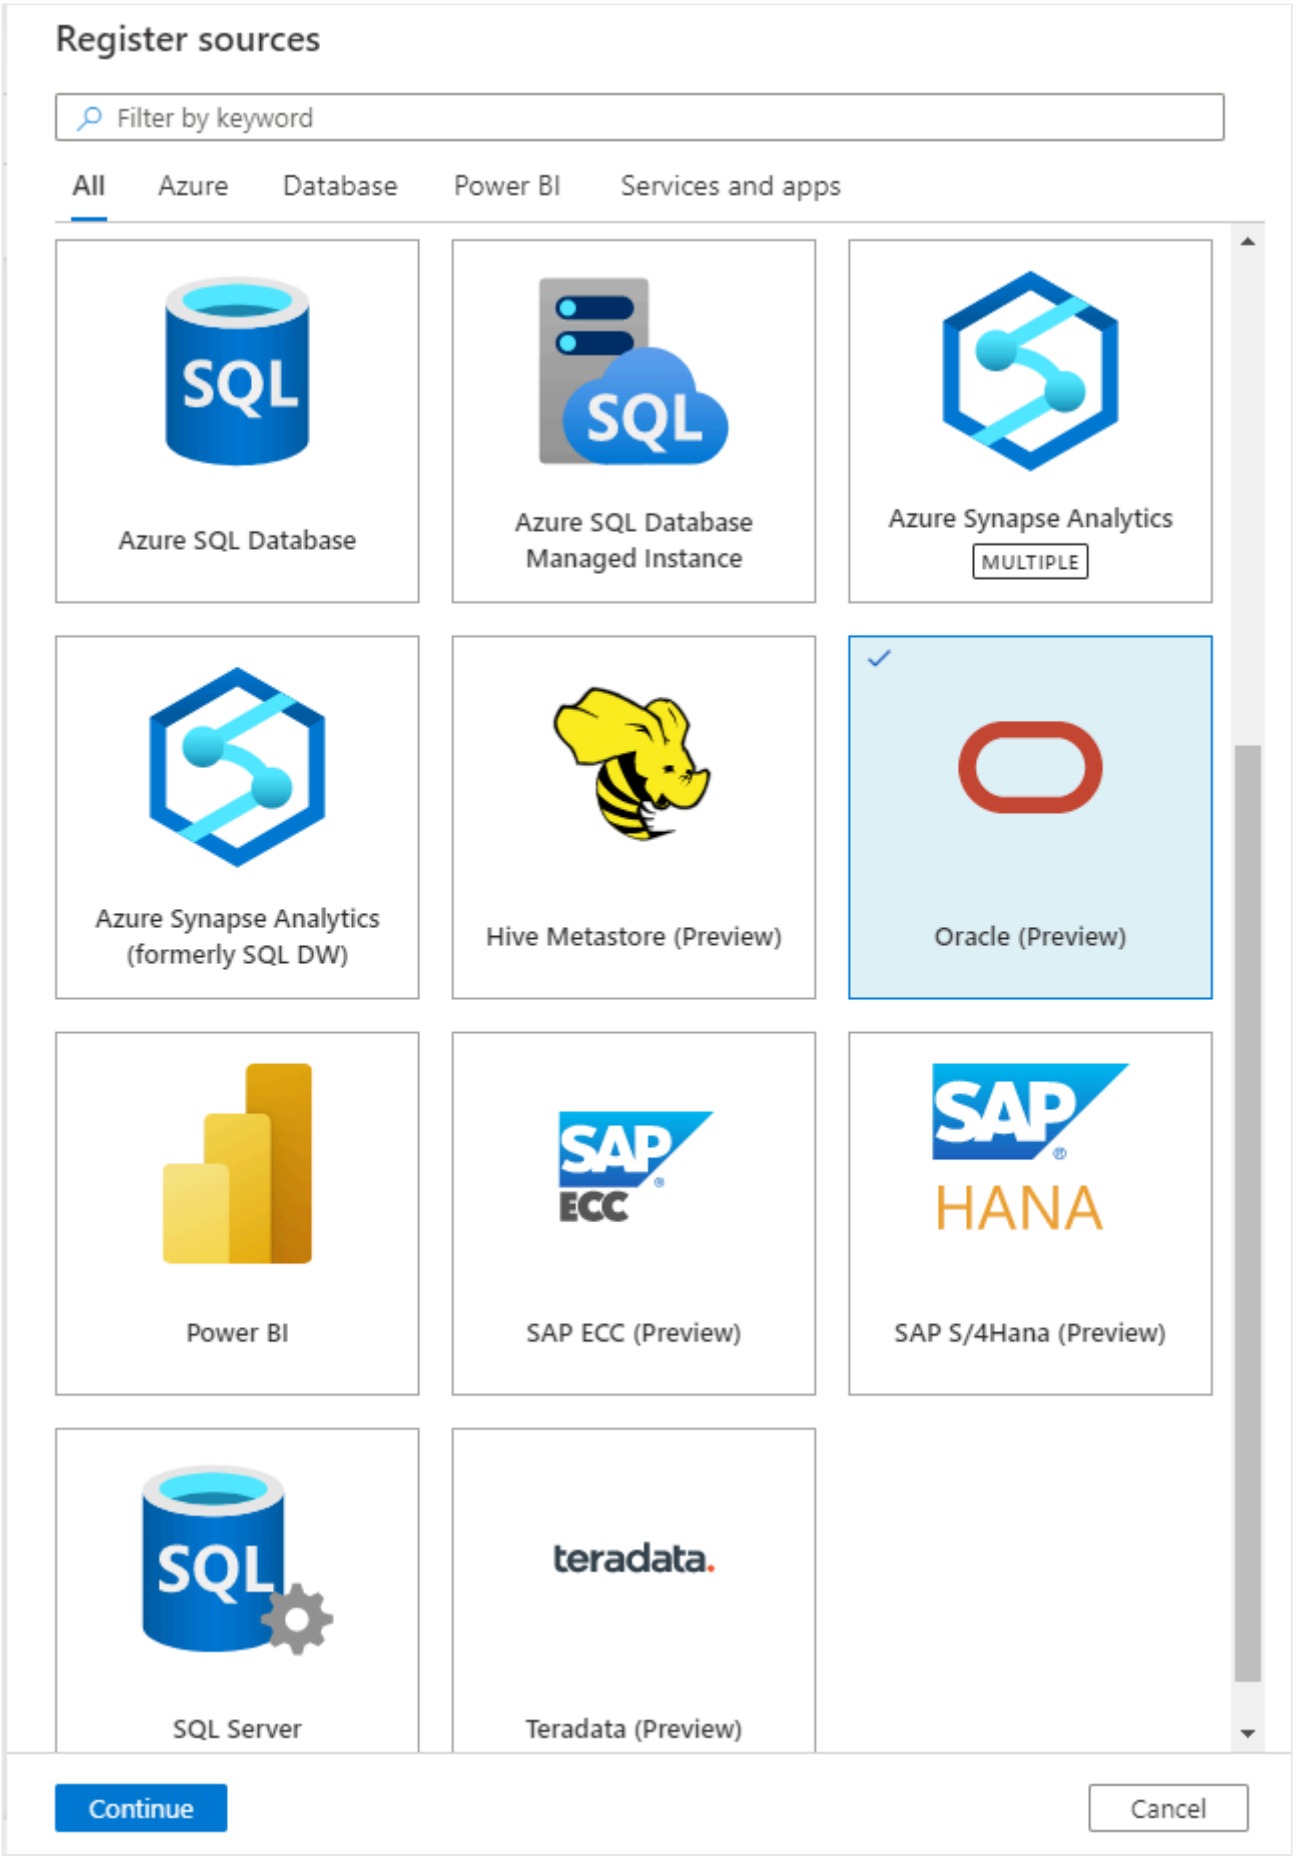
```
GRANT SELECT ANY TABLE TO [purview_user];
```

Register

This section describes how to register Oracle in Microsoft Purview using the Microsoft Purview portal.

Steps to register

To register a new Oracle source in your data map, do the following:



1. Accessing the Microsoft Purview Data Map depends on which portal experience you're using.

    - If you're using the Microsoft Purview portal, navigate directly to the portal (https://purview.microsoft.com) and select the **Data Map** solution.
    - If you're using the classic Microsoft Purview governance portal, navigate directly to the portal (https://web.purview.azure.com), select your Microsoft Purview account, and select **Data map** from the left menu.

2. Select **Data sources**

3. Select **Register**

4. On Register sources, select **Oracle**. Select **Continue**.

On the **Register sources (Oracle)** screen, do the following:

1. Enter a **Name** that the data source will be listed within the Catalog.

2. Enter the **Host** name to connect to an Oracle source. This can either be:

    - A host name used to connect to the database server. For example: `MyDatabaseServer.com`
    - An IP address. For example: `192.169.1.2`

3. Enter the **Port number** used to connect to the database server (1521 by default for Oracle).

4. Enter the **Oracle service name** (not Oracle UID) used to connect to the database server.

5. Select a collection from the list.

6. Finish to register the data source.

Scan

Follow the steps below to scan Oracle and automatically classify assets. For more information about scanning in general, see our introduction to scans and ingestion.

> **Tip**
>
> To troubleshoot any issues with scanning:

1. Confirm you have followed all **prerequisites**.
2. Review our **scan troubleshooting documentation**.

Create and run scan

To create and run a new scan, do the following:

1. Under **Source management** in the data map, select **Integration runtimes**. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned here to create a self-hosted integration runtime.

2. Navigate to **Sources**.

3. Select the registered Oracle source.

4. Select **+ New scan**.

5. Provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the configured self-hosted integration runtime

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

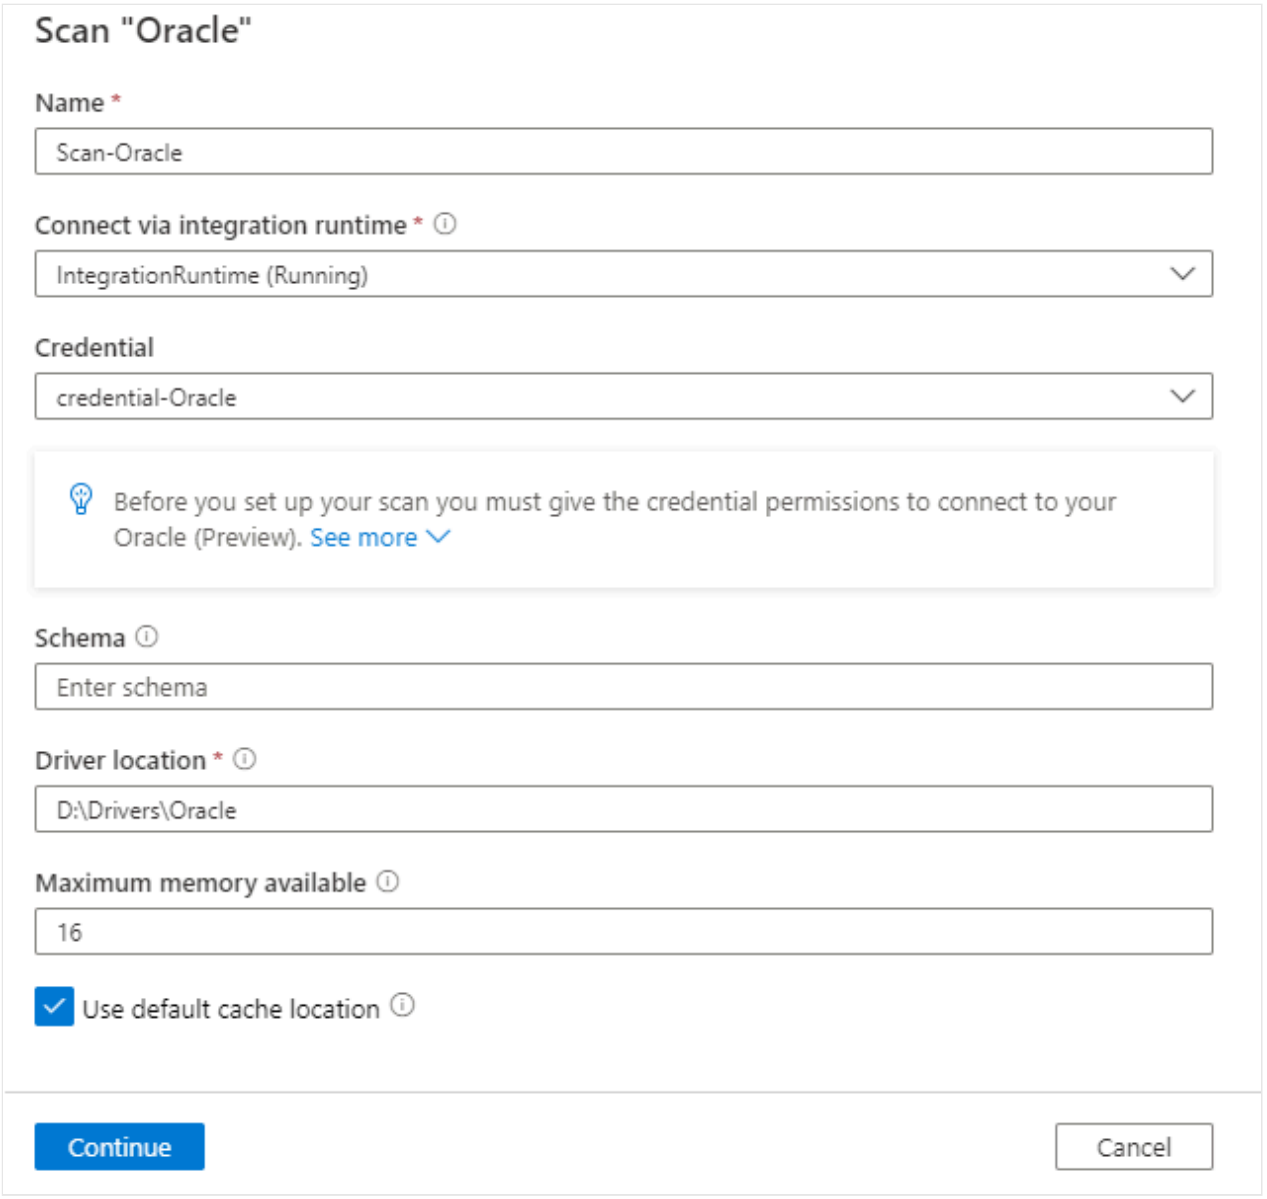
      - Select Basic Authentication while creating a credential.
      - Provide the user name used to connect to the database server in the User name input field.
      - Store the user password used to connect to the database server in the secret key.

   d. **Schema**: List subset of schemas to import expressed as a semicolon separated list in **case-sensitive** manner. For example, `schema1;schema2`. All user schemas are imported if that list is empty. All system schemas (for example, SysAdmin) and objects are ignored by default.

      Acceptable schema name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

Usage of NOT and special characters aren't acceptable.



e. **Driver location**: Specify the path to the JDBC driver location in your machine where self-host integration runtime is running. For example: `D:\Drivers\Oracle`.
   i. For self-hosted integration runtime on a local machine: `D:\Drivers\Oracle`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime; learn more at prerequisites.

f. **Stored procedure details**: Controls the number of details imported from stored procedures:

   - Signature: The name and parameters of stored procedures.
   - Code, signature: The name, parameters, and code of stored procedures.
   - Lineage, code, signature: The name, parameters and code of stored procedures, and the data lineage derived from the code.
   - None: Stored procedure details aren't included.

g. **Maximum memory available**: Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of Oracle source to be scanned.

   > ⓘ **Note**
   >
   > As a rule of thumb, please provide 1GB memory for every 1000 tables

6. Select **Test connection**.

> **Note**
>
> Use the "Test connection" button in the scan setup UI to test the connection. The "Test Connection" in self-hosted integration runtime configuration manager UI -> Diagnostics tab does not fully validate the connectivity.

7. Select **Continue**.

8. Select a **scan rule set** for classification. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

9. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

10. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Oracle source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Oracle lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Last updated on 04/20/2026

Connect to and manage PostgreSQL in Microsoft Purview

This article outlines how to register PostgreSQL, and how to authenticate and interact with PostgreSQL in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported PostgreSQL server versions are 8.x to 16.x.

When scanning PostgreSQL source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Databases
  - Schemas
  - Tables including the columns
  - Views including the columns
- Fetching static lineage on assets relationships among tables and views.

When setting up scan, you can choose to scan an entire PostgreSQL database, or scope the scan to a subset of schemas matching the given name(s) or name pattern(s).

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.

> **Note**
>
> **If your data store is not publicly accessible** (if your data store limits access from on-premises network, private network or specific IPs, etc.), **you will need to configure a self hosted integration runtime to connect to it**.

- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - **To use a kubernetes supported self-hosted integration runtime:**
      - Follow the article to create and configure a kubernetes supported integration runtime.

Required permissions for scan

- The PostgreSQL user needs read access to system tables in order to access advanced metadata.
- The user must be granted CONNECT permission on the default postgres database (Command: GRANT CONNECT ON DATABASE postgres TO [user];).

Register

This section describes how to register PostgreSQL in Microsoft Purview using the Microsoft Purview governance portal.

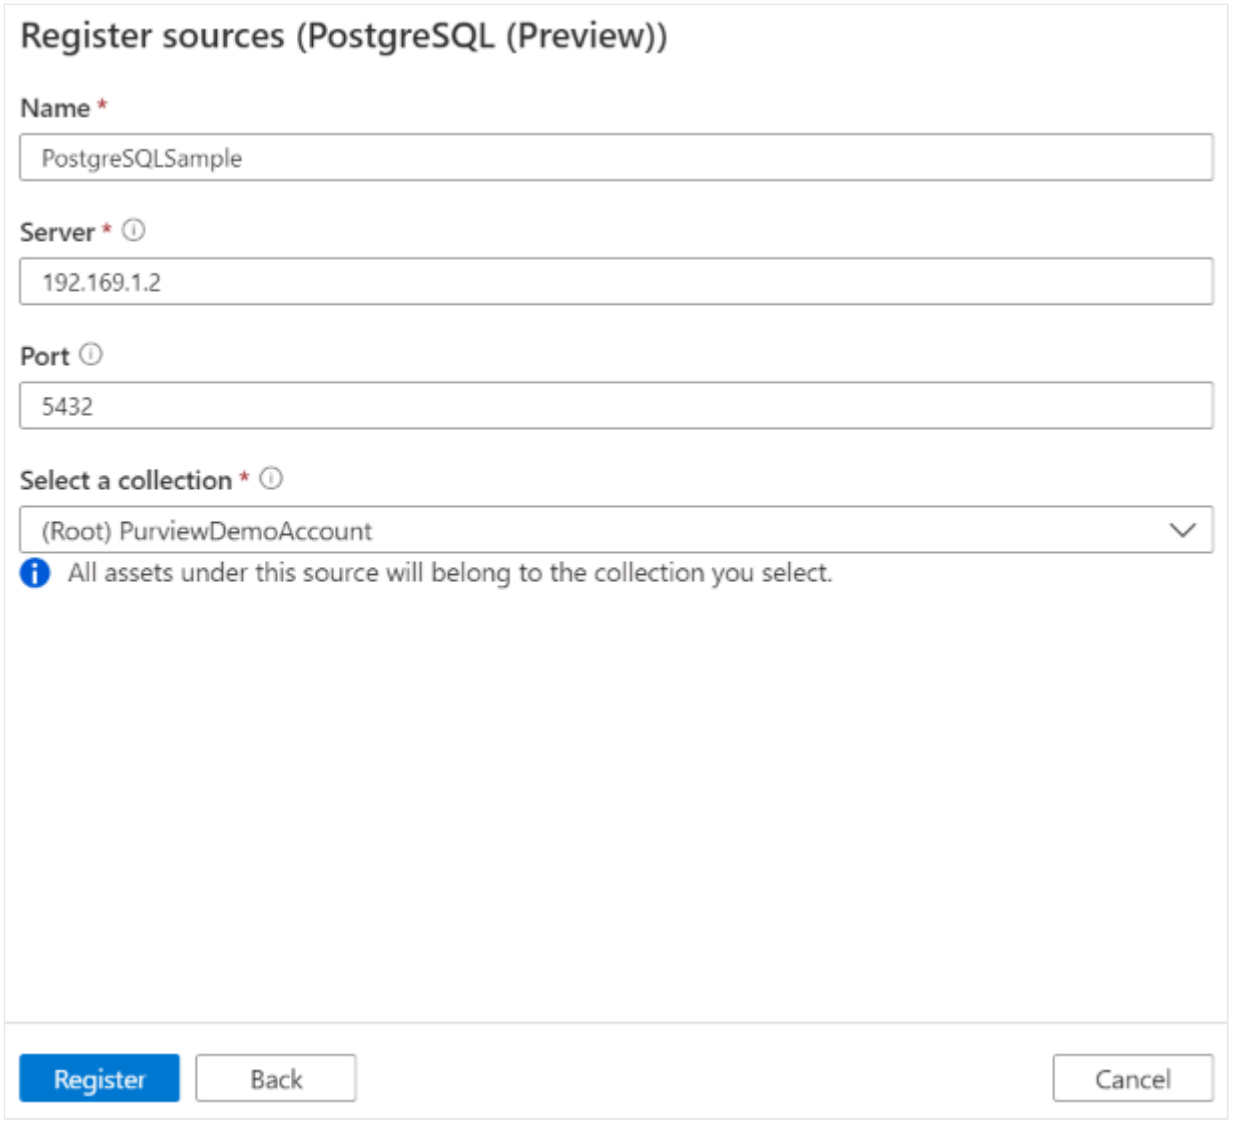
Steps to register

To register a new PostgreSQL source in Microsoft Purview Unified Catalog, follow these steps:

1. Navigate to your Microsoft Purview account in the Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**
4. On Register sources, select **PostgreSQL**. Select **Continue**.

On the **Register sources (PostgreSQL)** screen, follow these steps:

1. Enter a **Name** that the data source will be listed within the Catalog.



2. Enter the **Server** name to connect to a PostgreSQL source. This can either be:

    - A host name used to connect to the database server. For example: `MyDatabaseServer.com`
    - An IP address. For example: `192.169.1.2`

3. Enter the **Port** used to connect to the database server (5432 by default for PostgreSQL).

4. Select a collection from the list.

5. Finish to register the data source.

Scan

Follow the steps below to scan PostgreSQL to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Authentication for a scan

The supported authentication type for a PostgreSQL source is **Basic authentication**.

Create and run scan

To create and run a new scan, follow these steps:

1. If your server is publicly accessible, skip to step two. Otherwise, you'll need to make sure your self-hosted integration runtime is configured:
   a. In the Microsoft Purview governance portal, got to the Management Center, and select **Integration runtimes**.

b. Make sure a self-hosted integration runtime is available. If one isn't set up, use the steps mentioned in prerequisites to set up a self-hosted integration runtime.

2. In the Microsoft Purview governance portal, navigate to **Sources**.

3. Select the registered PostgreSQL source.

4. Select + **New scan**.

5. Provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the Azure auto-resolved integration runtime if your server is publicly accessible, or your configured self-hosted integration runtime if it isn't publicly available.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select **Basic Authentication** while creating a credential.
      - Provide the user name used to connect to the database server in the User name input field.
      - Store the user password used to connect to the database server in the secret key.

   d. **Database**: Specify the name of the database instance to import.

   e. **Schema**: List subset of schemas to import expressed as a semicolon separated list. For example, `schema1;schema2`. All user schemas are imported if that list is empty. All system schemas (for example, SysAdmin) and objects are ignored by default.

      Acceptable schema name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

      Usage of NOT and special characters aren't acceptable.

   f. **Maximum memory available** (applicable when using self-hosted integration runtime): Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of PostgreSQL source to be scanned.

      > ⓘ **Note**

As a rule of thumb, please provide 1GB memory for every 1000 tables

6. Select **Test connection** to validate the settings (available when using Azure Integration Runtime).

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your PostgreSQL source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported PostgreSQL lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage a Power BI tenant in Microsoft Purview (same tenant)

Article • 05/21/2025

This article outlines how to register a Power BI tenant in a **same-tenant scenario**, and how to authenticate and interact with the tenant in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

> **Note**
>
> The Power BI data source in Microsoft Purview has been renamed to Fabric in all regions. You can still use "Power BI" as the keyword to quickly locate the source to register a Power BI tenant and set up a scan.
>
> Starting from December 13th 2023, scanning Fabric tenants registered with the Fabric data source in Microsoft Purview will capture metadata and lineage from Fabric items including Power BI. There are no other configuration steps needed to enable scanning Fabric items besides Power BI for existing scans. Fabric tenants and Power BI tenants will share the same data source and same experience to set up scans. For scanning a Fabric tenant, see our Fabric documentation.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

When scanning Power BI source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Workspaces
  - Dashboards
  - Reports
  - Datasets including the tables and columns
  - Dataflows
  - Datamarts
- Fetching static lineage on assets relationships among above Power BI artifacts and external data source assets. Learn more from Power BI lineage.

See a list of metadata available for Power BI.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Supported scenarios for Power BI scans

Expand table

Scenarios	Microsoft Purview public access allowed/denied	Power BI public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Public access with Azure IR	Allowed	Allowed	Azure Runtime	Managed Identity / Delegated authentication / Service principal	Review deployment checklist
Public access with Self-hosted IR	Allowed	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist

Scenarios	Microsoft Purview public access allowed/denied	Power BI public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Private access	Denied	Allowed	Managed VNet IR (v2 only)	Managed Identity / Delegated authentication / Service principal	Review deployment checklist
Private access	Allowed	Denied	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist
Private access	Denied	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist
Private access	Denied	Denied	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist

Known limitations

- If Power BI tenant is protected behind a private endpoint, standard or kubernetes supported self-hosted runtimes are the only options to scan.
- Delegated authentication and service principal are the only supported authentication options when a self-hosted integration runtime is used during the scan.
- If Power BI dataset schema isn't shown after scan, it's due to one of the current limitations with Power BI Metadata scanner.
- Empty workspaces are skipped.
- Other limits please refer to Microsoft Purview limits.

Prerequisites

Before you start, make sure you have the following prerequisites:

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

Authentication options

- Managed Identity
- Delegated Authentication
- Service Principal

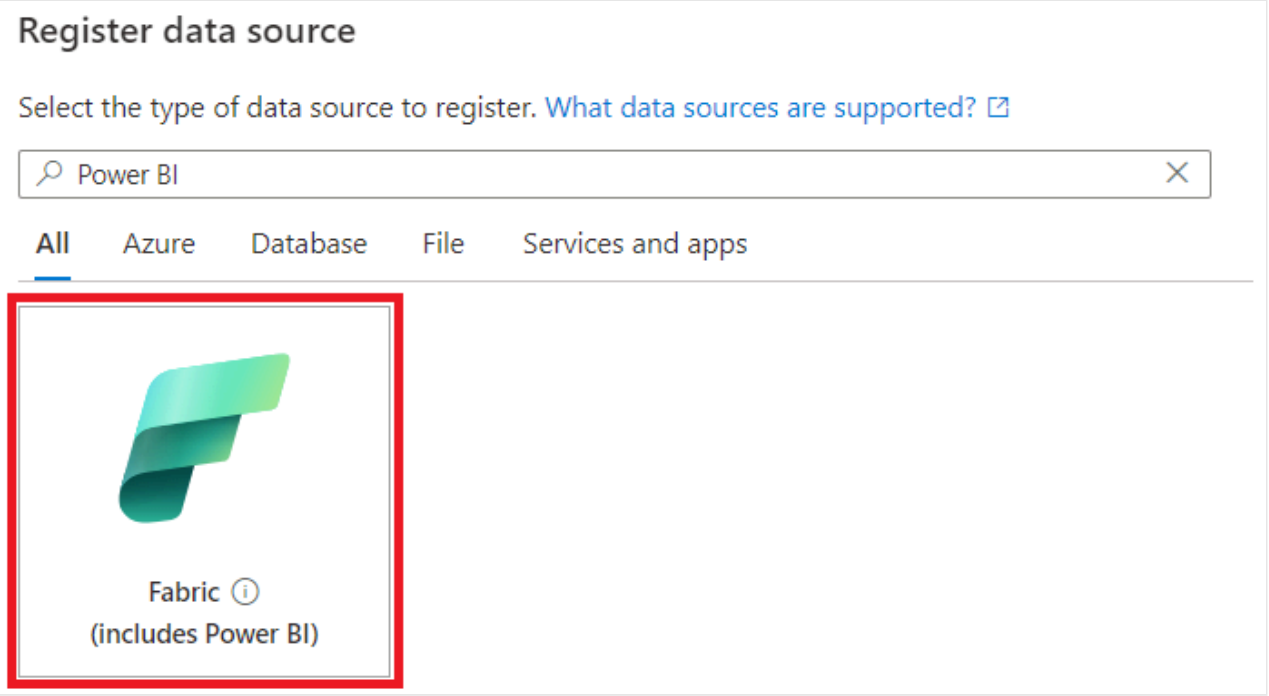
Deployment checklist

Use any of the following deployment checklists during the setup or for troubleshooting purposes, based on your scenario:

Public access with Azure IR

Scan same-tenant Power BI using Azure IR and Managed Identity in public network

1. Make sure Power BI and Microsoft Purview accounts are in the same tenant.
2. Make sure Power BI tenant ID is entered correctly during the registration.
3. Make sure your Power BI Metadata model is up to date by enabling metadata scanning.
4. From Azure portal, validate if Microsoft Purview account Network is set to public access.
5. From Power BI tenant Admin Portal, make sure Power BI tenant is configured to allow public network.
6. In Microsoft Entra tenant, create a security group.
7. From Microsoft Entra tenant, make sure Microsoft Purview account MSI is member of the new security group.
8. On the Power BI Tenant Admin portal, validate if Allow service principals to use read-only Power BI admin APIs is enabled for the new security group.



Register Power BI tenant

This section describes how to register a Power BI tenant in Microsoft Purview for same-tenant scenario.

1. Select the **Data Map** on the left navigation.

2. Then select **Register**.

   Select **Fabric** as your data source. It includes Power BI sources and assets.

3. Give your data source a name.

   The name must be between 3-63 characters long and must contain only letters, numbers, underscores, and hyphens. Spaces aren't allowed.

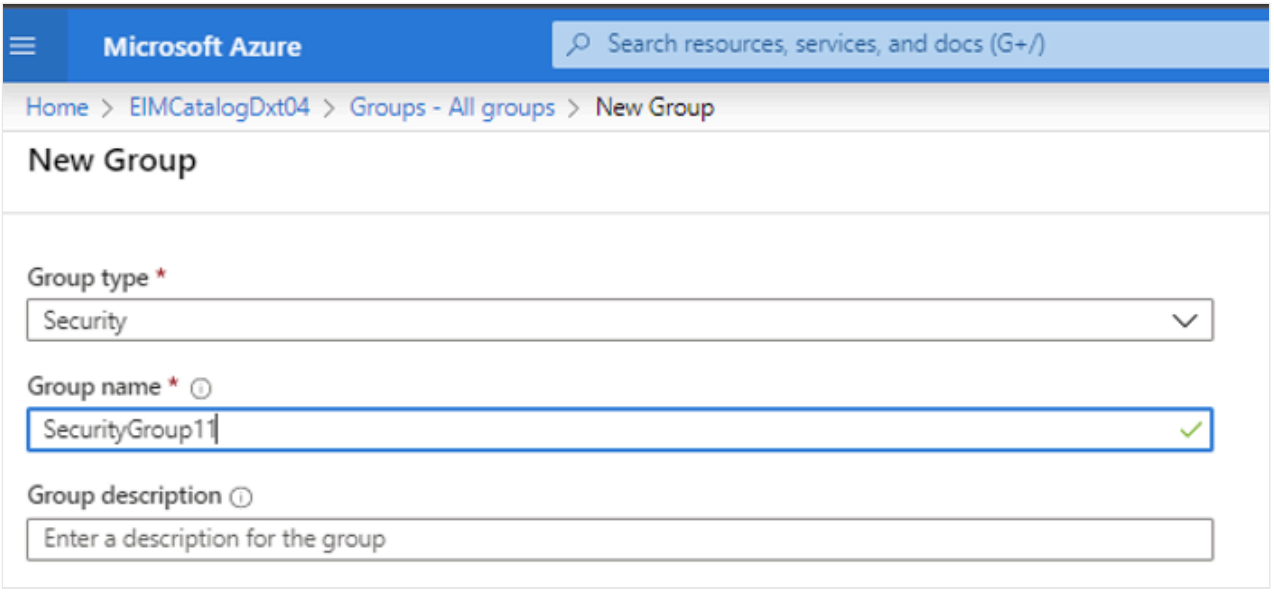
   By default, the system will find the Fabric tenant that exists in the same Microsoft Entra tenant.

4. Select the collection where you want to register the source.

5. Select **Register**.

Scan same-tenant Power BI

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have completed the deployment checklist for your scenario.
> 2. Review our scan troubleshooting documentation.



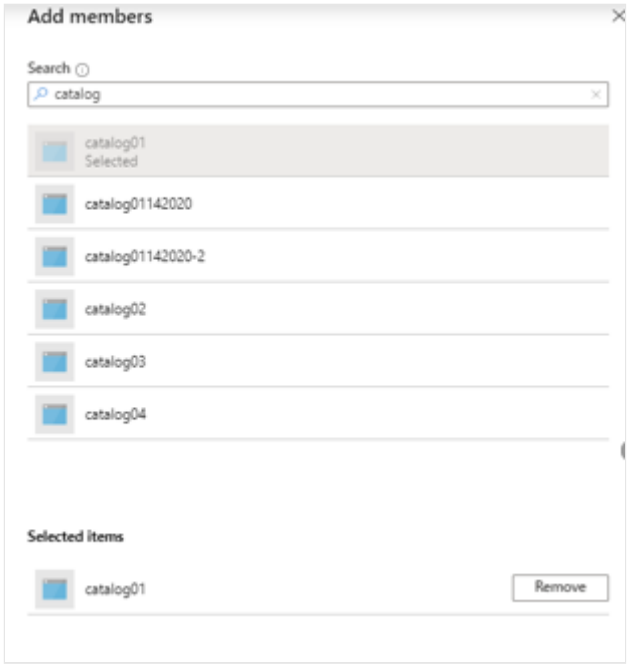
Authenticate to Power BI tenant

In Microsoft Entra tenant, where Power BI tenant is located:

1. In the Azure portal, search for **Microsoft Entra ID**.
2. Create a new security group in your Microsoft Entra ID, by following Create a basic group and add members using Microsoft Entra ID.

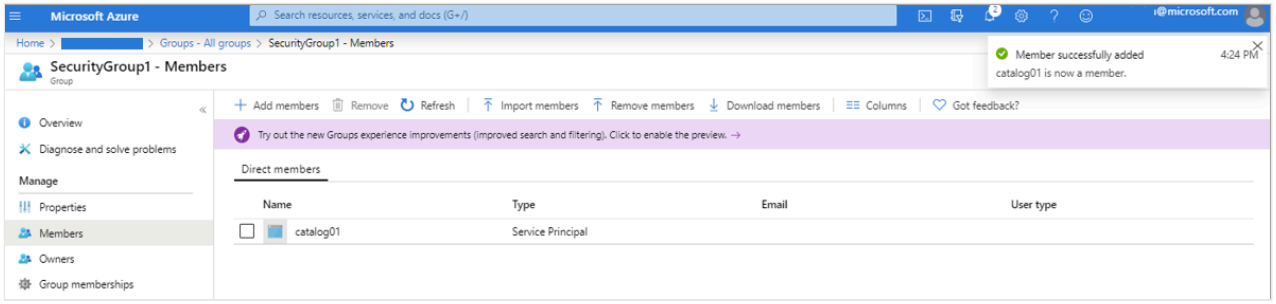
   > **Tip**
   >
   > You can skip this step if you already have a security group you want to use.

3. Select **Security** as the **Group Type**.



4. Add relevant user to the security group:

   - If you're using **Managed Identity** as authentication method, add your Microsoft Purview managed identity to this security group. Select **Members**, then select **+ Add members**.

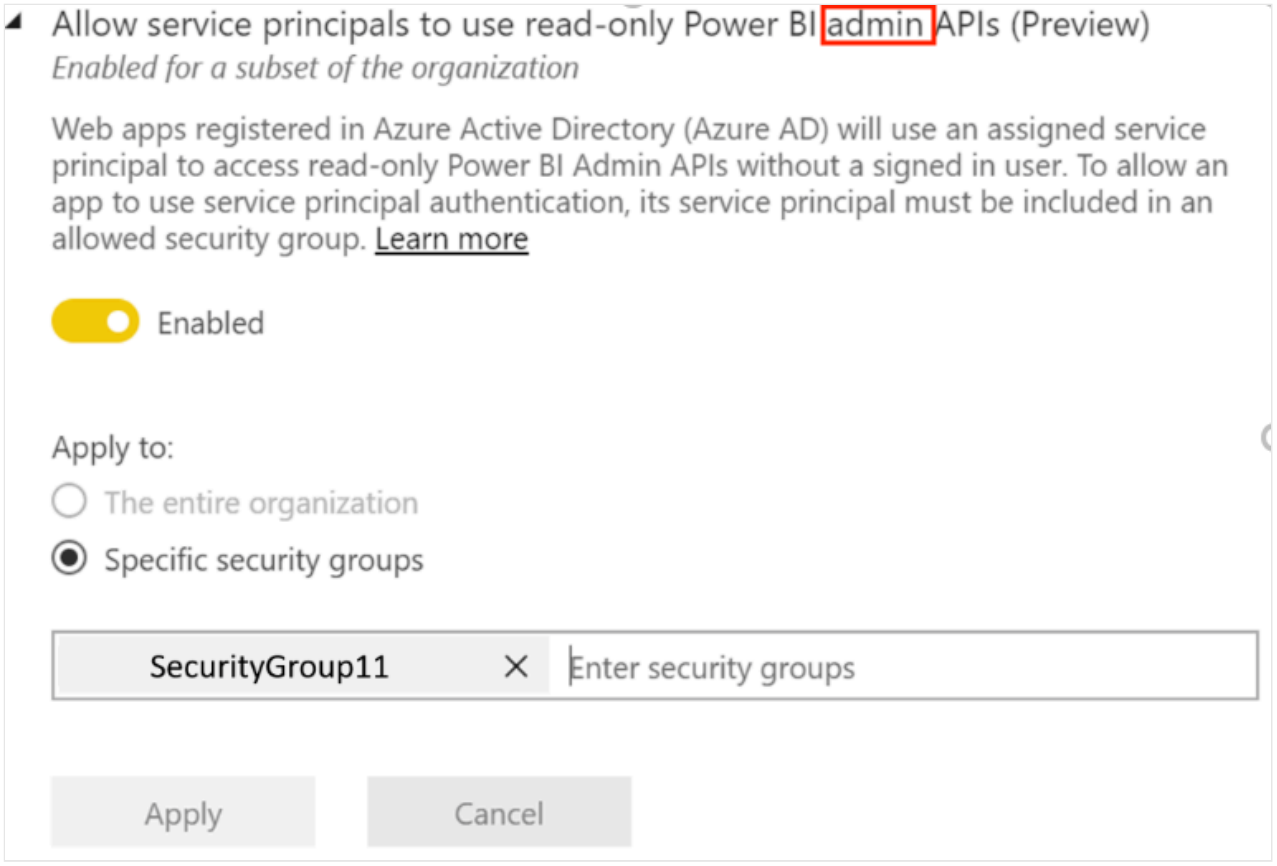


- If you're using **delegated authentication** or **service principal** as authentication method, add your **service principal** to this security group. Select **Members**, then select **+ Add members**.

5. Search for your Microsoft Purview managed identity or service principal and select it.

You should see a success notification showing you that it was added.

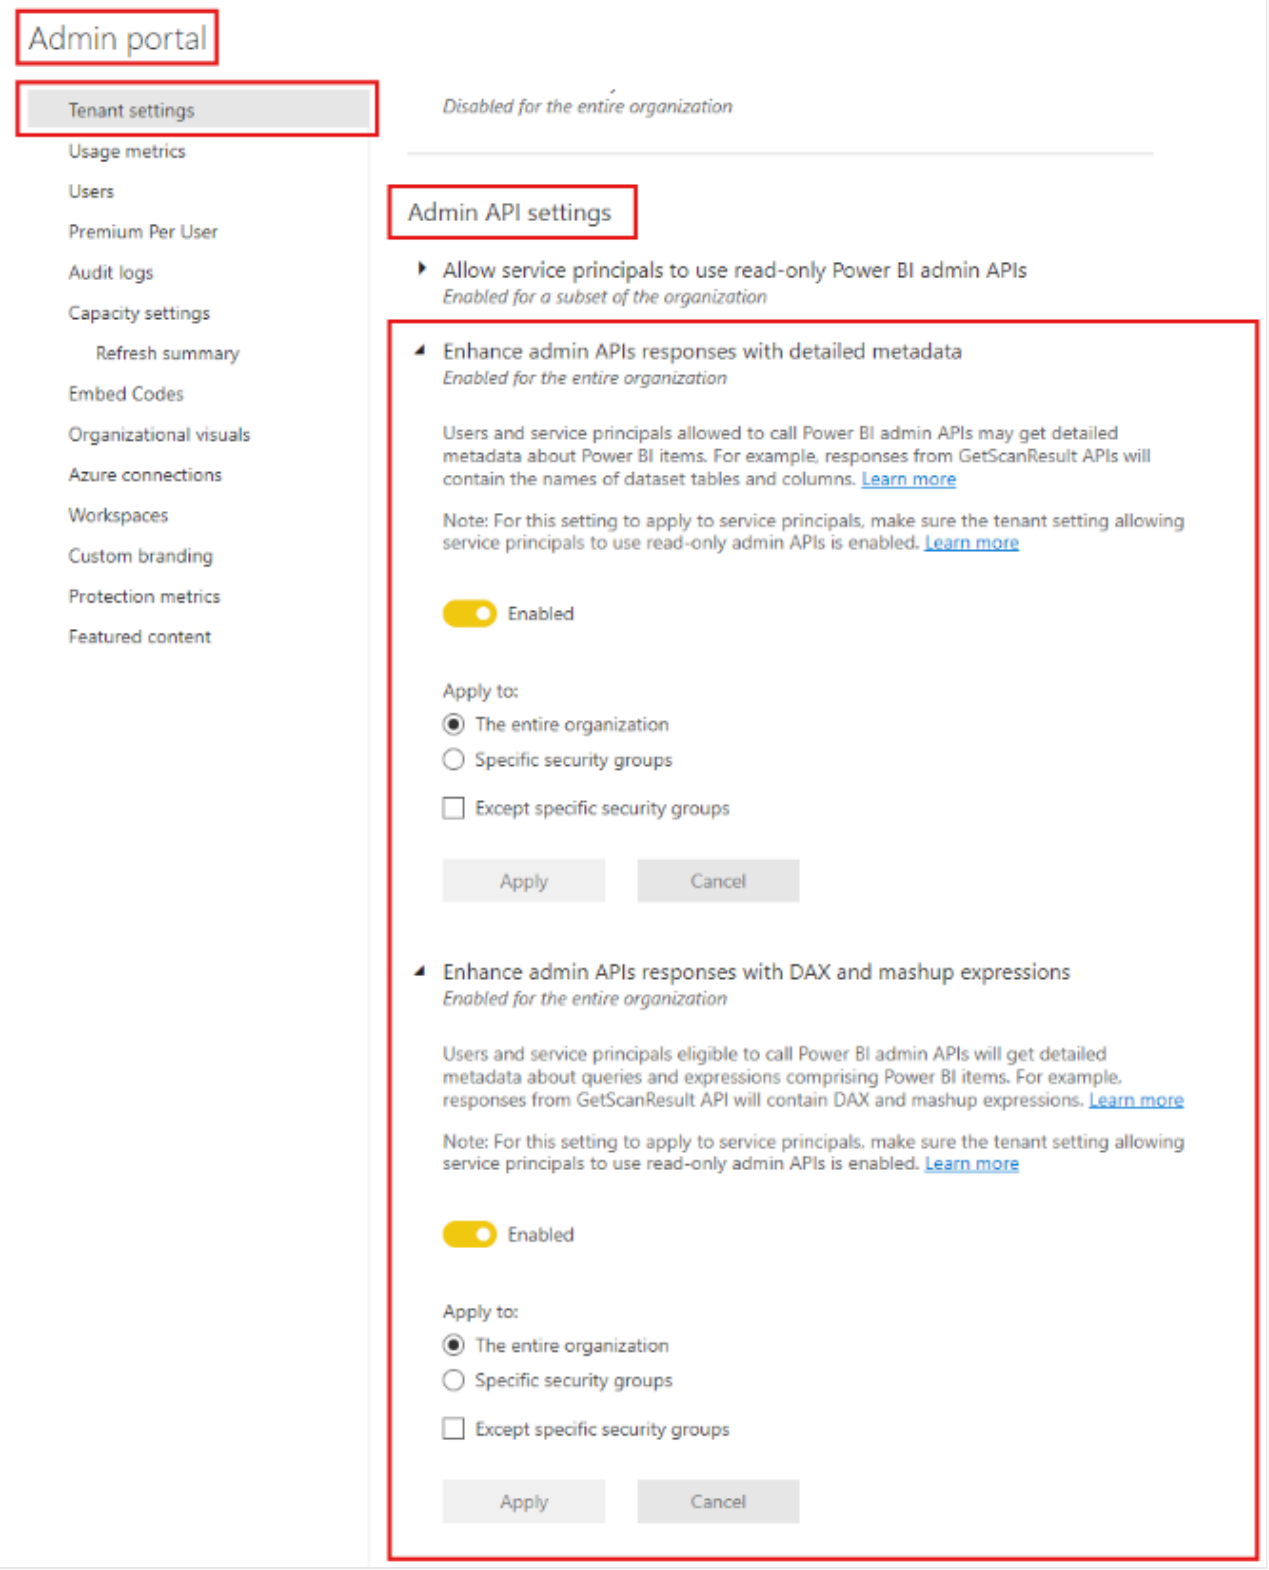
Associate the security group with Power BI tenant



1. Log into the Power BI admin portal.

2. Select the **Tenant settings** page.

> **Important**
>
> You need to be a Power BI Admin to see the tenant settings page.



3. Select **Admin API settings** > **Allow service principals to use read-only Power BI admin APIs (Preview)**.

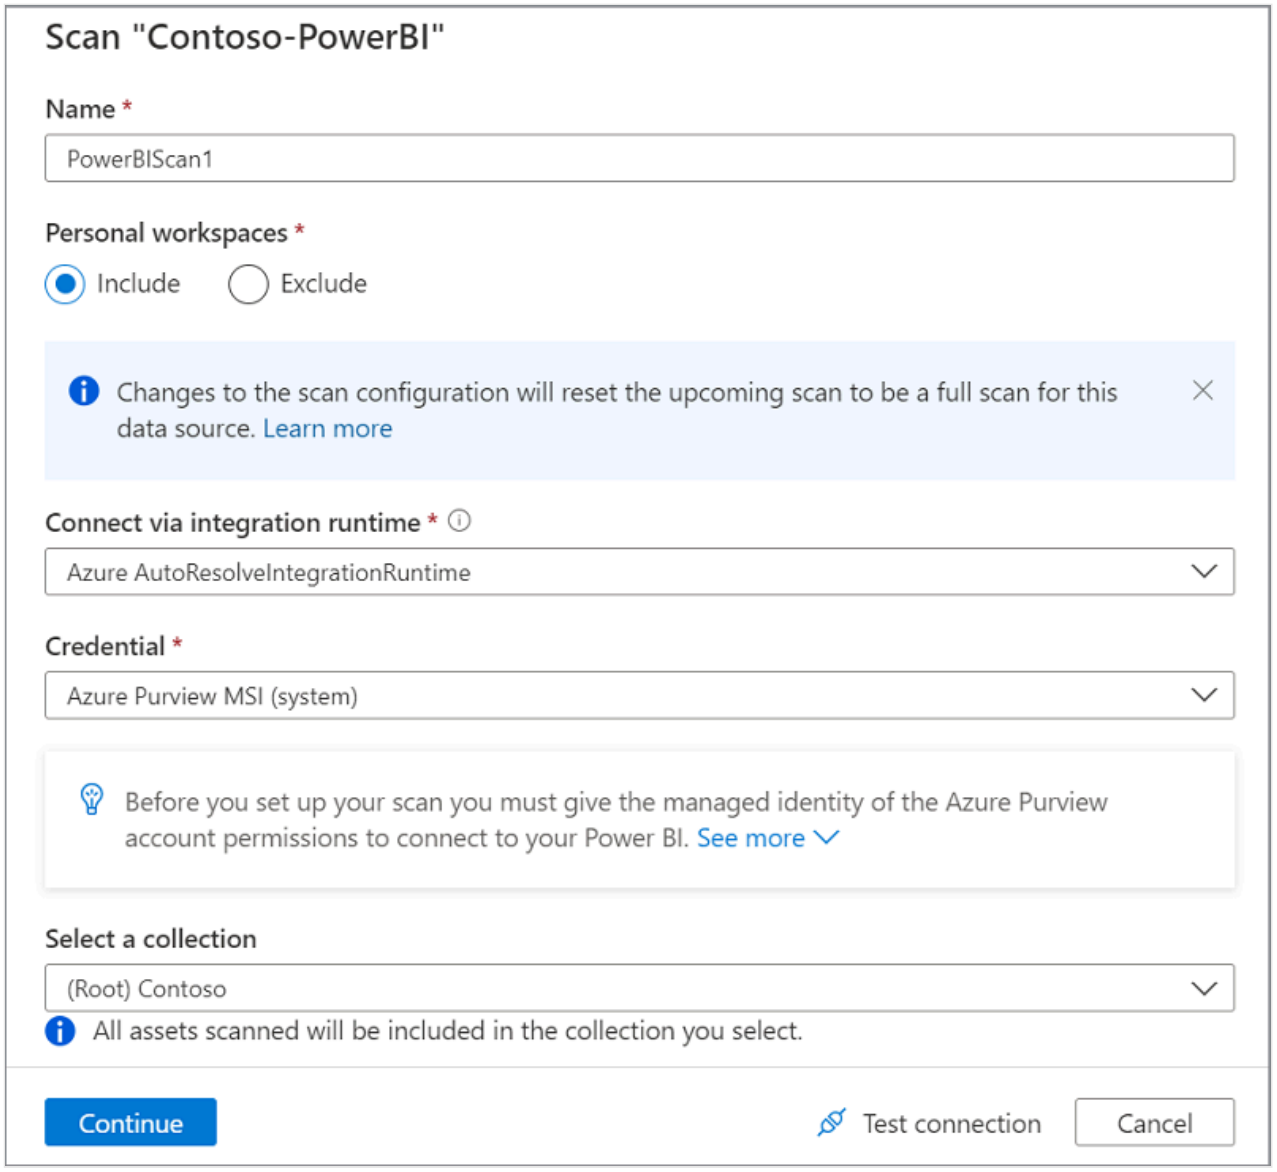
4. Select **Specific security groups**.

5. Select **Admin API settings** > **Enhance admin APIs responses with detailed metadata** and **Enhance admin APIs responses with DAX and mashup expressions** > Enable the toggle to allow Microsoft Purview Data Map automatically discover the detailed metadata of Power BI datasets as part of its scans.

> **ⓘ Important**
>
> After you update the Admin API settings on your power bi tenant, wait around 15 minutes before registering a scan and test connection.

⊗ Caution

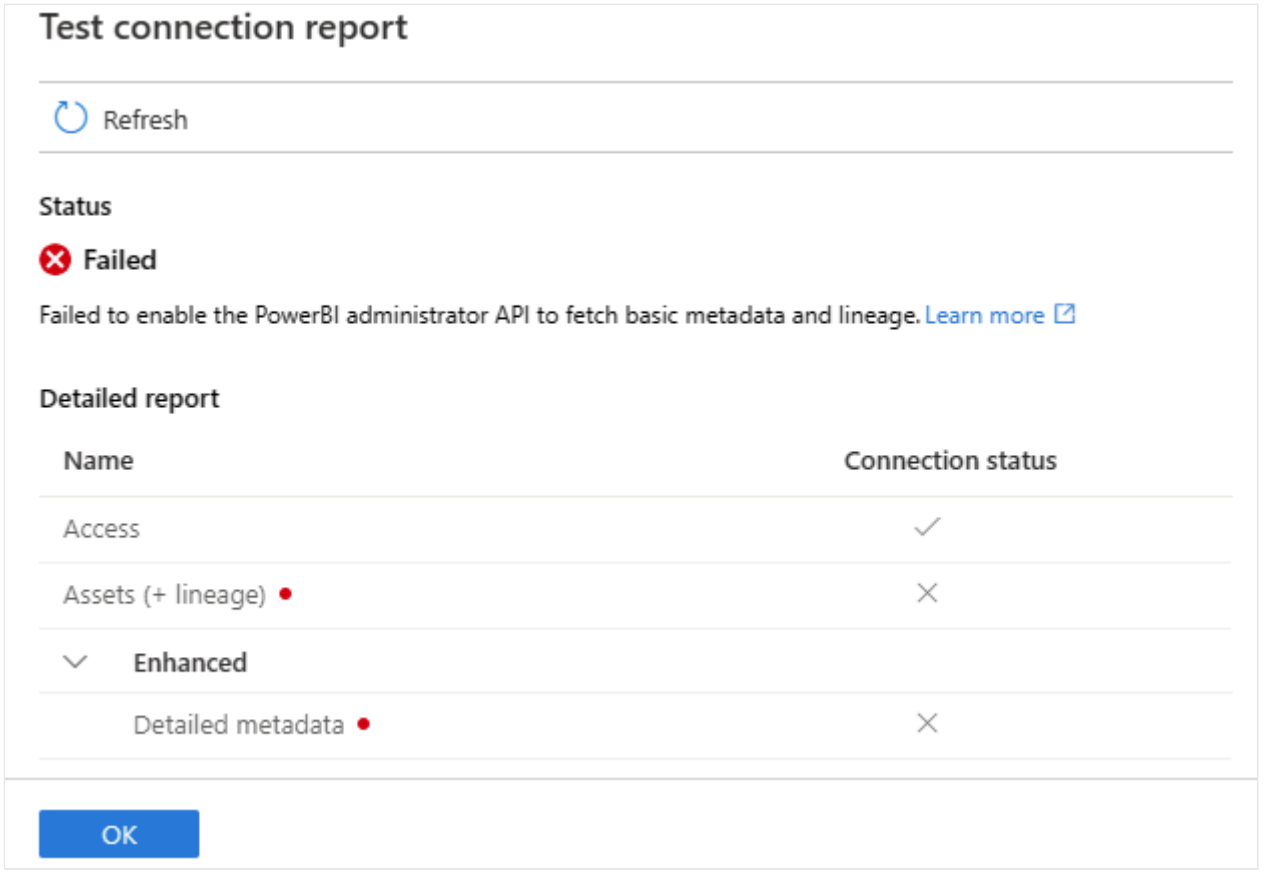
When you allow the security group you created (that has your Microsoft Purview managed identity as a member) to use read-only Power BI admin APIs, you also allow it to access the metadata (e.g. dashboard and report names, owners, descriptions, etc.) for all of your Power BI artifacts in this tenant. Once the metadata has been pulled into the Microsoft Purview, Microsoft Purview's permissions, not Power BI permissions, determine who can see that metadata.



> **Note**
>
> You can remove the security group from your developer settings, but the metadata previously extracted won't be removed from the Microsoft Purview account. You can delete it separately, if you wish.

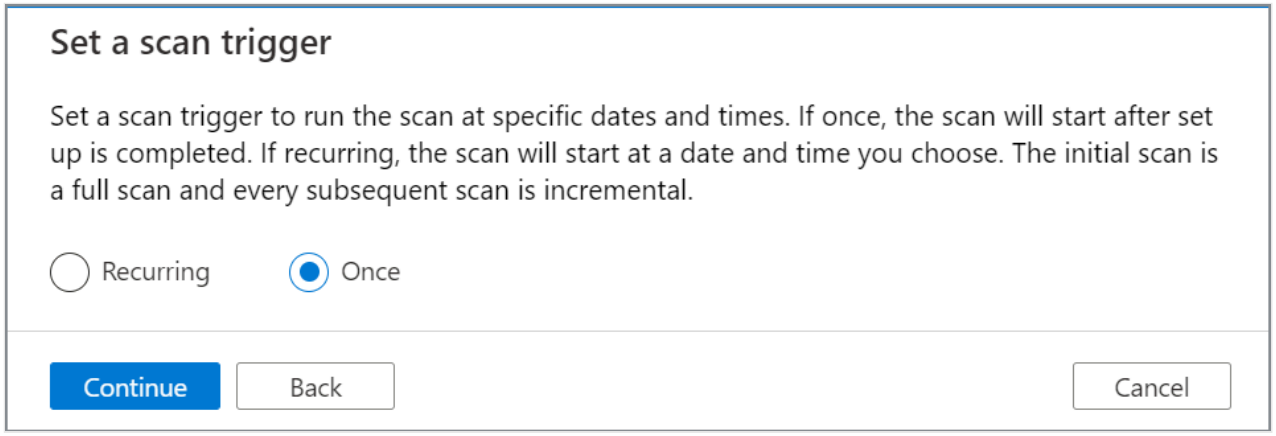
Create scan for same-tenant Power BI using Azure IR and Managed Identity

This is a suitable scenario, if both Microsoft Purview and Power BI tenant are configured to allow public access in the network settings.

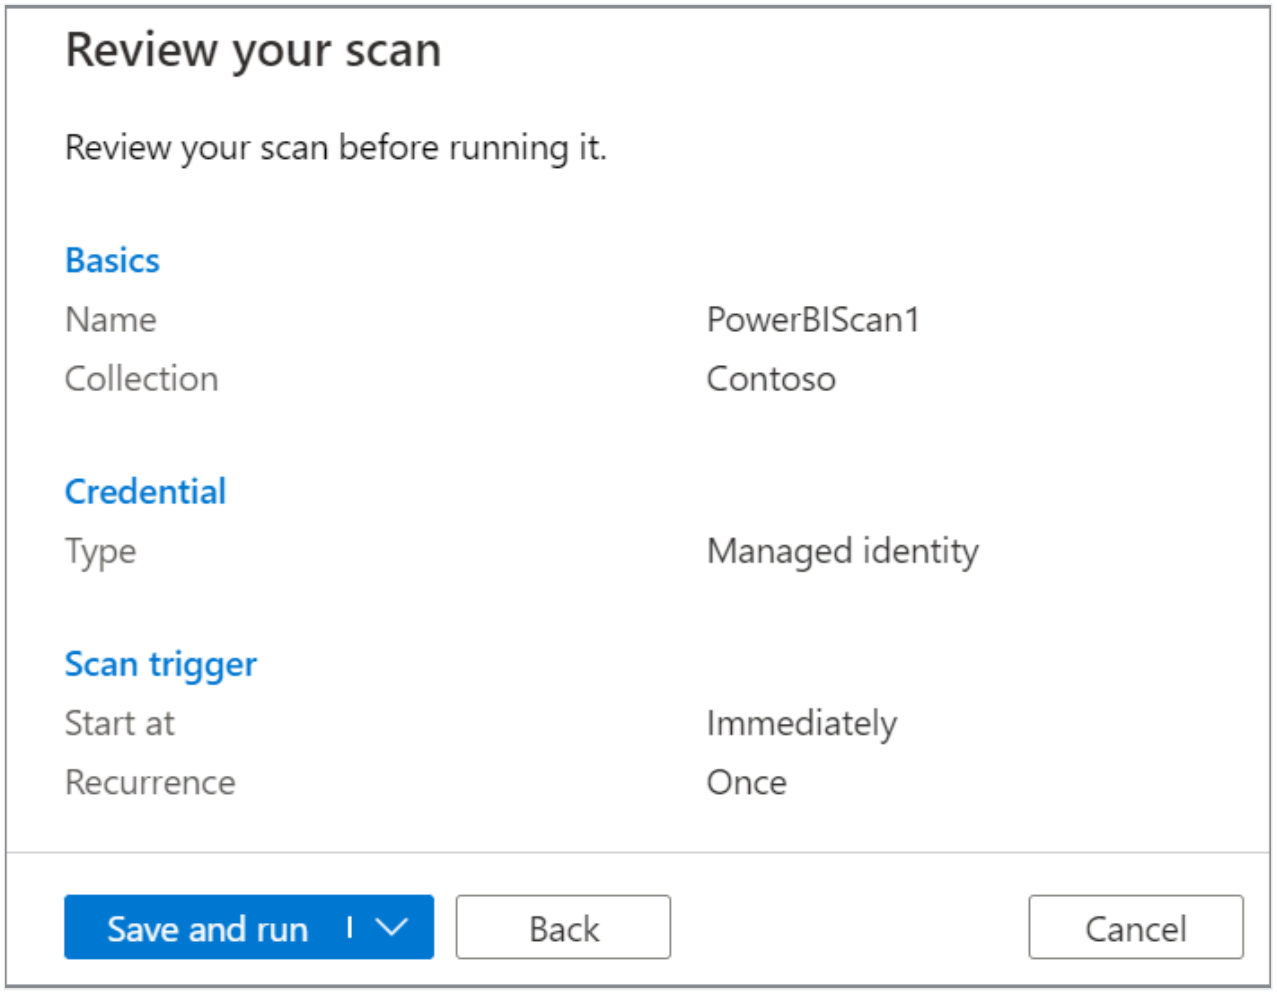


To create and run a new scan, do the following:

1. In the Microsoft Purview Studio, navigate to the **Data map** in the left menu.
2. Navigate to **Sources**.
3. Select the registered Power BI source.
4. Select + **New scan**.
5. Give your scan a name. Then select the option to include or exclude the personal workspaces.



> **Note**
>
> Switching the configuration of a scan to include or exclude a personal workspace will trigger a full scan of Power BI source.

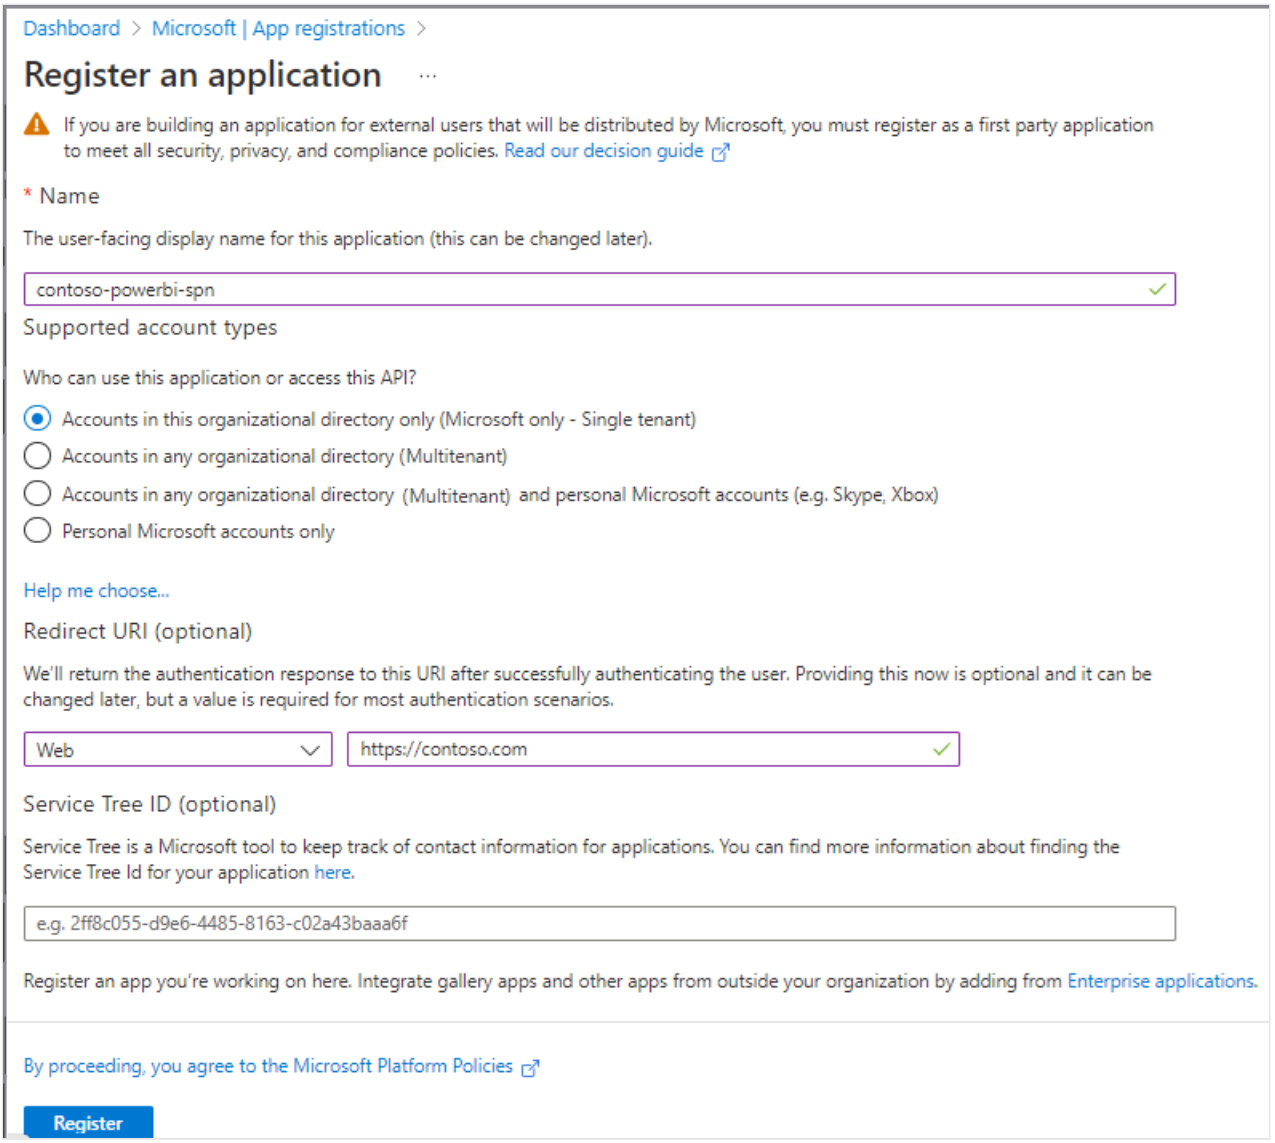


6. Select **Test Connection** before continuing to next steps. If **Test Connection** failed, select **View Report** to see the detailed status and troubleshoot the problem.
   a. Access - Failed status means the user authentication failed. Scans using managed identity will always pass because no user authentication required.
   b. Assets (+ lineage) - Failed status means the Microsoft Purview - Power BI authorization has failed. Make sure the Microsoft Purview managed identity is added to the security group associated in Power BI admin portal.
   c. Detailed metadata (Enhanced) - Failed status means the Power BI admin portal is disabled for the following setting - **Enhance admin APIs responses with detailed metadata**

7. Set up a scan trigger. Your options are **Recurring**, and **Once**.

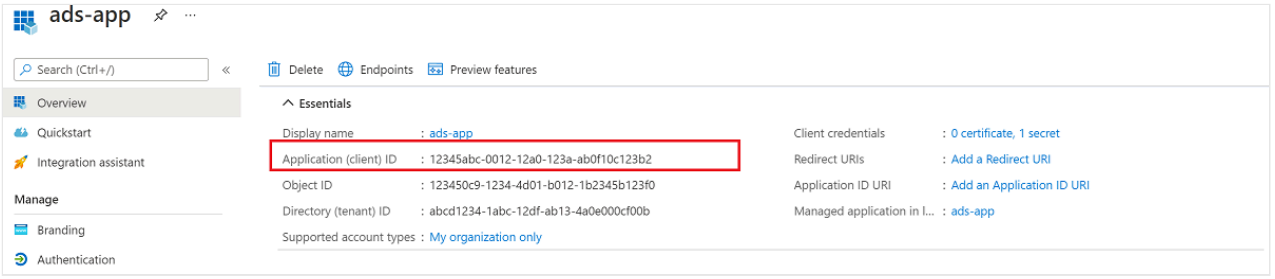
8. On **Review new scan**, select **Save and run** to launch your scan.

Create scan for same-tenant using self-hosted IR with service principal



This scenario can be used when Microsoft Purview and Power BI tenant or both, are configured to use private endpoint and deny public access. Additionally, this option is also applicable if Microsoft Purview and Power BI tenant are configured to allow public access.

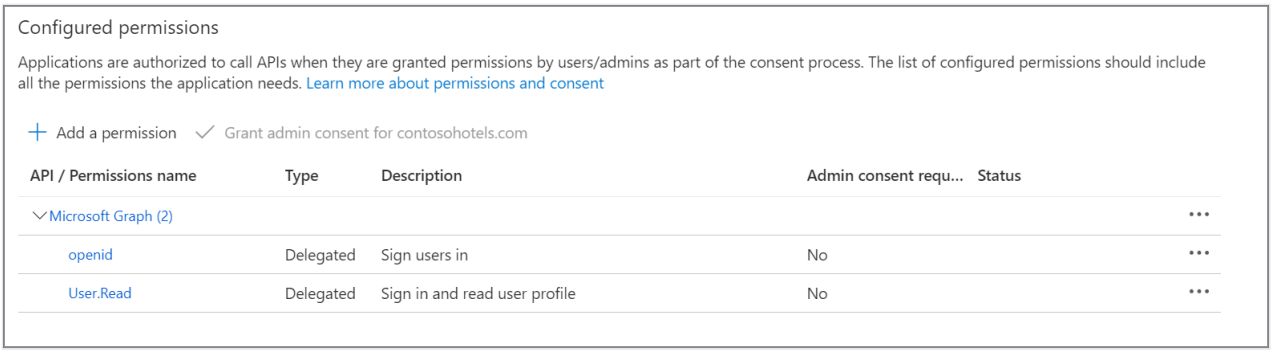
For more information related to Power BI network, see How to configure private endpoints for accessing Power BI.



For more information about Microsoft Purview network settings, see Use private endpoints for your Microsoft Purview account.

To create and run a new scan, do the following:

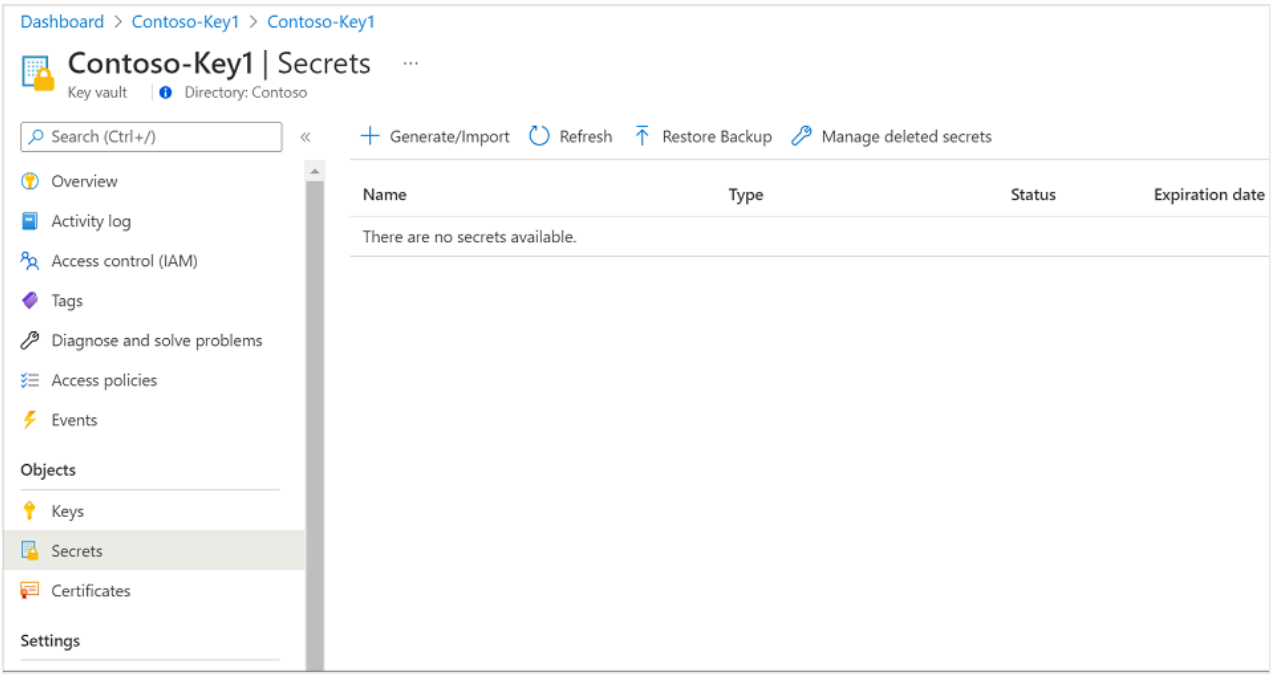
1. In the Azure portal, select **Microsoft Entra ID** and create an App Registration in the tenant. Provide a web URL in the **Redirect URI**. For information about the Redirect URI see this documentation from Microsoft Entra ID.



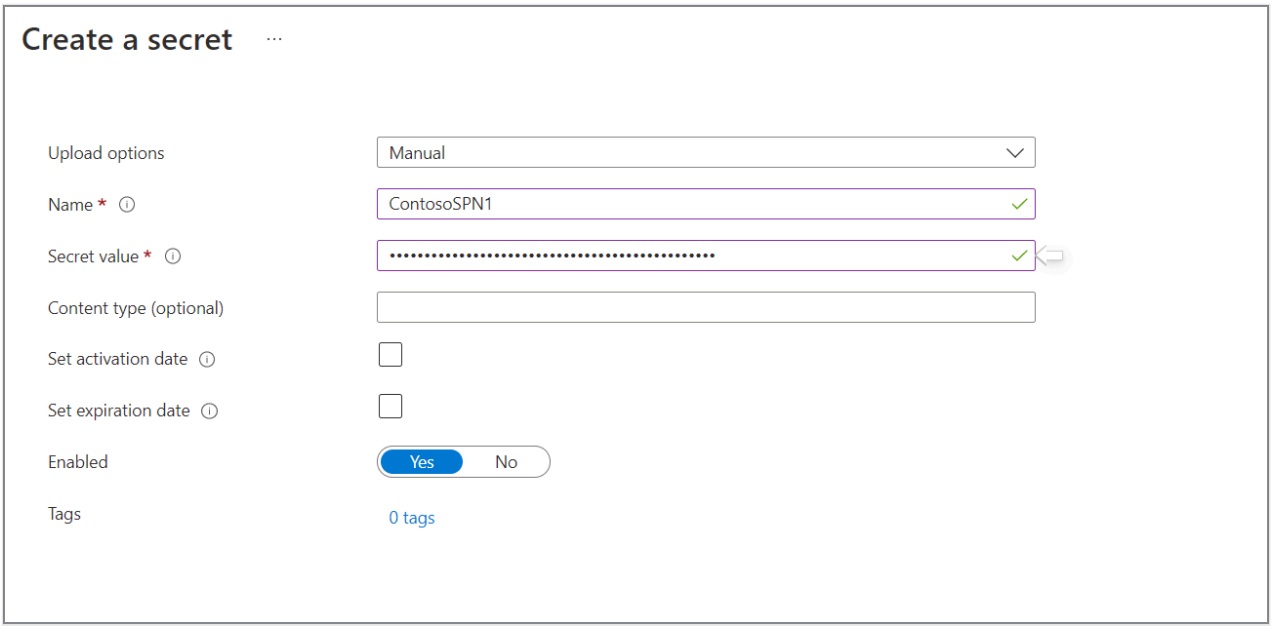
2. Take note of Client ID(App ID).

3. From Microsoft Entra dashboard, select newly created application and then select **App registration**. From **API Permissions**, assign the application the following delegated permissions:

   - Microsoft Graph openid
   - Microsoft Graph User.Read



4. Under **Advanced settings**, enable **Allow Public client flows**.



5. Under **Certificates & secrets**, create a new secret and save it securely for next steps.

6. In Azure portal, navigate to your Azure key vault.

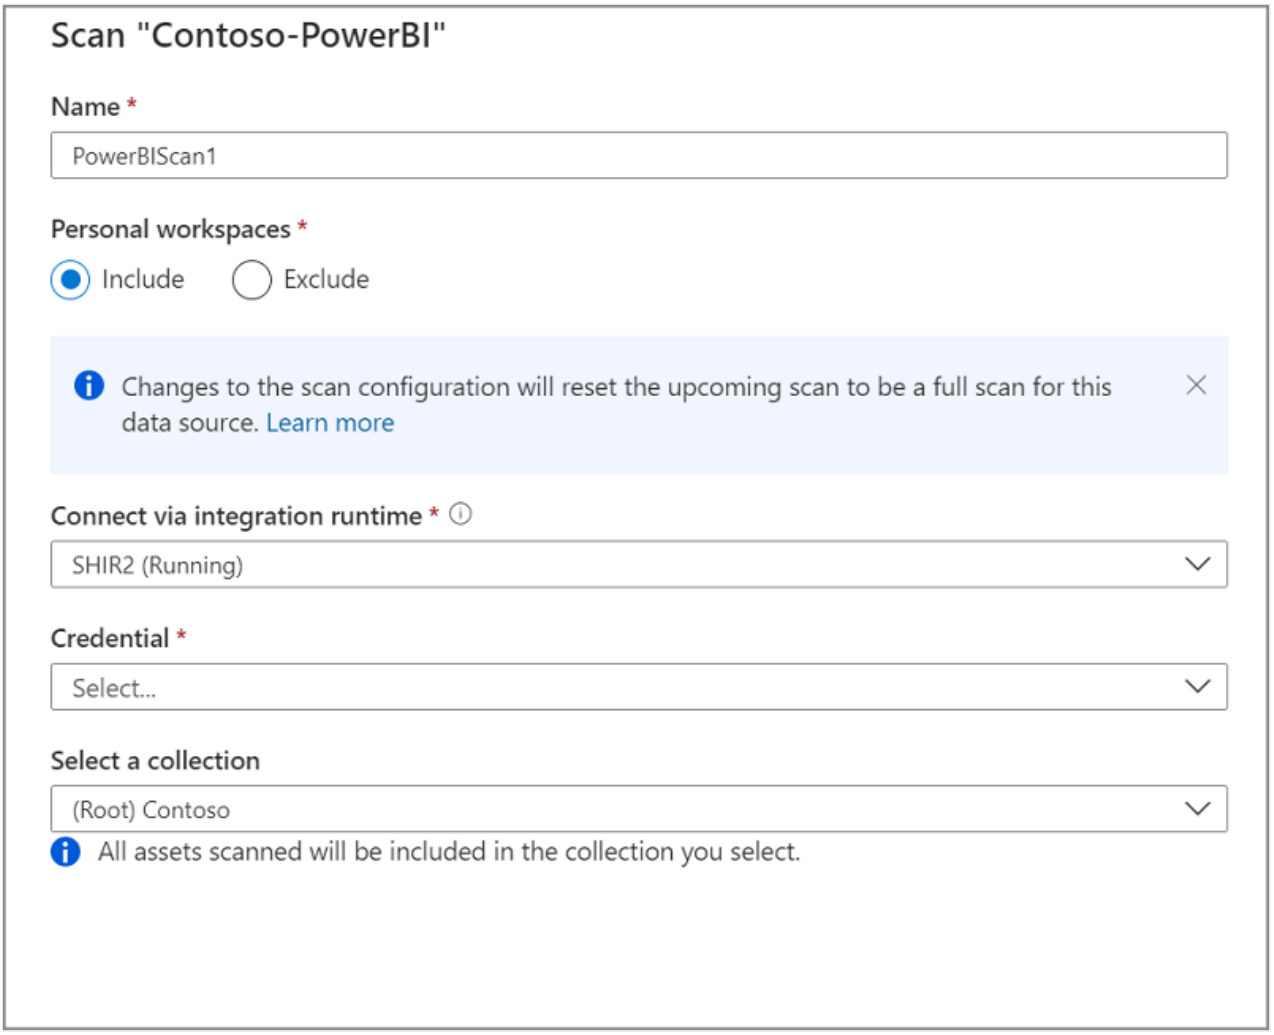
7. Select **Settings** > **Secrets** and select **+ Generate/Import**.

8. Enter a name for the secret and for **Value**, type the newly created secret for the App registration. Select **Create** to complete.

9. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection

10. In the Microsoft Purview Studio, navigate to the **Data map** in the left menu.

11. Navigate to **Sources**.

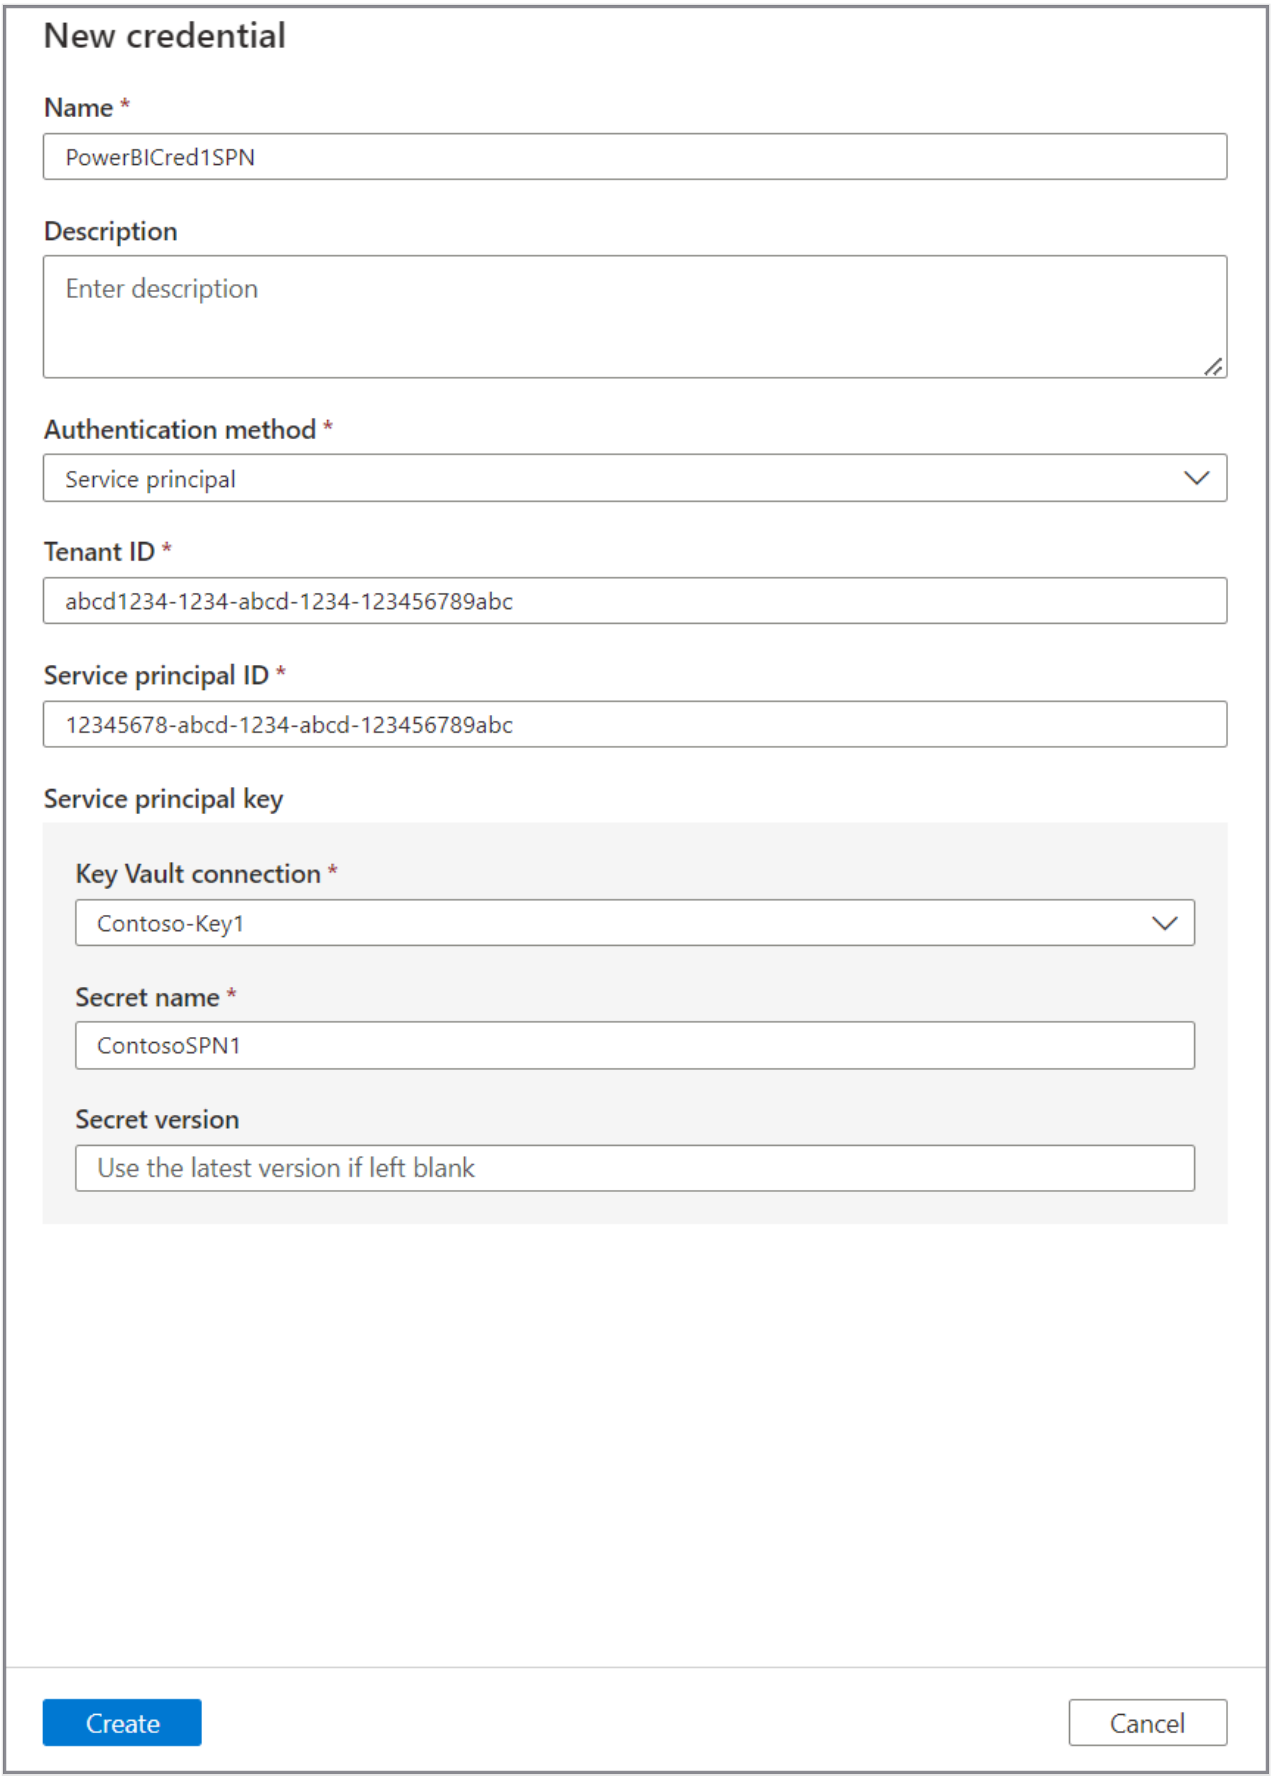


12. Select the registered Power BI source.

13. Select + **New scan**.

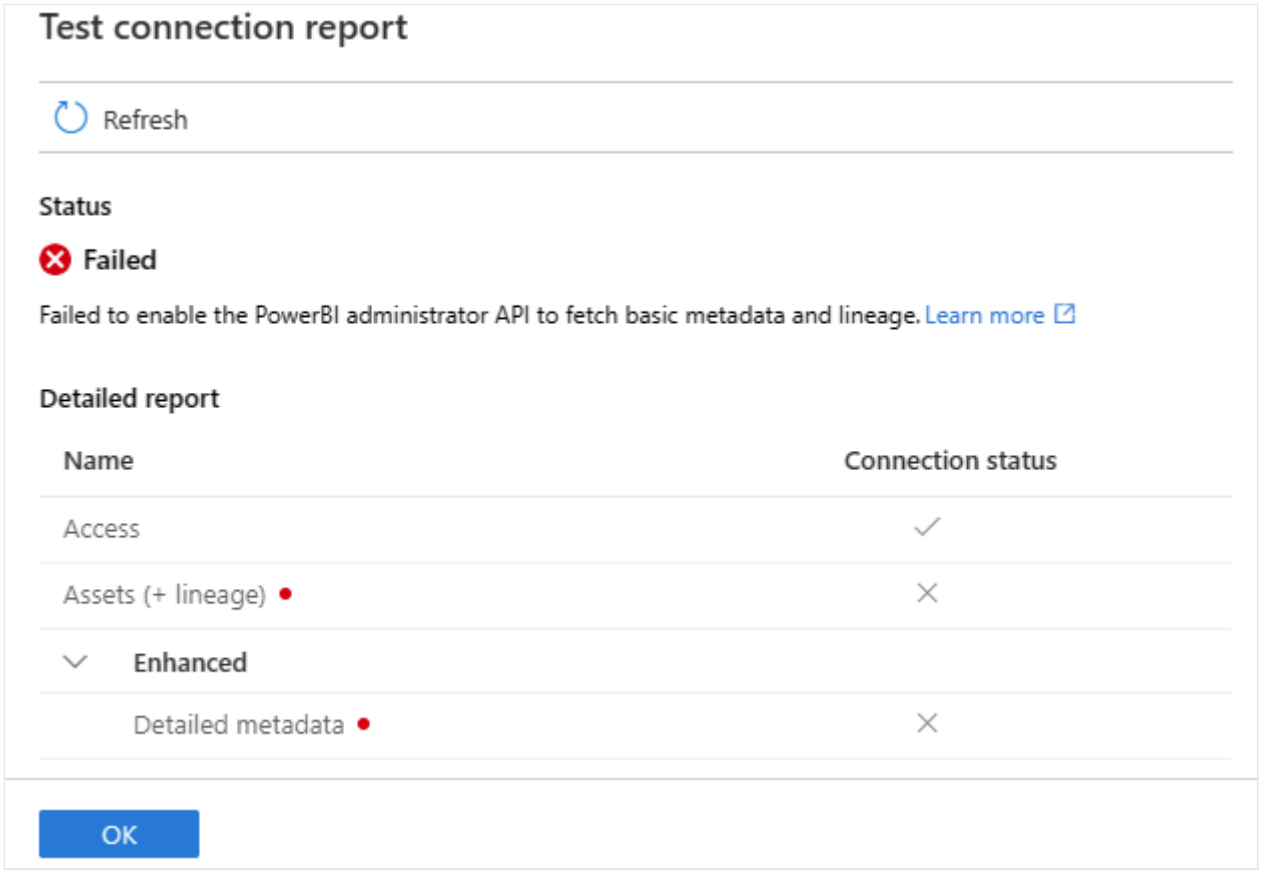
14. Give your scan a name. Then select the option to include or exclude the personal workspaces.

    > **Note**
    >
    > Switching the configuration of a scan to include or exclude a personal workspace will trigger a full scan of Power BI source.



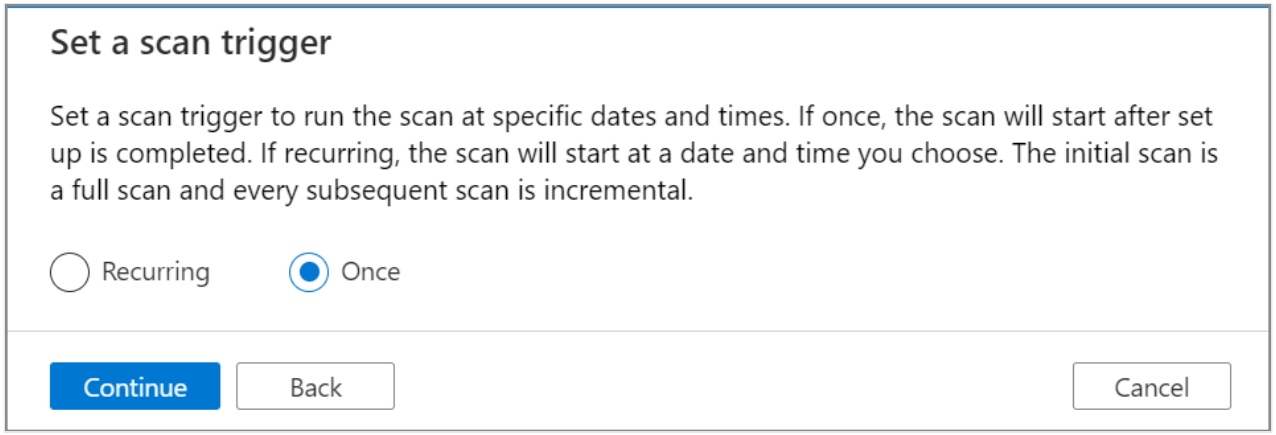
15. Select your self-hosted integration runtime from the drop-down list.

16. For the **Credential**, select **service principal** and select **+ New** to create a new credential.



17. Create a new credential and provide required parameters:

    - **Name**: Provide a unique name for credential
    - **Authentication method**: Service principal
    - **Tenant ID**: Your Power BI tenant ID
    - **Client ID**: Use Service Principal Client ID (App ID) you created earlier



18. Select **Test Connection** before continuing to next steps. If **Test Connection** failed, select **View Report** to see the detailed status and troubleshoot the problem
    a. Access - Failed status means the user authentication failed. Scans using managed identity will always pass because no user authentication required.

b. Assets (+ lineage) - Failed status means the Microsoft Purview - Power BI authorization has failed. Make sure the Microsoft Purview managed identity is added to the security group associated in Power BI admin portal.
c. Detailed metadata (Enhanced) - Failed status means the Power BI admin portal is disabled for the following setting - **Enhance admin APIs responses with detailed metadata**

19. Set up a scan trigger. Your options are **Recurring**, and **Once**.

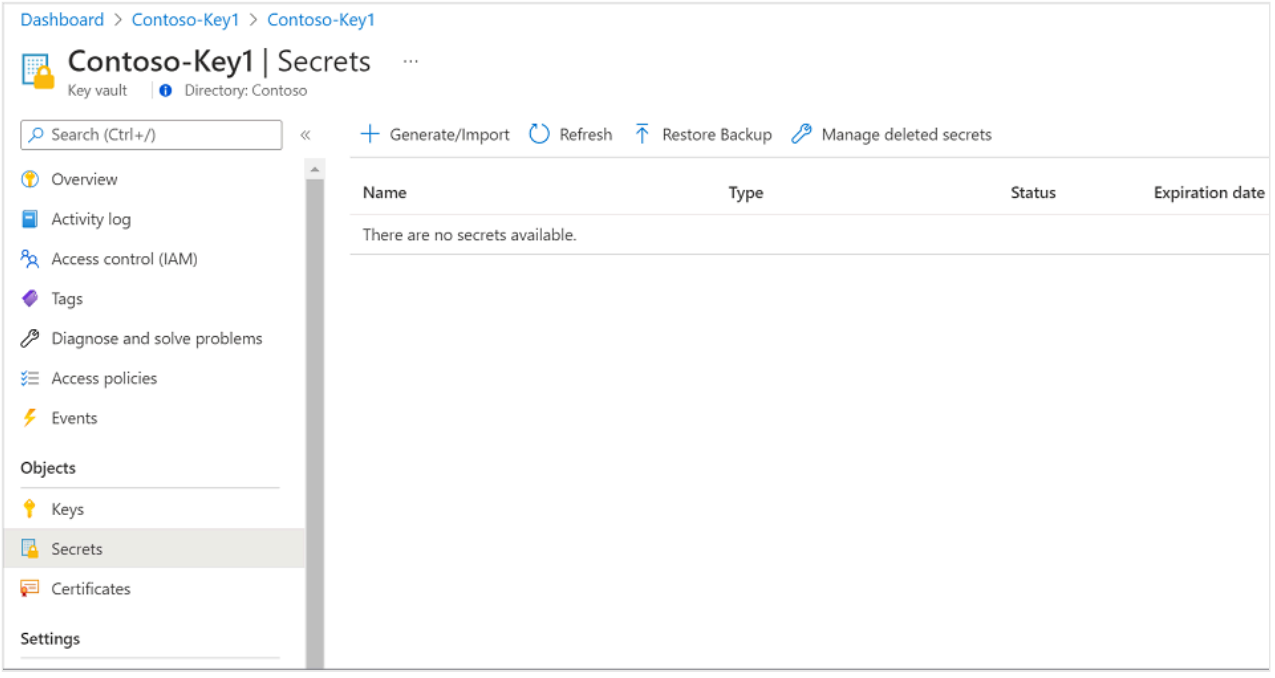
20. On **Review new scan**, select **Save and run** to launch your scan.

Create scan for same-tenant using self-hosted IR with delegated authentication

This scenario can be used when Microsoft Purview and Power BI tenant or both, are configured to use private endpoint and deny public access. Additionally, this option is also applicable if Microsoft Purview and Power BI tenant are configured to allow public access.

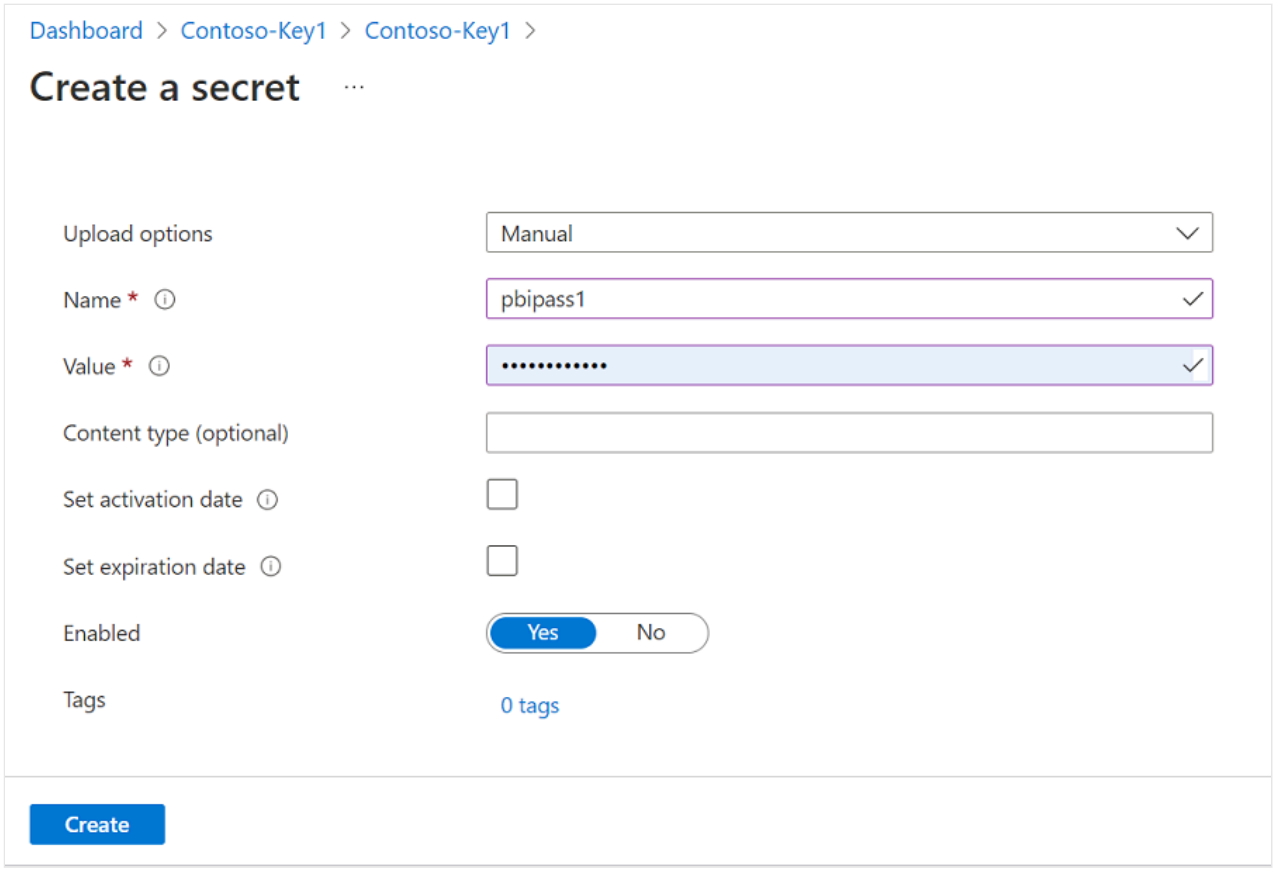
For more information related to Power BI network, see How to configure private endpoints for accessing Power BI.

For more information about Microsoft Purview network settings, see Use private endpoints for your Microsoft Purview account.



To create and run a new scan, do the following:

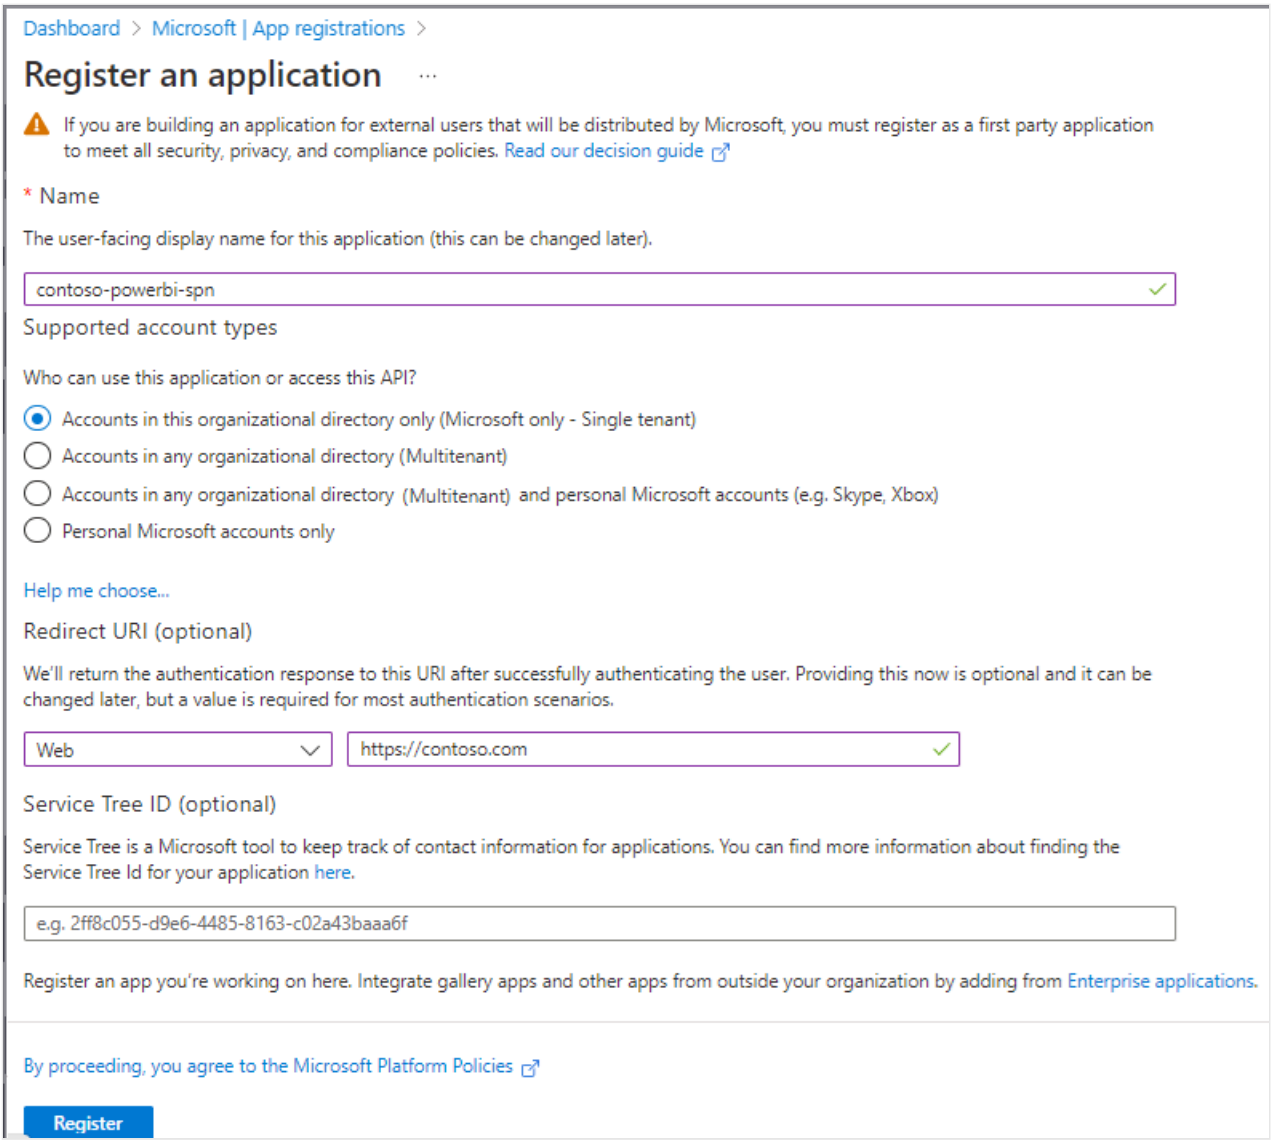
1. Create a user account in Microsoft Entra tenant and assign the user to Microsoft Entra role, **Fabric Administrator**. Take note of username and sign in to change the password.



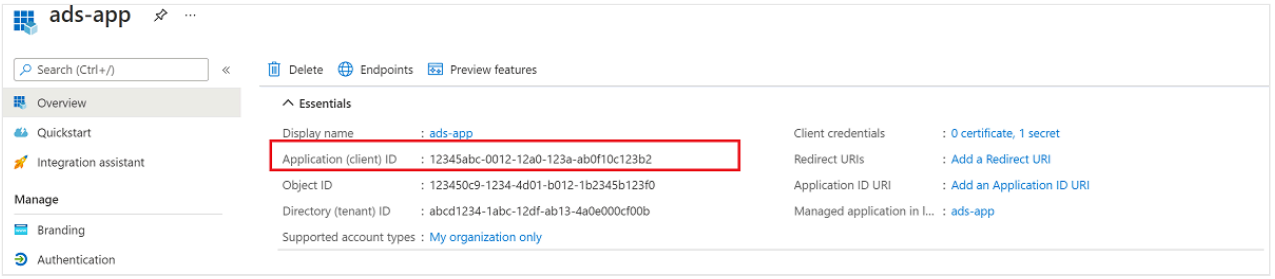
2. Assign proper Power BI license to the user.

3. Navigate to your Azure key vault.

4. Select **Settings** > **Secrets** and select **+ Generate/Import**.

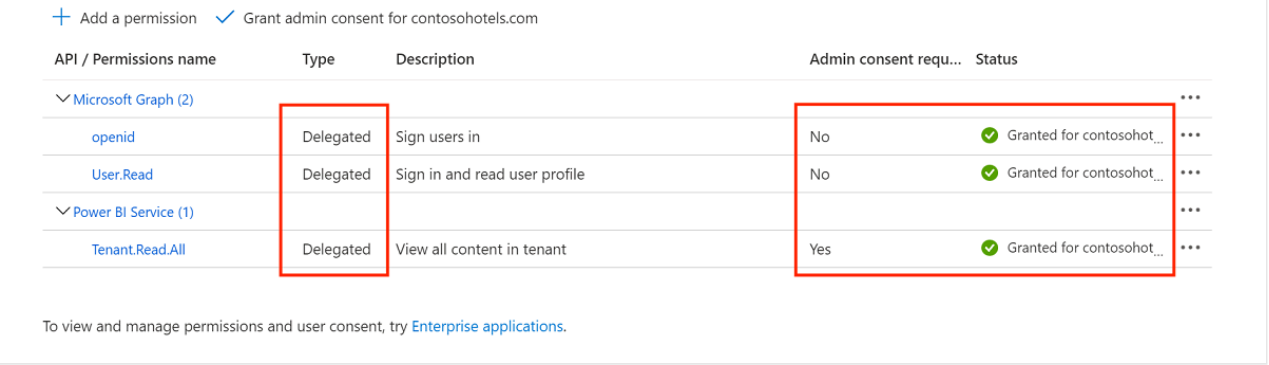


5. Enter a name for the secret and for **Value**, type the newly created password for the Microsoft Entra user. Select **Create** to complete.



6. If your key vault isn't connected to Microsoft Purview yet, you'll need to create a new key vault connection

7. Create an App Registration in your Microsoft Entra tenant. Provide a web URL in the **Redirect URI**.



8. Take note of Client ID(App ID).

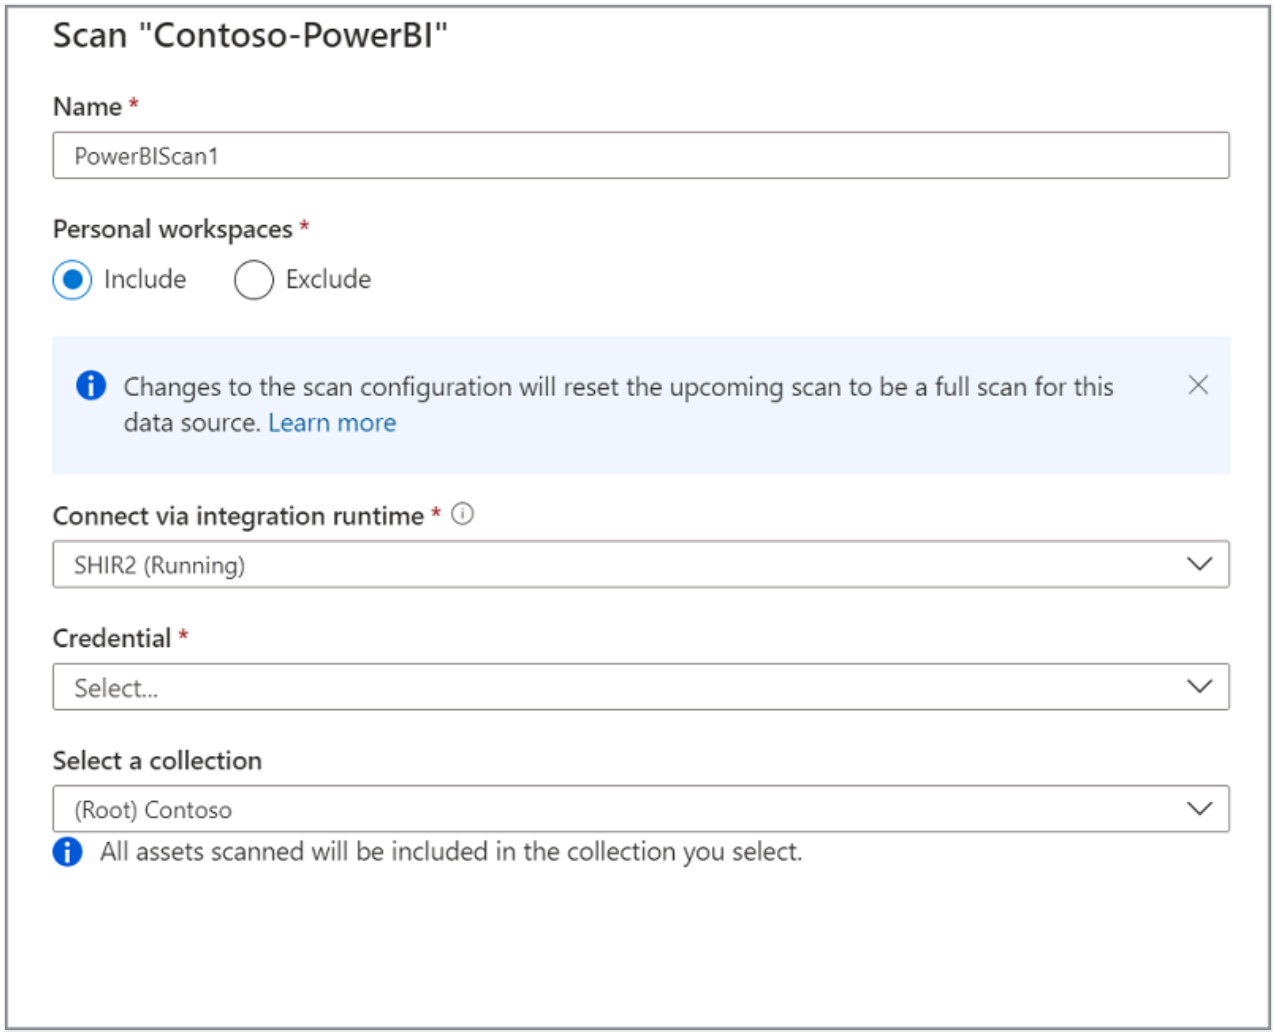
9. From Microsoft Entra dashboard, select newly created application and then select **App registration**. Assign the application the following delegated permissions, and grant admin consent for the tenant:

   - Power BI Service Tenant.Read.All
   - Microsoft Graph openid
   - Microsoft Graph User.Read

10. Under **Advanced settings**, enable **Allow Public client flows**.

11. In the Microsoft Purview Studio, navigate to the **Data map** in the left menu.

12. Navigate to **Sources**.

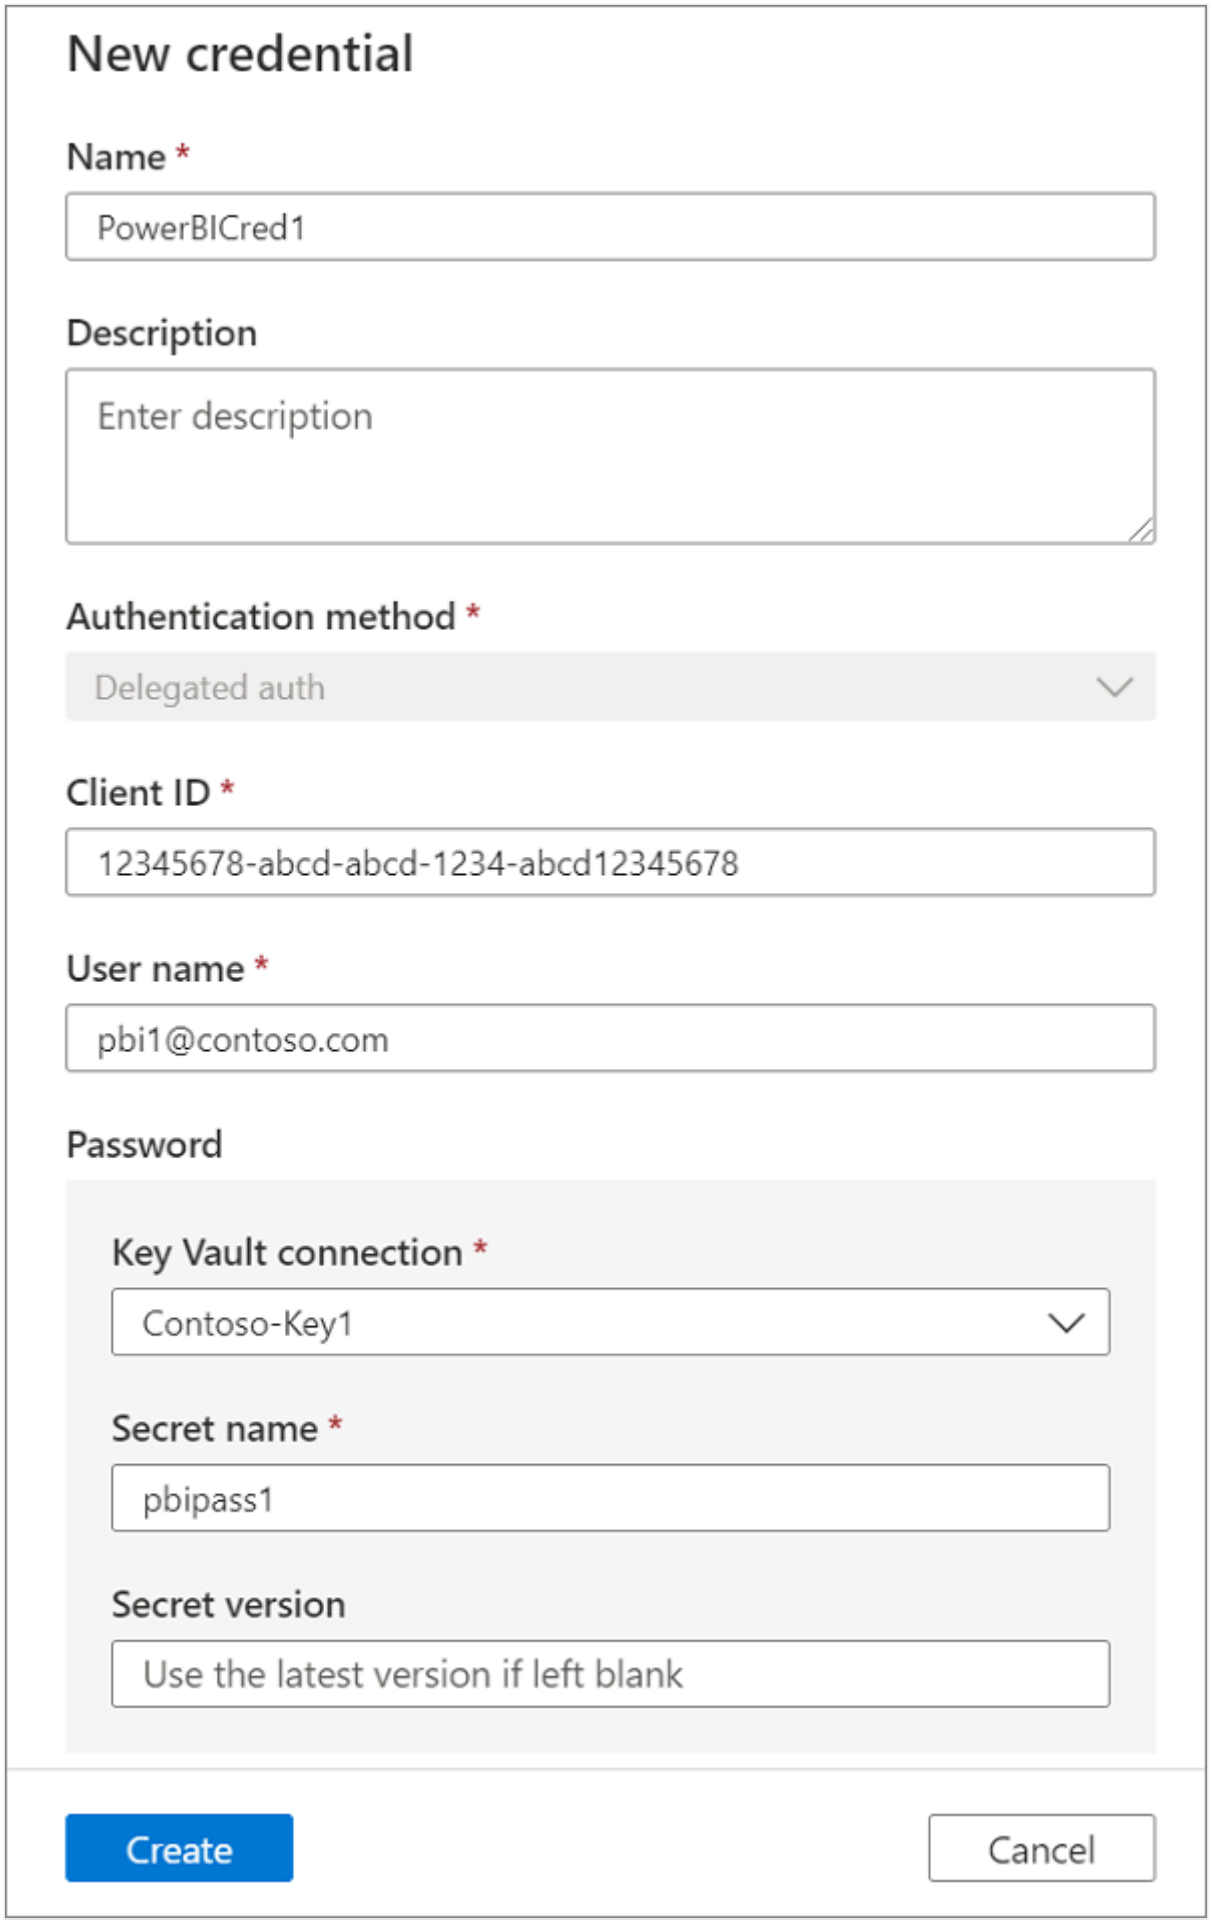


13. Select the registered Power BI source.

14. Select **+ New scan**.

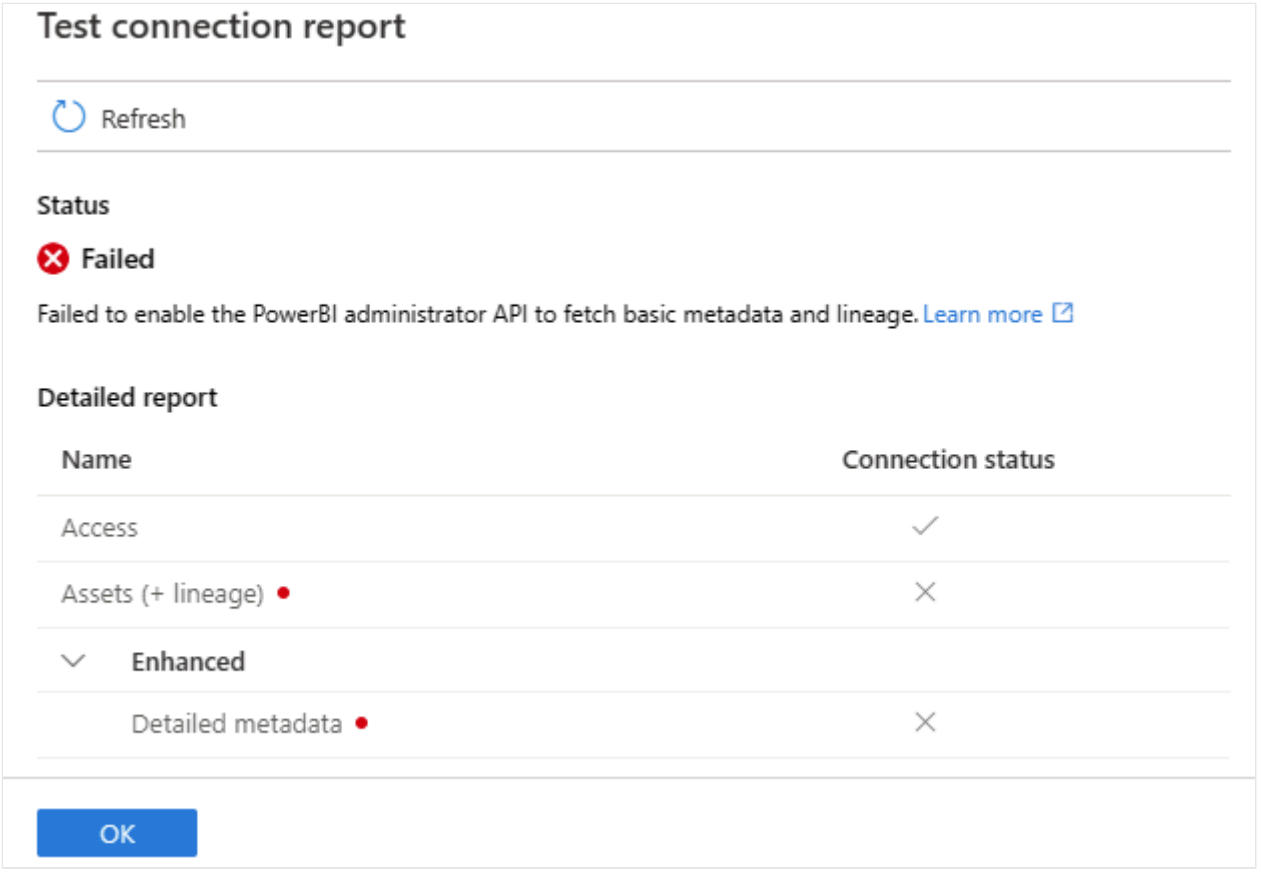
15. Give your scan a name. Then select the option to include or exclude the personal workspaces.

    > **Note**
    >
    > Switching the configuration of a scan to include or exclude a personal workspace will trigger a full scan of Power BI source.



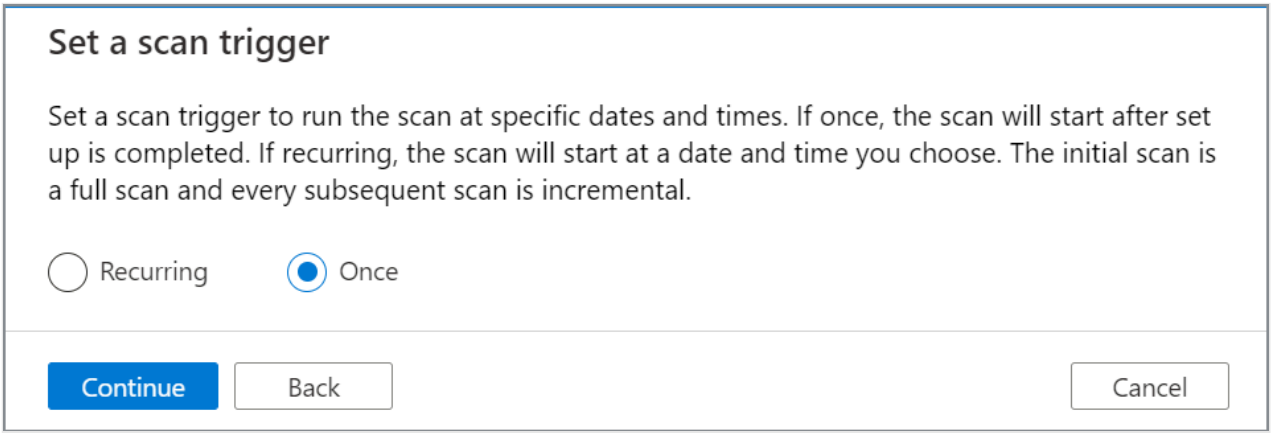
16. Select your self-hosted integration runtime from the drop-down list.

17. For the **Credential**, select **Delegated authentication** and select **+ New** to create a new credential.

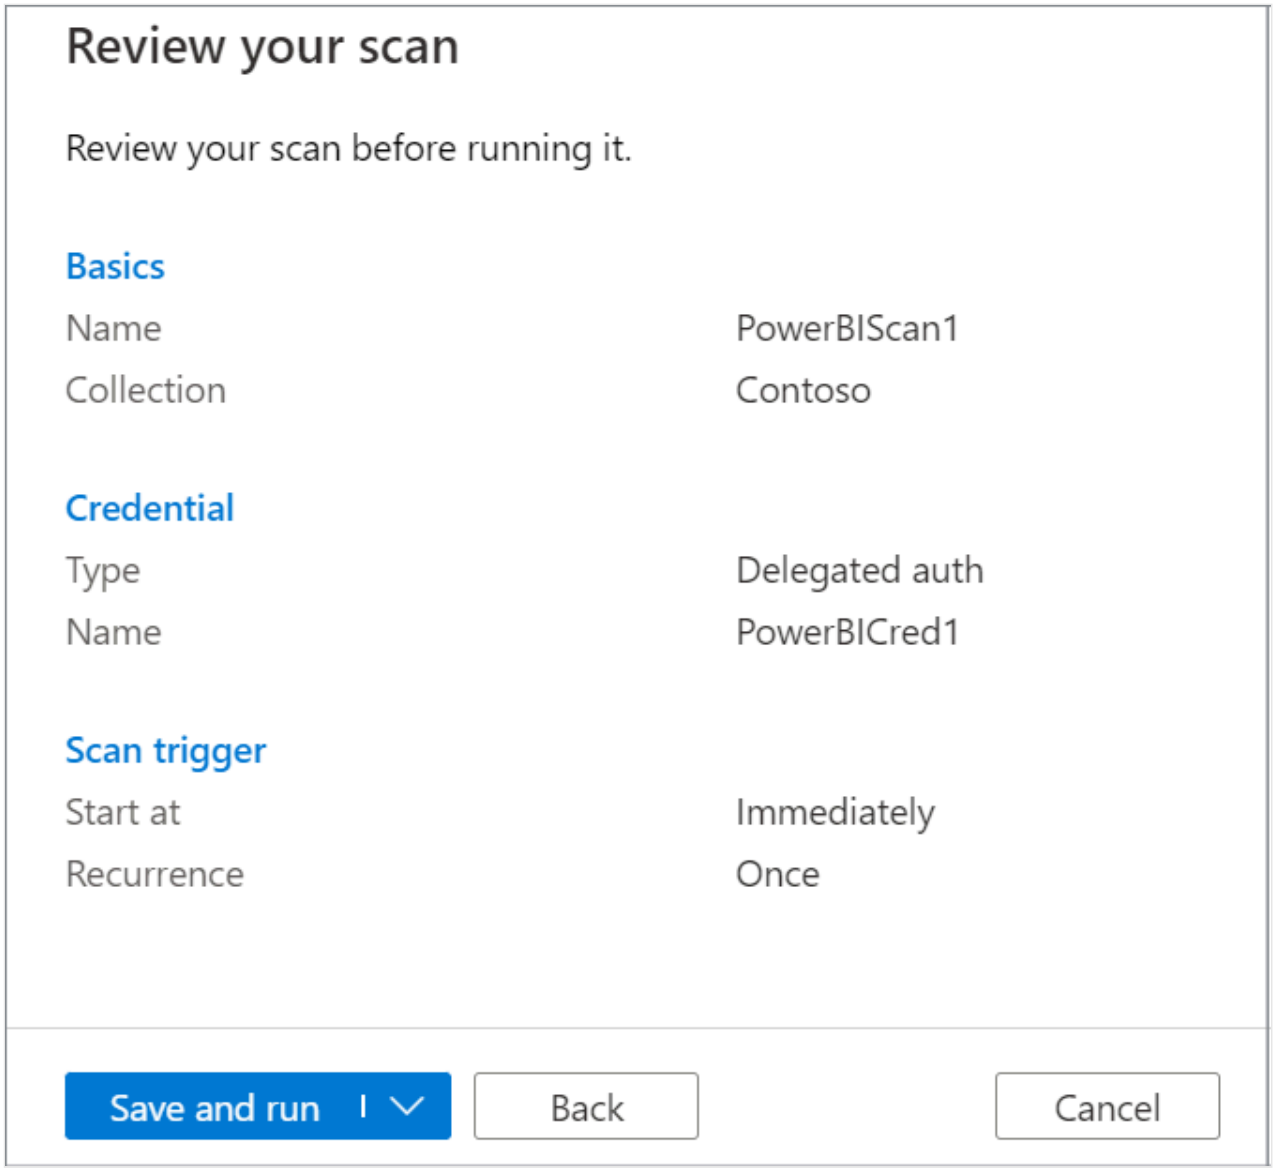


18. Create a new credential and provide required parameters:

    - **Name**: Provide a unique name for credential
    - **Authentication method**: Delegated auth
    - **Client ID**: Use Service Principal Client ID (App ID) you created earlier
    - **User name**: Provide the username of Fabric Administrator you created earlier
    - **Password**: Select the appropriate Key vault connection and the **Secret name** where the Power BI account password was saved earlier.

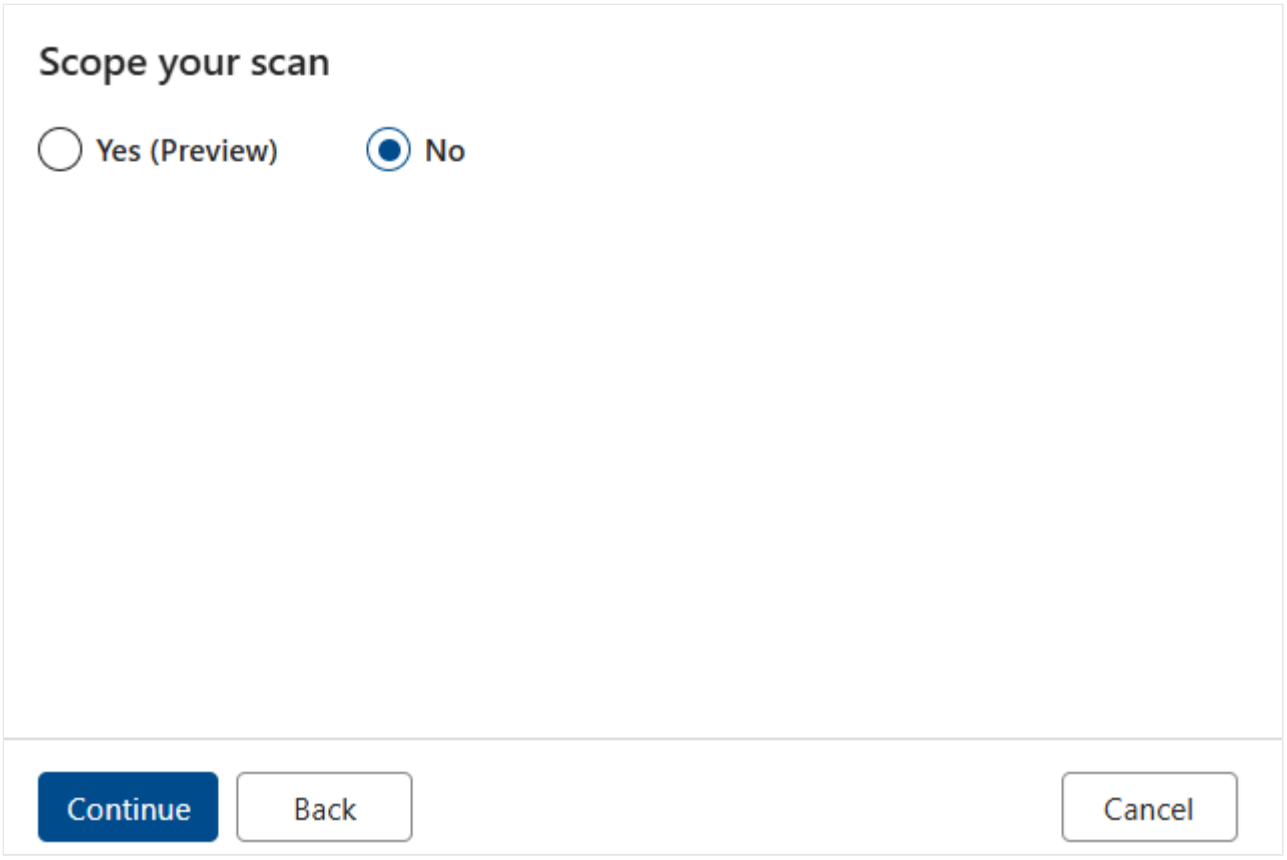


19. Select **Test Connection** before continuing to next steps. If **Test Connection** failed, select **View Report** to see the detailed status and troubleshoot the problem

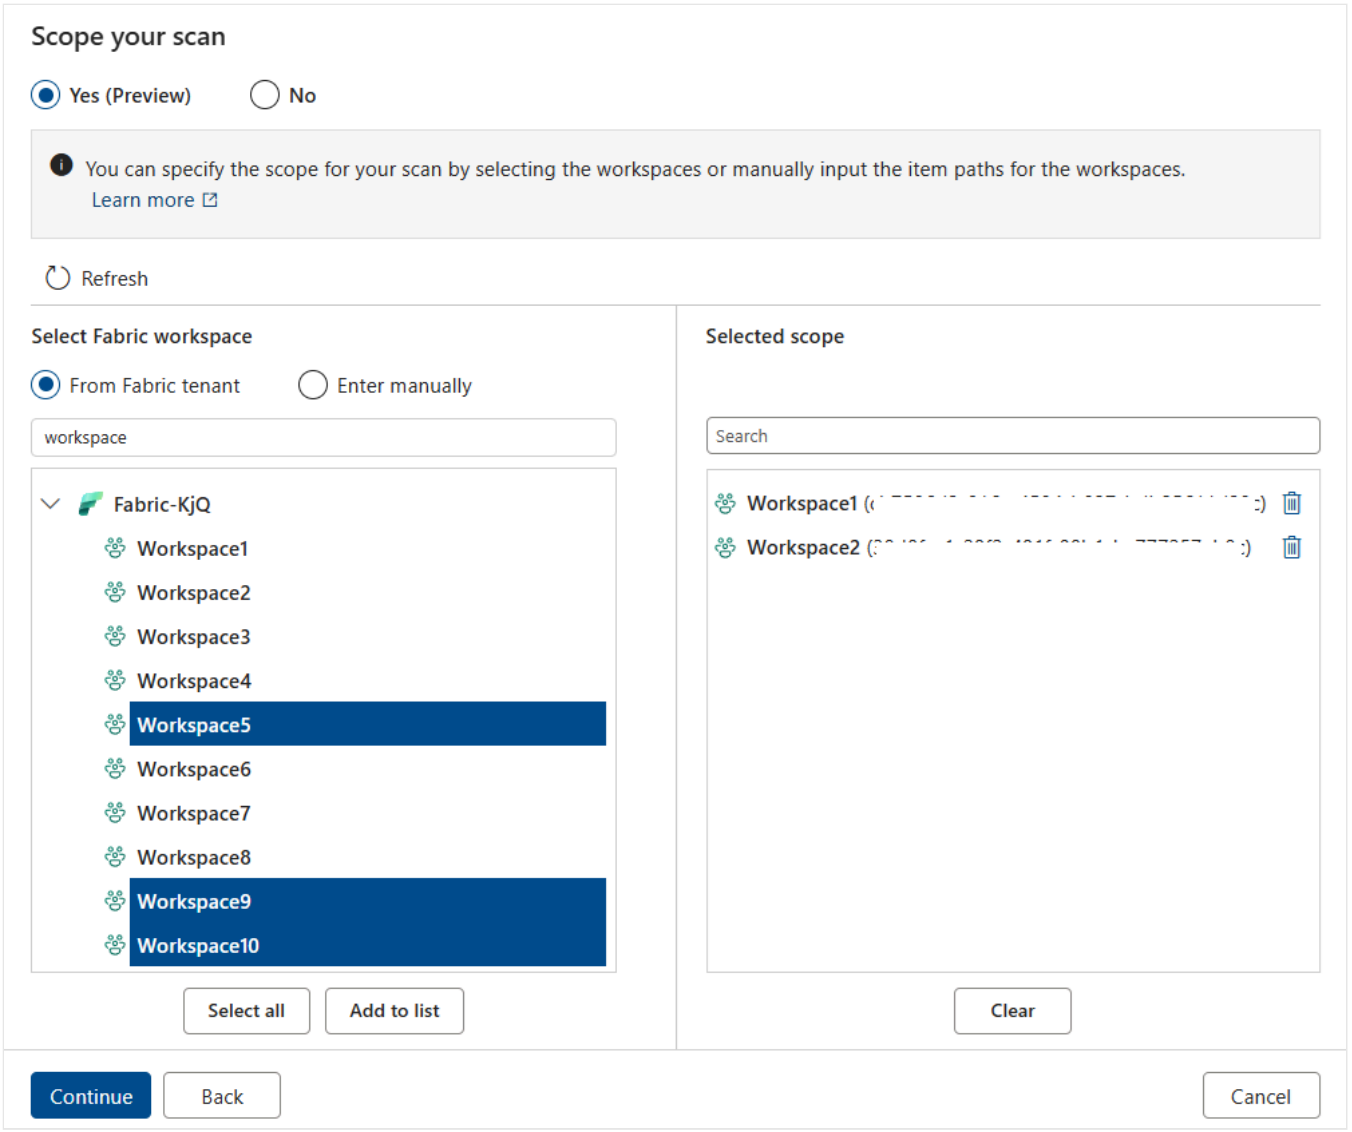


a. Access - Failed status means the user authentication failed. Scans using managed identity will always pass because no user authentication required.
b. Assets (+ lineage) - Failed status means the Microsoft Purview - Power BI authorization has failed. Make sure the Microsoft Purview managed identity is added to the security group associated in Power BI admin portal.
c. Detailed metadata (Enhanced) - Failed status means the Power BI admin portal is disabled for the following setting - **Enhance admin APIs responses with detailed metadata**

20. Set up a scan trigger. Your options are **Recurring**, and **Once**.

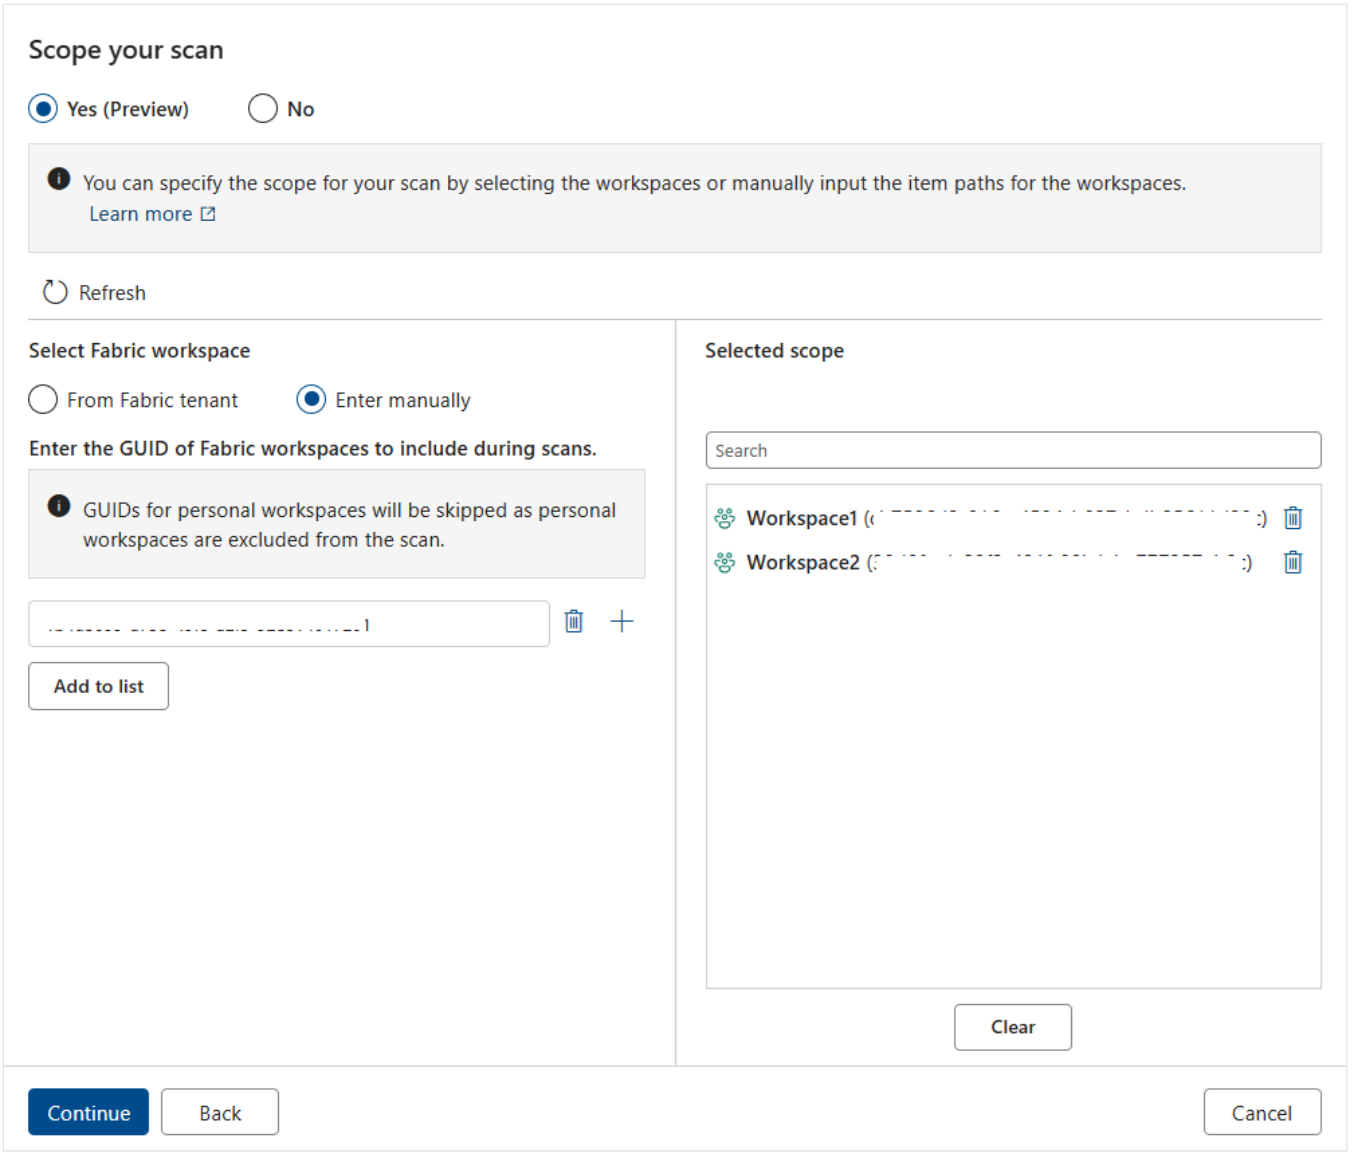


21. On **Review new scan**, select **Save and run** to launch your scan.



Scope your scan

This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.



In the Scope your scan stage, data source administrators can scope the scans by specifying the workspaces as needed. Data source administrators can either select from the workspace list under the tenant or directly input the workspace GUIDs to scope the scan. No additional permission is required to use the scoped scan. There are two options available and by default the option "No" is selected and you can directly click on "Continue" to proceed to run a full scan or select the "Yes" to enable the scoped scan experience.

If the scoped scan is enabled, you will see a list of existing workspaces under the tenant on the left hand side (currently there's a limitation that the UI selection experience only supports less than 5000 workspaces) and you can select the workspaces and add to the list on the right hand side. If personal workspace is configured as "Include", personal workspaces will show in the workspace list with a prefix "PersonalWorkspace ". You can directly click on the workspace(s) and click on the button "Add to list" to put the workspaces to the list of selected workspaces. You can input keyword of the workspace name or workspace GUID in the search box to filter out the workspace(s) for selection.

You can also directly input the workspace GUID and add it to the list of selected workspaces.

> **Note**
>
> - Scoping scan by selecting from Microsoft Fabric or Power BI tenant is only supported when the total number of workspaces is less than 5000 (include or exclude personal workspaces will be considered), or you need to switch to manual input of workspace GUIDs to scope your scan.
> - You can switch between selecting workspaces from Microsoft Fabric or Power BI tenant, or entering workspace GUID manually and the input will be merged into the same list of selected workspaces.
> - Microsoft Purview will check whether the GUID input by user has a correct format but will not check whether the GUID represents a valid workspace in the Microsoft Fabric or Power BI tenant. If invalid GUIDs are included in scoped scan, the scan will complete with exceptions and you can find those invalid GUIDs in the scan log.
> - If personal workspace is configured as "Exclude", the GUIDs for personal workspaces can still be added to the list of selected workspaces but will be skipped in the scan

and these GUIDs will be included in the scan log.

- If self-hosted integration runtime is used, version 5.40.8836.1 and above is required and only manual input of workspace GUIDs is supported in the scoped scan.
- If managed VNet integration runtime (v2) is used, only manual input of workspace GUIDs is supported in the scoped scan.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview

- Search Unified Catalog

Connect to and manage a Power BI tenant in Microsoft Purview (cross-tenant)

Article • 05/21/2025

This article outlines how to register a Power BI tenant in a cross-tenant scenario, and how to authenticate and interact with the tenant in Microsoft Purview. If you're unfamiliar with the service, see Learn about Microsoft Purview.

> **Note**
>
> For scanning a Microsoft Fabric tenant, see our Microsoft Fabric documentation.

Supported capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan	Classification	Labeling	Access Policy	Lineage	Data Sharing	Live view
Yes	Yes	Yes	Yes	No	No	No	Yes	No	No

* Power BI items in a Microsoft Fabric tenant are available using live view.

When scanning Power BI source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Workspaces
  - Dashboards
  - Reports
  - Datasets including the tables and columns
  - Dataflows
  - Datamarts
- Fetching static lineage on assets relationships among above Power BI artifacts and external data source assets. Learn more from Power BI lineage.

Supported scenarios for Power BI scans

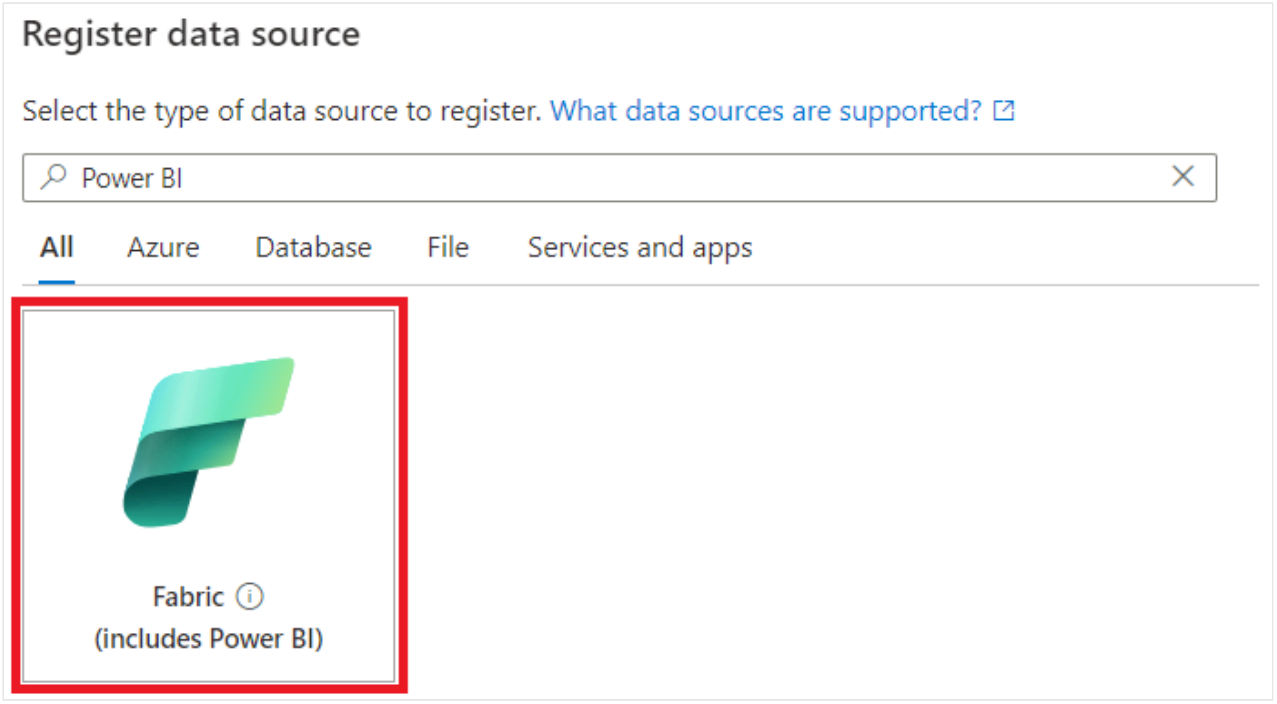
Expand table

Scenario	Microsoft Purview public access	Power BI public access	Runtime option	Authentication option	Deployment checklist
Public access with Azure integration runtime	Allowed	Allowed	Azure runtime	Delegated authentication / Service principal	Deployment checklist
Public access with self-hosted integration runtime	Allowed	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Deployment checklist
Private access	Denied	Allowed	Managed VNet IR (v2 only)	Delegated authentication / Service principal	Review deployment checklist
Private access	Allowed	Denied	Self-hosted runtime	Delegated authentication / Service principal	Deployment checklist
Private access	Denied	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Deployment checklist
Private access	Denied	Denied	Self-hosted runtime	Delegated authentication / Service principal	Deployment checklist

Known limitations

- If Power BI tenant is protected behind a private endpoint, standard or kubernetes supported self-hosted runtimes are the only options to scan.
- For the cross-tenant scenario, delegated authentication and service principal are the only supported authentication options for scanning.
- If the Power BI dataset schema isn't shown after the scan, it's due to one of the current limitations with the Power BI metadata scanner.
- Empty workspaces are skipped.

Prerequisites



Before you start, make sure you have the following:

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.

Register the Power BI tenant

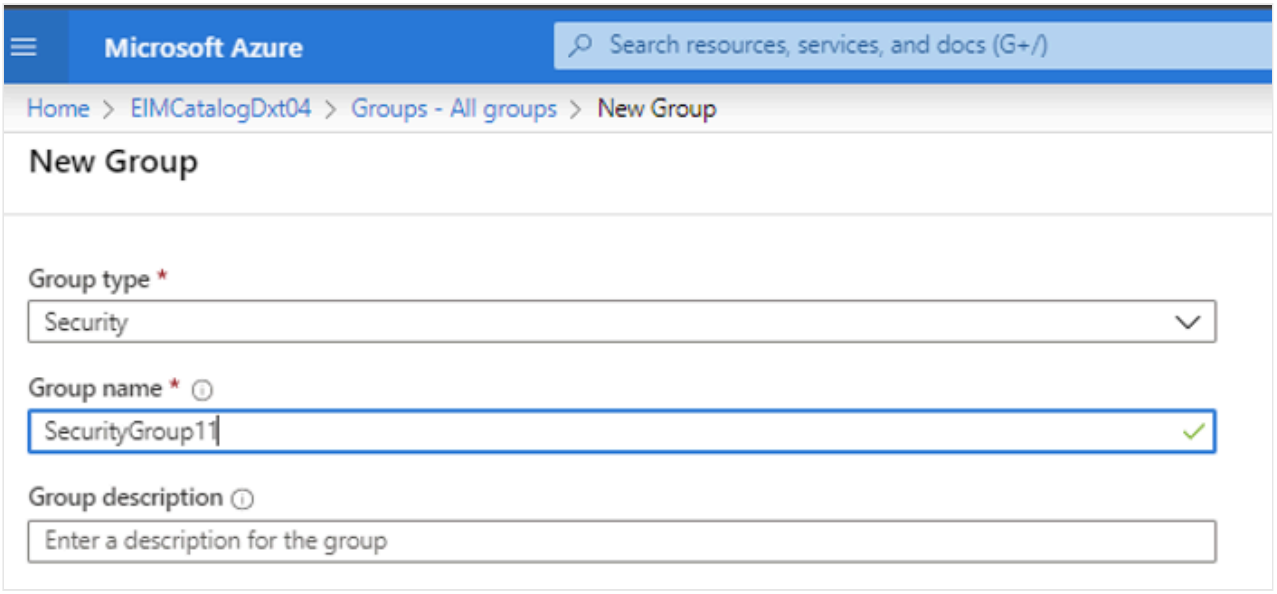
1. From the options on the left, select **Data Map**.

2. Select **Register**, and then select **Fabric** as your data source. It includes Power BI sources and assets.

3. Give your data source a friendly name. The name must be 3 to 63 characters long, and must contain only letters, numbers, underscores, and hyphens. Spaces aren't allowed.

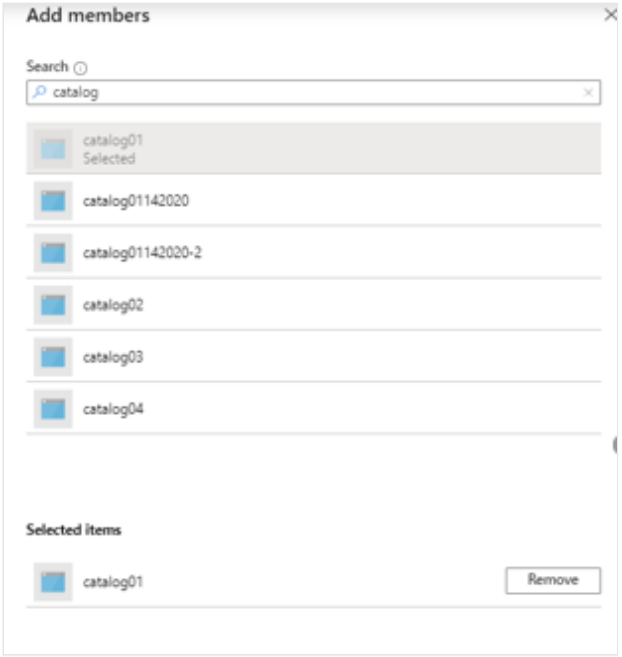
4. Edit the **Tenant ID** field, to replace with the tenant for the cross-tenant Power BI that you want to register and scan. By default, Microsoft Purview's tenant ID is populated.

5. Select **Register**.



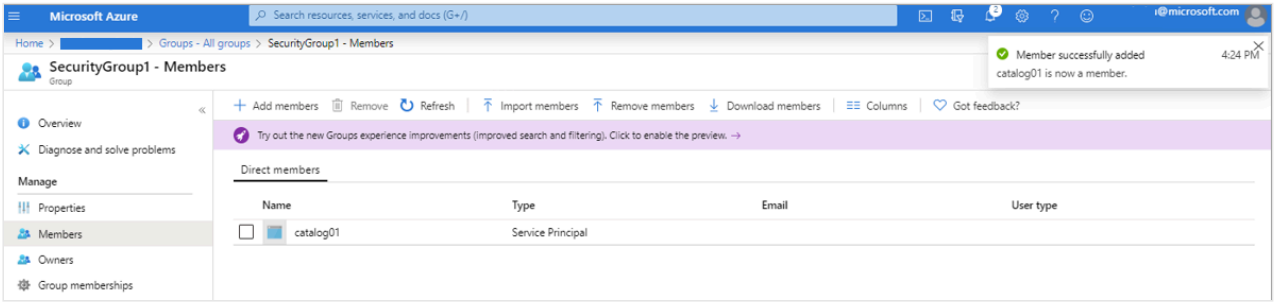
Authenticate to Power BI tenant

In Microsoft Entra tenant, where Power BI tenant is located:



1. In the Azure portal, search for **Microsoft Entra ID**.
2. Create a new security group in your Microsoft Entra ID, by following Create a basic group and add members using Microsoft Entra ID.

   > **Tip**
   >
   > You can skip this step if you already have a security group you want to use.

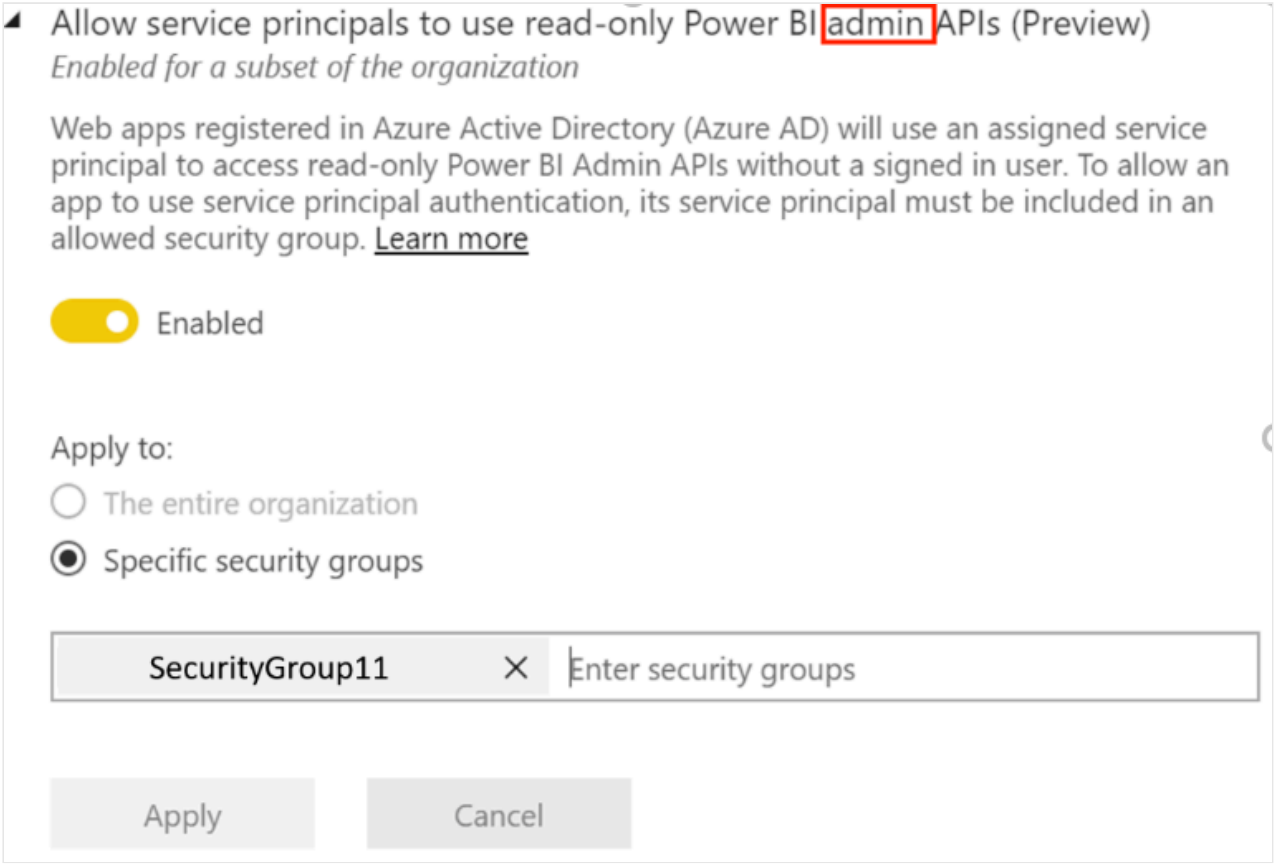


3. Select **Security** as the **Group Type**.

4. Select **Members**, then select **+ Add members**.
5. Search for your Microsoft Purview managed identity or service principal and select it.

You should see a success notification showing you that it was added.

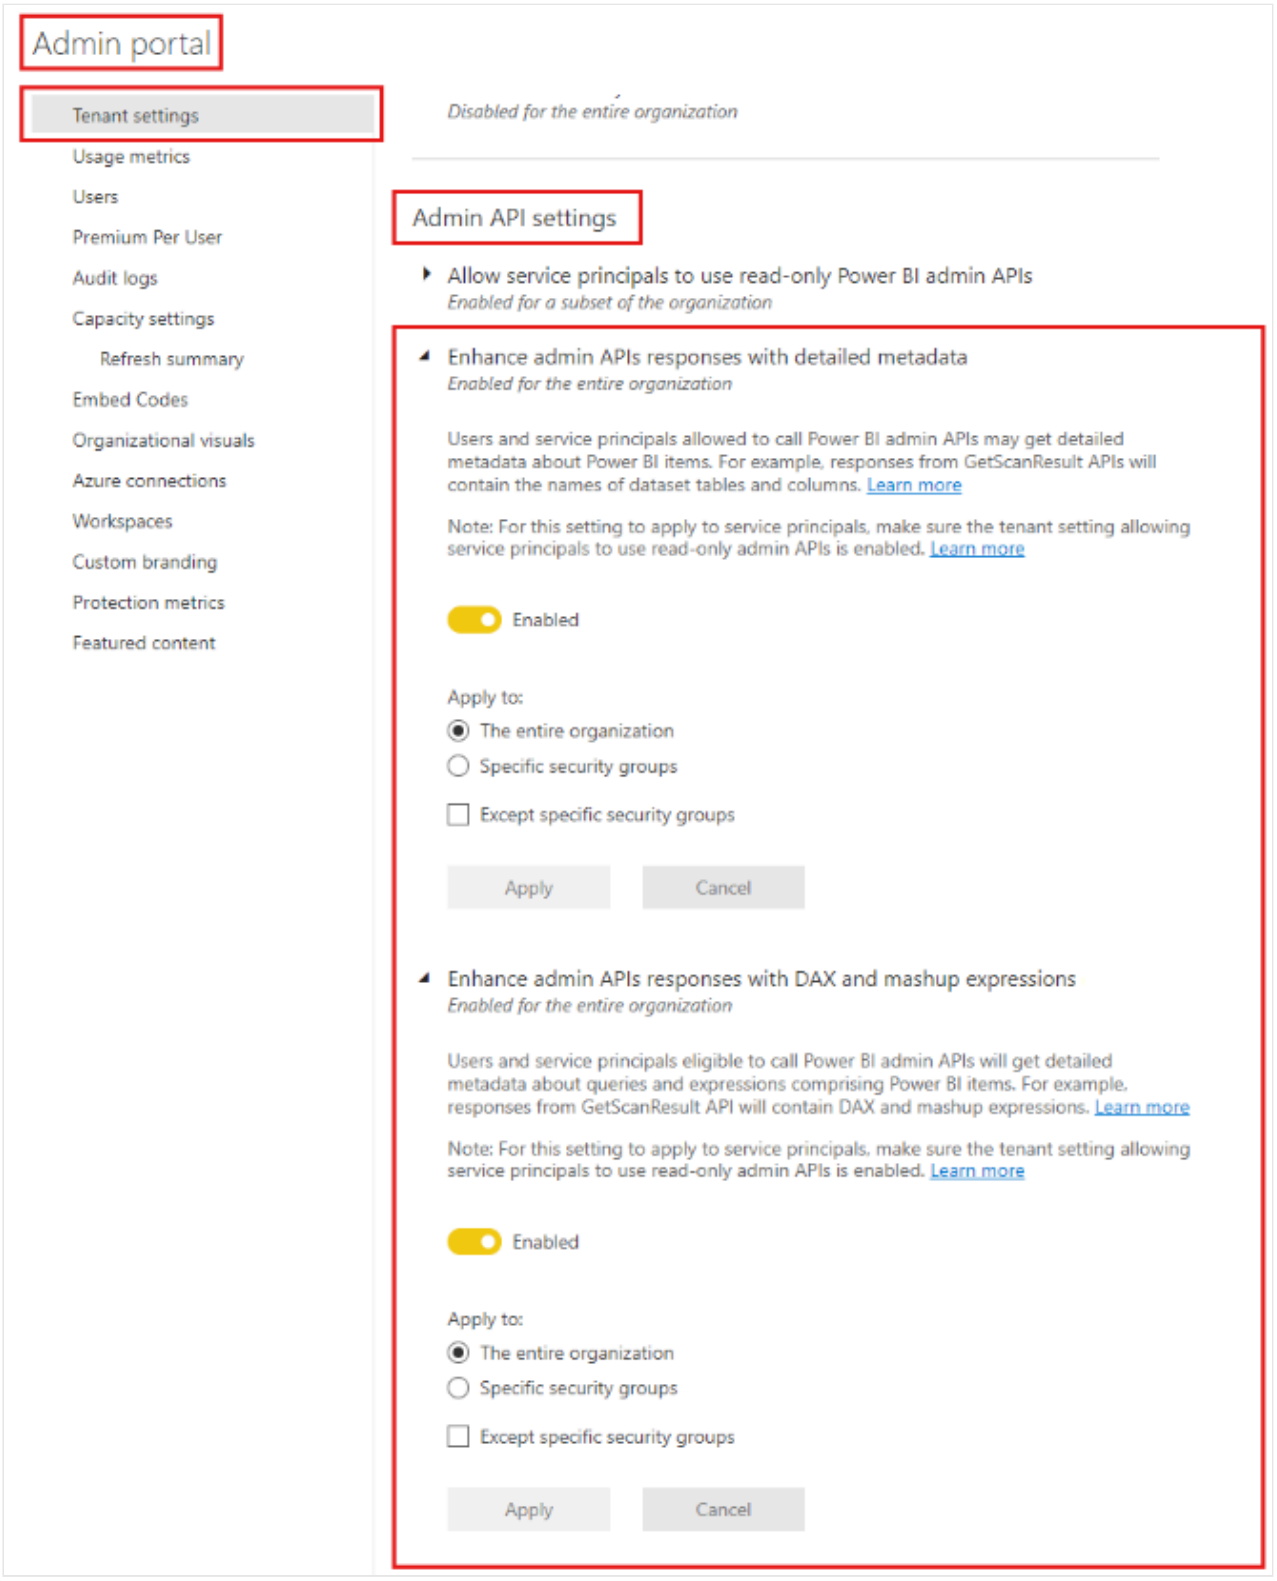
Associate the security group with Power BI tenant



1. Log into the Power BI admin portal.

2. Select the **Tenant settings** page.

> **Important**
>
> You need to be a Power BI Admin to see the tenant settings page.



3. Select **Admin API settings** > **Allow service principals to use read-only Power BI admin APIs (Preview)**.

4. Select **Specific security groups**.

5. Select **Admin API settings** > **Enhance admin APIs responses with detailed metadata** and **Enhance admin APIs responses with DAX and mashup expressions** > Enable the toggle to allow Microsoft Purview Data Map automatically discover the detailed metadata of Power BI datasets as part of its scans.

   > **Important**
   >
   > After you update the Admin API settings on your power bi tenant, wait around 15 minutes before registering a scan and test connection.

⊗ Caution

When you allow the security group you created (that has your Microsoft Purview managed identity as a member) to use read-only Power BI admin APIs, you also allow it to access the metadata (e.g. dashboard and report names, owners, descriptions, etc.) for all of your Power BI artifacts in this tenant. Once the metadata has been pulled into the Microsoft Purview, Microsoft Purview's permissions, not Power BI permissions, determine who can see that metadata.

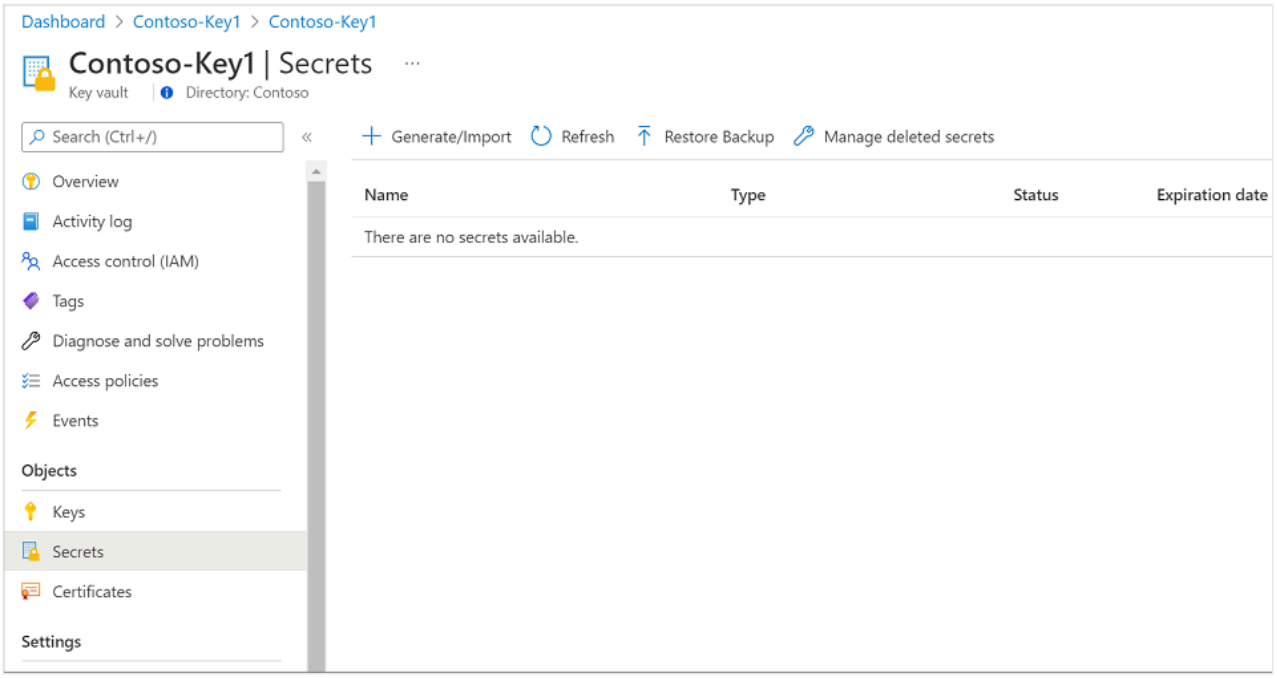
> **Note**
>
> You can remove the security group from your developer settings, but the metadata previously extracted won't be removed from the Microsoft Purview account. You can delete it separately, if you wish.

Scan cross-tenant Power BI

Delegated authentication and service principals are the only supported options for cross-tenant scanning. You can scan using either:

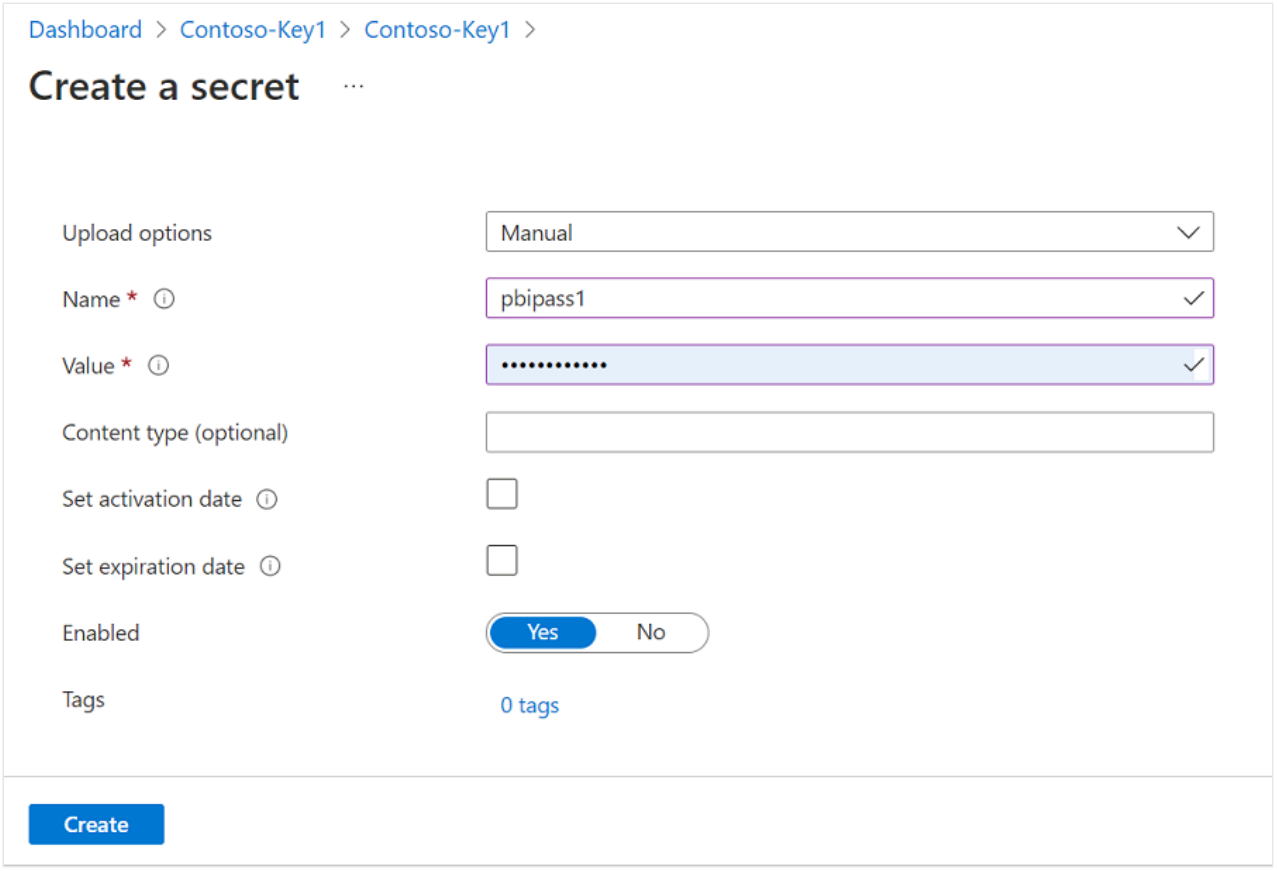
- The Azure integration runtime
- A self-hosted integration runtime

Create scan for cross-tenant using Azure IR with delegated authentication



To create and run a new scan by using the Azure runtime, perform the following steps:

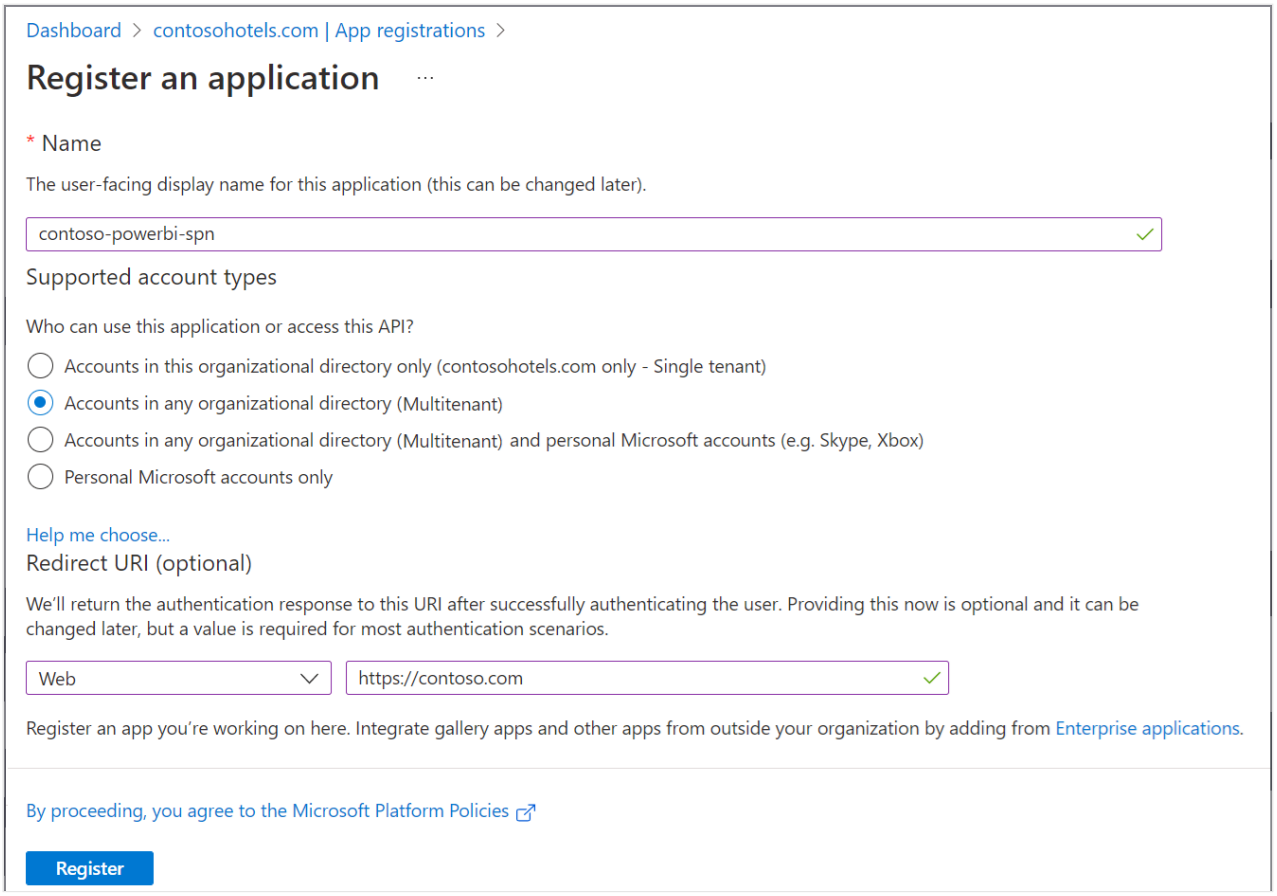
1. Create a user account in the Microsoft Entra tenant where the Power BI tenant is located, and assign the user to this role: **Fabric Administrator**. Take note of the username and sign in to change the password.



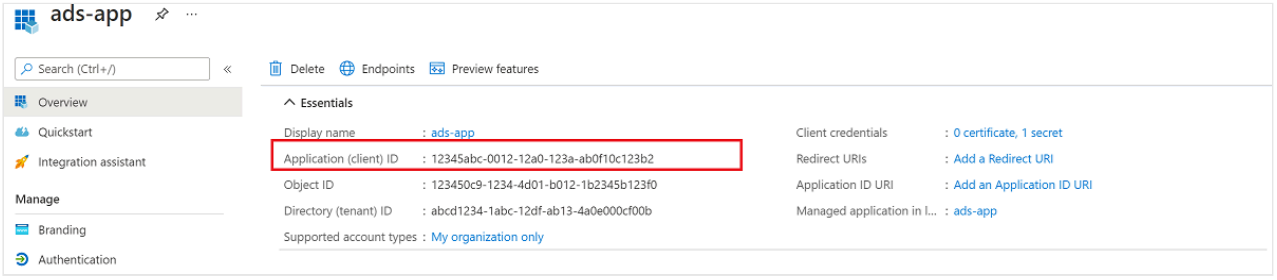
2. Assign the proper Power BI license to the user.

3. Go to the instance of Azure Key Vault in the tenant where Microsoft Purview is created.

4. Select **Settings** > **Secrets**, and then select **+ Generate/Import**.

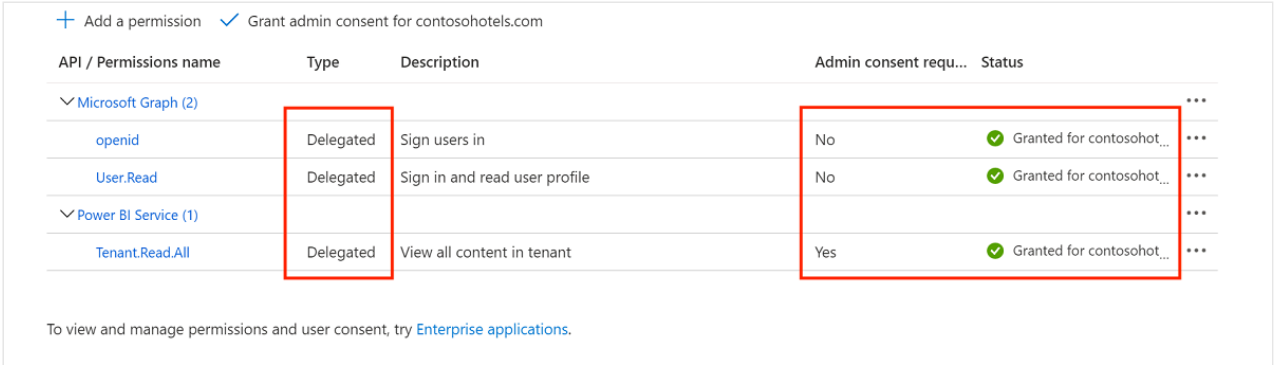


5. Enter a name for the secret. For **Value**, type the newly created password for the Microsoft Entra user. Select **Create** to complete.

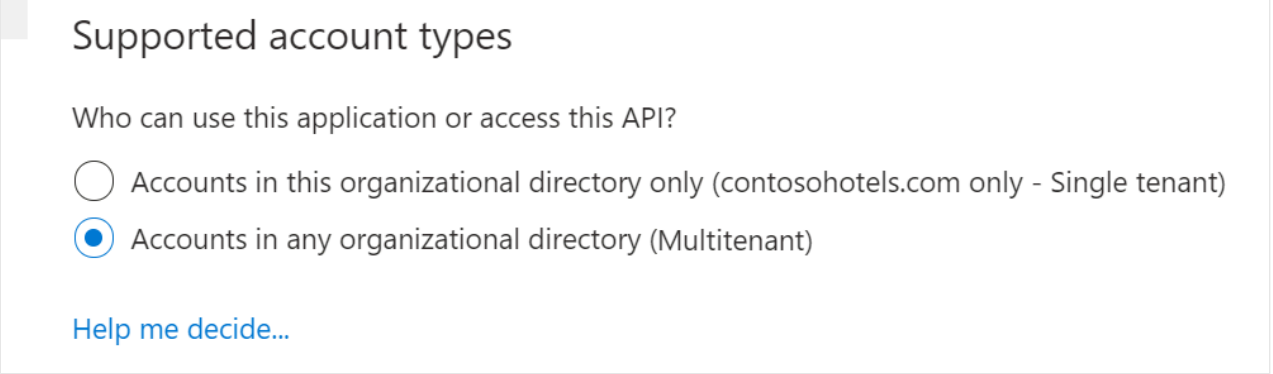


6. If your key vault isn't connected to Microsoft Purview yet, you need to create a new key vault connection.

7. Create an app registration in your Microsoft Entra tenant where Power BI is located. Provide a web URL in the **Redirect URI**.



8. Take note of the client ID (app ID).



9. From the Microsoft Entra dashboard, select the newly created application, and then select **App permissions**. Assign the application the following delegated permissions, and grant admin consent for the tenant:

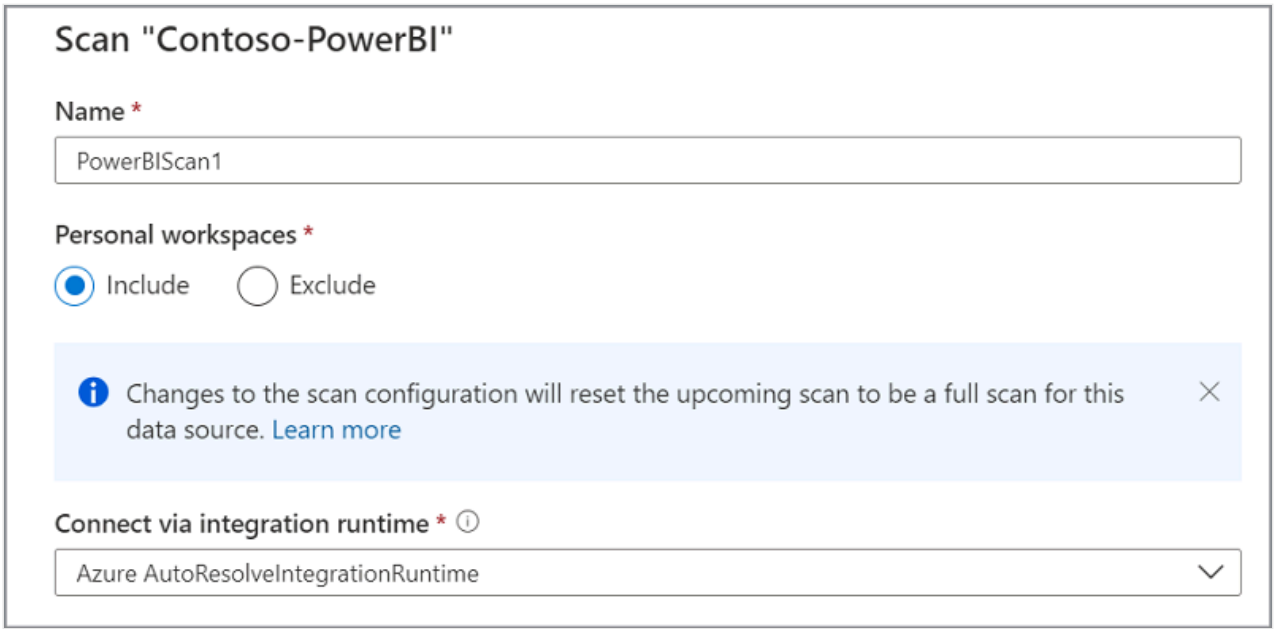
   - Power BI Service Tenant.Read.All
   - Microsoft Graph openid
   - Microsoft Graph User.Read

10. From the Microsoft Entra dashboard, select the newly created application, and then select **Authentication**. Under **Supported account types**, select **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)**.

11. Under **Implicit grant and hybrid flows**, select **ID tokens (used for implicit and hybrid flows)**.

12. Under **Advanced settings**, enable **Allow Public client flows**.

13. In the Microsoft Purview Studio, go to the **Data map** in the left menu. Go to **Sources**.

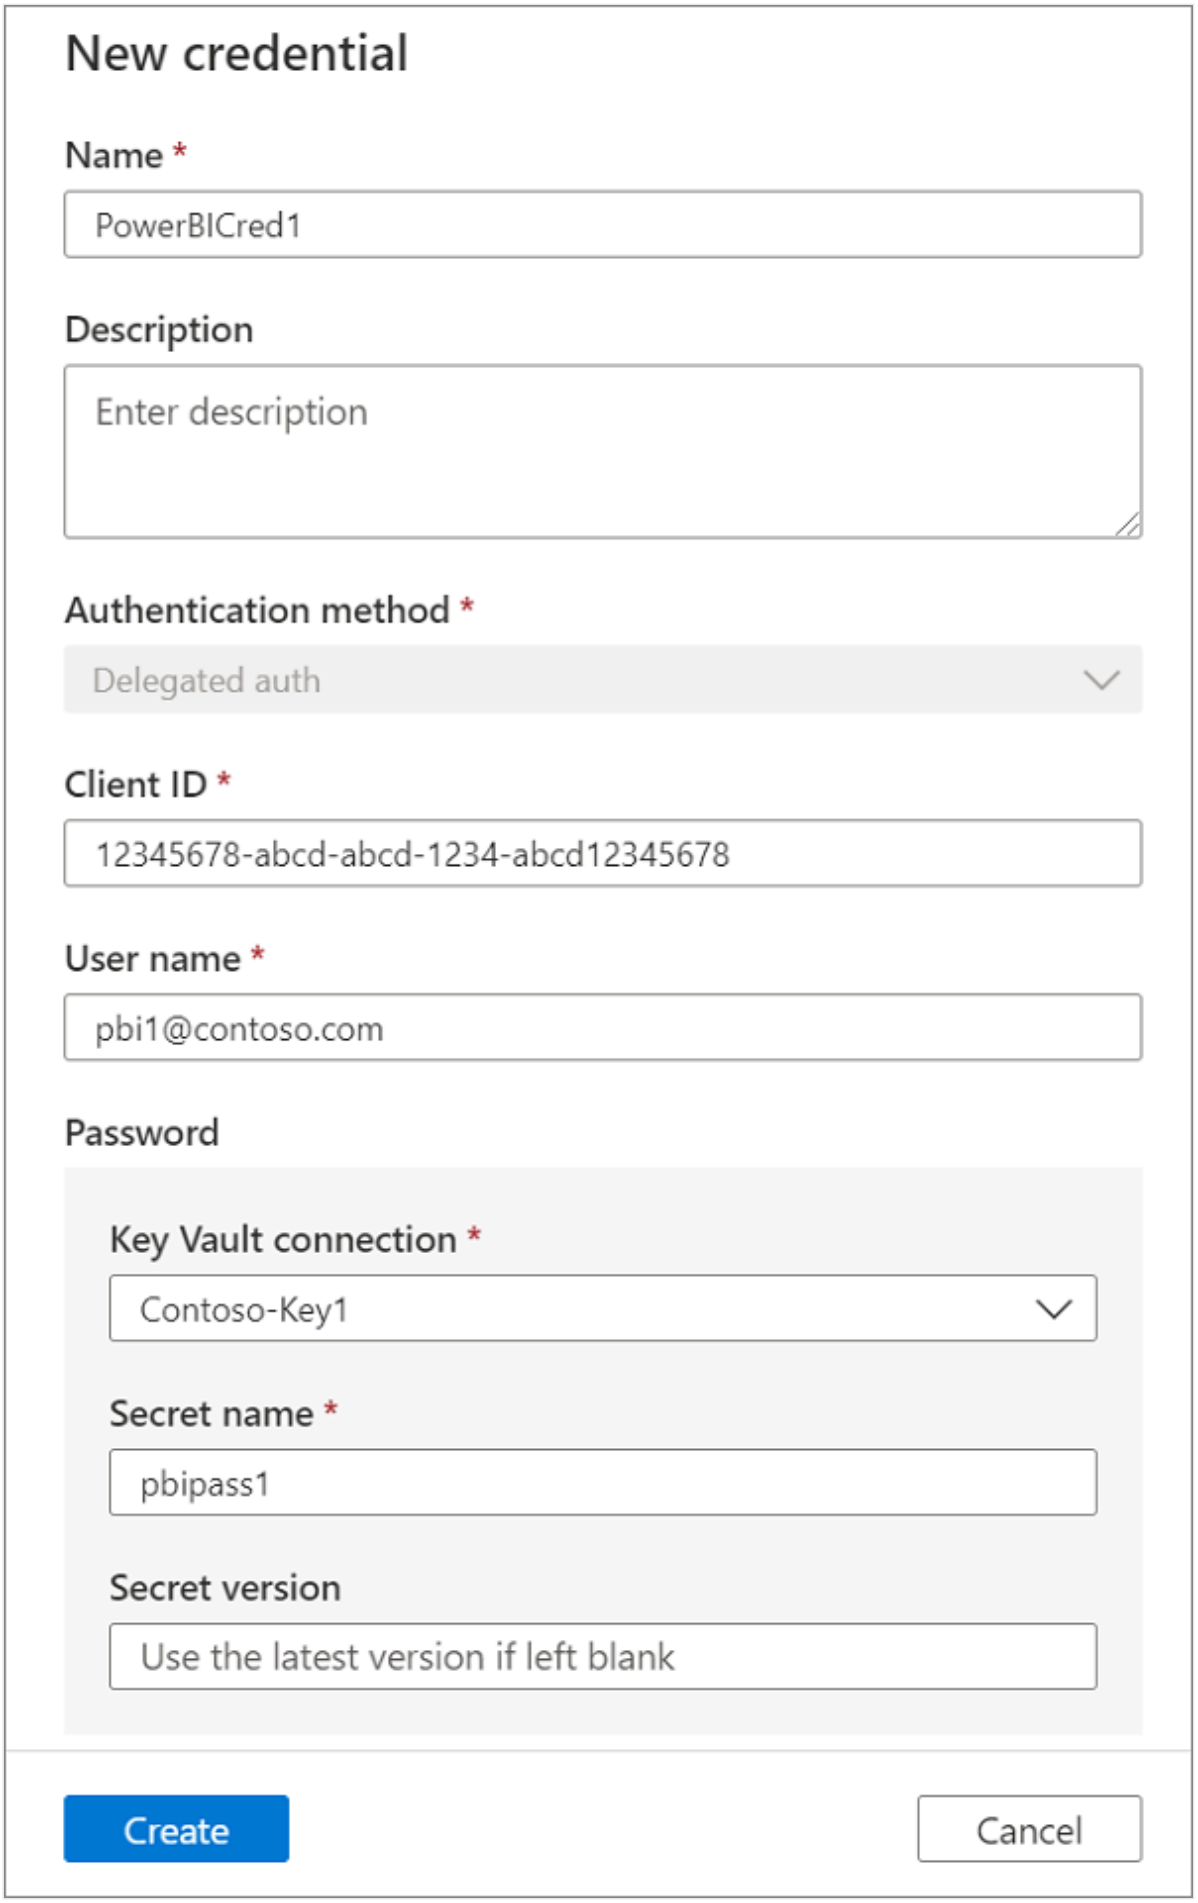


14. Select the registered Power BI source from cross-tenant.

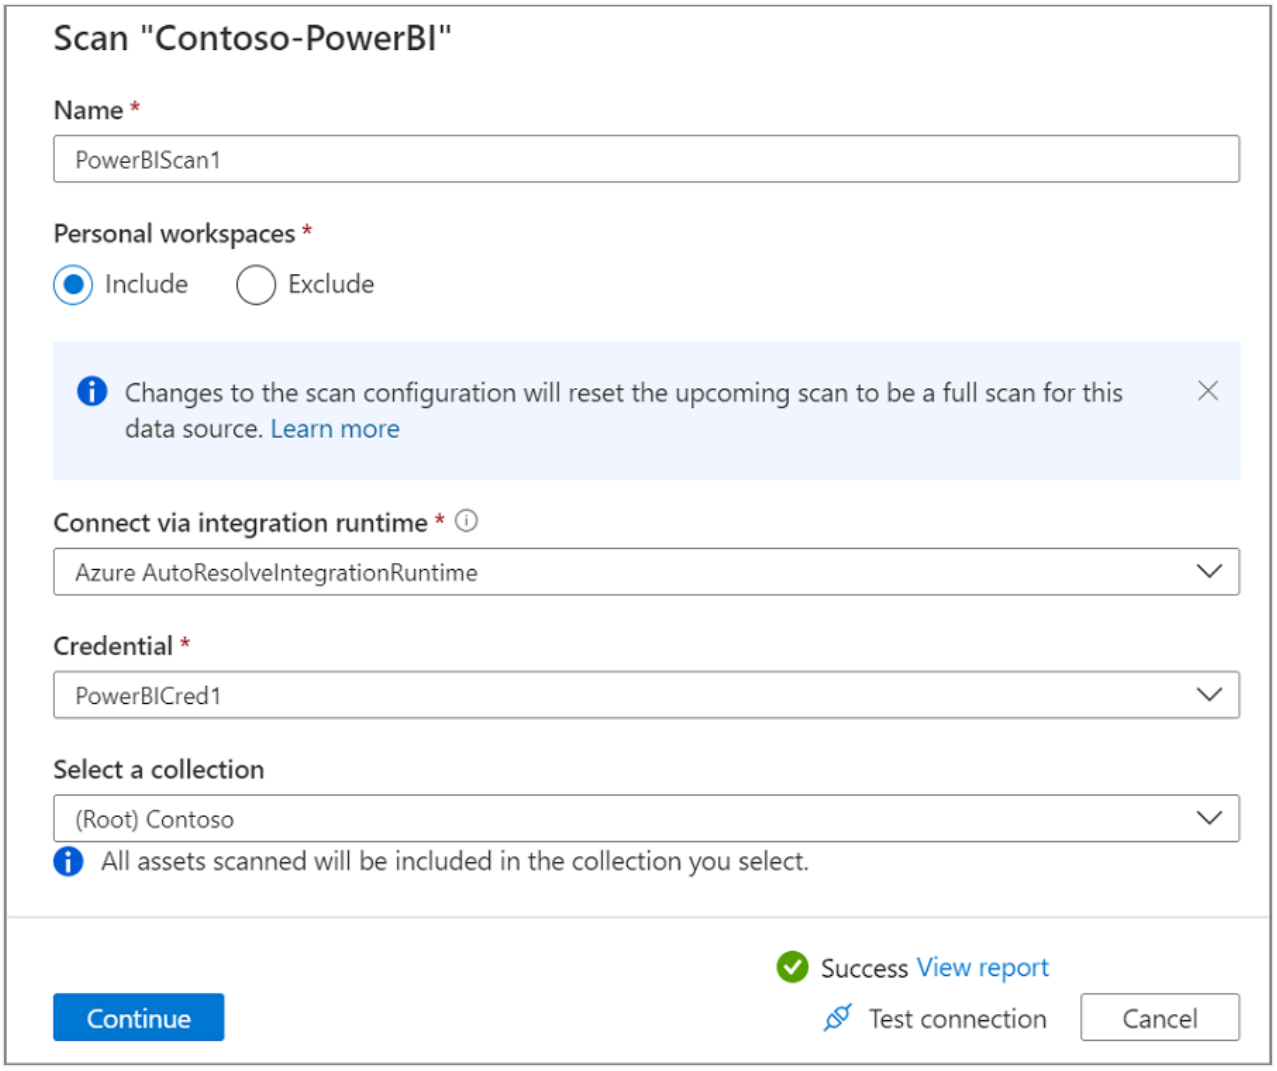
15. Select **+ New scan**.

16. Give your scan a name. Then select the option to include or exclude the personal workspaces.

> **Note**
>
> If you switch the configuration of a scan to include or exclude a personal workspace, you trigger a full scan of the Power BI source.



17. Select **Azure AutoResolveIntegrationRuntime** from the dropdown list.

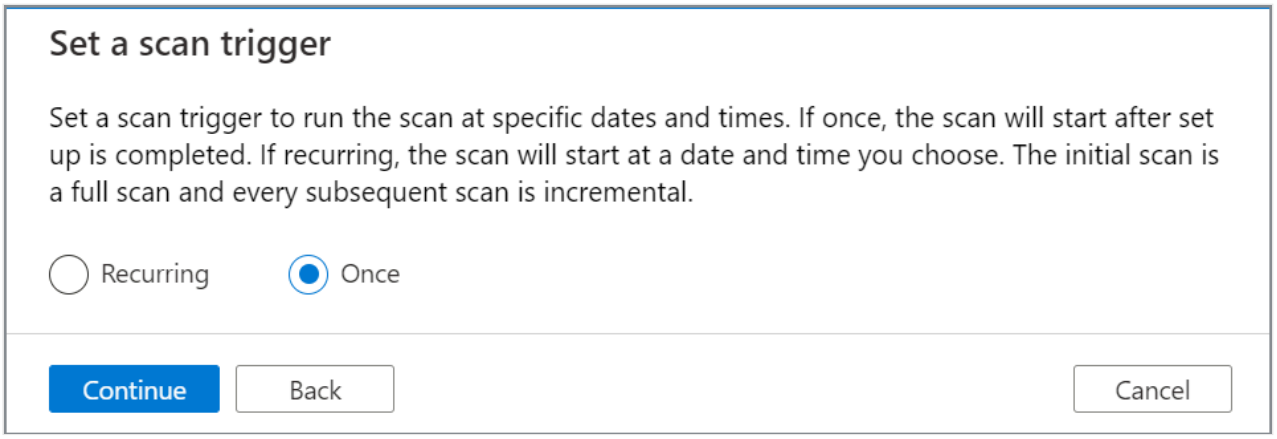


18. For the **Credential**, select **Delegated authentication**, and then select **+ New** to create a new credential.

19. Create a new credential and provide the following required parameters:

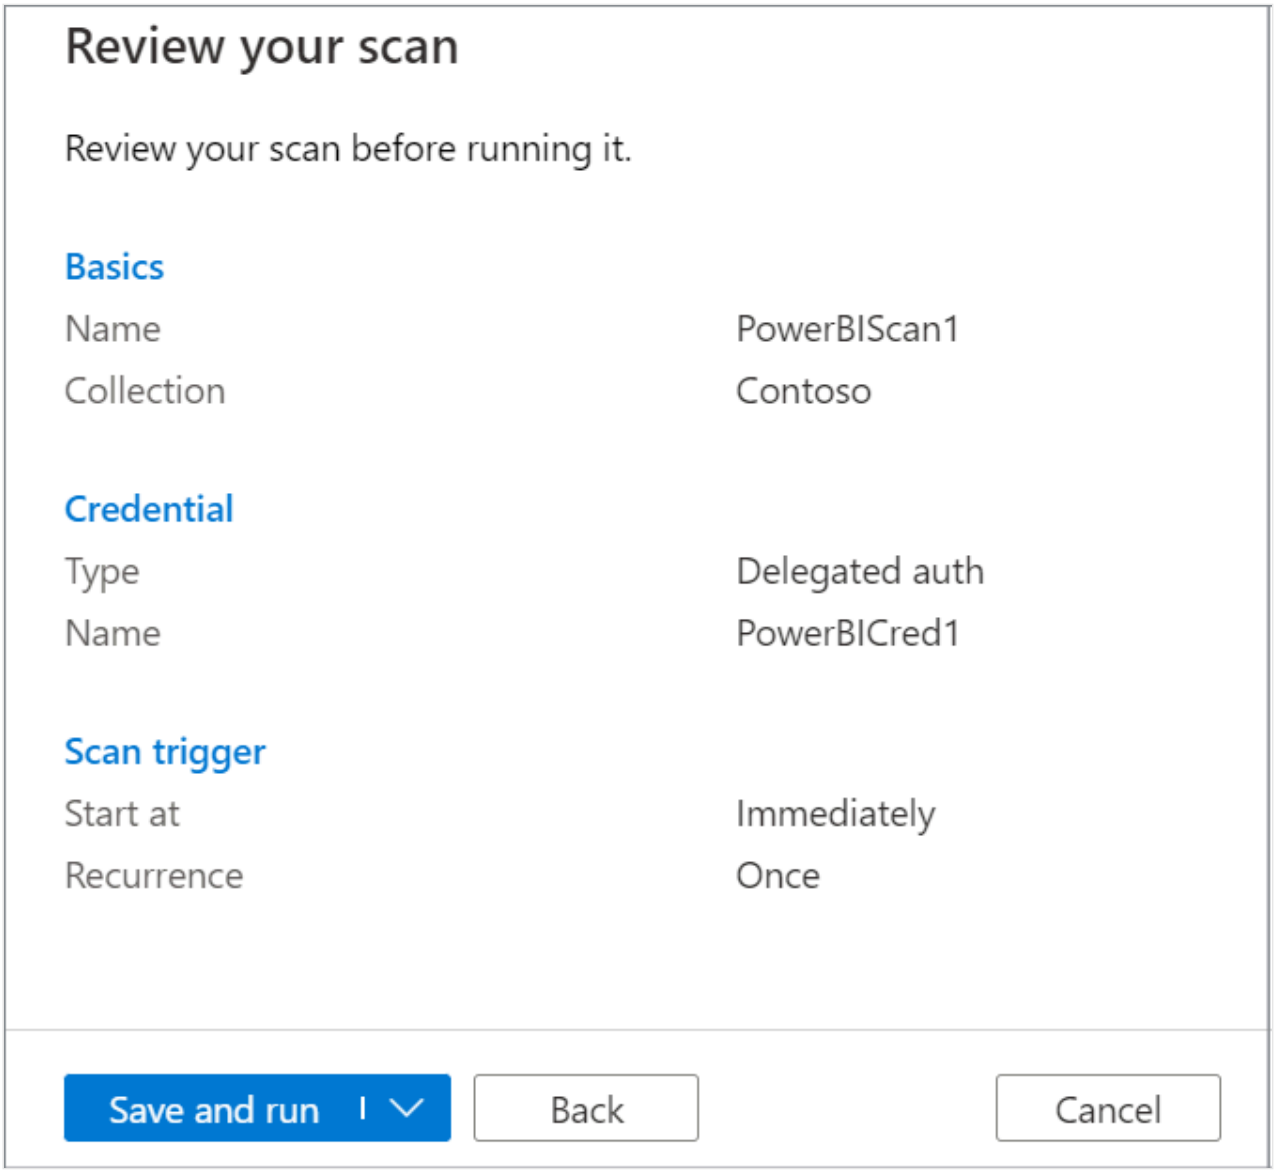
    - **Name**: Provide a unique name for the credential.
    - **Client ID**: Use the service principal client ID (app ID) that you created earlier.
    - **User name**: Provide the username of the Fabric administrator that you created earlier.
    - **Password**: Select the appropriate Key Vault connection, and the **Secret name** where the Power BI account password was saved earlier.

20. Select **Test connection** before continuing to the next steps.



If the test fails, select **View Report** to see the detailed status and troubleshoot the problem:

a. *Access - Failed* status means that the user authentication failed. Validate if the username and password are correct. Review if the credential contains the correct client (app) ID from the app registration.



b. *Assets (+ lineage) - Failed* status means that the authorization between Microsoft Purview and Power BI has failed. Make sure that the user is added to the Fabric Administrator role (former Power BI Administrator role), and has the proper Power BI license assigned.

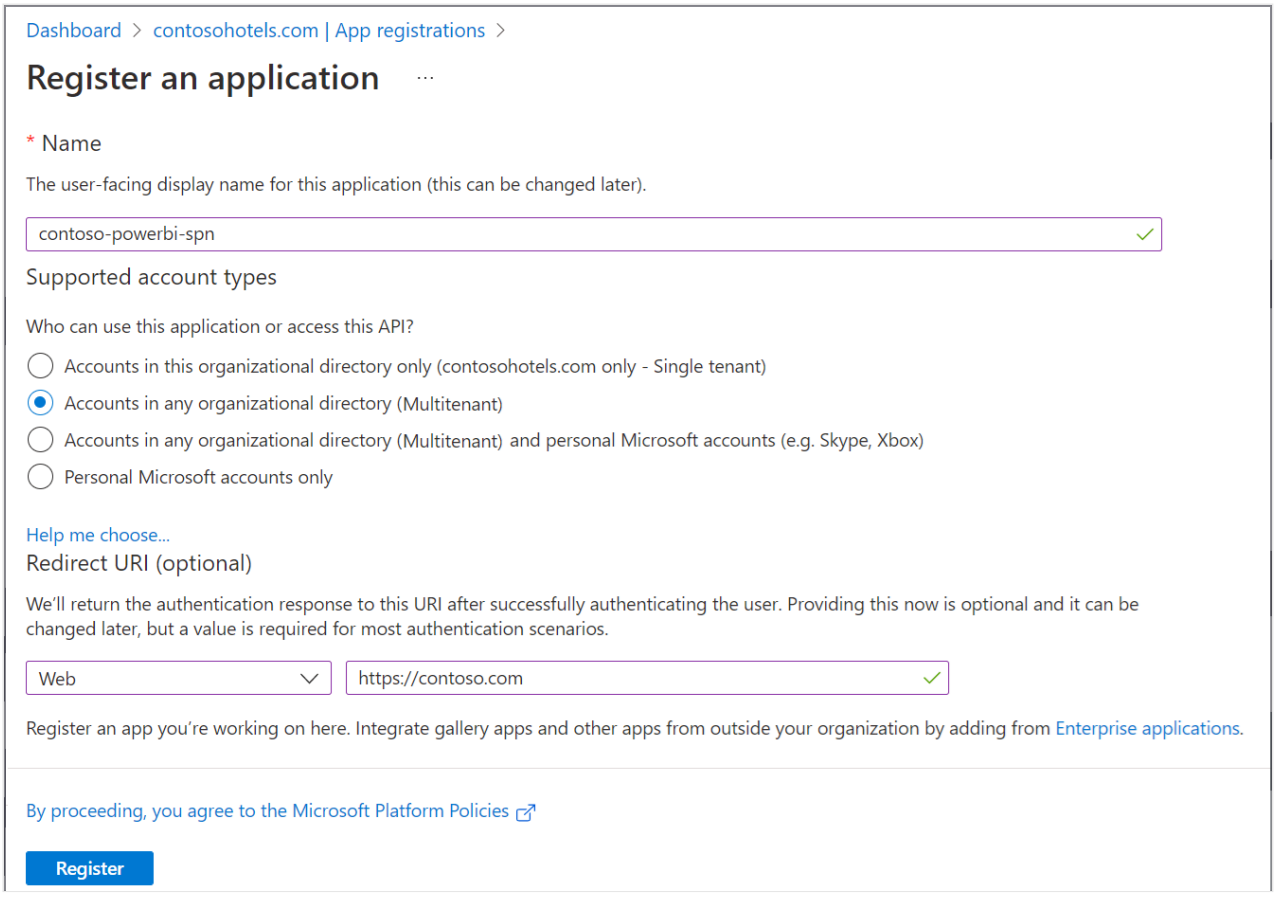
c. *Detailed metadata (Enhanced) - Failed* status means that the Power BI admin portal is disabled for the following setting: **Enhance admin APIs responses with detailed metadata**.

21. Set up a scan trigger. Your options are **Recurring** or **Once**.

22. On **Review new scan**, select **Save and run** to launch your scan.

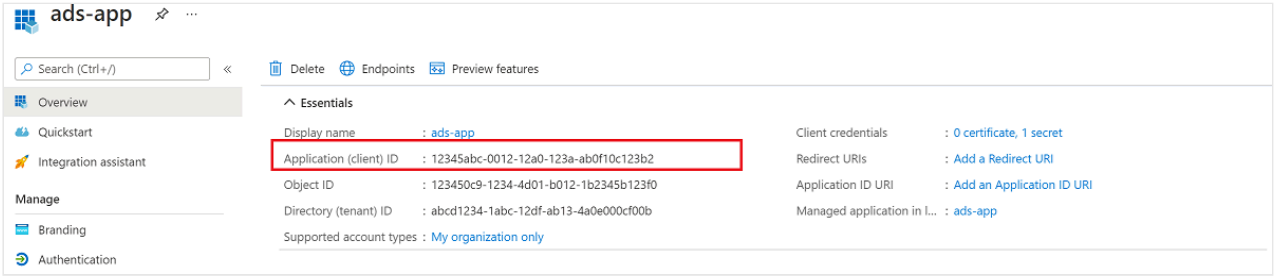
Tip

To troubleshoot any issues with scanning:



1. Confirm you have completed the deployment checklist for your scenario.

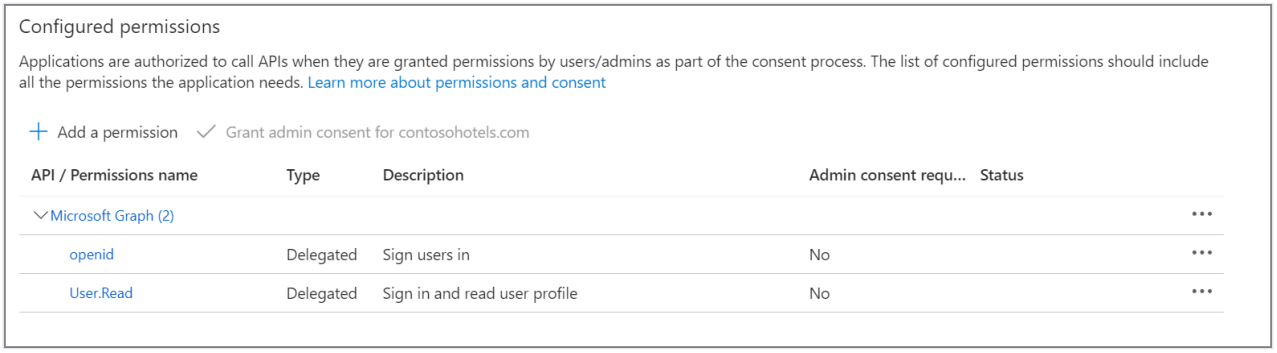
2. Review our scan troubleshooting documentation.



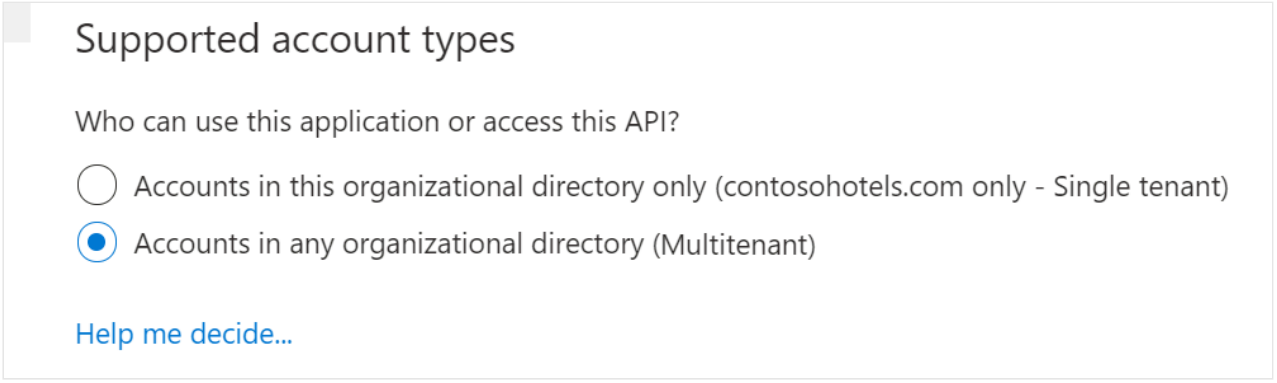
Create scan for cross-tenant using self-hosted IR with service principal

To create and run a new scan by using the self-hosted integration runtime, perform the following steps:

1. Create an app registration in your Microsoft Entra tenant where Power BI is located. Provide a web URL in the **Redirect URI**.

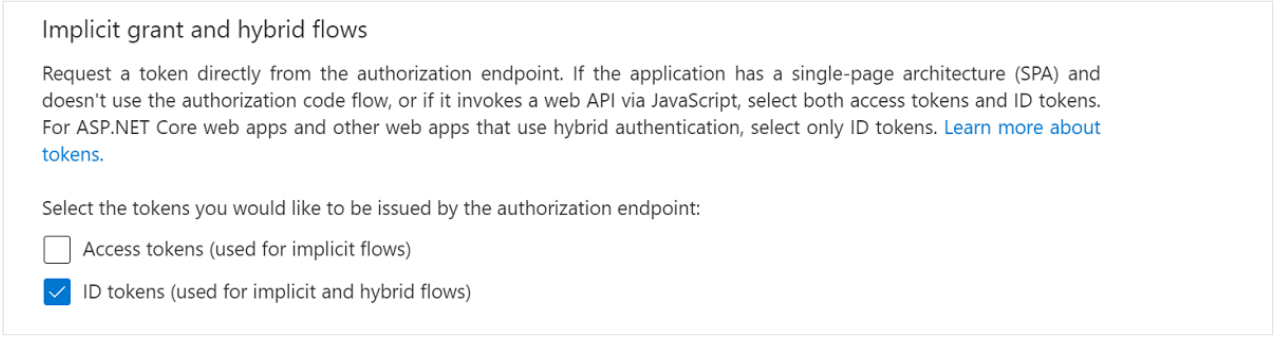


2. Take note of the client ID (app ID).



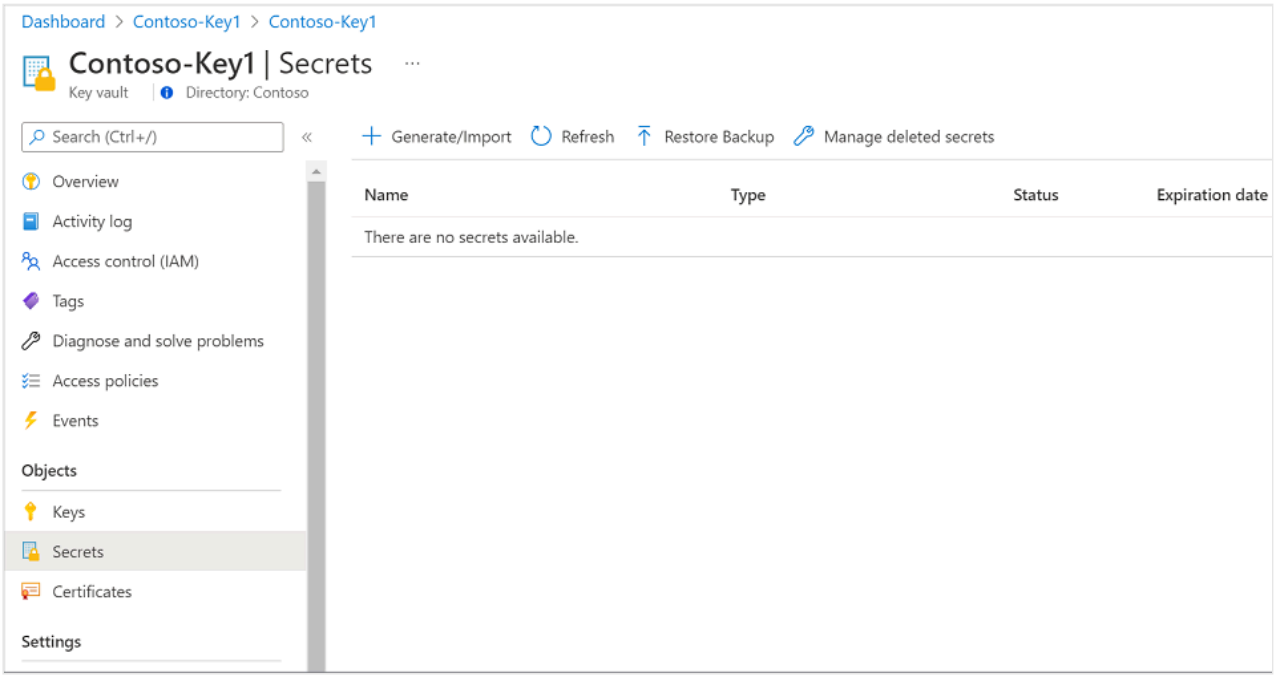
3. From the Microsoft Entra dashboard, select the newly created application, and then select **App permissions**. Assign the application the following delegated permissions:

   - Microsoft Graph openid



- Microsoft Graph User.Read

4. From the Microsoft Entra dashboard, select the newly created application, and then select **Authentication**. Under **Supported account types**, select **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)**.

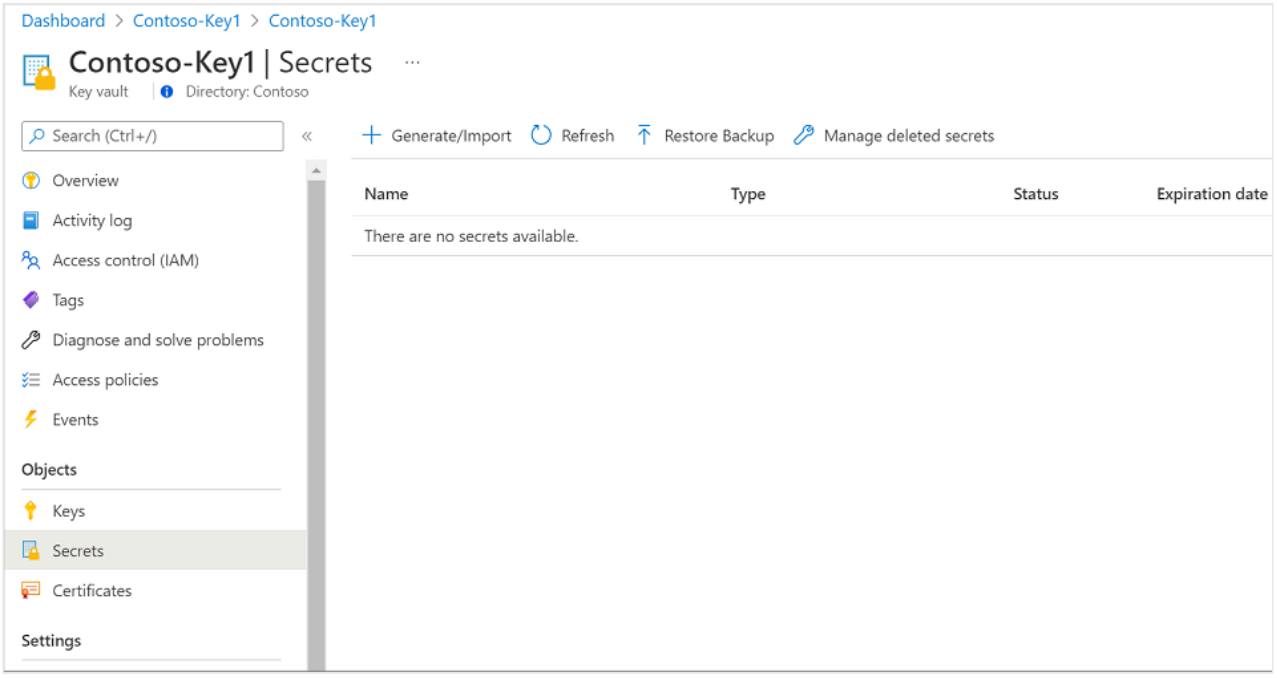


5. Under **Implicit grant and hybrid flows**, select **ID tokens (used for implicit and hybrid flows)**.

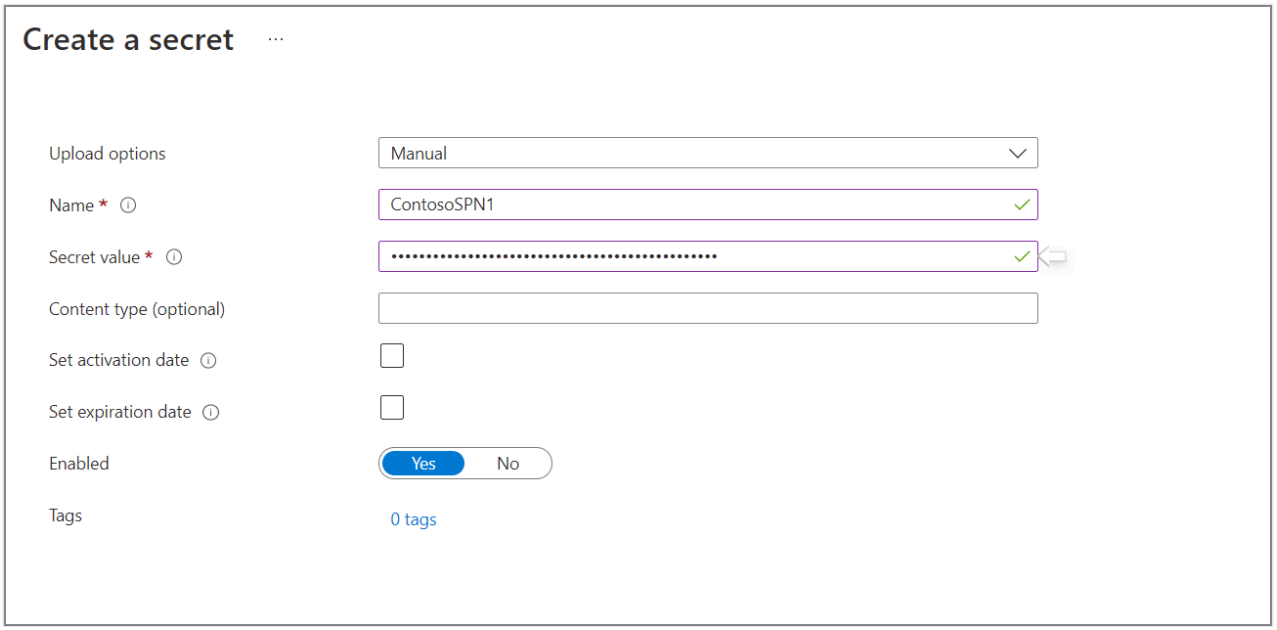
6. Under **Advanced settings**, enable **Allow Public client flows**.

7. In the tenant where Microsoft Purview is created go to the instance of Azure Key Vault.

8. Select **Settings** > **Secrets**, and then select **+ Generate/Import**.



9. Enter a name for the secret. For **Value**, type the newly created secret for the App registration. Select **Create** to complete.



10. Under **Certificates & secrets**, create a new secret and save it securely for next steps.

11. In Azure portal, navigate to your Azure key vault.

12. Select **Settings** > **Secrets** and select + **Generate/Import**.

13. Enter a name for the secret and for **Value**, type the newly created secret for the App registration. Select **Create** to complete.

14. If your key vault isn't connected to Microsoft Purview yet, you need to create a new key vault connection.

15. In the Microsoft Purview Studio, go to the **Data map** in the left menu. Go to **Sources**.

16. Select the registered Power BI source from cross-tenant.

17. Select + **New scan**.

18. Give your scan a name. Then select the option to include or exclude the personal workspaces.

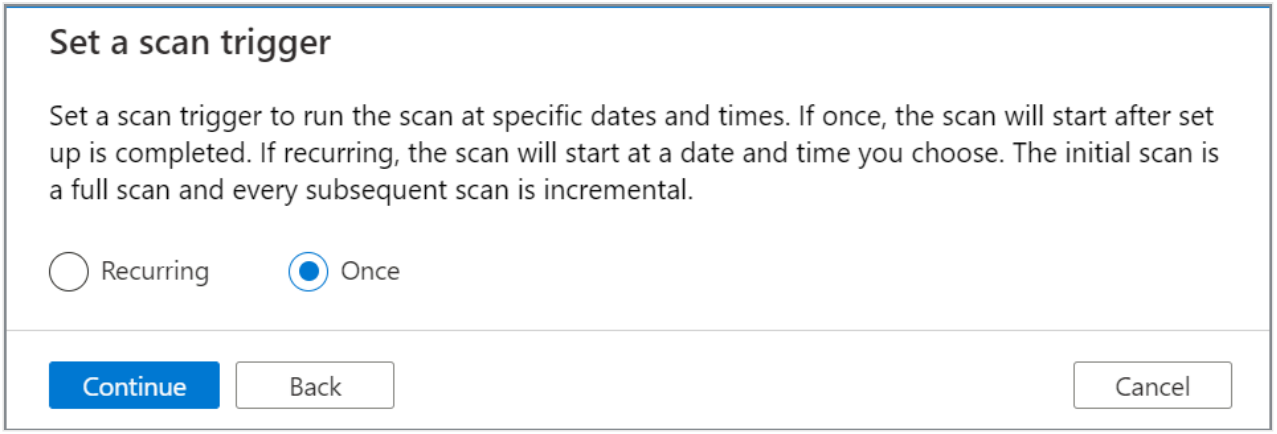
    > **Note**
    >
    > If you switch the configuration of a scan to include or exclude a personal workspace, you trigger a full scan of the Power BI source.

19. Select your self-hosted integration runtime from the drop-down list.

20. For the **Credential**, select **Service Principal**, and then select + **New** to create a new credential.

21. Create a new credential and provide the following required parameters:

    - **Name**: Provide a unique name for credential
    - **Authentication method**: Service principal
    - **Tenant ID**: Your Power BI tenant ID
    - **Client ID**: Use Service Principal Client ID (App ID) you created earlier



22. Select **Test connection** before continuing to the next steps.

    If the test fails, select **View Report** to see the detailed status and troubleshoot the problem:

a. *Access - Failed* status means that the user authentication failed. Validate if the App ID and secret are correct. Review if the credential contains the correct client (app) ID from the app registration.
b. *Assets (+ lineage) - Failed* status means that the authorization between Microsoft Purview and Power BI has failed. Make sure that the user is added to the Fabric Administrator role (former Power BI Administrator role), and has the proper Power BI license assigned.
c. *Detailed metadata (Enhanced) - Failed* status means that the Power BI admin portal is disabled for the following setting: **Enhance admin APIs responses with detailed metadata**.

23. Set up a scan trigger. Your options are **Recurring** or **Once**.

24. On **Review new scan**, select **Save and run** to launch your scan.

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have completed the deployment checklist for your scenario.
> 2. Review our scan troubleshooting documentation.

Deployment checklist

The deployment checklist is a summary of all the steps you'll need to take to set up a cross-tenant Power BI source. You can use it during setup or for troubleshooting, to confirm you've followed all the necessary steps to connect.

Public access with Azure IR

Scan cross-tenant Power BI by using delegated authentication in a public network

1. Make sure the Power BI tenant ID is entered correctly during the registration. By default, the Power BI tenant ID that exists in the same Microsoft Entra instance as Microsoft Purview will be populated.

2. Make sure your Power BI metadata model is up to date by enabling metadata scanning.

3. From the Azure portal, validate if the Microsoft Purview account network is set to **public access**.

4. From the Power BI tenant admin portal, make sure the Power BI tenant is configured to allow a public network.

5. Check your instance of Azure Key Vault to make sure:
   a. There are no typos in the password or secret.
   b. Microsoft Purview managed identity has **get** and **list** access to secrets.

6. Review your credential to validate that the:
   a. Client ID matches the *Application (Client) ID* of the app registration.
   b. For **delegated auth**, username includes the user principal name, such as `johndoe@contoso.com`.

7. In the Power BI Microsoft Entra tenant, validate the following Power BI admin user settings:
   a. The user is assigned to the Fabric Administrator role (former Power BI Administrator role).
   b. At least one Power BI license is assigned to the user.
   c. If the user is recently created, sign in with the user at least once, to make sure that the password is reset successfully, and the user can successfully initiate the session.
   d. There are no multifactor authentication or conditional access policies enforced on the user.

8. In the Power BI Microsoft Entra tenant, validate the following app registration settings:
   a. The app registration exists in your Microsoft Entra tenant where the Power BI tenant is located.
   b. If service principal is used, under **API permissions**, the following **delegated permissions** are assigned with read for the following APIs:

      - Microsoft Graph openid

- Microsoft Graph User.Read

c. If delegated authentication is used, under **API permissions**, the following **delegated permissions** and **grant admin consent for the tenant** is set up with read for the following APIs:

- Power BI Service Tenant.Read.All
- Microsoft Graph openid
- Microsoft Graph User.Read

d. Under **Authentication**:

i. **Supported account types** > **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)** is selected.

ii. **Implicit grant and hybrid flows** > **ID tokens (used for implicit and hybrid flows)** is selected.

iii. **Allow public client flows** is enabled.

9. In Power BI tenant, from Microsoft Entra tenant, make sure Service Principal is member of the new security group.

10. On the Power BI Tenant Admin portal, validate if Allow service principals to use read-only Power BI admin APIs is enabled for the new security group.

Troubleshoot Power BI tenant scans in Microsoft Purview

Article • 05/21/2025

This article explores common troubleshooting methods for scanning Power BI tenants in Microsoft Purview.

Supported scenarios for Power BI scans

Same-tenant

Expand table

Scenarios	Microsoft Purview public access allowed/denied	Power BI public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Public access with Azure IR	Allowed	Allowed	Azure Runtime	Microsoft Purview Managed Identity	Review deployment checklist
Public access with self-hosted IR	Allowed	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist
Private access	Allowed	Denied	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist
Private access	Denied	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist
Private access	Denied	Denied	Self-hosted runtime	Delegated authentication / Service principal	Review deployment checklist

Cross-tenant

Expand table

Scenarios	Microsoft Purview public access allowed/denied	Power BI public access allowed /denied	Runtime option	Authentication option	Deployment checklist
Public access with Azure IR	Allowed	Allowed	Azure runtime	Delegated Authentication	Deployment checklist
Public access with Self-hosted IR	Allowed	Allowed	Self-hosted runtime	Delegated authentication / Service principal	Deployment checklist

Troubleshooting tips

If delegated auth is used:

- Check your key vault. Make sure there are no typos in the password.
- Assign proper Power BI license to Power BI administrator user.
- Validate if user is assigned to Power BI Administrator role.
- If user is recently created, make sure password is reset successfully and user can successfully initiate the session.

My schema is not showing up after scanning

It can take some time for schema to finish the scanning and ingestion process, depending on the size of your Power BI Tenant. Currently if you have a large PowerBI tenant, this process could take a few hours.

Error code: Test connection failed - AASDST50079

- **Message**: `Failed to get access token with given credential to access Power BI tenant. Authentication type PowerBIDelegated Message: AASDST50079 Due to a configuration change made by your administrator or because you moved to a new location, you must enroll in multi-factor authentication.`
- **Cause**: Authentication is interrupted, due multi-factor authentication requirement for the Power BI admin user.
- **Recommendation**: Disable multi-factor authentication requirement and exclude user from conditional access policies. Login with the user to Power BI dashboard to validate if user can successfully login to the application.

Error code: Test connection failed - AASTS70002

- **Message**: `Failed to access token with given credential to access Power BI tenant. Authentication type: PowerBiDelegated Message AASTS70002: The request body must contain the following parameter: 'client_assertion' or 'client_secret'.`
- **Cause**: If Delegated Authentication is used, the problem could be a misconfiguration on the app registration.
- **Recommendation**: Review Power BI deployment checklist based on your scenario.

Error code: Test connection failed - Detailed metadata

- **Message**: `Failed to enable the PowerBI administrator API to fetch basic metadata and lineage.`
- **Cause**: **Allow service principals to use read-only Power BI admin APIs** is disabled.
- **Recommendation**: Under Power BI Admin portal, enable **Allow service principals to use read-only Power BI admin APIs**.

Issue: Test Connection succeeded. No assets discovered.

- **Message**: N/A
- **Cause**: This problem can occur in same-tenant or cross-tenant scenarios, due problem with networking or authentication issues.
- **Recommendation**:
  - If Delegated Authentication is used, validate Power BI Admin user sign in logs in Microsoft Entra logs to make sure user sign in is successful. Login with the user to Power BI dashboard to validate if user can successfully login to the application.
  - Review your network configurations. Private endpoint is required for **both** Power BI tenant and Purview account, if one of these services (Power BI tenant or Microsoft Purview) is configured to block public access.

Next steps

Follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview

- Search Unified Catalog

Available metadata for Power BI in Unified Catalog

Article • 05/21/2025

This article lists the metadata that is available for a Power BI tenant in the Microsoft Purview Unified Catalog.

Power BI

Connect to and manage Qlik Sense in Microsoft Purview

Article • 03/28/2025

This article outlines how to register Qlik Sense, and how to authenticate and interact with Qlik Sense in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	No

The supported Qlik Sense version is 11.11 to 14.x.

When scanning Qlik Sense, Microsoft Purview supports extracting technical metadata including:

- Server
- Folders
- Streams
- Applications
- Stories
- Dimensions
- Measures
- Expressions
- QVD (QlikView Data)
- Tables and the columns
- Sheets and the lists, charts, report tables, pivot tables, axes, text boxes, text fields

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

- When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need an Azure Key Vault, and to grant Microsoft Purview permissions to access secrets.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario. If your data source isn't publicly accessible, set up the latest kubernetes supported self-hosted integration runtime.

Required permissions for scan

Microsoft Purview extracts metadata via Qlik Engine API (JSON over WebSocket). It supports **Qlik Sense certificate authentication** for scanning Qlik Sense. Make sure:

- User account must have read access granted.
- This may be accomplished by creating security rules for a specific application and user.
- Another alternative is if the application is published to a specific stream and the user has rights to read from this stream.

The user must have appropriate permissions:

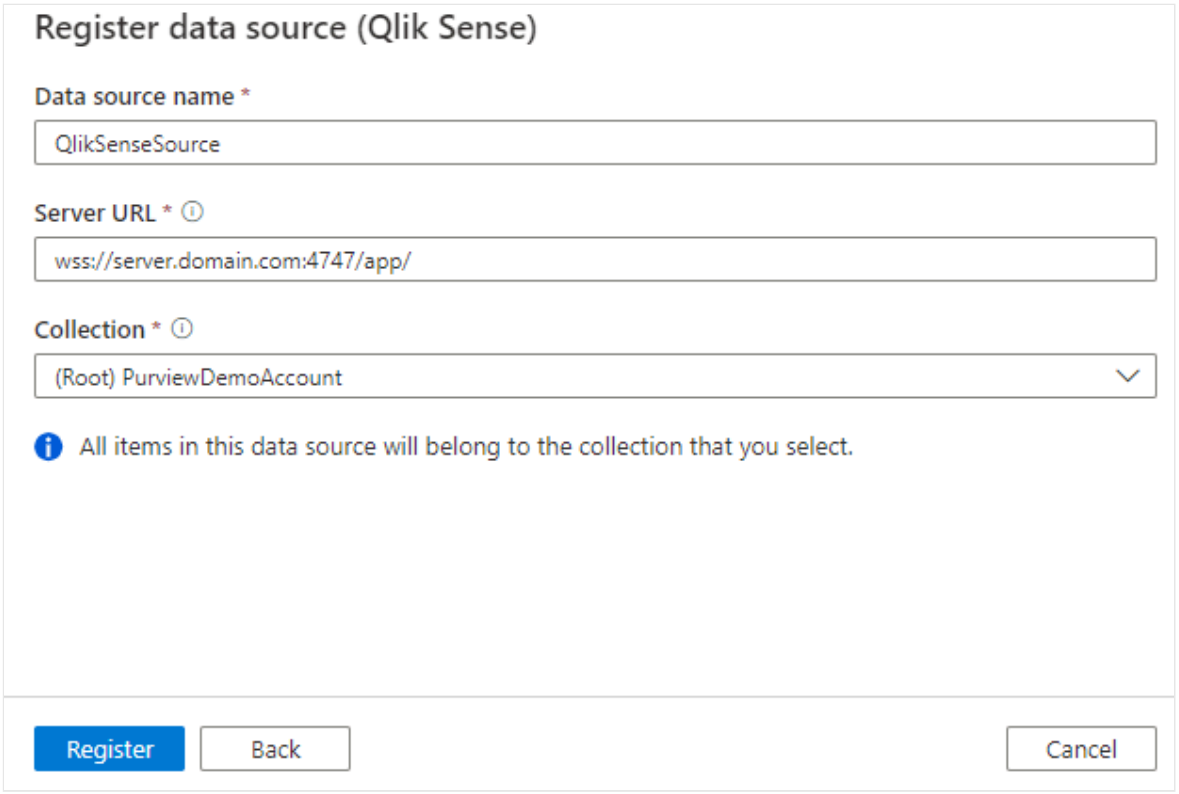
- Read all application objects (especially script).
- Read all data connections (or at least data connections specified in application).

Create Qlik Sense certificate

You need to export the certificate from Qlik Sense. Learn more from Exporting certificates through the QMC.

1. Launch Qlik Management Console (QMC): https://your_QPS_server_name/qmc.
2. Under **CONFIGURE SYSTEM**, click **Certificates**.
3. Enter the machine name, and optionally input the certificate password or leave it empty.
4. Keep the export file format as "Windows format".
5. Note the location where the certificate will be exported to, and then click Export certificates.
6. In File Explorer, navigate to where the certificate was exported to, e.g. `C:\ProgramData\Qlik\Sense\Repository\Exported Certificates`.

Next, store the **client.pfx** certificate you exported in your Azure Key Vault. You can choose to store it as a certificate or as a secret.



- To store it as a certificate, follow the steps in Tutorial: Import a certificate in Azure Key Vault. If your certificate is protected by a password, note after imported in Key Vault, its associated password isn't saved. The password is required only once during the import operation.
- To store it as a secret, you can convert the content of client.pfx to Base64 format using https://www.base64encode.org/, and put the resulted string as secret value. If your certificate is protected by a password, also save the password as another secret.

Register

This section describes how to register a Qlik Sense server in Microsoft Purview by using the Microsoft Purview governance portal.

1. Go to your Microsoft Purview account.
2. Select **Data Map** on the left pane.
3. Select **Register**.
4. In **Register sources**, select **Qlik Sense** > **Continue**.
5. On the **Register sources (Qlik Sense)** screen, do the following:
   a. For **Name**, enter a name that Microsoft Purview will list as the data source.
   b. For **Server URL**, enter the URL of your Qlik Sense server. In order to use the Qlik Engine API, you need to open a WebSocket to the engine using one of the following URIs: `wss://server.domain.com:4747/app/` or `wss://server.domain.com[/virtual proxy]/app/`.

c. Select a collection from the list.

6. Select **Register**.

Scan

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have followed all **prerequisites**.
> 2. Review our **scan troubleshooting documentation**.

Use the following steps to scan Qlik Sense server to automatically identify assets. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

1. Go to **Sources**.

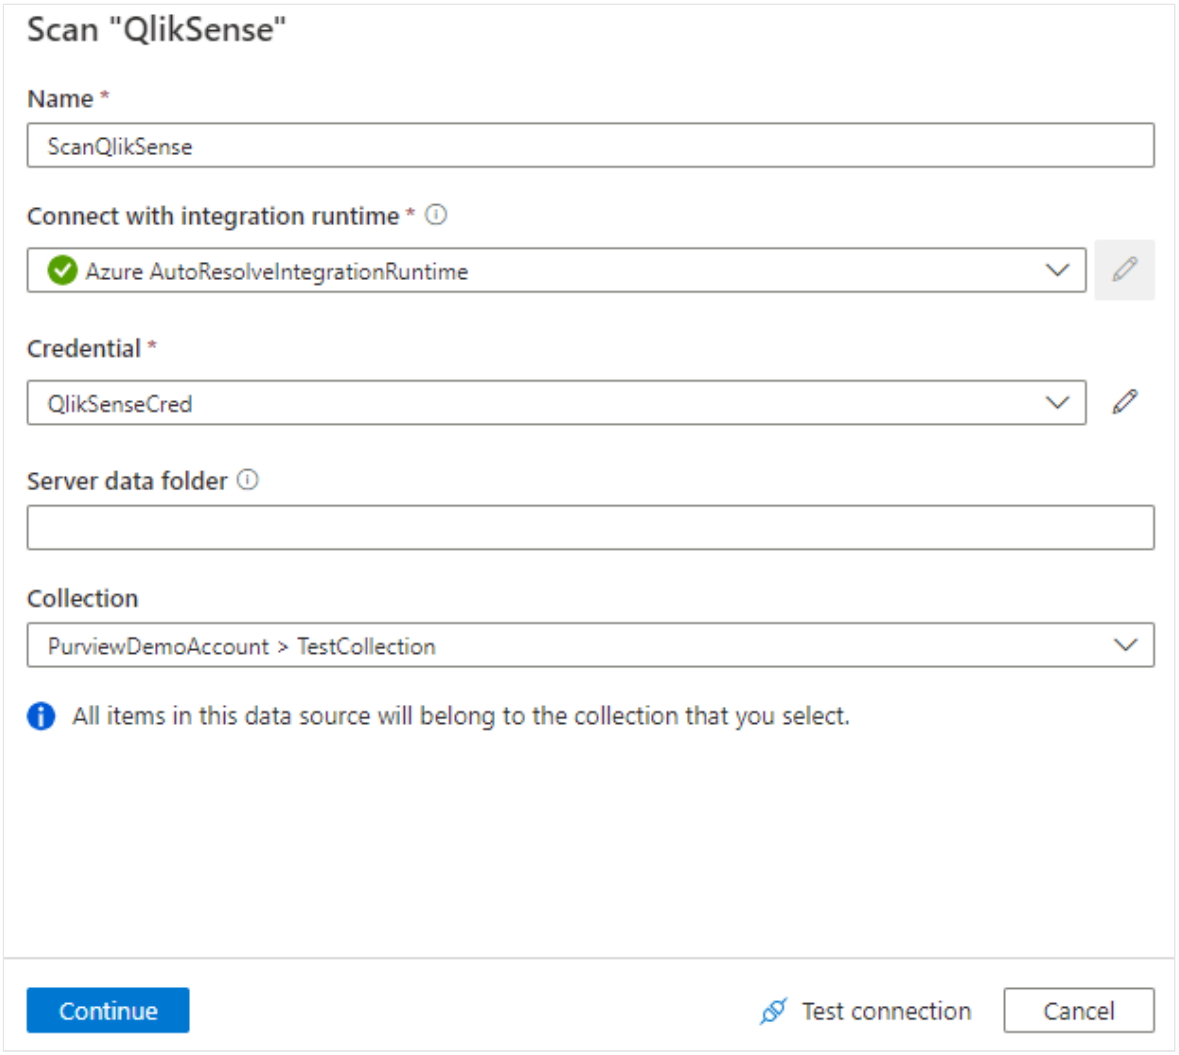
2. Select the registered Qlik Sense source.

3. Select + **New scan**.

4. Provide the following details:

   a. **Name**: Enter a name for the scan.

b. **Connect via integration runtime**: Choose the proper type of integration runtime. Learn more from Choose the right integration runtime configuration for your scenario.



c. **Credential**: Select the credential to connect to your data source. Follow the steps to Create Qlik Sense certificate and store it in Azure Key Vault. When creating the credential, make sure to:

   - Select **Qlik Sense certificate Authentication** while creating a credential.
   - Specify the user name.
   - Specify the user directory. See the "Users" page in the Qlik Management Console (https://your_QPS_server_name/qmc).
   - For the certificate, specify the Key Vault certificate or secret name.
   - If your certificate is protected by a password and you store the certificate as a Key Vault secret, also specify the Key Vault secret name for the password.

   For more information, see Credentials for source authentication in Microsoft Purview.

d. **Server data folder**: The network shared location of Qlik Sense Server's Qlik View Data (QVD) folder, e.g. `\\QlikSense\qliksenseshare`. If specified, Microsoft Purview tries to access the network shared location and scan the QVD files.

5. Click **Test connection** to validate the settings.

6. Select **Continue**.

7. For **Scan trigger**, choose whether to set up a schedule or run the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Browse, search, and view assets

After successfully scanning your Qlik Sense server, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Search the Unified Catalog

Connect to and manage Salesforce in Microsoft Purview

Article • 03/28/2025

This article outlines how to register Salesforce, and how to authenticate and interact with Salesforce in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

When scanning Salesforce source, Microsoft Purview supports extracting technical metadata including:

- Organization
- Objects including the fields, foreign keys, and unique_constraints

When setting up scan, you can choose to scan an entire Salesforce organization, or scope the scan to a subset of objects matching the given names or name patterns.

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- A Salesforce connected app, which will be used to access your Salesforce information.
  - If you need to create a connected app, you can follow the Salesforce documentation.
  - You'll need to enable OAuth for your Salesforce application.

> **Note**
>
> **If your data store is not publicly accessible** (if your data store limits access from on-premises network, private network or specific IPs, etc.), **you will need to configure a self hosted integration runtime to connect to it**.

- If your data source isn't publicly accessible, set up the latest self-hosted integration runtime.
  - Choose the right integration runtime for your scenario:
    - **To use a self-hosted integration runtime:**
      - Follow the article to create and configure a self-hosted integration runtime.
      - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
      - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
      - Ensure the self-hosted integration runtime machine's IP is within the trusted IP ranges for your organization set on Salesforce.
    - **To use a kubernetes supported self-hosted integration runtime:**
      - Follow the article to create and configure a kubernetes supported integration runtime.
      - Ensure the self-hosted integration runtime machine's IP is within the trusted IP ranges for your organization set on Salesforce.

Required permissions for scan

If users will be submitting Salesforce Documents, certain security settings must be configured to allow this access on Standard Objects and Custom Objects. To configure permissions:

- Within Salesforce, select Setup and then select Manage Users.
- Under the Manage Users tree select Profiles.
- Once the Profiles appear on the right, select which Profile you want to edit and select the Edit link next to the corresponding profile.

For Standard Objects, ensure that the "Documents" section has the Read permissions selected. For Custom Objects, ensure that the Read permissions selected for each custom objects.

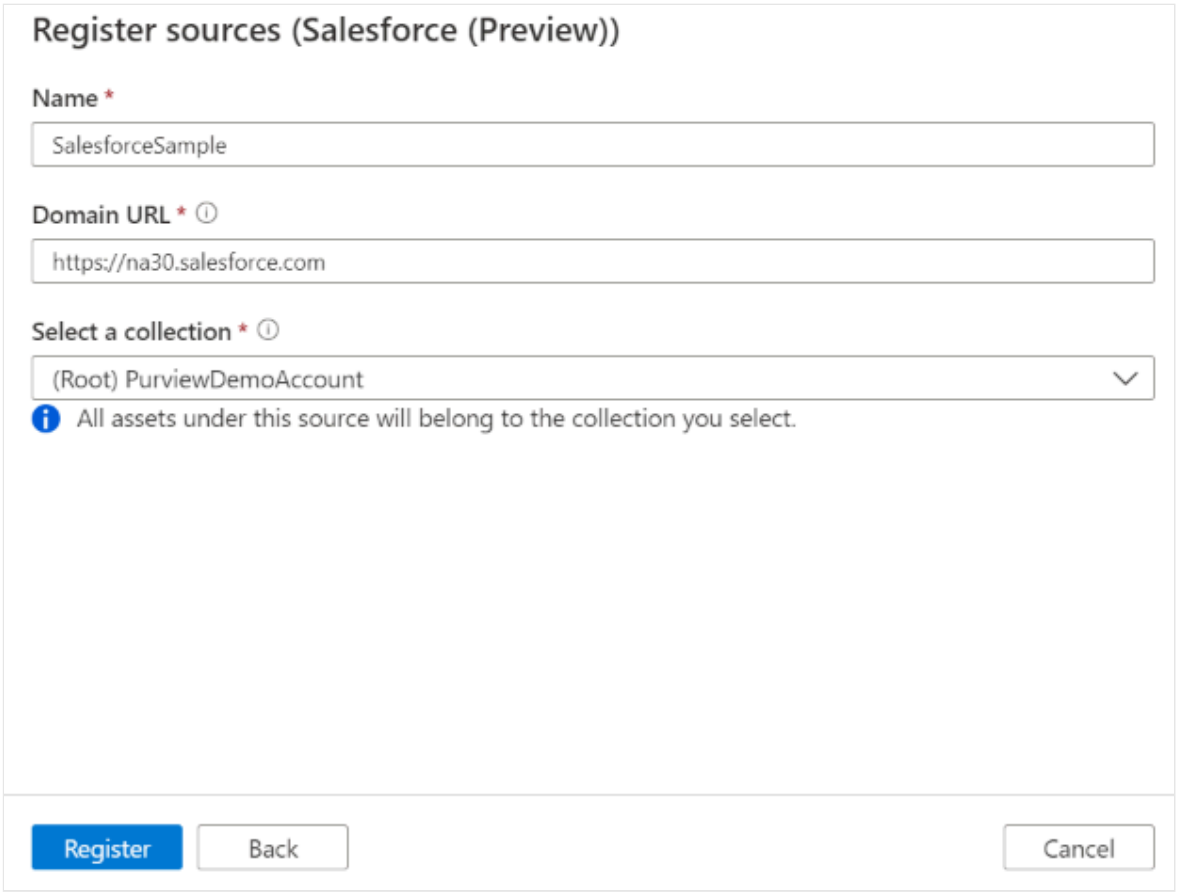
Register

This section describes how to register Salesforce in Microsoft Purview using the Microsoft Purview governance portal.

Steps to register

To register a new Salesforce source in Microsoft Purview Unified Catalog, follow these steps:

1. Navigate to your Microsoft Purview account in the Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register**
4. On Register sources, select **Salesforce**. Select **Continue**.



On the **Register sources (Salesforce)** screen, follow these steps:

1. Enter a **Name** that the data source will be listed within the Catalog.

2. Enter the Salesforce sign in endpoint URL as **Domain URL**. For example, `https://login.salesforce.com`. You can use your company's instance URL (such as `https://na30.salesforce.com`) or My Domain URL (such as `https://myCompanyName.my.salesforce.com/`) or Sandbox URL (such as `https://myCompanyName.sandbox.my.salesforce.com/`).

3. Select a collection from the list.

4. Finish to register the data source.

Scan

Follow these steps to scan Salesforce to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Microsoft Purview uses Salesforce REST API version 41.0 to extract metadata, including REST requests like 'Describe Global' URI (/v41.0/sobjects/),'sObject Basic Information' URI (/v41.0/sobjects/sObject/), and 'SOQL Query' URI (/v41.0/query?).

Authentication for a scan

The supported authentication type for a Salesforce source is **Consumer key authentication**.

Create and run scan

To create and run a new scan, follow these steps:

1. If your server is publicly accessible, skip to step two. Otherwise, you'll need to make sure your self-hosted integration runtime is configured:
   a. In the Microsoft Purview governance portal, got to the Management Center, and select **Integration runtimes**.

b. Make sure a self-hosted integration runtime is available. If one isn't set up, use the steps mentioned in prerequisites to set up a self-hosted integration runtime.

2. In the Microsoft Purview governance portal, navigate to **Sources**.

3. Select the registered Salesforce source.

4. Select + **New scan**.

5. Provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the Azure autoresolved integration runtime if your server is publicly accessible, or your configured self-hosted integration runtime if it isn't publicly available.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select **Consumer key** while creating a credential.
      - Provide the username of the user that the connected app is imitating in the User name input field.
      - Store the password of the user that the connected app is imitating in an Azure Key Vault secret.
        - If your self-hosted integration runtime machine's IP is within the trusted IP ranges for your organization set on Salesforce, provide just the password of the user.
        - Otherwise, **concatenate the password and security token as the value of the secret**. The security token is an automatically generated key that must be added to the end of the password when logging in to Salesforce from an untrusted network. Learn more about how to get or reset a security token.
      - Provide the consumer key from the connected app definition. You can find it on the connected app's Manage Connected Apps page or from the connected app's definition.
      - Stored the consumer secret from the connected app definition in an Azure Key Vault secret. You can find it along with consumer key.

   d. **Objects**: Provide a list of object names to scope your scan. For example, `object1; object2`. An empty list means it's retrieving all available objects. You can specify object names as a wildcard pattern. For example, `topic?`, `*topic*`, or `topic_?,*topic*`.

e. **Maximum memory available** (applicable when using self-hosted integration runtime): Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of Salesforce source to be scanned.

> **Note**
>
> As a rule of thumb, please provide 1GB memory for every 1000 tables

6. Select **Test connection** to validate the settings (available when using Azure Integration Runtime).

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage SAP Business Warehouse in Microsoft Purview

This article outlines how to register SAP Business Warehouse (BW), and how to authenticate and interact with SAP BW in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	No

Purview supports SAP BW versions 7.3 to 7.5, and SAP BW/4HANA.

When you scan an SAP BW source, Microsoft Purview extracts technical metadata, including:

- Instance
- InfoArea
- InfoSet
- InfoSet query
- Classic InfoSet
- InfoObject, including unit of measurement, time characteristic, navigation attribute, data packet characteristic, currency, characteristic, field, and key figure
- Data store object (DSO), including its schema of InfoObject attributes and primary keys
- Advanced data store object (ADSO), including its schema of InfoObject attributes and primary keys
- Aggregation level
- Open hub destination
- Query, including the query condition
- Query view
- HybridProvider
- MultiProvider

- InfoCube
- Aggregate
- Dimension
- Time dimension

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

- When you delete an object from the data source, the subsequent scan doesn't automatically remove the corresponding asset in Purview.
- You can extract only the `sap_bw_query_condition` under the `sap_bw_query`.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview resource.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the classic Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- When you create a scan for the first time, you need to create a function module in your SAP server. Microsoft Purview provides some code in the asset page in the Microsoft Purview Data Map to create the module. To download this code, you need to have Data Source Administrator permissions on the root collection in your data map.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.

    - The connector reads metadata from SAP using the SAP Java Connector (JCo) 3.0 API. Make sure the Java Connector is available on your machine where self-hosted integration runtime is installed. Make sure that you use the correct JCo distribution for your environment, and the **sapjco3.jar** and **sapjco3.dll** files are available.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.
    - The connector reads metadata from SAP using the SAP Java Connector (JCo) 3.0 API. Make sure the Java Connector is available on your machine where self-hosted integration runtime is installed. Make sure that you use the correct JCo distribution for your environment, and the **sapjco3.jar** and **sapjco3.dll** files are available.

    > **Note**
    >
    > The driver should be accessible to all accounts in the machine. Don't put it in a path under user account.

  - Self-hosted integration runtimes communicate with the SAP server over dispatcher port 32NN and gateway port 33NN, where NN is your SAP instance number from 00 to 99. Make sure the outbound traffic is allowed on your firewall.

- Deploy the metadata extraction ABAP function module on the SAP server by following the steps mentioned in ABAP functions deployment guide. You need to download a separate ABAP module for SAP BW/4 HANA version from the scan page. You need an ABAP developer account to create the RFC function module on the SAP server. For scan execution, the user account requires sufficient permissions to connect to the SAP server and execute the following RFC function modules:

- STFC_CONNECTION (check connectivity)
  - RFC_SYSTEM_INFO (check system information)
  - OCS_GET_INSTALLED_COMPS (check software versions)
  - Z_MITI_BW_DOWNLOAD (main metadata import, the function module you create following the Purview guide)

  The underlying SAP Java Connector (JCo) libraries might call more RFC function modules, such as. RFC_PING, RFC_METADATA_GET. Refer to SAP support note 460089 for details.

Register

This section describes how to register SAP BW in Microsoft Purview using the classic Microsoft Purview governance portal.

Authentication for registration

The only supported authentication method for an SAP BW source is **Basic authentication**.

Steps to register

1. Open the classic Microsoft Purview governance portal by:

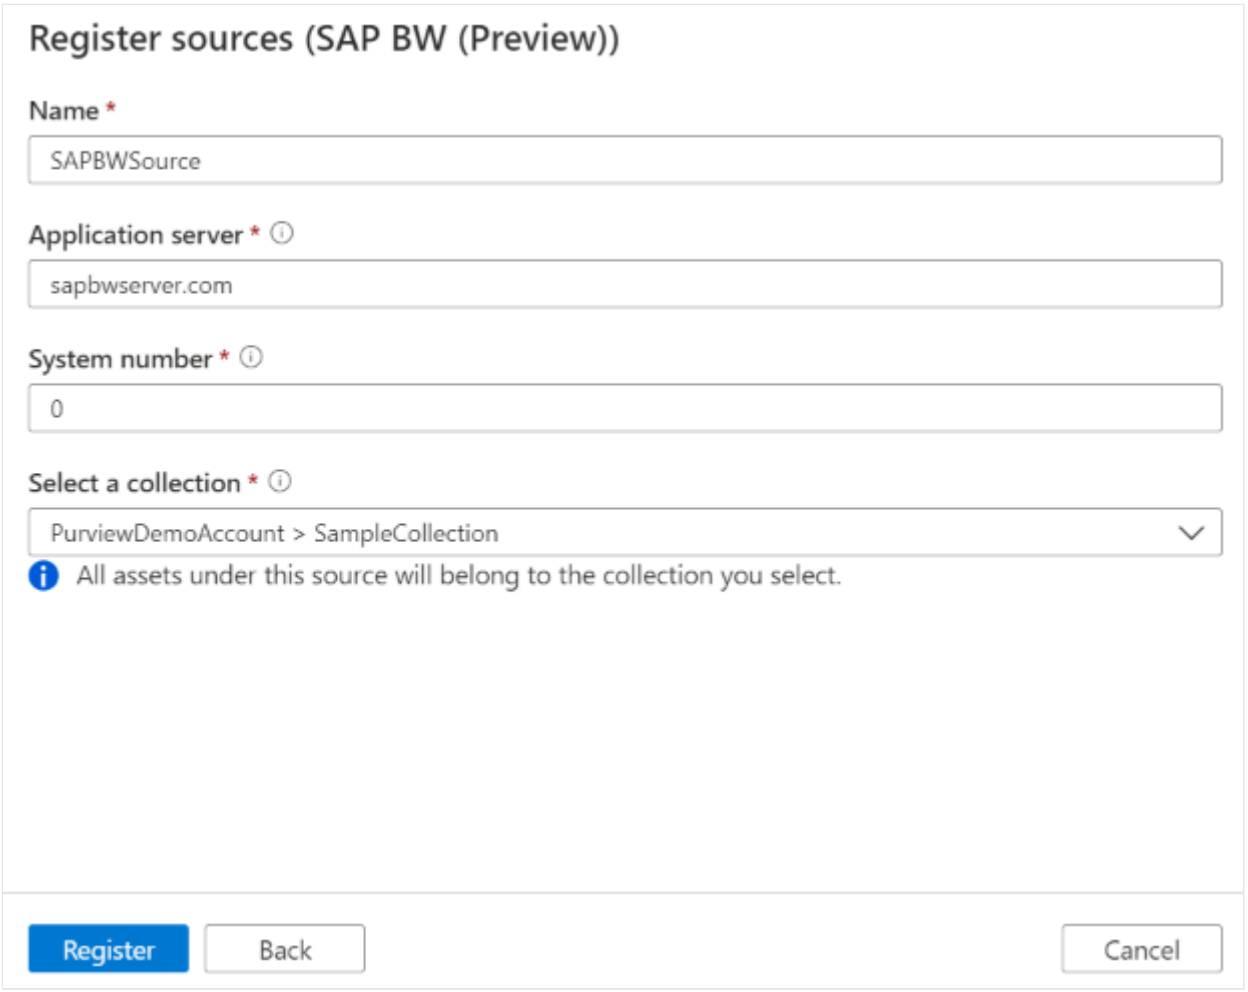
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.

3. Select **Register**.

4. In **Register sources**, select **SAP BW** > **Continue**.

On the **Register sources (SAP BW)** screen, complete the following steps:



1. Enter a **Name** for the data source to list it within the catalog.

2. Enter the **Application server** name to connect to the SAP BW source. You can also enter an IP address for the SAP application server host.

3. Enter the SAP **System number**. It's an integer between 0 and 99.

4. Select a collection from the list.

5. Finish the registration of the data source.

Scan

Follow the steps in this section to scan SAP BW and automatically identify assets. For more information about scanning, see introduction to scans and ingestion.

> **Important**
>
> When you create a scan for the first time, you need to create a function module in your SAP server. Microsoft Purview provides some code in the asset page in the Microsoft Purview Data Map to create the module. To download this code, you need to have Data Source Administrator permissions on the root collection in your data map.

Create and run scan

1. In the Management Center, select **Integration runtimes**. Make sure you set up a self-hosted integration runtime. If you don't have a self-hosted integration runtime, use the steps mentioned in prerequisites to create one.

2. Go to **Sources**.

3. Select the registered SAP BW source.

4. Select **New scan**.

5. Enter the following details:

   a. **Name**: The name of the scan.

   b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select Basic Authentication while creating a credential.
      - Provide a user ID to connect to SAP server in the User name input field.
      - Store the user password used to connect to SAP server in the secret key.

   d. **Client ID**: Enter the SAP Client ID. It's a three-digit numeric number from 000 to 999.

   e. **SNC Mode (Optional)**: Turn the toggle **on** if you prefer to use Secure Network Communications (SNC) mode for securing your technical connections to SAP RFCs through a certificate-based authentication mechanism. SNC Mode is **off** by default. Follow the steps to set up the SAP personal secure environment with SNC certificate.

   f. **JCo library path**: Specify the directory path where the JCo libraries are located, for example: `D:\Drivers\SAPJCo`. Make sure the path is accessible by the self-hosted integration runtime, learn more from prerequisites section.

      - For self-hosted integration runtime on a local machine: `D:\Drivers\SAPJCo`. It's the path to a valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime. To learn more, see the prerequisites section.

      - For Kubernetes-supported self-hosted integration runtime: `./drivers/SAPJCo`. It's the path to a valid JAR folder location. The value must be a valid relative file path. Refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

   g. **Maximum memory available:** Maximum memory (in GB) available on the self-hosted integration runtime machine to be used by scanning processes. This value depends on

the size of SAP BW source to be scanned.

6. Select **Test connection**.

7. Select **Continue**.

8. Choose your **scan trigger**. You can set up a schedule or run the scan once.

9. Review your scan and select **Save and run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Set up SAP personal secure environment with SNC certificate

Get SAPCAR

- Go to the SAP Software Download Center and sign in with your SAP credentials.
- Search for SAPCAR and select the latest nonarchived version.
- Select your operating system.
- Download the `.EXE file to C:\sap\SAR`.

Get SAP Common Crypto Library

- In the SAP Software Download Center, search for "COMMONCRYPTOLIB" and select the latest version.
- Select your operating system.

- Download the .SAR file with the most recent release date to `C:\sap\SAR`.

Extract SAP Common Crypto Library

- Open PowerShell and go to `C:\sap\SAR`.
- Enter the following command, replacing xxxx with your values: `.\SAPCAR_xxxx.EXE -xvf .\SAPCRYPTOLIBP_xxxx.SAR -R .\..\libs\sapcryptolib`.
- Confirm that `sapgenpse.exe` is in the `C:\sap\libs\sapcryptolib` directory.

Generate certificates

> **Note**
>
> This method is for demonstration purposes only and isn't recommended for production systems. For production systems, consult your internal PKI guidance or security team.

- Set up the folder structure:
  - `mkdir rootCA`
  - `mkdir sncCert`
- Create the necessary serial and index files if they don't exist:
  - `if (-Not (Test-Path "rootCA\index.txt")) { New-Item -Path "rootCA\index.txt" ItemType File }`
  - `if (-Not (Test-Path "rootCA\serial")) { Set-Content -Path "rootCA\serial" -Value "01" }`
- Generate a Root CA:
  - `openssl genpkey -algorithm RSA -out rootCA/ca.key.pem -pkeyopt rsa_keygen_bits:2048`
  - `openssl req -x509 -new -key rootCA/ca.key.pem -days 7305 -sha256 -extensions v3_ca -out rootCA/ca.cert.pem -subj "/O=Contoso/CN=Root CA"`
- Generate the SNC certificate
  - `openssl genrsa -out sncCert/snc.key.pem 2048`
  - `openssl req -key sncCert/snc.key.pem -new -sha256 -out sncCert/snc.csr.pem subj "/O=Contoso/CN=SNC"`
- Create an OpenSSL configuration file, `sncCert/extensions.cnf`, for signing:
  - `subjectKeyIdentifier = hash`
  - `authorityKeyIdentifier = keyid,issuer`
  - `basicConstraints = critical,CA:false`

- `keyUsage = critical,digitalSignature,keyEncipherment,dataEncipherment`
- `extendedKeyUsage = clientAuth,emailProtection`

- Sign the SNC certificate with the Root CA:
  - `openssl x509 -req in sncCert/snc.csr.pem CA rootCA/ca.cert.pem CAkey rootCA/ca.key.pem CAcreateserial out sncCert/snc.cert.pem days 3650 sha256 extfile sncCert\extensions.cnf extensions v3_leaf`

Create a personal secure environment

Create a personal secure environment (PSE) for the on-premises data gateway. The NCo library looks for the SNC certificate inside the PSE.

- Create a PKCS#12 container:
  - `openssl pkcs12 -export -out snc.p12 -inkey sncCert\snc.key.pem -in sncCert\snc.cert.pem -certfile rootCA\ca.cert.pem`
- Create the SECUDIR environment variable.
- Open **System Properties**: In **File Explorer**, right-click **This PC**, and then select **Properties** > **Advanced system settings**.
- Select **Environment Variables**.
- Under **System variables**, select **New**.
- Set the variable name to **SECUDIR**.
- Set the value to `C:\sapsecudir`.
- Select **OK**.

Import the PKCS#12 container into a PSE: `C:\sap\libs\sapcryptolib\sapgenpse.exe import_p12 -p SAPSNCSKERB.pse C:\pki certs\snc.p12`

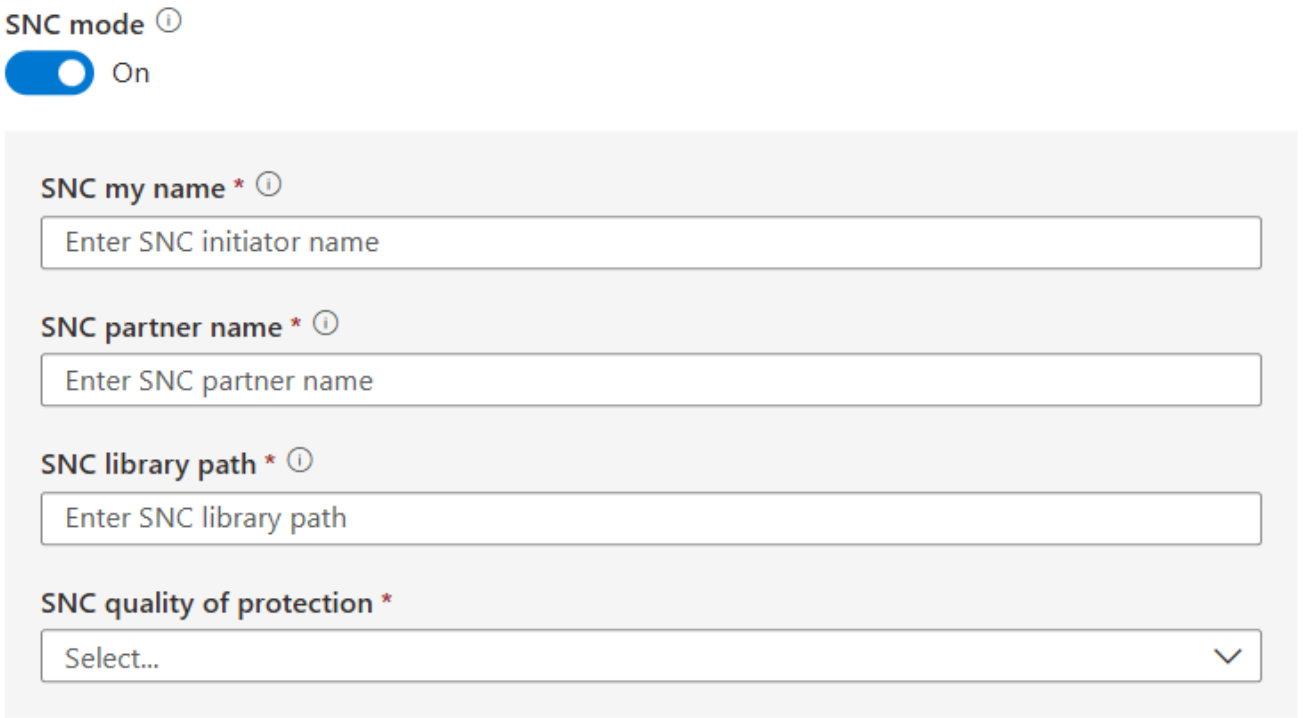
Allow your SHIR process to use your SAP PSE

Verify which user or service is being used by your SNC client to obtain the certificate to communicate with SAP. The Microsoft Purview SHIR uses the service user **NT SERVICE\DIAHostService**.

- Add a credential to allow the certificate retrieval request from the PSE: `.\sapgenpse.exe seclogin -p C:\sapsecudir\SAPSNCSKERB.pse -x your-pse-pin -O "NT`

`SERVICE\DIAHostService"`

- Verify credentials like this: `.\sapgenpse.exe seclogin -l -O "NT SERVICE\DIAHostService"`
- You can delete them like this: `.\sapgenpse.exe seclogin -d -O "NT SERVICE\DIAHostService"`
- Use the -h parameter to get help with the sapgenpse command line tool or check the command reference here.



Give permission to access the SAP JCo library to SHIR process

Verify if Microsoft Purview SHIR user **NT SERVICE\DIAHostService** has **Read/Write/Execute/List** permissions over these folders:

- SNC Library Path: The folder that has the SNC Library, `sapcrypto.dll`. Example: `C:\Users\shir-admin\Desktop\snc\SAPCRYPTOLIBP_8557-20011729\sapcrypto.dll`
- JCo Library Path: The folder that has the SAP Java Connector jar file. Example: `C:\Users\shir-admin\Desktop\snc\sapjco3-ntamd64-3.1\sapjco3-ntamd64-3.1.3`

SAP NCo Library should also be installed on the virtual machine for test connection to work properly, as it still uses NCo library. This isn't necessary, and Test Connection can be skipped.

Enter SCN details for **my name**, **partner name**, **library path**, and **quality of protection**, as seen below, and initiate the scan:

Next steps

After registering your source, explore the following guides to learn more about Purview and your data:

Connect to and manage SAP ECC in Microsoft Purview

06/25/2025

This article outlines how to register SAP ECC, and how to authenticate and interact with SAP ECC in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	No

When scanning SAP ECC source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Instance
  - Application components
  - Packages
  - Tables including the fields, foreign keys, indexes, and index members
  - Views including the fields
  - Transactions
  - Programs
  - Classes
  - Function groups
  - Function modules
  - Domains including the domain values
  - Data elements
- Fetching static lineage on assets relationships among tables and views.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - Download the 64-bit SAP Connector for Microsoft .NET 3.0 from SAP's website and install it on the self-hosted integration runtime machine. During installation, make sure you select the **Install Assemblies to GAC** option in the **Optional setup steps** window.
    - The connector reads metadata from SAP using the SAP Java Connector (JCo) 3.0 API. Make sure the Java Connector is available on your virtual machine where self-hosted integration runtime is installed. Make sure that you're using the correct JCo distribution for your environment. For example: on a Microsoft Windows machine, make sure the sapjco3.jar and sapjco3.dll files are available. Note down the folder path which you will use to set up the scan.
    - Self-hosted integration runtime communicates with the SAP server over dispatcher port 32NN and gateway port 33NN, where NN is your SAP instance number from 00 to 99. Make sure the outbound traffic is allowed on your firewall.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.

- Download the 64-bit SAP Connector for Microsoft .NET 3.0 from SAP's website and install it on the self-hosted integration runtime machine. During installation, make sure you select the **Install Assemblies to GAC** option in the **Optional setup steps** window.
- The connector reads metadata from SAP using the SAP Java Connector (JCo) 3.0 API. Make sure the Java Connector is available on your virtual machine where self-hosted integration runtime is installed. Make sure that you're using the correct JCo distribution for your environment. For example: on a Microsoft Windows machine, make sure the sapjco3.jar and sapjco3.dll files are available. Note down the folder path which you'll use to set up the scan.
- Self-hosted integration runtime communicates with the SAP server over dispatcher port 32NN and gateway port 33NN, where NN is your SAP instance number from 00 to 99. Make sure the outbound traffic is allowed on your firewall.

> **Note**
>
> Scanning SAP ECC is a memory intensive operation, you're recommended to install Self-hosted Integration Runtime on a machine with at least 128 GB RAM.

- Deploy the metadata extraction ABAP function module on the SAP server by following the steps mentioned in ABAP functions deployment guide. You need an ABAP developer account to create the RFC function module on the SAP server. For scan execution, the user account requires sufficient permissions to connect to the SAP server and execute the following RFC function modules:
  - STFC_CONNECTION (check connectivity)
  - RFC_SYSTEM_INFO (check system information)
  - OCS_GET_INSTALLED_COMPS (check software versions)
  - Z_MITI_DOWNLOAD (main metadata import, the function module you create following the Purview guide)

  The underlying SAP Java Connector (JCo) libraries might call more RFC function modules; for example, RFC_PING, RFC_METADATA_GET, etc. See SAP support note 460089 for details.

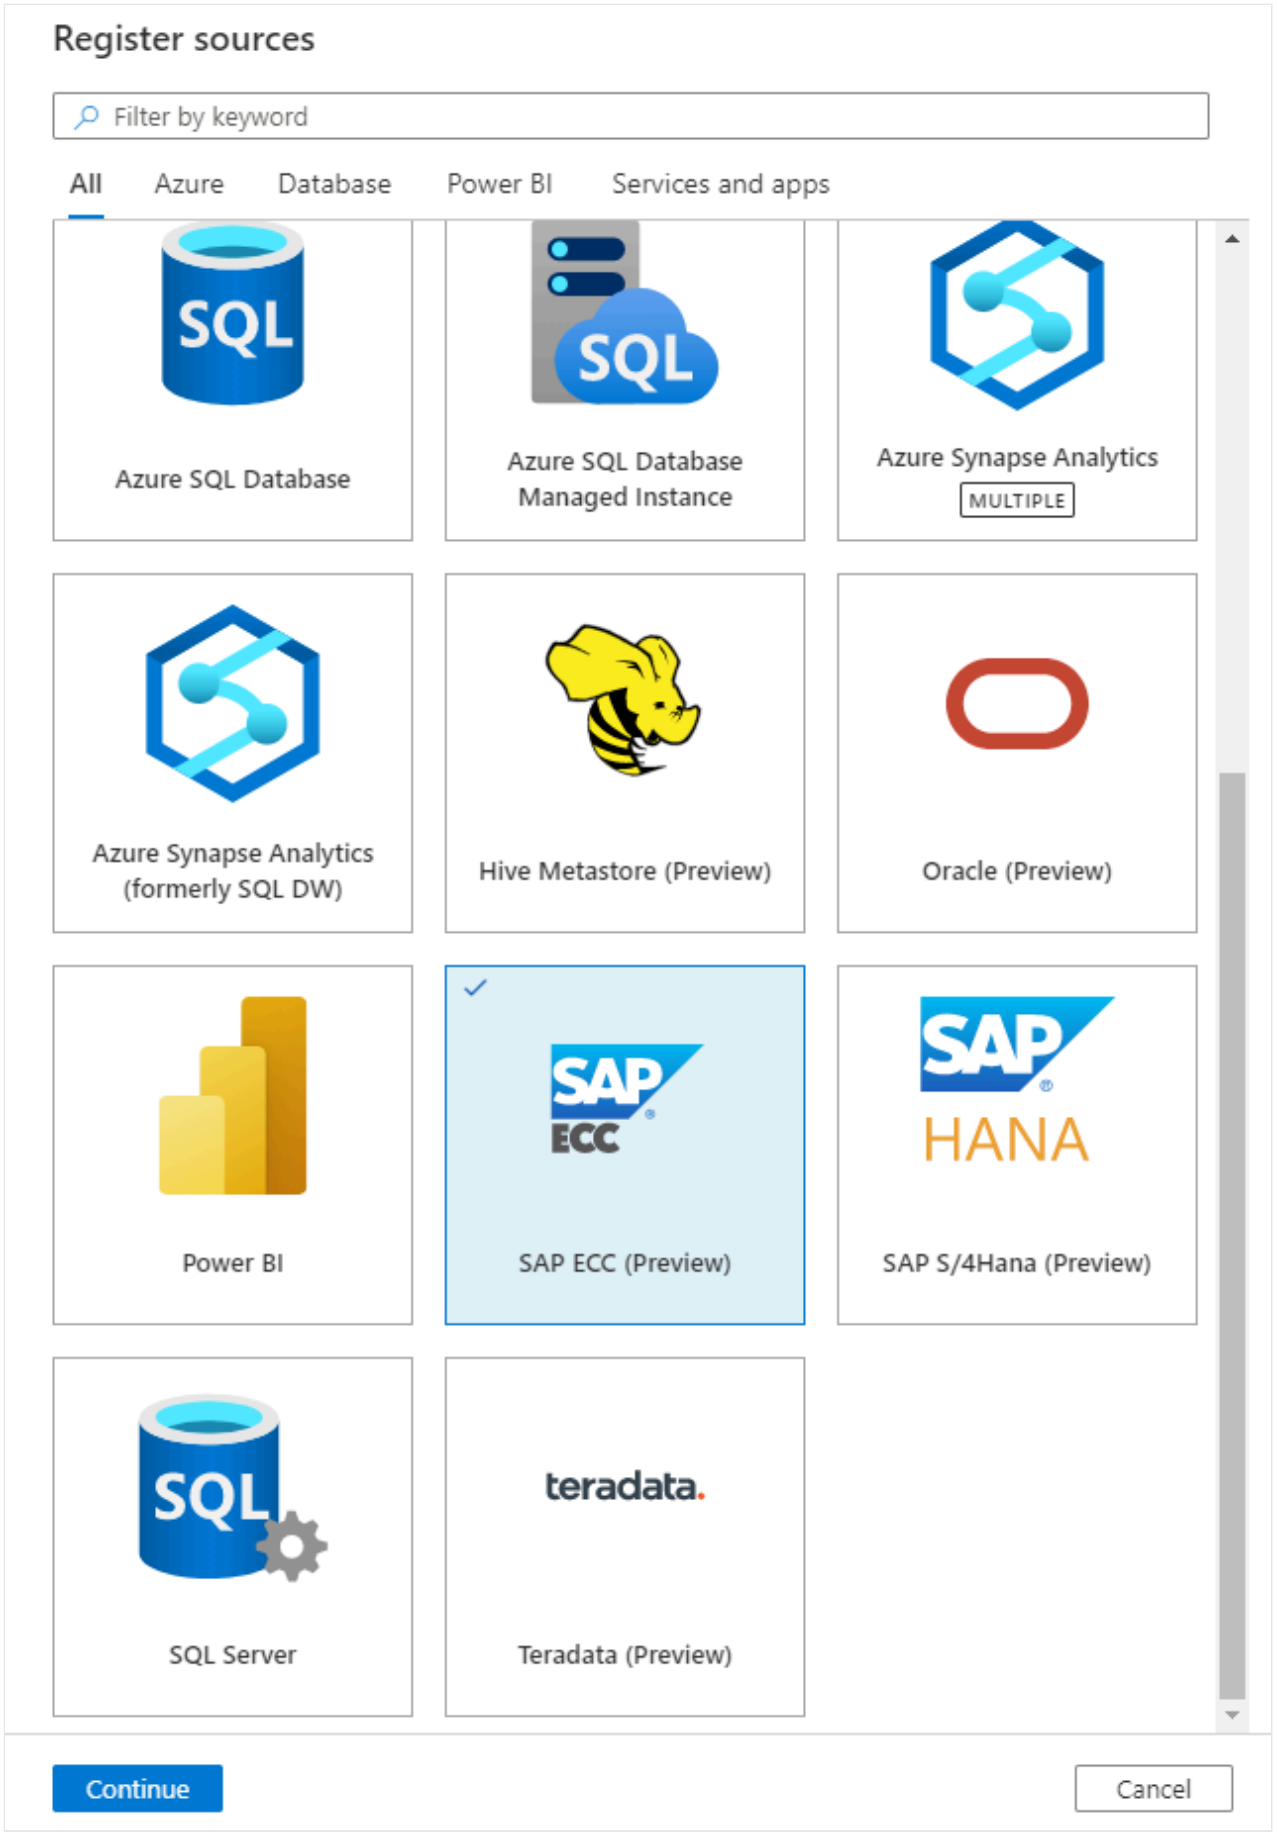
Register

This section describes how to register SAP ECC in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

The only supported authentication for SAP ECC source is **Basic authentication**.

Steps to register



1. Open the Microsoft Purview governance portal by:

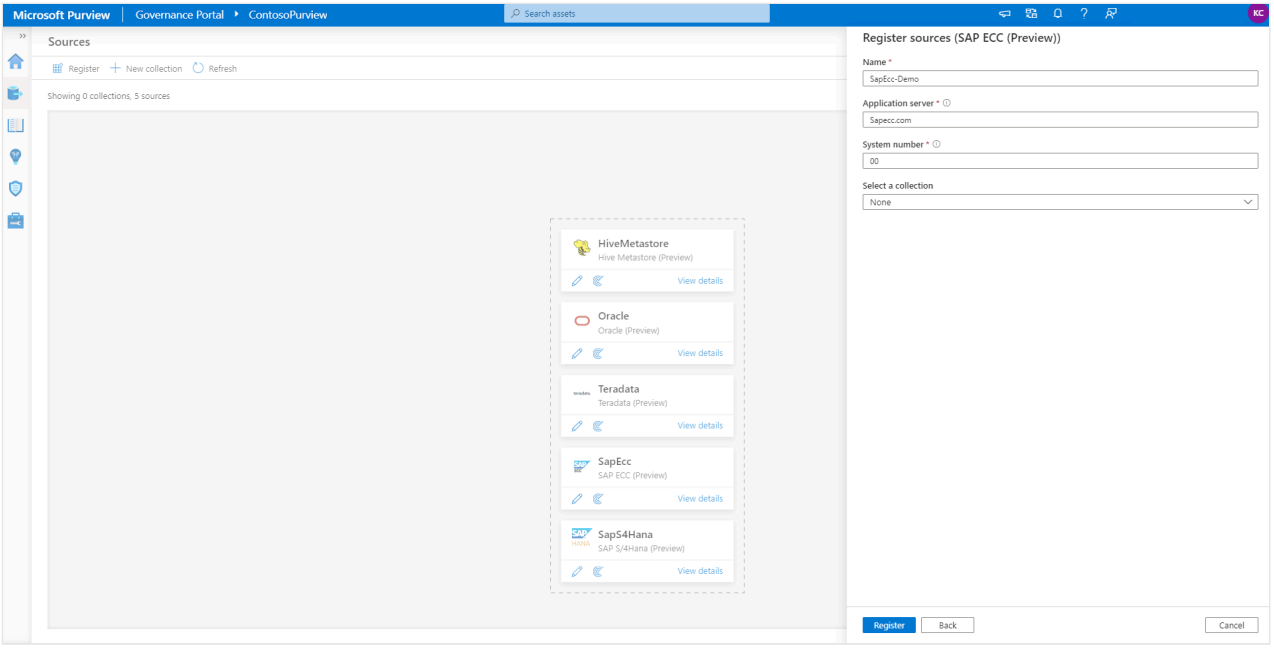
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.

3. Select **Register**

4. On Register sources, select **SAP ECC**. Select **Continue.**

On the **Register sources (SAP ECC)** screen, do the following:



1. Enter a **Name** that the data source will be listed within the Catalog.

2. Enter the **Application server** name to connect to SAP ECC source. It can also be an IP address of the SAP application server host.

3. Enter the SAP **System number**. This is a two-digit integer between 00 and 99.

4. Select a collection from the list.

5. Finish to register the data source.

Scan

Follow the steps below to scan SAP ECC to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Create and run scan

1. In the Management Center, select Integration runtimes. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned in prerequisites to create a self-hosted integration runtime.

2. Navigate to **Sources**

3. Select the registered SAP ECC source.

4. Select + **New scan**

5. Provide the below details:

   a. **Name**: The name of the scan

b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

c. **Credential**: Select the credential to connect to your data source. Make sure to:

- Select Basic Authentication while creating a credential.
- Provide a user ID to connect to SAP server in the User name input field.
- Store the user password used to connect to SAP server in the secret key.

d. **Client ID**: Enter the SAP Client ID. It's a three-digit numeric number from 000 to 999.

e. **SNC Mode (Optional)**: Turn the toggle **on** if you prefer to use Secure Network Communications (SNC) mode for securing your technical connections to SAP RFCs through a certificate-based authentication mechanism. SNC Mode is **off** by default.

Follow these steps to set up the SAP Personal Secure Environment with SNC Certificate:

Get SAPCAR

- Go to the SAP Software Download Center and sign in with your SAP credentials.
- Search for SAPCAR and select the latest nonarchived version.
- Select your operating system.
- Download the `.EXE file to C:\sap\SAR`.

Get SAP Common Crypto Library

- In the SAP Software Download Center, search for "COMMONCRYPTOLIB" and select the latest version.
- Select your operating system.
- Download the .SAR file with the most recent release date to `C:\sap\SAR`.

Extract SAP Common Crypto Library

- Open PowerShell and navigate to `C:\sap\SAR`.
- Enter the following command, replacing xxxx with your values: `.\SAPCAR_xxxx.EXE -xvf .\SAPCRYPTOLIBP_xxxx.SAR -R .\..\libs\sapcryptolib`.
- Confirm that `sapgenpse.exe` is in the `C:\sap\libs\sapcryptolib` directory.

Generate certificates

Note: This method is for demonstration purposes only and isn't recommended for production systems. For production systems, consult your internal PKI guidance or security team.

- Set up the folder structure:

    - `mkdir rootCA`
    - `mkdir sncCert`

- Create the necessary serial and index files if they don't exist:
    - `if (-Not (Test-Path "rootCA\index.txt")) { New-Item -Path "rootCA\index.txt" ItemType File }`
    - `if (-Not (Test-Path "rootCA\serial")) { Set-Content -Path "rootCA\serial" -Value "01" }`

- Generate a Root CA:
    - `openssl genpkey -algorithm RSA -out rootCA/ca.key.pem -pkeyopt rsa_keygen_bits:2048`
    - `openssl req -x509 -new -key rootCA/ca.key.pem -days 7305 -sha256 -extensions v3_ca -out rootCA/ca.cert.pem -subj "/O=Contoso/CN=Root CA"`

- Generate the SNC certificate
    - `openssl genrsa -out sncCert/snc.key.pem 2048`
    - `openssl req -key sncCert/snc.key.pem -new -sha256 -out sncCert/snc.csr.pem subj "/O=Contoso/CN=SNC"`

- Create an OpenSSL configuration file, `sncCert/extensions.cnf`, for signing:
    - `subjectKeyIdentifier = hash`
    - `authorityKeyIdentifier = keyid,issuer`
    - `basicConstraints = critical,CA:false`
    - `keyUsage = critical,digitalSignature,keyEncipherment,dataEncipherment`
    - `extendedKeyUsage = clientAuth,emailProtection`

- Sign the SNC certificate with the Root CA:
    - `openssl x509 -req in sncCert/snc.csr.pem CA rootCA/ca.cert.pem CAkey rootCA/ca.key.pem CAcreateserial out sncCert/snc.cert.pem days 3650 sha256 extfile sncCert\extensions.cnf extensions v3_leaf`

Create a Personal Secure Environment

Create a Personal Secure Environment (PSE) for the on-premises data gateway. The NCo library looks for the SNC certificate inside the PSE.

- Create a PKCS#12 container:
    - `openssl pkcs12 -export -out snc.p12 -inkey sncCert\snc.key.pem -in sncCert\snc.cert.pem -certfile rootCA\ca.cert.pem`

- Create the SECUDIR environment variable.

- Open **System Properties**: In **File Explorer**, right-click **This PC**, and then select **Properties** > **Advanced system settings**.
- Select **Environment Variables**.
- Under **System variables**, select **New**.
- Set the variable name to **SECUDIR**.
- Set the value to `C:\sapsecudir`.
- Select **OK**.

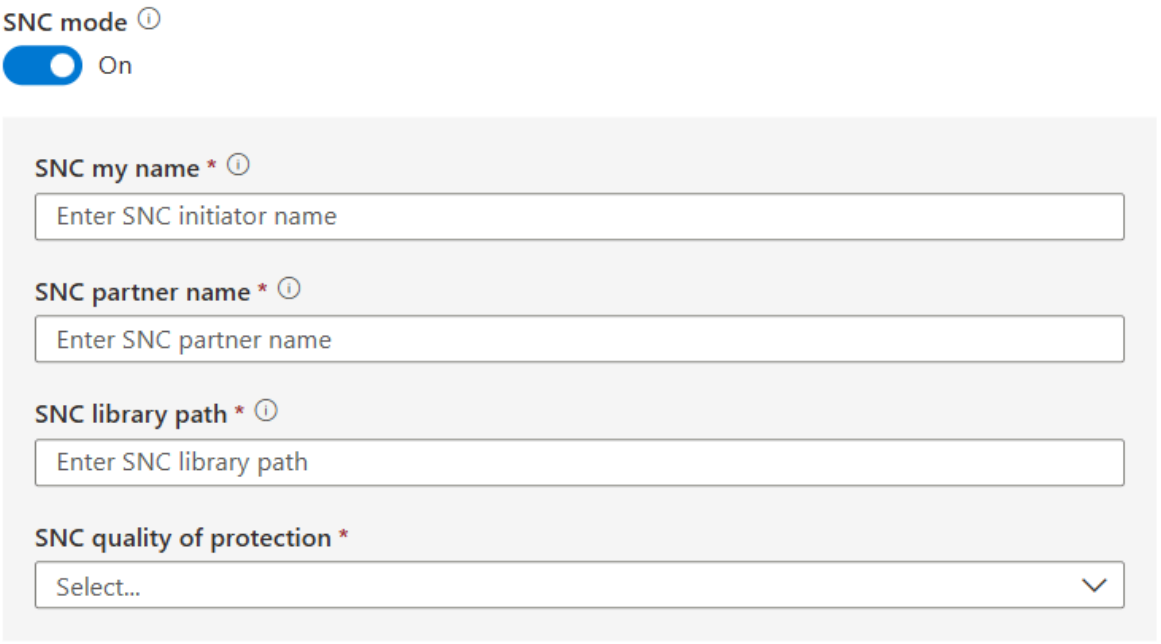
Import the PKCS#12 container into a PSE: `C:\sap\libs\sapcryptolib\sapgenpse.exe import_p12 -p SAPSNCSKERB.pse C:\pki certs\snc.p12`

Allow your SHIR process to use your SAP PSE

Verify which user or service is being used by your SNC client to obtain the certificate to communicate with SAP. The Microsoft Purview SHIR uses the service user **NT SERVICE\DIAHostService**.

- Add a credential to allow the certificate retrieval request from the PSE: `.\sapgenpse.exe seclogin -p C:\sapsecudir\SAPSNCSKERB.pse -x your-pse-pin -O "NT SERVICE\DIAHostService"`
- Verify credentials like this: `.\sapgenpse.exe seclogin -l -O "NT SERVICE\DIAHostService"`
- You can delete them like this: `.\sapgenpse.exe seclogin -d -O "NT SERVICE\DIAHostService"`
- Use the -h parameter to get help with the sapgenpse command line tool or check the command reference here.

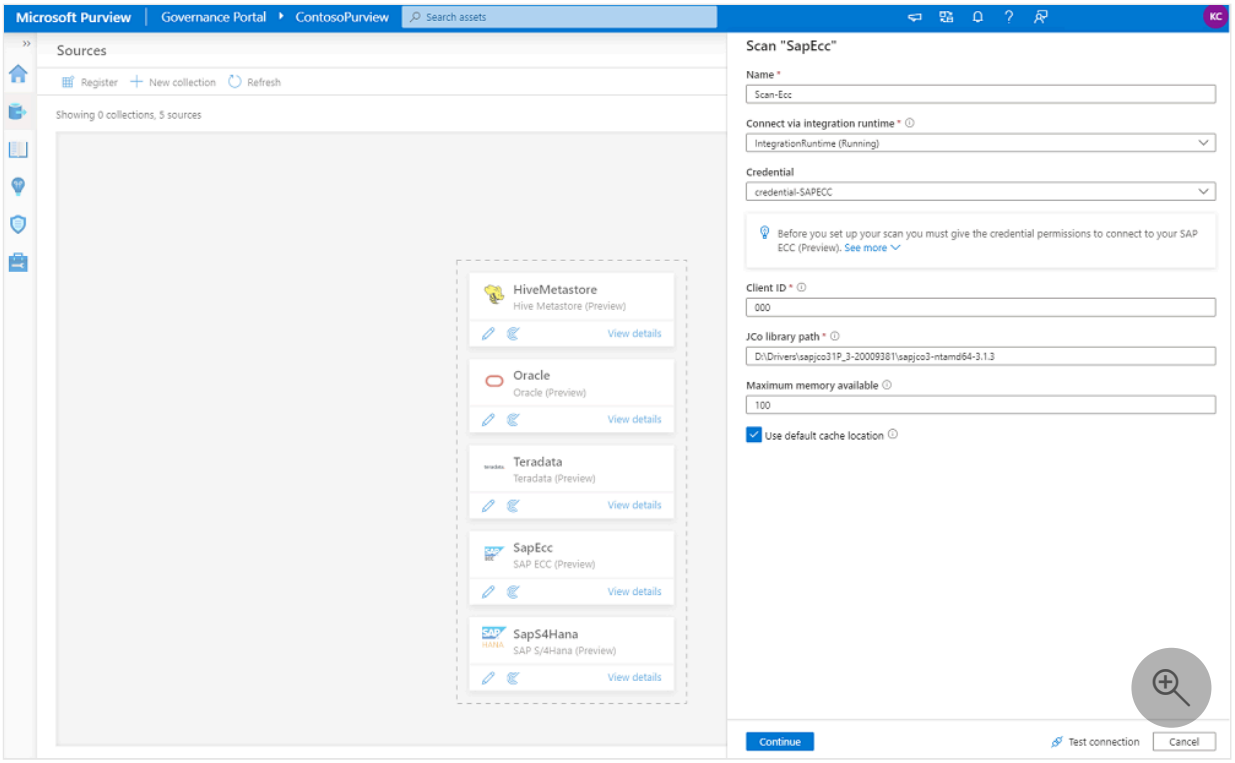
Give permission to access the SAP JCo library to SHIR Process



Verify if Microsoft Purview SHIR user **NT SERVICE\DIAHostService** has **Read/Write/Execute/List** permissions over these folders:

- SNC Library Path: The folder that has the SNC Library, `sapcrypto.dll`. Example: `C:\Users\shir-admin\Desktop\snc\SAPCRYPTOLIBP_8557-20011729\sapcrypto.dll`
- JCo Library Path: The folder that has the SAP Java Connector jar file. Example: `C:\Users\shir-admin\Desktop\snc\sapjco3-ntamd64-3.1\sapjco3-ntamd64-3.1.3`

SAP NCo Library should also be installed on the virtual machine for test connection to work properly, as it still uses NCo library. This isn't necessary, and Test Connection can



be skipped.

Enter SCN details for **my name**, **partner name**, **library path**, and **quality of protection**, as seen below, and initiate the scan:

f. **JCo library path**: Specify the directory path where the JCo libraries are located, for example: `D:\Drivers\SAPJCo`. Make sure the path is accessible by the self-hosted integration runtime, learn more from prerequisites section.
   i. For self-hosted integration runtime on a local machine: `D:\Drivers\SAPJCo`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime; learn more from prerequisites section.
   ii. For Kubernetes-supported self-hosted integration runtime: `./drivers/SAPJCo`. It's the path to valid JAR folder location. The value must be a valid relative file path. Refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

g. **Maximum memory available:** Maximum memory (in GB) available on the Self-hosted Integration Runtime machine to be used by scanning processes. This is dependent on the size of SAP ECC source to be scanned. It's recommended to provide large available memory, for example, 100.

6. Select **Continue**.

7. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

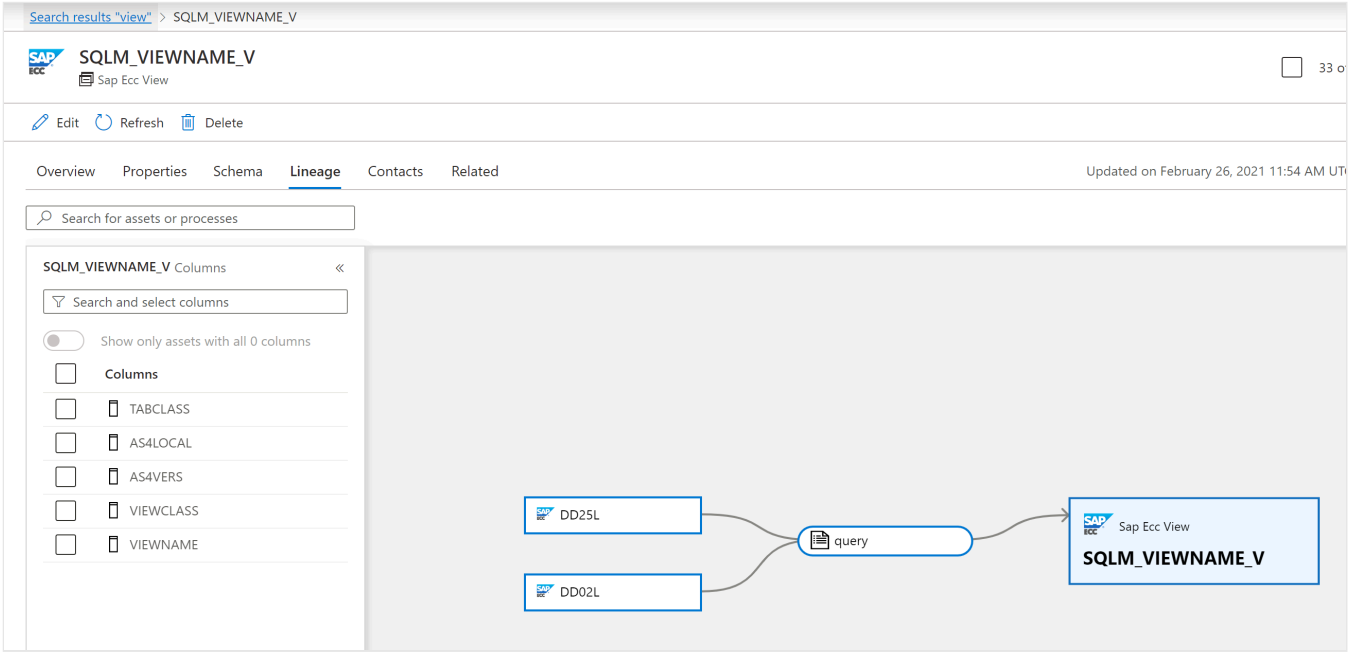
Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:



- Edit the scan by selecting **Edit scan**.
- Cancel an in-progress scan by selecting **Cancel scan run**.
- Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your SAP ECC source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported SAP ECC lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Connect to and manage SAP HANA in Microsoft Purview

This article outlines how to register SAP HANA, and how to authenticate and interact with SAP HANA in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

When scanning SAP HANA source, Microsoft Purview supports extracting technical metadata including:

- Server
- Databases
- Schemas
- Tables, including the columns, foreign keys, indexes, and unique constraints.
- Views, including the columns.
- Calculation views. These are scanned as a part of _SIS_BIC schema. For scoped scan scenarios, this schema needs to be included.
- Stored procedures including the parameter dataset and result set.
- Functions, including the parameter dataset.
- Sequences
- Synonyms

When setting up scan, you can choose to scan an entire SAP HANA database, or scope the scan to a subset of schemas matching the given names or name patterns.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - Download the SAP HANA JDBC driver (JAR ngdbc) on the machine where your self-hosted integration runtime is running. Note down the folder path that you'll use to set up the scan.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.
    - Download the SAP HANA JDBC driver (JAR ngdbc) on the machine where your self-hosted integration runtime is running. Note down the folder path that you'll use to set up the scan.

> **Note**
>
> The driver should be accessible by the self-hosted integration runtime. By default, self-hosted integration runtime uses local service account "NT SERVICE\DIAHostService".

Make sure it has "Read and execute" and "List folder contents" permission to the driver folder.

Required permissions for scan

Microsoft Purview supports basic authentication (username and password) for scanning SAP HANA.

The SAP HANA user you specified must have the permission to select metadata of the schemas you want to import.

SQL

```
CREATE USER <user> PASSWORD <password> NO FORCE_FIRST_PASSWORD_CHANGE;
GRANT SELECT METADATA ON SCHEMA <schema1> TO <user>;
GRANT SELECT METADATA ON SCHEMA <schema2> TO <user>;
```

And the user must have the permission to select on system table _SYS_REPO.ACTIVE_OBJECT and on system schemas _SYS_BI and _SYS_BIC.

SQL

```
GRANT SELECT ON _SYS_REPO.ACTIVE_OBJECT TO <user>;
GRANT SELECT ON SCHEMA _SYS_BI TO <user>;
GRANT SELECT ON SCHEMA _SYS_BIC TO <user>;
```

Register

This section describes how to register an SAP HANA in Microsoft Purview by using the classic Microsoft Purview governance portal.

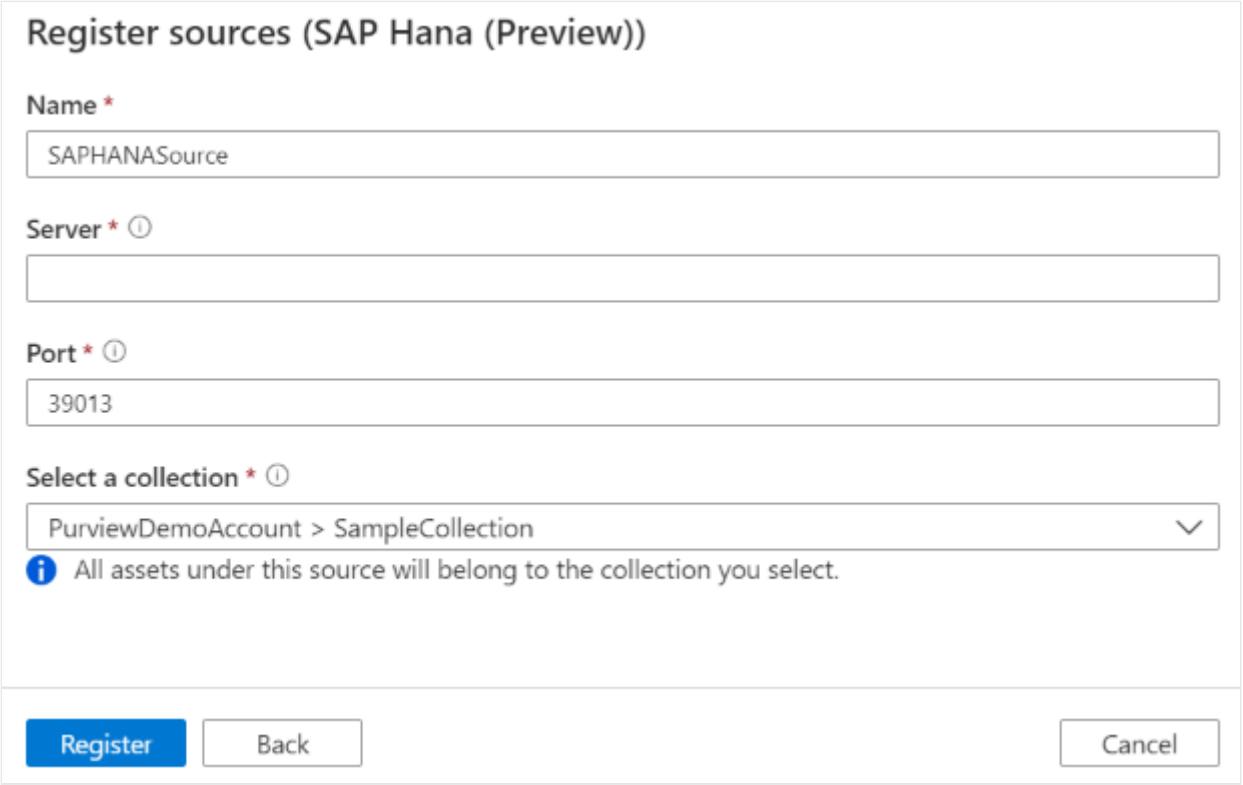
1. Open the classic Microsoft Purview governance portal by:

   - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
   - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the classic Microsoft Purview governance portal button.

2. Select **Data Map** on the left pane.

3. Select **Register**.

4. In **Register sources**, select **SAP HANA** > **Continue**.



5. On the **Register sources (SAP HANA)** screen, do the following:

   a. For **Name**, enter a name that Microsoft Purview will list as the data source.

   b. For **Server**, enter the host name or IP address used to connect to an SAP HANA source. For example, `MyDatabaseServer.com` or `192.169.1.2`.

   c. For **Port**, enter the port number used to connect to the database server (39013 by default for SAP HANA).

   d. Select a collection from the list.

6. Select **Finish**.

Scan

Use the following steps to scan SAP HANA databases to automatically identify assets. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

Authentication for a scan

The supported authentication type for an SAP HANA source is **Basic authentication**.

Create and run scan

1. In the Management Center, select integration runtimes. Make sure that a self-hosted integration runtime is set up. If it isn't set up, use the steps in in prerequisites.

2. Go to **Sources**.

3. Select the registered SAP HANA source.

4. Select **+ New scan**.

5. Provide the following details:

   a. **Name**: Enter a name for the scan.

   b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select **Basic Authentication** while creating a credential.
      - Provide the user name used to connect to the database server in the User name input field.
      - Store the user password used to connect to the database server in the secret key.

      For more information, see Credentials for source authentication in Microsoft Purview.

   d. **Database**: Specify the name of the database instance to import.

   e. **Schema**: List subset of schemas to import expressed as a semicolon separated list. For example, `schema1; schema2`. All user schemas are imported if that list is empty. All system schemas and objects are ignored by default.

      Acceptable schema name patterns that use SQL `LIKE` expression syntax include the percent sign (%). For example, `A%; %B; %C%; D` means:

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

      Usage of NOT and special characters aren't acceptable.

   f. **Driver location**: Specify the path to the JDBC driver location in your machine where self-host integration runtime is running. For example: `D:\Drivers\SAPHANA`.

i. For self-hosted integration runtime on a local machine: `D:\Drivers\SAPHANA`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime; learn more from prerequisites section.

ii. For Kubernetes-supported self-hosted integration runtime: `./drivers/SAPHANA`. It's the path to valid JAR folder location. The value must be a valid relative file path. Refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

g. **Maximum memory available**: Maximum memory (in gigabytes) available on the customer's machine for the scanning processes to use. This value is dependent on the size of SAP HANA database to be scanned.

6. Select **Continue**.

7. For **Scan trigger**, choose whether to set up a schedule or run the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Data Estate Insights in Microsoft Purview

- Lineage in Microsoft Purview
- Search the Unified Catalog

Last updated on 04/27/2026

Connect to and manage SAP S/4HANA in Microsoft Purview

06/25/2025

This article outlines how to register SAP S/4HANA, and how to authenticate and interact with SAP S/4HANA in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	No

When scanning SAP S/4HANA source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Instance
  - Application components
  - Packages
  - Tables including the fields, foreign keys, indexes, and index members
  - Views including the fields
  - Transactions
  - Programs
  - Classes
  - Function groups
  - Function modules
  - Domains including the domain values
  - Data elements
- Fetching static lineage on assets relationships among tables and views.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario:
  - **To use a self-hosted integration runtime:**
    - Follow the article to create and configure a self-hosted integration runtime.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure that Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the machine where the self-hosted integration runtime is running. If you don't have this update installed, download it now.
    - Download the 64-bit SAP Connector for Microsoft .NET 3.0 from SAP's website and install it on the self-hosted integration runtime machine. During installation, make sure you select the **Install Assemblies to GAC** option in the **Optional setup steps** window.
    - The connector reads metadata from SAP using the SAP Java Connector (JCo) 3.0 API. Make sure the Java Connector is available on your virtual machine where self-hosted integration runtime is installed. Make sure that you're using the correct JCo distribution for your environment. For example: on a Microsoft Windows machine, make sure the sapjco3.jar and sapjco3.dll files are available. Note down the folder path which you'll use to set up the scan.
    - Self-hosted integration runtime communicates with the SAP server over dispatcher port 32NN and gateway port 33NN, where NN is your SAP instance number from 00 to 99. Make sure the outbound traffic is allowed on your firewall.
  - **To use a kubernetes supported self-hosted integration runtime:**
    - Follow the article to create and configure a kubernetes supported integration runtime.

- Download the 64-bit SAP Connector for Microsoft .NET 3.0 from SAP's website and install it on the self-hosted integration runtime machine. During installation, make sure you select the **Install Assemblies to GAC** option in the **Optional setup steps** window.
- The connector reads metadata from SAP using the SAP Java Connector (JCo) 3.0 API. Make sure the Java Connector is available on your virtual machine where self-hosted integration runtime is installed. Make sure that you're using the correct JCo distribution for your environment. For example: on a Microsoft Windows machine, make sure the sapjco3.jar and sapjco3.dll files are available. Note down the folder path which you'll use to set up the scan.
- Self-hosted integration runtime communicates with the SAP server over dispatcher port 32NN and gateway port 33NN, where NN is your SAP instance number from 00 to 99. Make sure the outbound traffic is allowed on your firewall.

> **Note**
>
> Scanning SAP ECC is a memory intensive operation, you're recommended to install Self-hosted Integration Runtime on a machine with at least 128 GB RAM.

- Deploy the metadata extraction ABAP function module on the SAP server by following the steps mentioned in ABAP functions deployment guide. You need an ABAP developer account to create the RFC function module on the SAP server. For scan execution, the user account requires sufficient permissions to connect to the SAP server and execute the following RFC function modules:
  - STFC_CONNECTION (check connectivity)
  - RFC_SYSTEM_INFO (check system information)
  - OCS_GET_INSTALLED_COMPS (check software versions)
  - Z_MITI_DOWNLOAD (main metadata import, the function module you create following the Purview guide)

  The underlying SAP Java Connector (JCo) libraries might call more RFC function modules; for example, RFC_PING, RFC_METADATA_GET, etc. See SAP support note 460089 for details.

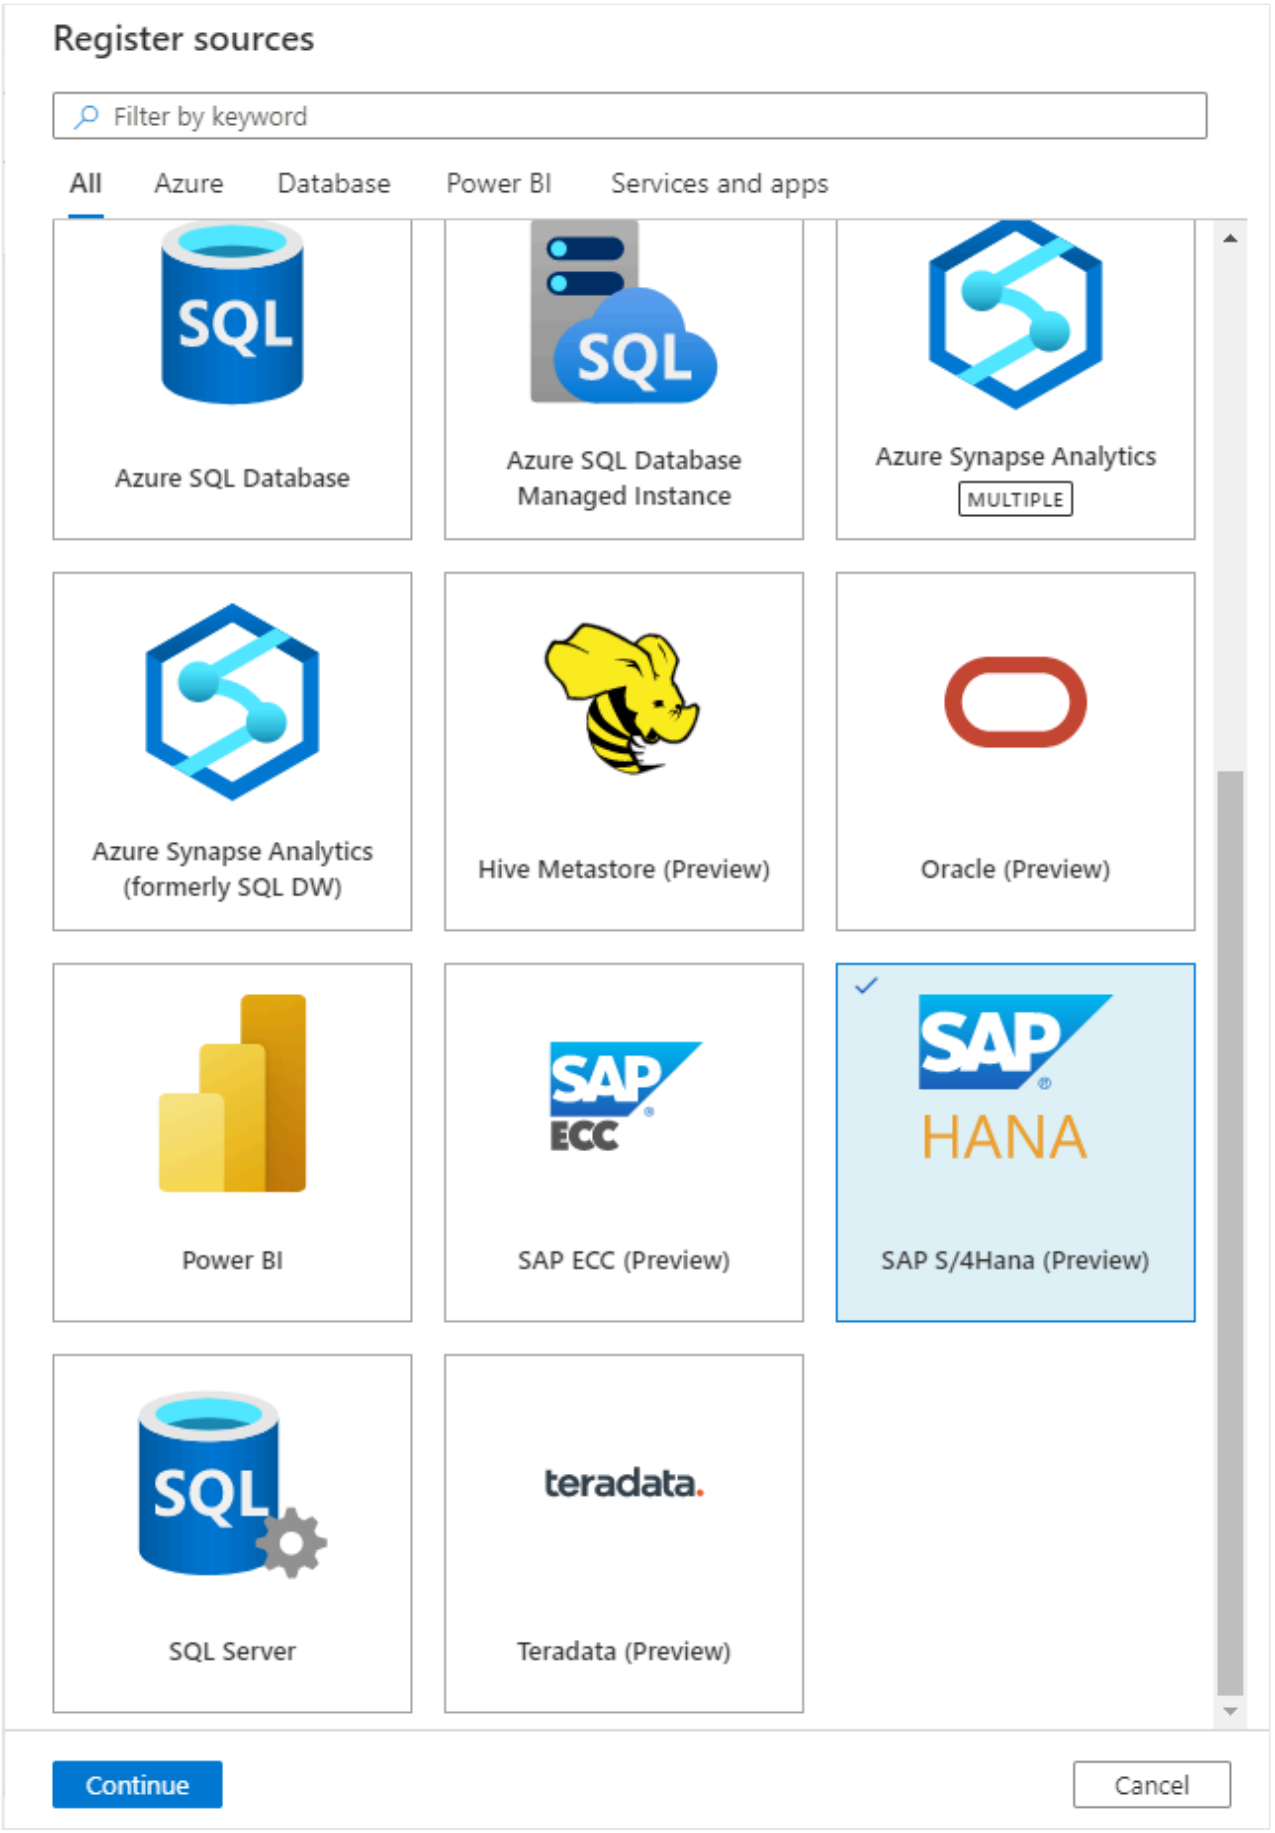
Register

This section describes how to register SAP S/4HANA in Microsoft Purview using the Microsoft Purview governance portal.

Authentication for registration

The only supported authentication for SAP S/4HANA source is **Basic authentication**.

Steps to register



1. Open the Microsoft Purview governance portal by:

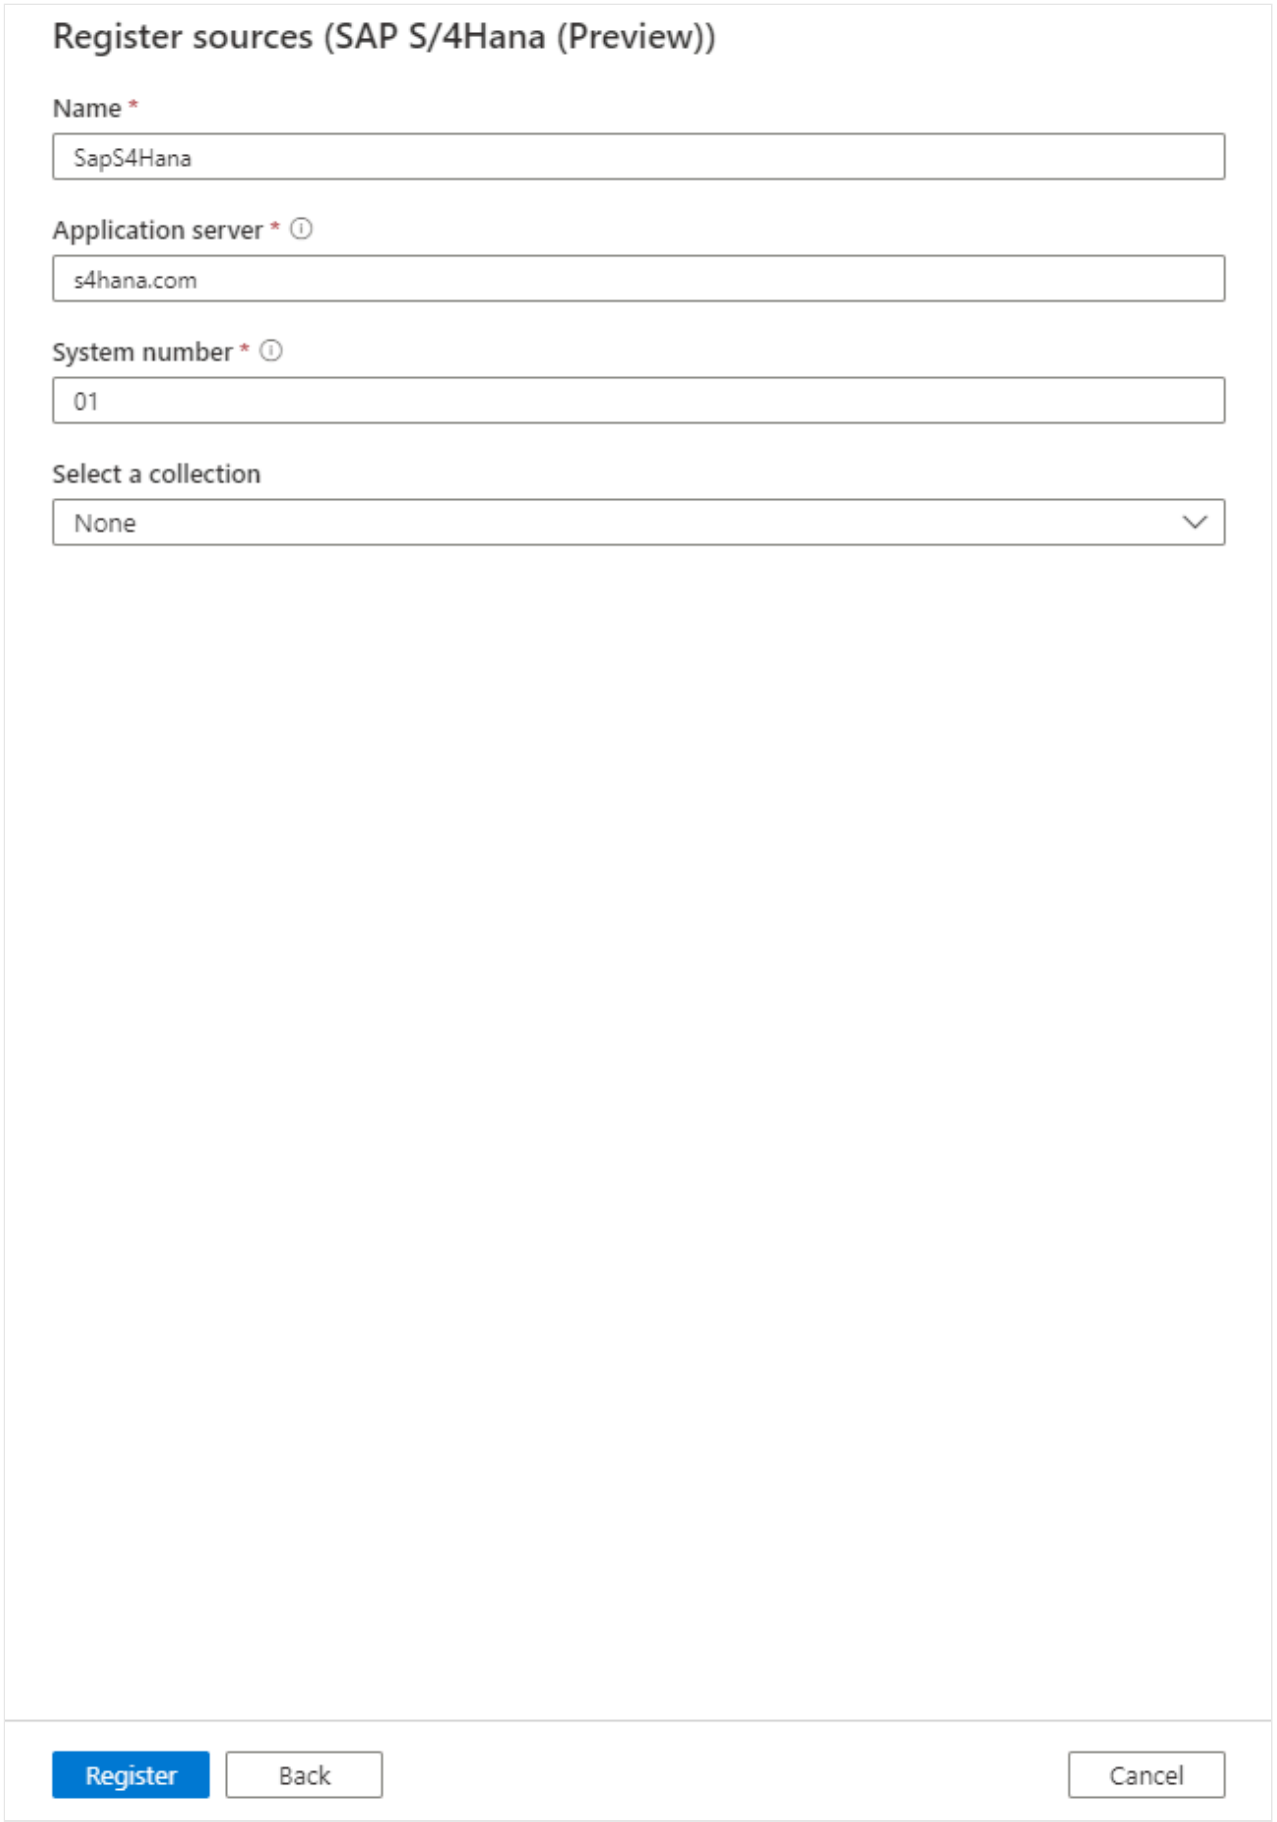
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

2. Select **Data Map** on the left navigation.

3. Select **Register**

4. On Register sources, select **SAP S/4HANA.** Select **Continue**

On the **Register sources (SAP S/4HANA)** screen, do the following:



1. Enter a **Name** that the data source will be listed within the Catalog.

2. Enter the **Application server** name to connect to SAP S/4HANA source. It can also be an IP address of the SAP application server host.

3. Enter the SAP **System number**. This is a two-digit integer between 00 and 99.

4. Select a collection from the list.

5. Finish to register the data source.

Register sources (SAP S/4Hana (Preview))
Name *
SapS4Hana
Application server *
s4hana.com
System number *
01

Cancel

Scan

Follow the steps below to scan SAP S/4HANA to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Create and run scan

1. In the Management Center, select Integration runtimes. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned in prerequisites to create a self-hosted integration runtime

2. Navigate to **Sources.**

3. Select the registered SAP S/4HANA source.

4. Select **+ New scan**

5. Provide the below details:

    a. **Name**: The name of the scan

    b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

    c. **Credential**: Select the credential to connect to your data source. Make sure to:

    - Select Basic Authentication while creating a credential.
    - Provide a user ID to connect to SAP server in the User name input field.
    - Store the user password used to connect to SAP server in the secret key.

    d. **Client ID**: Enter the SAP Client ID. It's a three-digit numeric number from 000 to 999.

    e. **SNC Mode (Optional)**: Turn the toggle **on** if you prefer to use Secure Network Communications (SNC) mode for securing your technical connections to SAP RFCs through a certificate-based authentication mechanism. SNC Mode is **off** by default.

    Follow these steps to set up the SAP Personal Secure Environment with SNC Certificate:

    Get SAPCAR

    - Go to the SAP Software Download Center and sign in with your SAP credentials.
    - Search for SAPCAR and select the latest nonarchived version.
    - Select your operating system.
    - Download the `.EXE file to C:\sap\SAR`.

    Get SAP Common Crypto Library

- In the SAP Software Download Center, search for "COMMONCRYPTOLIB" and select the latest version.
- Select your operating system.
- Download the .SAR file with the most recent release date to `C:\sap\SAR`.

Extract SAP Common Crypto Library

- Open PowerShell and navigate to `C:\sap\SAR`.
- Enter the following command, replacing xxxx with your values: `.\SAPCAR_xxxx.EXE -xvf .\SAPCRYPTOLIBP_xxxx.SAR -R .\..\libs\sapcryptolib`.
- Confirm that `sapgenpse.exe` is in the `C:\sap\libs\sapcryptolib` directory.

Generate certificates

Note: This method is for demonstration purposes only and isn't recommended for production systems. For production systems, consult your internal PKI guidance or security team.

- Set up the folder structure:
  - `mkdir rootCA`
  - `mkdir sncCert`
- Create the necessary serial and index files if they don't exist:
  - `if (-Not (Test-Path "rootCA\index.txt")) { New-Item -Path "rootCA\index.txt" ItemType File }`
  - `if (-Not (Test-Path "rootCA\serial")) { Set-Content -Path "rootCA\serial" -Value "01" }`
- Generate a Root CA:
  - `openssl genpkey -algorithm RSA -out rootCA/ca.key.pem -pkeyopt rsa_keygen_bits:2048`
  - `openssl req -x509 -new -key rootCA/ca.key.pem -days 7305 -sha256 -extensions v3_ca -out rootCA/ca.cert.pem -subj "/O=Contoso/CN=Root CA"`
- Generate the SNC certificate
  - `openssl genrsa -out sncCert/snc.key.pem 2048`
  - `openssl req -key sncCert/snc.key.pem -new -sha256 -out sncCert/snc.csr.pem subj "/O=Contoso/CN=SNC"`
- Create an OpenSSL configuration file, `sncCert/extensions.cnf`, for signing:
  - `subjectKeyIdentifier = hash`
  - `authorityKeyIdentifier = keyid,issuer`

- `basicConstraints = critical,CA:false`
- `keyUsage = critical,digitalSignature,keyEncipherment,dataEncipherment`
- `extendedKeyUsage = clientAuth,emailProtection`

- Sign the SNC certificate with the Root CA:
  - `openssl x509 -req in sncCert/snc.csr.pem CA rootCA/ca.cert.pem CAkey rootCA/ca.key.pem CAcreateserial out sncCert/snc.cert.pem days 3650 sha256 extfile sncCert\extensions.cnf extensions v3_leaf`

Create a Personal Secure Environment

Create a Personal Secure Environment (PSE) for the on-premises data gateway. The NCo library looks for the SNC certificate inside the PSE.

- Create a PKCS#12 container:
  - `openssl pkcs12 -export -out snc.p12 -inkey sncCert\snc.key.pem -in sncCert\snc.cert.pem -certfile rootCA\ca.cert.pem`

- Create the SECUDIR environment variable.
- Open **System Properties**: In **File Explorer**, right-click **This PC**, and then select **Properties** > **Advanced system settings**.
- Select **Environment Variables**.
- Under **System variables**, select **New**.
- Set the variable name to **SECUDIR**.
- Set the value to `C:\sapsecudir`.
- Select **OK**.

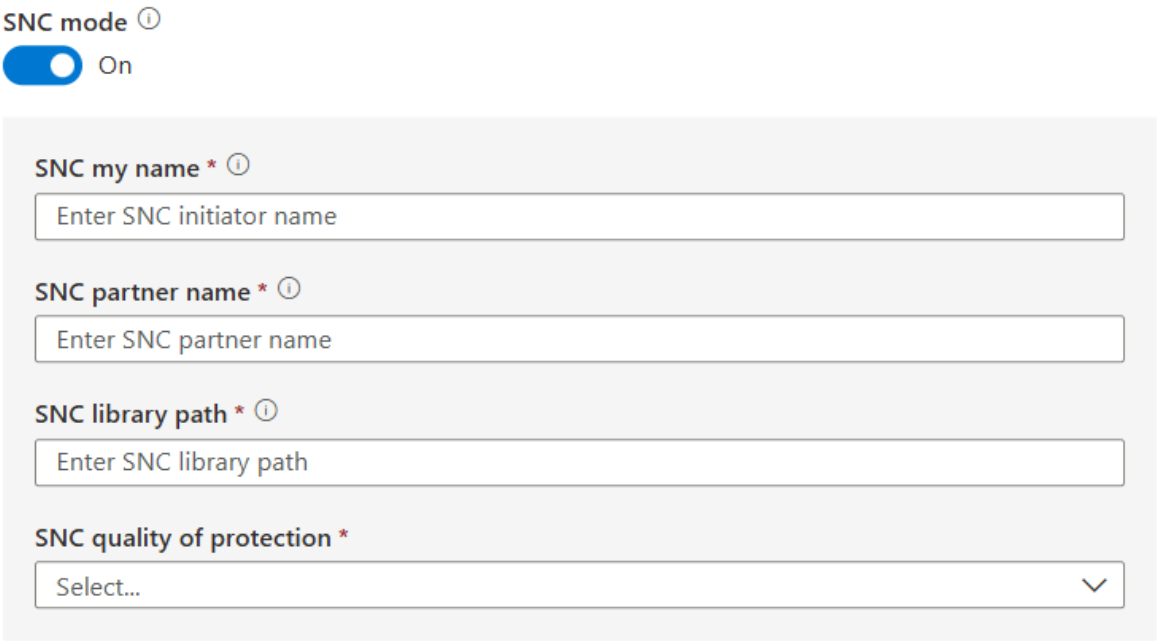
Import the PKCS#12 container into a PSE: `C:\sap\libs\sapcryptolib\sapgenpse.exe import_p12 -p SAPSNCSKERB.pse C:\pki certs\snc.p12`

Allow your SHIR process to use your SAP PSE

Verify which user or service is being used by your SNC client to obtain the certificate to communicate with SAP. The Microsoft Purview SHIR uses the service user **NT SERVICE\DIAHostService**.

- Add a credential to allow the certificate retrieval request from the PSE: `.\sapgenpse.exe seclogin -p C:\sapsecudir\SAPSNCSKERB.pse -x your-pse-pin -O "NT SERVICE\DIAHostService"`

- Verify credentials like this: `.\sapgenpse.exe seclogin -l -O "NT SERVICE\DIAHostService"`
- You can delete them like this: `.\sapgenpse.exe seclogin -d -O "NT SERVICE\DIAHostService"`
- Use the -h parameter to get help with the sapgenpse command line tool or check the command reference here.



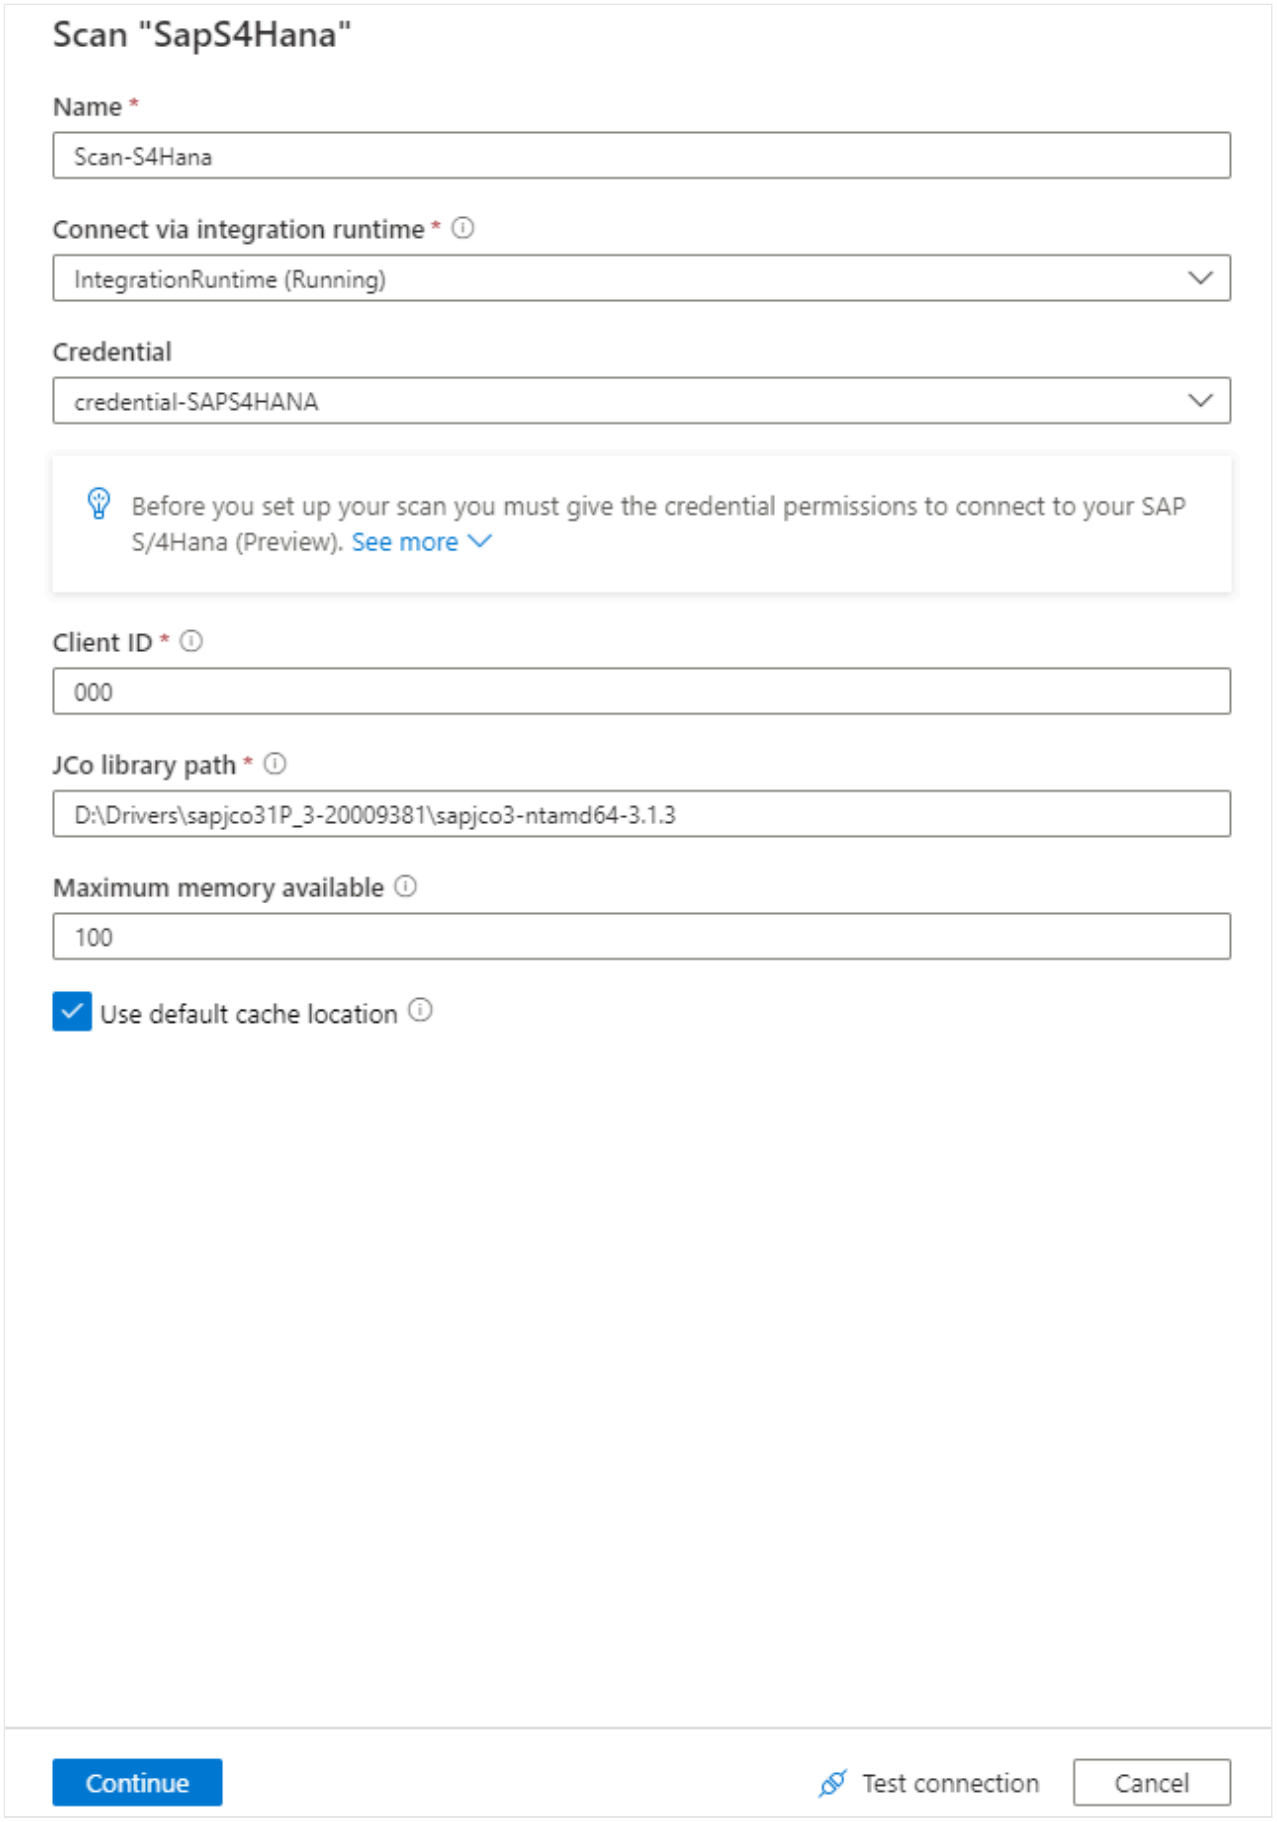
Give permission to access the SAP JCo library to SHIR Process

Verify if Microsoft Purview SHIR user **NT SERVICE\DIAHostService** has **Read/Write/Execute/List** permissions over these folders:

- SNC Library Path: The folder that has the SNC Library, `sapcrypto.dll`. Example: `C:\Users\shir-admin\Desktop\snc\SAPCRYPTOLIBP_8557-20011729\sapcrypto.dll`
- JCo Library Path: The folder that has the SAP Java Connector jar file. Example: `C:\Users\shir-admin\Desktop\snc\sapjco3-ntamd64-3.1\sapjco3-ntamd64-3.1.3`

SAP NCo Library should also be installed on the virtual machine for test connection to work properly, as it still uses NCo library. This isn't necessary, and Test Connection can be skipped.

Enter SCN details for **my name**, **partner name**, **library path**, and **quality of protection**, as seen below, and initiate the scan:



f. **JCo library path**: Specify the directory path where the JCo libraries are located, for example: `D:\Drivers\SAPJCo`. Make sure the path is accessible by the self-hosted integration runtime, learn more from prerequisites section.

i. For self-hosted integration runtime on a local machine: `D:\Drivers\SAPJCo`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime; learn more from prerequisites section.

ii. For Kubernetes-supported self-hosted integration runtime: `./drivers/SAPJCo`. It's the path to valid JAR folder location. The value must be a valid relative file path. Refer to the documentation to set up a scan with external drivers for uploading drivers in advance.

g. **Maximum memory available:** Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of SAP S/4HANA source to be scanned. It's recommended to provide large available memory, for example, 100.

6. Select **Continue**.

7. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your SAP S/4HANA source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported SAP S/4HANA lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

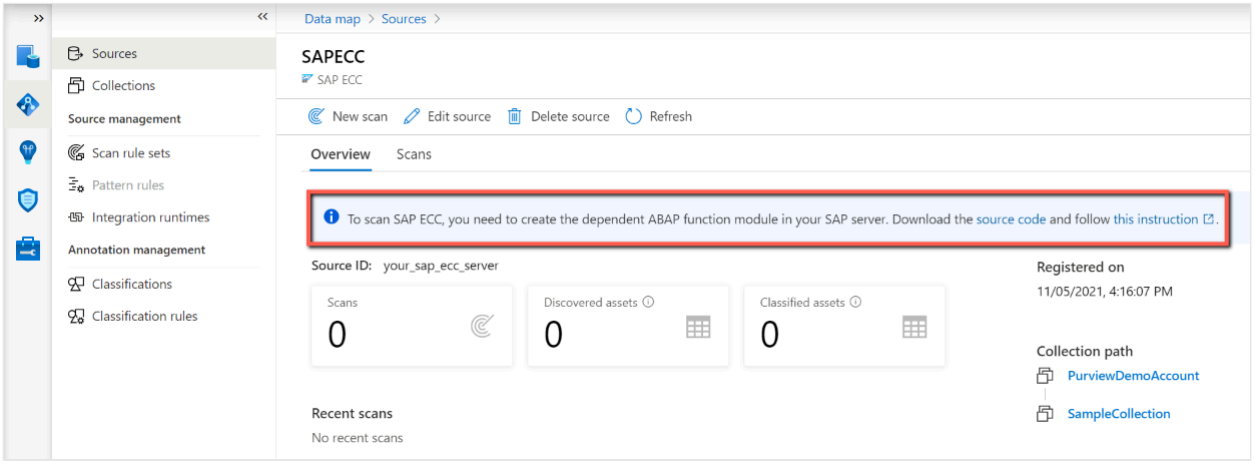
Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

SAP ABAP function module deployment guide

Article • 04/18/2024



When you scan SAP ECC, SAP S/4HANA, and SAP BW sources in Microsoft Purview, you need to create the dependent ABAP function module in your SAP server. Microsoft Purview invokes this function module to extract the metadata from your SAP system during scan.

This article describes the steps required to deploy this module.

> **Note**
>
> The following instructions were compiled based on the SAP GUI v. 7.2.

Prerequisites

Download the SAP ABAP function module source code from the Microsoft Purview governance portal. After you register a source for SAP ECC, SAP S/4HANA, or SAP BW, you can find a download link on top as shown in the following image. You can also see the link when you create a new scan or edit a scan. To download this code, you need to have Data Source Administrator permissions on the root collection in your data map.

Deploy the module

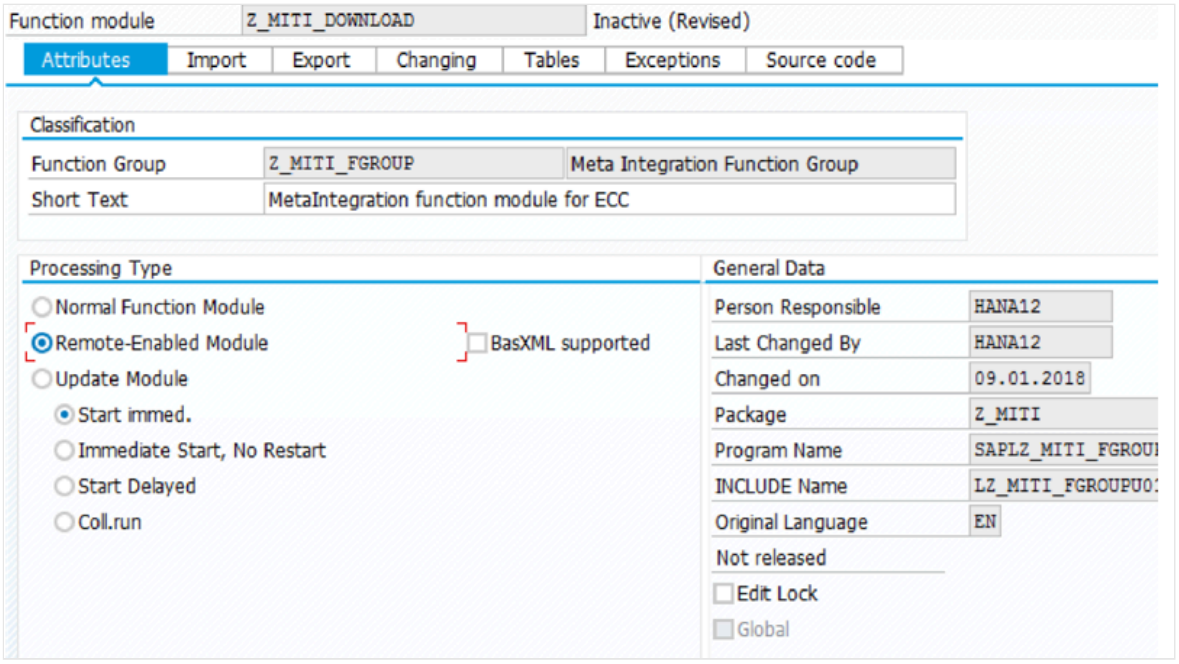
Follow the instructions to deploy a module.

Create a package

This step is optional, and an existing package can be used.

1. Sign in to the SAP server and open **Object Navigator** (SE80 transaction).
2. Select **Package** from the list and enter a name for the new package. For example, use **Z_MITI**. Then select **Display**.
3. In the **Create Package** window, select **Yes**. In the **Package Builder: Create Package** window, enter a value in the **Short Description** box. Select the **Continue** icon.
4. In the **Prompt for local Workbench request** window, select **Own Requests**. Select the **development** request.

Create a function group



1. In **Object Navigator**, select **Function Group** from the list and enter a name in the input box. For example, use **Z_MITI_FGROUP**. Select the **View** icon.
2. In the **Create Object** window, select **yes** to create a new function group.
3. Enter a description in the **Short Text** box and select **Save**.
4. Select a package that was prepared in the **Create a Package** step, and select **Save**.
5. Confirm a request by selecting **Continue**.
6. Activate the function group.

Create the ABAP function module

1. After the function group is created, select it.
2. Select and hold (or right-click) the function group name in the repository browser. Select **Create** and then select **Function Module**.
3. In the **Function module** box, enter **Z_MITI_DOWNLOAD** in case of SAP ECC or S/4HANA and **Z_MITI_BW_DOWNLOAD** in case of SAP BW. Enter a description in the **Short Text** box.

After the module is created, specify the following information:

1. Go to the **Attributes** tab.
2. Under **Processing Type**, select **Remote-Enabled Module**.

3. Go to the **Source code** tab. There are two ways to deploy code for the function:

   a. On the main menu, upload the text file you downloaded from the Microsoft Purview governance portal as described in Prerequisites. To do so, select **Utilities** > **More Utilities** > **Upload/Download** > **Upload**.

   b. Alternatively, open the file and copy and paste the contents in the **Source code** area.

4. Go to the **Import** tab and create the following parameters:

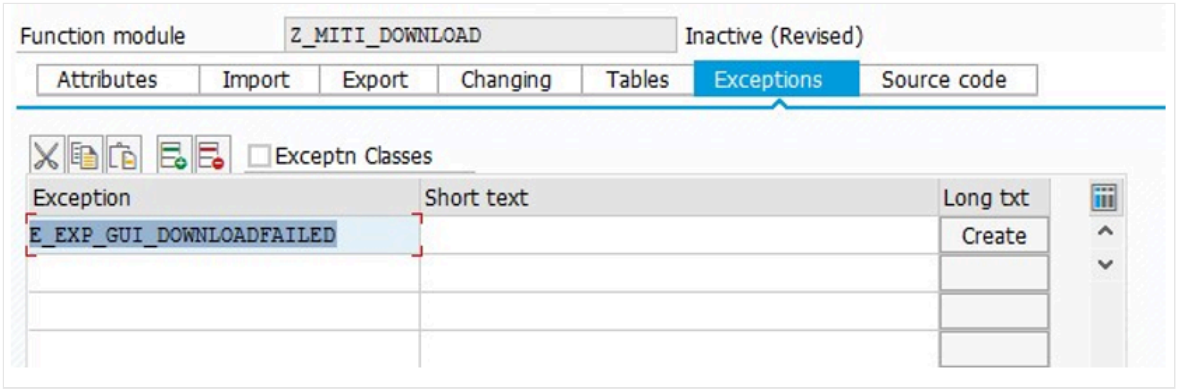
   a. *P_AREA TYPE DD02L-TABNAME* (**Optional** = True)

   b. *P_LOCAL_PATH TYPE STRING* (**Optional** = True)

   c. *P_LANGUAGE TYPE L001TAB-DATA DEFAULT 'E'*

   d. *ROWSKIPS TYPE SO_INT DEFAULT 0*

   e. *ROWCOUNT TYPE SO_INT DEFAULT 0*



> ⓘ **Note**
>
> Select the **Pass Value** checkbox for all the parameters.

5. Go to the **Tables** tab and define *EXPORT_TABLE LIKE TAB512*.

6. Go to the **Exceptions** tab and define the exception *E_EXP_GUI_DOWNLOADFAILED*.

7. Save the function by selecting **Ctrl+S**. Or select **Function module** and then select **Save** on the main menu.

8. Select the **Activate** icon on the toolbar and then select **Continue**. You can also select **Ctrl+F3**. If prompted, select the generated includes to be activated along with the main function module.

Test the function

After you finish the previous steps, test the function:

1. Open the **Z_MITI_DOWNLOAD** or **Z_MITI_BW_DOWNLOAD** function module you created.

2. On the main menu, select **Function Module** > **Test** > **Test Function Module**. You can also select **F8**.

3. Enter a path to the folder on the local file system in the parameter *P_LOCAL_PATH*. Then select the **Execute** icon on the toolbar. You can also select **F8**.

4. Enter the name of the area of interest in the **P_AREA** field if a file with metadata must be downloaded or updated. After the function finishes working, the folder indicated in the *P_LOCAL_PATH* parameter must contain several files with metadata inside. The names of files mimic areas that can be specified in the **P_AREA** field.

The function finishes its execution and metadata is downloaded much faster if it's launched on the machine that has a high-speed network connection with the SAP server.

Next steps

- Connect to and manage SAP ECC source
- Connect to and manage SAP S/4HANA source
- Connect to and manage SAP Business Warehouse (BW) source

Connect to and manage Snowflake in Microsoft Purview

This article outlines how to register Snowflake, and how to authenticate and interact with Snowflake in Microsoft Purview. For more information about Microsoft Purview, read the Microsoft Purview overview.

> **Important**
>
> Snowflake announced the deprecation of basic authentication and plans to disable it by August 2026. To align with the change and avoid any service disruptions, Microsoft Purview customers using the Snowflake Data Map connector should transition to Key Pair (SHIR) authentication.
>
> **Recommended action (complete by July 2026)**: To provide customers with more time, Snowflake allows service users of type **LEGACY_SERVICE** to continue using basic authentication until July 2026. This policy helps ensure there's no disruption to your service while you transition to the new authentication method. You can continue to use basic authentication for a limited period of time, while at the same time setting up and validating the new authentication mechanism Key Pair.
>
> We recommend that Microsoft Purview customers update their users to the **LEGACY_SERVICE** type. This change ensures continued access and provides more time to complete the transition. **This update must be completed before the end of July 2026 by running the following command in Snowflake**:
>
> ```
> *ALTER USER <purview_user_name> SET TYPE = LEGACY_SERVICE;
> ```
>
> The creation of new users with the LEGACY_SERVICE type isn't permitted beginning August 2026.

Supported capabilities

The following sections describe the capabilities available when scanning Snowflake in Microsoft Purview.

Scanning capabilities

The following table summarizes the scanning capabilities supported for Snowflake in Microsoft Purview.

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

When scanning a Snowflake source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Databases
  - Schemas
  - Tables including the columns, foreign keys, and unique constraints
  - Views including the columns
  - Stored procedures including the parameter dataset and result set
  - Functions including the parameter dataset
  - Pipes
  - Stages
  - Streams including the columns
  - Tasks
  - Sequences
- Fetching static lineage on assets relationships among tables, views, streams, and stored procedures.

For stored procedures, you can choose the level of detail to extract in the Create and run scan section. Stored procedure lineage is supported for Snowflake Scripting (SQL) and JavaScript languages, and generated based on the procedure definition.

When setting up a scan, you can choose to scan one or more Snowflake databases entirely based on the given names or name patterns, or further scope the scan to a subset of schemas matching the given names or name patterns.

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

Be aware of the following limitations when scanning Snowflake in Microsoft Purview.

- When you delete an object from the data source, the subsequent scan doesn't automatically remove the corresponding asset in Microsoft Purview.
- Stored procedure lineage isn't supported for the following patterns:
  - Stored procedure defined in Java, Python, and Scala languages.
  - Stored procedure using SQL EXECUTE IMMEDIATE with static SQL query as variable.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview portal. For more information about permissions, see Access control in Microsoft Purview.
- Choose the right integration runtime configuration for your scenario.
  - To use Managed Virtual Network Integration Runtime to connect to Snowflake via private link, follow the steps in Connect to Snowflake via Managed Private Endpoint to set up the private endpoint.
  - To use Self-hosted Integration Runtime for scan, set up the latest self-hosted integration runtime. For more information, see the create and configure a self-hosted integration runtime guide.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.
    - Ensure Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the self-hosted integration runtime machine. If you don't have this update installed, download the Visual C++ Redistributable.

Required permissions for scan

Microsoft Purview supports basic authentication (username and password) for scanning Snowflake. The default role of the given user will be used to perform the scan. The Snowflake

user must have usage rights on a warehouse and the databases to be scanned, and read access to system tables to access advanced metadata.

Here's a sample walkthrough to create a user specifically for Microsoft Purview scan and set up the permissions. If you choose to use an existing user, make sure it has adequate rights to the warehouse and database objects.

1. Set up a `purview_reader` role. You need *ACCOUNTADMIN* rights to do this.

```SQL
USE ROLE ACCOUNTADMIN;

--create role to allow read only access - this will later be assigned to the Microsoft Purview user
CREATE OR REPLACE ROLE purview_reader;

--make sysadmin the parent role
GRANT ROLE purview_reader TO ROLE sysadmin;
```

2. Create a warehouse for Microsoft Purview to use and grant rights.

```SQL
--create warehouse - account admin required
CREATE OR REPLACE WAREHOUSE purview_wh WITH
    WAREHOUSE_SIZE = 'XSMALL'
    WAREHOUSE_TYPE = 'STANDARD'
    AUTO_SUSPEND = 300
    AUTO_RESUME = TRUE
    MIN_CLUSTER_COUNT = 1
    MAX_CLUSTER_COUNT = 2
    SCALING_POLICY = 'STANDARD';

--grant rights to the warehouse
GRANT USAGE ON WAREHOUSE purview_wh TO ROLE purview_reader;
```

3. Create a user `purview` for Microsoft Purview scan.

```SQL
CREATE OR REPLACE USER purview
    PASSWORD = '<password>';

--note the default role will be used during scan
ALTER USER purview SET DEFAULT_ROLE = purview_reader;
```

```
--add user to purview_reader role
GRANT ROLE purview_reader TO USER purview;
```

4. Grant reader rights to the database objects.

SQL

```
GRANT DATABASE ROLE SNOWFLAKE.OBJECT_VIEWER TO USER purview_reader;
GRANT USAGE ON DATABASE <your_database_name> TO purview_reader;

--grant reader access to all the database structures that purview can currently
scan
GRANT USAGE ON ALL SCHEMAS IN DATABASE <your_database_name> TO role
purview_reader;
GRANT USAGE ON ALL FUNCTIONS IN DATABASE <your_database_name> TO role
purview_reader;
GRANT USAGE ON ALL PROCEDURES IN DATABASE <your_database_name> TO role
purview_reader;
GRANT SELECT ON ALL TABLES IN DATABASE <your_database_name> TO role
purview_reader;
GRANT SELECT ON ALL VIEWS IN DATABASE <your_database_name> TO role
purview_reader;
GRANT USAGE, READ on ALL STAGES IN DATABASE <your_database_name> TO role
purview_reader;

--grant reader access to any future objects that could be created
GRANT USAGE ON FUTURE SCHEMAS IN DATABASE <your_database_name> TO role
purview_reader;
GRANT USAGE ON FUTURE FUNCTIONS IN DATABASE <your_database_name> TO role
purview_reader;
GRANT USAGE ON FUTURE PROCEDURES IN DATABASE <your_database_name> TO role
purview_reader;
GRANT SELECT ON FUTURE TABLES IN DATABASE <your_database_name> TO role
purview_reader;
GRANT SELECT ON FUTURE VIEWS IN DATABASE <your_database_name> TO role
purview_reader;
GRANT USAGE, READ ON FUTURE STAGES IN DATABASE <your_database_name> TO role
purview_reader;
```

Register

This section describes how to register Snowflake in Microsoft Purview using the classic Microsoft Purview governance portal.

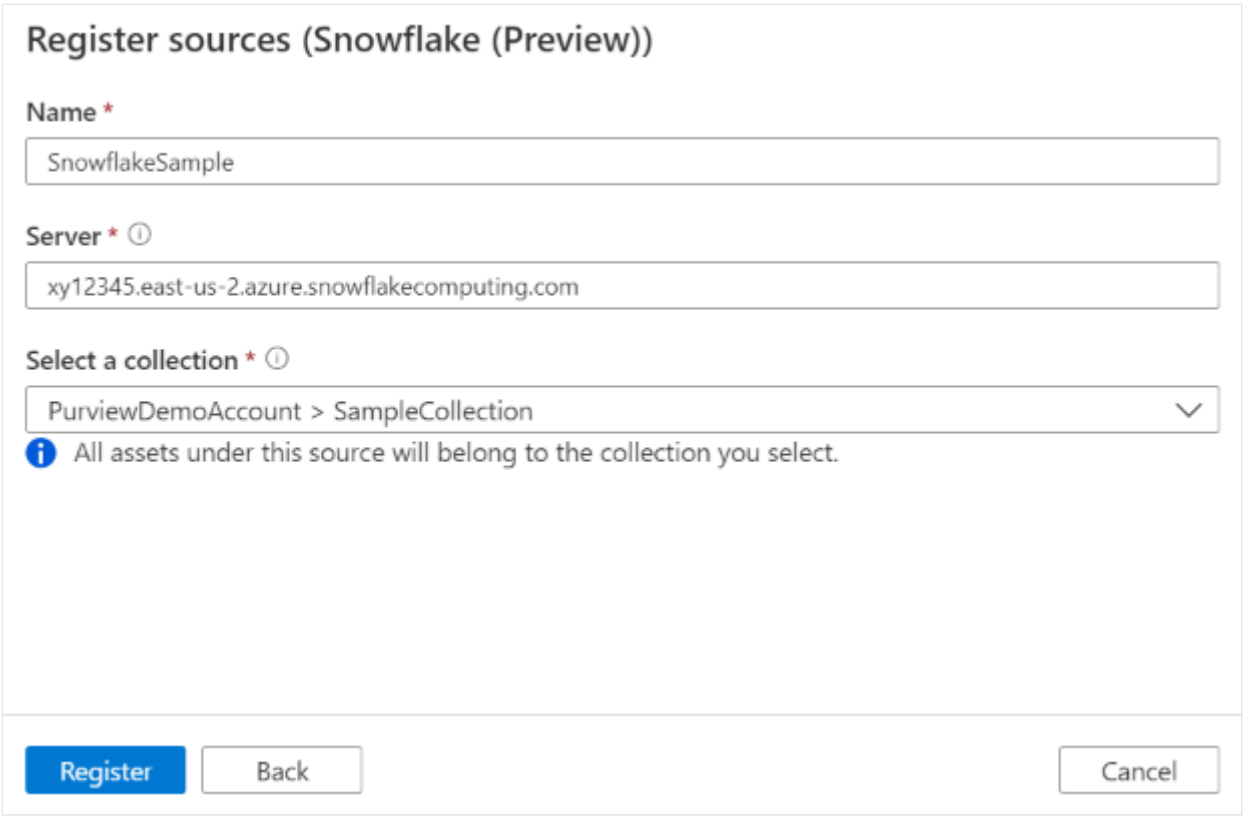
Steps to register

To register a new Snowflake source in Microsoft Purview Unified Catalog, follow these steps:

1. Navigate to your Microsoft Purview account in the classic Microsoft Purview governance portal.
2. Select **Data Map** on the left navigation.
3. Select **Register.**
4. On Register sources, select **Snowflake**. Select **Continue**.

On the **Register sources (Snowflake)** screen, follow these steps:

1. Enter a **Name** that the data source will be listed within the Catalog.



2. Enter the **server** URL in the form of `<account_identifier>.snowflakecomputing.com`, for example, `orgname-accountname.snowflakecomputing.com`. Learn more about Snowflake account identifier. Note this URL is used as part of the Snowflake assets' fully qualified name, and is the default endpoint for Microsoft Purview to connect to Snowflake during scan.

3. Add **additional hosts** if applicable. Specify it when you want the scan operations to connect to a Snowflake endpoint other than the server URL. You can choose the host for connection during scan setup.

   > **Tip**
   >
   > If you already scanned Snowflake but want to switch to use another endpoint, for example, from public endpoint to private endpoint, you can add another host in data source and choose that host for connection in scan to ensure Microsoft Purview generate the assets with the same fully qualified name as previous.
   >
   > When registering a data source, Microsoft Purview performs uniqueness check that the server URL and other hosts doesn't overlap with any existing sources.

4. Select a collection from the list.

5. Finish to register the data source.

Scan

Follow these steps to scan Snowflake to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Authentication for a scan

The supported authentication types for a Snowflake source are **Basic authentication** and **Key Pair**.

Follow this process to configure a Key Pair credential.

Prerequisites for Key Pair Authentication

Before starting, ensure you have:

1. **Snowflake Access**

   a. Snowflake account with admin privileges

   b. User account for Microsoft Purview scanning (for example, purview_scanner)

   c. Access to execute ALTER USER commands

2. **Tools & Software**

a. OpenSSL installed (for key generation)

b. Azure CLI or PowerShell (for Key Vault operations)

c. Access to Microsoft Purview Portal

d. Ensure you have Microsoft Open JDK 11. Download Microsoft Open JDK 11. Other JDK variants might have issues with advanced encrypted algorithms.

Step by Step Configuration

Part 1: Snowflake Configuration

This step involves creating public and private keys and then assigning the public key to the purview user ('purview_scanner' in below example) that connects to Snowflake to perform the scan.

Step 1.1: Generate RSA Key Pair

- Generate Private Key

Open a terminal and generate the private key:

```text
--For Encrypted Private Key (Recommended):

openssl genrsa 2048 | openssl pkcs8 -topk8 -v2 aes-256-cbc -v2prf hmacWithSHA512 -
inform PEM -out rsa_key.p8

--Note: You'll be prompted to enter a passphrase. Remember this passphrase!
```

OR

```text
--For Unencrypted Private Key:

openssl genrsa 2048 | openssl pkcs8 -topk8 -v2 aes-256-cbc -v2prf hmacWithSHA512 -
inform PEM -out rsa_key.p8 -nocrypt
```

Note: Use the above commands to generate the key

- Generate Public Key

```text
```

```
openssl rsa -in rsa_key.p8 -pubout -out rsa_key.pub
```

- Extract Public Key Content

View and copy the public key content (excluding headers):

text

```
cat rsa_key.pub
```

text

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEA...
... -----END PUBLIC KEY-----
```

Copy everything between the BEGIN and END lines (don't include the delimiter lines).

Step 1.2: Assign Public Key to Snowflake User

Connect to Snowflake and execute:

SQL

```
-- Create user if it doesn't exist
CREATE USER IF NOT EXISTS purview_scanner
  DEFAULT_ROLE = 'PUVRIEW_READER'
  TYPE = 'SERVICE'  ;
 -- Assign the public key (paste your key without the BEGIN/END lines)
ALTER USER purview_scanner
SET RSA_PUBLIC_KEY='MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEA...';
 -- Grant necessary privileges
GRANT ROLE purview_reader TO USER purview_scanner;
 -- Verify the fingerprint
DESC USER purview_scanner;
```

Step 1.3: Verify Key Configuration [optional step to validate]

Verify the public key fingerprint matches:

In Snowflake:

SQL

```
DESC USER purview_scanner ->> SELECT SUBSTR(
(SELECT "value" FROM $1
```

```
WHERE "property" = 'RSA_PUBLIC_KEY_FP'),
LEN('SHA256:') + 1) AS key;
```

In Command Line:

```
text
openssl rsa -pubin -in rsa_key.pub -outform DER | openssl dgst -sha256 -binary |
openssl
enc -base64
```

Note that both should produce the same fingerprint hash.

Part 2: Azure Key Vault Setup

Step 2.1: Prepare Private Key Content

View your private key:

```
text
cat rsa_key.p8
```

Copy the entire content including the -----BEGIN ENCRYPTED PRIVATE KEY----- and -----END ENCRYPTED PRIVATE KEY----- lines.

Step 2.2: Store Secrets in Azure Key Vault

You need to store TWO secrets in Azure Key Vault:

Secret 1: Private Key

CRITICAL REQUIREMENT: The private key **MUST be stored using Azure CLI or Azure Cloud Shell**.

DO NOT use the Azure Portal UI for creating the private key secret because:

- The Azure Portal text input doesn't preserve multi-line formatting
- It converts line breaks to spaces, corrupting the PEM format
- **Snowflake connections will FAIL** with malformed key errors

The password/passphrase secret CAN be created via Portal (single-line value).

Method 1: Azure CLI (Recommended)

```text
# Replace with your values
KEY_VAULT_NAME="your-keyvault-name"
CREDENTIAL_NAME="snowflake-purview-cred"

# Store the private key from file (preserves multi-line format)
az keyvault secret set \
 --vault-name $KEY_VAULT_NAME \
 --name "${CREDENTIAL_NAME}-privateKey" \
 --file rsa_key.p8
```

OR

Method 2: Azure Cloud Shell

1. Open Azure Cloud Shell (https://shell.azure.com)
2. Upload your rsa_key.p8 file using the upload button (folder icon)
3. Run the command:

```text
az keyvault secret set \
  --vault-name your-keyvault-name \
  --name "snowflake-purview-cred-privateKey" \
  --file rsa_key.p8
```

OR

Method 3: PowerShell with Azure CLI

```PowerShell
# Read the private key preserving line breaks
$privateKeyContent = Get-Content -Path "rsa_key.p8" -Raw

# Store in Key Vault using Azure CLI
az keyvault secret set `
  --vault-name "your-keyvault-name" `
  --name "snowflake-purview-cred-privateKey" `
  --value $privateKeyContent
```

OR

Verify the Private Key Format After Upload: [optional step]

text

```
# Retrieve and check the secret maintains proper formatting
az keyvault secret show \
  --vault-name $KEY_VAULT_NAME \
  --name "${CREDENTIAL_NAME}-privateKey" \
  --query value -o tsv

# Expected output: Multiple lines like this
# -----BEGIN ENCRYPTED PRIVATE KEY-----
# MIIFHDBOBgkqhkiG9w0BBQ0wQTApBgkqhkiG9w0BBQwwHAQI...
# (multiple lines of base64 encoded content)
# ...
# -----END ENCRYPTED PRIVATE KEY-----
```

Correct: Multiple lines with line breaks preserved

Incorrect: Single long line or text with spaces instead of newlines

Secret 2: Private Key Passphrase

The passphrase **can be created using either Azure Portal or Azure CLI** (it's a single-line value).

text

```
# Store the passphrase (if your key is encrypted)
az keyvault secret set \
 --vault-name $KEY_VAULT_NAME \
 --name "${CREDENTIAL_NAME}-password" \
 --value "your_passphrase_here"
```

Important: If you used an **unencrypted** private key, you still need to create the .password secret, but set it to an empty string or a placeholder value.

Using Azure Portal:

1. Go to **Secrets** → **Generate/Import**
2. Name: snowflake-purview-cred.password
3. Value: Your passphrase (or empty string for unencrypted keys)
4. Select **Create**

Create and run scan

To create and run a new scan, follow these steps:

1. In the classic Microsoft Purview governance portal, navigate to **Sources**.

2. Select the registered Snowflake source.

3. Select + **New scan**.

4. Provide the following details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the Azure autoresolved integration runtime, Managed Virtual Network IR or SHIR according to your scenario. Learn more from Choose the right integration runtime configuration for your scenario. To use Managed Virtual Network IR to connect to Snowflake via private link, follow the steps in Connect to Snowflake via Managed Private Endpoint to set up the private endpoint first.

   c. **Host for connection**: Choose the endpoint used to establish connection to Snowflake during scan. You can choose from the server URL or the other hosts that you configured in Register.

   d. **Credential**: Select the credential to connect to your data source.

      If using **Basic Authentication** while creating a credential.

      - Provide the user name used to connect to Snowflake in the User name input field.
      - Store the user password used to connect to Snowflake in the secret key.

      If using **Key Pair** while creating a credential

      - Provide User name: purview_scanner (your Snowflake user)
      - Password Key Vault Reference:
      - Key Vault Connection: Select your Key Vault
      - Secret Name: snowflake-purview-cred.password
      - Private Key Vault Reference:
      - Key Vault Connection: Select your Key Vault
      - Secret Name: snowflake-purview-cred.privateKey

   e. **Warehouse**: Specify the name of the warehouse instance used to empower scan in uppercase. The default role assigned to the user specified in the credential must have

USAGE rights on this warehouse.

f. **Databases**: Specify one or more database instance names to import in uppercase. Separate the names in the list with a semi-colon (;). For example, `DB1;DB2`. The default role assigned to the user specified in the credential must have adequate rights on the database objects.

> ⓘ **Note**
>
> Classification is not applied to tables when more than one database instance names are specified.

Acceptable database name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`:

- Start with A or
- End with B or
- Contain C or
- Equal D

g. **Schema**: List subset of schemas to import expressed as a semicolon separated list. For example, `schema1;schema2`. All user schemas are imported if that list is empty. All system schemas and objects are ignored by default.

Acceptable schema name patterns using can be static names or contain wildcard %. For example: `A%;%B;%C%;D`:

- Start with A or
- End with B or
- Contain C or
- Equal D

Usage of NOT and special characters aren't acceptable.

h. **Stored procedure details**: Controls the number of details imported from stored procedures:

- Signature (default): The name and parameters of stored procedures.
- Code, signature: The name, parameters, and code of stored procedures.
- Lineage, code, signature: The name, parameters and code of stored procedures, and the data lineage derived from the code.

- None: Stored procedure details aren't included.

> ⓘ **Note**
>
> If you use Self-hosted Integration Runtime for scan, customized setting other than the default Signature is supported since version 5.30.8541.1. The earlier versions always extract the name and parameters of stored procedures.

i. **Maximum memory available** (applicable when using self-hosted integration runtime): Maximum memory (in GB) available on customer's VM to be used by scanning processes. It's dependent on the size of Snowflake source to be scanned.

> ⓘ **Note**
>
> As a rule of thumb, provide 1GB memory for every 1000 tables.

5. Select **Test connection** to validate the settings (available when using Azure Integration Runtime).

6. Select **Continue**.

7. Select a **scan rule set** for classification. You can choose between the system default, existing custom rule sets, or create a new rule set inline. For more information, see Apply classifications automatically in Microsoft Purview.

> ⓘ **Note**
>
> Classification won't be applied to tables or views when the table name, view name, schema name, or database name contain special characters.

> ⓘ **Note**
>
> If you're using self-hosted runtime, you need to upgrade to version 5.26.404.1 or higher to use Snowflake classification. Download the latest Microsoft Integration Runtime.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

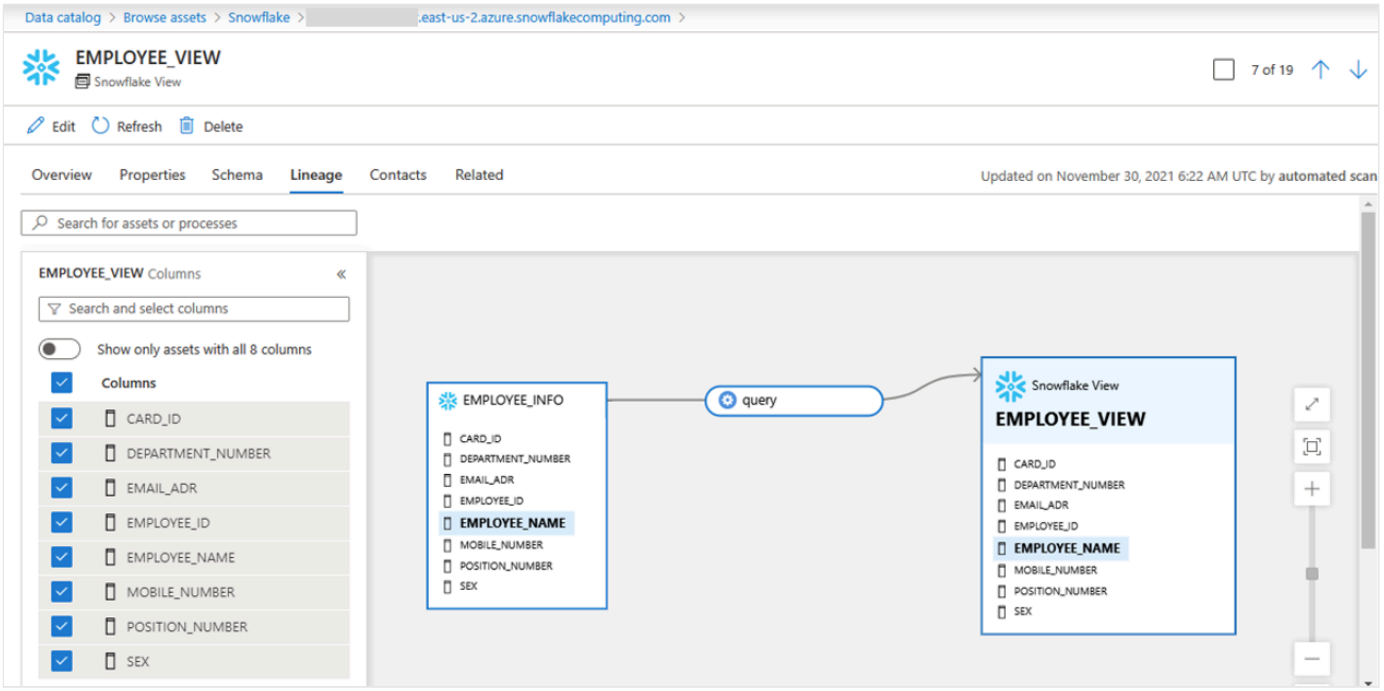
View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:



1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Snowflake source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Snowflake lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

> **Note**
>
> If a view was created by tables from different databases or different schemas, scan all databases and schemas simultaneously using the names in the semicolon (;) list.

Connect to Snowflake via Managed Private Endpoint

This section describes the required steps to set up a Managed Private Endpoint (PE) from Microsoft Purview to Snowflake on Azure. Learn more about Azure Private Link and Snowflake.

1. In your Snowflake account, retrieve the target endpoints and resource ID. Run the system function SYSTEM$GET_PRIVATELINK_CONFIG() with Account Admin role, and note down the values of the following properties:

    - privatelink-pls-id
    - privatelink-account-url
    - regionless-privatelink-account-url
    - privatelink_ocsp-url

    SQL

    ```
    use role accountadmin;
    select key, value::varchar from
    table(flatten(input=>parse_json(SYSTEM$GET_PRIVATELINK_CONFIG())));
    ```

2. In Microsoft Purview, create a managed private endpoint to Snowflake.

a. Follow the steps to Create a Managed Virtual Network Integration Runtime. If you already have one, make sure it's in version 2, which supports Snowflake PE.
b. Create a managed private endpoint for Snowflake. Navigate to **Managed private endpoint** -> **+ New** -> **Snowflake**, and fill in the following information.

- **Resource ID or alias**: Fill in the value of **privatelink-pls-id** you retrieved.
- **Fully qualified domain names**: Add the **privatelink_ocsp-url**, **regionless-privatelink-account-url** and **privatelink-account-url**.

3. After creating the PE, you can see its provisioning state as **Succeeded** and approval state as **Pending**. Open the PE and find the **Managed private endpoint resource ID** in details page.

4. Contact Snowflake Technical Support and provide the resource ID to let Snowflake approve this PE.

5. Once Snowflake Support confirms the PE is approved, you should see your managed private endpoint approval state as **Approved** in Microsoft Purview.

6. Register the data source and set up a scan. When setting up scan, choose the Managed Virtual Network IR associated with the Snowflake PE.

Troubleshooting tips

If you encounter issues while registering or scanning Snowflake, review the following tips.

- Check your account identifier in the source registration step. Don't include `https://` at the beginning.
- Make sure the warehouse name and database name are in uppercase on the scan setup page.
- Check your key vault. Make sure there are no typos in the password.
- Check the credential you set up in Microsoft Purview. The user you specify must have a default role with the necessary access rights to both the warehouse and the database you're trying to scan. See Required permissions for scan. USE `DESCRIBE USER;` to verify the default role of the user you specified for Microsoft Purview.
- Use Query History in Snowflake to see if any activity is coming across.
  - If there's a problem with the account identifier or password, you won't see any activity.
  - If there's a problem with the default role, you should at least see a `USE WAREHOUSE . . .` statement.
  - You can use the QUERY_HISTORY_BY_USER table function to identify what role is being used by the connection. Setting up a dedicated Microsoft Purview user makes troubleshooting easier.

Troubleshooting for Key Pair authentication

This section covers common connection issues when using Snowflake key pair authentication in Microsoft Purview.

Issue 1: "Test Connection Failed"

Symptoms: Connection test fails in Purview

Possible causes and solutions:

1. **Public Key Not Assigned**

   a. Verify in Snowflake: DESC USER purview_scanner;

   b. Check RSA_PUBLIC_KEY_FP is populated

2. **Key Vault Access Issues**

    a. Verify Managed Identity has Get and List permissions

    b. Check Key Vault firewall settings

3. **Incorrect Secret Names**

    a. Verify: {credentialName}.password exists

    b. Verify: {credentialName}.privateKey exists

Issue 2: "Invalid Private Key Format" or "Connection Failed with Key Error"

Symptoms:

- Authentication fails with "invalid private key format" error
- Connection test fails immediately
- Error messages about malformed PEM or key parsing errors

Common cause: Private key was stored via Azure Portal (corrupted multi-line format)

Solution:

1. Verify if the key format is corrupted:

```text
# Retrieve the secret and check format
az keyvault secret show \
 --vault-name your-keyvault \
 --name "snowflake-purview-cred-privateKey" \
 --query value -o tsv | head -5

# Should show multiple lines starting with:
# -----BEGIN ENCRYPTED PRIVATE KEY-----
# MIIFHDBOBgkqhkiG9w0BBQ0wQTApBgkqhkiG9w...
# (NOT a single long line)
```

2. If corrupted, DELETE and recreate using CLI:

```text
# Delete the corrupted secret az keyvault secret delete \
 --vault-name your-keyvault \
```

```
 --name "snowflake-purview-cred-privateKey"

# Wait for soft-delete purge (or purge immediately if needed)
az keyvault secret purge \
 --vault-name your-keyvault \
 --name "snowflake-purview-cred-privateKey"

# Recreate using CLI with
 --file parameter az keyvault secret set \
 --vault-name your-keyvault \
 --name "snowflake-purview-cred-privateKey" \
 --file rsa_key.p8
```

3. Additional checks:

   a. Ensure private key is in PKCS#8 PEM format

   b. Include -----BEGIN ENCRYPTED PRIVATE KEY----- and -----END ENCRYPTED PRIVATE KEY----- lines

   c. Verify key locally first:

```
text
openssl rsa -in rsa_key.p8 -check
```

Remember: Always use Azure CLI or Cloud Shell for private key secrets, NEVER the Azure Portal UI.

Issue 3: "Public Key Fingerprint Mismatch"

Symptom: Authentication succeeds but wrong key is being used

Solution:

```
text
# Regenerate public key from private key
openssl rsa -in rsa_key.p8 -pubout -out rsa_key_new.pub

# Verify fingerprint
openssl rsa -pubin -in rsa_key_new.pub -outform DER | openssl dgst sha256 -binary |
openssl enc -base64

# Update in Snowflake
ALTER USER purview_scanner SET RSA_PUBLIC_KEY='';
```

Issue 4: "Passphrase Incorrect"

Symptom: Key decryption fails

Solution:

1. Verify passphrase in Key Vault matches the one used during key generation
2. Test passphrase locally:

```text
openssl rsa -in rsa_key.p8 -check
# Enter passphrase when prompted
```

Issue 5: "Missing Snowflake Permissions"

Symptom: Connection succeeds but scan fails

Solution:

Grant required privileges to the Snowflake user:

```SQL
-- Create role for Purview
CREATE ROLE IF NOT EXISTS purview_reader;

-- Grant usage on warehouse
GRANT USAGE ON WAREHOUSE COMPUTE_WH TO ROLE purview_reader;

-- Grant usage on database
GRANT USAGE ON DATABASE my_database TO ROLE purview_reader;

-- Grant usage on all schemas
GRANT USAGE ON ALL SCHEMAS IN DATABASE my_database TO ROLE  purview_reader;

-- Grant select on all tables
GRANT SELECT ON ALL TABLES IN DATABASE my_database TO ROLE  purview_reader;
GRANT SELECT ON FUTURE TABLES IN DATABASE my_database TO ROLE  purview_reader;

-- Grant select on all views
GRANT SELECT ON ALL VIEWS IN DATABASE my_database TO ROLE  purview_reader;
GRANT SELECT ON FUTURE VIEWS IN DATABASE my_database TO ROLE  purview_reader;

-- Assign role to user
GRANT ROLE purview_reader TO USER purview_scanner;

-- Set as default role
ALTER USER purview_scanner SET DEFAULT_ROLE = purview_reader;
```

Connect to and manage Tableau in Microsoft Purview (Preview)

Article • 03/28/2025

This article outlines how to register Tableau, and how to authenticate and interact with Tableau in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported Tableau Server version is 8.x to 2023.x.

When scanning Tableau, Microsoft Purview supports extracting technical metadata including:

- Server
- Projects
- Workbooks
- Dashboards
- Data sources
- Stories
- Worksheets and the fields/axes
- Workbook data sources
- Tables and the columns

When setting up scan, you can choose to scan an entire Tableau server, or if you have multiple sites installed, to scope the scan to a given site.

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

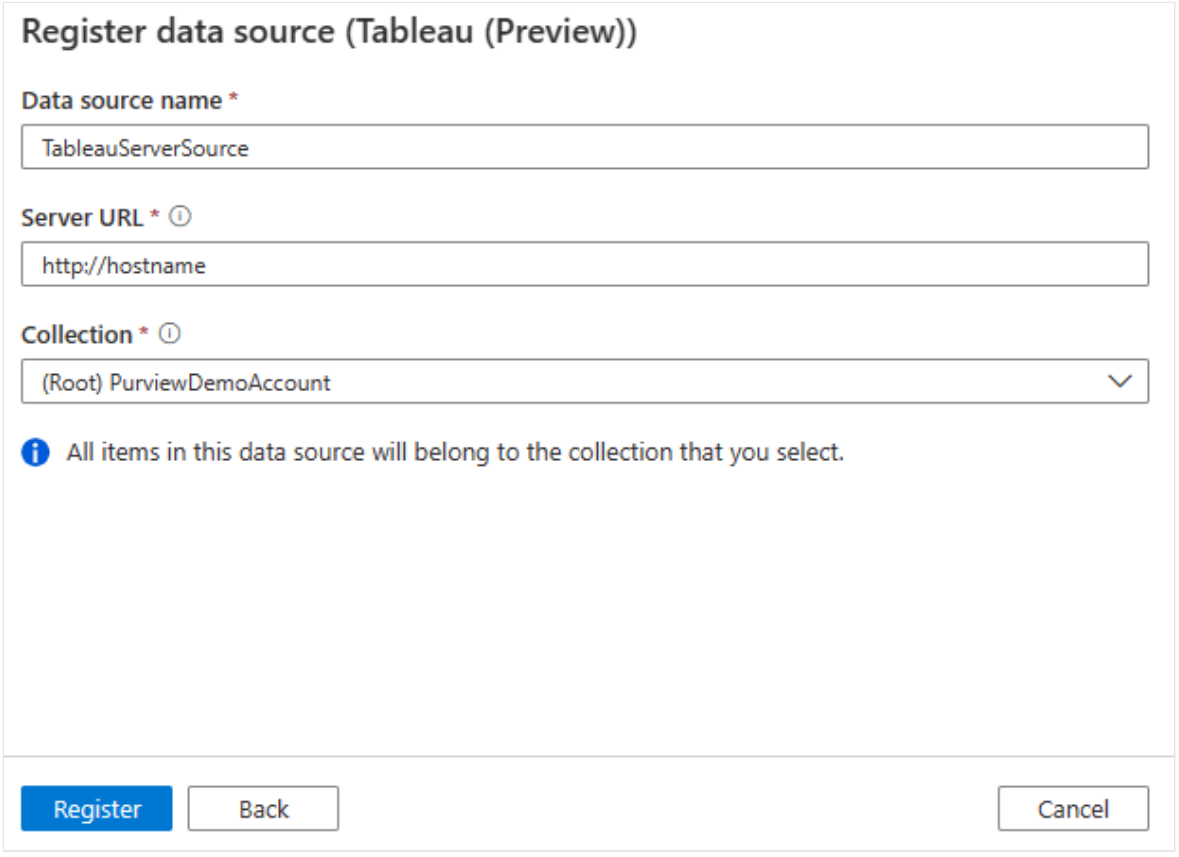
Known limitations

- Currently, scan isn't supported if your Tableau server doesn’t allow access from public network.
- When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

- You must have an Azure account with an active subscription. Create an account for free.
- You must have an active Microsoft Purview account.
- You need an Azure Key Vault, and to grant Microsoft Purview permissions to access secrets.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the right integration runtime for your scenario. If your data source isn't publicly accessible, set up the latest kubernetes supported self-hosted integration runtime.

Required permissions for scan



Microsoft Purview supports basic authentication (username and password) for scanning Tableau server.

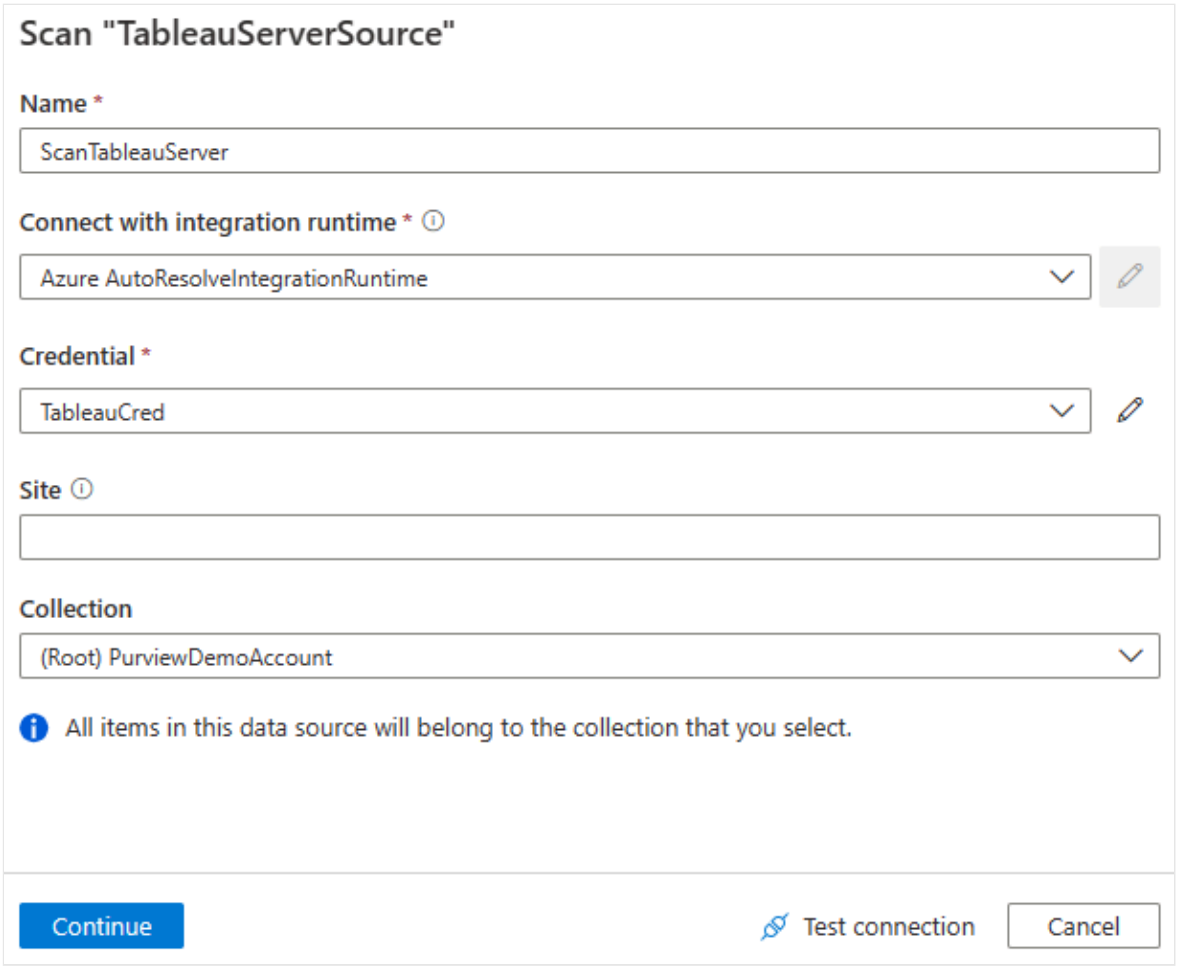
The user account must be licensed as "Interactor" (renamed to "Explorer" in the latest versions) on the Tableau server, and must have 'View' and 'Download' rights for all of the Workbooks, Data Sources and Projects that are about to import. It is preferable to use an account that has "Site Administrator" security role.

Register

This section describes how to register a Tableau server in Microsoft Purview by using the Microsoft Purview governance portal.

1. Go to your Microsoft Purview account.
2. Select **Data Map** on the left pane.
3. Select **Register**.
4. In **Register sources**, select **Tableau** > **Continue**.
5. On the **Register sources (Tableau)** screen, do the following:
   a. For **Name**, enter a name that Microsoft Purview will list as the data source.
   b. For **Host**, enter the URL of your Tableau server. If SSL is used, the URL must start by https and possibly end with a custom port if the SSL default port of 443 is not used.
   c. Select a collection from the list.

6. Select **Register**.



Scan

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have followed all **prerequisites**.
> 2. Review our **scan troubleshooting documentation**.

Use the following steps to scan Tableau server to automatically identify assets. For more information about scanning in general, see Scans and ingestion in Microsoft Purview.

1. Go to **Sources**.
2. Select the registered Tableau source.
3. Select + **New scan**.
4. Provide the following details:
    a. **Name**: Enter a name for the scan.
    b. **Connect via integration runtime**: Choose the default Azure integration runtime, Managed VNet IR, or a Kubernetes supported self-hosted integration runtime you created.
    c. **Credential**: Select the credential to connect to your data source. Make sure to:
        - Select **Basic Authentication** while creating a credential.
        - Provide the user name used to connect to Tableau server in the User name input field.
        - Store the user password used to connect to Tableau server in the secret key.

        For more information, see Credentials for source authentication in Microsoft Purview.
    d. **Site**: Site is only required when connecting to an online Tableau server with multiple sites installed. The value is case sensitive, and must not contain any space as it is used in the URL to connect to Tableau.
5. Click **Test connection** to validate the settings.

6. Select **Continue**.

7. For **Scan trigger**, choose whether to set up a schedule or run the scan once.

8. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Browse, search, and view assets

After successfully scanning your Tableau server, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Next steps

Now that you've registered your source, use the following guides to learn more about Microsoft Purview and your data:

- Search the Unified Catalog
- Data Estate Insights in Microsoft Purview

Connect to and manage Teradata in Microsoft Purview

Article • 03/28/2025

This article outlines how to register Teradata, and how to authenticate and interact with Teradata in Microsoft Purview. For more information about Microsoft Purview, read the introductory article.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

The supported Teradata database versions are 12.x to 17.x.

When scanning Teradata source, Microsoft Purview supports:

- Extracting technical metadata including:
  - Server
  - Databases
  - Tables including the columns, foreign keys, indexes, and constraints
  - Views including the columns
  - Stored procedures including the parameter dataset and result set
  - Functions including the parameter dataset
- Fetching static lineage on assets relationships among tables and views.

When setting up scan, you can choose to scan an entire Teradata server, or scope the scan to a subset of databases matching the given name(s) or name pattern(s).

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

Known limitations

When object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Required permissions for scan

Microsoft Purview supports basic authentication (username and password) for scanning Teradata. The user should have SELECT permission granted for every individual system table listed below:

SQL

```
grant select on dbc.tvm to [user];
grant select on dbc.dbase to [user];
grant select on dbc.tvfields to [user];
grant select on dbc.udtinfo to [user];
grant select on dbc.idcol to [user];
grant select on dbc.udfinfo to [user];
```

To retrieve data types of view columns, Microsoft Purview issues a prepare statement for `select * from <view>` for each of the view queries and parse the metadata that contains the data type details for better performance. It requires the SELECT data permission on views. If the permission is missing, view column data types will be skipped.

For classification, user also needs to have read permission on the tables/views to retrieve sample data.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You need Data Source Administrator and Data Reader permissions to register a source and manage it in the Microsoft Purview governance portal. For more information about permissions, see Access control in Microsoft Purview.
- Set up the latest self-hosted integration runtime. For more information, see the create and configure a self-hosted integration runtime guide.
    - Ensure JDK 11 is installed on the machine where the self-hosted integration runtime is installed. Restart the machine after you newly install the JDK for it to take effect.

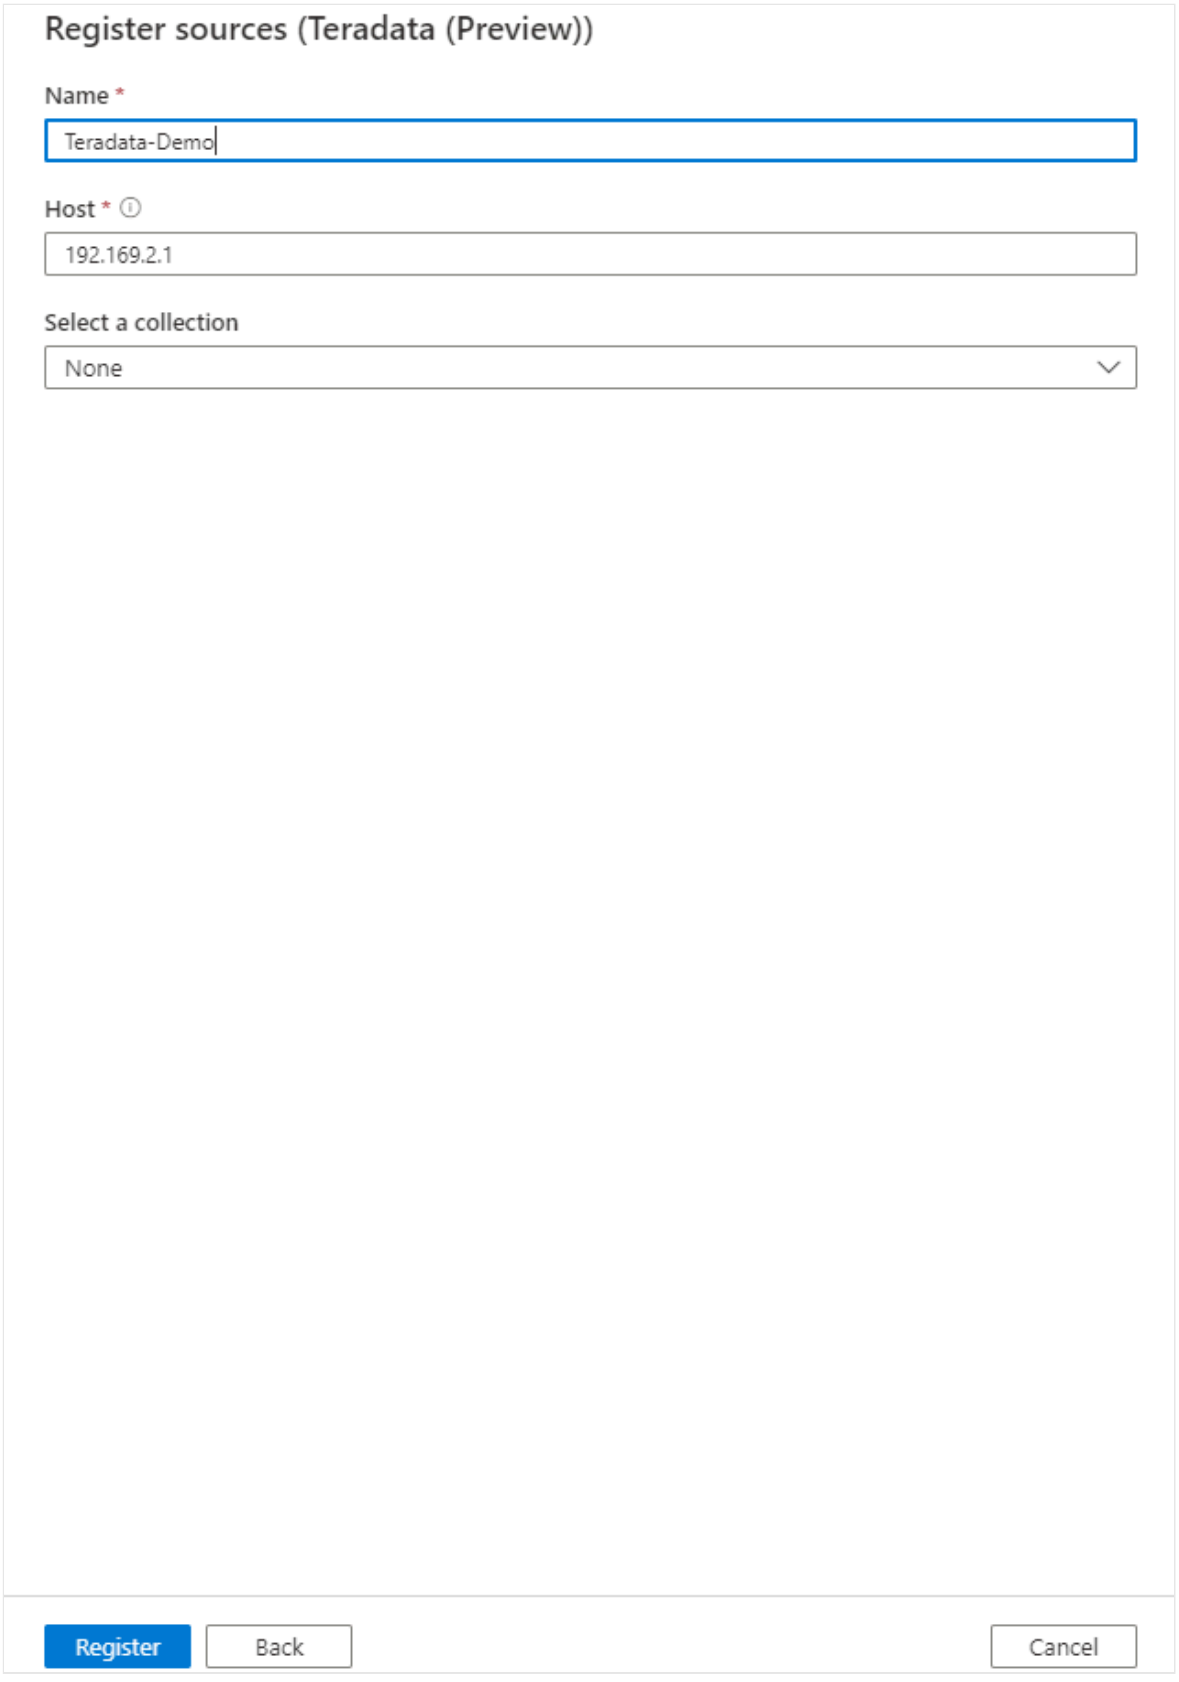
- Ensure Visual C++ Redistributable (version Visual Studio 2012 Update 4 or newer) is installed on the self-hosted integration runtime machine. If you don't have this update installed, you can download it here.
- Download the Teradata JDBC driver on the machine where your self-hosted integration runtime is running. Note down the folder path which you will use to set up the scan.

  > **Note**
  >
  > The driver should be accessible by the self-hosted integration runtime. By default, self-hosted integration runtime uses local service account "NT SERVICE\DIAHostService". Make sure it has "Read and execute" and "List folder contents" permission to the driver folder.

Register

This section describes how to register Teradata in Microsoft Purview using the Microsoft Purview governance portal.

Steps to register



1. Open the Microsoft Purview governance portal by:
   - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
   - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.
2. Select **Data Map** on the left navigation.
3. Select **Register**
4. On Register sources, select **Teradata**. Select **Continue**

On the **Register sources (Teradata)** screen, do the following:

1. Enter a **Name** that the data source will be listed with in the Catalog.
2. Enter the **Host** name to connect to a Teradata source. It can also be an IP address of the server.
3. Select a collection from the list.

4. Finish to register the data source.

Scan

Follow the steps below to scan Teradata to automatically identify assets. For more information about scanning in general, see our introduction to scans and ingestion.

Create and run scan

1. In the Management Center, select **Integration runtimes**. Make sure a self-hosted integration runtime is set up. If it isn't set up, use the steps mentioned here to set up a self-hosted integration runtime

2. Select the **Data Map** tab on the left pane in the Microsoft Purview governance portal.

3. Select the registered Teradata source.

4. Select **New scan**

5. Provide the below details:

   a. **Name**: The name of the scan

   b. **Connect via integration runtime**: Select the configured self-hosted integration runtime.

   c. **Credential**: Select the credential to connect to your data source. Make sure to:

      - Select Basic Authentication while creating a credential.
      - Provide a user name to connect to database server in the User name input field
      - Store the database server password in the secret key.

      To understand more on credentials, refer to the link here

   d. **Schema**: List subset of databases to import expressed as a semicolon separated list. For Example: `schema1;schema2`. All user databases are imported if that list is empty. All system databases (for example, SysAdmin) and objects are ignored by default.

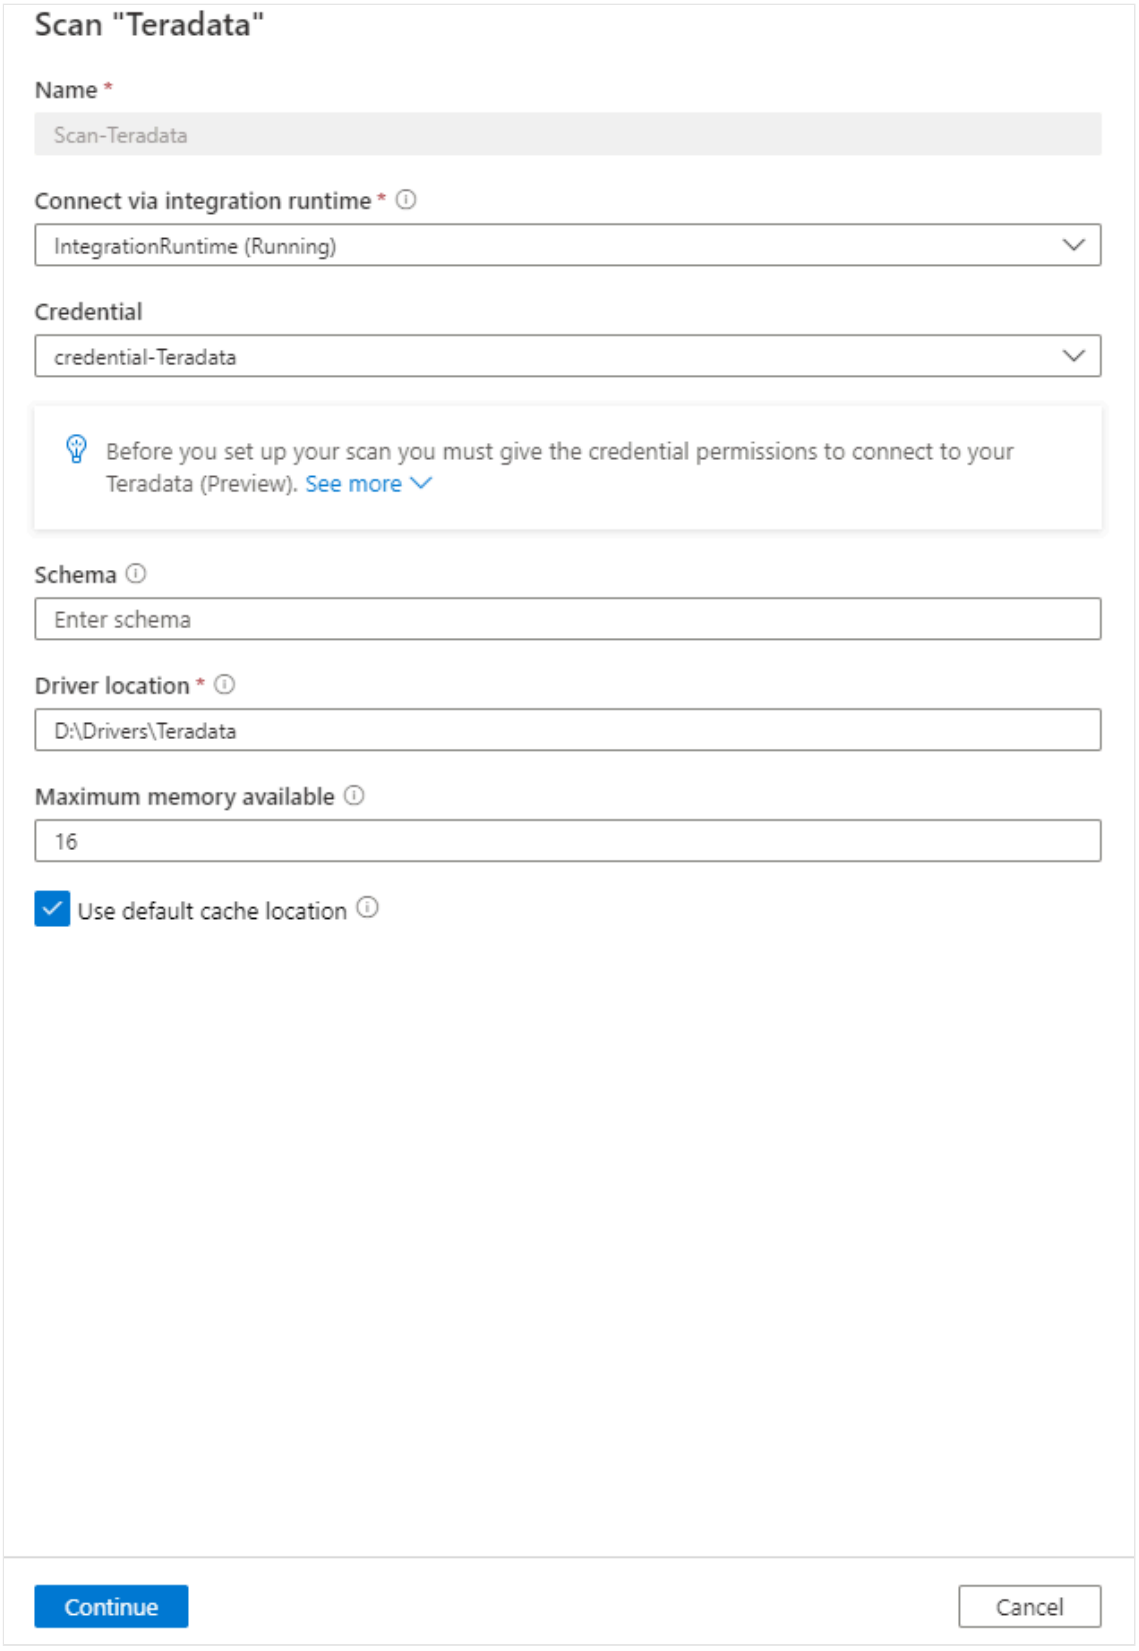
      Acceptable database name patterns can be static names or contain wildcard %. For example: `A%;%B;%C%;D`

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

      Usage of NOT and special characters aren't acceptable

   e. **Driver location**: Specify the path to the JDBC driver location in your machine where self-host integration runtime is running. For example:

`D:\Drivers\Teradata`.



i. For self-hosted integration runtime on a local machine: `D:\Drivers\Teradata`. It's the path to valid JAR folder location. The value must be a valid absolute file path and doesn't contain space. Make sure the driver is accessible by the self-hosted integration runtime;; learn more from prerequisites section.

f. **Stored procedure details**: Controls the number of details imported from stored procedures:

- Signature: The name and parameters of stored procedures.
- Code, signature: The name, parameters and code of stored procedures.
- Lineage, code, signature: The name, parameters and code of stored procedures, and the data lineage derived from the code.
- None: Stored procedure details aren't included.

g. **Maximum memory available:** Maximum memory (in GB) available on customer's VM to be used by scanning processes. This is dependent on the size of Teradata source to be scanned.

> ⓘ **Note**
>
> As a rule of thumb, please provide 2GB memory for every 1000 tables

6. Select **Continue**.

7. Select a **scan rule set** for classification. You can choose between the system default, existing custom rule sets, or create a new rule set inline.

8. Choose your **scan trigger**. You can set up a schedule or ran the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.

2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.

3. Select the scan that you want to manage. You can then:

    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Lineage

After scanning your Teradata source, you can browse Unified Catalog or search Unified Catalog to view the asset details.

Go to the asset -> lineage tab, you can see the asset relationship when applicable. Refer to the supported capabilities section on the supported Teradata lineage scenarios. For more information about lineage in general, see data lineage and lineage user guide.

Next steps

Now that you've registered your source, follow the below guides to learn more about Microsoft Purview and your data.

- Data Estate Insights in Microsoft Purview
- Lineage in Microsoft Purview
- Search Unified Catalog

Amazon RDS Multicloud Scanning Connector for Microsoft Purview (preview)

The Multicloud Scanning Connector for Microsoft Purview allows you to explore your organizational data across cloud providers, including Amazon Web Services, in addition to Azure storage services.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

This article describes how to use Microsoft Purview to scan your structured data currently stored in Amazon RDS, including both Microsoft SQL and PostgreSQL databases, and discover what types of sensitive information exist in your data. You'll also learn how to identify the Amazon RDS databases where the data is currently stored for easy information protection and data compliance.

> **Important**
>
> The Multicloud Scanning Connectors for Microsoft Purview are separate add-ons to Microsoft Purview. The terms and conditions for the Multicloud Scanning Connectors for Microsoft Purview are contained in the agreement under which you obtained Microsoft Azure Services. For more information, see Microsoft Azure Legal Information at https://azure.microsoft.com/support/legal/.

Microsoft Purview scope for Amazon RDS

- **Supported database engines**: Amazon RDS structured data storage supports multiple database engines. Microsoft Purview supports Amazon RDS with/based on Microsoft SQL and PostgreSQL.
- **Supported regions**: For private databases that use Kubernetes supported self-hosted integration runtime, there's no region limitation for Amazon RDS databases.

For public databases that use Amazon AutoResolveIntegrationRuntime, Microsoft Purview only supports Amazon RDS databases that are located in the following AWS regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Canada (Central)
- Africa (Cape Town)
- Asia Pacific (Hong Kong Special Administrative Region)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka-Local)
- Asia Pacific (Seoul)
- Asia Pacific (Tokyo)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Milan)
- Europe (Stockholm)
- Middle East (Bahrain)
- South America (São Paulo)

Known issues: The following functionality isn't currently supported:

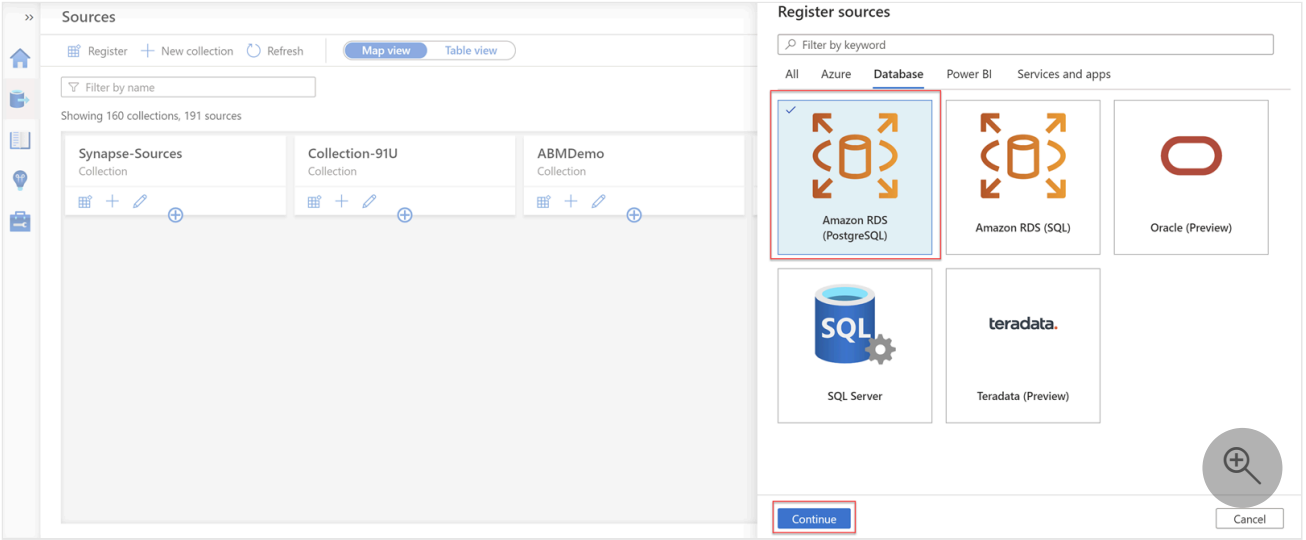
- The **Test connection** button. The scan status messages indicate any errors related to connection setup.
- Selecting specific tables in your database to scan.
- Data lineage.

For more information, see:

- Manage and increase quotas for resources with Microsoft Purview
- Supported data sources and file types in Microsoft Purview
- Use private endpoints for your Microsoft Purview account

Prerequisites

Ensure that you've performed the following prerequisites before adding your Amazon RDS database as Microsoft Purview data sources and scanning your RDS data.



- ✔ You need to be a Microsoft Purview Data Source Admin.
- ✔ You need a Microsoft Purview account. Create a Microsoft Purview account instance, if you don't yet have one.
- ✔ You need an Amazon RDS PostgreSQL or Microsoft SQL database, with data.
- ✔ You need to create a Self-hosted Integration Runtime if you are connecting to a private database. Choose the right integration runtime configuration for your scenario.
  - To use Self-hosted Integration Runtime for scan, set up a Kubernetes supported self-hosted integration runtime.

Register an Amazon RDS data source

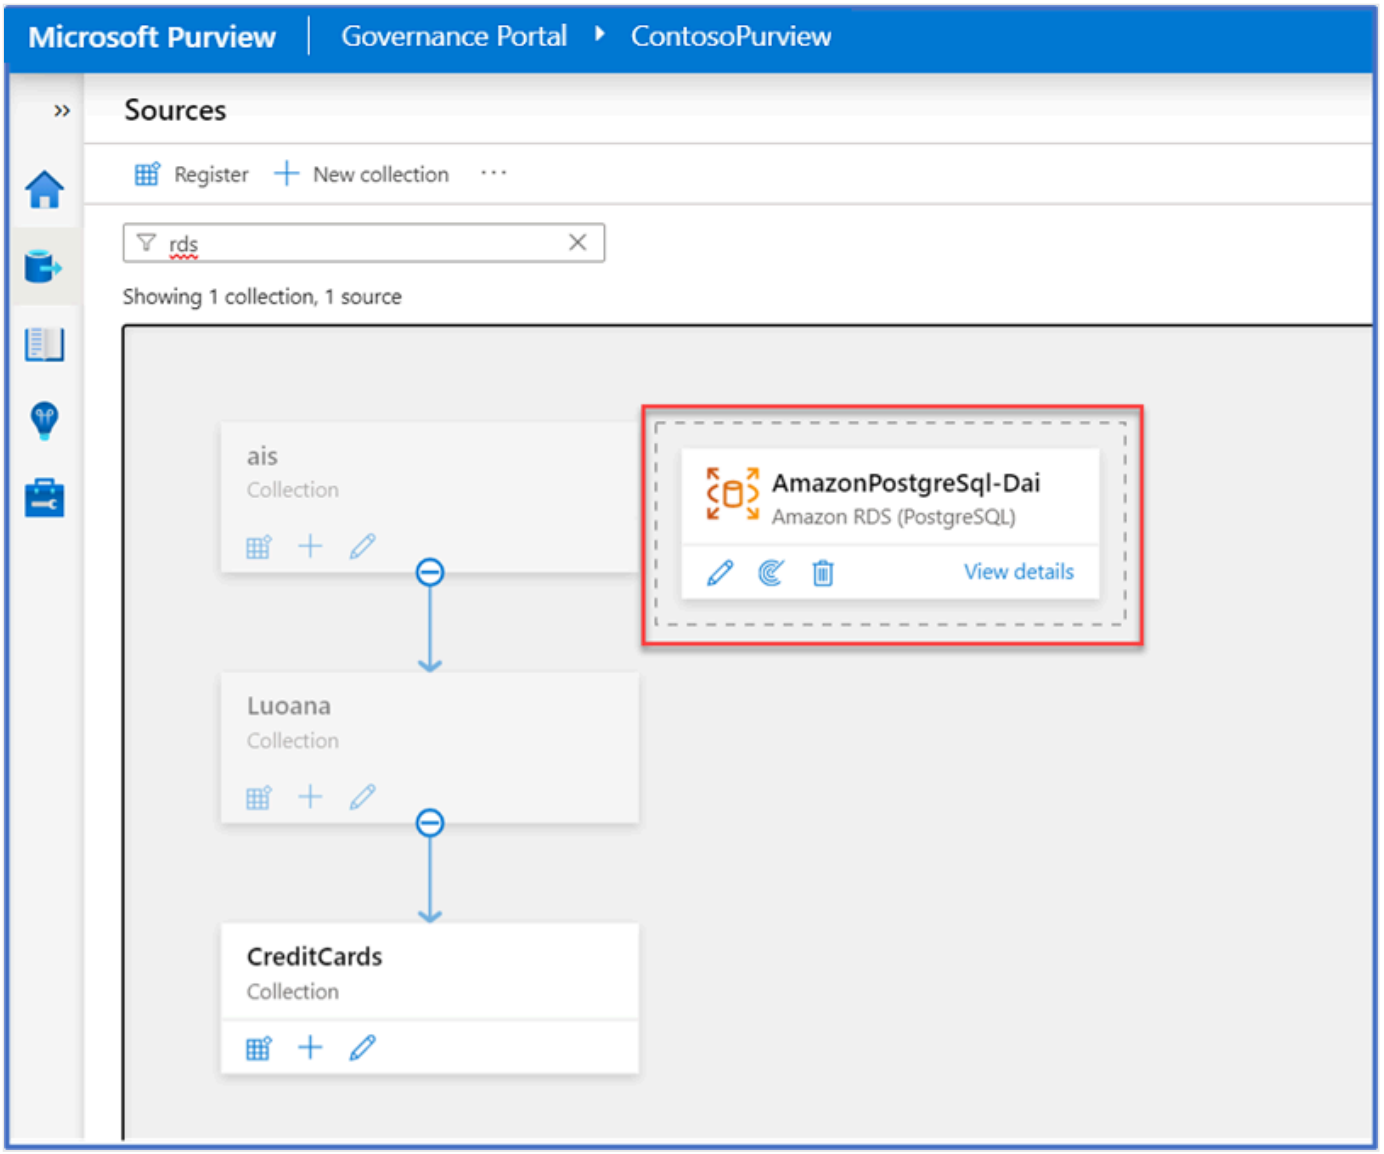
To add your Amazon RDS server as a Microsoft Purview data source:

1. In Microsoft Purview, navigate to the **Data Map** page, and select **Register** .

2. On the **Sources** page, select **Register.** On the **Register sources** page that appears on the right, select the **Database** tab, and then select **Amazon RDS (PostgreSQL)** or **Amazon RDS (SQL)**.

3. Enter the details for your source:

Expand table



Field	Description
Name	Enter a meaningful name for your source, such as `AmazonPostgreSql-Contoso`

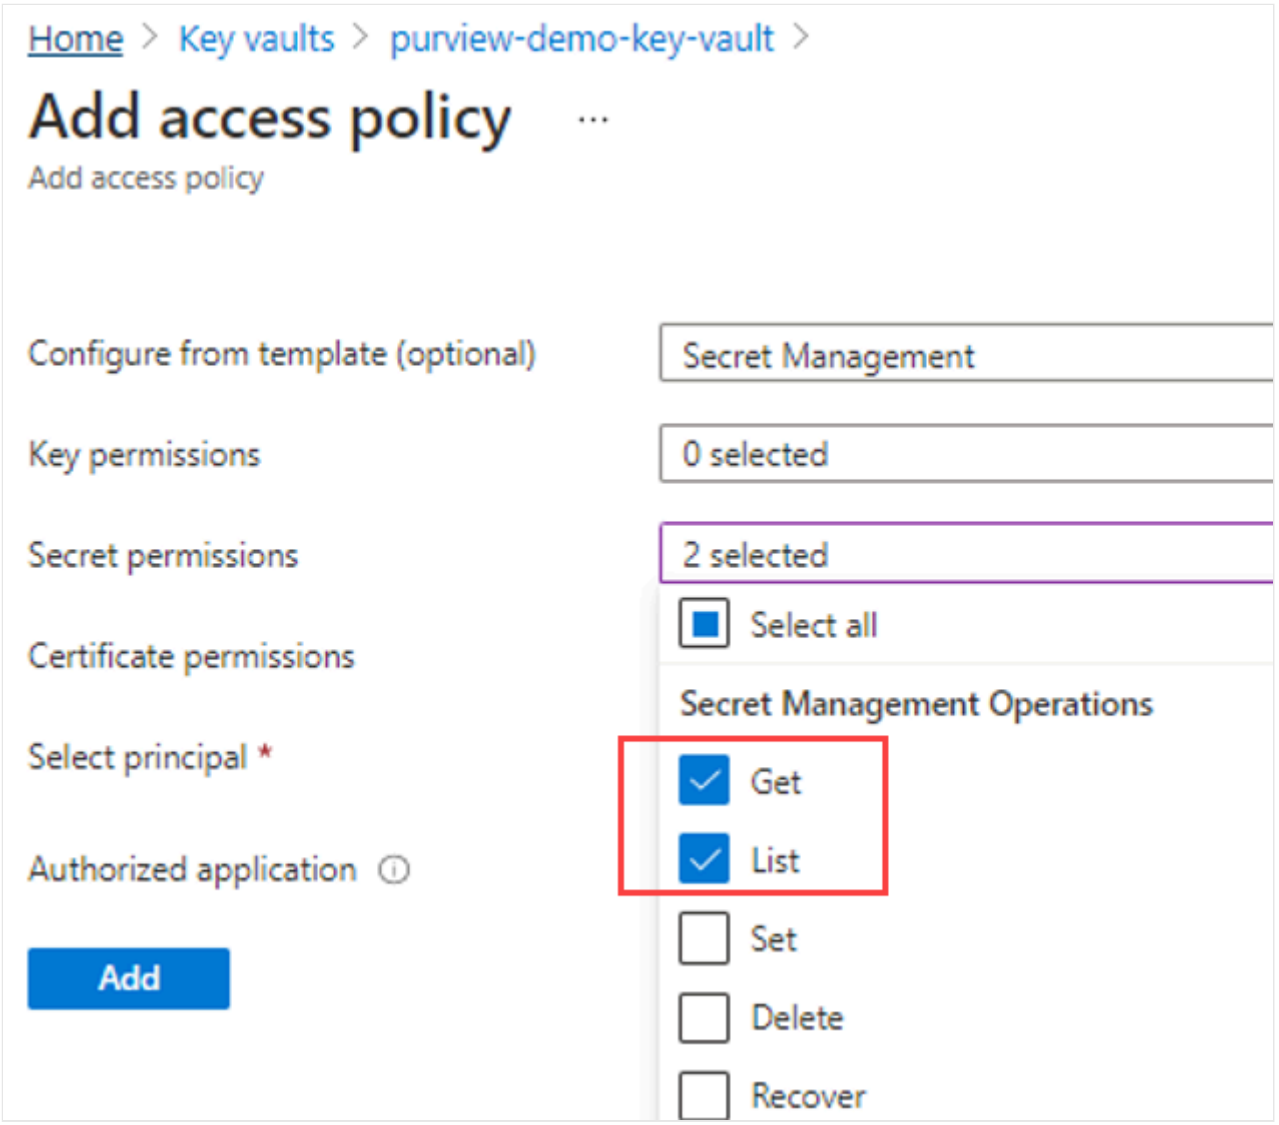
Field	Description
Server name	Enter the name of your RDS database in the following syntax: `<instance identifier>.<xxxxxxxxxxxx>.<region>.rds.amazonaws.com` We recommend that you copy this URL from the Amazon RDS portal, and make sure that the URL includes the AWS region.
Port	Enter the port used to connect to the RDS database: - PostgreSQL: `5432` - Microsoft SQL: `1433`
Collection (optional)	Select a collection to add your data source to. For more information, see Manage data sources in Microsoft Purview (Preview).

4. Select **Register** when you're ready to continue.

> **Note**
>
> You can't register a data source with a name that already exists for a given server name. You must use a different name for the data source.

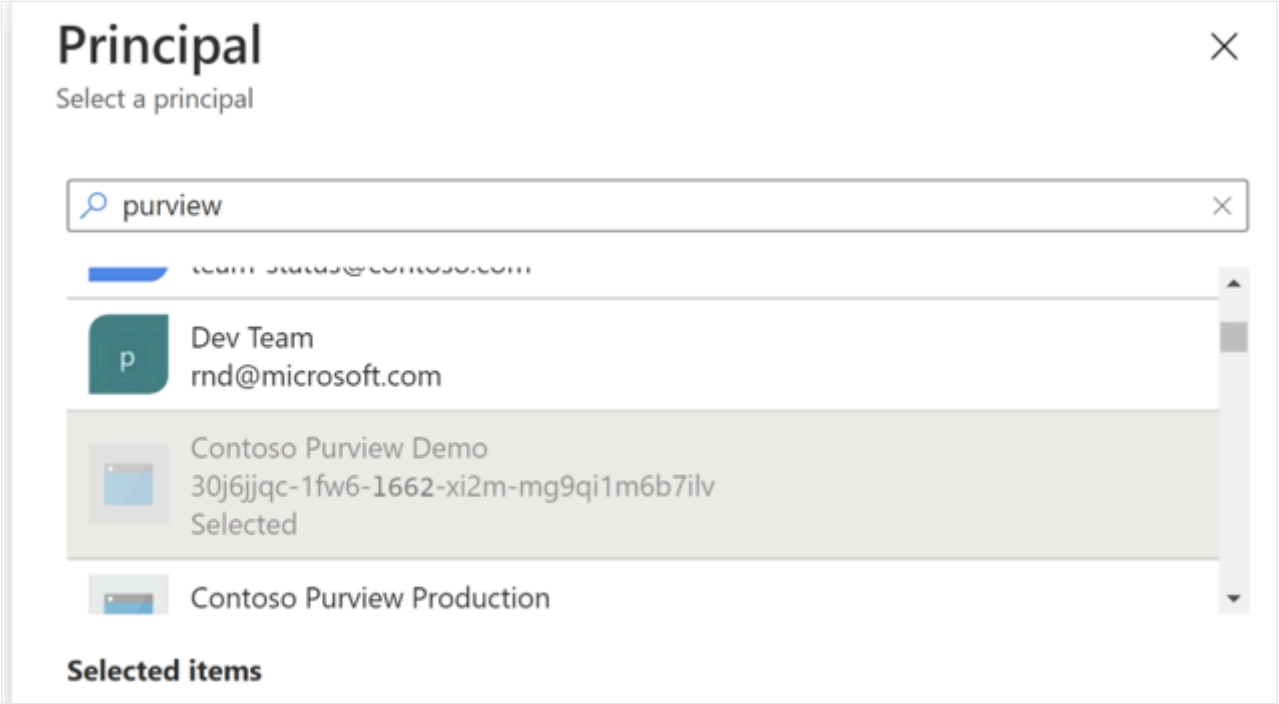
Your RDS data source appears in the Sources map or list. For example:

Create Microsoft Purview credentials for your RDS scan



Credentials supported for Amazon RDS data sources include username/password authentication only, with a password stored in an Azure KeyVault secret.

> **Note**
>
> Because Amazon RDS connections in Microsoft Purview require SQL authentication (username and password), we recommend the following security practices:
>
> - Store credentials in Azure Key Vault, as described below.
> - Use strong, unique passwords and rotate them regularly.
> - Restrict network access to your RDS instance using security groups or private connectivity.



Create a secret for your RDS credentials to use in Microsoft Purview

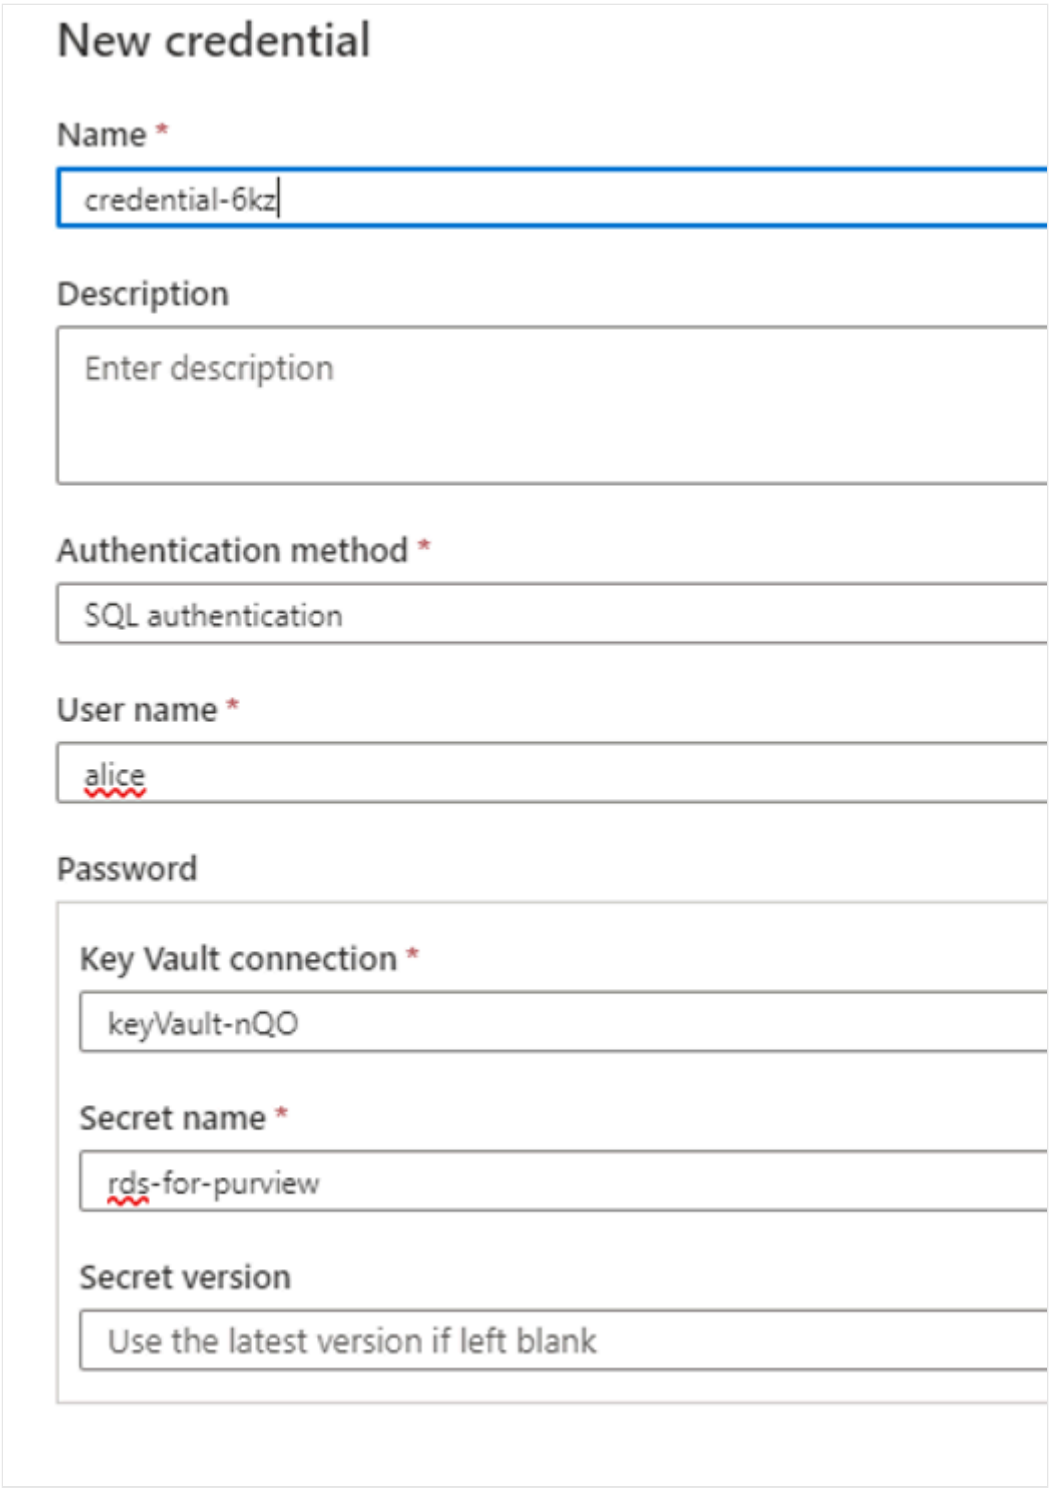
1. Add your password to an Azure KeyVault as a secret. For more information, see Set and retrieve a secret from Key Vault using Azure portal.

2. Add an access policy to your KeyVault with **Get** and **List** permissions. For example:

When defining the principal for the policy, select your Microsoft Purview account. For example:

Select **Save** to save your Access Policy update. For more information, see Assign an Azure Key Vault access policy.

3. In Microsoft Purview, add a KeyVault connection to connect the KeyVault with your RDS secret to Microsoft Purview. For more information, see Credentials for source authentication in Microsoft Purview.



Create your Microsoft Purview credential object for RDS

In Microsoft Purview, create a credentials object to use when scanning your Amazon RDS account.

1. In the Microsoft Purview **Management** area, select **Security and access** > **Credentials** > **New**.

2. Select **SQL authentication** as the authentication method. Then, enter details for the Key Vault where your RDS credentials are stored, including the names of your Key Vault and secret.

   For example:

For more information, see Credentials for source authentication in Microsoft Purview.

Scan an Amazon RDS database

To configure a Microsoft Purview scan for your RDS database:

1. From the Microsoft Purview **Sources** page, select the Amazon RDS data source to scan.
2. Select **New scan** to start defining your scan. In the pane that opens on the right, enter the following details, and then select **Continue**.

- **Name**: Enter a meaningful name for your scan.
- **Connect with integration runtime**: Choose an integration runtime based on your database type.
  - Amazon AutoResolveIntegrationRuntime: Select for a public database.
  - Self-Hosted Integration Runtime: Create new Kubernetes-based SHIR and use for a private database.
- **Database name**: Enter the name of the database you want to scan. You need to find the names available from outside Microsoft Purview, and create a separate scan for each database in the registered RDS server.
- **Credential**: Select the credential you created earlier for the Multicloud Scanning Connectors for Microsoft Purview to access the RDS database.

3. On the **Select a scan rule set** pane, select the scan rule set you want to use, or create a new one. For more information, see Create a scan rule set.

4. On the **Set a scan trigger** pane, select whether you want to run the scan once, or at a recurring time, and then select **Continue**.

5. On the **Review your scan** pane, review the details and then select **Save and Run**, or **Save** to run it later.

While you run your scan, select **Refresh** to monitor the scan progress.

> ⓘ **Note**
>
> When working with Amazon RDS PostgreSQL databases, only full scans are supported. Incremental scans aren't supported as PostgreSQL doesn't have a **Last Modified Time** value.

Explore scanning results

After a Microsoft Purview scan is complete on your Amazon RDS databases, drill down in the Microsoft Purview **Data Map** area to view the scan history. Select a data source to view its details, and then select the **Scans** tab to view any currently running or completed scans.

Use the other areas of Microsoft Purview to find out details about the content in your data estate, including your Amazon RDS databases:

- **Explore RDS data in the catalog**. The Microsoft Purview catalog shows a unified view across all source types, and RDS scanning results are displayed in a similar way to Azure SQL. You

can browse the catalog using filters or browse the assets and navigate through the hierarchy. For more information, see:
    - Tutorial: Browse assets in Microsoft Purview (preview) and view their lineage
    - Search the Microsoft Purview Unified Catalog
    - Register and scan an Azure SQL Database

- **View Insight reports** to view statistics for the classification, sensitivity labels, file types, and more details about your content.

  All Microsoft Purview Insight reports include the Amazon RDS scanning results, along with the rest of the results from your Azure data sources. When relevant, an **Amazon RDS** asset type is added to the report filtering options.

  For more information, see the Understand Data Estate Insights in Microsoft Purview.

- **View RDS data in other Microsoft Purview features**, such as the **Scans** and **Glossary** areas. For more information, see:
    - Create a scan rule set
    - Tutorial: Create and import glossary terms in Microsoft Purview (preview)

RDS errors

The following errors may appear in Microsoft Purview:

- `Unknown database`. In this case, the database defined doesn't exist. Check to see that the configured database name is correct

- `Failed to login to the Sql data source. The given auth credential does not have permission on the target database.` In this case, your username and password is incorrect. Check your credentials and update them as needed.

Legacy AWS RDS Scan Configuration

> **Note**
>
> The method described below will be deprecated soon and should only be used for reference. We strongly recommend using the new AWS RDS Scan configuration method.

Previously, configuring Microsoft Purview to connect to your RDS VPC involved setting up a direct connection using a VPN or other network configuration methods. This approach required

following steps for setup of network peering, security groups, and routing configurations.

1. **Set Up VPN or Direct Connect**: Establish a secure connection between your AWS VPC and the Microsoft Purview scanning infrastructure.
2. **Configure Network Peering**: Create VPC peering connections between your VPC and the VPC used by Microsoft Purview.
3. **Security Group Adjustments**: Modify security groups to allow traffic from Microsoft Purview IP ranges to your RDS instances.
4. **Route Table Updates**: Update route tables to ensure proper routing of traffic between the VPCs.

By transitioning to the new AWS Kubernetes-based Integration Runtime configuration, you can achieve a more secure, reliable, and simpler connection setup, ensuring better integration with Microsoft Purview.

Connect to Amazon Redshift in Microsoft Purview

Article • 03/28/2025

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	No	Yes

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

This document introduces the preview for scanning Amazon Redshift in Microsoft Purview.

Supported capabilities

Other capabilities

View a table listing the supported capabilities for classifications, sensitivity labels, policies, data lineage, and live view.

When scanning Amazon Redshift, Microsoft Purview supports extracting technical metadata including:

- Server
- Databases
- Schemas
- Tables including the columns, foreign keys and unique constraints
- Views including the columns
- Stored procedures including the parameter dataset
- Functions including the parameter dataset

When setting up scan, you can choose to scan an entire Amazon Redshift database, or scope the scan to a subset of schemas matching the given name(s) or name pattern(s).

Known limitations

- When an object is deleted from the data source, currently the subsequent scan won't automatically remove the corresponding asset in Microsoft Purview.

Prerequisites

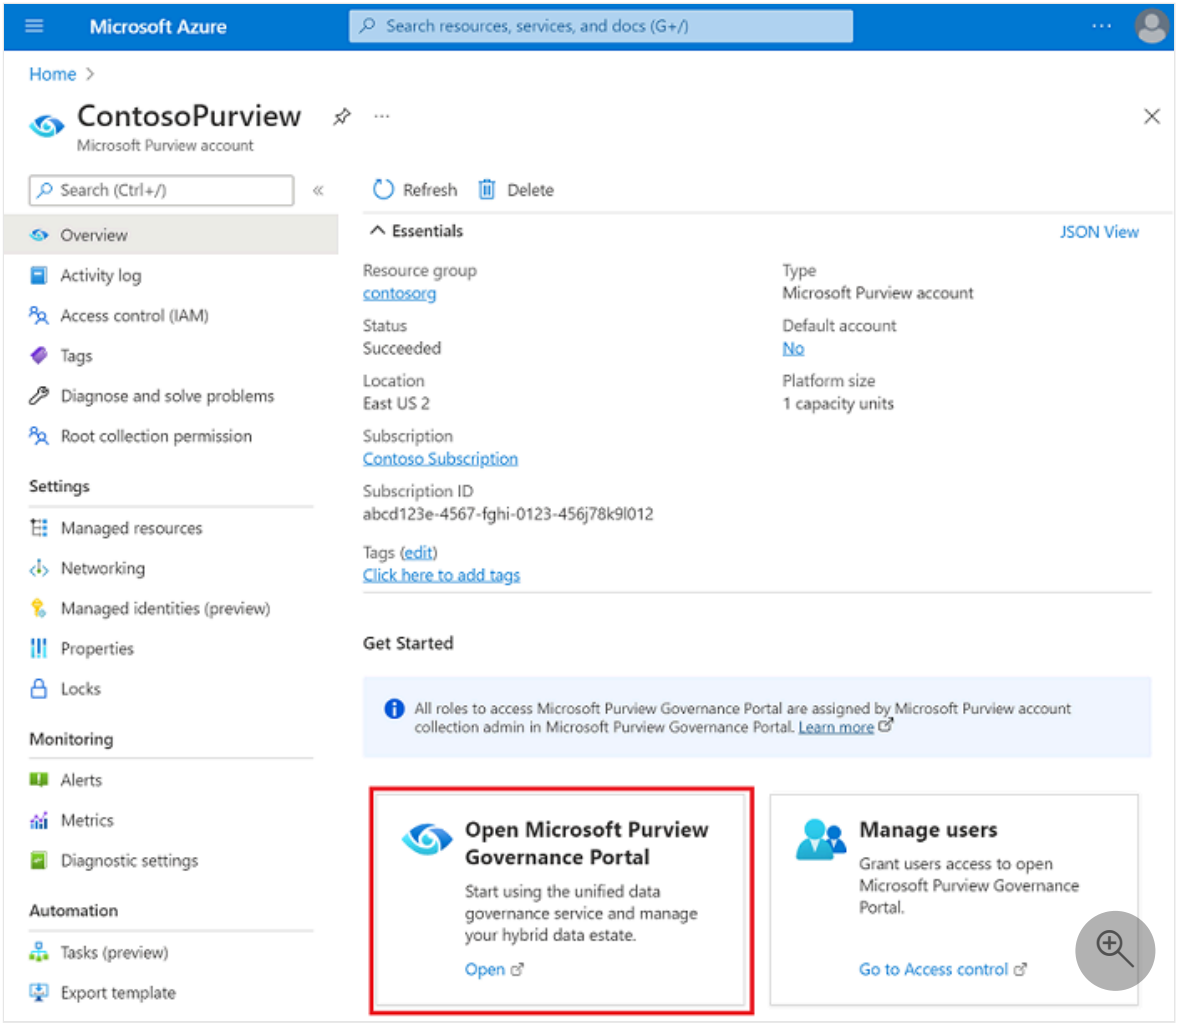
- An Azure account with an active subscription. Create an account for free.
- An active Microsoft Purview account.
- You'll need to be a Data Source Administrator and Data Reader to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.
- Set up the right integration runtime for your scenario. If your data source isn't publicly accessible, set up the latest kubernetes supported self-hosted integration runtime.

Register

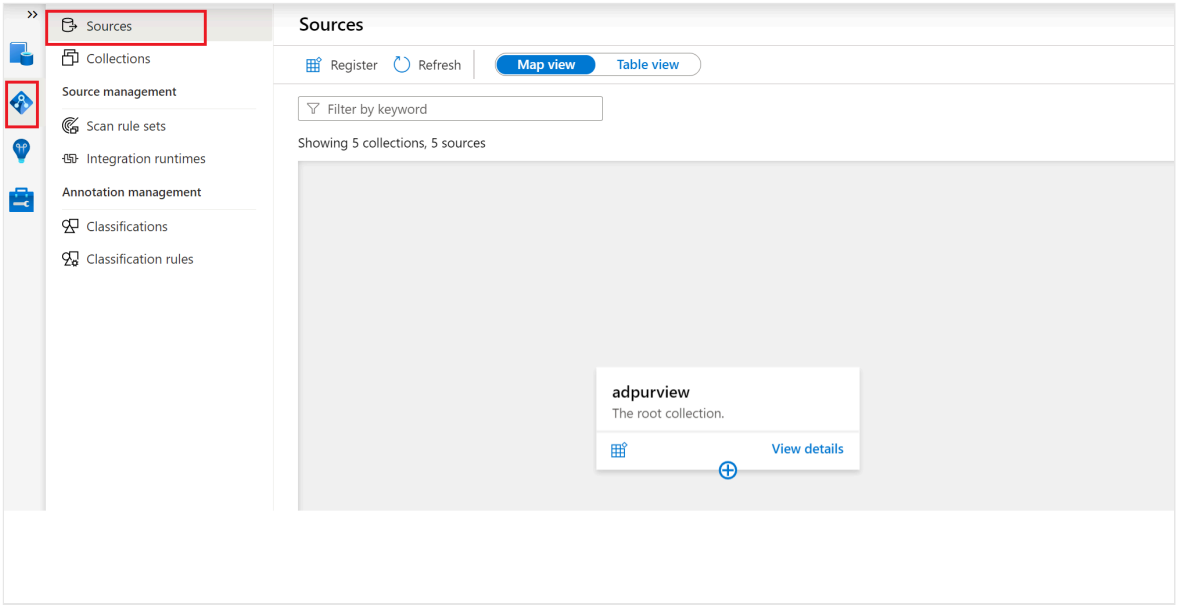
This section will enable you to register the Amazon Redshift data source for scan and data share in Purview.

Prerequisites for register

- You'll need to be a Data Source Admin and one of the other Purview roles (for example, Data Reader or Data Share Contributor) to register a source and manage it in the Microsoft Purview governance portal. See our Microsoft Purview Permissions page for details.



Steps to register

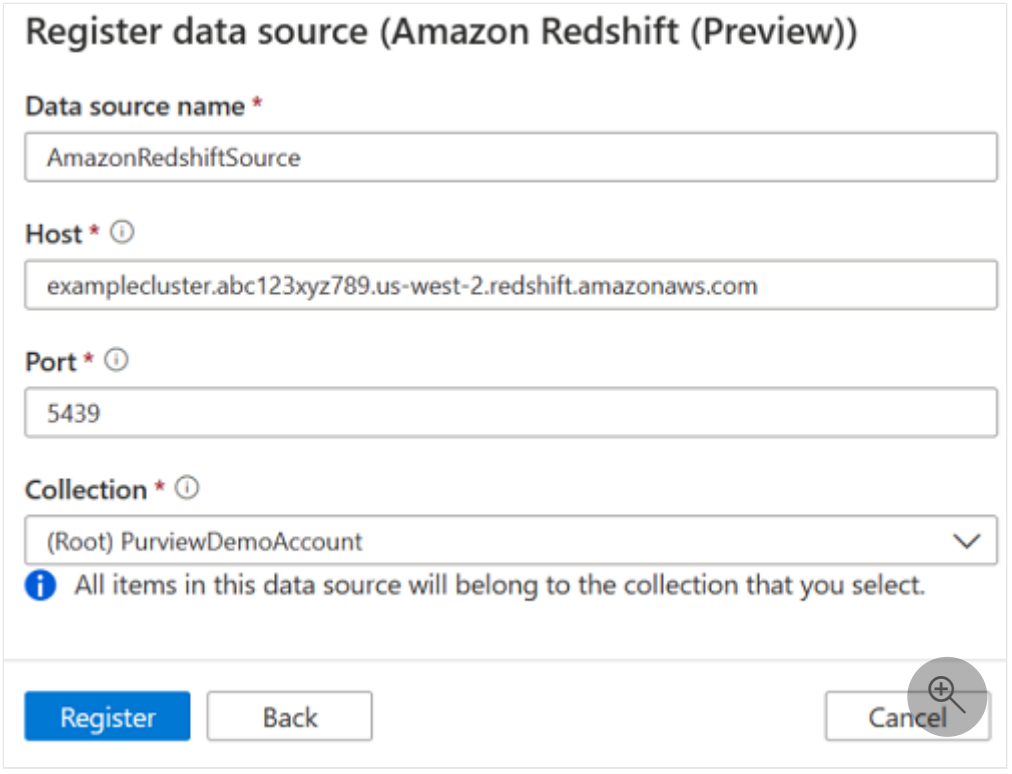


It's important to register the data source in Microsoft Purview prior to setting up a scan for the data source.

1. Go to the Microsoft Purview governance portal by:

- Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
- Opening the Azure portal, searching for and selecting the Microsoft Purview account. Select the **the Microsoft Purview governance portal** button.

2. Navigate to the **Data Map --> Sources**



3. Navigate to the appropriate collection under the **Sources** menu and select the **Register** icon to register a new Amazon Redshift data source.

4. Select the **Amazon Redshift** data source and select **Continue**.

5. Provide a suitable **Name** for the data source, and provide these details:
   a. Endpoint - The endpoint of your Amazon Redshift cluster. For example: `examplecluster.abc123xyz789.us-west-2.redshift.amazonaws.com`
   b. Port - The port number that you specified when you launched the cluster. The default is 5439.

6. The Amazon Redshift cluster is shown under the selected Collection

Scan

> **Tip**
>
> To troubleshoot any issues with scanning:
>
> 1. Confirm you have properly set up authentication for scanning.
> 2. Review our scan troubleshooting documentation.

Authentication for a scan

Microsoft Purview supports basic authentication (username and password) for scanning Amazon Redshift.

The user should have **SELECT** permission granted for every individual system table for Microsoft Purview to query metadata from:

- svv_external_tables
- svv_external_columns
- svv_table_info
- information_schema.routines
- information_schema.parameters
- pg_views
- pg_database
- pg_description

And user should have **EXECUTE** permission granted for system function for Microsoft Purview to query metadata from:

- pg_get_late_binding_view_cols

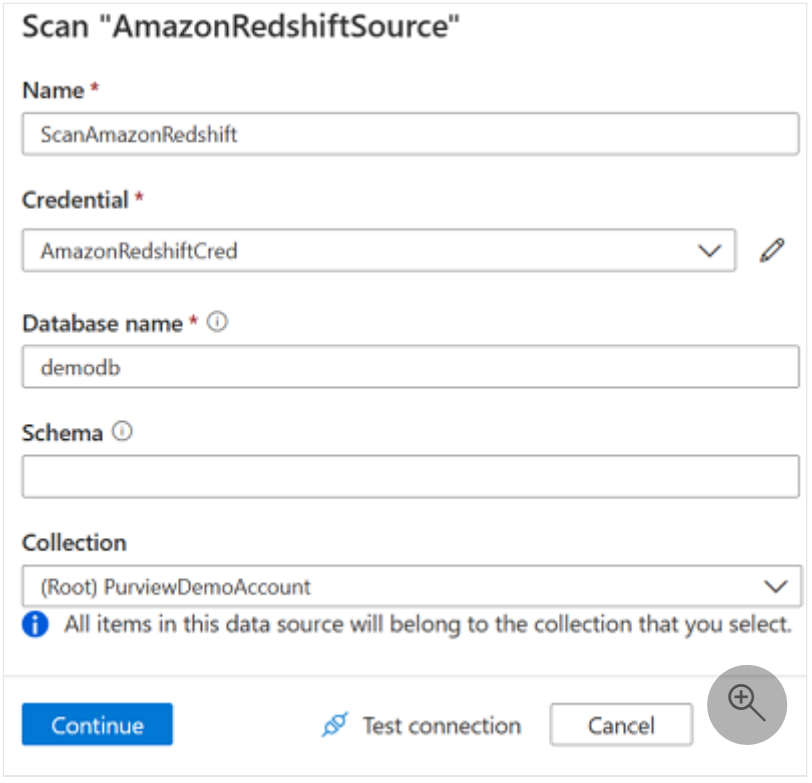
Create a credential

Microsoft Purview uses **Azure Key Vault** to safely store the credentials it uses to authenticate with sources.

- If you haven't set up an Azure Key Vault to store credentials, first create an Azure Key Vault and then follow these steps to connect your Microsoft Purview account to your Azure Key Vault.
- Once you have an Azure Key Vault, store your Amazon Redshift password as a secret in the Key Vault, and then follow these steps to create a credential with this information:
  - Basic authentication credential
  - Add your user name in the input field
  - Add your Key Vault connection and the name of the secret where your password is stored

Create the scan

1. Open your **Microsoft Purview account** and select the **Open Microsoft Purview governance portal**



2. Navigate to the **Data map** --> **Sources** to view the collection hierarchy

3. Select the **New Scan** icon under the **Amazon Redshift data source** registered earlier.

4. Select your integration runtime.

5. Provide these details:
   a. Name - a name for your scan
   b. Credential - choose the credential you created earlier
   c. Database - name of the database instance to scan
   d. Schema - The subset of schemas to import expressed as a semicolon separated list of schemas. For example: "schema1;schema2". All user schemas are imported if that list is empty. All system schemas and objects are ignored by default. Acceptable schema name patterns can be static names or contain wildcard %. For example: "A%;%B;%C%;D":

      - Start with A or
      - End with B or
      - Contain C or
      - Equal D

6. Select **Test connection** to validate the settings.

7. Select **Continue**.

8. For **Scan trigger** choose whether to set up a schedule or run the scan once.

9. Review your scan and select **Save and Run**.

View your scans and scan runs

To view existing scans:

1. Go to the Microsoft Purview portal. On the left pane, select **Data map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that has results you want to view. The pane shows you all the previous scan runs, along with the status and metrics for each scan run.
4. Select the run ID to check the scan run details.

Manage your scans

To edit, cancel, or delete a scan:

1. Go to the Microsoft Purview portal. On the left pane, select **Data Map**.
2. Select the data source. You can view a list of existing scans on that data source under **Recent scans**, or you can view all scans on the **Scans** tab.
3. Select the scan that you want to manage. You can then:
    - Edit the scan by selecting **Edit scan**.
    - Cancel an in-progress scan by selecting **Cancel scan run**.
    - Delete your scan by selecting **Delete scan**.

> ⓘ **Note**
>
> - Deleting your scan does not delete catalog assets created from previous scans.

Browse, search, and view assets

After successfully scanning your Amazon Redshift clusters, you can browse the Unified Catalog or search Unified Catalog to view the asset details.

Next steps

Follow the below guides to learn more about Microsoft Purview and your data.

- Browse or Search Microsoft Purview Unified Catalog.

- Data Estate Insights in Microsoft Purview

Amazon S3 Multicloud Scanning Connector for Microsoft Purview

The Multicloud Scanning Connector for Microsoft Purview allows you to explore your organizational data across cloud providers, including Amazon Web Services in addition to Azure storage services.

This article describes how to use Microsoft Purview to scan your unstructured data currently stored in Amazon S3 standard buckets, and discover what types of sensitive information exist in your data. This how-to guide also describes how to identify the Amazon S3 Buckets where the data is currently stored for easy information protection and data compliance.

For this service, use Microsoft Purview to provide a Microsoft account with secure access to AWS, where the Multicloud Scanning Connector for Microsoft Purview will run. The Multicloud Scanning Connector for Microsoft Purview uses this access to your Amazon S3 buckets to read your data, and then reports the scanning results, including only the metadata and classification, back to Azure. Use the Microsoft Purview classification and labeling reports to analyze and review your data scan results.

> **Important**
>
> The Multicloud Scanning Connector for Microsoft Purview is a separate add-on to Microsoft Purview. The terms and conditions for the Multicloud Scanning Connector for Microsoft Purview are contained in the agreement under which you obtained Microsoft Azure Services. For more information, see Microsoft Azure Legal Information at https://azure.microsoft.com/support/legal/.

Supported capabilities

Scanning capabilities

Expand table

Metadata Extraction	Full Scan	Incremental Scan	Scoped Scan
Yes	Yes	Yes	Yes

Other capabilities

For **classifications**, **sensitivity labels**, **policies**, **data lineage**, and **live view**, see the list of supported capabilities.

Known limitations

When scanning Amazon S3 of Glacier storage classes, schema extraction, classification, and sensitivity labels aren't supported.

Microsoft Purview private endpoints aren't supported when scanning Amazon S3.

For more information about Microsoft Purview limits, see:

- Manage and increase quotas for resources with Microsoft Purview
- Supported data sources and file types in Microsoft Purview

Storage and scanning regions

The Microsoft Purview connector for the Amazon S3 service is currently deployed in specific regions only. The following table maps the regions where your data is stored to the region where it would be scanned by Microsoft Purview.

> **Important**
>
> Customers are charged for all related data transfer charges according to the region of their bucket.

Expand table

Storage region	Scanning region
US East (Ohio)	US East (Ohio)
US East (N. Virginia)	US East (N. Virginia)
US West (N. California)	US West (N. California)
US West (Oregon)	US West (Oregon)
Africa (Cape Town)	Europe (Frankfurt)
Asia Pacific (Hong Kong Special Administrative Region)	Asia Pacific (Tokyo)
Asia Pacific (Mumbai)	Asia Pacific (Singapore)
Asia Pacific (Osaka-Local)	Asia Pacific (Tokyo)

Storage region	Scanning region
Asia Pacific (Seoul)	Asia Pacific (Tokyo)
Asia Pacific (Singapore)	Asia Pacific (Singapore)
Asia Pacific (Sydney)	Asia Pacific (Sydney)
Asia Pacific (Tokyo)	Asia Pacific (Tokyo)
Canada (Central)	US East (Ohio)
China (Beijing)	Not supported
China (Ningxia)	Not supported
Europe (Frankfurt)	Europe (Frankfurt)
Europe (Ireland)	Europe (Ireland)
Europe (London)	Europe (London)
Europe (Milan)	Europe (Paris)
Europe (Paris)	Europe (Paris)
Europe (Stockholm)	Europe (Frankfurt)
Middle East (Bahrain)	Europe (Frankfurt)
South America (São Paulo)	US East (Ohio)

Prerequisites

Ensure that you've performed the following prerequisites before adding your Amazon S3 buckets as Microsoft Purview data sources and scanning your S3 data.

- ✓ You need to be a Microsoft Purview Data Source Admin.
- ✓ Create a Microsoft Purview account if you don't yet have one
- ✓ Create a new AWS role for use with Microsoft Purview
- ✓ Create a Microsoft Purview credential for your AWS bucket scan
- ✓ Configure scanning for encrypted Amazon S3 buckets, if relevant
- ✓ Make sure that your bucket policy does not block the connection. For more information, see Bucket policy requirements and SCP policy requirements. For these items, you may need to consult with an AWS expert to ensure that your policies allow required access.
- ✓ When adding your buckets as Microsoft Purview resources, you'll need the values of your AWS ARN, bucket name, and sometimes your AWS account ID.

Create a Microsoft Purview account

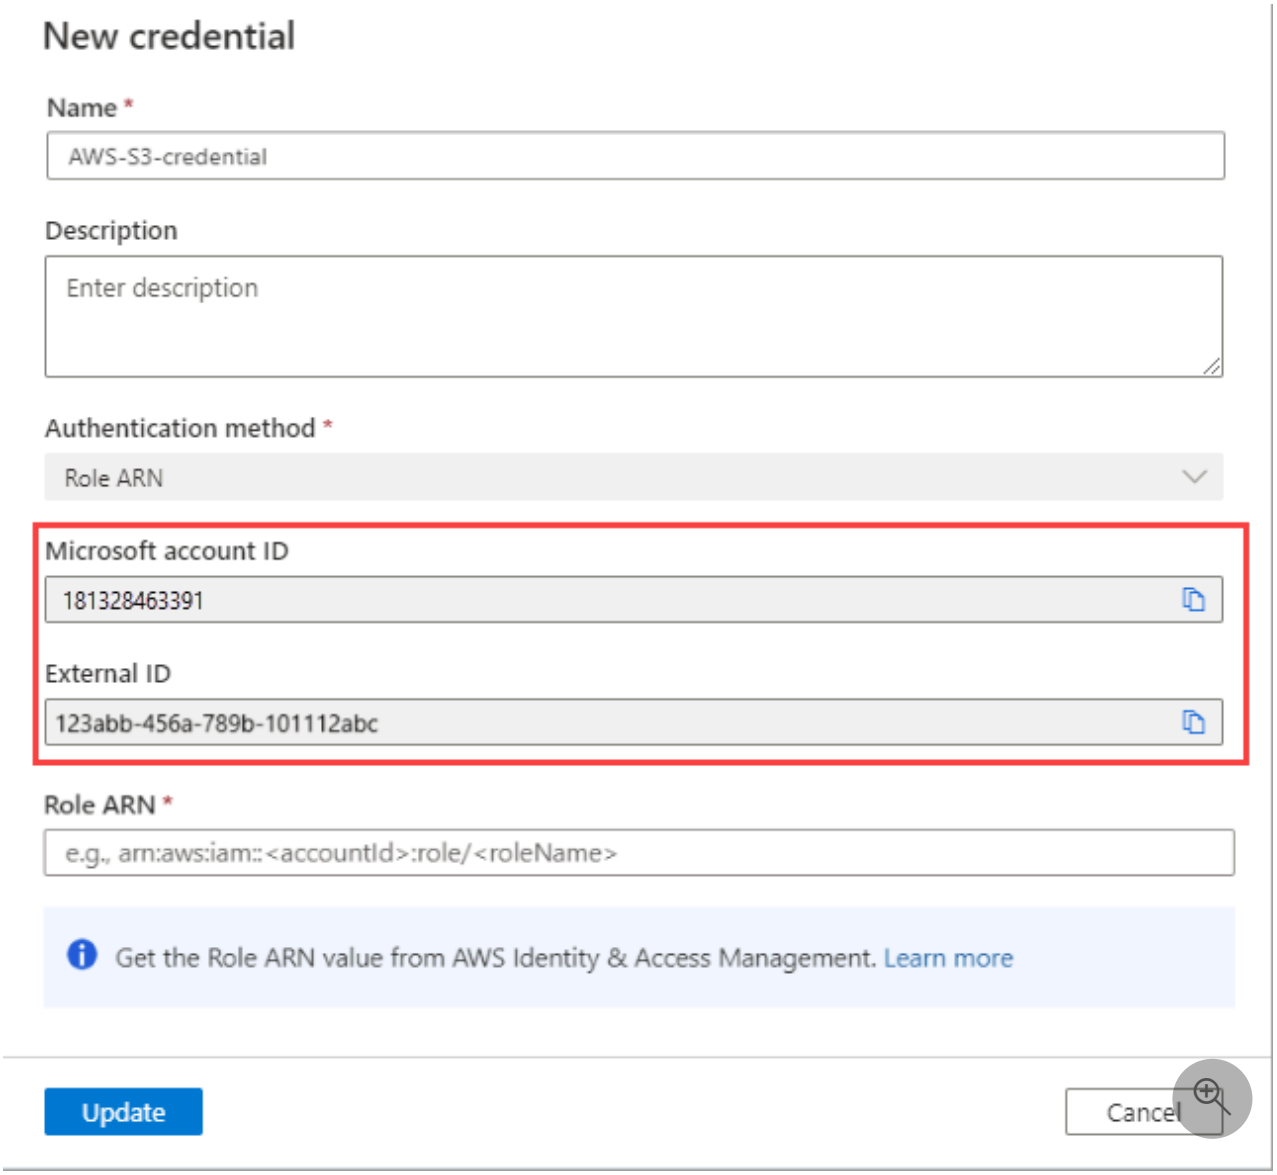
- **If you already have a Microsoft Purview account,** you can continue with the configurations required for AWS S3 support. Start with Create a Microsoft Purview credential for your AWS bucket scan.
- **If you need to create a Microsoft Purview account,** follow the instructions in Create a Microsoft Purview account instance. After creating your account, return here to complete configuration and begin using Microsoft Purview connector for Amazon S3.

Create a new AWS role for Microsoft Purview

The Microsoft Purview scanner is deployed in a Microsoft account in AWS. To allow the Microsoft Purview scanner to read your S3 data, you must create a dedicated role in the AWS portal, in the IAM area, to be used by the scanner.

This procedure describes how to create the AWS role, with the required Microsoft Account ID and External ID from Microsoft Purview, and then enter the Role ARN value in Microsoft Purview.

To locate your Microsoft Account ID and External ID:



1. To locate credentials:

    - In the Microsoft Purview portal: go to **Data Map** > **Source management** > **Credentials**.
    - In the classic Microsoft Purview governance portal go to the **Management Center** > **Security and access** > **Credentials**.

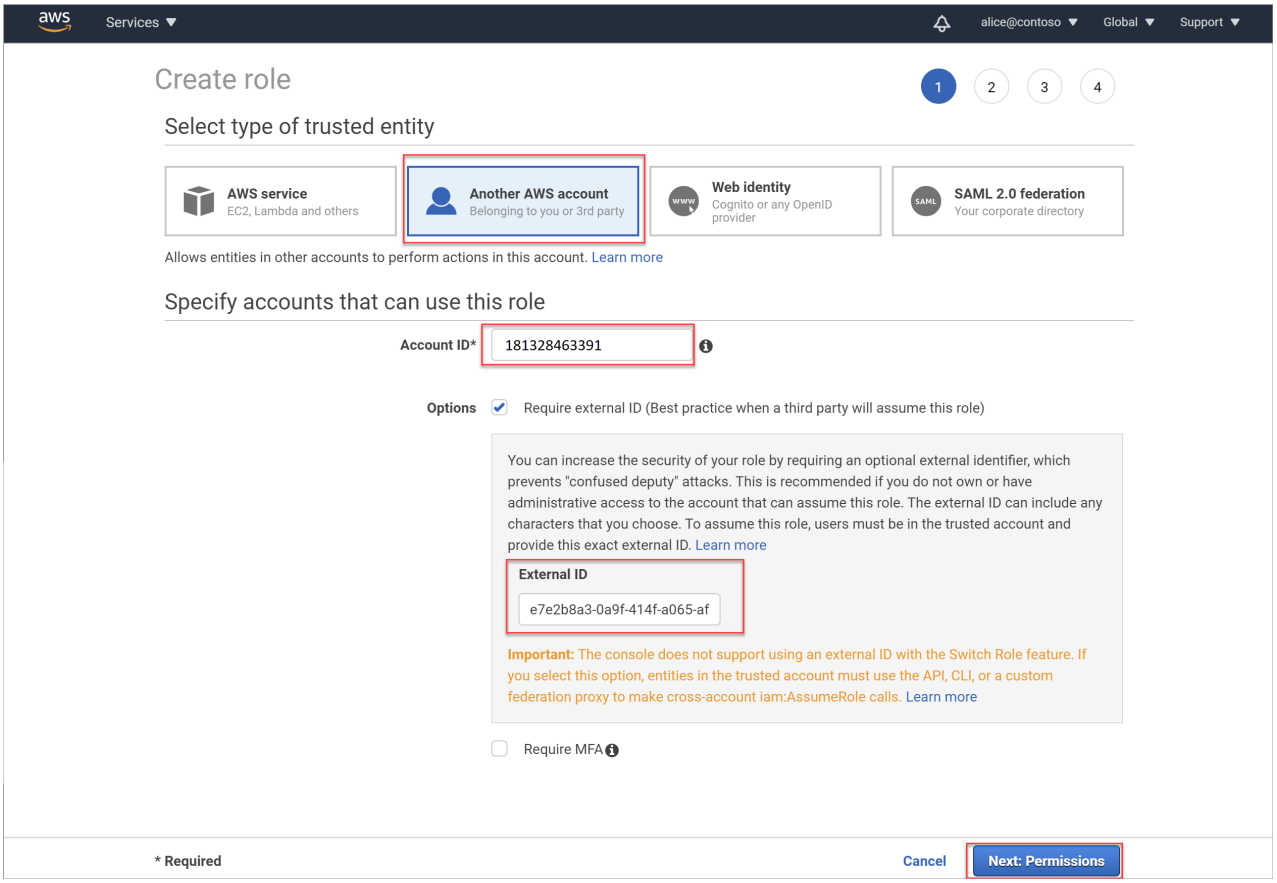
2. Select **New** to create a new credential.

    In the **New credential** pane that appears, in the **Authentication method** dropdown, select **Role ARN**.

    Then copy the **Microsoft account ID** and **External ID** values that appear to a separate file, or have them handy for pasting into the relevant field in AWS. For example:

To create your AWS role for Microsoft Purview:

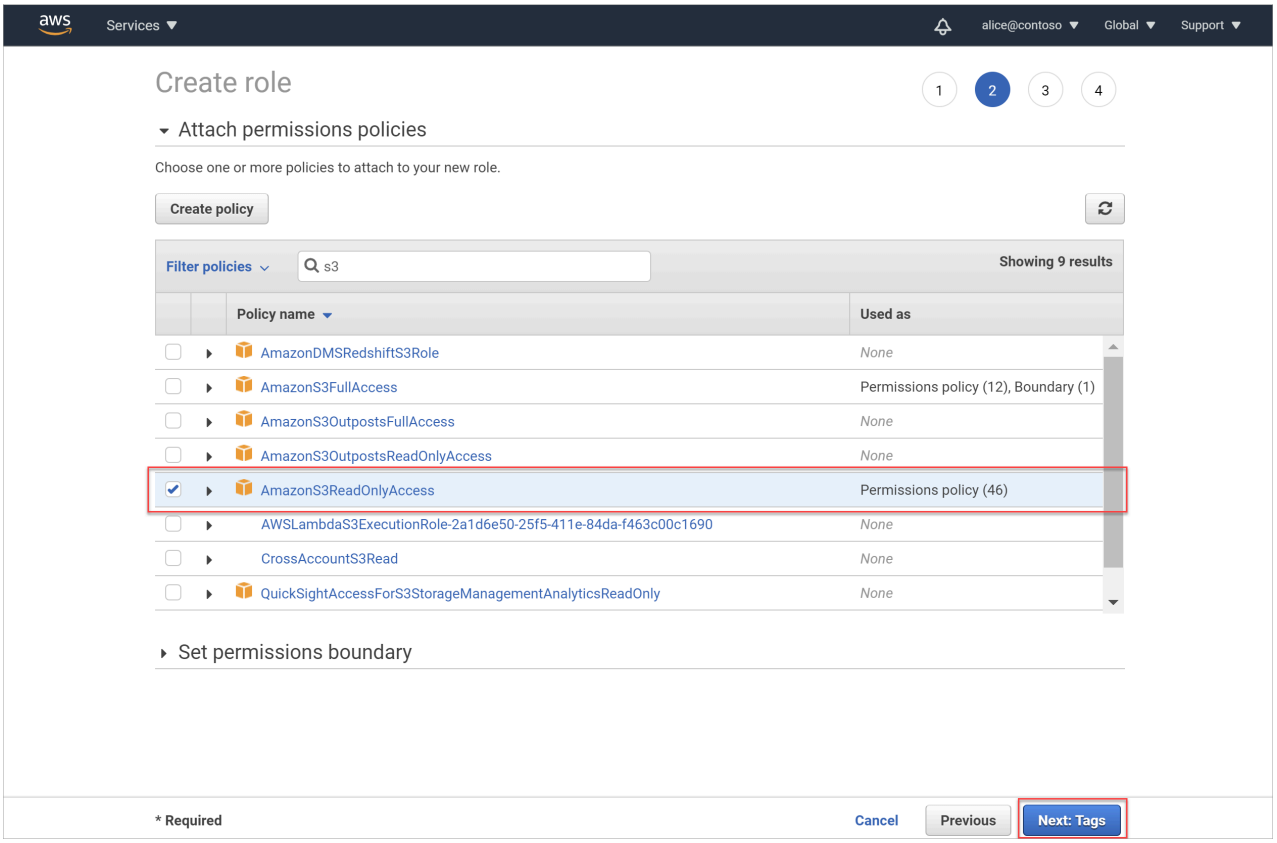
1. Open your **Amazon Web Services** console, and under **Security, Identity, and Compliance**, select **IAM**.



2. Select **Roles** and then **Create role**.

3. Select **Another AWS account**, and then enter the following values:

Expand table

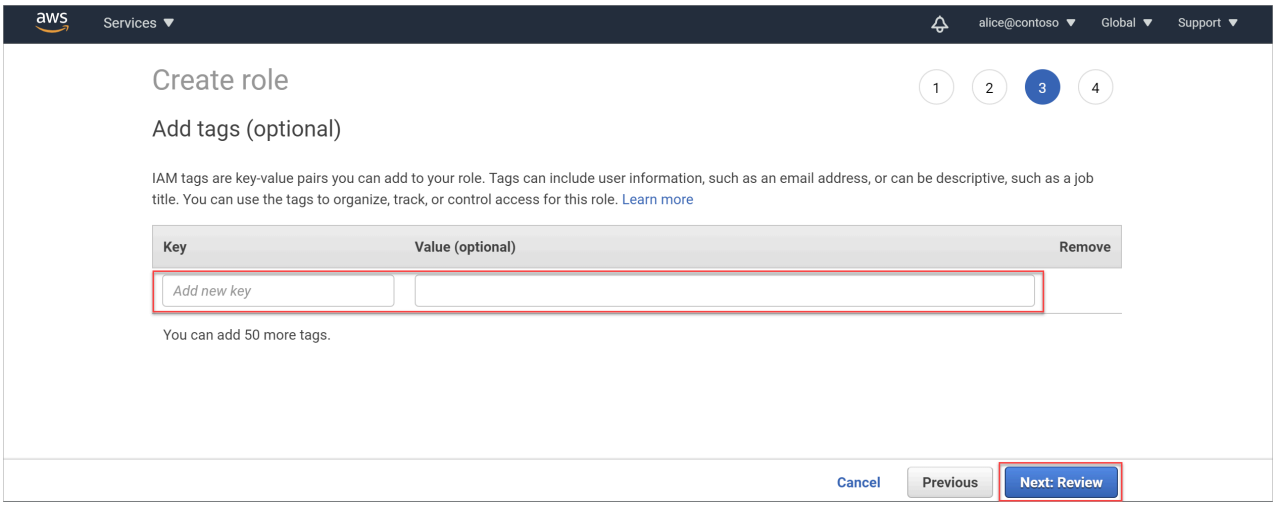


Field	Description
Account ID	Enter your Microsoft Account ID. For example: `181328463391`
External ID	Under options, select **Require external ID...**, and then enter your External ID in the designated field. For example: `e7e2b8a3-0a9f-414f-a065-afaf4ac6d994`

For example:

4. In the **Create role** > **Attach permissions policies** area, filter the permissions displayed to **S3**. Select **AmazonS3ReadOnlyAccess**. If you also want to be able to apply protection policies, add these permissions also:

    - GetBucketLocation
    - GetBucketPublicAccessBlock
    - GetObject
    - PutBucketPolicy
    - PutObjectTagging
    - DeleteBucketPolicy
    - List Bucket



> **ⓘ Important**
>
> The **AmazonS3ReadOnlyAccess** policy provides minimum permissions required for scanning your S3 buckets, and may include other permissions as well.
>
> To apply only the minimum permissions required for scanning your buckets, create a new policy with the permissions listed in Minimum permissions for your AWS policy, depending on whether you want to scan a single bucket or all the buckets in your account.
>
> Apply your new policy to the role instead of **AmazonS3ReadOnlyAccess.**

5. Select **Next: Tags.**

6. In the **Add tags (optional)** area, you can optionally choose to create a meaningful tag for this new role. Useful tags enable you to organize, track, and control access for each role you create.

   If you also want to be able to apply protection policies, add a tag with the key: `msftpurview_allowlisted` and the value `true`.

   Enter a new key and value for your tag as needed. When you're done, or if you want to skip this step, select **Next: Review** to review the role details and complete the role creation.

7. In the **Review** area, do the following:

    - In the **Role name** field, enter a meaningful name for your role
    - In the **Role description** box, enter an optional description to identify the role's purpose
    - In the **Policies** section, confirm that the correct policy (**AmazonS3ReadOnlyAccess**) is attached to the role.

    Then select **Create role** to complete the process. For example:

Extra required configurations:

- For buckets that use **AWS-KMS** encryption, special configuration is required to enable scanning.

- Make sure that your bucket policy doesn't block the connection. For more information, see:

- Confirm your bucket policy access
- Confirm your SCP policy access

Create a Microsoft Purview credential for your AWS S3 scan

This procedure describes how to create a new Microsoft Purview credential to use when scanning your AWS buckets.

> **Tip**
>
> If you're continuing directly on from Create a new AWS role for Microsoft Purview, you may already have the **New credential** pane open in Microsoft Purview.
>
> You can also create a new credential in the middle of the process, while configuring your scan. In that case, in the **Credential** field, select **New**.

1. In Microsoft Purview, go to the **Management Center**, and under **Security and access**, select **Credentials**.

2. Select **New**, and in the **New credential** pane that appears on the right, use the following fields to create your Microsoft Purview credential:

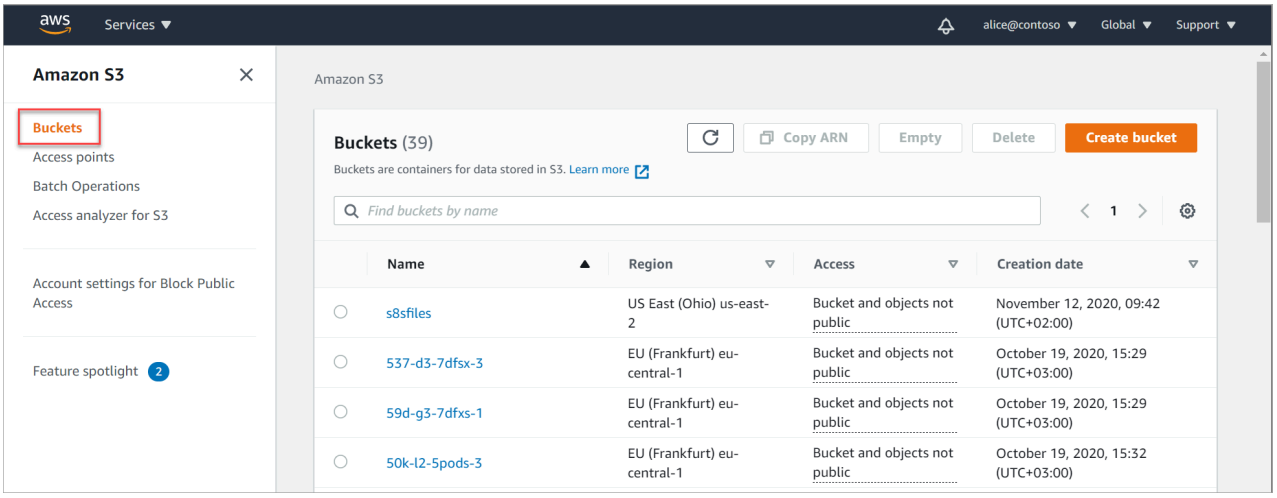
   Expand table

Field	Description
Name	Enter a meaningful name for this credential.
Description	Enter an optional description for this credential, such as `Used to scan the tutorial S3 buckets`
Authentication method	Select **Role ARN**, since you're using a role ARN to access your bucket.
Role ARN	Once you've created your Amazon IAM role, navigate to your role in the AWS IAM area, copy the **Role ARN** value, and enter it here. For example: `arn:aws:iam::181328463391:role/S3Role`. For more information, see Retrieve your new Role ARN.

   The **Microsoft account ID** and the **External ID** values are used when creating your Role ARN in AWS..

3. Select **Create** when you're done to finish creating the credential.

For more information about Microsoft Purview credentials, see Credentials for source authentication in Microsoft Purview.

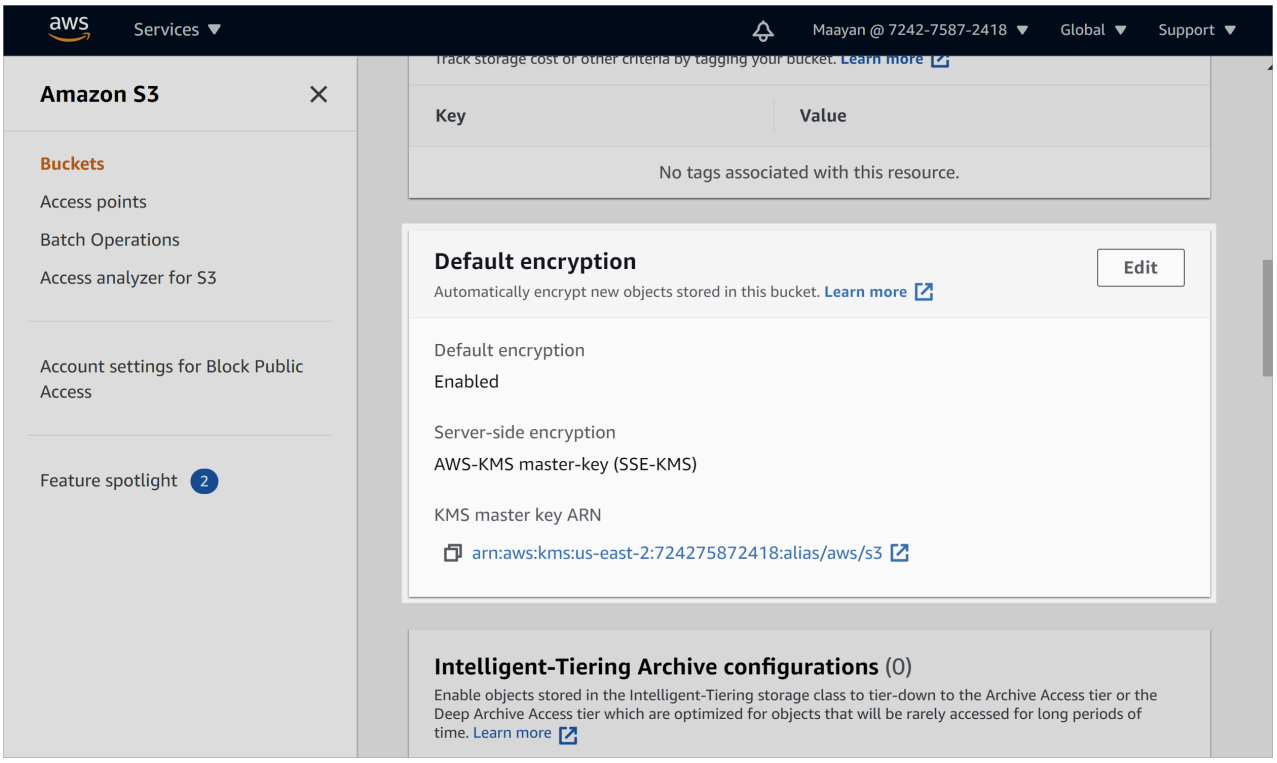


Configure scanning for encrypted Amazon S3 buckets

AWS buckets support multiple encryption types. For buckets that use **AWS-KMS** encryption, special configuration is required to enable scanning.

> **Note**
>
> For buckets that use no encryption, AES-256 or AWS-KMS S3 encryption, skip this section and continue to Retrieve your Amazon S3 bucket name.

To check the type of encryption used in your Amazon S3 buckets:

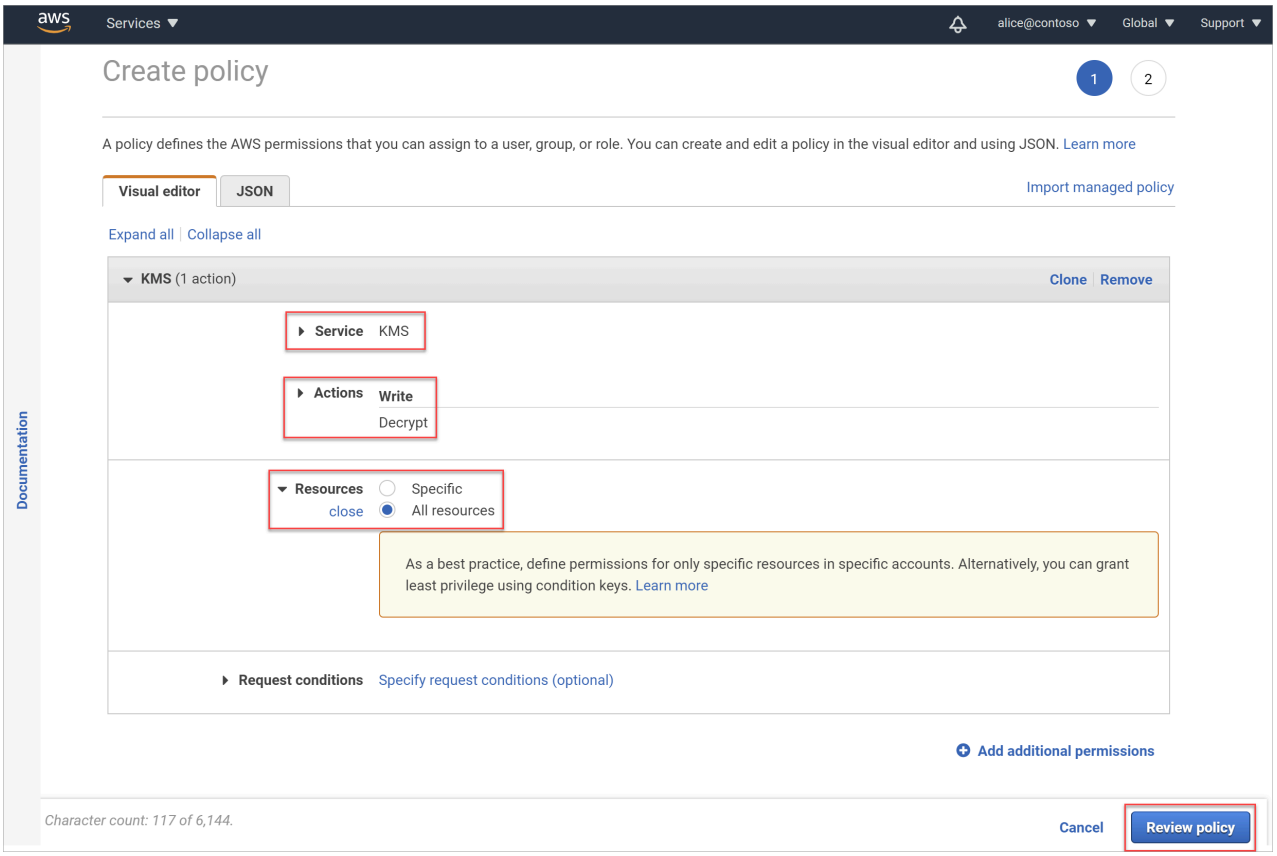


1. In AWS, navigate to **Storage** > **S3** > and select **Buckets** from the menu on the left.

2. Select the bucket you want to check. On the bucket's details page, select the **Properties** tab and scroll down to the **Default encryption** area.

    - If the bucket you selected is configured for anything but **AWS-KMS** encryption, including if default encryption for your bucket is **Disabled**, skip the rest of this procedure and continue with Retrieve your Amazon S3 bucket name.
    - If the bucket you selected is configured for **AWS-KMS** encryption, continue as described below to add a new policy that allows for scanning a bucket with custom **AWS-KMS** encryption.

    For example:



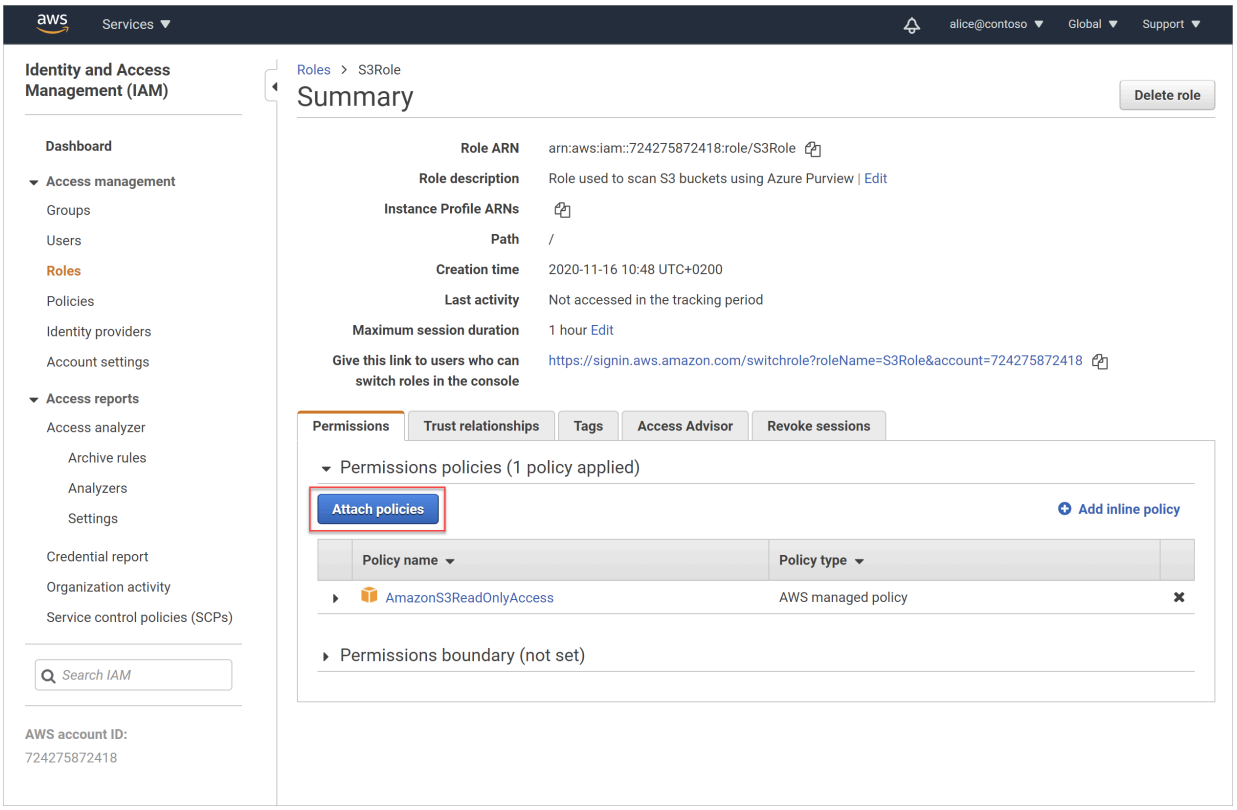
To add a new policy to allow for scanning a bucket with custom AWS-KMS encryption:

1. In AWS, navigate to **Services** > **IAM** > **Policies**, and select **Create policy**.
2. On the **Create policy** > **Visual editor** tab, define your policy with the following values:

Expand table

Field	Description
Service	Enter and select **KMS**.
Actions	Under **Access level**, select **Write** to expand the **Write** section. Once expanded, select only the **Decrypt** option.
Resources	Select a specific resource or **All resources**.

When you're done, select **Review policy** to continue.



3. On the **Review policy** page, enter a meaningful name for your policy and an optional description, and then select **Create policy**.

   The newly created policy is added to your list of policies.

4. Attach your new policy to the role you added for scanning.

   a. Navigate back to the **IAM** > **Roles** page, and select the role you added earlier.

   b. On the **Permissions** tab, select **Attach policies**.

c. On the **Attach Permissions** page, search for and select the new policy you created above. Select **Attach policy** to attach your policy to the role.

The **Summary** page is updated, with your new policy attached to your role.

Confirm your bucket policy access

Make sure that the S3 bucket policy doesn't block the connection:

1. In AWS, navigate to your S3 bucket, and then select the **Permissions** tab > **Bucket policy**.
2. Check the policy details to make sure that it doesn't block the connection from the Microsoft Purview scanner service.

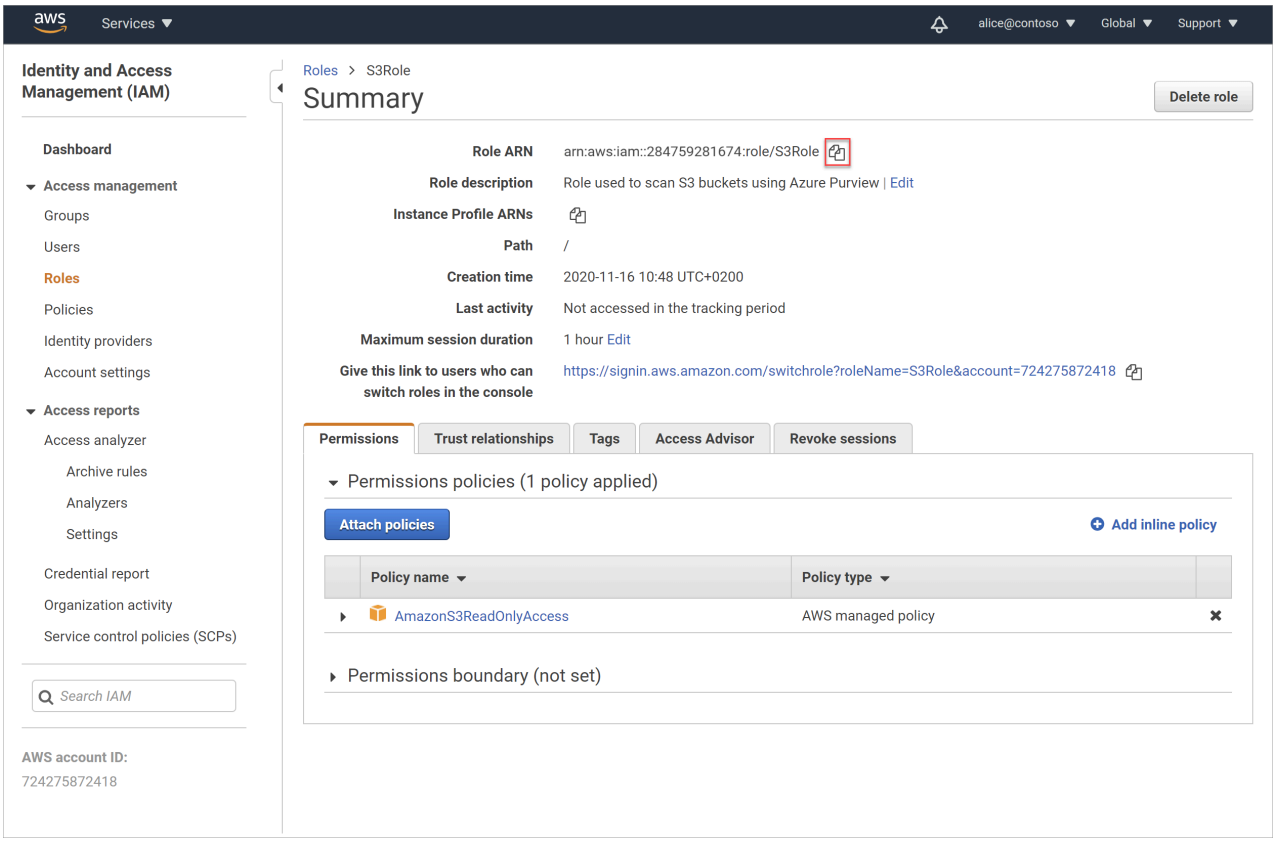
Confirm your SCP policy access

Make sure that there's no SCP policy that blocks the connection to the S3 bucket.

For example, your SCP policy might block read API calls to the AWS Region where your S3 bucket is hosted.

- Required API calls, which must be allowed by your SCP policy, include: `AssumeRole`, `GetBucketLocation`, `GetObject`, `ListBucket`, `GetBucketPublicAccessBlock`.
- Your SCP policy must also allow calls to the **us-east-1** AWS Region, which is the default Region for API calls. For more information, see the AWS documentation.

Follow the SCP documentation, review your organization's SCP policies, and make sure all the permissions required for the Microsoft Purview scanner are available.



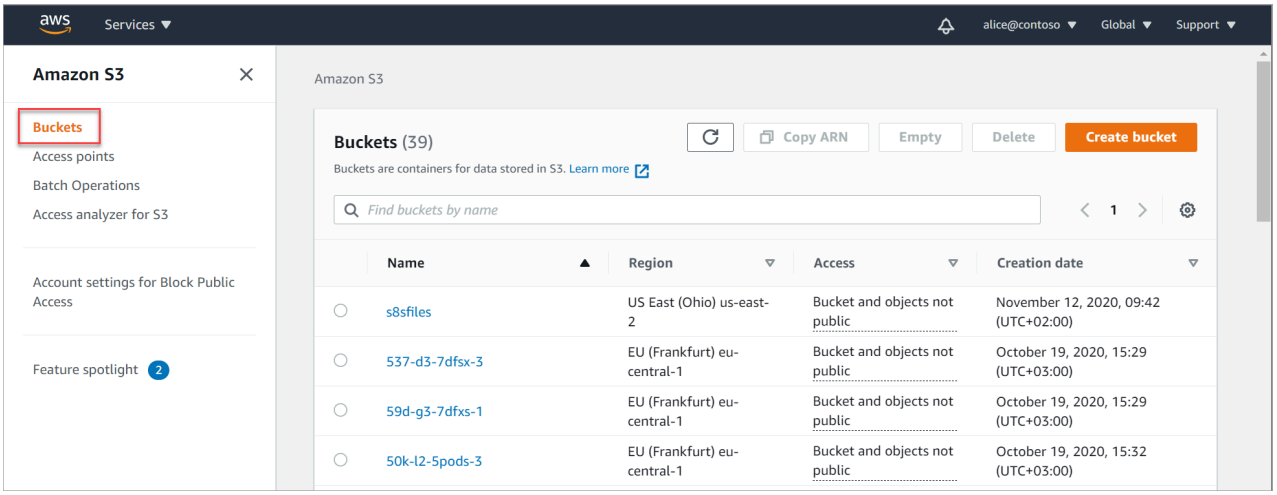
Retrieve your new Role ARN

You need to record your AWS Role ARN and copy it in to Microsoft Purview when creating a scan for your Amazon S3 bucket.

To retrieve your role ARN:

1. In the AWS **Identity and Access Management (IAM)** > **Roles** area, search for and select the new role you created for Microsoft Purview.

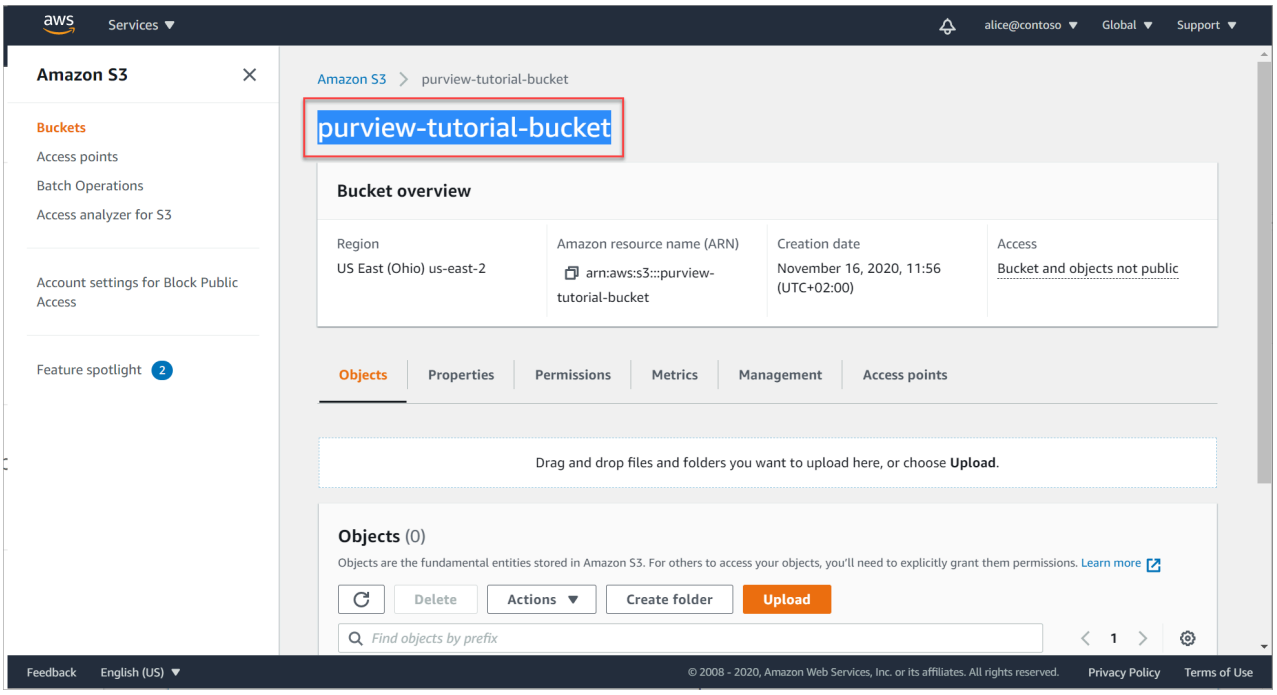
2. On the role's **Summary** page, select the **Copy to clipboard** button to the right of the **Role ARN** value.



In Microsoft Purview, you can edit your credential for AWS S3, and paste the retrieved role in the **Role ARN** field. For more information, see Create a scan for one or more Amazon S3 buckets.

Retrieve your Amazon S3 bucket name

You need the name of your Amazon S3 bucket to copy it in to Microsoft Purview when creating a scan for your Amazon S3 bucket



To retrieve your bucket name:

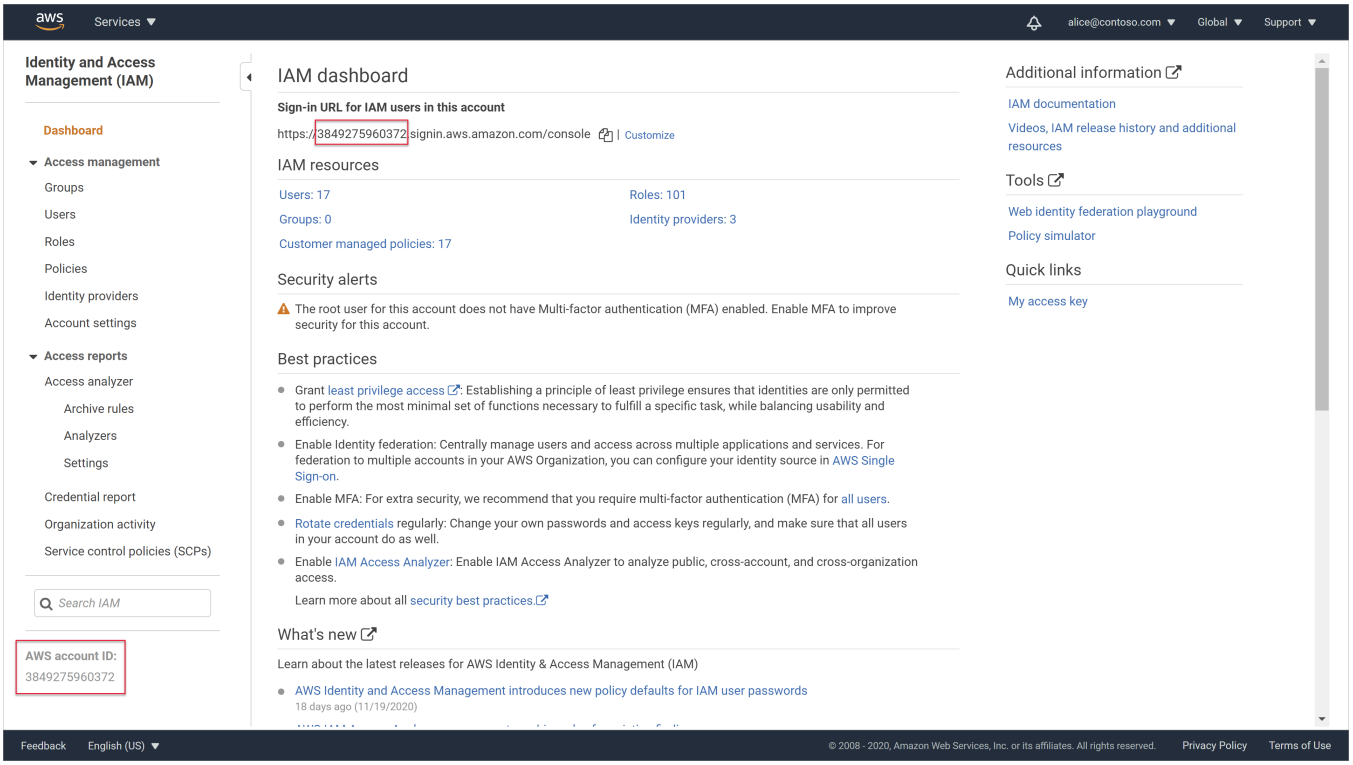
1. In AWS, navigate to **Storage** > **S3** > and select **Buckets** from the menu on the left.

2. Search for and select your bucket to view the bucket details page, and then copy the bucket name to the clipboard.

   For example:

   Paste your bucket name in a secure file, and add an `s3://` prefix to it to create the value you need to enter when configuring your bucket as a Microsoft Purview account.

   For example: `s3://purview-tutorial-bucket`



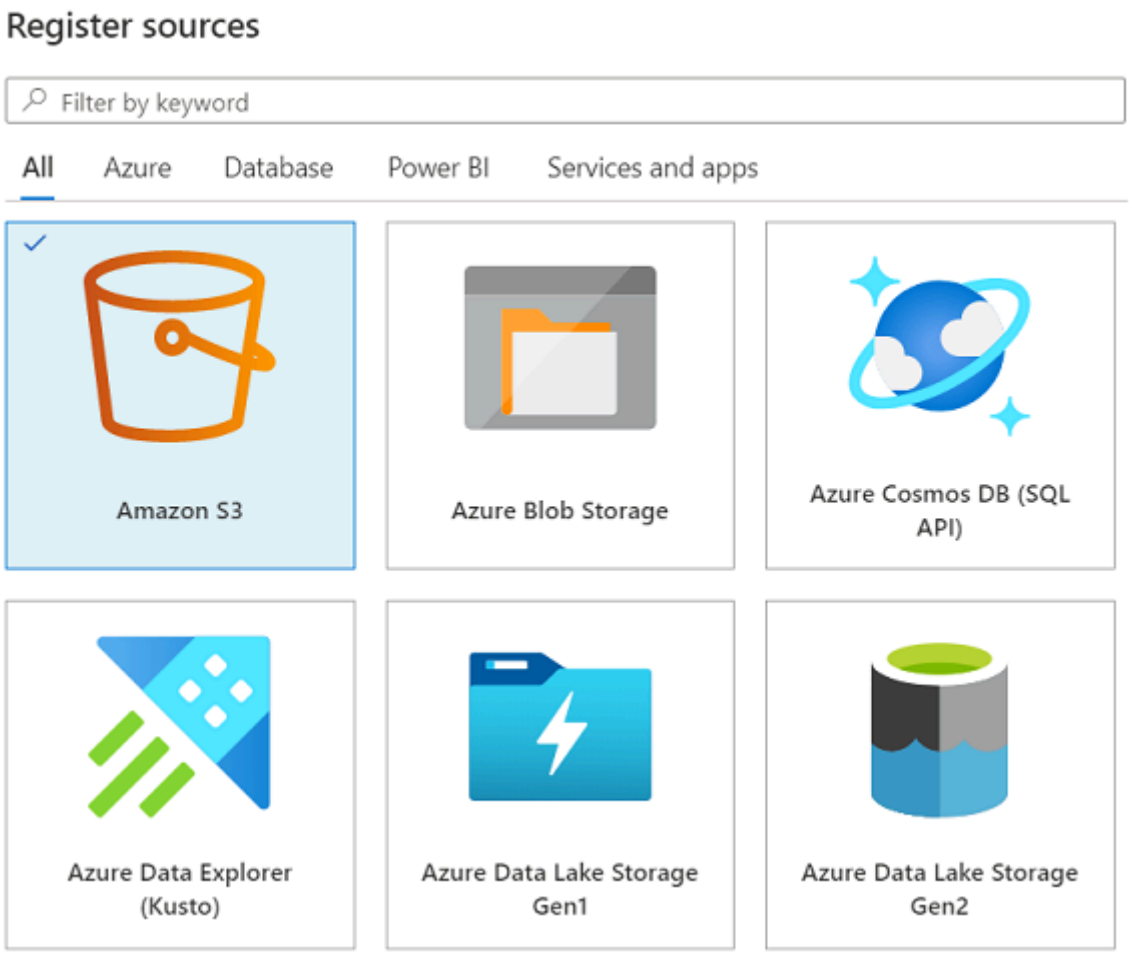
> **Tip**
>
> Only the root level of your bucket is supported as a Microsoft Purview data source. For example, the following URL, which includes a sub-folder is *not* supported: `s3://purview-tutorial-bucket/view-data`
>
> However, if you configure a scan for a specific S3 bucket, you can select one or more specific folders for your scan. For more information, see the step to scope your scan.

Locate your AWS account ID

You need your AWS account ID to register your AWS account as a Microsoft Purview data source, together with all of its buckets.

Your AWS account ID is the ID you use to sign in to the AWS console. You can also find it once you're logged in on the IAM dashboard, on the left under the navigation options, and at the top, as the numerical part of your sign-in URL:

For example:



Add a single Amazon S3 bucket as a Microsoft Purview account

Use this procedure if you only have a single S3 bucket that you want to register to Microsoft Purview as a data source, or if you have multiple buckets in your AWS account, but don't want to register all of them to Microsoft Purview.

To add your bucket:

1. In Microsoft Purview, go to the **Data Map**, and select **Data sources** > **Register** > **Amazon S3** > **Continue**.

> **Tip**
>
> If you have multiple collections and want to add your Amazon S3 to a specific collection, select the **Map view** at the top right, and then select the **Register** button inside your collection.

2. In the **Register sources (Amazon S3)** pane that opens, enter the following details:

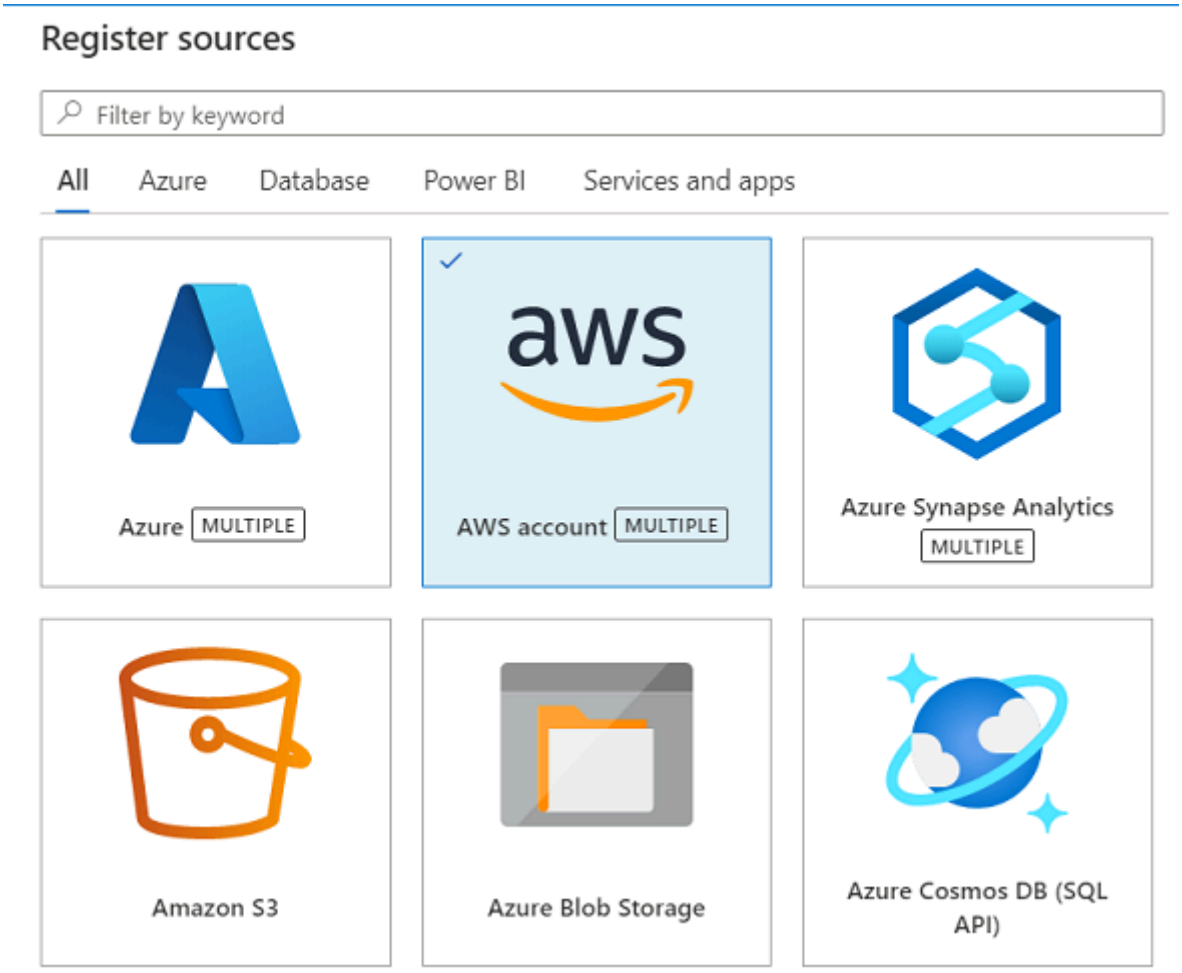
Expand table

Field	Description
Name	Enter a meaningful name, or use the default provided.
Bucket URL	Enter your AWS bucket URL, using the following syntax: `s3://<bucketName>` **Note**: Make sure to use only the root level of your bucket. For more information, see Retrieve your Amazon S3 bucket name.
Select a collection	If you selected to register a data source from within a collection, that collection already listed. Select a different collection as needed, **None** to assign no collection, or **New** to

Field	Description
	create a new collection now. For more information about Microsoft Purview collections, see Manage data sources in Microsoft Purview.

When you're done, select **Finish** to complete the registration.

Continue with Create a scan for one or more Amazon S3 buckets..



Add an AWS account as a Microsoft Purview account

Use this procedure if you have multiple S3 buckets in your Amazon account, and you want to register all of them as Microsoft Purview data sources.

When configuring your scan, you are able to select the specific buckets you want to scan, if you don't want to scan all of them together.

To add your Amazon account:

1. In Microsoft Purview, go to the **Data Map** page, and select **Data sources** > **Register** > **Amazon accounts** > **Continue**.

> **Tip**
>
> If you have multiple collections and want to add your Amazon S3 to a specific collection, select the **Map view** at the top right, and then select the **Register** button inside your collection.

2. In the **Register sources (Amazon S3)** pane that opens, enter the following details:

Expand table

Field	Description
Name	Enter a meaningful name, or use the default provided.
AWS account ID	Enter your AWS account ID. For more information, see Locate your AWS account ID
Select a collection	If you selected to register a data source from within a collection, that collection already listed. Select a different collection as needed, **None** to assign no collection, or **New** to create a new collection now.

Field	Description
	For more information about Microsoft Purview collections, see Manage data sources in Microsoft Purview.

When you're done, select **Finish** to complete the registration.

Continue with Create a scan for one or more Amazon S3 buckets.

Create a scan for one or more Amazon S3 buckets

Once you've added your buckets as Microsoft Purview data sources, you can configure a scan to run at scheduled intervals or immediately.

1. Select the **Data Map** in the Microsoft Purview portal:

   - In the **Map view**, select **New scan** in your data source box.
   - In the **List view**, hover over the row for your data source, and select **New scan**.

2. On the **Scan...** pane that opens on the right, define the following fields and then select **Continue**:

Expand table

Field	Description
Name	Enter a meaningful name for your scan or use the default.
Type	Displayed only if you've added your AWS account, with all buckets included. Current options include only **All** > **Amazon S3**. Stay tuned for more options to select as Microsoft Purview's support matrix expands.
Credential	Select a Microsoft Purview credential with your role ARN. **Tip**: If you want to create a new credential at this time, select **New**. For more information, see Create a Microsoft Purview credential for your AWS bucket scan.
Amazon S3	Displayed only if you've added your AWS account, with all buckets included. Select one or more buckets to scan, or **Select all** to scan all the buckets in your account.

Microsoft Purview automatically checks that the role ARN is valid, and that the buckets and objects within the buckets are accessible, and then continues if the connection succeeds.

For **Integration runtime**, see the list of supported data sources for scans to choose the right integration runtime according to the scenario.

> **Tip**
>
> To enter different values and test the connection yourself before continuing, select **Test connection** at the bottom right before selecting **Continue**.

3. On the **Scope your scan** pane, select the specific buckets or folders you want to include in your scan.

   When creating a scan for an entire AWS account, you can select specific buckets to scan. When creating a scan for a specific AWS S3 bucket, you can select specific folders to scan.

4. On the **Select a scan rule set** pane, either select the **AmazonS3** default rule set, or select **New scan rule set** to create a new custom rule set. Once you have your rule set selected, select **Continue**.

   If you select to create a new custom scan rule set, use the wizard to define the following settings:

Expand table

Pane	Description
New scan rule set / **Scan rule description**	Enter a meaningful name and an optional description for your rule set
Select file types	Select all the file types you want to include in the scan, and then select **Continue**. To add a new file type, select **New file type**, and define the following: - The file extension you want to add - An optional description - Whether the file contents have a custom delimiter, or are a system file type. Then, enter your custom delimiter, or select your system file type. Select **Create** to create your custom file type.
Select classification rules	Navigate to and select the classification rules you want to run on your dataset.

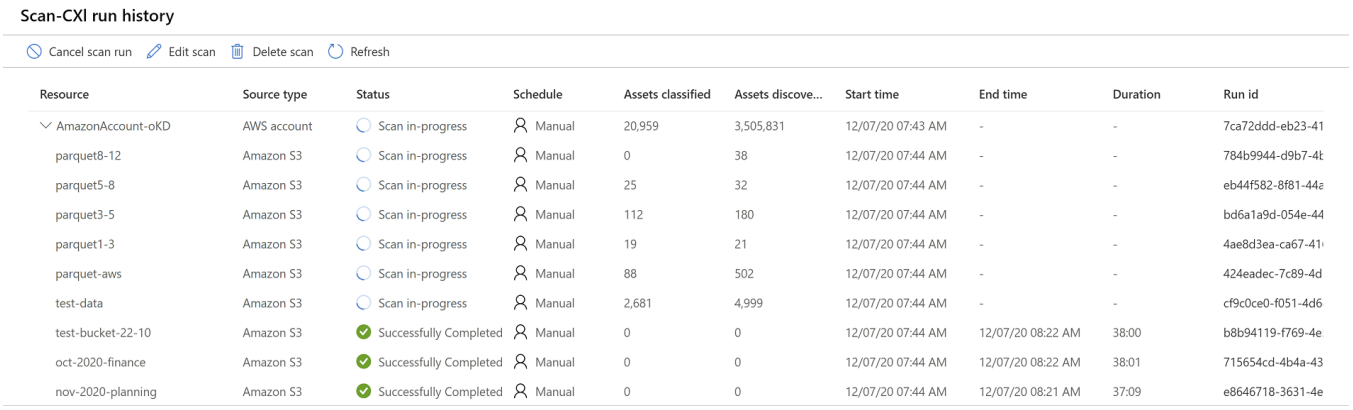
   Select **Create** when you're done to create your rule set.

5. On the **Set a scan trigger** pane, select one of the following, and then select **Continue**:

    - **Recurring** to configure a schedule for a recurring scan
    - **Once** to configure a scan that starts immediately

6. On the **Review your scan** pane, check your scanning details to confirm that they're correct, and then select **Save** or **Save and Run** if you selected **Once** in the previous pane.

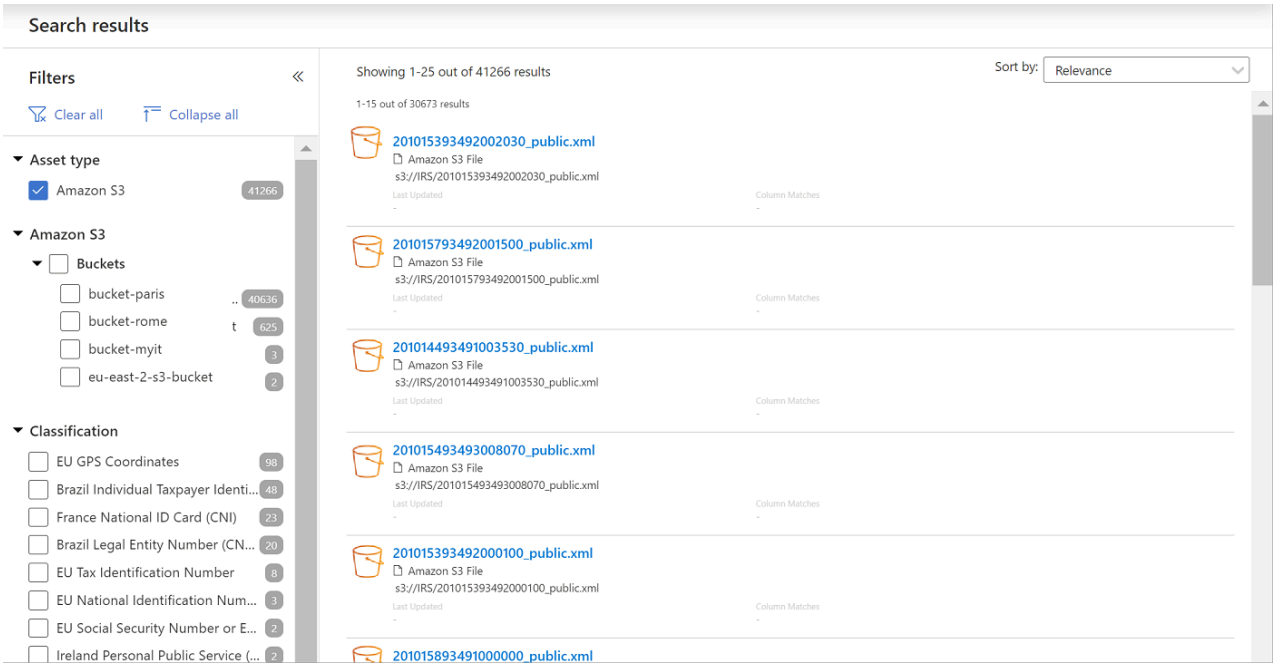
    > **Note**
    >
    > Once started, scanning can take up to 24 hours to complete. You'll be able to review your **Insight Reports** and search the catalog 24 hours after you started each scan.



For more information, see Explore Microsoft Purview scanning results.

Explore Microsoft Purview scanning results

Once a Microsoft Purview scan is complete on your Amazon S3 buckets, drill down in the Microsoft Purview **Data Map** area to view the scan history.



Select a data source to view its details, and then select the **Scans** tab to view any currently running or completed scans. If you've added an AWS account with multiple buckets, the scan history for each bucket is shown under the account.

For example:

Use the other areas of Microsoft Purview to find out details about the content in your data estate, including your Amazon S3 buckets:

- **Search the Microsoft Purview Unified Catalog,** and filter for a specific bucket. For example:

- **View Insight reports** to view statistics for the classification, sensitivity labels, file types, and more details about your content.

  All Microsoft Purview Insight reports include the Amazon S3 scanning results, along with the rest of the results from your Azure data sources. When relevant, another **Amazon S3** asset type was added to the report filtering options.

  For more information, see the Understand Data Estate Insights in Microsoft Purview.

Minimum permissions for your AWS policy

The default procedure for creating an AWS role for Microsoft Purview to use when scanning your S3 buckets uses the **AmazonS3ReadOnlyAccess** policy.

The **AmazonS3ReadOnlyAccess** policy provides minimum permissions required for scanning your S3 buckets, and might include other permissions as well.

To apply only the minimum permissions required for scanning your buckets, create a new policy with the permissions listed in the following sections, depending on whether you want to scan a single bucket or all the buckets in your account.

Apply your new policy to the role instead of **AmazonS3ReadOnlyAccess.**

Individual buckets

When scanning individual S3 buckets, minimum AWS permissions include:

- `GetBucketLocation`

- `GetBucketPublicAccessBlock`
- `GetObject`
- `ListBucket`

Make sure to define your resource with the specific bucket name. For example:

JSON

```
{
"Version": "2012-10-17",
"Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketLocation",
                "s3:GetBucketPublicAccessBlock",
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::<bucketname>"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3::: <bucketname>/*"
        }
    ]
}
```

All buckets in your account

When scanning all the buckets in your AWS account, minimum AWS permissions include:

- `GetBucketLocation`
- `GetBucketPublicAccessBlock`
- `GetObject`
- `ListAllMyBuckets`
- `ListBucket`.

Make sure to define your resource with a wildcard. For example:

JSON

```
{
"Version": "2012-10-17",
"Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketLocation",
                "s3:GetBucketPublicAccessBlock",
                "s3:GetObject",
                "s3:ListAllMyBuckets",
                "s3:ListBucket"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "*"
        }
    ]
}
```

Troubleshooting

Scanning Amazon S3 resources requires creating a role in AWS IAM to allow the Microsoft Purview scanner service running in a Microsoft account in AWS to read the data.

Configuration errors in the role can lead to connection failure. This section describes some examples of connection failures that might occur while setting up the scan, and the troubleshooting guidelines for each case.

If all of the items described in the following sections are properly configured, and scanning S3 buckets still fails with errors, contact Microsoft support.

> **Note**
>
> For policy access issues, make sure that neither your bucket policy, nor your SCP policy are blocking access to your S3 bucket from Microsoft Purview.
>
> For more information, see Confirm your bucket policy access and Confirm your SCP policy access.

Bucket is encrypted with KMS

Make sure that the AWS role has **KMS Decrypt** permissions. For more information, see Configure scanning for encrypted Amazon S3 buckets.

AWS role is missing an external ID

Make sure that the AWS role has the correct external ID:

1. In the AWS IAM area, select the **Role** > **Trust relationships** tab.
2. Follow the steps in Create a new AWS role for Microsoft Purview again to verify your details.

Error found with the role ARN

This is a general error that indicates an issue when using the Role ARN. For example, you may want to troubleshoot as follows:

- Make sure that the AWS role has the required permissions to read the selected S3 bucket. Required permissions include `AmazonS3ReadOnlyAccess` or the minimum read permissions, and `KMS Decrypt` for encrypted buckets.

- Make sure that the AWS role has the correct Microsoft account ID. In the AWS IAM area, select the **Role** > **Trust relationships** tab and then follow the steps in Create a new AWS role for Microsoft Purview again to verify your details.

For more information, see Can't find the specified bucket,

Can't find the specified bucket

Make sure that the S3 bucket URL is properly defined:

1. In AWS, navigate to your S3 bucket, and copy the bucket name.
2. In Microsoft Purview, edit the Amazon S3 data source, and update the bucket URL to include your copied bucket name, using the following syntax: `s3://<BucketName>`

Protection policy

Protection access control policies (protection policies) enable organizations to automatically protect sensitive data across data sources. Microsoft Purview already scans data assets and identifies sensitive data elements, and this new feature allows you to automatically restrict access to that data using sensitivity labels from Microsoft Purview Information Protection.

To set up protection policies for Amazon S3 sources, see: How to create protection policies for Amazon S3.

Scans and ingestion in Data Map

This article provides an overview of the scanning and ingestion features in Microsoft Purview Data Map. These features connect your Microsoft Purview account to your sources to populate Data Map and Unified Catalog so you can begin exploring and managing your data through Microsoft Purview.

- **Scanning** captures metadata from data sources and brings it to Microsoft Purview.
- **Ingestion** processes metadata and stores it in Unified Catalog from both:
  - Data source scans - scanned metadata is added to Data Map.
  - Lineage connections - transformation resources add metadata about their sources, outputs, and activities to Data Map.

Scanning

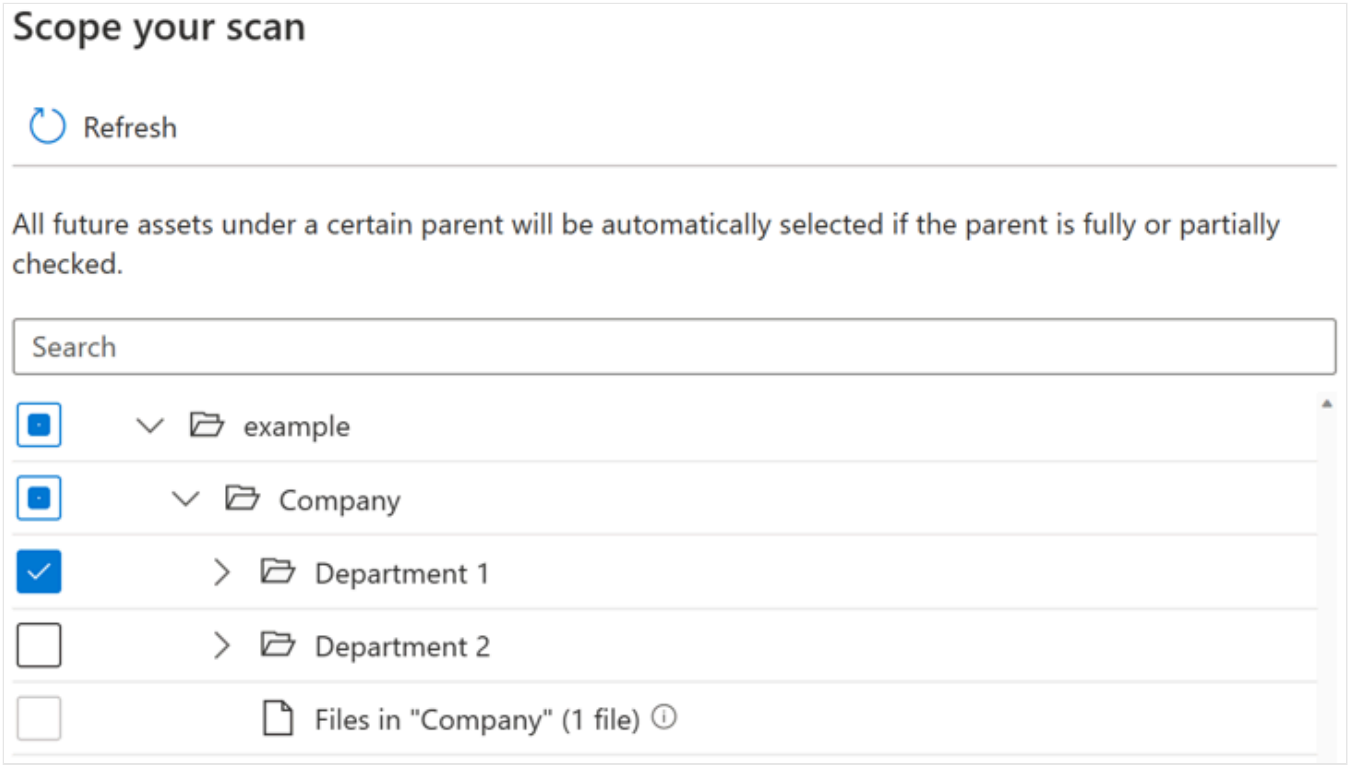
After you register data sources in your Microsoft Purview account, scan the data sources. The scanning process connects to the data source and captures technical metadata like names, file size, columns, and more. It also extracts schema for structured data sources, applies classifications on schemas, and applies sensitivity labels if your Data Map is connected to Microsoft Purview portal. You can trigger the scanning process to run immediately or schedule it to run periodically to keep your Microsoft Purview account up to date.

For each scan, you can customize the process so that you only scan the information you need, rather than the whole source.

Choose an authentication method for your scans

Microsoft Purview is secure by default. It doesn't store passwords or secrets directly, so you need to choose an authentication method for your sources. You can authenticate your Microsoft Purview account in several ways, but not all methods are supported for each data source.

- Managed Identity
- Service Principal
- SQL Authentication
- Windows Authentication
- Role ARN
- Delegated Authentication
- Consumer Key
- Account Key or Basic Authentication

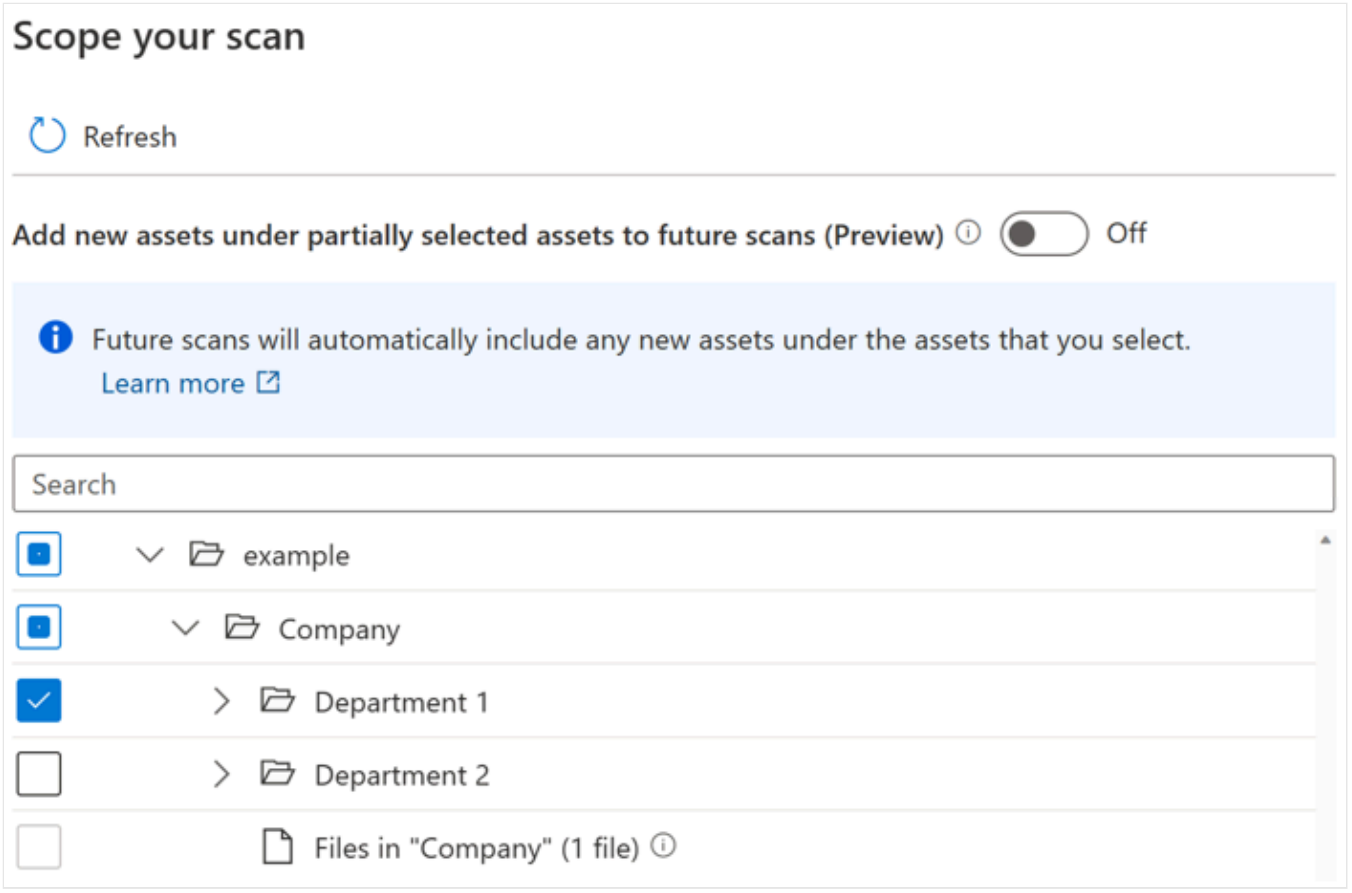


Whenever possible, use a Managed Identity because it eliminates the need for storing and managing credentials for individual data sources. This method can greatly reduce the time you and your team spend setting up and troubleshooting authentication for scans. When you enable a managed identity for your Microsoft Purview account, an identity is created in Microsoft Entra ID (Entra ID) and is tied to the lifecycle of your account.

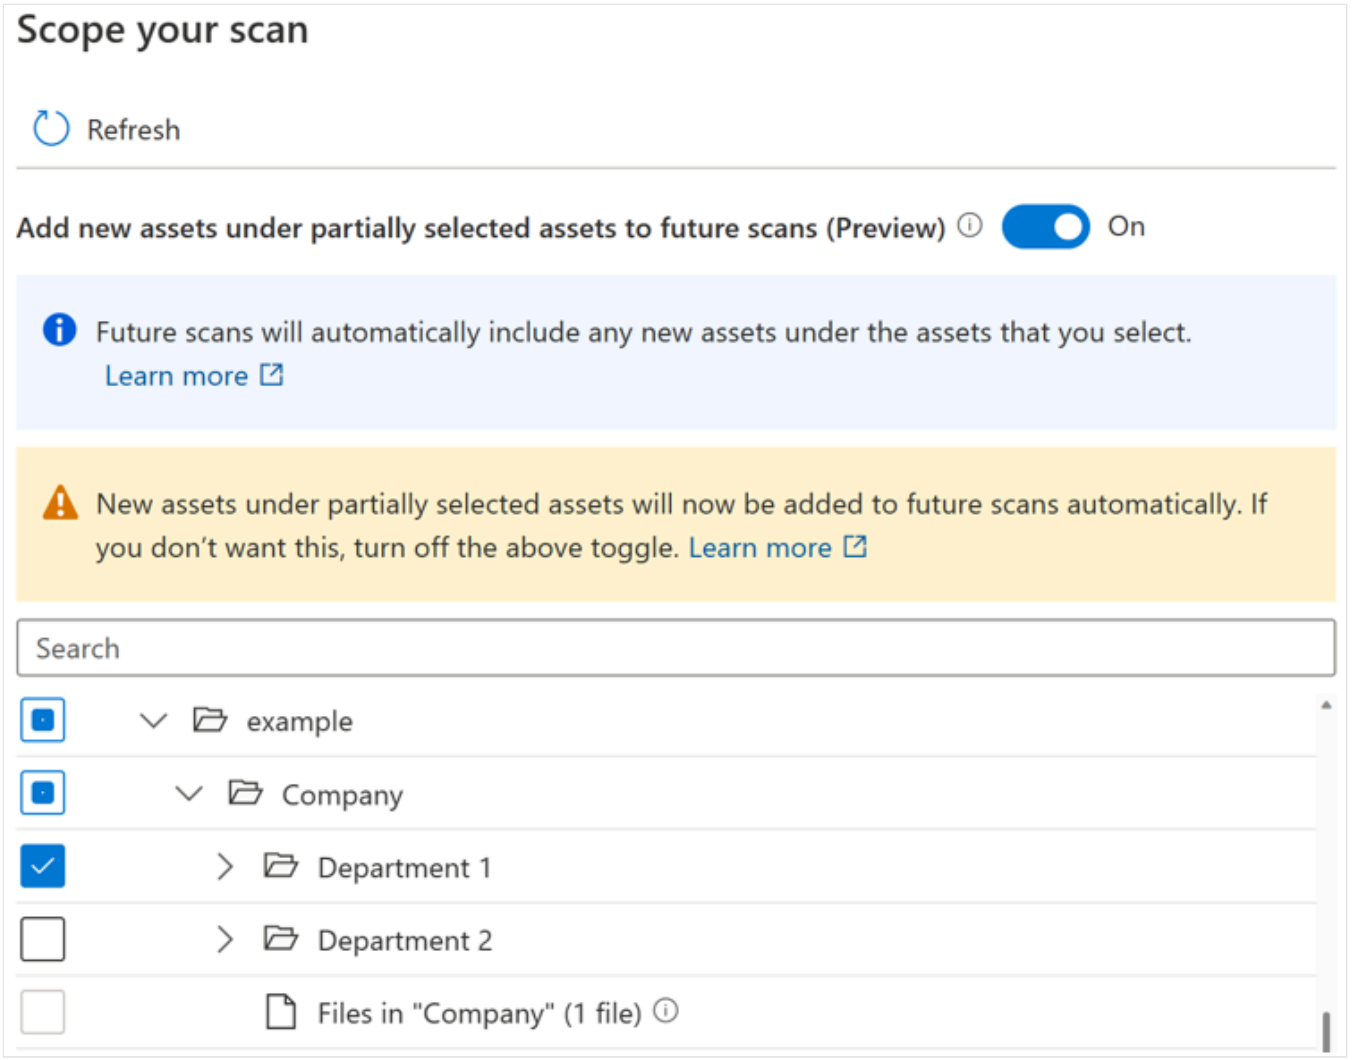
Scope your scan

When scanning a source, you can scan the entire data source or choose only specific entities (folders or tables) to scan. The available options depend on the source you're scanning. You can define these options for both one-time and scheduled scans.

For example, when creating and running a scan for an Azure SQL Database, you can choose which tables to scan, or select the entire database.



For each entity (folder or table), three selection states exist: fully selected, partially selected, and not selected. In the following example, if you select **Department 1** on the folder hierarchy, **Department 1** is considered as fully selected. The parent entities for **Department 1**, which are **Company** and **example**, are considered as partially selected, since the other entities under the same parent (for example, **Department 2**) aren't selected. Different icons are used on the UI for entities with different selection states.



After you run the scan, it's likely that new assets will be added in the source system. By default, future assets under a certain parent are automatically selected if the parent is fully or partially selected when you run the scan again. In the preceding example, after you select **Department 1**

and run the scan, any new assets under folder **Department 1** or under **Company** and **example** are included when you run the scan again.

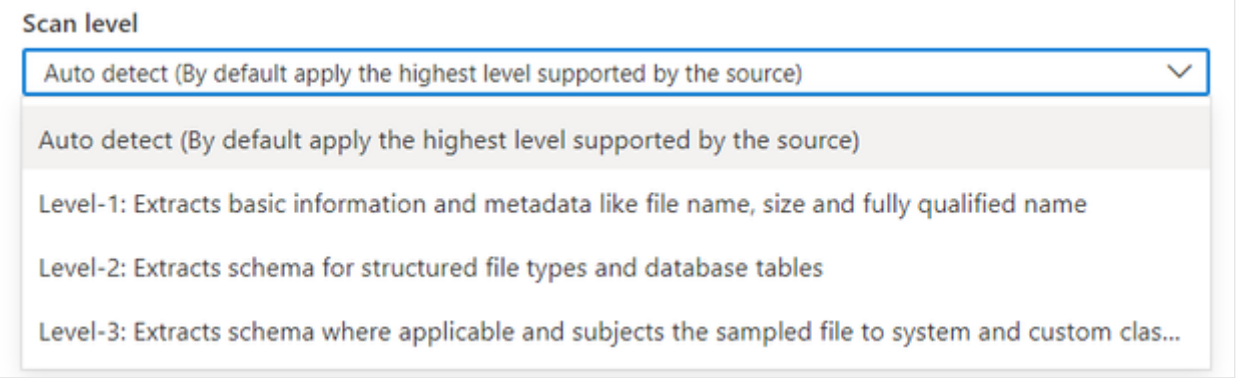
A toggle button, as seen in the image below, allows users to control the automatic inclusion for new assets under partially selected parent. By default, the toggle is turned off and the automatic inclusion behavior for a partially selected parent is disabled. With the toggle turned off, any new assets under partially selected parents like **Company** and **example** aren't included when you run the scan again; only new assets under **Department 1** are included in future scan.

If the toggle is turned on, the new assets under a parent are automatically selected if the parent is fully or partially selected when you run the scan again. The inclusion behavior is the same as before the toggle is introduced.

> **Note**
>
> - The availability of the toggle button depends on the data source type. Currently it's available in public preview for sources including Azure Blob Storage, Azure Data Lake Storage Gen 1, Azure Data Lake Storage Gen 2, Azure Files, and Azure Dedicated SQL pool (formerly SQL DW).
> - For any scans created or scheduled before the toggle is introduced, the toggle state is set as **On** and can't be changed. For any scans created or scheduled after the toggle is introduced, the toggle state can't be changed after the scan is saved. You need to create a new scan to change the toggle state.
> - When the toggle is turned off, for sources of storage type like Azure Data Lake Storage Gen 2, it can take up to four hours before the browse by source type experience becomes fully available after your scan job is completed.

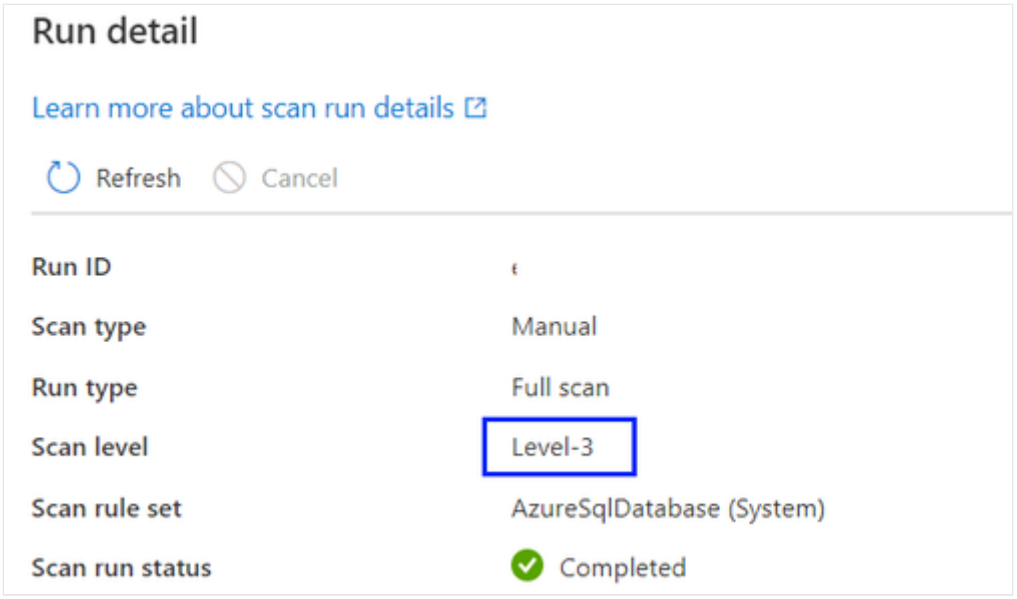
Known limitations

When the toggle is turned off:



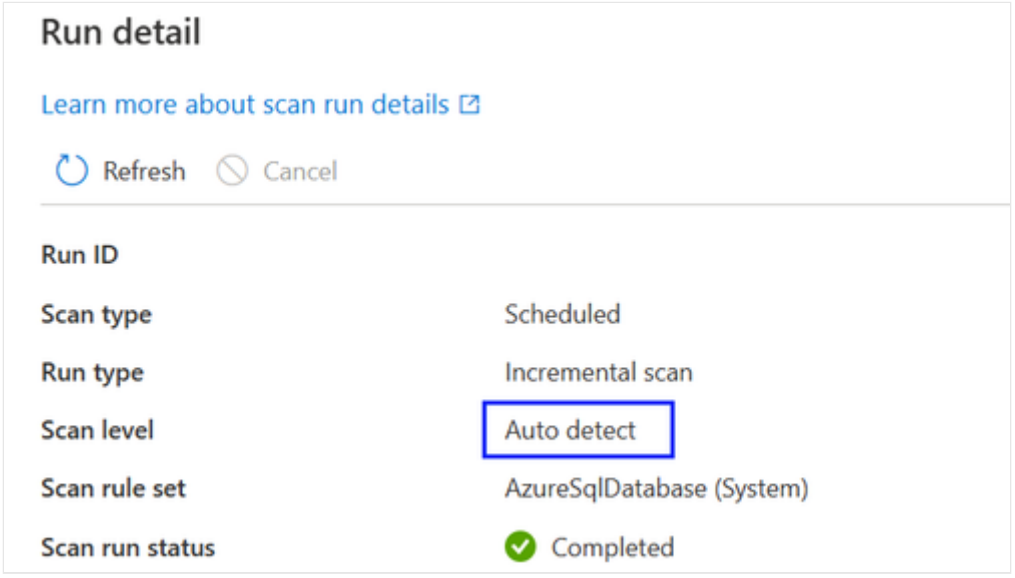
- The file entities under a partially selected parent aren't scanned.
- If all existing entities under a parent are explicitly selected, the parent is considered fully selected, and any new assets under the parent are included when you run the scan again.

Customize scan level



In Data Map terminology, three different levels of scanning exist based on the metadata scope and functionalities:

- L1 scan: Extracts basic information and metadata like file name, size, and fully qualified name
- L2 scan: Extracts schema for structured file types and database tables
- L3 scan: Extracts schema where applicable and subjects the sampled file to the system and custom classification rules



When you set up a new scan or edit an existing scan, you can customize the scan level for scanning data sources that support the scan level configuration.

By default, the "Auto detect" will be selected, which means Microsoft Purview applies the highest scan level available for this data source. Take Azure SQL Database as an example, the "Auto detect" will be resolved as “Level-3” when the scan is executed as the data source has already supported classification in Microsoft Purview. The scan level in the scan run detail shows the actual level applied.

For all scan runs in the scan history that completed before customizing scan level as a new feature, the scan level is set and displayed as **Auto detect**.

- When a higher scan level becomes available for a data source, the saved or scheduled scans that have scan level set to **Auto detect** automatically apply the new scan level. For example, if classification as a new feature is enabled for a given data source, all existing scans on this data source automatically apply classification.
- The scan level setting shows in the scan monitoring interface for each scan run.
- If you select **Level-1**, scanning returns only basic technical metadata like asset name, asset size, modified timestamp, and more, based on the existing metadata availability of a specific data source. For SQL Database, the process creates asset entities like tables in Data Map but doesn't extract the table schema. (Note: users can still see the table schema via live view if they have necessary permissions in the source system).
- If you select **Level-2**, scanning returns table schemas and basic technical metadata, but it doesn't perform data sampling and classification. For Azure SQL Database, table asset

entities capture the table schema without classification information.

- If you select **Level-3**, scanning performs the data sampling and classification. This is a standard configuration for Azure SQL Database scanning before scan level as a new feature is introduced.
- If you set a scheduled scan to a lower scan level and later modify it to a higher scan level, the next scan run automatically performs a full scan and updates all existing data assets from the data source with metadata introduced by a higher scan level setting. For example, when you change a scheduled scan set with **Level-2** on an Azure SQL Database to **Level-3**, the next scan run is a full scan and updates all existing Azure SQL Database table and view assets with classification information. All scans thereafter resume as incremental scans set with **Level-3**.
- If you set a scheduled scan to a higher scan level and later modify it to a lower scan level, the next scan run continues to perform an incremental scan and all new data assets from the data source only have metadata introduced by a lower scan level setting. For example, when you change a scheduled scan set with **Level-3** on an Azure SQL Database to **Level-2**, the next scan run is an incremental scan and all new Azure SQL Database table and view assets added in Data Map have no classification information. All existing data assets still keep the classification information generated from the previous scan set with **Level-3**.

> ⓘ **Note**
>
> - Customizing scan level is currently available for the following data sources: Azure SQL Database, Azure SQL Managed Instance, Azure Cosmos DB for NoSQL, Azure Database for PostgreSQL, Azure Database for MySQL, Azure Data Lake Storage Gen2, Azure Blob Storage, Azure Files, Azure Synapse Analytics, Azure Dedicated SQL pool (formerly SQL DW), Azure Data Explorer, Dataverse, Azure Multiple (Azure Subscription), Azure Multiple (Azure Resource Group), Snowflake, Azure Databricks Unity Catalog
> - Currently the feature is only available on Azure integration runtime and Managed Virtual Network integration runtime v2.

Scan rule set

A scan rule set determines the kinds of information a scan looks for when it's running against one of your sources. Available rules depend on the kind of source you're scanning, but include things like the file types you should scan, and the kinds of classifications you need.

Many data source types already have system scan rule sets, but you can also create your own scan rule sets to tailor your scans to your organization.

Schedule your scan

Microsoft Purview gives you a choice of scanning daily, weekly, or monthly at a specific time you choose. Learn more about the supported schedule options. Daily or weekly scans might be appropriate for data sources with structures that are actively under development or frequently change. Monthly scanning is more appropriate for data sources that change infrequently. Work with the administrator of the source you want to scan to identify a time when compute demands on the source are low.

How scans detect deleted assets

A Microsoft Purview catalog is only aware of the state of a data store when it runs a scan. For the catalog to know if a file, table, or container is deleted, it compares the last scan output against the current scan output. For example, suppose that the last time you scanned an Azure Data Lake Storage Gen2 account, it included a folder named *folder1*. When the same account is scanned again, *folder1* is missing. Therefore, the catalog assumes the folder is deleted.

> **Tip**
>
> Because of how deleted files are detected, you might need multiple successful scans to detect and resolve deleted assets. If Unified Catalog isn't registering deletions for a scoped scan, try multiple full scans to resolve the issue.

Detecting deleted files

The logic for detecting missing files works for multiple scans by the same user and by different users. For example, suppose a user runs a one-time scan on a Data Lake Storage Gen2 data store on folders A, B, and C. Later, a different user in the same account runs a different one-time scan on folders C, D, and E of the same data store. Because folder C was scanned twice, the catalog checks it for possible deletions. Folders A, B, D, and E, however, were scanned only once, and the catalog doesn't check them for deleted assets.

To keep deleted files out of your catalog, it's important to run regular scans. The scan interval is important, because the catalog can't detect deleted assets until another scan is run. So, if you run scans once a month on a particular store, the catalog can't detect any deleted data assets in that store until you run the next scan a month later.

When you enumerate large data stores like Data Lake Storage Gen2, there are multiple ways (including enumeration errors and dropped events) to miss information. A particular scan might miss that a file was created or deleted. So, unless the catalog is certain a file is deleted, it doesn't delete it from the catalog. This strategy means there can be errors when a file that doesn't exist in the scanned data store still exists in the catalog. In some cases, a data store might need to be scanned two or three times before it catches certain deleted assets.

> ⓘ **Note**
>
> - Assets that are marked for deletion are deleted after a successful scan. Deleted assets might continue to be visible in your catalog for some time before they're processed and removed.
> - Deletion detection is supported only for these sources within Microsoft Purview: Azure Synapse Analytics workspaces, Azure Arc-enabled SQL Server, Azure Blob Storage, Azure Files, Azure Cosmos DB, Azure Data explorer, Azure Database for MySQL, Azure Database for PostgreSQL, Azure Dedicated SQL pool, Azure Machine Learning, Azure SQL Database, and Azure SQL Managed instance. For these sources, when an asset is deleted from the data source, subsequent scans will automatically remove the corresponding metadata and lineage in Microsoft Purview.

Ingestion

Ingestion is the process that populates Data Map with metadata gathered through its various processes.

> ⓘ **Note**
>
> The combined count of all child objects (referred entities) and contacts (owner, expert) must not exceed 20,000 entities.

Ingestion from scans

The scanning process identifies technical metadata or classifications and sends them to ingestion. Ingestion analyzes the input from the scan, applies resource set patterns, populates available lineage information, and then automatically loads Data Map. You can discover or curate assets and schemas only after ingestion is complete. If your scan completes but you

don't see your assets in the Data Map or catalog, you need to wait for the ingestion process to finish.

Ingestion from lineage connections

You can connect resources like Azure Data Factory and Azure Synapse to Microsoft Purview to bring data source and lineage information into Data Map. For example, when a copy pipeline runs in an Azure Data Factory that you connected to Microsoft Purview, the service ingests metadata about the input sources, the activity, and the output sources. The information is added to Data Map.

If you add a data source to Data Map through a scan, the lineage information about the activity is added to the existing source. If you haven't yet added the data source to Data Map, the lineage ingestion process adds it to the root collection with its lineage information.

For more information about the available lineage connections, see the lineage user guide.

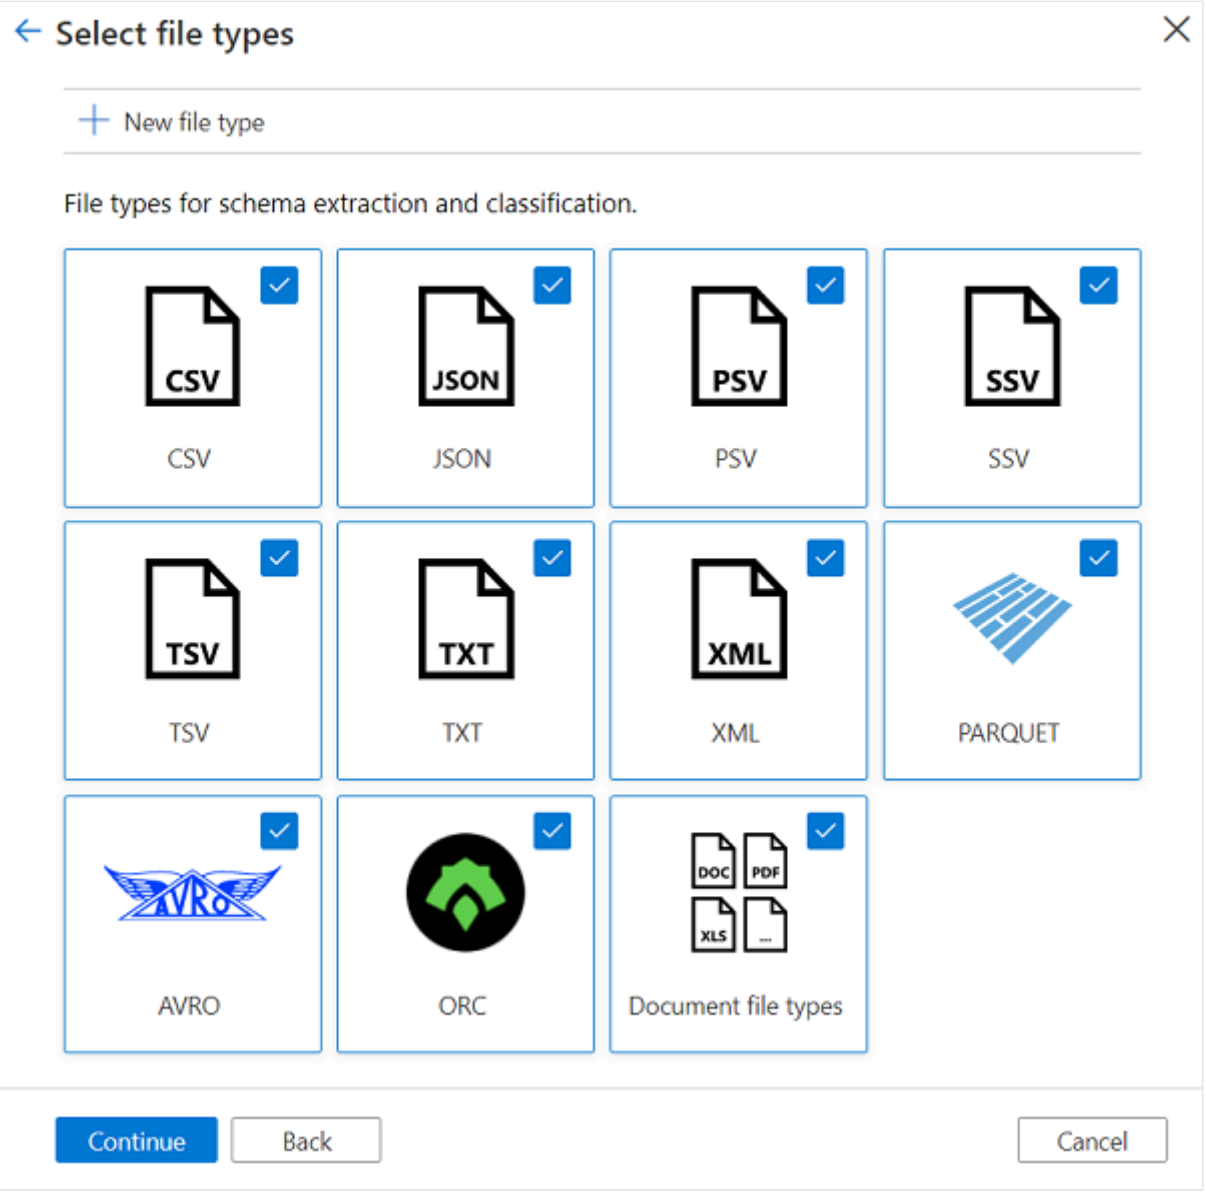
Create a scan rule set in Data Map

In Microsoft Purview Data Map, you can create scan rule sets to customize data source scans in your organization.

A scan rule set is a container that groups a set of scan rules together. You can easily associate a scan rule set with a scan. For example, you might create a default scan rule set for each of your data source types, and then use these scan rule sets by default for all scans within your company. You might also want users with the right permissions to create other scan rule sets with different configurations based on business need.

Steps to create a scan rule set



To create a scan rule set:

1. In the Microsoft Purview portal, select the **Data Map** solution.
2. Under the **Source management** section, select **Scan rule sets**, and then select **New**.
3. From the **New scan rule set** page, select the data sources that the catalog scanner supports from the **Source Type** dropdown list. You can create a scan rule set for each type of data source you intend to scan.
4. Enter a **Name** for the scan rule set. The maximum length is 63 characters, with no spaces allowed. Optionally, enter a **Description**. The maximum length is 256 characters.
5. Select a domain.

   > ⓘ **Important**
   >
   > You can only use the scan rule set in the domain where you create it.

6. Select **Continue**.

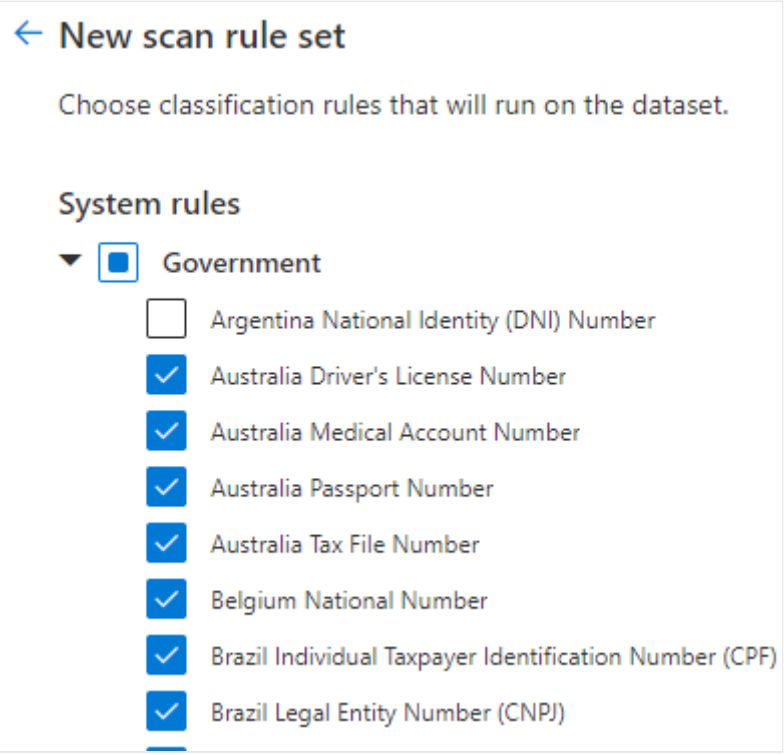
   The **Select file types** page appears. Notice that the file type options on this page vary based on the data source type that you chose on the previous page. All the file types are enabled by default.

The **Document file types** selection on this page allows you to include or exclude the following Microsoft Office file types: `.doc; .docm; .docx; .dot; .odp; .ods; .odt; .pdf; .pot; .pps; .ppsx; .ppt; .pptm; .pptx; .xlc; .xls; .xlsb; .xlsm; .xlsx; xlt`.

7. Enable or disable a file type for schema and classification by selecting or clearing its check box. If you choose a Data Lake type data source (for example, Azure Data Lake Storage Gen2 or Azure Blob), enable the file types for which you want to have schema extracted and classified.

   > **ⓘ Important**
   >
   > Deselecting a file type **doesn't** prevent ingestion. The file's information is still ingested, but its schema and classifications aren't extracted.

8. For certain data source types, you can also Create a custom file type.



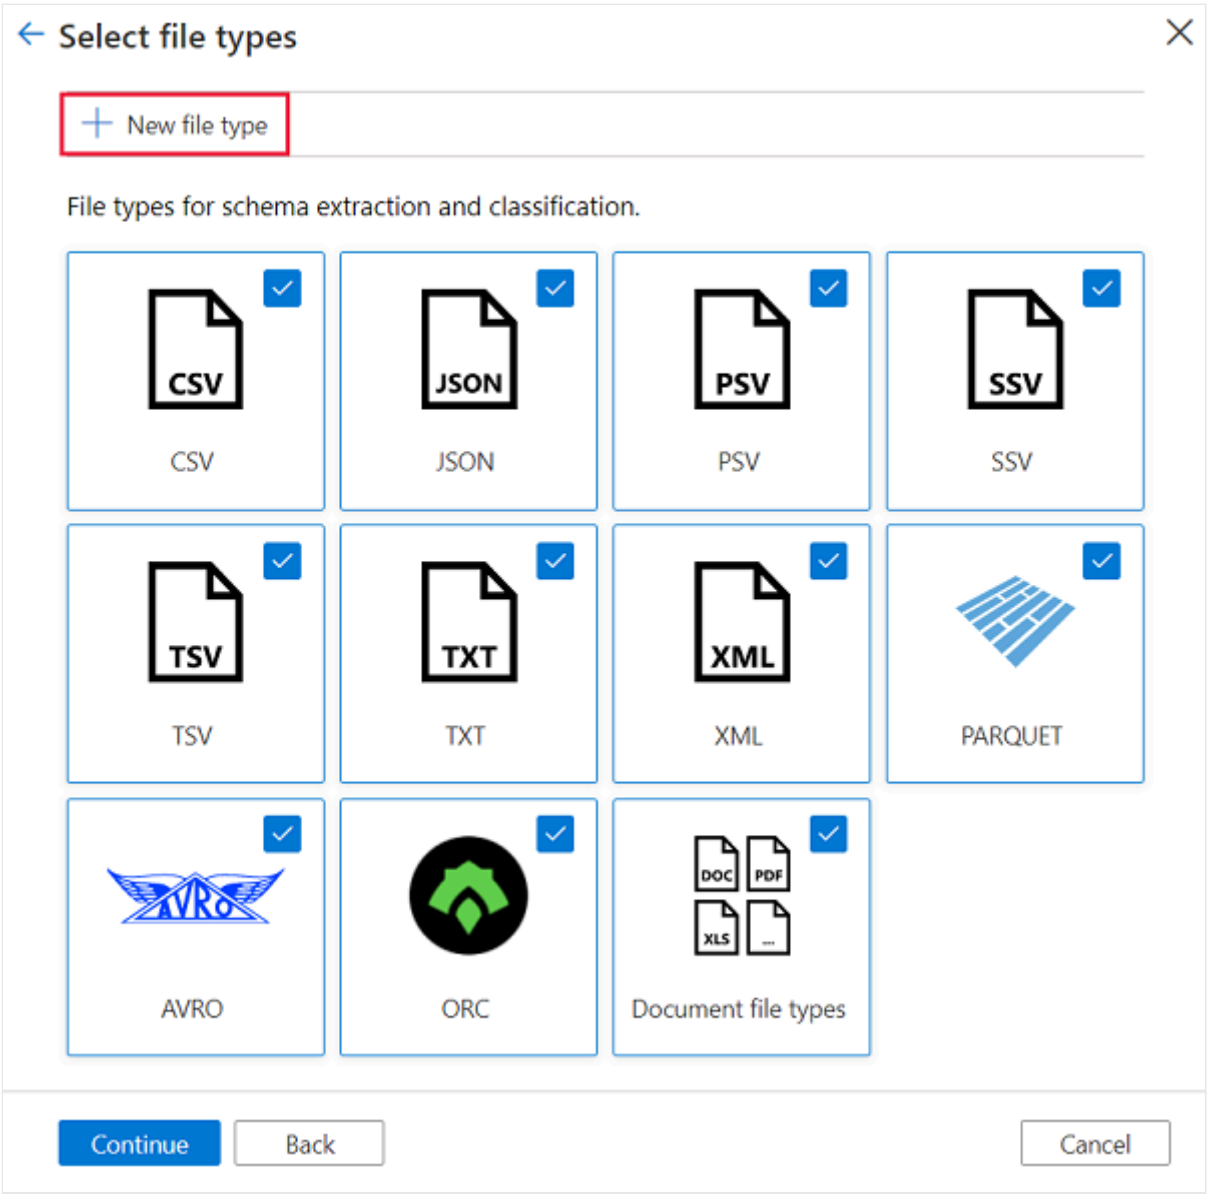
9. Select **Continue**.

The **Select classification rules** page appears. This page displays the selected **System rules** and **Custom rules**, and the total number of classification rules selected. By default, all the **System rules** check boxes are selected.

10. For the rules you want to include or exclude, select or clear the **System rules** classification rule checkboxes globally by category.

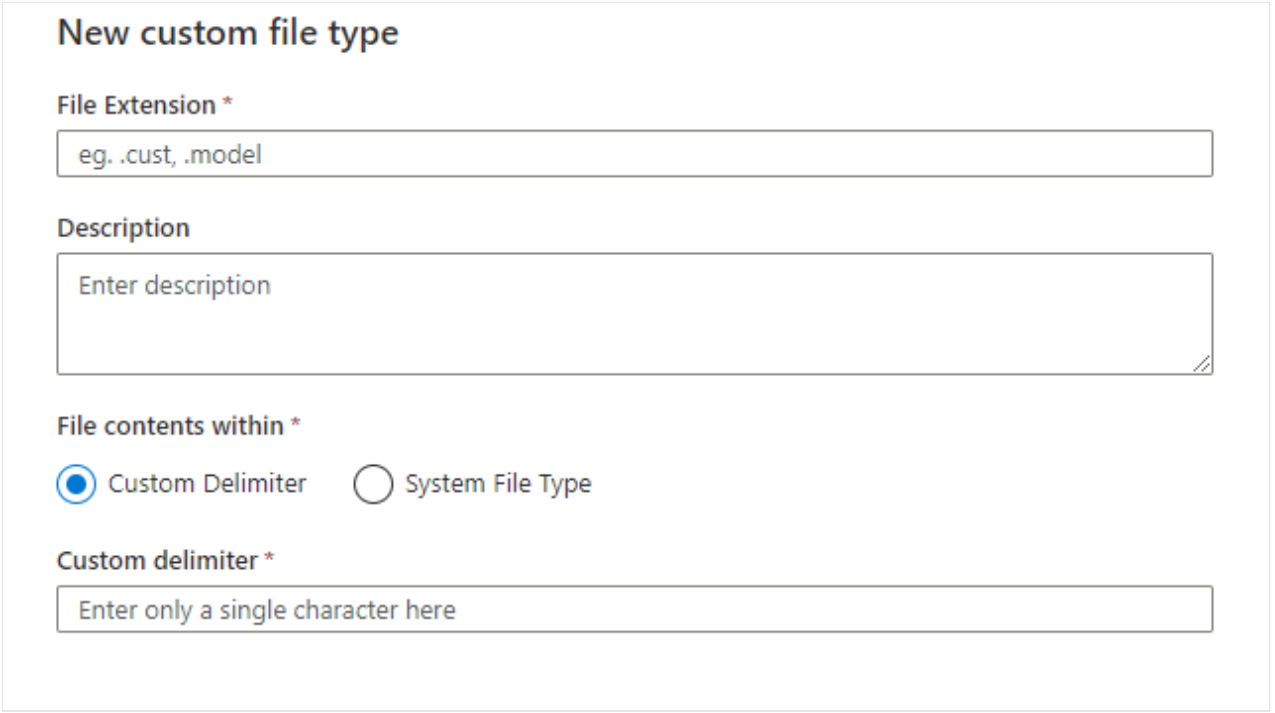
11. You can expand the category node and select or clear individual check boxes. For example, if the rule for **Argentina.DNI Number** has high false positives, you can clear that specific check box.

12. Select **Create** to finish creating the scan rule set.



Create a custom file type

Microsoft Purview supports adding a custom extension and defining a custom column delimiter in a scan rule set.

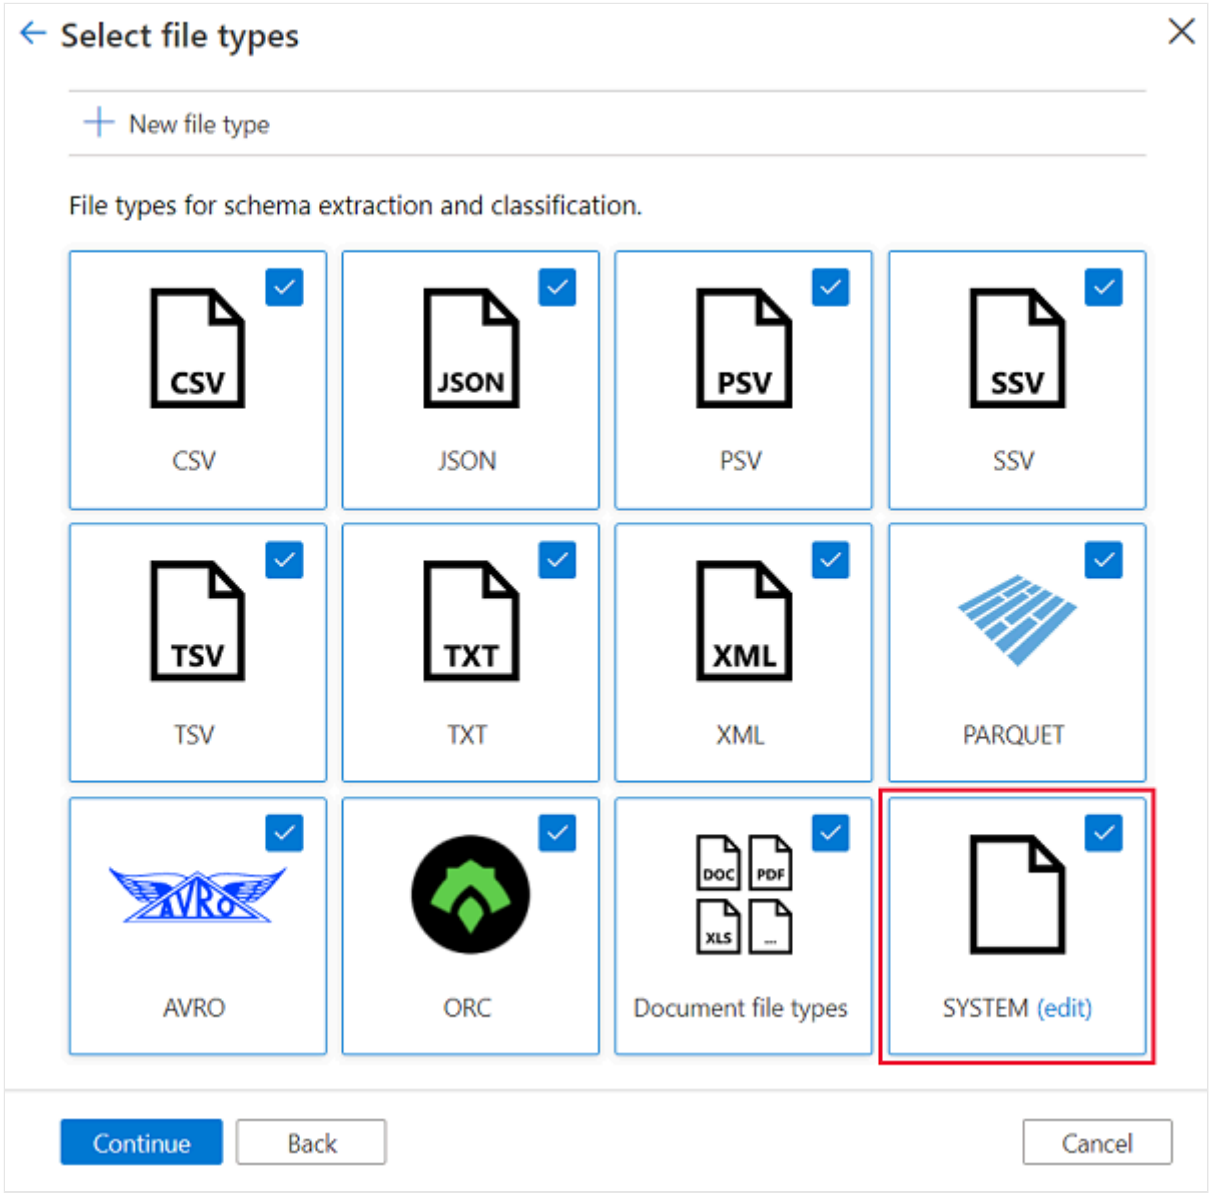


To create a custom file type:

1. Follow steps 1–5 in Steps to create a scan rule set or edit an existing scan rule set.

2. On the **Select file types** page, select **New file type** to create a new custom file type.

3. Enter a **File Extension** and an optional **Description**.

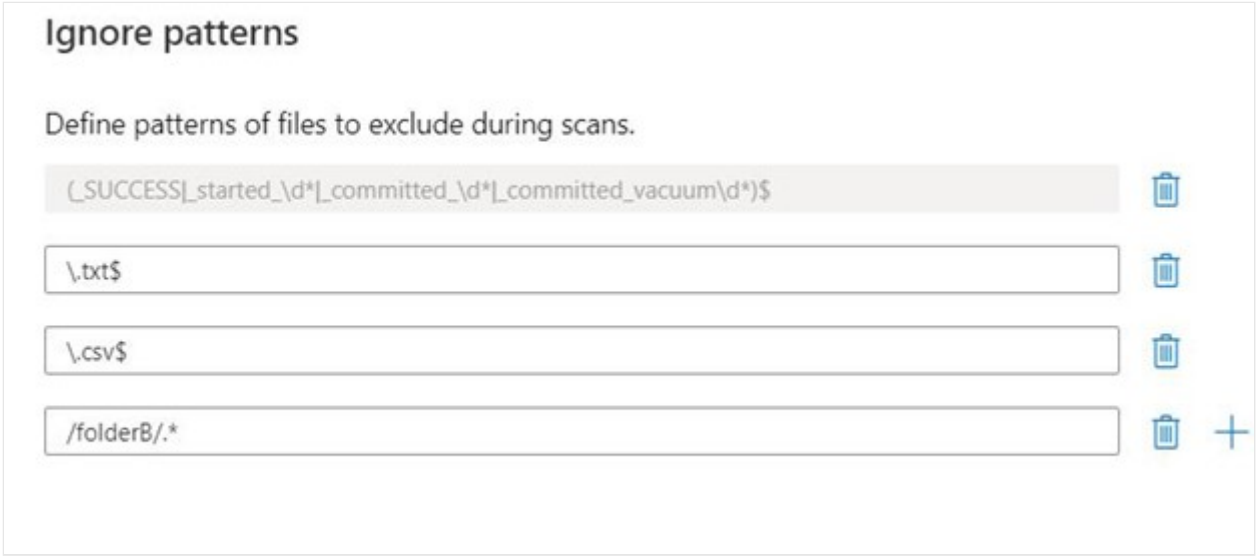


4. Make one of the following selections for **File contents within** to specify the type of file contents within your file:

    - Select **Custom Delimiter** and enter your own **Custom delimiter** (single character only).
    - Select **System File Type** and choose a system file type (for example XML) from the **System file type** drop-down list.

5. Select **Create** to save the custom file.

    The system returns to the **Select file types** page and inserts the new custom file type as a new tile.



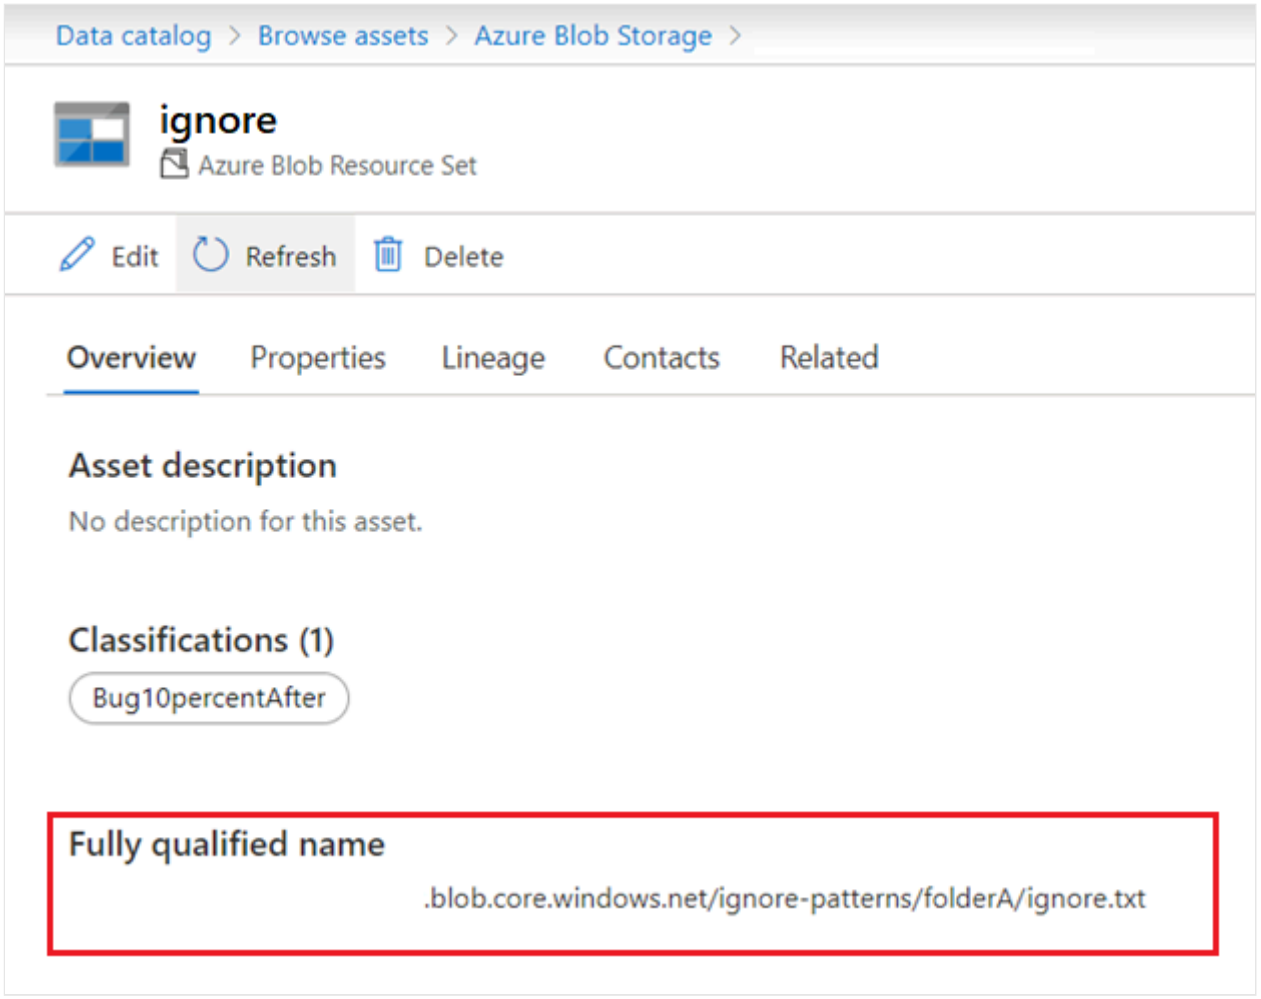
6. Select **Edit** in the new file type tile if you want to change or delete it.

7. Select **Continue** to finish configuring the scan rule set.

Ignore patterns

Microsoft Purview supports defining regular expressions (regex) to exclude assets during scanning. During scanning, Purview compares the asset's URL against these regular expressions. Microsoft Purview ignores all assets that match any of the regexes.

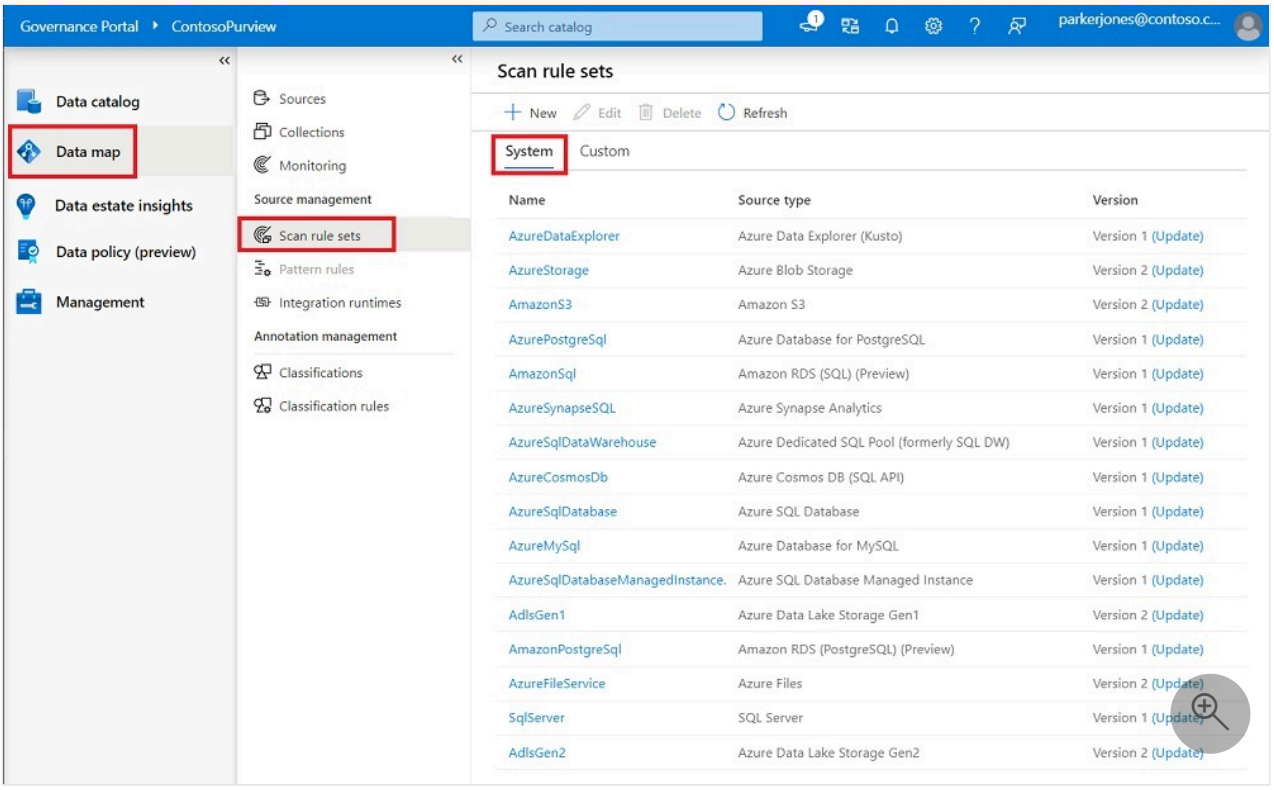
The **Ignore patterns** pane prepopulates one regex for spark transaction files. You can remove the preexisting pattern if it isn't required. You can define up to 10 ignore patterns.



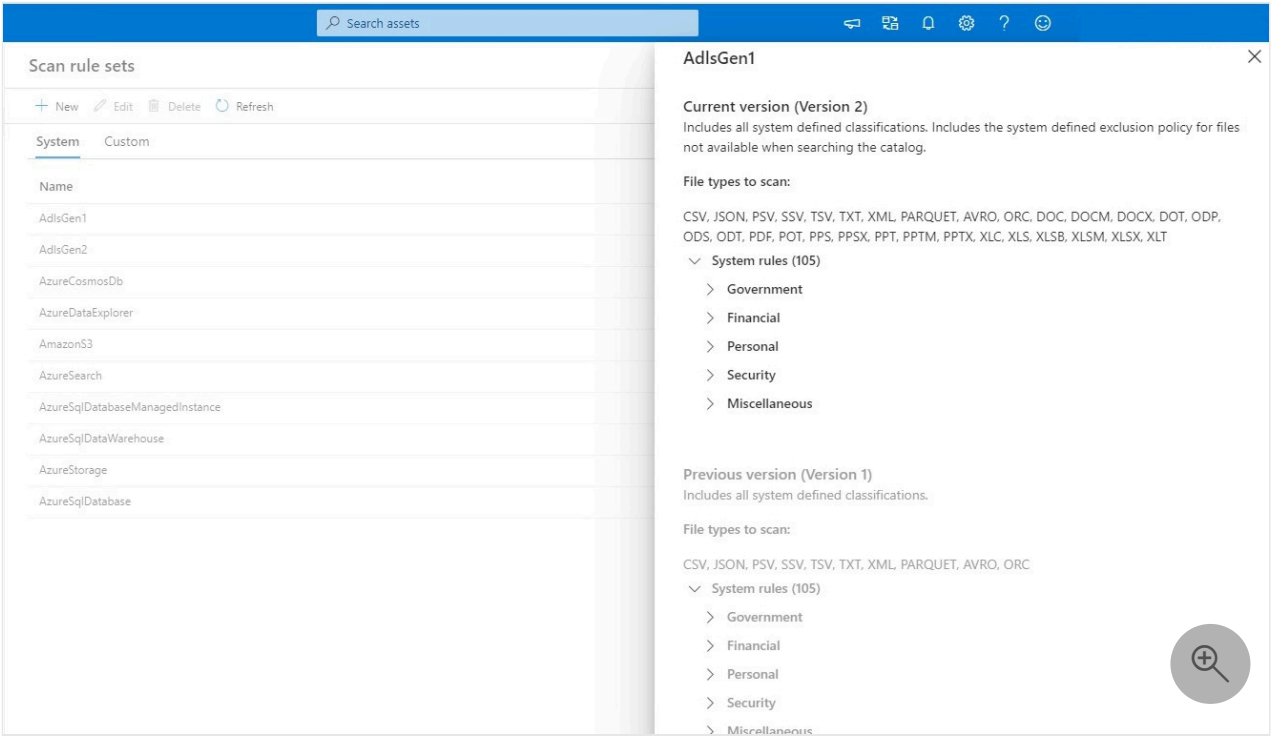
In the preceding example:

- Regexes 2 and 3 ignore all files ending with .txt and .csv during scanning.
- Regex 4 ignores /folderB/ and all its contents during scanning.

Here are some more tips you can use to ignore patterns:

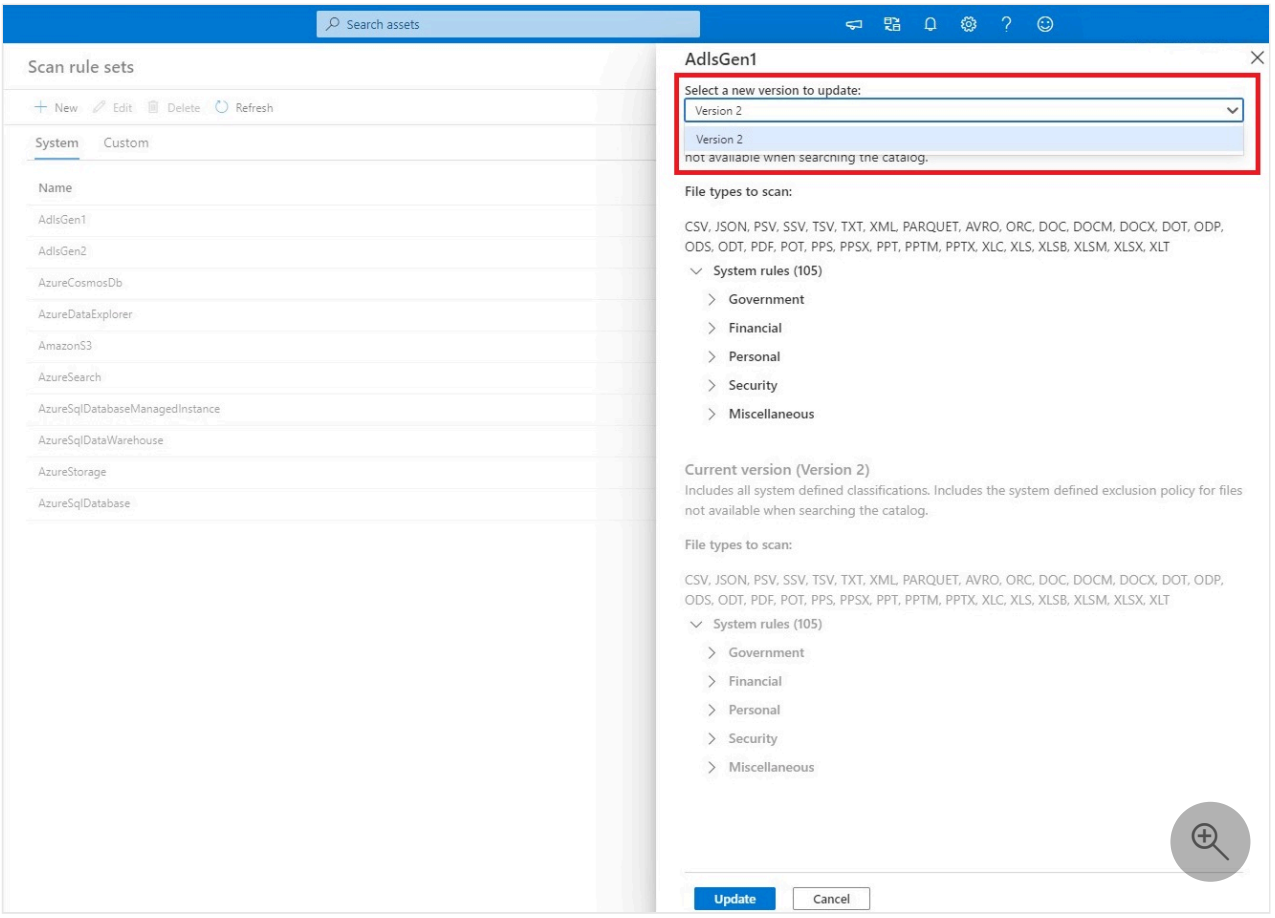


- While processing the regex, Microsoft Purview adds $ to the regex by default.
- To understand what URL the scanning agent compares with your regular expression, browse through Microsoft Purview Unified Catalog, find the asset you want to ignore in the future, and see its fully qualified name (FQN) in the **Overview** tab.



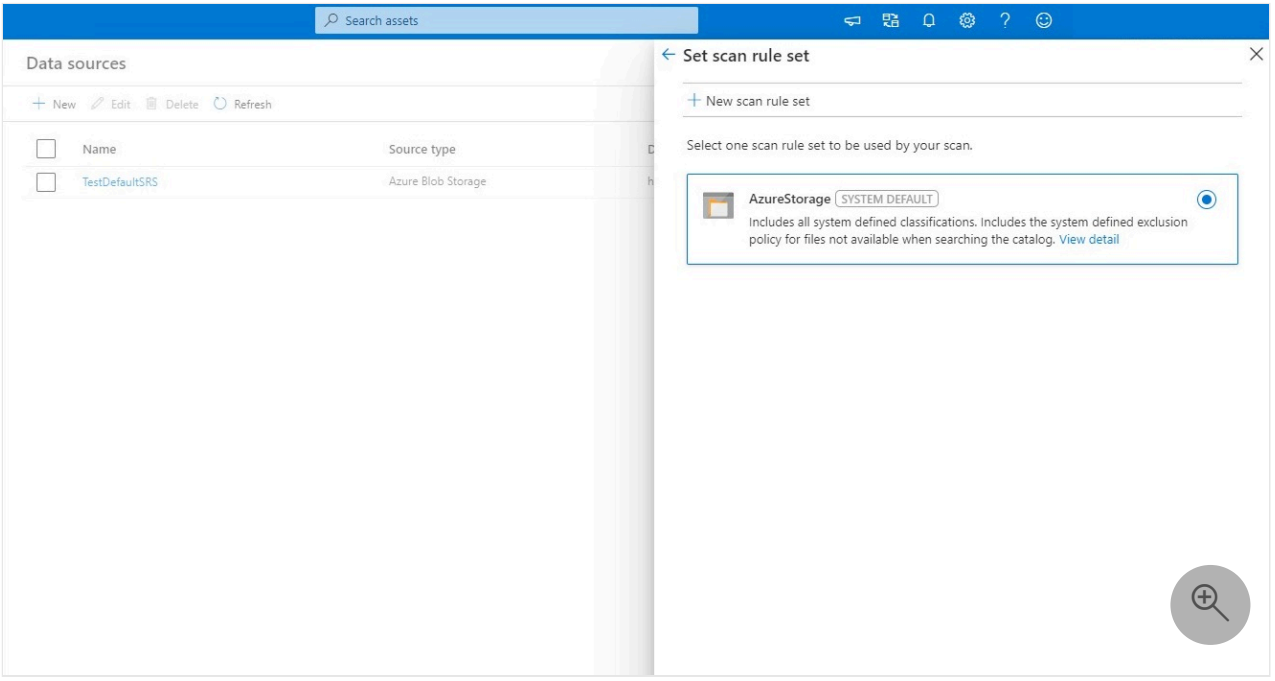
System scan rule sets

System scan rule sets are Microsoft-defined scan rule sets that are automatically created for each Microsoft Purview catalog. Each system scan rule set is associated with a specific data source type. When you create a scan, you can associate it with a system scan rule set. Every time Microsoft makes an update to these system rule sets, you can update them in your catalog, and apply the update to all the associated scans.



1. To view the list of system scan rule sets, select **Scan rule sets** in the **Management Center** and choose the **System** tab.

2. Each system scan rule set has a **Name**, **Source type**, and a **Version**. If you select the version number of a scan rule set in the **Version** column, you see the rules associated with the current version and the previous versions (if any).



3. If an update is available for a system scan rule set, you can select **Update** in the **Version** column. In the system scan rule page, choose a version from the **Select a new version to update** drop-down list. The page provides a list of system classification rules associated with the new version and current version.

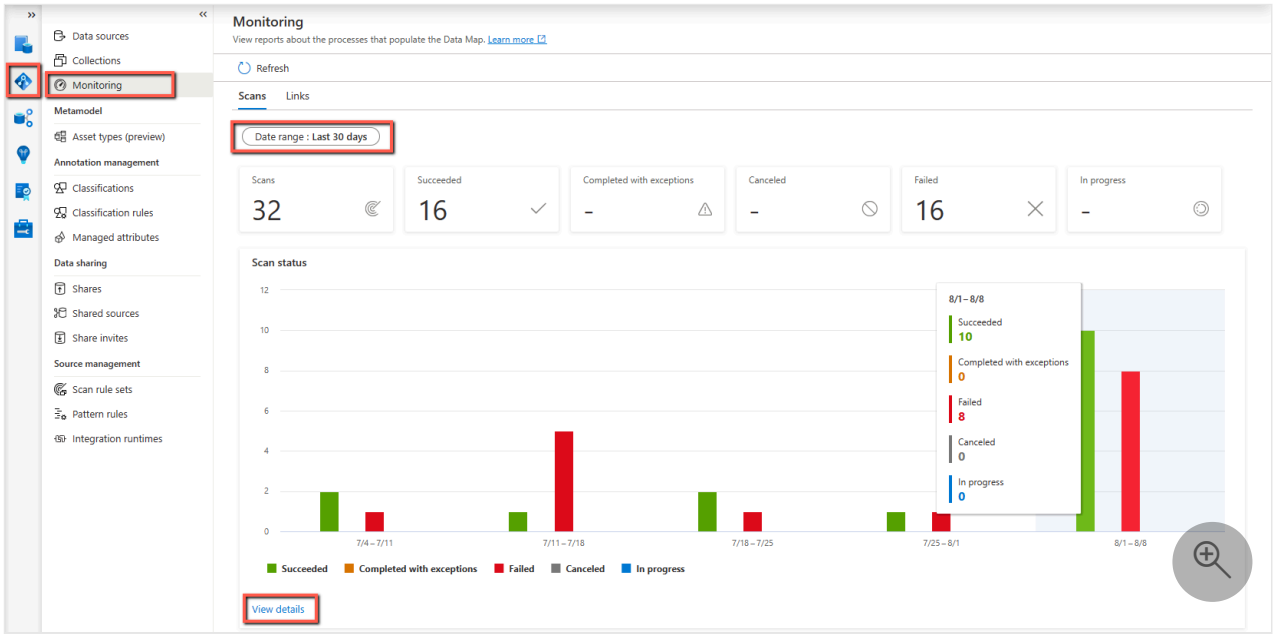
Associate a scan with a system scan rule set

When you create a scan, choose to associate it with a system scan rule set as follows:

1. On the **Select a scan rule set** page, select the system scan rule set.

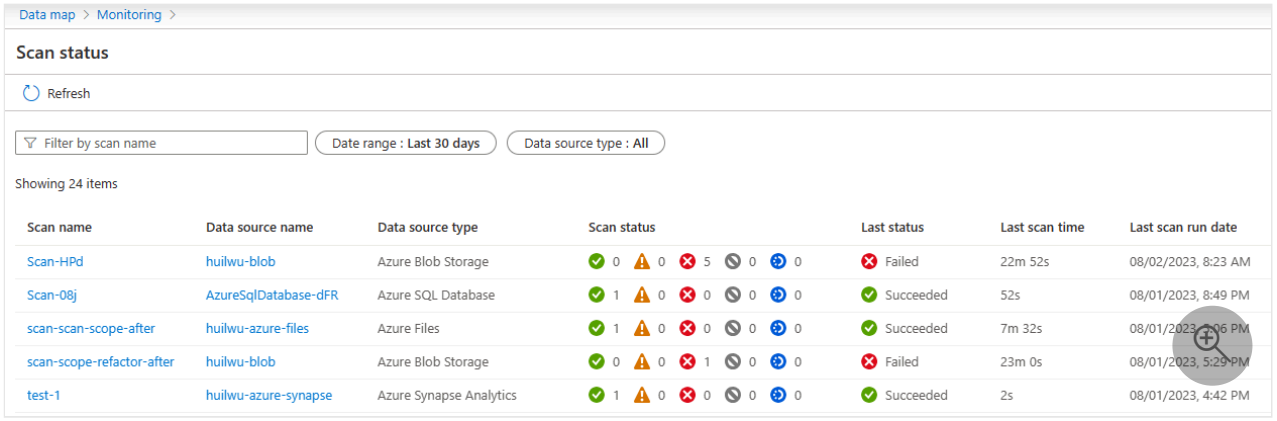
2. Select **Continue**, and then select **Save and Run**.

Last updated on 12/09/2025



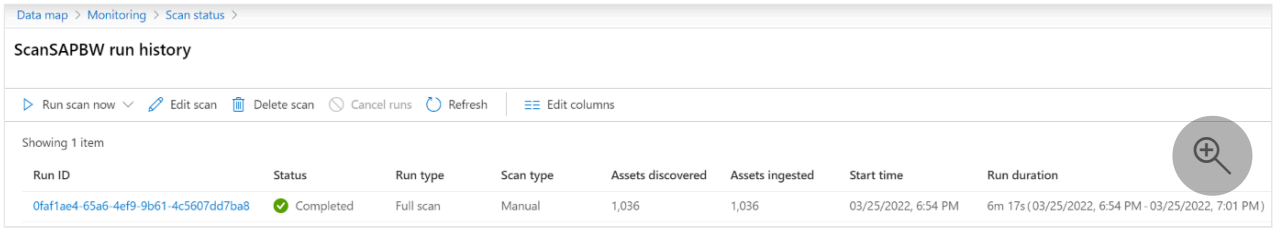
Monitor Data Map population in Microsoft Purview

In Microsoft Purview, you can scan various types of data sources and view the scan status over time. You can also connect other services with Microsoft Purview and view the trends of the ingested assets and relationships. This article outlines how to monitor and get a bird's eye view of the Purview Data Map population.



Monitor scan runs

1. Open your Microsoft Purview account and select **Data Map** -> **Monitoring**. You need to have the **Data source admin** role on any collection to access this page. You can see the scan runs that belong to the collections on which you have data source admin privilege.



2. The high-level KPIs show total scan runs within a period. The default time period is the last 30 days. You can also choose to select the last seven days. Based on the time filter you select, you can see the distribution of succeeded, completed with exceptions, failed, canceled, and in progress scan runs by week or by the day in the graph. It's the scan run end-to-end status including the discovery and ingestion phases. For more information about the status details, see the scan run details section.

3. At the bottom of the graph, there's a **View more** link for you to explore further. The link opens the **Scan status** page. Here you can see a scan name and the number of times it has status of succeeded, completed with exceptions, failed, or canceled in the time period. You can also filter the list by source types.

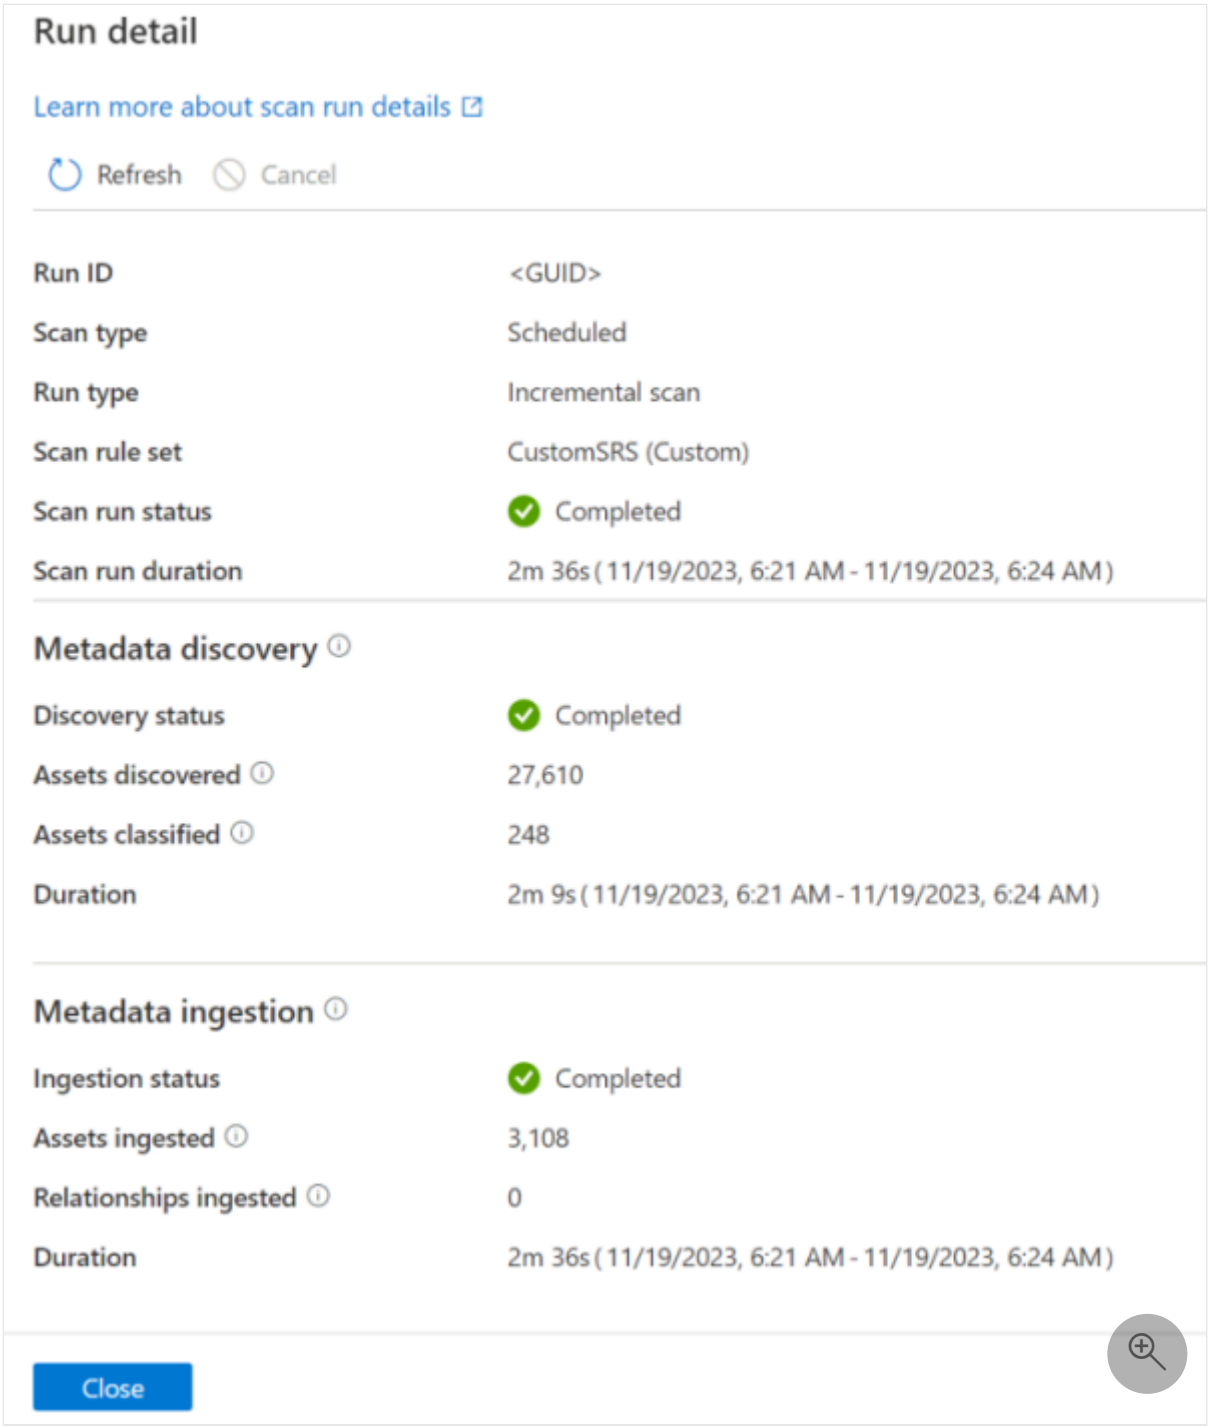
4. You can explore a specific scan further by selecting the **scan name**. It connects you to the scan history page, where you can find the list of scan runs with more execution details.

5. Select **run ID** to check more about the scan run details.

Known limitations

Currently, this monitoring experience doesn't include the following information. You can check the corresponding scan run details.

- Lineage extraction scan runs for Azure SQL Database aren't covered.
- For scans of Azure Synapse Analytics workspace, Azure subscription/resource group, and Amazon Web Services (AWS) account, it only captures the parent scan run's status/count but not child scan runs' per resource.



Scan run details

You can view the scan run history for a given scan from different places:

- Go to **Data Map** -> **Monitoring** as described in the Monitor scan runs section.
- Go to **Data Map** -> **Sources** -> select the desired data source -> see **Scans**, **Recent scans**, or **Recent failed scans**.
- Go to **Data Map** -> **Collections** -> select the desired collection -> **Scans** -> select the scan name that you want to view.

The retention of the scan run history is 90 days.

Select **run ID** to check more about the scan run details:

- The section on top provides an overview of the scan run, including the following information:
  - **Run ID**: A GUID used to identify this particular scan run.
  - **Scan type**: Manual or scheduled scan.
  - **Run type**: Full or incremental scan.
  - **Scan rule set**: The scan rule set used in the run, if applicable.
  - **Scan run status**: Overall scan status. It combines the metadata discovery and ingestion phases' status.
  - **Scan run duration**: The end-to-end execution duration and the start/end time.

- **Metadata discovery** section summarizes the metrics for discovery phase that Purview connects to the source, extracts the metadata/lineage and classifies the data.

- **Discovery status**:

Expand table

Status	Description
Completed	The metadata discovery succeeds.
Completed with exceptions	The metadata discovery completes, while some underlying operation fails that might cause asset, metadata, or classification missing in the scan result. You can view details in the exception logs.
Failed	The metadata discovery fails. You can check the error details by selecting the "More info" link next to it.
Canceled	The scan run is canceled by user.
In Progress	The metadata discovery is running in progress.
Queued	The metadata discovery is waiting for available integration runtime resource. If you use self-hosted integration runtime, note each node can run many concurrent scans at the same time depending on your machine specification (CPU and memory). More scans are in Queued status.
Throttled	The metadata discovery is being throttled. It means this Microsoft Purview account at the moment has more ongoing scan runs than the allowed max concurrent count. Learn more about the limit here. This particular scan run is waiting and will start once your other ongoing scans finish.

  The scan run isn't charged during "Throttled" or "Queued" status.
  - **Assets discovered**: The number of assets enumerated from the source. For both full and incremental scans, it includes all assets in the configured scope, regardless of whether they're existing assets or newly created or updated assets since the last scan run. For incremental scan, Microsoft Purview extracts detailed metadata only for newly created or updated assets.
  - **Assets classified**: The number of assets sampled to classify the data, regardless of whether the assets have any matching classification or not. It's a subset of the discovered assets based on the sampling mechanism. For incremental scan, only newly created or updated assets might be selected for classification.
  - **Duration**: The discovery phase duration and the start/end time.
- **Metadata ingestion** section summarizes the metrics for ingestion phase that populates Data Map with the identified metadata and relationship.
  - **Ingestion status**:

Expand table

Status	Description
Completed	All of the assets and relationships are ingested into Data Map successfully.
Completed with exceptions (previous "Partially completed")	Partial of the assets and relationships are ingested into Data Map successfully, while some fail. You can view details in the exception logs.
Failed	The ingestion phase fails.
Canceled	The scan run is canceled by user, thus the ingestion is canceled along.
In Progress	The ingestion is running in progress.
Queued	The ingestion is waiting for available service resource or waiting for scan to discover metadata.

- **Assets ingested**: The number of assets ingested into Data Map. For incremental scan, it only includes the newly created or updated assets, in which case might be less than the "assets discovered" count. When scanning file-based source, it's the raw assets count before resource set aggregation.
- **Relationships ingested**: The number of relationships ingested into Data Map. It includes lineage and other relationships like foreign key relationships.
- **Duration**: The ingestion duration, and the start and end times.

View the exception log (preview)

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

When some assets or relationships fail to be discovered from the source or fail to ingest into Data Map during a scan run, the scan status shows **completed with exceptions**. You can view the exception log by following these steps:

1. Select the scan.
2. Select the run ID of a scan with failures or exceptions.

3. Select **Download log** in the scan run details panel. It provides you with the exception log files that capture the details of the failures.

Discovery phase log

The following table shows the schema of a discovery phase log file.

Expand table

Column	Description
TimeStamp	The UTC timestamp when the discovery operation happens.
ErrorCode	Error code of the exception.
OperationName	It contains the following values: - **Enumerate**: Indicates the operation of enumerating the child objects under a given scope; for example, list the folders/files under a container, list the tables under a database. When there's a failure, the operation item's child objects aren't included in the scan result. - **GetMetadata**: Indicates the operation of extracting the metadata for an object, such as a table or file. When there's a failure, the asset of the operation item might not contain full metadata. - **SampleResourceSet**: Indicates the operation of sampling the latest file matching the resource set pattern when you scan file-based data sources. When there's a failure, the resource set that the operation item belongs to might miss classification or schema. - **ReadData**: Indicates the operation of retrieving sample data from the source. When there's a failure, the operation item isn't classified. If it's a file-based source, it might also miss schema. - **Classify**: Indicates the operation of applying the classifications. When there's a failure, the operation item might miss classification. - **GenerateAsset**: Indicates the operation of converting the discovered metadata into Purview asset. When there's a failure, usually due to system error, the asset of the operation item doesn't show up in Data Map at last.
OperationItem	Identifier for the failed asset or relationship, usually uses the fully qualified name.
Message	More information on which asset or relationship failed to discover and the reason for the failure.

Known limitations:

- The discovery phase log is supported when you use Azure integration runtime or Managed Virtual Network integration runtime for scan.
- The discovery phase log is supported when you scan Azure or Power BI data sources.
- Currently, it might not capture all the exceptions that happen during a scan run.

Ingestion phase log

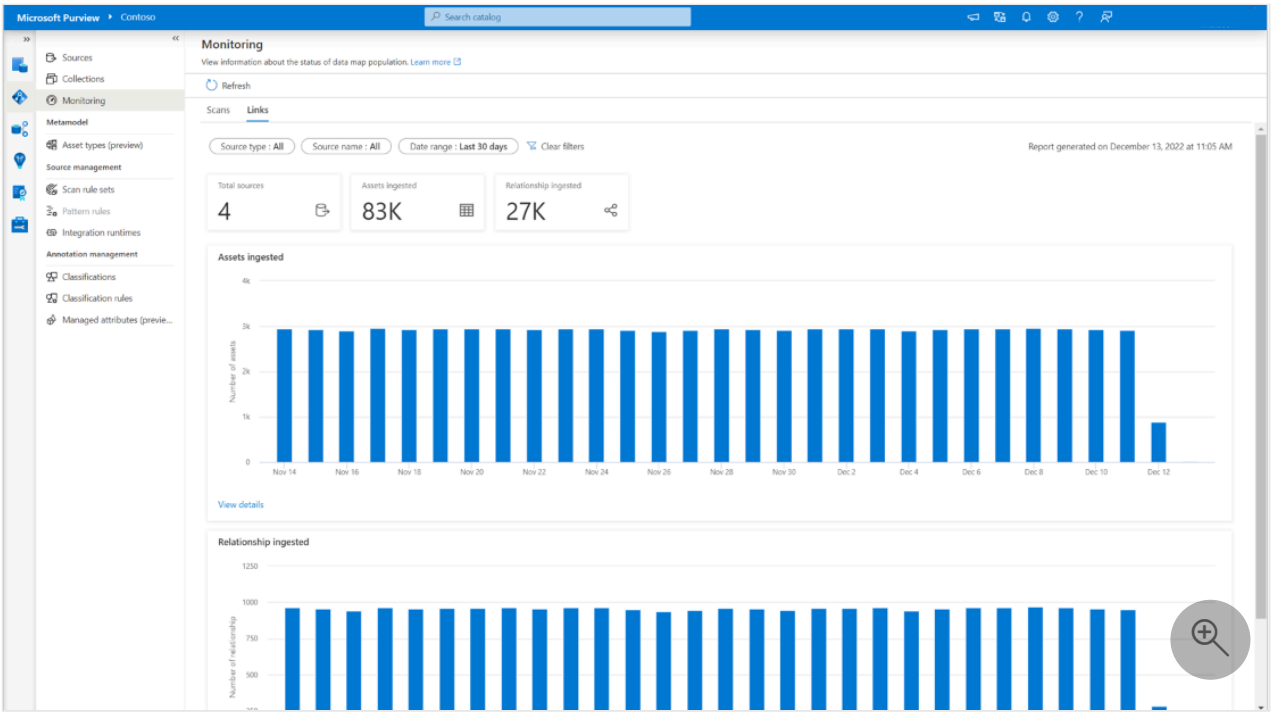
The following table shows the schema of an ingestion phase log file.

Expand table

Column	Description
TimeStamp	The UTC timestamp when the ingestion operation happens.
ErrorCode	Error code of the exception.
OperationItem	Identifier for the failed asset or relationship, usually uses the fully qualified name.
Message	More information on which asset or relationship failed to ingest and the reason for the failure. If there's an ingestion failure for a resource set, it might apply to multiple assets that match the same naming pattern, and the message includes the impacted count.

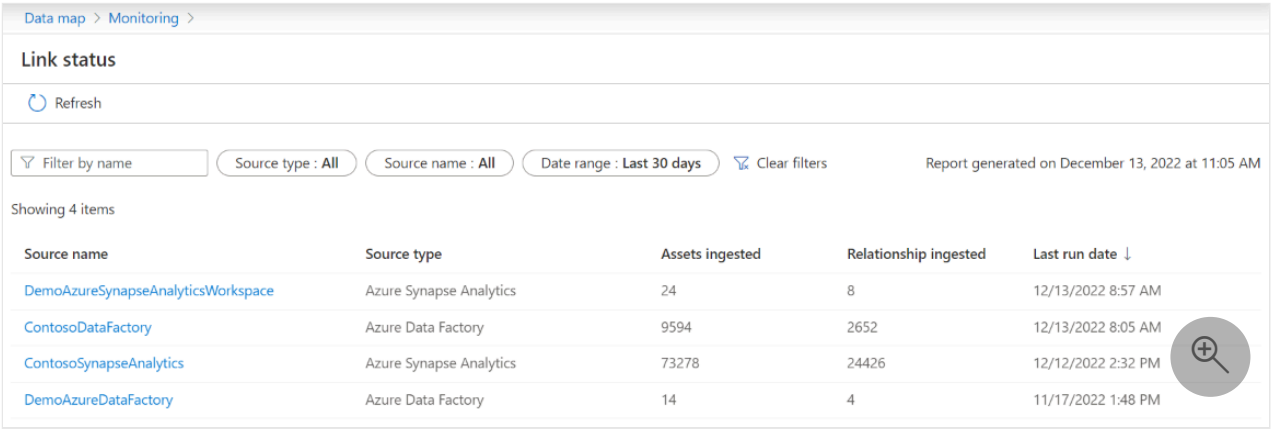
Monitor links

You can connect other services with Microsoft Purview to establish a "link", which makes the metadata and lineage of that service's assets available to Microsoft Purview. Currently, link is supported for Azure Data Factory and Azure Synapse Analytics.



To monitor the assets and relationship ingested over the links:

1. Go to your Microsoft Purview account -> open **Microsoft Purview governance portal** -> **Data Map** -> **Monitoring** -> **Links**. You need to have **Data source admin** role on any collection to access the Monitoring tab. And you can see the results that belong to the collections on which you have data source admin privilege. Permission on root collection is needed to monitor Azure Data Factory and Azure Synapse Analytics links.



2. You can see the high-level KPIs including total number of sources, number of ingested assets and relationship (lineage), followed by trending charts over time. You can apply more filters on the following to narrow down the results:

   - Source type
   - Source name
   - Date range: Default is 30 days. You can also choose last seven days or a custom date range. The retention is 45 days.

   The metrics are reported till the date time shown at the top right corner. And the aggregation happens hourly.

3. At the bottom of the graph, there's a **View more** link for you to explore further. In the **Link status** page, you can see a list of source names along with the source type, assets ingested, relationship ingested and the last run date time. The filters in the previous page are carried over, and you can further filter the list by source type, source name, and date range.

4. You can drill down to each source to see the next level details by clicking the source name. For example, for Azure Data Factory, it shows how each pipeline activity reports the assets and relationship to Microsoft Purview, with the name in the format of `<pipeline_name>/<activity_name>`.

Known limitations

- For Azure Data Factory and Azure Synapse Analytics, currently this link monitoring captures the assets and relationship generated from copy activity, but not data flow and SSIS activities.
- The aggregation and date filter are in UTC time.

Scans no longer run

If your Microsoft Purview scan used to run successfully but now fails, check these things:

1. Check the error message for failure details.
2. Did you change or rotate credentials to your resource? If so, update your scan with the correct credentials.
3. Is an Azure Policy preventing **updates to Storage accounts**? If so, follow the Microsoft Purview exception tag guide to create an exception for Purview accounts.
4. Are you using a self-hosted integration runtime? Check that it's up to date with the latest software and that it's connected to your network.

Next steps

- Microsoft Purview supported data sources and file types
- Manage data sources
- Scan and ingestion

Understanding resource sets

This article helps you understand how resource sets are used in Microsoft Purview to map data assets to logical resources.

> **Note**
>
> Now rolling out, the advanced resource sets capability is available to all customers in Microsoft Purview Unified Catalog. Pricing for advanced resource sets is consistent with existing rates for classic Microsoft Purview data governance.

Background info

At-scale data processing systems typically store a single table in storage as multiple files. In the Microsoft Purview Unified Catalog, this concept is represented by using resource sets. A resource set is a single object in the catalog that represents a large number of assets in storage.

For example, suppose your Spark cluster has persisted a DataFrame into an Azure Data Lake Storage (ADLS) Gen2 data source. Although in Spark the table looks like a single logical resource, on the disk there are likely thousands of Parquet files, each of which represents a partition of the total DataFrame's contents. IoT data and web log data have the same challenge. Imagine you have a sensor that outputs log files several times a second. It won't take long until you have hundreds of thousands of log files from that single sensor.

How Microsoft Purview detects resource sets

Microsoft Purview supports detecting resource sets in Azure Blob Storage, ADLS Gen1, ADLS Gen2, Azure Files, and Amazon S3.

Microsoft Purview automatically detects resource sets when scanning. This feature looks at all of the data that's ingested via scanning and compares it to a set of defined patterns.

For example, suppose you scan a data source whose URL is `https://myaccount.blob.core.windows.net/mycontainer/machinesets/23/foo.parquet`. Microsoft Purview looks at the path segments and determines if they match any built-in patterns. It has built-in patterns for GUIDs, numbers, date formats, localization codes (for example, en-us), and so on. In this case, the number pattern matches *23*. Microsoft Purview assumes that this file is part of a resource set named `https://myaccount.blob.core.windows.net/mycontainer/machinesets/{N}/foo.parquet`.

Or, for a URL like `https://myaccount.blob.core.windows.net/mycontainer/weblogs/en_au/23.json`, Microsoft Purview matches both the localization pattern and the number pattern, producing a resource set named `https://myaccount.blob.core.windows.net/mycontainer/weblogs/{LOC}/{N}.json`.

Using this strategy, Microsoft Purview would map the following resources to the same resource set, `https://myaccount.blob.core.windows.net/mycontainer/weblogs/{LOC}/{N}.json`:

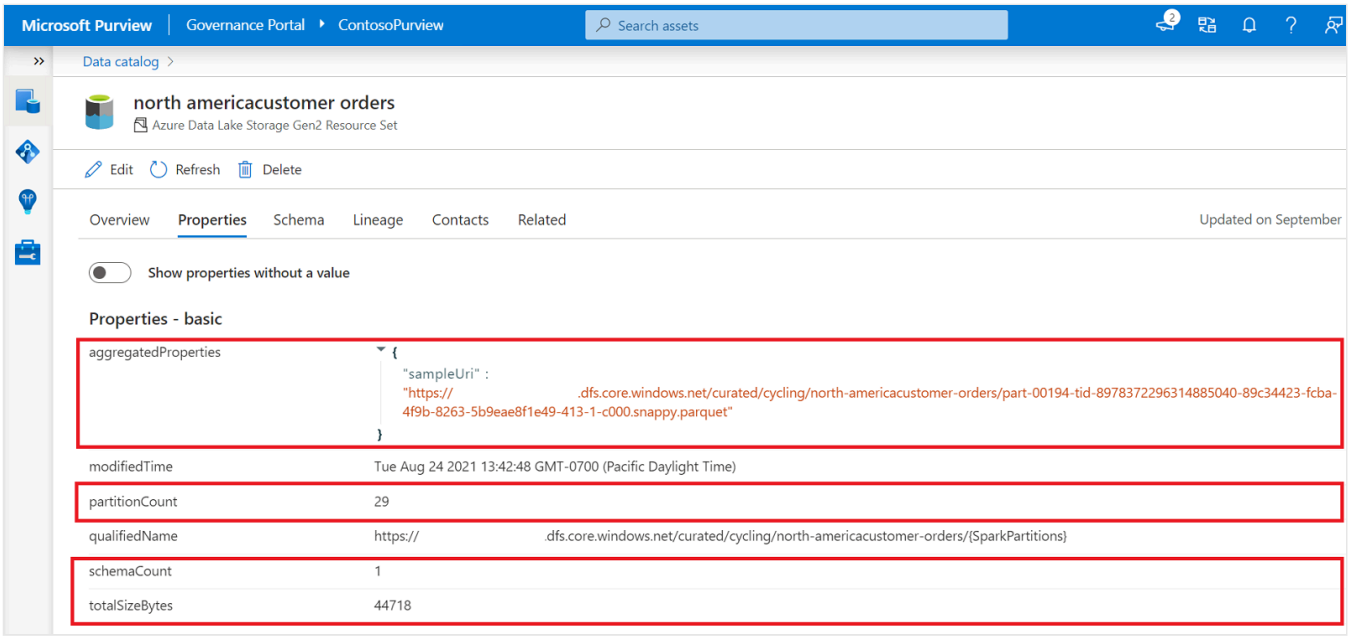
- `https://myaccount.blob.core.windows.net/mycontainer/weblogs/cy_gb/1004.json`
- `https://myaccount.blob.core.windows.net/mycontainer/weblogs/cy_gb/234.json`
- `https://myaccount.blob.core.windows.net/mycontainer/weblogs/de_Ch/23434.json`

File types that Microsoft Purview will not detect as resource sets

Microsoft Purview intentionally doesn't try to classify most document file types like Word, Excel, or PDF as Resource Sets. The exception is CSV format since that is a common partitioned file format.

How Microsoft Purview scans resource sets

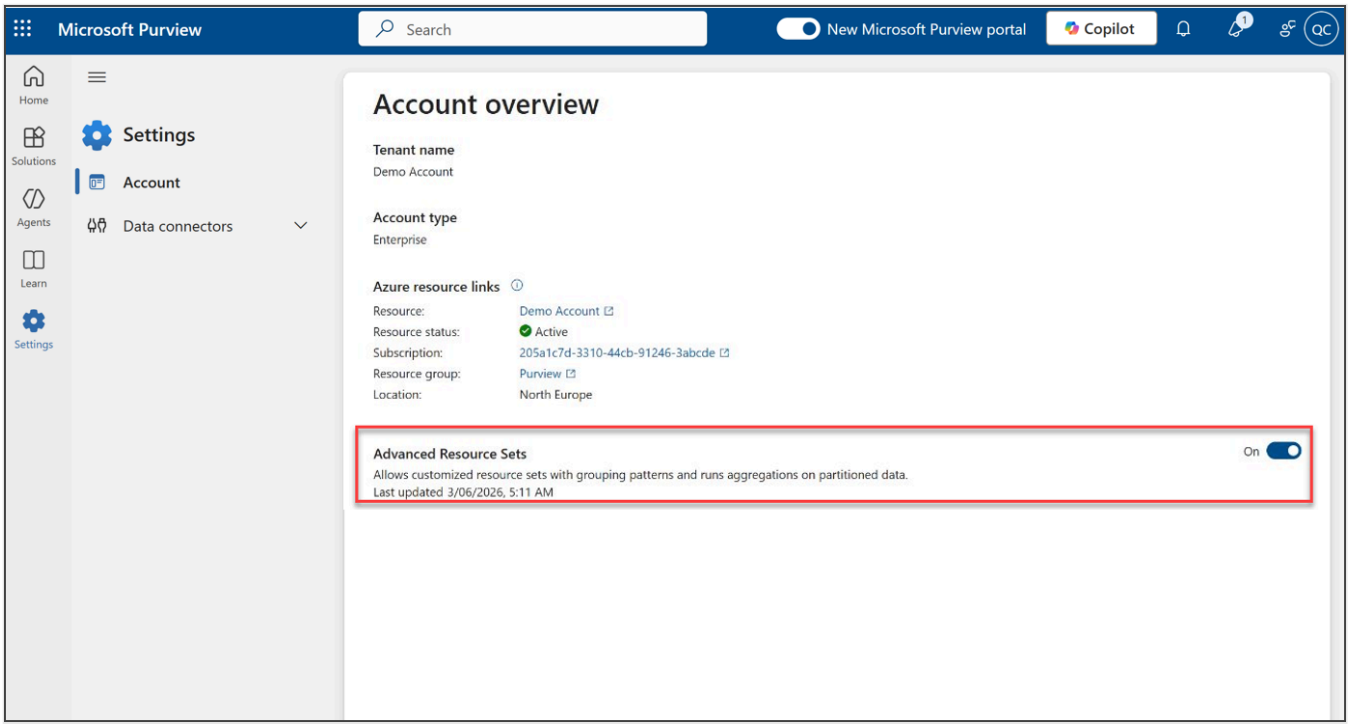
When Microsoft Purview detects resources that it thinks are part of a resource set, it switches from a full scan to a sample scan. A sample scan opens only a subset of the files that it thinks are in the resource set. For each file it opens, it uses its schema and runs its classifiers. Microsoft Purview then finds the newest resource among the opened resources and uses that resource's schema and classifications in the entry for the entire resource set in the catalog.



Advanced resource sets

Microsoft Purview can customize and further enrich your resource set assets through the **Advanced Resource Sets** capability. Advanced resource sets allow Microsoft Purview to understand the underlying partitions of data ingested and enables the creation of resource set pattern rules that customize how Microsoft Purview groups resource sets during scanning.

When Advanced Resource Sets are enabled, Microsoft Purview runs extra aggregations to compute the following information about resource set assets:



- A sample path from a file that comprises the resource set.
- A partition count that shows how many files make up the resource set.
- The total size of all files that comprise the resource set.

These properties can be found on the asset details page of the resource set.

Turning on advanced resource sets

Advanced resource sets are off by default in all new Microsoft Purview instances. Only users with the Data Curator role at root collection can manage Advanced Resource Sets settings. To enable advanced resource sets, go to **Microsoft Purview portal** > **Settings** > **Account**, and select the toggle for **Advanced Resources Sets**, as seen in this image:

After enabling advanced resource sets, the extra enrichments will occur on all newly ingested assets. These enrichments could take up to **12 hours** to be available on your assets after ingestion. The Microsoft Purview team recommends waiting an hour before scanning in new data lake data after toggling on the feature.

> **Important**
>
> Enabling advanced resource sets affects the refresh rate of asset and classification insights. When advanced resource sets are on, asset and classification insights update twice a day.
>
> Also, when you enable advanced resource sets, it could take up to **12 hours** to see schema updates.

Built-in resource set patterns

Microsoft Purview supports the following resource set patterns. These patterns can appear as a name in a directory or as part of a file name.

Regex-based patterns

Expand table

Pattern Name	Display Name	Description
Guid	{GUID}	A globally unique identifier as defined in RFC 4122
Number	{N}	One or more digits
Date/Time Formats	{Year}{Month}{Day}{N}	We support various date/time formats but all are represented with {Year}[delimiter]{Month}[delimiter]{Day} or series of {N}s.
4ByteHex	{HEX}	A four-digit HEX number.
Localization	{LOC}	A language tag as defined in BCP 47, both - and _ names are supported (for example, en_ca and en-ca)

Complex patterns

Expand table

Pattern Name	Display Name	Description
SparkPath	{SparkPartitions}	Spark partition file identifier
Date(yyyy/mm/dd)InPath	{Year}/{Month}/{Day}	Year/month/day pattern spanning multiple folders

How resource sets are displayed in Unified Catalog

When Microsoft Purview matches a group of assets into a resource set, it attempts to extract the most useful information to use as a display name in the catalog. Some examples of the default naming convention applied:

Example 1

Qualified name: `https://myblob.blob.core.windows.net/sample-data/name-of-spark-output/{SparkPartitions}`

Display name: "name of spark output"

Example 2

Qualified name: `https://myblob.blob.core.windows.net/my-partitioned-data/{Year}-{Month}-{Day}/{N}-{N}-{N}-{N}/{GUID}`

Display name: "my partitioned data"

Example 3

Qualified name: `https://myblob.blob.core.windows.net/sample-data/data{N}.csv`

Display name: "data"

Customizing resource set grouping using pattern rules

When scanning a storage account, Microsoft Purview uses a set of defined patterns to determine if a group of assets is a resource set. In some cases, Microsoft Purview's resource set grouping might not accurately reflect your data estate. These issues can include:

- Incorrectly marking an asset as a resource set.
- Putting an asset into the wrong resource set.
- Incorrectly marking an asset as not being a resource set.

To customize or override how Microsoft Purview detects which assets are grouped as resource sets and how they're displayed within the catalog, you can define pattern rules in the management center. For step-by-step instructions and syntax, see resource set pattern rules.

Known limitations with resource sets

- By default, resource set assets will only be deleted by a scan if Advanced Resource sets are enabled. If this capability is off, resource set assets can only be deleted manually or via API.

Next steps

To get started with Microsoft Purview, see Quickstart: Create a Microsoft Purview account.

Last updated on 03/31/2026

Create resource set pattern rules

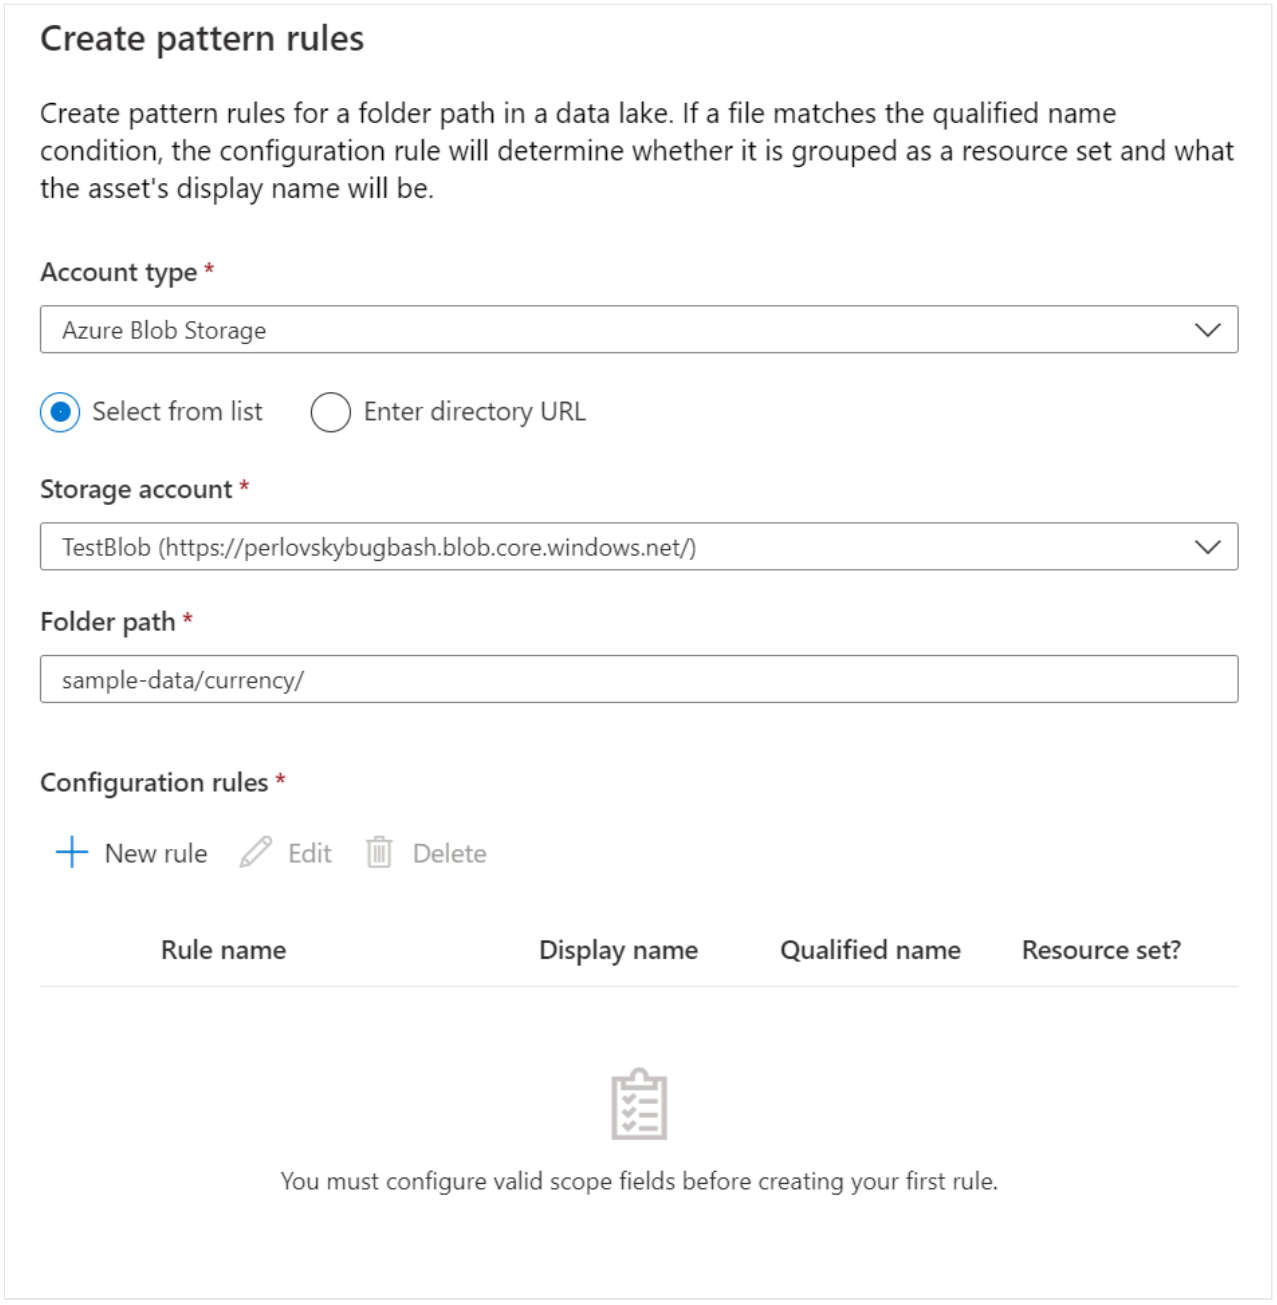
06/06/2025

At-scale data processing systems typically store a single table in storage as multiple files. This concept is represented in Microsoft Purview by using resource sets. A resource set is a single object in Microsoft Purview Unified Catalog that represents a large number of assets in storage. To learn more, see Understanding resource sets.

When scanning a storage account, Microsoft Purview uses a set of defined patterns to determine if a group of assets is a resource set. In some cases, the resource set grouping might not accurately reflect your data estate. Resource set pattern rules allow you to customize or override how Microsoft Purview detects which assets are grouped as resource sets and how they're displayed within the catalog.

Pattern rules are currently supported in the following source types:

- Azure Data Lake Storage Gen2
- Azure Blob Storage
- Azure Files
- Amazon S3



The Advanced resource set feature set must be enabled to create resource set pattern rules. To learn more, see Understanding Advanced resource sets.

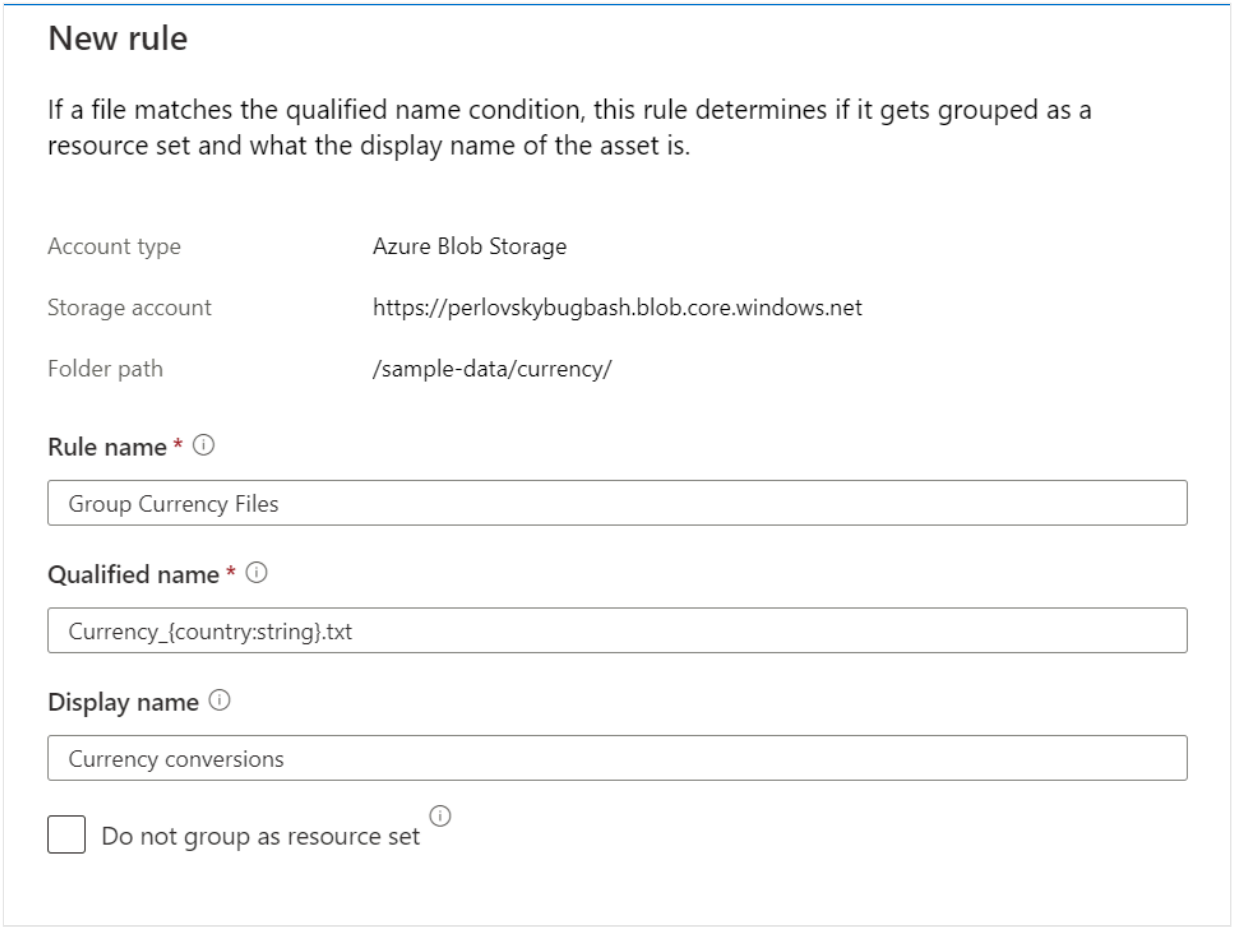
How to create a resource set pattern rule

Follow the steps below to create a new resource set pattern rule:

1. Go to Data Map and select **Source management**, select **Pattern rules**, then select **New** to create a new rule set.

2. Enter the scope of your resource set pattern rule. Select your storage account type and the name of the storage account you wish to create a rule set on. Each set of rules is applied relative to a folder path scope specified in the **Folder path** field.

3. To enter a rule for a configuration scope, select **+ New Rule**.



4. Enter in the following fields to create a rule:

   a. **Rule name:** The name of the configuration rule. This field has no effect on the assets the rule applies to.

   b. **Qualified name:** A qualified path that uses a combination of text, dynamic replacers, and static replacers to match assets to the configuration rule. This path is relative to the scope of the configuration rule. See the syntax section below for detailed instructions on how to specify qualified names.

   c. **Display name:** The display name of the asset. This field is optional. Use plain text and static replacers to customize how an asset is displayed in the catalog. For more detailed instructions, see the syntax section below.

d. **Do not group as resource set:** If enabled, matched resource won't be grouped into a resource set.

5. Save the rule by selecting **Add**.

> **Note**
>
> After a pattern rule is created, all new scans will apply the rule during ingestion. Existing assets in Unified Catalog will be updated via a background process which can take up to a few hours.

Pattern rule syntax

When creating resource set pattern rules, use the following syntax to specify which assets rules apply to.

Dynamic replacers (single brackets)

Single brackets are used as **dynamic replacers** in a pattern rules. Specify a dynamic replacer in the qualified name using format `{<replacerName>:<replacerType>}`. If matched, dynamic replacers are used as a grouping condition that indicate assets should be represented as a

resource set. If the assets are grouped into a resource set, the resource set qualified path would contain `{replacerName}` where the replacer was specified.

For example, If two assets `folder1/file-1.csv` and `folder2/file-2.csv` matched to rule `{folder:string}/file-{NUM:int}.csv`, the resource set would be a single entity `{folder}/file-{NUM}.csv`.

Special case: Dynamic replacers when not grouping into resource set

If *Don't group as resource set* is enabled for a pattern rule, the replacer name is an optional field. `{:<replacerType>}` is valid syntax. For example, `file-{:int}.csv` would successfully match for `file-1.csv` and `file-2.csv` and create two different assets instead of a resource set.

Static replacers (double brackets)

Double brackets are used as **static replacers** in the qualified name of a pattern rule. Specify a static replacer in the qualified name using format `{{<replacerName>:<replacerType>}}`. If matched, each set of unique static replacer values creates different resource set groupings.

For example, If two assets `folder1/file-1.csv` and `folder2/file-2.csv` matched to rule `{{folder:string}}/file-{NUM:int}.csv`, two resource sets would be created `folder1/file-{NUM}.csv` and `folder2/file-{NUM}.csv`.

Static replacers can be used to specify the display name of an asset matching to a pattern rule. Using `{{<replacerName>}}` in the display name of a rule uses the matched value in the asset name.

Available replacement types

Below are the available types that can be used in static and dynamic replacers:

Expand table

Type	Structure
string	A series of one or more Unicode characters including delimiters like spaces.
int	A series of 1 or more 0-9 ASCII characters, it can be 0 prefixed (for example, 0001).
guid	A series of 32 or 8-4-4-4-12 string representation of an UUID as defined in RFC 4122.
date	A series of 6 or 8 0-9 ASCII characters with optionally separators: yyyymmdd, yyyy-mm-dd, yymmdd, yy-mm-dd, specified in RFC 3339.

Type	Structure
time	A series of 4 or 6 0-9 ASCII characters with optionally separators: HHmm, HH:mm, HHmmss, HH:mm:ss specified in RFC 3339.
timestamp	A series of 12 or 14 0-9 ASCII characters with optionally separators: yyyy-mm-ddTHH:mm, yyyymmddhhmm, yyyy-mm-ddTHH:mm:ss, yyyymmddHHmmss specified in RFC 3339.
boolean	Can contain 'true' or 'false', case insensitive.
number	A series of 0 or more 0-9 ASCII characters, it can be 0 prefixed (for example, 0001) followed by optionally a dot '.' and a series of 1 or more 0-9 ASCII characters, it can be 0 postfixed (for example, .100)
hex	A series of one or more ASCII characters from the set 0-1 and A-F, the value can be 0 prefixed
locale	A string that matches the syntax specified in RFC 5646.

Order of resource set pattern rules getting applied

Below is the order of operations for applying pattern rules:

1. More specific scopes take priority if an asset matches to two rules. For example, rules in a scope `container/folder` will apply before rules in scope `container`.
2. Order of rules within a specific scope. This can be edited in the UX.
3. If an asset doesn't match to any specified rule, the default resource set heuristics apply.

Examples

Example 1

SAP data extraction into full and delta loads

Inputs

Files:

- `https://myazureblob.blob.core.windows.net/bar/customer/full/2020/01/13/saptable_customer_20200101_20200102_01.txt`
- `https://myazureblob.blob.core.windows.net/bar/customer/full/2020/01/13/saptable_customer_20200101_20200102_02.txt`

- `https://myazureblob.blob.core.windows.net/bar/customer/delta/2020/01/15/saptable_customer_20200101_20200102_01.txt`
- `https://myazureblob.blob.core.windows.net/bar/customer/full/2020/01/17/saptable_customer_20200101_20200102_01.txt`
- `https://myazureblob.blob.core.windows.net/bar/customer/full/2020/01/17/saptable_customer_20200101_20200102_02.txt`

Pattern rule

Scope: `https://myazureblob.blob.core.windows.net/bar/`

Display name: 'External Customer'

Qualified Name: `customer/{extract:string}/{year:int}/{month:int}/{day:int}/saptable_customer_{date_from:date}_{date_to:time}_{sequence:int}.txt`

Resource Set: true

Output

One resource set asset

Display Name: External Customer

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/customer/{extract}/{year}/{month}/{day}/saptable_customer_{date_from}_{date_to}_{sequence}.txt`

Example 2

IoT data in avro format

Inputs

Files:

- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-001.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-002.avro`

- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/02-01-2020/22:33:22-001.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-90/01-01-2020/22:33:22-001.avro`

Pattern rules

Scope: `https://myazureblob.blob.core.windows.net/bar/`

Rule 1

Display name: 'machine-89'

Qualified Name: `raw/machinename-89/{date:date}/{time:time}-{id:int}.avro`

Resource Set: true

Rule 2

Display name: 'machine-90'

Qualified Name: `raw/machinename-90/{date:date}/{time:time}-{id:int}.avro`

Resource Set: true

Outputs

Two resource sets

Resource Set 1

Display Name: machine-89

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/{date}/{time}-{id}.avro`

Resource Set 2

Display Name: machine-90

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-90/{date}/{time}-{id}.avro`

Example 3

IoT data in avro format

Inputs

Files:

- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-001.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-002.avro`
- `https://myazureblob.blob.core.windows.netbar/raw/machinename-89/02-01-2020/22:33:22-001.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-90/01-01-2020/22:33:22-001.avro`

Pattern rule

Scope: `https://myazureblob.blob.core.windows.net/bar/`

Display name: 'Machine-{{machineid}}'

Qualified Name: `raw/machinename-{{machineid:int}}/{date:date}/{time:time}-{id:int}.avro`

Resource Set: true

Outputs

Resource Set 1

Display name: machine-89

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/{date}/{time}-{id}.avro`

Resource Set 2

Display name: machine-90

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-90/{date}/{time}-{id}.avro`

Example 4

Don't group into resource sets

Inputs

Files:

- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-001.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-002.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/02-01-2020/22:33:22-001.avro`
- `https://myazureblob.blob.core.windows.net/bar/raw/machinename-90/01-01-2020/22:33:22-001.avro`

Pattern rule

Scope: `https://myazureblob.blob.core.windows.net/bar/`

Display name: `Machine-{{machineid}}`

Qualified Name: `raw/machinename-{{machineid:int}}/{{:date}}/{{:time}}-{{:int}}.avro`

Resource Set: false

Outputs

Four individual assets

Asset 1

Display name: machine-89

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-001.avro`

Asset 2

Display name: machine-89

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/01-01-2020/22:33:22-002.avro`

Asset 3

Display name: machine-89

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-89/02-01-2020/22:33:22-001.avro`

Asset 4

Display name: machine-90

Qualified Name: `https://myazureblob.blob.core.windows.net/bar/raw/machinename-90/01-01-2020/22:33:22-001.avro`

Next steps

Get started by registering and scanning an Azure Data Lake Gen2 storage account.

Scan data sources in Data Map

In Microsoft Purview, after you register your data source, you can scan your source to capture technical metadata, extract schema, and apply classifications to your data.

- For more information about scanning, see Scans and ingestion in Data Map.
- Review scanning best practices.

In this article, you learn the basic steps for scanning any data source.

> **Tip**
>
> Each source has its own instructions and prerequisites for scanning. For the most complete scanning instructions, select your source from the **supported sources list** and review its scanning instructions.

Prerequisites

Review the list of sources that are available to register and scan in Microsoft Purview.

Before you can scan your data source, complete these steps:

1. Register your data source. This step essentially gives Microsoft Purview the address of your data source and maps it to a collection or domain in Data Map.
2. Consider your network and choose the right integration runtime configuration for your scenario.
3. Consider what credentials you use to connect to your source. All source pages have a **Scan** section that includes details about what authentication types are available.

Create a scan

In the following steps, use Azure Blob Storage as an example, and authenticate by using the Microsoft Purview Managed Identity.

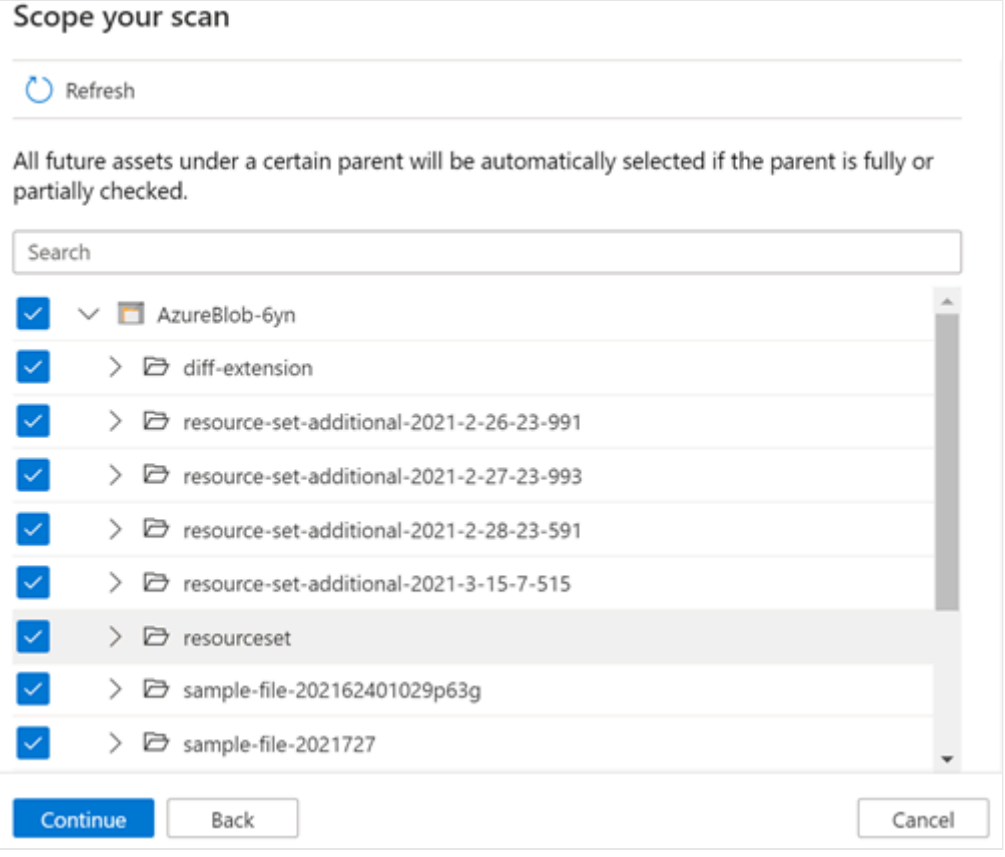
> **Important**
>
> These steps describe how to create a scan. For source-specific prerequisites and scanning instructions, see **Data sources that connect to Data Map**.

1. Open the Microsoft Purview portal and go to **Data Map** > **Data sources**. You can view your registered sources in either a map or table view.

> **Tip**
>
> If your Data Map has a large number of registered sources, the table view might perform better.

2. Find your source and select **New Scan**.

3. Enter a **Name** for the scan.



4. For **Credential**, select your authentication method.

5. Choose the current domain, collection, or a subcollection for the scan. The collection or domain you choose is where the scan stores the discovered metadata.

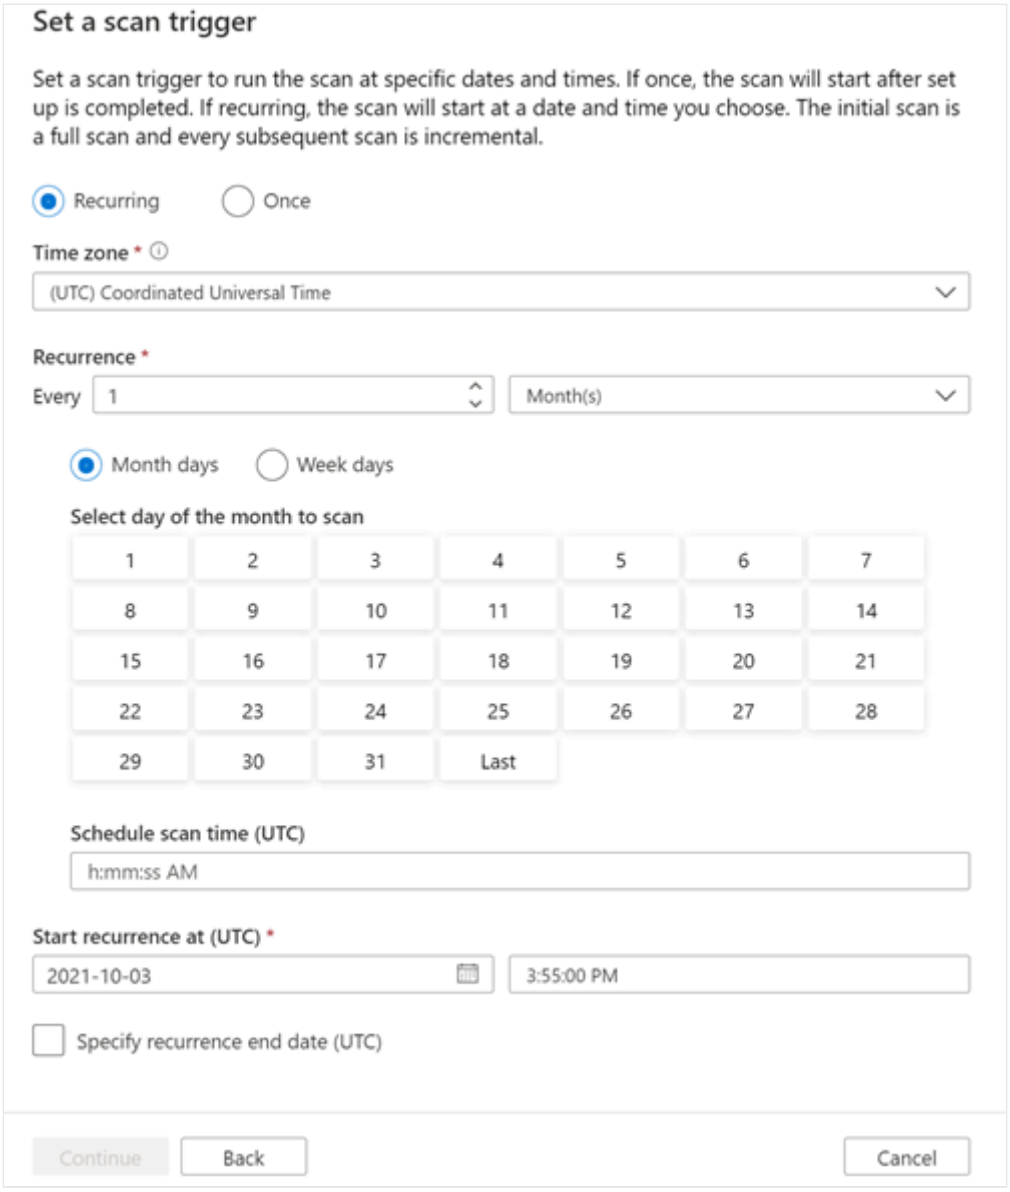
   > **Note**
   >
   > The scan is always in the same domain as the registered source, but you can select a subcollection.

6. Select **Test connection**. If the connection is successful, select **Continue**. See troubleshooting if the connection isn't successful.

7. Depending on the source, you can scope your scan to a specific subset of data. For Azure Blob Storage, select folders and subfolders by choosing the appropriate items in the list.

8. Select a scan rule set. The scan rule set contains the kinds of data classifications your scan checks. You can choose the system default (which contains all classifications available for the source), existing custom rule sets made by others in your organization, or create a new rule set inline.

   > **Note**
   >
   > You can only select the credentials and scan rule sets associated with the domain where you registered your source.



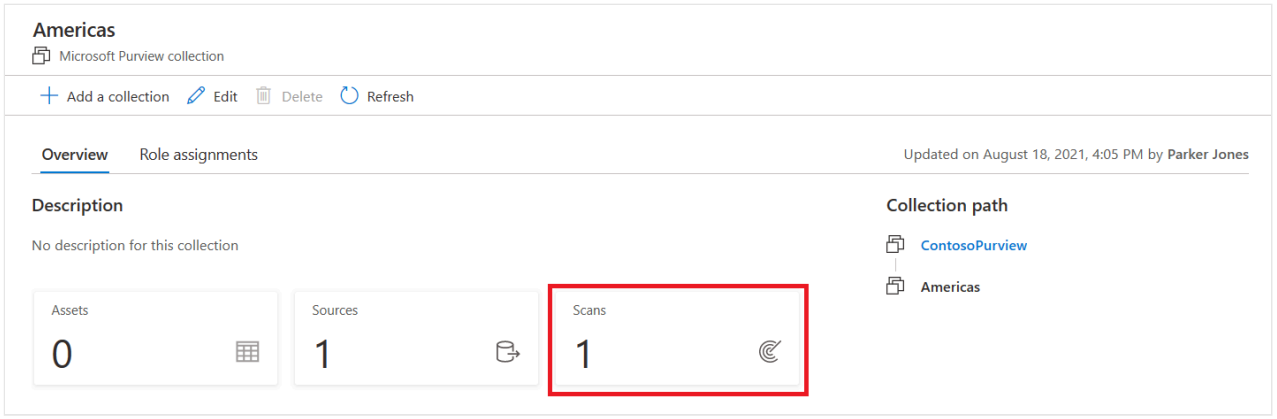
9. Choose your scan trigger. You can set up a schedule or run the scan once. Learn more about the supported schedule options.

10. Review your scan and select **Save and run**.

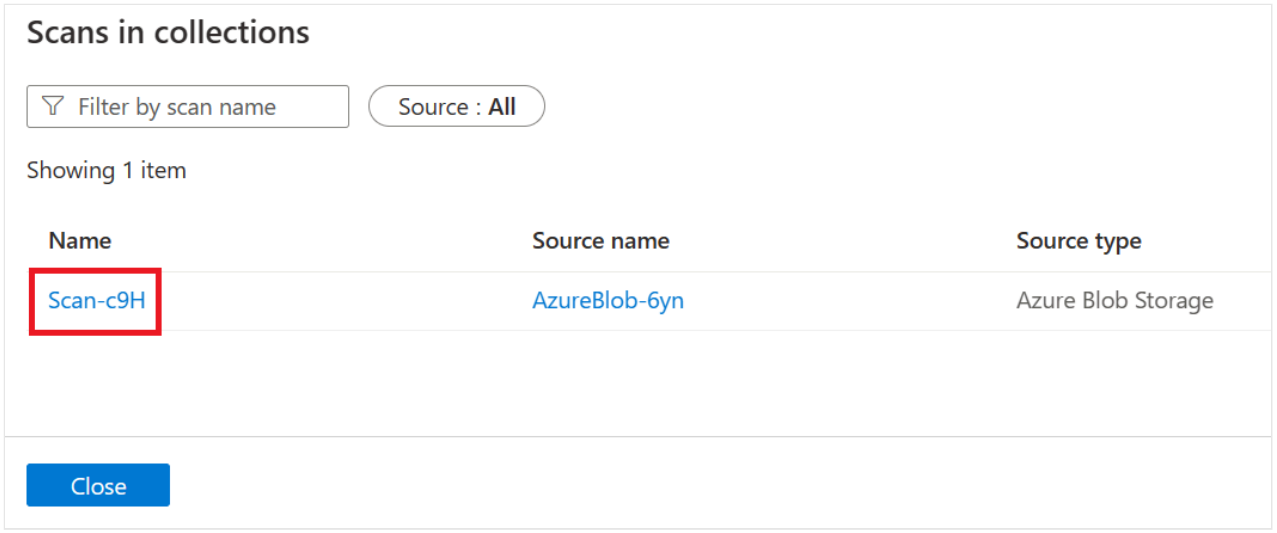
Schedule a scan

When you set up the scan, choose to run it once or on demand, or set up a recurring schedule. You can configure the following schedule options:

- **Time zone**: Select the time zone you'd like to align your scan schedule with. If the time zone you select observes daylight savings, the trigger autoadjusts for the difference.
- **Recurrence**: Select a **daily**, **weekly**, or **monthly** scan recurrence.
  - **Daily recurrence**: Set recurrence to every X days, and specify the scan start time of the day.
  - **Weekly recurrence**: Set recurrence to every X weeks, select one or multiple days of the week, and specify the scan start time of the day.
  - **Monthly recurrence**: Set recurrence to every X months, choose between by month days or by weekdays, select one or multiple days or weekdays of the month, and specify the scan start time of the day.
- **Start recurrence at**: Set when the scan schedule begins.
- **Specify recurrence end date** (optional): If you want to stop the scan after a certain amount of time, enable this option by selecting the check box and provide an end date.

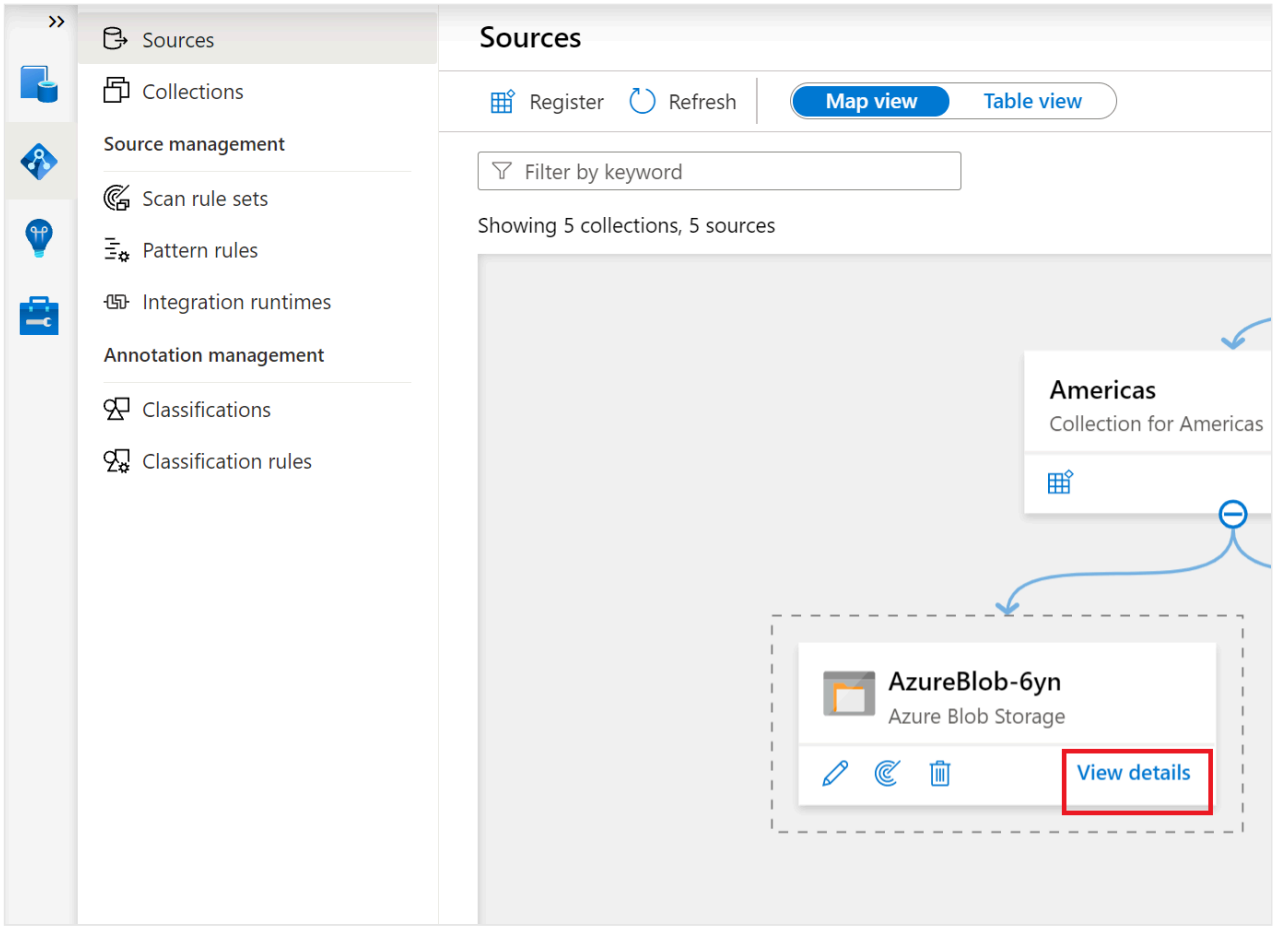


View a scan

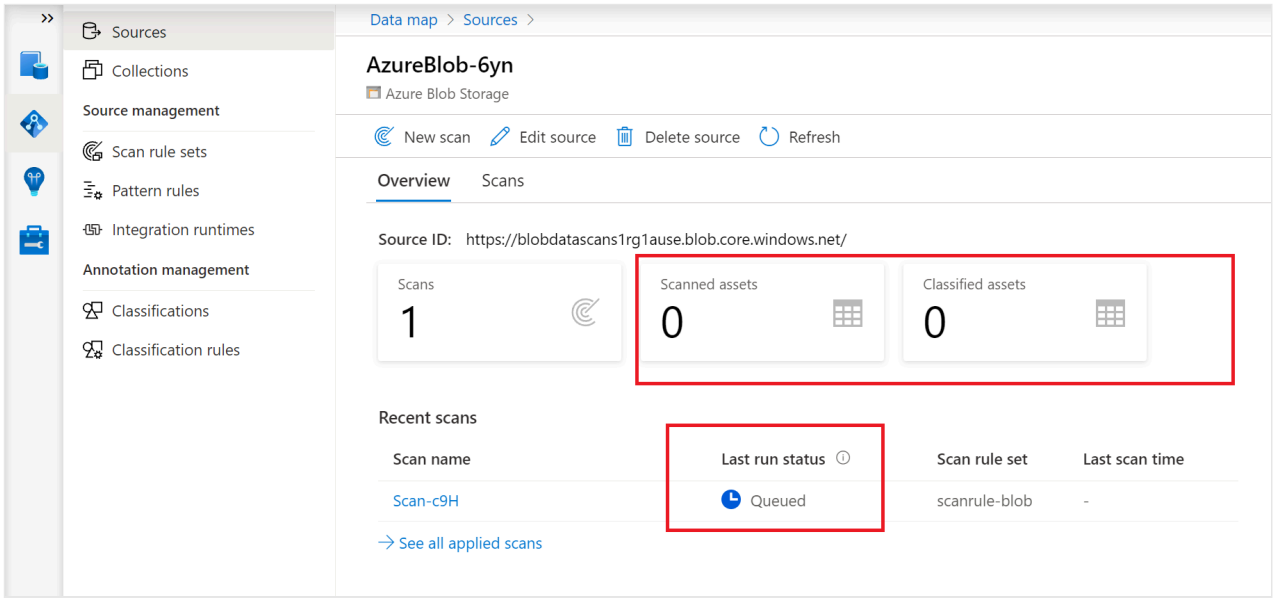


Depending on the amount of data in your data source, a scan can take some time to run. Here's how you can check on progress and see results when the scan is complete.

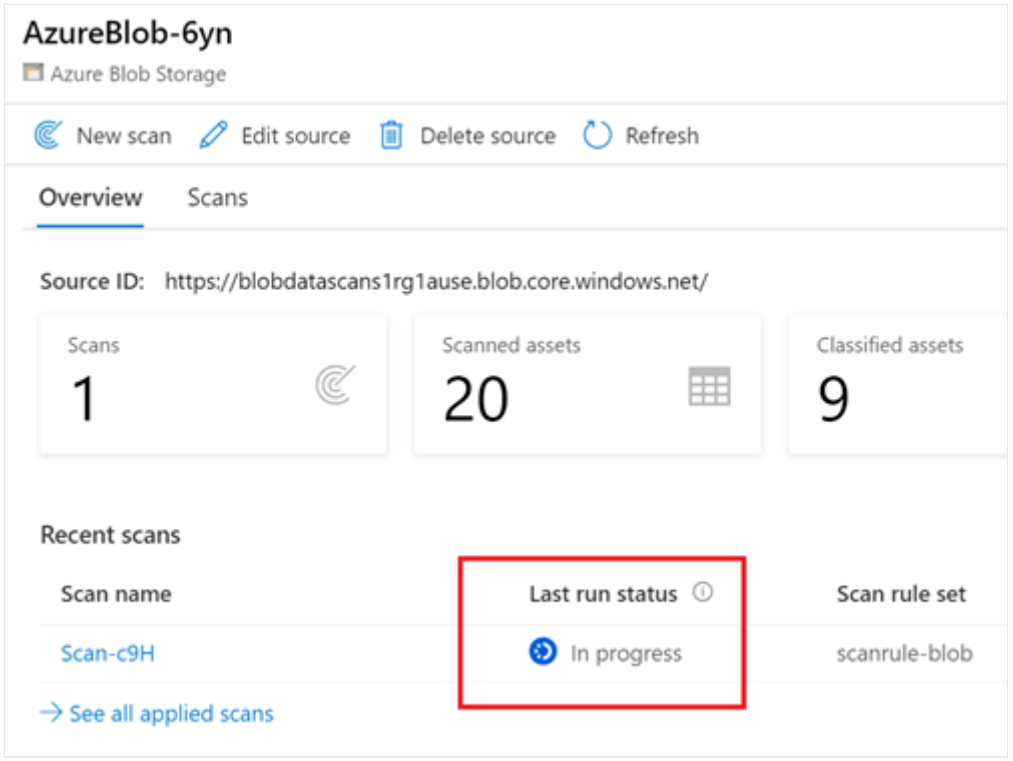
1. You can view your scan from the collection, domain, or from the source itself.



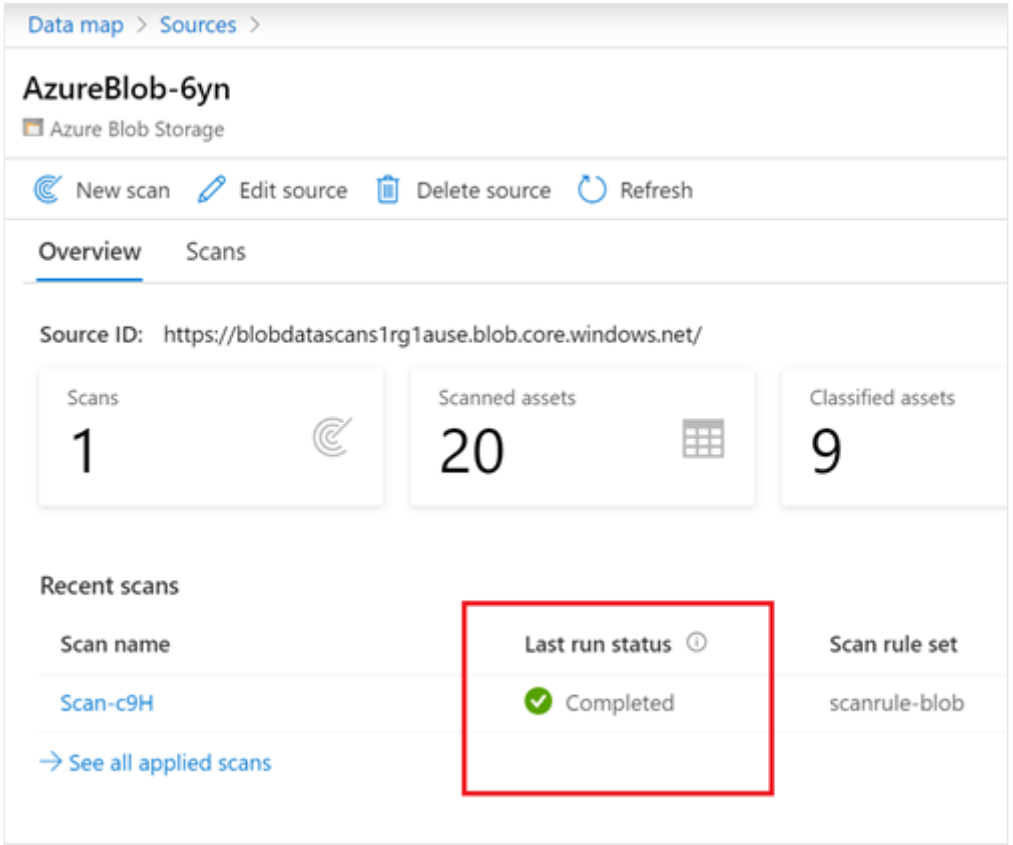
2. To view from the collection or domain, go to your *Collection* or *Domain* in Data Map and select **Scans**.



3. Select your scan name to see details.

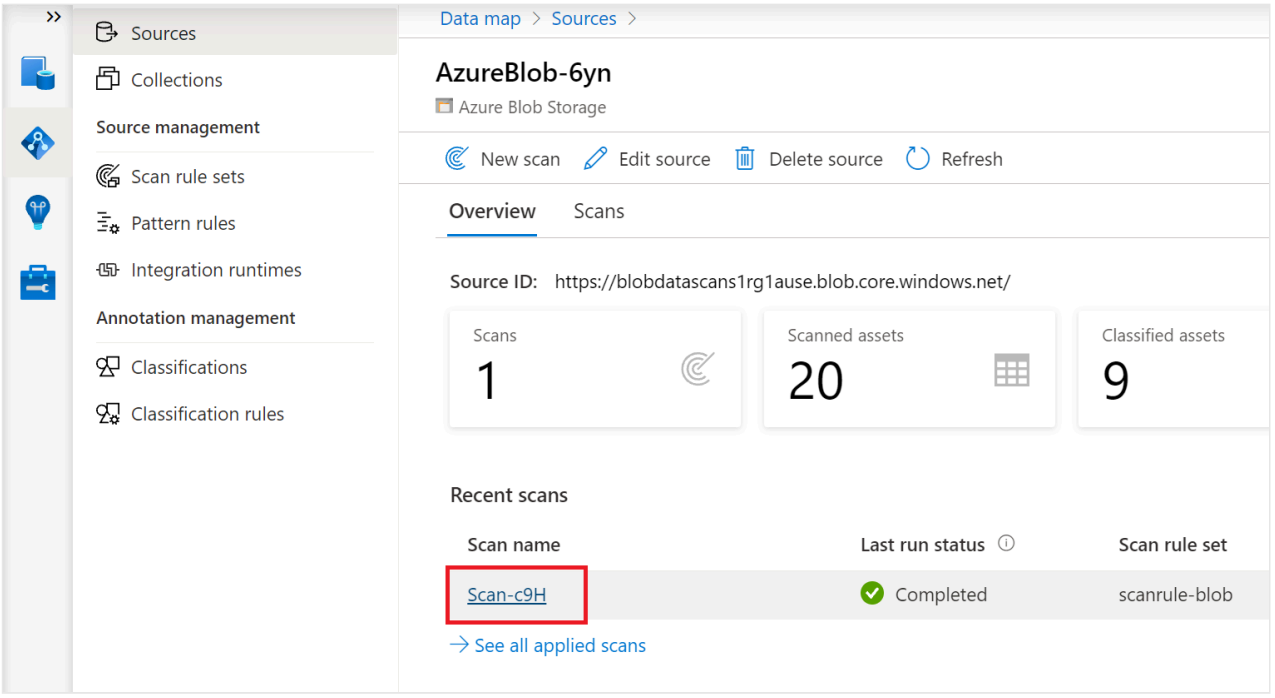


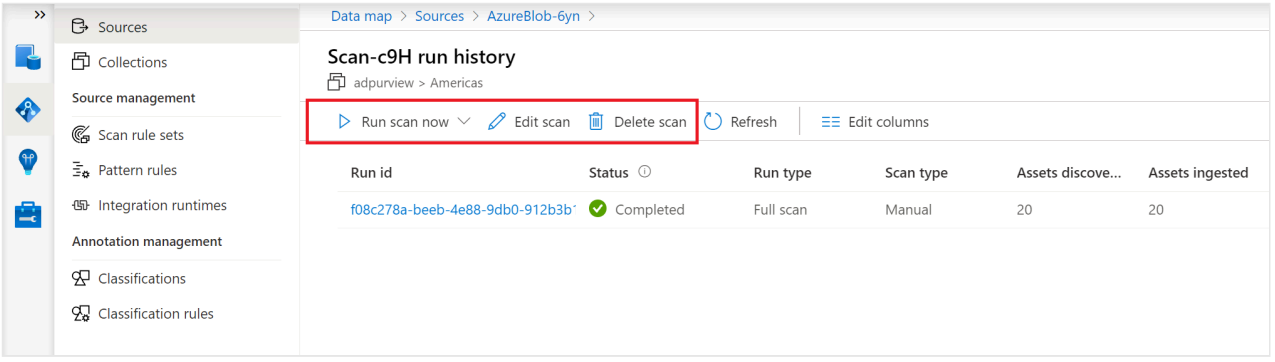
4. Or, you can go directly to the *data source* in its *Collection* or *Domain* and select **View Details** to check the status of the scan.



5. The scan details show the progress of the scan in the **Last run status** and the number of assets *scanned* and *classified*.

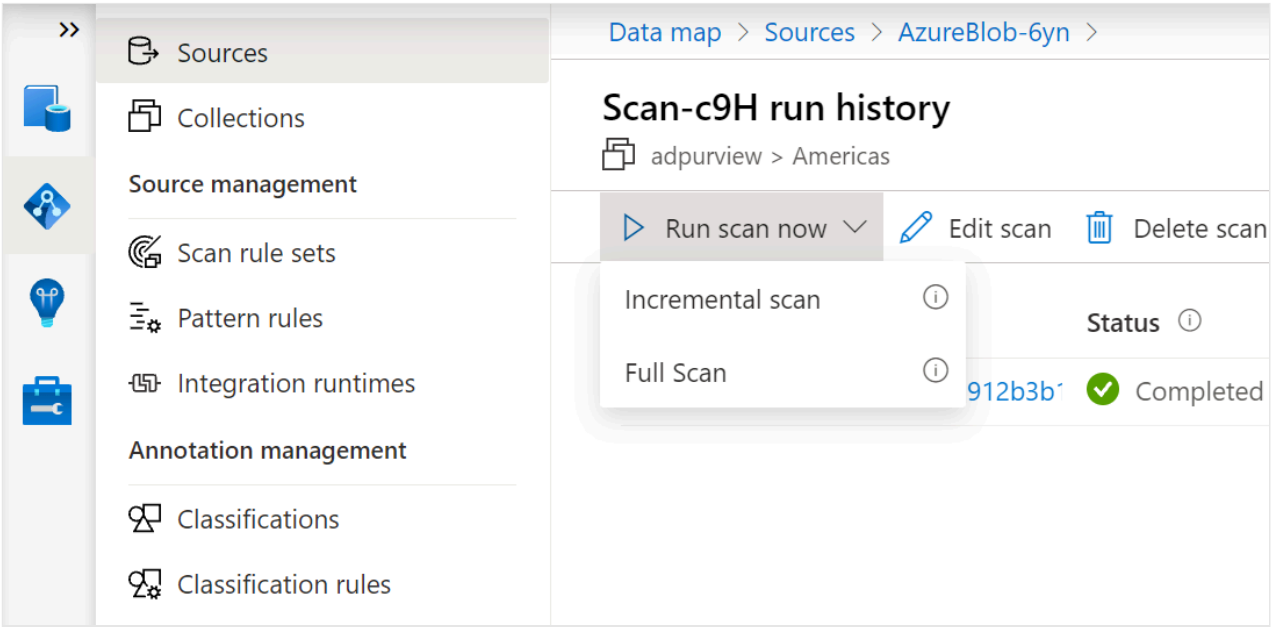
6. The **Last run status** updates to **In progress** and then **Completed** once the entire scan runs successfully.





Manage a scan

After a scan finishes, you can manage it or run it again.



1. Select the **Scan name** from either the collections list or the source page to manage the scan.

2. You can run the scan again, edit the scan, or delete the scan.

3. You can run a full scan, which scans all the content in your scope. Some sources also have an **Incremental scan** option. An **Incremental scan** scans only those resources that are updated since the last scan. Check the **supported capabilities** table in your source page to see if incremental scan is available for your source after the first scan.

Troubleshooting

Setting up the connection for your scan can be complex, since it's a custom set up for your network and your credentials.

If you can't connect to your source, follow these steps:

1. Review your source page prerequisites to make sure you didn't miss anything.
2. Review your authentication option in the **Scan** section of your source page to confirm you set up the authentication method correctly.
3. Review troubleshoot connections.
4. Create a support request, so the support team can help you troubleshoot your specific environment.

Data Map scanning best practices

Microsoft Purview Data Map supports automated scanning of on-premises, multicloud, and software as a service (SaaS) data sources.

When you run a scan, the process starts to ingest metadata from the registered data sources. At the end of the scan and curation process, you get curated metadata that includes technical metadata. This metadata can include data asset names such as table names or file names, file size, columns, and data lineage. For structured data sources, schema details are also captured. A relational database management system is an example of this type of source.

The curation process applies automated classification labels on the schema attributes based on the scan rule set you configure. If your Microsoft Purview account is connected to the Microsoft Purview portal, sensitivity labels are applied.

> **Important**
>
> If you have any Azure Policies that prevent updates to storage accounts, these policies cause errors for the Microsoft Purview scanning process. See Create an Azure policy exclusion for Microsoft Purview to create an exception for Microsoft Purview accounts.

Why do you need best practices to manage data sources?

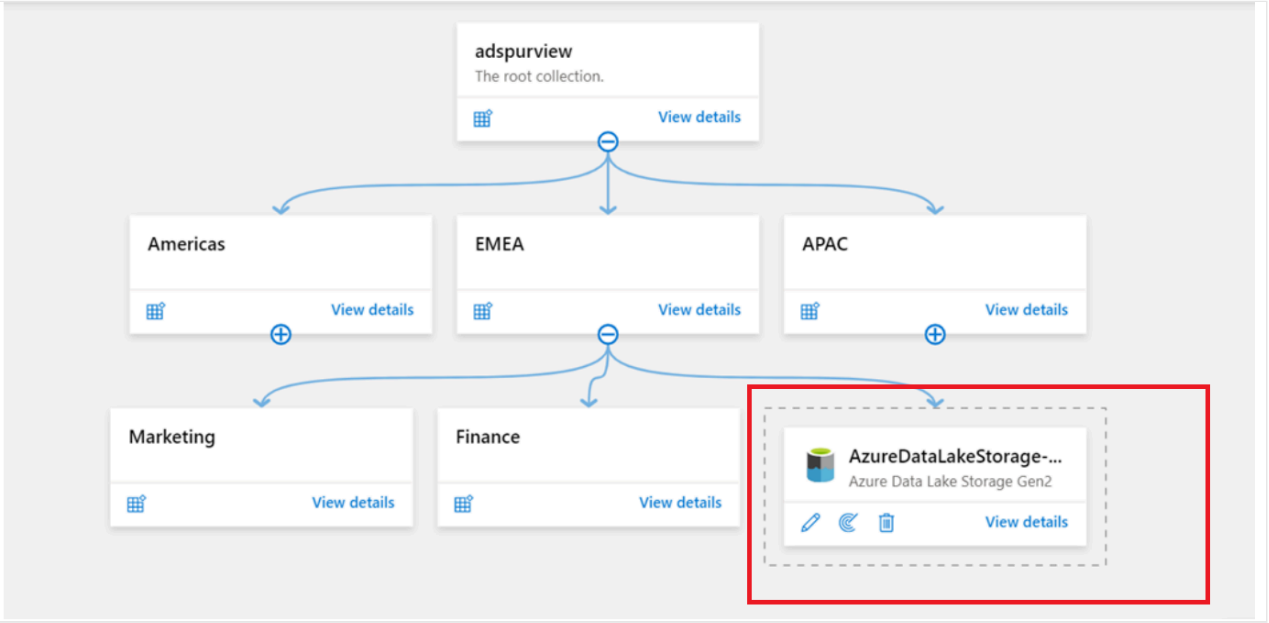
Best practices help you:

- Optimize cost.
- Build operational excellence.
- Improve security compliance.
- Gain performance efficiency.

Register a source and establish a connection

The following design considerations and recommendations help you register a source and establish a connection.

Design considerations



- Use collections to create the hierarchy that aligns with the organization's strategy, such as geographical location, business function, or source of data. The hierarchy defines the data

sources to register and scan.

- By design, you can't register data sources multiple times in the same Microsoft Purview account. This architecture helps you avoid the risk of assigning different access control to the same data source.

Design recommendations

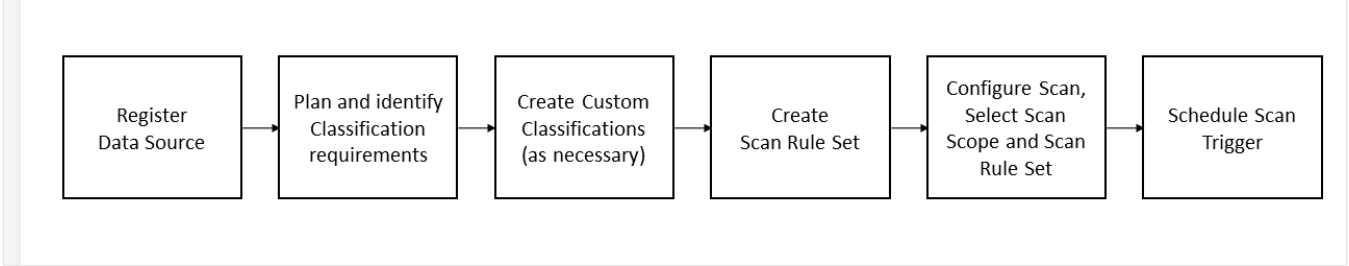
- If multiple teams consume the metadata of the same data source, register and manage the data source at a parent collection. Then, create corresponding scans under each subcollection. In this way, relevant assets appear under each child collection. The map view groups sources without parents in a dotted box. No arrows link them to parents.

- Use the **Azure Multiple** option if you need to register multiple sources, such as Azure subscriptions or resource groups, in the cloud. For more information, see the following documentation:
  - Scan multiple sources in Microsoft Purview
  - Check data source readiness at scale
  - Configure access to data sources for Microsoft Purview MSI at scale

- After you register a data source, you can scan the same source multiple times. Different teams or business units might use the same source in different ways.

For more information on how to define a hierarchy for registering data sources, see Best practices on collections architecture.

Scanning



The following design considerations and recommendations are organized based on the key steps involved in the scanning process.

Design considerations

- After you register the data source, set up a scan to manage automated and secure metadata scanning and curation.
- Scan setup includes configuring the name of the scan, scope of scan, integration runtime, scan trigger frequency, scan rule set, and resource set uniquely for each data source per scan frequency.
- Before you create any credentials, consider your data source types and networking requirements. This information helps you decide which authentication method and integration runtime you need for your scenario.

Design recommendations

After you register your source in the relevant collection, plan and follow the order shown in this example when you set up the scan. This process order helps you avoid unexpected costs and rework.

1. Identify your classification requirements from the system in-built classification rules. Or create specific custom classification rules, as necessary. Base them on specific industry, business, or regional requirements, which aren't available out of the box:

    - See the classification best practices.
    - See how to create a custom classification and classification rule.

2. Create scan rule sets before you configure the scan. When you create the scan rule set, ensure the following points:

    - Verify if the system default scan rule set is sufficient for the data source you're scanning. Otherwise, define your custom scan rule set.

    - The custom scan rule set can include both system default and custom rules, so clear those options that aren't relevant for the data assets you're scanning.

- Where necessary, create a custom rule set to exclude unwanted classification labels. For example, the system rule set contains generic government code patterns for the planet, not just the United States. Your data might match the pattern of some other type, such as "Belgium Driver's License Number."
- Limit custom classification rules to *most important* and *relevant* labels to avoid clutter. You don't want to have too many labels tagged to the asset.
- If you modify the custom classification or scan rule set, a full scan is triggered. Configure the classification and scan rule set appropriately to avoid rework and costly full scans.

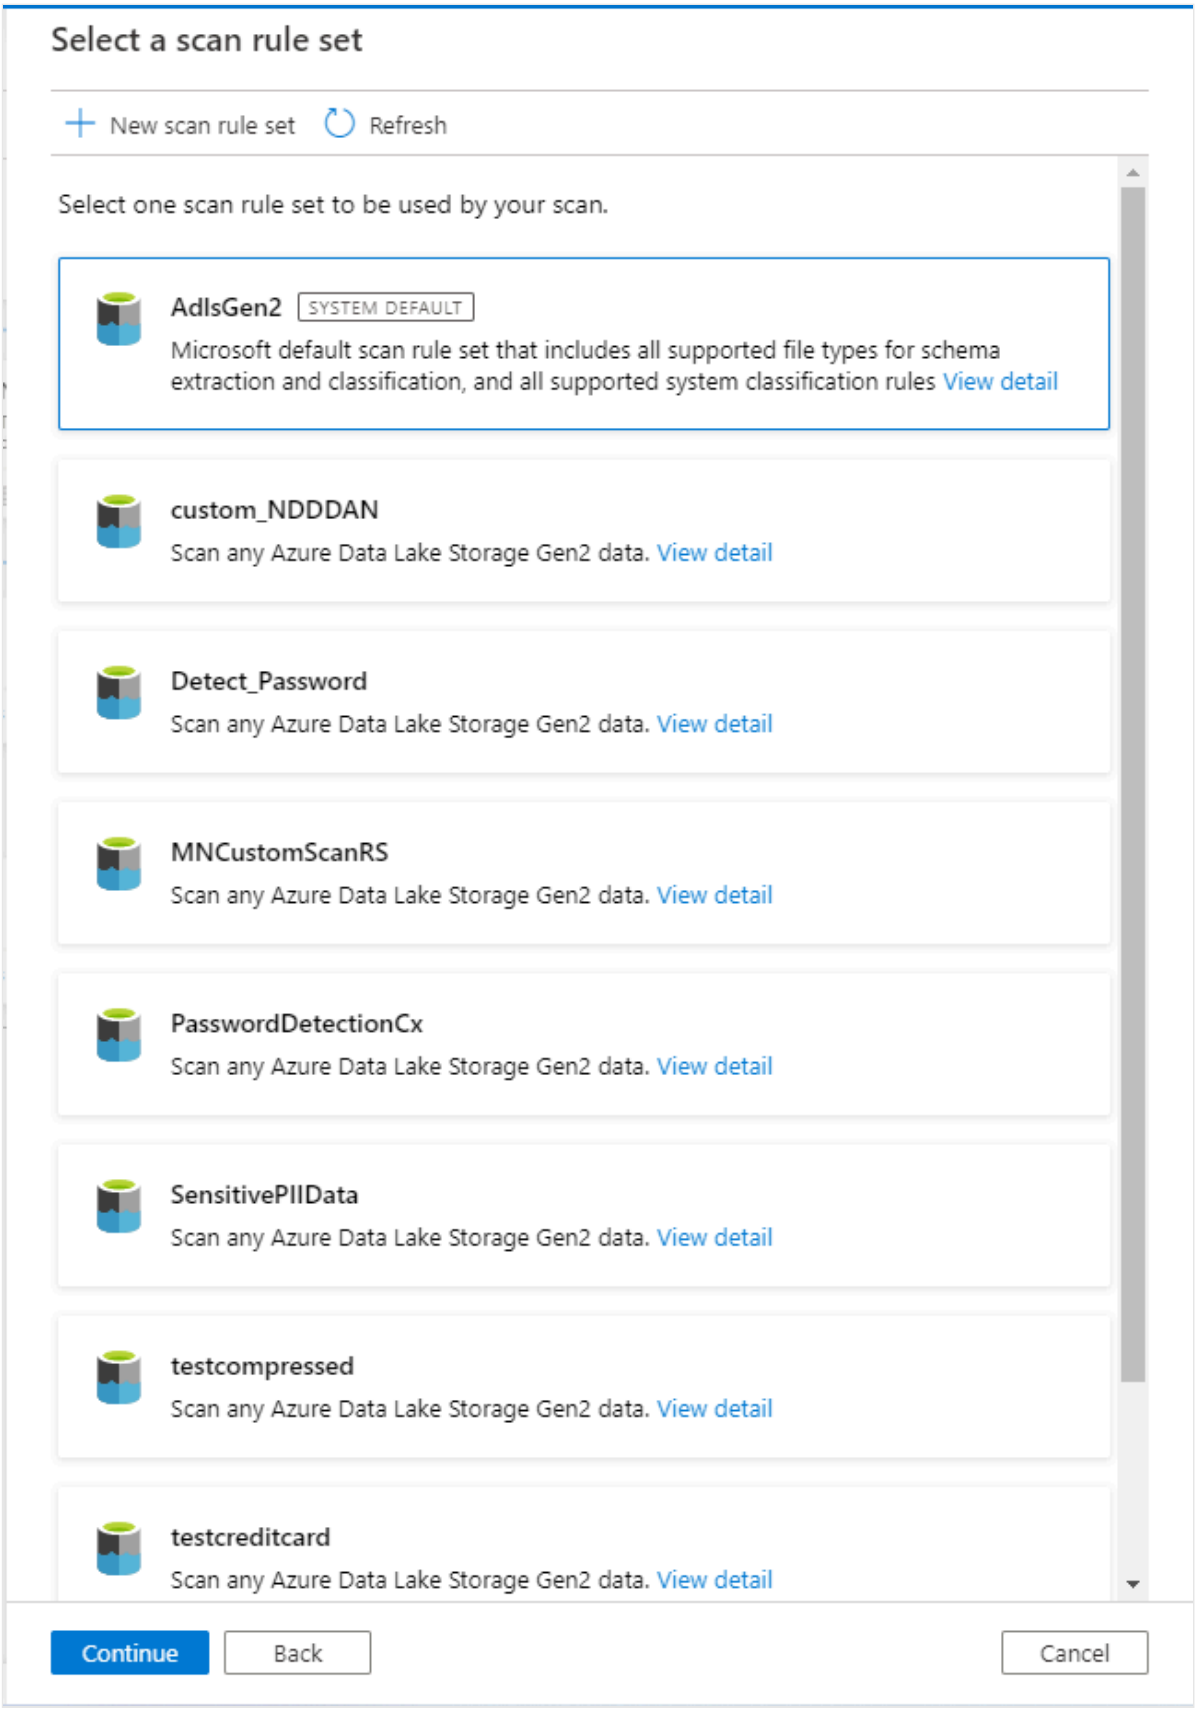
  > ⓘ **Note**
  >
  > When you scan a storage account, Microsoft Purview uses a set of defined patterns to determine if a group of assets forms a resource set. You can use resource set pattern rules to customize or override how Microsoft Purview detects which assets are grouped as resource sets. The rules also determine how the assets are displayed within the catalog. For more information, see Create resource set pattern rules. This feature has cost considerations. For information, see the Microsoft Purview pricing site.

3. Set up a scan for the registered data sources. - **Scan name**: By default, Microsoft Purview uses the naming convention **SCAN-[A-Z][a-z][a-z]**, which isn't helpful when you're trying to identify a scan that you ran. Use a meaningful naming convention. For instance, you could name the scan *environment-source-frequency-time* as DEVODS-Daily-0200. This name represents a daily scan at 0200 hours.

   - **Authentication**: Microsoft Purview offers various authentication methods for scanning data sources, depending on the type of source. It could be Azure cloud or on-premises or non-Microsoft sources. Follow the least-privilege principle for the authentication method in this order of preference:
     - Microsoft Purview MSI - Managed Service Identity (for example, for Azure Data Lake Storage Gen2 sources)
     - User-assigned managed identity
     - Service principal
     - SQL authentication (for example, for on-premises or Azure SQL sources)
     - Account key or basic authentication (for example, for SAP S/4HANA sources)

     For more information, see the how-to guide to manage credentials.

     > ⓘ **Note**



> If you enable a firewall for the storage account, you must use the managed identity authentication method when you set up a scan. When you set up a new credential, the credential name can only contain *letters, numbers, underscores, and hyphens*.

- **Integration runtime**
  - For more information, see Network architecture best practices.
  - If self-hosted integration runtime (SHIR) is deleted, any ongoing scans that rely on it fail.
  - When you use SHIR, make sure that the memory is sufficient for the data source you're scanning. For example, when you use SHIR for scanning an SAP source, if you see "out of memory error":
    - Ensure the SHIR machine has enough memory. The recommended amount is 128 GB.
    - In the scan setting, set the maximum memory available as some appropriate value, for example, 100.
    - For more information, see the prerequisites in Scan to and manage SAP ECC Microsoft Purview.

- **Scope scan**
  - When you set up the scope for the scan, select only the assets that are relevant at a granular level or parent level. This practice ensures that the scan cost is optimal and performance is efficient. All future assets under a certain parent are automatically selected if the parent is fully or partially checked.
  - Some examples for some data sources:
    - For Azure SQL Database or Data Lake Storage Gen2, you can scope your scan to specific parts of the data source. Select the appropriate items in the list, such as folders, subfolders, collections, or schemas.
    - For Oracle, Hive Metastore Database, and Teradata sources, you can specify a specific list of schemas to be exported through semicolon-separated values or schema name patterns.
    - For Google Big query, you can specify a specific list of datasets to be exported through semicolon-separated values.
    - When you create a scan for an entire AWS account, you can select specific buckets to scan. When you create a scan for a specific AWS S3 bucket, you can select specific folders to scan.
    - For Erwin, you can scope your scan by providing a semicolon-separated list of Erwin model locator strings.
    - For Cassandra, you can specify a specific list of key spaces to be exported through semicolon-separated values or through key spaces name patterns.

    - For Looker, you can scope your scan by providing a semicolon-separated list of Looker projects.
    - For Power BI tenant, you might only specify whether to include or exclude personal workspace.
  - In general, use ignore patterns where they're supported, based on wild cards (for example, for data lakes) to exclude temp, config files, RDBMS system tables, or backup or STG tables.
  - When you scan documents or unstructured data, avoid scanning a huge number of such documents. The scan processes the first 20 MB of such documents and might result in longer scan duration.

- **Scan rule set**
  - When you select the scan rule set, make sure to configure the relevant system or custom scan rule set that you created earlier. - You can create custom file types and fill in the details accordingly. Currently, Microsoft Purview supports only one character in Custom Delimiter. If you use custom delimiters, such as ~, in your actual data, you need to create a new scan rule set.

- **Scan type and schedule**
  - You can configure the scan process to run full or incremental scans.
  - Run the scans during nonbusiness or off-peak hours to avoid any processing overload on the source.
  - The initial scan is a full scan, and every subsequent scan is incremental. You can schedule subsequent scans as periodic incremental scans. Learn more about the

supported schedule options.
    - The frequency of scans should align with the change management schedule of the data source or business requirements. For example:
        - If the source structure could potentially change weekly, the scan frequency should be in sync. Changes include new assets or fields within an asset that are added, modified, or deleted.
        - If the classification or sensitivity labels need to be up to date on a weekly basis, perhaps for regulatory reasons, the scan frequency should be weekly. - If partition files are added every week in a source data lake, you might schedule monthly scans. You don't need to schedule weekly scans because there's no change in metadata. This suggestion assumes there are no new classification scenarios.
        - The maximum duration that the scan can run is seven days, possibly because of memory issues. This time period excludes the ingestion process. If progress isn't updated after seven days, the scan is marked as failed. The ingestion (into catalog) process currently doesn't have any such limitation.

- **Canceling scans**
    - Currently, you can cancel or pause scans only if the status of the scan transitions into an "In Progress" state from "Queued" after you trigger the scan.
    - Canceling an individual child scan isn't supported.

Points to note

- If you remove a field, column, table, or file from the source system after a scan runs, Microsoft Purview only shows the removal after the next scheduled full or incremental scan.
- You can delete an asset from a Microsoft Purview catalog by selecting **Delete** under the asset name. This action doesn't remove the object in the source. If you run a full scan on the same source, the scan reingests the object in the catalog. If you run an incremental scan, the deleted asset isn't picked up unless the object is modified at the source. For example, if a column is added or removed from the table.
- To understand the behavior of subsequent scans after *manually* editing a data asset or an underlying schema through the classic Microsoft Purview governance portal, see classic catalog asset details.
- For more information, see how to view, edit, and delete assets.

Troubleshoot your scans and connections in the Microsoft Purview Data Map

Article • 04/30/2024

This article describes how to troubleshoot connection errors while setting up scans on data sources in Microsoft Purview, or errors that could occur with your scans.

Permission the credential on the data source

If you're using a managed identity or service principal as a method of authentication for scans, you'll have to allow these identities to have access to your data source.

There are specific instructions for each source type.

> **Important**
>
> Verify that you have followed all prerequisite and authentication steps for the source you are connecting to. You can find all available sources listed in the Microsoft Purview supported sources article.

Verifying Azure Role-based Access Control to enumerate Azure resources in the Microsoft Purview governance portal

Registering single Azure data source

To register a single data source in Microsoft Purview, such as an Azure Blob Storage or an Azure SQL Database, you must be granted at least **Reader** role on the resource or inherited from higher scope such as resource group or subscription. Some Azure RBAC roles, such as Security Admin, don't have read access to view Azure resources in control plane.

Verify this by following the steps below:

1. From the Azure portal, navigate to the resource that you're trying to register in Microsoft Purview. If you can view the resource, it's likely, that you already have at

least reader role on the resource.
2. Select **Access control (IAM)** > **Role Assignments**.
3. Search by name or email address of the user who is trying to register data sources in Microsoft Purview.
4. Verify if any role assignments, such as Reader, exist in the list or add a new role assignment if needed.

Scanning multiple Azure data sources

1. From the Azure portal, navigate to the subscription or the resource group.
2. Select **Access Control (IAM)** from the left menu.
3. Select **+Add**.
4. In the **Select input** box, select the **Reader** role and enter your Microsoft Purview account name (which represents its MSI name).
5. Select **Save** to finish the role assignment.
6. Repeat the steps above to add the identity of the user who is trying to create a new scan for multiple data sources in Microsoft Purview.

Scanning data sources using Private Link

If public endpoint is restricted on your data sources, to scan Azure data sources using Private Link, you need to set up a Self-hosted integration runtime and create a credential.

> **Important**
>
> Scanning multiple data sources which contain databases as Azure SQL database with *Deny public network access*, would fail. To scan these data sources using private Endpoint, instead use registering single data source option.

For more information about setting up a self-hosted integration runtime, see the article about ingestion private endpoints and scanning sources.

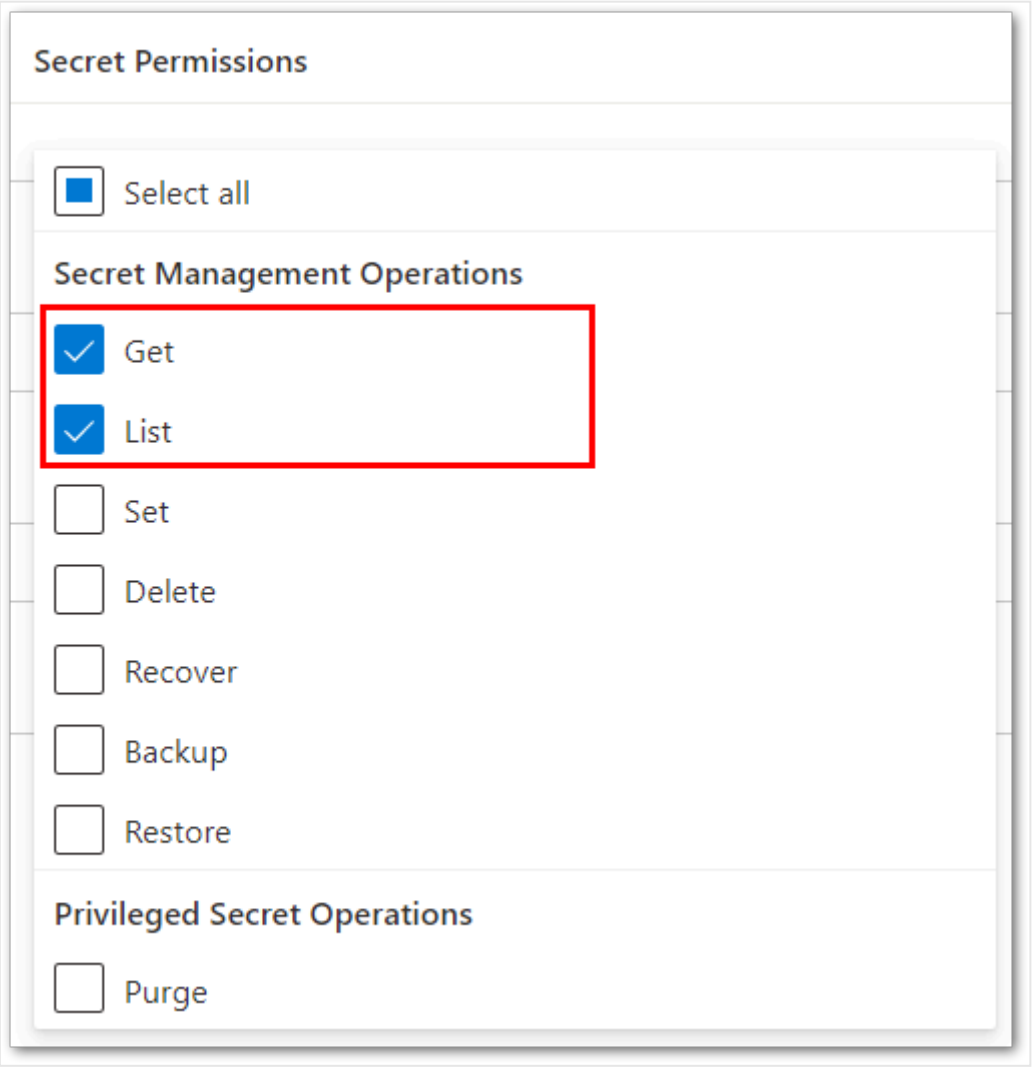
For more information how to create a new credential in Microsoft Purview, see the article about credentials for source authentication in Microsoft Purview.

Storing your credential in your key vault and using the right secret name and version

You must also store your credential in your Azure Key Vault instance and use the right secret name and version.

Verify this by following the steps below:

1. Navigate to your Key Vault.
2. Select **Settings** > **Secrets**.
3. Select the secret you're using to authenticate against your data source for scans.
4. Select the version that you intend to use and verify that the password or account key is correct by selecting **Show Secret Value**.



Verify permissions for the Microsoft Purview managed identity on your Azure Key Vault

Verify that the correct permissions have been configured for the Microsoft Purview managed identity to access your Azure Key Vault.

To verify this, do the following steps:

1. Navigate to your key vault and to the **Access policies** section

2. Verify that your Microsoft Purview managed identity shows under the *Current access policies* section with at least **Get** and **List** permissions on Secrets

If you don't see your Microsoft Purview managed identity listed, then follow the steps in Create and manage credentials for scans to add it.

Scans no longer run

If your Microsoft Purview scan used to successfully run, but are now failing, check these things:

1. Have credentials to your resource changed or been rotated? If so, you'll need to update your scan to have the correct credentials.
2. Is an Azure Policy preventing **updates to Storage accounts**? If so follow the Microsoft Purview exception tag guide to create an exception for Microsoft Purview accounts.
3. Are you using a self-hosted integration runtime? Check that it's up to date with the latest software and that it's connected to your network.

Test connection passes but scan fails with connection error

Are you using private endpoints or virtual networks? Confirm your network settings, paying attention to your Network Security Group (NSG) rules.

Receive JDK error when using a self-hosted integration runtime

Many sources that require a self-hosted integration runtime also require a certain version of Java to be installed on the machine where the self-hosted integration runtime is hosted. If you receive a JDK error, check the prerequisites on your specific data source's page and install the recommended JDK version.

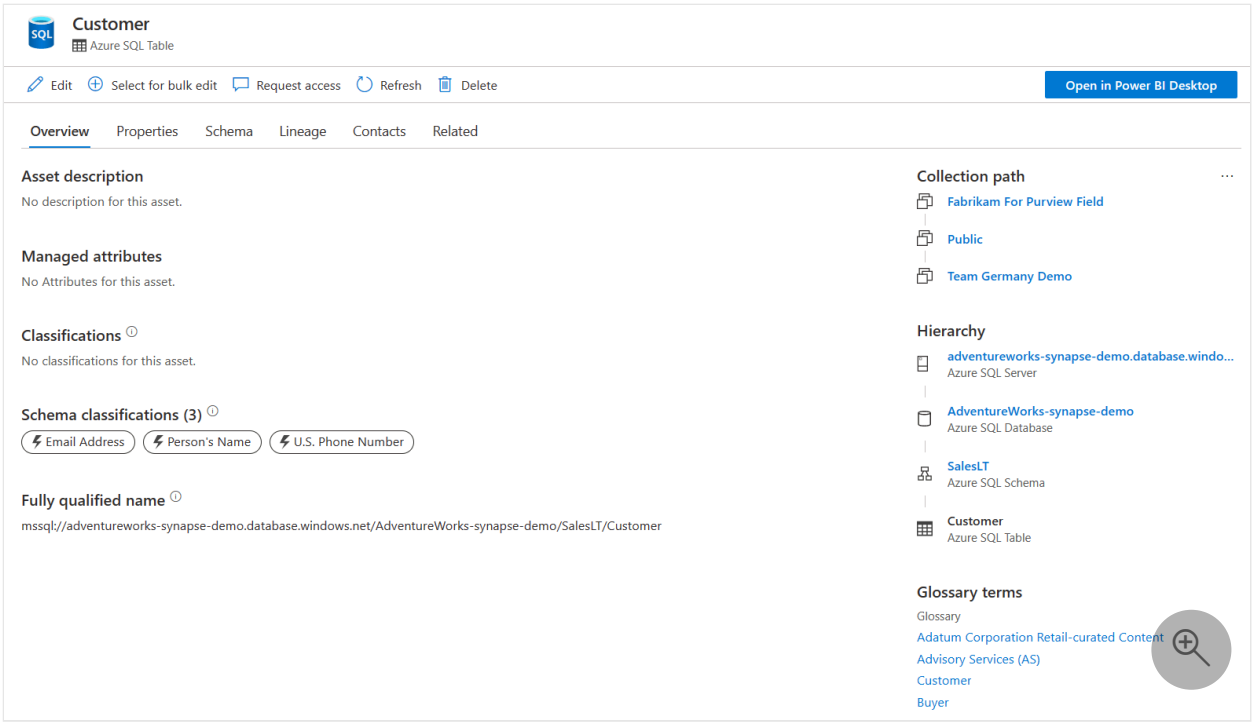
Data classification in Data Map

Article • 03/04/2025

Data classification in Microsoft Purview Data Map is a way of categorizing data assets by assigning unique logical tags or classes to the data assets. Classification is based on the business context of the data. For example, you might classify assets by *Passport Number*, *Driver's License Number*, *Credit Card Number*, *SWIFT Code*, *Person's Name*, and so on.

When you classify data assets, you make them easier to understand, search, and govern. Classifying data assets also helps you understand the risks associated with them. This in turn can help you implement measures to protect sensitive or important data from ungoverned proliferation and unauthorized access across the data estate.



Data Map provides an automated classification capability while you scan your data sources. You get more than 200+ built-in system classifications and the ability to create custom classifications for your data. You can classify assets automatically when they're ingested as part of a configured scan, or you can edit them manually in the Microsoft Purview governance portal after they're scanned and ingested.

Uses of classification

Classification is the process of organizing data into *logical categories* that make the data easy to retrieve, sort, and identify for future use. This can be important for data governance. Among other reasons, classifying data assets is important because it helps you:

- Narrow down the search for data assets that you're interested in.
- Organize and understand the variety of data classes that are important in your organization and where they're stored.
- Understand the risks associated with your most important data assets and then take appropriate measures to mitigate them.

Following image shows classification applied while scanning on the *Customer* table in Azure SQL Database.

Types of classification

The Microsoft Purview governance portal supports both system and custom classifications.

- **System classifications**: 200+ system classifications supported are out of the box. See the full list of available system classifications.

  In the example in the preceding image, *Person's Name* is a system classification. System classification has the thunderbolt icon along with classification name. Hovering over the classification itself provides more details on the type of classification, and more details on how it was applied

- **Custom classifications**: You can create custom classifications when you want to classify assets based on a pattern or a specific column name that's unavailable as a system classification. Custom classification rules can be based on a *regular expression* pattern or *dictionary*.

  Let's say that the *Employee ID* column follows the EMPLOYEE{GUID} pattern (for example, EMPLOYEE9c55c474-9996-420c-a285-0d0fc23f1f55). You can create your own custom classification by using a regular expression, such as `\^Employee\[A-Za-z0-9\]{8}-\[A-Za-z0-9\]{4}-\[A-Za-z0-9\]{4}-\[A-Za-z0-9\]{4}-\[A-Za-z0-9\]{12}\$`.

> **Note**

Sensitivity labels are different from classifications. Sensitivity labels categorize assets in the context of data security and privacy, such as *Highly Confidential*, *Restricted*, *Public*, and so on. To use sensitivity labels in the Microsoft Purview Data Map, you'll need at least one Microsoft 365 license or account within the same Microsoft Entra tenant as your Microsoft Purview Data Map. For more information about the differences between sensitivity labels and classifications, see **sensitivity labels in the Microsoft Purview governance portal FAQ**.

Automatically apply classifications on assets in Data Map

Article • 03/25/2025

After data sources are registered in Microsoft Purview Data Map, the next step is to scan the data sources. The scanning process establishes a connection to the data source, captures technical metadata, and can automatically classify data using either the supported system classifications or rules for your custom classifications.

For example, if you have a file named *multiple.docx* and it has a National ID number in its content, during the scanning process Data Map adds the classification **EU National Identification Number** to the file asset's detail page.

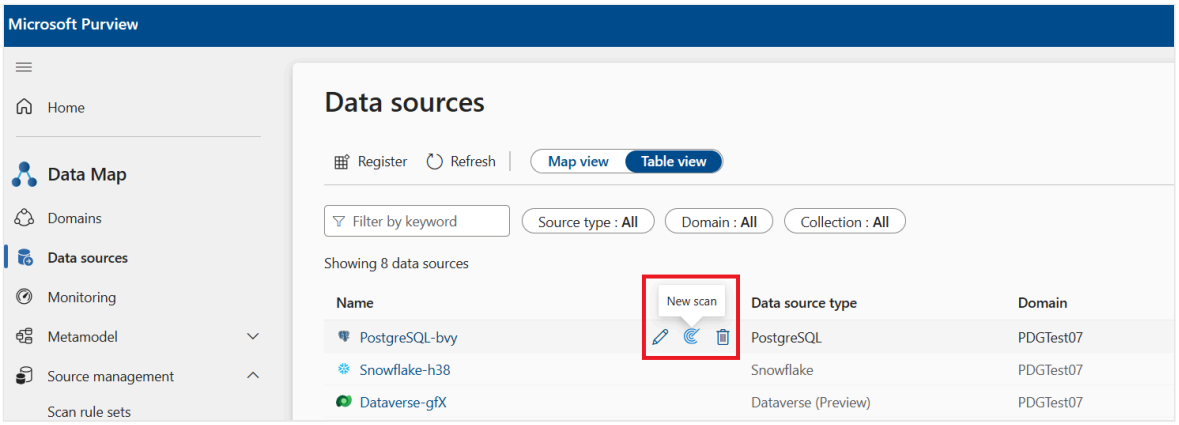
These classifications help you and your team identify the kinds of data you have across your data estate. For example: if files or tables contain credit card numbers, or addresses. Then you can more easily search for certain kinds of information, like customer IDs, or prioritize security for sensitive data types.

Classifications can be automatically applied on file and column assets during scanning.

In this article we'll discuss:

- The steps to automatically apply classifications
- How Microsoft Purview classifies assets

Automatically apply classifications



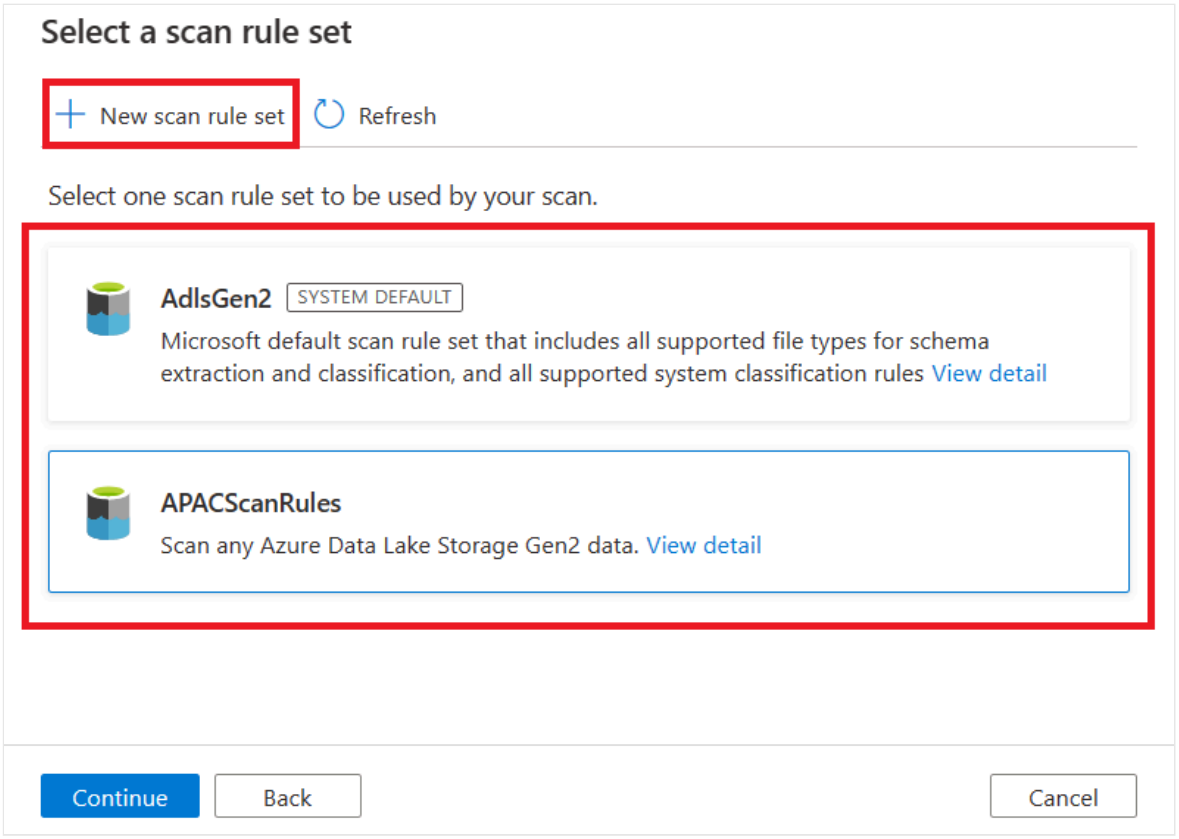
> **Note**
>
> Table assets are not automatically assigned classifications, because the classifications are assigned to their columns, but you can manually apply classifications to table assets.

After data sources are registered, you can automatically classify data in that source's data assets by running a scan.

1. Check the **Scan** section of the source article for your data source to confirm any prerequisites or authentication are set up and ready for a scan.

2. Search the Microsoft Purview Data Map the registered source that has the data assets (files and columns), you want to classify.

3. Select the **New Scan** icon under the resource.



> **Tip**
>
> If you don't see the New Scan button, you may not have correct permissions. To run a scan, you'll need at least data source administrator permissions on the collection where the source is registered.

4. Select your credential and authenticate with your source. (For more information about authenticating with your source, see the **prerequisite** and **scan** sections of your specific source source article.) Select **Continue**.

5. If necessary, select the assets in the source you want to scan. You can scan all assets, or a subset of folders, files, or tables depending on the source.

6. Select your scan rule set. You'll see a list of available scan rule sets and can select one, or you can choose to create a new scan rule set using the **New scan rule set** button at the top. The scan rule set will determine which classifications will be compared and applied to your data. For more information, see how Microsoft Purview classifies assets.

> **Tip**
>
> For more information about the options available when creating a scan rule set, start at step 4 of these steps to create a scan rule set.

7. Schedule your scan.

8. Save and run your scan. Applicable classifications in your scan rule set will be automatically applied to the assets you scan. You'll be able to view and manage them once the scan is complete.

View classification details

Microsoft Purview captures important details like who applied a classification and when it was applied. To view the details, hover over the classification to revel the Classification details card. The classification details card shows the following information:

- Classification name - Name of the classification applied on the asset or column.
- Applied by - Who applied the classification. Possible values are scan and user name.
- Applied time - Local timestamp when the classification was applied via scan or manually.
- Classification type - System or custom.

Users with Data Curator role can see more details for classifications that were applied automatically through a scan. These details include sample count that the scanner read to classify the data, and distinct data count in the sample that the scanner found.

Impact of rescanning on existing classifications

Classification tags are automatically applied the first time based on sampling your data and matching those samples against predefined RegEx patterns or dictionaries. Subsequent rescans can preserve, remove, or incrementally add classification tags depending on several factors:

- A scan run doesn't remove classification tags that were manually applied.
- A scan run doesn't reapply classification tags that were manually removed.
- A later run of a scan that continues to use the same scan rule can update the classification tags.
- For a scan run, classification tags from the previous scans can get removed or retained based on the criteria listed in this table:

Expand table

File type	File size	Classification tags from previous scan will be:
File types with no size (for example, SQL)	All	Retained
.doc, .docm, .docx, .dot, .odp, .ods, .odt, .pdf, .pot, .pps, .ppsx, .ppt, .pptm, .pptx, .txt, .xlc, .xls, .xlsb, .xlsm, .xlsx, .xlt	>20 MB	Retained
.doc, .docm, .docx, .dot, .odp, .ods, .odt, .pdf, .pot, .pps, .ppsx, .ppt, .pptm, .pptx, .txt, .xlc, .xls, .xlsb, .xlsm, .xlsx, .xlt	<20 MB	Removed
GZ	>400 KB	Retained
GZ	<400 KB	Removed
Files with no extension or structured file types	> 1 MB	Retained
Files with no extension or structured file types	< 1 MB	Removed

How Microsoft Purview classifies assets

When a data source is scanned, Microsoft Purview compares data in the asset to a list of possible classifications called a scan rule set.

There are system scan rule sets already available for each data source that contains every currently available system classification for that data source. Or, you can create a custom scan rule set to make a list of classifications tailored to your data set.

Making a custom rule sets for your data can be a good idea if your data is limited to specific kinds of information, or regions, as comparing your data to fewer classification types will speed up the scanning process. For example, if your dataset only contains European data, you could create a custom scan rule set that excludes identification for other regions.

You might also make a custom rule set if you've created custom classifications and classification rules, so that your custom classifications can be automatically applied during scanning.

For more information about the available system classifications and how your data is classified, see the list of system classifications.

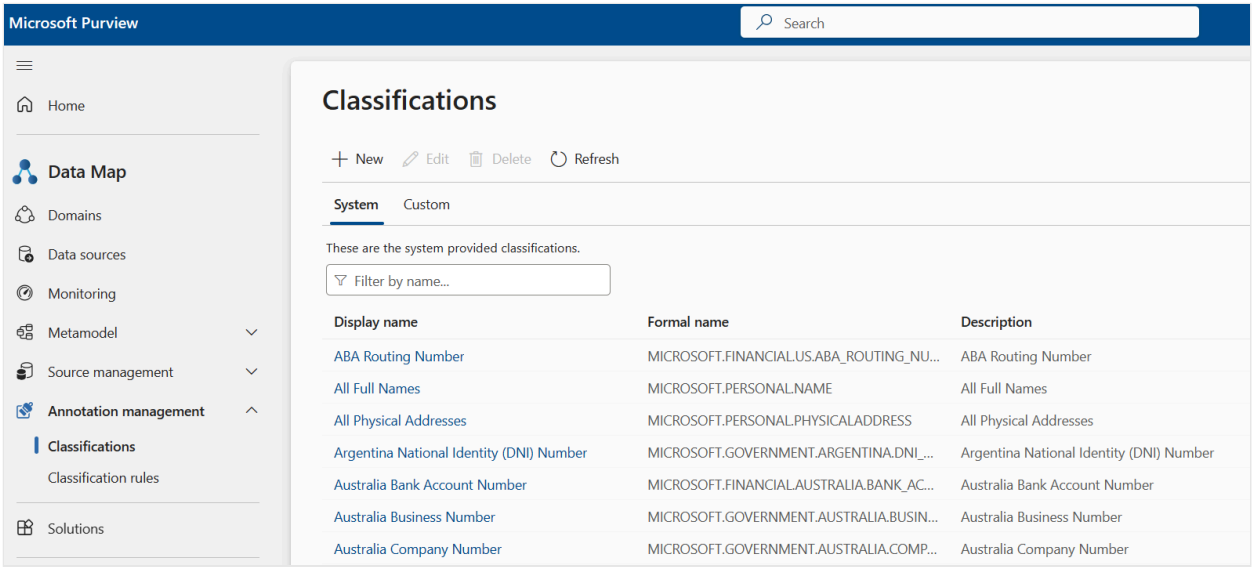
Custom classifications in Data Map



Article • 03/04/2025

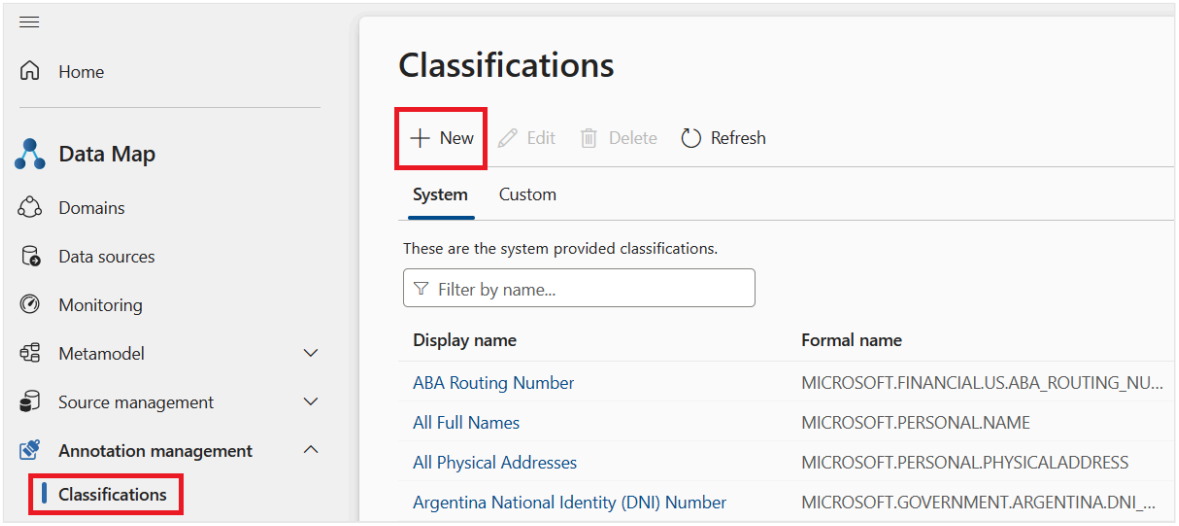
This article describes how you can create custom classifications in Microsoft Purview Data Map to define data types in your data estate that are unique to your organization. It also describes the creation of custom classification rules that let you find specified data throughout your data estate.

> **Important**
>
> To create a custom classification you need either **data curator** or **data source administrator** permission on a domain or collection. Permissions at any collection level are sufficient. For more information about permissions, see Microsoft Purview data governance permissions.

Default system classifications

Data Map provides a large set of default system classifications that represent typical personal data types that you might have in your data estate. See the list of available system classifications in Data Map.

You also have the ability to create custom classifications, if any of the default classifications don't meet your needs.



> **Note**

- Our data sampling rules are applied to both system and custom classifications.
- Custom classifications are only applied to structured data sources like SQL and CosmosDB, and to structured file types like CSV, JSON, and Parquet. Custom classification isn't applied to unstructured data file types like DOC, PDF, and XLSX.

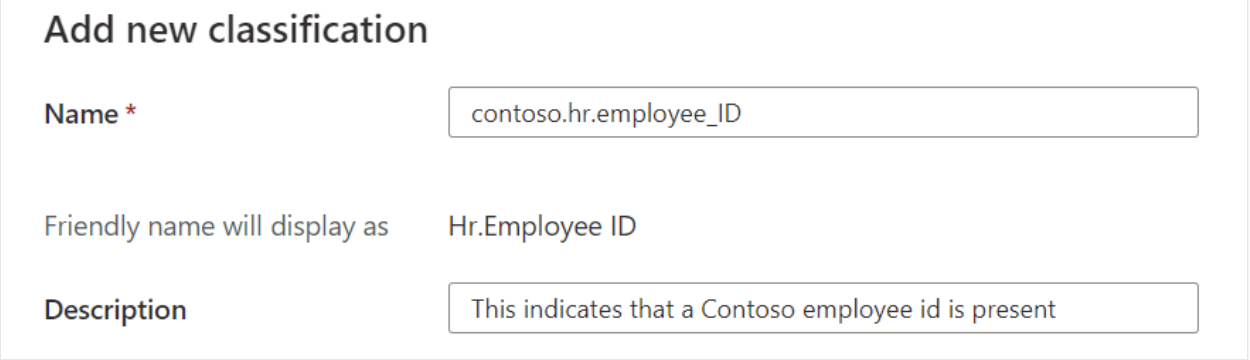
Steps to create a custom classification

To create a custom classification, follow these steps:

1. You'll need **data curator** or **data source administrator** permissions on any collection to be able to create a custom classification.
2. In the Microsoft Purview portal, open the **Data map** solution.
3. Select **Annotation management** select **Classifications**.
4. Select + **New**.

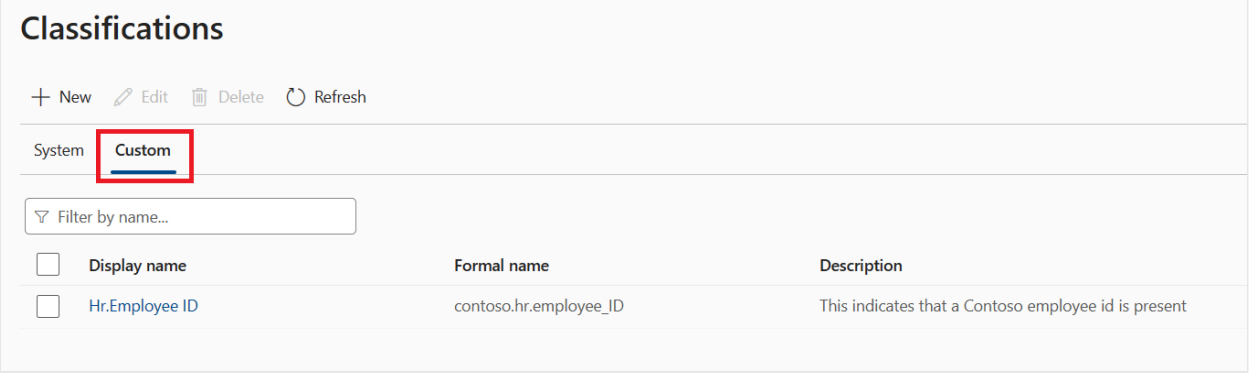
The **Add new classification** pane opens, where you can give your classification a name and a description. It's good practice to use a name-spacing convention, such as `your company name.classification name`.

The Microsoft system classifications are grouped under the reserved `MICROSOFT.` namespace. An example is **MICROSOFT.GOVERNMENT.US.SOCIAL_SECURITY_NUMBER**.



The name of your classification must start with a letter followed by a sequence of letters, numbers, and period (.) or underscore characters. As you type, the UX automatically

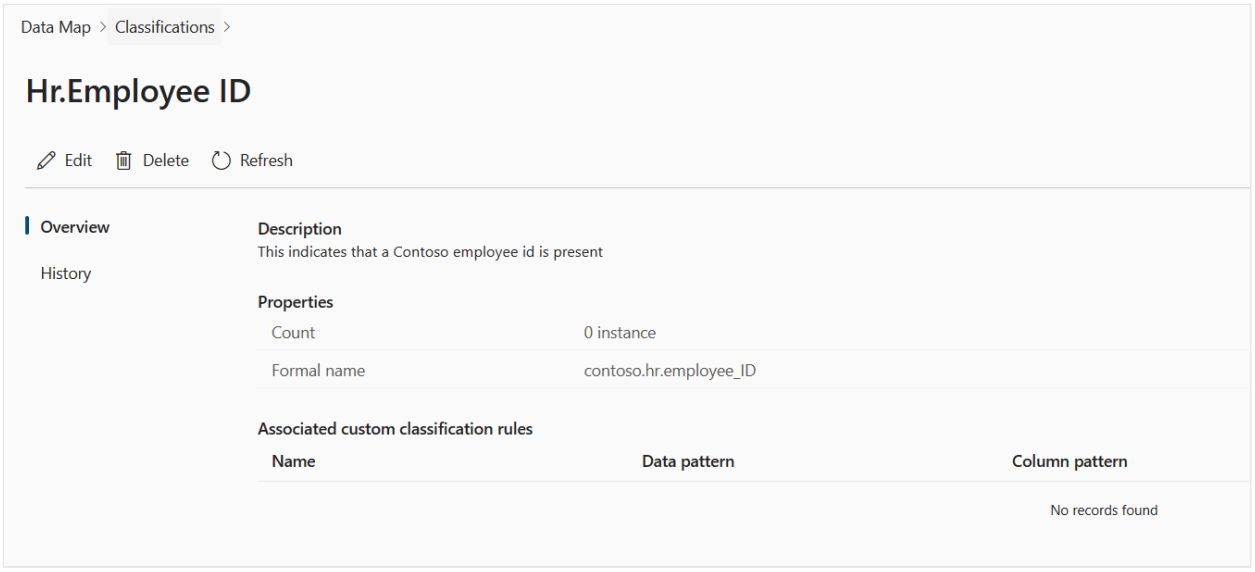
generates a friendly name. This friendly name is what users see when you apply it to an asset in the catalog.



To keep the name short, the system creates the friendly name based on the following logic:

- All but the last two segments of the namespace are trimmed.
- The casing is adjusted so that the first letter of each word is capitalized.
- All underscores (_) are replaced with spaces.

As an example, if you named your classification **contoso.hr.employee_ID**, the friendly name is stored in the system as **Hr.Employee ID**.



Select **OK**, and your new classification is added to your **Custom** classification list.

Selecting the classification in the list opens the classification details page. Here, you find all the details about the classification.

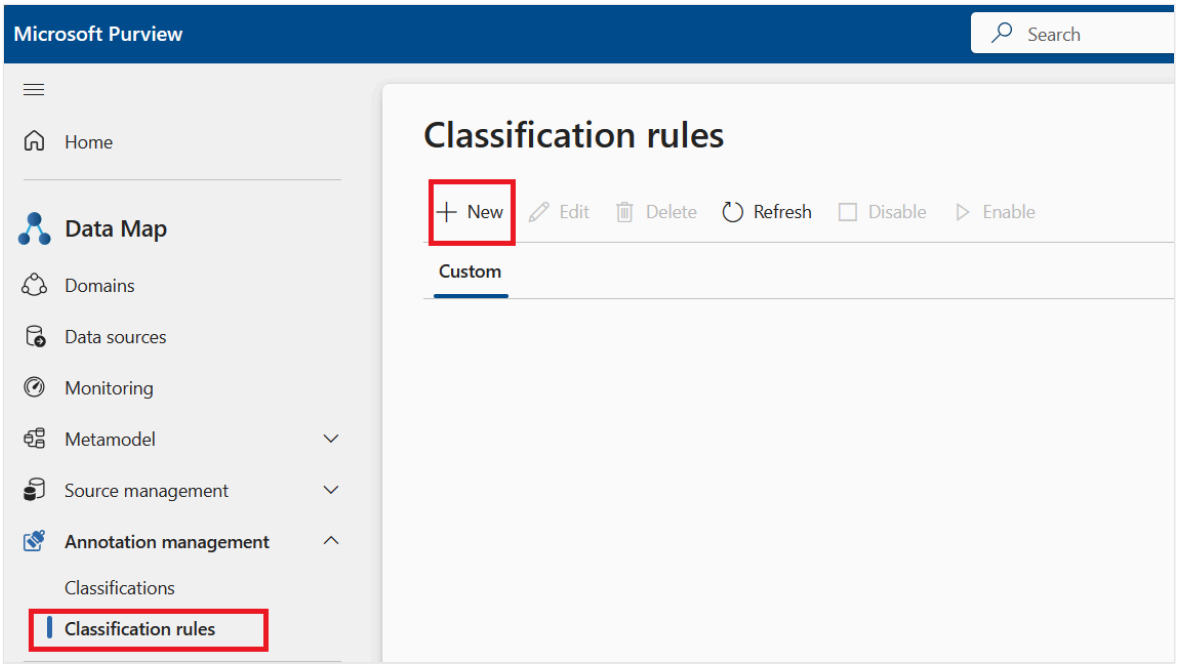
These details include the count of how many instances there are, the formal name, associated classification rules (if any), and the owner name.

Custom classification rules

The data map provides a set of default classification rules that are used by the scanner to automatically detect certain data types. You can also add your own custom classification rules to detect other types of data that you might be interested in finding across your data estate. This capability can be powerful when you're trying to find data within your data estate.

> **Note**
>
> Custom classification rules are only supported in the English language.

As an example, let's say that a company named Contoso has employee IDs that are standardized throughout the company with the word "Employee" followed by a GUID to create EMPLOYEE{GUID}. For example, one instance of an employee ID looks like `EMPLOYEE9c55c474-9996-420c-a285-0d0fc23f1f55`.

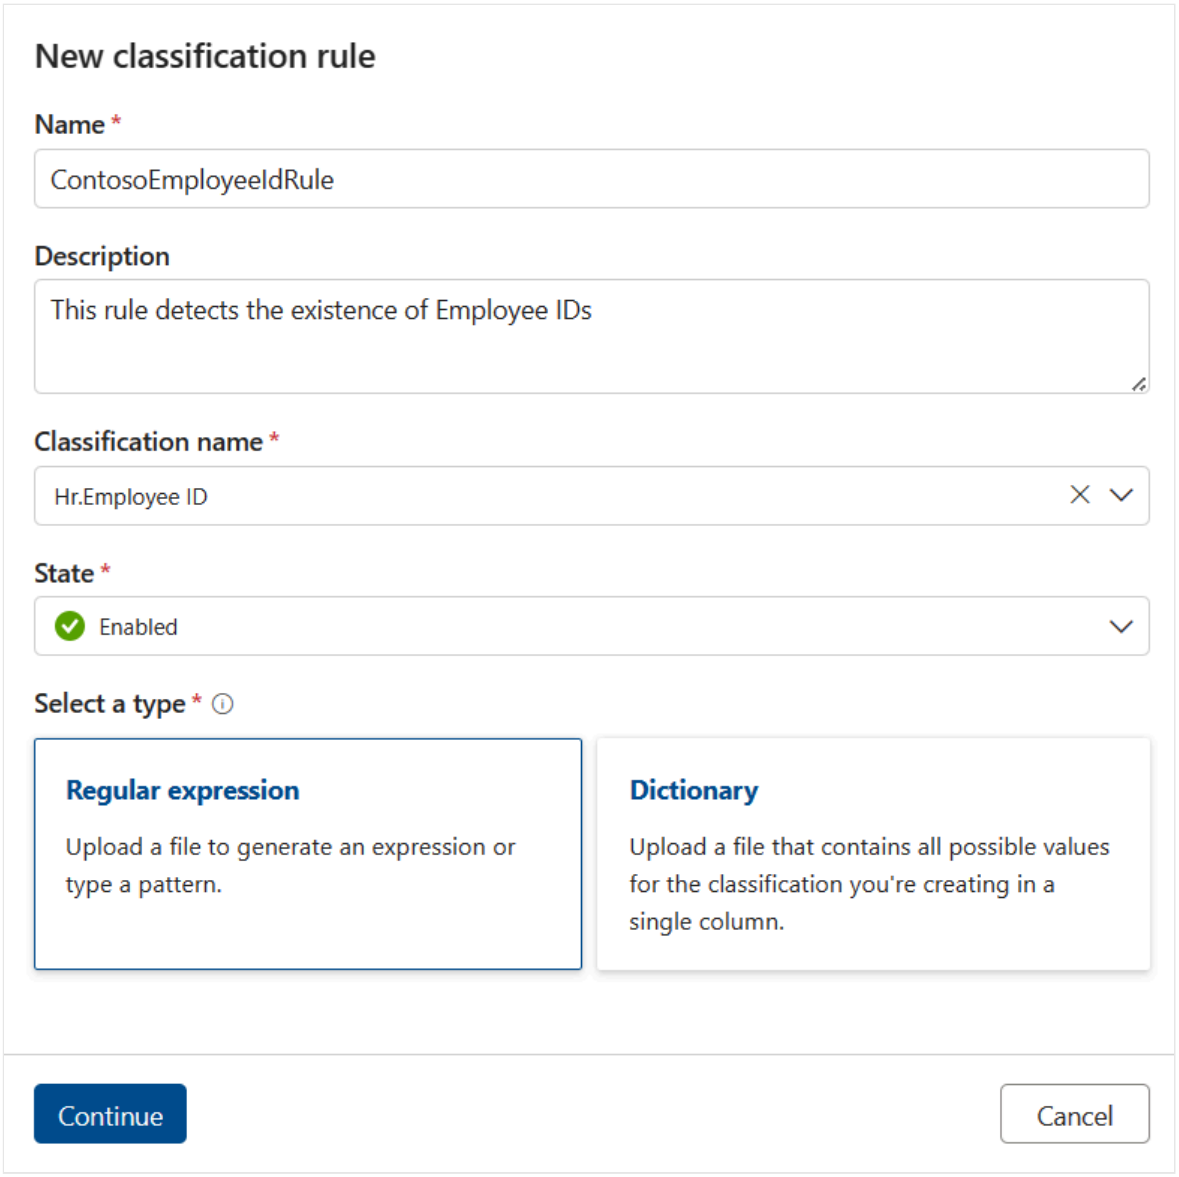


Contoso can configure the scanning system to find instances of these IDs by creating a custom classification rule. They can supply a regular expression that matches the data pattern, in this case, `\^Employee\[A-Za-z0-9\]{8}-\[A-Za-z0-9\]{4}-\[A-Za-z0-9\]{4}-\[A-Za-z0-9\]{4}-\[A-Za-z0-9\]{12}\$`. Optionally, if the data usually is in a column that they know the name of, such as Employee_ID or EmployeeID, they can add a column pattern regular expression to make the scan even more accurate. An example regex is Employee_ID|EmployeeID.

The scanning system can then use this rule to examine the actual data in the column and the column name to try to identify every instance of where the employee ID pattern is found.

Steps to create a custom classification rule

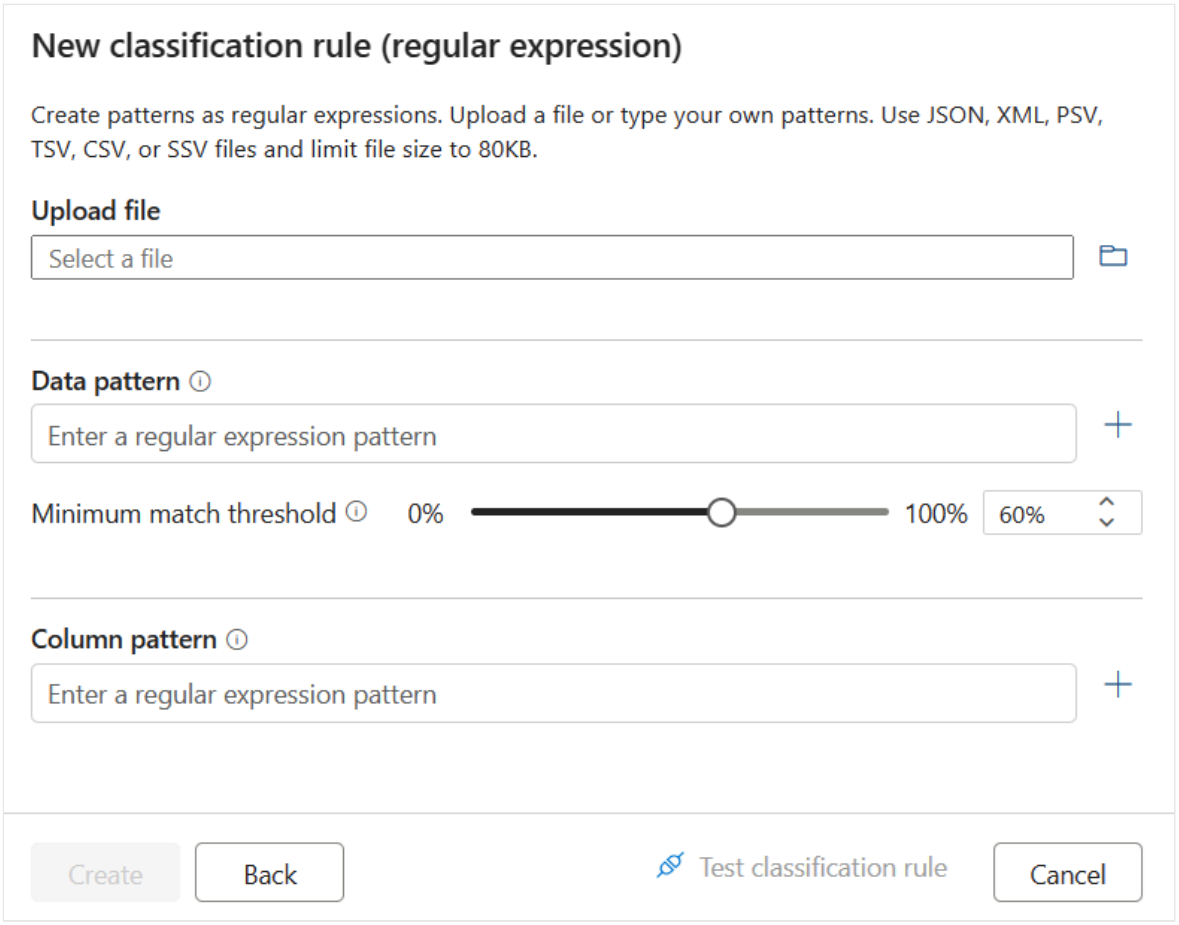
Create a custom classification that following the instructions in the previous section. You'll add this custom classification in the classification rule configuration so that the system applies it when it finds a match in the column.



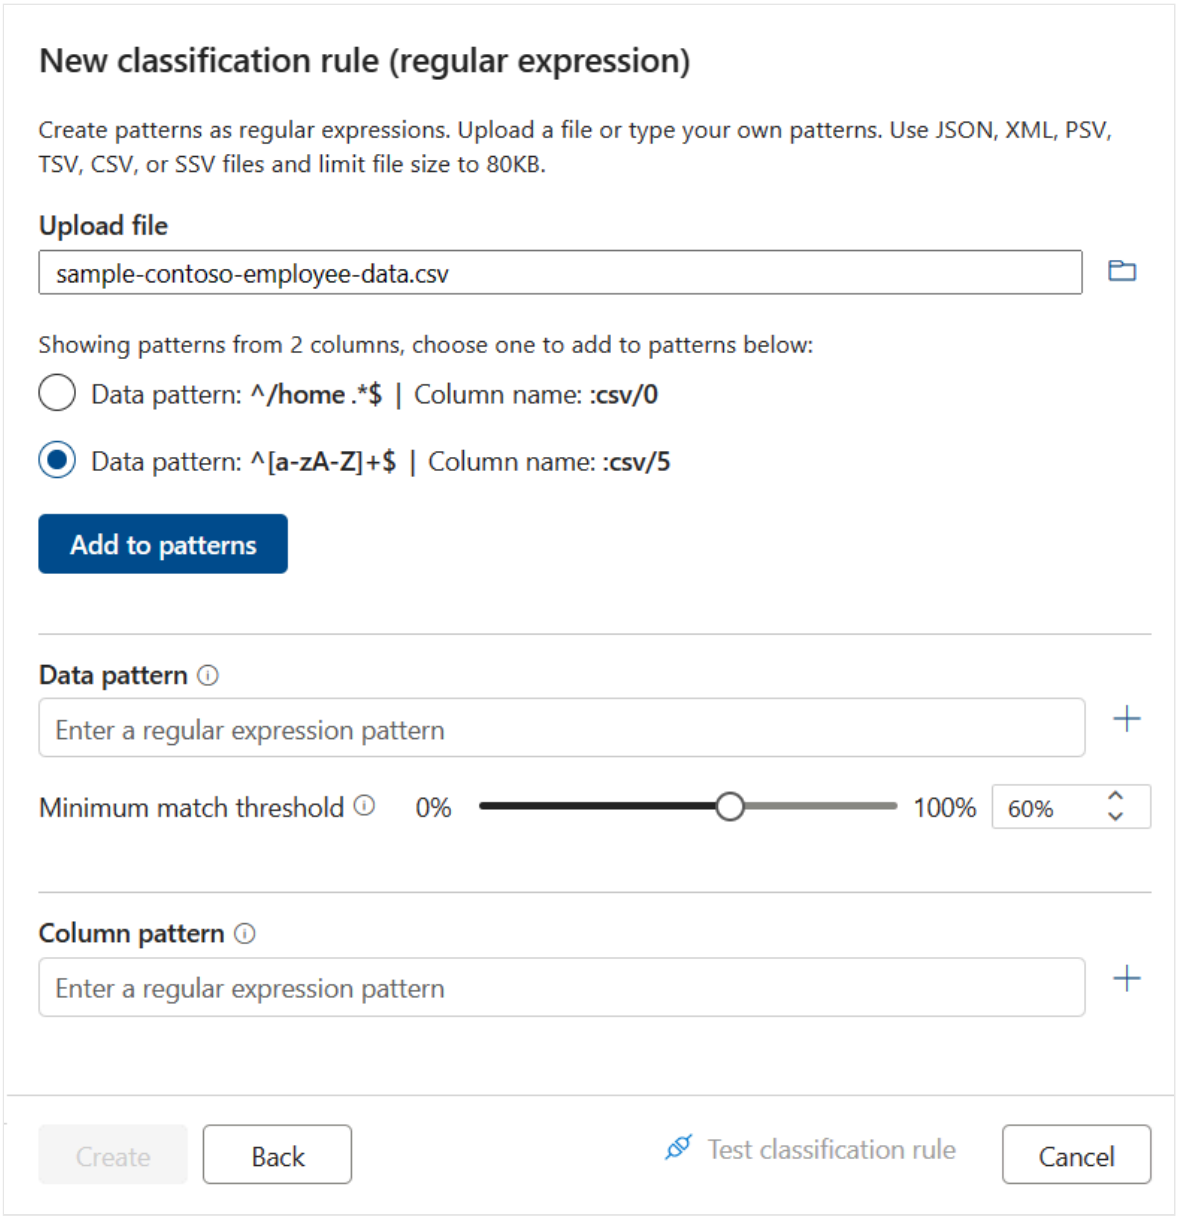
1. In the Microsoft Purview portal, open the **Data map** solution.
2. Under **Annotation management**, select the **Classifications rules** section.
3. Select **New**.

4. The **New classification rule** dialog box opens. Fill in the fields and decide whether to create a **regular expression rule** or a **dictionary rule**.

Expand table



Field	Description
Name	Required. The maximum is 100 characters.
Description	Optional. The maximum is 256 characters.
Classification Name	Required. Select the name of the classification from the drop-down list to tell the scanner to apply it if a match is found.
State	Required. The options are enabled or disabled. Enabled is the default.



Creating a Regular Expression Rule

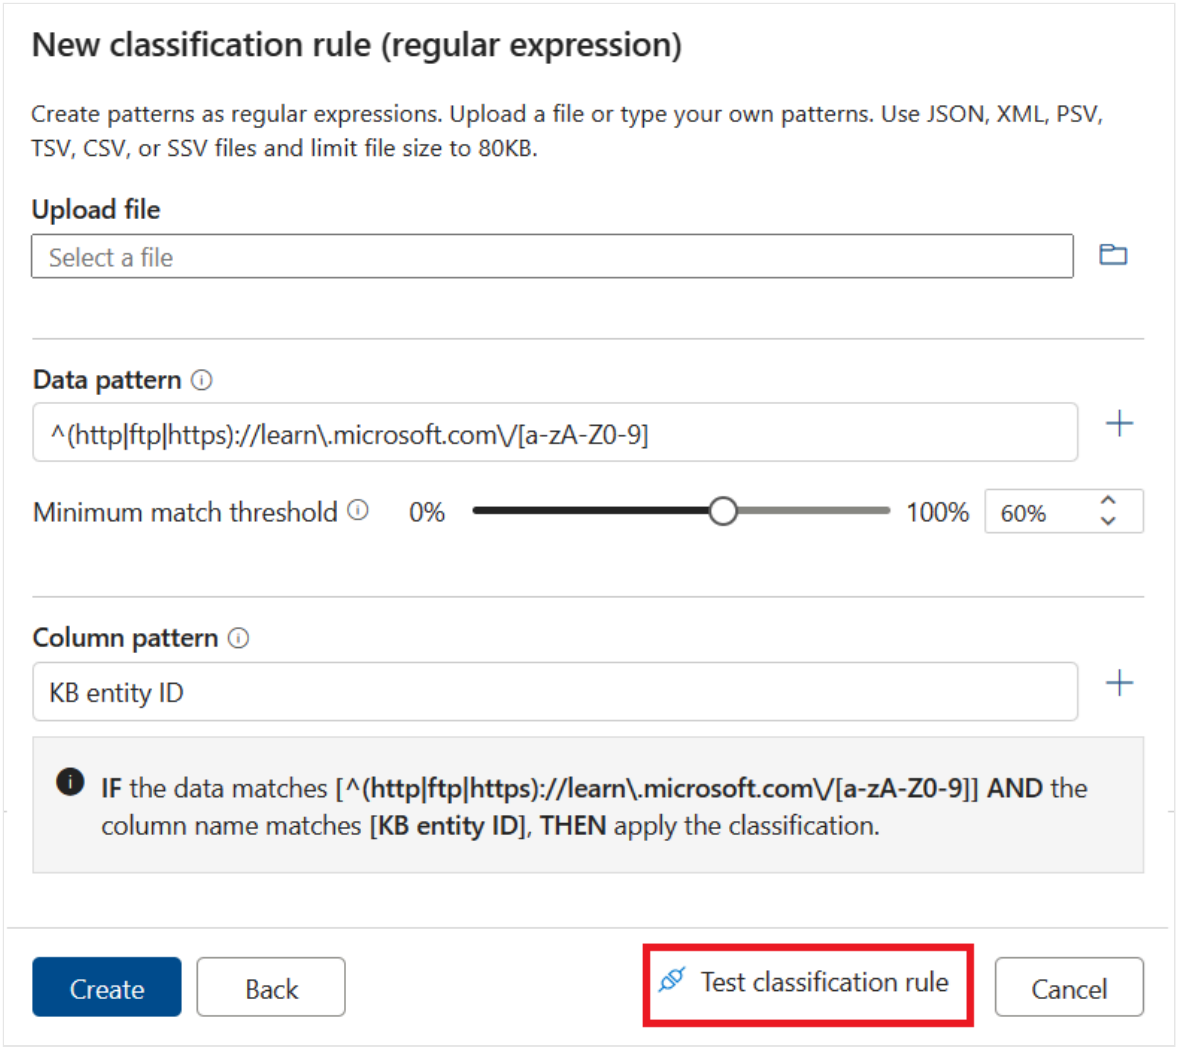
> **ⓘ Important**
>
> Regular expressions in custom classifications are case insensitive.

1. If creating a regular expression rule, you'll see the following screen. You could optionally upload a file that will be used to **generate suggested regex patterns** for your rule. Only English language rules are supported.

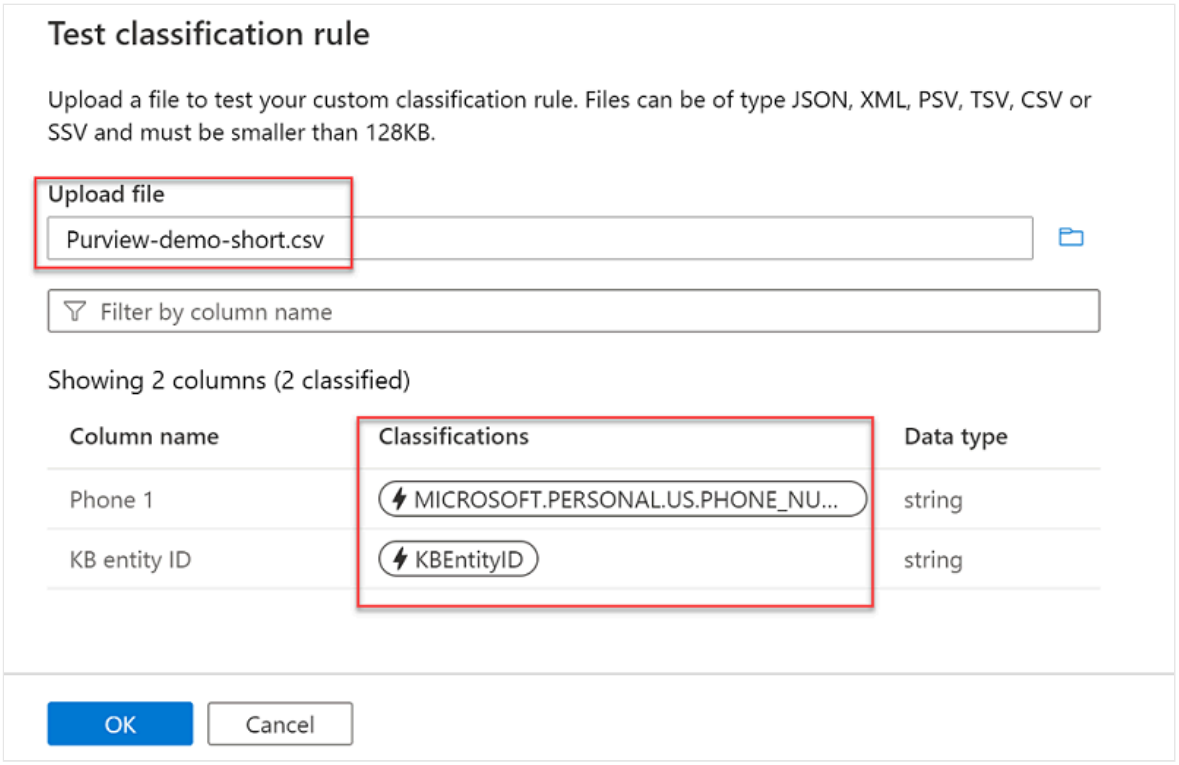
2. If you decide to generate a suggested regex pattern, after uploading a file, select one of the suggested patterns and select **Add to Patterns** to use the suggested data and column patterns. You can tweak the suggested patterns or you may also type your own patterns without uploading a file.

Expand table

Field	Description
Data Pattern	Optional. A regular expression that represents the data that's stored in the data field. The limit is large. In the previous example, the data patterns test for an employee ID that's literally the word `Employee{GUID}`.
Column Pattern	Optional. A regular expression that represents the column names that you want to match. The limit is large.



3. Under **Data Pattern** you can use the **Minimum match threshold** to set the minimum percentage of the distinct data value matches in a column that must be found by the scanner for the classification to be applied. The suggested value is 60%. If you specify multiple data patterns, this setting is disabled and the value is fixed at 60%.

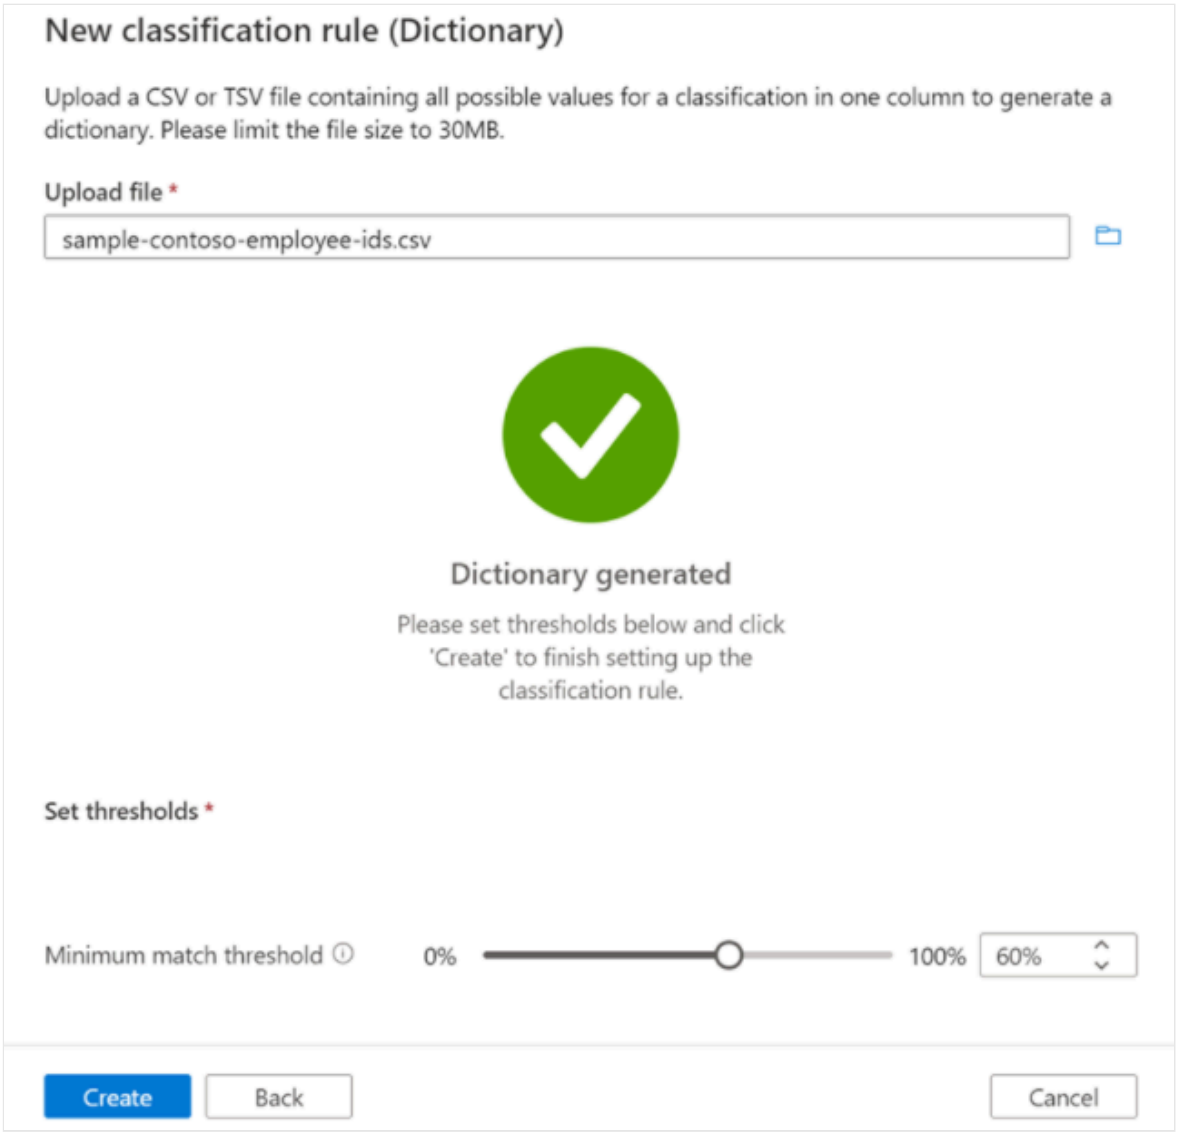


> **Note**
>
> The Minimum match threshold must be at least 1%.

4. You can now verify your rule and **create** it.

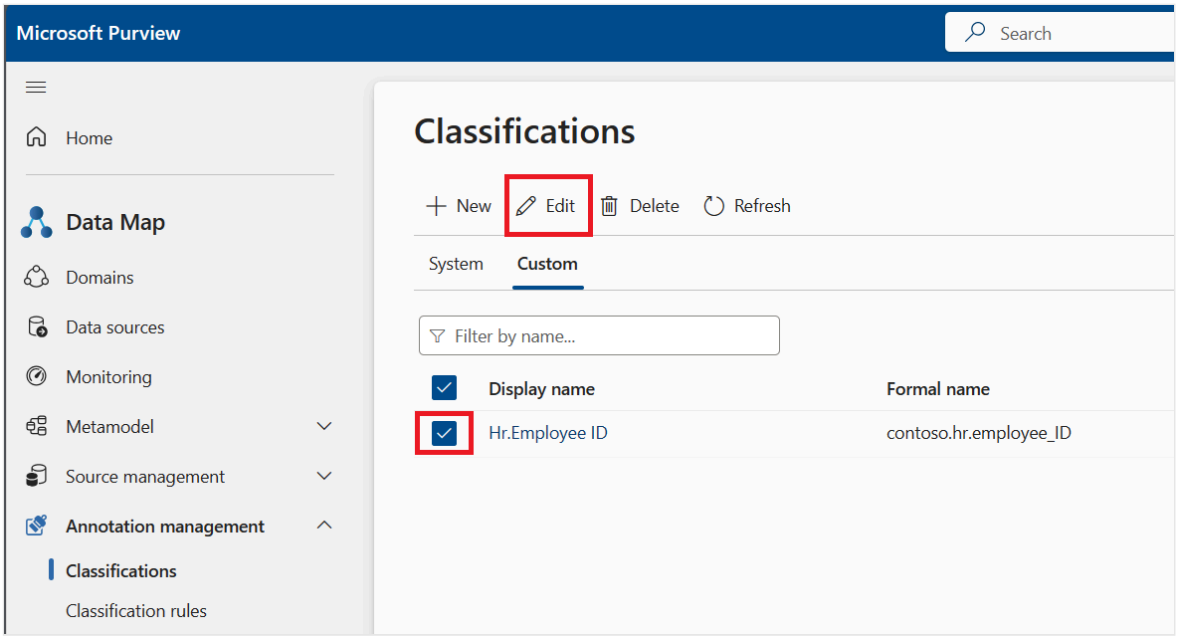
5. Test the classification rule before completing the creation process to validate that it will apply tags to your assets. The classifications in the rule will be applied to the sample data uploaded just as it would in a scan. This means all of the system classifications and your custom classification will be matched to the data in your file.

   Input files could include delimited files (CSV, PSV, SSV, TSV), JSON, or XML content. The content will be parsed based on the file extension of the input file. Delimited data might have a file extension that matches any of the mentioned types. For example, TSV data can exist in a file named MySampleData.csv. Delimited content must also have a minimum of three columns.



Creating a Dictionary Rule

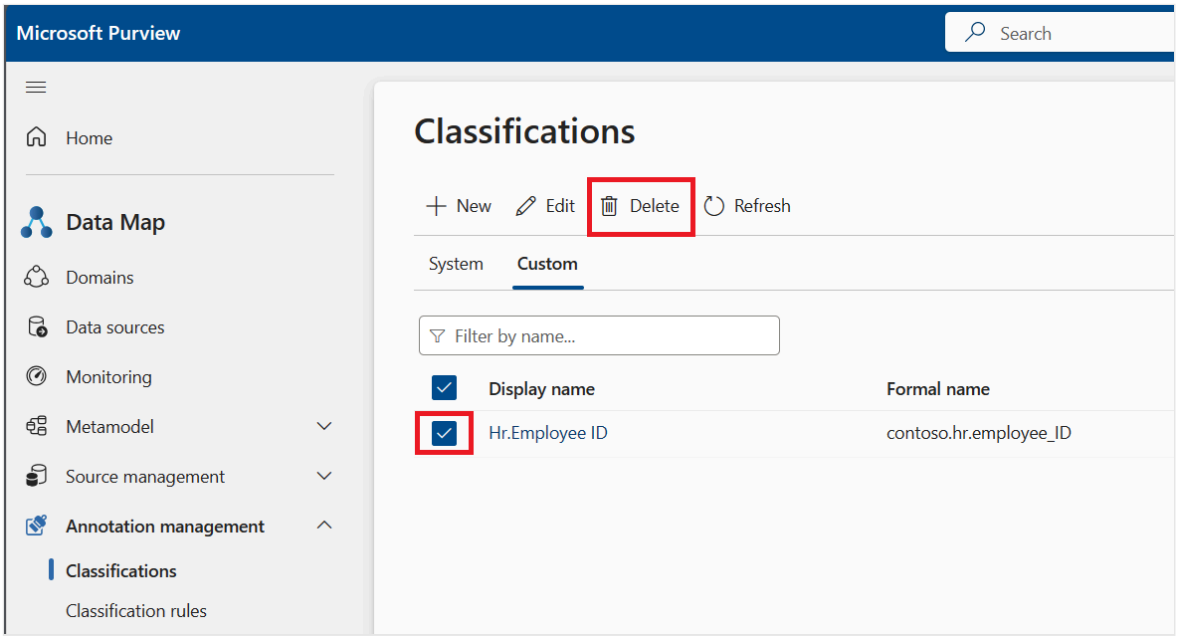
1. If creating a dictionary rule, you'll see the following screen. Upload a file that contains all possible values for the classification you're creating in a single column. Only English language rules are supported.



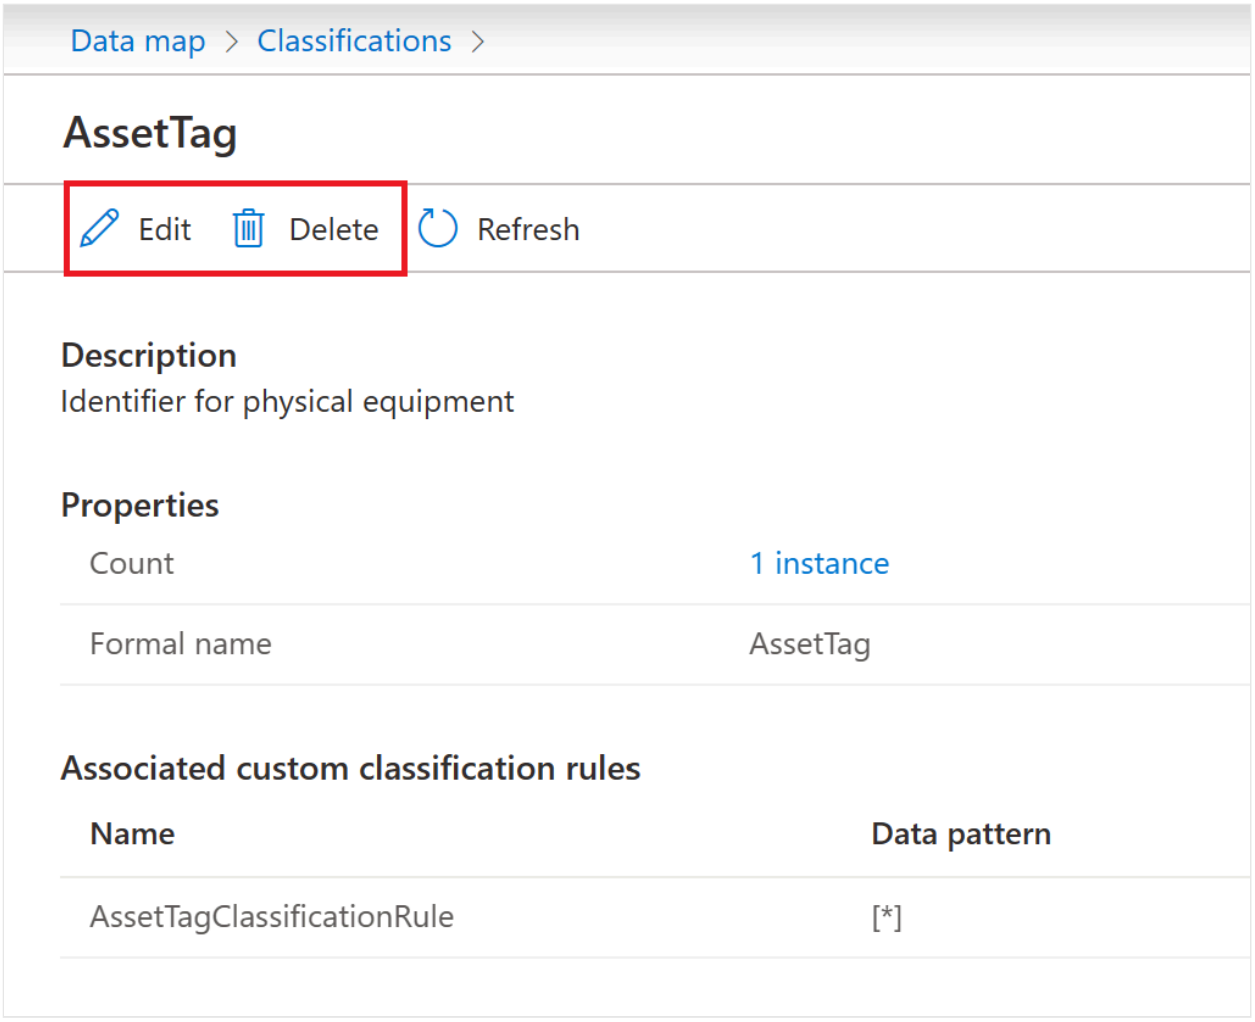
2. After the dictionary is generated, you can adjust the minimum match threshold and submit the rule.

Edit or delete a custom classification

To update or edit a custom classification, follow these steps:



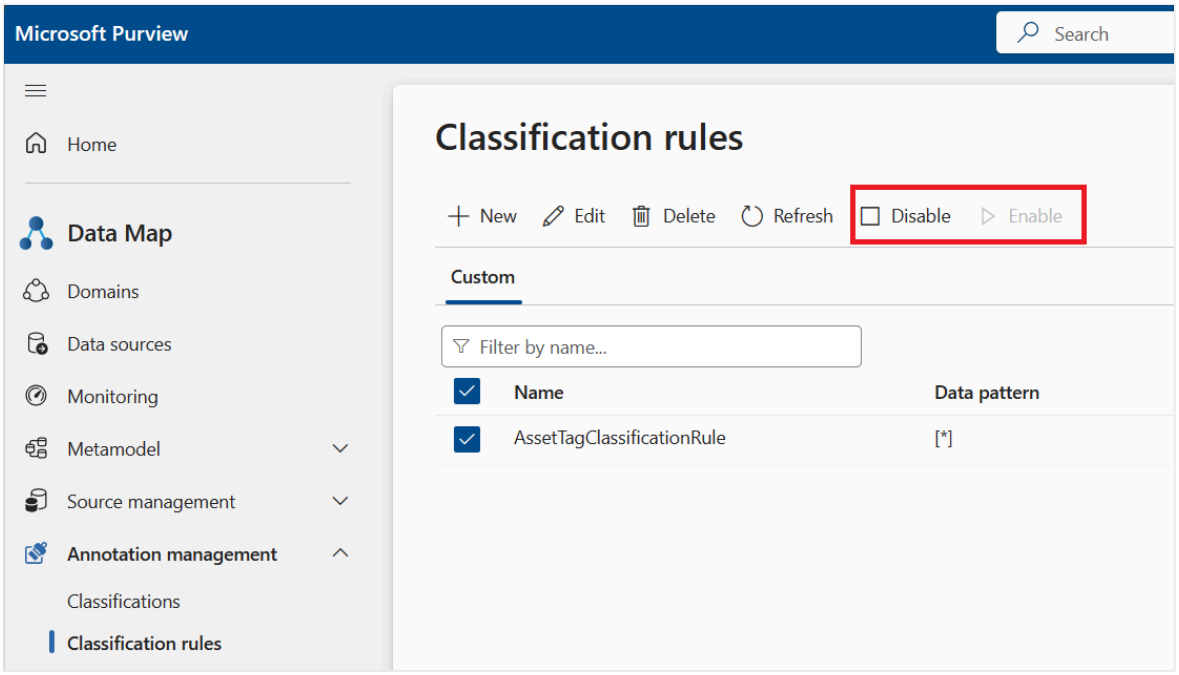
1. In the Microsoft Purview portal, open the **Data map** solution.
2. Under **Annotation management** select **Classifications**.
3. Select the **Custom** tab.
4. Select the classification you want to edit, then select the **Edit** button.



5. Now can edit the description of this custom classification. Select the **Ok** button when you're finished to save your changes.

To delete a custom classification:

1. After opening the **Data map**, and then **Classifications**, select the **Custom** tab.
2. Select the classification you want to delete, or multiple classifications you want to delete, and then select the **Delete** button.

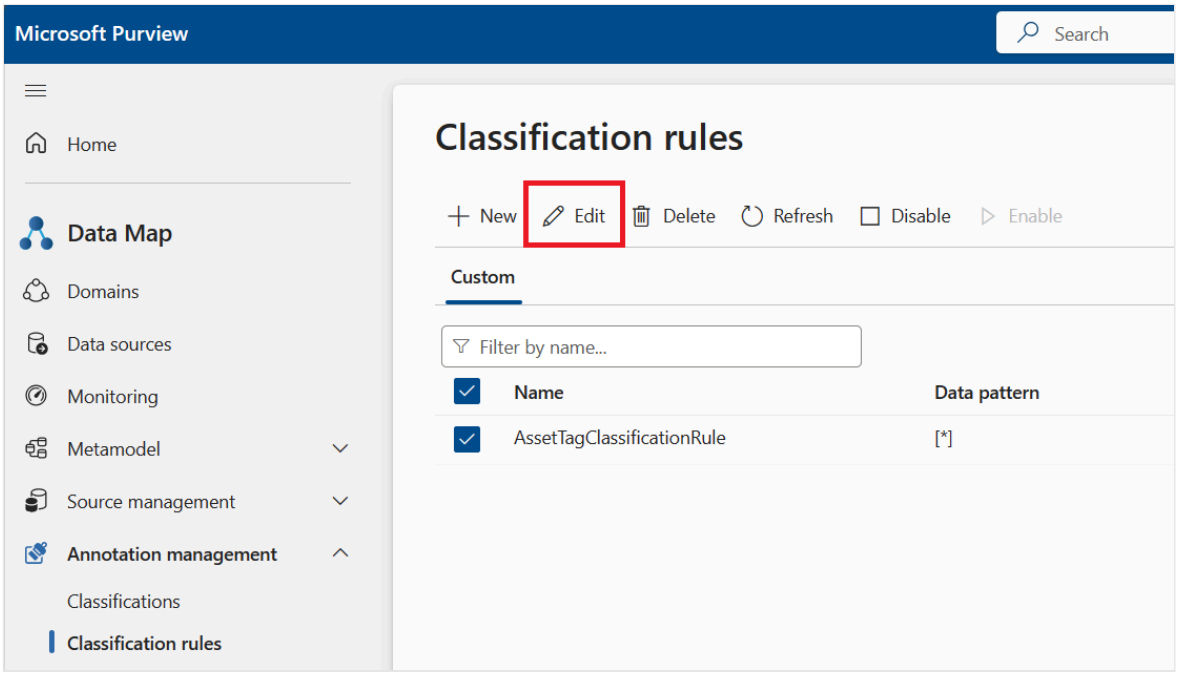


You can also edit or delete a classification from inside the classification itself. Just select your classification, then select the **Edit** or **Delete** buttons in the top menu.

Enable or disable classification rules

1. In your Microsoft Purview account, select the **Data map**, and then **Classification rules**.
2. Select the **Custom** tab.
3. You can check the current status of a classification rule by looking at the **Status** column in the table.
4. Select the classification rule, or multiple classification rules, that you want to enable or disable.
5. Select either the **Enable** or **Disable** buttons in the top menu.

You can also update the status of a rule when editing the rule.



Edit or delete a classification rule

To update or edit a custom classification rule, follow these steps:

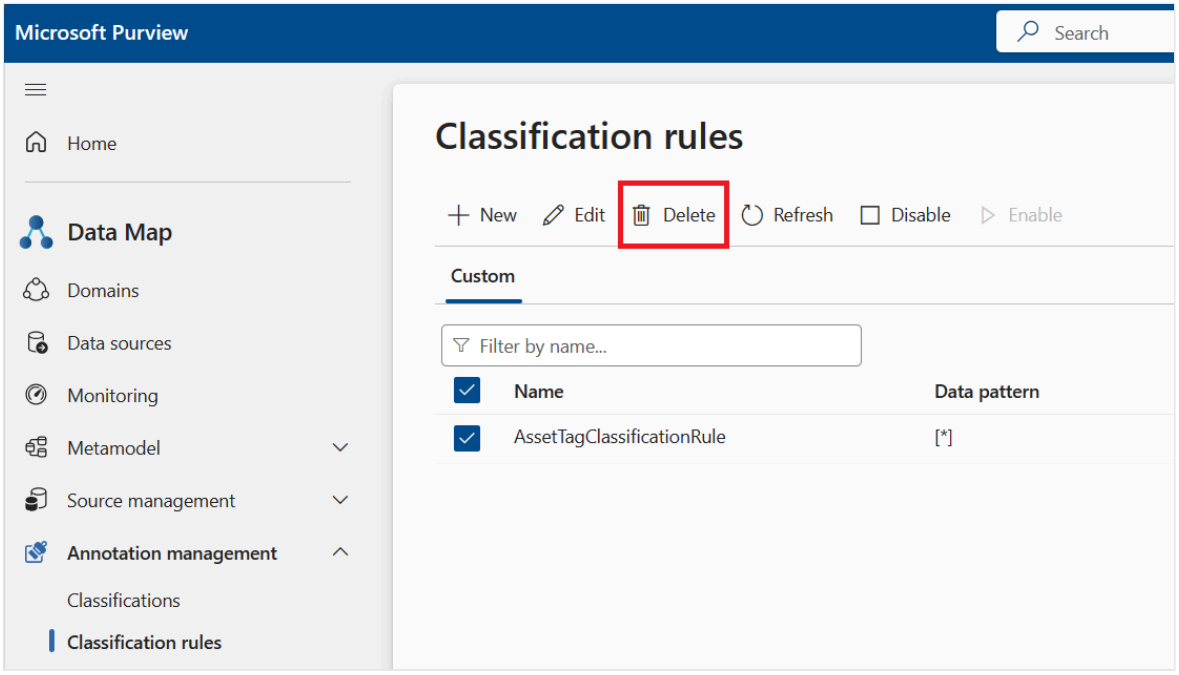
1. In your Microsoft Purview account, select the **Data map**, and then **Classification rules**.

2. Select the **Custom** tab.

3. Select the classification rule you want to edit, then select the **Edit** button.

4. Now you can edit the state, the description, and the associated classification rule.

5. Select the **Continue** button.



6. You can upload a new file for your regular expression or dictionary rule to match against, and update your match threshold and column pattern match.

7. Select **Apply** to save your changes. Scans will need to be rerun with the new rule to apply changes across your assets.

To delete a custom classification:

1. After opening the **Data map**, and then **Classification rules**, select the **Custom** tab.

2. Select the classification rule you want to delete, and then select the **Delete** button.

Next steps

Now that you've created your classification rule, it's ready to be added to a scan rule set so that your scan uses the rule when scanning. For more information, see Create a scan rule set.

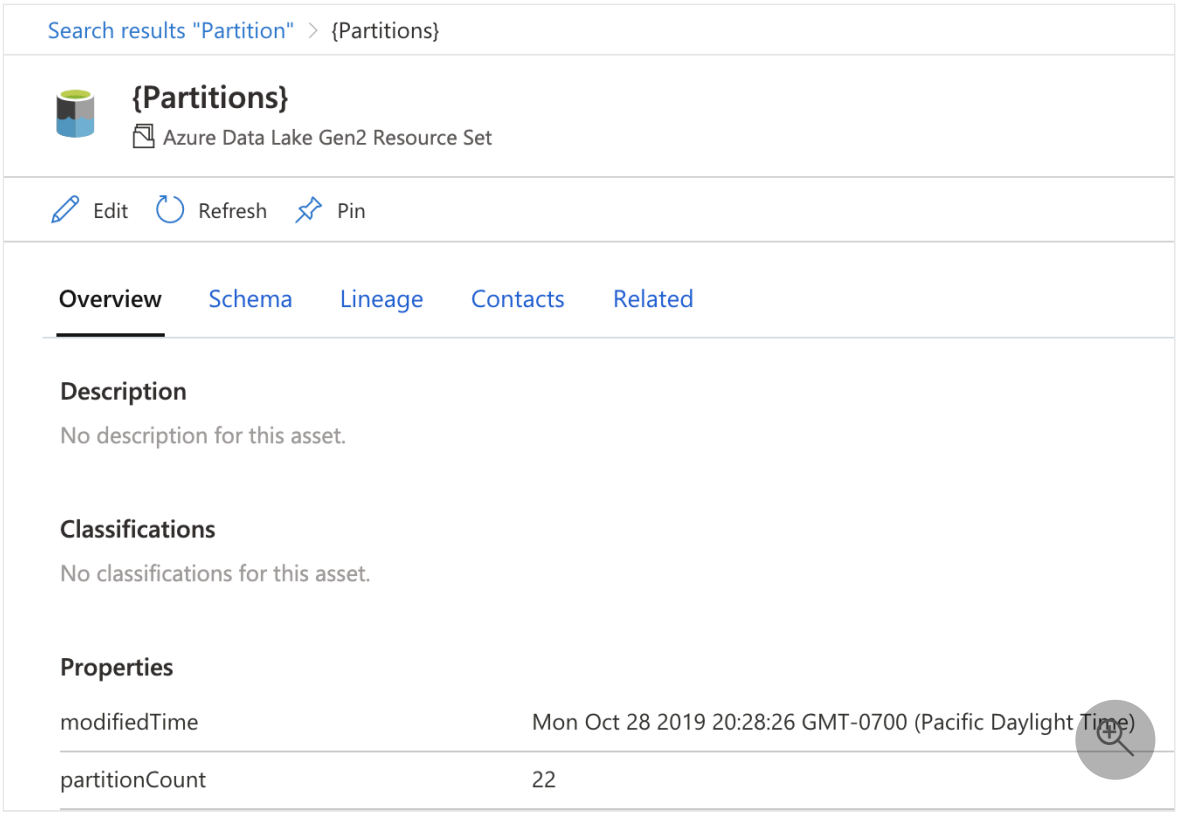
Manually apply classifications on assets in Data Map

Article • 03/04/2025

This article discusses how to manually apply classifications on assets in Microsoft Purview Data Map.

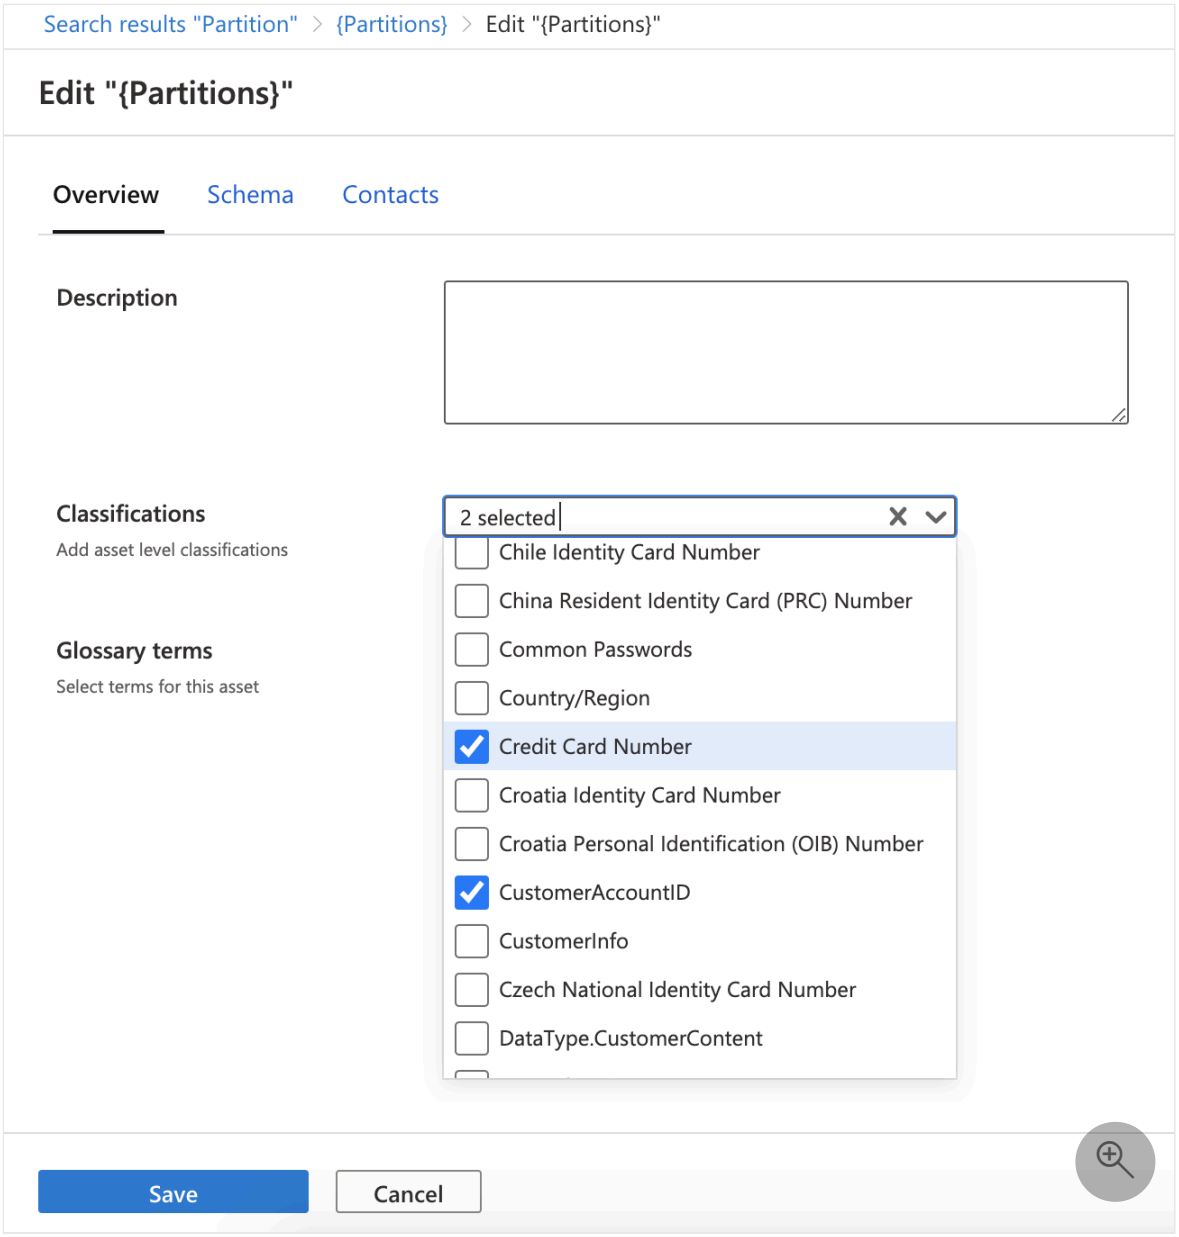
Classifications are logical labels to help you and your team identify the kinds of data you have across your data estate. For example: if files or tables contain credit card numbers, or addresses.



Microsoft Purview automatically applies classifications to some assets during the scanning process, but there are some scenarios when you may want to manually apply more classifications. For example, Microsoft Purview doesn't automatically apply classifications to table assets (only their columns), or you might want to apply custom classifications, or add classifications to assets grouped a resource set.

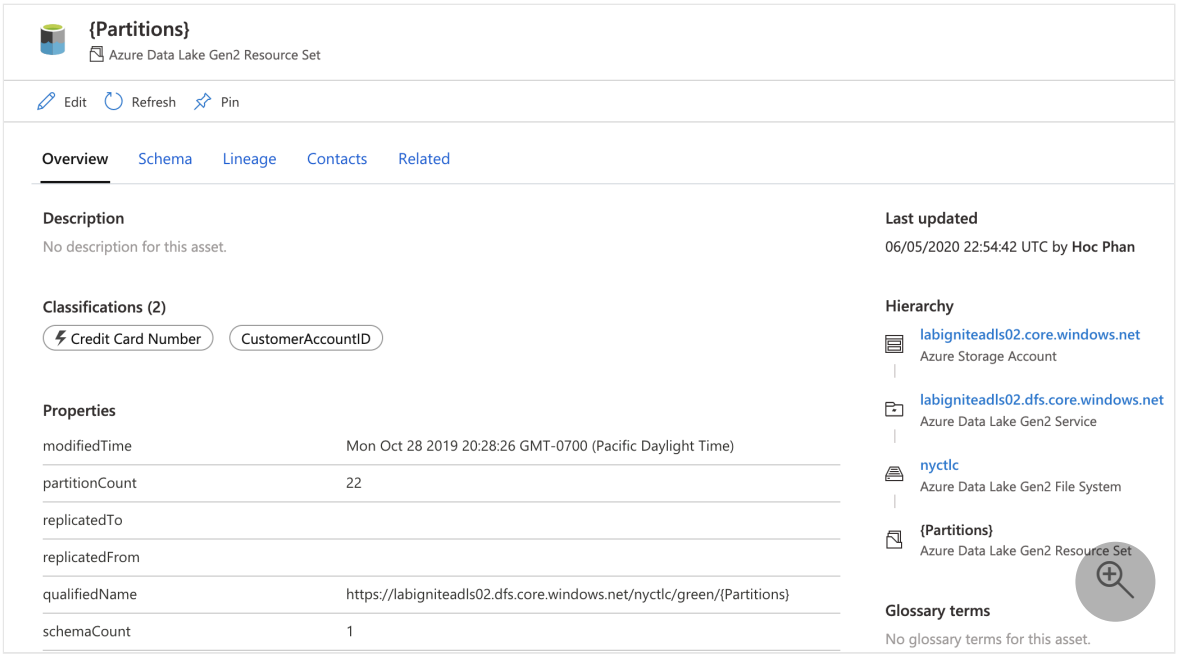
> ⓘ **Note**
>
> Some custom classifications can be automatically applied after setting up a custom classification rule.

Follow the steps in this article to manually apply classifications to file, table, and column assets.



Manually apply classification to a file asset

1. Search or browse Microsoft Purview Unified Catalog for the file you're interested in and navigate to the asset detail page.

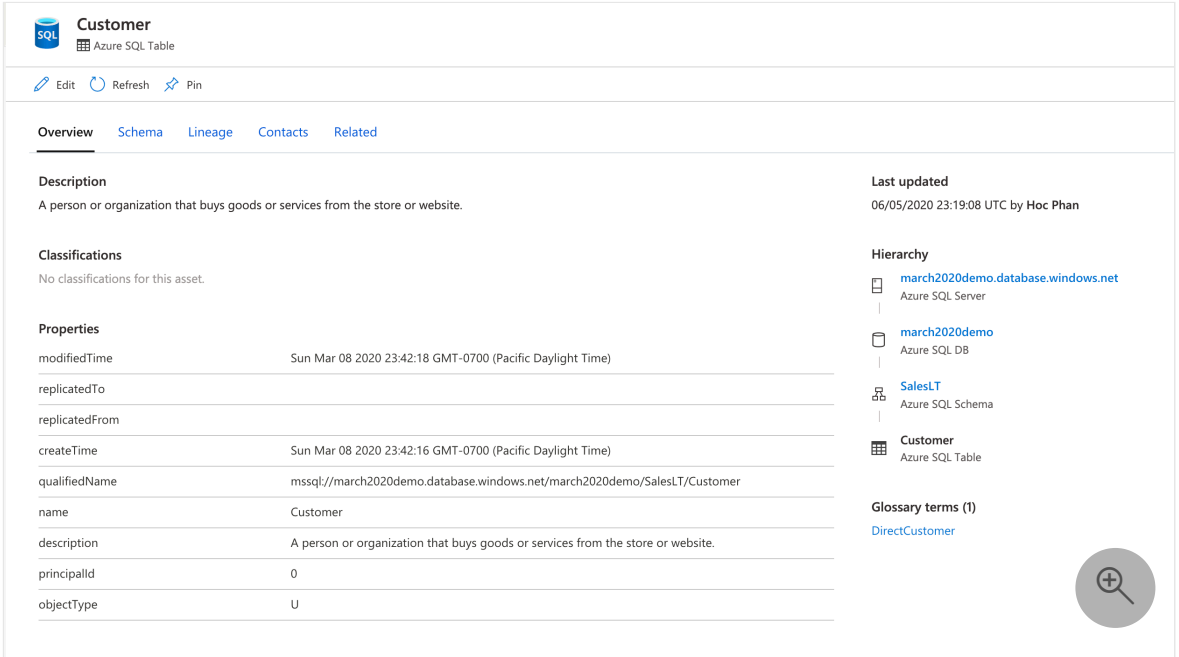


2. On the **Overview** tab, view the **Classifications** section to see if there are any existing classifications. Select **Edit**.

3. From the **Classifications** drop-down list, select the specific classifications you're interested in. In our example, we're adding **Credit Card Number**, which is a system classification and **CustomerAccountID**, which is a custom classification.

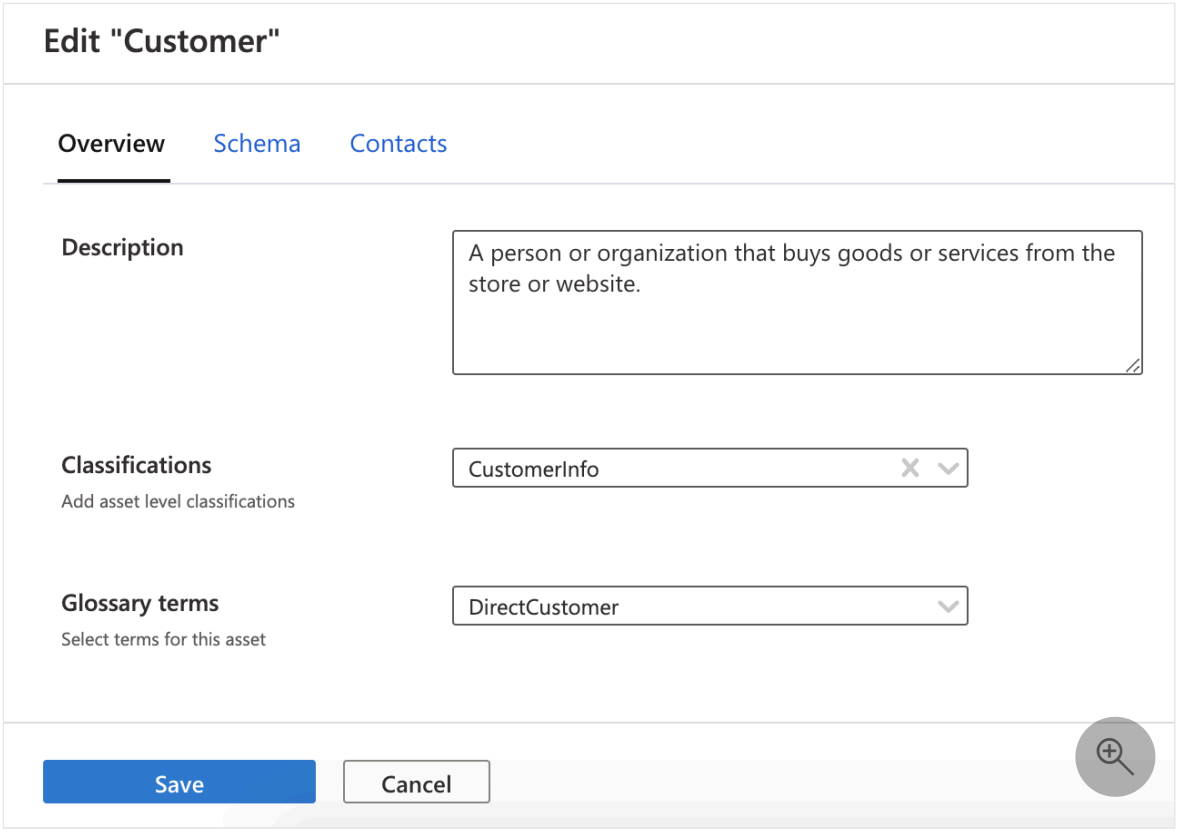
4. Select **Save**.

5. On the **Overview** tab, confirm that the classifications you selected appear under the **Classifications** section.



Manually apply classification to a table asset

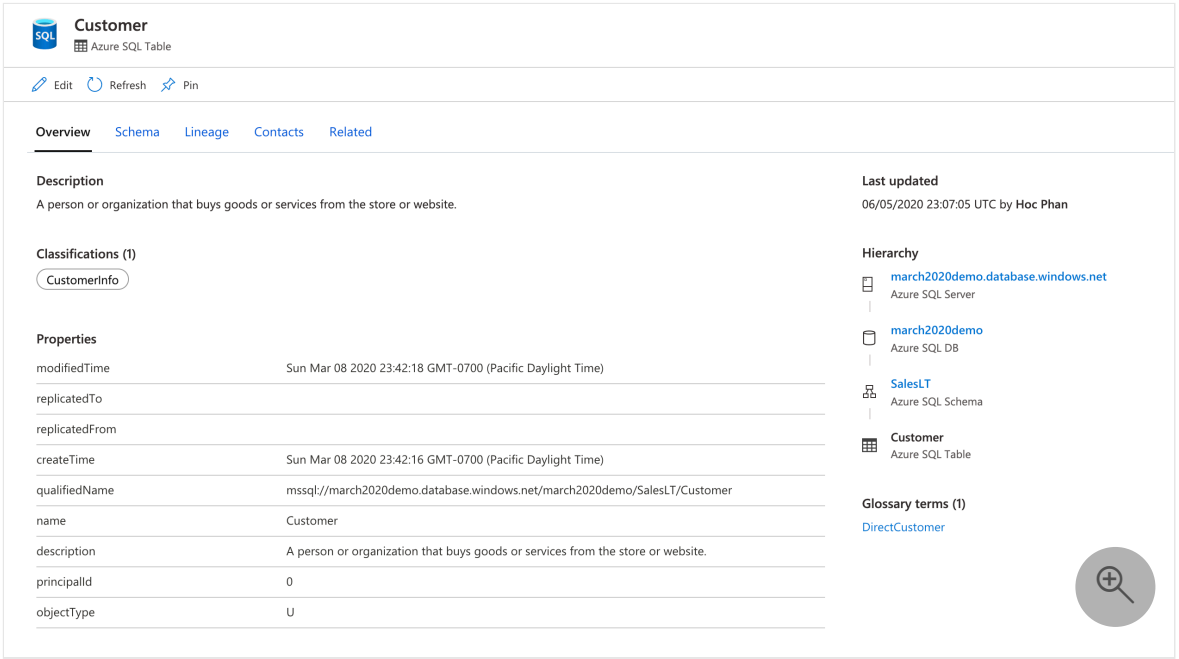
When Microsoft Purview scans your data sources, it doesn't automatically assign classifications to table assets (only on columns). For a table asset to have classifications, you must add them manually:



To add a classification to a table asset:

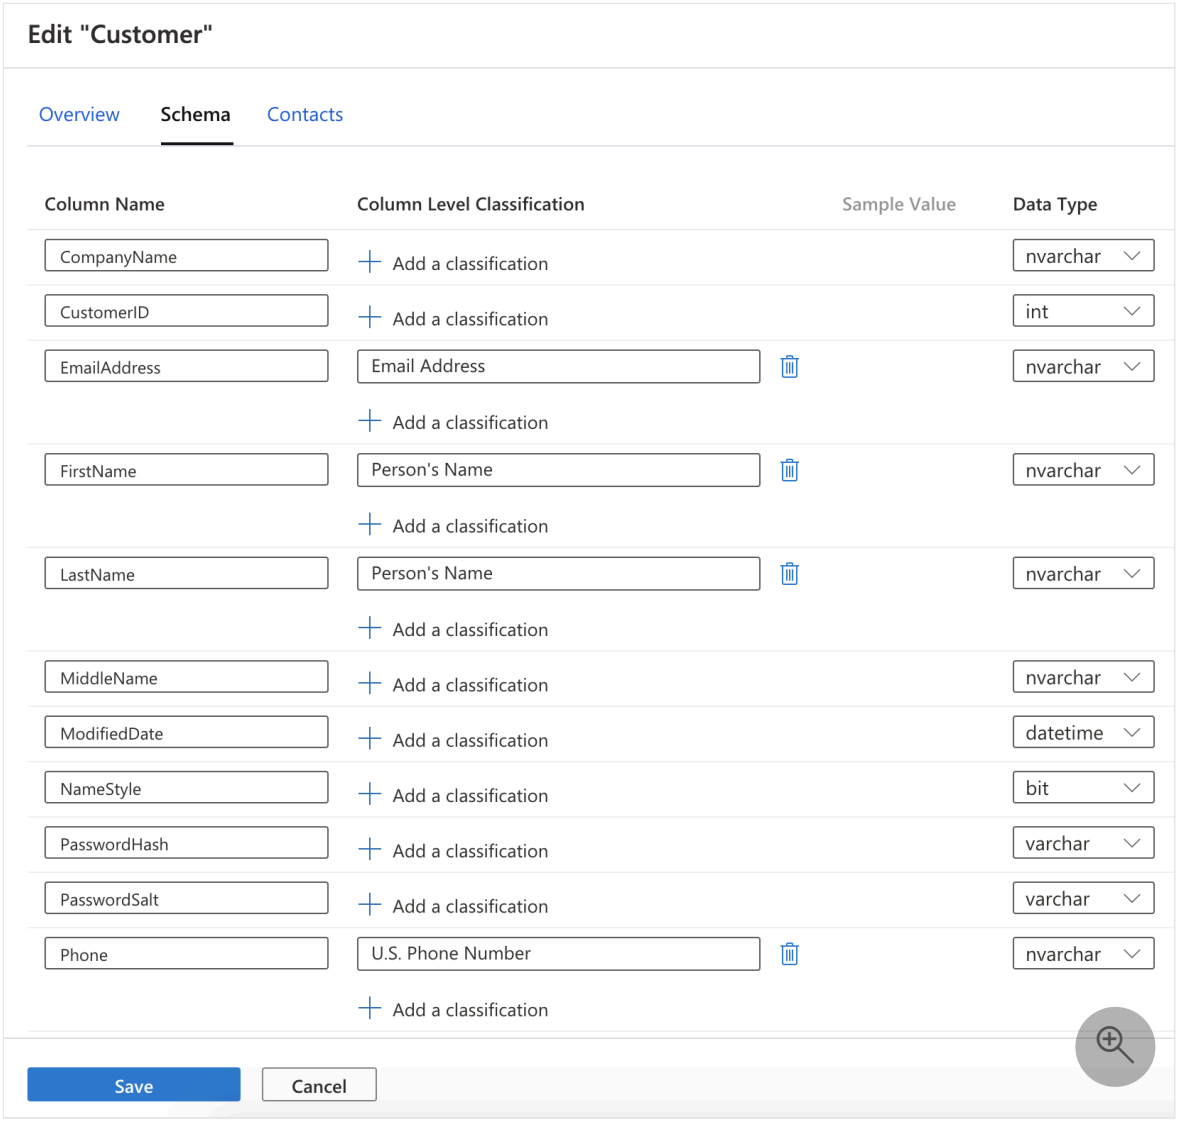
1. Search or browse Unified Catalog for the table asset that you're interested in. For example, **Customer** table.

2. Confirm that no classifications are assigned to the table. Select **Edit**.

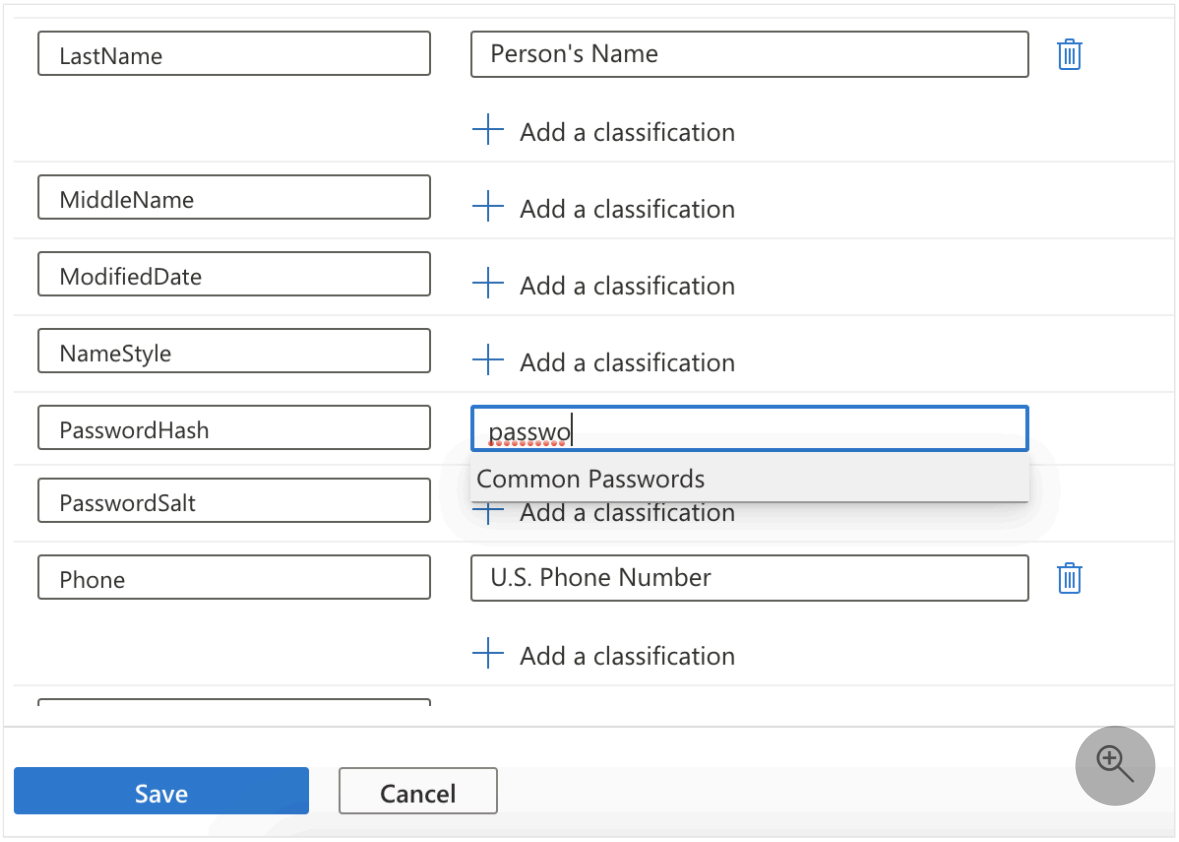


3. From the **Classifications** drop-down list, select one or more classifications. This example uses a custom classification named **CustomerInfo**, but you can select any classifications for this step.

4. Select **Save** to save the classifications.



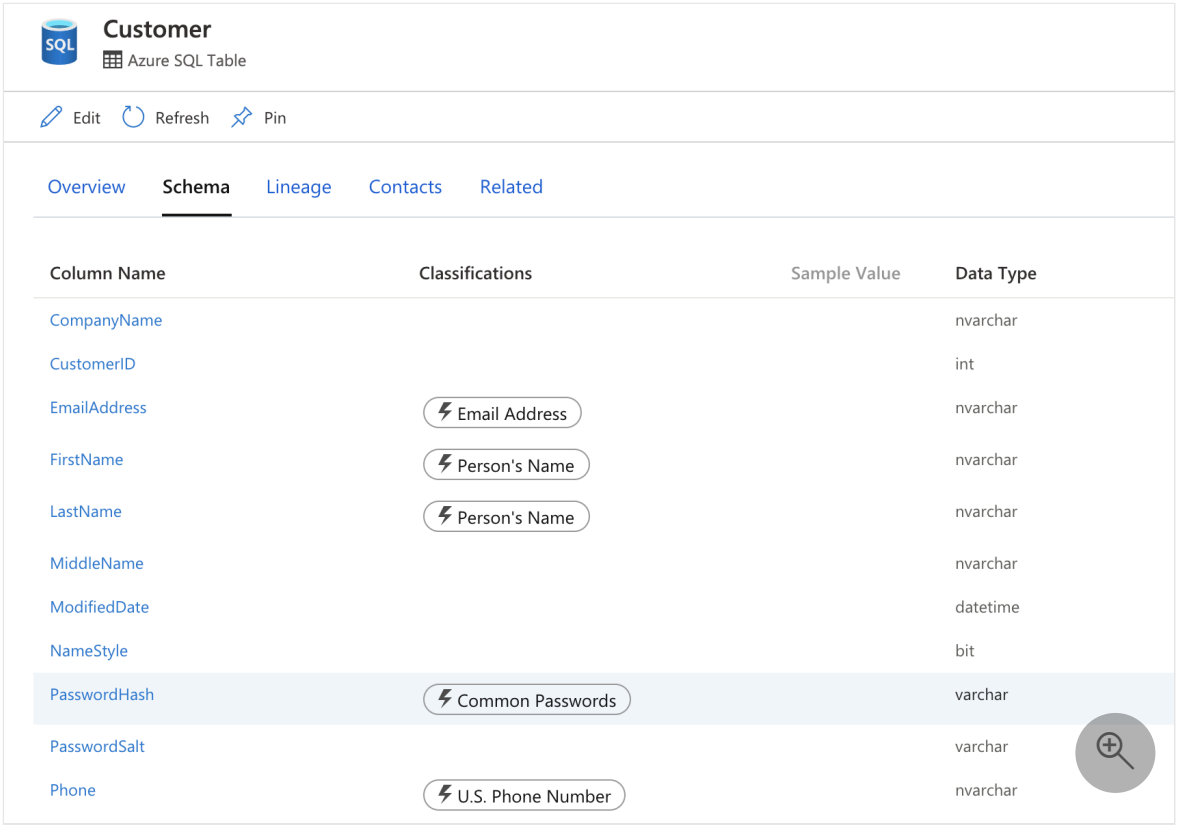
5. On the **Overview** page, verify that Microsoft Purview added your new classifications.



Manually add classification to a column asset

Microsoft Purview automatically scans and adds classifications to all column assets. However, if you want to change the classification, you can do so at the column level:

1. Search or browse Unified Catalog for the table asset that contains the column you want to update.
2. Select **Edit** from the **Overview** tab.
3. Select the **Schema** tab.



4. Identify the columns you're interested in and select **Add a classification**. This example adds a **Common Passwords** classification to the **PasswordHash** column.

5. Select **Save**.

6. Select the **Schema** tab and confirm that the classification has been added to the column.

View classification details

Microsoft Purview captures important details like who applied a classification and when it was applied. To view the details, hover over the classification to revel the Classification details card. The classification details card shows the following information:

- Classification name - Name of the classification applied on the asset or column.
- Applied by - Who applied the classification. Possible values are scan and user name.
- Applied time - Local timestamp when the classification was applied via scan or manually.
- Classification type - System or custom.

Users with Data Curator role can see more details for classifications that were applied automatically through a scan. These details include sample count that the scanner read to classify the data, and distinct data count in the sample that the scanner found.

Impact of rescanning on existing classifications

Classification tags are automatically applied the first time based on sampling your data and matching those samples against predefined RegEx patterns or dictionaries. Subsequent rescans can preserve, remove, or incrementally add classification tags depending on several factors:

- A scan run doesn't remove classification tags that were manually applied.
- A scan run doesn't reapply classification tags that were manually removed.
- A later run of a scan that continues to use the same scan rule can update the classification tags.
- For a scan run, classification tags from the previous scans can get removed or retained based on the criteria listed in this table:

Expand table

File type	File size	Classification tags from previous scan will be:
File types with no size (for example, SQL)	All	Retained
.doc, .docm, .docx, .dot, .odp, .ods, .odt, .pdf, .pot, .pps, .ppsx, .ppt, .pptm, .pptx, .txt, .xlc, .xls, .xlsb, .xlsm, .xlsx, .xlt	>20 MB	Retained
.doc, .docm, .docx, .dot, .odp, .ods, .odt, .pdf, .pot, .pps, .ppsx, .ppt, .pptm, .pptx, .txt, .xlc, .xls, .xlsb,	<20 MB	Removed

System classifications supported in Data Map

Article • 03/04/2025

This article lists the supported system classifications in Microsoft Purview Data Map. To learn more about classification, see Data classification in Data Map.

Microsoft Purview classifies data by using RegEx, Bloom Filter and Machine Learning models. The following lists describe the format, pattern, and keywords for the Microsoft Purview defined system classifications. Each classification name is prefixed by *MICROSOFT*.

> **Note**
>
> Microsoft Purview can classify both structured (CSV, TSV, JSON, SQL Table etc.) as well as unstructured data (DOC, PDF, TXT etc.). However, there are certain classifications that are only applicable to structured data. Here is the list of classifications that Microsoft Purview doesn't apply on unstructured data - City Name, Country Name, Date Of Birth, Email, Ethnic Group, GeoLocation, Person Name, U.S. Phone Number, U.S. States, U.S. ZipCode

> **Note**
>
> **Minimum match threshold**: It is the minimum percentage of data value matches in a column that must be found by the scanner for the classification to be applied. For system classification minimum match threshold value is set at 60% and cannot be changed. For custom classification, this value is configurable.

Bloom Filter based classifications

World Cities, Country

The City and Country classifier identifies the data based on their full names as well as short codes.

Keywords

Keywords for City

Machine Learning based classifications

> ⓘ **Note**
>
> Machine learning based classifiers are only supported for structured data like tabular or columnar data sources.

Person's Name

Person Name machine learning model has been trained using global datasets of names in English language. Microsoft Purview classifies full names stored in the same column as well as first and last names in separate columns.

Person's Address

Person's address classification is used to detect full address stored in a single column containing the following elements: House number, Street Name, City, State,

Country/Region, Zip Code. Person's Address classifier uses machine learning model that is trained on the global addresses data set in English language.

Supported formats

Currently the address model supports the following formats in the same column:

- number, street, city
- name, street, pincode or zipcode
- number, street, area, pincode or zipcode
- street, city, pincode or zipcode
- landmark, city

Person's Gender

Person's Gender machine learning model has been trained using US Census data and other public data sources in English language. It supports classifying 50+ genders out of the box.

Keywords

- sex
- gender
- sexual
- orientation

Person's Age

Person's Age machine learning model detects age of an individual specified in various different formats. The qualifiers for days, months, and years must be in English language.

Keywords

- age
- ages

Supported formats

- {%y} y, {%m} m

Italy fiscal code

Format

a 16-character combination of letters and digits in the specified pattern

Pattern

A 16-character combination of letters and digits:

- three letters that correspond to the first three consonants in the family name
- three letters that correspond to the first, third, and fourth consonants in the first name
- two digits that correspond to the last digits of the birth year

- one letter that corresponds to the letter for the month of birth—letters are used in alphabetical order, but only the letters A to E, H, L, M, P, R to T are used (so, January is A and October is R)
- two digits that correspond to the day of the month of birth in order to differentiate between genders, 40 is added to the day of birth for women
- four digits that correspond to the area code specific to the municipality where the person was born (country-wide codes are used for foreign countries/regions)
- one parity digit

Checksum

Yes

U.K. driver's license number

Format

Combination of 18 letters and digits in the specified format

Pattern

18 letters and digits:

- Five letters (not case-sensitive) or the digit "9" in place of a letter.
- One digit.
- Five digits in the date format MMDDY for date of birth. The seventh character is incremented by 50 if driver is female; for example, 51 to 62 instead of 01 to 12.
- Two letters (not case-sensitive) or the digit "9" in place of a letter.
- Five digits.

Checksum

Yes

U.K. national insurance number (NINO)

This sensitive information type entity is included in the EU National Identification Number sensitive information type. It's also available as a stand-alone sensitive information type entity.

Format

seven characters or nine characters separated by spaces or dashes

Pattern

two possible patterns:

- two letters (valid NINOs use only certain characters in this prefix, which this pattern validates; not case-sensitive)
- six digits
- either 'A', 'B', 'C', or 'D' (like the prefix, only certain characters are allowed in the suffix; not case-sensitive)

OR

- two letters
- a space or dash
- two digits
- a space or dash

U.S. social security number (SSN)

Format

nine digits, which may be in a formatted or unformatted pattern

> ⓘ **Note**
>
> If issued before mid-2011, an SSN has strong formatting where certain parts of the number must fall within certain ranges to be valid (but there's no checksum).

Pattern

four functions look for SSNs in four different patterns:

- Func_ssn finds SSNs with pre-2011 strong formatting that are formatted with dashes or spaces (ddd-dd-dddd OR ddd dd dddd)
- Func_unformatted_ssn finds SSNs with pre-2011 strong formatting that are unformatted as nine consecutive digits (ddddddddd)
- Func_randomized_formatted_ssn finds post-2011 SSNs that are formatted with dashes or spaces (ddd-dd-dddd OR ddd dd dddd)
- Func_randomized_unformatted_ssn finds post-2011 SSNs that are unformatted as nine consecutive digits (ddddddddd)

Data Map history (preview)

06/06/2025

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

When a user updates an asset in Microsoft Purview, Data Map history logs that change and makes the information available in the Microsoft Purview portal. Information about who added or edited an asset, what edits were made, and when the edit happened, is stored for reference later. This information helps data auditors and business owners to maintain compliance and security in their Microsoft Purview accounts. It also allows data stewards and admins to debug issues and curation in their data assets.

Data Map history is available to users in both the free and enterprise versions of Microsoft Purview.

Currently, you can view your assets' history either:

- In the Audit solution in the Microsoft Purview portal
- Within individual solutions
- Using the REST API

Prerequisites

Before you can use Data Map history, make sure that the audit log is turned on in your organization. If it's not, you need to turn it on to access your Data Map history.

Which assets have history

Currently, these kinds of assets have Data Map history available:

- Classifications*
- Data assets*
- Glossary terms*
- Business assets*
- Domains
- Collections

- Role assignments
- Data sources
- Scan
- Scan rule set
- Credential
- Policy

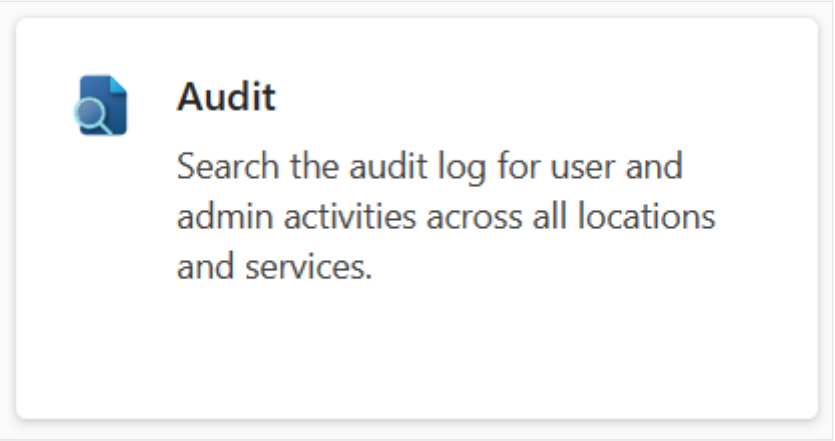
* In-solution experience is currently only available for classifications, data assets, business assets, and glossary terms.

How to use Data Map history

Data Map history allows you to see the operational history of changes to your Data Map assets in Microsoft Purview.

You're able to see the history for select operations that include:

- Creation
- Updates
- Assignment



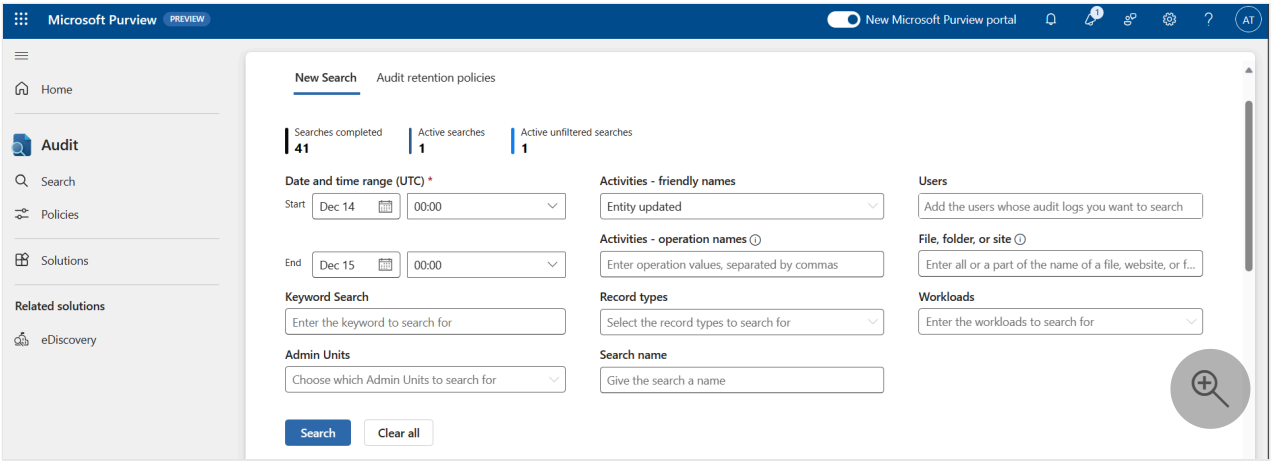
For a full list of available operations in Data Map History, see the audit log activities documentation.

> **Important**
>
> Data Map history entries are kept in Audit for 180 days, and are available for 30 days in the **in-solution experience**. To view audit history for longer, you can use **Microsoft Purview Audit (Premium)**.

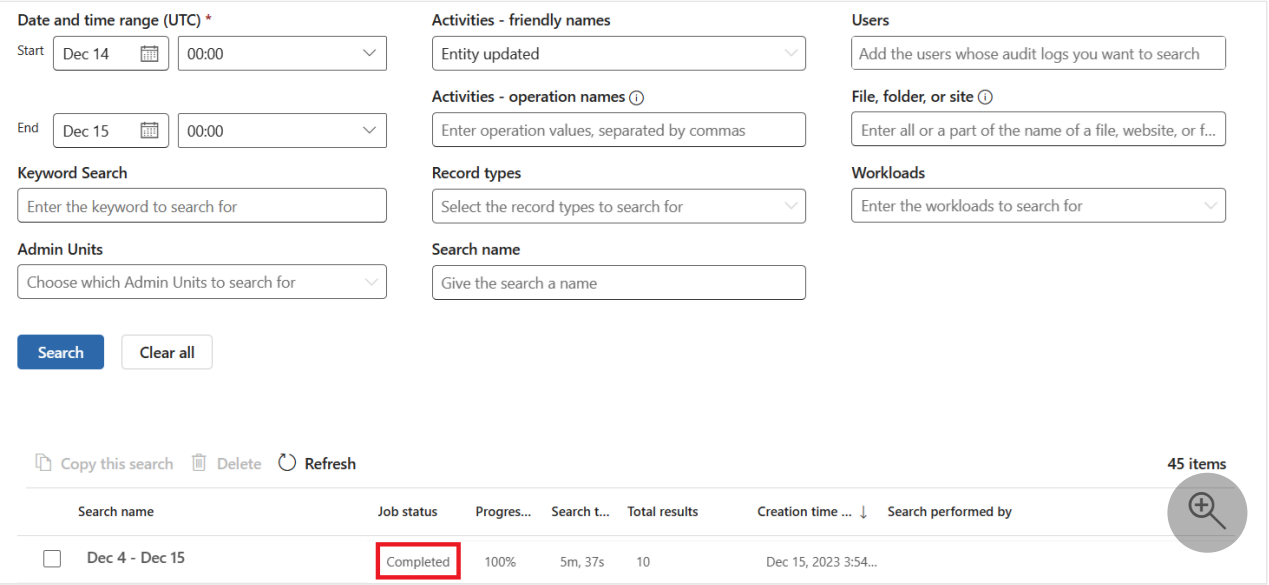
Audit solution experience

To view the activities within the Audit solution, follow these instructions:

1. Navigate to the Audit solution within Microsoft Purview

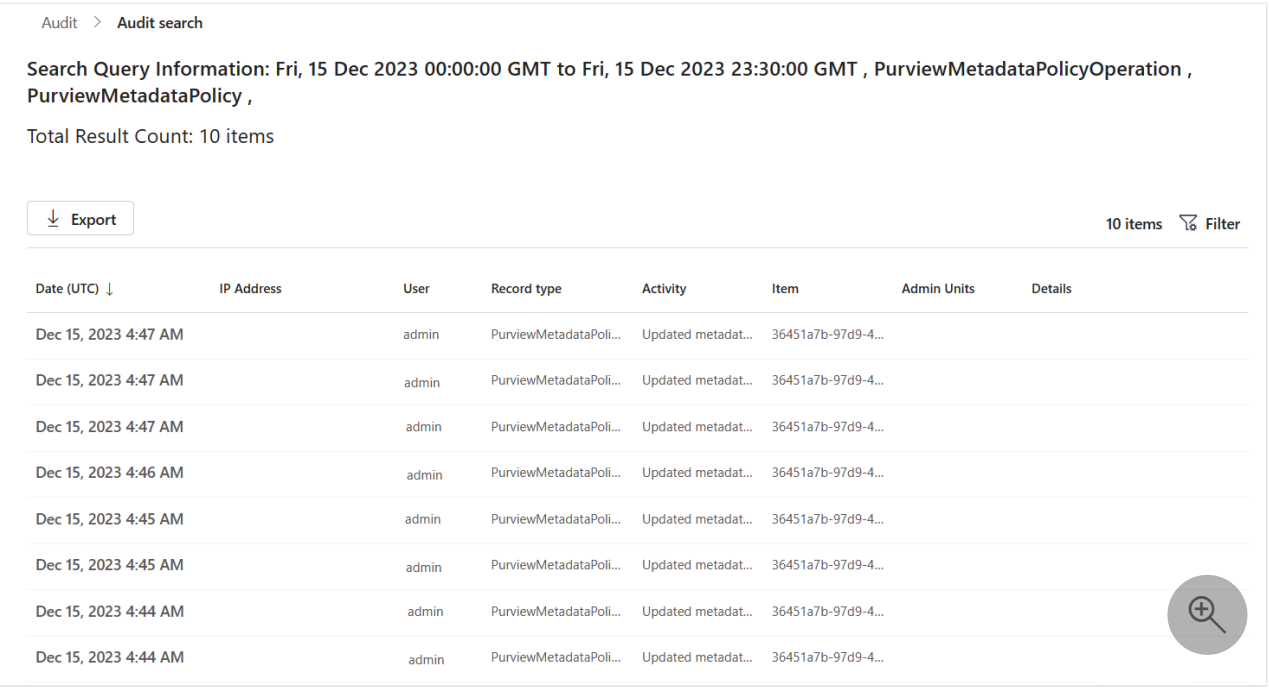


2. Select **Search** to search for audit records



3. Select time range for activity.

4. Narrow the scope of your search using **Activities - friendly names**, **Activities - operation names**, or **Record types**.

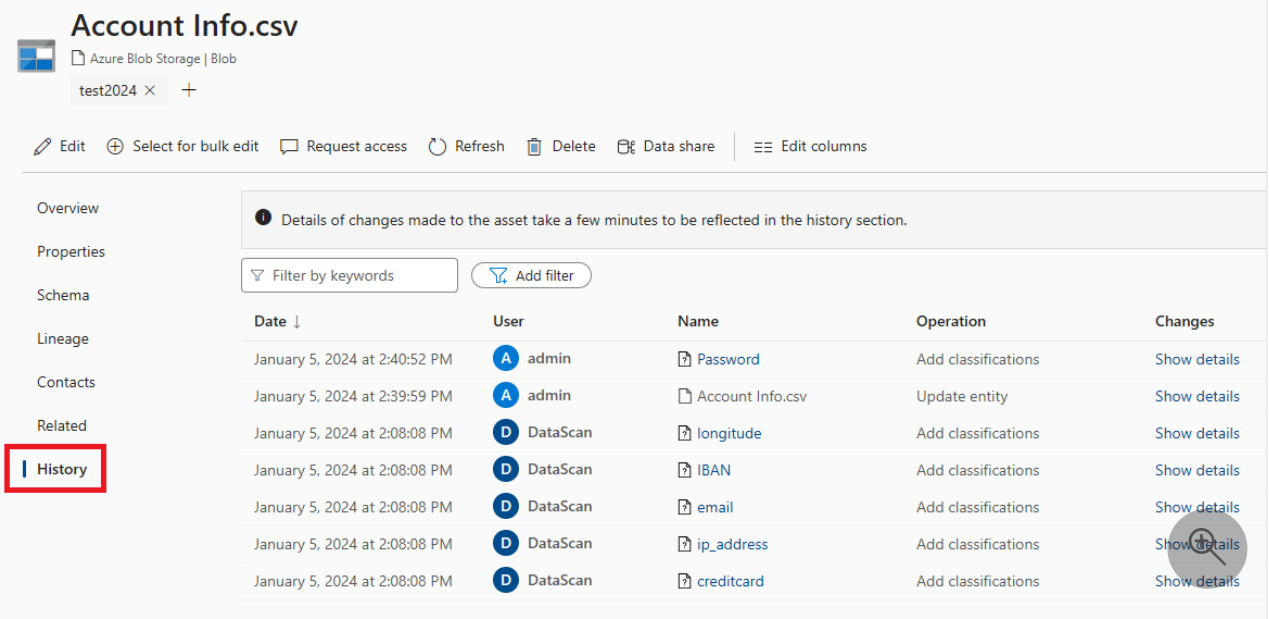


> **Tip**
>
> For the list of available activities, see the [audit log activities page]

5. Select **Search** and wait for job state to change to **Complete**.

6. Select your search from the list, and scroll through or filter the history table to find the operations you're looking for.

In-solution history experience



> **Note**
>
> In-solution experience is currently only available for classifications, data assets, business assets, and glossary terms.

To view the activities, follow these instructions:

1. Search for a data asset, glossary term, or classification in Microsoft Purview Unified Catalog.

2. Select the **History** tab.

3. Scroll through or filter the history table to find the operations you're looking for.

Query Audit log using the REST API

You also can use the Microsoft Purview REST API to access your Data Map history.

1. To authenticate with the REST API, follow the instructions on the Authenticate for APIs page.
2. Use the authentication token to POST to this request URL: `https://api.purview-service.microsoft.com/datamap/api/audit/query?api-version=2023-10-01-preview`

Here are a few example API calls you can use to get started:

- Retrieve an asset's history in a time range
- Retrieve the history of a specific operation
- Filter by user who edited an asset
- Filter by keywords
- Example with pagination

Retrieve an asset's history in a time range

Get all audit history of an asset within a specific time range.

JSON

```
{
  "category": "Asset",
  "guid": "f432d351-5442-4724-945b-516d5d501fc9",
```

```
  "startTime": "2024-01-01T00:00:00.000Z",
  "endTime": "2024-01-06T00:00:00.000Z",
  "sortBy": "CreationTime",
  "sortOrder": "Descending"
}
```

Retrieve the history of a specific operation

Get the history of specific operation type. For example, when classifications are applied to the asset.

> **Tip**
>
> For the list of available operations, see the audit log activities page.

JSON

```
{
  "category": "Asset",
  "guid": "f432d351-5442-4724-945b-516d5d501fc9",
  "operationType": "ClassificationAdded",
  "sortBy": "CreationTime",
  "sortOrder": "Descending"
}
```

Filter by user who edited an asset

JSON

```
{
  "category": "Asset",
  "guid": "f432d351-5442-4724-945b-516d5d501fc9",
  "userId": "contoso@microsoft.com",
  "sortBy": "CreationTime",
  "sortOrder": "Descending"
}
```

Filter by keywords

Filter by keywords such as a changed attribute name, attribute value, etc.

JSON

```
{
  "category": "Asset",
  "guid": "f432d351-5442-4724-945b-516d5d501fc9",
  "keywords": "userDescription",
  "sortBy": "CreationTime",
  "sortOrder": "Descending"
}
```

Example with pagination

After the first query, if the "lastPage" property in the response body is false, the use can use the "continuationToken" in the response body to fetch the next page.

JSON

```
{
  "continuationToken": "TY7BbsIwEAV%2fKDZr4oQ0KAcEVKo4klNvK…",
  "category": "Asset",
  "guid": "f432d351-5442-4724-945b-516d5d501fc9",
  "sortBy": "CreationTime",
  "sortOrder": "Descending",
  "pageSize": 10
}
```

Limitations

1. Currently, it takes a couple minutes for an operational item to appear in an assets **History** tab.
2. Currently, to see a new item in the **History** tab, you need to manually refresh the tab.

Next steps

- Metadata curation
- Use the new Microsoft Purview portal
- Roles and permissions

Choose the right integration runtime configuration for your scenario

The integration runtime (IR) is the compute infrastructure that Microsoft Purview uses to power data scan across different network environments. This article introduces the different types of integration runtime available in Microsoft Purview, and provides guidance on how to choose the right integration runtime configuration for your scenario.

Types of integration runtimes

Purview provides the following types of integration runtimes:

- **Azure integration runtime**: The Azure integration runtime is a fully managed and elastic compute that you can use to scan Azure or non-Azure data sources. The Azure IR supports connections to data stores and compute services with publicly accessible endpoints. It's the default integration runtime that you don't need to create anything to get started.

- **Managed Virtual Network integration runtime**: You can create a Managed Virtual Network integration runtime, which resides in a Purview Managed Virtual Network. It can use private endpoints to securely connect to and scan the supported data sources. Learn more at Managed Virtual Network and managed private endpoints.

- **Self-hosted integration runtime**: The self-hosted integration runtime can be used to scan data sources in an on-premises network or a virtual network. You can install it on an on-premises machine or a virtual machine inside your private network. Learn more at Create and manage self-hosted integration runtimes.

- **Kubernetes supported self-hosted integration runtime**: This integration runtime is hosted on a Kubernetes cluster and can be used to scan data sources in an on-premises network or a virtual network. Kubernetes support improves overall performance and allows the integration runtime to scale with the job. Learn more at Create and manage Kubernetes supported self-hosted integration runtimes.

- **AWS integration runtime**: The AWS integration runtime is a fully managed and elastic computed hosted by Microsoft Purview in AWS. It's applicable when scanning Amazon data sources like S3, RDS.

Choose the right integration runtime

Choose the right integration runtime for your needs. Consider your existing architecture and requirements for data integration. Also think about how to meet growing business needs and any future increase in workload.

The following considerations can help you make your decision:

1. **What data source types do you want to scan?**

   Check the supported data sources section to learn about the supported IR types for the data sources you want to scan.

2. **What's the network access control on your data source?**

   Different data sources have different network firewall settings to protect them from random access over the internet. These settings apply to on-premises, cloud, and SaaS data stores. The following table lists some common firewall options. Choose the supported IR type according to your scenario.

Expand table

Data source firewall	Azure IR	Managed Virtual Network IR	SHIR	Kubernetes supported SHIR
Allow public access	✓	✓	✓	✓
Allow Azure service or trusted service	✓	✓	✓	✓
Allow access from specific Azure virtual network		✓ (with managed private endpoint support)	✓	✓
Allow specific IP / IP range			✓	✓
Other on-premises or private network access			✓	✓

3. **What's the firewall setting of your Microsoft Purview?**

   Purview provides different network firewall options. Learn more from Configure Microsoft Purview firewall. Choose the supported IR type according to your scenario.

Expand table

Purview firewall	Azure IR	Managed Virtual Network IR	SHIR	Kubernetes supported SHIR
Enabled from all networks	✓	✓	✓	✓
Disabled from all networks		✓ (managed private endpoint required)	✓ (need to create private endpoint from your network)	✓ (need to create private endpoint from your network)

4. **What level of security do you require during data transmission?**

   The integration runtime location defines the location of its back-end compute and where the scan operations are performed. For data residency consideration:

   - When you use Azure IR, Purview automatically detects the data source's location and uses the IR in that region. If Purview can't detect the region, it uses the Purview account's region.
   - When you use Managed Virtual Network IR, it runs in the region you configure for the managed virtual network.
   - When you use SHIR, you can fully decide the location in your on-premises or Azure virtual machines.

     To protect against, for example, man-in-the-middle attacks during data transmission, use a private endpoint and private link to ensure data security.
   - You can create managed private endpoints to your data stores when using Managed Virtual Network IR. The Purview service maintains the private endpoints within the managed virtual network.
   - You can also create private endpoints in your virtual network and the SHIR can use them to access data stores.

5. **What level of maintenance are you able to provide?**

   Maintaining infrastructure, servers, and equipment is one of the important tasks of the IT department of an enterprise. It usually takes much time and effort.

   - When using Azure IR and Managed Virtual Network IR, you don't need to worry about maintenance such as updates, patches, and versions. The Purview service takes care of all the maintenance efforts.

- Because the SHIR is installed on your machines and the Kubernetes supported SHIR is on your Kubernetes clusters, you need to manage the maintenance.
  - The SHIR supports autoupdate to automatically get the latest version whenever there's' an update. Learn more from Self-hosted integration runtime autoupdate and expiration.
  - Currently, the Kubernetes supported self-hosted integration runtime only supports manual updates.

6. **Performance and scalability**

   Use the fully managed and autoscaled Azure IR, Managed Virtual Network IR, or the Kubernetes-supported self-hosted integration runtime whenever applicable. By using elasticity, they can provide you with better performance and scalability, especially when scanning large-scale data systems.

Hibernation of managed virtual network integration runtime

If the integration runtime is inactive (no scans on the integration runtime for more than 90 days), your Managed Virtual Network Integration Runtime automatically goes into hibernation. Its status shows as **Hibernated** when you select the integration runtime.

What this change means for you

1. When you run Test Connection on a hibernated integration runtime, the test connection fails. You see a message to try Test Connection after 15 minutes. By this time, your Managed Virtual Network returns to a normal state. After this, you can run your Test Connections and Scans normally.

2. When you run a scan directly by using **Run scan now** or **Edit Scan** options without running a Test Connection first from a hibernated Integration Runtime, or you run a scan through API, you see a message that this scan takes up to 15 extra minutes. This extra time is for the hibernated Integration Runtime to wake up and the scan process to begin. You see your scan status as **Queued_Waking Up IR** instead of **Queued** state that you see in case of normal scan. After the first scan, you can run all your following scans normally.

Supported data sources

The following table shows all the data sources that Purview scan supports, and the supported integration runtime types.

Expand table

Category	Supported data store	Azure IR/AWS IR	Managed Virtual Network IR	SHIR	Kubernetes SHIR

Create and manage a self-hosted integration runtime

09/30/2025

The integration runtime (IR) is the compute infrastructure that Microsoft Purview uses to power data scan across different network environments.

A self-hosted integration runtime (SHIR) can be used to scan data source in an on-premises network or a virtual network. The installation of a self-hosted integration runtime needs an on-premises machine or a virtual machine inside a private network.

This article covers both setup of a self-hosted integration runtime, and troubleshooting and management.

> **Important**
>
> Download the self-hosted integration runtime from: Microsoft Integration Runtime.

	Troubleshoot connectivity
Management	General

> **Note**

The Microsoft Purview Integration Runtime can't be shared with an Azure Synapse Analytics or Azure Data Factory Integration Runtime on the same machine. It needs to be installed on a separated machine.

Prerequisites

- The supported versions of Windows are:
  - Windows 8.1
  - Windows 10
  - Windows 11
  - Windows Server 2012
  - Windows Server 2012 R2
  - Windows Server 2016
  - Windows Server 2019
  - Windows Server 2022
- Installation of the self-hosted integration runtime on a domain controller isn't supported.
- FIPS mode isn't currently supported for SHIR machines.

> **ⓘ Important**
>
> Scanning some data sources requires extra setup on the self-hosted integration runtime machine. For example, JDK, Visual C++ Redistributable, or specific driver. For your source, refer to each source article for prerequisite details. Any requirements will be listed in the **Prerequisites** section.

- To add and manage a SHIR in Microsoft Purview, you'll need data source administrator permissions in Microsoft Purview.
- Self-hosted integration runtime requires a 64-bit Operating System with .NET Framework 4.7.2 or above. See .NET Framework System Requirements for details.
- The recommended minimum configuration for the self-hosted integration runtime machine is a 2-GHz processor with 8 cores, 28 GB of RAM, and 80 GB of available hard drive space. Scanning some data sources may require higher machine specification based on your scenario. Also check the prerequisites in corresponding connector article.
- If the host machine hibernates, the self-hosted integration runtime doesn't respond to data requests. Configure an appropriate power plan on the computer before you install

the self-hosted integration runtime. If the machine is configured to hibernate, the self-hosted integration runtime installer prompts with a message.

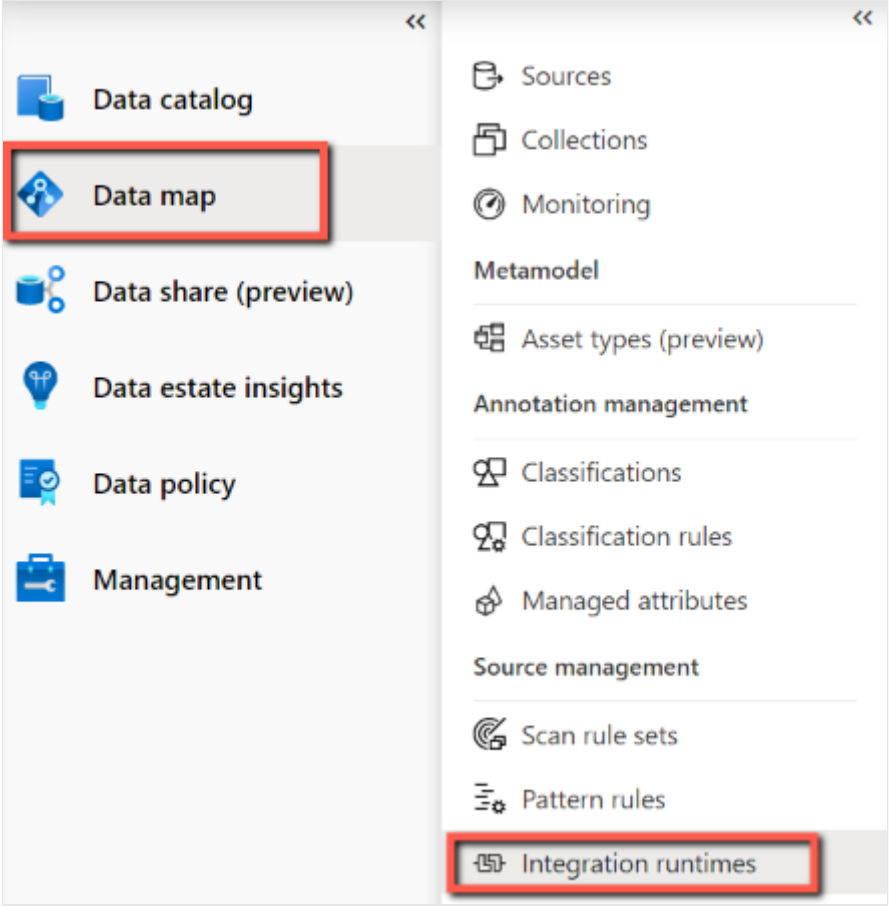
- You must be an administrator on the machine to successfully install and configure the self-hosted integration runtime.
- Scan runs happen with a specific frequency per the schedule you've set up. Processor and RAM usage on the machine follows the same pattern with peak and idle times. Resource usage also depends heavily on the amount of data that is scanned. When multiple scan jobs are in progress, you see resource usage goes up during peak times.
- Enable Windows long path by default by following these steps.

> ⓘ **Important**
>
> If you use the Self-Hosted Integration runtime to scan Parquet files, you need to install the **64-bit JRE 8 (Java Runtime Environment) or OpenJDK** on your IR machine. Check our Java Runtime Environment section at the bottom of the page for an installation guide.

Considerations for using a self-hosted IR

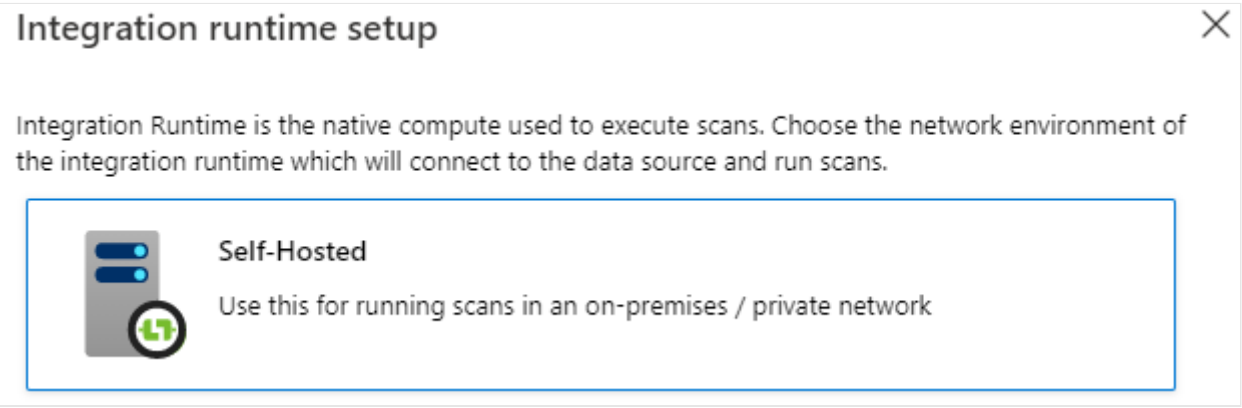
- You can use a single self-hosted integration runtime for scanning multiple data sources.
- You can install only one instance of self-hosted integration runtime on any single machine. If you have two Microsoft Purview accounts that need to scan on-premises data sources, install the self-hosted IR on two machines, one for each Microsoft Purview account.
- The self-hosted integration runtime doesn't need to be on the same machine as the data source, unless specially called out as a prerequisite in the respective source article. Having the self-hosted integration runtime close to the data source reduces the time for the self-hosted integration runtime to connect to the data source.
- To optimize disk space, it's recommended to periodically clean up the numerical folders, along with numerical folders under the **Data Scan** and **MITIlib** folder that are older than seven days, in the Temp folder generated on your machine.

Setting up a self-hosted integration runtime



To create and set up a self-hosted integration runtime, use the following procedures.

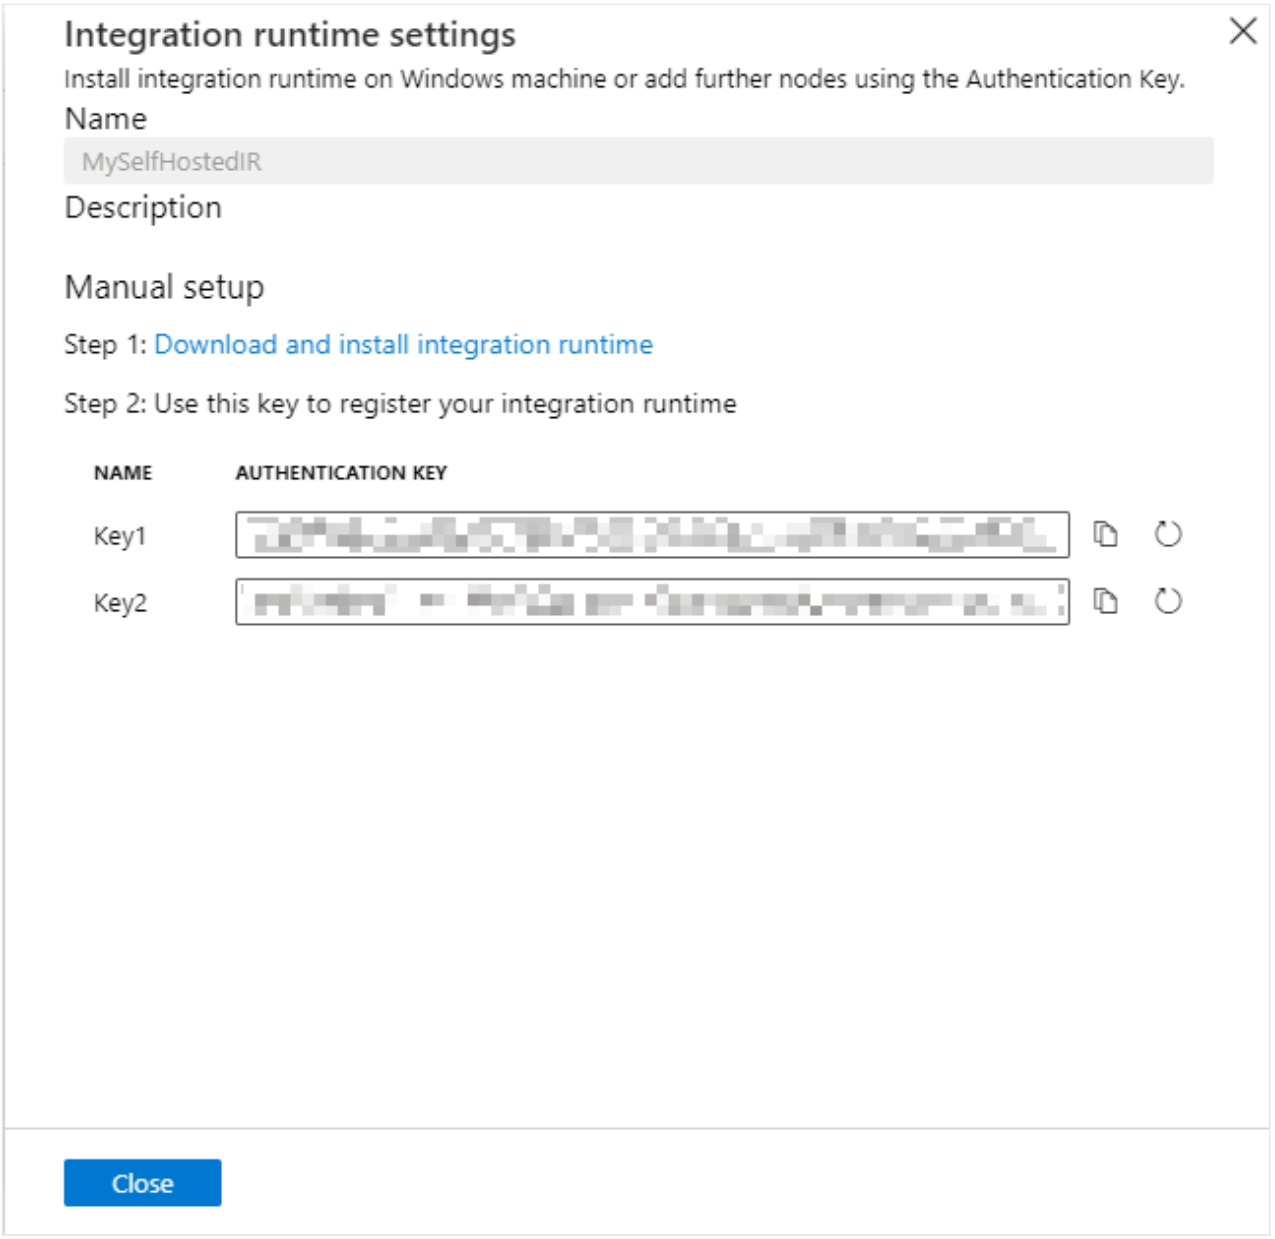
Create a self-hosted integration runtime



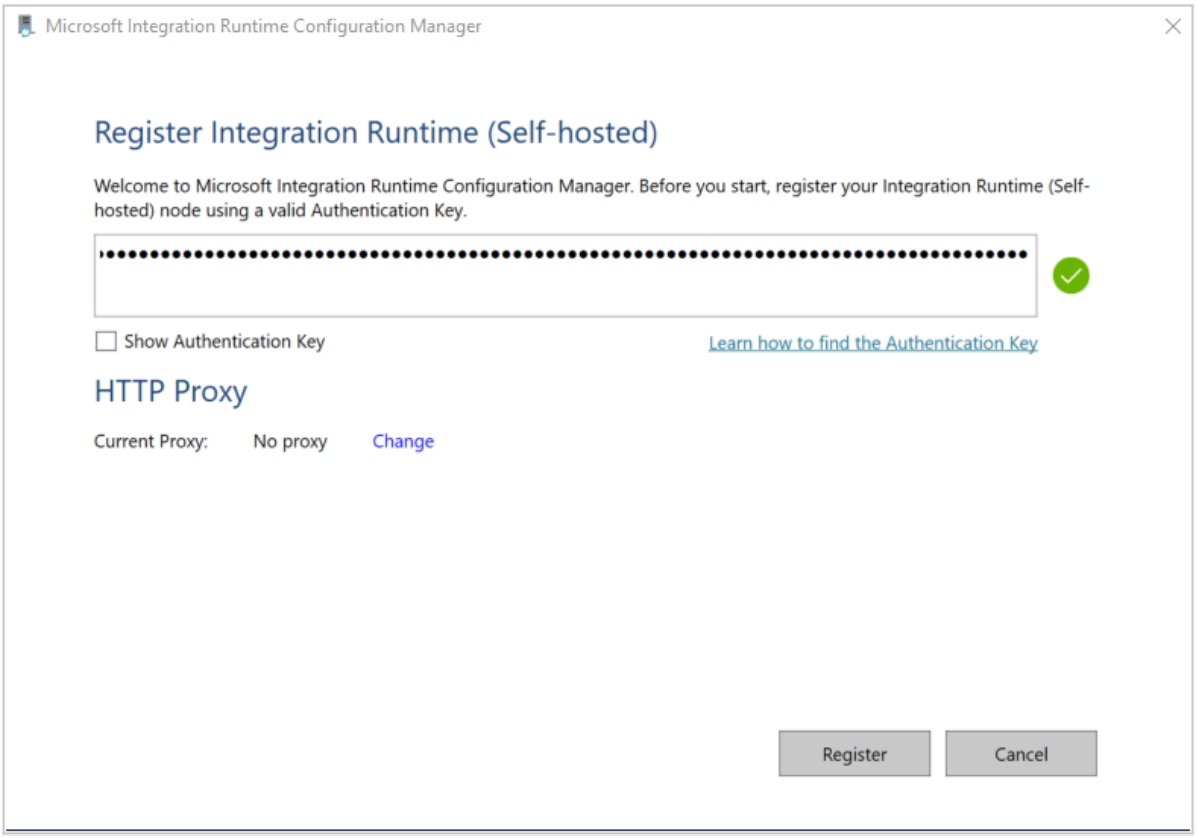
> **Note**
>
> To add or manage a SHIR in Microsoft Purview, you'll need data source administrator permissions in Microsoft Purview.

1. On the home page of the classic Microsoft Purview governance portal, select **Data Map** from the left navigation pane.

2. Under **Sources and scanning** on the left pane, select **Integration runtimes**, and then select + **New**.

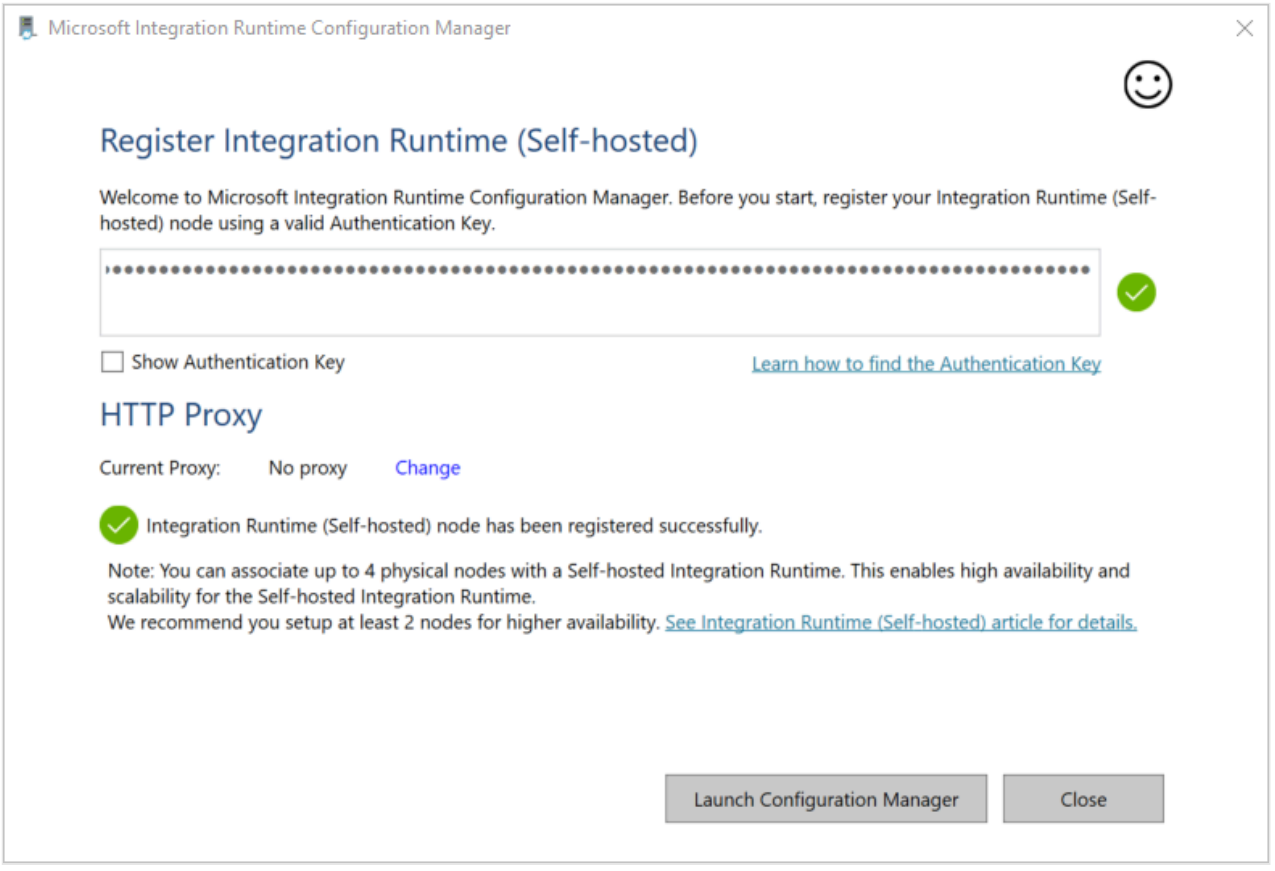


3. On the **Integration runtime setup** page, select **Self-Hosted** to create a self-Hosted IR, and then select **Continue**.



4. Enter a name for your IR, and select Create.

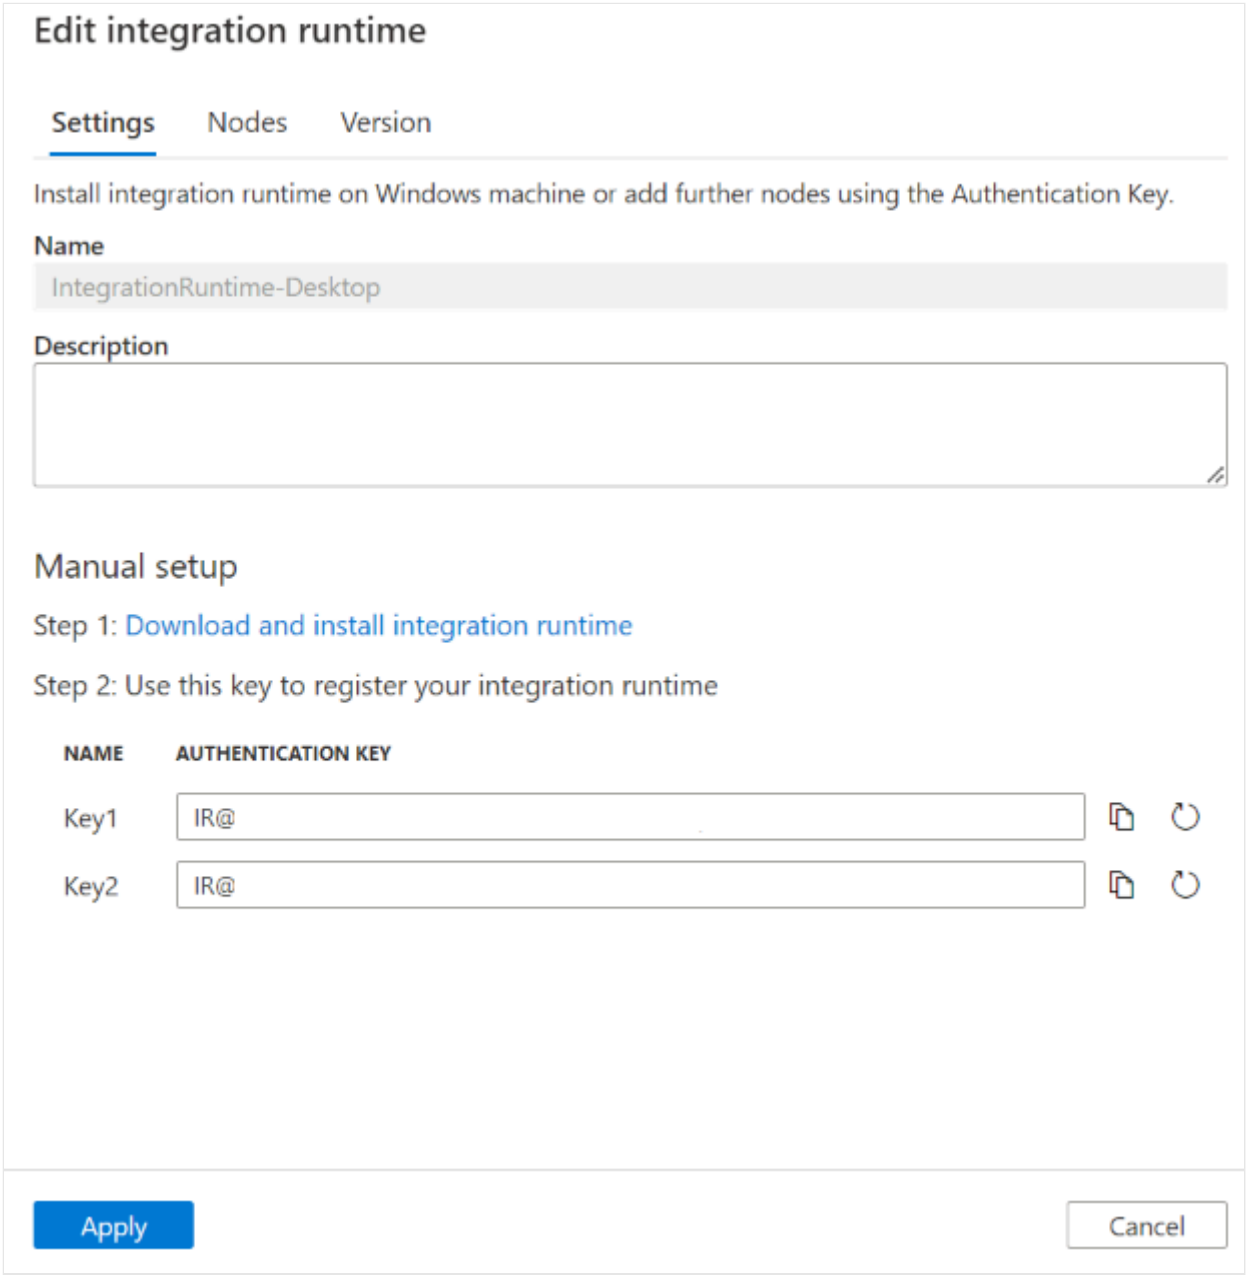
5. On the **Integration Runtime settings** page, follow the steps under the **Manual setup** section. You'll have to download the integration runtime from the download site onto a VM or machine where you intend to run it.



- Copy and paste the authentication key.
- Download the self-hosted integration runtime from Microsoft Integration Runtime on a local Windows machine. Run the installer. Self-hosted integration runtime versions such as 5.4.7803.1 and 5.6.7795.1 are supported.
- On the **Register Integration Runtime (Self-hosted)** page, paste one of the two keys you saved earlier, and select **Register**.

- On the **New Integration Runtime (Self-hosted) Node** page, select **Finish**.

6. After the Self-hosted integration runtime is registered successfully, you see the following window:



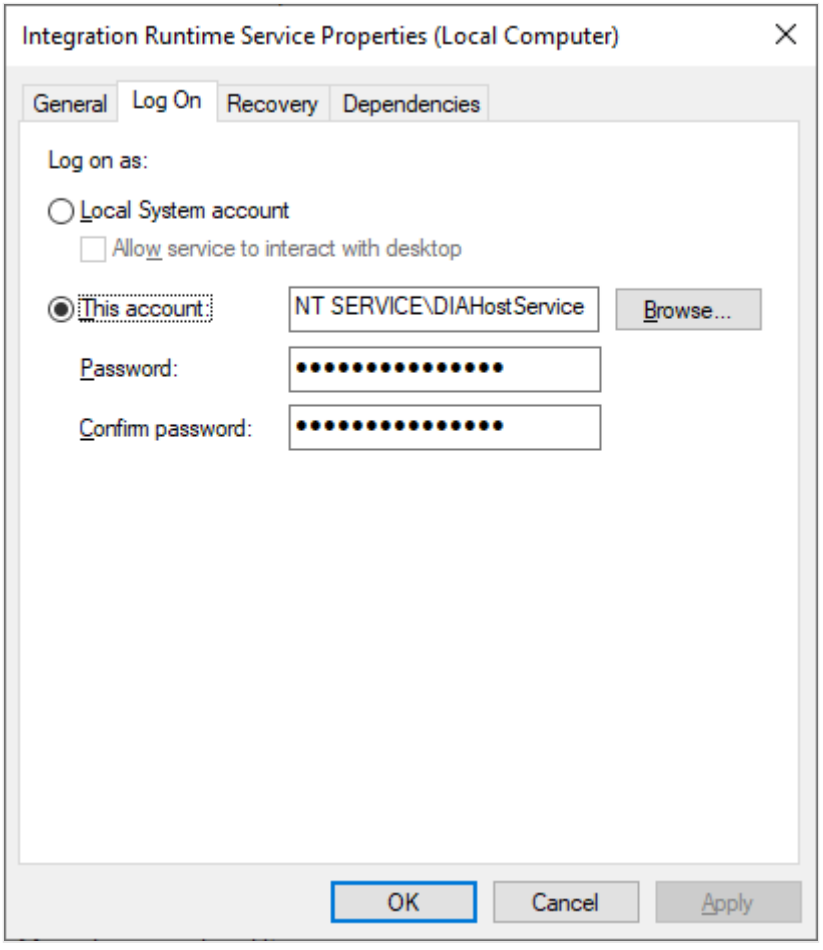
You can register multiple nodes for a self-hosted integration runtime using the same key. Learn more from High availability and scalability.

Manage a self-hosted integration runtime

You can edit a self-hosted integration runtime by navigating to **Integration runtimes** in the classic Microsoft Purview governance portal by hovering on the IR, then select **Edit**.

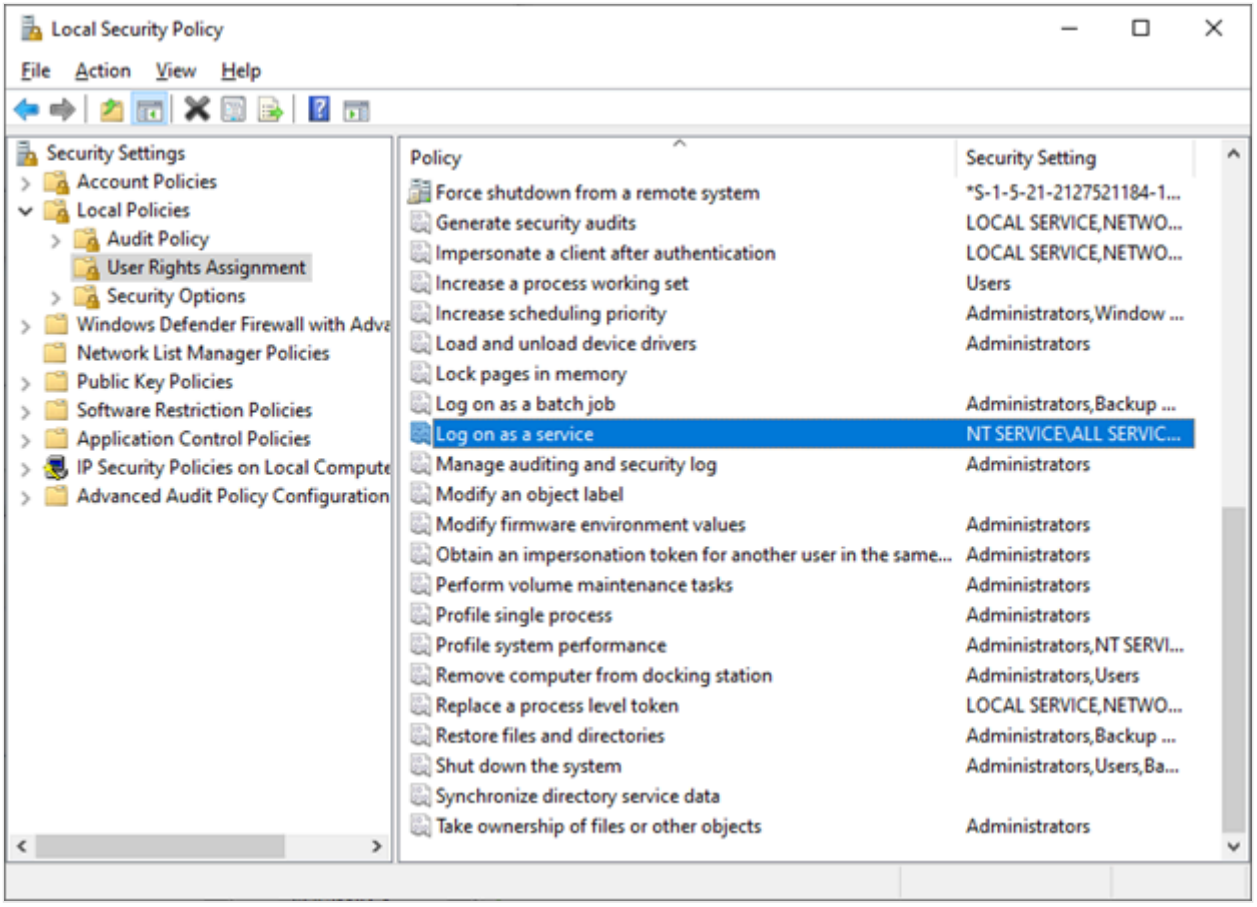
- In the **Settings** tab, you can update the description, copy the key, or regenerate new keys.
- In the **Nodes** tab, you can see a list of the registered nodes, along with the status, IP address, and the option of node deletion. Learn more from High availability and scalability.
- In the **Version** tab, you can see the IR version status. Learn more from Self-hosted integration runtime autoupdate and expire notification.

You can delete a self-hosted integration runtime by navigating to **Integration runtimes**, hover on the IR then select the **Delete** button.

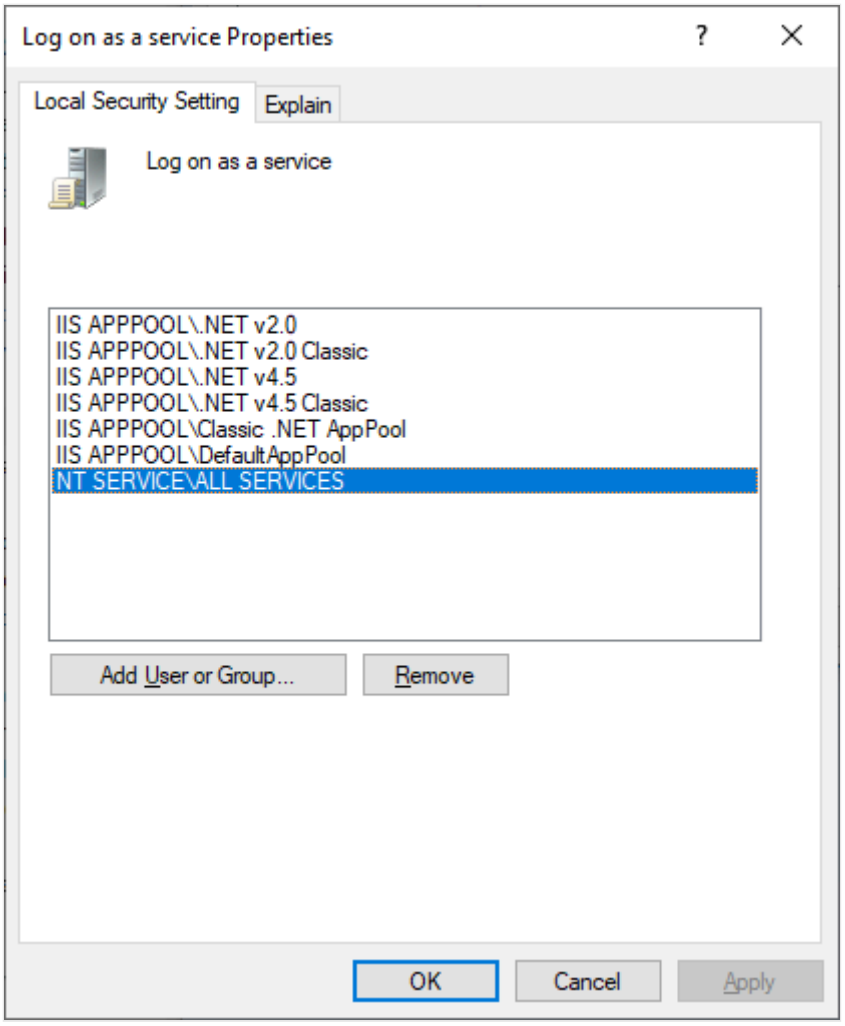


Notification area icons and notifications

If you move your cursor over the icon or message in the notification area, you can see details about the state of the self-hosted integration runtime.



Service account for Self-hosted integration runtime



The default sign-in service account of self-hosted integration runtime is **NT SERVICE\DIAHostService**. You can see it in **Services** -> **Integration Runtime Service** -> **Properties** -> **Log on**.

Make sure the account has the permission of Log-on as a service. Otherwise self-hosted integration runtime can't start successfully. You can check the permission in **Local Security**

Policy -> Security Settings -> Local Policies -> User Rights Assignment -> Log on as a service

High availability and scalability

You can associate a self-hosted integration runtime with multiple on-premises machines or virtual machines in Azure. These machines are called nodes. You can have up to four nodes associated with a self-hosted integration runtime. The benefits of having multiple nodes are:

- Higher availability of the self-hosted integration runtime so that it's no longer the single point of failure for scan. This availability helps ensure continuity when you use up to four nodes.
- Run more concurrent scans. Each self-hosted integration runtime can empower many scan runs at the same time, auto determined based on the machine's CPU/memory. You can install more nodes if you have more concurrency need.
- When scanning sources like Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2 and Azure Files, each scan run can use all those nodes to boost the scan performance. For other sources, scan will be executed on one of the nodes.

You can associate multiple nodes by installing the self-hosted integration runtime software from Download Center. Then, register it by using the same authentication key.

> **Note**
>
> Before you add another node for high availability and scalability, ensure that the **Remote access to intranet** option is enabled on the first node. To do so, select **Microsoft Integration Runtime Configuration Manager** > **Settings** > **Remote access to intranet**.

Networking requirements

Your self-hosted integration runtime machine needs to connect to several resources to work correctly:

- The Microsoft Purview services used to manage the self-hosted integration runtime.
- The data sources you want to scan using the self-hosted integration runtime.
- If your account was created before December 15, 2023, your integration runtime needs to be able to connect to the managed storage account created by Microsoft Purview. If your account is created after this date (or deployed using API version 2023-05-01-preview onwards), an ingestion storage account is used. Microsoft Purview uses this resource to ingest the results of the scan, among many other things.

There are two firewalls to consider:

- The *corporate firewall* that runs on the central router of the organization
- The *Windows Firewall* that is configured as a daemon on the local machine where the self-hosted integration runtime is installed

Here are the domains and outbound ports that you need to allow at both **corporate and Windows/machine firewalls**.

> **Tip**
>
> - For domains listed with '<managed_storage_account>', add the name of the managed resources associated with your Microsoft Purview account. You can find them from Azure portal -> your Microsoft Purview account -> **Settings** -> **Managed resources** tab.
> - If your account doesn't have a managed storage account, it's using ingestion storage. Refer to the domains with '<ingestion_storage_account>' in below table. You can find the storage information from Azure portal -> **Properties** -> **Ingestion storage ID**. To check the endpoint details, go to **Overview** -> **JSON View** -> "**primaryEndpoint**" property.

Expand table

Domain names	Outbound ports	Description
Public cloud: `*.frontend.clouddatahub.net` Azure Government: `*.frontend.datamovement.azure.us` China: `*.frontend.datamovement.azure.cn`	443	Required to connect to the Microsoft Purview service. Currently wildcard is required as there's no dedicated resource.
Public cloud: `*.servicebus.windows.net` Azure Government: `*.servicebus.usgovcloudapi.net` China: `*.servicebus.chinacloudapi.cn`	443	Required for setting up scan in the classic Microsoft Purview governance portal. This endpoint is used for interactive authoring from UI, for example, test connection, browse folder list and table list to scope scan. To avoid using wildcard, see Get URL of Azure Relay.
Public cloud: `<tenantId>-api.purview-service.microsoft.com` Azure Government: `<tenantId>-api.purview-service.microsoft.us` China: `<tenantId>-api.purview-service.microsoft.cn`	443	Required to connect to Microsoft Purview service. If you use Purview Private Endpoints, this endpoint is covered by *platform private endpoint*.
Public cloud: `<purview_account>.purview.azure.com` Azure Government: `<purview-account>.purview.azure.us` China: `<purview_account>.purview.azure.cn`	443	Required to connect to Microsoft Purview service. If you use Purview Private Endpoints, this endpoint is covered by *account private endpoint*.
Public cloud: `<managed_storage_account>.blob.core.windows.net` or `<ingestion_storage_account>.*.blob.storage.azure.net` Azure Government: `<managed_storage_account>.blob.core.usgovcloudapi.net` or `<ingestion_storage_account>.blob.core.usgovcloudapi.net` China:	443	Required to connect to the Microsoft Purview managed Azure Blob storage account. If you use Purview Private Endpoints, this endpoint is covered by *ingestion private endpoint*.

Domain names	Outbound ports	Description
`<managed_storage_account>.blob.core.chinacloudapi.cn` or `<ingestion_storage_account>.blob.core.chinacloudapi.cn`		
Public cloud: `<managed_storage_account>.queue.core.windows.net` or `<ingestion_storage_account>.*.queue.storage.azure.net` Azure Government: `<managed_storage_account>.queue.core.usgovcloudapi.net` or `<ingestion_storage_account>.queue.core.usgovcloudapi.net` China: `<managed_storage_account>.queue.core.chinacloudapi.cn` or `<ingestion_storage_account>.queue.core.chinacloudapi.cn`	443	Required to connect to the Microsoft Purview managed Azure Queue storage account. If you use Purview Private Endpoints, this endpoint is covered by *ingestion private endpoint*.
`download.microsoft.com`	443	Required to download the self-hosted integration runtime updates. If you have disabled autoupdate, you can skip configuring this domain.
Public cloud: `login.windows.net` and `login.microsoftonline.com` Azure Government: `login.microsoftonline.us` China: `login.partner.microsoftonline.cn`	443	Required to sign in to the Microsoft Entra ID.

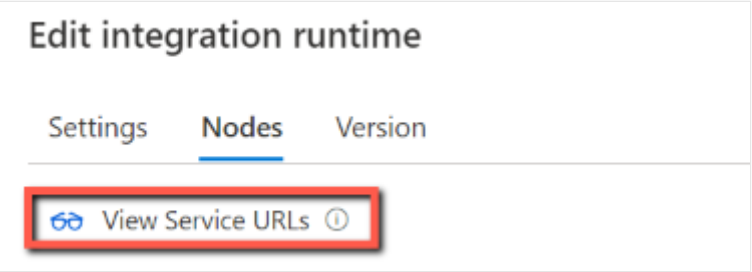
> **Note**
>
> As currently Azure Relay doesn't support service tag, you have to use service tag AzureCloud or Internet in NSG rules for the communication to Azure Relay.

Depending on the sources you want to scan, you also need to allow other domains and outbound ports for other Azure or external sources. A few examples are provided here:

Expand table

Domain names	Outbound ports	Description
`<your_storage_account>.dfs.core.windows.net`	443	When scan Azure Data Lake Store Gen 2.
`<your_storage_account>.blob.core.windows.net`	443	When scan Azure Blob storage.

Domain names	Outbound ports	Description
`<your_sql_server>.database.windows.net`	1433	When scan Azure SQL Database.
`*.powerbi.com` and `*.analysis.windows.net`	443	When scan Power BI tenant.
`<your_ADLS_account>.azuredatalakestore.net`	443	When scan Azure Data Lake Store Gen 1.
Various domains	Dependent	Domains and ports for any other sources the SHIR will scan.



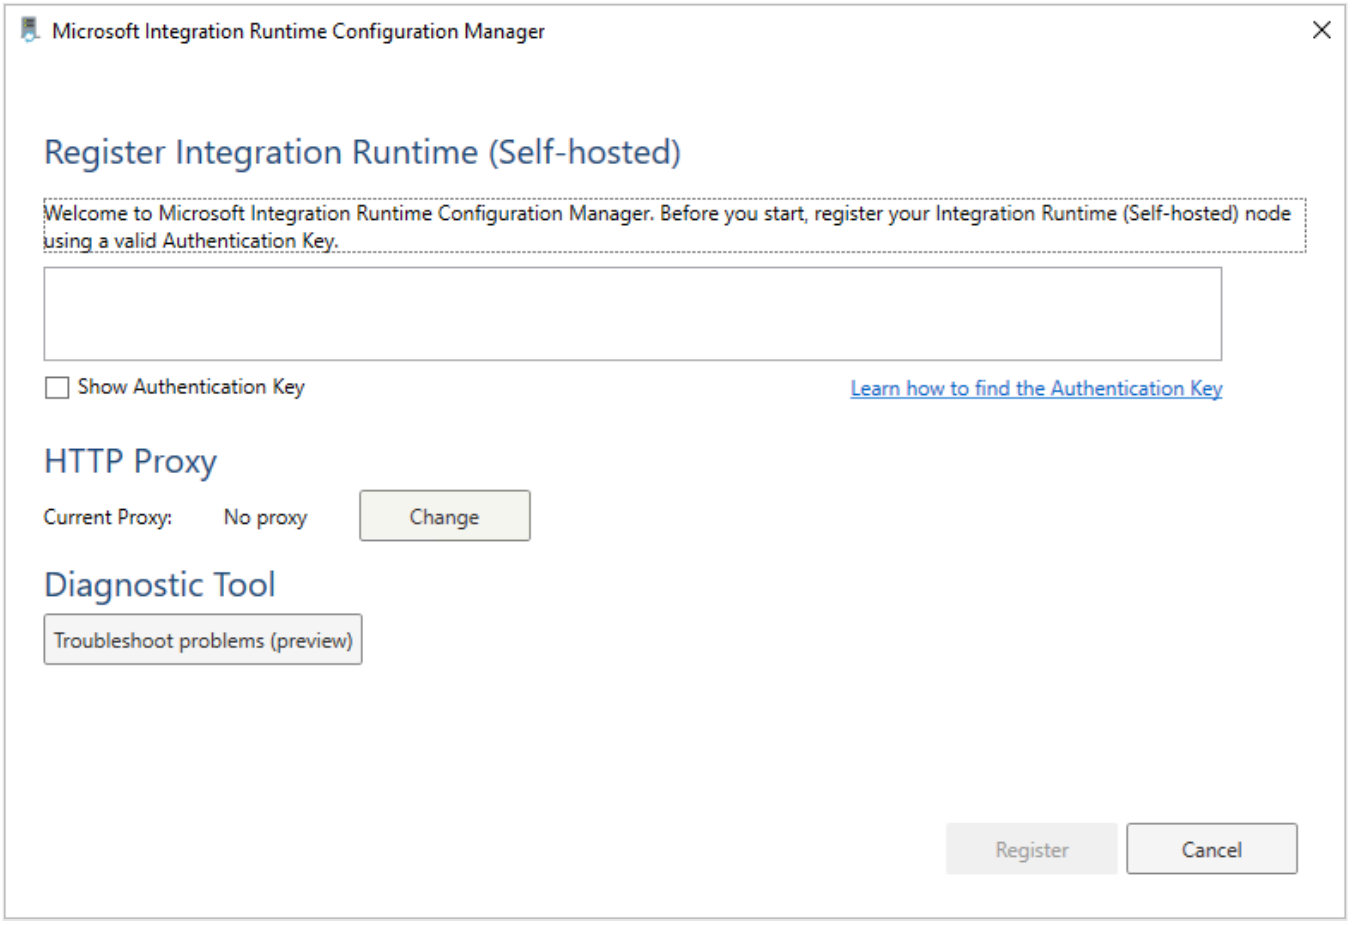
For some cloud data stores such as Azure SQL Database and Azure Storage, you may need to allow IP address of self-hosted integration runtime machine on their firewall configuration, or you can create private endpoint of the service in your self-hosted integration runtime's network.

> **Important**
>
> In most environments, you will also need to make sure that your DNS is correctly configured. To confirm, you can use **nslookup** from your SHIR machine to check connectivity to each of the domains. Each nslookup should return the IP of the resource. If you are using Private Endpoints, the private IP should be returned and not the Public IP. If no IP is returned, or if when using Private Endpoints the public IP is returned, you need to address your DNS/VNet association, or your Private Endpoint/VNet peering.

Get URL of Azure Relay

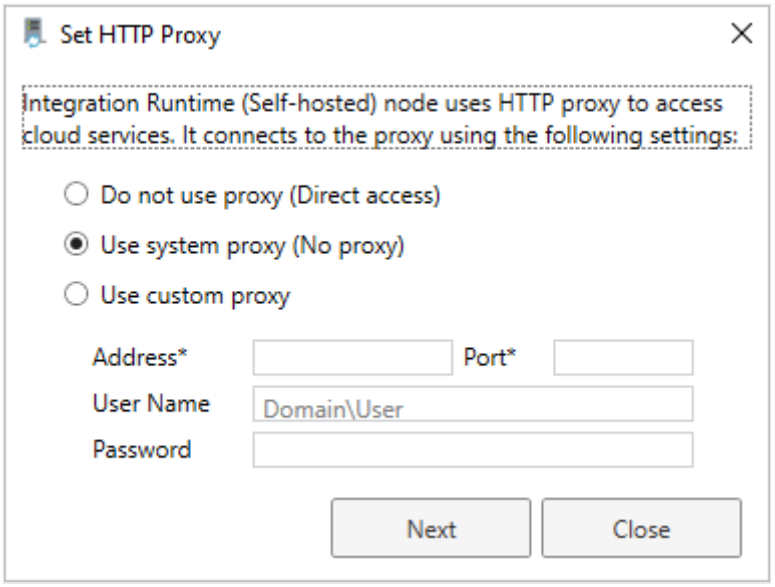
One required domain and port that need to be put in the allowlist of your firewall is for the communication to Azure Relay. The self-hosted integration runtime uses it for interactive authoring such as test connection and browse folder/table list. If you don't want to allow **.servicebus.windows.net** and would like to have more specific URLs, then you can see all the FQDNs that are required by your self-hosted integration runtime. Follow these steps:

1. Go to the classic Microsoft Purview governance portal -> Data Map -> Integration runtimes, and edit your self-hosted integration runtime.
2. In Edit page, select **Nodes** tab.
3. Select **View Service URLs** to get all FQDNs.



4. You can add these FQDNs in the allowlist of firewall rules.

> ⓘ **Note**
>
> For the details related to Azure Relay connections protocol, see Azure Relay Hybrid Connections protocol.



Proxy server considerations

If your corporate network environment uses a proxy server to access the internet, configure the self-hosted integration runtime to use appropriate proxy settings. You can set the proxy during the initial registration phase or after it's being registered.

When configured, the self-hosted integration runtime uses the proxy server to connect to the services that use HTTP or HTTPS protocol. This is why you select **Change link** during initial

setup.

There are two supported configuration options by Microsoft Purview:

- **Do not use proxy**: The self-hosted integration runtime doesn't explicitly use any proxy to connect to cloud services.
- **Use system proxy**: The self-hosted integration runtime uses the proxy setting that is configured in the executable's configuration files. If no proxy is specified in these files, the self-hosted integration runtime connects to the services directly without going through a proxy.
- **Use custom proxy**: Configure the HTTP proxy setting to use for the self-hosted integration runtime, instead of using configurations in diahost.exe.config and diawp.exe.config. **Address** and **Port** values are required. **User Name** and **Password** values are optional, depending on your proxy's authentication setting. All settings are encrypted with Windows DPAPI on the self-hosted integration runtime and stored locally on the machine.

> ⓘ **Note**
>
> Connecting to data sources via proxy isn't supported for connectors other than Azure data sources and Power BI.

The integration runtime host service restarts automatically after you save the updated proxy settings.

After you register the self-hosted integration runtime, if you want to view or update proxy settings, use Microsoft Integration Runtime Configuration Manager.

1. Open **Microsoft Integration Runtime Configuration Manager**.
2. Select the **Settings** tab.

3. Under **HTTP Proxy**, select the **Change** link to open the **Set HTTP Proxy** dialog box.
4. Select **Next**. You then see a warning that asks for your permission to save the proxy setting and restart the integration runtime host service.

> **Note**
>
> If you set up a proxy server with NTLM authentication, the integration runtime host service runs under the domain account. If you later change the password for the domain account, remember to update the configuration settings for the service and restart the service. Because of this requirement, we suggest that you access the proxy server by using a dedicated domain account that doesn't require you to update the password frequently.

If using system proxy, make sure your proxy server allow outbound traffic to the network rules.

Configure proxy server settings

If you select the **Use system proxy** option for the HTTP proxy, the self-hosted integration runtime uses the proxy settings in the following four files under the path C:\Program Files\Microsoft Integration Runtime\5.0\ to perform different operations:

- .\Shared\diahost.exe.config
- .\Shared\diawp.exe.config
- .\Gateway\DataScan\Microsoft.DataMap.Agent.exe.config
- .\Gateway\DataScan\DataTransfer\Microsoft.DataMap.Agent.Connectors.Azure.DataFactory.ServiceHost.exe.config

When no proxy is specified in these files, the self-hosted integration runtime connects to the services directly without going through a proxy.

The following procedure provides instructions for updating the **diahost.exe.config** file.

1. In File Explorer, make a safe copy of C:\Program Files\Microsoft Integration Runtime\5.0\Shared\diahost.exe.config as a backup of the original file.

2. Open Notepad running as administrator.

3. In Notepad, open the text file C:\Program Files\Microsoft Integration Runtime\5.0\Shared\diahost.exe.config.

4. Find the default **system.net** tag as shown in the following code:

```
XML
```

```
<system.net>
    <defaultProxy useDefaultCredentials="true" />
</system.net>
```

You can then add proxy server details as shown in the following example:

XML

```
<system.net>
  <defaultProxy>
    <proxy bypassonlocal="true" proxyaddress="<your proxy server e.g.
http://proxy.domain.org:8888/>" />
  </defaultProxy>
</system.net>
```

The proxy tag allows other properties to specify required settings like `scriptLocation`. See <proxy> Element (Network Settings) for syntax.

XML

```
<proxy autoDetect="true|false|unspecified"
bypassonlocal="true|false|unspecified" proxyaddress="uriString"
scriptLocation="uriString" usesystemdefault="true|false|unspecified "/>
```

5. Save the configuration file in its original location.

Repeat the same procedure to update **diawp.exe.config** and **Microsoft.DataMap.Agent.exe.config** files.

Then go to path C:\Program Files\Microsoft Integration Runtime\5.0\Gateway\DataScan\DataTransfer, create a file named "**Microsoft.DataMap.Agent.Connectors.Azure.DataFactory.ServiceHost.exe.config**", and configure the proxy setting as follows. You can also extend the settings as described above.

XML

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <system.net>
    <defaultProxy>
      <proxy bypassonlocal="true" proxyaddress="<your proxy server e.g.
http://proxy.domain.org:8888/>" />
    </defaultProxy>
  </system.net>
</configuration>
```

Local traffic must be excluded from proxy, for example if your Microsoft Purview account is behind private endpoints. In such cases, update the following four files under the path to include bypass list C:\Program Files\Microsoft Integration Runtime\5.0\ with required bypass list:

- .\Shared\diahost.exe.config
- .\Shared\diawp.exe.config
- .\Gateway\DataScan\Microsoft.DataMap.Agent.exe.config
- .\Gateway\DataScan\DataTransfer\Microsoft.DataMap.Agent.Connectors.Azure.DataFactory.ServiceHost.exe.config

An example for bypass list for scanning an Azure SQL Database and ADLS gen 2 Storage:

XML

```
 <system.net>
   <defaultProxy>
     <bypasslist>
       <add address="scaneastus4123.blob.core.windows.net" />
       <add address="scaneastus4123.queue.core.windows.net" />
       <add address="Atlas-abc12345-1234-abcd-a73c-
394243a566fa.servicebus.windows.net" />
       <add address="contosopurview123.purview.azure.com" />
       <add address="contososqlsrv123.database.windows.net" />
       <add address="contosoadls123.dfs.core.windows.net" />
       <add address="contosoakv123.vault.azure.net" />
     </bypasslist>
     <proxy proxyaddress=http://proxy.domain.org:8888 bypassonlocal="True" />
   </defaultProxy>
 </system.net>
```

Restart the self-hosted integration runtime host service, which picks up the changes. To restart the service, use the services applet from Control Panel. Or from Integration Runtime Configuration Manager, select the **Stop Service** button, and then select **Start Service**. If the service doesn't start, you likely added incorrect XML tag syntax in the application configuration file that you edited.

> **Important**
>
> Don't forget to update all four files mentioned above.

You also need to make sure that Microsoft Azure is in your company's allowlist. You can download the list of valid Azure IP addresses. IP ranges for each cloud, broken down by region and by the tagged services in that cloud are now available on MS Download:

- Public: https://www.microsoft.com/download/details.aspx?id=56519

Possible symptoms for issues related to the firewall and proxy server

If you see error messages like the following ones, the likely reason is improper configuration of the firewall or proxy server. Such configuration prevents the self-hosted integration runtime from connecting to Microsoft Purview services. To ensure that your firewall and proxy server are properly configured, refer to the previous section.

- When you try to register the self-hosted integration runtime, you receive the following error message: "Failed to register this Integration Runtime node! Confirm that the Authentication key is valid and the integration service host service is running on this machine."

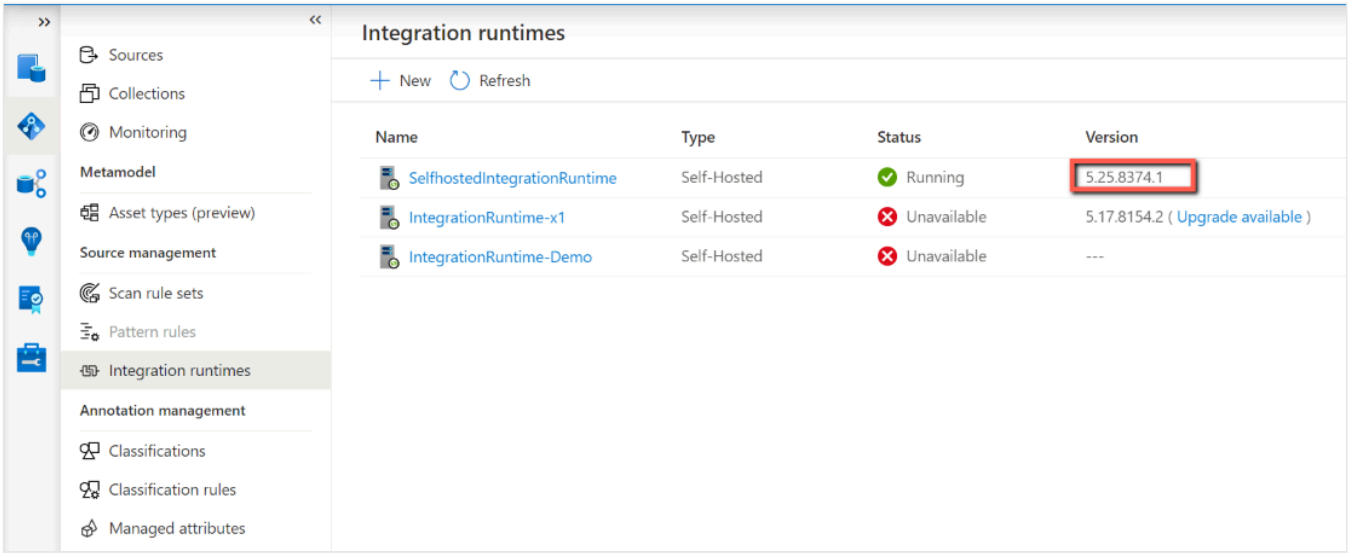
- When you open Integration Runtime Configuration Manager, you see a status of **Disconnected** or **Connecting**. When you view Windows event logs, under **Event Viewer** > **Application and Services Logs** > **Microsoft Integration Runtime**, you see error messages like this one:

  Output

  ```
  Unable to connect to the remote server
  A component of Integration Runtime has become unresponsive and restarts
  automatically. Component name: Integration Runtime (Self-hosted)
  ```

Java Runtime Environment Installation

If you scan Parquet files using the self-hosted integration runtime with Microsoft Purview, you'll need to install either the Java Runtime Environment or OpenJDK on your self-hosted IR machine.



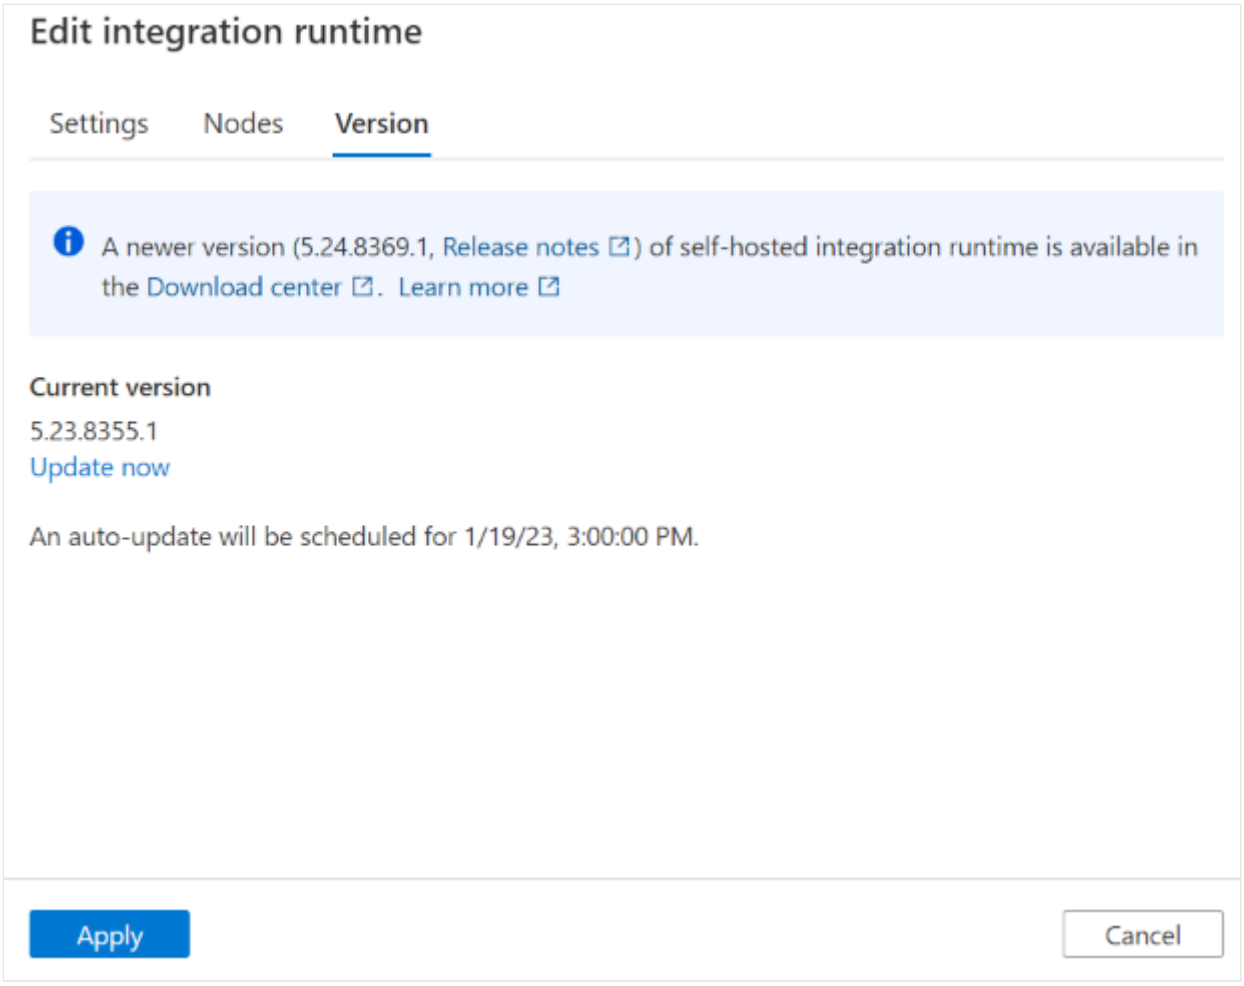
When scanning Parquet files using the self-hosted IR, the service locates the Java runtime by firstly checking the registry `(HKEY_LOCAL_MACHINE\SOFTWARE\JavaSoft\Java Runtime Environment\{Current Version}\JavaHome)` for JRE, if not found, secondly checking system variable `JAVA_HOME` for OpenJDK. You can set JAVA_HOME under System Settings, Environment Variables on your machine. Create or edit the JAVA_HOME variable to point to the Java jre on your machine. For example: `C:\Program Files\Java\jdk1.8\jre`

- **To use JRE**: The 64-bit IR requires 64-bit JRE. You can find it from here.
- **To use OpenJDK**: It's supported since IR version 3.13. Package the jvm.dll with all other required assemblies of OpenJDK into self-hosted IR machine, and set system environment

variable JAVA_HOME accordingly.

How to check your self-hosted integration runtime version

You can check the version of your self-hosted integration runtime in the classic Microsoft Purview governance portal -> Data Map -> Integration runtimes:



You can also check the version in your self-hosted integration runtime client -> Help tab.

Self-hosted Integration Runtime autoupdate

Auto update is enabled by default when you install a self-hosted integration runtime. You have two options to manage the version of self-hosted integration runtime: autoupdate or maintain manually. Typically, Microsoft Purview releases two new versions of self-hosted integration runtime every month, which includes new feature release, bug fix or enhancement. So we recommend users to update to newer version in order to get the latest feature and enhancement.

The self-hosted integration runtime is automatically updated to newer version. When new version is available while not yet scheduled for your instance, you can also trigger the update from the portal.

> **Note**
>
> If you have multiple self-hosted integration runtime nodes, there's no downtime during autoupdate. The autoupdate happens in one node first while others are working on tasks. When the first node finishes the update, it takes over the remaining tasks when other nodes are updating. If you only have one self-hosted integration runtime node, then it has some downtime during the autoupdate.

Autoupdate version vs latest version

To ensure the stability of self-hosted integration runtime, although we release two versions, we only push one version every month. So sometimes you find that the autoupdate version is the previous version of the actual latest version. If you want to get the latest version, you can go to download center and do so manually. Additionally, **auto-update** to a new version is managed by the service, and you can't change it.

The self-hosted integration runtime **Version** tab in the classic Microsoft Purview governance portal shows the newer version if current version is old. When your self-hosted integration runtime is online, this version is the autoupdate version and automatically updates your self-

hosted integration runtime in the scheduled time. But if your self-hosted integration runtime is offline, the page only shows the newer version.

If you have multiple nodes, and for some reasons that some of them aren't autoupdated successfully. Then these nodes roll back to the version, which was the same across all nodes before autoupdate.

Self-hosted Integration Runtime expiration

Each version of self-hosted integration runtime expires in one year. The expiring message is shown in the classic Microsoft Purview governance portal and the self-hosted integration runtime client **90 days** before expiration.

Next steps

- Microsoft Purview network architecture and best practices
- Use private endpoints with Microsoft Purview

Troubleshoot Microsoft Purview self-hosted integration runtime (SHIR)

Article • 09/26/2023

This article explores common troubleshooting methods for self-hosted integration runtime (SHIR) in Microsoft Purview.

The self-hosted integration runtime (SHIR) is also used by Azure Data Factory and Azure Synapse Analytics. Though many of the troubleshooting steps overlap, follow this guide to troubleshoot your SHIR for those products:

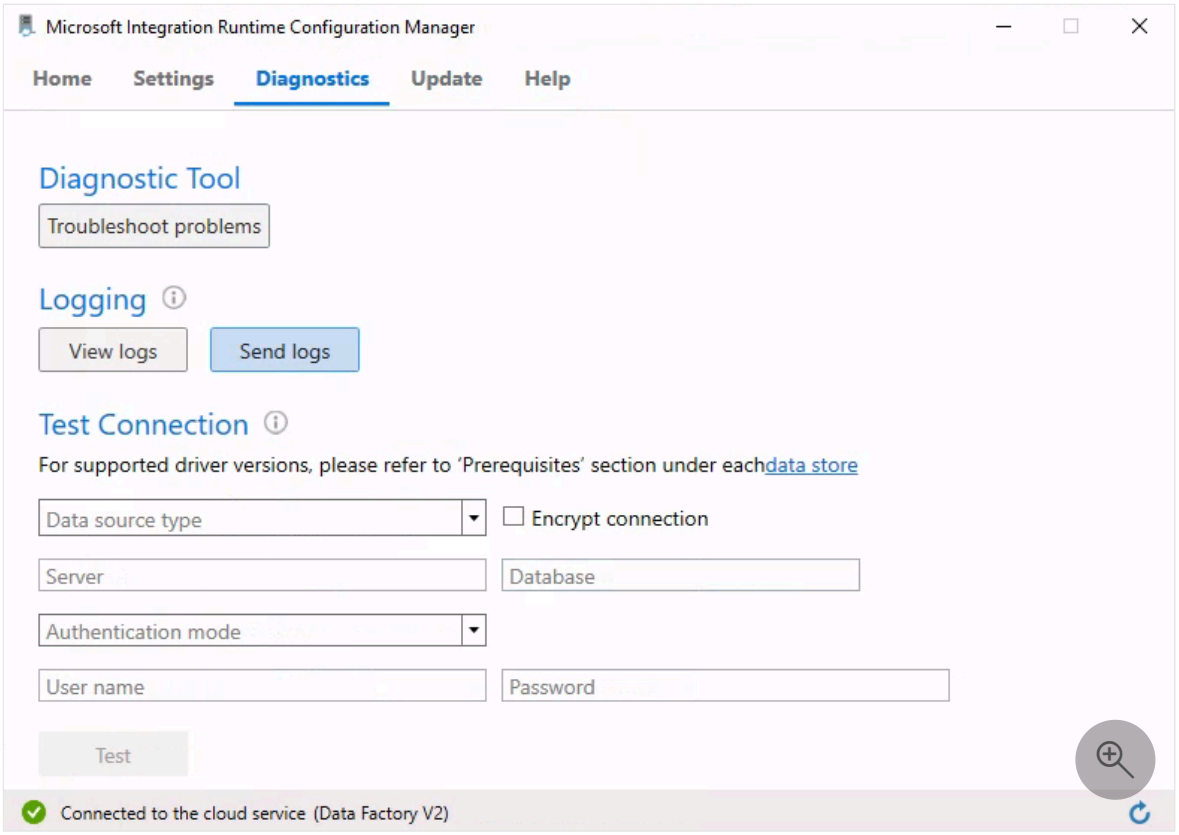
- Troubleshoot SHIR for Azure Data Factory and Azure Synapse Analytics

Gather Microsoft Purview specific SHIR self-hosted integration runtime logs

For failed Microsoft Purview scans that are running on a self-hosted IR, the service supports viewing and uploading error logs from the Windows Event Viewer.

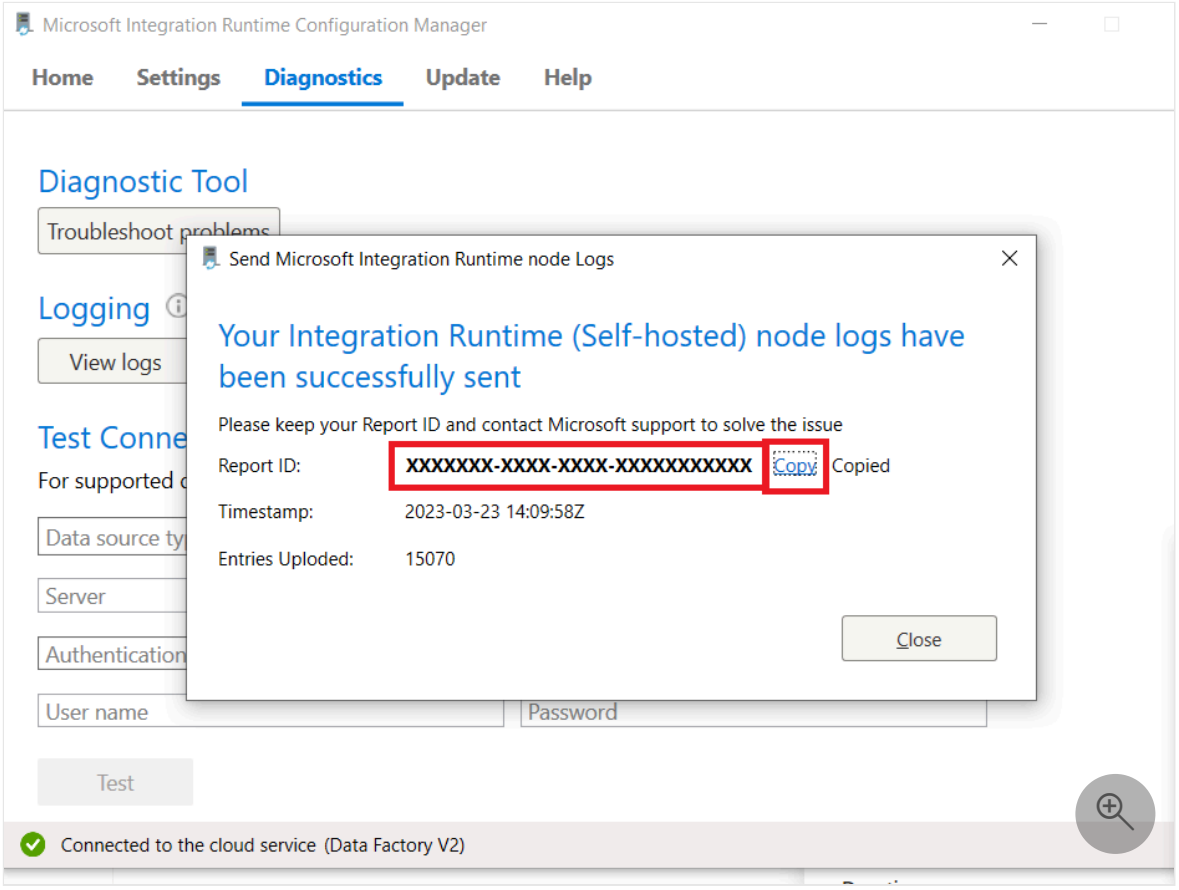
You can look up any errors you see in the error guide below. To get support and troubleshooting guidance for SHIR issues, you may need to generate an error report ID and reach out to Microsoft support.

To generate the error report ID for Microsoft Support, follow these instructions:



1. Before starting a scan in the Microsoft Purview governance portal:
   a. Navigate to the machine where the self-hosted integration runtime is installed and open the Windows Event Viewer.
   b. Clear the windows event viewer logs in the **Integration Runtime** section. Right-click on the logs and select the clear logs option.
   c. Navigate back to the Microsoft Purview governance portal and start the scan.

2. Once the scan shows status **Failed**, navigate back to the SHIR VM, or machine and refresh the event viewer in the **Integration Runtime** section.



3. The activity logs are displayed for the failed scan run.

4. For further assistance from Microsoft, select **Send Logs**.

   The **Share the self-hosted integration runtime (SHIR) logs with Microsoft** window opens.

5. When the logs are uploaded, keep a record of the Report ID to use if you reach out to Microsoft support.

Self-hosted integration runtime SHIR general failure or error

There are lots of common errors, warnings, and issues between the Purview SHIR, Azure Data Factory, or Azure Synapse SHIR. The guide below covers many of the most common issues.

Self-hosted IR general failure or error

Out of memory issue

Symptoms

An OutOfMemoryException (OOM) error occurs when you try to run a scan with a self-hosted IR.

Cause

A new scan can throw an OOM error if the IR machine experiences momentary high memory usage. The issue might be caused by a large volume of concurrent activity or a low amount of memory and the error is by design.

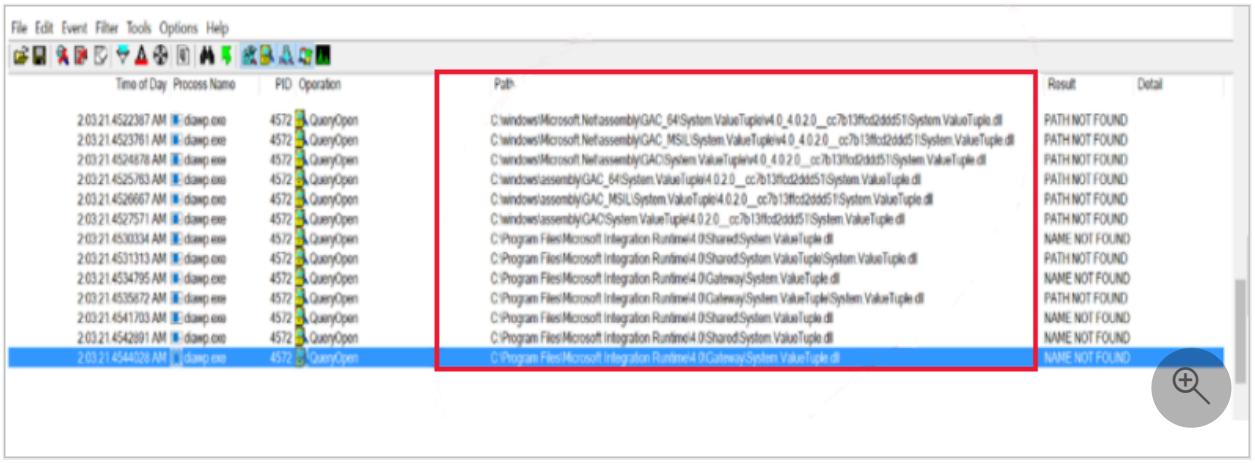
Resolution

Check the resource usage to confirm if any other software is running at the same time, and confirm that your SHIR machine meets the recommended configurations.

Self-hosted IR could not load file or assembly

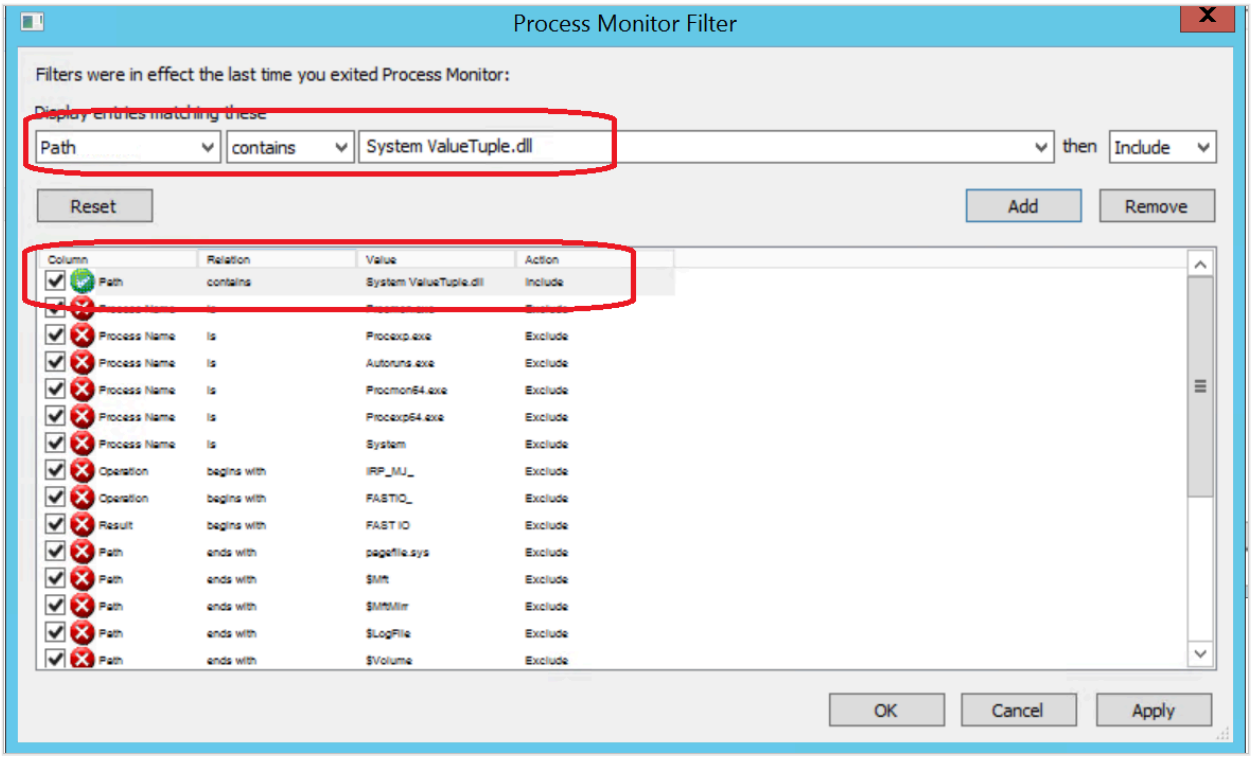
Symptoms

You get the following error message:



"Could not load file or assembly 'XXXXXXXXXXXXXXXX, Version=4.0.2.0, Culture=neutral, PublicKeyToken=XXXXXXXXX' or one of its dependencies. The system cannot find the file specified. Activity ID: 92693b45-b4bf-4fc8-89da-2d3dc56f27c3"

Here is a more specific error message:



"Could not load file or assembly 'System.ValueTuple, Version=4.0.2.0, Culture=neutral, PublicKeyToken=XXXXXXXXX' or one of its dependencies. The system cannot find the file specified. Activity ID: 92693b45-b4bf-4fc8-89da-2d3dc56f27c3"

Cause

In Process Monitor, you can view the following result:

> **Tip**
>
> In Process Monitor, you can set filters as shown in following screenshot. The preceding error message says that the DLL System.ValueTuple is not located in the related *Global Assembly Cache* (GAC) folder, in the *C:\Program Files\Microsoft Integration Runtime\4.0\Gateway* folder, or in the *C:\Program Files\Microsoft Integration Runtime\4.0\Shared* folder. Basically, the process loads the DLL first from the *GAC* folder, then from the *Shared* folder, and finally from the *Gateway* folder. Therefore, you can load the DLL from any path that's helpful.

Resolution

You'll find the *System.ValueTuple.dll* file in the *C:\Program Files\Microsoft Integration Runtime\4.0\Gateway\DataScan* folder. To resolve the issue, copy the *System.ValueTuple.dll* file to the *C:\Program Files\Microsoft Integration Runtime\4.0\Gateway* folder.

You can use the same method to resolve other missing file or assembly issues.

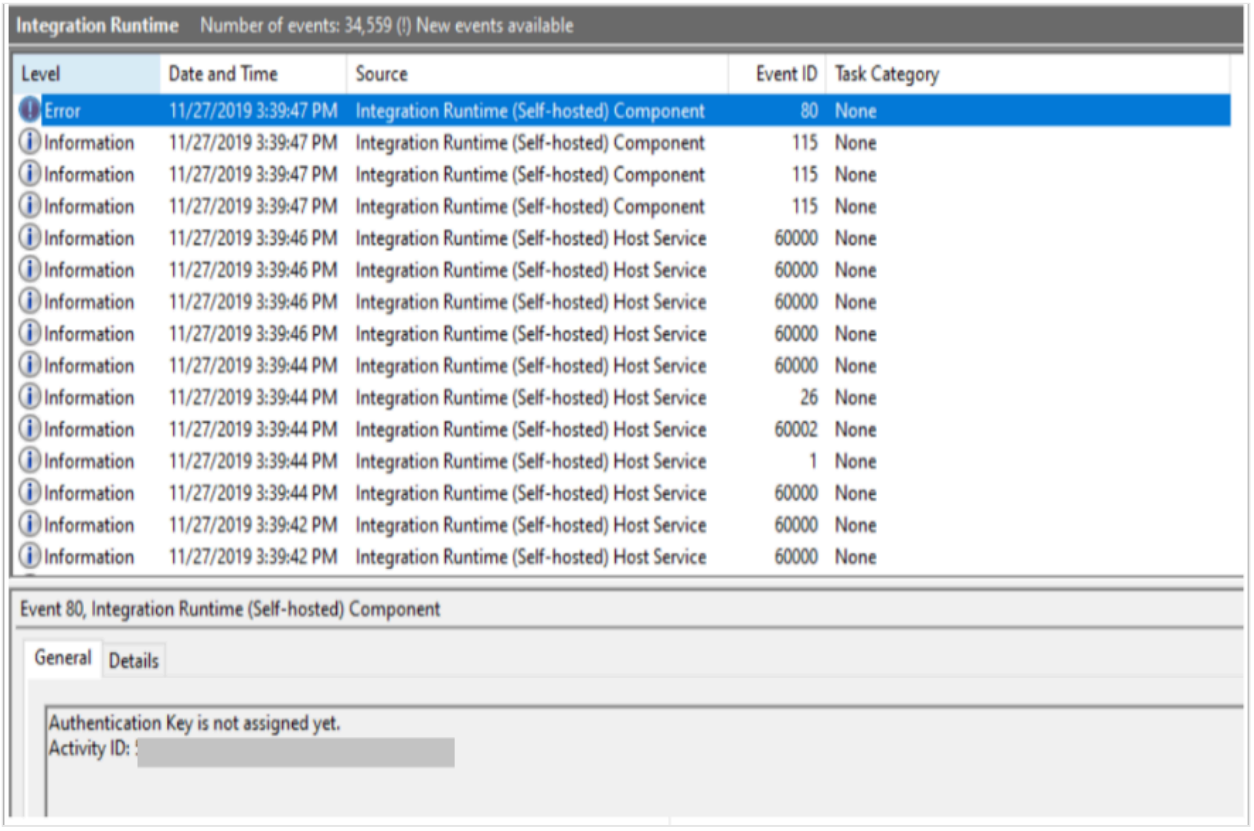
More information

The reason why you see the *System.ValueTuple.dll* under *%windir%\Microsoft.NET\assembly* and *%windir%\assembly* is that this is a .NET behavior.

In the following error, you can clearly see that the *System.ValueTuple* assembly is missing. This issue arises when the application tries to check the *System.ValueTuple.dll* assembly.

> "<LogProperties><ErrorInfo>[{"Code":0,"Message":"The type initializer for 'Npgsql.PoolManager' threw an exception.","EventType":0,"Category":5,"Data":{},"MsgId":null,"ExceptionType":"System.TypeInitializationException","Source":"Npgsql","StackTrace":"","InnerEventInfos":[{"Code":0,"Message":"Could not load file or assembly 'System.ValueTuple, Version=4.0.2.0, Culture=neutral, PublicKeyToken=XXXXXXXXX' or one of its dependencies. The system cannot find

> the file specified.","EventType":0,"Category":5,"Data":{},"MsgId":null,"ExceptionType":"System.IO.FileNotFoundException","Source":"Npgsql","StackTrace":"","InnerEventInfos":[]}]}]</ErrorInfo></LogProperties>"



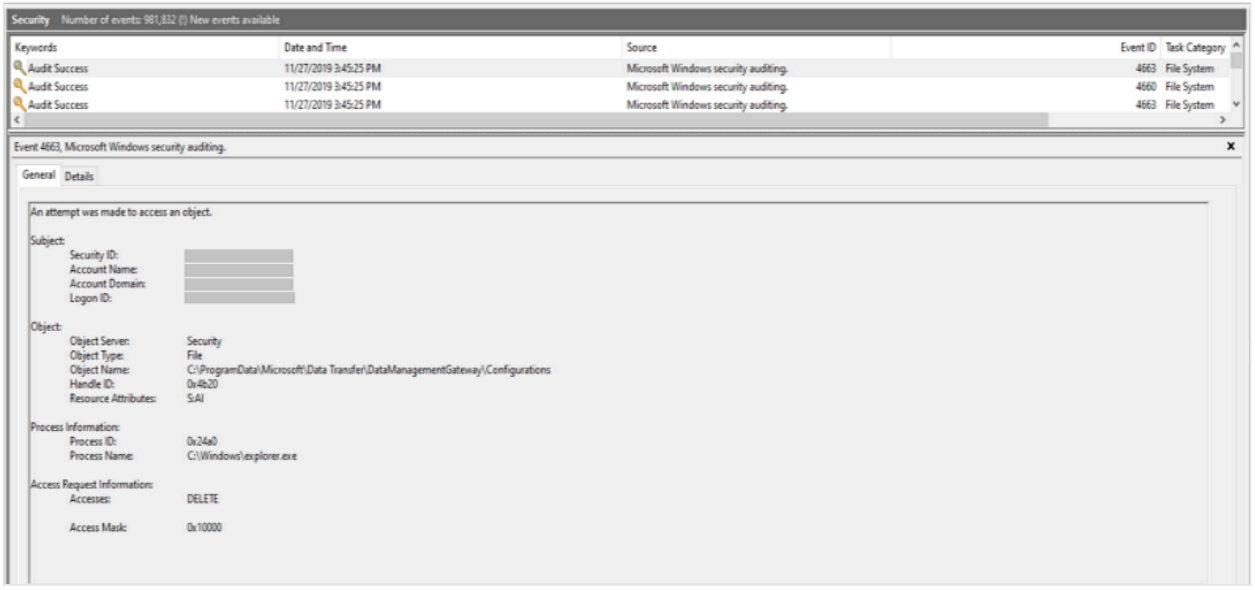
For more information about GAC, see Global Assembly Cache.

Self-hosted integration runtime Authentication Key is missing

Symptoms

The self-hosted integration runtime suddenly goes offline without an Authentication Key, and the Event Log displays the following error message:

"Authentication Key is not assigned yet"

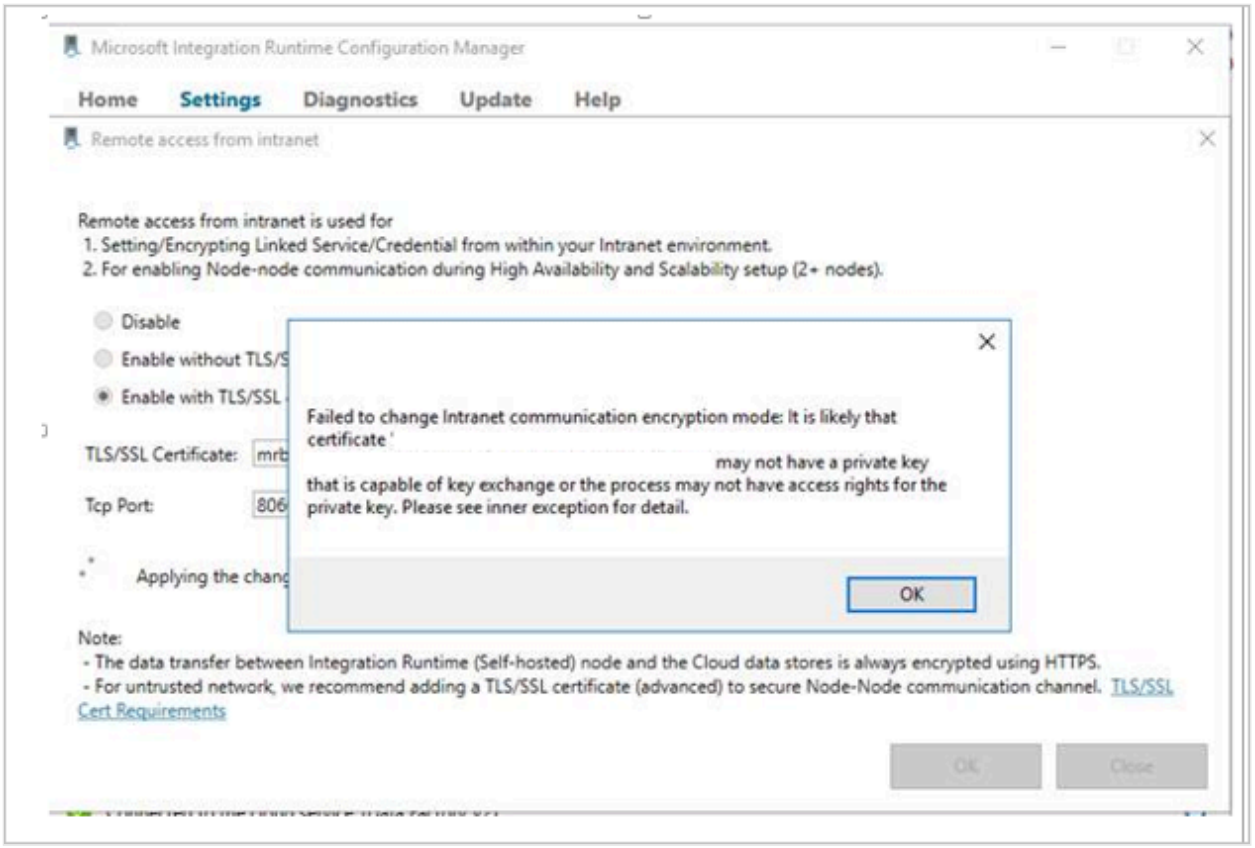


Cause

The self-hosted IR node or logical self-hosted IR in the Microsoft Purview portal was deleted, or a clean uninstall was performed.

Resolution

If neither of the preceding causes applies, you can go to the *%programdata%\Microsoft\Data Transfer\DataManagementGateway* folder to see whether the *Configurations* file has been deleted. If it was deleted, follow the instructions in the Netwrix article Detect who deleted a file from your Windows file servers.



Can't choose the certificate because the private key is missing

Symptoms

- You've imported a PFX file to the certificate store.
- When you selected the certificate through the IR Configuration Manager UI, you received the following error message:

"Failed to change intranet communication encryption mode. It is likely that certificate '<*certificate name*>' might not have a private key that is capable of key exchange or the process might not have access rights for the private key. Please see inner exception for detail."

Cause

- The user account has a low privilege level and can't access the private key.
- The certificate was generated as a signature but not as a key exchange.

Resolution

- To operate the UI, use an account with appropriate privileges for accessing the private key.
- Import the certificate by running the following command:

```
certutil -importpfx FILENAME.pfx AT_KEYEXCHANGE
```

UserErrorJreNotFound error message when you run a scan

Symptoms

When you try to scan a data source using a Java-based tool or program (for example, Parquet format files), you receive an error message that resembles the following:

> ErrorCode=UserErrorJreNotFound,'Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,Message=Java Runtime Environment is not found. Go to `http://go.microsoft.com/fwlink/?LinkId=808605` to download and install on your Integration Runtime (Self-hosted) node machine. Note 64-bit Integration Runtime requires 64-bit JRE and 32-bit Integration Runtime requires 32-bit JRE.,Source=Microsoft.DataTransfer.Common,''Type=System.DllNotFoundException,Message=Unable to load DLL 'jvm.dll': The specified module could not be found. (Exception from HRESULT: 0x8007007E),Source=Microsoft.DataTransfer.Richfile.HiveOrcBridge

Cause

This issue occurs for either of the following reasons:

- Java Runtime Environment (JRE) isn't installed correctly on your Integration Runtime server.
- Your Integration Runtime server lacks the required dependency for JRE.

By default, Integration Runtime resolves the JRE path by using registry entries. Those entries should be automatically set during JRE installation.

Resolution

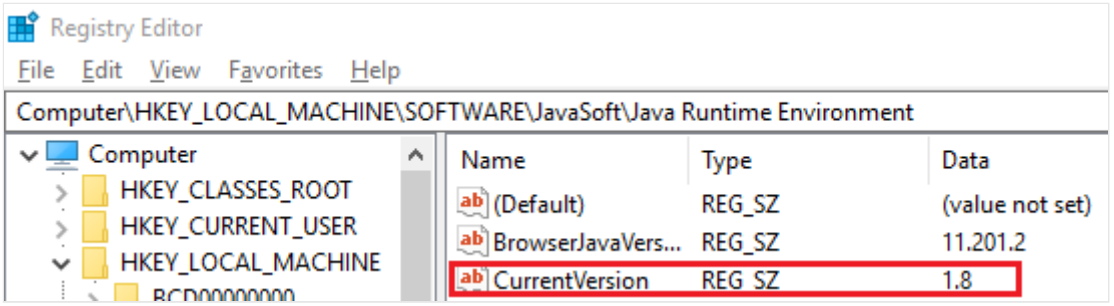
Follow the steps in this section carefully. Serious problems might occur if you modify the registry incorrectly. Before you modify it, back up the registry for restoration in case problems occur.

To fix this issue, follow these steps to verify the status of the JRE installation:

1. Make sure that Integration Runtime (Diahost.exe) and JRE are installed on the same platform. Check the following conditions:
    - 64-bit JRE for 64-bit ADF Integration Runtime should be installed in the folder: `C:\Program Files\Java\`

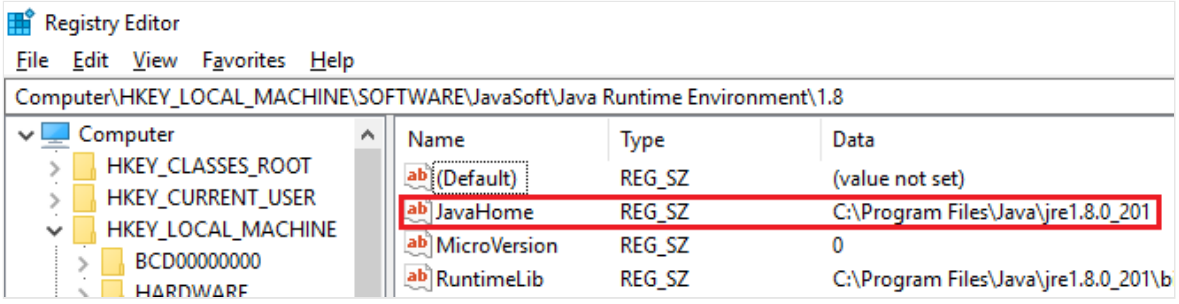
      > **Note**
      >
      > The folder is not `C:\Program Files (x86)\Java\`

    - JRE 11 is compatible for scanning. JRE 8 is also compatible, but versions that are earlier than JRE 8 have not been validated for this use.



2. Check the registry for the appropriate settings. To do this, follow these steps:

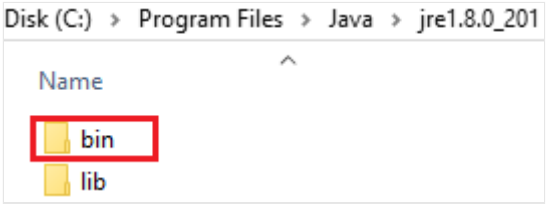
3. In the **Run** menu, type **Regedit**, and then press Enter.



4. In the navigation pane, locate the following subkey:

   `HKEY_LOCAL_MACHINE\SOFTWARE\JavaSoft\Java Runtime Environment`.

   In the **Details** pane, there should be a Current Version entry that shows the JRE version (for example, 1.8).



5. In the navigation pane, locate a subkey that is an exact match for the version (for example 1.8) under the JRE folder. In the details pane, there should be a **JavaHome** entry. The value of this entry is the JRE installation path.

6. Locate the bin\server folder in the following path:

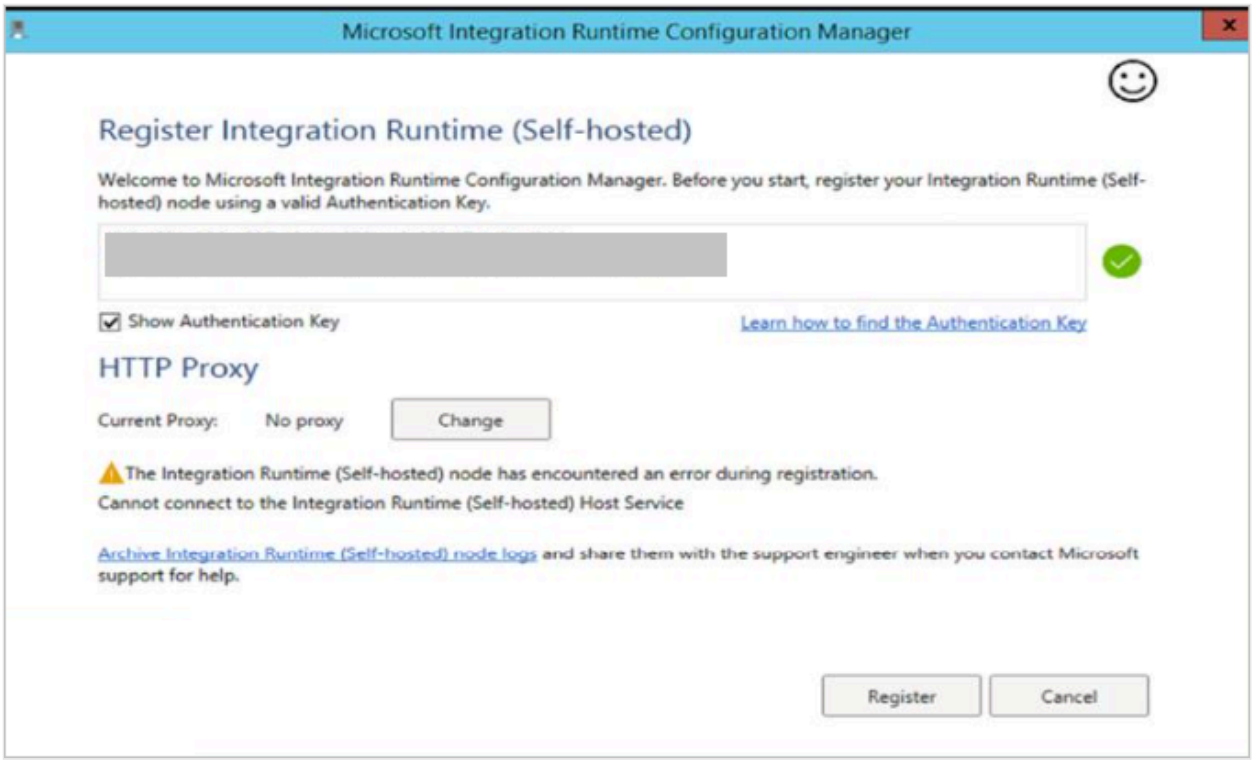
   `C:\Program Files\Java\jre1.xx.xxx`

7. Check whether this folder contains a jvm.dll file. If it does not, check for the file in the `bin\client` folder.

> **Note**
>
> - If any of these configurations are not as described in these steps, use the JRE windows installer to fix the problems.
> - If all the configurations in these steps are correct as described, there might be a VC++ runtime library missing in the system. You can fix this problem by installing the VC++ 2010 Redistributable Package.

Self-hosted IR setup

Integration runtime registration error



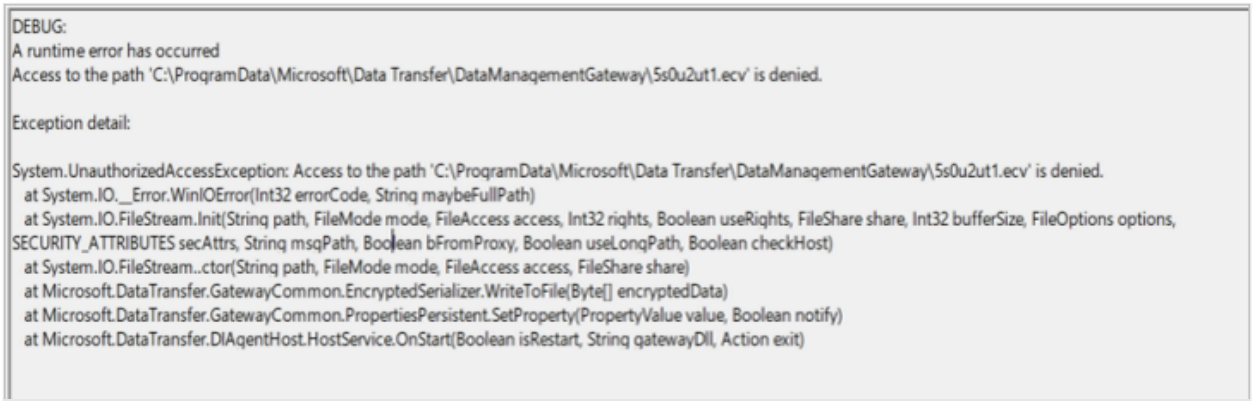
Symptoms

You might occasionally want to run a self-hosted IR in a different account for either of the following reasons:

- Company policy disallows the service account.
- Some authentication is required.

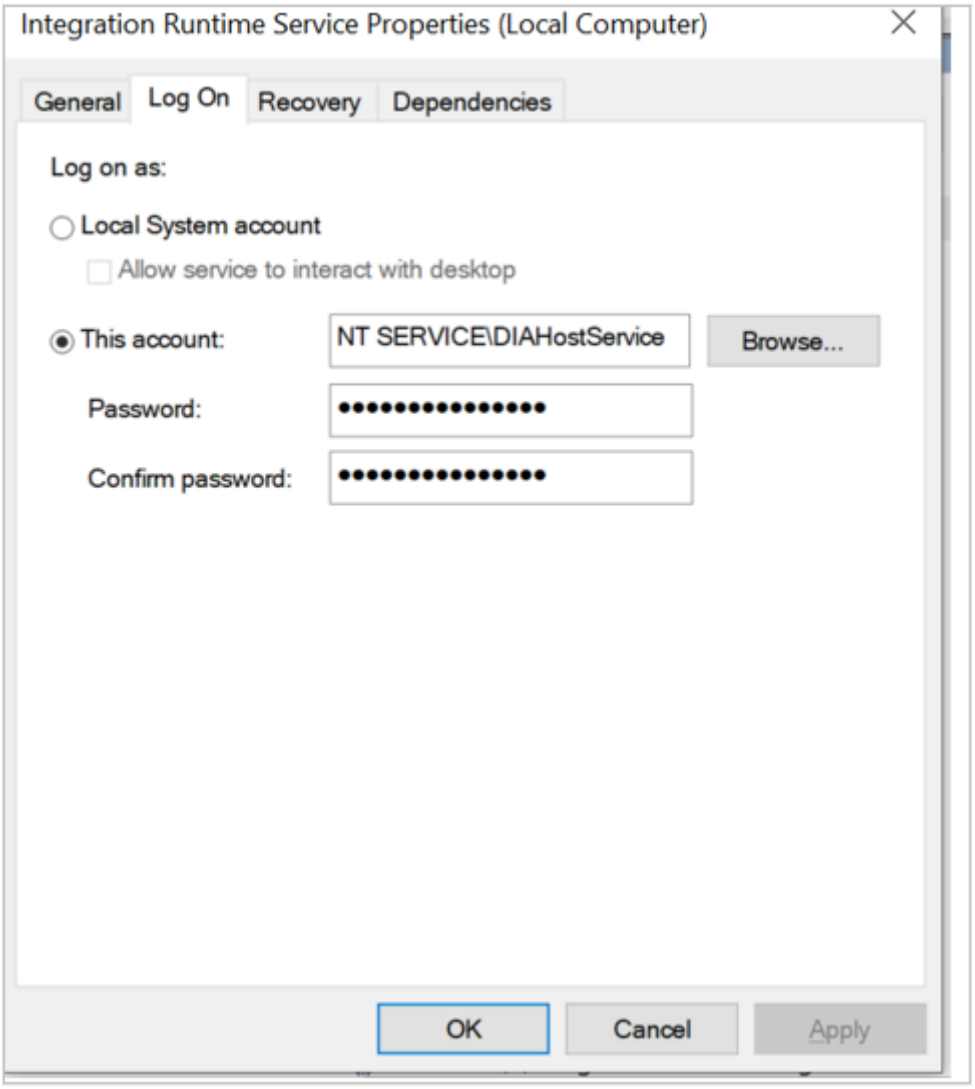
After you change the service account on the service pane, you might find that the integration runtime stops working, and you get the following error message:

"The Integration Runtime (Self-hosted) node has encountered an error during registration. Cannot connect to the Integration Runtime (Self-hosted) Host Service."



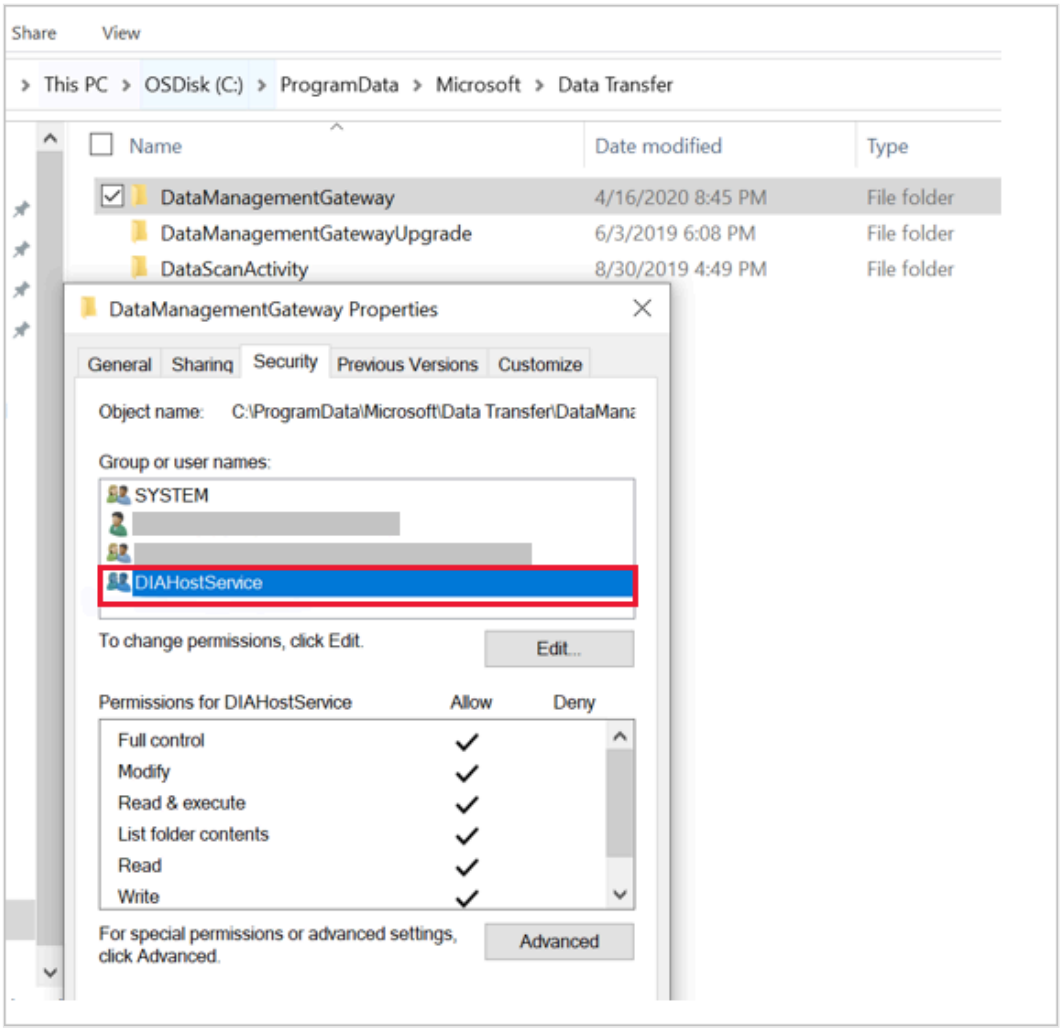
Cause

Many resources are granted only to the service account. When you change the service account to another account, the permissions of all dependent resources remain unchanged.



Resolution

Go to the integration runtime event log to check the error.

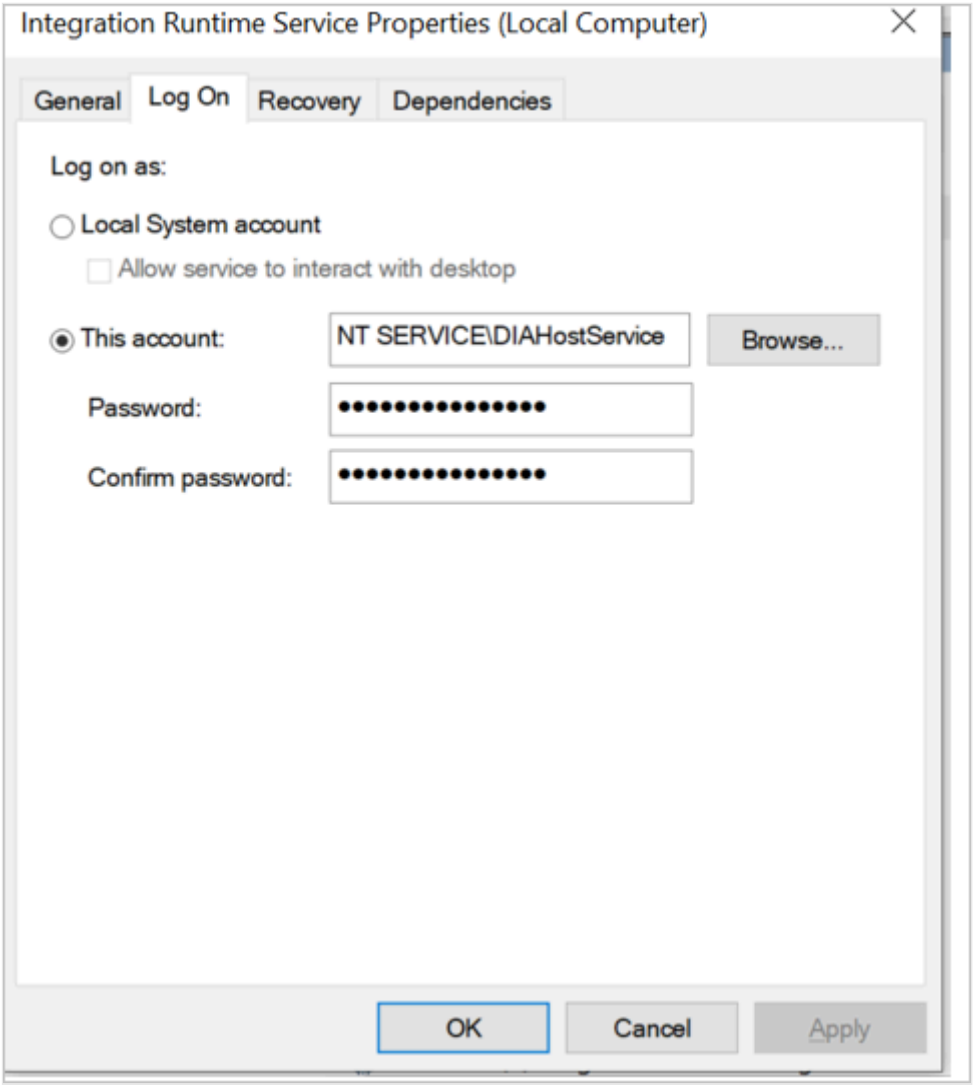


- If the error in the event log is "UnauthorizedAccessException," do the following:

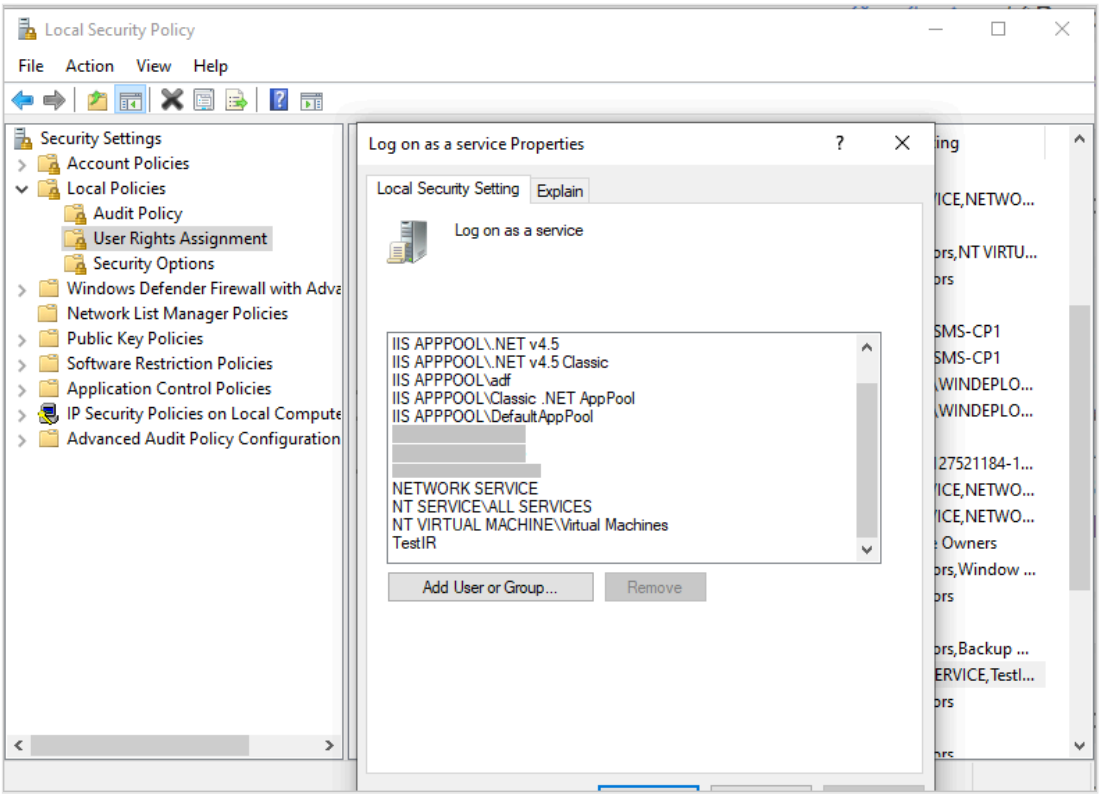
    1. Check the *DIAHostService* sign-in service account in the Windows service panel.

2. Check to see whether the sign-in service account has read/write permissions for the *%programdata%\Microsoft\DataTransfer\DataManagementGateway* folder.

    - By default, if the service sign-in account hasn't been changed, it should have read/write permissions.



- If you've changed the service sign-in account, mitigate the issue by doing the following:
  a. Perform a clean uninstallation of the current self-hosted IR.
  b. Install the self-hosted IR bits.
  c. Change the service account by doing the following:
    i. Go to the self-hosted IR installation folder, and then switch to the *Microsoft Integration Runtime\4.0\Shared* folder.
    ii. Open a Command Prompt window by using elevated privileges. Replace <*user*> and <*password*> with your own username and password, and then run the following command: `dmgcmd.exe -SwitchServiceAccount "<user>" "<password>"`
    iii. If you want to change to the LocalSystem account, be sure to use the correct format for this account: `dmgcmd.exe -SwitchServiceAccount "NT Authority\System" ""`
    iv. Do *not* use this format: `dmgcmd.exe -SwitchServiceAccount "LocalSystem" ""`
    v. Optionally, because Local System has higher privileges than Administrator, you can also directly change it in "Services".
    vi. You can use a local/domain user for the IR service sign-in account.



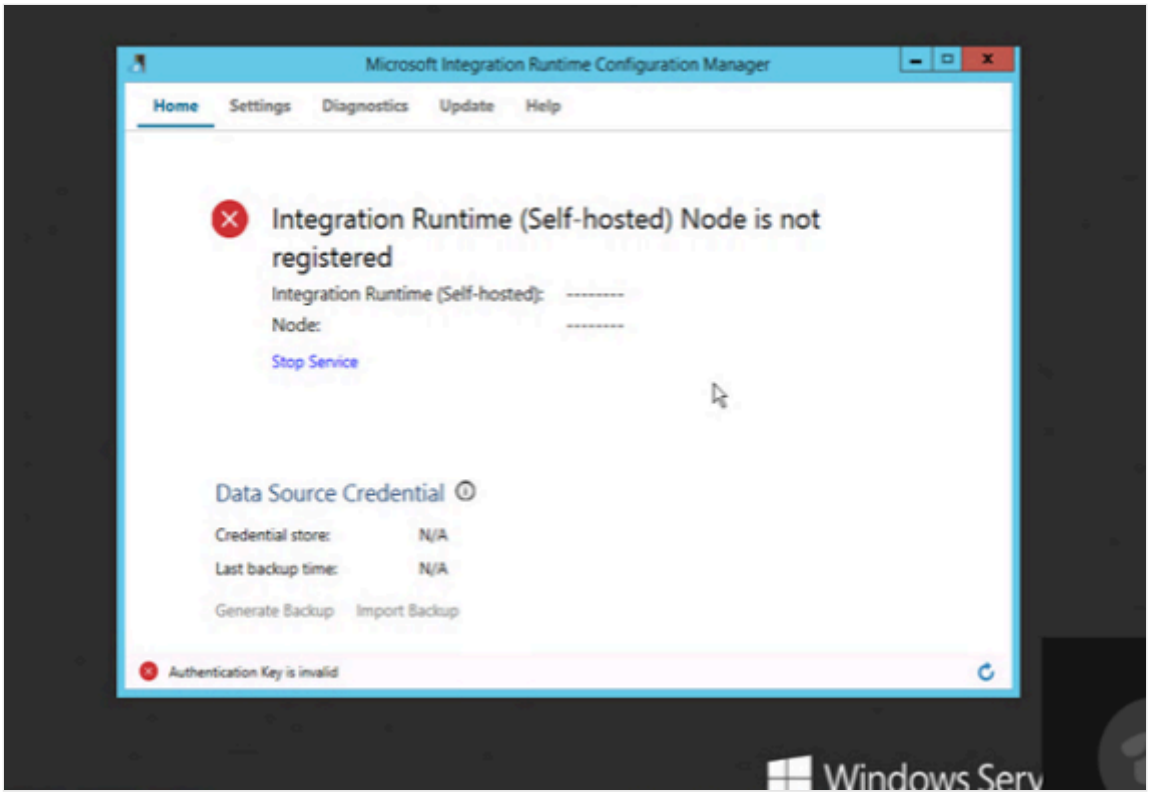
d. Register the integration runtime.

- If the error is "Service 'Integration Runtime Service' (DIAHostService) failed to start. Verify that you have sufficient privileges to start system services," do the following:

    1. Check the *DIAHostService* sign-in service account in the Windows service panel.

    2. Check to see whether the sign-in service account has **Log on as a service** permission to start the Windows service:

More information



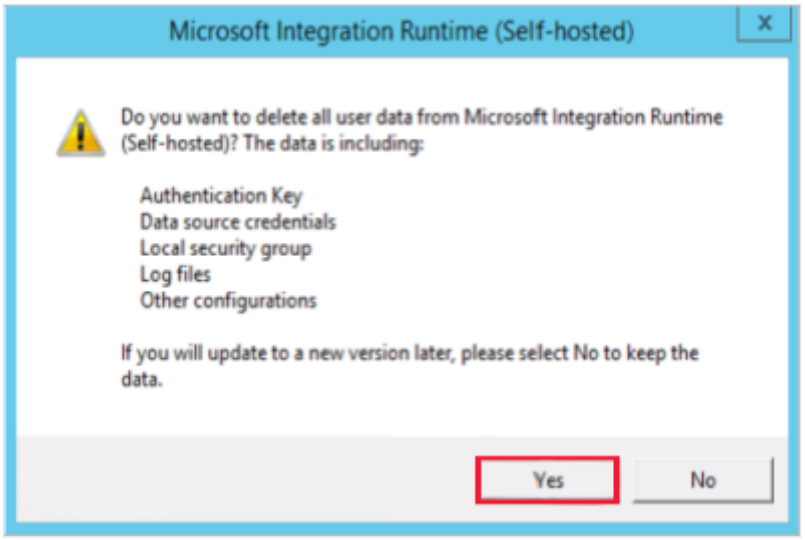
If neither of the preceding two resolution patterns applies in your case, try to collect the following Windows event logs:

- Applications and Services Logs > Integration Runtime
- Windows Logs > Application

Can't find the Register button to register a self-hosted IR

Symptoms

When you register a self-hosted IR, the **Register** button isn't displayed on the Configuration Manager pane.



Cause

As of the release of Integration Runtime 3.0, the **Register** button on existing integration runtime nodes has been removed to enable a cleaner and more secure environment. If a node has been registered to an integration runtime, whether it's online or not, re-register it to another integration runtime by uninstalling the previous node, and then install and register the node.

Resolution

1. In Control Panel, uninstall the existing integration runtime.

   > ⓘ **Important**
   >
   > In the following process, select **Yes**. Do not keep data during the uninstallation process.

2. If you don't have the integration runtime installer MSI file, go to download center to download the latest integration runtime.

3. Install the MSI file, and register the integration runtime.

Unable to register the self-hosted IR because of localhost

Symptoms

You're unable to register the self-hosted IR on a new machine when you use get_LoopbackIpOrName.

Debug: A runtime error has occurred. The type initializer for 'Microsoft.DataTransfer.DIAgentHost.DataSourceCache' threw an exception. A nonrecoverable error occurred during a database lookup.

Exception detail: System.TypeInitializationException: The type initializer for 'Microsoft.DataTransfer.DIAgentHost.DataSourceCache' threw an exception. ---> System.Net.Sockets.SocketException: A nonrecoverable error occurred during a database lookup at System.Net.Dns.GetAddrInfo(String name).

Cause

The issue usually occurs when the localhost is being resolved.

Resolution

Use localhost IP address 127.0.0.1 to host the file and resolve the issue.

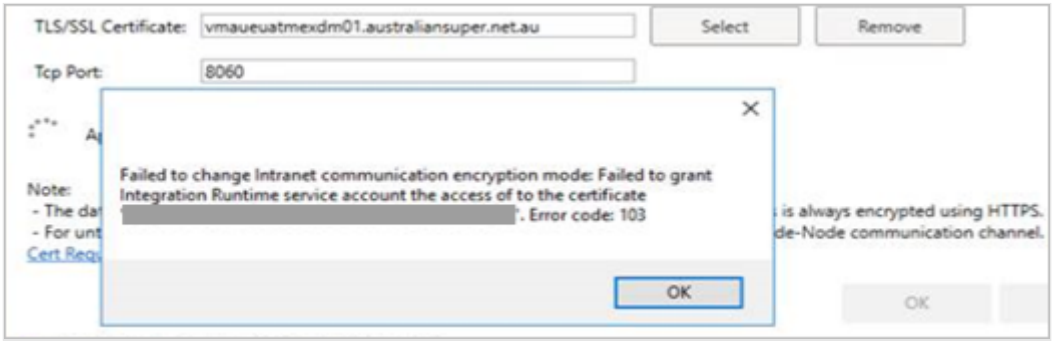
Self-hosted setup failed

Symptoms

You're unable to uninstall an existing IR, install a new IR, or upgrade an existing IR to a new IR.

Cause

The integration runtime installation depends on the Windows Installer service. You might experience installation problems for the following reasons:



- Insufficient available disk space.
- Lack of permissions.
- The Windows NT service is locked.
- CPU utilization is too high.
- The MSI file is hosted in a slow network location.
- Some system files or registries were touched unintentionally.

The IR service account failed to fetch certificate access

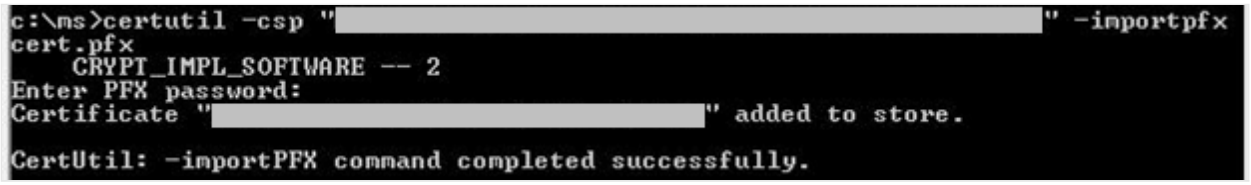
Symptoms

When you install a self-hosted IR via Microsoft Integration Runtime Configuration Manager, a certificate with a trusted certificate authority (CA) is generated. The certificate couldn't be applied to encrypt communication between two nodes, and the following error message is displayed:

"Failed to change Intranet communication encryption mode: Failed to grant Integration Runtime service account the access of to the certificate '<*certificate name*>'. Error code 103"

Cause

The certificate is using key storage provider (KSP) storage, which is not supported yet. To date, self-hosted IR supports only cryptographic service provider (CSP) storage.



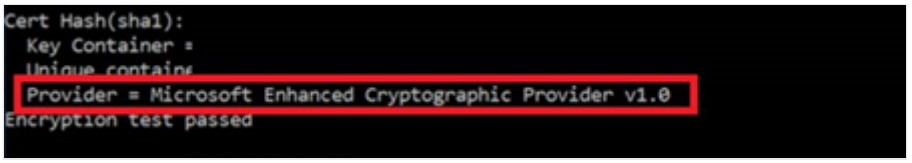
Resolution

We recommend that you use CSP certificates in this case.

Solution 1

To import the certificate, run the following command:

```
Certutil.exe -CSP "CSP or KSP" -ImportPFX FILENAME.pfx
```



Solution 2

To convert the certificate, run the following commands:

```
openssl pkcs12 -in .\xxxx.pfx -out .\xxxx_new.pem -password pass: <EnterPassword>
openssl pkcs12 -export -in .\xxxx_new.pem -out xxxx_new.pfx
```

Before and after conversion:

Self-hosted integration runtime version 5.x

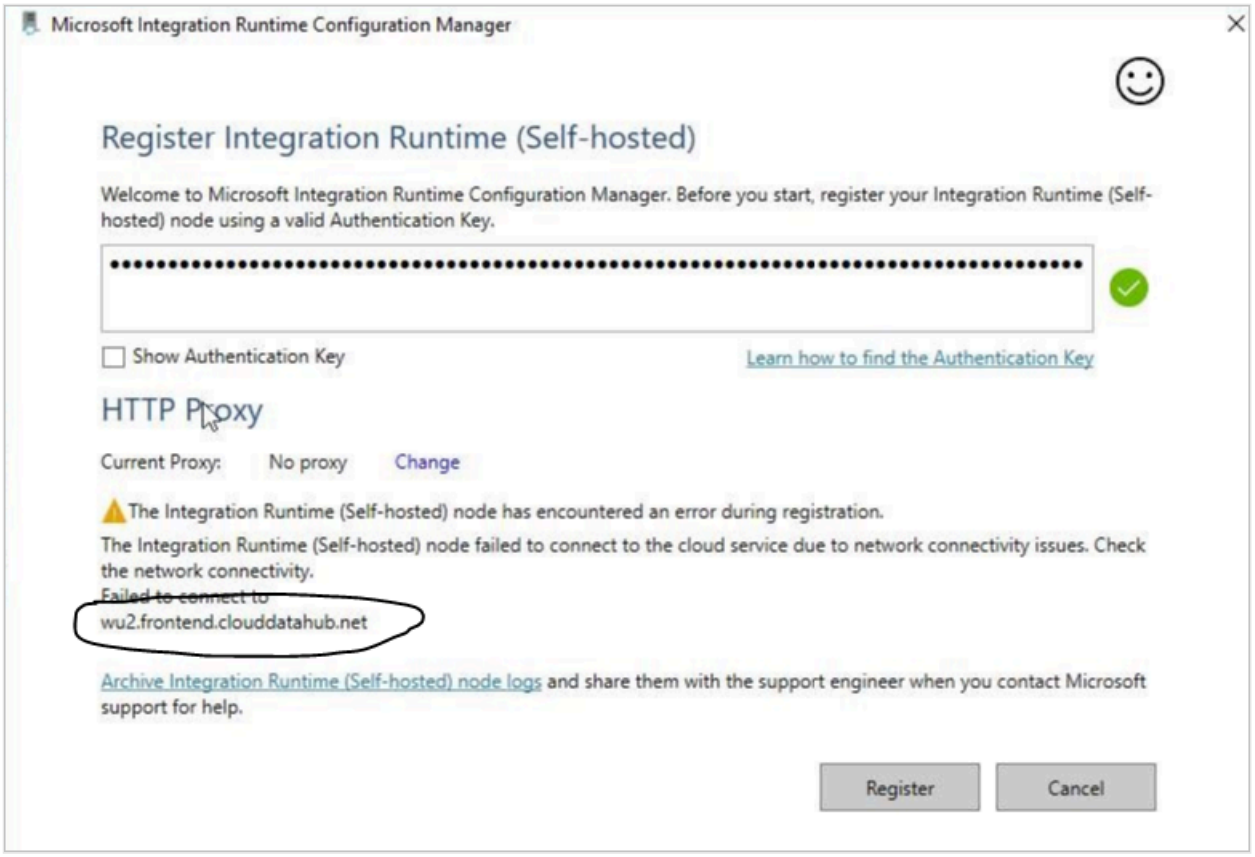
For the upgrade to version 5.x of the self-hosted integration runtime, we require **.NET Framework Runtime 4.7.2** or later. On the download page, you'll find download links for the latest 4.x version and the latest two 5.x versions.

For Azure Data Factory v2 and Azure Synapse customers:

- If automatic update is on and you've already upgraded your .NET Framework Runtime to 4.7.2 or later, the self-hosted integration runtime will be automatically upgraded to the latest 5.x version.
- If automatic update is on and you haven't upgraded your .NET Framework Runtime to 4.7.2 or later, the self-hosted integration runtime won't be automatically upgraded to the latest 5.x version. The self-hosted integration runtime will stay in the current 4.x version. You can see a warning for a .NET Framework Runtime upgrade in the portal and the self-hosted integration runtime client.
- If automatic update is off and you've already upgraded your .NET Framework Runtime to 4.7.2 or later, you can manually download the latest 5.x and install it on your machine.
- If automatic update is off and you haven't upgraded your .NET Framework Runtime to 4.7.2 or later. When you try to manually install self-hosted integration runtime 5.x and register the key, you will be required to upgrade your .NET Framework Runtime version first.

For Azure Data Factory v1 customers:

- Self-hosted integration runtime 5.X doesn't support Azure Data Factory v1.
- The self-hosted integration runtime will be automatically upgraded to the latest version of 4.x. And the latest version of 4.x won't expire.
- If you try to manually install self-hosted integration runtime 5.x and register the key, you'll be notified that self-hosted integration runtime 5.x doesn't support Azure Data Factory v1.



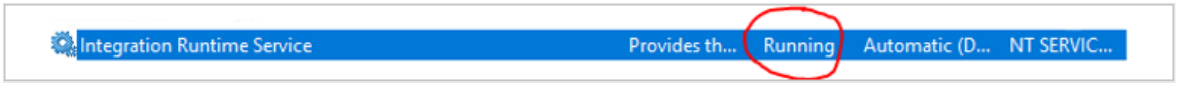
Self-hosted IR connectivity issues

Self-hosted integration runtime can't connect to the cloud service

Symptoms

When you attempt to register the self-hosted integration runtime, Configuration Manager displays the following error message:

"The Integration Runtime (Self-hosted) node has encountered an error during registration."

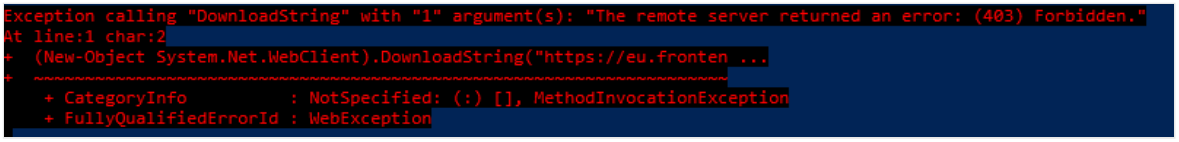


Cause

The self-hosted IR can't connect to the service back end. This issue is usually caused by network settings in the firewall.

Resolution

1. Check to see whether the integration runtime service is running. If it is, go to step 2.



2. If no proxy is configured on the self-hosted IR, which is the default setting, run the following PowerShell command on the machine where the self-hosted integration runtime is installed:

```PowerShell
 (New-Object System.Net.WebClient).DownloadString("https://wu2.frontend.clouddatahub.net/")
```

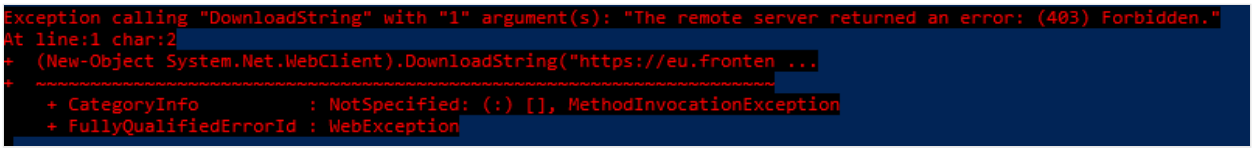
> **Note**

> The service URL might vary, depending on the location of your data factory or Synapse workspace instance. To find the service URL, use the Manage page of the UI in your data factory or Azure Synapse instance to find **Integration runtimes** and select your self-hosted IR to edit it. There select the **Nodes** tab and select **View Service URLs**.

3. The following is the expected response:

4. If you don't receive the response you had expected, use one of the following methods, as appropriate:

   - If you receive a "Remote name could not be resolved" message, there's a Domain Name System (DNS) issue. Contact your network team to fix the issue.
   - If you received an "ssl/tls cert is not trusted" message, check the certificate (`https://wu2.frontend.clouddatahub.net/`) to see whether it's trusted on the machine, and then install the public certificate by using Certificate Manager. This action should mitigate the issue.
   - Go to **Windows** > **Event viewer (logs)** > **Applications and Services Logs** > **Integration Runtime**, and check for any failure that's caused by DNS, a firewall rule, or company network settings. If you find such a failure, forcibly close the connection. Because every company has its own customized network settings, contact your network team to troubleshoot these issues.



5. If "proxy" has been configured on the self-hosted integration runtime, verify that your proxy server can access the service endpoint. For a sample command, see PowerShell, web requests, and proxies.

PowerShell

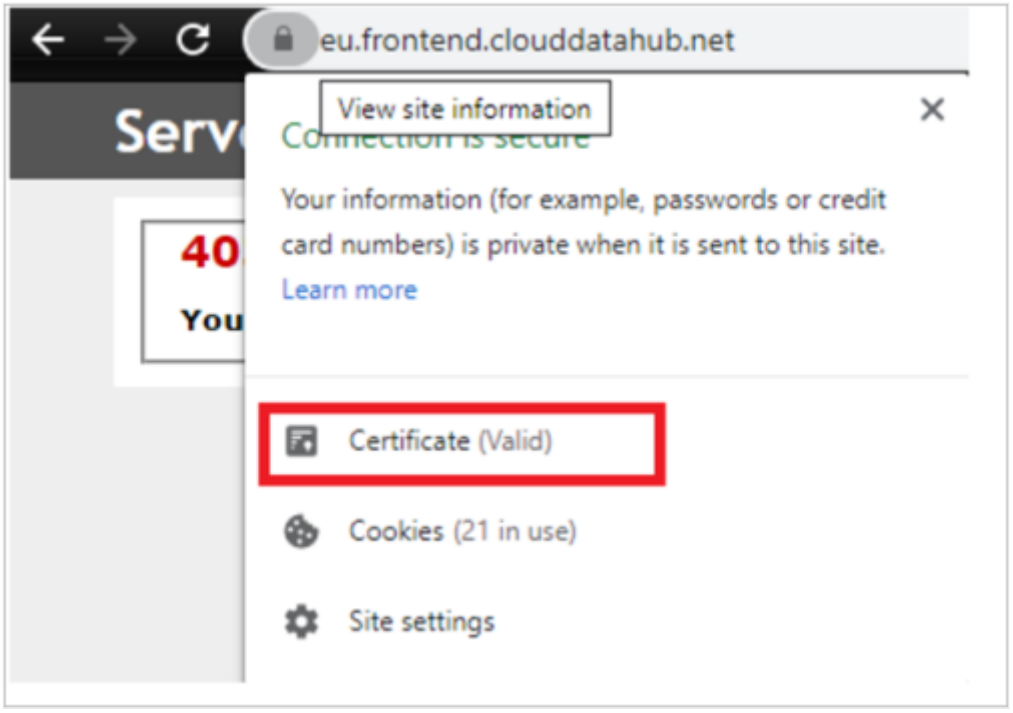
```
$user = $env:username
$webproxy = (get-itemproperty
'HKCU:\Software\Microsoft\Windows\CurrentVersion\Internet
Settings').ProxyServer
$pwd = Read-Host "Password?" -assecurestring
$proxy = new-object System.Net.WebProxy
$proxy.Address = $webproxy
$account = new-object System.Net.NetworkCredential($user,
[Runtime.InteropServices.Marshal]::PtrToStringAuto([Runtime.InteropServ
ices.Marshal]::SecureStringToBSTR($pwd)), "")
$proxy.credentials = $account
```

```
$url = "https://wu2.frontend.clouddatahub.net/"
$wc = new-object system.net.WebClient
$wc.proxy = $proxy
$webpage = $wc.DownloadData($url)
$string = [System.Text.Encoding]::ASCII.GetString($webpage)
$string
```

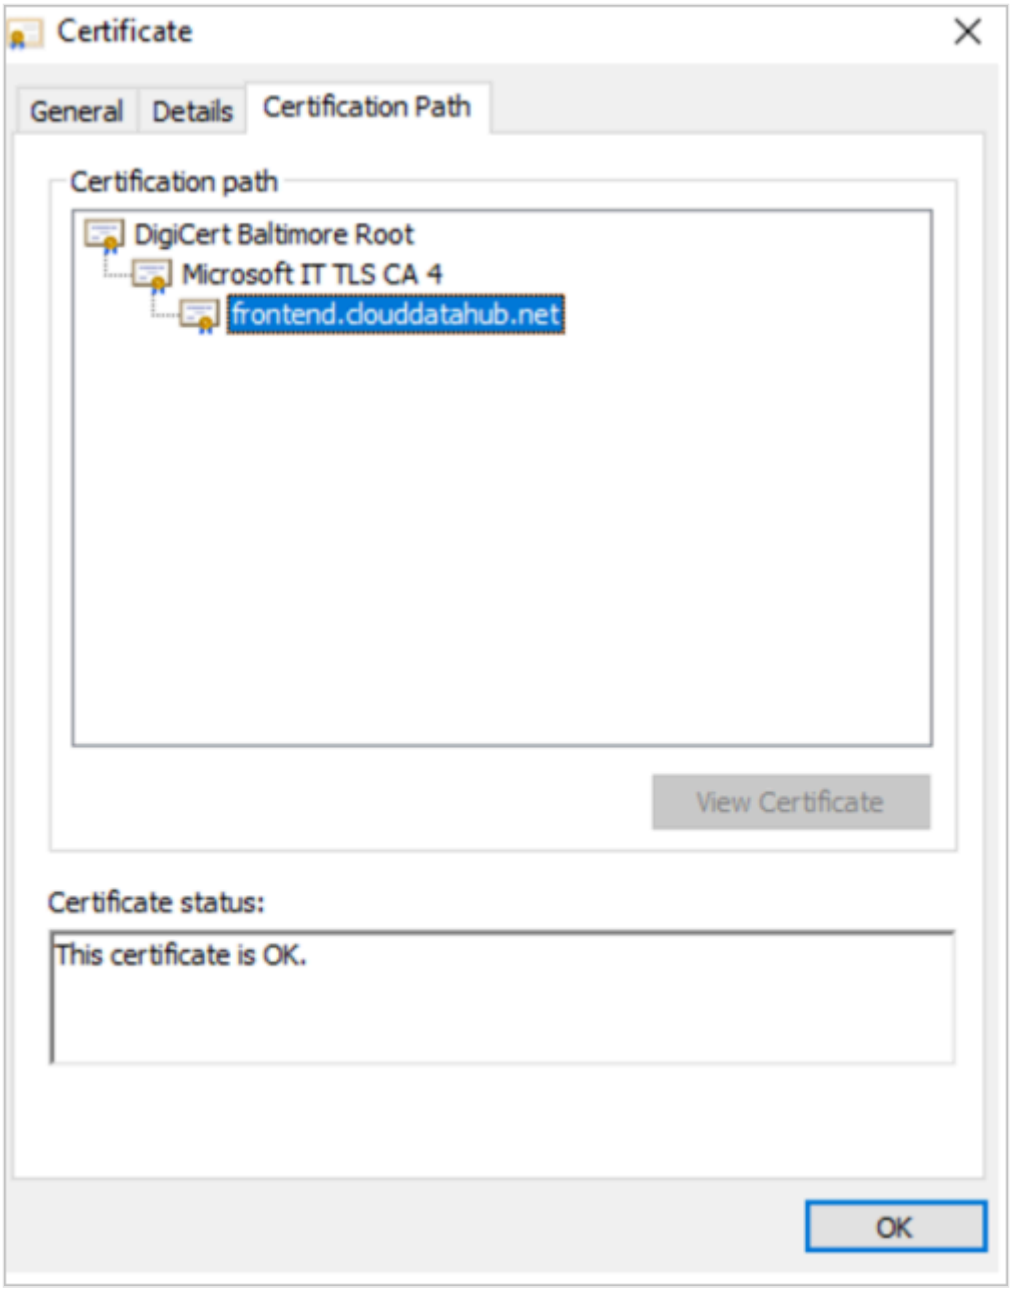
The following is the expected response:

> ⓘ Note
>
> Proxy considerations:
>
> - Check to see whether the proxy server needs to be put on the Safe Recipients list. If so, make sure these domains are on the Safe Recipients list.
> - Check to see whether SSL/TLS certificate "wu2.frontend.clouddatahub.net/" is trusted on the proxy server.
> - If you're using Active Directory authentication on the proxy, change the service account to the user account that can access the proxy as "Integration Runtime Service."

Couldn't establish a trust relationship for the SSL/TLS secure channel



Symptoms



The self-hosted IR couldn't connect to Microsoft Purview.

When you check the self-hosted IR event log after going to **Windows** > **Event viewer (logs)** > **Applications and Services Logs** > **Integration Runtime**, you'll find the following error message:

"The underlying connection was closed: Could not establish trust relationship for the SSL/TLS secure channel. The remote certificate is invalid according to the validation procedure."

The simplest way to check the server certificate of the service is to open the service URL in your browser. For example, open the check server certificate link (`(https://eu.frontend.clouddatahub.net/`) on the machine where the self-hosted IR is installed, and then view the server certificate information.

Cause

There are two possible reasons for this issue:

- Reason 1: The root CA of the service's server certificate isn't trusted on the machine where the self-hosted IR is installed.
- Reason 2: You're using a proxy in your environment, the server certificate of the service is replaced by the proxy, and the replaced server certificate isn't trusted by the machine where the self-hosted IR is installed.

Resolution

- For reason 1: Make sure that the service's server certificate and its certificate chain are trusted by the machine where the self-hosted IR is installed.

- For reason 2: Either trust the replaced root CA on the self-hosted IR machine, or configure the proxy not to replace the service's server certificate.

For more information about trusting certificates on Windows, see Installing the trusted root certificate.

More information

We've rolled out a new SSL certificate, which is signed from DigiCert. Check to see whether the DigiCert Global Root G2 is in the trusted root CA.

If it isn't in the trusted root CA, download it here.

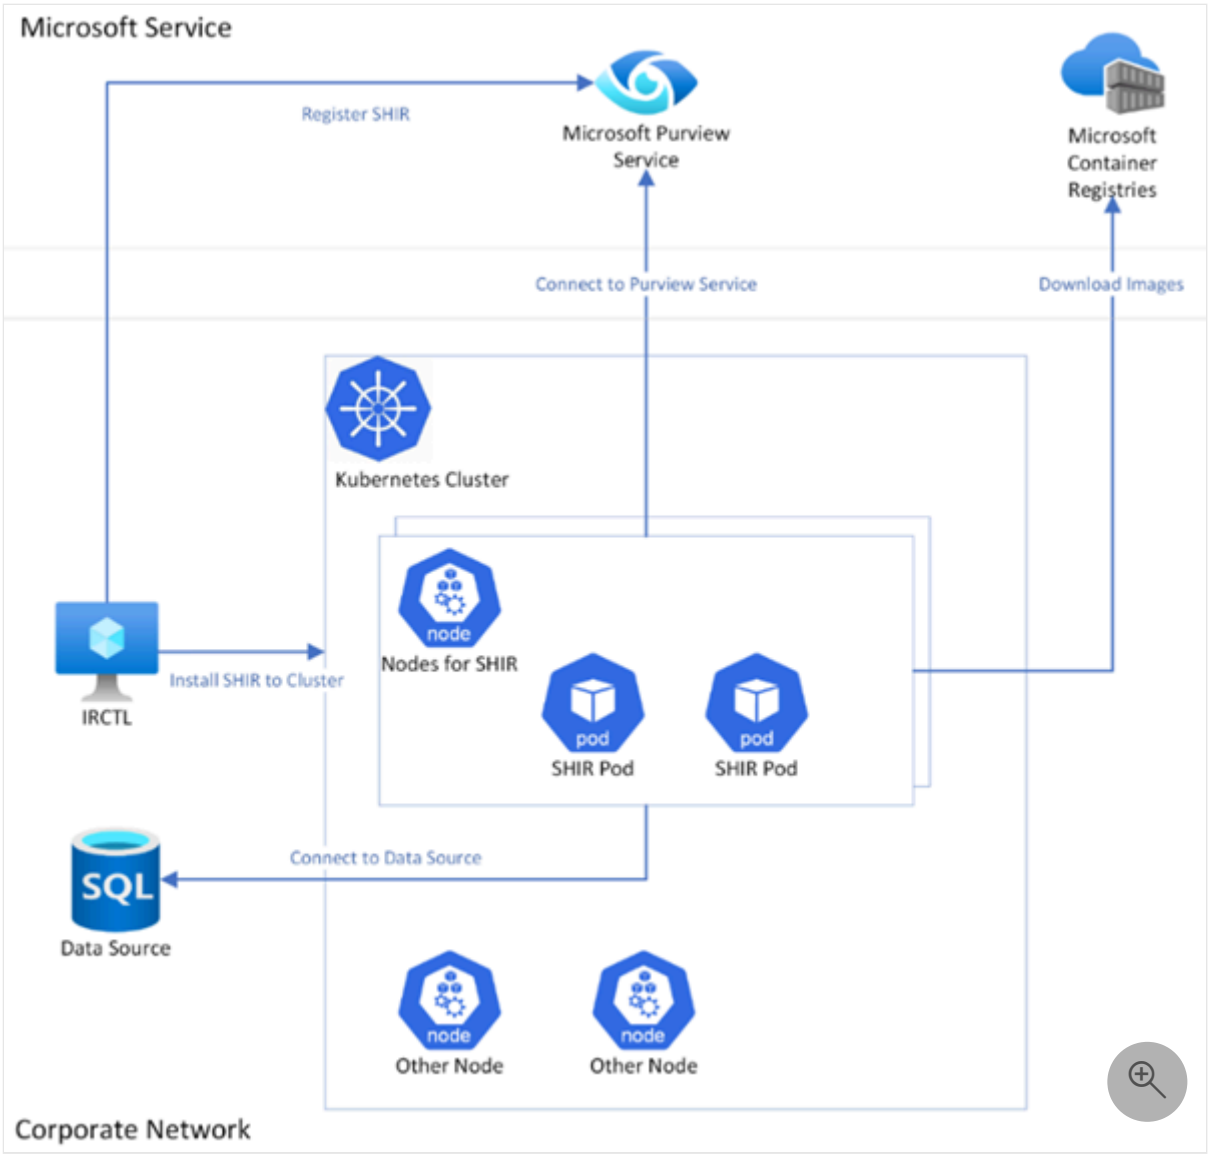
Create and manage a Kubernetes supported self-hosted integration runtime

07/15/2025

This article covers the details for the new SHIR feature that is Kubernetes-based for Linux that improves the underlying infrastructure to provide several benefits:

- **Scalability**: Ability to scale to hundreds of machines.
- **Performance**: Improved performance in scanning workloads.
- **Security** (containerized): Ability to have containerized security on a Kubernetes cluster, instead of hosting SHIR on a Windows machine directly

This article covers the details to install and manage a Kubernetes supported self-hosted integration runtime.



Supported data sources

For a list of all supported sources, see the supported data sources for each integration runtime table.

Architecture

At a high-level architectural view, when a Kubernetes based SHIR is installed, several pods get autocreated on the nodes of users' Kubernetes cluster. This installation can be triggered by a command line tool named IRCTL (more detail in following sections). IRCTL connects to the Microsoft Purview Service to register the SHIR and connect to the Kubernetes cluster to install the SHIR.

During the installation, SHIR images are downloaded from MCR (Microsoft Container Registries) to the SHIR pods. After installation is done, the pods in users' cluster will connect to the Microsoft Purview Service to pull scan jobs. As a scan job is pulled, it can connect users' on-premises Data Source for Data Scanning.

Prerequisites

- A Microsoft Purview account using enterprise data governance solutions.
- **Kubernetes cluster**: You need to have an existing Linux-based Kubernetes cluster or to prepare one. The nodes can be identified by node selector, which follows the definition of Kubernetes node selector. Minimum configuration:
  - Container type: Linux
  - Kubernetes version: 1.24.9 or above
  - Node OS: Linux based OS running on x86 architecture
  - Node spec: minimal eight cores CPU, 32-GB memory, and at least 80 GB of available hard disk space
  - Node count: >=1 (should be fixed, **not** enable cluster auto scaler)
  - Pod number per Node: >= 20 (max Pod number – count of other Pods not belonging to Self-Hosted IR)

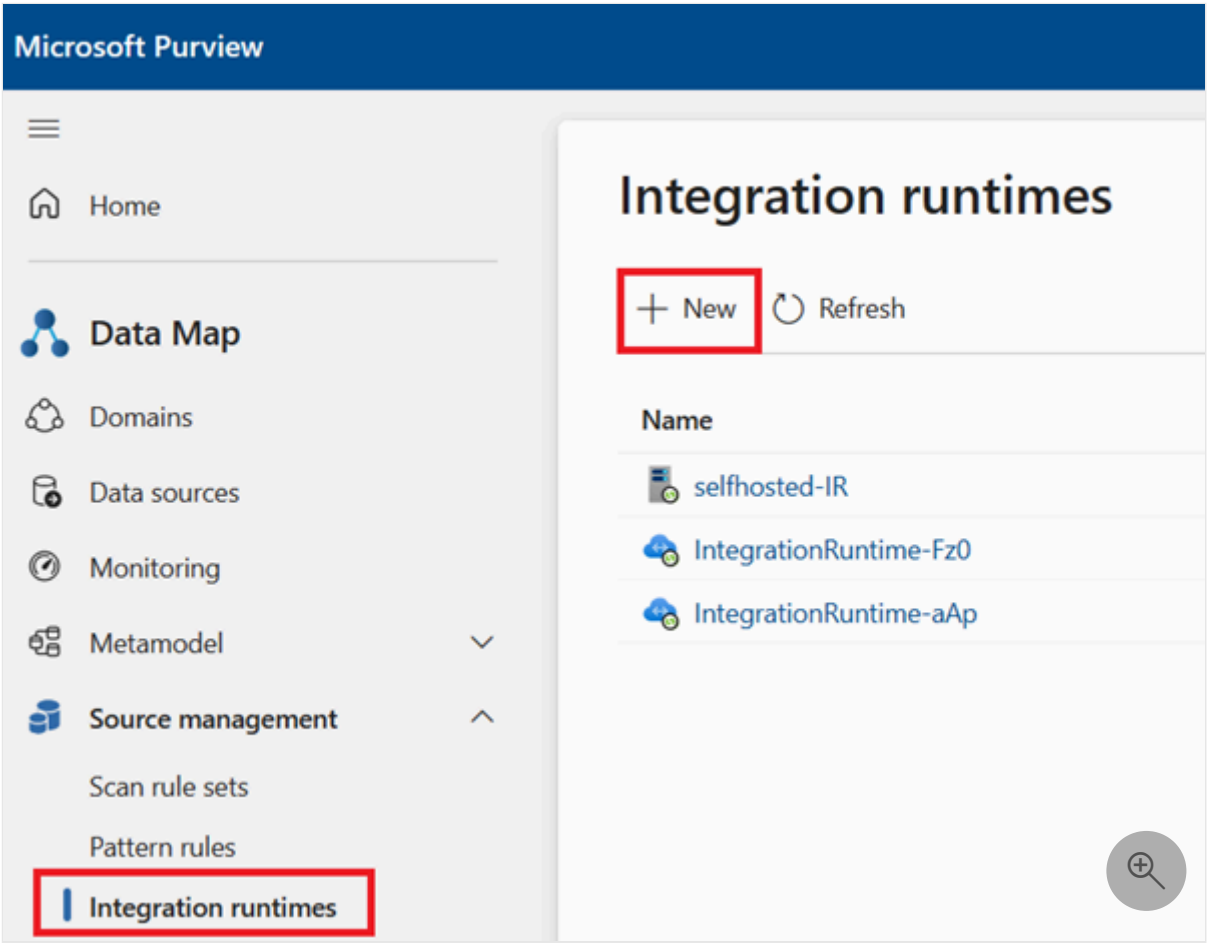
> ⓘ **Note**

> The folder /var/irstorage/ of each Node is reserved for SHIR. It is readable and writable to SHIR. You can get logs being persisted from this folder or upload external drivers to this folder. It will be created by SHIR if it doesn't exist, and it will not be deleted after SHIR being deleted. The container images used by SHIR are managed by Kubernetes Garbage Collection, which won't be cleaned-up by SHIR. Configure the proper threshold for your Kubernetes cluster.

- **Kubernetes cluster network**: The Kubernetes cluster you have should be able to connect to the endpoint listed in networking requirements.
- **Integration runtime command line tool**: In order manage your Microsoft Purview Kubernetes SHIR locally, you need a command line tool named IRCTL. You can download this tool during the SHIR creation process. IRCTL is a command line tool to manage your Microsoft Purview SHIR. For more information, see the IRCTL documentation.
- **Kubernetes context**: Kubernetes context, which contains Kubernetes cluster information and user's permissions and credential for this cluster, is needed to talk to your Kubernetes cluster. To ease the configuration for the user's permissions for SHIR management, you can start with Kubernetes Admin role. This context is generated with the setup of your Kubernetes cluster and saved in a config file. Where and how you can get this file depends on your setting up the Kubernetes cluster.
  - If you use `kubeadm init` to set up the Kubernetes cluster, you can find the config file under `/etc/Kubernetes/admin.conf`.
  - If you use AKS, you can follow the guidance of AKS to use Az PowerShell module command to get credentials of this cluster to your local machine. The context can be merged to the config file under `$HOME/.kube/config` directly.
  - If you're using other tools setting up a Kubernetes cluster, refer to the Kubernetes documentation.
  - As you have the config file of the Kubernetes context, merge it to the config file, which is `$HOME/.kube/config`, on the machine you would like to run IRCTL command. Or you can set the config file of the Kubernetes context in an environment variable named KUBECONFIG as well. For more information about the Kubernetes context, see Configure Access to Multiple Clusters.

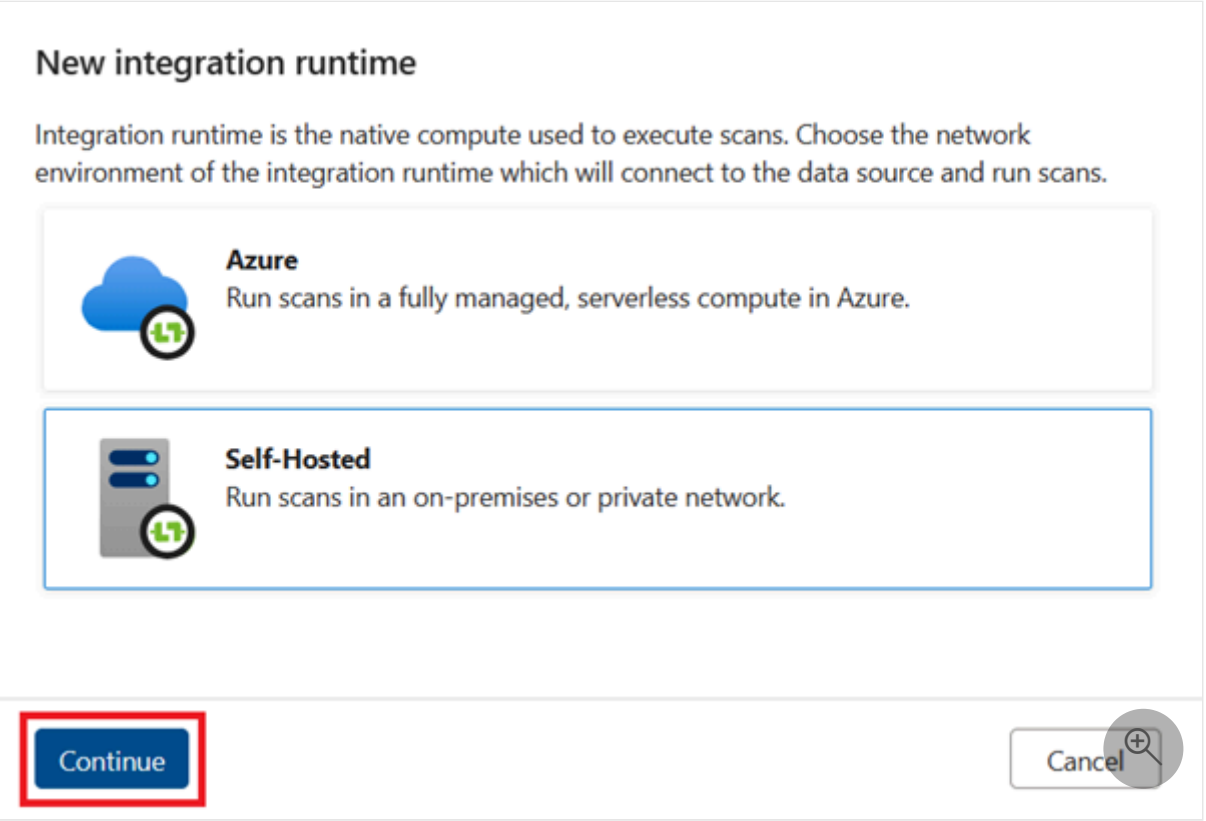
Create Kubernetes supported self-hosted integration runtime

To control and manage a Kubernetes SHIR, users can download a command line tool named IRCTL. The following are the steps to your Kubernetes supported self-hosted integration runtime.



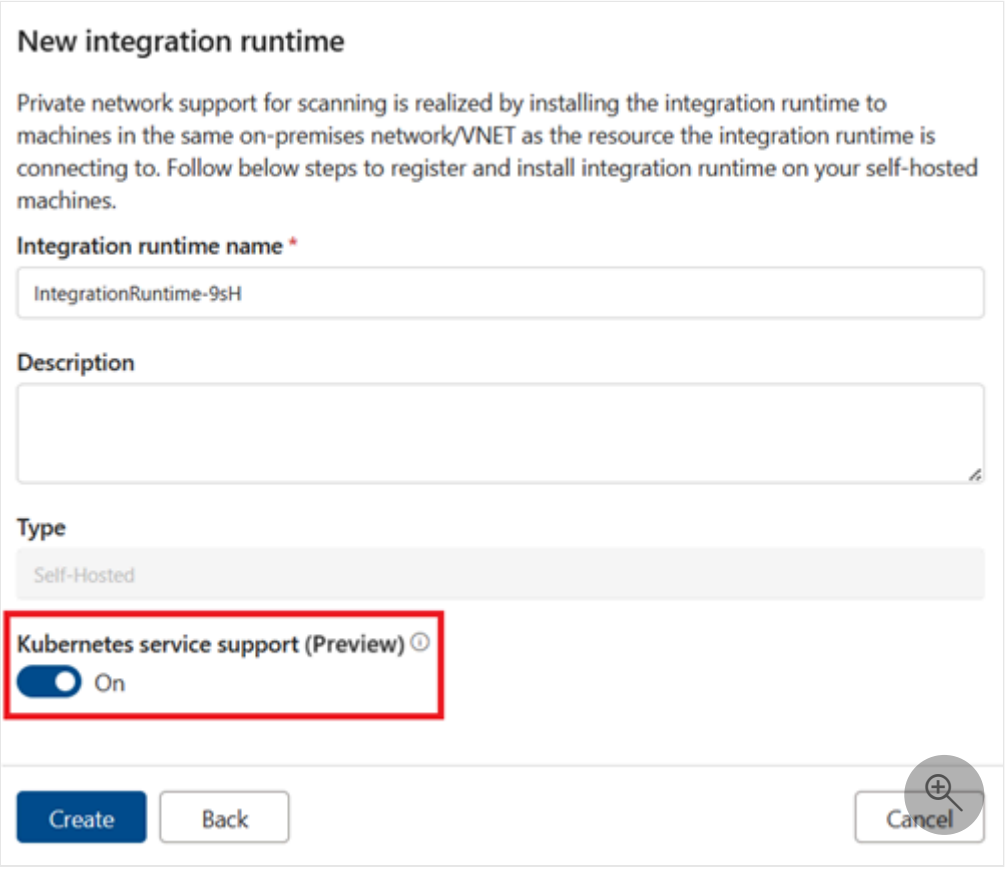
The steps take you through downloading IRCTL, but for direct links, see the IRCTL documentation.

Set up a Kubernetes supported self-hosted integration runtime



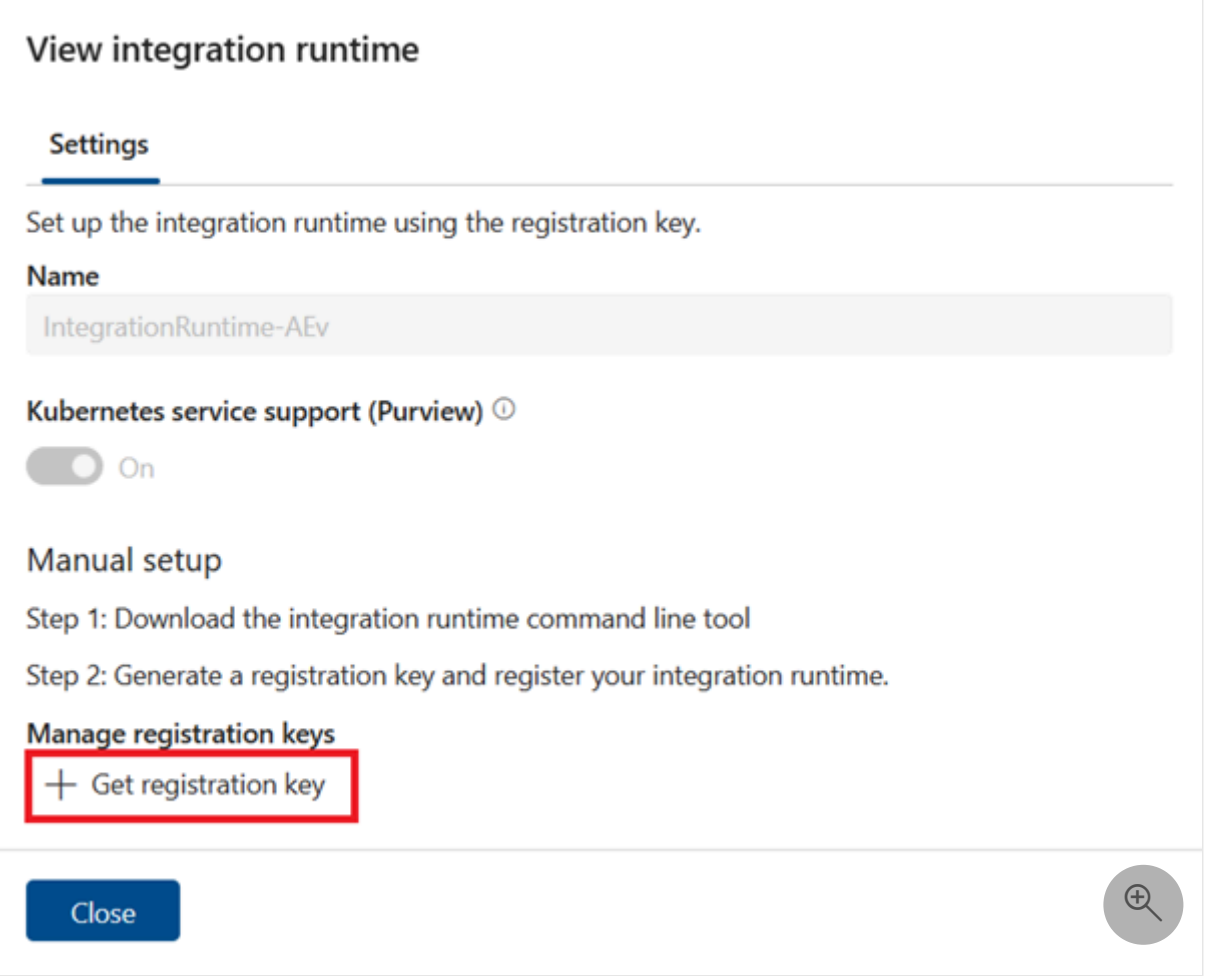
1. Open the **Integration runtimes** window in the Microsoft Purview Data Map

    - If you're using the new Microsoft Purview portal:
        a. Open the **Data Map**
        b. Select **Source management**
        c. Select **Integration runtimes**
    - If you're using the classic Microsoft Purview governance portal:
        a. Open the **Data Map**
        b. Select **Integration runtimes**



2. Select the + **New** button

3. Select **Self-hosted** and then select **Continue**



4. Give your runtime a name, then select the **Kubernetes service support** toggle to enable

5. Select **Create**

6. Select **Get registration key**

7. Copy the key value. You need it to run commands in IRCTL later.

> **Tip**
>
> If needed, you can regenerate a key or revoke a generated key.

8. Select the **Download IRCTL and install integration runtime** link to download the IRCTL tool. (You can also follow these steps to download IRCTL directly.)

9. On the machine where you want to run the IRCTL command line, install IRCTL from the download. IRCTL connects to your Kubernetes cluster by context of the Kube config. If context isn't specified, IRCTL uses the current context. You can set the context in one of two ways:

    - Run kubectl command line and execute this command to confirm the current context:

      Bash

      ```
      kubectl config get-contexts – List all contexts configured on the machine
      ```

```
Bash

kubectl config current-context – Get the current context name
```

```
Bash

kubectl config use-context <name of context>
```

- Run IRCTL and execute `--context` to specify the context in the Kube config

10. Run the IRCTL command line and execute this command with the registration key you copied.

```
Bash

./irctl create --registration-key <registration key copied from the portal>
```

> **Note**
>
> If node selector isn't specified, will use all nodes of the Kubernetes cluster. For AKS, we suggest using the label of AKS node pool as the node selector or you can customize different labels to the SHIR nodes.

11. You see this printout:

```
Bash

[Info] Start to create SHIR with Kubernetes context [your-context]......
[Info] Environment validation passed!
[Info] Registering SHIR[example-k8s-shir] for Microsoft Purview Account
[yourpurviewaccount]......
[Info] SHIR Registration done!
[Info] Provisioning SHIR, it may take about 5-30 minutes......done!
[Info] SHIR creation succeeded!
```

> **Tip**
>
> If the installation progress is broken by Ctrl-C or other reasons, the following command can be used to monitor the installation progress: `./irctl install status`

12. Once installation is complete, to check the current status of the SHIR, run this command:

```bash
./irctl describe
```

13. You can also check the status of your SHIR in the Microsoft Purview portal, on the **Integration runtimes** page.

Set up a scan with external drivers

When scanning some data sources, you need to install the corresponding driver on the machine where the SHIR is installed for Microsoft Purview to connect with the data source. Below is an example for Db2 scan. Refer to respective connector article for specific prerequisites.

> **Note**
>
> Data sources that need these external drivers have the information listed in their prerequisites.

In this example, we are installing the Db2 driver. Steps for other drivers are similar.

1. First, install the integration runtime.
2. Download the driver (each source has their individual driver listed.) For example, you can find the DB2 driver here: Connect to and manage Db2.
3. Upload the driver to each node for your integration runtime. You can use a command like this:

   ```bash
   ./irctl storage upload --source jdbc_sqlj/db2_driver --destination driver/db2
   ```

   A successful upload confirmation looks like this:

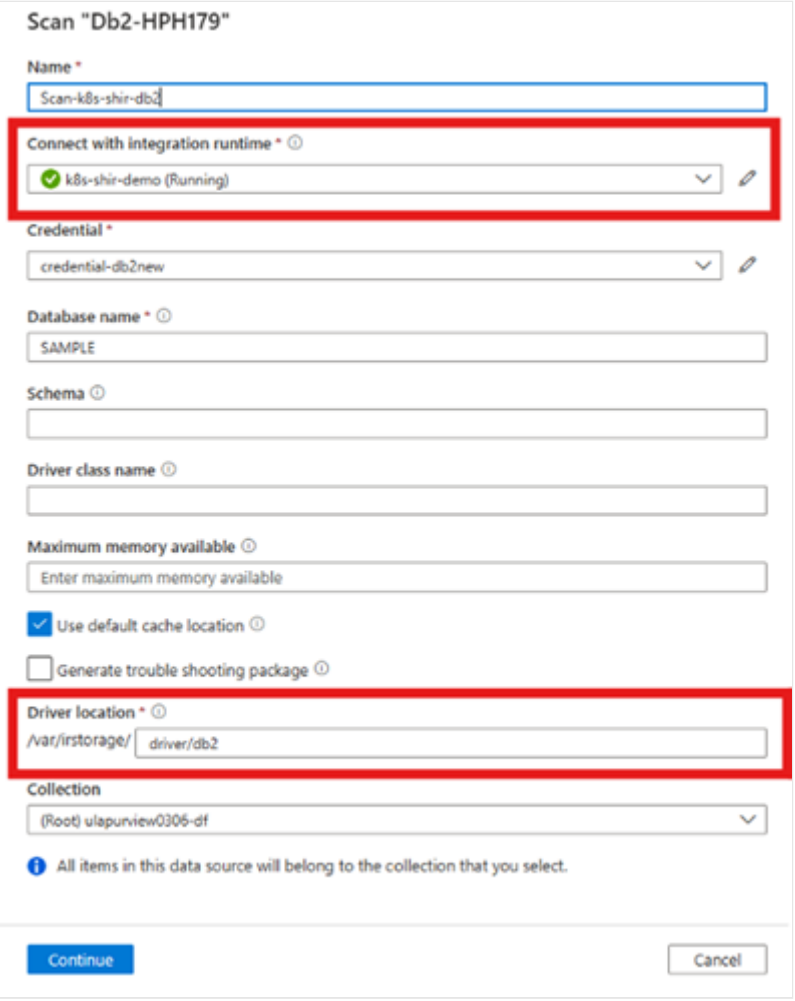
   ```bash
   ========== Context ==========
   Kubernetes Context             : k8s-shir-test-cluster
   Purview Account                : test-purview-1
   Self-hosted Intrgration Runtime: k8s-shir-demo
   ========== Progress ==========
   Processing 2/2 nodes...
   aks-shirpool-27141791-vmss000000: SUCCEEDED
   ```

```
aks-shirpool-27141791-vmss000001: SUCCEEDED
========== Results ==========
jdbc_sqlj/db2_driver -> /var/irstorage/driver/db2
```

> **Note**
>
> If you replace nodes or scale out to new nodes, you need to upload the external driver again.

4. Verify the files uploaded with this command:

```
Bash



./irctl storage list driver/db2
```

You should see a response like this:

```
Bash

========== Context ==========
Kubernetes Context             : k8s-shir-test-cluster
Purview Account                : test-purview-1
Self-hosted Intrgration Runtime: k8s-shir-demo
========== Progress ==========
Processing 2/2 nodes...
aks-shirpool-27141791-vmss000000: SUCCEEDED
aks-shirpool-27141791-vmss000001: SUCCEEDED
========== Results ==========
Node: aks-shirpool-27141791-vmss000000 - Succeeded
/var/irstorage/driver/db2
total 9364
drwxr-xr-x    2 root     root          4096 May 15 14:23 .
drwxr-xr-x    3 root     root          4096 May 15 14:23 ..
-rwxrwxr-x    1 root     root       6568346 May 15 14:23 db2jcc4.jar
Node: aks-shirpool-27141791-vmss000001 - Succeeded
/var/irstorage/driver/db2
total 9364
drwxr-xr-x    2 root     root          4096 May 15 14:23 .
drwxr-xr-x    3 root     root          4096 May 15 14:23 ..
-rwxrwxr-x    1 root     root       6568346 May 15 14:23 db2jcc4.jar
```

5. Create scan with the value for **DriverLocation** with the **Destination** value from step 3.

High availability and scalability

You can assign multiple nodes of the Kubernetes cluster to have high availability by using the node-selector during the Kubernetes supported self-hosted integration runtime installation. The benefits of having multiple nodes are:

- Higher availability of the self-hosted integration runtime so that it's no longer the single point of failure for scans.
- Run more concurrent scans. Each node can empower many scan runs at the same time. You can manually scale out nodes of the Kubernetes cluster if you need more concurrent scans.
- When scanning some sources like Azure Blob, Azure Data Lake Storage Gen2, and Azure Files, each scan run can use multiple nodes to boost the scan performance. For other sources, scans are executed on only one of the nodes.

The capability of Kubernetes supported self-hosted integration runtime can be updated by manually scaling out/in nodes of the Kubernetes cluster.

> ⓘ **Note**

You must upload all necessary drivers for scanning on each new node.

Networking requirements

Expand table

Domain name	Outbound ports	Description
Public cloud: `<tenantID>-api.purview-service.microsoft.com` Azure Government: `<tenantID>-api.purview-service.microsoft.us` China: `<tenantID>-api.purview-service.microsoft.cn`	443	Required to connect to Microsoft Purview service. If you use Microsoft Purview Private Endpoints, this endpoint is covered by account private endpoint.
Public cloud: `<purview_account>.purview.azure.com` Azure Government: `<purview_account>.purview.azure.us` China: `<purview_account>.purview.azure.cn`	443	Required to connect to Microsoft Purview service. If you use Microsoft Purview Private Endpoints, this endpoint is covered by account private endpoint.
Public cloud: `<managed_storage_account>.blob.core.windows.net` or `<ingestion_storage_account>.*.blob.storage.azure.net` Azure Government: `<managed_storage_account>.blob.core.usgovcloudapi.net` or `<ingestion_storage_account>.blob.core.usgovcloudapi.net` China: `<managed_storage_account>.blob.core.chinacloudapi.cn` or `<ingestion_storage_account>.blob.core.chinacloudapi.cn`	443	Required to connect to the Microsoft Purview managed Azure Blob storage account.
Public cloud: `<managed_storage_account>.queue.core.windows.net` or `<ingestion_storage_account>.*.queue.storage.azure.net` Azure Government: `<managed_storage_account>.queue.core.usgovcloudapi.net` or `<ingestion_storage_account>.queue.core.usgovcloudapi.net` China: `<managed_storage_account>.queue.core.chinacloudapi.cn` or `<ingestion_storage_account>.queue.core.chinacloudapi.cn`	443	Required to connect to the Microsoft Purview managed Azure Queue storage account.
Public cloud: `*.compute.governance.azure.com` Azure Government: `*.compute.governance.azure.us` China: `*.compute.governance.azure.cn`	443	Required to connect to the Microsoft Purview service. Currently

Domain name	Outbound ports	Description
		wildcard is required as there's no dedicated resource.
mcr.microsoft.com	443	Required to download images.
*.data.mcr.microsoft.com	443	Required to download images.

> **Note**
>
> Depending on the sources users want to scan, they also need to allow other domains and outbound ports for other Azure or external sources.

Version

Typically, we release one new minor version of self-hosted integration runtime every month, which includes features, enhancements, and bug fixes.

Each version of the self-hosted integration runtime expires in one year.

How to check the current version

You can check the version of your Kubernetes self-hosted integration runtime either on the portal, or with the IRCTL.

Portal

1. In the Microsoft Purview portal, navigate to the Data Map.
2. Select **Integration runtimes**
3. The fourth column in your integration runtime's description line will be **Version**, and you can check the version there.

IRCTL (1.1.0 and above)

The describe command returns the integration runtime's version.

```
Bash
```

```
./irctl describe
```

Auto-update

Starting from version 1.1.0, the Kubernetes self-hosted integration runtime supports auto-update, which is enabled by default. This feature ensures your integration runtime is automatically upgraded to the latest Microsoft-managed version approximately once a month.

Opt-out

We recommend keeping auto-update enabled to benefit from the newest features and enhancements. However, you have the option to opt-out of auto-update using IRCTL. The auto-update configuration persists through reinstallation, so you don't need to disable it with each installation.

Bash

```
./irctl config set autoUpdate.enabled false
./irctl config view
```

Auto-update version vs latest version

To ensure stability, the auto-update is usually behind the latest version with a one-month delay. The auto-update version is managed by Microsoft.

If you would like to upgrade your integration runtime to newer versions, a manual upgrade should be performed with IRCTL of the specific version.

Next Steps

- Choose the right integration runtime configuration
- IRCTL instructions and details
- Troubleshoot kubernetes supported integration runtime

IRCTL for Kubernetes supported self-hosted integration runtime

07/15/2025

In order to manage your Microsoft Purview Kubernetes SHIR locally, you need a command line tool named IRCTL. You can download this tool during the SHIR creation process. IRCTL is a command line tool to manage your Microsoft Purview SHIR.

Prerequisites

The system requirements for IRCTL are:

- **Machine running IRCTL** - OS is Linux or Windows supporting TLS 1.2
- The machine to run IRCTL should be able to connect to the following endpoints:

Expand table

Domain name	Outbound ports	Description
Public cloud: `*.compute.governance.azure.com` Azure Government: `*.compute.governance.azure.us` China: `*.compute.governance.azure.cn`	443	Required to connect to Microsoft Purview service. If you use Microsoft Purview Private Endpoints, this endpoint is covered by account private endpoint.

- **Kubernetes context**: Kubernetes context, which contains Kubernetes cluster information and user's permissions and credential for this cluster, is needed to talk to your Kubernetes cluster. To ease the configuration for the user's permissions for SHIR management, you can start with Kubernetes Admin role. This context is generated with the setup of your Kubernetes cluster and saved in a config file. Where and how you can get this file depends on your setting up the Kubernetes cluster.
  - If you use `kubeadm init` to set up the Kubernetes cluster, you can find the config file under `/etc/Kubernetes/admin.conf`.
  - If you use AKS, you can follow the guidance of AKS to use Az PowerShell module command to get credentials of this cluster to your local machine. The context can be merged to the config file under `$HOME/.kube/config` directly.
  - If you're using other tools setting up a Kubernetes cluster, refer to the Kubernetes documentation.

- As you have the config file of the Kubernetes context, merge it to the config file, which is `$HOME/.kube/config`, on the machine you would like to run IRCTL command. Or you can set the config file of the Kubernetes context in an environment variable named KUBECONFIG as well. For more information about the Kubernetes context, see Configure Access to Multiple Clusters.

Install and run IRCTL

To control and manage a Kubernetes supported self-hosted integration runtime, users can download a command line tool named IRCTL. Users can also monitor the status on the Portal by IRCTL and kubectl command line. The following are the steps to your Kubernetes supported self-hosted integration runtime.

Windows

Download Latest IRCTL for Windows

Specific version

To download a specific version of the IRCTL, change the version segment in the URL: `https://aka.ms/purview-irctl/irctl-windows-<version>.tar.gz`

For example for version 1.0.0: `https://aka.ms/purview-irctl/irctl-windows-1.0.0.tar.gz`

Available IRCTL versions can be found in the IRCTL release notes.

After you download the tool:

1. Unzip and open the tool folder.
2. Move it to a location on your machine where you can access it from the command line.
3. Open the command line and navigate to the folder where the IRCTL application is housed.
4. Use the below commands to interact with IRCTL and follow these steps to install a Kubernetes supported integration runtime.

IRCTL command details

You can download the IRCTL command line tool from your integration runtime settings in Microsoft Purview. Select your integration runtime and under **Settings** you can see the **Download IRCTL and install integration runtime** link. Select it to download the tool.

You can use the IRCTL command line to set up or manage a Kubernetes supported self-hosted integration runtime. Use this syntax to run IRCTL commands from your terminal window:

```
Bash

./irctl [command][flags]...
```

- **Command** specifies the operation you want to perform
- **Flags** specifies parameters for the operation

Expand table

Command	Description
config	Manages IRCTL configurations
create	Create a new SHIR resource
delete	Delete an SHIR resource
describe	Describes the SHIR running on the Kubernetes cluster
help	Provides help about any command
storage	Manage local storage reserved for SHIR
log	Manage logs of SHIR
upgrade	Upgrade an SHIR to the same version with IRCTL

Config

Manage IRCTL configurations.

```
Bash

./irctl config [flags]
./irctl config [command]
```

Expand table

Command	Description
set	Modify one SHIR configuration.
view	View all SHIR configurations.

Expand table

Flag	Parameter type	Description
-h,--help		Help for config

Config set

Modify one self-hosted integration runtime configuration.

Bash

```
./irctl config set <config-name> <config-value> [flags]
```

Expand table

Flag	Parameter type	Description
-c, --context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-h,--help		Help for config

Config view

View all SHIR configurations.

Bash

```
./irctl
```

Expand table

Flag	Parameter type	Description
-c, --context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-h,--help		Help for config

Allowed SHIR Configurations

Expand table

Config name	Config type	Valid values	Default value (value unset)	Description	Persists through reinstallation
autoUpdate.enabled	Boolean	true/false	true	Controls whether the current SHIR should be autoupdated.	Yes

Create

Create a new SHIR resource.

Bash

```
./irctl create [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used
-h,--help		Help for create
-r,--registration-key	string	Key to register SHIR
-s,--selector	string	Node selector (label query) to filter on, supports '='. (for example,--selector key1=value1,key2=value2) Select nodes by given labels for SHIR

Flag	Parameter type	Description
		to run on. Default is empty, which means SHIR runs on all nodes.

Example:

```
Bash

./irctl create --registration-key 1234@keyvalue
```

Upgrade

Upgrade an SHIR to the same version with IRCTL.

```
Bash

./irctl upgrade [flags]
./irctl upgrade [command]
```

Expand table

Command	Description
status	Monitors the status the latest SHIR upgrade.

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used
-h,--help		Help for upgrade

Delete

Delete an SHIR resource.

```
Bash

./irctl delete [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used
-h,--help		Help for delete

Describe

Describe SHIR running on the Kubernetes cluster.

```
Bash

./irctl describe [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used
-h,--help		Help for describe

Storage

Manage files in SHIR shared storage.

```
Bash

./irctl storage [flags]
./irctl storage [command]
```

Expand table

Command	Description
upload	Upload files to SHIR shared storage.
list	List files in SHIR shared storage.

Command	Description
delete	Delete files in SHIR shared storage.

Expand table

Flag	Parameter type	Description
-h,--help		Help for storage

Storage upload

Upload files to SHIR shared storage.

Bash

```
./irctl storage upload -s <source> -d <destination> [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-d,--destination string	string	Path to store file/folder uploaded in SHIR shared storage.
-h,--help		Help for delete
-s,--source	string	Path to the file/folder to be uploaded.

Storage list

List files in SHIR shared storage.

Bash

```
./irctl storage list <path> [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-h,--help		Help for list.

Storage delete

Delete files in SHIR shared storage.

```
Bash

./irctl storage delete <path> [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-h,--help		Help for delete.

Log

Log operations from SHIR.

```
Bash

./irctl log [flags]
./irctl log [command]
```

Expand table

Command	Description
upload	Upload logs from SHIR.
download	Download logs from SHIR.

Expand table

Flag	Parameter type	Description
-h,--help		Help for log.

Log upload

Upload logs from SHIR.

```
Bash

./irctl log upload [flags]
./irctl log upload [command]
```

Expand table

Command	Description
Status	Monitors the status of SHIR log uploading.

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-h,--help		Help for upload.
-t,--timeout	int	Timeout for the log upload operation in seconds: [900, 3600]. Default is 900 seconds. (Default 900)

Log download

Upload logs from SHIR.

```
Bash

./irctl log download [flags]
```

Expand table

Flag	Parameter type	Description
-c,--context	string	Name of the Kubernetes context to use, if not specified, current context of Kube config is used.
-d,--destination	string	Local path to store logs downloaded from SHIR.
-h,--help		Help for download.

Next Steps

- Install and configure kubernetes supported integration runtime
- Choose the right integration runtime configuration
- Troubleshoot kubernetes supported integration runtime

Troubleshoot a Kubernetes supported self-hosted integration runtime

Article • 10/14/2024

This article covers the details for troubleshooting the new self-hosted integration runtime that is Kubernetes-based for Linux.

You can look up any errors you see in the error guide below. To get support and troubleshooting guidance for SHIR issues, you might need to generate a Log Upload ID and reach out to Microsoft support.

Gather Kubernetes self-hosted integration runtime logs

To generate the Log Upload ID for Microsoft Support:

1. Once a scan shows status Failed, navigate to the VM or machine where your IRCTL tool is installed.
2. Use the `./irctl log upload` command.
3. When the logs are uploaded, keep a record of the Log Upload ID that's printed.
4. If the self-hosted integration runtime fails to register, use the guide below to download logs to local and send it to Microsoft support

To collect the self-hosted integration runtime log and scan run log to troubleshoot your SHIR, use the `./irctl log download` command.

For example:

```Bash
./irctl log download --destination "C:\Users\user\logs\"
```

Logs will be downloaded to the destination path.

> **Note**
>
> The log will be reserved for 14 days. Please persist it by uploading it to Microsoft or downloading it to your local machine.

IRCTL connectivity error to Kubernetes

You might get a Kubernetes context configuration from your Kubernetes administrator, and the registration could fail with one of the following error messages:

- `Error: invalid flag context [] .kube/config: no such file or directory`
- `[Warning] Failed to create kube client with context [] with error`

Cause

When installing a self-hosted integration runtime, a correct Kubernetes config and a stable connectivity is required.

Resolution

1. Make sure the Kubernetes context file is located in the correct path.
2. Make sure the IRCTL machine can reach the Kubernetes cluster API server.

IRCTL permission error

When connecting you could see the following error messages:

- `[Error] Failed to list namespaces to get Running SHIR`
- `[Error] Failed to get configmap/ create job/ etc.`

Cause

When installing a self-hosted integration runtime, sufficient permissions to multiple Kubernetes resources are required.

Resolution

Regenerate the Kubernetes service-account-token with an Admin Role.

IRCTL connectivity error to Microsoft Purview service endpoint

When you attempt to register the Kubernetes supported self-hosted integration runtime, the IRCTL create command could return the following errors:

- `[Error] Failed to register SHIR with error: Post “https://[REGION].compute.governance.azure.com/purviewAccounts/[]/integrationruntimes/[]/registerselfhostedintegrationruntime: []”`

Cause

IRCTL can't connect to service backend. Such issue is usually caused by network settings or firewall.

Resolution

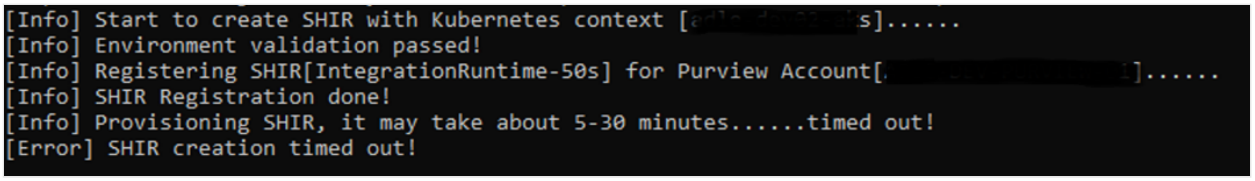
Review the network topology of the IRCTL host machine. Refer to these sections of the general integration runtime troubleshooting page: Firewall, DNSServer, SSL cert trusts, and http proxy.

Registration key isn't authorized

When you attempt to register the Kubernetes supported self-hosted integration runtime, the IRCTL create command could return the following errors:

- `[Error] failed to register SHIR with error: Request is not authorized.`

Cause



They had expired or was manually revoked.

Resolution

Regenerate the key from the integration runtime's page in the Microsoft Purview portal and register again.

Kubernetes self-hosted IR creation timed out error

When you attempt to register the Kubernetes supported self-hosted integration runtime, the IRCTL create command could run long until it eventually times out.

You can start with checking the status of Pods under the namespaces mentioned by the `irctl describe` command.

For example:

Bash

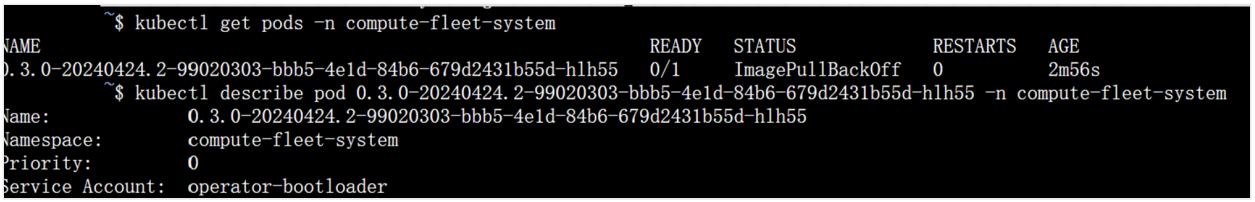
```
./irctl describe

K8s SHIR Name:shir-demo
Purview AccountName:   shirdemopurview
Installation ID:       00000000-0000-0000-0000-000000000000
Kubernetes Namespace:  shirdemopurview-shir-demo, compute-fleet-
system(control-plane)
K8s SHIR Version:      Unknown (Installation not completed)
Status:                Initializing
Healthiness:           Unhealthy

kubectl get pods --namespace shirdemopurview-shir-demo

NAME                                    READY   STATUS    RESTARTS   AGE
batch-defaultspec-4pbwx                 0/1     Pending   0          10m
batch-defaultspec-7t9bl                 0/1     Pending   0          10m
dynamic-config-provider-778c686fdc-9mkjb   0/1     Pending   0          10m
interactive-schemaprocess-bcrmf         0/1     Pending   0          10m
interactive-schemaprocess-fn66x         0/1     Pending   0          10m
logagent-ds-84jqn                       0/1     Pending   0          10m
logagent-ds-k7vw8                       0/1     Pending   0          10m
user-credential-proxy-579c899b64-d4q5v     0/1     Pending   0          10m
```

There are a couple potential causes, listed below:



- Connectivity with the Microsoft Purview service endpoint
- Kubernetes node configuration error

Cause - Connectivity with the Microsoft Purview service endpoint

Kubernetes can't connect to MCR (mcr.microsoft.com). This error is usually caused by network settings or a firewall.

If seeing the status as 'ImagePullBackOff', it means your Kubernetes cannot connect to MCR (mcr.microsoft.com) to download Pod images. This error is usually caused by

network settings or a firewall.

Resolution - Connectivity with the Microsoft Purview service endpoint

Review the network topology for your Kubernetes cluster. For example, for Azure Kubernetes you should check:

- DNS Resolution
- Egress outbound
- VNet/Firewall

> **Note**
>
> The troubleshooting steps required will be different for each Kubernetes provider. Deployment location and individual network details will vary between networks. You'll need to review connectivity through your organization's network.

Review the network topology of the IRCTL host machine. Refer to these sections of the general integration runtime troubleshooting page: Firewall, DNSServer, SSL cert trusts, and http proxy.

Cause - Kubernetes node configuration error

If the status of some of the Pods stuck in 'Pending', use the describe pod command to see details of the Pod.

For example:

```Bash
kubectl describe pod batch-defaultspec-4pbwx  --namespace shirdemopurview-shir-demo

Events:
  Type     Reason            Age                From               Message

  ----     ------            ----               ----               -------
```

```
  Warning  FailedScheduling  13m                default-scheduler  0/5 nodes
are available: 1 Too many pods. preemption: 0/5 nodes are available: 5 No
preemption victims found for incoming pod..
```

The Events from the describe command can tell the reason why the Pod is pending. The FailedScheduling error with detailed message shows that the total number of Pods is exceeded the maximum number of the Pod on a Node. A new Pod cannot be scheduled to the selected Node.

> ⓘ **Note**
>
> If there are no Events seen under the description, please try to delete the Pod manually by `kubectl delete pod` command and track the newly created one.

Resolution - Kubernetes node configuration error

Reserve 20 pod number for the kubernetes integration runtime to support normal utilization and upgrade scenarios.

Kubernetes connectivity error with Microsoft Purview service endpoint

When you attempt to register the Kubernetes supported self-hosted integration runtime, the IRCTRL create command could run long until it eventually times out. Or, after a successful installation, the self-hosted integration runtime status shows as unhealthy or offline in the Microsoft Purview portal.

Check the logs using this command: `kubectl logs [podName] -n compute-fleet-system`

You could see one of these errors:

- `“TraceMessage”:”HttpRequestFailed”, “Host”: “fleet.[REGION].compute.governance.azure.com”`
- `Exception":"System.Net.Http.HttpRequestException: Connection refused fleet.[REGION].compute.governance.azure.com:443`
- `System.AggregateException: Failed to acquire identity token from https://fleet. [REGION].compute.governance.azure.com:443`

Cause

Kubernetes can't connect to the service backend. This error is usually caused by network settings or a firewall.

Resolution

Review the network topology for your Kubernetes cluster. For example, for Azure Kubernetes you should check:

- DNS Resolution
- Egress outbound
- VNet/Firewall

> **Note**
>
> The troubleshooting steps required will be different for each Kubernetes provider. Deployment location and individual network details will vary between networks. You'll need to review connectivity through your organization's network.

Review the network topology of the IRCTL host machine. Refer to these sections of the general integration runtime troubleshooting page: Firewall, DNSServer, SSL cert trusts, and http proxy.

Unregister a runtime whose local resource is unavailable

If your local self-hosted integration runtime is deleted from the Kubernetes cluster by accident, you can't delete it using the irctl delete command and you can't install it to another Kubernetes cluster.

Cause

A self-hosted integration runtime can only be installed on one Kubernetes cluster. After it's registered, it can't be installed on another cluster before it's unregistered.

Resolution

1. Check the self-hosted integration local status. You should see that no running self-hosted integration runtime is found.

   ```
   Bash
   ```

```
$./irctl describe
```

2. Check the self-hosted integration runtime in the Microsoft Purview portal. You should see an **Offline** status. (Though, there's a 1 hour latency for token expiration.)
3. Select **Unregister installation** next to the status and confirm the operation.
4. After the unregistration is complete, you can see the status shows as **Not registered**.
5. Select the integration runtime and get the registration key.
6. Reinstall the integration runtime.

Next Steps

- Install and configure kubernetes supported integration runtime
- Choose the right integration runtime configuration
- IRCTL instructions and details

Learn about sensitivity labels in Data Map (preview)

07/16/2025

> **Important**
>
> Labeling in the Microsoft Purview Data Map is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

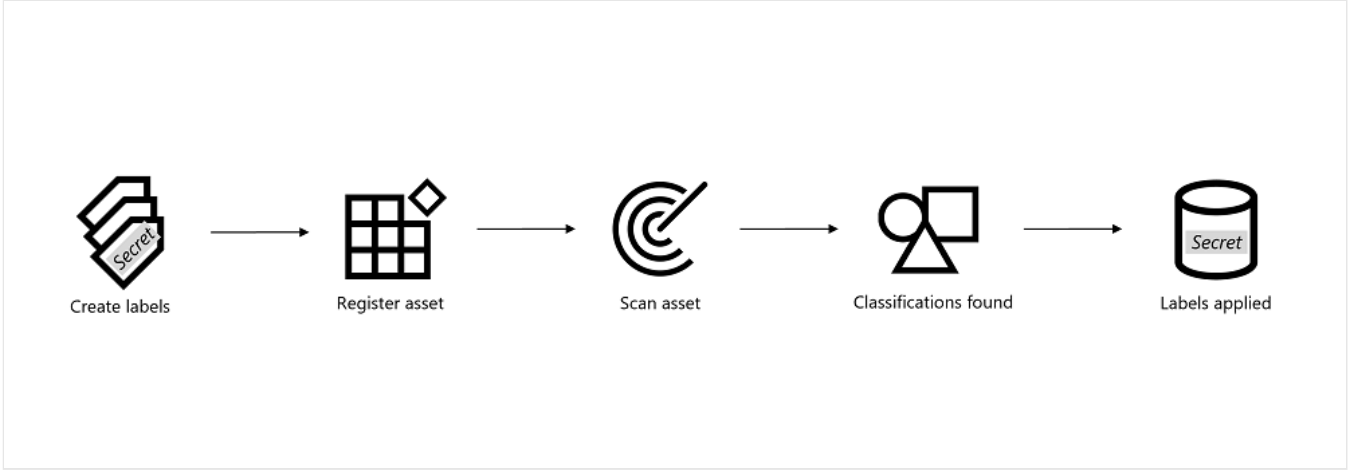
To get work done, people in your organization collaborate with others both inside and outside the organization. Data doesn't always stay in your cloud, and often roams everywhere, across devices, apps, and services. When your data roams, you still want it to be secure in a way that meets your organization's business and compliance policies.

Applying sensitivity labels to your content enables you to keep your data secure by stating how sensitive certain data is in your organization. It also abstracts the data itself, so you use labels to track the type of data, without exposing sensitive data on another platform.

For example, applying a sensitivity label 'highly confidential' to a document that contains social security number and credit card numbers helps you identify the sensitivity of the document without knowing the actual data in the document.

Benefits of labeling in Microsoft Purview

Microsoft Purview allows you to apply sensitivity labels to assets, enabling you to classify and protect your data.



- **Label travels with the data:** The sensitivity labels created in Microsoft Purview Information Protection can also be extended to the Microsoft Purview Data Map, SharePoint, Teams, Power BI, and SQL. When you apply a label on an office document and then scan it into the Microsoft Purview Data Map, the label will be applied to the data asset. While the label is applied to the actual file in Microsoft Purview Information Protection, it's only added as metadata in the Microsoft Purview map. While there are differences in how a label is applied to an asset across various services/applications, labels travel with the data and is recognized by all the services you extend it to.
- **Overview of your data estate:** Microsoft Purview provides insights into your data through precanned reports. When you scan data into the Microsoft Purview Data Map, we hydrate

the reports with information on what assets you have, scan history, classifications found in your data, labels applied, glossary terms, etc.

- **Automatic labeling:** Labels can be applied automatically based on sensitivity of the data. When an asset is scanned for sensitive data, autolabeling policies are used to decide which sensitivity label to apply. You can create autolabeling policies for sensitivity labels, defining which classification/sensitive information types when found will apply a label automatically.
- **Apply labels to files and database columns:** Labels can be applied to files in storage such as Azure Data Lake or Azure Files and to table columns in Azure SQL Database.

Sensitivity labels are tags that you can apply on assets to classify and protect your data. Learn more about sensitivity labels here.

How to apply labels to assets in the Microsoft Purview Data Map

Being able to apply labels to your asset in the data map requires you to perform the following steps:

1. Create new or apply existing sensitivity labels. You can apply any sensitivity label with label scope of **Files & other data assets** to Microsoft Purview assets.
2. Register and scan your asset in the Microsoft Purview Data Map.
3. Microsoft Purview applies **classifications**: When you schedule a scan on an asset, Microsoft Purview scans the type of data in your asset and applies classifications to it in the data map. Application of classifications is done automatically by Microsoft Purview, there's no action for you.
4. Create an auto-labeling policy for non-Microsoft 365 workloads: Create an auto-labeling policy scoped to All or specific assets within supported non-Microsoft 365 locations. Define the out of the box classifications that once detected in the next data scan will result in the automatic labeling of the selected sensitivity label.

> **Note**
>
> Autolabeling policies are conditions that you specify, stating when a particular label should be applied. When the data is next scanned Purview data map will check if these conditions are met to automatically assign the label to the data. If you don't see a supported data source show up in the auto-labeling policy for selection, verify that the data source was correctly registered and shows up in data map. The locations shown for auto-labeling policy scoping depends on what assets have already been registered.

Supported data sources

You can find the data sources that support labeling on the supported sources page.

Labeling for SQL databases

Microsoft also supports labeling for SQL database columns using the SQL data classification in SQL Server Management Studio (SSMS). While Microsoft Purview uses the global sensitivity labels, SSMS only uses labels defined locally.

Labeling in Microsoft Purview and labeling in SSMS are separate processes that don't currently interact with each other. Therefore, **labels applied in SSMS are not shown in Microsoft Purview, and vice versa**. We recommend Microsoft Purview for labeling SQL databases, because the labels can be applied globally, across multiple platforms.

For more information, see the SQL data discovery and classification documentation.

Apply sensitivity labels to your data in Data Map (preview)

07/16/2025

> **Important**
>
> Labeling in the Microsoft Purview Data Map is currently in preview and involves pay-as-you-go billing model. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Create new or apply existing sensitivity labels in Data Map

If you don't already have sensitivity labels, you need to create them and make them scoped for **Files & other data assets**. Existing sensitivity labels from Microsoft Purview Information Protection can also be modified with this scope to make them available to Data Map.

Step 1: Licensing requirements

Sensitivity labels are created and managed in the Microsoft Purview Information Protection. To create sensitivity labels for use through Microsoft Purview, you must have an active Microsoft 365 license that offers the benefit of automatically applying sensitivity labels and set up of pay as you go billing model.

To understand pay as you go billing by assets protected, see this pay-as-you-go billing model. For information about the specific licenses required, see this information on sensitivity labels. Microsoft 365 E5 trial licenses can be attained for your tenant by navigating here from your environment. For the full list of licenses, see the Sensitivity labels in Microsoft Purview FAQ. If you don't already have the required license, you can sign up for a trial of Microsoft 365 E5.

Step 2: Create or modify existing label to be scoped to "Files & other data assets" so they're available for Data Map

To create new sensitivity labels or modify existing labels, follow these instructions:

1. Sign in to the Microsoft Purview portal > **Information Protection** card > **Sensitivity labels**. If the **Information Protection** solution card isn't displayed, select **View all**

solutions and then select **Information Protection** from the **Data Security** section.

2. Select + **Create a label**.
3. Name the label. Then, under **Define the scope for this label**, select **Files & other data assets**.
4. Follow the rest of the prompts to configure the label settings. For more information about configuration options, see What sensitivity labels can do in the Microsoft 365 documentation.
5. To modify existing labels, browse to **Information Protection** > **Labels**, and select your label. Then select **Edit label** to open the **Edit sensitivity label** configuration, with all of the settings you defined when you created the label.
6. When you're done creating all of your labels, make sure to view your label order, and reorder them as needed.

   To change the order of a label, select **...** > **More actions** > **Move up** or **Move down.**

   For more information, see the documentation for label priority (order matters).

Step 3: Create auto-labeling policies scoped to non-Microsoft 365 workloads

To create an auto-labeling policy for non-Microsoft 365 workloads, follow these instructions:

1. Sign in to the Microsoft Purview portal. Go to **Information Protection** > **Policies** > **Auto-labeling policies**.
2. Select + **Create auto-labeling policy**.
3. At **Choose info you want this label applied to**, you can select any **non-enhanced** templated or Custom.
4. Name your auto-labeling policy and give it an optional description.
5. Select a sensitivity label with the **Files & other data assets** scope.
6. Keep the admin units set as **Full directory**, then select **Next**.
7. Select the non-Microsoft 365 locations you want to label. Select to label all assets within a location or specify which assets in each location you want to label. If you don't see a supported data source show up in the auto-labeling policy for selection, verify that the data source was correctly registered and shows up in Data Map. The locations displayed

for auto-labeling policy scoping depend on what assets have already been registered. Check the list of supported data sources for auto-labeling.

8. Define **Common rules** to specify the same auto-labeling conditions/rules across multiple selected non-Microsoft locations. Select **Advanced rules** to define different specific rules for each location.

9. Create a new rule and select Microsoft's prebuilt, out of the box classifiers as conditions for auto-labeling. Custom sensitive info types and advanced classifiers like named entities (All Full Names, All Physical Addresses), trainable classifiers, credentials, and Exact Data Match are **not** supported.

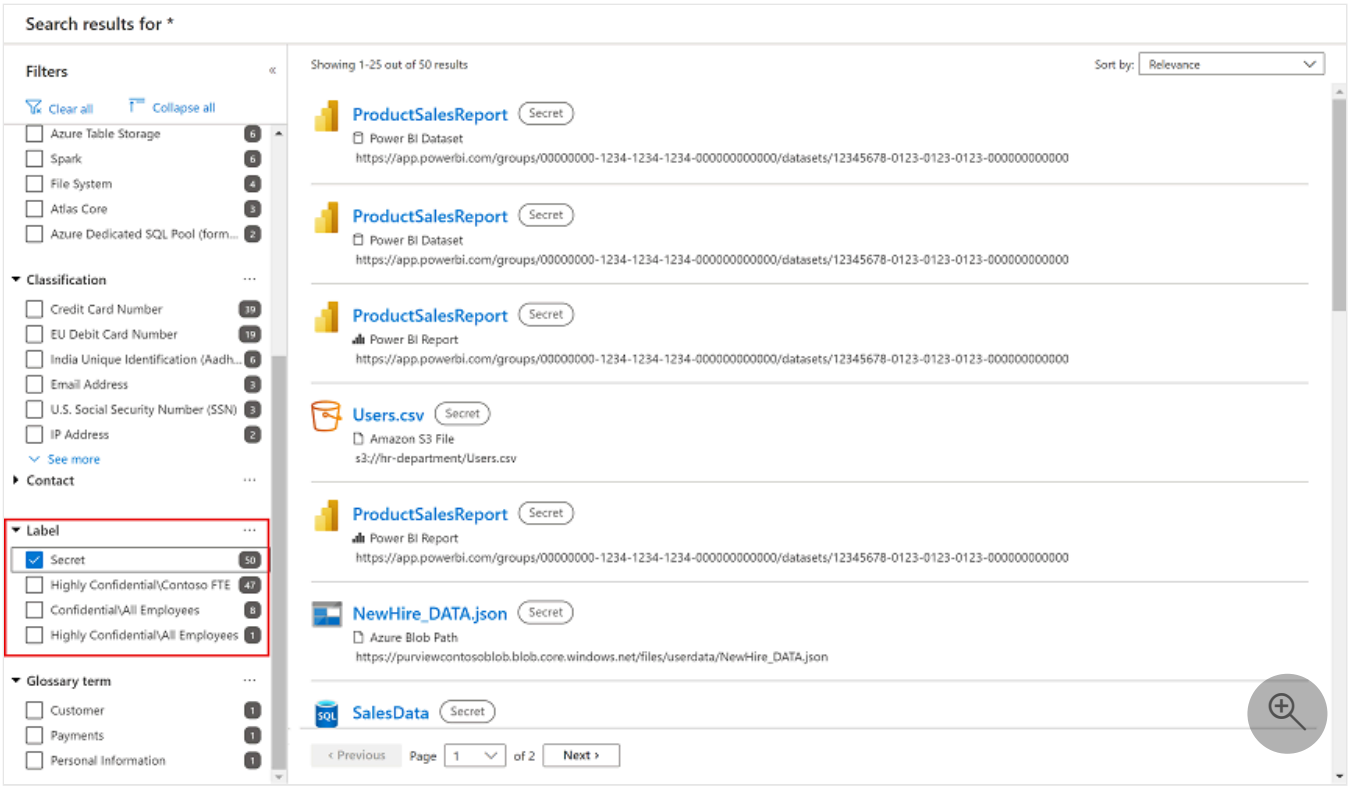
10. Select **Run policy in simulation mode**, and select the checkbox if you want to automatically turn on the policy after seven days.

    > ⓘ **Note**
    >
    > Microsoft Purview Data Map locations don't support simulation.

11. Review your selected configurations and select **Create policy**.

Step 4: Scan your data to apply sensitivity labels automatically

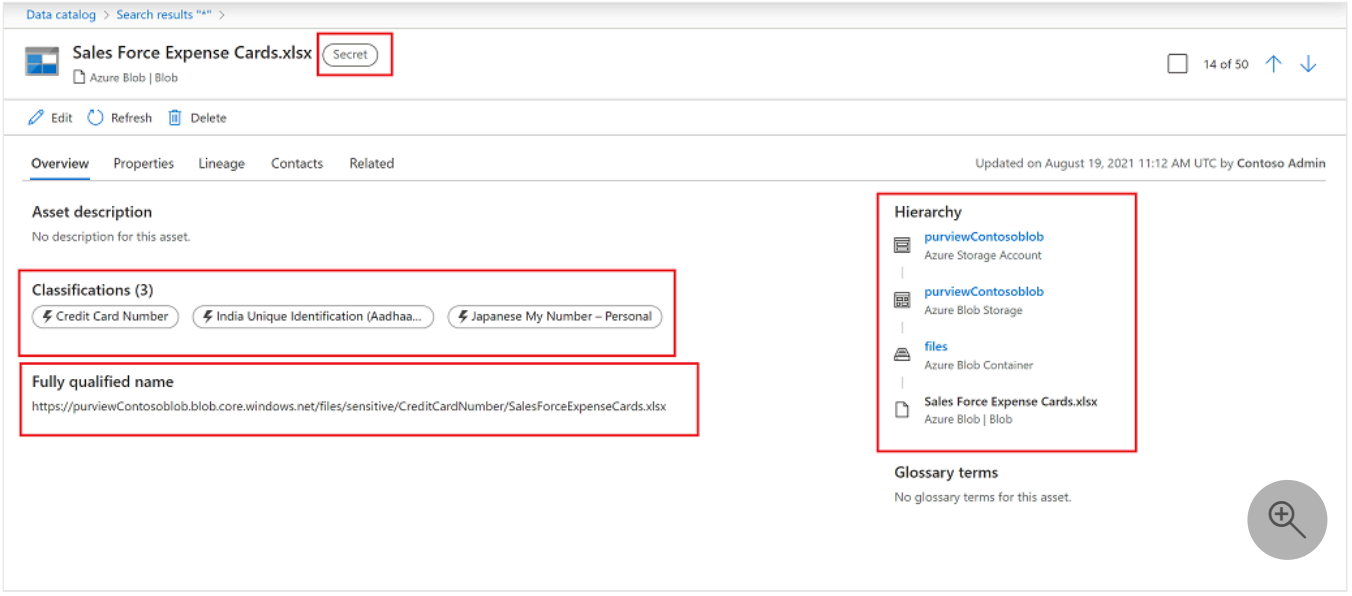
Wait 15 minutes after auto-labeling policy creation for policy to saturate. Scan your data in Data Map to automatically apply the labels you've created, based on the auto-labeling policy you've defined.



For more information on how to set up scans on various assets in Data Map, find links to each data source that connect to Data Map.

View labels on assets in the catalog

Once you've configured auto-labeling policies for the non-Microsoft 365 workloads in Microsoft Purview Information Protection and scanned your data in Data Map, labels are automatically applied to your assets in Data Map.



To view the labels applied to your assets in the Microsoft Purview catalog:

In Microsoft Purview Unified Catalog, use the **Label** filtering options to show assets with specific labels only. For example:

To view details of an asset including classifications found and label applied, select the asset in the results.

For example:

View Insight reports for the classifications and sensitivity labels

Find insights on your classified and labeled data in Data Map use the **Classification** and **Sensitivity labeling** reports.

Sensitivity label insights

Overview of Labeling in Microsoft Purview

Labeling Frequently Asked Questions

Sensitivity labels in Data Map FAQ (preview)

This article lists frequently asked questions about sensitivity labeling in the Microsoft Purview Data Map, with their answers and links to more information.

> **Important**
>
> Labeling in the Microsoft Purview Data Map is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include other legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Licensing and setup

What are the licensing requirements to apply sensitivity labels in Microsoft Purview Data Map?

To use sensitivity labels in the Microsoft Purview Data Map, you'll need at least one Microsoft 365 license/account within the same Microsoft Entra tenant as your Microsoft Purview account.

The following Microsoft 365 licenses are required to automatically apply sensitivity labels to your assets in Microsoft 365 and the Microsoft Purview Data Map:

- Microsoft 365 E5/A5/G5
- Microsoft 365 E5/A5/G5 Compliance
- Microsoft 365 E5/A5/G5 Information Protection, and Governance
- Office 365 E5, Enterprise Mobility + Security E5/A5/G5, and AIP Plan 2

For more information, see the Microsoft Purview service description.

To use auto-labeling and protection policies for non-Microsoft 365 data sources, 1 Microsoft 365 E5 licenses and set up of pay as you go billing model will be required. To understand pay as you go billing by assets protected, see the pay-as-you-go billing model. For information about the specific licenses required, see this information on sensitivity labels. Microsoft 365 E5 trial licenses can be attained for your tenant by navigating here from your environment.

How are sensitivity labels applied to non-Microsoft 365 locations?

You can create and apply autolabeling policies to detect Microsoft out-of-the-box classifiers to specific or all data assets that are registered in Data Map for supported locations.

- Sensitivity labels are applied only to the asset metadata in Data Map and aren't applied to the actual files and database columns. These sensitivity labels don't modify your files and databases in any way.

Classifications vs sensitivity labels

What is the difference between classifications and sensitivity labels?

The following table lists the differences between classifications and sensitivity labels:

Expand table

Comparison	Classifications	Sensitivity labels
Definition	Classifications are regular expressions or patterns that can help identify data types that exist inside an asset.	Sensitivity labels are tags that allow organizations to categorize data based on business impact, while abstracting the type of data from the user.
Examples	Social Security Number, Drive license number, Bank account number, etc.	Highly confidential, Confidential, General, Public, etc.
Scope	The scope of classifications applied to an asset is limited to the Microsoft Purview Data Map where the classifications were applied. If the data moves to an asset managed by another Microsoft Purview Data Map, classifications applied in the original location aren't visible in the new location.	Sensitivity labels applied on an asset travel with the data no matter where the data goes. For example, this means that sensitivity labels applied to a file in Microsoft Purview Information Protection are automatically visible and remain applied to the file, even if it moves to Azure, SharePoint, or Teams.

Comparison	Classifications	Sensitivity labels
Scan Process	Scanning an asset in the Microsoft Purview Data Map looks for both system-defined and user-defined (custom) classifications in your data. If found, classifications are added in the Microsoft Purview map for the scanned asset.	If you have an auto-labeling policy for Azure Storage or Azure SQL, scanning an asset in the Microsoft Purview Data Map applies the labels to assets in the catalog based on the out-of-the-box classifications found in the scan and defined in the auto-labeling policy.
Authoring environment	Custom classifications and classification rules can be created in the Microsoft Purview Data Map. You can also create custom classifications in Microsoft Purview Information Protection. However, we don't yet support importing them to the Microsoft Purview Data Map.	Manage auto-labeling of sensitivity labels in Microsoft Purview using the Microsoft Purview Information Protection.
Assignment Limits	Assets can have no classifications, or one or more classifications assigned.	Each asset/ database column can have only one sensitivity label.
Asset application workflow	You can use Microsoft Purview Unified Catalog to manually add or modify classifications that are assigned to an asset.	In the Microsoft Purview Data Map, sensitivity labels are automatically assigned to assets based on classifications found. Applying labels manually in the Microsoft Purview Data Map isn't currently supported.
More Information	Learn more about classifications.	Learn more about sensitivity labels.

Are classifications and Sensitive Information Types (SITs) the same thing?

While classifications and SITs are fundamentally the same things, classifications are a Microsoft Purview Data Map concept and SITs are a Microsoft Purview Information Protection concept. Both classifications and SITs are used by their respective services to identify the type of data found in an asset.

Labeling capabilities in the Microsoft Purview Data Map

Which data sources can I apply sensitivity labels to in the Microsoft Purview Data Map?

You can apply sensitivity labels to all the data sources listed under Supported data sources for sensitivity labels in the Microsoft Purview Data Map.

Which file types can I apply sensitivity labels to in the Microsoft Purview Data Map?

You can apply sensitivity labels to all Microsoft Purview Data Map supported file types.

Can I use my custom Sensitive Information Type (SIT) in Microsoft Purview Information Protection for schematized data assets?

No, custom sensitive information types aren't supported in the Microsoft Purview Data Map at this time. The Microsoft Purview Data Map currently only supports Microsoft Purview Information Protection built-in sensitive information types.

Can I use the advanced classifiers from Microsoft Purview Information Protection in the Microsoft Purview Data Map?

No, advanced classifiers aren't currently supported in the Microsoft Purview Data Map and won't appear.

Can autolabeling for Purview Data Map apply to assets that might include credential content?

Data Map currently doesn't support scanning for credentials. When Data Map supports scanning for credentials, you should be able to apply labels based on credentials found.

Can I manually label an asset, or manually modify or remove a label in the Microsoft Purview Data Map?

The Microsoft Purview Data Map supports auto-labeling only. Labels are automatically applied to assets in the data map based on autolabeling policy configuration.

The Data Map doesn't currently support manually applying a label, modifying, or removing a label from an asset. However, when you apply a label on an office document and then scan it into Data Map, the label will be applied to the data asset. While the label is applied to the actual file in Microsoft Purview Information Protection, it's only added as metadata in Data Map. While there are differences in how a label is applied to an asset across various services/applications, labels travel with the data and are recognized by all the services you extend it to.

Can I apply encryption and/or content marking to files in the Microsoft Purview Data Map, as I can for Office documents and emails?

No, although the sensitivity label might be configured for these protection actions, we don't currently support encryption and content marking for files in the Microsoft Purview Data Map. We only support protection actions that are configured in protection policies.

Does the Microsoft Purview Data Map support data loss prevention?

No, Data Map doesn't currently provide data loss prevention (DLP) capabilities. Data Loss Prevention is currently supported only for Microsoft 365 apps and services, including Fabric.

Access and roles

Where can I manage my autolabeling policies for labeling beyond Microsoft 365?

Sensitivity labels and autolabeling policies are managed in Microsoft Purview Information Protection. For more information, see How to create sensitivity labels in Microsoft Purview Information Protection.

Who can manage sensitivity labels?

The following built-in admin roles include permissions to manage sensitivity labels (most to least permissive):

- Global Administrator
- Compliance Administrator
- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

For more information, see Permissions required to create and manage sensitivity labels. After you have compliance and global administrators configured, those administrators can give access to individual users.

> **Note**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should be limited to emergency scenarios when you can't use an existing role.

Who can search and browse assets with sensitivity labels in Microsoft Purview Unified Catalog?

All users with at least data reader access to the Microsoft Purview Data Map have permissions to search and browse assets with sensitivity labels in Unified Catalog.

Who can view the sensitivity label insights report in Microsoft Purview Data Estate Insights?

All users with the insights reader role and at least data reader permissions on applicable collections will have permissions to view sensitivity label insights reports in Microsoft Purview Data Estate Insights.

Technical details

Does the Microsoft Purview Data Map scan an entire asset when applying autolabeling policies to the database columns?

The Microsoft Purview scanner samples the data. For more information, see sampling data for classification and autolabeling.

If there are multiple sensitivity labels that meet the classification criteria, which label is applied?

Sensitivity labels have a priority 'order' and the Microsoft Purview Data Map uses this order to assign labels. If there are multiple labels meeting the classification criteria, the Microsoft Purview Data Map selects the label with the highest order.

For more information, see Label priority order matters.

SQL data discovery and classification

Why does Microsoft support two classification experiences for SQL databases, Microsoft Purview and SQL data discovery and classification?

Microsoft Purview provides a classification and labeling experience for all your Azure assets including SQL databases. Microsoft Purview is intended for organizations that want to manage their entire data estate in a single place with the power of classification, labeling, alerting, and more. Microsoft Purview uses sensitivity labels, which have a global scope and travel with your data no matter where it moves to or what it transforms into.

In contrast, SQL data discovery and classification is built into SQL. SQL data discovery and classification existed before Microsoft Purview as a way to provide basic capabilities for discovering, classifying, labeling, and reporting the sensitive data in your SQL databases. SQL data discovery and classification use local labels that don't have a global scope and don't support sensitivity labels.

I applied labels in SQL data discovery and classification. Why are these labels not showing up on my asset in Microsoft Purview?

SQL classification uses local labels, while Microsoft Purview uses sensitivity labels. Labels applied in the SQL classification experience won't show up in Microsoft Purview. For more information, see Labeling for SQL databases.

For more information, see:

- How to automatically label your content
- Sensitivity label insights
- Classification insights

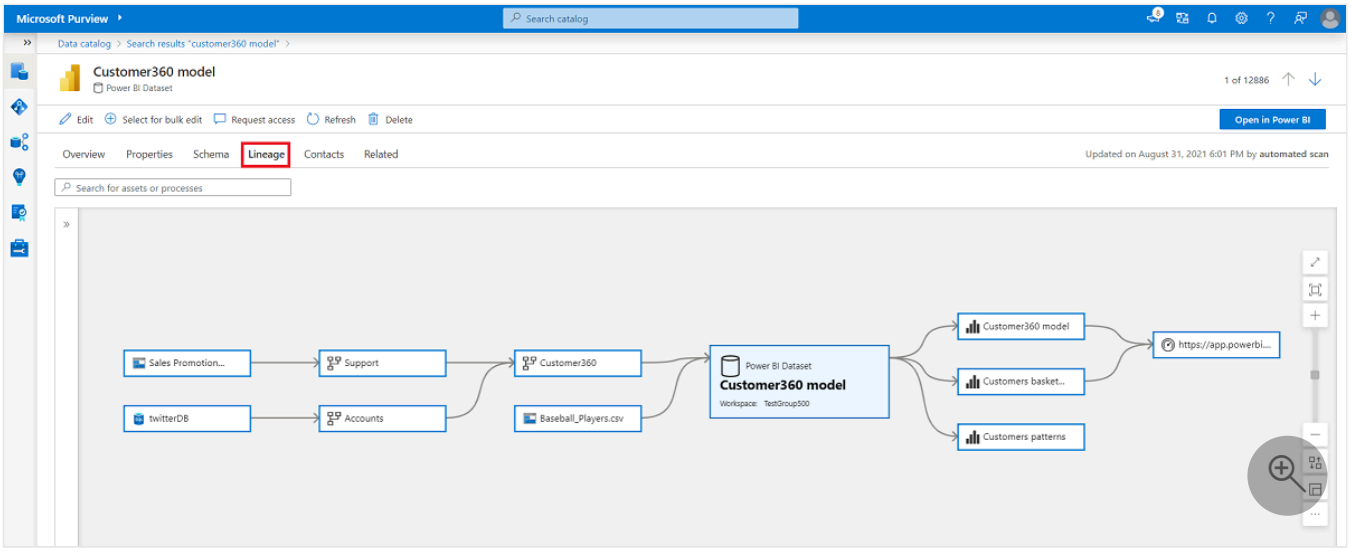
Last updated on 06/01/2026

Data lineage in classic Data Catalog

07/18/2025

This article provides an overview of data lineage in the classic Microsoft Purview Data Catalog. It also details how data systems can integrate with the catalog to capture lineage of data. Microsoft Purview can capture lineage for data in different parts of your organization's data estate, and at different levels of preparation including:

- Raw data staged from various platforms
- Transformed and prepared data
- Data used by visualization platforms



For data lineage in the Unified Catalog, see how to view data asset details and lineage information.

Use cases

Data lineage is broadly understood as the lifecycle that spans the data's origin, and where it moves over time across the data estate. It's used for different kinds of backwards-looking scenarios such as troubleshooting, tracing root cause in data pipelines and debugging. Lineage is also used for data quality analysis, compliance and "what if" scenarios often referred to as impact analysis. Lineage is represented visually to show data moving from source to destination including how the data was transformed. Given the complexity of most enterprise data environments, these views can be hard to understand without doing some consolidation or masking of peripheral data points.

Lineage experience in the classic Data Catalog

The catalog connects with other data processing, storage, and analytics systems to extract lineage information. The information is combined to represent a generic, scenario-specific lineage experience in the catalog.

Your data estate might include systems doing data extraction, transformation (ETL/ELT systems), analytics, and visualization systems. Each of the systems captures rich static and operational metadata that describes the state and quality of the data within the systems boundary. The goal of lineage in a data catalog is to extract the movement, transformation, and operational metadata from each data system at the lowest grain possible.

The following example is a typical use case of data moving across multiple systems, where a catalog would connect to each of the systems for lineage.

- Data Factory copies data from on-prem/raw zone to a landing zone in the cloud.
- Data processing systems like Synapse, Databricks would process and transform data from landing zone to Curated zone using notebooks.
- Further processing of data into analytical models for optimal query performance and aggregation.
- Data visualization systems will consume the datasets and process through their meta model to create a BI Dashboard, ML experiments and so on.

Lineage granularity

The following section covers the details about the granularity of which the lineage information is gathered by Microsoft Purview. This granularity can vary based on the data systems supported in Microsoft Purview.

Entity level lineage: Sources > Process > Targets

- Lineage is represented as a graph, typically it contains source and target entities in Data storage systems that are connected by a process invoked by a compute system.
- Data systems connect to the catalog to generate and report a unique object referencing the physical object of the underlying data system for example: SQL Stored procedure,

notebooks, and so on.
- High fidelity lineage with other metadata like ownership is captured to show the lineage in a human readable format for source & target entities. for example: lineage at a hive table level instead of partitions or file level.

Column or attribute level lineage

Identify attributes of a source entity that is used to create or derive attributes in the target entity. The name of the source attribute could be retained or renamed in a target. Systems like Azure Data Factory (ADF) can do a one-one copy from on-premises environment to the cloud. For example: `Table1/ColumnA -> Table2/ColumnA`.

Process execution status

To support root cause analysis and data quality scenarios, we capture the execution status of the jobs in data processing systems. This requirement has nothing to do with replacing the monitoring capabilities of other data processing systems, neither the goal is to replace them.

Summary

Lineage is a critical feature to support quality, trust, and audit scenarios. The goal of a data catalog is to build a robust framework where all the data systems within your environment can naturally connect and report lineage. Once the metadata is available, the catalog can bring together the metadata provided by data systems to power data governance use cases.

Next steps

- Quickstart: Create a Microsoft Purview account in the Azure portal
- Quickstart: Create a Microsoft Purview account using Azure PowerShell/Azure CLI
- Use the Microsoft Purview governance portal

Data lineage user guide for classic Data Catalog

07/18/2025

This article provides an overview of the data lineage features in the classic Microsoft Purview Data Catalog.

To view data lineage in the Unified Catalog, you need to first search for a data product, then view data asset details.

Background

One of the platform features of Microsoft Purview is the ability to show the lineage between datasets created by data processes. Systems like Data Factory, Data Share, and Power BI capture the lineage of data as it moves. Custom lineage reporting is also supported via Atlas hooks and REST API.

Lineage collection

Metadata collected in Microsoft Purview from enterprise data systems are stitched across to show an end to end data lineage. Data systems that collect lineage into Microsoft Purview are broadly categorized into following three types:

- Data processing systems
- Data storage systems
- Data analytics and reporting systems

Each system supports a different level of lineage scope. Check the sections below, or your system's individual lineage article, to confirm the scope of lineage currently available.

Known limitations

- Database Views used as source of process activity(Azure Data Factory, Synapse Pipelines, Azure SQL Database, Azure Data Share) are currently captured as Database Table objects in Microsoft Purview. If the Database is also scanned, the View assets are discovered separately in Microsoft Purview. In this scenario, two assets with same name captured in Microsoft Purview, one as a Table with data lineage and another as a View.
- If a stored procedure contains drop or create statements, they are not currently captured in lineage.

Data processing systems

Data integration and ETL tools can push lineage into Microsoft Purview at execution time. Tools such as Data Factory, Data Share, Synapse, Azure Databricks, and so on, belong to this category of data processing systems. The data processing systems reference datasets as source from different databases and storage solutions to create target datasets. The list of data processing systems currently integrated with Microsoft Purview for lineage are listed in below table.

Expand table

Data processing system	Supported scope
Airflow	Airflow lineage
Azure Data Share	Share snapshot
Azure Data Factory	Copy activity Data flow activity Execute SSIS package activity
Azure SQL Database (Preview)	Lineage extraction for stored procedure executions
Azure Synapse Analytics	Copy activity Data flow activity

Data storage systems

Databases & storage solutions such as Oracle, Teradata, and SAP have query engines to transform data using scripting language. Data lineage information from views/stored procedures/etc is collected into Microsoft Purview and stitched with lineage from other systems. Lineage is supported for the following data sources via Microsoft Purview data scan. Learn more about the supported lineage scenarios from the respective article.

Expand table

Category	Data source
Azure	Azure Databricks
Database	Cassandra
	Db2
	Google BigQuery
	Hive Metastore Database

Category	Data source
	MySQL
	Oracle
	PostgreSQL
	Snowflake
	Teradata
Services and apps	Erwin
	Looker
	SAP ECC
	SAP S/4HANA

Data analytics and reporting systems

Data analytics and reporting systems like Azure Machine Learning and Power BI report lineage into Microsoft Purview. These systems will use the datasets from storage systems and process through their meta model to create BI Dashboards, ML experiments and so on.

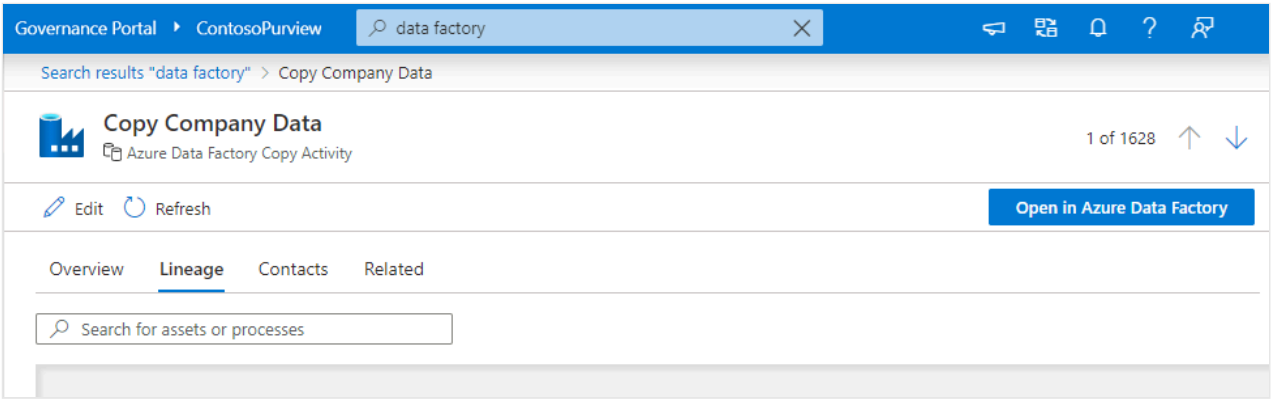
Expand table

Data analytics & reporting system	Supported scope
Power BI	Datasets, Dataflows, Reports & Dashboards

Get started with lineage

Lineage in Microsoft Purview includes datasets and processes. Datasets are also referred to as nodes while processes can be also called edges:

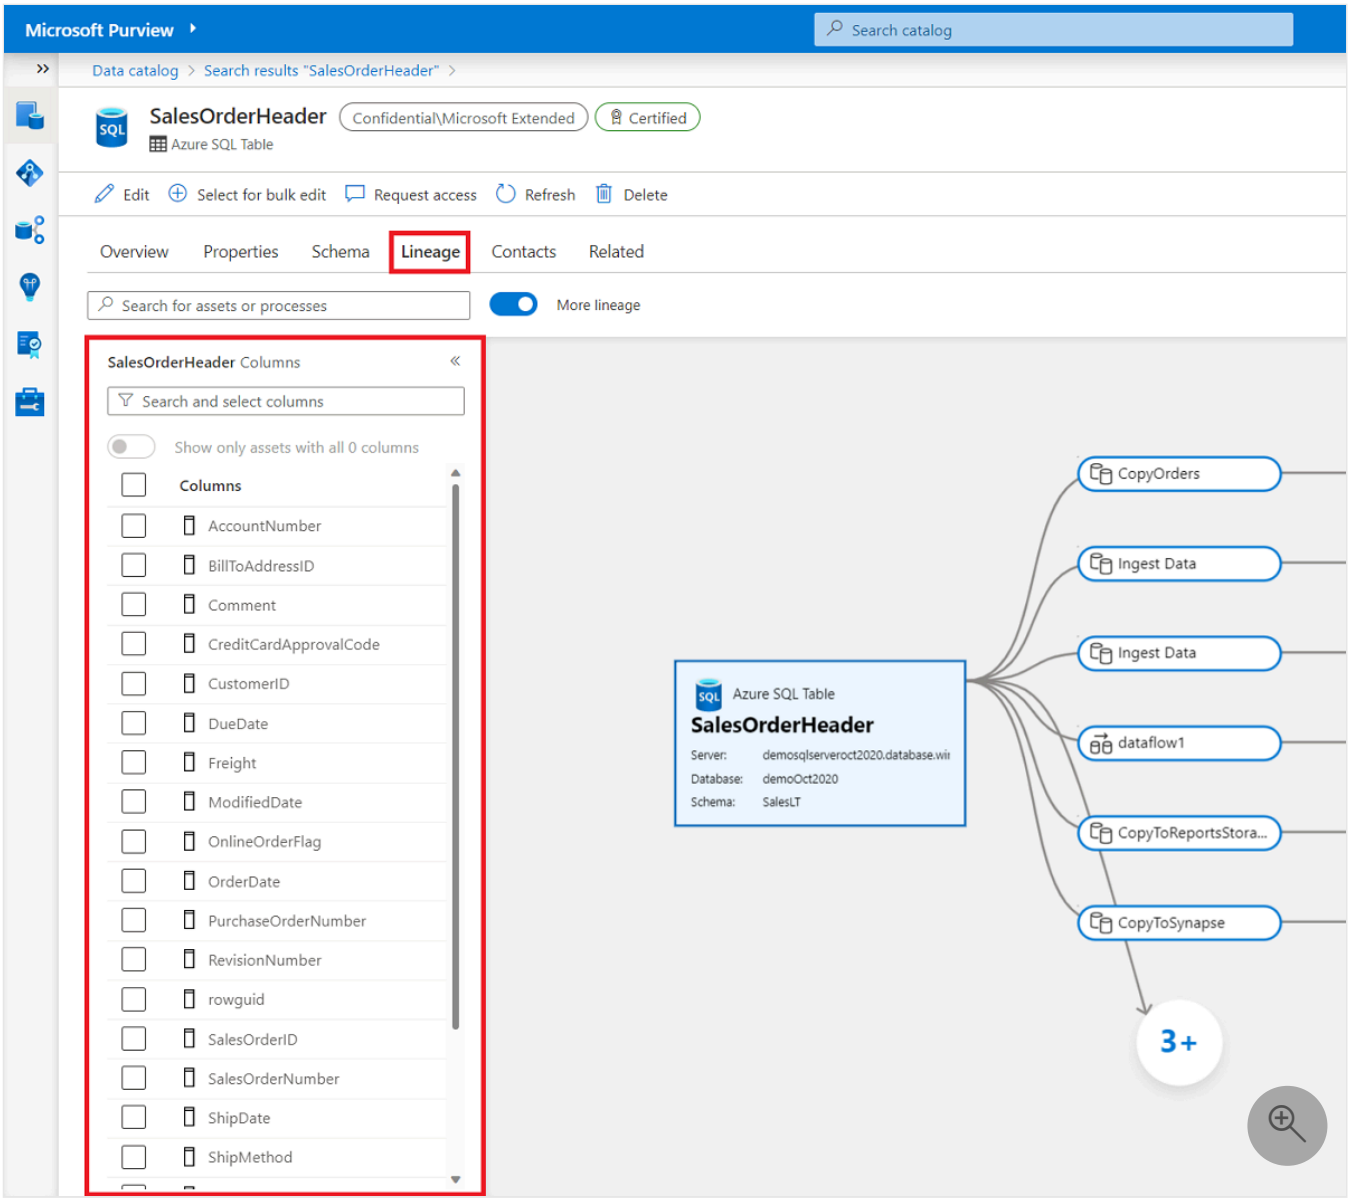
- **Dataset (Node)**: A dataset (structured or unstructured) provided as an input to a process. For example, a SQL Table, Azure blob, and files (such as .csv and .xml), are all considered datasets. In the lineage section of Microsoft Purview, datasets are represented by rectangular boxes.
- **Process (Edge)**: An activity or transformation performed on a dataset is called a process. For example, ADF Copy activity, Data Share snapshot and so on. In the lineage section of Microsoft Purview, processes are represented by round-edged boxes.



To access lineage information for an asset in Microsoft Purview, follow the steps:

1. Open the classic Microsoft Purview governance portal by:

    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

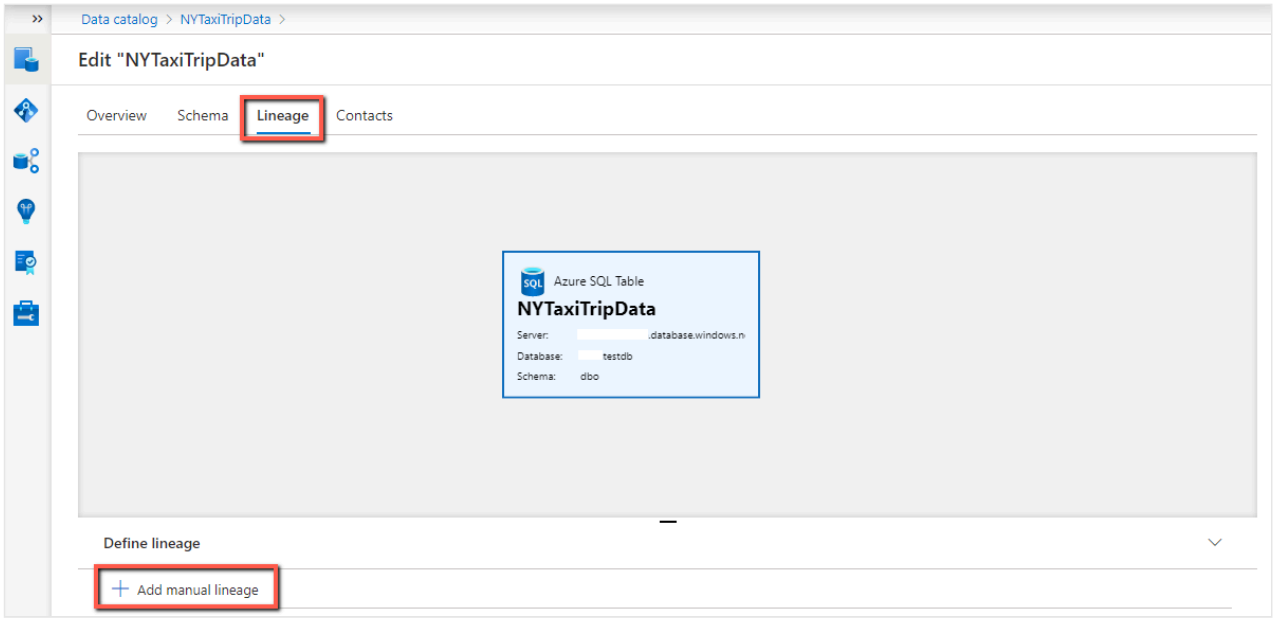


2. On the Microsoft Purview governance portal **Home** page, search for a dataset name or the process name such as ADF Copy or Data Flow activity. And then press Enter.

3. From the search results, select the asset and select its **Lineage** tab.

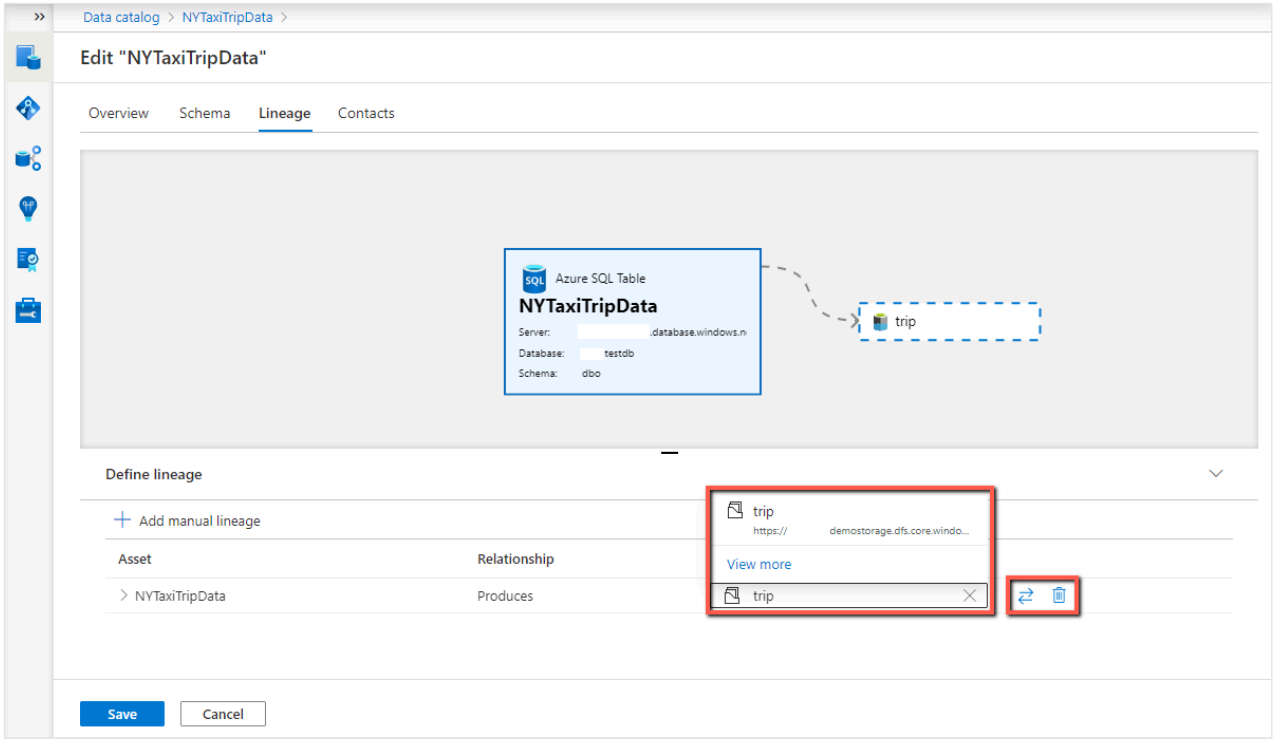
Asset-level lineage

Microsoft Purview supports asset level lineage for the datasets and processes. To see the asset level lineage go to the **Lineage** tab of the current asset in the catalog. Select the current dataset asset node. By default the list of columns belonging to the data appears in the left pane.



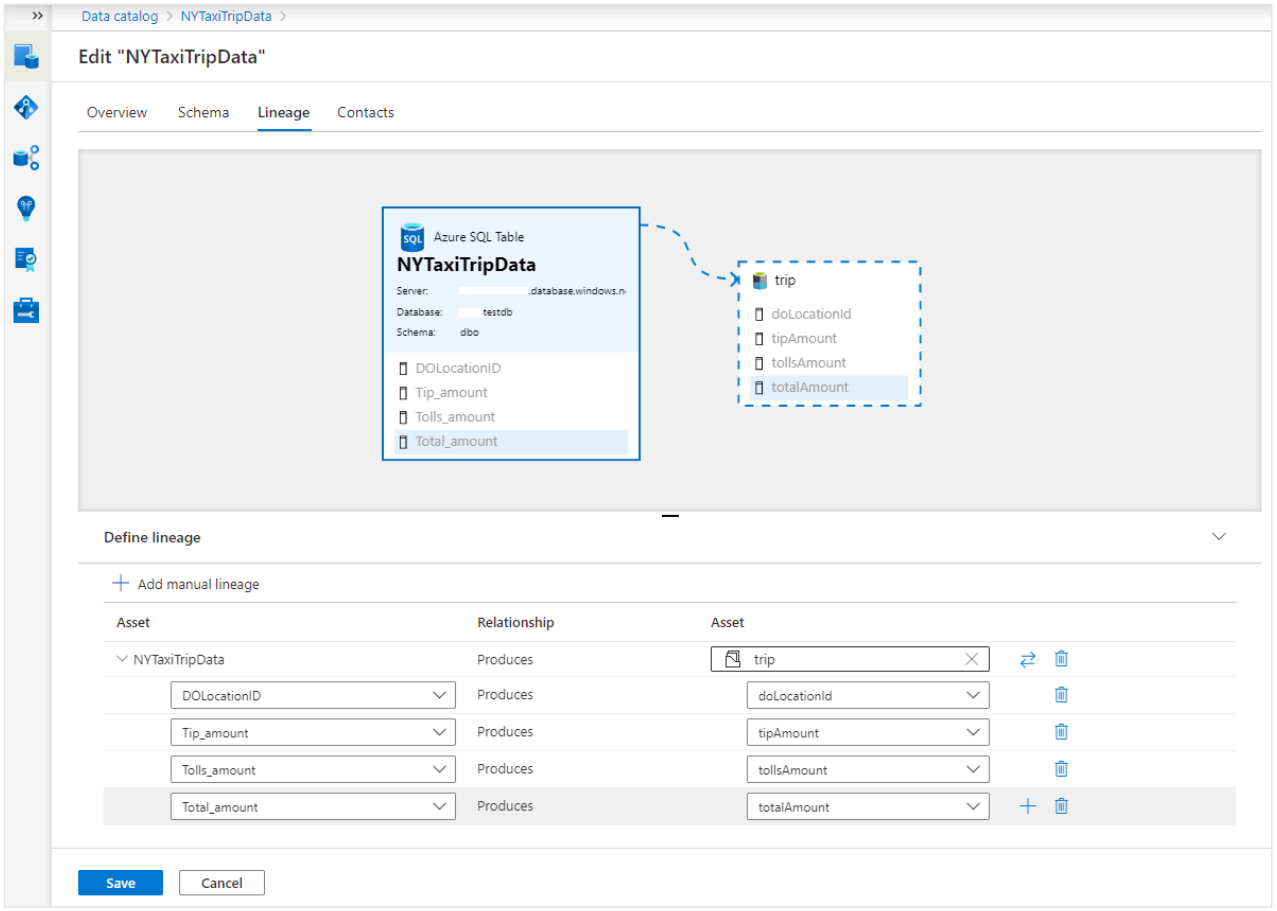
Manual lineage

Data lineage in Microsoft Purview is automated for many assets in on-premises, multicloud, and SaaS environments. While we continue to add more automated sources, manual lineage allows you to document lineage metadata for sources where automation isn't yet supported, without using any code.



To add manual lineage for any of your assets, follow these steps:

1. Search for your asset in the classic Data Catalog and select it to view details.

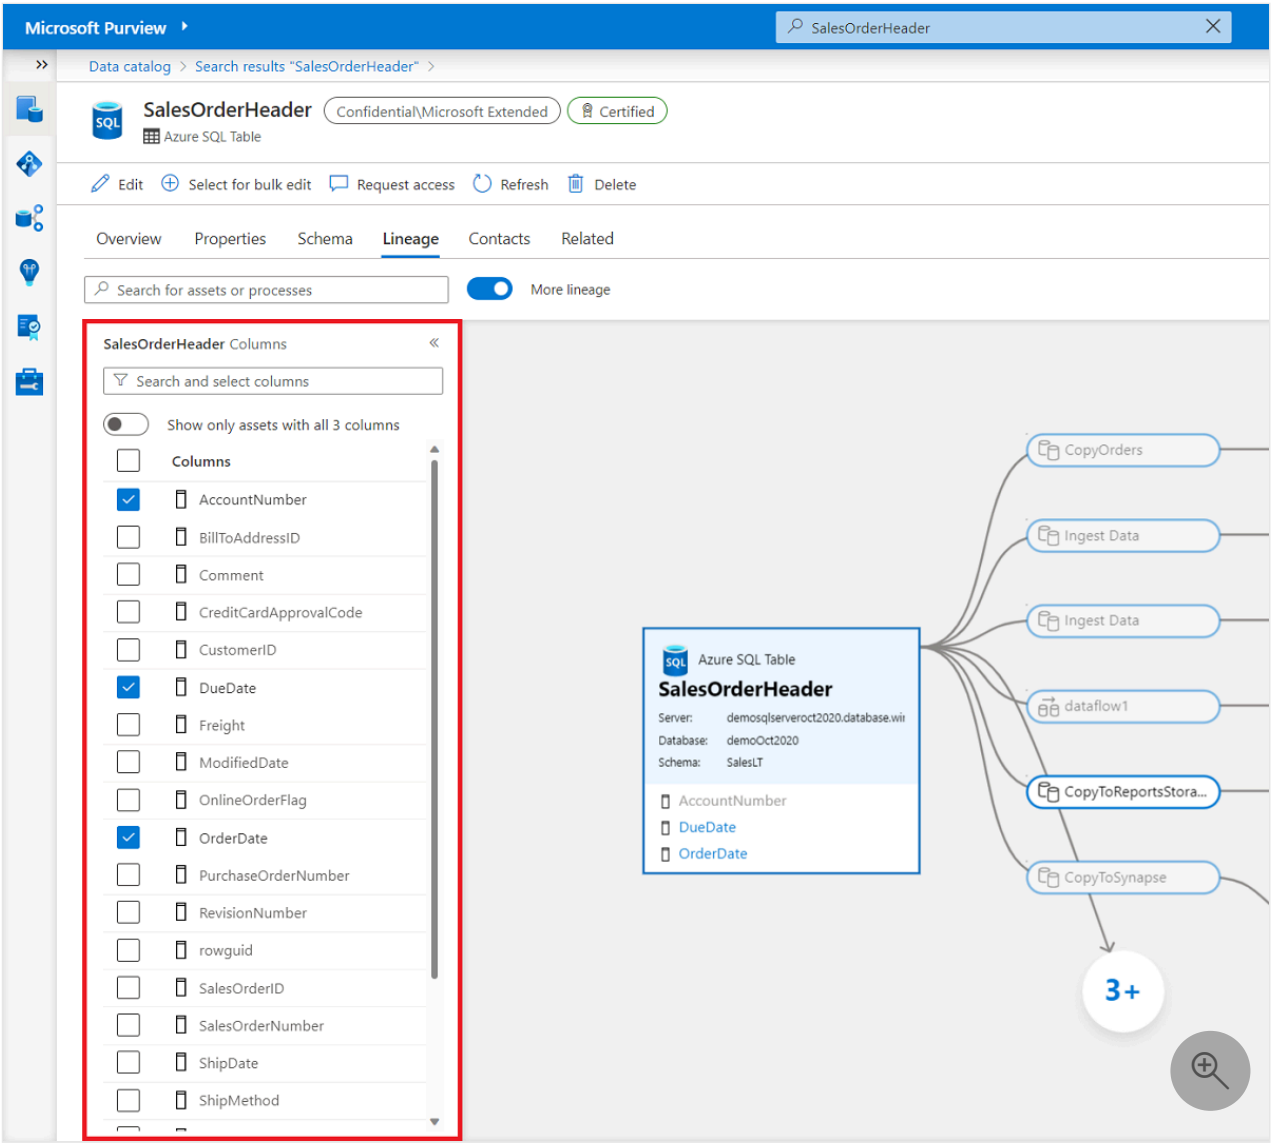


2. Select **Edit**, navigate to the **Lineage** tab, and select **Add manual lineage** in the bottom panel.

3. To configure the asset lineage:
   a. Select the asset dropdown to find the asset from the suggested list or **View more** to search the full catalog. Select the asset you'd like to link.
   b. Select the swap icon to configure the relationship direction as **Produces** (for downstream lineage) or **Consumes** (for upstream lineage).
   c. If you want to delete a lineage, select the trash can icon.

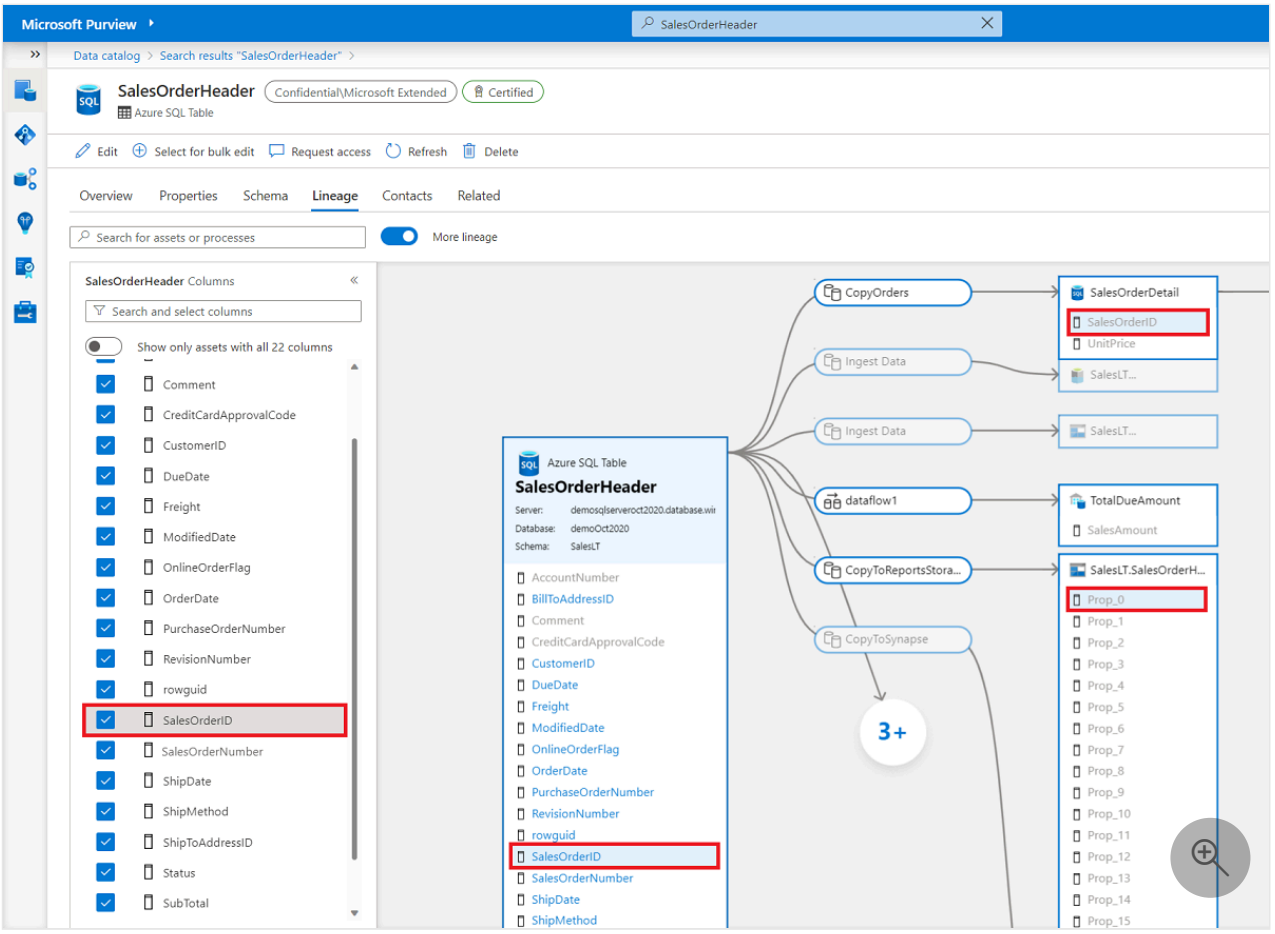
4. When you add lineage between two data assets, you can additionally configure the column level lineage. Select the expand icon at the beginning of the row, select the upstream and downstream columns from the corresponding dropdown lists to configure the column mapping. Select the plus icon to add more column lineage; select the trash bin icon to delete existing ones.

5. You can add more asset level lineage by selecting the **Add manual lineage** button again. When you're finished, select the **Save** button to save your lineage and exit edit mode.



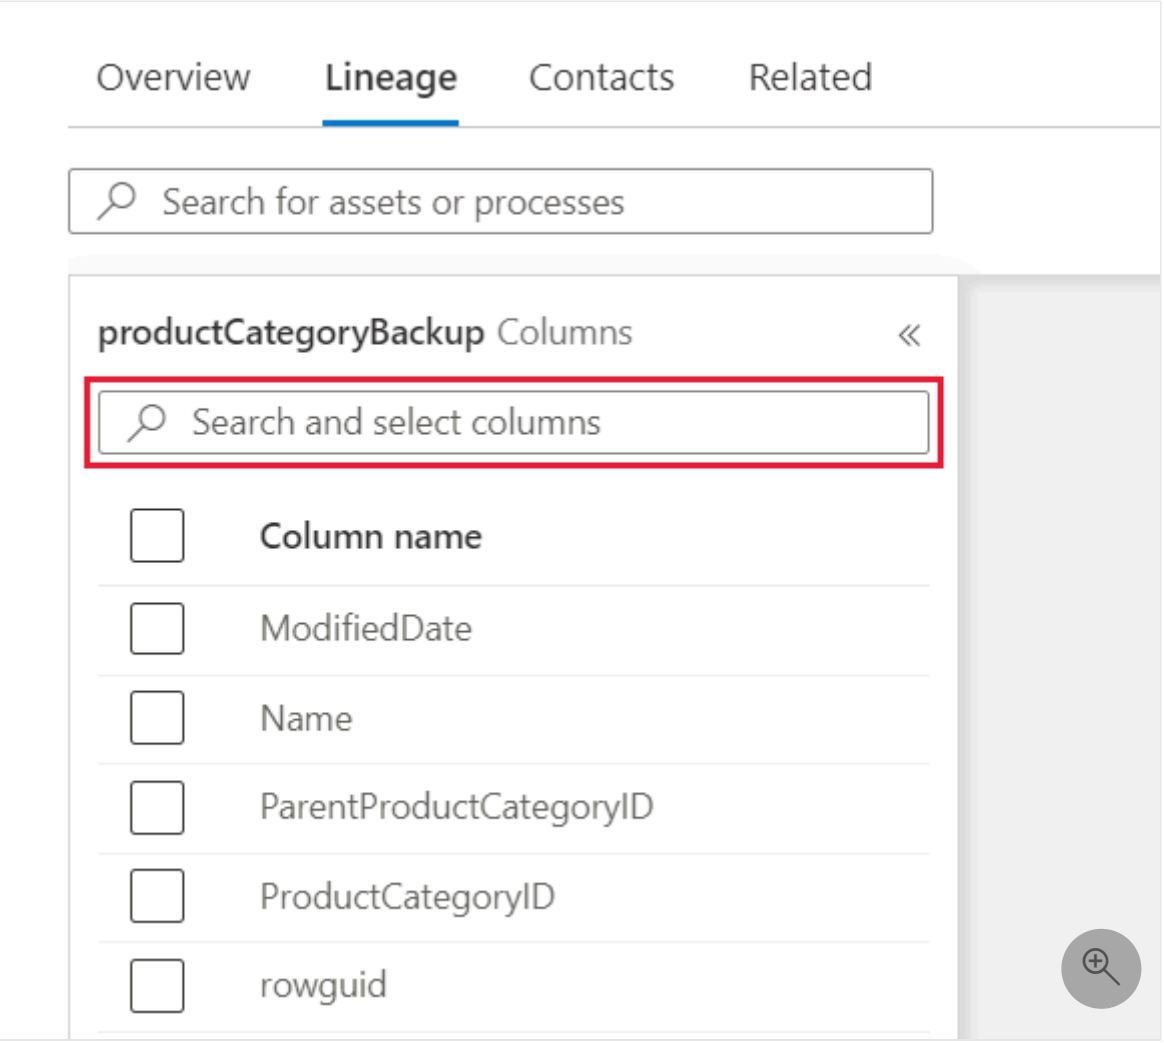
Known limitations of manual lineage

- Current asset picker experience allows selecting only one asset at a time.
- Column level manual lineage is currently supported for lineage between two data assets, while not supported when process asset is involved in-between.
- Data curation access required for both source and target assets.
- These asset types don't currently allow manual lineage because they support automated lineage:
  - Azure Data Factory
  - Synapse pipelines
  - Power BI datasets
  - Teradata stored procedure
  - Azure SQL stored procedure

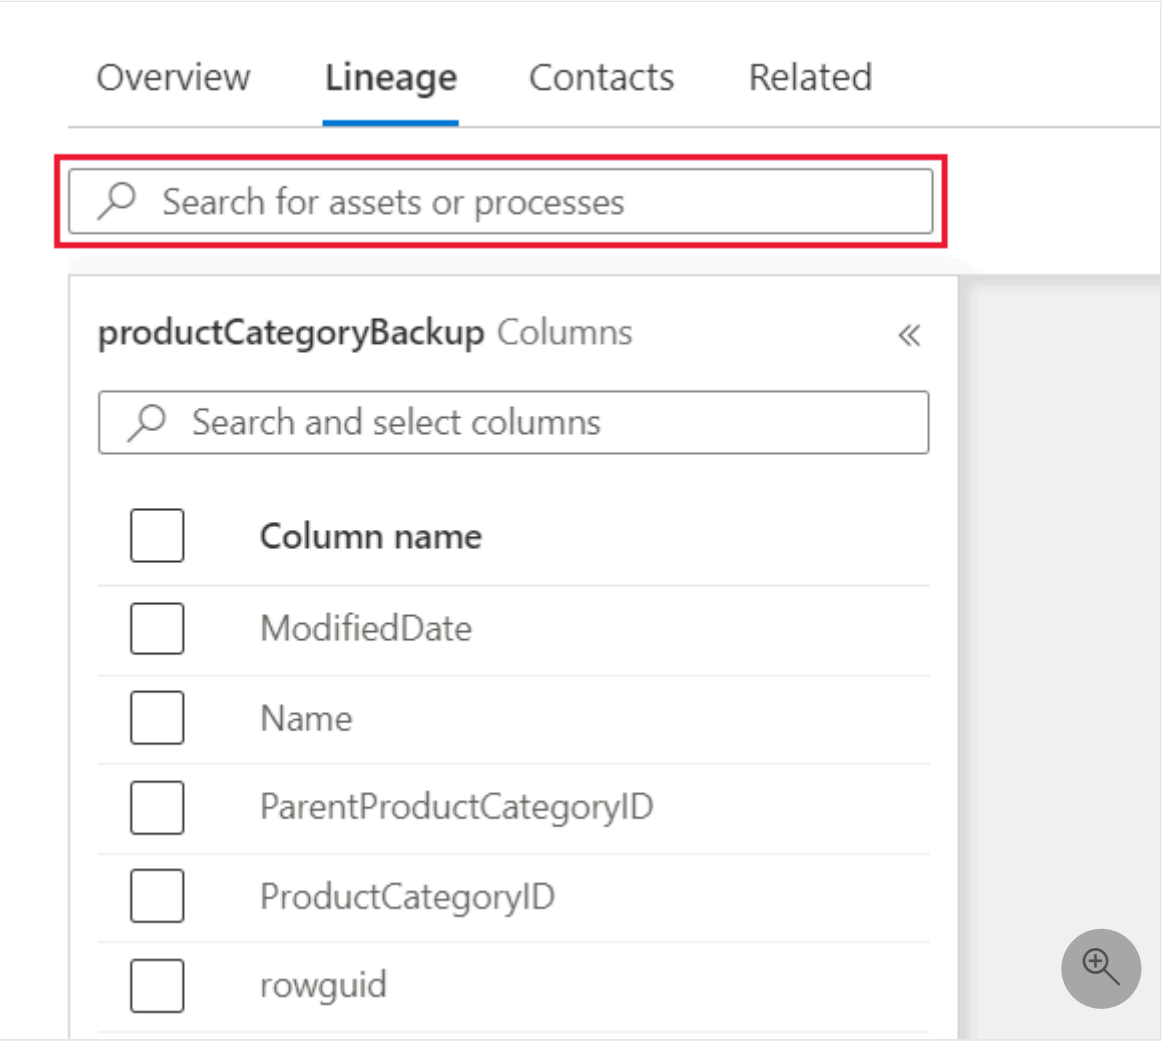


Dataset column lineage

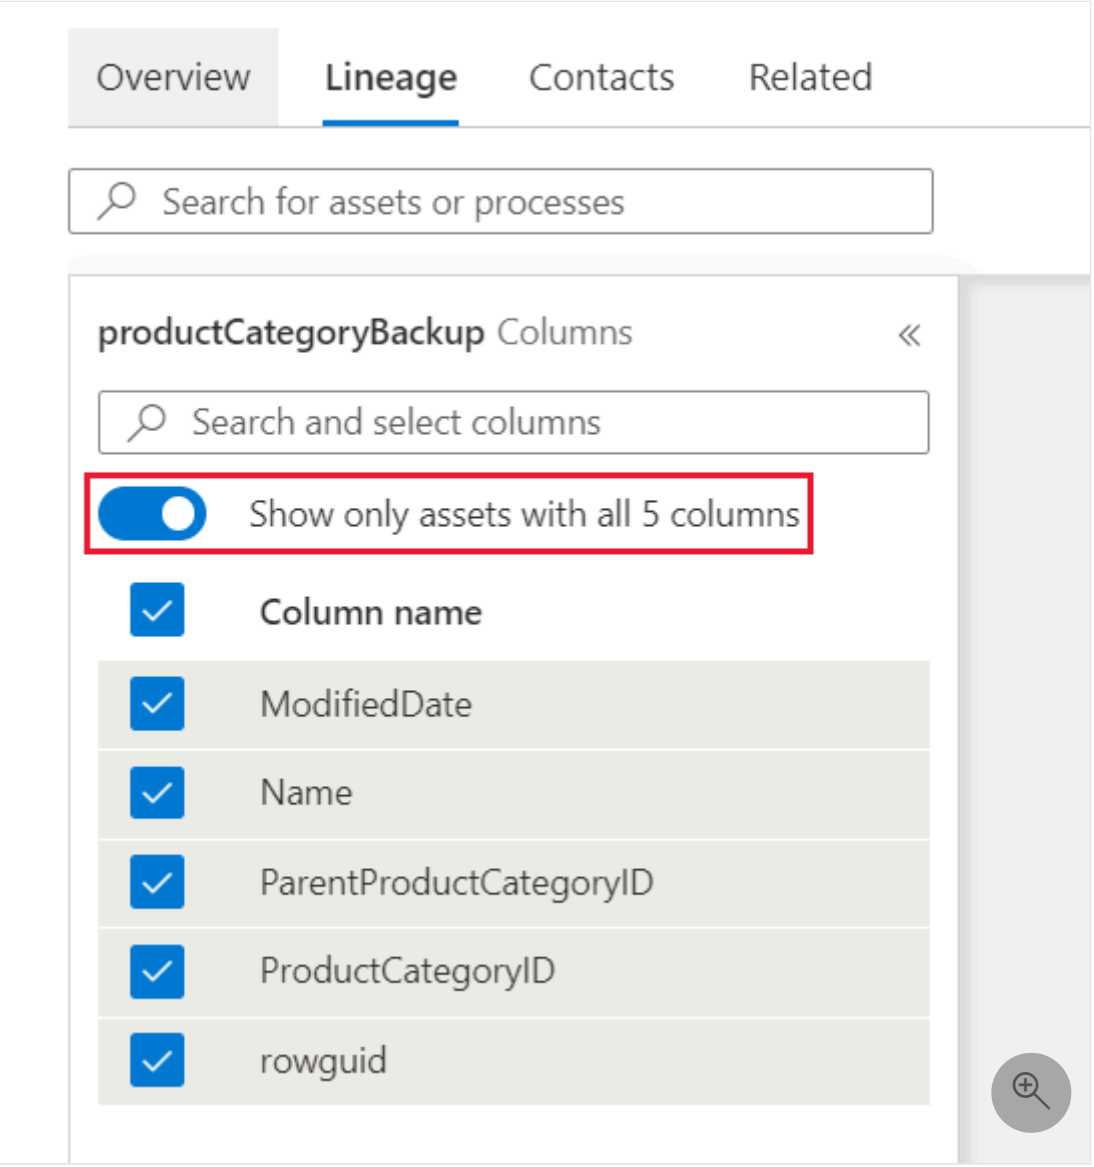
To see column-level lineage of a dataset, go to the **Lineage** tab of the current asset in the catalog and follow below steps:



1. Once you are in the lineage tab, in the left pane, select the check box next to each column you want to display in the data lineage.

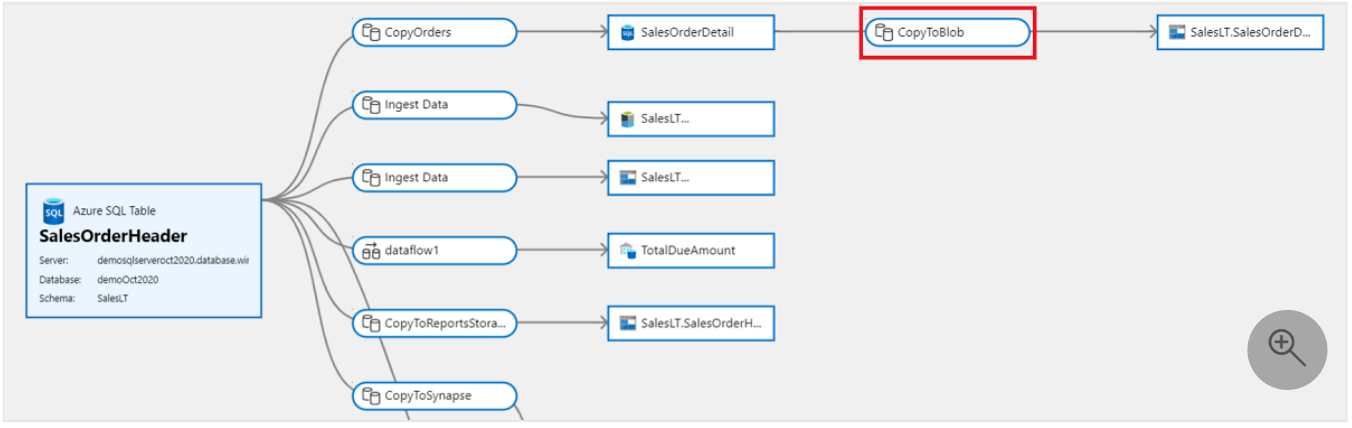


2. Hover over a selected column on the left pane or in the dataset of the lineage canvas to see the column mapping. All the column instances are highlighted.

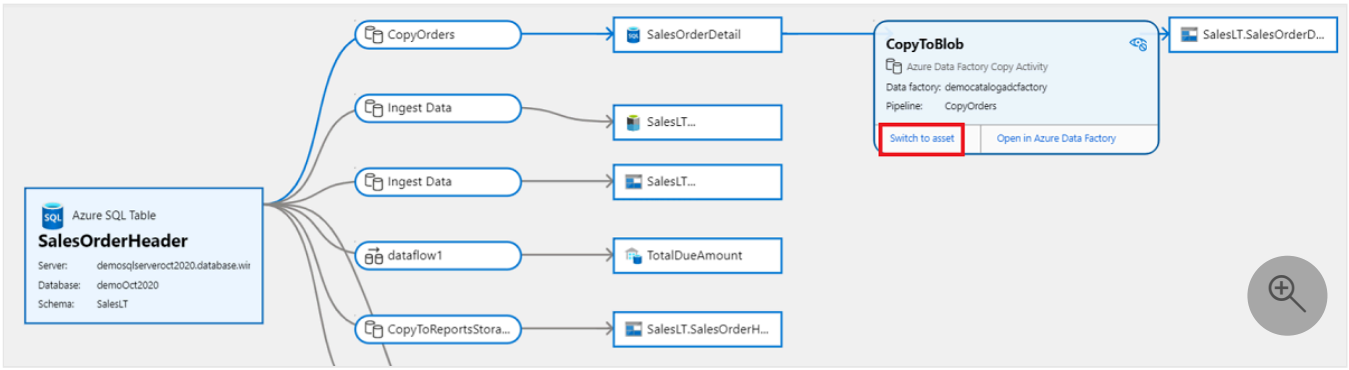


3. If the number of columns is larger than what can be displayed in the left pane, use the filter option to select a specific column by name. Alternatively, you can use your mouse to scroll through the list.

4. If the lineage canvas contains more nodes and edges, use the filter to select data asset or process nodes by name. Alternatively, you can use your mouse to pan around the lineage window.

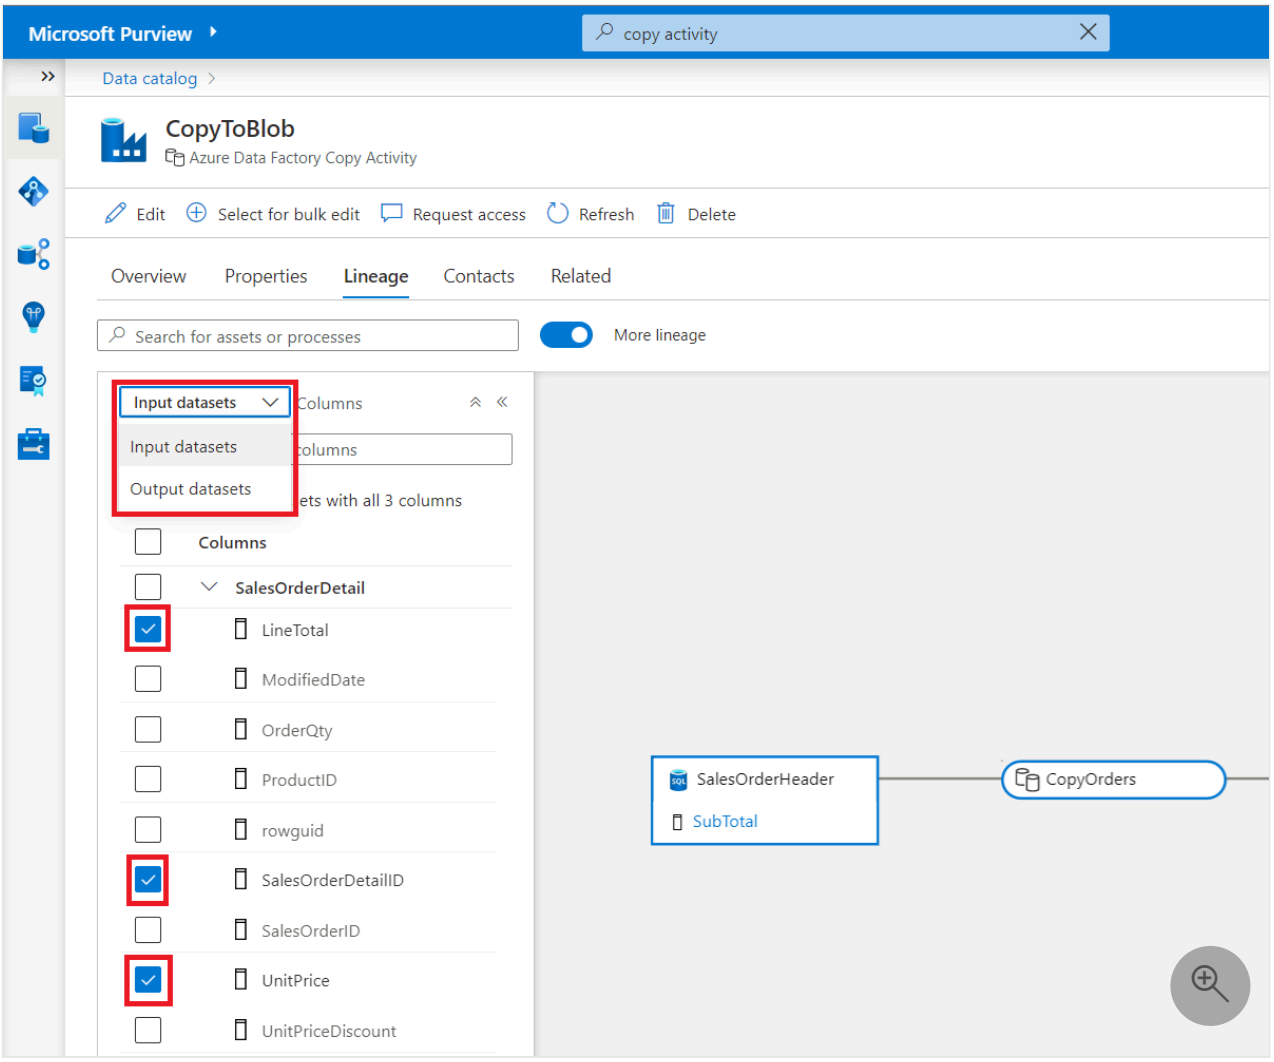


5. Use the toggle in the left pane to highlight the list of datasets in the lineage canvas. If you turn off the toggle, any asset that contains at least one of the selected columns is displayed. If you turn on the toggle, only datasets that contain all of the columns are displayed.

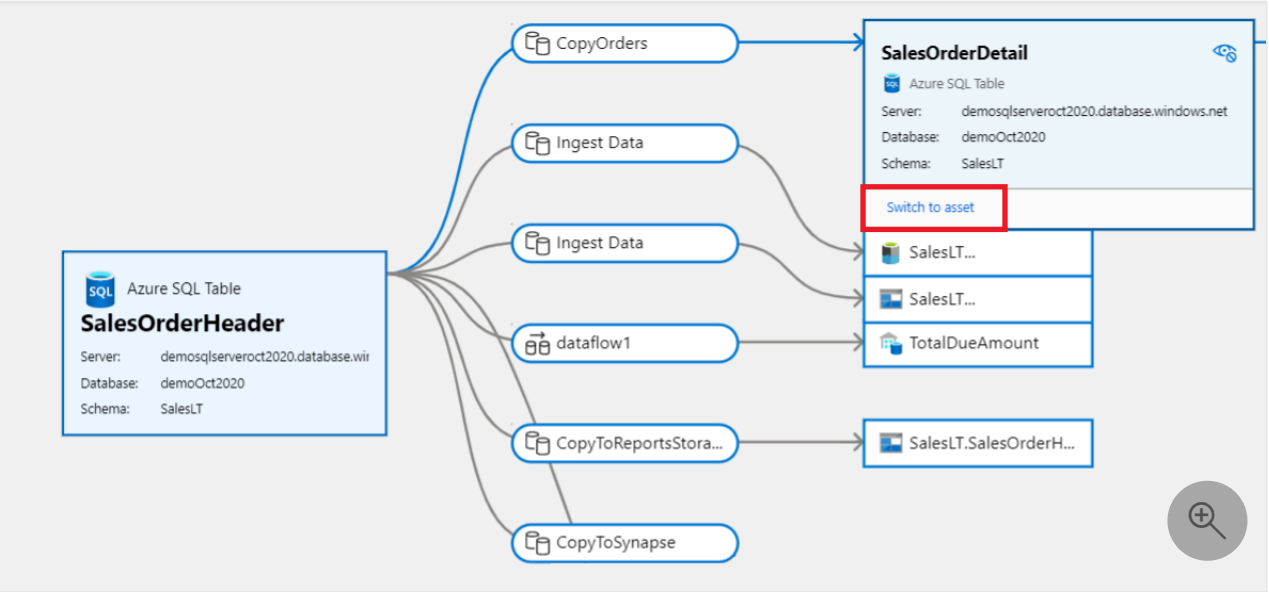


Process column lineage

You can also view data processes, like copy activities, in the catalog. For example, in this lineage flow, select the copy activity:

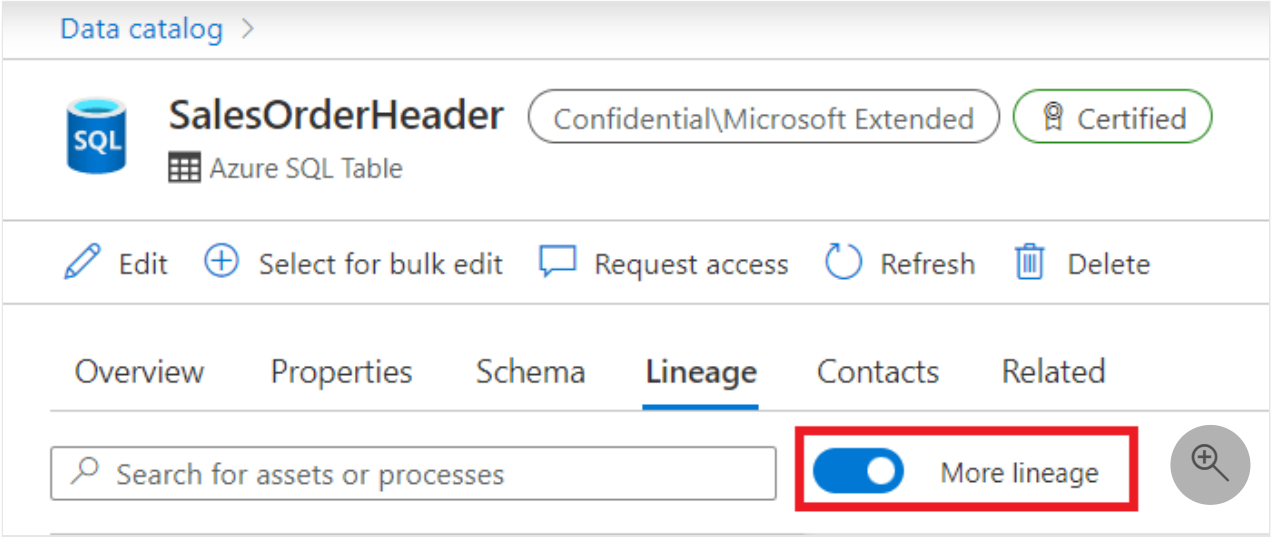


The copy activity will expand, and then you can select the **Switch to asset** button, which will give you more details about the process itself.



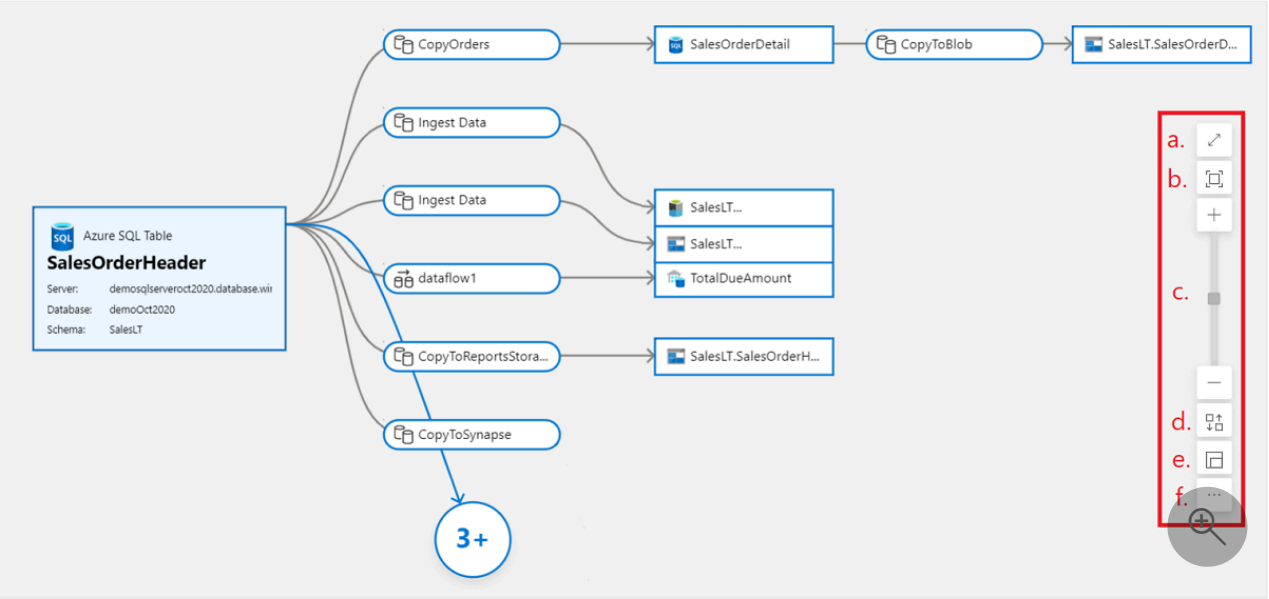
Data process can take one or more input datasets to produce one or more outputs. In Microsoft Purview, column level lineage is available for process nodes.

1. Switch between input and output datasets from a drop-down in the columns panel.
2. Select columns from one or more tables to see the lineage flowing from input dataset to corresponding output dataset.



Browse assets in lineage

1. Select **Switch to asset** on any asset to view its corresponding metadata from the lineage view. Doing so is an effective way to browse to another asset in the catalog from the lineage view.



2. The lineage canvas could become complex for popular datasets. To avoid clutter, the default view will only show five levels of lineage for the asset in focus. The rest of the lineage can be expanded by selecting the bubbles in the lineage canvas. Data consumers can also hide the assets in the canvas that are of no interest. To further reduce the clutter, turn off the toggle **More Lineage** at the top of lineage canvas. This action will hide all the bubbles in lineage canvas.

3. Use the smart buttons in the lineage canvas to get an optimal view of the lineage:
   a. Full screen
   b. Zoom to fit
   c. Zoom in/out
   d. Auto align
   e. Zoom preview

f. And more options:
   i. Center the current asset
   ii. Reset to default view

Build custom lineage manually or with REST APIs

One of the important platform features of Microsoft Purview is the ability to show the lineage between datasets created by data processes. Systems like Data Factory, Data Share, and Power BI capture the lineage of data as it moves. In certain situations, automatically generated lineage by Purview is incomplete or missing for practical visualization and/or enterprise reporting purposes. In those scenarios, you can create custom lineage entries manually in the Microsoft Purview portal, or via Apache Atlas hooks and the REST API. Another major benefit of using REST APIs to report or build custom lineage is to overcome or mitigate the limitations of functionality exposed by Manual Lineage.

To build custom lineage manually, you can follow this user guide: Manual lineage entries in Microsoft Purview.

To build custom lineage in Microsoft Purview using the REST APIs, follow this user guide: Microsoft Purview - Building Custom Lineage using REST APIs.

> **Tip**
>
> In some cases, the REST APIs can provide more input and customization options than building the lineage entries manually through the portal.

Lineage best practices

- Link to Azure Data Share for lineage

Microsoft Purview - Build custom lineage with the REST APIs

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article provides the steps to create data lineage entries using the REST API in the Microsoft Purview Data Catalog. In scenarios where the automatically generated lineage in Microsoft Purview is incomplete or missing, lineage can be custom built either manually in the Microsoft Purview portal or using the REST APIs. This article focuses on using REST APIs that can overcome manual lineage known limitations and provide more options.

Background

The ability to show the lineage between datasets is one of Microsoft Purview's important platform features. Systems like Data Factory, Data Share, and Power BI capture the lineage of data as it moves. In certain situations, Microsoft Purview's automatically generated lineage is incomplete or missing for practical visualization and enterprise reporting purposes. In those scenarios, custom lineage reporting is supported by Apache Atlas hooks and the REST API.

Using the REST APIs to build custom lineage allows you to overcome some of manual lineage's limitations as described in the following articles:

- Power BI lineage in Microsoft Purview
- Microsoft Purview manual lineage user guide
- Lineage - known limitations

The rest of this article explains the use of Microsoft Purview REST APIs to build and report custom lineage on Microsoft Purview.

Prerequisites

- For step-by-step guidance on how to use the Purview Python SDK Packages, refer Purview Python SDK Tutorial and Exploring Purview's REST API with Python
- For step-by-step guidance on how to use the *Purview REST APIs*, refer Purview Python SDK Tutorial

Scenarios

There are two use cases when building custom lineage becomes necessary:

A. Create new entities created and link them with lineage

B. Link existing entities or lineage to another existing entity or lineage

A. Create new entities and link them with lineage

As an example, lineage needs to be reported between entities A & B, but A & B don't exist currently.

To create the entities A & B, invoke the Microsoft Purview REST API: *Entity - Bulk Create Or Update - REST API*

HTTP

```
POST
https://{accountname}.purview.azure.com/datamap/api/atlas/v2/entity/bulk?
api-version=2023-09-01
```

Python

```
sample_entity_json = '{"entity": {"status": "ACTIVE","version": 0,"name":
ENTITY_A"}.......{"entity": ........}}'
#Send POST JSON containing entities to be created
CreateOrUpdateEntitesUrl =
'https://<purview_account_name>.purview.azure.com/datamap/api/atlas/v2/entit
y/bulk'
EntitiesResponse = requests.post(CreateOrUpdateEntitesUrl, json =
json.loads(sample_entity_json) ,headers=headers)
entitiesRes = json.loads(EntitiesResponse.text)
```

API Response "201 Created" indicates entities are successfully created and their respective GUIDs are contained in the output JSON.

Now that the entities A & B are created, move to step B to link the entities in the lineage chain using the same REST API.

B. Link existing entities or lineage to another existing entity or lineage

- If the number of entities to be linked isn't time or resource intensive (for example, less than 20-30 entities), you can connect the lineage manually in the Microsoft Purview portal. Follow the manual lineage user guide for steps to manually create lineage connections.
- If you have a high number of lineage connections to make, the process needs to be automated, or if manual lineage using the Microsoft Purview portal isn't feasible, proceed with the API process of linking and building custom lineage.

Custom Lineage JSON Payload:

Execute the *POST /entity/bulk* *Entity - Bulk Create Or Update - REST API* using the payload as illustrated:

HTTP

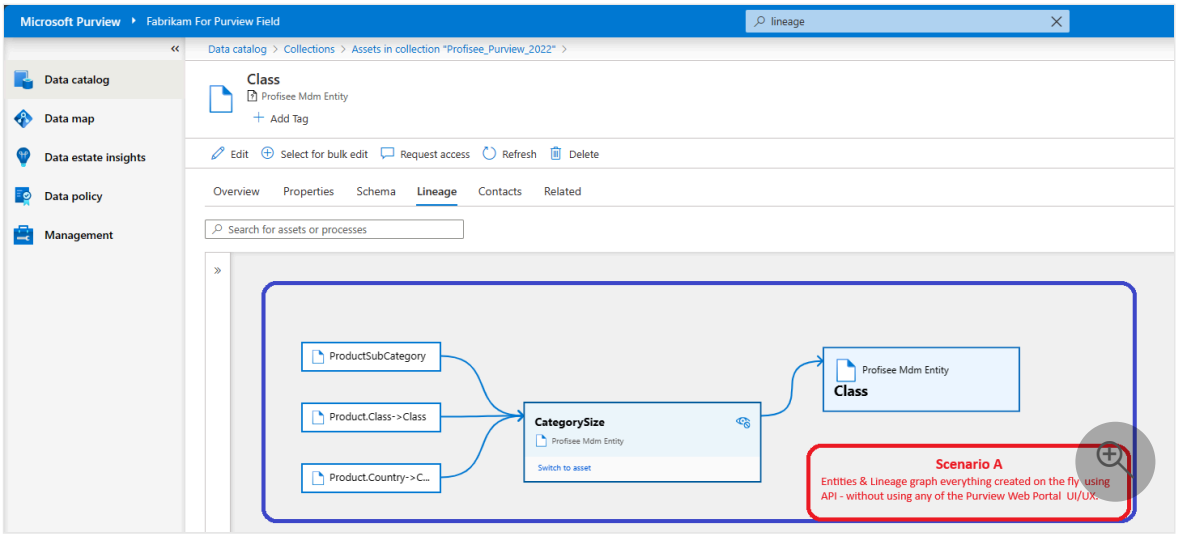
```
POST
https://{accountname}.purview.azure.com/datamap/api/atlas/v2/entity/bulk?
api-version=2023-09-01
```

Python

```
sample_entity_json = '{
  "entities": [
    {
      "status": "ACTIVE",
      "version": 1,
      "typeName": "Process",
      "attributes": {
        "inputs": [
          {
            "guid": "24558fd8-9cdc-47de-9310-56a58108bab0",
            “guid”: “27163581-9aca-212a-782a-213612639abc”
          }
        ],
        "outputs": [
          {
            "guid": "e33c694a-2c4f-4cae-8c27-06f6f6f60000"
          }
        ],
        "qualifiedName": "cassandra://query",
        "name": "query"
      }
    }
  ]
}'
```

```
#In this code snippet, we send the JSON as POST request containing the two GUIDs as input and "output" GUID as output. This creates lineage with 2 directional inputs and 1 directional output.
#Note: using the same API and SDK code you can create lineage with any number of inputs, any number of processes in between, any number of typedefs and any number of outputs.
#The API/SDK method is the most flexible and versatile menthod of creating lineage.

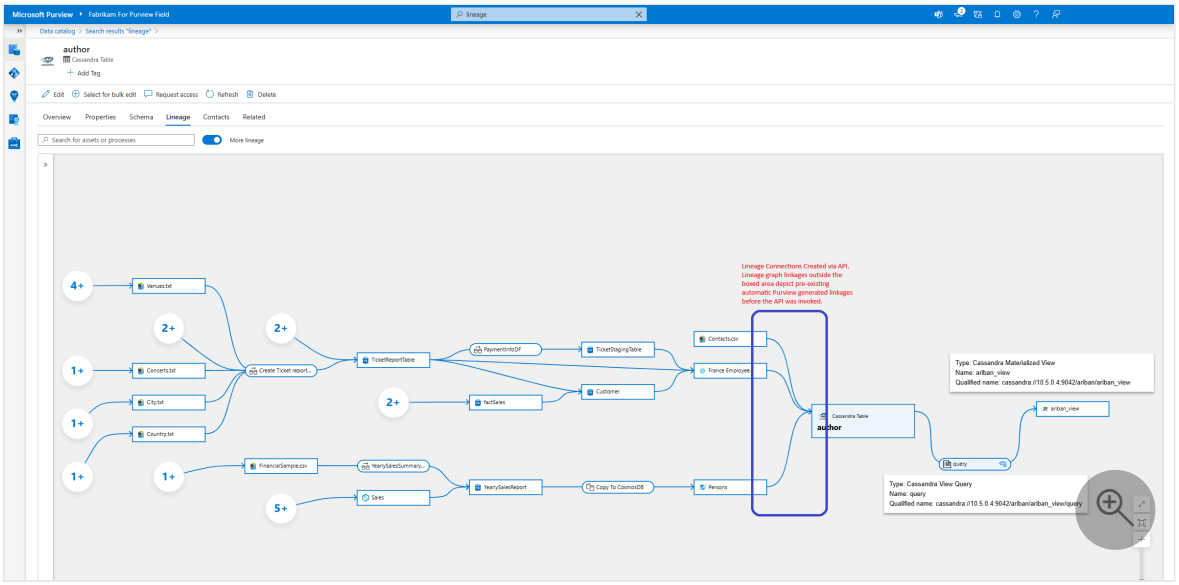
CreateLineageEntitesUrl = 'https://<purview_account_name>.purview.azure.com/datamap/api/atlas/v2/entity/bulk'
EntitiesResponse = requests.post(CreateLineageEntitesUrl, json = json.loads(sample_entity_json),headers=headers)
entitiesRes = json.loads(EntitiesResponse.text)
```



This JSON payload creates the custom lineage. It works for already existing assets whose GUIDs are supplied in the "inputs" JSON. For example "guid": "24558fd8-9cdc-47de-9310-56a58108bab0" and "27163581-9aca-212a-782a-213612639abc" refers to the directional input of the lineage and "guid": "e33c694a-2c4f-4cae-8c27-06f6f6f60000" refers to the directional output of the lineage, which was an existing asset automatically scanned by Purview. We just created the lineage between the two assets.

> ⓘ **Note**
>
> If the assets don't exist already, you need to run Bulk Entity create API before this step to create those entities before creating the lineage relationship. The bulk entity creation process using the POST /entity/bulk API and Python code snippet is described in step A.

Scenario Outcomes



API Response "201 Created" indicates successful lineage graph linkage creation and the created GUIDs are contained in the output JSON. Lineage appears in the Microsoft Purview portal:

- Scenario A: Custom built lineage from assets created via API:

- Scenario B: Custom built lineage from pre-existing assets linked via API.

> **Note**
>
> If the lineage is created from pre-existing entities, observe that the pre-existing lineage graph remains intact and the new linkage is created and displayed additionally.

How to get lineage from Airflow into Microsoft Purview (preview)

07/18/2025

Airflow is an open-source workflow automation and scheduling platform that can be used to author and manage data pipelines. Microsoft Purview supports collecting Airflow lineage by integrating with OpenLineage, an open framework for data lineage collection and analysis. Learn about how Airflow works with OpenLineage from here.

Enabling OpenLineage in Airflow automatically tracks metadata and lineage about jobs and datasets as DAGs execute. The information is sent to an Azure Event Hubs that you configure. Microsoft Purview subscribes to the events, parse them and ingest into the data map.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Supported capabilities

The supported Airflow versions are 1.10+ and 2.0-2.7.

Microsoft Purview supports metadata and lineage collection when the following types of data sources are used in Airflow:

- Amazon RDS for PostgreSQL
- Azure Database for PostgreSQL
- Google BigQuery
- PostgreSQL
- Snowflake

The following Airflow metadata are captured along:

- Airflow workspace
- Airflow DAG
- Airflow task

Lineage is collected into Microsoft Purview upon successful DAG runs in an event-based manner.

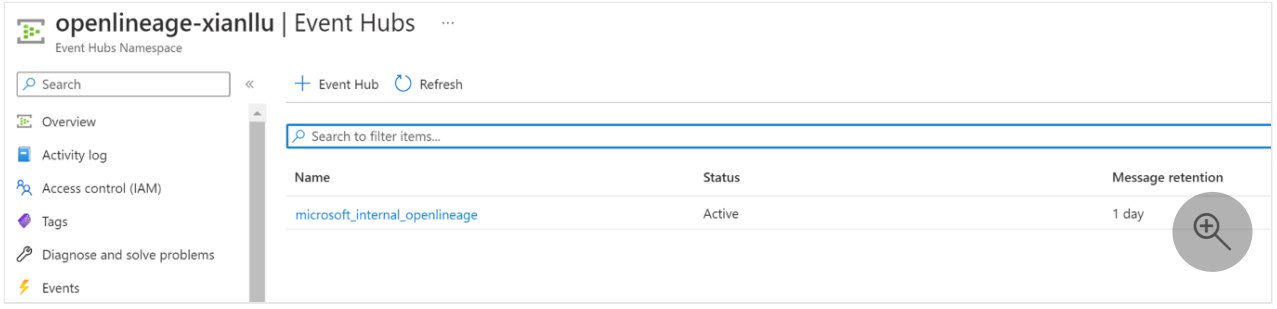
Known limitations

- Column level lineage is currently not supported. The schema of the data assets is captured.
- If database views are referenced in the tasks, they're currently captured as table assets.
- All the metadata are ingested into Microsoft Purview root collection. The assets already existed in the data map are preserved in the configured collection.

How to bring Airflow lineage into Microsoft Purview

As a prerequisite, you need a running Airflow instance.

To get lineage from Airflow into Microsoft Purview, you need to:



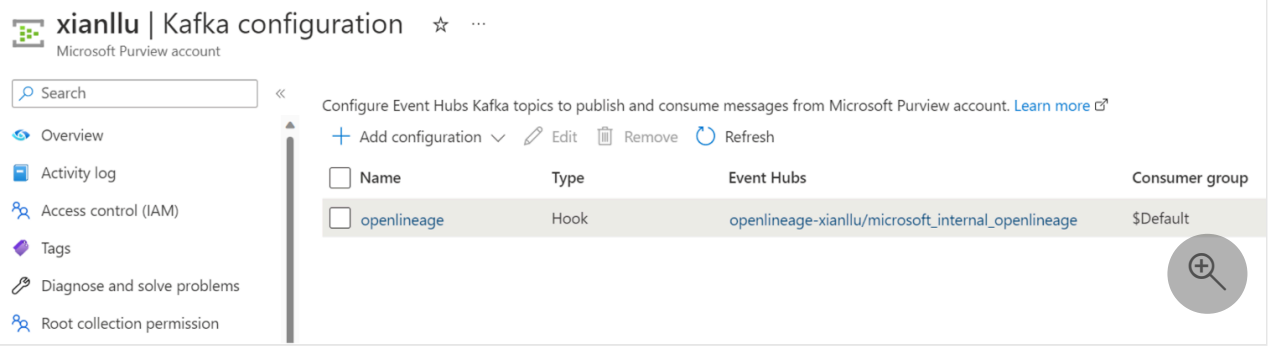
1. Set up an Azure Event Hubs
2. Configure Event Hubs to publish messages to Microsoft Purview
3. Configure your Airflow with OpenLineage
4. Run Airflow jobs and view the assets/lineage

Set up Azure Event Hubs

Set up an Azure Event Hubs as the receiver of the metadata and lineage tracked by OpenLineage in Airflow.

1. Create an Azure Event Hubs namespace.

2. Create an event hub. Name your event hub as "**microsoft_internal_openlineage**".



3. Go to your "microsoft_internal_openlineage" event hubs -> **Access control (IAM)** -> **Add role assignment**, assign "**Azure Event Hubs Data Receiver**" role to your Microsoft Purview account's managed identity. For detailed steps, see Assign Azure roles using the Azure portal.

Configure Event Hubs to publish messages to Microsoft Purview

Microsoft Purview supports consuming and pushing events from/to your own Event Hubs. Follow this doc to configure Event Hubs for Microsoft Purview: Configure Event Hubs with Microsoft Purview to send and receive Atlas Kafka topics messages.

In summary:

- Go to your Microsoft Purview account -> Managed resources tab, disable the managed Event Hubs namespace.
- Go to Kafka configuration tab -> **+ Add configuration** -> **Hook configuration**, input a name, and select the Event Hubs namespace and Event Hubs you created in previous step.

Configure your Airflow with OpenLineage

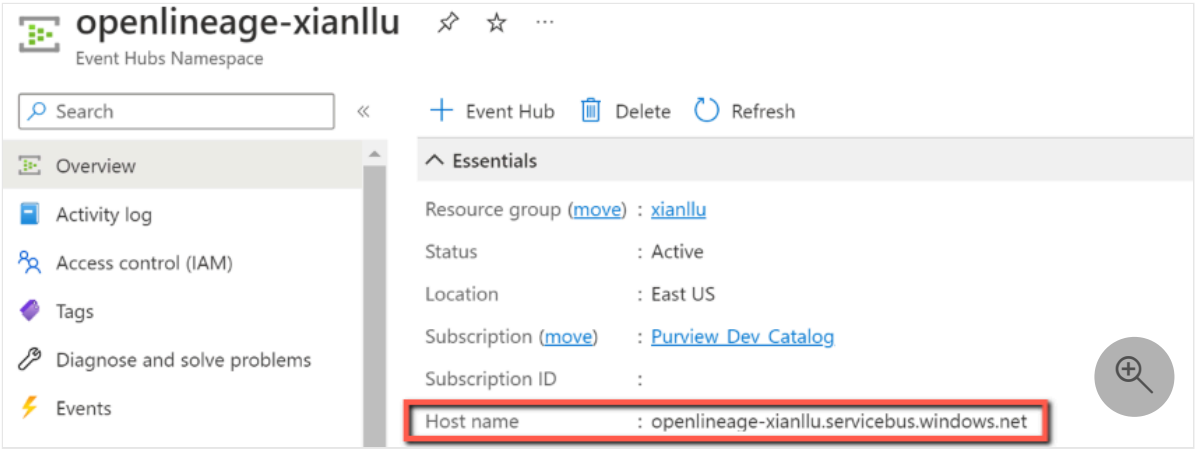
Installation:

To download and install the latest 'openlineage-airflow' library, update the 'requirements.txt' file of your running Airflow instance with:

```
openlineage-airflow
```

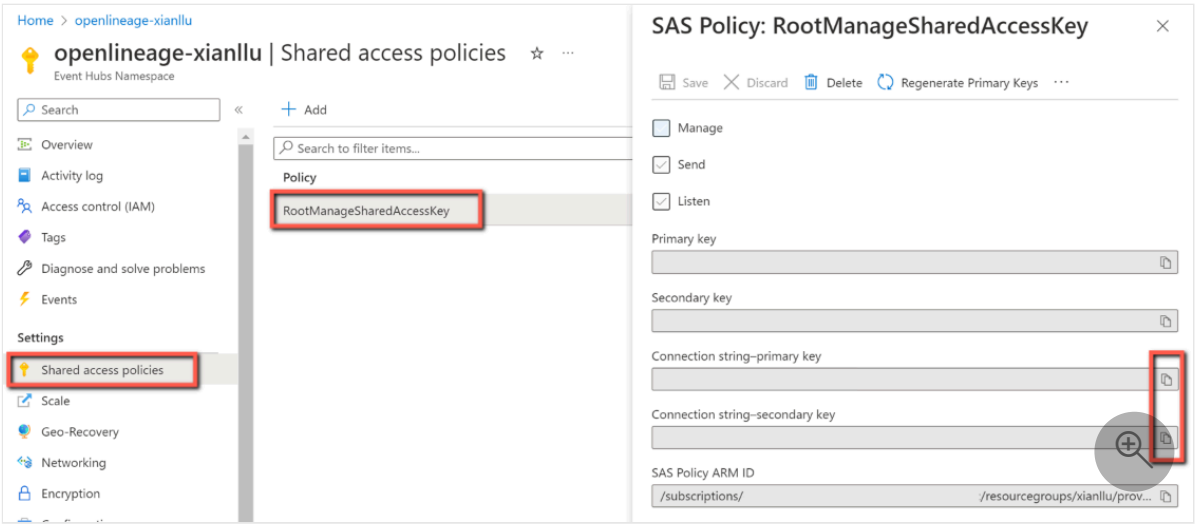
> **Note**
>
> The Airflow version and the openlineage-airflow version need to match. For example, when you use Airflow 2.7.1, you can use openlineage-airflow version 1.1.0 or 1.2.0. You can view matching versions on this website.

Configuration:



Next, configure your Azure Event Hubs instance as the target to which OpenLineage sends the events.

1. Create an 'openlineage.yml' file under your Airflow root path. The content of the file is as below:

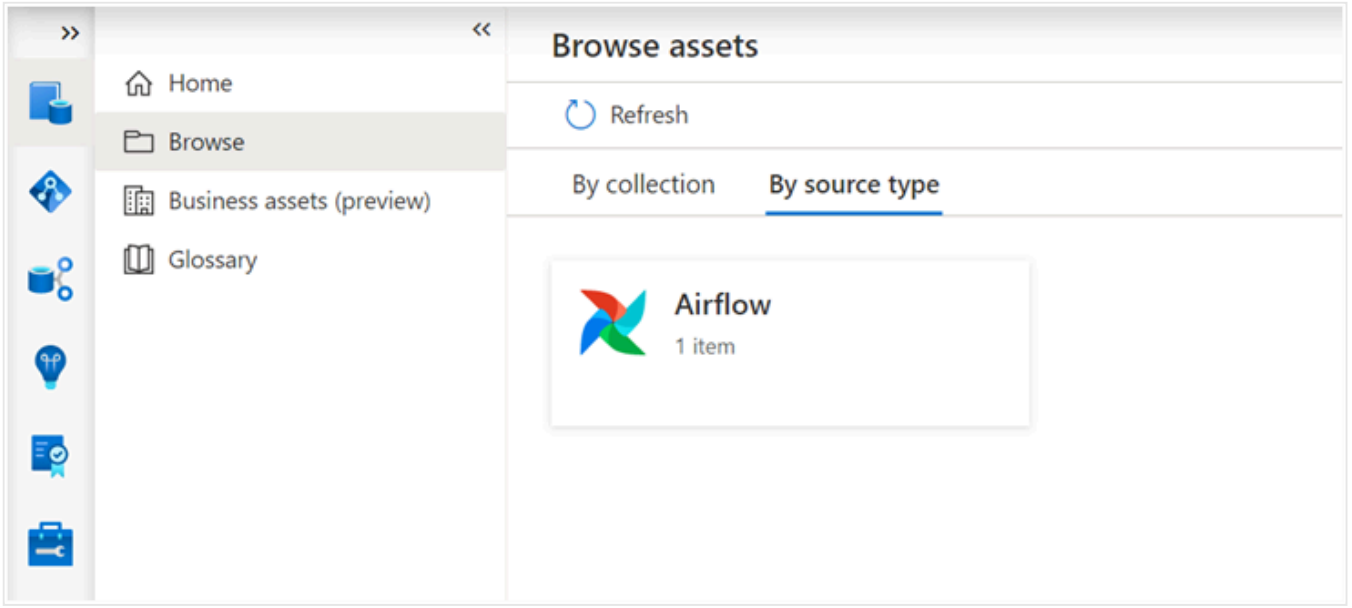


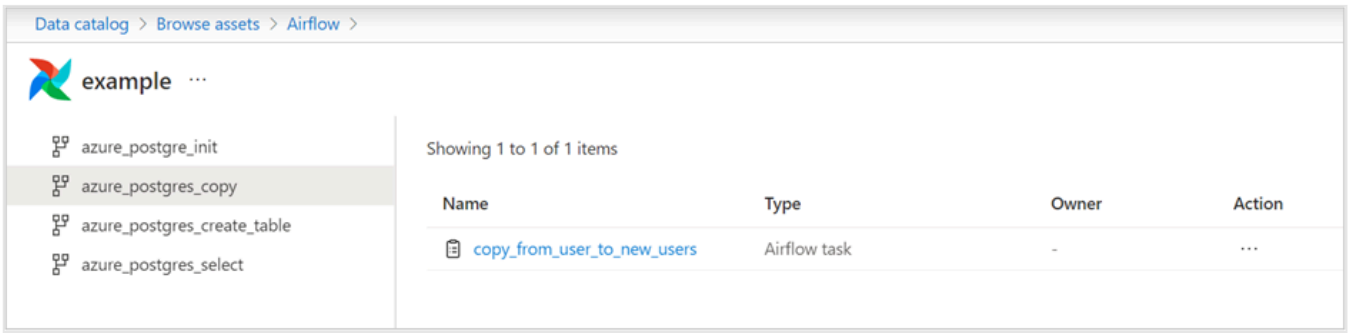
```yml
transport:
  type: "kafka"
  config:
    bootstrap.servers: "{EVENTHUB_SERVER}:9093"
    security.protocol: "SASL_SSL"
    sasl.mechanism: "PLAIN"
    sasl.username: "$ConnectionString"
    sasl.password: "{PASSWORD}"
    client.id: "airflow-client"
  topic: "microsoft_internal_openlineage"
  flash: True
```

   Replace the two place-holders with values:

   - Get the `{EVENTHUB_SERVER}` from your Event Hubs namespace -> **Host name**:

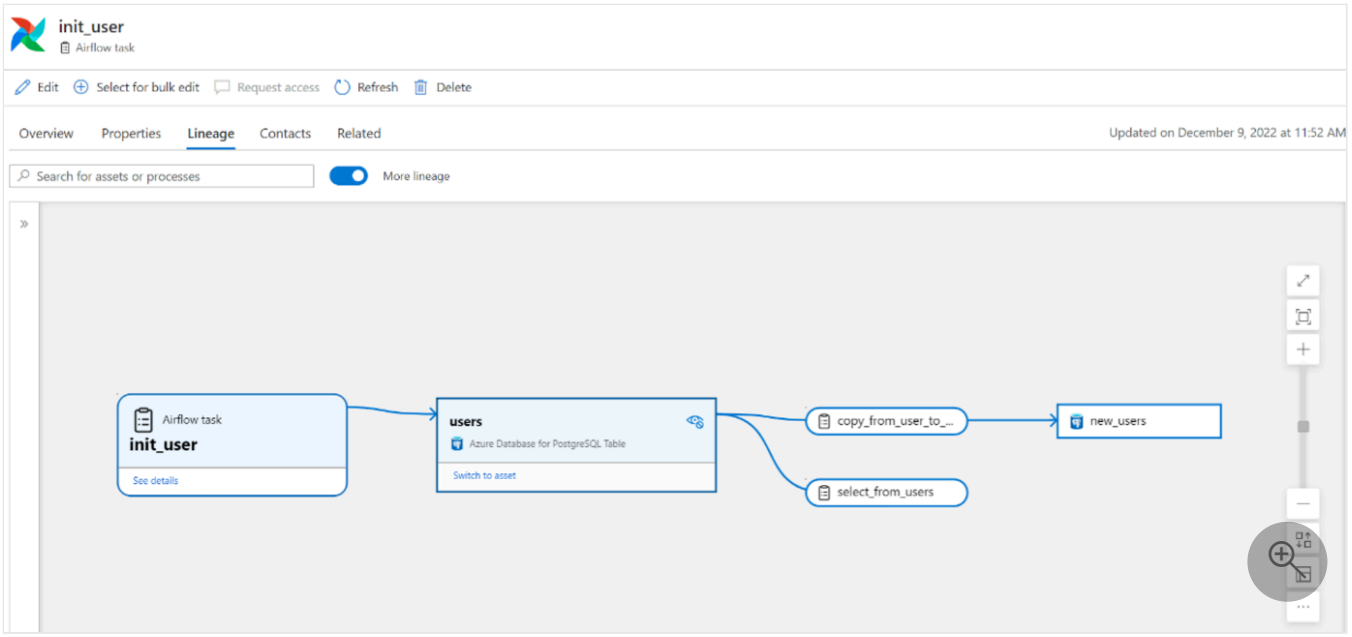
   - Get the `{PASSWORD}` from your Event Hubs namespace -> **Shared access policies** -> **Connection string - primary key** or **Connection string - secondary key**:





2. Restart your Airflow server.

Run Airflow jobs and view the assets/lineage



You can now run your Airflow jobs, then go to Microsoft Purview Governance portal to browse/search/view assets. The assets should show up shortly after a successful DAG run.

Browse Airflow assets:

View Airflow task asset details with lineage:

Troubleshooting tips

If you run the Airflow job but don't see the corresponding assets/lineage shown up in Microsoft Purview:

- Check if your Airflow use case is supported by Microsoft Purview. Refer to the supported capabilities section.
- Go to your Event Hubs instance to check if any incoming requests and messages. If no, double check your OpenLineage configuration in Airflow.

- Learn about Data lineage in Microsoft Purview

How to connect Azure Data Factory and Microsoft Purview

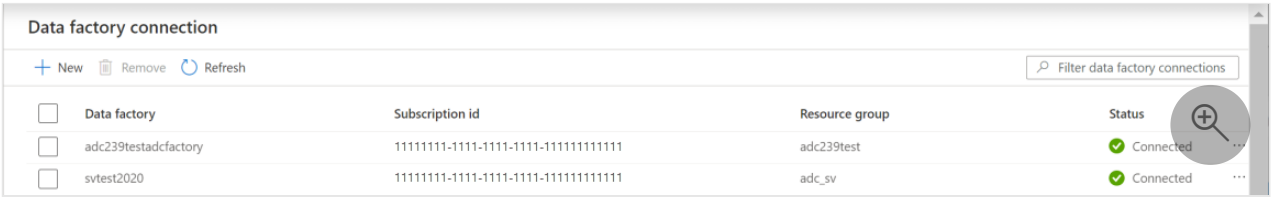
Summarize this article for me

This article explains the steps required for connecting an Azure Data Factory account with a Microsoft Purview account to track data lineage and ingest data sources. The article also explains details of the activity coverage scope and supported lineage patterns.

When you connect an Azure Data Factory to Microsoft Purview, whenever a supported Azure Data Factory activity runs, it automatically ingests metadata about the activity's source data, output data, and the activity into Microsoft Purview Data Map.

If a data source is already scanned and exists in Data Map, the ingestion process adds the lineage information from Azure Data Factory to that existing source. If the source or output doesn't exist in Data Map and is supported by Azure Data Factory lineage, Microsoft Purview automatically adds their metadata from Azure Data Factory into Data Map under the root collection.

This connection is an excellent way to monitor your data estate as users move and transform information by using Azure Data Factory.



View existing Data Factory connections

Multiple Azure Data Factorys can connect to a single Purview to push lineage information. The current limit allows you to connect up to 10 Azure Data Factory accounts at a time from the Microsoft Purview management center. To show the list of Azure Data Factory accounts connected to your Microsoft Purview account, follow these steps:

1. Select **Management** on the left navigation pane.

2. Under **Lineage connections**, select **Data Factory**.

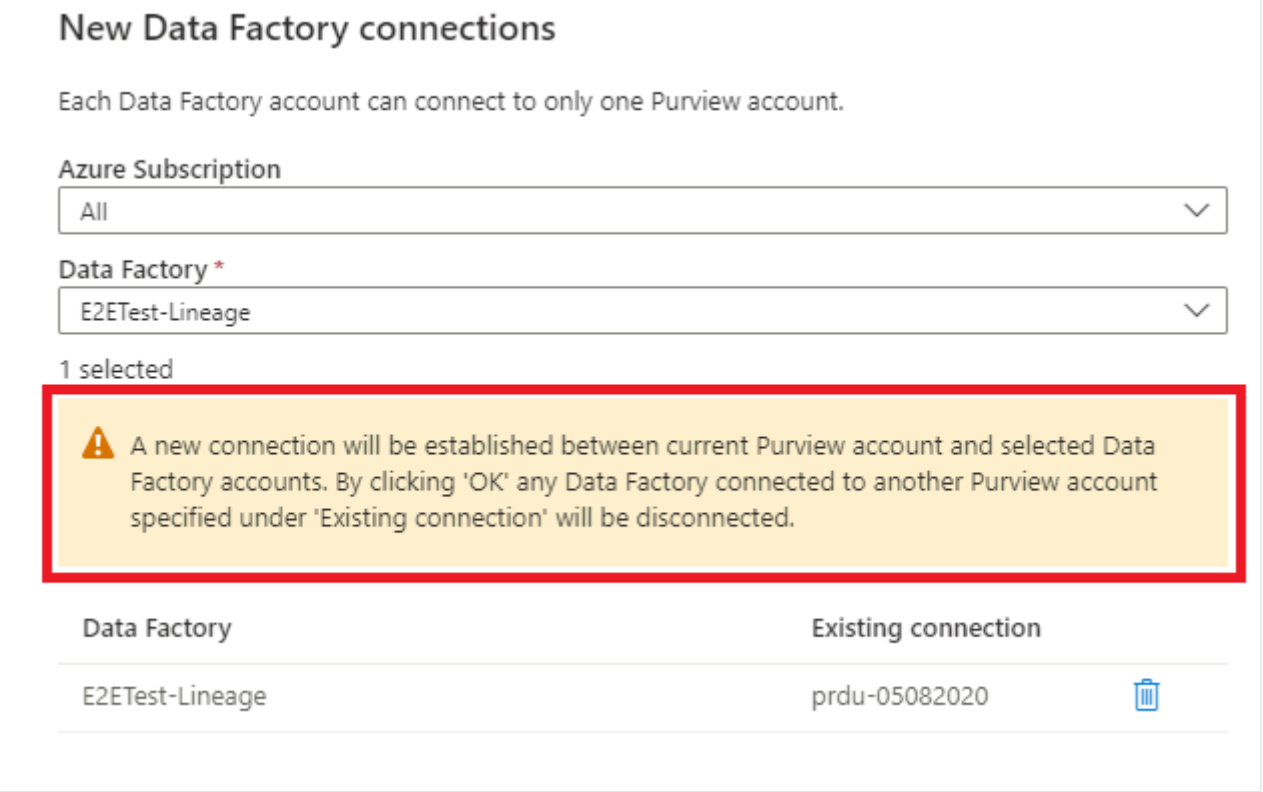
3. The Data Factory connection list appears.

4. Notice the various values for connection **Status**:

    - **Connected**: The Data Factory is connected to the Microsoft Purview account.

- **Disconnected**: The Data Factory has access to the catalog, but it's connected to another catalog. As a result, data lineage won't be reported to the catalog automatically.
- **Unknown**: The current user doesn't have access to the Data Factory, so the connection status is unknown.

> ⓘ Note
>
> To view the Data Factory connections, you need to be assigned the following role. Role inheritance from management group isn't supported. **Collection admins** role on the root collection.



Create new Azure Data Factory connection

> ⓘ Note
>
> To add or remove the Azure Data Factory connections, you need to be assigned the following role. Role inheritance from management group is not supported. **Collection admins** role on the root collection.
>
> Also, you need to be the Azure Data Factory's "Owner" or "Contributor".
>
> Your Azure Data Factory needs to have system assigned managed identity enabled.

Follow the steps below to connect an existing Azure Data Factory to your Microsoft Purview account. You can also connect Data Factory to Microsoft Purview account from ADF.

1. Select **Management** on the left navigation pane.
2. Under **Lineage connections**, select **Data Factory**.
3. On the **Data Factory connection** page, select **New**.
4. Select your Azure Data Factory account from the list and select **OK**. You can also filter by subscription name to limit your list.

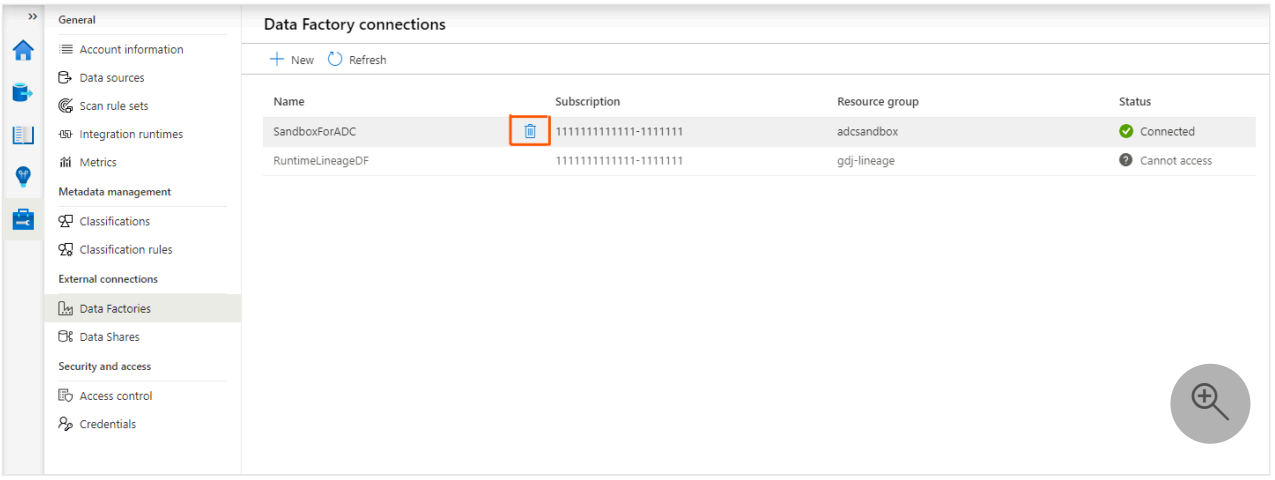
   Some Azure Data Factory instances might be disabled if the Azure Data Factory is already connected to the current Purview account, or the Azure Data Factory doesn't have a managed identity. A warning message is displayed if any of the selected Azure Data Factorys are already connected to other Microsoft Purview account. When you select **OK**, the Azure Data Factory connection with the other Microsoft Purview account is disconnected. No other confirmations are required.

> **Note**
>
> You can add up to 10 Azure Data Factory accounts at once. To add more than 10 Azure Data Factory accounts, add them in multiple batches.

How authentication works

Azure Data Factory uses its managed identity to authenticate lineage push operations from Microsoft Purview. When you connect your Azure Data Factory to Purview in the UI, it adds the role assignment automatically.

Grant the Azure Data Factory's managed identity the **Data Curator** role on Microsoft Purview **root collection**. To learn more, see Access control in Microsoft Purview and Add roles and restrict access through collections.



Remove Data Factory connections

> **Important**
>
> Even if the Data Factory connection is removed, any ongoing ingestion won't be canceled. Azure Data Factory lineage ingestion is an asynchronous operation.

To remove an Azure Data Factory connection, complete the following steps:

1. On the **Data Factory connection** page, select the **Remove** button next to one or more Azure Data Factory connections.

2. Select **Confirm** in the popup to delete the selected Azure Data Factory connections.

Monitor the Azure Data Factory links

In Microsoft Purview portal, you can monitor the Data Factory links.

Supported Azure Data Factory activities

Microsoft Purview captures runtime lineage from the following Azure Data Factory activities:

- Copy Data
- Data Flow
- Execute SSIS Package

> **Important**
>
> Microsoft Purview drops lineage if the source or destination uses an unsupported data storage system.

The integration between Azure Data Factory and Microsoft Purview supports only a subset of the data systems that Azure Data Factory supports. For more information, see the following sections.

Copy activity support

Expand table

Data store	Supported
Azure Blob Storage	Yes
Azure Cognitive Search	Yes
Azure Cosmos DB for NoSQL *	Yes
Azure Cosmos DB for MongoDB *	Yes
Azure Data Explorer *	Yes
Azure Data Lake Storage Gen1	Yes
Azure Data Lake Storage Gen2	Yes
Azure Database for MariaDB *	Yes
Azure Database for MySQL *	Yes
Azure Database for PostgreSQL *	Yes
Azure Files	Yes
Azure SQL Database *	Yes
Azure SQL Managed Instance *	Yes
Azure Synapse Analytics *	Yes
Azure Dedicated SQL pool (formerly SQL DW) *	Yes
Azure Table Storage	Yes
Amazon S3	Yes
Hive *	Yes
Oracle *	Yes
SAP Table *(when connecting to SAP ECC or SAP S/4HANA)*	Yes
SQL Server *	Yes
Teradata *	Yes

** Microsoft Purview currently doesn't support query or stored procedure for lineage or scanning. Lineage is limited to table and view sources only.*

If you use Self-hosted Integration Runtime, note the minimal version with lineage support for:

- Any use case: version 5.9.7885.3 or later

- Copying data from Oracle: version 5.10 or later
- Copying data into Azure Synapse Analytics via COPY command or PolyBase: version 5.10 or later

Limitations on copy activity lineage

Currently, if you use the following copy activity features, the lineage is not yet supported:

- Copy data into Azure Data Lake Storage Gen1 using Binary format.
- Compression setting for Binary, delimited text, Excel, JSON, and XML files.
- Source partition options for Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, SQL Server, and SAP Table.
- Copy data to file-based sink with setting of max rows per file.
- Column level lineage is not currently supported by copy activity when source/sink is resource set.

In additional to lineage, the data asset schema (shown in Asset -> Schema tab) is reported for the following connectors:

- CSV and Parquet files on Azure Blob, Azure Files, ADLS Gen1, ADLS Gen2, and Amazon S3
- Azure Data Explorer, Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, SQL Server, Teradata

Data Flow support

Expand table

Data store	Supported
Azure Blob Storage	Yes
Azure Cosmos DB for NoSQL *	Yes
Azure Data Lake Storage Gen1	Yes
Azure Data Lake Storage Gen2	Yes
Azure Database for MySQL *	Yes
Azure Database for PostgreSQL *	Yes
Azure SQL Database *	Yes
Azure SQL Managed Instance *	Yes
Azure Synapse Analytics *	Yes

Data store	Supported
Azure Dedicated SQL pool (formerly SQL DW) *	Yes

** Microsoft Purview currently doesn't support query or stored procedure for lineage or scanning. Lineage is limited to table and view sources only.*

Limitations on data flow lineage

- Data flow lineage may generate folder level resource set without visibility on the involved files.
- Column level lineage is not currently supported when source/sink is resource set.
- For the lineage of data flow activity, Microsoft Purview only supports showing the source and sink involved. The detailed lineage for data flow transformation isn't supported yet.
- Lineage is not supported when flowlets are part of the dataflow.
- Currently Purview doesn't support lineage reporting for Synapse tables (LakeHouse DB/Workspace DB)

Execute SSIS Package support

Refer to supported data stores.

Access secured Microsoft Purview account

If a firewall protects your Microsoft Purview account, learn how to let Azure Data Factory access a secured Microsoft Purview account through Microsoft Purview private endpoints.

Bring Azure Data Factory lineage into Microsoft Purview

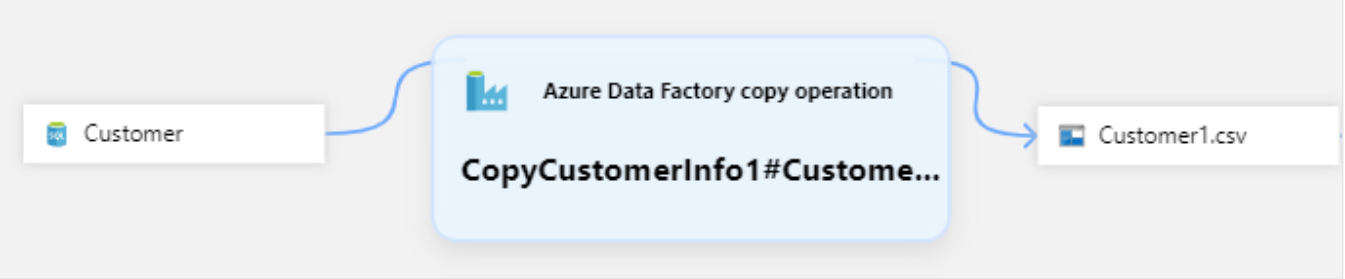
For an end-to-end walkthrough, see the Tutorial: Push Data Factory lineage data to Microsoft Purview.

Supported lineage patterns

Microsoft Purview supports several patterns of lineage. The generated lineage data depends on the type of source and sink used in the Azure Data Factory activities. Although Azure Data Factory supports over 80 sources and sinks, Microsoft Purview supports only a subset. For the supported sources and sinks, see Supported Azure Data Factory activities.

To configure Azure Data Factory to send lineage information, see Get started with lineage.

You can find information in the lineage view by using the following methods:



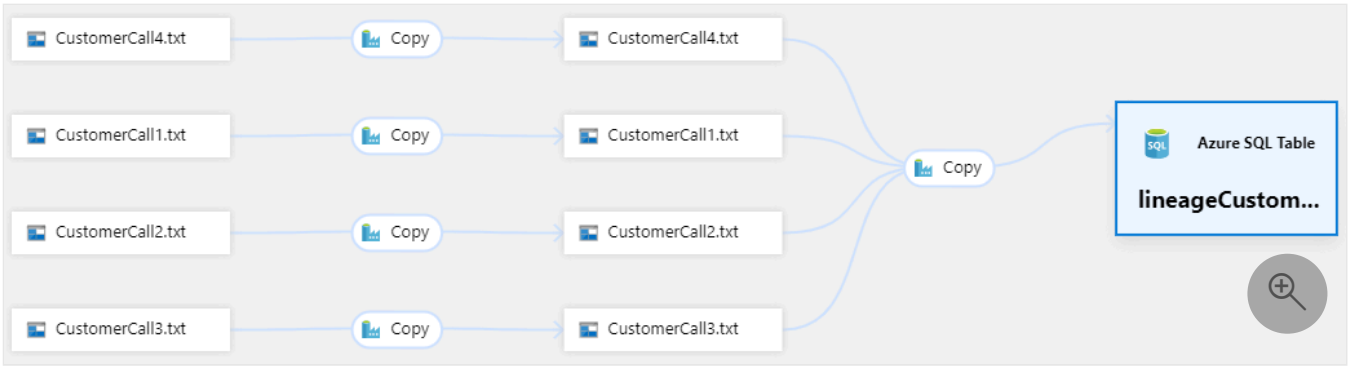
- In the **Lineage** tab, hover on shapes to preview additional information about the asset in the tooltip.
- Select the node or edge to see the asset type it belongs to or to switch assets.
- The **Lineage** tab displays columns of a dataset on the left side. For more information about column-level lineage, see Dataset column lineage.

Data lineage for 1:1 operations

The most common pattern for capturing data lineage moves data from a single input dataset to a single output dataset, with a process in between.

An example of this pattern includes the following components:

- 1 source/input: *Customer* (SQL Table)
- 1 sink/output: *Customer1.csv* (Azure Blob)
- 1 process: *CopyCustomerInfo1#Customer1.csv* (Data Factory Copy activity)

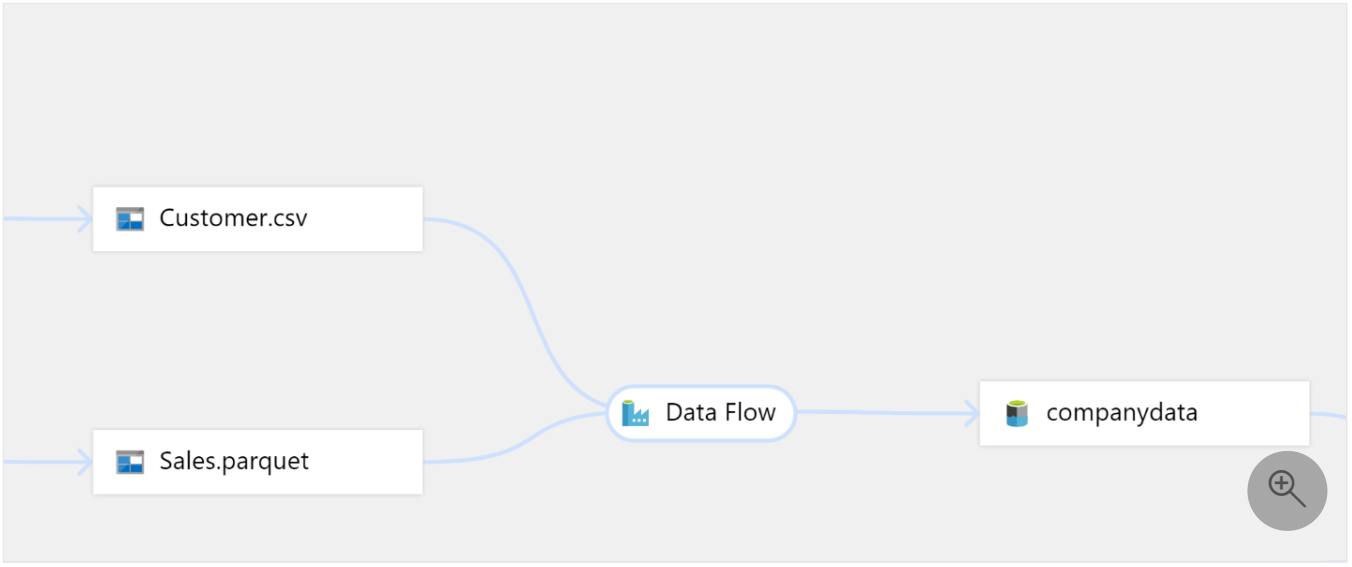


Data movement with 1:1 lineage and wildcard support

Another common scenario for capturing lineage is using a wildcard to copy files from a single input dataset to a single output dataset. The wildcard allows the copy activity to match multiple files for copying by using a common portion of the file name. Microsoft Purview captures file-level lineage for each individual file copied by the corresponding copy activity.

An example of this pattern includes the following components:

- Source/input: *CustomerCall*.csv* (ADLS Gen2 path)
- Sink/output: *CustomerCall*.csv* (Azure blob file)
- 1 process: *CopyGen2ToBlob#CustomerCall.csv* (Data Factory Copy activity)

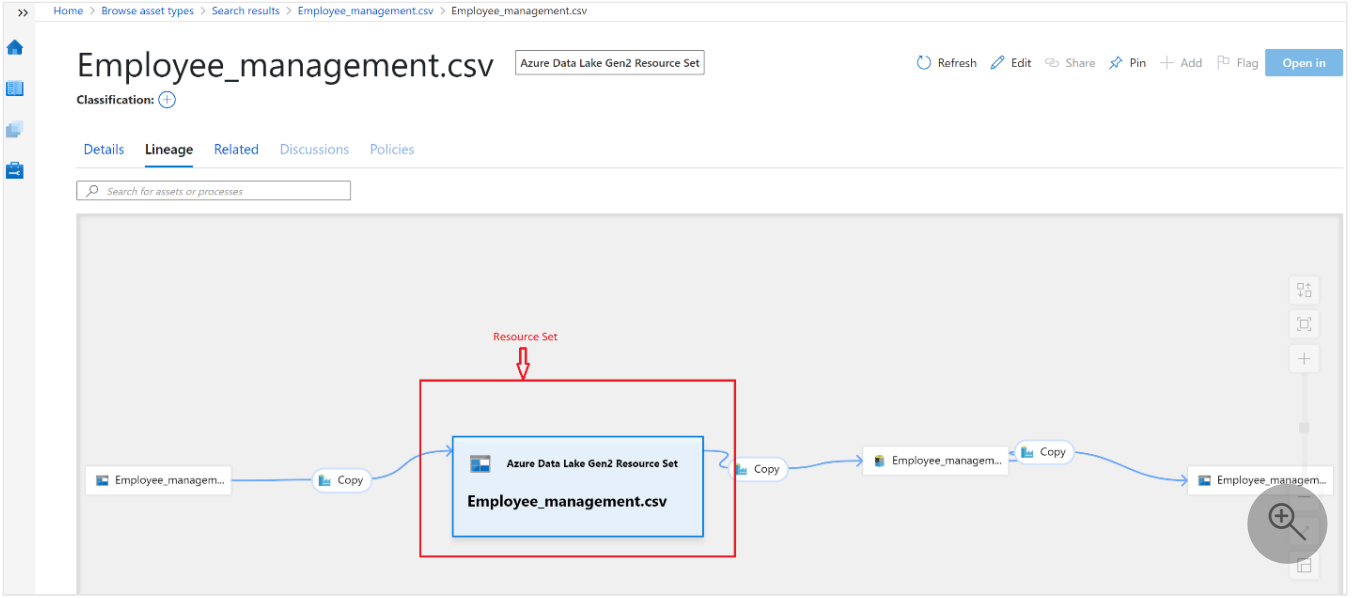


Data movement with n:1 lineage

You can use Data Flow activities to perform data operations like merge, join, and so on. You can use more than one source dataset to produce a target dataset. In this example, Microsoft Purview captures file-level lineage for individual input files to a SQL table that is part of a Data Flow activity.

An example of this pattern includes the following components:

- 2 sources/inputs: *Customer.csv*, *Sales.parquet* (ADLS Gen2 Path)
- 1 sink/output: *Company data* (Azure SQL table)
- 1 process: *DataFlowBlobsToSQL* (Data Factory Data Flow activity)



Lineage for resource sets

A resource set is a logical object in the catalog that represents many partition files in the underlying storage. For more information, see Understanding Resource sets. When Microsoft Purview captures lineage from Azure Data Factory, it applies the rules to normalize the individual partition files and create a single logical object.

In the following example, an Azure Data Lake Gen2 resource set is produced from an Azure Blob:

- 1 source/input: *Employee_management.csv* (Azure Blob)
- 1 sink/output: *Employee_management.csv* (Azure Data Lake Gen 2)
- 1 process: *CopyBlobToAdlsGen2_RS* (Azure Data Factory Copy activity)

Link to Azure Data Share for lineage

Last updated on 02/24/2026

How to connect Azure Data Share and Microsoft Purview

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article discusses how to connect your Azure Data Share account with Microsoft Purview and govern the shared datasets (both outgoing and incoming) in your data estate. Various data governance personas can discover and track lineage of data across boundaries like organizations, departments and even data centers.

> **Important**
>
> - This article is about lineage for the Azure Data Share service. If you are using data sharing in Microsoft Purview, use this article for lineage: Microsoft Purview Data Sharing lineage.
> - Data sharing is accessed through the classic Microsoft Purview governance portal: https://web.purview.azure.com

Common scenarios

Data Share Lineage is aimed to provide detailed information for root cause analysis and impact analysis.

Scenario 1: 360 view of datasets shared in/out for a partner organization or internal department

Data officers can see a list of all datasets that are bi-directionally shared with their partner organizations. They can search and discover the datasets by organization name and see a complete view of all outgoing and incoming shares.

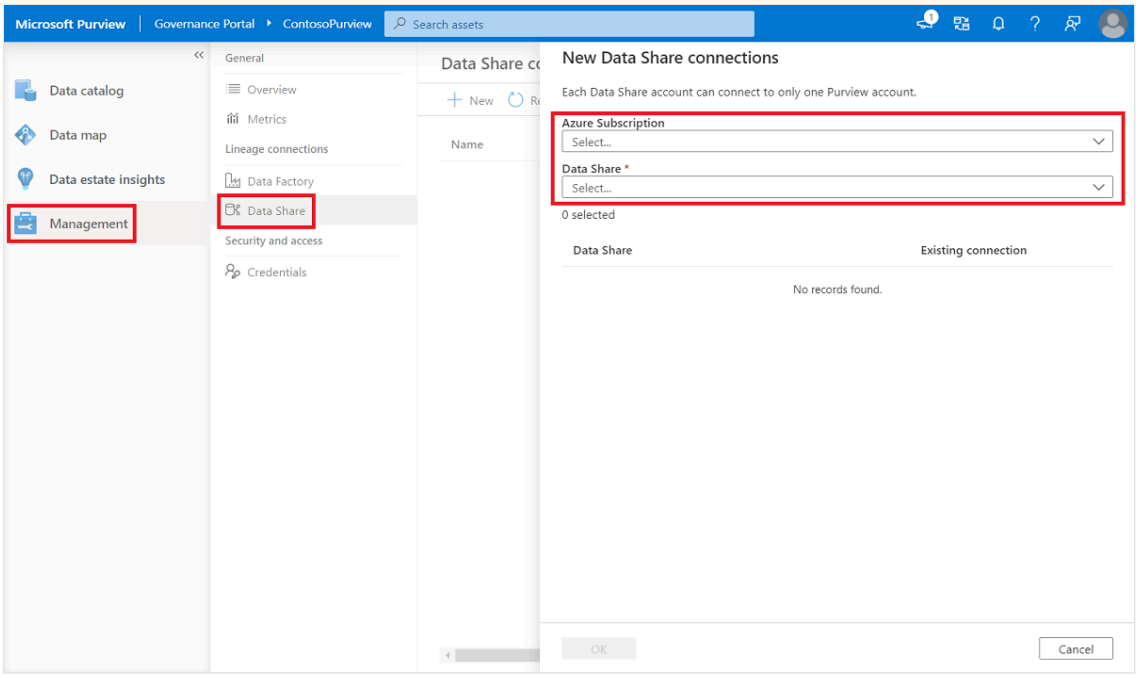
Scenario 2: Root cause analysis - upstream dependency on datasets coming into organization (consumer view of incoming shares)

A report has incorrect information because of upstream data issues from an external Data Share account. The data engineers can understand upstream failures, be informed about the reasons, and further contact the owner of the share to fix the issues causing their data discrepancy.

Scenario 3: Impact analysis on datasets going outside organization (provider view of outgoing shares)

Data producers want to know who will be impacted upon making a change to their dataset. Using lineage, a data producer can easily understand the impact of the downstream internal or external partners who are consuming data using Azure Data Share.

Azure Data Share and Microsoft Purview connected experience



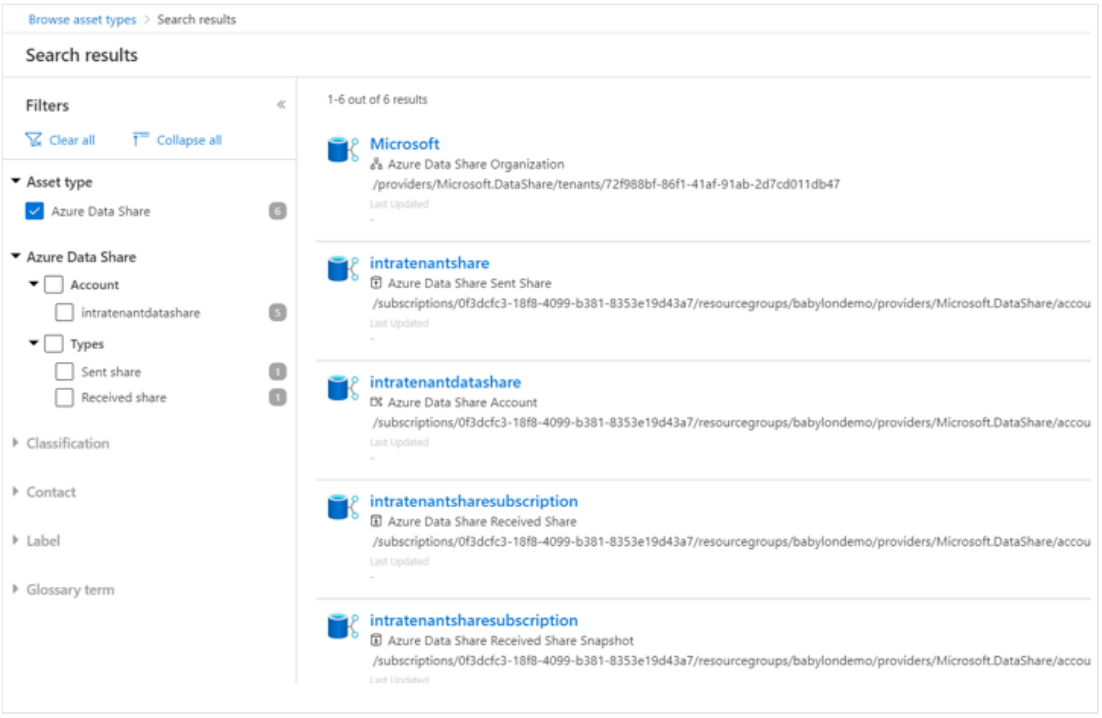
To connect your Azure Data Share and Microsoft Purview account, do the following:

1. Create a Microsoft Purview account. All the Data Share lineage information will be collected by a Microsoft Purview account. You can use an existing one or create a new Microsoft Purview account.

2. Connect your Azure Data Share to your Microsoft Purview account.

    a. In the Microsoft Purview governance portal, you can go to **Management Center** and connect your Azure Data Share under the **External connections** section.

    b. Select **+ New** on the top bar, find your Azure Data Share in the pop-up side bar and add the Data Share account. Run a snapshot job after connecting your Data Share to Microsoft Purview account, so that the Data Share assets and lineage information is visible in Microsoft Purview.



3. Execute your snapshot in Azure Data Share.

    - Once the Azure Data share connection is established with Microsoft Purview, you can execute a snapshot for your existing shares.
    - If you don't have any existing shares, go to the Azure Data Share portal to share your data and subscribe to a data share.
    - Once the share snapshot is complete, you can view associated Data Share assets and lineage in Microsoft Purview.

4. Discover Data Share accounts and share information in your Microsoft Purview account.

    - In the home page of Microsoft Purview account, select **Browse by asset type** and select the **Azure Data Share** tile. You can search for an account name, share name, share snapshot, or partner organization. Otherwise apply filters on the Search result page for account name, share type (sent vs received shares).

> **ⓘ Important**
>
> For Data Share assets to show in Microsoft Purview, a snapshot job must be run after you connect your Data Share to Microsoft Purview.

5. Track lineage of datasets shared with Azure Data Share.

    - From the Microsoft Purview search result page, choose the Data share snapshot (received/sent) and select the **Lineage** tab, to see a lineage graph with upstream and downstream dependencies.

How to get lineage from Azure Synapse Analytics into Microsoft Purview

07/18/2025

This article explains the steps required for connecting an Azure Synapse workspace with a Microsoft Purview account to track data lineage and ingest data sources. The article also explains details of the activity coverage scope and supported lineage capabilities.

When you connect Azure Synapse Analytics to Microsoft Purview, whenever a supported pipeline activity is run, metadata about the activity's source data, output data, and the activity will be automatically ingested into the Microsoft Purview Data Map.

If a data source has already been scanned and exists in the data map, the ingestion process will add the lineage information from Azure Synapse Analytics to that existing source. If the source or output doesn't exist in the data map and is supported by Azure Synapse Analytics lineage Microsoft Purview will automatically add their metadata from Synapse Analytics into the data map under the default domain root collection.

This can be an excellent way to monitor your data estate as users move and transform information using Azure Synapse Analytics.

Supported Azure Synapse capabilities

Currently, Microsoft Purview captures runtime lineage from the following Azure Synapse pipeline activities:

- Copy Data
- Data Flow

> **Important**
>
> Microsoft Purview drops lineage if the source or destination uses an unsupported data storage system.

Copy activity support

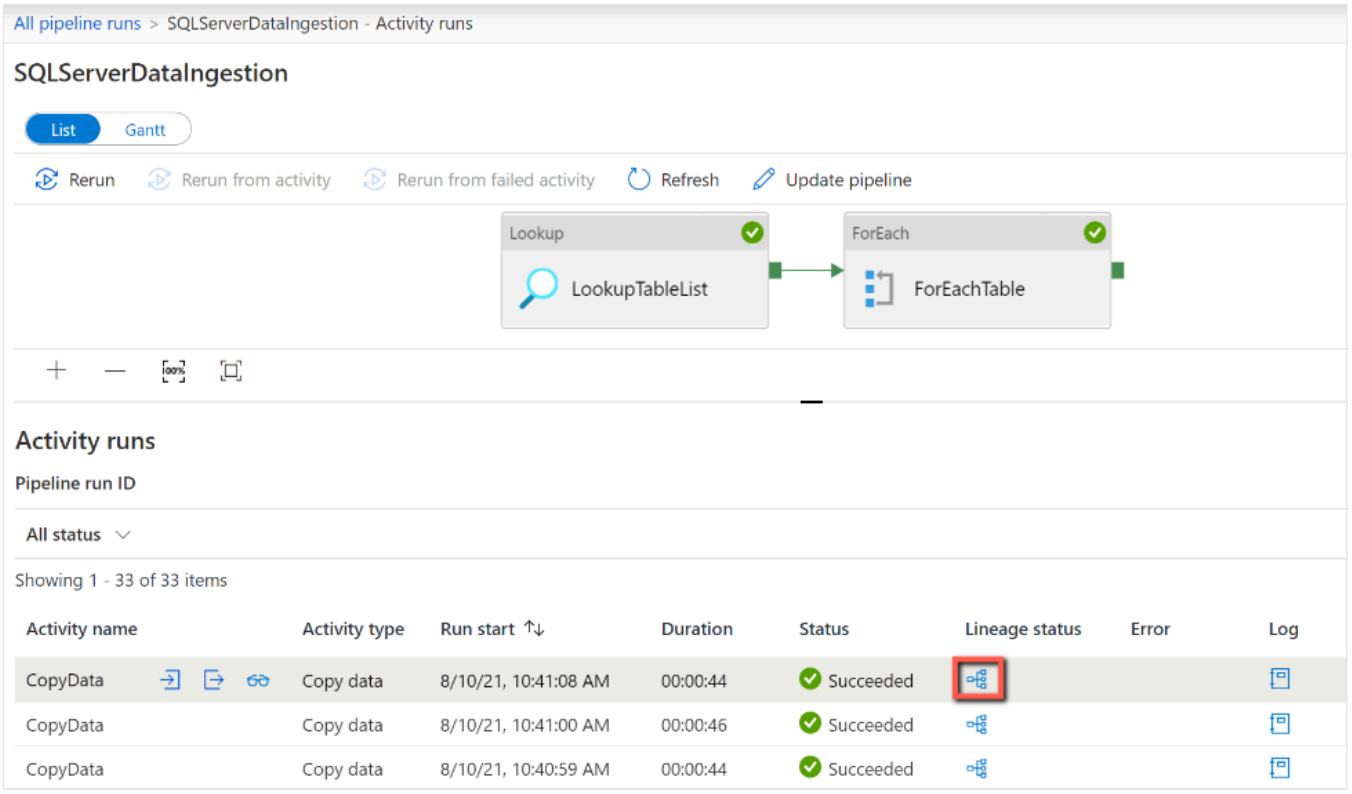
- Lineage is not supported when flowlets are part of the dataflow.
- Currently Purview doesn't support lineage reporting for Synapse tables (LakeHouse DB/Workspace DB)

Access secured Microsoft Purview account

If your Microsoft Purview account is protected by firewall, learn how to let Azure Synapse access a secured Microsoft Purview account through Microsoft Purview private endpoints.

Bring Azure Synapse lineage into Microsoft Purview

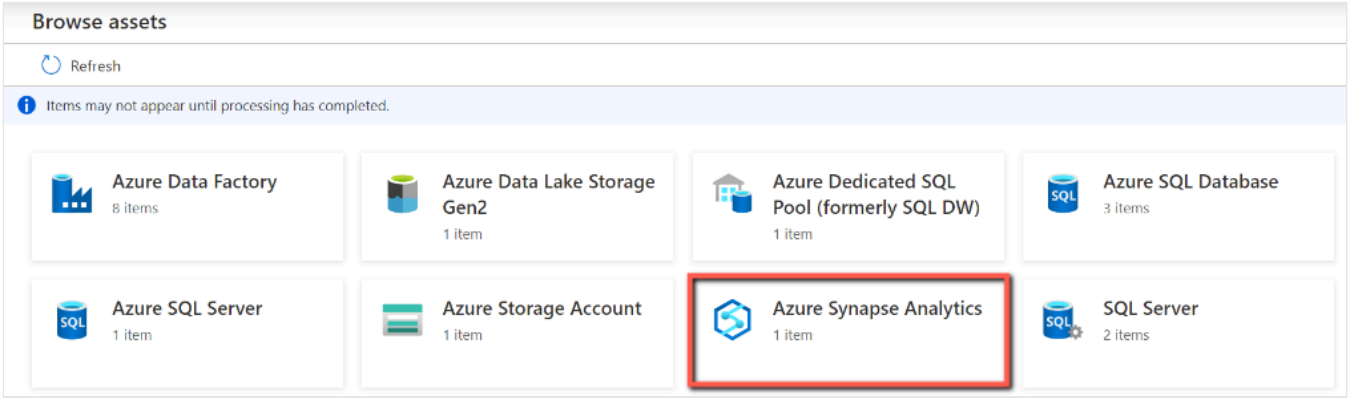
Step 1: Connect Azure Synapse workspace to your Microsoft Purview account



You can connect an Azure Synapse workspace to Microsoft Purview, and the connection enables Azure Synapse to push lineage information to Microsoft Purview. Follow the steps in Connect Synapse workspace to Microsoft Purview. Multiple Azure Synapse workspaces can connect to a single Microsoft Purview account for holistic lineage tracking.

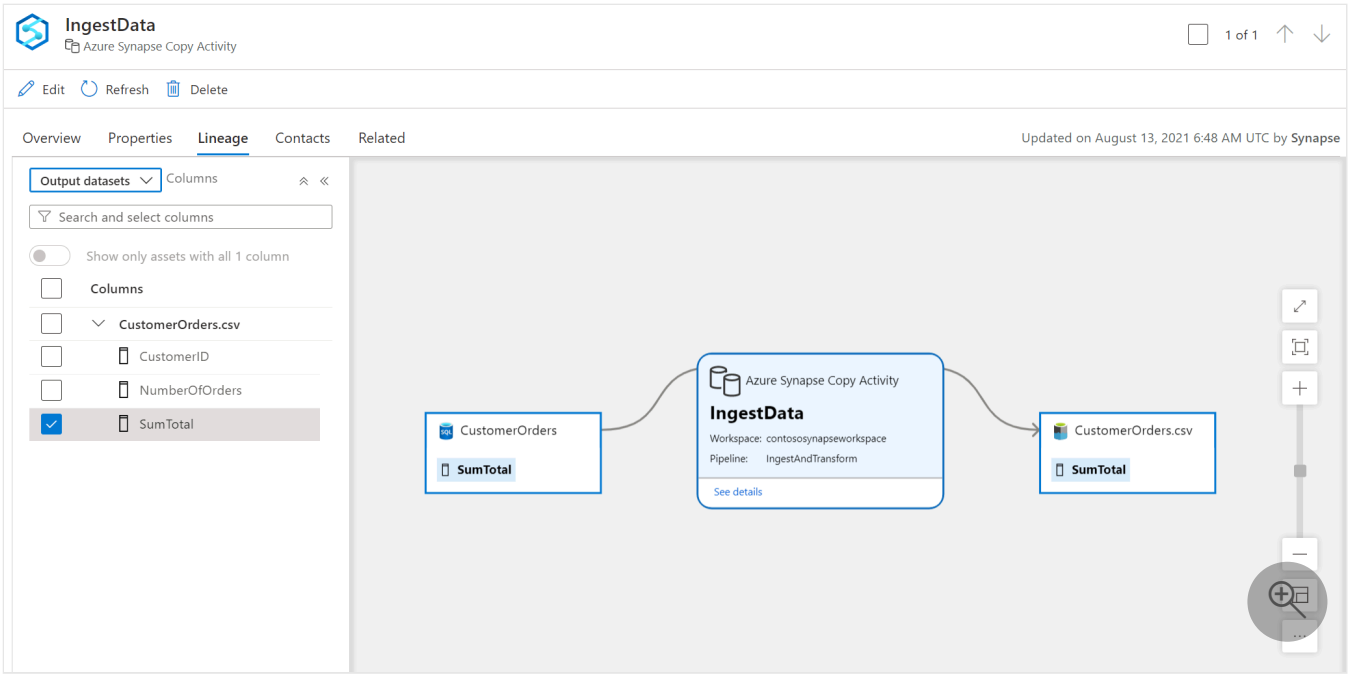
Step 2: Run pipeline in Azure Synapse workspace

You can create pipelines with Copy activity in Azure Synapse workspace. You don't need any other configuration for lineage data capture. The lineage data will automatically be captured during the activities execution.



Step 3: Monitor lineage reporting status

After you run the Azure Synapse pipeline, in the Synapse pipeline monitoring view, you can check the lineage reporting status by selecting the following **Lineage status** button. The same information is also available in the activity output JSON -> `reportLineageToPurvew` section.



Step 4: View lineage information in your Microsoft Purview account

In your Microsoft Purview account, you can browse assets and choose type "Azure Synapse Analytics". You can also search Unified Catalog using keywords.

Select the Synapse account -> pipeline -> activity, you can view the lineage information.

Monitor the Azure Synapse Analytics links

In Microsoft Purview governance portal, you can monitor the Azure Synapse Analytics links.

Catalog lineage user guide

Link to Azure Data Share for lineage

How to get lineage from Microsoft Fabric items into Microsoft Purview

07/18/2025

This article explains data lineage for Microsoft Fabric items in Microsoft Purview.

Prerequisites

To see data lineage in Microsoft Purview for Fabric items, you must first register and scan your Fabric tenant.

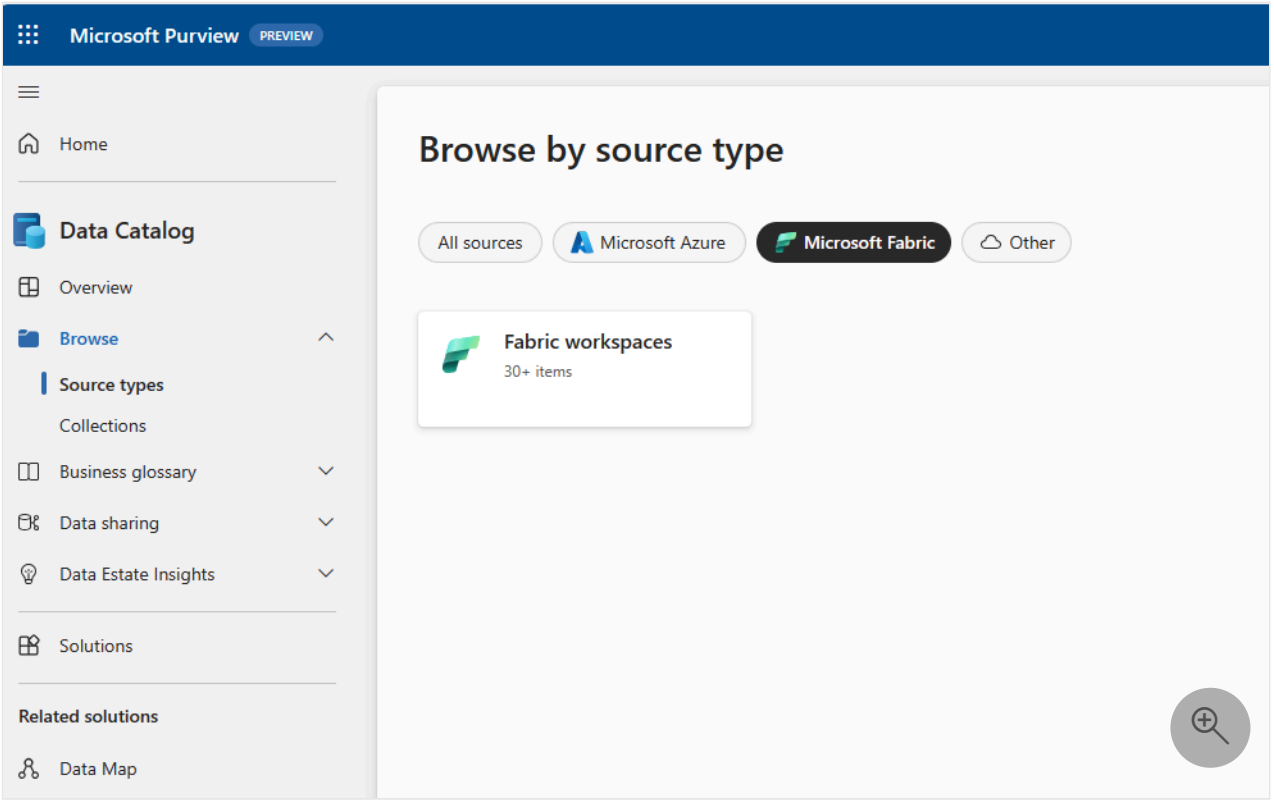
Supported capabilities

Scanning a Microsoft Fabric tenant will automatically bring in metadata and lineage from Fabric items including Power BI into Microsoft Purview Unified Catalog.

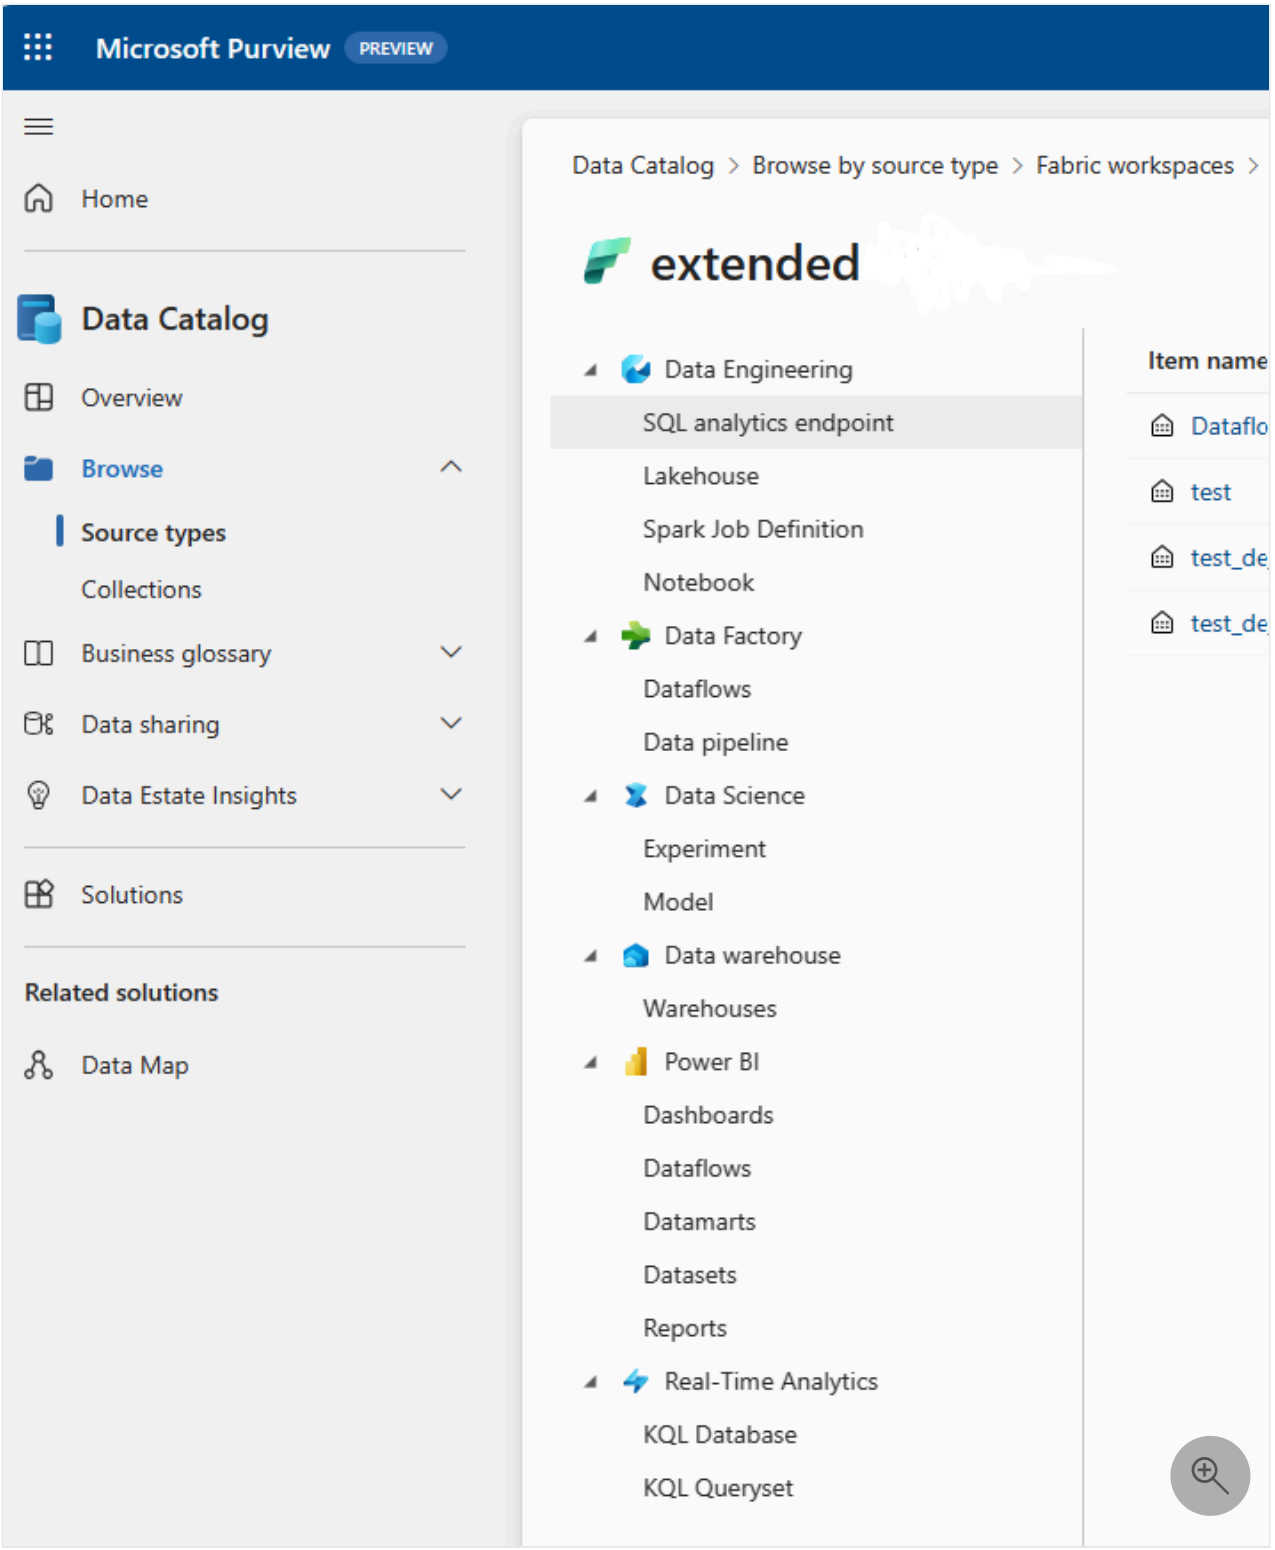
- For all Fabric items besides Power BI, only item level metadata and lineage can be scanned.
- For Lakehouse tables and files, sub-item level metadata scanning is now available in preview but sub-item level lineage is still not supported.

Lineage of Fabric items in Microsoft Purview

Once the scan of your Fabric tenant is complete, following Fabric items are inventoried in Microsoft Purview:



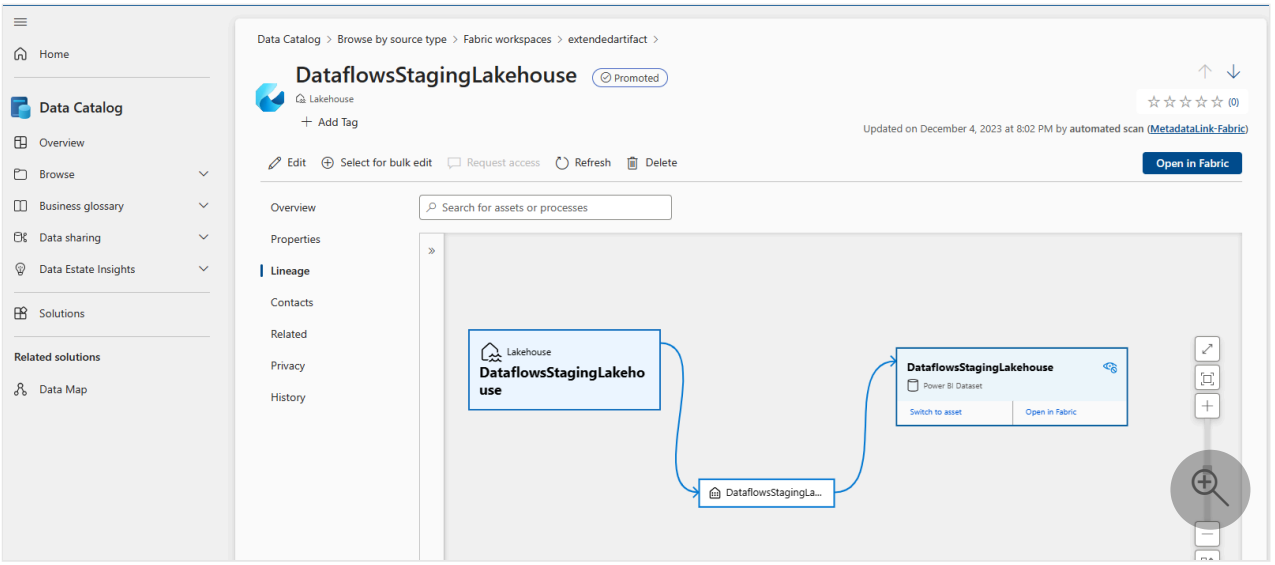
Expand table



Experiences	Fabric items	Available in scan	Available in live view (same tenant only)
Real-Time Analytics	KQL Database	Yes	Yes
	KQL Queryset	Yes	Yes
Data Science	Experiment	Yes	Yes
	ML model	Yes	Yes
Data Factory	Data pipeline	Yes	Yes

Experiences	Fabric items	Available in scan	Available in live view (same tenant only)
	Dataflow Gen2	Yes	Yes
Data Engineering	Lakehouse	Yes	Yes
	Notebook	Yes	Yes
	Spark Job Definition	Yes	Yes
	SQL analytics endpoint	Yes	Yes
Data Warehouse	Warehouse	Yes	Yes
Power BI	Dashboard	Yes	Yes
	Dataflow	Yes	Yes
	Datamart	Yes	Yes
	Semantic model (Dataset)	Yes	Yes
	Report	Yes	Yes
	Paginated report	Yes	

To see lineage for Fabric items in Microsoft Purview:



1. Select Unified Catalog -> Browse -> Source Types -> Microsoft Fabric -> Fabric Workspaces
2. Select the particular Fabric workspace, select the experience, and then the Fabric item of interest

30+ items

Alternatively, users can search for a Fabric item by name, description, or other details to see relevant results.

3. Select the Lineage tab. Asset relationships are shown with the upstream and downstream dependencies.

Lineage of Power BI artifacts in Microsoft Purview

Refer to Power BI lineage for key details and limitations around Power BI lineage in Fabric.

Known limitations

- For non-Power BI Fabric items, external data sources as upstream sources in lineage aren't yet supported.
- Cross workspace lineage for non-Power BI items isn't supported.
- Notebook -> Pipeline lineage isn't supported.

Next steps

- Learn about lineage in Microsoft Fabric

How to view Microsoft Purview Data Sharing lineage

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently being retired, with support provided until September 2025 to allow for migration to Microsoft Fabric external data sharing.

This article discusses how to view the lineage of datasets shared using Microsoft Purview Data Sharing. With these tools, users can discover and track lineage of data across boundaries like organizations, departments, and even data centers.

> **Important**
>
> This article is about lineage for Microsoft Purview Data Sharing. If you are using Azure Data Share, use this article for lineage: Azure Data Share lineage.

Common scenarios

Data Sharing lineage aims to provide detailed information for root cause analysis and impact analysis.

Some common scenarios include:

- Full view of datasets shared in and out of your organization
- Root cause analysis for upstream dataset dependencies
- Impact analysis for shared datasets

Full view of datasets shared in and out of your organization

Data officers can see a list of all bi-directionally shared datasets with their partner organizations. They can search and discover the datasets by organization name and see a complete view of all outgoing and incoming shares.

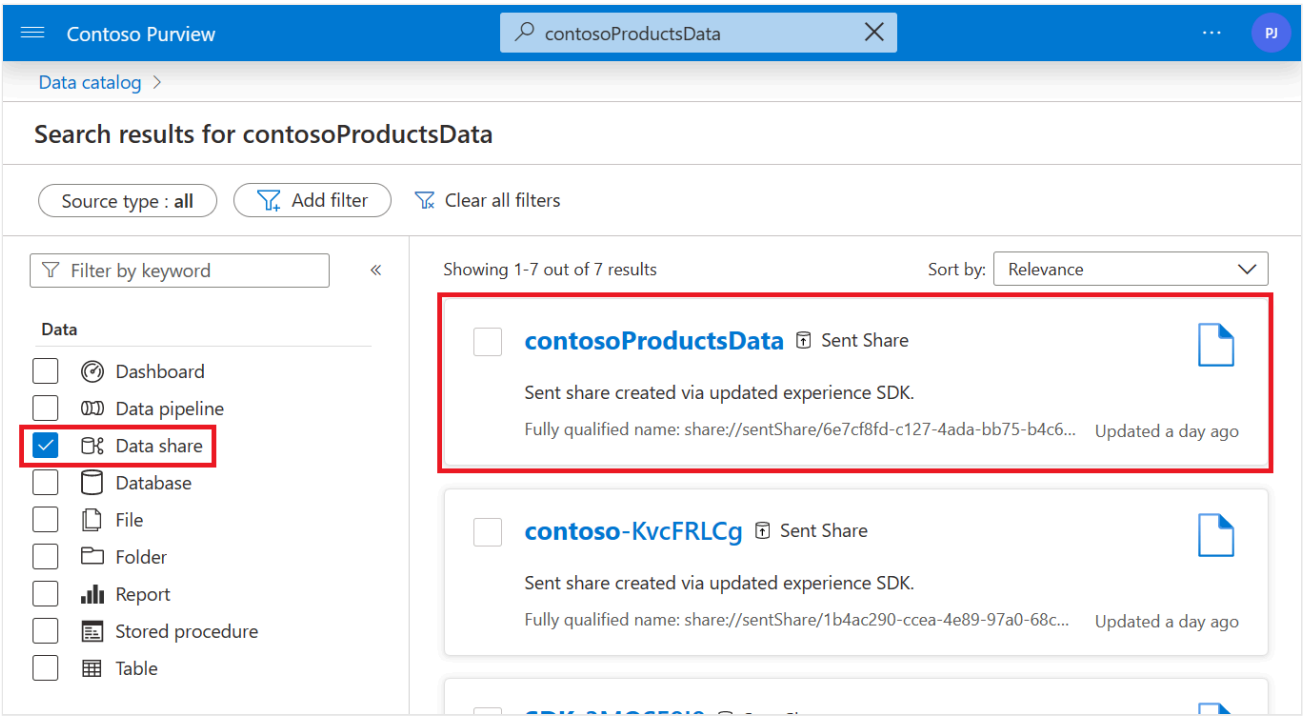
See the Microsoft Entra ID share lineage section to see a full view of outgoing and incoming shares.

Root cause analysis for upstream dataset dependencies

A report has incorrect information because of upstream data issues from an external Microsoft Purview Data Sharing activity. The data engineers can understand upstream failures, understand possible cause, and further contact the owner of the share to fix the issues causing their data discrepancy.

See the lineage of a share or Microsoft Entra ID share lineage sections to see the upstream dependencies for your assets.

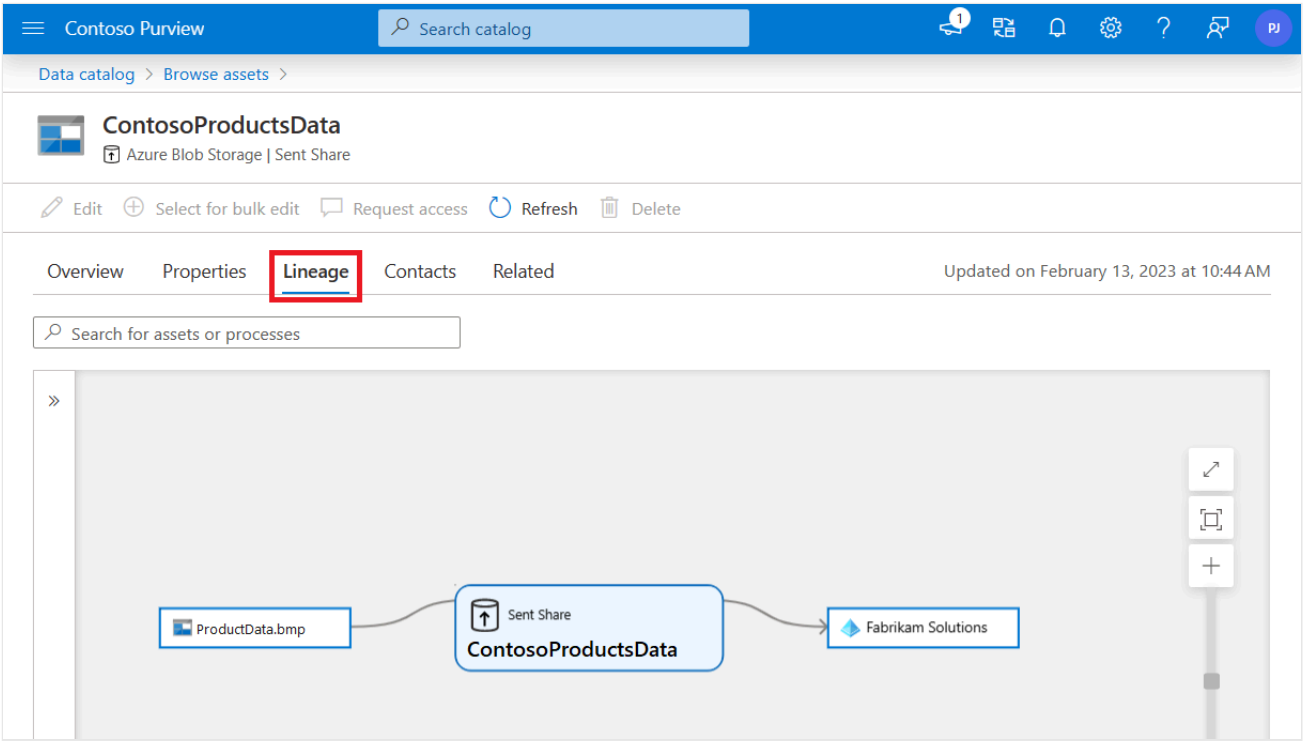
Impact analysis for shared datasets



Data producers want to know who will be impacted when they make a change to their datasets. With a lineage map, a data producer can easily understand the impact of the downstream internal or external partners who are consuming data using Microsoft Purview Data Sharing.

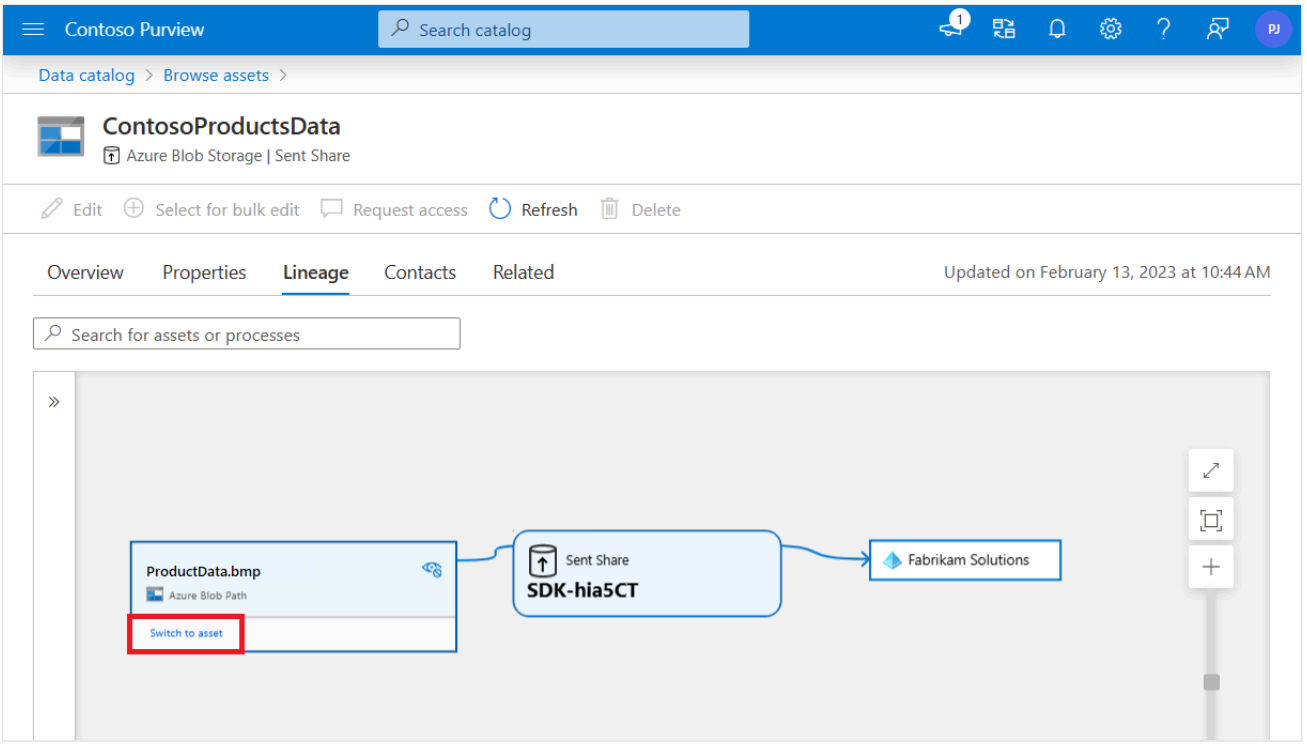
See the lineage of a share or Microsoft Entra ID share lineage sections to see downstream dependencies of your shared assets.

Lineage of a share



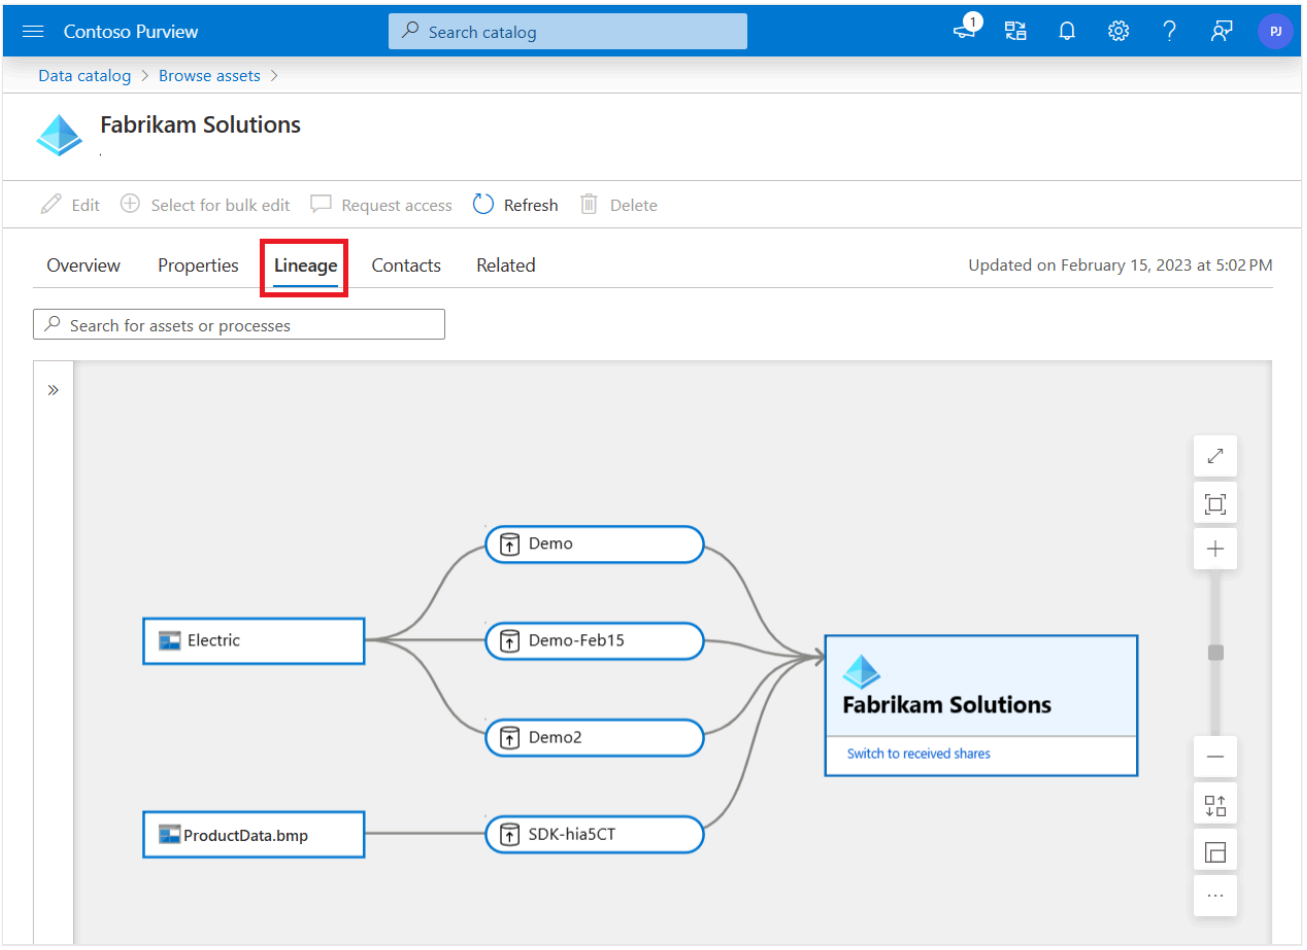
To see the data sharing lineage for your sent share or received share asset, you only need to have data reader permissions on the collection where the asset is housed.

1. Discover your sent share or received share asset in the Catalog search or browse for the share in the data catalog, and narrow results to only data shares.

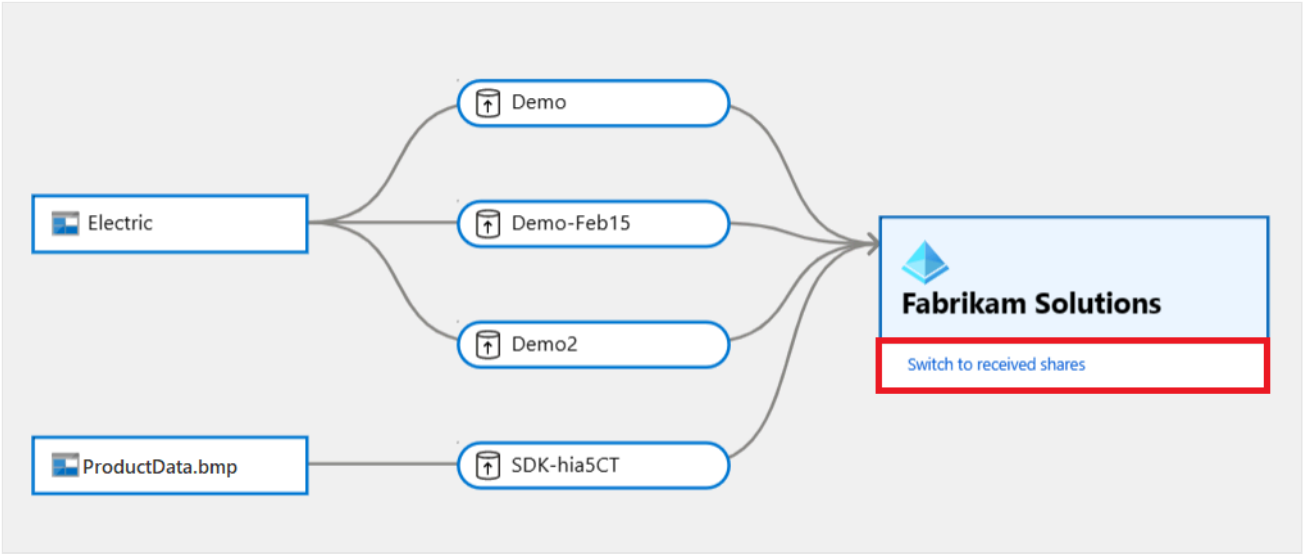


2. Select your data share asset.

3. Select the lineage tab to see a graph with upstream and downstream dependencies.



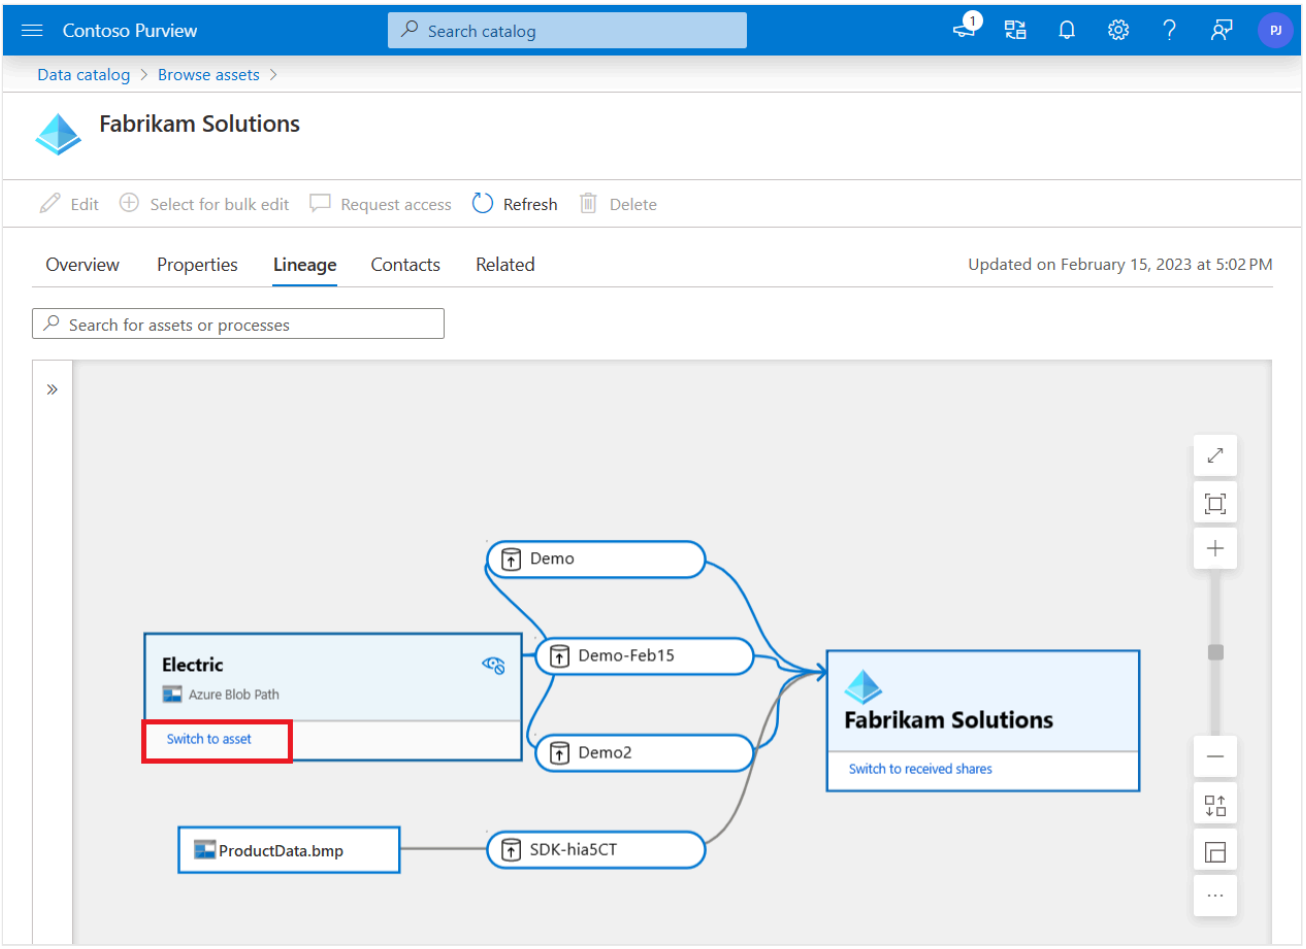
4. You can select the files or folders, or the Microsoft Entra asset in the lineage canvas and see the data sharing lineage for those assets.



Microsoft Entra ID share lineage

1. You can search for your Microsoft Entra tenant asset in the Catalog using the search bar, or filtering by **Source type** and selecting **Microsoft Entra ID**.

2. Select your Microsoft Entra ID, then select the **Lineage** tab to see a lineage graph with either upstream or downstream dependencies.



3. If you're seeing all sent shares, or all received shares, you can select the button to switch the view to see the other.

> **Note**
>
> If you do not see this button it may be because your Microsoft Entra ID does not have any sent/received shares, or that you do not have permission on the collection where the sent/received shares are housed.

4. You can also select any file or folder in the lineage canvas and see the data sharing lineage for those assets.

> **Important**
>
> For Data Share assets to show in Microsoft Purview, the ADLS Gen2 or Blob Storage account that the shares (sent share or received share) belong to should be registered with Microsoft Purview and the user needs Reader permission on the collection where they are housed.

Troubleshoot

Here are some common issues when viewing data sharing lineage and their possible resolutions.

Can't see the recipient Microsoft Entra tenant on the sent share lineage

If you're unable to see the recipient Microsoft Entra tenant on the sent share lineage, it means the recipient hasn't attached the share yet.

Can't find a sent share or received share asset in the Catalog

Sent or received share assets are housed in the same collection as their registered storage account assets.

- If the storage accounts the share assets belong to aren't registered, the share assets won't be discoverable.
- If you don't have a minimum of Data Reader permission to the collection where the share asset is housed, the share assets aren't discoverable.

How to get lineage from Power BI into Microsoft Purview

07/18/2025

This article elaborates on the data lineage for Power BI sources in Microsoft Purview.

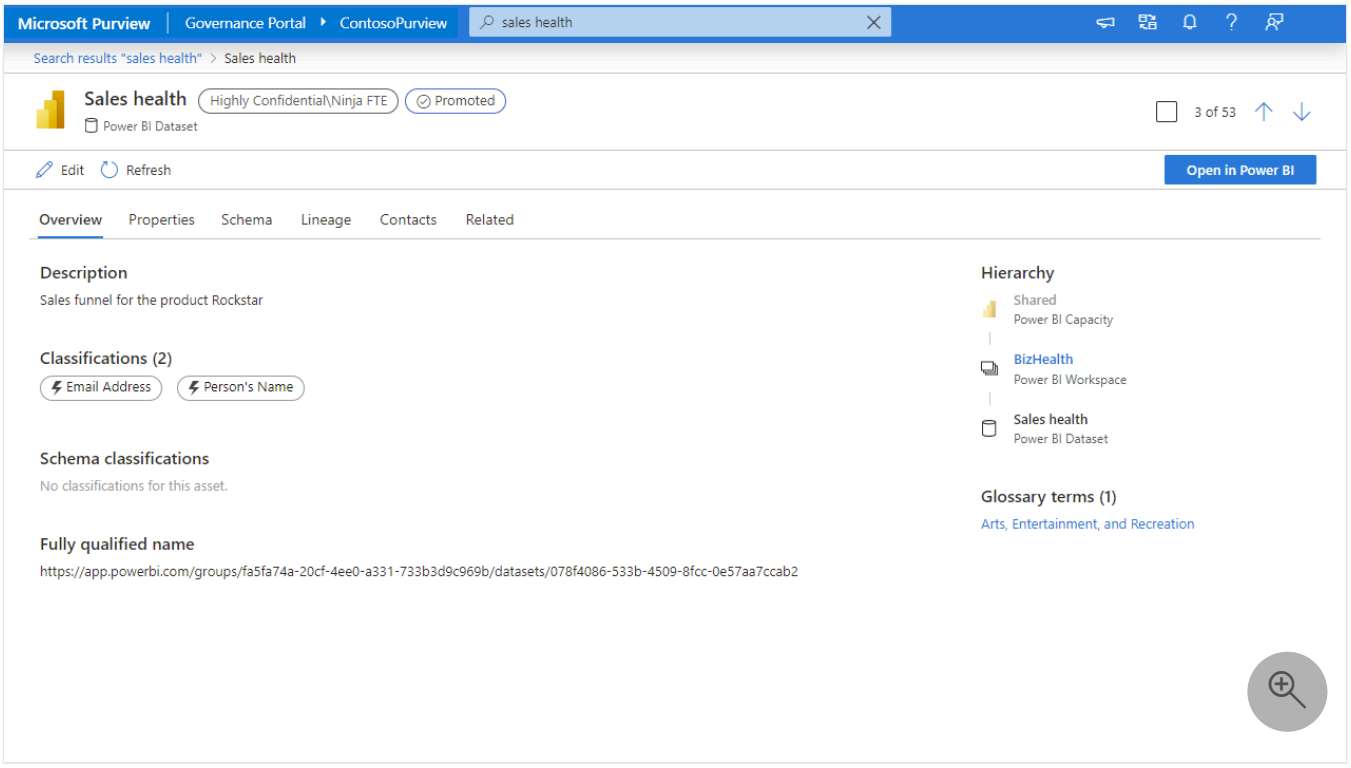
Prerequisites

To see data lineage in Microsoft Purview for Power BI, you must first register and scan your Power BI source.

Common scenarios

After a Power BI source has been scanned, lineage information for your current data assets, and data assets referenced by Power BI, will automatically be added in the Microsoft Purview Unified Catalog.

1. Data consumers can perform root cause analysis of a report or dashboard from Microsoft Purview. For any data discrepancy in a report, users can easily identify the upstream datasets and contact their owners if necessary.



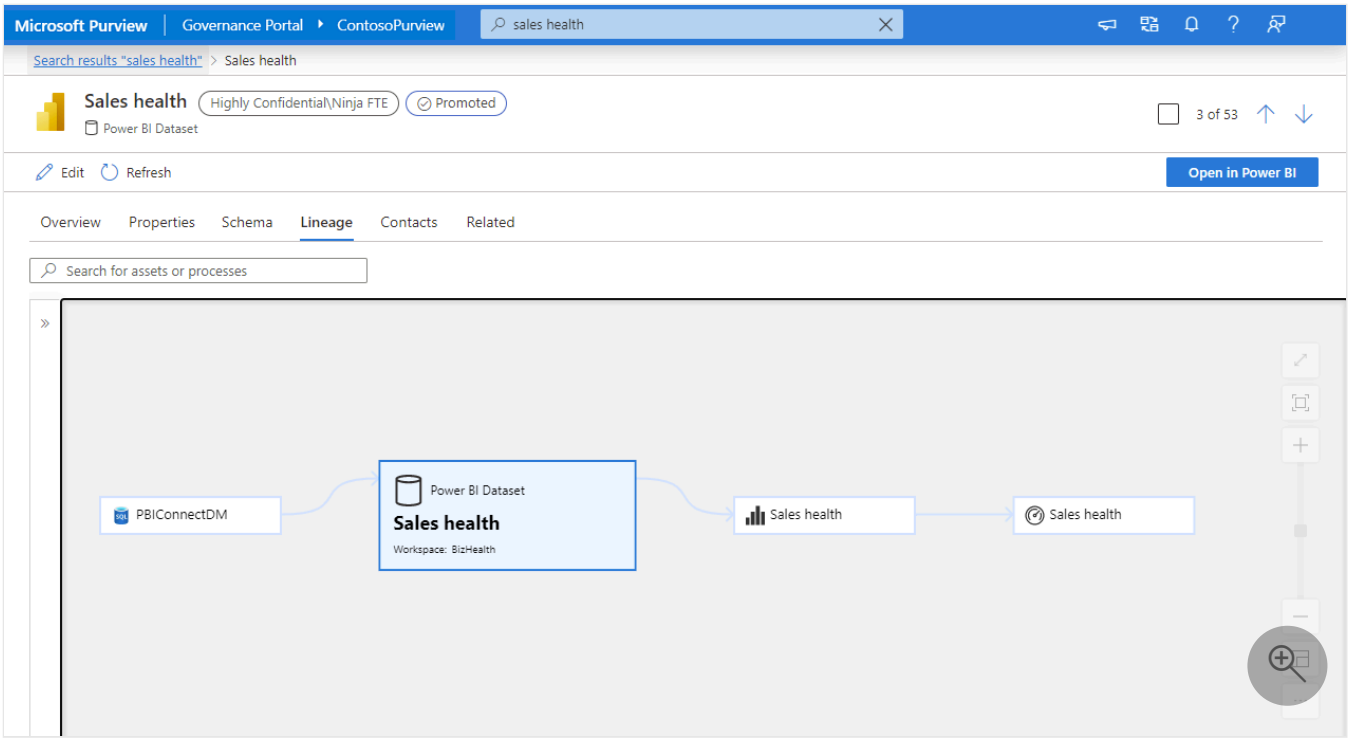
2. Data producers can see the downstream reports or dashboards consuming their dataset. Before making any changes to their datasets, the data owners can make informed decisions.

3. Users can search by name, endorsement status, sensitivity label, owner, description, and other business facets to return the relevant Power BI artifacts.

Power BI artifacts in Microsoft Purview

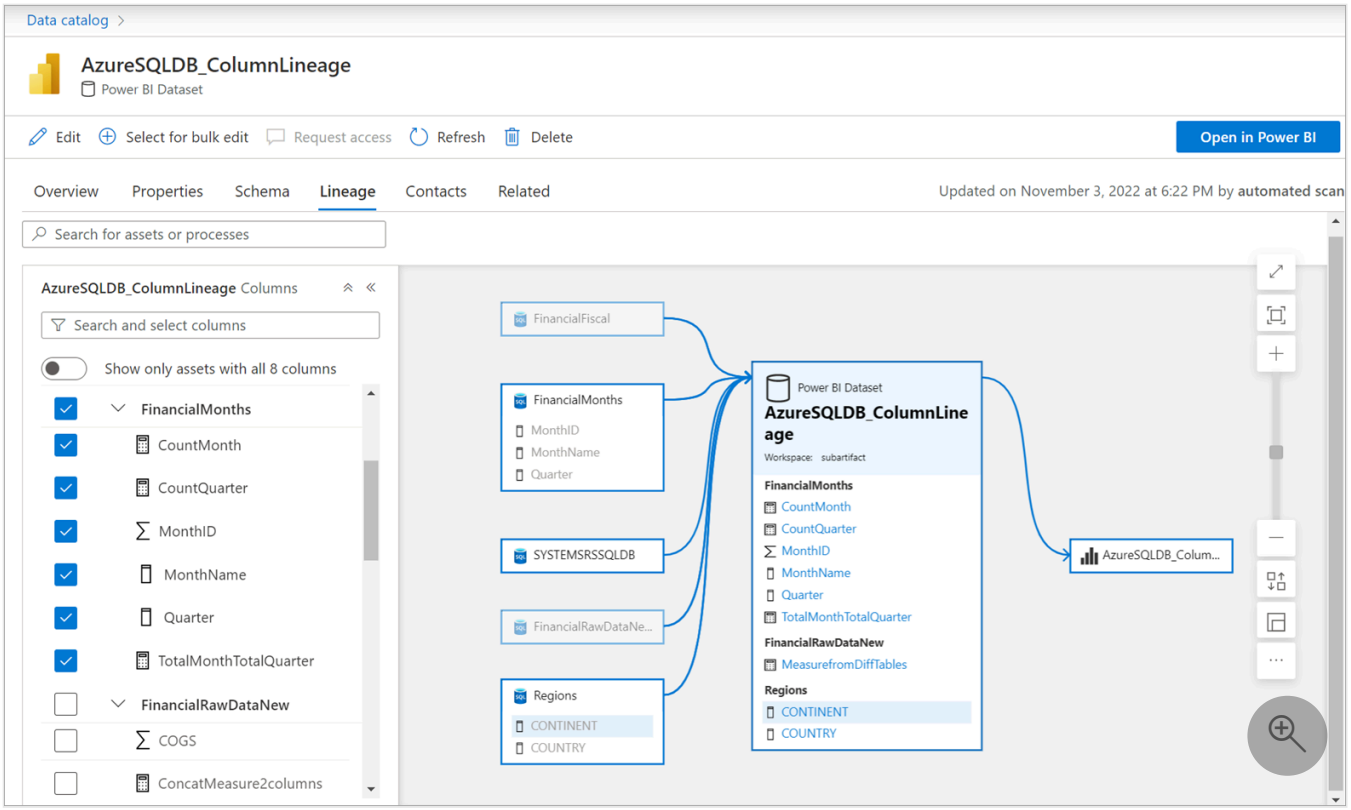
Once the scan of your Power BI is complete, following Power BI artifacts will be inventoried in Microsoft Purview:

- Workspaces
- Dashboards
- Reports
- Datasets
- Dataflows
- Datamarts



Lineage of Power BI artifacts in Microsoft Purview

Users can search for a Power BI artifact by name, description, or other details to see relevant results. Under the asset overview and properties tabs, the basic details such as description, classification are shown. Under the lineage tab, asset relationships are shown with the upstream and downstream dependencies.



Microsoft Purview captures lineage among Power BI artifacts (for example: Dataflow -> Dataset -> Report -> Dashboard) and external data assets.

> **Note**
>
> For lineage between Power BI artifacts and external data assets, currently the supported source types are:
>
> - Azure SQL Database
> - Azure Blob Storage
> - Azure Data Lake Store Gen1
> - Azure Data Lake Store Gen2

In addition, column level lineage (Power BI subartifact lineage) and transformation inside of Power BI datasets (except for Dataflows) are captured when using Azure SQL Database as source. For measures, you can further select column -> Properties -> expression to see the transformation details.

> **Note**
>
> Column level lineage and transformations (except for Dataflows) are supported when using Azure SQL Database as source. Other sources are currently not supported.

Known limitations

- Microsoft Purview leverages the scanner API to retrieve the metadata and lineage. Learn about some API limitations from Metadata scanning - Considerations and limitations.
- In case you have the dataset table connected to another dataset table, when the middle dataset disables the "Enable load" option inside the Power BI desktop, and the lineage can't be extracted.
- For lineage between Power BI artifacts and external data assets:
  - Currently the supported source types are Azure SQL Database, Azure Blob Storage, Azure Data Lake Store Gen1 and Azure Data Lake Store Gen2.
  - Column level lineage and transformations (except for Power BI Dataflows) are only supported when using Azure SQL Database as source. Other sources are currently not supported.
  - Lineage is not captured when you use dynamic M query parameters in Power BI, e.g. pass server/database names as parameter values.
  - Limited information is currently shown for data sources where the Power BI Dataflow is created. For example, for a SQL server source of Power BI dataset, only server/database name is captured.
  - Note due to the following limitations, if you have such scenarios and scan both Power BI and the data sources that Power BI artifacts connect to, currently you may see duplicate assets in the catalog.
    - The source object names in assets and fully qualified names follow the case used in Power BI settings/queries, which may not align with the object case in original data

source.
    - When Power BI references SQL views, they are currently captured as SQL table assets.
    - When Power BI references Azure Dedicated SQL pool (formerly SQL DW) sources, it's currently listed as Azure SQL Database assets. (Lineage between Power BI artifacts and external Azure Dedicated SQL pools isn't currently supported.)
- For Power BI subartifact lineage:
    - Some measures aren't shown in the subartifact lineage, for example, `COUNTROWS`.
    - In the lineage graph, when selecting a measure that is derived by columns using the COUNT function, the underlying column isn't selected automatically. Check the measure expression in the column properties tab to identify the underlying column.
    - If you scanned your Power BI source before subartifact lineage was supported, you may see a database asset along with the new table assets in the lineage graph, which isn't removed.
- Currently for the same data asset in Azure SQL Database which has UTF-8 characters in name, the full qualified name generated from scanning Power BI may be different with the fully qualified name generated from scanning Azure SQL Database as the former will go through additional encoding, and it may introduce duplicate Azure SQL data assets.

How to get lineage from SQL Server Integration Services (SSIS) into Microsoft Purview

07/18/2025

This article elaborates on the data lineage aspects of SQL Server Integration Services (SSIS) in Microsoft Purview.

Prerequisites

- Lift and shift SQL Server Integration Services workloads to the cloud

Supported scenarios

The current scope of support includes the lineage extraction from SSIS packages executed by Azure Data Factory SSIS integration runtime.

On premises SSIS lineage extraction is not supported yet.

Only source and destination are supported for Microsoft Purview SSIS lineage running from Data Factory's SSIS Execute Package activity. Transformations under SSIS are not yet supported.

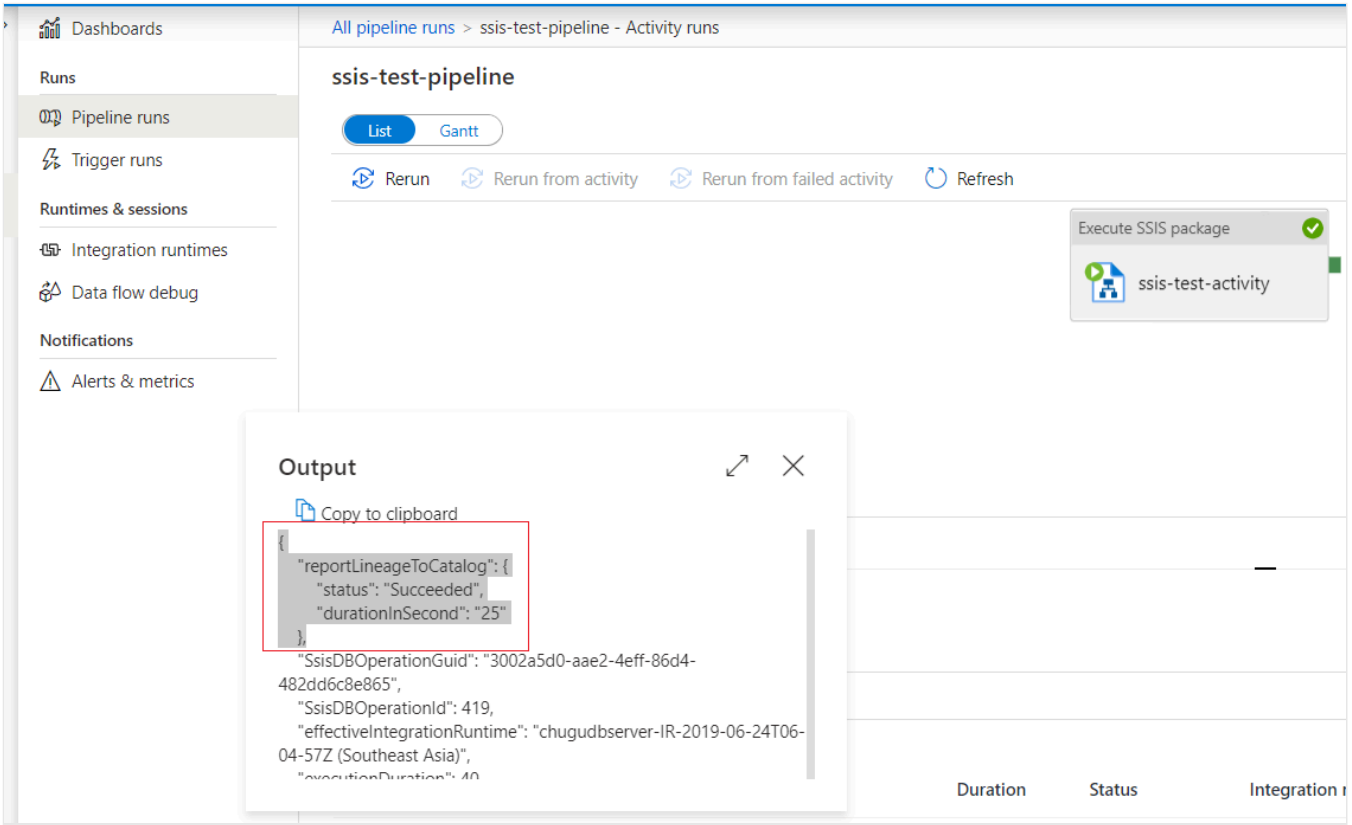
Supported data stores

Expand table

Data store	Supported
Azure Blob Storage	Yes
Azure Data Lake Storage Gen1	Yes
Azure Data Lake Storage Gen2	Yes
Azure Files	Yes
Azure SQL Database *	Yes
Azure SQL Managed Instance *	Yes
Azure Synapse Analytics *	Yes

Data store	Supported
SQL Server *	Yes

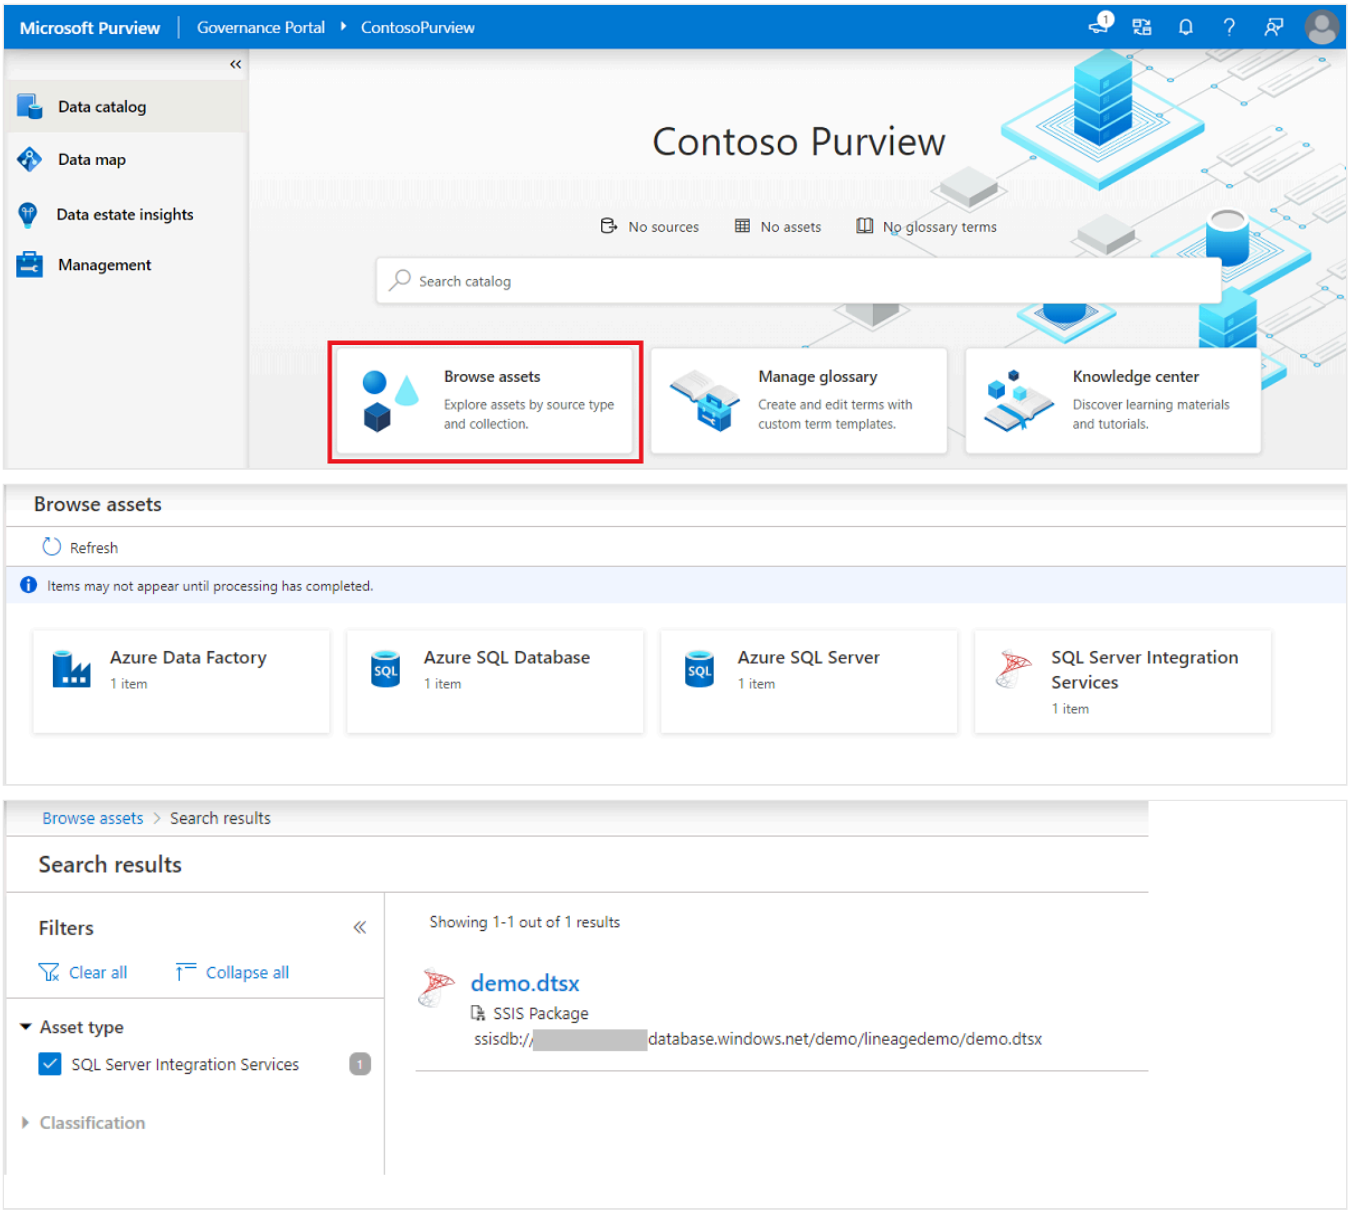
** Microsoft Purview currently doesn't support query or stored procedure for lineage or scanning. Lineage is limited to table and view sources only.*



How to bring SSIS lineage into Microsoft Purview

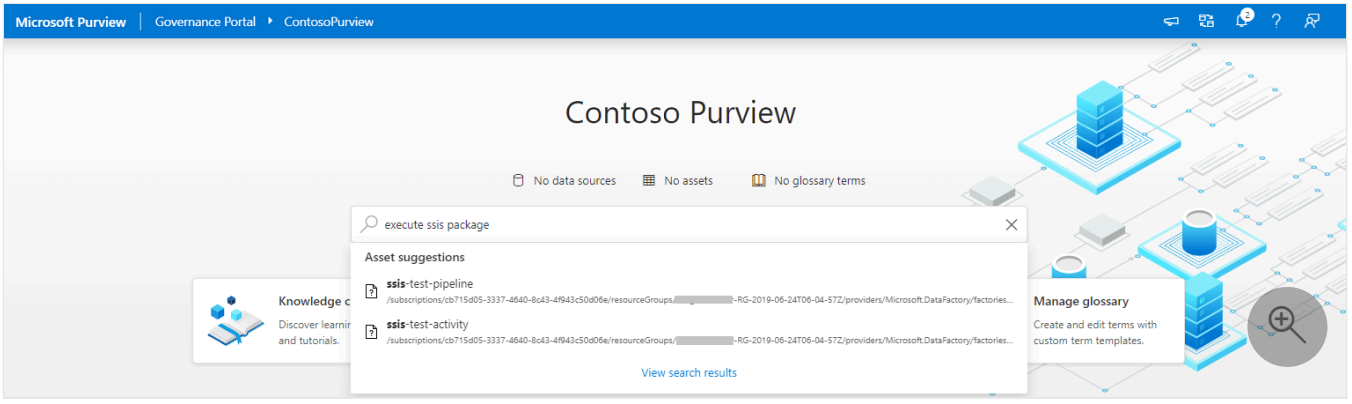
Step 1: Connect a Data Factory to Microsoft Purview

Step 2: Trigger SSIS activity execution in Azure Data Factory

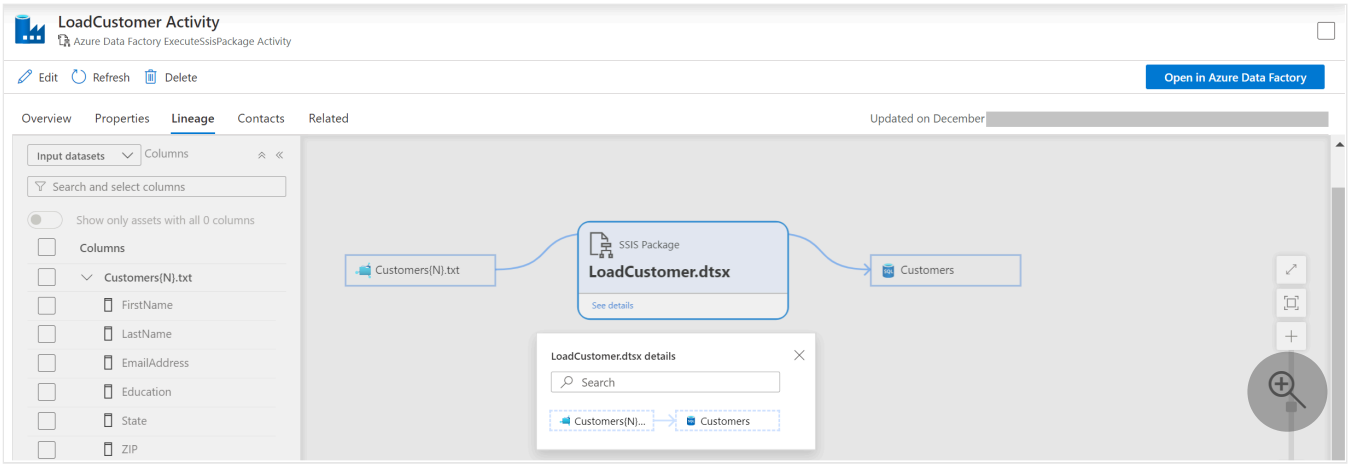


You can run SSIS package with Execute SSIS Package activity or run SSIS package with Transact-SQL in ADF SSIS Integration Runtime.

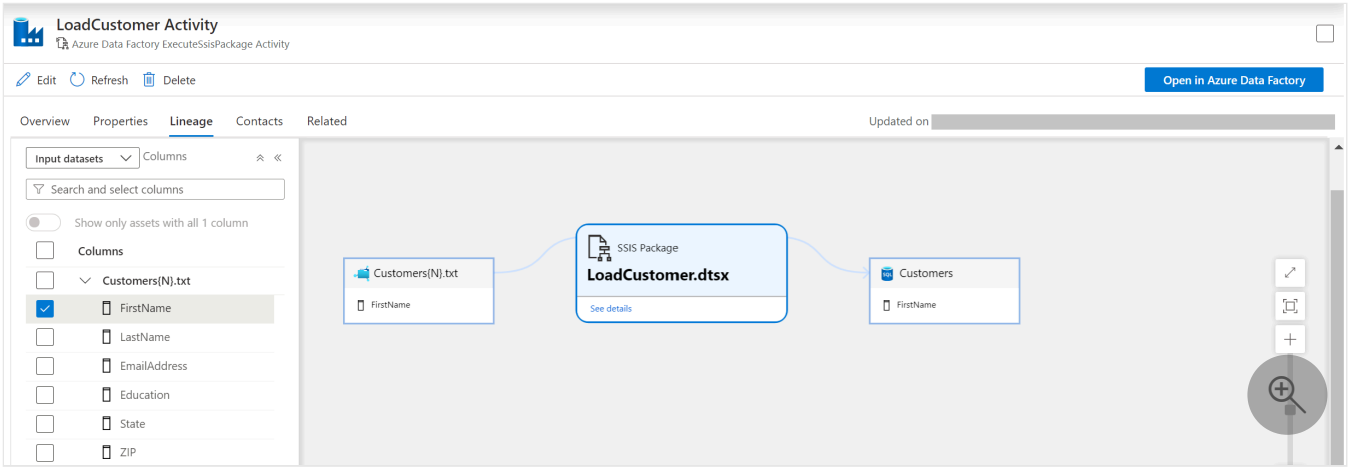
Once Execute SSIS Package activity finishes the execution, you can check lineage report status from the activity output in Data Factory activity monitor.



Step 3: Browse lineage Information in your Microsoft Purview account



- You can browse Unified Catalog by choosing asset type “SQL Server Integration Services”.



- You can also search Unified Catalog using keywords.

- You can view lineage information for an SSIS Execute Package activity and open in Data Factory to view/edit the activity settings.

- You can choose one data source to drill into how the columns in the source are mapped to the columns in the destination.

Next steps

- Lift and shift SQL Server Integration Services workloads to the cloud
- Learn about Data lineage in Microsoft Purview
- Link Azure Data Factory to push automated lineage

Connections page in the Microsoft Purview Data Map

Article • 09/10/2024

The **Connections** page in the Microsoft Purview Data Map is a page for creating unique connections to services to use more of Microsoft Purview Data Map's features.

This page is **not** for registered data sources. Instead this page is for connections in workflows and protection policies.

To view and manage connections, you can find the connections page by:

- In the Microsoft Purview portal:

    1. Select the Data Map application.
    2. Select the **Source management** dropdown.
    3. Select the **Connections** page.

- In the classic Microsoft Purview governance portal:

    1. Select the **Management** application.
    2. Under the **Security and access** list, select **Connections**.

Use

You might use the connection page when creating connections for some workflows or protection policies that require you to make special connections to partner resources.

For example:

- Connect to ServiceNow in workflows
- Create a policy enforcement connection for Amazon S3

On this page, you can edit and delete your connections by hovering over a connection and either selecting the **Edit** pencil button, or the **Delete** trashcan button.

Configure Event Hubs with Microsoft Purview to send and receive Atlas Kafka topics messages

07/21/2025

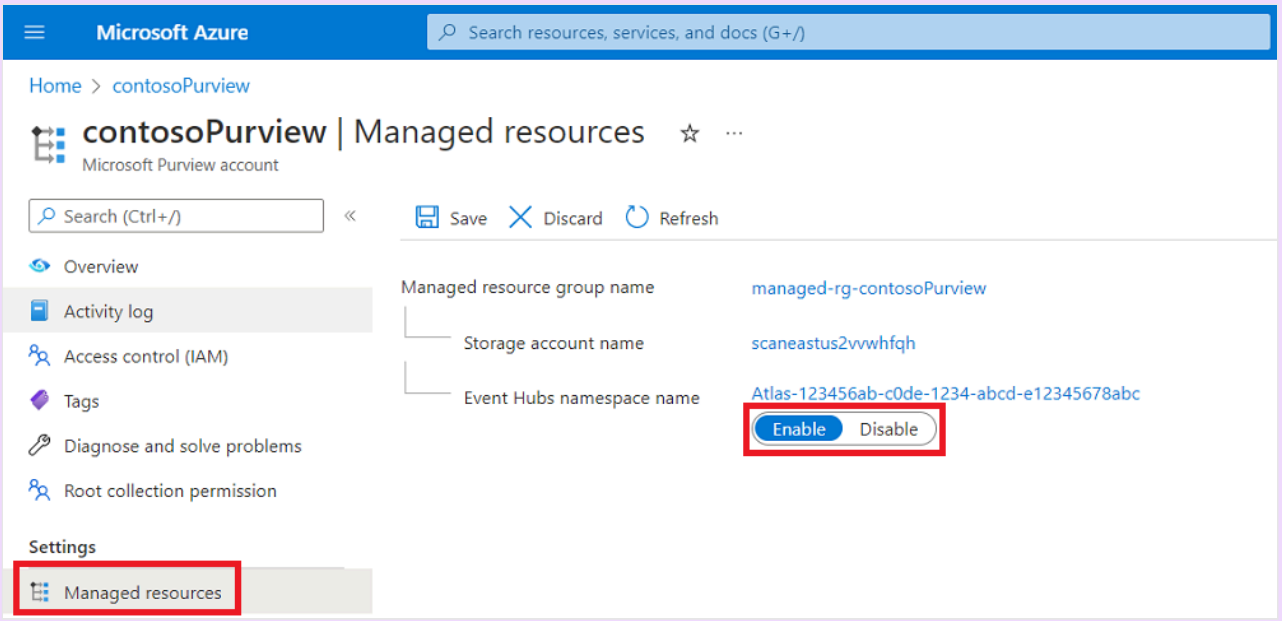
This article explains how to configure Microsoft Purview to be able to send and receive *Atlas Kafka* topics events with Azure Event Hubs.

If you have already configured your environment, learn how to get started with the **Azure.Messaging.EventHubs** .NET library to send and receive messages.

Prerequisites

To configure your environment, you need certain prerequisites in place:

- **A Microsoft Azure subscription**. To use Azure services, including Event Hubs, you need an Azure subscription. If you don't have an Azure account, you can sign up for a free trial or use your MSDN subscriber benefits when you create an account.
- An active Microsoft Purview account.



Configure Event Hubs

To send or receive Atlas Kafka topics messages, you'll need to configure at least one Event Hubs namespace. You can either:

- Create your own Azure Event Hubs namespace and configure it to work with Microsoft Purview
- Use the REST API to create a managed namespace

> **Note**
>
> If your Microsoft Purview account was created before December 15, 2022, you might have a managed Event Hubs resource already associated with your account. You can check in **Managed Resources** under settings on your Microsoft Purview account page in the Azure

portal .

- If you don't see this resource, or it's **disabled**, follow the steps below to configure your Event Hubs.
- If it's **enabled**, you can continue to use this managed Event Hubs namespace if you prefer. (There's associated cost. See see the pricing page .) If you want to manage your own Event Hubs account, you must first **disable** this feature and follow the steps below. **To keep the Event Hub's supported TLS version updated, we recommend using BYO Event Hub. If you disable the managed Event Hubs resource you won't be able to re-enable a managed Event Hub resource. You will only be able to configure your own Event Hubs.**

Bring your own Event Hubs namespace

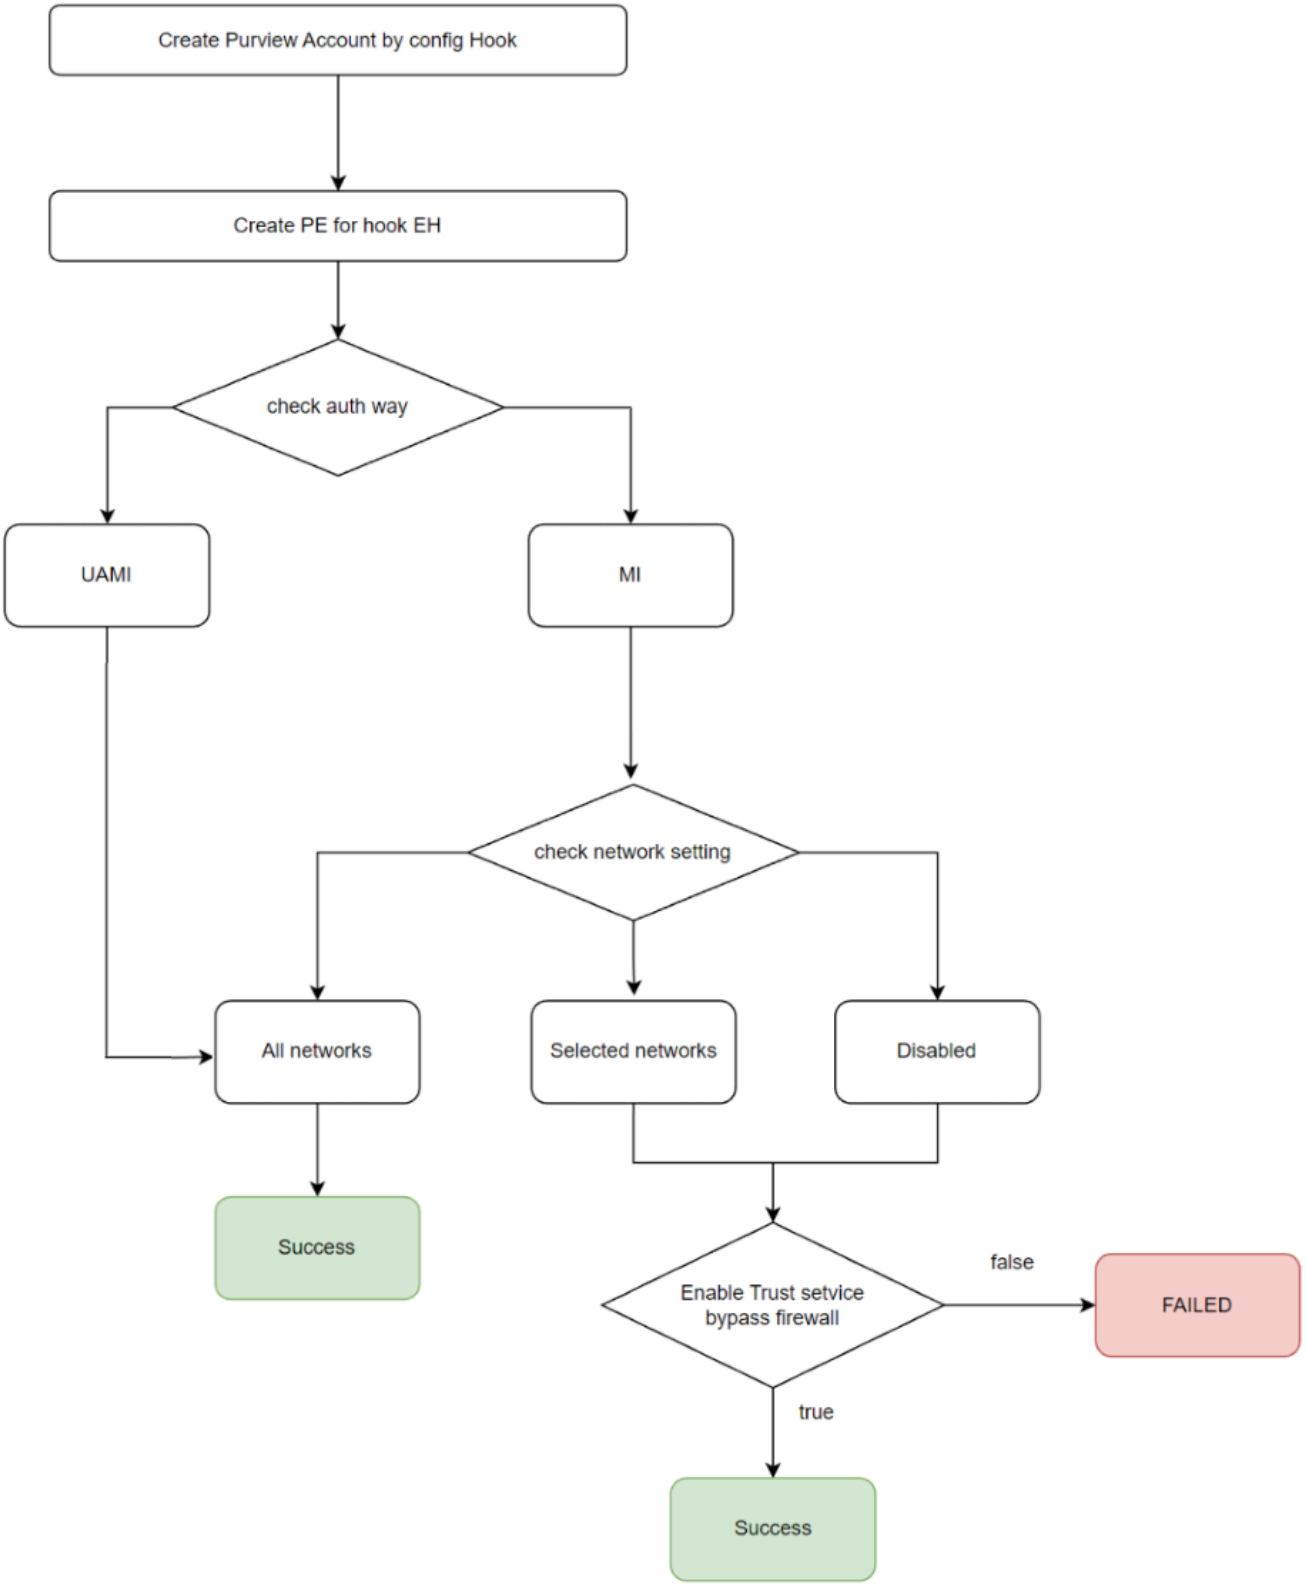
You can configure an existing Azure Event Hubs namespace with an Event Hubs or create a new one to connect with Microsoft Purview.

Event Hubs permissions

To authenticate with your Event Hubs, you can either use:

- Microsoft Purview managed identity(Recommended)
- User assigned managed identity - only available when configuring namespaces after account creation **and** if using Event Hubs with an open network.

These identities need **at least contributor permissions on your Event Hubs** to be able to configure them to use with Microsoft Purview.



Event Hubs networking

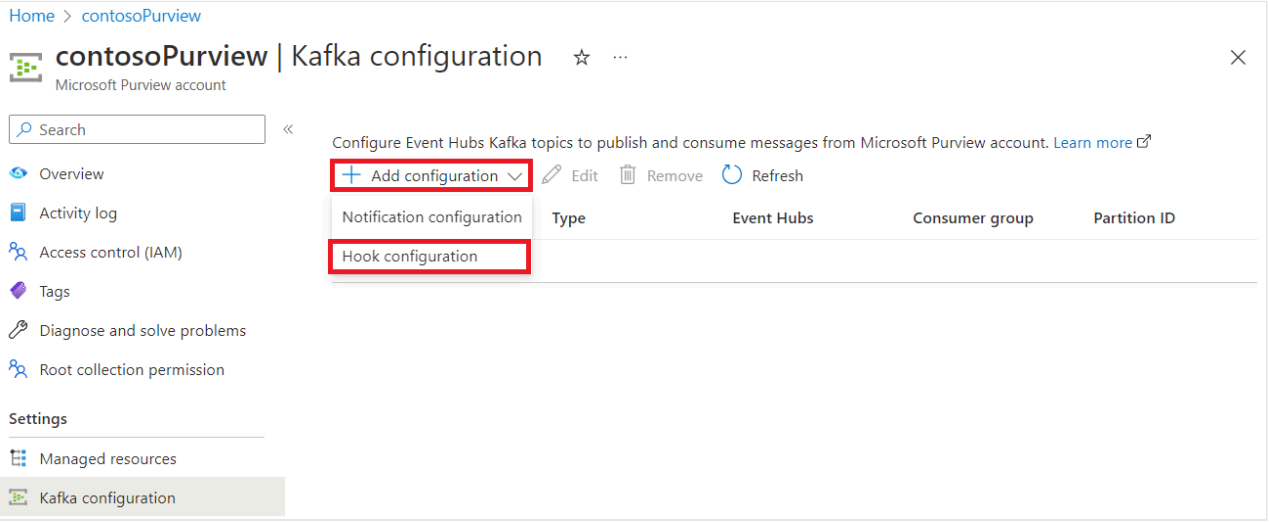
1. If your Microsoft Purview account is using private endpoints, set up an ingestion private endpoint to connect to Event Hubs.

2. Your Event Hubs workspace network needs to be configured in one of two ways:

    - *Public network access* set to **Selected networks** or **Disabled**, *Allow trusted Microsoft services to bypass this firewall* set to **Yes**, and using the Microsoft Purview managed identity to authenticate.
    - *Public network access* set to **All networks** and using the Microsoft Purview managed identity or a user assigned managed identity to authenticate.

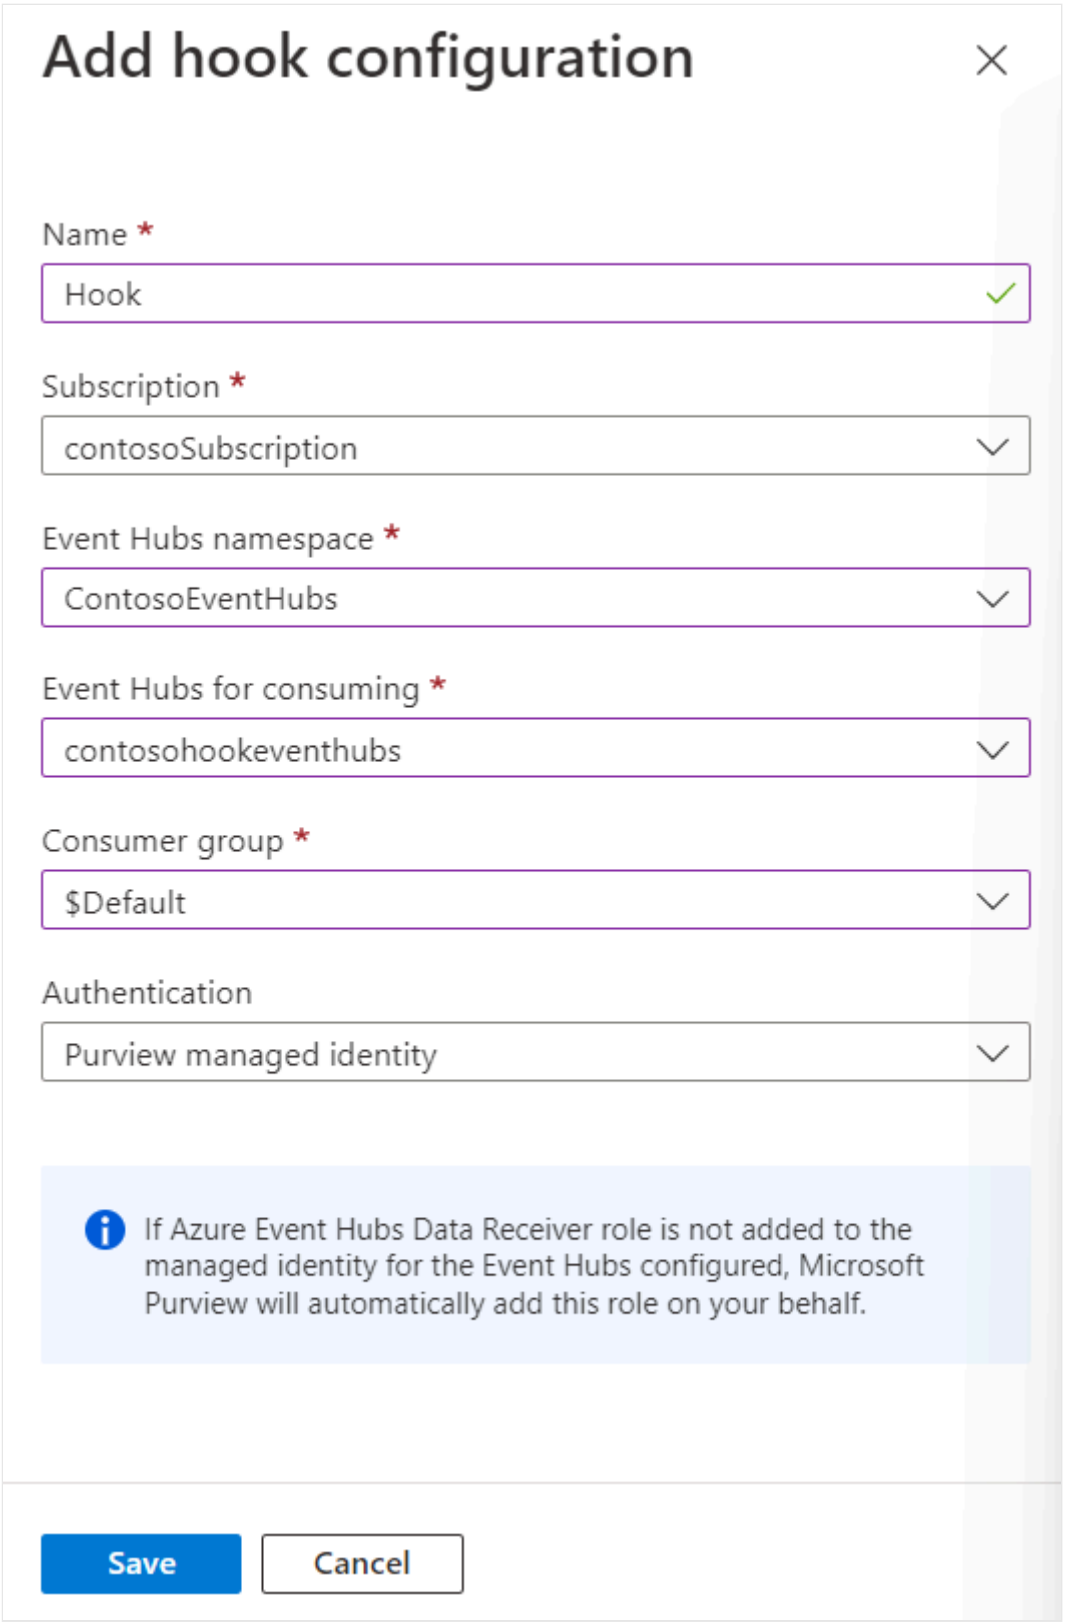
    Microsoft Purview's status as a trusted service means that, as long as *Allow trusted Microsoft services to bypass this firewall* is set to **Yes** on your Event Hubs resource, your hooks can still receive messages from Event Hubs.

For more information about networking for Event Hubs, see the Azure Event Hubs documentation.



Configure Event Hubs to publish messages to Microsoft Purview

1. Navigate to **Kafka configuration** under settings on your Microsoft Purview account page in the Azure portal.

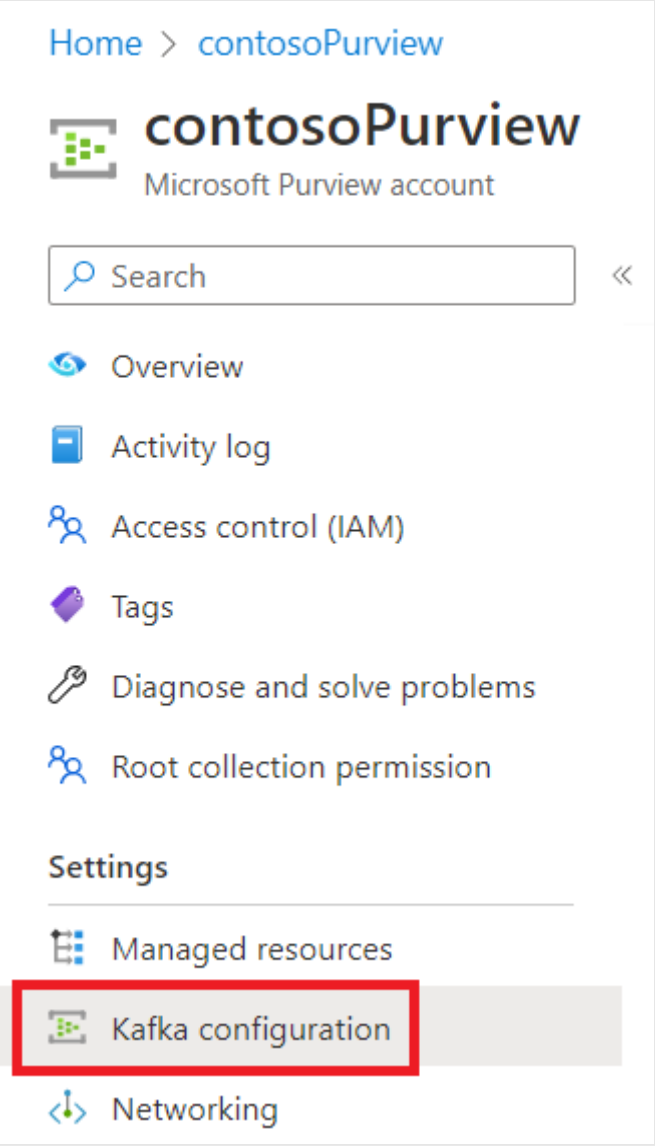


2. Select **Add configuration** and **Hook configuration**.

> **Note**
>
> You can add as many hook configurations as you need.

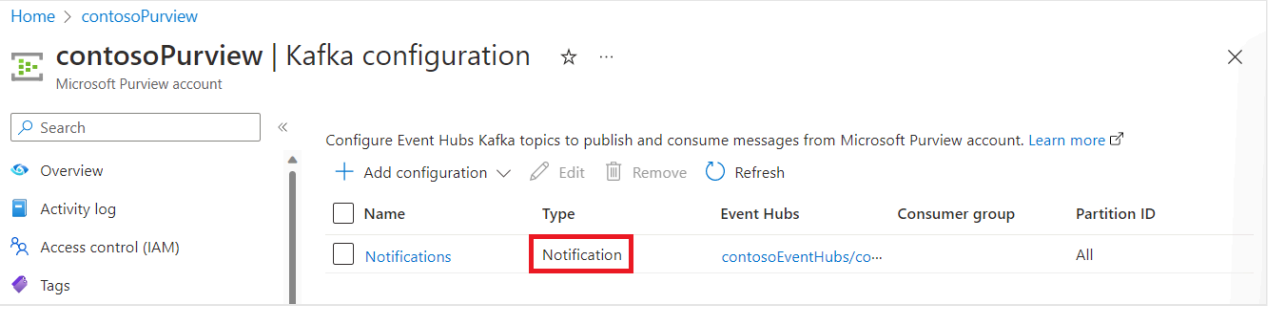
3. Give a name to your hook configuration, select your subscription, an existing Event Hubs namespace, an existing Event Hubs to send the notifications to, the consumer group you want to use, and the kind of authentication you would like to use.

   > **Tip**
   >
   > You can use the same Event Hubs namespace more than once, but each configuration will need its own Event Hubs.



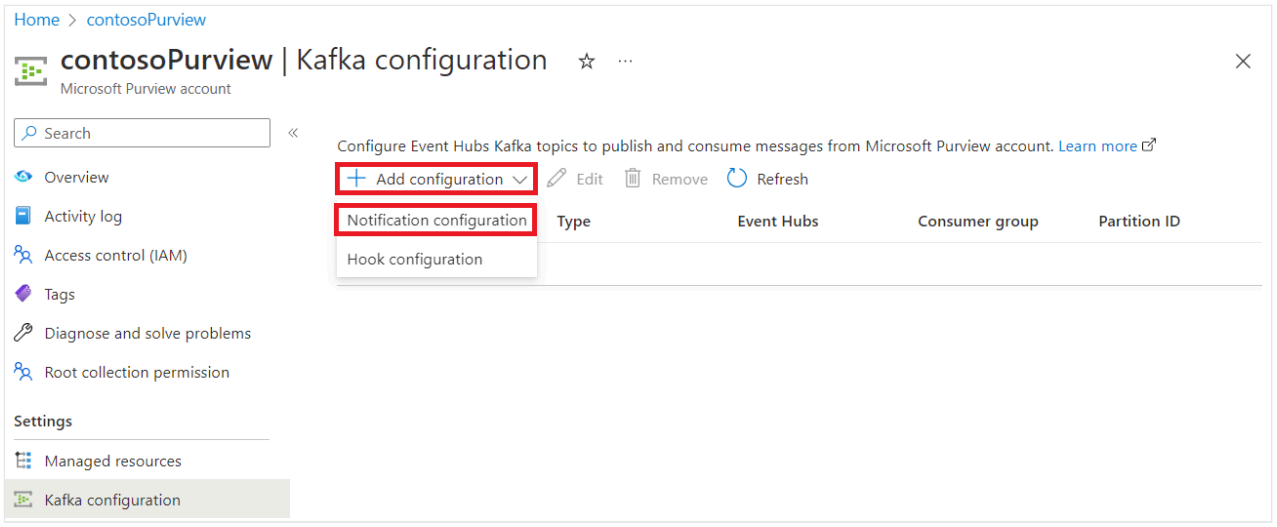
4. Select **Save**. It takes a couple minutes for your configuration to complete.

5. Once configuration is complete, you can begin the steps to publish messages to Microsoft Purview.



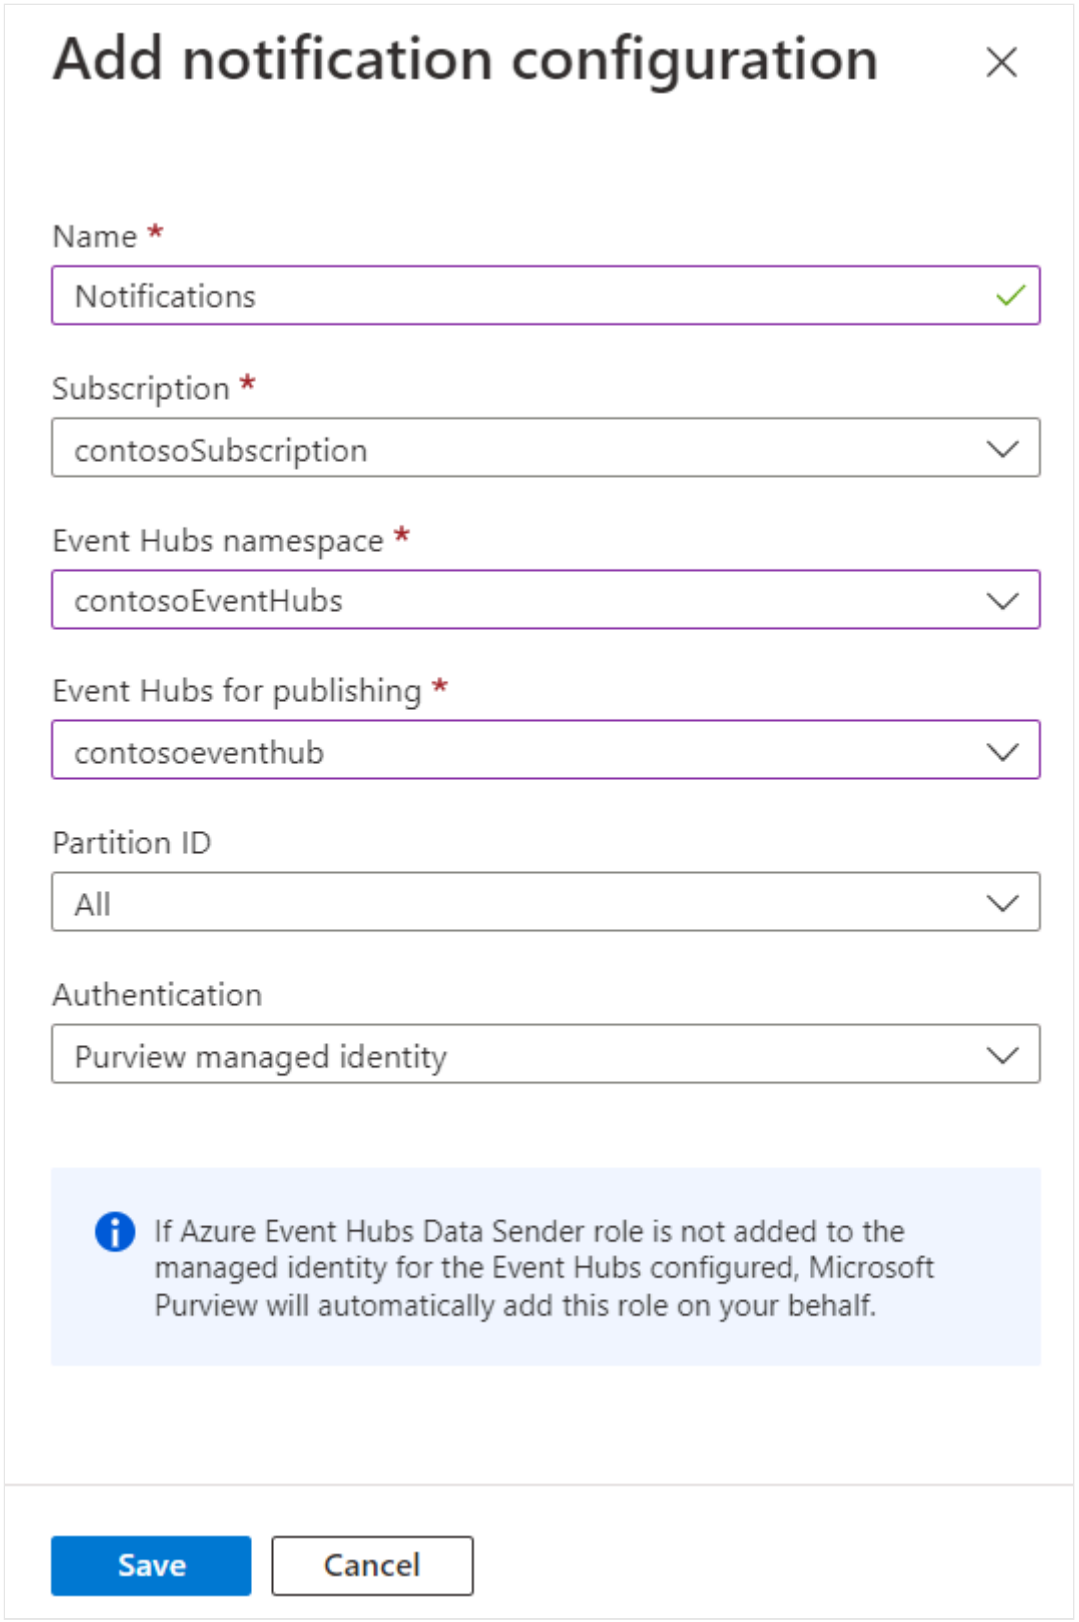
Configure Event Hubs to receive messages from Microsoft Purview

1. Navigate to **Kafka configuration** under settings on your Microsoft Purview account page in the Azure portal.



2. If there's a configuration already listed as type **Notification**, Event Hubs is already configured, and you can begin the steps to receive Microsoft Purview messages.

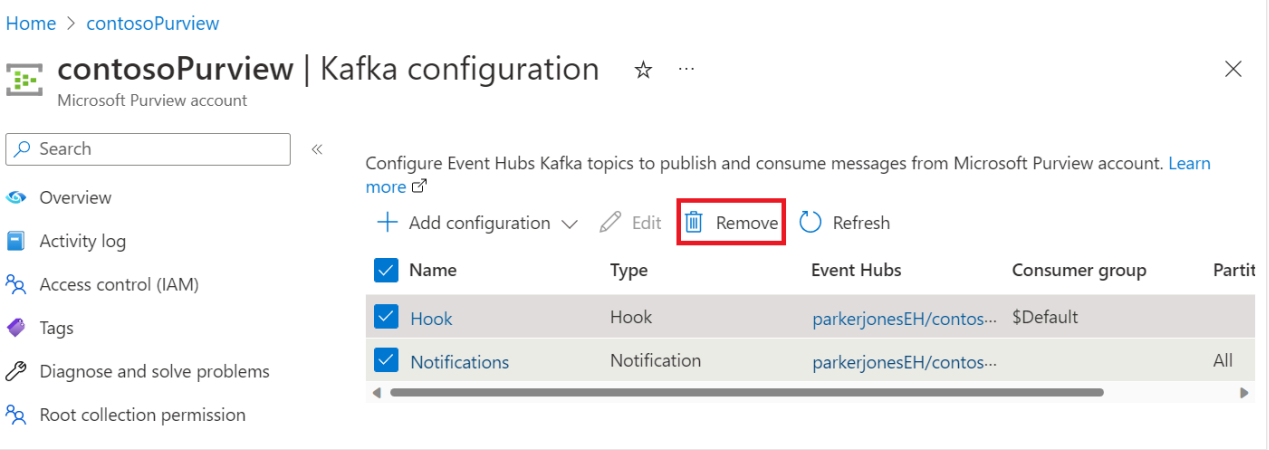
> **Note**
>
> Only one *Notification* Event Hubs can be configured at a time.



3. If there isn't a **Notification** configuration already listed, select **Add configuration** and **Notification configuration**.

4. Give a name to your notification configuration, select your subscription, an existing Event Hubs namespace, an existing Event Hubs to send the notifications to, the partitions you want to use, and the kind of authentication you would like to use.

> **Tip**
>
> You can use the same Event Hubs namespace more than once, but each configuration will need its own Event Hubs.



5. Select **Save**. It takes a couple minutes for your configuration to complete.

6. Once configuration is complete, you can begin the steps to receive Microsoft Purview messages.

Remove configured Event Hubs

To remove configured Event Hubs namespaces, you can follow these steps:

1. Search for and open your Microsoft Purview account in the Azure portal.
2. Select **Kafka configuration** under settings on your Microsoft Purview account page in the Azure portal.
3. Select the Event Hubs you want to disable. (Hook hubs send messages to Microsoft Purview. Notification hubs receive notifications.)
4. Select **Remove** to save the choice and begin the disablement process. This can take several minutes to complete.

Create a managed namespace

If you prefer to have a managed Event Hubs namespace, you need to use the REST API to configure your account.

You can use below script (set apiVersion = 2021-12-01) to update an account and this way will only affect the event hub configuration:

```
$body = @{"properties" = @{ "managedEventHubState" = "Enabled" }; "location" =
$($location); "identity" = @{ "type"= $($type) } } | ConvertTo-Json
$Token=Get-AzAccessToken
$Headers = @{ "Authorization" = "Bearer $($Token.Token)" }
$Uri =
"https://management.azure.com/subscriptions/$($subscription)/resourceGroups/$($rg)
/providers/Microsoft.Purview/accounts/$($accountName)?api-version=$($apiVersion)"

Invoke-WebRequest -URI $Uri -Method Put -Body $body -Headers $Headers -ContentType
"application/json"
```

Next steps

- Publish and process Atlas Kafka topics messages using your Event Hubs
- Event Hubs samples in GitHub
- Event processor samples in GitHub
- An introduction to Atlas notifications

Use Event Hubs and .NET to send and receive Atlas Kafka topics messages

07/21/2025

This quickstart teaches you how to send and receive *Atlas Kafka* topics events. We'll make use of *Azure Event Hubs* and the **Azure.Messaging.EventHubs** .NET library.

Prerequisites

If you're new to Event Hubs, see Event Hubs overview before you complete this quickstart.

To follow this quickstart, you need certain prerequisites in place:

- **A Microsoft Azure subscription**. To use Azure services, including Event Hubs, you need an Azure subscription. If you don't have an Azure account, you can sign up for a free trial or use your MSDN subscriber benefits when you create an account.
- **Microsoft Visual Studio 2022**. The Event Hubs client library makes use of new features that were introduced in C# 8.0. You can still use the library with previous C# versions, but the new syntax won't be available. To make use of the full syntax, it's recommended that you compile with the .NET Core SDK 3.0 or higher and language version set to `latest`. If you're using a Visual Studio version prior to Visual Studio 2019, it doesn't have the tools needed to build C# 8.0 projects. Visual Studio 2022, including the free Community edition, can be downloaded here.
- An active Microsoft Purview account.
- An Event Hubs configured with your Microsoft Purview account to sent and receive messages:
  - Your account may already be configured. You can check your Microsoft Purview account in the Azure portal under **Settings**, **Kafka configuration**. If it isn't already configured, follow this guide.

Publish messages to Microsoft Purview

Let's create a .NET Core console application that sends events to Microsoft Purview via Event Hubs Kafka topic, **ATLAS_HOOK**.

To publish messages to Microsoft Purview, you need either a managed Event Hubs, or at least one Event Hubs with a hook configuration..

Create a Visual Studio project

Next create a C# .NET console application in Visual Studio:

1. Launch **Visual Studio**.
2. In the Start window, select **Create a new project** > **Console App (.NET Framework)**. .NET version 4.5.2 or above is required.
3. In **Project name**, enter **PurviewKafkaProducer**.
4. Select **Create** to create the project.

Create a console application

1. Start Visual Studio 2022.
2. Select **Create a new project**.
3. On the **Create a new project** dialog box, do the following steps: If you don't see this dialog box, select **File** on the menu, select **New**, and then select **Project**.
   a. Select **C#** for the programming language.
   b. Select **Console** for the type of the application.
   c. Select **Console App (.NET Core)** from the results list.
   d. Then, select **Next**.

Add the Event Hubs NuGet package

1. Select **Tools** > **NuGet Package Manager** > **Package Manager Console** from the menu.

2. Run the following command to install the **Azure.Messaging.EventHubs** NuGet package and **Azure.Messaging.EventHubs.Producer** NuGet package:

   Windows Command Prompt

   ```
   Install-Package Azure.Messaging.EventHubs
   ```

   Windows Command Prompt

   ```
   Install-Package Azure.Messaging.EventHubs.Producer
   ```

Write code that sends messages to the event hub

1. Add the following `using` statements to the top of the **Program.cs** file:

   C#

   ```
   using System;
   using System.Text;
   ```

```
using System.Threading.Tasks;
using Azure.Messaging.EventHubs;
using Azure.Messaging.EventHubs.Producer;
```

2. Add constants to the `Program` class for the Event Hubs connection string and Event Hubs name.

```
C#

private const string connectionString = "<EVENT HUBS NAMESPACE - CONNECTION
STRING>";
private const string eventHubName = "<EVENT HUB NAME>";
```

3. Replace the `Main` method with the following `async Main` method and add an `async ProduceMessage` to push messages into Microsoft Purview. See the comments in the code for details.

```
C#

    static async Task Main()
    {
        // Read from the default consumer group: $Default
        string consumerGroup =
EventHubConsumerClient.DefaultConsumerGroupName;

        / Create an event producer client to add events in the event hub
        EventHubProducerClient producer = new
EventHubProducerClient(ehubNamespaceConnectionString, eventHubName);

        await ProduceMessage(producer);
    }

    static async Task ProduceMessage(EventHubProducerClient producer)

    {
        // Create a batch of events
        using EventDataBatch eventBatch = await
producerClient.CreateBatchAsync();

        // Add events to the batch. An event is a represented by a collection
of bytes and metadata.
        eventBatch.TryAdd(new EventData(Encoding.UTF8.GetBytes("<First
event>")));
        eventBatch.TryAdd(new EventData(Encoding.UTF8.GetBytes("<Second
event>")));
        eventBatch.TryAdd(new EventData(Encoding.UTF8.GetBytes("<Third
event>")));

        // Use the producer client to send the batch of events to the event
hub
```

```
        await producerClient.SendAsync(eventBatch);
        Console.WriteLine("A batch of 3 events has been published.");

    }
```

4. Build the project. Ensure that there are no errors.

5. Run the program and wait for the confirmation message.

> ⓘ Note
>
> For the complete source code with more informational comments, see this file in GitHub

Sample code that creates an sql table with two columns using a Create Entity JSON message

JSON

```
    {
    "msgCreatedBy":"nayenama",
    "message":{
        "type":"ENTITY_CREATE_V2",
        "user":"admin",
        "entities":{
            "entities":[
                {
                    "typeName":"azure_sql_table",
                    "attributes":{
                        "owner":"admin",
                        "temporary":false,

"qualifiedName":"mssql://nayenamakafka.eventhub.sql.net/salespool/dbo/SalesOrderTa
ble",
                        "name":"SalesOrderTable",
                        "description":"Sales Order Table added via Kafka"
                    },
                    "relationshipAttributes":{
                        "columns":[
                            {

                }
            }
        }
    },
    "version":{
        "version":"1.0.0"
    },
    "msgCompressionKind":"NONE",
    "msgSplitIdx":1,
    "msgSplitCount":1
}
```

Receive Microsoft Purview messages

Next learn how to write a .NET Core console application that receives messages from event hubs using an event processor. The event processor manages persistent checkpoints and parallel receptions from event hubs. This simplifies the process of receiving events. You need to use the ATLAS_ENTITIES event hub to receive messages from Microsoft Purview.

To receive messages from Microsoft Purview, you need either a managed Event Hubs, or an Event Hubs notification configuration..

> ⚠ **Warning**

Event Hubs SDK uses the most recent version of Storage API available. That version may not necessarily be available on your Stack Hub platform. If you run this code on Azure Stack Hub, you'll experience runtime errors unless you target the specific version you're using. If you're using Azure Blob Storage as a checkpoint store, review the **supported Azure Storage API version for your Azure Stack Hub build** and in your code, target that version.

The highest available version of the Storage service is version 2019-02-02. By default, the Event Hubs SDK client library uses the highest available version on Azure (2019-07-07 at the time of the release of the SDK). If you're using Azure Stack Hub version 2005, in addition to following the steps in this section, you'll also need to add code that targets the Storage service API version 2019-02-02. To learn how to target a specific Storage API version, see **this sample in GitHub**.

Create an Azure Storage and a blob container

We'll use Azure Storage as the checkpoint store. Use the following steps to create an Azure Storage account.

1. Create an Azure Storage account
2. Create a blob container
3. Get the connection string for the storage account

   Make note of the connection string and the container name. You'll use them in the receive code.

Create a Visual Studio project for the receiver

1. In the Solution Explorer window, select and hold (or right-click) the **EventHubQuickStart** solution, point to **Add**, and select **New Project**.
2. Select **Console App (.NET Core)**, and select **Next**.
3. Enter **PurviewKafkaConsumer** for the **Project name**, and select **Create**.

Add the Event Hubs NuGet package

1. Select **Tools** > **NuGet Package Manager** > **Package Manager Console** from the menu.
2. Run the following command to install the **Azure.Messaging.EventHubs** NuGet package:

   Windows Command Prompt

```
Install-Package Azure.Messaging.EventHubs
```

3. Run the following command to install the **Azure.Messaging.EventHubs.Processor** NuGet package:

```
Windows Command Prompt
```

```
Install-Package Azure.Messaging.EventHubs.Processor
```

Update the Main method

1. Add the following `using` statements at the top of the **Program.cs** file.

```
C#
```

```
using System;
using System.Text;
using System.Threading.Tasks;
using Azure.Storage.Blobs;
using Azure.Messaging.EventHubs;
using Azure.Messaging.EventHubs.Consumer;
using Azure.Messaging.EventHubs.Processor;
```

2. Add constants to the `Program` class for the Event Hubs connection string and the event hub name. Replace placeholders in brackets with the real values that you got when you created the event hub and the storage account (access keys - primary connection string). Make sure that the `{Event Hubs namespace connection string}` is the namespace-level connection string, and not the event hub string.

```
C#
```

```
    private const string ehubNamespaceConnectionString = "<EVENT HUBS
NAMESPACE - CONNECTION STRING>";
    private const string eventHubName = "<EVENT HUB NAME>";
    private const string blobStorageConnectionString = "<AZURE STORAGE
CONNECTION STRING>";
    private const string blobContainerName = "<BLOB CONTAINER NAME>";
```

   Use **ATLAS_ENTITIES** as the event hub name when sending messages to Microsoft Purview.

3. Replace the `Main` method with the following `async Main` method. See the comments in the code for details.

C#

```
    static async Task Main()
    {
        // Read from the default consumer group: $Default
        string consumerGroup =
EventHubConsumerClient.DefaultConsumerGroupName;

        // Create a blob container client that the event processor will use
        BlobContainerClient storageClient = new
BlobContainerClient(blobStorageConnectionString, blobContainerName);

        // Create an event processor client to process events in the event
hub
        EventProcessorClient processor = new
EventProcessorClient(storageClient, consumerGroup,
ehubNamespaceConnectionString, eventHubName);

        // Register handlers for processing events and handling errors
        processor.ProcessEventAsync += ProcessEventHandler;
        processor.ProcessErrorAsync += ProcessErrorHandler;

        // Start the processing
        await processor.StartProcessingAsync();

        // Wait for 10 seconds for the events to be processed
        await Task.Delay(TimeSpan.FromSeconds(10));

        // Stop the processing
        await processor.StopProcessingAsync();
    }
```

4. Now add the following event and error handler methods to the class.

C#

```
    static async Task ProcessEventHandler(ProcessEventArgs eventArgs)
    {
        // Write the body of the event to the console window
        Console.WriteLine("\tReceived event: {0}",
Encoding.UTF8.GetString(eventArgs.Data.Body.ToArray()));

        // Update checkpoint in the blob storage so that the app receives
only new events the next time it's run
        await eventArgs.UpdateCheckpointAsync(eventArgs.CancellationToken);
    }

    static Task ProcessErrorHandler(ProcessErrorEventArgs eventArgs)
    {
        // Write details about the error to the console window
        Console.WriteLine($"\tPartition '{ eventArgs.PartitionId}': an
unhandled exception was encountered. This was not expected to happen.");
        Console.WriteLine(eventArgs.Exception.Message);
```

```
            return Task.CompletedTask;
        }
```

5. Build the project. Ensure that there are no errors.

> **Note**
>
> For the complete source code with more informational comments, see this file on the GitHub.

6. Run the receiver application.

An example of a Message received from Microsoft Purview

JSON

```
{
    "version":
        {"version":"1.0.0",
         "versionParts":[1]
        },

Disaster recovery for Data Map (manual)

This article provides backup and recovery guidance for data governance admins who use Microsoft Purview Data Map in a production deployment. It covers manual business continuity and disaster recovery (BCDR) methods. Before you begin, review the prerequisites described first in this article. For detailed BCDR steps for Unified Catalog, see Disaster recovery for Unified Catalog (manual).

Prerequisites

Step 1. Create an Enterprise tier account

Create a Purview Data Governance account at the **Enterprise** tier. This serves as the **primary account** with full governance capabilities.

Step 2. Request Classic Purview provisioning in a secondary region

Create a support ticket through the Customer Support channel requesting enablement of Classic Purview account provisioning in a **secondary (paired) region** for BCDR purposes. This region shouldn't be the same as the primary region.

Step 3. Create a Classic Purview account

After Classic provisioning is enabled in the secondary region, create a **Classic Purview account**. This account serves as the **secondary (backup) account** with limited capabilities.

> ⓘ **Note**
>
> The first three steps are common to both Data Map and Unified Catalog BCDR.

Step 4. Make note of MSI identities

Capture the primary account's managed identity object ID (Identity A) and the secondary account's managed identity object ID (Identity B).

Step 5. Confirm Key Vault DR readiness

Make sure that either the secondary-region key vault holds the same secret names, or the key vault is geo-resilient with the paired secondary region.

Step 6. Confirm data source DR readiness

Make sure that each data source that's registered and scanned in Microsoft Purview has source-side DR (geo-replication/RA-GRS, SQL failover group, and so on) that provides a reachable copy in or near the secondary region.

Set up the secondary account and networking

Set up the secondary account to mirror the primary account, and then configure networking:

1. Recreate the collection hierarchy in the secondary account to match the primary account (same names).
2. Assign role-based access control (RBAC) roles on the secondary account collections (Collection Admin, Data Source Admin, Data Curator, Data Reader) to the same principals as the primary account.
3. Create the integration runtimes (IRs) in the secondary account (Managed virtual network (VNet) IR, Azure IR, or both) matching the primary account. Make sure the integration runtimes are present and **Running**.
4. If a self-hosted integration runtime (SHIR) is used, install a new SHIR node and register it against the secondary account by using the secondary account's authentication key.
5. Recreate the managed virtual network and managed private endpoints in the secondary region.
6. Approve each managed private endpoint on the target resource side.
7. Create private endpoints (account/portal/ingestion) and private DNS records for the secondary account.

Configure identity and access on data sources

Grant the secondary account's identity the same access on each data source that the primary account's identity has:

1. For each data source, grant Identity B the same data-plane role that Identity A has (for example, Storage Blob Data Reader, SQL `db_datareader`, and so on).

2. Open the data source firewalls and network rules for the secondary account's integration runtime or account (IP ranges, service endpoints, private endpoints, **Allow trusted Microsoft services**). This access is required for the secondary account to reach the source over the network.
3. Register the key vault connection in the secondary account and grant Identity B get/list secret permission on the key vault. Use a DR-enabled or secondary-region key vault that holds the same secret names.

Mirror scan configuration to the secondary account

Replicate the primary account's scan configuration in the secondary account:

1. Register the same data sources in the secondary account under the matching collections.
2. Create the same credentials in the secondary account (referencing the secondary account key vault connection and the same secret names).
3. Recreate custom classification rules in the secondary account (same names).
4. Recreate scan rulesets in the secondary account (system and custom) matching the primary account.
5. Create the same scans in the secondary account with matching scope selection, ruleset, and integration runtime binding.
6. Create the same triggers and schedules in the secondary account.

Validate regularly

In the steady state, check the following for your primary and secondary accounts:

1. For manually triggered or scheduled scans in the secondary account, make sure each scan reaches the **Succeeded** state (not **Failed** or **Completed with error**).
2. Compare discovered asset counts between the primary and secondary accounts after both complete a scan of the same source. Counts and asset qualified names should match within one scan interval of each other.
3. Spot-check classifications applied by rulesets on the same assets in the primary and secondary accounts. The same classifications should be present in the secondary account.
4. Verify schema parity on a representative tabular asset. Column names and types should match.

Fail over during a disaster recovery event

When a disaster recovery event occurs, create a support ticket requesting the following actions:

1. Promote the secondary (Classic) account to **Enterprise** tier.
2. Demote the primary (Enterprise) account to **Secondary**.

Share the tenant ID, account name, and region for both the primary and secondary accounts in the support ticket.

The failover completes, and the previously secondary account becomes the new primary with full Enterprise capabilities.

Resolve common errors

Expand table

Symptom	Most likely cause	Fix
Secondary account scan fails at authentication	Identity B isn't granted on the data source	Grant Identity B the data-plane role.
Secondary account scan fails with a network or timeout error	Data source firewall isn't opened for the secondary account, or the managed private endpoint isn't approved	Open the firewall or approve the managed private endpoint.
Credential **Test connection** fails in the secondary account	Key vault connection is missing, or Identity B lacks secret access	Register the key vault connection and grant secret get/list permission.
Assets present in the primary account but missing in the secondary account	Configuration drift — source or scan not mirrored	Mirror the configuration and run reconciliation.
Can't create the secondary account	Single instance per tenant, or Classic provisioning isn't enabled	Raise a support ticket.

Private endpoints for data governance solutions

Article • 05/01/2025

> **Important**
>
> This article covers private endpoints for governance solutions in the Microsoft Purview portal. If you're using the classic governance portal, follow the documentation for private endpoints in the classic portal.

You can use private links to secure access to Microsoft Purview Unified Catalog and Data Map, and secure data traffic between Microsoft Purview and your private networks. Azure Private links and Azure Networking private endpoints are used to route traffic across Microsoft's infrastructure, instead of using the internet. To learn more about Azure Private Link in general, see: What is Azure Private Link?

A private endpoint is a single, directional technology that lets clients initiate connections to a given service, but doesn't allow the service to initiate a connection into the customer network. For multitenant services, this model provides link identifiers to prevent access to other customers' resources hosted within the same service. When you use private endpoints, only a limited set of other PaaS resources can be accessed from services using the integration.

You can deploy an *ingestion* private endpoint if you need to scan Azure IaaS and PaaS data sources inside Azure virtual networks and on-premises data sources through a private connection. This method ensures network isolation for your metadata flowing from the data sources to Microsoft Purview Data Map.

You can deploy a *platform* private endpoint to allow only client calls to the Microsoft Purview governance portal that originates from within the private network and connect to the Microsoft Purview governance portal using a private network connectivity.

> **Important**
>
> Private endpoints ensure that your organization's user traffic and resources within Azure, follow your organization's configured private link network path, and you can configure Microsoft Purview to deny all request from outside that network path.
>
> However, for external sources private endpoints do not manage all network traffic. You to configure traffic isolation from non-Azure based infrastructure, like on-premises

infrastructure, you need to configure ExpressRoute, or virtual private networks, and use integration runtimes to further secure your data sources.

Prerequisites

Before deploying private endpoints for your Microsoft Purview governance resources and the Microsoft Purview portal, ensure you meet the following prerequisites:

1. An Azure account with an active subscription. Create an account for free.
2. To configure private endpoints, you need to be a Microsoft Purview admin and have permissions in Azure to create and configure resources like virtual machines (VMs) and virtual networks (VNets).
3. Currently, Azure Data Factory, Azure Machine Learning, and Azure Synapse connections aren't supported with the platform private endpoint, and might not work after switching.

Deployment checklist

Following the instructions further in this guide, you can deploy these private endpoints for an existing Microsoft Purview account:

1. Choose an appropriate Azure virtual network and a subnet to deploy Microsoft Purview private endpoints. Select one of the following options:
    - Deploy a new virtual network in your Azure subscription.
    - Locate an existing Azure virtual network and a subnet in your Azure subscription.
2. Define an appropriate DNS name resolution method, so you can access Microsoft Purview account and scan data sources using a private network.
3. Create a platform private endpoint.
4. Enable ingestion private endpoints
5. Disable public access for Microsoft Purview.
6. Enable access to Microsoft Entra ID if your private network has network security group rules set to deny for all public internet traffic.
7. Deploy and register a Self-hosted integration runtime inside the same virtual network or a peered virtual network where Microsoft Purview account and ingestion private endpoints are deployed.
8. After completing this guide, adjust DNS configurations if needed.

Create a virtual network

> **Tip**
>
> These instructions will create a basic virtual network. For more information about virtual network options and features, see the virtual network documentation.

The next step is to create a virtual network and subnet. The number of IP address your subnet will need is made up of the number of capacities on your tenant plus three. For example, if you're creating a subnet for a tenant with seven capacities, you'll need 10 IP addresses.

Replace the sample parameters in the following table with your own to create a virtual network and subnet.

Expand table

Parameter	Value
`<resource-group-name>`	myResourceGroup
`<virtual-network-name>`	myVirtualNetwork
`<region-name>`	Central US
`<address-space>`	10.0.0.0/16
`<subnet-name>`	mySubnet
`<subnet-address-range>`	10.0.0.0/24

1. Open the Azure portal.
2. Select **Create a resource** > **Networking** > **Virtual network** or search for **Virtual network** in the search box.
3. In **Create virtual network**, enter or select the following information in the **Basics** tab:

Expand table

Settings	Value
Project details	
Subscription	Select your Azure Subscription
Resource group	Select **Create new**, enter `<resource-group-name>`, then select **OK**, or select an existing `<resource-group-name>` based on parameters.

Settings	Value
Instance details	
Name	Enter `<virtual-network-name>`

4. Select the **IP addresses** tab and enter the subnet address range.

5. Select **Review + create** > **Create**.

Define a DNS name resolution method

Follow this article to select and deploy a DNS name resolution method that bets fits your organization's needs: Configure DNS Name Resolution for private endpoints.

Create a platform private endpoint

The next step is to create the platform private endpoint for Microsoft Purview.

1. Open the Azure portal.

2. Select **Create a resource** > **Networking** > **Private Link**.

3. In **Private Link Center - Overview**, under the option to **Build a private connection to a service**, select **Create private endpoint**.

4. In the **Create a private endpoint - Basics** tab, enter or select the following information:

Expand table

Settings	Value
Project details	
Subscription	Select your Azure Subscription
Resource group	Select **myResourceGroup**. You created this in the previous section
Instance details	
Name	Enter *myPrivateEndpoint*. If this name is taken, create a unique name.
Network Interface Name	Filled automatically by the instance name.
Region	Selected automatically based on your resource group.

5. Once that information is complete, select **Next: Resource** and in the **Create a private endpoint - Resource** page, enter or select the following information:

Expand table

Settings	Value
Connection method	Select connect to an Azure resource in my directory
Subscription	Select your subscription
Resource type	Select **Microsoft.Purview/accounts**
Resource	Select your Microsoft Purview resource
Target subresource	Platform

6. Once that information is properly input, select **Next: Virtual Network** and enter or select the following information:

Expand table

Settings	Value
NETWORKING	
Virtual network	Select the virtual network you created earlier.
Subnet	Select the subnet you created earlier.
PRIVATE IP configuration	Select **Dynamically allocate IP address**.

7. Select **Next: DNS** and enter the following information:

Expand table

Settings	Value
Integrate with private DNS zone	Select **Yes**
Subscription	Select your subscription where your DNS zone is configured.
Resource group	Select the resource group where your DNS zone is configured.

8. Select **Next: Tags** and on the tags page you can optionally add any tags your organization is using in Azure.

9. Select **Next: Review + create** which displays the **Review + create** page where Azure validates your configuration. When you see the **Validation passed** message, select **Create**.

Enable *ingestion* private endpoint

1. Go to the Azure portal, search for and then select your Microsoft Purview account.
2. From your Microsoft Purview account, under **Settings** select **Networking**, and then select **Ingestion private endpoint connections**.
3. Under Ingestion private endpoint connections, select **+ New** to create a new ingestion private endpoint.
4. Fill in the basic information, selecting your existing virtual network and a subnet details. Optionally, select **Private DNS integration** to use Azure Private DNS Zones. Select correct Azure Private DNS Zones from each list.

   > **Note**
   >
   > You can also use your existing Azure Private DNS zones or create DNS records in your DNS Servers manually. For more information, see Configure DNS Name Resolution for private endpoints

5. Select **Create** to finish the setup.

Disable public access for Microsoft Purview

To cut off access to the Microsoft Purview account completely from the public internet, follow these steps. This setting applies to both private endpoint and ingestion private endpoint connections.

1. From the Azure portal, go to the Microsoft Purview account, and under **Settings**, select **Networking**.
2. Go to the **Firewall** tab, and ensure that the toggle is set to **Disable from all networks**.

Enable access to Microsoft Entra ID

> **Note**

If your VM, VPN gateway, or virtual network peering gateway has public internet access, it can access the Microsoft Purview governance portal and the Microsoft Purview account enabled with private endpoints. For this reason, you don't have to follow the rest of the instructions. If your private network has network security group rules set to deny all public internet traffic, you'll need to add some rules to enable Microsoft Entra ID access. Follow the instructions to do so.

These instructions are provided for accessing Microsoft Purview securely from an Azure VM. Similar steps must be followed if you're using VPN or other virtual network peering gateways.

1. Go to your VM in the Azure portal, and under **Settings**, select **Networking**. Then select **Outbound port rules** > **Add outbound port rule**.

2. On the **Add outbound security rule** pane:
   a. Under **Destination**, select **Service Tag**.
   b. Under **Destination service tag**, select **AzureActiveDirectory**.
   c. Under **Destination port ranges**, select *.
   d. Under **Action**, select **Allow**.
   e. Under **Priority**, the value should be higher than the rule that denied all internet traffic.

   Create the rule.

3. Follow the same steps to create another rule to allow the **AzureResourceManager** service tag. If you need to access the Azure portal, you can also add a rule for the **AzurePortal** service tag.

4. Connect to the VM and open the browser. Go to the browser console by selecting Ctrl+Shift+J, and switch to the network tab to monitor network requests. Enter web.purview.azure.com in the URL box, and try to sign in by using your Microsoft Entra credentials. Sign-in will probably fail, and on the **Network** tab on the console, you can see Microsoft Entra ID trying to access aadcdn.msauth.net but getting blocked.

5. In this case, open a command prompt on the VM, ping aadcdn.msauth.net, get its IP, and then add an outbound port rule for the IP in the VM's network security rules. Set the **Destination** to **IP Addresses** and set **Destination IP addresses** to the aadcdn IP. Because of Azure Load Balancer and Azure Traffic Manager, the Microsoft Entra Content Delivery Network IP might be dynamic. After you get its IP, it's better to add it into the VM's host file to force the browser to visit that IP to get the Microsoft Entra Content Delivery Network.

6. After the new rule is created, go back to the VM and try to sign in by using your Microsoft Entra credentials again. If sign-in succeeds, then the Microsoft Purview governance portal is ready to use. But in some cases, Microsoft Entra ID redirects to other domains to sign in

based on a customer's account type. For example, for a live.com account, Microsoft Entra ID redirects to live.com to sign in, and then those requests are blocked again. For Microsoft employee accounts, Microsoft Entra ID accesses msft.sts.microsoft.com for sign-in information.

Check the networking requests on the browser **Networking** tab to see which domain's requests are getting blocked, redo the previous step to get its IP, and add outbound port rules in the network security group to allow requests for that IP. If possible, add the URL and IP to the VM's host file to fix the DNS resolution. If you know the exact sign-in domain's IP ranges, you can also directly add them into networking rules.

7. Now your Microsoft Entra sign-in should be successful. The Microsoft Purview governance portal will load successfully, but listing all the Microsoft Purview accounts won't work because it can only access a specific Microsoft Purview account. Enter `web.purview.azure.com/resource/{PurviewAccountName}` to directly visit the Microsoft Purview account that you successfully set up a private endpoint for.

Deploy self-hosted integration runtime (IR) and scan your data sources

Once you deploy ingestion private endpoints for your Microsoft Purview, you need to setup and register at least one self-hosted integration runtime (IR):

- All on-premises source types like Microsoft SQL Server, Oracle, SAP, and others are currently supported only via self-hosted IR-based scans. The self-hosted IR must run within your private network and then be peered with your virtual network in Azure.
- For all Azure source types like Azure Blob Storage and Azure SQL Database, you must explicitly choose to run the scan by using a self-hosted integration runtime that is deployed in the same virtual network or a peered virtual network where Microsoft Purview account and ingestion private endpoints are deployed.

Follow the steps in Create and manage a self-hosted integration runtime to set up a self-hosted IR. Then set up your scan on the Azure source by choosing that self-hosted IR in the **Connect via integration runtime** dropdown list to ensure network isolation.

> **Important**
>
> Make sure you download and install the latest version of self-hosted integration runtime from Microsoft download center.

Test your private connection

To test your new private endpoints, you can create a virtual machine within your private virtual network and access your platform private endpoint to ensure it's working.

1. Create a virtual machine (VM).
2. Connect to a VM using Remote Desktop (RDP).
3. Access Microsoft Purview privately from the virtual machine.

Create a virtual machine (VM)

The next step is to create a VM.

1. On the upper-left side of the screen in your Azure portal, select **Create a resource** > **Compute** > **Virtual Machine**.

2. In the **Basics** tab, enter or select the following information:

Expand table

Settings	Value
Project details	
Subscription	Select your Azure Subscription
Resource group	Select **myResourceGroup** which you created in the previous section
Instance details	
VM name	Enter **myVM**
Region	Select **West US**
Availability options	Leave the default **No infrastructure redundancy required**
Image	Select **Windows 10 Pro**
Size	Leave the default **Standard DS1 v2**
ADMINISTRATOR ACCOUNT	
Username	Enter a username of your choosing
Password	Enter a password of your choosing. The password must be at least 12 characters long and meet the defined complexity requirements

Settings	Value
Confirm password	Reenter password
INBOUND PORT RULES	
Public inbound ports	Leave the default **None**
LICENSING	
I have an eligible Windows 10/11 license	Check the box

3. Select **Next: Disks**.
4. In the **Disks** tab, leave the defaults and select **Next: Networking**.
5. In the **Networking** tab, select the following information:

Expand table

Settings	Value
Virtual network	Leave the default **MyVirtualNetwork**
Address space	Leave the default **10.0.0.0/24**
Subnet	Leave the default **mySubnet (10.0.0.0/24)**
Public IP	Leave the default **(new) myVM-ip**
Public inbound ports	Select **Allow selected**
Select inbound ports	Select **RDP**

6. Select **Review + create**. You're taken to the **Review + create** page where Azure validates your configuration.
7. When you see the **Validation passed** message, select **Create**.

Connect to a VM using Remote Desktop (RDP)

After you create your VM, called **myVM**, connect to it from the internet using the following steps:

1. In the portal's search bar, enter *myVM*.
2. Select the **Connect** button, and choose **RDP** from the dropdown menu.

3. Enter an IP address, then select **Download RDP File**. Azure creates a Remote Desktop Protocol (.rdp) file and downloads it to your computer.
4. Open the *.rdp* file to start Remote Desktop Connection, then select **Connect**.
5. Enter the username and password you specified when creating the VM in the previous step.
6. Select **OK**.
7. You might receive a certificate warning during the sign-in process. If you receive a certificate warning, select **Yes** or **Continue**.

Access Microsoft Purview privately from the VM

The next step is to access Microsoft Purview privately, from the virtual machine you created in the previous step, using the following steps:

1. In the Remote Desktop of myVM, open PowerShell.
2. Enter `nslookup <tenant-object-id>-api.purview-service.microsoft.com`.
3. You receive a response similar to the following message:

```
Server:  UnKnown
Address:  168.63.129.16

Non-authoritative answer:
Name:    <tenantid>-api.purview-service.microsoft.com
Address:  10.5.0.4
```

4. Open the browser and go to https://purview.microsoft.com to access Microsoft Purview privately.

Completion of private endpoint configuration

Once you've followed the steps in the previous sections and the private link is successfully configured, your organization implements private links based on the following configuration selections, whether the selection is set upon initial configuration or later changed.

If Azure Private Link is properly configured and **Block public Internet access** is **enabled**:

- Microsoft Purview is only accessible for your organization from private endpoints, and isn't accessible from the public Internet.
- Traffic from the virtual network targeting endpoints and scenarios that support private links are transported through the private link.
- Traffic from the virtual network targeting endpoints and scenarios that don't* support private links will be blocked by the service, and won't work.
- There could be scenarios that don't support private links, which therefore will be blocked at the service when **Block public Internet access** is enabled.

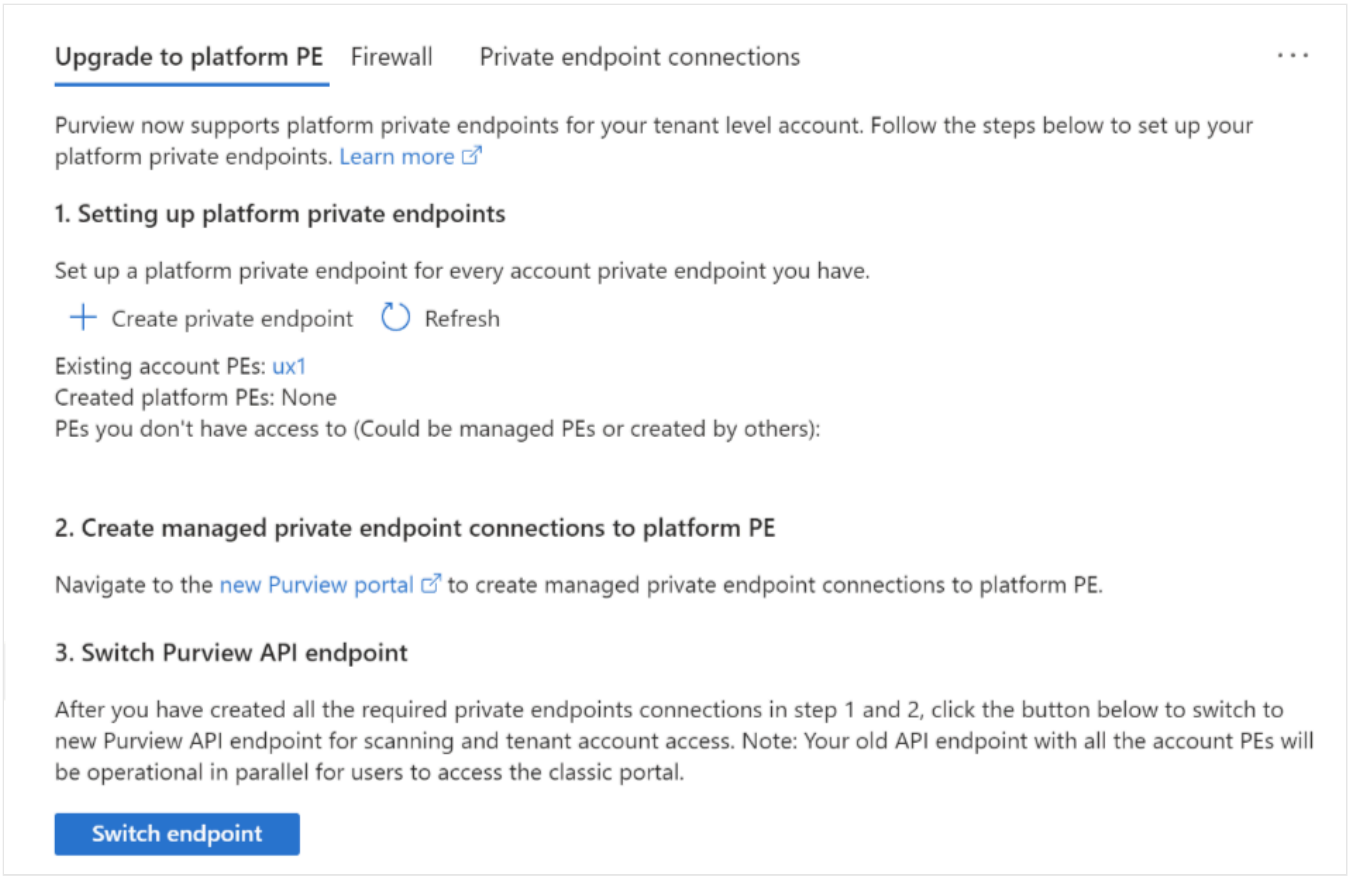
If Azure Private Link is properly configured and **Block public Internet access** is **disabled**:

- Traffic from the public Internet will be allowed by Microsoft Purview services
- Traffic from the virtual network targeting endpoints and scenarios that support private links are transported through the private link.
- Traffic from the virtual network targeting endpoints and scenarios that don't* support private links are transported through the public Internet, and will be allowed by Microsoft Purview services.
- If the virtual network is configured to block public Internet access, scenarios that don't support private links will be blocked by the virtual network, and won't work.'

Migrate governance private endpoints from classic portal to Microsoft Purview portal

Article • 05/01/2025

> **Important**
>
> This article covers migrating private endpoints for governance solutions from the classic governance portal to the Microsoft Purview portal. If you're building your private endpoint connections for the first time, follow the full private endpoints article instead.



> **Note**
>
> Currently, Azure Data Factory, Azure Machine Learning, and Azure Synapse connections aren't supported with the platform private endpoint, and might not work after switching.

Microsoft Purview now supports platform private endpoints for your organization-level account. You can follow these steps to migrate your existing Microsoft Purview account private endpoints to the new platform private endpoints.

Prerequisites

If you're still using version 1 of the managed virtual network (which you can check), to migrate to the new private endpoints you need to upgrade to the latest version of the virtual network.

Migrate your existing private endpoints

1. In the Azure portal, search for and open your Microsoft Purview account.
2. Select the **Networking** page.
3. If it's not already open, select the **Upgrade to platform PE** tab.
4. Set up your platform private endpoints
5. Create managed private endpoint connections to platform private endpoints
6. Switch your Microsoft Purview API endpoint

Set up your platform private endpoints

For every account private endpoint you'll need to set up a platform private endpoint. All the account private endpoints you have are listed under the step. For each existing endpoint:

1. In the Azure portal, search for and open your Microsoft Purview account.
2. Select the **Networking** page.
3. If it's not already open, select the **Upgrade to platform PE** tab.
4. Select the **+ Create platform private endpoint** button.
5. In the **Create a private endpoint - Basics** tab, enter or select the following information:

Expand table

Settings	Value
Project details	
Subscription	Select your Azure Subscription
Resource group	Select your resource group.
Instance details	
Name	Create a unique name.
Network Interface Name	Filled automatically by the instance name.
Region	Selected automatically based on your resource group.

6. Once that information is complete, select **Next: Resource** and in the **Create a private endpoint - Resource** page, enter or select the following information:

Expand table

Settings	Value
Connection method	Select connect to an Azure resource in my directory
Subscription	Select your subscription
Resource type	Select **Microsoft.Purview/accounts**
Resource	Select your Microsoft Purview resource
Target subresource	Platform

7. Once that information is properly input, select **Next: Virtual Network** and enter or select the following information:

Expand table

Settings	Value
NETWORKING	
Virtual network	Select your existing virtual network.
Subnet	Select your existing subnet
PRIVATE IP configuration	Select **Dynamically allocate IP address**.

8. Select **Next: DNS** and enter the following information:

Expand table

Settings	Value
Integrate with private DNS zone	Select **Yes**
Subscription	Select your subscription where your DNS zone is configured.
Resource group	Select the resource group where your DNS zone is configured.

9. Select **Next: Tags** and on the tags page you can optionally add any tags your organization is using in Azure.

10. Select **Next: Review + create** which displays the **Review + create** page where Azure validates your configuration. When you see the **Validation passed** message, select **Create**.

11. If you configured firewall allowlist rules for your account endpoints (`{account-name}.purview.azure.com`), you need to update your firewall configuration for the new platform private endpoints: `{tenant id}-api.purview-service.microsoft.com`, `api.purview-service.microsoft.com`. The use of the endpoint `api.purview-service.microsoft.com` will require additional configuration and checks. This will depend on your network setup, and we recommend using `{tenant id}-api.purview-service.microsoft.com` for ease of setup.

> **Note**
>
> `api.purview-service.microsoft.com` won't be automatically configured in the DNS to point to `{tenant id}-api.purview-service.microsoft.com` when the private endpoint is created; it will continue to point to the public IP of the purview instance unless overridden by subsequent customer network or DNS configuration changes.

Create managed private endpoint connections to platform private endpoints

1. In the Microsoft Purview portal open the Microsoft Purview Data Map.

2. Navigate to **Source management**, and select **Managed private endpoints**.

3. Select the pop-up link that says, 'Click here to provision platform managed PE for all your managed VNets'.

4. Microsoft Purview will create managed platform private endpoints for all your existing managed account endpoints.

5. Select each approval link to approve the endpoints, or approve them directly by:
   a. In the Azure portal search for your Microsoft Purview account and open it.
   b. Select **Networking**
   c. Select **Private endpoints**
   d. Approve the new list of private endpoints.

Switch your Microsoft Purview API endpoint

Now that you've created the required private endpoints, connected your resources, and recreated your scans, you can update your API endpoint. On the networking page, select the **Switch endpoint** button to switch to the new Microsoft Purview API endpoint for scanning and tenant account access.

The new API endpoint you'll be using is either:

`https://api.purview-service.microsoft.com/`

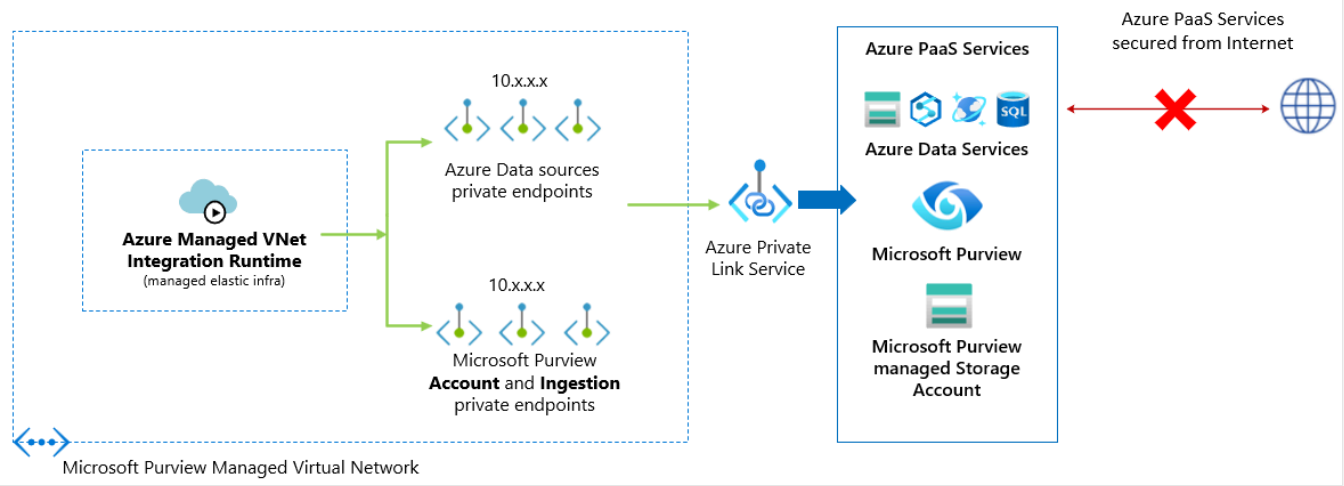
`https://{your-tenant-id}-api.purview-service.microsoft.com/`

> **Note**
>
> The old endpoint will be operational in parallel for users with access to the classic portal. Scans that were already running will continue to use the existing endpoint until they finish. New scans will use the new platform endpoint.

Remove account endpoints

Once all your currently running scans have completed, remove your existing account endpoints to switch completely to your new platform private endpoints.

Use managed virtual network with your Microsoft Purview account



Article • 05/01/2025

This article describes managed virtual networks and managed private endpoints in Microsoft Purview.

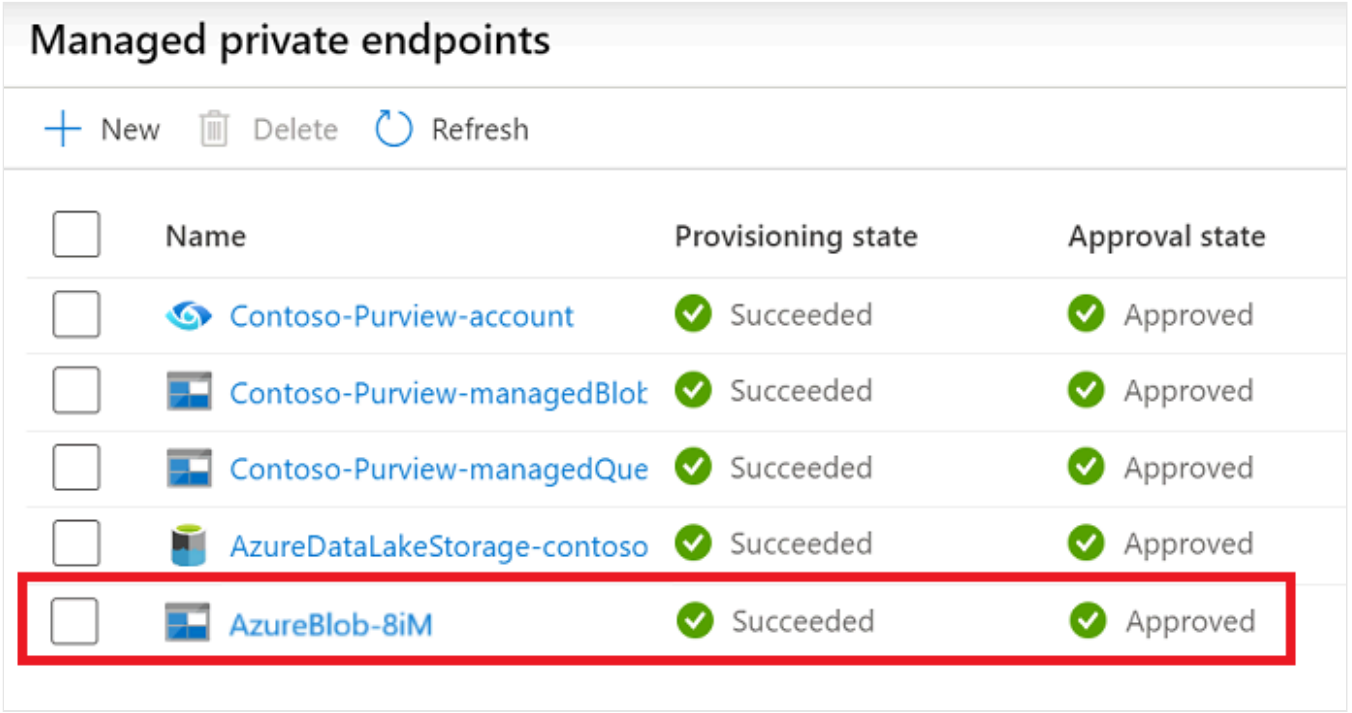
> **Note**
>
> - Microsoft Purview added new version of Managed Virtual Network support mid November 2023. New managed private endpoints no longer support the old managed virtual network. Create new a managed virtual network, and all your newly created resources will be using the latest version. Learn about the difference here.
> - Microsoft Purview accounts that were deployed before December 15, 2023 include a managed storage account. Microsoft Purview accounts that are deployed after (or deployed using API version 2023-05-01-preview onwards) don't have manage storage accounts deployed to the Azure subscription. Instead, these accounts include an ingestion storage account that's deployed to Microsoft's internal Azure subscriptions.

Managed Virtual Network

A Managed Virtual Network (virtual network) is a virtual network that is deployed and managed by Microsoft Purview to empower scanning data sources inside a private network, without having to deploy and manage any self-hosted integration runtime virtual machines by the customer in Azure.

You can deploy Azure Managed Virtual Network Integration Runtimes (IR) within Microsoft Purview Managed Virtual Networks in any available Microsoft Purview region. From there, the managed virtual network IR can use private endpoints to securely connect to and scan the supported data sources.

Creating a Managed virtual network IR within Managed Virtual Network ensures that data integration process is isolated and secure.



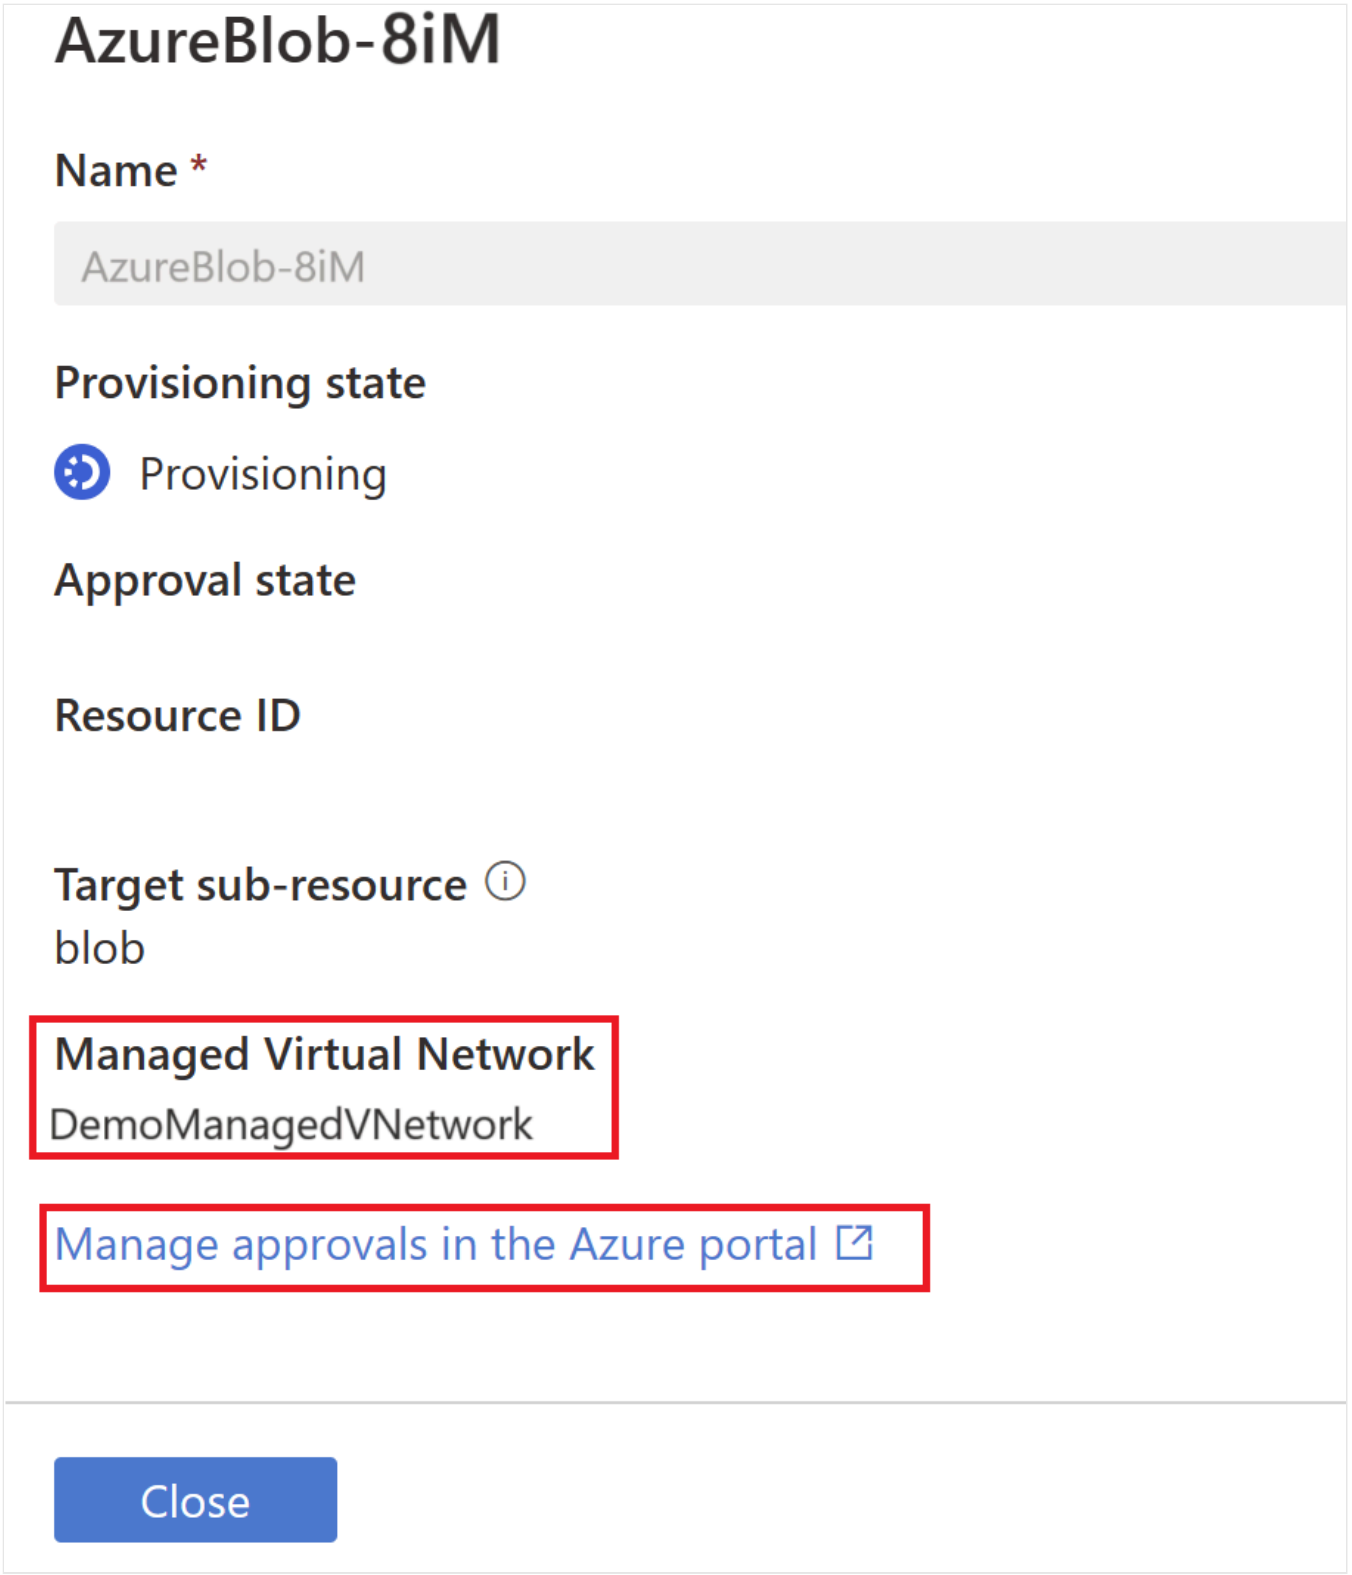
Benefits of using Managed Virtual Network:

- With a Managed Virtual Network, you can offload the burden of managing the Virtual Network to Microsoft Purview. You don't need to create and manage VNets or subnets for Azure Integration Runtime to use for scanning Azure data sources.
- It doesn't require deep Azure networking knowledge to do data integrations securely. Using a Managed Virtual Network is much simplified for data engineers.
- Managed Virtual Network along with Managed private endpoints protects against data exfiltration.

A managed virtual network is created for your Microsoft Purview account when you create a Managed Virtual Network Integration Runtime for the first time in your Microsoft Purview account. You can't view or manage the virtual networks outside of Microsoft Purview.

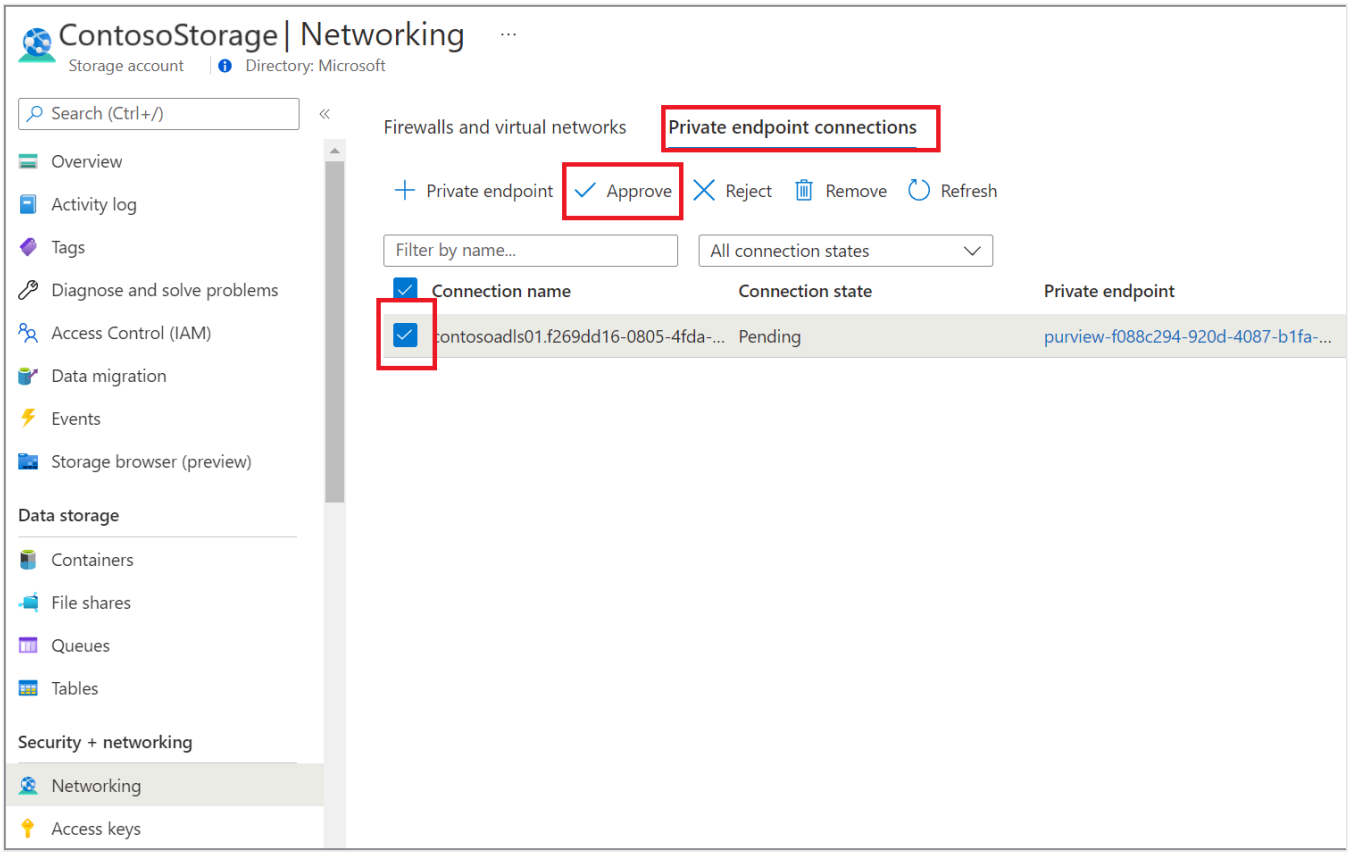
Managed private endpoints

Managed private endpoints are private endpoints created in the Microsoft Purview Managed Virtual Network establishing a private link to Microsoft Purview and Azure resources. Microsoft Purview manages these private endpoints on your behalf.



Microsoft Purview supports private links. Private link enables you to access Azure services like Azure Storage, Azure SQL Database, Azure Cosmos DB, Azure Synapse Analytics.

When you use a private link, traffic between your data sources and Managed Virtual Network traverses entirely over the Microsoft backbone network. Private Link protects against data exfiltration risks. You establish a private link to a resource by creating a private endpoint.



Private endpoint uses a private IP address in the Managed Virtual Network to effectively bring the service into it. Private endpoints are mapped to a specific resource in Azure and not the entire service. Customers can limit connectivity to a specific resource approved by their organization. Learn more about private links and private endpoints.

> ⚠ **Warning**
>
> If an Azure PaaS data store (Blob, Azure Data Lake Storage Gen2, Azure Synapse Analytics) has a private endpoint already created against it, and even if it allows access from all networks, Microsoft Purview would only be able to access it using a managed private endpoint. If a private endpoint does not already exist, you must create one in such scenarios.

A private endpoint connection is created in a "Pending" state when you create a managed private endpoint in Microsoft Purview. An approval workflow is initiated. The private link resource owner is responsible to approve or reject the connection.

If the owner approves the connection, the private link is established. Otherwise, the private link won't be established. In either case, the Managed private endpoint is updated with the status of the connection.

Only a Managed private endpoint in an approved state can send traffic to a given private link resource.

Supported regions and data sources

Supported regions: Managed Virtual Network is available in all the Microsoft Purview supported regions. Up to five managed virtual networks can be deployed across different regions in a single Microsoft Purview instance.

Supported data sources for scan: You can use the Managed Virtual Network Integration Runtime to scan many types of data source. Refer to the supported data sources.

Supported systems with managed private endpoint: The following services have native private endpoint support. They can be connected through private link from Microsoft Purview's Managed Virtual Network:

- Azure Blob Storage
- Azure Cosmos DB
- Azure Data Lake Storage Gen 2
- Azure Database for MySQL
- Azure Database for PostgreSQL
- Azure Databricks
- Azure Dedicated SQL pool (formerly SQL DW)
- Azure Files

- Azure Key Vault
- Azure SQL Database
- Azure SQL Managed Instance
- Azure Synapse Analytics
- Snowflake

Pricing details

When using Managed Virtual Network feature, you're charged by two parts:

- **Charge per scan run** (pay as you go): based on scan duration * used vCore hours * unit price per vCore hour. This is the common charge for scan running on any integration runtime types.
- **Charge on Managed VNet IR uptime** (always on): based on **Managed VNet IR life time * 1/8 vCore hour** * unit price per vCore hour. Managed virtual network IR life time means from the IR instance being successfully created until its deleted. The charge applies no matter you have scan run or not.

You can find details for "Automated Scanning, Ingestion & Classification" pricing from Microsoft Purview pricing page.

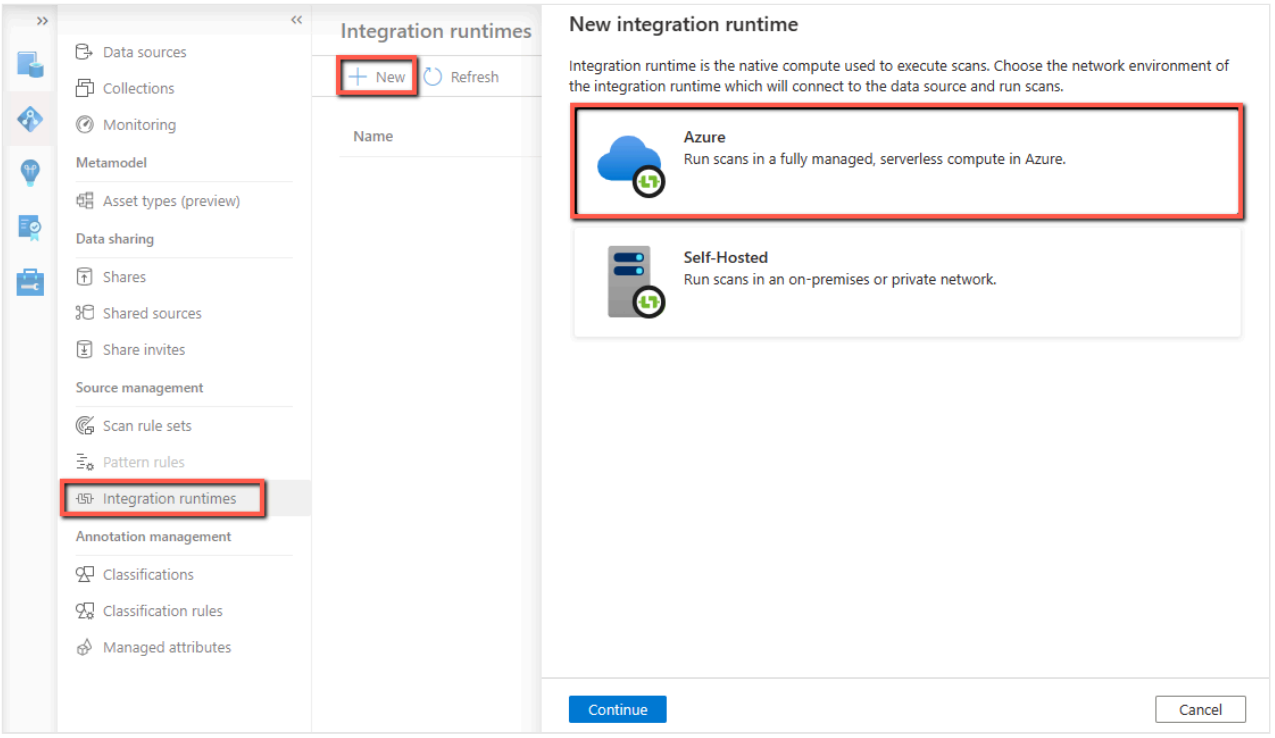
As an example, for a given month, you scan various data sources and the execution consumes X vCore hours of "Scanning Ingestion and Classification - Standard vCore" in total, and the managed virtual network runtime is provisioned to run for the whole month. The charge is: X vCore hours * $0.63 per vCore hour for scan runs + 1/8 * $0.63 per vCore hour * 730 hours for Managed virtual network IR uptime.

Deployment steps

Prerequisites

Before deploying a Managed virtual network and Managed Virtual Network Integration Runtime for a Microsoft Purview account, ensure you meet the following prerequisites:

1. From Microsoft Purview roles, you need Data Source Administrator permission on any collection in your Microsoft Purview account.
2. From Azure RBAC roles, you must be contributor on the Microsoft Purview account and data source to approve private links.



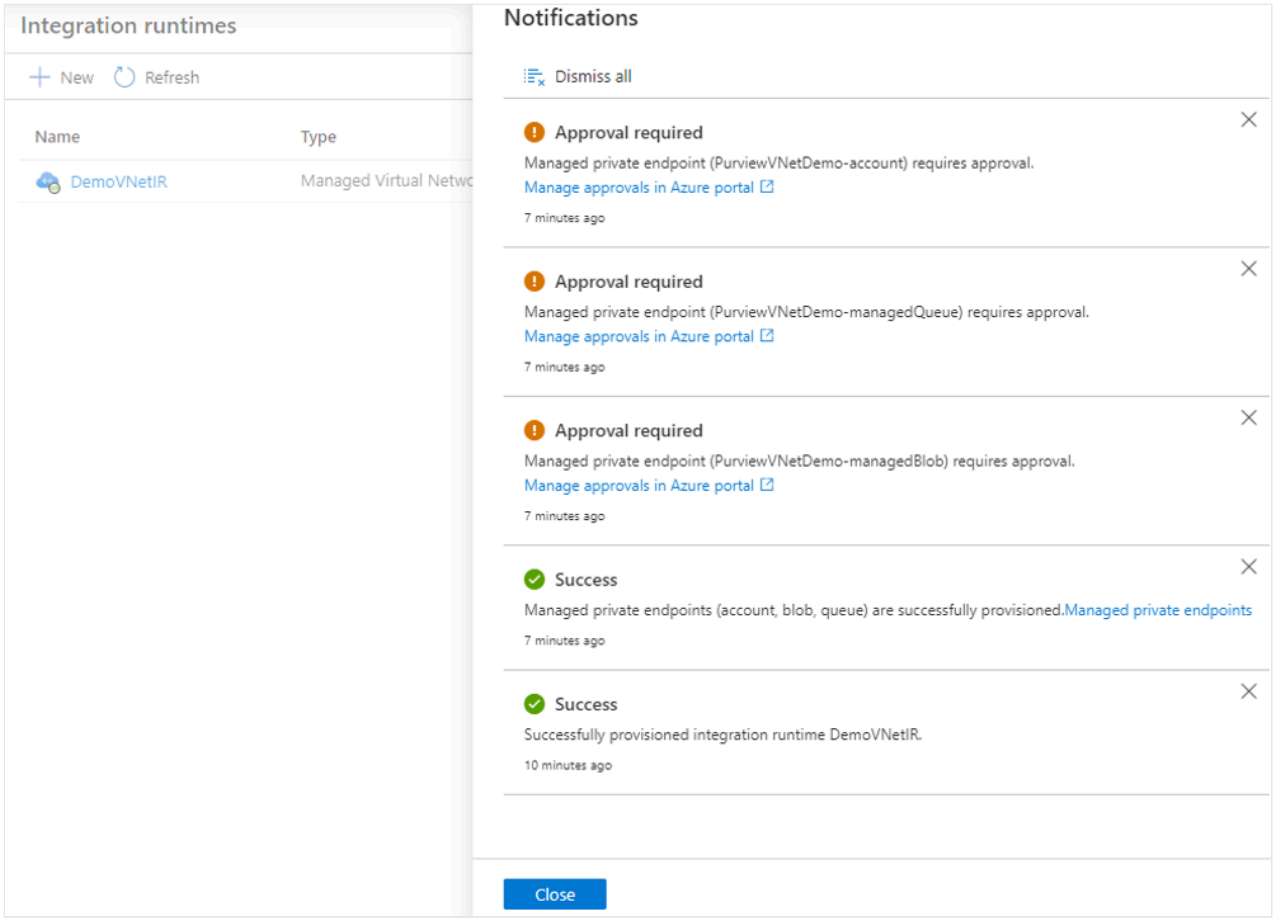
Create Managed Virtual Network Integration Runtime

1. Open the Microsoft Purview governance portal by:

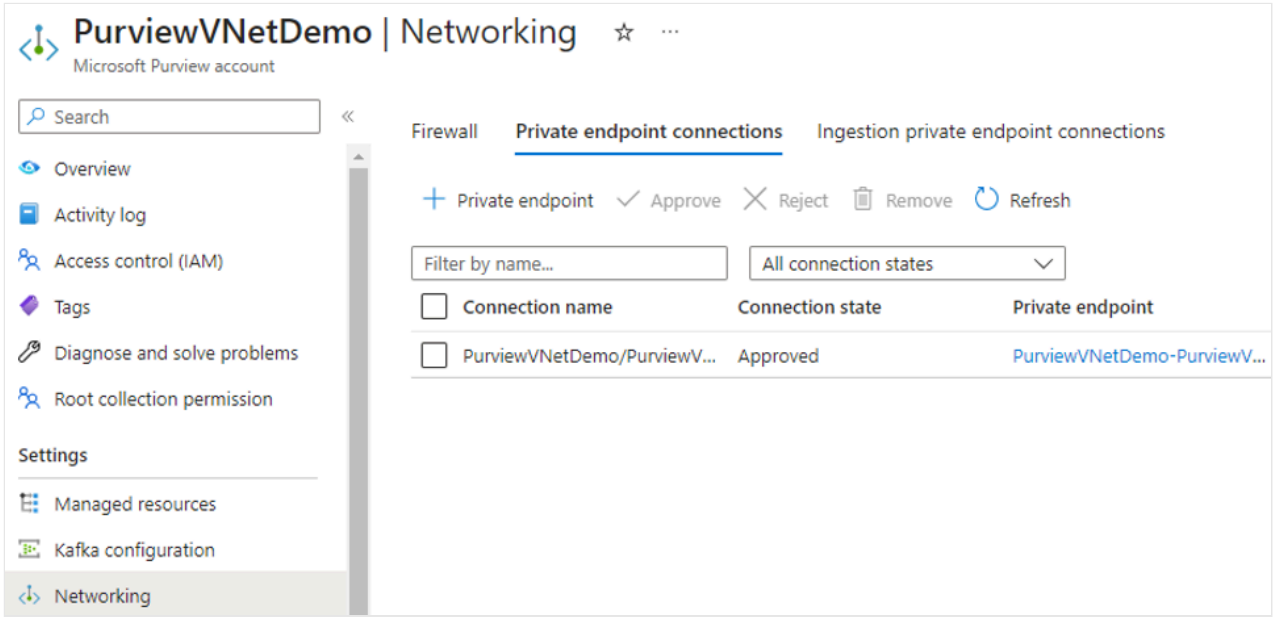
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

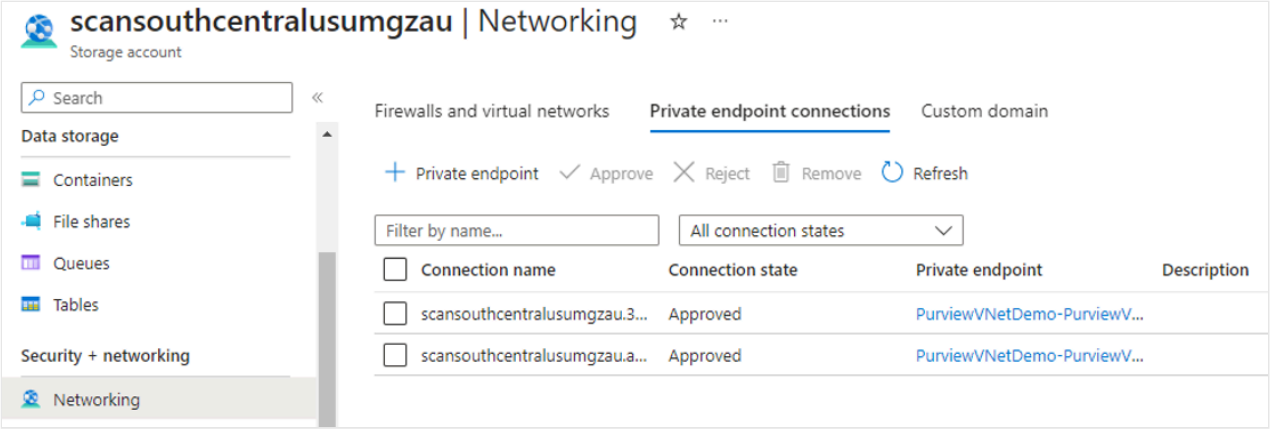
2. Navigate to the **Data Map** -> **Integration runtimes**.

3. From **Integration runtimes** page, select + **New** icon, to create a new runtime. Select **Azure** and then select **Continue**.



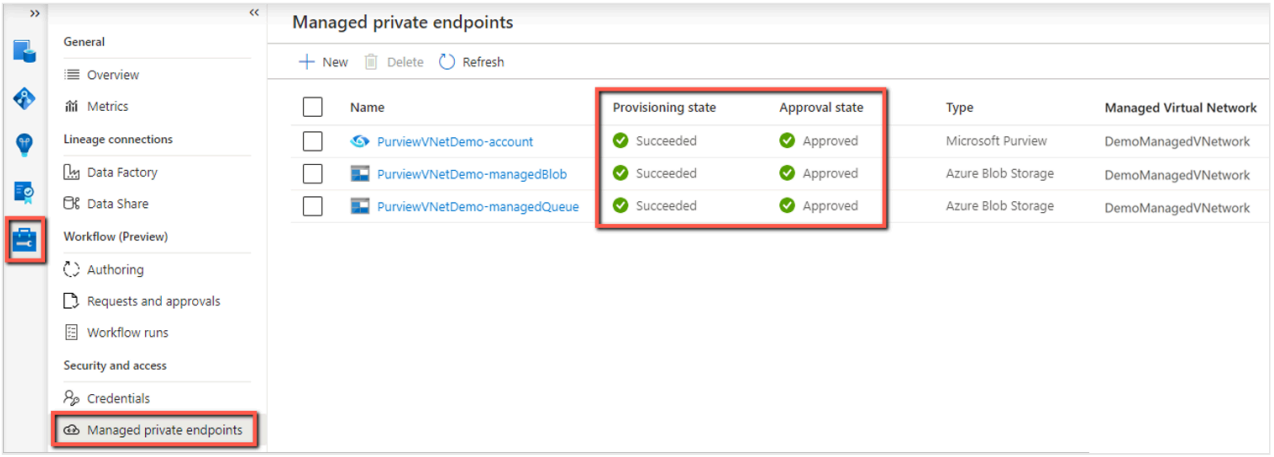
4. Provide a **name** for your Managed Virtual Network Integration Runtime, select a region, and give your managed virtual network a name.



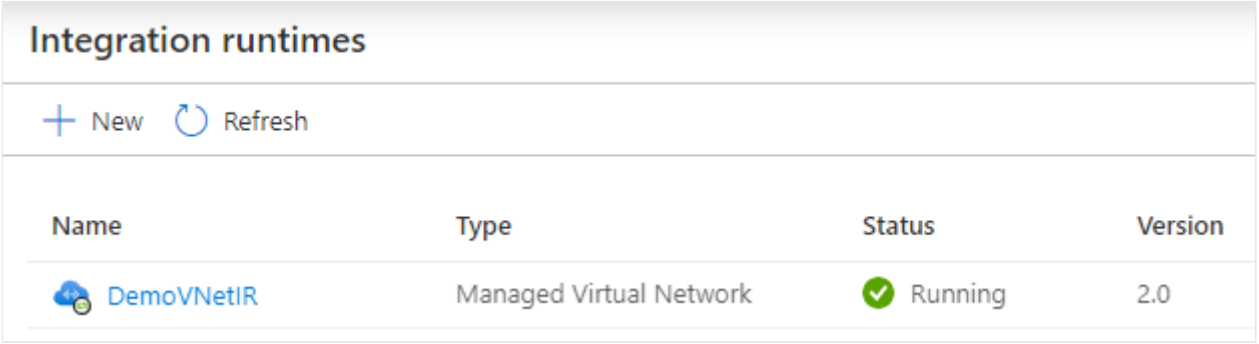


5. Select **Create**.

6. Deploying the Managed Virtual Network Integration Runtime triggers multiple workflows in the Microsoft Purview governance portal for creating managed private endpoints for Microsoft Purview and its managed Storage Account. Select each workflow to approve the private endpoint for the corresponding Azure resource.



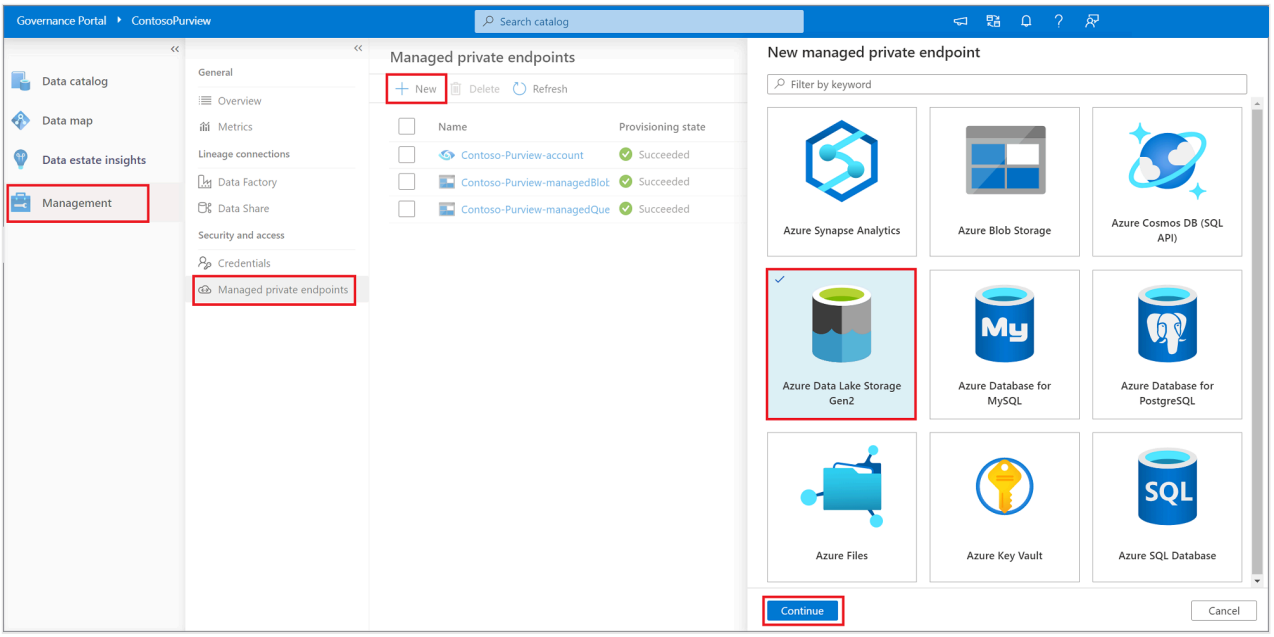
7. In Azure portal, from your Microsoft Purview account resource window, approve the managed private endpoint. From managed storage account page approve the managed private endpoints for blob and queue services:



8. From Management, select Managed private endpoint to validate if all managed private endpoints are successfully deployed and approved.

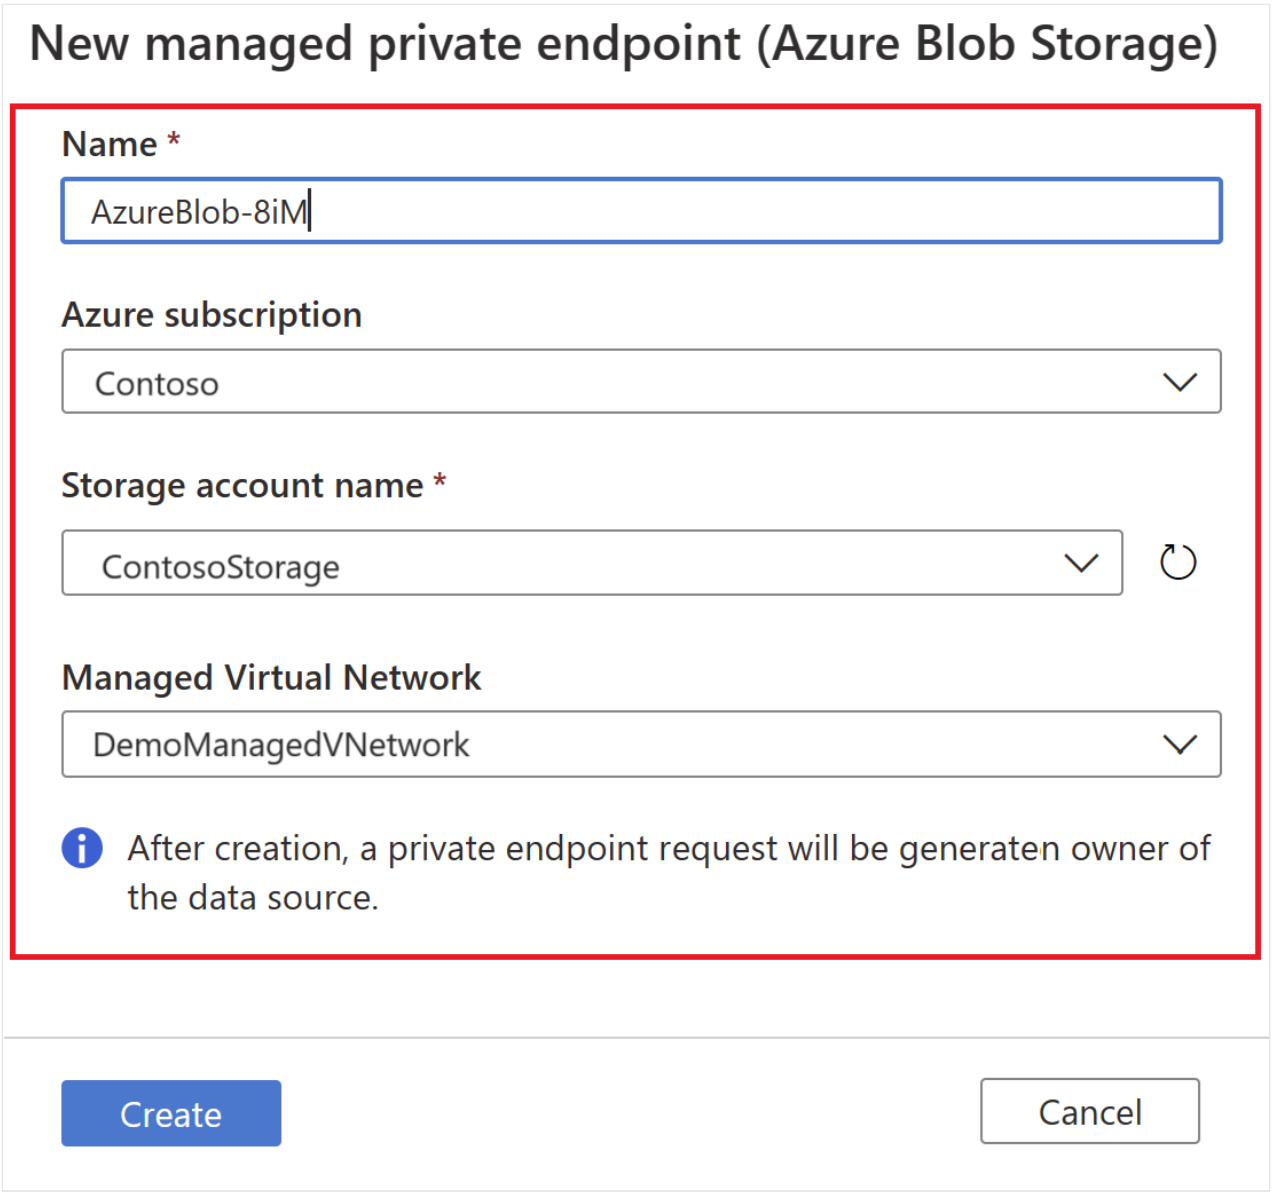
9. Go to the Integration runtimes page, you'll see the IR status shown up as "Initializing" upon creation. Wait until it turns into "**Running**" state to use in scan. It usually takes several minutes.

> **Tip**
>
> You can create multiple managed virtual networks in different regions in your Microsoft Purview account to securely access resources across regions.



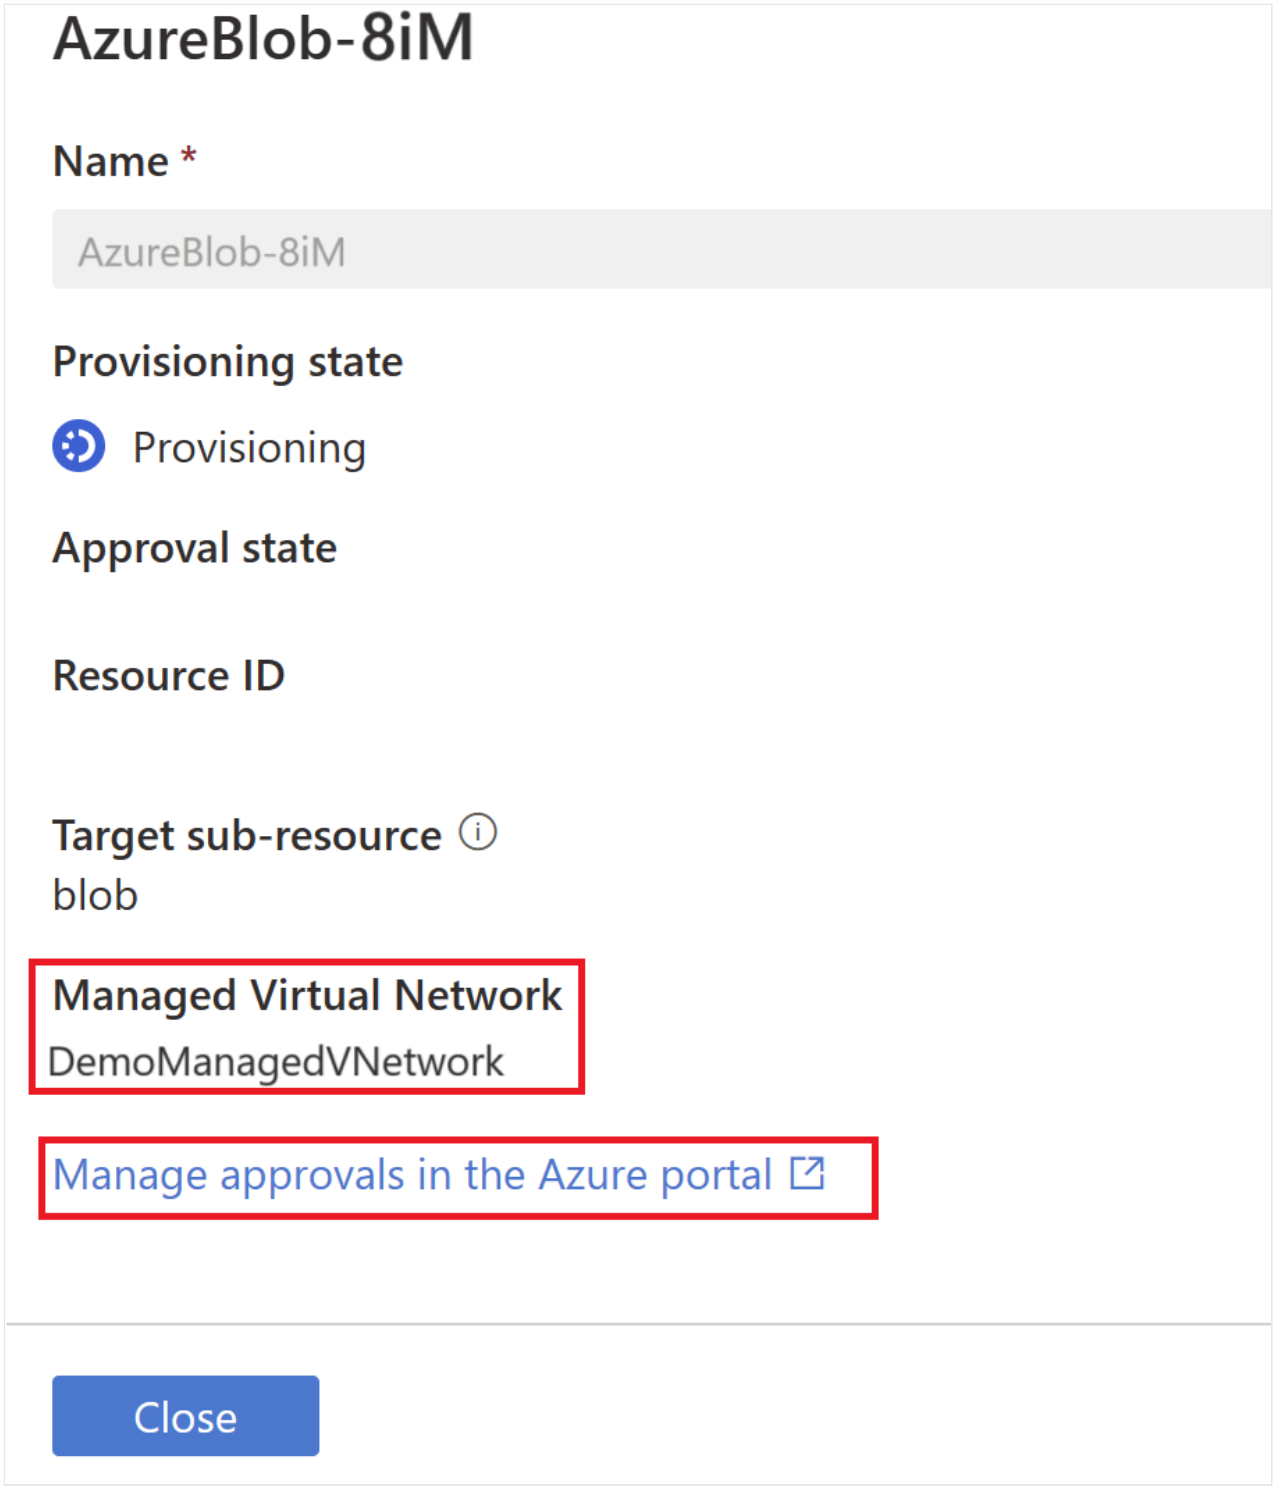
Create managed private endpoints for data sources

You can use managed private endpoints to connect your data sources to ensure data security during transmission.

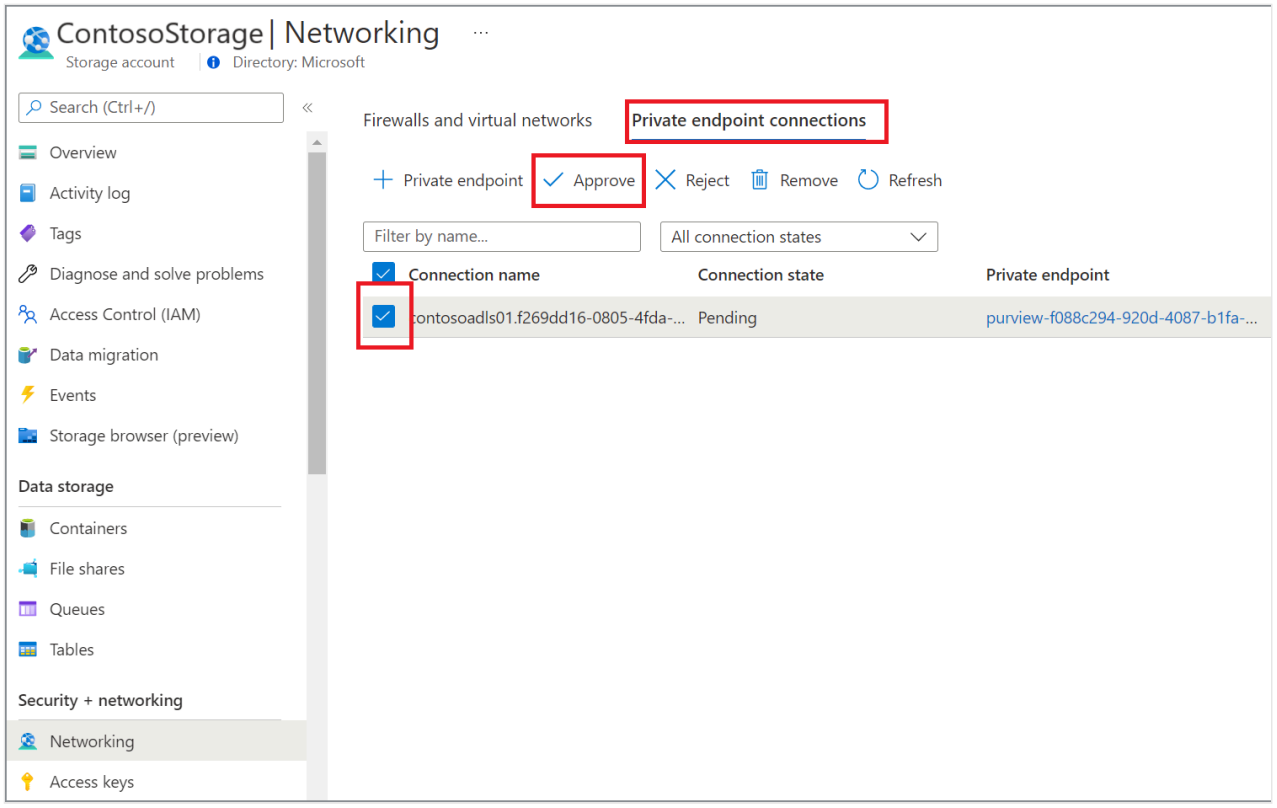


> **Tip**
>
> If your data source allows public access and you want to connect via public network, you can skip this step. Scan runs can be executed as long as the integration runtime can connect to your data source.

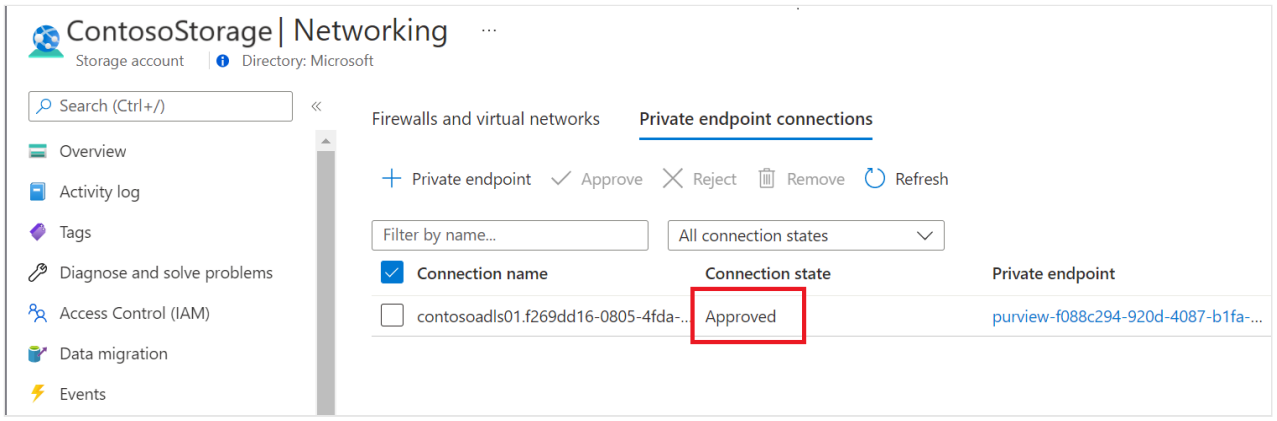
To deploy and approve a managed private endpoint for a data source, follow these steps selecting data source of your choice from the list:



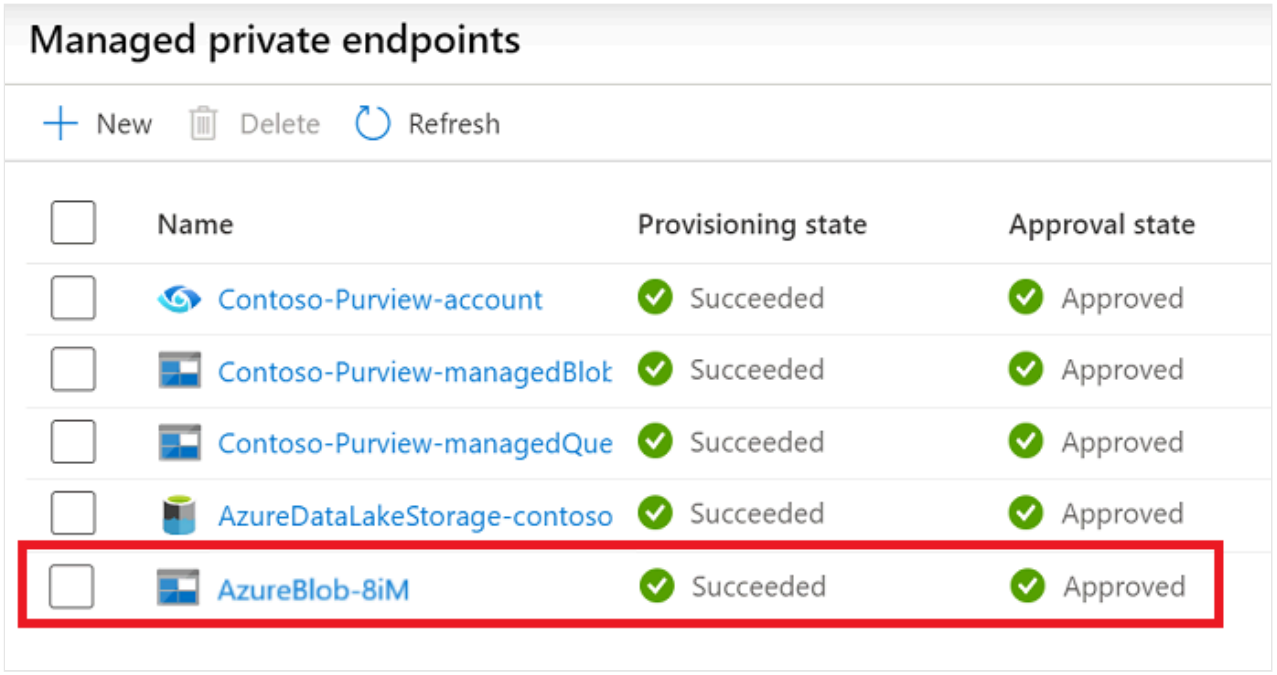
1. Navigate to **Management**, and select **Managed private endpoints**.
2. Select **+ New**.
3. From the list of supported data sources, select the type that corresponds to the data source you're planning to scan using Managed Virtual Network Integration Runtime.



4. Provide a name for the managed private endpoint, select the Azure subscription, data source, and Managed Virtual Network from the drop-down lists. Select **Create**.

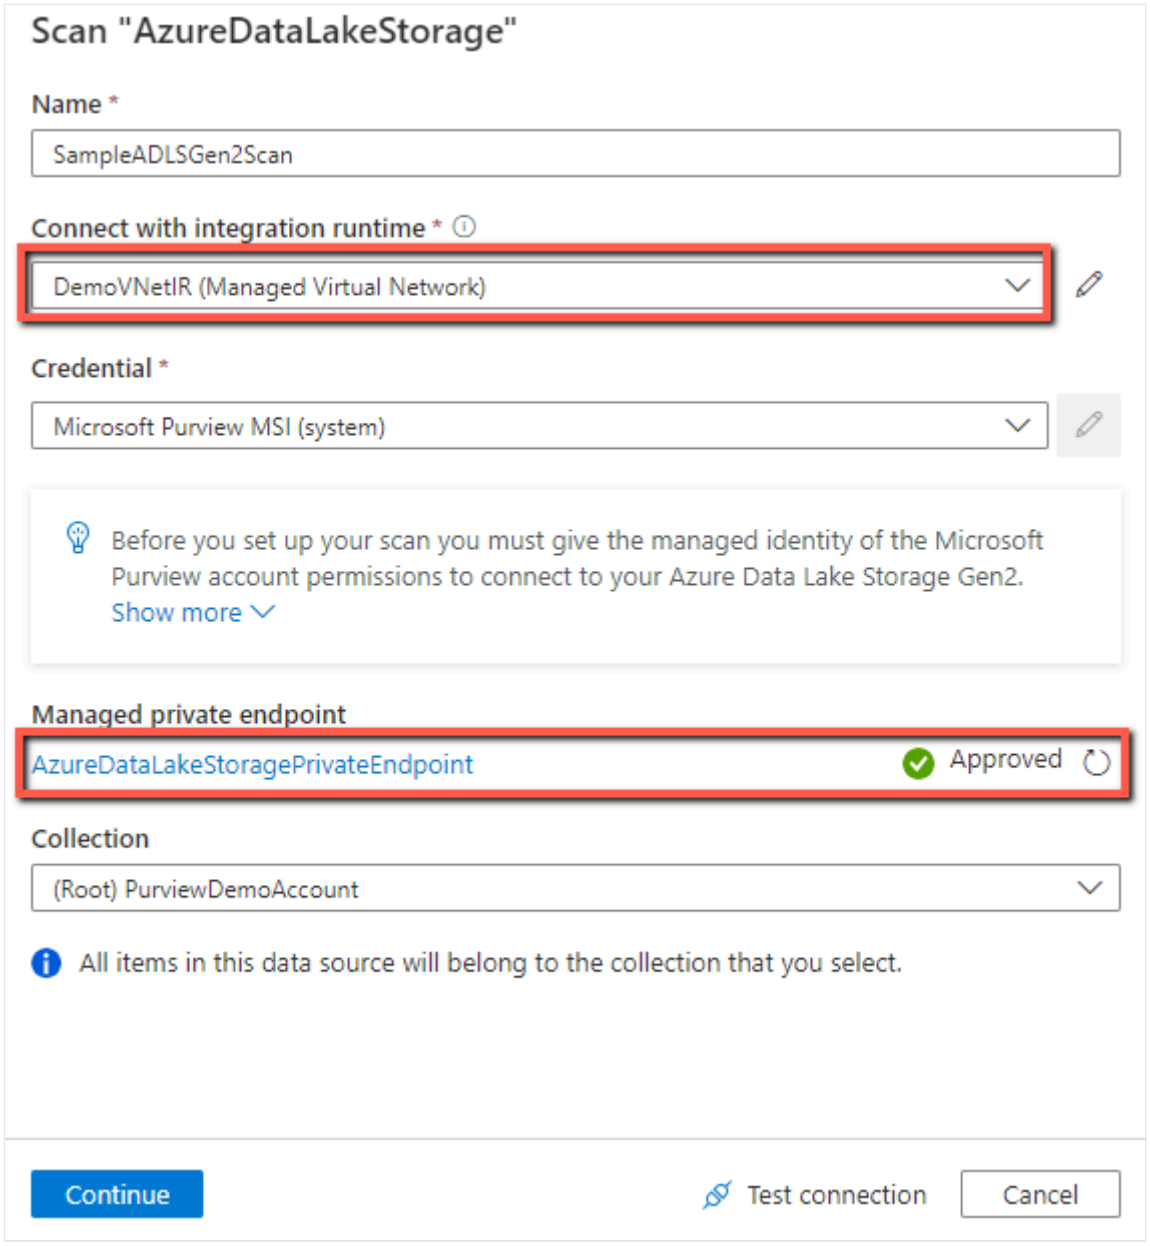


5. From the list of managed private endpoints, select the newly created managed private endpoint for your data source and then select on **Manage approvals in the Azure portal**, to approve the private endpoint in Azure portal.



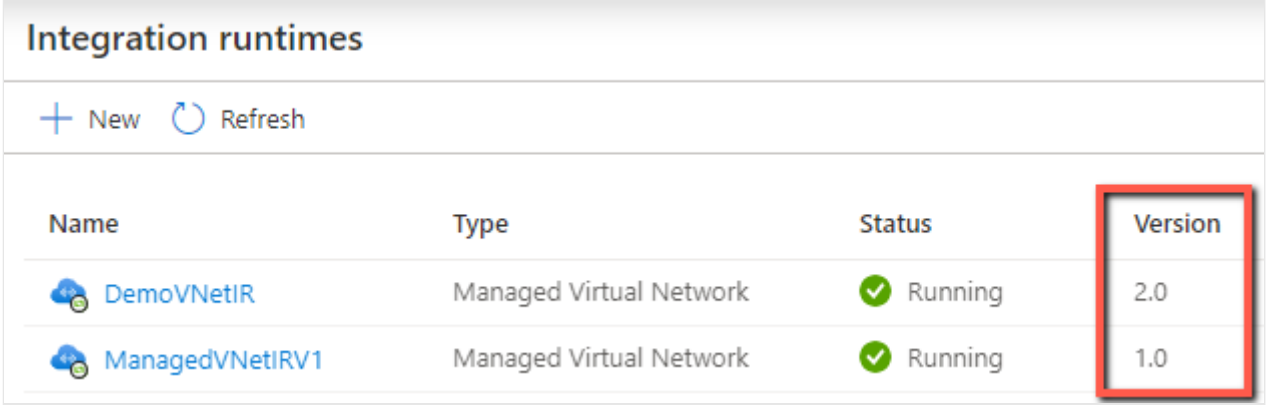
6. By selecting the link, you're redirected to Azure portal. Under the private endpoints connection, select the newly created private endpoint and select **Approve**.

7. Inside the Microsoft Purview governance portal, the managed private endpoint must be shown as approved as well.



Set up scan to use managed virtual network IR

1. Go to **Data map** -> **Sources**, register the source that you want to scan if not already done.



2. Go to your source -> **+ New scan**.

3. Under the **Connect via integration runtime**, select the managed virtual network IR you created. Configure the other scan settings as usual, and trigger a run.

Earlier version of Managed Virtual Network

To check the version of managed virtual network IR that you're using, go to **Data Map** -> **Integration runtimes**, and see the **Version** column.

The concept and architecture of Managed Virtual Network and managed private endpoint apply for both versions. The following table lists the differences in some aspects of the two versions. The version 2 provides better scan performance as well.

Expand table

Area	Version 1	Version 2 (current)
Supported regions	Available only in Australia East, Canada Central, East US, East US 2, North Europe, and West Europe.	Available in all Microsoft Purview supported regions.
Multi-vnet & multi-region	Only one virtual network supported at a time.	Up to five virtual networks supported across multiple regions.
Supported data source types for scan	Support scanning the following Azure data sources only. - Azure Blob Storage - Azure Cosmos DB - Azure Data Lake Storage Gen 2 - Azure Database for MySQL - Azure Database for PostgreSQL - Azure Dedicated SQL pool (formerly SQL DW) - Azure Files - Azure SQL Database - Azure SQL Managed Instance - Azure Synapse Analytics	Expanded to support scanning more data sources. See full list here.
Interactive authoring from Microsoft Purview portal (test connection, browse source during scan setup)	Need to turn on in Managed virtual network IR settings.	Always available
Name of the managed virtual network	default (autogenerated)	Configurable
Pricing	Charge on scan and ingestion jobs.	Charge on scan and ingestion jobs, and the running period of the managed virtual network IR. Learn more from Pricing details.

Update to latest version

Microsoft Purview added new version of Managed Virtual Network support mid-November 2023. All the newly created resources will be using the new offering. If you're using the earlier

version (which you can check), you can update to the latest version of the managed virtual network.

There are several advantages of using the new version of Managed Virtual Network:

- Generally available in all Microsoft Purview supported regions.
- Expanded data source support, including Databricks, Snowflake, Fabric, and all the sources that are supported by the default Azure integration runtime.
- Better scan performance.
- Interactive operations from Purview portal are always available (test connection, browse source during scan setup, etc.)

To upgrade, you can follow the instructions on this page: Upgrade to the new managed virtual network integration runtime.

Next steps

- Manage data sources in Microsoft Purview

Migrate to managed virtual network integration runtime

Article • 05/01/2025

Microsoft Purview added new version of Managed Virtual Network support mid-November 2023. All the newly created resources will be using the new offering. If you're using the earlier version (which you can check), you can update to the latest version of the managed virtual network.

There are several advantages of using the new version of Managed Virtual Network:

- Generally available in all Microsoft Purview supported regions.
- Expanded data source support, including Databricks, Snowflake, Fabric, and all the sources that are supported by the default Azure integration runtime.
- Better scan performance.
- Interactive operations from Purview portal are always available (test connection, browse source during scan setup, etc.)

> **Important**
>
> There is a pricing change to use a managed virtual network with Microsoft Purview. For more information about the capabilities of managed virtual networks and for pricing details, see the managed virtual network article.

To upgrade, you need to create a new Managed Virtual Network IR and switch your scans to this new IR. Here's an overview of what you'll need to do to migrate. All specific steps are listed after:

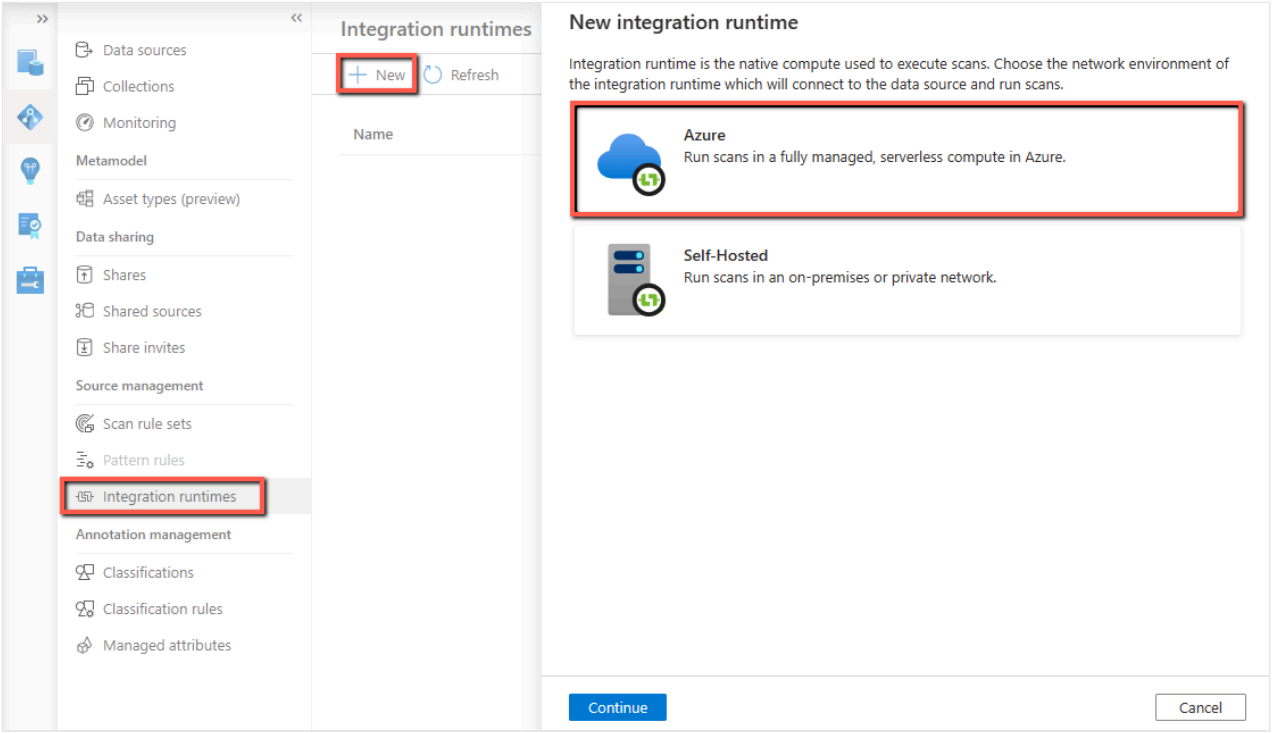
1. Ensure you meet prerequisites
2. Create a new Managed Virtual Network IR
3. Create managed private endpoints for data sources
4. Link your existing scans to the new managed virtual network IR
5. Delete the old managed virtual network V1

Deployment steps

Prerequisites

Before deploying a Managed virtual network and Managed Virtual Network Integration Runtime for a Microsoft Purview account, ensure you meet the following prerequisites:

1. From Microsoft Purview roles, you need Data Source Administrator permission on any collection in your Microsoft Purview account.
2. From Azure RBAC roles, you must be contributor on the Microsoft Purview account and data source to approve private links.



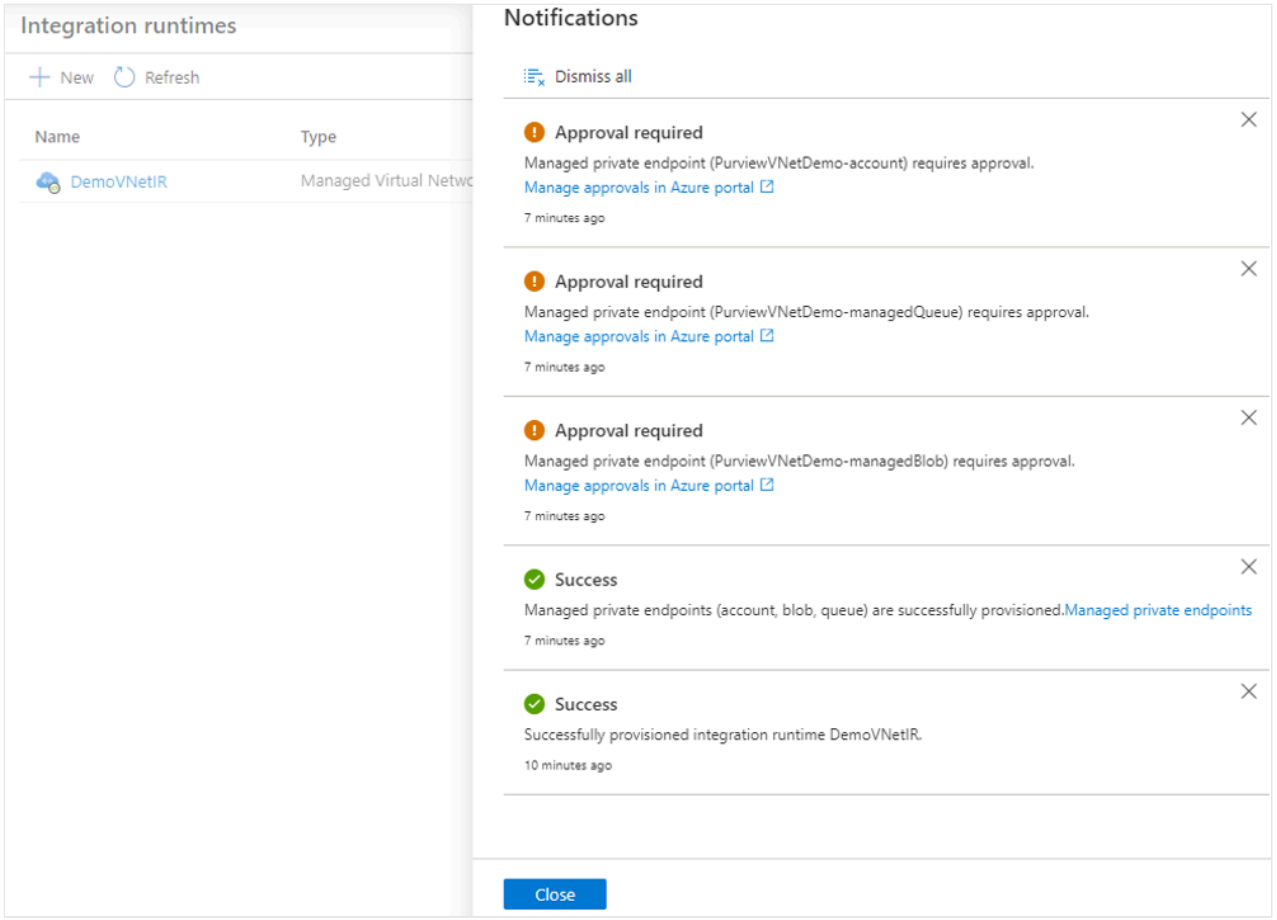
Create Managed Virtual Network Integration Runtime

1. Open the Microsoft Purview governance portal by:

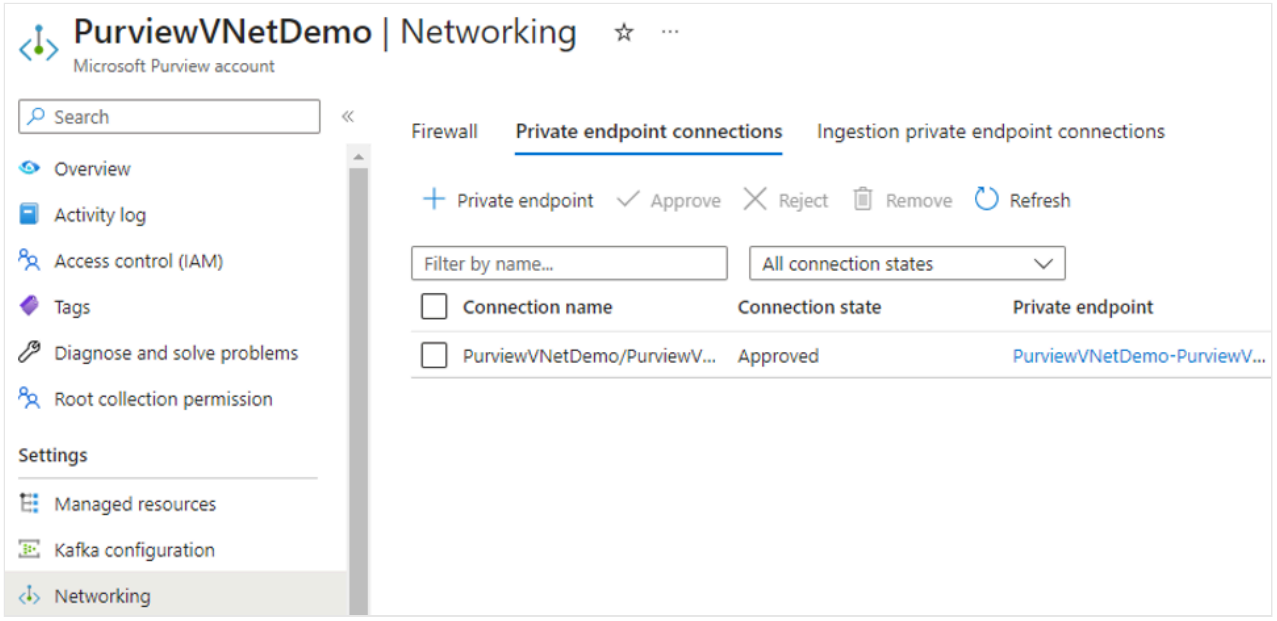
    - Browsing directly to https://web.purview.azure.com and selecting your Microsoft Purview account.
    - Opening the Azure portal, searching for and selecting the Microsoft Purview account. Selecting the **the Microsoft Purview governance portal** button.

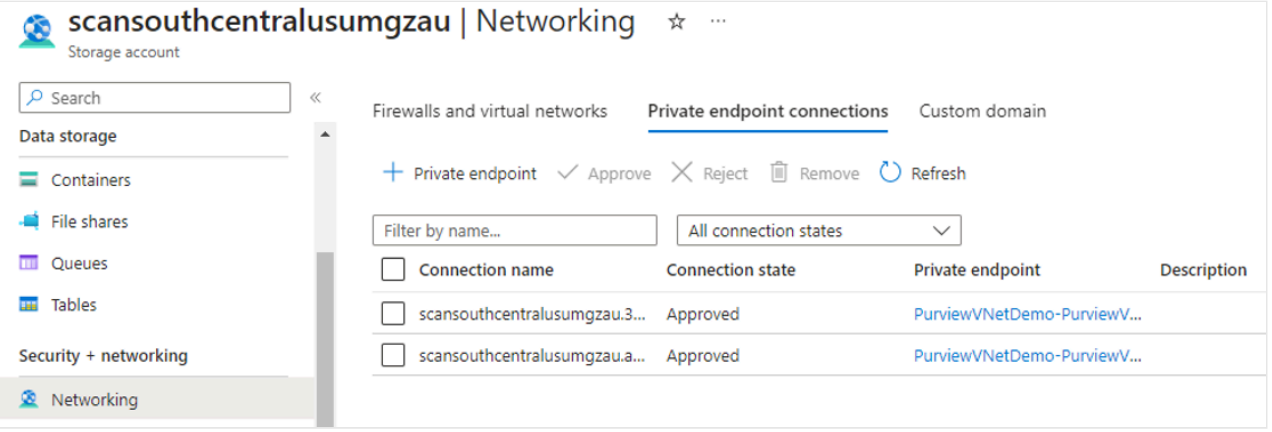
2. Navigate to the **Data Map -> Integration runtimes**.

3. From **Integration runtimes** page, select **+ New** icon, to create a new runtime. Select **Azure** and then select **Continue**.



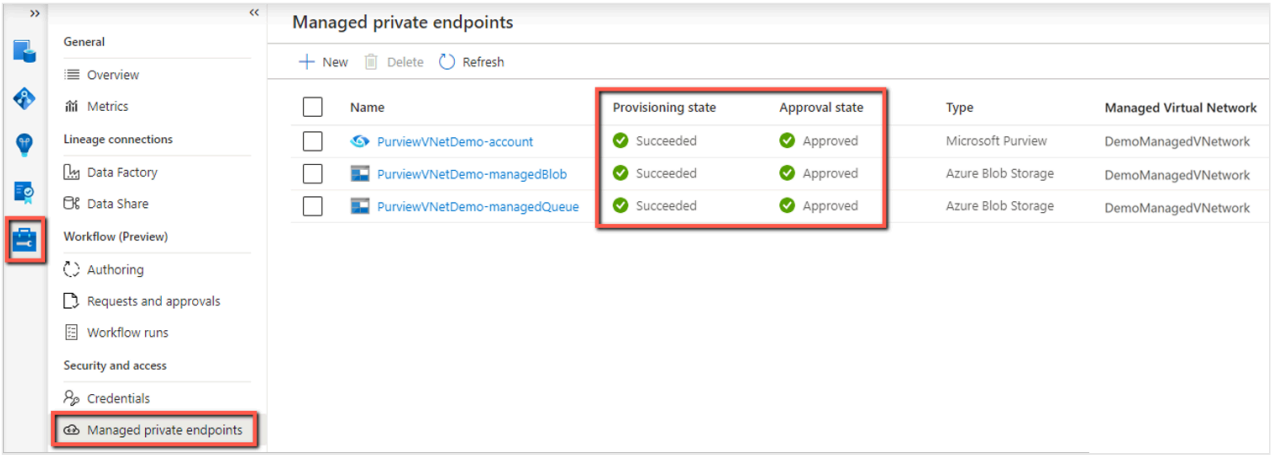
4. Provide a **name** for your Managed Virtual Network Integration Runtime, select a region, and give your managed virtual network a name.



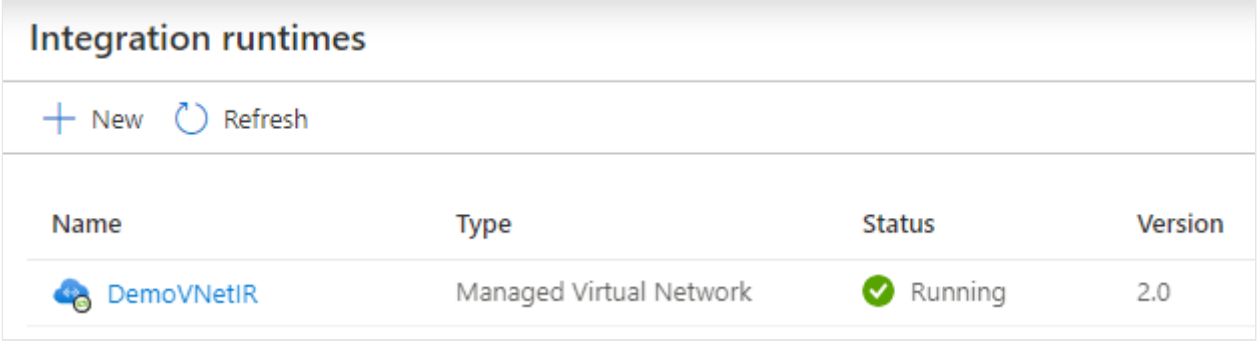


5. Select **Create**.

6. Deploying the Managed Virtual Network Integration Runtime triggers multiple workflows in the Microsoft Purview governance portal for creating managed private endpoints for Microsoft Purview and its managed Storage Account. Select each workflow to approve the private endpoint for the corresponding Azure resource.



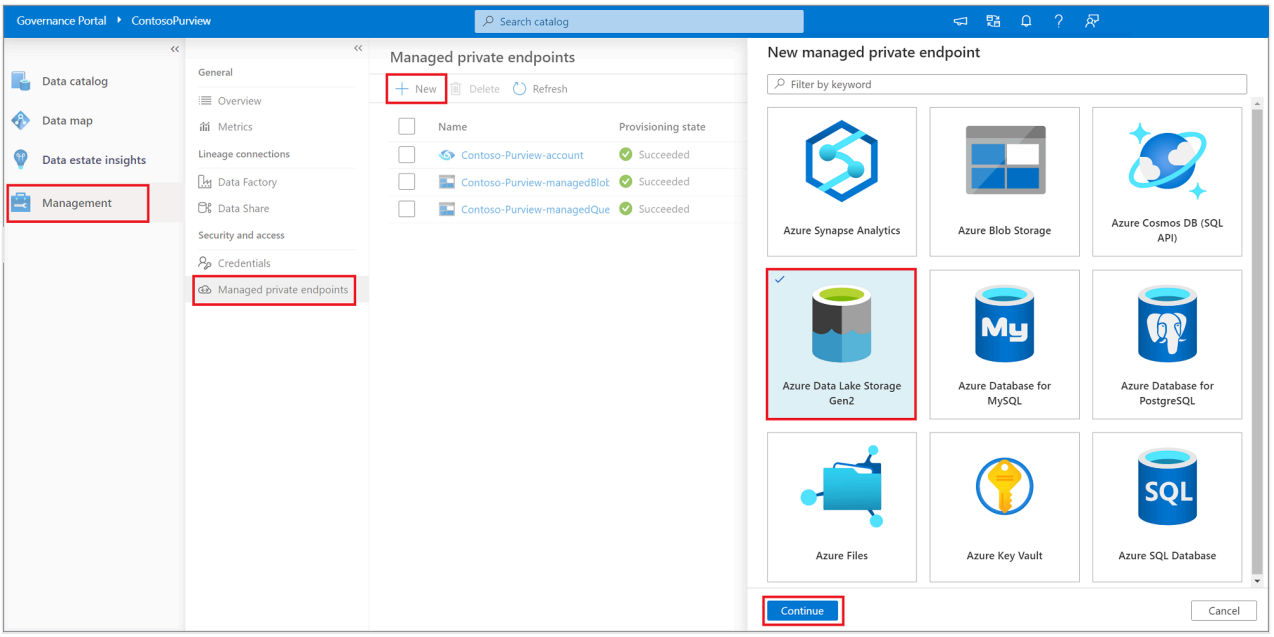
7. In Azure portal, from your Microsoft Purview account resource window, approve the managed private endpoint. From managed storage account page approve the managed private endpoints for blob and queue services:



8. From Management, select Managed private endpoint to validate if all managed private endpoints are successfully deployed and approved.

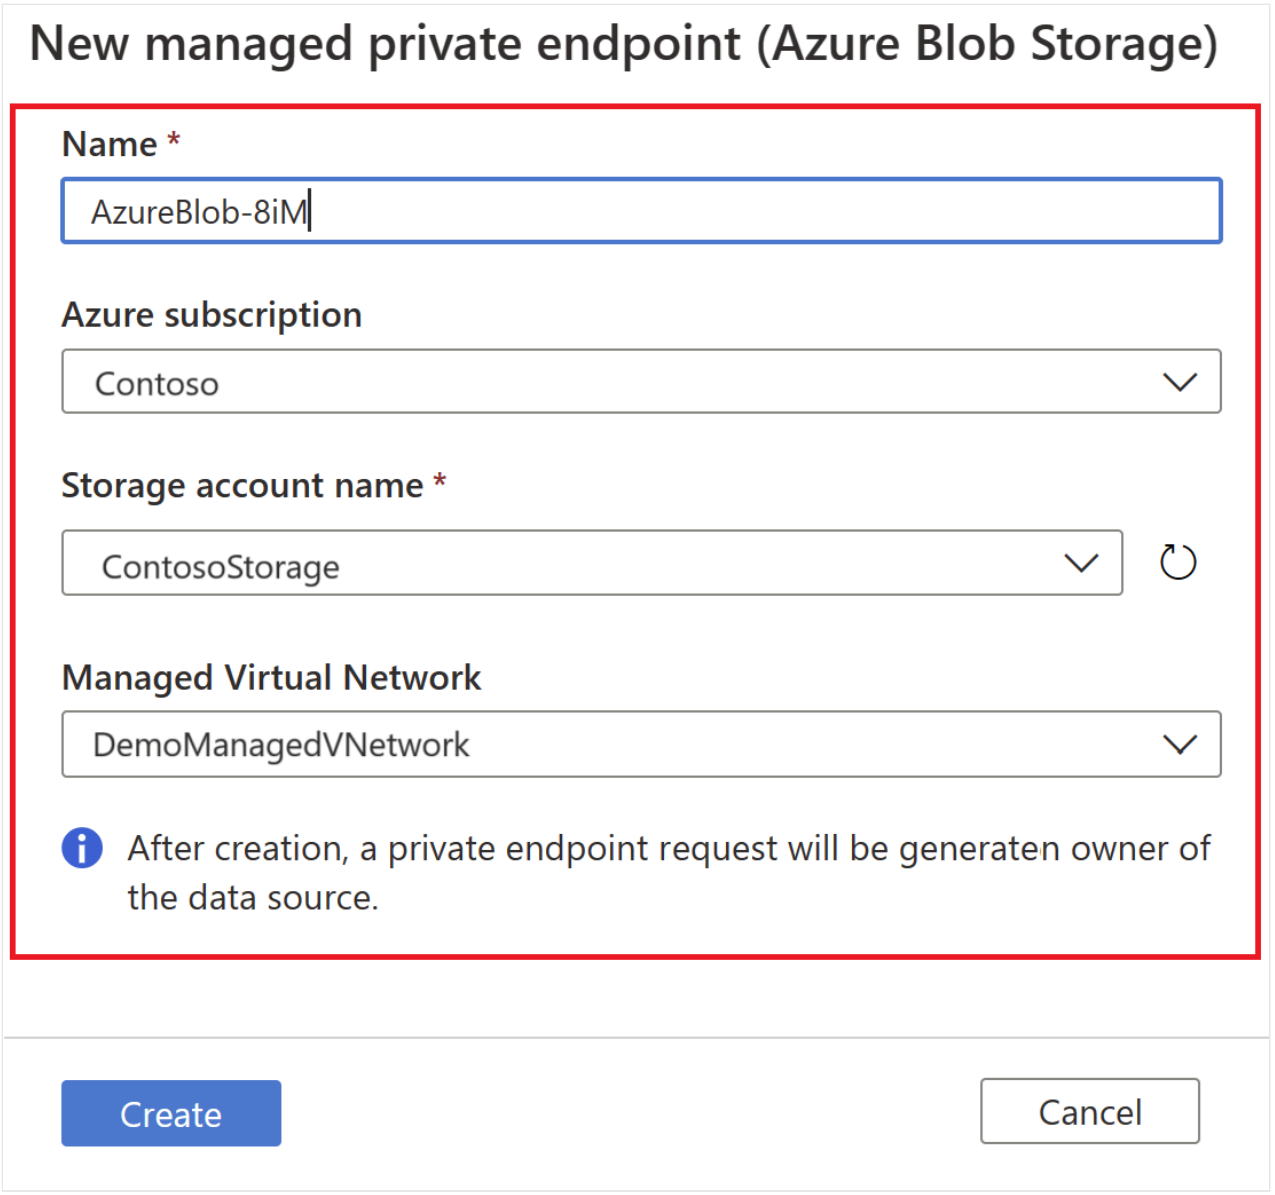
9. Go to the Integration runtimes page, you'll see the IR status shown up as "Initializing" upon creation. Wait until it turns into "**Running**" state to use in scan. It usually takes several minutes.

> **Tip**
>
> You can create multiple managed virtual networks in different regions in your Microsoft Purview account to securely access resources across regions.



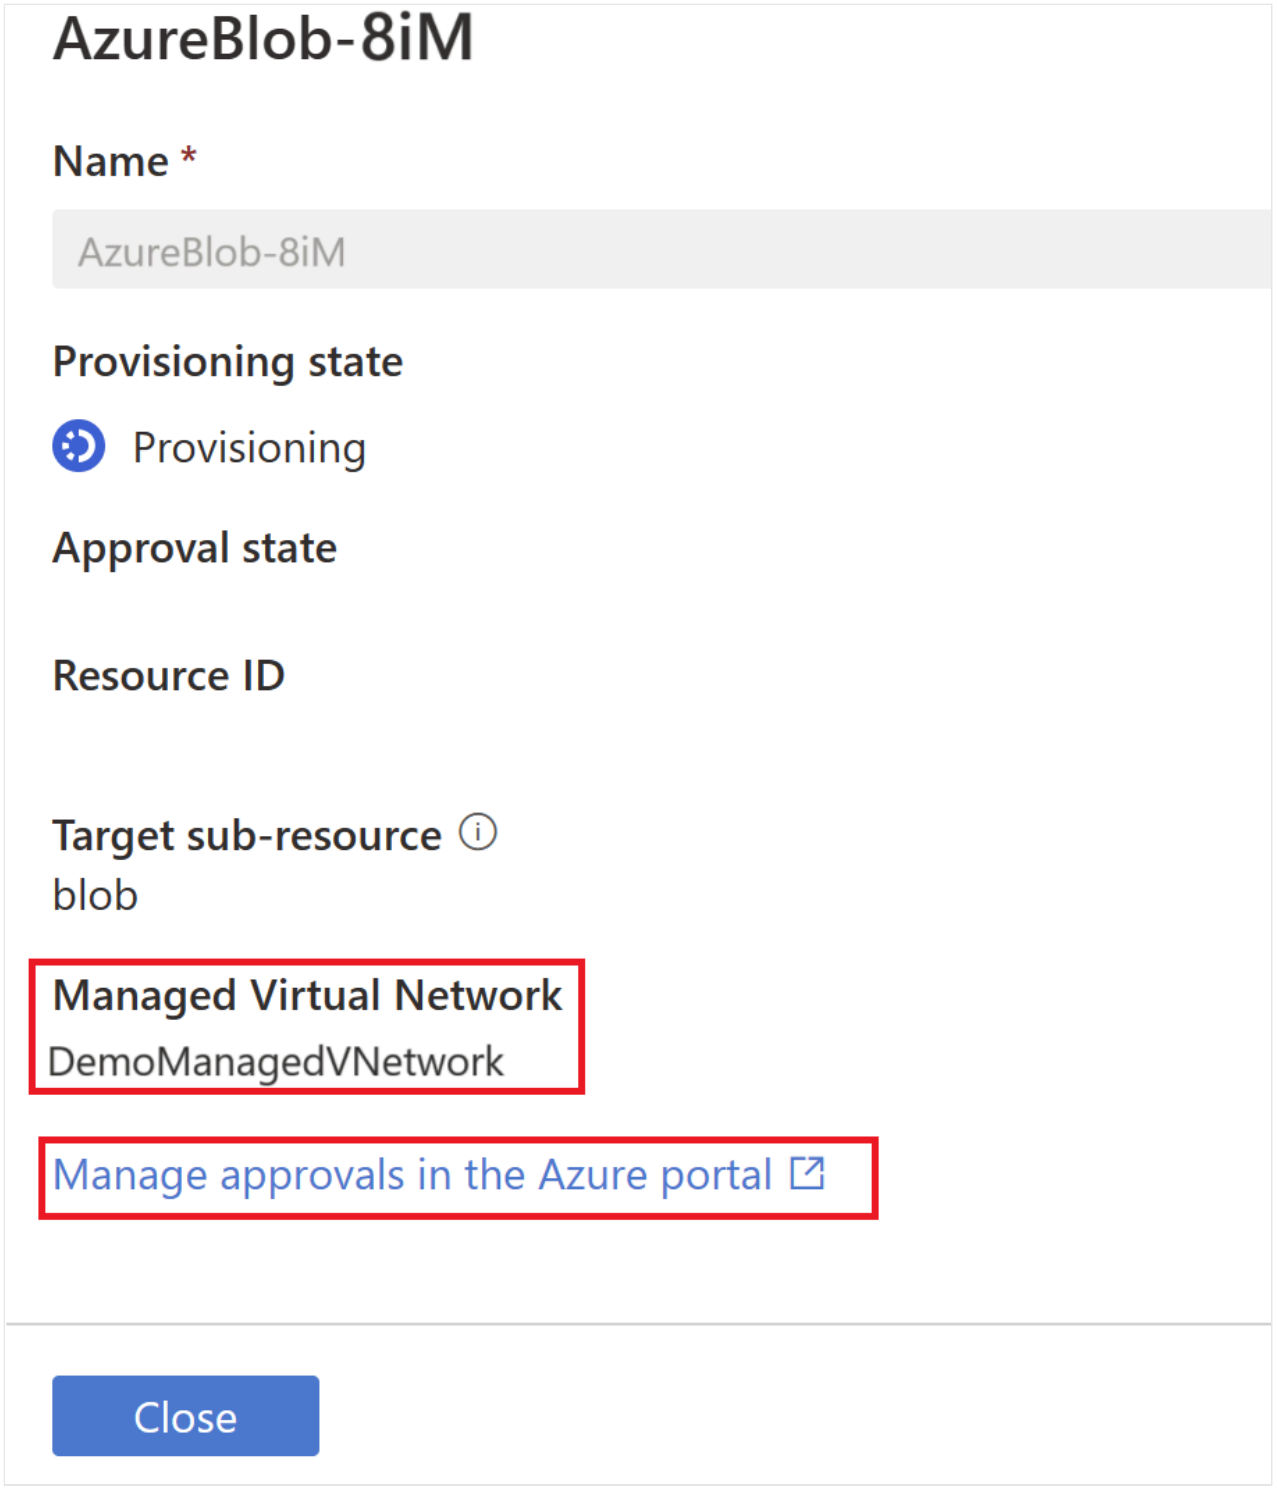
Create managed private endpoints for data sources

You can use managed private endpoints to connect your data sources to ensure data security during transmission.

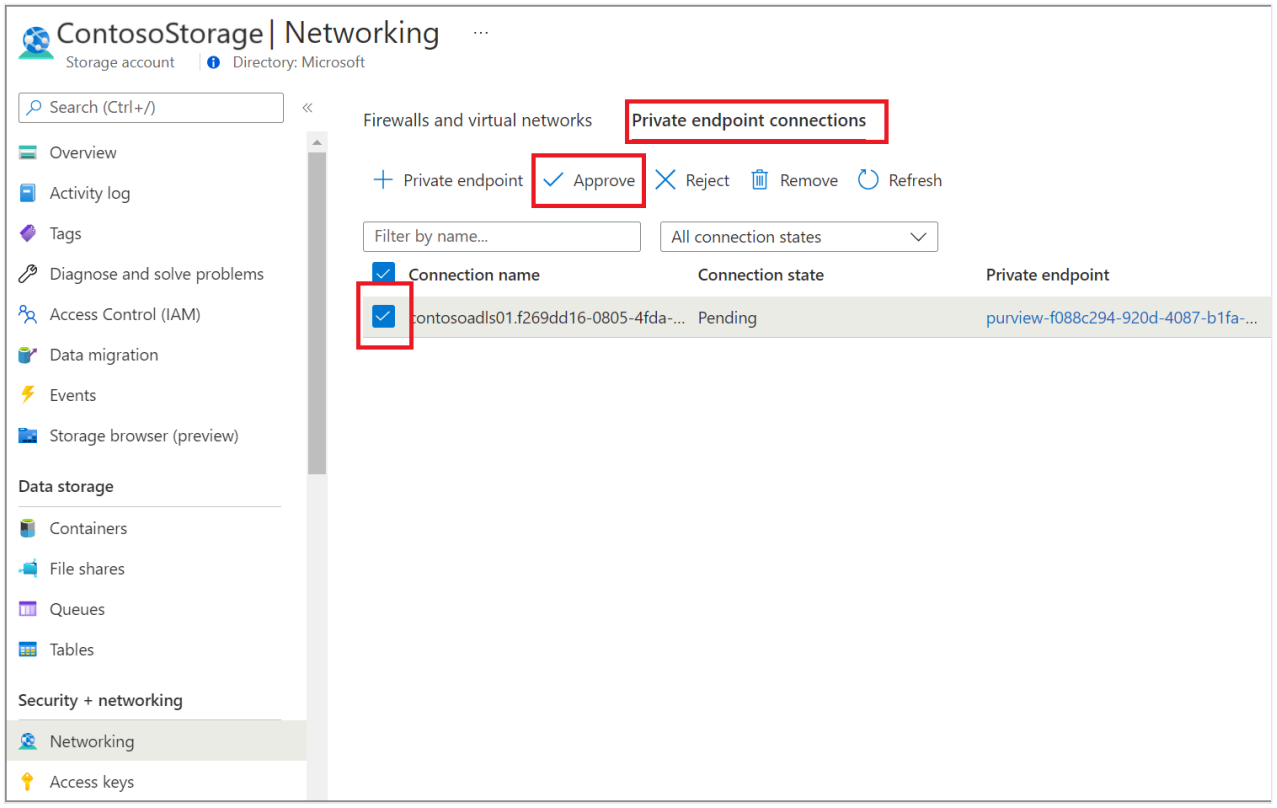


> **Tip**
>
> If your data source allows public access and you want to connect via public network, you can skip this step. Scan runs can be executed as long as the integration runtime can connect to your data source.

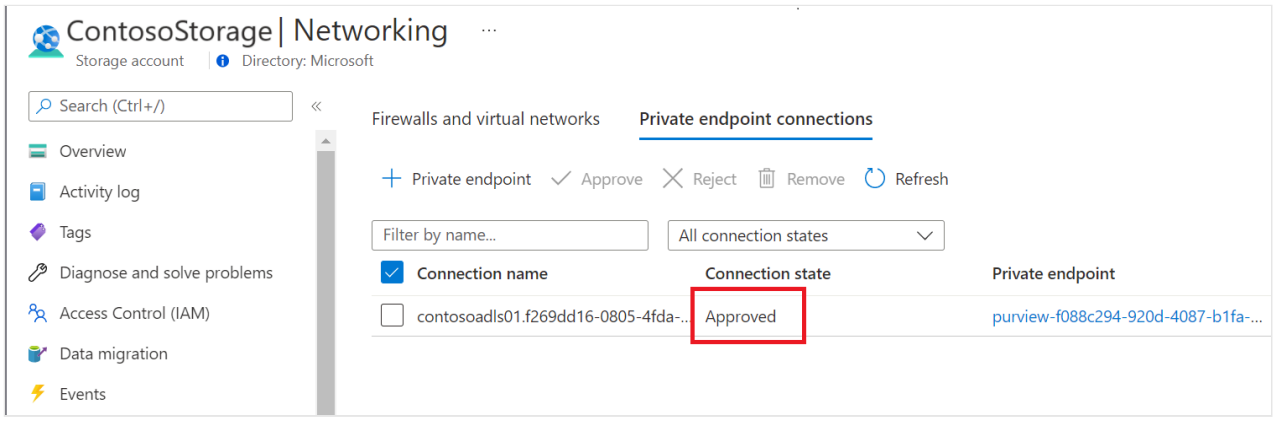
To deploy and approve a managed private endpoint for a data source, follow these steps selecting data source of your choice from the list:



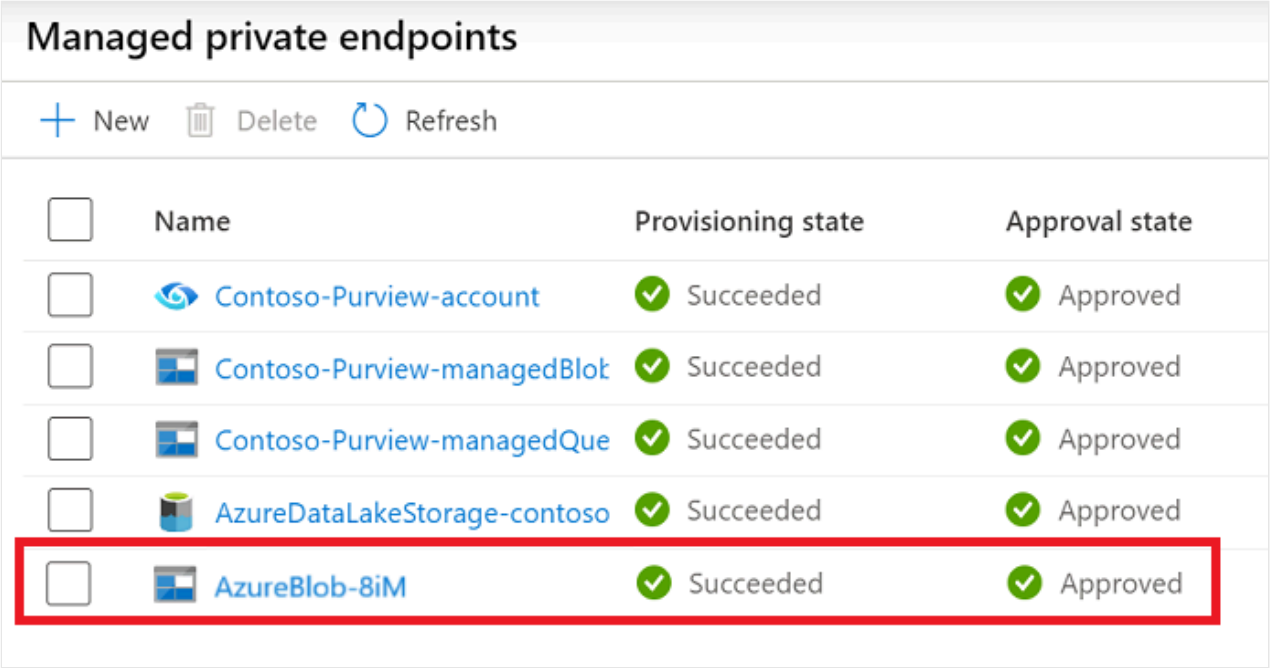
1. Navigate to **Management**, and select **Managed private endpoints**.
2. Select **+ New**.
3. From the list of supported data sources, select the type that corresponds to the data source you're planning to scan using Managed Virtual Network Integration Runtime.



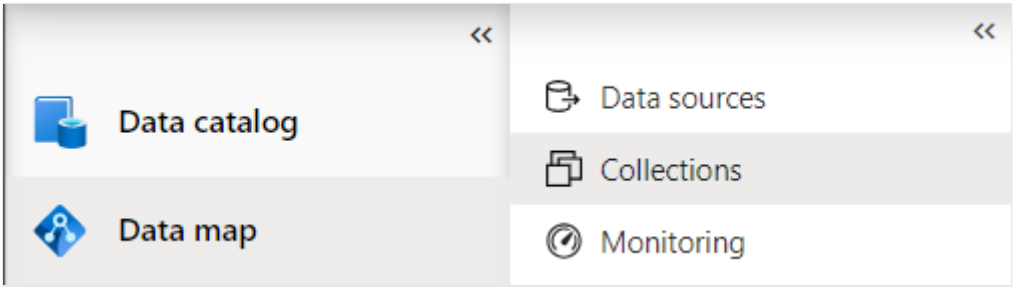
4. Provide a name for the managed private endpoint, select the Azure subscription, data source, and Managed Virtual Network from the drop-down lists. Select **Create**.



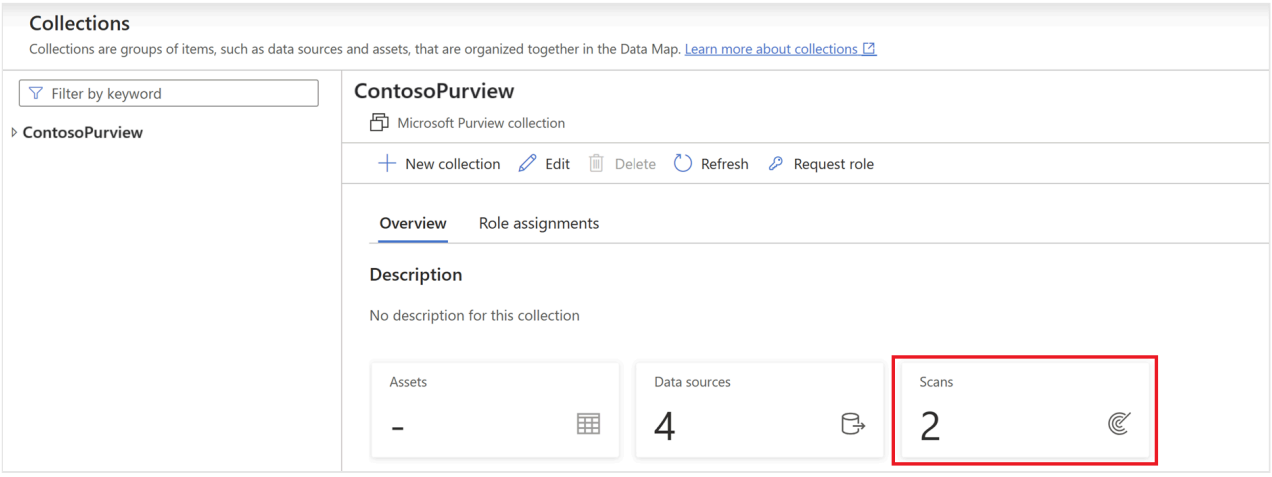
5. From the list of managed private endpoints, select the newly created managed private endpoint for your data source and then select on **Manage approvals in the Azure portal**, to approve the private endpoint in Azure portal.



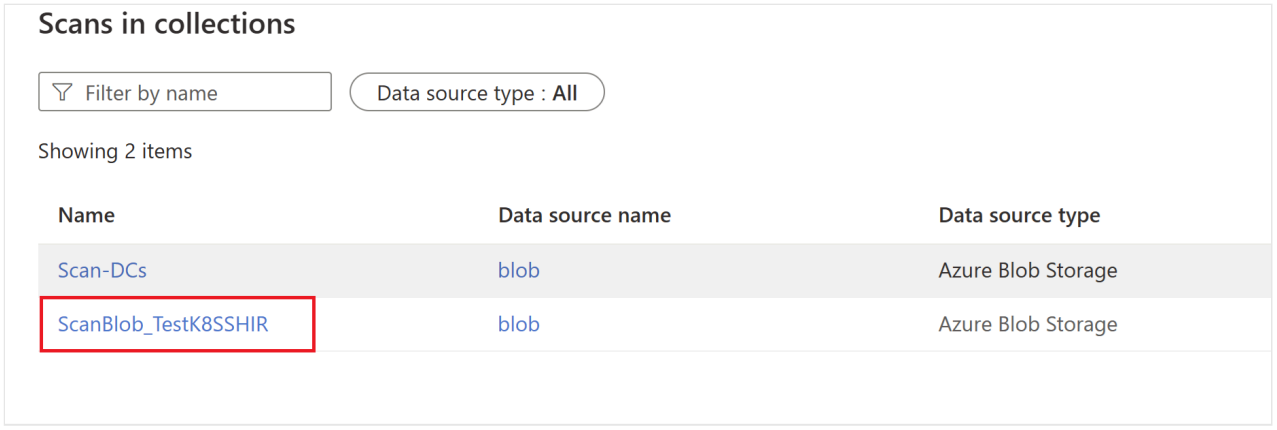
6. By selecting the link, you're redirected to Azure portal. Under the private endpoints connection, select the newly created private endpoint and select **Approve**.



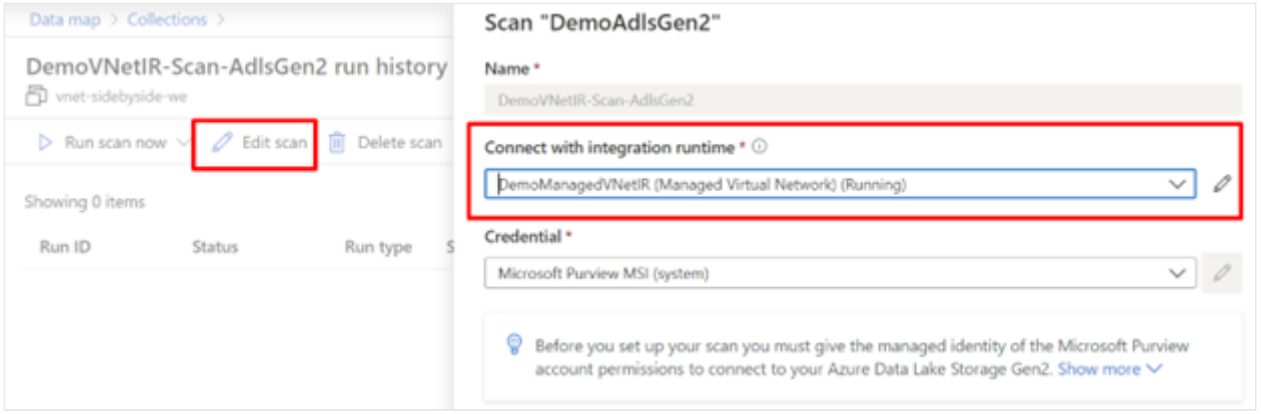
7. Inside the Microsoft Purview governance portal, the managed private endpoint must be shown as approved as well.



Link your existing scans to the new managed virtual network IR

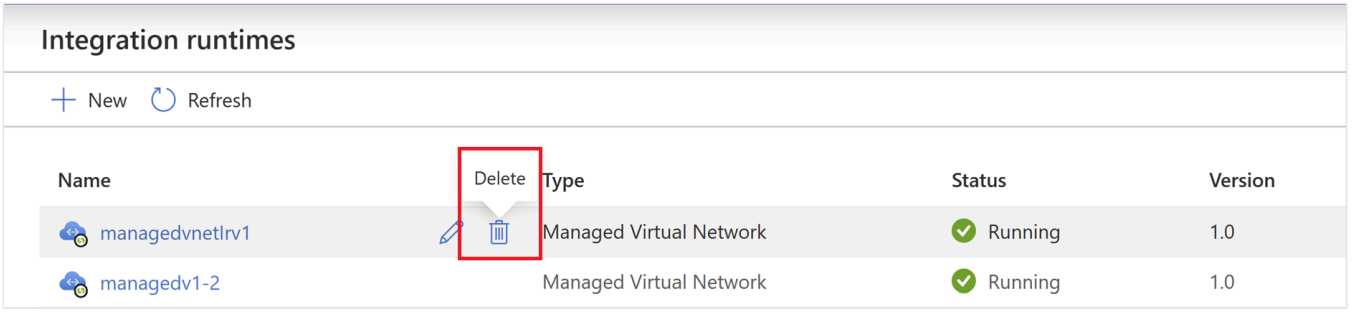


1. Inside Microsoft Purview, navigate to **Data Map**->**Collections**.



2. Select to your collections with scans and select the **Scans** button.

3. Select your scan name to see details.



4. Select **Edit scan** and choose your new Managed Virtual Network IR from the drop-down.

5. Save your changes and edit any other scans.

Delete the old managed virtual network V1

You can look for your old Managed Virtual Network IRs under **Integration Runtimes** and delete them.

Next steps

- Manage data sources in Microsoft Purview

Master data management in Microsoft Purview

Master data management (MDM) serves as a foundational element to build comprehensive data governance framework. Master data management creates a source of truth for your data, so you can check your key assets against this source of truth to confirm your data is trustworthy. You do this by creating a deduplicated set of master data records, a golden standard by which to measure your data. The standardization process you use to create this set of master data records differs across organizations, and Microsoft Purview integrates with partner solutions to offer helpful strategies.

Partner MDM integration with Microsoft Purview

Microsoft Purview integrates with various MDM solutions to empower data product owners to create and publish golden records that represent the authoritative version of master data assets. These integrations operate bi-directionally, enabling MDM systems to access metadata from Microsoft Purview and connect with the source systems to unify, cleanse, and standardize data, thereby creating master data assets. Later, the metadata of these master data assets is published back to Microsoft Purview in Unified Catalog, where it can be curated as a data product.

Conversely, the creation of golden data assets for master data products is facilitated within the integrated MDM solution, applying its capabilities for data management and governance. This collaborative approach ensures that organizations can use the full potential of master data for analytics and insights while maintaining data integrity and compliance.

Partner solutions and integration instructions

CluedIn

Semarchy

- Master data management with Semarchy
- Microsoft Purview and Semarchy integration

Data flow and integration steps

Here's a step-by-step guide on how to accomplish the tasks mentioned using Microsoft Purview and a partner MDM application:

1. Register and scan a data source in your Microsoft Purview Data Map.
2. Create a data product to use as your master data product.
3. Create a glossary term and link it to your data product.
4. Curate the master data product:
    a. Within the master data product, review the existing data assets and determine which ones are relevant to include.
    b. Add details description, use cases, etc., to ensure that the master data product contains the most relevant and up-to-date information.
5. The master data management application receives signal and pulls metadata:
    a. Configure your master data management application to listen for signals or events indicating changes in the Microsoft Purview metadata. This process is slightly different depending on which application you're using.
    b. When a signal is received, the MDM application pulls the required metadata related to the master data product and associated data assets from Microsoft Purview.
6. The master data management application connects data sources and copies data to create master dataset:
    a. Configure the MDM application to connect to the relevant data sources where the data assets are located.
    b. Copy the data from these sources to the MDM application's storage environment.
7. Unify, clean, and standardize the data
    a. Within the MDM application, unify, clean, and standardize the copied data to ensure consistency and accuracy.
    b. Apply data governance rules and transformations as needed to prepare the data for creating the master data asset.
8. Create a master data asset of Golden Records

a. Utilize the MDM application's capabilities to create a master data asset comprised of golden records that represent the consolidated and standardized view of the data.
b. Ensure that the master data asset meets the defined criteria and quality standards.

9. Publish the metadata to Microsoft Purview and link the new data asset to your data product.

By following these steps, you can seamlessly integrate with a partner MDM solution to manage glossary terms, curate master data products, synchronize metadata, and create and publish master data assets. This integration helps maintain data consistency, quality, and governance across your organization's data landscape

Where to find master data assets in Unified Catalog

Master data assets are found on a data product's details page of data produts. On the details page, locate the **Data assets** section. Each MDM asset is listed on a card labeled with the name of the MDM solution provider, such as Profisee or Semarchy. Learn more about searching for and browsing data products.

Microsoft Purview and CluedIn integration for master data management

Article • 04/03/2025

The CluedIn architecture provides businesses with metrics about the quality of data it ingests, intelligently detecting dirty data and preparing it for cleaning by data engineers and data stewards. Proprietary fuzzy logic machine learning algorithms help business users and curators label data, and teach the system to identify, correct, and prevent data quality issues over time.

Architecture

Dataflow

The CluedIn solution consists of various functional layers that run in a Kubernetes cluster in Azure Kubernetes Service (AKS). A combination of .NET Core microservice applications

handles distinct functions like data ingestion, streaming data processing, queuing, and user interface.

1. The CluedIn crawling layer ingests data from customer cloud sources like Azure SQL DB, Azure Cosmos DB, PostgreSQL, and Salesforce databases via Azure Data Factory connectors.

   CluedIn also takes input from on-premises accessible systems like SAP, Oracle, IBM, and Hadoop, or can use on-premises agents to crawl non-public data.

2. The enterprise service bus connects through ports 5672 and 15672 for admin endpoints. Crawlers send data to the bus, and the processing layer consumes data from the bus, over port 5672.

3. The transaction log layer takes results from the processing layer.

4. In the persistence layer, databases consume data from the transaction log and persist it to provide eventual consistency across the different data stores. All the stores run in high-availability (HA) mode.

   Unlike with data virtualization, the CluedIn persistence layer ingests parts of the source data and preserves the highest fidelity version of data and its structure. This high fidelity means that the CluedIn Data Fabric can serve business requests for data in any format or model.

5. The data abstraction layer connects to the different data stores through the ports for each store.

6. Data access is through GraphQL, REST, and WebSockets calls over port 443. GraphQL and REST use a pull model, and WebSockets uses a push model.

   CluedIn protects data access through throttling and Cross-Site Request Forgery (CSRF) prevention.

7. The CluedIn ASP.NET Core web application communicates through a combination of REST and GraphQL calls over port 443.

   All communication from the browser into the application uses a set of ingress definitions, which require only a single public IP address. In a production environment, all communication is over secure socket layer (SSL).

8. The CluedIn application provides cleaned, processed data to analytics services like Power BI and Azure Synapse Analytics for generating insights. The system backs up and stores all data in SQL or Redis databases.

Components

CluedIn runs on Azure Kubernetes Service (AKS), a highly available, secure, and fully managed Kubernetes service for deploying and managing containerized applications. AKS offers serverless Kubernetes, integrated CI/CD, and enterprise-grade security and governance.

CluedIn uses and supports many database sources and services, including:

- Azure SQL Database, a managed relational cloud database service that is always up to date and can automatically scale resources on demand.
- Azure SQL Managed Instance, for broad SQL Server engine compatibility with existing SQL Server applications. SQL Managed Instance provides on-premises database infrastructures with Azure cloud benefits like elastic scale, unified management, and a cloud billing model.
- Azure Cosmos DB, a fully managed, nonrelational NoSQL serverless database for modern app development.
- Azure Data Lake, a scalable data storage and analytics service.
- Azure Data Factory, a fully managed, serverless data integration solution for ingesting, preparing, and transforming data at scale. CluedIn uses over 90 built-in Data Factory connectors to acquire data from sources like Amazon Redshift, Google BigQuery, HDFS, Oracle Exadata, Teradata, Salesforce, Marketo, ServiceNow, and all Azure data services.

CluedIn provides processed, governed data to many analytics apps and services, including:

- Azure Databricks, a fast, easy, and collaborative Apache Spark-based analytics service.
- Azure Synapse Analytics, a limitless analytics service that brings together enterprise data warehousing and Big Data analytics.
- Log Analytics, an Azure portal tool to edit, run, and analyze queries from Azure Monitor log data.
- Azure Cognitive Services, a comprehensive family of AI services and cognitive APIs for building intelligent apps.
- Power BI, a Microsoft business analytics service that combines interactive visualizations and business intelligence with an easy-to-use report creation interface.

Scenario details

Modern enterprise companies base many processes and projects on data, but the raw data has to be prepared for consumption. Data use cases from advanced analytics to machine learning all require similar data preparation processes and attention.

1. Data projects start with data *discovery*, to determine where data is and what systems it uses.
2. Data *integration* then brings multiple data sources together into a unified or connected data set.
3. The next step is to *normalize, standardize, harmonize,* and *clean* the data so machines can process it in a uniform, consistent, and high-fidelity manner.
4. Finally, the data must be made easily and readily available for business needs.

During these processes, *governance* must ensure data control and privacy protection with clear ownership, full traceability, and an audit trail of data origins, processing, and use.

The CluedIn platform encapsulates these data management processes and pillars into a coherent, consistent, end-to-end Master Data Management (MDM) solution. CluedIn uses a data integration technique called *eventual connectivity* that yields better results than classic *extract, transform, load (ETL)* or *extract, load, transform (ELT)* models. Eventual connectivity uses GraphQL queries to blend data seamlessly from across many siloed data sources.

With eventual connectivity, data isn't joined or blended upon entry or loading into other systems. Instead, CluedIn loads the data as is, and tags records using metadata. Eventually, records with the same tags merge or build a relationship in the graph.

This sophisticated data merging technique provides a foundation for data-driven solutions. The CluedIn Data Fabric integrates data into a pipeline that cleans, prepares, models, governs, enriches, deduplicates, and catalogs data to make it easily available and accessible for business uses.

CluedIn provides businesses with metrics about the quality of data it ingests, intelligently detecting dirty data and preparing it for cleaning by data engineers and data stewards. Proprietary fuzzy logic machine learning algorithms help business users and curators label data, and teach the system to identify, correct, and prevent data quality issues over time.

CluedIn includes enterprise-grade governance, for assurance that you can use your data safely and confidently. CluedIn can stream cleaned, governed data directly to analysis systems like Power BI, Azure Databricks, Azure Synapse Analytics, or Azure Cognitive Services to make it easily available to the rest of the business. Native support for

autoscaling uses the power of Azure to provide a scalable environment for the biggest data workloads.

Potential use cases

Building a single view of data

- Due to CluedIn's semantic modeling, it makes building a Single View of your Master Data an easier thing to achieve compared to traditional approaches. CluedIn's customers are using CluedIn to build a connected, historical, and high quality view of their most critical business data. CluedIn not only supports mastering of classic Master domains like People, Companies, Vendors, and Products - it supports and endless number of different domains as well as unstructured domains like files, mail, events, and more. If you require a centralized repository of master data that is clean, enriched, governed, quality-controlled, and cataloged, then CluedIn is a good fit for your use cases.

A data fabric

- CluedIn is a Gartner Cool Vendor in 2020, due to its ability to orchestrate data from across 10s, 100s and 1000s of different and complex datasources into a unified data hub. If you need to wrangle data from many different datasources with ease, then CluedIn can be used as a data fabric to achieve this. This can provide a streaming infrastructure for your data that can also proactively clean and master the data as it flows onto downstream consumers.

Sophisticated merging and linking of master data

- CluedIn's unique data modeling approach utilizes a graph database, which allows for complex data to be merged and linked with simplicity. Unlike traditional approaches, to solve this challenge, CluedIn adds more machine learning and graph analytics to merge, match, and link records with a high precision.

Considerations

These considerations implement the pillars of the Azure Well-Architected Framework, which is a set of guiding tenets that can be used to improve the quality of a workload. For more information, see Microsoft Azure Well-Architected Framework.

Reliability

Reliability ensures your application can meet the commitments you make to your customers. For more information, see Overview of the reliability pillar.

- CluedIn takes automatic daily database backups and keeps them in long-term storage for 30 days by default. The entire platform is built on redundant, fault tolerant stacks that maintain backups for all subsystems. Round the clock monitoring systems ensure that services are as untainted as possible. CluedIn follows industry standard practices for infrastructure redundancy.
- CluedIn surfaces and stores only a representation of your data, not the original version. If CluedIn detects destructive data intrusion, it can temporarily wipe the CluedIn data from your servers. Once the intrusion subsides, CluedIn regathers the data to get back to its original state.
- All data stores run in high-availability mode.

Scalability

- CluedIn runs in Docker containers and uses Kubernetes to host and orchestrate the different pieces of the application. This architecture means that CluedIn works well in elastic environments and can automatically scale to needed sizes and infrastructure.
- Native support for autoscaling applies the power of Azure to provide a scalable environment for the biggest data workloads.
- Schemaless graph modeling automatically infers a data model from the source data. New data sources automatically connect to all other data sources, rather than having to be explicitly integrated. The number of data sources can scale infinitely without increasing integration complexity.

Security

Security provides assurances against deliberate attacks and the abuse of your valuable data and systems. For more information, see Overview of the security pillar.

- CluedIn security grants permissions and controls access to different services through Azure RBAC, with Azure Key Vault security key control and Azure Monitor access tracking and logging.

- In addition to authenticated user accounts, CluedIn also supports single sign-on (SSO) and identity frameworks. Requests to the CluedIn application use encrypted access tokens that have no correlation with user identity.
- CluedIn manages stored data representations behind multiple firewall and proxy layers, and authenticates them with a set of unique keys.
- CluedIn stores all sourced data with 256-bit AES encryption, which is stronger than or equal to the encryption level of the supported data sources.
- Throttling and CSRF prevention protect data access.

DevOps

- CluedIn uses Azure Pipelines continuous integration and continuous delivery (CI/CD) pipelines to handle deployments and rolling updates to the AKS environment.
- CluedIn supports unit, integration, and functional testing to ensure that data transforms as expected. Virtualized processing pipelines can run in memory for sandbox testing. Production-grade assertions can help debug and track down data issues.
- For testing and production environments, CluedIn provides a Helm package manager chart to install CluedIn quickly in a Kubernetes cluster. Fully scripted data deployment processes support setup, test, and rollout.

Cost optimization

Cost optimization is about looking at ways to reduce unnecessary expenses and improve operational efficiencies. For more information, see Overview of the cost optimization pillar.

The pricing for CluedIn is open and transparent. You can see the pricing on their website.

Azure sizing and starting a trial

You can start a 7-day trial of CluedIn on their website, which can also help you scope your Azure hosting costs with prebuilt Azure estimates for different sized environments.

Deploy this scenario

- To deploy CluedIn for development and evaluation purposes using Docker, see CluedIn with Docker.
- To install CluedIn quickly in a Kubernetes cluster, see CluedIn with Kubernetes. The Helm chart installs the CluedIn server, website, and other required services, like storage and queues.

Next steps

- For more information about CluedIn, see the CluedIn website.
- For CluedIn documentation, see the CluedIn documentation.

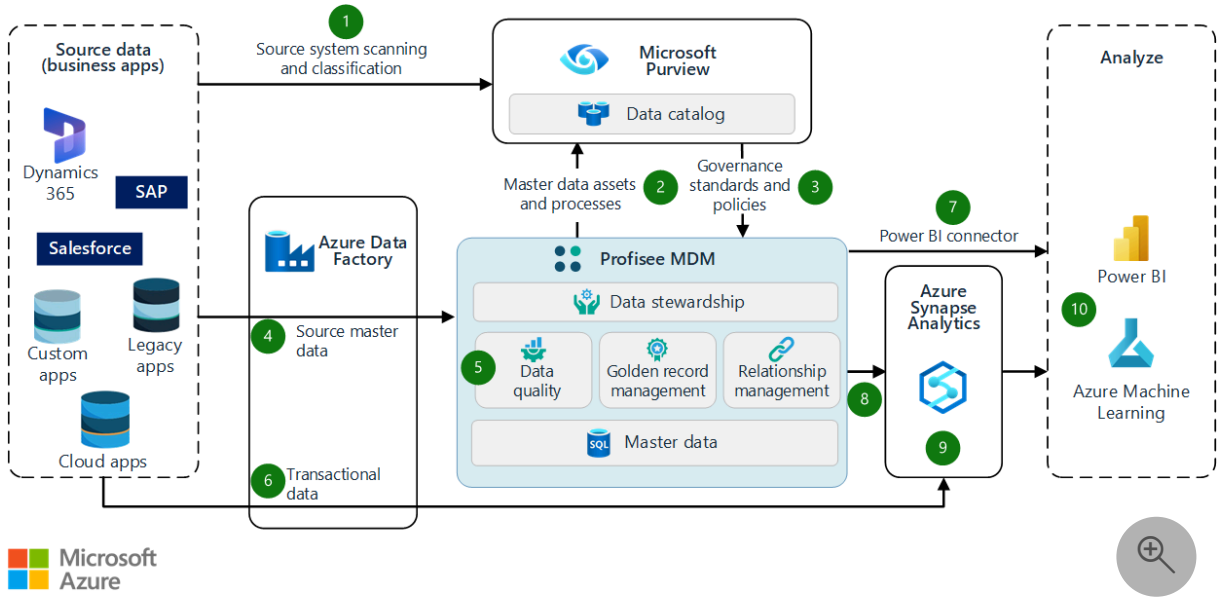
Microsoft Purview and Profisee integration for master data management



Article • 04/03/2025

Enterprise systems can have multiple sources of master data—the common data that's shared across systems. This fact can become apparent when you catalog data sources. Examples of master data include customer, product, location, asset, and vendor data. When you use Profisee to merge, validate, and correct your master data, you can make that data effective. Specifically, you can use it to build a common trusted platform for analytics and operational improvement. By using the governance definitions, insights, and expertise that are detailed in Microsoft Purview, you can build your platform effectively.

This reference architecture presents a governance and data management solution that features Microsoft Purview and the Profisee master data management (MDM) platform. These services work together to provide a foundation of high-quality, trusted data that maximizes the business value of data in Azure. For a short video about this solution, see The power of fully integrated master data management in Azure.

Architecture

The following diagram shows the steps that you take when you develop and operate your master data solution. Think of these steps as highly iterative. As your solution evolves, you might repeat these steps and phases, sometimes automatically and sometimes manually. Whether you use automatic or manual steps depends on the changes that your master data solution, metadata, and data undergo.

Dataflow

Metadata and data flow include these steps, which are shown in the preceding figure:

1. Prebuilt Microsoft Purview connectors are used to build a Unified Catalog from source business applications. The connectors scan data sources and populate Unified Catalog.

2. The master data model is published to Microsoft Purview. Master data entities that are created in Profisee MDM are seamlessly published to Microsoft Purview. This step further populates the Unified Catalog and ensures that there's a record of this critical source of data in Microsoft Purview.

3. Governance standards and policies for data stewardship are used to enrich master data entity definitions. The data is enriched in Microsoft Purview with data dictionary and glossary information, ownership data, and sensitive data classifications. Any definitions and metadata that are available in Microsoft Purview are visible in real time in Profisee as guidance for the MDM data stewards.

4. Master data from source systems is loaded into Profisee MDM. A data integration toolset like Azure Data Factory extracts data from the source systems by using any of more than 100 prebuilt connectors or a REST gateway. Multiple streams of master data are loaded into Profisee MDM.

5. The master data is standardized, matched, merged, enriched, and validated according to governance rules. Other systems, like Microsoft Purview, might define data quality and governance rules. But Profisee MDM is the system that enforces these rules. Source records are matched and merged within and across source systems to create the most complete and correct record possible. Data quality

rules check each record for compliance with business and technical requirements. Any record that fails validation or that returns a low probability score is subject to remediation. To remediate failed validations, a workflow process assigns records that require review to data stewards who are experts in their business data domain. After a record has been verified or corrected, it's ready to use as a *golden record* master.

6. Transactional data is loaded into a downstream analytics solution. A data integration toolset like Data Factory extracts transactional data from source systems by using any of more than 100 prebuilt connectors or a REST gateway. The toolset loads the data directly into an analytics data platform like Azure Synapse Analytics. Analysis on this raw information without the proper master golden data is subject to inaccuracy, because data overlaps, mismatches, and conflicts aren't yet resolved.

7. Power BI connectors provide direct access to the curated master data. Power BI users can use the master data directly in reports. A dedicated Power BI connector recognizes and enforces role-based security. It also hides various system fields to simplify use.

8. High-quality, curated master data is published to a downstream analytics solution. If master data records have been merged into a single golden record, parent-child links to the original records are preserved.

9. The analytics platform has a set of data that's certified in the sense that it's complete, consistent, and accurate. That data includes properly curated master data and associated transactional data. That combination forms a solid foundation of trusted data that's available for further analysis.

10. The high-quality master data is visualized and analyzed, and machine learning models are applied. The system delivers sound insights for driving the business.

Components

- Microsoft Purview is a data governance solution that provides broad visibility into on-premises and cloud data estates. Microsoft Purview offers a combination of data discovery and classification, lineage, metadata search and discovery, and usage insights. All these features help you manage and understand data across your enterprise data landscape.

- Profisee MDM is a fast and intuitive MDM platform that integrates seamlessly with Microsoft technologies and the Azure data management ecosystem.

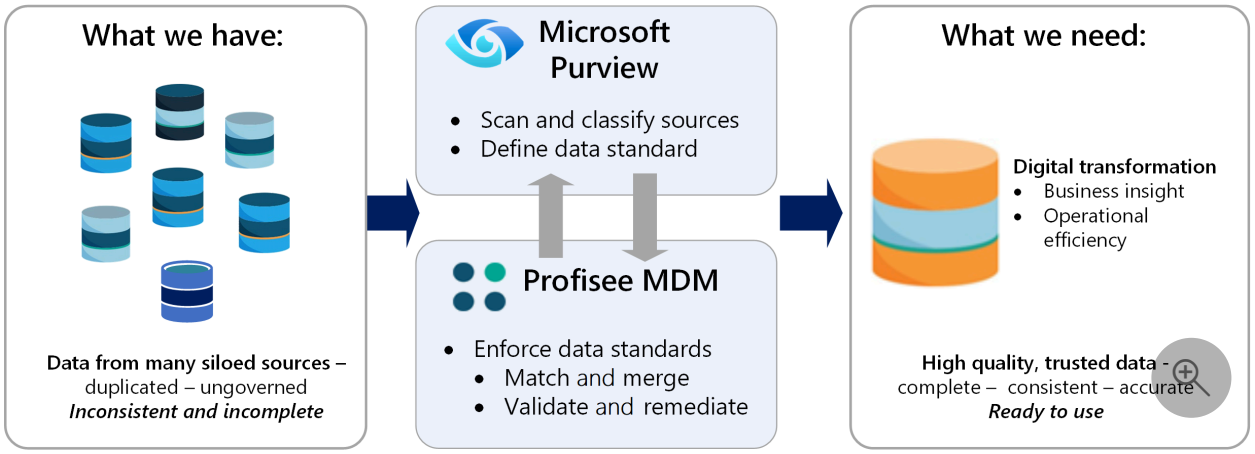
- Data Factory is a hybrid data integration service. You can use Data Factory to create, schedule, and orchestrate extract, transform, and load (ETL) and extract, load, and transform (ELT) workflows. Data Factory also offers more than 100 prebuilt connectors and a REST gateway that you can use to extract data from source systems.

- Azure Synapse Analytics is a fast, flexible, and trusted cloud data warehouse that uses a massive parallel processing architecture. You can use Azure Synapse Analytics to scale, compute, and store data elastically and independently.

- Power BI is a suite of business analytics tools that delivers insights throughout your organization. You can use Power BI to connect to hundreds of data sources, simplify data preparation, and drive improvised analysis. You can also produce beautiful reports and then publish them for your organization to consume on the web and on mobile devices.

Alternatives

If you don't have a dedicated MDM application, you can find some of the technical capabilities that you need to build an MDM solution in Azure:



- Data quality. When you load data into an analytics platform, you can build data quality into integration processes. For example, you can use hard-coded scripts to apply data quality transformations in a Data Factory pipeline.
- Data standardization and enrichment. Azure Maps can provide data verification and standardization for address data. You can use the standardized data in Azure Functions and Data Factory. To standardize other data, you might need to develop hard-coded scripts.
- Duplicate data management. You can use Data Factory to deduplicate rows if sufficient identifiers are available for an exact match. You likely need custom hard-coded scripts to implement the logic that's needed to merge matched rows while applying appropriate data survivorship techniques.
- Data stewardship. You can use Power Apps to quickly develop basic data stewardship solutions to manage data in Azure. You can also develop appropriate user interfaces for reviews, workflows, alerts, and validations.

In Microsoft-centric environments, Azure Synapse Analytics is preferred as an analytics service. But you can use any analytics database. Snowflake and Databricks are common choices.

Scenario details

As the amount of data that you load into Azure increases, the need to properly govern and manage that data across all your data sources, and data consumers grows. Data that seems adequate in the source system is often found to be deficient when it's shared. It might have missing or incomplete information, or duplications and conflicts. Its overall quality might be poor. What's needed is data that's complete, consistent, and accurate.

Without high-quality data in your Azure data estate, the business value of Azure is undermined, perhaps critically. The solution is to build a foundation for data governance and management that can produce and deliver a source of truth for high-quality, trusted data. Microsoft Purview and Profisee MDM work together to form this enterprise platform.

Microsoft Purview catalogs all your data sources and identifies any sensitive information and lineage. It gives the data architect a place to consider the appropriate data standards to impose on all data. Microsoft Purview focuses on governance to find, classify, and define policies and standards. The tasks of enforcing policies and standards, cataloging data sources, and remediating deficient data fall to technologies like MDM systems.

Profisee MDM is designed to accept master data from any source. Profisee MDM then matches, merges, standardizes, verifies, corrects, and synchronizes the data across systems. This process ensures that data can be properly integrated and that it meets the needs of downstream systems, such as business intelligence (BI) and machine learning applications. The integrative Profisee platform enforces governance standards across multiple data silos.

Better together

Microsoft Purview and Profisee MDM work better together. When integrated, they streamline data management tasks and ensure that all systems work to enforce the same standards. Profisee MDM publishes its master data model to Microsoft Purview,

where it can participate in governance. Microsoft Purview then shares the output of governance, such as a Unified Catalog and glossary information. Profisee can review the output and enforce standards. By working jointly, Microsoft Purview and Profisee create a natural, better-together synergy that goes deeper than each independent offering.

For example, after you catalog enterprise data sources, you might determine that master data is present in multiple systems. Master data is the data that defines a domain entity. Examples of master data include customer, product, asset, location, vendor, patient, household, menu item, and ingredient data. Resolving differing definitions and matching and merging this data across systems is critical to the ability to use this data in a meaningful way. To be effective, you should merge, validate, and correct master data in Profisee MDM by using governance definitions, insights, and expertise that are detailed in Microsoft Purview. In this way, Microsoft Purview and Profisee MDM form a foundation for governance and data management, and they maximize the business value of data in Azure.

The alternative is to use whatever information you can get. But when you take this approach, you risk generating misleading results that can damage your business. When you instead use high-quality master data, you eliminate common data quality issues. Then your system delivers sound insights that you can use to drive your business, no matter which tools you use for analysis, machine learning, and visualization. Well-curated master data is a key aspect of building a solid, reliable data foundation.

When you use Profisee MDM with Microsoft Purview, you experience the following benefits:

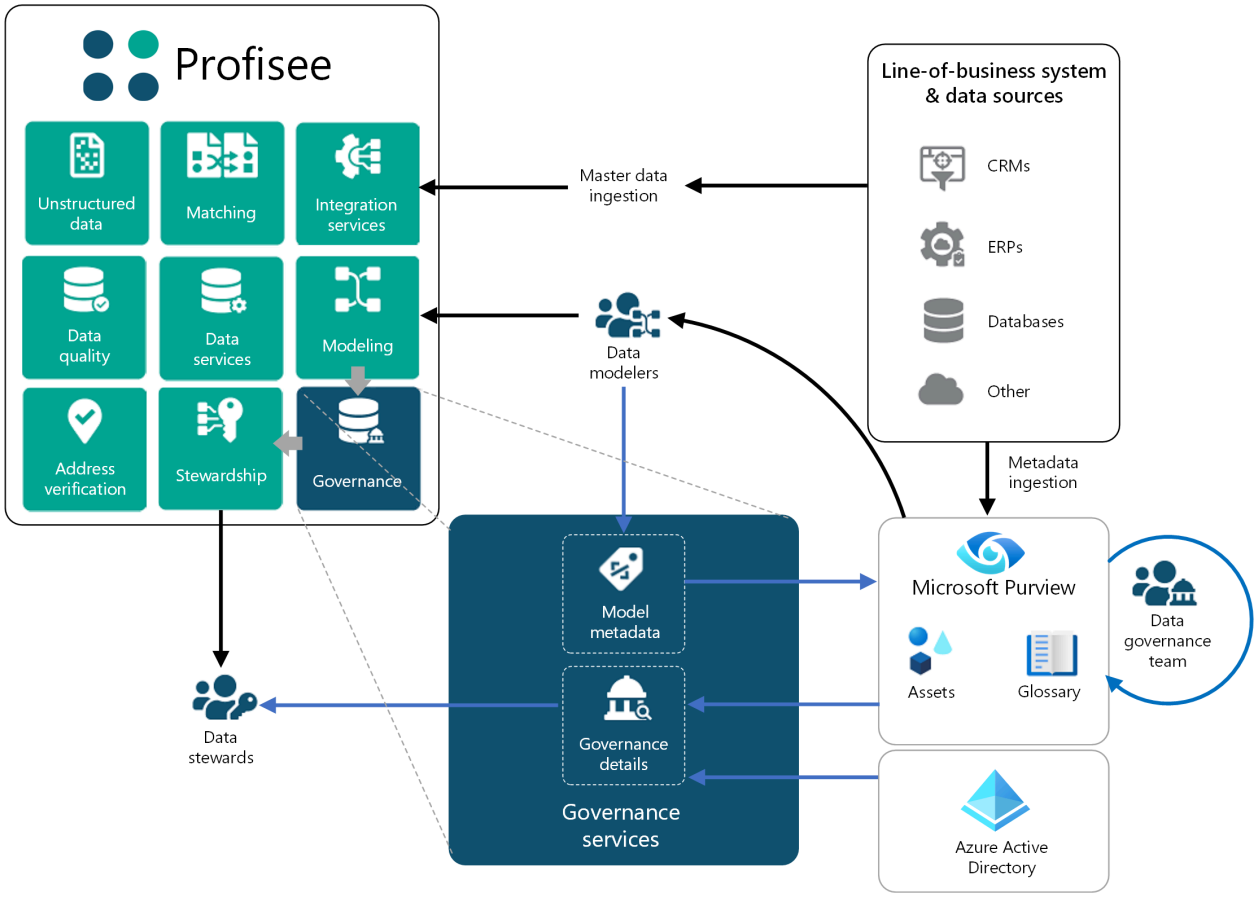
- A common technical foundation. Profisee originated in Microsoft technologies. Profisee and Microsoft use common tools, databases, and infrastructure, which makes the Profisee solution familiar to anyone who works with Microsoft technologies. In fact, for many years, Profisee MDM was built on Microsoft Master Data Services. Now Master Data Services is nearing the end of its lifecycle, and Profisee is the premier upgrade and replacement solution.
- Developer collaboration and joint development. Profisee and Microsoft Purview developers collaborate extensively to ensure a good, complementary fit between their respective solutions. This collaboration delivers a seamless integration that meets customer needs.
- Joint sales and deployments. Profisee has more MDM deployments on Azure, and jointly with Microsoft Purview, than any other MDM vendor. You can purchase Profisee through Azure Marketplace. In fiscal year 2023, Profisee is the only MDM vendor with a top-tier Microsoft partner certification that has an infrastructure as a service (IaaS), containers as a service (CaaS), or software as a service (SaaS) offering on Azure Marketplace.

- Rapid and reliable deployment. A critical feature of all enterprise software is rapid and reliable deployment. According to the Gartner Peer Insights platform, Profisee has more implementations that take fewer than 90 days to complete than any other MDM vendor.
- Multiple domains. Profisee offers an approach to MDM that inherently uses multiple domains. There are no limitations to the number of master data domains that you can create. This design aligns well with customers who plan to modernize their data estates. A customer might start with a limited number of domains, but they ultimately benefit from maximizing their domain coverage across their whole data estate. This domain coverage is matched to their data governance coverage.
- Engineering that's designed for Azure. Profisee is engineered to be cloud native with options for SaaS and managed IaaS or CaaS deployments on Azure.

Potential use cases

For a detailed list of MDM use cases of this solution, see MDM use cases later in this article. Key MDM use cases include the following retail and manufacturing examples:

- Consolidating customer data for analytics.
- Having a 360-degree view of product data in a consistent and accessible form, such as each product's name, description, and characteristics.
- Establishing reference data to consistently augment descriptions of master data. For example, reference data includes lists of countries/regions, currencies, colors, sizes, and units of measure.



These MDM solutions also help financial organizations that rely heavily on data for critical activities, such as timely reporting.

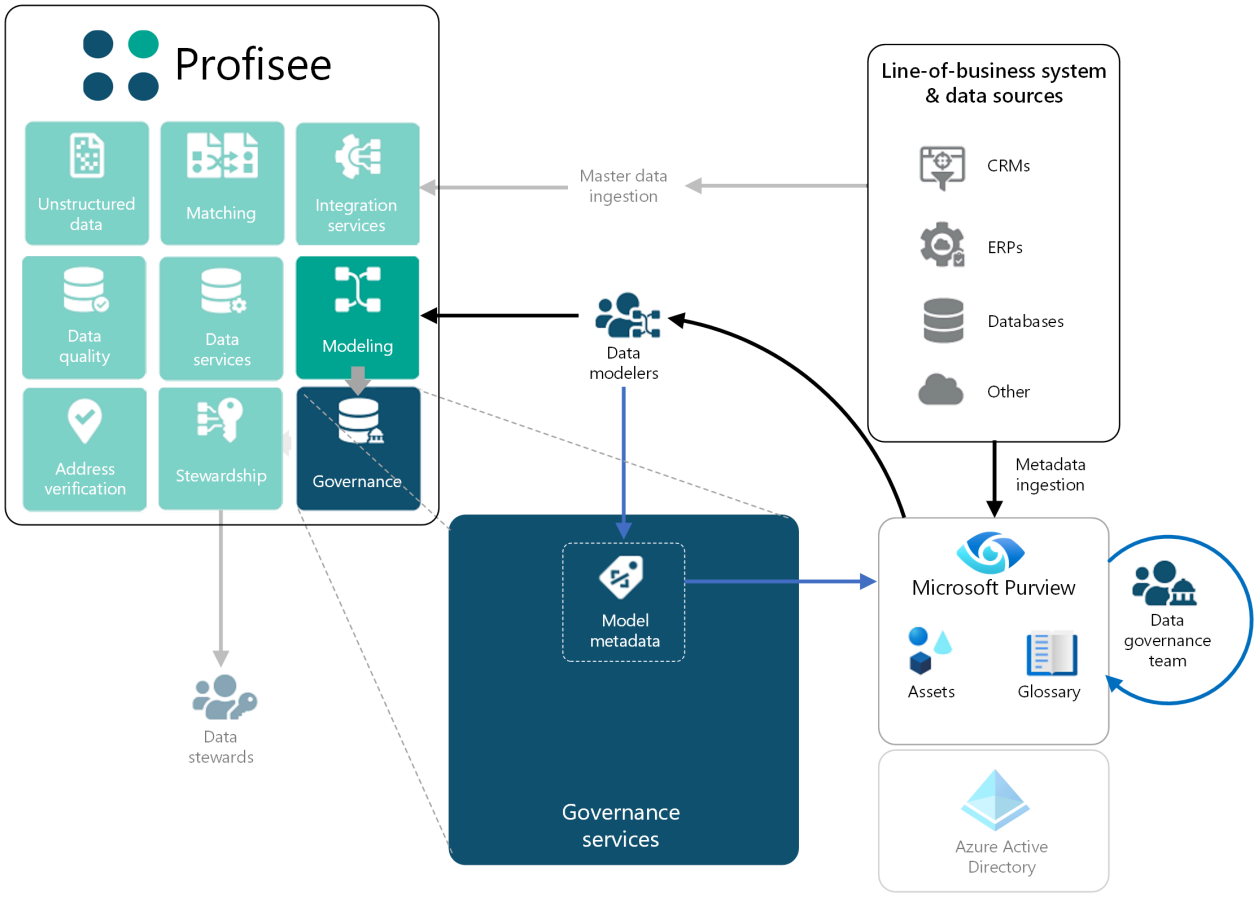
MDM integration with Microsoft Purview

The following diagram illustrates in detail the integration of Profisee MDM in Microsoft Purview. To support this integration, the Profisee governance subsystem provides bidirectional integration with Microsoft Purview, which consists of two distinct flows:

- Solution metadata publishing occurs when your data modelers make changes to your master data model, matching strategies, and their related subartifacts. These changes are seamlessly published to Microsoft Purview as they occur. Publishing these changes syncs the metadata that's related to your master data model and solution. As a result, Unified Catalog is further populated, and Microsoft Purview has a record of this critical data source.

- Governance details are returned and provided to data stewards and business users. These details are available as the users view data, enrich data, and remediate data quality issues by using the Profisee FastApp portal.

Microsoft Purview integration capabilities



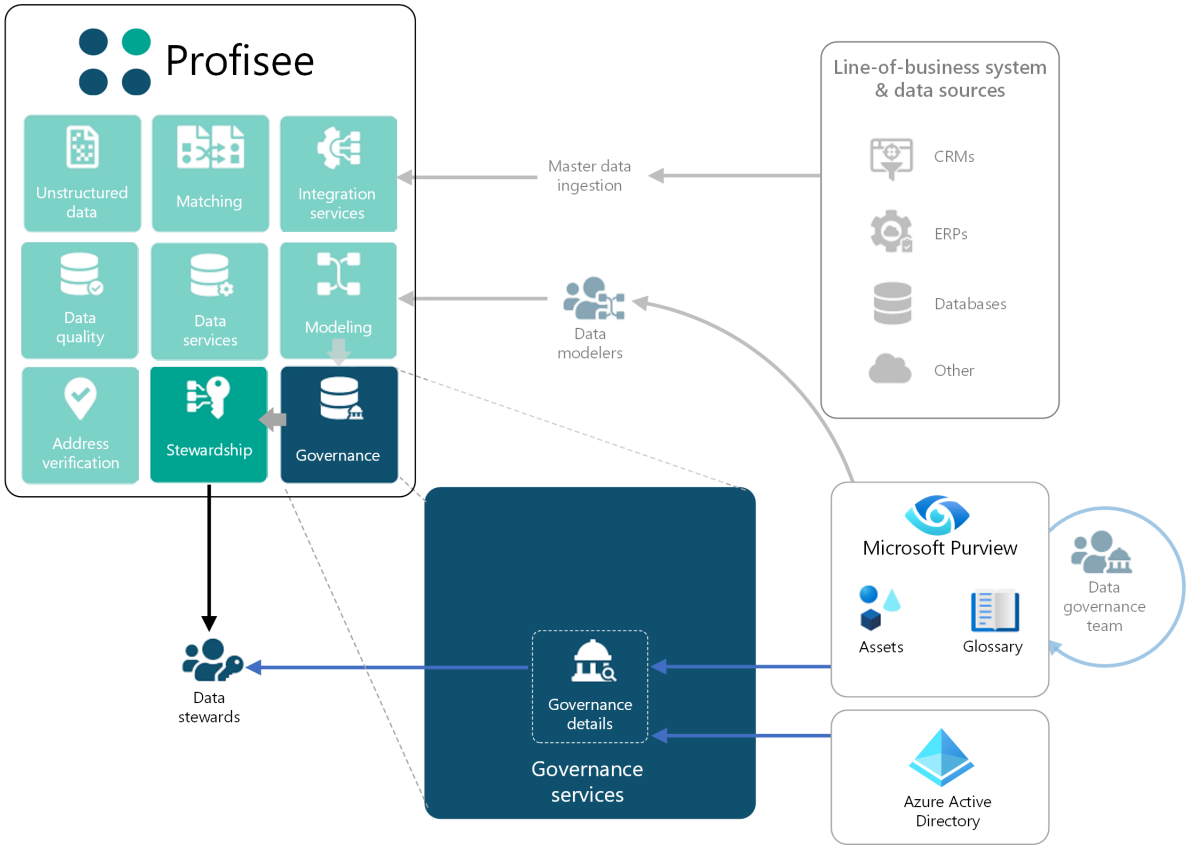
The Microsoft Purview catalog and glossary can help you maximize integration.

Master data model design

One of the challenges of preparing an MDM solution is determining what constitutes master data and which data sources to use when you populate your master data model. You can use Microsoft Purview to help with this effort. You can take advantage of the ability to scan your critical data sources, and you can engage your data stewards and subject matter experts (SMEs). This way, you can enrich Unified Catalog with information that your stewards can then access, to better align your master data model with your line-of-business systems. You can reconcile conflicting terminology. This process yields a master data model that optimally reflects the terminology and definitions that you want to standardize for your business. It also avoids outdated and misleading verbiage.

The following excerpt from the broader diagram illustrates this integration use case. First, you use Microsoft Purview system scanning functions to ingest metadata from your line-of-business systems. Next, your data stewards and SMEs prepare a solid

catalog and contacts. Then the data modelers who work with Profisee MDM modeling services can prepare and evolve your master data model. This work aligns with the standards that you define in Microsoft Purview.



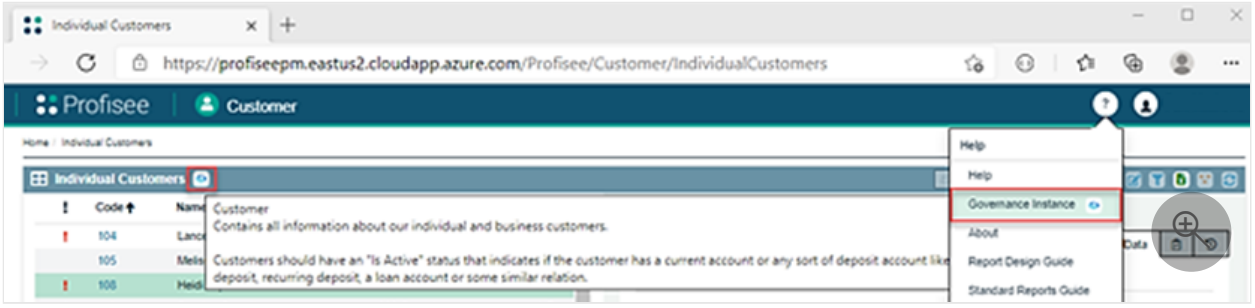
As your data stewards evolve the model, the modeling services within the Profisee MDM platform publish changes that Profisee MDM governance services receive. In turn, Profisee MDM prepares and forwards those changes to Microsoft Purview for inclusion in its updated Unified Catalog. These additions to the catalog ensure that your master data definitions are included in the broader data estate and that they can be governed and controlled in the same manner as your line-of-business system metadata. By ensuring that this information is cataloged together, you're in a better position to manage the relationships between your master data and your line-of-business system data.

Data stewardship

Large enterprises that have correspondingly complex and expansive data estates can present challenges to data stewards, who are responsible for managing and remediating issues as they arise. Key data domains can be complex, with many obscure attributes that only tenured employees who have significant institutional knowledge understand. Through the Profisee MDM integration with Microsoft Purview, you can capture this institutional knowledge within Microsoft Purview and make it available for use within

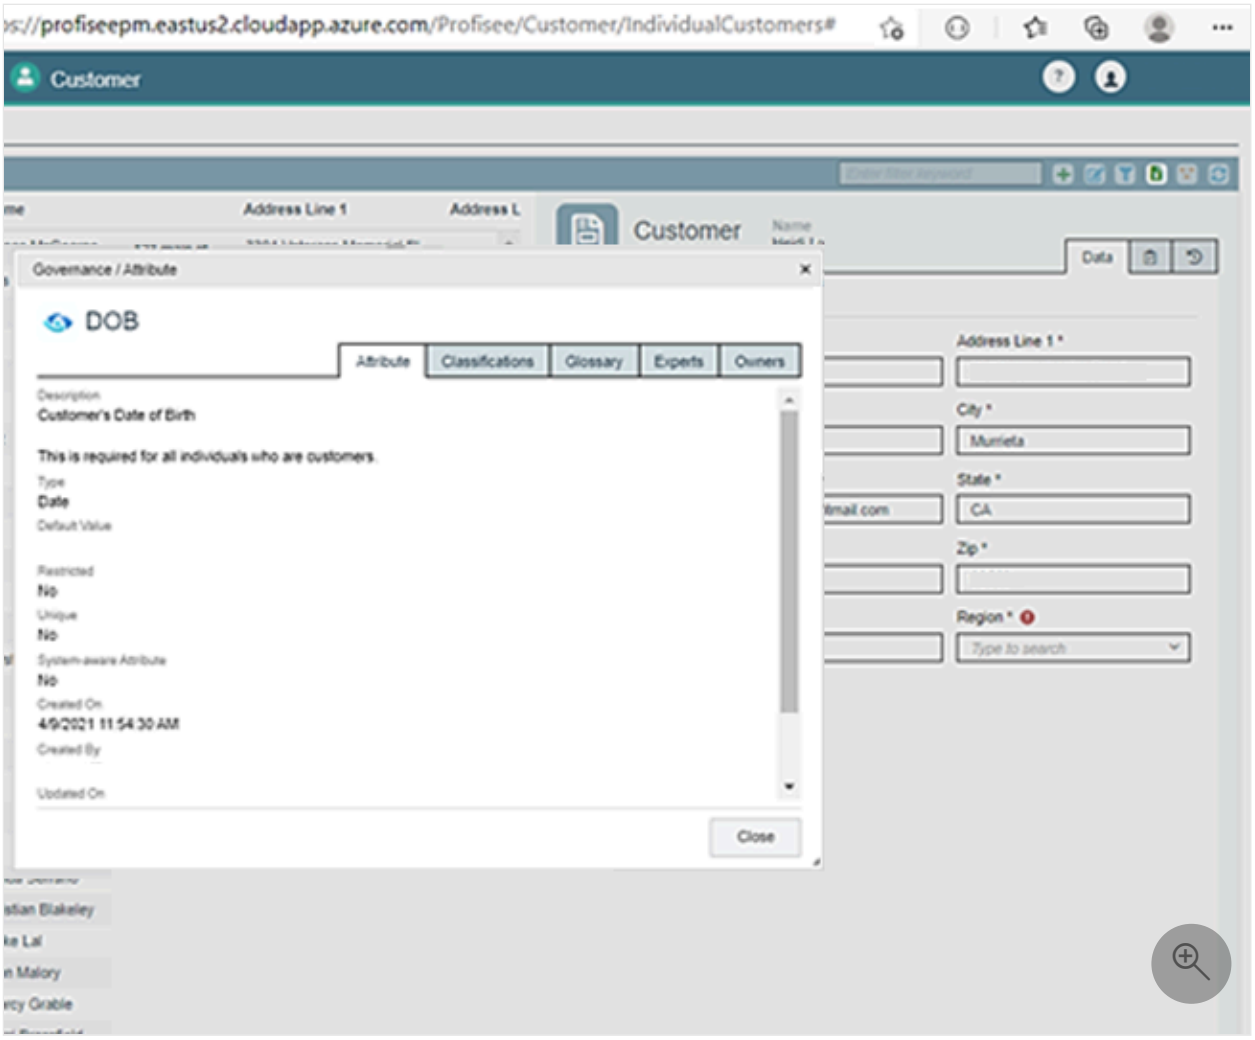
Profisee MDM. As a result, you alleviate a great need for corporate data knowledge when you manage critical and time-sensitive information.

The following figure illustrates the flow of information from Microsoft Purview to the data stewards who work in the Profisee FastApp portal. The governance data service integrates with Microsoft Purview and Microsoft Entra ID. This service provides lookup functionality. FastApp portal users can use this functionality to retrieve enriched governance data about the entities and the attributes that they work with.



Governance services also resolve contacts that are received from Microsoft Purview to their full profile details, which are available in Microsoft Entra ID. With complete profile details, stewards can effectively collaborate with data owners and experts as they work to enhance the quality of your master data.

The Profisee MDM Governance dialog is the interface through which data stewards and users interact with governance-level details. This UI renders information that's obtained from Microsoft Purview to users. By using this information, users can review the details behind the data from which the dialog was launched. If the information that's provided in the Governance dialog is insufficient, users can go directly to the Microsoft Purview user experience.



Data stewards and business users can access three Profisee MDM data asset types via the FastApp portal:

- Profisee Instance, which provides the infrastructure properties of the specific instance of the Profisee MDM platform that the user is viewing
- Profisee Entity, which provides the properties of the master data entity (the table) that the steward or user is currently viewing
- Profisee Attribute, which provides the properties of the attribute (such as the field or column) in which the user is interested

The following figure illustrates where users who are working in the FastApp portal can view governance details for each of these asset types. You can find instance-level details on the **Help** menu. You can access entity details from the page zone header, which contains an entity grid. For attribute details, go to the form that's associated with the entity grid. Access the details from the labels that are associated with the attribute.

To see summary information, hover over the governance icon, such as Microsoft Purview. Select the icon to display the full governance dialog:

To go to the full Microsoft Purview user experience, select the governance icon in the dialog header. Selecting the icon takes you to Microsoft Purview in the context of the asset that you're currently viewing. You then can easily move around in Microsoft Purview based on your discovery needs.

MDM processing

The power of an MDM solution is in the details.

Data modeling

The heart of your MDM solution is the underlying data model. It represents the definition of *master data* within your company. Developing a master data model involves the following tasks:

- Identify elements of source data from across your systems landscape that are critical to your company's operations and central to analyzing performance.
- Enrich the model with elements that you obtain from other third-party sources that render the data more useful, accurate, and trustworthy.

- Establish clear ownership and permissions related to the elements of your data model. This practice helps ensure that you factor visibility and change management into your model's design.

Data governance provides a critical foundation of support:

- Your governance Unified Catalog, dictionary, glossary, and supporting resources are invaluable sources of information to your governance data stewards. These resources help stewards determine what to include in your master data model. They also help determine ownership and sensitive data classifications in Microsoft Purview. You can reinforce terminology in your model. Through this practice, you can establish an official lexicon for your business. By integrating terminology, your master data model can also translate any esoteric terms that are in use in various source systems to the approved language of the business.
- Third-party systems are often a source of master data that's separate and apart from your line-of-business systems. It's critical to add elements to your model to capture the information that these systems add to your data, and to reflect these sources of information back into Unified Catalog.
- You can use ownership and data access, as identified in your governance catalog, to enforce access and change management permissions within your MDM solution. As a result, you align your corporate policies and needs with the tools that you use to manage and steward your master data.

Source data load

Ideally, your disparate line-of-business systems load data into your master data model with little or no change or transformation. The goal is to have a centralized version of the data as it exists in the source system. There should be as little loss of fidelity as possible between the source system and your master data repository. By limiting the complexity of your loading process, you make lineage simpler. And when you use technology like Data Factory pipelines, your governance solution can inspect the flow. Then your solution can identify the relationships between your source system and your master data model. Specifically, your solution can extract data from source systems by using any of more than 100 prebuilt connectors and a REST gateway.

Data enrichment and standardization

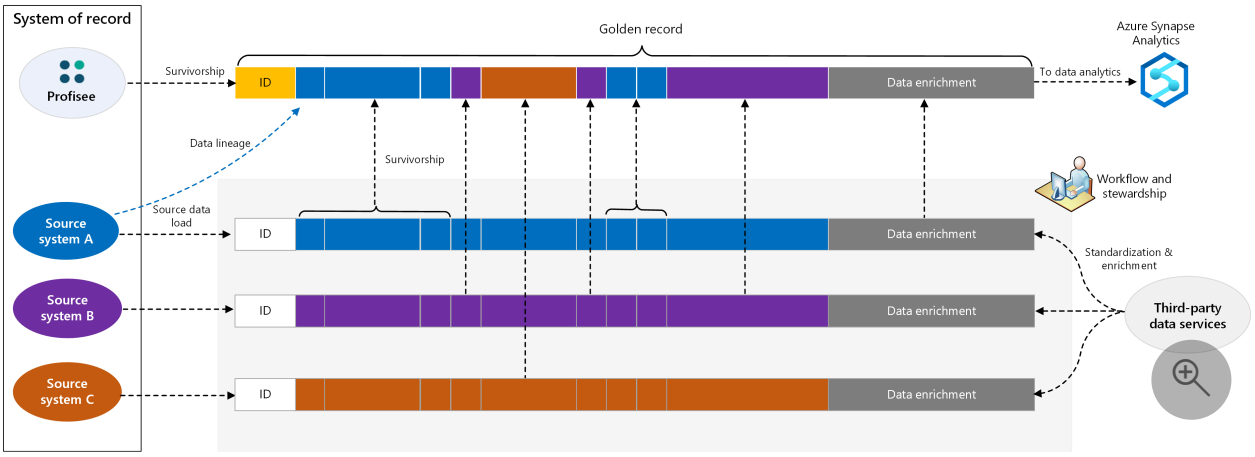
After you load source data into your model, you can extend it by tapping into rich sources of third-party data. You can use these systems to improve the data that you obtain from your line-of-business systems. You can also use these systems to augment

the source data with information that enhances its use for other downstream consumers. For example:

- You can use address-verification services like Bing to correct and improve source system addresses. These services can standardize and add missing information that's crucial to geo-location and mail delivery.
- Third-party information services like Dun & Bradstreet can provide general-purpose or industry-specific data. You can use this data to extend the value of your golden master record. Specifically, you might add information that was unavailable or in conflict in your disparate line-of-business systems.

Profisee's publish/subscribe infrastructure makes it easy to integrate your own third-party sources into your solution as needed.

The ability to understand the sources and meaning behind this data is as critical for third-party data as it is for your internal line-of-business systems. By integrating your master data model into your governance Unified Catalog, you can manage the relationships between internal and external sources of data while enriching your model with governance details.



Data quality validation and stewardship

After you load and enrich your data, it's important to check it for quality and adherence to standards that you establish through your governance processes. Microsoft Purview can again be a rich source of standards information. You can use Microsoft Purview to drive the data quality rules that your MDM solution enforces. Profisee MDM can also publish data quality rules as assets to your governance catalog. The rules can be subject to review and approval, which helps you provide top-down oversight of quality standards that are associated with your master data. Your rules are tied to master data entities and attributes, and those attributes can be traced back to the source system. For these reasons, you can establish the root cause of the poor data quality that originates from your line-of-business systems.

Data stewards are experts in their governance domain. As stewards address issues that your master data solution reveals, they can use the Microsoft Purview data governance catalog. The catalog helps stewards understand and resolve quality issues as they arise. Backed by the support of data owners and experts, the stewards are prepared to address data quality issues quickly and accurately.

Matching and survivorship

With enriched, high-quality source data, you're positioned to produce a golden record master that represents the most accurate information across your disparate line-of-business systems. The following figure illustrates how all the steps culminate in high-quality data that's ready to use for business analysis. At any time, you can sync this data across your data estate.

The Profisee MDM matching engine produces a golden record master as part of the survivorship process. Survivorship rules selectively populate the golden record with information that you've chosen across all your source systems.

The Profisee MDM history and audit tracking subsystem tracks changes that users make. This subsystem also tracks changes that system processes like survivorship make. Matching and survivorship make it possible to trace the flow of information from your source records to the master. Profisee MDM has a record of the source system that's responsible for a specific source record. You also know how disparate source records populate the golden record. As a result, you can achieve data lineage from your analytics back to the source data that your reports reference.

MDM use cases

Although there are numerous use cases for MDM, a few use cases cover most real-world MDM implementations. These use cases focus on a single domain, but they're unlikely to be built from only that domain. Even these focused use cases most likely involve multiple domains. In each use case, MDM meets the goal of providing a 360 degree, or unified, view of essential data types.

Customer data

Consolidating and standardizing customer data for BI analytics is the most common MDM use case. Organizations capture customer data across an increasing number of systems and applications. Duplicate customer data records result. These duplicates are

located in and across applications, and they contain inconsistencies and discrepancies. The poor quality of the customer data limits the value of modern analytics solutions. Symptoms include the following challenges:

- It's hard to answer basic business questions like, "Who are our top customers?" and "How many new customers do we have?" Answering these questions requires significant manual effort.
- You have missing and inaccurate customer information, which makes it difficult to roll up or drill down into the data.
- You're unable to uniquely identify or verify a customer across organizational and system boundaries. As a result, you're unable to analyze your customer data across systems or business units.
- You have poor-quality insights from AI and machine learning due to the poor-quality input data.

Product data

Product data is often spread across multiple enterprise applications, such as enterprise resource planning (ERP), product lifecycle management (PLM), or e-commerce applications. As a result, it's challenging to understand the total catalog of products that have inconsistent definitions for properties, such as the product name, description, and characteristics. Different definitions of reference data complicate this situation. Symptoms include the following challenges:

- You're unable to support different alternative hierarchical roll-up and drill-down paths for product analytics.
- With finished goods or material inventory, you have difficulty evaluating product inventory and established vendors. You also have duplicate products, which leads to excess inventory.
- It's hard to rationalize products due to conflicting definitions. This situation leads to missing or inaccurate information in analytics.

Reference data

In the context of analytics, reference data exists as numerous lists of data. These lists are often used to further describe other sets of master data. For example, reference data includes lists of countries/regions, currencies, colors, sizes, and units of measure. Inconsistent reference data leads to obvious errors in downstream analytics. Symptoms are:

- Multiple representations of the same value. For example, the state of Georgia is listed as *GA* and *Georgia*, which makes it difficult to consistently aggregate and

drill down into data.
- Difficulty streamlining data across systems due to an inability to *crosswalk*, or map, reference data values between systems. For example, the color red is represented by *R* in the ERP system and *Red* in the PLM system.
- Difficulty tying numbers across organizations due to differences in established reference data values that are used for data categorization.

Financial data

Financial organizations rely heavily on data for critical activities, such as monthly, quarterly, and annual reporting. Organizations that have multiple finance and accounting systems often have financial data across multiple general ledgers that needs to be consolidated to produce financial reports. MDM can provide a centralized hub to map and manage accounts, cost centers, business entities, and other financial datasets. Through the centralized hub, MDM provides a consolidated view of these datasets. Symptoms include the following challenges:

- Difficulty aggregating financial data across multiple systems into a consolidated view
- Lack of process for adding and mapping new data elements in financial systems
- Delays in producing end-of-period financial reports

Considerations

These considerations implement the pillars of the Azure Well-Architected Framework, which is a set of guiding tenets that can be used to improve the quality of a workload. For more information, see Microsoft Azure Well-Architected Framework.

Consider these factors when you choose a data management solution for your organization.

Reliability

Reliability ensures your application can meet the commitments you make to your customers. For more information, see Overview of the reliability pillar.

Profisee runs natively on Azure Kubernetes Service (AKS) and Azure SQL Database. Both services offer out-of-the-box capabilities to support high availability.

Security

Security provides assurances against deliberate attacks and the abuse of your valuable data and systems. For more information, see Overview of the security pillar.

Profisee authenticates users by using OpenID Connect, which implements an OAuth 2.0 authentication flow. Most organizations configure Profisee MDM to authenticate users against Microsoft Entra ID, which ensures that you can apply and enforce your enterprise policies for authentication.

Cost optimization

Cost optimization is about looking at ways to reduce unnecessary expenses and improve operational efficiencies. For more information, see Overview of the cost optimization pillar.

Running costs consist of a software license and Azure consumption. For more information, contact Profisee.

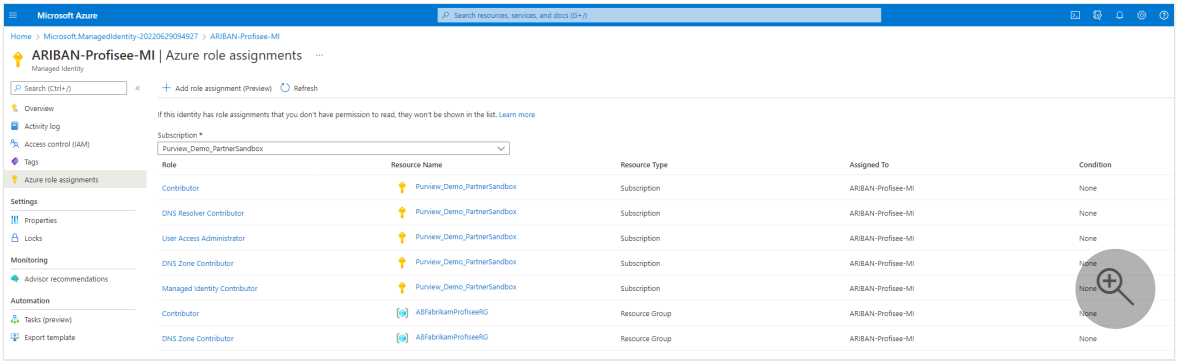
Performance efficiency

Performance efficiency is the ability of your workload to scale to meet the demands placed on it by users in an efficient manner. For more information, see Performance efficiency pillar overview.

Profisee MDM runs natively on AKS and SQL Database. You can configure AKS to scale Profisee MDM up, down, and across your business functions. You can deploy SQL Database in numerous configurations to balance performance, scalability, and costs.

Dynamic scaling is inherent in the cloud-native architecture of Profisee, which uses microservices and containers. If you run Profisee in your cloud tenant via Kubernetes, you can dynamically scale up and out based on your load. With the Profisee SaaS service that runs on AKS, you can configure large node pools for your pods. These pools scale dynamically based on the load on the system across the multitenant infrastructure.

For detailed information about how to deploy Profisee and Microsoft Purview on AKS, see Microsoft Purview - Profisee MDM integration.



Deploy this scenario

Profisee MDM is a packaged Kubernetes service. You can deploy Profisee MDM as a PaaS in your Azure tenant, in any other cloud tenant, or on-premises. You can also deploy Profisee MDM as a SaaS that Profisee hosts and manages.

1. Get the license file from Profisee by raising a support ticket on https://support.profisee.com/. The only pre-requisite for this step is your need to pre-determine the DNS resolved URL your Profisee setup on Azure. In other words, keep the DNS HOST NAME of the load balancer used in the deployment. It will be something like "[profisee_name].[region].cloudapp.azure.com". For example, DNSHOSTNAME="purviewprofisee.southcentralus.cloudapp.azure.com". Supply this DNSHOSTNAME to Profisee support when you raise the support ticket and Profisee will revert with the license file. You'll need to supply this file during the next configuration steps below.

2. Create a user-assigned managed identity in Azure. You must have a managed identity created to run the deployment. After the deployment is done, the managed identity can be deleted. Based on your ARM template choices, you'll need some or all of the following roles and permissions assigned to your managed identity:

    - Contributor role to the resource group where AKS will be deployed. It can either be assigned directly to the resource group **OR** at the subscription level and down.
    - DNS Zone Contributor role to the particular DNS zone where the entry will be created **OR** Contributor role to the DNS Zone resource group. This DNS role is needed only if updating DNS hosted in Azure.
    - Application Administrator role in Microsoft Entra ID so the required permissions that are needed for the application registration can be assigned.
    - Managed Identity Contributor and User Access Administrator at the subscription level. Required in order for the ARM template managed identity to be able to create a Key Vault specific managed identity that will be used by Profisee to pull the values stored in the Key Vault.

3. Create an application registration that will act as the login identity once Profisee is installed. It needs to be a part of the Microsoft Entra ID that will be used to sign in to Profisee. Save the **Application (client) ID** for use later.

    - Set authentication to match the settings below:

    - Support ID tokens (used for implicit and hybrid flows)
    - Set the redirect URL to: https://<your-deployment-url>/profisee/auth/signin-microsoft
        - Your deployment URL is the URL you'll have provided Profisee in step 1

4. Create a service principal that Microsoft Purview will use to take some actions on itself during this Profisee deployment. To create a service principal, create an application like you did in the previous step, then create an application secret. Save the **Object ID** for the application, and the **Value** of the secret you created for later use.

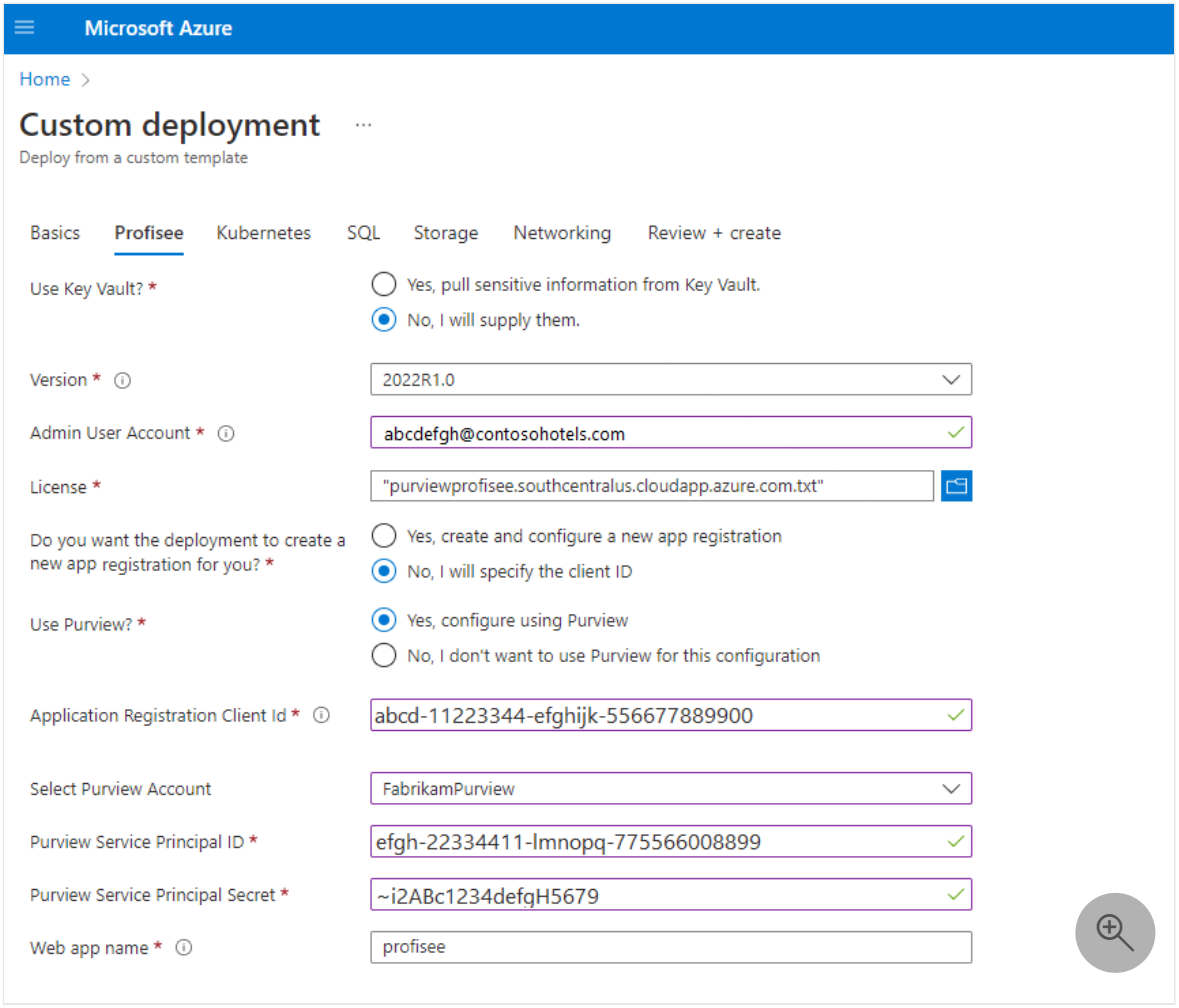
    - Give this service principal (using the name or Object ID to locate it) **Data Curator** permissions on the root collection of your Microsoft Purview account.

5. Go to https://github.com/Profisee/kubernetes and select Microsoft Purview **Azure ARM**.

    - The ARM template will deploy Profisee on a load balanced AKS (Azure Kubernetes Service) infrastructure using an ingress controller.
    - The readme includes troubleshooting steps.
    - Read all the steps and troubleshooting wiki page carefully.

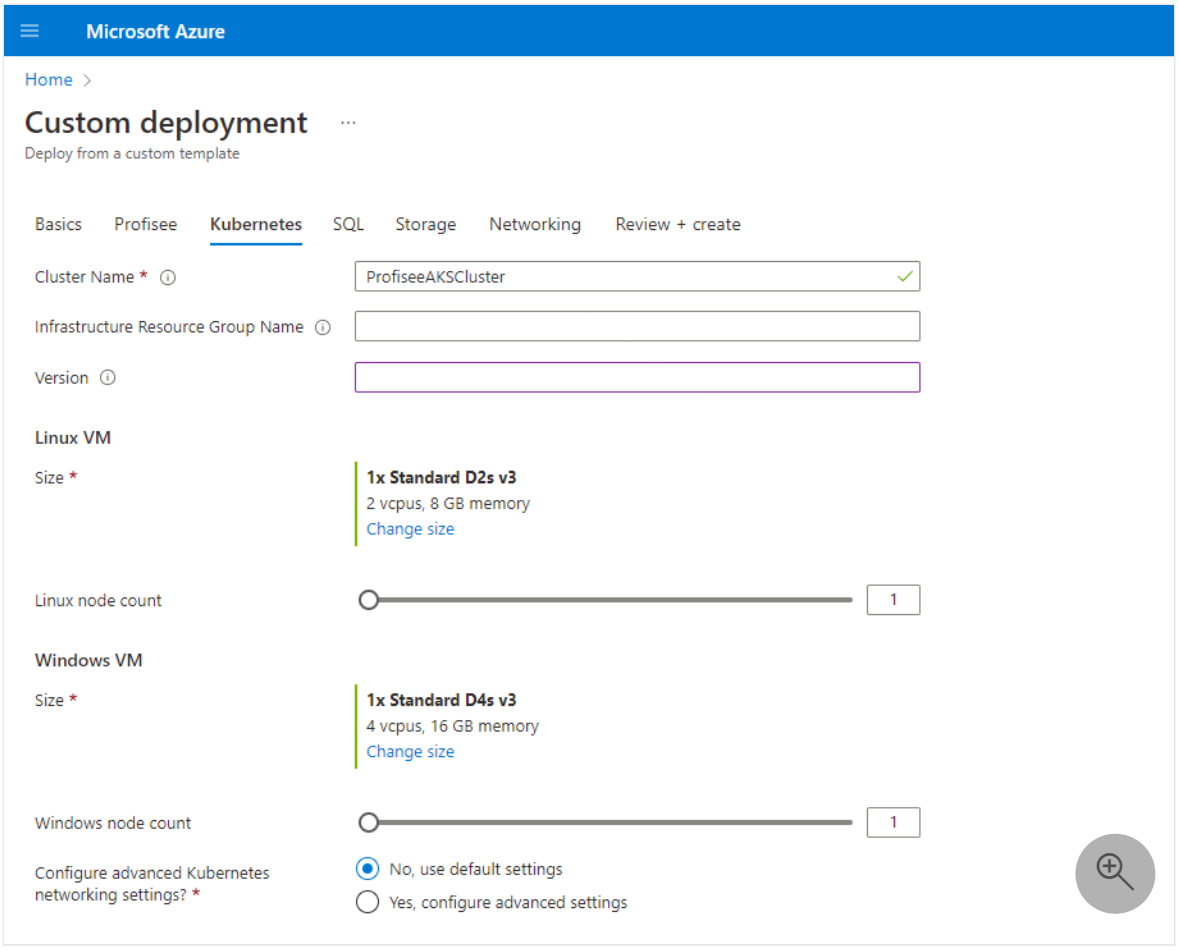
6. Select "Deploy to Azure"

    - The configurator wizard will ask for the inputs as described here - Deploying the AKS Cluster using the ARM Template
    - Make sure to give the exact same RG (Resource Group) in the deployment as you gave permissions to the managed identity in Step1.



7. Once deployment completes, select Microsoft Purview "Go to Resource Group" and open the Profisee AKS Cluster.

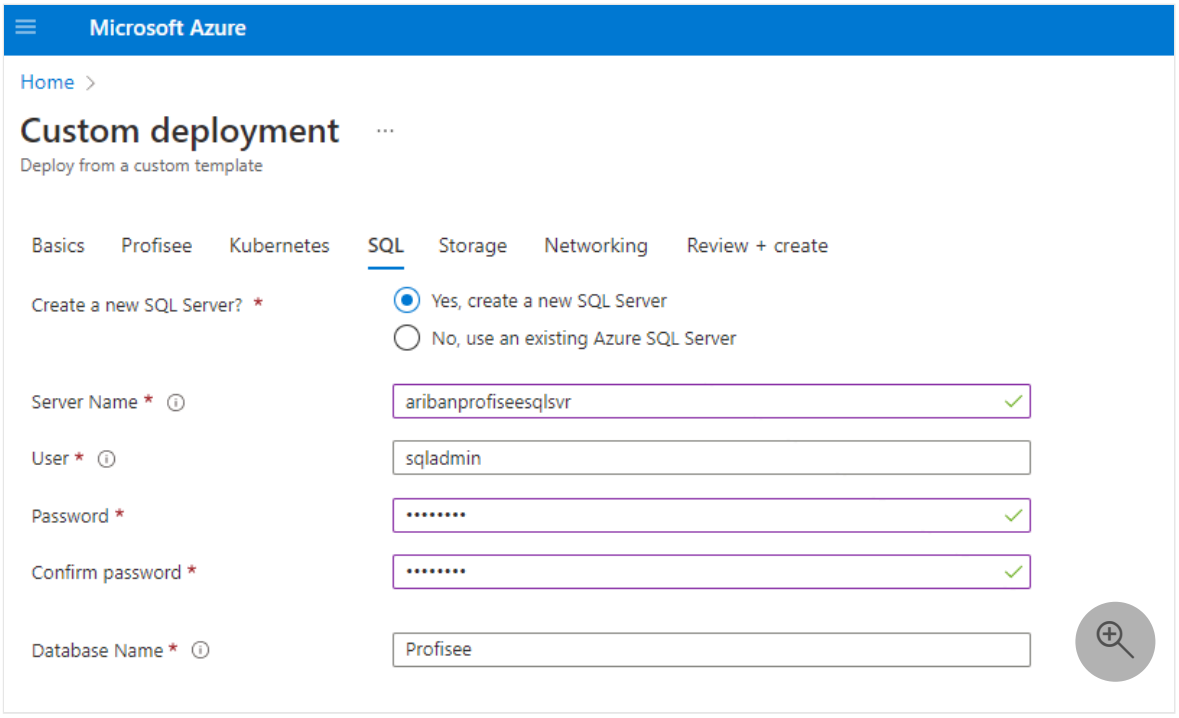
Stages of a typical Microsoft Purview - Profisee deployment run



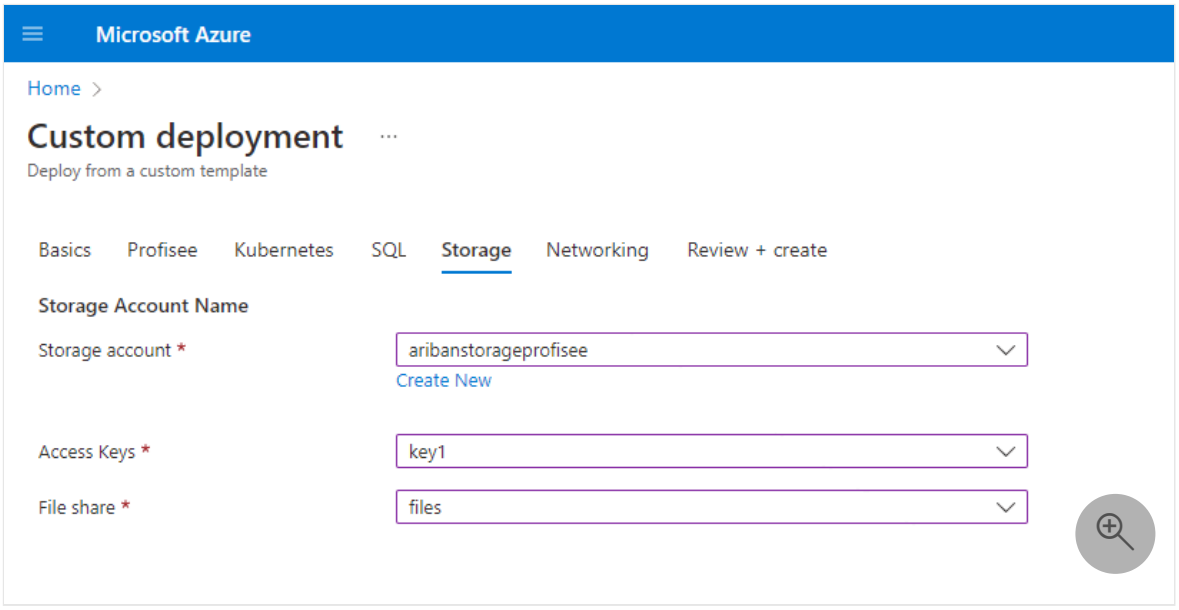
1. On the basics page, select the user-assigned managed identity you created earlier to deploy the resources.

2. For your Profisee configuration, you can have your information stored in Key Vault or supply the details during deployment.

a. Choose your Profisee version, and provide your admin user account and license.
b. Select to configure using Microsoft Purview.
c. For the Application Registration Client ID, provide the **application (client) ID** for the application registration you created earlier.
d. Select your Microsoft Purview account.
e. Add the **object ID** for the service principal you created earlier.
f. Add the value for the secret you created for that service principal.
g. Give your web application a name.

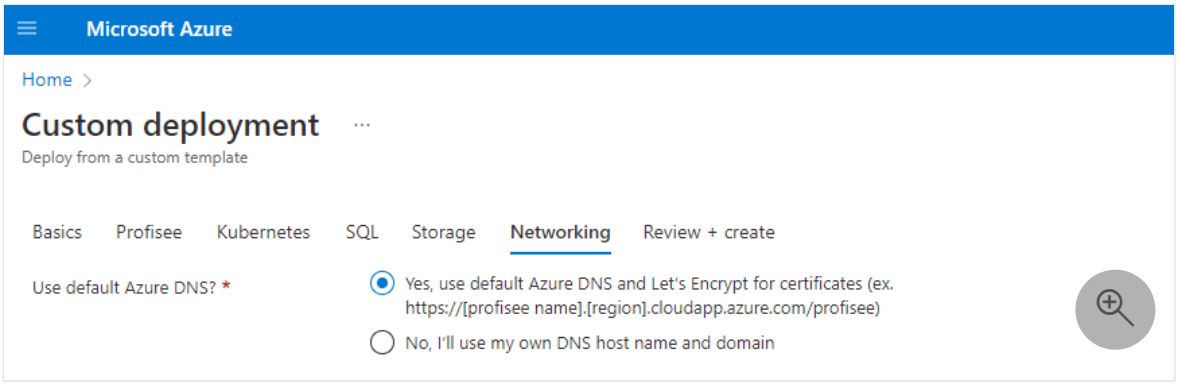


3. On the Kubernetes page, you may choose an older version of Kubernetes if needed, but leave the field **blank** to deploy the **latest** version.

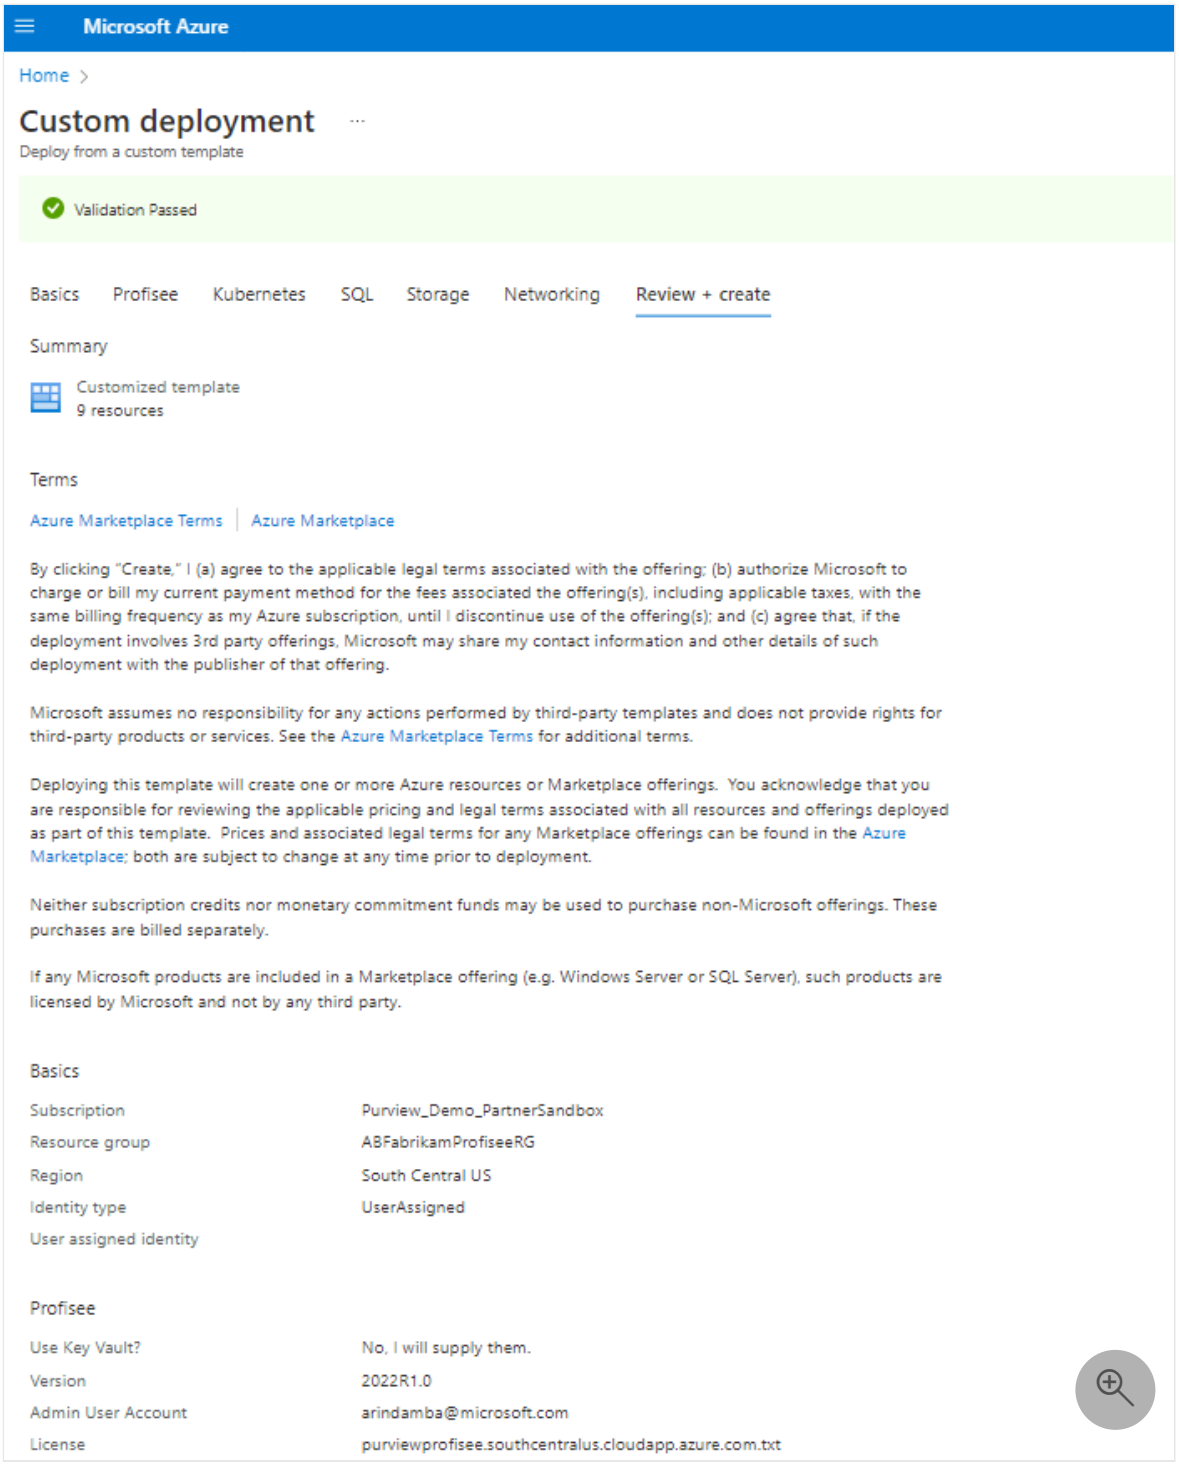


> **Tip**
>
> In most cases, leaving the version field blank is sufficient, unless there is a reason you need to deploy using an older version of Kubernetes AKS specifically.

4. On the SQL configuration page you can choose to deploy a new Azure SQL server, or use an existing Azure SQL Server. You'll provide login details and a database name to use for this deployment.

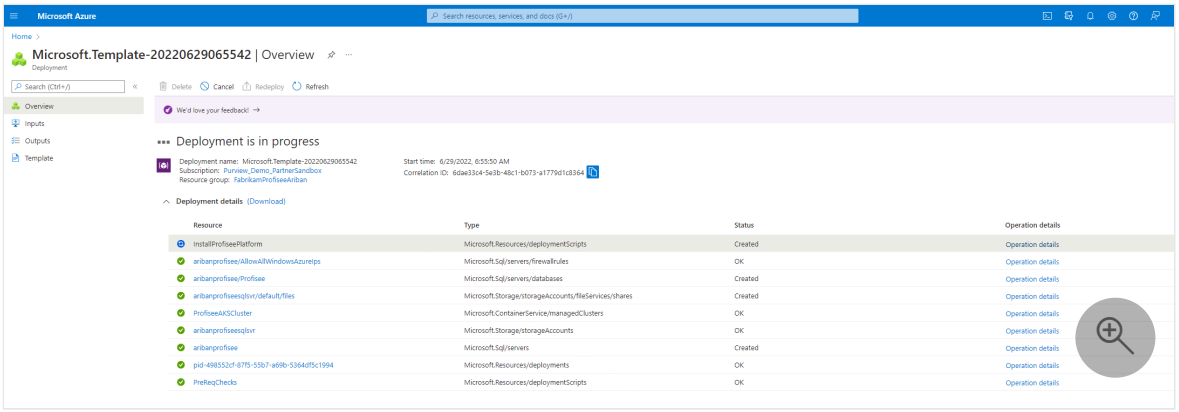


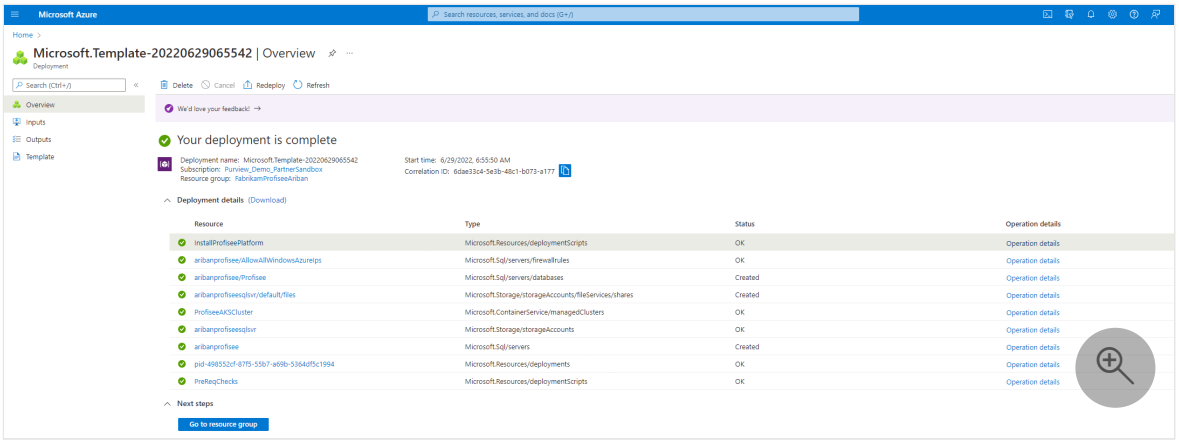
5. On the storage configuration page, you can choose to create a new storage account or use an existing one. You'll need to provide an access key and the name of an existing file share if you choose an existing account.



6. On the networking configuration page, you'll choose to either use the default Azure DNS or provide your own DNS host name.

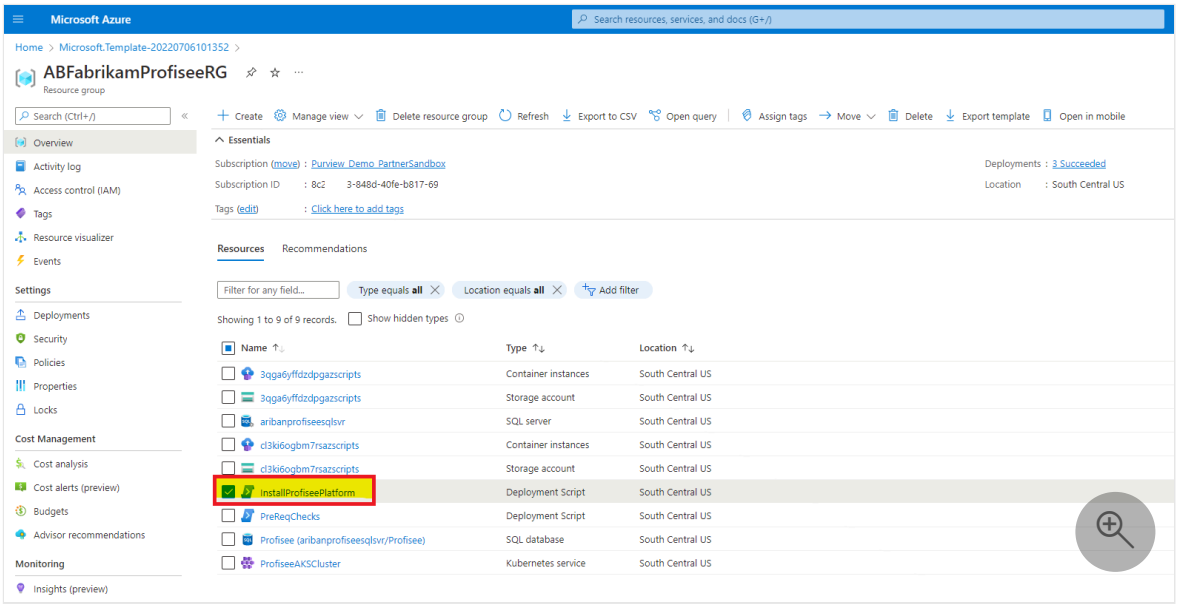
> **Tip**
>
> **Yes, use default Azure DNS** is the recommended configuration. Choosing Yes, the deployer automatically creates a Let's Encrypt certificate for HTTP/TLS. If you choose **No** you'll need to supply various networking configuration parameters and your own HTTPS/TLS certificate.



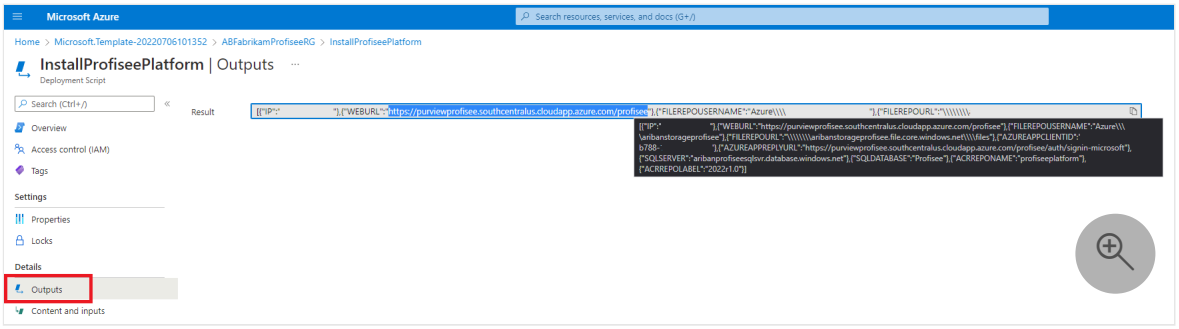


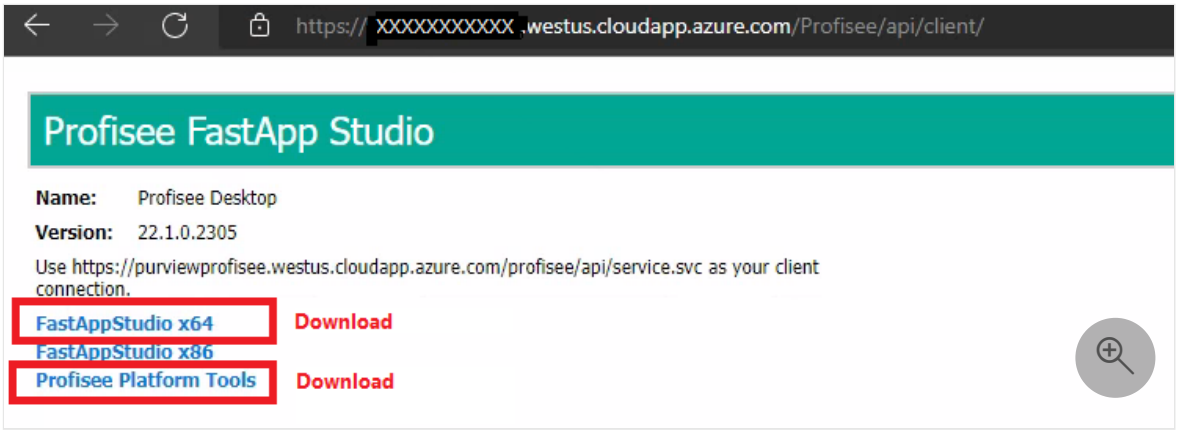
> ⚠ **Warning**
>
> The default Azure DNS URL (for example URL="https://purviewprofisee.southcentralus.cloudapp.azure.com/profisee") will be picked up by thr ARM template deployment wizard from the license file supplied to you by Profisee. If you intend to make changes and not use the default Azure DNS, make sure to communicate the full DNS and the fully qualified URL of the Profisee DNS to the Profisee support team so that they can re-generate and provide you the updated license file. Failure to do this will result in a malfunctioning installation of Profisee.

7. On the review + create page, review your details to ensure they're correct while the wizard validates your configuration. Once validation passes, select **Create**.

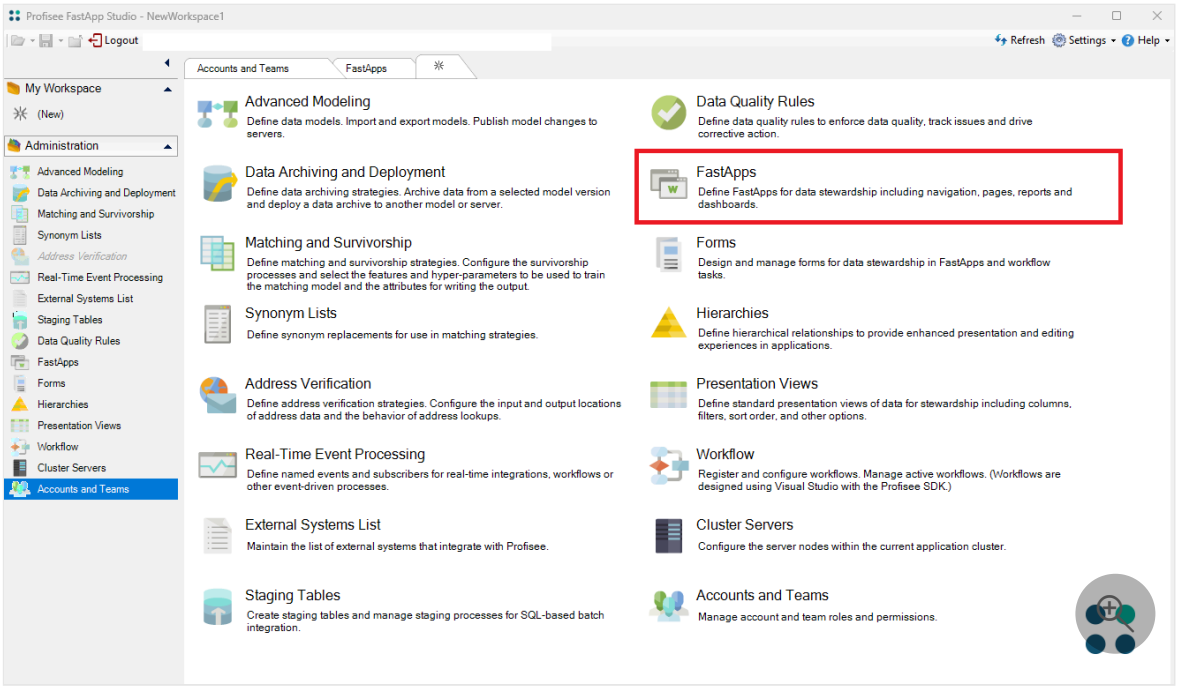


8. It will take around 45-50 Minutes for deployment to complete installing Profisee. During the deployment, you'll see the aspects that are in progress, and can refresh the page to review progress. The deployment will show as complete when all is finished. Completion of "InstallProfiseePlatform" stage also indicates deployment is complete!





9. Once deployment is completed, open the resource group where you deployed your integration.



10. Under outputs, fetch the final deployment URL. The final WEBURL is what you need to paste on your browser address bar and start enjoying Profisee-Purview integration! This URL will be the same that you'd have supplied to Profisee support while obtaining the license file. Unless you chose to change the URL format, it will look something like - "https://[profisee_name].[region].cloudapp.azure.com/profisee/

11. Populate and hydrate data to the newly installed Profisee environment by installing FastApp. Go to your Profisee deployment URL and select **/Profisee/api/client**. It should look something like - "https://[profisee_name].[region].cloudapp.azure.com/profisee/api/client". Select the Downloads for "Profisee FastApp Studio" utility and the "Profisee Platform Tools". Install both these tools on your local client machine.

12. Log in to FastApp Studio and perform the rest of the MDM Administration and configuration management for Profisee. Once you log in with the administrator email address supplied during the setup; you should be able to see the administration menu on the left pane of the Profisee FastApp Studio. Navigate to these menus and perform the rest of your MDM journey using FastApp tool. Being able to see the administration menu as seen in the image below confirms successful installation of Profisee on Azure Platform.

13. As a final validation step to ensure successful installation and for checking whether Profisee has been successfully connected to your Microsoft Purview instance, go to **/Profisee/api/governance/health** It should look something like - "https://[profisee_name].[region].cloudapp.azure.com//Profisee/api/governance/health". The output response will indicate the words "**Status**": "**Healthy**" on all the Microsoft Purview subsystems.

JSON

```
{
  "OverallStatus": "Healthy",
  "TotalCheckDuration": "0:XXXXXXX",
  "DependencyHealthChecks": {
    "purview_service_health_check": {
      "Status": "Healthy",
      "Duration": "00:00:NNNN",
      "Description": "Successfully connected to Purview."
    },
    "governance_service_health_check": {
      "Status": "Healthy",
      "Duration": "00:00:NNNN",
      "Description": "Purview cache loaded successfully.
      Total assets: NNN; Instances: 1; Entities: NNN; Attributes: NNN;
Relationships: NNN; Hierarchies: NNN"
    },
    "messaging_db_health_check": {
      "Status": "Healthy",
      "Duration": "00:00:NNNN",
      "Description": null
    },
    "logging_db_health_check": {
      "Status": "Healthy",
```

```
      "Duration": "00:00:NNNN",
      "Description": null
    }
  }
}
```

An output response that looks similar as the above confirms successful installation, completes all the deployment steps; and validates whether Profisee has been successfully connected to your Microsoft Purview and indicates that the two systems are able to communicate properly.

Next steps

- Understand the capabilities of the REST copy connector in Data Factory.
- Learn more about Profisee running natively in Azure.
- Learn how to deploy Profisee to Azure by using an Azure Resource Manager template (ARM template).
- View Profisee Data Factory templates.

Microsoft Purview and Reltio integration for master data management

Article • 04/03/2025

Reltio Integration for Microsoft Purview is implemented through our Reltio Integration Hub (RIH). The integration consists of Reltio and Microsoft Purview connections and recipes to read the tenant business config from Reltio and create corresponding objects in Microsoft Purview.

The integration supports these objects:

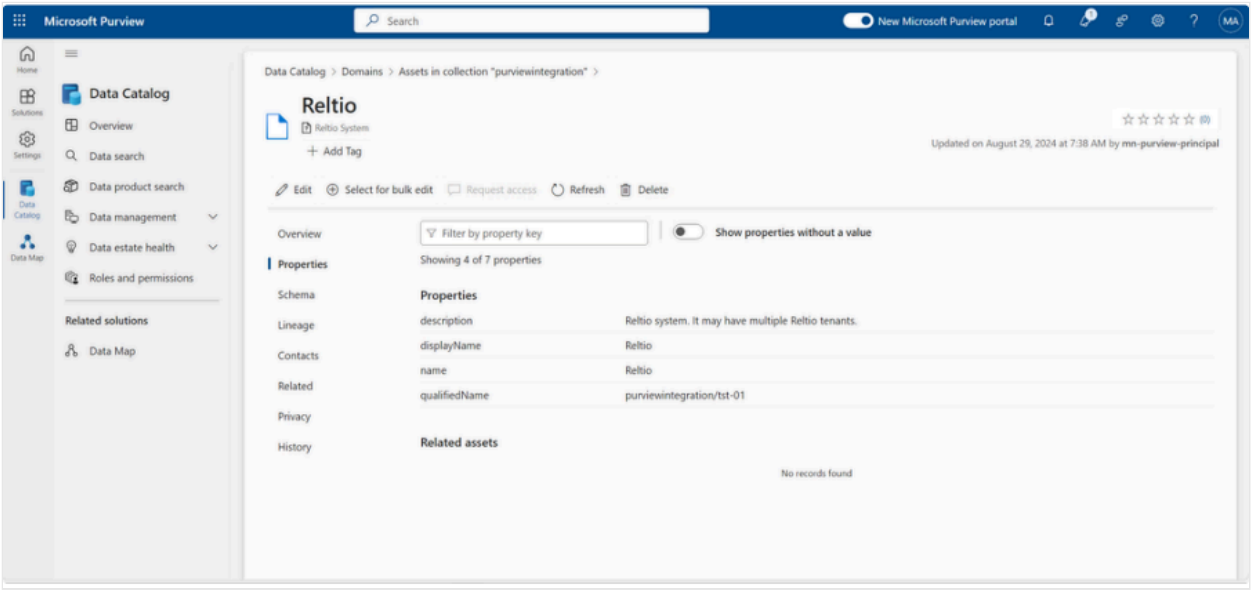
- Entity types
- Entity attributes - Simple, Nested, Reference
- Relationship types
- Relationship attributes - Simple, Nested

The foundation of the integration is creating the EntityDefs in Microsoft Purview's Data Map for every Reltio's object.

Microsoft Purview's Data Map is like a central inventory which powers the Microsoft Purview Unified Catalog, the Microsoft Purview Data Estate Insights and the Microsoft Purview Data Policy as unified experiences within the Microsoft Purview governance portal.

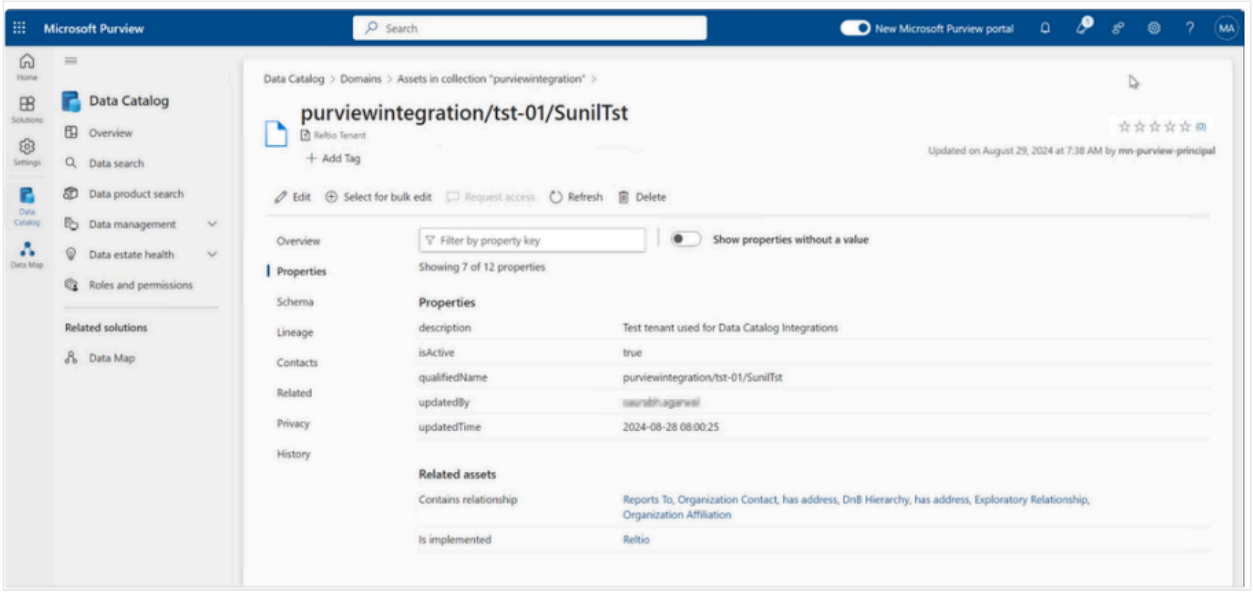
EntityDef is like a class in object-oriented programming and provides the schema or blueprint for all the Reltio objects. It defines the structure of the entities, attributes, relationships, and their types. This schema ensures that all instances of the entity adhere to rules and constraints for the entities.

Expand table



Reltio	Microsoft Microsoft Purview
System	EntityDef "reltio_system"
Tenant	EntityDef "reltio_tenant"
Entity Type	EntityDef "reltio_entity_type"
Simple attribute (Entity Type, Relationship Type)	EntityDef "reltio_attribute"
Nested attribute (Entity Type, Relationship Type)	EntityDef "reltio_attribute"

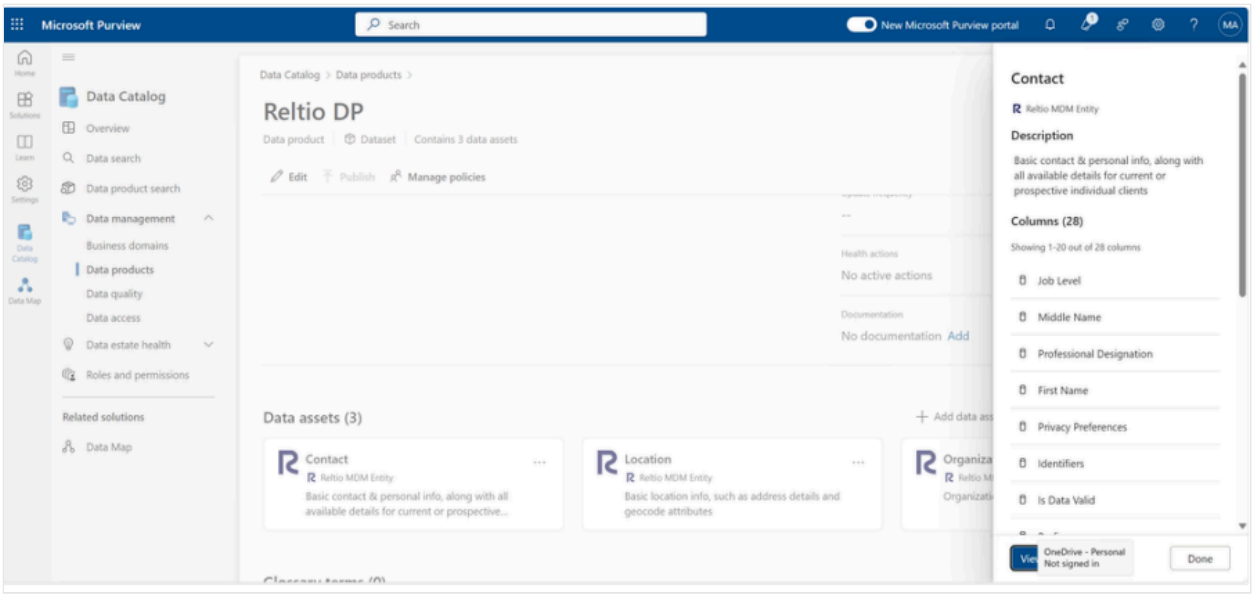
Reltio	Microsoft Microsoft Purview
Reference attribute (Entity Type)	EntityDef “reltio_attribute”
Relationship Type	EntityDef “reltio_relationship_type”



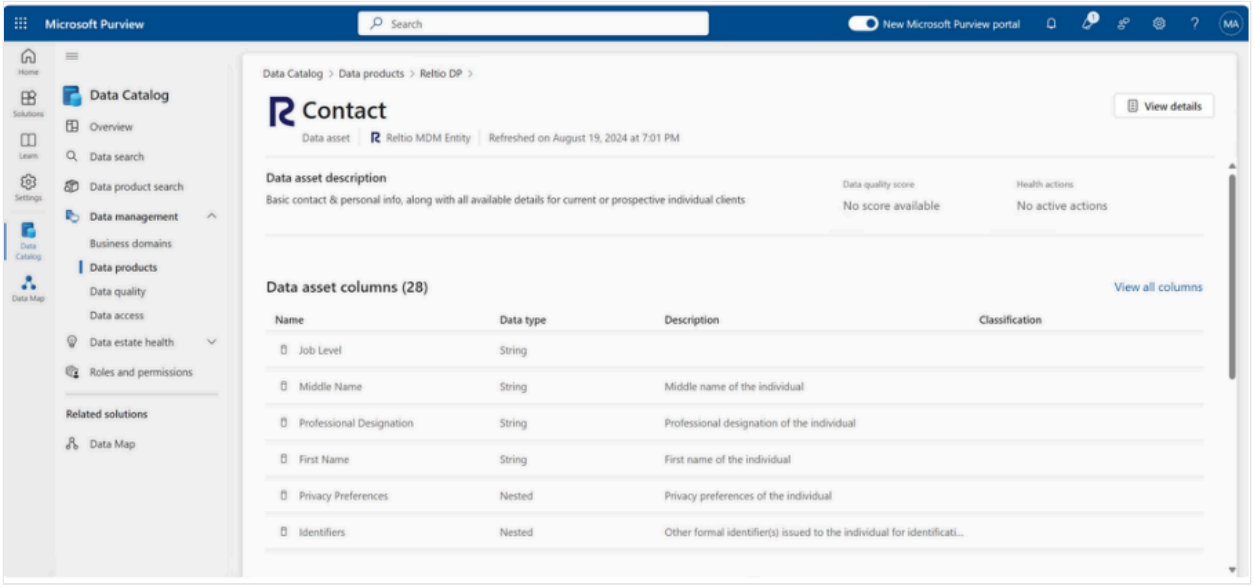
Later the integration creates a Reltio System as an Entity in Microsoft Purview's Data Map. The Reltio tenant is created also as an Entity under the Reltio System in Microsoft Purview using the implements relationship.

Reltio System contains the following properties: description, displayName (same as Reltio label), name (last part of Reltio URI), qualifiedName (unique identifier).

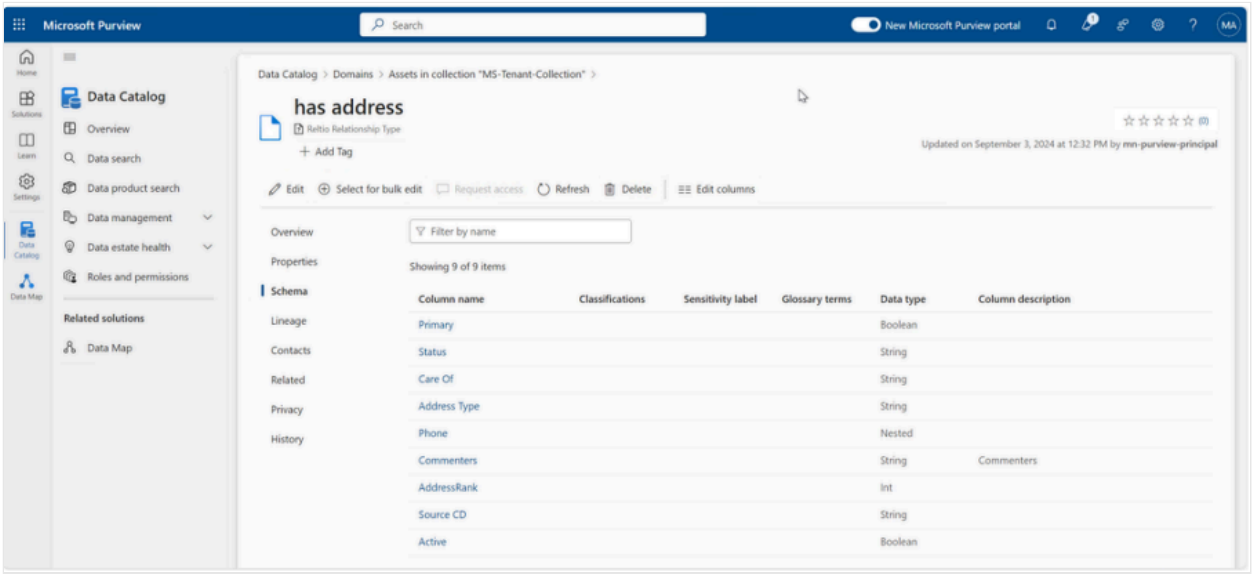
Reltio Tenant contains the following properties: description, displayName, isActive (if entity isn't removed on Reltio), name, qualifiedName, updatedBy (autopopulated), updatedTime (autopopulated).



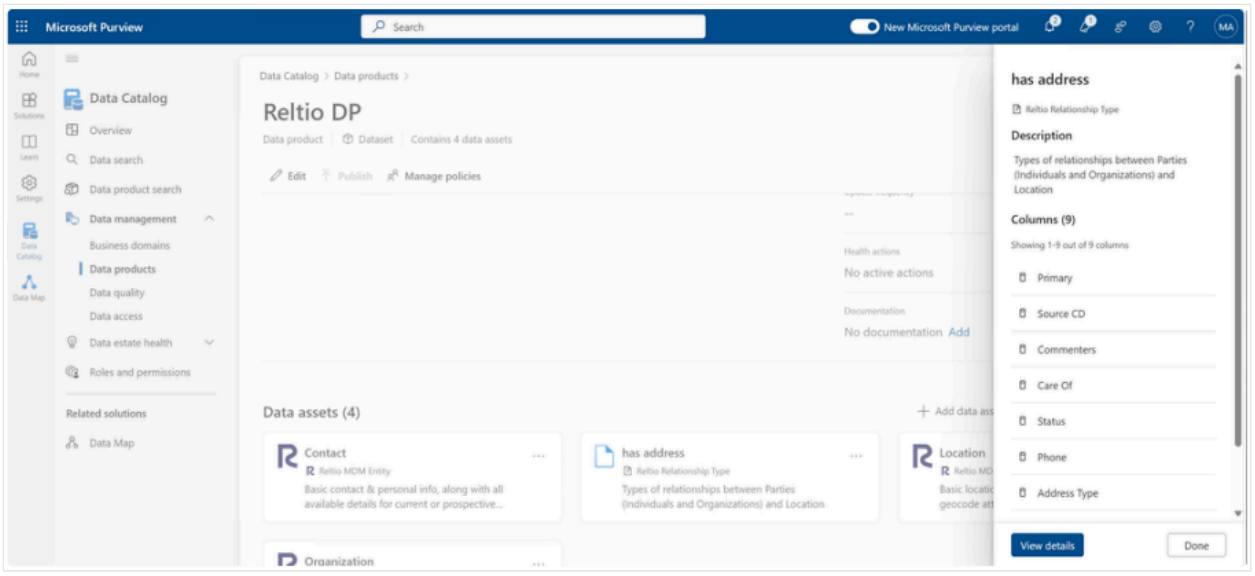
Properties are descriptive attributes or metadata that provide context about the data asset, helping with discovery, management, and governance without affecting the actual structure or format of the data.



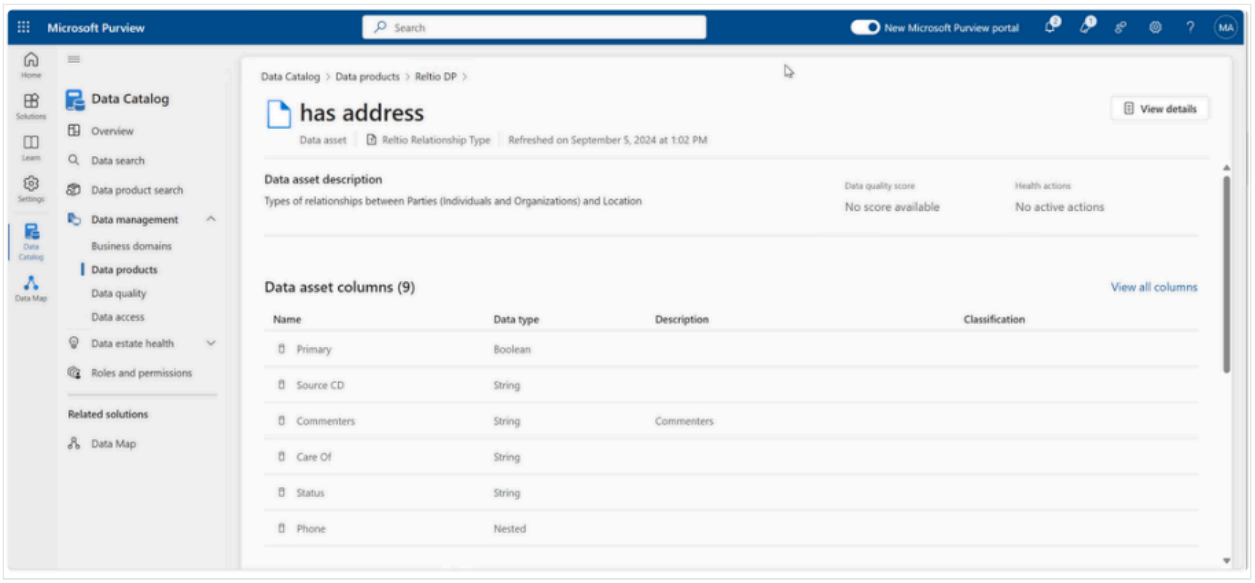
The Microsoft Purview Entity qualifiedName is derived using the



```
<collectionId>/<env>/<tenantId>/<URI>
```



Since the Entity qualifiedName uses the tenant ID and env, it's always unique for a tenant, so the same Microsoft Purview account can be used for multiple tenants.



The created Entities can be verified under DataMap->Domains->Collection (by default root)-> Assets-> search the name of your Asset/Entity. To ensure Entities appear in Unified Catalog add them manually to Microsoft Purview Data Product where they need to be published. Entities appear in Unified Catalog assigned to chosen Data Products as Data Assets, with their attributes (subnested and referenced attributes not included) in the Schema section. Schema section is available only for the Entities of specific Asset types: Reltio Entity Type, Reltio Relationship Type. Schema defines the structure of the data and dictates how the data is stored, queried, and maintained. It governs how data must be formatted and what relationships exist within the data

Schema

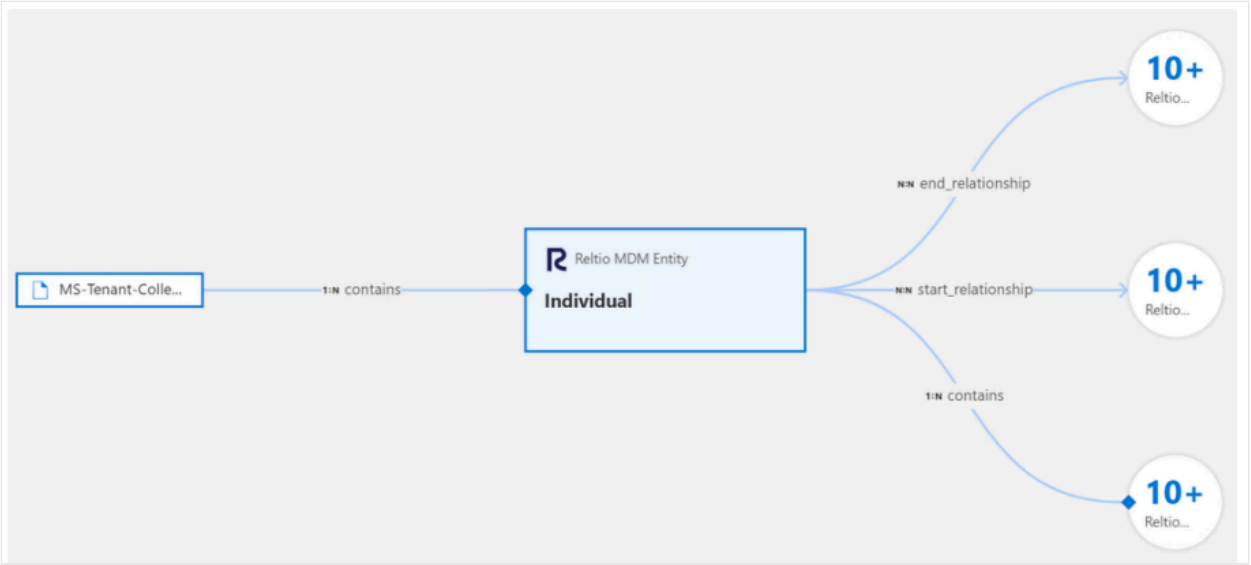
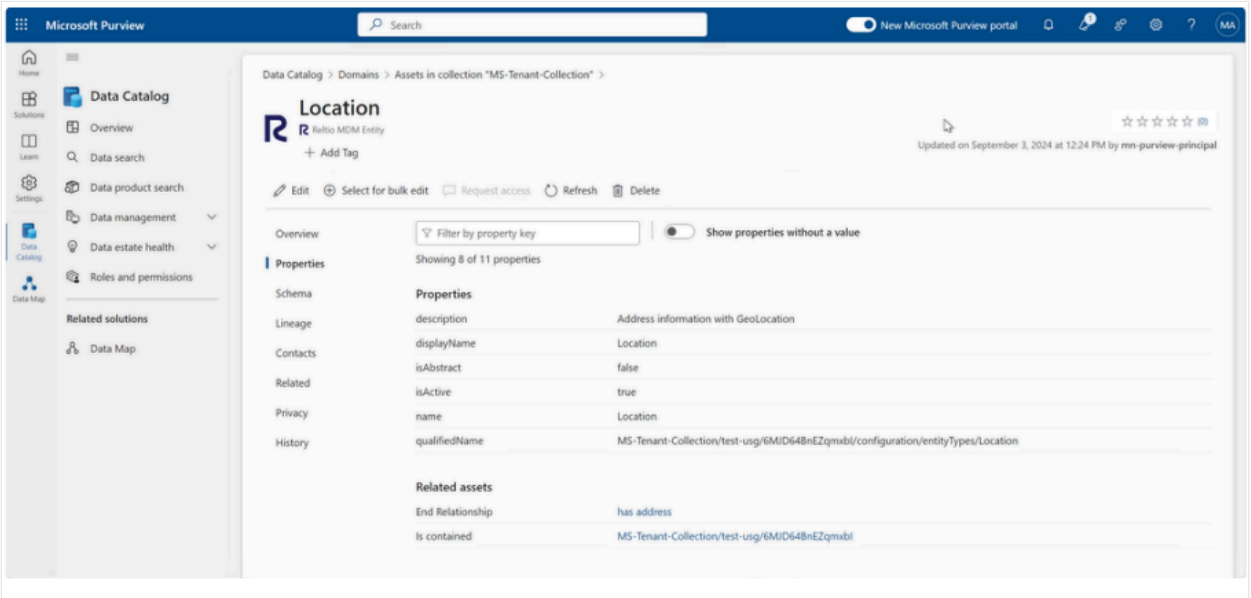
Schema is an important concept that reflects how data is stored and organized in the data store. It reflects the structure of the data and the data restrictions of the elements that construct the structure. Elements on the same schema can be classified differently (due to their content). Also, different transformation (lineage) can happen to only a subset of elements. Due to these aspects, Microsoft Purview can model schema and schema elements as entities, hence schema is usually a relationship attribute to the data asset entity. Examples of schema elements are: columns of a table, json properties of json schema, xml elements of xml schema etc.



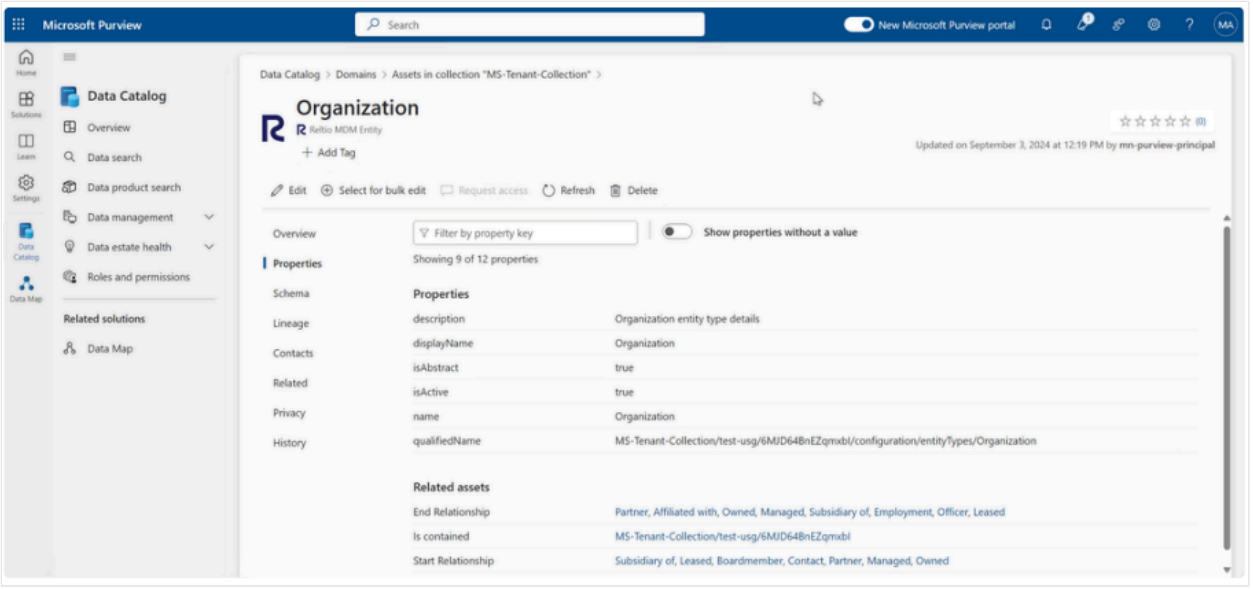
Type definitions and how to create custom types in Microsoft Purview

Reltio objects mapping to Microsoft Purview entities

Entity Types

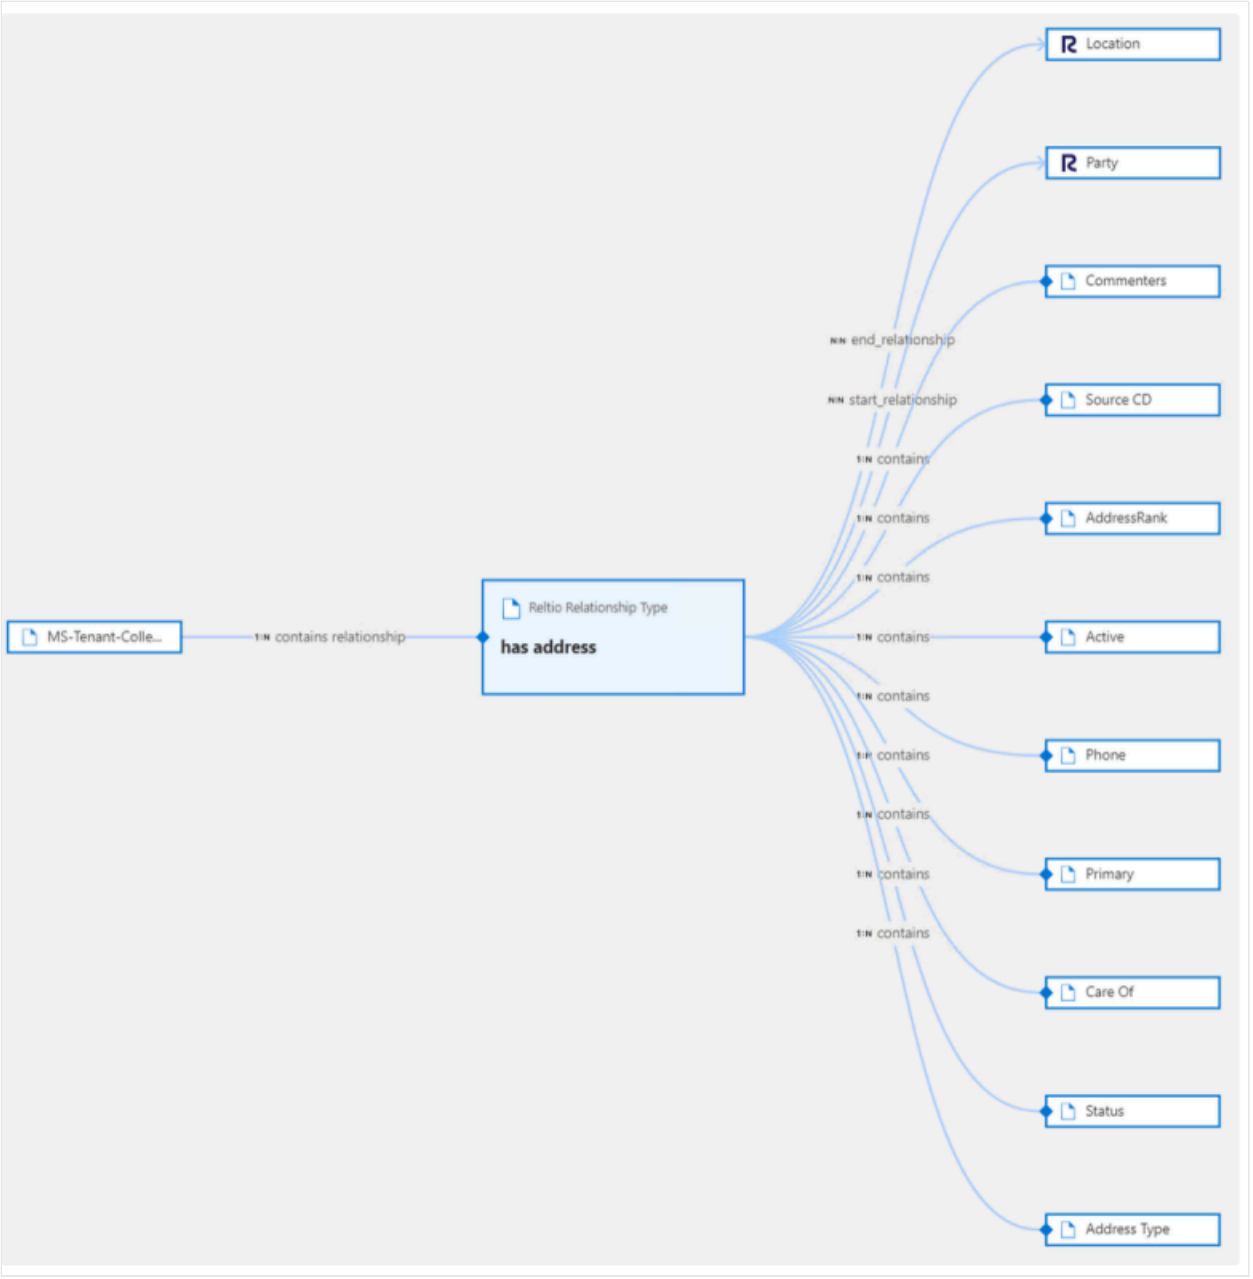


Entity Types within a tenant are created as Entities called Reltio MDM Entity in Microsoft Purview with a contains relationship with the tenant.

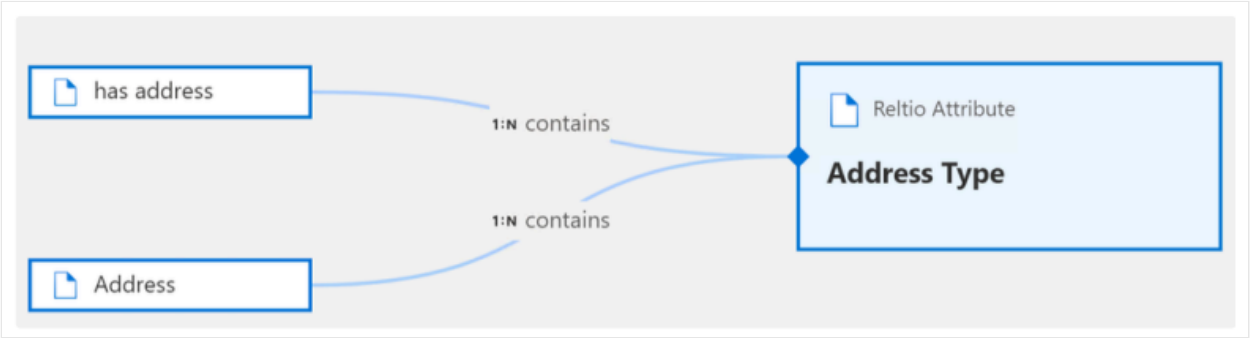


Properties of Reltio MDM Entity

Reltio MDM entity contains these properties: description, displayName, isAbstract (if the entity is abstract on Reltio), isActive, name, qualifiedName.

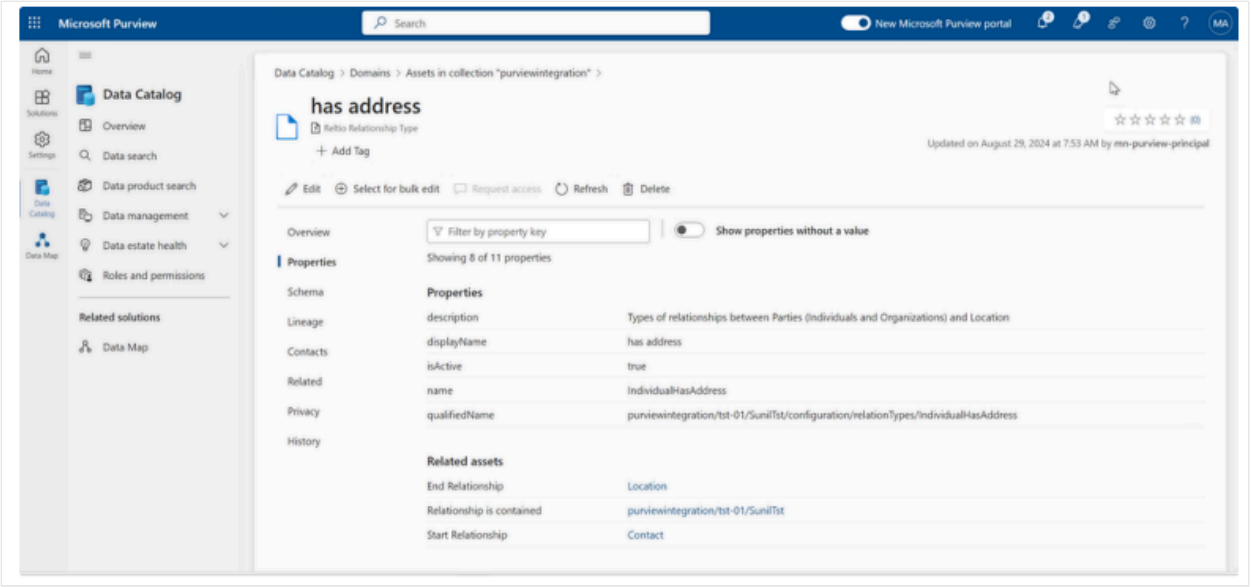


Relationship Types



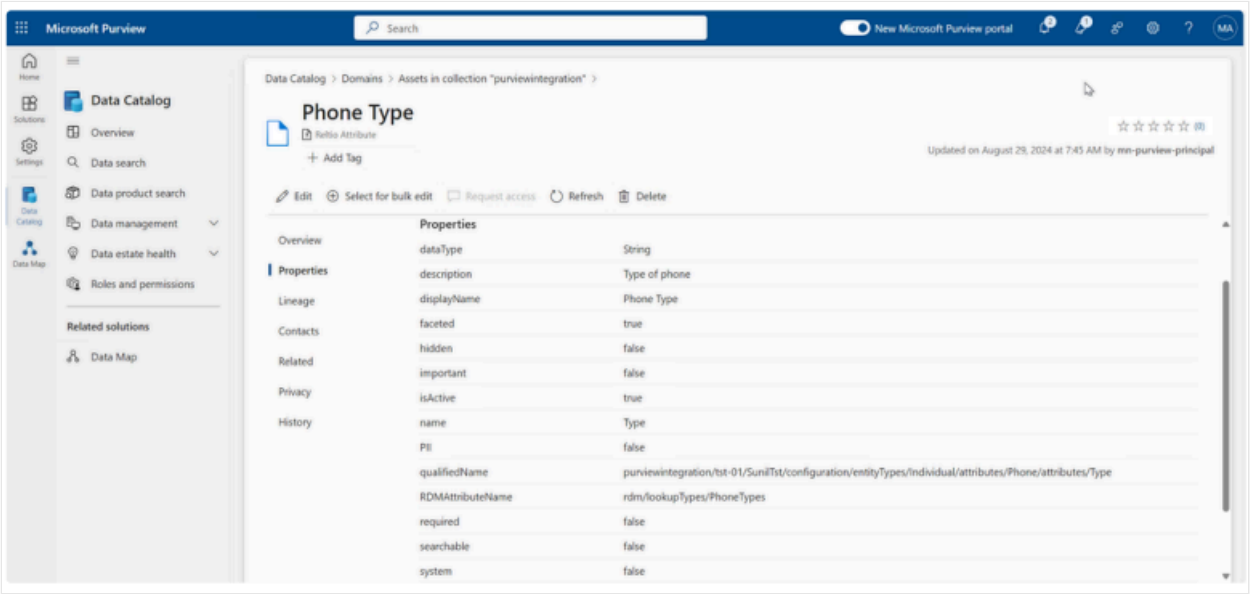
Relationship Types within a tenant are created as Entities called Reltio Relationship Type in Microsoft Purview with a contains relationship with the tenant.

Also, Reltio Relationship Type Entity has relations with two Reltio MDM Entities: start_relationship and end_relationship. Relationship attributes are added as Entities called Reltio Attributes with a contains relation with the Reltio **Relationship Type Entity.**



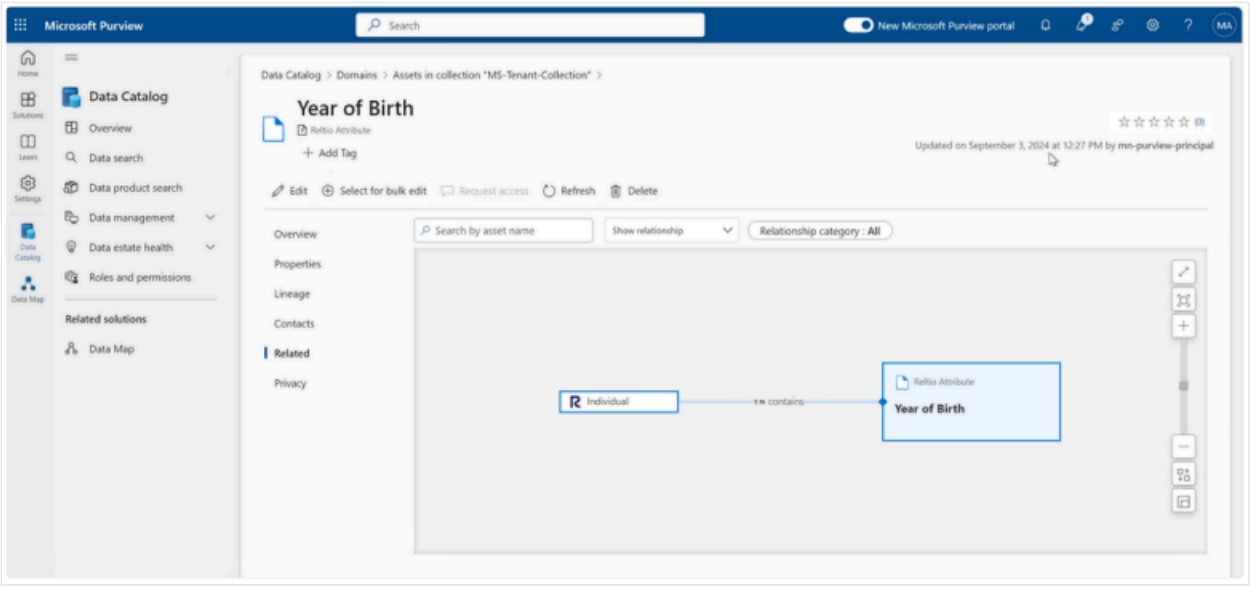
This screenshot shows a Contact Reltio MDM Entity connected to have address Reltio Relationship Type Entity with start_relationship Relationship. And later has address Reltio Relationship Type Entity is connected to Location Reltio Entity **Type Entity** with end_relationship Relationship. The **has address** Reltio Relationship Type Entity has four simple data attributes with contains relation: Address Type, Address. Rank, Active, Status.

Relationship attributes can further have a contains relation with the Reference attribute. In the example, the Address Type relationship data attributes references the Contact Reltio Entity Type Entity.

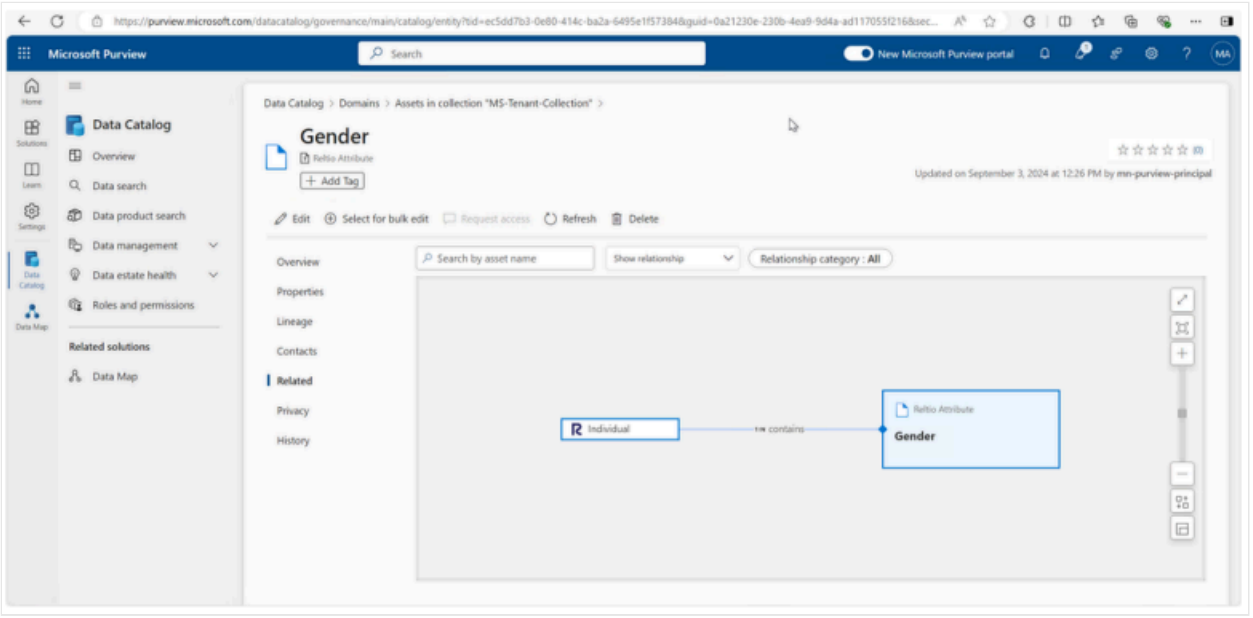


Also, Reltio Relationship Type Entities contain the same properties as Reltio Entity Type Entities: description, displayName, isActive, name, qualifiedName.

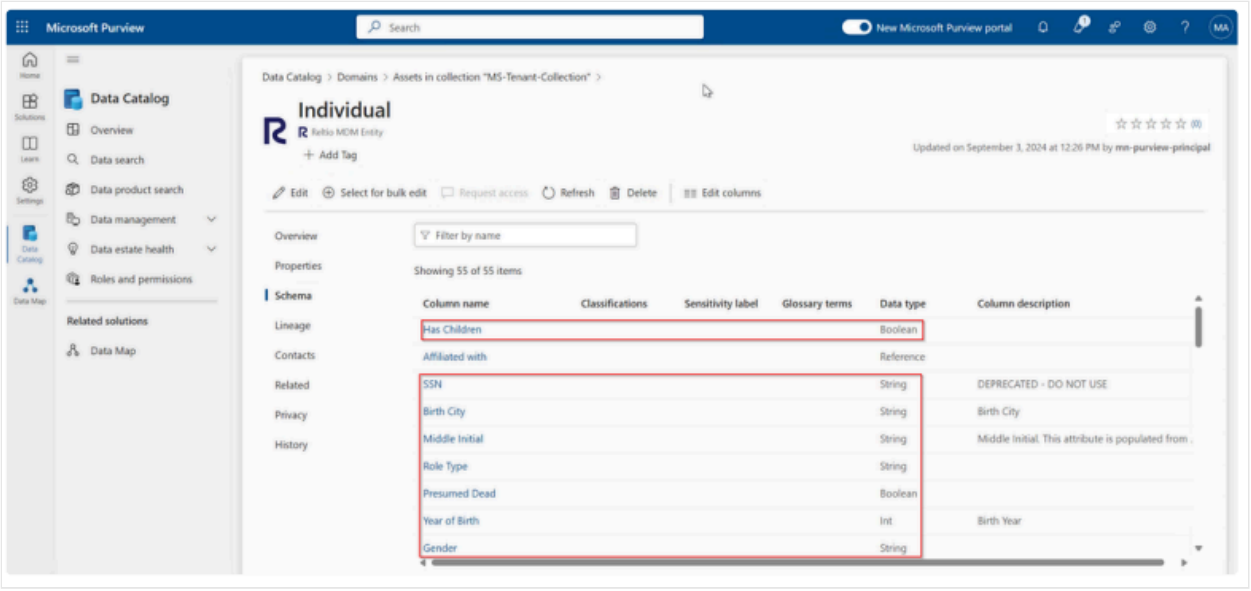
Attributes



All Reltio Attribute Entities (Simple, Nested, Reference) may contain the following properties (depending on the availability on Reltio):

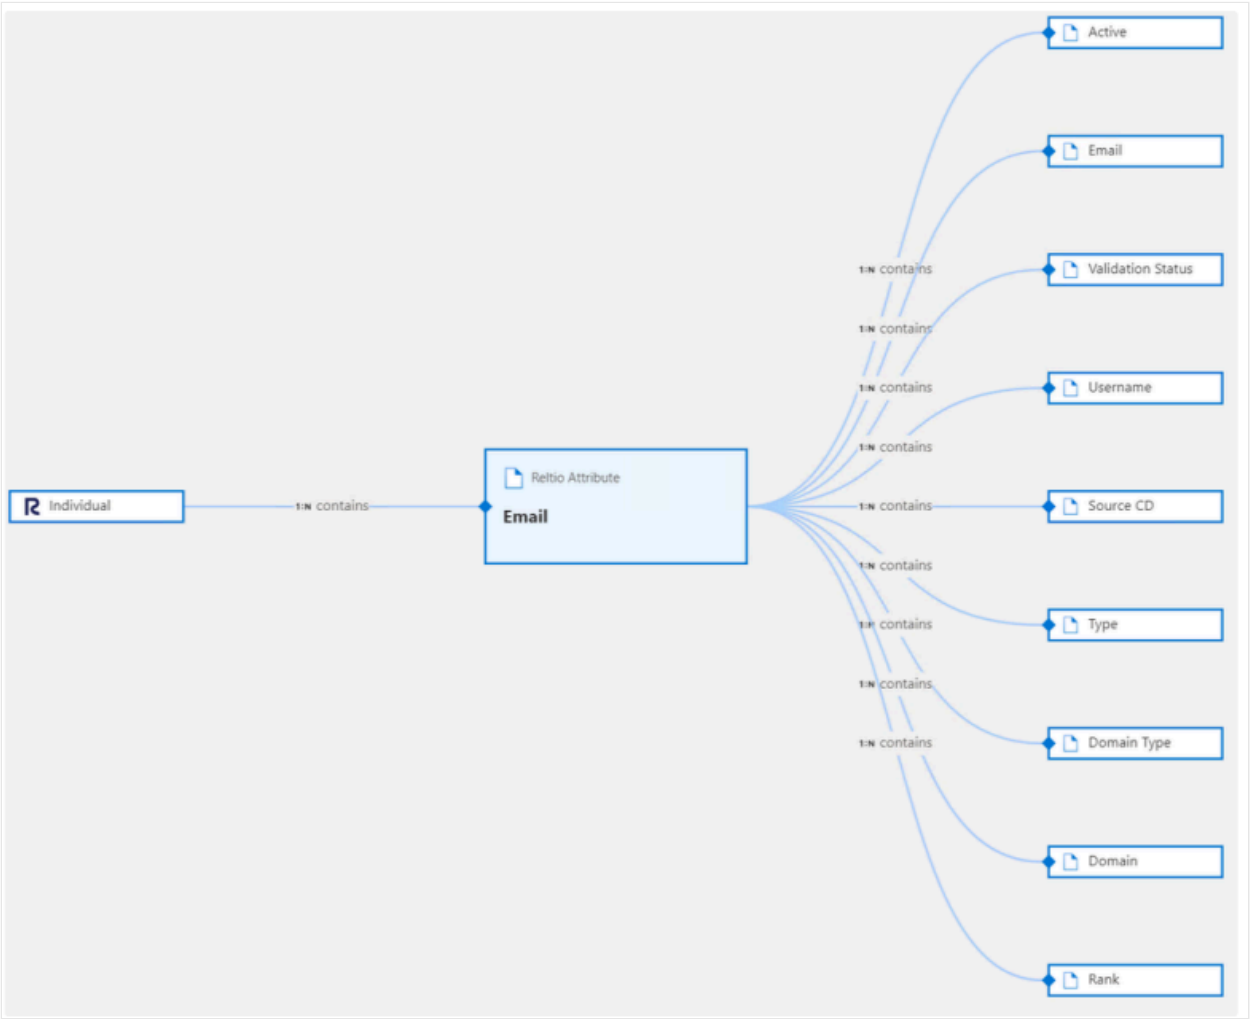


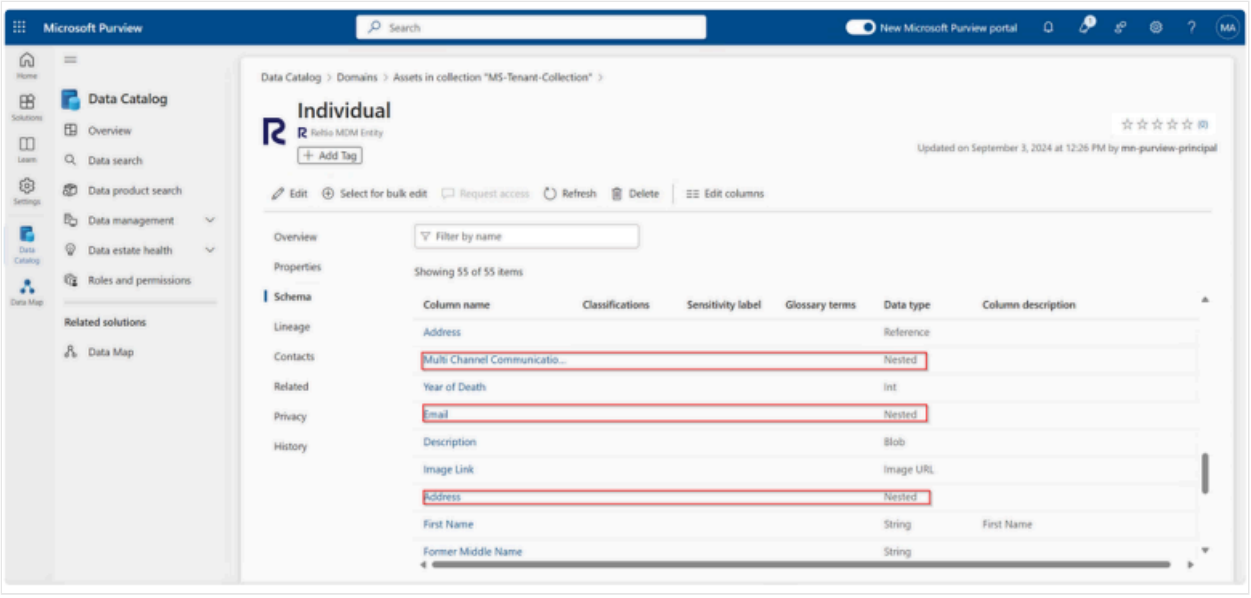
- dataType (Nested, Reference, or data type for Simple attributes),
- description, displayName, isActive, name, qualifiedName,
- faceted
- hidden
- important
- PII
- RDMAttributeName
- required
- searchable
- system



Simple Attributes

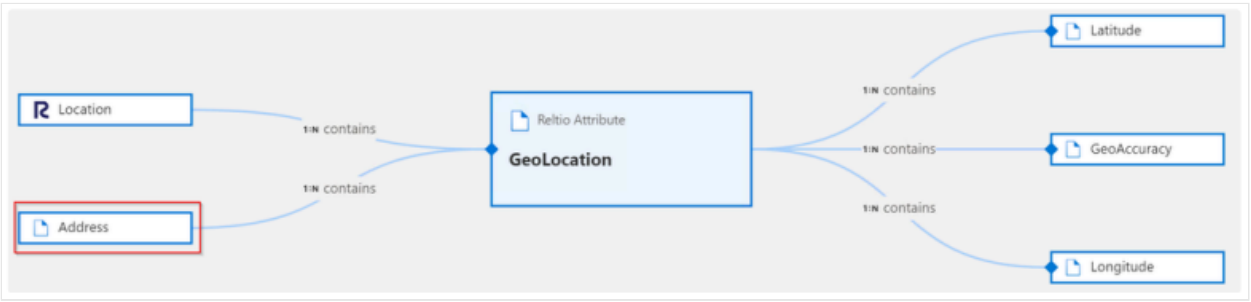
Simple attributes are created as Entities called Reltio Attribute in Microsoft Purview with a contains relationship with its entity.

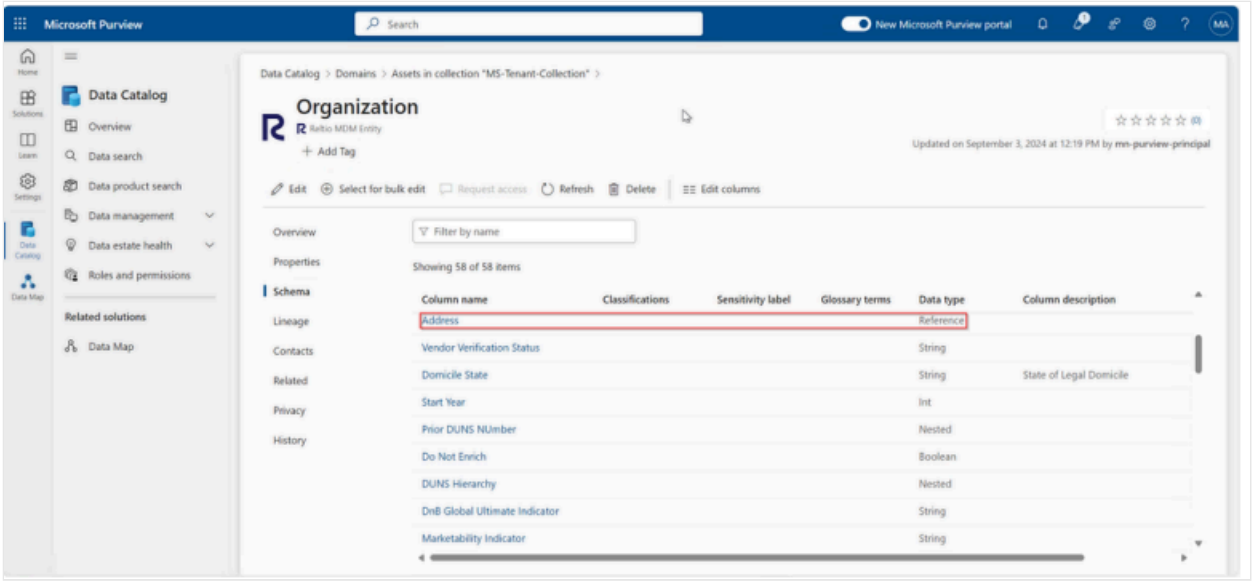




Nested Attributes

Nested attributes are created as Entities called Reltio Attribute in Microsoft Purview with a relationship with its entity. Sub nested attributes are also created as Entities called Reltio Attribute with a relationship with the parent nested attribute. This screenshot shows a Contact Reltio Entity Type that contains the Email nested attribute, which further contains multiple sub nested attributes like username, domain type, etc.





Reference Attributes

A Reference attribute in a Reltio Entity Type is also created as Entities called Reltio Attribute in Microsoft Purview with a contains relationship with its entity. Sub referenced attributes are also created as Entities called Reltio Attribute with a contains relationship with the parent reference attribute.

This screenshot shows a Contact Reltio Entity Type entity with a Reference attribute called Address, which contains multiple simple attributes like verification status, PO Box, state, country, etc., and some nested attributes like Zip and Geo Location.

Lookup tables

- Microsoft Purview Created Assets
- Stores Microsoft Purview asset GUID. Will be used for soft delete of Microsoft Purview assets.
- Microsoft Purview Reference Attributes Table
- Stores ID of reference attributes and its array of referred URIs. This is created for avoiding going through the L3 configuration twice in order to create reference attributes.

Microsoft Purview Recursion Table

Acts as a stack for storing function calls for implementing recursive calls for processing nested attributes. Stores attribute's json, asset ID of parent, asset type of parent, relationship type. Contains a dummy field called processed which is not used but is required for getting a single entry from the table.

Configure RIH recipes

You need to have the Microsoft Purview connector license in your contract. Reach out to your Reltio Account Manager for licensing needs.

Once you have the Microsoft Purview connector license in your Reltio contract, the Microsoft Purview connector recipes and connections are deployed to your tenant's Reltio Integration Hub (RIH) instance.

- Configure Connections

- Configure Environment properties.

To configure the recipes: Check the recipes

The recipes package contains two connections and seven recipe functions. The package is deployed in the Reltio Solution Templates project in your RIH account.

- Connect with your Reltio tenant
  - Enter the connection details
    - Connection Name: for example, Microsoft Purview
    - Environment URL: for example, 361, tst-01 etc
    - Tenant Id: for example, a0bcdEf1ghiJ2Kl
    - Set Client Authorization to No
    - Reltio User Name and Password
  - Select Connect
- The status changes to Connected and the button to Disconnect when the connection is established
- Connect with your Purview account

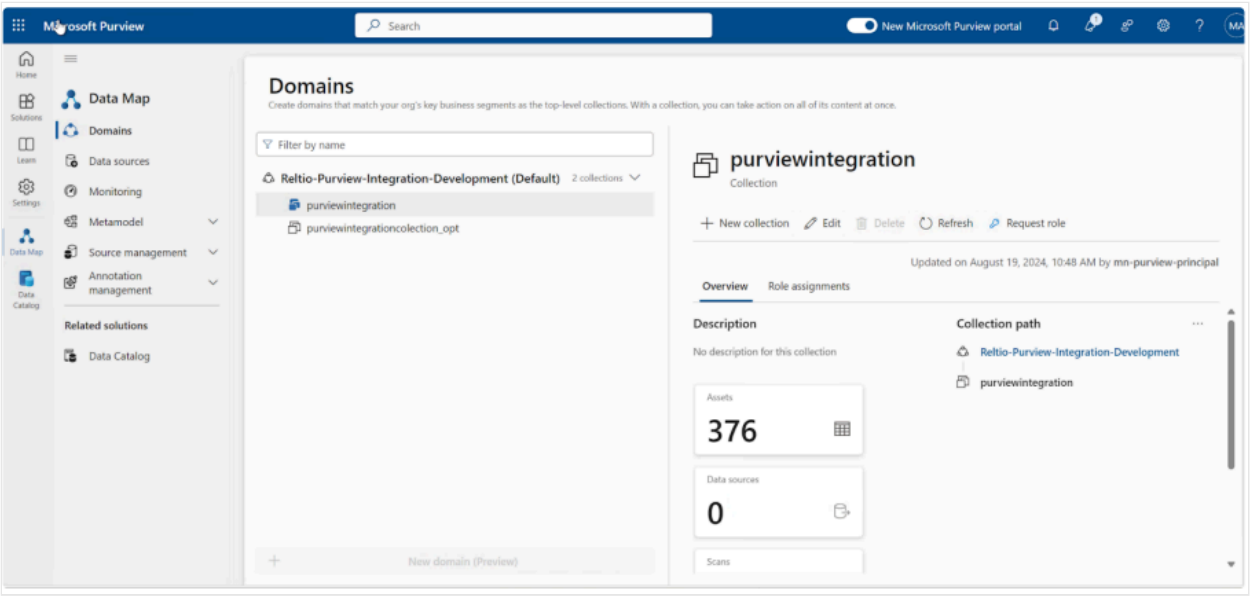
Before you're able to connect you need to generate the client ID and client secret based on this documentation - API authentication for Microsoft Purview Data Planes

1. Enter the connection details

- Connection Name - for example, Microsoft Purview Portal
- Connection Type - Cloud
- Authentication type - Azure OAuth 2
- Azure Tenant ID - for example, a0bcdEf1ghiJ2Kl
- Azure OAuth client ID & client secret
- Base URL

```
https://api.purview-service.microsoft.com
```

- OAuth scopes



2. Select Connect

- The status changes to Connected and the button to Disconnect when the connection is established.

Manually create a Microsoft Purview Domain in the Data Map domains and add it to the recipe parameters (name of parameter) & add Collection to the recipe parameters name

to create the Reltio system in an existing Domain & Collection. Make sure the User ID of Collection creator matches the UserID of integration recipe, otherwise data won't be populated there. If you don't create the Domain then the recipe fails. If you don't provide a value for Collection then the integration uses this default value:

- Collection - purviewintegration

Use Reltio integration for Microsoft Purview

Let's cover the usage scenarios for Reltio Integration for Microsoft Purview. The following recipes and functions are deployed to the Recipes folder:

- Main
- Initial setup
- Create Entities
- Create Attributes
- Create Relationships
- Create reference attribute relationships
- Soft-delete Assets

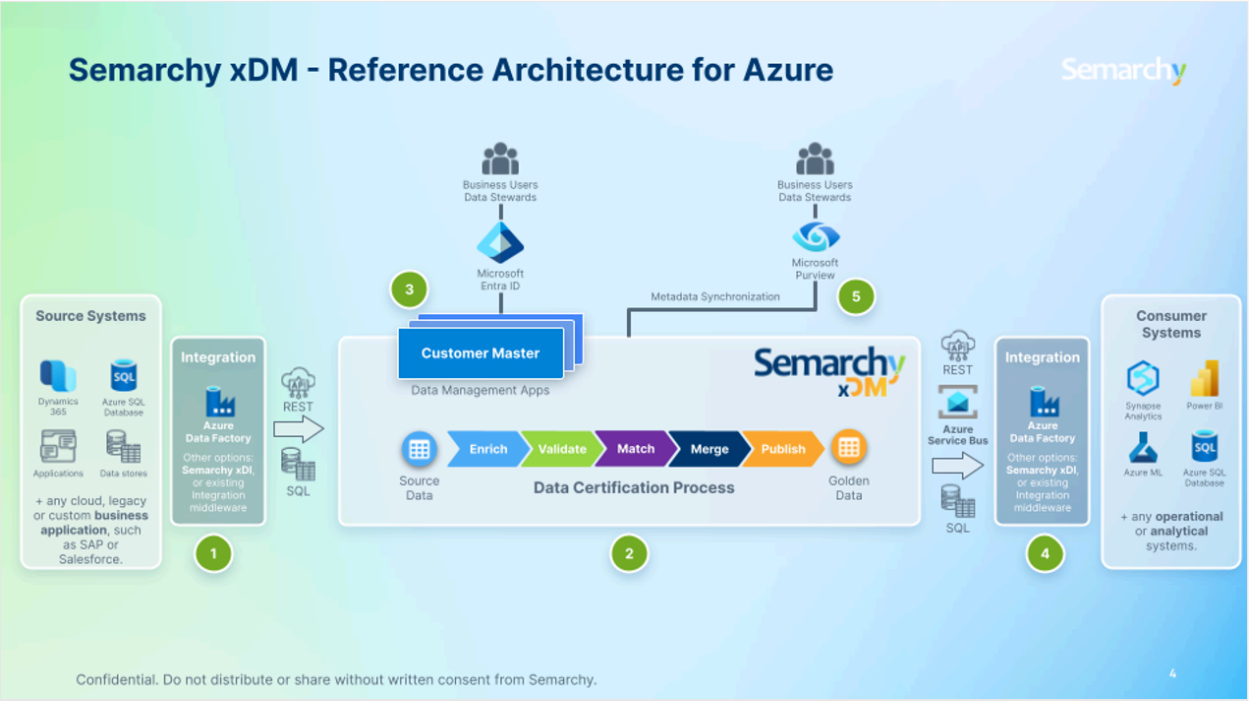
Microsoft Purview and Semarchy integration for master data management



Article • 04/03/2025

Modern organizations generate large quantities of data, often from numerous, disparate sources. The Semarchy Data Platform is the intelligent data hub for data integration, master data management (MDM), reference data management (RDM), application data management (ADM), data integration, quality, and governance. Semarchy Data Management (xDM) brings extreme agility for defining and implementing data management applications and releasing them to production.

This architecture demonstrates how to include Master Data Management (MDM) into the Azure ecosystem to enable quality, validation, matching, deduplication, authoring, curation, and collaboration for your critical data assets.

Architecture

The following architecture illustrates the Semarchy xDM architecture and data flow.

Data Flow

Metadata and data flow include the following steps:

- **Source data integration** from identified source systems:
  - This integration uses Azure Data Factory, Semarchy xDI (Semarchy's data integration component), or your integration solution.
  - semarchy xDM exposes SQL or REST endpoints for batch and real-time integration.
  - Incoming data can be profiled with Semarchy xDM Discovery and reviewed to help define the master data model structure and rules.
  - At any time, the REST endpoints can also be used by applications to interact (read/write) with the master data managed in xDM, and use xDM as their master data backend.

- **Automatic Data Certification**
  - Data undergoes enrichment, standardization, and quality validation through a combination of rules, plugins, AI models (including Azure Machine Learning and Azure OpenAI), and third-party services. semarchy xDM supports these automated quality processes with data recycling and incorporates user corrections to ensure optimal data quality.
  - Matching, merging, and survivorship processes are automatically carried out by combining sophisticated automation with informed user decisions, to produce accurate, and reliable consolidated golden records.
  - Golden records produced by the certification process feature complete lineage to the source systems, user change tracking, and optional historization. This guarantees data integrity, traceability, and comprehensive historical record tracking.

- **Customized Data Management Applications** are available for users to:
  - Authenticate via Microsoft Entra ID,
  - Browse and search certified data with complete traceability through each certification stage, alongside comprehensive historization,
  - Manage and curate data:
    - Users can author and import new data,
    - review and fix errors,
    - manually match and merge records with override options,
    - and perform soft or hard deletes as necessary,
  - Collaborate with Data-Driven Workflows.

- **Golden data distribution** to consumer operational and analytical applications such as Azure Synapse Analytics, Power BI, Azure Machine Learning, and Azure OpenAI, ensures uninterrupted integration and usage across platforms:
  - This integration uses Azure Data Factory, Semarchy xDI, or your integration solution.

    - Semarchy xDM provides built-in SQL and REST endpoints, and Data Notifications for event-based propagation in Azure Service Bus.

- **Synchronize xDM metadata** with Microsoft Purview to gain comprehensive visibility and lineage of the entire master data flow.

Components

This architecture involves the following components.

Core Components

- Semarchy xDM is a no-code platform that allows data teams to quickly develop customized master data management solutions, offering a wide range of capabilities for complex data ecosystems.
- Azure Database for SQL Server and PostgreSQL are fully managed databases as a service with built-in capabilities, such as high availability and intelligence. They store both the Semarchy metadata and master data hubs managed in xDM. Data processing is performed in the database layer, guaranteeing the best performance and scalability.
- Microsoft Entra ID, for user authentication and single sign-on to the Semarchy platform.
- Azure Key Vault is a cloud service that provides secure storage for secrets. You can use it to encrypt, decrypt, and store secrets (passwords, for example) used in xDM.

AI Components

- **Azure Machine Learning** is a cloud service for accelerating and managing machine learning (ML) projects. Semarchy xDM can use customized Azure Machine Learning models in the data hub certification processes.
- **Azure OpenAI** is a suite of AI services providing access to OpenAI's powerful language models. Semarchy xDM includes built-in plug-ins using these language models to enrich and certify data, for example for content generation, summarization, or translation.

Governance Components

- **Microsoft Purview** is a data governance solution that provides broad visibility into on-premises and cloud data estates. Semarchy xDM integrates with Microsoft Purview to provide insights into Semarchy Data Hubs as data products and end-to-end master data lineage.

Source and Consumer Systems Among others, this architecture includes the following systems from which you collect master data to be managed in Semarchy xDM, or to which you send golden data produced by Semarchy xDM.

- **Azure Synapse Analytics** is a fast, flexible, and trusted cloud data warehouse that uses a massively parallel processing architecture. Semarchy Data Hubs act as providers of certified metadata for Azure Synapse.
- **Power BI** is a business analytics suite that delivers insights throughout your organization. You can use Power BI to build dashboards and reports on top of Semarchy Discovery metrics and the Semarchy Data Hubs.

Scenario Details

Data-driven initiatives, such as digital transformation, business intelligence, or AI projects require accurate and trustable data. Master Data Management is an essential step to deliver this clean, accurate data.

A common use case for an MDM solution is to consolidate master data from multiple sources while allowing collaborative authoring and stewardship of this master data to serve analytical and operational applications with golden data.

Design data applications

Semarchy xDM Data Management Applications provide all users with a customized experience to access and manage their data. Through these applications, master data records are displayed in fully customizable interfaces, supporting data management, authoring, and stewardship operations. Users with different roles and personas collaborate in Data-Driven Workflows to manage data. The power of Semarchy xDM lies in the flexibility in the design of your data applications, allowing them to adapt to your domains, organization, and business needs.

Integrate and certify master data

Data curated in external source systems, such as Customer Relationship Management (CRM), Enterprise Resource Planning (ERP), or other systems (known as the publishers) is pushed to Semarchy xDM's data hubs via an integration layer, such as Azure Data Factory or Semarchy xDI.

As data changes appear in the data hub, through data loads or authoring, it passes through the entire certification process, during which it's enriched, standardized, validated for data quality, and then matched and merged the records.

Consume data from the hub

Data can be pushed to or consumed from Semarchy xDM using REST API endpoints, or through SQL. Changes made to the data through the data hub can also be propagated in real-time to downstream systems using data notifications.

Considerations

The Semarchy Data Platform has several features that address the issues of reliability, security, cost optimization, operational excellence, and performance efficiency. Further information about architectural excellence can be found in this article on the ** pillars of well-architected Azure frameworks.**

Reliability

Reliability ensures your application fulfills the promises you make to your customers. For more information, see Overview of the reliability pillar.

Semarchy xDM runs natively on Azure Kubernetes Service and Azure SQL Database, which offers out-of-the-box capabilities to support high availability.

Security

Security shields against intentional attacks and misuse of your valuable data and systems. For more information, see Security overview in Microsoft learn page.

Semarchy xDM authenticates users via its identity management layer that supports role mapping, lookup, and profile synchronization. It provides native support for multiple IDPs, including Microsoft Entra ID. It also includes advanced security features such as fine-grained privileges to secure access and operations.

Performance Efficiency

Performance efficiency is the capability of your system to scale and effectively meet user needs. For more information, see Performance Efficiency learn page in microsoft learn.

Semarchy xDM runs natively on Azure Kubernetes Service and Azure SQL Database. You can configure Azure Kubernetes Service to scale up and out. You can deploy and configure Azure SQL Database to balance performance, scalability, and costs.

Cost Optimization

Cost optimization involves finding ways to reduce unnecessary expenses and enhance operational efficiency. For more information, see Cost Optimization learn page in Microsoft learn.

Running costs consist of the Semarchy software subscription license and Azure consumption. Contact Semarchy for more information.

Deploy this scenario

To deploy this scenario:

1. Deploy Semarchy xDM using Azure Kubernetes Services.
2. Configure Secrets Management to use Azure Key Vault.
3. Configure Authentication with Microsoft Entra ID.
4. Design and deploy your customized master data model in xDM
5. Integrate your data into xDM using Azure Data Factory.

Create an Azure policy exclusion for Microsoft Purview

Article • 05/14/2025

Many subscriptions have Azure Policies in place that restrict the creation or update of some resources. This is to maintain subscription security and cleanliness. However, Microsoft Purview accounts created before December 15, 2023 (or deployed using API version previous to 2023-05-01-preview) deployed an Azure Storage account when it was created. It's managed by Azure, so you don't need to maintain it, but it's necessary for Microsoft Purview to run correctly. Existing policies could block Microsoft Purview from updating this Azure Storage account, which can cause errors during scanning.

Overall, your approach to resolving this error is going to be dependent on your organizations needs and policies, but here are a few ways you could update your policies to resolve this issue.

To maintain your policies in your subscription, but still allow the creation and updates to these managed resources, you can create an exclusion. For example, adding an exclusion for the resource group where your Microsoft Purview account is being deployed.

For steps to create an exclusion for your policies, see these steps to add an exclusion to your policy.

Use resource selectors on a created policy

Depending on other policies deployed in your subscription, or depending on your region, you could need to add **Resource selectors** under the **Advanced** tab when assigning a policy. For example, you might need to add a resource selector for **resourceLocation** set to the region where you'll deploy your Microsoft Purview account. For more information about these conditions, see our documentation on location conditions.

Create an exemption

Exemptions are recommended for time-bound or specific scenarios where a resource or resource hierarchy should still be tracked and would otherwise be evaluated, but there's a specific reason it shouldn't be assessed for compliance. It would allow a temporary exception to your policy for a resource to exist for a finite amount of time.

For more information, see the documentation for policy exemptions.

Next steps

To set up Microsoft Purview by using Private Link, see Use private endpoints for your Microsoft Purview account.

GraphQL API with Microsoft Purview (preview)

Article • 05/14/2025

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

In this tutorial, learn to programmatically interact with Microsoft Purview using the GraphQL API. For more information about GraphQL in general, see this introduction to GraphQL.

Using GraphQL is similar to using the REST APIs, in that you send a JSON payload to a service endpoint. However, GraphQL allows us to return complete information in a single fetch, eliminating the need for multiple API calls.

GraphQL also uses declarative data fetching. Declarative data fetching is useful for selective fetch on fields like classification/term/related entity linked to the original entity. By using GraphQL with these query patterns, we can optimize backend database fetching and data transmission. A good example is "Get Entity with filtered related entities, separated by aliases."

With its introspection feature, the GraphQL API becomes self-descriptive, enabling clients to retrieve schema details such as available queries, types, and query parameters. See more about introspection.

Prerequisites

- If you don't have an Azure subscription, create a free account before you begin.
- You must have an existing Microsoft Purview account. If you don't, see the quickstart for creating a Microsoft Purview account.
- To establish a bearer token and to call any APIs, see the documentation about how to authenticate APIs for Microsoft Purview.

GraphQL Endpoint

For all the requests, you can send a `POST` request to the following endpoint:

```
.NET CLI
```

```
POST https://{{endpoint}}/datamap/api/graphql
```

- If you're using the new Microsoft Purview portal, the {{endpoint}} value is: `api.purview-service.microsoft.com`.
- If you're using the classic Microsoft Purview governance portal, the {{endpoint}} value is: `{your_purview_account_name}.purview.azure.com`.

Basic query

Entity - List By Guids

JSON

```
query {
    entities(where: { guid: ["<guid1>", "<guid2>"] }) { #Values in the array are
combined as a logical-OR.
        guid
        createTime
        updateTime
        typeName
        attributes
        name
        qualifiedName
        description
    }
}
```

Sample Response:

JSON

```
{
    "data": {
        "entities": [
            {
                "guid": "9fb74c11-ac48-4650-95bc-760665c5bd92",
                "createTime": 1553072455110,
                "updateTime": 1553072455110,
                "typeName": "azure_storage_account",
                "attributes": {
                    "qualifiedName": "https://exampleaccount.core.windows.net",
                    "name": "ExampleStorageAccount",
                },
                "name": "ExampleStorageAccount",
                "qualifiedName": "https://exampleaccount.core.windows.net",
                "description": "Example Storage Account"
```

```
            }
        ]
    }
}
```

Query entities by type and qualified name

JSON

```
query {
    entities(
        where: {
            type: { typeName: ["<entityType1>", "<entityType2>"] }
            qualifiedName: { in: ["<qualifiedName1>", "<qualifiedName2>"] }
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

The operator `in` is used to query multiple qualified names.

Possible Operators could be `exists|eq|ne|in|nin|gt|ge|lt|le`. You can find more server schema details with introspection.

Declarative data fetching

Get entity with selected fields

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        businessAttributes
        qualifiedName
    }
}
```

Get entity with all fields

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        createTime
        createdBy
        updateTime
        updatedBy
        lastModifiedTS
        typeName
        attributes
        businessAttributes
        collectionId
        customAttributes
        hierarchyInfo {
            ...hierarchyInfoFields
        }
        labels
        sensitivityLabel {
            ...sensitivityLabelFields
        }
        source
        sourceDetails
        qualifiedName
        name
        description
        displayName
        userDescription
        classifications {
            ...classificationFields
        }
        relatedEntities {
            ...relatedEntitiesFields
        }
        assignedTerms {
            ...assignedTermsFields
        }
    }
}
```

Get entity with classifications

- with all classifications

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
```

```
        typeName
        attributes
        classifications {
            typeName
            attributes
        }
    }
}
```

- with filtered classifications

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        classifications(where: { type: { typeName: "<classificationType>" } }) {
            typeName
            attributes
        }
    }
}
```

Get entity with related entities

- with all related entities

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        relatedEntities {
            relationshipAttributeName
            relationship {
                guid
                typeName
                attributes
            }
            entity {
                guid
                typeName
                qualifiedName
                attributes
```

```
            }
        }
    }
}
```

- with filtered related entities

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        relatedEntities(where: { relationshipAttributeName: "<relAttrName1>" }) {
            entity {
                guid
                typeName
                qualifiedName
                attributes
            }
        }
    }
}
```

- with filtered related entities, separated by aliases

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        alias1: relatedEntities(where: { relationshipAttributeName: "
<relAttrName1>" }) {
            entity {
                guid
                typeName
                attributes
            }
        }
        alias2: relatedEntities(where: { relationshipAttributeName: "
<relAttrName2>" }) {
            entity {
                guid
                typeName
                attributes
            }
```

```
        }
    }
}
```

Get entity with glossary terms

- with all glossary terms

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        assignedTerms {
            confidence
            createdBy
            description
            expression
            steward
            source
            status
            term {
                qualifiedName
                name
                shortDescription
                longDescription
            }
        }
    }
}
```

- with filtered glossary terms

JSON

```
query {
    entities(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        assignedTerms {
            confidence
            createdBy
            description
            expression
            steward
```

```
            source
            status
            term {
                qualifiedName
                name
                shortDescription
                longDescription
            }
        }
    }
}
```

Filtering (preview)

The performance of exact matching for 'GUID' and 'Qualified-Name' is guaranteed in the examples provided in the 'basic queries' section. However, there are some limitations for other filtering patterns:

- **Filtering on Non-indexed Fields**: Fields other than GUID & qualified name are currently not indexed (as examples in the "Simple filter" section). Filtering over nonindexed fields without criteria on GUID/Qualified-name will result in a table scan and might cause performance issues on large datasets.
- **Nested Filtering**: Similar to nonindexed fields, nested filtering can cause table scans, which might cause performance issues on large datasets. For example, finding an entity with a linked classification/term/related entity.

Despite these limitations, this call pattern is superior to client-side filtering and is currently used by our internal client.

Simple filter

Query entities by type and system attributes

JSON

```
query {
    entities(
        where: {
            type: { typeName: "<entityType>" }
            name: { eq: "<value>" }
            createTime: { timerange: LAST_7D }
            updateTime: { gt: "<timestamp>" }
        }
    ) {
        guid
        typeName
```

```
        qualifiedName
