Session started	SessionStarted	A user started a new clinical documentation session in Dragon Copilot.
Session ended	SessionEnded	A user ended a clinical documentation session in Dragon Copilot.
Recording started	RecordingStarted	A user started audio recording during a clinical session.
Recording ended	RecordingEnded	A user stopped audio recording during a clinical session.

eDiscovery activities

The audit log records eDiscovery activities that you perform in the Microsoft Purview portal. It logs events when administrators or eDiscovery managers (or any user assigned eDiscovery permissions) perform the following tasks in the Microsoft Purview portal:

- Creating and managing eDiscovery cases.
- Creating and editing searches for eDiscovery cases.
- Performing search actions, such as generating statistics, creating a sample, and exporting from search.
- Creating, editing, and removing holds for eDiscovery cases.
- Creating review sets and performing review activities in eDiscovery cases.

For more information about searching the audit log, the permissions that are required, and exporting search results, see Search the audit log.

How to search for and view eDiscovery activities

The audit log records eDiscovery activities that you perform in the Microsoft Purview portal or in PowerShell. To search for eDiscovery activities, see Search for eDiscovery activities in the audit log.

eDiscovery activity reference

The following table lists the eDiscovery activities that are logged when an administrator or eDiscovery manager performs an eDiscovery-related activity by using the Microsoft Purview portal. Some activities performed in the classic eDiscovery user experience might be returned when you search for activities in this list.

> **Note**
>
> The client IP field is included for all activities performed in the new eDiscovery experience. To distinguish activities performed in the new experience from those in the classic experience, check for the presence of the client IP field in the audit entry. (In the following image, the first entry is eDiscovery case deleted in new modern ux and the other two entries without IP addresses are classic ux).

Expand table

Friendly name	Operation	Description
Added favorite	FavoriteSet	User set a case to favorite.
Added Purview search	PurviewSearchAdded	A new search was created. This audit activity includes the case name, case ID, and search name that was created.
Added review set	ReviewSetAdded	User created a review set.
Added saved search for a review set	ReviewSetSavedSearchAdded	User created saved filters in a review set. The audit activity includes the review set name, saved filters name, and the query used.
Added tag template	TagTemplateAdded	User created tag template in eDiscovery settings.
Cancelled sample view	SampleViewCancelled	User canceled sample view. The audit activity includes the canceled search's

Friendly name	Operation	Description
		name, ID, query, and associated settings.
Cancelled statistics view	StatisticsViewCancelled	User canceled statistics view. The audit activity includes the canceled search's name, ID, query, and associated settings.
Changed eDiscovery case	CaseUpdated	Updated an eDiscovery case.
Changed hold in eDiscovery case	HoldUpdated	Hold was modified or edited. This audit activity includes the hold name, ID, and the specific data sources and query values that were modified.
Closed eDiscovery case	CaseClosed	An eDiscovery case was closed.
Copied review set	ReviewSetCopied	User triggers the "Add to another review set" process.
Created eDiscovery case	CaseAdded	Added a new eDiscovery case.
Created hold in eDiscovery case	HoldCreated	A new hold was created. This audit activity includes the case name, case ID, and hold name that was created.
Deleted eDiscovery case	CaseRemoved	An eDiscovery case was deleted. You must remove any hold associated with the case before you can delete the case.
Deleted file for Purview search	PurviewSearchDeleteFile	User deleted a file from a search. This audit activity includes the case name, case ID, search name, search ID, and the ID of the file the user deleted.
Deleted hold in eDiscovery case	HoldRemoved	A hold that is associated with an eDiscovery case was deleted. Deleting a hold releases all of the content locations from the hold.
Deleted Purview search	PurviewSearchDeleted	A search was deleted. This activity includes the deleted case name, case ID, and search name.
Deleted Purview Search export job	PurviewSearchExportJobDeleted	An export from search was deleted. This activity includes the deleted export name, the case information in which the export is included, the user, and the deletion timestamp.

Friendly name	Operation	Description
Removed favorite	FavoriteRemoved	User removed a case from favorites.
Removed saved search for a review set	ReviewSetSavedSearchRemoved	User deleted saved filters in a review set.
Removed tag template	TagTemplateRemoved	User removed a tag template in eDiscovery settings. The audit activity includes the name and object ID of the tag template removed.
Reopened eDiscovery case	CaseReopened	An eDiscovery case was reopened.
Retried distribution sync for hold	HoldRetryDistributionSync	User triggered “retry policy” in a hold.
Retrieved actions for all review sets	GetActionsForAllReviewSets	User viewed a list of actions associated with all review sets in a case.
Retrieved all action for hold	GetActionsForAllHolds	User viewed a list of actions associated with all holds in a case. The audit activity includes case name, ID, hold name, ID, and the name of the list of actions.
Retrieved all action for search	GetActionsForSearch	User viewed a list of actions (such as exports) associated with a search. The audit activity includes case name, ID, search name, ID, and the name of the list of actions.
Retrieved all actions for all exports	GetActionsForAllExports	User viewed a list of exports in a case. The audit activity includes case name, ID, case settings, and the list of export names viewed.
Retrieved all actions for case	GetActionsForCase	User viewed a list of actions (such as exports) associated with an eDiscovery case.
Retrieved all actions for hold	GetActionsForHold	User viewed a list of actions associated with a hold.
Retrieved all actions for review set	GetActionsForReviewSet	User viewed a list of actions (such as exports) associated with a review set. The audit activity includes case name, ID,

Friendly name	Operation	Description
		review set name, ID, and the name of the list of actions.
Retrieved single action for case	GetSingleActionForCase	User viewed a single action associated with an eDiscovery case. For example, the user viewed the export process in process manager. The audit activity includes case name, ID, and settings and ID associated with the process.
Retrieved single action for hold	GetSingleActionForHold	User viewed a single action associated with a hold.
Retrieved single action for review set	GetSingleActionForReviewSet	User viewed a single action associated with a review set.
Retrieved single action for search	GetSingleActionForSearch	User viewed a single action associated with a search. For example, the user viewed the export process in the search's process manager. The audit activity includes case name, ID, and settings and ID associated with the process.
Submitted new algo job	AlgoJobSubmitted	User ran analytics on the documents in a review set.
Submitted new burn job	BurnJobSubmitted	User converted all the redacted documents in a review set to PDF files.
Submitted purview search add to review set job	PurviewSearchAddToReviewSetJobSubmitted	User triggered an "add to review set" process from a search. This audit activity includes the search name, ID, and the specific data sources and query values that were associated to the search. It also includes relevant add to review set process settings used.
Submitted purview search export job	PurviewSearchExportJobSubmitted	User triggered an "export" process from a search. This audit activity includes the search name, ID, and the specific data sources and query values that were associated to the search. It also includes relevant export process settings used and the export name.
Submitted purview search sample job	PurviewSearchSampleJobSubmitted	User triggered a "generate sample" process from a search. This audit activity includes the search name, ID, and the

Friendly name	Operation	Description
		specific data sources and query values that were associated to the search. It also includes relevant sample process settings used.
Submitted purview search statistics job	PurviewSearchStatisticsJobSubmitted	User triggered a “generate statistics” process from a search. This audit activity includes the search name, ID, and the specific data sources and query values that were associated to the search. It also includes relevant statistics process settings used.
Submitted review set export job	ReviewSetExportJobSubmitted	Exported documents from review set. This audit activity includes the review set name, list of documents IDs being exported and relevant export process settings.
Tagged documents by ID for a review set	ReviewSetDocumentsTaggedById	User applied tags to specific documents in a review set. The audit activity includes the case name, review set name, and the list of items being tagged.
Tagged documents by query for a review set	ReviewSetDocumentsTaggedByQuery	User applied tags to specific documents in a review set after filtering by query. The audit activity includes the case name, review set name, and the list of items being tagged.
Updated case members	CaseMembersUpdated	Case membership was updated. As a member of a case, a user can perform various case-related tasks depending on whether they're assigned the necessary permissions.
Updated case settings	CaseSettingsUpdated	User modified the settings for a case. Case settings include case information, premium feature access, case permissions, and settings that control search and analytics behavior.
Updated notes for a review set	ReviewSetNotesUpdated	User updated note for a review set document.
Updated Purview search	PurviewSearchUpdated	Search was modified or edited. This audit activity includes the search name, ID, and the specific data sources and query values that were modified.

Friendly name	Operation	Description
Updated review set	ReviewSetUpdated	User updated the review set such as review set name and description.
Updated review set annotation	ReviewSetAnnotationsUpdated	User annotated a document in a review set. This audit activity includes the review set name and other information such as the annotated document ID.
Updated saved search for a review set	ReviewSetSavedSearchUpdated	User modified saved filters in a review set. The audit activity includes the review set name, saved filters name, and the query used.
Updated tag template	TagTemplateUpdated	User updated a tag template in eDiscovery settings. The audit activity includes the name and object ID of the tag template updated.
Updated tags	TagsUpdated	User updated review set tags in a case.
Updated tags for a tag template	TagTemplateTagsUpdated	User updated tags for a tag template. The audit activity includes the name and ID of the tag template tags updated.
Updated tenant settings	TenantSettingsUpdated	User updated eDiscovery's organization settings.
Viewed analytics review set attachments report	AlgoGetReviewSetAttachmentsReport	User viewed analytics attachment report. This audit activity includes case and review set name and ID.
Viewed analytics review set documents report	AlgoGetReviewSetDocumentsReport	User viewed analytics document report.
Viewed analytics review set email report	AlgoGetReviewSetEmailsReport	User viewed analytics email report.
Viewed analytics review set report	AlgoGetReviewSetReport	User viewed analytics report in a review set. This audit activity includes case and review set name and ID, as well as the report type.
Viewed analytics review set	AlgoGetReviewSetReportByFileType	User viewed analytics report graph by file type.

Friendly name	Operation	Description
report by file type		
Viewed analytics review set report by source	AlgoGetReviewSetReportBySource	User viewed analytics document by source. This audit activity includes case and review set name and ID.
Viewed case metadata	CaseMetadataViewed	Metadata about an eDiscovery case was viewed.
Viewed case settings	CaseSettingsViewed	User viewed the settings for a case. Case settings include case information, premium feature access, case permissions, and settings that control search and analytics behavior.
Viewed data processing errors for a review set	ReviewSetDataProcessingErrorViewed	User viewed processing errors in a review set.
Viewed default case settings	CaseSettingsDefaultViewed	Default case setting viewed.
Viewed eDiscovery case	CaseViewed	A user viewed an eDiscovery case in the Microsoft Purview portal. The audit record for this event includes the name, case settings, and case ID of the case that was viewed.
Viewed eDiscovery case list	CaseListViewed	This activity is logged when a user viewed a list of eDiscovery cases. The audit record includes the name and ID of the cases that was viewed in the cases list.
Viewed favorite list	FavoriteListViewed	User viewed a list of favorite cases.
Viewed hold	HoldViewed	User viewed a hold inside a case. This audit activity includes the hold name and ID the user viewed. It also includes the specific data sources and query values inside the hold that was viewed by the user.
Viewed hold list	HoldListViewed	User viewed the holds list inside a case. This audit activity includes the case name, case ID, and the list of holds name and ID the user viewed.

Friendly name	Operation	Description
Viewed hold results	HoldResultsViewed	User viewed hold's results. The audit activity includes case name, case ID, hold name, and hold ID.
Viewed hold status	HoldStatusViewed	User viewed hold's status. The audit activity includes case name, case ID, hold name, and hold ID.
Viewed if analytics settings are changed	AlgoIsSettingChanged	This audit activity includes case and review set name and ID.
Viewed load count in case	LoadCountInCaseViewed	User viewed the count of load sets in a case.
Viewed load list	LoadListViewed	User viewed a list of load sets in review set.
Viewed Purview search	PurviewSearchViewed	User viewed a specific search. This audit activity includes the search name, ID, and the specific data sources and query values inside the search that was viewed by the user.
Viewed Purview search list	PurviewSearchListViewed	User viewed the searches list inside a case. This audit activity includes the case name, case ID, and the list of searches name and ID the user viewed.
Viewed query report for a review set	ReviewSetQueryReportViewed	User viewed query report inside a review set.
Viewed review set document	ReviewSetDocumentViewed	User viewed a document inside a review set. This audit activity includes the case name, case ID, review set name, review set ID and other information such as the ID of the document viewed.
Viewed review set list	ReviewSetListViewed	User viewed the list of review sets in a case.
Viewed review set summary	ReviewSetSummaryViewed	User viewed the Overview of a Review set.
Viewed sample results	SampleResultsViewed	User viewed search sample results view.

Friendly name	Operation	Description
Viewed sample status	SampleStatusViewed	User viewed search sample view's status. The audit activity includes search's name, ID, query, and associated settings.
Viewed saved search list for a review set	ReviewSetSavedSearchListViewed	User viewed a list of saved filters in a review set. The audit activity includes the review set name and the name of the list of saved filters viewed.
Viewed search count for a review set	ReviewSetSearchCountViewed	User ran a search within a review set and viewed the count returned. The audit activity includes the case name, review set name and the count of items returned in the search results.
Viewed search options for a review set	ReviewSetSearchOptionsViewed	User viewed the settings of a review set. The audit activity includes the case name and review set name.
Viewed search results for a review set	ReviewSetSearchRun	User ran a search within a review set. The audit activity includes the case name, review set name and the list of items returned in the search results.
Viewed statistics results	StatisticsResultsViewed	User viewed search statistics results.
Viewed statistics status	StatisticsStatusViewed	User viewed search statistics view's status. The audit activity includes search's name, ID, query, and associated settings.
Viewed tag template list	TagTemplateListViewed	User viewed the list of tag template in eDiscovery settings. The audit activity includes the list of tag templates viewed.
Viewed tags	TagsViewed	User viewed review set tags in a case.
Viewed tags for a tag template	TagTemplateTagsViewed	User viewed tags for a tag template. The audit activity includes the name and ID of the tag template tags viewed.
Viewed tenant settings	TenantSettingsViewed	User viewed eDiscovery's organization settings. The audit activity contains information on the setting values.

Detailed properties for eDiscovery activities

The following table lists the properties that the portal shows on the details page for an eDiscovery activity listed in the search results. These properties are also included in the CSV file when you export the audit log search results. An audit log record for an eDiscovery activity doesn't include every detailed property listed in the following table.

> **Tip**
>
> When you export the search results, the CSV file contains a column named **AuditData**, which contains the detailed properties described in the following table in a multivalue property. You can use the Power Query feature in Excel to split this column into multiple columns so that each property has its own column. This setup lets you sort and filter on one or more of these properties. For more information, see Search the audit log.

Property	Description
CaseId	The identity (GUID) of the eDiscovery case created, changed, or deleted.
CaseName	The name of the eDiscovery case created, changed, or deleted.
ClientApplication	eDiscovery cmdlet activities have a value of **EMC** for this property. This value indicates the activity was performed by using the Microsoft Purview portal GUI or running the cmdlet in PowerShell.
ClientIP	The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format.
ClientRequestId	For eDiscovery activities, this property is typically blank.
CmdletVersion	The build number for the version of the Microsoft Purview portal running in your organization.
CreationTime	The creation date and time in Coordinated Universal Time (UTC) for the activity.
DataSources	A list of source ID, source name, and location details associated to the activity.
EffectiveOrganization	The name of the Microsoft 365 organization.
ExportName	Name of the eDiscovery export.
ExtendedProperties	Additional properties related to the eDiscovery activity. For example, when case members are updated, this field contains the updated case member information; or when the review set description is updated, this field contains the updated review set description updated by the user.
ID	The ID of the report entry. The ID uniquely identifies the audit log entry.
Item	The name of the item associated with the activity. For example, this field contains the name of the document viewed when a user views a review set document.

Property	Description
JobId	The GUID of the eDiscovery process.
ObjectId	The GUID of the object (for example, a search, hold, or review set) created, accessed, or changed, by the activity listed in the *Operation* property.
ObjectName	The name of the object (for example, a search, hold or review set) created, accessed, or changed, by the activity listed in the Operation property.
ObjectType	The type of eDiscovery object created, deleted, or modified. For example, a search action (generate sample results or trigger an export from search) are listed as *Search* in this field.
Operation	The name of the operation that corresponds to the eDiscovery activity that was performed.
OrganizationId	The GUID for your Microsoft 365 organization.
QueryId	The GUID of the query associated with the activity.
QueryText	The query text associated with the activity, such as a search statistic process or add to review process.
RecordType	The type of operation indicated by the record.
ResultStatus	If the action (specified in the Operation property) was successful or not.
Settings	Settings applied to the eDiscovery activity.
StartTime	The date and time in Coordinated Universal Time (UTC) when the eDiscovery activity was started.
UserCancelled	Whether the specific activity was canceled by the user.
UserId	The user who performed the activity (specified in the Operation property) that resulted in the record being logged.
UserKey	An alternative ID for the user identified in the UserId property. For eDiscovery activities, the value for this property is typically the same as the UserId property.
UserServicePlan	The subscription used by your organization. For eDiscovery activities, this property is typically blank.
UserType	The type of user that performed the operation. The following values indicate the user type. 0 A regular user. 2 An administrator in your organization. 3 A Microsoft datacenter administrator or datacenter system account. 4 A system account. 5 An application. 6 A service principal.
Version	The version number of the activity (identified by the Operation property) that's logged.

Property	Description
Workload	The service where the activity occurred.

Encrypted message portal activities

Your organization can access logs for encrypted messages through the encrypted message portal. These logs help you determine when your external recipients read and forward messages. For more information about enabling and using encrypted message portal activity logs, see Encrypted message portal activity log.

Each audit entry for a tracked message contains the following fields:

- **MessageID**: Contains the ID of the message being tracked. Use this key identifier to follow a message through the system.
- **Recipient**: List of all recipient email addresses.
- **Sender**: The originating email address.
- **AuthenticationMethod**: Describes the authenticating method for accessing the message, such as OTP, Yahoo, Gmail, or Microsoft.
- **AuthenticationStatus**: Contains a value indicating that the authentication succeeded or failed.
- **OperationStatus**: Whether the indicated operation succeeded or failed.
- **AttachmentName**: Name of the attachment.
- **OperationProperties**: A list of optional properties. For example, the number of OTP passcodes sent, or the email subject.

eSignature activities

The following table lists the eSignature activities that the Microsoft 365 audit log records. For more information, see eSignature for Microsoft 365.

Friendly name	Operation	Description
Cancelled by the requestor	ESignatureRequestCanceled	The signing request was cancelled by the requestor.
Declined by a signer	ESignatureRequestDeclined	A signer declined the request.
Document was downloaded	ESignatureRequestDownloaded	The document was downloaded by a member of the workflow.
Document was viewed	ESignatureDocumentViewed	The document was viewed by a member of the workflow.

Friendly name	Operation	Description
Link to the signed document expired	ESignatureRequestExpired	The link to the signed document expired.
Request was completed	ESignatureRequestCompleted	An electronic signature request was completed.
Request was created	ESignatureRequestCreated	An electronic signature request was created by a member of the organization.
Request was sent	ESignatureRequestSent	An electronic signature request was sent to recipients.
Request was signed by a user	ESignatureDocumentSigned	An electronic signature request was signed by a recipient.

Exchange admin activities

Exchange administrator audit logging (which Microsoft 365 enables by default) logs an event in the audit log when an administrator (or a user assigned administrative permissions) makes a change in your Exchange Online organization. The Exchange admin audit log records changes made by using the Exchange admin center or by running a cmdlet in Exchange Online PowerShell. The audit log doesn't record cmdlets that begin with the verbs **Get-**, **Search-**, or **Test-**. For more detailed information about admin audit logging in Exchange, see Administrator audit logging.

> **ⓘ Important**
>
> Some Exchange Online cmdlets aren't logged in the Exchange admin audit log or in the audit log. Many of these cmdlets relate to maintaining the Exchange Online service and Microsoft datacenter personnel or service accounts run them. These cmdlets aren't logged because they would result in a large number of "noisy" auditing events. If there's an Exchange Online cmdlet that isn't being audited, submit a design change request (DCR) to Microsoft Support.

Use these tips to search for Exchange admin activities when searching the audit log:

- Use the date range boxes and the **Users** list to narrow the search results for cmdlets run by a specific Exchange administrator within a specific date range.
- Select the **Activity** column to sort the cmdlet names in alphabetical order and display events from the Exchange admin audit log.

- Select the **Download all results** option to export the search results and get information about what cmdlet was run, which parameters and parameter values were used, and what objects were affected. For more information, see Export, configure, and view audit log records.
- Use the `Search-UnifiedAuditLog -RecordType ExchangeAdmin` command in Exchange Online PowerShell to return only audit records from the Exchange admin audit log. It might take up to 30 minutes after an Exchange cmdlet is run for the corresponding audit log entry to be returned in the search results. For more information, see Search-UnifiedAuditLog. For information about exporting the search results returned by the **Search-UnifiedAuditLog** cmdlet to a CSV file, see the "Tips for exporting and viewing the audit log" section in Export, configure, and view audit log records.

Exchange mailbox activities

The following table lists the activities recorded in the Microsoft 365 audit log. Mailbox audit logging automatically logs mailbox activities performed by the mailbox owner, a delegated user, or an administrator in the audit log for up to 180 days. An admin can turn off mailbox audit logging for all users in your organization. In this case, no mailbox actions for any user are logged. For more information, see Manage mailbox auditing.

> **Important**
>
> The default retention period for Audit (Standard) changed from 90 days to 180 days. Audit (Standard) logs generated before October 17, 2023, are retained for 90 days. Audit (Standard) logs generated on or after October 17, 2023, follow the new default retention of 180 days.

You can also search for mailbox activities by using the **Search-UnifiedAuditLog** cmdlet in Exchange Online PowerShell.

Friendly name	Operation	Description
Accessed mailbox attachments	AttachmentAccess	A message attachment was accessed.
Accessed Mailbox folder	FolderBind	A mailbox folder was accessed. This action is also logged when the admin or delegate opens the mailbox. Audit records for folder bind actions performed by delegates are consolidated. One audit record is

Friendly name	Operation	Description
		generated for individual folder access within a 24-hour period.
Accessed mailbox items	MailItemsAccessed	Messages were read or accessed in mailbox. Audit records for this activity are triggered in one of two ways: when a mail client (such as Outlook) performs a bind operation on messages or when mail protocols (such as Exchange ActiveSync or IMAP) sync items in a mail folder. Analyzing audit records for this activity is useful when investigating compromised email account.
Accessed message	MessageBind	A message was viewed in the preview pane or opened by an admin. This value is available only for users without E5/A5/G5 licenses.
Added delegate mailbox permissions	Add-MailboxPermission	An administrator assigned the FullAccess mailbox permission to a user (known as a delegate) to another person's mailbox. The FullAccess permission allows the delegate to open the other person's mailbox, and read and manage the contents of the mailbox. The audit record for this activity is also generated when a system account in the Microsoft 365 service periodically performs maintenance tasks in behalf of your organization. A common task performed by a system account is updating the permissions for system mailboxes. For more information, see System accounts in Exchange mailbox audit records.
Added or removed user with delegate access to calendar folder	UpdateCalendarDelegation	A user was added or removed as a delegate to the calendar of another user's mailbox. Calendar delegation gives someone else in the same organization permissions to manage the mailbox owner's calendar.
Added permissions to folder	AddFolderPermissions	A folder permission was added. Folder permissions control which users in your organization can access folders in a mailbox and the messages located in those folders.
Copied messages to another folder	Copy	A message was copied to another folder.
Created mailbox item	Create	An item is created in the Calendar, Contacts, Notes, or Tasks folder in the mailbox. For example, a new meeting request is created. Creating, sending, or receiving a message isn't audited. Also, creating a mailbox folder isn't audited.

Friendly name	Operation	Description
Created new inbox rule in Outlook web app	New-InboxRule	A mailbox owner or other user with access to the mailbox created an inbox rule in the Outlook web app.
Delete priority cleanup label item	PriorityCleanupDelete	The item with a label of Priority Cleanup type is getting deleted.
Deleted messages from Deleted Items folder	SoftDelete	A message was permanently deleted or deleted from the Deleted Items folder. These items are moved to the Recoverable Items folder. Messages are also moved to the Recoverable Items folder when a user selects it and presses **Shift+Delete**.
Label message as a record		A user applied a retention label to an email message and that label is configured to mark the item as a record.
Labeled item as a record	ApplyRecord	An item is labeled as a record.
Labeled message as a record	ApplyRecordLabel	A message was classified as a record. Occurs when a retention label that classifies content as a record is manually or automatically applied to a message.
Modified folder permission	ModifyFolderPermissions	A folder permission was changed. Folder permissions control which users in your organization can access mailbox folders and the messages in the folder.
Modified inbox rule from Outlook web app	Set-InboxRule	A mailbox owner or other user with access to the mailbox modified an inbox rule using the Outlook web app.
Moved messages to another folder	Move	A message was moved to another folder.
Moved messages to Deleted Items folder	MoveToDeletedItems	A message was deleted and moved to the Deleted Items folder.
Perform search query	SharepointSearchQueryInitiated	The user performs a search on SharePoint.
Preserve Mailbox item	PreservedMailItemProactively	The mail item is proactively preserved. Proactive preservation is a Microsoft Purview Data Lifecycle

Friendly name	Operation	Description
		Management (DLM) feature, where mails deleted by risky users in the tenant are preserved in dumpster.
Priority cleanup label applied	ApplyPriorityCleanup	The Priority Cleanup label is applied to an item.
Priority cleanup label applied on Exchange item	ApplyPriorityCleanup	A retention label for priority cleanup is applied to an item on Exchange.
Purged messages from the mailbox	HardDelete	A message was purged from the Recoverable Items folder (permanently deleted from the mailbox).
Removed delegate mailbox permissions	Remove-MailboxPermission	An administrator removed the FullAccess permission (that was assigned to a delegate) from a person's mailbox. After the FullAccess permission is removed, the delegate can't open the other person's mailbox or access any content in it.
Removed permissions from folder	RemoveFolderPermissions	A folder permission was removed. Folder permissions control which users in your organization can access folders in a mailbox and the messages located in those folders.
Search items in a mailbox	SearchQueryInitiated	A person uses Outlook (Windows, Mac, iOS, Android, or Outlook on the web) or the Mail app for Windows 10 to search for items in a mailbox.
Sent message	Send	A message was sent, replied to, or forwarded.
Sent message using Send As permissions	SendAs	A message was sent using the SendAs permission. This means that another user sent the message as though it came from the mailbox owner.
Sent message using Send On Behalf permissions	SendOnBehalf	A message was sent using the SendOnBehalf permission. This means that another user sent the message on behalf of the mailbox owner. The message the recipient to whom the message was sent on behalf of and who actually sent the message.
Update item label	UpdateComplianceTag	When the label is applied to an item.
Updated inbox rules from Outlook client	UpdateInboxRules	A mailbox owner or other user with access to the mailbox created, modified, or removed an inbox rule by using the Outlook client.

Friendly name	Operation	Description
Updated message	Update	A message or its properties was changed.
User signed in to mailbox	MailboxLogin	The user signed in to their mailbox.

System accounts in Exchange mailbox audit records

In audit records for some mailbox activities, especially **Add-MailboxPermissions**, you might see the user who performed the activity identified as NT AUTHORITY\SYSTEM or NT SERVICE\MSExchangeAdminApiNetCore(Microsoft.Exchange.AdminApi.NetCore). This system account in the Exchange service in the Microsoft cloud performs scheduled maintenance tasks on behalf of your organization. For example, a common audited activity performed by the NT SERVICE\MSExchangeAdminApiNetCore(Microsoft.Exchange.AdminApi.NetCore) account is updating the permissions on the DiscoverySearchMailbox, which is a system mailbox. This update verifies that the FullAccess permission (which is the default) is assigned to the Discovery Management role group for the DiscoverySearchMailbox. This update ensures that eDiscovery administrators can perform necessary tasks in their organization.

Another system user account that might appear in an audit record for **Add-MailboxPermission** is Administrator@apcprd03.prod.outlook.com. This service account also appears in mailbox audit records related to verifying and updating the FullAccess permission assigned to the Discovery Management role group for the DiscoverySearchMailbox system mailbox. Specifically, audit records that identify the Administrator@apcprd03.prod.outlook.com account typically trigger when Microsoft support personnel run a role-based access control diagnostic tool on behalf of your organization.

Fabric activities

The following table lists the Microsoft Fabric activities in Power BI that the Microsoft 365 audit log records. You can search the audit log for these activities in Power BI. For information about audit settings, see Audit and usage tenant settings.

Friendly name	Operation	Description
Applied a PostgreSQL database schema	ApplyPostgreSQLDatabaseSchema	Generated when a user applies (plans and executes) a PostgreSQL database schema through the custom PG schema service (pgschema-based ALM

Friendly name	Operation	Description
		flow). The audit log records caller identity, operation result, and the affected PostgreSQL database artifact.
Assign Warehouse Server Alias	AssignWarehouseServerAlias	A workspace administrator assigned a server alias to a Fabric Warehouse workspace.
Automatically bound user credentials to Git	AutoBoundGitCredentials	Automatically bound user credentials to Git.
Branch workspace admin profile configured	GitBranchWorkspaceAdminProfileConfigured	Branch workspace admin profile configured.
Branch workspace configured	GitBranchWorkspaceConfigured	Branch workspace configured.
Branched out to a workspace in Git	GitBranchedOut	Branched out to a workspace in Git.
Browsed PostgreSQL database objects	PgSQLDbObjectExplorer	Generated when a user browses PostgreSQL database schema objects through Object Explorer. The audit log records caller identity, operation result, and the affected PostgreSQL database artifact.
Cancelled a Digital Operations Ontology Agent conversation	DigitalOperationsOntologyAgentConversationCancelled	A user canceled a Digital Operations Ontology Agent conversation.
Checked out Git branch	GitCheckedOutBranch	Checked out Git branch.
Compute Items Sizes	ComputeItemsSize	Calculated current size of all items for the OneLake item-size report.

Friendly name	Operation	Description
Create the cross tenant auth mapping	CreateCrossTenantAuthMapping	Create a user mapping for the cross tenant auth feature.
Created Artifact Definition	CreatedArtifactDefinition	Created Artifact Definition is a Fabric External Sources activity which is generated when an External Sources artifact definition is created. Shared across item types: for MirroredStorage it carries SourceType and ConnectionId; for AWS Databricks Catalog it carries CatalogName, WorkspaceConnectionId, and MirroringMode.
Created AWS Databricks Catalog	CreatedAWSDatabricksCatalog	Created AWS Databricks Catalog is an AWSDatabricksCatalog activity which is generated when a Fabric AWS Databricks Catalog item is created, capturing the bound AWS Databricks workspace ConnectionId and the initial MirroredScope (catalogs/schemas/tables selected for mirroring).
Created a Digital Operations Ontology Agent conversation	DigitalOperationsOntologyAgentConversationCreated	A user created a Digital Operations Ontology Agent conversation.
Created a Fabric Copilot session	FabricCopilotSessionCreated	A user created a Fabric Copilot session.
Create a Microsoft Fabric free trial	CreatedFabricTrial	A new Microsoft Fabric free trial capacity was started.
Created MirroredStorage	CreatedMirroredStorage	Generated when a user or service principal creates a Fabric MirroredStorage item, linking an external storage source to a workspace as OneLake shortcuts.

Friendly name	Operation	Description
Created workspace relation	CreatedWorkspaceRelation	Created workspace relation.
Deleted a Fabric Copilot session	FabricCopilotSessionDeleted	A user deleted a Fabric Copilot session.
Deleted a task flow	DeletedTaskFlow	Deleted a task flow.
Deleted connection by tenant admin	DeletedGatewayClusterDatasourceAsAdmin	A tenant admin deleted the connection.
Deleted connection role assignment by tenant admin	DeletedGatewayDatasourceByAdmin	A tenant admin deleted the connection role assignment.
Deleted workspace relation	DeletedWorkspaceRelation	Deleted workspace relation.
Downloaded dataflow refresh logs	DownloadedDataflowRefreshLogs	Downloaded dataflow refresh logs.
Edited Power BI semantic model options	EditedSemanticModelOptions	A user made a change to their semantic model options. This occurs when changes are made in the model options dialog.
Executed a tenant relocation	TenantRelocationExecuted	Executed tenant relocation.
Export item definitions	ExportItemDefinitions	Export multiple item definitions from a workspace.
Exported a PostgreSQL database schema	ExportPostgreSQLDatabaseSchema	Generated when a user dumps a PostgreSQL database schema through the custom PG schema service (pgschema-based ALM flow). The audit log records caller identity, operation result, and the affected PostgreSQL database artifact.

Friendly name	Operation	Description
Get Items Sizes	GetItemsSize	Retrieved cached item sizes for the OneLake item-size report.
Get connection by tenant admin	GetGatewayClusterDatasourceAsAdmin	A tenant admin retrieved the connection details.
Get on-demand billing limits	GetOnDemandBillingLimits	Generated when a capacity admin opens the On-demand billing page and the current billing categories and their 24-hour compute limits are returned for a Fabric capacity.
Get on-demand billing quota	GetOnDemandBillingQuota	Generated when the On-demand billing experience loads and the subscription-level on-demand billing quota usage and limits are retrieved.
Get Capacity Overage Config. This can happen via Public API or using UX.	GetCapacityOverageBillingConfiguration	Get Capacity Overage Config. This can happen via Public API or using UX.
Git connection settings updated	GitConnectionSettingsUpdated	Git connection settings updated.
Granted consent to tenant relocation	TenantRelocationConsentGranted	Tenant relocation consent granted.
Import item definitions	ImportItemDefinitions	Import multiple item definitions into a workspace.
Imported OneLake lifecycle policy	ImportedLifecyclePolicy	Imported OneLake Lifecycle policy.
Imported PostgreSQL sample data	ImportSampleDataToPostgreSQLDatabase	Generated when a user imports supported sample data into a Fabric Native PostgreSQL database. The audit log records caller identity, operation result, and the affected PostgreSQL database artifact.

Friendly name	Operation	Description
Initialized connection to Git	GitConnectionInitialized	Initialized connection to Git.
Item definition exported	ItemDefinitionExported	A Fabric item definition has been exported.
List all of the cross tenant auth mappings	ListCrossTenantAuthMappings	List cross tenant auth mappings in a tenant.
Logged in to Git provider	ConfiguredGitProviderCredentials	Logged in to Git provider.
Logged out of Git provider	DeletedGitProviderCredentials	Logged out of Git provider.
Microsoft Fabric Audit activity to retrieve FMI bindings	GetFabricManagedIdentityBindings	Microsoft Fabric Audit activity to retrieve FMI bindings.
Migrate Gen1 dataflow	MigrateGen1Dataflow	A user upgraded a Power BI Gen1 dataflow to a Fabric Gen2.1 dataflow in place by using the Upgrade Wizard.
Modified OneLake default tier	ModifiedDefaultTier	Modified OneLake default tier.
Modified OneLake file soft-delete settings	ModifiedOneLakeFileSoftDeleteSettings	Generated when a workspace admin changes the OneLake file-level soft-delete retention settings (enable/disable, retention period).
Planning session upgraded	PlanningSessionUpgraded	Session type is upgraded in planning workload.
Recover an artifact	ArtifactRecovered	A user recovered a previously soft-deleted artifact, such as a gateway or gateway cluster member, restoring it to active state.
Refreshed AWS Databricks	RefreshedAWSDatabricksCatalogShortcuts	Refreshed AWS Databricks Catalog shortcuts is an

Friendly name	Operation	Description
Catalog Shortcuts		AWSDatabricksCatalog activity which is generated when the refresh-catalog-metadata operation re-syncs the already-mirrored shortcuts against the underlying AWS Databricks Unity Catalog.
Retrieved artifact's Logical Id	ArtifactLogicalIdRetrieved	Retrieved artifact's Logical Id.
Retrieved PostgreSQL SQL audit policy	GetSqlAuditPolicyOnDatabase	Generated when a user retrieves the SQL audit policy settings for a PostgreSQL database artifact. The audit log records caller identity, operation result, and the affected PostgreSQL database artifact.
Revoked consent to tenant relocation	TenantRelocationConsentRevoked	Tenant relocation consent revoked.
Sent a Digital Operations Ontology Agent message	DigitalOperationsOntologyAgentMessageSent	A user sent a message in a Digital Operations Ontology Agent conversation.
Sent a Fabric Copilot message	FabricCopilotSessionMessageSent	A user sent a message in a Fabric Copilot session.
Set PostgreSQL SQL audit policy	SetSqlAuditPolicyOnDatabase	Generated when a user updates SQL audit policy settings for a PostgreSQL database artifact. The audit log records caller identity, operation result, and the affected PostgreSQL database artifact.
Set Warehouse Connection Mode To Automatic	SetWarehouseConnectionModeToAutomatic	A workspace administrator set the Fabric Warehouse SQL connection mode to Automatic.

Friendly name	Operation	Description
Set Warehouse Connection Mode To Proxy	SetWarehouseConnectionModeToProxy	A workspace administrator set the Fabric Warehouse SQL connection mode to Proxy.
Set Warehouse Connection Mode To Redirect	SetWarehouseConnectionModeToRedirect	A workspace administrator set the Fabric Warehouse SQL connection mode to Redirect.
Set Warehouse Hardware Acceleration	SetWarehouseHardwarePlatform	Changed the current hardware acceleration settings for warehouses in a workspace.
Soft delete an artifact	ArtifactSoftDeleted	A user soft deleted an artifact, such as a gateway or gateway cluster member, marking it for deletion while allowing recovery within a retention period.
Switched Git branch	GitSwitchedBranch	Switched Git branch for workspace.
Update on-demand billing limits	UpdateOnDemandBillingLimits	Generated when a capacity admin enables or disables a billing category, or changes its 24-hour compute limit, on a Fabric capacity. One audit event is emitted per billing category.
Update Capacity Overage Config. This can happen via Public API or using UX.	UpdateCapacityOverageBillingConfiguration	Update Capacity Overage Config. This can happen via Public API or using UX.
Updated a Fabric Copilot session	FabricCopilotSessionUpdated	A user updated a Fabric Copilot session.
Updated a Fabric Copilot session state	FabricCopilotSessionStateUpdated	A user updated the state of a Fabric Copilot session.
Updated artifact's Logical Id	ArtifactLogicalIdUpdated	Updated artifact's Logical Id.

Friendly name	Operation	Description
Updated authorization setting in GraphQL	UpdatedAuthorizationSettingGraphQL	Updated authorization setting in GraphQL.
Updated Artifact Definition	UpdatedArtifactDefinition	Updated Artifact Definition is a Fabric External Sources activity which is generated when an External Sources artifact definition is updated via the update-item-definition API. Shared across item types (e.g. MirroredStorage, AWS Databricks Catalog); the properties carried depend on the item type.
Updated AWS Databricks Catalog Definition	UpdatedAWSDatabricksCatalogDefinition	Updated AWS Databricks Catalog definition is an AWSDatabricksCatalog activity which is generated when the item's Databricks workspace connection or mirrored scope (catalogs/schemas/tables) is updated via the update-item-definition API.
Updated connection role assignment by tenant admin	UpdatedGatewayDatasourceByAdmin	A tenant admin add or updates the connection role assignment.
Updated git items selection	GitItemsSelectionUpdated	Updated git items selection.
Updated MirroredStorage definition	UpdatedMirroredStorageDefinition	Generated when a user or service principal modifies the mirroring scope of an existing MirroredStorage item, changing which external paths are exposed in OneLake.
Unassign Warehouse Server Alias	UnassignWarehouseServerAlias	A workspace administrator assigned a server alias to a Fabric Warehouse workspace.
Workspace relations	WorkspaceRelationsRetrieved	Workspace relations retrieved.

Friendly name	Operation	Description
retrieved		

File and page activities

The following table lists the file and page activities in SharePoint and OneDrive that the Microsoft 365 audit log records.

Friendly name	Operation	Description
(none)	FileAccessedExtended	This activity is related to the "Accessed file" (FileAccessed) activity. A FileAccessedExtended event is logged when the same person continually accesses a file for an extended period (up to three hours). The purpose of logging FileAccessedExtended events is to reduce the number of FileAccessed events that are logged when a file is continually accessed. This approach helps reduce the noise of multiple FileAccessed records for what is essentially the same user activity, and lets you focus on the initial (and more important) FileAccessed event.
(none)	FileModifiedExtended	This activity is related to the "Modified file" (FileModified) activity. A FileModifiedExtended event is logged when the same person continually modifies a file for an extended period (up to three hours). The purpose of logging FileModifiedExtended events is to reduce the number of FileModified events that are logged when a file is continually modified. This approach helps reduce the noise of multiple FileModified records for what is essentially the same user activity, and lets you focus on the initial (and more important) FileModified event.

Friendly name	Operation	Description
(none)	FilePreviewed	User previews files on a SharePoint or OneDrive site. These events typically occur in high volumes based on a single activity, such as viewing an image gallery.
(none)	PagePrefetched	A user's client (such as website or mobile app) requests the indicated page to help improve performance if the user browses to it. This event is logged to indicate that the page content is served to the user's client. This event isn't a definitive indication that the user navigated to the page. When the client renders the page content (as per the user's request), it should generate a ClientViewSignaled event. Not all clients support indicating a prefetch, and therefore some prefetched activities might instead be logged as PageViewed events.
(none)	PageViewedExtended	This activity is related to the "Viewed page" (PageViewed) activity. A PageViewedExtended event is logged when the same person continually views a web page for an extended period (up to three hours). The purpose of logging PageViewedExtended events is to reduce the number of PageViewed events that are logged when a page is continually viewed. This approach helps reduce the noise of multiple PageViewed records for what is essentially the same user activity, and lets you focus on the initial (and more important) PageViewed event.
Accessed file	FileAccessed	User or system account accesses a file. After a user accesses a file, the system doesn't log the FileAccessed event again for the same user and file for the next five minutes.

Friendly name	Operation	Description
Archived file	FileArchived	A user or system account archived a file with Microsoft 365 Archive. When an automatic file archive policy archives the file, the event includes the policy ID, policy version, and the file's last access date.
Changed record status to locked	LockRecord	The record status of a retention label that classifies a document as a record is locked. This status means the document wasn't modified or deleted. Only users assigned at least the contributor permission for a site can change the record status of a document.
Changed record status to unlocked	UnlockRecord	The record status of a retention label that classifies a document as a record is unlocked. This status means that the document can be modified or deleted. Only users assigned at least the contributor permission for a site can change the record status of a document.
Changed retention label for a file	ComplianceSettingChanged	A retention label is applied to or removed from a document. This event is triggered when a retention label is manually or automatically applied to a message.
Checked in file	FileCheckedIn	User checks in a document that they checked out from a document library.
Checked out file	FileCheckedOut	User checks out a document located in a document library. Users can check out and make changes to documents that are shared with them.
Copied file	FileCopied	User copies a document from a site. The copied file can be saved to another folder on the site.
Deleted file	FileDeleted	User deletes a document from a site.
Deleted file from recycle	FileDeletedFirstStageRecycleBin	User deletes a file from the recycle bin of a site.

Friendly name	Operation	Description
bin		
Deleted file from second-stage recycle bin	FileDeletedSecondStageRecycleBin	User deletes a file from the second-stage recycle bin of a site.
Deleted file marked as a record	RecordDelete	A document or email that was marked as a record is deleted. An item is considered as a record when a retention label that marks items as a record is applied to content.
Detected document sensitivity mismatch	DocumentSensitivityMismatchDetected	User uploads a document to a site that's protected with a sensitivity label and the document has a higher priority sensitivity label than the sensitivity label applied to the site. For example, a document labeled Confidential is uploaded to a site labeled General. This event isn't triggered if the document has a lower priority sensitivity label than the sensitivity label applied to the site. For example, a document labeled General is uploaded to a site labeled Confidential. For more information about sensitivity label priority, see Label priority (order matters).
Detected malware in file	FileMalwareDetected	SharePoint anti-virus engine detects malware in a file.
Discarded file checkout	FileCheckOutDiscarded	User discards (or undoes) a checked out file. That means any changes they made to the file when it was checked out are discarded, and not saved to the version of the document in the document library.
Downloaded file	FileDownloaded	User downloads a document from a site.
Modified file	FileModified	User or system account modifies the content or the properties of a document on a site. The system waits five minutes before it logs another

Friendly name	Operation	Description
		FileModified event when the same user modifies the content or properties of the same document.
Moved file	FileMoved	User moves a document from its current location on a site to a new location.
Performed search query	SearchQueryPerformed	User or system account performs a search in SharePoint or OneDrive. Some common scenarios where a service account performs a search query include applying an eDiscovery holds and retention policy to sites and OneDrive accounts, and autoapplying retention or sensitivity labels to site content. To enable logging for this activity, see Get started with auditing solutions.
Priority cleanup move file to recycle bin	PriorityCleanupFileRecycled	An item is moved to Stage 2 recycle bin by a priority cleanup policy on OneDrive or SharePoint Online.
Priority cleanup permanent delete of file	PriorityCleanupFileDeleted	An item is permanently deleted by a priority cleanup policy on OneDrive or SharePoint Online.
Reactivated file	FileUnarchived	A file archived with Microsoft 365 Archive was reactivated and is available to access.
Recycled a file	FileRecycled	User moves a file into the SharePoint Recycle Bin.
Recycled a folder	FolderRecycled	User moves a folder into the SharePoint Recycle Bin.
Recycled all minor versions of file	FileVersionsAllMinorsRecycled	User deletes all minor versions from the version history of a file. The deleted versions are moved to the site's recycle bin.
Recycled all versions of file	FileVersionsAllRecycled	User deletes all versions from the version history of a file. The deleted

Friendly name	Operation	Description
		versions are moved to the site's recycle bin.
Recycled version of file	FileVersionRecycled	User deletes a version from the version history of a file. The deleted version is moved to the site's recycle bin.
Renamed file	FileRenamed	User renames a document.
Requested file reactivation	FileUnarchiveRequested	A user requested to reactivate a file archived with Microsoft 365 Archive.
Restored file	FileRestored	User restores a document from the recycle bin of a site.
Started bulk deleting file versions	FileVersionBulkDeletionStarted	Admin started a bulk deletion of file versions across a SharePoint site or document library to reclaim storage space by permanently removing old versions that exceed the version policy.
Started bulk expiring file versions by using a schedule file	FileVersionBulkExpirationByScheduleStarted	Admin starts a bulk expiration of file versions using a schedule file on a SharePoint site, applying version expiration according to that schedule.
Started generating file version expiration report	FileVersionExpirationReportStarted	Admin started generating a file version expiration report for a SharePoint site or document library that includes certain version metadata and expiration information.
Started tenant apply file version policy	TenantApplyFileVersionPolicyStarted	Admin started applying the tenant-level file version policy across all sites in the organization, which sets version limits or trims existing versions for all document libraries tenant-wide.
Started updating version settings on all document libraries in the site	DocumentLibraryVersionPolicyBulkUpdateStarted	Admin started a bulk update of version policy settings across all document libraries in a SharePoint site.
Uploaded file	FileUploaded	User uploads a document to a folder

Friendly name	Operation	Description
		on a site.
View signaled by client	ClientViewSignaled	A user's client (such as website or mobile app) signals that the indicated page is viewed by the user. This activity is often logged following a PagePrefetched event for a page. **NOTE**: Because ClientViewSignaled events are signaled by the client, rather than the server, it's possible the event might not be logged by the server and therefore might not appear in the audit log. It's also possible that information in the audit record might not be trustworthy. However, because the user's identity is validated by the token used to create the signal, the user's identity listed in the corresponding audit record is accurate. The system waits five minutes before it logs the same event when the same user's client signals that the page is viewed again by the user.
Viewed page	PageViewed	User views a page on a site. This activity doesn't include using a Web browser to view files located in a document library. After a user views a page, the system doesn't log the PageViewed event again for the same user and page for the next five minutes.

Frequently asked questions about FileAccessed and FilePreviewed events

Can non-user activities trigger FilePreviewed audit records that include a user agent like "OneDriveMpc-Transform_Thumbnail"?

There are no known scenarios where non-user actions generate events like these. User actions like opening a user profile card (by selecting their name or email address in a message in Outlook on the web) generate similar events.

Are calls to the OneDriveMpc-Transform_Thumbnail always intentionally triggered by the user?

No. But browser prefetch can result in similar events.

If I see a FilePreviewed event coming from a Microsoft-registered IP address, does that mean the preview shows on the screen of the user's device?

No. Browser prefetch might log the event.

Are there scenarios where a user previewing a document generates FileAccessed events?

Both the FilePreviewed and FileAccessed events indicate that a user's call led to a read of the file (or a read of a thumbnail rendering of the file). While these events are intended to align with preview versus access intention, the event distinction isn't a guarantee of the user's intent.

What causes FileAccessed audit events in Insider Risk Management scenarios?

Creating a case in Insider Risk Management and enabling Content Explorer generates and records a FileAccessed event in the audit log. In this scenario, the event is generated by the Insider Risk Management/Content Explorer workflow rather than by a direct user file-open action, and the same ApplicationId value, `00001111-aaaa-2222-bbbb-3333cccc4444`, is used for these events. This is important for administrators because it helps distinguish these system-generated FileAccessed events from other FileAccessed activity during an investigation. You can use the ApplicationId field as one of the properties to help identify or filter these specific events when reviewing audit log results.

The app@sharepoint user in audit records

In audit records for some file activities (and other SharePoint-related activities), you might notice the user who performed the activity (identified in the User and UserId fields) is app@sharepoint. This user means that an application performed the activity. In this case, the application was granted permissions in SharePoint to perform organization-wide actions (such as searching a SharePoint site or OneDrive account) on behalf of a user, admin, or service. This process of giving permissions to an application is called *SharePoint App-Only* access. This user means that an application, instead of a user, presented the authentication to SharePoint to perform an action. This is why the app@sharepoint user is identified in certain audit records. For more information, see Grant access using SharePoint App-Only.

For example, app@sharepoint is often identified as the user for "Performed search query" and "Accessed file" events. That's because an application with SharePoint App-Only access in your organization performs search queries and accesses files when applying retention policies to sites and OneDrive accounts.

Here are a few other scenarios where app@sharepoint might be identified in an audit record as the user who performed an activity:

- **Microsoft 365 Groups**. When a user or admin creates a new group, audit records are generated for creating a site collection, updating lists, and adding members to a SharePoint group. An application performs these tasks on behalf of the user who created the group.
- **Microsoft Teams**. Similar to Microsoft 365 Groups, audit records are generated for creating a site collection, updating lists, and adding members to a SharePoint group when a team is created.
- **Compliance features**. When an admin implements compliance features, such as retention policies, eDiscovery holds, and autoapplying sensitivity labels.

In these and other scenarios, you might also notice that multiple audit records with app@sharepoint as the specified user were created within a short time frame, often within a few seconds of each other. This pattern also means they were probably triggered by the same user-initiated task. Also, the ApplicationDisplayName and EventData fields in the audit record might help you identify the scenario or application that triggered the event.

Microsoft 365 Archive file-level policy activities

The following table lists Microsoft 365 Archive file-level policy activities in SharePoint and OneDrive that are recorded in the Microsoft 365 audit log. For audit activity generated when an individual file is archived, see File and page activities.

Friendly name	Operation	Description
Added site to file archive policy	FileArchivePolicySiteAdded	An admin added a site to an automatic file archive policy.
Changed file archive policy	FileArchivePolicyChanged	An admin changed an automatic file archive policy.
Completed file archive policy run	FileArchivePolicyRunCompleted	A run of an automatic file archive policy completed. The event includes the run outcome, number of files archived, amount of storage archived, number of sites processed, and whether the policy ran in what-if mode.
Created file archive policy	FileArchivePolicyCreated	An admin created an automatic file archive policy.
Deleted file archive policy	FileArchivePolicyDeleted	An admin deleted an automatic file archive policy.

Friendly name	Operation	Description
Removed site from file archive policy	FileArchivePolicySiteRemoved	An admin removed a site from an automatic file archive policy.
Started file archive policy	FileArchivePolicyStarted	An admin started an automatic file archive policy.

Folder activities

The following table lists the folder activities in SharePoint and OneDrive recorded in the Microsoft 365 audit log. Audit records for some SharePoint activities indicate the app@sharepoint user performed the activity on behalf of the user or admin who initiated the action. For more information, see The app@sharepoint user in audit records.

Friendly name	Operation	Description
Copied folder	FolderCopied	User copies a folder from a site to another location in SharePoint or OneDrive.
Created folder	FolderCreated	User creates a folder on a site.
Deleted folder	FolderDeleted	User deletes a folder from a site.
Deleted folder from recycle bin	FolderDeletedFirstStageRecycleBin	User deletes a folder from the recycle bin on a site.
Deleted folder from second-stage recycle bin	FolderDeletedSecondStageRecycleBin	User deletes a folder from the second-stage recycle bin on a site.
Modified folder	FolderModified	User modifies a folder on a site. This action includes changing the folder metadata, such as changing tags and properties.
Moved folder	FolderMoved	User moves a folder to a different location on a site.
Renamed folder	FolderRenamed	User renames a folder on a site.
Restored folder	FolderRestored	User restores a deleted folder from the recycle bin on a site.

Forms activities

The following table lists the user and admin activities in Microsoft Forms that the Microsoft 365 audit log records. Microsoft Forms is a forms, quiz, and survey tool you can use to collect data for

analysis. Some operations include additional activity parameters, as noted in the descriptions.

If a coauthor or an anonymous responder performs a Forms activity, the audit log records it slightly differently. For more information, see the Forms activities performed by coauthors and anonymous responders section.

Friendly name	Operation	Description
Added form coauthor	AddFormCoauthor	A user uses a collaboration link to help design the form or view responses. This event is logged when a user uses a collaboration URL (not when the collaboration URL is first generated).
Added specific responder	AddSpecificResponder	Form owner adds a new user or group to the specific responders list.
Allowed share form for copy	AllowShareFormForCopy	Form owner creates a template link to share the form with other users. This event is logged when the form owner selects to generate the template URL.
Connected to Excel workbook	ConnectToExcelWorkbook	Connected the form to an Excel workbook. Property ExcelWorkbookLink:string is the associated Excel workbook ID of the current form.
Created a collection	CollectionCreated	Form owner created a collection.
Created comment	CreateComment	Form owner adds comment or score to a quiz.
Created form	CreateForm	Form owner creates a new form. Property DataMode:string is the current form is set to sync with a new or existing Excel workbook if the property value equals DataSync. Property ExcelWorkbookLink:string is the associated Excel workbook ID of the current form.
Created response	CreateResponse	Similar to receiving a new response. A user submitted a response to a form. Property ResponseId:string and Property ResponderId:string is which result is being viewed. For an anonymous responder, the ResponderId property is null.
Created summary link	GetSummaryLink	Form owner creates summary results link to share results.

Friendly name	Operation	Description
Deleted all responses	DeleteAllResponses	Form owner deletes all response data.
Deleted collection from the Recycle Bin	CollectionHardDeleted	Form owner hard-deleted a collection from the Recycle Bin.
Deleted form	DeleteForm	Form owner deletes a form. This action includes SoftDelete (delete option used and form moved to recycle bin) and HardDelete (Recycle bin is emptied).
Deleted Response	DeleteResponse	Form owner deletes one response. Property ResponseId:string is the response being deleted.
Deleted summary link	DeleteSummaryLink	Form owner deletes summary results link.
Disabled anyone can respond setting	DisallowAnonymousResponse	Form owner turns off the setting allowing anyone to respond to the form.
Disabled collaboration	DisableCollaboration	Form owner turns off the setting of collaboration on the form.
Disabled specific people can respond setting	DisableSpecificResponse	Form owner turns off the setting allowing only specific people or specific groups in the current organization to respond to the form.
Disallowed share form for copy	DisallowShareFormForCopy	Form owner deletes template link.
Edited form	EditForm	Form owner edits a form such as creating, removing, or editing a question. The property *EditOperation:string* is the edit operation name. The possible operations are: - CreateQuestion - CreateQuestionChoice - DeleteQuestion - DeleteQuestionChoice - DeleteFormImage - DeleteQuestionImage - UpdateQuestion - UpdateQuestionChoice - UploadFormImage/Bing/Onedrive

Friendly name	Operation	Description
		- UploadQuestionImage - ChangeTheme FormImage includes any place within Forms where the user can upload an image, such as in a query or as a background theme.
Enabled anyone can respond setting	AllowAnonymousResponse	Form owner turns on the setting allowing anyone to respond to the form.
Enabled Office 365 work or school account collaboration	EnableWorkOrSchoolCollaboration	Form owner turns on the setting allowing users with a Microsoft 365 work or school account to view and edit the form.
Enabled people in my organization collaboration	EnableSameOrgCollaboration	Form owner turns on the setting allowing users in the current organization to view and edit the form.
Enabled specific people can respond setting	EnableSpecificResponse	Form owner turns on the setting allowing only specific people or specific groups in the current organization to respond to the form.
Enabled specific people collaboration	EnableSpecificCollaboaration	Form owner turns on the setting allowing only specific people or specific groups in the current organization to view and edit the form.
Exported form	ExportForm	Form owner exports results to Excel. Property ExportFormat:string is if the Excel file is Download or Online.
Listed forms	ListForms	Form owner is viewing a list of forms. Property ViewType:string is which view the form owner is looking at: All Forms, Shared with Me, or Group Forms.
Moved a form into collection	MovedFormIntoCollection	Form owner moved a form into a collection.
Moved a form out of collection	MovedFormOutofCollection	Form owner moved a form out of a collection.

Friendly name	Operation	Description
Moved collection to the Recycle Bin	CollectionSoftDeleted	Form owner moved a collection to the Recycle Bin.
Moved form	MoveForm	Form owner moves a form. Property DestinationUserId:string is the user ID of the person who moved the form. Property NewFormId:string is the new ID for the newly copied form. Property IsDelegateAccess:boolean is the current form move action is performed through the admin delegate page.
Previewed form	PreviewForm	Form owner previews a form by using the Preview function.
Removed form coauthor	RemoveFormCoauthor	Form owner deletes a collaboration link.
Removed specific responder	RemoveSpecificResponder	Form owner removes a user or group from the specific responders list.
Renamed a collection	CollectionRenamed	Form owner changed the name of a collection.
Sent Forms Pro invitation	ProInvitation	User selects to activate a Pro trial.
Submitted response	SubmitResponse	A user submits a response to a form. Property IsInternalForm:boolean is if the responder is within the same organization as the form owner.
Updated a collection	CollectionUpdated	Form owner updated a collection property.
Updated form phishing status	UpdatePhishingStatus	This event is logged whenever the detailed value for the internal security status changes, regardless of whether this change affects the final security state (for example, form is now Closed or Opened). This change might result in duplicate events without a final security state change. The possible status values for this event are: - Take Down - Take Down by Admin - Admin Unblocked - Auto Blocked - Auto Unblocked

Friendly name	Operation	Description
		- Customer Reported - Reset Customer Reported.
Updated form setting	UpdateFormSetting	Form owner updates one or multiple form settings. Property FormSettingName:string is updated sensitive settings' name. Property NewFormSettings:string is updated settings' name and new value. Property thankYouMessageContainsLink:boolean is updated thank-you message contains a URL link.
Updated response	UpdateResponse	Form owner updated a comment or score on a quiz. Property ResponseId:string and Property ResponderId:string is which result is being viewed. For an anonymous responder, the ResponderId property is null.
Updated user phishing status	UpdateUserPhishingStatus	This event is logged whenever the value for the user security status changes. The value of the user status in the audit record is **Confirmed as Phisher** when the user created a phishing form that the Microsoft Online safety team took down. If an admin unblocks the user, the value of the user's status is set to **Reset as Normal User**.
Updated user setting	UpdateUserSetting	Form owner updates a user setting. Property UserSettingName:string is the setting's name and new value.
Viewed form (design time)	ViewForm	Form owner opens an existing form for editing. Property AccessDenied:boolean is access of current form is denied due to permission check. Property FromSummaryLink:boolean is current request comes from the summary link page.
Viewed response	ViewResponse	Form owner views a particular response. Property ResponseId:string and Property ResponderId:string is which result is being viewed. For an anonymous responder, the ResponderId property is null.

Friendly name	Operation	Description
Viewed response page	ViewRuntimeForm	User opened a response page to view. This event is logged regardless of whether the user submits a response or not.
Viewed responses	ViewResponses	Form owner views the aggregated list of responses. Property ViewType:string is whether form owner is viewing Detail or Aggregate.

Forms activities performed by coauthors and anonymous responders

Forms supports collaboration when designing forms and analyzing responses. A form collaborator is known as a *coauthor*. Coauthors can do everything a form owner can do, except delete or move a form. Forms also allows you to create a form that can be responded to anonymously. This means the responder doesn't have to sign in to your organization to respond to a form.

The following table lists the auditing activities and information recorded in the Microsoft 365 audit log for activities performed by coauthors and anonymous responders.

Activity type	Internal or external user	User ID that's logged	Organization logged in to	Forms user type
Coauthoring activities	External	`urn:forms:coauthor#a0b1c2d3@forms.office.com` (The second part of the ID is a hash, which differs for different users)	Form owner's org	Coauthor
Coauthoring activities	External	UPN	Coauthor's org	Coauthor
Coauthoring activities	Internal	UPN	Form owner's org	Coauthor
Response activities	Anonymous	`urn:forms:anonymous#a0b1c2d3@forms.office.com` (The second part of the User ID is a hash, which differs for different users)	Form owner's org	Responder
Response activities	External	`urn:forms:external#a0b1c2d3@forms.office.com` (The second part of the User ID is a hash, which differs for different users)	Form owner's org	Responder
Response activities	External	UPN	Responder's org	Responder

Information barriers activities

The following table lists the activities in Information Barriers that the Microsoft 365 audit log records. For more information about Information Barriers, see Learn about Information Barriers in Microsoft 365.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Friendly name	Operation	Description
Applied information barrier mode to site	SiteIBModeSet	A SharePoint or global administrator applied a mode to the site.
Applied segments to site	SiteIBSegmentsSet	A SharePoint, global administrator, or site owner added one or more information barriers segments to a site.
Changed AppBypassInformationBarrier setting for the tenant	AppBypassInformationBarrier	A SharePoint or global administrator changed apps access for SharePoint sites.
Changed information barrier mode of site	SiteIBModeChanged	A SharePoint or global administrator updated the mode of the site.

Friendly name	Operation	Description
Changed segments of site	SiteIBSegmentsChanged	A SharePoint or global administrator changed one or more information barriers segments for a site.
Disabled information barriers for SharePoint and OneDrive	SPOIBIsDisabled	A SharePoint or global administrator disabled information barriers for SharePoint and OneDrive in the organization.
Enabled information barriers for SharePoint and OneDrive	SPOIBIsEnabled	A SharePoint or global administrator disabled information barriers for SharePoint and OneDrive in the organization.
Information barriers insights report completed	InformationBarriersInsightsReportCompleted	System completes build of the information barriers insights report.
Information barriers insights report OneDrive section queried	InformationBarriersInsightsReportOneDriveSectionQueried	An administrator queries the information barriers insights report for

Friendly name	Operation	Description
		OneDrive accounts.
Information barriers insights report scheduled	InformationBarriersInsightsReportSchedule	An administrator schedules the information barriers insights report.
Information barriers insights report SharePoint section queried	InformationBarriersInsightsReportSharePointSectionQueried	An administrator queries the information barriers insights report for SharePoint sites.
Removed segment from site	SiteIBSegmentsRemoved	A SharePoint or global administrator removes one or more information barriers segments from a site.

Microsoft 365 Admin Center Agent Management activities

The following table lists Agent Management activities that the Microsoft 365 audit log records. For more information, see Manage Microsoft 365 Copilot agents in the Microsoft 365 admin center.

Friendly name	Operation	Description
Blocked Agent	BlockedAgent	An admin blocked an agent. Users in the organization can't use the agent.
Deleted Agent	DeletedAgent	An admin deleted a shared agent that deletes the underlying files and the agent.

Friendly name	Operation	Description
Deployed Agent	DeployedAgent	An admin deployed an agent. The agent becomes active and usable for specific users, groups, or the entire organization.
Removed Agent	RemovedAgent	An admin removed a previously installed agent for the whole organization or for specific users and groups.
Unblocked Agent	UnblockedAgent	An admin unblocked a previously blocked agent.
Updated Agent	UpdatedAgent	An admin updated a custom agent by uploading the latest manifest file.
Updated Tenant-level Agent Settings	UpdatedTenantSettings	An admin updated tenant level settings that apply to agents.

Microsoft 365 Apps Admin Services cloud policy activities

The following table lists the activities for policy configuration changes in the Cloud Policy service that the Microsoft 365 audit log records.

Friendly name	Operation	Description
Created policy configuration	CreatedPolicyConfig	A new policy configuration was created.
Deleted policy configuration	DeletedPolicyConfig	A policy configuration was deleted.
Updated policy configuration	UpdatedPolicyConfig	An existing policy configuration was updated, for example by adding, changing, or removing policy settings, or by changing the policy configuration's name, description, or scope.
Updated policy configuration priority	UpdatedPolicyConfigPriority	The priority of a policy configuration was changed.

Microsoft 365 Apps Admin Services cloud update activities

The following table lists the activities for configuration changes and triggered actions in the Cloud Update service that the Microsoft 365 audit log records.

Friendly name	Operation	Description
Device configuration updated	updateddeviceconfiguration	An action for a device managed by Cloud Update was triggered. This action includes triggering a rollback, resuming a rolled back device, or changing the update channel.
Profile configuration updated	updatedprofileconfiguration	A Cloud Update profile's configuration changed. This change includes updates to the profile's state, set deadline, Update Validation enablement, and configured waves and wave delay.
Tenant configuration updated	updatedtenantconfiguration	The Cloud Update's organization-wide configuration changed. This change includes updates to exclusions, exclusion windows, and generating a new Tenant Association Key (TAK).

Microsoft 365 Backup activities

The following table lists the activities in Microsoft 365 Backup that the Microsoft 365 audit log records. Microsoft 365 Backup is designed to ensure your organization's data is always protected and easily recoverable. For more information about Microsoft 365 Backup, see Overview of Microsoft 365 Backup.

Friendly name	Operation	Description
Activated a Backup Policy	BackupPolicyActivated	A Microsoft 365 Backup policy is activated from an inactive state.
Activated Draft Restore Task	RestoreTaskActivated	A draft restore task for Microsoft 365 Backup is activated. This is a long running operation.
Backup Item Created	BackupItemAdded	One or more backup items are added to a Microsoft 365 Backup policy.
Backup Item Removed	BackupItemRemoved	One or more backup items are removed from a Microsoft 365 Backup policy.
Browsed Site for Restore	SiteBrowsedForRestore	A site was browsed in Microsoft 365 Backup to identify and select items for granular restore.
Cancel Offboard Backup Item	CancelOffboardBackupItem	Offboarding canceled for a backup item.
Completed Granular Restore for Backup Item	BackupItemGranularRestoreCompleted	A granular restore for one or more backup items is completed in Microsoft 365 Backup.

Friendly name	Operation	Description
Completed Granular Restore Session	GranularRestoreSessionCompleted	A granular restore session is completed in Microsoft 365 Backup.
Completed Restore Task	RestoreTaskCompleted	A restore task is completed in Microsoft 365 Backup.
Created Draft Restore Task	DraftRestoreTaskCreated	A restore task is created in Microsoft 365 Backup. By default, the restore task is created as draft.
Created Granular Browse Session	GranularBrowseSessionCreated	A granular browse session is created in Microsoft 365 Backup to enable browsing of backed-up content for item-level restore.
Created Granular Restore Session	GranularRestoreSessionCreated	A granular restore session is created in Microsoft 365 Backup.
Created new Backup policy	NewBackupPolicyCreated	A new Microsoft 365 Backup policy was created by a Global Admin. By default, a backup policy is created in an inactive state.
Deleted a Backup Policy	BackupPolicyDeleted	A Microsoft 365 Backup policy is deleted.
Deleted Draft Restore Task	DraftRestoreTaskDeleted	A draft restore task is deleted in Microsoft 365 Backup.
Edited a Backup Policy	BackupPolicyEdited	A Microsoft 365 Backup policy was updated. You can update a backup policy by performing any of the following actions: 1. Renaming the policy. 2. Add one or more protection units. 3. Removing one or more protection units.
Edited Draft Restore Task	DraftRestoreTaskEdited	A draft restore task is edited in Microsoft 365 Backup.
Offboard Backup Item	OffboardBackupItem	Backup item is offboarding.
Paused a Backup Policy	BackupPolicyPaused	A Microsoft 365 Backup policy is paused from active state.
Programmatically got Backup Item	GetBackupItem	User requests the protection unit backed up using Microsoft 365 Backup

Friendly name	Operation	Description
		programmatically.
Programmatically got Details of Backup Policy	ViewBackupPolicyDetails	Details of a Microsoft 365 Backup policy are accessed programmatically.
Programmatically got Details of Restore Task	GetRestoreTaskDetails	A user requests details of restore task by its identifier in Microsoft 365 Backup.
Programmatically got list of all Backup Policies	ListAllBackupPolicies	A user programmatically gets the list of all backup policies backed up using Microsoft 365 Backup.
Programmatically got list of Backup Items in Backup Policies	ListAllBackupItemsInPolicies	A list of all protection units present in a backup policy in Microsoft 365 Backup is requested programmatically.
Programmatically got list of Backup Items in Tenant	ListAllBackupItemsInTenant	A user programmatically gets list of all protection units in the organization backed up using Microsoft 365 Backup.
Programmatically got list of Backup Items in Workload	ListAllBackupItemsInWorkload	A user programmatically gets list of all protection units in workload (SharePoint, OneDrive, or Exchange) backed up using Microsoft 365 Backup.
Programmatically got list of Restore Items in Restore Task	GetAllRestoreArtifactsInTask	A user programmatically gets all artifacts in a restore task in Microsoft 365 Backup.
Programmatically got list of Restore Points	ListAllRestorePoints	A user programmatically gets all restore points in Microsoft 365 Backup. Restore Points represent the timestamp when an artifact is protected (per Protection Policy). Only Global Admins have access.
Programmatically got list of Restore Tasks	ListAllRestoreTasks	A user programmatically gets the list of existing restore sessions in Microsoft 365 Backup. This list includes the restore session created for every service type enrolled in the organization.
Restore item restoration complete	BackupItemRestoreCompleted	The restoration of an item backed up by Microsoft 365 Backup is completed.
Restore item restoration triggered	BackupItemRestoreTriggered	Restore is triggered for an item backed up with Microsoft 365 Backup.
Triggered Granular Restore for Backup	BackupItemGranularRestoreTriggered	A granular restore is triggered for a backup item in a granular restore session

Friendly name	Operation	Description
Item		in Microsoft 365 Backup.
Triggered Granular Restore Session	GranularRestoreSessionTriggered	A granular restore session is triggered in Microsoft 365 Backup. This is a long running operation.

Microsoft 365 Copilot admin activities

The following table lists admin activities related to Microsoft 365 Copilot and Microsoft 365 Copilot Chat that the Microsoft 365 audit log records. You can access Copilot across Microsoft services. The audit log records activities that show how and when users interact with Copilot. This information includes the Microsoft service where the activity took place and references to the files accessed during the interaction.

To access the text from the user's prompt during the interaction, see Content Search or view the **AI interaction** event from the activity explorer in Data Security Posture Management for AI.

For more information about auditing and other compliance management options for Microsoft 365 Copilot, see Use Microsoft Purview to manage data security & compliance for Microsoft 365 Copilot & Microsoft 365 Copilot Chat.

For more information about events related to user interactions with AI, see Audit logs for Copilot and AI activities.

Friendly name	Operation	Description
Created a new Copilot plugin	CreatePlugin	A user (or admin or system on behalf of a user) created a new Copilot plugin.
Created a new Copilot promptbook	CreatePromptBook	A user (or admin or system on behalf of a user) created a new promptbook in Copilot.
Deleted a Copilot plugin	DeletePlugin	A user (or admin or system on behalf of a user) deleted a Copilot plugin.
Deleted a Copilot promptbook	DeletePromptBook	A user (or admin or system on behalf of a user) deleted a Copilot promptbook.
Disabled a Copilot plugin	DisableCopilotPlugin	A user (or admin or system on behalf of a user) disabled a Copilot plugin.
Disabled a Copilot promptbook	DisablePromptBook	A user (or admin or system on behalf of a user) disabled a Copilot promptbook.

Friendly name	Operation	Description
Enabled a Copilot plugin	EnablePlugin	A user (or admin or system on behalf of a user) enabled a Copilot plugin.
Enabled a Copilot promptbook	EnablePromptBook	A user (or admin or system on behalf of a user) enabled a Copilot promptbook.
Exported AI Interactions	AIEnterpriseInteractionsExported	An admin exported interactions with Copilot.
Interacted with Copilot	CopilotInteraction	A user (or admin or system on behalf of a user) entered prompts in Copilot.
Sent change notification for AI interaction creation	AIInteractionCreatedNotification	A change notification was sent to notify a subscribed listener application of a new Copilot AI interaction.
Sent change notification for AI interaction deletion	AIInteractionDeletedNotification	A change notification was sent to notify a subscribed listener application of a deleted Copilot AI interaction.
Sent change notification for AI interaction update	AIInteractionUpdatedNotification	A change notification was sent to notify a subscribed listener application of an updated Copilot AI interaction.
Subscribed to AI interactions	SubscribedToAIInteractions	A subscription was created by a listener application to receive change notifications for Copilot AI interactions.
Updated a Copilot plugin setting	UpdatePlugin	A user (or admin or system on behalf of a user) updated a Copilot plugin setting.
Updated a Copilot promptbook setting	UpdatePromptBook	A user (or admin or system on behalf of a user) updated a Copilot promptbook setting.
Updated a Copilot setting	UpdateTenantSettings	An admin (or system on behalf of an admin) updated a Copilot setting.

Microsoft 365 Copilot scheduled prompts activities

By using Copilot Scheduled Prompts, users can automate Copilot prompts to run on a defined schedule in Microsoft 365 Copilot chat. The following table lists the activities recorded in the Microsoft 365 audit log. Admins can manage this feature in your organization. For more information, see Manage scheduled prompts for Microsoft 365 Copilot.

Friendly name	Operation	Description
Created a scheduled prompt	ScheduledPromptCreated	A user scheduled a Copilot prompt from Microsoft 365 Copilot Chat (Office.com chat).

Friendly name	Operation	Description
Deleted a scheduled prompt	ScheduledPromptDeleted	A user deletes a scheduled prompt from the management window. The prompt is removed from the list and no longer runs.
Executed a scheduled prompt	ScheduledPromptExecute	Logged at the start of each scheduled run. It doesn't confirm the prompt was completed.

Microsoft Defender for Cloud activities

The following table lists Microsoft Defender for Cloud activities that are logged in the Microsoft 365 audit log. For more information, see What is Microsoft Defender for Cloud?.

Friendly name	Operation	Description
Connector created	ConnectorCreated	A user created a cloud environment connector for AWS, Azure, Google Cloud Platform (GCP), GitHub, JFrog, or Azure DevOps.
Connector deleted	ConnectorDeleted	A user deleted a cloud environment connector.
Connector modified	ConnectorModified	A user updated the configuration of an existing cloud environment connector.
Enablement rule collection created	EnablementRuleCollectionCreated	A user created an enablement rule collection to configure Defender plans and extensions for an environment.
Enablement rule collection deleted	EnablementRuleCollectionDeleted	A user deleted an enablement rule collection.
Enablement rule collection modified	EnablementRuleCollectionModified	A user modified an enablement rule collection to change Defender plan or extension settings.
Global setting modified	GlobalSettingModified	A user modified a global setting.
Rule collection created	RuleCollectionCreated	A user created a rule collection.
Rule collection deleted	RuleCollectionDeleted	A user deleted a rule collection and its associated rules.
Rule collection disabled	RuleCollectionDisabled	A user disabled an active rule collection without deleting it.
Rule collection enabled	RuleCollectionEnabled	A user enabled a previously disabled rule collection.

Friendly name	Operation	Description
Rule collection modified	RuleCollectionModified	A user modified a rule collection.
Rule created	RuleCreated	A user created a rule.
Rule deleted	RuleDeleted	A user deleted a rule.

Microsoft Defender for Endpoint general settings activities

The following table lists the activities for Microsoft Defender for Endpoint general settings recorded in the Microsoft 365 audit log. For more information about the settings Microsoft Defender for Endpoint, see Configure general Defender for Endpoint settings.

Friendly name	Operation	Description
Changed data retention	ChangeDataRetention	Edited the data retention settings for Defender for Endpoint.
Downloaded offboarding package	DownloadOffboardingPkg	Downloaded the package used to remove devices from Defender for Endpoint.
Downloaded onboarding package	DownloadOnboardingPkg	Downloaded the package used to onboard devices to Defender for Endpoint.
Set advanced features	SetAdvancedFeatures	Changed advanced features in Defender for Endpoint, enabling more precise controls during an incident. Only settings for advanced features that are generally available are logged in the Microsoft 365 audit log.

Microsoft Defender for Endpoint indicator settings activities

The following table lists the activities for Microsoft Defender for Endpoint indicator settings that the Microsoft 365 audit log records. For more information about Microsoft Defender for Endpoint indicators, see Manage indicators.

Friendly name	Operation	Description
Added indicator	AddIndicator	Created a new indicator of compromise used to track attacks and events.

Friendly name	Operation	Description
Deleted indicator	DeleteIndicator	Removed an indicator of compromise.
Edited indicator	EditIndicator	Edited an indicator of compromise.

Microsoft Defender for Endpoint response actions activities

The following table lists the activities for Microsoft Defender for Endpoint response actions, including Live response, that the Microsoft 365 audit log records. For more information about Microsoft Defender for Endpoint response actions, see Take response actions on a device.

Friendly name	Operation	Description
Collected investigation package	CollectInvestigationPackage	Collected information about a device that's used to understand attack tools and techniques.
Collected Logs	LogsCollection	Collected log information about Defender for Endpoint.
Downloaded file	DownloadFile	Downloaded a suspicious file for further investigation.
Isolated device	IsolateDevice	Isolated a device from the network, helping prevent attacks from spreading.
Offboarded device	DeviceOffBoarding	Removed a device from Defender for Endpoint.
Ran Antivirus scan	RunAntiVirusScan	Ran Microsoft Defender Antivirus scan on a device.
Ran get Live response file link	LiveResponseGetFile	Opened a Live response session, opening a remote shell into a device.
Ran Live response API	RunLiveResponseApi	Opened a Live response session via an API call, opening a remote shell into a device.
Ran Live response session	RunLiveResponseSession	Ran a Live response session, opening a remote shell into a device.
Released from isolation	ReleaseFromIsolation	Added an isolated device back onto the network.
Removed app restrictions	RemoveAppRestrictions	Allow an app to run.
Restricted app execution	RestrictAppExecution	Prevent a malicious app from running.

Friendly name	Operation	Description
Stopped and quarantined file	StopAndQuarantineFile	Quarantined a suspicious file for further analysis.

Microsoft Defender for Endpoint roles settings activities

The following table lists the activities for Microsoft Defender for Endpoint role settings that the Microsoft 365 audit log records. For more information about roles in Microsoft Defender for Endpoint, see Create and manage roles for role-based access control.

Friendly name	Operation	Description
Added role	AddRole	Added new security role and permissions.
Deleted role	DeleteRole	Removed security roles and permissions.
Edited role	EditRole	Edited security roles and permissions.

Microsoft Defender for Experts activities

The following table lists the activities in Microsoft Defender Experts that the Microsoft 365 audit log records. For more information about Microsoft Defender Experts, see Learn about Microsoft Defender Experts for XDR and Learn about Microsoft Defender Experts for Hunting.

Friendly name	Operation	Description
Defender Experts analyst permission created	DefenderExpertsAnalystPermissionCreated	An administrator granted one or more role permissions to Defender Experts analysts to investigate incidents or remediate threats.
Defender Experts analyst permission modified	DefenderExpertsAnalystPermissionModified	An administrator modified role permissions for Defender Experts analysts to investigate incidents or remediate threats.

Microsoft Defender for Identity activities

The following table lists the activities for Microsoft Defender for Identity that the Microsoft 365 audit log records.

Friendly name	Operation	Description
Added alert notification recipient	AlertNotificationsRecipientAdded	A recipient was added to the security alerts notification configuration.
Added exclusions configuration	ExclusionConfigurationAdded	A global exclusion was added for an alert or for an entity.
Added health issues notification recipient	MonitoringAlertNotificationRecipientAdded	A recipient was added to the health issues notification configuration.
Added remediation action	RemediationActionAdded	A remediation action was added to the queue.
Added sensor	SensorCreated	A new sensor was added.
Created workspace	WorkspaceCreated	The workspace was created.
Deleted alert notification recipient	AlertNotificationsRecipientDeleted	A recipient was removed from the security alerts notification configuration.
Deleted exclusions configuration	ExclusionConfigurationDeleted	A global exclusion was deleted for an alert or for an entity.
Deleted health issues notification recipient	MonitoringAlertNotificationRecipientDeleted	A recipient was removed from the heath issues notification configuration.
Deleted workspace	WorkspaceDeleted	The workspace was deleted.
Downloaded Domain Controller coverage Excel	DomainControllerCoverageExcelDownloaded	The Domain Controller coverage Excel file was downloaded.
Downloaded report	ReportDownloaded	A report was downloaded.
Downloaded security alert Excel	AlertExcelDownloaded	The detailed Excel file of an alert was downloaded.
Regenerated sensor deployment key	SensorDeploymentAccessKeyUpdated	The sensors access key was regenerated.
Removed sensor	SensorDeleted	A sensor was deleted.
Retrieved sensor deployment key	SensorDeploymentAccessKeyReceived	The sensors access key was retrieved.
Updated alert threshold configuration	WorkspaceAlertThresholdLevelUpdated	The alerts thresholds configuration was updated.

Friendly name	Operation	Description
Updated directory services account configuration	DirectoryServicesAccountConfigurationUpdated	The Directory services accounts set was modified.
Updated entity remediation configuration	EntityRemediatorConfigurationUpdated	The Manage action accounts mode was modified.
Updated entity tags	TaggingConfigurationUpdated	A tag was added or removed from an entity.
Updated exclusions configuration	ExclusionConfigurationUpdated	A global exclusion was updated for an alert or for an entity.
Updated health issue	MonitoringAlertUpdated	A health issue was modified.
Updated remediation action	RemediationActionUpdated	A remediation action was completed.
Updated remediation action configuration	RemediationActionConfigurationUpdated	The Manage action accounts set was modified.
Updated reporter configuration	ReporterConfigurationUpdated	A report's scheduling was modified.
Updated security notification configuration	NotificationConfigurationUpdated	The security alerts or health issues notifications configuration was modified.
Updated sensor configuration	SensorConfigurationUpdated	A sensor's configuration was updated.
Updated sensors activation mode	SensorActivationMethodConfigurationUpdated	The sensors activation mode was modified.
Updated syslog forwarding configuration	SyslogServiceConfigurationUpdated	The syslog forwarding configuration was modified.
Updated Unified RBAC configuration	URbacAuthorizationStatusChanged	The Unified Role Based Access Control configuration was modified.
Updated VPN configuration	VpnConfigurationUpdated	The VPN (radius accounting) configuration was modified.

Microsoft Defender for Office 365 activities

The following table lists the activities for Microsoft Defender for Office 365 logged in the Microsoft 365 audit log. For more information about Microsoft Defender for Office 365, see Microsoft Defender for Office 365 overview.

> **Note**
>
> These events aren't listed as friendly names in audit search. This table is a complementary resource for the Office 365 Management Activity API schema.

Events	Operation	Description
Alert events	SecurityComplianceAlerts	Security and compliance alert signals for alerts generated based on Alert policies in the Microsoft Purview compliance portal.
Attack Simulation admin events	AttackSimAdmin	Events related to admin activities in Attack Simulation & Training in Microsoft Defender for Office 365.
Attack Simulation training events	UserTraining	Events related to user training in Attack Simulation & Training in Microsoft Defender for Office 365.
Attack Simulation user events	AttackSim	Events related to user activities in Attack Simulation & Training in Microsoft Defender for Office 365.
Automated incident response (AIR) events	AirInvestigation	Automated incident response (AIR) events and data.
Campaign events	Campaign	Email campaign events from Microsoft Defender for Office 365.
Content detection events	ThreatIntelligenceAtpContent	Phishing and malware events for files in SharePoint, OneDrive for Business, and Microsoft Teams from Microsoft Defender for Office 365.
Outbound spam events	HygieneEvent	Events related to outbound spam protection.
Phishing and malware events	ThreatIntelligence	Phishing and malware events from the built-in security add-on for on-premises mailboxes (formerly Exchange Online Protection) and Microsoft Defender for Office 365.
Quarantine events	Quarantine	Quarantine events from Microsoft Defender for Office 365.
Submission events	MailSubmission	Admin and user submission events from the built-in security add-on for on-premises mailboxes (formerly

Events	Operation	Description
		Exchange Online Protection) and Microsoft Defender for Office 365.
URL Click Events	ThreatIntelligenceUrl	Safe links time-of-block and block override events from Microsoft Defender for Office 365.

Microsoft Defender XDR automation activities

The following table lists automation activities for Microsoft Defender XDR recorded in the Microsoft 365 audit log. For more information, see Search the audit log for events in Microsoft Defender XDR.

Friendly name	Operation	Description
Created a generated playbook	GeneratedPlaybookCreated	A user created a generated playbook.
Created an automation rule	AutomationRuleCreated	A user created an automation rule.
Deactivated a generated playbook	GeneratedPlaybookInactive	A user deactivated a generated playbook.
Deactivated an automation rule	AutomationRuleInactive	A user deactivated an automation rule.
Edited a generated playbook	GeneratedPlaybookEdited	A user edited a generated playbook.
Edited an automation rule	AutomationRuleEdited	A user edited an automation rule.
Activated a generated playbook	GeneratedPlaybookActivated	A user activated a generated playbook.
Activated an automation rule	AutomationRuleActivated	A user activated an automation rule.
Removed a generated playbook	GeneratedPlaybookRemoved	A user removed a generated playbook.
Removed an automation rule	AutomationRuleRemoved	A user removed an automation rule.
Triggered a generated playbook	TriggerGeneratedPlaybook	A user manually triggered a generated playbook.

Microsoft Defender XDR case management activities

The following table lists the case management activities that are logged in the Microsoft 365 audit log when users create and manage cases in the Microsoft Defender portal. For more information, see Microsoft Defender XDR.

Friendly name	Operation	Description
A case was assigned to a different user or team member	ChangedCaseAssignment	Generated when a case is assigned or reassigned to a different user.
A comment in a case was edited	UpdatedCommentInCase	Generated when an existing comment on a case is edited.
A comment was added to a case	AddedCommentToCase	Generated when a comment is added to a case.
A comment was deleted from a case	DeletedCommentFromCase	Generated when a comment is deleted from a case.
A new case was created in the system	CreatedCase	Generated when a user creates a new case. Not logged for cases created by application or service accounts.
An existing case was deleted from the system	DeletedCase	Generated when a case is deleted.
An object was linked to a case	LinkedObject	Generated when an object, such as an alert or entity, is linked to a case.
An object was unlinked from a case	UnlinkedObject	Generated when an object is unlinked from a case.
Case content was changed	UpdatedCase	Generated when a case is updated with changes, such as custom fields, that aren't captured by a more specific operation.
One or more tags were added to a case	AddedTagsToCase	Generated when one or more tags are added to a case.
One or more tags were removed from a case	RemovedTagsFromCase	Generated when one or more tags are removed from a case.
The classification of a case was changed	ChangedCaseClassification	Generated when the classification of a case is changed.
The closing notes of a case were modified or updated	ChangedCaseClosingNotes	Generated when the closing notes of a case are changed.
The description of a case was modified or updated	ChangedCaseDescription	Generated when the description of a case is changed.
The name or title of a case was changed	ChangedCaseName	Generated when the name (title) of a case is changed.
The priority level of a case was modified	ChangedCasePriority	Generated when the priority of a case is changed.

Friendly name	Operation	Description
The severity of a case was changed	ChangedCaseSeverity	Generated when the severity of a case is changed.
The status of a case was updated	ChangedCaseStatus	Generated when the status of a case is changed.

Microsoft Defender XDR custom detection activities

The following table lists the custom detection activities for Microsoft Defender XDR recorded in the Microsoft 365 audit log. For more information about Microsoft Defender XDR custom detections, see Create and manage custom detections rules.

Friendly name	Operation	Description
Changed custom detection rule status	ChangeCustomDetectionRuleStatus	A custom detection rule was turned off or on.
Created custom detection rule	CreateCustomDetection	A new custom detection rule was created.
Deleted custom detection rule	DeleteCustomDetection	A custom detection rule was removed.
Edited custom detection rule	EditCustomDetection	A custom detection rule was modified.
Ran custom detection rule	RunCustomDetection	A custom detection rule was manually run.

Microsoft Defender XDR incident activities

The following table lists the incident activities for Microsoft Defender XDR recorded in the Microsoft 365 audit log. For more information about incidents in Microsoft Defender XDR, see Incidents overview.

Friendly name	Operation	Description
Added comment to incident	AddCommentToIncident.	Added comment to incident.
Added tags to incident	AddTagsToIncident	Added tags to incident.
Assigned user to incident	AssignUserToIncident	Assigned user to incident.
Edit incident classification	EditIncidentClassification	Edit incident classification.
Removed tags from incident	RemoveTagsFromIncident	Removed tags from the incident.

Friendly name	Operation	Description
Unassigned user to incident	UnAssignUserFromIncident	Unassigned user to incident.
Updated incidents status	UpdateIncidentStatus	Updated incidents status.

Microsoft Defender XDR suppression rule activities

The following table lists the activities for suppression rules for Microsoft Defender XDR recorded in the Microsoft 365 audit log. For more information about suppression rules in Microsoft Defender XDR, see Manage suppression rules.

Friendly name	Operation	Description
Created suppression rule	CreateSuppressionRule	Created alert suppression rule.
Deleted suppression rule	DeleteSuppressionRule	Deleted alert suppression rule.
Disabled suppression rule	DisableSuppressionRule	Disabled alert suppression rule.
Edited suppression rule	EditSuppressionRule	Deleted alert suppression rule.
Enabled suppression rule	EnableSuppressionRule	Enabled alert suppression rule.

Microsoft Edge WebContentFiltering activities

The following table lists the browsing activities in Microsoft Edge recorded in the Microsoft 365 audit log for the WebContentFiltering feature. The table includes the friendly name that displays in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the .csv file when you export the search results.

Search the audit log describes how you can search the audit logs from the Microsoft Purview portal. Users need to be a global admin or have audit read permissions to access audit logs. Use the **Activities** filter to search for specific activities. To list all WebContentFiltering activities, select *WebContentFiltering* in the **Record type** filter. Use the date range boxes and the **Users** list to scope the search results further if needed.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Friendly name	Operation	Description
Allowed URL Navigation in Microsoft Edge	URLNavigationAllowed	User browsed a URL.
Blocked URL Navigation in Microsoft Edge	URLNavigationBlocked	Browsed URL is blocked by WebContentFiltering policy.

Microsoft Entra group administration activities

The following table lists group administration activities that the Microsoft 365 audit log records when an admin or a user creates or changes a Microsoft 365 group or when an admin creates a security group by using the Microsoft 365 admin center or the Azure management portal. For more information about groups in Microsoft 365, see View, create, and delete Groups in the Microsoft 365 admin center.

Friendly name	Operation	Description
Added group	AddGroup	A group was created.
Added member to group	AddMemberToGroup.	A member was added to a group.
Deleted group	Delete group.	A group was deleted.
Removed member from group	RemoveMemberFromGroup.	A member was removed from a group.
Updated group	UpdateGroup.	A property of a group was changed.

Microsoft Entra risk detection activities

The following table lists risk detection activities recorded in the Microsoft 365 audit log when using Microsoft Entra ID Protection. For more information about risk detection, see Learn about risk detections..

Friendly name	Operation	Description
Compromised sign-in detection	CompromisedSignIn	Sign-in risk detections represent the probability that a given authentication request isn't the authorized owner of the account.
Compromised user detection	CompromisedUser	User risk detections might flag a legitimate user account as at risk, when a potential threat actor gains access to an account by compromising their credentials or when they detect some type of anomalous user activity.

Microsoft Graph Data Connect

The following table lists the user and admin activities in Microsoft Graph Data Connect recorded in the Microsoft 365 audit log. The table includes the friendly name that displays in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the CSV file when you export the search results.

Friendly name	Operation	Description
Approved or denied an app	ConsentModificationRequest	A user performed a consent modification request.
Extraction ran	DataAccessRequestOperation	A user performed an extraction. Partner datasets and ISV runs are excluded.

Microsoft Places Directory activities

The following table lists the admin activities in Microsoft Places Directory that the Microsoft 365 audit log records. The table includes the friendly name that displays in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the CSV file when you export the search results.

Friendly name	Operation	Description
Created a place	CreatedPlace	An admin performed an operation for creating places.
Deleted a place	DeletedPlace	An admin performed an operation for deleting places.
Updated a place	UpdatedPlace	An admin performed an operation for updating places.

Microsoft Purview Audit solution activities

The following table lists activities associated with audit solutions in the Microsoft Purview portal and the Audit Search Graph API. The *SecurityComplianceCenter* workload audits these activities. For more information, see Search the audit log.

Audit search and export activities that use Search-UnifiedAuditLog aren't audited.

Friendly name	Operation	Description
Audit search canceled	AuditSearchCancelled	An audit search job was canceled.
Audit search completed	AuditSearchCompleted	An audit search job was completed.
Audit search created	AuditSearchCreated	A new audit search request was submitted.
Audit search deleted	AuditSearchDeleted	An audit search job was deleted.

Friendly name	Operation	Description
Audit search export job completed	AuditSearchExportJobCompleted	The export job to export the search results of an audit search query was completed.
Audit search export job created	AuditSearchExportJobCreated	An export job was created to export the search results of an audit search query.
Audit search export results downloaded	AuditSearchExportResultsDownloaded	The search results from an audit search query were downloaded.

Microsoft Purview governance activities

The following table lists Microsoft Purview governance activities recorded in the Microsoft 365 audit log. For more information, see Microsoft Purview governance solutions.

Friendly name	Operation	Description
Asset or entity created	EntityCreated	A new asset or entity was created or added to an existing asset.
Classification added	ClassificationAdded	Added classifications to asset entity.
Classification definition created	ClassificationDefinitionCreated	Created a classification type.
Classification definition deleted	ClassificationDefinitionDeleted	Deleted a classification type.
Classification definition updated	ClassificationDefinitionUpdated	Updated a classification type.
Classification deleted	ClassificationDeleted	Deleted classifications from asset entity.
Classification updated	ClassificationUpdated	Updated classifications on asset entity.
Entity deleted	EntityDeleted	An asset or entity was deleted from an existing asset.
Entity updated	EntityUpdated	**Includes**: attribute update, business attribute update, collection info (only include collection ID), contacts update, customAttributes, hierarchy, homeId, labels, sourceDetails.
Glossary term assigned	GlossaryTermAssigned	Assigned terms to asset entity.

Friendly name	Operation	Description
Glossary term created	GlossaryTermCreated	Created a term.
Glossary term deleted	GlossaryTermDeleted	Deleted a term.
Glossary term disassociated	GlossaryTermDisassociated	Disassociated terms from asset entity.
Glossary term updated	GlossaryTermUpdated	Updated a term.
Sensitivity label changed	SensitivityLabelChanged	Sensitivity label was added, updated, or deleted.

Microsoft Purview on-demand classification activities

The following table lists the activities from Microsoft Purview on-demand classification that the Microsoft 365 audit log records. For more information about on-demand classification, see Learn about on-demand classification in Microsoft Purview.

> **Note**
>
> These audit activities are only available in Audit (Premium). You must be assigned the appropriate license before these activities are logged in the audit log. For more information, see Audit (Premium). For Audit (Premium) licensing requirements, see Auditing solutions in Microsoft 365.

Friendly name	Operation	Description
Classified file as part of an on-demand classification scan	DataScanClassification	File was evaluated for sensitive content as part of an on-demand classification scan for SharePoint or OneDrive.
Classified file on device as part of an on-demand classification scan	SensitiveInfoDiscovered	File was evaluated for sensitive content as part of an on-demand classification scan for Endpoint devices.
Declassified file as part of an on-demand classification scan	DataScanDeClassification	File no longer matches the sensitive information types defined in the corresponding On-demand classification scan triggered for SharePoint or OneDrive locations.

Microsoft Purview permission activities

The following table lists Microsoft Purview administration activities that the Microsoft 365 audit log records when an administrator manages role-based access control (RBAC) role groups and user assignments. For more information, see Permissions in the Microsoft Purview portal. See Office 365 Management Activity API schema for the audit log schema.

Friendly name	Operation	Description
Create RBAC role group definition	CreateRBACRoleGroupDefinition	An RBAC role group definition is created.
Delete RBAC role group definition	DeleteRBACRoleGroupDefinition	An RBAC role group definition is deleted.
Update RBAC role group definition	UpdateRBACRoleGroupDefinition	An RBAC role group definition is updated.
Add user assignments to role group	GrantPermissionsAsync	User assignments to an RBAC role group are added.
Remove user assignments to role group	DeletePermissionAsync	User assignments to an RBAC role group are removed.
Updated user role assignments expiration in role group	UpdatePermission	A user assignment expiration date is updated in an RBAC role group.

Microsoft Security Copilot agent management

The following table lists the Agent management operations in Security Copilot that the Microsoft 365 audit log records. These activities characterize activities for agents and the components necessary for them to function such as triggers. For more information about Security Copilot agent management, see Microsoft Security Copilot agents overview.

Friendly name	Operation	Description
Created a new Security Copilot agent	CreateCopilotAgent	A user (or admin or system on behalf of a user) created a new Security Copilot agent.
Created a new Security Copilot agent trigger	CreateCopilotforSecurityAgentTrigger	A user (or admin or system on behalf of a user) created a new promptbook in Copilot.
Deleted a Security Copilot agent	DeleteCopilotAgent	A user (or admin or system on behalf of a user) deleted a Security Copilot agent.

Friendly name	Operation	Description
Deleted a Security Copilot agent trigger	DeleteCopilotForSecurityAgentTrigger	A user (or admin or system on behalf of a user) deleted a Security Copilot trigger.
Updated a Security Copilot agent setting	UpdateCopilotAgent	A user (or admin or system on behalf of a user) updated a Security Copilot agent setting.
Updated a Security Copilot agent trigger	UpdateCopilotforSecurityAgentTrigger	A user (or admin or system on behalf of a user) updated a Security Copilot agent trigger setting.

Microsoft Security Copilot interactions

The following table lists the types of user interactions with AI components in Security Copilot that the Microsoft 365 audit log records. These operations represent individual prompting, embedded experiences, or agentic workflows. For more information about Security Copilot interactions, see Prompting in Security Copilot and Microsoft Security Copilot agents overview.

Friendly name	Operation	Description
Interacted with Copilot	CopilotInteraction	A user (or admin or system on behalf of a user) entered prompts in Copilot or an agent.

Microsoft Security Copilot platform management

The following table lists management operations of a Security Copilot and its components that the Microsoft 365 audit log records. These operations represent tenant or workspace settings or AI components such as plugins and promptbooks. For more information about the management elements of Security Copilot, see What is Microsoft Security Copilot.

Friendly name	Operation	Description
Created a new Copilot plugin	CreatePlugin	A user (or admin or system on behalf of a user) created a new Copilot plugin.
Created a new Copilot promptbook	CreatePromptBook	A user (or admin or system on behalf of a user) created a new promptbook in Copilot.
Deleted a Copilot plugin	DeletePlugin	A user (or admin or system on behalf of a user) deleted a Copilot plugin.
Deleted a Copilot promptbook	DeletePromptBook	A user (or admin or system on behalf of a user) deleted a Copilot promptbook.

Friendly name	Operation	Description
Disabled a Copilot plugin	DisableCopilotPlugin	A user (or admin or system on behalf of a user) disabled a Copilot plugin.
Disabled a Copilot promptbook	DisablePromptBook	A user (or admin or system on behalf of a user) disabled a Copilot promptbook.
Enabled a Copilot plugin	EnablePlugin	A user (or admin or system on behalf of a user) enabled a Copilot plugin.
Enabled a Copilot promptbook	EnablePromptBook	A user (or admin or system on behalf of a user) enabled a Copilot promptbook.
Updated a Copilot plugin setting	UpdatePlugin	A user (or admin or system on behalf of a user) updated a Copilot plugin setting.
Updated a Copilot promptbook setting	UpdatePromptBook	A user (or admin or system on behalf of a user) updated a Copilot promptbook setting.
Updated a Copilot setting	UpdateTenantSettings	An admin (or system on behalf of an admin) updated a Copilot setting.

Microsoft Sentinel AI tool activities

The following table lists the AI tool related activities in Microsoft Sentinel data lake recorded in the Microsoft 365 audit log. For more information about MCP tools in Microsoft Sentinel data lake, see Tool collection in Microsoft Sentinel MCP server.

Friendly name	Operation	Description
Completed AI tool run	SentinelAIToolRunCompleted	Microsoft Sentinel AI tool run completed.
Created AI tool	SentinelAIToolCreated	User creates a Microsoft Sentinel AI tool.
Started AI tool run	SentinelAIToolRunStarted	Microsoft Sentinel AI tool run started.

Microsoft Sentinel data lake job activities

The following table lists the job activities in Microsoft Sentinel data lake that the Microsoft 365 audit log records. For more information about jobs in Microsoft Sentinel data lake, see Create and manage Jupyter notebook jobs (preview) and Create KQL jobs in the Microsoft Sentinel data lake (preview).

Friendly name	Operation	Description
Completed a job run adhoc	JobRunAdhocCompleted	Ad hoc Job execution completed.

Friendly name	Operation	Description
Completed a job run scheduled	JobRunScheduledCompleted	Scheduled Job execution completed.
Created job	JobCreated	A job is created.
Deleted a custom table	CustomTableDelete	As part of a job run, the custom table was deleted.
Deleted job	JobDeleted	A job is deleted.
Disabled job	JobDisabled	The job is disabled.
Enabled job	JobEnabled	A disabled job is reenabled.
Ran a job adhoc	JobRunAdhoc	Job is triggered manually and run started.
Ran a job on schedule	JobRunScheduled	Job run is triggered due to schedule.
Read from table	TableRead	As part of the job run, a table is read.
Stopped a job run	JobRunStopped	User manually cancels or stops an ongoing job run.
Updated job	JobUpdated	The job definition and/or configuration and schedule details of the job if updated.
Wrote to a custom table	CustomTableWrite	As part of the job run, data was written to a custom table.

Microsoft Sentinel data lake KQL activities

The following table lists the KQL activities in Microsoft Sentinel data lake that the Microsoft 365 audit log records. For more information about KQL in Microsoft Sentinel data lake, see KQL and the Microsoft Sentinel data lake (preview).

Friendly name	Operation	Description
Completed KQL query	KQLQueryCompleted	User runs interactive queries via KQL on data in their Microsoft Sentinel data lake.

Microsoft Sentinel data lake notebook activities

The following table lists the notebook activities in Microsoft Sentinel Data lake recorded in the Microsoft 365 audit log. For more information about notebooks in Microsoft Sentinel data lake, see Use notebooks in Microsoft Sentinel data lake.

Friendly name	Operation	Description
Deleted a custom table	CustomTableDelete	User deleted a table as part of their notebook execution.
Read from table	TableRead	User read a table as part of their notebook execution.
Started session	SessionStarted	User started a notebook session.
Stopped session	SessionStopped	User stopped a notebook session.
Wrote to a custom table	CustomTableWrite	User wrote to a table as part of their notebook execution.

Microsoft Sentinel data lake onboarding activities

The following table lists the Microsoft Sentinel data lake onboarding activities recorded in the Microsoft 365 audit log. For more information about onboarding to Microsoft Sentinel data lake, see Onboarding to Microsoft Sentinel data lake (preview).

Friendly name	Operation	Description
Changed subscription of Sentinel lake	SentinelLakeSubscriptionChanged	User modified the billing subscription ID or resource group associated with the data lake.
Onboarded data for Sentinel lake	SentinelLakeDefaultDataOnboarded	During onboarding, default data onboard is logged.
Set up Sentinel lake	SentinelLakeSetup	At the time of onboarding, Microsoft Sentinel data lake is set up and the details are logged.

Microsoft Sentinel graph activities

The following table lists the graph activities in Microsoft Sentinel recorded in the Microsoft 365 audit log. For more information about Microsoft Sentinel graph, see What is Microsoft Sentinel Graph? (preview).

Friendly name	Operation	Description
Created a graph scenario	GraphScenarioCreated	User created a graph instance for a predefined graph scenario.
Deleted a graph scenario	GraphScenarioDeleted	User deleted or disable a graph instance for a predefined graph scenario.
Ran a graph query	GraphQueryRun	User ran a graph query.

Microsoft Sentinel data lake customer managed keys activities

The following table lists the customer-managed key (CMK) activities in Microsoft Sentinel data lake that the Microsoft 365 audit log records. For more information about CMK in Microsoft Sentinel data lake, see Set up Microsoft Sentinel customer-managed key.

Friendly name	Operation	Description
Disabled CMK encryption	CMKDisabled	The customer-managed key was removed and encryption reverted to Microsoft-managed keys for the data lake.
Enabled CMK encryption	CMKEnabled	A customer-managed key was configured for the data lake successfully.
Received CMK encryption request	CMKRequestReceived	A request to enable customer-managed key encryption was received for the data lake, including the required key details.
Accepted CMK encryption request	CMKRequestAccepted	The request to enable customer-managed key encryption was accepted for the data lake.
Rejected CMK encryption request	CMKRequestRejected	A key wrap, unwrap, or validation operation failed.
Rolled back CMK operation	CMKRollbackExecuted	The customer-managed key configuration could not be completed, so the operation was rolled back for the data lake and reverted to Microsoft-managed keys.
Updated CMK encryption	CMKUpdated	The encryption key was rotated or changed for the data lake.

Microsoft To Do activities

The following table lists the activities in Microsoft To Do that the Microsoft 365 audit log records. For more information about Microsoft To Do, see Support for Microsoft To Do.

> **Note**
>
> To audit events for Microsoft To Do activities, you need a paid Project Plan 1 license (or higher) in addition to the relevant Microsoft 365 license that includes entitlements to Audit (Standard).

Friendly name	Operation	Description
Accepted sharing link on folder	AcceptedSharingLinkOnFolder	Accepted sharing link for a folder.
Attachment created	AttachmentCreated	An attachment was created for a task.
Attachment deleted	AttachmentDeleted	An attachment was deleted.
Attachment updated	AttachmentUpdated	An attachment was updated.
Folder sharing link shared	FolderSharingLinkShared	Created a sharing link for a folder.
Linked entity created	LinkedEntityCreated	A linked entity of task was created.
Linked entity deleted	LinkedEntityDeleted	A linked entity was deleted.
Linked entity updated	LinkedEntityUpdated	A linked entity was updated.
SubTask created	SubTaskCreated	A subtask was created.
SubTask deleted	SubTaskDeleted	A subtask was deleted.
SubTask updated	SubTaskUpdated	A subtask was updated.
Task created	TaskCreated	A task was created.
Task deleted	TaskDeleted	A task was deleted.
Task read	TaskRead	A task was read.
Task updated	TaskUpdated	A task was updated.
TaskList created	TaskListCreated	A task list was created.
TaskList read	TaskListRead	A task list was read.
TaskList updated	TaskListUpdated	A task list was updated.
User invited	UserInvited	Invited user to a folder.

Microsoft 365 Organizational Data Service activities

The following table lists the activities in Microsoft 365 Organizational Data Service that the Microsoft 365 audit log records. For more information about Microsoft 365 Organizational Data Service, see Microsoft 365 Organizational Data Service.

Friendly name	Operation	Description
Updated data sharing settings	DataSharingSettingsUpdated	Logged when a customer updates the list of apps allowed to share data, including which attributes each app can access.

Friendly name	Operation	Description
Updated access policies	AccessPoliciesUpdated	Logged when a customer updates access policies that control access to organizational data.
Updated access policy associations	AccessPolicyAssociationsUpdated	Logged when a customer updates attribute or app associations to access policies that control access to organizational data.

People Skills activities

The following table lists the activities in People Skills (Viva) that are logged in the Microsoft 365 audit log. For more information about this feature, see **People Skills documentation**.

Friendly name	Operation	Description
Added custom skills	CustomSkillsAdded	Generated when a tenant administrator adds custom skills to the tenant skills library.
Added graph skills	GraphSkillsAdded	Generated when a tenant administrator adds graph-based skills to the tenant library.
Added skill from inference	SkillAddedFromInference	Generated when the system adds an inferred skill to a user profile via TBA-triggered inference.
Added skill from learning	SkillAddedFromLearning	Generated when the system adds a skill inferred from learning activity.
Added user skill	UserSkillAdded	Generated when a user adds a skill to their own profile.
Applied external bulk tag	ExternalBulkTagApplied	Generated when a third-party application applies bulk content tags via the service-to-service (S2S) API.
Changed inferencing setting	InferencingToggleChanged	Generated when the E3/E5 inferencing toggle status changes.
Completed tenant offboarding	TenantOffboardCompleted	Generated when tenant offboarding completes and all tenant data has been deleted.
Deactivated tenant auto-on	TenantAutoOnDeactivated	Generated when the auto-on tenant setting is deactivated by the system.
Deleted custom skills	CustomSkillsDeleted	Generated when a tenant administrator deletes custom skills from the tenant library.
Deleted external skills	ExternalSkillsDeleted	Generated when a third-party application deletes previously ingested skills data.
Deleted graph skills	GraphSkillsDeleted	Generated when a tenant administrator removes graph-based skills from the tenant library.

Friendly name	Operation	Description
Deleted tenant skills library	TenantSkillsLibraryDeleted	Generated when the tenant skills library is removed as part of offboarding.
Deleted user data	UserDataDeleted	Generated when user data is deleted during tenant offboarding.
Deleted user skill	UserSkillDeleted	Generated when a user removes a skill from their profile.
Exported skills	SkillsExported	Generated when a tenant administrator exports skills data from the service.
Ingested external skills	ExternalSkillsIngested	Generated when a third-party application ingests skills data into People Skills via the service-to-service (S2S) API.
Provisioned skills library	SkillsLibraryProvisioned	Generated when the skills library is auto-provisioned for a tenant.
Provisioned tenant	TenantProvisioned	Generated when a tenant administrator provisions the People Skills skills library for their tenant.
Started tenant offboarding	TenantOffboardKickoff	Generated when tenant offboarding (data deletion) is initiated by the system.
Updated tenant settings	TenantSettingsUpdated	Generated when a tenant administrator modifies People Skills tenant-level configuration settings.
Updated user skill	UserSkillUpdated	Generated when a user updates metadata on an existing skill in their profile.
Validated custom skills	CustomSkillsValidated	Generated when a tenant administrator validates custom skills data (marks skills as validated).

Personal insights activities

The following table lists the activities in personal insights recorded in the Microsoft 365 audit log. For more information about personal insights, see Admin guide for personal insights.

Friendly name	Operation	Description
Updated organization MyAnalytics settings	UpdatedOrganizationMyAnalyticsSettings	Admin updates organization-level settings for personal insights.
Updated user MyAnalytics settings	UpdatedUserMyAnalyticsSettings	Admin updates user settings for personal insights.

Planner activities

The following table lists the user and admin activities in Microsoft Planner that the Microsoft 365 audit log records. The table includes the friendly name that displays in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the CSV file when you export the search results.

> **Note**
>
> Portfolio activity in Planner is logged with Microsoft Project for web roadmap activity. For details, see the Project for the web activities section.

Friendly name	Operation	Description
Added a member to a roster	RosterMemberAdded	A member was added to a roster. If the add operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, the *MemberIds* is a list of member IDs attempted.
Added a reaction to a chat message	ChatMessageReactionAdded	A reaction was added to a chat message by a user or an app.
Assigned a task	TaskAssigned	A task's assignee was modified by a user or an app. This might be an unassigned task getting assigned or an assigned task with a new assignee.
Completed a task	TaskCompleted	A task was marked completed by a user or an app.
Copied a plan	PlanCopied	A plan was copied by a user or an app. If the copy operation was a *ResultStatus.Failure* or *ResultStatus.Failure*, the *newPlanId* is null, the *newContainerType* is *ContainerType.Invalid*, and *newContainerId* is null.
Created a chat message	ChatMessageCreated	A chat message was created by a user or an app.
Created a goal	GoalCreated	A goal was created by a user or an app. If the create operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, the *ObjectId* is null and *PlanId* is null.
Created a plan	PlanCreated	A plan was created by a user or an app. If the create operation was a *ResultStatus.Failure* or

Friendly name	Operation	Description
		ResultStatus.AuthorizationFailure, the *ObjectId* is null, *ContainerType* is *ContainerType.Invalid* and *ContainerId* is null.
Created a roster	RosterCreated	A roster was created by a user or an app. If the create operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, the *ObjectId* is null, *MemberIds* is an empty string.
Created a task	TaskCreated	A task was created by a user or an app. If the create operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, the *ObjectId* is null and *PlanId* is null.
Deleted a chat message	ChatMessageDeleted	A chat message was deleted from a task chat by a user or an app.
Deleted a goal	GoalDeleted	A goal was deleted by a user or an app.
Deleted a plan	PlanDeleted	A plan was deleted by a user or an app.
Deleted a roster	RosterDeleted	A roster was deleted by a user or an app.
Deleted a task	TaskDeleted	A task was deleted by a user or an app.
Modified a chat message	ChatMessageModified	A chat message was modified by a user or an app.
Modified a goal	GoalModified	A goal was modified by a user or an app.
Modified a plan	PlanModified	A plan was modified by a user or an app.
Modified a task	TaskModified	A task was modified by a user or an app.
Read a goal	GoalRead	A goal was read by a user or an app. If the read operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, the *PlanId* is null.
Read a list of chat messages	ChatMessageListRead	A list of chat messages was queried by a user or an app. - if the query operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *MessageList* is an empty string.

Friendly name	Operation	Description
Read a list of goals	GoalListRead	A list of goals was queried by a user or an app. If the query operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *GoalList* is an empty string.
Read a list of plans	PlanListRead	A list of plans was queried by a user or an app. If the query operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *PlanList* is an empty string.
Read a list of tasks	TaskListRead	A list of tasks was queried by a user or an app. If the query operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *TaskList* is an empty string.
Read a plan	PlanRead	A plan was read by a user or an app. If the read operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *ContainerType* is *ContainerType.Invalid* and ContainerId is null.
Read a task	TaskRead	A task was read by a user or an app. If the read operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *PlanId* is null.
Removed a member to a roster	RosterMemberDeleted	A member was removed from a roster. If the remove operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, *MemberIds* is the list of member IDs attempted.
Removed a reaction to a chat message	ChatMessageReactionRemoved	A reaction was removed from a chat message by a user or an app
Updated a roster's sensitivity label	RosterSensitivityLabelUpdated	A user or an app updates a roster's sensitivity label.
Updated tenant settings	TenantSettingsUpdated	Organization settings are updated by an organization admin. If the update operation was a *ResultStatus.Failure* or *ResultStatus.AuthorizationFailure*, the *ObjectId* is original settings, and *TenantSettings* is the attempted organization settings.

Power Apps activities

You can search the audit log for app-related activities in Power Apps. These activities include creating, launching, and publishing an app. Assigning permissions to apps is also audited. For a description of all Power Apps activities, see Activity logging for Power Apps.

> **Note**
>
> Alert Policies (Protection Alert) audit events (RecordType:45) aren't currently supported for PowerApps.

Power Automate activities

You can search the audit log for activities in Power Automate (formerly called Microsoft Flow). These activities include creating, editing, and deleting flows, and changing flow permissions.

Project for the web activities

You can search the audit log for activities in Microsoft Project for the web. Microsoft Project for the web is built on the Microsoft Dataverse and has an associated Project Power App. To enable auditing for scenarios where the user is using the Microsoft Dataverse or the Project Power App, see the System Settings Auditing tab guidance. For a list of entities related to Project for the web, see the Export user data from Project for the web guidance.

For information about Microsoft Project for the web, see Microsoft Project for the web.

> **Note**
>
> Auditing events for Microsoft Project for the web activities requires a paid Project Plan 1 license (or higher).

The following table lists the Microsoft Project for web activities recorded in the Microsoft 365 audit log:

Friendly name	Operation	Description
Created project	ProjectCreated	A project was created by a user or app.
Created roadmap	RoadmapCreated	A roadmap or portfolio was created by a user or app.
Created roadmap item	RoadmapItemCreated	A roadmap or portfolio item was created by a user or app.

Friendly name	Operation	Description
Created task	TaskCreated	A task was created by a user or app.
Deleted project	ProjectDeleted	A project was deleted by a user or app.
Deleted roadmap	RoadmapDeleted	A roadmap or portfolio was deleted by a user or app.
Deleted roadmap item	RoadmapItemDeleted	A roadmap or portfolio item was deleted by a user or app.
Deleted task	TaskDeleted	A task was deleted by a user or app.
Project accessed	ProjectAccessed	A project was read by a user or app.
Project home accessed	ProjectListAccessed	A user queried a list of projects and/or roadmaps.
Roadmap accessed	RoadmapAccessed	A roadmap or portfolio was read by a user or app.
Roadmap item accessed	RoadmapItemAccessed	A roadmap or portfolio item was read by a user or app.
Task accessed	TaskAccessed	A task was read by a user or app.
Updated project	ProjectUpdated	A project was modified by a user or app.
Updated project settings	ProjectForTheWebProjectSettings	An admin updated project settings.
Updated roadmap	RoadmapUpdated	A roadmap or portfolio was modified by a user or app.
Updated roadmap item	RoadmapItemUpdated	A roadmap or portfolio item was modified by a user or app.
Updated roadmap settings	ProjectForTheWebRoadmaptSettings	An admin updated roadmap or portfolio settings.
Updated task	TaskUpdated	A task was modified by a user or app.

Quarantine activities

The following table lists the quarantine activities recorded in the Microsoft 365 audit log. For more information about quarantine, see Quarantine email messages.

Friendly name	Operation	Description
Deleted quarantine message	QuarantineDeleteMessage	An admin or user deleted an email message that was harmful.
Denied quarantine message release request	QuarantineReleaseRequestDeny	An admin denial for a release request from a user for an email message that was harmful.
Exported quarantine message	QuarantineExport	An admin or user exported an email message that was harmful.
Previewed quarantine message	QuarantinePreview	An admin or user previewed an email message that was harmful.
Release request quarantine message	QuarantineReleaseRequest	A user requested the release of an email message that was harmful.
Released quarantine message	QuarantineRelease	An admin or user released an email message from quarantine that was harmful.
Viewed quarantine message's header	QuarantineViewHeader	An admin or user viewed the header of an email message that was harmful.

Report activities

The following table lists the activities for usage reports recorded in the Microsoft 365 audit log.

Friendly name	Operation	Description
Updated usage report privacy settings	UpdateUsageReportsPrivacySetting	Admin updated privacy settings for usage reports.

Retention policy and retention label activities

The following table lists the configuration activities recorded in the Microsoft 365 audit log for retention policies and retention labels when you create, reconfigure, or delete them.

Friendly name	Operation	Description
Changed adaptive scope membership	ApplicableAdaptiveScopeChange	Users, sites, or groups were added to or removed from the adaptive scope. These changes result from running the scope's query. Because the changes are system-initiated, the reported user displays as a GUID rather than a user account.
Configured settings for a retention policy	NewRetentionComplianceRule	Administrator configured the retention settings for a new retention policy. Retention settings include how long items are retained, and what happens to items when the retention period expires (such as

Friendly name	Operation	Description
		deleting items, retaining items, or retaining and then deleting them). This activity also corresponds to running the New-RetentionComplianceRule cmdlet.
Created adaptive scope	NewAdaptiveScope	Administrator created an adaptive scope.
Created retention label	NewComplianceTag	Administrator created a new retention label.
Created retention policy	NewRetentionCompliancePolicy	Administrator created a new retention policy.
Deleted adaptive scope	RemoveAdaptiveScope	Administrator deleted an adaptive scope.
Deleted retention label	RemoveComplianceTag	Administrator deleted a retention label.
Deleted retention policy	RemoveRetentionCompliancePolicy	Administrator deleted a retention policy.
Deleted settings from a retention policy	RemoveRetentionComplianceRule	Administrator deleted the configuration settings of a retention policy. Most likely, this activity is logged when an administrator deletes a retention policy or runs the Remove-RetentionComplianceRule cmdlet.
Enabled regulatory record option for retention labels	SetRestrictiveRetentionUI	Administrator ran the Set-RegulatoryComplianceUI cmdlet so that an administrator can then select the UI configuration option for a retention label to mark content as a regulatory record.
Priority cleanup label applied on file	PriorityCleanupTagApplied	A retention label for priority cleanup is applied to an item on OneDrive or SharePoint (includes label replacement).
Retained email item proactively	ExchangeDataProactivelyPreserved	Adaptive protection automatically applied a retention label to retain an item in Exchange.
Retained file proactively	SharePointDataProactivelyPreserved	Adaptive protection automatically applied a retention label to retain an item in SharePoint or OneDrive.
Updated adaptive scope	SetAdaptiveScope	Administrator changed the description or query for an existing adaptive scope.

Friendly name	Operation	Description
Updated retention label	SetComplianceTag	Administrator updated an existing retention label.
Updated retention policy	SetRetentionCompliancePolicy	Administrator updated an existing a retention policy. Updates that trigger this event include adding or excluding content locations that the retention policy is applied to.
Updated settings for a retention policy	SetRetentionComplianceRule	Administrator changed the retention settings for an existing retention policy. Retention settings include how long items are retained, and what happens to items when the retention period expires (such as deleting items, retaining items, or retaining and then deleting them). This activity also corresponds to running the Set-RetentionComplianceRule cmdlet.

Role administration activities

The following table lists Microsoft Entra role administration activities recorded in the Microsoft 365 audit log when an admin manages admin roles in the Microsoft 365 admin center or in the Azure management portal.

Friendly name	Operation	Description
Add member to Role	Add member to role.	Added a user to an admin role in Microsoft 365.
Removed a user from a directory role	Remove member from role.	Removed a user to from an admin role in Microsoft 365.
Set company contact information	Set company contact information.	Updated the company-level contact preferences for your organization. This includes email addresses for subscription-related email sent by Microsoft 365, and technical notifications about services.

Sensitive information types activities

The following table lists the audit events for activities recorded in the Microsoft 365 audit log involving creation and updating of sensitive information types.

Friendly name	Operation	Description
Created new sensitive information type	CreateRulePackage / EditRulePackage*	A new sensitive information type was created. This information includes any SITs created by copying an out of the box SIT. **Note**: This activity surfaces under the audit activities 'Created rule package' or 'Edited rule package'.
Deleted a sensitive information type	EditRulePackage / RemoveRulePackage	An existing sensitive information type was deleted. This activity surfaces under the audit activity "Edited rule package" or "Removed rule package."
Edited a sensitive information type	EditRulePackage	An existing sensitive information type was edited. This information can include operations like adding or removing a pattern and editing the regex or keyword associated with the sensitive information type. This activity surfaces under the audit activity "Edited rule package."

Sensitivity label activities

The following table lists events recorded in the Microsoft 365 audit log that result from using sensitivity labels with containers and items managed by Microsoft Purview. Containers include SharePoint sites, Teams sites, and Loop workspaces. Items include documents, emails, calendar events, Loop components and pages, and Copilot pages. For auto-labeling policies, items also include files and data assets in Microsoft Purview Data Map.

Friendly name	Operation	Description
Applied sensitivity label to file	FileSensitivityLabelApplied SensitivityLabelApplied	A sensitivity label was applied to an item by using Microsoft 365 apps, Office for the web, the details pane in a SharePoint document library or from the Files tab in Teams, or an auto-labeling policy. The operations for this activity are different depending on how the label was applied: - Office for the web, details pane in a SharePoint document library or the Files tab in Teams, or an auto-labeling policy (FileSensitivityLabelApplied) - Microsoft 365 apps (SensitivityLabelApplied).
Applied sensitivity label to site	SiteSensitivityLabelApplied	A sensitivity label was applied to a SharePoint site, Teams site that isn't group-connected, or a Loop workspace.
Changed sensitivity	FileSensitivityLabelChanged	A different sensitivity label was applied to an item.

Friendly name	Operation	Description
label applied to file	SensitivityLabelUpdated	The operations for this activity are different depending on how the label was changed: - Office for the web, details pane in a SharePoint document library or the Files tab in Teams, or an auto-labeling policy (FileSensitivityLabelChanged) - Microsoft 365 apps (SensitivityLabelUpdated).
Changed sensitivity label on a site	SiteSensitivityLabelChanged	A different sensitivity label was applied to a SharePoint site, Teams site that isn't group-connected, or a Loop workspace.
Failed to apply file sensitivity label	FileSensitivityLabelAppliedFailed	A sensitivity label failed to be applied to an item by using Office for the web, the details pane in a SharePoint document library or from the Files tab in Teams, or an auto-labeling policy.
Failed to change file sensitivity label	FileSensitivityLabelChangedFailed	A different sensitivity label failed to be applied to an item using Office for the web, the details pane in a SharePoint document library or from the Files tab in Teams, or an auto-labeling policy.
Failed to remove file sensitivity label	FileSensitivityLabelRemovedFailed	A sensitivity label failed to be removed from an item by using Office for the web, the details pane in a SharePoint document library or from the Files tab in Teams, or an auto-labeling policy.
Removed sensitivity label from file	FileSensitivityLabelRemoved SensitivityLabelRemoved	A sensitivity label was removed from an item by using Microsoft 365 apps, Office for the web, the details pane in a SharePoint document library or the Files tab in Teams, an auto-labeling policy, or the Unlock-SPOSensitivityLabelEncryptedFile cmdlet. The operations for this activity are different depending on how the label was removed: - Office for the web, details pane in a SharePoint document library or the Files tab in Teams, or an auto-labeling policy (FileSensitivityLabelRemoved) - Microsoft 365 apps (SensitivityLabelRemoved).
Removed sensitivity label from site	SiteSensitivityLabelRemoved	A sensitivity label was removed from a SharePoint site, Teams site that isn't group-connected, or a Loop workspace.

The following table lists descriptions for values recorded in the Microsoft 365 audit log included in the *FailureReason* property for audit activities that log failures to apply, change, or remove

sensitivity labels. These properties aren't available for other sensitivity label activities:

FailureReason property	Property description
CannotOverrideCurrentLabel	A sensitivity label wasn't assigned to the file because the currently applied sensitivity label has a higher priority.
DowngradeJustificationTextMissing	Sensitivity label wasn't assigned to the file because justification text is required for this operation.
FileEncrypted	A sensitivity label wasn't assigned to the file because it's encrypted.
FileExtensionNotSupported	A sensitivity label wasn't assigned to the file because the file type isn't supported for this operation.
FileLockedOrCheckedOut	A sensitivity label wasn't assigned to the file because it's locked or checked out.
FileNotFound	A sensitivity label wasn't assigned to the file because it isn't available.
FileNotSupported	A sensitivity label wasn't assigned to the file because it doesn't support this operation.
FileTooLarge	A sensitivity label wasn't assigned to the file because it's too large to support this operation.
InvalidArgument	A sensitivity label wasn't assigned to the file because some parameters provided to perform this operation aren't valid.
LabelIdNotFound	A sensitivity label wasn't assigned to the file because the sensitivity label provided is unavailable or isn't valid.
LabelNotSupported	A sensitivity label wasn't assigned to the file because the sensitivity label provided isn't supported.
LabelOperationsDisabled	A sensitivity label wasn't assigned to the file because the sensitivity label operation is disabled on the file.
MinorVersionLimitExceeded	A sensitivity label wasn't assigned to the file because the version limit is exceeded.
UnauthorizedAccessException	A sensitivity label wasn't assigned to the file because the current user isn't authorized to perform this operation.
Unknown	A sensitivity label wasn't assigned to the file because of an internal error.
ZeroByteFileError	A sensitivity label wasn't assigned to the file because the operation can't be performed on a zero-byte file.

Additional auditing information for sensitivity labels:

- When you use sensitivity labels for Microsoft 365 Groups, and therefore Teams sites that are group-connected, the labels are audited with group management in Microsoft Entra ID. For more information, see Audit logs in Microsoft Entra ID.
- When you use sensitivity labels for Teams meeting invites, and Teams meeting options and chat, see Search the audit log for events in Microsoft Teams.
- When you use sensitivity labels with Power BI, see Audit schema for sensitivity labels in Power BI.
- When you use sensitivity labels with Microsoft Defender for cloud apps, see Governing connected apps and the labeling information for file governance actions.

SharePoint list activities

The following table lists the activities recorded in the Microsoft 365 audit log related to when users interact with lists and list items in SharePoint. Audit records for some SharePoint activities show that the app@sharepoint user performed the activity on behalf of the user or admin who initiated the action. For more information, see The app@sharepoint user in audit records.

Friendly name	Operation	Description
Created list	ListCreated	A user created a SharePoint list.
Created list column	ListColumnCreated	A user created a SharePoint list column. A list column is a column that's attached to one or more SharePoint lists.
Created list content type	ListContentTypeCreated	A user created a list content type. A list content type is a content type that's attached to one or more SharePoint lists.
Created list item	ListItemCreated	A user created an item in an existing SharePoint list.
Created site column	SiteColumnCreated	A user created a SharePoint site column. A site column is a column that isn't attached to a list. A site column is also a metadata structure that can be used by any list in a given web.
Created site content type	Site ContentType Created	A user created a site content type. A site content type is a content type that's attached to the parent site.
Deleted list	ListDeleted	A user deleted a SharePoint list.
Deleted list column	List Column Deleted	A user deleted a SharePoint list column.
Deleted list content type	ListContentTypeDeleted	A user deleted a list content type.

Friendly name	Operation	Description
Deleted list item	List Item Deleted	A user deleted a SharePoint list item.
Deleted site column	SiteColumnDeleted	A user deleted a SharePoint site column.
Deleted site content type	SiteContentTypeDeleted	A user deleted a site content type.
Recycled list item	ListItemRecycled	A user moved a SharePoint list item to the Recycle Bin.
Restored list	ListRestored	A user restored a SharePoint list from the Recycle Bin.
Restored list item	ListItemRestored	A user restored a SharePoint list item from the Recycle Bin.
Updated list	ListUpdated	A user updated a SharePoint list by modifying one or more properties.
Updated list column	ListColumnUpdated	A user updated a SharePoint list column by modifying one or more properties.
Updated list content type	ListContentTypeUpdated	A user updated a list content type by modifying one or more properties.
Updated list item	ListItemUpdated	A user updated a SharePoint list item by modifying one or more properties.
Updated list view	ListViewUpdated	A user updated a SharePoint list view by modifying one or more properties.
Updated site column	SiteColumnUpdated	A user updated a SharePoint site column by modifying one or more properties.
Updated site content type	SiteContentTypeUpdated	A user updated a site content type by modifying one or more properties.

SharePoint Embedded container type activities

The following table lists SharePoint Embedded container type activities that the Microsoft 365 audit log records. For more information about SharePoint Embedded, see SharePoint Embedded overview.

Friendly name	Operation	Description
Created container type	ContainerTypeCreated	A SharePoint Embedded container type was created.
Deleted container type	ContainerTypeDeleted	A SharePoint Embedded container type was deleted.
Updated container type	ContainerTypeUpdated	A SharePoint Embedded container type was updated.
Updated container type owners	ContainerTypeOwnersUpdated	The owners of a SharePoint Embedded container type were updated.

Sharing and access request activities

The following table lists the user sharing and access request activities in SharePoint and OneDrive recorded in the Microsoft 365 audit log. For sharing events, the **Detail** column under **Results** identifies the name of the user or group the item was shared with and whether that user or group is a member or guest in your organization. For more information, see Use sharing auditing in the audit log.

> **Note**
>
> Users can be either *members* or *guests* based on the UserType property of the user object. A member is usually a user within the organization, and a guest is usually a collaborator outside of your organization. When a user accepts a sharing invitation (and isn't already part of your organization), a guest account is created for them in your organization's directory. After the guest user has an account in your directory, you might share resources directly with them (without requiring an invitation).

Friendly name	Operation	Description
Accepted access request	AccessRequestAccepted	An access request to a site, folder, or document was accepted and the requesting user was granted access.
Accepted sharing invitation	SharingInvitationAccepted	User (member or guest) accepted a sharing invitation and was granted access to a resource. This event includes information about the user who was invited and the email address that was used to accept the invitation (they could be different). This activity is often accompanied by a second event that describes how the user was granted access to the resource,

Friendly name	Operation	Description
		for example, adding the user to a group that has access to the resource.
Added permission level to site collection	PermissionLevelAdded	A permission level was added to a site collection.
Blocked sharing invitation	SharingInvitationBlocked	A sharing invitation sent by a user in your organization is blocked because of an external sharing policy that either allows or denies external sharing based on the domain of the target user. In this case, the sharing invitation was blocked because: The target user's domain isn't included in the list of allowed domains. Or The target user's domain is included in the list of blocked domains. For more information about allowing or blocking external sharing based on domains, see Restricted domains sharing in SharePoint and OneDrive.
Created a company shareable link	CompanyLinkCreated	User created a company-wide link to a resource. Company-wide links can only be used by members in your organization. They can't be used by guests.
Created access request	AccessRequestCreated	User requests access to a site, folder, or document they don't have permissions to access.
Created an anonymous link	AnonymousLinkCreated	User created an anonymous link to a resource. Anyone with this link can access the resource without having to be authenticated.
Created secure link	SecureLinkCreated	A secure sharing link was created to this item.
Created sharing invitation	SharingInvitationCreated	User shared a resource in SharePoint or OneDrive with a user who isn't in your organization's directory.
Deleted secure link	SecureLinkDeleted	A secure sharing link was deleted.
Denied access request	AccessRequestDenied	An access request to a site, folder, or document was denied.
Removed a company	CompanyLinkRemoved	User removed a company-wide link to a resource. The link can no longer be used to access the resource.

Friendly name	Operation	Description
shareable link		
Removed an anonymous link	AnonymousLinkRemoved	User removed an anonymous link to a resource. The link can no longer be used to access the resource.
Shared file, folder, or site	SharingSet	User (member or guest) shared a file, folder, or site in SharePoint or OneDrive with a user in your organization's directory. The value in the **Detail** column for this activity identifies the name of the user the resource was shared with and whether this user is a member or a guest. This activity is often accompanied by a second event that describes how the user was granted access to the resource. For example, adding the user to a group that has access to the resource.
Unshared file, folder, or site	SharingRevoked	User (member or guest) unshared a file, folder, or site that was previously shared with another user.
Updated access request	AccessRequestUpdated	An access request to an item was updated.
Updated an anonymous link	AnonymousLinkUpdated	User updated an anonymous link to a resource. The updated field is included in the EventData property when you export the search results.
Updated sharing invitation	SharingInvitationUpdated	An external sharing invitation was updated.
Used a company shareable link	CompanyLinkUsed	User accessed a resource by using a company-wide link.
Used an anonymous link	AnonymousLinkUsed	An anonymous user accessed a resource by using an anonymous link. The user's identity might be unknown, but you can get other details such as the user's IP address.
Used secure link	SecureLinkUsed	A user used a secure link.
User added to secure link	AddedToSecureLink	A user was added to the list of entities who can use a secure sharing link.
User removed from secure link	RemovedFromSecureLink	A user was removed from the list of entities who can use a secure sharing link.

Friendly name	Operation	Description
Withdrew sharing invitation	SharingInvitationRevoked	User withdrew a sharing invitation to a resource.

Site administration activities

The following table lists events that result from site administration tasks in SharePoint and are recorded in the Microsoft 365 audit log. Audit records for some SharePoint activities indicate the app@sharepoint user performed the activity on behalf of the user or admin who initiated the action. For more information, see The app@sharepoint user in audit records.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Friendly name	Operation	Description
Added allowed data location	AllowedDataLocationAdded	A SharePoint or global administrator added an allowed data location in a multigeo environment.
Added exempt user agent	ExemptUserAgentSet	A SharePoint or global administrator added a user agent to the list of exempt user agents in the SharePoint admin center.
Added geo location admin	GeoAdminAdded	A SharePoint or global administrator added a user as a geo admin of a location.
Allowed user to create groups	AllowGroupCreationSet	Site administrator or owner adds a permission level to a site that allows a user assigned that permission to create a group for that site.
Apply theme to a web	WebThemeApplied	A SharePoint, global administrator, or a site owner applied a web theme.
Canceled site geo move	SiteGeoMoveCancelled	A SharePoint or global administrator canceled a SharePoint or OneDrive site geo move. The multigeo capability lets an organization span multiple Microsoft datacenter geographies, which are called geos. For more information, see Multi-Geo Capabilities in OneDrive and SharePoint.

Friendly name	Operation	Description
Changed a sharing policy	SharingPolicyChanged	A SharePoint or global administrator changed a SharePoint sharing policy by using the Microsoft 365 admin center, SharePoint admin center, or SharePoint Management Shell. Any change to the settings in the sharing policy in your organization are logged. The policy that was changed is identified in the **ModifiedProperties** field in the detailed properties of the event record.
Changed device access policy	DeviceAccessPolicyChanged	A SharePoint or global administrator changed the unmanaged devices policy for your organization. This policy controls access to SharePoint, OneDrive, and Microsoft 365 from devices that aren't joined to your organization. Configuring this policy requires an Enterprise Mobility + Security subscription. For more information, see Control access from unmanaged devices.
Changed exempt user agents	CustomizeExemptUsers	A SharePoint or global administrator customized the list of exempt user agents in the SharePoint admin center. You can specify which user agents to exempt from receiving an entire web page to index. This means when a user agent you specified as exempt encounters an InfoPath form, the form is returned as an XML file, instead of an entire web page. This makes indexing InfoPath forms faster.
Changed network access policy	NetworkAccessPolicyChanged	A SharePoint or global administrator changed the location-based access policy (also called a trusted network boundary) in the SharePoint admin center or by using SharePoint PowerShell. This type of policy controls who can access SharePoint and OneDrive resources in your organization based on authorized IP address ranges that you specify. For more information, see Control access to SharePoint and OneDrive data based on network location.
Completed migration job	MigrationJobCompleted	A migration job completed.
Completed site geo move	SiteGeoMoveCompleted	A site geo move that a global administrator in your organization scheduled completed. The multigeo capability lets an organization span multiple Microsoft datacenter geographies, which are called geos. For more information, see Multi-Geo Capabilities in OneDrive and SharePoint.

Friendly name	Operation	Description
Create tenant-wide theme	TenantWideThemeCreated	A SharePoint administrator, global administrator, or brand manager created a custom theme applied across all SharePoint sites in your organization.
Created Sent To connection	SendToConnectionAdded	A SharePoint or global administrator creates a new Send To connection on the Records management page in the SharePoint admin center. A Send To connection specifies settings for a document repository or a records center. When you create a Send To connection, a Content Organizer can submit documents to the specified location.
Created site collection	SiteCollectionCreated	A SharePoint or global administrator creates a site collection in your SharePoint organization or a user provisions their OneDrive site.
Delete tenant-wide theme	TenantWideThemeDeleted	A SharePoint administrator, global administrator, or brand manager deleted a custom theme applied across all SharePoint sites in your organization.
Deleted orphaned hub site	HubSiteOrphanHubDeleted	A SharePoint or global administrator deleted an orphan hub site, which is a hub site that doesn't have any sites associated with it. An orphaned hub is likely caused by the deletion of the original hub site.
Deleted Sent To connection	SendToConnectionRemoved	A SharePoint or global administrator deletes a Send To connection on the Records management page in the SharePoint admin center.
Deleted site	SiteDeleted	Site administrator deletes a site.
Enabled document preview	PreviewModeEnabledSet	Site administrator enables document preview for a site.
Enabled legacy workflow	LegacyWorkflowEnabledSet	Site administrator or owner adds the SharePoint 2013 Workflow Task content type to the site. Global administrators can also enable workflows for the entire organization in the SharePoint admin center.
Enabled Office on Demand	OfficeOnDemandSet	Site administrator enables Office on Demand, which lets users access the latest version of Office desktop applications. Office on Demand is enabled in the SharePoint admin center and requires a Microsoft 365 subscription that includes full, installed Office applications.
Enabled result source for People Searches	PeopleResultsScopeSet	Site administrator creates the result source for People Searches for a site.

Friendly name	Operation	Description
Enabled RSS feeds	NewsFeedEnabledSet	Site administrator or owner enables RSS feeds for a site. Global administrators can enable RSS feeds for the entire organization in the SharePoint admin center.
Joined site to hub site	HubSiteJoined	A site owner associates their site with a hub site.
Modified site collection quota	SiteCollectionQuotaModified	Site administrator modifies the quota for a site collection.
Permanently delete site	SitePermanentlyDeleted	A SharePoint or global administrator permanently deletes a site from SharePoint Admin Center Deleted Sites.
Registered hub site	HubSiteRegistered	A SharePoint or global administrator creates a hub site. The results are that the site is registered to be a hub site.
Removed allowed data location	AllowedDataLocationDeleted	A SharePoint or global administrator removed an allowed data location in a multigeo environment.
Removed geo location admin	GeoAdminDeleted	A SharePoint or global administrator removed a user as a geo admin of a location.
Renamed site	SiteRenamed	Site administrator or owner renames a site.
Restore Site	SiteRestored	A SharePoint or global administrator restores a site from SharePoint Admin Center Deleted Sites.
Scheduled site geo move	SiteGeoMoveScheduled	A SharePoint or global administrator scheduled a SharePoint or OneDrive site geo move. The multigeo capability lets an organization span multiple Microsoft datacenter geographies, which are called geos. For more information, see Multi-Geo Capabilities in OneDrive and SharePoint.
Set host site	HostSiteSet	A SharePoint or global administrator changes the designated site to host personal or OneDrive sites.
Set storage quota for geo location	GeoQuotaAllocated	A SharePoint or global administrator configured the storage quota for a geo location in a multigeo environment.
Unjoined site from hub site	HubSiteUnjoined	A site owner disassociates their site from a hub site.
Unregistered hub site	HubSiteUnregistered	A SharePoint or global administrator unregisters a site as a hub site. When a hub site is unregistered,

Friendly name	Operation	Description
		it no longer functions as a hub site.
Update DisableSiteBranding config	UpdateDisableSiteBranding	A SharePoint or global administrator enables or disables site branding.
Update tenant-wide theme	TenantWideThemeUpdated	A SharePoint administrator, global administrator, or brand manager updated a custom theme applied across all SharePoint sites in your organization.

Site permissions activities

The following table lists events related to assigning permissions in SharePoint and using groups to give (and revoke) access to sites recorded in the Microsoft 365 audit log. Audit records for some SharePoint activities indicate the app@sharepoint user performed the activity on behalf of the user or admin who initiated the action. For more information, see The app@sharepoint user in audit records.

Friendly name	Operation	Description
Added site collection admin	SiteCollectionAdminAdded	Site collection administrator or owner adds a person as a site collection administrator for a site. Site collection administrators have full control permissions for the site collection and all subsites. This activity is also logged when an admin gives themselves access to a user's OneDrive account (by editing the user profile in the SharePoint admin center or by using the Microsoft 365 admin center).
Added user or group to SharePoint group	AddedToGroup	User added a member or guest to a SharePoint group. This action might be intentional or the result of another activity, such as a sharing event.
Broke permission level inheritance	PermissionLevelsInheritanceBroken	An item was changed so that it no longer inherits permission levels from its parent.
Broke sharing inheritance	SharingInheritanceBroken	An item was changed so that it no longer inherits sharing permissions from its parent.
Created group	GroupAdded	Site administrator or owner creates a group for a site, or performs a task that results in a group being created. For example, the first time a user creates a link to share a file, a system group is added to the user's OneDrive site. This event can also be a result

Friendly name	Operation	Description
		of a user creating a link with edit permissions to a shared file.
Deleted group	GroupRemoved	User deletes a group from a site.
Modified 'Members Can Share' setting	WebMembersCanShareModified	The **Members Can Share** setting was modified on a site.
Modified access request setting	WebRequestAccessModified	The access request settings were modified on a site.
Modified permission level on a site collection	PermissionLevelModified	A permission level was changed on a site collection.
Modified site permissions	SitePermissionsModified	Site administrator or owner (or system account) changes the permission level that is assigned to a group on a site. This activity is also logged if all permissions are removed from a group. **NOTE**: This operation is deprecated in SharePoint. To find related events, you can search for other permission-related activities such as **Added site collection admin**, **Added user or group to SharePoint group**, **Allowed user to create groups**, **Created group**, and **Deleted group.**
Removed permission level from site collection	PermissionLevelRemoved	A permission level was removed from a site collection.
Removed site collection admin	SiteCollectionAdminRemoved	Site collection administrator or owner removes a person as a site collection administrator for a site. This activity is also logged when an admin removes themselves from the list of site collection administrators for a user's OneDrive account (by editing the user profile in the SharePoint admin center). To return this activity in the audit log search results, you have to search for all activities.
Removed user or group from SharePoint group	RemovedFromGroup	User removed a member or guest from a SharePoint group. This action might be intentional or the result of another activity, such as an unsharing event.

Friendly name	Operation	Description
Requested site admin permissions	SiteAdminChangeRequest	User requests to be added as a site collection administrator for a site collection. Site collection administrators have full control permissions for the site collection and all subsites.
Restored sharing inheritance	SharingInheritanceReset	A change was made so that an item inherits sharing permissions from its parent.
Updated group	GroupUpdated	Site administrator or owner changes the settings of a group for a site. This change can include the group's name, who can view or edit the group membership, and how membership requests are handled.

Stream activities

You can search the audit log for activities in Microsoft Stream. These activities include video activities performed by users, group channel activities, and admin activities such as managing users, managing organization settings, and exporting reports. For a description of these activities, see the "Actions logged in Stream" section in Audit Logs in Microsoft Stream.

Synchronization activities

The following table lists file synchronization activities recorded in the Microsoft 365 audit log for SharePoint and OneDrive.

Friendly name	Operation	Description
Allowed computer to sync files	ManagedSyncClientAllowed	User established a sync relationship with a site. The sync relationship is successful because the user's computer is a member of a domain that's been added to the list of domains (called the *safe recipients list*) that can access document libraries in your organization. For more information about this feature, see Use PowerShell cmdlets to enable OneDrive sync for domains that are on the safe recipients list.
Blocked computer from syncing files	UnmanagedSyncClientBlocked	User tries to establish a sync relationship with a site from a computer that isn't a member of your organization's domain or is a member of a domain that hasn't been added to the list of domains (called the *safe recipients list)* that can access document libraries in your organization. The sync relationship isn't allowed, and the user's computer is blocked from syncing, downloading,

Friendly name	Operation	Description
		or uploading files on a document library. For information about this feature, see Use PowerShell cmdlets to enable OneDrive sync for domains that are on the safe recipients list.
Downloaded file changes to computer	FileSyncDownloadedPartial	This event is deprecated along with the old OneDrive sync app (Groove.exe).
Downloaded files to computer	FileSyncDownloadedFull	User downloaded a file to their computer from a SharePoint document library or OneDrive using OneDrive sync app (OneDrive.exe).
Uploaded file changes to document library	FileSyncUploadedPartial	This event is deprecated along with the old OneDrive sync app (Groove.exe).
Uploaded files to document library	FileSyncUploadedFull	User uploaded a new file or changes to a file in SharePoint document library or OneDrive by using OneDrive sync app (OneDrive.exe).

SystemSync activities

The following table lists the activities for SystemSync recorded in the Microsoft 365 audit log.

Friendly name	Operation	Description
Data Share Created	DataShareCreated	When the user created the data export.
Data Share Deleted	DataShareDeleted	When the user deleted the data export.
Download Copy Of Lake Data	DownloadCopyOfLakeData	When the copy of Lake Data is downloaded.
Generate Copy Of Lake Data	GenerateCopyOfLakeData	When the copy of Lake Data is generated.

Teams activities

The following table lists Microsoft Teams activities recorded in the Microsoft 365 audit log. You can search the audit log for user and admin activities in Microsoft Teams. Teams is a chat-centered workspace in Microsoft 365. It brings a team's conversations, meetings, files, and notes together into a single place. For more detailed search guidance, see Search the audit log for events in Microsoft Teams.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Friendly name	Operation	Description
Accept message	UserAccepted	Accept a new message from a person who never established contact with.
Added bot to team	BotAddedToTeam	A user adds a bot to a team.
Added channel	ChannelAdded	A user adds a channel to a team.
Added connector	ConnectorAdded	A user adds a connector to a channel.
Added details about Teams meeting [9]	MeetingDetail	Teams added information about a meeting, including the start time, the end time, the URL to join the meeting, and the recording start/stop time for the meeting.
Added information about call participants [10, 11, 12]	CallParticipantDetail	Teams added information about the participants of a call, including the user ID of each participant, the time each participant joined and left the call, and participant connection information.
Added information about meeting participants [9, 12, 14]	MeetingParticipantDetail	Teams added information about the participants of a meeting, including the user ID of each participant, the time a participant joined the meeting, the time a participant left the meeting, and the start/stop time of a meeting recording by the user. You can also see logs with timestamps and information about: - Who joined a meeting - Where screensharing occurred - Who started the screenshare - When screensharing occurred - When screensharing stopped - When take, give, or request control was activated - If these control requests were accepted

Friendly name	Operation	Description
		- Who accepted these control requests - Who the content was shared with.
Added members [6, 8]	MemberAdded	A team owner adds members to a team, channel, or group chat.
Added tab	TabAdded	A user adds a tab to a channel.
Applied sensitivity label	SensitivityLabelApplied	A user or meeting organizer applied a sensitivity label to a Teams meeting.
Approved request	ApprovedRequest	After the user views the details of the approval request, they approved it.
Block user	UserBlocked	Block a user from sending messages to you.
Canceled approval request	CanceledApprovalRequest	User canceled an approval request they made.
Cancelled approval asynchronously	CancelledApprovalAsync	User cancels an approval request asynchronously.
Changed channel setting	ChannelSettingChanged	The ChannelSettingChanged operation is logged when the following activities are performed by a team member. For each of these activities, a description of the setting that was changed (shown in parentheses) is displayed in the **Item** column in the audit log search results. • Changes name of a team channel (**Channel name**) • Changes description of a team channel (**Channel description**).
Changed organization setting	TeamsTenantSettingChanged	The TeamsTenantSettingChanged operation is logged when the following activities are performed by a global admin in the Microsoft 365 admin center. These activities affect org-wide Teams settings. For more information, see Manage Teams settings for your organization. For each of these activities, a description of the setting that was changed (shown in parentheses) is displayed in the **Item** column in the audit log search results. • Enables or disables Teams for the organization (**Microsoft Teams**).

Friendly name	Operation	Description
		• Enables or disables interoperability between Microsoft Teams and Skype for Business for the organization (**Skype for Business interoperability**). • Enables or disables the organizational chart view in Microsoft Teams clients (**Org chart view**). • Enables or disables the ability for team members to schedule private meetings (**Private meeting scheduling**). • Enables or disables the ability for team members to schedule channel meetings (**Channel meeting scheduling**). • Enables or disables video calling in Teams meetings (**Video for Skype meetings**). • Enables or disables screen sharing in Microsoft Teams meetups for the organization (**Screen sharing for Skype meetings**). • Enables or disables that ability to add animated images (called Giphys) to Teams conversations (**Animated images**). • Changes the content rating setting for the organization (**Content rating**). The content rating restricts the type of animated image that can be displayed in conversations. • Enables or disables the ability for team members to add customizable images (called custom memes) from the internet to team conversations (**Customizable images from the Internet**). • Enables or disables the ability for team members to add editable images (called stickers) to team conversations (**Editable images**). • Enables or disables that ability for team members to use bots in Microsoft Teams chats and channels (**Org-wide bots)**. • Enables specific bots for Microsoft Teams. This doesn't include the T-Bot, which is Teams help bot that's available when bots are enabled for the organization (**Individual bots**). • Enables or disables the ability for team members to add extensions or tabs (**Extensions or tabs**).

Friendly name	Operation	Description
		• Enables or disables the side-loading of proprietary bots for Microsoft Teams (**Side loading of Bots**). • Enables or disables the ability for users to send email messages to a Microsoft Teams channel (**Channel email**).
Changed role of members in team	MemberRoleChanged	A team owner changes the role of members in a team. The following values indicate the role type assigned to the user. **1** - The Member role. **2** - The Owner role. **3** - The Guest role. The Members property also includes the name of your organization and the member's email address.
Changed sensitivity label	SensitivityLabelChanged	A user changed a sensitivity label on a Teams meeting.
Changed team setting	TeamSettingChanged	The TeamSettingChanged operation is logged when the following activities are performed by a team owner. For each of these activities, a description of the setting that was changed (shown in parentheses) is displayed in the **Item** column in the audit log search results. • Changes the access type for a team. Teams can be set as private or public (**Team access type**). When a team is private (the default setting), users can access the team only by invitation. When a team is public, it's discoverable by anyone. • Changes the information classification of a team (**Team classification**). For example, team data can be classified as high business impact, medium business impact, or low business impact. • Changes the name of a team (**Team name**). • Changes the team description (**Team description**). • Changes made to team settings. To access these settings, a team owner can right-click a team, select **Manage team**, and

Friendly name	Operation	Description
		then select the **Settings** tab. For these activities, the name of the setting that was changed is displayed in the **Item** column in the audit log search results.
Create org scoped template instance	CreateOrgScopedTemplateInstance	User created an organization scoped template instance.
Create team scoped template instance	CreateTeamScopedTemplateInstance	User created a team scoped template instance.
Create update request	CreateUpdateRequest	User created a new update template.
Created a chat [1, 6]	ChatCreated	A Teams chat was created.
Created approval	CreatedApproval	User created a new approval request.
Created approval asynchronously	CreatedApprovalAsync	User creates a new approval request asynchronously.
Created export job	CreatedExportJob	User created an export job.
Created provisioning	CreatedProvisioning	User created provisioning of CDS (Common Data Service) instance.
Created team	TeamCreated	A user creates a team.
Delete update request	DeleteUpdateRequest	User deletes an update template.
Deleted a message [2]	MessageDeleted	A message in a chat or channel was deleted.
Deleted all organization apps	DeletedAllOrganizationApps	Deleted all organization apps from the catalog.
Deleted app	AppDeletedFromCatalog	An app was deleted from the catalog.
Deleted channel	ChannelDeleted	A user deletes a channel from a team.
Deleted team	TeamDeleted	A team owner deletes a team.
Detected impersonation	TeamsImpersonationDetected	An external message sender is detected to have potential impersonation activity.

Friendly name	Operation	Description
attempt		
Detected security risk in call	SecurityRiskInCallDetected	A security risk was detected during an incoming call in Microsoft Teams, such as brand, domain, or user impersonation.
Downloaded file	DownloadedFile	User downloaded file attached to an approval request.
Edit org scoped template instance	EditOrgScopedTemplateInstance	User edited an organization scoped template instance.
Edit team scoped template instance	EditTeamScopedTemplateInstance	User edited a team scoped template instance.
Edit update request	EditUpdateRequest	User opens template edit wizard and selects the save button to confirm any update or enable/disable templates.
Edited a message	GraphMessageUpdated	A user updates a chat or channel message.
Edited a message with a URL link in Teams	MessageEditedHasLink	A user edits a message and adds a URL link to it in Teams.
Edited approval request	EditedApprovalRequest	User took an edit action on an approval request.
Exported messages [1, 2]	MessagesExported	Chat or channel messages were exported.
Exported recordings [1]	RecordingsExported	Chat recordings were exported.
Exported transcripts [1]	TranscriptsExported	Chat transcripts were exported.
Failed to validate invitation to shared channel [3]	FailedValidation	A user responds to an invitation to a shared channel but the invitation failed validation.
Fetched all hosted content of a message[1]	MessageHostedContentsListed	All hosted content in a message, such as images or code snippets, was retrieved.
Fetched chat [1]	ChatRetrieved	A Microsoft Teams chat was retrieved.

Friendly name	Operation	Description
Get org scoped template instance	GetOrgScopedTemplateInstance	User fetched an organization scoped template instance.
Get team scoped template instance	GetTeamScopedTemplateInstance	User fetched a team scoped template instance.
Got async operation	GotAsyncOperation	User got async operation entity.
Installed app	AppInstalled	An app was installed.
Obtain list of meeting recordings [13]	GraphMeetingRecordingsListed	List recording details for an online meeting.
Obtain list of meeting transcripts [13]	GraphMeetingTranscriptsListed	List transcript details for an online meeting.
Obtain meeting transcript content [13]	GraphMeetingTranscriptContentRead	Get the transcript content for an online meeting or an ad hoc call.
Obtain meeting transcript instance [13]	GraphMeetingTranscriptRead	Get the transcript details for an online meeting or ad hoc call.
Obtained meeting recording content [13]	GraphMeetingRecordingContentRead	Get the recording content for an online meeting or an ad hoc call.
Obtained meeting recording instance [13]	GraphMeetingRecordingRead	Get the recording details for an online meeting or an ad hoc call.
Performed action on card	PerformedCardAction	A user took action on an adaptive card within a chat. Adaptive cards are typically used by bots to allow the rich display of information and interaction in chats. Only inline input actions on an adaptive card inside a chat are available in the audit log. For example, when a user submits a poll response in a channel conversation on an adaptive card generated by a Poll bot. User actions such as

Friendly name	Operation	Description
		"View result", which opens a dialog, or user actions inside dialogs aren't available in the audit log.
Populate AI-generated notes in chat	AINotesUpdate	AI-generated notes were populated for a group chat.
Populate AI-generated notes in live meetings	LiveNotesUpdate	AI-generated notes were populated for a live meeting.
Posted new message [3, 4, 6, 8]	MessageSent	A new message was posted to a chat or a channel.
Published app	AppPublishedToCatalog	An app was added to the catalog.
Read a message [1]	MessageRead	A message of a chat or channel was retrieved.
Read hosted content of a message [1]	MessageHostedContentRead	Hosted content in a message, such as an image or a code snippet, was retrieved.
Reassigned approval request	ReassignedApprovalRequest	User reassigned an approval request to another user.
Received Read Receipt on a message	MessageReadReceiptReceived	A read receipt was received indicating that a user has read one or more messages in a chat. The audit record includes the chat thread and the point up to which messages were read.
Rejected approval request	RejectedApprovalRequest	After the user views the details of the approval request, they rejected it.
Removed bot from team	BotRemovedFromTeam	A user removes a bot from a team.
Removed connector	ConnectorRemoved	A user removes a connector from a channel.
Removed members [6, 8]	MemberRemoved	A team owner removes members from a team, channel, or group chat.
Removed sensitivity label	SensitivityLabelRemoved	A user removed a sensitivity label from a Teams meeting.
Removed sharing of team channel [3]	TerminatedSharing	A team or channel owner disabled sharing for a shared channel.

Friendly name	Operation	Description
Removed tab	TabRemoved	A user removes a tab from a channel.
Responded to approval	RespondedToApproval	User took action on an approval request.
Responded to invitation for shared channel [3]	InviteeResponded	A user responded to a shared channel invitation.
Responded to invitee response to shared channel [3]	ChannelOwnerResponded	A channel owner responded to a response from a user who responded to a shared channel invitation.
Responded with custom response	RespondedWithCustomResponse	User responded with a custom response text to an approval request.
Restored sharing of team channel [3]	SharingRestored	A team or channel owner re-enabled sharing for a shared channel.
Retrieved messages [1]	MessagesListed	Messages from a chat or channel were retrieved.
Sensitive content shared	SensitiveContentShared	Logged when **Detect sensitive content during screen sharing** meeting option is enabled for a Teams meeting and within that meeting there's sensitive content (for example, credit card numbers, bank account numbers, social security numbers and similar identification numbers) displayed on screen during a screen sharing session. For more information, see Manage whether meetings in your organization can detect sensitive content during screen sharing.
Sent a message with a URL link in Teams	MessageCreatedHasLink	A user sends a message containing a URL link in Teams.
Sent change notification for message creation [1]	MessageCreatedNotification	A change notification was sent to notify a subscribed listener application of a new message.
Sent change notification for message deletion [1]	MessageDeletedNotification	A change notification was sent to notify a subscribed listener application of a deleted message.

Friendly name	Operation	Description
Sent change notification for message update [1]	MessageUpdatedNotification	A change notification was sent to notify a subscribed listener application of an updated message.
Sent invitation for shared channel [3]	InviteSent	A channel owner or member sends an invitation to a shared channel. Invitations to shared channels can be sent to people outside of your organization if the channel policy is configured to share the channel with external users.
Submit update	SubmitUpdate	User submitted a new update.
Subscribed to message change notifications [1]	SubscribedToMessages	A subscription was created by a listener application to receive change notifications for messages.
Security Risk detected in a Teams call	SecurityRiskInCallDetected	An external Teams call is detected to have potential security concern such as impersonation
Teams Admin Action	TeamsAdminAction	Logged when a Teams admin performs actions like updating, adding, or deleting Teams related settings or configurations using admin tools like PowerShell, Admin Center, API, etc.
Thread creation probed	CreateThreadProbe	A user probed whether they can create a chat with users in your organization. The following properties are populated for each of these activities: **Activity**: The name of this activity, CreateThreadProbe. **CorrelationId**: Unique request identifier for the audit log. **CreationTime**: The time at which the audit log was created.ExtraProperties**: Contains a single key-value pair that describes the environment where the probe request initiated. **ID**: The ID of the report entry. The ID uniquely identifies the audit log entry. **OrganizationId**: The GUID for your Microsoft 365 organization. **ParticipantInfo**: Contains a list of objectId and tenantId pairs describing the set of target users against which the initiating user (UserKey user) initiated the probe. In other words, these are the set of users with which the initiating user wants

Friendly name	Operation	Description
		to create a thread. Only contains users from your organization. **RecordType**: The type of operation indicated by the record. **UserID**: The user principal name of the user that initiated the probe. **UserKey**: GUID of the user that initiated the probe. **UserSIPDomain**: The SIP domain of the user that initiated the probe. **UserTenantId**:The tenant of the user that initiated the probe. **UserType**: The type of the user that initiated the probe. Only takes on the value 0, which represents a regular AAD user. **Version**: The version number of the activity (identified by the Operation property) that's logged. **Workload**: The service where the activity occurred.
Unblock User	UserUnblocked	Unblock a user that was previously blocked.
Undeleted a message	GraphMessageUndeleted	A message in a chat or channel was deleted.
Uninstalled app	AppUninstalled	An app was uninstalled.
Update Teams Message	GraphMessageUpdated	Occurs when a user edits an existing chat message.
Updated a chat [1]	ChatUpdated	A Teams chat was updated.
Updated a message [1]	MessageUpdated	A message of a chat or channel was updated.
Updated app	AppUpdatedInCatalog	An app was updated in the catalog.
Updated approval request asynchronously	UpdatedApprovalRequestAsync	User took action on an approval request asynchronously.
Updated connector	ConnectorUpdated	A user modified a connector in a channel.
Updated tab	TabUpdated	A user modified a tab in a channel.
Upgraded app	AppUpgraded	An app was upgraded to its latest version in the catalog.

Friendly name	Operation	Description
User signed in to Teams	TeamsSessionStarted	A user signs in to a Microsoft Teams client. This event doesn't capture token refresh activities.
View approval request	ViewApprovalRequest	User makes a request to view an approval request.
View update	ViewUpdate	User views the details of the update.
Viewed approval request	ViewedApprovalRequest	User views the details of the approval request from either the adaptive card or within the app.
Viewed approval with additional field	ViewedApprovalWithAdditionalField	User views the details of the approval request that contains at least one editable text field.
Viewed approval with group request	ViewedApprovalWithGroupRequest	User views the details of the approval request with a group included.

Note

[1] An audit record for this event is only logged when the operation is performed by calling a Microsoft Graph API. If the operation is performed in the Teams client, an audit record isn't logged.

[2] This event is only available in Audit (Premium). That means users must be assigned the appropriate license before these events are logged in the audit log. For more information about activities only available in Audit (Premium), see Audit (Premium) in Microsoft Purview. For Audit (Premium) licensing requirements, see Auditing solutions in Microsoft 365.

[3] This event is in public preview.

[4]This event is generated for chat only if there are guests, federated and/or anonymous users.

[5] This event is currently unavailable in Government Community Cloud (GCC), Government Community Cloud High (GCC-High), and Department of Defense (DoD) organizations.

[6] This event is included in all participating tenants for federated chats.

[7] This event has participating domain info for 1:1 federated chats. [8] This event is included in all chat conversations between external Teams users managed by an organization and external Teams users not managed by an organization.

[9] This event is currently available in Government Community Cloud (GCC), Government Community Cloud High (GCC-High), Department of Defense (DoD) organizations and air-gapped environments.

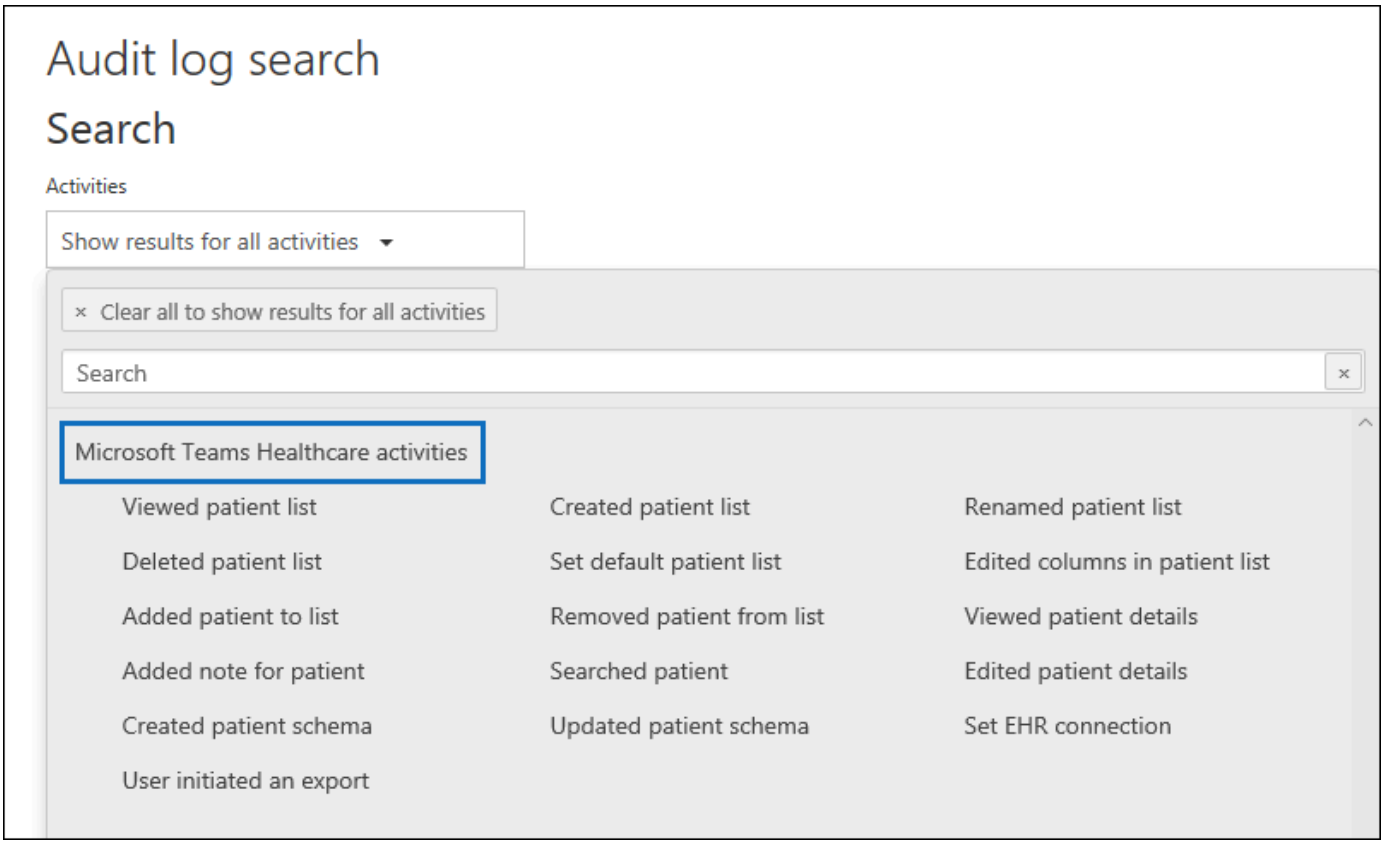
[10] This event is included in all participating tenants.

[11] An audit record isn't logged for activities with Agents or Bots. This capability is currently in development.

[12] Calls that are recorded or transcribed are included in MeetingParticipantDetail.

[13] This event is logged by Graph API access and not by Teams client.

[14] This event is now shared with all participating tenants, not just the organizer tenant. Participating tenants will receive Meeting Participant Detail audit records for their own users who attended a Teams meeting organized by another tenant.



Teams Evaluation Data Hub activities

The following table lists activities for Teams Evaluation Data Hub recorded in the Microsoft 365 audit log. Teams Evaluation Data Hub provides storage and data-access capabilities for conversational data sets (for example, meetings, chats, and Q&A logs) used to evaluate Microsoft Teams experiences. The audit log records when users or services read or write data sets in the hub and when access permissions on a data set are granted or revoked.

Friendly name	Operation	Description
Granted access permission	PermissionGranted	A user or service was granted access permission to a Teams Evaluation Data Hub data set or data asset.
Read data from storage	DataRead	A user or service read, browsed, or downloaded data from Teams Evaluation Data Hub storage.
Revoked access permission	PermissionRevoked	A user or service had access permission revoked for a Teams Evaluation Data Hub data set or data asset.
Wrote data to storage	DataWrite	Data in Teams Evaluation Data Hub storage was created, updated, overwritten, or deleted by a user or service.

Teams Healthcare activities

If your organization uses the Patients application in Microsoft Teams, you can search the audit log for activities related to the Patients app. If your environment is configured to support the Patients app, an additional activity group for these activities is available in the **Activities** picker list.

For a description of the Patients app activities, see Audit logs for Patients app.

Teams Shifts activities

The following table lists Shift app in Microsoft Teams activities recorded in the Microsoft 365 audit log. If your organization uses the Shifts app in Microsoft Teams, you can search the audit log for activities related to the Shifts app. If your environment is configured to support Shifts apps, the **Activities** picker list includes an additional activity group for these activities.

Friendly name	Operation	Description
Accepted off shift message	OffShiftDialogAccepted	A user acknowledged the off-shift message to access Teams after shift hours.
Added open shift	OpenShiftAdded	A user added an open shift to a scheduling group.
Added scheduling group	ScheduleGroupAdded	A user added a new scheduling group to the schedule.
Added shift	ShiftAdded	A user added a shift.
Added shift request	RequestAdded	A user added a shift request.
Added Time clock entry	TimeClockEntryAdded	A user added a new manual Time clock entry on Time Sheet.
Added time off	TimeOffAdded	A user added time off on the schedule.

Friendly name	Operation	Description
Added workforce integration	WorkforceIntegrationAdded	The Shifts app is integrated with a third-party system.
Canceled shift request	RequestCancelled	A user canceled a shift request.
Changed schedule setting	ScheduleSettingChanged	A user changed a setting in Shifts settings.
Clocked in using Time clock	ClockedIn	A user clocked in using Time clock.
Clocked out using Time clock	ClockedOut	A user clocked out using Time clock.
Deleted open shift	OpenShiftDeleted	A user deleted an open shift from a scheduling group.
Deleted scheduling group	ScheduleGroupDeleted	A user deleted a scheduling group from the schedule.
Deleted shift	ShiftDeleted	A user deleted a shift.
Deleted Time clock entry	TimeClockEntryDeleted	A user deleted a Time clock entry on Time Sheet.
Deleted time off	TimeOffDeleted	A user deleted time off.
Edited open shift	OpenShiftEdited	A user edited an open shift in a scheduling group.
Edited scheduling group	ScheduleGroupEdited	A user edited a scheduling group.
Edited shift	ShiftEdited	A user edited a shift.
Edited Time clock entry	TimeClockEntryEdited	A user edited a Time clock entry on Time Sheet.
Edited time off	TimeOffEdited	A user edited time off.
Ended break using Time clock	BreakEnded	A user ended a break during an active Time clock session.
Responded to shift request	RequestRespondedTo	A user responded to a shift request.
Shared schedule	ScheduleShared	A user shared a team schedule for a date range.
Started break using Time clock	BreakStarted	A user started a break during an active Time clock session.

Friendly name	Operation	Description
Withdrew schedule	ScheduleWithdrawn	A user withdrew a published schedule.

Teams Updates activities

The following table lists activities for the Updates app in Microsoft Teams recorded in the Microsoft 365 audit log. If your organization uses the Updates app in Microsoft Teams, you can search the audit log for activities related to the Updates app. If your environment is configured to support Updates apps, the **Activities** picker list includes an additional activity group for these activities.

Friendly name	Operation	Description
Create an update request	CreateUpdateRequest	A user created an update request.
Edit an update request	EditUpdateRequest	A user opens the request editing workflow and selects **Save** to confirm and save any changes, or enables or disables the update request directly.
Submit an update	SubmitUpdate	A user submitted an update.
View the details of one update	ViewUpdate	A user views the details of the update.

Teams User Concern activities

The following table lists user concern activities in Microsoft Teams recorded in the Microsoft 365 audit log. These events are generated when a user reports a concern about a message, call, or another user in Microsoft Teams. For more information, see End user reporting for Security.

Friendly name	Operation	Description
Reported call in Teams	CallReported	A user reported a call as a concern in Microsoft Teams.
Reported message in Teams	MessageReported	A user reported a message as a concern in Microsoft Teams.
Reported user in Teams	UserReported	A user reported another user as a concern in Microsoft Teams.

Trainable Classifier activities

The following table lists the activities for trainable classifiers recorded in the Microsoft 365 audit log.

Friendly name	Operation	Description
Created Purview Data Classification model	ModelCreate	A user (or admin or system on behalf of a user) created a new trainable model in Purview Data Classification.
Deleted Purview Data Classification model	ModelUpdate	A user (or admin or system on behalf of a user) updated a new trainable model in Purview Data Classification.
Published Purview Data Classification model	ModelPublish	A user (or admin or system on behalf of a user) published a new trainable model in Purview Data Classification.
Updated Purview Data Classification model	ModelDelete	A user (or admin or system on behalf of a user) deleted a new trainable model in Purview Data Classification.

Universal Print management activities

The following table lists the activities recorded in the Microsoft 365 audit log when actions are performed on printers, connectors, printer shares, and tenant-level settings using the Universal Print service.

Friendly name	Operation	Description
Added group access to printer share	ShareAccessControlGroupAdded	A group is granted access to a printer share.
Added member to pull-print printer	PullPrintPrinterMemberAdded	A member is added to a pull-print printer group for access control.
Added user access to printer share	ShareAccessControlUserAdded	A user is granted access to a printer share.
Created printer share	ShareCreated	A printer share is created, allowing multiple users to access the printer.
Created pull-print printer	PullPrintPrinterCreated	A pull-print virtual printer is created for secure print release.
Deleted printer share	ShareDeleted	A printer share is deleted, removing shared access.
Deleted pull-print printer	PullPrintPrinterDeleted	A pull-print virtual printer is deleted from Universal Print.
Disabled allow-all access for printer share	ShareAccessControlAllowAllDisabled	Universal access to the printer share is disabled.

Friendly name	Operation	Description
Disabled include-all-printers	PullPrintPrinterIncludeAllPrintersDisabled	All printers are excluded from the pull-print configuration.
Downloaded report	ReportDownloaded	A report is downloaded from Universal Print for analysis or auditing.
Enabled allow-all access for printer share	ShareAccessControlAllowAllEnabled	All users are allowed access to the printer share.
Enabled include-all-printers	PullPrintPrinterIncludeAllPrintersEnabled	All printers are included in the pull-print configuration.
Modified printer settings	PrinterSettingsModified	Printer configuration settings are updated in Universal Print.
Modified printer share settings	ShareSettingsModified	Settings for a printer share are updated in Universal Print.
Modified pull-print printer settings	PullPrintPrinterSettingsModified	Settings for a pull-print printer are updated in Universal Print.
Modified tenant print settings	TenantPrintSettingsModified	Tenant-level print settings are updated in Universal Print.
Registered connector	ConnectorRegistered	The connector is registered with Universal Print, enabling communication between printers and the cloud service.
Registered printer	PrinterRegistered	A printer is registered with Universal Print, making it available for cloud-based printing.
Removed group access from printer share	ShareAccessControlGroupRemoved	A group's access to a printer share is removed.
Removed member from pull-print printer	PullPrintPrinterMemberRemoved	A member is removed from a pull-print printer group.
Removed user access from printer share	ShareAccessControlUserRemoved	A user's access to a printer share is removed.
Swapped printer	PrinterSwapped	A printer is replaced or swapped with another device in Universal Print.
Unregistered connector	ConnectorUnregistered	The connector is unregistered from Universal Print, removing its ability to

Friendly name	Operation	Description
		manage printers.
Unregistered printer	PrinterUnregistered	A printer is removed from Universal Print, making it unavailable for cloud-based printing.

Universal Print print job activities

The following table lists the activities recorded in the Microsoft 365 audit log when actions are performed on print jobs using the Universal Print service.

Friendly name	Operation	Description
Aborted print job	PrintJobAborted	The print job is terminated unexpectedly due to an error or interruption.
Acknowledged print job	PrintJobAcknowledged	The print job is acknowledged by the printer, indicating that the printer has received and is ready to process the print job.
Canceled print job	PrintJobCanceled	The print job is canceled by the user or system before completion.
Completed print job	PrintJobCompleted	The print job finishes successfully, and all pages are printed.
Fetched print job document	PrintJobDocumentFetched	A print job document is retrieved by the printer or the Universal Print connector.
Submitted print job	PrintJobCreated	The print job is submitted to the print queue, indicating the start of the printing process.
Uploaded print job document	PrintJobDocumentUploaded	A print job document is successfully uploaded to Universal Print.

User administration activities

The following table lists user administration activities recorded in the Microsoft 365 audit log when an admin adds or changes a user account by using the Microsoft 365 admin center or the Azure management portal.

Friendly name	Operation	Description
Added user	Add user.	A user account is created.
Changed user license	Change user license.	The license assigned to a user changed. To see what licenses were changed, see the corresponding **Updated user** activity.

Friendly name	Operation	Description
Changed user password	Change user password.	A user changes their password. Self-service password reset has to be enabled (for all or selected users) in your organization to allow users to reset their password. You can also track self-service password reset activity in Microsoft Entra ID. For more information, see Reporting options for Microsoft Entra password management.
Deleted user	Delete user.	A user account was deleted.
Reset user password	Reset user password.	Administrator resets the password for a user.
Set license properties	Set license properties.	Administrator modified the properties of a license assigned to a user.
Set property that forces user to change password	Set force change user password.	Administrator set the property that forces a user to change their password the next time the user signs in to Microsoft 365.
Updated user	Update user.	Administrator changes one or more properties of a user account. For a list of the user properties that can be updated, see the "Update user attributes" section in Microsoft Entra audit Report Events.

Viva Engage activities

The following table lists the user and admin activities in Viva Engage recorded in the Microsoft 365 audit log. To return Viva Engage-related activities from the audit log, select **Show results for all activities** in the **Activities** list. Use the date range boxes and the **Users** list to narrow the search results.

> **Note**
>
> Some Viva Engage audit activities are only available in Audit (Premium). That means users must be assigned the appropriate license before these activities are logged in the audit log. For more information, see Audit (Premium). For Audit (Premium) licensing requirements, see Auditing solutions in Microsoft 365.
>
> In the following table, Audit (Premium) activities are highlighted with an asterisk (*).

Friendly name	Operation	Description
Added corporate communicator	AddUserRole	A user is assigned as a corporate communicator.

Friendly name	Operation	Description
Changed custom usage policy	UsagePolicyUpdated	A tenant admin updates a custom usage policy.
Changed data retention policy	SoftDeleteSettingsUpdated	Verified admin updates the setting for the network data retention policy to either Hard Delete or Soft Delete. Only verified admins can perform this operation.
Changed network configuration	NetworkConfigurationUpdated	Network or verified admin changes the Viva Engage network's configuration. This change includes setting the interval for exporting data and enabling chat.
Changed network profile settings	ProcessProfileFields	Network or verified admin changes the information that appears on member profiles for network users network.
Changed private content mode	SupervisorAdminToggled	Verified admin turns *Private Content Mode* on or off. This mode lets an admin view the posts in private groups and view private messages between individual users (or groups of users). Only verified admins only can perform this operation.
Changed security configuration	NetworkSecurityConfigurationUpdated	Verified admin updates the Viva Engage network's security configuration. This update includes setting password expiration policies and restrictions on IP addresses. Only verified admins can perform this operation.
Conversation closed	CloseConversation	The Viva Engage thread was closed, preventing users from replying to it. This action is available to an admin, corporate communicator, or a user delegate.
Conversation opened	OpenConversation	The Viva Engage thread conversation was opened which allows users to reply to the thread. This action is available to an admin, corporate communications, or a user delegate.
Create a segment	SegmentCreated	Admin creates a segmentation.
Created file	FileCreated	User uploads a file.
Created group	GroupCreation	User creates a group.
Created message	MessageCreation	User creates a message.

Friendly name	Operation	Description
Delete a segment	SegmentDeleted	Admin deletes a segmentation.
Deleted group	GroupDeletion	A group is deleted from Viva Engage.
Deleted message	MessageDeleted	User deletes a message.
Download segmentation admin reports	SegmentationReportDownloaded	Admin reports are downloaded.
Downloaded file	FileDownloaded	User downloads a file.
Event content exported	EventContentExported	Event organizer exports event questions, replies, reaction, and upvote count to a CSV. This action is available to event organizer, co-organizers only. Network admin can toggle this feature off for the entire network in the Engage admin settings.
Event moderation enabled	EventModerationEnabled	Event organizer enabled moderation for an event. This action is available to event organizers only.
Exported data	DataExport	Verified admin exports Viva Engage network data. Only verified admins can perform this operation.
Failed to access file	FileAccessFailure	User failed to access a file.
Failed to access group	GroupAccessFailure	User failed to access a group.
Failed to access thread	ThreadAccessFailure	User failed to access a message thread.
Generate segmentation admin reports	SegmentationReportGenerated	Admin user triggers a report generation.
Reacted to message	MarkedMessageChanged	User reacted to a message.
Remove curated topic*	RemoveCuratedTopic	User removes a curated topic.
Removed Corporate Communicator	RemoveUserRole	A user is removed from the Corporate Communicator role.

Friendly name	Operation	Description
Shared file	FileShared	User shares a file with another user.
Suspended network user	NetworkUserSuspended	Network or verified admin suspends (deactivates) a user from Viva Engage.
Suspended user	UserSuspension	User account is suspended (deactivated).
Tenant Usage Policy Acceptance	UsagePolicyAcceptance	A user accepts an organization-specific usage policy.
Thread Muted	AdminThreadMuted	A thread was muted by admin or watch alert (system user). A watch alert occurs when a thread is flagged for a certain theme (set by the admin) and is automuted by the system.
Thread Unmuted	AdminThreadUnmuted	Admin unmuted a thread.
Updated file description	FileUpdateDescription	User changes the description of a file.
Updated file name	FileUpdateName	User changes the name of a file.
Updated message	MessageUpdated	User updates a message.
Updated role assignment for Network Admin	NetworkAdminUpdated	A user is either promoted or demoted to the Network Admin role.
Updated role assignment for Verified Admin	NetworkVerifiedAdminUpdated	A user is either promoted or demoted to the Verified Admin role.
Viewed file	FileVisited	User views a file.
Viewed thread	ThreadViewed	User views a message thread.

Viva Glint activities

The following table lists the user and admin activities in Viva Glint that the Microsoft 365 audit log records. The table includes the friendly name that's displayed in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the .csv file when you export the search results.

Search the audit log explains how you can search for audit logs from the Microsoft Purview portal. To access audit logs, you need to be a global admin or have audit read permissions. Use the *Activities* filter to search for specific activities and to list all Viva Glint activities by choosing

VivaGlint in the *Record type* filter. Use the date range boxes and the *Users* list to narrow the search results further.

Friendly name	Operation	Description
Added agentic policy	PolicyAdded	An agentic policy was added.
Added Company Admin	AddCompanyAdmin	A user was added to the Company Admin role.
Added Support User	AddSupportUser	A user was added to the Support User role.
Assigned User Role	AssignRole	A user is assigned to a new role.
Changed Client Details	ClientDetailsChanged	Change activity in Viva Glint General Settings or Advanced Configuration: Details.
Company Admin Logged In	AdminLogin	A Company Admin user logged into Viva Glint.
Company Admin Logged Out	AdminLogout	A Company Admin user logged out of Viva Glint.
Completed agentic campaign	CampaignCompleted	An agentic campaign was completed.
Created agentic campaign	CampaignCreated	An agentic campaign was created.
Created User Role	RoleCreated	Glint User Role creation activity.
Deleted agentic campaign	CampaignDeleted	An agentic campaign was deleted.
Deleted agentic policy	PolicyDeleted	An agentic policy was deleted.
Deleted retained agentic campaign data	CampaignRetentionDeleted	Retained agentic campaign data was deleted.
Deleted Support Access	GlintSupportAccessDeleted	A user was removed from the Support User role.
Deleted System	GlintSystemDeleted	The Viva Glint system was deleted.
Deleted tenant data for a DSR request	DsrTenantDeleted	Tenant data was deleted for a data subject rights (DSR) request.
Deleted User	GlintUserDeleted	Viva Glint user deletion activity.
Deleted user data for a	DsrUserDeleted	User data was deleted for a data

Friendly name	Operation	Description
DSR request		subject rights (DSR) request.
Disabled Advanced Configuration Access	UserAdvConfigDisabled	A Company Admin user disabled Advanced Configuration access in Viva Glint.
Disabled Glint to Insights integration	GlintToInsightsIntegrationDisabled	A user disabled importing Viva Insights data in Viva Glint
Enabled Advanced Configuration Access	UserAdvConfigEnabled	A Company Admin user enabled Advanced Configuration access in Viva Glint.
Enabled Glint to Insights integration	GlintToInsightsIntegrationEnabled	A user enabled importing Viva Insights data in Viva Glint
Executed Data Apps Job	GlintDataAppsJobRun	Viva Glint Advanced Configuration Data app and Upload activity.
Exported agentic campaign policy violations	VivaGlintAgenticPolicyViolationsExported	Agentic campaign policy violations export activity.
Exported agentic campaign topic analysis	VivaGlintAgenticTopicAnalysisExported	Agentic campaign topic analysis export activity.
Exported all agentic campaign data	VivaGlintAgenticAllDataExported	Agentic campaign raw data export activity.
Exported Glint 360 Feedback	GlintFeedbackProgramExport	Viva Glint 360 feedback program data export activity.
Exported Glint Distribution Lists	GlintUserGroupExport	Distribution List export activity.
Exported Glint People	GlintUserExport	Glint People data export activity.
Exported Glint Pulse Program Response Rate	GlintPulseProgramRespondentRateExport	Glint pulse program response rate export activity.
Exported Glint Question Library	GlintQuestionExport	Glint question library export activity.
Exported Glint Survey Program	GlintPulseProgramExport	Glint survey program content export activity.
Exported Glint User Role	GlintRoleExport	Glint User Role data export activity.
Exported Raw Survey Data	RawSurveyReponseExport	Raw survey response data export activity.

Friendly name	Operation	Description
Exported User Data	UserDataExport	Employee data export activity.
Generated agentic campaign report	ReportGenerated	An agentic campaign report was generated.
Imported Glint 360 Feedback	GlintFeedbackProgramImport	360 Feedback program data import activity.
Imported Glint SFTP	GlintRubiconImport	Employee data SFTP import activity.
Imported Glint User Data	GlintUserImport	Employee data import activity.
Imported Glint User Role	GlintRoleImport	User Role employee data activity.
Launched agentic campaign	CampaignLaunched	An agentic campaign was launched.
Removed Company Admin	RemoveCompanyAdmin	A user was removed from the Company Admin role.
Reopened Survey	SurveyReopen	A closed Viva Glint survey was reopened.
Reordered agentic policy priorities	PolicyPrioritiesReordered	Agentic policy priorities were reordered.
Set Data DSR Control	DataDsrControlSet	User Data controls for survey data deletion in General Settings update activity.
Set Discarding Employee IDs	DiscardingEmployeeIdsSet	User Data controls for Employee ID reuse in General Settings update activity.
Shared agentic campaign report	ReportShared	An agentic campaign report was shared.
Unassigned User Role	UnassignRole	A user is removed from a role.
Updated agentic campaign	CampaignUpdated	An agentic campaign was updated.
Updated agentic policy	PolicyUpdated	An agentic policy was updated.
Updated agentic settings	AgenticSettingsUpdated	Agentic settings were updated.

Friendly name	Operation	Description
Updated Glint to Insights integration	GlintToInsightsIntegrationUpdated	A user updated the configuration for importing Viva Insights data in Viva Glint
Viewed As	ViewAs	Admins' "View As" another user activity.

Viva Goals activities

The following table lists the user and admin activities in Viva Goals that the Microsoft 365 audit log records. The table includes the friendly name that displays in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the CSV file when you export the search results.

Search the audit log explains how you can search for audit logs from the Microsoft Purview portal. To access audit logs, you need to be a global admin or have audit read permissions. You can use the **Activities** filter to search for specific activities. To list all Viva Goals activities, select **VivaGoals** in the **Record type** filter. You can also use the date range boxes and the **Users** list to narrow the search results further.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Friendly name	Operation	Description
Dashboard created	Dashboard created	User created a new dashboard on Viva Goals.
Dashboard deleted	Dashboard deleted	User deleted a dashboard on Viva Goals.
Dashboard updated	Dashboard updated	User updated a dashboard on Viva Goals.
Data exported	Data exported	A user exported list of OKRs or list of users in an organization on Viva Goals.
Goals policy updated	Goals policy updated	The global admin modified the policy or settings at organization level on Viva Goals. For example, the global admin configured who can create organizations on Viva Goals.

Friendly name	Operation	Description
OKR or Project created	OKR or Project created	User created an OKR or Project on Viva Goals.
OKR or Project deleted	OKR or Project deleted	User deleted an OKR or Project.
OKR or Project updated	OKR or Project updated	An OKR/Project was modified or a check-in was made by the user or an integration on Viva Goals.
Organization created	Organization created	Admin or the user created a new organization on Viva Goals.
Organization integrations updated	Organization integrations updated	The user (typically Organization owners or admins) configured a third party integration or updated an existing third party integration for an organization on Viva Goals.
Organization settings updated	Organization settings updated	The user (typically Organization owners or admins) updated organization specific settings on Viva Goals.
Team added	Team added	A new team was created within an organization on Viva Goals.
Team deleted	Team deleted	A team within an organization on Viva Goals was deleted by the user.
Team updated	Team updated	A team within an organization on Viva Goals was modified or updated.
User added	User added	A new user was added to an organization on Viva Goals.
User deactivated	User deactivated	A user was deactivated in an organization.
User deleted	User deleted	A user was deleted from an organization on Viva Goals.
User logged in	User logged in	User signed in to Viva Goals.

Viva Insights activities

Viva Insights provides insight into how groups collaborate across your organization. The following table lists activities recorded in the Microsoft 365 audit log that users assigned the Administrator or Analyst roles in Viva Insights perform. Users assigned the Analyst role have full access to all service features and use the product to do analysis. Users assigned the Administrator role can configure privacy settings and system defaults, and can prepare, upload, and verify organizational data in Viva Insights. For more information, see Introducing Microsoft Viva Insights.

Friendly name	Operation	Description
Accessed OData link	AccessedOdataLink	Analyst accessed the OData link for a query.
Added delegate access	AddDelegates	A user added delegate access for organization insights or Copilot dashboard.
Canceled query	CanceledQuery	Analyst canceled a running query.
Created meeting exclusion	MeetingExclusionCreated	Analyst created a meeting exclusion rule.
Deleted result	DeletedResult	Analyst deleted a query result.
Downloaded report	DownloadedReport	Analyst downloaded a query result file.
Executed query	ExecutedQuery	Analyst ran a query.
Modified CXO Settings	ModifiedCXOSettings	This event logs the assignment or removal of users/groups to access the Microsoft 365 Copilot Dashboard.
Modified Exclusion List Using Entra Group	ModifiedExclusionListUsingEntraGroup	This event logs changes to the exclusion list using the Entra group in the Copilot Dashboard.
Modified Minimum Group Size	ModifiedMinimumGroupSize	This event logs modifications to the organization's minimum group size for generating insights in the Copilot Dashboard and Viva Insights advanced analysis.
Removed delegate access	RemoveDelegates	A user removed delegate access for organization insights or Copilot dashboard.
Updated data access setting	UpdatedDataAccessSetting	Admin updated data access settings.
Uploaded organization data	UploadedOrgData	Admin uploaded organizational data file.
User logged in*	UserLoggedIn	A user signed in to their Microsoft 365 user account.
Viewed Explore	ViewedExplore	Analyst viewed visualizations in one or more Explore page tabs.

Note

*A Microsoft Entra sign-in activity event is created when a user signs in. This activity is logged even if you don't turn on Viva Insights in your organization. For more information about user sign in activities, see Sign-in logs in Microsoft Entra ID.

Viva Pulse activities

The following table lists the user and admin activities in Viva Pulse recorded in the Microsoft 365 audit log. The table includes the friendly name that's displayed in the **Activities** column and the name of the corresponding operation that appears in the detailed information of an audit record and in the CSV file when you export the search results.

Search the audit log explains how you can search for audit logs from the Microsoft Purview portal. To access audit logs, you need to be a global admin or have audit read permissions. You can use the **Activities** filter to search for specific activities. To list all Viva Pulse activities, select *VivaPulse* in the **Record type** filter. You can also use the date range boxes and the **Users** list to narrow the search results further.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Friendly name	Operation	Description
Admin deleted a user's data	PulseDeleteUserData	Admin deleted a user's data.
Admin updated tenant's settings	PulseTenantSettingsUpdate	Admin updated an organization setting for Viva Pulse.
Confidential conversation started	PulseConfidentialConversationStarted	Author started a confidential conversation.
Conversation message deleted	PulseConfidentialConversationMessageDeleted	User deleted a conversation message.
Conversation response added	PulseConfidentialConversationResponded	Author or recipient responded on a conversation.
User canceled a Pulse survey	PulseCancel	User canceled a Pulse survey.

Friendly name	Operation	Description
User created a Pulse draft	PulseCreateDraft	User created a Pulse draft.
User created a Pulse survey	PulseCreate	New Viva Pulse feedback request is created.
User deleted a Pulse draft	PulseDeleteDraft	User deleted a Pulse draft.
User deleted a question for Library	PulseQuestionDeleted	User removed a question for pulse question library.
User extended their pulse survey deadline	PulseExtendDeadline	User extended the deadline for the existing Viva Pulse feedback request.
User invited additional users to Pulse survey	PulseInvite	User invited additional users to an existing Viva Pulse feedback request.
User request a pulse data export	PulseDataExport	Admin or Author request a pulse export operation.
User shared a pulse report	PulseShareResults	User shared Viva Pulse feedback results with other users.
User submitted response to a pulse survey	PulseSubmit	Admin or user provided feedback for a Viva Pulse feedback request.

Windows 365 Customer Lockbox activities

The following table lists the user and admin activities in Windows 365 Customer Lockbox that the Microsoft 365 audit log records. To return Windows 365 Customer Lockbox-related activities from the audit log, select **Windows365CustomerLockbox** under **Record types**. Use the date range boxes and the **Users** list to narrow the search results.

Friendly name	Operation	Description
Backfill CMD Agent	AddDevicesToBackfill Operation	Backfill CMD Agent on Cloud PC.
Bulk reinstall CMD Agent	TriggerClientAgentCheckBulkAction Operation	Bulk reinstall CMD agent on demand.
Check PowerShell Execution Policy	Check PowerShell Execution Policy	Check PowerShell execution policy.

Friendly name	Operation	Description
Create LogCollection Request	Create LogCollection Request	Create log collection request to Cloud PC.
Create new work items (Scheduler)	Create new work items (Scheduler)	Create new work items, such as Provision, Deprovision, Reprovision, and others.
Create Remote Action Operation in ActionModeratorService	Create Remote Action Operation in ActionModeratorService	Create remote action by tenantID, workspaceID, actionType, actionParameters.
Create VmExtension Request	Create VmExtention Request	Creates VM extension requests to execute VM extension to run custom scripts on the customer device.
Execute AppHealthPlugin	Execute AppHealthPlugin	Execute AppHealthPlugin.
Install RD agent	Install RD agent	Install RD agent on the device of the user.
OCE Run Commands on VM	OCE Run Commands on VM	Run commands by tenantID, deviceID list, and script.
Post Remote Action Operation	Post Remote Action Operation	Post Remote Action, plus polling the result by GetActions operation.
Reinstall CMD Agent	AddDevicesToReinstall Operation	Reinstall CMD Agent on demand.
Run hybrid AADJ extension	Run hybrid AADJ extension	Run hybrid AADJ extension on the device of the user.
Trigger CMD Agent Canary check.	Trigger CMD Agent Canary check.	Trigger CMD Agent Canary check on specific device.
Trigger device remediation	Trigger device remediation	Trigger device remediation.
Trigger generic action	Trigger generic action	Trigger device action for user.
Trigger generic action by SaaF	Trigger generic action by SaaF	Trigger device action (Retargeting, EnableRdpAccessForCitrix, DisableRdpAccessFprCitrix) for user.
Trigger generic action with options	Trigger generic action with options	Trigger device action with option parameters, more powerful than that of trigger generic action.
Trigger orchestrator	Trigger orchestrator	Trigger orchestrator for the user.

Friendly name	Operation	Description
Upload folder to blob	Upload folder to blob	Compress and upload customer device's folder to blob.

Fabric Workspace Inbound External Data Share setting

The following table lists the Fabric admin activities for enabling and disabling the Workspace Inbound External Data Share setting.

Friendly name	Operation	Description
Enabled external data shares bypass on the workspace	ExternalDataSharesBypassForWorkspaceEnabled	Admin allowed External Data Shares to access data in workspaces where inbound public network access is restricted.
Disabled external data shares bypass on the workspace	ExternalDataSharesBypassForWorkspaceDisabled	Admin blocked External Data Shares from accessing data in workspaces where inbound public network access is restricted.

Detailed activity properties in the audit log

Summarize this article for me

When you export the results of an audit log search from the Microsoft Purview portal, you can download all the results that meet your search criteria. You can export this information by selecting **Export results** > **Download all results** on the **Audit log search** page. For more information, see Search the audit log.

When you export all results for an audit log search, the raw data from the unified audit log is copied to a comma-separated value (CSV) file that you download to your local computer. This file contains extra property information from each audit activity record in a column named **AuditData**. This column contains a multi-value property for multiple properties from the audit log record. Each of the **property: value** pairs in this multi-value property are separated by a comma.

The following table describes the activity properties that are included (depending on the service in which an activity occurs) in the multi-property **AuditData** column. The **Microsoft service that has this property** column indicates the service and type of activity (user or admin) that includes the property. For more detailed information about these properties or about properties that might not be listed in this article, see Management Activity API Schema.

> **Tip**
>
> You can use the JSON transform feature in Power Query in Excel to split the **AuditData** column into multiple columns so that each property has its own column. This feature lets you sort and filter on one or more of these properties. To learn how to do this, see **Export, configure, and view audit log records**.

Expand table

Property	Description	Microsoft service that has this property
Actor	The user or service account that performed the action.	Microsoft Entra ID
AddOnName	The name of an add-on that was added, removed, or updated in a team. The type of add-ons in Microsoft Teams is a bot, a connector, or a tab.	Microsoft Teams

Property	Description	Microsoft service that has this property
AddOnType	The type of an add-on that was added, removed, or updated in a team. The following values indicate the type of add-on. **1** - Indicates a bot. **2** - Indicates a connector. **3** - Indicates a tab.	Microsoft Teams
AppAccessContext	The application context for the user or service principal that performed the action.	Microsoft Teams
ArtifactShared	Files or content shared by the user.	Microsoft Teams
AzureActiveDirectoryEventType	The type of Microsoft Entra ID activity. The following values indicate the type of activity. **0** - Indicates an account sign-in activity. **1** - Indicates an Azure application security activity.	Microsoft Entra ID
ChannelGuid	The ID of a Microsoft Teams channel. The team that the channel is located in is identified by the **TeamName** and **TeamGuid** properties.	Microsoft Teams
ChannelName	The name of a Microsoft Teams channel. The team that the channel is located in is identified by the **TeamName** and **TeamGuid** properties.	Microsoft Teams
Client	The client device, the device OS, and the device browser used for the sign-in activity (for example, Nokia Lumia 920; Windows Phone 8; IE Mobile 11).	Microsoft Entra ID
ClientInfoString	Information about the email client that was used to perform the operation, such as a browser version, Outlook version, and mobile device information	Exchange (mailbox activity)
ClientIP	The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format. For some services, the value displayed in this property might be the IP address for a trusted application (for example, Office on the web apps) calling into the service on behalf of a user and	Microsoft Entra ID, Exchange, SharePoint

Property	Description	Microsoft service that has this property
	not the IP address of the device used by person who performed the activity. Also, for admin activity (or activity performed by a system account) for Microsoft Entra ID-related activities, the IP address isn't logged and the value for the ClientIP property is `null`.	
CreationTime	The date and time in Coordinated Universal Time (UTC) when the audit log record is generated.	All
CurrentProtectionType	A complex property type containing fields to describe the current protection status of a document. Includes the following: **ProtectionType**: Enumerates the type of protection applied to the document. These values and their meanings apply: *0* (no protection), *1* (template-based protection), *2* (don't forward, for email), *3* (encrypt only), and *4* (custom, user configured protection) **Owner**: The email address of the user that configured protection. **TemplateId**: When the *ProtectionType* is set to *1* (template), this field contains the GUID of the template applied to the document. When the value of *ProtectionType* doesn't equal *1*, this field is blank. **DocumentEncrypted**: Boolean flag indicating if any type of encryption is applied to the document. Values are *True* or *False*.	All
DestinationFileExtension	The file extension of a file that is copied or moved. This property is displayed only for the FileCopied and FileMoved user activities.	SharePoint
DestinationFileName	The name of the file is copied or moved. This property is displayed only for the FileCopied and FileMoved actions.	SharePoint
DestinationRelativeUrl	The URL of the destination folder where a file is copied or moved. The combination of the values for the **SiteURL**, the **DestinationRelativeURL**, and the **DestinationFileName** property is the same as the value for the **ObjectID** property, which is the full path name for the file that was copied. This	SharePoint

Property	Description	Microsoft service that has this property
	property is displayed only for the FileCopied and FileMoved user activities.	
EventSource	Identifies that an activity occurred in SharePoint. Possible values are **SharePoint** and **ObjectModel**.	SharePoint
ExtendedProperties	The extended properties for Microsoft Purview and Microsoft Entra ID activities.	Microsoft Entra ID Microsoft Purview
ExternalAccess	For Exchange admin activity, specifies whether the cmdlet was run by a user in your organization, by Microsoft datacenter personnel or a datacenter service account, or by a delegated administrator. The value **False** indicates that the cmdlet was run by someone in your organization. The value **True** indicates that the cmdlet was run by datacenter personnel, a datacenter service account, or a delegated administrator. For Exchange mailbox activity, specifies whether a mailbox was accessed by a user outside your organization.	Exchange
ID	The ID of the report entry. The ID uniquely identifies the report entry.	All
InternalLogonType	Reserved for internal use.	Exchange (mailbox activity)
IsJoinedFromLobby	Whether or not the user joined a Teams session from the lobby.	Microsoft Teams
ItemType	The type of object that was accessed or modified. Possible values include **File**, **Folder**, **Web**, **Site**, **Tenant**, and **DocumentLibrary**.	SharePoint
LoginStatus	Identifies sign-in failures that might have occurred.	Microsoft Entra ID
LogonType	The type of mailbox access. The following values indicate the type of user who accessed the mailbox.	Exchange (mailbox activity)

Property	Description	Microsoft service that has this property
	0 - Indicates a mailbox owner. **1** - Indicates an administrator. **2** - Indicates a delegate. **3** - Indicates the transport service in the Microsoft datacenter. **4** - Indicates a service account in the Microsoft datacenter. **6** - Indicates a delegated administrator.	
MailboxGuid	The Exchange GUID of the mailbox that was accessed.	Exchange (mailbox activity)
MailboxOwnerUPN	The email address of the person who owns the mailbox that was accessed.	Exchange (mailbox activity)
Members	Lists the users that have been added or removed from a team. The following values indicate the Role type assigned to the user. **1** - Indicates the Member role. **2** - Indicates the Owner role. **3** - Indicates the Guest role. The Members property also includes the name of your organization, and the member's email address.	Microsoft Teams
ModifiedProperties (Name, NewValue, OldValue)	The property is included for admin activities, such as adding a user as a member of a site or a site collection admin group. The property includes the name of the property that was modified (for example, the Site Admin group) the new value of the modified property (such the user who was added as a site admin, and the previous value of the modified object).	All (admin activity)
NewValue	The value after a change, includes all properties updated or deleted.	Microsoft Purview (governance)
ObjectFullyQualifiedName	The fully qualified name for an entity.	Microsoft Purview (governance)

Property	Description	Microsoft service that has this property
ObjectId	For Exchange admin audit logging, the name of the object that was modified by the cmdlet. For SharePoint activity, the full URL path name of the file or folder accessed by a user. For Azure AD activity, the name of the user account that was modified.	All
ObjectName	The main entity name.	Microsoft Purview (governance)
ObjectType	The entity type.	Microsoft Purview (governance)
OldValue	The value before a change, includes all properties updated or deleted.	Microsoft Purview (governance)
Operation	The name of the user or admin activity. The value of this property corresponds to the value that was selected in the **Activities** drop down list. If **Show results for all activities** was selected, the report will included entries for all user and admin activities for all services. For a description of the operations/activities that are logged in the audit log, see the **Audited activities** tab in Search the audit log in the Office 365. For Exchange admin activity, this property identifies the name of the cmdlet that was run.	All
OrganizationId	The GUID for your organization.	All
Parameters	For Exchange admin activity, the name and value for all parameters that were used with the cmdlet that is identified in the Operation property.	Exchange (admin activity)
ParticipantInfo	Additional properties about the participant identity.	Microsoft Teams
ParticipatingDomainInformation	Domain information about the participant.	Microsoft Teams
Path	The name of the mailbox folder where the message that was accessed is located. This	Exchange (mailbox activity)

Property	Description	Microsoft service that has this property
	property also identifies the folder a where a message is created in or copied/moved to.	
PreviousProtectionType	A complex property type containing fields to describe the previous protection status of a document. Includes the following: **ProtectionType**: Enumerates the type of protection applied to the document. These values and their meanings apply: *0* (no protection), *1* (template-based protection), *2* (don't forward, for email), *3* (encrypt only), *4* (custom, user configured protection) **Owner**: The email address of the user that configured protection. **TemplateId**: When the *ProtectionType* is set to *1* (template), this field contains the GUID of the template applied to the document. When the value of *ProtectionType* doesn't equal *1*, this field is blank. **DocumentEncrypted**: Boolean flag indicating if any type of encryption is applied to the document. Values are *True* or *False*.	All
ProtectionEventType	Enumerates how the protection was changed by the operation being audited. The following values and meanings apply: **0** - Indicates unchanged. **1** - Indicates added. **2** - Indicates changed. **3** - Indicates removed.	All
RecordType	The type of operation indicated by the record. This property indicates the service or feature that the operation was triggered in. For a list of record types and their corresponding ENUM value (which is the value displayed in the **RecordType** property in an audit record), see Audit log record type.	
ResultStatus	Indicates whether the action (specified in the **Operation** property) was successful or not. For Exchange admin activity, the value is either **True** (successful) or **False** (failed).	All

Property	Description	Microsoft service that has this property
SecurityComplianceCenterEventType	Indicates that the activity was a Microsoft Purview portal activity. All Microsoft Purview portal activities have a value of **0** for this property.	Microsoft Purview portal
SensitivityLabel	The sensitivity label assigned to a specific mail item.	Exchange
SharingType	The type of sharing permissions that you assigned to the user that you shared the resource with. This user is identified in the **UserSharedWith** property.	SharePoint
Site	The GUID of the site where the file or folder accessed by the user is located.	SharePoint
SiteUrl	The URL of the site where the file or folder accessed by the user is located.	SharePoint
SourceFileExtension	The file extension of the file that the user accessed. This property is blank if the object that was accessed is a folder.	SharePoint
SourceFileName	The name of the file or folder accessed by the user.	SharePoint
SourceRelativeUrl	The URL of the folder that contains the file the user accessed. The combination of the values for the **SiteURL**, the **SourceRelativeURL**, and the **SourceFileName** property is the same as the value for the **ObjectID** property, which is the full path name for the file the user accessed.	SharePoint
Subject	The subject line of the message that was accessed.	Exchange (mailbox activity)
TabType	The type of tab added, removed, or updated in a team. The possible values for this property are: **Excel pin** - An Excel tab. **Extension** - All first-party and third-party apps; such as Class Schedule, VSTS, and Forms. **Notes** - OneNote tab. **Pdfpin** - A PDF tab. **Powerbi** - A Power BI tab.	Microsoft Teams

Property	Description	Microsoft service that has this property
	Powerpointpin - A PowerPoint tab. **Sharepointfiles** - A SharePoint tab. **Webpage** - A pinned website tab. **Wiki-tab** - A wiki tab. **Wordpin** - A Word tab.	
Target	The user that the action (identified in the **Operation** property) was performed on. For example, if a guest is added to SharePoint or a Microsoft Team, that user is listed in this property.	Microsoft Entra ID
TeamGuid	The ID of a team in Microsoft Teams.	Microsoft Teams
TeamName	The name of a team in Microsoft Teams.	Microsoft Teams
UserAgent	Information about the user's browser. The browser provides this information.	SharePoint
UserDomain	Identity information about the tenant organization of the user (actor) who performed the action.	Microsoft Entra ID
UserId	The user who performed the action (specified in the **Operation** property) that resulted in the record being logged. Audit records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included in the audit log. Another common value for the UserId property is app@sharepoint. This value indicates that the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service. For more information, see: The app@sharepoint user in audit records or System accounts in Exchange mailbox audit records.	All

Property	Description	Microsoft service that has this property
UserKey	Contains a valid Microsoft Entra ID Object ID in GUID format or hex format. For scenarios where the primary actor isn't a user, the *UserKey* is an empty string. See UserType and UserKey scenarios for details on various *UserKey* scenarios.	All
UserType	The type of user that performed the operation. See the UserType and UserKey scenarios for details on various *UserType* scenarios.	All
Version	Indicates the version number of the activity (identified by the **Operation** property) that's logged.	All
Workload	The Microsoft 365 service where the activity occurred.	All

UserType and UserKey scenarios

The following table provides details for *UserType* and *UserKey* scenarios:

Expand table

Value	UserType member name	Description	UserKey
0	Regular	A regular user without admin permissions.	Microsoft Entra Object ID in GUID format
2	Admin	An administrator in your Microsoft 365 organization.[1]	Microsoft Entra Object ID in GUID format
3	DCAdmin	A Microsoft datacenter administrator or datacenter system account.	Microsoft Entra Object ID in GUID format
4	System	An audit event triggered by server-side logic. For example, Windows services or background processes.	Guid.Empty.ToString() (or the value '00000000-0000-0000-0000-000000000000').

Value	UserType member name	Description	UserKey
5	Application	An audit event triggered by a Microsoft Entra application.	Microsoft Entra Application Name or Application ID (when available). Otherwise, an empty string.
6	ServicePrincipal	A service principal.	Guid.Empty.ToString() (or the value '00000000-0000-0000-0000-000000000000').
7	CustomPolicy	A customer created or managed policy.	Guid.Empty.ToString() (or the value '00000000-0000-0000-0000-000000000000').
8	SystemPolicy	A Microsoft-managed or system policy.	Guid.Empty.ToString() (or the value '00000000-0000-0000-0000-000000000000').
9	PartnerTechnician	A partner tenant's user working on behalf of the customer tenant (in GDAP scenarios).	Guid.Empty.ToString() (or the value '00000000-0000-0000-0000-000000000000').
10	Guest	A guest or anonymous user.	Guid.Empty.ToString() (or the value '00000000-0000-0000-0000-000000000000').
11	Agent	An AI agent	Microsoft Entra Object ID of the primary agent in GUID format.

Note

[1] For Microsoft Entra related events, the value for an administrator isn't used in an audit record. Audit records for activities performed by administrators indicate that a regular user (for example, **UserType: 0**) performed the activity. The **UserID** property identifies the person (regular user or administrator) who performed the activity.

Learn about properties in Exchange audit records

This article explains the properties and fields you see in Exchange audit records returned by Search-UnifiedAuditLog. It's written for Exchange and Microsoft 365 admins who investigate mailbox activity or build scripts to parse audit output. You find a concise description of primary properties, representative AuditData JSON for common operations, PowerShell extraction examples, and a quick reference for common property values and investigation scenarios.

Use this reference to understand:

- Key properties in audit record results
- What each field represents and contains
- Common property values and their meanings
- How to extract basic information from audit data

Audit record structure reference

Exchange audit records contain several key properties that provide different types of information about the audited activity.

Primary audit record properties

When you run Search-UnifiedAuditLog, each result contains these main properties:

Expand table

Property	Data Type	Description	Example value
AuditData	JSON String	Detailed JSON data about the activity	Complex JSON structure
CreationDate	DateTime	When the activity occurred	11/17/2025 2:30:15 PM
Identity	GUID	Unique identifier for the audit record	00aa00aa-bb11-cc22-dd33-44ee44ee44ee
Operations	String	What type of activity occurred	SoftDelete, HardDelete, Move
ResultCount	Integer	Total results available	150

Property	Data Type	Description	Example value
ResultIndex	Integer	Position in search results	1, 2, 3...
UserIds	String	Who performed the activity	`<user@domain.com>`

AuditData JSON structure reference

The *AuditData* property contains detailed information in JSON format. Here are some typical JSON response structures for common operations:

- **Email deletion (SoftDelete/HardDelete)**

JSON

```

      "Id": "AAMkADM2NDIyMzUzLWE1ZjQtNGVkNS04OGE3LTg5NzY4ZDc1ZTZhNwAuAAAAAAC7...",
      "Path": "[\\Inbox](file:///\\inbox\)",
      "FolderItems": \[
        {
          "Id": "AAMkADM2NDIyMzUzLWE1ZjQtNGVkNS04OGE3LTg5NzY4ZDc1ZTZhNwBGAAAAAAC7...",

          "Subject": "Weekly Status Report"
        }
      \]
    }
  \],
  "OperationCount": 5,
  "SessionId": "33333333-4444-5555-6666-777777777777"
}
```

Here are the key fields organized by category:

User and session information

Expand table

Field	Data type	Description	Example value
ClientInfoString	String	Client application information	Client=OWA, Client=WebServices
ClientIP	String	IP address of the client	192.168.1.100
SessionId	GUID	Unique session identifier	00aa00aa-bb11-cc22-dd33-44ee44ee44ee
UserId	String	User who performed the action	user@domain.com
UserKey	String	User identifier key	user@domain.com
UserType	String	Type of user account	Regular, Admin, System, Application

Activity details

Expand table

Field	Data type	Description	Example value
CreationTime	DateTime	When the activity occurred (UTC)	2025-11-17T14:30:15Z

Field	Data type	Description	Example value
Operation	String	Specific operation performed	SoftDelete, New-InboxRule, MailItemsAccessed
OrganizationId	GUID	Organization identifier	00aa00aa-bb11-cc22-dd33-44ee44ee44ee
RecordType	String	Type of audit record	ExchangeItem, ExchangeAdmin
Workload	String	Microsoft 365 service	Exchange, SharePoint, OneDrive

Target information

Expand table

Field	Data type	Description	Example value
Item.Id	String	Exchange item identifier	AAMkADM2...
Item.ParentFolder.Name	String	Folder name where item was located	Inbox, Sent Items, Deleted Items
Item.ParentFolder.Path	String	Full folder path	\Inbox, \Deleted Items
Item.Subject	String	Email subject line	Meeting Request
MailboxGuid	GUID	Target mailbox identifier	00aa00aa-bb11-cc22-dd33-44ee44ee44ee
MailboxOwnerUPN	String	Mailbox owner's email address	mailboxowner@domain.com

Basic data extraction techniques

Use these techniques to extract and inspect key values from the AuditData JSON payload.

Convert JSON data

To extract information from the `AuditData` JSON, use the following commands:

```
\$AuditData = ConvertFrom-Json \$Results[0].AuditData
\$AuditData.UserId
\$AuditData.ClientIP
\$AuditData.MailboxOwnerUPN
```

Display key properties

To see the main properties in a readable format, use the following command:

```
\$Results \| Select CreationDate, UserIds, Operations, @{Name="MailboxOwner";Expression={(ConvertFrom-Json \$\_.AuditData).MailboxOwnerUPN}} \| Format-Table -AutoSize
```

Understanding common property values

The following tables help you understand common values found in audit record properties.

Operation types

The following table lists common Exchange audit operations and what they typically indicate during an investigation.

Expand table

Operation	Description	Investigation focus
HardDelete	Item permanently removed	Permanent deletions
MailItemsAccessed	Mailbox items were accessed	Unauthorized access investigation
Move	Item moved between folders	Folder organization changes
New-InboxRule	New mailbox rule created	Rule creation investigation
Send	Email was sent	Email communication tracking
Set-InboxRule	Mailbox rule modified	Rule modification tracking
SoftDelete	Item moved to Deleted Items	User-initiated deletions

RecordType values

The following table explains common RecordType values and the Exchange activities they represent.

Expand table

RecordType	Workload	Typical operations
ExchangeAdmin	Exchange	New-InboxRule, Set-InboxRule, Set-Mailbox
ExchangeAggregatedOperation	Exchange	MailItemsAccessed (bulk operations)
ExchangeItem	Exchange	SoftDelete, HardDelete, Move, Send

UserType values

UserType identifies what kind of account performed the audited action.

Expand table

UserType	Description	Investigation notes
Admin	Administrator account	Administrative actions
Application	Application service principal	App-based access
Regular	Standard user account	Normal user activity
System	System or service account	Automated processes

ClientInfoString examples

ClientInfoString values show which client, protocol, or access method was used.

Expand table

ClientInfoString	Description	Access method
Client=ActiveSync	Exchange ActiveSync	Mobile device sync
Client=IMAP4	IMAP protocol	IMAP client access
Client=OWA	Outlook Web App	Web browser access
Client=POP3	POP3 protocol	POP3 client access
Client=WebServices	Exchange Web Services (EWS)	Programmatic access

Quick reference

Use the following tables as a quick lookup for the most useful audit properties and PowerShell techniques.

Essential properties for investigations

The following table highlights which audit properties are most useful for common investigation scenarios.

Expand table

Investigation type	Key properties to focus on
Bulk Operations	SessionId, ItemCount, ClientIP, UserIds, Operations
Email Deletions	CreationDate, UserIds, Operations, Item.Subject, Item.ParentFolder.Name
Rule Changes	UserIds, Operations, Parameters, ClientIP, MailboxOwnerUPN
Unauthorized Access	UserIds, ClientIP, ClientInfoString, MailboxOwnerUPN, SessionId

Useful PowerShell techniques

These PowerShell techniques help you inspect, filter, and present Exchange audit records more effectively.

Expand table

Technique	Command example	Purpose
Convert JSON	`ConvertFrom-Json \$\_.AuditData`	Extract detailed audit information
Filter Data	`Where-Object {\$\_.ClientIP -like "192.168.\*"}`	Focus on specific criteria
Format Output	`Format-Table -Wrap -AutoSize`	Display results clearly
Group Results	`Group-Object ClientIP`	Identify patterns and anomalies
Select Properties	Select CreationDate, UserIds, Operations	Show only relevant information

Next steps

- Search the audit log for mailbox activities: Search for specific mailbox activities.
- Use a PowerShell script to search the audit log: Automate audit log searches with PowerShell.
- Use MailItemsAccessed to investigate compromised accounts: Investigate mailbox access patterns.

Microsoft services that support auditing

Summarize this article for me

You can search the unified audit log for activities performed in different Microsoft services. The following table lists the Microsoft services, apps, and features that the unified audit log supports.

Expand table

Microsoft service or feature	Record types
Microsoft Entra ID	AzureActiveDirectory, AzureActiveDirectoryAccountLogon, AzureActiveDirectoryStsLogon
Azure Information Protection (For the Microsoft Purview Information Protection client and scanner)	AipDiscover, AipSensitivityLabelAction, AipProtectionAction, AipFileDeleted, AipHeartBeat
Communication compliance	ComplianceSupervisionExchange
Content explorer	LabelContentExplorer
Data connectors	ComplianceConnector
Data loss prevention (DLP)	ComplianceDLPSharePoint, ComplianceDLPExchange, DLPEndpoint
Dynamics 365	CRM
eDiscovery (Standard + Premium)	Discovery, AeD
Encrypted message portal	OMEPortal
Exact Data Match	MipExactDataMatch
Exchange Online	ExchangeAdmin, ExchangeItem, ExchangeItemAggregated
Forms	MicrosoftForms

Microsoft service or feature	Record types
Information barriers	InformationBarrierPolicyApplication
Microsoft Defender XDR	AirInvestigation, AirManualInvestigation, AirAdminActionInvestigation, MS365DCustomDetection
Microsoft 365 Copilot and Microsoft 365 Copilot Chat	CopilotInteraction
Microsoft Defender Experts	DefenderExpertsforXDRAdmin
Microsoft Defender for Identity (MDI)	MicrosoftDefenderForIdentityAudit
Microsoft Planner	PlannerCopyPlan, PlannerPlan, PlannerPlanList, PlannerRoster, PlannerRosterSensitivityLabel, PlannerTask, PlannerTaskList, PlannerTenantSettings
Microsoft Project for the web	ProjectAccessed, ProjectCreated, ProjectDeleted, ProjectTenantSettingsUpdated, ProjectUpdated, RoadmapAccessed,RoadmapCreated, RoadmapDeleted, RoadmapItemAccessed,RoadmapItemCreated,RoadmapItemDeleted, RoadmapItemUpdated, RoadmapTenantSettingsUpdated, RoadmapUpdated, TaskAccessed, TaskCreated,TaskDeleted, TaskUpdated
Microsoft Purview Information Protection (MIP) labels	MIPLabel, MipAutoLabelExchangeItem, MipAutoLabelSharePointItem, MipAutoLabelSharePointPolicyLocation
Microsoft Teams	MicrosoftTeams
Microsoft To Do	MicrosoftToDo, MicrosoftToDoAudit
MyAnalytics	MyAnalyticsSettings
OneDrive for Business	OneDrive
Power Apps	PowerAppsApp, PowerAppsPlan
Power Automate	MicrosoftFlow
Power BI	PowerBIAudit
Quarantine	Quarantine

Microsoft service or feature	Record types
Sensitive information types	DlpSensitiveInformationType
Sensitivity labels	MIPLabel, SensitivityLabelAction, SensitivityLabeledFileAction, SensitivityLabelPolicyMatch
SharePoint Online	SharePoint, SharePointFileOperation,SharePointSharingOperation, SharePointListOperation, SharePointCommentOperation
Stream	MicrosoftStream
SystemSync	DataShareCreated, DataShareDeleted, GenerateCopyOfLakeData, DownloadCopyOfLakeData
Threat Intelligence	ThreatIntelligence, ThreatIntelligenceUrl, ThreatFinder, ThreatIntelligenceAtpContent
Viva Goals	VivaGoals
Viva Insights	VivaInsights
Viva Engage	Yammer

For more information about the operations that each service audits, see the Audit log activities article.

The previous table also identifies the record type value to use to search the audit log for activities in the corresponding service by using the **Search-UnifiedAuditLog** cmdlet in Exchange Online PowerShell or by using a PowerShell script. Some services have multiple record types for different types of activities within the same service. For a more complete list of auditing record types, see Office 365 Management Activity API schema.

For more information about using PowerShell to search the audit log, see:

- Search-UnifiedAuditLog
- Use a PowerShell script to search the audit log

Last updated on 02/18/2026

Use the Microsoft Graph security API

The Microsoft Graph security API provides a unified interface and schema to integrate with security solutions from Microsoft and ecosystem partners. This empowers customers to streamline security operations and better defend against increasing cyber threats. The Microsoft Graph security API federates queries to all onboarded security providers and aggregates responses. Use the Microsoft Graph security API to build applications that:

- Consolidate and correlate security alerts from multiple sources.
- Pull and investigate all incidents and alerts from services that are part of or integrated with Microsoft 365 Defender.
- Unlock contextual data to inform investigations.
- Automate security tasks, business processes, workflows, and reporting.
- Send threat indicators to Microsoft products for customized detections.
- Invoke actions to in response to new threats.
- Provide visibility into security data to enable proactive risk management.

The Microsoft Graph security API provides key features as described in the following sections.

Advanced hunting

Advanced hunting is a query-based threat-hunting tool that lets you explore up to 30 days of raw data. You can proactively inspect events in your network to locate threat indicators and entities. The flexible access to data enables unconstrained hunting for both known and potential threats.

Use runHuntingQuery to run a Kusto Query Language (KQL) query on data stored in Microsoft 365 Defender. Use the returned result set to enrich an existing investigation or to uncover undetected threats in your network.

Quotas and resource allocation

The following conditions relate to all queries.

1. Queries explore and return data from the past 30 days.
2. Results can return up to 100,000 rows.
3. You can make up to at least 45 calls per minute per tenant. The number of calls varies per tenant based on its size.
4. Each tenant is allocated CPU resources, based on the tenant size. Queries are blocked if the tenant reaches 100% of the allocated resources until after the next 15-minute cycle. To avoid blocked queries due to excess consumption, follow the guidance in Optimize your queries to avoid hitting CPU quotas.
5. If a single request runs for more than three minutes, it times out and returns an error.
6. A `429` HTTP response code indicates that you reached the allocated CPU resources, either by the number of requests sent or by allotted running time. Read the response body to understand the limit you reached.
7. Query results have an overall size limit of 50 MB. This limit doesn't just refer to the number of records; factors such as the number of columns, data types, and field lengths also contribute to the query result size.

Migrate from the older APIs

The advanced hunting APIs in Microsoft Graph replace the older version of the API that was available through the `https://api.security.microsoft.com/api/advancedhunting/run` and `https://api.security.microsoft.com/api/advancedqueries/run` endpoints. The older APIs are now retired and will stop returning data on February 1, 2027.

To migrate to the advanced hunting APIs in Microsoft Graph, update the following parameters in your application:

Expand table

Subject	Older parameters	Microsoft Graph
Endpoints	https://api.securitycenter.microsoft.com/api/advancedqueries/run https://api.security.microsoft.com/api/advancedhunting/run	https://graph.microsoft.com/beta/security/run
Resource URI	Microsoft Defender for Endpoint on `https://api.securitycenter.microsoft.com`	Microsoft Graph on `https://graph.microsoft.`
API permissions	*AdvancedQuery.Read* (delegated) and *AdvancedQuery.Read.All* (application) under Microsoft Defender for Endpoint (formerly Windows Defender Advanced Threat Protection) *AdvancedHunting.Read* (delegated) and *AdvancedHunting.Read.All* (application) under Microsoft Threat Protection	*ThreatHunting.Read.All* (delegated and applica
Request body	**Query** property. For example `{"Query":"DeviceProcessEvents |where InitiatingProcessFileName =~ 'powershell.exe' |where ProcessCommandLine contains 'appdata'|project Timestamp, FileName, InitiatingProcessFileName, DeviceId|limit 2"}`	**Query** and **Timespan** properties. For example, `"DeviceProcessEvents", "Timespan": "P90D"}`
Response	**QueryResponse** object consisting of **Stats**, **Schema**, and **Results**	huntingQueryResults resource type", consistin (instead of **Schema**) and **results** (instead of **Re**

For more information about how to authorize your app to call Microsoft Graph APIs, see Get access on behalf of a user and Get access without a user.

Power Platform flow migration (PowerApps / Power Automate / Logic Apps)

Microsoft Graph does't have a built-in Advanced Hunting action that was available in the Power Platform connector for Microsoft Defender ATP. To continue using Advanced Hunting in your Power Platform flows, create a custom connector. For more information, see Create a Microsoft Graph JSON Batch Custom Connector for Power Automate and use the Microsoft Graph parameters described in the preceding table.

Power BI flow migration

If you're using a custom Power BI report created with the older API, update your Power BI query to use the Microsoft Graph parameters described in the preceding table. For more information, see Create custom Microsoft Defender XDR reports using Microsoft Graph security API and Power BI.

Alerts

Alerts are detailed warnings about suspicious activities in a customer's tenant that Microsoft or partner security providers identified and flagged for action. Attacks typically employ various techniques against different types of entities, such as devices, users, and mailboxes. The result is alerts from multiple security providers for multiple entities in the tenant. Piecing the individual alerts together to gain insight into an attack can be challenging and time-consuming.

The security API offers two types of alerts that aggregate other alerts from security providers and make analyzing attacks and determining responses easier:

- Alerts and incidents - these are the latest generation of alerts in the Microsoft Graph security API. They're represented by the alert resource and its collection, incident resource, defined in the `microsoft.graph.security` namespace.
- Legacy alerts - these are the first generation of alerts in the Microsoft Graph security AI. They're represented by the alert resource defined in the `microsoft.graph` namespace.

> **Important**
>
> To view Sentinel alerts and incidents you must onboard Sentinel to the Defender Portal. For more information see Connect Microsoft Sentinel to the Microsoft Defender portal.

Alerts and incidents

These alert resources first pull alert data from security provider services, that are either part of or integrated with Microsoft 365 Defender. Then they consume the data to return rich, valuable clues about a completed or ongoing attack, the impacted assets, and associated evidence. In addition, they automatically correlate other alerts with the same attack techniques or the same attacker into an incident to provide a broader context of an attack. They recommend response and remediation actions, offering consistent actionability across all the different providers. The rich content makes it easier for analysts to collectively investigate and respond to threats.

Alerts from the following security providers are available via these rich alerts and incidents:

- Microsoft Entra ID Protection
- Microsoft 365 Defender
- Microsoft Defender for Cloud Apps
- Microsoft Defender for Endpoint
- Microsoft Defender for Identity
- Microsoft Defender for Office 365
- Microsoft Purview Data Loss Prevention
- Microsoft Purview Insider Risk Management

Legacy alerts

> **Note**

The legacy alerts API is deprecated. We recommend that you migrate to the new alerts and incidents API.

The legacy alert resources federate calling of supported Azure and Microsoft 365 Defender security providers. They aggregate common alert data among the different domains to allow applications to unify and streamline management of security issues across all integrated solutions. They enable applications to correlate alerts and context to improve threat protection and response.

The legacy version of the security API offers the alert resource that federates calling of supported Azure and Microsoft 365 Defender security providers. This **alert** resource aggregates alert data that's common among the different domains to allow applications to unify and streamline management of security issues across all integrated solutions. This enables applications to correlate alerts and context to improve threat protection and response.

With the alert update capability, you can sync the status of specific alerts across different security products and services that are integrated with the Microsoft Graph security API by updating your **alert** entity.

Alerts from the following providers are available via the **alert** resource. Support for GET alerts, PATCH alerts, and subscribe (via webhooks) is indicated in the following table.

Expand table

Security provider	GET alert	PATCH alert	Subscribe to alert
Microsoft Entra ID Protection	✓	File issue *	✓
Microsoft 365 • Default • Cloud App Security • Custom Alert	✓	File issue	File issue
Microsoft Defender for Cloud Apps	✓	File issue *	✓
Microsoft Defender for Endpoint **	✓	✓	File issue
Microsoft Defender for Identity ***	✓	File issue *	✓
Microsoft Sentinel (formerly Azure Sentinel)	✓	Not supported in Microsoft Sentinel	✓

> **Note:** New providers are continuously onboarding to the Microsoft Graph security ecosystem. To request new providers or for extended support from existing providers, file an issue in the Microsoft Graph security GitHub repo.

* File issue: Alert status gets updated across Microsoft Graph security API integrated applications but not reflected in the provider's management experience.

** Microsoft Defender for Endpoint requires additional user roles to those required by the Microsoft Graph security API. Only the users in both Microsoft Defender for Endpoint and Microsoft Graph security API roles can access the Microsoft Defender for Endpoint data. Because

application-only authentication isn't limited by this, we recommend that you use an application-only authentication token.

*** Microsoft Defender for Identity alerts are available via the Microsoft Defender for Cloud Apps integration. This means you get Microsoft Defender for Identity alerts only if you joined Unified SecOps and connected Microsoft Defender for Identity to Microsoft Defender for Cloud Apps. Learn more about how to integrate Microsoft Defender for Identity and Microsoft Defender for Cloud Apps.

Attack simulation and training

Attack simulation and training is part of Microsoft Defender for Office 365. This service lets users in a tenant experience a realistic benign phishing attack and learn from it. Social engineering simulation and training experiences for end users help reduce the risk of users being breached via those attack techniques. The attack simulation and training API enables tenant administrators to view launched simulation exercises and trainings, and get reports on derived insights into online behaviors of users in the phishing simulations.

eDiscovery

Microsoft Purview eDiscovery provides an end-to-end workflow to preserve, collect, analyze, review, and export content that's responsive to your organization's internal and external investigations.

Audit log query

Microsoft Purview Audit provides an integrated solution to help organizations effectively respond to security events, forensic investigations, internal investigations, and compliance obligations. Thousands of user and admin operations performed in dozens of Microsoft 365 services and solutions are captured, recorded, and retained in your organization's unified audit log. Audit records for these events are searchable by security ops, IT admins, insider risk teams, and compliance and legal investigators in your organization. This capability provides visibility into the activities performed across your Microsoft 365 organization.

Identities

Health issues

The Microsoft Defender for Identity health issues API allows you to monitor the health status of your sensors and agents across your hybrid identity infrastructure. You can use the health issues API to retrieve information about the current health issues of your sensors, such as the issue type, status, configuration, and severity. You can also use this API to identify and resolve any issues that might affect the functionality or security of your sensors and agents.

> **Note:** The Microsoft Defender for Identity health issues API is only available on the Defender for Identity plan or Microsoft 365 E5/A5/G5/F5 Security service plans.

Sensors

The Defender for Identity sensors management APIs allows you to:

- Create detailed reports of the sensors in your workspace, including information about the server name, sensor version, type, state, and health status.
- Manage sensor settings, such as adding descriptions, enabling or disabling delayed updates, and specifying the domain controller that the sensor connects to for querying Entra ID.
- Identify sensors that are ready to be activated.
- Define whether the sensors in your infrastructure are to be activated automatically or manually.
- Identify servers that are ready to be activated with the unified agent.
- Enable or disable the automatic activation of eligible servers for the unified agent.
- Activate or deactivate the unified agent on eligible servers.
- Enable or disable the automatic enabling of the required events auditing configuration during the sensor's activation.

identityAccounts

The identityAccounts resource and related APIs allows you to retrieve details of users that are flagged by Microsoft Defender for Identity alerts, and apply actions such as disabling accounts and resetting the user password for the compromised user.

Incidents

An incident is a collection of correlated alerts and associated data that make up the story of an attack. Incident management is part of Microsoft 365 Defender and is available in the Microsoft 365 Defender portal (https://security.microsoft.com/).

Microsoft 365 services and apps create alerts when they detect a suspicious or malicious event or activity. Individual alerts provide valuable clues about a completed or ongoing attack. However, attacks typically employ various techniques against different types of entities, such as devices, users, and mailboxes. The result is multiple alerts for multiple entities in your tenant.

Because piecing the individual alerts together to gain insight into an attack can be challenging and time-consuming, Microsoft 365 Defender automatically aggregates the alerts and their associated information into an incident.

Grouping related alerts into an incident gives you a comprehensive view of an attack. For example, you can see:

- Where the attack started.
- What tactics were used.
- How far the attack went into your tenant.
- The scope of the attack, such as how many devices, users, and mailboxes were impacted.
- All of the data associated with the attack.

The incident resource and its APIs allow you to sort through incidents to create an informed cybersecurity response. It exposes a collection of incidents, with their related alerts, that were flagged in your network, within the time range you specified in your environment retention policy.

Information protection

The Microsoft Graph threat assessment API helps organizations assess the threat received by any user in a tenant. This empowers customers to report spam emails, phishing URLs, or malware attachments they receive to Microsoft. The policy check result and rescan result can help tenant administrators understand the threat scanning verdict and adjust their organizational policy.

Records management

Most organizations need to manage data to proactively comply with industry regulations and internal policies, reduce risk in the event of litigation or a security breach, and let people effectively and agilely share knowledge that is current and relevant to them. You can use the records management APIs to systematically apply retention labels to different types of content that require different retention settings. For example, you can configure the start of the retention period from when the content was created, last modified, labeled, or when an event occurs for a particular event type. Further, you can use file plan descriptors to improve the manageability of these retention labels.

Secure Score

Microsoft Secure Score is a security analytics solution that gives you visibility into your security portfolio and how to improve it. With a single score, you can better understand what you did to reduce your risk in Microsoft solutions. You can also compare your score with other organizations and see how your score has been trending over time. The Microsoft Graph security secureScore and secureScoreControlProfile entities help you balance your organization's security and productivity needs while enabling the appropriate mix of security features. You can also project what your score would be after you adopt security features.

Threat intelligence

Microsoft Defender Threat Intelligence delivers world-class threat intelligence to help protect your organization from modern cyber threats. You can use Threat Intelligence to identify adversaries and their operations, accelerate detection and remediation, and enhance your security investments and workflows.

The threat intelligence APIs allow you to operationalize intelligence found within the user interface. This includes finished intelligence in the forms of articles and intel profiles, machine intelligence such as IoCs and reputation verdicts, and enrichment data such as passive DNS, cookies, components, and trackers.

Common use cases

The following are some of the most popular requests for working with the Microsoft Graph security API.

Expand table

Use cases	REST resources	Try it in Graph Explorer
Update secure score control profiles	Update secureScoreControlProfile	https://graph.microsoft.com/v1.0/security/secureScoreControlProfiles/{id}

Office 365 Management Activity API reference

Article • 12/03/2024

Use the Office 365 Management Activity API to retrieve information about user, admin, system, and policy actions and events from Office 365 and Microsoft Entra activity logs.

You can use the actions and events from the Office 365 and Microsoft Entra audit and activity logs to create solutions that provide monitoring, analysis, and data visualization. These solutions give organizations greater visibility into actions taken on their content. These actions and events are also available in the Office 365 Activity Reports. For more information, see Search the audit log in Microsoft 365.

> **Tip**
>
> If you're interested in creating custom reports from Audit Logs, you might find the following blogs helpful.
>
> - Microsoft Purview audit log activities via O365 Management API - Part 1
> - Microsoft Purview audit log activities via O365 Management API - Part 2

The Office 365 Management Activity API is a REST web service that you can use to develop solutions using any language and hosting environment that supports HTTPS and X.509 certificates. The API relies on Microsoft Entra ID and the OAuth2 protocol for authentication and authorization. To access the API from your application, you'll need to first register it in Microsoft Entra ID and configure it with appropriate permissions. This will enable your application to request the OAuth2 access tokens it needs to call the API. For more information, see Get started with Office 365 Management APIs.

For information about the data that the Office 365 Management Activity API returns, see Office 365 Management Activity API schema.

> **Important**
>
> Before you can access data through the Office 365 Management Activity API, you must enable unified audit logging for your Office 365 organization. You do this by turning on the Office 365 audit log. For instructions, see Turn Office 365 audit log search on or off.

Working with the Office 365 Management Activity API

The Office 365 Management Activity API aggregates actions and events into tenant-specific content blobs, which are classified by the type and source of the content they contain. Currently, these content types are supported:

- Audit.AzureActiveDirectory
- Audit.Exchange
- Audit.SharePoint
- Audit.General (includes all other workloads not included in the previous content types)
- DLP.All (DLP events only for all workloads)

For details about the events and properties associated with these content types, see Office 365 Management Activity API schema.

To begin retrieving content blobs for a tenant, you first create a subscription to the desired content types. If you are retrieving content blobs for multiple tenants, you create multiple subscriptions to each of the desired content types, one for each tenant.

After you create a subscription, you can poll regularly to discover new content blobs that are available for download, or you can register a webhook endpoint with the subscription and we will send notifications to this endpoint as new content blobs are available.

> ⓘ **Note**
>
> When a subscription is created, it can take up to 12 hours for the first content blobs to become available for that subscription. The content blobs are created by collecting and aggregating actions and events across multiple servers and datacenters. As a result of this distributed process, the actions and events contained in the content blobs will not necessarily appear in the order in which they occurred. One content blob can contain actions and events that occurred prior to the actions and events contained in an earlier content blob. We are working to decrease the latency between the occurrence of actions and events and their availability within a content blob, but we can't guarantee that they appear sequentially.

> **Note**
>
> DLP sensitive data is only available in the activity feed API to users that have been granted "Read DLP sensitive data" permissions. For more on Data Loss Prevention (DLP) see Overview of Data Loss Prevention Policies

Activity API operations

All API operations are scoped to a single tenant and the root URL of the API includes a tenant ID that specifies the tenant context. The tenant ID is a GUID. For information about how to get the GUID, see Get started with Office 365 Management APIs.

Because the notifications we send to your webhook include the tenant ID, you can use the same webhook to receive notifications for all tenants.

The URL for the API endpoint that you use is based on the type of Microsoft 365 or Office 365 subscription plan for your organization.

DoD government plan

HTTP

```
https://manage.protection.apps.mil/api/v1.0/{tenant_id}/activity/feed/{operation}
```

All API operations require an Authorization HTTP header with an access token obtained from Microsoft Entra ID. The tenant ID in the access token must match the tenant ID in the root URL of the API and the access token must contain the ActivityFeed.Read claim (this corresponds to the permission [Read activity data for an organization] that you configured for you application in Microsoft Entra ID).

JSON

```
Authorization: Bearer eyJ0e...Qa6wg
```

The Activity API supports the following operations:

- **Start a subscription** to begin receiving notifications and retrieving activity data for a tenant.
- **Stop a subscription** to discontinue retrieving data for a tenant.
- **List current subscriptions**
- **List available content** and the corresponding content URLs.
- **Receiving notifications** sent by a webhook when new content is available.
- **Retrieving content** by using the content URL.
- **List notifications** sent by a webhook.
- **Retrieve resource friendly names** for objects in the data feed identified by guids.

Start a subscription

This operation starts a subscription to the specified content type. If a subscription to the specified content type already exists, this operation is used to:

- Update the properties of an active webhook.
- Enable a webhook that was disabled because of excessive failed notifications.
- Re-enable an expired webhook by specifying a later or null expiration date.
- Remove a webhook.

Expand table

Subscription	Description
Path	`/subscriptions/start?contentType={ContentType}`
Parameters	contentType - Must be a valid content type.
PublisherIdentifier	The tenant GUID of the vendor coding against the API. This is **not** the application GUID or the GUID of the customer using the application, but the GUID of the company writing the code. This parameter is used for throttling the request rate. Make sure this parameter is specified in all issued requests to get a dedicated quota. All requests received without this parameter will share the same quota.
Body	webhook - Optional JSON object with three properties: • **address**: Required HTTPS endpoint that can receive notifications. A test message will be sent to the webhook to validate the webhook before creating the subscription. • **authId**: Optional string that will be included as the WebHook-AuthID header in notifications sent to the webhook as a means of identifying and authorizing the source of the request to the webhook. • **expiration**: Optional datetime that indicates a datetime after which notifications should no longer be sent to the webhook.
Response	contentType - The content type specified in the call.
status	The status of the subscription. If a subscription is disabled, you'll not be able to list or retrieve content.
webhook	The webhook properties specified in the call together with the status of the webhook. If the webhook is disabled, you'll not receive notification, but you'll still be able to list and retrieve content, provided the subscription is enabled.

Sample request

JSON

```
POST {root}/subscriptions/start?
contentType=Audit.SharePoint&PublisherIdentifier=46b472a7-c68e-4adf-8ade-
3db49497518e
Content-Type: application/json; utf-8
Authorization: Bearer eyJ0e...Qa6wg

{
    "webhook" : {
        "address": "https://webhook.myapp.com/o365/",
        "authId": "o365activityapinotification",
        "expiration": ""
    }
```

```
}
```

Sample response

JSON

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=utf-8

{
    "contentType": "Audit.SharePoint",
    "status": "enabled",
    "webhook": {
        "status": "enabled",
        "address":  "https://webhook.myapp.com/o365/",
        "authId": "o365activityapinotification",
        "expiration": null
    }
}
```

Webhook validation

When the /start operation is called and a webhook is specified, we will send a validation notification to the specified webhook address to validate that an active listener can accept and process notifications. If we do not receive an HTTP 200 OK response, the subscription will not be created. Or, if /start is being called to add a webhook to an existing subscription and a response of HTTP 200 OK is not received, the webhook will not be added and the subscription will remain unchanged.

Sample request

JSON

```
POST {webhook address}
Content-Type: application/json; charset=utf-8
Webhook-AuthID: (webhook authId, if provided)
Webhook-ValidationCode: (random opaque string)

{
    "validationCode": (random opaque string, same as header)
}
```

Sample response

JSON

```
HTTP/1.1 200 OK
```

Stop a subscription

This operation stops a subscription to the specified content type.

When a subscription is stopped, you'll no longer receive notifications and you'll not be able to retrieve available content. If the subscription is later restarted, you'll have access to new content from that point forward. You will not be able to retrieve content that was available between the time the subscription was stopped and restarted.

Expand table

Subscription	Description
Path	`/subscriptions/stop?contentType={ContentType}`
Parameters	contentType - Must be a valid content type.
PublisherIdentifier	The tenant GUID of the vendor coding against the API. This is **not** the application GUID or the GUID of the customer using the application, but the GUID of the company writing the code. This parameter is used for throttling the request rate. Make sure this parameter is specified in all issued requests to get a dedicated quota. All requests received without this parameter will share the same quota.
Body	(empty)
Response	(empty)

Sample request

JSON

```
POST {root}/subscriptions/stop?
contentType=Audit.SharePoint&PublisherIdentifier=46b472a7-c68e-4adf-8ade-
3db49497518e
Authorization: Bearer eyJ0e...Qa6wg
```

Sample response

JSON

```
HTTP/1.1 200 OK
```

List current subscriptions

This operation returns a collection of the current subscriptions together with the associated webhooks.

Expand table

	Subscription	Description
Path	`/subscriptions/list`	
Parameters	PublisherIdentifier	The tenant GUID of the vendor coding against the API. This is **not** the application GUID or the GUID of the customer using the application, but the GUID of the company writing the code. This parameter is used for throttling the request rate. Make sure this parameter is specified in all issued requests to get a dedicated quota. All requests received without this parameter will share the same quota.
Body	(empty)	
Response	JSON array	Each subscription will be represented by a JSON object with three properties: • **contentType**: Indicates the content type. • **status**: Indicates the status of the subscription. • **webhook**: Indicates the configured webhook, together with the status (enabled, disabled, expired) of the webhook. If a subscription does not have a webhook, the webhook property will be present but with null value.

Sample request

JSON

```
GET {root}/subscriptions/list?PublisherIdentifier=46b472a7-c68e-4adf-8ade-
3db49497518e
```

```
Authorization: Bearer eyJ0e...Qa6wg
```

Sample response

JSON

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=utf-8

[
    {
        "contentType" : "Audit.SharePoint",
        "status": "enabled",
        "webhook": {
            "status": "enabled",
            "address": "https://webhook.myapp.com/o365/",
            "authId": "o365activityapinotification",
            "expiration": null
        }
    },

    ...

    {
        "contentType": "Audit.Exchange",
        "webhook": null
    }
]
```

List available content

This operation lists the content currently available for retrieval for the specified content type. The content is an aggregation of actions and events harvested from multiple servers across multiple datacenters. The content will be listed in the order in which the aggregations become available, but the events and actions within the aggregations are not guaranteed to be sequential. An error is returned if the subscription status is disabled.

Expand table

Subscription	Description
Path	`/subscriptions/content?contentType={ContentType}&startTime={0}&endTime={1}`

Subscription	Description
Parameters	contentType - Must be a valid content type.
PublisherIdentifier	The tenant GUID of the vendor coding against the API. This is **not** the application GUID or the GUID of the customer using the application, but the GUID of the company writing the code. This parameter is used for throttling the request rate. Make sure this parameter is specified in all issued requests to get a dedicated quota. All requests received without this parameter will share the same quota.
startTime endTime	Optional datetimes (UTC) indicating the time range of content to return, based on when the content became available. The time range is inclusive with respect to startTime (startTime <= contentCreated) and exclusive with respect to endTime (contentCreated < endTime), so that non-overlapping, incrementing time intervals can used to page through available content. • YYYY-MM-DD • YYYY-MM-DDTHH:MM • YYYY-MM-DDTHH:MM:SS Both must be specified (or both omitted) and they must be no more than 24 hours apart, with the start time no more than 7 days in the past. By default, if startTime and endTime are omitted, then the content available in the last 24 hours is returned. **NOTE**: Even though it is possible to specify a startTime and endTime more than 24 hours apart, this is not recommended. Furthermore, if you do get any results in response to a request for more than 24 hours, these could be partial results and should not be taken into account. The request should be issued with an interval of no more than 24 hours between the startTime and endTime.
Response	JSON array - The available content will be represented by JSON objects with the following properties: • **contentType**: Indicates the content type. • **contentId**: An opaque string that uniquely identifies the content. • **contentUri**: The URL to use when retrieving the content. • **contentCreated**: The datetime when the content was made available. • **contentExpiration**: The datetime after which the content will no longer be available for retrieval.

Sample request

JSON

```
GET {root}/subscriptions/content?
contentType=Audit.SharePoint&PublisherIdentifier=46b472a7-c68e-4adf-8ade-
3db49497518e
```

```
Authorization: Bearer eyJ0e...Qa6wg
```

Sample response

JSON

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=utf-8

[
    {
        "contentType": "Audit.SharePoint",
        "contentId":
"492638008028$492638008028$f28ab78ad40140608012736e373933ebspo2015043022$4a8
1a7c326fc4aed89c62e6039ab833b$04",
        "contentUri": "https://manage.office.com/api/v1.0/f28ab78a-d401-
4060-8012-
736e373933eb/activity/feed/audit/492638008028$492638008028$f28ab78ad40140608
012736e373933ebspo2015043022$4a81a7c326fc4aed89c62e6039ab833b$04",
        "contentCreated": "2015-05-23T17:35:00.000Z",
        "contentExpiration": "2015-05-30T17:35:00.000Z"
    },
    ...
]
```

Pagination

When listing available content for a time range, the number of results returned is limited to prevent response timeouts. If there are more results in the specified time range than can be returned in single response, the results will be truncated and a header will be added to the response indicating the URL to use to retrieve the next page of results. The URL will contain the same *startTime* and *endTime* parameters that were specified in the original request, together with a parameter indicating the internal ID of the next page. If *startTime* and *endTime* were not specified in the original request, they will be set to reflect the 24-hour interval that preceded the original request.

JSON

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=utf-8
NextPageUri:
https://manage.office.com/api/v1/{tenant_id}/activity/feed/subscriptions/con
tent?contentType=Audit.SharePoint&startTime=2015-10-01&endTime=2015-10-
```

```
02&nextPage=2015101900R022885001761
```

To list all available content for a specified time range, you might need to retrieve multiple pages until a response without the **NextPageUri** header is received.

Receiving notifications

Notifications are sent to the configured webhook for a subscription as new content becomes available. Because the notification includes the tenant identifier, you can use the same webhook to receive notifications for all tenants for which you have subscriptions.

The notification is made as an HTTP POST over TLS (TLS 1.0 and later versions) to the specified webhook address. If the webhook configuration includes an auth ID, we will send it as an HTTP header: Webhook-AuthID. Any response other than HTTP 200 OK will be considered a failure and the notification will be retried. You can also configure your webhook to require client certificate-based authentication and we will authenticate using the manage.office.com certificate.

The body of the request will contain an array of one or more JSON objects that represent the available content blobs. The number of content blobs in each notification is limited to keep the size of the notification relatively small. Because this limit might change, your implementation should query for the length of the array instead of expecting a fixed size. Each object will include the same properties returned by the /content operation, together with the GUID of the tenant to which the data belongs and the GUID of your application that created the subscriptions. This allows the webhook to establish context when it is being used with multiple tenants and applications.

- **tenantId**: The GUID of the tenant to which the content belongs.
- **clientId**: The GUID of your application that created the subscription.
- **contentType**: Indicates the content type.
- **contentId**: An opaque string that uniquely identifies the content.
- **contentUri**: The URL to use when retrieving the content.
- **contentCreated**: The datetime when the content was made available.
- **contentExpiration**: The datetime after which the content will no longer be available for retrieval.

The following is an example of a notification.

JSON

```
POST https://webhook.myapp.com/o365/
Content-Type: application/json; utf-8
Webhook-AuthID: o365activityapinotification

[
    {
        "tenantId": "{GUID}",
        "clientId": "{GUID}",
        "contentType": "Audit.SharePoint",
        "contentId":
"492638008028$492638008028$f28ab78ad40140608012736e373933ebspo2015043022$4a8
1a7c326fc4aed89c62e6039ab833b$04",
        "contentUri": "https://manage.office.com/api/v1.0/f28ab78a-d401-
4060-8012-
736e373933eb/activity/feed/audit/492638008028$492638008028$f28ab78ad40140608
012736e373933ebspo2015043022$4a81a7c326fc4aed89c62e6039ab833b$04",
        "contentCreated": "2015-05-23T17:35:00.000Z",
        "contentExpiration": "2015-05-30T17:35:00.000Z"
    },
    ...
]
```

Notification failure and retry

The notification system sends notifications as new content becomes available. If we encounter excessive failures when sending notifications, our retry mechanism will exponentially increase the time between retries. If we continue to encounter failures, we reserve the right to disable the webhook and stop sending notifications to it altogether. The /start operation can be used to re-enable a disabled webhook.

Retrieve content

To retrieve a content blob, make a GET request against the corresponding content URI that is included in the list of available content and in the notifications sent to a webhook. The returned content will be a collection of one more actions or events in JSON format.

Sample request

JSON

```
GET https://manage.office.com/api/v1.0/41463f53-8812-40f4-890f-
865bf6e35190/activity/feed/audit/301299007231$301299007231$41463f53881240f48
90f865bf6e35190aad2015062920$e1c2ab19858a469fb1f1fd097effffc9$04 HTTP/1.1
Authorization: Bearer eyJ0e...Qa6wg
```

Sample response

JSON

```

```

List notifications

This operation lists all notification attempts for the specified content type. If you did not include a webhook when starting the subscription to the content type, there will be no notifications to retrieve. Because we retry notifications in the event of failure, this operation can return multiple notifications for the same content, and the order in which the notifications are sent will not necessarily match the order in which the content became available (especially when there are failures and retries).

You can use this operation to help investigate issues related to webhooks and notifications, but you should not use it to determine what content is currently available for retrieval. Use the /content operation instead. We return an error if the subscription status is disabled.

Expand table

Subscription	**Description**
Path	`/subscriptions/notifications?contentType={ContentType}&startTime={0}&endTime={1}`
Parameters	contentType - Must be a valid content type.
PublisherIdentifier	The tenant GUID of the vendor coding against the API. This is **not** the application GUID or the GUID of the customer using the application, but the GUID of the company writing the code. This parameter is used for throttling the request rate. Make sure this parameter is specified in all issued requests to get a dedicated quota. All requests received without this parameter will share the same quota.
startTime endTime	Optional datetimes (UTC) that indicate the time range of content to return, based on when the content became available. The time range is inclusive with respect to *startTime* (*startTime* <= contentCreated) and exclusive with respect to *endTime* (*contentCreated* < endTime), so that non-overlapping, incrementing time intervals can used to page through available content. • YYYY-MM-DD • YYYY-MM-DDTHH:MM • YYYY-MM-DDTHH:MM:SS Both must be specified (or both omitted) and they must be no more than 24 hours apart, with the start time no more than 7 days in the past. By default, if *startTime* and *endTime* are omitted, the content available in the last 24 hours is returned.
Response	JSON array - The notifications will be represented by JSON objects with the following properties: • **contentType**: indicates the content type. • **contentId**: an opaque string that uniquely identifies the content. • **contentUri**: the URL to use when retrieving the content.

Subscription	Description
	• **contentCreated**: the datetime when the content was made available. • **contentExpiration**: the datetime after which the content will no longer be available for retrieval. • **notificationSent**: the datetime when the notification was sent. • **notificationStatus**: indicates the success or failure of the notification attempt.

Pagination

When listing notification history for a time range, the number of results returned is limited to prevent response timeouts. If there are more results in the specified time range than can be returned in a single response, the results are truncated and a header is added to the response indicating the URL to use to retrieve the next page of results. The URL will contain the same *startTime* and *endTime* parameters that were specified in the original request, together with a parameter indicating the internal ID of the next page. If *startTime* and *endTime* were not specified in the original request, they will be set to reflect the 24-hour interval that preceded the original request.

JSON

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=utf-8
NextPageUri:
https://manage.office.com/api/v1/{tenant_id}/activity/feed/subscriptions/con
tent?contentType=Audit.SharePoint&startTime=2015-10-01&endTime=2015-10-
02&nextPage=2015101900R022885001761
```

To list all available content for a specified time range, you might need to retrieve multiple pages until a response without the **NextPageUri** header is received.

Retrieve resource friendly names

This operation retrieves friendly names for objects in the data feed identified by guids. Currently "DlpSensitiveType" is the only supported object.

Expand table

Object	Subscription	Description
Path	`/resources/dlpSensitiveTypes`	
Parameters	PublisherIdentifier	The tenant GUID of the vendor coding against the API. This is **not** the application GUID or the GUID of the customer using the application, but the GUID of the company writing the code. This parameter is used for throttling the request rate. Make sure this parameter is specified in all issued requests to get a dedicated quota. All requests received without this parameter will share the same quota.

Object	Subscription	Description
Headers	Accept-Language	Header to specify the desired language for localized names. For example, use "en-US" for English or "es" for Spanish. The default language (en-US) will be returned if this header is not present.
Body	(empty)	
Response	JSON array	The available content will be represented by JSON objects with the following properties: • **id**: Indicates the guid of the sensitive information type. • **name**: The friendly name of the sensitive information type.

Sample request

JSON

```
GET {root}/resources/dlpSensitiveTypes?PublisherIdentifier=46b472a7-c68e-
4adf-8ade-3db49497518e
Authorization: Bearer eyJ0e...Qa6wg
Accept-Language: {language code}
```

Sample response

JSON

```
HTTP/1.1 200 OK

```

API throttling

Organizations that access auditing logs through the Office 365 Management Activity API were restricted by throttling limits at the publisher level. This means that for a publisher pulling data on behalf of multiple customers, the limit was shared by all those customers.

We're moving from a publisher-level limit to a tenant-level limit. The result is that each organization will get their own fully allocated bandwidth quota to access their auditing data. All organizations are initially allocated a baseline of 2,000 requests per minute. This is not a static, predefined limit but is modeled on a combination of factors including the number of seats in the organization and that Office 365 and Microsoft 365 E5 organizations will get approximately twice as much bandwidth as non-E5 organizations. There will also be cap on the maximum bandwidth to protect the health of the service.

For more information, see the "High-bandwidth access to the Office 365 Management Activity API" section in Advanced audit in Microsoft 365.

> **Note**
>
> Even though each tenant can initially submit up to 2,000 requests per minute, Microsoft cannot guarantee a response rate. The response rate depends on various factors, such as client system performance, network capacity, and network speed.

Errors

When the service encounters an error, it will report the error response code to the caller, using standard HTTP error-code syntax. . Additional information is included in the body of the failed call as a single JSON object. An example of a full JSON error body is shown below:

JSON

```
{
    "error":{
        "code":"AF50000",
        "message": "An internal server error occurred. Retry the request."
    }
}
```

Expand table

Code	Message
AF10001	The permission set ({0}) sent in the request did not include the expected permission **ActivityFeed.Read**. {0} = the permission set in the access token.
AF20001	Missing parameter: {0}. {0} = the name of the missing parameter.
AF20002	Invalid parameter type: {0}. Expected type: {1} {0} = the name of the invalid parameter. {1} = the expected type (int, datetime, guid).
AF20003	Expiration {0} provided is set to past date and time. {0} = the expiration passed in the API call.
AF20010	The tenant ID passed in the URL ({0}) does not match the tenant ID passed in the access token ({1}). {0} = tenant ID passed in the URL{1} = tenant ID passed in the access token
AF20011	Specified tenant ID ({0}) does not exist in the system or has been deleted. {0} = tenant ID passed in the URL
AF20012	Specified tenant ID ({0}) is incorrectly configured in the system. {0} = tenant ID passed in the URL
AF20013	The tenant ID passed in the URL ({0}) is not a valid GUID. {0} = tenant ID passed in the URL
AF20020	The specified content type is not valid.

AF20031	Invalid nextPage Input: {0}. {0} = the next page indicator passed in the URL
AF20050	The specified content ({0}) does not exist. {0} = resource id or resource URL
AF20051	Content requested with the key {0} has already expired. Content older than 7 days cannot be retrieved. {0} = resource id or resource URL
AF20052	Content ID {0} in the URL is invalid. {0} = resource id or resource URL
AF20053	Only one language may be present in the Accept-Language header.
AF20054	Invalid syntax in Accept-Language header.
AF429	Too many requests. Method={0}, PublisherId={1} {0} = HTTP Method {1} = Tenant GUID used as PublisherIdentifier
AF50000	An internal error occurred. Retry the request.

Office 365 Management Activity API schema

The Office 365 Management Activity API schema is provided as a data service in two layers:

- **Common schema**. The interface to access core Office 365 auditing concepts such as Record Type, Creation Time, User Type, and Action as well as to provide core dimensions (such as User ID), location specifics (such as Client IP address), and service-specific properties (such as Object ID). It establishes consistent and uniform views for users to extract all Office 365 audit data in a few top level views with the appropriate parameters, and provides a fixed schema for all the data sources, which significantly reduces the cost of learning. Common schema is sourced from product data that is owned by each product team, such as Exchange, SharePoint, Azure Active Directory, Viva Engage, and OneDrive. The Object ID field can be extended by Microsoft 365 product teams to add service-specific properties.
- **Service-specific schema**. Built on top of the Common schema to provide a set of Microsoft 365 service-specific attributes; for example, SharePoint schema, OneDrive schema, and Exchange admin schema.

Office 365 Management API schemas

This article provides details on the Common schema as well as service-specific schemas. The following table describes the available schemas.

Expand table

Name of schema	Description
Common schema	The view to extract Record Type, User ID, Client IP, User type and Action along with core dimensions such as user properties (such as UserID), location properties (such as Client IP), and service-specific properties (such as Object Id).
Copilot schema	Events include how and when to interact with Copilot, in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction.
SharePoint Base schema	Extends the Common schema with the properties specific to all SharePoint audit data.
SharePoint File Operations	Extends the SharePoint Base schema with the properties specific to file access and manipulation in SharePoint.
SharePoint List Operations	Extends the SharePoint Base schema with the properties specific to interactions with lists and list items in SharePoint.

Name of schema	Description
SharePoint Sharing schema	Extends the SharePoint Base schema with the properties specific to file sharing.
SharePoint schema	Extends the SharePoint Base schema with the properties specific to SharePoint, but unrelated to file access and manipulation.
Project schema	Extends the SharePoint Base schema with the properties specific to Project.
Exchange Admin schema	Extends the Common schema with the properties specific to all Exchange admin audit data.
Exchange Mailbox schema	Extends the Common schema with the properties specific to all Exchange mailbox audit data.
OWA Auth schema	Extends the Common schema with the properties specific to OWA Auth data.
Microsoft Entra ID Base schema	Extends the Common schema with the properties specific to all Microsoft Entra audit data.
Microsoft Entra account Logon schema	Extends the Microsoft Entra ID Base schema with the properties specific to all Microsoft Entra logon events.
Microsoft Entra ID Secure STS Logon schema	Extends the Microsoft Entra ID Base schema with the properties specific to all Microsoft Entra ID Secure Token Service (STS) logon events.
Microsoft Entra schema	Extends the Common schema with the properties specific to all Microsoft Entra audit data.
DLP schema	Extends the Common schema with the properties specific to Data Loss Prevention events.
Security and Compliance Center schema	Extends the Common schema with the properties specific to all Security & Compliance Center events.
Security and Compliance Alerts schema	Extends the Common schema with the properties specific to all Office 365 security and compliance alerts.
Viva Engage schema	Extends the Common schema with the properties specific to all Viva Engage events.
Data Center Security Base schema	Extends the Common schema with the properties specific to all data center security audit data.
Data Center Security Cmdlet schema	Extends the Data Center Security Base schema with the properties specific to all data center security cmdlet audit data.
Microsoft Teams schema	Extends the Common schema with the properties specific to all Microsoft Teams events.
Microsoft Defender for Office 365 and Threat Investigation and Response schema	Extends the Common schema with the properties specific to Defender for Office 365 and threat investigation and response data.

Name of schema	Description
Submission schema	Extends the Common schema with the properties specific to user and admin submissions in Microsoft Defender for Office 365.
Automated investigation and response events in Microsoft Defender for Office 365 Plan 2	Extends the Common schema with the properties specific to Office 365 automated investigation and response (AIR) events. To see an example, see Tech Community blog: Improve the Effectiveness of your SOC with Microsoft Defender for Office 365 and the Office 365 Management API .
Hygiene events schema	Extends the Common schema with the properties specific to events in the built-in security features for all cloud mailboxes and Microsoft Defender for Office 365.
Power BI schema	Extends the Common schema with the properties specific to all Power BI events.
Dynamics 365 schema	Extends the Common schema with the properties specific to Dynamics 365 events.
Viva Insights schema	Extends the Common schema with the properties specific to all Microsoft Viva Insights events.
Quarantine schema	Extends the Common schema with the properties specific to all quarantine events.
Microsoft Forms schema	Extends the Common schema with the properties specific to all Microsoft Forms events.
MIP label schema	Extends the Common schema with the properties specific to sensitivity labels manually or automatically applied to email messages.
Encrypted message portal event schema	Extends the Common schema with the properties specific to encrypted message portal accessed by external recipients.
Communication compliance Exchange schema	Extends the Common schema with the properties specific to the Communication compliance offensive language model.
Reports schema	Extends the Common schema with the properties specific to all reports events.
Compliance connector schema	Extends the Common schema with the properties specific to importing non-Microsoft data by using data connectors.
SystemSync schema	Extends the Common schema with the properties specific to data ingested via SystemSync.
Viva Goals schema	Extends the Common schema with the properties specific to all Viva Goals events.
Microsoft Planner schema	Extends the Common schema with the properties specific to Microsoft Planner events.
Microsoft Project for the web schema	Extends the Common schema with the properties specific to Microsoft Project for the web events.

Name of schema	Description
Viva Pulse schema	Extends the Common schema with the properties specific to all Viva Pulse events.
Compliance Manager schema	Extends the Common schema with the properties specific to Compliance Manager events.
Backup Policy Schema	Extends the Common schema with the properties specific to Microsoft 365 Backup Policies.
Restore Task schema	Extends the Common schema with the properties specific to Microsoft 365 Backup Restore Tasks.
Backup Item schema	Extends the Common schema with the properties specific to Microsoft 365 Backup artifacts.
Restore Item schema	Extends the common schema with the properties specific to Microsoft 365 Backup Restore Items.
Granular Browse Task schema	Extends the Common schema with the properties specific to Microsoft 365 Backup Granular Browse Tasks.
Cloud Policy service schema	Extends the Common schema with the properties specific to all Cloud Policy service audit data.
Cloud Update profile configuration schema	Extends the Common schema with the properties specific to the Cloud Update profile configuration audit data.
Cloud Update tenant configuration schema	Extends the Common schema with the properties specific to the Cloud Update tenant configuration audit data.
Cloud Update device configuration schema	Extends the Common schema with the properties specific to the Cloud Update device configuration audit data.
Microsoft Entra Risk Detection schema	Extends the Common schema with the properties specific to Microsoft Entra Risk Detection events.
Microsoft Edge WebContentFiltering schema	Extends the Common schema with the properties specific to Microsoft Edge WebContentFiltering events.
Microsoft 365 Copilot scheduled prompt schema	Extends the Common schema with the properties specific to Microsoft 365 Copilot scheduled prompt audit data.
Microsoft Places Directory schema	Extends the Common schema with the properties specific to Microsoft Places Directory audit data.
Teams Evaluation Data Hub schema	Extends the Common schema with the properties specific to Teams Evaluation Data Hub data-access and permission-change events.
Security and Compliance RBAC	Extends the Common schema with the properties specific to Security and Compliance RBAC permission events.
Dragon Copilot Admin schema	Extends the Common schema with the properties specific to Dragon Copilot administrative audit data.
Microsoft Agent 365 schema	Events generated by Microsoft Agent 365, including AI guardrail

Name of schema	Description
	evaluations, decisions, findings, and policy enforcement actions.

Common schema

EntityType Name: AuditRecord

Expand table

Parameter	Type	Mandatory?	Description
Id	Combination GUIDEdm.Guid	Yes	Unique identifier of an audit record.
RecordType	Self.AuditLogRecordType	Yes	The type of operation indicated by the record. See the AuditLogRecordType table for details on the types of audit log records.
CreationTime	Edm.Date	Yes	The date and time in Coordinated Universal Time (UTC) when the audit log record was generated.
Operation	Edm.String	Yes	The name of the user or admin activity. For a description of the most common operations/activities, see Search the audit log. For Exchange admin activity, this property identifies the name of the cmdlet that was run. For Dlp events, this can be "DlpRuleMatch", "DlpRuleUndo" or "DlpInfo", which are described under "DLP schema" below.
OrganizationId	Edm.Guid	Yes	The GUID for your organization's Office 365 tenant. This value is always the same for your organization, regardless of the Office 365 service in which it occurs.
UserType	Self.UserType	Yes	The type of user that performed the operation. See the UserType table for details on the types of users.
UserKey	Edm.String	Yes	An alternative ID for the user identified in the UserId property. This property is populated with the passport unique ID (PUID) for events performed by users in SharePoint, OneDrive, and Exchange.

Parameter	Type	Mandatory?	Description
Workload	Edm.String	Yes	The Office 365 service where the activity occurred.
ResultStatus	Edm.String	No	Indicates whether the action (specified in the Operation property) was successful or not. Possible values are **Succeeded**, **PartiallySucceeded**, or **Failed**. For Exchange admin activity, the value is either **True** or **False**. **Important**: Different workloads might overwrite the value of the ResultStatus property. For example, for Microsoft Entra ID STS logon events, a value of **Succeeded** for ResultStatus indicates only that the HTTP operation was successful; it doesn't mean the logon was successful. To determine if the actual logon was successful or not, see the LogonError property in the Microsoft Entra ID STS Logon schema. If the logon failed, the value of this property contains the reason for the failed logon attempt.
ObjectId	Edm.string	No	For SharePoint and OneDrive activity, the full path name of the file or folder accessed by the user. For Exchange admin audit logging, the name of the object that was modified by the cmdlet. For Cloud Policy service, the object ID of the policy configuration. For TrainableClassifier activity, the id of the model created, published, updated, or deleted by the user.
UserId	Edm.string	Yes	The UPN (User Principal Name) of the user who performed the action (specified in the Operation property) that resulted in the record being logged; for example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed

Parameter	Type	Mandatory?	Description
			the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.
ClientIP	Edm.String	Yes	The IPv4 or IPv6 address of the device that was used when the activity was logged. For some services, the value displayed in this property might be the IP address for a trusted application (for example, Office on the web apps) calling into the service on behalf of a user and not the IP address of the device used by person who performed the activity. Also, for Microsoft Entra ID-related events, the IP address isn't logged and the value for the ClientIP property is `null`.
Scope	Self.AuditLogScope	No	Event created by one of the following sources: • **online**: A service in Microsoft 365. • **onprem**: A service in an on-premises organization. Currently, SharePoint is the only workload sending events from on-premises to Microsoft 365.
AppAccessContext	CollectionSelf.AppAccessContext	No	The application context for the user or service principal that performed the action.

AgentAdminActivity

Expand table

Parameters	Type	Mandatory?	Description
AgentID	Edm.String	Yes	Unique identifier of the Agent
AgentName	Edm.String	Yes	The name of the Agent

Parameters	Type	Mandatory?	Description
AgentType	Edm.Int32	Yes	The type of the Agent - Microsoft (1P), External (3P), Shared by users (Shared), Built by your org (External).
UserAssignments	Collection (Edm.Guid)	No	Collection of GUID of Users and Groups associated with the agent activity.
ForAllUsers	Edm.Boolean	Yes	Whether the activity associated with the agent was captured for the entire organization or not. True when it applies to all users in the organization. False when it applies to specific users/group.

AgentSettingsAdminActivity

Expand table

Parameters	Type	Mandatory?	Description
Property	Edm.String	Yes	The tenant wide setting name that was updated by the admin.
RemovedIdentities	Collection(Edm.Guid)	No	Collection of GUID of Users or Groups that were removed.
AddedIdentities	Collection(Edm.Guid)	No	Collection of GUID of Users or Groups that were added.
NewValue	Edm.String	Yes	The new value of the setting.
ForAllUsers	Edm.Boolean	Yes	Boolean value indicating if the tenant wide setting impacted all users.
OldValue	Edm.String	Yes	The old value or the new setting.

Enum: AuditLogRecordType - Type: Edm.Int32

AuditLogRecordType

Expand table

Value	Member name	Description
1	ExchangeAdmin	Events from the Exchange admin audit log.
2	ExchangeItem	Events from an Exchange mailbox audit log for actions that are performed on a single item, such as creating or receiving an email message.
3	ExchangeItemGroup	Events from an Exchange mailbox audit log for actions that can be performed on multiple items, such as moving or deleted one or more email messages.

Value	Member name	Description
4	SharePoint	SharePoint events.
6	SharePointFileOperation	SharePoint file operation events.
7	OneDrive	OneDrive events.
8	AzureActiveDirectory	Microsoft Entra ID events.
9	AzureActiveDirectoryAccountLogon	Microsoft Entra ID OrgId logon events (deprecated).
10	DataCenterSecurityCmdlet	Data Center security cmdlet events.
11	ComplianceDLPSharePoint	Data loss protection (DLP) events in SharePoint and OneDrive.
13	ComplianceDLPExchange	Data loss protection (DLP) events in Exchange, when configured via Unified DLP Policy. DLP events based on Exchange Transport Rules are not supported.
14	SharePointSharingOperation	SharePoint sharing events.
15	AzureActiveDirectoryStsLogon	Secure Token Service (STS) logon events in Microsoft Entra ID.
16	SkypeForBusinessPSTNUsage	Public Switched Telephone Network (PSTN) events from Skype for Business.
17	SkypeForBusinessUsersBlocked	Blocked user events from Skype for Business.
18	SecurityComplianceCenterEOPCmdlet	Admin actions in the built-in security features for all cloud mailboxes from the Microsoft Defender portal.
19	ExchangeAggregatedOperation	Aggregated Exchange mailbox auditing events.
20	PowerBIAudit	Power BI events.
21	CRM	Dynamics 365 events.
22	Viva Engage	Viva Engage events.
23	SkypeForBusinessCmdlets	Skype for Business events.
24	Discovery	Events for eDiscovery activities performed by running content searches and managing eDiscovery cases in the Microsoft Purview portal.
25	MicrosoftTeams	Events from Microsoft Teams.
28	ThreatIntelligence	Phishing and malware events from the built-in security features for all cloud mailboxes and Microsoft Defender for Office 365.
29	MailSubmission	Submission events from the built-in security features for all cloud mailboxes and Microsoft Defender for Office 365.

Value	Member name	Description
30	MicrosoftFlow	Microsoft Power Automate (formerly called Microsoft Flow) events.
31	AeD	Advanced eDiscovery events.
32	MicrosoftStream	Microsoft Stream events.
33	ComplianceDLPSharePointClassification	Events related to DLP classification in SharePoint.
34	ThreatFinder	Campaign-related events from Microsoft Defender for Office 365.
35	Project	Microsoft Project events.
36	SharePointListOperation	SharePoint List events.
37	SharePointCommentOperation	SharePoint comment events.
38	DataGovernance	Events related to retention policies and retention labels in the Microsoft Purview portal.
39	Kaizala	Kaizala events.
40	SecurityComplianceAlerts	Security and compliance alert signals.
41	ThreatIntelligenceUrl	Safe links time-of-block and block override events from Microsoft Defender for Office 365.
42	SecurityComplianceInsights	Events related to insights and reports in the Microsoft Defender portal.
43	MIPLabel	Events related to the detection in the Transport pipeline of email messages that have been tagged (manually or automatically) with sensitivity labels.
44	VivaInsights	Viva Insights events.
45	PowerAppsApp	Power Apps events.
46	PowerAppsPlan	Subscription plan events for Power Apps.
47	ThreatIntelligenceAtpContent	Phishing and malware events for files in SharePoint, OneDrive, and Microsoft Teams from Microsoft Defender for Office 365.
48	LabelContentExplorer	Events related to data classification content explorer.
49	TeamsHealthcare	Events related to the Patients app in Microsoft Teams for Healthcare.
50	ExchangeItemAggregated	Events related to the MailItemsAccessed mailbox auditing action.
51	HygieneEvent	Events related to outbound spam protection.
52	DataInsightsRestApiAudit	Data Insights REST API events.

Value	Member name	Description
53	InformationBarrierPolicyApplication	Events related to the application of information barrier policies.
54	SharePointListItemOperation	SharePoint list item events.
55	SharePointContentTypeOperation	SharePoint list content type events.
56	SharePointFieldOperation	SharePoint list field events.
57	MicrosoftTeamsAdmin	Teams admin events.
58	HRSignal	Events related to HR data signals that support the Insider risk management solution.
59	MicrosoftTeamsDevice	Teams device events.
60	MicrosoftTeamsAnalytics	Teams analytics events.
61	InformationWorkerProtection	Events related to compromised user alerts.
62	Campaign	Email campaign events from Microsoft Defender for Office 365.
63	DLPEndpoint	Endpoint DLP events.
64	AirInvestigation	Automated incident response (AIR) events.
65	Quarantine	Quarantine events.
66	MicrosoftForms	Microsoft Forms events.
67	ApplicationAudit	Application audit events.
68	ComplianceSupervisionExchange	Events tracked by the Communication compliance offensive language model.
69	CustomerKeyServiceEncryption	Events related to the customer key encryption service.
70	OfficeNative	Events related to sensitivity labels applied to Office documents.
71	MipAutoLabelSharePointItem	Auto-labeling events in SharePoint.
72	MipAutoLabelSharePointPolicyLocation	Auto-labeling policy events in SharePoint.
73	MicrosoftTeamsShifts	Teams Shifts events.
75	MipAutoLabelExchangeItem	Auto-labeling events in Exchange.
76	CortanaBriefing	Briefing email events.
78	WDATPAlerts	Events related to alerts generated by Windows Defender for Endpoint.
79	PowerAppsResource	Events related to Microsoft Power Platform

Value	Member name	Description
		Connectors (Preview).
82	SensitivityLabelPolicyMatch	Events generated when the file labeled with a sensitivity label is opened or renamed.
83	SensitivityLabelAction	Event generated when sensitivity labels are applied, updated, or removed from a file.
84	SensitivityLabeledFileAction	Events generated when a file labeled with a sensitivity label is opened or renamed.
85	AttackSim	Events related to user activities in Attack Simulation & Training in Microsoft Defender for Office 365.
86	AirManualInvestigation	Events related to manual investigations in Automated investigation and response (AIR).
87	SecurityComplianceRBAC	Security and compliance RBAC events.
88	UserTraining	Events related to user training in Attack Simulation & Training in Microsoft Defender for Office 365.
89	AirAdminActionInvestigation	Events related to admin actions in Automated investigation and response (AIR).
90	MSTIC	Threat intelligence events in Microsoft Defender for Office 365.
91	PhysicalBadgingSignal	Events related to physical badging signals that support the Insider risk management solution.
92	TeamsEasyApprovals	Events related to Teams Easy Approvals
93	AipDiscover	AIP scanner events
94	AipSensitivityLabelAction	AIP sensitivity label events
95	AipProtectionAction	AIP protection events
96	AipFileDeleted	AIP file deletion events
97	AipHeartBeat	AIP heartbeat events
98	MCASAlerts	Events corresponding to alerts triggered by Microsoft Cloud App Security.
99	OnPremisesFileShareScannerDlp	Events related to scanning for sensitive data on file shares.
100	OnPremisesSharePointScannerDlp	Events related to scanning for sensitive data in SharePoint.
101	ExchangeSearch	Events related to using Outlook on the web (OWA) to search for mailbox items.
102	SharePointSearch	Events related to searching an organization's

Value	Member name	Description
		SharePoint home site.
103	PrivacyInsights	Privacy insight events.
105	MyAnalyticsSettings	MyAnalytics events.
106	SecurityComplianceUserChange	Events related to modifying or deleting a user.
107	ComplianceDLPExchangeClassification	Exchange DLP classification events.
109	MipExactDataMatch	Exact Data Match (EDM) classification events.
113	MS365DCustomDetection	Events related to custom detection actions in Microsoft 365 Defender.
147	CoreReportingSettings	Reports settings events.
148	ComplianceConnector	Events related to importing non-Microsoft data using data connectors in the Microsoft Purview portal.
154	OMEPortal	Encrypted message portal event logs generated by external recipients.
157	MipLabelAnalyticsAuditRecord	MIP Label Analytics events.
164	ScorePlatformGenericAuditRecord	Generic Audit Record used for Data Connectors.
174	DataShareOperation	Events related to sharing of data ingested via SystemSync.
181	EduDataLakeDownloadOperation	Events related to the export of SystemSync ingested data from the lake.
183	MicrosoftGraphDataConnectOperation	Events related to extractions done by Microsoft Graph Data Connect.
186	PowerPagesSite	Activities related to Power Pages site.
187	PowerPlatformAdminDlp	Events related to Microsoft Power Platform DLP (Preview).
188	PlannerPlan	Microsoft Planner plan events.
189	PlannerCopyPlan	Microsoft Planner copy plan events.
190	PlannerTask	Microsoft Planner task events.
191	PlannerRoster	Microsoft Planner roster and roster membership events.
192	PlannerPlanList	Microsoft Planner plan list events.
193	PlannerTaskList	Microsoft Planner task list events.
194	PlannerTenantSettings	Microsoft Planner tenant settings events.
195	ProjectForThewebProject	Microsoft Project for the web project events.

Value	Member name	Description
196	ProjectForThewebTask	Microsoft Project for the web task events.
197	ProjectForThewebRoadmap	Microsoft Project for the web roadmap events.
198	ProjectForThewebRoadmapItem	Microsoft Project for the web roadmap item events.
199	ProjectForThewebProjectSettings	Microsoft Project for the web project tenant settings events.
200	ProjectForThewebRoadmapSettings	Microsoft Project for the web roadmap tenant settings events.
202	MicrosoftTodoAudit	Microsoft To Do Audit events.
206	MicrosoftTeamsSensitivityLabelAction	Microsoft Teams Sensitivity Label events.
216	Viva Goals	Viva Goals events.
217	MicrosoftGraphDataConnectConsent	Events for consent actions performed by tenant admins for Microsoft Graph Data Connect applications.
218	AttackSimAdmin	Events related to admin activities in Attack Simulation & Training in Microsoft Defender for Office 365.
230	TeamsUpdates	Teams Updates App Events.
231	PlannerRosterSensitivityLabel	Microsoft Planner roster sensitivity label events.
235	MicrosoftDefenderForIdentityAudit	Microsoft Defender for Identity audit events.
237	DefenderExpertsforXDRAdmin	Microsoft Defender Experts Administrator action events.
251	VfamCreatePolicy	Viva Access Management policy create events.
252	VfamUpdatePolicy	Viva Access Management policy update events.
253	VfamDeletePolicy	Viva Access Management policy delete events.
256	PowerPlatformAdministratorActivity	Power Platform Administrator activity events.
257	Windows365CustomerLockbox	Windows365 Customer Lockbox audit events.
261	CopilotInteraction	Copilot interaction events.
265	VivaLearning	User activities in Viva Learning.
266	VivaLearningAdmin	Admin activities in Viva Learning.
269	PeopleAdminSettings	Audit events for People Admin settings.
275	OWAAuth	Access Token for Resource issued successfully events.
277	SharePointESignature	SharePoint eSignature audit events.

Value	Member name	Description
278	Dynamics365BusinessCentral	Audit events for Dynamics 365 Business Central.
279	MeshWorlds	Audit events for Mesh.
280	VivaPulseResponse	Viva Pulse survey response events.
281	VivaPulseOrganizer	Viva Pulse survey organizer events.
282	VivaPulseAdmin	Viva Pulse admin events.
283	VivaPulseReport	Viva Pulse report related events.
284	AIAppInteraction	Audit events for user interactions with third-party (non-Microsoft and non-custom-built) AI applications.
285	ComplianceDLMExchange	ComplianceDLMExchange events.
286	ComplianceDLMSharePoint	ComplianceDLMSharePoint events.
287	ProjectForThewebAssignedToMeSettings	Microsoft Project for the web assigned to me tenant settings events.
288	CloudPolicyService	Events from the Cloud Policy service.
291	SensitiveInfoDiscovered	Events from Purview On-Demand classification for Endpoint devices.
292	InsiderRiskScopedUserInsights	Events related to scoped user insights in Insider Risk Management.
293	MicrosoftTeamsRetentionLabelAction	Audit events for retention labels in Microsoft Teams.
294	AadRiskDetection	Audit events for Risk Detection in Microsoft Entra (previously called Azure Active Directory).
295	AuditSearch	Audit events for an admin interacting with Search in Purview Audit.
296	AuditRetentionPolicy	Audit events for an admin interacting with Retention Policies in Purview Audit.
297	AuditConfig	Audit events for an admin interacting with configuration settings related to Purview Audit.
298	BackupPolicy	Events related to Microsoft 365 Backup Policies.
299	RestoreTask	Events related to Microsoft 365 Backup Restore Tasks.
300	RestoreItem	Events related to artifacts backed up with Microsoft 365 Backup.
301	BackupItem	Events related to items being restored using Microsoft 365 Backup.
302	URBACAssignment	Events related to Unified RBAC assignments.

Value	Member name	Description
303	URBACRole	Events related to Unified RBAC roles.
304	URBACEnableState	Events related to Unified RBAC state enablement.
306	PurviewInsiderRiskCases	Events related to Purview Insider Risk cases.
307	PurviewInsiderRiskAlerts	Events related to Purview Insider Risk alerts.
308	InsiderRiskScopedUsers	Events related to Purview Insider Risk scoped users.
310	CreateCopilotPlugin	Audit events for Copilot plugin creation.
311	UpdateCopilotPlugin	Audit events for updating a Copilot plugin.
312	DeleteCopilotPlugin	Audit events for deleting a Copilot plugin.
313	EnableCopilotPlugin	Audit events for enabling a Copilot plugin.
314	DisableCopilotPlugin	Audit events for disabling a Copilot plugin.
315	CreateCopilotWorkspace	Audit events for creating a Copilot workspace.
316	UpdateCopilotWorkspace	Audit events for updating a Copilot workspace.
317	DeleteCopilotWorkspace	Audit events for deleting a Copilot workspace.
318	EnableCopilotWorkspace	Audit events for enabling a Copilot workspace.
319	DisableCopilotWorkspace	Audit events for disabling a Copilot workspace.
320	CreateCopilotPromptBook	Audit events for creating a Copilot promptbook.
321	UpdateCopilotPromptBook	Audit events for updating a Copilot promptbook.
322	DeleteCopilotPromptBook	Audit events for deleting a Copilot promptbook.
323	EnableCopilotPromptBook	Audit events for enabling a Copilot promptbook.
324	DisableCopilotPromptBook	Audit events for disabling a Copilot promptbook.
325	UpdateCopilotSettings	Audit event for updating user or tenant settings related to Copilot.
328	ConnectedAIAppInteraction	Audit events related to user interactions with third-party (non-Microsoft developed) AI applications which are deployed within the organization's Microsoft tenant.
329	PrivaPrivacyConsentOperation	Audit events related to Consent in Microsoft Priva.
330	PrivaPrivacyAssessmentOperation	Audit events related to Assessments in Microsoft Priva.
331	DataCatalogAccessRequests	Audit events related to Data Catalog access requests.
332	ComplianceSettingsChange	Microsoft Purview Compliance settings change

Value	Member name	Description
		events.
333	DataSecurityInvestigation	Events from Data Security Investigations in Microsoft Purview.
334	TeamCopilotInteraction	Audit events for user interactions with Facilitator and activities performed by Facilitator in Microsoft Teams.
335	IRMActivityAuditTrail	Events from Purview Insider Risk Management.
336	SharePointContentSecurityPolicy	Events from Content Security Policy in SharePoint.
337	CloudUpdateProfileConfig	Events from the Cloud Update's profile configuration.
338	CloudUpdateTenantConfig	Events from the Cloud Update's tenant configuration.
339	CloudUpdateDeviceConfig	Events from Cloud Update's managed devices configuration.
341	DeviceDiscoverySettingsExclusion	Events related to Exclusions in Device Discovery settings.
342	DeviceDiscoverySettingsAuthenticatedScans	Events related to Authenticated Scans in Device Discovery settings.
344	DeviceDiscoverySettings	Events related to settings in Device Discovery.
345	USXWorkspaceOnboarding	Events related to workspace onboarding in Microsoft Defender USX.
346	VivaGlintAdvancedConfiguration	Events related to Advanced Configuration in Viva Glint.
347	VivaGlintPulseProgram	Events related to Pulse Program in Viva Glint.
348	VivaGlintPulseProgramRespondentRate	Events related to Pulse Program Respondent Rate in Viva Glint.
349	VivaGlintQuestion	Events related to Questions in Viva Glint.
350	VivaGlintRole	Events related to Roles in Viva Glint.
351	VivaGlintRubicon	Events related to Rubicon in Viva Glint.
352	VivaGlintSupportAccess	Events related to Support Access in Viva Glint.
353	VivaGlintSystem	Events related to system activities in Viva Glint.
354	VivaGlintUser	Events related to user activities in Viva Glint.
355	VivaGlintUserGroup	Events related to user group activities in Viva Glint.
356	VivaGlintFeedbackProgram	Events related to Feedback Programs in Viva Glint.
357	FabricAudit	Events related to Microsoft Fabric.
358	TrainableClassifier	Events from Purview Data Classification.

Value	Member name	Description
359	WebContentFiltering	Events from Microsoft Edge WebContentFiltering.
360	NoisyAlertPolicy	Events related to Noisy Alert Policies in Microsoft Defender.
361	DataScanClassification	Events from Purview On-Demand classification for SharePoint and OneDrive.
362	AIInteractionsExport	Events related to export of AI interactions.
363	Microsoft365CopilotScheduledPrompt	Events from Microsoft 365 Copilot scheduled prompt.
364	PlacesDirectory	Events from Microsoft Places Directory.
365	SentinelNotebookOnLake	Events from notebook execution on Sentinel data lake.
366	SentinelJob	Events from operations on jobs in Sentinel data lake.
367	SentinelKQLOnLake	Events from running KQL on Sentinel data lake.
368	SentinelLakeOnboarding	Events from onboarding to Sentinel data lake.
369	SentinelLakeDataOnboarding	Data loading events into Sentinel data lake.
370	SentinelAITool	Events from operations on AI tool in Microsoft Sentinel
371	SentinelGraph	Events related to Graph in Microsoft Sentinel.
372	CrossTenantAccessPolicy	Events from Cross Tenant Access Policies.
373	OutlookCopilotAutomation	Events related to back-end automation (without an explicit user interaction) in Microsoft Outlook driven by Agents, Copilot, or other AI scenarios.
374	VivaEngageNetworkAssociation	Events related to Network Association in Viva Engage.
375	AppAdminActivity	Events related to app admin activity.
376	AppSettingsAdminActivity	Events related to app settings admin activity.
377	UniversalPrintPrintJob	Audit events related to Print Jobs in Microsoft Universal Print.
378	VivaAmplifyOutlookSensitivityLabel	Events related to Outlook Sensitivity Labels in Viva Amplify.
379	AIInteractionsSubscription	Events related to AI interaction subscriptions.
380	AIInteractionsChangeNotification	Events related to AI interaction change notifications.
381	FilteringMailMetadataExtended	Events related to filtering mail metadata.

Value	Member name	Description
382	OfficeRestrictedModeAction	Audit events related to activities performed in Office Restricted Mode.
383	CopilotForSecurityTrigger	Events related to triggers for Security Copilot agents.
384	CopilotAgentManagement	Events related to admin activities for Microsoft Copilot agents.
385	P4AIAssessmentFabricScannerRecord	Events related to Purview for AI Assessment Fabric Scanner.
386	PlannerGoal	Microsoft Planner goal events.
387	PlannerGoalList	Microsoft Planner goal list events.
401	PlannerChatMessage	Microsoft Planner chat message events.
402	PlannerChatMessageList	Microsoft Planner chat message list events.
414	VivaEngageSegment	Viva Engage segmentation events.
422	VivaEngageEvents	Events related to Viva Engage hosted events.
427	UniversalPrintManagement	Audit events related to Management events in Microsoft Universal Print.
430	PurviewPostureAgent	Data Security Posture Agent events.
431	GranularBrowseTask	Events related to browsing backed up site's restore point using Microsoft 365 Backup.
444	TeamsEvalDataHubDataAccess	Teams Evaluation Data Hub data access events.
445	TeamsEvalDataHubPermissionChange	Teams Evaluation Data Hub permission change events.
454	DragonCopilotAdmin	Events from Dragon Copilot administrative operations.
462	MicrosoftTeamsUserConcern	Events related to user security concern in Microsoft Teams.
463	VivaGlintAgenticCampaign	Events related to agentic campaigns in Viva Glint.
479	VivaGlintVivaInsightsIntegration	Events related to the Viva Insights to Viva Glint integration.
480	PeopleSkillsAdmin	People Skills (Viva) events for tenant administrator and application (service-to-service) operations.
481	PeopleSkillsUser	People Skills (Viva) events for user and system operations on user skills.
489	AIGuardrail	Events generated when an AI guardrail evaluates content and applies a guardrail decision.

Enum: User Type - Type: Edm.Int32

User Type

Expand table

Value	Member name	Description
0	Regular	A regular user without admin permissions.
1	Reserved	A reserved value, not for use.
2	Admin	An administrator in your Microsoft 365 organization.
3	DCAdmin	A Microsoft datacenter administrator or datacenter system account.
4	System	An audit event triggered by server-side logic. For example, Windows services or background processes.
5	Application	An audit event triggered by a Microsoft Entra application.
6	ServicePrincipal	A service principal.
7	CustomPolicy	A customer created or managed policy.
8	SystemPolicy	A Microsoft-managed or system policy.
9	PartnerTechnician	A partner tenant's user working on behalf of the customer tenant (in GDAPscenarios).
10	Guest	A guest or anonymous user.

> **Note**
>
> ** For Microsoft Entra related events, the value for an administrator isn't used in an audit record. Audit records for activities performed by administrators indicate that a regular user (for example, **UserType: 0**) performed the activity. The **UserID** property identifies the person (regular user or administrator) who performed this activity.

Enum: AuditLogScope - Type: Edm.Int32

AuditLogScope

Expand table

Value	Member name	Description
0	Online	This event was created by a Microsoft 365 service.
1	Onprem	This event was created by an on-premises server.

Complex Type AppAccessContext

Expand table

Parameters	Type	Mandatory?	Description
AADSessionId	Edm.String	No	The Microsoft Entra SessionId of the Entra sign-in that was performed by the app on behalf of the user.
APIId	Edm.String	No	The Id for the API pathway that is used to access the resource; for example access via the Microsoft Graph API.
ClientAppId	Edm.String	No	The Id of the Microsoft Entra app that performed the access on behalf of the user.
ClientAppName	Edm.String	No	The name of the Microsoft Entra app that performed the access on behalf of the user.
CorrelationId	Edm.String	No	An identifier that can be used to correlate a specific user's actions across Microsoft 365 services.
UniqueTokenId	Edm.String	No	UniqueTokenId gets set if the Microsoft Entra token is available for the request. It's a unique, per-token identifier that is case-sensitive.
IssuedAtTime	Edm.Date	No	"Issued At" gets set if the Microsoft Entra token is available for the request and it indicates when the authentication for this Microsoft Entra token occurred.

SharePoint Base schema

Expand table

Parameter	Type	Mandatory?	Descripti
Site	Edm.Guid	No	The GUID the site where the or folder accessed the user is located.
ItemType	Edm.String String="Microsoft.Office.Audit.Schema.SharePoint.ItemType"	No	The type object tha was acces or modifie See the ItemType table for details on types of objects.

Parameter	Type	Mandatory?	Descripti
EventSource	Edm.String String="Microsoft.Office.Audit.Schema.SharePoint.EventSource"	No	Identifies an event occurred i SharePoin Possible values are **SharePoir ObjectMc**
SourceName	Edm.String	No	The entity that trigg the audite operation Possible values are SharePoin **ObjectMc**
UserAgent	Edm.String	No	Informatic about the user's clie or browse This informatic provided the client browser.
MachineDomainInfo	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Informatic about dev sync operation This informatic reported if it's pres in the request.
MachineId	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Informatic about dev sync operation This informatic reported if it's pres in the request.
ListItemUniqueId	Edm.Guid	No	The Guid uniquely a identifiabl

Parameter	Type	Mandatory?	Descripti
			item of lis This informatic present o if it is applicable
ListId	Edm.Guid	No	The Guid the list. Th informatic present o if it is applicable
ApplicationId	Edm.String	No	The ID of applicatio performin the operation
ApplicationDisplayName	Edm.String	No	The displa name of t applicatio performin the operation
IsWorkflow	Edm.Boolean	No	This is set `True` if SharePoin Workflow triggered audited event.

Enum: ItemType - Type: Edm.Int32

ItemType

Expand table

Value	Member name	Description
0	Invalid	The item is none of the other item types (that are listed in this table).
1	File	The item is a file.
5	Folder	The item is a folder.
6	web	The item is a web.
7	Site	The item is a site.

Value	Member name	Description
8	Tenant	The item is a tenant.
9	DocumentLibrary	The item is a document library.
11	Page	The item is a Page.

Value	Member name	Description
0	SharePoint	The event source is SharePoint.
1	ObjectModel	The event source is ObjectModel.

Enum: SharePointAuditOperation - Type: Edm.Int32

Expand table

Member name	Description
AccessInvitationAccepted	The recipient of an invitation to view or edit a shared file (or folder) has accessed the shared file by clicking on the link in the invitation.
AccessInvitationCreated	User sends an invitation to another person (inside or outside their organization) to view or edit a shared file or folder on a SharePoint or OneDrive site. The details of the event entry identifies the name of the file that was shared, the user the invitation was sent to, and the type of the sharing permission selected by the person who sent the invitation.
AccessInvitationExpired	An invitation sent to an external user expires. By default, an invitation sent to a user outside of your organization expires after 7 days if the invitation isn't accepted.
AccessInvitationRevoked	The site administrator or owner of a site or document in SharePoint or OneDrive withdraws an invitation that was sent to a user outside your organization. An invitation can be withdrawn only before it's accepted.
AccessInvitationUpdated	The user who created and sent an invitation to another person to view or edit a shared file or folder on a SharePoint or OneDrive site resent the invitation.
AccessRequestApproved	The site administrator or owner of a site or document in SharePoint or OneDrive approves a user request to access the site or document.

Member name	Description
AccessRequestCreated	User requests access to a site or document in SharePoint or OneDrive that they don't have permission to access.
AccessRequestRejected	The site administrator or owner of a site or document in SharePoint declines a user request to access the site or document.
ActivationEnabled	Users can browser-enable form templates that don't contain form code, require full trust, enable rendering on a mobile device, or use a data connection managed by a server administrator.
AdministratorAddedToTermStore	Term store administrator added.
AdministratorDeletedFromTermStore	Term store administrator deleted.
AllowGroupCreationSet	Site administrator or owner adds a permission level to a SharePoint or OneDrive site that allows a user assigned that permission to create a group for that site.
AppCatalogCreated	App catalog created to make custom business apps available for your SharePoint Environment.
AuditPolicyRemoved	Document LifeCycle Policy has been removed for a site collection.
AuditPolicyUpdate	Document LifeCycle Policy has been updated for a site collection.
AzureStreamingEnabledSet	A video portal owner has allowed video streaming from Azure.
CollaborationTypeModified	The type of collaboration allowed on sites (for example, intranet, extranet, or public) has been modified.
ConnectedSiteSettingModified	User has either created, modified or deleted the link between a project and a project site or the user modifies the synchronization setting on the link in Project web app.
ContainerTypeCreated	A SharePoint Embedded container type was created.
ContainerTypeDeleted	A SharePoint Embedded container type was deleted.
ContainerTypeOwnersUpdated	The owners of a SharePoint Embedded container type were updated.
ContainerTypeUpdated	A SharePoint Embedded container type was updated.
CreateSSOApplication	Target application created in Secure store service.
CustomFieldOrLookupTableCreated	User created a custom field or lookup table/item in Project web app.
CustomFieldOrLookupTableDeleted	User deleted a custom field or lookup table/item in Project web app.

Member name	Description
CustomFieldOrLookupTableModified	User modified a custom field or lookup table/item in Project web app.
CustomizeExemptUsers	Global administrator customized the list of exempt user agents in SharePoint admin center. You can specify which user agents to exempt from receiving an entire web page to index. This configuration means when an exempt user agent encounters an InfoPath form, the form is returned as an XML file instead of an entire web page. This result makes indexing InfoPath forms faster.
DefaultLanguageChangedInTermStore*	Language setting changed in the terminology store.
DelegateModified	User created or modified a security delegate in Project web app.
DelegateRemoved	User deleted a security delegate in Project web app.
DeleteSSOApplication	An SSO application was deleted.
eDiscoveryHoldApplied	An In-Place Hold was placed on a content source. In-Place Holds are managed by using an eDiscovery site collection (such as the eDiscovery Center) in SharePoint.
eDiscoveryHoldRemoved	An In-Place Hold was removed from a content source. In-Place Holds are managed by using an eDiscovery site collection (such as the eDiscovery Center) in SharePoint.
eDiscoverySearchPerformed	An eDiscovery search was performed using an eDiscovery site collection in SharePoint.
EngagementAccepted	User accepts a resource engagement in Project web app.
EngagementModified	User modifies a resource engagement in Project web app.
EngagementRejected	User rejects a resource engagement in Project web app.
EnterpriseCalendarModified	User copies, modifies or delete an enterprise calendar in Project web app.
EntityDeleted	User deletes a timesheet in Project web app.
EntityForceCheckedIn	User forces a check-in on a calendar, custom field or lookup table in Project web app.
ExemptUserAgentSet	Global administrator adds a user agent to the list of exempt user agents in the SharePoint admin center.
FeatureActivated	Site admin activates a site collection feature.
FeatureDeactivated	Site admin deactivates a site collection feature.
FileAccessed	User or system account accesses a file on a SharePoint or OneDrive site. System accounts can also generate FileAccessed events.

Member name	Description
FileCheckOutDiscarded	User discards a checked out file. That means any changes they made to the file when it was checked out are discarded, and not saved to the version of the document in the document library.
FileCheckedIn	User checks in a document that they checked out from a SharePoint or OneDrive document library.
FileCheckedOut	User checks out a document located in a SharePoint or OneDrive document library. Users can check out and make changes to documents that have been shared with them.
FileCopied	User copies a document from a SharePoint or OneDrive site. The copied file can be saved to another folder on the site.
FileDeleted	User deletes a document from a SharePoint or OneDrive site.
FileDeletedFirstStageRecycleBin	User deletes a file from the recycle bin on a SharePoint or OneDrive site.
FileDeletedSecondStageRecycleBin	User deletes a file from the second-stage recycle bin on a SharePoint or OneDrive site.
FileDownloaded	User downloads a document from a SharePoint or OneDrive site.
FileFetched	This event has been replaced by the FileAccessed event, and has been deprecated.
FileModified	User or system account modifies the content or the properties of a document located on a SharePoint or OneDrive site.
FileMoved	User moves a document from its current location on a SharePoint or OneDrive site to a new location.
FilePreviewed	User previews a document on a SharePoint or OneDrive site.
FileRecycled	User moves a document into the SharePoint or OneDrive Recycle Bin.
FileRenamed	User renames a document on a SharePoint or OneDrive site.
FileRestored	User restores a document from the recycle bin of a SharePoint or OneDrive site.
FileSyncDownloadedFull	User downloads a file to their computer from a SharePoint document library or OneDrive using OneDrive sync app (OneDrive.exe).
FileSyncDownloadedPartial	This event has been deprecated along with the old OneDrive sync app (Groove.exe).
FileSyncUploadedFull	User uploads a new file or changes to a file in SharePoint document library or OneDrive using OneDrive sync app (OneDrive.exe).

Member name	Description
FileSyncUploadedPartial	This event has been deprecated along with the old OneDrive sync app (Groove.exe).
FileUploaded	User uploads a document to a folder on a SharePoint or OneDrive site.
FileViewed	This event has been replaced by the FileAccessed event, and has been deprecated.
FolderCopied	User copies a folder from a SharePoint or OneDrive site to another location in SharePoint or OneDrive.
FolderCreated	User creates a folder on a SharePoint or OneDrive site.
FolderDeleted	User deletes a folder from a SharePoint or OneDrive site.
FolderDeletedFirstStageRecycleBin	User deletes a folder from the recycle bin on a SharePoint or OneDrive site .
FolderDeletedSecondStageRecycleBin	User deletes a folder from the second-stage recycle bin on a SharePoint or OneDrive site.
FolderModified	User modifies a folder on a SharePoint or OneDrive site. This event includes folder metadata changes, such as tags and properties.
FolderMoved	User moves a folder from a SharePoint or OneDrive site.
FolderRecycled	User moves a folder into the SharePoint or OneDrive Recycle Bin.
FolderRenamed	User renames a folder on a SharePoint or OneDrive site.
FolderRestored	User restores a folder from the Recycle Bin on a SharePoint or OneDrive site.
GroupAdded	Site administrator or owner creates a group for a SharePoint or OneDrive site, or performs a task that results in a group being created. For example, the first time a user creates a link to share a file, a system group is added to the user's OneDrive site. This event can also be a result of a user creating a link with edit permissions to a shared file.
GroupRemoved	User deletes a group from a SharePoint or OneDrive site.
GroupUpdated	Site administrator or owner changes the settings of a group for a SharePoint or OneDrive site. This can include changing the group's name, who can view or edit the group membership, and how membership requests are handled.
LanguageAddedToTermStore	Language added to the terminology store.
LanguageRemovedFromTermStore	Language removed from the terminology store.
LegacyWorkflowEnabledSet	Site administrator or owner adds the SharePoint Workflow Task content type to the site. Global administrators can also enable

Member name	Description
	work flows for the entire organization in the SharePoint admin center.
LookAndFeelModified	User modifies a quick launch, Gantt chart formats, or group formats. Or the user creates, modifies, or deletes a view in Project web app.
ManagedSyncClientAllowed	User successfully establishes a sync relationship with a SharePoint or OneDrive site. The sync relationship is successful because the user's computer is a member of a domain that's been added to the list of domains (called the safe recipients list) that can access document libraries in your organization. For more information, see Get started with SharePoint Online Management Shell to enable OneDrive sync for domains that are on the safe recipients list.
MaxQuotaModified	The maximum quota for a site has been modified.
MaxResourceUsageModified	The maximum allowable resource usage for a site has been modified.
MySitePublicEnabledSet	The flag enabling users to have public MySites has been set by the SharePoint administrator.
NewsFeedEnabledSet	Site administrator or owner enables RSS feeds for a SharePoint or OneDrive site. Global administrators can enable RSS feeds for the entire organization in the SharePoint admin center.
ODBNextUXSettings	New UI for OneDrive has been enabled.
OfficeOnDemandSet	Site administrator enables Office on Demand, which lets users access the latest version of Office desktop applications. Office on Demand is enabled in the SharePoint admin center and requires an Office 365 subscription that includes full, installed Office applications.
PageViewed	User views a page on a SharePoint site or OneDrive site. This does not include viewing document library files from a SharePoint site or One Drive for Business site on a browser.
PeopleResultsScopeSet	Site administrator creates or changes the result source for People Searches for a SharePoint site.
PermissionSyncSettingModified	User modifies the project permission sync settings in Project web app.
PermissionTemplateModified	User creates, modifies or deletes a permissions template in Project web app.
PortfolioDataAccessed	User accesses portfolio content (driver library, driver prioritization, portfolio analyses) in Project web app.
PortfolioDataModified	User creates, modifies, or deletes portfolio data (driver library, driver prioritization, portfolio analyses) in Project web app.

Member name	Description
PreviewModeEnabledSet	Site administrator enables document preview for a SharePoint site.
ProjectAccessed	User accesses project content in Project web app.
ProjectCheckedIn	User checks in a project that they checked out from a Project web app.
ProjectCheckedOut	User checks out a project located in a Project web app. Users can check out and make changes to projects that they have permission to open.
ProjectCreated	User creates a project in Project web app.
ProjectDeleted	User deletes a project in Project web app.
ProjectForceCheckedIn	User forces a check in on a project in Project web app.
ProjectModified	User modifies a project in Project web app.
ProjectPublished	User publishes a project in Project web app.
ProjectWorkflowRestarted	User restarts a workflow in Project web app.
PWASettingsAccessed	User access the Project web app settings via CSOM.
PWASettingsModified	User modifies the a Project web app configuration.
QueueJobStateModified	User cancels or restarts a queue job in Project web app.
QuotaWarningEnabledModified	Storage quota warning modified.
RenderingEnabled	Browser-enabled form templates are rendered by InfoPath forms services.
ReportingAccessed	User accessed the reporting endpoint in Project web app.
ReportingSettingModified	User modifies the reporting configuration in Project web app.
ResourceAccessed	User accesses an enterprise resource content in Project web app.
ResourceCheckedIn	User checks in an enterprise resource that they checked out from Project web app.
ResourceCheckedOut	User checks out an enterprise resource located in Project web app.
ResourceCreated	User creates an enterprise resource in Project web app.
ResourceDeleted	User deletes an enterprise resource in Project web app.
ResourceForceCheckedIn	User forces a check in of an enterprise resource in Project web app.
ResourceModified	User modifies an enterprise resource in Project web app.

Member name	Description
ResourcePlanCheckedInOrOut	User checks in or out a resource plan in Project web app.
ResourcePlanModified	User modifies a resource plan in Project web app.
ResourcePlanPublished	User publishes a resource plan in Project web app.
ResourceRedacted	User redacts an enterprise resource removing all personal information in Project web app.
ResourceWarningEnabledModified	Resource quota warning modified.
SSOGroupCredentialsSet	Group credentials set in Secure store service.
SSOUserCredentialsSet	User credentials set in Secure store service.
SearchCenterUrlSet	Search center URL set.
SecondaryMySiteOwnerSet	A user has added a secondary owner to their MySite.
SecurityCategoryModified	User creates, modifies or deletes a security category in Project web app.
SecurityGroupModified	User creates, modifies or deletes a security group in Project web app.
SendToConnectionAdded	Global administrator creates a new Send To connection on the Records management page in the SharePoint admin center. A Send To connection specifies settings for a document repository or a records center. When you create a Send To connection, a Content Organizer can submit documents to the specified location.
SendToConnectionRemoved	Global administrator deletes a Send To connection on the Records management page in the SharePoint admin center.
SharedLinkCreated	User creates a link to a shared file in SharePoint or OneDrive. This link can be sent to other people to give them access to the file. A user can create two types of links: a link that allows a user to view and edit the shared file, or a link that allows the user to just view the file.
SharedLinkDisabled	User disables (permanently) a link that was created to share a file.
SharingInvitationAccepted*	User accepts an invitation to share a file or folder. This event is logged when a user shares a file with other users.
SharingRevoked	User unshared a file or folder that was previously shared with other users. This event is logged when a user stops sharing a file with other users.
SharingSet	User shares a file or folder located in SharePoint or OneDrive with another user inside their organization.
SiteAdminChangeRequest	User requests to be added as a site collection administrator for a SharePoint site collection. Site collection administrators have

Member name	Description
	full control permissions for the site collection and all subsites.
SiteCollectionAdminAdded*	Site collection administrator or owner adds a person as a site collection administrator for a SharePoint or OneDrive site. Site collection administrators have full control permissions for the site collection and all subsites.
SiteCollectionCreated	Global administrator creates a new site collection in your SharePoint organization.
SitePermanentlyDeleted	A SharePoint or global administrator permanently deletes a site from SharePoint Admin Center Deleted Sites.
SiteRenamed	Site administrator or owner renames a SharePoint or OneDrive site
SiteRestored	A SharePoint or global administrator restores a site from SharePoint Admin Center Deleted Sites.
StatusReportModified	User creates, modifies or deletes a status report in Project web app.
SyncGetChanges	User clicks **Sync** in the action tray on in SharePoint or OneDrive to synchronize any changes to file in a document library to their computer.
SyntexBillingSubscriptionSettingsChanged	The Syntex Billing subscription settings have changed. This event is triggered when a Syntex trial expires.
TaskStatusAccessed	User accesses the status of one or more tasks in Project web app.
TaskStatusApproved	User approves a status update of one or more tasks in Project web app.
TaskStatusRejected	User rejects a status update of one or more tasks in Project web app.
TaskStatusSaved	User saves a status update of one or more tasks in Project web app.
TaskStatusSubmitted	User submits a status update of one or more tasks in Project web app.
TenantWideThemeCreated	A SharePoint administrator, global administrator, or brand manager creates a custom theme that applies across all SharePoint sites in your organization.
TenantWideThemeDeleted	A SharePoint administrator, global administrator, or brand manager deletes a custom theme that applies across all SharePoint sites in your organization.
TenantWideThemeUpdated	A SharePoint administrator, global administrator, or brand manager updates a custom theme that applies across all SharePoint sites in your organization.

Member name	Description
TimesheetAccessed	User accesses a timesheet in Project web app.
TimesheetApproved	User approves timesheet in Project web app.
TimesheetRejected	User rejects a timesheet in Project web app.
TimesheetSaved	User saves a timesheet in Project web app.
TimesheetSubmitted	User submits a status timesheet in Project web app.
UnmanagedSyncClientBlocked	User tries to establish a sync relationship with a SharePoint or OneDrive site from a computer that isn't a member of your organization's domain or is a member of a domain that hasn't been added to the list of domains (called the safe recipients list) that can access document libraries in your organization. The sync relationship is not allowed, and the user's computer is blocked from syncing, downloading, or uploading files on a document library.
UpdateDisableSiteBranding	A SharePoint or global administrator enables or disables site branding.
UpdateSSOApplication	Target application updated in Secure store service.
UserAddedToGroup	Site administrator or owner adds a person to a group on a SharePoint or OneDrive site. Adding a person to a group grants the user the permissions that were assigned to the group.
UserRemovedFromGroup	Site administrator or owner removes a person from a group on a SharePoint or OneDrive site. After the person is removed, they no longer are granted the permissions that were assigned to the group.
WebThemeApplied	A SharePoint or global administrator, or a site owner applies a web theme.
WorkflowModified	User creates, modifies, or deletes an Enterprise Project Type or Workflow phases or stages in Project web app.

SharePoint file operations

File and page events returned in audit log searches use this schema.

Expand table

Parameter	Type	Mandatory?	Description
SiteUrl	Edm.String	Yes	The URL of the site where the file or folder accessed by the user is located.
SourceRelativeUrl	Edm.String	No	The URL of the folder that contains the file accessed by the user. The combination of the values for the *SiteURL*, *SourceRelativeURL*, and

Parameter	Type	Mandatory?	Description
			SourceFileName parameters is the same as the value for the **ObjectID** property, which is the full path name for the file accessed by the user.
SourceFileName	Edm.String	Yes	The name of the file or folder accessed by the user.
SourceFileExtension	Edm.String	No	The file extension of the file that was accessed by the user. This property is blank if the object that was accessed is a folder.
DestinationRelativeUrl	Edm.String	No	The URL of the destination folder where a file is copied or moved. The combination of the values for *SiteURL*, *DestinationRelativeURL*, and *DestinationFileName* parameters is the same as the value for the **ObjectID** property, which is the full path name for the file that was copied. This property is displayed only for FileCopied and FileMoved events.
DestinationFileName	Edm.String	No	The name of the file that is copied or moved. This property is displayed only for FileCopied and FileMoved events.
DestinationFileExtension	Edm.String	No	The file extension of a file that is copied or moved. This property is displayed only for FileCopied and FileMoved events.
UserSharedWith	Edm.String	No	The user that a resource was shared with.
SharingType	Edm.String	No	The type of sharing permissions that were assigned to the user that the resource was shared with. This user is identified by the *UserSharedWith* parameter.
SourceLabel	Edm.String	No	The original label of the file before it's changed by a user action.
DestinationLabel	Edm.String	No	The final label of the file after it's changed by a user action.
SensitivityLabelOwnerEmail	Edm.String	No	The email address of the owner of the sensitivity label.
SensitivityLabelId	Edm.String	No	The current sensitivity label ID of the file.

SharePoint list operations

SharePoint list events returned in audit log searches use this schema.

Expand table

Parameter	Type	Mandatory?	Description
ListTitle	Edm.String	No	The title of the SharePoint list.
ListName	Edm.String	No	The name of the SharePoint list.
ListUrl	Edm.String	No	The URL of the list relative to the containing website.
ListBaseType	Edm.String	No	Specifies the base type for a list.
ListBaseTemplateType	Edm.String	No	The list definition type on which the list is based.
IsHiddenList	Edm.Boolean	No	This value is set to `True` if the SharePoint list is hidden.
IsDocLib	Edm.Boolean	No	This value is set to `True` if the SharePoint list is of the type Document Library.

SharePoint Sharing schema

Sharing and access request events returned in audit log searches use this schema.

The file share-related SharePoint events. They are different from file- and folder-related events in that a user is taking an action that has some effect on another user. For information about the SharePoint Sharing schema, see Use sharing auditing in the audit log.

Expand table

Parameter	Type	Mandatory?	Description
TargetUserOrGroupName	Edm.String	No	Stores the UPN or name of the target user or group that a resource was shared with.
TargetUserOrGroupType	Edm.String	No	Identifies whether the target user or group is a Member, Guest, Group, or Partner.
EventData	XML code	No	Conveys follow-up information about the sharing action that has occurred, such as adding a user to a group or granting edit permissions.
SiteUrl	Edm.String	No	The URL of the site where the file or folder accessed by the user is located.
SourceRelativeUrl	Edm.String	No	The URL of the folder that contains the file accessed by the user. The combination of the values for the *SiteURL*, *SourceRelativeURL*, and *SourceFileName* parameters is the same as the value for the **ObjectID** property, which is the full path name for the file accessed by the user.
SourceFileName	Edm.String	No	The name of the file or folder accessed by the user.
SourceFileExtension	Edm.String	No	The file extension of the file that was accessed by the user. This property is blank if the object that

Parameter	Type	Mandatory?	Description
			was accessed is a folder.
UniqueSharingId	Edm.String	No	The unique sharing ID associated with the sharing operation.

SharePoint schema

SharePoint events (excluding the file and folder events) returned in audit log searches use this schema.

Parameter	Type	Mandatory?	Description
CustomEvent	Edm.String	No	Optional string for custom events.
EventData	Edm.String	No	Optional payload for custom events.
ModifiedProperties	Collection(ModifiedProperty)	No	The property is included for admin events, such as adding a user as a member of a site or a site collection admin group. The property includes the name of the property that was modified (for example, the Site Admin group), the new value of the modified property (such the user who was added as a site admin), and the previous value of the modified object.

Project schema

Microsoft Project for the web events returned in audit log searches use these schemas.

Parameter	Type	Mandatory?	Description
Entity	Edm.String	Yes	ProjectEntity the audit was for.
Action	Edm.String	Yes	ProjectAction that was taken.
OnBehalfOfResId	Edm.Guid	No	The resource Id the action was taken on behalf of.

Enum: Project Action - Type: Edm.Int32

Project action

Member name	Description
Accepted	The user accepted an event or workflow.
Accessed	The user accessed an entity.
Activated	The user activated an entity, event or workflow.

Member name	Description
Cancelled	The user cancelled an event or workflow.
CheckedIn	The user check in an entity.
CheckedOut	The user checkout an entity.
Copied	The user copied an entity.
Created	The user created an entity.
Deactivated	The user deactivated an entity.
Deleted	The user deleted an entity.
Exported	The user exported an entity.
ForceCheckedIn	The user caused an entity to be force checked in.
Modified	The user modified an entity.
Published	The user published an entity.
Redacted	The user redacted an entity.
Rejected	The user rejected an entity.
Restarted	The user restarted an event or workflow.
Saved	The user saved an entity.
Sent	The user sent an entity.
Submitted	The user submitted an entity for review or workflow.

Enum: Project Entity - Type: Edm.Int32

Project entity

Member name	Description
CustomField	Represents an enterprise custom field.
Driver	Represents a portfolio driver.
DriverPrioritization	Represents a portfolio prioritization.
Engagement	Represents a resource engagement.
EnterpriseCalendar	Represents a enterprise resource calendar.
EnterpriseProjectType	Represents an enterprise project type.
FiscalPeriod	Represents a fiscal period.
GanttChartFormat	Represents a Gantt chart format.

Member name	Description
GroupingFormat	Represents a view grouping format.
LineClassification	Represents a timesheet line classification.
LookupTable	Represents a enterprise lookup table.
PermissionTemplate	Represents a security permission template.
PortfolioAnalysis	Represents a portfolio analysis.
Project	Represents a project.
QueueJob	Represents a queue job.
QuickLaunch	Represents a quick launch item.
Reporting	Represents the reporting endpoint.
Resource	Represents an enterprise resource.
ResourcePlan	Represents a resource plan associated with A project.
SecurityCategory	Represents a security category.
SecurityGroup	Represents a security group.
Setting	Represents a Project web app setting.
Statusing	Represents a task status update.
StatusReport	Represents a status report.
TimeReportingPeriod	Represents a period of time for a timesheet.
Timesheet	Represents a timesheet entity.
TimesheetAuditLog	Represents a timesheet audit log.
TimesheetManager	Represents the manager of a timesheet.
UserDelegate	Represents a user delegation for another user.
View	Represents a view definition.
WorkflowPhase	Represents a phase in a workflow.
WorkflowStage	Represents a stage in a workflow.

Exchange Admin schema

Parameters	Type	Mandatory	Description
ModifiedObjectResolvedName	Edm.String	No	This is the user friendly name of the object that was

Parameters	Type	Mandatory	Description
			modified by the cmdlet. This is logged only if the cmdlet modifies the object.
Parameters	Collection(Common.NameValuePair)	No	The name and value for all parameters that were used with the cmdlet that is identified in the Operations property.
ModifiedProperties	Collection(Common.ModifiedProperty)	No	The property is included for admin events. The property includes the name of the property that was modified, the new value of the modified property, and the previous value of the modified object.
ExternalAccess	Edm.Boolean	Yes	Specifies whether the cmdlet was run by a user in your organization, by Microsoft datacenter personnel or a datacenter service account, or by a delegated administrator. The value **False** indicates that the cmdlet was run by someone in your organization. The value **True** indicates that the cmdlet was run by datacenter personnel, a datacenter service account, or a delegated administrator.

Parameters	Type	Mandatory	Description
OriginatingServer	Edm.String	No	The name of the server from which the cmdlet was executed.
OrganizationName	Edm.String	No	The name of the tenant.
DeviceId	Edm.String	No	Available only for registered/domain joined device.
TokenObjectId	Edm.String	Yes	oid claim of the Microsoft Entra tokens.
TokenTenantId	Edm.String	Yes	tid claim of the Microsoft Entra tokens.

Exchange Mailbox schema

Exchange mailbox events returned in audit log searches use these schemas.

Parameters	Type	Mandatory	Description
LogonType	Self.LogonType	Yes	Indicates the type of user who accessed the mailbox and performed the operation that was logged.
InternalLogonType	Self.LogonType	Yes	Reserved for internal use.
MailboxGuid	Edm.String	No	The Exchange GUID of the mailbox that was accessed.
MailboxOwnerUPN	Edm.String	No	The email address of the person who owns the mailbox that was accessed.
MailboxOwnerSid	Edm.String	No	The SID of the mailbox owner.
MailboxOwnerMasterAccountSid	Edm.String	No	Mailbox owner account's master account SID.

Parameters	Type	Mandatory	Description
LogonUserSid	Edm.String	No	The SID of the user who performed the operation.
LogonUserDisplayName	Edm.String	No	The user-friendly name of the user who performed the operation.
ExternalAccess	Edm.Boolean	Yes	This is true if the logon user's domain is different from the mailbox owner's domain.
OriginatingServer	Edm.String	No	This is from where the operation originated.
OrganizationName	Edm.String	No	The name of the tenant.
ClientInfoString	Edm.String	No	Information about the email client that was used to perform the operation, such as a browser version, Outlook version, and mobile device information.
ClientIPAddress	Edm.String	No	The IP address of the device that was used when the operation was logged. The IP address is displayed in either an IPv4 or IPv6 address format.
ClientMachineName	Edm.String	No	The machine name that hosts the Outlook client.
ClientProcessName	Edm.String	No	The email client that was used to access the mailbox.
ClientVersion	Edm.String	No	The version of the email client.
SessionId	Edm.String	No	Unique identifier for the session. It helps to differentiate attacker actions vs day-to-day user activities on the

Parameters	Type	Mandatory	Description
			same account (useful for compromised accounts)
AppId	Edm.String	No	Application Identifier
ClientAppId	Edm.String	No	Original caller(service/protocol) identifier of the request.
HostAppId	Edm.String	No	The executing service/protocol identifier.
OperationProperties	Collection(Common.NameValuePair)	No	Collection of operation-specific properties.
ClientRequestId	Edm.String	No	Identifier for the client request.
ExternalUserTenantId	Edm.String	No	Tenant identifier for external users.
ActorIP	Edm.String	No	IP address of the actor performing the operation.
ActorInfoString	Edm.String	No	Name of the cloud instance (e.g., Public, GCC, GCC-H)
DeviceId	Edm.String	No	Available only for registered/domain joined device.
CloudInstanceName	Edm.String	No	Name of the cloud instance (e.g., Public, GCC, GCC-H)
TokenObjectId	Edm.String	No	oid claim of the Microsoft Entra tokens.
TokenTenantId	Edm.String	No	tid claim of the Microsoft Entra tokens.
AuthType	Edm.String	No	Specifies the authentication scheme used by the client to access the service.

Parameters	Type	Mandatory	Description
TokenType	Edm.String	No	Indicates the type of token presented during authentication, providing context on the token's role and scope.
recipientCount	Edm.Int64	No	Represents the total number of recipients, to whom email was sent.
recipientList	Collection(Self.EmailAddress)	No	Captures the list of mailbox recipients, maximum 1000.

Enum: LogonType - Type: Edm.Int32

LogonType

Value	Member name	Description
0	Owner	The mailbox owner.
1	Admin	A person with administrative privileges for someone's mailbox.
2	Delegated	A person with the delegate privileges for someone's mailbox.
3	Transport	A transport service in the Microsoft datacenter.
4	SystemService	A service account in the Microsoft datacenter
5	BestAccess	Reserved for internal use.
6	DelegatedAdmin	A delegated administrator.

ExchangeMailboxAuditGroupRecord schema

Parameters	Type	Mandatory?	Description
Folder	Self.ExchangeFolder	No	The folder where a group of items is located.
CrossMailboxOperations	Edm.Boolean	No	Indicates if the operation involved more than one mailbox.
DestMailboxId	Edm.Guid	No	Set only if the CrossMailboxOperations parameter is **True**.

Parameters	Type	Mandatory?	Description
			Specifies the target mailbox GUID.
DestMailboxOwnerUPN	Edm.String	No	Set only if the CrossMailboxOperations parameter is **True**. Specifies the UPN of the owner of the target mailbox.
DestMailboxOwnerSid	Edm.String	No	Set only if the CrossMailboxOperations parameter is **True**. Specifies the SID of the target mailbox.
DestMailboxOwnerMasterAccountSid	Edm.String	No	Set only if the CrossMailboxOperations parameter is **True**. Specifies the SID for the master account SID of the target mailbox owner.
DestFolder	Self.ExchangeFolder	No	The destination folder, for operations such as Move.
Folders	Collection(Self.ExchangeFolder)	No	Information about the source folders involved in an operation; for example, if folders are selected and then deleted.
AffectedItems	Collection(Self.ExchangeItem)	No	Information about each item in the group.
Teams	Self.TeamsData	No	Microsoft Teams-related data for group operations.

ExchangeMailboxAuditRecord schema

Parameters	Type	Mandatory?	Description
Item	Self.ExchangeItem	No	Represents the item upon which the operation was performed
ModifiedProperties	Collection(Edm.String)	No	Properties that are modified.

Parameters	Type	Mandatory?	Description
MbxLoginLocalQueueADLookupInfo	Self.LocalQueueADLookupInfo	No	Contains Active Directory lookup details for the mailbox login context.
SendAsUserSmtp	Edm.String	No	SMTP address of the user who is being impersonated.
SendAsUserMailboxGuid	Edm.Guid	No	The Exchange GUID of the mailbox that was accessed to send email as.
SendOnBehalfOfUserSmtp	Edm.String	No	SMTP address of the user on whose behalf the email is sent.
SendOnBehalfOfUserMailboxGuid	Edm.Guid	No	The Exchange GUID of the mailbox that was accessed to send mail on behalf of.
ContactEmail1EmailAddress	Edm.String	No	First email address for contact information.
ContactEmail1DisplayName	Edm.String	No	Display name for first contact email.
ContactEmail2EmailAddress	Edm.String	No	Second email address for contact information.
ContactEmail2DisplayName	Edm.String	No	Display name for second contact email.
ContactEmail3EmailAddress	Edm.String	No	Third email address for contact information.
ContactEmail3DisplayName	Edm.String	No	Display name for third contact email.
AttachmentId	Edm.String	No	Identifier for email attachment.
AttachmentSizeInBytes	Edm.Int64	No	Size of attachment in bytes.

Parameters	Type	Mandatory?	Description
SaveToSentItems	Edm.Boolean	No	Flag indicating whether item should be saved to sent items folder.
Teams	Self.TeamsData	No	Microsoft Teams-related data.

ExchangeAggregatedMailboxAuditRecord schema

Parameters	Type	Mandatory?	Description
OperationCount	Edm.Int32	No	The total number of operations performed on the aggregated set of items.
Folders	Collection(Self.ExchangeAggregatedFolder)	No	A collection of aggregated folder objects involved in the operation.
Messages	Collection(Self.ExchangeAggregatedMessage)	No	A collection of aggregated message objects involved in the operation.

ExchangeAggregatedOperationRecord schema

Parameters	Type	Mandatory?	Description
OperationCount	Edm.Int32	No	The total number of operations included aggregated in this record.
AggregateDurationInSeconds	Edm.Int32	No	Combined duration of all aggregated operations in seconds.

ExchangeItem complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	Yes	The store ID.
Subject	Edm.String	No	The subject line of the message that was accessed.
ParentFolder	Self.ExchangeFolder	No	The name of the folder where the item is located.
ParentMessage	Self.ExchangeMessage	No	Parent message if this item is nested.

Parameters	Type	Mandatory?	Description
Attachments	Edm.String	No	A list of the names and file size of all items that are attached to the message.
ImmutableId	Edm.String	No	A permanent, unchanging identifier for the item.
InternetMessageId	Edm.String	No	Internet message identifier.
ComplianceLabel	Edm.String	No	Compliance label applied to the item.
IsRecord	Edm.Boolean	No	Flag indicating if the item is a record.
IsPriorityCleanup	Edm.Boolean	No	Flag for priority cleanup processing
SizeInBytes	Edm.Int64	No	Size of the Exchange item in bytes.
Sensitivity	Edm.String	No	Indicates the sensitivity level of the item (e.g., Normal, Personal, Private, Confidential).

LocalQueueADLookupInfo complex type

Parameters	Type	Mandatory?	Description
Puid	Edm.String	No	Passport unique identifier (Puid) for a Microsoft account or user object.
OrgIdPuid	Edm.String	No	Organization identifier PUID.
Smtp	Edm.String	No	SMTP address for AD lookup.
SearchScope	Edm.String	No	Active Directory search scope
ConsumerMailbox	Edm.String	No	Flag indicating if this is a consumer mailbox.

EmailAddress complex type

Parameters	Type	Mandatory?	Description
Address	Edm.String	No	Email address associated with user.
Name	Edm.String	No	Display name for email address.

ExchangeFolder complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	Yes	The store ID of the folder object.
Path	Edm.String	No	The name of the mailbox folder where the message that was accessed is located.

Parameters	Type	Mandatory?	Description
Name	Edm.String	No	Folder Name
MemberSid	Edm.String	No	Member security identifier
MemberRights	Edm.String	No	Access Rights on the folder
MemberUpn	Edm.String	No	Member user principal name

ExchangeMessage complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	Yes	Unique identifier for the Message.
Path	Edm.String	No	The path where the message is located

ExchangeFolderItem complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	No	A guid that identifies the folder item within Exchange.
ImmutableId	Edm.String	No	Immutable identifier for each Exchange folder item.
InternetMessageId	Edm.String	No	Internet message identifier for each folder item.
CreationTime	Edm.Date	No	Time when Record/item was created.
Subject	Edm.String	No	Subject of the record/item.
SizeInBytes	Edm.Int64	No	Size of the record/item in bytes.
Sensitivity	Edm.String	No	Sensitivity labels of the record/item.
ClientRequestId	Edm.String	No	A unique identifier for the client request that triggered the operation.
Teams	Self.TeamsData	No	Microsoft Teams-related data

ExchangeMessageItem complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	No	A guid that identifies the Exchange Message Item.
SizeInBytes	Edm.Int64	No	The size of the message in bytes, including any attachments.

ExchangeAggregatedFolder complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	Yes	The guid of the aggregated folder.
Path	Edm.String	No	The path of the aggregated folder.
FolderItems	Collection(Self.ExchangeFolderItem)	No	The collection of Exchange folder items.

ExchangeAggregatedMessage complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	Yes	The guid of the aggregated message container.
Path	Edm.String	No	The path of the aggregated message.
MessageItems	Collection(Self.ExchangeMessageItem)	No	The collection of exchange message items.

OWA Auth schema

Parameters	Type	Mandatory?	Description
UniqueTokenIdentifier	Edm.String	No	A unique identifier for the resource.
ResourceURL	Edm.String	No	The resource URL.

Azure Active Directory Base schema

Parameters	Type	Mandatory?	Description
AzureActiveDirectoryEventType	Self.AzureActiveDirectoryEventType	Yes	The type of Microsoft Entra event.
ExtendedProperties	Collection(Common.NameValuePair)	No	The extended properties of the Microsoft Entra event.
ModifiedProperties	Collection(Common.ModifiedProperty)	No	This property is included for admin events. The property includes the name of the property that was modified, the new value of the modified

Parameters	Type	Mandatory?	Description
			property, and the previous value of the modified property.

Enum: AzureActiveDirectoryEventType - Type -Edm.Int32

AzureActiveDirectoryEventType

Member name	Description
AccountLogon	The account login event.
AzureApplicationAuditEvent	The Azure application security event.

Azure Active Directory Account Logon schema

Parameters	Type	Mandatory?	Description
Application	Edm.String	No	The application that triggers the account login event, such as Office 15.
Client	Edm.String	No	Details about the client device, device OS, and device browser that was used for the of the account login event.
LoginStatus	Edm.Int32	Yes	This property is from OrgIdLogon.LoginStatus directly. The mapping of various interesting logon failures could be done by alerting algorithms.
UserDomain	Edm.String	Yes	The Tenant Identity Information (TII).

Enum: CredentialType - Type: Edm.Int32

Value	Member name	Description
-1	Other	Other authentication.
0	Password	User credential is username and password.
1	MobilePhone	User credential is mobile phone.
2	SecretQuestion	User credential is secret question.
3	SecurePin	User credential is secure PIN.
4	SecurePinReset	User credential is secure PIN reset.
11	EasyID	User credential is EasyID.
14	PasswordIndexCredentialType	User credential is PasswordIndexCredentialType.

Value	Member name	Description
16	Device	User credential is a device.
17	ForeignRealmIndex	User credential is ForeignRealmIndex.

Enum: LoginType - Type: Edm.Int32

Value	Member name	Description
-1	Other	Other i type.
1	InitialAuth	Login with initial authentication
2	CookieCopy	Login with cookie.
3	SilentReAuth	Login with silent re-authentication.

Enum: AuthenticationMethod - Type: Edm.Int32

Value	Member name	Description
0	Min	The authentication method is a Min
1	Password	The authentication method is a password.
2	Digest	The authentication method is a digest.
3	ProxyAuth	The authentication method is a ProxyAuth.
4	InfoCard	The authentication method is an InfoCard
5	DAToken	The authentication method is a DAToken.
6	Sha1RememberMyPassword	The authentication method is a Sha1RememberMyPassword.
7	LMPasswordHash	The authentication method is an LMPasswordHash.
8	ADFSFederatedToken	The authentication method is an ADFSFederatedToken.
9	EID	The authentication method is an EID.
10	DeviceID	The authentication method is a DeviceID.
11	MD5	The authentication method is MD5.
12	EncProxyPasswordHash	The authentication method is a EncProxyPasswordHash.
13	LWAFederation	The authentication method is a LWAFederation.
14	Sha1HashedPassword	The authentication method is a Sha1HashedPassword.
15	SecurePin	The authentication method is a secure Pin.
16	SecurePinReset	The authentication method is a secure PIN reset.

Value	Member name	Description
17	SAML20PostSimpleSign	The authentication method is a SAML20PostSimpleSign.
18	SAML20Post	The authentication method is a SAML20Post.
19	OneTimeCode	The authentication method is a one-time code.

Azure Active Directory schema

Parameters	Type	Mandatory?	Description
Actor	Collection(Self.IdentityTypeValuePair)	No	The user or service principal that performed the action.
ActorContextId	Edm.String	No	The GUID of the organization that the actor belongs to.
ActorIpAddress	Edm.String	No	The actor's IP address in IPV4 or IPV6 address format.
InterSystemsId	Edm.String	No	The GUID that track the actions across components within the Office 365 service.
IntraSystemsId	Edm.String	No	The GUID that's generated by Azure Active Directory to track the action.
SupportTicketId	Edm.String	No	The customer support ticket ID for the action in "act-on-behalf-of" situations.
Target	Collection(Self.IdentityTypeValuePair)	No	The user that the action (identified by the Operation property) was performed on.
TargetContextId	Edm.String	No	The GUID of the organization that the targeted user belongs to.

Complex Type IdentityTypeValuePair

Parameters	Type	Mandatory?	Description
ID	Edm.String	Yes	The value of the identity given the type.
Type	Self.IdentityType	Yes	The type of the identity.

Enum: IdentityType - Type: Edm.Int32

IdentityType

Member name	Description
Claim	The identity is a claim for authorization purpose.
Name	The audit action actor or target identity display name.
Other	The identity of the actor is other type, such as the ObjectId in GUID generated by the Office 365 service.
PUID	The audit action actor or the target passport unique ID (PUID).
SPN	The identity of a service principal if the action is performed by the Office 365 service.
UPN	The user principal name.

Azure Active Directory Secure Token Service (STS) Logon schema

Parameters	Type	Mandatory?	Description
ApplicationId	Edm.String	No	The GUID that represents the application that is requesting the login. The display name can be looked up via the Azure Active Directory Graph API.
Client	Edm.String	No	Client device information, provided by the browser performing the login.
DeviceProperties	Collection(Common.NameValuePair)	No	This property includes various device details, including Id, Display name, OS, Browser, IsCompliant, IsCompliantAndManaged, SessionId, and DeviceTrustType. The DeviceTrustType property can have the following values: **0** - Microsoft Entra registered **1** - Microsoft Entra joined **2** - Hybrid Microsoft Entra joined
ErrorCode	Edm.String	No	For failed logins (where the value for the Operation property is UserLoginFailed), this property contains the Azure Active Directory STS (AADSTS) error code. For descriptions of these error codes, see Authentication and authorization error codes. A value of `0` indicates a successful login.

Parameters	Type	Mandatory?	Description
LogonError	Edm.String	No	For failed logins, this property contains a user-readable description of the reason for the failed login.

DLP schema

Data loss prevention (DLP) events in Microsoft Purview are available for Exchange Online, Endpoint(devices), and SharePoint and OneDrive.

DLP events always have `UserKey="DlpAgent"` in the common schema. There are three types of DlpEvents that are stored as the value of the Operation property of the common schema:

- **DlpRuleMatch**: Indicates a rule was matched. These events exist in all Exchange, Endpoint(devices) and SharePoint and OneDrive. For Exchange it includes false positive and override information. For SharePoint and OneDrive, false positive and overrides generate separate events.
- **DlpRuleUndo**: SharePoint and OneDrive only. Indicates a previously applied policy action has been "undone" due to:
  - AFalse positive/override designation by user.
  - The document is no longer subject to policy (either due to policy change or change to content in doc).
- **DlpInfo**: SharePoint and OneDrive only. Indicates a false positive designation but no action was "undone."

Parameters	Type	Mandatory	Description
SharePointMetaData	Self.SharePointMetadata	No	Describes metadata about the document in SharePoint or OneDrive that contained the sensitive information.
ExchangeMetaData	Self.ExchangeMetadata	No	Describes metadata about the email message that contained the sensitive information.
EndpointMetaData	Self.EndpointMetadata	No	Describes metadata about the document in endpoint that contained the sensitive information
ExceptionInfo	Edm.String	No	Identifies reasons why a policy no longer applies and/or any information about false positive and/or

Parameters	Type	Mandatory	Description
			override noted by the end user.
PolicyDetails	Collection(Self.PolicyDetails)	Yes	Information about 1 or more policies that triggered the DLP event.
SensitiveInfoDetectionIsIncluded	Boolean	Yes	Indicates whether the event contains the value of the sensitive data type and surrounding context from the source content. Accessing sensitive data requires the "Read DLP policy events including sensitive details" permission in Azure Active Directory.

eDiscovery schema

The eDiscovery audit schema is designed to capture and log activities related to eDiscovery processes within the organization.

Parameters	Type	Mandatory	Description
CaseId	Edm.Guid	No	The identity (GUID) of the eDiscovery case.
CaseName	Edm.String	No	The name of the eDiscovery case.
Object1Id	Edm.String	No	The ID of the object (for example, a search, hold, or review set) that was created, accessed, or changed.
Object1Name	Edm.String	No	The name of the object (for example, a search, hold or review set) that was created, accessed, or changed.
Object1Type	Edm.String	No	The type of the eDiscovery object that the user created, deleted, or modified.
Object2Id	Edm.String	No	The ID of the object (for example, a search, hold, or review set) that was created, accessed, or changed.
Object2Name	Edm.String	No	The name of the object (for example, a search, hold or review

Parameters	Type	Mandatory	Description
			set) that was created, accessed, or changed.
Object2Type	Edm.String	No	The type of the eDiscovery object that the user created, deleted, or modified.
StartTime	Edm.Date	No	The date and time in Coordinated Universal Time (UTC) when the eDiscovery activity was started.
EndTime	Edm.Date	No	The date and time in Coordinated Universal Time (UTC) when the eDiscovery activity was ended.
UserCancelled	Edm.Boolean	No	Whether the specific activity was cancelled by the user.
ItemIds	Collection(Edm.String)	No	Item IDs associated with the activity.
ItemNames	Collection(Edm.String)	No	Item names associated with the activity.
DataSources	Collection(Edm.String)	No	A list of source IDs, source names and locations associated to the activity.
QueryId	Edm.String	No	The ID of the query associated with the activity.
QueryText	Edm.String	No	The query text associated with the activity, such as a search statistic process or add to review process.
QueryFiles	Collection(Edm.String)	No	Input file names used to generate the query. This is specific to the search by file gesture.
Settings	Collection(Common.NameValuePair)	No	Settings applied to the eDiscovery activity.
ExtendedProperties	Collection(Common.NameValuePair)	No	Additional properties related to the eDiscovery activity.
ExportName	Edm.String	No	Name of the eDiscovery export.
JobId	Edm.String	No	The GUID of the eDiscovery process.

Parameters	Type	Mandatory	Description
RecordNumber	Edm.String	No	Used when an audit record is divided into multiple parts due to size. It indicates the sequence of each part within the total splits.

SharePointMetadata complex type

Parameters	Type	Mandatory?	Description
From	Edm.String	Yes	The user who triggered the event. Values are the FileOwner, LastModifier, or LastSharer.
itemCreationTime	Edm.Date	Yes	Date/time stamp in UTC of when event logged.
SiteCollectionGuid	Edm.Guid	Yes	The GUID of the site collection.
SiteCollectionUrl	Edm.String	Yes	Name of the SharePoint site.
FileName	Edm.String	Yes	Name of the path.
FileOwner	Edm.String	Yes	The document owner.
FilePathUrl	Edm.String	Yes	The URL of the document
DocumentLastModifier	Edm.String	Yes	The user who last modified the document.
DocumentSharer	Edm.String	Yes	The user who last modified sharing of the document.
UniqueId	Edm.String	Yes	A guid that identifies the file.
LastModifiedTime	Edm.DateTime	Yes	Timestamp in UTC for when doc was last modified.
IsViewableByExternalUsers	Edm.Boolean	Yes	Determines if the file is accessible to any external user.

ExchangeMetadata complex type

Parameters	Type	Mandatory?	Description
MessageID	Edm.String	Yes	The message ID of the email that triggered the event.
From	Edm.String	Yes	The user who sent the email.
To	Collection(Edm.String)	No	A collection of email addresses that were on the To line of the message.
CC	Collection(Edm.String)	No	A collection of email addresses that were on the CC line of the message.

Parameters	Type	Mandatory?	Description
BCC	Collection(Edm.String)	No	A collection of email addresses that were on the BCC line of the message.
Subject	Edm.String	Yes	Subject of the email message.
Sent	Edm.DateTime	Yes	The time in UTC of when the email was sent.
RecipientCount	Edm.Int32	Yes	The total number of all recipients on the TO, CC, and BCC lines of the message.

EndpointMetadata complex type

Parameters	Type	Mandatory?	Description
SensitiveInformation	Collection(Self.SensitiveInformation)	No	Information about the type of sensitive information detected.
EnforcementMode	Edm.String	Yes	Indicate whether the DLP Rule set to 1/2/3/4/5 depicting audit/warn(block with override)/warn and bypass/block/allow(audit without alerts) respectively.
FileExtension	Edm.String	No	The file extension of the document that contained the sensitive information.
FileType	Edm.String	No	The file type of the document that contained the sensitive information.
DeviceName	Edm.String	No	The name of the device on which DLP rule match was detected.

PolicyDetails complex type

Parameters	Type	Mandatory?	Description
PolicyId	Edm.Guid	Yes	The guid of the DLP policy for this event.
PolicyName	Edm.String	Yes	The friendly name of the DLP policy for this event.
Rules	Collection(Self.Rules)	Yes	Information about the rules within the policy that were matched for this event.

Rules complex type

Parameters	Type	Mandatory?	Description
RuleId	Edm.Guid	Yes	The guid of the DLP rule for this event.
RuleName	Edm.String	Yes	The friendly name of the DLP rule for this event.
Actions	Collection(Edm.String)	No	A list of actions taken as a result of a DLP RuleMatch event.
OverriddenActions	Collection(Edm.String)	No	A list of actions previously taken that were now undone as a result of a DLPRuleUndo event.
Severity	Edm.String	No	The severity (Low, Medium and High) of the rule match.
RuleMode	Edm.String	Yes	Indicate whether the DLP Rule was set to Enforce, Audit with Notify, or Audit only.
ConditionsMatched	Self.ConditionsMatched	No	Details about what conditions of the rule were matched for this event.

ConditionsMatched complex type

Parameters	Type	Mandatory?	Description
SensitiveInformation	Collection(Self.SensitiveInformation)	No	Information about the type of sensitive information detected.
DocumentProperties	Collection(NameValuePair)	No	Information about document properties that triggered a rule match.
OtherConditions	Collection(NameValuePair)	No	A list of key value pairs describing any other conditions that were matched.

SensitiveInformation complex type

Parameters	Type	Mandatory?	Description
Confidence	Edm.Int	Yes	The aggregated confidence of all pattern matches for the Sensitive Information Type.
Count	Edm.Int	Yes	The total number of sensitive

Parameters	Type	Mandatory?	Description
			instances detected.
Location	Edm.String	No	
SensitiveType	Edm.Guid	Yes	A guid that identifies the type of sensitive data detected.
SensitiveInformationDetections	Self.SensitiveInformationDetections	No	An array of objects that contain sensitive information data with the following details: matched value and context of matched value.
SensitiveInformationDetailed ClassificationAttributes	Collection(SensitiveInformationDetailed ConfidenceLevelResult)	Yes	Information about the count of sensitive information type detected for each of the three confidence levels (High, Medium and Low) and wether it matches the DLP rule or not.
SensitiveInformationTypeName	Edm.String	No	The name of the sensitive information type.
UniqueCount	Edm.Int32	Yes	The unique count of sensitive instances detected.

SensitiveInformationDetailedClassificationAttributes complex type

Parameters	Type	Mandatory?	Description
Confidence	Edm.int32	Yes	The confidence level of the pattern that was detected.

Parameters	Type	Mandatory?	Description
Count	Edm.Int32	Yes	The number of sensitive instances detected for a particular confidence level.
IsMatch	Edm.Boolean	Yes	Indicates if the given count and confidence level of the sensitive type detected results in a DLP rule match.

SensitiveInformationDetections complex type

DLP sensitive data is only available in the activity feed API to users that have been granted "Read DLP sensitive data" permissions.

Parameters	Type	Mandatory?	Description
DetectedValues	Collection(Common.NameValuePair)	Yes	An array of sensitive information that was detected. Information contains key value pairs with Value = matched value (eg. Value of credit card) and Context = an excerpt from source content that contains the matched value.
ResultsTruncated	Edm.Boolean	Yes	Indicates if the logs were truncated due to large number of results.

ExceptionInfo complex type

Parameters	Type	Mandatory?	Description
Reason	Edm.String	No	For a DLPRuleUndo event, this indicates why the rule no longer applies, which can be one of 3 reasons: Override, Document Change, or Policy Change
FalsePositive	Edm.Boolean	No	Indicates whether the user designated this event as a false positive.
Justification	Edm.String	No	If the user chose to override policy, any user-specified justification is captured here.
Rules	Collection(Edm.Guid)	No	A collection of GUIDs for each rule that was designated as a false positive or override, or for which an action was undone.

Security and Compliance Center schema

Parameters	Type	Mandatory	Description
StartTime	Edm.Date	No	The date and time when the cmdlet was run.

Parameters	Type	Mandatory	Description
ClientRequestId	Edm.String	No	A GUID that can be used to correlate this cmdlet with portal operations. This information is used only by Microsoft support.
CmdletVersion	Edm.String	No	The build version of the cmdlet when it was run.
EffectiveOrganization	Edm.String	No	The GUID for the organization impacted by the cmdlet. (Deprecated: This parameter will eventually stop appearing.)
UserServicePlan	Edm.String	No	The service plan assigned to the user who ran the cmdlet.
ClientApplication	Edm.String	No	If the cmdlet was run by an application, as opposed to remote PowerShell, this field contains the application name.
Parameters	Edm.String	No	The name and value for parameters that were used with the cmdlet that do not include personal data.
NonPiiParameters	Edm.String	No	The name and value for parameters that were used with the cmdlet that include personal data. (Deprecated: This field will eventually stop appearing and its content will be merged with the Parameters field.)

Security and Compliance Alerts schema

Alert signals include:

- All alerts generated by Alert policies in the Microsoft Defender portal.
- Microsoft 365 related alerts generated in Microsoft Defender for Cloud Apps.

The UserId and UserKey of these events are always SecurityComplianceAlerts. There are three types of alert events that are stored as the value of the Operation property of the common schema:

- **AlertTriggered**: A new alert is generated due to a policy match.
- **AlertEntityGenerated**: A new entity is added to an alert. This event is only applicable to alerts generated based on Alert policies in the Microsoft Defender portal. Each generated alert can be associated with one or multiple of these events. For example, an alert policy is defined to trigger an alert if any user deletes more than 100 files in 5 minutes. If two users exceed the threshold around the same time, there are two AlertEntityGenerated events, but only one AlertTriggered event.
- **AlertUpdated**: An update was made to the metadata of an alert. This event is logged when the status of an alert is changed (for example, from **Active** to **Resolved**) and when someone adds a comment to the alert.

Parameters	Type	Mandatory	Description
AlertId	Edm.Guid	Yes	The Guid of the alert.
AlertType	Self.String	Yes	Type of the alert. Alert types include: • System • Custom
Name	Edm.String	Yes	Name of the alert.
PolicyId	Edm.Guid	No	The Guid of the policy that triggered the alert.
Status	Edm.String	No	Status of the alert. Statuses include: • Active • Investigating • Resolved • Dismissed
Severity	Edm.String	No	Severity of the alert. Severity levels include: • Low • Medium • High
Category	Edm.String	No	Category of the alert. Categories include: • AccessGovernance • DataGovernance • DataLossPrevention • InsiderRiskManagement • MailFlow • ThreatManagement • Other
Source	Edm.String	No	Source of the alert. Sources include: • Office 365 Security & Compliance • Cloud App Security
Comments	Edm.String	No	Comments left by the users who have viewed the alert. By default, it's "New alert".
Data	Edm.String	No	The detailed data blob of the alert or alert entity.
AlertEntityId	Edm.String	No	The identifier for the alert entity. This parameter is only applicable to AlertEntityGenerated events.
EntityType	Edm.String	No	Type of the alert or alert entity. Entity types include: • User • Recipients • Sender • MalwareFamily This parameter applies only to AlertEntityGenerated events.

Viva Engage schema

Viva Engage events returned in audit log searches use this schema.

Parameters	Type	Mandatory	Description
ActorUserId	Edm.String	No	Email of user that performed the operation.
ActorYammerUserId	Edm.Int64	No	ID of user that performed the operation.
DataExportType	Edm.String	No	Returns "data" if data export includes messages, notes, files, topics, users and groups; returns "user" if data export includes users only.
FileId	Edm.Int64	No	ID of the file in the operation.
FileName	Edm.String	No	Name of the file in the operation. Appears blank if not relevant to the operation.
GroupName	Edm.String	No	Name of the group in the operation. Appears blank if not relevant to the operation.
IsSoftDelete	Edm.Boolean	No	Returns "true" if the network's data retention policy is set to Soft Delete; returns "false" if the network's data retention policy is set to Hard Delete.
MeetingId	Edm.String	No	The ID of the event/teams meeting in the operation.
MessageId	Edm.Int64	No	ID of the message in the operation.
ModifiedProperties	Collection(ModifiedProperty)	No	Includes the name of the property that was modified, the new value of the modified object and the previous value of the modified object.
YammerNetworkId	Edm.Int64	No	Network ID of the user that performed the operation.
TargetObjectId	Edm.String	No	Entra Id of the target user in the operation.
TargetUserId	Edm.String	No	Email of target user in the operation. Appears blank if not relevant to the operation.
TargetYammerUserId	Edm.Int64	No	ID of target user in the operation.
ThreadId	Edm.Int64	No	ID of the Message thread in the operation.

Parameters	Type	Mandatory	Description
VersionId	Edm.Int64	No	Version ID of the file in the operation.

Data Center Security Base schema

Parameters	Type	Mandatory?	Description
DataCenterSecurityEventType	Self.DataCenterSecurityEventType	Yes	The type of cmdlet event in lock box.

Enum: DataCenterSecurityEventType - Type: Edm.Int32

DataCenterSecurityEventType

Member name	Description
DataCenterSecurityCmdletAuditEvent	This is the enum value for cmdlet audit type event.

Data Center Security Cmdlet schema

Parameters	Type	Mandatory?	Description
StartTime	Edm.Date	Yes	The start time of the cmdlet execution.
EffectiveOrganization	Edm.String	Yes	The name of the tenant that the elevation/cmdlet was targeted at.
ElevationTime	Edm.Date	Yes	The start time of the elevation.
ElevationApprover	Edm.String	Yes	The name of a Microsoft manager.
ElevationApprovedTime	Edm.Date	No	The timestamp for when the elevation was approved.
ElevationRequestId	Edm.Guid	Yes	A unique identifier for the elevation request.
ElevationRole	Edm.String	No	The role the elevation was requested for.
ElevationDuration	Edm.Int32	Yes	The duration for which the elevation was active.
GenericInfo	Edm.String	No	Used for comments and other generic information.

Microsoft Teams schema

Microsoft Teams events returned in audit log searches use these schemas.

Parameters	Type	Mandatory?	Description
Action	Edm.String	No	For shared channel events, the action taken by the invitee or the channel

Parameters	Type	Mandatory?	Description
			owner for a share with team invite.
AddOnGuid	Edm.Guid	No	A unique identifier for the add-on that generated the event.
AddOnName	Edm.String	No	The name of the add-on that generated the event.
AddOnType	Self.AddOnType	No	The type of add-on that generated this event.
CallId	Edm.String	No	A unique identifier for the call.
ChannelGuid	Edm.Guid	No	A unique identifier for the channel being audited.
ChannelName	Edm.String	No	The name of the channel being audited.
ChannelType	Edm.String	No	The type of channel being audited (Standard/Private).
ExtraProperties	Collection(Self.KeyValuePair)	No	A list of extra properties.
HostedContents	Collection(Self.HostedContent)	No	A collection of chat or channel message hosted contents.
ImpersonationType	Edm.String	No	The type of impersonation detected, such as brand, domain, or user.
Invitee	Edm.String	No	For shared channel events, the UPN of the invitee team owner who accepts or declines the invite for a share with team invite.
Members	Collection(Self.MicrosoftTeamsMember)	No	A list of users within a Team.
MessageId	Edm.String	No	An identifier for a chat or channel message.
MessageURLs	Edm.String	No	Present for any URL sent in Teams messages.
Messages	Collection(Self.Message)	No	A collection of chat or channel messages.
MessageSizeInBytes	Edm.Int64	No	The size of a chat or channel message in bytes

Parameters	Type	Mandatory?	Description
			with UTF-16 encoding.
Name	Edm.String	No	Only present for settings events. Name of the setting that changed.
NewValue	Edm.String	No	Only present for settings events. New value of the setting.
OldValue	Edm.String	No	Only present for settings events. Old value of the setting.
Organizer	Self.MicrosoftTeamsMember	No	The organizer of the meeting or call.
SubscriptionId	Edm.String	No	A unique identifier of a Microsoft Graph change notification subscription.
TabType	Edm.String	No	Only present for tab events. The type of tab that generated the event.
TeamGuid	Edm.Guid	No	A unique identifier for the team being audited.
TeamName	Edm.String	No	The name of the team being audited.

MicrosoftTeamsMember complex type

Parameters	Type	Mandatory?	Description
UPN	Edm.String	No	The user principal name of the user.
Role	Self.MemberRoleType	No	The role of the user within the team.
DisplayName	Edm.String	No	The display name of the user.

Enum: MemberRoleType - Type: Edm.Int32

MemberRoleType

Value	Member name	Description
0	Member	A user who is a member of the team.
1	Owner	A user who is the owner of the team.
2	Guest	A user who is not a member of the team.

KeyValuePair complex type

Parameters	Type	Mandatory?	Description
Key	Edm.String	No	The key of the key-value pair.
Value	Edm.String	No	The value of the key-value pair.

Enum: AddOnType - Type: Edm.Int32

AddOnType

Value	Member name	Description
1	Bot	A Microsoft Teams bot.
2	Connector	A Microsoft Teams connector.
3	Tab	A Microsoft Teams tab.

HostedContent complex type

Parameters	Type	Mandatory?	Description
Id	Edm.String	Yes	A unique identifier of the message hosted content.
SizeInBytes	Edm.Int64	No	The message hosted content size in bytes.

Message complex type

Parameters	Type	Mandatory?	Description
AADGroupId	Edm.String	No	A unique identifier of the group in Azure Active Directory that the message belongs to.
Id	Edm.String	Yes	A unique identifier of the chat or channel message.
ChannelGuid	Edm.String	No	A unique identifier of the channel the message belongs to.
ChannelName	Edm.String	No	The name of the channel the message belongs to.
ChannelType	Edm.String	No	The type of the channel the message belongs to.
ChatName	Edm.String	No	The name of the chat the message belongs to.
ChatThreadId	Edm.String	No	A unique identifier of the chat the message belongs to.
ParentMessageId	Edm.String	No	A unique identifier of the parent chat or channel message.
SizeInBytes	Edm.Int64	No	The size of the message in bytes with UTF-16 encoding.
TeamGuid	Edm.String	No	A unique identifier of the team the message belongs to.

Parameters	Type	Mandatory?	Description
TeamName	Edm.String	No	The name of the team the message belongs to.
Version	Edm.String	No	The version of the chat or channel message.

Microsoft Teams user concern schema

Microsoft Teams user concern events returned in audit log searches use this schema. These events have `RecordType` set to `MicrosoftTeamsUserConcern`(462), and apply to the following operations: `MessageReported`, `CallReported`, and `UserReported`.

Parameters	Type	Mandatory?	Description
SubmissionId	Edm.String	Yes	A unique identifier of the user concern report submission.
ReportMetadata	Edm.String	Yes	A JSON-encoded string containing metadata about the report, including the report reason and details about the reported entity (message, call, or user).

Microsoft Defender for Office 365 and Threat Investigation and Response schema

Microsoft Defender for Office 365 events are available for Microsoft 365 customers who have Defender for Office 365, either included or as an add-on subscription. For example, Microsoft 365 Business Premium includes Defender for Office 365 Plan 1, and Microsoft 365 A5/E5/G5 includes Defender for Office 365 Plan 2.

Threat Investigation and Response events are available only to customers with Defender for Office 365 Plan 2.

Each event in the Defender for Office 365 feed corresponds to the following features:

- Delivered email messages detected and acted on by zero-hour auto purge (ZAP).
- URLs detected at time-of-click by Safe Links.
- Files detected by Safe Attachments for SharePoint, OneDrive, and Microsoft Teams.
- Alerts that triggered automated investigations (Defender for Office 365 Plan 2 only).
- Attack simulation training events (Defender for Office 365 Plan 2 only).

Email message events

Parameters	Type	Mandatory?	Description
AttachmentData	Collection(Self.AttachmentData)	No	Data about attachments in the email message that triggered the event.

Parameters	Type	Mandatory?	Description
DetectionType	Edm.String	Yes	The type of detection. For example • **Inline** • Detected at delivery. • **Delayed**: Detected after delivery • **ZAP**: Removed after delivery by zero-hour auto purge (ZAP). Events with ZAP detection type are typically preceded by a message with a **Delayed** detection type.
DetectionMethod	Edm.String	Yes	The detection method or technology used by Defender for Office 365.
InternetMessageId	Edm.String	Yes	The Internet Message Id.
NetworkMessageId	Edm.String	Yes	The Exchange Online Network Message Id.
P1Sender	Edm.String	Yes	The MAIL FROM address used in SMTP transmission of the email message between email servers (also known as the `5321.MailFrom` address, P1 sender, or envelope sender).
P2Sender	Edm.String	Yes	The From address (also known as the `5322.From` address or P2 sender) that's shown in email clients.
Policy	Self.Policy	Yes	The type of threat policy (for example, **Anti-spam** or **Anti-phish**) and related action type (for example, **High Confidence Spam**, **Spam**, or **Phish**) relevant to the email message.
Policy	Self.PolicyAction	Yes	The action configured in the threat policy (for example, **Move to Junk Mail folder** or **Quarantine**)

Parameters	Type	Mandatory?	Description
			relevant to the email message.
Recipients	Collection(Edm.String)	Yes	An array of recipients of the email message.
SenderIp	Edm.String	Yes	The IPv4 or IPv6 address that submitted the message.
Subject	Edm.String	Yes	The subject line of the message.
Verdict	Edm.String	Yes	The message verdict.
MessageTime	Edm.Date	Yes	Date and time in Coordinated Universal Time (UTC) the email message was received or sent.
EventDeepLink	Edm.String	Yes	Deep-link to the email event in Threat Explorer or Real-time detections.
Delivery Action	Edm.String	Yes	The original delivery action on the email message.
Original Delivery location	Edm.String	Yes	The original delivery location of the email message.
Latest Delivery location	Edm.String	Yes	The latest delivery location of the email message at the time of the event.
Directionality	Edm.String	Yes	Identifies whether an email message was inbound, outbound, or an intra-org message.
ThreatsAndDetectionTech	Edm.String	Yes	The threats and the corresponding detection technologies. This field exposes all the threats on an email message, including the latest addition on spam verdict. For example, `["Phish: [Spoof DMARC]","Spam: [URL malicious reputation]"]`. The different detection threat

Parameters	Type	Mandatory?	Description
			and detection technologies are described in Detection technologies.
AdditionalActionsAndResults	Collection(Edm.String)	No	The additional actions that were taken on the email, such as ZAP or Manual Remediation. Also includes the corresponding results.
Connectors	Edm.String	No	The names and GUIDs of the connectors associated with the email.
AuthDetails	Collection(Self.AuthDetails)	No	The authentication checks that are done for the email. Also includes the values for SPF, DKIM, DMARC, and CompAuth.
SystemOverrides	Collection(Self.SystemOverrides)	No	Overrides that are applicable to the email. These can be system or user overrides.
Phish Confidence Level	Edm.String	No	Indicates the confidence level associated with Phish verdict. It can be Normal or High.

> **Note**
>
> We recommend that you use the new ThreatsAndDetectionTech field because it shows multiple verdicts and the updated detection technologies. This field also aligns with the values you see within other experiences like Threat Explorer and Advanced Hunting.

Detection technologies

Name	Description
Advanced filter	Machine learning models to detect phishing and spam.
Antimalware protection	Detection from signature-based anti-malware.
Bulk	Detection for advertising/marketing and similar message types with their relative bulk complaint levels (BCL).
Campaign	Messages identified and grouped as part of a malware or phishing campaign.

Name	Description
Domain reputation	The message was sent from a domain that was identified as spam or phishing domain, based on internal or external signals.
File detonation	Safe Attachments detected a malicious attachment during detonation within a sandbox.
File detonation reputation	File attachments previously detected by Safe Attachments during detonation.
File reputation	The message contains a file that was previously identified as malicious by other sources.
Fingerprint matching	The message resembles a previously detected malicious or spam message.
General filter	Phishing or spam signals based on analyst heuristics.
Impersonation brand	Sender impersonation of well-known brands.
Impersonation domain	Impersonation of sender domains that you own or specified for protection in anti-phishing policies.
Impersonation user	Impersonation of protected senders that you specified in anti-phishing policies.
IP reputation	The message was sent from an IP that was identified as potentially malicious.
LLM content analysis	Analysis by Microsoft's purpose-built large language models to detect harmful email.
Mail bombing	A distributed denial of service (DDoS) attack that typically subscribes recipients to a large number of legitimate newsletters and services. The resulting volume of incoming email within minutes intends to overwhelm the recipient's mailbox and email security systems, and acts as a precursor to malware, ransomware, or data exfiltration.
Mailbox intelligence impersonation	Sender detected as impersonating an address in the user's personal sender map.
Mixed analysis detection	Multiple filters contributed to the verdict for this message.
Spoof DMARC	The message failed DMARC authentication.
Spoof external domain	Spoof intelligence detected email spoofing of a domain that is external to your organization.
Spoof intra-org	Spoof intelligence detected email spoofing of a user or domain that is internal to your organization.
URL detonation	Safe Links detected a malicious URL in the message during detonation within a sandbox.
URL detonation	URLs previously detected by Safe Links during detonation.

Name	Description
reputation	
URL malicious reputation	The message contains a URL that was previously identified as malicious or spam by other sources.

AttachmentData complex type

AttachmentData

Parameters	Type	Mandatory?	Description
FileName	Edm.String	Yes	The file name of the attachment.
FileType	Edm.String	Yes	The file type of the attachment.
FileVerdict	Self.FileVerdict	Yes	The file malware verdict.
MalwareFamily	Edm.String	No	The file malware family.
SHA256	Edm.String	Yes	The file SHA256 hash.

> **Note**
>
> Within the Malware family, you see the exact MalwareFamily name (for example, HTML/Phish.VS!MSR) or Malicious Payload as a static string. A Malicious Payload should still be treated as malicious email when a specific name isn't identified.

SystemOverrides complex type

SystemOverrides

Parameters	Type	Mandatory?	Description
Details	Edm.String	No	The details about the specific override (such as ETR or Safe Sender) that was applied.
FinalOverride	Edm.String	No	Indicates the override that impacted the delivery in the case of multiple overrides.
Result	Edm.String	No	Indicates whether the email was set to allowed or blocked based on the override.
Source	Edm.String	No	Indicates whether the override was user-configured or tenant-configured.

AuthDetails complex type

AuthDetails

Parameters	Type	Mandatory?	Description
Name	Edm.String	No	The name of the specific auth check, such as DKIM or DMARC.
Value	Edm.String	No	The value associated with the specific auth check, such as True or False.

Enum: FileVerdict - Type: Edm.Int32

FileVerdict

Value	Member name	Description
0	Good	No threats detected.
1	Bad	Malware found in attachment.
-1	Error	Scan / analysis error.
-2	Timeout	Scan / analysis timeout.
-3	Pending	Scan / analysis not complete.

Enum: Policy - Type: Edm.Int32

Policy type and action type

Value	Member name	Description
1	Anti-spam, HSPM	High Confidence Spam (HSPM) action in the anti-spam policy.
2	Anti-spam, SPM	Spam (SPM) action in the anti-spam policy.
3	Anti-spam, Bulk	Bulk action in the anti-spam policy.
4	Anti-spam, PHSH	Phish (PHSH) action in the anti-spam policy.
5	Anti-phish, DIMP	Domain Impersonation (DIMP) action in the anti-phishing policy.
6	Anti-phish, UIMP	User Impersonation (UIMP) action in the anti-phishing policy.
7	Anti-phish, SPOOF	Spoof action in the anti-phishing policy.
8	Anti-phish, GIMP	Mailbox intelligence action in the anti-phishing policy.
9	Anti-malware, AMP	Malware policy action in the anti-malware policy.
10	Safe attachment, SAP	Policy action in the Safe Attachments policy.
11	Exchange transport rule, ETR	Policy action in the Exchange mail flow rule (also known as transport rule).

Value	Member name	Description
12	Anti-malware, ZAPM	Malware policy action in the anti-malware policy applied to zero-hour auto purge (ZAP).
13	Anti-phish, ZAPP	Phishing policy action in the anti-phishing policy applied to ZAP.
14	Anti-phish, ZAPS	Spam policy action in the anti-spam policy applied to ZAP.
15	Anti-spam, High confidence phish email (HPHISH)	High confidence Phish policy action in anti-spam policy.
17	Anti-spam, Outbound spam policy (OSPM)	Policy action in the outbound spam policy.

Enum: PolicyAction - Type: Edm.Int32

Policy action

Value	Member name	Description
0	MoveToJMF	Policy action is to move the message to the Junk Email folder.
1	AddXHeader	Policy action is to add an X-header to the email message.
2	ModifySubject	Policy action is to modify subject in the email message with information specified by the threat policy.
3	Redirect	Policy action is to redirect email message to email address specified by the threat policy.
4	Delete	Policy action is to delete (drop) the email message.
5	Quarantine	Policy action is to quarantine the email message.
6	NoAction	Policy is configured to take no action on the email message.
7	BccMessage	Policy action is to Bcc the email message to email address specified by the threat policy.
8	ReplaceAttachment	Policy action is to replace the attachment in the email message as specified by the threat policy.

URL time-of-click events

Parameters	Type	Mandatory?	Description
UserId	Edm.String	Yes	Identifier (for example, email address) of the user who clicked on the URL.
AppName	Edm.String	Yes	Office 365 service from which the URL was clicked (for example, Mail).

Parameters	Type	Mandatory?	Description
URLClickAction	Self.URLClickAction	Yes	Click action for the URL based on the organization's policies for Safe Links.
SourceId	Edm.String	Yes	Identifier for the Office 365 service from which the URL was clicked (for example, for email, this value is the Exchange Online Network Message Id).
TimeOfClick	Edm.Date	Yes	The date and time in Coordinated Universal Time (UTC) when the user clicked the URL.
URL	Edm.String	Yes	URL clicked by the user.
UserIp	Edm.String	Yes	The IPv4 or IPv6 address of the user who clicked the URL.

Enum: URLClickAction - Type: Edm.Int32

URLClickAction

Value	Member name	Description
2	Blockpage	User blocked from navigating to the URL by Safe Links.
3	PendingDetonationPage	User presented with the detonation pending page by Safe Links.
4	BlockPageOverride	User blocked from navigating to the URL by Safe Links, but the user overrode the block to navigate to the URL.
5	PendingDetonationPageOverride	User presented with the detonation page by Safe Links, but the user overrode the page to navigate to the URL.

File events

Parameters	Type	Mandatory?	Description
FileData	Self.FileData	Yes	Data about the file that triggered the event.
SourceWorkload	Self.SourceWorkload	Yes	Workload or service where the file was found (for example, SharePoint, OneDrive, or Microsoft Teams)
DetectionMethod	Edm.String	Yes	The method or technology used by Microsoft Defender for Office 365 for the detection.
LastModifiedDate	Edm.Date	Yes	The date and time in Coordinated Universal Time (UTC) when the file was created or last modified.
LastModifiedBy	Edm.String	Yes	Identifier (for example, an email address) for the user who created or last modified the file.
EventDeepLink	Edm.String	Yes	Deep-link to the file event in Threat Explorer or Real-time detections.

FileData complex type

FileData

Parameters	Type	Mandatory?	Description
DocumentId	Edm.String	Yes	Unique identifier for the file in SharePoint, OneDrive, or Microsoft Teams.
FileName	Edm.String	Yes	Name of the file that triggered the event.
FilePath	Edm.String	Yes	Path (location) for the file in SharePoint, OneDrive, or Microsoft Teams.
FileVerdict	Self.FileVerdict	Yes	The file malware verdict.
MalwareFamily	Edm.String	No	The file malware family.
SHA256	Edm.String	Yes	The file SHA256 hash.
FileSize	Edm.String	Yes	Size for the file in bytes.

Enum: SourceWorkload - Type: Edm.Int32

SourceWorkload

Value	Member name
0	SharePoint
1	OneDrive
2	Microsoft Teams

Attack Sim schema in Microsoft Defender for Office 365 Plan 2

Attack simulation training events are available for Microsoft 365 customers who have Defender for Office 365 Plan 2, either included or as an add-on subscription. For example Microsoft 365 A5/E5/G5 includes Defender for Office 365 Plan 2.

Parameters	Type	Mandatory?	Description
Batch ID	Edm.String	Yes	A unique identifier for a group of records that are processed together.
Campaign ID	Edm.String	Yes	A unique identifier for the attack simulation training campaign.

Parameters	Type	Mandatory?	Description
UserDisplayName	Edm.String	No	The display name of the user involved in the attack simulation training campaign.
AttackTechnique	Edm.String	No	The attack technique used in the simulation.
CampaignType	Edm.String	No	The type of attack simulation campaign. The different types are simulation campaign, training campaign, simulation automation.
TimeData	Edm.Date	No	Campaign launch time.
EndTimeData	Edm.Date	No	Campaign end time.
AttackSimEvent	Self.AttackSimEventType	Yes	Type of event (user activity or message delivery state).
ExtendedProperties	Collection(Common.NameValuePair)	Yes	Additional properties associated with the audit record.

Enum: AttackSimEventType - Type: Edm.Int32

Value	Member Name	Description
1	MessageDelivered	Message delivered to recipient successfully.
2	MessageFailed	Message delivery failed.
6	CredentialEntered	User entered credentials in the phish simulation for techniques such as Credential Harvesting, Link in attachment.
7	PermissionGranted	User granted permission in the phish simulation for technique such as Oauth consent grant.
8	LinkClicked	User clicked on phish simulation URL.
10	AttachmentOpened	Attachment opened by user for techniques such as Malware attachment, Link in attachment.
12	MessageRead	Message opened and read by recipient.
13	MessageReplied	Recipient replied to the message.
14	MessageForwarded	Message forwarded to another user.
15	MessageReported	Message reported as phish by recipient.
16	MessageDeleted	Message deleted by recipient.
17	OutOfOffice	Automatic replies in Outlook enabled for recipient.

Value	Member Name	Description
18	PositiveReinforcementMessageDelivered	Positive reinforcement message delivered successfully to recipient.

Attack Sim Admin schema in Microsoft Defender for Office 365 Plan 2

Attack simulation training admin events are available for Microsoft 365 customers who have Defender for Office 365 Plan 2, either included or as an add-on subscription. For example Microsoft 365 A5/E5/G5 includes Defender for Office 365 Plan 2.

Parameters	Type	Mandatory?	Description
Batch ID	Edm.String	Yes	A unique identifier for a group of records that are processed together.
Campaign ID	Edm.String	Yes	A unique identifier for an attack simulation training campaign.
AttackTechnique	Edm.String	No	The attack technique used in a simulation.
CampaignType	Edm.String	No	The type of attack simulation campaign. The different types are simulation campaign, training campaign, simulation automation.
TimeData	Edm.Date	Yes	Campaign launch time.
EndTimeData	Edm.Date	Yes	Campaign end time.
AttackSimAdminEvent	Self.AttackSimAdminEventType	Yes	The type of attack sim admin event.
ExtendedProperties	Collection(Common.NameValuePair)	Yes	Additional properties associated with the audit record.

Enum: AttackSimAdminEventType - Type: Edm.Int32

Value	Member Name	Description
0	CampaignLaunched	When an attack simulation training campaign was launched. The different types of campaigns are simulation, training campaign.
1	CampaignCompleted	When an attack simulation training campaign was completed.
2	CampaignReportDownloaded	Admin downloaded a campaign report.

Value	Member Name	Description
3	CampaignReportViewed	Admin viewed a campaign report.
4	CampaignCancelled	When an attack simulation training campaign was cancelled.
5	CampaignScheduled	When an attack simulation training campaign was scheduled.
6	CampaignDeleted	When an attack simulation training campaign was deleted.
7	SimulationExcluded	When a simulation was excluded from reporting.
8	AutomationSubmitted	When an automation was submitted, includes simulation and payload automation.
9	AutomationTurnOn	When an automation was turned on, includes simulation and payload automation.
10	AutomationTurnOff	When an automation was turned off, includes simulation and payload automation.
11	AutomationCompleted	When a simulation automation was completed.
12	AutomationDeleted	When an automation was deleted, includes simulation and payload automation.

User Training schema

Parameters	Type	Mandatory?	Description
Batch ID	Edm.String	Yes	A unique identifier for a group of records that are processed together.
Campaign ID	Edm.String	Yes	A unique identifier for an attack simulation training campaign.
Course ID	Edm.String	Yes	A unique identifier for a training course.
UserDisplayName	Edm.String	No	The display name of the user involved in the attack simulation.
CampaignType	Edm.String	Yes	The type of attack simulation campaign. The different types are simulation campaign, training campaign, simulation automation.
TimeData	Edm.Date	Yes	Campaign launch time.
EndTimeData	Edm.Date	Yes	Campaign end time.
UserTrainingEvent	Self.UserTrainingEventType	Yes	The type of user training event.

Parameters	Type	Mandatory?	Description
ExtendedProperties	Collection(Common.NameValuePair)	Yes	Additional properties associated with the audit record.

Enum: UserTrainingEventType - Type: Edm.Int32

Value	Member Name	Description
1	TrainingAssigned	Training assigned to user.
2	TrainingUpdated	Training updated for user.
3	TrainingCompleted	User completed training.
4	TrainingPreviouslyAssigned	Previously assigned training to user.
5	TrainingNotCompleted	User did not complete assigned training.

Submission schema

Events for submitting false positives or false negatives to Microsoft for analysis are available in all organizations with mailboxes in Exchange Online. Each event in the submission feed corresponds to false positives or false negatives that were submitted by:

- Admins: Messages, files, or URLs submitted to Microsoft for analysis.
- Users: Messages reported by users to admins or Microsoft for review.

Submission events

Parameters	Type	Mandatory?	Description
AdminSubmissionRegistered	Edm.String	No	Admin submission is registered and is pending for processing.
AdminSubmissionDeliveryCheck	Edm.String	No	Admin submission system checked the email's policy.
AdminSubmissionSubmitting	Edm.String	No	Admin submission system is submitting the email.
AdminSubmissionSubmitted	Edm.String	No	Admin submission system submitted the email.
AdminSubmissionTriage	Edm.String	No	Admin submission triaged by grader.
AdminSubmissionTimeout	Edm.String	No	Admin submission timed out with no result.
UserSubmission	Edm.String	No	Submission was first reported by an end user.
UserSubmissionTriage	Edm.String	No	User submission is triaged by grader.

Parameters	Type	Mandatory?	Description
CustomSubmission	Edm.String	No	Message reported by a user was sent to the organization's custom mailbox as set in the user reported messages settings.
AttackSimUserSubmission	Edm.String	No	The user-reported message was actually a phish simulation training message.
AdminSubmissionTablAllow	Edm.String	No	An allow entry in the Tenant Allow/Block List was created at time of submission to immediately take action on similar messages while it is being rescanned.
SubmissionNotification	Edm.String	No	Admin feedback is sent to end user.

Automated investigation and response events in Microsoft Defender for Office 365 Plan 2

Automated investigation and response (AIR) events are available for Microsoft 365 customers who have Defender for Office 365 Plan 2, either included or as an add-on subscription. For example Microsoft 365 A5/E5/G5 includes Defender for Office 365 Plan 2.

Investigation events are logged based on a change in investigation status. For example, when an admin takes an action that changes the status of an investigation from Pending Actions to Completed, an event is logged.

Currently, only automated investigation are logged. The following status values are logged:

- Investigation Started
- No threats found
- Terminated by System
- Pending Action
- Threats Found
- Remediated
- Failed
- Terminated by throttling
- Terminated By User
- Running

Main investigation schema

Name	Type	Description
InvestigationId	Edm.String	Investigation ID/GUID.
InvestigationName	Edm.String	Name of the investigation.

Name	Type	Description
InvestigationType	Edm.String	Type of the investigation. Can take one of the following values: • User-Reported Messages • Zapped Malware • Zapped Phish • Url Verdict Change (Currently, manual investigations aren't available.)
LastUpdateTimeUtc	Edm.Date	UTC time of the last update for an investigation.
StartTimeUtc	Edm.Date	Start time for an investigation.
Status	Edm.String	State of investigation, Running, Pending Actions, etc.
DeeplinkURL	Edm.String	Deep link URL to an investigation in the Microsoft Defender portal.
Actions	Collection (Edm.String)	Collection of actions recommended by an investigation.
Data	Edm.String	Data string which contains more details about investigation entities, and information about alerts related to the investigation. Entities are available in a separate node within the data blob.

Actions

Field	Type	Description
ID	Edm.String	Action ID
ActionType	Edm.String	The type of the action, such as email remediation.
ActionStatus	Edm.String	Values include: • Pending • Running • Waiting on resource • Completed • Failed
ApprovedBy	Edm.String	Null if auto approved; otherwise, the username/id (this is coming soon)
TimestampUtc	Edm.DateTime	The timestamp of the action status change.
ActionId	Edm.String	Unique identifier for action.
InvestigationId	Edm.String	Unique identifier for investigation.
RelatedAlertIds	Collection(Edm.String)	Alerts related to an investigation.
StartTimeUtc	Edm.DateTime	Timestamp of action creation.
EndTimeUtc	Edm.DateTime	Action final status update timestamp.

Field	Type	Description
Resource Identifiers	Edm.String	Consists of the Azure Active Directory tenant ID.
Entities	Collection(Edm.String)	List of one or more affected entities by action.
Related Alert IDs	Edm.String	Alert related to an investigation.

Entities

MailMessage (email)

Field	Type	Description
Type	Edm.String	"mail-message"
Files	Collection (Self.File)	Details about the files of this message's attachments.
Recipient	Edm.String	The recipient of this mail message.
Urls	Collection(Self.URL)	The Urls contained in this mail message.
Sender	Edm.String	The sender's email address.
SenderIP	Edm.String	The sender's IP address.
ReceivedDate	Edm.DateTime	The received date of this message.
NetworkMessageId	Edm.Guid	The network message id of this mail message.
InternetMessageId	Edm.String	The internet message id of this mail message.
Subject	Edm.String	The subject of this mail message.

IP

Field	Type	Description
Type	Edm.String	"ip"
Address	Edm.String	The IP address as a string, such as `127.0.0.1`.

URL

Field	Type	Description
Type	Edm.String	"url"
Url	Edm.String	The full URL to which an entity points.

Mailbox (also equivalent to the user)

Field	Type	Description
Type	Edm.String	"mailbox"
MailboxPrimaryAddress	Edm.String	The mailbox's primary address.
DisplayName	Edm.String	The mailbox's display name.
Upn	Edm.String	The mailbox's UPN.

File

Field	Type	Description
Type	Edm.String	"file"
Name	Edm.String	The file name without path.
FileHashes	Collection (Edm.String)	The file hashes associated with the file.

FileHash

Field	Type	Description
Type	Edm.String	"filehash"
Algorithm	Edm.String	The hash algorithm type, which can be one of these values: • Unknown • MD5 • SHA1 • SHA256 • SHA256AC
Value	Edm.String	The hash value.

MailCluster

Field	Type	Description
Type	Edm.String	"MailCluster" Determines the type of entity being discussed.
NetworkMessageIds	Collection (Edm.String)	List of the mail message IDs that are part of the mail cluster.
CountByDeliveryStatus	Collections (Edm.String)	Count of mail messages by DeliveryStatus string representation.
CountByThreatType	Collections (Edm.String)	Count of mail messages by ThreatType string representation.
Threats	Collections	The threats of mail messages that are part of the mail cluster.

Field	Type	Description
	(Edm.String)	Threats include values like Phish and Malware.
Query	Edm.String	The query that was used to identify the messages of the mail cluster.
QueryTime	Edm.DateTime	The query time.
MailCount	Edm.int	The number of mail messages that are part of the mail cluster.
Source	String	The source of the mail cluster; the value of the cluster source.

Hygiene events schema

Hygiene events are related to outbound spam protection. These events are related to users who are restricted from sending email. For more information, see the following articles:

- Outbound spam protection
- Remove blocked users from the Restricted entities page

Parameters	Type	Mandatory?	Description
Audit	Edm.String	No	System information related to the hygiene event.
Event	Edm.String	No	The type of hygiene event. The values for this parameter are **Listed** or **Delisted**.
EventId	Edm.Int64	No	The ID of the hygiene event type.
EventValue	Edm.String	No	The user who was impacted.
Reason	Edm.String	No	Details about the hygiene event.

Power BI schema

The Power BI events listed in Search the audit log use this schema.

Parameters	Type	Mandatory?	Description
AppName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the app where the event occurred.
DashboardName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the dashboard where the event occurred.
DataClassification	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The data classification, if any, for the dashboard

Parameters	Type	Mandatory?	Description
			where the event occurred.
DatasetName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the dataset where the event occurred.
ActivityStatus	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The status of the Gen1 dataflow migration audit event. Possible values include `Started`, `Succeeded`, and `Failed`.
MigrationTriggerType	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The source that triggered the Gen1 dataflow migration, such as the Upgrade Wizard or another migration entry point.
MembershipInformation	Collection(MembershipInformationType) Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Membership information about the group.
OrgAppPermission	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Permissions list for an organizational app (entire organization, specific users, or specific groups).
ReportName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the report where the event occurred.
SharingInformation	Collection(SharingInformationType) Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Information about the person to whom a sharing invitation is sent.
SwitchState	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Information about the state of various

Parameters	Type	Mandatory?	Description
			tenant level switches.
WorkSpaceName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the workspace where the event occurred.

MembershipInformationType complex type

Parameters	Type	Mandatory?	Description
MemberEmail	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The email address of the group.
Status	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	Not currently populated.

SharingInformationType complex type

Parameters	Type	Mandatory?	Description
RecipientEmail	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The email address of the recipient of a sharing invitation.
RecipientName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the recipient of a sharing invitation.
ResharePermission	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The permission being granted to the recipient.

Dynamics 365 schema

The audit records for events related to model-driven apps in Dynamics 365 events use both a base and an entity operation schema. For more information, see Enable and use Activity Logging.

Dynamics 365 base schema

Parameters	Type	Mandatory?	Description
CrmOrganizationUniqueName	Edm.String	Yes	The unique name of the organization.

Parameters	Type	Mandatory?	Description
InstanceUrl	Edm.String	Yes	The URL to the instance.
ItemUrl	Edm.String	No	The URL to the record emitting the log.
ItemType	Edm.String	No	The name of the entity.
UserAgent	Edm.String	No	The unique identifier of the user GUID in the organization.
Fields	Collection(Common.NameValuePair)	No	A JSON object that contains the property key-value pairs that were created or updated.

Dynamics 365 entity operation schema

Entity events from model-driven apps in Dynamics 365 use this schema to build on the Dynamics 365 base schema. This schema includes information about the entity operation that triggered the audited event.

Parameters	Type	Mandatory?	Description
EntityId	Edm.Guid	No	The unique identifier of the entity.
EntityName	Edm.String	Yes	The name of the entity in the organization. Example of entities include `contact` or `authentication`.
Message	Edm.String	Yes	This parameter contains the operation that was performed in related to the entity. For example, if a new contact was created, the value of the Message property is `Create` and the corresponding value of the EntityName property is `contact`.
Query	Edm.String	No	The parameters of the filter query that was used while executing the FetchXML operation.
PrimaryFieldValue	Edm.String	No	Indicates the value for the attribute that is the primary field for the entity.

eSignature schema

This schema includes eSignature for Microsoft 365 events returned in audit log searches.

Parameters	Type	Mandatory?	Description
AgreementId	Edm.Guid	Yes	ID of the electronic signature request.
AgreementSender	Edm.String	Yes	Sender of the electronic signature request.
AgreementCreationDateTime	Edm.Date	Yes	Date & time request was sent.
AgreementStatus	Self.AgreementStatusType	Yes	Status of the request.
AgreementRecipients	Collection(Self.AgreementRecipient)	Yes	Recipients of the request.

Viva Insights schema

Viva Insights events returned in audit log searches use this schema.

Parameters	Type	Mandatory?	Description
WpaUserRole	Edm.String	No	The Viva Insights role of the user who performed the action.
ModifiedProperties	Collection (Common.ModifiedProperty)	No	This property includes the name of the property that was modified, the new value of the modified property, and the previous value of the modified property.
OperationDetails	Collection (Common.NameValuePair)	No	A list of extended properties for the setting that was changed. Each property has a **Name** and **Value**.

Quarantine schema

Quarantine events returned in audit log searches use this schema. For more information about quarantine, see Quarantined email messages in cloud organizations.

Parameters	Type	Mandatory?	Description
RequestType	Self.RequestType	No	The type of quarantine request performed by a user.
RequestSource	Self.RequestSource	No	Quarantine request come from the Microsoft Defender portal, a cmdlet, or a URLlink.
NetworkMessageId	Edm.String	No	The network message id of quarantined email message.
ReleaseTo	Edm.String	No	The recipient of the email message.

Enum: RequestType - Type: Edm.Int32

Value	Member name	Description
0	Preview	User request to preview an email message identified as harmful.
1	Delete	User request to delete an email message identified as harmful.
2	Release	User request to release an email message identified as harmful.
3	Export	User request to export an email message identified as harmful.
4	ViewHeader	User request to view the header of an email message identified as harmful.
5	Release request	User request to release an email message identified as harmful.

Enum: RequestSource - Type: Edm.Int32

The source of a user request to preview, delete, release, export, or view the header of a potentially harmful email message.

Value	Member name	Description
0	SCC	The Microsoft Defender portal.
1	Cmdlet	A cmdlet.
2	URLlink	A link.

Microsoft Forms schema

Microsoft Forms events returned in audit log searches use this schema.

Parameters	Type	Mandatory?	Description
FormsUserTypes	Collection(Self.FormsUserTypes)	Yes	The role of the user who performed the action. The values for this parameter are Admin, Owner, Responder, or Coauthor.
SourceApp	Edm.String	Yes	Indicates if the action is from Forms website or from another App.
FormName	Edm.String	No	The name of the current form.
FormId	Edm.String	No	The Id of the target form.
FormTypes	Collection(Self.FormTypes)	No	Indicates whether this is a Form, Quiz, or Survey.
ActivityParameters	Edm.String	No	JSON string containing activity parameters. For more information, see Microsoft Forms activities.

Enum: FormsUserTypes - Type: Edm.Int32

FormsUserTypes

Value	Form User Type	Description
0	Admin	An administrator who has access to the form.
1	Owner	A user who is the owner of the form.
2	Responder	A user who has submitted a response to a form.
3	Coauthor	A user who has used a collaboration link provided by the form owner to login and edit a form.

Enum: FormTypes - Type: Edm.Int32

FormTypes

Value	Form Types	Description
0	Form	Forms that are created with the New Form option.
1	Quiz	Quizzes that are created with the New Quiz option. A quiz is a special type of form that includes additional features such as point values, auto and manual grading, and commenting.
2	Survey	Surveys that are created with the New Survey option. A survey is a special type of form that includes additional features such as CMS integration and support for Flow rules.

MIP label schema

Events in the Microsoft Purview Information Protection label schema are triggered when Microsoft 365 detects an email message processed by agents in the Transport pipeline that has a sensitivity label applied to it. The sensitivity label might have been applied manually or automatically, and it might have been applied within or outside of the Transport pipeline. Sensitivity labels can be automatically applied to email messages by auto-apply label policies.

The intent of this audit schema is to represent the sum of all email activity that involves sensitivity labels. In other words, there should be an recorded audit activity for each email message that is sent to or from users in the organization that has a sensitivity label applied to it, regardless of when or how the sensitivity label was applied. For more information about sensitivity labels, see:

- Learn about sensitivity labels
- Apply a sensitivity label to content automatically

Parameters	Type	Mandatory?	Description
Sender	Edm.String	No	The email address in the From field of the email message.
Receivers	Collection(Edm.String)	No	All email addresses in the To, CC, and Bcc fields of the email message.
ItemName	Edm.String	No	The string in the Subject field of the email message.
LabelId	Edm.Guid	No	The GUID of the sensitivity label applied to the email message.
LabelName	Edm.String	No	The name of the sensitivity label applied to the email message.
LabelAction	Edm.String	No	The actions specified by the sensitivity label that were applied to the email message before the message entered the mail transport pipeline.
LabelAppliedDateTime	Edm.Date	No	The date the sensitivity label was applied to the email message.
ApplicationMode	Edm.String	No	Specifies how the sensitivity label was applied to the email message. The **Privileged** value indicates the label was manually applied by a user. The **Standard** value indicates the label was auto-applied by a client-side or service-side labeling process.

Encrypted message portal events schema

Events for encrypted message portal schema are triggered when when Purview Message Encryption detects an encrypted email message is accessed through the portal by an external recipient. The mail might have been encrypted manually with a sensitivity label or an RMS template, or automatically by a transport rule, a Data Loss Prevention policy, or an auto-labeling policy.

The intent of this audit schema is to represent the sum of all portal activity that involves accessing the encrypted mail by external recipients. In other words, there should be a recorded audit activity for a recipient that attempts to sign in to the portal and any activities related to accessing the encrypted mail. This includes mail sent to or from users in the organization when the mail has encryption applied to it, regardless of when or how the encryption was applied. For more information, see, Learn about encrypted message portal logs.

Parameters	Type	Mandatory?	Description
MessageId	Edm.String	No	The Id of the message.

Parameters	Type	Mandatory?	Description
Recipient	Edm.String	No	Recipient email address.
Sender	Edm.String	No	Email address of sender.
AuthenticationMethod	Self.AuthenticationMethod	No	Authentication method when accessing the message, i.e. OTP, Yahoo, Gmail, Microsoft.
AuthenticationStatus	Self.AuthenticationStatus	No	0: Success, 1: Failure.
OperationStatus	Self.OperationStatus	No	0: Success, 1: Failure.
AttachmentName	Edm.String	No	Name of the attachment.
OperationProperties	Collection(Common.NameValuePair)	No	Extra properties, i.e. number of OTP passcode sent, email subject, etc.

Communication compliance Exchange schema

The communication compliance events listed in the Office 365 audit log use this schema. This includes audit records for the **SupervisoryReviewOLAudit** operation that's generated when email message content contains offensive language identified by anti-spam models with a match accuracy of >= 99.5%.

Parameters	Type	Mandatory?	Description
ExchangeDetails	ExchangeDetails	No	Properties of the email message that triggered the SupervisoryReviewOLAudit event.

Enum: ExchangeDetails - Type: ExchangeDetails

ExchangeDetails

Member name	Type	Description
NetworkMessageId	Edm.Guid	The network message ID of the email message.
InternetMessageId	Edm.String	The internet message ID of the email message.
AttachmentData	Collection(AttachmentDetails)	Information about files attached to the email message.
Recipients	Collection(Edm.String)	The email addresses in the To, Cc, and Bcc fields of the email message.
Subject	Edm.String	The text in the Subject field of the email message.
MessageTime	Edm.Date	The date and time the email message was sent.

Member name	Type	Description
From	Edm.String	The email address in the From field of the email message.
Directionality	Edm.String	The origination status of the email message.

Enum: AttachmentDetails - Type: Edm.Int32

AttachmentDetails

Member name	Type	Description
FileName	Edm.String	The name of the file attached to the email message.
FileType	Edm.String	The file extension of the file attached to the email message.
SHA256	Edm.String	The SHA-256 hash of the file attached to the email message.

Reports schema

Report events returned in audit log searches use this schema.

Parameters	Type	Mandatory?	Description
ModifiedProperties	Collection (Common.ModifiedProperty)	No	This property includes the name of the property that was modified, the new value of the modified property, and the previous value of the modified property.

Compliance connector schema

Events in the compliance connector schema are triggered when items that are imported by a data connector are skipped or failed to be import to user mailboxes. For more information about data connectors, see Learn about connectors for third-party data.

Parameters	Type	Mandatory?	Description
JobId	Edm.String	No	This is a unique identifier of the data connector.
TaskId	Edm.String	No	Unique identifier of the periodic data connector instance. Data connectors import data in periodic intervals.
JobType	Edm.String	No	The name of the data connector.
ItemId	Edm.String	No	Unique identifier of the item (for example, an email message) being imported.
ItemSize	Edm.Int64	No	The size of the item being imported.

Parameters	Type	Mandatory?	Description
SourceUserId	Edm.String	No	The unique identifier of the user from the third-party data source. For example, for a Slack data connector, this property specifies the user Id in Slack workspace.
FailureType	Self.FailureType	No	Indicates the type of data import failure. For example, the value **incorrectusermapping** indicates the item wasn't imported because no user mapping between the third-party data source and Microsoft 365 could be found.
ResultMessage	Edm.String	No	Indicates the type of failure, such as **Duplicate message**.
IsRetry	Edm.Boolean	No	Indicates whether the data connector retried to import the item.
Attachments	Collection.Attachment	No	A list of attachments received from the third-party data source.

Enum: FailureType - Type: Edm.Int32

Value	Member name
0	Default
1	MailboxWrite

Attachment complex type

Parameters	Type	Mandatory?	Description
FileName	Edm.String	No	The name of the attachment.
Details	Edm.String	No	Other details about the attachment.

SystemSync schema

Events in the SystemSync schema are triggered when the SystemSync ingested data is either exported via Data Lake or shared via other services.

DataLakeExportOperationAuditRecord

Parameters	Type	Mandatory?	Description
DataStoreType	DataStoreType	Yes	Indicates which data store the data was downloaded from. Refer DataStoreType for all possible values.

Parameters	Type	Mandatory?	Description
UserAction	DataLakeUserAction	Yes	Indicates what action user had performed on the data store. Refer DataLakeUserAction for all possible values.
ExportTriggeredAt	Edm.DateTimeOffset	Yes	Indicates when the data export was triggered.
NameOfDownloadedZipFile	Edm.String	No	The name of the compressed file the admin had downloaded from the Data Lake.

DataShareOperationAuditRecord

Parameters	Type	Mandatory?	Description
Invitation	DataShareInvitationType	No	Details of the invite sent to the recipient of the Data Share.

DataShareInvitationType complex type

Parameters	Type	Mandatory?	Description
ShareId	Edm.Guid	Yes	System assigned identifier for the Data Share.
Invitees	Collection(Edm.Guid)	Yes	List of admin users the invite was sent to.
InviteeTenantId	Edm.Guid	Yes	The target tenant whom the invite is intended to.
ShareName	Edm.String	Yes	System assigned name for the Data Share.
SyncFrequency	Self.SyncFrequency	Yes	Frequency at which the data is synced to the destination storage account once share is established. See SyncFrequency for possible values.
SyncStartTime	Edm.DateTimeOffset	Yes	Date and time of first sync.

Enum: SyncFrequency - Type: Edm.Int32:

Value	Member name	Description
0	Hourly	Indicates the data is synced every hour.
1	Daily	Indicates the data is synced once a day.

Enum: DataStoreType - Type: Edm.Int32:

Value	Member name	Description
0	CanonicalStore	Indicates data is downloaded from Canonical store.
1	StagingStore	Indicates data is downloaded from Staging store.

Enum: DataLakeUserAction - Type: Edm.Int32:

Value	Member name	Description
0	TriggerExport	The admin user triggered export from Data Lake.
1	DownloadZipFile	The admin user downloaded the exported data.

MicrosoftGraphDataConnectOperation complex type

Parameters	Type	Mandatory?	Description
ApplicationId	Edm.Guid	Yes	The application identification.
ApplicationName	Edm.String	Yes	The application name.
PipelineName	Edm.String	Yes	The pipeline name.
PipelineRunId	Edm.Guid	No	The identification of this pipeline run.
CopyActivityRunId	Edm.Guid	No	The identification of the ADF copy activity.
RunStartTime	Edm.Date	Yes	Date and time of the extraction.
RunEndTime	Edm.Date	Yes	Date and time of the extraction.
DatasetName	Edm.String	Yes	The dataset name being extracted.
DatasetColumns	Edm.String	Yes	The set of selected columns being extracted.
ScopeList	Edm.String	Yes	The scope of the extraction.
ScopeCountRequested	Edm.Int64	No	The requested scope count for this extraction.
ScopeCountDelivered	Edm.Int64	No	The delivered scope count for this extraction.
UndeliveredScope	Edm.String	No	The undelivered scope of the extraction.
RowCount	Edm.Int64	No	The number of rows extracted.
Status	Edm.String	Yes	The extraction status.
Reason	Edm.String	No	The error message in case of failure.

AipDiscover

The following table contains information related to Azure Information Protection (AIP) scanner events.

Event	Description
ApplicationId	The ID of the application performing the operation.
ApplicationName	Friendly name of the application performing the operation. Outlook (for email), OWA (for email), Word (for file), Excel (for file), PowerPoint (for file).

Event	Description
ClientIP	The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format. For some services, the value displayed in this property might be the IP address for a trusted application (for example, Office on the web apps) calling into the service on behalf of a user and not the IP address of the device used by person who performed the activity. Also, for Azure Active Directory-related events, the IP address isn't logged and the value for the ClientIP property is null. The IP address is displayed in either an IPv4 or IPv6 address format.
CreationTime	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the audit log record was generated.
DataState	Describes the state of the data.
DeviceName	The device on which the activity happened.
Id	GUID of the current record.
IsProtected	Whether protected: True/False
Location	The location of the document with respect to the user's device. The possible values are **unknown**, **localMedia**, **removableMedia**, **fileshare**, and **cloud**.
ObjectId	File full path (URL). For SharePoint and OneDrive activity, the full path name of the file or folder accessed by the user.
Operation	Describes type of access.
OrganizationId	The GUID for your organization's Office 365 tenant. This value is always the same for your organization, regardless of the Office 365 service in which it occurs.
Platform	Device platform (Win, OSX, Android, iOS)
ProcessName	The relevant process name. For example, `Outlook`, `msip.app`, or `WinWord`.
ProductVersion	Version of the AIP client.
ProtectionOwner	Rights Management owner in UPN format.
ProtectionType	Protection type can be template or ad-hoc.
RecordType	The type of operation indicated by the record. See the AuditLogRecordType table for details on the types of audit log records. For a complete updated list and full description of the Log RecordType, see the Microsoft 365 Compliance audit log activities via Office 365 Management API blog post. Here we only list the relevant MIP Record types.
Scope	Event created by one of the following sources: • **online**: A service in Microsoft 365. • **onprem**: A service in an on-premises organization. Currently, SharePoint is the only workload sending events from on-premises to Microsoft 365.
SensitiveInfoTypeData	Stores the datatype of the Sensitive Info type data.

Event	Description
SensitivityLabelId	The current MIP sensitivity label GUID. Use the **Get-Label** to get the full values of the GUID.
TemplateId	TemplateID parameter to get a specific template. The Get-AipServiceTemplate cmdlet gets all existing or selected protection templates from Azure Information Protection.
UserId	The UPN (User Principal Name) of the user who performed the action (specified in the Operation property) that resulted in the record being logged; for example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.
UserKey	An alternative ID for the user identified in the UserId property. This property is populated with the passport unique ID (PUID) for events performed by users in SharePoint, OneDrive, and Exchange.
UserType	The type of user that performed the operation. See the UserType table for details on the types of users. 0 = Regular 1 = Reserved 2 = Admin 3 = DcAdmin 4 = System 5 = Application 6 = ServicePrincipal 7 = CustomPolicy 8 = SystemPolicy
Version	Version ID of the file in the operation.
Workload	Stores the Office 365 service where the activity occurred.

AipSensitivityLabelAction

The following table contains information related to AIP sensitivity label events.

Event	Description
ApplicationId	Corresponds to the Microsoft Entra Application ID.
ApplicationName	Application friendly name of the application performing the operation.
CreationDate	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the user performed the activity.
DataState	Specifies the state of the data.
DeviceName	The name of the user's device.

Event	Description
Identity	The identity of the user or service to be authenticated.
IsProtected	Whether protected: True/False
IsProtectedBefore	Whether the content was protected before change: True/False
IsValid	Boolean
Location	The location of the document with respect to the user's device. The possible values are unknown, localMedia, removableMedia, fileshare, and cloud.
ObjectState	Specifies the state of the object.
Operation	The operation type for the audit log.The name of the user or admin activity. For a description of the most common operations/activities: SensitivityLabelApplied SensitivityLabelUpdated SensitivityLabelRemoved SensitivityLabelPolicyMatched SensitivityLabeledFileOpened.
Identity	The identity of the user or service to be authenticated.
PSComputerName	Computer Name
PSShowComputerName	The value is False for documented edited in Office 365.
Platform	Device platform (Win, OSX, Android, iOS).
ProcessName	Process that hosts MIP SDK.
ProductVersion	Version of the Azure Information Protection client that performed the audit action.
ProtectionType	Protection type can be template or ad-hoc.
RecordType	Shows the value of Label Action. The operation type indicated by the record. For more information, see the full list of record types.
RunspaceId	The Runspace is a specific instance of PowerShell which contains modifiable collections of commands, providers, variables, functions, and language elements that are available to the command line user.
SensitiveInfoTypeData	Stores the datatype of the Sensitive Info Type Data
TemplateId	TemplateID parameter to get a specific template. The Get-AipServiceTemplate cmdlet gets all existing or selected protection templates from Azure Information Protection.
UserId	The User Principal Name (UPN) of the user who performed the action (specified in the Operation property) that resulted in the record being logged; for example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint,

Event	Description
	another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.

AipProtectionAction

Event	Description
PSComputerName	Computer name
RunspaceId	The Runspace is a specific instance of PowerShell which contains modifiable collections of commands, providers, variables, functions, and language elements that are available to the command line user.
PSShowComputerName	The value is false for a documented edited in Office 365.
RecordType	Shows the value of Label Action. The operation type indicated by the record. Here we are only listing the relevant MIP Record types. For more information, see the full list of record types.
CreationTime	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the audit log record was generated.
UserId	The User Principal Name (UPN) of the user who performed the action (specified in the Operation property) that resulted in the record being logged. For example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.
Operation	The operation type for the audit log. The name of the user or admin activity. For a description of the most common operations/activities. SensitivityLabelApplied SensitivityLabelUpdated SensitivityLabelRemoved SensitivityLabelPolicyMatched SensitivityLabeledFileOpened.
Identity	The identity of the user or service to be authenticated.
ObjectState	State of the Object after the current event.
ApplicationId	The application where the activity happened and displayed in GUID.
ApplicationName	Application friendly name of the application performing the operation.Outlook (for email), OWA (for email), Word (for file), Excel (for file), PowerPoint (for file).

Event	Description
ProcessName	Process name of the Office application.
Platform	The platform on which the activity happened. For example, Windows.
DeviceName	Device the event was recorded on.
ProductVersion	Version of the Azure Information Protection client that performed the audit action.
UserId	The UPN of the user who performed the action (specified in the Operation property) that resulted in the record being logged; for example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.
ClientIP	The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format. For some services, the value displayed in this property might be the IP address for a trusted application (for example, Office on the web apps) calling into the service on behalf of a user and not the IP address of the device used by person who performed the activity. Also, for Azure Active Directory-related events, the IP address isn't logged and the value for the ClientIP property is null. The IP address is displayed in either an IPv4 or IPv6 address format.
Id	GUID of the current record.
RecordType	Shows the value of Label Action. The operation type indicated by the record. Here we are only listing the relevant MIP Record types.
CreationTime	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the audit log record was generated.
Operation	The name of the user or admin activity. For a description of the most common operations/activities, see Search the audit log.
OrganizationId	The GUID for your organization's Office 365 tenant. This value is always the same for your organization, regardless of the Office 365 service in which it occurs.
UserType	The type of user that performed the operation. See the UserType table for details on the types of users. 0 = Regular 1 = Reserved 2 = Admin 3 = DcAdmin 4 = System 5 = Application 6 = ServicePrincipal 7 = CustomPolicy 8 = SystemPolicy

Event	Description
UserKey	An alternative ID for the user identified in the UserId property. This property is populated with the passport unique ID (PUID) for events performed by users in SharePoint, OneDrive, and Exchange.
Workload	Stores the Office 365 service where the activity occurred.
Version	Version of the Azure Information Protection client that performed the audit action
Scope	Specifies scope.

AipFileDeleted

Event	Description
PSComputerName	Computer name
RunspaceId	The Runspace is a specific instance of PowerShell which contains modifiable collections of commands, providers, variables, functions, and language elements that are available to the command line user.
PSShowComputerName	The value is false for a documented edited in Office 365.
RecordType	Shows the value of Label Action. The operation type indicated by the record. Here we are only listing the relevant MIP Record types. For more information, see the full list of record types.
CreationTime	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the audit log record was generated.
UserId	The User Principal Name (UPN) of the user who performed the action (specified in the Operation property) that resulted in the record being logged. For example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.
Operation	The operation type for the audit log. The name of the user or admin activity. For a description of the most common operations/activities. SensitivityLabelApplied SensitivityLabelUpdated SensitivityLabelRemoved SensitivityLabelPolicyMatched SensitivityLabeledFileOpened.
Identity	The identity of the user or service to be authenticated.
ObjectState	State of the Object after the current event.

Event	Description
ApplicationId	The application where the activity happened and displayed in GUID.
ApplicationName	Application friendly name of the application performing the operation.Outlook (for email), OWA (for email), Word (for file), Excel (for file), PowerPoint (for file).
ProcessName	Process name of the Office application.
Platform	The platform on which the activity happened. For example, Windows.
DeviceName	Device the event was recorded on.
ProductVersion	Version of the Azure Information Protection client that performed the audit action.
UserId	The UPN of the user who performed the action (specified in the Operation property) that resulted in the record being logged; for example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service..
ClientIP	The IP address of the device that was used when the activity was logged. The IP address is displayed in either an IPv4 or IPv6 address format. For some services, the value displayed in this property might be the IP address for a trusted application (for example, Office on the web apps) calling into the service on behalf of a user and not the IP address of the device used by person who performed the activity. Also, for Azure Active Directory-related events, the IP address isn't logged and the value for the ClientIP property is null. The IP address is displayed in either an IPv4 or IPv6 address format.
Id	GUID of the current record.
RecordType	Shows the value of Label Action. The operation type indicated by the record. Here we are only listing the relevant MIP Record types.
CreationTime	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the audit log record was generated.
Operation	The name of the user or admin activity. For a description of the most common operations/activities, see Search the audit log.
OrganizationId	The GUID for your organization's Office 365 tenant. This value is always the same for your organization, regardless of the Office 365 service in which it occurs.
UserType	The type of user that performed the operation. See the UserType table for details on the types of users. 0 = Regular 1 = Reserved 2 = Admin 3 = DcAdmin

Event	Description
	4 = System 5 = Application 6 = ServicePrincipal 7 = CustomPolicy 8 = SystemPolicy
UserKey	An alternative ID for the user identified in the UserId property. This property is populated with the passport unique ID (PUID) for events performed by users in SharePoint, OneDrive, and Exchange.
Workload	Stores the Office 365 service where the activity occurred.
Version	Version of the Azure Information Protection client that performed the audit action
Scope	Specifies scope.

AipHeartBeat

The following table contain information related to AIP heartbeat events.

Event	Description
ApplicationId	Corresponds to the Microsoft Entra Application ID.
ApplicationName	Application friendly name of the application performing the operation.
CreationDate	The date and time in Coordinated Universal Time (UTC) in ISO8601 format when the user performed the activity.
DataState	Specifies the state of the data.
DeviceName	The name of the user's device.
Identity	The identity of the user or service to be authenticated.
IsProtected	Whether protected: True/False
IsProtectedBefore	Whether the content was protected before change: True/False
IsValid	Boolean
Location	The location of the document with respect to the user's device. The possible values are unknown, localMedia, removableMedia, fileshare, and cloud.
ObjectState	Specifies the state of the object.
Operation	The operation type for the audit log. The name of the user or admin activity.
PSComputerName	Computer Name
PSShowComputerName	The value is False for documented edited in Office 365.
Platform	Device platform (Win, OSX, Android, iOS).
ProcessName	Process that hosts MIP SDK.

Event	Description
ProductVersion	Version of the Azure Information Protection client that performed the audit action.
ProtectionType	Protection type can be template or ad-hoc.
RecordType	Shows the value of Label Action. The operation type indicated by the record. For more information, see the full list of record types.
RunspaceId	The Runspace is a specific instance of PowerShell which contains modifiable collections of commands, providers, variables, functions, and language elements that are available to the command line user.
SensitiveInfoTypeData	Stores the datatype of the Sensitive Info Type Data.
TemplateId	TemplateID parameter to get a specific template. The Get-AipServiceTemplate cmdlet gets all existing or selected protection templates from Azure Information Protection.
UserId	The UPN of the user who performed the action (specified in the Operation property) that resulted in the record being logged; for example, `my_name@my_domain_name`. **Note**: Records for activity performed by system accounts (such as SHAREPOINT\system or NT AUTHORITY\SYSTEM) are also included. In SharePoint, another value display in the UserId property is `app@sharepoint`. This value indicates the "user" who performed the activity was an application that has the necessary permissions in SharePoint to perform organization-wide actions (such as search a SharePoint site or OneDrive account) on behalf of a user, admin, or service.
UserType	The type of user that performed the operation. See the UserType table for details on the types of users. 0 = Regular 1 = Reserved 2 = Admin 3 = DcAdmin 4 = System 5 = Application 6 = ServicePrincipal 7 = CustomPolicy 8 = SystemPolicy
UserKey	An alternative ID for the user identified in the UserId property. This property is populated with the passport unique ID (PUID) for events performed by users in SharePoint, OneDrive, and Exchange.

MicrosoftGraphDataConnectConsent complex type

Parameters	Type	Mandatory?	Description
ApplicationId	Edm.Guid	Yes	The application identification.
ApplicationVersion	Edm.String	Yes	The application version.

Parameters	Type	Mandatory?	Description
AppRegistrationTenantId	Edm.Guid	Yes	The application registration tenant id.
Approver	Edm.String	Yes	The approver's user principal name.
ApprovalUpdatedDateInUTC	Edm.Date	Yes	The update date time in UTC.
ApprovalExpiryDateInUTC	Edm.Date	Yes	The expiry date time in UTC.
ApprovalValidDays	Edm.Int32	Yes	The number of days from update for which the approval is valid.
DestinationSinks	Edm.String	Yes	The destination sinks.
DestinationTenantId	Edm.Guid	Yes	The destination tenant id.
Reason	Edm.String	No	The reason provided by the admin who performed the operation.
State	Edm.String	Yes	The consent state.
Datasets	CollectionSelf.MGDCDataset	Yes	Details on the datasets which were consented to as part of this operation.

Complex Type MGDCDataset

Parameters	Type	Mandatory?	Description
DatasetName	Edm.String	Yes	The name of the dataset in the consent operation.
DatasetColumns	Edm.String	Yes	The list of columns for the dataset in the consent operation.
DenyGroups	Edm.String	No	The deny groups list for the dataset in the consent operation.
Scope	Edm.String	Yes	The scope types for the dataset in the consent operation. Possible values are **All**, **List**, and **FilterUri**.
ScopeFiltersUris	Edm.String	No	The scope filter URI for the dataset in the consent operation.
ScopeList	Edm.String	No	The scope group list for the dataset in the consent operation.
PrivacyPolicyType	Edm.String	Yes	The privacy policy types for the dataset in the consent operation. Possible values are None and DenyList.

Viva Glint schema

Viva Glint events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
ClientUUID	Edm.String	Y	The Client UUID of the Viva Glint instance.
CampaignUUID	Edm.String	N	The stable internal identifier of the agentic campaign.
DataSubjectUUID	Edm.String	N	The stable internal identifier of the data subject affected by a data subject rights deletion.
ExportFormat	Edm.String	N	The format of the exported agentic campaign data.
ModifiedProperties	Edm.String	N	The properties that were changed by the operation.
PolicyUUID	Edm.String	N	The stable internal identifier of the agentic policy.
ReportUUID	Edm.String	N	The stable internal identifier of the agentic campaign report.
RetentionCutoff	Edm.Date	N	The retention cutoff date used when agentic campaign data is deleted by the retention process.
SharedWith	Edm.String	N	The recipients or scope with which an agentic campaign report was shared.
ImportType	Edm.String	N	The data import source type.
DataDSRControl	Edm.String	N	This in-platform control determines whether survey data is deleted when a user is removed from the Viva Glint platform.
DiscardEmployeeIds	Edm.String	N	This in-platform control specifies whether the Employee IDs of previously deleted employees are disregarded or retained in the Viva Glint platform.
JobName	Edm.String	N	The name of a Glint data app job that was run.
ExtendedCompletionDate	Edm.Date	N	The new date to which a closed survey cycle has been extended.
FeedBackComponentName	Edm.String	N	The name of a specific component within the 360 feedback program.
ExportApiClientAppId	Edm.String	N	The application ID which made the data export request using APIs.

Viva Goals schema

Viva Goals events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
Detail	Edm.String	No	A description of the event or the activity that occurred in Viva Goals.
Username	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the user who triggered the event.
UserRole	Edm.String	No	The role of the user who triggered this event in Viva Goals. This value mentions if the user is an organization admin or an owner.
OrganizationName	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The name of the organization in Viva Goals where the event was triggered.
OrganizationOwner	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The owner of the organization in Viva Goals where the event occurred.
OrganizationAdmins	Collection(Edm.String) Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The admin(s) of the organization in Viva Goals where the event occurred. There can be one or more admins in the organization.
UserAgent	Edm.String Term="Microsoft.Office.Audit.Schema.PIIFlag" Bool="true"	No	The user agent (browser details) of the user who triggered the event. UserAgent might not be present in case of a system generated event.
ModifiedFields	Collection(Common.NameValuePair)	No	A list of attributes that were modified along with its new and old values output as a JSON.
ItemDetails	Collection(Common.NameValuePair)	No	Additional properties about the object that was modified.

Microsoft Planner schema

Microsoft Planner events returned in audit log searches use this schema.

Microsoft Planner overwrites the definition of ObjectId and ResultStatus in the Common schema. Microsoft Planner's ObjectId definition is bound to each Microsoft Planner's record type and is illustrated individually.

Microsoft Planner's ResultStatus is defined as the following.

Enum: ResultStatus - Type: Edm.Int32

ResultStatus

Value	Member name	Description
1	Success	The user request succeeded.
2	Failure	The user request failed due to reasons other than authorization.
3	AuthorizationFailure	The user requested failed due to failed authorization.

Microsoft Planner extends the Common schema with the following record types.

PlannerGoal record type

Properties	Type	Description
ObjectId	Edm.String	Id of the goal requested.
PlanId	Edm.String	Id of the plan containing the goal.

PlannerPlan record type

Properties	Type	Description
ObjectId	Edm.String	Id of the plan requested.
ContainerType	Self.ContainerType	Type of the container associated with the plan.
ContainerId	Edm.String	Id of the container associated with the plan.
SharedWithContainerId	Edm.String	Id of the container with shared access to the plan.
SharedWithContainerType	Self.ContainerType	Type of the container with shared access to the plan.
SharedWithContainerAccessLevel	Self.PlanAccessLevel	Level of access given to container with shared access to the plan.

Enum: ContainerType - Type Edm.Int32

ContainerType

Value	Member name	Description
0	Invalid	Used when the requested plan is not found.
2	Group	The plan is associated with a Microsoft 365 Group.
3	TeamsConversation	The plan is associated with a Teams conversation.
4	OfficeDocument	The plan is associated with an Office document.
5	Roster	The plan is associated with a roster group.
6	Project	The plan originates from Microsoft Project.
7	User	The plan is associated with a user.
8	TeamsChannel	The plan is associated with a Teams channel.
10	PlannerTask	The plan is associated with a Planner task.

Enum: PlanAccessLevel - Type Edm.Int32

PlanAccessLevel

Value	Member name	Description
1	ReadAccess	Access to read Plan.
2	ReadWriteAccess	Access to read and write to Plan.
3	FullAccess	Access to read, write and configure Plan.

PlannerCopyPlan record type

Properties	Type	Description
ObjectId	Edm.String	Id of the plan being copied.
OriginalPlanId	Edm.String	Id of the plan being copied. Same as ObjectId.
OriginalContainerType	Self.ContainerType	Type of the container associated with the original plan.
OriginalContainerId	Edm.String	Id of the container associated with the original plan.
NewPlanId	Edm.String	Id of the new plan. Null when the operation failed.
NewContainerType	Self.ContainerType	Type of the container associated with the new plan.
NewContainerId	Edm.String	Id of the container associated with the new plan.

PlannerTask record type

Properties	Type	Description
ObjectId	Edm.String	Id of the task requested.
PlanId	Edm.String	Id of the plan containing the task.

PlannerRoster record type

Properties	Type	Description
ObjectId	Edm.String	Id of the roster requested.
MemberIds	Edm.String	A comma-separated string of member ids changed to the roster.

PlannerGoalList record type

Properties	Type	Description
ObjectId	Edm.String	A representation of the view query for a list of goals.
GoalList	Edm.String	A comma-separated string of goal ids queried.

PlannerPlanList record type

Properties	Type	Description
ObjectId	Edm.String	A representation of the view query for a list of plans.
PlanList	Edm.String	A comma-separated string of plan ids queried.

PlannerTaskList record type

Properties	Type	Description
ObjectId	Edm.String	A representation of the view query for a list of tasks.
TaskList	Edm.String	A comma-separated string of task ids queried.

PlannerTenantSettings record type

Properties	Type	Description
ObjectId	Edm.String	Original tenant settings in JSON.
TenantSettings	Edm.String	New tenant settings in JSON.

PlannerRosterSensitivityLabel record type

Properties	Type	Description
ObjectId	Edm.String	Id of the sensitivity label. Null when the sensitivity label is removed.
Roster	Edm.String	Id of the roster to which the sensitivity label is changed.
AssignmentMethod	Self.SensitivityLabelAssignmentMethod	The assignment method of the sensitivity label.

Enum: SensitivityLabelAssignmentMethod - Type Edm.Int32

SensitivityLabelAssignmentMethod

Value	Member name	Description
0	Standard	The sensitivity label is automatically applied but not allowed to override a privileged label assignment.
1	Privileged	The sensitivity label is applied manually by a user or by an admin.
2	Auto	The sensitivity label is automatically applied and is allowed to override a privileged label assignment.

PlannerChatMessage record type

Properties	Type	Description
ObjectId	Edm.String	Id of the chat message
ThreadType	Self.ThreadType	The type of chat. Only option is Task, for a chat scoped to a single Task.
ParentEntityId	Edm.String	Id of the element containing the chat, the Task id.

Enum: ThreadType - Type Edm.Int32

ThreadType

Value	Member name	Description
0	Task	Chat is contained inside of a Task.

PlannerChatMessageList record type

Properties	Type	Description
ObjectId	Edm.String	A representation of the view query for a list of chat messages.
MessageList	Edm.String	A comma-separated string of chat message ids queried.

Microsoft Project for the web schema

Microsoft Project For The web extends the Common schema with the following record types.

ProjectForThewebProject record type

Properties	Type	Mandatory?	Description
ProjectId	Edm.Guid	No	Id of the Project being audited.
AdditionalInfo	CollectionSelf.AdditionalInfo	No	Additional information.

ProjectForThewebTask record type

Properties	Type	Mandatory?	Description
ProjectId	Edm.Guid	Yes	Id of the Project being audited.
TaskId	Edm.Guid	Yes	Id of the Task being audited.
AdditionalInfo	CollectionSelf.AdditionalInfo	No	Additional information.

ProjectForThewebRoadmap record type

Properties	Type	Mandatory?	Description
RoadmapId	Edm.Guid	Yes	Id of the Roadmap being audited.
AdditionalInfo	CollectionSelf.AdditionalInfo	No	Additional information.

ProjectForThewebRoadmapItem record type

Properties	Type	Mandatory?	Description
RoadmapItemId	Edm.Guid	Yes	Id of the Roadmap Item being audited.
AdditionalInfo	CollectionSelf.AdditionalInfo	No	Additional information.

Complex Type AdditionalInfo

Parameters	Type	Mandatory?	Description
EnvironmentName	Edm.String	No	Id of the environment where action was performed.

ProjectForThewebProjectSetting record type

Properties	Type	Mandatory?	Description
ProjectEnabled	Edm.Boolean	Yes	The value that was set for Project for the web (1= enabled, 0 disabled).

ProjectForThewebRoadmapSetting record type

Properties	Type	Mandatory?	Description
RoadmapEnabled	Edm.Boolean	Yes	The value that was set for Roadmap (1= enabled, 0 disabled).

ProjectForThewebAssignedToMeSetting record type

Properties	Type	Mandatory?	Description
AssignedToMeEnabled	Edm.Boolean	Yes	The value that was set for AssignedToMe (1= enabled, 0 disabled).

Viva Pulse schema

Viva pulse events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
EventName	Edm.String	No	A description of the event or the activity that occurred in Viva Pulse.
PulseId	Edm.String	No	Id of the pulse survey.
EventDetails	Collection(Common.NameValuePair)	No	Additional properties about the event.

Some of the VivaPulse events record different properties in EventDetails. Each property recorded in EventDetail are described in the table.

EventName	PropertName	Description
PulseReportShare	Recipients	List of recipient ids with whom the pulse survey is shared.
PulseCreate	Recipients	List of user ids who are participants of the specified pulse survey.

EventName	PropertName	Description
PulseInvite	Recipients	List of user IDs who are additionally invited to the pulse.
PulseTenantSettingsUpdate	TenantSettingName	Changed settings name.
PulseSubmit	Not Applicable	This event does not record any property into EventDetails.
PulseExtendDeadline	Not Applicable	This event does not record any property into EventDetails.
PulseCancel	Not Applicable	This event does not record any property into EventDetails.
PulseCreateDraft	Not Applicable	This event does not record any property into EventDetails.
PulseDeleteDraft	Not Applicable	This event does not record any property into EventDetails.
PulseDeleteUserData	Not Applicable	This event does not record any property into EventDetails.
PulseQuestionDeleted	Not Applicable	This event does not record any property into EventDetails.
PulseDataExport	ExportType,ExportCompletedDate	ExportType indicates whether the data export is an Admin-level or Author-level export, ExportCompletedDate specifies when the data export was finalized.
PulseConfidentialConversationStarted	Not Applicable	This event does not record any property into EventDetails.
PulseConfidentialConversationResponded	Not Applicable	This event does not record any property into EventDetails.

EventName	PropertName	Description
PulseConfidentialConversationMessageDeleted	Not Applicable	This event does not record any property into EventDetails.

Compliance Manager schema

Compliance Manager events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
Details	Collection(SettingsChange)	No	A description of the event that occurred for a Microsoft Purview Compliance Manager.

Values taken by SettingsChange properties in Details for different operations are described in the table below.

Operation	PropertyName	Description
All Operations	Name	Name of setting involved in the Compliance Manager operation.
All Operations	NewValue	New value for the new settings.
All Operations	OriginalValue	Original value for new setting.

> **Note**
>
> - For role changes the name is the role type.
> - The audit record reflects the change in event, such as user is assigned a role or revoked role.
> - The original and new value have the emails of the user for which the role has changed.
> - In case there is no change in the role, that role type isn't present in the audit record.

Backup Policy schema

Parameters	Type	Mandatory?	Description
PolicyID	Edm.String	Yes	The ID of the policy.
EditMethodology	Edm.String	No	How the policy was created / edited.
CountOfArtifactsBeingAdded	Edm.Int32	No	Number of artifacts being added.
CountOfArtifactsBeingRemoved	Edm.Int32	No	Number of artifacts being removed.
ServiceType	Edm.String	No	Whether it is a SharePoint, Exchange, or OneDriveForBusiness policy.

Parameters	Type	Mandatory?	Description
BillingPolicyId	Edm.String	No	The ID of the associated Billing Policy.

Granular Browse Task schema

Parameters	Type	Mandatory?	Description
SessionId	Edm.String	Yes	The ID of the Browse Task.
RestoreTime	Edm.Date	No	Restore Point dateTime on which browse session was created.
BackupItemId	Edm.String	No	Artifact Id for which browse session was created.
ServiceType	Edm.String	Yes	Whether it is a SharePoint, Exchange, or OneDriveForBusiness policy.

Restore Task schema

Parameters	Type	Mandatory?	Description
TaskID	Edm.String	Yes	The ID of the Restore Task.
CreationMethodology	Edm.String	No	How the Restore Task was created / edited.
CountOfArtifactsBeingAdded	Edm.Int32	No	Number of artifacts being added.
CountOfArtifactsBeingRemoved	Edm.Int32	No	Number of artifacts being removed.
ServiceType	Edm.String	No	Whether it is a SharePoint, Exchange, or OneDriveForBusiness policy.

Restore Item schema

Parameters	Type	Mandatory?	Description
RestoreTime	Edm.DateTime	Yes	Time which the item is being restored to.
RestoreLocationType	Edm.String	Yes	Location type that the item is being restored to.
RestoreLocation	Edm.String	No	Location that the item is being restored to.
TaskID	Edm.String	Yes	The ID of the Restore task.
BackupItemID	Edm.String	Yes	ID of the Backup Item being restored.
ProtectionUnitID	Edm.String	Yes	Protection Unit ID of the item being restored.
SuccessStatus	Edm.String	No	Whether the restore operation was successful.
BackupItemType	Edm.String	Yes	Whether the Backup Item is a Site / Account / Mailbox.

Parameters	Type	Mandatory?	Description
ServiceType	Edm.String	No	Whether it is a SharePoint, Exchange, or OneDriveForBusiness policy.

Backup Item schema

Parameters	Type	Mandatory?	Description
PolicyID	Edm.String	Yes	Policy ID of the Policy the item is getting added to.
ItemID	Edm.String	Yes	ID of the Backup Item.
ProtectionUnitID	Edm.String	Yes	Protection Unit ID of the item being backed up.
ResultStatus	Edm.String	No	Whether the restore operation was successful.
BackupItemType	Edm.String	Yes	Whether the Backup Item is a Site / Account / Mailbox.
EditMethodology	Edm.String	No	How the backup item is to be added.
ServiceType	Edm.String	No	Whether it is a SharePoint, Exchange, or OneDriveForBusiness policy.

Cloud Policy service schema

The audit records for events related to the Cloud Policy service extend the Common schema as follows:

PolicyConfigChangeAuditRecord

Parameters	Type	Mandatory?	Description
ConfigId	Edm.String	No	ID of the policy configuration
ConfigName	Edm.String	No	Given name of policy configuration
Description	Edm.String	No	Description provided for policy configuration
ConfigScope	Self.CPSScope	No	Scope of policy configuration
Groups	Collection(Common.NameValuePair)	No	List of configured groups
Priority	Edm.Int32	No	Priority value of policy configuration
Policies	Collection(Self.Policy)	No	List of configured policy settings
Priorities	Collection(Self.PrioritySetting)	No	List of policy configurations and their priority values

Enum: CPSScope - Type: Edm.Int32

Value	Member name	Description
1	Tenant	The policy configuration is scoped to all users in the tenant.
2	Anonymous	The policy configuration is scoped to anonymous users.
3	User	The policy configuration is scoped to users in configured Microsoft Entra group(s).

Complex Type Policy

Parameters	Type	Mandatory?	Description
PolicyId	Edm.String	No	ID of the policy setting
PolicyName	Edm.String	No	Name of policy setting
Value	Edm.String	No	Configured value of policy setting
Settings	Collection(Self.Setting)	No	Configured setting

Complex Type Setting

Parameters	Type	Mandatory?	Description
SettingId	Edm.String	No	ID of the setting
SettingName	Edm.String	No	Name of setting
Value	Edm.String	No	Configured value of setting

Complex Type PrioritySetting

Parameters	Type	Mandatory?	Description
ConfigId	Edm.String	No	ID of the policy configuration
ConfigName	Edm.String	No	Given name of policy configuration
Value	Edm.String	No	Configured priority of policy configuration

Cloud update profile configuration schema

The Cloud Update profile configuration related events extend the Common schema with the following record types.

CloudUpdateProfileConfigAuditRecord

Parameters	Type	Mandatory?	Description
ProfileName	Edm.String	Yes	Name of profile
ProfileState	Self.ProfileState	No	State of profile
Deadline	Edm.Int32	No	Configured deadline
UpdateValidationState	Self.UpdateValidationState	No	State of Update Validation
Waves	Collection(Self.Wave)	No	Collection containing configured waves
WaveDelay	Edm.Int32	No	Set delay between waves

Enum: ProfileState - Type: Edm.Int32

Value	Member name	Description
1	Enabled	The profile is enabled and active.
2	Disabled	The profile is disabled.
3	Paused	The profile is enabled, but in paused state.

Enum: UpdateValidationState - Type: Edm.Int32

Value	Member name	Description
1	Enabled	Update Validation is enabled.
2	Disabled	Update Validation is disabled.

Complex Type Wave

Parameters	Type	Mandatory?	Description
Name	Edm.String	No	Name of wave
Type	Self.WaveType	No	Wave specified by administrator or automatic catch-all wave
Groups	Collection(Common.NameValuePair)	No	Collection of groups configured for this wave

Enum: WaveType - Type: Edm.Int32

Value	Member name	Description
1	Groups	Wave was configured by administrator using groups.

Value	Member name	Description
2	RemainingDevices	Automatically created wave which includes all devices in profile's scope which are not covered by previous waves.

Cloud Update tenant configuration schema

The Cloud Update tenant configuration related events extend the Common schema with the following record types.

CloudUpdateTenantConfigAuditRecord

Parameters	Type	Mandatory?	Description
ProfileExclusionWindows	Collection(Self.ExclusionWindow)	No	Collection of configured exclusion windows
ExclusionList	Collection(Common.NameValuePair)	No	Collection of configured exclusions
TAK	Edm.String	No	Tenant Association Key

Complex Type ExclusionWindow

Parameters	Type	Mandatory?	Description
Name	Edm.String	No	Given name of exclusion window
StartDate	Edm.Date	No	Start date of exclusion windows
EndDate	Edm.Date	No	End date of exclusion windows
Groups	Collection(Common.NameValuePair)	No	Collection of groups the exclusion window is scoped to

Cloud Update device schema

The Cloud Update device related events extend the Common schema with the following record types.

CloudUpdateDeviceConfigAuditRecord

Parameters	Type	Mandatory?	Description
RollbackDevices	Self.Rollback	No	Rollbacks triggered
ChannelChangeDevices	Self.ChannelChange	No	Channel changes triggered

Complex Type Rollback

Parameters	Type	Mandatory?	Description
RollbackType	Self.RollbackType	No	Type of rollback
RollbackBuildNumber	Edm.String	No	Targeted build number to roll back to
Devices	Collection(Edm.String)	No	Collection of devices targeted by rollback

Enum: RollbackType - Type: Edm.Int32

Value	Member name	Description
1	SpecificDevices	Rollback was targeted at a specific subset of devices.
2	AllDevices	Rollback was targeted at all devices within the profile's scope.

Complex Type ChannelChange

Parameters	Type	Mandatory?	Description
ChannelChange	Self.Channel	No	Targeted update channel
Devices	Collection(Edm.String)	No	Collection of targeted devices
Groups	Collection(Common.NameValuePair)	No	Collection of targeted groups

Enum: Channel - Type: Edm.Int32

Value	Member name	Description
1	MonthlyEnterpriseChannel	Monthly Enterprise Channel
2	CurrentChannel	Current Channel

Microsoft Entra Risk Detection schema

Microsoft Entra risk detection events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
Activity	Edm.String	No	The activity type for which risk was detected.
ActivityDateTime	Edm.Date	No	The date and time in Coordinated Universal Time (UTC) when the risky activity occurred.
AdditionalInfo	Edm.String	No	Additional Information in JSON format for the detected risk.

Parameters	Type	Mandatory?	Description
CorrelationId	Edm.String	No	An identifier that can used to correlate sign-in activities associated with a risk detection.
DetectedDateTime	Edm.Date	No	The date and time in Coordinated Universal Time (UTC) when the risk was detected.
DetectionTimingType	Edm.String	No	Indicates the timing type of the detected risk. Possible values are real-time/offline.
LastUpdatedDateTime	Edm.Date	No	The date and time in Coordinated Universal Time (UTC) when the risk detection was last updated.
Location	Self.LocationType	No	Information about the location from which the sign-in activity was detected.
RequestId	Edm.String	No	Indicates the Request Id of the sign-in activity for which risk was detected. If risk detection is not associated with sign-in then this property is null.
RiskDetail	Edm.String	No	The details of the detected risk.
RiskEventType	Edm.String	No	The type of event for which risk was detected.
RiskId	Edm.String	No	An unique identifier for the risk detection.
RiskLevel	Edm.String	No	The level of the risk detected.
RiskState	Edm.String	No	The risk state of a risky user or a sign-in linked to the risk detection.
Source	Edm.String	No	The source of the detected risk.
TokenIssuerType	Edm.String	No	The type of token issuer for the sign-in linked to the risk detection.
UserDisplayName	Edm.String	No	The user principal name (UPN) of the user for whom the risk was detected.

LocationType complex type

Parameters	Type	Mandatory?	Description
City	Edm.String	No	The city where the sign-in was performed.
CountryOrRegion	Edm.String	No	The country or region where the sign-in was performed.
GeoCoordinates	Self.GeoCoordinatesType	No	The geo co-ordinates of the location where the sign-in was performed.
State	Edm.String	No	The state where the sign-in was performed.

GeoCoordinatesType complex type

Parameters	Type	Mandatory?	Description
Altitude	Edm.String	No	The altitude of the location where the sign-in was performed.
Latitude	Edm.String	No	The latitude of the location where the sign-in was performed.
Longitude	Edm.String	No	The longitude of the location where the sign-in was performed.

Microsoft Edge WebContentFiltering schema

Microsoft Edge WebContentFiltering events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
URLPath	Edm.String	Yes	The URL that was browsed.
DomainURL	Edm.String	Yes	The domain URL that was browsed.
Category	Edm.String	Yes	Category of browsed URL.

Microsoft 365 Copilot scheduled prompt schema

Microsoft 365 Copilot scheduled prompt events returned in audit log searches use this schema (and also the Common schema).

Copilot scheduled prompts allow users to automate Copilot prompts, so they run on a defined schedule in Microsoft 365 Copilot Chat.

Parameters	Type	Mandatory?	Description
ScenarioType	Edm.String	Yes	The name of automation.
PromptText	Edm.String	No	The Copilot prompt that's run by the LLM.
AutomationId	Edm.String	Yes	A unique identifier that correlates all activities related to each run of the Copilot prompt.
TriggerMode	Edm.String	No	The schedule for when the Copilot prompt runs, shown in cron format.

Microsoft Places Directory schema

Microsoft Places Directory events returned in audit log searches use this schema (and also the Common schema).

Parameters	Type	Mandatory?	Description
PlaceType	Edm.String	No	The type for the place item that is

Parameters	Type	Mandatory?	Description
			created/updated/deleted by the request. For example, "Building", "Room", "Desk", and so on.
Parameters	Collection(Common.NameValuePair)	No	The name and value for all parameters that were used with the cmdlet that is identified in the Operations property.
ModifiedProperties	Collection(Common.ModifiedProperty)	No	The property includes the name of the property that was modified, the new value of the modified property, and the previous value of the modified object.

Teams Evaluation Data Hub schema

Teams Evaluation Data Hub events returned in audit log searches use the Common schema. Teams Evaluation Data Hub doesn't introduce additional service-specific properties beyond the Common schema. For these events, the following Common schema properties have service-specific meanings.

Parameters	Type	Mandatory?	Description
Workload	Edm.String	Yes	The Office 365 service where the activity occurred. Always `TeamsEvalDataHub`.
RecordType	Self.AuditLogRecordType	Yes	The type of operation indicated by the record. `TeamsEvalDataHubDataAccess` (444) for `DataRead` and `DataWrite` operations; `TeamsEvalDataHubPermissionChange` (445) for `PermissionGranted` and `PermissionRevoked` operations.
Operation	Edm.String	Yes	The name of the user or service activity. One of `DataRead`, `DataWrite`, `PermissionGranted`, or `PermissionRevoked`.
ObjectId	Edm.String	No	Identifies the data set or access-control object that the operation targets.

Microsoft Sentinel data lake and graph schema

The following Microsoft Sentinel events returned in audit log searches use these schemas (and also the Common schema).

SentinelNotebookOnLake

For audit log activities, see Microsoft Sentinel data lake notebook activities.

Parameter	Type	Mandatory?	Description
EventTime	Edm.Date	Yes	Timestamp when the Spark Notebook execution was submitted/started.
Compute	Edm.String	No	Compute selected.
DatabaseName	Edm.String	No	The workspace the command ran on.
TableName	Edm.String	No	Name of the table.
SessionDurationInSecs	Edm.String	Yes	Total duration of the session.
SessionStartTime	Edm.Date	No	Start time for the session.
SessionEndTime	Edm.Date	No	End time for the session.
KernalId	Edm.Guid	Yes	Jupyter KernelId, uniquely identifies the Notebook session.
SessionId	Edm.Guid	No	Correlation ID for the various code blocks executed with a Spark session.
Interface	Edm.String	Yes	Interface from where the notebook was run.

SentinelJob

For audit log activities, see Microsoft Sentinel data lake job activities.

Parameter	Type	Mandatory?	Description
EventTime	Edm.Date	Yes	Timestamp when the operation on job was initiated.
Operation	Edm.String	Yes	Job Operation name.
Job Type	Edm.String	Yes	Type of Job like Notebook, KQL.
Job ID	Edm.Guid	Yes	Unique identifier of a job.
Job Name	Edm.String	Yes	Name of the job.
Compute	Edm.String	No	Compute configuration of the job.
Schedule	Edm.String	No	Schedule details, if configured for the job.
Run ID	Edm.Guid	No	ID of a specific job run instance.
JobRunStatus	Edm.String	No	Status of the job execution.
Logs	Edm.String	No	Logs from the notebook run.

Parameter	Type	Mandatory?	Description
JobExecutionDurationInSecs	Edm.Int64	No	Time taken for job execution.
JobTotalDurationInSecs	Edm.Int64	No	Total Duration of the job operation including session.
JobStartTime	Edm.Date	No	Start time of the job.
JobEndTime	Edm.Date	No	End time of the job.
Interface	Edm.String	Yes	Interface from where the job operation was done.
DatabasesRead	Collection(Edm.String)	No	The list of workspaces read by the job.
DatabasesWrite	Collection(Edm.String)	No	The list of workspaces written to by the job
TablesRead	Collection(Edm.String)	No	The list of tables read by the job.
TablesWrite	Collection(Edm.String)	No	The list of tables written to by the job.
Query	Edm.String	No	KQL query or notebook executed in the job.

SentinelKQLOnLake

For audit log activities, see Microsoft Sentinel data lake KQL activities.

Parameter	Type	Mandatory?	Description
EventTime	Edm.Date	Yes	Timestamp of KQL query execution.
DatabaseName	Collection(Edm.String)	Yes	The workspaces the KQL query ran on.
ResultTableCount	Edm.Int64	No	Output Table Count.
QueryResponse	Edm.String	Yes	Response from executing the KQL query.
TotalRows	Collection(Edm.Int64)	Yes	Total Rows returned from query execution. List of values if multiple queries executed at once.
ComponentFault	Edm.String	No	The entity that caused the query to fail. For example, if the query result is too large, the ComponentFault is 'Client'. If an internal error occurred, the ComponentFault is 'Server'.
FailureReason	Edm.String	No	If KQL query failed, the reason for failure.
ExecutionDuration	Edm.Int64	Yes	Time taken for query execution, in milliseconds.
TotalCPU	Edm.Int64	Yes	Total CPU Duration of the run.

Parameter	Type	Mandatory?	Description
MemoryPeak	Edm.Int64	Yes	Memory Peak of the KQL query execution.
Interface	Edm.String	Yes	Interface from where the KQL query was executed.
TablesRead	Collection(Edm.String)	Yes	The list of tables read in the KQL query.
QueryText	Edm.String	Yes	The KQL query executed in scrubbed form.

SentinelLakeOnboarding

For audit log activities, see Microsoft Sentinel data lake onboarding activities.

Parameter	Type	Mandatory?	Description
BillingAzureSubscriptionId	Edm.String	No	Azure subscription chosen for Sentinel data lake billing.
BillingAzureResourceGroupName	Edm.String	No	Azure resource group chosen for Sentinel data lake billing.
TenantId	Edm.String	No	Tenant ID associated with the lake setup or update.
ProvisioningStatus	Edm.String	No	Status of provisioning the lake.

SentinelLakeDataOnboarding

Property Name	Type	Mandatory?	Description
DataOnboardingAtSetup	Edm.String	No	Data sets ingested during Sentinel data lake onboarding.
Tables	Collection(Edm.String)	No	List of table names ingested during Sentinel data lake onboarding.
SubscriptionsEnabled	Collection(Edm.String)	No	List of subscriptions enabled for ARG ingestion.
DataOnboardingStatus	Edm.String	No	Status of operation.

SentinelAITool

For audit log activities, see Microsoft Sentinel AI tool activities.

Parameter	Type	Mandatory?	Description
EventOccurenceTime	Edm.Date	Yes	Timestamp of the operation.
ToolID	Edm.Guid	Yes	Identifier of the AI Tool.
ToolName	Edm.String	Yes	Name of the AI Tool.

Parameter	Type	Mandatory?	Description
Interface	Edm.String	Yes	Interface from where the AI Tool was run.
InputParameters	Edm.String	No	Parameters given to the tool.
DatabasesRead	Collection(Edm.String)	No	The list of databases read from in the run.
TablesRead	Collection(Edm.String)	No	The list of tables read from in the run.
APIsCalled	Collection(Edm.String)	No	APIs called by the AI Tool.
FailureReason	Edm.String	No	If the run failed, the reason for failure.
TotalRows	Collection(Edm.Int64)	No	Total Rows returned.
DataScanned	Edm.Int64	No	Total GBs Scanned.
ExecutionDuration	Edm.Int64	No	Time taken for query execution, in milliseconds.
TotalCpuHours	Edm.Int64	No	Total CPU Duration of the run.
TotalSCUHours	Edm.Int64	No	Total SCUs used in the run.

SentinelGraph

For audit log activities, see Microsoft Sentinel graph activities.

Parameters	Type	Mandatory?	Description
EventTime	Edm.Date	Yes	Timestamp of the operation.
GraphName	Edm.String	Yes	Name of the graph instance.
Operation	Edm.string	Yes	Action taken on graph.
OperationInput	Edm.string	No	Parameters of graph action.
GraphQuery Stats	Edm.string	No	Collection of response metadata.
GraphQuery Status	Edm.String	No	Response of the query or action on graph.
Interface	Edm.String	Yes	Interface from where the graph action was taken.

Purview On-demand classification schema

Microsoft Purview on-demand classification events returned in audit log searches use this schema.

DataScanClassification schema

The DataScanClassification audit schema is designed to capture and log activities when a file was evaluated for sensitive content as part of an On-demand classification scan for SharePoint or

OneDrive.

Parameters	Type	Mandatory	Description
ClassificationInfo	Collection(Self.SensitiveInformation)	No	Details about sensitive information found in the file after the scan.
PolicyId	Edm.Guid	Yes	The guid of the On-demand classification scan.
ClassificationMode	Edm.Int32	Yes	Whether scan was executed for specific classifiers or all.
ClassificationPosture	Edm.Int32	Yes	Comparison of sensitive info discovered before and after the scan.
ClassificationResult	Edm.Int32	Yes	File classification status.
DocumentMetaData	Self.DocumentMetadata	No	Describes metadata about the document in SharePoint or OneDrive that contained the sensitive information.
PreviousClassificationInfo	Collection(Self.SensitiveInformation)	No	Details about sensitive information found in the file after the scan.

DocumentMetaData complex type

Parameters	Type	Mandatory?	Description
itemCreationTime	Edm.Date	Yes	Datetimestamp in UTC of when event logged.
SiteCollectionGuid	Edm.Guid	Yes	The GUID of the site collection.
SiteCollectionUrl	Edm.String	Yes	Name of the SharePoint site.
FileName	Edm.String	Yes	Name of the path.
FileOwner	Edm.String	Yes	The document owner.
FileOwnerEmail	Edm.String	Yes	Email address of document owner.
FilePathUrl	Edm.String	Yes	The URL of the document
DocumentLastModifier	Edm.String	Yes	The user who last modified the document.
UniqueId	Edm.String	Yes	A guid that identifies the file.
LastModifiedTime	Edm.DateTime	Yes	Timestamp in UTC for when doc was last modified.

Enum: ClassificationMode - Type: Edm.Int32

Value	Description
1	File evaluated for all classifiers configured in tenant.
2	File evaluated only for selected classifiers specified in scan.

Enum: ClassificationPosture - Type: Edm.Int32

Value	Description
1	File did not match any classifiers both before and after the scan.
2	No new classifier found after the scan.
3	File did not match any classifier before the scan. One or more classifiers found in file after the scan.
4	File matched some classifiers before the scan. One or more classifiers no longer match
5	File matched some classifiers before the scan. New classifier or change in existing classifier count or confidence level after the scan.

Enum: ClassificationResult - Type: Edm.Int32

Value	Description
1	File classification completed successfully.
2	File classification completed with error. One or more classifier evaluation failed.
3	File classification failed.

Security and Compliance RBAC schema

The Securityand Compliance RBAC audit schema is designed to capture and log activities when role and role groups management and assignments occur in the Microsoft Purview portal and Microsoft Defender portal. Some of the fields and values specific to the common audit schema are listed below.

Parameters	Type	Mandatory	Description
`Operation`	`Edm.String`	Yes	Name of the SecurityComplianceRBAC operation.
`RecordType`	`Self.AuditLogRecordType`	Yes	Audit record type. SecurityComplianceRBAC record value is 87.
`ResultStatus`	`Edm.String`	Yes	Result of the operation. Values emitted by this workload are `Success` and `Failed`.
`PreExecutionMessage`	`Edm.String`	No	Operation-specific input details. See the applicable operation schema.

Parameters	Type	Mandatory	Description
`PostExecutionMessage`	`Edm.String`	No	Operation-specific result details. See the applicable operation schema.
`AssociatedAdminUnits`	`Collection(Edm.Guid)`	No	Administrative units associated with the record.

CreateRBACRoleGroupDefinition Operation

Creates an RBAC role-group definition.

Parameters	Type	Mandatory	Description
`PreExecutionMessage`	`Edm.String`	Yes	Custom role group object information.
`PreExecutionMessage.RoleGroupId`	`Edm.Guid`	Yes	Identifier of the role group.
`PreExecutionMessage.RoleGroupName`	`Edm.String`	Yes	Internal name of the role group.
`PreExecutionMessage.RoleGroupDisplayName`	`Edm.String`	No	User-facing display name of the role group.
`PreExecutionMessage.RoleGroupDescription`	`Edm.String`	No	Description of the role group.
`PreExecutionMessage.RolesDetail`	`Collection(RoleDetail)`	No	Roles included in the role group.
`PreExecutionMessage.RolesDetail[].RoleId`	`Edm.Guid`	No	Identifier of an included role.
`PreExecutionMessage.RolesDetail[].RoleName`	`Edm.String`	No	Name of an included role.
`PostExecutionMessage`	`Edm.String`	No	New custom role group object information.
`PostExecutionMessage.RoleGroupId`	`Edm.Guid`	No	Identifier of the created role group.
`PostExecutionMessage.RoleGroupName`	`Edm.String`	No	Internal name of the created role group.
`PostExecutionMessage.RoleGroupDisplayName`	`Edm.String`	No	Display name of the created role group.

Parameters	Type	Mandatory	Description
`PostExecutionMessage.RoleGroupDescription`	`Edm.String`	No	Description of the created role group.
`PostExecutionMessage.RolesDetail`	`Collection(RoleDetail)`	No	Roles included in the created role group.
`PostExecutionMessage.RolesDetail[].RoleId`	`Edm.Guid`	No	Identifier of an included role.
`PostExecutionMessage.RolesDetail[].RoleName`	`Edm.String`	No	Name of an included role.

UpdateRBACRoleGroupDefinition Operation

Updates an existing RBAC role-group definition.

Parameters	Type	Mandatory	Description
`PreExecutionMessage`	`Edm.String`	Yes	Custom role group object information.
`PreExecutionMessage.RoleGroupId`	`Edm.Guid`	Yes	Identifier of the role group.
`PreExecutionMessage.RoleGroupName`	`Edm.String`	Yes	Internal name of the role group.
`PreExecutionMessage.RoleGroupDisplayName`	`Edm.String`	No	Updated display name of the role group.
`PreExecutionMessage.RoleGroupDescription`	`Edm.String`	No	Updated description of the role group.
`PreExecutionMessage.RolesDetail`	`Collection(RoleDetail)`	No	Updated collection of roles included in the role group.
`PreExecutionMessage.RolesDetail[].RoleId`	`Edm.Guid`	No	Identifier of an included role.
`PreExecutionMessage.RolesDetail[].RoleName`	`Edm.String`	No	Name of an included role.
`PostExecutionMessage`	`Edm.String`	No	Empty field.

DeleteRBACRoleGroupDefinition Operation

Deletes an RBAC role-group definition.

Parameters	Type	Mandatory	Description
`PreExecutionMessage`	`Edm.String`	Yes	Custom role group object information.
`PreExecutionMessage.RoleGroupId`	`Edm.Guid`	Yes	Identifier of the role group being deleted.
`PreExecutionMessage.RoleGroupName`	`Edm.String`	Yes	Internal name of the role group being deleted.
`PreExecutionMessage.RoleGroupDisplayName`	`Edm.String`	No	Display name of the role group being deleted.
`PreExecutionMessage.RoleGroupDescription`	`Edm.String`	No	Description of the role group being deleted.
`PreExecutionMessage.RolesDetail`	`Collection(RoleDetail)`	No	Roles included in the role group being deleted.
`PreExecutionMessage.RolesDetail[].RoleId`	`Edm.Guid`	No	Identifier of an included role.
`PreExecutionMessage.RolesDetail[].RoleName`	`Edm.String`	No	Name of an included role.
`PostExecutionMessage`	`Edm.String`	No	Empty field.

DeletePermissionAsync Operation

Remove assigned members from a role-group.

Parameters	Type	Mandatory	Description
`PreExecutionMessage`	`Edm.String`	Yes	Input container.
`PreExecutionMessage.MemberDetail`	`MemberDetail`	No	Member assigned to role group.
`PreExecutionMessage.MemberDetail.MemberId`	`Edm.Guid`	No	Identifier of the assigned member.
`PreExecutionMessage.MemberDetail.MemberType`	`Edm.String`	No	Member category, such as `User`, `SecurityGroup`, `ServicePrincipal`, `Application`.
`PreExecutionMessage.MemberDetail.MemberName`	`Edm.String`	No	Name of the assigned member.

Parameters	Type	Mandatory	Description
`PreExecutionMessage.MemberDetail.MemberDisplayName`	`Edm.String`	No	Display name of the assigned member.
`PreExecutionMessage.RoleGroupDetail`	`RoleGroupDetail`	No	Role group being removed from the member.
`PreExecutionMessage.RoleGroupDetail.RoleGroupId`	`Edm.Guid`	No	Identifier of the role group.
`PreExecutionMessage.RoleGroupDetail.RoleGroupName`	`Edm.String`	No	Name of the role group.
`PreExecutionMessage.ScopeDetail`	`ScopeDetail`	No	Scope of the role assignment. Null for global scope.
`PreExecutionMessage.ScopeDetail.ScopeId`	`Edm.Guid`	No	Identifier of the assigned scope.
`PreExecutionMessage.ScopeDetail.ScopeType`	`Edm.String`	No	Resource type of the assigned scope.
`PreExecutionMessage.ScopeDetail.ScopeFeature`	`Edm.String`	No	Feature associated with the assigned scope.
`PreExecutionMessage.ScopeDetail.ScopePathById`	`Edm.String`	No	Resource path identifying the assigned scope.
`PreExecutionMessage.ExceptionMessage`	`Edm.String`	No	Reserved field, currently `null`.
`PreExecutionMessage.ExpiresAt`	`Edm.String`	No	Expiration of the role assignment.
`PostExecutionMessage`	`Edm.String`	No	Empty.

GrantPermissionsAsync Operation

Assigns members to a role-group.

Parameters	Type	Mandatory	Description
`PreExecutionMessage`	`Edm.String`	Yes	Input container.
`PreExecutionMessage.MemberDetail`	`MemberDetail`	No	Member assigned to role group.

Parameters	Type	Mandatory	Description
`PreExecutionMessage.MemberDetail.MemberId`	`Edm.Guid`	No	Identifier of the assigned member.
`PreExecutionMessage.MemberDetail.MemberType`	`Edm.String`	No	Member category, such as `User`, `SecurityGroup`, `ServicePrincipal`, `Application`.
`PreExecutionMessage.MemberDetail.MemberName`	`Edm.String`	No	Name of the assigned member.
`PreExecutionMessage.MemberDetail.MemberDisplayName`	`Edm.String`	No	Display name of the assigned member.
`PreExecutionMessage.RoleGroupDetail`	`RoleGroupDetail`	No	Role group being assigned.
`PreExecutionMessage.RoleGroupDetail.RoleGroupId`	`Edm.Guid`	No	Identifier of the assigned role group.
`PreExecutionMessage.RoleGroupDetail.RoleGroupName`	`Edm.String`	No	Name of the assigned role group.
`PreExecutionMessage.ScopeDetail`	`ScopeDetail`	No	Scope of the role assignment. Null for global scope.
`PreExecutionMessage.ScopeDetail.ScopeId`	`Edm.Guid`	No	Identifier of the assigned scope.
`PreExecutionMessage.ScopeDetail.ScopeType`	`Edm.String`	No	Resource type of the assigned scope, such as `Case`.
`PreExecutionMessage.ScopeDetail.ScopeFeature`	`Edm.String`	No	Feature associated with the assigned scope, such as `InsiderRiskManagement`
`PreExecutionMessage.ScopeDetail.ScopePathById`	`Edm.String`	No	Resource path identifying the assigned scope.
`PreExecutionMessage.ExceptionMessage`	`Edm.String`	No	Reserved field, currently `null`.
`PreExecutionMessage.ExpiresAt`	`Edm.String`	No	Expiration of the assignment. The value is `Permanent` or an ISO 8601 UTC timestamp.
`PostExecutionMessage`	`Edm.String`	No	Result role assignment output container.

Parameters	Type	Mandatory	Description
			Empty when the operation fails before returning a result.
`PostExecutionMessage.MemberDetail`	`MemberDetail`	No	Member contained in the resulting assignment. Uses the same `MemberDetail` schema as the input.
`PostExecutionMessage.RoleGroupDetail`	`RoleGroupDetail`	No	Role group contained in the resulting assignment. Uses the same `RoleGroupDetail` schema as the input.
`PostExecutionMessage.ScopeDetail`	`ScopeDetail`	No	Scope contained in the resulting permission. Uses the same `ScopeDetail` schema as the input.
`PostExecutionMessage.ExceptionMessage`	`Edm.String`	No	Reserved field, currently `null`.
`PostExecutionMessage.ExpiresAt`	`Edm.String`	No	Expiration of the resulting assignment. The value is `Permanent` or an ISO 8601 UTC timestamp.

UpdatePermission Operation

Updates role assignment expiration in a role-group.

Parameters	Type	Mandatory	Description
`PreExecutionMessage`	`Edm.String`	Yes	Input container.
`PreExecutionMessage.MemberDetail`	`MemberDetail`	No	Member assigned to role group.
`PreExecutionMessage.MemberDetail.MemberId`	`Edm.Guid`	No	Identifier of the assigned member.
`PreExecutionMessage.MemberDetail.MemberType`	`Edm.String`	No	Member category, such as `User`, `SecurityGroup`, `ServicePrincipal`, `Application`.
`PreExecutionMessage.MemberDetail.MemberName`	`Edm.String`	No	Name of the assigned member.

Parameters	Type	Mandatory	Description
`PreExecutionMessage.MemberDetail.MemberDisplayName`	`Edm.String`	No	Display name of the assigned member.
`PreExecutionMessage.RoleGroupDetail`	`RoleGroupDetail`	No	Role group being assigned.
`PreExecutionMessage.RoleGroupDetail.RoleGroupId`	`Edm.Guid`	No	Identifier of the assigned role group.
`PreExecutionMessage.RoleGroupDetail.RoleGroupName`	`Edm.String`	No	Name of the assigned role group.
`PreExecutionMessage.ScopeDetail.ScopeId`	`Edm.Guid`	No	Identifier of the assigned scope.
`PreExecutionMessage.ScopeDetail.ScopeType`	`Edm.String`	No	Resource type of the assigned scope, such as `Case`.
`PreExecutionMessage.ScopeDetail.ScopeFeature`	`Edm.String`	No	Feature associated with the assigned scope, such as `InsiderRiskManagement`
`PreExecutionMessage.ScopeDetail.ScopePathById`	`Edm.String`	No	Resource path identifying the assigned scope.
`PreExecutionMessage.ExceptionMessage`	`Edm.String`	No	Reserved field, currently `null`.
`PreExecutionMessage.ExpiresAt`	`Edm.String`	No	Updated role assignment expiration. The value is `Permanent` or an ISO 8601 UTC timestamp.
`PostExecutionMessage`	`Edm.String`	No	Result role assignment output container.
`PostExecutionMessage.MemberDetail`	`MemberDetail`	No	Member contained in the resulting assignment. Uses the same `MemberDetail` schema as the input.
`PostExecutionMessage.RoleGroupDetail`	`RoleGroupDetail`	No	Role group contained in the resulting assignment. Uses the same `RoleGroupDetail` schema as the input.
`PostExecutionMessage.ScopeDetail`	`ScopeDetail`	No	Scope contained in the resulting permission.

Parameters	Type	Mandatory	Description
			Uses the same `ScopeDetail` schema as the input.
`PostExecutionMessage.ExceptionMessage`	`Edm.String`	No	Reserved field, currently `null`.
`PostExecutionMessage.ExpiresAt`	`Edm.String`	No	Expiration of the resulting assignment. The value is `Permanent` or an ISO 8601 UTC timestamp.

PurviewPostureAgent schema

Data Security Posture Agent events, returned in audit log searches use this schema (and also the Common schema).

PurviewPostureAgent schema

The PurviewPostureAgent audit schema is designed to capture and log activities related to the Data Security Posture Agent.

Parameters	Type	Mandatory?	Description
DiscoveryId	Edm.String	No	Unique identifier for the exploration event.
Scope	Collection(Self.PostureAgentSearchLocation)	No	Collection of search location information for the posture agent.
OldLabel	Edm.String	No	The previous label value before the change.
NewLabel	Edm.String	No	The new label value after the change.
FileName	Edm.String	No	The name of the file associated with the posture agent event.

PostureAgentSearchLocation complex type

Parameters	Type	Mandatory?	Description
Type	Edm.String	Yes	The type of the search location.
Id	Edm.String	Yes	The identifier of the search location.

Dragon Copilot Admin schema

Dragon Copilot admin events returned in audit log searches use this schema (and also the Common schema). These events have `RecordType` set to `DragonCopilotAdmin` (454).

For more information about Dragon Copilot, see the Dragon Copilot documentation.

Parameters	Type	Mandatory?	Description
EnvironmentId	Edm.String	No	The Dragon Copilot environment GUID. Enables customers to scope or filter audit logs by organizational unit. Only present for environment-scoped operations.
ProductType	Edm.String	No	The Dragon Copilot product the operation is scoped to. Possible values: `Physician`, `Nursing`, `Radiology`. Only present when the operation is product-scoped (for example, `ProvisionedProduct`, `DeprovisionedProduct`).
ModifiedProperties	Collection(Common.ModifiedProperty)	No	This property is included for certain admin events. The property includes the name of the property that was modified, the new value of the modified property, and the previous value of the modified property.

Microsoft Agent 365 schema

Microsoft Agent 365 events returned in audit log searches use the Common schema and the applicable event-specific schema described in this section.

AI Guardrail schema

AI guardrail events use this schema and the Common schema. These events have `RecordType` set to `AIGuardrail` (489) and `Operation` set to `AIGuardrailApplied`.

Parameters	Type	Mandatory?	Description
ContentInputId	Edm.String	No	The identifier of the content submitted to the guardrail for evaluation.
ContentModified	Edm.Boolean	No	Indicates whether the guardrail modified the evaluated content.

Parameters	Type	Mandatory?	Description
ContentOutputId	Edm.String	No	The identifier of the content produced after the guardrail evaluation.
ConversationId	Edm.String	No	The identifier of the conversation associated with the guardrail evaluation.
DecisionCode	Edm.String	No	The provider-specific code associated with the guardrail decision.
DecisionReason	Edm.String	No	The reason for the guardrail decision.
DecisionType	Self.DecisionType	Yes	The action selected by the guardrail after evaluating the content.
ExternalEventId	Edm.String	No	The identifier assigned to the event by the originating system or provider.
Findings	Collection(Self.AIGuardrailFinding)	No	The risks or policy findings identified during the guardrail evaluation.
GuardianId	Edm.String	Yes	The unique identifier of the guardrail that evaluated the content.
GuardianName	Edm.String	Yes	The name of the guardrail that evaluated the content.
GuardianVersion	Edm.String	No	The version of the guardrail that evaluated the content.
ParentSpanId	Edm.String	Yes	The identifier of the parent span in the distributed trace.
PlatformType	Edm.String	Yes	The platform on which the guardrail evaluation occurred.
PolicyId	Edm.String	No	The identifier of the policy applied during the evaluation.
PolicyName	Edm.String	No	The name of the policy applied during the evaluation.
PolicyVersion	Edm.String	No	The version of the policy applied during the evaluation.
ProviderName	Edm.String	Yes	The name of the provider that performed the guardrail evaluation.
SpanId	Edm.String	Yes	The identifier of the span representing the guardrail

Parameters	Type	Mandatory?	Description
			evaluation.
TargetId	Edm.String	No	The identifier of the resource or target evaluated by the guardrail.
TargetType	Edm.String	Yes	The type of resource or target evaluated by the guardrail.
TraceId	Edm.String	Yes	The identifier used to correlate the evaluation with other spans in the same distributed trace.
ContentId	Edm.String	No	A reference to the content associated with the guardrail event.

Complex Type AIGuardrailFinding

Parameters	Type	Mandatory?	Description
RiskCategory	Edm.String	Yes	The category of the risk identified by the guardrail.
RiskSeverity	Self.RiskSeverity	Yes	The severity assigned to the identified risk.
RiskScore	Edm.Double	No	The numeric score assigned to the identified risk.
RiskMetadata	Collection(Edm.String)	No	Additional metadata associated with the finding.
DecisionType	Self.DecisionType	Yes	The guardrail decision associated with the finding.
PolicyId	Edm.String	No	The identifier of the policy that generated the finding.
PolicyName	Edm.String	No	The name of the policy that generated the finding.
PolicyVersion	Edm.String	No	The version of the policy that generated the finding.

Enum: DecisionType - Type: Edm.Int32

DecisionType

Value	Member name	Description
0	block	The content or operation was blocked.
1	audit	The evaluation was recorded without blocking the content or operation.
2	allow	The content or operation was allowed.
3	warn	A warning was generated for the content or operation.
4	modify	The content was modified before it was allowed to continue.

Enum: RiskSeverity - Type: Edm.Int32

RiskSeverity

Value	Member name	Description
0	low	The finding has low severity.
1	medium	The finding has medium severity.
2	high	The finding has high severity.
3	critical	The finding has critical severity.
4	none	No risk severity was assigned.

People Skills schema

Extends the Common schema with the properties specific to People Skills (Viva) audit data. These properties apply to both the `PeopleSkillsAdmin` (476) and `PeopleSkillsUser` (477) record types. For more information about this feature, see People Skills documentation.

Parameters	Type	Mandatory?	Description
APIEndpoint	Edm.String	Yes	The originating API route or processor name for the operation.
RequestId	Edm.String	Yes	The per-request correlation id, present on every record.
SkillId	Edm.String	No	The identifier of the affected skill. Emitted for skill-scoped operations.
OperationCount	Edm.Int32	No	The count of affected items for the operation.
SourceApp	Edm.String	No	The originating client app or source of the operation.
ResponseTimeMs	Edm.Double	No	The server-side response time, in milliseconds.

Office 365 Management Activity API FAQs and troubleshooting

Article • 04/09/2025

The Office 365 Management Activity API (also known as the *Unified Auditing API*) is a part of Office 365 security and compliance offerings, that:

- Allows programmatic access to multiple auditing pipeline workloads (such as SharePoint and Exchange)
- Is the main interface used by a variety of third-party vendor products to aggregate and index auditing data

The Management Activity API shouldn't be confused with the Office 365 Service Communications API. The Management Activity API is for auditing end user activities in the various workloads. The Service Communications API is for auditing status and messages that are sent by the services that are available in Office 365 (such as Dynamics CRM or Identity Service).

Frequently asked questions about the Office 365 Management Activity API

How do I onboard to the Management Activity API?

To get started with the Office 365 Management Activity API, see Get started with Office 365 Management APIs.

What happens if I disable auditing for my Office 365 organization? Will I still get events via the Management Activity API?

No. Office 365 unified auditing must be enabled for your organization to pull records via the Management Activity API. For instructions, see Turn audit log search on or off.

What events are audited for a specific Office 365 service?

Office 365 Management Activity API schema documentation has a comprehensive list of events. For details, see Office 365 Management Activity API schema. Also see the "Audited activities" section in Search the audit log in the Security & Compliance Center for a list of events for most of the Office 365 services that are audited.

Are there any differences in the records that are fetched by the Management Activity API versus the records that are returned by using the audit log search tool in the Microsoft

Purview compliance portal?

The data that is returned by both methods is the same. The only difference is that with the API, you can get data for the last 7 days only (more details in the questions below). When searching the audit log in the Security & Compliance Center (or by using the corresponding **Search-UnifiedAuditLog** cmdlet in Exchange Online PowerShell), you can get data for the retention period in effect when the data is generated (for example, 90 days or one year).

What is the maximum time I will have to wait before a notification is sent about a given Office 365 event?

There is no guaranteed maximum latency for notification delivery (in other words, there is no SLA). Typically, most notifications are sent within one hour of the event. Often the latency is much shorter, but this period might be longer since this varies from workload to workload.

How long before events show within the Office 365 service?

The Office 365 Audit service doesn't guarantee a specified time when events will be delivered. Audit tries to deliver data as quickly as possible. However, some issues may arise (such as server outages) upstream from the Audit service and are unavoidable. Because audit events are often used for forensic investigations, Microsoft prioritizes data completeness over latency. For core services (such as Exchange, SharePoint, OneDrive, and Teams) event availability is typically 60 to 90 minutes. For other services, event availability may be longer. While these are typical event delivery times, we acknowledge that anomalies may occur. For these reasons, Microsoft doesn't commit to a specific delivery time.

Aren't webhook notifications more immediate?

No. Recently, there have been longer wait times for notifications when using a webhook compared to querying the API directly with the `/content` operation.

How long will the content remain available to fetch via the API?

Content is available to fetch via the API for 7 days after the notification of the content availability. Even if the notification is delayed for an unusually long period (for example, in the case of a service interruption), you would still have 7 days after the first availability of the notification to download the content blob related to the originating event.

Can I query the Management Activity API for a particular event ID or RecordType or other properties in the content blob?

No. The Management Activity API provides all the event details for a particular log. It can be used to download the entire details, and then you can implement your own query logic on the downloaded data; for example, by using a custom application or a third-party tool.

How do I know the data coming from my existing auditing solution, which collects data from the Management Activity API, is accurate and complete?

The short answer is that Microsoft doesn't provide any kind of a log that allows you to cross-check any given application or third-party (ISV) application. There are other Microsoft security products that obtain their data from the same pipeline, but those products fall outside the scope of this discussion and can't be used to directly cross-check the Management Activity API. If you're concerned about discrepancies between what your existing solution is providing and what you expect, you should implement the operations illustrated above. But this can be difficult, depending on how your existing tool or solution lists and indexes data. If your existing solution only presents data sorted by the creation time of the actual event, there's no way to query the API by event creation time so that you can compare result sets. In this scenario, you'd have to collect the notified content blobs for several days, index or sort them manually, and then do a manual comparison.

What is the throttling limit for the Management Activity API?

All organizations are initially allocated a baseline of 2,000 requests per minute. The throttling limit is then adjusted based on a combination of factors, including the number of seats in the organization. Also, Office 365 E5 and Microsoft 365 E5 organizations will get approximately twice as much bandwidth as non-E5 organizations. There will also be cap on the maximum bandwidth to protect the health of the service.

> ⓘ **Note**
>
> Even though each tenant can initially submit up to 2,000 requests per minute, Microsoft cannot guarantee a response rate. The response rate depends on various factors, such as client system performance, network capacity, and network speed.

I'm encountering a throttling error in the Management Activity API. What should I do?

Open a ticket with Microsoft Support and request a new throttling limit, and include a business justification for increasing the limit. We will evaluate the request, and if accepted, we will increase the throttling limit.

Why are TargetUpdatedProperties no longer in ExtendedProperties in the audit logs for Microsoft Entra activities?

TargetUpdatedProperties were appearing in ExtendedProperties. However, they have been removed from ExtendedProperties and now appear in ModifiedProperties.

Why aren't audit logs with UserAccountNotFound "LogonError" for Microsoft Entra sign-in activities available via the Management Activity API?

Starting in November 2020, audit logs for Microsoft Entra sign-in activities are ingested into the unified audit log from Microsoft Entra Event Hubs. As a result of this change, populating the "LogonError" property with the UserAccountNotFound value is not possible. Starting the first week of February 2021, the ErrorCode property in the Microsoft Entra logon auditing schema now matches AADSTS error codes. Also, the UserId parameter will not be populated with the user name from the attempted login for UserAccountNotFound errors because that user name doesn't exist in the organization's Microsoft Entra directory.

I can see duplicate audit logs when using the Management Activity API. Why is this happening?

This duplication of events is an expected and designed behavior intended to prevent the loss of any audit events. When an error is encountered by an audit event, the audit service retries the process, which may result in duplicate audit events being generated and stored in the audit log storage(s). While exporting audit search results using the UI from the Microsoft Purview portal automatically removes duplicates, the Office 365 Management Activity API does not have this de-duplication feature. Consequently, duplicates may appear in the results returned by the Office 365 Management Activity API. It is the responsibility of the SIEM solution to implement logic to remove such duplicated events upon ingestion.

Troubleshooting the Office 365 Management Activity API

One thing that should be made clear for anyone who's getting started with the Office 365 Management Activity API is that there is no concept of querying by event specifics, such as date that the event occurred, which site collection an event might have been fired from, or the type of event. Instead, you create subscriptions to specific workloads (for example, SharePoint or Microsoft Entra ID) and each subscription is per tenant.

The following sections summarizes the most common questions that customers have in using the Office 365 Management Activity API:

- Questions about third-party tools and clients
- Enable unified audit logging in Office 365
- Connect to the API
- Check your subscriptions
- Create a new subscription
- Check content availability

- Use webhooks
- Request content blobs and throttling
- Service tags

We'll show a selection of simple PowerShell scripts that can help you answer the most common questions asked by customers or get you started implementing a custom solution by demonstrating the main operations. Not all the operations are explained in these sections, but they are all listed in Office 365 Management Activity API reference.

Questions about third-party tools and clients

The most common category of questions come from customers using third-party products to download and aggregate auditing data. Depending on the third-party product, customers may encounter difficulty with the setup or experience an interruption or an inconsistency in the data exposed in those products. Here it should be stated that the first action such customers should take is to contact their vendor's support organization. Typically, a tenant-specific vendor configuration or service problem is the cause of customer complaints.

Enable unified audit logging in Office 365

If you've just set up an app that's trying to use the Management Activity API and it's not working, be sure that you've enabled unified audit logging for your Office 365 organization. You do this by turning on the Office 365 audit log. For instructions, see Turn Office 365 audit log search on or off.

> **Note**
>
> The unified audit log configuration change can take up to 60 minutes to take effect.

If unified auditing isn't enabled, you'll typically receive an error that contains the following string: `Microsoft.Office.Compliance.Audit``.DataServiceException: Tenant <tenantID> does not exist.`

Connect to the API

Most applications connect to the API using a straightforward Client Credentials OAuth2 flow. Therefore, the first step is to create a Microsoft Entra application that has the permissions needed to access the Management Activity API data. It's outside the scope of this article to

explain the steps to create a Microsoft Entra App registration. For more information, see Register your application with your Microsoft Entra tenant.

Azure application permissions

The three permissions currently used for the Office 365 Management Activity API are:

1. Read activity data for your organization
2. Read service health information for your organization
3. Read Data Loss Prevention (DLP) policy events, including detected sensitive information

> **Note**
>
> You should enable both the Application Permissions and the Delegated Permissions for at least the first two of the above permission sets. Read DLP policy events will only be necessary if you are interested in the DLP workloads.

Get an access token

The following PowerShell script uses the App ID and a Client Secret to obtain the OAuth2 token from the Management Activity API authentication endpoint. It then places the access token into the `$headerParams` array variable, which you'll attach to your HTTP request. For the value for the API endpoint (in the $resource variable) use one of the following values based on your organization's Microsoft 365 or Office 365 subscription plan:

- Enterprise plan: `manage.office.com`
- GCC government plan: `manage-gcc.office.com`
- GCC High government plan: `manage.office365.us`
- DoD government plan: `manage.protection.apps.mil`

PowerShell

```
# Create app of type Web app / API in Azure AD, generate a Client Secret, and
update the client id and client secret here
$ClientID = "<YOUR_APPLICATION_ID"
$ClientSecret = "<YOUR_CLIENT_SECRET>"
$loginURL = "https://login.microsoftonline.com/"
$tenantdomain = "<YOUR_DOMAIN>.onmicrosoft.com"
# Get the tenant GUID from Properties | Directory ID under the Azure Active
Directory section. For $resource, use one of these endpoint values based on your
```

```
subscription plan: Enterprise - manage.office.com; GCC - manage-gcc.office.com;
GCC High: manage.office365.us; DoD: manage.protection.apps.mil
$TenantGUID = "<YOUR_TENANT_GUID>"
$resource = "https://<YOUR_API_ENDPOINT>"
# auth
$body =
@{grant_type="client_credentials";resource=$resource;client_id=$ClientID;client_se
cret=$ClientSecret}
$oauth = Invoke-RestMethod -Method Post -Uri $loginURL/$tenantdomain/oauth2/token?
api-version=1.0 -Body $body
$headerParams = @{'Authorization'="$($oauth.token_type) $($oauth.access_token)"}
```

The `$oauth` variable will contain the response object, which has several properties including the access token. Here's an example of a response:

JSON

```
token_type     : Bearer
expires_in     : 3599
ext_expires_in : 0
expires_on     : 1508285860
not_before     : 1508281960
resource       : https://manage.office.com
access_token   :
eyJ0eXAiOiJKV1QiLCJhbGciOiJSUzI1NiIsIng1dCI6IjJLVmN1enFBaWRPTHFXU2FvbDd3Z0ZSR0NZby
IsImtpZCI6IjJLVmN1enFBaWRPTHFXU2FvbDd3Z0ZSR0NZbyJ9.eyJhdWQiOiJodHRwczov…
```

Check your subscriptions

If you've experienced an interruption in data flowing to an existing Management Activity API client or solution, you might wonder if something happened to your subscription. To check your active subscriptions, add the following to the previous script:

PowerShell

```
Invoke-WebRequest -Headers $headerParams -Uri
"$resource/api/v1.0/$tenantGUID/activity/feed/subscriptions/list"
```

Sample response

JSON

```
StatusCode        : 200
Status Description : OK
Content           :
[{"contentType":"Audit.Exchange","status":"enabled","webhook":null},
{"contentType":"Audit.SharePoint","status":"enabled","webhook":
```

```
{"authId":"","address":"https://mvcwebapiwebhookreceiver.azurewebsite...
RawContent        : HTTP/1.1 200 OK
                    Pragma: no-cache
                    Content-Length: 266
                    Cache-Control: no-cache
                    Content-Type: application/json; charset=utf-8
                    Expires: -1
                    Server: Microsoft-IIS/8.5,Microsoft-IIS/8.5
                    X-AspNet-Versi...
Forms             : {}
Headers           : {[Pragma, no-cache], [Content-Length, 266], [Cache-Control,
no-cache], [Content-Type, application/json; charset=utf-8]...}
Images            : {}
InputFields       : {}
Links             : {}
ParsedHtml        : mshtml.HTMLDocumentClass
RawContentLength  : 266
```

This says that the tenant has both Audit.Exchange and Audit.SharePoint subscriptions enabled. The Exchange subscription has no webhook enabled (null) and the SharePoint subscription has a webhook enabled with the address of the registered endpoint shown.

Create a new subscription

To create a new subscription, you use the /start operation. For the API endpoint, use one of these values base on your subscription plan:

- Enterprise plan: `manage.office.com`
- GCC government plan: `manage-gcc.office.com`
- GCC High government plan: `manage.office365.us`
- DoD government plan: `manage.protection.apps.mil`

PowerShell

```
Invoke-WebRequest -Method Post -Headers $headerParams -Uri
"https://<YOUR_API_ENDPOINT>/api/v1.0/$tenantGUID/activity/feed/subscriptions/star
t?contentType=Audit.AzureActiveDirectory"
```

> **Note**
>
> Remember that `$headerParams` was populated in the first part of the script listed in the Connect to the API section in this article.

The previous code will create a new subscription to the Audit.AzureActiveDirectory content type, with a webhook that is null. You can then check your subscriptions using the code in the Check your subscriptions section in this article.

Check content availability

To check what content blobs were created during a certain period, you can add the following line to the script in the "Connecting to the API" section.

PowerShell

```
Invoke-WebRequest -Method GET -Headers $headerParams -Uri
"$resource/api/v1.0/$tenantGUID/activity/feed/subscriptions/content?
contentType=Audit.SharePoint"
```

The previous example will get all the content notifications that became available today, which means from 12:00 AM UTC to the current time. If you want to specify a different time period (keeping in mind that the maximum period for which you can query is 24 hours), add the *starttime* and *endtime* parameters to the URI; for example:

PowerShell

```
Invoke-WebRequest -Method GET -Headers $headerParams -Uri
"$resource/api/v1.0/$tenantGUID/activity/feed/subscriptions/content?
contentType=Audit.SharePoint&startTime=2017-10-13T00:00&endTime=2017-10-13T11:59"
```

> **Note**
>
> You must use either both *starttime* and *endtime* parameters or neither.

JSON

```
[{      "contentUri" :
"https://<your_API_endpoint>/api/v1.0/<your_tenant_guid>/activity/feed/audit/20171
014180051748005825$20171014180051748005825$audit_sharepoint$Audit_SharePoint",
        "contentId" :
"20171014180051748005825$20171014180051748005825$audit_sharepoint$Audit_SharePoint
",
        "contentType" : "Audit.SharePoint",
        "contentCreated" : "2017-10-13T18:00:51.748Z",
        "contentExpiration" : "2017-10-20T18:00:51.748Z",
}]
```

> **ⓘ Important**
>
> - The *contentUri* property is the URI from which you can retrieve the content blob. The blob itself is what contains the event details; it will contain details about 1 – N events. While there may be 30 JSON objects in the collection, there may be many more events detailed in those 30 content URIs.
> - The *contentCreated* property is not the date that the event being notified was created. This is the date the notification was created. The events detailed in that blob may have been created well before the content blob was created. Therefore, you can never query the API directly for events that occurred within any given period.

Page contents for busy tenants

Many larger Office 365 tenants have thousands of events being generated every hour. If this is the case with your organization, and you try to execute a query for a 24-hour period like in the example above, you may need to retrieve more notifications than can be returned in one response. In this case, you'll need to implement a logical loop of some kind, each time checking the response headers for the **NextPageUrl:** header value. See the Pagination section in the Office 365 Management Activity API reference for more details.

PowerShell

```
IF the NextPageUrl header is present in the response...

THEN issue a new request substituting the Uri parameter in the above Invoke-
WebRequest example for the value of the NextPageUrl header...

ELSE exit the loop
```

It will be difficult to test this looping code unless you have a very active tenant. In our testing, we tried to execute several thousand update operations in a script and was unable to generate a large enough number of notifications to require the **NextPageUrl** header to be sent.

Use webhooks

There two ways to get a notification that content blobs have been created. The *push* approach is implemented with a webhook endpoint, which is a web application that you create and host yourself or on a cloud platform. You register the webhook at the time you create a subscription to an audited content type. You may also add a webhook registration to an existing

subscription using the approach shown below. The *pull* approach requires you to query for a particular timespan (no more than 24 hours) using the /content operation. The response will tell you which content blobs were created during the period specified.

Before you add a webhook, be aware of the following two issues:

1. Webhooks are being de-emphasized by Microsoft because of the difficulty in debugging and troubleshooting. Typically, you would host a WebApi endpoint that responds to incoming requests. Many customers either use hosting environments (which they don't have full control over) or on-premises environments (that have difficulty allowing incoming HTTP requests). Support has seen many problems where the incoming requests from the Office 365 auditing pipeline have been blocked by a firewall or router. In this case, the API will implement a back-off algorithm, which can be confusing and may result in disabling the webhook in the subscription.

2. The webhook must be ready to immediately respond to a validation request after the start operation is executed. If there is a bug in the webhook application, the validation will fail, and the webhook will not be enabled. For information about the validation request schema, see the Webhook validation section in the Office 365 Management Activity API reference. You should seriously consider the challenges in producing a production-ready webhook to respond to Management Activity API notifications.

If you decide to implement a webhook, it should be tested to verify that the endpoint is prepared to respond with an HTTP 200 response to both the validation request and the normal notification requests before any /start operation that specifies a webhook endpoint is called for the first time. Typically, you would use a mocked request from the API to test this readiness. Carefully read and observe both the Webhook validation and Retrieving content sections in the Office 365 Management Activity API reference to understand the schema of these two types of requests.

To add a subscription with a webhook endpoint, add a body parameter to the POST to the /start endpoint; for example:

JSON

```
$body = '{
    "webhook" : {
        "address": "https://webhook.myapp.com/o365/",
        "authId": "o365activityapinotification",
        "expiration": ""
    }}'
$uri =
"https://manage.office.com/api/v1.0/$tenantGUID/activity/feed//subscriptions/start
?contentType=Audit.SharePoint"
Invoke-RestMethod -Method Post -uri $uri -Headers $headerParams -Body $body
```

Immediately following this call, a validation request will be sent out to `https://webhook.myapp.com/o365/ …` and there should be a listener ready to respond, as per the description in the Webhook validation section in the Office 365 Management Activity API reference. Your listener must respond with HTTP 200. If you immediately run the /list operation at this point, you'll not see the webhook shown as other than null until the validation has returned successfully.

Check notifications to webhooks

It's important to distinguish between the /notifications operation and the /content operation. Checking notifications is only relevant if you have subscribed with a webhook endpoint. This operation will let you know if attempts to send notifications to your webhook have been successful or not. This operation should not be used to list available content. To cross-check the availability of content against what you may have already received in your webhook, you would use the /content operation. But be sure to first check for failed notifications using the /notifications operation.

Request content blobs and throttling

After you've obtained a list of content URIs, you must request the blobs specified by the URIs. The following is an example of requesting a content blob (using the manage.office.com API endpoint for Enterprise organizations) using PowerShell. This example assumes you have already used the previous example in the Get an access token section in this article to get an access token and have populated the `$headerParams` variable appropriately.

PowerShell

```
# Get a content blob
$uri = 'https://manage.office.com/api/v1.0/<<your-tenant-
guid>>/activity/feed/audit/<<ContentID>$audit_sharepoint$Audit_SharePoint'
$contents = Invoke-WebRequest -Method GET -Headers $headerParams -Uri $uri
```

Note the following things about the *$uri* variable in the previous example:

- We used single quotes so that the *$* symbols aren't interpreted as variables in PowerShell
- The entire URI will be returned in the *contentUri* property of the response to your previous call to the /content endpoint. The placeholder tokens shown are just for illustration.

When attempting to retrieve the available content blobs, many customers (mostly working with busy tenants) have experienced errors that look like this:

JSON

```
Response Code 403: {'error':{'code':'AF429','message':'Too many requests.
Method=GetBlob, PublisherId=00000000-0000-0000-0000-000000000000'}}
```

This is likely due to throttling. Note that the value of the PublisherId parameter likely indicates that the client didn't specify the *PublisherIdentifier* in the request. Also, keep in mind that the correct parameter name is *PublisherIdentifier* even though you see *PublisherId* listed in the 403 error responses.

> **Note**
>
> In the API reference, the *PublisherIdentifier* parameter is listed in every operation of the API, but it should also be included in the GET request to the contentUri URL when retrieving the content blob.

If you're doing simple API calls to troubleshoot problems (for example, checking if a given subscription is active) you can safely omit the *PublisherIdentifier* parameter, but absolutely any code that is eventually meant for production use should include the *PublisherIdentifier* parameter on every call.

If you're implementing a client for your company's tenant, the *PublisherIdentifier* is the Tenant GUID. If you are creating an ISV application or add-in for multiple customers, the *PublisherIdentifier* should be the ISV's Tenant GUID, and not the tenant GUID of end user's company.

If you include the valid *PublisherIdentifier*, then you'll be in a pool that is allotted 60K requests per minute per tenant. This is an exceptionally large number of requests. However, if you don't include the *PublisherIdentifier* parameter, you'll be in the general pool allotted 60K requests per minute for all tenants. In this case, you'll more than likely find that your calls are getting throttled. To prevent this, here's how you would request a content blob using the *PublisherIdentifier*:

JSON

```
$contentUri = ($response.Content | ConvertFrom-Json).contentUri[0]
$uri = $contentUri + '?PublisherIdentifier=82b24b6d-0591-4604-827b-705d55d0992f'
$contents = Invoke-WebRequest -Method GET -Headers $headerParams -Uri $uri
```

The previous example assumes that the *$response* variable was populated with the response to a request to the /content endpoint and that the *$headerParams* variable includes a valid access token. The script grabs the first item in the array of content URIs from the response and then

invokes the GET to download that blob and put it in the *$contents* variable. Your code will likely loop through the contentUri collection, issuing the GET for each *contentUri*.

Service tags

The Office 365 Management Activity API and Office 365 Management Activity API Webhook now support service tags to find the required IP address prefixes that need to be allowed through the firewall. A service tag represents a pre-defined group of IP address prefixes that is managed and updated by Microsoft. Service tags help minimize the complexity for security rule creation.

The following service tags include the IP address prefixes that support the Office 365 Management Activity API and Office 365 Management Activity API Webhook:

- M365ManagementActivityApi
- M365ManagementActivityApiWebhook

For a list of the IP address prefixes that are encompassed by previous service tags, download one of the following files:

- Microsoft Azure IP Ranges and Service Tags – Public Cloud
- Microsoft Azure IP Ranges and Service Tags – US Government Cloud
- Microsoft Azure IP Ranges and Service Tags – China Cloud

After you download the appropriate file, search for the strings "M365ManagementActivityApi" and "M365ManagementActivityApiWebhook" to find the section that contains the IP address prefixes for each service tag.

Configure service tags for network security groups

You can use Az or AzureRM PowerShell cmdlets to set the network security group rule with service tag. You can configure security group rules with service tags, and then add those rules to a new network security group. A few resources, such as Azure Functions, also provide a service tag option to configure network security groups using the Azure portal

For information about using Az or AzureRM PowerShell to set up network security rules and network security groups, see:

- New-AzNetworkSecurityRuleConfig
- New-AzNetworkSecurityGroup

Here's an example of a AzureRM PowerShell script that restricts outbound traffic to all IP address prefixes except for the ones included in M365ManagementActivityApi service tag. The example script creates two outbound network security group rules. The first one allows outbound traffic to the IP address prefixes included in the M365ManagementActivityApi service tag. The second one denies outbound traffic to the Internet. The rules are then added to a network security group, which can then be configured to specific Azure services.

PowerShell

```
$allowMyServiceRule = New-AzureRmNetworkSecurityRuleConfig ` -Name
"AllowMyService"  -Access Allow  -Protocol Tcp  -Direction Outbound  -Priority 100
-DestinationAddressPrefix M365ManagementActivityApi  -SourcePortRange * -
SourceAddressPrefix * -DestinationPortRange *
$denyInternetRule = New-AzureRmNetworkSecurityRuleConfig -Name "denyInternetOut" -
Access Deny `
-Protocol Tcp -Direction Outbound  -Priority 4000 -DestinationAddressPrefix
Internet -SourcePortRange * -SourceAddressPrefix * -DestinationPortRange *
$nsg = New-AzureRmNetworkSecurityGroup `
-ResourceGroupName $resourceGroupName `
-Location $location `
-Name $nsgName `
-SecurityRules $denyInternetRule,$allowMyServiceRule
```

An inbound rule to accept traffic only from M365ManagementActivityApiWebhook can be configured in a similar way.

Communication Compliance

08/20/2025

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Protecting sensitive information and detecting and acting on workplace harassment incidents is an important part of compliance with internal policies and standards. Microsoft Purview Communication Compliance helps minimize these risks by helping you quickly detect, capture, and take remediation actions for email, Microsoft Teams communications, Microsoft 365 Copilot, and Microsoft 365 Copilot Chat interactions. These communications can include potentially inappropriate communications containing profanity, threats, and harassment and communications that share sensitive information inside and outside of your organization.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Microsoft Purview Communication Compliance is an insider risk solution that helps you detect, capture, and act on inappropriate messages that can lead to potential data security or compliance incidents within your organization. Communication Compliance evaluates text and image-based messages in Microsoft and third-party apps (Teams, Microsoft 365 Copilot and Microsoft 365 Copilot Chat, Viva Engage, Outlook, WhatsApp, and others) for potential business policy violations including inappropriate sharing of sensitive information, threatening or harassing language, and potential regulatory violations such as stock and capital manipulations.

Communication Compliance's mission is to foster safe and compliant communications across customers' enterprise communication channels. With role-based access controls, human

investigators can take remediation actions such as removing a message from Teams or notifying senders of potentially inappropriate conduct.

System capabilities

> **Important**
>
> Microsoft is committed to making sure artificial intelligence (AI) systems are developed responsibly and in ways that warrant people's trust. As part of this commitment, Microsoft Purview engineering teams are operationalizing the six core principles of Microsoft's Responsible AI strategy to design, build, and manage AI solutions. As part of our effort to responsibly deploy AI, we provide documentation, role-based access, scenario attestation, and more to help organizations use AI systems responsibly.

Communication Compliance uses machine learning models and keyword matching to identify messages containing potential business conduct or regulatory policy violations that an investigator reviews. Communication Compliance cultivates user privacy with pseudonymization and responsible use of the product by providing role-based access controls.

Users get permissions that allow them to perform the tasks in their role, such as:

- **Administrator role**: Administrators configure policies to detect specific patterns in an organization. Admins choose which machine learning classifiers to include in policies and can use the value of machine learning classifiers alongside keyword and phrase matching to meet organizational needs.
- **Investigator role**: Investigators view and remediate potentially risky messages flagged by built-in classifiers. Investigators have a range of actions they can take to address the displayed message and no automatic actions are taken without manual investigator review. Investigators can share feedback on messages misclassified by Microsoft classifiers via the *Report as Misclassified* action, which aims to continually improve classifier performance through customer submitted feedback.
- **Communication Compliance role**: Communication Compliance role can create policies for the organization and review policy matches for every policy.

Intended uses of Communication Compliance

> **Important**
>
> Microsoft Purview Communication Compliance provides built-in machine learning tools for detecting messages that might violate regulatory, code of conduct, or organizational

requirements. Users can choose built-in classifiers during policy configuration to evaluate organization communications. Admins can edit policy settings at any time according to organizational needs. Built with privacy by design, Microsoft doesn't receive any customer data or evaluations unless your organization's investigators explicitly consent to the *Report as Misclassified* action.

Communication Compliance empowers organizations to detect, triage, and remediate communications with potential business conduct and regulatory compliance violations. Communication Compliance provides the following policy templates that use machine learning classifiers for users:

- **Business conduct**: Discrimination, Profanity, Threat, and Targeted harassment classifiers
- **Regulatory compliance**: Corporate sabotage, customer complaints, gifts & entertainment, money laundering, regulatory collusion, stock manipulation, unauthorized disclosure classifiers

Metrics used to evaluate and measure performance

Communication Compliance considers many metrics to holistically evaluate system accuracy and performance. False positive rates and true positive rates (also known as recall rates) from test data sets are two of the most important metrics that inform the classifier's performance. Quantitative metrics, such as the number of hits, and qualitative feedback from customers also help evaluate performance and improve the classifiers.

Operational factors and settings

Operational factors and settings allow for effective and responsible use of the system. The following table details these factors and settings:

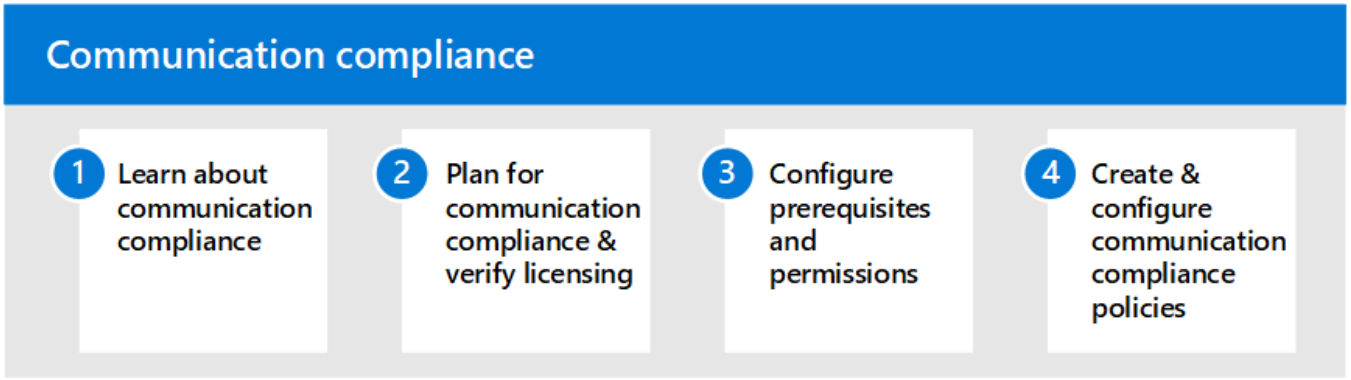
Expand table

Operational factor	Benefits
Role-based access control	- No individual has too much power to influence usage of Communication Compliance in the organization: - Investigators can only view policies they have permission to view - Administrators can only create and edit policies - Communication Compliance role has the most widespread permissions to view and edit policies.
Using multiple conditions in a policy	You can fine-tune the value from machine learning classifiers with other capabilities such as key phrase matching, detection of sensitive

Operational factor	Benefits
	information, or scoping to specific domains.
End user reporting of inappropriate content in Teams	Message recipients can report messages they find inappropriate or deem a data security incident as a proactive approach to identifying communication risks.
Keyword highlighting of messages caught by built-in classifiers	Investigators gain clarity on which key phrases trigger which classifiers.
Pseudonymization	Sender and recipient aliases are pseudonymized to minimize investigation bias.
Users choose which communication channels to detect for patterns in	Users can choose which channels, such as Microsoft Teams, Exchange, Viva Engage, or third-party sources, to identify and detect content patterns.
Feedback loop to report misclassified items	Items misclassified by machine learning classifiers can be reported to Microsoft to improve future performance of classifiers. User privacy is honored as per the Microsoft Privacy Statement.

Limitations of Communication Compliance

Every artificial intelligence solution has limitations. You can minimize the impact of these limitations when using Communication Compliance. The following table describes these limitations.



Expand table

Limitations	Impacted users	Ways to minimize impact
False positive messages	Message senders	- Communications compliance uses a feedback loop to report misclassified items to continually improve classifier performance. - Human reviewers must view message before action is taken.
False negative messages	Admins and message recipients	Machine learning classifiers can be combined with multiple conditions such as key phrase matching or user scoping to satisfy unique organizational needs.
Limited support for evasive typing and other adversarial inputs	Message recipients	Basic evasive typing coverage is provided to address swapping letters with numbers with improvements to come in future releases.
Not all languages covered	Message	12 languages supported today corresponding to highest

Limitations	Impacted users	Ways to minimize impact
	recipients	usage regions.

Configure Communication Compliance

Use the following steps to configure Communication Compliance for your organization:

1. Learn about Communication Compliance
2. Plan for Communication Compliance and verify licensing
3. Configure prerequisites and permissions
4. Create and configure Communication Compliance policies

More information about Communication Compliance

- Investigate and remediate alerts
- Case study: Contoso quickly configures an inappropriate content policy for Microsoft Teams, Exchange, and Viva Engage communications

Learn about Communication Compliance

07/18/2025

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Microsoft Purview Communication Compliance is an insider risk solution that helps minimize communication risks by helping you detect, capture, and act on potentially inappropriate messages in your organization. Predefined and custom policies allow you to check internal and external communications for policy matches so they can be examined by designated reviewers. Reviewers can investigate email, Microsoft Teams, Microsoft 365 Copilot and Microsoft 365 Copilot Chat, Viva Engage, or third-party communications in your organization and take appropriate actions to make sure they're compliant with your organization's message standards.

Communication Compliance policies in Microsoft 365 help you overcome many modern challenges associated with compliance and internal and external communications, including:

- Checking increasing types of communication channels
- The increasing volume of message data
- Regulatory enforcement and the risk of fines

Additionally, there may be a separation of duties between your IT admins and your compliance management team. Communication Compliance supports the separation between configuration of policies and the investigation and review of messages. For example, the IT group for your organization may be responsible for setting up Communication Compliance role permissions, groups, and policies and investigators and reviewers may be responsible for message triage, review, and mitigation actions.

For more information and an overview of the planning process to address compliance and risky activities in your organization, see Starting an Insider Risk Management program.

Watch the following video to learn how to fulfill regulatory compliance requirements with Communication Compliance:

https://learn-video.azurefd.net/vod/player?id=bf50d9ad-7ecb-4d3c-b0ec-0d9b1f3f7dcd&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance

> **Important**
>
> Communication Compliance is currently available in tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that Communication Compliance is supported for your organization, see Azure dependency availability by country/region.

Scenarios for Communication Compliance

Communication Compliance policies can assist with reviewing messages in your organization in several important compliance areas:

- **Corporate policies**

  Users must comply with acceptable use, ethical standards, and other corporate policies in all their business-related communications. Communication Compliance policies can detect policy matches and help you take corrective actions to help mitigate these types of incidents. For example, you could check user communications in your organization for human resources concerns such as harassment or the use of potentially inappropriate or offensive language.

- **Risk management**

  Organizations are responsible to all communications distributed throughout their infrastructure and corporate network systems. Using Communication Compliance policies to help identify and manage potential legal exposure and risk can help minimize risks before they can damage corporate operations. For example, you could check messages in your organization for unauthorized communications and conflicts of interest about confidential projects such as upcoming acquisitions, mergers, earnings disclosures, reorganizations, or leadership team changes.

- **Regulatory compliance**

  Most organizations must comply with some type of regulatory compliance standards as part of their normal operating procedures. These regulations often require organizations to implement some type of scoping or oversight process for messaging that is appropriate for their industry. The Financial Industry Regulatory Authority (FINRA) Rule 3110 is a good example of a requirement for organizations to have scoping procedures in place to check user communications and the types of businesses in which it engages. Another example may be a need to review broker-dealer communications in your organization to safeguard against potential insider trading, collusion, or bribery activities. Communication Compliance policies can help your organization meet these requirements by providing a process to both analyze and report on corporate communications. For more information on support for financial organizations, see Key compliance and security considerations for US banking and capital markets.

Key feature areas

Communication Compliance offers several important features to help address compliance concerns on your messaging platforms:

- Intelligent customizable templates
- Flexible remediation workflows
- Actionable insights

Intelligent customizable templates

Intelligent customizable templates in Communication Compliance allow you to apply machine learning to intelligently detect communication violations in your organization.

- **Customizable pre-configured templates**: Policy templates help address the most common communications risks. Initial policy creation and follow-on updating are now quicker with predefined templates to analyze and mitigate potentially inappropriate content, sensitive information, conflict of interest, and regulatory compliance issues.
- **New machine learning support**: Built-in classifiers to analyze and mitigate discrimination, threats, harassment, profanity, and potentially inappropriate images and help reduce misclassified content in communication messages, saving reviewers time during the investigation and remediation process.
- **Improved condition builder**: Configure policy conditions that are now streamlined into a single, integrated experience in the policy workflow, reducing confusion in how conditions are applied for policies.

Flexible remediation workflows

Built-in remediation workflows allow you to quickly identify and take action on messages with policy matches in your organization. The following new features increase efficiency for investigation and remediation activities:

- **Flexible remediation workflow**: New remediation workflow helps you quickly take action on policy matches, including new options to escalate messages to other reviewers and to send email notifications to users with policy matches.
- **Conversation policy matching**: Messages in conversations are grouped by policy matches to give you more visibility about how conversations relate to your communication policies. For example, conversation policy matching in the **Pending** tab will automatically show all messages in a Teams channel that have matches for your communications policies for analyzing and mitigating potentially inappropriate messages. Other messages in conversations that don't match your communications policies wouldn't be displayed.
- **Keyword highlighting**: Terms matching policy conditions are highlighted in the message text view to help reviewers quickly analyze and remediate policy alerts.
- **Optical character recognition (OCR)**: Check, detect, and investigate printed and handwritten text within images embedded or attached to email or Microsoft Teams chat messages.
- **New filters**: Investigate and remediate policy alerts faster with message filters for several fields, including sender, recipient, date, domains, and many more.
- **Improved message views**: Investigation and remediation actions are now quicker with new message source and text views. Message attachments are now viewable to provide complete context when taking remediation actions.
- **User history**: Historical view of all user message remediation activities, such as past notifications and escalations for policy matches, now provides reviewers with more context during the remediation workflow process. First-time or repeat instances of policy matches for users are now archived and easily viewable.
- **Pattern detected notification**: Many harassing and bullying actions take place over time and involve reoccurring instances of the same behavior by a user. The pattern detected notification displayed in alert details helps raise attention to these alerts and this type of behavior.
- **Translation**: Quickly investigate message details in eight languages using translate support in the remediation workflow. Messages in other languages are automatically converted to the display language of the reviewer.
- **Attachment detection**: Check, detect, and investigate linked content (Modern attachments) from OneDrive and Microsoft Teams that match policy classifiers and conditions for Microsoft Teams messages. Attachment content is automatically extracted to a text file for detailed review and action.

- **Summarize message content for policy matches**: Save time for investigators by using Microsoft Copilot in Microsoft Purview to summarize lengthy Teams, email, or Viva Engage messages. Copilot in Microsoft Purview creates a summary of the conversation, including recordings, meeting transcripts, and attachments.

Actionable insights

New interactive dashboards for alerts, policy matches, actions, and trends help you quickly view the status of pending and resolved alerts in your organization.

- **Proactive intelligent alerts**: Alerts for policy matches requiring immediate attention include new dashboards for pending items sorted by severity and new automatic email notifications sent to designated reviewers.
- **Interactive dashboards**: New dashboards display policy matches, pending and resolved actions, and trends by users and policy.
- **Auditing support**: A full log of policy and review activities is easily exported from the Microsoft Purview portal to help support audit review requests.

Integration with Microsoft 365 services

Communication Compliance policies check, detect, and capture messages across several communication channels to help you quickly review and remediate compliance issues:

- **Generative AI**: Use Communication Compliance policies to analyze interactions (prompts and responses) entered into generative AI applications to help detect inappropriate or risky interactions or sharing of confidential information. Coverage is supported for Microsoft 365 Copilot, Copilots built using Microsoft Copilot Studio, AI applications connected by Microsoft Entra or Microsoft Purview Data Map connectors, and more.
- **Microsoft Teams**: Chat communications for public and private Microsoft Teams channels and individual chats are supported in Communication Compliance as a standalone channel source or with other Microsoft 365 services. You can also detect communications included in meetings transcripts (preview). You need to manually add individual users, distribution groups, or specific Microsoft Teams channels when you select users and groups to apply a Communication Compliance policy to. Teams users can also self-report potentially inappropriate messages in private and group channels and chats for review and remediation.
- **Exchange Online**: All mailboxes hosted on Exchange Online in your Microsoft 365 organization are eligible for analyses. Emails and attachments matching Communication Compliance policy conditions are instantly available for investigation and in compliance reports. Exchange Online is now an optional source channel and is no longer required in Communication Compliance policies.

- **Microsoft 365 Copilot and Microsoft 365 Copilot Chat**: Interactions (prompts and responses) entered by users into Copilot are detected by Communication Compliance policies.
- **Viva Engage**: Private messages and public community conversations in Viva Engage are supported in Communication Compliance policies. Viva Engage is an optional channel and must be in native mode to support checking of messages and attachments.
- **Third-party sources**: You can check messages from third-party sources for data imported into mailboxes in your Microsoft 365 organization. Communication Compliance supports connections to several popular platforms, including Instant Bloomberg and others.

To learn more about messaging channel support in Communication Compliance policies, see Detect channel signals with Communication Compliance.

Watch the video below to learn how to detect communication risks in Microsoft Teams with Communication Compliance:

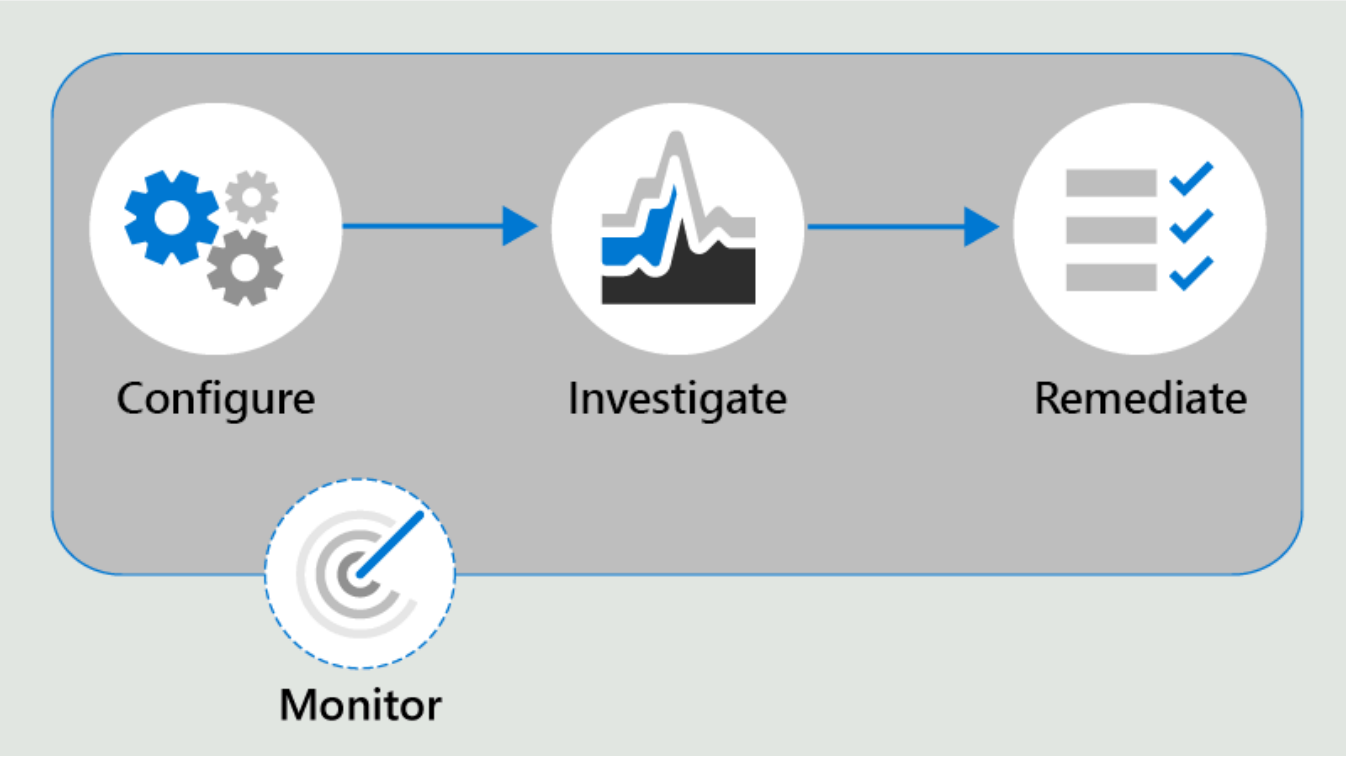
https://learn-video.azurefd.net/vod/player?id=7857b91f-d0c1-4b9f-ac84-5c70a8453216&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance

Integration with Microsoft Purview Insider Risk Management

When users experience employment stressors, they may engage in risky activities. Workplace stress can lead to uncharacteristic or malicious behavior by some users that could surface as potentially inappropriate behavior on your organization's messaging systems. Counterproductive work behavior can be a pre-cursor to more serious violations, such as sabotaging company assets or leaking sensitive information. By integrating Communication Compliance with Microsoft Purview Insider Risk Management, you can detect for stressors that indicate an unhealthy workplace environment.

Learn more about integrating Communication Compliance with Insider Risk Management

Get started with recommended actions



Whether you're setting up Communication Compliance for the first time or getting started with creating new policies, the new recommended actions experience can help you get the most out of Communication Compliance capabilities. Recommended actions include setting up permissions, creating distribution groups, creating policies, and more.

Workflow

Communication Compliance helps you address common pain points associated with complying with internal policies and regulatory compliance requirements. With focused policy templates and a flexible workflow, you can use actionable insights to quickly resolve detected compliance issues.

Before you create a policy, you can decide whether you want to apply an **adaptive scope**. For more information, see Adaptive policy scopes for compliance solutions. If you decide to create an adaptive policy, you must create one or more adaptive scopes before you create your policy, and then select them during the create new policy process. For instructions, see Configuration information for adaptive scopes.

Identifying and resolving compliance issues with Communication Compliance uses the following workflow:

Configure

In this workflow step, you identify your compliance requirements and configure applicable Communication Compliance policies. Policy templates are a great way to not only quickly configure a new compliance policy, but to also quickly modify and update policies as your requirements change. For example, you may want to quickly test a policy for potentially inappropriate content on communications for a small group of users before configuring a policy for all users in your organization.

> ⓘ **Important**

By default Global Administrators do not have access to Communication Compliance features. To enable permissions for Communication Compliance features, see Make Communication Compliance available in your organization.

You can choose from the following policy templates in the Microsoft Purview portal:

- **Detect inappropriate text**: Use this template to quickly create a policy that uses built-in classifiers to automatically detect text in messages that may be considered inappropriate, abusive, or offensive.
- **Detect inappropriate images**: Use this template to quickly create a policy that uses built-in classifiers to automatically detect content that contains adult and racy images that may be considered as inappropriate in your organization.
- **Detect sensitive info types**: Use this template to quickly create a policy to check communications containing defined sensitive information types or keywords to help make sure that important data isn't shared with people that shouldn't have access.
- **Detect financial regulatory compliance**: Use this template to quickly create a policy to check communications for references to standard financial terms associated with regulatory standards.
- **Detect conflict of interest**: Use this template to quickly create a policy to detect communications between two groups or two users to help avoid conflicts of interest.
- **Custom policy**: Use this template to configure specific communication channels, individual detection conditions, and the amount of content to detect and review in your organization.
- **User-reported messages policy**: This system policy supports user reported messages from channel, group, and private chat messages. Enabled by default in the Teams admin center.

Tip

Use recommended actions to help you determine if you need a sensitive information type policy or if you need to update existing inappropriate content policies.

Investigate

In this step, you can look deeper into the issues detected as matching your Communication Compliance policies. This step includes the following actions available in the Microsoft Purview portal:

- **Alerts**: When a group of messages matches a policy condition, an alert is automatically generated. For each alert, you can see the status, the severity, the time detected, and if an

eDiscovery (Premium) case is assigned and its status. New alerts are displayed on the Communication Compliance home page and the **Alerts** page and are listed in order of severity.

- **Issue management**: For each alert, you can take investigative actions to help remediate the issue detected in the message.
- **Document review**: During the investigation of an issue, you can use several views of the message to help properly evaluate the detected issue. The views include a conversation summary, text-only, and detail views of the communication conversation.
- **Reviewing user activity history**: View the history of user message activities and remediation actions, such as past notifications and escalations, for policy matches.
- **Filters**: Use filters such as sender, recipient, date, and subject to quickly narrow down the message alerts that you want to review.

Remediate

The next step is to remediate Communication Compliance issues you've investigated using the following options:

- **Resolve**: After reviewing an issue, you can remediate by resolving the alert. Resolving an alert removes it from the **Pending** tab, and the action is preserved as an entry on the **Resolved** tab for the matching policy. Alerts are automatically resolved after marking the alert as misclassified, sending a notice to a user about the alert, or opening a new case for the alert.
- **Tag a message**: As part of the resolution of an issue, you can tag a policy match as *Compliant*, *Non-compliant*, or *Questionable* as it relates to the policies and standards for your organization. You can also create a custom tag. Tagging can help you micro-filter policy alerts for escalations or as part of other internal review processes. You can filter on any tag value.
- **Notify the user**: Often, users accidentally or inadvertently violate a Communication Compliance policy. You can use the notify feature to provide a warning notice to the user and to resolve the issue.
- **Escalate to another reviewer**: Sometimes, the initial reviewer of an issue needs input from other reviewers to help resolve the incident. You can easily escalate message issues to reviewers in other areas of your organization as part of the resolution process.
- **Report as misclassified**: Messages incorrectly detected as matches of compliance policies will occasionally slip through to the review process. You can mark these types of alerts as misclassified, submit feedback to Microsoft about the misclassification to help improve global classifiers, and automatically resolve the issue.
- **Remove message in Teams**: Potentially inappropriate messages may be removed from displaying in Microsoft Teams channels or personal and group chat messages. Those

identified messages that are removed are replaced with a notification that the message has been removed for a policy violation.

- **Escalate for investigation**: In the most serious situations, you may need to share Communication Compliance information with other reviewers in your organization. Communication Compliance is tightly integrated with other Microsoft Purview features to help you with end-to-end risk resolution. Escalating a case for investigation allows you to transfer data and management of the case to Microsoft Purview eDiscovery (Premium). eDiscovery (Premium) provides an end-to-end workflow to preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external investigations. It allows legal teams to manage the entire legal hold notification workflow. To learn more about eDiscovery (Premium) cases, see Overview of Microsoft Purview eDiscovery (Premium).

Maintain

Keeping track and mitigating compliance issues identified by Communication Compliance policies spans the entire workflow process. As alerts are generated and investigation and remediation actions are implemented, existing policies may need review and updates, and new policies may need to be created.

- **Review and report**: Use Communication Compliance dashboard widgets, export logs, and events recorded in the unified audit logs to continually evaluate and improve your compliance posture.
- **Get insights on policy health**: Communication Compliance provides warnings and recommendations to improve policy health. Learn more about policy health

Plan for Communication Compliance

08/20/2025

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Before you get started with Communication Compliance in your organization, your information technology and compliance management teams should review important planning activities and considerations. Thoroughly understanding and planning for deployment in the following areas helps ensure that your implementation and use of Communication Compliance features goes smoothly and aligns with the best practices for the solution.

To learn how to fulfill regulatory compliance requirements with Communication Compliance, watch the following video:

https://learn-video.azurefd.net/vod/player?id=bf50d9ad-7ecb-4d3c-b0ec-0d9b1f3f7dcd&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance-plan

For more information and an overview of the planning process to address compliance and risky activities in your organization, see Starting an Insider Risk Management program.

To see how Insider Risk Management and Communication Compliance work together to help minimize data risks from users in your organization, watch the Microsoft Mechanics video.

> **Important**
>
> Communication Compliance is currently available in tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that Communication Compliance is supported for your organization, see Azure dependency availability by country/region.

> **Tip**

If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

Work with stakeholders in your organization

Identify the appropriate stakeholders in your organization to collaborate for taking actions on Communication Compliance alerts. Consider including the following stakeholders in your initial planning and the end-to-end Communication Compliance workflow:

- Information technology
- Compliance
- Privacy
- Security
- Human resources
- Legal

Plan for the investigation and remediation workflow

Select dedicated stakeholders to investigate and review the alerts and cases on a regular cadence in the Microsoft Purview portal. Make sure you understand how you assign users and stakeholders to different Communication Compliance role groups in your organization.

> **Important**
>
> After configuring your role groups, it might take up to 30 minutes for the role group permissions to apply to assigned users across your organization.

Configure permissions

Six role groups configure initial permissions to manage Communication Compliance features. To make **Communication Compliance** available as a menu option in Microsoft Purview portal and to continue with these configuration steps, you must be assigned to one those groups. For more information, see Assign permissions in Communication Compliance.

Scoped users

Before you start using Communication Compliance, determine who needs their communications reviewed. In the policy, user email addresses identify individuals or groups of people to apply the policy to. Some examples of these groups are Microsoft 365 Groups, Exchange-based distribution lists, Viva Engage communities, and Microsoft Teams channels. You can also exclude specific users or groups from checking with a specific exclusion group or a list of groups. For more information about groups types supported in Communication Compliance policies, see Get started with Communication Compliance.

> **Important**
>
> Users covered by Communication Compliance policies must have either a Microsoft 365 E5 Compliance license, an Office 365 Enterprise E3 license with the Advanced Compliance add-on, or be included in an Office 365 Enterprise E5 subscription. If you don't have an existing Enterprise E5 plan and want to try Communication Compliance, you can **sign up for a trial of Office 365 Enterprise E5**.

Reviewers

When you create a Communication Compliance policy, you decide who reviews the messages from the scoped users. In the policy, user email addresses identify individuals or groups of people who review scoped communications. All reviewers must have mailboxes hosted on Exchange Online, be assigned to either the *Communication Compliance Analysts* or *Communication Compliance Investigators* role groups, and be assigned in the policy they need to investigate. When you add reviewers to a policy, they automatically receive an email message that notifies them of the assignment to the policy and provides links to information about the review process.

Groups for scoped users and reviewers

To simplify your setup, we recommend creating groups for people who need their communications reviewed and groups for people who review those communications. If you use groups, you might need several. For example, you might want to identify communications between two distinct groups of people, or you might want to specify a group that isn't in scope. When you assign a Distribution group in the policy, the policy detects all emails from each user in the Distribution group. When you assign a Microsoft 365 group in the policy, the policy detects all emails sent to that group, not the individual emails received by each group member.

> **Note**

Before you create a policy, decide whether you want to apply an **adaptive scope** for users or groups. For more information, see Adaptive policy scopes for compliance solutions.

Adding groups and distribution lists to Communication Compliance policies are part of the overall conditions and rules set, so the maximum number of groups and distribution lists that a policy supports varies depending on the number of conditions you also add to the policy. Each policy supports approximately 20 groups or distribution lists, depending on the number of additional conditions present in the policy.

The following chart can help you configure groups in your organization for Communication Compliance policies:

Expand table

Policy Member	Supported Groups	Unsupported Groups
Scoped users Excluded users	Distribution groups Microsoft 365 Groups	Dynamic distribution groups Nested distribution groups Mail-enabled security groups Microsoft 365 groups with dynamic membership
Reviewers	None	Distribution groups Dynamic distribution groups Nested distribution groups Mail-enabled security groups

Privacy

Protecting the privacy of users that have policy matches is important and can help promote objectivity in data investigation and analysis reviews for Communication Compliance alerts. This setting applies only to user names displayed the Communication Compliance solution. It doesn't affect how names are displayed in other compliance solutions or admin center.

For users with a Communication Compliance match, you can choose one of the following settings in **Communication Compliance settings**:

- **Show anonymized versions of usernames**: User names are anonymized to prevent users in *Communication Compliance Analysts* role group from seeing who is associated with policy alerts. Users in the *Communication Compliance Investigators* role group always see user names, not the anonymized versions. For example, a user 'Grace Taylor' appears with a randomized pseudonym such as 'AnonIS8-988' in all areas of the Communication Compliance experience. Choosing this setting anonymizes all users with current and past policy matches and applies to all policies. User profile information in the Communication

Compliance alert details isn't available when you choose this option. However, user names are displayed when adding new users to existing policies or when assigning users to new policies. If you turn off this setting, user names are displayed for all users that have current or past policy matches.

- **Do not show anonymized versions of usernames**: User names are displayed for all current and past policy matches for Communication Compliance alerts. User profile information (the name, title, alias, and organization or department) is displayed for the user for all Communication Compliance alerts.

Plan for Communication Compliance policies

Creating Communication Compliance policies is quick and easy with the predefined templates for analyzing potentially inappropriate content, sensitive information, and regulatory compliance issues. Custom Communication Compliance policies give you the flexibility to detect and investigate issues specific to your organization and requirements.

When planning for Communication Compliance policies, consider the following areas:

- Consider adding all users in your organization as in-scope for your Communication Compliance policies. Identifying specific users as in-scope for individual policies can be useful in some circumstances. However, most organizations should include all users in Communication Compliance policies optimized for harassment or discrimination detection.
- Decide whether you want to apply an adaptive scope to your Communication Compliance policy. For more information, see Adaptive policy scopes for retention. Creating multiple policies can result in higher administrative overhead.
- Configure the percentage of communications to review at 100% to ensure that policies catch all issues of concern in communications for your organization.
- You can analyze communications from non-Microsoft sources for data imported into mailboxes in your Microsoft 365 organization. To include review of communications in these platforms, you need to configure a third-party connector to these services before messages meeting policy conditions are detected by a communication policy.
- Policies can support detecting languages other than English in custom Communication Compliance policies. Build a custom keyword dictionary of offensive words in the language of your choice or build your own machine learning model by using trainable classifiers in Microsoft 365.
- All organizations have different communication standards and policy needs. Detect specific keywords by using Communication Compliance policy conditions or detect specific types of information with custom sensitive information types.

Migrating between Microsoft 365 US Government Cloud and the commercial cloud

If you migrate your organization from the Microsoft 365 US Government Cloud to the worldwide commercial cloud or from the worldwide commercial cloud to the Government Cloud, active cases and alerts aren't migrated. Close any alerts and cases before starting the migration.

Create a Communication Compliance policy walkthrough

Want to see an in-depth walkthrough of setting up a new Communication Compliance policy and remediating an alert? Check out the following 15-minute video to see a demonstration of how Communication Compliance policies can help you detect potentially inappropriate messages, investigate potential violations, and remediate compliance issues.

https://learn-video.azurefd.net/vod/player?id=643aa064-e8bd-4b0e-b3ad-f58ab1585626&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance-plan

Ready to get started?

To configure Communication Compliance for your Microsoft 365 organization, see Configure Communication Compliance or check out the case study for Contoso and how they quickly configured a Communication Compliance policy to detect potentially inappropriate content in Microsoft Teams, Exchange Online, and Viva Engage communications.

Get started with Communication Compliance

09/26/2025

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Use Communication Compliance policies to identify user communications for analysis by internal or external reviewers. For more information about how Communication Compliance policies can help you detect communications in your organization, see Communication Compliance policies. To see how Contoso quickly configured a Communication Compliance policy to detect potentially inappropriate content in Microsoft Teams, Exchange Online, and Viva Engage communications, check out this case study.

Subscriptions and billing

Before getting started with Communication Compliance, confirm your Microsoft 365 subscription and any add-ons. To access and use Communication Compliance, administrators need to verify that their organization has a supported subscription and that users have the appropriate licenses assigned. For more information about subscriptions and licensing, see the subscription requirements for Communication Compliance.

Additionally, to detect inappropriate or risky interactions for non-Microsoft 365 AI data, you need to enable pay-as-you-go billing in your organization. Non-Microsoft 365 AI data includes information from other generative AI applications from Microsoft and connected external AI applications. This data type includes Copilot in Microsoft Fabric, Microsoft Security Copilot, Microsoft Copilot Studio, and any connected or cloud AI application. There aren't any pay-as-you-go billing requirements or charges for Microsoft 365 detecting inappropriate or risky interaction for Microsoft 365 Copilot data.

> **Important**

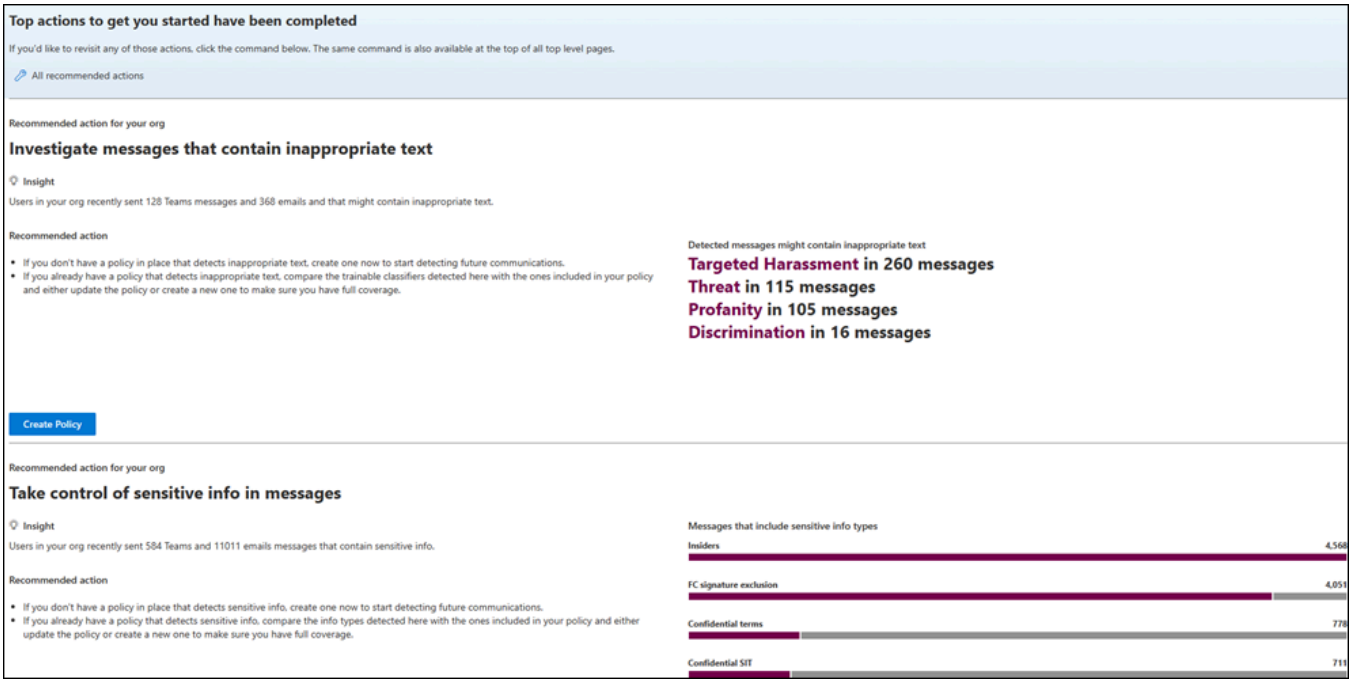
Communication Compliance is currently available for tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that Communication Compliance is supported for your organization, see Azure dependency availability by country/region.

Recommended actions

Recommended actions can help your organization quickly get started with Communication Compliance. Included on the **Overview** page, recommended actions help guide you through the steps to configure and deploy policies.

The following recommendations help you get started and maximize your Communication Compliance configuration:

- **Get to know Communication Compliance**: Before completing set up, review our official documentation to learn about, plan for, and deploy Communication Compliance in your organization.
- **Assign permissions to ensure your team can get their jobs done**: Ensure that only the appropriate stakeholders can access the solution by assigning team members responsible for managing Communication Compliance features and investigating and reviewing alerts.
- **Create distribution groups for users' whose communications you want to detect**: Create distribution groups containing users who are included in Communication Compliance policies.
- **Create your first policy to start detecting communications**: Detect and investigate potential regulatory compliance violations by first setting up a policy that identifies potential violations across your organization's internal and/or external communications.
- **Review alerts to investigate detected messages and take action**: Identify and analyze messages that match a policy's conditions to trigger alerts that provide context around a policy violation, so you can investigate and take action if needed.
- **Review reports for quick insights into how policies are performing**: Get quick insights into how your policies are performing, view detailed reports to drill down further, and export results for further analyses.



Each action in Communication Compliance has three attributes:

- **Action**: The name and description of the recommended action.
- **Recommended, required, or optional**: Whether the recommended action is highly recommended, required, or optional for Communication Compliance features to function as expected.

- **Estimated time to complete**: Estimated time to complete the recommended action in minutes.

Select recommendations from the list to get started with configuring Communication Compliance. Each recommended action guides you through the required activities for the recommendation, including any requirements, what to expect, and the impact of configuring the feature in your organization. Some recommended actions are automatically marked as complete when configured. If not, manually select the action as complete when configured.

Recommended actions insights on the **Policies** page help summarize current sensitive information types and potential regulatory compliance violations in communications in your organization. Data classification and the application of sensitivity labels, retention labels, and sensitive information type classification support these insights. These insights are aggregated and don't include any personal data for users in your organization.

Activity in messages aggregates by trainable classifier type from existing policies that use the *Detect inappropriate text* policy template or custom policies that use classifiers. Investigate alerts for these messages on the **Alert dashboard** for your policies.

Activity involving sensitive information types detects in messages covered in existing policies and for messages that aren't covered by existing policies. Insight messages that aren't covered by existing policies can't be investigated and remediated, a new policy must be created to detect and remediate similar activity in future messages. Insights aggregate for all sensitive information types, including ones that your organization didn't previously define in an existing Communication Compliance policy. Use these insights to create a new Communication Compliance policy or to update existing policies. After creating a new policy, message alerts for this policy might or might not match an equal number of messages identified in a similar

insight. Your policy might have different conditions, a different number of in-scope users, and only detects message activity that occurs after the policy is active.

> **Tip**
>
> To disable the display of recommended action insights, open a request with Microsoft Support.

Step 1 (required): Assign permissions for Communication Compliance

To use any of the Communication Compliance-related tools in the Microsoft Purview portal, users need the appropriate permissions. The easiest way to assign roles is to add the user to the appropriate role group on the **Role groups** page in the Microsoft Purview portal.

For step-by-step guidance, see Assign permissions in Communication Compliance.

Step 2 (required): Enable the audit log

Communication Compliance requires audit logs to show alerts and log remediation actions that reviewers take. The audit logs summarize all activities associated with a defined organizational policy or any time a Communication Compliance policy changes.

Auditing is enabled for Microsoft 365 organizations by default. Some organizations might disable auditing for specific reasons. If auditing is disabled for your organization, another administrator might have turned it off. We recommend confirming that it's OK to turn auditing back on when you complete this step.

For step-by-step instructions to turn on auditing, see Turn audit log search on or off. After you turn on auditing, a message is displayed that says the audit log is being prepared and that you can run a search in a couple of hours after the preparation is complete. You only need to perform this action once. For more information about using the audit log, see Search the audit log.

Step 3 (optional): Set up groups for Communication Compliance

When you create a Communication Compliance policy, you define who has their communications reviewed and who performs reviews. In the policy, use email addresses to

identify individuals or groups of people. To simplify your setup, you can create groups for people who have their communication reviewed and groups for people who review those communications. If you use groups, you might need several. For example, you might need multiple groups if you want to detect communications between two distinct groups of people or if you want to specify a group that isn't going to be scoped.

Use the following chart to help you configure groups in your organization for Communication Compliance policies:

Expand table

Policy Member	Supported Groups	Unsupported Groups
Scoped users Excluded users	Distribution groups Microsoft 365 Groups Mail-enabled security groups	Dynamic distribution groups Shared mailbox Nested distribution groups Microsoft 365 Groups with dynamic membership
Reviewers	None	Distribution groups Dynamic distribution groups Nested distribution groups Mail-enabled security groups

When you assign a *distribution group* in the policy, the policy detects all emails and Teams chats from each user in the *distribution group*. When you assign a *Microsoft 365 group* in the policy, the policy detects all emails and Teams chats sent to the *Microsoft 365 group*,* not the individual emails and chats received by each group member*. We recommend using distribution groups in Communication Compliance policies so that individual emails and Teams chats from each user are automatically detected.

> **Tip**
>
> For a more flexible configuration and to reduce administrative overhead, consider using an **adaptive scope** instead of a distribution group.

If you're an organization with an Exchange on-premises deployment or an external email provider and you want to detect Microsoft Teams chats for your users, you must create a distribution group for the users with on-premises or external mailboxes. Later in these steps, you assign this distribution group by using the **Choose users and groups** selection in the policy workflow. For more information about the requirements and limitations for enabling cloud-based storage and Teams support for on-premises users, see Search for and export Teams chat data for on-premises users.

To manage scoped users in large enterprise organizations, you might need to detect messages for all users across large groups. You can use PowerShell to configure a distribution group for a global Communication Compliance policy for the assigned group. This configuration enables you to detect messages for thousands of users with a single policy and keep the Communication Compliance policy updated as new employees join your organization.

1. Create a dedicated distribution group for your global Communication Compliance policy with the following properties: Make sure that you don't use this distribution group for other purposes or other Office 365 services.

   - **MemberDepartRestriction = Closed**. Ensures that users can't remove themselves from the distribution group.
   - **MemberJoinRestriction = Closed**. Ensures that users can't add themselves to the distribution group.
   - **ModerationEnabled = True**. Ensures that all messages sent to this group are subject to approval and that the group isn't being used to communicate outside of the Communication Compliance policy configuration.

   PowerShell

   ```
   New-DistributionGroup -Name <your group name> -Alias <your group alias> -
   MemberDepartRestriction 'Closed' -MemberJoinRestriction 'Closed' -
   ModerationEnabled $true
   ```

2. Select an unused Exchange custom attribute to log users added to the Communication Compliance policy in your organization.

3. Run the following PowerShell script on a recurring schedule to add users to the Communication Compliance policy:

   PowerShell

   ```
   $Mbx = (Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited -
   Filter {CustomAttribute9 -eq $Null})
   $i = 0
   ForEach ($M in $Mbx)
   {
     Write-Host "Adding" $M.DisplayName
     Add-DistributionGroupMember -Identity <your group name> -Member
   $M.DistinguishedName -ErrorAction SilentlyContinue
     Set-Mailbox -Identity $M.Alias -<your custom attribute name> SRAdded
     $i++
   }
   Write-Host $i "Mailboxes added to supervisory review distribution group."
   ```

For more information about setting up groups, see:

- Create and manage distribution groups
- Overview of Microsoft 365 Groups

Step 4 (optional): Verify your Viva Engage tenant is in Native Mode

In Native Mode, all Viva Engage users are in Microsoft Entra ID, all groups are Microsoft 365 Groups, and all files are stored in SharePoint Online. Your Viva Engage tenant must be in Native Mode for Communication Compliance policies to check and identify risky conversations in private messages and community conversations in Viva Engage.

For more information about configuring Viva Engage in Native Mode, see:

- Overview of Viva Engage Native Mode in Microsoft 365
- Configure your Viva Engage network for Native Mode for Microsoft 365

Step 5 (required): Create a Communication Compliance policy

You can quickly create a Communication Compliance policy by choosing from several policy templates, or you can create a custom policy.

> **Important**
>
> If your role is scoped by one or more admin units, you can't create a policy based on a template. You can create a custom policy, however.

When you create a policy from a template, many settings are automatically chosen for you based on the template you choose. As the final step, you can customize the policy if you want to change any of the settings.

When you create a custom policy, you select all of the settings yourself.

Create a policy from a template

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Go to the **Communication Compliance** solution.

3. Select **Policies** in the left navigation.

4. Select **Create policy**, then select one of the policy templates. For example, select **Detect inappropriate text**.

5. In the pane on the right side of the screen:
   a. In the **Policy name** field, confirm or update the policy name. You can't change policy names after you create the policy.
   b. In the **Users or groups in scope** field, choose the users or groups to apply the policy to. If you select the *Detect conflict of interest* template, select two scoped groups or two scoped users to detect internal communications.
   c. In the **Reviewers** field, choose the reviewers for the policy. Reviewers that you add in this field are the reviewers that you can choose from when escalating an alert in the investigation and remediation workflow. When you add reviewers to a policy, they automatically receive an email message that notifies them of the assignment to the policy and links to information about the review process. **Reviewers are individual users and all reviewers must have mailboxes hosted on Exchange Online.**
   d. Review the list of settings that are automatically chosen based on the template you choose. To customize any settings, select **Customize policy**, then make the changes you want. If everything looks OK, select **Create policy**.

> ⓘ **Note**
>
> To enable optical character recognition (OCR) to identify embedded or attached images in messages for printed or handwritten text that match policy conditions, select **Customize policy**, then on the **Choose conditions and percentage** page, select the **Use OCR to extract text from images** checkbox.

Create a custom policy

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Go to the **Communication Compliance** solution.

3. Select **Policies** in the left navigation.

4. Select **Create policy**, then select **Custom policy**.

5. On the **Name and describe your policy** page, enter a name (required) and description (optional) for the policy. You can't change the policy name after you create it. Select **Next** when you're done.

6. If one or more admin units exist for your organization, you see the **Admin units (preview)** page. Otherwise, you see the **Choose users and reviewers** page (next step) and a banner with a link to learn more about admin units.

   To scope the policy to one or more admin units, select **Add admin units**, select the admin units to apply to the policy, then select **Save**.

   > ⓘ **Note**
   >
   > You can only see the admin units that are scoped to your role. If you're an unrestricted administrator, you can see all admin units for the organization. To view a summary of the role groups and admin units that you're assigned to, select **View my permissions**.

   Select **Next** when you're done with the **Admin units (preview)** page.

7. On the **Choose users and reviewers** page:
   a. In the **Choose users and groups** section, select one of the following options:

   - **All users**: This option is the most inclusive and recommended for the broadest protection.

     > ⓘ **Note**
     >
     > If the policy is scoped by one or more admin units, selecting this option selects all users in the admin units.

   - **Select users**: Start typing to find specific users or groups. The **Show insights and recommendations for users who match this policy's conditions but weren't included in the policy** checkbox appears when you select this option. Leave this checkbox selected if you want to reduce blind spots by receiving recommendations when users outside of the selected users match the policy conditions. This setting isn't available if you choose the **All users** option or the **Select adaptive scopes** option.

     > ⓘ **Note**
     >
     > If the policy is scoped by one or more admin units, you can only select users that are part of those admin units.

- **Select adaptive scopes**: An adaptive scope uses a query that you specify to define the membership of users or groups. To use an adaptive policy, create the adaptive scope before you create your policy, then select the scope when you choose this option. Site scopes aren't applicable to Communication Compliance so you won't see them when you add a scope. Learn more about the advantages of using an adaptive scope.

  > ⓘ Note
  >
  > If the policy is scoped by one or more admin units the **Select adaptive scopes** option doesn't appear. At this time, you can't use adaptive scopes together with admin units.

a. In the **Excluded users and groups** section, add any users or groups to exclude from the policy.

> ⓘ Note
>
> If the policy is scoped by one or more admin units, you can only exclude users and groups that are part of those admin units.

b. In the **Reviewers** section, choose the reviewers for the policy. Reviewers you add in this section are the reviewers you can choose when escalating an alert in the investigation and remediation workflow. When you add reviewers to a policy, they automatically receive an email message that notifies them of the assignment to the policy and links to information about the review process. **Reviewers are individual users and all reviewers must have mailboxes hosted on Exchange Online.**

c. Select **Next** when you're done.

8. On the **Choose locations to detect communications** page, choose the communication channels to check, including **Exchange**, **Teams**, **Viva Engage**, or a specific generative AI channel. Supported generative AI channels include **Microsoft Copilot experiences**, **Enterprise AI apps**, and **Other AI apps**. You can also choose to check third-party sources if you configured a connector in Microsoft 365. Select **Next** to move to the next page.

9. On the **Choose conditions and review percentage** page:
   a. In the **Communication direction** section, choose the communication direction to detect, including inbound, outbound, or internal communications.
   b. In the **Conditions** section, add the conditions you want to detect. You can choose from many different conditions for messages and message attachments, including

conditions that detect for:

- Default or custom sensitive information types. You can create sensitive info types before running the workflow or create them from the workflow.
- Default or custom keyword dictionaries.
- Microsoft provided trainable classifiers. Microsoft provided trainable classifiers can detect potentially inappropriate language and images sent or received in the body of email messages or other types of text. You can choose from the following built-in Microsoft provided trainable classifiers: *Targeted threat*, *Profanity*, *Targeted harassment*, *Adult images*, *Racy images*, and *Gory images*. Communication Compliance also includes content safety classifiers (preview) for Microsoft Teams that are based on large language models (LLMs). These classifiers include *Hate*, *Sexual*, *Violence*, and *Self-harm*. Learn more about content safety classifiers based on large language models.

a. In the **Optical character recognition (OCR)** section, to enable optical character recognition (OCR) to identify embedded or attached images in messages for printed or handwritten text that match policy conditions, select the **Use OCR to extract text from images** checkbox. One or more conditional settings associated with text, keywords, Microsoft provided trainable classifiers, or sensitive info types must be configured in the policy to enable the selection of the checkbox.
b. In the **Review percentage** section, move the slider to change the amount of content to review.
c. In the **Filter email blasts** section, the **Filter out messages from email blasting services** check box is selected by default. This setting causes messages sent from email blast services to be excluded. Messages that match specific conditions won't generate alerts. This exclusion includes bulk email (such as newsletters), spam, phishing, and malware. You can view a report containing the bulk email senders that are filtered out. The list of senders is filtered before the content is analyzed so there might be senders that don't match the content conditions (extra senders included in the report).
d. Select **Next** to move to the next page.

10. On the **Review and finish** page, review your policy selections, then select **Create policy**.

Notes and tips on creating Communication Compliance policies

- After configuring a policy, learn about best practices for managing the volume of alerts.
- You can't use PowerShell to create and manage Communication Compliance policies. You must use the Communication Compliance solution.

- For an in-depth walkthrough of setting up a new Communication Compliance policy and remediating an alert, see this 15-minute video:

  https://learn-video.azurefd.net/vod/player?id=643aa064-e8bd-4b0e-b3ad-f58ab1585626&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance-configure

Test conditions (preview) when you create or edit a policy

If you create or edit a policy without testing conditions first, you might wait a long time before you can verify that the policy works as intended. Typically, you need to create a pilot policy and test it for several days before rolling the policy out to the wider organization. If you're a member of the Communication Compliance Admins role group or the Communication Compliance role group, you can save time by testing your conditions when you create or edit a policy. You can fine-tune the conditions to make sure the policy works as intended before rolling it out to the wider organization.

> **Note**
>
> Currently, you can only test the following conditions:
>
> - *Content matches any of these classifiers*
> - *Content contains any of these sensitive info types*

1. Make sure you're a member of the Communication Compliance Admins role group or the Communication Compliance role group. You must be a member of one of these role groups to use this feature.
2. Create a policy or edit an existing policy.
3. On the **Conditions and percentage** page, after entering your conditions, select **Test your conditions**.

> **Tip**
>
> You can also access the **Test your conditions** command from the list of policies on the **Policies** page or in the policy details panel if you choose to edit the policy.

4. In the **Test policy conditions** pane that appears on the right side of the page, do one of the following actions:

   - Select the **Enter messages to test** option, then enter some messages that you expect the policy to detect. Separate messages with a comma.
   - If you have a .txt file that includes a list of messages to detect, select the **Upload a file to test whether the trainable classifiers detects the matching elements you specified** option, then select **Upload file** to upload your text file.

5. Select **Test** to see a list of test results.

> **Tip**
>
> If you don't see the results you're looking for:
>
> - Check the definition of the sensitive info type or the trainable classifier to make sure it's designed to detect the type of info you expect.
> - Make sure that the message meets minimum word count requirements.

Step 6 (optional): Update compliance boundaries for Communication Compliance policies

Compliance boundaries create logical boundaries within an organization that control the user content locations (such as mailboxes, OneDrive accounts, and SharePoint sites) that eDiscovery managers can search.

If you configure compliance boundaries in your organization, update the compliance boundaries to allow certain users access to mailboxes that support Communication Compliance policies. You need to allow access to Communication Compliance administrators and Communication Compliance reviewers for your policy management and investigation and remediation actions to work properly.

To allow access for Communication Compliance admins and reviewers, run the following PowerShell commands. You only need to run these commands once, even if you add new Communication Compliance policies in the future:

PowerShell

```
Import-Module ExchangeOnlineManagement
$UserCredential = Get-Credential
Connect-IPPSSession -Credential $UserCredential
New-ComplianceSecurityFilter -FilterName "CC_mailbox" -Users <list your
Communication Compliance admins and reviewers user alias or email address> -
Filters "Mailbox_Name -like 'SupervisoryReview{*'" -Action All
```

For more information about cmdlet syntax, see New-ComplianceSecurityFilter.

Step 7 (optional): Create notice templates and configure user anonymization

If you want to respond to a policy alert by sending a reminder notice to the associated user, create at least one notice template in your organization. The notice template fields are editable before they're sent as part of the alert remediation process. We recommend creating a customized notice template for each Communication Compliance policy.

You can also choose to enable anonymization for displayed usernames when investigating policy matches and taking action on messages.

Create templates and configure user anonymization

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Settings** in the upper-right corner of the page, select **Communication Compliance**, select the **Privacy** tab, select **Show anonymized versions of usernames**, and then select **Save**.
4. Select the **Notice templates** tab, then select **Create notice template**.
5. In the right pane, complete the following fields:
    - Template name (required)
    - Send from (required)
    - Cc and Bcc (optional)
    - Subject (required)
    - Message body (required)
6. Select **Save** to create and save the notice template.

Step 8 (optional): Test your Communication Compliance policy

After you create a Communication Compliance policy, test it to make sure that the policy properly enforces the conditions you defined. If your Communication Compliance policies include sensitive information types, you might also want to test your Microsoft Purview Data Loss Prevention (DLP) policies. Make sure you give your policies time to activate so that the communications you want to test are captured.

> **Tip**
>
> To save time, you can test the following conditions before creating your policy:
>
> - *Content matches any of these classifiers*
> - *Content contains any of these sensitive information types*
>
> Learn more about testing conditions before creating a policy.

Follow these steps to test your Communication Compliance policy:

1. Open an email client, Microsoft Teams, or Viva Engage while signed in as a scoped user defined in the policy you want to test.

2. Send an email, Microsoft Teams chat, or Viva Engage message that meets the criteria you defined in the Communication Compliance policy. This test can be a keyword, attachment size, domain, and more. Make sure you determine if your configured conditional settings in the policy are too restrictive or too lenient.

   > **Note**
   >
   > Email messages can take approximately 24 hours to fully process in a policy. Communications in Microsoft Teams, Viva Engage, and third-party platforms can take approximately 48 hours to fully process in a policy.

3. Sign in to Microsoft 365 as a reviewer designated in the Communication Compliance policy. Go to **Communication Compliance** > **Alerts** to view the alerts for your policies.

4. Remediate the alert by using the remediation controls and verify that the alert is properly resolved.

Next steps

After you complete these steps to create your first Communication Compliance policy, you start to receive alerts from activity indicators after 24-48 hours. Configure additional policies as needed by using the guidance in Step 5 of this article.

To learn more about investigating Communication Compliance alerts, see Investigate and remediate Communication Compliance alerts.

To keep up with the latest Communication Compliance updates, select **What's new** in Communication Compliance for your organization.

Assign permissions in Communication Compliance

08/20/2025

Use six role groups to configure initial permissions for managing Communication Compliance features. To make **Communication Compliance** available as a menu option in Microsoft Purview portal and to continue with these configuration steps, you must be assigned to one of the following roles or role groups:

- Microsoft Entra ID *Global Administrator* role
- Microsoft Entra ID *Compliance Administrator* role
- Microsoft Purview portal *Organization Management* role group
- Microsoft Purview portal *Compliance Administrator* role group
- *Communication Compliance* role group
- *Communication Compliance Admins* role group

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

Members of the following roles have the same solution permissions included with the *Communication Compliance Admins* role group:

- Microsoft Entra ID *Global Administrator*
- Microsoft Entra ID *Compliance Administrator*
- Microsoft Purview portal *Organization Management*
- Microsoft Purview portal *Compliance Administrator*

> **Important**
>
> Make sure you always have at least one user in the *Communication Compliance* or *Communication Compliance Admins* role groups (depending on the option you choose) so that your Communication Compliance configuration doesn't get in to a 'zero administrator' scenario if specific users leave your organization.

Depending on how you want to manage Communication Compliance policies and alerts, assign users to specific role groups to manage different sets of Communication Compliance features. You can assign users with different compliance responsibilities to specific role groups to manage

different areas of Communication Compliance features. Or you might decide to assign all user accounts for designated administrators, analysts, investigators, and viewers to the *Communication Compliance* role group. Use a single role group or multiple role groups to best fit your compliance management requirements.

> **Important**
>
> After configuring your role groups, it might take up to 30 minutes for the role group permissions to apply to assigned users across your organization.

Choose from these solution role group options when configuring and managing Communication Compliance:

Expand table

Actions	Communication Compliance	Communication Compliance Admins	Communication Compliance Analysts	Communication Compliance Investigators	Communication Compliance Viewers
Access and investigate alerts	Yes	No	Yes	Yes	No
Access reports	Yes	No	No	No	Yes
Configure policies and settings	Yes	Yes	No	No	No
Create message details report	Yes	No	No	Yes	No
Manage privacy settings and notice templates	Yes	Yes	No	No	No
Take advanced remediation actions: - Escalate for investigation - Remove	Yes	No	No	Yes	No

Actions	Communication Compliance	Communication Compliance Admins	Communication Compliance Analysts	Communication Compliance Investigators	Communication Compliance Viewers
message in Teams - Download items and reports - Run Power Automate flows					
View **Conversation** and **Translation** tabs for a specific message	Yes	No	No	Yes	No
View and export policy updates	Yes	Yes	No	No	Yes

Consider admin units if you want to scope user permissions to a region or department

You can use administrative units in Communication Compliance to scope user permissions to a particular geography or department. For example, a global company that has subsidiaries throughout the world might want to create an admin unit that provides a German scope for investigators so that they only see user activity for German users.

To use admin units in Communication Compliance, you must first create the admin units (if they aren't already created), then assign the admin units to members of role groups. After you assign admin units to members of role groups, those members become *restricted administrators* and have limited access to Communication Compliance settings, policies, and user data in the organization. Members who aren't assigned administrative units are *unrestricted administrators* and have access to all settings, policies, and user data.

> **ⓘ Important**
>
> At this time, you can't use administrative units together with adaptive scopes in Communication Compliance. SharePoint sites and inactive mailboxes can only be segmented through adaptive scopes.

Effect of admin unit scoping on Communication Compliance roles

The following table shows how admin units, when enforced, affect each combination of Communication Compliance task and role.

> **Note**
>
> *Scoped*, in the following table, means that the admin actions for that role are limited by their assigned admin unit.

Expand table

Task	Scoped Communication Compliance	Scoped Communication Compliance Admins	Scoped Communication Compliance Analysts	Scoped Communication Compliance Investigators	Scoped Communication Compliance Viewers
Access and investigate alerts	Scoped	No	Scoped	Scoped	No
Access reports	No	No	No	No	No
Configure policies	Scoped	Scoped	No	No	No
Configure settings (including notice templates)	No	No	No	No	No
View and export audit logs	No	No	No	No	No

Option 1: Assign all compliance users to the Communication Compliance role group

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, select **Roles and groups**, then select **Role groups** in the left navigation pane.
3. Select the *Communication Compliance* role group, then select **Edit**.

4. Select **Choose users**, then select the checkboxes for all the users you want to add to the role group.
5. Select **Select**, then select **Next**.
6. Select **Save** to add the users to the role group, then select **Done**.

Option 2: Assign users to specific Communication Compliance role groups

Use this option to assign users to specific role groups to segment Communication Compliance access and responsibilities among different users in your organization.

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, then select **Role groups** in the left navigation pane.
3. Select one of the Communication Compliance role groups, then select **Edit**.
4. Select **Choose users**, then select the checkboxes for all the users you want to add to the role group.
5. Select **Select**, then select **Next**.
6. Select **Save** to add the users to the role group.
7. Select the next Communication Compliance role group, then repeat the previous steps for each required role group.
8. Select **Close** when you're done.

For more information about role groups and permissions, see Permissions in the Microsoft Purview portal.

Case study - Contoso configures a Communication Compliance policy to identify potentially inappropriate text

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Microsoft Purview Communication Compliance helps you minimize communication risks by helping you detect, capture, and act on messages with potentially inappropriate text in your organization. Potentially inappropriate text might include profanity, threats, harassment, and adult content. Predefined and custom policies allow you to review internal and external communications for policy matches, so designated reviewers can examine them. Reviewers can investigate alerts for email, Microsoft Teams, Viva Engage, or third-party communications throughout your organization and take appropriate remediation actions to make sure they're compliant with your organization's message standards.

The Contoso Corporation is a fictional organization that needs to quickly configure a policy to detect potentially inappropriate text. They use Microsoft 365 primarily for email, Microsoft Teams, and Viva Engage support for their users, but have new requirements to enforce company policy around workplace harassment. Contoso IT administrators and compliance specialists have a basic understanding of the fundamentals of working with Microsoft 365 and are looking for end-to-end guidance for how to quickly get started with Communication Compliance.

This case study covers the basics for quickly configuring a Communication Compliance policy to detect potentially inappropriate text. This guidance includes:

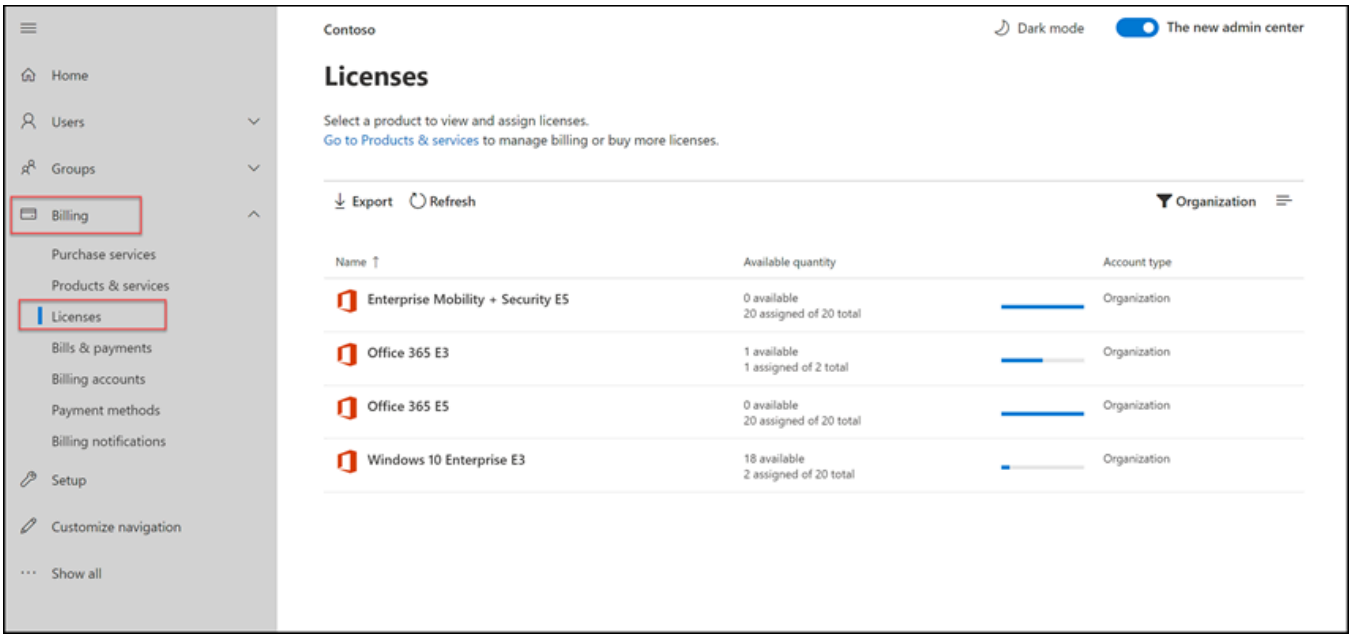
- Step 1: Planning for Communication Compliance
- Step 2: Accessing Communication Compliance
- Step 3: Configuring prerequisites and creating a Communication Compliance policy
- Step 4: Investigate and remediate alerts

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Step 1: Planning for Communication Compliance

Contoso IT administrators and compliance specialists attend online webinars about compliance solutions in Microsoft Purview and decide that Communication Compliance policies can help them meet the updated corporate policy requirements for reducing workplace harassment. Working together, they develop a plan to create and enable a Communication Compliance policy to detect potentially inappropriate messages. This configuration includes detecting text for chats sent in Microsoft Teams, private messages and community conversations in Viva Engage, and in email messages sent in Exchange Online.

Their plan includes identifying the:



- IT administrators who need access to Communication Compliance features.
- Compliance specialists who need to create and manage Communication Compliance policies.
- Compliance specialists and other colleague in other departments (Human Resources, Legal, etc.) who need to investigate and remediate Communication Compliance alerts.
- Users who are in-scope for the Communication Compliance potentially inappropriate text policy.

Licensing

First, confirm whether Contoso's Microsoft 365 licensing includes support for the Communication Compliance solution. To access and use Communication Compliance, Contoso IT administrators need to verify Contoso has a supported subscription and assigned the appropriate licenses to users. For more information about subscriptions and licensing, see the subscription requirements for Communication Compliance.

Contoso IT administrators take the following steps to verify the licensing support for Contoso:

1. IT administrators sign in to the Microsoft 365 admin center and go to Microsoft 365 admin center > **Billing** > **Licenses**.
2. They confirm that they have one of the license options that includes support for Communication Compliance.

Permissions for Communication Compliance

Five role groups used to configure permissions manage Communication Compliance features. To make **Communication Compliance** available as a menu option in Microsoft Purview portal and to continue with these configuration steps, assign Contoso administrators the *Communication Compliance Admins* role.

Contoso decides to use the *Communication Compliance* role group and assign all the Communication Compliance administrators, analysts, investigators, and viewers to the group. This role group configuration makes it easier for Contoso to get started quickly and best fits their compliance management requirements.

Use the Microsoft Purview portal to select the *Communication Compliance* role group.

1. Contoso IT admins sign in to the Microsoft Purview portal with credentials for an admin account in their Microsoft 365 organization.
2. The administrators select **Settings** in the upper-right corner of the page, then select **Role groups** in the left navigation pane.
3. The administrators select the *Communication Compliance* role group, then select **Edit**.
4. The administrators select **Choose users**, then select the checkboxes for all the Contoso users who manage Communication Compliance and investigate and review alerts.
5. The administrators choose **Select**, then choose **Next** to review the role group changes.
6. They select **Save** to add Contoso users to the role group.

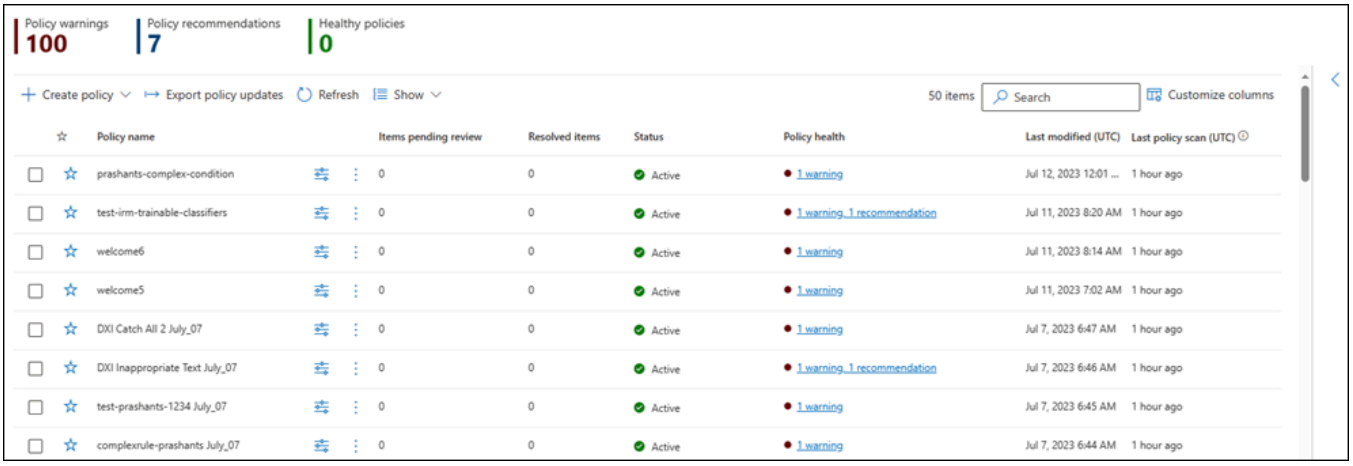
Step 2: Accessing Communication Compliance

After configuring the permissions for Communication Compliance, Contoso IT administrators and compliance specialists assigned to the Communication Compliance role group can access

the Communication Compliance solution in Microsoft Purview. Contoso IT administrators and compliance specialists have a couple of ways to access Communication Compliance and get started creating a new policy:

- Starting from the Microsoft Purview portal
- Starting directly from the Communication Compliance solution

Starting from the Microsoft Purview portal



Admins and compliance specialists can sign in to the Microsoft Purview portal and then go to the Communication Compliance solution.

1. Sign in to the Microsoft Purview portal.
2. Select the **Communication Compliance** solution.

Starting directly from the Communication Compliance solution

To quickly access the solution, sign in directly. Sign directly into Communication Compliance in the Microsoft Purview portal.

When they select one of these links, Contoso IT administrators and compliance specialists go to the Communication Compliance page where they can quickly review the status of alerts and create new policies from the predefined templates.

Step 3: Configuring prerequisites and creating a Communication Compliance policy

To get started with a Communication Compliance policy, Contoso IT administrators need to configure several prerequisites before setting up the new policy to detect potentially inappropriate text. After completing these prerequisites, Contoso IT administrators and

compliance specialists can configure the new policy. Compliance specialists can start investigating and remediating any generated alerts.

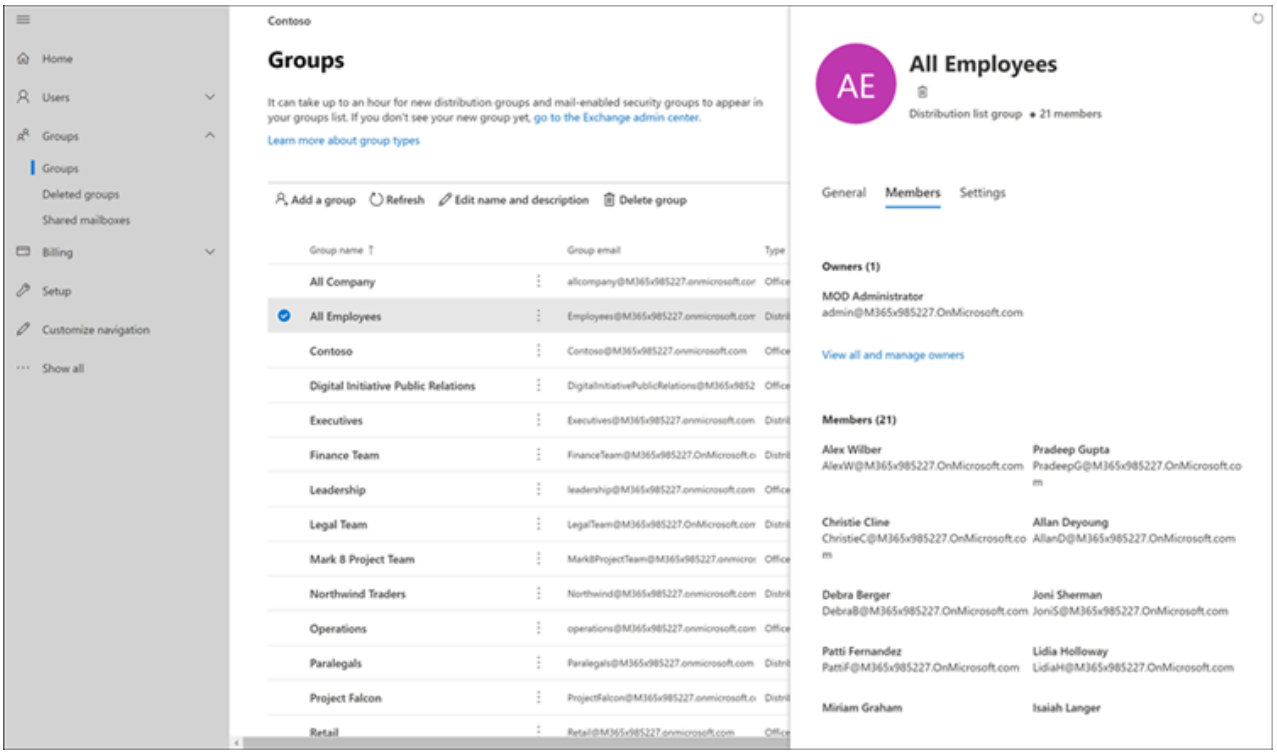
Enabling auditing in Microsoft 365

Communication Compliance requires audit logs to show alerts and track remediation actions that reviewers take. The audit logs summarize all activities associated with a defined organizational policy or anytime there's a change to a Communication Compliance policy.

Contoso IT administrators review and complete the step-by-step instructions to turn on auditing. After they turn on auditing, a message displays that says the audit log is being prepared and that they can run a search in a couple of hours after the preparation is complete. The Contoso IT administrators only need to perform this action once.

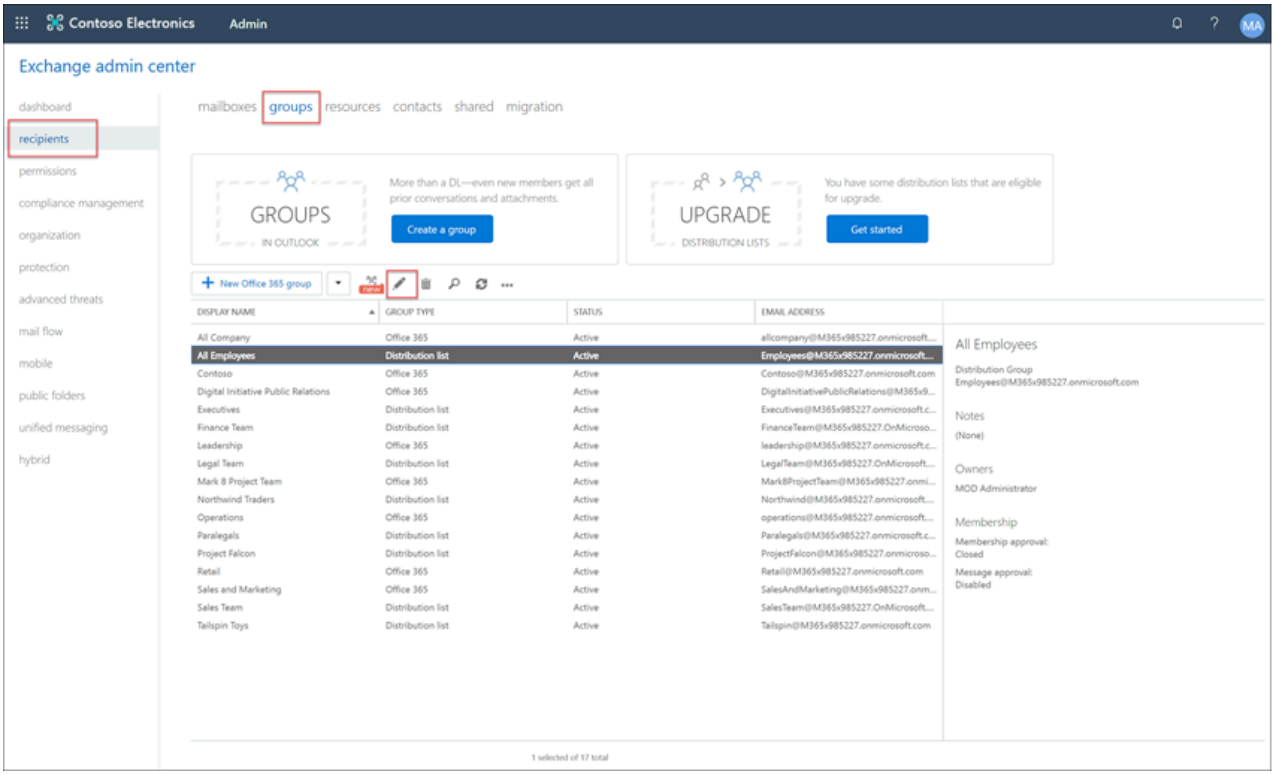
Configuring Viva Engage tenant for Native Mode

Communication Compliance requires that the Viva Engage tenant for an organization is in Native Mode to detect potentially inappropriate text in private messages and public community conversations.



Contoso IT administrators make sure they review the information in the Overview of Viva Engage Native Mode in Microsoft 365 article and follow the steps for running the migration tool in the Configure your Viva Engage network for Native Mode for Microsoft 365 article.

Setting up a group to add users to the policy



Contoso compliance specialists want to add all users to the communication policy that detects potentially inappropriate text. They could decide to add each user account to the policy separately, but they decide it's easier and saves time to use an **All Users** distribution group for the users for this policy.

They need to create a new group to include all Contoso users, so they take the following steps:

1. Contoso IT administrators sign in to the Microsoft 365 admin center and go to Microsoft 365 admin center > **Groups** > **Groups**.
2. They select **Add a group** and complete the workflow to create a new *Microsoft 365 group* or *Distribution group*.

3. After they create the new group, they add all Contoso users to the new group. They open the Exchange admin center and navigate to **Exchange admin center** > **recipients** > **Groups**. The Contoso IT administrators select the Membership area and the new *All Employees* group they created and select the **Edit** control to add all Contoso users to the new group in the workflow.

Creating the policy to detect potentially inappropriate text

After completing all the prerequisites, the IT administrators and compliance specialists for Contoso are ready to configure the Communication Compliance policy to detect potentially inappropriate text. By using the text policy template, you can quickly and easily configure this new policy.

1. Contoso IT admins sign in to the Microsoft Purview portal with credentials for an admin account in their Microsoft 365 organization.
2. They go to the **Communication Compliance** solution. This step opens a dashboard with quick links to Communication Compliance policy templates.
3. They choose **Policies** in the left navigation, select **Create policy**, and then select **Detect inappropriate text** to open the *Detect communications for inappropriate text* template.
4. In the policy template workflow, the Contoso IT administrators and compliance specialists work together to complete the three required fields: **Policy name**, **Users or groups in scope**, and **Reviewers**.
5. Since the policy workflow already suggests a name for the policy, the IT administrators and compliance specialists decide to keep the suggested name and focus on the remaining fields. They select the *All users* group for the **Users or groups in scope** field and select the compliance specialists who should investigate and remediate policy alerts for the **Reviewers** field. To finish configuring the policy and start gathering alert information, they select **Create policy**.

Step 4: Investigate and remediate alerts

After configuring the Communication Compliance policy to detect potentially inappropriate text, the Contoso compliance specialists investigate and remediate any alerts the policy generates. It can take up to an hour for the policy to fully process communications in all the communication source channels and for alerts to show up in the **Alert dashboard**.

When alerts are generated, Contoso compliance specialists follow the workflow instructions to investigate and remediate potentially inappropriate text issues.

Microsoft Purview Insider Risk Management and Communication Compliance privacy guide

08/20/2025

Microsoft Purview insider risk solutions give organizations the tools to help detect and reduce potential risks and policy violations. The Microsoft Purview insider risk solutions include:

- **Microsoft Purview Insider Risk Management** uses different signals to find potential malicious or accidental insider risks, such as intellectual property theft, data leakage, and security violations. Insider risk management lets customers create policies to manage security and compliance.
- **Microsoft Purview Communication Compliance** provides tools to help organizations detect potential regulatory compliance issues (for example SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content.

Insider risk management and communication compliance are built with privacy by design and balance user privacy with tools that help detect and reduce organizational risks. We're committed to protecting user trust and maintaining user-level privacy through our core privacy principles:

- Pseudonymization
- Role-based access controls
- Admin explicit opt-in
- Audit logs

Pseudonymization

Pseudonymization helps protect end-user privacy by removing identifiable user details like user name or email address. Pseudonymization also helps prevent potential bias and conflicts of interest by removing identifiable user details (name, email) and personal data (title, department, or location) exposed in the solution. For example, a user named John Smith is pseudonymized into a nonpersonal identifier such as ANON2340. Pseudonyms are on by default for specific roles such as *Insider Risk Management Analysts* and *Insider Risk Management Investigators* (review alerts and take action respectively) and *Communication Compliance Analysts* (review policy alerts).

Role-based access controls

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

We recommend using stringent role-based access controls so only authorized insider risk management and communication compliance roles can use and access alerts and insights into potential policy violations. By default, global administrators don't have access to insider risk management and communication compliance features. This default setting helps ensure that only the appropriate stakeholders can access the solution and details specific to their role permissions. Organizations can assign users to specific role groups to manage different sets of features based on their responsibilities. For example, insider risk management and communication compliance admins can create, configure, and delete policies but can't access or investigate alerts or cases. On the other hand, insider risk management and communication compliance investigators can access and investigate alerts and cases but can't configure policies.

> **Note**
>
> Insider risk management admins can allow investigators and analysts to make edits to policy indicators and thresholds by using the inline alert customization setting.

Whether your organization chooses a single role group or multiple role groups to fit your organization's compliance and privacy requirements, both insider risk management and communication compliance allow admins to choose from predefined role group options within each solution.

Learn more about role group options for each solution:

- Get started with insider risk management
- Get started with communication compliance

Admin explicit opt-in

Insider risk management and communication compliance policies detect risky activities and communications and potential policy violations that could result in a security incident. An admin with the right permissions can explicitly scope employees into a policy.

Additionally, by default, insider risk management and communication compliance indicators that help detect risky activities and communications that might lead to potential data security incidents are disabled. For example, indicators like "downloading content from OneDrive", "sharing SharePoint files with people outside the organization", or "sending sensitive information or harassing messages" are off by default. Insider risk management and communication compliance don't detect those activities without an admin's explicit opt-in. Admins with the right permissions must explicitly select and opt in to one or more indicators in settings before a policy can detect those activities.

Admin explicit opt-in controls help safeguard end-user privacy by ensuring the solutions only flag alerts and policy violations for users and indicators specified in the policies.

Audit logs

Microsoft Purview insider risk solutions audit logs record all admin actions. With these logs, organizations can stay informed about all actions taken within Microsoft Purview insider risk solutions, including when an admin creates or edits a policy, adds a user, views user activity insights, or adds indicators.

Audit logs are enabled by default for all Microsoft 365 organizations. With these logs, organizations can audit privileged admins' actions and meet compliance and privacy requirements.

For more information about audit logs capabilities for each solution, see:

- Review activities with the insider risk management audit log
- Use communication compliance reports and audits

Protect user trust and build a holistic insider risk program

User privacy and trust are essential for organizations to establish a holistic insider risk program. The right set of tools can help you address risks in a way that meets security needs. Learn how to build a holistic insider risk management program with five elements that help companies have stronger data protection while ensuring user trust.

Create and manage Communication Compliance policies

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Create and manage policies

Create Communication Compliance policies for Microsoft 365 organizations in the Microsoft Purview portal. Communication Compliance policies define which communications and users are subject to review in your organization, set custom conditions the communications must meet, and specify who should do reviews.

- Users assigned the *Communication Compliance Admins* role can set up policies and access the **Communication Compliance** page and global settings in Microsoft Purview.
- You can export the modification history to a .csv file that includes the status of alerts pending review, escalated items, and resolved items.
- You can't rename policies, but you can delete them when no longer needed.

> **Important**
>
> PowerShell isn't supported for creating and managing Communication Compliance policies. To create and manage these policies, use the policy management controls in the Communication Compliance solution.

Choose a policy template

Policy templates are predefined policy settings that you can use to quickly create policies to address common compliance scenarios. Each of these templates has differences in conditions

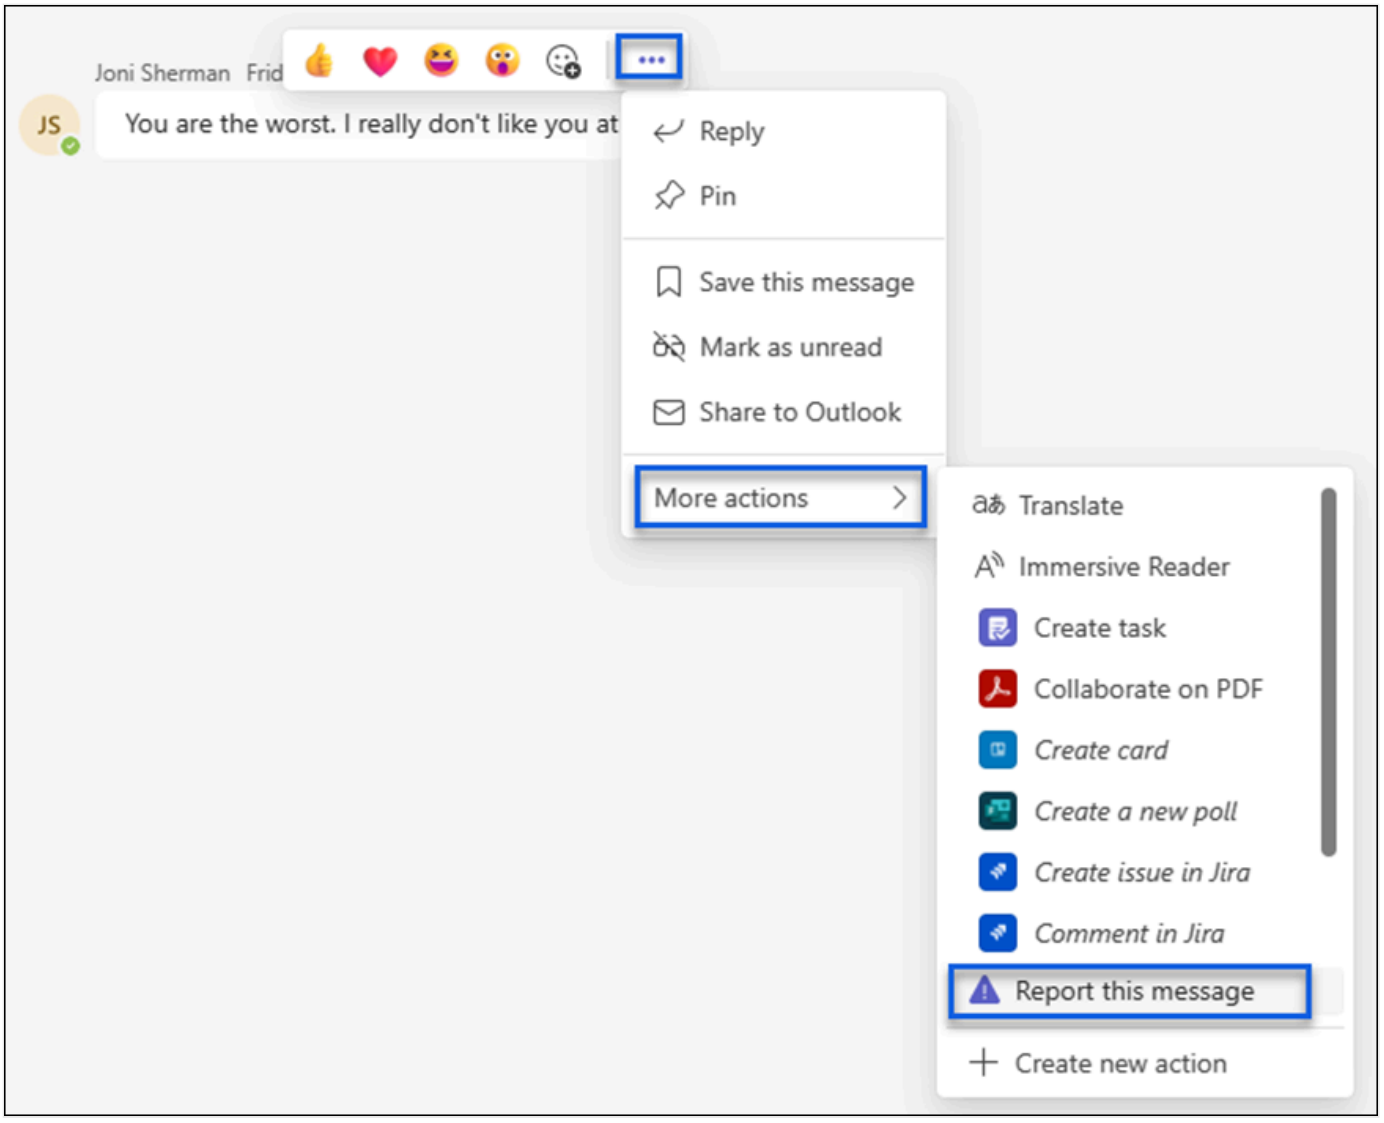
and scope. All templates use the same types of detection signals. You can choose from the following policy templates:

Expand table

Area	Policy Template	Details
Conflict of interest	Detect conflict of interest	- Locations: Exchange Online, Microsoft Teams, Viva Engage - Direction: Internal - Review Percentage: 100% - Conditions: None
Copilot interactions	Detect Microsoft 365 Copilot and Microsoft 365 Copilot Chat interactions	- Location: Microsoft 365 Copilot and Microsoft 365 Copilot Chat - Direction: Inbound, Outbound, Internal - Review Percentage: 100% - Conditions: Prompt Shields, Protected material classifiers
Inappropriate content	Detect inappropriate content	- Location: Microsoft Teams, Viva Engage - Direction: Inbound, Outbound, Internal - Review Percentage: 100% - Conditions: Hate, Violence, Sexual, Self-harm classifiers
Inappropriate images	Detect inappropriate images	- Locations: Exchange Online, Microsoft Teams - Direction: Inbound, Outbound, Internal - Review Percentage: 100% - Conditions: Adult and Racy image classifiers
Inappropriate text	Detect inappropriate text	- Locations: Exchange Online, Microsoft Teams, Viva Engage - Direction: Inbound, Outbound, Internal - Review Percentage: 100% - Conditions: Threat, Discrimination, and Targeted harassment classifiers
Regulatory compliance	Detect financial regulatory compliance	- Locations: Exchange Online, Microsoft Teams, Viva Engage - Direction: Inbound, Outbound - Review Percentage: 10% - Conditions: Customer complaints, Gifts & entertainment, Money laundering, Regulatory collusion, Stock manipulation, and Unauthorized disclosure classifiers
Sensitive information	Detect sensitive info types	- Locations: Exchange Online, Microsoft Teams, Viva Engage - Direction: Inbound, Outbound, Internal

Area	Policy Template	Details
		- Review Percentage: 10% - Conditions: Sensitive information, out-of-the-box content patterns, and types, custom dictionary option, attachments larger than 1 MB

User-reported messages policy



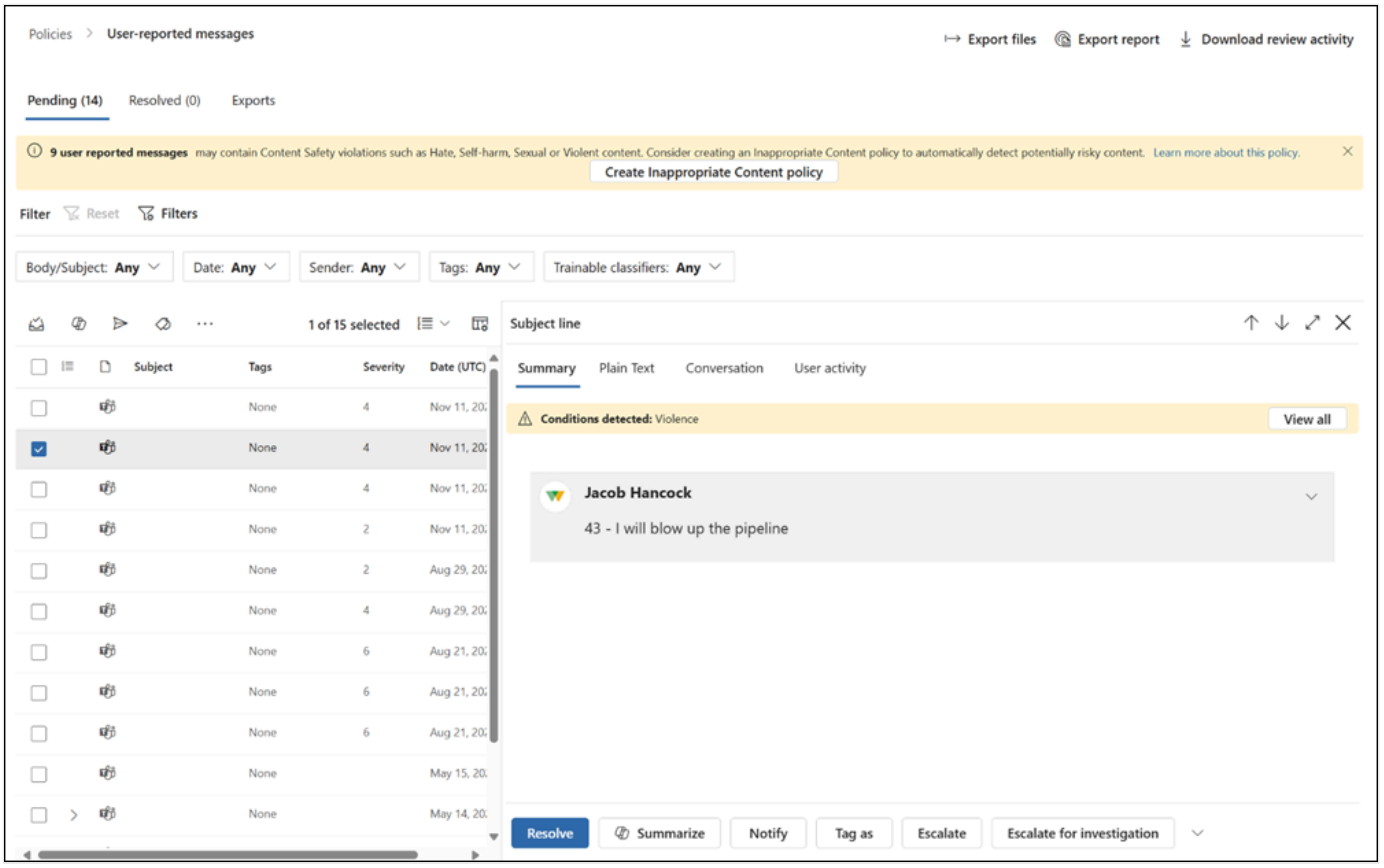
The *User-reported messages* policy is implemented for your organization when you purchase a license that includes Microsoft Purview Communication Compliance. However, this feature can take up to 30 days to become available after license purchase.

As part of a layered defense to detect and remediate inappropriate messages in your organization, you can supplement Communication Compliance policies with user-reported messages in Microsoft Teams and Viva Engage (preview). To support a safe and compliant work environment, this feature empowers users in your organization to self-report inappropriate internal Teams chat messages and Viva Engage conversations, such as harassing or threatening language, sharing of adult content, and sharing of sensitive or confidential information.

User-reported messages in Microsoft Teams

Enabled by default in the Teams admin center, the *Report inappropriate content* option in Teams messages lets users in your organization submit inappropriate internal personal and group chat messages for review by Communication Compliance reviewers for the User-reported messages policy. A default system policy supports these messages and supports reporting messages in Teams group and private chats.

Azure AI Content Safety's hate, self-harm, sexual, and violence classifiers evaluate user-reported messages. This evaluation helps investigators quickly assess potential risk in user-reported content and take action.



When a user submits a Teams chat message for review, the message is copied to the User-reported message policy. Reported messages initially remain visible to all chat members and there's no notification to chat members or the submitter that a message has been reported in channel, private, or group chats. A user can't report the same message more than once and the message remains visible to all users included in the chat session during the policy review process.

During the review process, Communication Compliance reviewers can perform all the standard remediation actions on the message, including removing the message from the Teams chat. Depending on how the messages are remediated, the message sender and recipients see different notification messages in Teams chats after the review. Any user-reported content that triggers the Content Safety classifiers shows the classifier name that flagged the message and a corresponding severity value is visible in the **Severity** column.

> **Important**

If a user reports a message that was sent before they were added to a chat, Teams message remediation isn't supported; the Teams message can't be removed from the chat.

User-reported messages from Teams chats are the only messages processed by the User-reported message policy and you can only modify the assigned reviewers for the policy. You can't edit all other policy properties. When you create the policy, all members of the *Communication Compliance Admins* role group (if populated with at least one user) or all members of your organization's *Global Admin* role group are assigned as initial reviewers. A randomly selected user from the *Communication Compliance Admins* role group (if populated with at least one user) or a randomly selected user from your organization's *Global Admin* role group is the policy creator.

> **ⓘ Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Admins should immediately assign custom reviewers to this policy as appropriate for your organization. This assignment might include reviewers such as your Compliance Officer, Risk Officer, or members of your Human Resources department.

Customize the reviewers for chat messages submitted as user-reported messages

To customize the reviewers assigned to the User-reported messages policy, complete the following steps:

1. Sign in to the Microsoft Purview portal using credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation.
4. Select the *User-reported messages* policy, then select **Edit**.
5. On the **Detect user-reported messages** pane, assign reviewers for the policy. Reviewers must have mailboxes hosted on Exchange Online. When you add reviewers to a policy, they automatically receive an email message that notifies them of the assignment to the policy and provides links to information about the review process.
6. Select **Save**.

The *Report inappropriate content* option is enabled by default and you can control it via Teams messaging policies in the Teams Admin Center. Users in your organization automatically receive the global policy, unless you create and assign a custom policy. Edit the settings in the global policy or create and assign one or more custom policies to turn on or turn off the *Report inappropriate content* option. For more information, see Manage messaging policies in Teams.

> **Important**
>
> If you use PowerShell to turn on or turn off the **End user reporting** option in the Teams Admin Center, use **Microsoft Teams cmdlets module version 4.2.0** or later.

User-reported messages in Viva Engage

The **Report Conversations** option is off by default in the Viva Engage admin center. When you turn on this option, you see different options depending on whether you have a license that includes Communication Compliance:

- **Licenses that don't include Communication Compliance**. If you don't have a license that includes Communication Compliance, when you turn on the option, the Viva Engage admin can specify an email address to receive reported conversations. The admin can also enter pre-submission instructions and post-submission confirmations for the user. Learn more

about enabling the **Report Conversations** option if you don't have a license that includes Communication Compliance

- **Licenses that do include Communication Compliance**. If you have a license that includes Communication Compliance, when you turn on the option, any reported conversations automatically route through Communication Compliance for investigation.

How upgrades and downgrades in licensing affect the reported conversations workflow

The following behaviors apply when your organization upgrades or downgrades between licenses that do and don't include Communication Compliance:

- If you upgrade from a license that doesn't include Communication Compliance to a license that includes Communication Compliance and turn on the **Report Conversations** option, reported conversations automatically route to Communication Compliance. The Viva Engage admin can continue to access earlier reported conversations and can view new reported conversations if they're added as an investigator in Communication Compliance.

- If you downgrade from a license that includes Communication Compliance to a license that doesn't include Communication Compliance and turn on the **Report Conversations** option, the workflow reverts to the process described in this article for customers that don't have a Communication Compliance license. To continue to use the feature, an admin must turn on the **Report Conversations** option in the Viva Engage admin center again and specify an email address to send reported conversations to.

User experience for customers that have a license that includes Communication Compliance

If you choose to route user-reported conversations through Communication Compliance, you can create pre-submission instructions for the user.

To report a conversation in Viva Engage, the user selects the ellipsis (three dots), then selects **Report conversation**.

The command name changes to **Report comment**, **Report question**, or **Report answer** depending on whether the user is viewing a comment, question, or answer in Viva Engage or Answers in Viva.

If the user submits the report successfully, they see a confirmation message.

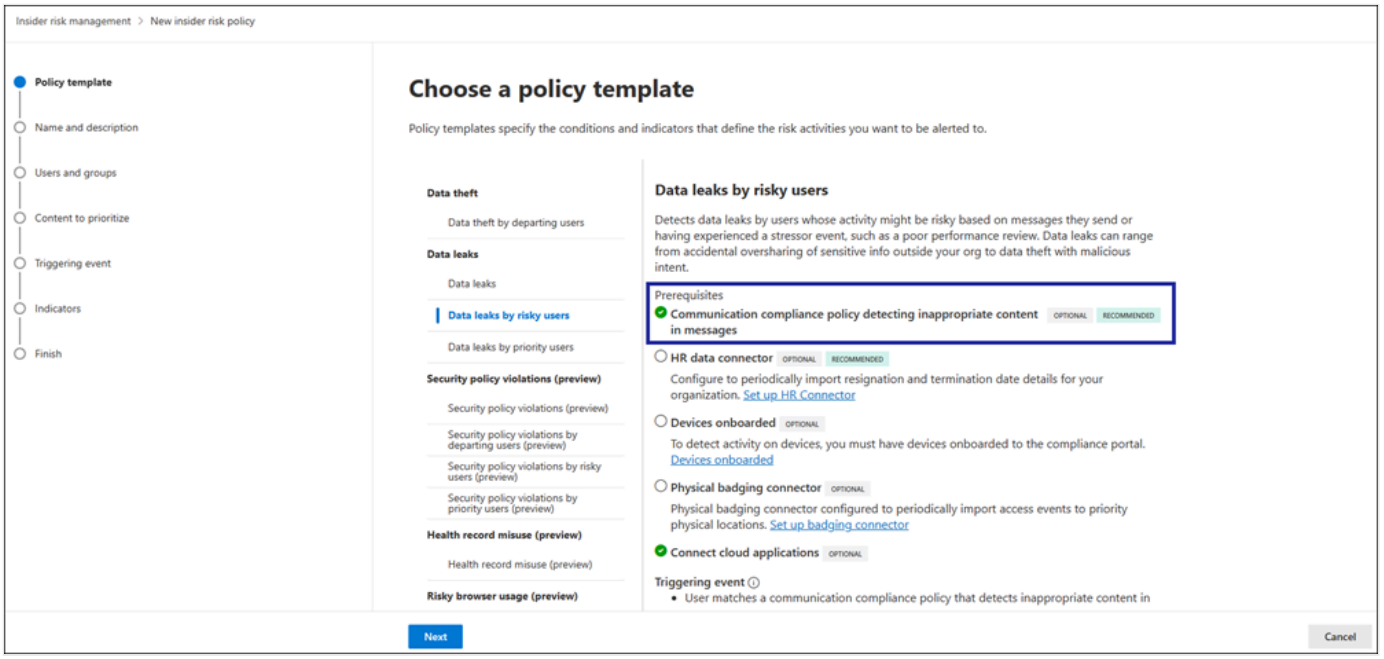
When a conversation is reported, the conversation is copied to the Communication Compliance User-reported message policy. The Communication Compliance investigator can review reported conversations in the User Reported policy inbox and can do all the standard remediation actions for the conversation.

Turn on the Report Conversation feature in the Viva Engage admin center

To turn on the Report Conversation feature in the Viva Engage admin center, complete the following steps:

1. Go to the Viva Engage admin center.
2. On the **Settings** page, select **Report Conversations**.
3. Turn on the setting.
4. Under **Report recipient**, add an email address to route reports to. This email address is used to notify the admin in case there's any problem with the configuration.
5. In the **Pre-submission details or instructions for users** box, enter any instructions you want to display for the user.
6. In the **Post-submission instructions to user** box, enter any instructions (optional) that the user will see after reporting a conversation.

Integrate Communication Compliance with Microsoft Purview Insider Risk Management



When users experience employment stressors, they might engage in risky activities. Workplace stress can lead to uncharacteristic or malicious behavior by some users that surfaces as potentially inappropriate behavior on your organization's messaging systems. Counterproductive work behavior can be a precursor to more serious violations, such as sabotaging company assets or leaking sensitive information. By integrating Communication Compliance with Microsoft Purview Insider Risk Management, you can detect stressors that indicate an unhealthy workplace environment.

You can integrate Communication Compliance with Insider Risk Management by automatically creating a Communication Compliance policy from Insider Risk Management. You can create this type of policy in two different ways:

- By creating an Insider Risk Management trigger for policy templates
- By selecting Insider Risk Management policy indicators for data-based policy templates
- By selecting generative AI policy indicators for policy templates

Create an Insider Risk Management trigger for policy templates

Communication Compliance can provide risk signals detected in applicable messages to Insider Risk Management risky user policies by using a dedicated Detect inappropriate text policy. This policy is automatically created if you select it as an option when creating a policy by using the Data leaks by risky users template or the Security policy violations by risky users template in Insider Risk Management. For example, the following screenshot shows the option selected in the *Data leaks by risky users* template.

When configured for an Insider Risk Management policy, Communication Compliance creates a dedicated policy named *Insider risk trigger - (date created)* and automatically includes all organization users in the policy. This policy starts detecting risky behavior in messages by using the Microsoft provided Threat, Harassment, and Discrimination trainable classifiers and automatically sends these signals to Insider Risk Management. If needed, you can edit this policy to update the scope of included users and the policy conditions and classifiers.

Users who send five or more messages classified as potentially risky within 24 hours are automatically brought in-scope for Insider Risk Management policies that include this option. Once in-scope, the Insider Risk Management policy detects potentially risky activities configured in the policy. The policy generates alerts as applicable. It can take up to 48 hours from the time risky messages are sent until the time a user is brought in-scope in an Insider Risk Management policy. If an alert is generated for a potentially risky activity detected by the Insider Risk Management policy, the triggering event for the alert is identified as being sourced from the Communication Compliance risky activity.

All users assigned to the Insider Risk Management Investigators role group are automatically assigned as reviewers in the dedicated Communication Compliance policy. Insider Risk Management investigators might need to review the associated risky user alert directly on the Communication Compliance alerts page (linked from the Insider Risk Management alert details). To enable this access, manually add them to the *Communication Compliance Investigators* role group.

Before integrating Communication Compliance with Insider Risk Management, consider the following guidance when detecting messages containing potentially inappropriate text:

- **For organizations without an existing *Detect inappropriate text* policy**. The Insider Risk Management policy workflow automatically creates the new *Risky user in messages - (date created)* policy. In most cases, you don't need to take any further action.
- **For organizations with an existing *Detect inappropriate text* policy**. The Insider Risk Management policy workflow automatically creates the new *Risky user in messages - (date created)* policy. Although you have two Communication Compliance policies for potentially inappropriate text in messages, investigators don't see duplicate alerts for the same activity. Insider Risk Management investigators only see alerts for the dedicated integration policy and Communication Compliance investigators only see the alerts for the existing policy. If needed, you can edit the dedicated policy to change the included users or individual policy conditions as applicable.

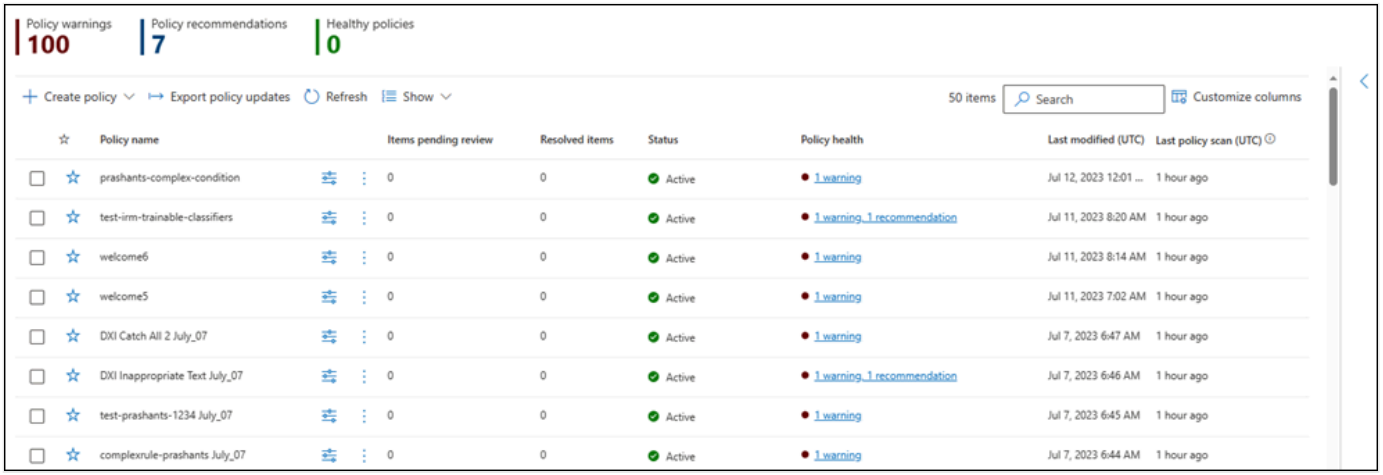
Select Insider Risk Management policy indicators for data-based policy templates

The **Policy indicators** setting in Insider Risk Management provides Communication Compliance indicators to choose from when using the *Data theft*, *Data leaks*, *Data leaks by risky users*, and *Data leaks by priority users* templates:

- Sending financial regulatory text that might be risky
- Sending inappropriate images
- Sending inappropriate content
- Sending messages that contain specific sensitive info types

For more information on creating a Communication Compliance policy this way, see Insider Risk Management policy indicators settings.

Select generative AI policy indicators for policy templates



The **Policy indicators** setting in Insider Risk Management provides generative AI app indicators to choose from when using the *Data leaks*, *Data leaks by risky users*, *Data leaks by priority users*, or *Risky AI usage* policy templates. These Azure AI Content Safety indicators help detect when prompts and responses in AI apps match the following classifiers:

- Prompt Shields
- Protected material detection

For more information on creating a Communication Compliance policy this way, see Insider Risk Management policy indicators settings. For more information on Azure AI Content Safety, see Azure AI Content Safety.

Policy health (preview)

The policy health status gives you insights into potential issues or optimizations for your Communication Compliance policies. At the top of the **Policies** page, you see a summary that lists the total number of policy warnings and recommendations, and the total number of healthy policies. If a specific policy has a warning or recommendations, the **Policy health** column lists a link to the warning or recommendations. When you select the link, a details pane opens on the right side of the screen with the **Policy Health** tab selected, which makes it easy to quickly review the warning or recommendation and take action on it.

The **Policy Health** tab has two parts. The upper part of the tab shows general information about the policy, including whether the policy is active, whether it's updated, and general tips. The lower part of the tab shows the specific warning or recommendations. If you're a member of the *Communication Compliance* or *Communication Compliance Admins* group, you can take action directly from the warning or recommendation. If you're a member of the *Communication Compliance Analysts* or *Communication Compliance Investigators* group, you can see the warning or recommendation so you can prompt your admin to take action.

- **Warnings**: If you don't take action on a warning, the policy stops working. For the policy health preview, there's one warning, related to a policy's storage limit size.
- **Recommendations**: Recommendations provide suggestions for optimizing policies. If you ignore a policy recommendation, the policy continues to work. If you're a member of the *Communication Compliance* or *Communication Compliance Admins* group, you can act on a recommendation as long as the policy is active and if it's not updating. If you're a member of the *Communication Compliance Analysts* or *Communication Compliance Investigators* group, you can see the recommendation and prompt your admin to take action. For the preview, there are two recommendations:
  - **Potentially reduce false positives by filtering out bulk emails**: This recommendation prompts you to turn on the Filter email blasts setting in Communication Compliance to exclude bulk emails from policy evaluation. This setting helps reduce false positives by excluding bulk emails, such as newsletters, and spam, phishing, and malware, from getting flagged by Communication Compliance policies if the policy conditions are matched.
  - **Reduce user scoping blind spots**: This recommendation prompts you to reduce blind spots by turning on the **Show insights and recommendations for users who match this policy's conditions but weren't included in the policy** checkbox (used with the **Selected users** policy option).
- **Healthy policies**: If there are no warnings or recommendations for a specific policy, the policy is considered healthy.

Reduce user scoping blind spots

You can reduce user-scoping related blind spots by turning on the **Show insights and recommendations for users who match this policy's conditions but weren't included in the policy** checkbox. When you turn on this checkbox, you see insights and recommendations for users who are sending messages that match the policy condition but aren't included in the scope of the policy. In this case, Communication Compliance recommends that you include those users in the scope of the policy so that you can review the messages sent by those users and take actions. You can select the specific users that you want to add or you can extend the policy to all users.

Insights for these users are aggregated; you can't see the messages sent by them until you add them to the scope of the policy.

If an admin doesn't act on a recommendation, the recommendation continues to recur. To turn off recommendations for users outside the scope of the policy, turn off the checkbox.

Pause a policy

After you create a Communication Compliance policy, you can temporarily pause the policy. Use pausing for testing or troubleshooting policy matches, or for optimizing policy conditions. Instead of deleting a policy in these circumstances, pausing a policy also preserves existing policy alerts and messages for ongoing investigations and reviews. Pausing a policy prevents inspection and alert generation for all user message conditions defined in the policy for the time the policy is paused. To pause or restart a policy, you must be a member of the *Communication Compliance Admins* role group.

To pause a policy, go to the **Policy** page, select a policy, then select **Pause policy** from the actions toolbar. On the **Pause policy** pane, confirm you'd like to pause the policy by selecting **Pause**. In some cases, it can take up to 24 hours for a policy to be paused. Once the policy is paused, alerts aren't generated for messages matching the policy. However, messages associated with alerts that you created before pausing the policy remain available for investigation, review, and remediation.

The policy status for paused policies can show several states:

- **Active**: The policy is active.
- **Paused**: The policy is fully paused.
- **Pausing**: The policy is in the process of being paused.
- **Resuming**: The policy in the process of being resumed.
- **Error in resuming**: An error was encountered when resuming the policy. For the error stack trace, hover your mouse over the *Error in resuming* status in the Status column on the Policy page.
- **Error in pausing**: An error was encountered when pausing the policy. For the error stack trace, hover your mouse over the *Error in pausing* status in the Status column on the Policy page.

To resume a policy, go to the **Policy** page, select a policy, then select **Resume policy** from the actions toolbar. On the **Resume policy** pane, confirm you'd like to resume the policy by selecting **Resume**. In some cases, it can take up to 24 hours for a policy to be resumed. Once the policy is resumed, alerts are generated for messages matching the policy and made available for investigation, review, and remediation.

Copy a policy

If your organization has existing Communication Compliance policies, you might find it helpful to create a new policy from an existing policy. When you copy a policy, you create an exact duplicate of an existing policy, including all included users, all assigned reviewers, and all policy conditions. Some scenarios where copying a policy is helpful include:

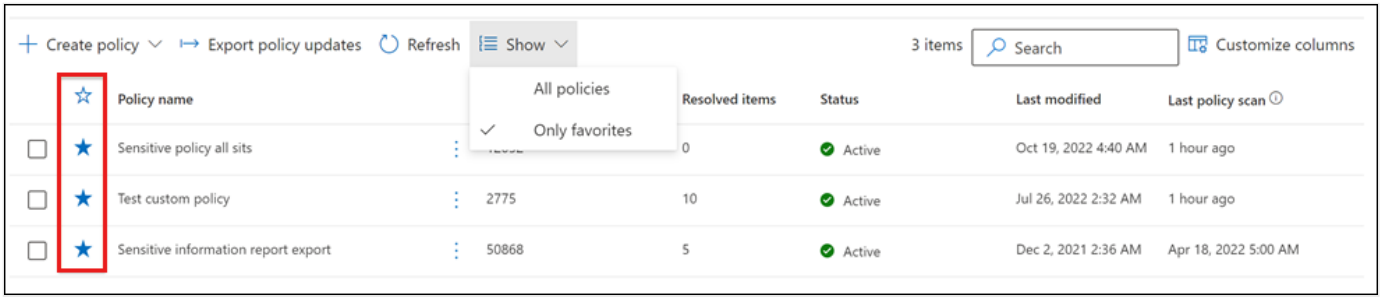
- **Policy storage limit reached**: Active Communication Compliance policies have message storage limits. When the storage limit for a policy is reached, the policy is automatically deactivated. If your organization needs to continue detecting, capturing, and acting on inappropriate messages covered by the deactivated policy, you can quickly create a new policy with an identical configuration.
- **Detect and review inappropriate messages for different groups of users**: Some organizations prefer to create multiple policies with the same configuration but include different groups of users and different reviewers for each policy.
- **Similar policies with small changes**: For policies with complex configurations or conditions, it might save time to create a new policy from a similar policy.

To copy a policy, you must be a member of the *Communication Compliance* or *Communication Compliance Admins* role groups. After you create a new policy from an existing policy, it can take up to 24 hours to view messages that match the new policy configuration.

To copy a policy and create a new policy, complete the following steps:

1. Select the policy you want to copy.
2. Select **Copy policy** on the command bar or select **Copy policy** from the action menu for the policy.
3. In the **Copy policy** pane, accept the default name for the policy in the **Policy name** field or rename the policy. The policy name for the new policy can't be the same as an existing active or deactivated policy. Complete the **Description** field as needed.
4. If you don't need further customization of the policy, select **Copy policy** to complete the process. If you need to update the configuration of the new policy, select **Customize policy**. This selection starts the policy workflow to help you update and customize the new policy.

Mark a policy as a favorite



After you create a Communication Compliance policy, you can mark the policy as a favorite. When you mark a policy as a favorite, you can filter favorite policies to appear at the top of the policies list. By marking a policy as a favorite, you can also easily sort policies by favorites.

To mark a policy as a favorite, you have the following options:

- **Mark as favorite**: Enables you to mark selected policies as favorites, so you can easily find the policies that you're most interested in rather than having to search for them.
- **Sort favorites**: Sorts the policies by favorites, so your favorite policies appear at the top of the list.
- **Customize columns**: Choose to list the favorites that you want to see. You can also choose to sort favorite policies in ascending or descending order.

To sort policies by groups:

- **All policies**: This is the default view, displaying all the policies in the list.
- **Only favorites**: Groups policies by favorites at the top of the list.

Policy activity detection

Communications are scanned every hour from the time you create a policy. For example, if you create an inappropriate content policy at 11:00 AM, the policy gathers Communication Compliance signals every hour starting from when you created the policy. Editing a policy doesn't change this time. To view the last scan date and Coordinated Universal Time (UTC) for a policy, go to the *Last policy scan* column on the **Policy** page. After creating a new policy, you might need to wait up to an hour to view the first policy scan date and time.

The following table outlines the time to detection for supported content types:

Expand table

Content type	Time to detection
Email attachment	24 hours
Email body content	1 hour
Email metadata	1 hour
Email OCR	24 hours

Content type	Time to detection
Microsoft 365 Copilot and Microsoft 365 Copilot Chat body content (prompts and responses)	1 hour
Team attachment	24 hours
Teams body content	1 hour
Teams metadata	1 hour
Teams modern attachment	24 hours
Teams OCR	24 hours
Teams shared channels	24 hours
Teams transcripts	1 hour
Viva Engage attachment	Up to 24 hours
Viva Engage body content	1 hour

For existing policies created before July 31, 2022, it might take up to 24 hours to detect messages and review alerts that match these policies. To reduce the latency for these policies, copy the existing policy and create a new policy from the copy. If you don't need to retain any data from the older policy, you can pause or delete it.

To identify an older policy, review *Last policy scan* column on the **Policy** page. Older policies display a full date for the scan while policies created after July 31, 2022 display *1 hour ago* for the scan. To reduce latency, you can also wait until February 28, 2023 for your existing policies to be automatically migrated to the new detection criteria.

Storage limit notification

Each Communication Compliance policy has a storage limit size of 100 GB or 1 million messages, whichever limit you reach first. As the policy approaches these limits, Communication Compliance automatically sends notification emails to users assigned to the *Communication Compliance* or *Communication Compliance Admins* role groups. Notification messages are sent when the storage size or message count reaches 80, 90, and 95 percent of the limit. When the policy limit is reached, the policy is automatically deactivated and stops processing messages for alerts.

> **Important**

If a policy is deactivated because it reached the storage and message limits, evaluate how to manage the deactivated policy. If you delete the policy, you permanently delete all messages, associated attachments, and message alerts. If you need to maintain these items for future use, don't delete the deactivated policy.

To manage policies that approach the storage and message limits, consider making a copy of the policy to maintain coverage continuity or take the following actions to help minimize current policy storage size and message counts:

- Reduce the number of users assigned to the policy. Removing users from the policy or creating different policies for different groups of users can help slow the growth of policy size and total messages.
- Examine the policy for excessive false positive alerts. Add exceptions or make changes to the policy conditions to ignore common false positive alerts.
- Make a copy of the policy if a policy reaches the storage or message limits and deactivates it to continue detecting and taking action for the same conditions and users.

Policy settings

The following settings control how Communication Compliance policies are scoped, evaluated, and reviewed.

Choose which users to include

You can select **All users**, define specific users in a Communication Compliance policy, or select an adaptive scope.

- **All users**: When you select **All users**, you apply the policy to all users and all groups that any user is included in as a member.
- **Select users**: When you define specific users, you apply the policy to the defined users and any groups the defined users are included in as a member. If you choose the **Selected users** option, the **Show insights and recommendations for users who match this policy's conditions but weren't included in the policy** checkbox automatically appears. Leave this checkbox selected if you want to receive recommendations when users outside of the selected users match the policy conditions. This setting isn't available if you choose the **All users** option or the **Select adaptive scopes** option.
- **Select adaptive scope**: An adaptive scope uses a query that you specify to define the membership of users or groups. If you decide to create an adaptive policy, you must create

one or more adaptive scopes before you create your policy, and then select them when you choose this option. The scopes that you can select depend on the scope types that you add. For example, if you only added a scope type of **User**, you can select **Groups**. To learn more, see Advantages of using an adaptive scope.

Choose the communication direction to monitor

By default, the **Direction is** condition appears and you can't remove it. Choose communication direction settings in a policy individually or together:

- **Inbound**: Detects communications sent **to** scoped users from external and internal senders, including other scoped users in the policy.
- **Outbound**: Detects communications sent **from** scoped users to external and internal recipients, including other scoped users in the policy.
- **Internal**: Detects communications **between** the scoped users or groups in the policy.

Choose sensitive information types

You can include sensitive information types as part of your Communication Compliance policy. Sensitive information types are either predefined or custom data types that help identify and protect credit card numbers, bank account numbers, passport numbers, and more. As part of Learn about Microsoft Purview Data Loss Prevention, the sensitive information configuration can use patterns, character proximity, confidence levels, and even custom data types to help identify and flag content that might be sensitive. The default sensitive information types are:

- Financial
- Medical and health
- Privacy
- Custom information type

> **Important**
>
> Sensitive info types have two different ways of defining the max unique instance count parameters. To learn more, see **Create custom sensitive information types**.

The Communication Compliance solution supports default sensitive information types and bundled named-entity sensitive information types, which are collections of sensitive information types. For more information about sensitive information details and the patterns included in the

default types, see Sensitive information type entity definitions. For information on supported bundled named-entity sensitive information types, see the following articles:

- All credentials
- All full names
- All medical terms and conditions
- All Physical Addresses

For more information about sensitive information details and the patterns included in the default types, see Sensitive information type entity definitions.

Configure custom keyword dictionaries

Configure custom keyword dictionaries (or lexicons) to easily manage keywords specific to your organization or industry. Keyword dictionaries support up to 100 KB of terms (post-compression) in the dictionary and support any language. The tenant limit is also 100 KB after compression. If needed, you can apply multiple custom keyword dictionaries to a single policy or have a single keyword dictionary per policy. You can source these dictionaries from a file, such as a .CSV or .TXT list, or from an imported keyword list. Use custom dictionaries when you need to support terms or languages specific to your organization and policies.

Use Microsoft-provided trainable classifiers

Communication Compliance policies that use Microsoft provided trainable classifiers inspect and evaluate messages that meet a minimum word count requirement, depending on the language of the content. Custom trainable classifiers aren't supported. For a complete list of supported languages, word count requirements, and file types for Microsoft provided trainable classifiers, see Trainable classifier definitions.

To identify and take action on messages containing inappropriate language content that doesn't meet the word count requirement, create a sensitive information type or custom keyword dictionary for Communication Compliance policies detecting this type of content.

Expand table

Microsoft provided trainable classifier	Description
Corporate sabotage	Detects messages that might mention acts to damage or destroy corporate assets or property. This classifier can help you manage regulatory compliance obligations such as NERC Critical Infrastructure Protection standards or state by state regulations like Chapter 9.05 RCW in Washington state.
Customer complaints	Detects messages that might suggest customer complaints made on your organization's products or services, as required by law for regulated industries. This classifier can help you manage regulatory compliance obligations such as FINRA Rule 4530, FINRA 4513, FINRA 2111, Consumer Financial Protection Bureau, Code of Federal Regulations Title 21: Food and Drugs, and the Federal Trade Commission Act.
Discrimination	Detects potentially explicit discriminatory language and is particularly sensitive to discriminatory language against the African American/Black communities when compared to other communities.
Gifts & entertainment	Detects messages that might suggest exchanging gifts or entertainment in return for service, which violates regulations related to bribery. This classifier can help you manage regulatory compliance obligations such as Foreign Corrupt Practices Act (FCPA), UK Bribery Act, and FINRA Rule 2320.
Harassment	Detects potentially offensive content in multiple languages that targets people regarding race, color, religion, national origin.
Money laundering	Detects signs that might suggest money laundering or engagement in acts to conceal or disguise the origin or destination of proceeds. This classifier can help you manage regulatory compliance obligations such as the Bank Secrecy Act, the USA Patriot Act, FINRA Rule 3310, and the Anti-Money Laundering Act of 2020.
Profanity	Detects potentially profane content in multiple languages that would likely offend most people.
Regulatory collusion	Detects messages that might violate regulatory anti-collusion requirements such as an attempted concealment of sensitive information. This classifier can help you manage regulatory compliance obligations such as the Sherman Antitrust Act, Securities Exchange Act 1933, Securities Exchange Act of 1934, Investment Advisers Act of 1940, Federal Commission Act, and the Robinson-Patman Act.
Stock manipulation	Detects signs of possible stock manipulation, such as recommendations to buy, sell, or hold stocks that might suggest an attempt to manipulate the stock price. This classifier can help you manage regulatory compliance obligations such as the Securities Exchange Act of 1934, FINRA Rule 2372, and FINRA Rule 5270.
Threat	Detects potential threatening content in multiple languages aimed at committing violence or physical harm to a person or property.

Microsoft provided trainable classifier	Description
Unauthorized disclosure	Detects sharing of information containing content that is explicitly designated as confidential or internal to unauthorized individuals. This classifier can help you manage regulatory compliance obligations such as FINRA Rule 2010 and SEC Rule 10b-5.

> **Important**
>
> Microsoft provided trainable classifiers might detect a large volume of bulk sender/newsletter content due to a known issue. You can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts check box** when you create the policy. You can also edit an existing policy to turn on this feature.

Content safety classifiers based on large language models

Communication Compliance includes a set of Azure AI classifiers for Microsoft 365 Copilot, Teams, and Viva Engage communications. These classifiers run on large language models and are highly accurate. They evaluate messages containing three or more words. If the evaluated severity is 4 or higher, the solution displays the message as an alert and adds a **Severity** column to the **Alerts** dashboard to make it easier to prioritize alerts. Investigators can sort and filter on the **Severity** column.

The **Severity** column only appears if the policy match comes from one of the classifiers listed in the following table. For all other classifiers, the column is empty.

The following table describes the classifiers:

Expand table

Classifier	Description
Hate	*Hate* refers to any content that attacks or uses pejorative or discriminatory language with reference to a person or identity group based on certain differentiating attributes of these groups, including but not limited to race, ethnicity, nationality, gender identity and expression, sexual orientation, religion, immigration status, ability status, personal appearance, and body size.
Sexual	*Sexual* describes language related to anatomical organs and genitals, romantic relationships, acts portrayed in erotic or affectionate terms, pregnancy, physical sexual acts, including those

Classifier	Description
	portrayed as an assault or a forced sexual violent act against one's will, prostitution, pornography, and abuse.
Violence	*Violence* describes language related to physical actions intended to hurt, injure, damage, or kill someone or something; describes weapons, guns and related entities, such as manufactures, associations, legislation, and so on.
Self-harm	*Self-harm* describes language related to physical actions intended to purposely hurt, injure, damage one's body, or kill oneself.

Learn more about Azure AI Content Safety

Considerations when using classifiers

Keep the following limitations and considerations in mind when using content safety classifiers:

- Only Microsoft 365 Copilot, Teams, and Viva Engage workloads are supported.
- The solution evaluates only messages containing five or more words. It doesn't evaluate attachments and OCR images.
- The solution doesn't evaluate Teams meeting transcripts.
- Feedback loop isn't yet supported to submit misclassified items to Microsoft.
- The solution supports up to 10,000 characters per message.
- Learn about supported languages

Detect risky generative AI interactions

Communication Compliance detects harmful user-generated and AI-generated content in applications and services. This detection includes evaluation of user prompts submitted to generative AI services and the inclusion of known text content that might be sensitive to your organization.

The following table describes the classifiers.

Expand table

Classifier	Description
Prompt Shield	Detects adversarial user input attacks such as user prompt injection attacks (jailbreak). User prompt injection attacks deliberately exploit system vulnerabilities to elicit unauthorized behavior from the large language model.
Protected material	Detects known text content that might be protected under copyright or branding laws. Detecting the display of protected material in generative AI responses ensures compliance

Classifier	Description
	with intellectual property laws and maintains content originality.

For more information, see Learn more about Azure AI Content Safety.

Configure optical character recognition (OCR) scanning

> **Note**
>
> Microsoft Purview includes **OCR (preview) settings** for Microsoft Purview Insider Risk Management, Microsoft Purview Data Loss Prevention, Microsoft Purview Data Loss Management, and auto-labeling. Use the OCR (preview) settings to provide image-scanning capabilities for those solutions and technologies. Communication Compliance has its own built-in OCR scanning functionality as described in this section and doesn't support the OCR (preview) settings at this time.

You can configure built-in or custom Communication Compliance policies to scan and identify printed or handwritten text from images that might be inappropriate in your organization. Integrated Azure AI services and optical scanning support for identifying text in images help analysts and investigators detect and act on instances where inappropriate conduct might be missed in communications that is primarily nontextual.

You can enable optical character recognition (OCR) in new policies from templates, custom policies, or update existing policies to expand support for processing embedded images and attachments. When you enable OCR in a policy created from a policy template, the solution automatically scans embedded or attached images in email and Microsoft Teams chat messages. For images embedded in document files, OCR scanning isn't supported. For custom policies, configure one or more conditional settings associated with keywords, Microsoft provided trainable classifiers, or sensitive info types in the policy to enable the selection of OCR scanning.

The solution scans and processes images from 100 KB to 4 MB in the following image formats:

- .jpg/.jpeg (joint photographic experts group)
- .png (portable network graphics)
- .bmp (bitmap)
- .tiff (tag image file format)

When you review pending policy matches for policies with OCR enabled, you see images identified and matched to policy conditions as child items for associated alerts. You can view the

original image to evaluate the identified text in context with the original message. It might take up to 48 hours for detected images to be available with alerts.

Choose conditions for your policies

The conditions you choose for a policy apply to communications from both email and third-party sources in your organization (Instant Bloomberg, for example).

At this time, the condition names that you choose depend on whether you're creating a new policy or an existing policy:

- For *new policies*, we recommend using the condition builder. The condition builder supports the *OR* operator, which enables you to combine multiple conditions in the same policy to create compound conditions with AND, OR, and NOT operators. This support helps you address complex scenarios for your unique compliance requirements. If you create a new policy with a template, Communication Compliance automatically uses the condition builder. Learn more about the condition builder.

  All exceptions in the condition builder are replaced with a NOT condition. You must include the NOT condition within a nested group.

- For *existing policies*, use the condition names listed in the first column in the following table.

> **Tip**
>
> To save time, you can **test certain conditions before creating your policy**.

Condition names for existing and new policies

The following table lists condition names to use for existing policies vs. new policies (using the condition builder). It also lists how to use each condition.

Expand table

Condition name for existing policies	Condition name for new policies	How to use this condition
Attachment contains any of these words	**Attachment contains**	To apply the policy when certain words or phrases are included or excluded in a message attachment (such as a Word document).

Condition name for existing policies	Condition name for new policies	How to use this condition
Attachment contains none of these words	**words or phrases**	Make sure to use the following syntax when entering conditional text: - Remove all leading and trailing spaces. - Add quotation marks before and after each keyword or key phrase. - Separate each keyword or key phrase with a comma. - Don't include spaces between items separated by a comma. **Example:** "banker","insider trading","confidential 123" Each word or phrase you enter is applied separately (only one word must apply for the policy to apply to the attachment). For more information about entering words or phrases, see the next section Matching words and phrases to emails or attachments.
Attachment is any of these file types **Attachment is none of these file types**	**Attachment file extension is**	To bring communications into scope that include or exclude specific types of attachments, enter the file extensions (such as .exe or .pdf). If you want to include or exclude multiple file extensions, enter file types separated by a comma (example *.exe,.pdf,.zip*). Don't include spaces between items separated by a comma. Only one attachment extension must match for the policy to apply.
Attachment is larger than **Attachment is not larger than**	**Attachment size equals or is larger than**	To review messages based on the size of their attachments, specify the maximum or minimum size an attachment can be before the message and its attachments are subject to review. For example, for an existing policy, if you specify **Attachment is larger than** > **2.0 MB**, all messages with attachments 2.01 MB and over are subject to review. You can choose bytes, kilobytes, megabytes, or gigabytes for this condition.
Content contains any of these sensitive info types	**Content contains sensitive info types**	Apply to the policy when any sensitive information types are included or excluded in a message. Each sensitive information type you choose is applied separately and only one of these sensitive information types must apply for the policy to apply to the message. For more information about custom sensitive information types, see Learn about sensitive information types.
Content matches any of these classifiers	**Content matches trainable classifiers**	Apply to the policy when any trainable classifiers are included or excluded in a message. Some classifiers are predefined in your organization, and custom classifiers must be configured separately before they're available for this condition. For existing policies, only one trainable classifier can be defined as a condition in a policy. If you're using the condition builder for a new policy, you're not limited to a single trainable classifier. For more information about configuring trainable classifiers, see Learn about trainable classifiers.

Condition name for existing policies	Condition name for new policies	How to use this condition
Message contains any of these words **Message contains none of these words**	**Message contains words or phrases**	To apply the policy when certain words or phrases are included or excluded in a message. Make sure to use the following syntax when entering conditional text: - Remove all leading and trailing spaces. - Add quotation marks before and after each keyword or key phrase. - Separate each keyword or key phrase with a comma. - Don't include spaces between items separated by a comma. **Example:** "banker","insider trading","confidential 123" Each word or phrase you enter is applied separately (only one word must apply for the policy to apply to the message). For more information about entering words and phrases, see the next section Matching words and phrases to emails or attachments.
Message is classified with any of these labels **Message is not classified with any of these labels**	**Message has retention labels applied**	To apply the policy when certain retention labels are included or excluded in a message. Retention labels must be configured separately and configured labels are chosen as part of this condition. Each label you choose is applied separately (only one of these labels must apply for the policy to apply to the message). For more information about retention labels, see Learn about retention policies and retention labels.
Message is received from any of these domains **Message is not received from any of these domains**	**Sender domain is**	Apply the policy to include or exclude specific domains in received messages. Make sure to use the following syntax when entering conditional text: -Enter each domain and separate multiple domains with a comma. -Don't include spaces between items separated by a comma. -Remove all leading and trailing spaces. Each domain entered is applied separately, only one domain must apply for the policy to apply to the message. If you want to use **Message is received from any of these domains** to look for messages from specific domains, you need to combine this with another condition like **Message contains any of these words**, or **Content matches any of these classifiers**, or you might get unexpected results. For existing policies, if you want to scan all emails but want to exclude messages from a specific domain that don't need review (newsletters,

Condition name for existing policies	Condition name for new policies	How to use this condition
		announcements, and so on), you must configure a **Message is not received from any of these domains** condition that excludes the domain (example 'contoso.com,wingtiptoys.com').
Message is received from any of these external email addresses **Message is not received from any of these external email addresses**	**Sender is**	Apply the policy to include or exclude messages received or not received from specific external email addresses (example someone@outlook.com). Use this condition to detect only messages that come from outside the organization (messages that cross the firewall). Make sure to use the following syntax when entering email addresses: - Enter each email address and separate multiple email addresses with a comma. - Don't include spaces between email addresses separated by a comma. - Remove all leading and trailing spaces. - Remove any single quote or double quotes
Message is sent to any of these domains **Message is not sent to any of these domains**	**Recipient domain is**	Apply the policy to include or exclude specific domains in sent messages. Make sure to use the following syntax when entering conditional text: -Enter each domain and separate multiple domains with a comma. -Don't include spaces between items separated by a comma. -Remove all leading and trailing spaces. Each domain is applied separately; only one domain must apply for the policy to apply to the message. For existing policies, if you want to exclude all emails sent to two specific domains, configure the **Message is not sent to any of these domains** condition with the two domains (example 'contoso.com,wingtiptoys.com').
Message is sent to any of these external email addresses **Message is not sent to any of these external email addresses**	**Recipient is**	Apply the policy to include or exclude messages sent or not sent to specific external email addresses (example someone@outlook.com). Use this condition to detect only messages that are sent outside the organization (messages that cross the firewall). Make sure to use the following syntax when entering email addresses: - Enter each email address and separate multiple email addresses with a

Condition name for existing policies	Condition name for new policies	How to use this condition
		comma. - Don't include spaces between email addresses separated by a comma. - Remove all leading and trailing spaces. - Remove any single quote or double quotes
Message size is larger than **Message size is not larger than**	**Message size equals or is larger than**	To review messages based on a certain size, use these conditions to specify the maximum or minimum size a message can be before it's subject to review. For example, for an existing policy, if you specify **Message size is larger than** > **1.0 MB**, all messages that are 1.01 MB and larger are subject to review. You can choose bytes, kilobytes, megabytes, or gigabytes for this condition.

> **Important**
>
> If a condition includes a list, don't include spaces between list items. For example, enter "bias,harassment" instead of "bias, harassment".

Matching words and phrases to emails or attachments

Each word you enter and separate with a comma is applied separately (only one word must apply for the policy condition to apply to the email or attachment). For example, let's use the condition **Message contains any of these words** with the keywords "banker", "confidential", and "insider trading" separated by a comma (banker,confidential,"insider trading"). The policy applies to any messages that includes the word "banker", "confidential", or the phrase "insider trading". Only one of these words or phrases must occur for this policy condition to apply. Words in the message or attachment must exactly match what you enter.

> **Important**
>
> When importing a custom dictionary file, each word or phrase must be separated with a carriage return and on a separate line. For example:
>
> *banker*
> *confidential*
> *insider trading*

To scan both email messages and attachments for the same keywords, create a custom keyword dictionary for the terms you want to scan. This policy configuration identifies defined keywords that appear in either the email message **OR** in the email attachment. Using the standard conditional policy settings (**Message contains any of these words** and **Attachment contains any of these words**) to identify terms in messages and in attachments requires the terms to be present in **BOTH** the message and the attachment.

Use the condition builder to create complex conditions (new policies)

If you want to create nested conditions or use the **OR** operator in addition to the **AND** operator in new policies, use the condition builder. To use multiple operators (both **AND** and **OR**) in the same condition, you must create a separate group for each operator. Select **Add group** to create a group.

To use the condition builder, you must first opt in. To do this, in the **Conditions** section, above the existing condition builder, turn the **Condition builder** option on. If you create a new policy by using a template, you don't have to opt in to the condition builder. Communication Compliance automatically uses the condition builder for new policies based on templates.

All exceptions in the condition builder are replaced with a NOT condition. For example, the existing condition builder includes the **Message is not received from any of these domains** condition. This condition is renamed to **Sender domain is** in the condition builder, so to build the **Message is not received from any of these domains** condition in the condition builder, use the **Sender domain is** condition together with the **NOT** condition. You must include the **NOT** condition within a nested group.

You can use conditions with trainable classifiers and sensitive info types as an exception by using the **NOT** condition in a nested group, but keyword highlighting isn't available in this case.

To make it easier to see a summary of a complex condition that includes multiple **AND** and **OR** operators or groups, the condition builder includes a simplified summary view of the condition. To see the summary for a condition you built, turn on the **Quick Summary** option.

For scenarios that show how to use conditions in policies, see Scenarios for using conditions in Communication Compliance policies.

Set the review percentage for policy matches

To reduce the amount of content to review, specify a percentage of all communications governed by a Communication Compliance policy. Communication Compliance selects a real-time, random

sample of content from the total percentage of content that matches chosen policy conditions. If you want reviewers to review all items, configure **100%** in a Communication Compliance policy.

Filter email blasts

Use the **Filter email blasts** setting to exclude messages sent from email blast services. Messages that match the conditions you specify don't generate alerts. This exclusion includes bulk email, such as newsletters, and spam, phishing, and malware. When you select this option, you can view a report that lists the bulk email senders that were filtered out. Reports are retained for 60 days. The list of senders is filtered before the content is analyzed, so there might be senders that don't match the content conditions.

This setting is on by default for new policies. If the **Filter email blasts setting** is off for existing policies, a recommendation is generated to turn on the setting.

Manage alert policies

After you configure a policy, Communication Compliance automatically creates a corresponding alert policy and generates alerts for messages that match conditions defined in the policy. It can take up to 24 hours after creating a policy to start receiving alerts from activity indicators. By default, all policy matches alert triggers are assigned a severity level of medium in the associated alert policy. Communication Compliance generates alerts for a policy once the aggregation trigger threshold level is met in the associated alert policy. A single email notification is sent once every 24 hours for any alerts, regardless of the number of individual messages that match policy conditions. For example, Contoso has an inappropriate content policy enabled and for January 1, there were 100 policy matches that generated six alerts. A single email notification for the six alerts is sent at end of January 1.

For Communication Compliance policies, the system configures the following alert policy values by default:

Expand table

Alert policy trigger	Default value
Aggregation	Simple aggregation
Threshold	Default: 4 activities Minimum: 3 activities Maximum: 2,147,483,647 activities

Alert policy trigger	Default value
Window	Default: 60 minutes Minimum: 60 minutes Maximum: 10,000 minutes

> **Note**
>
> The alert policy threshold trigger settings for activities support a minimum value of 3 or higher for Communication Compliance policies.

You can change the default settings for triggers on number of activities, period for the activities, and for specific users in alert policies on the **Alert policies** page in Microsoft Purview.

Change the severity level for an alert policy

To change the severity level for an alert policy, see Alert policies in the Microsoft Defender portal.

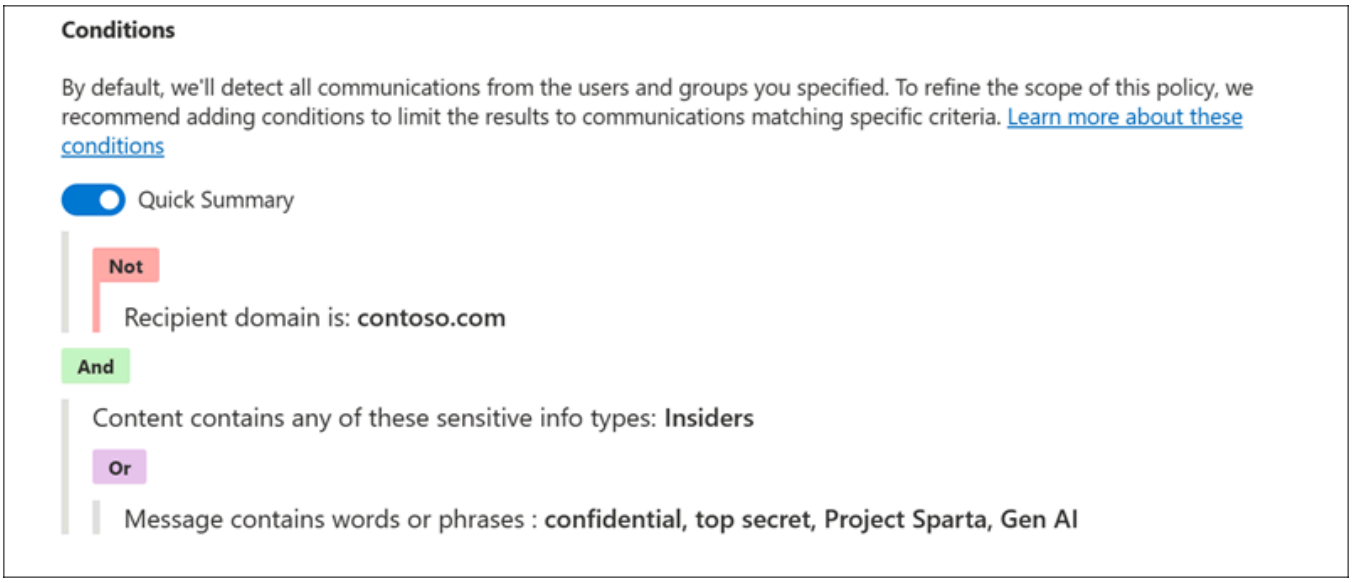
Configure conditions for key Communication Compliance scenarios

08/13/2025

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

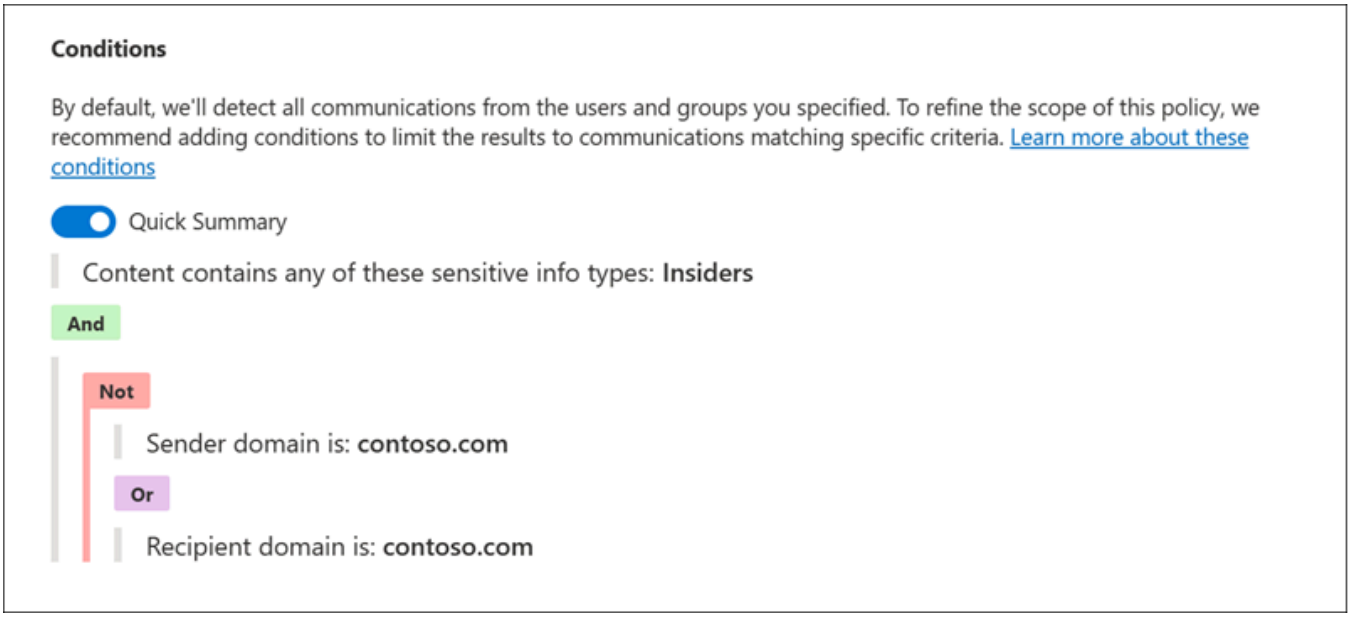
This article provides multiple examples of creating conditions with the condition builder in Microsoft Purview Communication Compliance. Use the examples for your own scenarios and modify as needed for your organization.



For general information on creating conditions for Communication Compliance policies, see Choose conditions for your Communication Compliance policies.

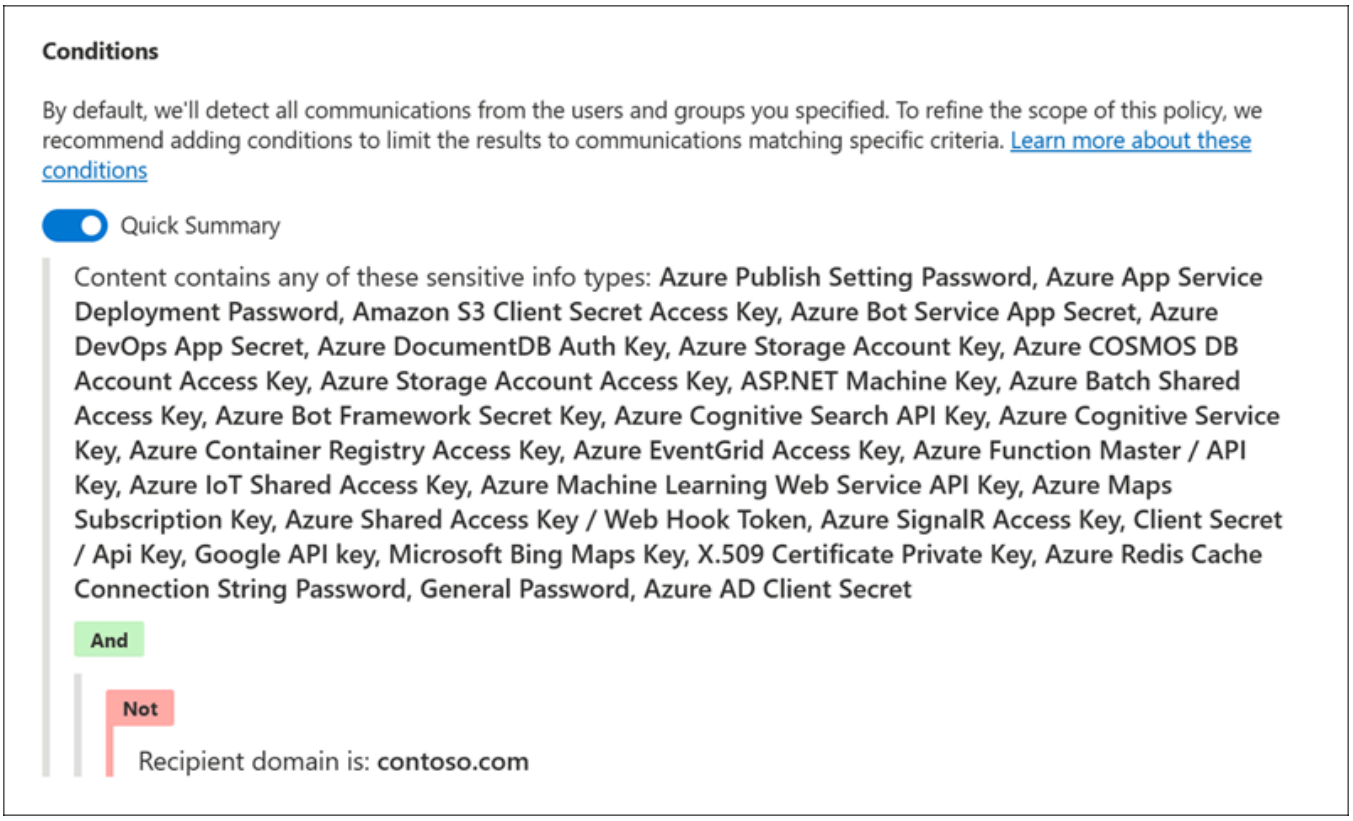
Data security examples

Example 1:



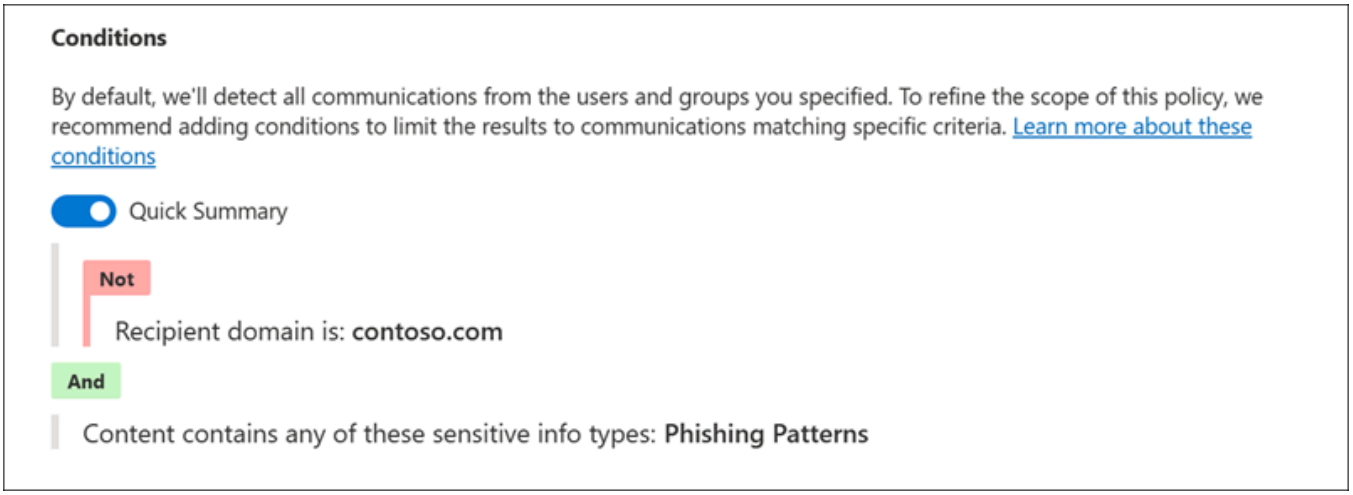
Detect all communications sent outside of Contoso.com that contain patterns detected by the *Insiders* sensitive info type OR that include any of these keywords:

- "confidential"
- "top secret"
- "Project Sparta"
- "GenAI"



Example 2:

Detect all communications coming from outside or sent outside contoso.com that contains patterns detected by the *Insiders* sensitive info type.

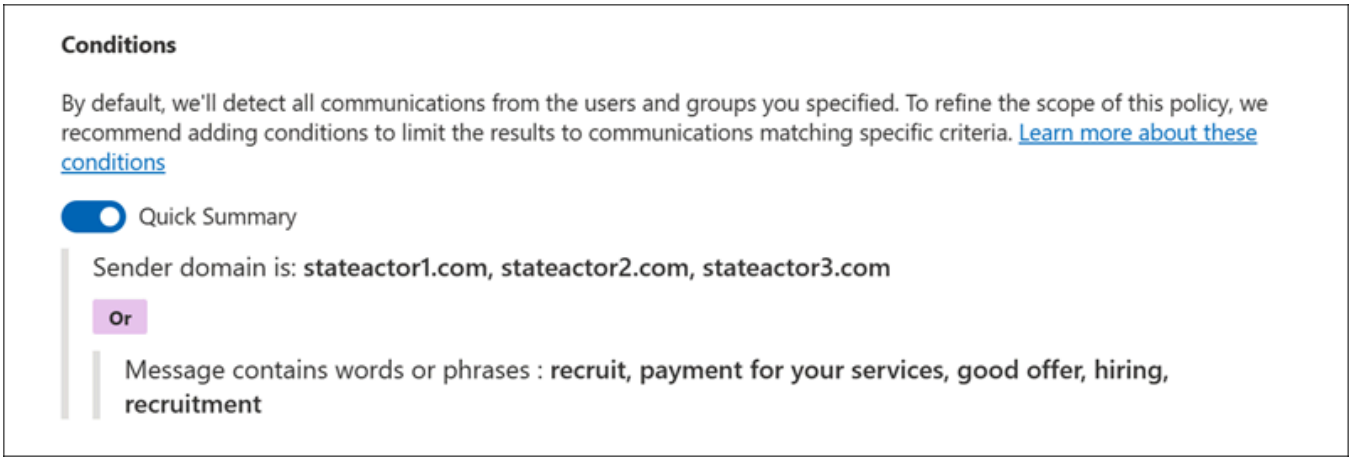


Example 3:

Proactively detect sharing of secret keys and passwords outside of contoso.com.

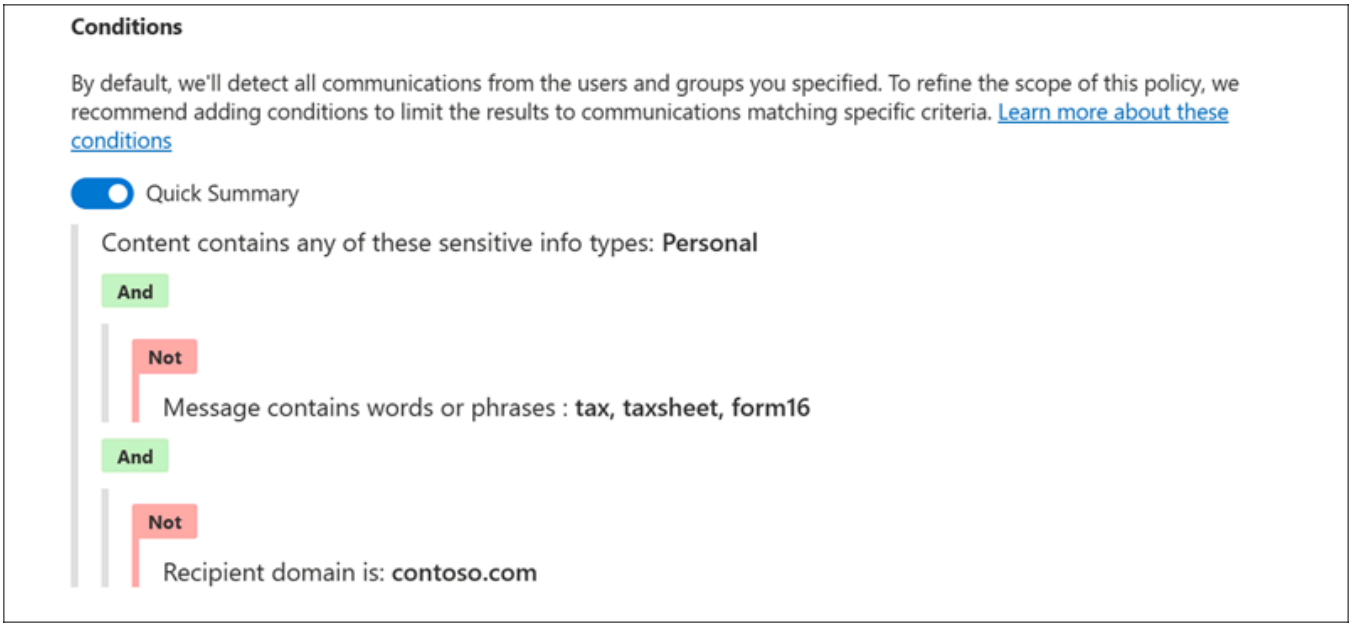
Example 4:

Detect Teams phishing requests sent as multifactor authentication requests by using the *Phishing Patterns* sensitive info type.



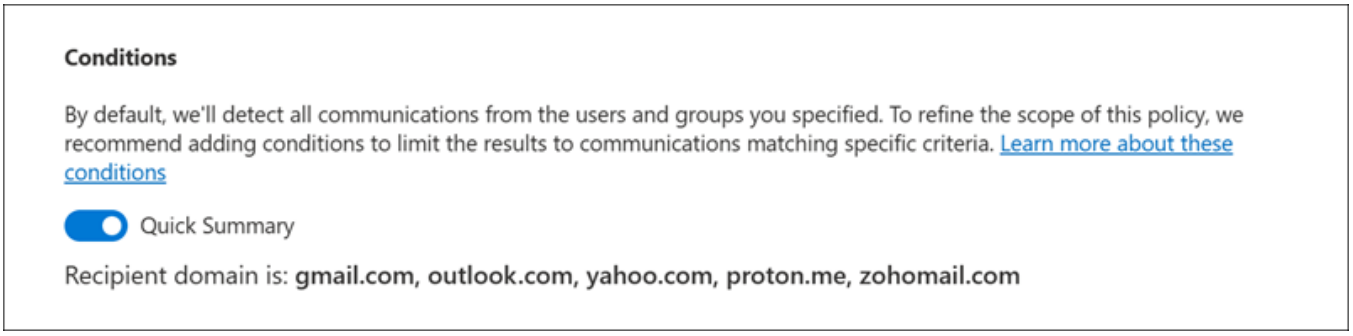
Example 5:

Analyze all messages coming from the stateactor1.com, stateactor2.com, and stateactor3.com domains OR messages containing these keywords:



- recruit
- payment for your services
- good offer

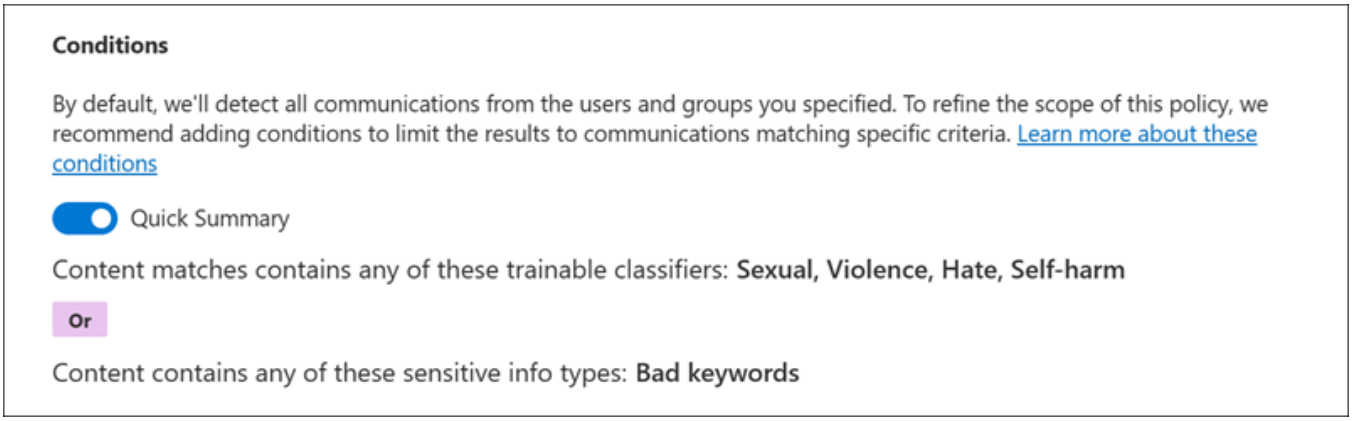
- hiring, recruitment



Example 6:

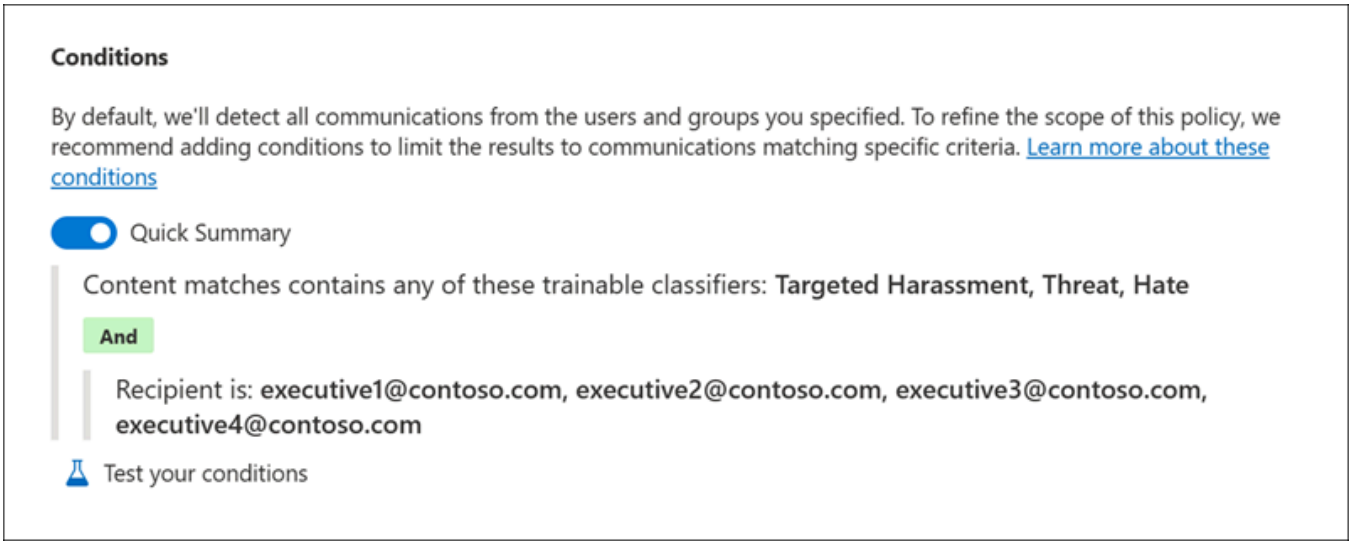
Analyze specific emails sent to external domains by detecting patterns using the *Personal* sensitive info type, but ignore specific keywords.

Example 7:



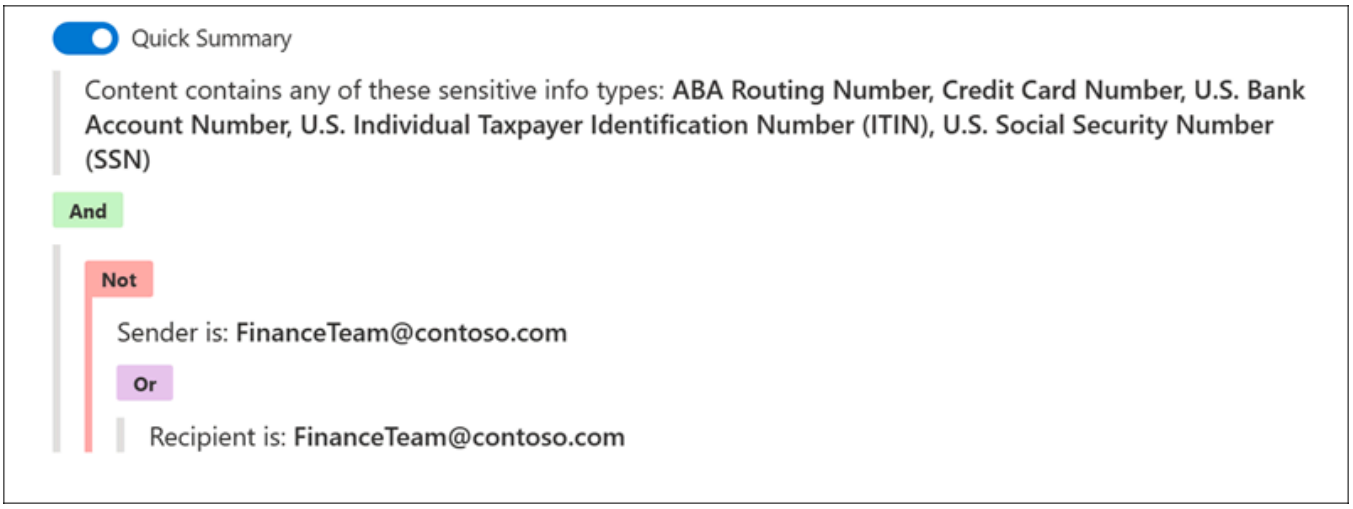
Analyze and view all emails sent to personal email accounts.

Business conduct examples



Example 1:

Detect inappropriate content sent in messages by using the *Sexual*, *Violence*, *Hate*, and *Self-harm* Microsoft provided trainable classifiers OR by using a curated keyword dictionary.



Example 2:

Detect threats and harassment addressed to Contoso's key executives by using the *Targeted Harassment*, *Threat*, and *Hate* Microsoft provided trainable classifiers.

Example 3:

Detect all messages that contain patterns detected by the *ABA Routing Number*, *Credit Card Number*, *U.S. Bank Account Number*, *U.S. Individual Taxpayer Identification Number (ITIN)*, and *U.S. Social Security Number (SSN)* sensitive information types sent by any user, but not sent to or sent by the Finance Team.

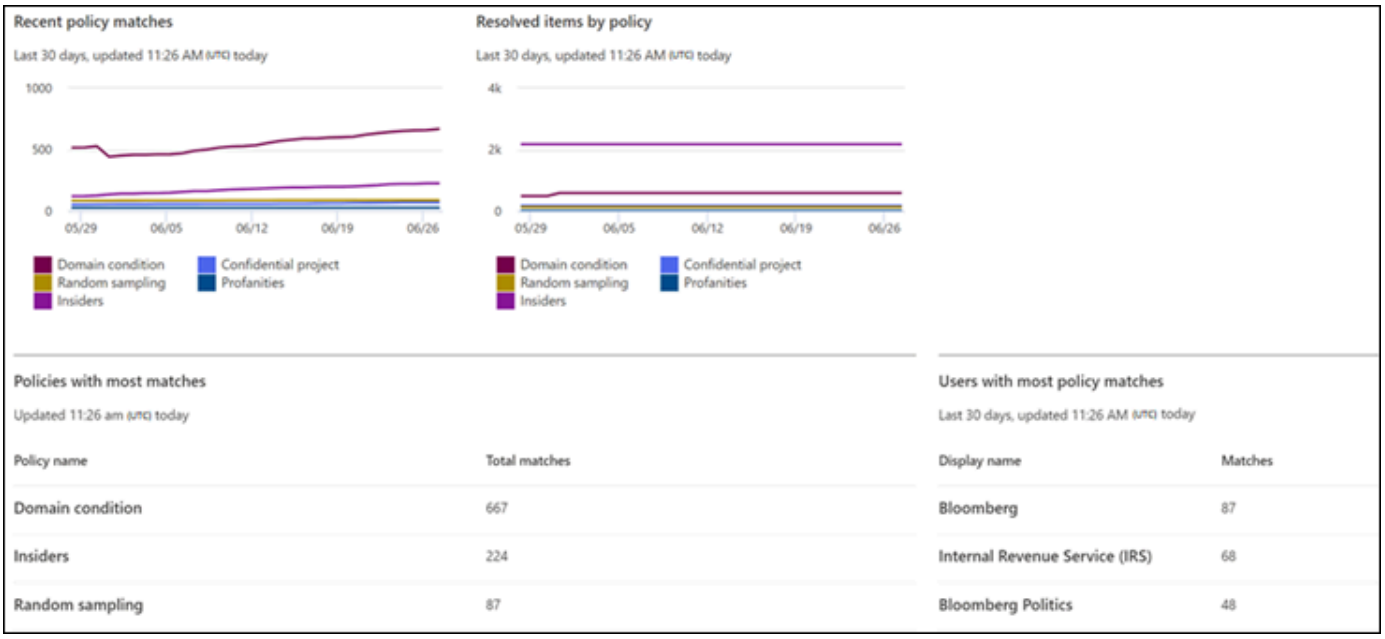
Use Communication Compliance reports and audits

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.



Use Communication Compliance reports

> **Note**
>
> Currently, if your role is scoped by one or more admin units in Microsoft Purview, the admin units don't apply to reports. You can see all reports in the organization.

The **Reports** dashboard is the central location for viewing all Communication Compliance reports. To view and manage reports, assign users to the *Communication Compliance Viewers* role group.

Report widgets provide a quick view of insights most commonly needed for an overall assessment of the status of Communication Compliance activities. You can't export the information contained in the report widgets. Detailed reports provide in-depth information related to specific Communication Compliance areas and offer the ability to filter, group, sort, and export information while reviewing.

For the date range filter, the date and time for events are listed in Coordinated Universal Time (UTC). When filtering messages, all filters for the report apply at the 00:00:00 UTC start date to the 23:59:59 UTC end date.

The **Reports dashboard** contains the following report widgets and detailed reports links:

Report widgets

The Reports dashboard includes the following widgets that provide at-a-glance summaries of policy activity:

- **Recent policy matches**: displays the number of matches by active policies over time.
- **Resolved items by policy**: displays the number of policy match alerts resolved by policies over time.
- **Policy with most matches**: displays the policies and the number of matches for a given period, ranked highest to lowest for matches.
- **Users with most policy match**: displays the users (or anonymized usernames) and number of policy matches for a given period.
- **Escalations by policy**: displays the number of escalations per policy over a given time.

Detailed reports

Use the *Export report* option to create a .CSV file containing the report details for any detailed report. The *Export report* option supports file size downloads up to 3 MB.

- **Policy settings and status**: provides a detailed look at policy configuration and settings, as well as the general status for each of the policy (matches and actions) on messages. Includes policy information and how policies are associated with users and groups, locations, review percentages, reviewers, status, and when the policy was last modified. Use the *Export* option to create a .CSV file containing the report details.

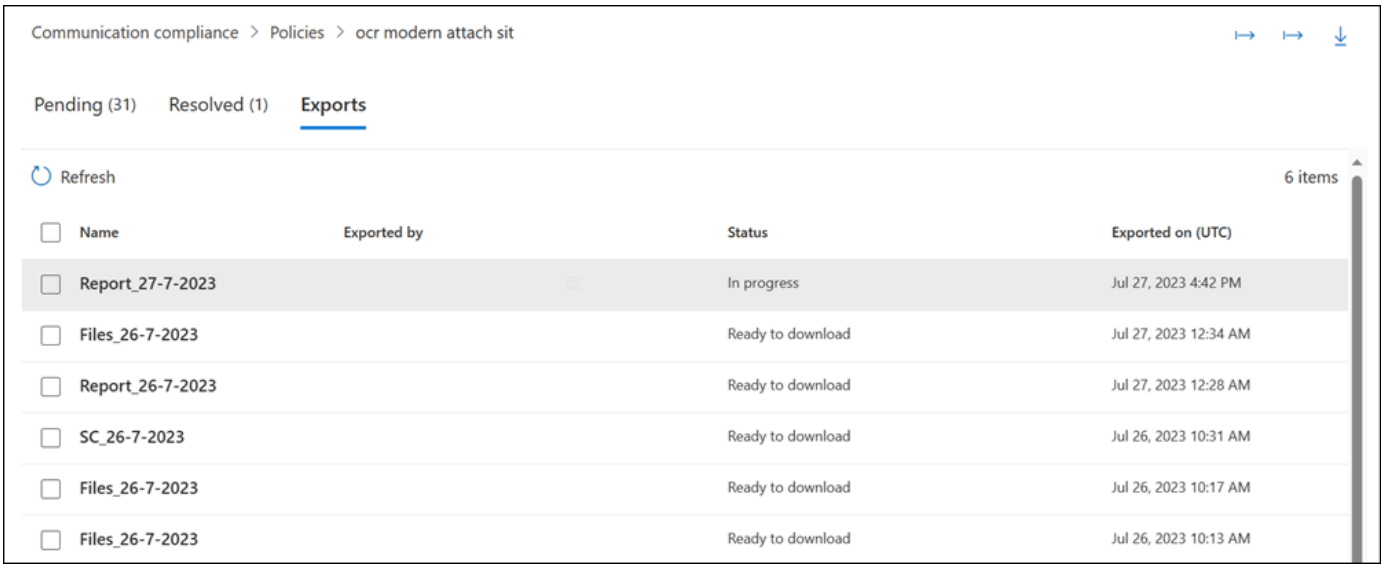
- **Items and actions per policy**: Review and export matching items and remediation actions per policy. Includes policy information and how policies are associated with:
  - Case created
  - Escalated items
  - Items matched
  - Items pending review
  - Resolved items
  - Tagged as compliant
  - Tagged as noncompliant
  - Tagged as questionable
  - User notified

- **Item and actions per location**: Review and export matching items and remediation actions per Microsoft 365 location. Includes information about how workload platforms are associated with:
  - Case created
  - Escalated items
  - Items matched
  - Items pending review
  - Resolved items
  - Tagged as compliant
  - Tagged as noncompliant
  - Tagged as questionable
  - User notified

- **Activity by user**: Review and export matching items and remediation actions per user. Includes information about how users are associated with:
  - Case created
  - Escalated items
  - Items matched
  - Items pending review
  - Resolved items
  - Tagged as compliant
  - Tagged as noncompliant
  - Tagged as questionable
  - User notified

> ⓘ **Note**

The items and actions displayed are only for the items and actions *matched* within the report's selected date range filter.



- **Sensitive information type per location** (preview): Review and export information about the detection of sensitive information types and the associated sources in Communication Compliance policies. Includes the overall total and the specific breakdown of sensitive information type instances in the sources configured in your organization. The values for each third-party source are displayed in separate columns in the .CSV file. Examples are:
  - **Email**: Sensitive information types detected in Exchange email messages.
  - **Teams**: Sensitive information types detected in Microsoft Teams channels and chat messages.
  - **Microsoft 365 Copilot and Microsoft 365 Copilot Chat**: Sensitive information types detected in Copilot interactions.
  - **Viva Engage**: Sensitive information types detected in Viva Engage inboxes, posts, chats, and replies.
  - **Third-party sources**: Sensitive information types detected for activities associated with third-party connectors configured in your organization. To view the breakdown of third-party sources for a specific sensitive information type in the report, hover your mouse over the value for the sensitive information type in the Third-party source column.
  - **Other**: Sensitive information types used for internal system processing. Selecting or deselecting this source for the report won't affect any values.

- **Email blast senders**: Review and export the list of senders of email blast messages that were filtered out from your Communication Compliance policies to reduce "noise." **Filter email blasts** is a Communication Compliance policy setting. The Email blast senders report includes the following fields:
  - Policy name
  - Policy last modified date
  - Sender
  - Number of mails filtered

Export a message details report

You can create custom reports and review details for messages brought into the scope of specific policies. Use these reports for all-up reviews of messages and for creating a report snapshot for a customizable time period. You can create a one-time report, or if you often need to create the same report, schedule report creation on a daily, weekly, or monthly basis. You can create up to five schedules per policy.

When you create a report, reviewers for the policy receive an email notification with a link to the **Exports** tab, where they can download the report as a CSV file.

Create the report

To create a message details report, complete the following steps:

1. Sign in to the Microsoft Purview portal using credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation.
4. Select a policy, then select **Export report** in the upper-right corner of the page.
5. On the **Export options** pane, under **Include items from these users**, select one of the following options:
    - **All users**. Select this option to create a report with message information for all users in the policy.
    - **Select users**. Select this option, then select specific users from the list, to create a report with messages sent by those specific users. Only the users who sent a message that the system flagged are available in the list.
6. In the **Select frequency** list, select how often you want to create the report.
7. If it's a one-time report, enter a start date and end date for the report. If it's a recurring report, enter a date to start sending reports and a date to stop sending reports.

> **Note**
>
> If you select **Daily**, **Weekly**, or **Monthly** for a recurring report, the report starts collecting messages from the previous day, week, or month, depending on which option you select. For example, if you choose **Daily** as the frequency and choose **June 4, 2024** as the start date for the report, the report starts collecting messages on June 3.

8. In the **Send report to these reviewers** list, add or delete reviewers as needed. By default, all reviewers for the policy (added during policy creation) are listed.
9. In the **Report name** field, accept the suggested name for the report or change it as needed.
10. Select **Create report** (for one-time reports) or **Start scheduled export** (for recurring reports).

    The **Preparing scheduled report** dialog box appears.
11. Select **Manage scheduled exports** to view the schedule of reports.

> **Tip**
>
> To edit a report schedule, select **Manage scheduled reports** from the **Exports** tab.

12. To make changes to a scheduled report:
    a. Select the checkbox for the report, then select **Edit**.
    b. In the **Export options** dialog box, make the changes that you want.

> **Note**
>
> To change the frequency or start date of the report, delete the report from the **Manage scheduled exports** page, then create the report again.

> **Note**
>
> You can create up to five scheduled reports per policy. If you already have five scheduled reports for a policy and want to create a new one, delete one of the existing report schedules before you can create a new one.

Download a report when it's ready

The time it takes to create a report depends on the number of scheduled reports and the size of the reports. Reviewers on the policy receive an email notification with a link to the **Exports** tab when a report is ready. To download a report from the **Exports** tab, select a report in the *Ready to download* state, then select **Download export(s)**.

> ⓘ **Note**
>
> If your selected time period doesn't return any message results in the report, it means there were no messages for the selected time period. The report is blank.

What's included in a Message details report

Message details reports contain the following information for each message item in the policy:

- **Match ID**: Unique ID for a copy of the message in Communication Compliance.
- **Internet Message ID**: Unique ID for the message across platforms.
- **Conversation Family ID**: Thread ID for the message.
- **Sender column**: Sender of the message. If the policy match is a response from Microsoft 365 Copilot and Microsoft 365 Copilot Chat, the value is "Copilot".
- **Recipient column**: Recipients included in the message. If the policy match is a prompt to Copilot, the value is "Copilot".
- **Date**: The date when the message was sent.
- **Location**: Channel where the message was sent. This channel can be Exchange Online, Teams, Viva Engage, or any third-party channel that Communication Compliance supports.
- **Subject**: Subject of the message. If it's a Copilot interaction, the subject of the message is "Copilot" and the name of the Microsoft 365 app. For example: "Copilot in Excel".
- **Contains Attachments**: Status of any attachments for the message. Values are either *Yes* or *No*.
- **Policy Name**: Name of the policy associated with the message. This value is the same for all messages in the report.
- **Item Status**: Status of the message item in the policy. Values are *Pending* or *Resolved*.
- **Tags**: Tags assigned to the message. Values are *Questionable, Compliant*, or *Noncompliant*.
- **Keyword Matches**: Keyword matches for the message.
- **Trainable Classifier ID**: ID of the trainable classifier that was matched.
- **Trainable Classifier Name and Matched Keywords**: The name of the trainable classifier and the keywords that triggered the classifier match.
- **Reviewers**: Reviewers assigned to message.

- **Pending for (days)**: Number of days the message has been in a pending state. For resolved messages, the value is 0.
- **Comment for Resolved**: Comments for the message entered when resolved.
- **Resolved Date**: Date and Coordinated Universal Time (UTC) the message was resolved.
- **Last Updated By**: User name of the last updater.
- **Last Updated On**: Date and Coordinated Universal Time (UTC) the message was last updated.
- **History of Comments**: List of all comments for the message alert, including comment author and date and Coordinated Universal Time (UTC) of the comment.

> **Tip**
>
> You can also archive message details outside of Communication Compliance.

Review Communication Compliance audit data

In some instances, you must provide information to regulatory or compliance auditors to prove that user activities and communications are scoped. This information might be a summary of all activities associated with a defined organizational policy or anytime a Communication Compliance policy changes. Communication Compliance policies have built-in audit trails for complete readiness for internal or external audits. Your communication policies capture detailed audit histories of every create, edit, and delete action to provide proof of scoped procedures.

> **Important**
>
> You must enable auditing for your organization before Communication Compliance events are recorded. To enable auditing, see Step 2: Enable the audit log in Communication Compliance configuration. When activities trigger events that the Microsoft 365 Audit log captures, it can take up to 48 hours before you can view these events in Communication Compliance policies.

To view Communication Compliance policy update activities, select the **Export policy updates** control on the main page for any policy. You must be assigned the *Global Admin* or *Communication Compliance Admins* roles to export update activities. This action generates an audit file in the .CSV format that contains the following information:

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Expand table

Field	Details
AuditData	Main data source for all policy update activities. All update activities are recorded and separated by comma delimiters.
CreationDate	Date the update activity was performed in a policy.
Operations	Update operations performed on the policy.
UserIds	User that performed the update activity in a policy.

To view Communication Compliance review activities for a policy, select the **Export review activities** control on the **Overview** page for a specific policy. You must be assigned the *Global Admin* or *Communication Compliance Admins* roles to export review activities. This action generates an audit file in the .CSV format that contains the following information:

Important

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Expand table

Field	Details
AuditData	Main data source for all policy review activities. All review activities are recorded and separated by comma delimiters.
CreationDate	Date the review activity was performed in a policy.
Operations	Review operations performed on the policy.
UserIds	User that performed the review activity in a policy.

You can also view audit activities in the unified audit log or with the Search-UnifiedAuditLog PowerShell cmdlet. To learn more about audit log retention policies, see Manage audit log

retention policies.

For example, the following command searches the unified audit log for all scoped review activities (policies and rules):

PowerShell

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -RecordType AeD -
Operations SupervisoryReviewTag
```

To audit when Communication Compliance policies are created, updated, or deleted, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -RecordType Discovery
-Operations SupervisionPolicyCreated,SupervisionPolicyUpdated,SupervisionPolicyDeleted
```

To review events where content matched your current Communication Compliance policy rules, search the audit log with the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -Operations
SupervisionRuleMatch
```

Communication Compliance policy matches are stored in a scoped mailbox for each policy. In some cases, you might need to check the size of your scoped mailbox for a policy to make sure you aren't approaching the current 100-GB storage size or 1 million message limit. If you reach the mailbox limit, the system doesn't capture policy matches and you need to create a new policy (with the same settings) to continue to capture matches for the same activities.

To check the size of a scoped mailbox for a policy, complete the following steps:

1. Connect to Exchange Online PowerShell.
2. Run the following command:

   PowerShell

   ```
   ForEach ($p in Get-SupervisoryReviewPolicyV2 | Sort-Object Name)
   {
      "<Name of your Communication Compliance policy>: " + $p.Name
   ```

```
    Get-MailboxStatistics $p.ReviewMailbox | ft ItemCount,TotalItemSize
}
```

Detect channel signals with Communication Compliance

08/28/2025

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

With Communication Compliance policies, you can choose to analyze messages in one or more of the following communication platforms as a group or as standalone sources. Your organization retains original messages captured across these platforms in the original platform location in accordance with your retention and hold policies. Communication Compliance policies retain copies of messages used for analysis and investigation for as long as a policy is in place, even if users leave your organization and their mailboxes are deleted. When you delete a communication policy, you also delete copies of messages associated with the policy.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Generative AI

> **Important**
>
> To detect inappropriate or risky interactions for non-Microsoft 365 AI data, you need to enable pay-as-you-go billing in your organization. Non-Microsoft 365 AI data includes information from other generative AI applications from Microsoft and other connected external AI applications. This data type includes Copilot in Microsoft Fabric, Microsoft Security Copilot, Microsoft Copilot Studio, and any connected or cloud AI application.

There aren't any pay-as-you-go billing requirements or charges for Microsoft 365 detecting inappropriate or risky interaction for Microsoft 365 Copilot data.

Communication Compliance supports numerous generative AI applications. You can use Communication Compliance policies to analyze interactions (prompts and responses) entered into these applications and help detect inappropriate or risky interactions or sharing of confidential information. Communication Compliance supports the following generative AI applications:

- **Microsoft Copilot experiences**: Support for user interactions in Microsoft 365 Copilot and other Copilots built using Microsoft Copilot Studio.
- **Enterprise AI apps**: Non-Copilot AI apps that you onboard or connect to your organization by using methods like Microsoft Entra registration and data connectors.
- **Other AI apps**: Other AI applications detected through browser activity and categorized as *Generative AI* in the Defender for Cloud Apps catalog.

Use the following links to learn more about creating a Communication Compliance policy that detects Microsoft 365 Copilot and Microsoft 365 Copilot Chat interactions and other Microsoft Purview data security and compliance protections for Microsoft 365 Copilot and Microsoft 365 Copilot Chat:

- Configure a Communication Compliance policy to detect for Microsoft 365 Copilot and Microsoft 365 Copilot Chat interactions
- Microsoft Purview data security and compliance protections for generative AI apps

Microsoft Teams

You can analyze chats in public and private Microsoft Teams channels and individual communications. When you assign users to a Communication Compliance policy with Microsoft Teams coverage selected, the solution automatically detects chat communications across all Microsoft Teams where users are a member.

To learn how to detect communication risks in Microsoft Teams with Communication Compliance, watch the following video:

https://learn-video.azurefd.net/vod/player?id=7857b91f-d0c1-4b9b-ac84-5c70a8453216&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance-channels

Microsoft Purview Communication Compliance automatically includes Microsoft Teams coverage for predefined policy templates and selects it as the default in the custom policy

template. Teams transcripts are also included. Teams chats matching Communication Compliance policy conditions might take up to 48 hours to process.

For Teams private chat and private channels, Communication Compliance policies support modern attachment analysis. Shared Channels support in Teams is handled automatically and doesn't require additional Communication Compliance configuration changes. The following table summarizes Communication Compliance behavior when sharing Teams channels with groups and users:

Expand table

Scenario	Communication Compliance behavior
Share a channel with an internal team	Communication Compliance policies apply to in-scope users and all messages in the shared channel
Share a channel with an external team	Communication Compliance policies apply to internal in-scope users and messages in the shared channel for the internal organization

Modern attachments are files sourced from OneDrive or SharePoint sites that are included in Teams messages. Text is automatically extracted from these attachments for automated processing and potential matches with active Communication Compliance policy conditions and classifiers. There's no extra configuration necessary for modern attachment detection and processing. Text is only extracted for attachments matching policy conditions at the time the message is sent. Text isn't extracted for attachments for messages with policy matches, even if the attachment also has a policy match.

Modern attachment analysis is supported for the following file types:

- Microsoft Word (.docx)
- Microsoft Excel (.xlsx, .xls, .csv)
- Microsoft PowerPoint (.pptx)
- Text (.txt)
- Portable Document Format (.pdf)

Modern attachments like files hosted on OneDrive or SharePoint sites are supported if shared as Teams messages. The extracted text from these attachments is saved as .txt files and included with the Teams message in Communication Compliance. Additionally, the URL to the original file is attached separately for review. Extracted text for modern attachments is included with the associated message on the **Pending** tab of the policy's dashboard. The extracted text for an attachment is named as the attachment file name (and format extension) and the .txt extension. For example, the extracted text for an attachment named *ContosoBusinessPlan.docx* appears as *ContosoBusinessPlan.docx.txt* in the **Pending** tab of the policy's dashboard.

Select the extracted attachment text to view the details in the *Source* and *Plain text* views. After reviewing, you can resolve or take action on the attachment text using the command bar controls. You can also download the attachment for review outside of the Communication Compliance review process.

Use the following group management configurations to bring individual user chats and channel communications in Teams in scope:

- **For Teams chats:** Assign individual users or assign a distribution group to the Communication Compliance policy. This setting is for one-to-one or one-to-many user/chat relationships.

- **For Teams channel communications:** If any member of the channel is a scoped user within a policy and the **Inbound** direction is configured as the **Communication direction** for the policy, all messages sent within the channel are subject to review by Communication Compliance, even for users in the channel that aren't explicitly scoped.

  For example, consider the following set of circumstances:

- User A is scoped in a Communication Compliance policy.
  - User A is a member of a Teams channel.
  - **Inbound** is selected as the direction for the policy.
  - User B and User C aren't scoped in a Communication Compliance policy.
  - User B and User C are members of the same Teams channel as User A.
  - User B and User C are posting in the channel, but aren't communicating directly with User A.

  In this scenario, a message from User B or User C can be flagged as a policy match even if they don't communicate directly with user A. This result is because User A is technically receiving the message from User B and User C since they're part of the same channel. In this case, if you want to exclude User B and User C from potentially being flagged for policy matches, select a different communication direction in the applicable Communication Compliance policy.

  On the other hand, if User B and User C have a conversation on another channel or in a chat that doesn't include User A, the conversation isn't reviewed by the policy even if the conversation would otherwise provide a policy match since User A, the scoped user, isn't included in the conversation.

- **For Teams chats with hybrid email environments**: Communication Compliance can detect chat messages for organizations with an Exchange on-premises deployment or an external email provider that enabled Microsoft Teams. You must create a distribution group for the users with on-premises or external mailboxes. When creating a Communication Compliance policy, assign this distribution group using **Choose users**

and groups in the policy workflow. For more information about the requirements and limitations for enabling cloud-based storage and Teams support for on-premises users, see Search for and export Teams chat data for on-premises users.

> **Tip**
>
> For a more flexible configuration and to reduce administrative overhead, consider using an **adaptive scope** instead of a distribution group.

Exchange

You can analyze all mailboxes hosted on Microsoft Exchange Online as part of your Microsoft 365 or Office 365 subscription. Exchange email messages and attachments that match Communication Compliance policy conditions might take about 24 hours to process. Supported attachment types for Communication Compliance are the same as the file types supported for Exchange mail flow rule content inspections.

Viva Engage

You can also analyze private messages, public conversations, and associated attachments in Microsoft Viva Engage communities. When you add users to a Communication Compliance policy that includes Viva Engage as a defined channel, the analysis includes communications across all Viva Engage communities that a user is a member of. Viva Engage chats without attachments that match Communication Compliance policy conditions can take up to one hour to process. Viva Engage chats with attachments can take up to 24 hours to process.

You must configure Viva Engage in Native Mode for Communication Compliance policies to detect Viva Engage communications and attachments. In Native Mode, all Viva Engage users are in Microsoft Entra ID, all groups are Microsoft 365 Groups, and all files are stored in SharePoint.

Non-Microsoft sources

You can analyze communications for data imported into all mailboxes in your Microsoft 365 organization from non-Microsoft sources like Instant Bloomberg, Slack, Zoom, SMS, and many others. For a full list of connectors supported in Communication Compliance, see Learn about connectors for third-party data.

You must configure a third-party connector for your Microsoft 365 organization before you can assign the connector to a Communication Compliance policy. The **Third-Party Sources** section

of the Communication Compliance policy workflow only displays currently configured third-party connectors.

> **Note**
>
> Content from all non-Microsoft channels (such as WhatsApp or Instant Bloomberg) takes 24 to 48 hours for detection by Communication Compliance, depending on how frequently the data is imported from those non-Microsoft channels.

Channel limits

Expand table

Channel	Current limit
All channels	Maximum of 25 attachments per policy match
Teams public channels	Maximum of 250 users for public channel messages for static scopes with users
Teams public channels	No support or coverage for public channel messages for adaptive scopes with users

Configure a Communication Compliance policy to detect generative AI interactions

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Overview

You can use Communication Compliance to analyze interactions (prompts and responses) to detect inappropriate or risky interactions or sharing of confidential information entered into numerous generative AI applications.

These applications include Microsoft 365 Copilot, Copilots built with Microsoft Copilot Studio, AI applications connected by Microsoft Entra or Microsoft Purview Data Map connectors, and more.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Microsoft Copilot experience

> **Important**
>
> To detect inappropriate or risky interactions for non-Microsoft 365 AI data, you must enable pay-as-you-go billing in your organization. Non-Microsoft 365 AI data includes information from other generative AI applications from Microsoft and connected external AI applications. Examples of non-Microsoft 365 AI data include Copilot in Microsoft Fabric, Microsoft Security Copilot, Microsoft Copilot Studio, and any connected or cloud AI application.

There are no pay-as-you-go billing requirements or charges for Microsoft 365 detecting inappropriate or risky interactions for Microsoft 365 Copilot data.

Communication Compliance can detect interactions in any message with the IPM.SkypeTeams.Message.Copilot.*application* item class. These item classes include Copilot applications in Microsoft solutions like Teams, Outlook, and many more.

For example, Communication Compliance detects interactions in Copilot messages with the IPM.SkypeTeams.Message.Copilot.Teams, IPM.SkypeTeams.Message.Copilot.Outlook item classes, and others.

Connected generative AI application

> **Important**
>
> To detect inappropriate or risky interactions for connected generative AI applications, you must enable pay-as-you-go billing in your organization.

Communication Compliance can detect prompt and response interactions with non-Copilot AI applications. These applications are generative AI applications connected by using Microsoft Entra and Microsoft Purview Data Map connectors.

Other AI applications

> **Important**
>
> To detect inappropriate or risky interactions for other AI applications, your organization must enable pay-as-you-go billing.

Communication Compliance can also detect interactions with AI applications from browser and network activity by users in your organization. This capability helps you detect inappropriate or risky interactions or sharing of confidential information that users enter into AI applications outside of your organization.

Prerequisites

To investigate Copilot interactions in Communication Compliance, you must be assigned one of the following roles:

- *Communication Compliance*
- *Communication Compliance Investigators*
- *Communication Compliance Analysts*

You must also be assigned as a reviewer in the Reviewers field when creating a communication compliance policy.

How it works

> **Important**
>
> Microsoft is committed to making sure artificial intelligence (AI) systems are developed responsibly and in ways that warrant people's trust. As part of this commitment, Microsoft Purview engineering teams operationalize the six core principles of Microsoft's Responsible AI strategy to design, build, and manage AI solutions. To responsibly deploy AI, we provide documentation, role-based access, scenario attestation, and more to help organizations use AI systems responsibly.

You can take advantage of all Communication Compliance features when you create a Communication Compliance policy that detects Microsoft 365 Copilot and Microsoft 365 Copilot Chat interactions, including:

- Sensitive information types
- Keywords
- Microsoft provided trainable classifiers
- Content safety classifiers for Teams based on large language models
- Conditions

Any prompt or response that a user enters into a supported generative AI app and that matches a Communication Compliance policy appears as a policy match on the **Policies** page on the **Pending** tab, with separate entries for prompts and responses. If only the prompt or only the response matches a policy, the **Pending** tab shows an item just for that policy match. You can remediate policy matches for generative AI apps in the same way that you remediate any other policy match.

The following information appears for each item on the **Pending** tab for AI policy matches:

- **Icons**: The Copilot icon identifies the policy match as a generative AI interaction with a Microsoft-based Copilot For all other generative AI interactions, this icon is an email icon.
- **Subject column**: The *[Copilot]* value in this column identifies the policy match as a generative AI interaction with Microsoft-based Copilots. The *[AI app]* value in this column identifies the policy match for all other generative AI interactions.
- **Sender column**: Sender of the message. Depending on the source AI application, the sender appears as follows:
  - If the policy match is a response from a Copilot application, the value is *Copilot*.
  - If the policy match is a response from a connected AI application, the value is *Connected AI app*.
  - If the policy match is a response from a cloud AI application, the value is *Cloud AI app*.
- **Recipient column**: Recipients included in the message. This value is the user interacting with the AI application.
- **Message text**: The message text that the user entered (the text that caused the policy match) appears on the right side of the screen in its entirety.

Create a policy that detects Microsoft Copilot interactions

Follow these steps to create a policy that detects Microsoft Copilot interactions:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation.
4. Select **Create policy**, then select the **Detect Microsoft Copilot interactions** template.
5. Enter the policy name, select the users and groups to apply the policy to, and select the reviewers for the policy. Learn more about these options when creating a policy from a template
6. Review the list of settings chosen for you based on the template. Select **Create policy** to create the policy or select **Customize policy** if you want to make any changes before creating the policy.

Add a generative AI app as a location for an existing policy

Follow these steps to add a generative AI app as a location for an existing Communication Compliance policy:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation.
4. Select **More actions** (ellipsis) in the row for the policy you want to change, then select **Edit**.
5. Select **Next** two times in the policy creation workflow to go to the **Choose locations to detect communications** page.
6. Select one or more of the following checkboxes to add a generative AI application as a location:
    - **Microsoft Copilot experiences**
    - **Enterprise AI apps**
    - **Other AI apps**
7. Make any other changes to the policy, then on the **Review and finish** page, select **Save**.

Create a policy to review all generative AI interactions

When you first work with generative AI interactions, consider reviewing all AI interactions to understand how people in your organization use these applications. To create a policy that reviews all generative AI interactions, when you create or edit the policy:

- Set the location to include all generative AI applications:
    - **Microsoft Copilot experiences**
    - **Enterprise AI apps**
    - **Other AI apps**
- Set the **Review percentage** option on the **Choose conditions and review percentage** page to 100%.
- Don't set any conditions for the policy.

> **Note**
>
> Depending on the size of your organization, a policy that detects all generative AI interactions might result in a high volume of detected messages. This volume could cause

your organization to reach its **storage limit**. If your organization reaches its storage limit, adjust the policy to reduce the number of detections.

Remediate policy matches and alerts that contain generative AI interactions

Remediate policy matches and alerts that contain generative AI interactions the same way you remediate any policy match or alert in Communication Compliance. For example, you can tag a policy match, escalate it, resolve it, download it, or export it. Learn more about resolving policy matches and alerts in Communication Compliance.

Reports

AI interactions that you bring into the scope of a Communication Compliance policy appear in Communication Compliance reports and audit data. Learn more about Communication Compliance reports and audits.

Microsoft Teams and Microsoft Purview Communication Compliance

08/20/2025Applies to: Microsoft Teams

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Microsoft Purview Communication Compliance is an insider risk solution in Microsoft 365 that helps you minimize communication risks by helping you detect, capture, and act on inappropriate messages in your organization.

For Microsoft Teams, Communication Compliance helps you identify the following types of inappropriate content in Teams channels, private Teams channels, or in 1:1 and group chats:

- Offensive, profane, and harassing language
- Adult, racy, and gory images
- Sharing of sensitive information

Watch the following video to learn how to detect communication risks in Microsoft Teams with Communication Compliance:

https://learn-video.azurefd.net/vod/player?id=7857b91f-d0c1-4b9f-ac84-5c70a8453216&locale=en-us&embedUrl=%2Fpurview%2Fcommunication-compliance-teams

You can also detect offensive communications included in Microsoft Teams transcripts (preview).

For more information on Communication Compliance and how to configure policies for your organization, see Learn about Communication Compliance.

> **Tip**

Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

How to use Communication Compliance in Microsoft Teams

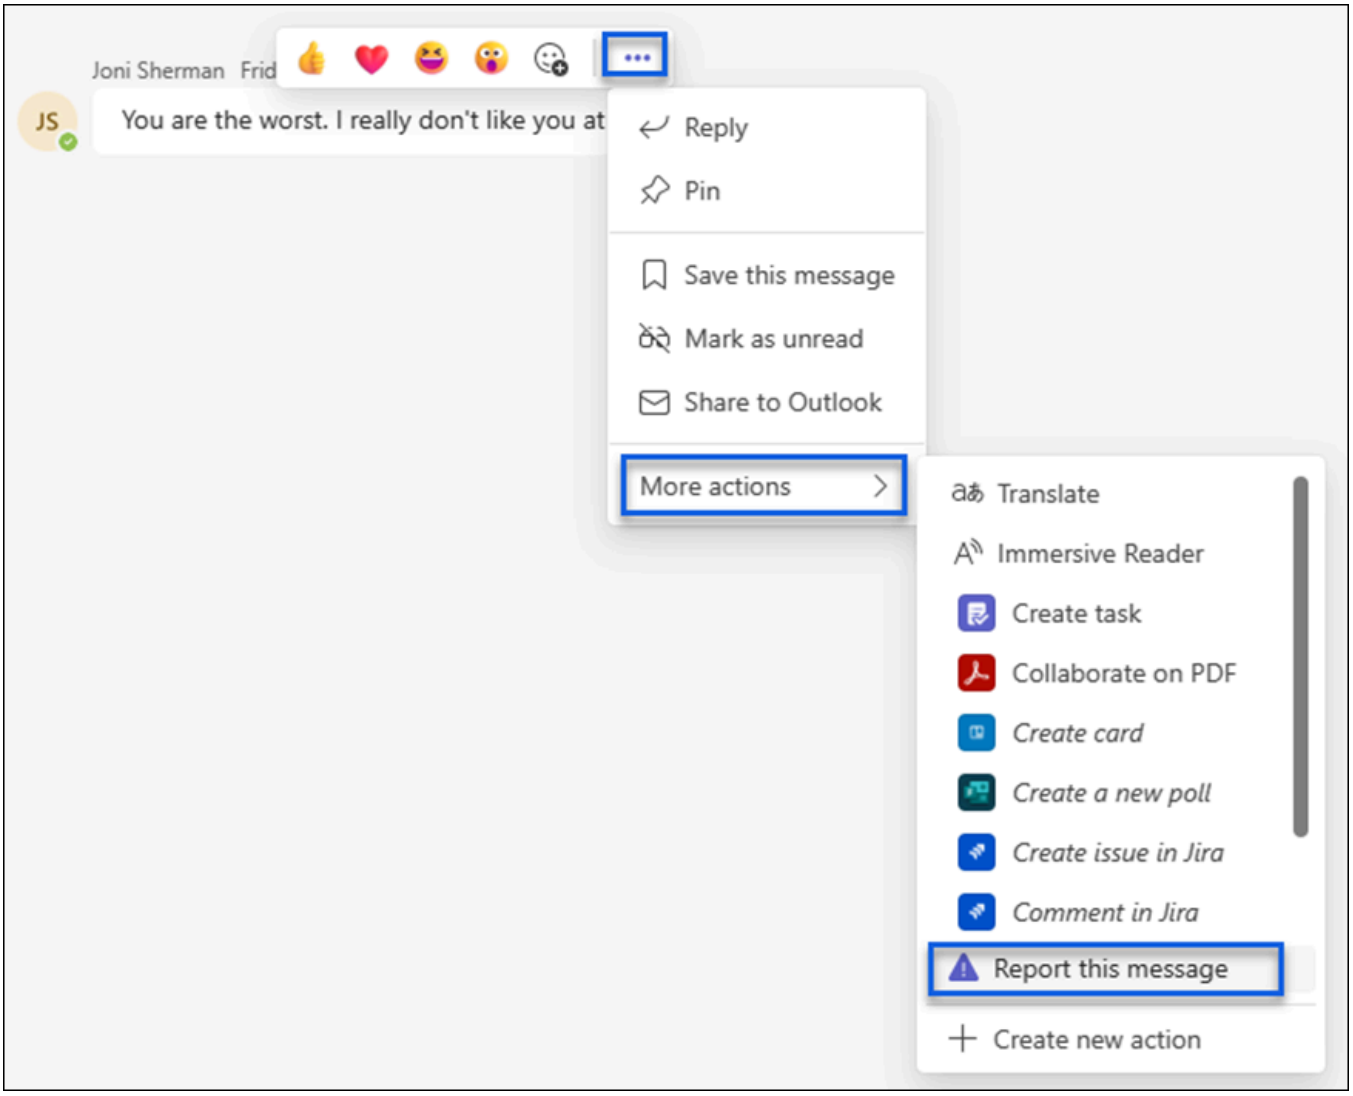
Communication Compliance and Microsoft Teams are tightly integrated and can help you minimize communication risks in your organization. After you configure your first Communication Compliance policies, you can actively manage inappropriate Microsoft Teams messages and content that the solution automatically flags in alerts.

Getting started

To get started with Communication Compliance in Microsoft Teams, plan and create predefined or custom policies to identify inappropriate user activities in Teams channels or in 1:1 and group chats. Remember that you need to configure some permissions and basic prerequisites as part of the configuration process.

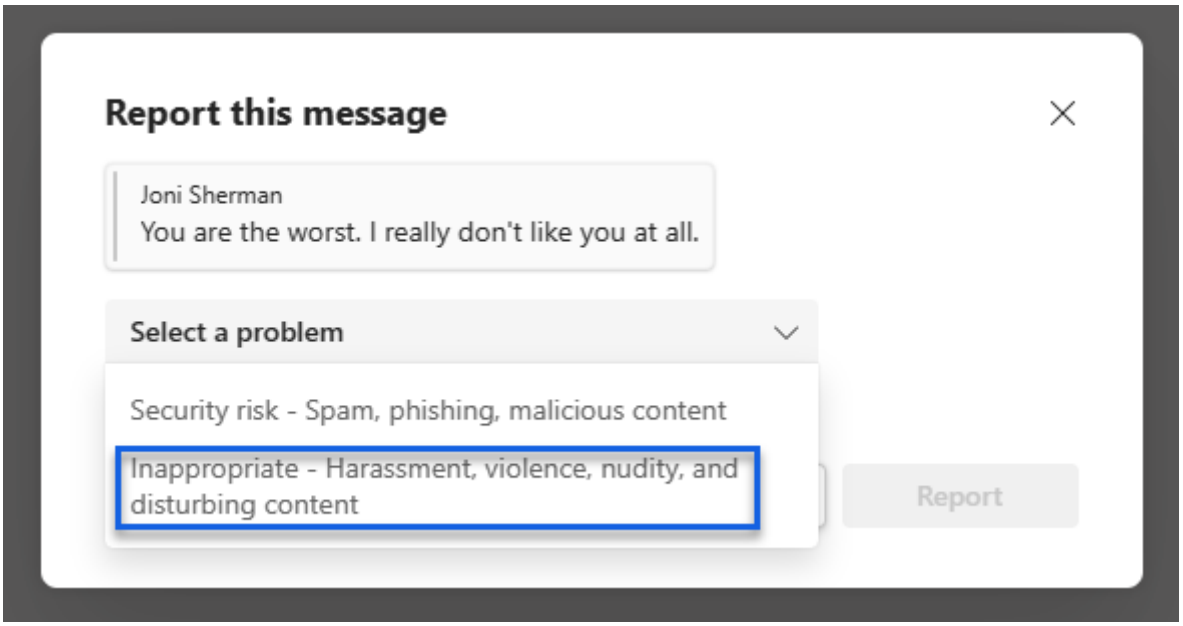
Teams administrators can configure Communication Compliance policies at the following levels:

- **User level**: Apply these policies to an individual Teams user or to all Teams users in your organization. These policies cover messages that users send in 1:1 or group chats. The solution automatically detects chat communications for the users across all Microsoft Teams where the users are a member.
- **Teams level**: Apply these policies to a Microsoft Teams channel, including a Private channel. These policies cover messages sent in the Teams channel only.



Report a message in Microsoft Teams

> **Note**
>
> After you create your first Communication Compliance policy, the organization implements the *User-reported messages* policy. It can take up to 30 days for this feature to become available after you create your first policy.

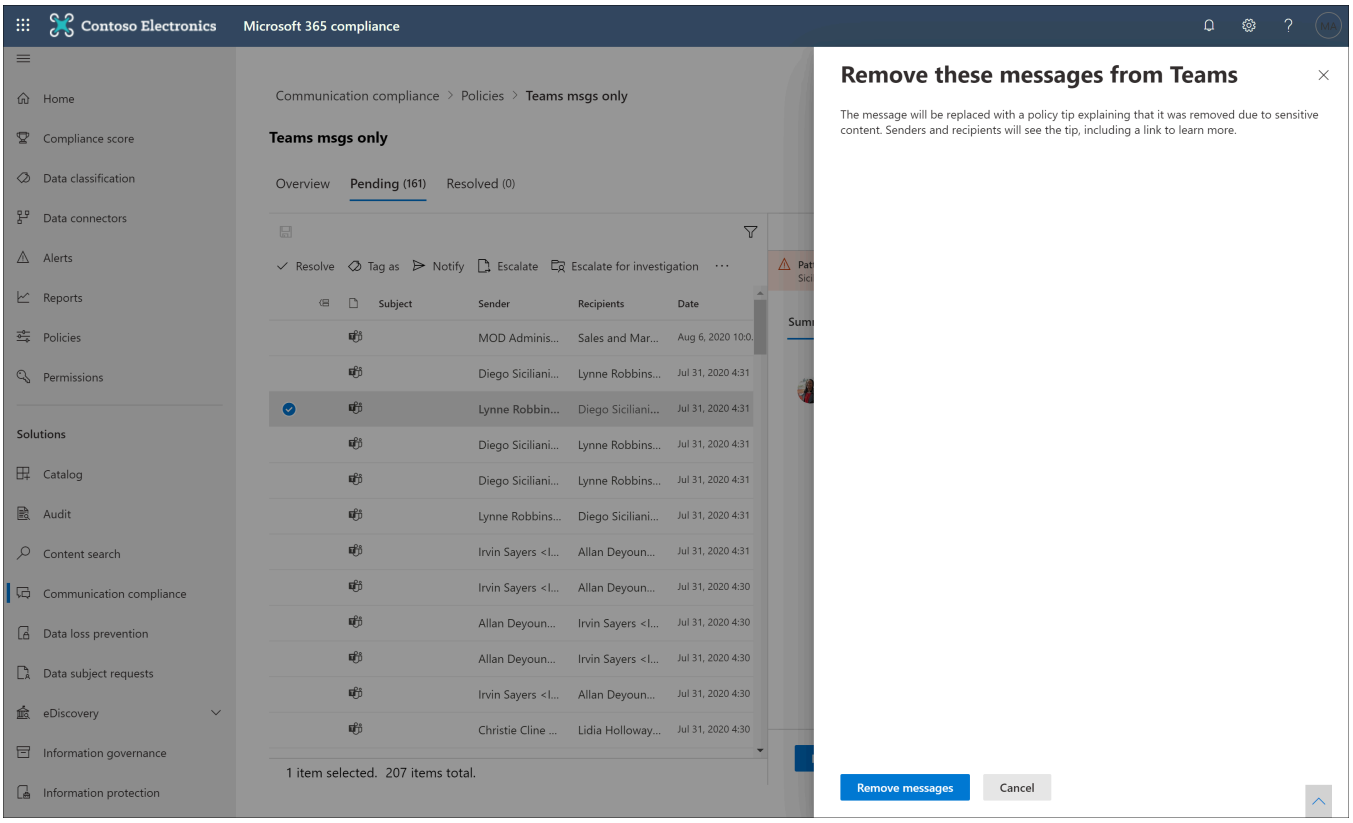


By default, Teams messaging policies in the Teams admin center enable the *Report inappropriate content* option for Teams personal and group chat messages. This option lets

users in your organization submit inappropriate internal chat messages for review by Communication Compliance reviewers for the policy. For more information about user-reported messages in Communication Compliance, see Communication Compliance policies.

To access the feature, a user selects **More options** (...) > **More actions** > **Report this message** from a Teams chat.

In the next dialog box, the user selects the **Inappropriate - Harassment, violence, nudity, and disturbing content** option from the **Select a problem** list.

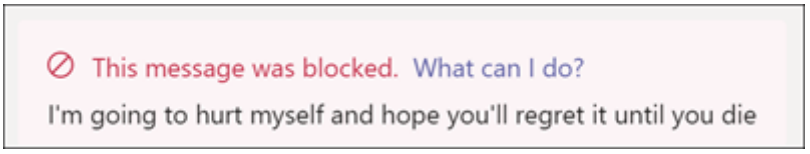


> **Note**
>
> Microsoft Defender for Office 365 manages the other choice in the list (**Security risk- Spam, phishing, malicious content**), if available. Depending on which policy options are turned on in the Microsoft Teams admin center, the user might also be presented with just the **Inappropriate - Harassment, violence, nudity, and disturbing content** option. Learn more about the Microsoft Defender for Office setting

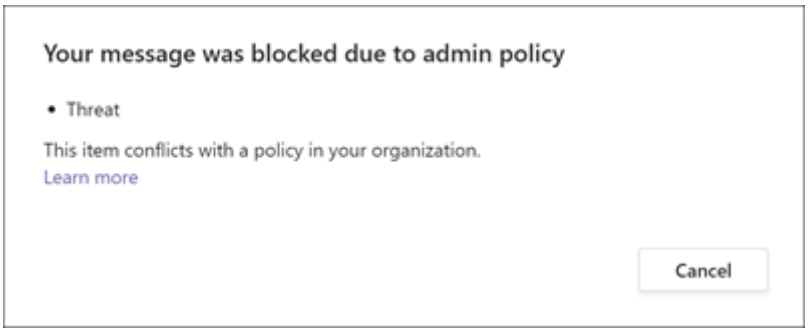
After submitting the message for review, the user receives a confirmation of the submittal in Microsoft Teams. Other participants in the chat don't see this notification.

Users in your organization automatically get the global policy unless you create and assign a custom policy. Edit the settings in the global policy or create and assign one or more custom policies to turn on or turn off this feature. For more information, see Manage messaging policies in Teams.

Act on inappropriate messages in Microsoft Teams



After you configure your policies and receive Communication Compliance alerts for Microsoft Teams messages, compliance reviewers in your organization can act on these messages. This process also includes user-reported messages if your organization enables that option. Reviewers help safeguard your organization by reviewing Communication Compliance alerts and removing flagged messages from view in Microsoft Teams.



> **Important**
>
> If a user reports a message that was sent before they were added to a chat, Teams message remediation isn't supported; the Teams message can't be removed.

When reviewers remove messages and content, viewers see notifications that explain the message or content was removed and what policy is applicable to the removal. The sender of the removed message or content also receives a removal notification and gets the original message content for context relating to its removal. The sender can view the specific policy condition that applies to the message removal.

Example of policy tip seen by sender:

Example of policy notification seen by the sender:

Example of policy tip seen by recipient:

Use Communication Compliance with SIEM solutions

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

Microsoft Purview Communication Compliance is an insider risk solution that helps you minimize communication risks by helping you detect, capture, and act on potentially inappropriate messages in your organization. Security information and event management (SIEM) solutions such as Microsoft Sentinel or Splunk are commonly used to aggregate and track threats within an organization.

A common need for organizations is to integrate Communication Compliance alerts and their SIEM solutions. With this integration, organizations can view Communication Compliance alerts in their SIEM solution and then remediate alerts within the Communication Compliance workflow and user experience.

For example, an employee sends an offensive message to another employee and the offensive message is detected by a Communication Compliance policy for potentially inappropriate content. Communication Compliance solution logs events such as policy matches for inappropriate content in Microsoft 365 Audit (also known as "unified audit log") and imports them into the SIEM solution. You can associate SIEM alerts that were created from Microsoft 365 Audit events with the corresponding Communication Compliance alerts. Investigators receive notifications of these alerts in their SIEM solution, and they can investigate and remediate the corresponding alerts in the Communication Compliance dashboard.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Communication Compliance alerts in Microsoft 365 Audit

Microsoft 365 Audit captures all Communication Compliance policy matches. The following examples show the details available for selected Communication Compliance policy match activities:

Example of audit log entry for an Inappropriate Content policy template match:

```

> **Note**
>
> Currently, there might be up to a 24-hour delay between the time Microsoft 365 Audit records a policy match and the time you can investigate policy matches in Communication Compliance.

Configure Communication Compliance and Microsoft Sentinel integration

When you use Microsoft Sentinel to aggregate Communication Compliance policy matches, Microsoft Sentinel uses Microsoft 365 Audit as the data source. To integrate Communication Compliance alerts with Microsoft Sentinel, complete the following steps:

1. Onboard to Microsoft Sentinel. As part of the onboarding process, you configure your data sources.

2. Configure the Microsoft Sentinel Microsoft Office 365 data connector and under connector configuration, select *Exchange*.

3. Configure search query to retrieve Communication Compliance alerts. For example:

   | *OfficeActivity* | *where OfficeWorkload == "Exchange" and Operation == "SupervisionRuleMatch"* | *sort by TimeGenerated*

   To filter for a specific user, use the following query format:

   | *OfficeActivity* | *where OfficeWorkload == "Exchange" and Operation == "SupervisionRuleMatch" and UserId == "User1@Contoso.com"* | *sort by TimeGenerated*

For more information about the Microsoft 365 Audit logs for Office 365 that Microsoft Sentinel collects, see Azure Monitor Logs reference.

Configure Communication Compliance and Splunk integration

To integrate Communication Compliance alerts with Splunk, complete the following steps:

1. Install the Splunk Add-on for Microsoft Office 365
2. Configure an integration application in Microsoft Entra ID for the Splunk Add-on for Microsoft Office 365
3. Configure search queries in your Splunk solution. Use the following search example to identify all Communication Compliance alerts:

   index= sourcetype="o365:management:activity" Workload=Exchange Operation=SupervisionRuleMatch*

To filter results for a specific Communication Compliance policy, use the *SRPolicyMatchDetails.SRPolicyName* parameter.

For example, the following search example returns alerts for matches to a Communication Compliance policy named *Inappropriate content*:

index= sourcetype='o365:management:activity' Workload=Exchange Operation=SupervisionRuleMatch SRPolicyMatchDetails.SRPolicyName=<Inappropriate content>*

The following table shows sample search results for different policy types:

Configure Communication Compliance with other SIEM solutions

To retrieve Communication Compliance policy matches from Microsoft 365 Audit, use PowerShell or the Office 365 Management API.

When you use PowerShell, you can use either of these parameters with the **Search-UnifiedAuditLog** cmdlet to filter audit log events for Communication Compliance activities.

Expand table

Audit log parameter	Communication Compliance parameter value
Operations	SupervisionRuleMatch
RecordType	ComplianceSupervisionExchange

The following examples show how to search for Communication Compliance matches.

PowerShell

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -Operations
SupervisionRuleMatch | ft CreationDate,UserIds,AuditData
```

The following is a sample search using the **RecordsType** parameter and the *ComplianceSupervisionExchange* value:

PowerShell

```
Search-UnifiedAuditLog -StartDate $startDate -EndDate $endDate -RecordType
ComplianceSuperVisionExchange | ft CreationDate,UserIds,AuditData
```

Additional SIEM integration resources

- Communication Compliance auditing
- Microsoft Purview Audit (Premium)
- Office 365 Management Activity API reference

Use Microsoft Power Automate with Communication Compliance

Microsoft Power Automate is a workflow service that automates actions across applications and services. By using flows from templates or creating them manually, you can automate common tasks associated with these applications and services. When you enable Power Automate flows for Communication Compliance, you can automate important tasks for alerts and users. You can configure Power Automate flows to notify managers when users have Communication Compliance alerts and other applications.

Customers with Microsoft 365 subscriptions that include Communication Compliance don't need extra Power Automate licenses to use the recommended default Communication Compliance Power Automate template. Customize the default template to support your organization and cover core Communication Compliance scenarios. If you choose to use premium Power Automate features in these templates, create a custom template by using the Microsoft Purview connector, or use Power Automate templates for other compliance areas in Microsoft Purview, you might need extra Power Automate licenses.

> **Important**
>
> Are you receiving requests for extra license validation when testing Power Automate flows? Your organization might not have received service updates for this preview feature yet. We're deploying updates, and all organizations with Microsoft 365 subscriptions that include Communication Compliance should have license support for flows created from the recommended Power Automate templates before October 30, 2020.

The following Power Automate template is provided to customers to support process automation for Communication Compliance alerts:

- **Notify manager when a user has a Communication Compliance alert**: Some organizations might need immediate management notification when a user has a Communication Compliance alert. When you configure and select this flow, the manager for the case user receives an email message with the following information about all alerts:
  - Applicable policy for the alert
  - Date and time of the alert
  - Severity level of the alert

Automate tasks for alerts and users with Microsoft Power Automate

To create a Power Automate flow from a recommended default template, use the **Manage Power Automate flows** option from **Automate** when working directly in an alert. To create a Power Automate flow with **Manage Power Automate flows**, you must be a member of at least one Communication Compliance role group.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation, then select the policy that includes the policy matches that you want to review.
4. Select the **Pending** tab, and select a policy match.
5. Select **Power Automate** from the alert action menu.
6. On the **Power Automate** page, select a default template from the **Communication Compliance templates you may like** section on the page.
7. Review the embedded connections needed for the flow and check the connection statuses. If needed, update any connections that aren't displayed as available. Select **Continue**.
8. By default, the recommended flows are preconfigured with the recommended Communication Compliance and Microsoft 365 service data fields required to complete the assigned task for the flow. If needed, customize the flow components by using **Show advanced options** and configuring the available properties for the flow component.
9. If needed, add any additional steps to the flow by selecting **New step**. In most cases, this change shouldn't be needed for the recommended default templates.
10. Select **Save draft** to save the flow for further configuration later, or select **Save** to complete the configuration for the flow.
11. Select **Close** to return to the **Power Automate flows** page. The new template is listed as a flow on the **My flows** tab and is automatically available for the user that created the flow when working with Communication Compliance alerts.

Share a Power Automate flow

By default, only the creator can access a Power Automate flow. To give other Communication Compliance users access to a flow, the creator must share it. Use **Power Automate** to share a flow when working directly in an alert.

To share a Power Automate flow, you must be a member of at least one Communication Compliance role group.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation, then select the policy that contains the policy matches you want to review.
4. Select the **Pending** tab, then select a pending policy match.

5. Select **Power Automate** from the alert action menu.
6. On the **Power Automate flows** page, select the **My flows** or **Team flows** tab.
7. Select the flow to share, then select **Share** from the **Flow Options** menu.
8. On the flow sharing page, enter the name of the user or group you want to add as an owner for the flow.
9. On the **Connection Used** dialog, select **OK** to acknowledge that the added user or group has full access to the flow.

Edit a Power Automate flow

Use **Power Automate** to edit a flow when working directly in an alert. To edit a Power Automate flow, you must be a member of at least one Communication Compliance role group.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation, then select the policy that contains the policy matches you want to review.
4. Select the **Pending** tab, then select a pending policy match.
5. Select **Power Automate** from the alert action menu.
6. On the **Power Automate flows** page, select the flow to edit. Select **Edit** from the flow control menu.
7. Select **ellipsis** > **Settings** to change a flow component setting or **ellipsis** > **Delete** to delete a flow component.
8. Select **Save**, then select **Close** when finished editing the flow.

Delete a Power Automate flow

If you need to delete a flow, use **Power Automate** when working directly in an alert. To delete a Power Automate flow, you must be a member of at least one Communication Compliance role group.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation, then select the policy that contains the policy matches you want to review.
4. Select the **Pending** tab, then select a pending policy match.

5. Select **Power Automate** from the alert action menu.
6. On the **Power Automate flows** page, select the flow that you want to delete. Select **Delete** from the flow control menu.
7. On the deletion confirmation dialog, select **Delete** to remove the flow or select **Cancel**.

Last updated on 06/25/2026

Use notification templates in Communication Compliance

08/20/2025

Create notification templates when you want to send users an email reminder for policy matches as part of the issue resolution process. You can only send notifications to the user email address associated with the policy match that generates the specific alert for remediation. When selecting a notification template to apply to a policy violation as part of the remediation workflow, you can choose to accept the field values defined in the template or overwrite the fields as needed.

Notice templates are custom email templates where you define the following message fields in the **Communication Compliance settings** area:

Expand table

Field	Required	Details
Template name	Yes	Friendly name for the notice template that you select in the notify workflow during remediation, supports text characters.
Sender address	Yes	Address of one or more users or groups that send the message to the user with a policy match, selected from the Active Directory for your subscription.
CC and BCC addresses	No	Optional users or groups to be notified of the policy match, selected from the Active Directory for your subscription.
Subject	Yes	Information that appears in the subject line of the message, supports text characters.
Message body	Yes	Information that appears in the message body, supports text or HTML values.

HTML for notices

If you want to create more than a simple text-based email message for notifications, you can create a more detailed message by using HTML in the message body field of a notice template. The following example provides the message body format for a basic HTML-based email notification template:

```
HTML
```

```
<!DOCTYPE html>
<html>
    <body>
        <h2>Action Required: Contoso Employee Code of Conduct Policy Training</h2>
        <p>A recent message you've sent has generated a policy alert for the
Contoso Employee <a href='https://www.contoso.com'>Code of Conduct Policy</a>.</p>
        <p>You are required to attend the Contoso Employee Code of Conduct <a
href='https://www.contoso.com'>training</a> within the next 14 days. Please
contact <a href='mailto:hr@contoso.com'>Human Resources</a> with any questions
about this training request.</p>
        <p>Thank you,</p>
        <p><em>Human Resources</em></p>
    </body>
</html>
```

> **Note**
>
> In Communication Compliance notification templates, the HTML href attribute implementation currently supports only single quotation marks instead of double quotation marks for URL references.

Investigate and remediate Communication Compliance alerts

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

After you configure Communication Compliance policies, you receive alerts for message issues that match your policy conditions. To view and act on alerts, assign users the following permissions:

- The *Communication Compliance Analysts* or the *Communication Compliance Investigators* role group
- Reviewer in the policy that is associated with the alert

After you establish required permissions, use the following working instructions to investigate and remediate issues.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Investigate policy matches and alerts

> **Important**
>
> On June 1, 2025, the new **Policy Match Preservation** setting goes into effect. On that date, existing policy matches might be permanently deleted based on the time period you select in the **Policy Match Preservation** setting. New policy matches are preserved for that time

period. You have until **May 19** to change the time period if you don't want to use the default setting of **1 year**. For details, see Policy Match Preservation setting.

To investigate issues detected by your policies, review policy matches and alerts. The Communication Compliance area provides several features to help you quickly investigate policy matches and alerts:

Policies page

When you sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization, select the **Communication Compliance** solution, then select the **Policies** page. This page shows Communication Compliance policies configured for your Microsoft 365 organization and links to recommended policy templates.

> **Note**
>
> If your role group is scoped by one or more admin units, you see a message at the top of the page that you can only view and manage the policies that you're scoped for. To learn more about what you can access, select **View role groups** in the banner.

Each policy listed includes the following columns:

- **Messages scanned today**: The total number of messages that the policy scanned on the current day for users and locations that are in scope of the policy. If there's a policy match, the item is added to the **New pending today** column. The number refreshes automatically once per hour, it doesn't update if you refresh the page. At the end of the UTC day, the count resets to zero.

  > **Tip**
  >
  > If the value in the column is 0 or a low number, it might be because the policy is too strict. For example, the policy might be focused on just one user or on just one location that the in-scope user doesn't use. You might see a wide variety of aggregate numbers in this column if your policies have different focuses. For example, one policy might be focused on an entire department of users sending messages from multiple locations while another policy might be focused on just one user or just one location.

- **New pending today**: Shows the number of policy matches for the current day. This value updates whenever you open the page. You can also select the **Refresh** button to get the latest count. At the end of the UTC day, the count resets to zero.
- **Total pending**: The count of policy matches that need review. This value updates whenever you open the page. You can select the **Refresh** button to get the latest count. After refreshing, this number matches the number on the **Pending** tab.
- **Total resolved**: The total number of resolved policy matches. This value updates whenever you open the page. You can select the **Refresh** button to get the latest count. After refreshing, this number matches the number on the **Resolved** tab.
- **Status**: The status of the policy (Active or Deactivated).
- **Last modified**: The date and Coordinated Universal Time (UTC) of the last policy modification.
- **Last policy scan**: The UTC date for the last policy scan.

To start remediation actions, select the policy associated with the alert to launch the **Policy details** page. From the **Policy details** page, you can review a summary of the activities, review, and act on policy matches on the **Pending** tab, summarize a lengthy message by using Microsoft Copilot in Microsoft Purview, or review the history of closed policy matches on the **Resolved** tab. For details, see Review and remediate policy matches and alerts.

Alerts page

Go to **Communication Compliance** > **Alerts** to display the last 30 days of alerts grouped by policy matches. This view lets you quickly see which Communication Compliance policies generate the most alerts, ordered by severity. An alert isn't the same thing as a policy match. An alert generally consists of multiple policy matches, not just one policy match. After the required number of policy matches is met for a particular alert, the alert is created and email is sent to the alert recipient.

- **Reports page**: Go to **Communication Compliance** > **Reports** to display Communication Compliance report widgets. Each widget provides an overview of Communication Compliance activities and statuses, including access to deeper insights about policy matches and remediation actions.

> **Tip**
>
> Analyze interactions entered into generative AI applications.

Tips for quickly reviewing policy matches on the Pending or Resolved tab

- When you select a message to review on the **Pending** tab or the **Resolved** tab, the condition that caused the policy match appears in an alert message bar (yellow banner) at the top of the **Source** tab. This alert message bar is a quick way to determine the condition or conditions that caused the policy match. If there are multiple conditions, select **View all** in the banner to see all the conditions that caused the policy match. At this time, only Microsoft provided trainable classifiers and sensitive information types are highlighted as conditions in the yellow banner.

- Sometimes it's useful to quickly review policy settings without opening a policy. For example, if you're testing multiple policies with different conditions, you might want to save time by reviewing conditions for each policy to determine risk before opening the policy. You can do this by selecting **Policy settings**, which opens a panel where you can view the policy settings. If you're a member of the Communication Compliance or Communication Compliance Admins role group, you can view and change settings from the panel. If you're a member of the Communication Compliance Investigators or Communication Compliance Analysts role group, you can view settings but you can't change them.

Policy Match Preservation setting

When a Communication Compliance policy finds a message that matches the policy, the solution stores a *copy* of the message (not the original message). Starting June 1, 2025, you can use the **Policy Match Preservation** setting to specify how long to save policy matches in Communication Compliance. You can choose **1 month**, **6 months**, **1 year**, or **7 years**. The default value is **1 year**.

> ⓘ **Note**
>
> You can also specify a preservation period when you create or edit a policy. The preservation period you select within a policy takes precedence over the global **Policy Match Preservation** setting.

When the global **Policy Match Preservation** setting goes into effect on April 1, 2025:

- The value in the **Policy Match Preservation** setting applies to all existing policy matches. The system automatically deletes policy matches that are older than the selected time period. For example, if the **Policy Match Preservation** setting is **1 year** (the default), the

system permanently deletes any policy matches older than 1 year as of September 1. Only the policy matches in Communication Compliance are deleted because they're copies of the original messages. This process doesn't delete original copies from user shards. You can use Microsoft Purview Data Lifecycle Management to set up a retention policy for original messages.

- New policy matches as of September 1 receive a timestamp with the preservation period specified in the setting.
- If you change the time period in the setting after September 1, the preservation period applies going forward. For example, if you select **1 year** as the time period on September 1, then change the setting to **7 years** on September 3, policy matches from September 1 and September 2 are preserved for 1 year, and policy matches starting on September 3 are preserved for 7 years.

What you need to do

The **Policy Match Preservation** setting becomes available for your organization on April 1, 2025. Between April 1 and May 30, select the time period for preserving policy matches for your organization. The selection isn't applied until June 1, 2025.

Change the time period for the global Policy Match Preservation setting

To change the global policy match preservation period, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select the **Settings** button in the upper-right corner of the page, then select **Communication Compliance** to go to the Communication Compliance global settings.
3. Select the **Policy Match Preservation** setting, then select a new time period.
4. Select **Confirm** in the confirmation dialog box.

Change the policy match preservation time period for a custom policy

You can also select a time period for preserving policy matches in the policy workflow for a custom policy. When you set a time period in a custom policy, it takes precedence over the selection in the global **Policy Match Preservation** setting. This option is useful for policies that are the exception to the norm.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution, then select **Policies** in the left navigation.

3. Select the **More actions** (ellipsis) button in the row for the policy you want to change, then select **Edit**.
4. On the **Name and describe your policy** page in the policy workflow, under **Preserve policy matches**, make a selection. If you leave the **Global Setting** selection, the policy uses the time period selected in the global **Policy Match Preservation** setting. If you choose any other time period, it takes precedence over the selection in the global setting.

Using filters

Sort the messages so it's easier for you to investigate. From the **Policy details** page, Communication Compliance supports multilevel filtering for several message fields to help you quickly investigate and review messages with policy matches. You can filter pending and resolved items for each configured policy. You can configure filter queries for a policy or configure and save custom and default filter queries for use in each specific policy. After configuring fields for a filter, you see the filter fields displayed on the top of the message queue that you can configure for specific filter values.

Key filters (the **Body/Subject**, **Date**, **Sender**, and **Tags** filters) always display on the **Pending** and **Resolved** tabs to make it easy to access those filters.

For the **Date** filter, the date and time for events are listed in Coordinated Universal Time (UTC). When filtering messages for views, the requesting user's local date/time determines the results based on the conversion of the user's local date/time to UTC. For example, if a user in U.S. Pacific Daylight Time (PDT) filters a report from 8/30/2021 to 8/31/2021 at 00:00, the report includes messages from 8/30/2021 07:00 UTC to 8/31/2021 07:00 UTC. If the same user was in U.S. Eastern Daylight Time (EDT) when filtering at 00:00, the report includes messages from 8/30/2021 04:00 UTC to 8/31/2021 04:00 UTC.

Filter details

Communication Compliance filters help you filter and sort messages for quicker investigation and remediation actions. You can filter on the **Pending** and **Resolved** tabs for each policy. To save a filter or filter set as a saved filter query, you must configure one or more values as filter selections.

The following table outlines filter details:

Expand table

Filter	Details
Body/Subject	The message body or subject. Use this filter to search for keywords or a keyword phrase in the body or subject of the message. The subject appears in the **Subject** column for email messages. For Teams messages, nothing appears in the **Subject** column.
Classifiers	The name of built-in and custom classifiers that apply to the message. Some examples include *Targeted Harassment*, *Profanity*, *Threat*, and more.
Date	The date the message was sent or received by a user in your organization. To filter for a single day, select a date range that starts with the day you want results for and end with the following day. For example, to filter results for 9/20/2020, choose a filter date range of 9/20/2020-9/21/2020.
Escalated To	The user name of the person included as part of a message escalation action.
File class	The class of the message based on the message type, either *message* or *attachment*.
Has attachment	The attachment presence in the message.
Item class	The source of the message based on the message type, email, Microsoft Teams chat, Bloomberg, and more. For more information, see Item Types and Message Classes.
Language	The detected language of text in the message. The message is classified according to the language of most the message text. For example, for a message containing both German and Italian text, but most text is German, the message is classified as German (DE). For a list of supported languages, see Trainable classifiers. You can also filter by more than one language. For example, to filter messages classified as German and Italian, enter 'DE,IT' (the two-digit language codes) in the Language filter search box. To view the detected language classification for a message, select a message, select View message details, and scroll to the *EmailDetectedLanguage* field.
Recipient domains	The domain to which the message was sent; this domain is typically your Microsoft 365 subscription domain by default.
Recipient	The user to which the message was sent. **Note**: The **Recipient** field includes recipients in the **To** and **CC** fields. **BCC** fields aren't supported.
Sender domain	The domain that sent the message.
Sender	The person who sent the message.
Size	The size of the message in KB.
Tags	The tags assigned to a message, either *Questionable*, *Compliant*, or *Noncompliant*.

Configure a filter

To configure a filter for policy matches, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation, then select a policy to see policy matches (if any) for that policy.
4. On the **Policy** page, select either the **Pending** or **Resolved** tab to display the items for filtering.
5. Select **Filters**.
6. Select one or more filter checkboxes, then select **Apply**.
7. To save the selected filters as a filter query, select **Save the query** after you configure at least one filter value. Enter a name for the filter query, then select **Save**. This filter is available to use for only this policy and is listed in the **Saved filter queries** section of the **Filters** page.

Review and remediate policy matches and alerts

After you review policy matches or alerts and configure filtering, take remediation action. Start your remediation process with the following workflow on the **Policy** or **Alerts** pages.

> **Note**
>
> If you see a policy prefaced with "DSPM for AI" (or "AI hub" from the preview name), the policy was created in Data Security Posture Management for AI, not in Communication Compliance. For more information about this solution, see Data Security Posture Management (DSPM) for AI.

Examine the message basics

Sometimes it's obvious from the source or subject that you can immediately remediate a message. The message might be spurious or incorrectly matched to a policy and you should resolve it as misclassified. To mark a message as misclassified, select **Resolve** and **Item was misclassified** to leave a note in the item's history that it's misclassified and remove it from the **Pending** queue. To share misclassified content with Microsoft, select **Send message content, attachments, and subject** to remove it from the **Pending** queue and report the items to Microsoft.

> **Note**
>
> Misclassified options in the **Resolve** pane don't appear if the condition that caused the policy match isn't based on a trainable classifier. Reporting misclassified items to Microsoft isn't supported for Content Safety classifiers yet.

From the source or sender information, you might already know how the message should be routed or handled in these circumstances. Consider using **Tag as** or **Escalate** to assign a tag to applicable messages or to send messages to a designated reviewer.

Examine the message details

After reviewing the message basics, open the message to examine the details and determine further remediation actions.

> **Tip**
>
> For lengthy messages, you can save time by summarizing the message (including attachments, transcripts, and recordings) with Copilot in Microsoft Purview.

Select a message to view the complete message header and body information. Several different options and views are available to help you decide the proper course of action:

- **Sentiment**: Messages include a sentiment evaluation (powered by Azure Cognitive Service for Language) to help investigators quickly prioritize potentially riskier messages to address first. The **Sentiment** column displays the message sentiment and is enabled in the default view. Messages are flagged with one of the following values:

Expand table

Value	Description
Positive	Messages with *Positive* sentiment indicate a lower priority for triaging.
Negative	Messages with *Negative* sentiment indicate messages to prioritize.
Neutral	Messages with *Neutral* sentiment are determined to be neither positive nor negative.
Not available	*Not available* appears in the column for file formats that aren't supported. For example, sentiment analysis isn't available for any image that's attached to a Teams or email

Value	Description
	message, text extracted from an OCR image, or text or recordings from a Teams transcript. *Not available* also appears if the message includes more than 5,120 words.
Scanning	*Scanning* appears in the the column when Communication Compliance is trying to determine the appropriate sentiment value for the message.

- **Attachments**: This option allows you to examine Modern attachments that match policy conditions. Modern attachments content is extracted as text and is viewable on the **Pending** tab. For more information, see the Communication Compliance feature reference.

- **Source**: This view is the standard message view commonly seen in most web-based messaging platforms. The header information is formatted in the normal style and the message body supports embedded graphic files and word-wrapped text. If optical character recognition (OCR) is enabled for the policy, images containing printed or handwritten text that match policy conditional are viewed as a child item for the associated message in this view.

- **Plain text**: Text view that displays a line-numbered text-only view of the message and includes keyword highlighting in messages and attachments for sensitive info type terms, terms identified by built-in classifiers assigned to a policy, or for terms included in a dedicated keyword dictionary assigned to a policy. Keyword highlighting, which is currently available for English language only, can help direct you to the area of interest in long messages and attachments. In some cases, highlighted text might be only in attachments for messages matching policy conditions. Embedded files aren't displayed and the line numbering in this view is helpful for referencing pertinent details among multiple reviewers.

- **Conversation**: This view, which is available for Teams chat messages, displays up to five messages before and after a message to help reviewers view the activity in the conversational context. Select **Load more** to load up to 20 messages before and after a message. To download messages, select **Download conversation**. This action downloads an image file of everything you see in the user interface and also a .csv file of all the message metadata (UserId, UserName, and so on).

  The Conversation view context helps reviewers quickly evaluate messages and make more informed message resolution decisions. Real-time message additions to conversations are displayed, including all inline images, emojis, and stickers available in Teams. Image or text file attachments to messages aren't displayed. Notifications are automatically displayed for messages that have been edited or for messages deleted from the Conversation window.

When a message is resolved, the associated conversational messages aren't retained with the resolved message.

- **Pattern detected** notification: Many harassing and bullying actions over time involve recurring instances of the same behavior by a user. The *Pattern detected* notification is displayed in the message details and raises attention to the message. Detection of patterns is on a per-policy basis and evaluates behavior over the last 30 days when at least two messages are sent to the same recipient by a sender. Investigators and reviewers can use this notification to identify repeated behavior to evaluate the message as appropriate.

- **Translation**: This view automatically converts message text to the language configured in the *Displayed language* setting in the Microsoft 365 subscription for each reviewer. This conversion includes the text for the policy match and everything included in the conversation view (up to five messages before and five messages after the policy match). The *Translation* view helps broaden investigative support for organizations with multilingual users and eliminates the need for additional translation services outside of the Communication Compliance review process. Using Microsoft translation services, Communication Compliance automatically detects if the text is in a different language than the user's current system setting and displays alert message text accordingly. For a complete list of supported languages, see Microsoft Translator Languages. Languages listed in the *Translator Language List* are supported in the *Translation* view.

- **User activity**: This view provides risk profile, policy matches, and user activities captured by Insider Risk Management and Communication Compliance. This integration helps Communication Compliance investigators quickly see risk severity and the associated activities for the user while investigating and triaging pending policy matches.

  The **User activity** view displays the *Insider risk severity* level for the user and has two sections, one for Communication Compliance policy matches and activities and one for Insider Risk Management risk activities. View the risk severity of the user from Insider Risk Management in the *Source* tab if data sharing is enabled. For more information, see Share Insider Risk Management data with other solutions.

  Communication Compliance policy matches: This section displays the total number of communication *Policy matches* and the total number of *Remediation actions* for the user included in this policy match.

  Select **View details** in this section to display a timeline of Communication Compliance activities for the user. This timeline includes:
  - Totals for *Policy matches* and *Remediation actions* for the user

- Details for each activity associated with the user for the past 30 days.

Insider risk activity: This section displays the total number of *Risk activities* and the total number of *Unusual activities* for activities associated with this user for Insider Risk Management policies. *Unusual activities* are activities for the user that are considered potentially risky, as they're unusual and a departure from their typical activities.

Select **View details** in this section to display a timeline of insider risk activity for the user. This timeline includes:

- The insider risk severity level.
- Totals for *All activities* and *Unusual activities*.
- Details for each activity associated with the user from the Activity explorer in Insider Risk Management.

To view the insider risk activities in insider risk management, select **Open in insider risk management**.

Timeline: This section displays a history of all communications for user activities. This timeline allows investigators to review all communications for a user, helping to identify any inappropriate handling of confidential information. Only previous policy matches for the user associated with the alert are displayed.

For each Copilot interaction, the details for the user prompt and the Copilot response are available for review. The date and time for each interaction are provided in UTC.

Summarize a message by using Copilot in Microsoft Purview

You can use Copilot in Microsoft Purview to get a contextual summary of a Teams, email, or Viva Engage message included in a policy match. The summary is in the context of one or more Microsoft provided trainable classifiers that flag the message (for example, stock manipulation). This feature saves time for investigators if the message content is lengthy.

Copilot in Microsoft Purview summarizes the entire message, including any video recordings, meetings transcripts, or attachments (docx, pdf, or txt files).

Limitations

Be aware of the following limitations when using Copilot in Microsoft Purview to summarize messages:

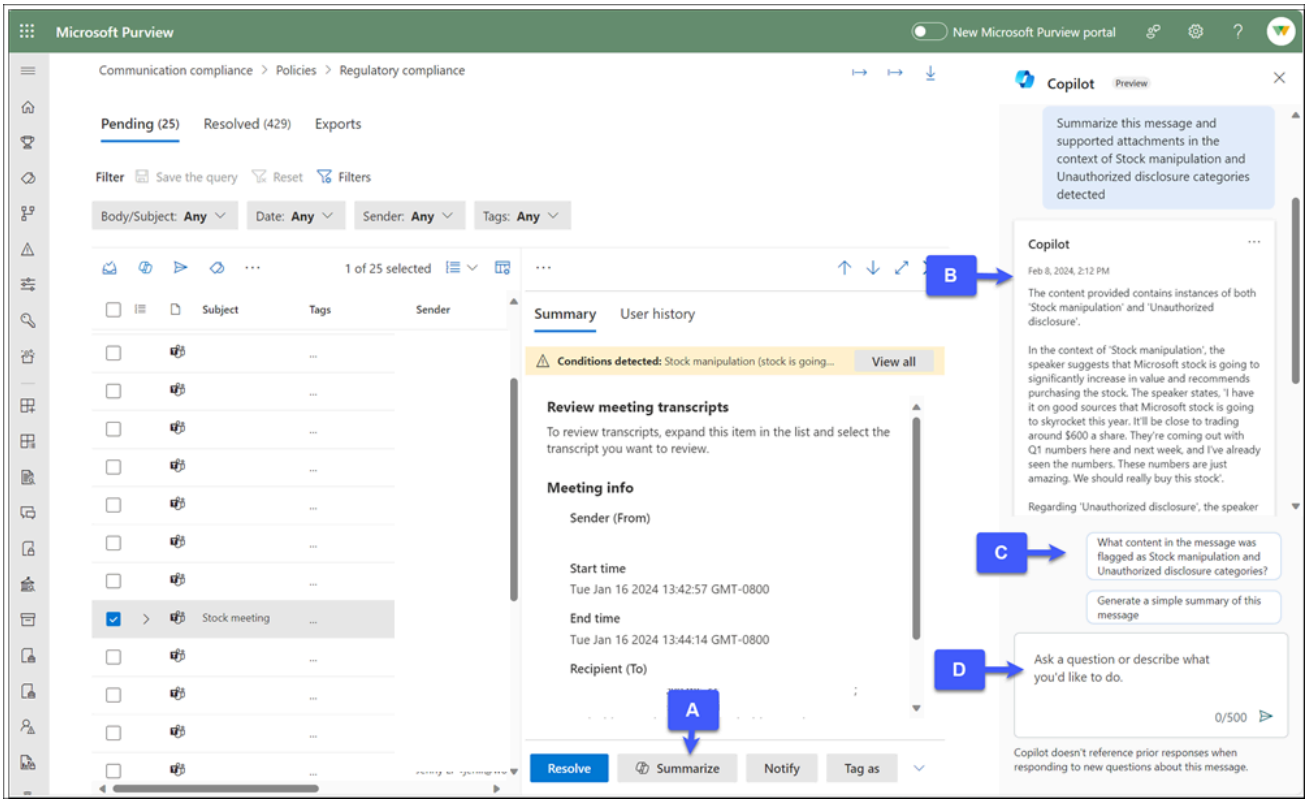
- The message content must be at least 100 words and less than 15,000 words. If the message content is fewer than 100 words or more than 15,000 words, Copilot in Microsoft Purview doesn't summarize it.
- Summarize items in various languages supported by Security Copilot. For more information, see Supported languages in Microsoft Security Copilot.
- At this time, only individual Teams messages can be summarized. If you summarize an individual Teams message, Copilot doesn't pull in the surrounding conversation.

Prerequisites for using Copilot in Microsoft Purview

To summarize a message in Communication Compliance by using Copilot in Microsoft Purview, you must have specific licenses and onboard your organization to Copilot in Microsoft Purview. For details, see Copilot in Microsoft Purview licensing requirements and onboarding. You must also be a member of the *Communication Compliance*, *Communication Compliance Analysts*, or *Communication Compliance Investigators* role.

Summarize a message

1. In Communication Compliance, go to the **Policies** page, and then open any policy to view policy matches for that policy.



2. Select a message in the list. You can select a parent item or a child item (but it's easier to select the parent item).

3. Select **Summarize**. This option appears below the message details. It opens the **Copilot** panel on the right side of the screen and displays a summary of the message.

   > **ⓘ Important**
   >
   > You might see a generic error message that says "An error occurred" after selecting **Summarize**. This error message can appear for any of the following reasons:
   >
   > - You don't have the required license for Copilot in Microsoft Purview.
   > - You don't have the required Communication Compliance role and/or the Security Copilot contributor role. To use Copilot in Microsoft Purview, you must have one of the following Communication Compliance roles: *Communication Compliance*, *Communication Compliance Analysts*, *Communication Compliance Investigators*. You must also have the Security Copilot contributor role, which should be turned on by default for all users in a Microsoft Entra organization.

- There's an internal error. Microsoft provides more information for these errors.

4. Select one of the suggested prompts at the bottom of the panel to use Copilot to create the summary. For example, if the classifier that flagged a message is Stock manipulation, select *Summarize this message and supported attachments in the context of Stock manipulation category detected*. You can also enter an open-ended question in the "Ask a question" box.

a. **Summarize**.
b. Summary generated by **Summarize**.
c. Suggested Copilot prompts.
d. "Ask a question" box for open-ended Copilot questions.

> **Note**
>
> Only message content is summarized. If you ask a question relevant to the message content, Copilot provides a result. If the question isn't relevant to message content, Copilot instructs you to ask a different question.

5. If you want to provide feedback on the summarized content, select the drop-down arrow in the lower-right corner below the summary, and then enter your feedback.

6. After reviewing the summary, you can remediate the policy match like any other policy match. For remediation options, see Decide on a remediation action.

> ⓘ Note
>
> Copilot in Microsoft Purview responses are also recorded in Microsoft Security Copilot.

Understanding hidden matches

When a Communication Compliance policy triggers, it highlights the exact matches in the **Plain text** tab. However, policies can also flag messages where the keywords are hidden and embedded in nonvisible metadata, such as HTML tags or encoded strings. By default, the plain text view doesn't show this content.

The following scenarios show where hidden content matches might occur:

- **HTML tags**: Hyperlinks embedded in HTML tags, for example:

  ```HTML
  <a href="https://example.com">Click here</a>.
  ```

- **Alternative text for images**: Descriptive text for images, for example:

  ```HTML
  <img src="sunset.png" alt="Sunset over the lake">
  ```

- **Encoded strings**: Encoded strings that represent different content when decoded, for example:

  `Base64: U3Vuc2V0IG92ZXIgdGhlIGxha2U=` decodes to *Sunset over the lake*

- **Filename of attachment**: The file name of the attachment might lead to a policy match but isn't clearly highlighted in the text view.

- **OCR:** Text extracted from images using Optical Character Recognition (OCR).

If a message doesn't appear to match the conditions you set for the policy, complete the following steps:

1. Select and download the message with the policy match.
2. Extract the contents of the zipped folder.
3. Locate the .eml file.

4. Open the .eml file with any text editor.
5. Use the *Find* function to search for the individual keywords in the policy conditions to identify where the match occurs.

Review Microsoft Teams meetings transcripts

If you deploy Microsoft Teams in your organization, you can review Teams meetings transcripts for actionable alerts. Teams transcripts are automatically included if you choose Teams as a Microsoft 365 location when you create a custom policy or when you create a policy based on a template.

- **Scheduled meetings**: Communication Compliance ignores communication direction for Teams transcripts. If an individual is an invitee or is present in a scheduled (nonrecurring) meeting, the policy includes all of the meeting content, regardless of who says what in the meeting. This approach also helps in situations where a user is attending the meeting through a hub device in a conference room, since it's not always possible to tell whether an offending communication comes from an in-scope user. Since all meeting content is included, an investigator can review the recording of the meeting to determine if the offending communication is by an in-scope user.

- **Recurring meetings**: For recurring meetings, the policy evaluates only the following users:
  - Users who were invited to the meeting
  - Users identified by the transcript as having spoken during the meeting

- **Unscheduled meetings**: For unscheduled meetings (Meet now meetings), the policy evaluates only users who are identified by the transcript as having spoken during the meeting.

Requirements

To review Teams meeting transcripts, you must turn on meeting transcripts for your organization, since meeting transcripts aren't turned on by default. Learn more about turning on meeting transcripts for your organization.

Limitations

The following limitations apply when reviewing Microsoft Teams meeting transcripts in Communication Compliance:

- You can set one or more of the following policy conditions:

- Content matches any of these classifiers.
- Content contains any of these sensitive info types.
- Message contains any of these words.
- Message contains none of these words.

Any other policy conditions are ignored. Choose conditions for your policies.

> ⓘ **Note**
>
> If you don't set any conditions, the policy captures transcripts for all meetings.

- Only sensitive info types, keyword lists, and regulatory Microsoft provided trainable classifiers are detected. Regulatory trainable classifiers include:
  - Corporate sabotage
  - Gifts and entertainment
  - Money laundering
  - Regulatory collusion
  - Stock manipulation
  - Unauthorized disclosure

  > ⓘ **Note**
  >
  > All other classifiers, including business conduct classifiers, aren't detected.

- Ad-hoc (unscheduled) meetings aren't captured.
- External meetings aren't captured if the meeting organizer is outside your organization.
- Meeting recordings started by an uninvited user aren't captured.

Resolve an alert for a communication in a meeting transcript

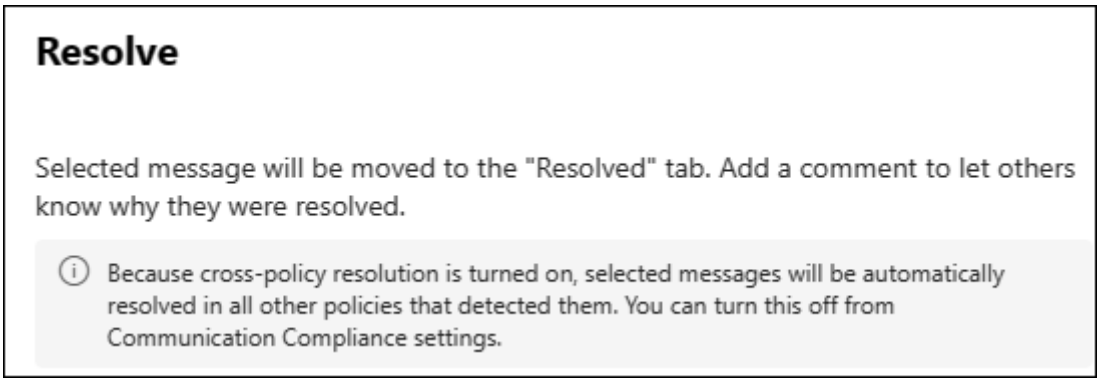
After you create a policy, an alert triggers when the policy detects a transcript that contains offending content. The alert brings the offending content and background context to the attention of an investigator.

To resolve an alert related to a meeting transcript:

1. Select the **Source** tab and then review the transcript for the offending content. The **Source** tab shows the entire transcript. When you select the **Source** tab, the transcript automatically

scrolls to the line that contains the policy match. The offensive keyword or phrase is highlighted.

2. Use the **Plain text** tab to do a line-by-line review of the text, including start and stop times in relation to the overall meeting time. Text is captured 30 seconds before and after the offending communication.
3. Select the **Translation** tab to review translations in up to eight languages for the **Plain text** tab. Messages in other languages are automatically converted to the display language of the reviewer.
4. Select the **User history** tab to see a historical view of all user message remediation activities, such as past notifications and escalations for policy matches.
5. Use **Resolve**, **Notify**, **Tag as**, **Escalate**, and **Escalate for investigation** options to resolve the alert. To learn more about these options, see Decide on a remediation action.



Decide on a remediation action

After reviewing message details, choose from several remediation actions:

- **Resolve**: Selecting **Resolve** immediately removes the message from the **Pending** queue and prevents any further action on the message. When you select **Resolve**, you close the message without further classification. You can also mark the message as misclassified if the alerting process or any Microsoft provided trainable classifiers incorrectly generated it. The **Resolved** tab displays all resolved messages.

  To save investigators time when duplicate policy matches appear across multiple policies, the solution turns on the **Cross-policy resolution** setting (preview) by default. When you resolve a policy match, Communication Compliance automatically resolves all instances of the same policy match in any policy where it's detected, regardless of the reviewer's scope. The item history for each policy notes cross-policy resolution actions, and the number of **Resolved** items increments in the *Items and actions per policy* and *Items and actions per location* reports for all related policies.

  When the **Cross-policy resolution** setting is turned on, this message appears in the **Resolve** pane.

If you don't want to automatically resolve all instances of the same policy match when an investigator resolves a policy match, turn off the **Cross-policy resolution** setting. Anyone who can resolve messages (anyone with the *Communication Compliance*, *Communication Compliance Investigators*, or *Communication Compliance Analyst* role) knows if the setting is turned off because the message in the **Resolve** pane disappears. To turn off the setting, in the Microsoft Purview portal, select **Settings** in the upper-right corner of the page, select **Communication Compliance**, then select the **Cross-policy resolution** setting.

- **Power Automate**: Use a Power Automate flow to automate process tasks for a message. By default, Communication Compliance includes the *Notify manager when a user has a Communication Compliance alert* flow template that reviewers can use to automate the notification process for users with message alerts. For more information about creating and managing Power Automate flows in Communication Compliance, see the Consider Power Automate flows.

- **Tag as**: Tag the message as *Compliant*, *Noncompliant*, or *Questionable* as it relates to the policies and standards for your organization. You can also create a custom tag. Adding tags and tagging comments helps you micro-filter messages for escalations or as part of other internal review processes. After tagging is complete, you can also choose to resolve the message to move it out of the pending queue. You can filter on any tag value.

- **Notify**: Use **Notify** to assign a custom notice template to the message and send a warning notice to the user. Choose the appropriate notice template configured in the **Communication Compliance settings** area and select **Send** to email a reminder to the user that sent the message and to resolve the issue.

- **Escalate**: Use **Escalate** to choose other people in your organization who should review the message. Choose from a list of reviewers configured in the Communication Compliance policy to send an email notification requesting additional review of the message. The selected reviewer can use a link in the email notification to go directly to items escalated to them for review.

- **Escalate for investigation**: Use **Escalate for investigation** to create a new eDiscovery (Premium) case for single or multiple messages. Provide a name and notes for the new case. The custodian is automatically filled in for you. You don't need any additional permissions to manage the case. Creating a case doesn't resolve or create a new tag for the message. You can select a total of 100 messages when creating an eDiscovery (Premium) case during the remediation process. Messages in all communication channels included in Communication Compliance are supported. For example, you could select 50 Microsoft Teams chats, 25 Exchange Online email messages, and 25 Viva Engage messages when you open a new eDiscovery (Premium) case for a user.

- **Remove message in Teams**: Use **Remove message in Teams** to block potentially inappropriate messages and content identified in messages from Microsoft Teams channels and 1:1 and group chats. This action includes Teams chat messages reported by users and chat messages detected using machine-learning and classifier-based Communication Compliance policies. Removed messages and content are replaced with a policy tip that explains that it's blocked and the policy that applies to its removal from view. Recipients are provided a link in the policy tip to learn more about the applicable policy and the review process. The sender receives a policy tip for the blocked message and content but can review the details of the blocked message and content for context regarding the removal.

Create a custom tag

You can tag a policy match as *Compliant*, *Non-compliant*, or *Questionable* as it relates to the policies and standards for your organization. If you need more flexibility than the standard tags provide, create a custom tag. For example, you might want to create an *Escalated* tag so investigators can let other team members know that a policy match is already escalated. Since you can apply multiple tags to any policy match, using the same example, investigators could apply that tag and also apply the *Non-compliant* tag for a policy match.

Keep the following points in mind for custom tags:

- You can apply tags to policy matches that appear on the **Pending** tab.
- You can apply multiple tags to a policy match.
- You can create up to 10 custom tags per policy.
- You create custom tags at the policy level so if you want to use the same custom tag for multiple policies, you must recreate the tag for each policy.
- When you apply a custom tag to a policy match:
  - The tag appears in the **Tags** column in the list of policy matches. If you apply more than one tag, each tag appears in the **Tags** column.

    - The tag appears in the **Tags** filter. You can then select the checkbox for that tag to filter all policy matches by that tag.
    - A **Custom tag** column appears in the following reports: *Items and actions per policy*, *Items and actions per location*, and *Activity by user*.
- If you delete a custom tag for a policy:
    - It's removed from any previous items that you tagged with that custom tag.
    - You can no longer filter by that tag.

> **Tip**
>
> Any action you take with custom tags is tracked in the **History of remediation actions** pane. Select **View item history** to display this pane.

Create and apply a custom tag for a policy match

1. On **Policies**, select a policy to view the policy matches for that policy.
2. Select the checkbox for the policy match that you want to create a custom tag for. Select the checkboxes for multiple policy matches if you want to apply a custom tag in bulk.
3. Select **Tag as** on the command bar.
4. In the **Tag item** pane, select **Add a new tag**.
5. Enter the name of the new tag, then press Enter to add the new tag.

   > **Note**
   >
   > A custom tag must be between 3 and 64 characters and can't include special characters. Spaces and hyphens are allowed.

6. Select the checkbox for the new tag to apply it to the policy match.
7. In the **Comment** box, add a comment to describe the purpose of the tag (optional).
8. Select **Save**.

Edit or delete a custom tag

1. On **Policies**, select a policy to view the policy matches for that policy.
2. Select the checkbox for the policy match that has the custom tag you want to edit.
3. Select **Tag as** on the command bar.
4. In the **Tag item** pane, select the ellipsis next to the custom tag.
5. Select **Edit**, make your changes, or select **Delete** to delete the tag.

> **Important**
>
> If you delete a custom tag, it's removed from any previous items that you tagged with that custom tag. You can no longer filter by that tag.

6. Select **Save**.

Unresolve messages

When you resolve messages, the messages are removed from the **Pending** tab and displayed in the **Resolved** tab. Investigation and remediation actions aren't available for messages in the *Resolved* tab. However, you might need to take extra action on a message that you mistakenly resolved or that needs further investigation after initial resolution. Use the **Unresolve** command to move one or more messages from the **Resolved** tab back to the **Pending** tab.

Unresolve a message

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Communication Compliance** solution.
3. Select **Policies** in the left navigation, then select a policy that contains the resolved message to view the policy matches.
4. Select the **Resolved** tab.
5. On the **Resolved** tab, select one or more messages.
6. On the command bar, select **Unresolve**.
7. On the **Unresolve item** pane, add any comments, then select **Save**.
8. Select the **Pending** tab to verify that the selected items are displayed.

Archive message details outside of Communication Compliance (optional)

Export or download message details if you need to archive the messages in a separate storage solution. If you select one or more policy matches and then select **Download** in the bar over the list, you automatically add the selected messages to a .zip file that you can save in storage outside of Microsoft 365. The size limit for files downloaded by using **Download** is 3 MB.

Export a collection of message details that exceeds 3 MB in size

To download messages that cumulatively exceed 3 MB in size, use **Export files** (displayed in the upper-right corner of the **Policies** page). For example, you might want to download policy matches each week for archiving purposes. The download size limit for the **Export files** command is 3 GB. The maximum number of items depends on whether you select documents (limit of 1,000 items) or users (limit of 50,000). Files are exported to a .zip file that you can then download. The .zip file contains all the message files as well as a summary .TXT file that includes data for the following fields: Document, Doc ID, Custodian, Subject/title, File name, File type, Error, and Message.

On the **Exports** tab, the export has a status of *In progress* or *Ready to download*. To download a file that has a *Ready to download* status, select the files batch in the **Name** list, then select **Download export(s)** over the list.

You can either select the policy matches that you want to export, select **Export files**, and then select the list of documents or users you want to export, or you can select **Export files** and then select the documents, users, and date ranges that you want to export. After you select **Export**, it takes a few minutes for the job to complete. You receive an email notification with a link to the **Exports** tab when the export is ready to download. To download a file that has a *Ready to download* status, select the files batch in the **Name** list, then select **Download export(s)** over the list.

> **Note**
>
> To include attachments in exported files, you must select them manually in the list of policy matches. They're not automatically included with their parent message file.

> **Tip**
>
> You can also **create and download a Message details report**.

Best practices for managing the volume of alerts in Communication Compliance

> **Important**
>
> Microsoft Purview Communication Compliance provides the tools to help organizations detect regulatory compliance (for example, SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content. Communication Compliance is built with privacy by design. Usernames are pseudonymized by default, role-based access controls are built in, investigators are opted in by an admin, and audit logs are in place to help ensure user-level privacy.

After you configure Microsoft Purview Communication Compliance, make some adjustments to manage the volume of alerts that you receive. Use the list of best practices in this article to help create policies that cover as many users as possible while reducing the number of nonactionable alerts.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Understand keyword list volumes

Many customers use custom keyword lists for compliance scenarios. Understanding the volume of policy matches for each keyword can help you tune your policies. Use the Sensitive information type per location report to analyze keyword lists to see which keywords trigger most matches. You can investigate further to see if those keywords have high false-positive rates. You can also use the Message details reports to get data on keyword matches for a specific policy.

Use Microsoft Purview Reports and the data explorers

It's important to understand the volume of items classified by Microsoft provided trainable classifiers and sensitive information types. Microsoft Purview Reports is the primary tool you

should use. You can also use these tools to help you understand the volume that you can expect for your organization.

- Get started with content explorer (classic)
- Get started with data explorer
- Get started with activity explorer

When you first start using Microsoft provided trainable classifiers, you might not get enough matches, or you might get too many matches. The following table shows the volume level to expect for different types of Microsoft provided trainable classifiers.

Expand table

Microsoft trainable classifier	Volume
Adult images	Low
Customer complaints	Medium
Discrimination	Low
Gifts & entertainment	Medium
Gory images	Medium
Money laundering	Medium
Profanity	Medium
Racy images	Medium
Regulatory collusion	Medium
Stock manipulation	Medium
Targeted harassment	Low
Threat	Low
Unauthorized disclosure	High

Consider using the *Adult images* classifier instead of the *Racy images* classifier since the *Adult images* classifier detects a more explicit image. You can use the Content explorer to help you understand the volume that you can expect for your organization for each of the Microsoft provided trainable classifiers.

Filter email blasts

You can filter out email messages that are generic and intended for mass communication. For example, you can filter out spam, newsletters, and similar messages. For more information, see Learn about the Email blast senders report.

Filter out email signatures and disclaimers

Sensitive information types can be triggered from footers in emails, such as disclaimers. If many of your nonactionable alerts come from a specific set of sentences or phrases in an email signature or disclaimer, you can filter out the email signature or disclaimer.

Use sentiment evaluation

Messages in alerts include sentiment evaluation to help you quickly prioritize potentially riskier messages to address first. Using sentiment evaluation doesn't reduce your detection volumes but makes it easier to prioritize detections. Messages are flagged as *Positive*, *Negative*, or *Neutral* sentiment. For some organizations, messages with *Positive* sentiment might be a lower priority, allowing you to spend more time on other message alerts.

Report messages as misclassified

Reporting false positives as misclassified helps improve Microsoft's models and reduces the number of false positives that you see in the future.

Filter out specific senders by using a condition

If you have senders that consistently trigger detections, you can filter out these particular senders by using the following conditional setting:

- Message isn't received from any of these domains.

Some examples of consistently triggering detections can occur through newsletters, automated mails, and so on. For more scenario information, see Scenarios for creating conditions in Communication Compliance policies.

Use communication direction to target a particular set of users

If you're detecting standards of business conduct scenarios and only care about communications from your users (not from guests), consider using a policy that detects only outbound

communications. If you make the entire organization in scope, you can ensure that all of the users in your organization are covered but exclude users from outside your organization.

Combine trainable classifiers

Consider combining two or more Microsoft provided trainable classifiers together. For example, combine the Threat and Profanity classifiers or the Targeted harassment and Profanity classifiers to raise the threshold for messages captured.

Lower the percentage of reviewed communications

To sample a subset of all the messages that trigger alerts, specify a percentage of communications to review.

Microsoft Purview Compliance Manager

What is Compliance Manager?

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

Watch the video below to learn how Compliance Manager can help simplify how your organization manages compliance:

https://learn-video.azurefd.net/vod/player?id=d9134cf3-a01d-4629-900e-8d32188377ee&locale=en-us&embedUrl=%2Fpurview%2Fcompliance-manager

Compliance Manager helps simplify compliance and reduce risk by providing:

- Pre-built assessments for common industry and regional standards and regulations, or custom assessments to meet your unique compliance needs (available assessments depend on your licensing agreement; learn more).
- Workflow capabilities to help you efficiently complete your risk assessments through a single tool.
- Detailed step-by-step guidance on suggested improvement actions to help you comply with the standards and regulations that are most relevant for your organization. For actions that are managed by Microsoft, you'll see implementation details and audit results.
- A risk-based compliance score to help you understand your compliance posture by measuring your progress in completing improvement actions.

The Compliance Manager overview page shows your current compliance score, helps you see what needs attention, and guides you to key improvement actions.

Understanding your compliance score

Compliance Manager awards you points for completing improvement actions taken to comply with a regulation, standard, or policy, and combines those points into an overall compliance score. Each action has a different impact on your score depending on the potential risks involved. Your compliance score can help prioritize which action to focus on to improve your

overall compliance posture. Compliance Manager gives you an initial score based on the Microsoft 365 data protection baseline. This baseline is a set of controls that includes key regulations and standards for data protection and general data governance.

- Understand scoring in Compliance Manager.
- Learn how to work with improvement actions.

Key elements: controls, assessments, regulations, improvement actions

Compliance Manager uses several data elements to help you manage your compliance activities. As you use Compliance Manager to assign, test, and monitor compliance activities, it's helpful to have a basic understanding of the key elements: controls, assessments, regulations, and improvement actions.

Be sure to check out the Compliance Manager glossary of terms.

Controls

A control is a requirement of a regulation, standard, or policy. It defines how you assess and manage system configuration, organizational process, and people responsible for meeting a specific requirement of a regulation, standard, or policy. Compliance Manager tracks the following types of controls:

1. **Microsoft managed controls**: controls for Microsoft cloud services, which Microsoft is responsible for implementing
2. **Your controls**: sometimes referred to as customer managed controls, these are controls implemented and managed by your organization
3. **Shared controls**: these are controls that both your organization and Microsoft share responsibility for implementing

Learn more about monitoring control progress.

Assessments

An assessment is grouping of controls from a specific regulation, standard, or policy. Completing the actions within an assessment help you meet the requirements of a standard, regulation, or law. For example, you may have an assessment that, when you complete all

actions within it, helps to bring your Microsoft 365 settings in line with ISO 27001 requirements. Assessments have several components:

- **In-scope services**: the specific set of Microsoft services applicable to the assessment
- **Microsoft managed controls**: controls for Microsoft cloud services, which Microsoft implements on your behalf
- **Your controls**: sometimes referred to as customer managed controls, these are controls implemented and managed by your organization
- **Shared controls**: these are controls that both your organization and Microsoft share responsibility for implementing
- **Assessment score**: shows your progress in achieving total possible points from actions within the assessment that are managed by your organization and by Microsoft

Learn more about creating and managing assessments.

Regulations

Compliance Manager provides over 360 regulatory templates to help you quickly create assessments. For organizations with unique compliance needs, you can also create custom regulation templates. Learn more about working with regulations in Compliance Manager and view the full list of regulations. Learn more about creating regulation templates.

Improvement actions

Improvement actions help centralize your compliance activities. Each improvement action provides recommended guidance that's intended to help you align with data protection regulations and standards. Improvement actions can be assigned to users in your organization to perform implementation and testing work. You can also store evidence, notes, and record status updates within the improvement action. Learn more about working with improvement actions.

Supported languages

Compliance Manager is available in the following languages:

- English
- Bahasa Indonesian
- Bahasa Malay
- Chinese (Simplified)
- Chinese (Traditional)
- Czech

- Danish
- Dutch
- Finnish
- French
- German
- Hebrew
- Hungarian
- Italian
- Japanese
- Korean
- Norwegian
- Polish
- Portuguese (Brazilian)
- Russian
- Spanish
- Swedish
- Thai
- Turkish

Next steps

- Sign in, assign permissions and roles, configure settings, and personalize your dashboard view.
- Learn about and set up multicloud support.
- Create assessments to help you comply with industry standards that matter most to your organization.
- Get detailed scenario-based guidance on using Compliance Manager and other Purview solutions to help you manage data privacy and data protection.

Compliance Manager glossary

Article • 02/04/2025

This glossary provides a brief description of important terms and concepts in the context of Microsoft Purview Compliance Manager. This glossary can help you learn and use the solution tools and features quickly and effectively.

Expand table

Term	Description
Assessment	A grouping of controls from a specific regulation, standard, or policy. Completing the actions within an assessment helps you meet the requirements of a standard, regulation, or law.
Control	Generally, a specific measure or action that an organization implements to mitigate or manage risks associated with a particular requirement or objective of a regulation, standard, or policy. As used in Compliance Manager: A control is a requirement of a regulation that defines how you assess and manage system configuration, organizational process, and people responsible for meeting a specific requirement of a regulation, standard, or policy.
Improvement action	A compliance activity with recommended implementation instructions, intended to help towards completion of a control.
License	In the context of Compliance Manager regulations: A single Compliance Manager license allows you to create an unlimited number of assessments for multiple versions of a regulation.
Regulation	A rule or requirement imposed by a governing authority, such as a government agency, to achieve a specific purpose. Also commonly understood as a standard or framework. Compliance Manager supports several industry regulations, providing over 360 regulatory templates for building assessments.
Service	A data source, such as Microsoft Azure or Amazon Web Services (AWS), or more broadly, the digital entity that's being assessed and that benefits from the actions taken. For an assessment, you designate the service that it should evaluate. Completing an improvement action in the assessment benefits the service.
Service instance	For Compliance Manager connectors, each service instance represents an account with a non-Microsoft service provider. For example, an organization may have multiple accounts in Salesforce, such as one for development and testing, one for production, etc. Connectors are set up for each service instance using one email address and password. So an organization may have several connectors for one service, which enables the organization to monitor assessment progress across all instances of a service.

Term	Description
Solution	A feature or capability used to complete an improvement action. For example, a Microsoft product, such as Microsoft Data Loss Prevention, or a setting in a service like Azure or AWS.
Subscription	A type of account to create, assess, and manage a service covered by Microsoft Defender for Cloud, such as Azure, Google Cloud Platform, or Amazon Web Services. Examples: an Azure account for development and testing purposes, an Azure account for production, etc.
Virtual resources	A cloud computing-based resource that is managed virtually, such as VMs and virtual storage disks.

Feedback

Was this page helpful? Yes No

Compliance Manager frequently asked questions

Are there licensing requirements for using Compliance Manager?

Yes. Organizations with Office 365 and Microsoft 365 licenses, and US Government Community (GCC) Moderate, GCC High, and Department of Defense (DoD) customers, have access to Compliance Manager. However, the assessments available to your organization and how you manage assessment templates depends on your licensing agreement. Visit the licensing guidance for details.

Can I use Compliance Manager for non-Microsoft products?

Yes. Learn more about multicloud support in Compliance Manager.

What changed with template licensing in December 2022?

Organizations at the E5/A5/G5 levels have greater flexibility in which regulatory templates they can use for free as part of their licensing agreement. These organizations can choose up to three premium regulatory templates for free instead of having a predetermined set of included templates. The Microsoft Data Protection Baseline is also included by default as part of your subscription.

For customers using any of the templates that were included before the December 2022 change (NIST 800-53, ISO 27001, GDPR), continued use of those templates will count against the allotted three free premium templates. Customers who have already purchased one or more premium templates can use three more premium templates for free.

Also new in December 2022: Templates that belong to the same regulation family now count as one template. For example, the templates for CMMC Levels 1 through 5, are now considered a

single template so that you don't need to purchase multiple versions. When you purchase a template license for a regulation, the license applies for all levels and versions of that regulation. Review the licensing details.

If I have a high score, does it mean I'm fully compliant?

No. Your compliance score measures your progress in completing recommended actions that help reduce risks around data protection and regulatory standards. It doesn't express an absolute measure of organizational compliance with regard to a particular standard or regulation. Compliance Manager, and your compliance score, shouldn't be interpreted as a guarantee in any way.

Get started with Compliance Manager

Article • 11/27/2024

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

Who can access Compliance Manager

Compliance Manager is available to organizations with Office 365 and Microsoft 365 licenses, and to US Government Community Cloud (GCC) Moderate, GCC High, and Department of Defense (DoD) customers. Assessment availability and management capabilities depend on your licensing agreement. View service description details.

Sign in

1. Sign in to the Microsoft Purview portal using credentials for an admin account in your Microsoft 365 organization:
2. Select **Compliance Manager** on the left navigation pane. You arrive at your Compliance Manager dashboard.

Set user permissions and assign roles

Compliance Manager uses a role-based access control (RBAC) permission model. Only users who are assigned a role can access Compliance Manager, and the actions allowed by each user are restricted by role type. Our RBAC model also allows you to grant user access to individual assessments. See role-based access to assessments below to learn more.

The person holding the Global Administrator role for your organization can set user permissions for Compliance Manager. Permissions can be set in one of the following places:

- Permissions in the Microsoft Purview portal
- Permissions in Microsoft Entra ID

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

> **Note**
>
> Users with Microsoft Entra identities who don't have Office 365 or Microsoft 365 subscriptions won't be able to access Compliance Manager in the Microsoft Purview portal. To seek assistance in accessing Compliance Manager, contact cmresearch@microsoft.com.

> **Note**
>
> Customers in US Government Community (GCC) High and Department of Defense (DoD) environments can only set user permissions and roles for Compliance Manager in Microsoft Entra ID. See the Microsoft Entra permissions instructions and role type definitions.

Role types

The table below shows the functions allowed by each role in Compliance Manager. The table also shows how each Microsoft Entra role maps to Compliance Manager roles. Users need at least the Compliance Manager reader role, or Microsoft Entra global reader role, to access Compliance Manager.

A user can only hold one role at a time. Any change in a user's role overrides their previous role.

Expand table

User can:	Compliance Manager role	Microsoft Entra role
Read but not edit data	Compliance Manager Reader	Microsoft Entra Global reader, Security reader

User can:	Compliance Manager role	Microsoft Entra role
Edit data and create assessments - for example, can edit improvement action status, enter notes, upload evidence; can create assessments	Compliance Manager Contribution	Compliance Administrator
Edit data only - can't create assessments	Compliance Manager Assessor	Compliance Administrator
Manage assessments, regulatory templates, and tenant data; assign improvement actions	Compliance Manager Administration	Compliance Administrator, Compliance Data Administrator, Security Administrator

Role-based access to assessments and regulations

You can assign roles to users in order to grant access to specific assessments, or all assessments based on the regulation. Granting user access in these ways is useful when you need to ensure that only the people working on certain regulatory requirements have access to that data.

These four roles provide access to assessments:

- Compliance Manager Reader
- Compliance Manager Contribution
- Compliance Manager Assessor
- Compliance Manager Administration

What you can do with each assessment remains restricted based on which activities the role allows.

To grant users access to an assessment or all assessments for a regulation, open its details page and select **Manage users access** to add users by role. If a user has a role assigned to them in the Microsoft Purview portal for overall access to Compliance Manager, any role you assign them for a specific assessment applies only to that assessment.

More information:

- See Grant user access to assessments for more detailed instructions.
- See Grant user access to regulations for more detailed instructions.
- Learn more about managing all users' access to assessments in Compliance Manager settings.

Start a premium assessments trial

The Compliance Manager premium assessments trial is a great way to quickly create assessments that are most relevant to your organization. Our library of over 360 regulatory templates correspond to governmental regulations and industry standards around the world. Learn more about the premium assessments trial.

Compliance Manager settings

To locate Compliance Manager settings in the Microsoft Purview portal, select the **Settings** icon at the top of the page, then select **Compliance Manager**.

The types of settings for Compliance Manager include:

- Testing source: Allows you to turn off or on the automatic testing of improvement actions.
- Manage user history: Allows you to manage the data of users associated to improvement actions, including the ability to reassign improvement actions to a different user.
- User access: Allows you to view and manage user roles for access to assessments or assessment templates.
- Connectors: Allows you to activate and manage connectors for non-Microsoft services. Get details about accessing connectors in the portal.

Compliance Manager settings are accessible by users who hold a Compliance Manager Administrator role or Global Administrator role.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

> **Note**
>
> The automated testing feature is not available to customers in GCC High and DoD environments because Secure Score isn't available in these environments. GCC High and DoD customers will need to manually implement and test their improvement actions.

Testing source for automated testing

Compliance Manager detects various signals to provide automated testing and monitoring of improvement actions. This automation derives from three primary sources: built-in, Microsoft Secure Score, and Microsoft Defender for Cloud (get details about automated testing sources). Compliance Manager also detects signals from Microsoft Priva (this capability is in preview; learn more). When an improvement action is successfully tested and implemented, you receive the maximum possible points for that action, which gets credited to your overall compliance score.

Initial settings

While automated testing helps maximize efficiency in your compliance activities, you have full control over whether to apply automated testing. Here's what's initially set up by Compliance Manager and how you can make changes:

- The first time you use Compliance Manager, automatic testing is turned on by default for all actions that can be automatically tested. It takes approximately seven days to fully collect data and factor that data into your compliance score.
- You can turn off automatic testing for all actions, which disables all automated activity on improvement actions by Compliance Manager. You can also select individual improvement actions for automatic testing. See Manage automated testing settings for instructions.

How to tell which actions are tested automatically

On an improvement action's details page, the **Testing type** status in the top information bar shows how the action is tested. If the value is listed as **Automatic**, then the action is automatically tested. If the value is **Manual**, then the action is tested by your organization. Get details about improvement action testing type.

When actions are added or updated

When automation becomes available for existing improvement actions, or when new automated improvement actions are added, the default behavior depends on your current settings and whether or not you've brought data into an improvement action. When you add your own testing data or evidence into an improvement action, automatic testing is turned off for that action to ensure that Compliance Manager doesn't overwrite any of your data.

If you've added data to an existing improvement action:

- Automated testing remains **off** by default for the action. You can choose to turn it back on.

If you haven't added data to an improvement action, or when new automated actions are added to Compliance Manager, the testing behavior follows your current settings:

- Automated testing is **on** if your setting is **on** for **all actions** or **per action**.
- Automated testing is **off** if your setting is **off for all actions**.

Manage automated testing settings

The Compliance Manager Administrator and the Global Administrator for your organization can change the settings for automated testing at any time. You can turn off automated testing for common improvement actions, or turn it on for individual actions. Follow the instructions below to change your automated testing settings. When you change a setting, it will be reflected in the audit log. Learn more about Compliance Manager activities in the audit log.

> **ⓘ Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

1. In Compliance Manager, select **Compliance Manager settings** in top right corner of the page.
2. Select **Testing source** from the left navigation.
3. Select your desired option for testing improvement actions:
   a. Turn on automatic testing for all actions.
   b. Turn off automatic testing for all actions.
   c. Turn on automatic testing per action.
4. If you select **Turn on per improvement action**, a list displays all the improvement actions that are eligible for testing. All actions are checked by default, so you need to uncheck the actions you **don't** want to be automatically tested.
5. Select **Save** to save your settings. You receive a confirmation message at the top of your screen that your selection was saved. If you receive a failure notice, try again.

Manage user history

The **Manage user history** settings help you quickly identify which users have worked with improvement actions in Compliance Manager. The identifiable user data associated with improvement actions includes the status of the improvement actions and documents they uploaded. Understanding and retrieving this type of data might be necessary for your organization's own compliance needs.

The user history settings also allow you to reassign all improvement actions from one user to another.

To find the user history settings:

1. In Compliance Manager, select **Compliance Manager settings** in the top right corner of the page.
2. Select **Manage user history** from the left navigation.

The **Manage user history** page shows a list of all users by email address who are assigned to an improvement action. Use the **Search** button to quickly find a specific user by typing in their email address.

To the right of each user's email address, the **Select** drop-down menu provides options to export a report, reassign improvement actions, or delete history. See each section below for details about each option.

Export a report of user history data

You can export an Excel file containing a list of improvement actions currently assigned to a user. The report also lists any evidence files uploaded by that user. This information can help you reassign open improvement actions.

The report reflects the improvement action's status as of its creation date. It's not a historical report of all previous changes to its status or assignment (learn how to export a report from your improvement actions page).

Follow the steps below to export a report by user:

1. In Compliance Manager, select **Compliance Manager settings** in top right part of the page.
2. Select **Manage user history** from the left navigation.

3. Find your intended user by searching the list email addresses, or by selecting **Search** and entering the user's email address.
4. From the **Select** drop-down menu, choose **Export report**.
5. Once the Excel file of your report is generated, you can open it and save it to your local machine.

Reassign improvement actions to another user

You can reassign ownership of improvement actions from one user to another. When you reassign an action, the evidence upload history doesn't change, but the name of the user who originally uploaded evidence no longer appears within the improvement action.

Follow the steps below to reassign improvement actions to another user:

1. In Compliance Manager, select **Compliance Manager settings** in top right corner of the page.
2. Select **Manage user history** from the left navigation.
3. Find a user by searching the list email addresses, or by selecting **Search** and entering that user's email address.
4. From the **Select** drop-down menu, choose **Reassign improvement actions**. The **Reassign improvement actions** flyout pane appears.
5. In the **Search users** field, enter the name or email address of the user to whom you're assigning the improvement actions.
6. When you see the name of your intended user under **Improvement actions will be assigned to**, select the user, then select **Assign actions**.
7. When the reassignment is complete, you see a confirmation message in the flyout pane confirming that all improvement actions from the previous user have been reassigned to the new user. If you receive a reassignment failure notice, close the window and try again. To close the flyout pane, select **Done**.

The new owner receives an email that they've been assigned to an improvement action. The email contains a direct link into the improvement action's details page.

> ⓘ **Note**

If you reassign an action that has a pending update, the direct link to the action in the reassignment email will break if the update is accepted after reassignment. You can fix this by re-assigning the action to the user after the update is accepted. Learn more about updates to improvement actions.

Delete user history

Deleting a user's history removes them as an owner of improvement actions and removes their name from all other fields in Compliance Manager. When you delete a user's history, the improvement actions they owned won't display an **Assigned to** value until a new user is assigned. Evidence uploaded to the improvement action shows **User removed** in place of the deleted user's name. Deleting user history is permanent.

To delete a user's history, follow the steps below:

1. In Compliance Manager, select **Compliance Manager settings** in top right corner of the page.
2. Select **Manage user history** from the left navigation.
3. Find a user by searching the list email addresses on the page, or by selecting **Search** and entering that user's email address.
4. From the **Select** drop-down menu, choose **Delete history**.
5. A window asks you to confirm the permanent deletion of the user's history. To continue with deletion, select **Delete history**. To leave without deleting the history, select **Cancel**.

You arrive back at the **Manage user history** page with a confirmation message at the top that the history for the user was deleted.

User access

The **User access** section of **Settings** displays a list of all users who have a role that allows access to one or more assessments. From this page, you can make changes to role assignments. When you change a setting, it will be reflected in the audit log. Learn more about Compliance Manager activities in the audit log.

- When you grant a user access to an **assessment**: The user has access to just that one assessment.

- When you grant a user access to a **regulation**: The user will have access to any assessment created with that regulation, including existing assessments and any assessments created in the future.

To add or remove user access roles for assessments and regulations, follow the steps below:

1. In Compliance Manager, select **Compliance Manager settings** in top right part of the page.
2. Select **User access** from the left navigation.
3. Select the checkbox next to the name of one or more users whose role you want to edit.
4. Depending on whether you're editing roles for assessments or regulations: From the **Edit assessment roles** or **Edit regulation roles** dropdown menu above the list of names, select **Add assessment/regulation permissions** or **Remove assessment/regulation permissions**.
5. **For adding a role**: From the flyout pane, go to the tab that corresponds to the role you want to add (Reader, Assessor, or Contributor), then select **Add assessments/regulations**. On the next flyout pane, choose the checkbox next to the assessments/regulations and select **Apply**, then select **Save**.
6. **For removing a role**: From the flyout pane, go to the tab that corresponds to the role you want to remove (Reader, Assessor, or Contributor). Select the button next to the assessments/regulations for which you want to remove access, and select the X mark in the **Remove** column.
    a. A **Remove access?** confirmation box appears. Select **Confirm** to remove the user's role, or select **Cancel** to cancel. The name of the assessments will now be removed from the role tab.
    b. Select **Save** on the flyout pane. The role removal won't be completed until you select the **Save** button. Selecting **Close** will cancel out of the process without saving the role removal.

The user list on the **User access** page will now reflect the changes you made.

> ⓘ **Note**
>
> Admins whose permissions for Compliance Manager were set in Microsoft Entra ID won't appear on the **User access** page. This means that if a user has access to one

or more assessments, and their role is Global Administrator, Compliance Administrator, Compliance Data Administrator, or Security Administrator, they won't appear on this page. Learn more about **setting Compliance Manager permissions**.

More information:

- Visit these instructions for assigning user roles from an assessment's details page.

Understand the Compliance Manager dashboard

The Compliance Manager dashboard is designed to provide you an at-a-glance view of your current compliance posture.

Overview page

Your compliance score

Your compliance score is featured prominently at the top of the **Overview** page. The score is a percentage based on points achievable for completing improvement actions that address key data protection standards and regulations. Points from Microsoft actions, which are managed my Microsoft, also count toward your compliance score.

When you come to Compliance Manager for the first time, your initial score is based on the Microsoft 365 data protection baseline. This baseline assessment, which is available to all organizations, is a set of controls that includes common industry regulations and standards. Compliance Manager checks your existing Microsoft 365 solutions and gives you an initial assessment based on your current privacy and security settings. As you add assessments that are relevant to your organization, your score becomes more meaningful for you.

Learn more: Understand how your compliance score is calculated.

Key improvement actions

This section lists the top improvement actions you can take right now to make the largest positive impact on your overall compliance score. Select **View all improvement actions** to go to your improvement actions page.

Solutions that affect your score

This section highlights solutions containing improvement actions that can positively impact your score, and the number of outstanding improvement actions in those solutions. Select **View all solutions** to visit your solutions page.

Compliance score breakdown

This section gives you a more detailed view of your score in two different ways:

- **Categories**: shows the percentage of your overall score within data protection categories, such as "protect information" or "manage devices."
- **Assessments**: shows the percentage of your progress in managing assessments for particular compliance and data protection standards, regulations, or laws, such as GDPR or NIST 800-53.

Filtering your dashboard view

You can filter your dashboard view to see only the items related to particular regulations and standards, solutions, type of action, assessment groups, or data protection categories. Filtering your view in this way will also filter the score on your dashboard, showing how many points you've achieved out of total possible points based on your filter criteria.

To apply filters:

1. Select **Filter** on the upper-right side of the dashboard.
2. Select your filter criteria from the **Filters** flyout pane, then select **Apply**.

After you apply a filter, you'll see your score adjusted in real time. The compliance score percentage and breakdown information, and the improvement actions and solutions, now only pertain to data covered by your filter criteria. If you sign out of Compliance Manager, your filtered view remains when you sign back in.

To remove filters:

- At the **Applied filters** heading above your compliance score, select the **X** next to the individual filter you want to remove; or
- Select **Filter** on the upper-right side of your dashboard, then on the **Filters** flyout pane, select **Clear filters**.

Improvement actions page

Improvement actions are recommended actions that can help to centralize your compliance activities and align with data protection regulations and standards. Each improvement action gives detailed implementation guidance and a link to launch you into the appropriate solution. Improvement actions can be assigned to users in your organization to perform implementation and testing work. You can also store evidence, notes, and record status updates within the improvement action.

Solutions page

The **Solutions** page shows the share of earned and potential points as organized by solution. Viewing your remaining points and improvement actions from this view helps you understand which solutions need more immediate attention.

Find the solutions page by selecting the **Solutions** tab on your Compliance Manager dashboard. You can also select **View all solutions** underneath **Solutions that affect your score** in the upper-right section of your dashboard. To filter your view of solutions:

1. Select **Filter** at the top-left corner of your assessments list.
2. On the **Filters** flyout pane, place a check next to the desired criteria (regulations, solutions, action types, groups, categories).
3. Select the **Apply** button. The filter pane closes and you see your filtered view.

You can also modify your view to see assessments by group, product, or regulation by selecting the type of grouping from the **Group** drop-down menu above your assessments list.

Taking action from the solution page

The **Solutions** page displays your organization's solutions that are connected to improvement actions. The table lists each solution's contribution to your overall score, the points achieved and possible within that solution, and the remaining number of improvement actions grouped in that solution that can increase your score.

There are two ways you can take action from this screen:

1. On the row of your intended solution, under the **Remaining actions** column, select the hyperlinked number. You see a filtered view of the improvement actions screen showing untested improvement actions for that solution.

2. On the row of your intended solution, under the **Open solution** column, select **Open**. You arrive at the solution's location in the Microsoft Purview portal,

Microsoft Defender portal, or its admin center, where you can take the recommended action.

Assessments page

The **Assessments** page lists all the assessments you set up for your organization. Your compliance score denominator is determined by all your tracked assessments. As you add more assessments, you see more improvement actions listed on your improvement actions page, and your compliance score denominator increases. See Build and manage assessments to learn about assessment status and how to create new assessments.

Regulations page

A regulatory template is a framework for creating an assessment in Compliance Manager. The **Regulations** page displays a list of regulatory templates and key details. The **Free regulation licenses used/Purchased regulation licenses used** counter near the top of the page shows the number of active regulations currently in use out of the total number available for your organization to use. See Regulation availability and licensing for more information.

Policies page

The **Policies** page lists policies you set up to alert you to key changes within Compliance Manager that affect your compliance score. Visit Compliance Manager alerts and alert policies to learn more.

Alerts page

The **Alerts** page lists alerts generated by policies you set up to track changes within Compliance Manager that affect your compliance score. Visit Compliance Manager alerts and alert policies to learn more.

Reports page

The **Reports** page displays a history report of activities in Compliance Manager within the previous seven days. You can look up data from the previous six months by adjusting filters.

The **Reports** page displays your compliance score and a chart representing your organization's overall compliance posture. Select **View detailed report** to bring up a detailed history report page. A table lists improvement actions that have had a score change within the last month. It takes about 24 hours for changes in an action to be reflected in the report.

Select an improvement action from its row on the table to see a details pane that explains the action, the related regulation, associated assessments, and score update. You can launch into the action by selecting **Go to action**. Select the **History** tab on the pane to view the score history for the action.

Filter by date range, regulation, and service

On the history report page, you can adjust the filters to broaden or refine the view of actions that appear in the table. Select the **Date range** filter to select a range that can retrieve data up to six months prior. Select **Add filter** to apply other filters that apply to actions based on regulation or by cloud service.

Next step

Begin setting up your assessments.

Multicloud support in Compliance Manager

09/26/2025

In this article: Learn how Compliance Manager helps you automatically assess and manage compliance across your multicloud environment.

Overview

Compliance Manager now integrates with Microsoft Defender for Cloud, which allows you to assess your compliance posture across Microsoft 365, Microsoft Azure, Google Cloud Platform (GCP), and Amazon Web Services (AWS) with resource-level testing and cloud-specific guidance. This new integration provides customers with a single interface in Compliance Manager to help make it easier to manage compliance across the organization's digital estate.

This integration allows Compliance Manger to track configurations in your organization's Microsoft Azure environment and detect signals from other services like GCP and AWS, so that you can assess your progress in meeting controls for the regulations you need to comply with. Compliance Manager provides guidance for implementing improvement actions in non-Microsoft services for meeting controls.

The integration with Defender for Cloud surfaces in two contexts within Compliance Manager:

1. Assessments: When you create an assessment in Compliance Manager, you'll select a supported regulation and then choose one or more services to assess. Compliance Manger then provides automatic monitoring of configurations in your selected services to determine whether controls are passing or failing.

2. Improvement actions: Using signals from Defender for Cloud, Compliance Manager automatically detects the test status and test result of improvement actions that pertain to Azure and to your non-Microsoft services. With these signals, Compliance Manager automatically tracks the status of actions and resource-level testing details from cloud services like AWS and GCP.

Supported services

The services listed below can be assessed by Compliance Manager:

- Microsoft 365
- Microsoft Azure cloud services

- Google Cloud Platform
- Amazon Web Services

Add a new service

If you want to assess a non-Microsoft service that isn't listed above, you can add it as a new service when you're creating a new assessment. When you add a new service, the universal version of the underlying regulation is used, and you perform manual implementation and testing work. For instructions on adding a new service, see step 5 of the assessment creation process.

> **Tip**
>
> Compliance Manager has a dedicated selection of connectors to support other non-Microsoft services such as Salesforce and Zoom. Visit **Working with connectors in Compliance Manager**.

Service subscriptions

When creating assessments, you can select a subscription if the service you choose for the assessment is monitored by Defender for Cloud. Your choice of subscription will affect the evaluation of improvement actions for that service. Learn more about monitoring assessment progress by service.

If you choose subscriptions that are in scope within Defender for Cloud for a matching regulation, automated test results are pulled from Defender for Cloud and shown in the assessment.

Supported regulations

View the list of regulations supported by both Compliance Manager and Defender for Cloud.

Get started

There are setup steps required before you can start building assessments for your cloud services. Visit Configure cloud settings to get started.

Resources

- Quickstart: Set up Microsoft Defender for Cloud

Configure cloud settings for use with Compliance Manager

Setting up for multicloud support

Compliance Manager integrates with Microsoft Defender for Cloud to provide multicloud support. Organizations must have at least one subscription within Microsoft Azure and then enable Defender for Cloud so that Compliance Manager can receive the necessary signals to monitor your cloud services. Once you have Defender for Cloud, you need to assign the relevant industry and regulatory standards to your subscriptions.

Depending on what your organization has already set up, use one of the following sections to get started:

- **You don't have Azure**: Activate Azure and create a subscription
- **You have Azure but don't have Defender for Cloud**: Enable Defender for Cloud on your Azure subscription
- **You have Defender for Cloud but haven't assigned standards**: Assign standards to your cloud service subscriptions

Standards supported by Compliance Manager and Defender for Cloud

The standards or regulations listed below are supported across Defender for Cloud and Compliance Manager. Each standard is available to support Microsoft 365 in addition to the other cloud services listed in parentheses.

> **Tip**
>
> Defender for Cloud refers to “standards,” while Compliance Manager uses “regulations” to refer to the same thing.

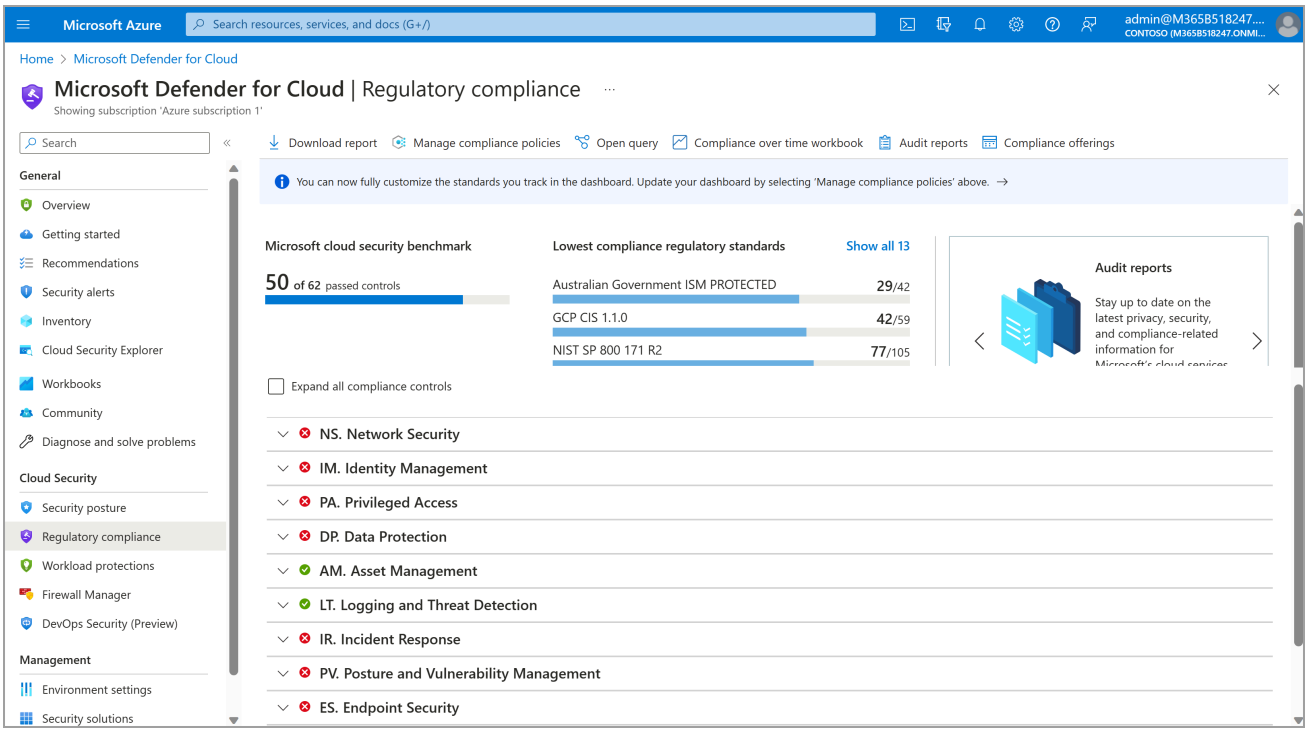
- AWS Foundational Security Best Practices
- CIS 1.1.0 (GCP)
- CIS Microsoft Azure Foundations Benchmark v1.1.0 (Azure)
- CIS 1.2.0 (AWS, GCP)

- CIS Microsoft Azure Foundations Benchmark v1.3.0 (Azure)
- CIS Microsoft Azure Foundations Benchmark v1.4.0 (Azure)
- FedRAMP High (Azure)
- FedRAMP Moderate (Azure)
- ISO 27001 (Azure, GCP)
- NIST SP 800-171 Rev.2 (Azure)
- NIST SP 800-53 Rev.4 (Azure)
- NIST SP 800 53 Rev.5 (Azure, AWS, GCP)
- PCI DSS 3.2.1 (AWS, GCP)
- PCI DSS v4.0 (Azure)
- SOC 2 Type 2 (Azure)
- SWIFT CSP-CDCF v2022 (Azure)

Activate Azure and create a subscription

Setting up a subscription within Microsoft Azure is a prerequisite for getting started with Defender for Cloud. If you don't have a subscription, you can sign up for an Azure free account.

Enable Defender for Cloud



Visit Quickstart: Set up Microsoft Defender for Cloud. Follow the steps to enable Defender for Cloud on your Azure subscription and become familiar with the Defender for Cloud Overview page. Once you've enabled Defender for Cloud, follow the steps below to make sure you're set up for Compliance Manager integration.

Most setup functions require the user to hold the Owner role in Azure. Get more details about User roles and permissions for Defender for Cloud.

Confirm access to Defender for Cloud Regulatory compliance

1. Go to Microsoft Defender for Cloud | Regulatory compliance.

2. Validate that you see a dashboard like this:

3. If you don't see the dashboard above and instead see a notice about insufficient licensing, follow the prompts to activate an applicable Defender for Cloud plan. We recommend enabling one of the two plans: **Foundational CSPM** or **Defender CSPM** (cloud security posture management plans). You can manually select the plans by completing the following steps:
   a. In Defender for Cloud, select **Environment settings** on the left navigation.
   b. Select **Azure** from your list of environments. Expand the item underneath **Azure** to view the subscription, then select the subscription. You arrive at the **Defender plans** page.
   c. In the **Plan** column, find the rows for **Foundational CSPM** and **Defender CSPM**. In the **Status** row, select the **On** button for both plans.

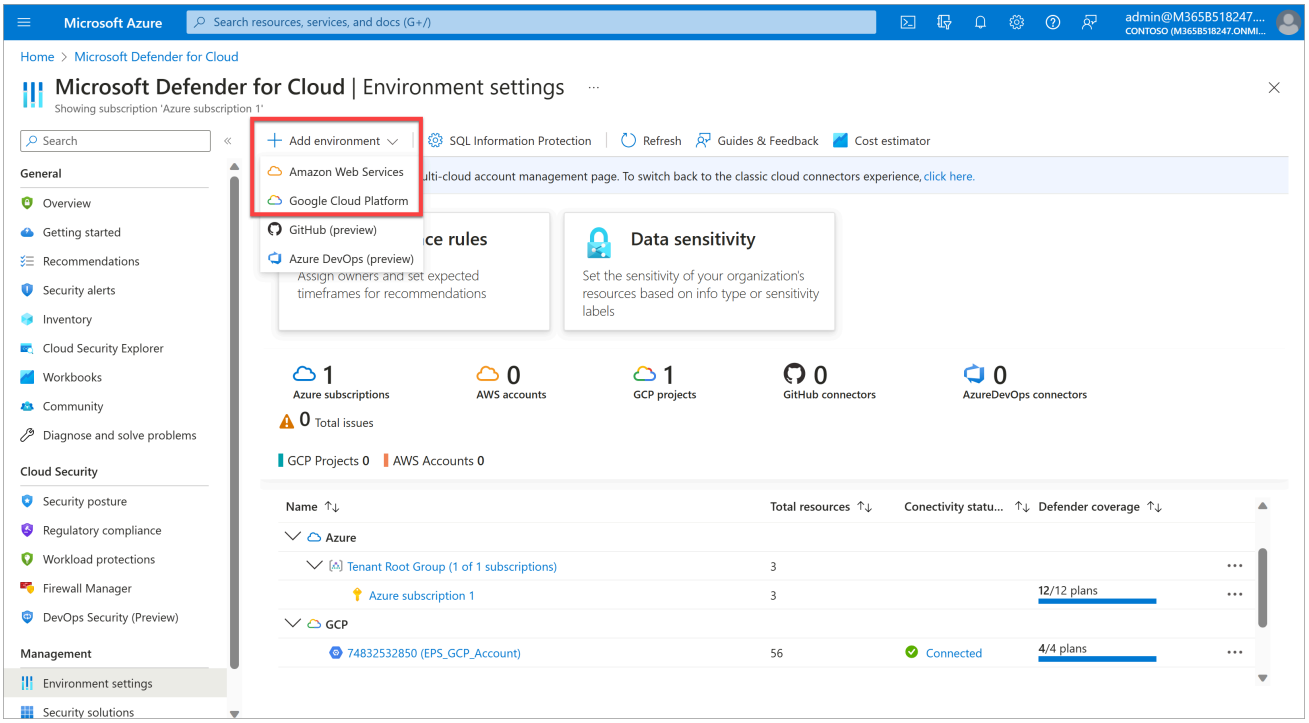
View available environments

1. In Defender for Cloud, select **Environment settings** on the left navigation.

2. View the available environments and subscriptions currently visible to MDC for your tenant. You may need to expand your management groups to view subscriptions, which you can do by selecting **Expand all** below the search bar. In addition to your Azure subscriptions, you'll also see any Google Cloud Platform (GCP) projects or Amazon Web Services (AWS) accounts connected to Defender for Cloud.

3. If you don't see an expected subscription and have already confirmed your Defender for Cloud licensing in the previous steps, check your current directory and subscription filters in your Azure Portal settings. In this view, you can adjust any subscription filters or switch to

a different directory if one is available, and then return to the **Environment settings** view to check the results.



4. If you don't see an expected AWS or GCP environment, account, or project, proceed to the next step to set up the necessary connectors.

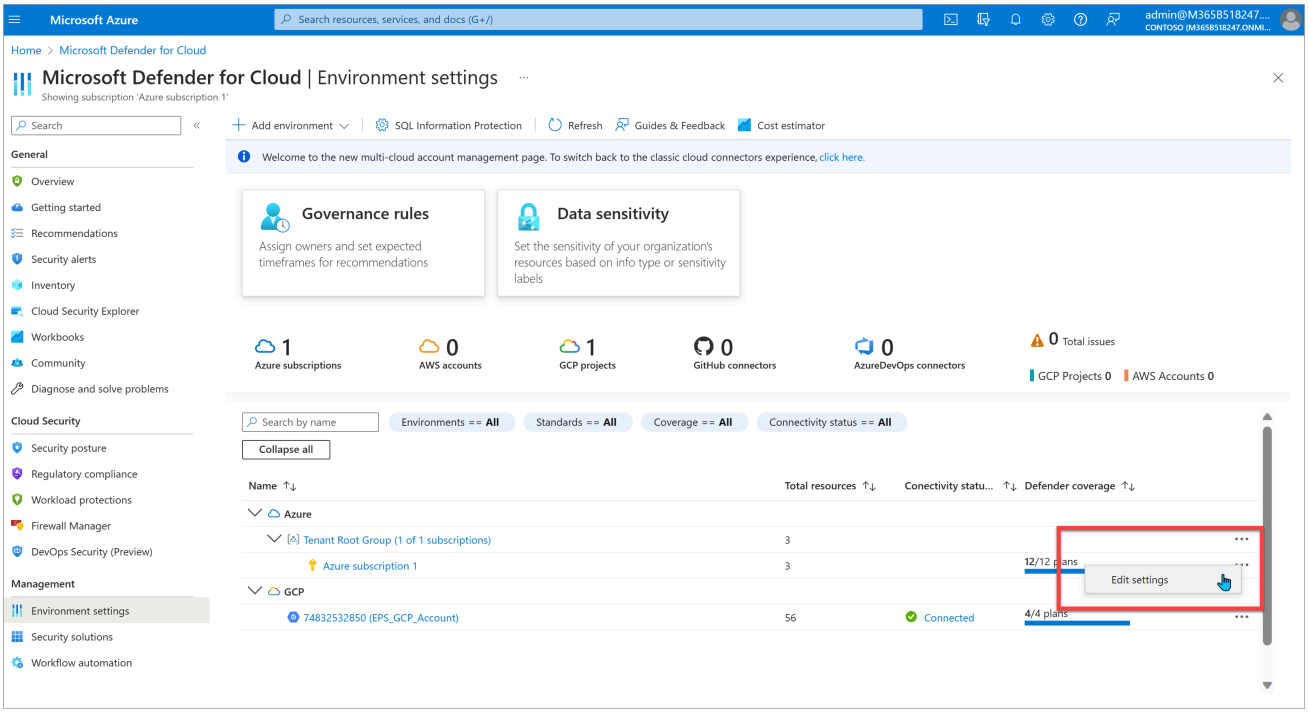
Connect to your Amazon Web Services or Google Cloud Provider accounts (optional)

Follow these instructions if you have an Amazon Web Services (AWS) account or Google Cloud Platform (GCP) project that you want Compliance Manager to assess compliance posture, and you don't already see those accounts or projects in your Azure Environment settings. When you complete this process, you can begin assigning standards to your connected AWS or GCP subscriptions within about an hour, though full data can take up to 24 hours to appear.

1. In Defender for Cloud, select **Environment settings** on the left navigation.

2. Select **Add environment** and choose either **Amazon Web Services** or **Google Cloud Platform**.

3. Follow the wizard steps to complete the account setup. Connecting to the accounts requires admin permissions in the AWS or GCP accounts being used, and some configuration steps within AWS or GCP. These steps are detailed in the wizard.
   a. For a simple setup option, consider starting with just one account such as GCP. In the first step of **Account details**, at **Onboard**, select **Single account**. This option requires the least amount of configuration effort.



Add standards to your subscriptions

Check the list of standards supported by Defender for Cloud and Compliance Manager to ensure your desired standard is supported. Then follow the steps below.

1. In Defender for Cloud, select **Environment settings** on the left navigation.

2. Your available environments and subscriptions are listed on the page. You may need to expand your management groups to view subscriptions, which you can do by selecting **Expand all** below the search bar. Find the subscription to which you want to add a standard.

3. On the row for the subscription, select the ellipses on the far right and select **Edit settings**.

4. On the left navigation, under **Policy settings**, select **Security policy**.

5. Browse the list of available standards under **Industry & regulatory standards**. You can view more standards by selecting the **Add more standards** button at the bottom of the list. Assign at least one of the supported standards listed below to your subscription by selecting **Enable** on the standard's row.

Working with connectors in Compliance Manager

Article • 03/31/2025

Compliance Manager offers a set of connectors designed to help you gain a clear understanding of your compliance obligations across the services used in your organization. The connectors provide a seamless link to non-Microsoft services so that you can include them in your assessments and take advantage of automatic monitoring and testing of controls. Connecting your services to Compliance Manager requires a few simple setup steps. Once your connector is activated, you can select it as an in-scope service when creating an assessment.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Available connectors

The connectors currently available for Compliance Manager are listed below:

- Corporate Sustainability
- Salesforce
- Zoom

> **Important**
>
> Compliance Manager connectors are unique to the Compliance Manager solution and are set up within Compliance Manager. The data connectors that are accessed from the left navigation of the Microsoft Purview portal aren't compatible with Compliance Manager. We recommend interacting with connectors by following these instructions below to ensure that any connectors you activate are the ones built specifically for use with Compliance Manager.

Roles for setting up connectors

Only users with a Data Connector Admininistrator role or a Global Administrator role can set up Compliance Manager connectors.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Connector setup steps

1. Configure settings in your service so that it can integrate with the connector.
2. Activate the connector in Compliance Manager.
3. Select the connector when building an assessment.

Step 1: Configure service settings to enable the connector

For each service, you need to do some configurations and get basic information about your accounts. This information is used to create the connection between the service and the Compliance Manager connector so that the connector can retrieve the necessary signals. Visit the pages listed below and follow the setup instructions before you activate its connector in Compliance Manager:

- Corporate Sustainability
- Salesforce setup
- Zoom setup

Step 2: Activate the connector in Compliance Manager

The next step is to "activate a connector" in Compliance Manager by connecting to your desired service. After you activate a connector, you can select it as a service to be monitored when creating an assessment. The connector allows Compliance Manager to receive signals from your designated non-Microsoft service and evaluate configurations in order to determine whether controls are passing or failing.

If you have more than one account for your product, such as accounts for production, for development and testing, or for backup disaster recovery, you need to activate a connector for each separate account. We refer to each account within a service as a **service instance**.

Follow the steps below to activate a connector:

1. Sign in to the Microsoft Purview portal. Select the **Settings** icon at the top of the page, then select **Compliance Manager**.
2. On the **Compliance Manager settings** page, select **Connectors**.
3. The page displays a list of available connectors to choose from. Select the checkbox next to the name for the product whose connector you want to activate, then select **Activate connector**.
4. You see an information page with details about the connector. Select **Add connector**, which takes you into the connector setup wizard.
5. Review the Microsoft Terms of Service, then select **Accept**.
6. On the **Connector name** page, enter a unique name. You might want a name that helps identify which account the connector is for; for example, "Salesforce Prod" for your Salesforce production account. Then select **Next**.
7. On the **Authentication** page, enter the credentials for the account that you want to link to the connector. The specific fields depend on the service you're connecting to, but are usually a variation of email or account ID, password, and token. See the setup instructions for each service to learn how to get this information. When done entering authentication information, select **Validate connection**. It takes a few seconds to validate the connection.
8. If the connection to your account is validated, you see a **Validation succeeded** message. If validation fails, enter your credentials again until the connection is validated. Select **Next**.
9. On the **Review and finish** page, review the connector details for accuracy. Select **Back** if you need to make changes. Select **Finish** to complete the process.

You arrive back at the Compliance Manager data connectors page. Go to **My activated connectors** tab to view your connector, along with any other connectors created by your organization. If you don't see the newly created connector, refresh your browser.

Step 3: Add a connector to assessments

Now you're ready to build an assessment with a connector so that it tracks progress related to the desired service.

1. From the **Assessments** page in Compliance Manager, select **Add assessment**.
2. From here, begin following the general assessment creations instructions.

   > **Tip**
   >
   > When selecting a regulation for the assessment, the **Supported services** column on the **Select regulation** flyout pane shows which services are supported by the regulation template. If the service related to your connector isn't listed, the connector won't show up as an option in step 3, below.

3. When you arrive at the **Select services** page and choose **Select services**, you should see the name of the product related to your activated connector; for example, Salesforce. Check the box next to the service name, select **Add**, then select **Next**.
4. At the **Service instances** page, you choose one or more connectors you activated for the service. On the row listing your service, select **Manage service instances**.
5. A flyout pane lists all the service instances for your connector. Each instance represents a connector activated by your organization. All service instances are checked by default. If you want the assessment to cover all instances, which means the assessment uses all connectors you activated for that service, leave them all checked and select **Cancel**. Or, uncheck any instances that you don't want to cover in the assessment and select **Update**.
6. Back at the **Service instances** page, select **Next**.
7. On the **Review and finish** page, confirm all your selections are correct, then select **Create assessment**.

The next screen confirms the assessment was created. When you select **Done**, you're taken to your new assessment's details page.

Viewing service data in an assessment

The assessment details page shows a detailed view of the assessment's rate of progress. When you add a connector as a service for the assessment, you see the connector name as one of the services listed on the assessment's **Progress** tab. You can view more details about service progress by selecting **View service details**.

Automated monitoring for connectors

Every 24 hours, connector signals are refreshed and any updated status is reflected in your assessment. This means that Compliance Manager provides daily automated refreshed status of configurations in the products for which you activated connectors.

All improvement actions that are monitored through connectors are automatically monitored and tested so that Compliance Manager can determine whether controls are passing or failing. Improvement action test status is reflected in your assessments so that you can take the necessary actions in your non-Microsoft products to satisfy a control requirement.

Editing a connector

If you need to edit a connector's name or account credentials, select the connector from your **My activated connectors** page and select the **Edit** command at the top of your connectors list.

Deleting a connector

To delete a connector, you need to first locate your connector in the **Data connectors** area of the Microsoft Purview portal. Follow the instructions below to delete a connector:

1. In the Microsoft Purview portal, select **Data connectors** in the left nav, then select **My connectors**.
2. Locate the connector that you want to delete on the list and select the checkbox next to its name. Select the **Delete** command at the top of the list.
3. In the delete confirmation dialog box, select **Delete**.

Your connector is deleted and removed from the list of your connectors.

Salesforce setup for Compliance Manager connector

09/26/2025

Follow the instructions on this page to enable the connection between your Salesforce account and the Compliance Manager connector for Salesforce.

This process involves obtaining a token for a given Salesforce account. Therefore, if you activate multiple connectors for multiple Salesforce accounts, you'll need to repeat this process for each account in order to get the token.

Setup steps

1. Sign in to your Salesforce account with your credentials.
2. Go to your account **Settings** and select **Reset My Security Token**. This can be done by any user.
3. Select **Reset Security** to get a new security token sent to your email.

   > ⓘ **Important**
   >
   > If the security token for your account is used anywhere else, resetting the token may cause issues in those locations.

4. Activate connector in Compliance Manager. When you activate a Salesforce connector in Compliance Manager, you'll provide your **Username**, **Password**, and **Security token**. Once you validate the connection during the connector activation process, you're all set up and ready to begin using the connector. Get details at Working with connectors in Compliance Manager.

Zoom setup for Compliance Manager connector

09/26/2025

Follow the instructions on this page to enable the connection between your Zoom account and the Compliance Manager connector for Zoom.

Zoom must authenticate each HTTP request made to the Zoom API. Zoom supports different authentication methods. Compliance Manager connectors use the **Server-to-Server OAuth app**, which enables you to securely integrate with Zoom APIs and get your account owner access token without user interaction. This is different from the OAuth app type, which requires user authentication. This app type is added and managed across an account by account admins. This app type also enables you to utilize event subscriptions using Webhooks. A paid Zoom account is required to access Zoom APIs.

Setup steps

1. Enable permissions

The user who handles the connector activation process for Zoom needs view and edit permissions so that they can set up a Server-to-Server OAuth app in Zoom. The administrator must enable the Server-to-Server OAuth app role by going to **User Management** > **Roles** > **Role Settings** > **Advanced features** and selecting the **View** and **Edit** checkboxes for **Server-to-Server OAuth** app. See Zoom's Using role management for details.

2. Create a Server-to-Server OAuth app

Follow the steps to create a Server-to-Server OAuth app to use with account credentials.

1. Sign in to your Zoom account and go to the Zoom App Marketplace: https://marketplace.zoom.com/develop/create.
2. From the **Develop** drop-down menu, select **Build application**.
3. Find the **Server-to-Server OAuth** app type card, then select **Create**.
4. Enter a name for your app, then select **Create**.
5. On the **App credentials** page: View and copy your Account ID, Client ID, and Client secret.

> **Tip**
>
> You'll enter these credentials when activating the Zoom connector in Compliance Manager. The client secret expires one hour after you generate it, so you may want to activate the Zoom connector in Compliance Manager soon after creating the Server-to-Server OAuth app.

6. On the **Information** page: Add information about your app, such as a short description and developer contact information (name and email address is required for activation).

7. On the **Feature** page: Set the toggle to your preferred setting for event subscriptions. If enabled, choose the event subscriptions you'd like to use.

8. On the **Scopes** page: If you have the role permission to add scopes, add any scopes that you'd like to enable. Choose **Add Scopes** to search for and add scopes. Select the required scopes listed below, which are required for Microsoft APIs:

    - account:read:lock_settings:admin
    - account:read:managed_domains:admin
    - account:read:settings:admin
    - user:read:user:admin
    - user:read:list_user:admin
    - scheduler:read:list_schedule:admin

9. On the **Activation** page: Select **Activate your app**. Your app should be activated. If you see errors preventing activation, address them and retry the activation. You won't be able to generate an access token to make API calls unless your app is activated.

If your app is deactivated, existing tokens will no longer work. You can also choose to deactivate your app in this section.

3. Activate connector in Compliance Manager

When you activate a Zoom connector in Compliance Manager, you'll provide your Account ID, Client ID, and Client secret. Once you validate the connection during the connector activation process, you're all set up and ready to begin using the connector. Get details at Working with connectors in Compliance Manager.

You can always retrieve your app credentials by following these steps:

1. From the Zoom App Marketplace, select **Manage** in the upper right corner.
2. Select the app you created in step 2 above.
3. On the **App credentials** page, select **Copy** next to the credentials you need to copy.

Build and manage assessments in Compliance Manager

Compliance Manager assessments help your organization evaluate its compliance with industry and regional regulations. Setting up the most relevant assessments for your organization can help you implement policies and operational procedures to limit your compliance risk. Ready-to-use regulatory templates for over 360 regulations contain the necessary controls and improvement actions for completing the assessment.

> **Tip**
>
> Get a comprehensive compliance overview before you deploy Microsoft services in your organization. Learn more about **predeployment compliance with Compliance Manager (preview)**.

Assessments page

All of your assessments are listed on the **Assessments** page Compliance Manager. You can create one assessment that covers multiple services. For example, you can create a single EU GDPR assessment that covers Microsoft 365, Microsoft Azure, Amazon Web Services (AWS), and Google Cloud Platform (GCP). The assessment details page shows a breakdown of control progress by service to help you evaluate how you're doing across all your services. Learn more about monitoring assessment progress from the assessment details page.

> **Important**
>
> The regulations that are available for your organization's use by default depend on your licensing agreement. **Review licensing details**.

The **Free regulation licenses used/Purchased regulation licenses used** counter near the top of the page shows the number of regulations currently in use out of the total number available for your organization to use. Learn more about regulation availability.

Assessment status and details

The assessments page summarizes key information about each assessment:

- **Assessment**: Name of the assessment.
- **Status**: See status types below.
  - **Complete**: All controls have a status of “Passed,” or at least one is passed and the rest are “Out of scope.”
  - **Incomplete**: At least one control has a status of “Failed." Review the failed controls and, within those controls, review both your improvement actions and Microsoft actions to see which have a "Failed" status.
  - **None**: Not all controls have been tested.
  - **In progress**: Improvement actions have a status of “In progress,” “Partial credit,” or “Undetected."
- **Progress**: The percentage of the work done toward completion, as measured by the number of controls successfully tested.
- **Your improvement actions**: The number of completed actions to satisfy implementation of your controls.
- **Microsoft actions**: The number of completed actions to satisfy implementation of Microsoft controls.
- **Group**: The name of the group to which the assessment belongs.
- **Service**: The services covered by the assessment, such as Microsoft 365, Microsoft Azure, or other cloud services.
- **Regulation**: The regulatory template serving as the basis for the assessment.

To filter your view of assessments, follow these steps:

1. Select **Filter** at the top-left corner of your assessments list.
2. On the **Filters** flyout pane, check your desired criteria.
3. Select the **Apply** button. The filter pane closes and you see your filtered view.

You can also modify your view to see assessments by group, product, or regulation by selecting the type of grouping from the **Group** drop-down menu above your assessments list.

Data protection baseline default assessment

To get you started, Microsoft provides a default **Data Protection Baseline** assessment that's included at all subscription levels. This baseline assessment has a set of controls for key regulations and standards for data protection and general data governance. The Data Protection Baseline assessment draws elements primarily from NIST CSF (National Institute of Standards and Technology Cybersecurity Framework) and ISO (International Organization for Standardization),

as well as from FedRAMP (Federal Risk and Authorization Management Program) and GDPR (General Data Protection Regulation of the European Union).

The default Data Protection Baseline assessment is used to calculate your initial compliance score the first time you come to Compliance Manager, before you configure any other assessments. Compliance Manager collects initial signals from your Microsoft 365 solutions. You see at a glance how your organization is performing relative to key data protection standards and regulations, and see suggested improvement actions to take. Compliance Manager becomes more helpful as you build and manage your own assessments to meet your organization's particular needs.

Assessments for AI regulations

Compliance Manager provides four premium regulatory templates to help your organization assess, implement, and strengthen its compliance against AI regulations. These templates are applicable to all generative AI apps that Microsoft Purview supports for AI interactions, such as Microsoft 365 Copilot, Security Copilot, ChatGPT Enterprise, Microsoft Foundry, Gemini and DeepSeek.

The AI regulations listed below align with compliance requirements such as monitoring AI interactions and preventing data loss in AI applications:

- EU Artificial Intelligence Act
- ISO/IEC 23894:2023
- ISO/IEC 42001:2023
- NIST AI Risk Management Framework (RMF) 1.0

Where to find AI regulation templates

On the **Regulations** page in Compliance Manager, the AI regulations are listed under the **Premium AI templates** header. All other premium regulations are listed under the **Premium templates** header. Using an AI regulation counts toward your purchased premium licenses. Learn more about regulation availability and licensing.

How to use AI regulation templates

The **Recommendations** section from Data Security Posture Management for AI provides guided assistance on working with AI regulations. This solution displays recent interactions with sensitive data and recommends actions to take to help you stay compliant with AI regulations.

Automatic Assessments for AI Apps and Agents in Compliance Manager

Compliance Manager integrates with Azure AI Foundry to automate compliance evaluations for AI models and agents. The Compliance Manager integration with Azure AI Foundry syncs evaluation results directly into Compliance Manager, reducing manual effort and improving regulatory alignment. Organizations benefit from built-in assessments for key AI regulations—including the EU AI Act, NIST AI RMF, and ISO/IEC standards—provided free for six months with Copilot or Agent licenses. The automated compliance evaluation capability enables quick compliance checks without additional purchases, streamlining governance for AI deployments.

Prerequisites

Before using automatic assessments for AI apps and agents, make sure the following prerequisites are met:

- The admin account must have either the Azure AI Project Manager or Azure AI User RBAC role assigned to the relevant AI Foundry accounts.
- The Azure AI Project Manager or Azure AI User RBAC role access is required to add Agents during assessment creation for the AI Foundry service in Compliance Manager.

Key Features

- **Scoped Assessments** – Users define the assessment scope directly in Compliance Manager.
- **Comprehensive Action Set** – AI Foundry provides 75 actions, including 15 automated evaluation actions for metrics like reliability, BLEU score, coherence, and fluency.
- **Automated Sync** – Compliance Manager regularly syncs these 15 evaluation actions from AI Foundry, displaying real-time pass/fail status and detailed metrics.
- **Flexible Action Management** – Users can convert automated actions to manual actions through Compliance Manager settings.
- **Manual Update Support** – Allows manual updates for organizations without AI Foundry access.
- **Effort Reduction** – Eliminates repetitive tasks by automatically syncing evaluation results.
- **Detailed Insights** – Provides granular evaluation metrics alongside compliance status for transparency.

Baseline Assessment for Microsoft 365 Copilot and Copilot Chat

Microsoft Purview Compliance Manager provides a baseline assessment for Microsoft Copilot for Microsoft 365 and Copilot Chat. The baseline assessment for Microsoft Copilot for Microsoft 365 and Copilot Chat is derived from the global AI regulations and includes recommended controls to help organizations maintain compliance and reduce risk.

When a Microsoft Copilot for Microsoft 365 or Copilot Chat license is purchased, the baseline assessment is automatically provisioned in the Microsoft 365 admin center. Administrators can view completed actions and pending tasks within the portal to track compliance progress and implement required controls.

Initial steps before creating assessments

Listed below are details about steps and information that will help you prepare for creating an assessment:

- Plan a grouping strategy for your assessments.
- Understand regulatory templates, which contain the controls and action recommendations for assessments.
- Set up connectors if you're assessing non-Microsoft services.

Groups for assessments

When you create an assessment, you must assign it to a group. Groups are containers that allow you to organize assessments in a way that is logical to you, such as by year or regulation, or based on your organization's divisions or geographies. Because groups determine how assessments are organized, we recommend planning a grouping strategy before you create assessments. Below are examples of two groups and their underlying assessments:

- **FFIEC IS assessment 2020**
  - FFIEC IS
- **Data security and privacy assessments**
  - ISO 27001:2013
  - ISO 27018:2014

Different assessments within a group or groups can share improvement actions. Improvement actions can be changes you make within technical solutions mapped to your tenant, like turning on two-factor authentication, or to nontechnical actions you perform outside the system, like instituting a new workplace policy. Any updates in details or status that you make to a technical improvement action will be picked up by assessments across all groups. Nontechnical

improvement action updates will be recognized by assessments within the group where you apply them. Shared improvement actions across assessments and groups allow you to implement one improvement action and meet several requirements simultaneously.

What to know when working with groups

- You can create a group during the process of creating an assessment.
- Groups can't be standalone entities. A group must contain at least one assessment.
- Group names must be unique within your organization.
- Groups don't have security properties. All permissions are associated with assessments.
- Once you add an assessment to a group, the grouping can't be changed.
- If you add a new assessment to an existing group, common information from assessments in that group are copied to the new assessment.
- Related assessment controls in different assessments within the same group automatically update when completed.
- Groups can contain assessments for the same certification or regulation, but each group can only contain one assessment for a specific product-certification pair. For example, a group can't contain two assessments for Office 365 and NIST CSF. A group can contain multiple assessments for the same product only if the corresponding certification or regulation for each one is different.
- Deleting an assessment breaks the relationship between that assessment and the group.
- Groups can't be deleted.

Set up connectors

Compliance Manager has an integrated set of connectors to build assessments that cover non-Microsoft services like Salesforce and Zoom. Visit Working with connectors to learn more and start the setup process.

Create assessments

To create and modify an assessment, a user must hold a role of Compliance Manager Administration, Compliance Manager Assessor, or Global Administrator. Learn more about roles and permissions.

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

Before starting to create an assessment, be sure you know which group you'll assign it to, or be prepared to create a new group for this assessment. Read details in the Groups for assessments section. To create an assessment, you use a guided process to select a regulation and designate services.

Build a custom assessment

You can modify a regulatory template by adding controls and improvement actions to create a customized assessment. Visit Build custom assessments (preview) for instructions.

Create an assessment using a guided process

1. From your **Assessments** page, select **Add assessment** to begin the assessment creation wizard.

2. On the **Base your assessment on a regulation** page, select **Select regulation** to choose the regulatory template for the assessment. The **Select regulation** flyout page opens.

3. Use the search box to find your desired regulation, then select the check bubble to the left of the regulation name. Select **Save**, confirm your selection, then select **Next**.

4. On the **Add name and group** page, enter values in the following fields:

   - **Assessment name**: Assessment names must be unique. If the name matches another assessment in any group, you receive an error asking you to create a different name.
   - **Assessment group**: Assign your assessment to a group in one of two ways:
     - **Use existing group** to assign it to a group you created; or
     - **Create new group** to which you'll assign the assessment. Enter a name for this group. You can also **Copy data from an existing group**, such as implementation and testing details and documents, by selecting the appropriate boxes.

   When finished, select **Next**.

5. On the **Select services** page, designate which services this assessment applies to (learn more about multicloud support) using the **Select services** command. The flyout pane shows which services are available for your chosen regulation. Place a check next to your desired services, then select **Add**. Then select **Next**.

- If your desired service isn't listed, you can add it as a new service. When you add a new service, the universal version of the underlying regulation is used, and you perform manual implementation and testing work. To add a new service:
  - On the **Select services** page, select **Add new service**.
  - Enter a name and description for the service.
  - Select **Add**. The service is listed on the **Service** section of the assessment's details page.

6. If you selected a service that has more than one subscription covered by Microsoft Defender for Cloud, you arrive at a substep for **Select service subscriptions**. Select **Manage subscriptions**. On the flyout pane, a tab for each service displays a list of all subscriptions within that service. All subscriptions are selected by default, but you can remove any by selecting the **X** next to the name. On the **Select services** page, select **Next**.

7. **Review and finish:** Review all your selections and make any necessary edits. When you're satisfied with the settings, select **Create assessment**.

The next screen confirms the assessment was created. When you select **Done**, you're taken to your new assessment's details page. If you see an **Assessment failed** screen after selecting **Create assessment**, select **Try again** to re-create your assessment.

Edit an assessment

After creating an assessment, you can edit it to update its name and add or remove services and subscriptions. To update an assessment:

1. From the assessment details page, select the ellipses in the upper right corner and select **Edit assessment**. The assessment update wizard opens.

2. You can update the assessment name on the **Update assessment name** page, or leave it as-is, then select **Next**.

3. On the **Select services** page, add or remove services, then select **Next**.

4. On the **Select service subscriptions** page, select **Manage subscriptions** to make any changes to your subscriptions. Then select **Next**.

5. Review your updates, then select **Modify assessment** to save your changes.

Monitor assessment progress and controls

Each assessment has a details page that gives an at-a-glance view of your progress in completing the assessment. The page shows how your services are performing, and the status of controls and improvement actions. Expand the **Overview** section at the left side of the page to see basic details about the assessment, including its group, regulation, associated services, completion status, and a description.

The **Progress** tab shows the percentage of progress toward assessment completion. The progress bar displays a breakdown showing the number of points achieved within each service covered by the assessment. Get details on each service in the Assessment progress by service section. See all controls within the assessment and their current status on the Controls tab. Quickly access the status of all your improvement actions for the assessment the Your improvement actions tab. The actions handled by Microsoft for the assessment are listed on the Microsoft actions tab.

Assessment progress by service

The **Service** section on the assessment's **Progress** tab helps you understand how you're doing with respect to a regulation with each of your services individually, even at the subscription level, and collectively across your organization. The assessment gets its data on available subscriptions and improvement action status from Microsoft Defender for Cloud. Any errors associated with subscription accessibility should be addressed in your Defender for Cloud. See Configure cloud settings for more information.

Select the **View service details** command, located next to or under the **Assessment progress** bar graph or in the upper-right command bar, to view a flyout pane with more details. The **View service details** flyout pane lists each service and its progress toward completing the assessment. Selecting **View** next to a service name displays another pane that lists each subscription within the service and its status.

On a service's details panel, you see the list of subscriptions within the service that are covered by the assessment. The **Service progress** counter indicates the number of points achieved so far by improvement actions pertaining to the service for the assessment out of the total number of achievable points.

You can add more subscriptions to the service that you want the assessment to cover by editing the assessment.

Controls tab

The **Controls** tab displays detailed information for each control in the assessment. The **Control status breakdown** chart shows the status of controls by family (for example, Configuration

Management and Incident Response) so you can see at a glance which groupings of controls need attention. The table underneath the breakdown chart lists all controls. You can filter the list by control family, status, and service. The table shows the following details about each control:

- **Control title**
- **Status**: The test status of the improvement actions within the control:
  - **Passed**: All improvement actions have a test status of "passed," or at least one is passed and the rest are "out of scope."
  - **Failed** At least one improvement action has a test status of "failed."
  - **None**: All improvement actions haven't been tested.
  - **Out of scope**: All improvement actions are out of scope for this assessment.
  - **In progress**: Improvement actions have a status other than the ones listed above, which could include "in progress," "partial credit," or "undetected."
- **Control ID**: The control's identification number, assigned by its corresponding regulation, standard, or policy.
- **Points achieved**: The number of points earned by completing actions, out of the total number achievable.
- **Your improvement actions**: The number of your actions completed out of the total number to be done.
- **Microsoft actions**: The number of actions completed by Microsoft.

Select a control from the list to view its details page. A graph indicates the test status of the improvement actions within the control. A table below the graph lists the improvement actions for that control. Select an improvement action from the list to drill into the improvement action's details page, from where you can manage implementation and testing. Get details about working with improvement actions.

Your improvement actions tab

The **Improvement actions** tab on the assessment details page lists all your improvement actions for the control. The status bar chart details the aggregated test status of your improvement actions in the assessment so you can quickly gauge what has been tested and what still needs to be done. Hover over or select a test status label to highlight only that status on the bar.

Beneath the bar, a table lists all the actions and key details, including: service, test status, the number of potential and earned points, associated regulations and standards, applicable solution, action type, and control family.

Filter by **Service** to view actions related to a service and their progress. From the table, select an improvement action to go to its details page, from where you can manage implementation and testing. Get details about working with improvement actions.

Microsoft actions tab

The Microsoft actions tab appears for assessments based on templates that support Microsoft products. It lists all the actions in the assessment that are managed by Microsoft. The list shows key action details, including: service, test status, points that contribute to your overall compliance score, associated regulations and standards, applicable solution, action type, and control family. Select an improvement action to view its details page.

Grant user access to individual assessments

When you assign users a Compliance Manager role in the Microsoft Purview portal, they can view or edit data within all assessments by default (review the Compliance Manager role types). You can restrict user access to only certain assessments by managing user roles from within an assessment. Restricting access in this way can help ensure that users who play a role in overseeing compliance with particular regulations or standards have access only to the data and information they need to perform their duties. (You can also set user access for regulations, which allows users to access all assessments created for that regulation.)

External users who need access for auditing or other purposes can also be assigned a role for viewing assessments and editing test data. You provide access to external individual by assigning them a Microsoft Entra role. Learn more about assigning roles.

Steps for granting access

Follow the steps to grant user access to an assessment.

1. From your **Assessments** page, find the assessment you want to grant access to. Select it to open its details page.

2. In the upper-right corner, select **Manage user access**.

3. A **Manage user access** flyout pane appears. It has three tabs, one for each role of Readers, Assessors, and Contributors. Navigate to the tab for the role you want your user to hold for this assessment. Users who currently have access to the assessment will have a blue box with a check mark to the left of their name.

4. Select the + **Add** command for the role tab you're on: **Add reader**, or **Add assessor** or **Add contributor**.

5. Another flyout pane appears which lists all the users in your organization. You can select the checkbox next to the username you want to add, or you can enter their name in the search bar and select the user from there. You can select multiple users at once.

6. After making all your selections, select **Add**.

   > ⓘ **Note**
   >
   > If you assign a role to someone who already has an existing role, the new role assignment you choose will override their existing role. In this case, you'll see a confirmation box asking you to confirm the change in role.

7. The flyout pane closes and you arrive back at your assessment details page. A confirmation message at the top confirms the new role assignment for that assessment.

Steps for removing access

You can remove a user's access to individual assessments by following the steps below:

1. On the assessment's details page, select **Manage user access**.

2. On the **Manage user access** flyout pane, go the tab corresponding to the user's role you want to remove.

3. Find the user whose role you want to remove. Check the circle to the left of their name, then select the **Remove** command just below the role tab. To remove all users at once, select the **Remove all** command without checking the circle next to every user's name.

4. A **Remove access?** dialog appears, asking you to confirm the removal. Select **Remove access** to confirm the role removal.

5. Select **Save** on the flyout pane. The users' roles will now be removed from the assessment.

Learn how to get a broad view of all users with access to assessments.

Note about multiple roles

- A user can have one role that applies to an assessment, while also holding another role that applies broadly to overall Compliance Manager access.

    - For example, if you assigned a user a **Compliance Manager Reader** role, you can also assign that user a **Compliance Manager Assessor** role for a specific assessment. In effect, the user holds the two roles at the same time, but their ability to edit data is limited to the assessment to which they've been assigned the **Assessor** role.
    - Removing an assessment-based role won't remove the user's overall Compliance Manager role if they have one. If you want to change a user's overall role, you have to change it the Microsoft Purview portal. Learn more about assigning roles and permissions.

- For an individual assessment, one user can only hold one assessment-based role at a time.
    - For example, if a user holds a reader role for a GDPR assessment and you want to change them to a contributor role, you'll first need to remove their reader role, and then reassign them the reader role.

> **Note**
>
> Admins whose permissions for Compliance Manager were set in Microsoft Entra ID won't appear on the **Manage user access** flyout pane. This means that if a user has access to one or more assessments, and their role is Global Administrator, Compliance Administrator, Compliance Data Administrator, or Security Administrator, they won't appear on this pane. Learn more about setting Compliance Manager permissions and roles.

Accept updates to assessments

When an update is available for an assessment, you see a notification and have the option to accept the update or defer it for a later time. Updates are available for assessments based on the regulatory templates provided in Compliance Manager. If your organization is using universal templates for assessing other products, inheritance might not be supported.

What causes an update

An assessment update occurs when there are underlying template changes that impact scoring. Changes might involve adjusting control mapping or other guidance based on regulatory changes or product changes. Assessment updates can originate from your organization and from Microsoft.

If Microsoft updates a Compliance Manager template that you extended, your assessment inherits those updates once you accept them. Your assessment retains the other attributes you

applied to the assessment when you extended it.

Custom assessments that you create don't receive any template updates from Microsoft. Custom assessments can receive improvement action updates, but any Microsoft updates to control mapping between assessments and improvement actions don't apply to custom templates.

> **Note**
>
> Updates to assessments apply only at the group level. If you have two assessments built from the same template that exist in two different groups, each assessment will have a pending update notification, and you'll need to accept the update to each assessment in its respective group individually.

Where you see assessment update notifications

The assessment details page also shows a **Pending update** label next to the assessment with an update. Select that assessment to get to its details page.

A message near the top of the assessment details page shows that an update is available for that assessment. Select the **Review update** button in the banner to review the specific changes and accept or defer the update.

The assessment details page might also list improvement actions that have a **Pending update** label next to them. Those updates are for specific changes to the improvement actions themselves and need to be accepted separately. Visit Accepting updates to improvement actions to learn more.

Review update to accept or defer

When you select **Review update** from the assessment details page, a flyout pane appears on the right side of your screen. The flyout pane provides the key details below about the pending update:

- The template title
- Source of the update (Microsoft, your organization, or a specific user)
- The date the update was created
- An overview explaining the update
- Specific details about the changes, including the impact to your compliance score, the amount of progress toward completion of the assessment, and the specific number of changes to improvement actions and controls.

Selecting the **Updated template** command downloads an Excel file containing control data for the version of the template with the pending updates. Selecting the **Current template** command downloads a file of the existing template without the updates.

To accept the update and make the changes to your assessment, select **Accept update**. Accepted changes are permanent.

If you select **Cancel**, the update won't be applied to the assessment. However, you continue to see the **Pending update** notification until you accept the update.

- **Why we recommend accepting updates**: Accepting updates helps ensure you have the most updated guidance on using solutions and taking appropriate improvement actions to help you meet the requirements of the certification at hand.
- **Why you might want to defer an update**: If you're in the middle of completing an assessment, you might want to ensure you finished work on it before you accept an update to the assessment that could disrupt control mapping. You can defer the update for a later time by selecting **Cancel** on the review update flyout pane.

Export an assessment report

You can export an assessment to an Excel file for compliance stakeholders in your organization or for external auditors and regulators. On the assessment details page, select the **Export actions** in the top right corner of the page, which creates an Excel file you can save and share. The report is a snapshot of the assessment as of the date and time of the export. It contains the details for controls managed by both you and Microsoft, including implementation status, test date, and test results.

Delete an assessment

Deleting an assessment removes it from the list on your assessments page. Note these important points about deleting assessments:

- **Deleting an assessment is permanent; you cannot get it back.** If you want to use the same assessment again, you need to re-create it.
- If the improvement actions in the assessment don't appear in any other assessment, they're deleted when the assessment is deleted.
- We recommend exporting a report of the assessment before you permanently delete it.

To delete an assessment, follow the steps below:

1. From the **Assessments** page, select the assessment you wish to delete.
2. On the assessment's details page, select **Delete assessment** in the upper-right corner of your screen. If you don't see this option, select the ellipsis (...) in the upper-right corner, then select **Delete assessment** from the list.
3. A window appears asking you to confirm that you want to permanently delete the assessment. Select **Delete assessment** to close the window. You get a confirmation window that your assessment was deleted from Compliance Manager.

> **Note**
>
> You can't delete all of your assessments. Organizations need at least one assessment for Compliance Manager to function properly. If the assessment you want to delete is the only one, add another assessment before deleting the other assessment.

Build custom assessments (preview) in Compliance Manager

Article • 11/27/2024

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Compliance Manager provides the option to modify a regulatory template by adding controls and improvement actions to suit your needs for building a custom assessment. First you copy a regulation, then add controls and improvement actions and services, then publish it so that you can start using it for assessments. This article explains how to copy and modify a regulation in order to create a customized assessment.

Customize a regulation

You can make changes to an existing Microsoft regulatory template in order to customize it for your needs. When you customize a regulation:

- It inherits all the controls and actions of the parent regulation.
- It inherits automatic updates to the Microsoft managed controls and automatically tested actions, except for any actions you modify.
- You can add more actions into a control that already exist in other controls.
- You can create your own actions and controls.
- You can add services.

> **Note**
>
> Copying a premium regulation activates the regulation for your organization and consumes a license for it. The license allows you to create multiple copies of a regulation, and build multiple assessments from a copied regulation. Learn more about regulation licensing.

Updates and versioning

When you customize a regulation, it inherits all of the details, controls, and actions from the parent regulation. The customized regulation receives updates from Microsoft when there are changes to the related regulation or product. However, if you modify an action that is automatically tested, your organization takes over testing and implementation, and the action doesn't receive updates by Microsoft.

> **Tip**
>
> We recommend not making changes to a copied and published regulation for now, as any udpates will not be reflected in versioning history. A versioning exprience that reflects all updates for customized regulations is in our product roadmap for the near future.

Steps for customizing a regulation

1. In Compliance Manager, go to the **Regulations** page.
2. Select the checkbox next to the name of the regulation you want to customize.
3. Select **Customize regulation** above the list of regulations.
4. In the **Create a copy of...** dialog, select **Copy**.

The copy of the assessment is created and the assessment's details page opens.

The name of the regulation is automatically created, starting with "Extension," followed by the name of the regulation, followed by "Copy 1." For example, if you copy the ISO 27005:2018 regulation, the name of the copied regulation will be "Extension ISO 27005:2018 Copy 1."

> **Tip**
>
> After you **publish** the regulation, you can **edit the copied regulation** to change the title or modify the description.

The **Controls** tab lists all of the controls inherited from the original, or parent, regulation. The **Service** lists the services to which the assessment applies, and is where you can add more services to the assessment.

The copied regulation has a status of **Draft** and can't be used to build an assessment until you publish it. To search for your newly copied regulation on the **Regulations** page, set the **Status** filter to **Draft** to see it and any other copied yet unpublished regulations.

A copied regulation can't be deleted.

Add controls

The **Controls** tab of the copied regulation's details page lists all the controls of the underlying regulation. You can add your own controls by following the steps below:

1. On the regulation's **Controls** tab, select **Create control**. The **Create control** flyout pane appears.
2. Enter a **Title** for the control.
3. Enter a **Control ID**. This must be a unique number, up to 150 characters. The ID can't belong to any existing control in this assessment or in any other regulation.
4. Select a control family from the dropdown menu. If the control family name you want isn't listed as an option, you can create a new family name as follows:
    - Select **Create new** from the **Control family** dropdown menu.
    - Enter a name for the new family in the **Control family name** field. This control family name will be added as a dropdown option after you create the control.
5. Enter an optional **Description** for the control.
6. Select **Create**.

After creating the control, you arrive at the details page for the control you created. The next step is to link improvement actions to the control.

Add improvement actions to controls

On the **Your improvement actions** tab of the control details page, you can import actions from the parent regulation, or you can create your own actions.

Import actions

You can import any of the other improvement actions that exist in other controls within the parent regulation into a control. Select **Import actions**. On the **Select actions to import** flyout pane, you can select all the actions by checking the box next to the **Improvement actions** column header. You can also check individual actions by selecting the checkbox next to the names.

After selecting your desired actions, select **Import**.

Create actions

You can create your own improvement actions to add to your copied regulation by following the steps below.

1. Enter a **Title** for the improvement action.
2. Select a **Score** value from the dropdown menu. Score values represent the maximum number of points awarded for action completion. Values are assigned based on whether the action is preventative, detective, or corrective actions, and whether they're mandatory or discretionary. Refer to this explanation of score values to see which number is assigned to which type of action.
3. At **Services**, select a service from the dropdown menu that the action applies to.
4. If the action applies to the Microsoft 365 service, then at **Solution**, select the appropriate solution from the dropdown menu.
5. Enter an optional **Description** for the action.
6. Select **Create**.

After the action is created, you arrive back at the control details page, and the improvement action you just created is listed on the **Your improvement actions** tab.

Add services

The **Services** tab lists the services that apply to the parent regulation. You can add a service that is available for that regulation by selecting **Add available services** and selecting one or more services. If there aren't any services listed, you can create a service and add it to the regulation.

To create your own service, select **Create service**. On the flyout pane, enter a name and description for the service, then select **Save**. After you publish regulation, the added service will be an available option if you make more copies of the same regulation.

Finalize changes by publishing

After adding controls and connecting improvement actions to the regulation you copied, you need to publish the changes in order to begin using the extended regulation for assessments.

1. Go to the details page of the extended regulation.

2. Select **Publish template** in the upper right corner.

After you publish the template, it will be listed on the **Regulations** page and it will be ready for assessment creation. The status of the regulation, which is a filter option, is now **Ready to use** instead of **Draft**.

Simple ways to search for a copied regulation on your **Regulations** page include:

- Set the **Created by** filter to your name.
- Select the **Includes custom content** column to sort by the **True** value. True indicates that the regulation has been customized.

> ⓘ **Note**
>
> You can't create an assessment from a copied regulation until you publish it by selecting **Publish template**.

Edit a copied regulation

After you publish a copied regulation, you can change its name, modify its description, and continue to add and edit controls and actions. To edit a regulation, select it from the list on the **Regulations** page. On the regulation details page, select the ellipsis (...) in the top right corner and select **Edit regulation**.

At this point, a working copy of the regulation is made so that you can make edits and save your work in progress without overriding the published copy. When you're done making edits, you need to again publish it by selecting **Publish template** in the upper right corner. When you select **Publish template**, a **Review and publish** flyout pane appears, where you can review your changes and add publishing notes. Select **Publish template** on the flyout pane to save the changes and republish your regulation.

Creating multiple copies of the same regulation

You can create multiple copies of a regulation so that you can customize it in different ways. You might want to have multiple versions of a regulation if you want to create different control configurations or include only certain services for the same regulation, and then create assessments based off of those extensions.

Multiple copies are automatically named with numbers appended to the name. For example, if you create two copies of the ISO 27005:2018 regulation, they're named as follows: "Extension ISO 27005:2018 Copy 1" and "Extension ISO 27005:2018 Copy 2."

We recommend editing the descriptions of extended regulations so that you can clearly identify how they differ or what they're intended to assess. To edit the description:

1. Go to the regulation's details page.
2. In the **Overview** section, under **Details**, select **Edit details**. The **Edit template details** flyout pane appears.
3. In the **Description** field, enter a detailed description.
4. Select **Save**.

Learn about regulations in Compliance Manager

09/26/2025

> **Important**
>
> The regulations that are available for your organization's use by default depend on your licensing agreement. Review licensing details.

Regulations overview

The **Regulations** page in Compliance Manager displays the list of regulations and certifications for which Compliance Manager provides control-mapping templates. When you build an assessment, you choose the underlying regulation by selecting from among our set of regulatory templates, then select the services you want to assess for that regulation. Setting up Compliance Manager for multicloud support provides you with greater automation in testing and monitoring of controls.

Each regulatory template also comes in a universal version, which provides general control mapping that can broadly apply to services. Universal templates provide the most general type of implementation guidance and require manual implementation and testing by the organization. Note that US Government Community (GCC) Moderate, GCC High, and Department of Defense (DoD) customers can't currently use universal templates.

List of regulations

Visit Compliance Manager regulations list to see the list of all regulatory templates available for building assessments.

Regulation availability and licensing

The Microsoft **Data Protection Baseline** regulatory template is available for organizations at all subscription levels to use. The regulations designated as **premium** require purchase of a license to use them.

On the **Regulations** page in Compliance Manager, the regulations are grouped under four headings:

- **Sub-service compliance readiness**: Use these to help assess your predeployment compliance posture (preview) (does not involve use of a license).
- **Included templates**: The Microsoft data protection baseline.
- **Premium AI templates**: To use for assessments for AI regulations.
- **Premium templates**: All other global, regional, and industry regulations.

When you purchase a license for a regulatory template, you can create as many assessments for that regulation as you wish. Depending on your licensing agreement, your organization might be able to use up to three more **premium** regulatory templates for free. When you begin creating assessments, Compliance Manager tracks how many templates are active so you can monitor your usage.

Resources

- Learn more about included regulations by subscription level.
- Go to the Compliance Manager service description.
- Understand your regulation usage through active and inactive regulation status.

Purchasing premium regulations

Licenses for premium regulatory templates can be obtained in various ways, depending on your Compliance Manager licensing agreement. Once your purchase has been finalized, the templates should become available in your tenant within 48 hours. Licenses for activated regulations are good for one year.

- **Commercial and GCC Moderate**: Purchase licenses in the admin center (learn more about subscriptions, licenses, and billing). Select the quantity of licenses you wish to purchase and your payment plan.
  - Commercial
  - GCC Moderate
  - You can also acquire licenses through your participation in the Cloud Solution Provider program or volume licensing.
- **GCC High and DOD accounts**: Purchase through volume licensing.

Staring a premium trial

You can try out premium regulation templates by acquiring trial versions of the licenses. Trial licenses are good for up to 25 templates for 90 days. Once you obtain your trial license, the templates should become available in your tenant within 48 hours. If your organization has a commercial license for Compliance Manager, you can learn how to start your trial at About the free trial for Microsoft Purview Compliance Manager premium assessments. If your

organization is under a GCC or DOD license, choose the appropriate trial link for your organization:

- GCC Moderate
- GCC High
- DOD

Active and inactive regulations

Regulations display a status as either active or inactive:

- **Active** indicates use in at least one assessment.
- **Inactive** indicates it's not being used for an assessment.

When you use a premium regulation to create an assessment, that regulation's availability status changes to **Active** and the purchased license is active for one year. Your purchase renews automatically unless you cancel.

Regulation licenses counter

The **Regulation licenses used** counter near the top of the **Regulations** page represents the number of regulatory templates in use out of the number you're eligible to use according to your licensing agreement and any purchased licenses. For example, if your counter shows 2/5, it means your organization has activated two regulations out of the five that are available to use. If your counter shows 5/2, it indicates that your organization exceeds its limits and needs to purchase three of the premium regulations in use.

Select **View details** the counter to view a detailed list of all regulations in use and their corresponding assessments.

Regulations details page

Select a regulation from the list on the **Regulations** page to open a regulation's details page. Regulatory templates that belong to the same regulation family are counted as one template. The regulation family is shown in the **Overarching regulation** column on the **Assessment templates** page. When you purchase a template license for a regulation and activate the template, it counts as one activated template even if you create assessments for different levels or versions of that regulation. For example, if you use a template for CMMC Level 1 and a template for CMMC Level 2, your activated templates counter increases by only one.

For more information, see Compliance Manager licensing guidance.

Grant user access to regulations

When you assign users a Compliance Manager role in the Microsoft Purview portal, their role extends by default to all regulations (review the Compliance Manager role types). This access means that, depending on the user's role type, they can view or interact with any existing or future assessments created with that regulation.

You can give users a specific role that applies to certain regulations by managing user roles from a regulation's details page. When you set a user's role for a regulation, the user will be able to interact at that role level for all assessments (existing and future) created with that regulation. (You can also restrict access to individual assessments following these instructions.)

External users who need access for auditing or other purposes can also be assigned an access role for regulations. You provide access to external individual by assigning them a Microsoft Entra role. Learn more about assigning roles.

Steps for granting access

Follow the steps to grant user access to a regulation.

1. From the **Regulations** page, find the regulation you want to grant access to. Select it to open its details page.
2. In the upper-right corner, select **Manage user access**.
3. A **Manage user access** flyout pane appears. It has three tabs, one for each role of Reader, Assessor, and Contributor. Navigate to the tab for the role you want your user to hold for this regulation.
4. Select the **+ Add** command for the role tab you're on: **Add readers**, or **Add assessors** or **Add contributors**.
5. Another flyout pane appears which lists all the users in your organization. You can select the checkbox next to the username you want to add, or you can enter their name in the search bar and select the user from there. You can select multiple users at once.
6. After making all your selections, select **Add**.

> **Note**
>
> If you assign a role to someone who already has an existing role, the new role assignment you choose will override their existing role. In this case, you'll see a confirmation box asking you to confirm the change in role.

7. The flyout pane closes and you arrive back at the regulation details page. Select **Save**. A confirmation message at the top confirms the new role assignment for that regulation.

Steps for removing access

You can remove a user's access to individual regulations by following these steps:

1. On the regulation's details page, select **Manage user access**.
2. On the **Manage user access** flyout pane, go the tab corresponding to the user's role you want to remove.
3. Find the user whose role you want to remove. Check the circle to the left of their name, then select the **Remove** command just below the role tab. To remove all users at once, select the **Remove all** command without checking the circle next to every user's name.
4. A **Remove access?** dialog appears, asking you to confirm the removal. Select **Remove access** to confirm the role removal.
5. Select **Save** on the flyout pane. The users' roles will now be removed from the assessment.

Note about multiple roles

- A user can have one role that applies to a regulation, while also holding another role that applies broadly to overall Compliance Manager access.
  - For example, if you've assigned a user a **Compliance Manager Reader** role, you can also assign that user a **Compliance Manager Assessor** role for a specific regulation. In effect, the user holds the two roles at the same time, but their ability to edit data will be limited to the assessment to which they've been assigned the **Assessor** role.
  - Removing a regulation-based role won't remove the user's overall Compliance Manager role if they have one. If you want to change a user's overall role, you have to change it in the Microsoft Purview portal. Learn more about assigning roles and permissions.
- For an individual regulation, one user can only hold one assessment-based role at a time.
  - For example, if a user holds a reader role for the GDPR regulation and you want to change them to a contributor role, you'll first need to remove their reader role, and then reassign them the reader role.

> **Note**

Admins whose permissions for Compliance Manager were set in Microsoft Entra ID won't appear on the **Manage user access** flyout pane. This means that if a user has access to one or more regulations, and their role is Global Administrator, Compliance Administrator, Compliance Data Administrator, or Security Administrator, they won't appear on this pane. Learn more about **setting Compliance Manager permissions and roles**.

Compliance Manager regulations list

Article • 03/06/2025

In this article: View the comprehensive list of **regulations** available to build assessments in Compliance Manager.

> **Important**
>
> The regulations that are available for your organization's use by default depend on your licensing agreement. Review licensing details.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Overview

Compliance Manager provides a comprehensive set of regulatory templates for creating assessments. These **regulations**, as they're referred to in Compliance Manager, can help your organization comply with national, regional, and industry-specific requirements governing the collection and use of data. Regulations are added to Compliance Manager as new laws and regulations are enacted. Compliance Manager also updates its regulations when the underlying laws or regulations change. Learn more about how to review and accept updates.

List of regulations and where to find them

Below is the complete list of regulations in Compliance Manager. In Compliance Manager, go to the **Regulations** page and select a regulation name to view its description, properties, controls, and associated improvement actions. Jump to a section below to view regulations by area or industry:

- AI
- Global
- Industry

- US Government
- US States and Territories
- Asia-Pacific Countries/Regions
- Europe, Middle East, and Africa (EMEA)
- Latin America
- North America
- South America

Included regulations

Some regulations are included in Compliance Manager by default, depending on subscription level:

- **Customers at all subscription levels**: The Microsoft Data Protection Baseline is included for all organizations as part of their subscription.
- **Customers at the A5/E5/G5 subscription levels**: In addition to the Microsoft Data Protection baseline, you can choose any three premium regulations to use for free.
- **US Government Community (GCC) Moderate, GCC High, and Department of Defense (DoD) customers**: Cybersecurity Maturity Model Certification (CMMC), levels 1 through 5, is included in addition to the Microsoft Data Protection Baseline.

Premium regulations

The regulatory templates listed below may be purchased by your organization. Certain licensing agreements allow for the use of three premium regulations for free. Review licensing details.

Creating regulation templates in Compliance Manager

Compliance Manager helps organizations manage regulatory requirements by providing ready-to-use templates. For organizations with unique compliance needs, you can create custom regulation templates using one of two methods:

- Upload a regulation in PDF format
- Start from a blank template

These options allow flexibility for organizations that need to comply with official standards or define custom internal regulations.

To learn more about regulations, see Learn about regulations in Compliance Manager. To see a list of available regulations, see Compliance Manager regulations list.

How It Works

The process starts when the admin uploads a regulatory PDF file. The system analyzes the document for malware, extracts controls and maps controls to existing improvement actions. Any detected errors are displayed for correction. The admin can then update existing controls, add new ones, and manually map actions to controls. Once all adjustments are complete, the draft template is published for use in Compliance Manager.

Requirements

- A user must hold a role of Compliance Manager Administration or Compliance Manager Assessor. Learn more about roles and permissions.
- For PDF upload:
  - A regulation document published by an official regulator or standards body.
  - PDF format only.

Create a new template based on regulation document (PDF)

1. From your **Regulations** page, select **Create new template**.
2. Select **Upload PDF document**.
3. Modify template name as needed.

4. Optionally, enter overarching regulation name if you want to group multiple templates.
5. Select applicable services.
6. Select **Scan and extract**.

   The system scans, extracts, and maps controls. This process may take several minutes to complete. When the process is complete, you see the results of the scan including malware found, controls extracted, and controls mapped.
7. When the scan is complete, select **Review draft template**.
8. Review the draft template. Add, remove, or edit the controls as needed. When you're satisfied, select **Publish template**.
9. Confirm template details and optionally provide notes, and then select **Publish template**.

The template is published and you can now create an assessment based on your new template.

Create a blank template

1. From your **Regulations** page, select **Create new template**.
2. Select **Create blank template**.
3. Enter a template name.
4. Enter overarching regulation name.
5. Select applicable services.
6. Select **Create draft template**.
7. Manually add controls to your template. Select **Create control**.
8. In the **Create control** dialog, complete each field and then select **Create**.
9. Manually assign improvement actions to your control. Select one of the following:

   - **Import actions** - select from a list of available actions.
   - **Create action** - define your action.
10. Add as many controls and actions as needed. When you're finish, select **Publish template**.
11. Confirm template details and optionally provide notes, and then select **Publish template**.

The template is published and you can now create an assessment based on your new template.

Learn about the Microsoft Purview Compliance Manager premium assessments trial

07/24/2025

Compliance Manager helps you automatically assess and manage compliance across your multicloud environment. The assessments you build are based on templates that correspond to governmental regulations and industry standards around the world.

Your licensing agreement to use Compliance Manager may include one or more built-in regulatory templates for building assessments. An extensive library of premium regulations is also available for building assessments specific to your organization's needs. To try out these regulatory templates before purchasing licenses, sign up for the free Compliance Manager premium assessments trial.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

Trial setup instructions

- Sign in to the Microsoft Purview portal.
- On the home page, go to the [**Trials and recommendations**](purview-portal.md#trials-and-recommendations section and select **View all trials and recommendations**.
- In the **Purview and Priva trials** section, find the **Compliance assessments** card and select **Try now**.

The premium assessment trial is available to organizations using Compliance Manager under a commercial license. For GCC and DOD information and trial options, see Learn about regulations in Compliance Manager.

Full access to Compliance Manager features depends on your licensing agreement for Compliance Manager. To learn more about the free compliance trial that includes Compliance Manager, see Learn about the Microsoft Purview risk and compliance solutions trial.

> **Note**
>
> Check your Microsoft 365 admin center settings to facilitate enrollment in the trial. In the Microsoft 365 admin center, go to the **Settings** > **Org settings** > **Services** page, and select **User owned apps and services**. Then check the box to let users start trials on behalf of your organization. When setup finishes in about two minutes, you can go back and uncheck the box to disable this setting. You can also start the trial without adjusting your org settings by going to the **Billing** > **Purchase services** page and searching for the Compliance Manager premium assessment trial.

Regulations available to use during the trial

When you start your one-time trial for premium assessments, you can use 25 premium regulatory templates of your choice for free for 90 days. You can create as many assessments from the 25 regulations as you wish. View the full list of Compliance Manager regulations.

After starting your trial, go to your **Assessments** tab in Compliance Manager and view the **Purchased regulation licenses used** counter to see how many regulations are available and are in use. This counter shows your 25 licensed regulatory templates. As you create assessments for these regulations, your activated number updates. Multiple assessments based on the same regulation count as one regulatory template use. For more information, see Learn about regulations in Compliance Manager.

Roles for starting the trial

A user with one of the roles listed below can start or end a trial:

- Billing Administrator
- Compliance Administrator
- Compliance Data Administrator
- Global Administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Get more details about roles for starting trials.

During your trial

Throughout your trial, you can review the **Trial summary** section of the **Overview** page in Compliance Manager to see how many assessments you created, the number of improvement actions taken, how your compliance score has changed, and how much time remains in your trial. From here, you can also review the list of available regulations and learn more about purchasing them for ongoing use.

After the trial

After your trial ends, the regulatory templates you used won't receive automatic updates and might fall out of date with any regulatory changes. We recommend that you delete assessments built from regulatory templates that you don't intend to purchase.

Ending the trial

Admins can disable the trial anytime by selecting **End trial** on the **Compliance assessments trial** card on the **Microsoft Purview trials and recommendations** page in the Microsoft Purview portal.

Learn more and explore other trials

To learn more about the features of Compliance Manager and how it can help your organization meet compliance and regulatory requirements, see Microsoft Purview Compliance Manager.

You can also learn about other Microsoft Purview solutions and how to start trials at Learn about the Microsoft Purview risk and compliance solutions trial.

Terms and conditions

See the terms and conditions for Microsoft 365 trials.

Working with improvement actions in Compliance Manager

Article • 02/24/2025

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Overview

Improvement actions help centralize your compliance activities. Each improvement action recommends an action to take, with detailed guidance intended to help you align with data protection regulations and standards. Improvement actions can be assigned to users in your organization to perform implementation and testing work. You can also store evidence, add notes, and record status updates within the action. Many improvement actions come with automatic testing and monitoring.

Compliance Manager works within a shared responsibility model where some actions are completed by you and others are completed automatically by Microsoft in order to meet the requirements of a regulation, standard, or certification. The actions listed on the Improvement actions tab in Compliance Manager are the ones that your organization is responsible for completing.

> **Tip**
>
> Visit the Compliance Manager glossary for helpful definitions of many of the terms on this page.

Automated testing and monitoring

While some improvement actions must be manually tested by your organization, many actions can be automatically tested and monitored for you. Compliance Manager automatically identifies settings in your Microsoft 365 environment and your multicloud environment that help determine when certain configurations meet improvement action

implementation requirements. Compliance Manager utilizes four types of automation, explained below.

Built-in automation

Compliance Manager has built-in functionality to receive signals from other Microsoft solutions and non-Microsoft services. Compliance Manager detects signals from other Microsoft Purview solutions that your organization may subscribe to, including Data Lifecycle Management, Information Protection, Data Loss Prevention, Communication Compliance, and Insider Risk Management. Compliance Manager also detects signals from Microsoft Priva (this capability is in preview). The automation applies specifically to the solution and isn't scoped to cloud services. Learn more about automatic testing settings.

Microsoft Secure Score automation

Compliance Manager detects signals from complementary improvement actions that are monitored by Microsoft Secure Score. Through these signals, Compliance Manager can automatically test certain improvement actions in order to provide continuous control assessment. When an improvement action is successfully tested and implemented, you receive the maximum possible points for that action, which gets credited to your overall compliance score.

Microsoft Defender for Cloud automation

Integration with Defender for Cloud allows Compliance Manager to facilitate improvement actions and provide continuous monitoring across multiple Microsoft and non-Microsoft cloud services, such as Microsoft Azure, Amazon Web Services (AWS), and Google Cloud Platform (GCP). The cloud infrastructure of this monitoring means that action status can be evaluated and graded at the subscription level of the intended service. You can see specific implementation and testing results for each improvement action within each subscription of your service. The overall score you receive for the improvement action is an aggregate of the individual scores of each subscription within that service. Learn more about multicloud support and scoring.

Connectors

We're rolling out a selection of connectors built specifically for Compliance Manager to support other non-Microsoft services. Connectors for Salesforce and Zoom are available

now, with more connectors releasing soon. Learn more at Working with connectors in Compliance Manager.

> **Note**
>
> An improvement action that is set to automatic testing can be changed to manual testing, unless that action is implemented through Microsoft Defender for Cloud.

Testing type

Compliance Manager provides options for how to test improvement actions. On the improvement action's details page, the **Testing type** status in the top information bar shows how the action is tested. From here you can choose how you want the action to be tested: **Manual** or **Automatic**.

> **Note**
>
> Testing source can't be changed on actions for services supported by Defender for Cloud. If you don't agree with an automated testing result, you can go to the related assessment in Defender for Cloud to alter the testing logic and scope.

Manual

Improvement actions set for manual testing are actions that you manually test and implement. You set the necessary implementation and test status states, and upload any evidence files on the **Evidence** tab. For some actions, this is the only available method for testing improvement actions.

Automatic

Certain improvement actions can be automatically tested by Compliance Manager. Get details on which improvement actions can and can't be tested automatically.

For those improvement actions that can be automatically tested, you'll see the **Automatic** option for **Testing type**. Compliance Manager detects signals from other compliance solutions and cloud services. When signals indicate that an improvement action has been successfully implemented, you automatically receive the eligible points for that action, which factor into scores for related controls and assessments. Learn more about scoring.

Automatic testing is on by default for all eligible improvement actions. You can adjust these settings to automatically test only certain improvement actions, or you can turn off automatic testing for all actions. Learn more about how automated testing works and how to adjust your settings at Set up automated testing.

Improvement actions page

All of the improvement actions managed by your organization are listed on the **Improvement actions** page in Compliance Manager. The list of improvement actions displays basic information related to each action, such as the regulations they correspond to, testing status and source, owner, and action type. See below for descriptions of some of the columns. Filter the columns to customize your view.

Points achieved

Each improvement action is worth a number of points that contribute to your overall compliance score. This column shows how many points have been earned out of the total available to achieve.

Service

The service is the data source, such as Microsoft Azure or Amazon Web Services, that the improvement action assesses and impacts.

Group

This column shows the assessment groups that the improvement action is associated with. Learn more about assessment groups.

Solutions

The solutions are the location where you perform the recommended action; for example, in Microsoft Communication Compliance, Microsoft Priva, or Microsoft Defender for Cloud.

Categories

Compliance Manager groups improvement actions into general categories to help you understand which areas need attention in order to bolster your overall compliance posture. The categories are: Control Access, Discover and Respond, Govern Information,

Infrastructure Cloud, Manage Compliance, Manage Devices, Manage Internal Risks, Privacy Management, Protect Against Threats, and Protect Information.

Action type

Improvement actions can be technical or nontechnical in nature:

- **Technical actions** are implemented by interacting with the technology of a solution (for example, changing a configuration).
- **Nontechnical actions** are managed by your organization and implemented in ways other than working with the technology of a solution. There are two types of nontechnical actions: **documentation** and **operational**.

Learn how action type affects scoring for improvement actions.

Improvement action details page

Select an improvement action from the list on the **Improvement actions** page to view the action's details page. The details page provides detailed implementation guidance and a link to launch you into the appropriate solution or service. Here's what you can do from an improvement actions details page:

- Get basic status quickly from the top information bar.
- Assign an owner, who is responsible for performing the work.
- Review implementation guidance on the **Details** tab. Follow a direct link into the recommended solution to start implementation work and add implementation notes.
- Review the action's status within your cloud services' subscriptions from the **Details** tab and drill into subscription-level details.
- Upload and store evidence files and links on the **Evidence** tab.
- Check the **Related controls** tab to see all the controls that include the improvement action. You can filter the control list by regulation.

Implementation and testing

Assign an owner

To begin implementation work on an improvement action, you can do the work yourself or assign it to another user as an owner. The owner could be a business policy owner, an IT implementer, or another employee with responsibility to perform the task. Once you

identify the appropriate assignee, be sure they hold a sufficient Compliance Manager role to perform the work.

To assign an owner to an improvement action, open the improvement action's details page. In the **Owner** box in the information bar at the top of the page, begin typing a user's name and select the name when it appears. The assigned user receives an email explaining that the improvement action has been assigned to them, with a direct link to the improvement action.

> **Note**
>
> US Government Community (GCC) High and Department of Defense (DoD) customers won't receive an email when improvement actions are assigned to them.

Assign multiple improvement actions to a single user

You can assign multiple improvement actions to one user by following these steps:

1. In Compliance Manager, go to the **Improvement actions** page.
2. Select the checkbox to the left of the improvement actions you want to assign.
3. Select **Assign to user** at the top of the improvement actions table. The **Assign improvement actions** flyout pane appears.
4. Enter a user's name in the search bar to search for the user, or select a name from the list of suggested people. After choosing the user, select **Assign**.

You arrive back at your **Improvement actions** page with the new owner listed in the **Assigned to** column for the actions you assigned.

Implementation work

Implementation guidance varies depending on whether you go to Microsoft Defender for Cloud to perform the work to complete the action. Learn more about multicloud support. Instructions for each action type's implementation are below.

Actions that you implement in Defender for Cloud

On an improvement action's details page, view the **Testing source** on the top information bar. If the testing source is **Defender for Cloud**, then the action pertains to cloud services such as Microsoft Azure, Amazon Web Services (AWS), and Google Cloud Platform (GCP), and the action is implemented and monitored using Compliance Manager's integration with Defender for Cloud. These actions belong to the category of

infrastructure cloud. Whether they can be automatically tested or not depends on the action type:

- Technical actions are automatically tested and monitored.
- Non-technical actions must be manually tested.

View the implementation instructions for each action type below.

Subscription monitoring

For actions implemented in Defender for Cloud, the **Subscription monitoring** section on the **Details** tab shows a list of all related subscriptions (view glossary). This view provides a more granular view into the action's status across each service's subscriptions. Select a subscription name to view a flyout pane with implementation details, virtual resources status, and the related assessments.

Implementation for manual actions:

- On the improvement action details page, review the **How to implement** guidance and perform the necessary steps. This may involve non-technical work that takes place offline.
- Each subscription listed under **Subscription monitoring** needs to have its status updated. Each subscription contains a single virtual resource, which represents the subscription itself. Select the subscription name to bring up a flyout pane for that subscription. Select the appropriate status, date, and enter notes.
- When you're done, select **Save**.

> ⓘ **Note**
>
> Manual actions don't synchronize status between Compliance Manager and Defender for Cloud. You can update the status in either location, however the statuses won't synch.

Implementation for automatic actions:

- Select each subscription, one at a time, listed under **Subscription monitoring**.
- If a subscription shows that there are virtual resources that aren't complete, select the subscription and on the flyout pane, select the **Virtual resources** tab.
- Inspect the status of each resource to determine which require ones require remediation.
- For the resources needing remediation, review the **How to implement** guidance. Then select **Go to Defender for Cloud** to make the necessary changes.

Updates to the improvement action's status show within 24 hours.

Actions that you don't implement in Defender for Cloud

The implementation guidance on the **Details** tab provides instructions and a link into the solution where you go to perform the implementation work. To perform and record your implementation work:

1. Review the **How to implement** guidance and follow the link into the related solution to perform the necessary work. This may involve non-technical work that takes place offline.

2. After performing implementation work, select one of the following status options from the **Implementation status** dropdown menu in the top information bar:

    - **Not implemented**
    - **Implemented**
    - **Alternative implementation** - select this option if you used other non-Microsoft tools or took other actions not included in Microsoft recommendations
    - **Planned**
    - **Out of scope** - not relevant to your organization and doesn't contribute to your score

3. You then need to record the date for the implementation status change. Select **Edit notes** above the action's information bar. The **Edit action details** flyout pane opens to the **Implementation** tab. You can also edit the implementation status here.

4. At the **Implementation date** field, select an implementation date.

5. In the notes field, enter optional implementation notes (learn more about notes).

6. Select **Save** on the flyout pane to close the pane.

7. Select **Save** or **Save and close** above the action's information bar to save the changes you made.

Common actions synchronize across groups. When two different assessments in the same group share improvement actions that are managed by you, any updates you make to an action's implementation details or status will automatically synchronize to the same action in any other assessment in the group. This synchronization allows you to implement one improvement action and meet several requirements across multiple regulations.

Testing work

The test status of an improvement action is displayed in the **Test status** field on the action's details page. After an improvement action has been implemented, you can update the test status for manually tested actions by following the instructions below. A user with editing permissions can adjust the action status.

1. On the improvement action details page, you can select one of the following status options from the **Test status** dropdown menu in the top information bar:

    - **None** - no work has started on the action
    - **Not assessed** - action hasn't been tested
    - **Passed** - implementation has been verified by an assessor
    - **Failed low risk**
    - **Failed medium risk**
    - **Failed high risk**
    - **Out of scope** - the action is out of scope for the assessment and doesn't contribute to your score
    - **To be determined**
    - **Could not be determined**
    - **Partially tested**
    - **In progress**

2. You then need to record the test date. Select **Edit notes** above the action's information bar. The **Edit action details** flyout pane appears.

3. On the **Test and verification** tab, select a test date. You can also edit the test status here.

4. In the notes field, enter optional testing notes (learn more about notes).

5. Select **Save** on the flyout pane to close the pane.

6. Select **Save** or **Save and close** above the action's information bar to save the changes you made.

For manually tested actions that are implemented in Defender for Cloud, refer to the implementation instructions for how to set test status within subscriptions.

> **Note**
>
> If the action is manually tested, you can edit test status, test date, and notes. You can't edit test status and notes for automatically tested actions.

Automatically tested actions may show a status of **Out of scope** when automatic monitoring through Defender for Cloud is first set up. This is because it can take up to 24 hours to process the signals from Defender for Cloud. Improvement action statuses refresh every 24 hours.

Automatically tested actions may also show one of the following test statuses:

- **To be detected** - awaiting signals that indicate test status
- **Could not be detected** - couldn't detect a test status; will be automatically checked again
- **Partially tested** - action has been partially tested; neither passes nor fails

Exporting testing history

You can export a report that shows you a history of all changes in test status for an improvement action. These reports are especially helpful for monitoring progress on actions that are automatically tested, since such actions are regularly or frequently updated based on your tenant's data.

On an improvement action's details page, select **Export testing history** above the top information bar. The report downloads as an Excel file.

Enter and view notes

You can enter notes for internal reference about your implementation or testing work. These notes can be added or edited by any user with editing permissions, not just by the action's assigned owner.

The notes don't display on the improvement action's details page. To view notes, or to add notes, you need to select the **Edit notes** command in the upper right of the improvement action's details page. When you select **Edit notes**, the **Edit action details** flyout pane appears. A text field for notes appears on both the **Implementation** and **Test and verification** tabs of the flyout pane (this is also where you can select status and dates for implementation and testing work.)

After adding notes, select **Save** on the flyout pane. The pane closes. Then select **Save** or **Save and close** above the action's information bar to save your notes.

> **Note**

Testing notes can't be manually edited for automatically tested improvement actions. Compliance Manager updates notes for you.

Storing evidence

You can upload evidence related to implementation and testing work, in the form of files or links, directly to the **Evidence** tab of an improvement action's details page. This environment is a secure, centralized repository to help you demonstrate satisfaction of controls to meet compliance standards and regulations. Any user with read-only access can read content in this section. Only users with editing rights can upload, download, and delete evidence.

Upload evidence

- On the improvement action's details page, go to the **Evidence** tab.
- Select **Add evidence** and select either **Document** or **Link**.
- For a document, browse to select the file you want to upload, then select **Done**. Accepted file types are:
  - Documents (.doc, .xls, .ppt, .txt, .pdf)
  - Images (.jpg, .png)
  - Video (.mkv)
  - Compressed files (.zip, .rar)
- For a link, enter a name for the link and its URL, then select **Done**.

Delete evidence

You can delete evidence when the improvement action hasn't yet reached a pass or fail status. To delete evidence files or links, select the action menu (the three dots) to the right of the item's name and select **Delete**. Confirm the deletion when prompted.

When an improvement action has a test status of **Passed, Failed**, or **Out of scope**, evidence files and links can no longer be deleted.

Assign improvement action to assessor for completion

After you complete the work, conduct testing, and upload evidence, the next step is to assign the improvement action to an assessor for validation. The assessor validates the work, examines the evidence, and selects the appropriate test status.

- **If action status is set to "Pass"**: The action is complete and receives the total number of points.
- **If action status is set to "Fail"**: The action doesn't meet the requirements, and the assessor can assign it back to the appropriate user for more work.

A **Compliance Manager Assessor** role allows a user to perform this work, without the full rights to create assessments. Learn how to set permissions and how to grant role-based access to assessments and regulations.

Accepting updates to improvement actions

When an update is available for an improvement action, you see a notification next to its name. You can either accept the update or defer it for a later time.

What causes an update

An update occurs when there are changes related to scoring, automation, or scope. Changes may involve new guidance for improvement actions based on regulatory changes, or could be because of product changes. Only the improvement actions managed by your organizations receive update notifications.

Where you see assessment update notifications

When an improvement action is updated, you see a **Pending update** label next to its name on the improvement actions page, and on the details page of its related assessments.

Go to the improvement action's details page, and select the **Review update** button in the top banner to review details about the changes and accept or defer the update.

Review update to accept or defer

When you select **Review update** from the improvement action details page, a flyout pane appears on the right side of your screen. The flyout pane provides key details about the update, such as the assessments impacted and changes in score and scope.

Select **Accept update** to accept all the changes to the improvement action. **Accepted changes are permanent**.

> ⓘ Note

When you accept an update to an action, you're also accepting updates to any other versions or instances of this action. Updates will propagate tenant-wide for technical actions, and will propagate group-wide for non-technical actions.

If you select **Cancel**, the update won't be applied to the improvement action. However, you continue to see the **Pending update** notification until you accept the update.

- **Why we recommend accepting updates**: Accepting updates helps ensure you have the most updated guidance on using solutions and taking appropriate improvement actions to help you meet the requirements of the certification at hand.
- **Why you might want to defer an update**: If you're in the middle of completing an assessment that includes the improvement action, you may want to ensure you've finished work on it before you accept the update. You can defer the update for a later time by selecting **Cancel** on the review update flyout pane.

Accept all updates at once

If you have multiple updates and want to accept them all at one time, select the **Accept all updates** link at the top of your improvement actions table. A flyout pane appears which lists the number of actions to be updated. Select the **Accept updates** button to apply all updates.

When you return to your improvement actions page, you may see a message across the top of the page asking you to refresh the page for the updates to be completed.

Set up alerts for improvement action changes

You can set up alerts to notify you immediately when certain changes to improvement actions occur, such as a change in implementation or test status, or an increase or decrease in score. Getting quick notifications of such changes can help you stay on top of possible compliance risks. Visit Compliance Manager alerts and alert policies to learn how to set up alerts.

Export a report of all improvement actions

On the improvement actions page, select **Export actions** above the list of actions. An Excel file downloads. The file contains all your improvement actions and the filter categories shown on the improvement actions page. This is the same file to use for

updating multiple improvement actions at once. Get details about how to work with the file in order to update multiple improvement actions.

Update improvement actions and bring compliance data into Compliance Manager

Overview

Compliance Manager enables organizations to bring their existing compliance activity data and evidence into the Compliance Manager solution. Uploading a specially formatted Excel file allows organizations who are new to Compliance Manager to migrate compliance activities completed in other systems into Compliance Manager and quickly start increasing their overall compliance score.

This upload process also gives new and existing Compliance Manager users greater flexibility and ability to update improvement actions on a larger scale. For example, you can:

- Add test results and evidence to multiple improvement actions that were tested in a system other than Compliance Manager.
- Assign improvement actions to various users based on the actions' score potential.
- Update the implementation status or testing status of multiple improvement actions all at one time.
- Change improvement actions' testing type from automatic to manual.

Get started with updating improvement actions

To migrate existing data into Compliance Manager or to perform a bulk update of improvement actions, you can start from one of two places in Compliance Manager:

- From **Assessments** page: Helps you update specific assessments with information from elsewhere, such as test results or evidence for actions that were tested by a separate system.
- From **Improvement actions** page: Facilitates updating multiple actions at once, such as assigning them to users, changing implementation or test status, and adding notes and evidence.

To begin the process of migrating data or updating actions, follow the steps in Steps for updating actions.

> **Important**

- Only the improvement actions managed by your organization, not Microsoft managed actions, can be updated by this process. (Learn more about types of improvement actions.)
- Improvement actions must already be associated to an assessment before you can update them through this process. (Learn more about building and managing assessments.)

Migrating your existing work into Compliance Manager

If you're new to Compliance Manager, the steps below illustrate the basic workflow for bringing your existing compliance activities into Compliance Manager:

1. **Create an assessment**: Compliance Manager can recommend assessments that may be most relevant to your organization, or you can create one through a guided process. Visit Create assessments for instructions.

2. **Export improvement actions**: You'll export an Excel file containing the action data that you want to update. It may make more sense to start the export from your **Assessments** page, but you can also export from the **Improvement actions** page. See Steps for updating actions.

3. **Update the improvement action Excel file**: Use the instructions on the **How to update actions** tab of the Excel file to add your information.

4. **Upload the Excel file**: Upload your edited Excel file by selecting the **Upload actions** command on the **Assessments** or **Improvement actions** page.

Updating multiple improvement actions at once

To update the status, evidence, notes, or other data in multiple improvement actions at one time, you'll follow the basic flow outlined below:

1. **Export improvement actions.** Export the improvement actions you want to update, staring either from your **Improvement actions** page or your **Assessments** page. The export is a downloaded Excel file containing improvement action data. See Steps for updating actions.

2. **Update the improvement action Excel file.** Use the instructions on the **How to update actions** tab of the Excel file to add or update the information in the specially formatted Excel file.

3. **Upload the Excel file.** Upload your edited Excel file by selecting the **Upload actions** command on the **Assessments** or **Improvement actions** page.

> ⓘ **Note**
>
> If you export the improvement actions from an assessment, the exported Excel file will include control-mapping data for that assessment. However, you won't be able to change the control-mapping data when you edit your Excel file.

Steps for updating actions

The following steps outline the process for bringing compliance activity data into your assessments and updating improvement actions.

1. In Compliance Manager, begin from either from the **Assessments** page or the **Improvement actions** page.

2. Export the improvement actions that you want to update:

   a. From the **Improvement actions** page: Find the improvement actions you want to update, and select the checkbox to the left of their names. Then select the **Export actions** command above the list of actions.

   b. From the **Assessments** page: Find the assessment or assessments you want to update, and select the checkbox to the left of their names. Then select the **Export actions** command above the list of assessments.

3. An Excel file will download, which contains all the data related to the actions. Open the file and refer to the formatting instructions on the tab labeled **How to update actions.**

4. Edit the information on the **Action Update** tab of the spreadsheet according to the formatting instructions. Then save your updated version of the Excel file to your computer.

5. On your **Assessments** page or **Improvement actions** page, select the **Update actions** command, which will open the improvement actions update wizard.

6. The first page in the wizard lists the main prerequisites: that all improvement actions must be associated to at least one assessment, and that your data needs to be formatted in an Excel file for upload. Check the boxes next to the reminders, then continue the process by selecting **Next**.

7. On the **Import updated improvement actions** page, select **Browse** to locate your updated Excel file from its saved location, then select **Next**. If there are any problems with the format of your file, an error message will give instructions for fixing the problem. Upload your corrected file again, then select **Next**.

8. On the **Review and finish** page, review the summary showing the number of actions that will be updated, their associated assessments, and how they affect your compliance score. From here you can upload a different file, or continue with the upload by selecting **Update actions**.

9. When your file has been successfully uploaded, you'll see a confirmation screen. Select **Finish** to exit the wizard and arrive back at the page where you began the update actions process.

Most of the updates will take effect right away, but it may take up to a day for all the updated information to be fully reflected in Compliance Manager.

> **Note**
>
> Control mapping won't be included in the Excel file that's downloaded when you generate a report by selecting *Export actions*.

Microsoft Purview Compliance Manager alerts and alert policies

Article • 10/15/2024

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Overview

Compliance Manager can alert you to changes as soon as they happen so that you can stay on track with your compliance goals. For example, you can set up alerts to inform you when an improvement action's score value has increased or decreased due to a configuration change in your tenant, or when an improvement action has been assigned to a user to perform implementation or testing work. View the types of events for which you can create alerts.

To create alerts, you first set up an alert policy to outline the conditions that trigger an alert and the frequency of notifications. When we detect a match to your policy conditions, you'll receive an email notification with details so you can determine whether to investigate or take further action.

All alerts are listed on the **Alerts** page in Compliance Manager, and all alert policies are listed on the **Policies** page. All organizations have a default score change policy already set up for them.

Understanding the Policies and Alerts pages

> **Important**
>
> Users must hold the **Security reader** role in Microsoft Entra ID in order to access the **Policies** and **Alerts** pages. Additional security and Compliance Manager roles are needed to work with alerts and alert policies. Get details below in Alert policy permissions.

Policies page

Select **Policies** (or **Alert policies** if using the classic portal) in Compliance Manager to view and manage your alert policies. The **Policies** page contains a table listing all the policies created by your organization. From this page, you can create new policies, edit existing policies, change activation status, and delete policies.

In the **Status column**, **Active** means the policy is in effect and triggering alerts when conditions are met. **Inactive** means the policy exists but isn't generating alerts. The policies table also shows you the severity of the policy and the date the policy was last modified.

To view an individual policy's details, select its row in the table. A flyout pane will appear that shows all details. Select the **Action** button at the bottom of the pane and select from options to edit the policy, view its alerts, or delete it. The commands to add, edit, delete, activate, and disable are also available near the top of the table, above the filters.

To get started creating an alert policy, see Create an alert policy.

Alerts page

Select **Alerts** in Compliance Manager to view and manage your alerts. The **Alerts** page contains a table listing each alert generated by an alert policy, along with its severity and the triggering event (for example, an action's score change) and date of the alert.

To view an individual alert, select its row in the table. A flyout pane will appear that shows all details on the **Overview** tab of the pane. The **Events log** tab displays actions taken by users that triggered the alert.

The **Actions** button at the bottom of the pane provides options to assign the alert to a user for follow-up, email the user whose actions generated the alert, or view the details of the policy that generate the alert. You can also take the same actions by selecting the round button that appears to the left of the alert name when you hover over its row, then selecting one of the buttons near the top of the table, above the filters.

To start working with alerts, see Viewing and managing alerts.

Alert policy permissions

The table below outlines which users can create and edit alerts and alert policies based on their role type. In addition to holding a Compliance Manager role, users also need a Microsoft Entra role as follows:

- To view alerts and alert policies: the **Security reader** role in Microsoft Entra ID.
- To create or update alert policies: the **Compliance Administrator**, **Compliance Data Administrator**, **Security Administrator**, or **Security Operator** role in Microsoft Entra ID.

Learn more about Azure roles in the Microsoft Purview portal.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Expand table

Role	Can create and edit policies	Can edit alerts
Compliance Manager Administration	Yes	Yes
Compliance Manager Assessor	Yes	Yes
Compliance Manager Contributor	Yes	Yes
Compliance Manager Reader	No	No
Global Administrator	Yes	Yes

Learn how to set user permissions and assign roles for Compliance Manager.

Create an alert policy

You can create policies to alert you when certain changes or events related to improvement actions happen. Event types are listed below.

Alert event types

- **Score change**: an increase or decrease in points awarded for an improvement action due to configuration changes made by someone in your organization. For example, if your organization creates an insider risk managing policy, that could increase your points for a certain action by a certain amount.
- **Assignment change**: an improvement action has been assigned to a user, reassigned to a different user, or unassigned from a user.

- **Implementation status change**: a user has changed an improvement action's implementation status.
- **Test status change**: a user has changed the testing status of an improvement action.
- **Evidence change**: a user has uploaded or deleted an evidence document in the **Documents** tab of the improvement action.

Default score change policy

Compliance Manager sets up a default alert policy to monitor for score changes in improvement actions. The default policy generates an alert when an improvement action's score changes. Most settings for the default policy can't be edited. But you can add other users as recipients of alert notifications, which we recommend.

Here are the settings for the default policy:

- All matches that are detected within a span of 60 minutes will be grouped into one single alert to reduce excessive notifications. For example, if five improvement actions experience a score change within one hour, one alert is generated.
- The severity level for these alerts is **medium**.
- The Global Admin for your organization is the default recipient of alert notifications.
- You can add more alert recipients by following these steps:
  - On the **Policies** page, find the **Compliance Manager default alert policy**.
  - Check the box to thee left of its name and select the **Edit** button near the top, above the filters.
  - Select the **Next** button until you come to the **Alert recipients** page.
  - Select **+Select recipients** and check the boxes next to each user name on the flyout pane whom you want to receive the email notification. When done, select **Add recipient**, then select **Next**.
  - On the **Review and finish** page, select **Update** to save your changes.
- The default policy can't be deleted, but you can disable it by following the steps outlined below.

Policy creation steps

To create a policy to generate alerts based on one or more events, follow the steps below:

1. In **Compliance Manager**, go to the **Policies** page and select **Add** to start the policy creation wizard.

   > **Tip**
   >
   > In the new Microsoft Purview portal, this page is called **Policies** and is found on the left navigation instead of as a tab at the top.

2. On the **Name and description** page, enter a name for the policy and an optional description, then select **Next**.

3. On the **Conditions** page, select one or more events that will trigger an alert. Under the **Improvement action activity** header, select **Add sub-conditions** and check the box that appears when hovering to the left of each condition name. You can choose one or more conditions for a policy: assignment change, evidence change, implementation status change, score change, test status change. When you're finished, select **Next**.

4. On the **Outcomes** page, choose what happens when a policy match is detected:

   - Select a severity level for the alert when a match is detected: low, medium, or high.
   - Select how often you want to be notified by email when a match is detected. You can choose to be notified with each match, or choose a threshold of a certain number of matches above three.
   - If you choose to be notified after three or more matches, you'll then designate the number of minutes within which that threshold must be reached (for example, 4 matches within 90 minutes).

   When you're done, select **Next**.

5. On the **Alert recipient** page, select additional users in your organization to receive an email when the policy conditions are met. The user who creates the policy is the default recipient. Select **+Select recipients** and check the boxes next to each user name on the flyout pane whom you want to receive the email notification. When done, select **Add recipients**, then select **Next**.

6. Review all selections, and make any changes to each section by selecting **Edit**. When finished reviewing, select **Create policy**.

7. When your policy is created, select **Done**. You arrive at your **Policies** page with the flyout pane for the policy you just created already open.

Your policy is active once you create it, which means it starts detecting matches and generating alerts. See the **Managing policies** section below for how to inactivate or delete policies.

It can take up to 24 hours after creating or updating a policy before alerts are generated by that policy. See View alert details below to learn about triggering events and alert aggregation.

Managing policies

The **Policies** page contains a table listing of all your policies. See Policies page to further understand this page. Any user in your organization can view policies, but certain actions are restricted to certain roles; see Alert policy permissions.

> **Tip**
>
> In the new Microsoft Purview portal, this page is called **Policies** and is found on the left navigation instead of as a tab at the top.

View policy details

Select a policy from its row on the **Policies** page to bring up a flyout panel showing the policy's details, including its match conditions, whether and when alert notifications are sent and to whom, and severity level.

The **Actions** button at the bottom of the panel gives you options to edit the policy, delete the policy, or view alerts.

View a policy's alerts

From the policy's flyout panel, select **Actions** and then **View alerts**. You are taken directly to the Alerts page with a filtered view of all the alerts generated by that policy. Learn how to work with alerts.

Edit a policy

You can edit any aspect of a policy except for its name. If you want to change its name, you need to create a new policy with a new name.

To edit a policy, select the round button that appears to the left of its name when you hover over its row on the **Policies** page and select the **Edit** button near the top, above the filters.

You are taken to the policy creation wizard where you can make and save changes to your policy. You can also select the policy to bring up its details panel, and from the **Actions** button, select **Edit policy**. After working your way through the wizard again, review your selections and in the final step, select **Update** to save your changes.

It can take up to 24 hours before alerts are generated by the updated policy.

Activate or inactivate a policy

Policies are activated by default as soon as they're created. When active, a policy will create an alert (shown on the **Alerts** page) when the conditions are met, and will send a notification email to the designated recipients.

To change a policy to an **inactive** state, which means it won't generate alerts, select the round button that appears to the left of the policy name when you hover over its row. Then select the **Disable** command above the table. The status of your policy will now read Inactive. To reactivate the policy, follow the same process and select the **Activate** button above the filters.

Delete a policy

To delete a policy, you can select the button next to its name on the **Policies** page and select **Delete** near the top of the page. You can also select the policy to bring up its details panel, and from the **Actions** button, select **Delete policy**.

Deleting is permanent. Once you delete a policy, it will no longer generate alerts or email notifications. Learn more about alerts connected to deleted policies.

Viewing and managing alerts

The **Alerts** page shows a table with all the alerts generated by all your policies. Alerts are generated almost immediately after an event matching the policy's conditions occurs. The alert name is the same name as the policy that generated the alert.

An alert can only be generated from an active policy. Once an alert is generated, it remains listed on the **Alerts** page regardless of whether the policy is active or inactive.

Filter your view of alerts

You can filter your view of alerts by selecting the **Filter** command above the table on your **Alerts** page. From the **Filter** flyout pane, select among these filter options:

- Event type
- Severity
- Status
- User assigned to
- Detection date
- Policy name

After making your selections, select **Apply**. The flyout pane closes and your updated **Alerts** page shows your filtered view. Your filters are displayed at the top of the table, though not all filter columns may show in the table.

View alert details

To view all the details about the alert, including the events which triggered it, select its row on the table. A flyout pane shows the details of the alert on the **Overview** tab of the panel.

The **Events log** tab of the flyout panel lists the activities that generated the alert, such as a score change or an assignment change, along with the name of the user associated to each action and the date detected.

Alert events

The **Event** column on the **Alerts** page indicates the conditions of a policy that were detected; in other words, the activity that generated the alert. The **Events log** tab on the alert's details panel lists each instance of an event, the associated user, and the date detected. Event values are listed below:

- **Score change**: shows the number of increase or decrease in points
- **Assignment change**: an improvement action has been assigned to a user, reassigned to a different user, or unassigned from a user
- **Implementation status change**: a user has changed an improvement action's implementation status
- **Test status change**: a user has changed the testing status of an improvement action.
- **Evidence change**: a user has uploaded or deleted an evidence document in the Documents tab of the improvement action
- **Multi-event**: multiple instances of the same type of event have been detected; for example, a single improvement action that has been reassigned multiple times

- **Multi-condition**: multiple conditions within a single policy were detected

Alert aggregation for multiple events within one minute

When multiple events that match the conditions of an alert policy occur with one minute, they're added to an existing alert by a process called alert aggregation.

For example, when one event occurs which matches a policy, an alert is generated and displayed on the **Alerts** page and a notification is sent. If another event matching the same policy occurs within one minute of the first event, then Compliance Manager adds details about the other event on the **Events log** tab of the existing alert instead of triggering a new alert. The goal of alert aggregation is to help reduce alert "fatigue" and let you focus and take action on fewer alerts.

Taking action on alerts

When one of your policies generates an alert, you can view the events that caused the alert and determine whether you need to verify or further investigate the events.

To take an action on an alert, select its row on the **Alerts** page to bring up the flyout panel with its details, select the **Actions** button, and chose among options listed below. You can also take actions by selecting the round button that appears to the left of the alert name when you hover over its row, and selecting one of the action buttons near the top of the page, above the filters.

Assign alert: You may want to assign the alert to a user to investigate or verify the events that caused the alert. When you choose this option, a panel opens where you can select a user in your organization and assign the alert to them. You can filter your alerts view by selecting **Filters** on the **Alerts** page, and entering the user's name in the **Assigned to** field.

Email alert: You may want to send an email to the user associated to the alert's activity to confirm that they took the action. When you chose this option, it opens an email template with basic information about the alert, which you can customize with further instructions and sent to the user.

View policy details: You may want to review the settings for the policy that triggered the alert. When you select this option, you are taken directly to the **Policies** page with the policy details panel already open. You'll no longer be on your **Alerts** page when you close the policy details panel.

Change status: You can update status for your alert based on your review of its impact and whether it needs investigating. Learn more about alert statuses in the next section.

Alert status

When an alert is created, its status is **Active**. As you review the details of each alert, you can update its status to any of the states listed below:

- **Active**: default state of the alert until its status is changed
- **Investigating**: alert is under investigation
- **Resolved**: the alert doesn't require further investigation or follow-up
- **Dismissed**: the alert isn't relevant or doesn't need investigation

To assign or change an alert's status, select an alert from its row on the table, select **Change status** near the top of the page, above the filters. From the Update alert status flyout pane, select a status from the drop-down menu, then select **Update alert**.

Once an alert is generated, its status is independent of the status of the policy that generated the alert. For example, it's possible to have an **active** alert associated to an **inactive** policy, and it's possible to have an **investigating** status on an alert that was generated by a policy that was later inactivated or deleted.

When policies are deleted

When a policy is deleted, any alerts that were generated by that policy remain on your **Alerts** page, but no new alerts are generated.

Email notifications of alerts

When you create a policy, an email is sent to the user who created the policy alerting them that a match was detected. You can choose to send these email notifications to more users in your organization. Alerts occur in near real-time, and the email notifications are sent out as soon as an alert is generated. The email contains the event name, severity, time detected, and a link to view the alert in Compliance Manager.

Remove users from receiving alerts

If you designate alert recipients and then later decide to remove them, follow the steps below. The policy creator will still receive email notifications when policy matches are detected.

1. Begin the steps to edit your policy.
2. When you arrive at the **Alert recipients** screen, select **+Select recipients**.
3. In the **Select recipients** flyout panel, find the user you want to remove from notifications and uncheck the box to the left of their name, then select the **Add**

recipients button (which has the effect of saving your selection).

4. Continue through the wizard and confirm that the user doesn't appear under **Recipients** on the Review and finish page. Select **Update** to save your settings and finish.

Compliance Manager scoring

09/26/2025

> **Important**
>
> Recommendations from Compliance Manager should not be interpreted as a guarantee of compliance. It is up to you to evaluate and validate the effectiveness of customer controls per your regulatory environment. These services are subject to the terms and conditions in Product Terms. See also Microsoft 365 licensing guidance for security and compliance.

Understanding your compliance score

The Compliance Manager dashboard displays your overall compliance score. This score measures your progress in completing recommended improvement actions within controls. Your score can help you understand your current compliance posture. It can also help you prioritize actions based on their potential to reduce risk.

A score value is assigned at these levels:

1. **Improvement action**: Each action has a different impact on your score depending on the potential risk involved. See Action types and scoring below for details.
2. **Assessment**: This score is calculated using improvement action scores. Each Microsoft action and each improvement action managed by your organization is counted once, regardless of how often it's referenced in a control.

The overall compliance score is calculated using improvement action scores, where each Microsoft action is counted once, each technical action you manage is counted once, and each nontechnical action you manage is counted once per group. This logic is designed to provide the most accurate accounting of how actions are implemented and tested in your organization. You may notice that this can cause your overall compliance score to differ from the average of your assessment scores. Read more below about how actions are scored.

Initial score based on Microsoft 365 data protection baseline

Compliance Manager gives you an initial score based on the Microsoft 365 data protection baseline. This baseline is a set of controls that includes key regulations and standards for data protection and general data governance. This baseline draws elements primarily from NIST CSF (National Institute of Standards and Technology Cybersecurity Framework) and ISO

(International Organization for Standardization), as well as from FedRAMP (Federal Risk and Authorization Management Program) and GDPR (General Data Protection Regulation of the European Union).

Your initial score is calculated according to the default Data Protection Baseline assessment provided to all organizations. Upon your first visit, Compliance Manager is already collecting signals from your Microsoft 365 solutions. You see at a glance how your organization is performing relative to key data protection standards and regulations, and see suggested improvement actions to take.

Because every organization has specific needs, Compliance Manager relies on you to set up and manage assessments to help minimize and mitigate risk as comprehensively as possible.

Action types and scoring

Improvement actions have points that are awarded when you complete the requirements for implementation. Your action status is updated on your dashboard within 24 hours of a change being made. Once you follow a recommendation to implement a control, you'll typically see the control status updated the next day.

Points are awarded per action per assessment. For example, if an action is worth 10 points but it appears in two assessments, the action is worth 20 points overall for your tenant. An exception is for technical actions that are scoped to your tenant; points for these actions are granted once per action, regardless of how many groups the action belongs to.

Actions for services supported by Microsoft Defender for Cloud

An improvement action's overall score is based on the average of scores received by its subscriptions. Each subscription is scored based on the status of the relevant virtual resources.

For example, consider an action with two subscriptions, A and B. Subscription A has 0 out of 1 resource completed, and subscription B has 1 out of 2 resources completed. The subscription scores are: A is 0%, B is 50%. The two subscription scores are averaged to get the overall action score of 25%.

How score values are determined

Actions are assigned a score value based on whether they're mandatory or discretionary, and whether they're preventative, detective, or corrective.

Mandatory and discretionary actions

- **Mandatory actions** can't be bypassed, either intentionally or accidentally. An example of a mandatory action is a centrally managed password policy that sets requirements for password length, complexity, and expiration. Users must follow these requirements to access the system.
- **Discretionary actions** rely upon users to understand and adhere to a policy. For example, a policy requiring users to lock their computer when unattended is a discretionary action because it relies on the user.

Preventative, detective, and corrective actions

- **Preventative actions** address specific risks. For example, protecting information at rest using encryption is a preventative action against attacks and breaches. Separation of duties is a preventative action to manage conflict of interest and guard against fraud.
- **Detective actions** actively monitor systems to identify irregular conditions or behaviors that represent risk, or that can be used to detect intrusions or breaches. Examples include system access auditing and privileged administrative actions. Regulatory compliance audits are a type of detective action used to find process issues.
- **Corrective actions** try to keep the adverse effects of a security incident to a minimum, take corrective action to reduce the immediate effect, and reverse the damage if possible. Privacy incident response is a corrective action to limit damage and restore systems to an operational state after a breach.

Each action has an assigned value in Compliance Manager based on the risk it represents:

Expand table

Type	Assigned score
Preventative mandatory	27
Preventative discretionary	9
Detective mandatory	3
Detective discretionary	1
Corrective mandatory	3
Corrective discretionary	1

How is your compliance score calculated?

	Preventative	Detective	Corrective
Mandatory	+27 points	+3 points	+3 points
Discretionary	+9 points	+1 points	+1 points

Assess predeployment compliance with Compliance Manager (preview)

09/26/2025

Compliance Manager provides a way for organizations to understand Microsoft's compliance posture with Microsoft services before deployment. By reviewing the data provided in the **Sub-service compliance readiness** group of regulations, you can analyze in detail how using Azure services can contribute to your organization's overall compliance posture in regard to these four regulations:

- ISO/IEC 27001:2013
- NIST 800-53 rev.4
- PCI DSS v4.0
- System and Organization Controls (SOC) 2

Get started on the Regulations page

In Compliance Manager, go to the **Regulations** page. The first grouping of regulations you see is **Sub-service compliance readiness**. You can filter your view to only these regulations by selecting **Pre-deployment** on the **Availability** filter. A deeper subservice filter is available once you select a regulation to start viewing its actions and controls.

The subservice compliance readiness regulations aren't for creating assessments, and interacting with these regulations doesn't activate them or require a license. When you open them, they display detailed information on the controls and improvement actions managed by you and Microsoft that can contribute to an improved compliance posture using Microsoft services.

To view an individual regulation, select its name from the list to open its details page.

Explore predeployment regulation details

When you select a regulation from the **Regulations** page, a details page opens. Each details page has expandable sections for **All actions** and **All controls.** When you open the regulation's page, the **All actions** section is automatically expanded. Minimize the **All actions** section to more easily get to the **All controls** section underneath.

All actions section

The **All actions** section of the regulation details page provides detailed information about the features supported by the service, and the relevant actions to be taken by your organization and actions managed by Microsoft (learn more about the shared responsibility model).

Your actions tab

The **Your actions** tab has a table with the features supported by the service. Select a name from the **Feature | Action** column to display a details panel along the right side, which you can maximize to full screen. The details screen includes a control description, feature description, and the related Cloud Security Benchmark ID. It also provides prescriptive guidance and the automated technical policies, with deep links to reference content, that you can enable for monitoring compliance. The **Related controls** tab displays related controls from various regulations to help you examine all potentially affected controls simultaneously.

An array of filters allows you to customize your view based on service, subservice, control family, and control ID.

Use the **Sub-service** filter to delve deeper into your service review. This detailed view provides specific information tailored to your selected subservice to enable a more customized compliance review process.

Microsoft actions tab

The **Microsoft actions** tab displays the actions that Microsoft takes care of as the service provider for meeting regulatory requirements. Select a name from the **Feature | Action** column to display a details panel along the right side. You can maximize the panel to full screen, which displays a control description, the Azure control framework ID, and, on the **Implementation** tab, details on the steps taken by Microsoft to fulfill the action. The **Related controls** tab displays related controls from various regulations to help you examine all potentially affected controls simultaneously.

All controls section

The **All controls** section displays a table listing all the controls for the regulation. Under the **Control title** column, select a control to display a details panel along the right side. You can maximize the panel to full screen, which displays details of the regulatory requirements, and tabs that list your actions and Microsoft actions.

Export action and control data

In both the **All actions** and **All controls** sections, there are commands at the top of each table that enable you to export all or selected actions and controls into a CSV or JSON file format.

Select **Export all** to export all items, and select your desired format from the dropdown. To export only selected items, check the box next to the action or control names, then select **Export selected**, then select the desired format.

Get started with Microsoft Service Trust Portal

The Microsoft Service Trust Portal provides a variety of content, tools, and other resources about how Microsoft cloud services protect your data, and how you can manage cloud data security and compliance for your organization.

Accessing the Service Trust Portal

The Service Trust Portal is Microsoft's public site for publishing audit reports and other compliance-related information associated with Microsoft's cloud services. STP users can download audit reports produced by external auditors and gain insight from Microsoft-authored whitepapers that provide details on how Microsoft cloud services protect your data, and how you can manage cloud data security and compliance for your organization. To access some of the resources on the Service Trust Portal, you must sign in as an authenticated user with your Microsoft cloud services account (Microsoft Entra organization account) and review and accept the Microsoft Non-Disclosure Agreement for Compliance Materials.

Existing customers

Existing customers can access the Service Trust Portal at https://aka.ms/STP with one of the following online subscriptions (trial or paid):

- Microsoft 365
- Dynamics 365
- Azure

> **Note**
>
> Microsoft Entra accounts associated with organizations have access to the full range of documents and resources like Compliance Manager.

New customers and customers evaluating Microsoft online services

To create a new account or to create a trial account, use one of the following sign-up forms (also used for trial accounts) to get access to the STP.

- Sign up for a new Microsoft 365 Apps for business trial account or a new Office 365 Enterprise trial account
- Sign up for a new Dynamics 365 trial account
- Sign up for a new Azure trial account.

When you sign up for either a free trial, or a subscription, you must enable Microsoft Entra ID to support your access to the STP.

Using the Service Trust Portal

The Service Trust Portal features and content are accessible from the main menu. The following sections describe each item in the main menu.

Service Trust Portal

The **Service Trust Portal** link displays the home page. It provides a quick way to get back to the home page.

Certifications, Regulations, and Standards

Provides a wealth of security implementation and design information with the goal of making it easier for you to meet regulatory compliance objectives by understanding how Microsoft Cloud services keep your data secure. To review content, select one of the following tiles.

- **ISO/IEC** - International Organization for Standardization (ISO) / International Electrotechnical Commission (IEC)
- **SOC** - System and Organization Controls (SOC) 1, 2, and 3 Reports
- **GDPR** - General Data Protection Regulation
- **FedRAMP** - Federal Risk and Authorization Management Program
- **PCI** - Payment Card Industry (PCI) Data Security Standards (DSS)
- **CSA Star** - Cloud Security Alliance (CSA) Security, Trust and Assurance Registry (STAR)
- **Australia IRAP** - Australia Information Security Registered Assessors Program (IRAP)
- **Singapore MTCS** - Multi-Tier Cloud Security (MTCS) Singapore Standard
- **Spain ENS** - Spain Esquema Nacional de Seguridad (ENS)

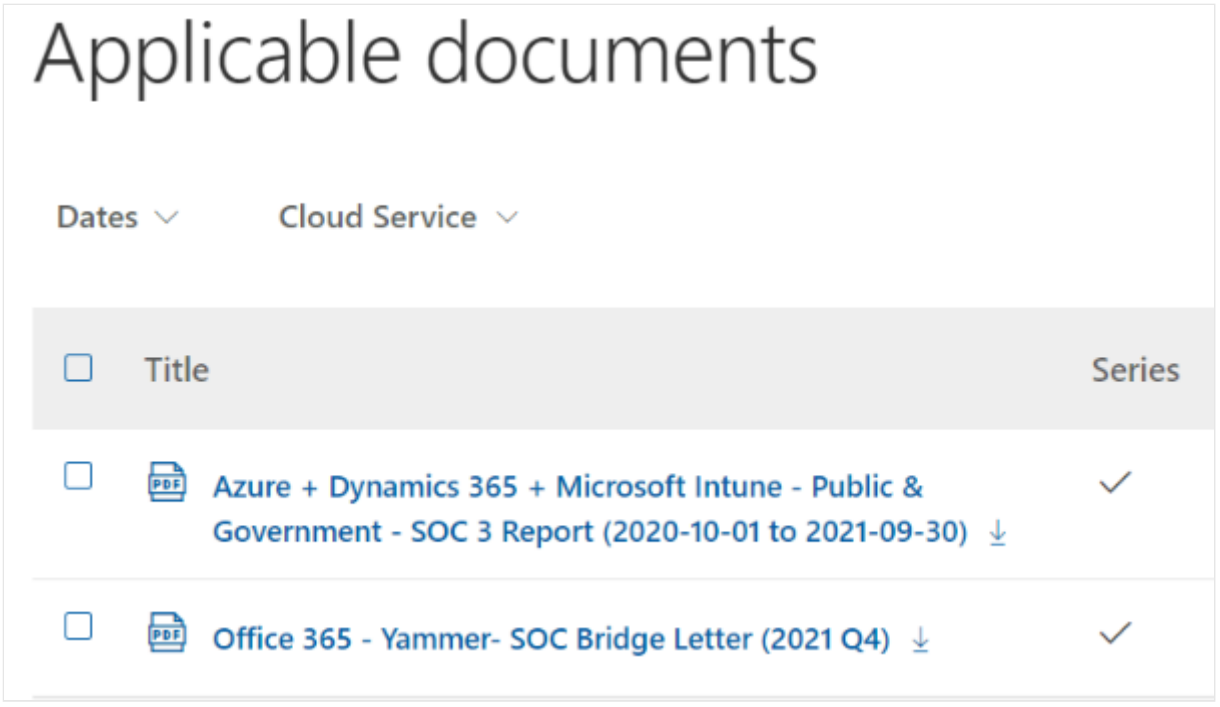
Reports, Whitepapers, and Artifacts

General documents relating to the following categories:

- **AI Resources**: Resources describing the approach to Compliance, Security, and Privacy in the AI solutions such as Microsoft Copilot and Azure OpenAI.
- **BCP and DR**: Business Continuity and Disaster Recovery.
- **Pen Test and Security Assessments**: Attestation of penetration tests and security assessments conducted by third parties.
- **Privacy and Data Protection**: Privacy and data protection resources.
- **FAQ and Whitepapers**: Whitepapers and answers to frequently asked questions.

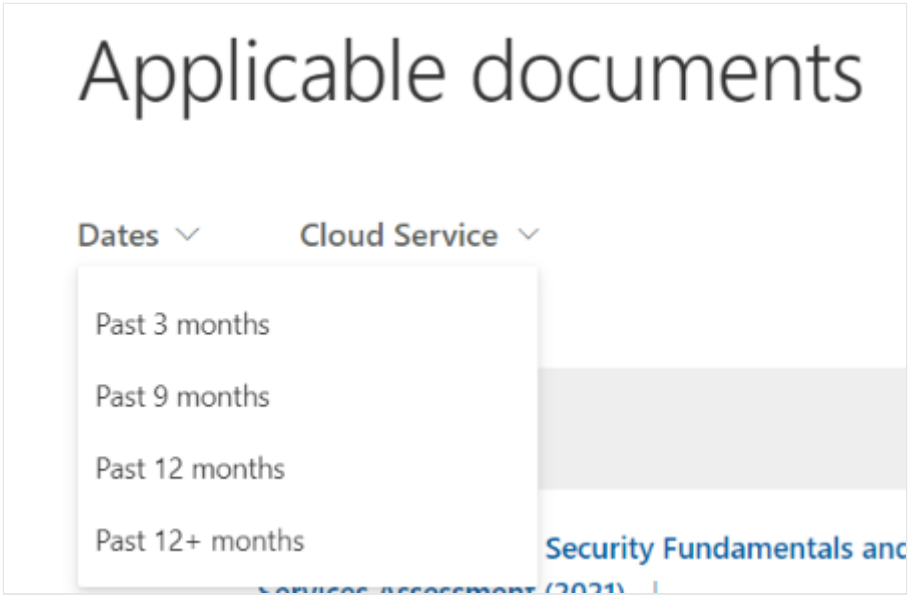
Industry and Regional Resources

Documents the apply to the following industries and regions:



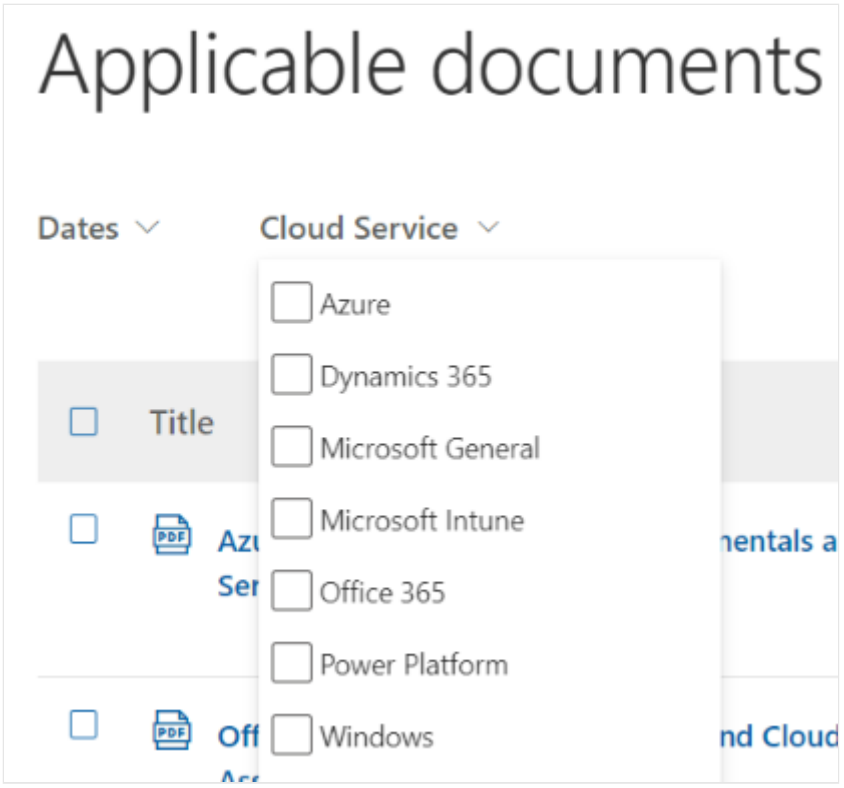
- **Financial Services** - Resources elaborating regulatory compliance guidance for FSI (by country/region)
- **Healthcare and Life Sciences** - Capabilities offered by Microsoft for Healthcare Industry
- **Media and Entertainment** - Media and Entertainment Industry Resources
- **United States Government** - Resources exclusively for US Government customers
- **Regional Resources** - Documents describing compliance of Microsoft's online services with various regional policies and regulations

Resources for your Organization



Documents applying to your organization (restricted by tenant).

- **Resources for your Organization** - Documents based on your organization's subscription and permissions



Resources with the series check mark indicate that the document has multiple versions, which can be viewed once you select the document and select **View all versions** on the download page.

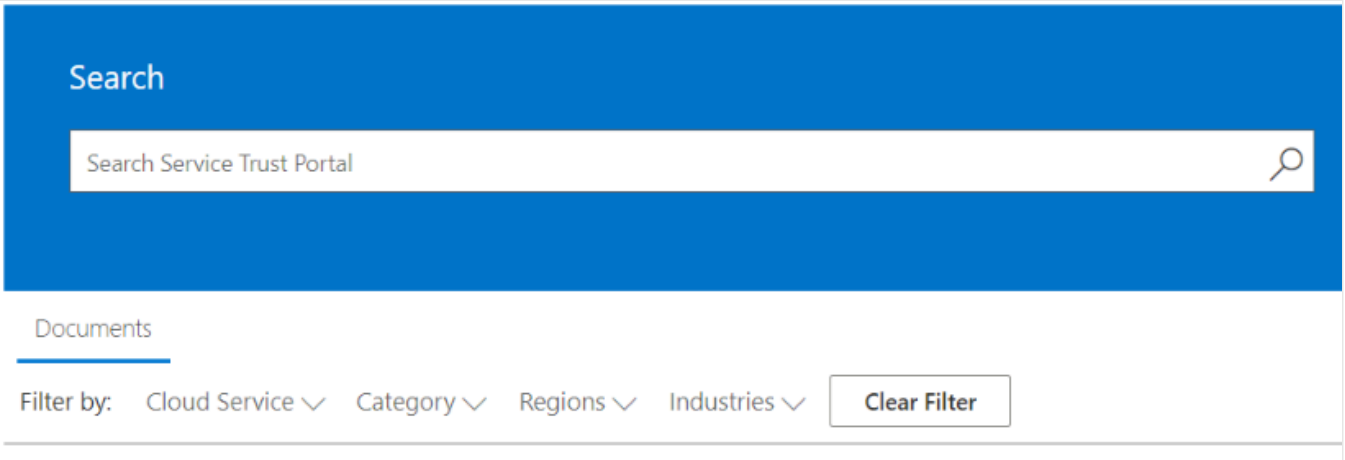
Filter by date and cloud service - When viewing the available documents, you can filter the results by date range by selecting **Dates** and then selecting the range you want to use.

Document download view - When viewing the available documents, you can filter the results by the applicable **Cloud Service**.

> **Note**
>
> Many of the files on the STP require acceptance of a license agreement. Some browser-based PDF viewers don't allow JavaScript to run, which prevents the license agreement from being displayed and the file from opening.

All Documents

This section displays all available documents. Select the documents to save into your My Library section. Documents are sorted under the same categories shown under Certifications, Standards, Regulations, and Industry Resources. To view all resources for a particular cloud service use the **Cloud Service** filter.



Restricted Documents

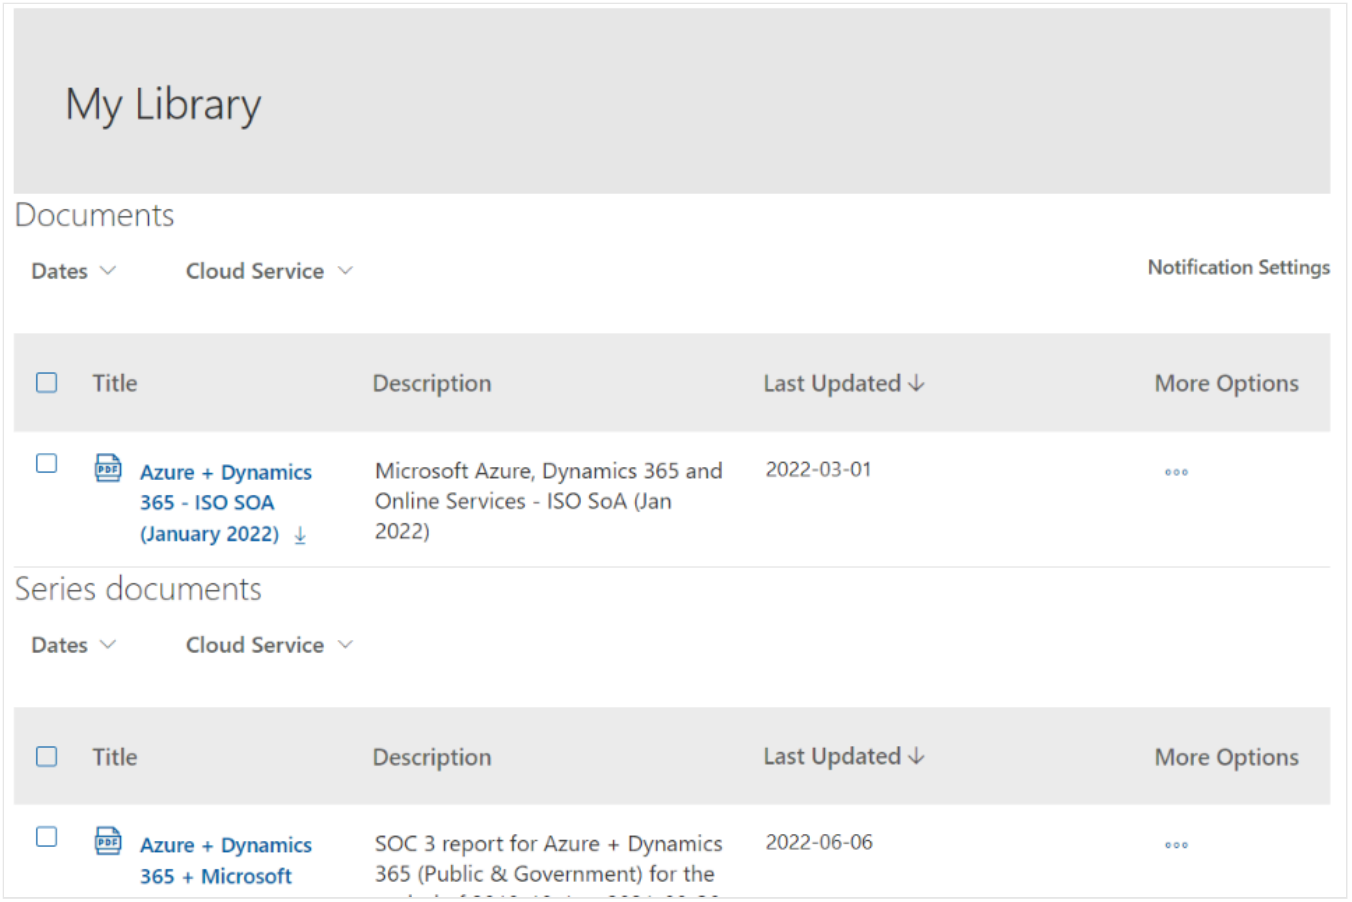
The Service Trust Portal has documents that, given the nature of their content, are available for users with specific permissions. You need to be assigned one of following roles to view restricted documents:

- Tenant Admin
- Compliance Administrator
- Security Administrator
- Security Reader

Search

Select the magnifying glass in the upper right-hand corner of the Service Trust Portal page to expand the box, enter your search terms, and press **Enter**. The **Search** page is displayed, with the search term displayed in the search box and the search results listed below.

By default, the search returns document results. You can filter the results by using the dropdown lists to refine the list of documents displayed. You can use multiple filters to narrow the list of documents. Filters include the specific cloud services, and regions. Select the document name link to download the document.



> **Note**
>
> Service Trust Portal reports and documents are available to download for at least 12 months after publishing or until a new version of document becomes available.

My Library

Use the My Library feature to add documents and resources on the Service Trust Portal to your My Library page. This lets you access documents that are relevant to you in a single place. To add a document to your My Library, select the ellipsis (...) menu to the right of a document and then select **Save to library**. You can add multiple documents to your My Library by clicking the checkbox next to one or more documents, and then clicking **Save to library** at the top of the page.

Additionally, the notifications feature lets you configure your My Library so that an email message is sent to you whenever Microsoft updates a document that you've added to your My Library. To set up notifications, go to your My Library and select **Notification Settings**. You can choose the frequency of notifications and specify an email address in your organization to send notifications to. Email notifications include links to the documents that have been updated and a brief description of the update.

If a document is part of a series, you'll be subscribed to the series and receive notifications when there's an update to that series. You can view the individual documents and Series documents that you have subscribed to, in two sections as shown below:

My Download History

On the My Download History tab, you can view and export a download history of documents downloaded from the Service Trust Portal within the last 18 months. The history includes the document title and download date, and the document status, such as whether it's live, has a newer version, or has been deleted. The full download history can be exported to a CSV file.

Localization support

The Service Trust Portal enables you to view the page content in different languages. To change the page language, select the globe icon in the lower left corner of the page and select the language of your choice.

Give feedback

We can help with questions about the Service Trust Portal, or errors you experience when you use the portal. You can also contact us with questions and feedback about Service Trust Portal

compliance reports and trust resources by using the Feedback link on the bottom of the STP pages.

Your feedback is important to us. Select **Feedback** at the bottom of the page to send us comments about what you did or didn't like, or suggestions you have for improving our products or product features.

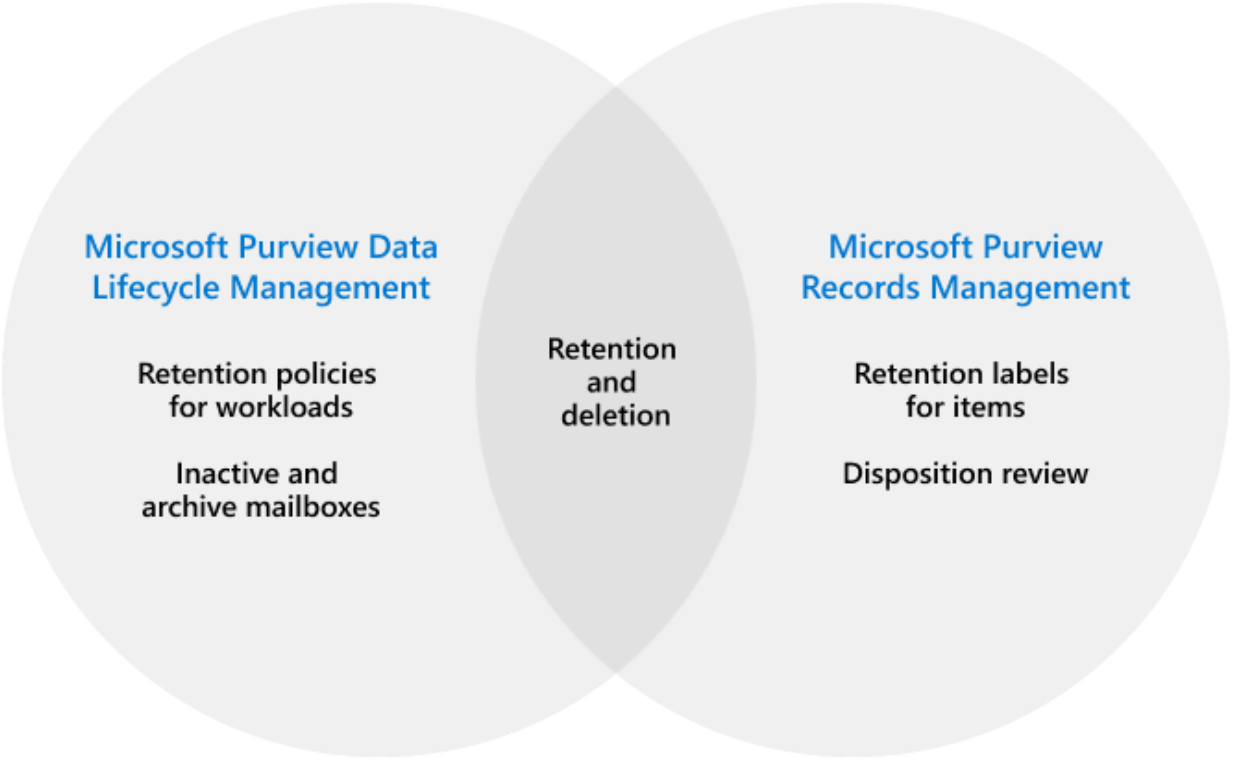
Data lifecycle and records management in Microsoft Purview

Summarize this article for me



> *Microsoft Purview service description*

Use the **Data Lifecycle Management** and **Records Management** solutions in Microsoft Purview to manage your organization's compliance and regulatory requirements for data & records across their lifecycle.

> **Tip**
>
> Looking to map and manage your data across your entire data estate, including multi-cloud, and software-as-a-service (SaaS)? Use **Microsoft Purview Data Map and Microsoft Purview Unified Catalog**.

From a licensing perspective, there can be considerable overlap between data lifecycle management and records management. Both solutions support retention and deletion of data for Microsoft 365 apps and services.

Use the following graphic to help you identify the main configurable components for these solutions that each have their own configuration area in the Microsoft Purview portal:

The following sections detail the main capabilities for each solution, with links to understand more. However, if you're looking for a guided deployment, see Deploy a data governance solution with Microsoft Purview.

Looking for complementary capabilities to protect your data? See Protect your data with Microsoft Purview.

Microsoft Purview Data Lifecycle Management

Keep what you need and delete what you don't:

Expand table

Capability	What problems does it solve?
Retention policies for Microsoft 365 workloads, with retention labels for exceptions	Lets you retain or delete content with policy management for email, documents, Teams and Viva Engage messages.
Inactive mailboxes	Lets you retain mailbox content after employees leave the organization so that this content remains accessible to administrators, compliance officers, and records managers.
Archive mailboxes	Provides additional mailbox storage space for users.

Capability	What problems does it solve?
Import service for PST files	Supports bulk-importing PST files to Exchange Online mailboxes to retain and search email messages for compliance or regulatory requirements.

Want to learn more? See Learn about data lifecycle management.

Ready to start using some or all of these capabilities? See Get started with data lifecycle management.

Microsoft Purview Records Management

Manage high-value items for business, legal, or regulatory record-keeping requirements:

Expand table

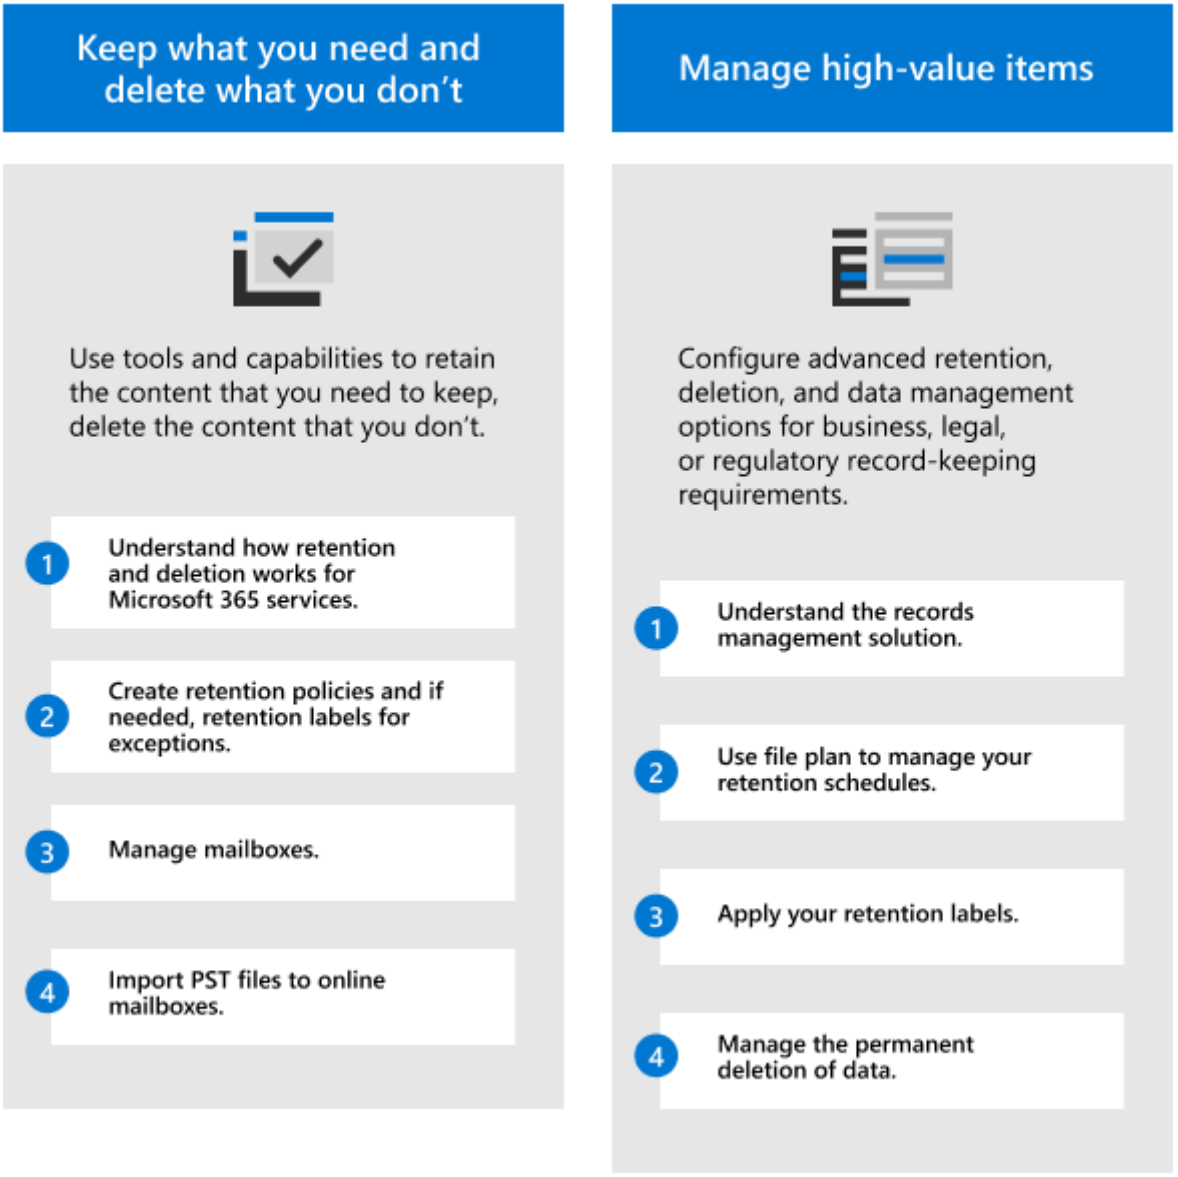
Capability	What problems does it solve?
File plan	Lets you create retention labels interactively or import in bulk, and export for analysis. Labels support additional administrative information (optional) to help you identify and track business or regulatory requirements.
Retention labels for individual items, retention policies if needed for baseline retention	Labels support flexible retention and deletion schedules that can be applied manually or automatically, with records declaration when needed.
Disposition review and proof of disposition	Manual review of content before it's permanently deleted, with proof of disposition of records.

Want to learn more? See Learn about records management.

Ready to start using some or all of these capabilities? See Get started with records management.

Licensing requirements

To understand your licensing requirements and options, see the information from the Microsoft Purview Service Description, Microsoft Purview Data Lifecycle Management & Records Management section for feature-level licensing requirements.



Last updated on 02/27/2026

Deploy Microsoft Purview data lifecycle and records management solutions

Summarize this article for me

> *Microsoft Purview service description*

Use **Microsoft Purview Data Lifecycle Management** and **Microsoft Purview Records Management** to manage compliance or regulatory requirements throughout the lifecycle of your Microsoft 365 data & records.

For data governance that maps and manages data across your data estate, including multi-cloud, and software-as-a-service (SaaS), use Microsoft Purview Data Map and Microsoft Purview Unified Catalog.

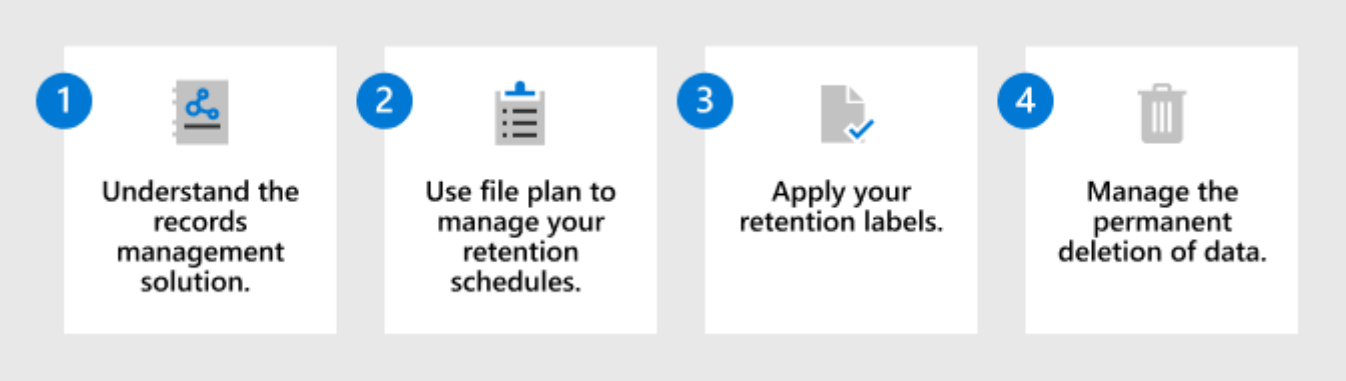
For a data protection solution, see Deploy an information protection solution with Microsoft Purview.

Licensing

To understand your licensing requirements and options, see the information from the Microsoft Purview Service Description, Microsoft Purview Data Lifecycle Management & Records Management section for feature-level licensing requirements.

Keep what you need and delete what you don't

Use **Microsoft Purview Data Lifecycle Management** to keep what you need and delete what you don't.



Expand table

Step	Description	More information
1	Understand how retention and deletion works for Microsoft 365 services. After you understand how you can use retention policies and retention labels, identify your workloads that need a retention policy and whether you need to create retention labels for exceptions.	Learn about retention policies and retention labels
2	Create retention policies and if needed, retention labels for exceptions. The most commonly used retention policies are for Exchange, SharePoint, Teams, Microsoft 365 Groups, and Viva Engage. You can configure exceptions for documents and emails, and dynamically apply retention labels for risky users.	Create retention policies Create and apply retention labels for your exceptions Dynamically mitigate the risk of accidental or malicious deletes

Step	Description	More information
	For exceptional circumstances, you might need to expedite the permanent deletion of sensitive information.	Expedite the permanent deletion of sensitive information from mailboxes
3	Manage mailboxes. Enable mailboxes for archiving and auto-expanding archiving, consider whether you need to customize when emails are moved to the archive mailbox, and make mailboxes inactive when users leave the organization.	Enable archive mailboxes Enable auto-expanding archiving Create and manage inactive mailboxes
4	Import PST files to online mailboxes. If you have PST files that contain data you want to oversee, you can import them by using network upload or drive shipping.	Use network upload to import your organization's PST files Use drive shipping to import your organization's PST files

To learn more about the capabilities from this solution, see Learn about data lifecycle management.

Manage high-value items

Use **Microsoft Purview Records Management** to manage your organization's high-value items for business, legal, or regulatory record-keeping requirements.

Expand table

Step	Description	More information
1	Understand the records management solution. Use retention labels with more flexible configuration options and when required, declare items as records.	Learn about records management

Step	Description	More information
2	Use file plan to manage your retention schedules. File plan lets you create retention labels interactively or import in bulk, and export for analysis. Labels that you create with file plan support additional administrative information to help you identify and track business or regulatory requirements.	Use file plan to create and manage retention labels
3	Apply your retention labels. Your retention labels can be published and applied manually or automatically in apps, or automatically applied based on sensitive information, keywords or searchable properties, trainable classifiers, or cloud attachments.	Publish retention labels and apply them in apps Apply a retention label to content automatically
4	Manage the permanent deletion of data. Known as the disposition of data, you can require a manual review of content before it's permanently deleted, and provide proof of disposition for records.	Manage content disposition

> **Tip**
>
> Check the list of **common scenarios** for additional configurations supported by records management.

To learn more about the capabilities from this solution, see Learn about records management.

Training resources

Interactive guides: Microsoft Purview Purview Data Lifecycle Management and Records Management

Learning modules for consultants and admins:

- Introduction to information protection and data lifecycle management in Microsoft Purview
- Manage the data lifecycle in Microsoft Purview
- Manage records in Microsoft Purview

For documentation to support users when these solutions are deployed, see the end user documentation sections for data lifecycle management and records management.

Learn about retention policies and retention labels

> *Microsoft Purview service description*

> **Note**
>
> If you're seeing messages about retention policies in Teams or have questions about retention labels in your apps, contact your IT department for information about how they have been configured for you. In the meantime, you might find the following articles helpful:
>
> - Teams messages about retention policies
> - Apply retention labels to files in SharePoint or OneDrive
>
> The information on this page is for IT administrators who can create retention policies and retention labels for compliance reasons.

For most organizations, the volume and complexity of their data is increasing daily—email, documents, instant messages, and more. Effectively managing or governing this information is important because you need to:

- **Comply proactively with industry regulations and internal policies** that require you to retain content for a minimum period of time—for example, the Sarbanes-Oxley Act might require you to retain certain types of content for seven years.
- **Reduce your risk in the event of litigation or a security breach** by permanently deleting old content that you're no longer required to keep.
- **Help your organization to share knowledge effectively and be more agile** by ensuring that your users work only with content that's current and relevant to them.

Retention settings that you configure can help you achieve these goals. Managing content commonly requires two actions:

Expand table

Action	Purpose
Retain content	Prevent permanent deletion and remain available for eDiscovery
Delete content	Permanently delete content from your organization

With these two retention actions, you can configure retention settings for the following outcomes:

- Retain-only: Retain content forever or for a specified period of time.
- Delete-only: Permanently delete content after a specified period of time.
- Retain and then delete: Retain content for a specified period of time and then permanently delete it.

These retention settings work with content in place that saves you the additional overheads of creating and configuring additional storage when you need to retain content for compliance reasons. In addition, you don't need to implement customized processes to copy and synchronize this data.

Use the following sections to learn more about how retention policies and retention labels work, when to use them, and how they supplement each other. But if you're ready to get started and deploy retention settings for some common scenarios, see Get started with data lifecycle management.

How retention settings work with content in place

When content has retention settings assigned to it, that content remains in its original location. Most of the time, people continue to work with their documents or mail as if nothing's changed. But if they edit or delete content that's included in the retention policy, a copy of the content is automatically retained.

- For SharePoint and OneDrive sites: The copy is retained in the **Preservation Hold** library.
- For Exchange mailboxes: The copy is retained in the **Recoverable Items** folder.
- For Teams, Viva Engage messages, Copilot and AI apps: The copy is retained in a hidden folder named **SubstrateHolds** as a subfolder in the Exchange **Recoverable Items** folder.

> **Note**

Because the Preservation Hold library is included in the site's storage quota, you might need to increase your storage when you use retention settings for SharePoint, OneDrive, and Microsoft 365 groups.

These secure locations and the retained content aren't visible to most people. In most cases, people don't even need to know that their content is subject to retention settings.

For more detailed information about how retention settings work for different workloads, see the following articles:

- Learn about retention for SharePoint and OneDrive
- Learn about retention for Teams
- Learn about retention for Viva Engage
- Learn about retention for Exchange
- Learn about retention for Copilot

Retention policies and retention labels

To assign your retention settings to content, use **retention policies** and **retention labels with label policies**. You can use just one of these methods, or combine them.

Use a retention policy to assign the same retention settings for content at a site or mailbox level, and use a retention label to assign retention settings at an item level (folder, document, email).

For example, if all documents in a SharePoint site should be retained for five years, it's more efficient to do this with a retention policy than apply the same retention label to all documents in that site. However, if some documents in that site should be retained for five years and others retained for 10 years, a retention policy wouldn't be able to do this. When you need to specify retention settings at the item level, use retention labels.

Unlike retention policies, retention settings from retention labels travel with the content if it's moved to a different location within your Microsoft 365 tenant. In addition, retention labels have the following capabilities that retention policies don't support:

- Options to start the retention period from when the content was labeled or based on an event, in addition to the age of the content or when it was last modified.
- Use trainable classifiers to identify content to label.
- Apply a default label for SharePoint items or Exchange messages.

- Supported actions at the end retention period:
  - Disposition review to review the content before it's permanently deleted.
  - Automatically apply another retention label
- Mark the content as a record as part of the label settings, and always have proof of disposition when content is deleted at the end of its retention period.

Retention policies

Retention policies can be applied to the following locations:

- Exchange mailboxes
- SharePoint classic and communication sites
- OneDrive accounts
- Microsoft 365 Group mailboxes & sites
- Skype for Business
- Exchange public folders
- Teams channel messages (standard channels, shared channels, and private channels post-migration)
- Teams chats
- Teams private channel messages (pre-migration only)
- Teams call logs
- Microsoft Copilot experiences
- Enterprise AI apps
- Other AI apps
- Viva Engage community messages
- Viva Engage user messages

> **Note**
>
> If you have existing retention policies for Teams chats and Copilot interactions, they continue to be supported, although they can't be edited when your tenant supports the separate locations. At this point, any new retention policies must use the new locations.

You can efficiently apply a single policy to multiple locations, or to specific locations or users.

For the start of the retention period, you can choose when the content was created or, supported only for files and the SharePoint, OneDrive, and Microsoft 365 Groups locations, when the content was last modified.

Items inherit the retention settings from their container specified in the retention policy. If they are, then moved outside that container when the policy is configured to retain content, a copy of that item is retained in the workload's secured location. However, the retention settings don't travel with the content in its new location. If that's required, use retention labels instead of retention policies.

Retention labels

Use retention labels for different types of content that require different retention settings. For example:

- Tax forms that need to be retained for a minimum period of time.
- Press materials that need to be permanently deleted when they reach a specific age.
- Competitive research that needs to be retained for a specific period and then permanently deleted.
- Work visas that must be marked as a record so that they can't be edited or deleted.

In all these cases, retention labels let you apply retention settings for governance control at the item level (document or email).

With retention labels, you can:

- **Enable people in your organization to apply a retention label manually** to content in Outlook and Outlook on the web, OneDrive, SharePoint, and Microsoft 365 groups. Users often know best what type of content they're working with, so they can classify it and have the appropriate retention settings applied.
- **Apply retention labels to content automatically** if it matches specific conditions, that includes cloud attachments that are shared in email or Teams, or when the content contains:
  - Specific types of sensitive information.
  - Specific keywords that match a query you create.
  - Pattern matches for a trainable classifier.
- **Start the retention period from when the content was labeled** for documents in SharePoint sites and OneDrive accounts, and for email items.
- **Start the retention period when an event occurs**, such as employees leave the organization, or contracts expire.

- **Apply a default retention label to a document library, folder, or document set** in SharePoint, so that all documents that are stored in that location inherit the default retention label.

- **Mark items as a record** as part of your records management strategy. When this labeled content remains in Microsoft 365, further restrictions are placed on the content that might be needed for regulatory reasons. For more information, see Compare restrictions for what actions are allowed or blocked.

Retention labels, unlike sensitivity labels, don't persist if the content is moved outside Microsoft 365.

Dynamically mitigate the risk of accidental or malicious deletes

In preview, you can use this solution with Insider Risk Management so that retention labels are automatically applied with Adaptive Protection.

When you enable Adaptive Protection for your tenant, retention labels are automatically applied to unlabeled content if it's deleted by users who have been identified as an elevated risk. If these users delete content from SharePoint, OneDrive, or Exchange, a retention label is automatically applied to that content to retain it for 120 days. As a result, that content remains accessible for search and eDiscovery from the secured locations used by the workload.

> **Note**
>
> If you enabled and configured Adaptive Protection before this integration with data lifecycle management released, you'll need to opt-in to create this auto-labeling policy. See the instructions at the end of this section.

When these items are retained with Adaptive Protection, the following auditing events are generated and identify the user and item:

- For SharePoint and OneDrive: **Retained file proactively**
- For Exchange: **Retained email item proactively**

After the 120 days expire, the items then become eligible for permanent deletion. To learn more about when permanent deletion occurs, see How retention works for SharePoint and OneDrive and How retention works for Exchange.

Unlike other labeling scenarios, users don't see the retention label, and you don't need to create or manage the retention label or auto-labeling retention policy. At this time, you can't change the retention period or assign different policies based on the different risk levels, or for different locations. The single retention label and auto-labeling retention policy for your tenant aren't visible in the Microsoft Purview portal.

If you're using Adaptive Protection but don't want to automatically retain content in this way, you can turn off the auto-labeling policy without affecting other Adaptive Protection policies. Use the same control if you need to turn on the auto-labeling retention policy for Adaptive Protection, and confirm the status.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Settings** > **Solution settings**> **Data lifecycle management** > **Adaptive protection**.

2. For **Adaptive protection in Data Lifecycle Management**, turn the setting off, confirm your choice, and select **Save**.

   Any retention labels that were applied as a result of Adaptive Protection are removed so that the items can then become eligible for permanent deletion.

You won't be able to turn on this setting unless Adaptive Protection is turned on for your tenant. If your account has the required permissions, you'll see an option to take you to the insider risk management solution where you can turn on and configure Adaptive Protection.

Override holds to reclaim disk space or permanently delete sensitive information

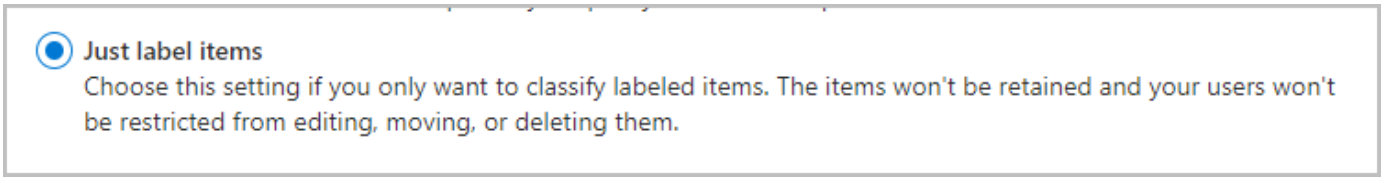
Also like adaptive protection, priority cleanup for files or mailbox items similarly applies retention labels under the covers. The labels are automatically configured and applied when you create a priority cleanup policy that identifies items with a query that you specify. This policy can override existing holds for retention and eDiscovery.

Priority cleanup is specific to data lifecycle management and isn't supported for labeled items that are marked as records. Typical uses depend on the workload:

- For SharePoint and OneDrive, you can use priority cleanup to periodically delete large files, such as Teams meeting recordings and transcripts. These files are regularly created if you're using the popular Copilot in Teams recap feature, and might be automatically retained with a retention policy that retains all items for many years. However, these specific files typically have little business value after 1-3 months, and you want to regularly delete them to save

disk space. You can also use priroty cleanup to delete files in the Preservation Hold library that can prevent OneDrive accounts from being deleted after a user leaves the organization.

- For Exchange, you can use priority cleanup to delete items when this action is required for security or privacy. For example, after a data spillage incident.



For more information and configuration instructions, see the following articles:

- Override holds to clean up files for Copilot and reclaim storage
- Expedite the permanent deletion of sensitive information from mailboxes.

Classifying content without applying any actions

Although the main purpose of retention labels is to retain or delete content, you can also use retention labels without turning on any retention or other actions. In this case, you can use a retention label simply as a text label, without enforcing any actions.

For example, you can create and apply a retention label named "Review later" with no actions, and then use that label to find that content later.

Using a retention label as a condition in a DLP policy

You can specify a retention label as a condition in a Microsoft Purview Data Loss Prevention (DLP) policy for documents in SharePoint. For example, configure a DLP policy to prevent documents from being shared outside the organization if they have a specified retention label applied to it.

For more information, see Create and Deploy data loss prevention policies.

Retention labels and policies that apply them

When you publish retention labels, they're included in a **retention label policy** that makes them available for admins and users to apply to content. As the following diagram shows:

1. A single retention label can be included in multiple retention label policies.

2. Retention label policies specify the locations to publish the retention labels. A single label retention policy can include multiple locations.

You can also create one or more **auto-apply retention label policies**, each with a single retention label. With this policy, a retention label is automatically applied when conditions that you specify in the policy are met.

Retention label policies and locations

Retention labels can be published to different locations, depending on what the retention label does.

Expand table

If the retention label is...	Then the label policy can be applied to...
Published to admins and end users	Exchange, SharePoint, OneDrive, Microsoft 365 Groups
Auto-applied based on sensitive information types, keywords or a query, or trainable classifiers	Exchange, SharePoint, OneDrive, Microsoft 365 Groups
Auto-applied to cloud attachments	SharePoint, OneDrive, Microsoft 365 Groups

Exchange public folders, Skype, Teams and Viva Engage messages don't support retention labels. To retain and delete content from these locations, use retention policies instead.

Only one retention label at a time

Unlike sensitivity labels, you can't configure priorities for retention labels. Use the following information to understand label behavior for retention labels.

As with sensitivity labels, an item such as an email or document can have only a single retention label applied to it at a time. A retention label can be applied manually by an end user or admin, or automatically by using any of the following methods:

- Auto-apply retention label policy
- A Microsoft Syntex model
- Default retention label for SharePoint or Outlook
- Outlook rules
- Power Automate compliance action of **Apply a retention label on the item**

If there are multiple auto-apply retention label policies that could apply a retention label, and the content meets the conditions of more than one of these policies, you can't control which retention label will be selected. However, in some cases, the retention label for the oldest auto-apply retention label policy (by date created) is selected. This happens only when the matching policies don't include multiple instances of the same type of condition (sensitive information types, specific keywords or searchable properties, or trainable classifiers).

For standard retention labels (they don't mark items as a record or regulatory record):

- Admins and end users can manually change or remove an existing retention label that's applied on content.
- When items already have a retention label applied, the existing label won't be automatically removed or replaced by another retention label with the following exceptions:
    - At the end of the retention period, the existing label is configured to automatically apply a different retention label, or the existing label is configured to run a Power Automate flow with the compliance action of **Relabel an item at the end of retention**.
    - You use the Power Automate compliance action of **Apply a retention label on the item**. If the item already has a retention label applied, it will be replaced.
    - The existing label was applied as a default label. When you use a default label, there are some scenarios when it can be replaced by another default label, or automatically removed. For more information, see Default labels for SharePoint and Outlook.

For retention labels that mark items as a record or a regulatory record:

- These retention labels are never automatically changed during their configured retention period, even if the existing label was applied as a default label, or identified for priority cleanup.
- Only admins for the container can manually change or remove retention labels that mark items as a record, but can't manually change or remove retention labels that mark items as a regulatory record. For more information, see Compare restrictions for what actions are allowed or blocked.
- At the end of the retention period, an existing label can be replaced if it's configured to mark items as a record and automatically apply a different retention label or to run a Power Automate flow with the compliance action of **Relabel an item at the end of retention**. You can't use these relabeling methods if the existing label is configured to mark items as a regulatory record.

Will an existing label be overridden or removed?

Use the following tables to help you quickly identify whether an existing retention label on items can be overridden by another retention label, or removed so that it's no longer labeled.

> **Note**
>
> Unless a labeled item is marked as a record or regulatory record, it can always be overridden by priority cleanup that under the covers, applies a retention label to delete the item.

A standard retention label refers to a retention label that isn't configured to mark items as records or regulatory records.

Will a label be overridden?

Expand table

New label application method	Standard retention label	Marks items as records	Marks items as regulatory records
Manually applied	Yes	Yes [1] if admin for the container	No
Applied with Power Automate actions	Yes	Yes [1]	Not applicable

New label application method	Standard retention label	Marks items as records	Marks items as regulatory records
Applied with the **Change label** label setting	Yes	Yes	Not applicable
Applied with the **Relabel** disposition review action	Yes	Yes	No
Applied with auto-apply retention label policy	No	No	Not applicable
Applied with Microsoft Syntex model	No	No	No
Outlook rules	No	No	No
Inherited from default label for SharePoint	Yes if originally applied by another default label [2]	No	No
Inherited from default label for Outlook	Yes if originally applied by another default label	No	No

Footnotes:

[1] The record must be locked.

[2] An exception is if you move the item to another location with a different default label, then the original label isn't overwritten. Only if you then change the default label for this new location will the original default label be overwritten.

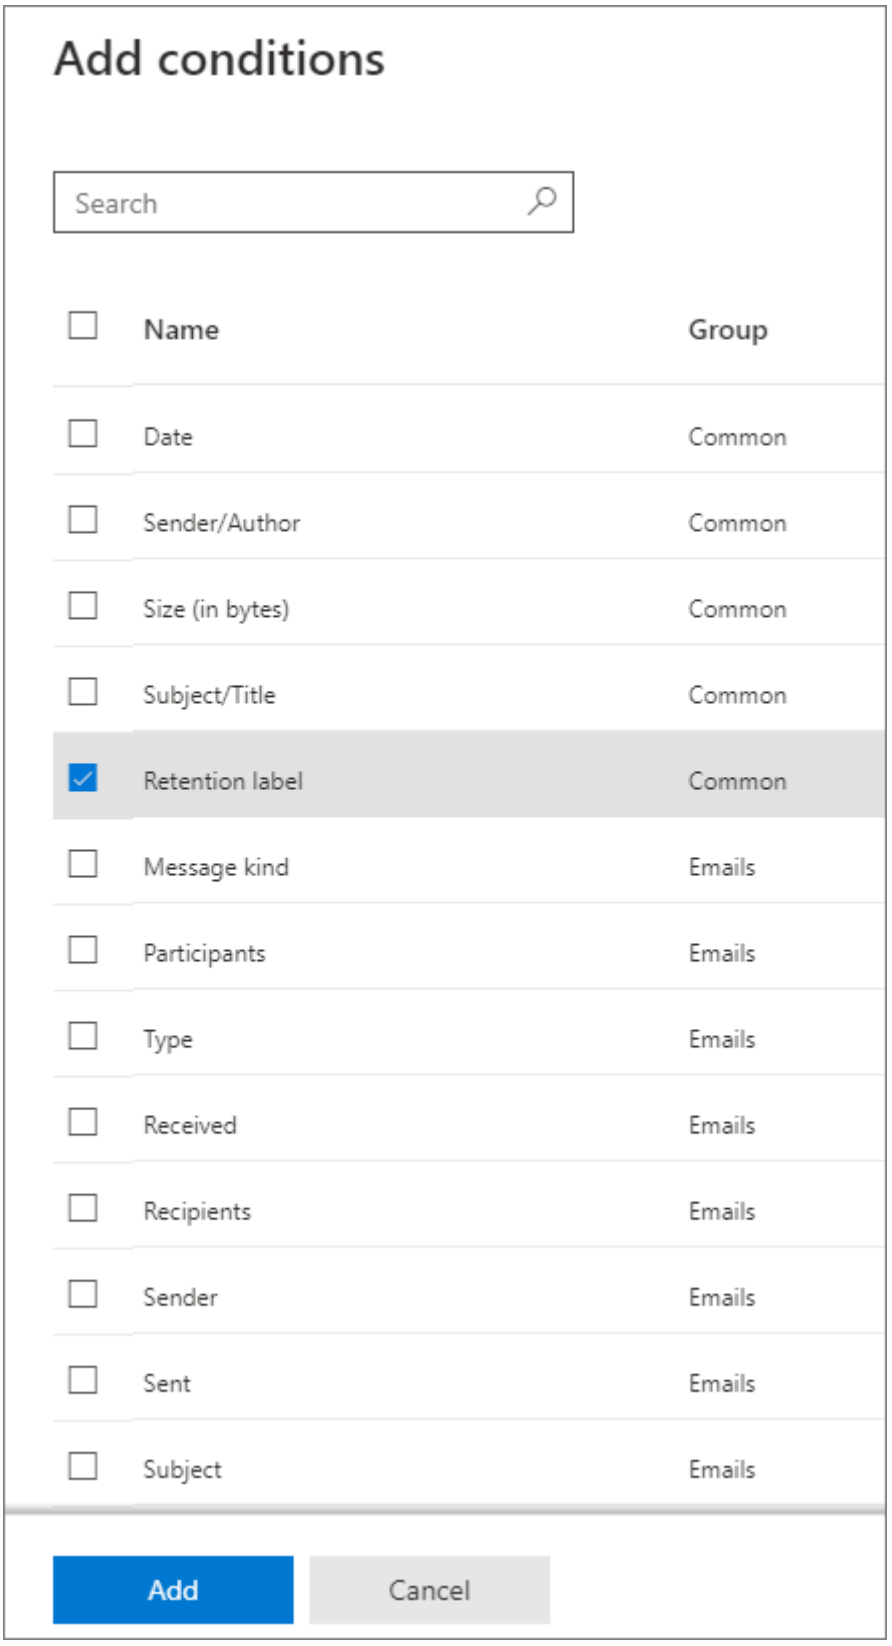
Monitoring retention labels

Use the Microsoft Purview portal to monitor how retention labels are being used in your tenant, and identify where your labeled items are located:

- Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Overview**

  You can then drill down to see details by selecting **View details** that loads content explorer and activity explorer.

For more information, including important prerequisites, see Learn about data classification.



> **Tip**

Consider using some of the other data classification insights, such as trainable classifiers and sensitive info types, to help you identify content that you might need to retain or delete, or manage as records.

Using Content Search to find all content with a specific retention label

After retention labels are applied to content, either by users or auto-applied, you can use content search to find all items that have a specific retention label applied.

When you create a content search, choose the **Retention label** condition, and then enter the complete retention label name or part of the label name and use a wildcard. For more information, see Keyword queries and search conditions for Content Search.

When the retention period starts

The start of the retention period depends on how you configure the retention policy or retention label:

- **When the content was created.** The default start of the retention period.

- **When the content was last modified.** Supported only for files in the SharePoint, OneDrive, and Microsoft 365 Groups locations.
- **When the content was labeled.** Available with retention labels, for documents in SharePoint and OneDrive, and for email items.
- **When an event occurs.** Available with retention labels that are configured for event-based retention, such as when employees leave the organization or contracts expire.

Compare capabilities for retention policies and retention labels

Use the following table to help you identify whether to use a retention policy or retention label, based on capabilities.

Expand table

Capability	Retention policy	Retention label
Retention settings that can retain and then delete, retain-only, or delete-only	Yes	Yes
Workloads supported: - Exchange - SharePoint - OneDrive - Microsoft 365 groups - Skype for Business - Teams - Copilot and AI apps - Viva Engage	 Yes Yes Yes Yes Yes Yes Yes	 Yes, except public folders Yes Yes Yes No No No
Retention applied automatically	Yes	Yes
Automatically apply different retention settings at the end of the retention period	No	Yes
Retention applied based on conditions - sensitive info types, KeyQL queries and keywords, trainable classifiers, cloud attachments	No	Yes
Retention settings applied manually	No	Yes
End-user interaction	No	Yes
Persists if the content is moved	No	Yes, within your Microsoft 365 tenant

Capability	Retention policy	Retention label
Declare item as a record	No	Yes
Start the retention period when labeled or based on an event	No	Yes
Run a Power Automate flow at the end of the retention period	No	Yes
Disposition review	No	Yes
Proof of disposition for up to seven years	No	Yes, when you use disposition review or item is marked as a record
Audit admin activities	Yes	Yes
Audit retention actions	No	Yes *
Identify items subject to retention: - Content Search - Data classification page, content explorer, activity explorer	 No No	 Yes Yes

Footnote:

* For retention labels that don't mark the content as a record or regulatory record, auditing events are limited to when an item in SharePoint or OneDrive has a label applied, changed, or removed. Or, when a retention label is used with priority-cleanup. For auditing details for retention labels, see the Auditing retention actions section on this page.

Combining retention policies and retention labels

You don't have to choose between using retention policies only or retention labels only. Both methods can be used together and in fact, complementary each other for a more comprehensive solution.

The following examples are just some of the ways in which you can combine retention policies and retention labels for the same location.

For more information about how retention policies and retention labels work together and how to determine their combined outcome, see the section on this page that explains the principles of retention and what takes precedence.

Example for users to override automatic deletion

Scenario: By default, content in users' OneDrive accounts is automatically deleted after five years but users must have the option to override this for specific documents.

1. You create and configure a retention policy that automatically deletes content five years after it's last modified, and apply the policy to all OneDrive accounts.

2. You create and configure a retention label that keeps content forever and add this to a label policy that you publish to all OneDrive accounts. You explain to users how to manually apply this label to specific documents that should be excluded from automatic deletion if not modified after five years.

Example to retain items for longer

Scenario: By default, SharePoint items are automatically retained and then deleted after five years, but documents in specific libraries must be retained for 10 years.

1. You create and configure a retention policy that automatically retains and then deletes content after five years, and apply the policy to all SharePoint and Microsoft 365 Groups instances.

2. You create and configure a retention label that automatically retains content for 10 years. You add this label to a label policy that you publish to all SharePoint and Microsoft 365 Groups instances so that SharePoint admins can then apply it as a default label to be inherited by all items in specific document libraries.

Example to delete items in a shorter time period

Scenario: By default, emails aren't retained but are automatically deleted after 10 years. However, emails related to a specific project that has a prerelease code name must be automatically deleted after one year.

1. You create and configure a retention policy that automatically deletes content after 10 years, and apply the policy to all Exchange recipients.

2. You create and configure a retention label that automatically deletes content after one year. Options for applying this label to relevant emails include:

    - You create an auto-labeling policy that identifies content by using the project code name as the keyword, and apply the policy to all Exchange recipients
    - You publish the label and instruct users involved in the project how to create an automatic rule in Outlook that applies this label

- You publish the label and instruct users to create a folder in Outlook for all emails related to the project and they apply the published label to the folder, and then create an Outlook rule to move all project-related emails to this folder

How long it takes for retention settings to apply

When you submit retention policies for workloads and label policies to automatically apply a retention label, allow up to seven days for the retention settings to be applied to content:

- How long it takes for retention policies to take effect
- How long it takes for retention labels to take effect

Similarly, allow up to seven days for retention labels to be visible in apps after you publish the labels:

- When retention labels become available to apply

Often, the policies take effect and labels are visible quicker than seven days. But with many potential variables that can impact this process, it's best to plan for the maximum of seven days.

Adaptive or static policy scopes for retention

When you create a retention policy or retention label policy, you must choose between adaptive and static to define the scope of the policy.

- An **adaptive scope** uses a query that you specify, so the membership isn't static but dynamic by running daily against the attributes or properties that you specify for the selected locations. You can use multiple adaptive scopes with a single policy.

  Example: Emails and OneDrive documents for executives require a longer retention period than standard users. You create a retention policy with an adaptive scope that uses the Microsoft Entra attribute job title of "Executive," and then select the Exchange email and OneDrive accounts locations for the policy. There's no need to specify email addresses or OneDrive URLs for these users because the adaptive scope automatically retrieves these values. For new executives, there's no need to reconfigure the retention policy because these new users with their corresponding values for email and OneDrive are automatically picked up.

- A **static scope** doesn't use queries and is limited in configuration in that it can apply to all instances for a specified location, or use inclusion and exclusions for specific instances for

that location. These three choices are sometimes referred to as "org-wide," "includes," and "excludes" respectively.

Example: Emails and OneDrive documents for executives require a longer retention period than standard users. You create a retention policy with a static scope that selects the Exchange email and OneDrive accounts locations for the policy. For the Exchange email location, you're able to identify a group that contains just the executives, so you specify this group for the retention policy, and the group membership with the respective email addresses is retrieved when the policy is created. For the OneDrive accounts location, you must identify and then specify individual OneDrive URLs for each executive. For new executives, you must reconfigure the retention policy to add the new email addresses and OneDrive URLs. You must also update the OneDrive URLs anytime there is a change in an executive's UPN.

OneDrive URLs are particularly challenging to reliably specify because by default, these URLs aren't created until the user accesses their OneDrive for the first time. And if a user's UPN changes, which you might not know about, their OneDrive URL automatically changes.

Advantages of using adaptive scopes over static scopes:

- No limits on the number of items per policy. Although adaptive policies are still subject to the maximum number of policies per tenant limitations, the more flexible configuration will likely result in far fewer policies.
- You can apply specific retention settings to just inactive mailboxes. This configuration isn't possible with a static scope because at the time the policy is assigned, static scopes don't support the specific inclusion of recipients with inactive mailboxes.

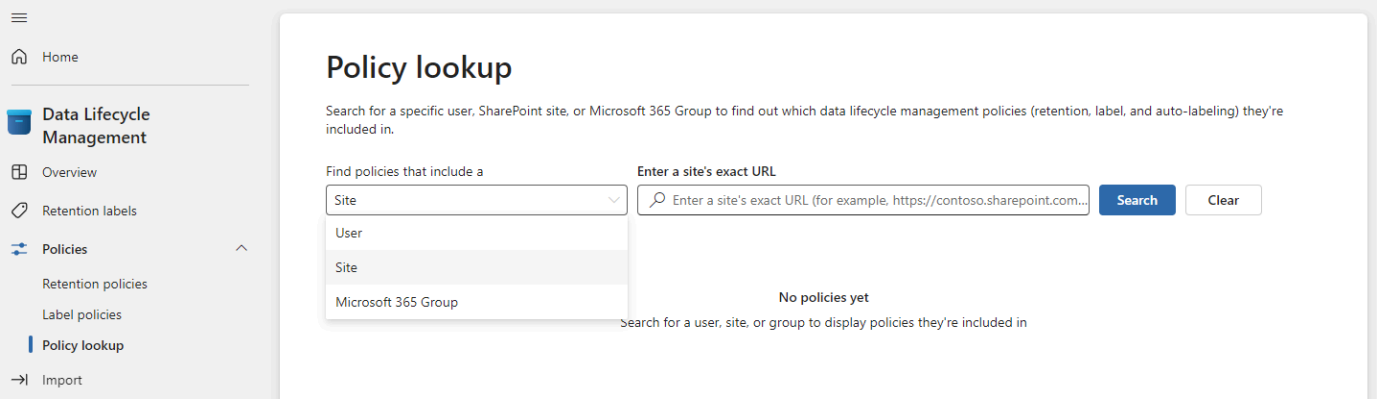
For more advantages of using adaptive scopes, see Adaptive scopes.

Advantages of using static scopes over adaptive scopes:

- Simpler configuration if you want all instances automatically selected for a workload.

  For "includes" and "excludes," this choice can be a simpler configuration initially if the numbers of instances that you have to specify are low and don't change. However, when these number of instances start to increase and you have frequent changes in your organization that require you to reconfigure your policies, adaptive scopes can be simpler to configure and easier to maintain.

- The **Skype for Business** and **Exchange public folders** locations don't support adaptive scopes. For those locations, you must use a static scope.



For configuration information, see Configuring adaptive scopes.

Currently, adaptive scopes don't support Preservation Lock to restrict changes to retention policies and retention label policies.

Policy lookup

You can configure multiple retention policies for Microsoft 365 locations, as well as multiple retention label policies that you publish or auto-apply. To find the policies for retention that are assigned to specific users, sites, and Microsoft 365 groups, use **Policy lookup** from the **Data lifecycle management** or **Records management** solutions in the Microsoft Purview portal.

For example, from the Microsoft Purview portal:

You must specify the exact email address for a user, exact URL for a site, or exact email address for a Microsoft 365 group. You can't use wildcards, or partial matches, for example.

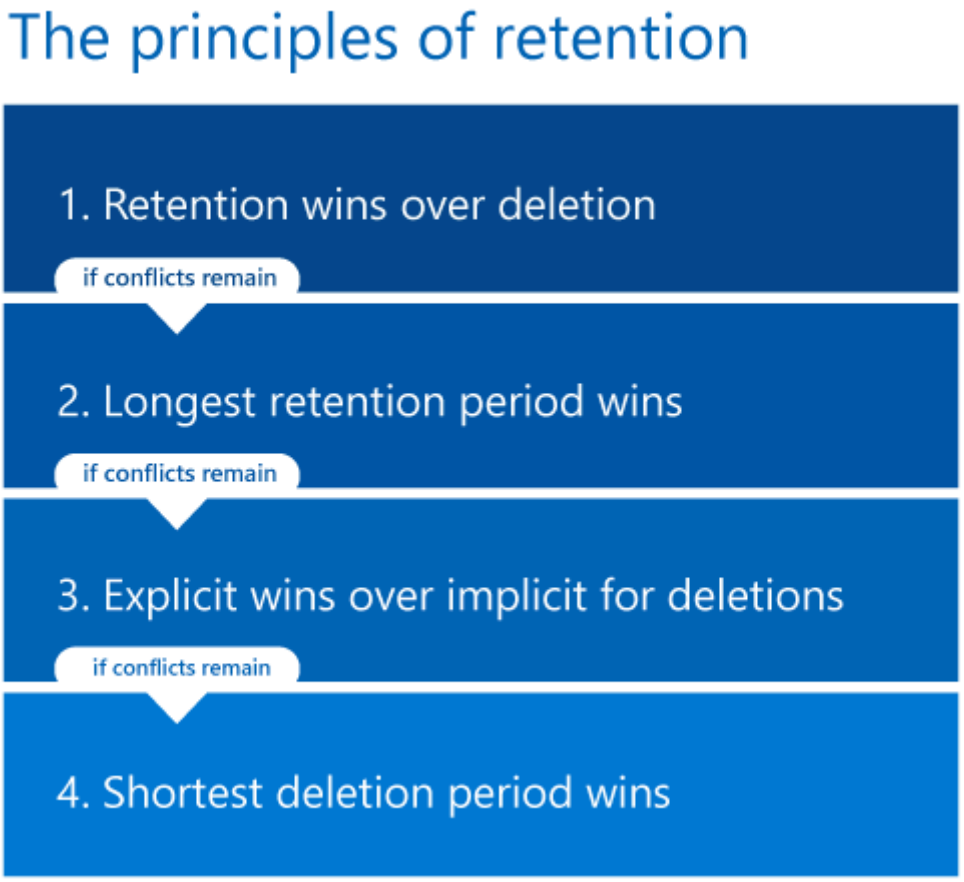
The option for sites includes OneDrive accounts. For information how to specify the URL for a user's OneDrive account, see Get a list of all user OneDrive URLs in your organization.

The principles of retention, or what takes precedence?

Unlike retention labels, you can apply more than one retention policy to the same content. Each retention policy can result in a retain action and a delete action. Additionally, that item could also be subject to these actions from a retention label.

In this scenario, when items can be subject to multiple retention settings that could conflict with one another, what takes precedence to determine the outcome?

The outcome isn't which single retention policy or single retention label wins, but how long an item is retained (if applicable) and when an item is deleted (if applicable). These two actions are calculated independently from each other, from all the retention settings applied to an item.



For example, an item might be subject to one retention policy that is configured for a delete-only action, and another retention policy that is configured to retain and then delete. Consequently, this item has just one retain action but two delete actions. The retention and deletion actions could be in conflict with one another and the two deletion actions might have a conflicting date. The principles of retention explain the outcome.

By default, retention always takes precedence over permanent deletion, and the longest retention period wins. These two simple rules always decide how long an item is retained unless it's subject to priority cleanup that might be needed to expedite permanent deletion for exceptional circumstances.

If you're not using priority cleanup, there are a few more factors that determine when an item is permanently deleted, which include the delete action from a retention label always takes precedence over the delete action from a retention policy.

Use the following flow to understand the retention and deletion outcomes for a single item that isn't subject to priority cleanup, where each level acts as a tie-breaker for conflicts, from top to bottom. If the outcome is determined by the first level because there are no further conflicts, there's no need to progress to the next level, and so on.

> **Important**
>
> If you are using retention labels: Before applying the principles to determine the outcome of multiple retention settings on the same item, make sure you know **which retention label is applied**.

Before explaining each principle in more detail, it's important to understand the difference between the retention period for the item vs. the specified retention period in the retention policy or retention label. That's because although the default configuration is to start the retention period when an item is created, so that the end of the retention period is fixed for the item, files also support the configuration to start the retention period from when the file is last modified. With this alternative configuration, every time the file is modified, the start of the retention period is reset, which extends the end of the retention period for the item. Retention labels also support starting the retention period when labeled and at the start of an event.

To apply the principles in action with a series of Yes and No questions, you can also use the retention flowchart.

Explanation for the four different principles:

1. **Retention wins over deletion.** Content won't be permanently deleted when it also has retention settings to retain it. While this principle ensures that content is preserved for compliance reasons, the delete process can still be initiated (user-initiated or system-initiated) and consequently, might remove the content from users' main view. However, permanent deletion is suspended. For more information about how and where content is retained, use the following links for each workload:

- How retention works for SharePoint and OneDrive
- How retention works with Microsoft Teams
- How retention works with Viva Engage
- How retention works for Exchange
- How retention works with Copilot & AI apps

Example for this first principle: An email message is subject to a retention policy for Exchange that is configured to delete items three years after they are created, and it also has a retention label applied that is configured to retain items five years after they are created.

The email message is retained for five years because this retention action takes precedence over deletion. The email message is permanently deleted at the end of the five years because of the delete action that was suspended while the retention action was in effect.

2. **The longest retention period wins.** If content is subject to multiple retention settings that retain content for different periods of time, the content is retained until the end of the longest retention period for the item.

   > ⓘ **Note**
   >
   > It's possible for a retention period of five years in a retention policy or label wins over a retention period of seven years in a retention policy or label, because the 5-year period is configured to start based on when the file is last modified, and the seven year period is configured to start from when the file is created.

   Example for this second principle: Documents in the Marketing SharePoint site are subject to two retention policies. The first retention policy is configured for all SharePoint sites to retain items for five years after they are created. The second retention policy is configured for specific SharePoint sites to retain items for 10 years after they are created.

   Documents in this Marketing SharePoint site are retained for 10 years because that's the longest retention period for the item.

3. **Explicit wins over implicit for deletions.** With conflicts now resolved for retention, only conflicts for deletions remain:

   a. A retention label (however it was applied) provides explicit retention in comparison with retention policies, because the retention settings are applied to an individual item rather

than implicitly assigned from a container. This means that a delete action from a retention label always takes precedence over a delete action from any retention policy.

Example 1 for this third principle (label): A document is subject to two retention policies that have a delete action of five years and 10 years respectively, and also a retention label that has a delete action of seven years.

The document is permanently deleted after seven years because the delete action from the retention label takes precedence.

Example 2 for this third principle (label): A document in the Marketing SharePoint site is subject to both a retention policy and a retention label. The retention policy is configured to retain items in all SharePoint sites for 10 years after creation, while the retention label specifies a delete action after seven years.

In this case, the document is retained for 10 years, which is the longest retention period. Because the retention label's delete action takes precedence, the document is permanently deleted after 10 years. The item is not moved to the Preservation Hold Library (PHL).

Example 3 for this third principle (label): An email message is subject to one retention policy and a retention label. The retention policy is configured for all Exchange mailboxes to retain items for 10 years after they are creation, and the retention label specifies a delete action after seven years.

The email message is retained for 10 years, which is the longest retention period. After seven years, the retention label causes the item to be moved to the Recoverable Items folder. The item remains there until the 10 year retention period expires, after which it is permanently deleted.

b. When you have retention policies only: If a retention policy for a location uses an adaptive scope or a static scope that includes specific instances (such as specific users for Exchange email) that retention policy takes precedence over a static scope that is configured for all instances for the same location.

   A static scope that is configured for all instances for a location is sometimes referred to as an "org-wide policy". For example, **Exchange mailboxes** and the default setting of **All mailboxes**. Or, **SharePoint classic and communication sites** and the default setting of **All sites**. When retention policies aren't org-wide but have been configured with an adaptive scope or a static scope that includes specific instances, they have equal precedence at this level.

Example 1 for this third principle (policies): An email message is subject to two retention policies. The first retention policy is unscoped and deletes items after 10 years. The second retention policy is scoped to specific mailboxes and deletes items after five years.

The email message is permanently deleted after five years because the deletion action from the scoped retention policy takes precedence over the org-wide retention policy.

Example 2 for this third principle (policies): A document in a user's OneDrive account is subject to two retention policies. The first retention policy is scoped to include this user's OneDrive account and has a delete action after 10 years. The second retention policy is scoped to include this user's OneDrive account and has a delete action after seven years.

When this document will be permanently deleted can't be determined at this level because both retention policies are scoped to include specific instances.

4. **The shortest deletion period wins.** Applicable to determine when items will be deleted from retention policies and the outcome couldn't be resolved from the previous level: Content is permanently deleted at the end of the shortest retention period for the item.

   > ⓘ **Note**
   >
   > It's possible that a retention policy that has a retention period of seven years wins over a retention policy of five years because the first policy is configured to start the retention period based on when the file is created, and the second retention policy from when the file is last modified.

   Example for this fourth principle: A document in a user's OneDrive account is subject to two retention policies. The first retention policy is scoped to include this user's OneDrive account and has a delete action of 10 years after the file is created. The second retention policy is scoped to include this user's OneDrive account and has a delete action of seven years after the file is created.

   This document will be permanently deleted after seven years because that's the shortest retention period for the item from these two scoped retention policies.

Items subject to eDiscovery hold also fall under the first principle of retention; they cannot be permanently deleted by any retention policy or retention label. When that hold is released, the principles of retention continue to apply to them. For example, they could then be subject to an unexpired retention period or a delete action.

Principles of retention examples that combine retain and delete actions

The following examples are more complex to illustrate the principles of retention when different retain and delete actions are combined. To make the examples easier to follow, all retention policies and labels use the default setting of starting the retention period when the item is created so the end of the retention period is the same for the item.

1. An item has the following retention settings applied to it:

   - A retention policy for delete-only after five years
   - A retention policy that retains for three years and then deletes
   - A retention label that retains-only for seven years

   Outcome: The item is retained for seven years because retention takes precedence over deletion and seven years is the longest retention period for the item. At the end of this retention period, the item is permanently deleted because of the delete action from the retention policies.

   Although the two retention policies have different dates for the delete actions, the earliest that the item can be permanently deleted is at the end of the longest retention period, which is longer than both deletion dates.

2. An item has the following retention settings applied to it:

   - An org-wide retention policy that deletes-only after 10 years
   - A retention policy scoped with specific instances that retains for five years and then deletes
   - A retention label that retains for three years and then deletes

   Outcome: The item is retained for five years because that's the longest retention period for the item. At the end of that retention period, the item is permanently deleted because of the delete action of three years from the retention label. Deletion from retention labels takes precedence over deletion from all retention policies. In this example, all conflicts are resolved by the third level.

Use Preservation Lock to restrict changes to policies

Some organizations might need to comply with rules defined by regulatory bodies such as the Securities and Exchange Commission (SEC) Rule 17a-4, which requires that after a policy for

retention is turned on, it cannot be turned off or made less restrictive.

Preservation Lock ensures your organization can meet such regulatory requirements because it locks a retention policy or retention label policy so that no one—including an administrator—can turn off the policy, delete the policy, or make it less restrictive.

You apply Preservation Lock after the retention policy or retention label policy is created. For more information and instructions, see Use Preservation Lock to restrict changes to retention policies and retention label policies.

Releasing a policy for retention

Providing your policies for retention don't have a Preservation Lock, you can delete your policies at any time, which effectively turns off the retention settings for a retention policy, and retention labels can no longer be applied from retention label policies. Any previously applied retention labels remain with their configured retention settings and for these labels, you can still update the retention period when it's not based on when items were labeled.

You can also keep a policy, but change the location status to off, or disable the policy. Another option is to reconfigure the policy so it no longer includes specific users, sites, groups, and so on.

Additional information for specific locations:

- **SharePoint sites and OneDrive accounts:**

  When you release a retention policy for SharePoint sites and OneDrive accounts, any content that's subject to retention from the policy continues to be retained for 30 days to prevent inadvertent data loss. During this 30-day grace period deleted files are still retained (files continue to be added to the Preservation Hold library), but the timer job that periodically cleans up the Preservation Hold library is suspended for these files so you can restore them if necessary.

  An exception to this 30-day grace period is when you update the policy to exclude one or more sites for SharePoint or accounts for OneDrive; in this case, the timer job deletes files for these locations in the Preservation Hold library without the 30-day delay.

  For more information about the Preservation Hold library, see How retention works for SharePoint and OneDrive.

  Because of the behavior during the grace period, if you re-enable the policy or change the location status back to on within 30 days, the policy resumes without any permanent data

loss during this time.

- **Exchange email and Microsoft 365 Groups**

  When you release a retention policy for mailboxes that are inactive at the time the policy is released:

  - If the retention policy is explicitly applied to a mailbox, the retention settings no longer apply. With no retention settings applied, an inactive mailbox becomes eligible for automatic deletion in the usual way.

    An explicit retention policy requires either an adaptive policy scope, or a static policy scope with an include configuration that specified an active mailbox at the time the policy was applied and later became inactive

  - If the retention policy is implicitly applied to a mailbox and the configured retention action is to retain, the retention policy continues to apply and an inactive mailbox never becomes eligible for automatic deletion. When the retain action no longer applies because the retention period has expired, the Exchange admin can now manually delete the inactive mailbox

    An implicit retention policy requires a static policy scope with the **All mailboxes** (for Exchange email) or **All groups** (for Microsoft 365 Groups) configuration.

    For more information about inactive mailboxes that have retention policies applied, see Inactive mailboxes and Microsoft 365 retention.

Auditing retention configuration and actions

When auditing is enabled, auditing events for retention are supported for both administration configuration (retention policies and retention labels) and retention actions (retention labels only).

Auditing retention configuration

Administrator configuration for retention policies and retention labels is logged as auditing events when a retention policy or label is created, reconfigured, or deleted.

For the full list of auditing events, see Retention policy and retention label activities.

Auditing retention actions

Retention actions that are logged as auditing events are available only for retention labels and not for retention policies:

- Specific to priority cleanup, use the **Cleanup ID** assigned to the priority cleanup policy as a keyword search term in the auditing log to find related activities.
- Specific to Adaptive Protection when a retention label is applied to an item:
  - For SharePoint and OneDrive, from **Retention policy and retention label activities**, select **Retained file proactively**
  - For Exchange, from **Retention policy and retention label activities**, select **Retained email item proactively**
- When a retention label is applied, changed, or removed from an item in SharePoint or OneDrive:
  - From **File and page activities**, select **Changed retention label for a file**
- When a labeled item in SharePoint is marked as a record, and it is unlocked or locked by a user:
  - From **File and page activities**, select **Changed record status to unlocked** and **Changed record status to locked**
- When a retention label that marks content as a record or regulatory record is applied to an item in Exchange:
  - From **Exchange mailbox activities**, select **Labeled message as a record**
- When a labeled item in SharePoint, OneDrive, or Exchange is marked as a record or regulatory record, and it is permanently deleted:
  - From **File and page activities**, select **Deleted file marked as a record**
- When a disposition reviewer takes action for an item that's reached the end of its retention period:
  - From **Disposition review activities**, select **Approved disposal**, **Extended retention period**, **Relabeled item**, or **Added reviewers**

PowerShell cmdlets for retention policies and retention labels

Use Security & Compliance PowerShell for Purview retention cmdlets that support configuration at scale, scripting for automation, or might be necessary for advanced configuration scenarios.

For a list of available cmdlets, and to identify which ones are supported for the different locations, see PowerShell cmdlets for retention policies and retention labels.

When to use retention policies and retention labels or eDiscovery holds

Although retention settings and holds that you create with an eDiscovery case can both prevent data from being permanently deleted, they are designed for different scenarios. To help you understand the differences and decide which to use, use the following guidance:

- Retention settings that you specify in retention policies and retention labels are designed for a long-term data lifecycle management strategy to retain or delete data for compliance requirements. The scope is usually broad with the main focus being the location and content rather than individual users. The start and end of the retention period is configurable, with the option to automatically delete content without additional administrator intervention.
- Holds for eDiscovery cases are designed for a limited duration to preserve data for a legal investigation. The scope is specific with the focus being content owned by identified users. The start and end of the preservation period isn't configurable but dependent on individual administrator actions, without an option to automatically delete content when the hold is released.

Summary to compare retention with holds:

Expand table

Consideration	Retention	eDiscovery holds
Business need:	Compliance	Legal
Time scope:	Long-term	Short-term
Focus:	Broad, content-based	Specific, user-based
Start and end date configurable:	Yes	No
Content deletion:	Yes (optional)	No
Administrative overheads:	Low	High

If content is subject to both retention settings and an eDiscovery hold, preserving content for the eDiscovery hold always takes precedence. In this way, the principles of retention expand to

eDiscovery holds because they preserve data until an administrator manually releases the hold. However, despite this precedence, don't use eDiscovery holds for long-term data lifecycle management. If you are concerned about automatic deletion of data, you can configure retention settings to retain items forever, or use disposition review with retention labels.

If you are using older eDiscovery tools to preserve data, see the following resources:

- Exchange:
  - In-Place Hold and Litigation Hold
  - How to identify the type of hold placed on an Exchange Online mailbox
- SharePoint and OneDrive:
  - Add content to a case and place sources on hold in the eDiscovery Center
- Retirement of legacy eDiscovery tools

Use retention policies and retention labels instead of older features

If you need to retain or delete content in Microsoft 365 for data lifecycle management, we recommend you use Microsoft 365 retention policies and retention labels instead of the following older features.

If you currently use these older features, they'll usually work side by side with Microsoft 365 retention policies and retention labels. Check their specific documentation for any restrictions. However, we recommend that going forward, you use Microsoft 365 retention policies and retention labels to benefit from a single solution to manage both retention and deletion of content across multiple workloads in Microsoft 365.

> **Tip**
>
> For SharePoint, see the following resources:
>
> - Use Microsoft Purview risk and compliance solutions instead of the older information management and records management features in SharePoint for Microsoft 365
> - Migration strategies for moving to Microsoft Purview risk and compliance solutions

Older features from Exchange Online:

- Retention tags and retention policies, also known as messaging records management (MRM) (deletion only)

  However, if you use the following MRM features, be aware that they aren't currently supported by Microsoft 365 retention policies:

  - An archive policy for archive mailboxes to automatically move emails from a user's primary mailbox to their archive mailbox after a specified period of time. An archive policy (with any settings) can be used in conjunction with a Microsoft 365 retention policy that applies to a user's primary and archive mailbox.
  - Retention policies applied by an admin to specific folders within a mailbox. A Microsoft 365 retention policy applies to all folders in the mailbox. However, an admin can configure different retention settings by using retention labels that a user can apply to folders in Outlook as a default retention label.

- Journaling (retention and archive)

  Might be required to integrate with third-party solutions and copies of email messages and their data communication are stored outside Exchange Online. Because you're moving data outside Microsoft 365, you must take extra precautions to secure it and also resolve any duplications that might result from this solution. It is your responsibility to monitor and follow up on any nondelivery receipts to the journaling mailbox that can occur because of external and dependent services. You don't have these additional administrative overheads when you use Microsoft 365 retention and other Microsoft Purview compliance solutions that also aren't limited to just email messages.

- Litigation hold (retention only)

  Although Litigation holds are still supported, we recommend you use Microsoft 365 retention or eDiscovery holds, as appropriate.

Older features from SharePoint and OneDrive:

- Document deletion policies (deletion only)
- Configuring in place records management (retention only)
- Use policies for site closure and deletion (deletion only)
- Information management policies (deletion only)

If you have configured SharePoint sites for content type policies or information management policies to retain content for a list or library, those policies are ignored while a retention policy or retention label policy is in effect.

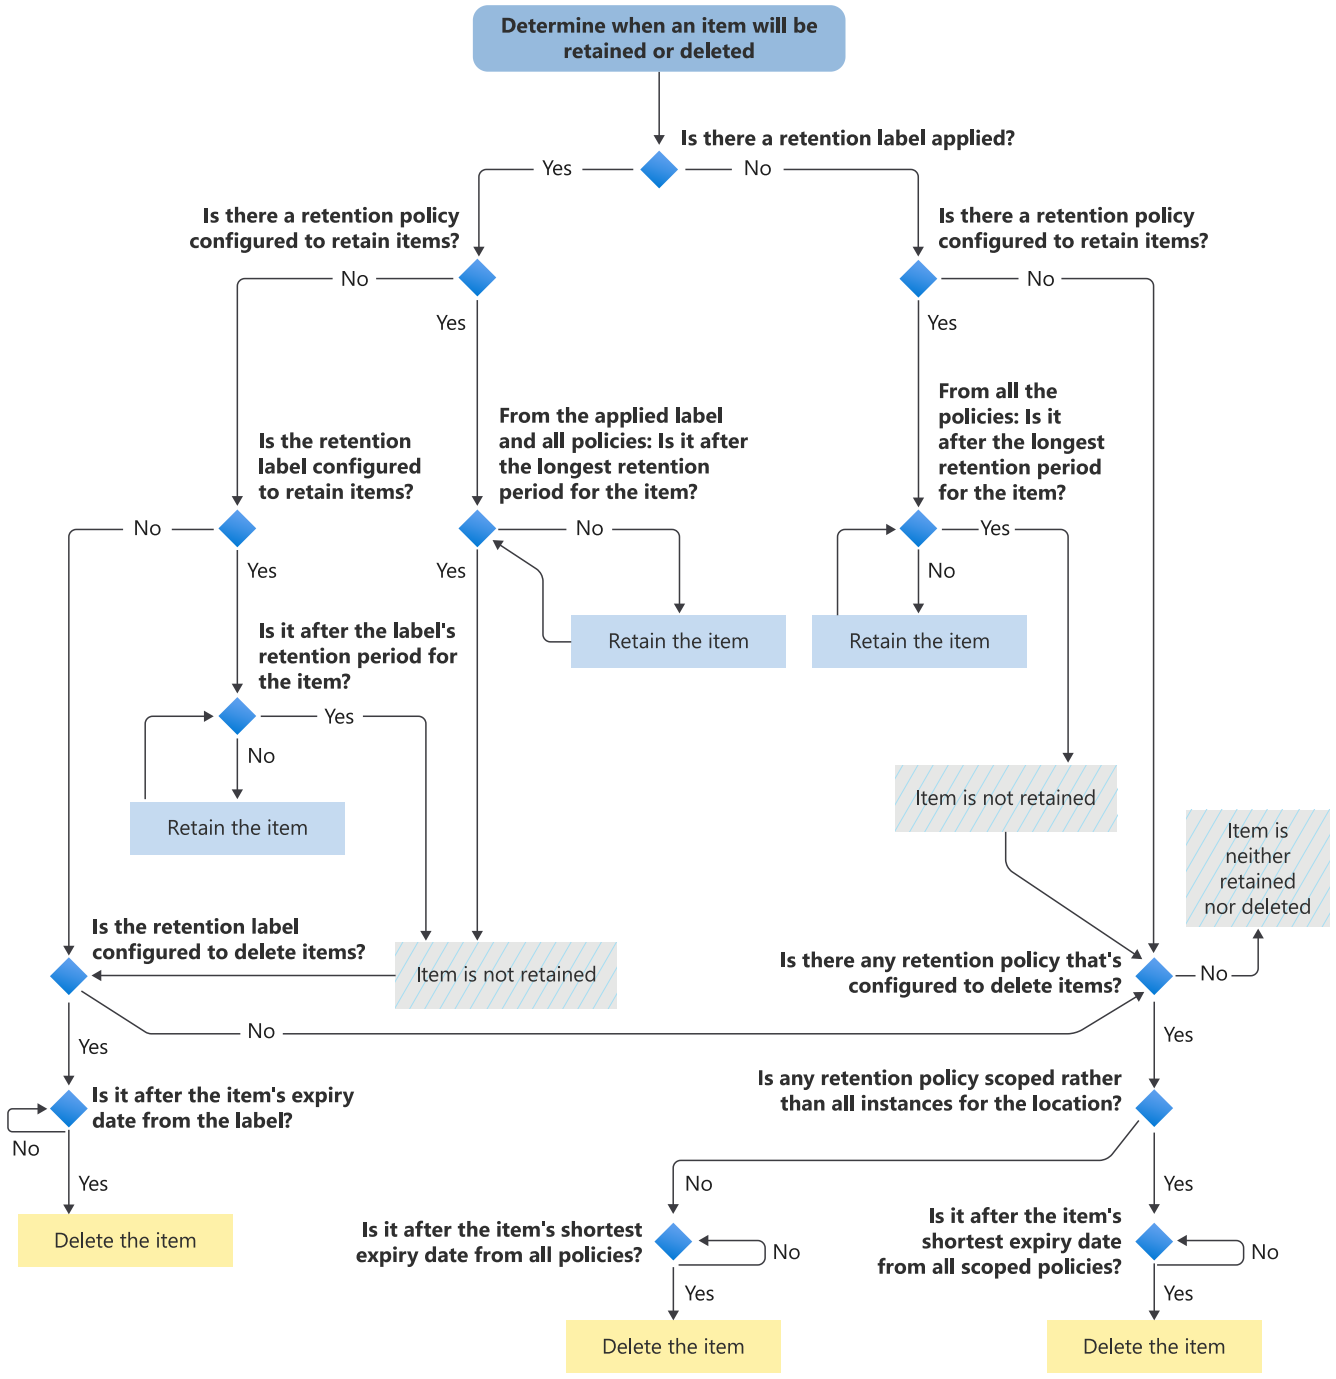
Flowchart to determine when an item will be retained or permanently deleted

Summarize this article for me

> *Microsoft Purview service description*



Use the following flowchart to apply the principles of retention to an item to determine if the system will retain it or permanently delete it as a result of a retention label or retention policy.

This logic flow is used for an item when any of the following conditions apply:

- There's more than one retention policy applied
- There's a retention label and one or more retention policies
- The item isn't subject to priority cleanup

When an item is subject to an eDiscovery hold (or the older technologies of Litigation hold or In-Place Hold), unless it is also subject to priority cleanup, it is always retained before the decision flows for retention policies and a retention label.

If any of the terms used in this flowchart are unfamiliar to you, see Learn about retention policies and retention labels.

> **Note**
>
> It's important to distinguish between the longest retention period for the item vs. the longest specified period in a retention policy or label. And similarly, between the shortest expiry date for the item vs. the shortest specified period in a retention policy.
>
> For more information, see the explanation after the graphic in the principles of retention section.

Learn about retention for SharePoint and OneDrive

09/22/2025

> *Microsoft 365 licensing guidance for security & compliance*.

The information in this article supplements Learn about retention because it has information that's specific to SharePoint and OneDrive.

For other workloads, see:

- Learn about retention for Microsoft Teams
- Learn about retention for Viva Engage
- Learn about retention for Exchange
- Learn about retention for Copilot

What's included for retention and deletion

> **Note**
>
> In preview, Microsoft Facilitator AI-generated notes in meetings are supported by retention policies and retention labels.

All files stored in SharePoint (and SharePoint Embedded) or OneDrive sites can be retained by applying a retention policy or retention label. For SharePoint, archived sites are supported in addition to active sites.

The following files can be deleted:

- When you use a retention policy: All files in document libraries, which include any automatically created SharePoint document libraries, such as **Site Assets**.
- When you use retention labels: All files in all document libraries, and all files at the root level that aren't in a folder.

> **Tip**

When you use a **query with an auto-apply policy for a retention label**, you can exclude specific document libraries by using the following entry: `NOT(DocumentLink:"<URL to document library>")`

Files that can be retained and deleted include those used by Microsoft Loop and Copilot Pages. For these apps, content can be stored in SharePoint Embedded containers. Although the containers aren't SharePoint sites, for the purposes of retention and deletion, they behave the same as SharePoint sites. For more information about where the files are stored, see Overview of Loop storage.

List items aren't supported by retention policies but are supported by retention labels with the exception of items in system lists. These are hidden lists used by SharePoint to manage the system and include the master page catalog, solution catalog, and data sources. When retention labels are applied to supported list items, they will always be retained according to the retention settings, but not deleted if they are hidden from search.

When you apply a retention label to a supported list item that has a document attachment:

- For a standard retention label (doesn't declare the item to be a record):
  - The document attachment doesn't automatically inherit the retention settings of the label, but can be labeled independently.
- For a retention label that declares the item a record:
  - The document attachment automatically inherits the retention settings from the label if the document isn't already labeled.

Retention settings from both retention policies and retention labels don't apply to organizing structures that include libraries, lists, folders, and Loop workspaces.

For retention policies and label policies: SharePoint sites must be indexed for the retention settings to be applied. However, if items in SharePoint document libraries are configured to not appear in search results, this configuration doesn't exclude files from the retention settings.

If a site is configured with the Set-SPOSite parameter *LockState* that's set to NoAccess or ReadOnly, items in that site can't be deleted with this site configuration.

How retention works for SharePoint and OneDrive

To store content that needs to be retained, SharePoint and OneDrive create a Preservation Hold library if one doesn't exist for the site. The Preservation Hold library is a hidden system location that isn't designed to be used interactively but instead, automatically stores files when this is needed for compliance reasons. It's not supported to edit, delete, or move these automatically retained files yourself. Or, change or remove retention labels and sensitivity

labels for these files. Instead, use compliance tools, such as those supported by eDiscovery to access the content in these files.

The Preservation Hold library works in the following way to support retention policies and retention labels:

When a user changes an item that's subject to retention from a retention policy or a retention label that marks items as a record, or deletes any item subject to retention, the original content is copied to the Preservation Hold library. This behavior lets the user change or delete the content in their app, while keeping a copy of the original for compliance reasons.

Expand table

Retention item	User edit or delete action	Copy created in the Preservation Hold library
Retention policy	Edit item	Yes *
	Delete item	Yes
Standard retention label (doesn't mark items as records or regulatory records)	Edit item	No
	Delete item	Yes
Retention label that marks items as records	Edit unlocked item	Yes
	Edit locked item	Not applicable – action blocked
	Delete item	Not applicable – action blocked
Retention label that marks items as regulatory records	Edit item	Not applicable – action blocked
	Delete item	Not applicable – action blocked

Footnote:

* New content isn't copied to the Preservation Hold library the first time it's edited. To retain all versions of a file, versioning must be turned on for the site.

This behavior for copying files into the Preservation Hold library applies to content that exists when the retention settings were applied. In addition, for retention policies, any new content that's created or added to the site after it was included in the policy will be retained in the Preservation Hold library.

A timer job periodically runs on the Preservation Hold library. For content that has been in the Preservation Hold library for more than 30 days, this job compares the content to all queries

used by the retention settings for that content. Content that is older than their configured retention period and isn't awaiting disposition review is then deleted from the Preservation Hold library, and from the original location if it's still there. This timer job runs every seven days, which means that together with the minimal 30 days, it can take up to 37 days for content to be deleted from the Preservation Hold library.

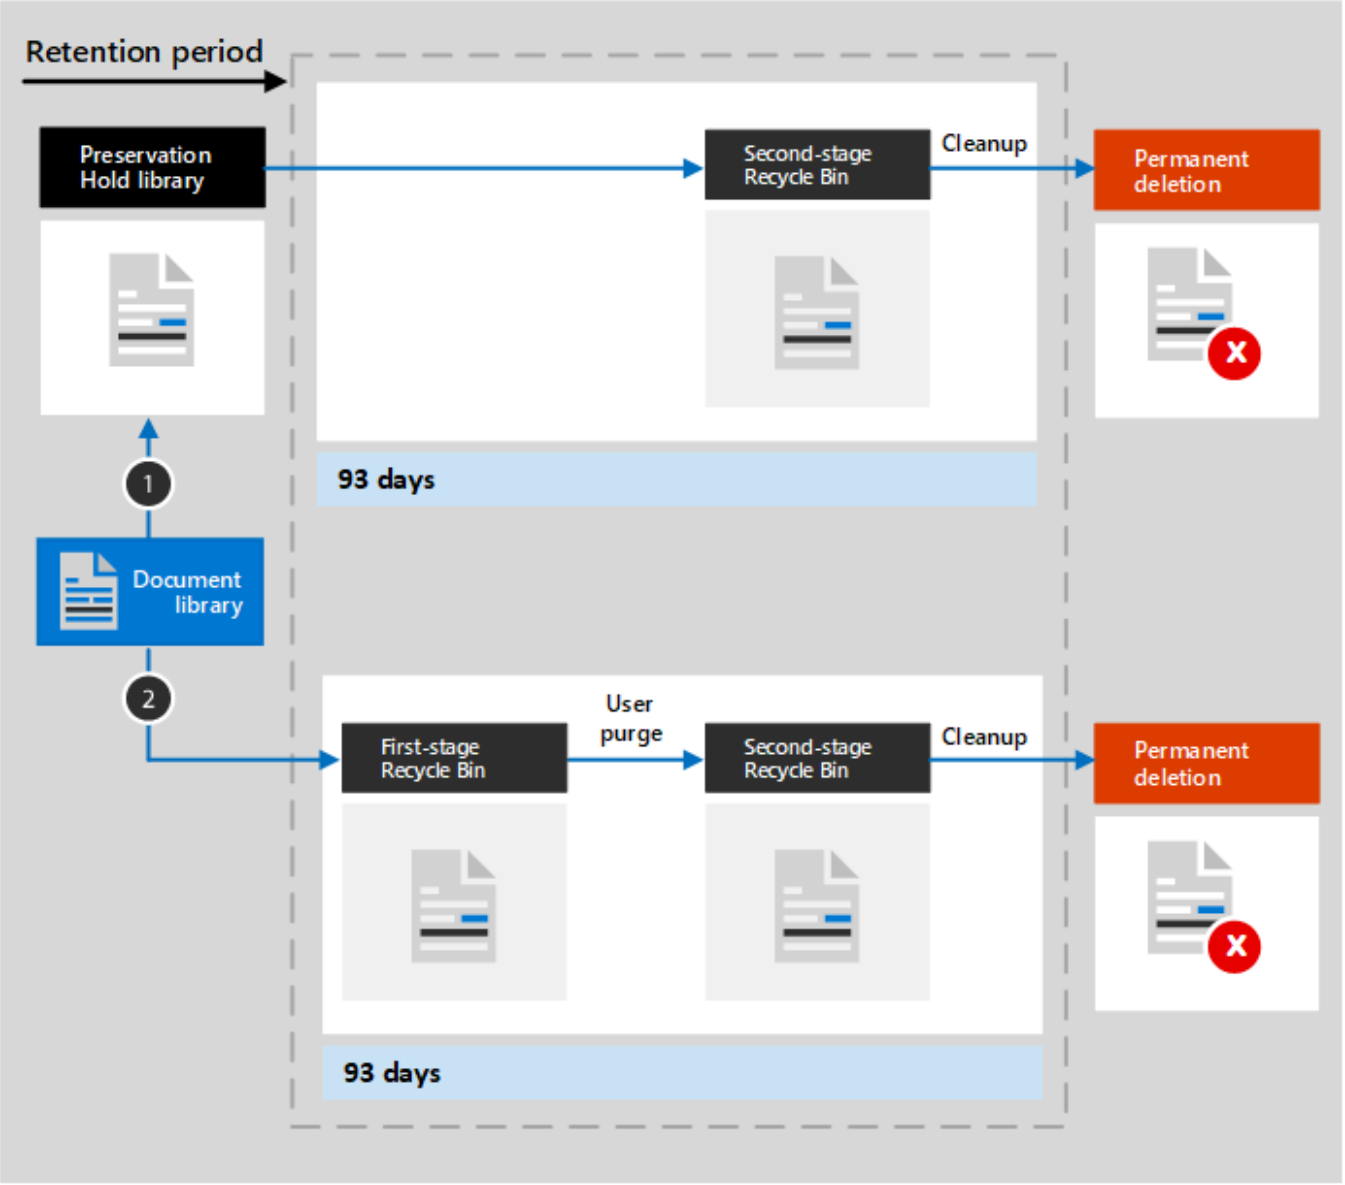
Users see an error message if they try to delete a library, list, or site that's subject to retention.

Users also see an error message if they try to delete a labeled item in any of the following circumstances. The item isn't copied to the Preservation Hold library but remains in the original location:

- The records management setting that allows users to delete labeled items is turned off.

  To check or change this setting, go to the records management settings in the Microsoft Purview portal: **Settings** > **Solution settings **> Records Management > **Retention Labels** > **Deleting content labeled for retention**. There are separate settings for OneDrive and SharePoint.

  Alternatively, and if you don't have access these settings in the portals, you can use *AllowFilesWithKeepLabelToBeDeletedSPO* and *AllowFilesWithKeepLabelToBeDeletedODB* from Get-PnPTenant and Set-PnPTenant.



- The retention label marks items as a record and it's locked.

  Only when the record is unlocked, does a copy of the last version get stored in the Preservation Hold library.

- The retention label marks items as a regulatory record, which always prevents the item from being edited or deleted.

After retention settings are assigned to content in a OneDrive account, SharePoint site, or SharePoint Embedded container for a Loop workspace, the paths the content takes depend on whether the retention settings are to retain and delete, to retain only, or delete only. In the explanations that follow, modified content is moved to the Preservation Hold library for retention policies, and retention labels that mark items as records (and the content is unlocked). Items that are modified with retention labels that don't mark items as records don't create copies in the Preservation Hold library, but do when items are deleted.

When the retention settings are to retain and delete:

1. **If the content is modified or deleted** during the retention period, a copy of the original content as it existed when the retention settings were assigned is created in the Preservation Hold library. There, the timer job identifies items whose retention period has expired. Those items are moved to the second-stage Recycle Bin, where they're permanently deleted at the end of 93 days. The second-stage Recycle Bin isn't visible to end users (only the first-stage Recycle Bin is), but site collection admins can view and restore content from there.

> ⓘ Note
>
> To help prevent inadvertent data loss, we no longer permanently delete content from the Preservation Hold library. Instead, we permanently delete content only from the Recycle Bin, so all content from the Preservation Hold library now goes through the second-stage Recycle Bin.

2. **If the content is not modified or deleted** during the retention period, the timer job moves this content to the first-stage Recycle Bin at the end of the retention period. If a user deletes the content from there or empties this Recycle Bin (also known as purging), the document is moved to the second-stage Recycle Bin. A 93-day retention period spans both the first- and second-stage recycle bins. At the end of 93 days, the document is permanently deleted from wherever it resides, in either the first-stage or second-stage Recycle Bin. The Recycle Bin isn't indexed and therefore unavailable for searching. As a result, an eDiscovery search can't find any Recycle Bin content on which to place a hold.

> ⓘ **Note**
>
> Because of the first principle of retention, permanent deletion is always suspended if the same item must be retained because of another retention policy or retention label, or it's under eDiscovery holds for legal or investigative reasons.

When the retention settings are retain-only, or delete-only, the contents paths are variations of retain and delete:

Content paths for retain-only retention settings

1. **If the content is modified or deleted** during the retention period: A copy of the original document is created in the Preservation Hold library and retained until the end of the retention period, when the copy in the Preservation Hold library is moved to the second-stage Recycle Bin and is permanently deleted after 93 days.

2. **If the content is not modified or deleted** during the retention period: Nothing happens before and after the retention period; the document remains in its original location.

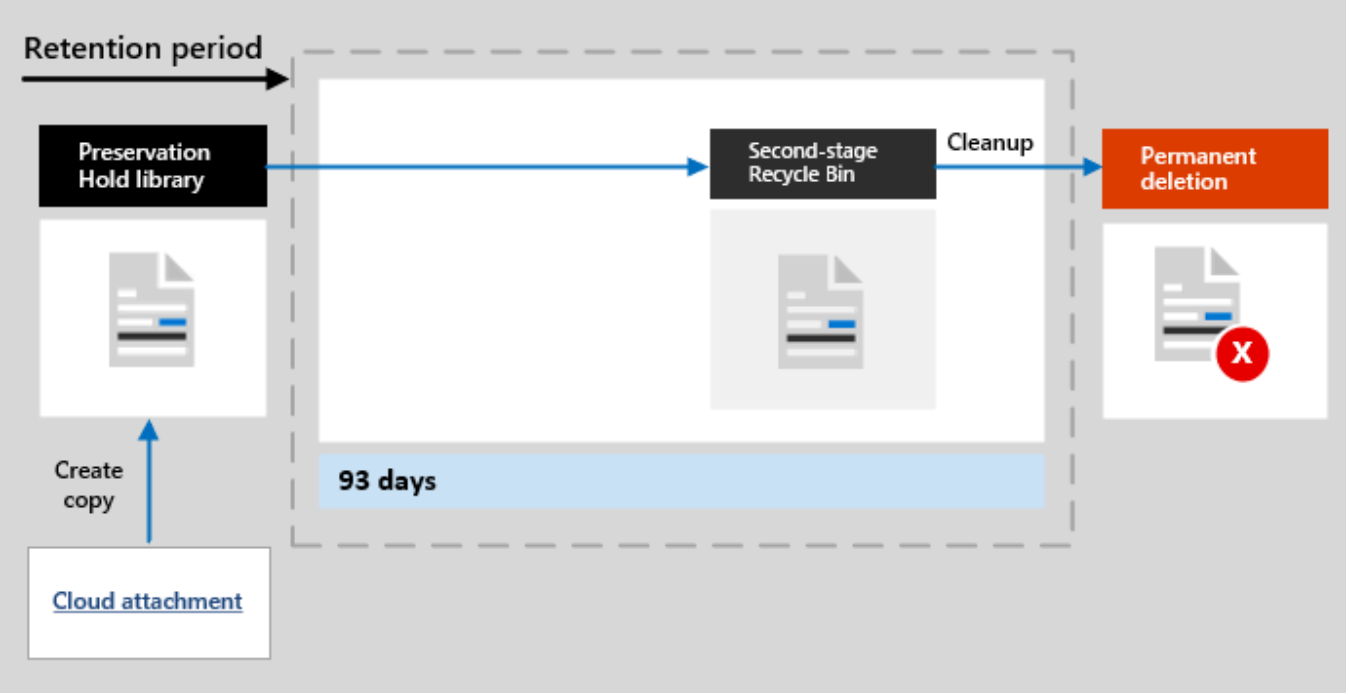
Content paths for delete-only retention settings

1. **If the content is deleted** during the configured period: The document is moved to first-stage Recycle Bin. If a user deletes the document from there or empties this Recycle Bin, the document is moved to the second-stage Recycle Bin. A 93-day retention period spans both the first-stage and second-stage recycle bins. At the end of 93 days, the document is permanently deleted from wherever it resides, in either the first-stage or second-stage Recycle Bin. If the content is modified during the configured period, it follows the same deletion path after the configured period.

2. **If the content is not deleted** during the configured period: At the end of the configured period in the retention policy, the document is moved to the first-stage Recycle Bin. If a user deletes the document from there or empties this Recycle Bin (also known as

purging), the document is moved to the second-stage Recycle Bin. A 93-day retention period spans both the first-stage and second-stage recycle bins. At the end of 93 days, the document is permanently deleted from wherever it resides, in either the first-stage or second-stage Recycle Bin. The Recycle Bin isn't indexed and therefore unavailable for searching. As a result, an eDiscovery search can't find any Recycle Bin content on which to place a hold.

How retention works with cloud attachments



Cloud attachments are embedded links to files that users share, or referenced in interactions for Microsoft 365 Copilot and Microsoft 365 Copilot Chat. They can be retained and deleted when your users share them in Outlook emails and Teams or Viva Engage messages, and they are referenced in interactions with Copilot. When you automatically apply a retention label to cloud attachments, the retention label is applied to a copy of the shared file, which is stored in the Preservation Hold library.

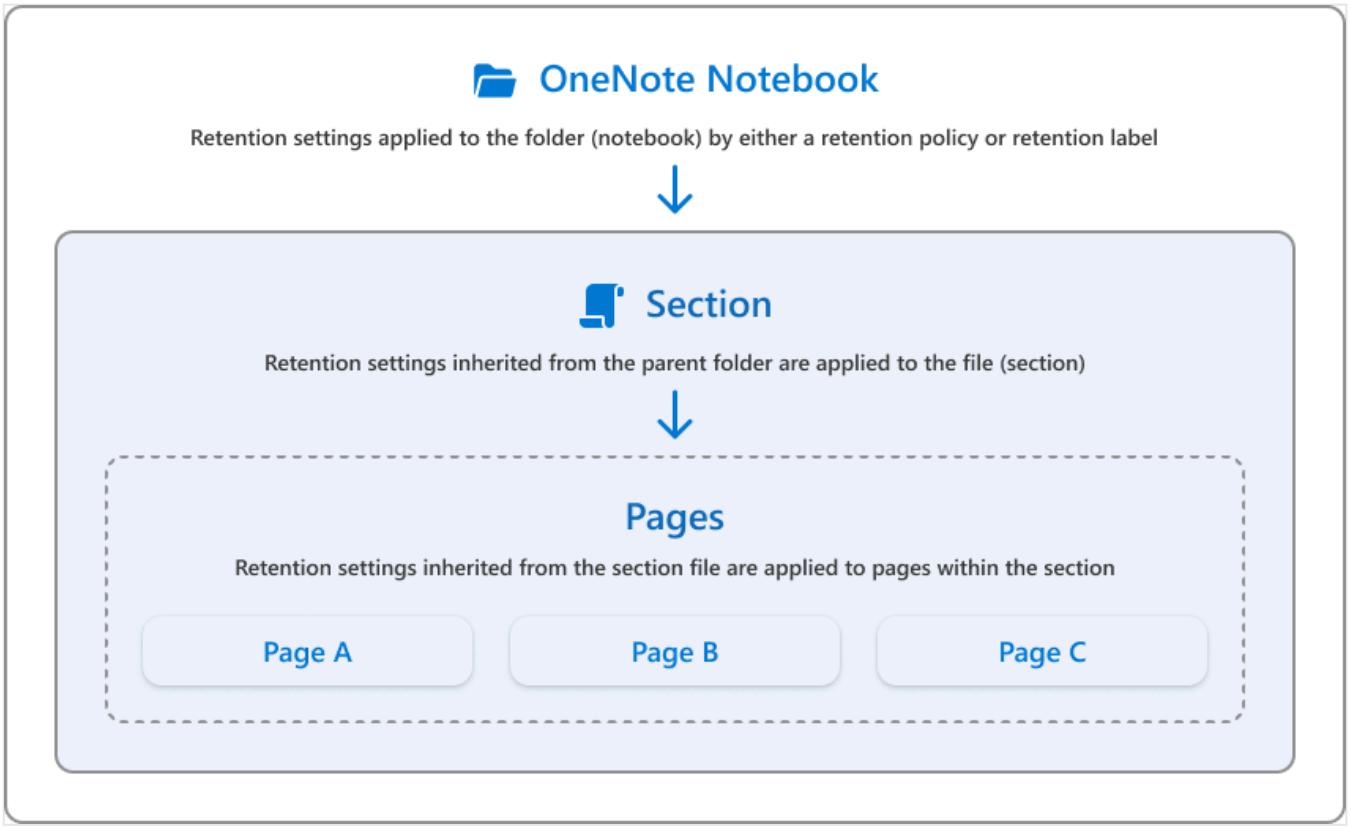
For this scenario, we recommend you configure the label setting to start the retention period based on when the item is labeled. If you do configure the retention period based on when the item is created or last modified, this date is taken from the original file at the time of sharing. If you configure the start of retention to be when last modified, this setting has no effect for this copy in the Preservation Hold library.

However, if the original file is modified and then shared again, a new copy of the file as a new version is saved and labeled in the Preservation Hold library.

If the original file is shared again but not modified, the labeled date of the copy in the Preservation Hold library is updated. This action resets the start of the retention period and is why we recommend you configure the start of the retention period to be based on when the item is labeled.

Because the retention label isn't applied to the original file, the labeled file is never modified or deleted by a user. The labeled file remains in the Preservation Hold library until the timer job identifies that its retention period has expired. If the retention settings are configured to delete items, the file is then moved to the second-stage Recycle Bin, where it's permanently deleted at the end of 93 days:

The copy that's stored in the Preservation Hold library is typically created within an hour from the cloud attachment being shared.



To safeguard against the original file being deleted or moved by users before the copy can be created and labeled, files in locations included in the auto-labeling policy are automatically copied into the Preservation Hold library if they are deleted or moved. These files have a temporary retention period of one day and then follow the standard cleanup process described on this page. When the original file has been deleted or moved, the copy for retaining cloud attachments uses this version of the file. The automatic and temporary retention of deleted or moved files in the Preservation Hold library is unique to auto-labeling policies for cloud attachments.

How retention works with OneNote content

When you apply a retention policy to a location that includes OneNote content, or a retention label to a OneNote folder, the different OneNote sections inherit the retention settings as individual files. Pages from each section are contained within the file and inherit the retention settings from their parent section.

Because of this structure, each section will be individually retained and deleted (with all its pages), according to the retention settings you specify.

Only sections are impacted by the retention settings that you specify. For example, although you see a **Modified** date for each individual notebook, this date isn't used by Microsoft 365 retention.

How retention works with document versions

Versioning is a feature of all document lists and libraries in SharePoint and OneDrive. By default, versioning retains a minimum of 500 major versions, although you can change this limit. For more information, see Enable and configure versioning for a list or library and How versioning works in lists and libraries.

When a document with versions is subject to retention settings to retain that content, and it's not marked as a record, how the versions are stored in the Preservation Hold library changed in July 2022 to improve performance. Now, all versions of that file are retained in a single file in the Preservation Hold library. Before the change, versions were copied to the Preservation Hold library as separate files, and after the change, remain as separate files.

> **Note**
>
> Versions that are from a record continue to be copied to the Preservation Hold library as separate files, which means that they can expire independently from each other and the current version.

If the label doesn't mark the item as a record and retention settings are configured to delete the item at the end of the retention period:

- If the retention period is based on when the content was created, when labeled, or when an event starts, each version has the same expiration date as the original document. The original document and its versions all expire at the same time.

- If the retention period is based on when the content was last modified:
  - **After the change where all versions of the file are retained in a single file in the Preservation Hold library**: Each version has the same expiration date as the last version of the document. The last version of the document and its versions all expire at the same time.
  - **Before the change where versions were copied to the Preservation Hold library as separate files**: Each version has its own expiration date based on when the original document was modified to create that version. The original document and its versions expire independently of each other.

When the retention action is to delete the document, all versions not in the Preservation Hold library are deleted at the same time according to the current version.

For items that are subject to a retention policy (or an eDiscovery hold), the versioning limits for the document library are ignored until the retention period of the document is reached (or the eDiscovery hold is released). In this scenario, old versions aren't automatically purged and users are prevented from deleting versions.

That's not the case for retention labels when the content isn't subject to a retention policy (or an eDiscovery hold). Instead, the versioning limits are honored so that older versions are automatically deleted to accommodate new versions, but users are still prevented from deleting versions.

How retention works with Microsoft 365 Archive

For administrators, there's very little change to how retention policies and retention labels work and are managed for sites that use Microsoft 365 Archive. For example, the default policy configuration of all sites automatically includes archived sites as well as active sites. An active site that's included in a retention policy and then changed to be an archive site will continue to be subject to the configuration settings in the retention policy. The same applies to labeled items in a site that becomes archived. You can create a new retention policy for an archived site, and auto-apply retention labels for archived sites. Items still support disposition review, Power Automate actions, simulation mode is supported, policy lookup, adaptive scopes, and Microsoft Graph API to programmatically apply and manage retention labels are all supported for archived sites.

The one exception is for cloud attachments, where an item that's currently in an archived site won't be retained with an auto-apply retention label policy. Cloud attachments that were

retained from an active site continue to to be subject to the configuration settings in the retention label.

Because users can't view and interact with items in archived sites, the user actions usually supported for retention labels won't be possible. For example, manually applying or removing retention labels, locking and unlocking records, editing of record properties that include the name and description. Similarly, although the Microsoft Purview portal supports disposition review, the contents of an item under disposition review can't be displayed and the URL link to the item won't work.

When a user leaves the organization

SharePoint:

When a user leaves your organization, any content created by that user isn't affected because SharePoint is considered a collaborative environment, unlike a user's mailbox or OneDrive account.

OneDrive:

If a user leaves your organization, any files that are subject to a retention policy or has a retention label will remain subject to the retention settings for the duration of the retention period specified in the policy or label. During that time, all sharing access continues to work and the content continues to be discoverable by Content Search and eDiscovery.

When the retention period expires and the retention settings included a delete action, content moves into the Site Collection Recycle Bin and isn't accessible to anyone except the admin.

Configuration guidance

If you're new to configuring retention in Microsoft 365, see Get started with data lifecycle management.

If you're ready to configure a retention policy or retention label for Exchange, see the following instructions:

- Create and configure retention policies
- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

Learn about retention for Microsoft Teams

> *Microsoft Purview service description*

> **Note**
>
> If you're seeing a message in Teams that your chats or messages have been deleted by a retention policy, see **Teams messages about retention policies**.
>
> The information on this page is for IT administrators who manage these retention policies.

The information in this article supplements Learn about retention because it has information that's specific to Microsoft Teams messages and call logs.

For other workloads, see:

- Learn about retention for SharePoint and OneDrive
- Learn about retention for Viva Engage
- Learn about retention for Exchange
- Learn about retention for Copilot

What's included for retention and deletion

> **Note**
>
> Retention policies support **shared channels**. Any shared channels inherit retention settings from the parent team.

Teams chats messages and Facilitator interactions in meetings, channel messages, and private channel messages can be deleted by using retention policies for Teams. In addition to the text in the messages, the following items from these interactions can be retained for compliance reasons: Video clips, embedded images, tables, hypertext links, links to other Teams messages and files, and card content.

These chat messages and private channel messages include all the names of the people in the conversation, and channel messages include the team name and the message title (if supplied).

Code snippets, recorded voice memos from the Teams mobile client, thumbnails, announcement images, and reactions from others in the form of emoticons aren't retained when you use retention policies for Teams messages.

Some control messages are supported when you use retention policies for Teams messages. Control messages are system generated messages that appear on the Teams client. The types of control messages supported for retention policies are the same types of control messages available from Microsoft Teams Export APIs.

Call logs are also supported. Microsoft Teams call logs represent the collection of call-related data generated by Teams, including call data records (CDRs, sometimes also known as call detail records or just call records) and other call metadata. This data can be stored across multiple underlying locations used by Teams, but can be targeted as a single workload for retention purposes. For more information about Teams call logs, see the following resources:

- Personal call logs - View your call history in Microsoft Teams
- Shared call queue logs - View call history in the Queues app in Microsoft Teams

Emails and files that you use with Teams aren't included in retention policies for Teams. These items have their own retention policies that use the **Microsoft 365 Group mailboxes & sites** or **SharePoint classic and communication sites** locations. Teams meeting transcripts and Teams meeting recordings and transcripts from channel meetings are included with these files. However, for files and Teams meeting recordings and transcripts from user chats, you need a retention policy that includes the organizer's **OneDrive account** as the location.

> **Tip**
>
> If you want to retain or delete just Teams meeting transcripts or recordings with their accompanying transcripts, use an **auto-apply retention label policy** that identifies these files.

Migration of private channel messages in 2025

Towards the end of 2025, Teams is changing where private channel messages are stored. Before the migration, these messages are stored in user mailboxes and require their own location in a Teams retention policy: **Teams private channel messages**

After the migration, they're stored in group mailboxes, in the same way as messages for standard channels and shared channels. The **Teams channel messages** location in a retention policy will

therefore apply to all channel messages. Post migration, if a team has any private channels, they inherit retention settings from their parent team in the same way as shared channels do.

> **Important**
>
> If messages from private channels need different retention settings, during and post migration, create new retention policies for the **Teams channel messages** location that apply just to the parent teams that have private channels. Because of the **principles of retention**, you might also need to edit your existing retention policy for Teams channel messages, to exclude these parent teams that are now specified in your new policy.

Any previously configured retention policies that use the **Teams private channel messages** location continues to enforce the retention settings.

For more information, see the Tech Community blog post: Enhancing Private Channels in Microsoft Teams to Unlock Their Full Potential

How retention works with Microsoft Teams messages

Use this section to understand how your compliance requirements are met by backend storage and processes, and should be verified by eDiscovery tools rather than by messages that are currently visible in the Teams app.

You can use a retention policy to retain data from chats and channel messages in Teams, and delete these chats and messages. Behind the scenes, Exchange mailboxes are used to store data copied from these messages. Data from Teams chats is stored in a hidden folder in the mailbox of each user included in the chat, and a similar hidden folder in a group mailbox is used for Teams channel messages. These hidden folders aren't designed to be directly accessible to users or administrators, but instead, store data that compliance administrators can search with eDiscovery tools.

These mailboxes are, listed by their RecipientTypeDetails attribute:

- **UserMailbox**: These mailboxes store message data for cloud-based Teams users, and Teams private channels and before the migration.
- **MailUser**: These mailboxes store message data for on-premises Teams users.
- **GroupMailbox**: These mailboxes store message data for Teams standard channels, and for Teams private channels post migration.
- **SubstrateGroup**: These mailboxes store message data for Teams shared channels.

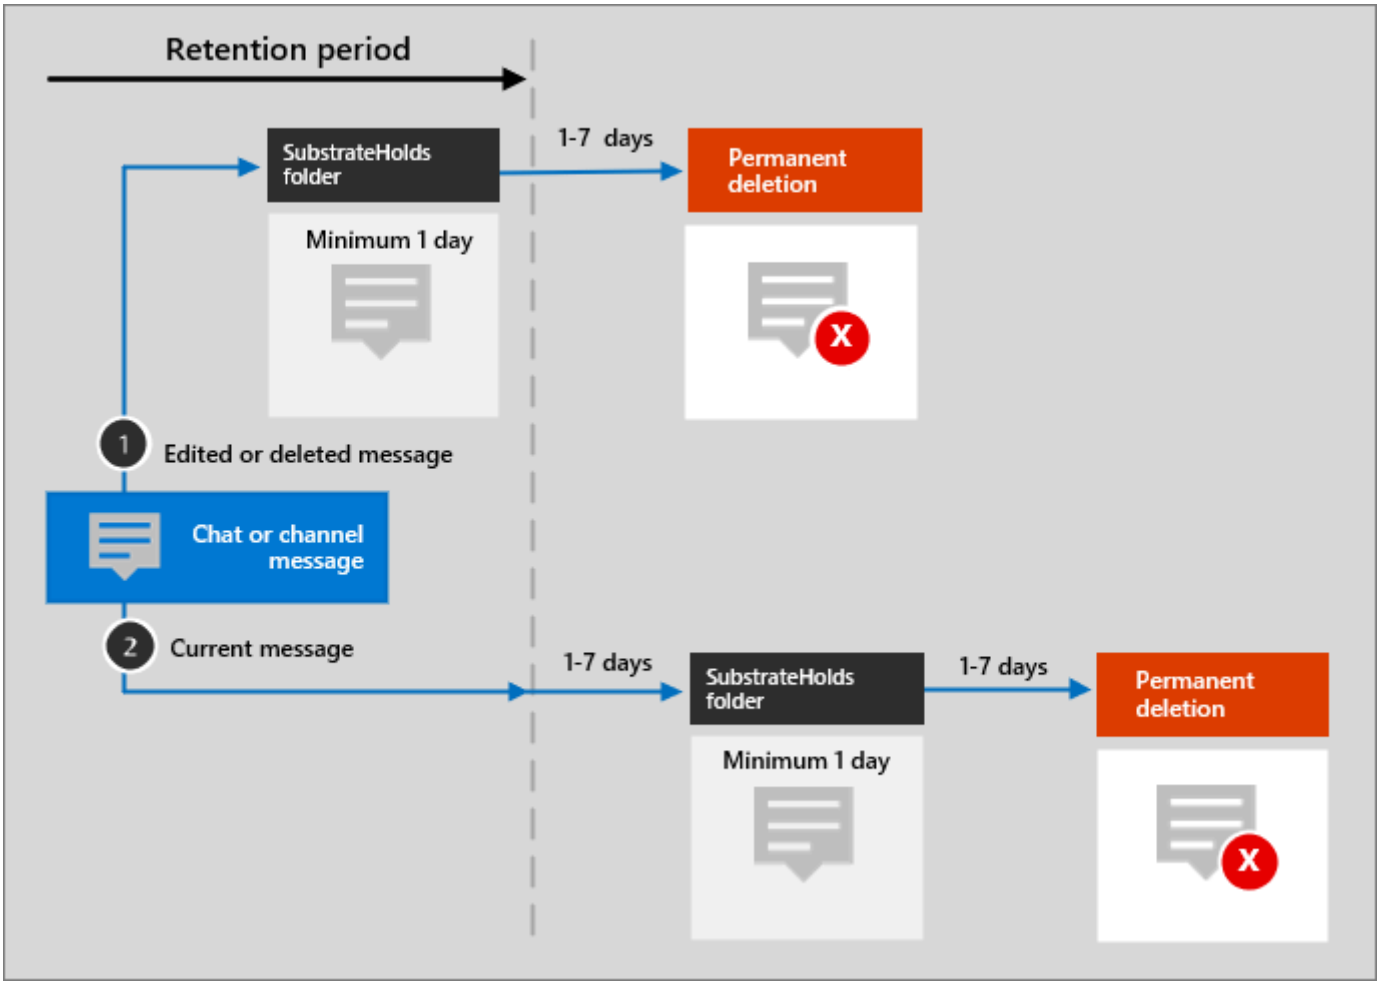
Other mailbox types, such as RoomMailbox that's used for Teams conference rooms, aren't supported for Teams retention policies.

Teams uses an Azure-powered chat service as its primary storage for all messages (chats and channel messages). If you need to delete Teams messages for compliance reasons, retention policies for Teams can delete messages after a specified period, based on when they were created. Messages are then permanently deleted from both the Exchange mailboxes where they stored for compliance operations, and from the primary storage used by the underlying Azure-powered chat service. For more information about the underlying architecture, see Security and compliance in Microsoft Teams and specifically, the Information Protection Architecture section.

Although this data from Teams chats and channel messages are stored in mailboxes, you must configure a retention policy for the **Teams channel messages** and **Teams chats** locations. Teams chats and channel messages aren't included in retention policies that are configured for Exchange user or group mailboxes. Similarly, retention policies for Teams don't affect other email items stored in mailboxes.

If a user is added to a chat, a copy of all messages shared with them are ingested into their mailbox. The created date of those messages doesn't change for the new user and remains the same for all users.

> ⓘ **Note**
>
> If a user is included in an active retention policy that retains Teams messages and you delete a mailbox of a user who is included in this policy, the mailbox is converted into an **inactive mailbox** to retain the Teams data. If you don't need to retain this Teams data for the user, exclude the user account from the retention policy and **wait for this change to take effect** before you delete their mailbox.



After a retention policy is configured for chat and channel messages, a timer job from the Exchange service periodically evaluates items in the hidden mailbox folder where these Teams messages are stored. The timer job typically takes 1-7 days to run. When these items have expired their retention period, they're moved to the SubstrateHolds folder—another hidden folder that's in every user or group mailbox to store "soft-deleted" items before they're permanently deleted.

Messages remain in the SubstrateHolds folder for at least 1 day, and then if they're eligible for deletion, the timer job permanently deletes them the next time it runs.

> **Important**
>
> Because of the [first principle of retention] and since Teams chat and channel messages are stored in Exchange Online mailboxes, permanent deletion from the SubstrateHolds folder is always suspended if the mailbox is affected by another Teams retention policy for the same location, Litigation Hold, delay hold, or if an eDiscovery hold is applied to the mailbox for legal or investigative reasons.
>
> While the mailbox is included in an applicable hold, Teams chat and channel messages that have been deleted will no longer be visible in the Teams app but will continue to be discoverable with eDiscovery.

After a retention policy is configured for chat and channel messages, the paths the content takes depend on whether the retention policy is to retain and then delete, to retain only, or delete only.

When the retention policy is to retain and then delete:

For the two paths in the diagram:

1. **If a chat or channel message is edited or deleted** by a user during the retention period, the original message is copied (if edited) or moved (if deleted) to the SubstrateHolds folder. When a user deletes a Teams message, although the message disappears from the Teams app, the message doesn't go into the SubstrateHolds folder for 21 days. The message is stored in the SubstrateHolds folder for at least 1 day. When the retention period expires, the message is permanently deleted the next time the timer job runs (typically between 1-7 days).

2. **If a chat or channel message is not deleted** by a user and for current messages after editing, the message is moved to the SubstrateHolds folder after the retention period expires. This action typically takes between 1-7 days from the expiry date. When the message is in the SubstrateHolds folder, it's stored there for at least 1 day, and then the message is permanently deleted the next time the timer job runs (typically between 1-7 days).

> ⓘ **Note**
>
> Messages stored in mailboxes, including the hidden folders, are searchable by eDiscovery tools. Until messages are permanently deleted from the SubstrateHolds folder, they remain searchable by eDiscovery tools.

When the retention period expires and moves a message to the SubstrateHolds folder, a delete operation is communicated to the backend Azure chat service, that then relays the same operation to the Teams client app. Delays in this communication or caching can explain why, for a short period of time, users continue to see these messages in their Teams app.

In this scenario where the Azure chat service receives a delete command because of a retention policy, the corresponding message in the Teams client app is deleted for all users in the conversation. Sometimes, this behavior might seem unexpected because some of these users can be from another organization, have a retention policy with a longer retention period, or no retention policy assigned to them. For these users, copies of the messages are still stored in their mailboxes and remain searchable for users in Teams and admins using eDiscovery until the messages are permanently deleted by another retention policy. Users won't be able to see the message in Teams.

> ⓘ **Important**

Messages visible in the Teams app are not an accurate reflection of whether they're retained or permanently deleted for compliance requirements.

When the retention policy is retain-only, or delete-only, the content's paths are variations of retain and delete.

Content paths for retain-only retention policy

1. **If a chat or channel message is edited or deleted** by a user during the retention period: The original message is copied (if edited) or moved (if deleted) to the SubstrateHolds folder. When a user deletes a Teams message, although the message disappears from the Teams app, the message doesn't go into the SubstrateHolds folder for 21 days. The message is stored in the SubstrateHolds folder for at least 1 day. If the retention policy is configured to retain forever, the item remains there. If the retention policy has an end date for the retention period and it expires, the message is permanently deleted the next time the timer job runs (typically between 1-7 days).

2. **If the chat or channel message is not modified or deleted** by a user and for current messages after editing during the retention period: Nothing happens before and after the retention period; the message remains in its original location.

Content paths for delete-only retention policy

1. **If the chat or channel message is edited or deleted** by a user during the retention period: The original message is copied (if edited) or moved (if deleted) to the SubstrateHolds folder. When a user deletes a Teams message, although the message disappears from the Teams app, the message doesn't go into the SubstrateHolds folder for 21 days. The message is stored in the SubstrateHolds folder for at least 1 day and permanently deleted the next time the timer job runs (typically between 1-7 days).

2. **If a chat or channel message is not deleted** by a user during the retention period: At the end of the retention period, the message is moved to the SubstrateHolds folder. This action typically takes between 1-7 days from the expiry date. The message is retained there for at least 1 day and then permanently deleted the next time the timer job runs (typically between 1-7 days).

Example flows and timings for retention policies

Use the following examples to see how the processes and timings explained in the previous sections apply to retention policies that have the following configurations:

- Example 1: Retain-only for 7 years
- Example 2: Retain for 30 days and then delete
- Example 3: Delete-only after 1 day

For all examples that refer to permanent deletion, because of the principles of retention, this action is suspended if the message is subject to another retention policy to retain the item or it's subject to an eDiscovery hold.

Example 1: Retain-only for 7 years

On day 1, a user creates a chat or channel message.

On day 5, the user edits that message.

On day 30, the user deletes the current message.

Retention outcomes:

- For the original message:
  - On day 5, the message is copied to the SubstrateHolds folder where it can still be searched with eDiscovery tools for a minimum of 7 years from day 1 (the retention period).
- For the current (edited) message:
  - On day 30, the message is no longer displayed in the Teams app and moves to the SubstrateHolds folder after 21 days where it continues to be searchable with eDiscovery tools for a minimum of 7 years from day 1 (the retention period).

If the user had deleted the current message after the specified retention period, instead of within the retention period, the message would still be moved to the SubstrateHolds folder after 21 days. However, now the retention period has expired, the message would be permanently deleted there after the minimum of 1 day and then typically within 1-7 days.

Example 2: Retain for 30 days and then delete

On day 1, a user creates a chat or channel message.

On day 10, the user edits that message.

The user doesn't make further edits and doesn't delete the message.

Retention outcomes:

- For the original message:
  - On day 10, the message is copied to the SubstrateHolds folder, where it can still be searched with eDiscovery tools.
  - At the end of the retention period (30 days from day 1), the message is permanently deleted typically within 1-7 days after the minimum of 1 day, and then won't be returned with eDiscovery searches.

- For the current (edited) message:
  - At the end of the retention period (30 days from day 1), the message moves to the SubstrateHolds folder typically within 1-7 days, where it can still be searched with eDiscovery tools.
  - The message is then permanently deleted typically within 1-7 days after the minimum of 1 day, and then won't be returned with eDiscovery searches.

Example 3: Delete-only after 1 day

> **Note**
>
> Because of the short one-day duration of this configuration and retention processes that operate within a time period of 1-7 days, this section shows example timings that are within the typical time ranges.

On day 1, a user creates a chat or channel message.

Example retention outcome if the user doesn't edit or delete the message:

- Day 5 (typically 1-7 days after the start of the retention period on day 2):
  - The message moves to the SubstrateHolds folder and remains there for at least 1 day where it can still be searched with eDiscovery tools.

- Day 9 (typically 1-7 days after a minimum of 1 day in the SubstrateHolds folder):
  - The message is permanently deleted and then won't be returned with eDiscovery searches.

As this example shows, although you can configure a retention policy to delete messages after just one day, the service undergoes multiple processes to ensure a compliant deletion. As a result, a delete action after 1 day could take 16 days before the message is permanently deleted so that it's no longer returned in eDiscovery searches.

How retention works with Microsoft Teams call logs

By default, Teams call logs are retained indefinitely. Use a retention policy for call logs if you need to delete this data for compliance reasons.

The deletion flow and process is the same as for Teams messages, only simplified because the call-related records in call logs can't be edited or deleted by users, and because deletion is the only applicable action. In the previous diagram and explanations, Teams call logs follow the "Content paths for delete-only retention policy" and the same behavior as "If a chat or channel message is not deleted".

As a result:

- At the end of the retention period, the call-related record is moved to the SubstrateHolds folder. This action typically takes between 1-7 days from the expiry date. The record is retained there for at least 1 day and then permanently deleted the next time the timer job runs (typically between 1-7 days).

From the previous section, only Example 3: Delete-only after 1 day is applicable for Teams call logs. Substitute "call-related record" for the word "message" and the behavior and timings remain the same.

Skype for Business and Teams interop chats

When a Skype for Business chat comes into Teams, it becomes a message in a Teams chat thread and is ingested into the appropriate mailbox. Teams retention policies apply to these messages from the Teams thread.

However, if conversation history is turned on for Skype for Business and from the Skype for Business client side that history is being saved into a mailbox, that chat data isn't handled by a Teams retention policy. For this content, use a retention policy that's configured for Skype for Business.

Messages and external users

When external users are included in a meeting or chat that your organization hosts:

- If an external user joins by using a guest account in your tenant, any Teams messages are stored in both your users' mailbox and a shadow mailbox that's granted to the guest account. However, retention policies aren't supported for shadow mailboxes, even though

they can be reported as included in a retention policy for the entire location (sometimes known as an "organization-wide policy").

- If an external user joins by using an account from another Microsoft 365 organization, your retention policies can't delete messages for this user because they're stored in that user's mailbox in another tenant. For the same meeting or chat however, your retention policies can delete messages for your users.

When a user leaves the organization

If a user who has a mailbox in Exchange Online leaves your organization and their Microsoft 365 account is deleted, their chat messages that are subject to retention are stored in an inactive mailbox. The chat messages remain subject to any retention policy that was placed on the user before their mailbox was made inactive, and the contents are available to an eDiscovery search. For more information, see Learn about inactive mailboxes.

If the user stored any files in Teams, see the equivalent section for SharePoint and OneDrive.

Configuration guidance

If you're new to configuring retention in Microsoft 365, see Get started with data lifecycle management.

If you're ready to configure a retention policy for Teams, see Create and configure retention policies.

Learn about retention for Viva Engage

> *Microsoft Purview service description*

The information in this article supplements Learn about retention because it has information that's specific to Viva Engage.

For other workloads, see:

- Learn about retention for SharePoint and OneDrive
- Learn about retention for Microsoft Teams
- Learn about retention for Exchange
- Learn about retention for Copilot

What's included for retention and deletion

Viva Engage user messages and community messages can be deleted by using retention policies for Viva Engage, and in addition to the text in these messages, the following items can be retained for compliance reasons: Hypertext links and links to other Viva Engage messages.

> **Note**
>
> As explained in the following section, user messages include private messages for an individual user, and any community messages associated with that user.
>
> User messages also include **storyline posts**, which are supported by retention policies.

User messages include all the names of the people in the conversation, and community messages include the community name and the message title (if supplied).

Reactions from others in the form of emoticons aren't retained when you use retention policies for Viva Engage.

Files that you use with Viva Engage aren't included in retention policies for Viva Engage. These items have their own retention policies.

How retention works with Viva Engage

Use this section to understand how your compliance requirements are met by backend storage and processes, and should be verified by eDiscovery tools rather than by messages that are currently visible in the Viva Engage app.

You can use a retention policy to retain data from community messages and user messages in Viva Engage, and delete these messages. Behind the scenes, Exchange mailboxes are used to store data copied from these messages. Data from Viva Engage user messages is stored in a hidden folder in the mailbox of each user included in the user message, and a similar hidden folder in a group mailbox is used for community messages.

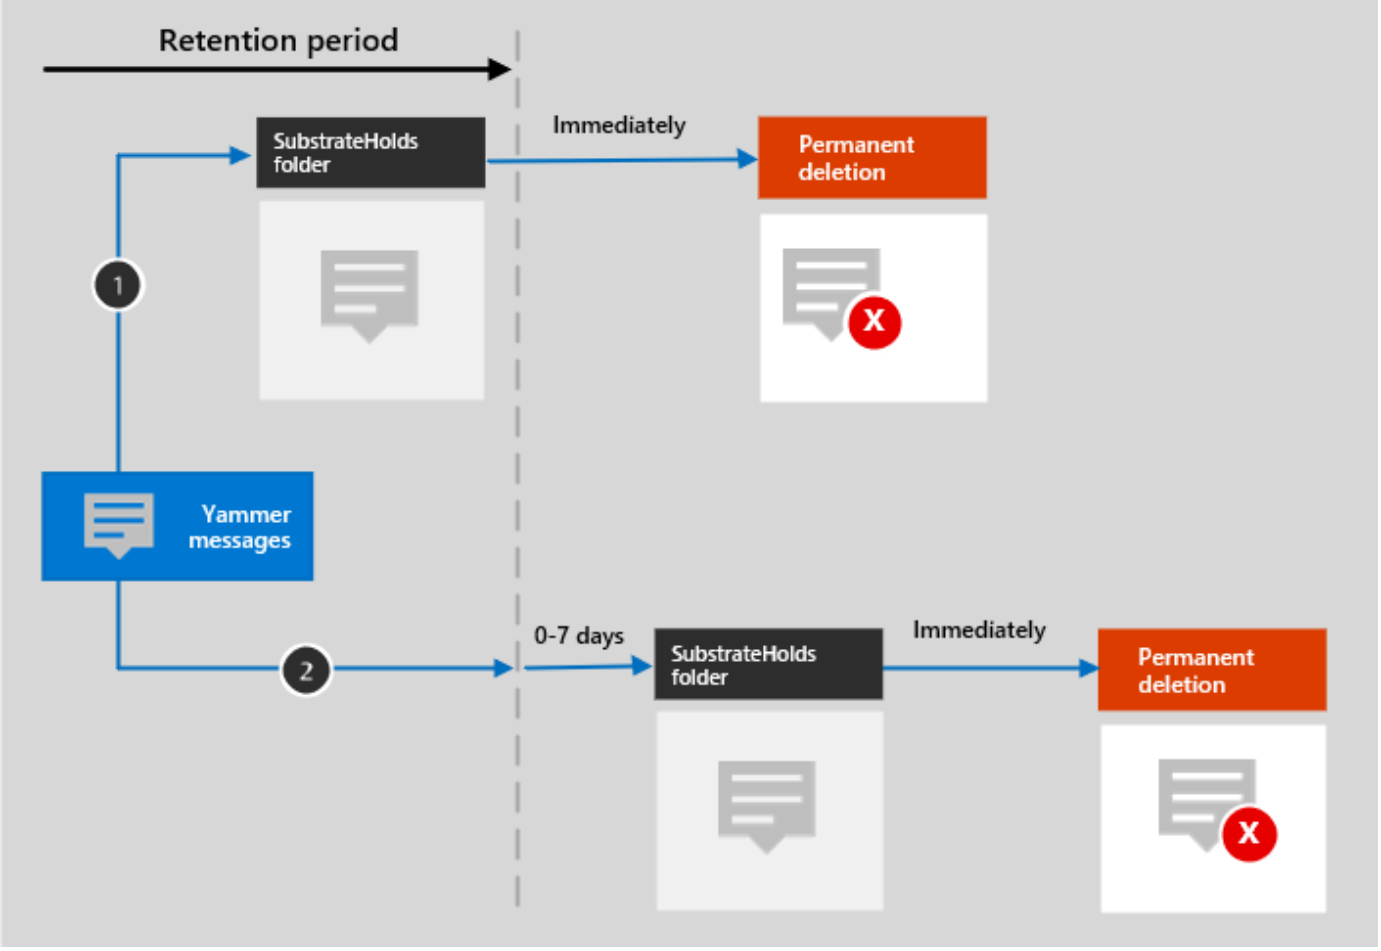
Copies of community messages can also be stored in the hidden folder of user mailboxes when they @ mention users or notify the user of a reply. Although these messages originate as a community message, a retention policy for Viva Engage user messages will often include copies of community messages. As a result, user messages aren't restricted to private messages.

These hidden folders aren't designed to be directly accessible to users or administrators, but instead, store data that compliance administrators can search with eDiscovery tools.

Even though they're stored in Exchange, Viva Engage messages are only included in a retention policy that's configured for the **Viva Engage community messages** or **Viva Engage user messages** locations.

> ⓘ **Note**
>
> If a user is included in an active retention policy that retains Viva Engage data and you delete a mailbox of a user who is included in this policy, to retain the Viva Engage data, the mailbox is converted into an inactive mailbox. If you don't need to retain this Viva Engage data for the user, exclude the user account from the retention policy before you delete their mailbox.

After a retention policy is configured for Viva Engage messages, a timer job from the Exchange service periodically evaluates items in the hidden folder where these Viva Engage messages are stored. The timer job takes up to seven days to run. When these items have expired their retention period, they're moved to the SubstrateHolds folder—a hidden folder that's in every user or group mailbox to store "soft-deleted" items before they're permanently deleted.



> ⓘ **Important**

Because of the first principle of retention and since Viva Engage messages are stored in Exchange Online mailboxes, permanent deletion from the SubstrateHolds folder is always suspended if the mailbox is affected by another Viva Engage retention policy for the same location, Litigation Hold, delay hold, or if an eDiscovery hold is applied to the mailbox for legal or investigative reasons.

While the mailbox is included in an applicable hold, Viva Engage messages that are deleted will no longer be visible in Viva Engage but continue to be discoverable with eDiscovery.

After a retention policy is configured for Viva Engage messages, the paths the content takes depend on whether the retention policy is to retain and then delete, to retain only, or delete only.

When the retention policy is to retain and then delete:

For the two paths in the diagram:

1. **If a Viva Engage message is edited or deleted** by the user during the retention period, the original message is immediately copied (if edited) or moved (if deleted) to the SubstrateHolds folder. The message is stored there until the retention period expires and then the message is immediately permanently deleted.

2. **If a Viva Engage message is not deleted** and for current messages after editing, the message is moved to the SubstrateHolds folder after the retention period expires. This action takes up to seven days from the expiry date. When the message is in the SubstrateHolds folder, it's then immediately permanently deleted.

> **Note**
>
> Messages in the SubstrateHolds folder are searchable by eDiscovery tools. Until messages are permanently deleted from the SubstrateHolds folder, they remain searchable by eDiscovery tools.

When the retention period expires and moves a message to the SubstrateHolds folder, a delete operation is communicated to the Viva Engage service, that then relays the same operation to the Viva Engage client app. Delays in this communication or caching can explain why, for a short period of time, users continue to see these messages in their Viva Engage app.

In this scenario where the Viva Engage service receives a delete command because of a retention policy, the corresponding message in the Viva Engage app is deleted for all users in the conversation. Some of these users might be from another organization, have a retention policy with a longer retention period, or no retention policy assigned to them. For these users, copies of the messages are still stored in their mailboxes and remain searchable for eDiscovery until the messages are permanently deleted by another retention policy.

> **Important**
>
> Messages visible in the Viva Engage app aren't an accurate reflection of whether they're retained or permanently deleted for compliance requirements.

When the retention policy is retain-only, or delete-only, the content's paths are variations of retain and delete.

Content paths for retain-only retention policy

1. **If a Viva Engage message is edited or deleted**: A copy of the original message is immediately created in the SubstrateHolds folder and retained there until the retention period expires. Then the message is immediately permanently deleted from the SubstrateHolds folder.

2. **If the Viva Engage message is not modified or deleted** and for current messages after editing during the retention period: Nothing happens before and after the retention period; the message remains in its original location.

Content paths for delete-only retention policy

1. **If the Viva Engage message is not deleted** during the retention period: At the end of the retention period, the message is moved to the SubstrateHolds folder. This action takes up to seven days from the expiry date. Then the message is immediately permanently deleted from the SubstrateHolds folder.

2. **If the Viva Engage message is deleted by the user** during the period, the item is immediately moved to the SubstrateHolds folder where it's immediately permanently deleted.

Example flows and timings for retention policies

Use the following examples to see how the processes and timings explained in the previous sections apply to retention policies that have the following configurations:

- Example 1: Retain-only for 7 years
- Example 2: Retain for 30 days and then delete
- Example 3: Delete-only after 1 day

For all examples that refer to permanent deletion, because of the principles of retention, this action is suspended if the message is subject to another retention policy to retain the item or it's subject to an eDiscovery hold.

Example 1: Retain-only for 7 years

On day 1, a user posts a new Viva Engage message.

On day 5, the user edits that message.

On day 30, the user deletes the current message.

Retention outcomes:

- For the original message:
  - On day 5, the message is copied to the SubstrateHolds folder where it can still be searched with eDiscovery tools for a minimum of 7 years from day 1 (the retention period).

- For the current (edited) message:
  - On day 30, the message moves to the SubstrateHolds folder where it can still be searched with eDiscovery tools for a minimum of 7 years from day 1 (the retention period).

If the user had deleted the current message after the specified retention period, instead of within the retention period, the message would still be moved to the SubstrateHolds folder. However, now the retention period has expired, the message would be permanently deleted after the minimum of 1 day and then typically within 1-7 days.

Example 2: Retain for 30 days and then delete

On day 1, a user posts a new Viva Engage message.

On day 10, the user edits that message.

The user doesn't make further edits and doesn't delete the message.

Retention outcomes:

- For the original message:
  - On day 10, the message is copied to the SubstrateHolds folder, where it can still be searched with eDiscovery tools.
  - At the end of the retention period (30 days from day 1), the message is permanently deleted typically within 1-7 days after the minimum of 1 day, and then won't be returned with eDiscovery searches.
- For the current (edited) message:
  - At the end of the retention period (30 days from day 1), the message moves to the SubstrateHolds folder typically within 1-7 days, where it can still be searched with eDiscovery tools.
  - The message is then permanently deleted typically within 1-7 days after the minimum of 1 day, and then won't be returned with eDiscovery searches.

Example 3: Delete-only after 1 day

> **Note**

Because of the short one-day duration of this configuration and retention processes that operate within a time period of 1-7 days, this section shows example timings that are within the typical time ranges.

On day 1, a user posts a new Viva Engage message.

Example retention outcome if the user doesn't edit or delete the message:

- Day 5 (typically 1-7 days after the start of the retention period on day 2):
  - The message moves to the SubstrateHolds folder and remains there for at least 1 day where it can still be searched with eDiscovery tools.
- Day 9 (typically 1-7 days after a minimum of 1 day in the SubstrateHolds folder):
  - The message is permanently deleted and then won't be returned with eDiscovery searches.

As this example shows, although you can configure a retention policy to delete messages after just one day, the service undergoes multiple processes to ensure a compliant deletion. As a result, a delete action after 1 day could take 16 days before the message is permanently deleted so that it's no longer returned in eDiscovery searches.

Messages and external users

By default, a retention policy for Viva Engage user messages applies to all users in your organization, but not external users. You can apply a retention policy to external users if you use the **Edit** option for users included, and specify their account.

At this time, Azure B2B guest users aren't supported.

When a user leaves the organization

If a user leaves your organization and their Microsoft 365 account is deleted, their Viva Engage user messages that are subject to retention are stored in an inactive mailbox. These messages remain subject to any retention policy that was placed on the user before their mailbox was made inactive, and the contents are available to an eDiscovery search. For more information, see Learn about inactive mailboxes.

If the user stored any files in Viva Engage, see the equivalent section for SharePoint and OneDrive.

Limitations

Be aware of the following limitation when you use retention for Viva Engage community messages and user messages:

- When you select **Edit** for the **Viva Engage user messages** location, you might see guests and nonmailbox users. Retention policies aren't designed for these users, so don't select them.

Configuration guidance

If you're new to configuring retention in Microsoft 365, see Get started with data lifecycle management.

If you're ready to configure a retention policy for Viva Engage, see Create and configure retention policies.

Last updated on 09/15/2024

Learn about retention for Exchange

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

The information in this article supplements Learn about retention because it has information that's specific to Exchange. For other workloads, see:

- Learn about retention for SharePoint and OneDrive
- Learn about retention for Microsoft Teams
- Learn about retention for Viva Engage
- Learn about retention for Copilot

What's included for retention and deletion

The following Exchange items from user mailboxes and shared mailboxes can be retained and deleted by using retention policies and retention labels: Mail messages (includes received messages, drafts, sent messages) with any attachments, tasks when they have an end date, and notes.

Calendar items that have an end date are supported for retention policies but aren't supported for retention labels.

Public folders are supported for retention policies but aren't supported for retention labels.

Contacts, and any tasks and calendar items that don't have an end date are not supported.

Other items stored in a mailbox, such as Skype and Teams messages, aren't included in retention policies or labels for Exchange. These items have their own retention policies.

Mailboxes must have at least 10 MB of data before retention settings will apply to them, and retention labels can be published to them.

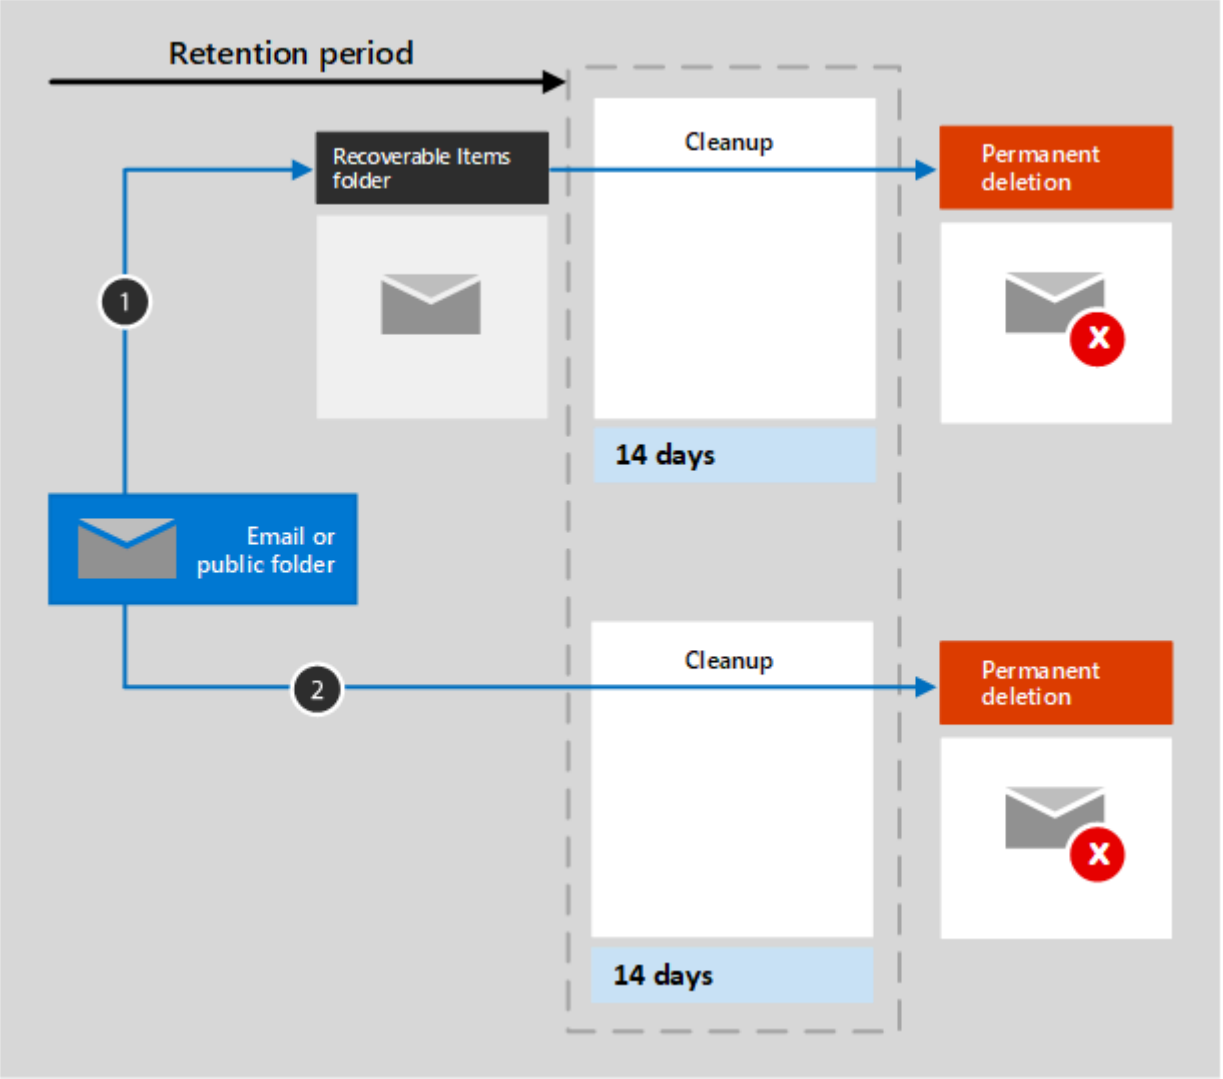
How retention works for Exchange

Both a mailbox and a public folder use the Recoverable Items folder to retain items. Only people who have been assigned eDiscovery permissions can view items in another user's Recoverable Items folder.

When a user deletes a message in a folder other than the Deleted Items folder, by default, the message moves to the Deleted Items folder. However, a user can soft delete an item

(Shift+Delete) in any folder, which bypasses the Deleted Items folder and moves the item directly to the Recoverable Items folder.

When you apply retention settings to Exchange data, a timer job periodically evaluates items in the Recoverable Items folder. If an item doesn't match the rules of at least one retention policy or retention label to retain the item, it is permanently deleted (also called hard deleted) from the Recoverable Items folder. Items configured for disposition review are never permanently deleted from the Recoverable Items folder until the disposition is confirmed.



> **Note**
>
> Because of the first principle of retention, permanent deletion is always suspended if the same item must be retained because of another retention policy or retention label, or it is under eDiscovery holds for legal or investigative reasons.

The timer job can take up to seven days to run and the Exchange location must contain at least 10 MB.

When a user attempts to change properties of a mailbox item—such as the subject, body, attachments, senders and recipients, or date sent or received for a message—a copy of the original item is saved to the Recoverable Items folder before the change is committed. This action happens for each subsequent change. At the end of the retention period, copies in the Recoverable Items folder are permanently deleted.

After retention settings are applied to Exchange content, the paths the content takes depend on whether the retention settings are to retain and delete, to retain only, or delete only.

When the retention settings are to retain and delete:

1. **If the item is modified or permanently deleted** by the user (either SHIFT+DELETE or deleted from Deleted Items) during the retention period: The item is moved (or copied, in the case of edit) to the Recoverable Items folder. There, a timer job runs periodically and identifies items whose retention period has expired, and these items are permanently deleted within 14 days of the end of the retention period. Note that 14 days is the default setting, but it can be configured up to 30 days.

2. **If the item is not modified or deleted** during the retention period: The same process runs periodically on all folders in the mailbox and identifies items whose retention period has expired, and these items are permanently deleted within 14 days of the end of the retention period. Note that 14 days is the default setting, but it can be configured up to 30 days.

When the retention settings are retain-only, or delete-only, the contents paths are variations of retain and delete:

Content paths for retain-only retention settings

1. **If the item is modified or deleted** during the retention period: A copy of the original item is created in the Recoverable Items folder and retained until the end of the retention period, when the copy in the Recoverable Items folder is permanently deleted within 14 days after the item expires.

2. **If the item is not modified or deleted** during the retention period: Nothing happens before and after the retention period; the item remains in its original location.

Content paths for delete-only retention settings

1. **If the item is not deleted** during the configured period: At the end of the configured period in the retention policy, the item is moved to the Recoverable Items folder.

2. **If the item is deleted** during the configured period: The item is immediately moved to the Recoverable Items folder. If a user deletes the item from there or empties the Recoverable Items folder, the item is permanently deleted. Otherwise, the item is permanently deleted after being in the Recoverable Items folder for 14 days.

User notification of expiry date

Retention policies for Exchange, unlike retention policies for the other Microsoft 365 workloads, have a user presence by displaying at the top of each email message the name of the retention policy that has the shortest expiry date for the item, and the calculated expiry date for that item. Users don't see this notification if the retention policy doesn't delete items (retain-only).

If a retention label is applied to an email message, the name of that label and corresponding expiry date is always displayed, and will replace the name and date from any retention policy applied to the mailbox.

Remember, in this context, the expiry date for when an email will be deleted is when users can expect the email message to automatically move to the Recoverable Items folder (if not already there). Emails in the Recoverable Items folder will not be permanently deleted but remain there for compliance purposes if they are subject to any retention settings to retain it, or they are under an eDiscovery hold for legal or investigative reasons.

When a user leaves the organization

If a user leaves your organization and the user's mailbox is included in a policy for retention, the mailbox becomes an inactive mailbox when the user's Microsoft 365 account is deleted. The contents of an inactive mailbox are still subject to any retention policy that was placed on

the mailbox before it was made inactive, and the contents are available to an eDiscovery search. For more information, see Inactive mailboxes in Exchange Online.

When the retention settings no longer apply because the data is permanently deleted or the retention period has expired, the Exchange admin can now delete the inactive mailbox. In this scenario, the inactive mailbox isn't automatically deleted.

Configuration guidance

If you're new to configuring retention in Microsoft 365, see Get started with data lifecycle management.

If you're ready to configure a retention policy or retention label for Exchange, see the following instructions:

- Create and configure retention policies
- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

Learn about retention for Copilot & AI apps

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

> **Note**
>
> Previously, messages from Microsoft 365 Copilot and Microsoft 365 Copilot Chat were automatically included in the retention policy location named **Teams chats and Copilot interactions** because they were retained and deleted by using the same mechanisms. Users didn't have to be using Teams for the retention policy to apply to Copilot.
>
> Retention policies for Microsoft 365 Copilot and Microsoft 365 Copilot Chat are now separate from Teams chats, and newly created retention policies support the following locations:
>
> - **Microsoft Copilot experiences**
> - Microsoft 365 Copilot
> - Security Copilot
> - Copilot in Fabric
> - Copilot Studio
> - **Enterprise AI apps**
> - Entra-registered AI apps
> - ChatGPT Enterprise
> - Azure AI services
> - **Other AI apps**
> - ChatGPT
> - Google Gemini
> - Microsoft Copilot (consumer version)
> - DeepSeek

The information in this article supplements Learn about retention because it has information that's specific to interactions with Copilot & AI apps.

For other workloads, see:

- Learn about retention for SharePoint and OneDrive
- Learn about retention for Viva Engage
- Learn about retention for Exchange

- Learn about retention for Teams

For more information about Microsoft Purview integration with Copilot & AI apps, see Microsoft Purview data security and compliance protections for generative AI apps.

What's included for retention and deletion

Retention policies for AI apps include user prompts and responses for Microsoft 365 Copilot and Copilot Studio, and also user prompts and responses for other Microsoft Copilots and generative AI apps when they have a collection policy with the setting to capture content. These messages can then be retained and deleted for compliance reasons.

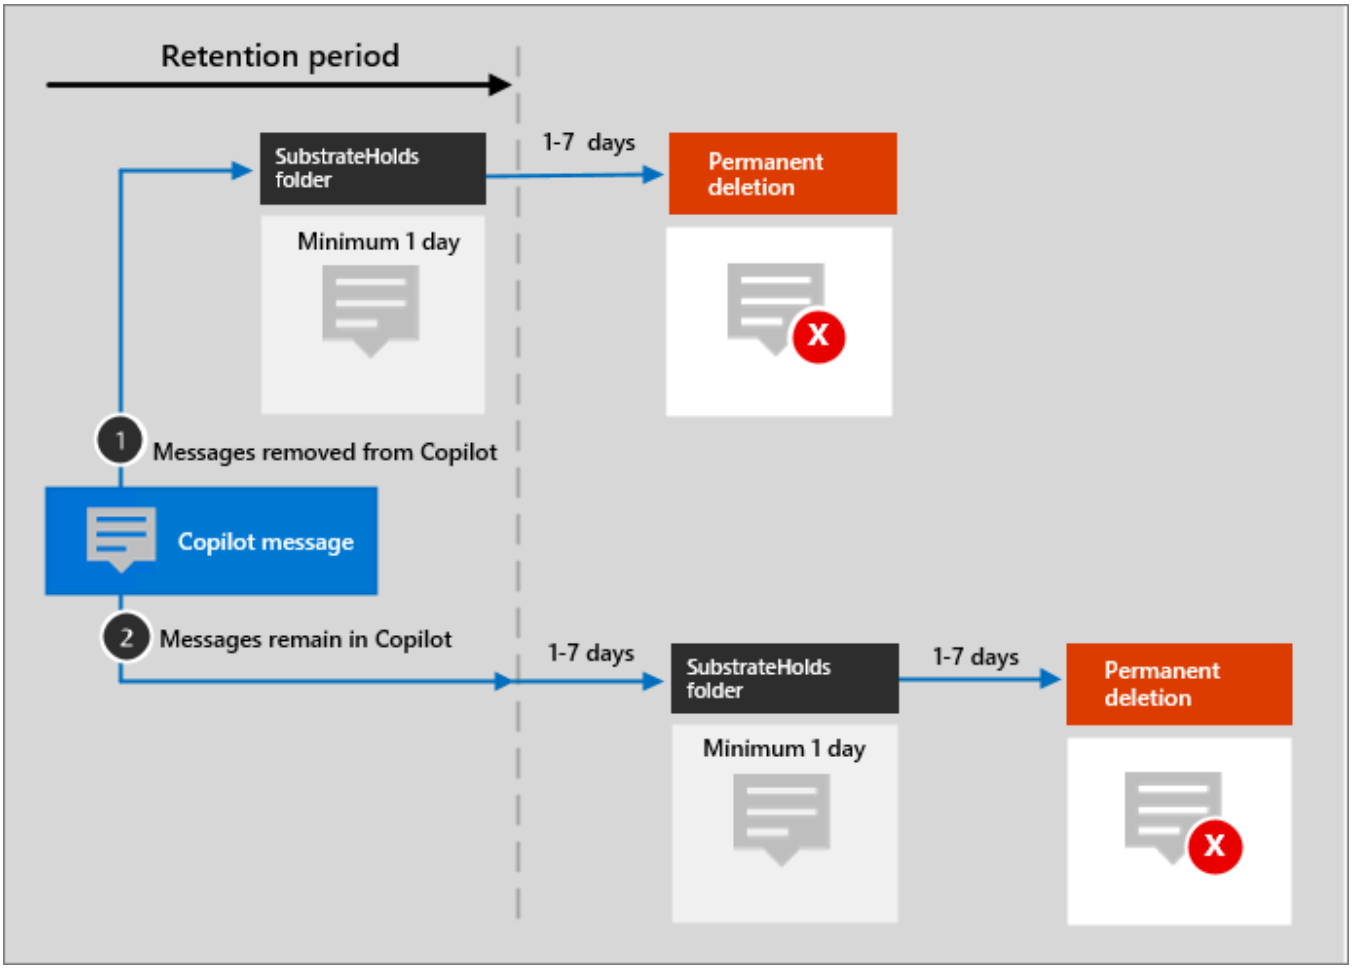
User prompts include text that users type, and selecting AI app prompts that are captured as a prepopulated message. AI app responses include text, links, and references. For Copilot in Teams chat and channels, responses include threaded summaries. Because messages to indicate that a response is in progress don't have business value, these messages aren't captured.

How retention works with AI apps

Use this section to understand how your compliance requirements are met by backend storage and processes, and should be verified by eDiscovery tools rather than by messages that are currently visible in your AI apps, such as Copilot.

You can use a retention policy to retain data from messages in Copilot or another AI app, and delete those messages. Behind the scenes, Exchange mailboxes are used to store data copied from these messages. Data from generative AI messages is stored in a hidden folder in the mailbox of the user who runs the AI app. This hidden folder isn't designed to be directly accessible to users or administrators, but instead, store data that compliance administrators can search with eDiscovery tools.

The Exchange mailbox for retaining these messages has the RecipientTypeDetails attribute of **UserMailbox**, which also stores message data for Teams private channels and cloud-based Teams users.



After a retention policy is configured for AI app interactions, a timer job from the Exchange service periodically evaluates items in the hidden mailbox folder where these messages are stored. The timer job typically takes 1-7 days to run. When these items have expired their retention period, they're moved to the SubstrateHolds folder—another hidden folder that's in every user mailbox to store "soft-deleted" items before they're permanently deleted.

Messages remain in the SubstrateHolds folder for at least 1 day, and then if they're eligible for deletion, the timer job permanently deletes them the next time it runs.

> **ⓘ Important**
>
> Because of the [first principle of retention], and because the AI app messages are stored in Exchange Online mailboxes, permanent deletion from the SubstrateHolds folder is always suspended if the mailbox is affected by another retention policy for the same location, Litigation Hold, delay hold, or if an eDiscovery hold is applied to the mailbox for legal or investigative reasons.

After a retention policy is configured, the paths the content takes depend on whether the retention policy is to retain and then delete, to retain only, or delete only.

When the retention policy is to retain and then delete, using Microsoft 365 Copilot as the example:

In most scenarios, these messages aren't removed. For example, they remain but are hidden when users close a chat window or close the app. However, Copilot messages are removed in the following scenarios:

- Users delete (when this option is available) the associated chat in Microsoft 365 Copilot Chat.
- A request is submitted to delete a user's history of all interactions with Microsoft 365 Copilot.

For the two paths in the diagram:

1. **If messages are removed from the AI app**, the message is moved to the SubstrateHolds folder where it remains for at least 1 day. When the retention period expires, the message is permanently deleted the next time the timer job runs (typically between 1-7 days).

2. **If messages remain in the AI app** after the retention period expires, the message is copied to the SubstrateHolds folder. This action typically takes between 1-7 days from the expiry date. When the message is in the SubstrateHolds folder, it's stored there for at least 1 day, and then the message is permanently deleted the next time the timer job runs (typically between 1-7 days).

> **Note**
>
> Messages stored in mailboxes, including the hidden folders, are searchable by eDiscovery tools. Until messages are permanently deleted from the SubstrateHolds folder, they remain searchable by eDiscovery tools.

When the retention period expires and copies a message to the SubstrateHolds folder, a delete operation is communicated to the backend service for Copilot, that then relays the same operation to the user app with Copilot. Delays in this communication or caching can explain why, for a short period of time, users continue to see these messages in Copilot.

> **Important**
>
> Messages visible in your AI apps are not an accurate reflection of whether they are retained or permanently deleted for compliance requirements.

When the retention policy is retain-only, or delete-only, the content's paths are variations of retain and delete.

Content paths for retain-only retention policy

1. **If messages are removed from your AI app** the message is moved to the SubstrateHolds folder after the retention period expires. This action typically takes between 1-7 days from the expiry date. If the retention policy is configured to retain forever, the item remains

there. If the retention policy has an end date for the retention period and it expires, the message is permanently deleted the next time the timer job runs (typically between 1-7 days).

2. **If messages remain in your AI app** after the retention period expires, nothing happens before and after the retention period; the message remains in its original location.

Content paths for delete-only retention policy

1. **If messages are removed from your AI app** during the retention period, the message is moved to the SubstrateHolds folder. The message is stored in the SubstrateHolds folder for at least 1 day and permanently deleted the next time the timer job runs (typically between 1-7 days).

2. **If messages remain in your AI app** after the retention period expires, the message is copied to the SubstrateHolds folder. This action typically takes between 1-7 days from the expiry date. The message is retained there for at least 1 day and then permanently deleted the next time the timer job runs (typically between 1-7 days).

Example flows and timings for retention policies

Use the following examples to see how the processes and timings explained in the previous sections apply to retention policies that have the following configurations:

- Example 1: Retain for 30 days and then delete
- Example 2: Delete-only after 1 day

For all examples that refer to permanent deletion, because of the principles of retention, this action is suspended if the message is subject to another retention policy to retain the item or it's subject to an eDiscovery hold.

Example 1: Retain for 30 days and then delete

On day 1, a user sends a prompt to Copilot and the prompt is removed after 10 days.

Retention outcome:

- After day 10, the message is moved to the SubstrateHolds folder, where it can still be searched with eDiscovery tools.
- At the end of the retention period (30 days from day 1), the message is permanently deleted typically within 1-7 days after the minimum of 1 day, and then won't be returned with eDiscovery searches.

Example 2: Delete-only after 1 day

> **Note**
>
> Because of the short one-day duration of this configuration and retention processes that operate within a time period of 1-7 days, this section shows example timings that are within the typical time ranges.

On day 1, a user sends a prompt to Copilot and this prompt isn't removed from Copilot.

Example retention outcome if the user's prompt isn't removed:

- Day 5 (typically 1-7 days after the start of the retention period on day 2):
  - The message is copied to the SubstrateHolds folder and remains there for at least 1 day.
- Day 9 (typically 1-7 days after a minimum of 1 day in the SubstrateHolds folder):
  - The message is permanently deleted and then won't be returned with eDiscovery searches.

As this example shows, although you can configure a retention policy to delete messages after just one day, the service undergoes multiple processes to ensure a compliant deletion. As a result, a delete action after 1 day could take 16 days before the message is permanently deleted so that it's no longer returned in eDiscovery searches.

When a user leaves the organization

If a user leaves your organization and their Microsoft 365 account is deleted, their Copilot and other AI app messages that are subject to retention are stored in an inactive mailbox. The messages remain subject to any retention policy that was placed on the user before their mailbox was made inactive, and the contents are available to an eDiscovery search. For more information, see Learn about inactive mailboxes.

Configuration guidance

If you're new to configuring retention in Microsoft 365, see Get started with data lifecycle management.

If you're ready to configure a retention policy for Copilot interactions, see Create and configure retention policies.

Common settings for retention policies and retention label policies

> *Microsoft 365 licensing guidance for security & compliance*.

Many settings for retention are common to both retention policies and retention label policies. Use the following information to help you configure these settings to proactively retain content, delete content, or both—retain and then delete the content.

For the scenarios that support these policies for retention, see:

- Create and configure retention policies.
- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

Settings that are specific to each scenario are explained in their respective documentation.

For overview information about policies for retention and how retention works in Microsoft 365, see Learn about retention policies and retention labels.

Scopes - adaptive and static

If you're unfamiliar with adaptive and static scopes, and to help you choose which one to use when you configure a policy for retention, see Adaptive or static policy scopes for retention.

When you've decided whether to use an adaptive or static scope, use the following information to help you configure it:

- Configuration information for adaptive scopes
- Configuration information for static scopes

> **Tip**
>
> If you have policies that use static scopes and you want to convert them to adaptive scopes, leave your existing policies in place while you create new policies that use adaptive scopes with the same retention settings. Validate these new policies are targeting the correct users, sites, and groups before you disable or delete the old policies with static scopes.

Configuration information for static scopes

When you choose to use static scopes, you must then decide whether to apply the policy to all instances for the selected location (the entire location) or to include or exclude specific instances (specific inclusions or exclusions).

A policy that applies to entire locations

Except Skype for Business, the default is that all instances for the selected locations are automatically included in the policy without you having to specify them as included.

For example, **All mailboxes** for the **Exchange email** location. With this default setting, all existing user mailboxes will be included in the policy, and any new mailboxes created after the policy is applied will automatically inherit the policy.

For locations that include SharePoint sites, all instances include archived sites as well as active sites, and all containers in SharePoint Embedded for Loop workspaces.

A policy with specific inclusions or exclusions

Be aware that if you use the optional configuration to scope your retention settings to specific users, specific Microsoft 365 groups, or specific sites, there are some limits per policy to be aware of. For more information, see Limits for retention policies and retention label policies.

To use the optional configuration to scope your retention settings, make sure the **Status** of that location is **On**, and then use the links to include or exclude specific users, Microsoft 365 groups, or sites.

> ⚠ **Warning**
>
> If you configure instances to include and then remove the last one, the configuration reverts to **All** for the location. Make sure this is the configuration that you intend before you save the policy.
>
> For example, if you specify one SharePoint site to include in your retention policy that's configured to delete data, and then remove the single site, by default all SharePoint sites will then be subject to the retention policy that permanently deletes data. The same applies to includes for Exchange mailboxes, OneDrive accounts, Teams chat users, and so on.
>
> In this scenario, toggle the location off if you don't want the **All** setting for the location to be subject to the retention policy. Alternatively, specify exclude instances to be exempt from

the policy.

Locations

Locations in policies for retention identify specific Microsoft 365 services that support retention settings, such as Exchange email and SharePoint sites. Use the following section for the locations that have configuration details and possible exceptions that you need to be aware of when you select them for your policy.

Configuration information for Exchange mailboxes and Exchange public folders

Both the **Exchange mailboxes** location and the **Exchange public folders** location require mailboxes to have at least 10 MB of data before retention settings will apply to them.

The **Exchange mailboxes** location supports retention for users' email, calendar, and other mailbox items, by applying retention settings at the level of a mailbox. Shared mailboxes and resource mailboxes for equipment and rooms are also supported.

Email contacts and Microsoft 365 group mailboxes aren't supported for Exchange email. For Microsoft 365 group mailboxes, select the **Microsoft 365 Group mailboxes & sites** location instead. Although the Exchange location initially allows a group mailbox to be selected for a static scope, when you try to save the retention policy, you receive an error that "RemoteGroupMailbox" isn't a valid selection for this location.

Depending on your policy configuration, inactive mailboxes might be included or not:

- Static policy scopes include inactive mailboxes when you use the default **All mailboxes** configuration but aren't supported for specific inclusions or exclusions. However, if you include or exclude a recipient that has an active mailbox at the time the policy is applied and the mailbox later goes inactive, the retention settings continue to be applied or excluded.
- Adaptive policy scopes, by default, include inactive mailboxes when they meet the scope's query. You can exclude them by using the advanced query builder and the OPATH property *IsInactiveMailbox*:

  Console

  ```
  (IsInactiveMailbox -eq "False")
  ```

If you use a static policy scope and choose recipients to include or exclude, you can select distribution groups and email-enabled security groups as an efficient way to select multiple recipients instead of selecting them one-by-one. When you use this option, behind the scenes, these groups are automatically expanded at the time of configuration to select the mailboxes of the users in the group. If the membership of those groups later change, your existing retention policy isn't automatically updated, unlike adaptive policy scopes.

For detailed information about which mailbox items are included and excluded when you configure retention settings for Exchange, see What's included for retention and deletion.

The **Exchange public folders** location applies retention settings to all public folders and can't be applied at the folder or mailbox level.

Configuration information for SharePoint sites and OneDrive accounts

The location name for the SharePoint sites location changes, depending on whether you're using adaptive policy scopes or static policy scopes. The name change reflects what type of sites are included:

- Static policy scopes: **SharePoint classic and communication sites**
  - Can retain and delete documents in SharePoint communication sites, team sites that aren't connected by Microsoft 365 groups, and classic sites. This includes sites associated with Teams shared channels and Teams private channels. Team sites connected by Microsoft 365 groups aren't supported with this option and instead, use the **Microsoft 365 Group mailboxes & sites** location that applies to content in the group's mailbox, site, and files.

- Adaptive policy scopes: **SharePoint sites**
  - Can retain and delete documents in OneDrive sites and Microsoft 365 group-connected sites in addition to SharePoint communication sites, team sites that aren't connected by Microsoft 365 groups, and classic sites.

> **Tip**
>
> You can use a **filter in the SharePoint admin center** or a **SharePoint PowerShell command** to confirm whether a site is group-connected.

Microsoft Loop files can be stored in OneDrive, SharePoint, and SharePoint Embedded. For more information, see Overview of Loop storage. When you use the default policy setting of all sites for SharePoint, this configuration automatically includes all Loop workspaces but you can specify individual workspaces by their container URL.

For detailed information about what's included and excluded when you configure retention settings for SharePoint and OneDrive, see What's included for retention and deletion.

When you specify your locations for SharePoint sites or OneDrive accounts, you don't need permissions to access the sites. For static scopes, no validation is done at the time you specify the URL on the **Edit locations** page. However, the SharePoint sites that you specify are checked that they exist on the final page of the configuration. If this check fails, you see a message that validation failed for the URL you entered, and the retention policy can't be created until the validation check passes. If you see this message, go back in the configuration process to change the URL or remove the site from the retention policy.

To specify individual OneDrive accounts, see Get a list of all user OneDrive URLs in your organization.

> **Note**
>
> When you specify individual OneDrive accounts, be aware that unless OneDrive accounts are pre-provisioned, the URL isn't created until a user accesses their OneDrive for the first time.
>
> Also, the OneDrive URL will automatically change if there is a change in the user's UPN. For example, a name-changing event such as marriage, or a domain name change to support an organization's rename or business restructuring. If the UPN changes, you will need to update the OneDrive URLs you specify for retention settings.
>
> Because of the challenges of reliably specifying URLs for individual users to include or exclude for static scopes, adaptive scopes with the **User** scope type are better suited for this purpose.

Configuration information for Microsoft 365 Group mailboxes & sites

To retain or delete content for a Microsoft 365 group (formerly Office 365 group), use the **Microsoft 365 Group mailboxes & sites** location. For retention policies, this location includes the

group mailbox and SharePoint teams site. For retention labels, this location includes the SharePoint teams site only.

For detailed information about which items are included and excluded for Microsoft 365 Groups:

- For group mailboxes, see What's included for retention and deletion for Exchange retention.
- For SharePoint teams sites, see What's included for retention and deletion for SharePoint retention.

Mailboxes that you target with this policy location require at least 10 MB of data before retention settings will apply to them.

> **Note**
>
> Even though a Microsoft 365 group has an Exchange mailbox, a retention policy for the **Exchange mailboxes** location won't include content in Microsoft 365 group mailboxes.

If you use static scopes: Although the **Exchange mailboxes** location for a static scope initially allows you to specify a group mailbox to be included or excluded, when you try to save the retention policy, you'll see an error that "RemoteGroupMailbox" isn't a valid selection for the Exchange location.

By default, a retention policy applied to a Microsoft 365 group includes the group mailbox and SharePoint teams site. Files stored in the SharePoint teams site are covered with this location, but not Teams chats or Teams channel messages that have their own retention policy locations.

To change the default because you want the retention policy to apply to either just the Microsoft 365 mailboxes, or just the connected SharePoint teams sites, use the Set-RetentionCompliancePolicy PowerShell cmdlet and the *Applications* parameter with one of the following values:

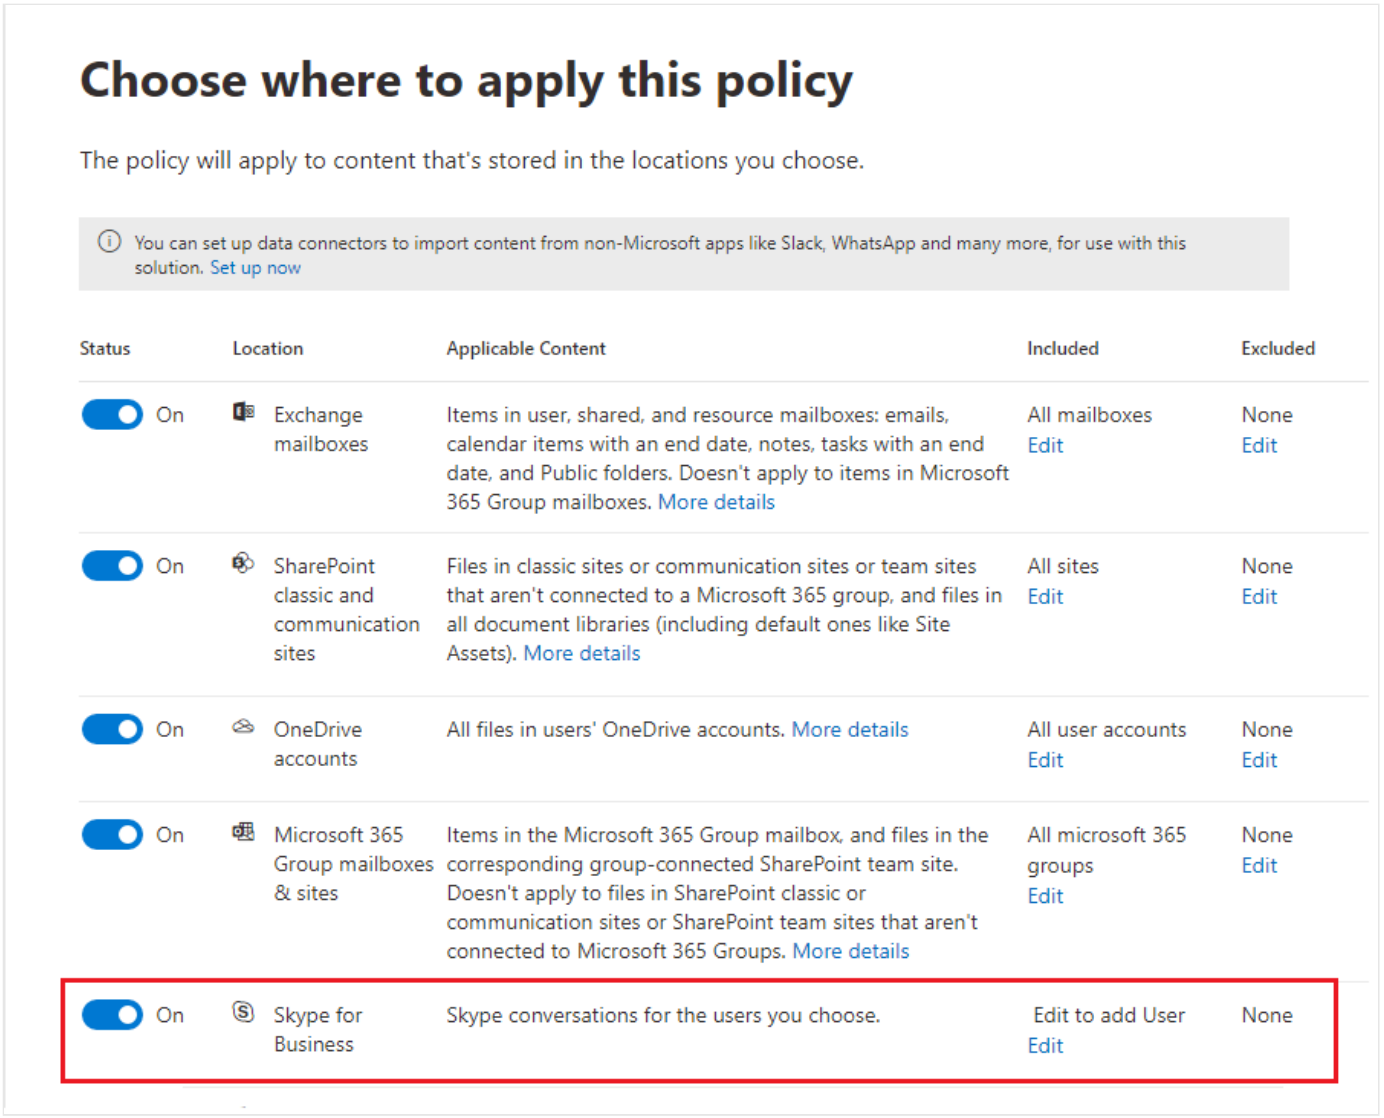
- `Group:Exchange` for just Microsoft 365 mailboxes that are connected to the group.
- `Group:SharePoint` for just SharePoint sites that are connected to the group.

To return to the default value of both the mailbox and SharePoint site for the selected Microsoft 365 groups, specify `Group:Exchange,SharePoint`.

What happens if a Microsoft 365 group is deleted after a policy is applied

When a policy for retention (static policy scope or adaptive) is applied to a Microsoft 365 group, and that group is then deleted from Microsoft Entra ID:

- The group-connected SharePoint site is preserved and continues to be managed by the retention policy with the **Microsoft 365 Group mailboxes & sites** location. Although users who were granted access to the group-connected SharePoint site via the SharePoint admin center continue to be able to access the site, users who were granted access to this site via the deleted group must now be granted permissions from the SharePoint admin center. Now the group is deleted, any new permissions must be granted from the SharePoint admin center.



- To release the retention policy from this site, use the *DeletedResources* parameter with the Set-RetentionCompliancePolicy PowerShell cmdlet.

- The mailbox for the deleted group becomes inactive and like the SharePoint site, remains subject to retention settings. For more information, see Inactive mailboxes in Exchange Online.

Configuration information for Skype for Business

> **Note**
>
> Skype for Business was retired July 31, 2021 and we encourage customers to migrate to Microsoft Teams. However, retention policies for Skype for Business continues to be supported for existing customers.

Unlike Exchange email, you can't toggle the status of the Skype location on to automatically include all users, but when you turn on that location, you must then manually choose the users whose conversations you want to retain:

After you select this **Edit** option, in the **Skype for Business** pane you can quickly include all users by selecting the hidden box before the **Name** column. However, it's important to understand that each user counts as a specific inclusion in the policy. So if you include 1,000 users by selecting this box, it's the same as if you manually selected 1,000 users to include, which is the maximum supported for Skype for Business.

Be aware that **Conversation History**, a folder in Outlook, is a feature that has nothing to do with Skype archiving. **Conversation History** can be turned off by the end user, but archiving for Skype is done by storing a copy of Skype conversations in a hidden folder that is inaccessible to the user but available to eDiscovery.

Settings for retaining and deleting content

By choosing the settings for retaining and deleting content, your policy for retention will have one of the following configurations for a specified period of time:

- Retain-only

For this configuration, choose the following options:

- For retention policies: On the **Decide if you want to retain content, delete it, or both** page, select **Retain items for a specific period**, specify the retention period and then for **At end of the retention period** select **Do nothing** for the retention settings to be removed. Or to retain without an end date, select **Retain items forever** on this page.
- For retention labels: On the **Define label settings page**, select **Retain items indefinitely or for a specific period**, and then:
  - For the retention settings to no longer be in effect on the labeled content after a specific time: On the **Define the retention period** page, for **Retain items for**, specify the time period. Then on the **Choose what happens after the retention period** page, select **Deactivate retention settings**. The label remains on the content but with no retention restrictions, as if it's a label that just classifies. However, if the label marks items as a record, the item still supports lock and unlock that has its own set of restrictions.
  - To retain without an end date: On the **Define the retention period** page, for **Retain items for**, select **An indefinite period**. The label remains on the content with any existing restrictions.

- Retain and then delete

  For this configuration, choose the following options:

  - For retention policies: On the **Decide if you want to retain content, delete it, or both** page, select **Retain items for a specific period**, specify the retention period and then for **At end of the retention period** select **Delete items automatically**.
  - For retention labels: On the **Define label settings** page, select **Retain items indefinitely or for a specific period**, specify the retention period and then for **Choose what happens after the retention period**, select either **Delete items automatically** or **Start a disposition review**. For information about disposition reviews, see Disposition review.

- Delete-only

  For this configuration, choose the following options:

  - For retention policies: On the **Decide if you want to retain content, delete it, or both** page, select **Only delete items when they reach a certain age**, and specify the time period.

- For retention labels: On the **Define label settings** page, select **Enforce actions after a specific period** and specify the time period, still referred to as the retention period. The option **Choose what happens after the period** is automatically set to **Delete items automatically**.

Archiving retained SharePoint files

For SharePoint, you can add an archive action to retention policies and retention labels. This action moves supported inactive files to Microsoft 365 Archive while the files remain subject to retention and legal holds. Items that don't support the archive action remain active. Archived files remain available for Microsoft Purview eDiscovery and content search but are excluded from Microsoft 365 Copilot indexing.

The archive action isn't enabled by default. Existing retention policies and labels don't archive files unless an administrator updates them to include the archive action. Event-based retention isn't supported for file-level archive.

To configure the archive action, select **Archive retained items in secure and compliant Microsoft 365 Archive to reduce cost** in the retention settings. Then specify when the archive period starts and how long files remain active before they're archived. The archive period can start when items were created or last modified.

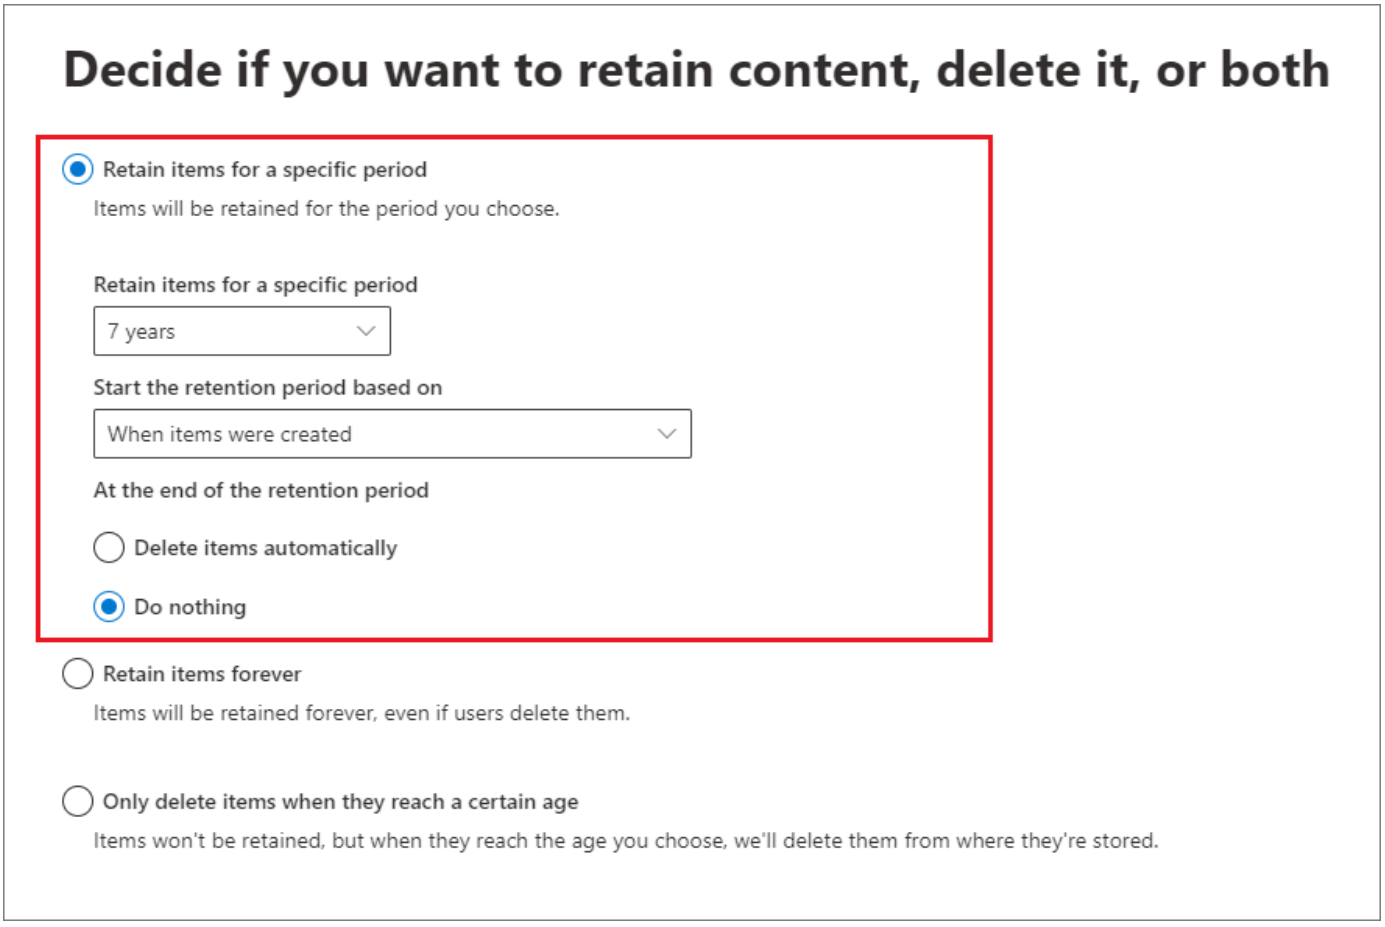
File-level archive requires a Microsoft 365 E5 license. No additional setup is required to archive files by using retention policies or labels. To use the cost-saving benefits of Microsoft 365 Archive, first set up pay-as-you-go billing for Microsoft 365 Archive.

Users with read access can reactivate an archived file when they need it. Retention and hold requirements continue to apply after reactivation or deletion. After a file is reactivated, the policy archives it again after a 120-day cooldown period.

For more information about managing archived files, see Manage Microsoft 365 Archive.

Retaining content for a specific period of time

When you configure a retention label or policy to retain content in the Microsoft Purview portal, you choose to retain items for a specific number of days, months (assumes 30 days), or years (assumes 365 days). Or alternatively, retain the items forever. The retention period isn't calculated from the time the policy was assigned, but according to the start of the retention period specified.



For the start of the retention period, you can choose when the content was created or, supported only for files and the SharePoint, OneDrive, and Microsoft 365 Groups, when the content was last modified. For retention labels, you can start the retention period from the content was labeled, and when an event occurs.

Examples:

- SharePoint: If you want to retain items in a site collection for seven years after this content is last modified, and a document in that site collection hasn't been modified in six years, the document will be retained for only another year if it's not modified. If the document is edited again, the age of the document is calculated from the new last modified date, and it will be retained for another seven years.

- Exchange: If you want to retain items in a mailbox for seven years, and a message was sent six years ago, the message will be retained for only one year. For Exchange items, the age is based on the date received for incoming email, or the date sent for outgoing email. Retaining items based on when it was last modified applies only to site content in OneDrive and SharePoint.

At the end of the retention period, you choose whether you want the content to be permanently deleted. For example, for retention policies:

Retention labels have two more options. As described in the next section, they can apply another retention label with its own retention period. Or, they can trigger a Power Automate flow for custom actions.

Before you configure retention, first familiarize yourself with capacity and storage limits for the respective workloads:

- For SharePoint and OneDrive, retained items are stored in the site's Preservation Hold library, which is included in the site's storage quota. For more information, see Manage site storage limits from the SharePoint documentation.
- For Exchange, Teams, AI apps, and Viva Engage, where retained messages are stored in mailboxes, see Exchange Online limits and enable auto-expanding archiving.

  In extreme cases where a high volume of email is deleted in a short time period, either by users or automatically from policy settings, you might also need to configure Exchange to more frequently move items from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in their archive mailbox. For step-by-step instructions, see Increase the Recoverable Items quota for mailboxes on hold.

Relabeling at the end of the retention period

When you configure a retention label to automatically apply a different retention label at the end of the retention period, the item is then subject to the retention settings of the newly selected retention label. This option lets you automatically change the retention settings for the item.

You can change the replacement label after you've created and saved the primary retention label. For items that already have the primary retention label applied and within the configured retention period, the change of replacement label will synchronize to these items. As with other label changes, allow up to 7 days for this synchronization period.

For the replacement label, you'll typically choose a label that has a longer retention period than the primary retention label. However, that isn't necessarily the case because of the label setting when to start the retention period. For example, the primary retention label is configured to start the retention period when the item is created, and the replacement label starts the retention period when labeled, or when an event occurs.

If there's also a change in whether the label marks the item as a record or a regularly record, the replacement retention label can also change the restrictions for what action are allowed or blocked for that item.

Relabeling example configuration

You create and configure a retention label for an industry-compliance requirement to retain content for three years after it's created, and mark the item as a record. When this label is applied, users won't be able to delete the item from their app, because that's one of the restrictions of a record.

At the end of the three years, you want to automatically retain the content for two more years because of internal compliance policies, but there's no need to mark it as a record with the restrictions that this configuration applies.

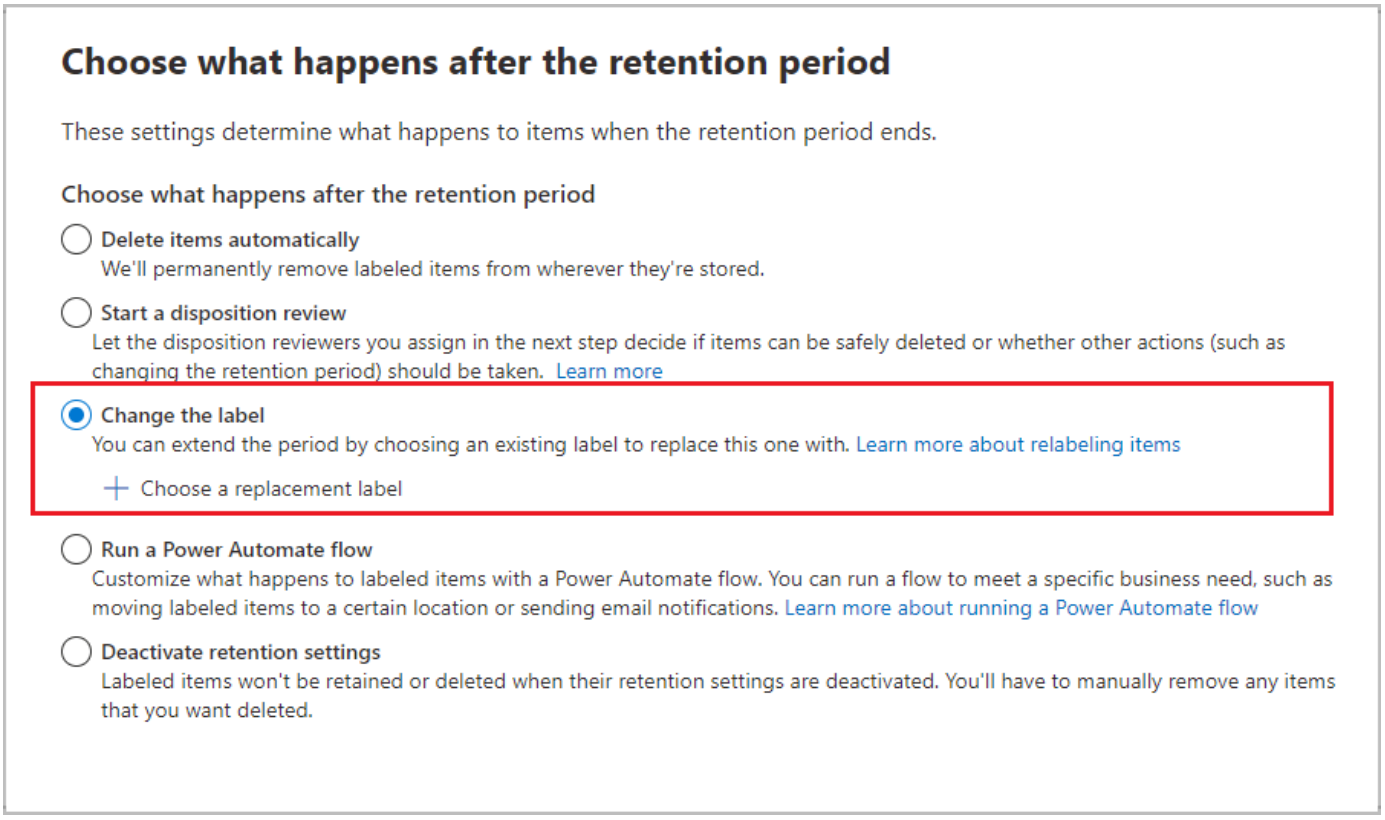
To complete the configuration, you select the label setting to change the label at the end of the retention period, and choose a label that retains content for five years after the content was created, and doesn't mark the item as a record.

With these concatenated settings, users will be able to delete the item from their app after three years but it remains accessible for eDiscovery searches for five years.

Considerations for the relabeling option

- You can't relabel a regulatory record but the replacement label can be configured to mark the content as a regulatory record.
- You won't be able to delete a retention label that's selected as a replacement label.
- You can choose a replacement label that's configured to apply another replacement label. There's no limit to the number of replacement labels an item can have.
- If the replacement label marks the item as a record or regulatory record but can't be applied because the file is currently checked out, the relabel process is retried when the file is checked back in again, or checkout is discarded.
- A replacement label is visible to users in Outlook only when that label is included in a published label policy for the same location, or it's configured for delete-only.

Configuration paths for relabeling



The option to relabel at the end of the retention period has two configuration paths when you create a retention label:

- If you need to initially retain content with the primary label (most typical): On the **Define label settings** page, select **Retain items indefinitely or for a specific period** and specify the

retention period. Then on the **Choose what happens after the retention period** page, select **Change the label** > **Choose a replacement label**.

- If you don't need to initially retain content with the primary label: On the **Define label settings** page, select **Enforce actions after a specific period**, specify the retention period, and then select **Change the label** > **Choose a replacement label**.

In both cases, the replacement label must already be created but doesn't need to be included in an existing label policy.

Alternatively, disposition reviewers can manually select a replacement label as part of the disposition review process if the label setting **Start a disposition review** is selected on this **Choose what happens after the retention period** page.

Deleting content that's older than a specific age

Retention settings can retain and then delete items, or delete old items without retaining them.

In both cases, if your retention settings delete items, it's important to understand that the time period you specify isn't calculated from the time the policy was assigned, but according to the start of the retention period specified. For example, from the time when the item was created or modified, or labeled.

For this reason, first consider the age of the existing content and how the settings might impact that content. Consider communicating your chosen settings to your users and help desk before the settings are applied to content, which gives them time to assess the possible impact.

A policy that applies to entire locations

When you choose locations, except for Skype for Business, the default setting is **All** when the status of the location is **On**.

When a retention policy applies to any combination of entire locations, there is no limit to the number of recipients, sites, accounts, groups, etc., that the policy can include.

For example, if a policy includes all Exchange email and all SharePoint sites, all sites and recipients will be included, no matter how many. And for Exchange, any new mailbox created after the policy is applied will automatically inherit the policy.

A policy with specific inclusions or exclusions

Be aware that if you use the optional configuration to scope your retention settings to specific users, specific Microsoft 365 groups, or specific sites, there are some limits per policy to be aware of. For more information, see Limits for retention policies and retention label policies.

To use the optional configuration to scope your retention settings, make sure the **Status** of that location is **On**, and then use the links to include or exclude specific users, Microsoft 365 groups, or sites.

> ⚠ **Warning**
>
> If you configure includes and then remove the last one, the configuration reverts to **All** for the location. Make sure this is the configuration that you intend before you save the policy.
>
> For example, if you specify one SharePoint site to include in your retention policy that's configured to delete data, and then remove the single site, by default all SharePoint sites will then be subject to the retention policy that permanently deletes data. The same applies to includes for Exchange recipients, OneDrive accounts, Teams chat users etc.
>
> In this scenario, toggle the location off if you don't want the **All** setting for the location to be subject to the retention policy. Alternatively, specify excludes to be exempt from the policy.

Updating policies for retention

Some settings can't be changed after a policy for retention is created and saved, which include:

- The policy name and the retention settings except the retention period and when to start the retention period.

If you edit a retention policy and items are already subject to the original settings in your retention policy, your updated settings will be automatically applied to these items in addition to items that are newly identified.

Usually this update is fairly quick but can take several days. When the policy replication across your Microsoft 365 locations is complete, you'll see the status of the retention policy in the Microsoft Purview portal change from **On (Pending)** to **On (Success)**.

Locking the policy to prevent changes

If you need to ensure that no one can turn off the policy, delete the policy, or make it less restrictive, see Use Preservation Lock to restrict changes to retention policies and retention label policies.

PowerShell cmdlets for retention policies and retention labels

> *Microsoft Purview service description*

Use the following sections to identify the main PowerShell cmdlets that are available for retention policies and retention labels that you might need for configuration at-scale, automated scripts, or advanced configuration scenarios. For the full list of cmdlets, see the policy-and-compliance-retention list from the PowerShell documentation.

Before you use these cmdlets, you must first connect to Security & Compliance PowerShell.

In the descriptions that follow, a policy for retention can refer to a retention policy (no labels), or a retention label policy. Each policy defines whether it's static or adaptive and the locations for the policy to be applied.

When you use retention policies, the policy requires one rule to complete the configuration, for example, a rule that defines the retention settings, such as retain for five years and then delete.

When you use retention labels, these labels contain the retention settings and their policies need different rules:

- A retention label policy that you publish needs a rule that defines which labels should be displayed in apps.
- An auto-apply retention label policy needs a rule that defines the label to apply and the conditions for applying the label.

Retention cmdlets for older locations

Use the cmdlets in the following table when the locations are **Exchange mailboxes**, **SharePoint sites** or **SharePoint classic and communication sites**, **OneDrive accounts**, **Microsoft 365 Group mailboxes & sites**, **Skype for Business**, **Exchange public folders**, **Teams chats and Copilot interactions**, or **Teams channel messages**.

Don't use these cmdlets when the locations are for Teams private channel messages (applicable premigration only), Viva Engage user messages, Viva Engage community messages, Teams chats

(without Copilot interactions), Microsoft Copilot experiences, Enterprise AI apps, or Other AI apps. These locations have alternative cmdlets that are identified in the next section.

Expand table

Cmdlet	Description	Applicable locations
Enable-ComplianceTagStorage Get-ComplianceTagStorage	A one-time operation to create storage, or view that storage for retention labels	Exchange mailboxes SharePoint sites (or SharePoint classic and communication sites) OneDrive accounts Microsoft 365 Group mailboxes & sites
Get-ComplianceTag New-ComplianceTag Remove-ComplianceTag Set-ComplianceTag	View, create, delete, configure retention labels	Exchange mailboxes SharePoint sites (or SharePoint classic and communication sites) OneDrive accounts Microsoft 365 Group mailboxes & sites
Get-RecordReviewNotificationTemplateConfig Set-RecordReviewNotificationTemplateConfig	View or configure the disposition review notification and reminder settings	Exchange mailboxes SharePoint sites (or SharePoint classic and communication sites) OneDrive accounts Microsoft 365 Group mailboxes & sites
Get-RetentionCompliancePolicy New-RetentionCompliancePolicy Remove-RetentionCompliancePolicy Set-RetentionCompliancePolicy	View, create, delete, configure retention policies and retention label policies	Exchange email SharePoint sites (or SharePoint classic and communication sites) OneDrive accounts Microsoft 365 Group

Cmdlet	Description	Applicable locations
		mailboxes & sites Skype for Business Exchange public folders Teams chats and Copilot interactions Teams channel messages
Get-RetentionComplianceRule New-RetentionComplianceRule Set-RetentionComplianceRule Remove-RetentionComplianceRule	View, create, configure, delete settings (rules) for retention policies and retention labels	Exchange email SharePoint sites (or SharePoint classic and communication sites) OneDrive accounts Microsoft 365 Group mailboxes & sites Skype for Business Exchange public folders Teams chats and Copilot interactions Teams channel messages

Retention cmdlets for newer locations

Use the following cmdlets when the locations are for **Teams private channel messages** (applicable premigration only), **Viva Engage user messages**, **Viva Engage community messages**, **Teams chats**, **Microsoft Copilot experiences**, **Enterprise AI apps**, **Other AI apps**, and for Teams call logs.

When the locations are for Teams chats and Copilot interactions, Teams channel messages, Exchange email, SharePoint sites (or SharePoint classic and communication sites), OneDrive accounts, Microsoft 365 Group mailboxes & sites, Skype for Business, or Exchange public folders, use the cmdlets listed in the previous section.

Expand table

Cmdlet	Description	Applicable locations
Get-AppRetentionCompliancePolicy New-AppRetentionCompliancePolicy Remove-AppRetentionCompliancePolicy Set-AppRetentionCompliancePolicy	View, create, delete, configure retention policies	Teams private channel messages Viva Engage user messages Viva Engage community messages Teams chats Teams call logs Microsoft Copilot experiences Enterprise AI apps Other AI apps
Get-AppRetentionComplianceRule New-AppRetentionComplianceRule Remove-AppRetentionComplianceRule Set-AppRetentionComplianceRule	View, create, configure, delete settings (rules) for retention policies	Teams private channel messages Viva Engage user messages Viva Engage community messages Teams chats Teams call logs Microsoft Copilot experiences Enterprise AI apps Other AI apps

Configuration guidance

Use the help pages associated with each cmdlet for detailed information and examples.

For guided help to create and then publish retention labels, see Create and publish retention labels by using PowerShell.

Last updated on 06/03/2026

Limits for retention policies and retention label policies

> *Microsoft Purview service description*

When you use retention policies and retention label policies to automatically retain or delete data for your organization, there are some maximum numbers to be aware of.

Maximum number of retention labels per tenant

A maximum of 1,000 retention labels are supported per tenant.

Maximum number of policies per tenant

A single tenant can have a maximum of 10,000 policies (any configuration). This maximum number includes the different policies for retention, and other policies for compliance such as policies for DLP, information barriers, eDiscovery holds, In-Place Holds, and sensitivity labels. However, this maximum excludes:

- Auto-labeling policies for SharePoint and OneDrive, unless they are for cloud attachments.
- Published label policies for SharePoint and OneDrive that delete-only, rather than retain-only, or retain and then delete.
- Exchange retention policies from messaging records management (MRM).
- Litigation holds.

Within this 10,000 policies limit, there are also some limits on the maximum number of policies for retention per workload:

- Exchange (any configuration): 1,800
  - Per mailbox: 25 is the recommended maximum before performance might be impacted; 50 is the supported limit.
- SharePoint or OneDrive: (all sites automatically included): 13
- SharePoint or OneDrive (specific locations included or excluded): 2,600

> ⓘ **Note**

These maximum numbers for Exchange and SharePoint are not exclusive to retention but are shared with other types of hold policies that include eDiscovery holds and In-Place Holds.

Although retention policies for Microsoft Teams and Viva Engage use mailboxes to store data for retention purposes, the maximum number of policies for Exchange Online exclude retention policies for Teams and Viva Engage.

Maximum number of items per policy

> **Important**
>
> Applicable only if you use static policy scopes rather than adaptive policy scopes.

For maximum limits for adaptive policy scopes, see Adaptive policy scopes.

If you use static scopes and the optional configuration to include or exclude specific users, specific Microsoft 365 groups, or specific sites, there are some limits per policy to be aware of.

Maximum numbers of items per policy for retention for static scopes:

- Exchange mailboxes: 1,000
- Microsoft 365 Groups: 500
- Teams channel messages: 500
- Teams chats messages: 1,000
- Copilot and other AI interactions: 1,000
- Viva Engage community messages: 1,000
- Viva Engage user messages: 1,000
- SharePoint sites: 100
- OneDrive accounts: 100

Skype for Business has to be scoped to specific users and the maximum number supported per policy is 1,000.

Because these limitations are per policy, if you need to use specific inclusions or exclusions that result in going over these numbers, you can create additional policies that have the same retention settings. See the next section for some example scenarios and solutions that use multiple retention policies for this reason.

However, multiple policies result in higher administrative overheads. Consider using adaptive scopes rather than creating and maintaining multiple policies with includes and excludes.

Examples of using multiple policies to avoid exceeding maximum numbers

The following examples are for static scopes and provide some design solutions for when you can't specify just the location for a retention policy, and must take into account the maximum number of items documented in the previous section.

Exchange example:

- **Requirement**: In an organization that has over 40,000 user mailboxes, most users must have their email retained for seven years but a subset of identified users (425) must have their email retained for only five years.
- **Solution**: Create one retention policy for Exchange email with a retention period of 7 years and exclude the subset of users. Then create a second retention policy for Exchange email with a retention period of 5 years and include the subset of users.

  The number included and excluded (425 in both cases) is below the maximum number (1,000) of specified mailboxes for a single policy. The subset of users must be explicitly excluded from the first policy because it has a longer retention period than the second policy. If the subset of users required a longer retention policy, you wouldn't need to exclude them from the first policy.

  With this solution, if anybody new joins the organization, their mailbox is automatically included in the first policy for 7 years and there is no impact to the maximum numbers supported. However, new users that require the 5-year retention period add to the include and exclude numbers, and this limit would be reached at 1,000.

SharePoint example:

- **Requirement**: An organization has several thousand SharePoint sites but only 2,000 sites require a retention period of 10 years, and 8,000 sites require a retention period of four years.

- **Solution**: Create 20 retention policies for SharePoint with a retention period of 10 years that includes 100 specific sites, and create 80 retention policies for SharePoint with a retention period of 4 years that includes 100 specific sites.

  Because you don't need to retain all SharePoint sites, you must create retention policies that specify the specific sites. Because a retention policy doesn't support more than 100 specified sites, you must create multiple policies for the two retention periods. These retention policies have the maximum number of included sites, so the next new site that needs retaining would require a new retention policy, irrespective of the retention period.

Maximum numbers for disposition review

For the disposition of content, there are some limits to be aware of:

- Maximum numbers per tenant:
  - 16,000,000 items in either of the following disposition review states: pending disposition or approved disposition
  - 16,000,000 items marked as records automatically disposed (no disposition review)
- Maximum number of disposition reviewers:
  - 10 reviewers per disposition stage in any combination of individual users and mail-enabled security groups
  - 200 reviewers per tenant in any combination of individual users and mail-enabled security groups. Because of this limit, we recommend using mail-enabled security groups whenever possible for larger organizations.
- Proof of disposition for up to 7 years after the item was disposed.

Learn about data lifecycle management

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

Microsoft Purview Data Lifecycle Management (formerly Microsoft Information Governance) provides you with tools and capabilities to retain the content that you need to keep, and delete the content that you don't.

Retaining and deleting content is often needed for compliance and regulatory requirement, but deleting content that no longer has business value also helps you manage risk and liability. For example, it reduces your attack surface.

Microsoft 365 features

Retention policies are the cornerstone for data lifecycle management. Use these policies for Microsoft 365 workloads that include Exchange, SharePoint, OneDrive, Teams, and Viva Engage. Configure whether content for these services needs to be retained indefinitely, or for a specific period if users edit or delete it. Or you can configure the policy to automatically permanently delete the content after a specified period if it's not already deleted. You can also combine these two actions for retain and then delete, which is a very typical configuration. For example, retain email for three years and then delete it.

When you configure a retention policy, you can target all instances in your organization (such as all mailboxes and all SharePoint sites), or individual instances (such as only the mailboxes for specific departments or regions, or just selected SharePoint sites).

If you need exceptions for individual emails or documents, such as a longer retention period for legal documents, you do this with **retention labels** that you publish to apps so that users can apply them, or automatically apply them by inspecting the content.

Retention labels are also used with **Adaptive Protection**, if you're using this solution with insider risk management. In this case, the retention label and auto-apply policy is automatically created for you. For details, see Dynamically mitigate the risk of accidental or malicious deletes.

Under the covers, retention labels are also used with priority cleanup for scenarios where you need to expedite the permanent deletion of sensitive information from mailboxes, even if they have existing holds for retention or eDiscovery.

For more information about retention policies and retention labels, and how retention works in Microsoft 365, see Learn about retention policies and retention labels.

> **Note**
>
> If you need to manage high-value items for business, legal, or regulatory record-keeping requirements, use retention labels with **records management** rather than retention labels with data lifecycle management.

Other data lifecycle management capabilities to help you keep what you need and delete what you don't:

- **Mailbox archiving** to provide users with additional mailbox storage space, and auto-expanding archiving for mailboxes that need more than 100 GB storage. A default archiving policy automatically moves email to the archive mailbox, and if required, you can customize this policy. For more information about mailbox archiving, see Learn about archive mailboxes.
- **Inactive mailboxes** that retain mailbox content after employees leave the organization. For more information about inactive mailboxes, see Learn about inactive mailboxes.
- **Import service for PST files** by using network upload or drive shipping. For more information, see Learn about importing your organization's PST files.

Exchange (legacy) features

Retention policies and retention tags from messaging records management (MRM), and **journaling rules** are older compliance features from Exchange that were originally configurable from the Classic Exchange admin center. They haven't been brought forward to the new Exchange admin center.

If you're not already using these features, or have a specific business requirement to use them instead of the Microsoft 365 features for data lifecycle management, we don't recommend you use these older compliance features. Instead, use the newer Microsoft 365 features that retain data in place and support policies across other Microsoft 365 services.

For more information, see Use retention policies and retention labels instead of older features.

Deployment guidance

For deployment guidance for data lifecycle management that includes a recommended deployment roadmap, licensing information, permissions, a list of supported scenarios, and end-user documentation, see Get started with data lifecycle management.

Looking for deployment guidance to protect your data? See Deploy an information protection solution with Microsoft Purview.

Get started with data lifecycle management

Summarize this article for me

> *Microsoft Purview service description*

Ready to start managing the lifecycle of your organization's data by retaining the content that you need to keep, and deleting the content that you don't? To get started, use the following guidance for Microsoft Purview Data Lifecycle Management:

1. **Understand how retention and deletion works** in Microsoft 365, and then identify the workloads that need a retention policy and whether you need to create retention labels for exceptions: Learn about retention

   > **Note**
   >
   > If you need to manage high-value items for business, legal, or regulatory record-keeping requirements: Use retention labels with **records management** rather than data lifecycle management.

2. **Create retention policies** for the workloads you identified, specifying retention settings and actions that are required by your organization policies or industry regulations: Create retention policies

   If needed, create and apply retention labels for your exceptions.

3. **Enable mailbox archiving** to provide users with additional mailbox storage space: Enable archive mailboxes in Microsoft 365

   If required to support archive mailboxes:

   - Enable auto-expanding archiving for mailboxes that need more than 100 GB storage.
   - Use retention tags with a retention policy from messaging records management (MRM) if you need to customize how emails are automatically moved from a user's primary mailbox to their archive mailbox, or if you need to specify retention and deletion settings for specific folders rather than the whole mailbox.

4. **Understand and manage inactive mailboxes** that retain mailbox content after employees leave the organization: Learn about inactive mailboxes

5. If you have PST files that contain data you want to govern: **Import PST files to online mailboxes** by using network upload or drive shipping: Learn about importing your organization's PST files

Licensing and billing requirements

A number of different subscriptions support data lifecycle management capabilities.

To see the options for licensing your users to benefit from Microsoft Purview features, see the Microsoft Purview service description. For the features listed on this page, see the Microsoft Purview Data Lifecycle Management & Records Management section for feature-level licensing requirements.

You must set up pay-as-you-go billing to create retention policies that include the locations Microsoft Copilot experiences, Enterprise AI apps, and Other AI apps. There's no charge for Microsoft 365 Copilot interactions.

Permissions

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

See the following section for information about roles and role groups to manage Microsoft 365 retention.

For permissions to manage mailboxes for archiving, inactive mailboxes, and import, these typically require Exchange permissions, such as the Mail Recipients role. By default, this role is assigned to the Recipient Management and Organization Management role groups. For the exact permissions requirement for each management task, see the documentation that accompanies the admin instructions.

Permissions for retention policies and retention labels

Members of your compliance team who will create and manage retention policies and retention labels need permissions to the Microsoft Purview portal. To grant permissions for this limited administration, we recommend that you add users to the **Compliance Administrator** admin role group.

Alternatively to using this default role, you can create a new role group and add the **Retention Management** role to this group. For a read-only role, use **View-Only Retention Management**.

Specific to priority cleanup that can override retention labels and policies when it's necessary to expedite the permanent deletion of sensitive information, admins must have the **Priority Cleanup Admin** role. This role isn't included by default in the **Compliance Administrator** admin role group.

For instructions to add users to the default roles or create your own role groups, use the following guidance, depending on the portal you're using:

- Permissions in the Microsoft Purview portal

These permissions are required only to create, configure, and apply retention policies and retention labels. The person configuring these policies and labels doesn't require access to the content.

Support for administrative units

Data lifecycle management supports administrative units that have been configured in Microsoft Entra ID:

- You can assign administrative units to members of custom role groups and any others that support administrative units. For example, role groups used with Microsoft Purview Records Management. Edit these role groups and select individual members, and then the **Assign admin units** option to select administrative units from Microsoft Entra ID. These administrators are now restricted to managing just the users in those administrative units.
- You can define the initial scope of retention policies and retention label policies when you create or edit these policies. When you select administrative units, only the users in those administrative units will be eligible for the policy.

> **Important**
>
> Don't select administrative units for a policy that you want to apply to SharePoint sites or to Exchange public folders. Because administrative units support only users and groups, if you configure policy for retention to use administrative units, you won't be able to select the locations for SharePoint sites or Exchange public folders.

- Both adaptive scopes and static scopes support administrative units.
- Additional impact for restricted administrators

    - Policy lookup: Restricted administrators will see policies only from users within their assigned administrative units
    - Import PST files: Restricted administrators won't be able to use the network upload feature to bulk-import PST files to Microsoft 365 mailboxes
    - Exchange legacy features: Restricted administrators won't be able to configure the Exchange legacy features of retention policies and retention tags from messaging records management (MRM), and journaling rules

- Currently, retention labels don't support administrative units.
- Currently, a restricted administrator can create and view adaptive scopes for all administrative units when they use PowerShell cmdlets.
- Currently, inactive mailboxes aren't supported in a policy when you select one or more administrative units. To include inactive mailboxes in the policy, you must be an unrestricted administrator and select **Full directory**.

For more information about how Microsoft Purview supports administrative units, see Administrative units.

Common scenarios

Use the following table to help you map your business requirements to the most common scenarios for data lifecycle management.

Expand table

I want to ...	Documentation
Efficiently retain or delete data for Microsoft 365 services and Copilot interactions: - Exchange - SharePoint - OneDrive - Microsoft 365 Groups - Teams - Copilot and AI apps - Viva Engage - Skype for Business	Create and configure retention policies
Automatically retain content that's deleted by users who have been identified as having an elevated risk level	Dynamically mitigate the risk of accidental or malicious deletes
Provide users with additional mailbox storage	Enable archive mailboxes in Microsoft 365

I want to ...	Documentation
Retain mailbox data after employees leave the organization	Create and manage inactive mailboxes
Upload mailbox data from PST files	Use network upload to import PST files

For scenarios that require data management of individual items, see the common scenarios for records management.

End-user documentation

See the following section for information about end-user documentation to support Microsoft 365 retention.

The data lifecycle management capabilities for inactive mailboxes and import of PST files don't require end-user documentation because these are admin operations only. To help users understand and interact with their archive mailboxes in Outlook after you've enabled this capability, see Manage email storage with online archive mailboxes.

End-user documentation for retention and deletion

Most retention policies work unobtrusively in the background without user interaction, and so need little documentation for users. Retention policies for Teams inform users when their messages have been deleted with a link to Teams messages about retention policies.

However, if you supplement retention policies with retention labels, these labels do have a UI presence in Microsoft 365 apps. Before you deploy these labels to your production network, make sure you provide information and instructions for end users and your help desk. To help users apply retention labels in SharePoint and OneDrive, see Apply retention labels to files in SharePoint or OneDrive.

The most effective end-user documentation will always be customized guidance and instructions you provide for the retention label names and configurations you choose.

Last updated on 02/27/2026

Create and configure retention policies

> *Microsoft Purview service description*

Use a retention policy to manage the data for your organization by deciding proactively whether to retain content, delete content, or retain and then delete the content.

A retention policy lets you do this very efficiently by assigning the same retention settings at the container level to be automatically inherited by content in that container. For example, all items in SharePoint sites, all email messages in users' Exchange mailboxes, all channel messages for teams that are used with Microsoft Teams. If you're not sure whether to use a retention policy at the container level or a retention label at the item level, see Retention policies and retention labels.

For more information about retention policies and how retention works in Microsoft 365, see Learn about retention policies and retention labels.

> **Note**
>
> The information on this page is for compliance administrators. If you are not an administrator and want to understand how retention policies have been configured for the apps that you use, contact your help desk, IT department, or administrator. If you're seeing messages about retention policies in Teams chats and channel messages, you might find it helpful to review **Teams messages about retention policies**.

Before you begin

To make sure you have permissions to create and edit retention policies, see the permissions information for data lifecycle management.

Decide before you create your retention policy whether it will be **adaptive** or **static**. For more information, see Adaptive or static policy scopes for retention. If you decide to use an adaptive policy, you must create one or more adaptive scopes before you create your retention policy, and then select them during the create retention policy process. For instructions, see Configuration information for adaptive scopes.

To retain prompts and responses for AI apps other than Microsoft 365 Copilot and Copilot Studio, you must first have a collection policy for these AI apps, and that policy includes the setting to capture content. For more information, see Collection Policies solution overview.

If you're creating a retention policy for Teams and use private channels, make sure you're aware of the migration of private channel messages in 2025 so you know whether to select **Teams private channel messages** or **Teams channel messages** as the location.

Create and configure a retention policy

Although a retention policy can support multiple services that are identified as "locations" in the retention policy, you can't create a single retention policy that includes all the supported locations:

- **Exchange mailboxes**
- **SharePoint sites** or **SharePoint classic and communication sites**
- **OneDrive accounts**
- **Microsoft 365 Group mailboxes & sites**
- **Skype for Business**
- **Exchange public folders**
- **Teams channel messages**
- **Teams chats**
- **Teams private channel messages** (applicable pre-migration only)
- **Teams call logs**
- **Microsoft Copilot experiences**
- **Enterprise AI apps**
- **Other AI apps**
- **Viva Engage community messages**
- **Viva Engage user messages**

If you select the Teams or Viva Engage locations when you create a retention policy, the other locations are automatically excluded. This means that the instructions to follow depend on whether you need to include the Teams or Viva Engage locations.

> ⓘ **Note**

When you use adaptive policies instead of static policies, you can configure a single retention policy to include both Teams and Viva Engage locations. This isn't the case for static policies where Teams and Viva Engage locations require their own retention policy.

When you've more than one retention policy, and when you also use retention labels, see The principles of retention, or what takes precedence? to understand the outcome when multiple retention settings apply to the same content.

Select the tab for instructions to create a retention policy for Teams, Copilots, AI apps, Viva Engage, or the other supported services (Exchange, SharePoint, OneDrive, Microsoft 365 Groups, Skype for Business):

Retention policy for Teams & AI apps

> **Note**
>
> For AI apps other than Microsoft 365 Copilot and Copilot Studio, see **Before you begin** about the prerequisite of collection policies.

Retention policies for Teams support shared channels. When you configure retention settings for the **Teams channel message** location, if a team has any shared channels, they inherit retention settings from their parent team.

From late April 2026, retention policies also support newly created Teams call logs when you create the retention policies with PowerShell. For more information, see Retention policy for Teams call logs.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Policies** > **Retention policies**.
2. Select **New retention policy** to start the **Create retention policy** configuration, and name your new retention policy.
3. For the **Assign admin units** page, keep the default of **Full directory**. Currently, admin units aren't supported for this policy.
4. For the **Choose the type of retention policy to create** page, select **Adaptive** or **Static**, depending on the choice you made from the Before you begin instructions. If you haven't already created adaptive scopes, you can select **Adaptive** but because there

won't be any adaptive scopes to select, you won't be able to finish the configuration with this option.

5. Depending on your selected scope:

   - If you chose **Adaptive**: On the **Choose adaptive policy scopes and locations** page, select **Add scopes** and select one or more adaptive scopes that have been created. Then, select one or more locations. The locations that you can select depend on the scope types added. For example, if you only added a scope type of **User**, you'll be able to select **Teams chats** but not **Teams channel messages**.

   - If you chose **Static**: On the **Choose locations to apply the policy** page, select one or more locations:
     - **Teams channel message**: Messages from standard and shared channel chats, and standard and shared channel meetings. Includes messages from private channel chats and private channel meetings post-migration only.
     - **Teams chats**: For Teams, messages from private 1:1 chats, group chats, meeting chats, and chat with yourself.
     - **Teams private channel messages**: Applicable pre-migration only. Messages from private channel chats and private channel meetings. If you select this option, you can't select the other Teams locations in the same retention policy.
     - **Microsoft Copilot experiences**: For built-in and custom Copilot experiences, all user prompts responses. Includes Microsoft 365 Copilot, Security Copilot, Copilot in Fabric, Copilot Studio.
     - **Enterprise AI apps**: For non-Copilot Enterprise AI apps onboarded or connected to your org using methods like Entra registration or data connectors, all user prompts and responses. Includes Entra-registered AI apps, ChatGPT Enterprise, Microsoft Foundry.
     - **Other AI Apps**: For other supported AI apps, all user prompts and responses. includes ChatGPT, Google Gemini, Microsoft Bing, DeepSeek.

     By default, all teams and all users are selected, but you can refine this by selecting the **Choose** and **Exclude** options.

6. For **Decide if you want to retain content, delete it, or both** page, specify the configuration options for retaining and deleting content.

   You can create a retention policy that just retains content without deleting, retains and then deletes after a specified period of time, or just deletes content after a specified period of time. For more information, see Settings for retaining and deleting content.

7. Complete the configuration and save your settings.

For guidance when to use retention policies for Teams and understand the end user experience, see Manage retention policies for Microsoft Teams from the Teams documentation.

For technical details about how retention works for Teams and Copilot data, including what elements of messages are supported for retention and timing information with example walkthroughs, see Learn about retention for Microsoft Teams and Learn about retention for Copilot.

Known configuration issues for Teams retention policies

- Although you can select the option to start the retention period when items were last modified, the value of **When items were created** is always used. For messages that are edited, a copy of the original message is saved with its original timestamp to identify when this pre-edited message was created, and the post-edited message has a newer timestamp.
- When you select **Edit** for the Teams chats location, you might see guests and non-mailbox users. Retention policies aren't designed for these users, so don't select them.
- Before late April 2026: Teams call data records (CDRs) for Teams chat and channel messages were included in Teams chat retention policies. Now, CDRs are included only in a retention policy for Teams call logs, as documented in the next section.

Retention policy for Teams call logs

Teams call logs represent the collection of call-related data generated by Teams, including call data records (CDRs) and other call metadata. CDRs are also sometimes referred to as call detail records, or just call records.

Prior to supporting the retention of Teams call logs in late April 2026, CDRs for Teams chat and Teams channels were included in retention policies for the Teams chat location. Going forward, new CDRs are supported only when you create a retention policy for Teams call logs. CDRs included in previous Teams chat retention policies continue to be managed by those same policies.

This separate retention policy for call logs can be created and modified only by using PowerShell. It has the following considerations:

- The policy includes call logs for both Teams chat and Teams channels.
- The policy applies only to new call logs that are created after the policy is configured and active.

After you create the retention policy for Teams call logs, it's displayed in **Data Lifecycle Management** > **Policies** in the Microsoft Purview portal, where it's visible but read-only.

To create a retention policy for Teams call logs, first use the New-AppRetentionCompliancePolicy cmdlet. As an example, the following command creates a Teams call log retention policy for all mailboxes:

PowerShell

```
New-AppRetentionCompliancePolicy -Name "<PolicyName>" -Applications
"User:MicrosoftTeamsCallLog" -ExchangeLocation "All"
```

Then use the New-AppRetentionComplianceRule cmdlet to create a retention rule that specifies the retention duration and action. For example, the following command creates a delete-only rule that permanently deletes Teams call log data after one year:

PowerShell

```
New-AppRetentionComplianceRule -Name "<RuleName>" -Policy "<PolicyName>" -
RetentionDuration 365 -RetentionDurationDisplayHint Days -
RetentionComplianceAction Delete
```

For more information about using PowerShell cmdlets to create and manage retention policies, see PowerShell cmdlets for retention policies and retention labels.

Additional retention policies needed to support Teams

Teams is more than just messages and call logs from chats and channels. If you have teams that were created from a Microsoft 365 group (formerly Office 365 group), you should additionally configure a retention policy that includes that Microsoft 365 group by using the **Microsoft 365 Group mailboxes & sites** location. This retention policy applies to content in the group's mailbox, site, and files. Files include Teams meeting recordings and transcripts from channel meetings.

To retain or delete Teams meeting recordings with their transcripts from user chats, you'll need a retention policy that includes the organizer's OneDrive account as the location.

If you have team sites that aren't connected to a Microsoft 365 group, which includes sites for Teams shared channels and Teams private channels, you need a retention policy that includes the **SharePoint classic and communication sites** or **OneDrive accounts** locations to retain and delete files in Teams:

- Files that are shared in chat are stored in the OneDrive account of the user who shared the file.
- Files that are uploaded to channels are stored in the SharePoint site for the team.

> **Tip**
>
> You can apply a retention policy to the files of just a specific team when it's not connected to a Microsoft 365 group by selecting the SharePoint site for the team, and the OneDrive accounts of users in the Team.

It's possible that a retention policy that's applied to Microsoft 365 groups, SharePoint sites, or OneDrive accounts could delete a file that's referenced in a Teams chat or channel message before those messages get deleted. In this scenario, the file still displays in the Teams message, but when users select the file, they get a "File not found" error. This behavior isn't specific to retention policies and could also happen if a user manually deletes a file from SharePoint or OneDrive.

Separate an existing 'Teams chats and Copilot interactions' policy

Previously, retention policies used the location **Teams chats and Copilot interactions** that combined Teams chat and Copilot interactions. There are now separate retention locations for Teams chat and Copilot interactions.

- You can separate Teams chats from Copilot interactions from an existing retention policy.
- You can create new retention policies for just Teams chats, or for just Copilot interactions.

Use the following PowerShell commands to separate an existing retention policy for **Teams chats and Copilot interactions**:

- To make your existing retention policy for the older locations a Teams chat only policy:

```
PowerShell
```

```
Set-RetentionCompliancePolicy -Identity "<policy name>" -Applications
"User:TeamsChatUserInteractions"
```

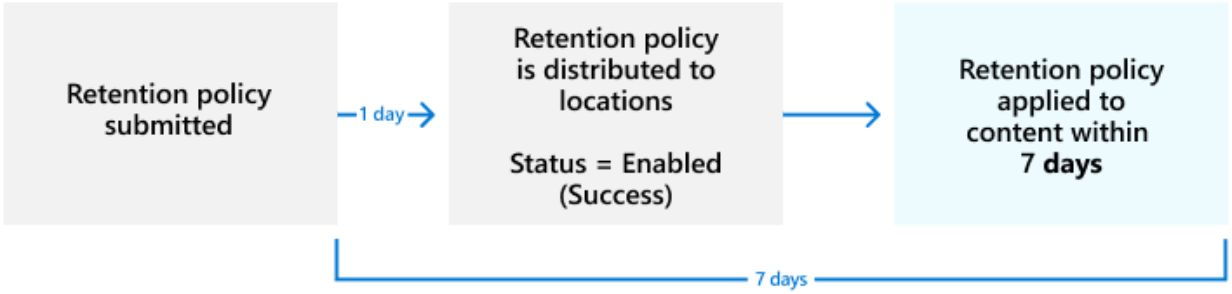
Or, if you have an existing retention policy for newer locations, such as Teams private channel messages and Viva Engage, you can add Teams chat to it:

PowerShell

```
Set-AppRetentionCompliancePolicy -Identity "<policy name>" -Applications
"User:TeamsChatUserInteractions"
```

- To add Microsoft 365 Copilot interactions to an existing retention policy for newer locations, such as Teams private channel messages and Viva Engage:

PowerShell



```
Set-AppRetentionCompliancePolicy -Identity “<policy name>” -Applications
"User:M365Copilot"
```

For new retention policies, select the new locations, such as **Teams chat** or **Microsoft Copilot Experiences**.

> ⓘ **Note**
>
> If you have existing retention policies for **Teams chats and Copilot interactions**, they continue to be supported, although they can't be edited when your tenant supports the separate locations. At this point, any new retention policies must use the new locations.

How long it takes for retention policies to take effect

When you create and submit a retention policy, it can take up to seven days for the retention policy to be applied:

First, the retention policy needs to be distributed to the locations that you selected, and then applied to content. You can always check the distribution status of the retention policy by selecting it from the **Retention policies** page in the Microsoft Purview portal. From the flyout pane, if you see **(Error)** included in the status, and in the details for the locations see a message that it's taking longer than expected to deploy the policy or to try redeploying the policy, try running the Set-AppRetentionCompliancePolicy or Set-RetentionCompliancePolicy PowerShell command to retry the policy distribution:

1. Connect to Security & Compliance PowerShell.
2. Run one of the following commands:

   - For the policy locations **Teams private channel messages**, **Viva Engage user messages** and **Viva Engage community messages**:

     PowerShell

     ```
     Set-AppRetentionCompliancePolicy -Identity <policy name> -RetryDistribution
     ```

   - For all other policy locations, such as **Exchange mailboxes**, **SharePoint classic and communication sites**, and **Teams channel messages**:

     PowerShell

     ```
     Set-RetentionCompliancePolicy -Identity <policy name> -RetryDistribution
     ```

Updating retention policies

When settings from the retention policy are already applied to content, a change in configuration to the policy will be automatically applied to this content in addition to content that's newly identified.

Some settings can't be changed after the policy is created and saved, which include the name of the retention policy, the scope type (adaptive or static), and the retention settings except the retention period.

If you no longer need the retention settings that you've configured, see Releasing a policy for retention.

Troubleshooting retention policies

If your retention policies aren't working as expected or you see errors related to your retention policies, use the following troubleshooting resources:

- Identify errors in Microsoft 365 retention and retention label policies
- Resolve errors in Microsoft 365 retention and retention label policies

Next steps

If some items for Exchange, SharePoint, OneDrive, or Microsoft 365 Groups need different retention settings from the retention policy settings you've configured, create retention labels for these exceptions.

However, if you're looking to manage high-value items for business, legal, or regulatory record-keeping requirements, use file plan to create and manage retention labels.

Last updated on 06/09/2026

Create retention labels for exceptions to your retention policies

> *Microsoft Purview service description*

As part of your data governance strategy to retain what you need and delete what you don't, you might need to create a few retention labels for items that need exceptions to your retention policies.

Whereas retention policies automatically apply to all items at the container level (such as SharePoint sites, user mailboxes, and so on), retention labels apply to individual items, such as a SharePoint document or an email message.

Make sure you understand the principles of retention before you use retention labels to supplement a retention policy for specific SharePoint, OneDrive, or Exchange items. Typically, you'll use retention labels to retain specific items longer than an applied retention policy, but they can also be used to override automatic deletion at the end of the retention period, or apply a different deletion period.

As a typical example: The majority of content on your SharePoint sites need to be retained for three years, which is covered with a retention policy. But you have some contract documents that must be retained for seven years. These exceptions can be addressed with retention labels. After assigning the retention policy to all SharePoint sites, you apply the retention labels to the contract documents. All SharePoint items will be retained for three years, and just the contract documents will be retained for seven years.

For more examples of how retention labels can be used as exceptions to retention policies, see Combining retention policies and retention labels.

Retention labels also support more capabilities than retention policies. For more information, see Compare capabilities for retention policies and retention labels.

Use the following information to help you create retention labels to supplement retention policies as part of your data lifecycle management strategy.

> **Note**

Create retention labels from the **Records management** solution rather than **Data lifecycle management** if you need to use retention labels to manage high-value items for business, legal, or regulatory record-keeping requirements. For example, you want to use event-based retention or disposition review. For instructions, see Use file plan to create and manage retention labels.

Before you begin

To make sure you have permissions to create and edit retention labels and their policies, see Permissions for retention policies and retention labels.

How to create retention labels for data lifecycle management

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Retention labels**.

2. Select **Create a label** and follow the prompts to create the retention label. Be careful what name you choose, because this can't be changed after the label is saved.

   > **Note**
   >
   > Double quotation marks ("") aren't supported in retention label names. For example, ""Permanent Label"" isn't supported.

   For more information about the retention settings, see Settings for retaining and deleting content.

3. After you have created the label and you see the options to publish the label, auto-apply the label, or just save the label: Select **Just save the label for now**, and then select **Done**.

4. Repeat these steps to create any more retention labels that you need for different retention settings.

To edit an existing label, select it, and then select the **Edit label** option to start the Edit retention label configuration that lets you change the label descriptions and any eligible settings.

Most settings can't be changed after the label is created and saved, which include the label name, and the retention settings except the retention period.

Next steps

Now you've created retention labels, they are ready to be added to items by publishing the labels, or automatically applying them:

- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

Expedite the permanent deletion of sensitive information from mailboxes

> *Microsoft 365 licensing guidance for security & compliance.*

> **Note**
>
> Priority cleanup is rolling out in preview and subject to change.
>
> Although this feature requires additional permissions and multiple approvals, highly regulated organizations that use Preservation Lock might want the additional safeguard of turning off priority cleanup at the tenant level to ensure that their policies remain in compliance with required regulations.

Use the **Priority cleanup** feature under **Data Lifecycle Management** in Microsoft Purview when you need to permanently delete sensitive content from Exchange mailboxes, despite retention settings that retain the item or eDiscovery holds. Items still go through the same deletion process with the same timings to ensure a compliant permanent deletion, but there's no need to wait for the retention period to expire or the hold to be released. Priority cleanup might be implemented for security or privacy in response to an incident, or for compliance with regulatory requirements. For example:

- **Privacy request**: You receive a request to remove personal information about an employee who has left the organization and all mailboxes have a retention policy to retain items for two years.
- **Data spillage**: An employee accidentally emailed sensitive information about a future acquisition and you need to delete this information, despite any eDiscovery holds in progress in the organization.

Because the deletion is irreversible and can override existing holds and even Preservation Lock, the process requires multiple approvals, specific roles, and is audited. After considering these safeguards, if your organization still has concerns about this capability, you can just continue to use retention policies and retention labels to ensure a compliant deletion of content instead of using priority cleanup.

Under the covers, priority cleanup uses retention labels with auto-apply policies. However, you don't interact manually with these labels and policies, and they supersede the principles of retention to achieve the required expedited deletion.

> **Note**
>
> If an item is subject to multiple priority cleanups, the newest takes priority.

Important exceptions for priority cleanup:

- You can't use priority cleanup for items that are marked as a record or regulatory record.
- Although priority cleanup can override eDiscovery holds, the data might already be copied to an eDiscovery review set where it can't be deleted by priority cleanup. This data is automatically deleted when the entire eDiscovery case is deleted by an eDiscovery admin.

Similar to auto-apply retention labels, priority cleanup supports simulation, so you can check the returned samples in case the policy configuration needs any fine-tuning.

Comparing priority cleanup for different workloads

Although you can use the priority cleanup feature for mailboxes and for files in SharePoint and OneDrive, the typical use cases are different. There are some other differences in behavior and configuration that are summarized in the following table. As a result of these differences, you can't create a cleanup policy for all three locations in same policy.

Expand table

Behavior or configuration	Exchange	SharePoint/OneDrive
Typical use case:	Data spillage Delete sensitive data for compliance requirements	Delete stale Teams meeting recordings and transcripts Delete retained files in the Preservation Hold library
Typical policy use:	Rare	For Teams meeting recordings and transcripts: Continual For the Preservation Hold library: After a user leaves the organization
Two-person rule:	Another priority cleanup admin is assigned in the policy to review items after the policy is turned on	Another priority cleanup admin is included in the policy configuration flow before the policy is turned on

Behavior or configuration	Exchange	SharePoint/OneDrive
Assign policy approvers:	- Priority cleanup admin - eDiscovery admin - Retention manager	- eDiscovery admin
Simulation required before running the policy:	No (but recommended)	Yes
Override Preservation Lock:	Yes	Only if the policy is configured for delete-only

Additionally, the required permissions for Exchange are different from the required permissions for SharePoint and OneDrive.

Prerequisites for priority cleanup

Make sure you can meet the prerequisites that must be in place before you can use priority cleanup to expedite the permanent deletion of sensitive data. These requirements include permissions and approvers.

Because of the built-in safeguards, the feature itself is enabled by default at the tenant level. However, priority cleanup can be turned off on the priority cleanup settings page. If you can't create new priority cleanup policies, see the instructions for turning off the feature to check the status and reverse the configuration.

> **Note**
>
> A mailbox must have at least 10-MB data to support priority cleanup.

Permissions for priority cleanup

To successfully access and manage **Priority cleanup** in the Microsoft Purview portal, users must have the **Priority Cleanup Admin** role. This role is required to create and manage priority cleanup policies, enable or disable the feature, or approve items within the initial approval stage. This role is automatically added to the Organization Management role group but must be manually added to any other role group.

Alternatively, the **Priority Cleanup Viewer** role allows only the visibility of priority cleanup policies and settings without the ability to make changes or create new policies.

Content Explorer List Viewer and **Content Explorer Content Viewer** roles are required to view item content and details in simulation mode and approval stages.

Similar to records management disposition, each person that accesses the **Priority cleanup** > **Pending cleanups** page sees only items that they're assigned to approve. To monitor the end-to-end process of a priority cleanup, use auditing and the priority cleanup ID as a search term.

Policy approvers

As a safeguard against accidental or malicious deletions, each item subject to priority cleanup always requires at least one other person to approve the permanent deletion in addition to the person who created the priority cleanup policy. Approvers must be individual users. Mail-enabled security groups are not currently supported.

- Priority cleanup admin approval is required for all policies.
- If an item is also subject to retention settings from a retention label or retention policies, retention manager approval is also required.
- If an item is also subject to one or more eDiscovery holds, eDiscovery admin approval is also required.

Approver role requirements

The approver at each stage of the review process must have the correct roles assigned before the policy can be created.

Expand table

Reviewer	Required roles
Priority cleanup admins	- Priority Cleanup admin - Data Classification Content Viewer - Data Classification List Viewer - Disposition Management
Retention managers	- Retention Management - Data Classification Content Viewer - Data Classification List Viewer - Disposition Management
eDiscovery admins	- Search And Purge - Hold - Review - Data Classification Content Viewer - Data Classification List Viewer - Disposition Management

> **Note**
>
> If the reviewer at any stage doesn't have the correct roles assigned in advance, policy creation fails with an error.

For instructions to add users to the default roles or create your own role groups, use the following guidance:

- Permissions in the Microsoft Purview portal

Although you can specify multiple approvers for each stage, just one person from each stage is required to approve for their stage.

Enable auditing

Make sure that auditing is enabled at least one day before you create and run the first priority cleanup policy. Auditing is also required to view simulation results if the policy is enabled in simulation mode. For more information, see Search the audit log.

Limitations of priority cleanup

- Group mailboxes are supported via adaptive scopes only.
- For the KeyQL query, some properties and conditions supported by eDiscovery aren't supported by priority cleanup. These include SenderAuthor, SubjectTitle, (c:c), and (c:s).
- In simulation mode, the priority cleanup policy may incorrectly show email items marked as records and regulatory records. These items are not actually in scope for priority cleanup outside simulation mode.
- Unlike disposition review for retention labels:
  - You can't customize the email notification
  - Approvers can't nominate additional approvers
  - There's no automatic approval after a specified period of time
- If an approver doesn't agree to permanently delete an identified item, they must assign an existing retention label (any configuration) to the item. Make sure your approvers know which retention labels are suitable for this action.
- Although you can delete a priority cleanup policy, if the approval process for it is complete, items might still be permanently deleted.

Create a priority cleanup policy

Decide before you create your priority cleanup policy whether to make it **adaptive** or **static**. For more information, see Adaptive or static policy scopes for retention. If you decide to use an adaptive policy, you must create one or more adaptive scopes before you create your priority cleanup policy, and then select them during the policy configuration. For instructions, see Configuration information for adaptive scopes.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Priority cleanup**, and then select **+ Create a priority cleanup**.

   If you don't see the **Priority cleanup** option, check your permissions.

2. Enter a name and description for this priority cleanup policy, and then select **Next**. The name is visible to end users, but the optional description is visible only to priority cleanup admins and the policy's specified approvers. This restriction means that any details you enter can be informative and specific, without worrying about unauthorized people seeing these details.

3. For **Choose the type of priority cleanup**, select **Adaptive** or **Static** then select **Next**.
   a. For Adaptive scope, add one or more adaptive scopes. For a user mailbox, add a user scope. For a group mailbox, add a Microsoft 365 Group scope. Then select one or more of the mailbox locations to match your scopes.
   b. For Static scope, select **Policy for Exchange Online** and then select Exchange Online location. Optionally, you can edit what mailboxes to include or exclude.

   To help you decide:

   - **All mailboxes are included**: Best when you're unsure where the content resides. It may take longer to apply the policy, but it's worth it if content might be in unknown mailboxes.
   - **Specific mailboxes**: Fastest option for a small, known set of mailboxes. Use to include or exclude up to 100 mailboxes confidently.
   - **User mailboxes by attributes**: You can't use a static scope if you want to use attributes to target user mailboxes by region, department, etc. Instead, go back in the policy configuration and choose to use adaptive scopes instead. However, avoid if the scope includes over 1 million mailboxes.

4. Select **Next**.

5. For the **Tell us what you're looking for** page, enter text into the KeyQL editor box to construct a query using Exchange email properties. You can refine your query by using search operators such as AND, OR, and NOT.

For example, to find all content sent after February 2, 2024, with an attachment named ContosoEmployeeSalaries.xlsx: **AttachmentNames:ContosoEmployeeSalaries.xlsx AND sent>=2024-02-02**

For more information about the query syntax that uses Keyword Query Language (KeyQL), see Keyword Query Language (KeyQL) syntax reference.

This query-based policy uses the same search index as eDiscovery content search to identify content. For more information about the searchable properties that you can use for email, see Finding content in Exchange Online.

6. For the **Choose when content should be deleted** page, choose whether to permanently delete the matched items as soon as possible or retain them for a specific period and then delete them. Most of the time, you'll select the first option so that you can delete the item as soon as possible. Use the alternative option only if the items should be retained for compliance reasons and you can't use a retention label for this purpose. For example, the item already has a retention label applied with a longer retention period.

   > ⓘ **Note**
   >
   > A priority cleanup policy overrides the principles of retention that normally determine when an item should be retained or permanently deleted.

7. For the **Assign who'll approve what gets deleted** page, this is where you need to specify another priority cleanup approver, an approver for when an identified item has retention settings applied (such as a retention policy, retention label, or litigation hold policy), and an approver for when an identified item has one or more eDiscovery holds applied.

   - **Priority cleanup admins**: Must be assigned the Priority Cleanup Admin role and is the first-stage approver for all priority cleanups for this policy. This should be a different person to the user who created the priority cleanup policy, but isn't enforced.
   - **Retention managers**: Must be assigned the Retention Management role. Approval from specified users is required if the identified content is subject to one or more retention policies or Litigation holds.
   - **eDiscovery admins**: Must be assigned the eDiscovery Administrator role. Approval from specified users is required if the identified content is subject to one or more eDiscovery holds.

8. For the **Choose the policy mode** page, choose whether to run the policy first in simulation mode or turn it on, or neither for the time being.

Running the policy in simulation mode delays permanent deletion but allows you to verify sample matches and refine the query. It also lets others review the results before approval, even if they're not designated approvers.

9. Specific to priority cleanup, you must acknowledge by selecting a checkbox that you understand how this policy can override eDiscovery holds and other applied retention settings.

10. On the **Your priority cleanup policy has been created** page, you see the **Cleanup ID** that's used to track and monitor this policy. Use the Copy function, or copy it later from the policy details so you can monitor the progress of this policy from auditing details.

If you chose to run the policy in simulation mode:

- You might need to wait a couple of hours for results, depending on the number of mailboxes to search.
- You can turn on the policy for up to seven days. After seven days, the simulation must be restarted.

If you turn on the policy, as with auto-apply retention label policies, it can take up to seven days to apply the policy to items and trigger the approval process.

Approval process for a priority cleanup policy

When the priority cleanup policy is turned on and items are identified, approvers for the policy are notified by email, with a reminder once a week. They can select the link in the notification and reminder emails to go directly to the **Data lifecycle management** > **Priority cleanup** > **Pending cleanups** page in the portal to review the content to approve. Alternately, the approvers can manually navigate to this page in the portal.

To implement the security control that uses the two-person rule, each priority cleanup always requires another priority cleanup admin to approve the permanent deletion of identified items. Then if the items have retention settings applied, they require a next stage approval from retention admins. And finally, if the items are included in an eDiscovery hold, they also require another approval from an eDiscovery admin. When all the required approvals are complete, items are permanently deleted and cannot be restored by users, by admins, or by Microsoft.

On the **Pending cleanups** page, items identified by a priority cleanup policy are listed with a status of **Pending disposition** and an estimated count of how many items are identified. These might be different items, or the same item in multiple mailboxes.

When the approver selects one of the list items, the next page shows them the individual items with the item names, locations, and senders. When an item is selected, the preview pane

displays the item's subject, source, details, and history. The history displays any priority cleanup approvals to date for that item, with approver comments if available.

After reviewing all the items, the approver can individually or multi-select them, and select **Approve disposal**. They must then acknowledge the action with an optional comment, and select **Apply**.

Alternatively, if the item shouldn't be permanently deleted as soon as possible, the approver must select **Relabel**, and select an existing retention label.

Items that are approved or relabeled are then moved to the **Disposed items** tab. Allow up to seven days for items to be permanently deleted.

Export the views

An approver can use the **Export** option from the **Pending cleanups** and **Disposed items** pages to export information about the items in either view as a .csv file that they can then sort and manage with Excel.

How to monitor priority cleanup

You can monitor the status of priority cleanups for each policy from **Data lifecycle management** > **Priority cleanup**. For example, the status displays **In simulation**, or **Enabled (Pending)** that changes to **Enabled (Success)**.

Use the details of a policy to identify its cleanup ID, and paste this number as a keyword search string from the auditing solution. To use the date range, remember to specify the dates in UTC.

There are two auditing events specific to priority cleanup for mailboxes:

- Operation name of **PriorityCleanupTagApplied**: When an item is identified for priority cleanup, and if this resulted in removing an existing retention label.
- Operation name of **PriorityCleanupDelete**: The deletion of a mailbox item by priority cleanup.

Currently, these events don't have friendly names to select from the Microsoft Purview portal.

Other auditing events are the same as those used for creating and configuring a retention label and auto-labeling policy, and events for disposition review.

The end user experience for priority cleanup

Because priority cleanup doesn't use a soft-delete process, users see a **Retention:** message bar on their emails in Outlook when they're identified for priority cleanup. They also see the name of the priority cleanup policy, then **(-1 days)** to indicate that it should be deleted as soon as possible, and an estimated expiry day and time based on that -1 days.

For example, if your priority cleanup policy is named "Cleanup policy test":

Retention: Cleanup policy test (-1 days) Expires: Thu 2/6/2024 AM

> **Tip**
>
> If you prefer end users to not see the retention message, you can achieve this by first using **eDiscovery search and purge** that soft-deletes items. When that completes, then apply the priority cleanup policy to permanently delete the soft deleted items.

After the final priority cleanup approval, the item silently disappears from Outlook.

Turn off priority cleanup for the tenant

After considering the safeguards of additional permissions and multiple approvals, if your organization still has concerns about this capability, you can turn off the ability to create priority cleanup policies. When you turn off priority cleanup, you're turning it off for SharePoint and OneDrive as well as for Exchange.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management**.
2. From the top right, select **Priority cleanup settings**.
3. From the **Configuration** page, turn off the control for priority cleanup, and select **Save**.

New priority cleanup policies can't be created until you turn on the control and select **Save** again.

If priority cleanup policies are already created when you turn off the control:

- Existing priority cleanup policies continue to function
- Existing priority cleanup policies can be deleted
- Existing priority cleanup policies can't be modified

Override holds to clean up files for Copilot and reclaim storage

Last updated on 12/03/2025

Override holds to clean up files for Copilot and reclaim storage

> *Microsoft 365 licensing guidance for security & compliance.*

Use the **Priority cleanup** feature under **Data Lifecycle Management** in Microsoft Purview when you need to override existing retention settings or eDiscovery holds to delete content from OneDrive and SharePoint. Despite the existing holds, items are moved to the second-stage Recycle Bin and from there, go through the same processes with the same time periods to ensure a compliant deletion process.

Although priority cleanup might be needed for security or privacy in response to an incident, or for compliance with regulatory requirements, typical use cases for SharePoint and OneDrive include the following;

- **Delete stale Teams meeting recordings and transcripts, turned on for Copilot recap**: The Copilot in Teams recap feature uses Teams meeting recordings and transcripts that might be covered by a retention policy. These files are typically large and have little business value after 1-3 months. To reclaim the space from these files, or any other similarly large files that don't need to be retained as long as your retention policies, you can take action to remove them.

  > **Tip**
  >
  > Most meeting recordings and transcripts are saved to OneDrive. However, recordings from channel meetings are stored in SharePoint. For more information, see **Use OneDrive and SharePoint to store meeting recordings**.

  Priority cleanup lets you delete these files by overriding existing retention policies so you can better manage your storage requirements. Because these files are continually created, leave the priority cleanup policy running to automatically find and delete the stale files.

- **Delete labeled items in OneDrive's Preservation Hold library when a user leaves the organization**: When one or more items in a Preservation Hold library have an unexpired retention period, the OneDrive site for the user can't be deleted. As a result, when users leave the organization, you might not be able to delete their OneDrive site until the longest retention period expires. Priority cleanup can delete these files instead of waiting for the expiration period to end, so you can then delete the site for the OneDrive account and reclaim that OneDrive storage space. Create a priority cleanup policy after a user has left the organization and their OneDrive account is blocked from deletion.

Because the deletion from priority cleanup can override existing holds and even Preservation Lock when the retention settings are for delete-only, the process requires multiple approvals, specific roles, and is audited. After considering these safeguards, if your organization still has concerns about this capability, you can just continue to use retention policies and retention labels to ensure a compliant deletion of content instead of using priority cleanup.

Under the covers, priority cleanup uses retention labels with auto-apply policies. However, you don't interact manually with these labels and policies, and they supersede the principles of retention so you don't need to wait for the longest retention period to expire.

> **Note**
>
> If an item is subject to multiple priority cleanups, the newest takes priority.

Important exceptions for priority cleanup:

- You can't use priority cleanup for items that are marked as a record or regulatory record.
- Although priority cleanup can override eDiscovery holds, the data might already be copied to an eDiscovery review set where it can't be deleted by priority cleanup. This data is automatically deleted when the entire eDiscovery case is deleted by an eDiscovery admin.

Similar to auto-apply retention labels, priority cleanup supports simulation, to check the returned samples in case the policy configuration needs any fine-tuning. For SharePoint and OneDrive, you must run simulation at least one time, and for any change other than the policy description.

Comparing priority cleanup for different workloads

Although you can use the priority cleanup feature for mailboxes and for files in SharePoint and OneDrive, the typical use cases are different. There are some other differences in behavior and configuration that are summarized in the following table. As a result of these differences, you can't create a cleanup policy for all three locations in same policy.

Expand table

Behavior or configuration	Exchange	SharePoint/OneDrive
Typical use case:	Data spillage	Delete stale Teams meeting recordings and transcripts

Behavior or configuration	Exchange	SharePoint/OneDrive
	Delete sensitive data for compliance requirements	Delete retained files in the Preservation Hold library
Typical policy use:	Rare	For Teams meeting recordings and transcripts: Continual For the Preservation Hold library: After a user leaves the organization
Two-person rule:	Another priority cleanup admin is assigned in the policy to review items after the policy is turned on	Another priority cleanup admin is included in the policy configuration flow before the policy is turned on
Assign policy approvers:	- Priority cleanup admin - eDiscovery admin - Retention manager	- eDiscovery admin
Simulation required before running the policy:	No (but recommended)	Yes
Override Preservation Lock:	Yes	Only if the policy is configured for delete-only

Additionally, the required permissions for Exchange are different from the required permissions for SharePoint and OneDrive.

Prerequisites for priority cleanup

Make sure you can meet the prerequisites that must be in place before you can use priority cleanup to override existing holds for SharePoint and OneDrive. These requirements include permissions and approvers.

Because of the built-in safeguards, the feature itself is enabled by default at the tenant level. However, priority cleanup can be turned off on the priority cleanup settings page. If you can't create new priority cleanup policies, see the instructions for turning off the feature to check the status and reverse the configuration.

Permissions for priority cleanup

To successfully access and manage **Priority cleanup** in the Microsoft Purview portal, you must have the **Priority Cleanup Admin** role. For SharePoint and OneDrive, this role is required to create and manage priority cleanup policies, and enable or disable the feature. This role is

automatically added to the Organization Management role group but must be manually added to any other role group.

Alternatively, the **Priority Cleanup Viewer** role allows only the visibility of priority cleanup policies and settings without the ability to make changes or create new policies.

Content Explorer List Viewer and **Content Explorer Content Viewer** roles are required to view item content and details in simulation mode, and approval stages.

Similar to records management disposition, each person that accesses the **Priority cleanup** > **Pending cleanups** page sees only items that they're assigned to approve. To monitor the end-to-end process of a priority cleanup, use auditing and the priority cleanup ID as a search term.

Policy approvers

As a safeguard against accidental or malicious deletions, each item subject to priority cleanup always requires at least one other person to approve the deletion in addition to the person who created the priority cleanup policy. Approvers must be individual users. Mail-enabled security groups aren't currently supported.

- Priority cleanup admin approval is required for all policies.
- If an item is also subject to one or more eDiscovery holds, eDiscovery admin approval is also required.
- Separate approval from a retention admin isn't required to override retention settings.

Approver role requirements

The approver at each stage of the review process must have the correct roles assigned.

Expand table

Reviewer	Required roles
Priority cleanup admins	- Priority Cleanup Admin - Data Classification Content Viewer - Data Classification List Viewer - Retention Management
eDiscovery admins	- Search And Purge - Hold - Review - Data Classification Content Viewer - Data Classification List Viewer - Disposition Management

> ⓘ Note
>
> If the reviewer for eDiscovery admin doesn't have the correct roles assigned in advance, policy creation fails with an error.

For instructions to add users to the default roles or create your own role groups, use the following guidance:

- Permissions in the Microsoft Purview portal

Although you can specify multiple approvers for eDiscovery, just one person is required to approve overriding eDiscovery holds.

Enable auditing

Make sure that auditing is enabled at least one day before you create and run the first priority cleanup policy. Auditing is also required to view simulation results. For more information, see Search the audit log.

Limitations of priority cleanup

- In simulation mode, items under preservation lock where the retention settings are configured for delete-only may show up. These items are not actually in scope for priority cleanup outside simulation mode.
- Unlike disposition review for retention labels:
  - You can't customize the email notification
  - Approvers can't nominate additional approvers
  - There's no automatic approval after a specified period of time
- If an approver doesn't agree to delete an identified item, they must assign an existing retention label (any configuration) to the item. Make sure your approvers know which retention labels are suitable for this action.
- Although you can delete a priority cleanup policy, if the approval process for it is complete, items might still be deleted.

Create a priority cleanup policy

Decide before you create your priority cleanup policy whether to make it **adaptive** or **static**. For more information, see Adaptive or static policy scopes for retention. If you decide to use an

adaptive policy, you must have one or more adaptive scopes before you create your priority cleanup policy so that you can select them during the policy configuration. For instructions, see Configuration information for adaptive scopes.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Priority cleanup**, and then select **+ Create a priority cleanup**.

   If you don't see the **Priority cleanup** option, check your permissions.

2. Enter a name and description for this priority cleanup policy, and then select **Next**. The name is visible to end users, but the optional description is visible only to priority cleanup admins and the policy's specified approvers. This restriction means that any details you enter can be informative and specific, without worrying about unauthorized people seeing these details.

3. For **Choose the type of priority cleanup**, select **Adaptive** or **Static** then select **Next**.
   a. For Adaptive scope, add one or more adaptive scopes. For OneDrive accounts, add a scope for users. For sites, add a scope for SharePoint sites or Microsoft 365 Groups, as needed. Then select one or more of the locations to match your scopes.
   b. For Static scope, select **Policy for SharePoint/OneDrive** and then select one or more of the locations for sites and OneDrive accounts. Optionally, you can edit what sites and user accounts to include or exclude.

4. Select **Next**.

5. For the **Tell us what you're looking for** page, enter text into the KeyQL editor box to construct a query to target specific files. You can refine your query by using search operators such as AND, OR, and NOT.

   For example, to find Teams meeting recordings and transcripts, use **ProgID:Media AND ProgID:Meeting**. For files in a Preservation Hold library, use **ParentLink:PreservationHoldLibrary**.

   For more information about the query syntax that uses Keyword Query Language (KeyQL), see Keyword Query Language (KeyQL) syntax reference and Automatically apply a retention label to retain or delete content.

   This query-based policy uses the same search index as eDiscovery content search to identify content.

6. For the **Choose when content should be deleted** page, choose whether to delete the matched items as soon as possible or retain them for a specific period and then delete them. Most of the time, you'll select the first option so that you can delete the item as soon as possible. Use the alternative option only if the items should be retained for

compliance reasons and you can't use a retention label for this purpose. For example, the item already has a retention label applied with a longer retention period.

> **Note**
>
> A priority cleanup policy overrides the principles of retention that normally determine when an item should be retained or deleted.

7. For the **Assign who'll approve what gets deleted** page, this is where you need to specify an approver for when an identified item has one or more eDiscovery holds applied:

   - **eDiscovery admins**: Must be assigned the eDiscovery Administrator role. Approval from specified users is required if the identified content is subject to one or more eDiscovery holds.

8. For the **Choose the policy mode** page, choose whether to run the policy first in simulation mode or leave it turned off.

   Running the policy in simulation mode is required to initially set up priority cleanup for SharePoint and OneDrive locations. Simulation mode lets you verify that sample results match your query, so you can fine-tune it before approval. It also facilitates review with another priority cleanup admin.

9. Specific to priority cleanup, you must acknowledge by selecting a checkbox that you understand how this policy can override eDiscovery holds and other applied retention settings. Select **Submit**

10. On the **Your priority cleanup policy has been created** page, you see the **Cleanup ID** that's used to track and monitor this policy. Use the Copy function, or copy it later from the policy details so you can monitor the progress of this policy from auditing details.

11. Once simulation results are available, ask a second priority cleanup admin to review the results from the **Priority Cleanup Policies** page. They should select the policy from the list, and then select **View simulation details**.

12. If the results are satisfactory, this second priority cleanup admin can select **Turn on policy**. However, if the policy needs reconfiguration to add or remove items, they should make those edits and rerun simulation, and view results again. They should continue to make edits and rerun simulation each time. When the results are satisfactory, you, as the first priority cleanup admin, can turn on the policy.

> **Important**

> The last person to edit the policy can't also turn it on. We recommend that only one priority admin edits the policy after it's first created. So as a variation to step 12, the original priority cleanup admin could edit the policy and rerun simulation, and the second priority cleanup admin turns it on.

The Locations box shows scanned areas, and sample counts may differ from match counts. After the policy is turned on, wait for the "Enabled (Success)" status, which may take up to seven days.

Approval process for a priority cleanup policy

When the priority cleanup policy is turned on and items are identified that are subject to eDiscovery, your assigned eDiscovery approvers for the policy are notified by email, with a reminder once a week. They can select the link in the notification and reminder emails to go directly to the **Data lifecycle management** > **Priority cleanup** > **Pending cleanups** page in the portal to review the content to approve. Alternately, the approvers can manually navigate to this page in the portal.

When any required approvals are complete, items are moved to the second-stage Recycle Bin.

On the **Pending cleanups** page, items identified by a priority cleanup policy are listed with a status of **Pending disposition** and an estimated count of how many items are identified. These might be different items, or the same item in multiple locations.

When the approver selects one of the list items, the next page shows them the individual items with the item names, locations, and senders. When an item is selected, the preview pane displays the item's subject, source, details, and history. The history displays any priority cleanup approvals to date for that item, with approver comments if available.

After reviewing all the items, the approver can individually or multi-select them, and select **Approve disposal**. They must then acknowledge the action with an optional comment, and select **Apply**.

Alternatively, if the item shouldn't be deleted, the approver must select **Relabel**, and select an existing retention label.

Items that are approved or relabeled are then moved to the **Disposed items** tab. Allow up to seven days for items to be deleted.

Export the views

An approver can use the **Export** option from the **Pending cleanups** and **Disposed items** pages to export information about the items in either view as a .csv file that they can then sort and manage with Excel.

How to monitor priority cleanup

You can monitor the status of priority cleanups for each policy from **Data lifecycle management** > **Priority cleanup**. For example, the status displays **In simulation**, or **Enabled (Pending)** that changes to **Enabled (Success)**.

Use the details of a policy to identify its cleanup ID, and paste this number as a keyword search string from the auditing solution. To use the date range, remember to specify the dates in UTC.

There are two auditing events specific to priority cleanup for SharePoint and OneDrive:

- Operation name of **PriorityCleanupTagApplied**: When an item is identified for priority cleanup, and if this resulted in removing an existing retention label.
- Operation name of **PriorityCleanupFileRecycled**: The deletion of an item in SharePoint or OneDrive by priority cleanup.

Currently, these events don't have friendly names to select from the Microsoft Purview portal.

Other auditing events are the same as those used for creating and configuring a retention label and auto-labeling policy, and events for disposition review.

The end user experience for priority cleanup

Files that are identified for priority cleanup display to users as an applied retention label that has the same name as the priority cleanup policy.

If users remove or replace this retention label, it will be automatically reapplied by the policy.

Turn off priority cleanup for the tenant

After considering the safeguards of additional permissions and multiple approvals, if your organization still has concerns about this capability, you can turn off the ability to create priority cleanup policies. When you turn off priority cleanup, you're turning it off for Exchange as well as for SharePoint and OneDrive.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management**.
2. From the top right, select **Priority cleanup settings**.
3. From the **Configuration** page, turn off the control for priority cleanup, and select **Save**.

New priority cleanup policies can't be created until you turn on the control and select **Save** again.

If priority cleanup policies are already created when you turn off the control:

- Existing priority cleanup policies continue to function
- Existing priority cleanup policies can be deleted
- Existing priority cleanup policies can't be modified

Permanently delete files with Microsoft Purview Priority Cleanup

> *Microsoft Purview service description*

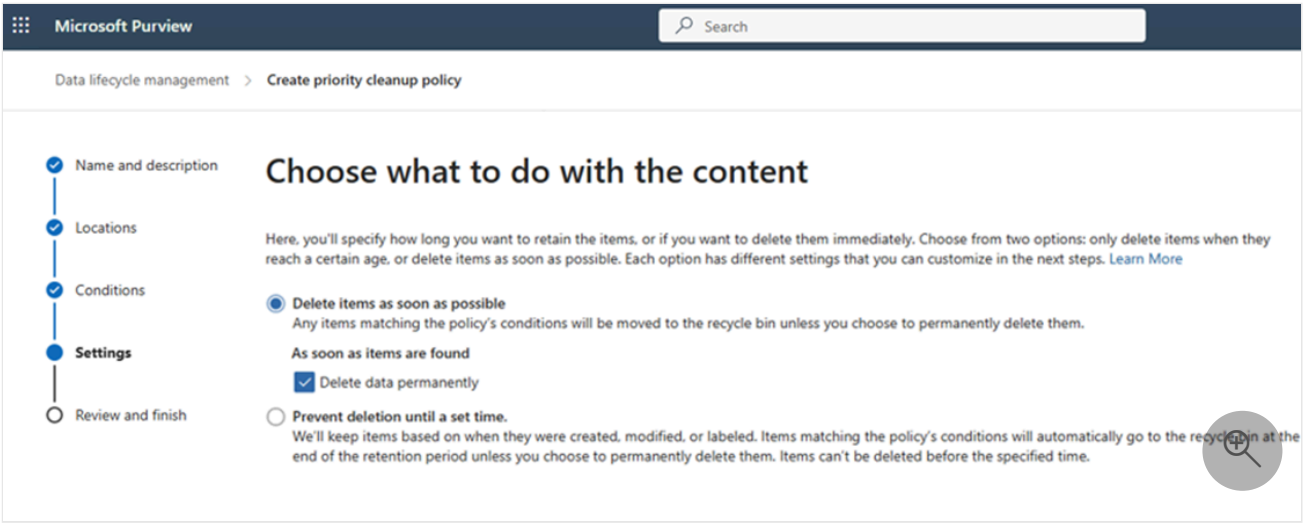
Use Microsoft Purview Priority Cleanup to permanently delete targeted files from SharePoint and OneDrive after the required review and approval. This option bypasses the SharePoint and OneDrive recycle bins. After deletion, the content is no longer discoverable in SharePoint search, Microsoft 365 Copilot, or eDiscovery.

Permanent deletion is an additional option for a Priority Cleanup policy. Use the standard Priority Cleanup workflow when you want identified items to move to the second-stage Recycle Bin.

Before you begin, review the required roles, approvers, auditing, and simulation requirements.

Prerequisites

Before you configure permanent deletion:



- Review the prerequisites, permissions, approver requirements, and simulation process in Override holds to clean up files for Copilot and reclaim storage.
- Assign the **Priority Cleanup Admin** role to the administrator who creates and manages the policy.
- Assign the required roles to each approver before policy creation.
- Enable auditing at least one day before you create and run the first Priority Cleanup policy.
- Confirm that the permanent deletion option is available in your tenant. Public preview rollout begins on August 24, 2026.

> ⓘ **Important**
>
> Permanent deletion can override retention settings or eDiscovery holds. Items already copied to an eDiscovery review set aren't deleted by Priority Cleanup.

Configure permanent deletion

Create a Priority Cleanup policy and explicitly select the permanent deletion option.

1. Sign in to the Microsoft Purview portal and go to **Solutions** > **Data Lifecycle Management** > **Priority cleanup**.
2. Select + **Create a priority cleanup**.
3. Enter the policy name and description, choose an adaptive or static scope, select the SharePoint or OneDrive locations, and define the query for the targeted files.
4. On the **Choose what to do with the content** page, select **Delete data permanently**.

5. Choose whether to delete matched items as soon as possible or prevent deletion until a set time.
6. Assign the required approvers.
7. Run the policy in simulation mode and review the returned samples.
8. After the simulation results are satisfactory, have a second Priority Cleanup admin review the results and turn on the policy.

> **Important**
>
> The last person to edit the policy can't also turn it on.

Review and approve permanent deletion

Required approvers review identified items before permanent deletion occurs.

1. In the Microsoft Purview portal, go to **Data Lifecycle Management** > **Priority cleanup** > **Pending cleanups**.

2. Select the cleanup and review the identified items, their locations, and their history.
3. Select the items to delete, and then select **Approve disposal**.
4. Acknowledge the action, optionally add a comment, and then select **Apply**.

After all required approvals are complete, the selected items bypass the recycle bins and are permanently deleted. The deleted content is no longer discoverable in SharePoint search, Microsoft 365 Copilot, or eDiscovery.

If an item shouldn't be deleted, select **Relabel**, and then assign an existing retention label.

Monitor permanent deletion

Use the cleanup ID and auditing to monitor the policy and deletion activity.

1. Go to **Data Lifecycle Management** > **Priority cleanup** and open the policy details.
2. Copy the cleanup ID.
3. In the auditing solution, use the cleanup ID as the keyword search string.
4. Check for the **PriorityCleanupFileDeleted** operation, which indicates that Priority Cleanup permanently deleted an item.

Remove a retention hold from an unlicensed OneDrive site

> *Microsoft Purview service description*

This article is for Microsoft Purview administrators who manage unlicensed OneDrive for Business sites. Use the `Fix-PurviewConfig` cmdlet in Security & Compliance PowerShell to force-exclude a specified retention hold from an unlicensed, archived site. Removing the blocking hold allows the site to be deleted when no other non-force-excluded holds apply.

Before you begin, review the account, site, and policy requirements in Prerequisites.

Prerequisites

Before you begin, make sure you have:

- An account that can connect to Security & Compliance PowerShell.
- The URL of the unlicensed OneDrive for Business site.
- The GUID of the retention or hold policy to remove. The policy must exist in EOP and apply to the specified site.
- Confirmation that the site owner is unlicensed and the OneDrive site is archived. For more information, see Manage unlicensed OneDrive user accounts.

Remove the retention hold

The `RemoveHoldFromUnlicencedODBSite` scenario removes the specified hold from the site. Review your organization's retention and legal requirements before you run the cmdlet because removing the blocking hold can allow site deletion.

1. Connect to Security & Compliance PowerShell.
2. Confirm the values that you will use for `SiteUrl` and `PolicyId`.
3. Run the `Fix-PurviewConfig` cmdlet with the following syntax:

```text
Fix-PurviewConfig -Scenario RemoveHoldFromUnlicencedODBSite
    -SiteUrl <String>
```

```
    -PolicyId <String>
```

For example:

PowerShell

```
Fix-PurviewConfig -Scenario RemoveHoldFromUnlicencedODBSite `
  -SiteUrl "https://<tenant>-my.sharepoint.com/personal/<user>" `
  -PolicyId "430b7b03-88b7-4ec5-9ae1-736f27bac9c3"
```

4. Review the result. A successful operation returns the following fields:

text

```
ScenarioName  : DLM_ODB_Remove_Hold_For_Unlicenced_Site
Description   : Remove hold from unlicenced ODB site.
Status        : Success
Comments      : {Successfully removed hold(s) from unlicenced ODB site.}
CorrelationId : 00000000-0000-0000-0000-000000000000
```

After successful execution, the specified hold is force-excluded. If no other non-force-excluded holds apply, site deletion is allowed.

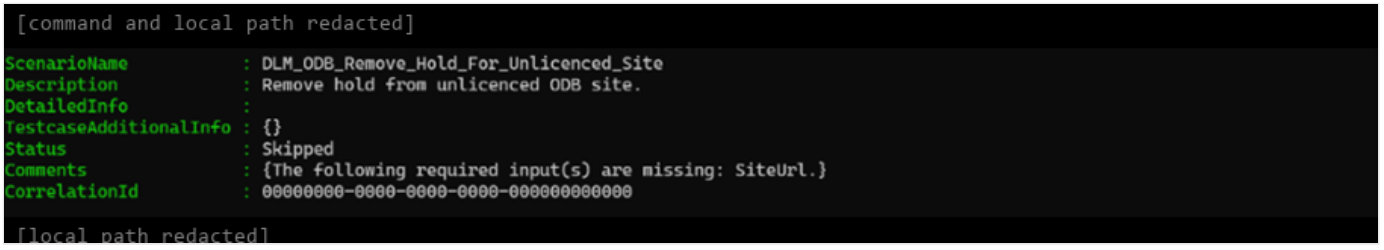
You can run the command again without changing the result. If the hold is already excluded, the cmdlet reports that the hold has already been removed.

Resolve validation errors

Use the following table to resolve validation errors returned by the cmdlet.

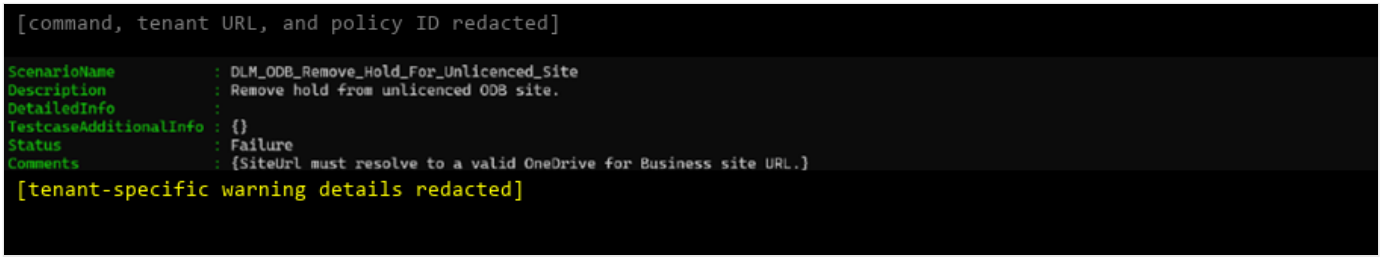
Expand table

Validation error	Action
`SiteUrl` isn't provided.	Provide the URL of the unlicensed OneDrive for Business site.
`SiteUrl` isn't a valid OneDrive for Business URL.	Correct the URL format and run the command again.
The specified site isn't present in OneDrive for Business.	Confirm that the site exists and that you entered the correct URL.
`PolicyId` isn't provided.	Provide the retention or hold policy GUID.
`PolicyId` doesn't exist in EOP.	Confirm the policy ID and run the command again.



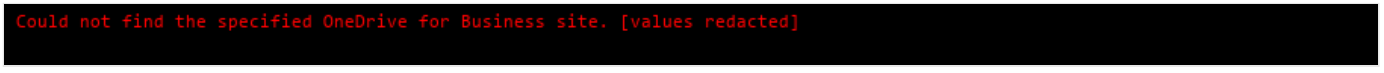
Validation error	Action
`PolicyId` isn't a valid GUID.	Provide a valid policy GUID.
The hold doesn't apply to the site.	Confirm that the policy applies to the specified site.
The site owner is licensed.	Remove the hold only after the site owner is unlicensed.

Review validation screenshots



The following screenshots show the validation outcomes from the approved test run. Tenant URLs, user aliases, local file paths, policy identifiers, browser property values, and exception internals are redacted. The cmdlet results and status messages are unchanged.

Validate the site URL



Site URL isn't provided

Learn about archive mailboxes

> *Microsoft Purview service description*

Use this article if you're an Exchange or compliance administrator and want to learn about mailbox archives that provide more storage space for users' online mailboxes. This additional mailbox storage might be needed to support your organization's message retention, eDiscovery, and hold requirements.

> **Note**
>
> Mailbox users can learn more about their archive mailbox storage by using the following article: Manage email storage with online archive mailboxes

After you turn on archive mailboxes, sometimes also known as *In-Place Archiving*, a user's current mailbox becomes their *primary mailbox* and an additional and associated mailbox is created, called the *archive mailbox*.

Both mailboxes are considered a user's mailbox for compliance features such as Content search from the Microsoft Purview portal, Microsoft 365 retention, and Litigation Hold.

Users can access and store messages in their archive mailboxes by using Outlook and Outlook on the web. Users can also move or copy messages between their primary mailbox and their archive mailbox. They can also recover deleted items from the Recoverable Items folder in their archive mailbox by using the Recover Deleted Items tool.

Managing archive mailboxes with messaging records management (MRM)

Messages can also be moved automatically to the archive mailbox by the default Exchange retention policy from the messaging records management (MRM) feature. This default policy is automatically assigned to every mailbox and does the following actions:

- Moves items that are two years or older from a user's primary mailbox to their archive mailbox.

- Moves items that are 14 days or older from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in their archive mailbox.

You can customize your organization's Exchange MRM policy with retention tags. For an example configuration, see Customize an archive and deletion policy for mailboxes in your organization.

> ⓘ **Note**
>
> MRM, like Microsoft 365 retention policies and retention labels, can also automatically delete emails after a specified period. As an older technology than Microsoft 365 retention, MRM continues to work side-by-side with retention policies and retention labels from Microsoft Purview. For more information, see Use retention policies and retention labels instead of older features.

Auto-expanding archiving

After a user's archive mailbox is enabled, up to 100 GB of extra storage becomes available. If users need more storage space than this 100 GB, enable auto-expanding archiving to provide up to 1.5 TB of additional storage in archive mailboxes. For more information, see Learn about auto-expanding archiving.

> ⓘ **Important**
>
> Microsoft is increasing the maximum auto-expanding archive capacity for eligible Exchange Online mailboxes from 1.5 TB to 3 TB. Rollout begins in mid-October 2026 and is expected to complete by late October.
>
> The increase applies to mailboxes assigned the following eligible licenses:
>
> - Office 365 E5, A5, or G5
> - Microsoft 365 E5, A5, or G5
> - Microsoft 365 Purview Suite
> - Microsoft 365 Purview Suite FLW, EDU, or GOV
> - Microsoft Defender + Purview Suite FLW
> - Microsoft 365 F5 Compliance
> - Microsoft 365 F5 Security + Compliance
> - The combination of the eDiscovery & Audit, Insider Risk Management, and Information Protection & Governance mini suites

Qualifying offerings that include Microsoft Purview E5 capabilities, such as E7, also support the increase. **For all other licenses, the existing 1.5 TB limit remains unchanged.**

For E5 licenses, verify that **Records Management** is selected and remains enabled in the user's license settings.

If auto-expanding archiving is already enabled, no additional configuration or per-GB charge applies. Existing archive content, retention policies, and holds are unchanged. Verify license eligibility and monitor archive growth.

Auto-archiving

If a user's primary mailbox fills up, auto-archiving helps prevent mail flow disruptions by automatically moving the oldest items to the archive mailbox when mailbox usage exceeds a safe threshold, which is 96% of the mailbox quota by default. Unlike the time-based MRM archive policy, auto-archiving is *threshold-based*: it's triggered by mailbox size rather than by item age, and it complements your existing archive and deletion policies without changing them.

Auto-archiving requires the archive mailbox to be provisioned and to have remaining storage capacity. Items tagged **Never Move to Archive** and recently received items are excluded, and the threshold is configurable for the organization. Setting the threshold to 100 turns off auto-archiving for the tenant. For more information, see Auto-archiving in Exchange Online.

Next steps

See Enable archive mailboxes in Microsoft 365.

Enable archive mailboxes for Microsoft 365

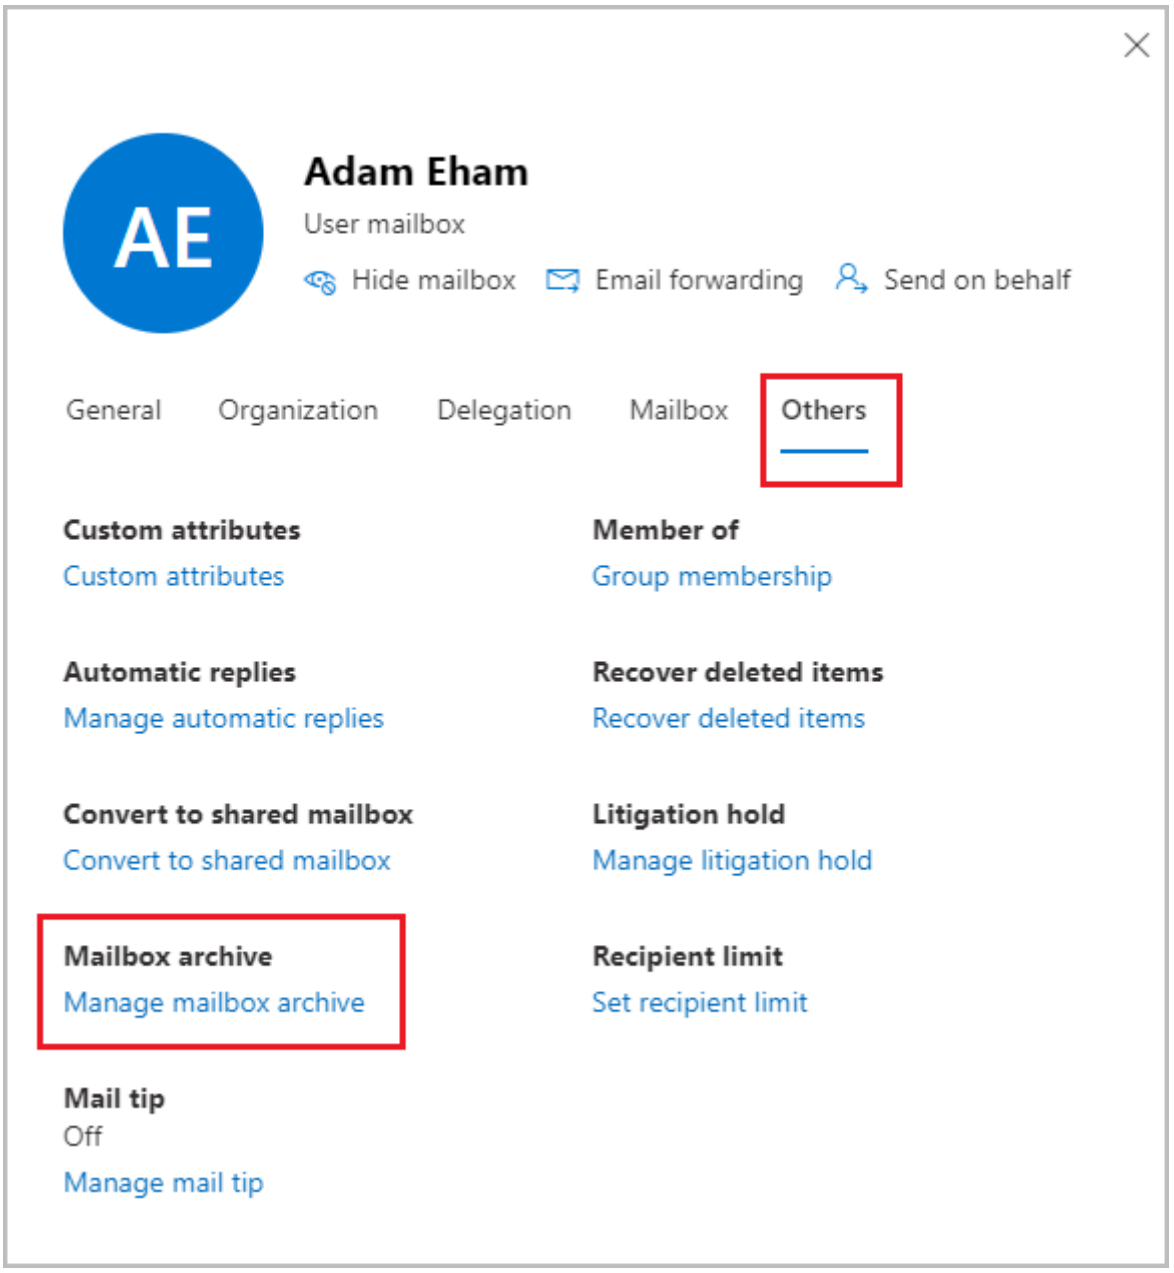
> *Microsoft Purview service description*

Email archiving in Microsoft 365 (also called *In-Place Archiving*) provides users with more mailbox storage space. For more information, see Learn about archive mailboxes.

Use the information in this article to enable or disable an archive mailbox by using the Exchange admin portal or by using PowerShell. Also learn how to run an automated diagnostic check on a user's archive mailbox to identify any problems and suggested resolutions.

Configuration to enable or disable archive mailboxes has moved to the new Exchange admin center (EAC).

Get the necessary permissions



You must be assigned the Mail Recipients role in Exchange Online to enable or disable archive mailboxes. By default, this role is assigned to the Recipient Management and Organization Management role groups on the **Permissions** page in the Exchange admin center.

How to enable an archive mailbox

> **Note**
>
> When you enable the archive mailbox, items in the user's mailbox that are older than the archiving policy assigned to the mailbox will be moved to the new archive mailbox.
>
> The default archive policy that is part of the retention policy assigned to Exchange Online mailboxes moves items to the archive mailbox two years after the date the item was delivered to the mailbox or created by the user. For more information, see Learn about archive mailboxes.

1. Sign in to the Exchange admin center (EAC) and navigate to **Recipients** > **Mailboxes**.
2. In the list of mailboxes, select the user to enable their mailbox for archive.

3. In the flyout pane, select **Others**, and under **Mailbox archive**, select **Manage mailbox archive**:

4. On the **Manage mailbox archive** pane, turn on **Mailbox archive**, and then **Save**.

It might take a few moments to create the archive mailbox. When it's created, **Active** is displayed in the **Archive status** column for the selected user, although you might need to refresh the page to see the change of status.

How to auto-enable archive mailboxes

You can use the Set-OrganizationConfig PowerShell command to automatically provision an archive mailbox when a primary Exchange Online mailbox reaches 90% of its storage quota. An archive mailbox is created automatically only if all of the following conditions are met:

- The mailbox is a User Mailbox or Shared Mailbox in Exchange Online.
- Archiving is included in the Microsoft 365 assigned license.
- The mailbox is not synchronized from an on-premises environment (the IsDirSynced property is set to False).

PowerShell

```
Set-OrganizationConfig -AutoEnableArchiveMailbox $true
```

How to disable an archive mailbox

Similarly to how you enable an archive mailbox, you can use the same configuration in the Exchange admin center to disable a user's archive mailbox. This time, turn **Mailbox archive** off in the Exchange admin center.

After you disable an archive mailbox, you can reconnect it to the user's primary mailbox within 30 days of disabling it. In this case, the original contents of the archive mailbox are restored. After 30 days, the contents of the original archive mailbox are permanently deleted and can't be recovered. So if you re-enable the archive more than 30 days after disabling it, a new archive mailbox is created.

The default archive policy assigned to users' mailboxes moves items to the archive mailbox two years after the date the item is delivered. If you disable a user's archive mailbox, no action will be taken on mailbox items and they'll remain in the user's primary mailbox.

Use Exchange Online PowerShell to enable or disable archive mailboxes

You can also use Exchange Online PowerShell to enable archive mailboxes. The primary reason to use PowerShell is that you can quickly enable the archive mailbox for all users in your organization.

The first step is to connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

After you're connected to Exchange Online, you can run the commands in the following sections to enable or disable archive mailboxes.

Enable archive mailboxes

Run the following command to enable the archive mailbox for a single user.

PowerShell

```
Enable-Mailbox -Identity <username> -Archive
```

Run the following command to enable the archive mailbox for all users in your organization whose archive mailbox is currently not enabled and who do not already have a disabled archive:

PowerShell

```
Get-Mailbox -Filter {ArchiveGuid -Eq "00000000-0000-0000-0000-000000000000" -AND
DisabledArchiveGuid -Eq "00000000-0000-0000-0000-000000000000" -AND
RecipientTypeDetails -Eq "UserMailbox"} | Enable-Mailbox -Archive
```

> ⓘ **Note**
>
> If archive for a mailbox was disabled more than 30 days ago, the command fails with the following error:
>
> "Write-ErrorMessage : |Microsoft.Exchange.Data.Directory.MissingDisconnectReceiptsException|AD modification is not allowed - disconnect of shard with ExchangeGuid *GUID* is not authorized".
>
> To resolve this error, run the Set-Mailbox cmdlet for the mailbox with -RemoveDisabledArchive. Then run the command again to enable the archive mailbox.

When enabling archiving for a specific user whose mailbox is on hold or assigned to a retention policy, the following configuration changes are implemented:

- The storage quota for the user's primary mailbox's Recoverable Items folder is expanded by 5 GB, raising it from 100 GB to 105 GB. This adjustment provides additional space to accommodate deleted items during the archiving process, even if auto-expanding archive isn't enabled. The Recoverable Items warning quota is also augmented by 5 GB, increasing it from 90 GB to 95 GB.

Disable archive mailboxes

Run the following command to disable the archive mailbox for a single user.

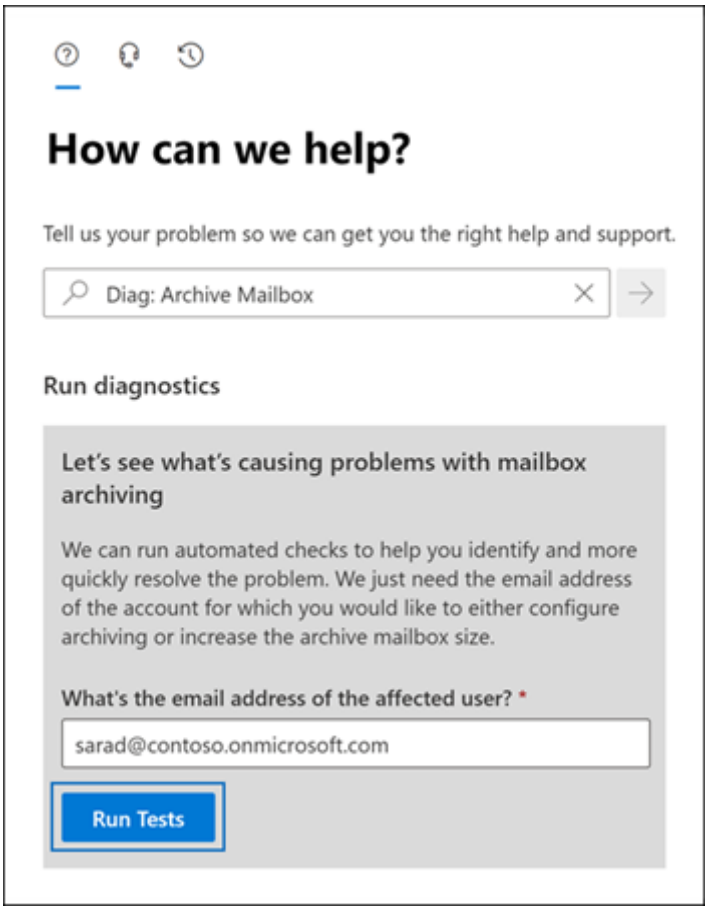
PowerShell

```
Disable-Mailbox -Identity <username> -Archive
```

Run the following command to disable the archive mailbox for all users in your organization (whose archive mailbox is currently enabled).

PowerShell

```
Get-Mailbox -Filter {ArchiveGuid -Ne "00000000-0000-0000-0000-000000000000" -AND
RecipientTypeDetails -Eq "UserMailbox"} | Disable-Mailbox -Archive
```



Run diagnostics on archive mailboxes

> ⓘ **Important**
>
> You must be a Microsoft 365 global admin to use the archive mailbox diagnostic check.
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

You can run an automated diagnostic check on a user's archive mailbox to identify any problems and suggested resolutions.

To run the diagnostic check, click the button below.

Run Tests: Archive Mailbox

A flyout page opens in the Microsoft 365 admin center. Enter the email address of the mailbox you want to check and click **Run Tests**.

> **Note**
>
> this feature isn't available in Microsoft 365 Government clouds, Microsoft 365 operated by 21Vianet, or Microsoft 365 Germany.

Instructions for end users

Explain to users how their archive mailbox works, and how they can interact with it in Outlook on Windows, macOS, and the web. The most effective documentation will be customized for your organization. But for basic instructions, see Manage email storage with online archive mailboxes.

Next steps

Consider enabling auto-expanding archiving for additional storage space. For instructions, see Enable auto-expanding archiving.

Last updated on 04/06/2026

Learn about auto-expanding archiving

> *Microsoft Purview service description*

Archive mailboxes in Microsoft Purview provide user mailboxes and shared mailboxes with additional mailbox storage space. After an archive mailbox is enabled, up to 100 GB of additional storage becomes available.

This archiving feature in Microsoft Purview (called *auto-expanding archiving*) provides up to 1.5 TB of additional storage in archive mailboxes. When the storage quota in the archive mailbox is reached, Microsoft Purview automatically (and incrementally) increases the size of the archive until the archive mailbox reaches 1.5 TB.

For step-by-step instructions for turning on auto-expanding archiving, see Enable auto-expanding archiving.

How auto-expanding archiving works

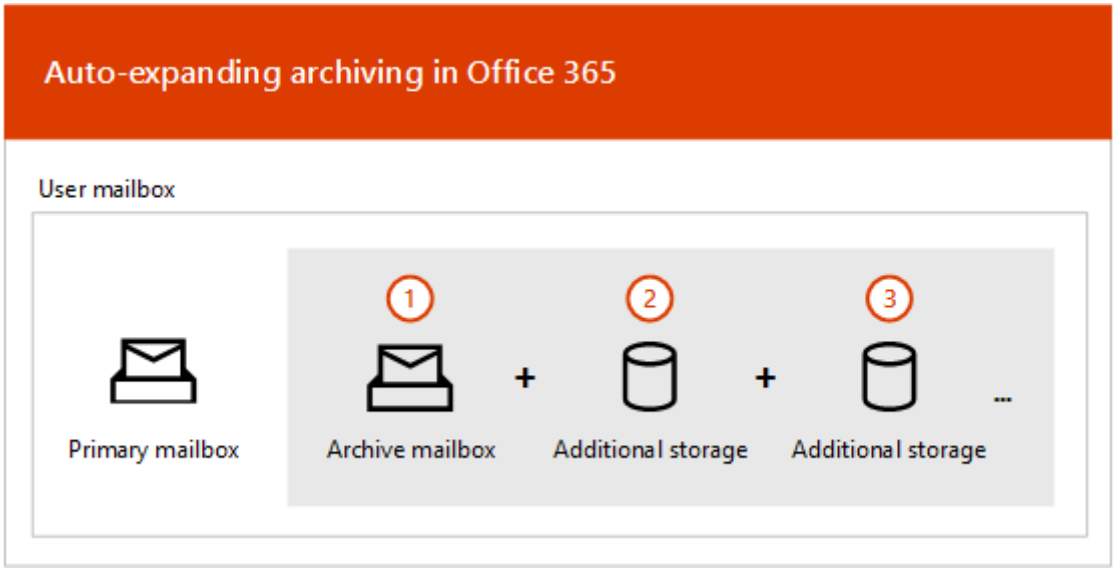
When auto-expanding archiving is enabled for a user's mailbox archive or a shared mailbox archive, Microsoft Purview periodically checks the size of the archive mailbox. When the archive mailbox gets close to its storage limit, additional storage space is automatically created and this process continues until the mailbox archive reaches 1.5 TB. The additional storage creation happens automatically, which means administrators don't have to request additional archive storage or manage auto-expanding archiving.

ⓘ Important

Microsoft is increasing the maximum auto-expanding archive capacity for eligible Exchange Online mailboxes from 1.5 TB to 3 TB. Rollout begins in mid-October 2026 and is expected to complete by late October.

The increase applies to mailboxes assigned the following eligible licenses:

- Office 365 E5, A5, or G5
- Microsoft 365 E5, A5, or G5
- Microsoft 365 Purview Suite
- Microsoft 365 Purview Suite FLW, EDU, or GOV



- Microsoft Defender + Purview Suite FLW
- Microsoft 365 F5 Compliance
- Microsoft 365 F5 Security + Compliance
- The combination of the eDiscovery & Audit, Insider Risk Management, and Information Protection & Governance mini suites

Qualifying offerings that include Microsoft Purview E5 capabilities, such as E7, also support the increase. **For all other licenses, the existing 1.5 TB limit remains unchanged.**

For E5 licenses, verify that **Records Management** is selected and remains enabled in the user's license settings.

If auto-expanding archiving is already enabled, no additional configuration or per-GB charge applies. Existing archive content, retention policies, and holds are unchanged. Verify license eligibility and monitor archive growth.

Here's a quick overview of the process.

1. Archiving is enabled for a user mailbox or a shared mailbox. An archive mailbox with 100 GB of storage space is created, and the warning quota for the archive mailbox is set to 90 GB.

2. An administrator enables auto-expanding archiving for the mailbox. If the mailbox has a hold or retention policy applied to it, the storage quota for the archive mailbox is increased to 110 GB and the archive warning quota is increased to 100 GB.

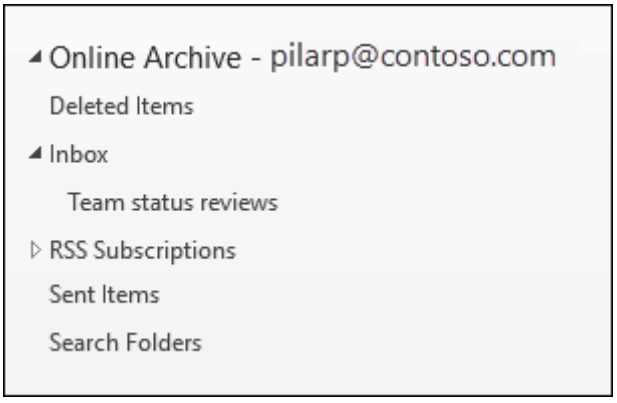
   Then, when the archive mailbox (including the Recoverable Items folder) reaches its storage quota, the archive mailbox is converted to an auto-expanding archive. Extra storage space is

added until it reaches a maximum size of 1.5 TB. It can take up to 30 days for the additional storage space to be provisioned.

3. Microsoft Purview automatically adds more storage space when necessary.

For information what happens when the maximum 1.5 TB is reached, and other size-related limitations for email storage, see Important considerations and limitations for auto-expanding archiving on this page.

What gets moved to the additional archive storage space?



To make efficient use of auto-expanding archive storage, folders may get moved. Microsoft Purview determines which folders get moved when additional storage is added to the archive. Sometimes when a folder is moved, one or more subfolders are automatically created and items from the original folder are distributed to these folders to facilitate the moving process. You might need to communicate this behavior to end users after enabling their mailbox for auto-expanding archives, to help set expectations.

When viewing the archive portion of the folder list in Outlook, these subfolders are displayed under the original folder. The naming convention that Microsoft 365 uses to name these subfolders is **<folder name>_yyyy (Created on mmm dd, yyyy h_mm)**, where:

- **yyyy** is the year the messages in the folder were received.
- **mmm dd, yyyy h_m** is the date and time that the subfolder was created by Office 365, in UTC format, based on the user's time zone and regional settings in Outlook.

The following screenshots show a folder list before and after messages are moved to an auto-expanded archive.

Before additional storage is added

After additional storage is added

> **Note**
>
> In some scenarios, a small number of archive mailboxes might display "Inbox_Archive" and/or "Sent Items_Archive" folders. These folders, if present, are part of organizational enhancements to maintain the archive folder structure. Users can continue to access their archived emails without any issues, and these folders don't affect the functionality or performance of the mailbox.

As previously described, Microsoft Purview moves items to subfolders (and names them using the naming convention described above) to help distribute content to an auxiliary archive. But moving items to subfolders might not always be the case. Sometimes an entire folder may be moved to an auxiliary archive. In this case, the folder will retain its original name. It won't be apparent in the folder list in Outlook that the folder was moved to an auxiliary archive.

Important considerations and limitations for auto-expanding archiving

Auto-expanded archiving is supported by new Outlook for Windows, classic Outlook for Windows, and Outlook on the web.

If a mailbox with an auto-expanding archive reaches a total of 1.5 TB of data stored in the auto-expanding archive, no more data will be stored in the auto-expanding archive or moved from the main archive to the auto-expanding archive.

> **Note**

The size that counts toward the 1.5 TB limit is the total of all items in the archive, including items in the Recoverable Items folder. An archive can therefore approach its limit even when the visible item size looks smaller. Additional storage is provisioned automatically and can take up to 30 days, and auto-expanding archiving supports a growth rate of no more than 1 GB per day.

Should the main archive also reaches its quota, no more data will be stored there, which can result in the primary mailbox also reaching its quota. Then, processing can stop for sending or receiving email and other items. To reduce this risk and minimize liability for your organization, we recommend using Microsoft 365 retention policies to delete content that no longer has business value. Configure these policies to delete items after a specified period. If you're not yet familiar with retention policies that can automatically delete email and other Microsoft 365 items, see Learn about retention policies and retention labels.

Auto-expanding archiving is supported only for mailboxes used for individual users (or shared mailboxes) with a growth rate that doesn't exceed 1 GB per day. A user's archive mailbox is intended for just that user. Using journaling, transport rules, or auto-forwarding rules to copy messages to an archive mailbox isn't permitted. Microsoft reserves the right to deny additional archiving in instances where a user's archive mailbox is used to store archive data for other users or in other cases of the inappropriate use.

Here are some things to consider before you enable a mailbox for auto-expanding archives:

- Users can access any folder in their archive mailbox, including ones that were moved to the auto-expanded storage area.
- If an archive mailbox has at least one auto-expanded storage area, users can't delete a folder from the archive mailbox or from the auxiliary archive. In other words, after an auto-expanded storage area has been provisioned, they can't delete any folders in the archive.
- Users can delete items in an auto-expanded storage area. However, they can't use the Recover Deleted Items feature to recover an item after auto-expanding archiving is enabled for their mailbox.
- Users can search for items in an auto-expanded archive with the following limitations:
  - For classic Outlook on Windows, search is restricted to the current Outlook search scope. For example, search from the primary mailbox won’t return items from auto-expanded archives.
  - Not supported in a cloud-only archive situation (primary mailbox still on-premises).

- Item counts in Outlook and Read/Unread counts (in Outlook and Outlook on the web) in an auto-expanded archive might not be accurate.

Auto-expanding archiving and other compliance features

This section explains the functionality between auto-expanding archiving and other compliance features.

- **eDiscovery:** When you use an eDiscovery tool, such as Content Search, the additional storage areas in an auto-expanded archive are also searched.
- **Retention:** When you put a mailbox on hold by using methods such as Microsoft 365 retention, eDiscovery case holds, and Litigation Hold in Exchange Online, content located in an auto-expanded archive is also placed on hold.
- **Messaging records management (MRM):** If you use MRM deletion policies in Exchange Online to permanently delete expired mailbox items, expired items located in the auto-expanded archive will also be deleted.

Next steps

For more technical details about auto-expanding archiving, see Microsoft 365: Auto-Expanding Archives FAQ.

If you're ready to enable auto-expanding archiving, see Enable auto-expanding archiving.

Enable auto-expanding archiving

> *Microsoft Purview service description*

You can use the Exchange Online auto-expanding archiving feature to enable additional storage space for archive mailboxes. When auto-expanding archiving is turned on, additional storage space is automatically added to a user's archive mailbox until it reaches the storage limit of 1.5 TB. You can turn on auto-expanding archiving for everyone in your organization or just for specific users. For more information about auto-expanding archiving, see Learn about auto-expanding archiving.

ⓘ Important

Microsoft is increasing the maximum auto-expanding archive capacity for eligible Exchange Online mailboxes from 1.5 TB to 3 TB. Rollout begins in mid-October 2026 and is expected to complete by late October.

The increase applies to mailboxes assigned the following eligible licenses:

- Office 365 E5, A5, or G5
- Microsoft 365 E5, A5, or G5
- Microsoft 365 Purview Suite
- Microsoft 365 Purview Suite FLW, EDU, or GOV
- Microsoft Defender + Purview Suite FLW
- Microsoft 365 F5 Compliance
- Microsoft 365 F5 Security + Compliance
- The combination of the eDiscovery & Audit, Insider Risk Management, and Information Protection & Governance mini suites

Qualifying offerings that include Microsoft Purview E5 capabilities, such as E7, also support the increase. **For all other licenses, the existing 1.5 TB limit remains unchanged.**

For E5 licenses, verify that **Records Management** is selected and remains enabled in the user's license settings.

If auto-expanding archiving is already enabled, no additional configuration or per-GB charge applies. Existing archive content, retention policies, and holds are unchanged. Verify license

eligibility and monitor archive growth.

Before you enable auto-expanding archiving

- Understand the following restrictions:
  - After you turn on auto-expanding archiving for your organization or for a specific user, it can't be turned off.
  - Administrators can't adjust the storage quota for auto-expanding archiving.
  - Auto-expanding archiving prevents you from recovering or restoring an inactive mailbox. This means if you enable auto-expanding archiving for a mailbox, and the mailbox becomes inactive in the future, you won't be able to recover the inactive mailbox or restore it.

    After you enable auto-expanding archiving for an inactive mailbox, the only way to recover data is by using the content search tool in the Microsoft Purview portal to export the data from the mailbox and import to another mailbox. For more information, see the Inactive mailboxes and auto-expanding archives.
- To enable auto-expanding archiving, you must be a global administrator in your organization or a member of the Organization Management role group in your Exchange Online organization. Alternately, to enable auto-expanding archiving for specific users, you must be a member of a role group that includes the Mail Recipients role.
- A user's mailbox must already be enabled for archive before you can enable auto-expanding archiving.
- After you turn on auto-expanding archiving, an archive mailbox is converted to an auto-expanding archive when the archive mailbox (including the Recoverable Items folder) reaches 90 GB. It can take up to 30 days for the additional storage space to be provisioned.
- Auto-expanding archiving also supports shared mailboxes.
- You can't use the Exchange admin center or the Microsoft Purview portal to enable auto-expanding archiving. You must use Exchange Online PowerShell.

Enable auto-expanding archiving for your entire organization

You can enable auto-expanding archiving for your entire organization. After you turn it on, auto-expanding archiving will be enabled for existing user mailboxes and for new user mailboxes that are created. When you create user mailboxes, be sure to enable the user's main archive mailbox so the auto-expanding archiving feature works for the new user mailbox.

1. Connect to Exchange Online PowerShell

2. To enable auto-expanding archiving for your entire organization, run the following command:

```
PowerShell
Set-OrganizationConfig -AutoExpandingArchive
```

Enable auto-expanding archiving for specific users

Instead of enabling auto-expanding archiving for every user in your organization, you can enable it only for specific users. You might decide on this strategy because only some users have a need for a large archive storage capacity.

When you enable auto-expanding archiving for a specific user and the user's mailbox in on hold or assigned to a retention policy, the following two configurations changes are made:

- The storage quota for the user's primary archive mailbox is increased by 10 GB (from 100 GB to 110 GB). The archive warning quota is also increased by 10 GB (from 90 GB to 100 GB).

- The storage quota for the Recoverable Items folder in the user's primary mailbox is increased by 10 GB (also from 100 GB to 110 GB). The Recoverable Items warning quota is also increased by 10 GB (from 90 GB to 100 GB). These changes are applicable only if the mailbox in on hold or assigned to a retention policy.

This additional space is added to prevent any storage issues that may occur before the auto-expanding archive is provisioned. Additional storage space isn't added when you enable auto-expanding archiving for your entire organization, as described in the previous section.

1. Connect to Exchange Online PowerShell

2. To enable auto-expanding archiving for a specific user, run the following command. As previously explained, the user's archive mailbox (main archive) must be enabled before you can turn on auto-expanding archiving for that user.

PowerShell

```
Enable-Mailbox <user mailbox> -AutoExpandingArchive
```

> **Important**
>
> In an Exchange hybrid deployment, you can't use the **Enable-Mailbox -AutoExpandingArchive** command to enable auto-expanding archiving for a specific user whose primary mailbox is on-premises and whose archive mailbox is cloud-based. To enable auto-expanding archiving for cloud-based archive mailboxes in an Exchange hybrid deployment, you have to run the **Set-OrganizationConfig -AutoExpandingArchive** command in Exchange Online PowerShell to enable auto-expanding archiving for the entire organization. If a user's primary and archive mailboxes are both cloud-based, then you can use the **Enable-Mailbox -AutoExpandingArchive** command to enable auto-expanding archiving for that specific user.

Verify that auto-expanding archiving is enabled

To verify that auto-expanding archiving is enabled for your organization, run the following command in Exchange Online PowerShell.

PowerShell

```
Get-OrganizationConfig | FL AutoExpandingArchiveEnabled
```

A value of `True` indicates that auto-expanding archiving is enabled for the organization.

To verify that auto-expanding archiving is enabled for a specific user, run the following command in Exchange Online PowerShell.

PowerShell

```
Get-Mailbox <user mailbox> | FL AutoExpandingArchiveEnabled
```

A value of `True` indicates that auto-expanding archiving is enabled for the user.

To determine if auto-expanding archiving is enabled for inactive mailboxes, run the following command in Exchange Online PowerShell.

PowerShell

```
Get-Mailbox -InactiveMailboxOnly | FL UserPrincipalName,AutoExpandingArchiveEnabled
```

A value of `True` indicates that auto-expanding archiving is enabled for the inactive mailbox. A value of `False` indicates that auto-expanding archiving isn't enabled.

Keep the following things in mind after you enable auto-expanding archiving:

- If you run the **Set-OrganizationConfig -AutoExpandingArchive** command to enable auto-expanding archiving for your organization, you don't have to run the **Enable-Mailbox -AutoExpandingArchive** on individual mailboxes. Running the **Set-OrganizationConfig** cmdlet to enable auto-expanding archiving for your organization doesn't change the *AutoExpandingArchiveEnabled* property on user mailboxes to `True`.

- Similarly, the values for the *ArchiveQuota* and *ArchiveWarningQuota* mailbox properties aren't changed when you enable auto-expanding archiving. In fact, when you enable auto-expanding archiving for a user mailbox and the *AutoExpandingArchiveEnabled* property is set to `True`, the *ArchiveQuota* and *ArchiveWarningQuota* properties are ignored. Here's an example of these mailbox properties after auto-expanding archiving is enabled for a user's mailbox.

  ```
  PS C:\> Get-Mailbox sarad | FL Archive*Quota,AutoExpandingArchiveEnabled

  ArchiveQuota                : 100 GB (107,374,182,400 bytes)
  ArchiveWarningQuota         : 90 GB (96,636,764,160 bytes)
  AutoExpandingArchiveEnabled : True
  ```

More information

- You can also use PowerShell to enable archive mailboxes. For example, you can run the following command in Exchange Online PowerShell to enable archive mailboxes for all users whose archive mailbox isn't already enabled.

  PowerShell

  ```
  Get-Mailbox -Filter {ArchiveStatus -Eq "None" -AND RecipientTypeDetails -eq
  "UserMailbox"} | Enable-Mailbox -Archive
  ```

- Auto-expanding archiving is supported for cloud-based archive mailboxes in an Exchange hybrid deployment for users who have an on-premises primary mailbox. However, after auto-expanding archiving is enabled for a cloud-based archive mailbox, you can't off-board

that archive mailbox back to the on-premises Exchange organization. Auto-expanding archiving isn't supported for on-premises mailboxes in any version of Exchange Server.

- As previously explained, 10 GB is added to the storage quota of the user's primary archive mailbox (and to the Recoverable Items folder if the mailbox is on hold) when you run the **Enable-Mailbox -AutoExpandingArchive** command. This increase provides additional storage until the auto-expanded storage space is provisioned (which can take up to 30 days). This additional storage space isn't added when you run the **Set-OrganizationConfig -AutoExpandingArchive** to enable auto-expanding archiving for all mailboxes in your organization. If you enabled auto-expanding archiving for the entire organization, but need to add the additional 10 GB of storage space for a specific user, you can run the **Enable-Mailbox -AutoExpandingArchive** command on that mailbox. You see an error saying that auto-expanding archiving is already enabled, but the additional storage space is added to the mailbox.

> **Important**
>
> Auto-expanding archiving is supported only for mailboxes used by individual users or for shared mailboxes with a growth rate that doesn't exceed 1 GB per day. Using journaling, transport rules, or auto-forwarding rules to copy messages to an archive mailbox for the purposes of archiving is not permitted. A user's archive mailbox is intended for just that user. Microsoft reserves the right to deny additional archiving in instances where a user's archive mailbox is used to store archive data for other users or in other cases of inappropriate use.

Next steps

Using the information from this article and Learn about auto-expanding archiving, make sure you prepare end users for the changes they can expect after enabling their mailbox for auto-expanding archives.

Customize an archive and deletion policy for mailboxes in your organization

To retain and delete emails, we recommend you use Microsoft 365 retention policies and retention labels rather than the older messaging records management (MRM) from Exchange Online. However, a valid reason to still use this older feature is to automatically move emails from a user's primary mailbox to their archive mailbox. You might also need to use MRM to apply retention and deletion settings to specific folders in the mailbox, rather than the entire mailbox.

Use this article as an example scenario to better understand these two valid reasons to use MRM retention policies and retention tags. For all other retention and deletion scenarios, use Microsoft 365 retention policies and retention labels.

The configuration steps in our example scenario require you to create an MRM retention policy that you then assign to mailboxes. This policy moves items to a user's archive mailbox after a specified period of time and also deletes items from the Deleted items folder after they reach a specific age limit.

> **Note**
>
> Instructions in this article use the Microsoft Purview portal and the Exchange admin center.

The actual rules that determine what items are moved or deleted and when that happens are called **retention tags**. Retention tags are linked to an **MRM retention policy**, that in turn is assigned to a user's mailbox. A retention tag applies retention settings to individual messages and folders in a user's mailbox. It defines how long a message remains in the mailbox and what action is taken when the message reaches the specified retention age. When a message reaches its retention age, it's either moved to the user's archive mailbox or it's deleted.

Example scenario for the instructions

The steps in this article set up an archiving and retention policy for a fictitious organization named Alpine House. This example deployment requires the following tasks:

- Step 1: Enable an archive mailbox for every user in the organization. This procedure gives users more mailbox storage, and is required so that a retention policy can automatically

move items to the archive mailbox. A user can also manually move items to their archive mailbox for archival storage.

- Step 2: Create two custom retention tags to do the following actions:
  - Automatically move items that are 3 years old to the user's archive mailbox. Moving items to the archive mailbox frees up space in a user's primary mailbox.
  - Automatically delete items that are 5 years old from the Deleted Items folder. This also frees up space in the user's primary mailbox. Users will have the opportunity to recover these items if necessary. For more information, see the final bullet in the More information section.
- Step 3: Create a new retention policy and add the new custom retention tags to it. Additionally, you'll add a built-in retention tag that can't be achieved with a recommended Microsoft 365 retention label because it also moves items to the archive mailbox. It's a personal tag for archiving after 1 year that users can assign to items in their mailbox when they want a shorter archive period than their default of 3 years.
- Step 4: Replace the Default MRM policy with the new retention policy you've created.

Optionally, you can also run the Managed Folder Assistant to apply the new settings, and make the new retention policy the default for your organization.

You can follow some or all of the steps in this article to help understand how to set up your own archive and deletion policy for mailboxes in your organization. We recommend that you test this process on a few mailboxes before implementing it on all mailboxes in your organization.

Before you set up the archive and deletion policy

- To follow this example configuration, use an isolated, test environment that won't impact users on your production network. Then take your learnings to your production network.
- In your isolated test environment, consider using a global administrator account so you can perform all the steps for this example scenario. In a production environment, always use administrative roles that grant least privilege.
- When you create a new user account and assign the user an Exchange Online license, a mailbox is automatically created for the user. When the mailbox is created, it's automatically assigned a default retention policy, named Default MRM Policy. In this example deployment, you'll create a new MRM retention policy and then assign it to user mailboxes, replacing the

Default MRM policy. A mailbox can have only one MRM retention policy assigned to it at any one time.

- To learn more about retention tags and MRM retention policies in Exchange Online, see Retention tags and retention policies and the associated instructions. For example:
  - Create a retention policy for Exchange Online
  - Add retention tags to or remove retention tags from a retention policy in Exchange Online

Step 1: Enable archive mailboxes for users

The first step is to ensure each user in your organization has an archive mailbox. A user's archive mailbox must be enabled so that for our example scenario, a retention tag with a "Move to Archive" retention action can move the item after the retention age expires.

For instructions to enable archive mailboxes, see Enable archive mailboxes in Microsoft 365.

> **Note**
>
> You can enable archive mailboxes any time during this process, just as long as they're enabled at some point before you complete the process. If an archive mailbox isn't enabled, no action is taken on any items that have an archive or deletion policy assigned to it.

Step 2: Create new retention tags for the archive and deletion policies

In this step, you'll create the two custom retention tags that were previously described for our example scenario.

- A custom archive default policy tag, which we'll name "Alpine House 3 Year Move to Archive".
- A custom retention policy tag configured for the Deleted Items folder, which we'll name "Alpine House Deleted Items 5 Years Delete and Allow Recovery".

For this configuration, you use the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Exchange (legacy)** > **MRM Retention tags**.

   A list of the retention tags for your organization is displayed.

Follow the step-by-steps instructions how to create the example retention tags for our scenario.

Create the custom archive default policy tag

First for our example scenario, you'll create a custom archive default policy tag (DPT) that will move items to the archive mailbox after 3 years.

1. On the **MRM Retention tags** page, select **+ New tag**, and then on the **Name your tag** page, type a name for the new retention tag, and an optional description that explains the purpose of the custom retention tag.

   For our example scenario, we'll name this tag "Alpine House 3 Year Move to Archive".

2. On the **Define how the tag will be applied** page, select **Automatically to entire mailbox (default)**.

3. On the **Define retention settings** page, complete the following fields:

   a. **When items reaches the following age (in days)** Enter the duration of the retention period. For this scenario, items will be moved to the archive mailbox after 1095 days (3 years).

   b. For the **Retention Action** Select **Move item to archive** to move items to the archive mailbox when the retention period expires.

4. Select **Next**, and then review and submit to create the custom archive DPT.

The new archive DPT is displayed in the list of retention tags.

Create the custom retention policy tag for the Deleted Items folder

The second retention tag to create for our example scenario is a custom retention policy tag (RPT) for the Deleted Items folder. This retention tag will delete items in the Deleted Items folder after 5 years, and provides a recovery period when users can use the Recover Deleted Items tool to recover an item.

1. Back on the **MRM Retention tags** page, select **+ New tag**, and on the **Name your tag** page, type a name for the new retention tag, and an optional description that explains the purpose of the custom retention tag.

For our example scenario, we'll name this tag "Alpine House Deleted Items 5 Years Delete and Allow Recovery".

2. On the **Define how the tag will be applied** page, select **Automatically to default folder** and then for the **Apply tag to this folder** option, select **Deleted items**.

3. On the **Define retention settings** page, complete the following fields:

   a. **When items reaches the following age (in days)** Enter the duration of the retention period. For this scenario, items will be deleted after 1825 days (5 years).

   b. For the **Retention Action** Select **Delete and allow recovery** to delete items when the retention period expires, but allow users to recover a deleted item within the deleted item retention period (which by default is 14 days).

4. Select **Next**, and then review and submit to create the custom deletion DPT.

The new RPT is displayed in the list of retention tags.

Step 3: Create a new retention policy

After you create the custom retention tags, the next step for our example scenario is to create a new retention policy and add the retention tags. You'll add the two custom retention tags that you created in Step 2, and a built-in tag that's preconfigured for you. In Step 4, you'll assign this new retention policy to user mailboxes.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** card > **Exchange (legacy)** > **MRM Retention policies**.

2. On the **MRM Retention policies** page, select **New policy**.

3. In the **Name** box, type a name for the new retention policy; for example, **Alpine House Archive and Deletion Policy**.

4. Select + **Add tag**.

   A list of the retention tags in your organization is displayed, which includes the custom tags that you created in Step 2.

5. Add the 3 retention tags that are described in more detail in the More information section:

   - **Alpine House 3 Year Move to Archive** - the custom archive default policy tag created in step 2 of these instructions

- **Alpine House Deleted Items 5 Years Delete and Allow Recovery** - the custom tag for the Deleted Items folder created in step 2 of these instructions
- **Personal 1 year move to archive** - a built-in tag that's preconfigured

To add these retention tags, select them, and then select **Add**.

6. Back on the **Configure your policy** page, select **Next** to review and submit the new policy.

The new retention policy is displayed in the list. Select it to display the retention tags linked to it in the details pane.

Step 4: Assign the new retention policy to user mailboxes

When a new mailbox is created, a retention policy named Default MRM policy is assigned to it by default. In this step for our example scenario, you'll replace this retention policy by assigning the new retention policy that you created in Step 3 to the user mailboxes in your organization.

Replacement is required because a mailbox can have only one MRM retention policy assigned to it at a time. This step assumes that you'll assign the new policy to all mailboxes in your organization.

To follow these steps, make sure you use the new Exchange admin center, rather than the classic version.

1. Sign in to the Exchange admin center (EAC), and go to **Recipients** > **Mailboxes**.

   A list of all user mailboxes in your organization is displayed.

2. Select all the mailboxes by selecting the box for **Display name**.

3. Select the **Mailbox policies** option.

4. In the **Mailbox policies** flyout pane, under **Retention Policy**, select the retention policy that you created in Step 3; for example, **Alpine House Archive and Retention Policy**.

5. Select **Save** to save the new retention policy assignment.

6. To verify that the new retention policy was assigned to mailboxes:

   a. Select a mailbox on the **Mailboxes** page.

   b. On the mailbox properties page for the selected user, select **Mailbox**.

The name of the new policy assigned to the mailbox is displayed for the **Retention policy**.

(Optional) Step 5: Run the Managed Folder Assistant to apply the new settings

After you apply the new retention policy to mailboxes in Step 4, it can take up to 7 days in Exchange Online for the new retention settings to be applied to the mailboxes. This is because a process called the *Managed Folder Assistant* processes mailboxes at least once every 7 days. Instead of waiting for the Managed Folder Assistant to run, you can force this to happen by running the **Start-ManagedFolderAssistant** cmdlet in Exchange Online PowerShell.

What happens when you run the Managed Folder Assistant? It applies the settings in the retention policy by inspecting items in the mailbox and determining whether they're subject to retention. It then stamps items subject to retention with the appropriate retention tag, and then takes the specified retention action on items past their retention age.

Here are the steps to connect to Exchange Online PowerShell, and then run the Managed Folder Assistant on every mailbox in your organization.

1. Connect to Exchange Online PowerShell.
2. Run the following two commands to start the Managed Folder Assistant for all user mailboxes in your organization.

PowerShell

```
$Mailboxes = Get-Mailbox -ResultSize Unlimited -Filter {RecipientTypeDetails -eq "UserMailbox"}
```

PowerShell

```
$Mailboxes.Identity | Start-ManagedFolderAssistant
```

That's it! You've set up an archive and deletion policy for the Alpine House organization.

More information about the Managed Folder Assistant

As previously stated, the Managed Folder Assistant processes mailboxes at least once every 7 days. So it's possible that a mailbox can be processed by the Managed Folder Assistant more frequently. Also, admins can't predict the next time a mailbox is processed by the Managed Folder Assistant, which is one reason why you might want to run it manually.

However, if you want to temporarily prevent the Managed Folder Assistant from applying the new retention settings to a mailbox, you can run the `Set-Mailbox -ElcProcessingDisabled $true` command to temporarily disable the Managed Folder Assistant from processing a mailbox.

To re-enable the Managed Folder Assistant for a mailbox, run the `Set-Mailbox -ElcProcessingDisabled $false` command.

Finally, if a mailbox user has a disabled account, items aren't moved to the archive mailbox for that mailbox.

(Optional) Step 6: Make the new retention policy the default for your organization

In Step 4, you have to assign the new retention policy to existing mailboxes. But you can configure Exchange Online so that the new retention policy is assigned to new mailboxes that are created in the future.

You do this by using Exchange Online PowerShell to update your organization's default mailbox plan. A *mailbox plan* is a template that automatically configures properties on new mailboxes. In this optional step, you can replace the current retention policy that's assigned to the mailbox plan (by default, the Default MRM Policy) with the MRM retention policy that you created in Step 3. After you update the mailbox plan, the new MRM retention policy will be assigned to new mailboxes.

1. Connect to Exchange Online PowerShell.

2. Run the following command to display information about the mailbox plans in your organization.

   PowerShell

   ```
   Get-MailboxPlan | Format-Table DisplayName,RetentionPolicy,IsDefault
   ```

   Note the mailbox plan that's set as the default.

3. Run the following command to assign the new MRM retention policy that you created in Step 3 (for example, **Alpine House Archive and Retention Policy**) to the default mailbox plan. This example assumes the name of the default mailbox plan is **ExchangeOnlineEnterprise**.

   PowerShell

```
Set-MailboxPlan "ExchangeOnlineEnterprise" -RetentionPolicy "Alpine House Archive and Retention Policy"
```

4. You can rerun the command in step 2 to verify that the MRM retention policy assigned to the default mailbox plan was changed.

More information

- The retention age of mailbox items is calculated from the date of delivery. Or from the date of creation for items such as draft messages that aren't sent but are created by the user. When the Managed Folder Assistant processes items in a mailbox, it stamps a start date and an expiration date for all items that have retention tags with the Delete and Allow Recovery or Permanently Delete retention action. Items that have an archive tag are stamped with a move date.

- The following table provides more information about each retention tag for the custom MRM retention policy in this article.

Expand table

Retention tag	What this tag does	Built-in or custom?	Type
Alpine House 3 Year Move to Archive	Moves items that are 1095 days (3 years) old to the archive mailbox.	Custom (See Step 2: Create new retention tags for the archive and deletion policies)	Default Policy Tag (archive); this tag is automatically applied to the entire mailbox.
Alpine House Deleted Items 5 Years Delete and Allow Recovery	Deletes items from the Deleted Items folder that are 5 years old. Users can recover these items for up 14 days after they're deleted. See the next list entry for more information.	Custom (See Step 2: Create new retention tags for the archive and deletion policies)	Retention Policy Tag (Deleted Items); this tag is automatically applied to items in the Deleted items folder.
Personal 1 year move to archive	Moves items to the archive mailbox after 1 year.	Built-in	Personal; this tag can be applied by users.

- Users can use the Recover Deleted Items tool in Outlook and Outlook on the web to recover a deleted item within the deleted item retention period, which by default is 14 days in Exchange Online. An administrator can use Exchange Online PowerShell to increase the deleted item retention period to a maximum of 30 days. For more information, see: Recover

deleted items in Outlook for Windows and Change the deleted item retention period for a mailbox in Exchange Online.

Last updated on 12/03/2024

Learn about inactive mailboxes

> *Microsoft Purview service description*

Your organization might need to retain former employees' email after they leave the organization. Depending on your organization's retention requirements, you might need to retain mailbox content for a few months or years after employment ends, or you might need to retain mailbox content indefinitely. Regardless of how long you need to retain email, you can create inactive mailboxes to retain the mailbox of former employees.

What are inactive mailboxes?

An inactive mailbox is a type of soft-deleted mailbox used to retain a former employee's email after they leave your organization.

When an employee leaves your organization (or goes on an extended leave of absence), you can remove their Microsoft 365 account. The employee's mailbox data is retained for 30 days after the account is removed. During this period, you can still recover the mailbox data by undeleting the account. After 30 days, the data is permanently removed.

But if a hold is applied to the mailbox prior to deleting the Microsoft 365 account, the mailbox will be converted into an inactive mailbox. The following sections contain information about holds that can be applied with Microsoft 365 retention and eDiscovery holds.

Inactive mailboxes are useful when your organization needs to retain mailbox content of former employees for regulatory or other reasons. While any type of hold listed in this document will force a mailbox to be made inactive when a user object is deleted, we recommend doing this by applying a Microsoft 365 retention policy or retention labels, confirm the hold is applied, and then remove the corresponding Microsoft 365 account. At that point, the contents of the inactive mailbox are retained for the duration of the retention period specified before the user account was deleted. You can still recover the corresponding user account for a 30-day period, however after 30 days, the mailbox is retained in Microsoft 365 as an inactive mailbox until the retention policy or retention labels are removed.

Important

As we mentioned previously, we recommend you use Microsoft 365 retention to create an inactive mailbox:

- In-Place Holds in the Exchange admin center are now retired. As of July 1, 2020, new In-Place Holds were unable to be created in Exchange Online. As of October 1, 2020, the hold duration of in-place holds could no longer be changed. Any inactive mailbox that has an In-Place Hold applied can only be deleted by removing the In-Place Hold. Existing inactive mailboxes that are on In-Place Hold will continue to be preserved until the hold is removed. For more information about In-Place Holds retirement, see Retirement of legacy eDiscovery tools.
- Litigation hold remains supported as an alternative method to retain content in a mailbox and make it inactive after a user account is deleted. However, as an older technology, we recommend you use Microsoft 365 retention instead.

When there are multiple holds on the same content, the principle of retention apply and the content is retained for the longest period.

Confirming a hold is applied to a mailbox

Whether you apply a Microsoft 365 retention policy, retention labels, eDiscovery hold, Litigation hold, or have an existing In-Place Hold, you can confirm the hold is successfully applied to the mailbox by using PowerShell. If you've recently configured the hold, you might need to wait until it's applied to the mailbox.

To prevent accidental or unintentional deletion, we recommend you confirm the hold before you delete the user account. If the hold isn't applied, the mailbox won't be converted into an inactive mailbox.

For instructions, see How to identify the type of hold placed on an Exchange Online mailbox.

A hold can also be applied automatically: after you remove a hold from a mailbox, Microsoft 365 applies a *delay hold* so that content isn't purged immediately. A mailbox with a delay hold is still treated as being on hold, so it stays an inactive mailbox until the delay hold is removed or expires. For more information, see Managing mailboxes on delay hold and Remove a delay hold from an inactive mailbox.

Inactive mailboxes and Microsoft 365 retention

If a Microsoft 365 retention policy is applied to a mailbox, or one or more email items in a mailbox have a retention label applied, and then the Microsoft 365 user account is deleted, the mailbox will be converted into an inactive mailbox. For the inactive mailbox to be created:

- The retention settings must be configured to retain content, or retain and then delete content. If the retention action is configured to only delete content, the mailbox won't become inactive when the user account is deleted. For inactive mailboxes, we recommend using the retain and then delete option.

- The retention settings must be applied to a retention location that is associated with an Exchange mailbox:
  - Exchange email
  - Microsoft 365 Groups
  - Skype for Business
  - Exchange public folders
  - Teams channel messages
  - Teams chats and Copilot interactions
  - Teams private channel messages
  - Viva Engage community messages
  - Viva Engage user messages

For more information about Microsoft retention, see Learn about retention policies and retention labels.

If Microsoft 365 retention is used to create an inactive mailbox, the retention settings from the retention policy or retention labels continue to apply to the inactive mailbox. This means if the retention settings are configured to retain and then delete content, items will be moved to the Recoverable Items folder when the retention duration expires, and then eventually purged from the inactive mailbox. If the retention settings aren't configured to delete items, then items that haven't been permanently deleted by the user (before the mailbox was made inactive) will not be moved to the Recoverable Items folder and will be retained indefinitely after the mailbox becomes inactive.

> **Tip**
>
> You can use the *ComplianceTagHoldApplied* property to identify whether a mailbox has items that have one or more retention labels applied to retain, or retain and then delete content.

For more information, see Identifying mailboxes on hold because a retention label has been applied to a folder or item.

Using adaptive policy scopes to manage retention of inactive mailboxes

With adaptive policy scopes, you can apply retention settings specifically to inactive mailboxes. Benefits of this configuration include:

- You can meet your organization's regulations or policies that require different retention periods for active employees and former employees.
- You can configure the retention settings to retain mailbox content for only as long as necessary to meet your organization's requirement for former employees.
- You can quickly identify the policy for retention that's assigned to inactive mailboxes in your organization, which makes it easier to change the retention settings if necessary.
- It's easier to permanently delete an inactive mailbox because you can remove it from the policy by configuring the adaptive scope to exclude it, based on attributes or properties of the inactive mailbox. Otherwise, you must use Exchange Online PowerShell before deleting the mailbox.

> **Note**
>
> Depending on the configuration of your adaptive policy scope, inactive mailboxes might or might not be included. To specifically target or to exclude inactive mailboxes from an adaptive policy scope, see configuration information for Exchange email and Exchange public folders.

Using static policy scopes and inactive mailboxes

If you don't use adaptive policy scopes and instead use a static scope with Microsoft 365 retention, consider the following:

- Static policy scopes include inactive mailboxes when you use the default **All mailboxes** configuration but aren't supported for specific inclusions or exclusions. However, if you include or exclude a recipient that has an active mailbox at the time the policy is applied

and the mailbox later goes inactive, the retention settings continue to be applied or excluded. In this scenario, specific inclusion and exclusion limits still apply.

> **Note**
>
> This also means that any new Microsoft 365 retention settings using a static scope that is applied to the default selection of **All mailboxes** will automatically include all existing inactive mailboxes.

- If you change the default selection of **All mailboxes** to include specific recipients, retention settings for the policy will no longer apply to any inactive mailboxes, which now become eligible for automatic deletion.
- If you want to release a retention policy that's applied to an inactive mailbox, see Releasing a policy for retention.

> **Caution**
>
> When you use Microsoft 365 retention to make a mailbox inactive, do not change or remove the user principal name (UPN) for the mailbox before you delete the corresponding user account. Additionally, do not change the primary SMTP address (that's derived from the UPN) or remove this email address from the list of secondary SMTP addresses associated with the mailbox before making the mailbox inactive.
>
> If you change the UPN or email addresses (that were assigned to the mailbox at the time the retention settings were applied) and then delete the user account to make the mailbox inactive, you won't be able to delete the inactive mailbox if you no longer need to retain it. That's because you can't remove the inactive mailbox from the policy by using a UPN or email address (to identify the inactive mailbox) that's different from the ones that existed when the retention settings were initially applied to the mailbox. For more information about deleting inactive mailboxes, see **Delete an inactive mailbox in Office 365**.

Inactive mailboxes and eDiscovery case holds

If a hold that's associated with an eDiscovery case is placed on a mailbox and then the mailbox or the user's account is deleted, the mailbox becomes an inactive mailbox. However, don't use eDiscovery case holds to make a mailbox inactive. That's because eDiscovery cases are intended for specific, time-bound cases related to a legal issue. At some point, a legal case probably ends,

the holds associated with the case are removed, and the eDiscovery case is closed. In fact, if a hold that's placed on an inactive mailbox is associated with an eDiscovery case, and then the hold is released or the eDiscovery case is closed (or deleted), the inactive mailbox is permanently deleted. Also, you can't create a time-based eDiscovery hold. This condition means that content in an inactive mailbox is retained forever or until the hold is removed and the inactive mailbox is deleted. Therefore, use Microsoft 365 retention for inactive mailboxes.

> **Important**
>
> When a mailbox with an **active eDiscovery hold** is deleted, the mailbox content is preserved as an inactive mailbox. The content remains searchable and exportable in eDiscovery for as long as the hold or associated case remains active.

For more information about the differences between eDiscovery holds and Microsoft 365 retention, see When to use retention policies and retention labels or eDiscovery holds.

Inactive mailboxes and auto-expanding archives

An inactive mailbox that's configured with an auto-expanding archive can't be recovered or restored. If, for compliance reasons, you need to recover data from an inactive mailbox with an auto-expanding archive, use content search to export the data from the mailbox. This action is supported for eDiscovery purposes only, and can't be used as a backup solution. For instructions to use search for the recovery of data for eDiscovery, see Create a search for a case in eDiscovery

Inactive mailboxes and Exchange MRM retention policies

Applying an Exchange retention policy (the messaging records management, or MRM, feature in Exchange Online) does not create an inactive mailbox when the user account is deleted.

However, if this MRM retention policy was applied to a mailbox before it went inactive, any deletion policies (MRM retention tags configured with a **Delete** action) will continue to be processed on the inactive mailbox. That means items that are tagged with an MRM deletion policy will be moved to the Recoverable Items folder when the retention period expires. Those items are purged from the inactive mailbox when the hold duration expires. If a hold duration isn't specified for the inactive mailbox, items in the Recover Items folder will be retained indefinitely.

Conversely, any archive policies (MRM retention tags configured with a **MoveToArchive** action) that are included in the MRM retention policy assigned to an inactive mailbox are ignored. That means items in an inactive mailbox that are tagged with an archive policy remain in the primary mailbox when the retention period expires. They're not moved to the archive mailbox or to the Recoverable Items folder in the archive mailbox. They will be retained indefinitely.

Next steps

To make a mailbox inactive and manage it, such as recovering, restoring, and deleting it, see Create and manage inactive mailboxes.

Last updated on 08/05/2026

Create and manage inactive mailboxes

> *Microsoft Purview service description*

Inactive mailboxes let you retain former employees' email after they leave your organization and can be accessed by authorized people who have been granted eDiscovery permissions for compliance or legal reasons. For example, administrators, compliance officers, and records managers who can then use Content Search to search and export the contents of an inactive mailbox. Inactive mailboxes can't receive email and aren't displayed in your organization's shared address book or other lists.

For more information about inactive mailboxes, see Learn about inactive mailboxes.

Create an inactive mailbox

Making a mailbox inactive requires a hold on the mailbox, and then deleting the mailbox or corresponding user account.

To make a mailbox inactive, it must be licensed correctly so that a hold can be applied to the mailbox before it's deleted. After the user account is deleted, any Exchange Online license associated with the user account will be available to assign to a new user.

We recommend you use Microsoft 365 retention to apply the hold on the mailbox. Other methods are covered in Learn about inactive mailboxes.

The best way to delete a mailbox is to delete the corresponding user account in the Microsoft 365 admin center. For information about deleting user accounts, see Delete a user from your organization. However, you can also delete the mailbox by using the **Remove-Mailbox** cmdlet in Exchange Online PowerShell. For more information, see Delete or restore user mailboxes in Exchange Online.

The following table summarizes the process of making an inactive mailbox for different retention scenarios.

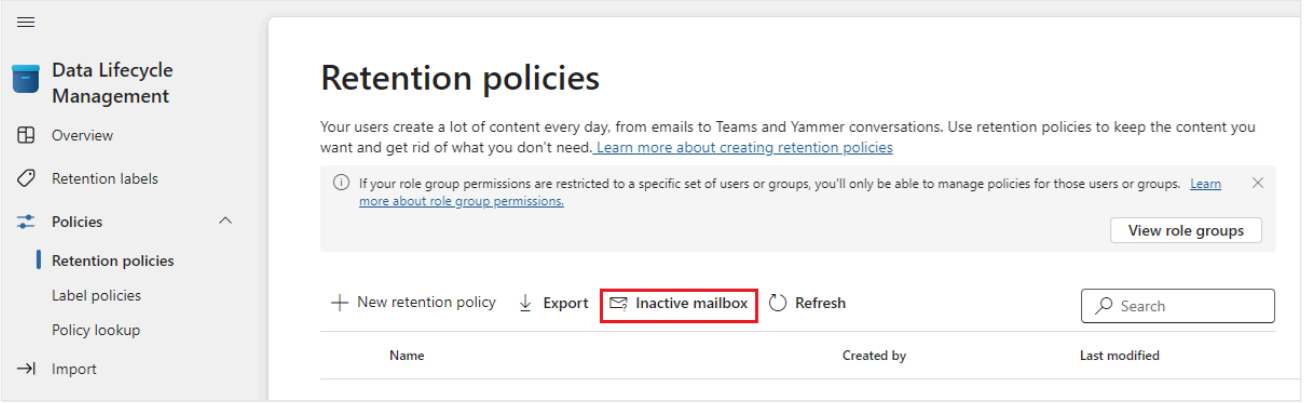
Expand table

To...	Do this...	Result
Retain mailbox content indefinitely after an employee leaves the organization	1. Apply Microsoft 365 retention settings with retain actions for the mailbox (a retention policy) or specific email items (one or more retention labels). 2. Wait for the retention settings to be applied. 3. Remove the user's Microsoft 365 account.	All content in the inactive mailbox that has retention settings applied, including items in the Recoverable Items folder, is retained indefinitely.
Retain all mailbox content for a specific period after an employee leaves the organization and then delete the mailbox	1. Apply a Microsoft 365 retention policy to the mailbox with retention settings that retain and then delete items when the retention period expires. 2. Wait for the retention settings to be applied. 3. Remove the user's Microsoft 365 account.	When the retention period for a mailbox item expires, the item is moved to the Recoverable Items folder and then it's permanently deleted (purged) from the inactive mailbox when the deleted item retention period (for Exchange mailboxes) expires. The retention period of the Microsoft 365 retention policy is always based on the original date a mailbox item was received or created.

> **Note**
>
> If Microsoft 365 retention settings that are configured to retain, or retain and then delete content, is already applied to the mailbox or mailbox items, or a Litigation hold is already placed on a mailbox, or then all you have to do to create an inactive mailbox is delete the corresponding user account.

View a list of inactive mailboxes

You can use the Microsoft Purview portal to view a list of the inactive mailboxes in your organization.



> **Note**

The portals are limited to displaying up to 5,000 inactive mailboxes. To view more than 5,000 inactive mailboxes, you must use Exchange Online PowerShell as described after the step instructions.

For this configuration, use the Microsoft Purview portal and a Compliance administrator account for your organization.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Policies** > **Retention policies**.

2. Select the **Inactive mailbox** option. For example, from the Microsoft Purview portal:

3. The **Inactive mailboxes** page displays a list of inactive mailboxes. Select one to see details about that inactive mailbox. Details include the Exchange identifier for the mailbox and whether it's on Litigation Hold.

   You won't see other types of holds in the details pane, for example a Microsoft 365 retention policy or eDiscovery hold. To find this information, see How to identify the type of hold placed on an Exchange Online mailbox.

If you have many inactive mailboxes, you might find it easier to search and sort a CSV file for the details you see in the list: On the **Inactive mailboxes** page, select **Export**.

Alternatively, you can run the following command in Exchange Online PowerShell to display the list of inactive mailboxes:

PowerShell

```
 Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited | FT
DisplayName,PrimarySMTPAddress,WhenSoftDeleted
```

You can also run the following command to export the list of inactive mailboxes and other information to a CSV file. In this example, the CSV file is created in the current directory.

PowerShell

```
Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited | Select
Displayname,PrimarySMTPAddress,DistinguishedName,ExchangeGuid,WhenSoftDeleted |
Export-Csv InactiveMailboxes.csv -NoTypeInformation
```

> **Note**
>
> It's possible that an inactive mailbox might have the same SMTP address as an active user mailbox. In this case, the value of the **DistinguishedName** or **ExchangeGuid** property can be used to uniquely identify an inactive mailbox.

Search and export the contents of an inactive mailbox

You can access the contents of the inactive mailbox by using the Content Search tool in the Microsoft Purview portal. For more information, see the Feature reference for Content search article.

Change the hold duration for an inactive mailbox

After a mailbox is made inactive, you might be able to change the duration of the hold applied to the inactive mailbox.

For step-by-step procedures, see Change the hold duration for an inactive mailbox.

Recover an inactive mailbox

If a former employee returns to your organization, or if a new employee is hired to take on the job responsibilities of the former employee, you can recover the contents of the inactive mailbox.

When you recover an inactive mailbox, the mailbox is converted to a new mailbox, the contents and folder structure of the inactive mailbox are retained, and the mailbox is linked to a new user account. After it's recovered, the inactive mailbox no longer exists.

For step-by-step procedures and more information about happens when you recover an inactive mailbox, see Recover an inactive mailbox.

Restore the contents of an inactive mailbox to another mailbox

If another employee takes on the job responsibilities of a former employee, or if another person needs access to the contents of the inactive mailbox, you can restore (or merge) the contents of the inactive mailbox to an existing mailbox.

When you restore an inactive mailbox, the contents are copied to another mailbox. The inactive mailbox is retained and remains an inactive mailbox. The inactive mailbox can still be searched using eDiscovery, its contents can be restored to another mailbox, or it can be recovered or deleted at a later date.

For step-by-step procedures, see Restore an inactive mailbox.

Delete an inactive mailbox

If you no longer need to retain the contents of an inactive mailbox, you can permanently delete the inactive mailbox by removing the hold applied to the inactive mailbox.

For more details and step-by-step procedures, see Delete an inactive mailbox.

> **Note**
>
> If a mailbox is still listed as inactive after you remove the last hold, check whether a delay hold is applied. A delay hold is applied automatically after another hold is removed, and it keeps the mailbox inactive until the delay hold is removed or expires. For instructions, see Remove a delay hold from an inactive mailbox.

Change the hold duration for an inactive mailbox

Article • 03/26/2024

> *Microsoft 365 licensing guidance for security & compliance*.

An inactive mailbox is mailbox state that is used to retain a former employee's email after they leave your organization. A mailbox becomes inactive when an applicable hold is applied to it before the Microsoft 365 user object is deleted. The following types of holds initiate the creation of an inactive mailbox upon user account deletion:

- Microsoft 365 retention policies and labels with retain-only, or retain and delete settings.
- A hold associated with an eDiscovery case.
- Litigation Hold.
- An existing In-Place Hold.

ⓘ Important

While any of the above holds will force a mailbox to become inactive upon Microsoft 365 user account deletion, it is strongly recommended that you use Microsoft 365 retention when proactively planning to utilize inactive mailboxes.

- eDiscovery holds are intended for specific, time-bound cases related to a legal issue. At some point, a legal case will probably end and the holds associated with the case will be removed and the eDiscovery case will be closed (or deleted). If a hold that's placed on an inactive mailbox is associated with an eDiscovery case, and the hold is released or the eDiscovery case is closed or deleted, the inactive mailbox will be permanently deleted.
- In-Place Holds in the Exchange admin center are now retired. As of July 1, 2020, new In-Place Holds were unable to be created in Exchange Online. As of October 1, 2020, the hold duration of in-place holds could no longer be changed. Any inactive mailbox that has an In-Place Hold applied can only be deleted by removing the In-Place Hold. Existing inactive mailboxes that are on In-Place Hold will continue to be preserved until the hold is removed. For

more information about In-Place Holds retirement, see [Retirement of legacy eDiscovery tools](#).

- [Litigation hold](#) remains supported as an alternative method to retain content in a mailbox and make it inactive after a user account is deleted. However, as an older technology, we recommend you use Microsoft 365 retention instead.

Once made inactive, the contents of the mailbox including the Recoverable Items folder are retained until the hold that was placed on the mailbox before it was made inactive no longer applies.

If the applicable hold is not time-based, such as a hold associated with an indefinite retain-only Microsoft 365 retention policy or label, an eDiscovery case or Litigation Hold (without a `LitigationHoldDuration` configured), the mailbox content is retained indefinitely until the hold is removed.

However, if the hold is time-based, the mailbox content is retained until the hold duration expires. At this time, any items in the Recoverable Items folder are permanently deleted (purged) from the inactive mailbox.

> **Note**
>
> For inactive mailboxes, we recommend using a retain and delete setting for your Microsoft 365 retention policy or labels. If you choose a retain only setting, the Recoverable Items folder will purge at the end of the hold duration, however any other non-deleted items will remain within the inactive mailbox indefinitely.

As regulations and policies evolve, there may be some situations in which you need to change the duration of the hold assigned to the inactive mailbox. The following steps outline how to do this.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the [Microsoft Purview trials hub](#). Learn details about [signing up and trial terms](#).

Connect to PowerShell

As we mentioned before, many different types of holds can trigger the creation of an inactive mailbox. For this reason, in order to change the hold duration applied to the inactive mailbox, you must first identify what type of holds are affecting it. To identify the type of holds, you must use Exchange Online PowerShell to identify the types of holds. If the inactive mailbox is affected by Microsoft 365 retention policies or labels, you must also use Security & Compliance PowerShell to identify the specific policies.

- To connect to Exchange Online PowerShell or Security & Compliance PowerShell, see one of the following topics:
  - Connect to Exchange Online PowerShell
  - Connect to Security & Compliance PowerShell

Step 1: Identify the holds on an inactive mailbox

Because different types of holds or one or more Microsoft 365 retention policies might be placed on an inactive mailbox, the first step is to identify the holds on an inactive mailbox.

Run the following command in Exchange Online PowerShell to display the hold information for a specific inactive mailbox in your organization.

PowerShell

```
Get-Mailbox -Identity <identity of inactive mailbox> -InactiveMailboxOnly |
FL
DisplayName,Name,DistinguishedName,ExchangeGuid,IsInactiveMailbox,Litigation
HoldEnabled,LitigationHoldDuration,LitigationHoldDate,LitigationHoldOwner,In
PlaceHolds,ComplianceTagHoldApplied
```

If you need to identify the type of hold for multiple inactive mailboxes and your organization has a large number of them, it may become unmanageable to view using PowerShell. In this case, you can export all of the applicable information to a CSV file using the following command and modifying the `Path` as needed for your environment:

PowerShell

```
Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited | Select
DisplayName,Name,DistinguishedName,ExchangeGuid,IsInactiveMailbox,Litigation
HoldEnabled,LitigationHoldDuration,LitigationHoldDate,LitigationHoldOwner,In
PlaceHolds,ComplianceTagHoldApplied | Export-Csv -NoTypeInformation -Path
"C:\Temp\InactiveMailboxHoldTypes.csv"
```

For the purposes of this example, the following shows results for six inactive mailboxes with different possible hold types.

> ⓘ **Note**
>
> Multiple holds including multiple types of holds can apply to a single inactive mailbox.

text

```
DisplayName               : Ann Beebe
Name                      : annb
DistinguishedName         : CN=annb,OU=Soft Deleted
                            Objects,OU=contoso.onmicrosoft.com,OU=Microsoft

The following table identifies the six different hold types that were used to make each mailbox inactive from the above example.

Expand table

Inactive mailbox	Hold type	How to identify the hold on the inactive mailbox
Ann Beebe	Litigation Hold	The `LitigationHoldEnabled` property is set to `True` indicating the mailbox is on Litigation Hold. Additionally, the `LitigationHoldDuration` is set to `365.00:00:00` indicating that mailbox items will no longer be subject to litigation hold 365 days after their creation date (sent/received). The `LitigationHoldDate` indicates the date LitigationHold was enabled and `LitigationHoldOwner` identifies the person who initiated the litigation hold.
Carol Olson	Microsoft 365 retention policy from the Microsoft Purview portal that is applied to specific mailboxes	The `InPlaceHolds` property contains the GUID of the Microsoft 365 retention policy that's applied to the inactive mailbox. You can identify the hold type is a retention policy that's applied to specific mailboxes because the GUID starts with the `mbx` prefix and ends in a `:2` or `:3`. For more information, see Understanding the format of the InPlaceHolds value for retention policies.
Megan Bowen	Microsoft 365 retention label with a retain-only, or retain and delete action is applied to at least one item in the mailbox	The `ComplianceTagHoldApplied` property is `True` indicating an item is labeled with a retain-only, or retain and delete label. Additionally, the `InPlaceHolds` property contains the GUID of the Microsoft 365 retention label policy that's applied to the inactive mailbox. For more information, see Identifying mailboxes on hold because a retention label has been applied to a folder or item
Mario Necaise	Organization-wide Microsoft 365 retention policy from the Microsoft Purview portal	The `InPlaceHolds` property is empty, `LitigationHoldEnabled` is `False` and `ComplianceTagHoldApplied` is `False`. This result indicates that one or more entire (Exchange) location Microsoft 365 retention policies applied to the organization that the inactive mailbox is inheriting.

Inactive mailbox	Hold type	How to identify the hold on the inactive mailbox
		For more information, see How to confirm that an organization-wide retention policy is applied to a mailbox
Abraham McMahon	eDiscovery case hold in the Microsoft Purview portal	The `InPlaceHolds` property contains the GUID of the eDiscovery case hold that's placed on the inactive mailbox. You can tell this result is an eDiscovery case hold because the GUID starts with the `UniH` prefix. For more information, see eDiscovery holds.
Pilar Pinilla	In-Place Hold	The `InPlaceHolds` property contains the GUID of the In-Place Hold that's placed on the inactive mailbox. You can tell this result is an In-Place Hold because the GUID doesn't start with a prefix. **NOTE**: As of October 1, 2020, the hold duration of in-place holds can no longer be changed. You can only remove an In-Place Hold that results in the deletion of the inactive mailbox. For more information, see Retirement of legacy eDiscovery tools.

Step 2: Change the hold duration for an inactive mailbox

After you identify what type of hold is placed on the inactive mailbox (and whether there are multiple holds), the next step is to change the duration for the hold. The process varies depending on the type of hold applied.

- Change the duration for a Microsoft 365 retention policy
- Change the duration for a Microsoft 365 retention label
- Change the duration for an eDiscovery Hold
- Change the duration for a Litigation Hold
- Change the duration for an In-Place Hold

Change the duration for a Microsoft 365 retention policy

In order to modify the hold duration for a Microsoft 365 retention policy, you must first identify the policy affecting the inactive mailbox by running `Get-RetentionCompliancePolicy` with the associated GUID from the `InPlaceHolds` property on the mailbox in Security & Compliance PowerShell.

Be sure to remove the prefix and suffix from the GUID when running this command. For example, using our previous sample information, take the `InPlaceHolds` value of `mbxcdbbb86ce60342489bff371876e7f224:3` then remove `mbx` and `:3` resulting in a policy GUID of `cdbbb86ce60342489bff371876e7f224`. In this example, run:

```
PowerShell

Get-RetentionCompliancePolicy cdbbb86ce60342489bff371876e7f224 | FL Name
```

Once you know the name of the policy, you can simply modify the retention policy in the Microsoft Purview portal. Retention policies are typically applied to more than one location, so modifying the policy affects all applied locations - both inactive and active, which may also include locations other than Exchange. For more information, see Create and configure retention policies.

> **ⓘ Important**
>
> Retention policies with **preservation lock** enabled can have the retention period extended, but not decreased or removed.

If the intention is to modify the retention period for only inactive mailboxes, or only specific inactive mailboxes, you may consider deploying adaptive policy scopes, which can be used to individually target specific mailboxes - or mailbox types, such as inactive mailboxes - using Microsoft Entra ID and Exchange attributes and properties.

Change the duration for a Microsoft 365 retention label

As with retention policies, when you modify the hold duration of a Microsoft 365 retention label, you must first identify the policy that publishes the label affecting the content within the inactive mailbox. To identify that policy, run `Get-RetentionCompliancePolicy` with the associated GUID from the `InPlaceHolds` property on the mailbox in Security & Compliance PowerShell.

Be sure to remove the prefix and suffix from the GUID when running this command. For example, using the previous sample information, you take the `InPlaceHolds` value of

`mbx6fe063689d404a5bb9940eed0f0bf5d2:1` then remove `mbx` and `:1`, which results in a policy GUID of `6fe063689d404a5bb9940eed0f0bf5d2`. In this example, you run:

PowerShell

```
Get-RetentionCompliancePolicy 6fe063689d404a5bb9940eed0f0bf5d2 | FL Name
```

After you identify the policy, you'll know which labels have been published and their settings. Because labels apply to individual items, depending on the number of labels published with the policy and their settings, you may not be able to directly identify which label is affecting the content.

One method that you can use to identify the content each label applies to is to use Content Search. For example, using the previous sample information, assume the policy publishes several labels, one of which is named "HR-Content". With the correct permissions, you can run a Content Search with the New-ComplianceSearch PowerShell command, specify the inactive mailbox's primary SMTP address, pre-pended with a period (`.`), and the `-AllowNotFoundExchangeLocationsEnabled $true` parameter to skip validation:

PowerShell

```
New-ComplianceSearch -Name "MeganB Inactive Mailbox HR-Content Label Search"
-ExchangeLocation .meganb@contoso.onmicrosoft.com -
AllowNotFoundExchangeLocationsEnabled $true -ContentMatchQuery
"compliancetag=HR-Content"
```

After the search is created, start the search using the following command:

PowerShell

```
Start-ComplianceSearch "MeganB Inactive Mailbox HR-Content Label Search"
```

Using this method, you can then identify which labels from the identified label policy apply to content within the inactive mailbox so that you can modify their retention periods. Retention labels are typically applied to more than one location, so modifying a label affects all applied locations and labeled content, which may also include locations and content other than Exchange. For more information, see Publish retention labels and apply them in apps.

> ⓘ **Note**

Not all types of retention labels can be modified. For some labels, you may only be able to increase the time of retention, and for others you may not be able to modify the retention period at all.

Change the duration for an eDiscovery Hold

Holds associated with eDiscovery cases are indefinite holds, which means there's no hold duration that can be changed. Items are held forever or until the hold is removed or the case is closed.

Change the duration for a Litigation Hold

You must use Exchange Online PowerShell to change the hold duration for a Litigation Hold that is placed on an inactive mailbox. You can't use the Exchange admin center. Run the following command to change the hold duration. In this example, the hold duration is changed to an unlimited period of time:

PowerShell

```
Set-Mailbox -InactiveMailbox -Identity <identity of inactive mailbox> -
LitigationHoldDuration unlimited
```

The result is that items in the inactive mailbox are retained indefinitely or until the hold is removed or the hold duration is changed to a different value.

Tip

The best way to identify an inactive mailbox is by using its **Distinguished Name** or **Exchange GUID** value. Using one of these values helps prevent accidentally specifying the wrong mailbox.

Change the duration for an In-Place Hold

In-Place Holds are retired and can no longer be modified. If an inactive mailbox has an In-Place Hold applied to it, you can't change the hold duration. You can only remove the In-Place Hold, which will result in the deletion of the inactive mailbox. For more information, see Delete an inactive mailbox.

More information

- **How is the hold duration calculated for an item in an inactive mailbox?** The duration is calculated from the original date a mailbox item was received or created.

- **What happens when the hold duration expires?** When the hold duration expires for a mailbox item in the Recoverable Items folder, the item is permanently deleted (purged) from the inactive mailbox. If there's no duration specified for the hold placed on the inactive mailbox, items in the Recoverable Items folder are never purged (unless the hold duration for the inactive mailbox is changed).

- **Is an Exchange MRM policy still processed on inactive mailboxes?** If an MRM retention policy was applied to a mailbox before it went inactive, any deletion policies (MRM retention tags configured with a **Delete** action) continue to be processed on the inactive mailbox. That means items that are tagged with an MRM deletion policy are be moved to the Recoverable Items folder when the retention period expires. Those items are purged from the inactive mailbox when the hold duration expires. If a hold duration isn't specified for the inactive mailbox, items in the Recover Items folder are retained indefinitely.

  Conversely, any archive policies (MRM retention tags configured with a **MoveToArchive** action) that are included in the MRM retention policy assigned to an inactive mailbox are ignored. That means items in an inactive mailbox that are tagged with an archive policy remain in the primary mailbox when the retention period expires. They're not moved to the archive mailbox or to the Recoverable Items folder in the archive mailbox. They are retained indefinitely.

  > ⓘ **Note**
  >
  > Applying an Exchange retention policy (the messaging records management, or MRM, feature in Exchange Online) does not create an inactive mailbox when the user account is deleted.

- **As with regular mailboxes, the Managed Folder Assistant (MFA) also processes inactive mailboxes.** In Exchange Online, the MFA processes mailboxes approximately once every seven days. After you change the hold duration for an inactive mailbox, you can use the **Start-ManagedFolderAssistant** cmdlet to immediately start processing the new hold duration for the inactive mailbox. Run the following command.

  ```
  PowerShell
  ```

```
Start-ManagedFolderAssistant -InactiveMailbox <identity of inactive
mailbox>
```

- **If many `InPlaceHolds` are placed on an inactive mailbox, not all of the hold GUIDs will be displayed.** You can run the following command to display the GUIDs for all `InPlaceHolds` that are placed on an inactive mailbox.

PowerShell

```
Get-Mailbox -InactiveMailboxOnly -Identity <identity of inactive
mailbox> | Select-Object -ExpandProperty InPlaceHolds
```

Recover an inactive mailbox

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

An inactive mailbox (which is a type of soft-deleted mailbox) is used to preserve a former employee's email after they leave your organization. If that employee returns to your organization or if another employee takes on the job responsibilities of the former employee, there are two ways that you can make the contents of the inactive mailbox available to a user:

- **Recover an inactive mailbox.** If the former employee returns to your organization, or if a new employee is hired to take on the job responsibilities of the former employee, you can recover the contents of the inactive mailbox. This method converts the inactive mailbox to a new, active mailbox that contains the contents of the inactive mailbox. After it's recovered, the inactive mailbox no longer exists. The procedures in this article describe this method.
- **Restore an inactive mailbox.** If another employee takes on the job responsibilities of the former employee, or if another user needs access to the contents of the inactive mailbox, you can restore (or merge) the contents of the inactive mailbox to an existing mailbox. You can also restore the archive from an inactive mailbox. For the procedures for this method, see Restore an inactive mailbox in Office 365.

See the More information section for more details about the differences between recovering and restoring an inactive mailbox, and for a description of what happens when an inactive mailbox is recovered. Both recover and restore operations are designed for email data and don't support restoring or recovering application data that can be stored in mailbox hidden folders.

> **Note**
>
> You can't recover or restore an inactive mailbox that's configured with an auto-expanding archive. If, for compliance reasons, you need to recover data from an inactive mailbox with an auto-expanding archive, use content search to export the data from the mailbox. This action is supported for eDiscovery purposes only, and can't be used as a backup solution. For instructions to use content search for the recovery of data for eDiscovery, see following articles:
>
> - Content search
> - Export content search results

Requirements to recover an inactive mailbox

- You must use Exchange Online PowerShell to recover an inactive mailbox. You can't use the Exchange admin center (EAC), or the Microsoft Purview portal for this procedure. For step-by-step instructions to use Exchange Online PowerShell, see Connect to Exchange Online PowerShell.

- Run the following command to get identity information for the inactive mailboxes in your organization.

  PowerShell

  ```
  Get-Mailbox -InactiveMailboxOnly | Format-List
  Name,DistinguishedName,ExchangeGuid,PrimarySmtpAddress
  ```

  Use the information returned by this command to recover a specific inactive mailbox.

Recover inactive mailboxes

Use the **New-Mailbox** cmdlet with the *InactiveMailbox* parameter to recover an inactive mailbox.

1. Create a variable that contains the properties of the inactive mailbox.

   PowerShell

   ```
   $InactiveMailbox = Get-Mailbox -InactiveMailboxOnly -Identity <identity of
   inactive mailbox>
   ```

   > **Important**
   >
   > In the previous command, use the value of the **ExchangeGUID** property to identify the inactive mailbox.

2. This example uses the properties obtained in the previous command and recovers the inactive mailbox to an active mailbox for the user Ann Beebe. Be sure that the values specified for the *Name* and *MicrosoftOnlineServicesID* parameters are unique within your organization.

   PowerShell

   ```
   New-Mailbox -InactiveMailbox $InactiveMailbox.ExchangeGuid -Name annbeebe -
   FirstName Ann -LastName Beebe -DisplayName "Ann Beebe" -
   ```

```
MicrosoftOnlineServicesID Ann.Beebe@contoso.com -Password (ConvertTo-
SecureString -String 'P@ssw0rd' -AsPlainText -Force) -
ResetPasswordOnNextLogon $true
```

The primary SMTP address for the recovered inactive mailbox will have the same value as the one specified by the *MicrosoftOnlineServicesID* parameter.

After you recover an inactive mailbox, a new user account is also created. You need to activate this user account by assigning a license. To assign a license in the Microsoft 365 admin center, see Add users and assign licenses at the same time.

More information

- **What's the main difference between recovering and restoring an inactive mailbox?** When you recover an inactive mailbox, the mailbox is converted to a new mailbox, the contents and folder structure of the inactive mailbox are retained, and the mailbox is linked to a new user account. After it's recovered, the inactive mailbox no longer exists, and any changes made to the content in the new mailbox will affect the content that was originally on hold in the inactive mailbox. Conversely, when you restore an inactive mailbox, the contents are merely copied to another mailbox. The inactive mailbox is preserved and remains an inactive mailbox. Any changes made to the content in the target mailbox won't affect the original content held in the inactive mailbox. The inactive mailbox can still be searched by using In-Place eDiscovery, its contents can be restored to another mailbox, or it can be recovered or deleted at a later date.

- **What happens when you recover an inactive mailbox?** When you recover an inactive mailbox, the following things occur:

  - The hold that was applied to an inactive mailbox is changed or removed based on the type of hold that was applied to the inactive mailbox before it was recovered.

    - **Microsoft 365 retention policy with Preservation Lock.** If the inactive mailbox was included in a retention policy that has Preservation Lock, the recovered mailbox is assigned to the same retention policy.

    - **Microsoft 365 retention policy without Preservation Lock.** The inactive mailbox is removed from the Microsoft 365 retention policy. However, Litigation Hold is enabled on the recovered mailbox to prevent the deletion of mailbox content based on any organization-wide retention policies that delete content older than a specific age. You can keep the Litigation Hold or remove it. For more information, see Create a Litigation Hold.

    - **Litigation Hold.** If Litigation Hold was enabled for the inactive mailbox, it's removed from the recovered mailbox.

    - **In-Place Hold** In-Place Holds are removed from the recovered mailbox. This means the recovered mailbox is removed as a source mailbox from any In-Place Hold or In-Place eDiscovery search.

  - The single item recovery period (which is defined by the **RetainDeletedItemsFor** mailbox property) is set to 30 days. Typically, when a new mailbox is created in Exchange Online, this retention period is set to 14 days. Setting this to the maximum value of 30 days gives you more time to recover any data that's been permanently deleted (or purged) from the inactive mailbox. You can also disable single item recovery or set the single item recovery period back to the default of 14 days. For more information, see Enable or disable single item recovery for a mailbox.

  - Retention hold is enabled, and the retention hold duration is set to 30 days. This means that the default Exchange retention policy and any organization-wide or Exchange-wide Microsoft 365 retention policies that are assigned to the new mailbox won't be processed for 30 days. This gives the returning employee or the new owner of the recovered inactive mailbox time to manage the old messages. Otherwise, the Exchange or Microsoft 365 retention policy might delete old mailbox items (or move items to the archive mailbox, if it's enabled) that have expired based on the settings configured for the Exchange or Microsoft 365 retention policies. After 30 days, the retention hold expires, the **RetentionHoldEnabled** mailbox property is set to **False**, and the Managed Folder Assistant starts processing the policies assigned to the mailbox. If you don't need this additional time, you can just remove the retention hold. Alternatively, you can increase the duration of the retention hold by using the **Set-Mailbox -EndDateForRetentionHold** command. For more information, see Place a mailbox on retention hold.

- **Put a hold on the recovered mailbox if you need to preserve the original state of the inactive mailbox.** To prevent the new mailbox owner or retention policy from permanently deleting any messages from the recovered inactive mailbox, you can place the mailbox on Litigation Hold. For more information, see Create a Litigation Hold.

- **What user ID can you use when recovering an inactive mailbox?** When you recover an inactive mailbox, the value that you specify for the *MicrosoftOnlineServicesID* parameter can be different from the original one that was associated with the inactive mailbox. You can also use the original user ID. But as previously stated, make sure that the values used for *Name* and *MicrosoftOnlineServicesID* are unique within your organization when you recover the inactive mailbox.

- **What if the mailbox retention period for the inactive mailbox hasn't expired?** If an inactive mailbox was soft-deleted less than 30 days ago, you can't use the **New-Mailbox -InactiveMailbox** command to recover it. You need to recover it by restoring the corresponding user account. For more information, see Delete a user from your organization.

- **How do you know if the soft-deleted mailbox retention period for an inactive mailbox has expired?** Run the following command:

  PowerShell

  ```
  Get-Mailbox -InactiveMailboxOnly <identity of inactive mailbox> | Format-List ExternalDirectoryObjectId
  ```

  - If there's no value for the **ExternalDirectoryObjectId** property, the mailbox retention period has expired, and you can recover the inactive mailbox by running the **New-Mailbox -InactiveMailbox** command.
  - If there's a value for the **ExternalDirectoryObjectId** property, the soft-deleted mailbox retention period hasn't expired and you have to recover the mailbox by restoring the user account.

- **Consider enabling the archive mailbox after you recover an inactive mailbox.** This lets the returning user or new employee move old messages to the archive mailbox. And when the retention hold expires, the archive policy that is part of the default Exchange MRM retention policy assigned to Exchange Online mailboxes will move items that are two years or older to the archive mailbox. If you don't enable the archive mailbox, items older than two years will remain in the user's primary mailbox. For more information, see Enable archive mailboxes.

Restore an inactive mailbox

Article • 03/26/2024

> *Microsoft 365 licensing guidance for security & compliance*.

An inactive mailbox (which is a type of soft-deleted mailbox) is used to retain a former employee's email after they leave your organization. If another employee takes on the job responsibilities of the former employee or if that employee returns to your organization, there are two ways that you can make the contents of the inactive mailbox available to a user:

- **Restore an inactive mailbox** If another employee takes on the job responsibilities of the former employee, or if another user needs access to the contents of the inactive mailbox, you can restore (or merge) the contents of the inactive mailbox to an existing mailbox. You can also restore the archive from an inactive mailbox. After it's restored, the inactive mailbox is preserved and is retained as an inactive mailbox. This article describes the procedures for restoring an inactive mailbox.

- **Recover an inactive mailbox** If the former employee returns to your organization, or if a new employee is hired to take on the job responsibilities of the former employee, you can recover the contents of the inactive mailbox. This method converts the inactive mailbox to a new mailbox that contains the contents of the inactive mailbox. After it's recovered, the inactive mailbox no longer exists. For the step-by-step procedures, see Recover an inactive mailbox in Office 365.

See the More information section in this article for more details about the differences between restoring and recovering an inactive mailbox. Both operations are designed for email data and don't support restoring or recovering application data that can be stored in mailbox hidden folders.

> **Note**
>
> You can't recover or restore an inactive mailbox that's configured with an auto-expanding archive. If, for compliance reasons, you need to recover data from an inactive mailbox with an auto-expanding archive, use content search to export the data from the mailbox. This action is supported for eDiscovery purposes only, and can't be used as a backup solution. For instructions to use content search for the recovery of data for eDiscovery, see following articles:
>
> - Content search

- Export content search results

Requirements to restore an inactive mailbox

- You must use Exchange Online PowerShell to restore an inactive mailbox. You can't use the Exchange admin center (EAC), or the Microsoft Purview portal for this procedure. For step-by-step instructions to use Exchange Online PowerShell, see Connect to Exchange Online PowerShell.
- Run the following command in Exchange Online PowerShell to get identity information for the inactive mailboxes in your organization.

  ```
  PowerShell

  Get-Mailbox -InactiveMailboxOnly | Format-List
  Name,DistinguishedName,ExchangeGuid,PrimarySmtpAddress
  ```

  Use the information returned by this command to identify and restore a specific inactive mailbox.
- For more information about inactive mailboxes, see Inactive mailboxes in Office 365.

Restore inactive mailboxes

Use the **New-MailboxRestoreRequest** cmdlet with the *SourceMailbox* and *TargetMailbox* parameters to restore the contents of an inactive mailbox to an existing mailbox. For more information about using this cmdlet, see New-MailboxRestoreRequest.

Before you can restore an inactive mailbox, you have to add the LegacyExchangeDN of the inactive mailbox to the target mailbox, as an X500 proxy address of the target mailbox. This has to be done because the **New-MailboxRestoreRequest** cmdlet checks to make sure the value of the **LegacyExchangeDN** property on the source and target

mailboxes is the same. After you restore the inactive mailbox, you can optionally remove the LegacyExchangeDN of the inactive mailbox from source mailbox. Be sure to wait until the mailbox restore request is complete before removing the LegacyExchangeDN.

Follow these steps to restore an inactive mailbox to an existing mailbox:

1. Create a variable that contains the properties of the inactive mailbox.

   PowerShell

   ```
   $inactiveMailbox = Get-Mailbox -InactiveMailboxOnly -Identity <identity
   of inactive mailbox>
   ```

   > **Important**
   >
   > In the previous command, use the value of the **DistinguishedName** or **ExchangeGUID** property to identify the inactive mailbox. These properties are unique for each mailbox in your organization, whereas it's possible that an active and an inactive mailbox might have the same primary SMTP address.

2. Display the LegacyExchangeDN of the inactive mailbox so that you can add it as a proxy address to the target mailbox in the next step.

   PowerShell

   ```
   $inactiveMailbox.LegacyExchangeDN
   ```

3. Add the LegacyExchangeDN of the inactive mailbox as an X500 proxy address to the target mailbox.

   PowerShell

   ```
   Set-Mailbox <identity of target mailbox> -EmailAddresses @{Add="X500:
   <LegacyExchangeDN of inactive mailbox>"}
   ```

4. Restore the contents of the inactive mailbox to an existing mailbox. The contents of the inactive mailbox (source mailbox) will be merged into the corresponding folders in the existing mailbox (target mailbox).

   PowerShell

   ```
   New-MailboxRestoreRequest -SourceMailbox
   $inactiveMailbox.DistinguishedName -TargetMailbox <identity of target
   ```

```
mailbox>
```

Alternatively, you can specify a top-level folder in the target mailbox in which to restore the contents from the inactive mailbox. If the specified target folder or target folder structure doesn't already exist in the target mailbox, it is created during the restore process.

This example copies mailbox items and subfolders from an inactive mailbox to a folder named "Inactive Mailbox" in the top-level folder structure of the target mailbox.

PowerShell

```
New-MailboxRestoreRequest -SourceMailbox
$InactiveMailbox.DistinguishedName -TargetMailbox <identity of target
mailbox> -TargetRootFolder "Inactive Mailbox"
```

5. After the restore request is complete, you can optionally remove the LegacyExchangeDN of the inactive mailbox from the target mailbox. Leaving the LegacyExchangeDN from the inactive mailbox won't affect the target mailbox.

PowerShell

```
Set-Mailbox <identity of target mailbox> -EmailAddresses
@{Remove="X500:<LegacyExchangeDN of inactive mailbox>"}
```

Restore the archive from an inactive mailbox

If an inactive mailbox has an archive mailbox, you can also restore it to the archive mailbox of an existing mailbox. To restore the archive from an inactive mailbox, you have to add the *SourceIsArchive* and *TargetIsArchive* switches to the command used to restore an inactive mailbox.

1. Create a variable that contains the properties of the inactive mailbox.

PowerShell

```
$inactiveMailbox = Get-Mailbox -InactiveMailboxOnly -Identity <identity
of inactive mailbox>
```

> **Note**

In the previous command, use the value of the **DistinguishedName** or **ExchangeGUID** property to identify the inactive mailbox. These properties are unique for each mailbox in your organization, whereas it's possible that an active and an inactive mailbox might have the same primary SMTP address.

2. Display the LegacyExchangeDN of the inactive mailbox so that you can add it as a proxy address to the target mailbox in the next step.

```
PowerShell

$inactiveMailbox.LegacyExchangeDN
```

3. Add the LegacyExchangeDN of the inactive mailbox as an X500 proxy address to the target mailbox.

```
PowerShell

Set-Mailbox <identity of target mailbox> -EmailAddresses @{Add="X500:
<LegacyExchangeDN of inactive mailbox>"}
```

4. Restore the contents of the archive from the inactive mailbox (source archive) to the archive of an existing mailbox (target archive). In this example, the contents from the source archive are copied to a folder named "Inactive Mailbox Archive" in the archive of the target mailbox.

```
PowerShell

New-MailboxRestoreRequest -SourceMailbox
$InactiveMailbox.DistinguishedName -SourceIsArchive -TargetMailbox
<identity of target mailbox> -TargetIsArchive -TargetRootFolder
"Inactive Mailbox Archive"
```

5. After the restore request is complete, you can optionally remove the LegacyExchangeDN of the inactive mailbox from the target mailbox. Leaving the LegacyExchangeDN from the inactive mailbox won't affect the target mailbox.

```
PowerShell

Set-Mailbox <identity of target mailbox> -EmailAddresses
@{Remove="X500:<LegacyExchangeDN of inactive mailbox>"}
```

More information

- **What's the main difference between recovering and restoring an inactive mailbox?** When you recover an inactive mailbox, the mailbox is converted to a new mailbox. The contents and folder structure of the inactive mailbox are retained, and the mailbox is linked to a new user account. After it's recovered, the inactive mailbox no longer exists, and any changes made to the content in the new mailbox will affect the content that was originally on hold in the inactive mailbox. Conversely, when you restore an inactive mailbox, the contents are merely copied to another mailbox. The inactive mailbox is preserved and remains an inactive mailbox. Any changes made to the content in the target mailbox won't affect the original content held in the inactive mailbox. The inactive mailbox can still be searched by using the Content Search tool, its contents can be restored to another mailbox, or it can be recovered or deleted at a later date.

- **How do you find inactive mailboxes?** To get a list of the inactive mailboxes in your organization and display information that is useful for restoring an inactive mailbox, you can run this command.

  PowerShell

  ```
  Get-Mailbox -InactiveMailboxOnly | Format-List
  Name,PrimarySMTPAddress,DistinguishedName,ExchangeGUID,LegacyExchangeDN
  ,ArchiveStatus
  ```

- **Use a Microsoft 365 retention policy or Litigation Hold or to retain inactive mailbox content.** If you want to retain the state of an inactive mailbox after it's restored, you can apply a Microsoft 365 retention policy to the target mailbox or place the target mailbox on Litigation Hold before you restore the inactive mailbox. This will prevent the permanent deletion of any items from the inactive mailbox after they're restored to the target mailbox.

- **Enable retention hold on the target mailbox before you restore an inactive mailbox.** Because mailbox items from an inactive mailbox could be old, you might consider enabling retention hold on the target mailbox before you restore an inactive mailbox. When you put a mailbox on retention hold, the retention policy that's assigned to it won't be processed until the retention hold is removed or until the retention hold period expires. This gives the owner of the target mailbox time to manage old messages from the inactive mailbox. Otherwise, the retention policy might delete old items (or move items to the archive mailbox, if it's enabled) that have expired based on the retention settings configured for the target mailbox. For more information, see Place a mailbox on retention hold in Exchange Online.

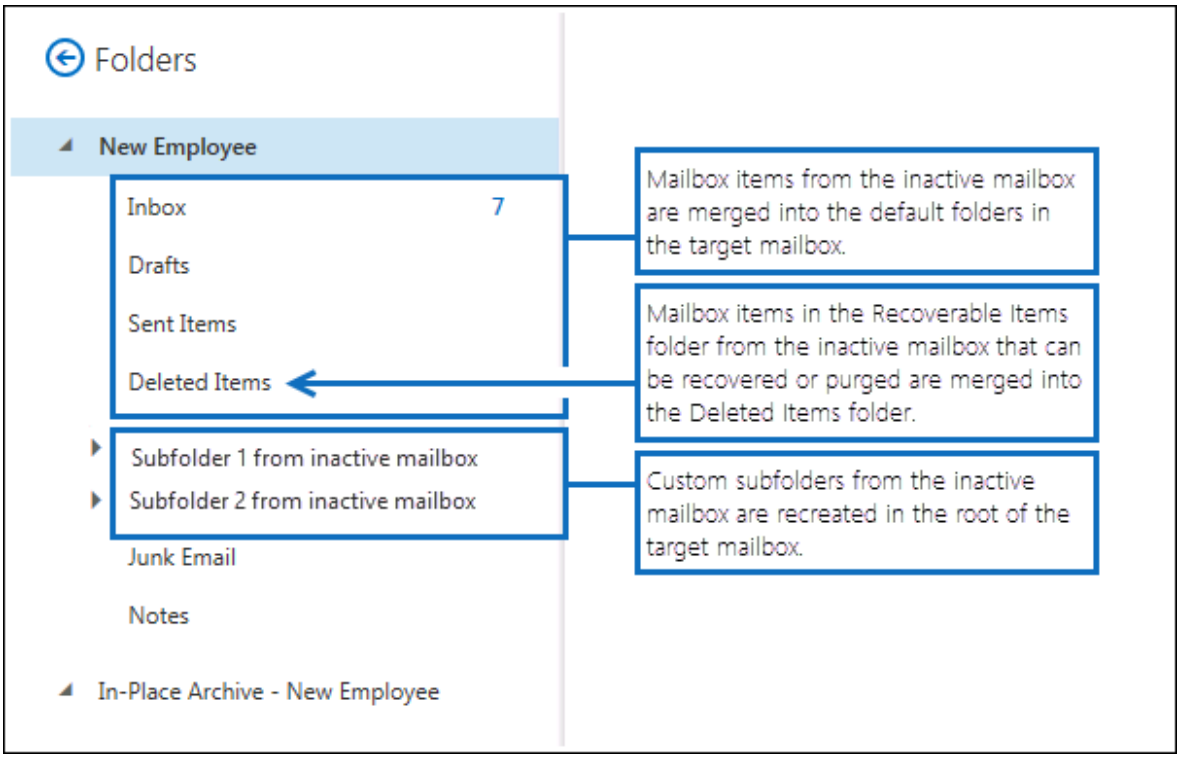
- **You can use other parameters with the New-MailboxRestoreRequest cmdlet to implement different restore scenarios for inactive mailboxes.** For example, you

can run this command to restore the archive from the inactive mailbox into the primary mailbox of the target mailbox.

```
PowerShell

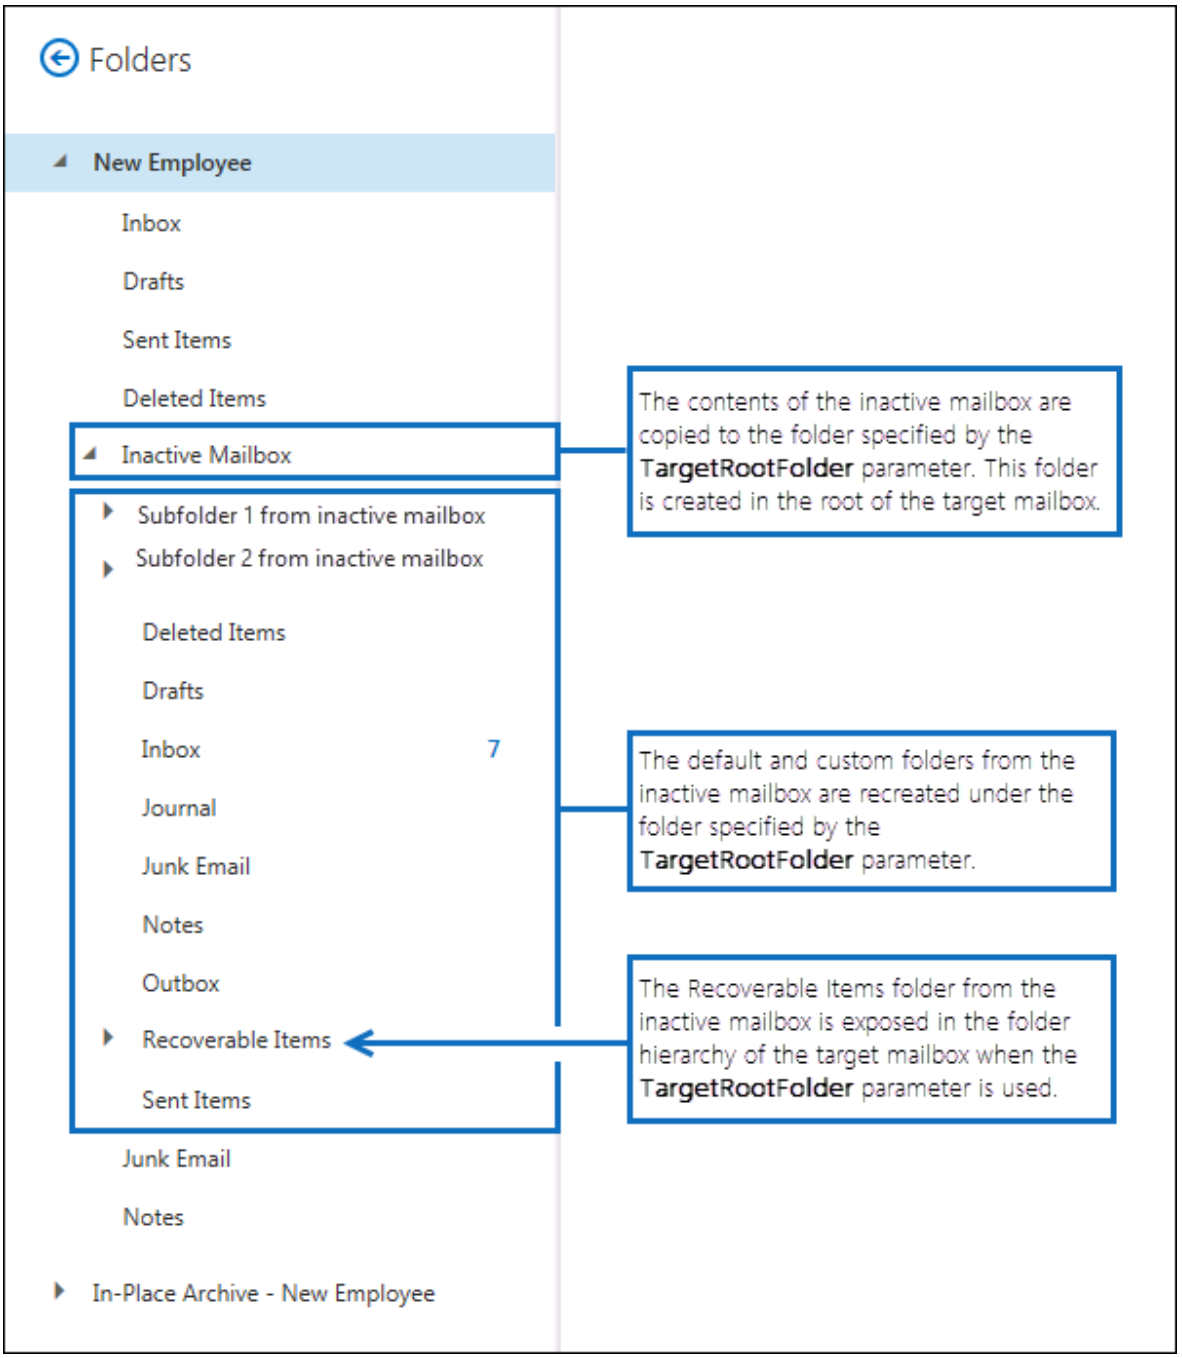
New-MailboxRestoreRequest -SourceMailbox <inactive mailbox> -
SourceIsArchive -TargetMailbox <target mailbox> -TargetRootFolder
"Inactive Mailbox Archive"
```

You can also restore the inactive primary mailbox into the archive of the target mailbox by running this command.



```
PowerShell

New-MailboxRestoreRequest -SourceMailbox <inactive mailbox> -
TargetMailbox <target mailbox> -TargetIsArchive -TargetRootFolder
"Inactive Mailbox"
```



- **What does the TargetRootFolder parameter do?** As previously explained, you can use the **TargetRootFolder** parameter to specify a folder in the top of the folder structure (also called the root) in the target mailbox in which to restore the contents of the inactive mailbox. If you don't use this parameter, mailbox items from the inactive mailbox are merged into the corresponding default folders of the target mailbox, and custom folders are re-created in the root of the target mailbox. The following illustrations highlight these differences between not using and using the **TargetRootFolder** parameter.

  > **Note**
  >
  > To restore the contents of a primary mailbox to an archive mailbox, use the **TargetRootFolder** parameter to specify the archive mailbox folders to migrate the content to. This content will be visible after it's restored. If you don't use this parameter, the restored content is not visible because it's mapped to locations in the archive mailbox that aren't visible to users.

  Folder hierarchy in the target mailbox when the TargetRootFolder parameter isn't used

Delete an inactive mailbox

> *Microsoft Purview service description*

When you no longer need to keep the contents of an inactive mailbox, you can permanently delete the mailbox by removing all holds on it. Then, the inactive mailbox is automatically marked for deletion and permanently deleted after it's processed.

Holds can be any of the following:

- Microsoft 365 retention policies and labels with retain or retain and delete settings
- A hold associated with an eDiscovery case
- Litigation hold
- An In-Place Hold
- A delay hold, which Microsoft 365 applies automatically after another hold is removed

Important

It is strongly recommended that you use Microsoft 365 retention when proactively planning to use inactive mailboxes.

- eDiscovery holds are intended for specific, time-bound cases related to a legal issue. At some point, a legal case will probably end and the holds associated with the case will be removed and the eDiscovery case will be closed (or deleted). If a hold that's placed on an inactive mailbox is associated with an eDiscovery case, and the hold is released or the eDiscovery case is closed or deleted, the inactive mailbox will be permanently deleted.

- In-Place Holds in the Exchange admin center are now retired. As of July 1, 2020, new In-Place Holds were unable to be created in Exchange Online. As of October 1, 2020, the hold duration of in-place holds could no longer be changed. Any inactive mailbox that has an In-Place Hold applied can only be deleted by removing the In-Place Hold. Existing inactive mailboxes that are on In-Place Hold will continue to be preserved until the hold is removed. For more information about In-Place Holds retirement, see Retirement of legacy eDiscovery tools.

- **Litigation hold** remains supported as an alternative method to retain content in a mailbox and make it inactive after a user account is deleted. However, as an older technology, we recommend you use Microsoft 365 retention instead.

See the More information section for a description of what happens after holds are removed from an inactive mailbox.

Before you delete an inactive mailbox

- You must use Exchange Online PowerShell to remove holds from an inactive mailbox. You can't use the Exchange admin center (EAC), or the Microsoft Purview portal for these procedures. For step-by-step instructions to use Exchange Online PowerShell, see Connect to Exchange Online PowerShell.
- Identify the holds on an inactive mailbox by using the instructions from Step 1: Identify the holds on an inactive mailbox. You'll need this information to know which holds to remove, and identifying information.
- Consider whether you want to copy the contents of an inactive mailbox to another mailbox before you remove the final hold that will result in the deletion of the inactive mailbox. For details, see Restore an inactive mailbox.
- Be aware that if you remove the final hold from an inactive mailbox the mailbox will be permanently deleted after the 30-day soft-deleted mailbox retention period expires. After the inactive mailbox is permanently deleted, it can't be recovered. Before you remove a hold, be sure that you no longer need the contents in the mailbox. If you want to reactivate an inactive mailbox, you can recover it. For details, see Recover an inactive mailbox.
- For more information about inactive mailboxes, see Learn about inactive mailboxes.

How to delete an inactive mailbox by removing holds

After you've identified what type of hold is placed on the inactive mailbox and whether there are multiple holds, you can remove the holds on the mailbox. An exception is if the inactive mailbox has one or more retention labels configured to retain items. In this case, you can't remove the hold.

When the last hold is removed, no further action is required from you because the inactive mailbox will be automatically deleted.

Use the instructions for the type of hold you need to remove:

- Remove an inactive mailbox from a retention policy
- Remove an inactive mailbox from an eDiscovery hold
- Remove Litigation hold from an inactive mailbox
- Remove an In-Place Hold from an inactive mailbox
- Remove a delay hold from an inactive mailbox

> **Note**
>
> A delay hold is applied automatically after you remove another hold, so it's a common reason a mailbox is still listed as inactive after you think you removed the last hold. Check for a delay hold before you conclude that hold removal didn't work.

> **Caution**
>
> When the instructions require you to specify an identity for the inactive mailbox, the best way to do this is by using its Distinguished Name or Exchange GUID value. Using one of these values instead of the SMTP address helps prevent accidentally specifying the wrong mailbox. However, for instructions that specifically tell you to use the primary SMTP address, you can't use the Distinguished Name or Exchange GUID value and must use the primary SMTP address.

Remove an inactive mailbox from a retention policy

The procedure to remove an inactive mailbox from a Microsoft 365 retention policy depends on whether the policy scope is adaptive or static.

You won't be able to remove an inactive mailbox if the retention policy has Preservation Lock applied.

How to remove an inactive mailbox from a retention policy with an adaptive scope

When you use the advanced query builder to define your adaptive scope for mailboxes, modify it to exclude inactive mailboxes by using the OPATH property *IsInactiveMailbox*:

Console

```
IsInactiveMailbox -eq "False"
```

You can't exclude inactive mailboxes by using the simple query builder. If the retention policy is configured to use an adaptive scope that used the simple query builder, create a new adaptive policy scope that uses the advanced query builder. Then modify the retention policy to use this new adaptive scope.

How to remove an inactive mailbox from a retention policy with a static scope

This procedure depends on whether the retention policy applied to the inactive mailbox is configured for the entire policy location (sometimes referred to as "organization-wide") or the policy is configured to include specific mailboxes (sometimes referred to as "explicit"). For more information, see Configuration information for static scopes.

Use the following PowerShell cmdlets to retrieve a policy GUID and identify the type of hold for a mailbox:

- If the policy is configured for the entire location: Use the **Get-OrganizationConfig** cmdlet in Exchange Online PowerShell to get information about these policies.
- If the policy is configured to include specific mailboxes: Use the **Get-Mailbox -IncludeInactiveMailbox** cmdlet and parameter in Exchange Online PowerShell to get information about these policies.

Static scope: How to remove an inactive mailbox from a retention policy that's configured for the entire location

Run the following PowerShell command for a specific retention policy:

PowerShell

```
Set-Mailbox <identity of inactive mailbox> -ExcludeFromOrgHolds <retention policy GUID without prefix or suffix>
```

Alternatively, you can run the following PowerShell commands to remove the inactive mailbox:

- For retention policies that use the older retention locations, such as **Exchange mailboxes**, **Teams chats and Copilot interactions**, and **Teams channel messages**:

  PowerShell

```
Set-Mailbox <identity of inactive mailbox> -ExcludeFromAllOrgHolds
```

- For retention policies that use the newer retention locations, such as **Teams private channel messages** (applicable pre-migration only), **Teams chats**, and **Microsoft Copilot experiences**:

  PowerShell

  ```
  Set-AppRetentionCompliancePolicy -Identity <retention policy GUID without prefix or suffix> -AddExchangeLocationException <identity of inactive mailbox> -DeletedResources "[{'EmailAddress':'<Primary SMTP address of inactive mailbox>'}]"
  ```

  You can also specify the identity of the inactive mailbox by using a variable and JSON, which is required if you need to specify more than one inactive mailbox with the same command. For more information, see the PowerShell examples.

  > **Important**
  >
  > Before you run the command, make sure you read the Caution information for the DeletedResources parameter about duplicate SMTP addresses.

Static scope: How to remove an inactive mailbox from a retention policy that's configured to include specific mailboxes

Run the following Security & Compliance PowerShell commands:

- For retention policies that use the older retention locations, such as **Exchange mailboxes**, **Teams chats and Copilot interactions**, and **Teams channel messages**:

  PowerShell

  ```
  Set-RetentionCompliancePolicy -Identity <retention policy GUID without prefix or suffix> -RemoveExchangeLocation <identity of inactive mailbox>
  ```

- For retention policies that use the newer retention locations, such as **Teams private channel messages**, **Teams chats**, and **Microsoft Copilot experiences**:

  PowerShell

  ```
  Set-AppRetentionCompliancePolicy -Identity <retention policy GUID without prefix or suffix> -RemoveExchangeLocation <identity of inactive mailbox>
  ```

Remove an inactive mailbox from an eDiscovery hold

See Removing content locations from an eDiscovery hold.

Remove a Litigation hold from an inactive mailbox

Run the following PowerShell command to remove a Litigation hold from a mailbox:

```
PowerShell
Set-Mailbox -InactiveMailbox -Identity <identity of inactive mailbox> -
LitigationHoldEnabled $false
```

Remove an In-Place Hold from an inactive mailbox

There are two ways to remove an In-Place Hold from an inactive mailbox:

- **Delete the In-Place Hold object**. If the inactive mailbox that you want to permanently delete is the only source mailbox for an In-Place Hold, you can just delete the In-Place Hold object.

  > ⓘ Note
  >
  > You have to disable the hold before you can delete an In-Place Hold object. If you try to delete an In-Place Hold object that has the hold enabled, you'll receive an error message.

- **Remove the inactive mailbox as a source mailbox of an In-Place Hold**. If you want to retain other source mailboxes for an In-Place Hold, you can remove the inactive mailbox from the list of source mailboxes and keep the In-Place Hold object.

How to remove an inactive mailbox from an eDiscovery In-Place Hold

If the eDiscovery hold is active, the user can be removed from eDiscovery location.

Use the Invoke-HoldRemovalAction) cmdlet to find and remove an eDiscovery in-place hold

1. When running the Invoke-HoldRemovalAction with GetHolds parameter, holds that apply on specified mailbox can be found:

   ```
   PowerShell
   ```

```
Invoke-HoldRemovalAction -Action GetHolds -ExchangeLocation <identity of inactive
mailbox>
```

If legacy eDiscovery hold is present, HoldId value will be only a GUID without any prefix or have "cld" one, see How to identify the type of hold placed on an Exchange Online mailbox.

1. The legacy eDiscovery holds or inactive case hold policy can be removed from the inactive mailbox by providing the HoldId:

PowerShell

```
Invoke-HoldRemovalAction -Action RemoveHold -ExchangeLocation <identity of
inactive mailbox> -HoldId <hold ID>
```

Remove a delay hold from an inactive mailbox

After you remove any other type of hold, Microsoft 365 automatically applies a *delay hold* so that content isn't purged immediately. While a delay hold is applied, the mailbox is still treated as being on hold, so it remains an inactive mailbox and isn't marked for deletion. This is a common reason a mailbox is still listed as inactive after you removed what you thought was the last hold.

A delay hold is applied by setting either of the following mailbox properties to **True**:

- *DelayHoldApplied* for Outlook content
- *DelayReleaseHoldApplied* for cloud content generated by non-Outlook apps such as Microsoft Teams

Run the following command to check whether either property is set on the inactive mailbox:

PowerShell

```
Get-Mailbox -InactiveMailbox -Identity <identity of inactive mailbox> | FL *Delay*
```

A delay hold expires automatically after 30 days. To remove it sooner, run one or both of the following commands, depending on which property is set to **True**:

PowerShell

```
Set-Mailbox -InactiveMailbox -Identity <identity of inactive mailbox> -
RemoveDelayHoldApplied
```

PowerShell

```
Set-Mailbox -InactiveMailbox -Identity <identity of inactive mailbox> -
RemoveDelayReleaseHoldApplied
```

> ⓘ Note
>
> You must be assigned the Legal Hold role in Exchange Online to use the *RemoveDelayHoldApplied* or *RemoveDelayReleaseHoldApplied* parameters.

Removing the delay hold also recalculates the hold status of the mailbox. If no other holds remain, the mailbox stops being an inactive mailbox and becomes a soft-deleted mailbox.

For more information about delay holds, including how they interact with each other, see Managing mailboxes on delay hold.

More information

- **An inactive mailbox is a type of soft-deleted mailbox.** In Exchange Online, a soft-deleted mailbox is a mailbox that's been deleted but can be recovered within a specific retention period. For soft-deleted mailboxes that aren't on hold, the mailbox is recoverable within 30 days. An inactive mailbox (a mailbox on hold before it was deleted) will remain in a soft-deleted with hold state until the hold is removed. After the last hold is removed from an inactive mailbox, the mailbox will no longer be in an inactive state. Instead it will become soft-deleted and remain in Exchange Online for 30 days from the day the hold was removed and recoverable during that time. After 30 days, a soft-deleted mailbox is marked for permanent deletion and can't be recovered.

- **What happens after you remove the last hold on an inactive mailbox?** The mailbox is treated like other soft-deleted mailboxes and is marked for permanent deletion after the 30-day soft-deleted mailbox retention period expires. This retention period starts on the date when the last hold is removed from the inactive mailbox. The *InactiveMailboxRetireTime* property is set when the mailbox transitions from being inactive (soft-deleted on hold) to no longer being inactive (soft-deleted with no holds). At that point, the *InactiveMailboxRetireTime* property is set to the current date when the transition occurred. There is an assistant that runs (called the *MailboxLifeCycle* assistant) that looks for mailboxes that have the *InactiveMailboxRetireTime* property set. If "InactiveMailboxRetireTime + 30 days" is less than the current date, then it will purge the mailbox.

If mailboxes still show as *Inactive* after you remove the last hold and *InactiveMailboxRetireTime* isn't set, first confirm that no hold is still applied — including a delay hold, which is applied automatically after another hold is removed:

PowerShell

```
Get-Mailbox -InactiveMailbox -Identity <identity of inactive mailbox> | FL
LitigationHoldEnabled,ComplianceTagHoldApplied,InPlaceHolds,*Delay*
```

If a hold is still applied, remove that hold. Recalculating the hold status doesn't remove a hold, so it doesn't change a mailbox that's still on hold.

If no holds remain, you can force the recalculation of the hold status for the inactive mailbox by using the following command:

PowerShell

```
Set-Mailbox -Identity <identity of inactive mailbox> -RecalculateInactiveMailbox
```

- **Is an inactive mailbox permanently deleted immediately after all holds are removed?** A formerly inactive mailbox will be available in the soft-deleted state for 30 days. After 30 days, the mailbox will be marked for permanent deletion.
- **How do you display information about an inactive mailbox after all holds are removed?** After all holds are removed and the inactive mailbox is reverted back to a soft-deleted mailbox, it won't be returned by using the *InactiveMailboxOnly* parameter with the **Get-Mailbox** cmdlet. But you can display information about the mailbox by using the **Get-Mailbox -SoftDeletedMailbox** command. For example:

PowerShell

```
Get-Mailbox -SoftDeletedMailbox -Identity pilarp | FL
Name,Identity,LitigationHoldEnabled,In
Placeholds,WhenSoftDeleted,IsInactiveMailbox,WasInactiveMailbox,InactiveMailboxRe
tireTime

Name                   : pilarp
Identity               : Soft Deleted Objects\pilarp
LitigationHoldEnabled  : False
InPlaceHolds           : {}
WhenSoftDeleted        : 6/16/2022 1:19:04 AM
IsInactiveMailbox      : False
WasInactiveMailbox     : True
InactiveMailboxRetireTime : 9/30/2022 11:16:23 PM
```

In the above example, the *WhenSoftDeleted* property identifies the soft-deleted date, which in this example is June 16, 2022. The *WasInactiveMailbox* property is listed as `True` because it was previously an inactive mailbox. The mailbox will be permanently deleted 30 days after September 30, 2022.

Learn about importing your organization's PST files

> **Note**
>
> This article is for administrators. Are you trying to import PST files to your own mailbox? See Import email, contacts, and calendar from an Outlook .pst file.

Use the Import service in the Microsoft Purview portal to quickly bulk-import PST files to Exchange Online mailboxes in your organization. You can import PST files to Microsoft 365 in two ways:

- **Network upload**: Upload the PST files over the network to a temporary Azure Storage location in the Microsoft cloud. Then use the Microsoft 365 Import service to import the PST data to mailboxes in your organization.
- **Drive shipping**: Copy the PST files to a BitLocker-encrypted hard drive and then physically ship the drive to Microsoft. When Microsoft receives the hard drive, data center personnel upload the data to a temporary Azure Storage location in the Microsoft cloud. Then use the Microsoft 365 Import service to import the data to mailboxes in your organization.

Why import email data to Microsoft 365?

- Import your organization's archival messaging data to Microsoft 365.
- Use the Intelligent Import feature to filter the items in PST files that get imported to the target mailboxes. This feature lets you trim the imported data by setting filters.
- Importing email data to Microsoft 365 helps address your organization's compliance needs by letting you:
  - Enable archive mailboxes and auto-expanding archiving to give users additional mailbox storage space.
  - Place mailboxes on Litigation Hold to retain content.
  - Use the Content Search tool to search for mailbox content.
  - Use eDiscovery cases to manage your organization's legal investigations.
  - Use retention policies in the Microsoft Purview portal to control how long mailbox content is retained, and then delete content after the retention period expires.

- Importing data to Microsoft 365 helps protect against data loss. Email data that you import to Microsoft 365 inherits the high availability features of Exchange Online.
- Because you store email data in the cloud, users can access it from all their devices.

Select your import method

Use the following table to help decide which import method is best for your organization:

Expand table

Factor	Network upload	Drive shipping
Cost	Free	Costs apply - see Microsoft Purview service description for details
Region availability	United States, Canada, Brazil, United Kingdom, France, Germany, Switzerland, Norway, Europe, India, East Asia, Southeast Asia, Japan, Republic of Korea, Australia, UAE, Israel, Mexico, Taiwan, New Zealand	United States, Canada, Brazil, United Kingdom, Europe, India, East Asia, Southeast Asia, Japan, Republic of Korea, Australia, Mexico, Taiwan, New Zealand (not available in Germany or Switzerland)
Licensing	All commercial licensing agreements	Microsoft Enterprise Agreement (EA) only. Not available through Microsoft Products and Services Agreement (MPSA).
Max data volume	Unlimited (network dependent)	10 TB per drive, maximum 10 drives per import job
Upload time	Several hours per TB (depends on your network capacity)	7-10 business days after Microsoft receives the drive
Best for	Ongoing imports or smaller migrations	Large one-time data migrations

Requirements and limits

Before you import PST files, review the following requirements and limits that apply to both import methods.

Permissions

To create import jobs and import PST files, you need the following roles:

- **Mailbox Import Export** role in Exchange Online. By default, no role group has this role assigned. You can add it to the **Organization Management** role group, or create a new role group and assign the role.

- **Mail Recipients** role in Exchange Online. By default, the **Organization Management** and **Recipient Management** role groups have this role assigned.

  Or

- You're a global administrator in your organization.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

> **Tip**
>
> Consider creating a new role group in Exchange Online specifically for importing PST files. Assign the **Mailbox Import Export** and **Mail Recipients** roles to the new role group, and then add members.

PST file format

Both ANSI and Unicode PST file formats are supported. Import files that use the Unicode PST file format. However, you can also import files that use the ANSI PST file format, such as those for languages that use a double-byte character set (DBCS). You can import PST files from Outlook 2007 and later versions to Microsoft 365.

For more information about ANSI PST files, see Step 4 in Use network upload to import PST files or Step 3 in Use drive shipping to import PST files.

Message size limit

If a PST file contains a mailbox item that's larger than 150 MB, the import process skips the item and doesn't import it. Items larger than 150 MB aren't imported because 150 MB is the message size limit in Exchange Online. For more information, see Message limits in Exchange Online.

Folder hierarchy limit

You can't import a PST file that has 300 or more levels of nested folders.

Supported mailbox scenarios

You can import PST files to the following mailbox types:

- **Inactive mailboxes**: You can import PST files to an inactive mailbox in Microsoft 365 by using either network upload or drive shipping. Specify the GUID of the inactive mailbox in the `Mailbox` parameter of the PST Import mapping file.
- **Online archive mailboxes in hybrid deployments**: You can import PST files to a cloud-based archive mailbox for a user whose primary mailbox is on-premises. Specify the email address for the user's on-premises mailbox in the `Mailbox` parameter, and set the `IsArchive` parameter to **TRUE** in the PST Import mapping file.
- **Public folders**: You can't import PST files to public folders.

PST file size

Upload or copy PST files that are no larger than 20 GB. Large PST files can affect the performance of the import process.

Archive mailbox import limit

When you import PST files to a user's archive mailbox (the `IsArchive` parameter set to **TRUE**), data is imported into the user's main archive mailbox only. The import doesn't target auto-expanding archive storage, because auto-expanding archive storage is provisioned on demand rather than in advance.

As a result, you can't import more than 100 GB of data into a user's archive in a single import. To import more than 100 GB, divide the data across multiple imports and allow time for the archive to auto-expand between imports. For more information, see Learn about auto-expanding archiving.

Plan your import

Before you start importing PST files, review the following planning considerations.

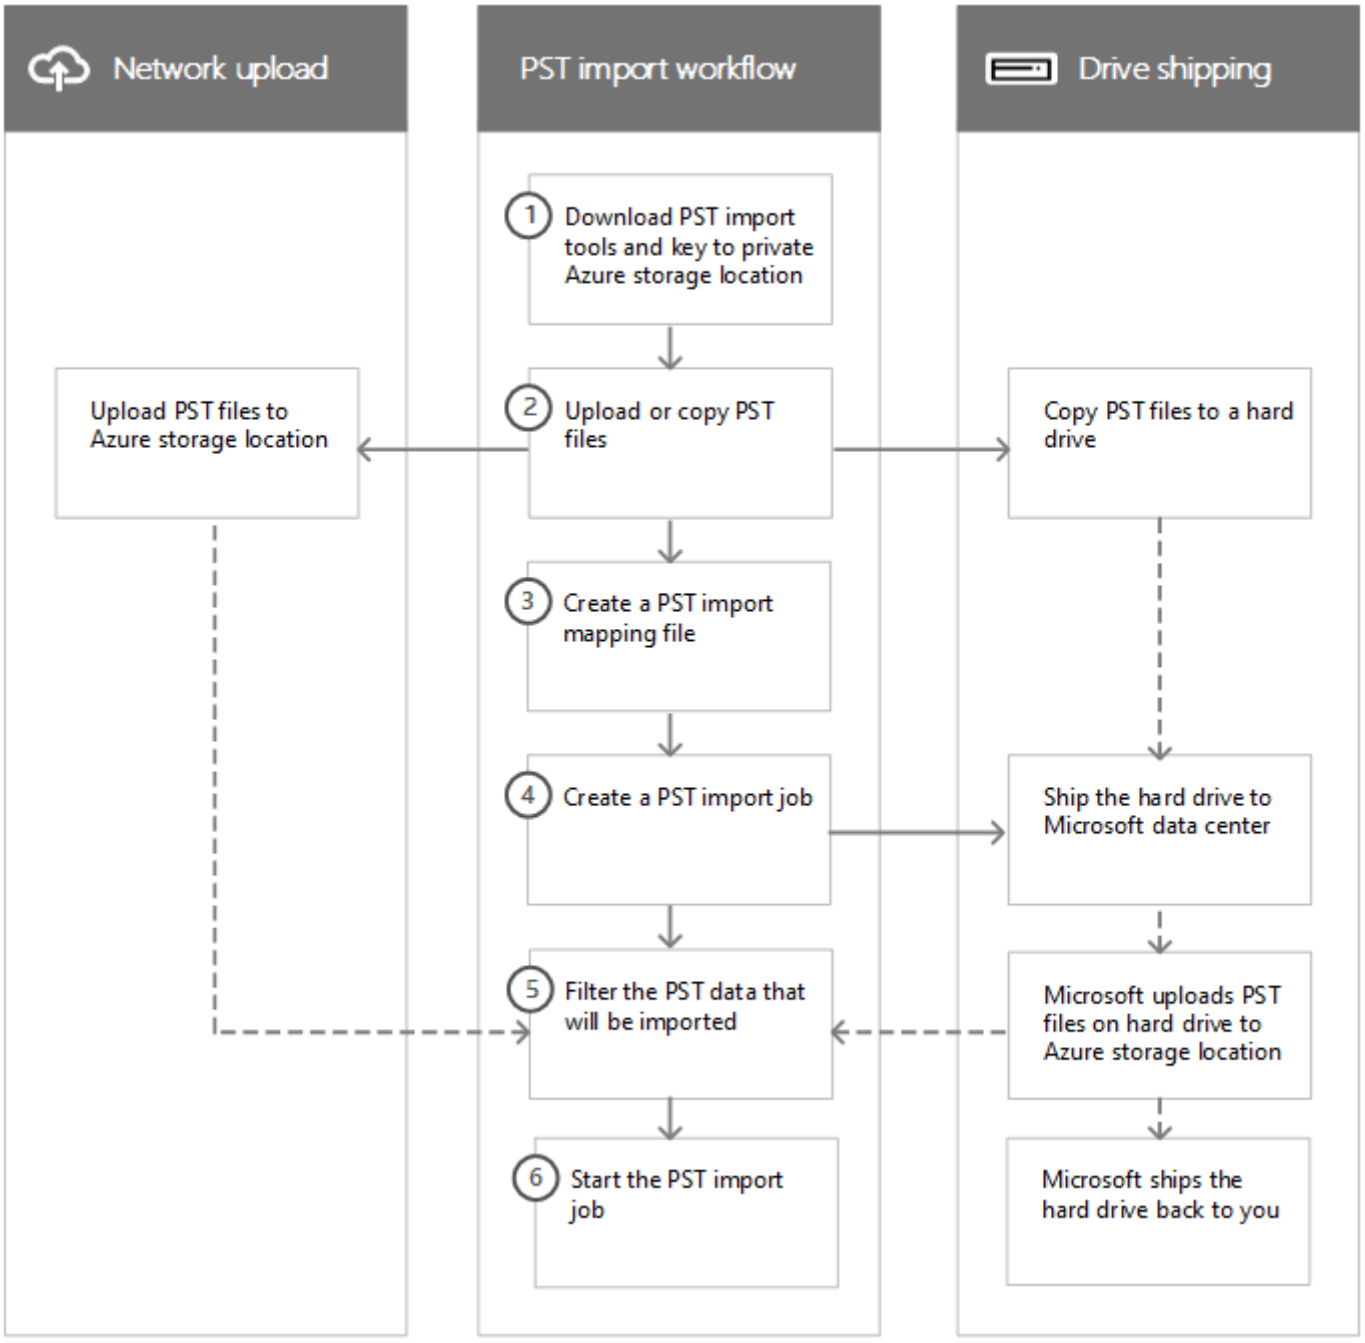
Import rate

A Microsoft 365 mailbox imports a PST file at a rate of about 24 GB per day. This rate isn't guaranteed and can vary based on server workload and transient performance issues. If this rate doesn't meet your needs, consider other methods for migrating email data to Microsoft 365. For more information, see Ways to migrate multiple email accounts to Microsoft 365.

If you import different PST files to different target mailboxes, the import process runs in parallel (each PST/mailbox pair is imported simultaneously). If you import multiple PST files to the same mailbox, the process imports them sequentially (one at a time).

Retention hold after import

After you import PST files to a Microsoft 365 mailbox, the retention hold setting for the mailbox is turned on indefinitely. This setting means that the retention policy assigned to the mailbox isn't processed until you turn off the retention hold or set a date to turn off the hold. If messages you import to a mailbox are old, the retention settings configured for the mailbox might cause those messages to be permanently deleted (purged). Placing the mailbox on retention hold gives the mailbox owner time to manage the newly imported messages, or gives you time to change the retention settings for the mailbox.



MaxReceiveSize property

By default, a Microsoft 365 mailbox can receive messages up to 35 MB. However, Microsoft 365 supports a maximum message receive size of 150 MB. If you import a PST file that contains an item larger than 35 MB, the Microsoft 365 Import service automatically sets the *MaxReceiveSize* property on the target mailbox to 150 MB.

> **Tip**
>
> To check the message receive size for a mailbox, run this command in Exchange Online PowerShell: `Get-Mailbox <user mailbox> | FL MaxReceiveSize`.

How the PST import process works

Here's an illustration and description of the complete PST import process. The illustration shows the primary workflow and highlights the differences between the network upload and drive shipping methods.

1. **Download the PST import tools and key to private Azure Storage location**: Download the tool and access key you use to upload the PST files or copy them to a hard drive. Get these items from the **Import** page in the Microsoft Purview portal. The key provides you (or Microsoft data center personnel in the case of drive shipping) with the necessary permissions to upload PST files to a private and secure Azure Storage location. This access key is unique to your organization and helps prevent unauthorized access to your PST files after you upload them to the Microsoft cloud. Importing PST files to Microsoft 365 doesn't require your organization to have a separate Azure subscription.

2. **Upload or copy the PST files**: The next step depends on whether you're using network upload or drive shipping to import PST files. In both cases, use the tool and secure storage key that you obtained in the previous step.

- **Network upload**: Use the AzCopy.exe tool (downloaded in step 1) to upload and store your PST files in an Azure Storage location in the Microsoft cloud. The Azure Storage location that you upload your PST files to is located in the same regional Microsoft datacenter as your organization.

  To upload them, the PST files that you want to import must be located in a file share or file server in your organization.

- **Drive shipping**: Use the WAImportExport.exe tool (downloaded in step 1) to copy your PST files to the hard drive. This tool encrypts the hard drive with BitLocker and then copies the PSTs to the hard drive. Like network upload, the PST files that you want to copy to the hard drive must be located in a file share or file server in your organization.

3. **Create a PST import mapping file**: After you upload the PST files to the Azure Storage location or copy them to a hard drive, create a comma-separated value (CSV) file that specifies which user mailboxes the PST files go to (and a PST file can go to a user's primary mailbox or their archive mailbox). Download a copy of the PST Import mapping file. The Microsoft 365 Import service uses the information to import the PST files.

4. **Create a PST import job**: Create a PST import job on the **Import PST files** page in the Microsoft Purview portal and submit the PST import mapping file you created in the previous step. For network upload (because the PST files are uploaded to Azure) Microsoft 365 analyzes the data in the PST files and then gives you an opportunity to set filters that control what data actually gets imported to the mailboxes specified in the PST import mapping file.

   For drive shipping, a few other things happen at this point in the process.

   - You physically ship the hard drive to a Microsoft data center (the shipping address for the Microsoft data center is displayed when the import job is created).

   - When Microsoft receives the hard drive, data center personnel upload the PST files on the hard drive to the Azure Storage location for your organization. As previously explained, your PST files are uploaded to an Azure Storage location that resides in the same regional Microsoft datacenter where your organization is located.

     > **Note**

> The PST files on the hard drive are uploaded to Azure within 7 to 10 business days after Microsoft receives the hard drive.

Like the network upload process, Microsoft 365 then analyzes the data in the PST files and gives you an opportunity to set filters that control what data actually gets imported to the mailboxes specified in the PST import mapping file.

- Microsoft ships the hard drive back to you.

5. **Filter the PST data that will be imported to mailboxes**: After you create the import job (and after the PST files from a drive shipping job are uploaded to the Azure Storage location) Microsoft 365 analyzes the data in the PST files (safely and securely) by identifying the age of the items and the different message types included in the PST files. When the analysis is completed and the data is ready to import, you have the option to import all the data contained in the PST files or you can trim the data that's imported by setting filters that control what data gets imported.

6. **Start the PST import job**: After you start the import job, Microsoft 365 uses the information in the PST import mapping file to import the PST files from the Azure Storage location to user mailboxes. Status information about the import job (including information about each PST file being imported) is displayed on the **Import PST files** page in the Microsoft Purview portal. When the import job finishes, the status for the job is set to **Complete**.

Step-by-step instructions

For detailed, step-by-step instructions for bulk-importing your organization's PST files to Microsoft 365, see one of the following articles:

- Use network upload to import PST files to Microsoft 365
- Use drive shipping to import PST files

Import SharePoint data to Microsoft 365

You can also import files and documents to SharePoint sites and OneDrive accounts in your organization. For more information, see the following articles:

- Migrate to SharePoint Online
- Introducing the SharePoint Migration Tool
- Migrate to SharePoint Online using PowerShell
- Migrate your file share content to SharePoint Online using the Azure Data Box

Frequently asked questions

For frequently asked questions about importing PST files, including duplicate handling, message properties, and common issues, see FAQ about importing PST files.

Use network upload to import your organization's PST files to Microsoft 365

> *Microsoft Purview service description*

> **Note**
>
> This article is for administrators. Are you trying to import PST files to your own mailbox? See Import email, contacts, and calendar from an Outlook .pst file.

Use the following step-by-step instructions to bulk-import multiple PST files to Microsoft 365 mailboxes by using network upload. For frequently asked questions about using network upload to bulk-import PST files to Microsoft 365 mailboxes, see FAQs for using network upload to import PST files. To import PST files by physically shipping a hard drive to Microsoft, see Use drive shipping to import PST files.

- Step 1: Copy the SAS URL and download AzCopy
- Step 2: Upload your PST files to Microsoft 365
- Step 3 (Optional): View a list of the uploaded PST files
- Step 4: Create the PST Import mapping file
- Step 5: Create a PST Import job
- Step 6: Filter data and start the PST Import job

You only need to perform Step 1 once to import PST files to Microsoft 365 mailboxes. After you perform Step 1, follow Step 2 through Step 6 each time you want to upload and import a batch of PST files.

Before you import PST files

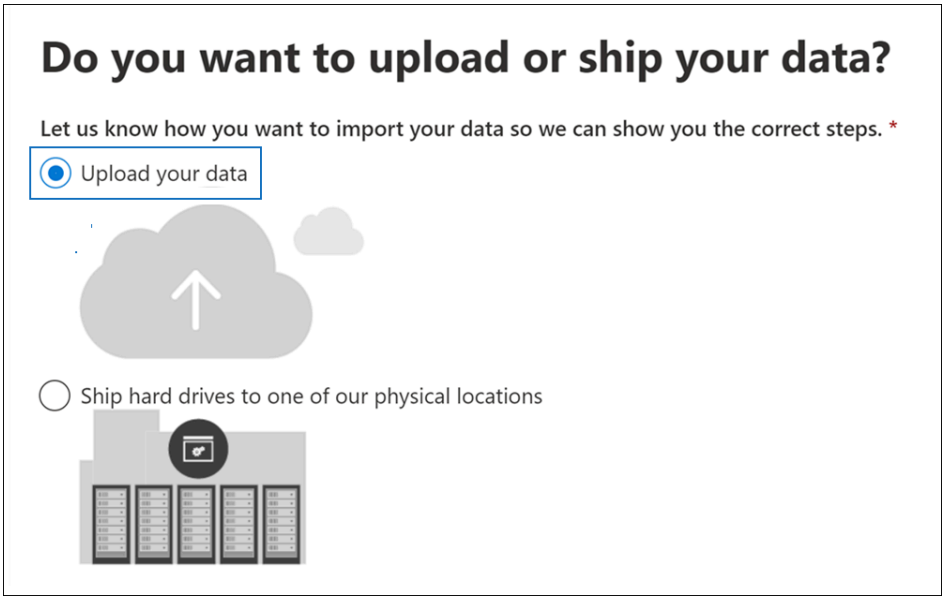
Before you begin, review the requirements, limits, and planning guidance for importing PST files. The following prerequisites are specific to the network upload method:

- The only supported method for importing PST files to Microsoft 365 is to use the AzCopy tool, as described in this article. You can't use the Azure Storage Explorer to upload PST files directly to the Azure Storage area.
- This procedure involves copying and saving a copy of a URL that contains an access key. You use this information in Step 2 to upload your PST files, and in Step 3 if you want to view a list of the PST files uploaded to Microsoft 365. Take precautions to protect this URL like you would protect passwords or other security-related information. For example, you might save it to a password-protected Microsoft Word document or to an encrypted USB drive. See the More information section for an example of this combined URL and key.
- For a high-level overview of the PST Import process, see How the import process works section in this article.

Step 1: Copy the SAS URL and download AzCopy

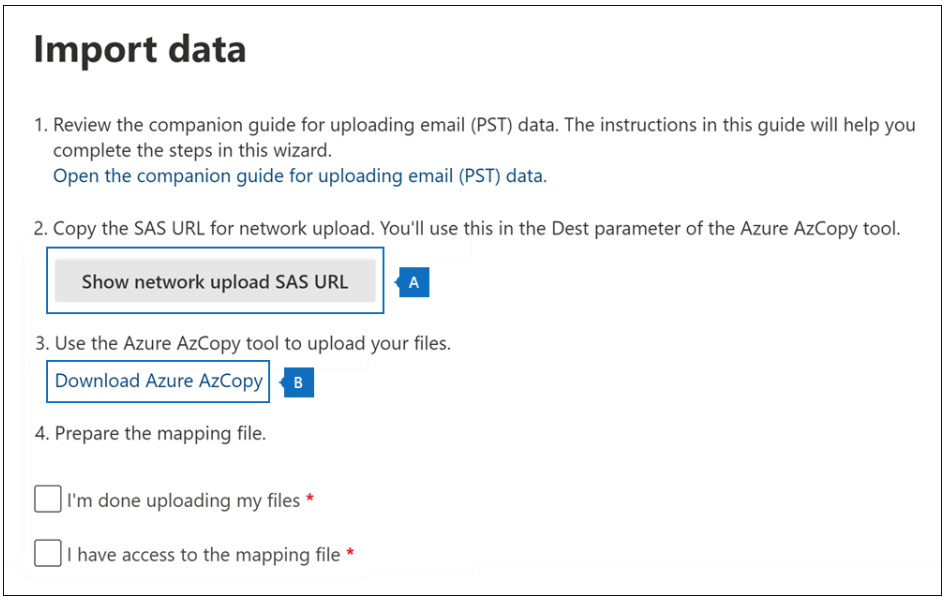
First, download the AzCopy tool. Use this tool in Step 2 to upload PST files to Microsoft 365. Also, copy the SAS URL for your organization. This URL combines the network URL for the Azure Storage location in the Microsoft cloud for your organization and a Shared Access Signature (SAS) key. This key gives you the necessary permissions to upload PST files to an Azure Storage location. Protect the SAS URL. It's unique to your organization and you use it in Step 2.

> **Important**
>
> To import PST files by using the network upload method and command syntax documented in this article, use the version of AzCopy that you can download in step 6b in the following procedure. You can also download that same version of AzCopy from here. Using a different version of AzCopy isn't supported.



1. Sign in to the Microsoft Purview portal by using the credentials for an administrator account in your organization.
2. In the left navigation, select **Data lifecycle management** > **Microsoft 365** > **Import**.

   > **Note**
   >
   > You must be assigned the appropriate permissions to access the **Import** page in the Microsoft Purview portal. See the **Before you begin** section for more information.



3. On the **Import** tab, select **+ New import job**.

   The import job wizard is displayed.

4. Type a name for the PST import job, and then select **Next**. Use lowercase letters, numbers, hyphens, and underscores. You can't use uppercase letters or include spaces in the name.
5. On the **Do you want to upload or ship data?** page, select **Upload your data** and then select **Next**.

6. On the **Import data** page, complete the following steps:

a. In step 2, select **Show network upload SAS URL**. After the SAS URL is displayed, select **Copy to clipboard** and then paste it and save it to a file.

b. In step 3, select **Download Azure AzCopy** to download the AzCopy tool to your local computer. This version of AzCopy is just an executable file, so there's nothing to install.

> ⓘ Note
>
> You can leave the **Import data** page open in case you need to copy the SAS URL again or select **Cancel** to close it.

Step 2: Upload your PST files to Microsoft 365

Now you're ready to use the AzCopy tool to upload PST files to Microsoft 365. This tool uploads and stores PST files in a Microsoft-provided Azure Storage location in the Microsoft cloud. As previously explained, the Azure Storage location that you upload your PST files to is located in the same regional Microsoft datacenter where your organization is located. To complete this step, the PST files must be located in a file share or file server in your organization or in an Azure Storage location managed by your organization. The PST storage location is known as the source location in this procedure. Each time you run the AzCopy tool, you can specify a different source location.

> ⓘ Note
>
> As previously stated, each PST file that you upload to the Azure Storage location should be no larger than 20 GB. PST files larger than 20 GB might impact the performance of the PST import process that you start in Step 6. Also, each PST file must have a unique name.

1. Open a Command Prompt on your local computer.
2. Go to the directory where you downloaded the azcopy.exe file in Step 1.
3. Run the following command to upload the PST files to Microsoft 365.

PowerShell

```
azcopy.exe copy "<Source location of PST files>" "<SAS URL>"
```

> **Important**
>
> You can specify a directory or an Azure Storage location as the source location in the previous command; you can't specify an individual PST file. All PST files in the source location are uploaded.

The following table describes the azcopy.exe fields and their required values. The information you obtained in the previous step is used in the values for these fields.

Expand table

Field	Description

Source	The first field specifies the source directory in your organization that contains the PST files that you want to upload Alternatively, you can specify an Azure Storage location as the source location of the PST files to upload.
	Be sure to surround the value of this field with double-quotation marks (" ").
	
	Examples:
	`"\\FILESERVER01\PSTs"`
	Or
	`"https://storageaccountid.blob.core.windows.net/PSTs?sp=racwdl&st=2021-09-21T07:25:53Z&se=2021-09-21T15:25:5 04&sr=c&sig=xxxxxx"`

Destination	Specifies the SAS URL that you obtained in Step 1.
	Be sure to surround the value of this parameter with double-quotation marks (" ").
	
	Note: If you use the SAS URL in a script or batch file, watch out for certain characters that need to be escaped. For e change `%` to `%%` and change `&` to `^&`.
	
	Tip: (Optional) You can specify a subfolder in the Azure Storage location to upload the PST files to. You do this by a location (after "ingestiondata") in the SAS URL. The first example doesn't specify a subfolder. That means the PST fil the root (named *ingestiondata*) of the Azure Storage location. The second example uploads the PST files to a subfol in the root of the Azure Storage location.
	
	Examples:
	`"https://3c3e5952a2764023ad14984.blob.core.windows.net/ingestiondata?sv=2012-02-12&se=9999-12- 31T23%3A59%3A59Z&sr=c&si=IngestionSasForAzCopy201601121920498117&sig=Vt5S4hVzlzMcBkuH8bH711atBffc`
	Or
	`"https://3c3e5952a2764023ad14984.blob.core.windows.net/ingestiondata/PSTFiles?sv=2012-02-12&se=9999-12- 31T23%3A59%3A59Z&sr=c&si=IngestionSasForAzCopy201601121920498117&sig=Vt5S4hVzlzMcBkuH8bH711atBffc`

`--recursive`	This optional flag specifies the recursive mode so that the AzCopy tool copies PST files that are located in subfolder directory that is specified by the source field. The default value for this flag is `true`. **Note:** If you include this flag, PST files in subfolders have a different file pathname in the Azure Storage location aft You have to specify the exact file pathname in the CSV file that you create in Step 4.
`--s2s-preserve-access-tier`	This optional flag is only required when the source location is a general-purpose v2 Azure Storage location that sup For the PST Import scenario, there's no need to preserve the access tier when you copy PST files from your Azure St Microsoft-provided Azure Storage location. In this case, you can include this flag and use a value of `false`. You don flag when copy PST files from a classic Azure Storage account, which doesn't support access tiers.

For more information about the **azcopy.exe copy** command, see azcopy copy.

Here are examples of the syntax for the AzCopy tool using actual values for each parameter.

Example 1

This example shows a source directory located on a file server or local computer.

PowerShell

```
azcopy.exe copy "\\FILESERVER1\PSTs"
"https://3c3e5952a2764023ad14984.blob.core.windows.net/ingestiondata?sv=2012-02-
```

```
12&amp;se=9999-12-
31T23%3A59%3A59Z&amp;sr=c&amp;si=IngestionSasForAzCopy2016011219204981l7&amp;sig=Vt5S4
hVzlzMcBkuH8bH711atBffdrOS72TlV1mNdORg%3D"
```

Example 2

This example shows a source directory located in a classic Azure Storage account with subdirectories.

PowerShell

```
azcopy.exe copy "https://storageaccountid.blob.core.windows.net/PSTs?
sp=racwdl&st=2021-09-21T07:25:53Z&se=2021-09-21T15:25:53Z&sv=2020-08-
04&sr=c&sig=xxxxxx"
"https://3c3e5952a2764023ad14984.blob.core.windows.net/ingestiondata?sv=2012-02-
12&amp;se=9999-12-
31T23%3A59%3A59Z&amp;sr=c&amp;si=IngestionSasForAzCopy2016011219204981l7&amp;sig=Vt5S4
hVzlzMcBkuH8bH711atBffdrOS72TlV1mNdORg%3D" --recursive
```

Example 3

This example shows a source directory located in a general-purpose v2 Azure Storage account. Access tiers aren't preserved when you upload the PST files.

PowerShell

```
azcopy.exe copy "https://storageaccountid.blob.core.windows.net/PSTs?
sp=racwdl&st=2021-09-21T07:25:53Z&se=2021-09-21T15:25:53Z&sv=2020-08-
04&sr=c&sig=xxxxxx"
"https://3c3e5952a2764023ad14984.blob.core.windows.net/ingestiondata?sv=2012-02-
12&amp;se=9999-12-
31T23%3A59%3A59Z&amp;sr=c&amp;si=IngestionSasForAzCopy2016011219204981l7&amp;sig=Vt5S4
hVzlzMcBkuH8bH711atBffdrOS72TlV1mNdORg%3D" --s2s-preserve-access-tier=false
```

When you run the command, status messages show the progress of uploading the PST files. A final status message shows the total number of files that you successfully uploaded.

> **Tip**
>
> After you successfully run the **azcopy.exe copy** command and verify that all the parameters are correct, save a copy of the command line syntax to the same secured file where you copied the information you obtained in Step 1. Then you can copy and paste this command in a Command Prompt each time that you want to run the AzCopy tool to upload PST files to Microsoft 365. The only value you might have to change is for the source field. This change depends on the source directory where the PST files are located.

(Optional) Step 3: View a list of the uploaded PST files

As an optional step, you can install and use the Microsoft Azure Storage Explorer (a free, open-source tool) to view the list of PST files that you uploaded to the Azure blob. Two good reasons to do this are:

- Verify that PST files from the shared folder or file server in your organization were successfully uploaded to the Azure blob.
- Verify the filename (and the subfolder pathname if you included one) for each PST file uploaded to the Azure blob. This verification is helpful when you're creating the PST mapping file in the next step because you need to specify both the folder pathname and

filename for each PST file. Verifying these names can help reduce potential errors in your PST mapping file.

The Azure Storage Explorer standalone application is generally available. You can download the latest version using the link in the following procedure.

> **Important**
>
> You can't use the Azure Storage Explorer to upload or modify PST files. The only supported method for importing PST files is to use AzCopy. Also, you can't delete PST files that you upload to the Azure blob. If you try to delete a PST file, you receive an error about not having the required permissions. All PST files are automatically deleted from your Azure storage area. If there are no import jobs in progress, all PST files in the **ingestiondata** container are deleted 30 days after the most recent import job was created.

To install the Azure Storage Explorer and connect to your Azure Storage area:

1. Download and install the Microsoft Azure Storage Explorer tool.
2. Start the Microsoft Azure Storage Explorer.
3. On the **Select Resource** page in the **Connect to Azure Storage** dialog, select **Blob container**.
4. On the **Select Authentication Method** page, select the **Shared access signature (SAS)** option, then select **Next**.
5. On the **Enter Connection Info** page, paste the SAS URL that you obtained in Step 1 into the box under **Blob container SAS URL**, then select **Next**. After you paste the SAS URL, the box under **Display name** is autopopulated with **ingestiondata**.
6. On the **Summary** page, review the connection information, then select **Connect**.

   The **ingestiondata** container opens. It contains the PST files that you uploaded in Step 2. The **ingestiondata** container is located under **Storage Accounts** > **(Attached Containers)** > **Blob Containers**.
7. When you're finished using the Microsoft Azure Storage Explorer, right-click **ingestiondata**, then select **Detach** to disconnect from your Azure Storage area. Otherwise, you receive an error the next time you try to attach.

Step 4: Create the PST Import mapping file

After you upload the PST files to the Azure Storage location for your organization, create a comma-separated value (CSV) file that specifies which user mailboxes the PST files go to. You'll submit this CSV file in the next step when you create a PST Import job.

1. Download a copy of the PST Import mapping file.
2. Open or save the CSV file to your local computer. The following example shows a completed PST Import mapping file (opened in NotePad). It's easier to use Microsoft Excel to edit the CSV file.

```
Console
Workload,FilePath,Name,Mailbox,IsArchive,TargetRootFolder,ContentCodePage,SPFileC
ontainer,SPManifestContainer,SPSiteUrl
Exchange,,annb.pst,annb@contoso.onmicrosoft.com,FALSE,/,,,,
```

```
Exchange,,annb_archive.pst,annb@contoso.onmicrosoft.com,TRUE,,,,,
Exchange,,donh.pst,donh@contoso.onmicrosoft.com,FALSE,/,,,,
Exchange,,donh_archive.pst,donh@contoso.onmicrosoft.com,TRUE,,,,,
Exchange,PSTFiles,pilarp.pst,pilarp@contoso.onmicrosoft.com,FALSE,/,,,,
Exchange,PSTFiles,pilarp_archive.pst,pilarp@contoso.onmicrosoft.com,TRUE,/Importe
dPst,,,,
Exchange,PSTFiles,tonyk.pst,tonyk@contoso.onmicrosoft.com,FALSE,,,,,
Exchange,PSTFiles,tonyk_archive.pst,tonyk@contoso.onmicrosoft.com,TRUE,/ImportedP
st,,,,
Exchange,PSTFiles,zrinkam.pst,zrinkam@contoso.onmicrosoft.com,FALSE,,,,,
Exchange,PSTFiles,zrinkam_archive.pst,zrinkam@contoso.onmicrosoft.com,TRUE,/Impor
tedPst,,,,
```

The first row, or header row, of the CSV file lists the parameters that the PST Import service uses to import the PST files to user mailboxes. Each parameter name is separated by a comma. Each row under the header row represents the parameter values for importing a PST file to a specific mailbox. You need a row for each PST file that you want to import to a user mailbox. You can have a maximum of 500 rows in the CSV mapping file. To import more than 500 PST files, create multiple mapping files and create multiple import jobs in Step 5.

> **Note**
>
> Don't change anything in the header row, including the SharePoint parameters; the PST Import process ignores them. Also, be sure to replace the placeholder data in the mapping file with your actual data.

3. Use the information in the following table to populate the CSV file with the required information.

Expand table

Parameter	Description	Example
`Workload`	Specifies the service that data is imported to. To import PST files to user mailboxes, use `Exchange`.	`Exchange`
`FilePath`	Specifies the folder location in the Azure Storage location that you uploaded the PST files to in Step 2. If you don't include an optional subfolder name in the SAS URL in the `/Dest:` parameter in Step 2, leave this parameter blank in the CSV file. If you include a subfolder name, specify it in this parameter (see the second example). The value for this parameter is case-sensitive. Either way, *don't* include "ingestiondata" in the value for the `FilePath` parameter. **Important:** The case for the file path name must be the same as the case you used if you include an optional subfolder name in the SAS URL in the destination field in Step 2. For example, if you use `PSTFiles` for the subfolder name and then use `pstfiles` in the `FilePath` parameter in CSV file, the import for the PST file fails. Be sure to use the same case in both instances.	(leave blank) Or `PSTFiles`

Parameter	Description	Example
`Name`	Specifies the name of the PST file that is imported to the user mailbox. The value for this parameter is case-sensitive. The file name of each PST file in the mapping file for an import job must be unique. **Important:** The case for the PST file name in the CSV file must be the same as the PST file that you uploaded to the Azure Storage location in Step 2. For example, if you use `annb.pst` in the `Name` parameter in the CSV file, but the name of the actual PST file is `AnnB.pst`, the import for that PST file fails. Be sure that the name of the PST in the CSV file uses the same case as the actual PST file.	`annb.pst`
`Mailbox`	Specifies the email address of the mailbox that the PST file is imported to. You can't specify a public folder or unified group because the PST Import Service doesn't support importing PST files to unified groups or to public folders. To import a PST file to an inactive mailbox, you have to specify the mailbox GUID for this parameter. To obtain this GUID, run the following PowerShell command in Exchange Online: `Get-Mailbox <identity of inactive mailbox> -InactiveMailboxOnly \FL ExchangeGuid`.	**Note:** Sometimes you have multiple mailboxes with the same email address, where one mailbox is an active mailbox and the other mailbox is in a soft-deleted (or inactive) state. In these situations, you have to specify the mailbox GUID to uniquely identify the mailbox to import the PST file to. To obtain this GUID for active mailboxes, run the following PowerShell command: `Get-Mailbox <identity of active mailbox> | FL ExchangeGuid`. To obtain the GUID for soft-deleted (or inactive) mailboxes, run this command: `Get-Mailbox <identity of soft-deleted or inactive mailbox> -SoftDeletedMailbox | FL ExchangeGuid`

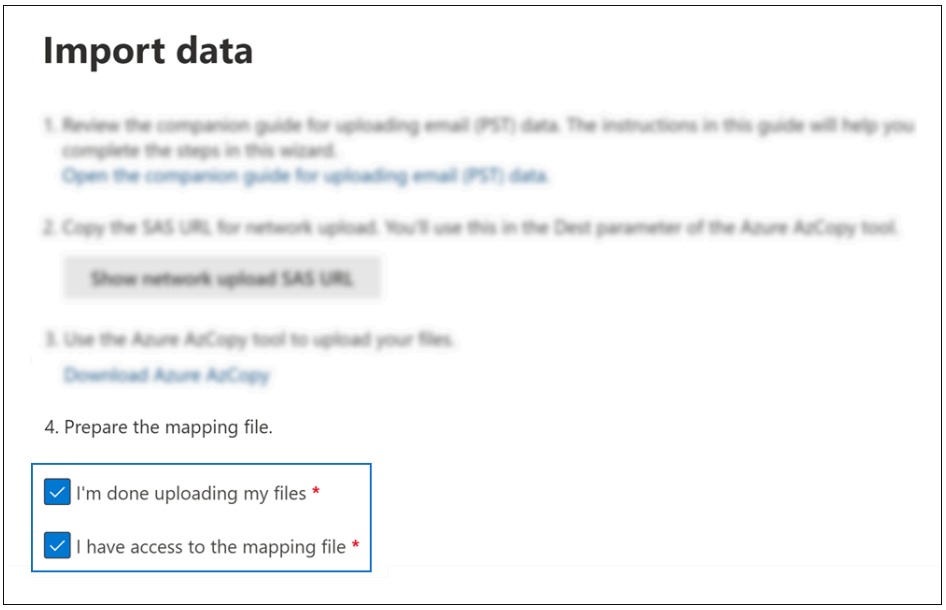
`IsArchive`	Specifies whether to import the PST file to the user's archive mailbox. There are two options:
	
	FALSE: Imports the PST file to the user's primary mailbox.
	TRUE: Imports the PST file to the user's archive mailbox. This assumes that the user's archive mailbox is enabled.
	
	If you set this parameter to `TRUE` and the user's archive mailbox isn't enabled, the import for that user fails. If an import fails for one user (because their archive isn't enabled and this property is set to `TRUE`), the other users in the import job isn't affected.
	If you leave this parameter blank, the PST file is imported to the user's primary mailbox.
	
	Note: To import a PST file to a cloud-based archive mailbox for a user whose primary mailbox is on-premises, just specify `TRUE` for this parameter and specify the email address for the user's
		`FALSE`
		Or
		`TRUE`

Parameter	Description	Example
	on-premises mailbox for the `Mailbox` parameter. **Note:** When this parameter is `TRUE`, the PST file is imported into the user's main archive mailbox only, and a 100-GB-per-import limit applies. For more information, see Archive mailbox import limit.	

`TargetRootFolder`	Specifies the mailbox folder that the PST file is imported to.
	
	If you leave this parameter blank, the PST file is imported to a new folder named **Imported** at the root level of the mailbox (the same level as the Inbox folder and the other default mailbox folders).
	
	If you specify `/`, the folders and items in the PST file are imported to the top of the folder structure in the target mailbox or archive. If a folder exists in the target mailbox (for example, default folders such as Inbox, Sent Items, and Deleted Items), the items in that folder in the PST are merged into the existing folder in the target mailbox. For example, if the PST file contains an Inbox folder, items in that folder are imported to the Inbox folder in the target mailbox. New folders are created if they don't exist in the folder structure for the target mailbox.
	
	If you specify `/<foldername>`, items and folders in the PST file are imported to a folder named <*foldername*> . For example, if you use `/ImportedPst`, items would be imported to a folder named **ImportedPst**. This folder is located in the user's mailbox at the same level as the Inbox folder.
	
	Tip: Consider running a few test batches to experiment with this parameter so you can determine the best folder location to import PST files.
		(leave blank)
		Or
		`/`
		Or
		`/ImportedPst`

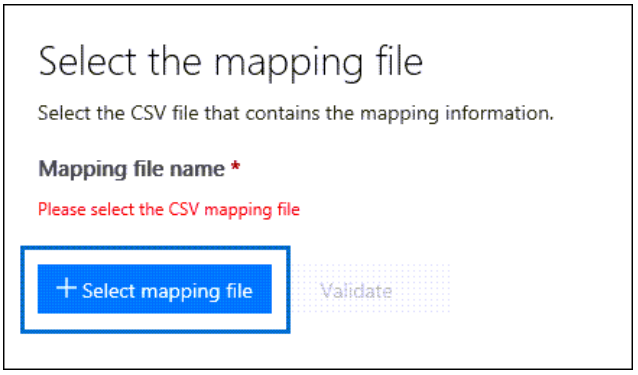
`ContentCodePage`	This optional parameter specifies a numeric value for the code page to use for importing PST files in the ANSI file format. This parameter is used for importing PST files from Chinese, Japanese, and Korean (CJK) organizations because these languages typically use a double byte character set (DBCS) for character encoding. If this parameter isn't used to import PST files for languages that use DBCS for mailbox folder names, the folder names are often garbled after they're imported. For a list of supported values to use for this parameter, see Code Page Identifiers.	(leave blank) Or `932` (which is the code page identifier for ANSI/OEM Japanese)

Parameter	Description	Example
	Note: As previously stated, this is an optional parameter and you don't have to include it in the CSV file. Or you can include it and leave the value blank for one or more rows.	
`SPFileContainer`	For PST Import, leave this parameter blank.	Not applicable
`SPManifestContainer`	For PST Import, leave this parameter blank.	Not applicable
`SPSiteUrl`	For PST Import, leave this parameter blank.	Not applicable



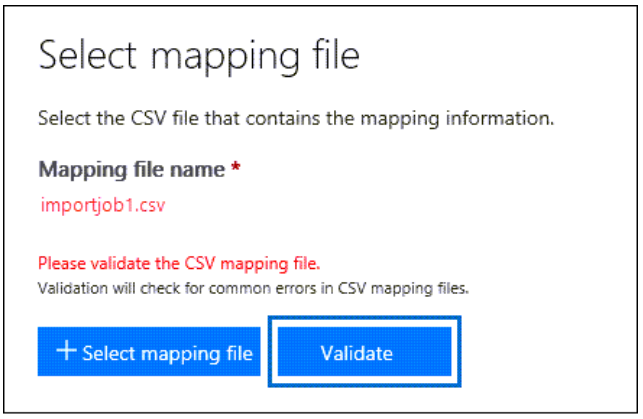
Step 5: Create a PST Import job

In this step, you create the PST import job in the Import service in Microsoft 365. As previously explained, you submit the PST import mapping file that you created in Step 4. After you create the job, Microsoft 365 analyzes the data in the PST files. Then, it gives you an opportunity to filter the data that actually gets imported to the mailboxes specified in the PST import mapping file (see Step 6).



1. Go to https://purview.microsoft.com and sign in with the credentials for an administrator account in your organization.
2. In the left pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.
3. On the **Import** tab, select **+ New import job**.

   > **Note**
   >
   > You need the appropriate permissions to access the **Import** page in the Microsoft Purview portal and create an import job. For more information, see the **Before you import PST files** section.



4. Type a name for the PST import job, and then select **Next**. Use lowercase letters, numbers, hyphens, and underscores. You can't use uppercase letters or include spaces in the name.
5. On the **Do you want to upload or ship data?** page, select **Upload your data** and then select **Next**.
6. In step 4 on the **Import data** page, select the **I'm done uploading my files** and **I have access to the mapping file** check boxes, and then select **Next**.

7. On the **Select the mapping file** page, select **Select mapping file** to submit the CSV mapping file that you created in Step 4.

8. After the name of the CSV file appears under **Mapping file name**, select **Validate** to check your CSV file for errors.

The CSV file must pass validation to create a PST import job. The file name turns green after successful validation. If validation fails, select the **View log** link. A validation error report opens, with an error message for each row in the file that failed.

> ⓘ Note
>
> As previously explained, a mapping file can have a maximum of 500 rows. Validation fails if the mapping file contains more than 500 rows. To import more than 500 PST files, create multiple mapping files and multiple import jobs.

9. After the mapping file is successfully validated, read the terms and conditions document, and then select the checkbox.

10. Select **Save** to submit the job, and then select **Close** after the job is successfully created.

    A status flyout page is displayed, with a status of **Analysis in progress**. The new import job is displayed in the list on the **Import PST files** page.

11. Select **Refresh** to update the status information displayed in the **Status** column. When the analysis completes and the data is ready to import, the status changes to **Analysis completed**.

    You can select the import job to display the status flyout page, which contains more detailed information about the import job such as the status of each PST file listed in the mapping file.

Step 6: Filter data and start the PST Import job

After you create the import job in Step 5, Microsoft 365 safely and securely analyzes the data in the PST files. It identifies the age of the items and the different message types included in the PST files. When the analysis is complete and the data is ready to import, you can import all the data contained in the PST files or trim the data by setting filters that control what data gets imported.

1. On the **Import** tab in the Microsoft Purview portal, select the import jobs that you created in Step 5. Then select **Import to Microsoft 365**.

   The **Filter your data** page appears. It contains the data insights from the analysis of the PST files, including information about the age of the data. You can filter the data that you import or import all the data as is.

2. Do one of the following steps:

   a. To trim the data that you import, select **Yes, I want to filter it before importing**.

      For detailed step-by-step instructions about filtering the data in the PST files and then starting the import job, see Filter data when importing PST files to Microsoft 365.

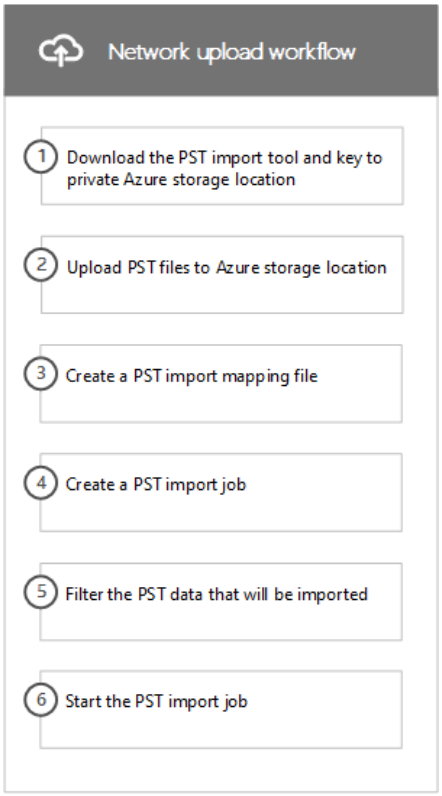
      Or

b. To import all data in the PST files, select **No, I want to import everything,** and select **Next**.

3. If you chose to import all the data, select **Import data** to start the import job.

   The **Import PST files** page displays the status of the import job. Select **Refresh** to update the status information in the **Status** column. Select the import job to display the status flyout page, which shows status information about each PST file being imported.

More information



- Why import PST files to Microsoft 365?
  - It's a good way to import your organization's archival messaging data to Microsoft 365.
  - The data is available to the user from all devices because it's stored in the cloud.
  - It helps address compliance needs of your organization by letting you apply Microsoft Purview features to the data from the PST files that you imported. This benefit includes:
  - Enabling archive mailboxes and auto-expanding archiving to give users additional mailbox storage space to store the data that you imported.
  - Placing mailboxes on Litigation Hold to retain the data that you imported.
  - Using Microsoft eDiscovery tools to search the data that you imported.
  - Using Microsoft 365 retention policies to control how long the data that you imported will be retained, and what action to take after the retention period expires.
  - Searching the audit log for mailbox-related events that affect the data that you imported.
  - Importing data to inactive mailboxes to archive data for compliance purposes.
  - Using data loss prevention policies to prevent sensitive data from leaking outside your organization.
- As previously explained, the Microsoft 365 Import service turns on the retention hold setting (for an indefinite duration) after PST files are imported to a mailbox. This setting means the *RetentionHoldEnabled* property is set to **True** so that the retention policy assigned to the mailbox isn't processed. This setting gives the mailbox owner time to manage the newly imported messages by preventing a deletion or archive policy from deleting or archiving older messages. Here are some steps you can take to manage this retention hold:
  - After a certain time, turn off the retention hold by running the **Set-Mailbox -RetentionHoldEnabled $false** command. For instructions, see Place a mailbox on retention hold.
  - Configure the retention hold so that it's turned off on some date in the future. Run the **Set-Mailbox -EndDateForRetentionHold *date*** command. For example, assuming that today's date is June 1, 2016 and you want the retention hold turned off in 30 days, run the following command: **Set-Mailbox -EndDateForRetentionHold 7/1/2016**. In this scenario, leave the **RetentionHoldEnabled** property set to *True*. For more information, see Set-Mailbox.
  - Change the settings for the retention policy that's assigned to the mailbox so that older items that you imported aren't immediately deleted or moved to the user's archive

mailbox. For example, you could lengthen the retention age for a deletion or archive policy that's assigned to the mailbox. In this scenario, turn off the retention hold on the mailbox after you change the settings of the retention policy. For more information, see Set up an archive and deletion policy for mailboxes in your organization.

How the import process works

Use the network upload option and the Microsoft 365 Import service to bulk-import PST files to user mailboxes. Network upload means that you upload the PST files to a temporary storage area in the Microsoft cloud. Then the Microsoft 365 Import service copies the PST files from the storage area to the target user mailboxes.

Here's an illustration and description of the network upload process to import PST files to mailboxes in Microsoft 365.

1. **Download the PST import tool and key to private Azure Storage location:** Download the AzCopy command-line tool and an access key to upload the PST files to an Azure Storage location in the Microsoft cloud. Get these from the **Import** page in the Microsoft Purview portal. The key, called a secure access signature (SAS) key, gives you the necessary permissions to upload PST files to a private and secure Azure Storage location. This access key is unique to your organization and helps prevent unauthorized access to your PST files after you upload them to the Microsoft cloud. Importing PST files doesn't require your organization to have a separate Azure subscription.

2. **Upload the PST files to the Azure Storage location:** Use the azcopy.exe tool (downloaded in step 1) to upload and store your PST files in an Azure Storage location that resides in the same regional Microsoft datacenter where your organization is located. To upload them, the PST files that you want to import must be located in a file share or file server in your organization.

   You can optionally view the list of PST files after you upload them to the Azure Storage location.

3. **Create a PST import mapping file:** After you upload the PST files to the Azure Storage location, create a comma-separated value (CSV) file that specifies which user mailboxes the PST files go to. A PST file can go to a user's primary mailbox or their archive mailbox. The Microsoft 365 Import service uses the information in the CSV file to import the PST files.

4. **Create a PST import job:** Create a PST import job on the **Import PST files** page in the Microsoft Purview portal and submit the PST import mapping file you created. After you create the import job, Microsoft 365 analyzes the data in the PST files, then gives you an opportunity to set filters that control what data actually gets imported to the mailboxes specified in the PST import mapping file.

5. **Filter the PST data that you import to mailboxes:** After you create and start the import job, Microsoft 365 safely and securely analyzes the data in the PST files by identifying the age of the items and the different message types included in the PST files. When the analysis completes and the data is ready to import, you can import all the data contained in the PST files or trim the data by setting filters that control what data gets imported.

6. **Start the PST import job:** After you start the import job, Microsoft 365 uses the information in the PST import mapping file to import the PSTs files from the Azure Storage location to user mailboxes. The **Import PST files** page in the Microsoft Purview portal displays status information about the import job, including information about each PST file being imported. When the import job finishes, the status for the job is set to **Complete**.

Use drive shipping to import your organization's PST files

This article is for administrators. Are you trying to import PST files to your own mailbox? See Import email, contacts, and calendar from an Outlook .pst file.

Use the Microsoft 365 Import service and drive shipping to bulk-import PST files to user mailboxes. Drive shipping means that you copy the PST files to a hard disk drive and then physically ship the drive to Microsoft. When Microsoft receives your hard drive, data center personnel copy the data from the hard drive to a storage area in the Microsoft cloud. Then you can trim the PST data that's imported to the target mailboxes by setting filters that control what data gets imported. After you start the import job, the Import service imports the PST data from the storage area to user mailboxes. Using drive shipping to import PST files to user mailboxes is one way to migrate your organization's email to Microsoft 365.

Here are the steps required to use drive shipping to import PST files to Microsoft 365 mailboxes:

- Step 1: Download the PST Import tool
- Step 2: Copy the PST files to the hard drive
- Step 3: Create the PST Import mapping file
- Step 4: Create a PST Import job
- Step 5: Ship the hard drive to Microsoft
- Step 6: Filter data and start the PST Import job

> **Important**
>
> You perform Step 1 once to download the import tool. After you perform these steps, follow Step 2 through Step 6 each time you want to ship a hard drive to Microsoft.

For frequently asked questions about using drive shipping to import PST files to Microsoft 365, see FAQs for using drive shipping to import PST files.

Before you import PST files

Before you begin, review the requirements, limits, and planning guidance for importing PST files. The following prerequisites are specific to the drive shipping method:

- You need to store the PST files on a file server or shared folder in your organization. In Step 2, you run the Azure Import Export tool (WAImportExport.exe) to copy the PST files from this file server or shared folder to the hard drive.

- The Microsoft 365 Import service supports only 2.5-inch solid-state drives (SSDs) or 2.5-inch or 3.5-inch SATA II/III internal hard drives. You can use hard drives up to 10 TB. For import jobs, the service processes only the first data volume on the hard drive. You must format the data volume with NTFS. When you copy data to a hard drive, you can attach it directly by using a 2.5-inch SSD or 2.5-inch or 3.5-inch SATA II/III connector, or you can attach it externally by using an external 2.5-inch SSD or 2.5-inch or 3.5-inch SATA II/III USB adapter.

  > **ⓘ Important**
  >
  > The Microsoft 365 Import service doesn't support external hard drives that come with a built-in USB adapter. Additionally, the disk inside the casing of an external hard drive can't be used. Don't ship external hard drives.

- You must encrypt the hard drive that you copy the PST files to by using BitLocker. The WAImportExport.exe tool that you run in Step 2 helps you set up BitLocker. It also generates a BitLocker encryption key that Microsoft data center personnel use to access the drive to upload the PST files to the Azure Storage area in the Microsoft cloud.

- You or your organization must have an account with FedEx or DHL.

  - Organizations in the United States, Brazil, and Europe must have FedEx accounts.

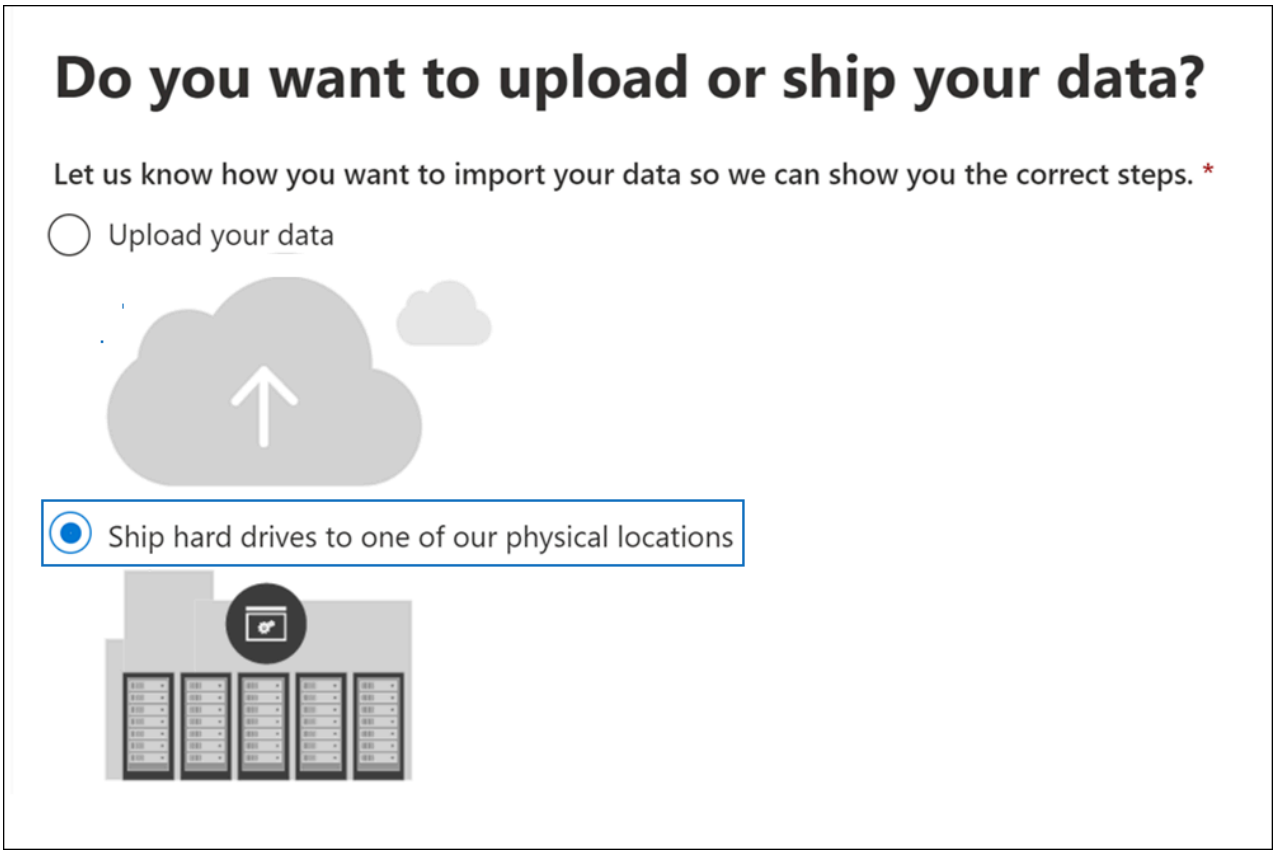
  - Organizations in East Asia, Southeast Asia, Japan, Republic of Korea, and Australia must have DHL accounts.

    Microsoft uses (and charges) this account to return the hard drive back to you.

- The hard drive that you ship to Microsoft might cross international borders. In this case, you're responsible for ensuring that the hard drive and the data it contains are imported and exported in accordance with the applicable laws. Before shipping a hard drive, check with your advisors to verify that your drive and data can legally be shipped to the identified Microsoft data center. This check helps ensure that it reaches Microsoft in a timely manner.

- This procedure involves copying and saving a BitLocker encryption key. Take precautions to protect these keys like you protect passwords or other security-related information. For example, you might save them to a password-protected Microsoft Word document or save them to an encrypted USB drive. See the More information section for an example of these keys.

Step 1: Download the PST Import tool



The first step is to download the tool. You use this tool in Step 2 to copy PST files to the hard drive.

> **Important**
>
> To successfully import PST files by using the drive shipping method, use Azure Import/Export tool version 1 (WAimportExportV1). Version 2 of the Azure Import/Export tool isn't supported. Using it results in incorrectly preparing the hard drive for the import job. Be sure to download the Azure Import/Export tool from the Microsoft Purview portal by following the procedures in this step.

1. Go to https://purview.microsoft.com and sign in by using the credentials for an administrator account in your organization.
2. In the left navigation pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.

   > **Note**
   >
   > As previously stated, you need the appropriate permissions to access the **Import** page in the Microsoft Purview portal.

3. On the **Import** tab, select **+ New import job**.
4. In the import job wizard, type a name for the PST import job, and then select **Next**. Use lowercase letters, numbers, hyphens, and underscores. You can't use uppercase letters or include spaces in the name.
5. On the **Choose import job type** page, select **Ship hard drives to one of our physical locations** and then select **Next**.

6. On the **Import data** page, complete the following steps:

   Download the Azure Import/Export tool to download and install the Azure Import/Export (version 1) tool.

   - In the pop-up window, select **Save** > **Save as** to save the WaImportExportV1.zip file to a folder on your local computer.
   - Extract the WaImportExportV1.zip file.

7. Select **Cancel** to close the wizard.

   You return to the **Import** page in the Microsoft Purview portal when you create the import job in Step 4.

Step 2: Copy the PST files to the hard drive

In this step, use the WAImportExport.exe tool to copy PST files to the hard drive. This tool encrypts the hard drive by using BitLocker, copies the PSTs to the hard drive, and creates a journal file that stores information about the copy process. To complete this step, you need to locate the PST files in a file share or file server in your organization. This location is known as the source directory in the following procedure.

Each PST file that you copy to the hard drive should be no larger than 20 GB. PST files larger than 20 GB might affect the performance of the PST import process that you start in Step 6.

> **Important**
>
> After you run the WAImportExport.exe tool the first time for a hard drive, use a different syntax each time after that. Step 4 explains this syntax to copy PST files to the hard drive.

1. Open a Command Prompt on your local computer.

   > **Tip**
   >
   > If you run the command prompt as an administrator (by selecting **Run as administrator** when you open it), error messages display in the command prompt window. This information can help you resolve issues running the WAImportExport.exe tool.

2. Go to the directory where you installed the WAImportExport.exe tool in Step 1.

3. Run the following command the first time that you use the WAImportExport.exe to copy PST files to a hard drive.

   PowerShell

   ```
   WAImportExport.exe PrepImport /j:<Name of journal file> /t:<Drive letter> /id:
   <Name of session> /srcdir:<Location of PST files> /dstdir:<PST file path>
   /blobtype:BlockBlob /encrypt /logdir:<Log file location>
   ```

   The following table describes the parameters and their required values.

   Expand table

Parameter	Description	Example
`/j:`	Specifies the name of the journal file.The tool saves this file to the same folder where the WAImportExport.exe tool is located. Each hard drive you ship to Microsoft must have one journal file. Every time you run the WAImportTool.exe to copy PST files to a hard drive, the tool appends information to the journal file for that drive. Microsoft data center personnel use the information in the journal file to	`/j:PSTHDD1.jrn`

Parameter	Description	Example
	associate the hard drive with the import job that you create in Step 4, and to upload the PST files to the Azure Storage area in the Microsoft cloud.	
`/t:`	Specifies the drive letter of the hard drive when it's connected to your local computer.	`/t:h`
`/id:`	Specifies the name of the copy session. A session is defined as each time you run the WAImportExport.exe tool to copy files to the hard drive. The PST files are copied to a folder named with the session name specified by this parameter.	`/id:driveship1`
`/srcdir:`	Specifies the source directory in your organization that contains the PST files that the tool copies during the session. Surround the value of this parameter with double-quotation marks (" ").	`/srcdir:"\\FILESERVER01\PSTs"`
`/dstdir:`	Specifies the destination directory in the Azure Storage area in the Microsoft cloud where the PSTs are uploaded. Use the value `ingestiondata/`. Surround the value of this parameter with double-quotation marks (" "). Optionally, you can also add an extra file path to the value of this parameter. For example, you can use the file path of the source directory on the hard drive (converted to a URL format), which is specified in the `/srcdir:` parameter. For example, `\\FILESERVER01\PSTs` is changed to `FILESERVER01/PSTs`. In this case, you still must include `ingestiondata` in the file path. So in this example, the value for the `/dstdir:` parameter would be `"ingestiondata/FILESERVER01/PSTs"`.	`/dstdir:"ingestiondata/"` Or `/dstdir:"ingestiondata/FILESERVER01/PSTs"`

Parameter	Description	Example
	One reason to add the additional file path is if you have PST files with the same filename. > [!NOTE]> If you include the optional pathname, the namespace for a PST file after it's uploaded to the Azure Storage area includes the pathname and the name of the PST file; for example, `FILESERVER01/PSTs/annb.pst`. If you don't include a pathname, the namespace is only the PST filename; for example `annb.pst`.	
`/blobtype:`	Specifies the type of blobs in the Azure Storage area to import the PST files to. For importing PST files, use the value **BlockBlob**. This parameter is required.	`/blobtype:BlockBlob`
`/encrypt`	This switch turns on BitLocker for the hard drive. This parameter is required the first time you run the WAImportExport.exe tool. The BitLocker encryption key is copied to the journal file and the log file that is created if you use the `/logfile:` parameter. As previously explained, the journal file is saved to the same folder where the WAImportExport.exe tool is located.	`/encrypt`
`/logdir:`	This optional parameter specifies a folder to save log files to. If not specified, the log files are saved to the same folder where the WAImportExport.exe tool is located. Surround the value of this parameter with double-quotation marks (" ").	`/logdir:"c:\users\admin\desktop\PstImportLogs"`

Here's an example of the syntax for the WAImportExport.exe tool using actual values for each parameter:

PowerShell

```
WAImportExport.exe PrepImport /j:PSTHDD1.jrn /t:f /id:driveship1
/srcdir:"\\FILESERVER01\PSTs" /dstdir:"ingestiondata/" blobtype:BlockBlob
/encrypt /logdir:"c:\users\admin\desktop\PstImportLogs"
```

After you run the command, status messages display that show the progress of copying the PST files to the hard drive. A final status message shows the total number of files that you successfully copied.

4. Run this command each subsequent time you run the WAImportExport.ext tool to copy PST files to the same hard drive.

PowerShell

```
WAImportExport.exe PrepImport /j:<Name of journal file> /id:<Name of new
session> /srcdir:<Location of PST files> /dstdir:<PST file path>
/blobtype:BlockBlob
```

Here's an example of the syntax for running subsequent sessions to copy PST files to the same hard drive.

PowerShell

```
WAImportExport.exe PrepImport /j:PSTHDD1.jrn /id:driveship2
/srcdir:"\\FILESERVER01\PSTs\SecondBatch" /dstdir:"ingestiondata/"
/blobtype:BlockBlob
```

Step 3: Create the PST Import mapping file

After Microsoft data center personnel upload the PST files from the hard drive to the Azure Storage area, the Import service uses the information in the PST Import mapping file, which is a comma-separated value (CSV) file, to know which user mailboxes to import the PST files to. You submit this CSV file in the next step when you create a PST Import job.

1. Download a copy of the PST Import mapping file.

2. Open or save the CSV file to your local computer. The following example shows a completed PST Import mapping file (opened in NotePad). It's easier to use Microsoft Excel to edit the CSV file.

text

```
Workload,FilePath,Name,Mailbox,IsArchive,TargetRootFolder,ContentCodePage,SPFi
leContainer,SPManifestContainer,SPSiteUrl
Exchange,FILESERVER01/PSTs,annb.pst,annb@contoso.onmicrosoft.com,FALSE,/,,,,
```

```
Exchange,FILESERVER01/PSTs,annb_archive.pst,annb@contoso.onmicrosoft.com,TRUE,
/ImportedPst,,,,
Exchange,FILESERVER01/PSTs,donh.pst,donh@contoso.onmicrosoft.com,FALSE,/,,,,
Exchange,FILESERVER01/PSTs,donh_archive.pst,donh@contoso.onmicrosoft.com,TRUE,
/ImportedPst,,,,
Exchange,FILESERVER01/PSTs,pilarp.pst,pilarp@contoso.onmicrosoft.com,FALSE,/,,
,,
Exchange,FILESERVER01/PSTs,pilarp_archive.pst,pilarp@contoso.onmicrosoft.com,T
RUE,/ImportedPst,,,,
Exchange,,tonyk.pst,tonyk@contoso.onmicrosoft.com,FALSE,/,,,,
Exchange,,tonyk_archive.pst,tonyk@contoso.onmicrosoft.com,TRUE,,,,,
Exchange,,zrinkam.pst,zrinkam@contoso.onmicrosoft.com,FALSE,/,,,,
Exchange,,zrinkam_archive.pst,zrinkam@contoso.onmicrosoft.com,TRUE,,,,,
```

The first row, or header row, of the CSV file lists the parameters that the PST Import service uses to import the PST files to user mailboxes. Each parameter name is separated by a comma. Each row under the header row represents the parameter values for importing a PST file to a specific mailbox. You need a row for each PST file that you copied to the hard drive. Be sure to replace the placeholder data in the mapping file with your actual data.

> **Note**
>
> Don't change anything in the header row, including the SharePoint parameters; the PST Import process ignores them.

3. Use the information in the following table to populate the CSV file with the required information.

Expand table

Parameter	Description	Example
`Workload`	Specifies the service that data is imported to.To import PST files to user mailboxes, use `Exchange`.	`Exchange`
`FilePath`	Specifies the folder location in the Azure Storage area that PST files are copied to when the hard drive is shipped to Microsoft. What you add in this column in the CSV file depends on what you specified in for the `/dstdir:` parameter in the previous step. If you have subfolders on the source location, then the value in the `FilePath` parameter must contain the relative path for the subfolder; for example, /folder1/user1/.	(leave blank) Or `FILESERVER01/PSTs`

Parameter	Description	Example
	If you used `/dstdir:"ingestiondata/"`, then leave this parameter blank in the CSV file. If you included an optional pathname for the value of the `/dstdir:` parameter (for example, `/dstdir:"ingestiondata/FILESERVER01/PSTs"`, then use that pathname (not including "ingestiondata") for this parameter in the CSV file. The value for this parameter is case-sensitive. Either way, *don't* include "ingestiondata" in the value for the `FilePath` parameter. Leave this parameter blank or specify only the optional pathname. > [!IMPORTANT]> The case for the file path name must be the same case that you specified in the `/dstdir:` parameter in the previous step. For example, if you used `"ingestiondata/FILESERVER01/PSTs"` for the subfolder name in the previous step, but then used `fileserver01/psts` in the `FilePath` parameter in CSV file, the import for the PST file fails. Be sure to use the same case in both instances.	
`Name`	Specifies the name of the PST file that is imported to the user mailbox. The value for this parameter is case-sensitive. > [!IMPORTANT]> The case for the PST file name in the CSV file must be the same as the PST file that was uploaded to the Azure Storage location in Step 2. For example, if you use `annb.pst` in the `Name` parameter in the CSV file, but the name of the actual PST file is `AnnB.pst`, the import for that PST file fails. Be sure that the name of the PST in the CSV file uses the same case as the actual PST file.	`annb.pst`

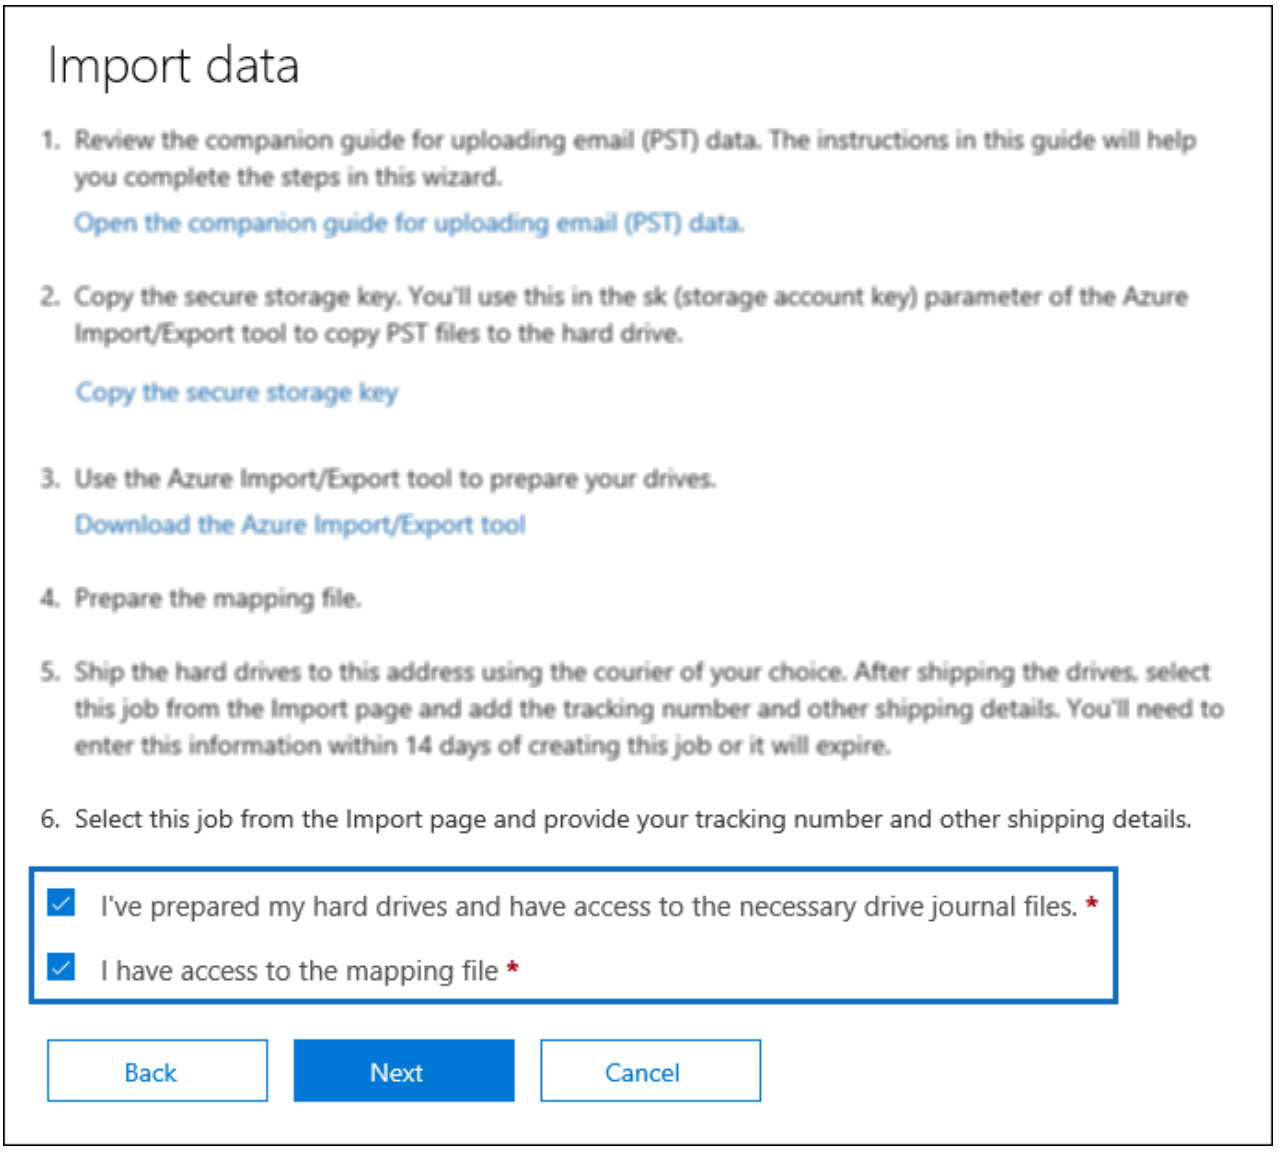
`Mailbox`	Specifies the email address of the mailbox that the PST file is imported to. You can't specify a public folder because the PST Import Service doesn't support importing PST files to public folders.
	To import a PST file to an inactive mailbox, you have to specify the mailbox GUID for this parameter. To obtain this GUID, run the following PowerShell command in Exchange
		`annb@contoso.onmicrosoft.com`
		Or
		`2d7a87fe-d6a2-40cc-8aff-1ebea80d4ae7`

Parameter	Description	Example
	Online: `Get-Mailbox <identity of inactive mailbox> -InactiveMailboxOnly | FL Guid` > [!NOTE]> Sometimes, you have multiple mailboxes with the same email address, where one mailbox is an active mailbox and the other mailbox is in a soft-deleted (or inactive) state. In these situations, you have to specify the mailbox GUID to uniquely identify the mailbox to import the PST file to. To obtain this GUID for active mailboxes, run the following PowerShell command: `Get-Mailbox <identity of active mailbox> | FL Guid`. To obtain the GUID for soft-deleted (or inactive) mailboxes, run this command: `Get-Mailbox <identity of soft-deleted or inactive mailbox> -SoftDeletedMailbox | FL Guid`.	

`IsArchive`	Specifies whether to import the PST file to the user's archive mailbox. There are two options:
	FALSE Imports the PST file to the user's primary mailbox.
	TRUE Imports the PST file to the user's archive mailbox. This assumes that the user's archive mailbox is enabled. If you set this parameter to `TRUE` and the user's archive mailbox isn't enabled, the import for that user fails. If an import fails for one user (because their archive isn't enabled and this property is set to `TRUE`), the other users in the import job isn't affected.
	If you leave this parameter blank, the PST file is imported to the user's primary mailbox.
	Note: To import a PST file to a cloud-based archive mailbox for a user whose primary mailbox is on-premises, just specify `TRUE` for this parameter and specify the email address for the user's on-premises mailbox for the `Mailbox` parameter.
		`FALSE`
		Or
		`TRUE`

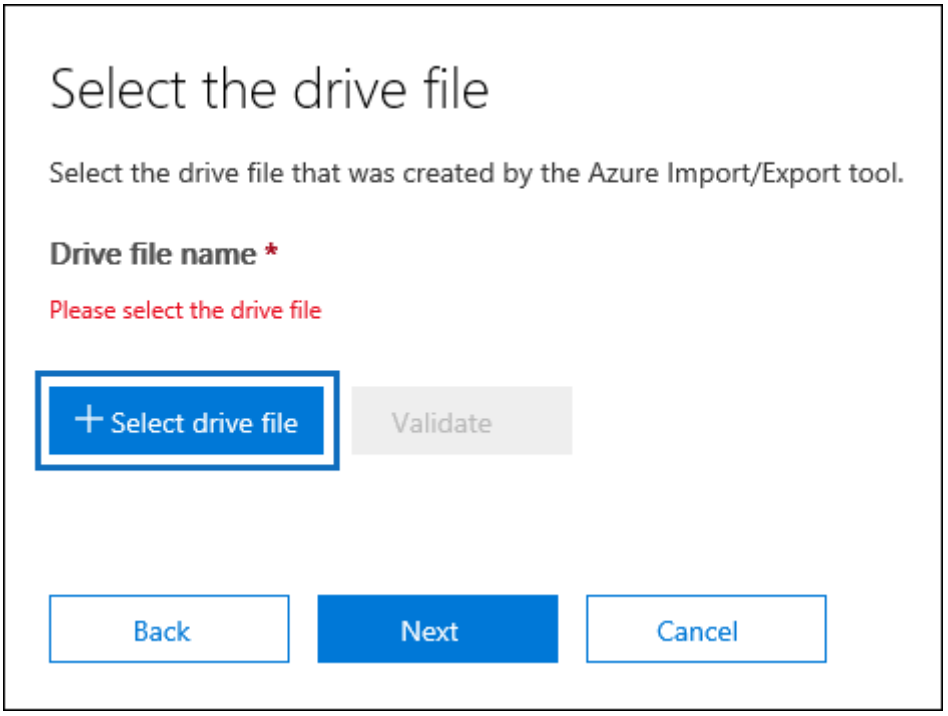
`TargetRootFolder`	Specifies the mailbox folder that the PST file is imported to.
	If you leave this parameter blank, the PST is imported to a new folder named **Imported** located at the root level of the mailbox (the same level as the Inbox folder and the other
		(leave blank)
		Or
		`/`
		Or
		`/ImportedPst`

Parameter	Description	Example
	default mailbox folders). If you specify `/`, items in the PST file are imported directly in to the user's Inbox folder. If you specify `/<foldername>`, items in the PST file are imported to a folder named *<foldername>*. For example, if you use `/ImportedPst`, items would be imported to a folder named **ImportedPst**. This folder is located in the user's mailbox at the same level as the Inbox folder.	
`ContentCodePage`	This optional parameter specifies a numeric value for the code page to use for importing PST files in the ANSI file format. This parameter is used for importing PST files from Chinese, Japanese, and Korean (CJK) organizations because these languages typically use a double byte character set (DBCS) for character encoding. If this parameter isn't used to import PST files for languages that use DBCS for mailbox folder names, the folder names are often garbled after they're imported. For a list of supported values to use for this parameter, see Code Page Identifiers. > [!NOTE]> As previously stated, this is an optional parameter and you don't have to include it in the CSV file. Or you can include it and leave the value blank for one or more rows.	(leave blank) Or `932` (which is the code page identifier for ANSI/OEM Japanese)
`SPFileContainer`	For PST Import, leave this parameter blank.	Not applicable
`SPManifestContainer`	For PST Import, leave this parameter blank.	Not applicable
`SPSiteUrl`	For PST Import, leave this parameter blank.	Not applicable



Step 4: Create a PST Import job

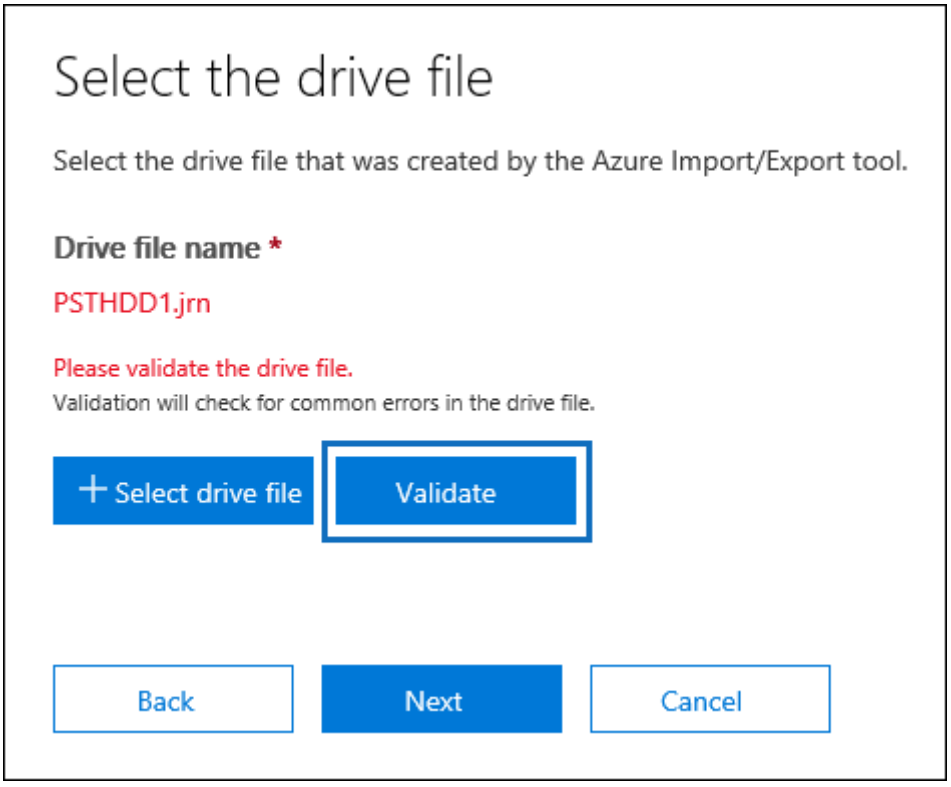
Next, create the PST Import job in the Import service in Microsoft 365. Submit the PST Import mapping file that you created in Step 3. After you create the job, the Import service uses the information in the mapping file to import the PST files to the specified user mailbox. The Import service imports the PST files after you copy the PST files from the hard drive to the Azure Storage area and you create and start the import job.



1. Go to https://purview.microsoft.com and sign in by using the credentials for an administrator account in your organization.
2. In the left navigation pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.
3. On the **Import** tab, select **+ New import job**.

   > **Note**
   >
   > As previously stated, you need the appropriate permissions to access the **Import** page in the Microsoft Purview portal.

4. Type a name for the PST import job, then select **Next**. Use lowercase letters, numbers, hyphens, and underscores. You can't use uppercase letters or include spaces in the name.
5. On the **Choose import job type** page, select **Ship hard drives to one of our physical locations** and then select **Next**.
6. Select the **I've prepared my hard drives and have access to the necessary drive journal files** and **I have access to the mapping file** check boxes, then select **Next**.

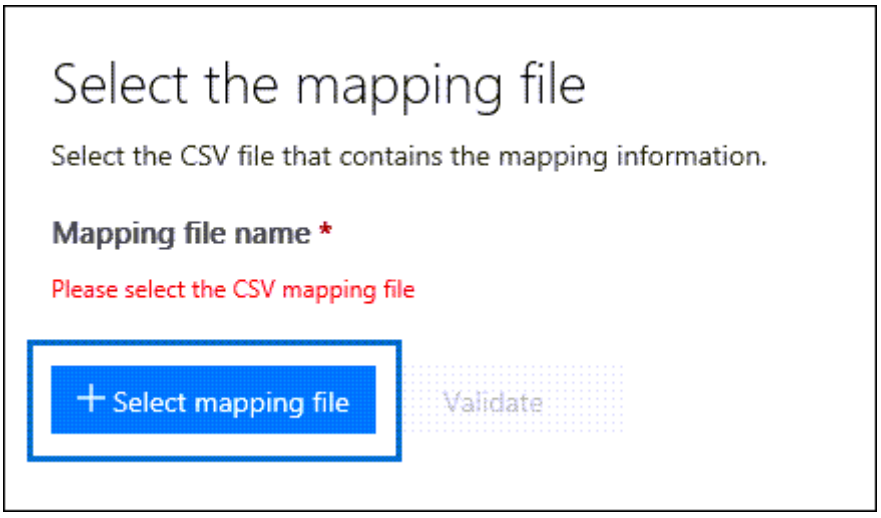


7. On the **Select the drive file** page, select **Select drive file**, then go to the same folder where the WAImportExport.exe tool is located. The journal file that you created in Step 2 is in this folder.

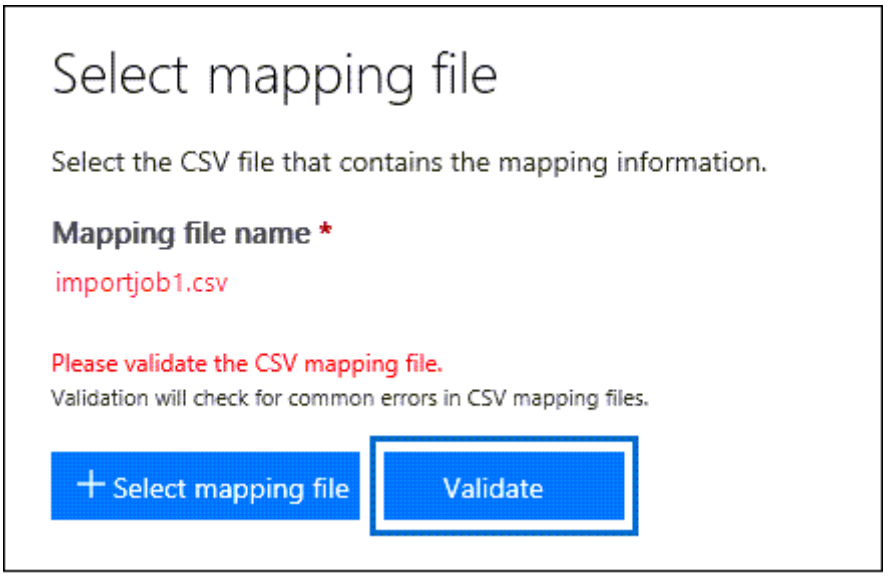
8. Select the journal file, such as `PSTHDD1.jrn`.

> **Tip**
>
> When you ran the WAImportExport.exe tool in Step 2, you specified the name of the journal file by using the `/j:` parameter.

9. After the name of the drive file appears under **Drive file name**, select **Validate** to check your drive file for errors.



You must successfully validate the drive file to create a PST Import job. The file name changes to green after it's successfully validated. If the validation fails, select the **View log** link. A validation error report opens, with an error message that explains why the file failed.



> **Note**
>
> You must add and validate a journal file for each hard drive you ship to Microsoft.

10. After adding and validating a journal file for each hard drive that you ship to Microsoft, select **Next**.

11. Select **+ Select mapping file** to submit the PST Import mapping file that you created in Step 3.

12. After the name of the CSV file appears under **Mapping file name**, select **Validate** to check your CSV file for errors.

    You must successfully validate the CSV file to create a PST Import job. The file name changes to green after it's successfully validated. If the validation fails, select the **View log** link. A validation error report opens, with an error message for each row in the file that failed.

13. After the PST mapping file is successfully validated, select **Next**.

14. On the **Provide contact information** page, type your contact information in the applicable boxes.

    The address for the Microsoft location that you ship your hard drives to is displayed. This address is autogenerated based on your Microsoft datacenter location. Copy this address to a file or take a screenshot.

15. Read the terms and conditions document, select the checkbox, then select **Save** to submit the import job.

When the import job is successfully created, a status page is displayed that explains the next steps of the drive shipping process.

16. On the **Import** tab, select **Refresh** to show the new drive shipping import job in the list of import jobs. The status is **Waiting for tracking number**. You can also select the import job to display the status flyout page, which contains more detailed information about the import job.

Step 5: Ship the hard drive to Microsoft

In this step, you ship the hard drive to Microsoft. You also provide the tracking number for the shipment and return shipment information for the drive shipping job. After Microsoft receives the drive, data center personnel take between 7 and 10 business days to upload your PST files to the Azure Storage area for your organization.

> **Note**
>
> If you don't provide the tracking number and return shipment information within 14 days of creating the import job, the import job expires. If this happens, you need to create a new drive shipping import job (see Step 4: Create a PST Import job) and re-submit the drive file and the PST import mapping file.

Ship the hard drive

Keep the following things in mind when you ship hard drives to Microsoft:

- Don't ship the SATA-to-USB adapter; you only need to ship the hard drive.
- Package the hard drive properly; for example, use an anti-static bag or bubble wrap.
- Use a delivery carrier of your choice to ship the hard drive to Microsoft.
- Ship the hard drive to the address for the Microsoft location that displays when you create the import job in Step 4. Be sure to include "Microsoft 365 Import Service" in the ship-to address.
- After you ship the hard drive, be sure to write down the name of the delivery carrier and the tracking number. You provide these in the next step.

Enter the tracking number and other shipping information

After you ship the hard drive to Microsoft, complete the following procedure on the Import service page.

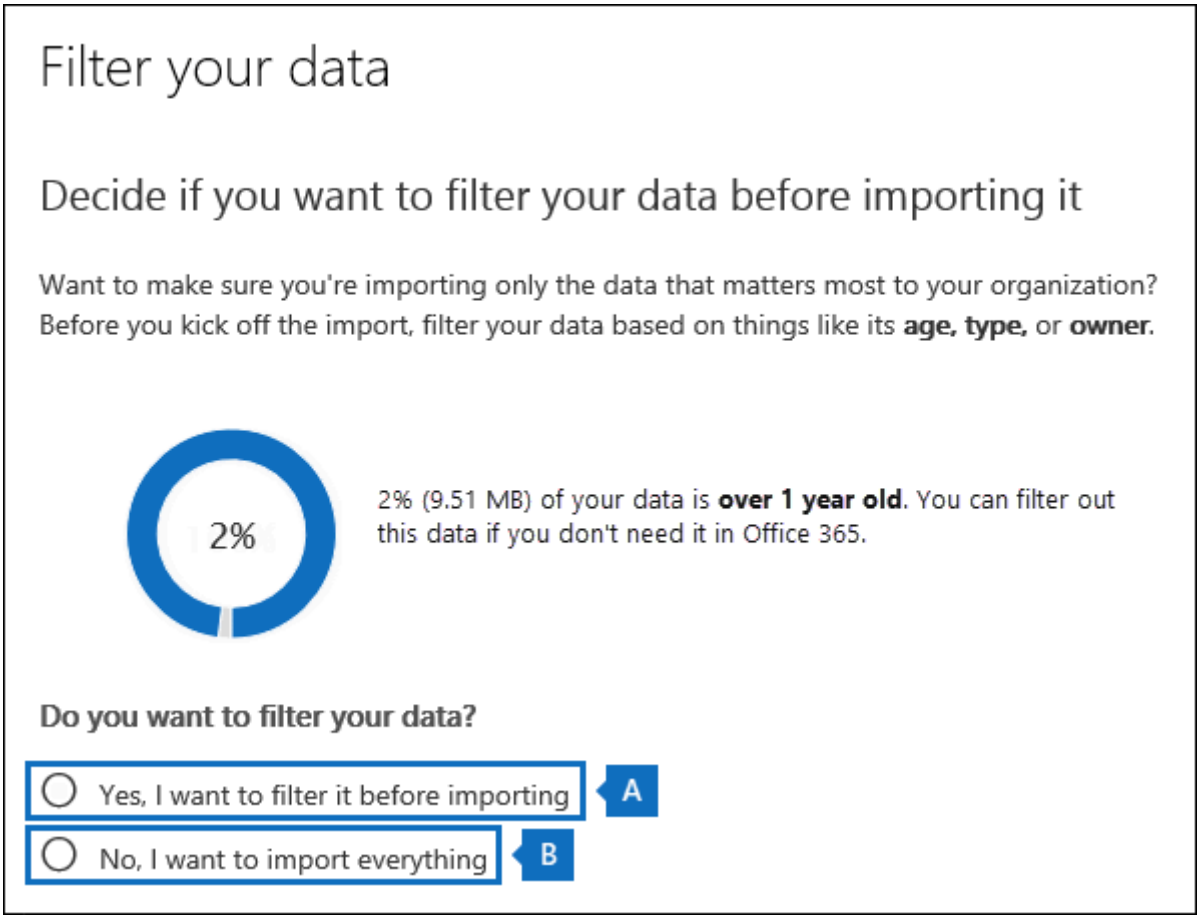
1. Go to https://purview.microsoft.com and sign in by using the credentials for an administrator account in your organization.
2. In the left navigation pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.
3. On the **Import** tab, select the job for the drive shipment that you want to enter the tracking number for.
4. On the status flyout page, select **Enter tracking number**.
5. Provide the following shipping information:
    a. **Delivery carrier** Type the name of the delivery carrier that you used to ship the hard drive to Microsoft.
    b. **Tracking number** Type the tracking number for the hard drive shipment.
    c. **Return carrier account number** Type your organization's account number for the carrier that listed under **Return carrier**. Microsoft uses (and charges) this account to ship your hard drive back to you. Organizations in the USA and Europe, must have an account with FedEx. Organizations in Asia and the rest of the world, must have an account with DHL.
6. Select **Save** to save this information for the import job.
    a. On the **Import** tab, select **Refresh** to update the information for your drive shipping import job. Notice that status is now set to **Drives in transit**.

Step 6: Filter data and start the PST Import job

After Microsoft receives your hard drive, the status for the import job on the **Import PST files** page changes to **Drives received**. Data center personnel use the information in the journal file to upload your PST files to the Azure Storage area for your organization. At this point, the status changes to **Import in-progress**. As previously stated, it takes between 7 and 10 business days after receiving your hard drive to upload the PST files.

After uploading the PST files to Azure, the status changes to **Analysis in progress**. This status indicates that Microsoft 365 is analyzing the data in the PST files (in a safe and secure manner) to identify the age of the items and the different message types included in the PST files. When the analysis completes and the data is ready to import, the status changes to **Analysis completed**. At this point, you can import all the data contained in the PST files or trim the data by setting filters that control what data gets imported.

1. Go to https://purview.microsoft.com and sign in by using the credentials for an administrator account in your organization.



2. In the left navigation pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.

3. On the **Import** tab, select the import job that you created in Step 4 and select **Import to Microsoft 365**.

   A flyout page appears with information about the PST files and other information about the import job.

4. Select **Import to Microsoft 365**.

5. The **Filter your data** page appears. It contains the data insights resulting from the analysis performed on the PST files by Microsoft 365, including information about the age of the data. At this point, you can filter the data that you want to import or import all the data as is.

6. Do one of the following steps:

   a. To trim the data that you import, select **Yes, I want to filter it before importing**.

      For detailed step-by-step instructions about filtering the data in the PST files and then starting the import job, see Filter data when importing PST files to Microsoft 365.

Or

b. To import all data in the PST files, select **No, I want to import everything,** and select **Next**.

7. If you chose to import all the data, select **Import data** to start the import job.

   The status of the import job appears on the **Import PST files** page. Select **Refresh** to update the status information that's displayed in the **Status** column. Select the import job to display the status flyout page, which displays status information about each PST file being imported. When the import completes and PST files are imported to user mailboxes, the status changes to **Completed**.

View a list of the PST files uploaded to Microsoft 365

Install and use Microsoft Azure Storage Explorer, a free, open-source tool, to view the list of PST files that Microsoft data center personnel uploaded to the Azure Storage area for your organization. Use this list to verify that PST files from the hard drives you sent to Microsoft were successfully uploaded to the Azure Storage area.

> **Important**
>
> You can't use Azure Storage Explorer to upload or modify PST files. The only supported method for importing PST files to Microsoft 365 is to use AzCopy. Also, you can't delete PST files that you upload to the Azure blob. If you try to delete a PST file, you receive an error about not having the required permissions. All PST files are automatically deleted from your Azure Storage area. If there are no import jobs in progress, the system deletes all PST files in the **ingestiondata** container 30 days after the most recent import job was created.

Perform the following steps to get the Shared Access Signature (SAS) URL for your organization. This URL combines the network URL for the Azure Storage location in the Microsoft cloud for your organization with an SAS key. This key provides you with the necessary permissions to access your organization's Azure Storage location.

To install Azure Storage Explorer and connect to your Azure Storage area:

1. Go to https://purview.microsoft.com and sign in by using the credentials for an administrator account in your organization.

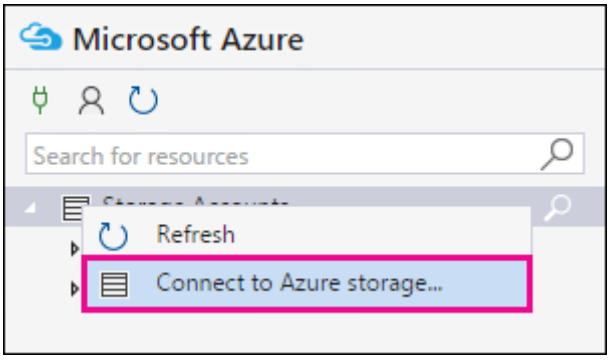
2. In the left pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.

3. On the **Import** tab, select **+ New import job**.

4. In the import job wizard, type a name for the PST import job, and then select **Next**. Use lowercase letters, numbers, hyphens, and underscores. You can't use uppercase letters or include spaces in the name.

5. On the **Choose import job type** page, select **Upload your data**, then select **Next**.

6. In step 2, select **Show network upload SAS URL**.



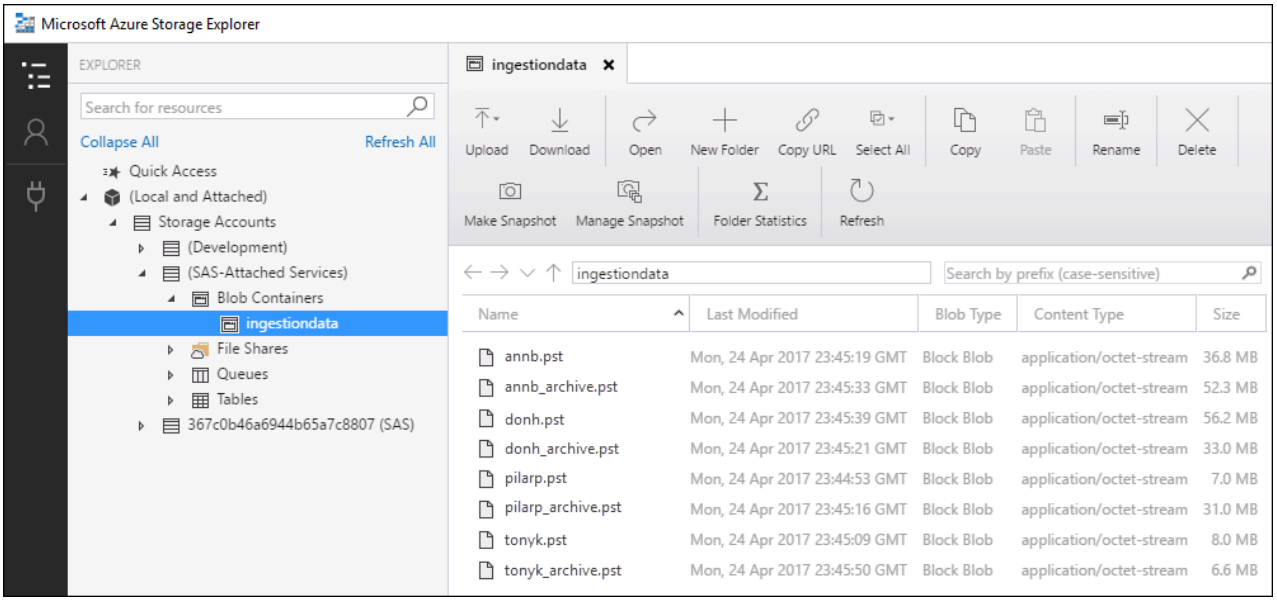
7. After the URL is displayed, copy it and save it to a file. Be sure to copy the entire URL.

   > **Important**
   >
   > Be sure to take precautions to protect the SAS URL. Anyone can use this URL to access the Azure storage area for your organization.

8. Select **Cancel** to close the import job wizard.

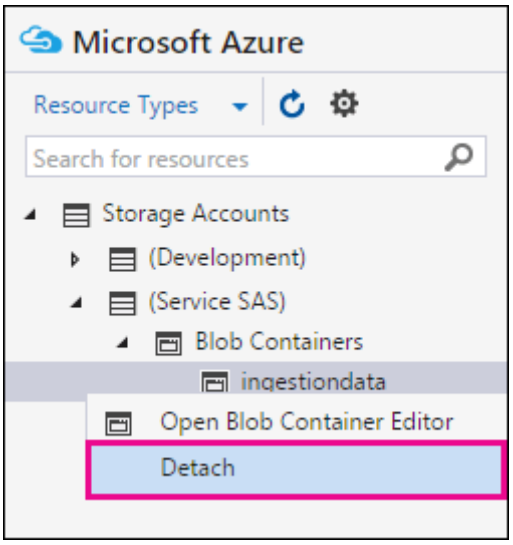
9. Download and install the Microsoft Azure Storage Explorer tool.

10. Start Microsoft Azure Storage Explorer, right-click **Storage Accounts** in the left pane, then select **Connect to Azure Storage**.



11. Select **Use a shared access signature (SAS) URI or connection string** and select **Next**.

12. Select **Use a SAS URI**, paste the SAS URL that you obtained in step 1 into the box under **URI**, then select **Next**.



13. On the **Connection summary** page, review the connection information, then select **Connect**.

    The **ingestiondata** container opens. It contains the PST files from your hard drive. The **ingestiondata** container is located under **Storage Accounts** > **(SAS-Attached Services)** >

Blob Containers.

14. When you're finished using Microsoft Azure Storage Explorer, right-click **ingestiondata**, then select **Detach** to disconnect from your Azure Storage area. Otherwise, you receive an error the next time you try to attach.

Resolve common import errors

- **What happens if the import job fails because of errors in the PST Import CSV mapping file?** If an import job fails because of errors in the mapping file, you don't need to reship the hard drive to Microsoft to create an import job. That's because the PST files from the hard drive that you submitted for the drive shipping import job are already uploaded to the Azure Storage area for your organization. In this case, you only need to fix the errors in the PST Import CSV mapping file, then create a new "network upload" import job and submit the revised CSV mapping file. For more information, see Step 5: Create a PST Import job in Microsoft 365 and Step 6: Filter data and start the PST Import job.

> **Note**
>
> To help resolve errors in the PST Import CSV mapping file, use the Azure Storage Explorer tool to view the folder structure in the **ingestiondata** container for the PST files from your hard drive that you uploaded to the Azure storage area. Mapping file errors typically occur because of an incorrect value in the FilePath parameter. This parameter specifies the location of a PST file in the Azure storage area. See the description of the FilePath parameter in table in Step 3. As previously explained, the location of PST files in the Azure storage area is specified by the `/dstdir:` parameter when you run the WAImportExport.exe tool in Step 2.

More information

- Drive shipping is an effective way to import large amounts of archival messaging data to Microsoft 365 so you can take advantage of the compliance features that are available to your organization. After archival data is imported to user mailboxes, you can:
  - Enable archive mailboxes and auto-expanding archiving to give users more mailbox storage space for the data.
  - Place mailboxes on Litigation Hold to retain the data.
  - Use Microsoft eDiscovery tools to search the data.
  - Apply Microsoft 365 retention policies to control how long the data is retained, and what action to take after the retention period expires.
  - Search the audit log for events related to this data.
  - Import data to inactive mailboxes to archive data for compliance purposes.
  - Protect your organization against data loss of sensitive information.

- Here's an example of the secure storage account key and a BitLocker encryption key. This example also contains the syntax for the WAImportExport.exe command that you run to copy PST files to a hard drive. Be sure to take precautions to protect these just like you would protect passwords or other security-related information.

```text
Secure storage account key:

yaNIIs9Uy5g25Yoak+LlSHfqVBGOeNwjqtBEBGqRMoidq6/e5k/VPkjOXdDIXJHxHvNoNoFH5NcVUJ
XHwu9ZxQ==

BitLocker encryption key:

397386-221353-718905-535249-156728-127017-683716-083391
```

```
COMMAND SYNTAX

First time:

WAImportExport.exe PrepImport /j:<Name of journal file> /t:<Drive letter> /id:
<Name of session> /srcdir:<Location of PST files> /dstdir:<PST file path>
/blobtype:BlockBlob /encrypt /logdir:<Log file location>

Subsequent times:

WAImportExport.exe PrepImport /j:<Name of journal file> /id:<Name of new
session> /srcdir:<Location of PST files> /dstdir:<PST file path>
/blobtype:BlockBlob

EXAMPLES

First time:

WAImportExport.exe PrepImport /j:PSTHDD1.jrn /t:f /id:driveship1
/srcdir:"\\FILESERVER1\PSTs" /dstdir:"ingestiondata/"
/blobtype:BlockBlob /encrypt /logdir:"c:\users\admin\desktop\PstImportLogs"

Subsequent times:

WAImportExport.exe PrepImport /j:PSTHDD1.jrn /id:driveship2
/srcdir:"\\FILESERVER1\PSTs\SecondBatch" /dstdir:"ingestiondata/"
/blobtype:BlockBlob
```

- As previously explained, the Microsoft 365 Import service turns on the retention hold setting (for an indefinite duration) after PST files are imported to a mailbox. This setting means the *RetentionHoldEnabled* property is set to `True` so that the retention policy assigned to the mailbox isn't processed. This setting gives the mailbox owner time to manage the newly imported messages by preventing a deletion or archive policy from deleting or archiving older messages. Here are some steps you can take to manage this retention hold:
  - After a certain period of time, you can turn off the retention hold by running the `Set-Mailbox -RetentionHoldEnabled $false` command. For instructions, see Place a mailbox on retention hold.
  - You can configure the retention hold so that it's turned off on some date in the future. You do this by running the `Set-Mailbox -EndDateForRetentionHold <date>` command. For example, assuming that today's date is June 1, 2016 and you want the retention hold turned off in 30 days, you would run the following command: `Set-Mailbox -EndDateForRetentionHold 7/1/2016`. In this scenario, you would leave the *RetentionHoldEnabled* property set to *True*. For more information, see Set-Mailbox.
  - You can change the settings for the retention policy that's assigned to the mailbox so that older items that were imported aren't immediately deleted or moved to the user's archive mailbox. For example, you could lengthen the retention age for a deletion or

archive policy that's assigned to the mailbox. In this scenario, you turn off the retention hold on the mailbox after you change the settings of the retention policy. For more information, see Set up an archive and deletion policy for mailboxes in your organization.

Filter data when importing PST files

> **Note**
>
> This article explains how to filter PST data during import. Before using this feature, create a PST import job by using network upload or drive shipping. For an overview of the PST import process, including requirements and limits, see Learn about importing PST files.

Use the new Intelligent Import feature in the Microsoft 365 Import service to filter the items in PST files that you import to the target mailboxes. Here's how it works:

- After you create and submit a PST import job, the process uploads PST files to an Azure storage area in the Microsoft cloud.
- Microsoft 365 analyzes the data in the PST files in a safe and secure manner. It identifies the age of the mailbox items and the different message types included in the PST files.
- When the analysis is complete and the data is ready to import, you can import all data in the PST files as is or trim the data by setting filters that control what data gets imported. For example, you can choose to:
  - Import only items of a certain age.
  - Import selected message types.
  - Exclude messages sent or received by specific people.
- After you configure the filter settings, Microsoft 365 imports only the data that meets the filtering criteria to the target mailboxes specified in the import job.

The following graphic shows the Intelligent Import process, and highlights the tasks you perform and the tasks performed by Microsoft 365.

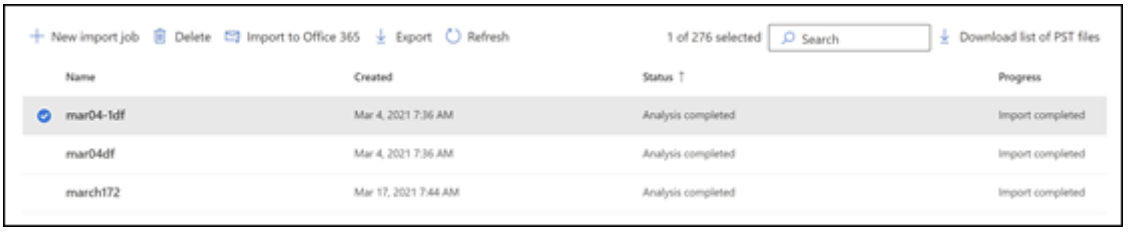
Create a PST Import job

- The steps in this article assume that you created a PST import job in the Microsoft 365 Import service by using network upload or drive shipping. For step-by-step instructions, see one of the following articles:
  - Use network upload to import PST files to Microsoft 365
  - Use drive shipping to import PST files to Microsoft 365

- After you create an import job by using network upload, the status for the import job on the Import page in the Microsoft Purview portal is set to **Analysis in progress**, which means that Microsoft 365 is analyzing the data in the PST files that you uploaded. Select **Refresh** to update the status for the import job.

- For drive shipping import jobs, Microsoft 365 analyzes the data after Microsoft datacenter personnel receive your hard drive and upload the PST files to the Azure storage area for your organization.

- For answers to common questions about importing PST files, see FAQ about importing PST files.



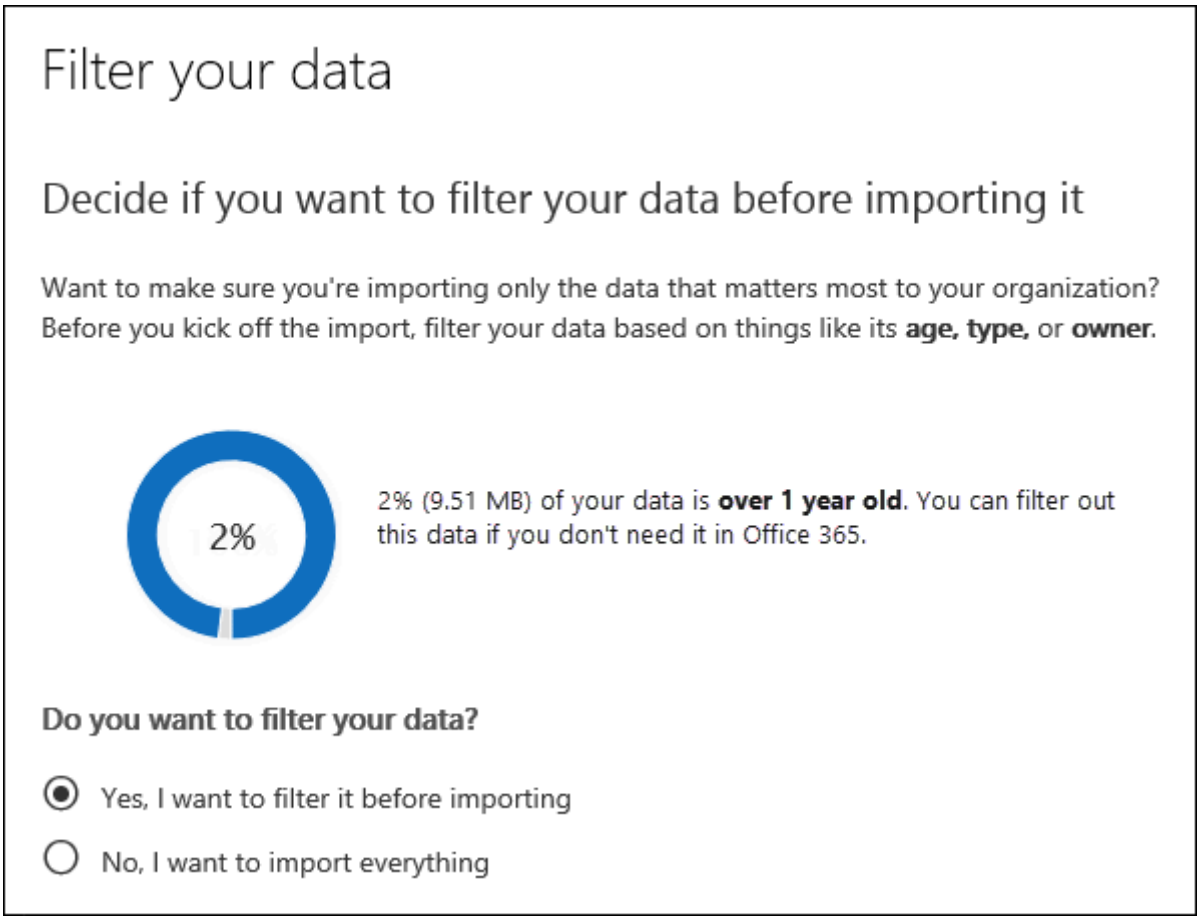
Filter data that gets imported to mailboxes

After you create a PST import job, follow these steps to filter the data before you import it to Microsoft 365.

1. Go to the Microsoft Purview portal and sign in by using the credentials for an administrator account in your organization.

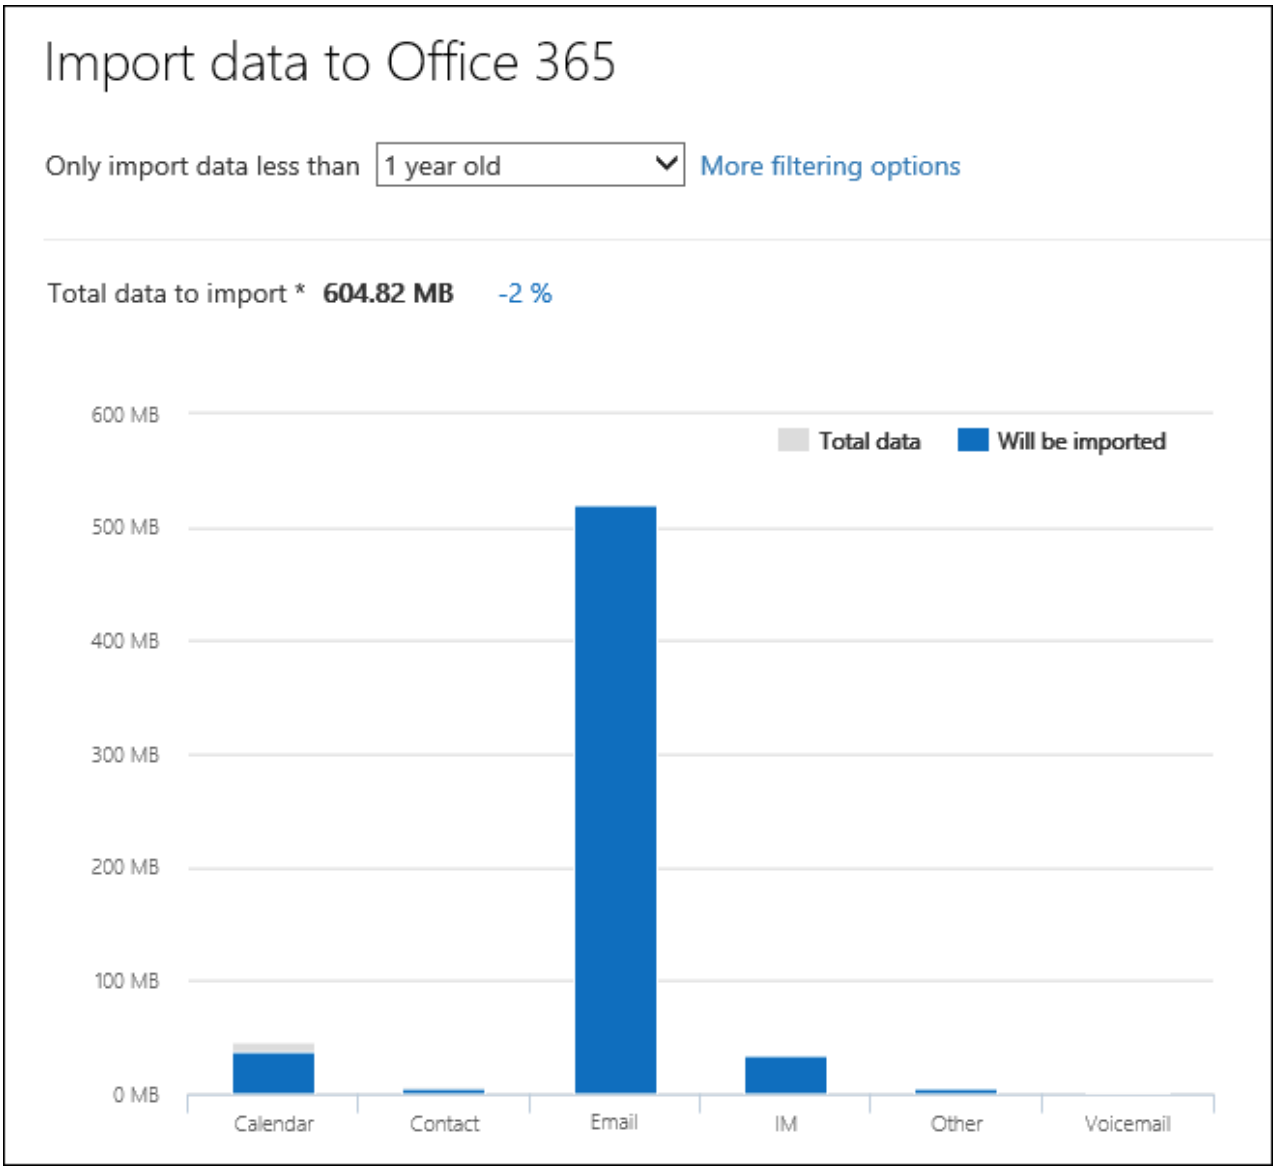
2. In the left pane of the Microsoft Purview portal, select **Data lifecycle management** > **Microsoft 365** > **Import**.

   The **Import** tab lists the import jobs for your organization. The **Analysis completed** value in the **Status** column indicates the import jobs that Microsoft 365 analyzed and are ready for you to import.



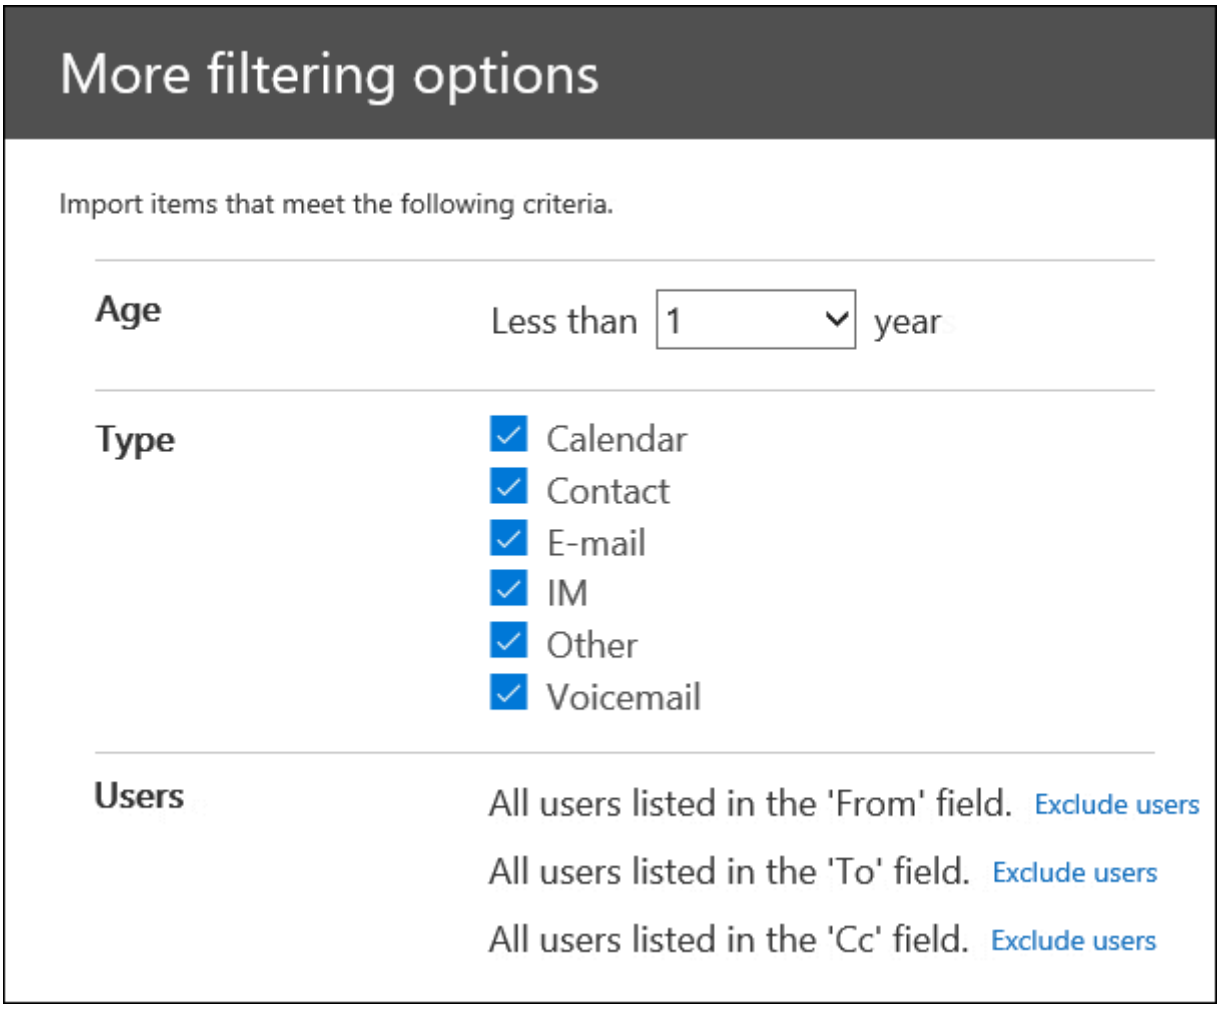
3. Select the import job that you want to complete and select **Import to Microsoft 365**.

   A flyout page is displayed with information about the PST files and other information about the import job.



4. Select **Import to Microsoft 365**.

   The **Filter your data** page is displayed. It contains data insights about the data in the PST files for the import job, including information about the age of the data.



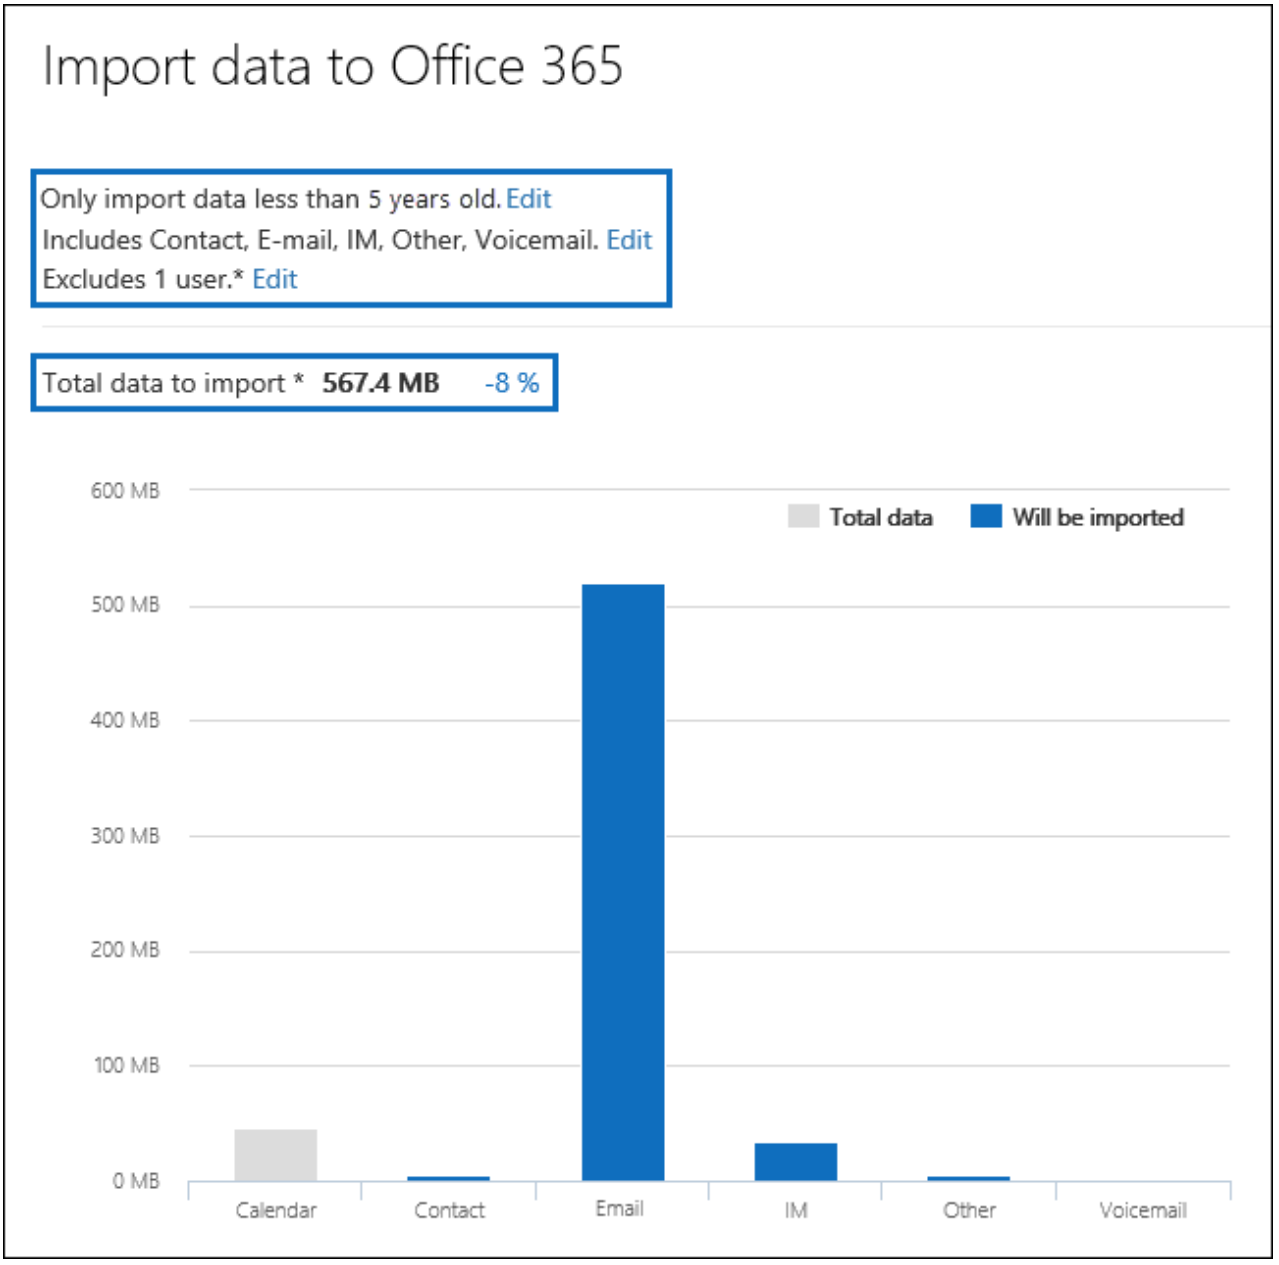
5. Based on whether you want to trim the data that's imported to Microsoft 365, under **Do you want to filter your data?**, do one of the following steps:
   a. Select **Yes, I want to filter it before importing** to trim the data that you import, and then select **Next**.

   The **Import data to Microsoft 365 page** is displayed with detailed data insights from the analysis that Microsoft 365 performed.

The graph on this page shows the amount of data that you import. It displays information about each message type found in the PST files. You can hover the cursor over each bar to display specific information about that message type. There's also a drop-down list with different age values based on the analysis of the PST files. When you select an age in the drop-down list, the graph is updated to show how much data is imported for the selected age.

a. To configure addition filters to reduce the amount of data that's imported, select **More filtering options**.

You can configure these filters:



- **Age** - Select an age so only items that are newer than the specified age are imported. See the More information section for a description about how Microsoft 365 determines the age buckets for the **Age** filter.
- **Type** - This section shows all the message types that Microsoft 365 found in the PST files for the import job. You can clear a check box next to a message type that you want to exclude. You can't exclude the Other message type. See the More information section for a list of mailbox items that are included in the Other category.
- **Users** - You can exclude messages that are sent or received by specific people. To exclude people who appear in the From: field, To: field, or the Cc: field of messages, select **Exclude users** next to that recipient type. Type the email address (SMTP address) of the person, select **Add+** to add them to the list of excluded users for that recipient type, and then select **Save** to save the list of excluded users.

  > ⓘ Note

> Microsoft 365 doesn't show data insights that result from setting the **People** filter. However, if you set this filter to exclude messages sent or received by specific people, those messages are excluded during the actual import process.

a. Select **Apply** in the **More filtering options** flyout page to save your filter settings.

The data insights on the **Import data to Microsoft 365** page are updated based on your filter settings, including the total amount of data that you import based on the filter settings. A summary of the filter settings is also shown. You can select **Edit** next to a filter to change the setting if necessary.

a. Select **Next**.

A status page is displayed showing your filter settings. Again, you can edit any of the filter settings.

a. Select **Import data** to start the import. The total amount of data that you import is displayed.

Or

a. Select **No, I want to import everything** to import all data in the PST files to Microsoft 365, and then select **Next**.

b. On the **Import data to Microsoft 365** page, select **Import data** to start the import. The total amount of data that will be imported is displayed.

6. On the **Import** tab, select **Refresh**. The **Status** column displays the status for the import job.

7. Select the import job to display more detailed information, such as the status for each PST file and the filter settings that you configured.

More information

- How does Microsoft 365 determine the increments for the age filter? When Microsoft 365 analyzes a PST file, it looks at the sent or received timestamp of each item. If an item has both a sent and received timestamp, Microsoft 365 selects the oldest date. Then Microsoft 365 looks at the year value for that timestamp and compares it to the current date to determine the age of the item. The software uses these ages as the values in the drop-down list for the **Age** filter. For example, if a PST file has messages from 2016, 2015, and 2014, the values in the **Age** filter are **1 year**, **2 years**, and **3 years**.

- The following table lists the message types that the **Other** category includes in the **Type** filter on the **More options** flyout page (see Step 5b in the previous procedure). Currently, you can't exclude items in the **Other** category when you import PSTs to Microsoft 365.

Expand table

Message class ID	Mailbox items that use this message class
IPM.Activity	Journal entries
IPM.Document	Documents and files (not attached to an email message)
IPM.File	(same as IPM.Document)
IPM.Note.IMC.Notification	Reports sent by Internet Mail Connect, which is the Exchange Server gateway to the Internet
IPM.Note.Microsoft.Fax	Fax messages
IPM.Note.Rules.Oof.Template.Microsoft	Out-of-office autoreply messages
IPM.Note.Rules.ReplyTemplate.Microsoft	Replies sent by an inbox rule

Message class ID	Mailbox items that use this message class
IPM.OLE.Class	Exceptions for a recurring series
IPM.Recall.Report	Message recall reports
IPM.Remote	Remote mail messages
IPM.Report	Item status reports

FAQ about importing PST files

This article is for administrators. Do you want to import PST files to your own mailbox? See Import email, contacts, and calendar from an Outlook .pst file

This article answers frequently asked questions about importing PST files to Microsoft 365 mailboxes. For requirements, limits, and planning guidance, see Learn about importing PST files.

For step-by-step instructions, see Use network upload to import PST files or Use drive shipping to import PST files. To learn about filtering imported data, see Filter data when importing PST files.

General

How does the PST import process handle duplicate email items?

The PST import process uses a SourceEntryId-based matching system to detect duplicate items. During import, each PST item's EntryId is stamped as a SourceEntryId property on the imported item in the target mailbox. The import process then checks for this property to determine whether an item was previously imported.

It's important to understand how this matching works in different scenarios:

- **Reimporting the same PST file to the same target folder**. Items imported during a previous import job already have a SourceEntryId stamp. The import process matches on this property and skips the item, preventing duplicates.
- **First-time import of a PST file**. Items that already exist natively in the target mailbox (items that weren't previously imported from a PST file) don't have a SourceEntryId property. Because no match is found, the import process copies the PST item to the mailbox, which can result in duplicate items.
- **Importing a different PST file that contains overlapping content**. SourceEntryId values differ between PST files. Even if a different PST file contains the same email content, the import process doesn't find a matching SourceEntryId and copies the item, which can result in duplicates.
- **Reimporting the same PST file to a different target folder**. If you specify a different target folder (using the TargetRootFolder property in the PST import mapping file) than the one

specified in a previous import job, all items in the PST file are reimported because the import process checks for matches only within the specified target folder.

The import process doesn't use content-based matching criteria such as message subject, date, body, or size to detect duplicates. The conflict resolution behavior (keeping the existing target item when a match is found) is built in to the import service and isn't configurable through the Microsoft Purview portal or the CSV mapping file.

Are message properties, such as when the message was sent or received, the list of recipients and other properties, preserved when PST files are imported to a Microsoft 365 mailbox?

Yes. The original message metadata isn't changed during the import process.

Are there any screen resolution requirements when I create an import job?

If the screen resolution on your local computer is set to 1366 x 768, you may have issues creating an import job. If so, we recommend that you change the screen resolution to a different setting and then create a new import job. We're working to fix this issue.

Network upload

After I upload my PST files to the Azure Storage area, how long are they kept in Azure before they're deleted?

When you use the network upload method to import PST files, you upload them to an Azure blob container named `ingestiondata`. If there are no import jobs in progress on the **Import PST files** page in the Microsoft Purview portal, then all PST files in the `ingestiondata` container in Azure are deleted 30 days after the most recent import job was created in the Microsoft Purview portal. That also means you have to create a new import job in the Microsoft Purview portal (described in Step 5 in the network upload instructions) within 30 days of uploading PST files to Azure.

This also means that after PST files are deleted from the Azure Storage area, they're no longer displayed in the list of files for a completed import job in the Microsoft Purview portal. Although

an import job might still be listed on the **Import PST files** page in the Microsoft Purview portal, the list of PST files might be empty when you view the details of older import jobs.

Drive shipping

After I ship my hard drive, how long does it take to get to the Microsoft data center?

That depends on a few things, such as your proximity to the Microsoft data center and what kind of shipping option you used to ship your hard drive (such as, next-day delivery, two-day delivery, or ground-delivery). With most shippers, you can use the tracking number to track the status of your delivery.

After Microsoft uploads my PST files to Azure, how long are they kept in Azure before they're deleted?

All PST files in the Azure Storage location for your organization (in blob container named `ingestiondata`), are deleted 30 days after the most recent import job was created on the **Import PST files** page in the Microsoft Purview portal.

This also means that after PST files are deleted from the Azure Storage area, they're no longer displayed in the list of files for a completed import job in the Microsoft Purview portal. Although an import job might still be listed on the **Import PST files** page in the Microsoft Purview portal, the list of PST files might be empty when you view the details of older import jobs.

Can Microsoft wipe my hard drive before they ship it back to me?

No, Microsoft can't wipe hard drives before shipping them back to customers. Hard drives are returned to you in the same state they were in when they were received by Microsoft.

Can Microsoft shred my hard drive instead of shipping it back to me?

No, Microsoft can't destroy your hard drive. Hard drives are returned to you in the same state they were in when they were received by Microsoft.

What courier services are supported for return shipping?

If you're a customer in the United States or Europe, Microsoft uses FedEx to return your hard drive. For all other regions, Microsoft uses DHL.

What are the return shipping costs?

Return shipping costs vary, depending on your proximity to the Microsoft data center that you shipped your hard drive to. Microsoft bills your FedEx or DHL account to return your hard drive. The cost of return shipping is your responsibility.

Can I use a custom courier shipping service, such as FedEx Custom Shipping, to ship my hard drive to Microsoft?

Yes.

If I have to ship my hard drive to another country/region, is there anything I need to do?

The hard drive that you ship to Microsoft might have to cross international borders. If so, you're responsible for ensuring that the hard drive and the data it contains are imported and/or exported in accordance with the applicable laws. Before shipping a hard drive, check with your advisors to verify that your drive and data can legally be shipped to the specified Microsoft data center. This helps to ensure that it reaches Microsoft in a timely manner.

Learn about records management

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*

A records management system, also known as records and information management, is a solution for organizations to manage regulatory, legal, and business-critical records. Records management for Microsoft Purview helps you achieve your organization's legal obligations, provides the ability to demonstrate compliance with regulations, and increases efficiency with regular disposition of items that are no longer required to be retained, no longer of value, or no longer required for business purposes.

Use the following capabilities to support your records management solution for Microsoft 365 data:

- **Label items as a record**. Create and configure retention labels to mark items as a record that can then be applied by users or automatically applied by identifying sensitive information, keywords, or content types.
- **Migrate and manage your retention requirements with file plan**. By using a file plan, you can bring in an existing retention plan to Microsoft 365, or build a new one for enhanced management capabilities.
- **Configure retention and deletion settings with retention labels**. Configure retention labels with the retention periods and actions based on various factors that include the date last modified or created.
- **Start different retention periods when an event occurs** with event-based retention.
- **Review and validate disposition** with disposition reviews and proof of records deletion.
- **Export information about all disposed items** with the export option.
- **Set specific permissions** for records manager functions in your organization to have the right access.

Using these capabilities, you can incorporate your organization's retention schedules and requirements into a records management solution that manages retention, records declaration, and disposition, to support the full lifecycle of your content.

In addition to the online documentation, you might find it useful to download a deck with FAQs from a records management webinar. The recording of the actual webinar is no longer available.

Records

When an item is declared a record by using a retention label:

- Restrictions are placed on the item in terms of what actions are allowed or blocked.
- Additional activities about the item are logged.
- You have proof of disposition when the item is deleted at the end of their retention period.

You use retention labels to mark items as a **record**, or a **regulatory record**. The difference between these two are explained in the next section. You can either publish those labels so that users and administrators can manually apply them to items, or for labels that mark items as a record, you can auto-apply those labels.

By using retention labels to declare records, you can implement a single and consistent strategy for managing records across your Microsoft 365 environment.

Compare restrictions for what actions are allowed or blocked

Use the following table to identify what restrictions are placed on items as a result of applying a standard retention label, and retention labels that mark items as a record or regulatory record.

A standard retention label has retention settings and actions but doesn't mark items as a record or a regulatory record.

> **Note**
>
> For completeness, the table includes columns for a locked and unlocked record, which is applicable to SharePoint and OneDrive, but not Exchange. The ability to lock and unlock a record uses record versioning that isn't supported for Exchange items. So for all Exchange items that are marked as a record, the behavior maps to the **Record - locked** column, and the **Record - unlocked column** is not relevant.

Expand table

Action	Retention label	Record - locked	Record - unlocked	Regulatory record
Edit contents	Allowed	**Blocked**	Allowed	**Blocked**

Action	Retention label	Record - locked	Record - unlocked	Regulatory record
Edit properties, including rename	Allowed	Allowed [1]	Allowed	**Blocked**
Delete	Allowed [2]	**Blocked**	**Blocked**	**Blocked**
Copy	Allowed	Allowed	Allowed	Allowed
Move within container [3]	Allowed	Allowed	Allowed	Allowed
Move across containers [3]	Allowed	Allowed if never unlocked	**Blocked**	**Blocked**
Open/Read	Allowed	Allowed	Allowed	Allowed
Change label	Allowed	Allowed - container admin only	**Blocked**	**Blocked**
Remove label [4]	Allowed	Allowed - container admin only	**Blocked**	**Blocked**
Override with priority cleanup	Allowed	**Blocked**	**Blocked**	**Blocked**

Footnotes:

[1] Editing properties for a locked record is allowed by default but can be blocked by a tenant setting in the Microsoft Purview portal: Sign in to the Microsoft Purview portal > **Settings** > **Solutions settings** > **Records Management** > **Retention Labels** > **Allow editing of record properties**

[2] Deleting labeled items in SharePoint and OneDrive can be blocked as a tenant setting in the Microsoft Purview portal: Sign in to the Microsoft Purview portal > **Settings** > **Solutions settings** > **Records Management** > **Retention Labels** > **Deletion of items**.

When you apply a standard retention label to a list item that has a document attachment, that document doesn't inherit the retention settings and can be deleted from the list item. In comparison, if that retention label marked items as a record or regulatory record, the document attachment would inherit the retention settings and couldn't be deleted.

[3] Containers include SharePoint sites, OneDrive accounts, and Exchange mailboxes.

[4] Labels can be removed from items even if the labels are no longer published.

> **Important**

The most important difference for a regulatory record is that after it is applied to content, nobody, not even a global administrator, can remove the label.

Retention labels configured for regulatory records also have the following admin restrictions:

- The retention period can't be made shorter after the label is saved, only extended.
- These labels aren't supported by auto-labeling policies, and must be applied by using retention label policies.

In addition, a regulatory label can't be applied to a document that's checked out in SharePoint.

Because of the restrictions and irreversible actions, make sure you really do need to use regulatory records before you select this option for your retention labels. To help prevent accidental configuration, this option is not available by default but must first be enabled by using PowerShell. Instructions are included in Declare records by using retention labels.

Validating migrated records

If you're migrating files to SharePoint or OneDrive and your organization needs to manage these items as records, you might need to validate that the files haven't been altered and retain their immutability status. For example, you're using a migration solution and need to meet the chain of custody requirements. Typical file properties and methods often used for this type of validation, such as file size or file hash, might not be sufficient because SharePoint automatically updates the metadata for a file when it's uploaded.

Instead, to validate your migrated files, you can use the value of the `vti_writevalidationtoken` property, which is a base64-encoded XOR hash of the file before it is modified by SharePoint. Use the following steps:

1. Generate the XOR hash of the original file by using the QuickXorHash algorithm. For more information, see the QuickXorHash Algorithm code snippet.
2. Base64-encode the XOR hash. For more information, see the Base64Encode method documentation.
3. After the file is migrated, retrieve the value of the `vti_writevalidationtoken` property from the uploaded file.

4. Compare the value generated in step 2 with the value retrieved in step 3. These two values should match. If they do, you've validated that the file hasn't changed.

Configuration guidance

See Get started with records management. This article has information about subscriptions, permissions, and links to end-to-end configuration guidance for records management scenarios.

Regulatory requirements for data lifecycle management and records management

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

Use the resources on this page to help you meet specific regulatory requirements for data lifecycle management and records management in Microsoft 365. Each section of this document focuses on one or more related regulations and includes any existing guidance or third-party assessment of how to configure Microsoft 365 to help with the requirements outlined.

These resources are available to download from the Data Protection Resources, FAQ, and White Papers page of the Service Trust Portal.

New Zealand Public Records Act

Supporting New Zealand's Public Records Act compliance obligations with Microsoft 365 - Download assessment

Applicable workloads: SharePoint, OneDrive, Teams, and Exchange

Released January 2021, this report has been produced in partnership with Microsoft New Zealand to assess the capabilities of Microsoft 365 services for recording, storing, and managing requirements for electronic records, as specified by:

- New Zealand Public Records Act 2005, which sets guidelines for preservation of public archives and local authority archives in New Zealand.

This report helps you understand how the system aspects of the New Zealand Public Records Act 2005 (PRA) are achievable when using Microsoft 365.

SEC 17a-4(f), FINRA 4511(c), and CFTC 1.31(c)-(d)

Cohasset Assessment - Microsoft 365 - SEC Rule 17a-4(f) - Immutable Storage for SharePoint, OneDrive, Exchange, Teams, and Viva Engage - Download assessment

Applicable workloads: SharePoint, OneDrive, Teams, Exchange, and Viva Engage

Latest version released July 2022, this report has been produced in partnership with Cohasset Associates, Inc. (Cohasset) to assess the capabilities of Microsoft 365 services for recording,

storing, and managing requirements for electronic records, as specified by:

- Securities and Exchange Commission (SEC) in 17 CFR § 240.17a-4(f), which regulates exchange members, brokers or dealers.
- Financial Industry Regulatory Authority (FINRA) Rule 4511(c), which defers to the format and media requirements of SEC Rule 17a-4(f).
- The principles-based electronic records requirements of the Commodity Futures Trading Commission (CFTC) in 17 CFR § 1.31(c)-(d).

The opinion from Cohasset is that when compliance features are properly configured and carefully applied and managed as described in their report, the assessed Microsoft 365 services meet the five requirements related to the recording and non-rewriteable, non-erasable storage of electronic records.

Declare records by using retention labels

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

To declare documents and emails as records, you use retention labels that mark the content as a **record** or a **regulatory record**.

If you're not sure whether to use a record or a regulatory record, see Compare restrictions for what actions are allowed or blocked. If you need to use regulatory records, you must first run a PowerShell command, as described in the next section.

You can then either publish those labels in a retention label policy so that users and administrators can apply them to content, or for labels that mark items as records (but not regulatory records), auto-apply those labels to content that you want to declare a record.

How to display the option to mark content as a regulatory record

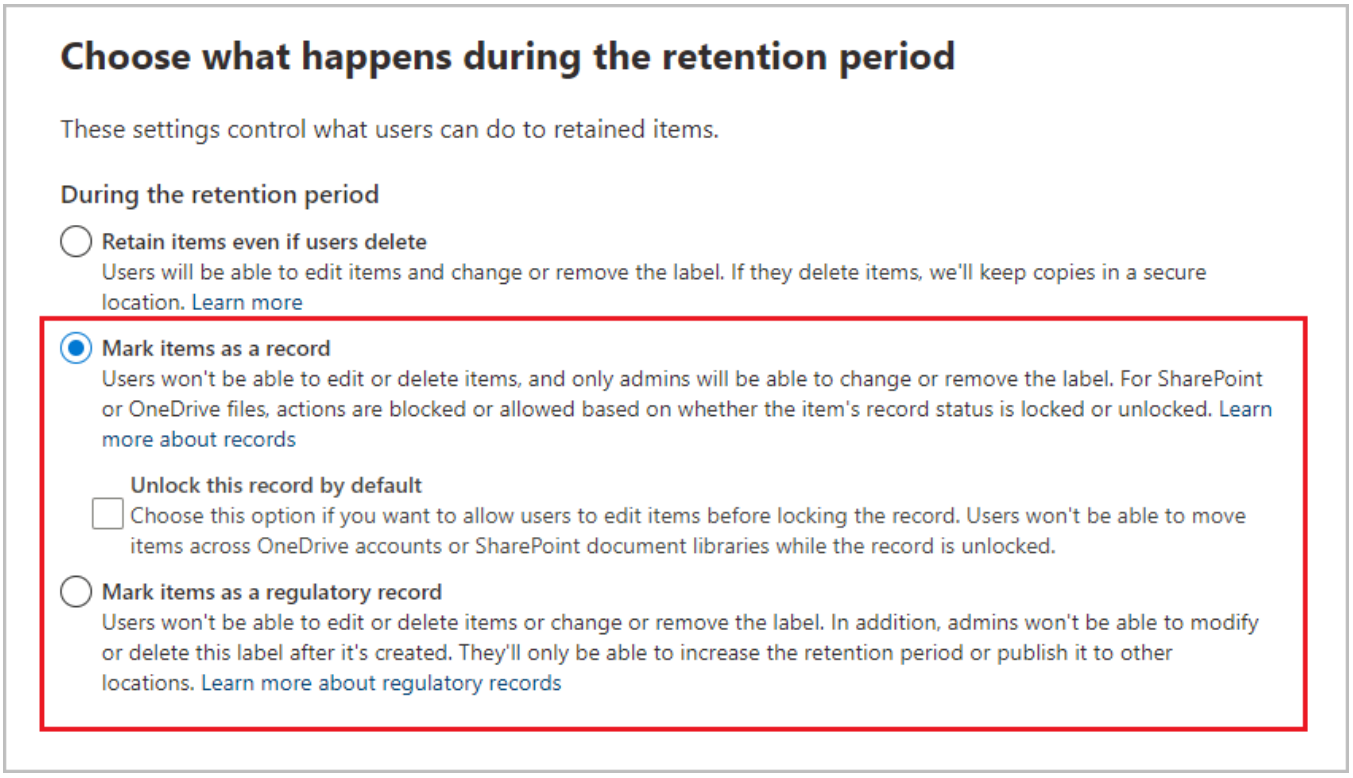
> **Note**
>
> The following procedure is an auditable action, logging **Enabled regulatory record option for retention labels** in the Retention policy and retention label activities section of the audit log.

By default, the retention label option to mark content as a regulatory record isn't displayed in the retention label wizard. To display this option, you must first run a PowerShell command:

1. Connect to the Office 365 Security & Compliance PowerShell.
2. Run the following cmdlet:

   ```
   PowerShell
   Set-RegulatoryComplianceUI -Enabled $true
   ```

   There is no prompt to confirm and the setting takes effect immediately.



If you change your mind about seeing this option in the retention label wizard, you can hide it again by running the same cmdlet with the **false** value: `Set-RegulatoryComplianceUI -Enabled`

`$false`

Configuring retention labels to declare records

When you create a retention label from the **Records Management** solution in the Microsoft Purview portal, you have the option to mark items as a record. If you ran the PowerShell command from the previous section, you can alternatively mark items as a regulatory record.

For example:

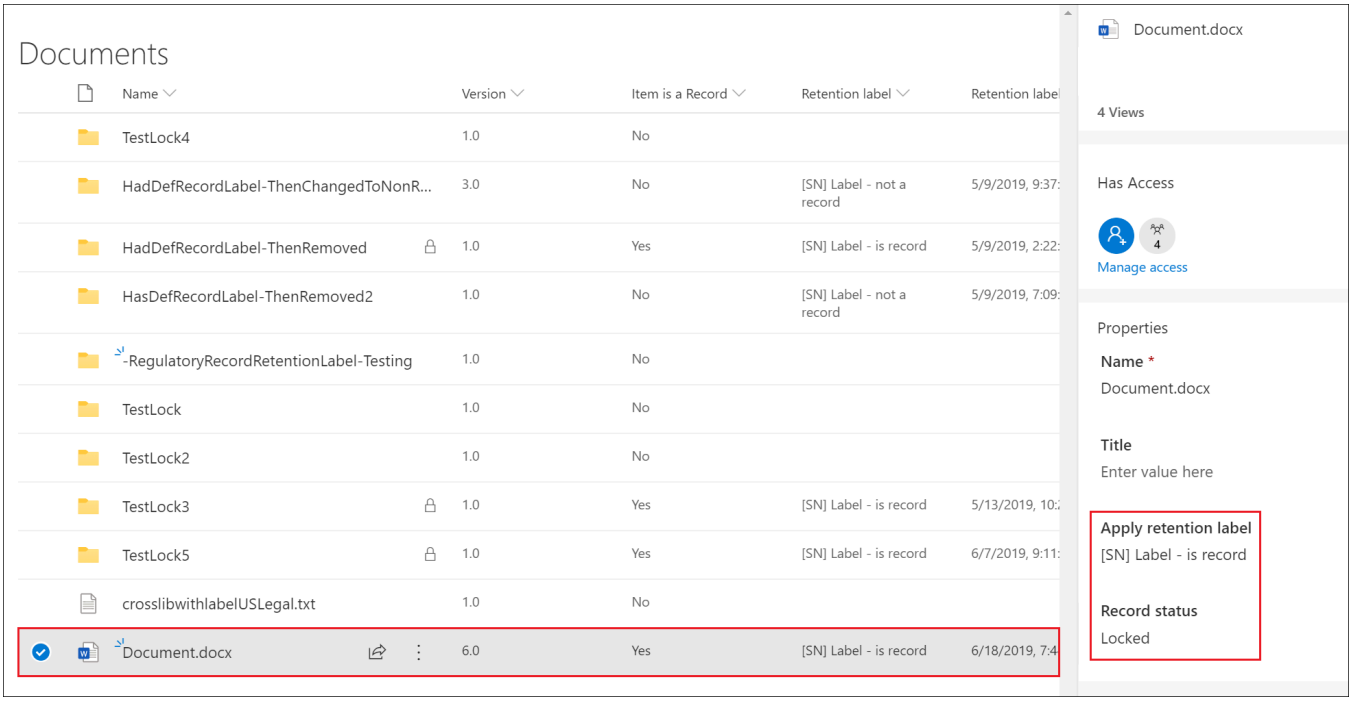
Using this retention label, you can now apply it to SharePoint or OneDrive documents and Exchange emails, as needed.

For full instructions:

- Publish retention labels and apply them in apps
- Apply a retention label to content automatically (not supported for regulatory records)

Tenant setting for editing record properties

If you'll use retention labels to declare items as records (rather than regulatory records) in SharePoint and OneDrive, consider whether you need to change the default tenant setting that allows users to edit the properties for a locked record when files are larger than 0 bytes.



To change this default, turn off the setting **Allow users to edit record properties**: Sign in to the Microsoft Purview portal > **Settings** > **Solutions settings** > **Records Management** > **Retention Labels** > **Allow users to edit record properties**

Applying the configured retention label to content

When retention labels that mark items as a record or regulatory record are made available for users to apply them in apps:

- For Exchange, any user with write-access to the mailbox can apply these labels.
- For SharePoint and OneDrive, any user in the default Members group (the Contribute permission level) can apply these labels.

Example of a document marked as record by using a retention label:

Searching the audit log for labeled items that were declared records

The actions of labeling to declare items as records are logged in the audit log.

For SharePoint items:

- From **File and page activities**, select **Changed retention label for a file**. This audit event is for retention labels that mark items as records, regulatory records, or that are standard retention labels.

For Exchange items:

- From **Exchange mailbox activities**, select **Labeled message as a record**. This audit event is for retention labels that mark items as records or regulatory records.

For more information about these events, see Audit log activities.

Next steps

Understand how you can use record versioning to update records stored in SharePoint or OneDrive.

Use record versioning to update records stored in SharePoint or OneDrive

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

> **Note**
>
> Because regulatory records block editing, record versioning is not available for regulatory records.
>
> You can also prevent record versioning for your tenant, even if you're not using regulatory records. In the Microsoft Purview portal, go to **Settings**> **Records Management** > **Retention Labels** > **Configure record versioning** and then for **Configure record versioning**, turn off the setting for **Enable record versioning**.

The ability to mark a document as a record and restrict actions that can be performed on the record is an essential goal for any records management solution. However, collaboration might also be needed for people to create subsequent versions.

For example, you might mark a sales contract as a record, but then need to update the contract with new terms and mark the latest version as a new record while still retaining the previous record version. For these types of scenarios, SharePoint and OneDrive support *record versioning*. OneNote notebook folders don't support record versioning.

To use record versioning, you first label the document with a retention label that's configured to mark items as a record. At this point, a document property, called *Record status* is displayed next to the retention label. Depending on whether the label is configured to unlock the record by default, the initial record status is either **Locked** or **Unlocked**.

You can now do the following things:

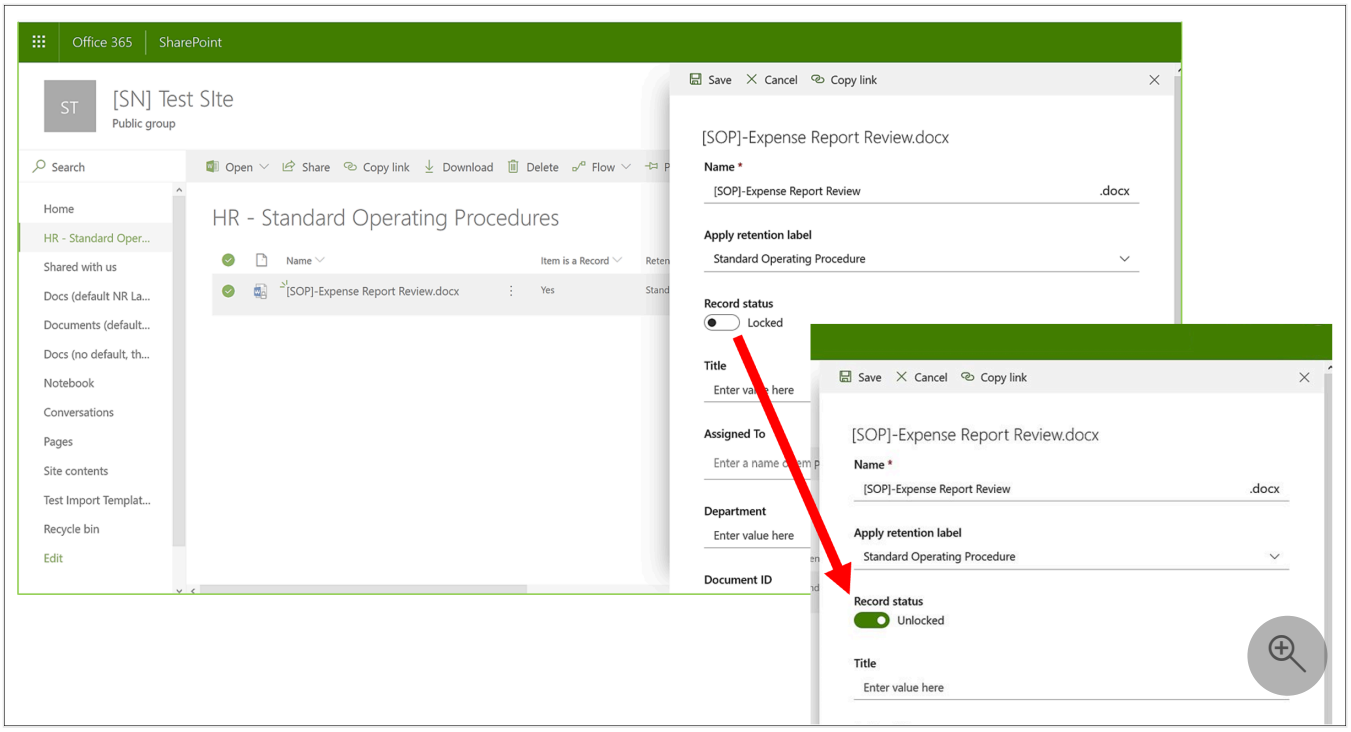
- **Continually edit and retain individual versions of the document as records, by unlocking and locking the Record status property.** Only when the **Record status** property is set to **Locked** is a new version of the record retained. This toggle of locked and unlocked reduces the risk of retaining unnecessary versions and copies of the document.

  > **Note**

If the label is configured to unlock the record by default, but versioning is not enabled by the admin, or prevented by the records management setting, users will not be able to unlock the document after they lock it.

- **Have the records automatically stored in an in-place records repository located with the site.** Each site in SharePoint and OneDrive preserves content in its Preservation Hold library. Record versions are stored in the Records folder in this library as individual files. For more information about how the Preservation Hold library works, see How retention works for SharePoint and OneDrive.

- **Maintain an evergreen document that contains all versions.** By default, each SharePoint and OneDrive document has a version history available on the item menu. In this version history, you can easily see which versions are records and view those documents.

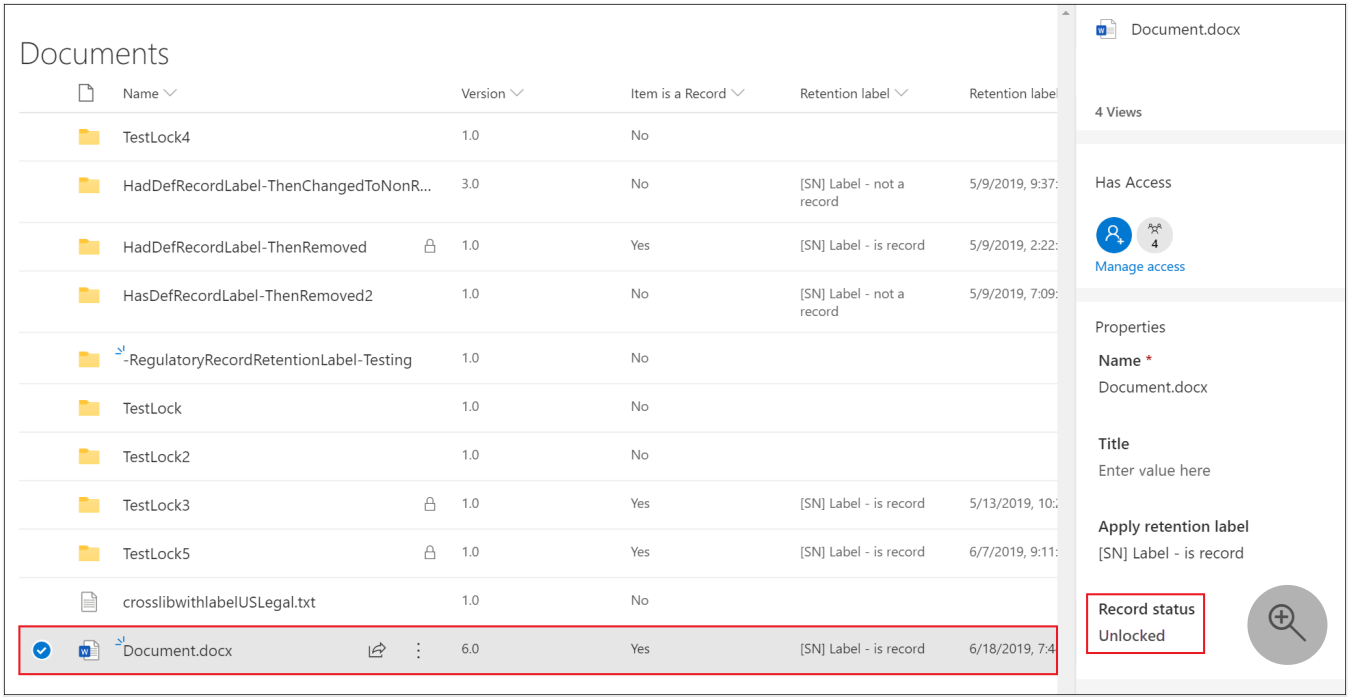


Tip

When you use record versioning with a retention label that has a delete action, consider configuring the retention setting **Start the retention period based on:** to be **When items were labeled**. With this label setting, the start of the retention period is reset for each new record version, which ensures that older versions will be deleted before newer versions.

If the retention label is configured for disposition review at the end of the retention period, each version undergoes its own disposition review.

By default, record versioning is automatically available for any document that has a retention label applied that marks the item as a record, and that label is published to the site. When a user views the document properties by using the details pane, they can toggle the **Record status** between **Locked** and **Unlocked**. A padlock icon might also be displayed for the document, to help identify when the file is locked.

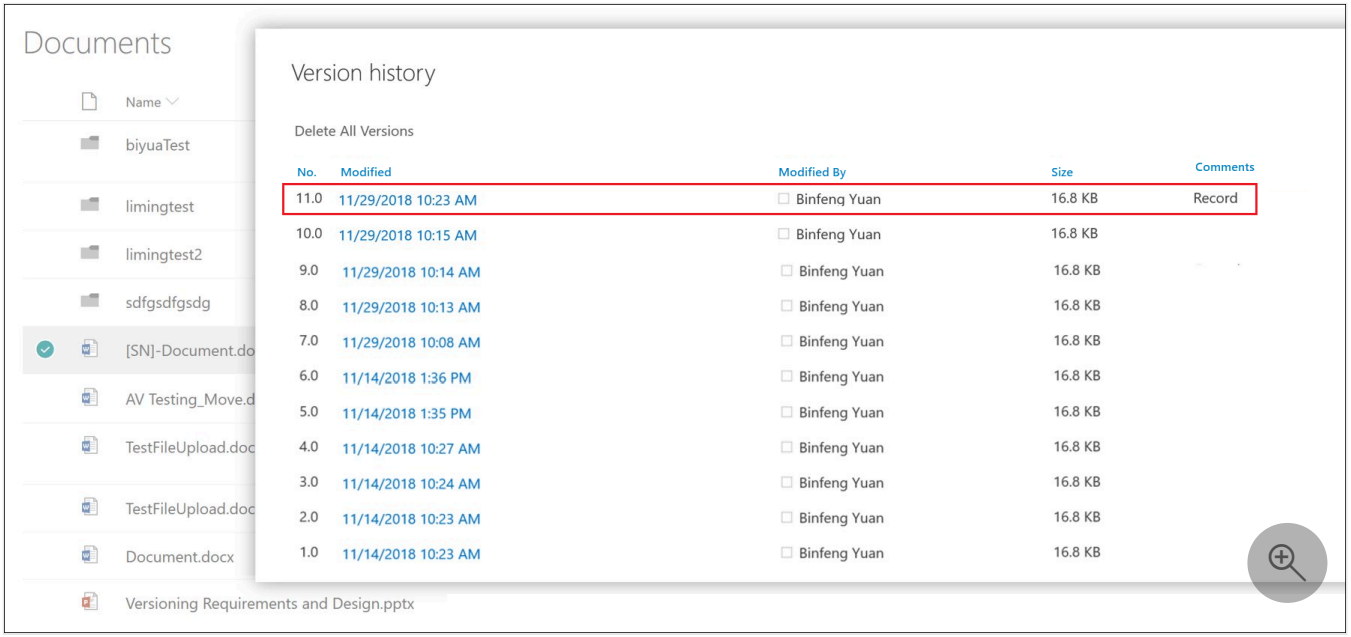


While the document is unlocked, any user with standard edit permissions can edit the file. However, users can't delete the file, because it's still a record. When editing is complete, a user can then toggle the **Record status** from **Unlocked** to **Locked**, which prevents further edits while in this status.

For more information about what user actions are allowed when a record is locked or unlocked, see Compare restrictions for what actions are allowed or blocked.

Locking and unlocking a record

After a retention label that marks content as a record is applied to a document, any user with Contribute permissions or a narrower permission level can unlock a record or lock an unlocked record.



When a record is unlocked, the following actions occur:

1. If the current site doesn't have a Preservation Hold library, one is created.
2. If the Preservation Hold library doesn't have a Records folder, one is created.
3. A **Copy to** action copies the latest version of the document to the Records folder. The **Copy to** action includes only the latest version and no prior versions. This copied document is now considered a record version of the document, and its file name has the format: [Title GUID Version#]
4. The copy created in the Records folder is added to the version history of the original document, and this version shows the word **Record** in the comments field.
5. The original document is a new version that can be edited, but not deleted. The document library column **Item is a Record** still shows the **Yes** value because the document is still a record, even if it can now be edited.

When a user locks a record, the original document again can't be edited. But it is the action of unlocking a record that copies a version to the Records folder in the Preservation Hold library.

Record versions

Each time a record is unlocked, the latest version is copied to the Preservation Hold library, and that version contains the value of **Record** in the **Comments** field of the version history.

To view the version history, select a document in the document library and then click **Version history** in the item menu.

Searching the audit log for record versioning events

The actions of locking and unlocking records are logged in the audit log. From **File and page activities**, select **Changed record status to locked** and **Changed record status to unlocked**.

For more information about searching for these events, see Audit log activities.

Next steps

For other scenarios supported by records management, see Common scenarios for records management.

Get started with records management

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

Ready to start managing your organization's high-value content for legal, business, or regulatory obligations by using a records management solution in Microsoft 365? Use the following guidance to get started:

1. **Understand how retention and deletion works** in Microsoft 365, and identify whether you need to use retention policies to supplement retention labels that manage documents and emails at the item level: Learn about retention policies and retention labels

   If necessary, create retention policies for baseline governance of data across Microsoft 365 workloads.

2. **Understand the records management solution** and how retention labels can be used to allow or block actions when documents and emails are declared records: Learn about records management

3. **Create your file plan for retention and deletion settings and actions, and when items should be marked as records** by importing an existing plan if you have one, or create new retention labels: Use file plan to create and manage retention labels

4. **Publish and apply your retention labels**. Retention labels are reusable building blocks that can be used in multiple policies and can be incorporated into user workflows:

   - Publish retention labels and apply them in apps
   - Apply a retention label to content automatically

> **Tip**
>
> If you're migrating records to Microsoft 365 and need to validate that they haven't been altered, see **Validating migrated records**.

Licensing and billing requirements

A number of different subscriptions support records management and the licensing requirements for users depends on the features you use.

To see the options for licensing your users to benefit from Microsoft Purview features, see the Microsoft 365 licensing guidance for security & compliance. For Records Management, see the Microsoft Purview Data Lifecycle Management & Microsoft Purview Records Management section for feature-level licensing requirements.

You must set up pay-as-you-go billing to create retention policies that include the locations Microsoft Copilot experiences, Enterprise AI apps, and Other AI apps. There's no charge for Microsoft 365 Copilot interactions.

Permissions

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Members of your compliance team who are responsible for records management need permissions to the Microsoft Purview portal. To grant permissions for this limited administration, we recommend that you add users to the **Records Management** admin role group. This role group grants permissions for all features related to records management, which include the permissions to create and manage adaptive policy scopes, and disposition review and verification.

For a read-only role, you can create a new role group and add the **View-Only Record Management** role to this group.

For instructions to add users to the default roles or create your own role groups, see Permissions in the Microsoft Purview portal.

These permissions are required only to create, configure, and apply retention labels that declare records, and manage disposition. The person configuring these labels doesn't require access to the content.

Support for administrative units

Records management supports administrative units that have been configured in Microsoft Entra ID:

- You can assign administrative units to members of role groups that are used with Microsoft Purview Records Management. Edit the Records Management role group or

other role groups that support administrative units. From these role groups, select individual members, and then the **Assign admin units** option to select administrative units from Microsoft Entra ID. These administrators are now restricted to managing just the users in those administrative units.

- You can define the initial scope of retention policies and retention label policies when you create or edit these policies. When you select administrative units, only the users in those administrative units will be eligible for the policy.

  > **Important**
  >
  > Don't select administrative units for a retention label policy that you want to apply to SharePoint sites. Because administrative units support only users and groups, if you configure a retention label policy to use administrative units, you won't be able to select the locations for SharePoint sites.

- Both adaptive scopes and static scopes support administrative units.
- Additional impact for restricted administrators
  - Policy lookup: Restricted administrators will see policies only from users within their assigned administrative units
  - Disposition review and verification: Restricted administrators will be able to add reviewers only from within their assigned administrative units, and see disposition reviews and items disposed only from users within their assigned administrative units
- Currently, retention labels and events don't support administrative units.
- Currently, retention policies for Copilots and AI apps don't support administrative units.
- Currently, a restricted administrator can create and view adaptive scopes for all administrative units when they use PowerShell cmdlets.
- Currently, inactive mailboxes aren't supported in a policy when you select one or more administrative units. To include inactive mailboxes in the policy, you must be an unrestricted administrator and select **Full directory**.

For more information about how Microsoft Purview supports administrative units, see Administrative units.

Common scenarios

Use the following table to help you map your business requirements to the scenarios that are supported by records management.

> **Tip**
>
> Need to comply with a specific industry regulation? Check **Regulatory requirements for data lifecycle management and records management** for regulation-specific guidance.

Expand table

I want to ...	Documentation
Declare a record	Declare records by using retention labels
Update a record	Use record versioning to update records stored in SharePoint or OneDrive
Let admins and users manually apply retain and delete actions for documents and emails: - SharePoint - OneDrive - Outlook and Outlook on the web	Publish retention labels and apply them in apps
Let site admins set default retain and delete actions for all content in a SharePoint library, folder, or document set	Publish retention labels and apply them in apps
Let users automatically apply retain and delete actions to emails by using Outlook rules	Publish retention labels and apply them in apps
Let admins apply retain and delete actions to a Microsoft Syntex model, so that these settings are automatically applied to identified files in a SharePoint library	Publish retention labels and apply them in apps
Automatically apply retain and delete actions to documents and emails	Apply a retention label to content automatically
Automatically retain and delete Teams meeting transcripts or recordings and their accompanying transcripts	Apply a retention label to content automatically
Automatically retain and delete documents and emails with a specific sensitivity label	Apply a retention label to content automatically
Start the retention period when an event occurs, such as: - Employees leave the organization - Contracts expire - End of product lifetime	Start retention when an event occurs
Do custom actions or integrate with other solutions at the end of the retention period	Customize what happens at the end of the retention period

I want to ...	Documentation
Restrict changes to policies to help meet regulatory requirements or safeguard against rogue administrators	Use Preservation Lock to restrict changes to retention policies and retention label policies
Manage the lifecycle of different document types in SharePoint	Use retention labels to manage the lifecycle of documents stored in SharePoint
Apply a retention label to a file when I receive an alert that content containing personal data is being stored or remains untouched for too long	Investigate and remediate alerts in Privacy Risk Management
Make sure somebody reviews and approves before content is deleted at the end of its retention period	Disposition reviews
Have proof of disposition for content that is permanently deleted at the end of its retention period	Disposition of records
Monitor how and where retain and delete settings are applied to items	Monitoring retention labels
Programamtically create retention labels, and manage events and event type retention triggers	Microsoft Graph API for records management
Programmatically apply and manage retention labels in SharePoint and OneDrive	Microsoft Graph API for retention labels in SharePoint and OneDrive: - lock and unlock records - set retention labels - remove retention labels - get metadata for retention labels

End-user documentation

If you're using retention policies for baseline data governance, they typically work unobtrusively in the background without user interaction. As a result, they need little documentation for users. Retention policies for Teams inform users when their messages have been deleted with a link to Teams messages about retention policies.

In comparison, retention labels have a UI presence in Microsoft 365 apps, so make sure you provide guidance for end users and your help desk before these labels are deployed to your production network. To help users apply retention labels in SharePoint and OneDrive, and information about unlocking records for editing, see Apply retention labels to files in SharePoint or OneDrive.

However, the most effective end-user documentation will be customized guidance and instructions you provide for the retention label names and configurations you choose.

Use file plan to create and manage retention labels

Summarize this article for me

> *Microsoft Purview service description*

Although you can create and manage retention labels from **Data lifecycle management** in the Microsoft Purview portal, file plan from **Records management** has additional management capabilities:

- You can bulk-create retention labels by importing the relevant information from a spreadsheet.
- You can export the information from existing retention labels for analysis and offline collaboration.
- More information about the retention labels is displayed to make it easier to see into and across the settings of all your retention labels from one view.
- File plan descriptors support additional and optional information for each label.

File plan can be used for all retention labels, even if they don't mark content as a record.

For information about what retention labels are and how to use them, see Learn about retention policies and retention labels.

Accessing file plan

To access file plan, you must have one of the following admin roles:

- Retention Manager
- View-only Retention Manager

Then sign in to the Microsoft Purview portal > **Solutions** > **Records Management** > **File plan**.

Navigating your file plan

If you've already created retention labels from **Data lifecycle management** in the Microsoft Purview portal, these labels automatically display in your file plan.

Similarly, if you now create retention labels in file plan, they're also available from **Data lifecycle management** if the labels aren't configured to mark content as a record.

On the **File plan** page, you see all your labels with their status and settings, optional file plan descriptors, an export option to analyze or enable offline reviews of your labels, and an import option to create retention labels.

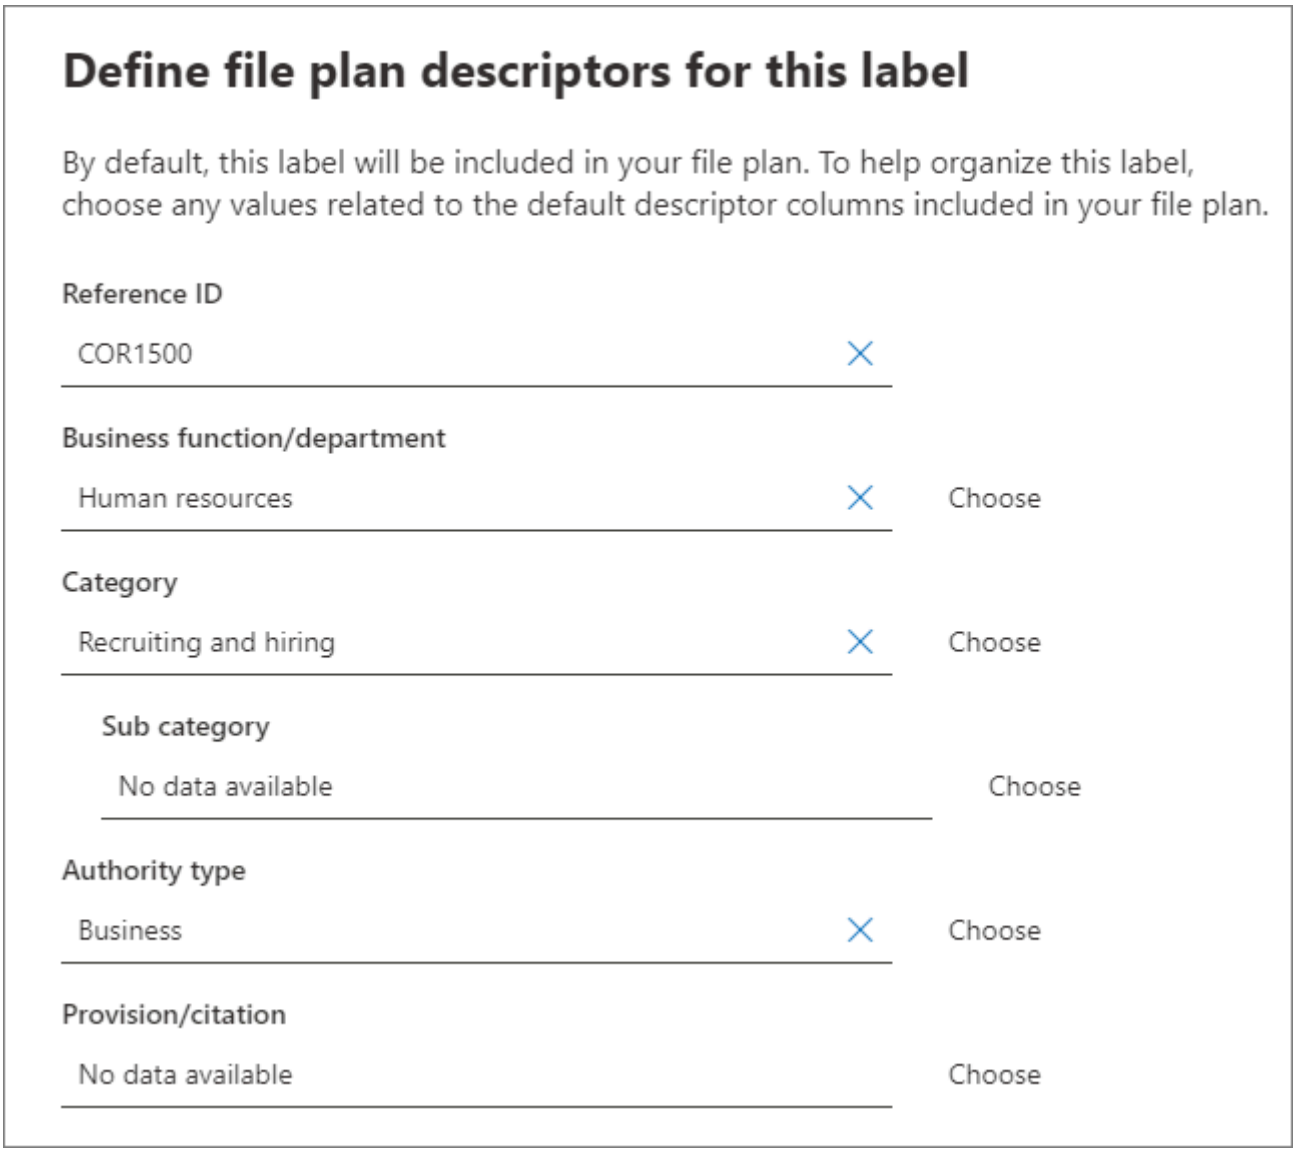
Label settings columns

All columns except the label **Name** can be displayed or hidden by selecting the **Customize columns** option. But by default, the first few columns display information about the label status and its settings:

- **Status** identifies whether the label is included in a label policy or auto-apply policy (**Active**) or not (**Inactive**).
- **Based on** identifies how or when the retention period begins. Valid values:
  - Event
  - When created
  - Last modified
  - When labeled
- **Is record** identifies if the item is marked as a record when the label is applied. Valid values:
  - No
  - Yes
  - Yes(Regulatory)
- **Is unlocked by default** identifies if the item marked as a record is unlocked when the label is applied. Valid values:
  - No
  - Yes
- **Relabel to** identifies if the label is configured to apply another label at the end of the retention period. Valid values:
  - Blank or the selected label name
- **Retention duration** identifies the retention period. Valid values:
  - Days
  - Months
  - Years
  - Forever
  - None

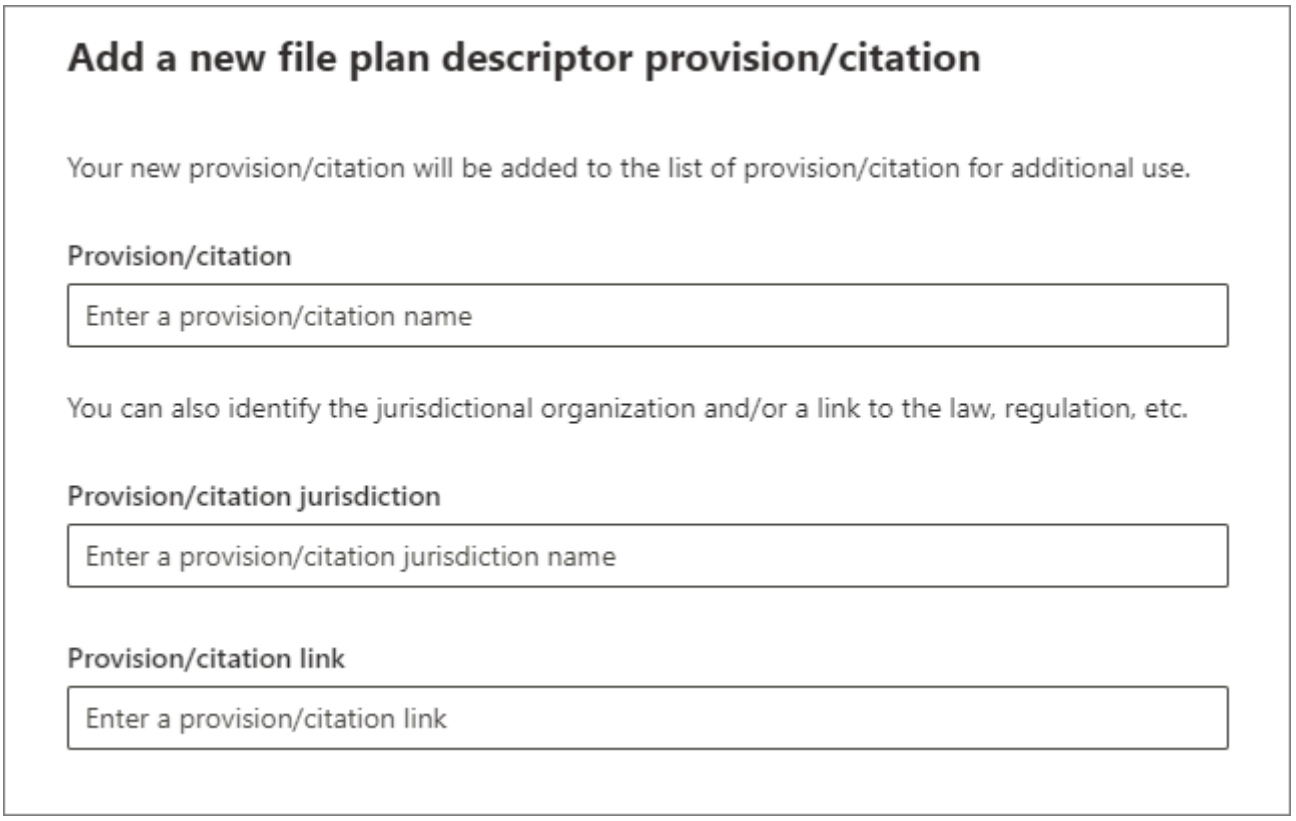
- **Disposition type** identifies what happens to the content at the end of the retention period. Valid values:
  - No action
  - Auto-delete
  - Review required

File plan descriptors columns



File plan lets you include more information as part of your retention labels. These file plan descriptors provide more options to improve the manageability and organization of the content you need to label.

By default, starting with **Reference ID**, the next few columns display these optional file plan descriptors that you can specify when you create a retention label, or edit an existing label.



To get you started, there are some out-of-box values for the following file plan descriptors:

- Business function/department
- Category
- Authority type
- Provision/citation

Example of file plan descriptors when you create or edit a retention label:

When you select **Choose** for each of these optional descriptors, you can select one of the out-of-box values, or create your own and then select it. For example:

Create retention labels

1. From the **File plan** page, select **+ Create a label** > **Retention label**

2. Follow the prompts for the configuration process. Be careful what name you choose, because this can't be changed after the label is saved.

   For more information about the retention settings, see Settings for retaining and deleting content.

   To use the retention label to declare records, select **Mark items as records**, or **Mark items as regulatory records**. For more information, see Configuring retention labels to declare records.

3. After you've created the label and you see the options to publish the label, auto-apply the label, or just save the label: Select **Just save the label for now**, and then select **Done**.

4. Repeat these steps to create more labels.

Edit retention labels

To edit an existing retention label, select it from the **File Plan** page, and then select the **Edit label** option to start the edit retention process that lets you change the label description and any eligible settings.

Some settings can't be changed after the label is created and saved, which include:

- The retention label name and the retention settings except the retention period.
- The option to mark items as a record.

Delete retention labels

You can delete retention labels that aren't currently included in any published or auto-apply retention label policies, that aren't configured for event-based retention, or that mark items as regulatory records.

For retention labels that you can delete, if they've been applied to items, the deletion fails and you see a link to content explorer to identify the labeled items.

However, it can take up to two days for content explorer to show the items that are labeled. In this scenario, the retention label might be deleted without showing you the link to content explorer.

Export all retention labels to analyze or enable offline reviews

From your file plan, you can export the details of all retention labels into a .csv file to help you facilitate periodic compliance reviews with data governance stakeholders in your organization.

To export all retention labels to *.csv file, navigate to the **File plan** page, and then select **Export**.

Import retention labels into your file plan

In file plan, you can bulk-import new retention labels by using a .csv file with a specific format:

1. Navigate to the **File plan** page, and then select **Import**.
2. On the **Fill out and import your file plan** pane, select **Download a blank template**.
3. After the template downloads, add one row for each label, and save the file. See the next section of this document for information about the properties and values for each.
4. Select **Upload a file** to upload and validate the completed template.
    - If validation fails: Note the row number and column name to correct in the import file. Correct the errors in the file and save it, and then retry.

- If validation passes: A success message displays and the entries are converted into retention labels.

You can now publish your new retention labels, or auto-apply them. You can do both from the **Label policies** tab by selecting **Publish labels**, or **Auto-apply a label**.

Information about the label properties for import

Use the following information to help you fill out the downloaded template to import new retention labels. Some values have a maximum length for import:

- **LabelName**: Maximum length of 64 characters
- **Comment** and **Notes**: Maximum length of 1024 characters
- All other values: Unlimited length

Expand table

Property	Type	Required	Valid values
LabelName	String	Yes	This property specifies the name of the retention label and must be unique in your tenant. Supported characters for import: a-z, A-Z, 0-9, hyphen (-) and the space character.
Comment	String	No	Use this property to add a description about the retention label for admins. This description appears only to admins who manage the retention label in the Microsoft Purview portal.
Notes	String	No	Use this property to add a description about the retention label for users. This description appears when users hover over the label in apps like Outlook, SharePoint, and OneDrive. If you leave this property blank, a default description is displayed, which explains the label's retention settings.
IsRecordLabel	String	No, unless **Regulatory** is **TRUE**	This property specifies whether the label marks the content as a record. Valid values are: **TRUE**: The label marks the item as a record and as a result, the item

Property	Type	Required	Valid values
			can't be deleted. **FALSE**: The label doesn't mark the content as a record. This is the default value. Group dependencies: When this property is specified, RetentionAction, RetentionDuration, and RetentionType must also be specified.
RetentionAction	String	No, unless **RetentionDuration**, **RetentionType**, or **ReviewerEmail** are specified	This property specifies what action to take after the value specified by the RetentionDuration property (if specified) expires. Valid values are: **Delete**: Items older than the value specified by the RetentionDuration property are deleted. **Keep**: Retain items for the duration specified by the RetentionDuration property and then do nothing when the duration period expires. **KeepAndDelete**: Retain items for the duration specified by the RetentionDuration property and then delete them when the duration period expires. Group dependencies: When this property is specified, RetentionDuration and RetentionType must also be specified.
RetentionDuration	String	No, unless **RetentionAction** or **RetentionType** are specified	This property specifies the number of days to retain the content. Valid values are: **Unlimited**: Items will be retained indefinitely. ***n**: A positive integer in days; for example, **365**. The maximum number supported is 36,525, which is 100 years. If you need longer than this maximum, use Unlimited instead. Group dependencies: When this

Property	Type	Required	Valid values
			property is specified, RetentionAction and RetentionType must also be specified.
RetentionType	String	No, unless **RetentionAction** or **RetentionDuration** are specified	This property specifies whether the retention duration (if specified) is calculated from the content creation date, event date, when labeled date, or last modified date. Valid values are: **CreationAgeInDays** **EventAgeInDays** **TaggedAgeInDays** **ModificationAgeInDays** Group dependencies: When this property is specified, RetentionAction and RetentionDuration must also be specified.
ReviewerEmail	SmtpAddress	No	When this property is specified, a disposition review will be triggered when the retention duration expires. This property specifies the email address of a reviewer in your tenant for the **KeepAndDelete** retention action. You can include the email address of individual users, distribution groups, or security groups in your tenant. Specify multiple email addresses by separating them with semicolons. Group dependencies: When this property is specified, **RetentionAction** (must be **KeepAndDelete**), **RetentionDuration**, and **RetentionType** must also be specified.
ReferenceId	String	No	This property specifies the value that's displayed in the **Reference Id** file plan descriptor, which you can

Property	Type	Required	Valid values
			use as a unique value to your organization.
DepartmentName	String	No	This property specifies the value that's displayed in the **Function/department** file plan descriptor.
Category	String	No	This property specifies the value that's displayed in the **Category** file plan descriptor.
SubCategory	String	No	This property specifies the value that's displayed in the **Sub category** file plan descriptor.
AuthorityType	String	No	This property specifies the value that's displayed in the **Authority type** file plan descriptor.
CitationName	String	No	This property specifies the name of the citation displayed in the **Provision/citation** file plan descriptor. For example, "Sarbanes-Oxley Act of 2002".
CitationUrl	String	No	This property specifies the URL that's displayed in the **Provision/citation** file plan descriptor.
CitationJurisdiction	String	No	This property specifies the jurisdiction or agency that's displayed in the **Provision/citation** file plan descriptor. For example, "U.S. Securities and Exchange Commission (SEC)".
Regulatory	String	No	This property specifies whether the label marks the content as a regulatory record, which is more restrictive than a record. To use this label configuration, your tenant must be configured to display the option to mark content as a regulatory record, or the import validation will fail. Valid values are: **TRUE**: The label marks the item as a regulatory record. You must also set

Property	Type	Required	Valid values
			the **IsRecordLabel** property to TRUE. **FALSE**: The label doesn't mark the content as a regulatory record. This is the default value.
EventType	String	No, unless **RetentionType** is **EventAgeInDays**	This property specifies an event type used for event-based retention. Specify an existing event type that's displayed in **Records management** > **Events** > **Manage event types**. Alternatively, use the Get-ComplianceRetentionEventType cmdlet to view the available event types. Although there are some built-in event types, such as **Employee activity** and **Product lifetime**, you can also create your own event types. If you specify your own event type, it must exist before the import because the name is validated as part of the import process.
IsRecordUnlockedAsDefault	String	No	This property specifies whether the item marked as a record is unlocked when the label is applied. Valid values are: **TRUE**: The item marked as a record is unlocked when the label is applied. The **IsRecordLabel** property must be set to TRUE and the property **Regulatory** can't be set to TRUE. **FALSE**: The item isn't marked as a record or is marked as record but locked when the label is applied. This is the default value.
ComplianceTagForNextStage	String	No	This property specifies the name of a replacement label to be applied at the end of the retention period. Do not specify this property if **Regulatory** is **TRUE**.

Label settings not currently supported for import:

- Multi-stage disposition review: Although you can configure the settings for a single disposition review stage when you import retention labels with a template, you can't specify additional review stages. Instead, configure these in the Microsoft Purview portal after the import succeeds.

Next steps

Now you've created retention labels, they're ready to be added to items by publishing the labels, or automatically applying them:

- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

Last updated on 02/27/2026

Start retention when an event occurs

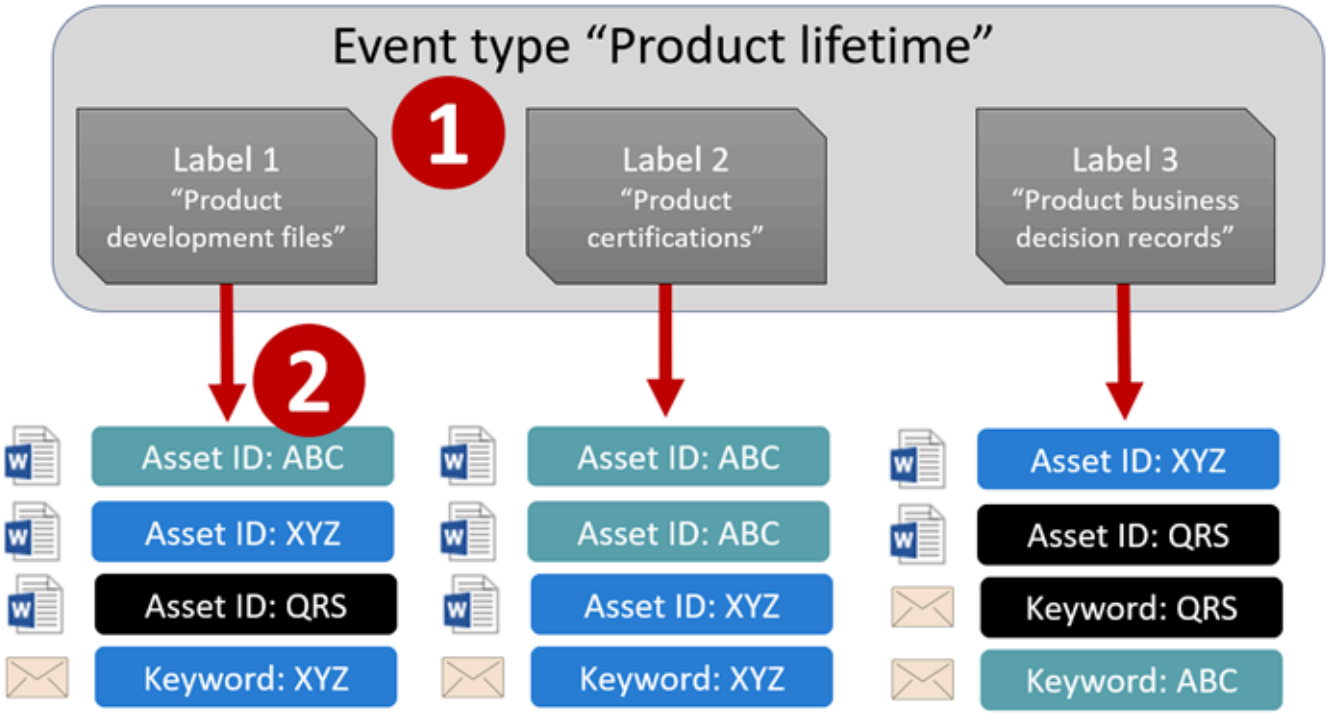
Summarize this article for me

> *Microsoft Purview service description*

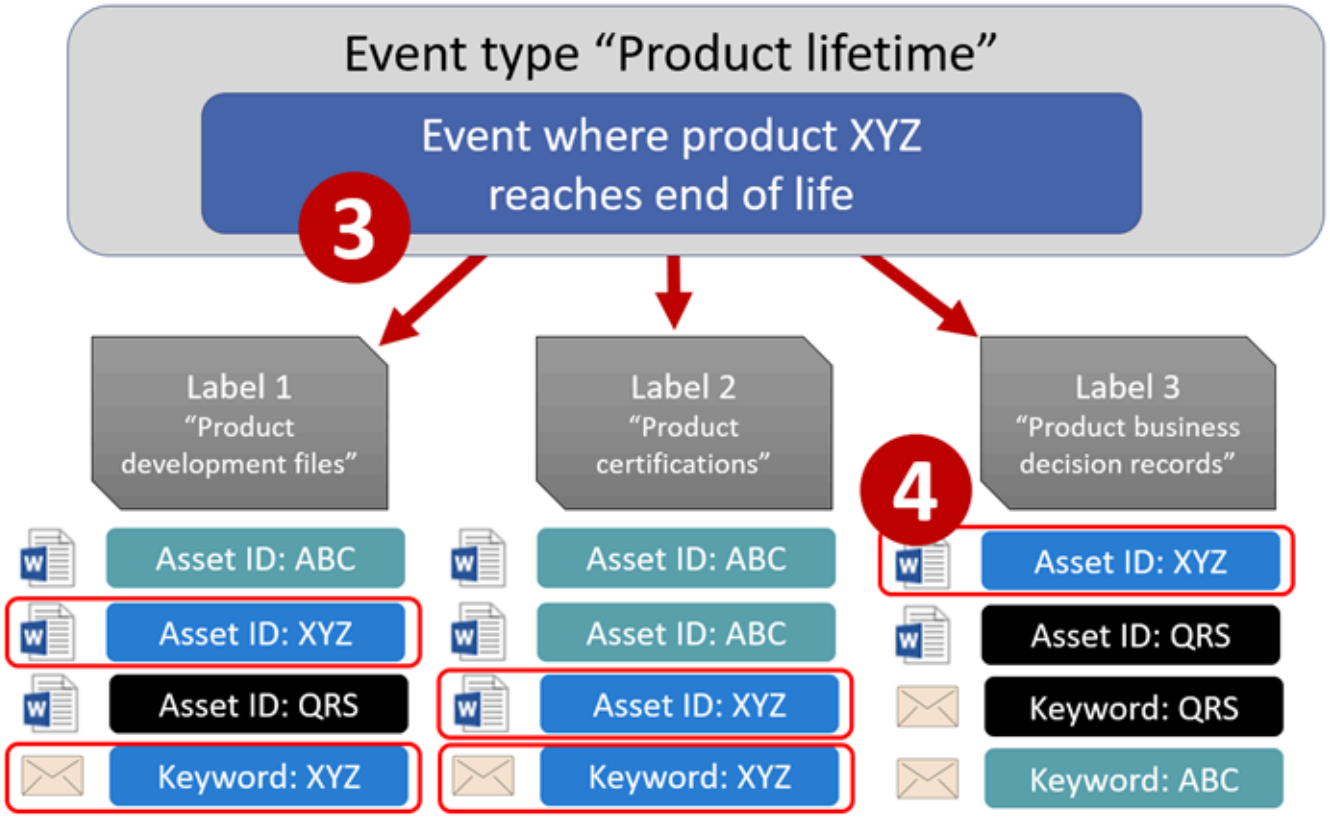
When you retain content, the retention period is often based on the age of the content. For example, you might retain documents for seven years after they're created and then delete them. But when you configure retention labels, you can also base a retention period on when a specific type of event occurs. The event triggers the start of the retention period, and all content with a retention label applied for that type of event get the label's retention actions enforced on them.

Examples for using event-based retention:

- **Employees leaving the organization** Suppose that employee records must be retained for 10 years from the time an employee leaves the organization. After 10 years elapse, all documents related to the hiring, performance, and termination of that employee must be disposed. The event that triggers the 10-year retention period is the employee leaving the organization.
- **Contract expiration** Suppose that all records related to contracts must be retained for five years from the time the contract expires. The event that triggers the five-year retention period is the expiration of the contract.
- **Product lifetime** Your organization might have retention requirements related to the last manufacturing date of products for content such as technical specifications. In this case, the last manufacturing date is the event that triggers the retention period.



Event-based retention, sometimes also referred to as "event-driven retention", is typically used with records management processes. This means that:



- Retention labels based on events also usually mark items as a record, as a part of a records management solution. For more information, see Learn about records management.
- A document that's been declared a record but whose event trigger hasn't yet happened is retained indefinitely. Until an event triggers that document's retention period, which then expires, records can't be permanently deleted.
- Retention labels based on events often trigger a disposition review at the end of the retention period, so that a records manager can manually review and dispose of the content. For more information, see Disposition of content.

A retention label based on an event has the same capabilities as any retention label in Microsoft Purview. For more information, see Learn about retention policies and retention labels.

Understanding the relationship between event types, labels, events, and asset IDs

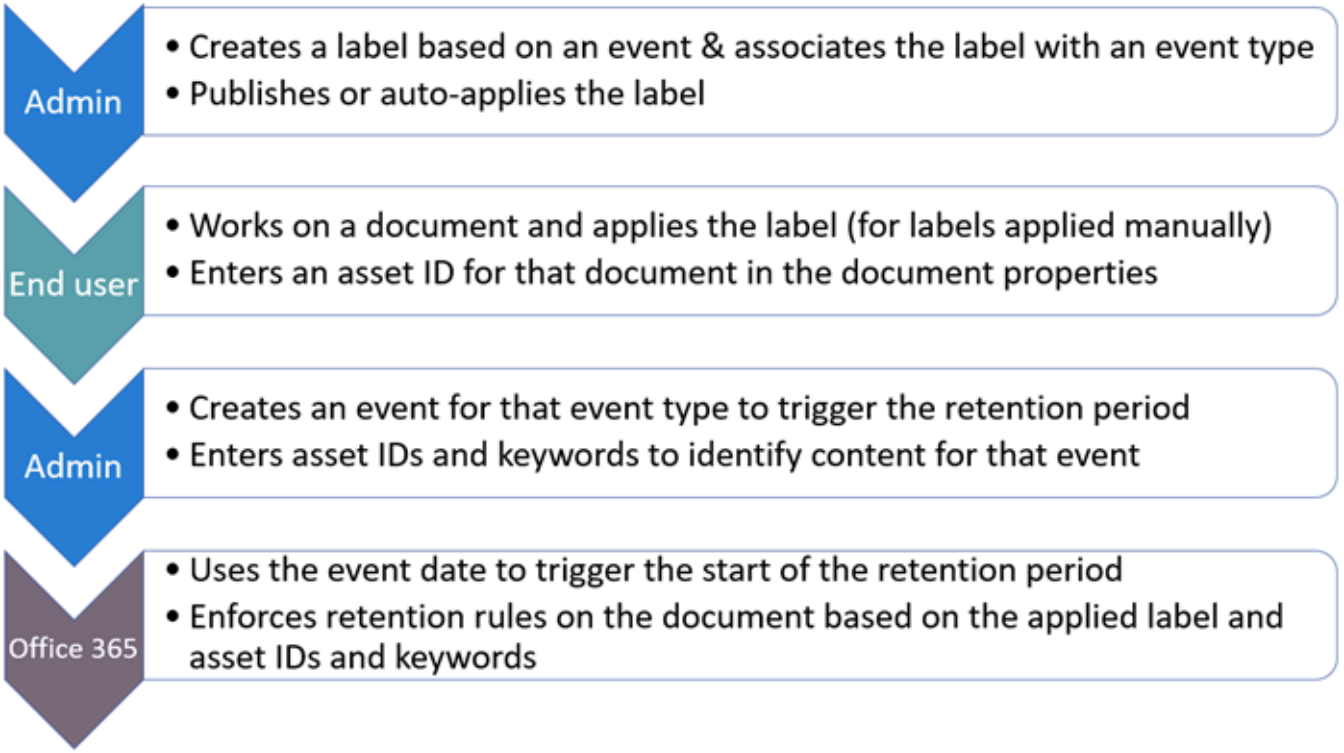
To successfully use event-based retention, it's important to understand the relationship between event types, retention labels, events, and asset IDs as illustrated in the diagrams and the explanation that follows:

1. You create retention labels for different types of content and then associate them with a type of event. For example, retention labels for different types of product files and records are associated with an event type named Product Lifetime because those records must be retained for 10 years from the time the product reaches its end of life.

2. Users that are typically records managers apply those retention labels to content and (for documents in SharePoint and OneDrive) enter an asset ID for each item. In this example, the asset ID is a product name or code used by the organization. Then, each product's records are assigned a retention label, and each record has a property that contains an asset ID. The diagram represents **all the content** for all product records in an organization, and each item bears the asset ID of the product whose record it is.

3. Product Lifetime is the event type; a specific product reaching end of life is an event. When an event of that event type occurs—in this case, when a product reaches its end of life—you create an event that specifies:

    - An asset ID (for SharePoint and OneDrive documents)
    - Keywords (for Exchange items). In this example, the organization uses a product code in messages containing product records, so the keyword for Exchange items is functionally the same as the asset ID for SharePoint and OneDrive documents.
    - The date when the event occurred. This date is used as the start of the retention period. This date can be the current, a past, or a future date.



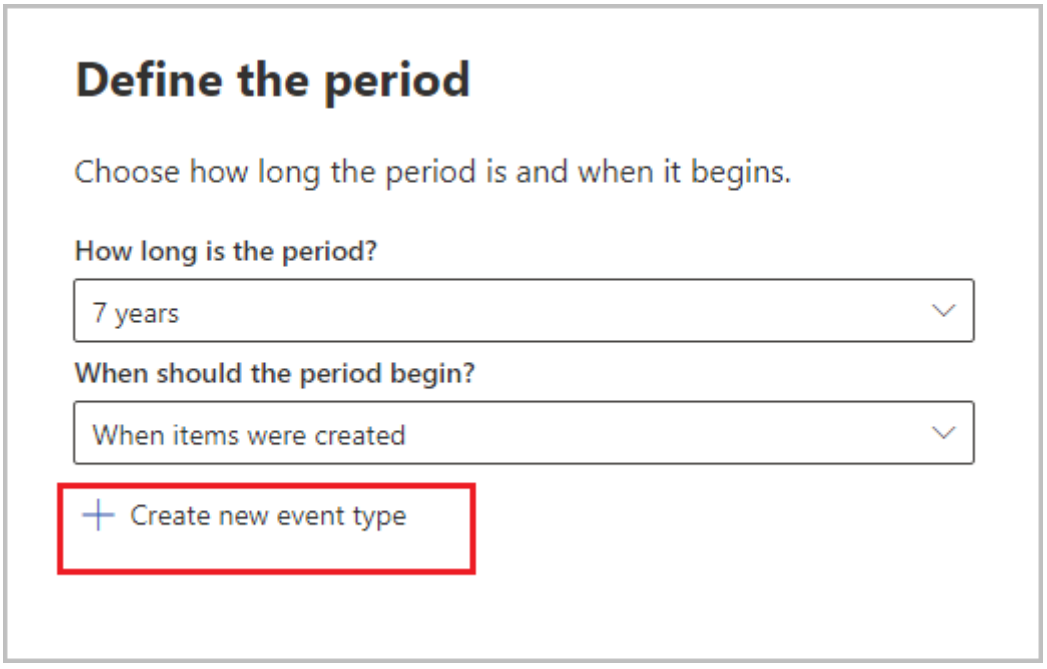
4. After you create an event, that event date is synchronized to all the content that has a retention label of that event type and that contains the specified asset ID or keyword. Like any retention label, this synchronization can take up to seven days. In the previous diagram, all the items circled in red have their retention period triggered by this event. In other words, when this product reaches its end of life, that event triggers the retention period for that product's records.

It's important to understand that if you don't specify an asset ID or keywords for an event, **all content** with a retention label of that event type will have its retention period triggered by the event. This means that in the previous diagram, all content would start being retained. It's unlikely this outcome is what you intended.

Finally, remember that each retention label has its own retention settings. In this example, they all specify 10 years, but it's possible for an event to trigger retention labels where each label has a different retention period.

How to set up event-based retention

High-level workflow for event-based retention:



> **Tip**
>
> See Use retention labels to manage the lifecycle of documents stored in SharePoint for a detailed scenario about using managed properties in SharePoint to auto-apply retention labels and implement event-based retention.

Step 1: Create a label whose retention period is based on an event

To create and configure your retention label, see the instructions for Create retention labels for records management. But specific to event-based retention:

- On the **Define label settings** page when you create the retention label, make sure you select **Retain items forever or for a specific period**. Then:

  On the **Define the period** page, after you've set the time period, select one of the default event types from the dropdown list for **When should the period begin?**. Or, create your own event type by selecting **Create new event type** and follow the configuration prompts:

An event type is simply a general description of an event that you want to associate with a retention label.

The default event types have **(event type)** after their name in the dropdown list for easier identification, and you can also see and create event type from the **Records management** > **Events** tab > **Manage event types**.

Event-based retention requires retention settings that:

- Retain the content.
- Delete the content automatically or trigger a disposition review at the end of the retention period.

Event-based retention is typically used for content that's declared a record, so now is a good time to check whether you also need to select the option that marks content as a record.

If you're using an existing event type rather than creating a new event type, skip to step 3.

> ⓘ **Note**
>
> After you choose an event type and save the retention label, the event type can't be changed.

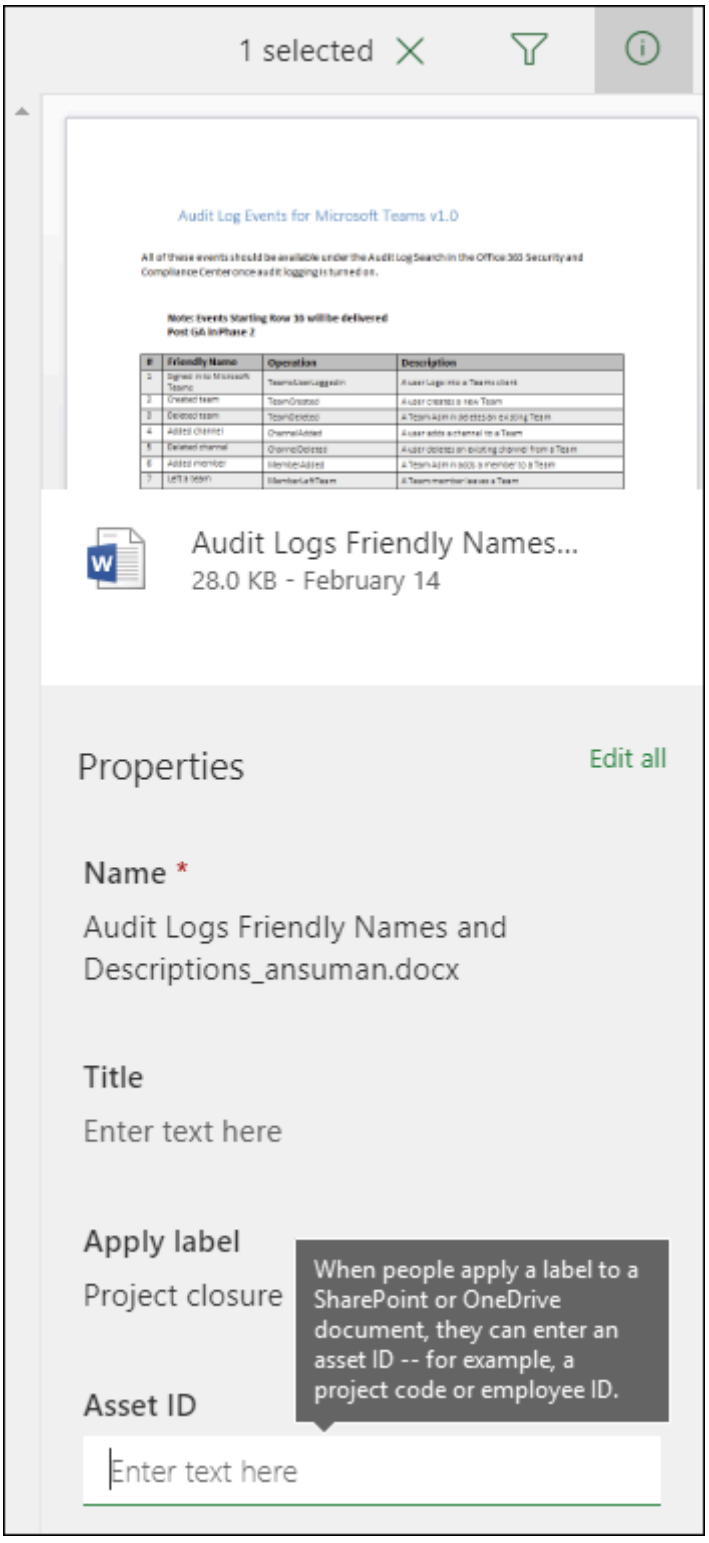
Step 2: Create a new event type for your label

For the retention settings, if you selected **Create new event type**, enter a name and description for your event type. Then select **Next**, **Submit**, and **Done**.

Back on the **Define the period** page, for **When should the period begin?**, use the dropdown list to select the event type that you created.

Step 3: Publish or auto-apply the event-based retention labels

Just like any retention label, you need to publish or auto-apply an event-based label, for it to be manually or automatically applied to content:



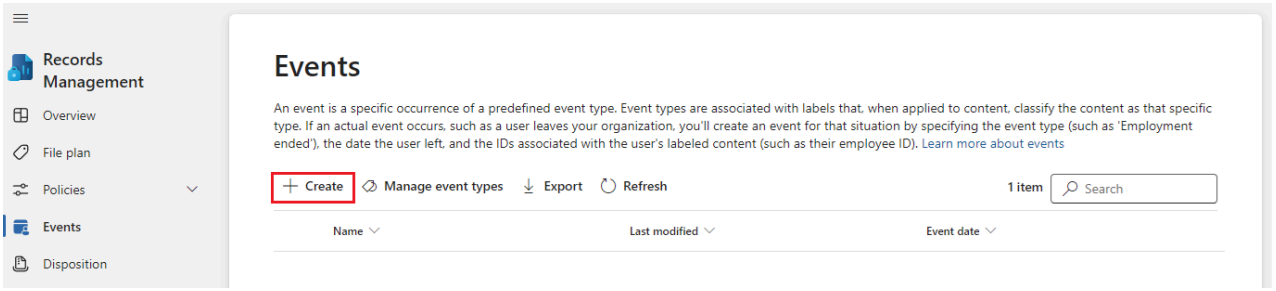
- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

Step 4: Enter an asset ID

After an event-based label is applied to content, you can enter an asset ID for each item. For example, your organization might use:

- Product codes that you can use to retain content for only a specific product.
- Project codes that you can use to retain content for only a specific project.
- Employee IDs that you can use to retain content for only a specific person.

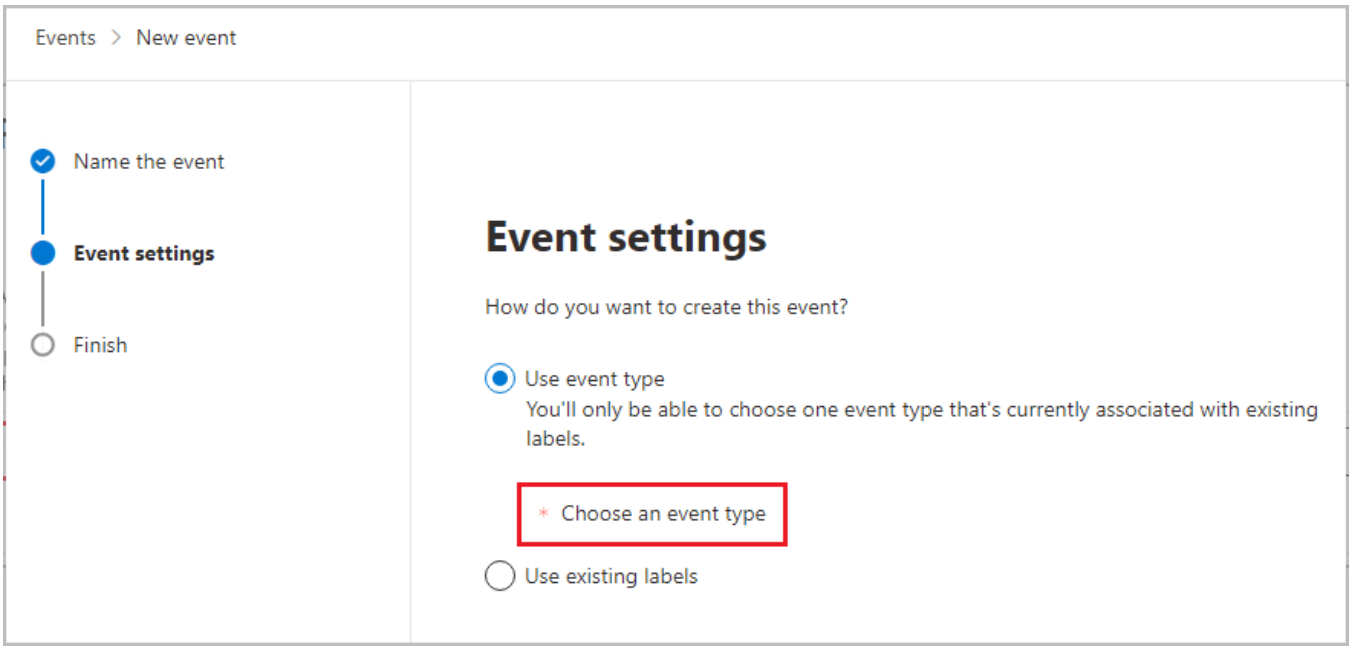
Asset ID is simply another document property that's available in SharePoint and OneDrive. Your organization might already use other document properties and IDs to classify content. If so, you can also use those properties and values when you create an event—see step 6 that follows. The important point is that you must use some *property:value* combination in the document properties to associate that item with an event type.



Step 5: Create an event

When a particular instance of that event type occurs, such as a product reaches its end of life, create an event in the Microsoft Purview portal:

1. Sign in to the Microsoft Purview portal > **Solutions** > **Records Management** > **Events**. **Events** tab.



2. Select + **Create** to create an event. You trigger the event by creating it, here. For example:

Up to 1,000,000 events are supported per tenant.

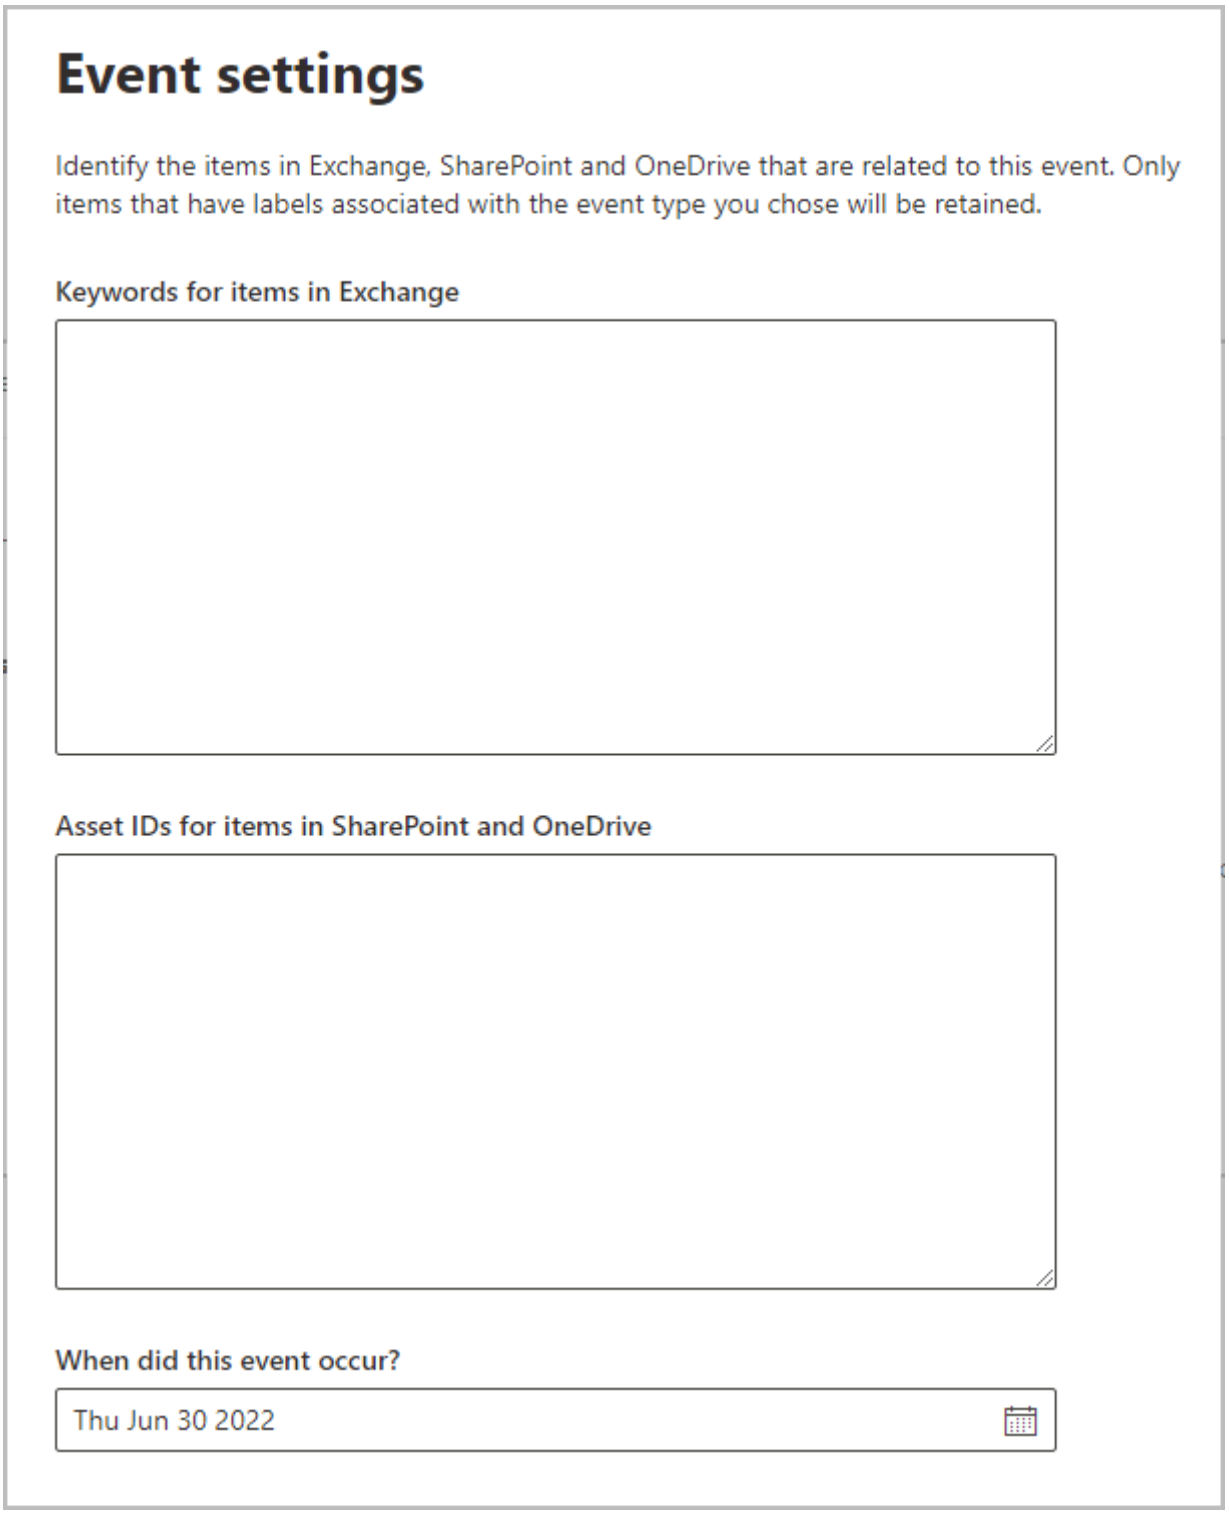
Step 6: Choose the same event type used by the label in step 2

When you create the event, choose the same event type specified in the retention label settings in step 2. For example, if you selected **Product Lifetime** as your event type for the label settings, select **Product Lifetime** when you create the event. Only content with retention labels applied to it of that event type will have its retention period triggered.

Alternatively, if you need to create an event for multiple retention labels that have different event types, select the **Choose Existing Labels** option. Then, select the labels that are configured for the event types you want to associate with this event.

Step 7: Enter keywords or a query, or asset ID for SharePoint and OneDrive

Now you narrow the scope of the content. You do this by specifying keywords or a query. For SharePoint and OneDrive content, you can also do this by specifying asset IDs.



Queries use Keyword Query Language (KeyQL). For more information about the query syntax, see Keyword Query Language (KeyQL) syntax reference. For more information about the searchable properties that you can use, see Keyword queries and search conditions for Content Search.

For asset IDs, retention will be enforced only on content with the specified *property:value* pair. For example, if you're using the Asset ID property, enter `ComplianceAssetID:<value>` in the box for asset IDs shown in the following picture.

If an asset ID isn't entered, all content with labels of that event type get the same retention date applied to them.

Your organization might have applied other properties and IDs to the documents related to this event type. For example, if you need to detect a specific product's records, the ID might be a combination of your custom property ProductID and the value "XYZ". In this case, you'd enter `ProductID:XYZ` in the box for asset IDs shown in the following picture.

Finally, choose the date when the event occurred; this date is used as the start of the retention period. After you create an event, that event date is synchronized to all the content with a retention label of that event type, asset ID, and keywords or queries. As with any retention label, this synchronization can take up to seven days.

After creating an event, the retention settings take effect for the content that's already labeled and indexed. If the retention label is added to new content after the event is created, you must create a new event with the same details.

Deleting an event doesn't cancel the retention settings that are now in effect for the content that's already labeled. Currently, you can't cancel events after they're triggered.

Use Content Search to find all content with a specific label or asset ID

After retention labels are assigned to content, you can use content search to find all content that has a specific retention label or that contains a specific asset ID:

- To find all content with a specific retention label, choose the **Retention label** condition, and then enter the complete label name or part of the label name and use a wildcard.
- To find all content with a specific asset ID, enter the **ComplianceAssetID** property and a value, using the format `ComplianceAssetID:<value>`.

For more information, see Keyword queries and search conditions for Content Search.

Automate events by using PowerShell

You can use a PowerShell script to automate event-based retention from your business applications. The PowerShell cmdlets available for event-based retention:

- Get-ComplianceRetentionEventType
- New-ComplianceRetentionEventType
- Remove-ComplianceRetentionEventType
- Set-ComplianceRetentionEventType
- Get-ComplianceRetentionEvent
- New-ComplianceRetentionEvent

to help identify other cmdlets to create retention labels and their policies, see PowerShell cmdlets for retention policies and retention labels.

Automate events by using Graph API

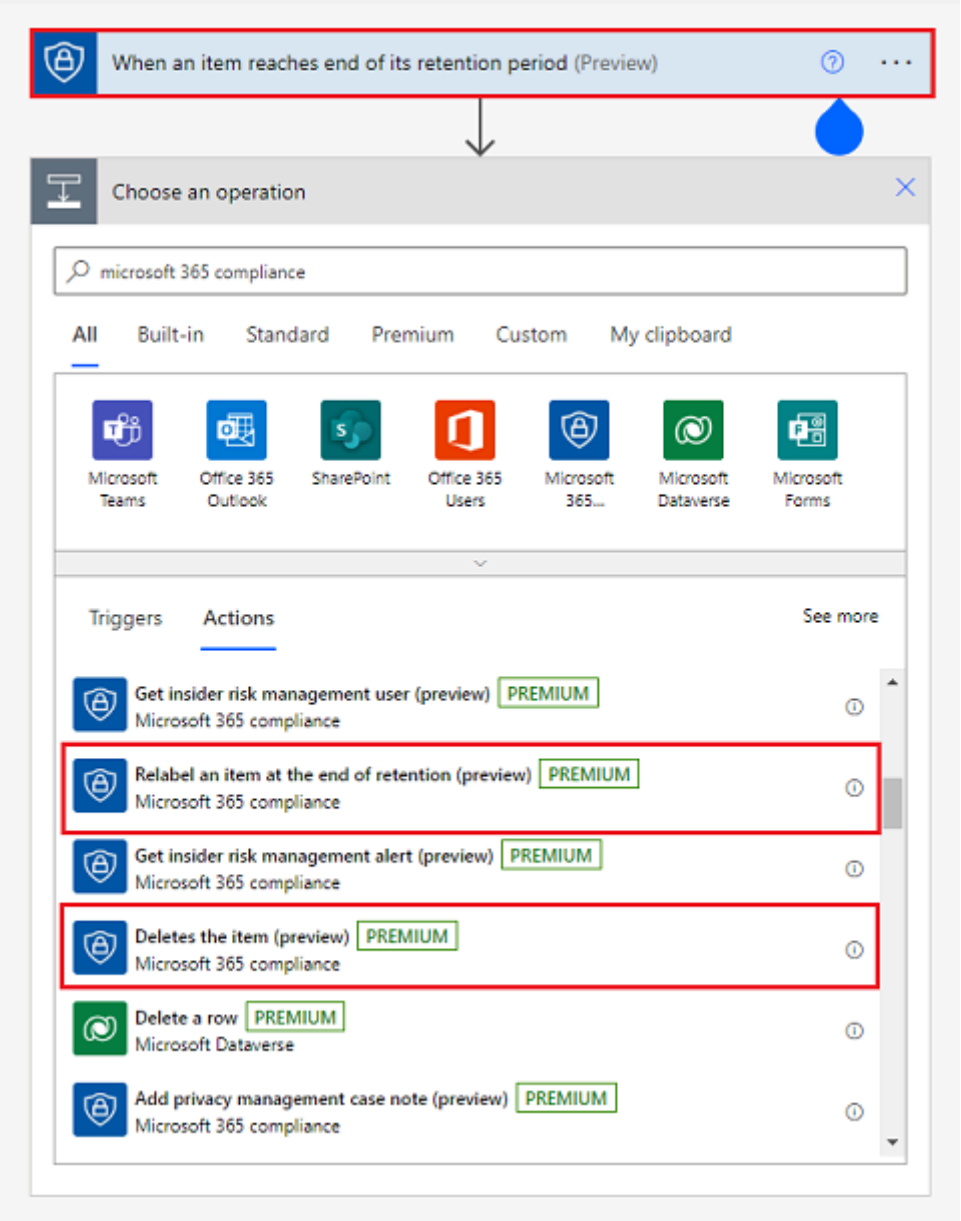
You can use Microsoft Graph Records Management APIs to automatically create the events and event types that trigger the start of the retention time.

> **Note**
>
> In the past, you could use REST APIs to automate the events. This method is now deprecated and no longer works. Instead, use Microsoft Graph API.

Last updated on 02/27/2026

Customize what happens at the end of the retention period

Summarize this article for me



> *Microsoft 365 licensing guidance for security & compliance*.

When you configure a retention label to retain items for a specific period, you specify what action to take at the end of that retention period. You can choose from the built-in actions of permanently deleting the item, relabeling the item, deactivating the label, and starting a disposition review.

However, if you choose the option to run a Power Automate flow, this label configuration supports custom actions such as:

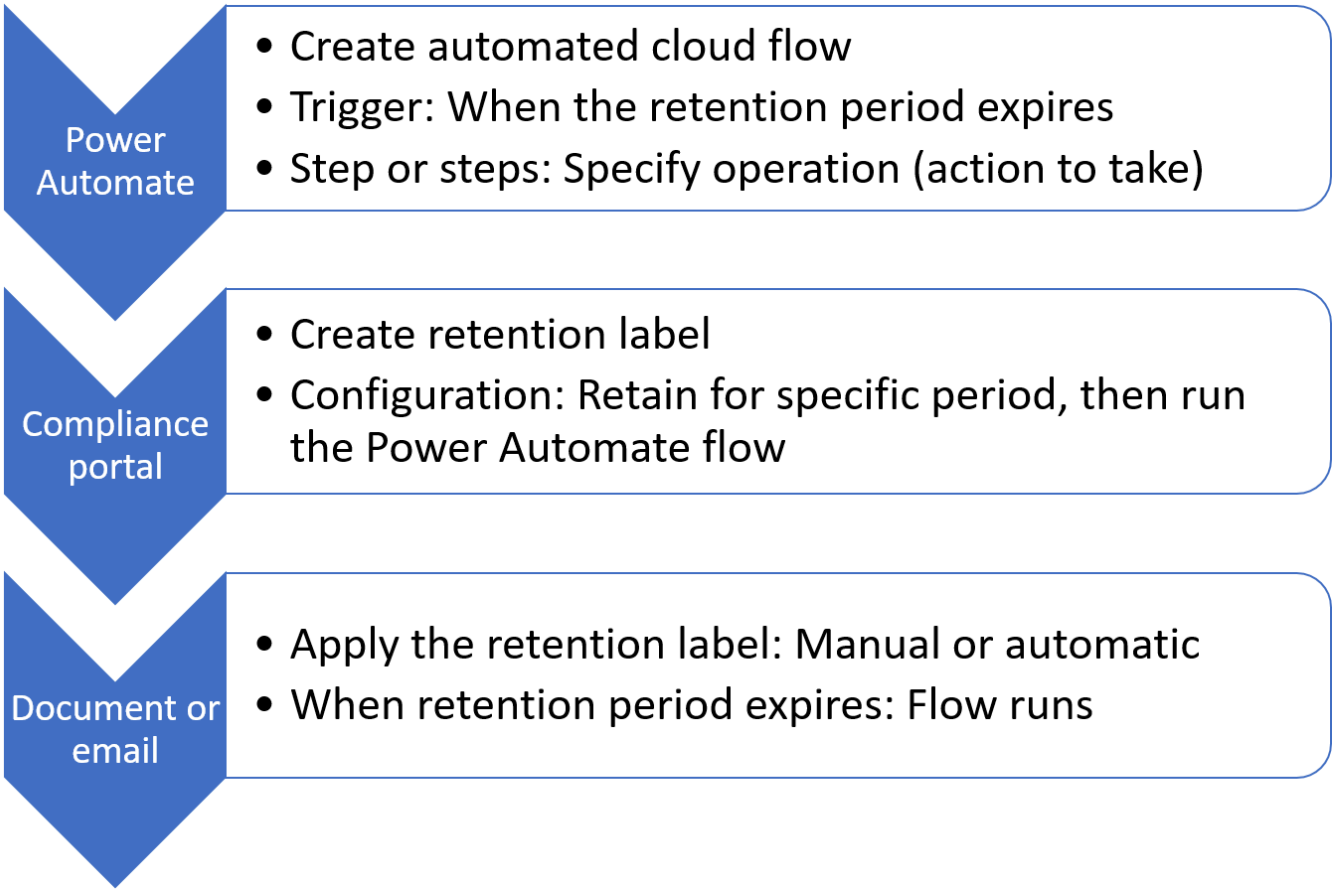
- Send an email notification to a records manager, or to the person who created or last modified a document
- Move a document item to a SharePoint location where you centrally store records

You can also select the Microsoft 365 compliance label-specific actions of relabel the item or permanently delete it:

For example, a flow can move the item, relabel it, and then send an email notification.

> **Note**
>
> You can also use the relabel action to remove the existing retention label when you select this action but don't specify a replacement label (leave the label name blank). If the existing retention label marked the item as a record, the record must be locked for the label to be removed.

The actions also allow integration with other apps and services. For example, you might have another solution that starts your own customized disposition review process when an email notification is received. Or your flow adds a new entry into a table and this change automatically starts an existing records management procedure.



It's outside the scope of this article to document all the ways in which you can configure a flow and integrate with other solutions. However, to learn more about Power Automate, see Get

started with Power Automate and Overview of cloud flows. In this article, you learn about:

- Overview of using retention labels with a Power Automate flow
- Limitations
- Power Automate dependency
- How to configure a retention label to run a Power Automate flow
- When the flow is triggered

Overview of using retention labels with a Power Automate flow

The following processes show the high-level overview of how retention labels work with a Power Automate flow:

In Power Automate, create an automated cloud flow from blank that uses the trigger **When an item reaches the end of its retention period**. Then, add one or more steps and specify the operations that run your choice of actions.

Next, in the Microsoft Purview portal, create a new retention label with the following configuration:

- Retain the item for a specified period of time
- At the end of the retention period, run the flow that you just created

Apply the label by using either of the following methods:

- Publish retention labels and apply them in apps
- Apply a retention label to content automatically

When the retention period expires, your configured flow runs.

> **Note**
>
> In a Power Automate flow, you can also select the action **Apply a retention label on the item**. This action is independent from this scenario that applies actions at the end of the retention period. Instead, it's the equivalent to manually applying a retention label. The label is applied immediately.

Add resilience to your flow

Although optional, we recommend you always add the **Trigger a new instance of the flow if an item can't be located** action before **Relabel an item at the end of retention** and **Deletes an item at the end of retention**.

This additional action is required for files that you move or rename after an instance of the flow is triggered but your specified compliance actions aren't completed. Without it, a renamed or moved file results in the flow failing because it can't find the file.

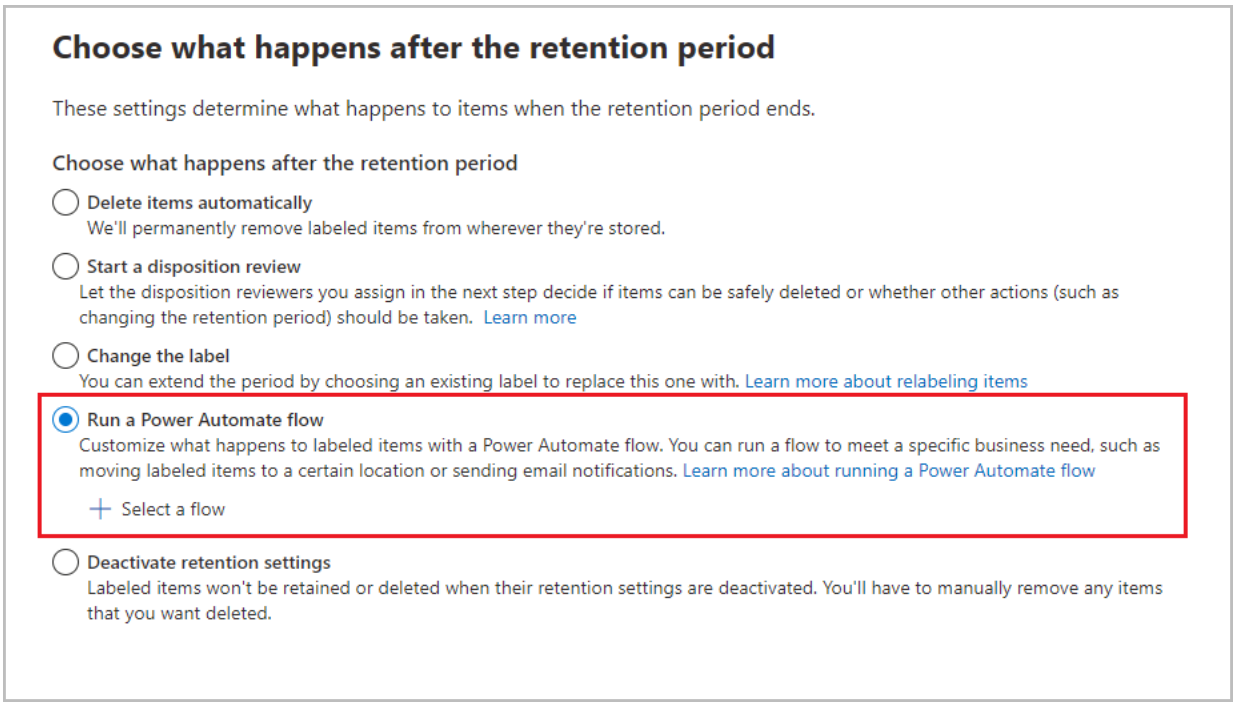
Although renaming and moving files after an instance of the flow is triggered are an unusual occurrence, adding this recommended action improves the reliability of the compliance actions succeeding because the current path and name of the file is retrieved automatically just before the selected actions run.

Limitations for this scenario

- You must create a new retention label to run a flow at the end of the retention period. You can't edit an existing retention label for this configuration.
- By default, the account that creates the Power Automate flow must be the same account that creates the retention label. If you share the flow in Power Automate, the people you share it with can also select the flow when they create a retention label.
- In Power Automate, you must use the option **My flows** to create the flow. Currently, creating a flow under **Solutions** isn't supported.

- If you select the relabel action in the flow, the retention label that you select as the replacement can't be configured to mark the item as a regulatory record. It can be configured to mark the item as a record, or not mark the item as a record.
- If your chosen flow uses an environment type other than Default, you must use PowerShell to create the retention label, and use the *FlowId* parameter.

Power Automate dependency



Power Automate is a workflow service that automates actions across applications and services. Specific to running a Power Automate flow at the end of the retention period:

- You must have a Power Automate plan that includes premium connectors, separate from your Microsoft 365 compliance plan.
- The Power Automate flow must be an automated cloud flow that you create from blank, and configure to use the trigger **When an item reaches the end of its retention period**.

For more information about how to use and configure the dependent automated cloud flows, see the Microsoft Power Automate Documentation.

How to configure a retention label to run a Power Automate flow

1. In the Microsoft Purview portal, create a new retention label with your preferred name and settings. For more information, see Use file plan to create and manage retention labels.
2. For this scenario, complete the following steps:
   a. On the **Define label settings** page, select **Retain items indefinitely or for a specific period** and specify the retention period.
   b. On the **Choose what happens after the retention period** page, select **Run a Power Automate flow**, and then **Select a flow**:

c. From the **Select a Power Automate flow** flyout pane, you'll see any automated cloud flows that you created (or somebody has shared with you) and that have the **When an item reaches the end of its retention period** trigger.

   Select the flow you want, and complete the configuration to create the retention label.

A retention label can be configured for only one Power Automate flow, but the same flow can be used by more than one retention label.

When the flow is triggered

Just as it can take up to seven days to automatically apply a retention label or display it so you can apply it, so you should allow up to seven days after the expiration period expires before the Power Automate flow is triggered. The initiation of the flow can then take a few hours.

For the Microsoft 365 compliance actions of delete and relabel, then allow up to seven days for these actions to complete. Specific for Exchange and the Microsoft 365 compliance actions of delete, allow up to 14 days.

Both the flow itself and the Microsoft 365 compliance actions in the flow are queued so that if there are any network or service delays, the flow and actions are automatically retried.

The principles of retention still apply to retention labels that are configured to run a flow at the end of the retention period, in that an item is always retained for the longest period if there is a conflict with one or more retention policies. However, the flow is always triggered at the end of the label's retention period.

Next steps

To help you track the retention labels with this configuration:

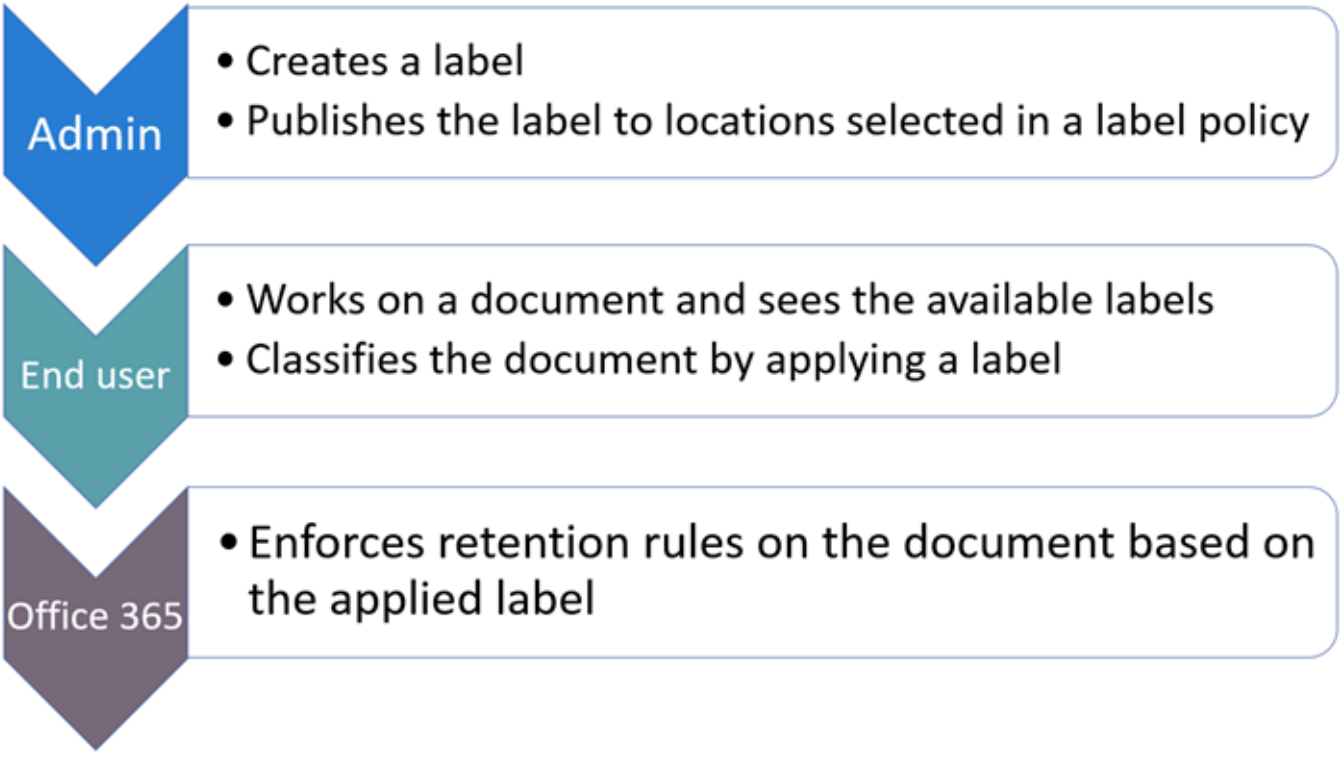
- Monitoring retention labels
- Using Content Search to find all content with a specific retention label
- Auditing retention actions

To confirm there aren't any failures or errors with your flow, go to the Power Automate dashboard, select **My flows**, and then select your flow to review the 28-day run history.

Last updated on 02/10/2026

Publish retention labels and apply them in apps

> *Microsoft 365 licensing guidance for security & compliance.*



> **Note**
>
> This scenario is supported for all retention label configurations, including regulatory records.

Use the following information to help you publish retention labels, and then apply them to documents and emails.

Retention labels help you retain what you need and delete what you don't at the item level (document or email). They're also used to declare an item as a record as part of a records management solution for your Microsoft 365 data.

Making retention labels available to people in your organization so that they can classify content is a two-step process:

1. Create the retention labels.
2. Publish the retention labels by using a retention label policy.

Use the following instructions for the two admin steps.

Before you begin

To make sure you have permissions to create and edit retention labels and their policies, see the permissions information for records management or data lifecycle management, depending on the solution you're using.

Make sure you have created the retention labels you want to apply to items.

How to publish retention labels

Decide before you create your retention label policy whether it will be **adaptive** or **static**. For more information, see Adaptive or static policy scopes for retention. If you decide to use an adaptive policy, you must create one or more adaptive scopes before you create your retention label policy, and then select them during the create retention label policy process. For instructions, see Configuration information for adaptive scopes.

1. Sign in to the Microsoft Purview portal and then:

   If you're using records management: **Solutions** > **Records Management** > **Policies** > **Label policies**

   If you're using data lifecycle management: **Solutions** > **Data Lifecycle Management** > **Policies** > **Label policies**

2. Select **Publish labels** and follow the prompts to create the retention label policy. Be careful what name you choose for the policy, because this can't be changed after the policy is saved.

3. Use the link to select the retention labels to publish, and then select **Next**.

4. For the **Assign admin units** page, keep the default of **Full directory**. Currently, admin units aren't supported for this policy.

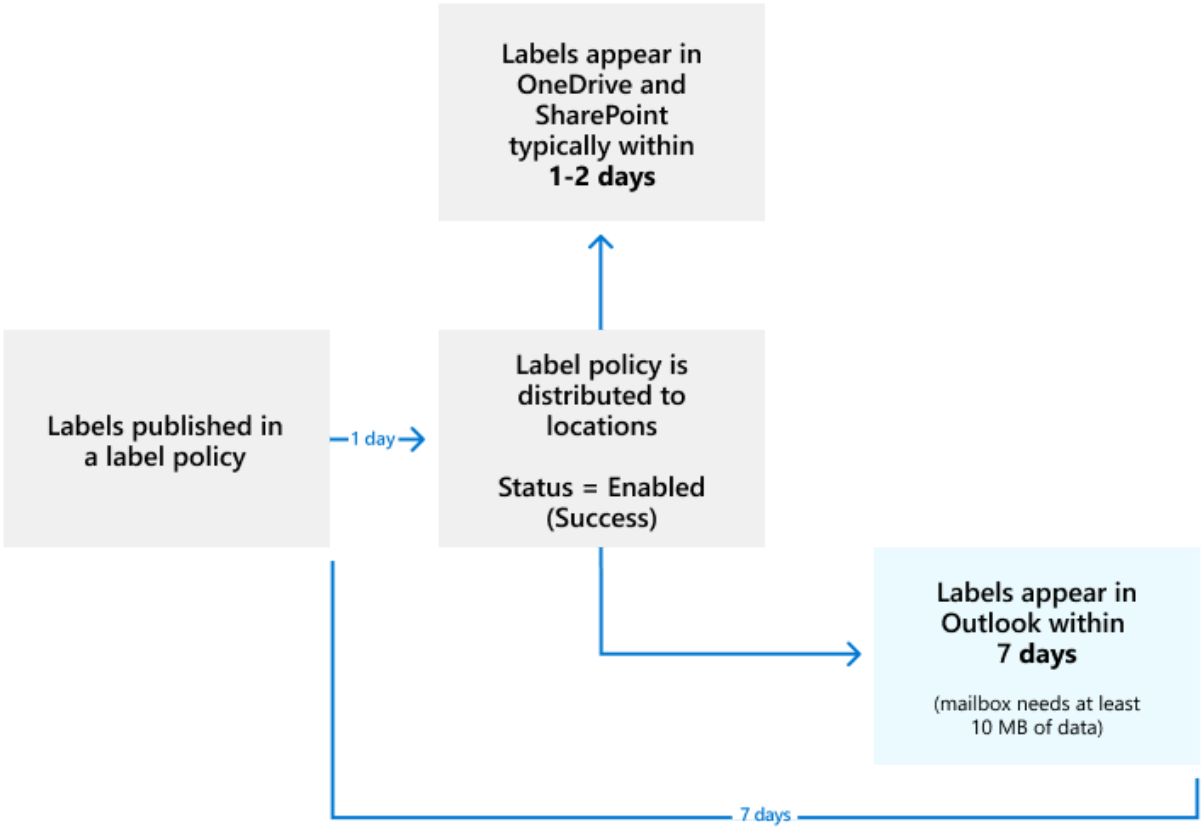
5. For the **Choose the type of retention policy to create** page, select **Adaptive** or **Static**, depending on the choice you made from the Before you begin instructions. If you haven't already created adaptive scopes, you can select **Adaptive** but because there won't be any adaptive scopes to select, you won't be able to finish the configuration with this option.

6. Depending on your selected scope:

   - If you chose **Adaptive**: On the **Choose adaptive policy scopes and locations** page, select **Add scopes** and select one or more adaptive scopes that have been created. Then, select one or more locations. The locations that you can select depend on the

scope types added. For example, if you only added a scope type of **User**, you'll be able to select **Exchange email** but not **SharePoint sites**.

- If you chose **Static**: On the **Choose locations** page, toggle on or off any of the locations. For each location, you can leave it at the default to apply the policy to the entire location, or specify includes and excludes



For information about the location choices, see Locations.

To edit an existing retention label policy (the policy type is **Publish**), select it, and then select the **Edit** option to start the **Edit retention policy** configuration.

When retention labels become available to apply

If you publish retention labels to SharePoint or OneDrive, those labels typically appear for users to select within one day. However, allow up to seven days.

If you publish retention labels to Exchange, it can take up to seven days for those retention labels to appear for users. As with all retention settings for Exchange, the mailbox must contain at least 10 MB of data.

If the labels don't appear after seven days, check the **Status** of the label policy by selecting it from the **Label policies** page in the Microsoft Purview portal. If you see **(Error)** included in the status and in the details for the locations see a message that it's taking longer than expected to deploy the policy or to try redeploying the policy, try running the Set-AppRetentionCompliancePolicy or Set-RetentionCompliancePolicy PowerShell command to retry the policy distribution:

1. Connect to Security & Compliance PowerShell.
2. Run one of the following commands:

   - For the policy locations **Teams private channel messages** (applicable pre-migration only), **Viva Engage user messages** and **Viva Engage community messages**:

     PowerShell

     ```
     Set-AppRetentionCompliancePolicy -Identity <policy name> -RetryDistribution
     ```

   - For all other policy locations, such as **Exchange mailboxes**, **SharePoint classic and communication sites**, **Teams channel messages** etc.:

     PowerShell

     ```
     Set-RetentionCompliancePolicy -Identity <policy name> -RetryDistribution
     ```

How to check on the status of retention labels published to Exchange

In Exchange Online, retention labels are made available to end users by a process that runs every seven days. By using PowerShell, you can see when this process last ran and therefore identify when it will run again.

1. Connect to Exchange Online PowerShell.
2. Run these commands.

   PowerShell

   ```
   $logProps = Export-MailboxDiagnosticLogs <user> -ExtendedProperties
   ```

   PowerShell

   ```
   $xmlprops = [xml]($logProps.MailboxLog)
   ```

PowerShell

```
$xmlprops.Properties.MailboxTable.Property | ? {$_.Name -like "ELC*"}
```

In the results, the `ELCLastSuccessTimeStamp` (UTC) property shows when the system last processed your mailbox. If it hasn't happened since the time you created the policy, the labels aren't going to appear. To force processing, run `Start-ManagedFolderAssistant -Identity <user>`.

If labels aren't appearing in Outlook on the web and you think they should be, make sure to clear the cache in your browser (CTRL+F5).

How to apply published retention labels

Use the following sections to learn how published retention labels can be applied in apps:

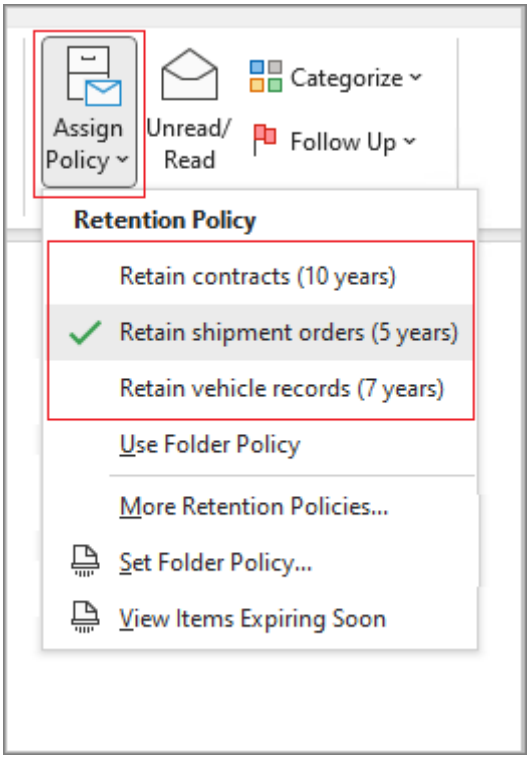
- Manually apply retention labels
- Default labels for SharePoint and Outlook
- Automatically apply a retention label to email by using Outlook rules

In addition, when you use Microsoft Syntex and publish retention labels to SharePoint locations, you can apply a retention label to a model so that identified files are automatically labeled.

After content is labeled, see the following information to understand when the applied label can be removed or changed: Only one retention label at a time.

Manually apply retention labels

Users can manually apply retention labels from the following locations:

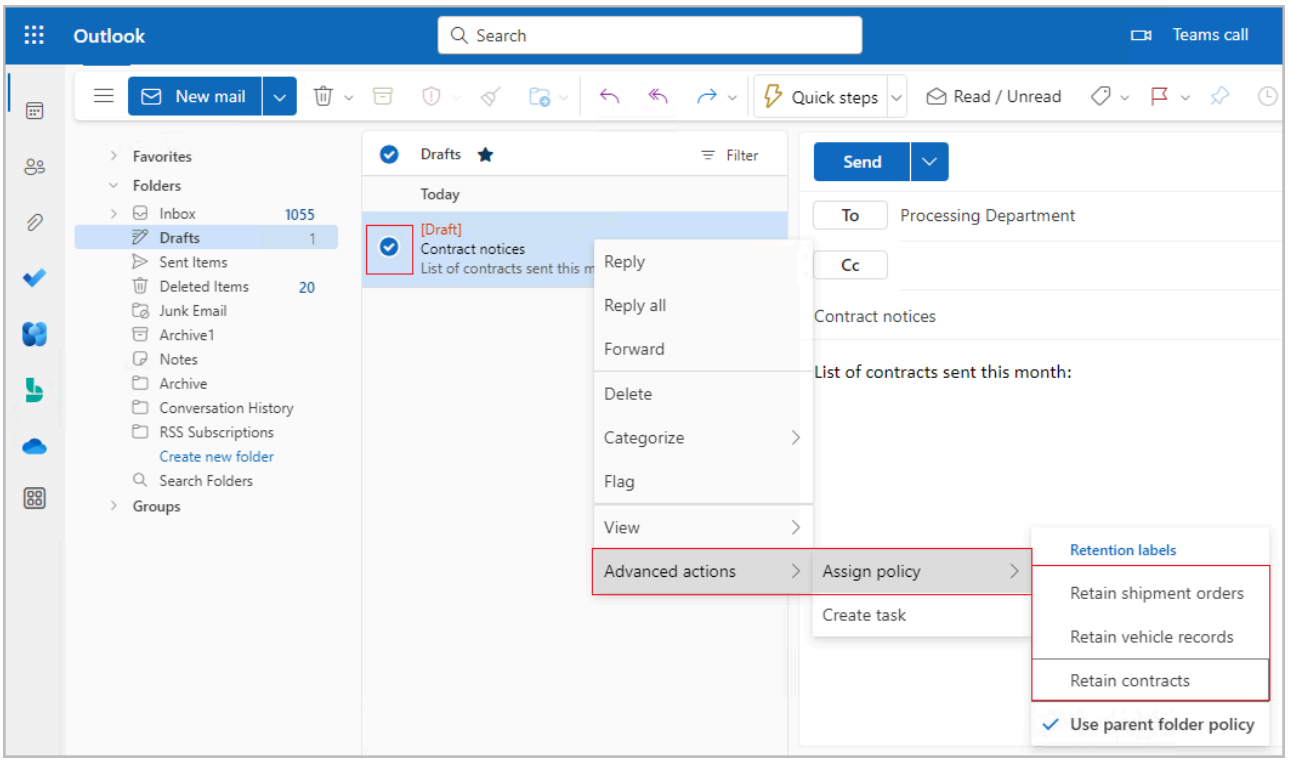


- Outlook
- OneDrive and SharePoint
- Teams site that's group-connected
- Loop and Copilot Pages

Use the following tabs to understand how to manually apply retention labels for each location:

Outlook

Your published retention labels display in Outlook alongside any legacy MRM retention tags that are assigned to the mailbox. Although you see references to retention policies, users can't select your Microsoft 365 retention policies in the Outlook apps.



To label an item in the Outlook desktop client, select the item. On the **Home** tab on the ribbon, select **Assign Policy**, and then choose the retention label. For example:

If you don't immediately see the option to assign policy, look for the **Tags** group on the ribbon.

You can also right-click an item from a folder, such as the **Inbox** folder for emails received or the **Drafts** folder for an email to be sent. Then, select **Assign Policy** in the context menu, and then choose the retention label. When you select multiple items, you can use this method to apply the same retention label to multiple items at once.

To label an item in Outlook on the web, first right-click the item from a folder. Then, select **Advanced actions** > **Assign policy**, and then choose the retention label. For example:

As with Outlook desktop, you can also use this labeling method if you multi-select items.

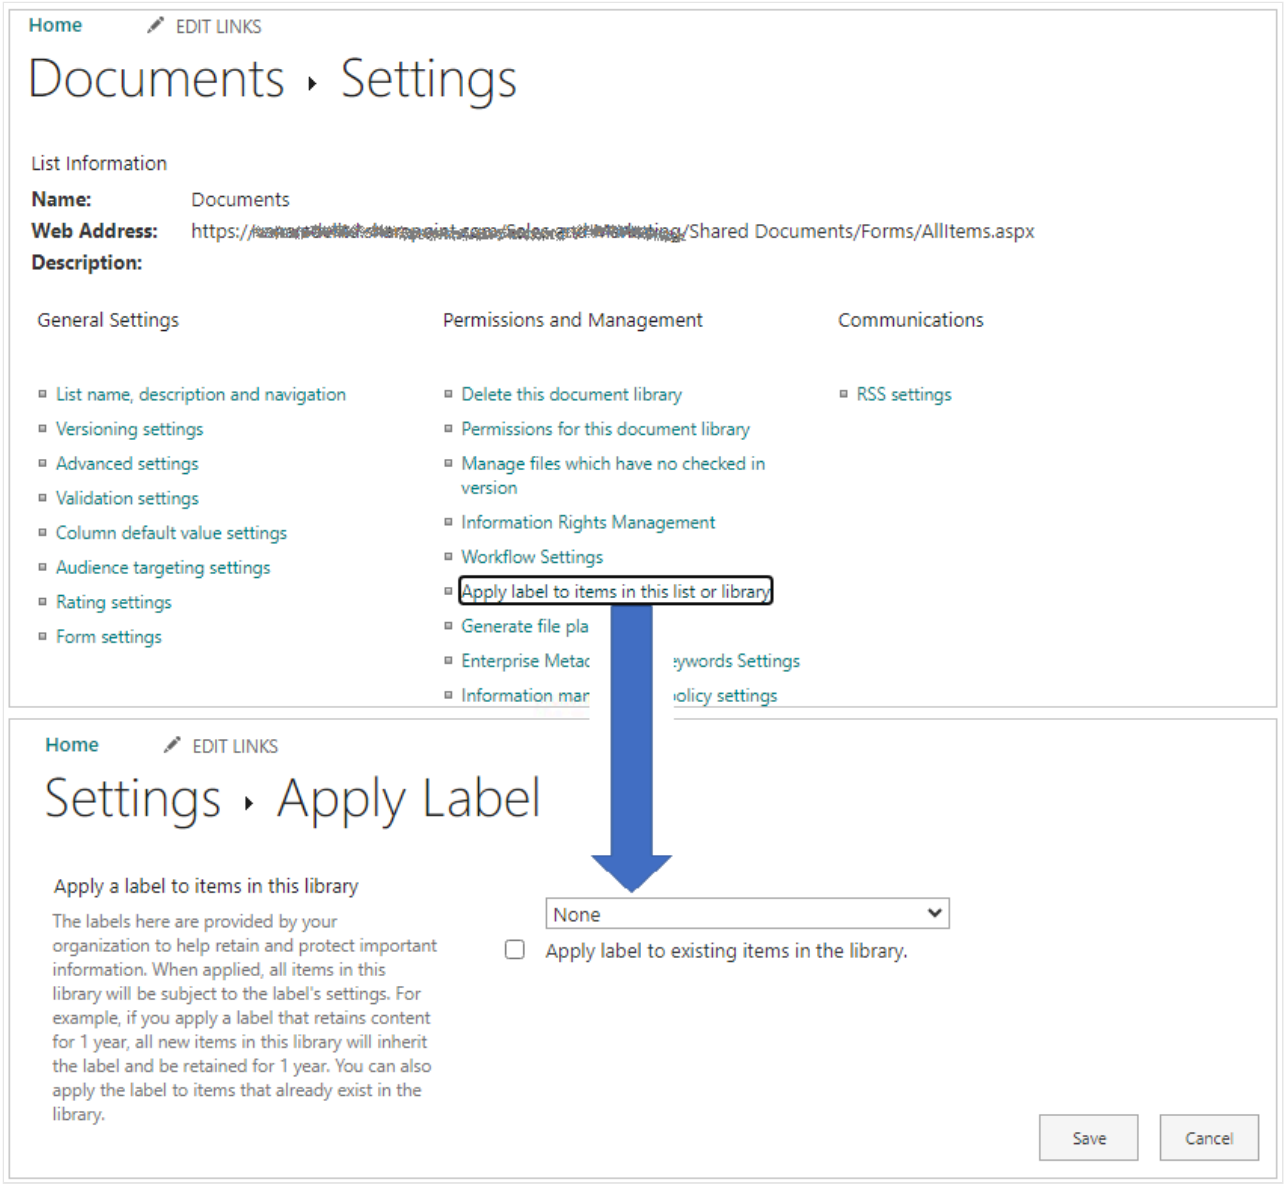
After the retention label is applied, you can view that retention label at the top of the item, and the calculated expired date. For example:

Label assigned to email in Outlook on the web.

For more information about the expiry date displayed to users, see User notification of expiry date.

Default labels for SharePoint and Outlook

After a retention label is published to SharePoint and Outlook, users can apply it as a default retention label so that it's inherited by all unlabeled items. Although the same label is applied, each item will be retained and deleted separately, according to the start of the retention period setting in the label.



When you use default retention labels, there are some scenarios that can result in the inherited label being replaced or removed. See each tab for details about the label behavior.

Default label for SharePoint

You can apply a default retention label to all content in a SharePoint library, folder, or document set. Documents in that location then inherit your selected default retention label.

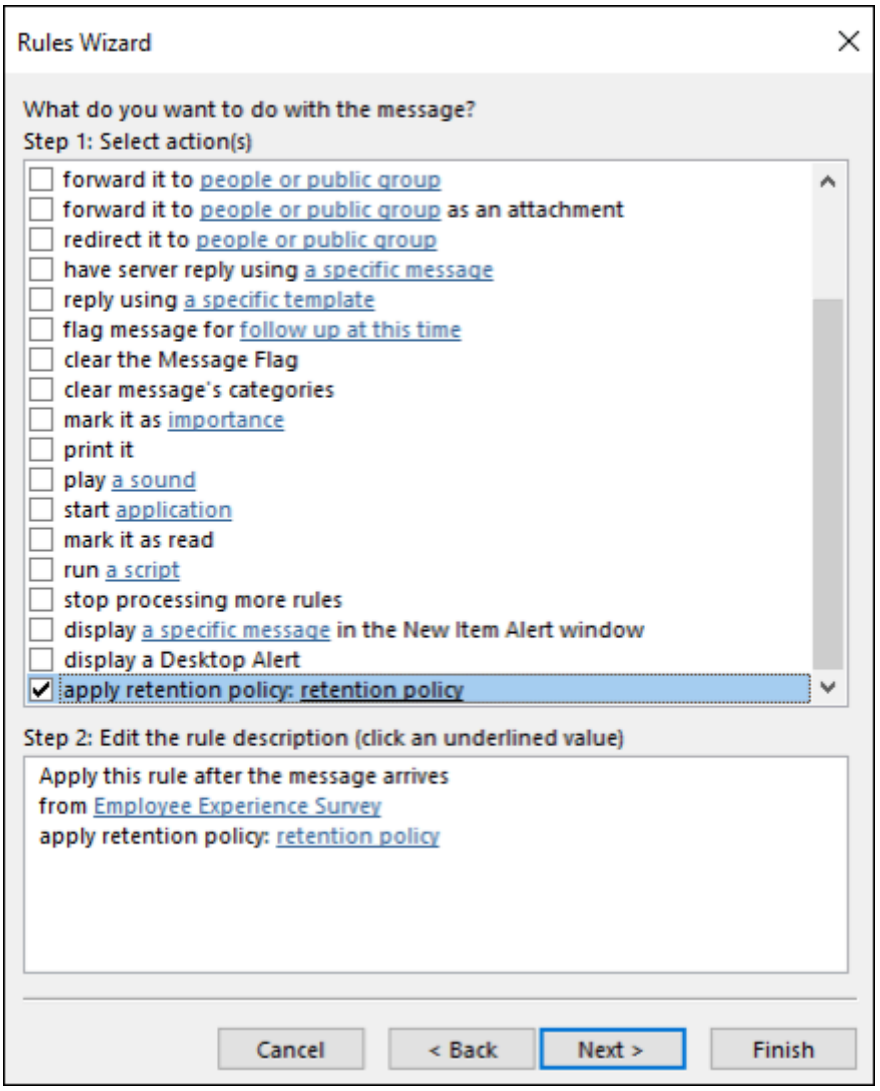
For a document library, the default label configuration is done on the **Library settings** page for a document library. When you choose the default retention label, you can also choose to apply it to existing items in the library.

For example, if you have a retention label for marketing materials, and you know a specific document library contains only that type of content, you can make the **Marketing Materials** retention label the default label for all documents in that library.

Label behavior when you use a default label for SharePoint

For standard retention labels that you apply as a default retention label to a library, folder, or document set:

- The default label is applied to all new unlabeled items in the container. However, this does not apply to subsequently migrated files.
- You can re-apply a default label to a location and select **Apply to existing items** to apply a default label to subsequently migrated items.



- For folders, the inheritance flows to any child folders and items inherit the label from their nearest folder.
- If you selected the option to apply the default label to existing items: Items that are already labeled retain their retention label, unless it was applied by a different default label.
- If you change the default retention label for the container: Existing retention labels applied to items in that container are changed only if you selected the option to apply the default label to existing items and those labels were applied by a default label.
- If you remove the default retention label for the container: Items retain their labels.
- If you move an item with a default retention label applied from one container to another container: The item keeps its existing default retention label, even if the new location has a different default retention label. Only if you then change the default label for this new location can the moved item inherit the default label from its current location.

When labels are applied that aren't standard retention labels but mark items as records (or regulatory records), these labels can only be manually changed or removed.

Automatically apply a retention label to email by using Outlook rules

In Outlook, you can create rules to apply a retention label. For example, you can create a rule that applies a specific retention label to all messages sent to or from a specific distribution group.

To create a rule, right-click an item, select **Rules** > **Create Rule** > **Advanced Options** > **Rules Wizard**. Specify the condition or conditions for the first step, and then **apply retention policy** for the action:

Although you see a reference to retention policies, retention labels are displayed and can be selected.

Updating retention labels and their policies

If you edit a retention label or a retention label policy, and the retention label or policy is already applied to content, your updated settings will automatically be applied to this content in addition to content that's newly identified.

Some settings can't be changed after the label or policy is created and saved, which include:

- Names for retention labels and their policies, the scope type (adaptive or static), and the retention settings except the retention period.
- The option to mark items as a record.

Deleting retention labels

To delete a retention label, all three conditions must apply:

- The label isn't included in any retention label policy
- The label isn't configured for event-based retention
- The label isn't configured to mark items as regulatory records

When all these conditions are met:

- You can always delete a retention label that doesn't mark items as records (sometimes referred to as a "standard retention label"). The deletion succeeds even if the label is applied to items, and the retention label is then removed from these items.

- You can delete a retention label that marks items as records only if the label isn't applied to items. If the label has been applied to items, the deletion fails and you see a link to content explorer to identify the labeled items. It can take up to two days for content explorer to show the items that are labeled. In this scenario, the retention label might be deleted without showing you the link to content explorer.

Locking the policy to prevent changes

If you need to ensure that no one can turn off the policy, delete the policy, or make it less restrictive, see Use Preservation Lock to restrict changes to retention policies and retention label policies.

Troubleshooting retention label policies

If your retention label policies aren't working as expected or you see errors related to these policies, use the following troubleshooting resources:

- Identify errors in Microsoft 365 retention and retention label policies
- Resolve errors in Microsoft 365 retention and retention label policies

Next steps

To help you track the labels applied from your published retention labeling policies:

- Monitoring retention labels
- Using Content Search to find all content with a specific retention label
- Auditing retention actions

Event-based retention is another supported scenario for retention labels. For more information, see Start retention when an event occurs.

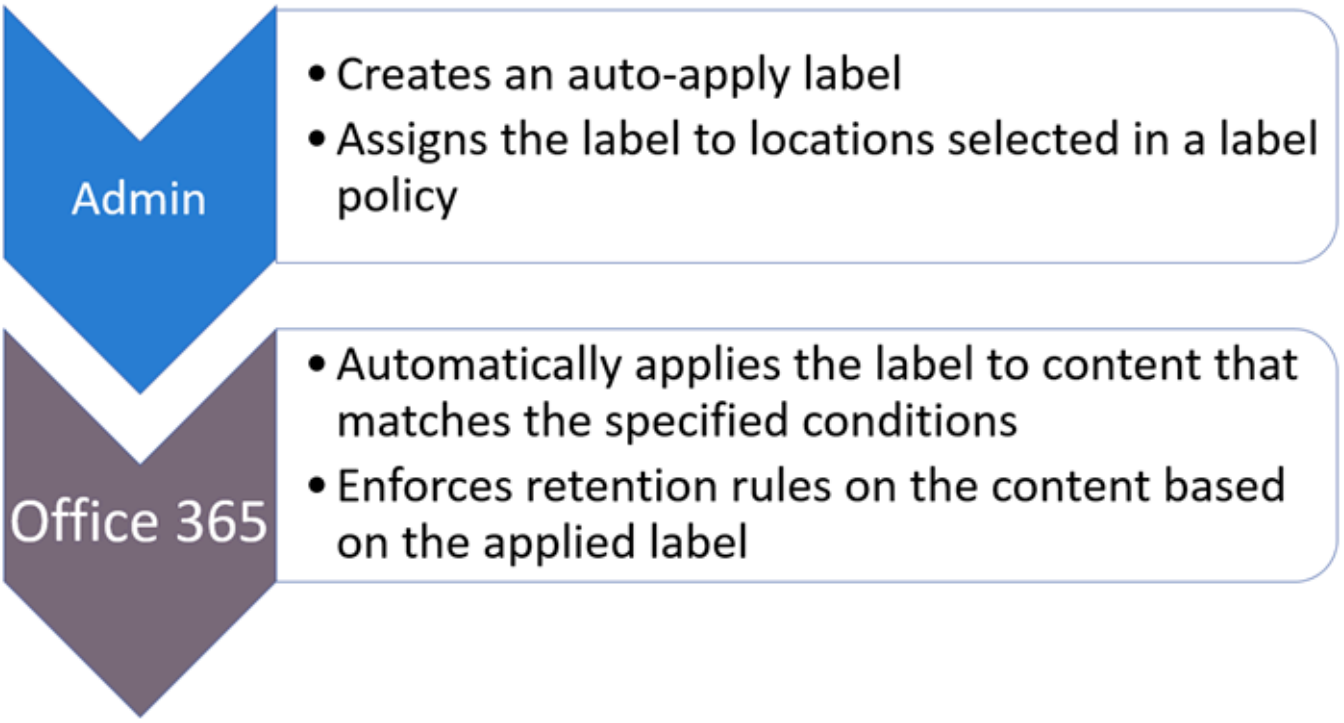
Automatically apply a retention label to retain or delete content

Summarize this article for me

> *Microsoft Purview service description*

> **Note**
>
> This scenario isn't supported for regulatory records or default labels for an organizing structure such as a document set or library in SharePoint, or a folder in Exchange. These scenarios require a published retention label policy.

One of the most powerful features of retention labels is the ability to apply them automatically to content that matches specified conditions. In this case, people in your organization don't need to apply the retention labels. Microsoft 365 does the work for them.



Auto-applying retention labels are powerful because:

- You don't need to train your users on all of your classifications.
- You don't need to rely on users to classify all content correctly.
- Users no longer need to know about data governance policies - they can focus on their work.

You can apply retention labels to content automatically when that content doesn't already have a retention label applied and contains sensitive information, keywords or searchable properties, or a match for trainable classifiers. You can also automatically apply a retention label to cloud attachments that are stored in SharePoint or OneDrive.

> **Tip**
>
> Use searchable properties to identify Teams meeting transcripts or recordings with accompanying transcripts and items that have a sensitivity label applied.

The processes to automatically apply a retention label based on these conditions:

Use the following instructions for the two admin steps.

> ⓘ **Note**
>
> Auto-policies use service-side labeling with conditions to automatically apply retention labels to items. You can also automatically apply a retention label with a label policy when you do the following:
>
> - Apply a retention label to a Microsoft Syntex model
> - Apply a default retention label for SharePoint and Outlook
> - Apply a retention label to email by using Outlook rules
>
> For these scenarios, see Publish retention labels and apply them in apps.

Learn about simulation mode

You can run an auto-labeling policy in simulation mode when it's configured for either of the following conditions:

- Specific types of sensitive information
- Specific keywords or searchable properties that match a query you create

Very similar to simulation mode for auto-labeling policies for sensitivity labels, this addition lets you run the auto-labeling deployment like the WhatIf parameter for PowerShell. You see results reported as if the auto-labeling policy applied your selected label, using the conditions that

you defined. You can then refine your conditions for accuracy if needed, and rerun the simulation.

Simulation mode also lets you gradually increase the scope of your auto-labeling policy before deployment. For example, you might start with a single location, such as a SharePoint site, with a single document library. Then, with iterative changes, increase the scope to multiple sites, and then to another location, such as OneDrive.

Typical workflow for an auto-labeling policy:

1. Create and configure an auto-labeling retention policy.
2. Run the policy in simulation mode, and wait for it to complete.
3. Review the results, and if necessary, refine your policy and rerun simulation. Wait for it to complete again.
4. Repeat step 3 as needed.
5. Deploy in production by turning on the policy.

Unlike simulation mode for automatically applying sensitivity labels:

- Simulation mode is optional, and not required to complete before you turn on the policy. You can even turn on the policy while simulation is still running.
- When simulation completes, the results automatically expire within seven days. Then, to view samples for your policy, you must restart the simulation.

Other considerations for simulation mode for auto-apply retention label policies:

- A maximum of 30 simulation jobs can be active in a 12-hour time period.
- A maximum of 100 item samples can be collected per mailbox.
- If you use adaptive scopes for your policy:
  - A maximum of 20,000 locations (any combination of sites and mailboxes) is supported.
  - Because these scopes use dynamic queries that run daily and can take a few days to fully populate, wait and confirm their membership before you start simulation.
  - For the **Microsoft 365 Group mailboxes & sites** location, items stored in AuxPrimary mailboxes aren't supported.
- You might need to be assigned additional permissions to see the simulation results. For information about the required roles, see the next section, Before you begin.
- Simulation counts all items matching the policy criteria at time of simulation. However, when the policy is turned on, only content that isn't already labeled is eligible for auto-applying retention labels.
- Although auto-labeling for sensitive information types applies to emails sent and received rather than emails stored in mailboxes, simulation for Exchange locations runs against

emails stored in mailboxes. Using historical data lets you more quickly assess the effectiveness of your chosen sensitive information types and configuration.

- For the **Microsoft 365 Group mailboxes & sites** and **OneDrive accounts** locations: Items that are stored in arbitration mailboxes aren't supported for simulation.
- Because simulation results are based on items available in the specified locations at the time the simulation job runs, remember to take the following considerations into account when you turn on the policy:
  - Items that are no longer within the specified location won't be labeled.
  - Items that no longer match the policy criteria won't be labeled.

On the **Label policies** page, the **Status** column displays **In simulation** for auto-labeling policies that are running in simulation, or configured for simulation and complete.

Simulation typically completes within one or two days, depending on the amount of data to analyze. The completed simulation triggers an email notification that's sent to the user configured to receive activity alerts.

To view the simulation results, select the policy from the **Label policies** page, and from the flyout pane, select **View simulation**. You can then view any samples, review the number of matching items and the locations, edit the policy, turn on the policy, or restart the simulation.

Before you begin

To make sure you have permissions to create and edit retention labels and their policies, see the permissions information for records management or data lifecycle management, depending on the solution you're using.

To run the policy in simulation mode:

- Auditing for Microsoft 365 must be turned on. If you need to turn on auditing or you're not sure whether auditing is already on, see Turn audit log search on or off.
- To view the list of samples, you must have the **Data Classification List Viewer** role, and to view file or email contents in the source view, you must have the **Data Classification Content Viewer** role.

Make sure you have created the retention labels you want to apply to items.

> **Note**
>
> You can extend your auto-labeling of retention labels to images. For more information, see Learn about optical character recognition in Microsoft Purview.

How to create an auto-apply retention label policy

Decide before you create your retention label policy whether to make it **adaptive** or **static**. For more information, see Adaptive or static policy scopes for retention. If you decide to use an adaptive policy, you must create one or more adaptive scopes before you create your retention label policy, and then select them during the create retention label policy process. For instructions, see Configuration information for adaptive scopes.

When you create an auto-apply policy, you select a retention label to automatically apply to content, based on the conditions that you specify:

1. Sign in to the Microsoft Purview portal and then:

   If you're using records management: **Solutions** > **Records Management** > **Policies** > **Label policies** > **Auto-apply a label**

   If you're using data lifecycle management: **Solutions** > **Data Lifecycle Management** > **Policies** > **Label policies** > **Auto-apply a label**

2. Enter a name and description for this auto-labeling policy, and then select **Next**.

3. For **Choose the type of content you want to apply this label to**, select one of the available conditions. For more information about the choices, see the Configuring conditions for auto-apply retention labels section on this page.

4. For the **Assign admin units** page, keep the default of **Full directory**. Currently, admin units aren't supported for this policy.

5. For the **Choose the type of retention policy to create** page, select **Adaptive** or **Static**, depending on the choice you made from the Before you begin instructions. If you haven't already created adaptive scopes, you can select **Adaptive** but because there won't be any adaptive scopes to select, you won't be able to finish the policy configuration with this option.

6. Depending on your selected scope:

   - If you chose **Adaptive**: On the **Choose adaptive policy scopes and locations** page, select **Add scopes** and select one or more adaptive scopes that have been created. Then, select one or more locations. The locations that you can select depend on the scope types added. For example, if you only added a scope type of **User**, you'll be able to select **Exchange mailboxes** but not **SharePoint sites**.

   - If you chose **Static**: On the **Choose locations** page, toggle on or off any of the locations. For each location, you can leave it at the default to apply the policy to the entire location, or specify includes and excludes

For information about the location choices, see Locations.

7. Follow the prompts to select a retention label, whether to run the policy in simulation mode or turn it on (if applicable for your chosen condition), and then review and submit your configuration choices.

To edit an existing retention label policy (the policy type is **Auto-apply**), select it, and then select the **Edit** option to start the **Edit retention policy** configuration.

After content is labeled by using an auto-apply label policy, the applied label can't be automatically removed or changed by changing the content or the policy, or by a new auto-apply label policy. For more information, see Only one retention label at a time.

> **Note**
>
> An auto-apply retention label policy will never replace an existing retention label that's applied to content. If you want to relabel content by using the conditions you configure, you'll need to manually remove the current retention label from existing content.

Configuring conditions for auto-apply retention labels

You can apply retention labels to content automatically when that content contains:

- Specific types of sensitive information
- Specific keywords or searchable properties that match a query you create
- A match for trainable classifiers

Or, you can automatically apply retention labels to newly shared cloud attachments.

When you configure retention labels to auto-apply based on sensitive information, keywords or searchable properties, or trainable classifiers, use the following table to identify when retention labels can be automatically applied.

SharePoint items that are in draft or that have never been published aren't supported for this scenario.

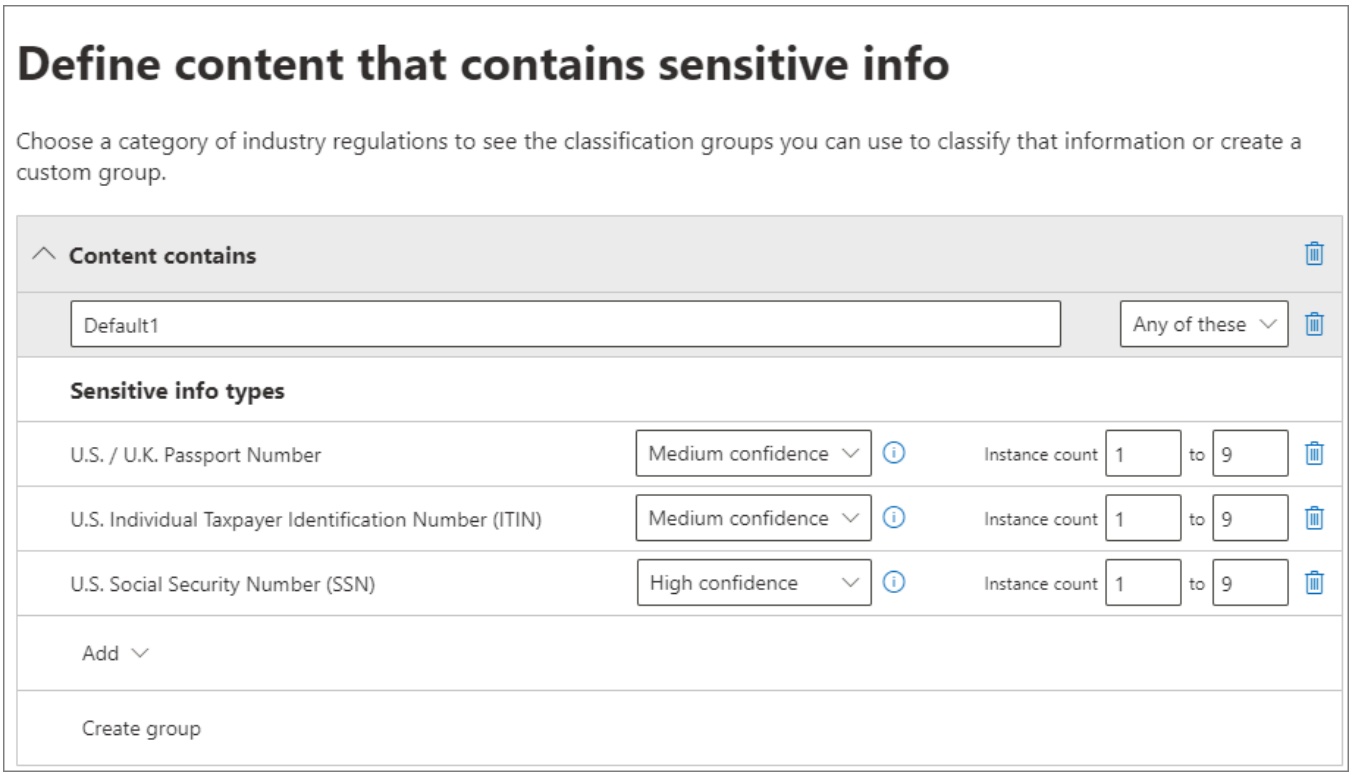
Exchange:

Expand table

Condition	Items in transit (sent or received)	Existing items (data at rest)
Sensitive info types	Yes	No
Specific keywords or searchable properties	Yes	Yes
Trainable classifiers	Yes	Yes (last six months only)

SharePoint and OneDrive:

Expand table



Condition	New or modified items	Existing items
Sensitive info types	Yes	Yes *
Specific keywords or searchable properties	Yes	Yes
Trainable classifiers	Yes	Yes (last six months only)

Footnote:

* Applies only to content that's already classified, which you can determine by using content explorer.

Auto-apply labels to content with specific types of sensitive information

When you create auto-apply retention label policies for sensitive information, you see the same list of policy templates as when you create a Microsoft Purview Data Loss Prevention (DLP) policy. Each template is preconfigured to look for specific types of sensitive information. In the following example, the sensitive info types are from the **Privacy** category, and **U.S Personally Identifiable Information (PII) Data** template:

To learn more about the sensitive information types, see Learn about sensitive information types. Currently, exact data match based sensitive information types and document fingerprinting aren't supported for this scenario.

After you select a policy template, you can add or remove any types of sensitive information, and you can change the confidence level and instance count. In the previous example screenshot, these options have been changed so that a retention label will be auto-applied only when:

- The type of sensitive information that's detected has a match accuracy (or confidence level) of at least **Medium confidence** for two of the sensitive info types, and **High confidence** for one. Many sensitive information types are defined with multiple patterns, where a pattern with a higher match accuracy requires more evidence to be found (such as keywords, dates, or addresses), while a pattern with a lower match accuracy requires less evidence. The lower the confidence level, the easier it is for content to match the condition but with the potential for more false positives.
- The content contains between 1 and 9 instances of any of these three sensitive info types. The default for the **to** value is **Any**.

For more information about these options, see the following guidance from the DLP documentation Test your Data Loss Prevention policies.

> ⓘ **Important**

Sensitive information types have two different ways of defining the max unique instance count parameters. To learn more, see Instance count supported values for SIT.

To consider when using sensitive information types to auto-apply retention labels:

- If you use custom sensitive information types, these can't auto-label existing items in SharePoint and OneDrive.

Auto-apply labels to content with keywords or searchable properties

You can auto-apply labels to content by using a query that contains specific words, phrases, or values of searchable properties. You can refine your query by using search operators such as AND, OR, and NOT.

For more information about the query syntax that uses Keyword Query Language (KeyQL), see Keyword Query Language (KeyQL) syntax reference.

Query-based auto-apply policies use the same search index as eDiscovery content search to identify content. For more information about the searchable properties that you can use, see Keyword queries and search conditions for Content Search.

Some things to consider when using keywords or searchable properties to auto-apply retention labels:

- For SharePoint, crawled properties and custom properties aren't supported for these KeyQL queries and you must use only predefined managed properties for documents. However, you can use mappings at the tenant level with the predefined managed

properties that are enabled as refiners by default (RefinableDate00-19, RefinableString00-99, RefinableInt00-49, RefinableDecimals00-09, and RefinableDouble00-09). For more information, see Overview of crawled and managed properties in SharePoint Server, and for instructions, see Create a new managed property.

- If you map a custom property to one of the refiner properties, wait 24 hours before you use it in your KeyQL query for a retention label.
- Although SharePoint managed properties can be renamed by using aliases, don't use these for KeyQL queries in your labels. Always specify the actual name of the managed property, for example, "RefinableString01".
- To search for values that contain spaces or special characters, use double quotation marks (`" "`) to contain the phrase; for example, `subject:"Financial Statements"`.
- Suffix wildcard searches (such as `*cat`) or substring wildcard searches (such as `*cat*`) aren't supported. However, prefix wildcard searches (such as `cat*`) are supported.
- Use the *DocumentLink* property instead of *Path* to match an item based on its URL. To include or exclude content inside a specific document library, use the *ParentLink* property.
- Be aware that partially indexed items can be responsible for not labeling items that you're expecting, or labeling items that you're expecting to be excluded from labeling when you use the NOT operator. For more information, see Partially indexed items in Content Search.
- We recommend that you don't use spaces between words in RefinableStrings values on documents. RefinableString isn't a word-break property.

Examples queries:

Expand table

Workload	Example	Description
Exchange	`subject:"Financial Statements"`	Finds emails with the exact phrase "Financial Statements" in the subject line, ignoring case.
Exchange	`recipients:garthf@contoso.com`	Finds emails sent to `garthf@contoso.com`, whether directly or copied.

Workload	Example	Description
SharePoint	`contenttype:document`	Finds all items classified as documents in SharePoint.
SharePoint	`site:https://contoso.sharepoint.com/sites/teams/procurement AND contenttype:document`	Finds all documents in the Procurement team site on SharePoint.
SharePoint	`ParentLink:SiteAssets`	Finds items stored in the Site Assets library of SharePoint sites.
SharePoint	`ParentLink:"https://contoso.sharepoint.com/sites/Legal/Shared Documents"`	Finds only items stored in the Shared Documents library of the Legal site.
SharePoint	`NOT ParentLink:"https://contoso.sharepoint.com/sites/Legal/Shared Documents"`	Finds all content except items stored in that document library.
OneDrive	`ParentLink:"https://contoso-my.sharepoint.com/personal/john_doe_contoso_com/Documents"`	Includes only content stored in John Doe's OneDrive Documents library.
OneDrive	`NOT ParentLink:"https://contoso-my.sharepoint.com/personal/john_doe_contoso_com/Documents"`	Excludes all content from that specific OneDrive library.
Exchange or SharePoint	`"customer information" OR "private"`	Finds content that includes either "customer information" or "private", in emails (Exchange) or documents (SharePoint).

More complex examples:

The following query for SharePoint identifies Word documents or Excel spreadsheets when those files contain the keywords **password**, **passwords**, or **pw**:

KeyQL

```
(password OR passwords OR pw) AND (filetype:doc* OR filetype:xls*)
```

The following query for Exchange identifies any Word document or PDF that contains the word **nda** or the phrase **non disclosure agreement** when those documents are attached to an email:

KeyQL

```
(nda OR "non disclosure agreement") AND (attachmentnames:.doc* OR
attachmentnames:.pdf)
```

The following query for SharePoint identifies documents that contain a credit card number:

KeyQL

```
sensitivetype:"credit card number"
```

The following query contains some typical keywords to help identify documents or emails that contain legal content:

KeyQL

```
ACP OR (Attorney Client Privilege*) OR (AC Privilege)
```

The following query contains typical keywords to help identify documents or emails for human resources:

KeyQL

```
(resume AND staff AND employee AND salary AND recruitment AND candidate)
```

Note that this final example uses the best practice of always including operators between keywords. A space between keywords (or two `property:value` expressions) is the same as using AND. By always adding operators, it's easier to see that this example query identifies only content that contains all these keywords, instead of content that contains any of the keywords. If your intention is to identify content that contains any of the keywords, specify OR instead of AND. As this example shows, when you always specify the operators, it's easier to correctly interpret the query.

Microsoft Teams meeting recordings and transcripts

To identify Microsoft meeting recordings and transcripts that are stored in users' OneDrive accounts or in SharePoint, specify the following for the **Keyword query editor**:

KeyQL

```
ProgID:Media AND ProgID:Meeting
```

Most of the time, meeting recordings and transcripts are saved to OneDrive. But for channel meetings, they're saved in SharePoint. For more information, see Use OneDrive and SharePoint to store meeting recordings.

The query will identify:

- A Teams meeting transcript, when there isn't an accompanying recording
- A Teams meeting recording and accompanying transcript

Because video transcripts are stored with the video in OneDrive or SharePoint, they can't be targeted for retention separately when there's a Teams meeting recordings video file.

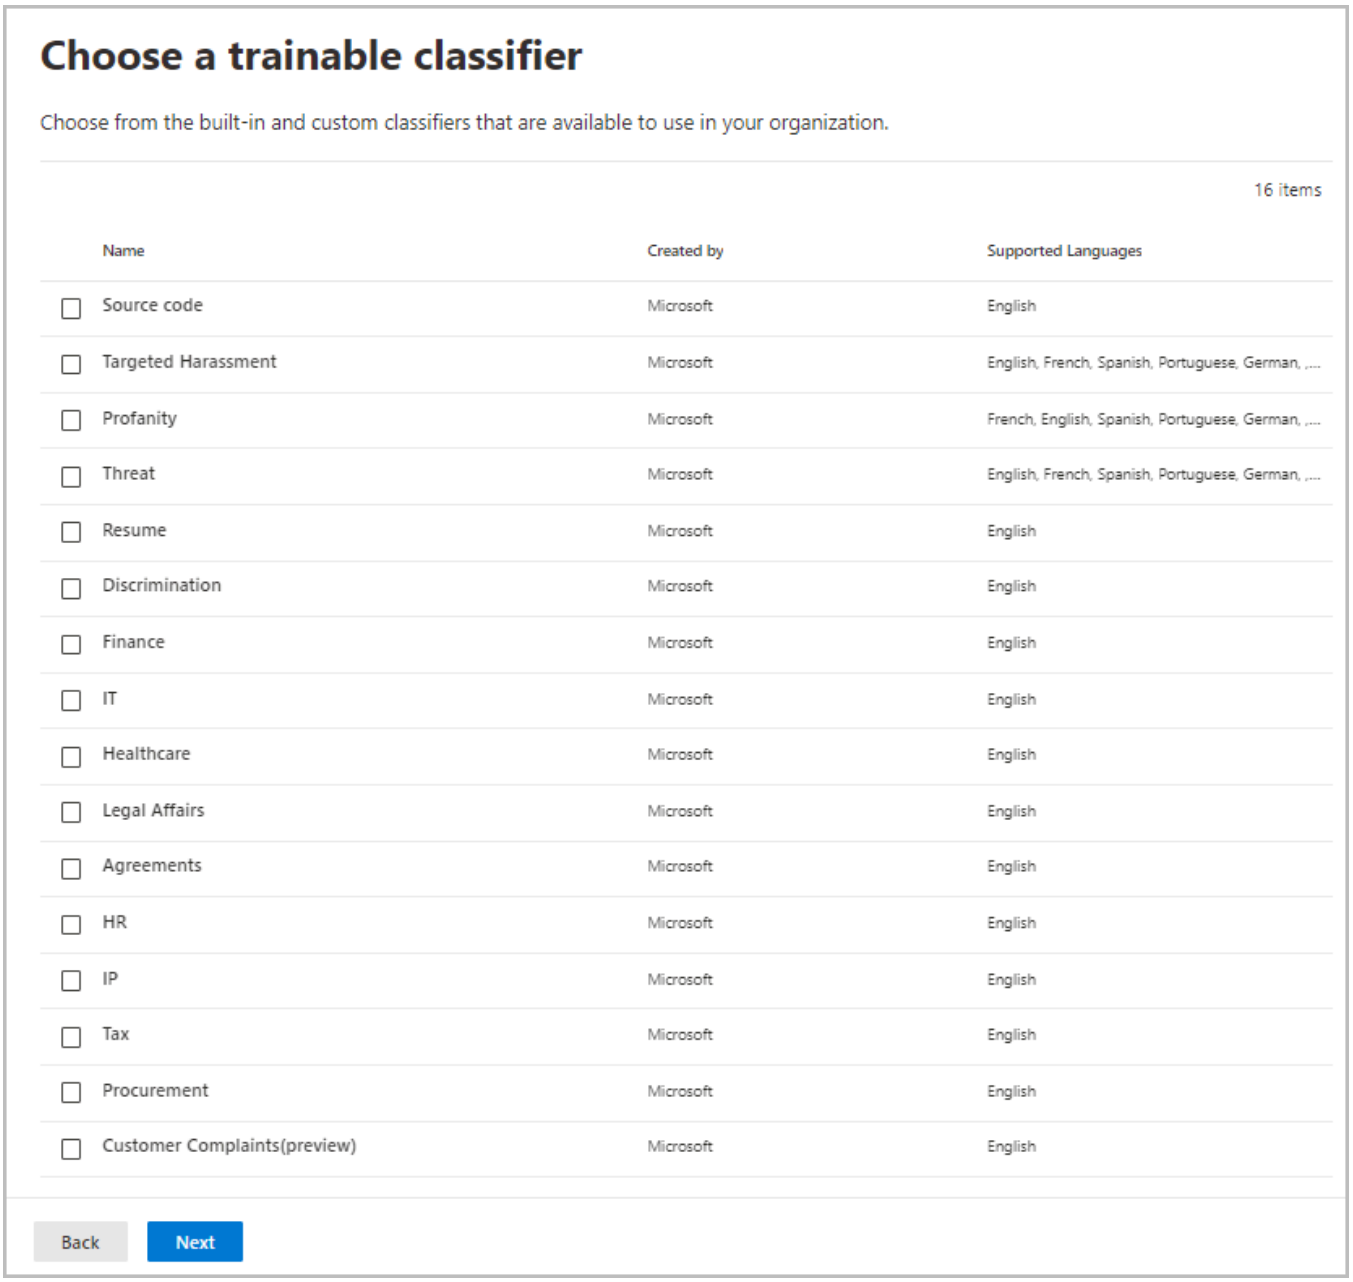
Identify files and emails that have a sensitivity label

To identify files in SharePoint or OneDrive and Exchange emails that have a specific sensitivity label applied, specify the following for the **Keyword query editor**:

KeyQL

```
InformationProtectionLabelId:<GUID>
```

To find the GUID, use the Get-Label cmdlet from Security & Compliance PowerShell:



PowerShell

```
Get-Label | Format-Table -Property DisplayName, Name, Guid
```

Auto-apply labels to content by using trainable classifiers

> **Important**
>
> Currently, trainable classifiers for auto-labeling can't be used with adaptive scopes. Use a static scope instead.

When you choose the option for a trainable classifier, you can select one or more of the pre-trained or custom trainable classifiers:

The available pre-trained classifiers are often updated, so there might be more entries to select than the ones displayed in this screenshot.

For more information about trainable classifiers, see Learn about trainable classifiers.

To automatically apply a label by using this option, SharePoint sites, as well as mailboxes, must have at least 10 MB of data.

To consider when using trainable classifiers to auto-apply retention labels:

- You can't auto-label SharePoint and OneDrive items that are older than six months.

Auto-apply labels to cloud attachments

> **Note**

Support for cloud attachments that are shared in Viva Engage is in preview.

You might need to use this option if you're required to capture and retain all copies of files in your tenant that are sent over communications by users, or files that are referenced in Microsoft 365 Copilot or Microsoft 365 Copilot Chat. You use this option in conjunction with retention policies for the communication services themselves; Exchange, Teams, Viva Engage, and Copilot.

> **Important**
>
> When you select a label to use for auto-applying retention labels for cloud attachments, ensure that the label retention setting **Start the retention period based on** is **When items were labeled**.

Cloud attachments, sometimes also known as modern attachments, are a sharing mechanism that uses embedded links to files that are stored in the cloud. They support centralized storage for shared content with collaborative benefits, such as version control. Cloud attachments are not attached copies of a file or a URL text link to a file. However, support for URL text links is also supported. You might find it helpful to refer to the visual checklists for supported cloud attachments in Outlook, Teams, and Viva Engage.

When you choose the option to apply a retention label to cloud attachments, for compliance purposes, a copy of that file is created at the time of sharing. Your selected retention label is then applied to the copy that can then be identified using eDiscovery. Users aren't aware of the copy that is stored in the Preservation Hold library. The retention label isn't applied to the message itself, or to the original file.

If the file is modified and shared again, a new copy of the file as a new version is saved in the Preservation Hold library. For more information, including why you should use the **When items were labeled** label setting, see How retention works with cloud attachments.

The cloud attachments supported for this option are files such as documents, videos, and images that are stored in SharePoint and OneDrive. For Teams, cloud attachments shared in chat messages, and standard and private channels are supported. For Viva Engage, cloud attachments shared with users in storylines, community posts, and Inbox messages are supported. For Copilot, files referenced to users in the chat conversation and referenced by users are supported.

Cloud attachments shared over meeting invites and apps other than Teams, Outlook, Viva Engage, and Copilot aren't supported. The cloud attachments must be shared by users or Copilot; cloud attachments sent via bots aren't supported.

Although not required for this option, we recommend that you ensure versioning is enabled for your SharePoint sites and OneDrive accounts so that the version shared can be accurately captured. If versioning isn't enabled, the last available version is retained. Documents in draft or that have never been published aren't supported.

When you select a label to use for auto-applying retention labels for cloud attachments, make sure the label retention setting **Start the retention period based on** is **When items were labeled**.

When you configure the locations for this option, you can select:

- **SharePoint classic and communication sites** for shared files stored in SharePoint communication sites, team sites that aren't connected by Microsoft 365 groups, and classic sites.
- **Microsoft 365 Groups** for shared files that are stored in team sites connected by Microsoft 365 groups.
- **OneDrive accounts** for shared files stored in users' OneDrive.

You'll need to create separate retention policies if you want to retain or delete the original files, email messages, or messages from Teams and Copilot, and Viva Engage.

> ⓘ **Note**
>
> If you want retained cloud attachments to expire at the same time as the messages that contained them, configure the retention label to have the same retain and then delete actions and timings as your retention policies for Exchange, Teams and Copilot, and Viva Engage.

To consider when auto-applying retention labels to cloud attachments:

- If cloud attachments and links in a Teams or Viva Engage message are changed after the message is sent by editing the message, those changed cloud attachments and links aren't supported for retention.

- When a user is added to a Teams conversation and given access to the full history of the conversation, that history can include cloud attachments and URL text links. If these attachments were shared within 48 hours of the user added to the conversation, current copies of the attachments are auto-labeled for retention. Attachments shared before this time period aren't supported for newly added users.

- Attachments and links shared outside Teams, Outlook, Viva Engage, and Copilot aren't supported, and the attachments and links must be content stored in SharePoint or OneDrive.

- Cloud attachments and links in encrypted emails or encrypted messages aren't supported.
- Sharing an existing Viva Engage message with an attachment isn't supported.
- Specific to shared documents from URL text links:
  - Supported in the message body but not in the email subject or Teams channel subject, announcement, or subheadings.
  - Not supported for previous responses in the same thread, only the current message
  - Total limit of 25 attachments in a single message, where this maximum can be any combination of cloud attachments and shared documents from URL text links
  - Not supported beyond 5,000 characters in the initial email body or in Teams, Copilot, and Viva Engage messages
- The following items aren't supported as attachments that can be retained:
  - SharePoint sites, pages, lists, forms, folders, document sets, and OneNote pages.
  - Files shared by users who don't have access to those files at the time of sharing.
  - Files that are deleted or moved before the cloud attachment is sent. For example, a user copies and pastes a previously shared attachment from another message, without first confirming that the file is still available. Or, somebody forwards an old message when the file is now deleted.
  - Files that are shared by guests or users outside your organization.
  - Files in draft emails and messages that aren't sent.
  - Empty files.

How long it takes for retention labels to take effect

When you auto-apply retention labels based on sensitive information, keywords or searchable properties, or trainable classifiers, it can take up to seven days for the retention labels to be applied:

If the expected labels don't appear after seven days, check the **Status** of the auto-apply policy by selecting it from the **Label policies** page in the Microsoft Purview portal. If you see the status of **Off (Error)** and in the details for the locations see a message that it's taking longer than expected to deploy the policy (for SharePoint) or to try redeploying the policy (for OneDrive), try running the Set-RetentionCompliancePolicy PowerShell command to retry the policy distribution:

1. Connect to Security & Compliance PowerShell.
2. Run the following command:

```
PowerShell
Set-RetentionCompliancePolicy -Identity <policy name> -RetryDistribution
```

Updating retention labels and their policies

For auto-apply retention label policies that are configured for sensitive information, keywords or searchable properties, or a match for trainable classifiers: When a retention label from the policy is already applied to content, a change in configuration to the selected label and policy will be automatically applied to this content in addition to content that's newly identified.

For auto-apply retention label policies that are configured for cloud attachments: Because this policy applies to newly shared files rather than existing files, a change in configuration to the selected label and policy will be automatically applied to newly shared content only.

Some settings can't be changed after the label or policy is created and saved, which include:

- Names for retention labels and their policies, the scope type (adaptive or static), and the retention settings except the retention period.
- The option to mark items as a record.

Deleting retention labels

To delete a retention label, all three conditions must apply:

- The label isn't included in any retention label policy
- The label isn't configured for event-based retention
- The label isn't configured to mark items as regulatory records

When all these conditions are met:

- You can always delete a retention label that doesn't mark items as records (sometimes referred to as a "standard retention label"). The deletion succeeds even if the label is applied to items, and the retention label is then removed from these items.
- You can delete a retention label that marks items as records only if the label isn't applied to items. If the label has been applied to items, the deletion fails and you see a link to content explorer to identify the labeled items. It can take up to two days for content explorer to show the items that are labeled. In this scenario, the retention label might be deleted without showing you the link to content explorer.

Locking the policy to prevent changes

If you need to ensure that no one can turn off the policy, delete the policy, or make it less restrictive, see Use Preservation Lock to restrict changes to retention policies and retention label policies.

Troubleshooting retention label policies

If your auto-apply retention label policies aren't working as expected or you see errors related to these policies, use the following troubleshooting resources:

- Identify errors in Microsoft 365 retention and retention label policies
- Resolve errors in Microsoft 365 retention and retention label policies

Additionally, if you're also using the older feature, MRM retention tags and retention policies, see Auto-apply retention label doesn't apply to items in a mailbox.

Next steps

To help you track the labels applied from your auto-labeling policies:

- Monitoring retention labels
- Using Content Search to find all content with a specific retention label
- Auditing retention actions

See Use retention labels to manage the lifecycle of documents stored in SharePoint for an example scenario that uses an auto-apply retention label policy with managed properties in SharePoint, and event-based retention to start the retention period.

Last updated on 02/26/2026

Use Preservation Lock to restrict changes to retention policies and retention label policies

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

> **ⓘ Important**
>
> Currently, adaptive policy scopes don't support Preservation Lock.

Preservation Lock locks a retention policy or retention label policy so that no one—including a global admin—can turn off the policy, delete the policy, or make it less restrictive. This configuration might be needed for regulatory requirements and can help safeguard against rogue administrators.

When a retention policy is locked:

- No one can disable the policy or delete it
- Locations can be added but not removed
- You can extend the retention period but not decrease it

When a retention label policy is locked:

- No one can disable the policy or delete it
- Locations can be added but not removed
- Labels can be added but not removed

In summary, a locked policy can be increased or extended, but it can't be reduced or turned off.

> **ⓘ Important**
>
> Before you lock a retention policy or retention label policy, it's critical that you understand the impact and confirm whether it's required for your organization. For example, it might be needed to meet regulatory requirements. Administrators won't be able to disable or delete these policies after the preservation lock is applied.

Configure Preservation Lock after you've created a retention policy, or a retention label policy that you publish and contains only labels that mark items as regulatory records.

How to lock a retention policy or retention label policy

You must use PowerShell if you need to use Preservation Lock. Because administrators can't disable or delete a policy for retention after this lock is applied, enabling this feature is not available in the UI to safeguard against accidental configuration.

All retention policies with any configuration support Preservation Lock. To apply Preservation Lock on a retention label policy, it must contain only labels that mark items as regulatory records.

1. Connect to Security & Compliance PowerShell.

2. Find the name of the policy that you want to lock by running Get-RetentionCompliancePolicy. For example:

```
PS C:\WINDOWS\system32> Get-RetentionCompliancePolicy
Name                 Workload                                                Enabled Mode
----                 --------                                                ------- ----
PII Retention Policy Exchange, SharePoint, OneDriveForBusiness, Skype, ModernGroup True    Enforce
Employee Records     Exchange, SharePoint, OneDriveForBusiness, Skype, ModernGroup True    Enforce
Personal Financial PII Exchange, SharePoint, OneDriveForBusiness, Skype, ModernGroup True    Enforce
```

3. To place a Preservation Lock on your policy, run the Set-RetentionCompliancePolicy cmdlet with the name of the policy, and the *RestrictiveRetention* parameter set to true:

```
PowerShell

Set-RetentionCompliancePolicy -Identity "<Name of Policy>" -
RestrictiveRetention $true
```

   For example:

```
PS C:\WINDOWS\system32> Set-RetentionCompliancePolicy -Identity "Employee Records" -RestrictiveRetention $true
```

   When prompted, read and acknowledge the restrictions that come with this configuration by entering **Y**:

```
Confirm
You chose to make this a restrictive preservation policy. After you turn this policy on, you'll only be able to
add new locations to search or extend the time frame to preserve the content. You won't be able to turn off the
policy, delete it, or make any other changes.
[Y] Yes  [A] Yes to All  [N] No  [L] No to All  [?] Help (default is "Y"):
```

A Preservation Lock is now placed on the policy. To confirm, run `Get-RetentionCompliancePolicy` again, but specify the policy name and display the policy parameters:

PowerShell

```
Get-RetentionCompliancePolicy -Identity "<Name of Policy>" |Fl
```

You should see **RestrictiveRetention** is set to **True**. For example:

```
PS C:\WINDOWS\system32> Get-RetentionCompliancePolicy -Identity "Employee Records" |Fl

Create and publish retention labels by using PowerShell

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

After you've decided to use retention labels to help you keep or delete documents and emails in Microsoft 365, you might have realized that you have many and possibly hundreds of retention labels to create and publish. The recommended method to create retention labels at scale is by using file plan from the Microsoft Purview portal. However, you can also use PowerShell.

Use the information, template files and examples, and script in this article to help you bulk-create retention labels and publish them in retention label policies. Then, the retention labels can be applied by administrators and users.

The supplied instructions don't support retention labels that are auto-applied.

Overview:

1. In Excel, create a list of your retention labels and a list of their retention label policies.
2. Use PowerShell to create the retention labels and retention label policies in those lists.

Disclaimer

The sample scripts provided in this article aren't supported under any Microsoft standard support program or service. The sample scripts are provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample scripts and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Create a .csv file for the retention labels

1. Copy the following sample .csv file for a template and example entries for four different retention labels, and paste them into Excel.
2. Convert the text to columns: **Data** tab > **Text to Columns** > **Delimited** > **Comma** > **General**
3. Replace the examples with entries for your own retention labels and settings. For more information about the parameter values, see New-ComplianceTag.
4. Save the worksheet as a .csv file in a location that's easy to find for a later step. For example: C:>Scripts\Labels.csv

Notes:

- If the .csv file contains a retention label with the same name as one that already exists, the script skips creating that retention label. No duplicate retention labels are created.
- Don't change or rename the column headers from the sample .csv file provided, or the script will fail.

Sample .csv file for retention labels

text

```
Name (Required),Comment (Optional),IsRecordLabel (Required),RetentionAction
(Optional),RetentionDuration (Optional),RetentionType (Optional),ReviewerEmail
(Optional)
LabelName_t_1,Record - keep and delete - 2
years,$true,KeepAndDelete,730,CreationAgeInDays,
LabelName_t_2,Keep and delete tag - 7
years,$false,KeepAndDelete,2555,ModificationAgeInDays,
LabelName_t_3,5 year delete,$false,Delete,1825,TaggedAgeInDays,
LabelName_t_4,Record label tag - financial,$true,Keep,730,CreationAgeInDays,
```

Step 2: Create a .csv file for the retention label policies

1. Copy the following sample .csv file for a template and example entries for three different retention label policies, and paste them into Excel.
2. Convert the text to columns: **Data** tab > **Text to Columns** > **Delimited** > **Comma** > **General**

3. Replace the examples with entries for your own retention label policies and their settings. For more information about the parameter values for this cmdlet, see New-RetentionCompliancePolicy.

4. Save the worksheet as a .csv file in a location that's easy to find for a later step. For example: `<path>Policies.csv`

Notes:

- If the .csv file contains a retention label policy with the same name as one that already exists, the script skips creating that retention label policy. No duplicate retention label policies are created.
- Don't change or rename the column headers from the sample .csv file provided, or the script will fail.

Sample .csv file for retention policies

text

```
Policy Name (Required),PublishComplianceTag (Required),Comment (Optional),Enabled
(Required),ExchangeLocation (Optional),ExchangeLocationException
(Optional),ModernGroupLocation (Optional),ModernGroupLocationException
(Optional),OneDriveLocation (Optional),OneDriveLocationException
(Optional),PublicFolderLocation (Optional),SharePointLocation
(Optional),SharePointLocationException (Optional),SkypeLocation
(Optional),SkypeLocationException (Optional)
Publishing Policy Red1,"LabelName_t_1, LabelName_t_2, LabelName_t_3,
LabelName_t_4",N/A,$true,All,,All,,All,,,All,,,
Publishing Policy Orange1,"LabelName_t_1, LabelName_t_2",N/A,$true,All,,,,,,,,,
Publishing Policy Yellow1,"LabelName_t_3, LabelName_t_4",N/A,$false,All,,,,,,,,,
```

Step 3: Create the PowerShell script

1. Copy and paste the following PowerShell script into Notepad.

2. Save the file by using a file name extension of **.ps1** in a location that's easy to find. For example: `<path>CreateRetentionSchedule.ps1`

Notes:

- The script prompts you to provide the two source files that you created in the previous two steps:
  - If you don't specify the source file to create the retention labels, the script moves on to create the retention label policies.

- If you don't specify the source file to create the retention label policies, the script creates the retention labels only.

- The script generates a log file that records each action it took and whether the action succeeded or failed. See the final step for instructions how to locate this log file.

PowerShell script

Powershell

```
<#
. Steps: Import and publish retention labels
    - Load retention labels csv file
    - Validate csv file input
    - Create retention labels
    - Create retention policies
    - Publish retention labels for the policies
    - Generate the log for retention labels and policies creation
    - Generate the csv result for the labels and policies created
. Syntax
    .\Publish-ComplianceTag.ps1 [-LabelListCSV <string>] [-PolicyListCSV <string>]
. Detailed Description
    1) [-LabelListCSV <string>]
    -LabelListCSV ".\SampleInputFile_LabelList.csv"
    Load compliance tag for creation.
    2) [-PolicyListCSV <string>]
    -PolicyListCSV ".\SampleInputFile_PolicyList.csv"
    Load compliance tag for creation.

            $row['ExchangeLocationException'] = $t.ExchangeLocationException
            $row['ModernGroupLocation'] = $t.ModernGroupLocation
            $row['ModernGroupLocationException'] = $t.ModernGroupLocationException
            $row['OneDriveLocation'] = $t.OneDriveLocation
            $row['OneDriveLocationException'] = $t.OneDriveLocationException
            $row['PublicFolderLocation'] = $t.PublicFolderLocation
            $row['SharePointLocation'] = $t.SharePointLocation
            $row['SharePointLocationException'] = $t.SharePointLocationException
            $row['SkypeLocation'] = $t.SkypeLocation
            $row['SkypeLocationException'] = $t.SkypeLocationException

            # Add the row to the table
            $table.Rows.Add($row)
        }
        $table | Export-Csv $tagPubRetFile -NoTypeInformation
    }
    catch
    {
        WriteToLog -Type "Failed" "Error in exporting results."
    }
}
# Create compliance tag
CreateComplianceTag -FilePath $LabelListCSV
# Create retention policy and publish compliance tag with the policy
CreateRetentionCompliancePolicy -FilePath $PolicyListCSV
# Export to result csv
if ($ResultCSV)
{
    ExportCreatedComplianceTag -LabelFilePath $LabelListCSV
    ExportPublishedComplianceTagAndPolicy -PolicyFilePath $PolicyListCSV
}
```

Step 4: Run the PowerShell script

First, Connect to Security & Compliance PowerShell.

Then, run the script that creates and publishes the retention labels:

1. In your Security & Compliance PowerShell session, enter the path, followed by the characters `.\` and the file name of the script, and then press ENTER to run the script. For example:

   ```
   PowerShell

   <path>.\CreateRetentionSchedule.ps1
   ```

2. The script prompts you for the locations of the .csv files that you created in the previous steps. Enter the path, followed by the characters `.\` and file name of the .csv file, and then press ENTER. For example, for the first prompt:

   ```
   PowerShell

   <path>.\Labels.csv
   ```

Step 5: View the log file with the results

Use the log file that the script created to check the results and identify any failures that need resolving.

You can find the log file at the following location, although the digits in the example file name vary.

```
DOS

<path>.\Log_Publish_Compliance_Tag_01112018_151239.txt
```

Use retention labels to manage the lifecycle of documents stored in SharePoint

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

This article describes how you can manage the lifecycle of documents that are stored in SharePoint by using automatically applied retention labels and event-based retention.

The auto-apply functionality can use SharePoint metadata for document classification. The example in this article is for product-related documents, but the same concepts can be used for other scenarios. For example, in the oil and gas industry, you could use it to manage the lifecycle of documents about physical assets such as oil platforms, well logs, or production licenses. In the financial services industry, you could manage bank account, mortgage, or insurance contract documents. In the public sector, you could manage construction permits or tax forms.

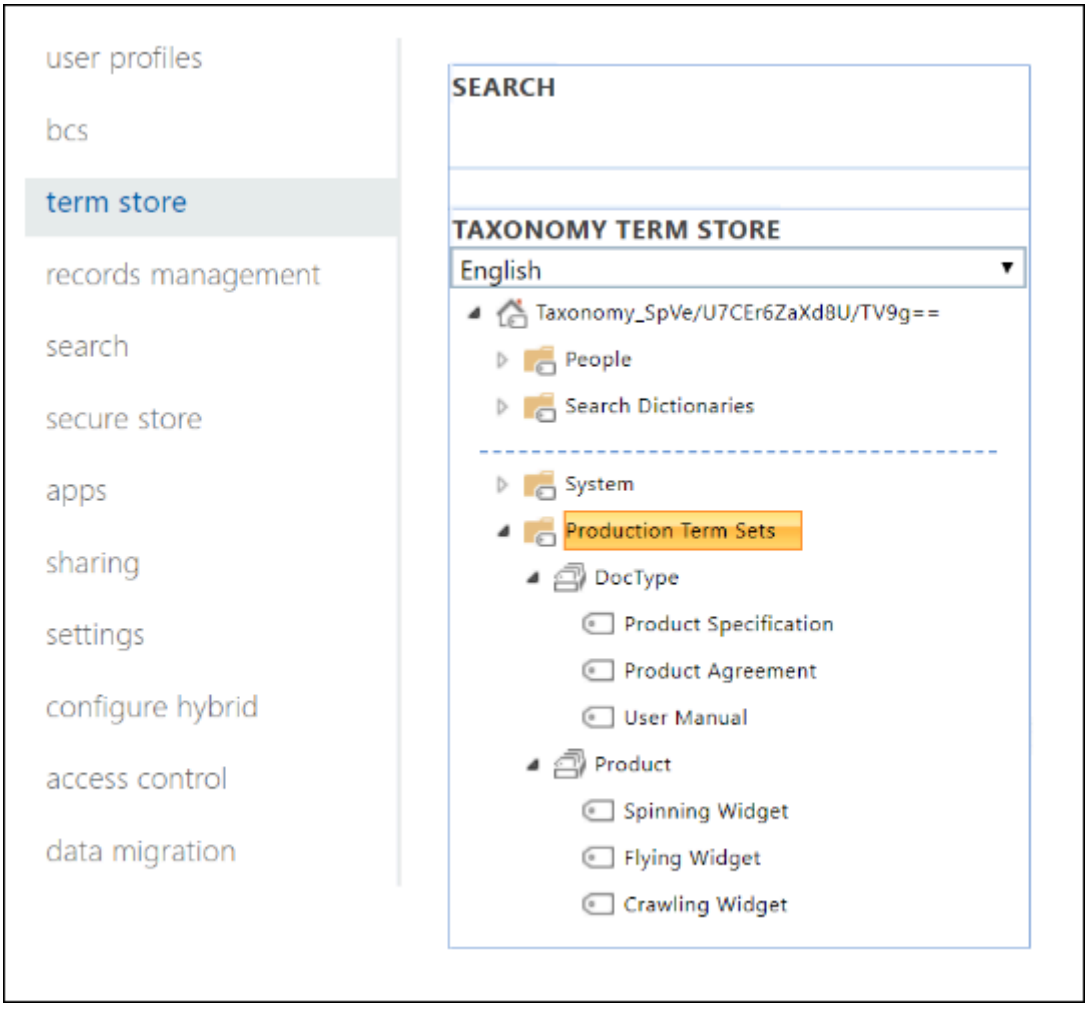
This article looks at the information architecture and definition of the retention labels, classifies documents by auto-applying the labels, then generates the events that start the retention period.

Information architecture

Our scenario is a manufacturing company that uses SharePoint to store all the documents about the products that the company develops. These documents include product specifications, agreements with suppliers, and user manuals. When these documents are stored in SharePoint through Enterprise Content Management policies, document metadata is defined to classify them. Each document has the following metadata properties:

- **Doc Type** (product specification, agreement, or user manual)
- **Product Name** (Spinning Widget, Flying Widget, Crawling Widget)
- **Status** (draft or final)

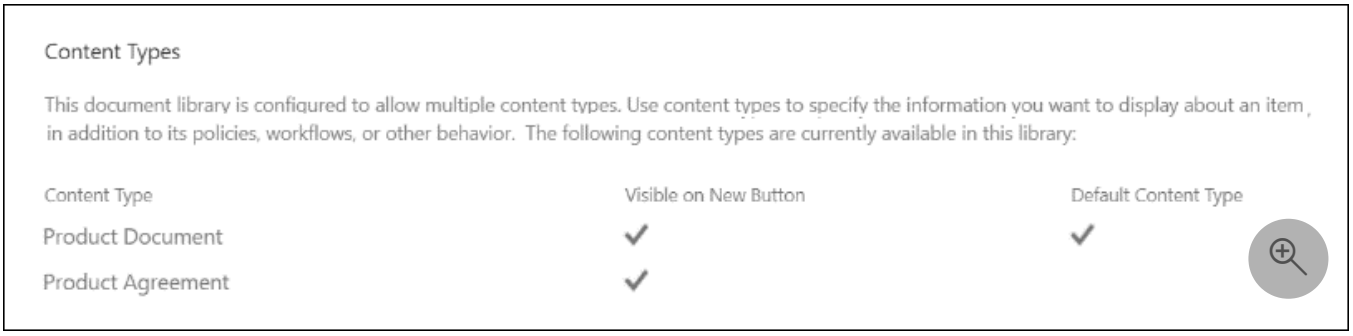
This metadata forms a base content type called *Production Document* for all the documents.



Columns

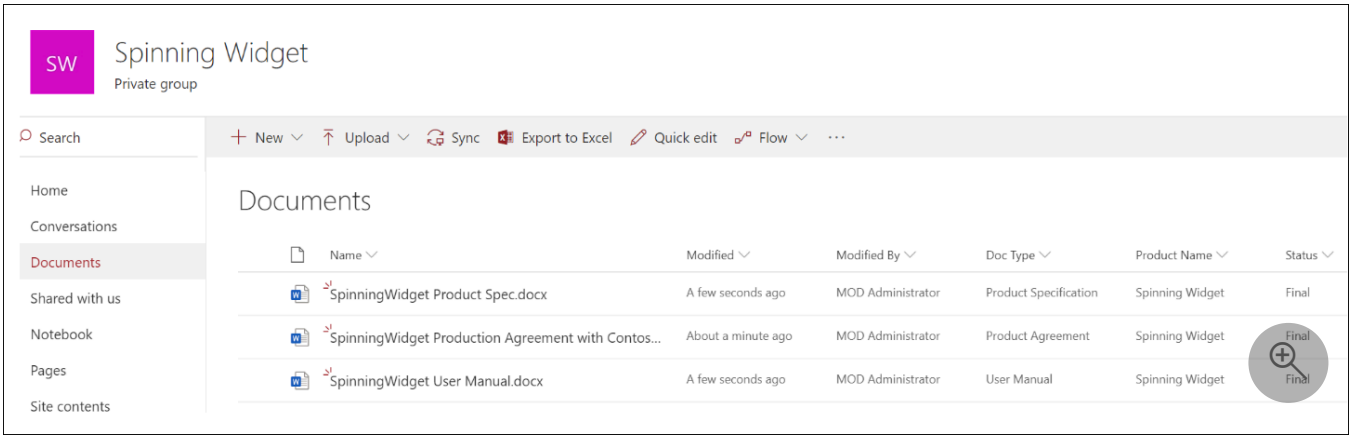
Name	Type	Status	Source
Name	File	Required	Document
Title	Single line of text	Optional	Item
Doc Type	Managed Metadata	Required	
Product Name	Managed Metadata	Required	
Status	Choice	Required	

> ⓘ **Note**
>
> The **Doc Type** and **Status** properties are used later in this scenario to classify and auto-apply retention labels.



We might have several content types that represent different types of documents. This scenario focuses on the product documentation.

Here we use the Managed Metadata service and the Term Store to create a term set for *Doc Type* and for *Product Name*. For each term set, we create a term for each value. The outcome looks like this in Term Store for our SharePoint organization:



Content Type can be created and published by using the Content Type Hub. You can also create and publish a content type by using site provisioning tools, such as the PnP provisioning framework or site design JSON schema.

Each product has a dedicated SharePoint site that contains one document library that has the right content types enabled. All documents are stored in this document library.

> **Note**
>
> In this article we focus on documents and use a site, but the manufacturing company in this scenario could instead use a Microsoft Team per product to support collaboration activties such as persistent chat and using the **Files** tab in Teams for document management.

A view of the document library for the Spinning Widget product:

With the basic information architecture in place for document management, next look at the retention and disposal strategy for the documents that use the metadata and how they're classified.

Retention and disposition

The manufacturing company's compliance and data governance policies dictate how data is preserved and disposed of. Product-related documents must be kept for as long as the

product is manufactured and retained for a period of time afterwards. The retention time period differs for product specifications, agreements, and user manuals. The following table indicates the retention and disposition requirements:

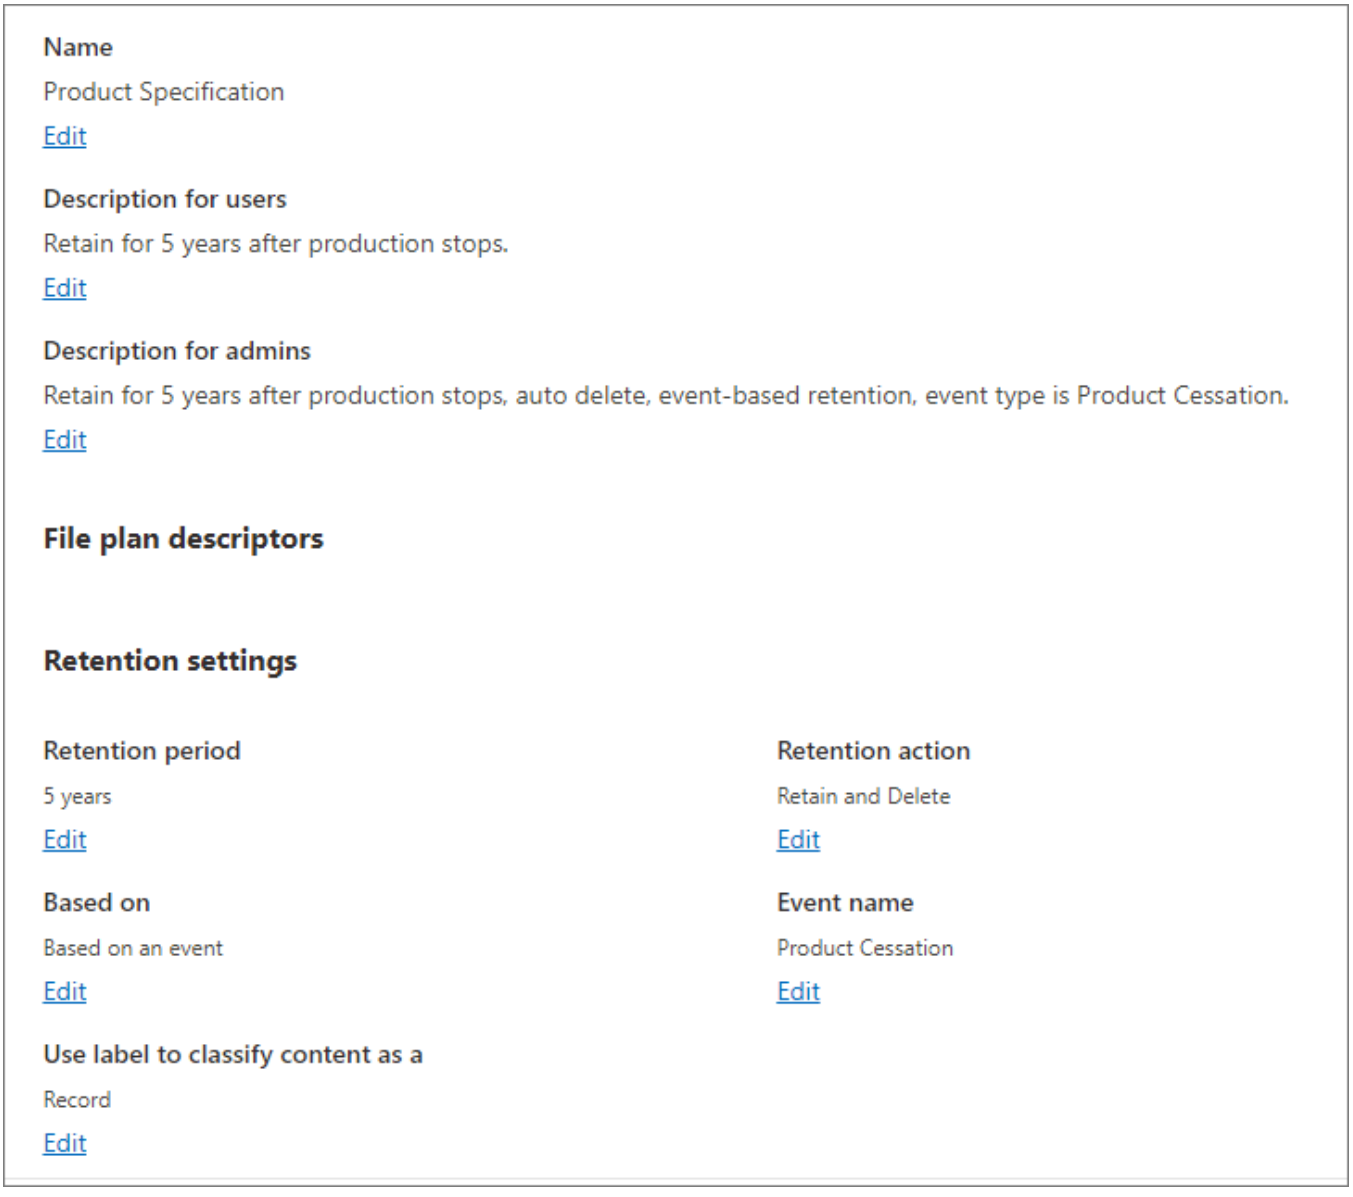
Expand table

Document type	Retention	Disposition Requirements
Product specifications	5 years after production stops	Delete
Product agreements	10 years after production stops	Review
User manuals	5 years after production stops	Delete
All other types of documents	Don't actively retain	Delete when document is older than 3 years. A document is considered older than 3 years if not modified within the last 3 years.

The Microsoft Purview portal is used to create the following retention labels:

- Product Specification
- Product Agreement
- User Manual

In this article, we show how to create and auto-apply the Product Specification retention label. To implement the complete scenario, also create and auto-apply retention labels for the other two document types.

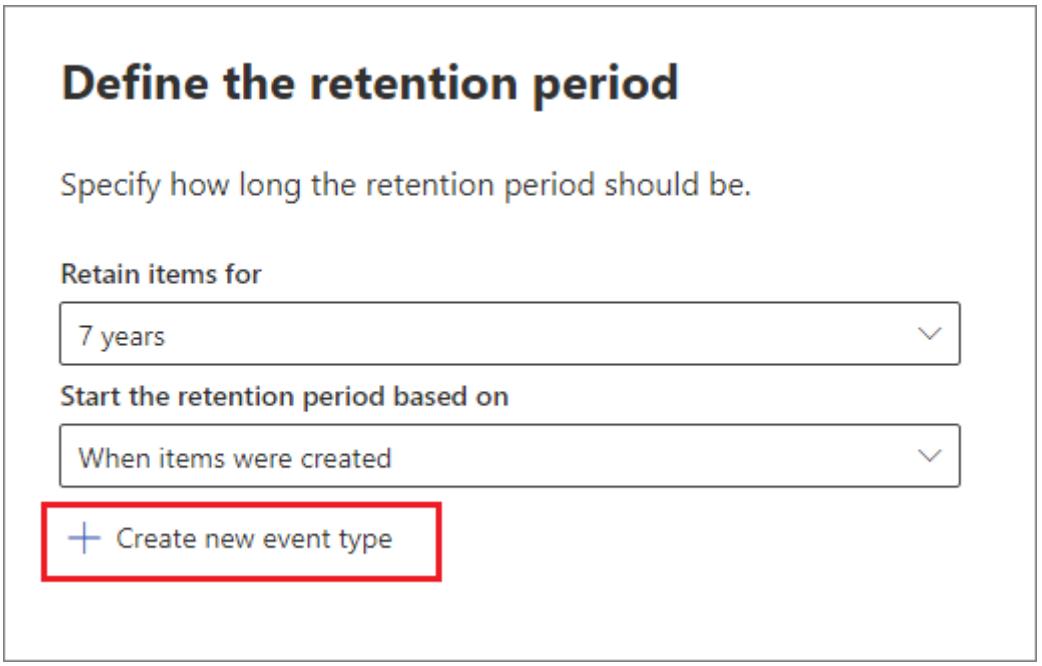


Settings for the Product Specification retention label

The file plan for the Product Specification retention label:

- **Name:** Product Specification
- **Description for users:** Retain for 5 years after production stops.
- **Description for admins:** Retain for 5 years after production stops, auto delete, event-based retention, event type is *Product Cessation*.
- **Retention action:** Retain and delete.

- **Retention duration:** 5 years (1,825 days).
- **Record label**: Configure the retention label to mark items as a record, which means users can't modify or delete the labeled documents.
- **File plan descriptors:** To simplify the scenario, no optional file descriptors are provided.



The following example shows a summary of the label settings when you create the Product Specification retention label in the Microsoft Purview portal. You can create the *Product Cessation* event type before you create the retention label, or during the retention label creation process.

> **Note**
>
> If you're recreating this scenario in a test enviornment, set the retention duration to a shorter period of time to avoid a five-year wait for document deletion.

Create an event type when you create a retention label

1. On the **Define the retention period** page of the retention label workflow, after **Start the retention period based on**, select **Create new event type**:

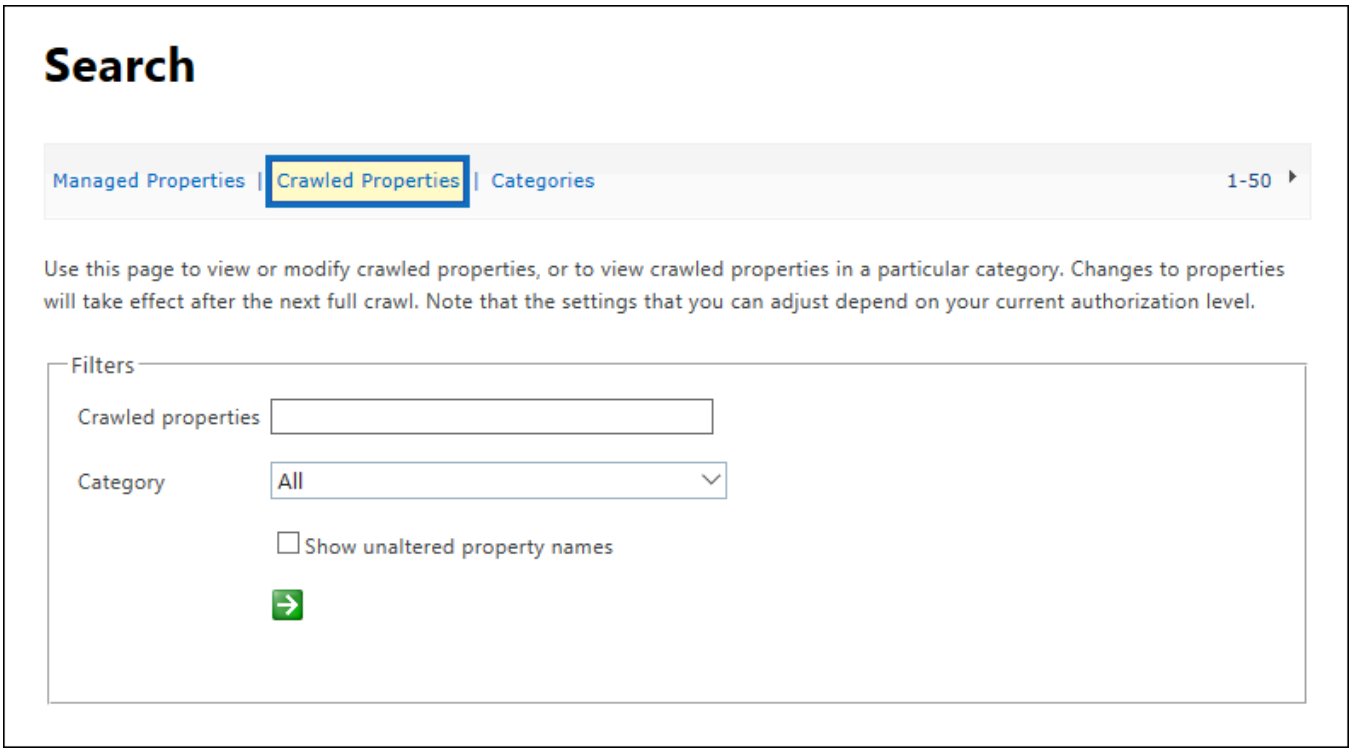
2. On the **Name your event type** page, enter **Product Cessation** and an optional description. Then select **Next**, **Submit**, and **Done**.

3. Back on the **Define the retention period** page, for **Start the retention period based on**, use the dropdown box to select the **Product Cessation** event type that you created.

> **Tip**
>
> For more detailed steps, see **Create a label whose retention period is based on an event**.

The next section shows how to auto-apply the retention label to product specification content.

Auto-apply retention labels to documents



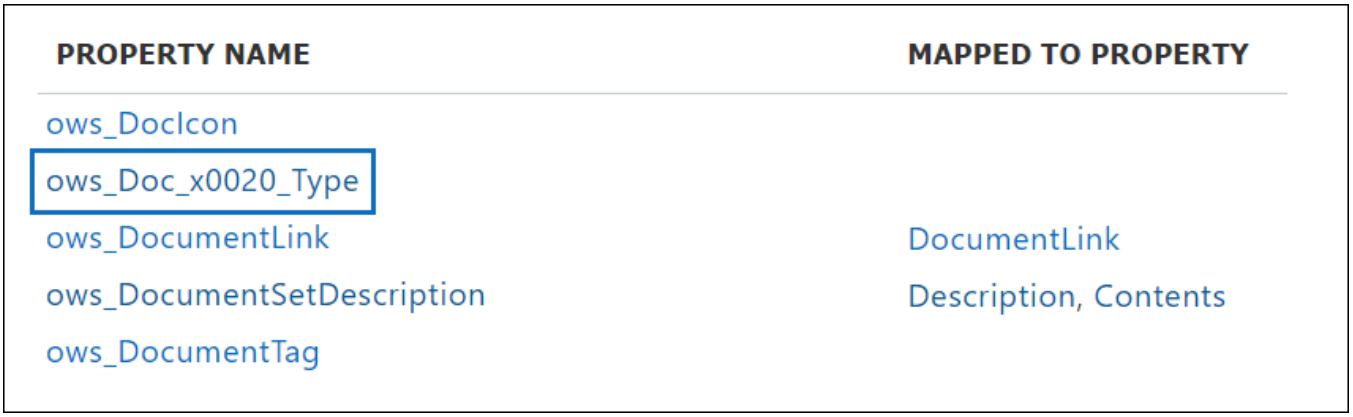
We're going to use Keyword Query Language (KeyQL) to auto-apply the retention labels that we created. KeyQL is the language used to build search queries. In KeyQL, you can search by using keywords or managed properties. For more information, see Keyword Query Language (KeyQL) syntax reference.

We need to configure the search schema to tell Microsoft 365 to "apply the **Product Specification** retention label to all documents that have a **Status** of **Final** and a **Doc Type** of

Product Specification." Recall that **Status** and **Doc Type** are the site columns that we defined for the Product Documentation content type in the Information architecture section.

When SharePoint indexes content, it automatically generates crawled properties for each site column. For this scenario, we're interested in the **Doc Type** and **Status** properties. We need documents in the library that are the right content type and have the site columns filled in for search to create the crawled properties.

In the SharePoint admin center, open the Search configuration, and select **Manage Search Schema** to view and configure the crawled properties.



Run a search for ***status*** using the **Crawled properties** filter. This shows results that include "status" in the property name field:

The previous example shows the **ows__Status** property (notice the double underscore). This property maps to the **Status** property of the Production Document content type that is used in this scenario.

Run a search for ***ows_doc*** using the **Crawled properties** filter. This shows results that include "ows_doc" in the property name field:

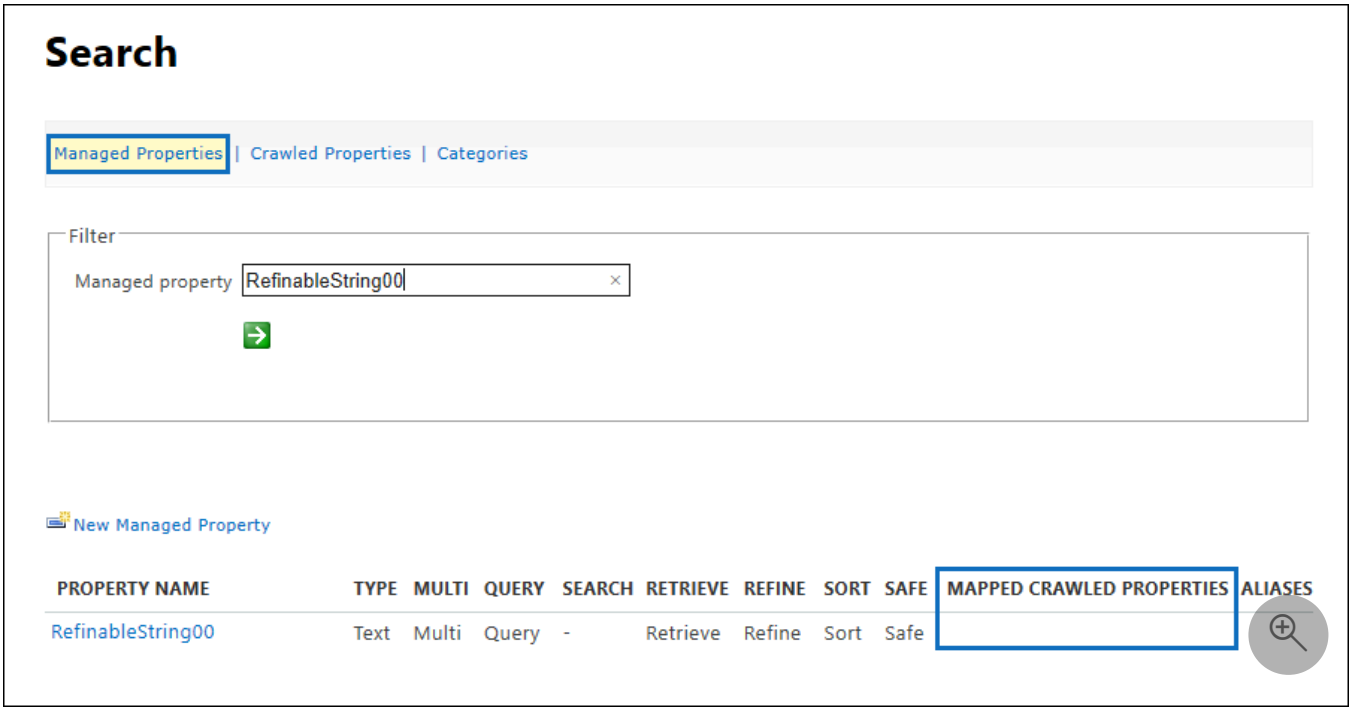
PROPERTY NAME	MAPPED TO PROPERTY
ows_DocIcon	
ows_Doc_x0020_Type	
ows_DocumentLink	DocumentLink
ows_DocumentSetDescription	Description, Contents
ows_DocumentTag	

The above example shows the **ows_Doc_x0020_Type** property. This property maps to the **Doc Type** property of the Production Document content type that is used in this scenario.

> **Tip**
>
> To identify the name of a crawled property for this scenario:
>
> 1. Go to the document library that contains the production documents.
> 2. Go to the library settings.
> 3. For **Columns**, select the name of the column (for example, **Status** or **Doc Type**) to open the site column page.
> 4. The *Field* parameter in the URL for that page contains the name of the field. This field name, prefixed with "ows_", is the name of the crawled property. For example, the URL `https://tenantname.sharepoint.com/sites/SpinningWidget/_layouts/15/FldEdit.aspx?List=%7BC38C2F45-3BD6-4C3B-AA3B-EF5DF6B3D172%7D&Field=_Status` corresponds to the *ows__Status* crawled property.

If the crawled properties you're looking for don't appear in the Manage Search Schema section in SharePoint admin center:

- The documents might not be indexed yet. You can force a reindex of the library by going to **Document library settings** > **Advanced Settings**.
- If the document library is in a modern site, make sure that the SharePoint admin is also a site collection admin.



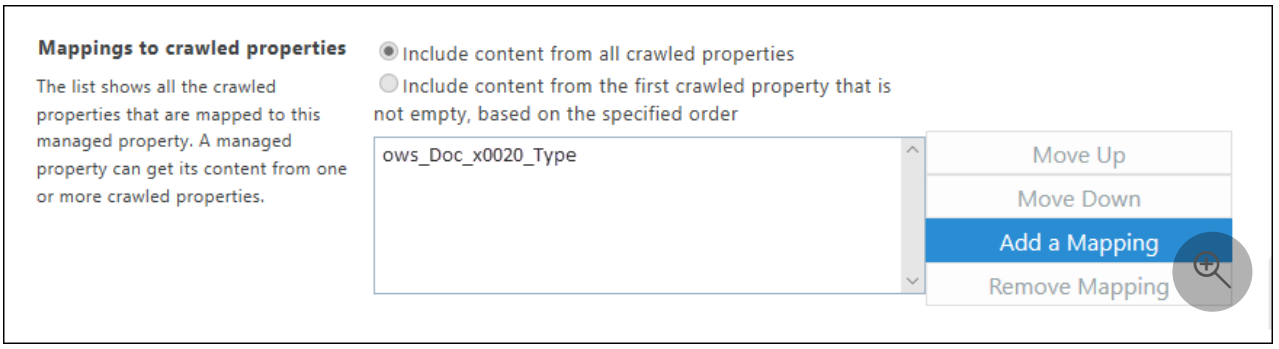
For more information about crawled and managed properties, see Automatically created managed properties in SharePoint Server.

Map crawled properties to predefined managed properties

KeyQL can't use crawled properties in search queries. It has to use a managed property. In a typical search scenario, create a managed property and map it to the crawled property. For auto-applying retention labels, you can only specify predefined managed properties in KeyQL (not custom managed properties). The system has a set of predefined (default) managed properties for string *RefinableString00* to *RefinableString199* that can be used. The default managed properties are typically used for defining search refiners. For a complete list, see Default unused managed properties.

For the KeyQL query to automatically apply the correct retention label to production document content, map the crawled properties *ows_Doc_x0020_Type and ows__Status* to two refinable managed properties.

In the scenario, **RefinableString00** and **RefinableString01** aren't being used. You can determine their use by looking at **Managed Properties** in **Manage Search Schema** in the SharePoint admin center:

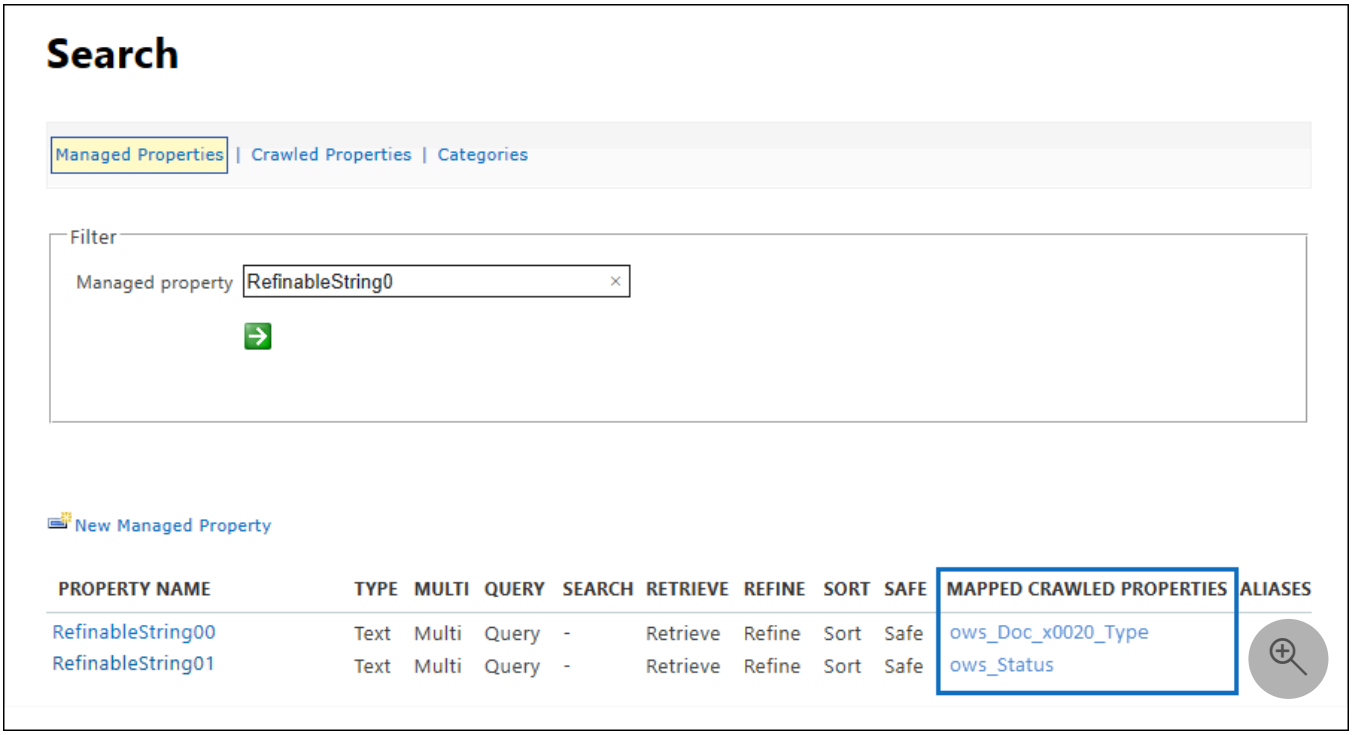


The **Mapped Crawled Properties** column in the previous example is empty for the managed property that isn't in use.

To map the **ows_Doc_x0020_Type** crawled property, follow these steps:

1. Run a search for ***RefinableString00*** using the **Managed property** filter.
2. In the results list, select the **RefinableString00** link, then navigate to the **Mappings to crawled properties** section.

3. Select **Add a Mapping**, and then run a search for ***ows_Doc_x0020_Type*** in the **Search for a crawled property name** box within the **Crawled property selection** window.



4. In the results list, select **ows_Doc_x0020_Type** and then select **OK**. The following example shows the new mapping in the **Mapped Crawled Properties** section:

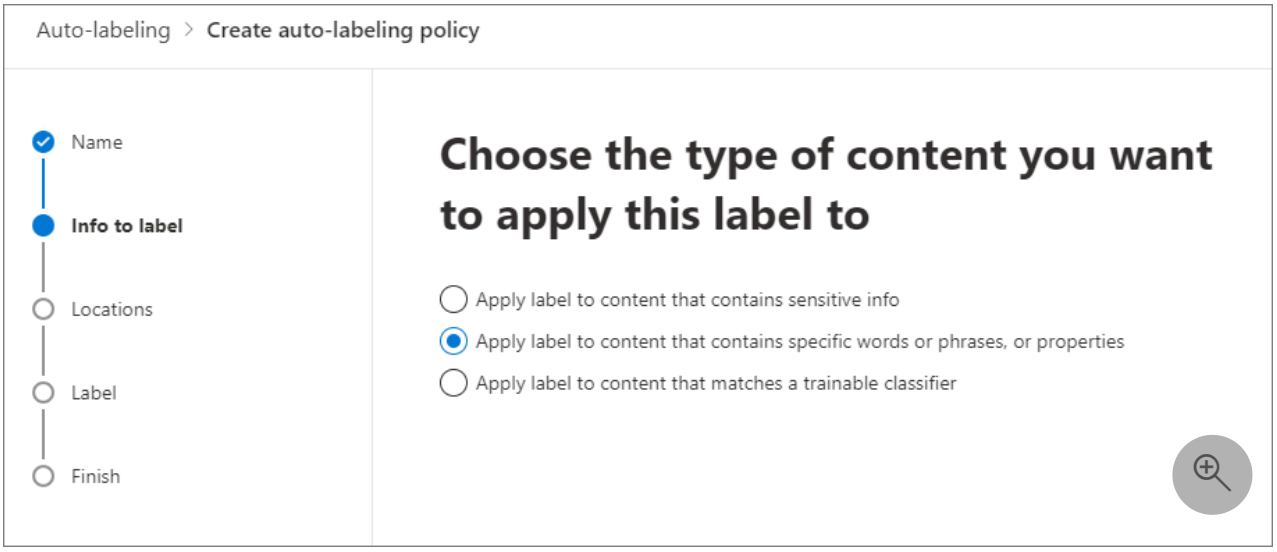
5. Save the mapping.

Repeat these steps to map **RefinableString01** and **ows__Status**.

The following example shows the results of two managed properties mapped to the two crawled properties:

Setup can be verified by running an enterprise search. In a browser, go to *https://<your_tenant>.sharepoint.com/search*. Search for ***RefinableString00:"Product Specification"***. This search returns all documents that have a **Product Specification** of ***Doc Type***.

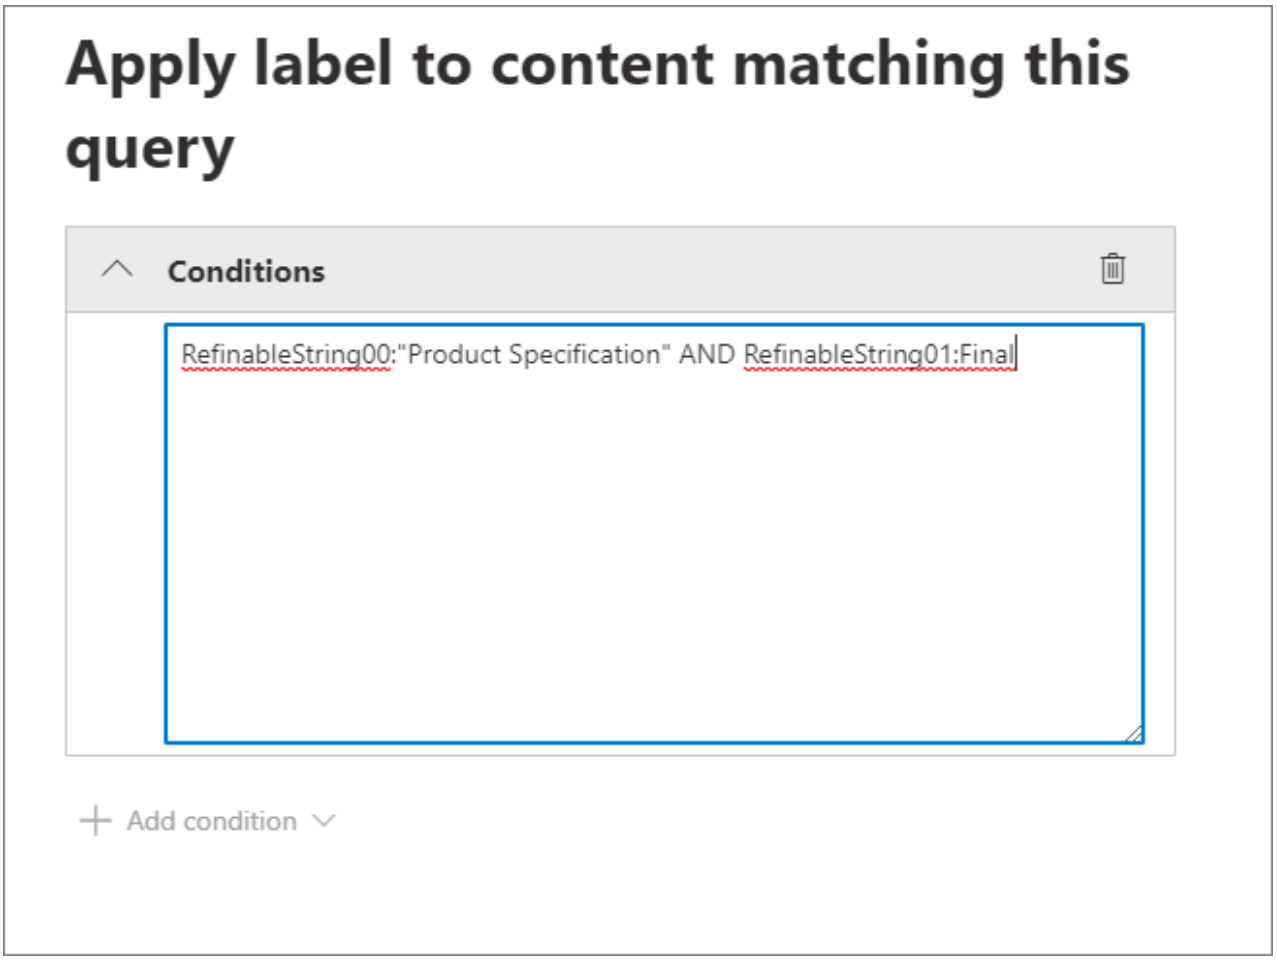
Next, search for **RefinableString00:"Product Specification" AND RefinableString01:Final**. This returns all documents that have **Product Specification** of ***Doc Type*** and a **Status** of ***Final***.



Create auto-apply label policies

After the KeyQL query is verified to return the expected documents, create an auto-apply label policy that uses a KeyQL query to automatically apply the Product Specification retention label to the appropriate documents.

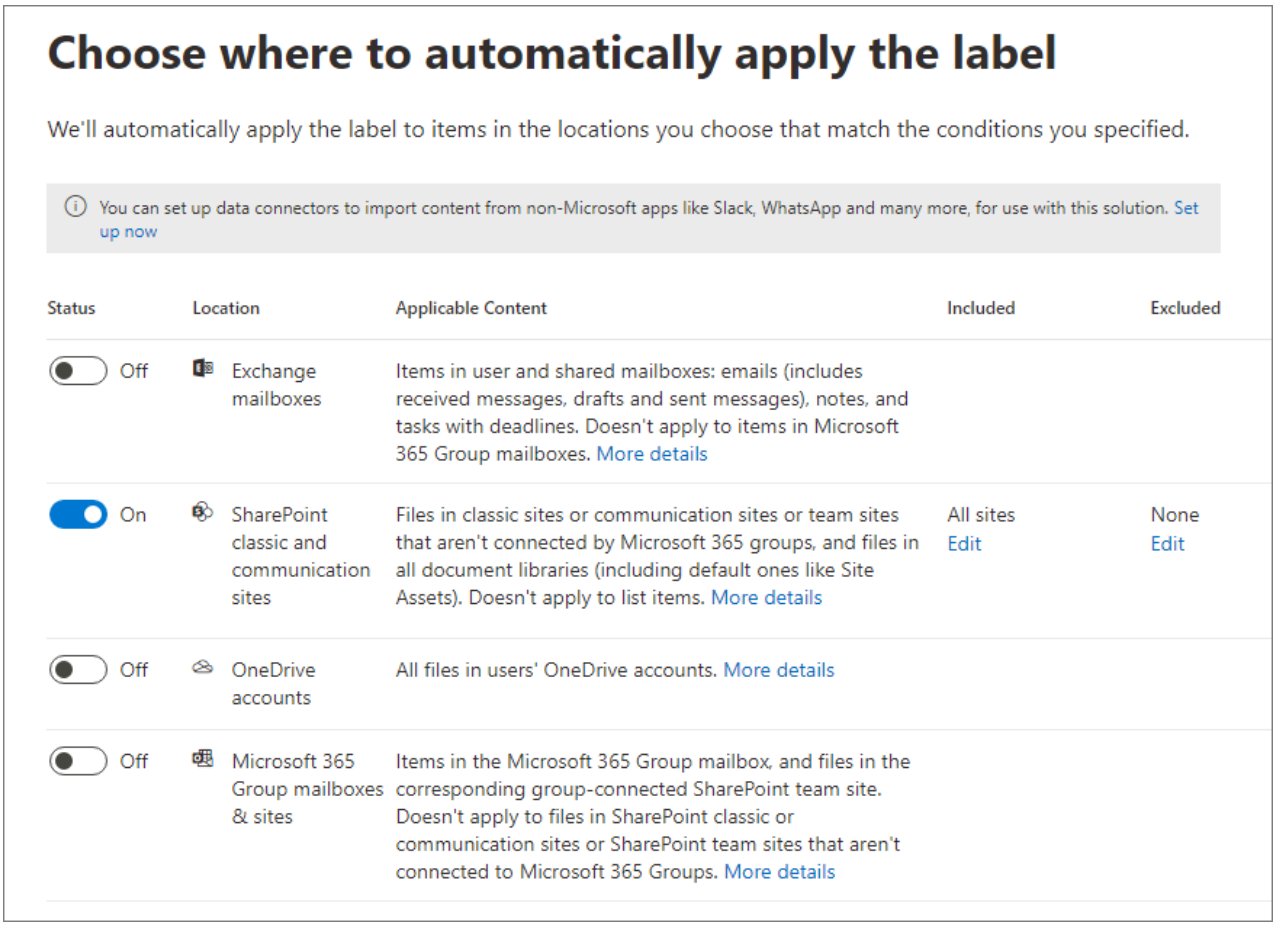
1. Sign in to the Microsoft Purview portal > **Solutions** > **Records management** > **Policies** > **Label policies** > **Retention labels**



2. Select **Auto-apply a label**. In the auto-labeling policy configuration, on the **Name your auto-labeling policy** page, enter a name such as **Auto-apply Product Specification label**, and an optional description. Then select **Next**.

3. On the **Choose the type of content you want to apply this label to** page, select **Apply label to content that contains specific words or phrases, or properties**, then select **Next**.

   This option lets us provide the same KeyQL search query that we tested in the previous section. The query returns all Product Specification documents that have a status of *Final*. When the same query is used in the auto-apply label policy, the Product Specification retention label is automatically applied to documents that match it.

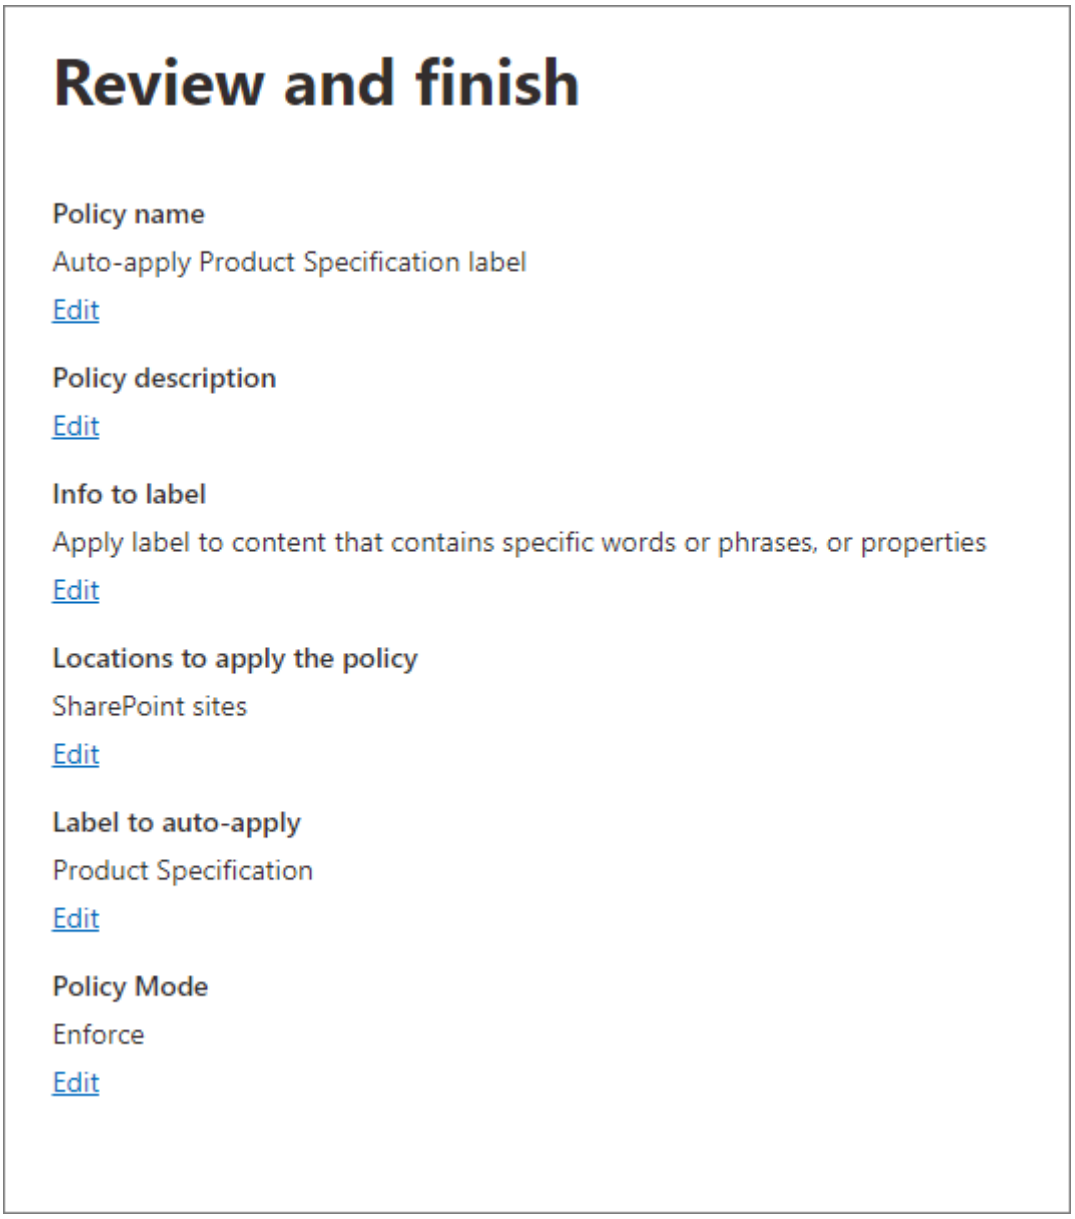


4. On the **Apply label to content matching this query** page, type **RefinableString00:"Product Specification" AND RefinableString01:Final**, then select **Next**.

5. For this scenario, choose **Static** on the **Choose the type of retention policy to create** page.

> **Note**
>
> For a production environment, we recommend adaptive scopes because they automatically update the locations included in the policy by using attributes and properties.

6. On the **Choose where to automatically apply the label** page, select the content locations that you want to apply the policy to. For this scenario, apply the policy only to **SharePoint classic and communication sites**. Toggle all other locations to **Off**:



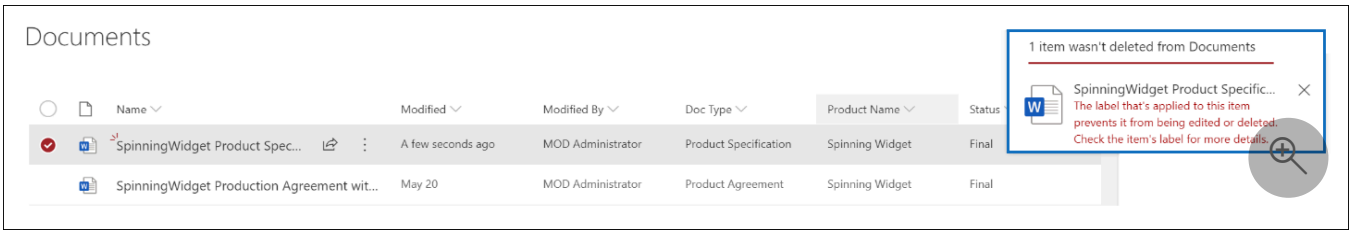
> **Tip**
>
> Instead of applying the policy to all SharePoint sites, you can apply the policy to individual sites by selecting **Edit** for the **Included** column and adding the site URLs.

7. On the **Choose a label to auto-apply** page, select the **Product Specification** label.

8. For this scenario, keep the default of **Turn on policy** on the **Decide whether to test or run your policy** page.

9. Review your settings to confirm accuracy before submitting:

10. Select **Submit** to create the auto-apply label policy.



Verify that the retention label was automatically applied

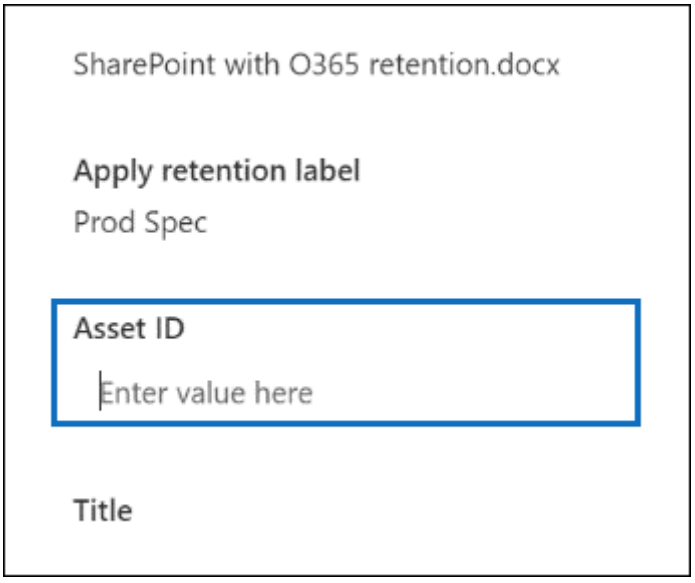
After you've allowed sufficient time for the retention labels to be auto-applied, use activity explorer in the Microsoft Purview portal to verify that the auto-apply label policy applied retention labels to the product documents.

Within SharePoint, the properties of the documents in the Document Library show when a label is applied in the document details pane.

When retention labels mark items as a record, they prevent users from deleting those items. Users see an error message if they attempt to delete the document and the delete action is blocked:

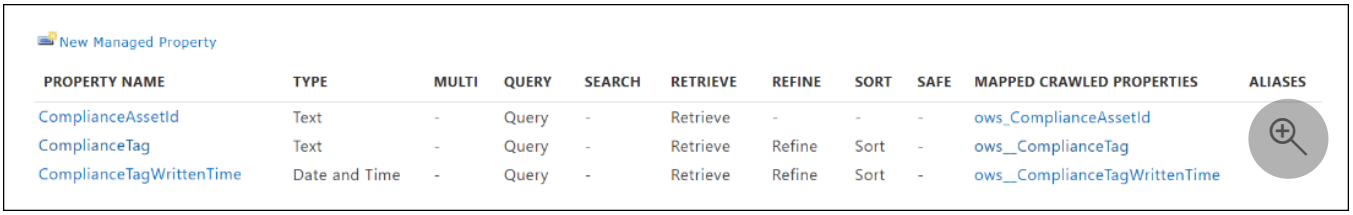
Generate the event that triggers the retention period

In this scenario, an event defines when a product reaches the end of production. For product specification documents, the five-year retention period begins when the "end of production" event is triggered. This event triggers the start of the retention period defined in the retention label.



Events can be created in the Microsoft Purview portal. Choose the event type, set the correct asset IDs, and enter a date for the event. For more information, see Start retention when an event occurs.

You can also create and manage events using Microsoft Graph Records Management APIs.



More about asset IDs

As explained in the Start retention when an event occurs article, it's important to understand the relationship between event types, retention labels, events, and asset IDs. The asset ID is a

document property in SharePoint and OneDrive. It helps identify the documents that have a retention period triggered by the event. By default, SharePoint has an **Asset ID** property that can be used for event-driven retention:

The following example shows the Asset ID managed property is **ComplianceAssetId**.

This scenario used the default **Asset ID** property. Other properties can also be used. If an Asset ID or keywords for an event aren't specified, the retention period is triggered for all the content that has a label of that event type.

Using advanced search in SharePoint

In the Asset Id example, there's another managed property related to retention labels called **ComplianceTag** that's mapped to a crawled property. The **ComplianceAssetId** managed property is also mapped to a crawled property. These managed properties can be used in advanced search to retrieve all documents that have a retention label applied.

Disposition of content

> *Microsoft Purview service description*

Use the **Disposition** page from **Records Management** in the Microsoft Purview portal to manage disposition reviews and view the metadata of items marked as records that have been automatically deleted at the end of their retention period.

Prerequisites for viewing content dispositions

To manage disposition reviews and confirm that items marked as records have been deleted, you must have sufficient permissions and auditing must be enabled. Also be aware of any limitations for disposition.

Permissions for disposition

To successfully access **Disposition** in the Microsoft Purview portal, users must have the **Disposition Management** role. This role is included in the **Records Management** default role group.

> ⓘ **Note**
>
> By default, a global admin isn't granted the **Disposition Management** role.

To grant users just the permissions they need for disposition reviews without granting them permissions to view and configure other features for retention and records management, create a custom role group (for example, named "Disposition Reviewers") and grant this group the **Disposition Management** role.

For instructions to add users to the default roles or create your own role groups, see Permissions in the Microsoft Purview portal.

Additionally:

- To view the contents of items during the disposition process, add users to the **Content Explorer Content Viewer** role group. If users don't have the permissions from this role group, they can still select a disposition review action to complete the disposition review,

but must do so without being able to view the item's contents from the mini-preview pane in the Microsoft Purview portal.

- By default, each person that accesses the **Disposition** page sees only items that they're assigned to review. For a records management administrator to see all items assigned to all users, and all retention labels that are configured for disposition review: From the Microsoft Purview portal, navigate to **Settings** > **Solution settings** > **Records Management ** > **Disposition** to select and then enable a mail-enabled security group that contains the administrator accounts. Permissions are then granted to the group members, but not the group owner.

  Microsoft 365 groups and security groups that aren't mail-enabled don't support this feature and don't display in the list to select. If you need to create a new mail-enabled security group, use the link to the Microsoft 365 admin center to create the new group.

  > **Important**
  >
  > After you've enabled the group, you can't change it in the Microsoft Purview portal. See the next section for how to enable a different group by using PowerShell.

- The Records Management settings are visible only to record management administrators.

Enabling another security group for disposition

After you've enabled a security group for disposition from the **Records Management settings** in the Microsoft Purview portal, you can't disable this permission for the group or replace the selected group in the portal. However, you can enable another mail-enabled security group by using the Enable-ComplianceTagStorage cmdlet.

For example:

PowerShell

```
Enable-ComplianceTagStorage -RecordsManagementSecurityGroupEmail
dispositionreviewers@contosoi.com
```

Enable auditing

Make sure that auditing is enabled at least one day before the first disposition action. For more information, see Search the audit log.

Disposition reviews

When content reaches the end of its retention period, there are several reasons why you might want to review that content and confirm whether it can be permanently deleted ("disposed"). For example, instead of deleting the content, you might need to:

- Suspend the deletion of relevant content for litigation or an audit.
- Assign a different retention period to the content, perhaps because the original retention settings were a temporary or provisional solution.
- Move the content from its existing location to an archive location, for example, if that content has research or historical value.

When a disposition review is triggered at the end of the retention period, your chosen reviewers receive an email notification that they have content to review. These reviewers can be individual users or members of a mail-enabled security group. When you use a mail-enabled security group, only group members and not the group owner receive the email notifications.

You can customize the notification email that reviewers receive, including instructions in different languages. For multi-language support, you must specify the translations yourself and this custom text is displayed to all reviewers irrespective of their locale.

Users receive an initial email notification per label at the end of the item's retention period, with a reminder per label once a week of all disposition reviews that they're assigned. They can click the link in the notification and reminder emails to go directly to the records management **Disposition** page in the Microsoft Purview portal to review the content and take an action. Alternately, the reviewers can navigate to this **Disposition** page in the Microsoft Purview portal. Then:

- Reviewers see only the disposition reviews that are assigned to them, whereas administrators who are added to the selected security group for records manager see all disposition reviews.
- Reviewers can add new users to the same disposition review. Note that this action does not automatically grant these added users the required permissions.
- For the disposition review process, a mini-review pane for each item shows a preview of the content if they have permissions to see it. If they don't have permissions, they can select the content link and request permissions. This mini-review pane also has tabs for additional information about the content:

- **Details** to display indexed properties, where it's located, who created it and when, and who last modified it and when.
- **History** that shows the history of any disposition review actions to date, with reviewer comments if available.

A disposition review can include content in Exchange mailboxes, SharePoint sites, and OneDrive accounts. Content pending a disposition review in those locations is permanently deleted only after a reviewer for the final stage of disposition chooses to permanently delete the content.

> **Note**
>
> A mailbox must have at least 10 MB data to support disposition reviews.

Administrators can see an overview of all pending dispositions in the **Overview** tab. Reviewers see only their items pending disposition.

Select the **View all pending dispositions**, to view them the **Disposition** page.

Disposition timelines

Disposition involves three separate timelines:

Expand table

Timeline	Length	Notes
Permanent deletion after approval	Within 15 days after the final (or only) reviewer selects **Approve disposal**	Applies when an item is marked as eligible for permanent deletion.
Auto-approval timeout (optional)	7-365 days; default 14 days	If reviewers take no manual action, the item advances to the next stage or, in the final stage, is disposed.
Configuration change propagation	Up to 7 days	Applies when you turn auto-approval on or off, or change the number of days, like all retention label changes.

Workflow summary for a disposition review

Basic workflow for a disposition review, single stage:

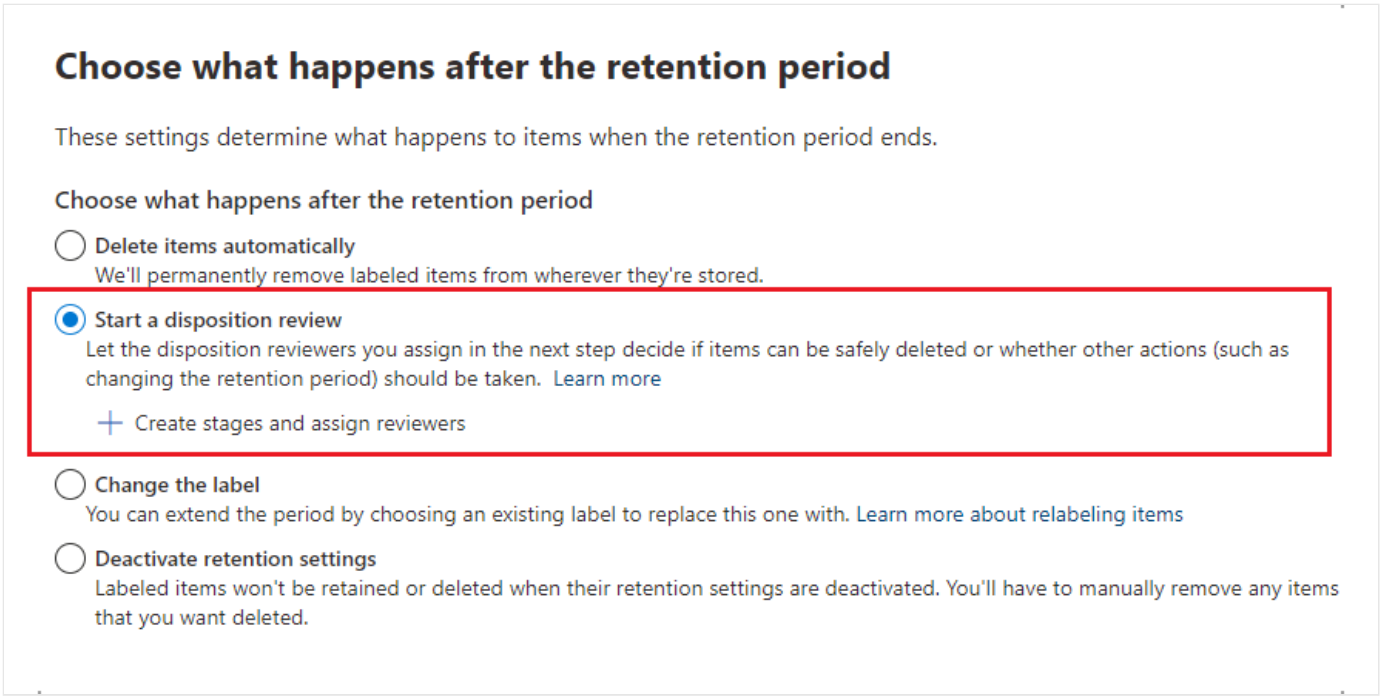
1. The admin configures a retention label to start a disposition review at the end of the retention period.
2. The admin publishes the label and a user applies the label to one or more items, or the admin automatically applies the retention label to items.
3. At the end of the retention period for each item, the designated disposition reviewers receive an email to review the item for disposition.
4. One of the reviewers selects the link to review the item in the disposition page from the Microsoft Purview portal, and confirms that the item should be permanently deleted.

Auto-approval for disposition

You can optionally specify a time period (7-365 days) for auto-approval. The default period if you select this option is 14 days.

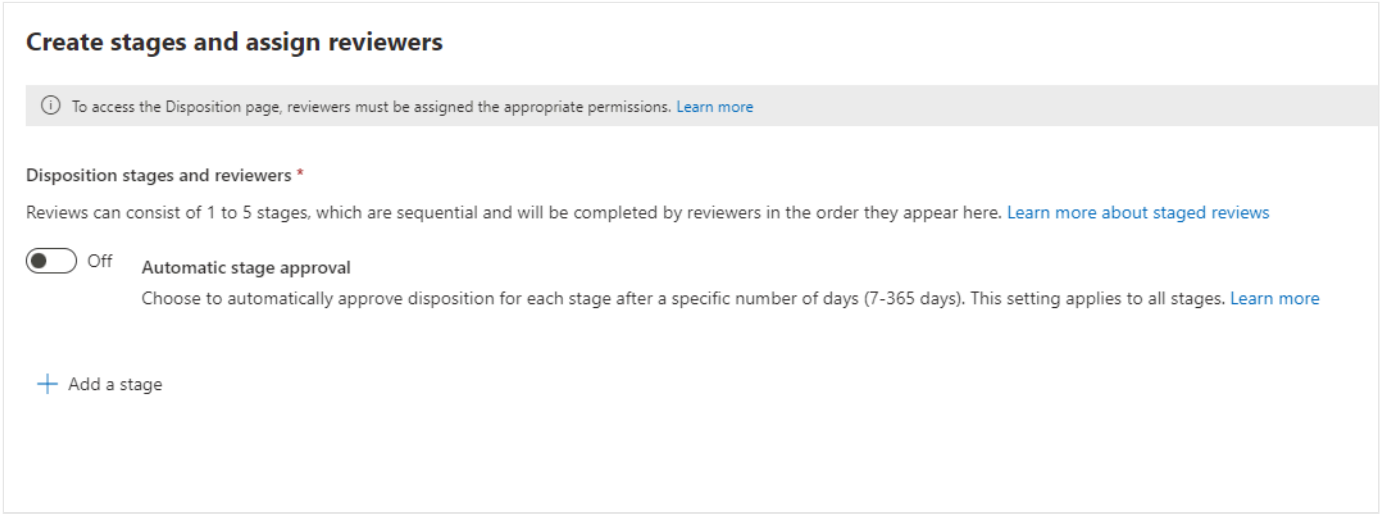
If designated reviewers don't take manual action during this time period by using the standard disposition review process, the item automatically passes to the next review stage. If the item is in the final review stage, the item is automatically disposed with permanent deletion.

> **Important**
>
> If you configure this option and items are already pending disposition review, they automatically become auto-approved if they have already exceeded the number of days that you specified for auto-approval. The time period always starts from when the item is ready for disposition review and not from when you configure the option.



As with all retention label changes, allow up to 7 days if you turn on, turn off, or change the number of days for this option.

There's no new auditing event for auto-approval. Instead, use the details in the existing Approved disposal auditing event to identify whether the item was manually approved or automatically approved by using this option.



How to configure a retention label for disposition review

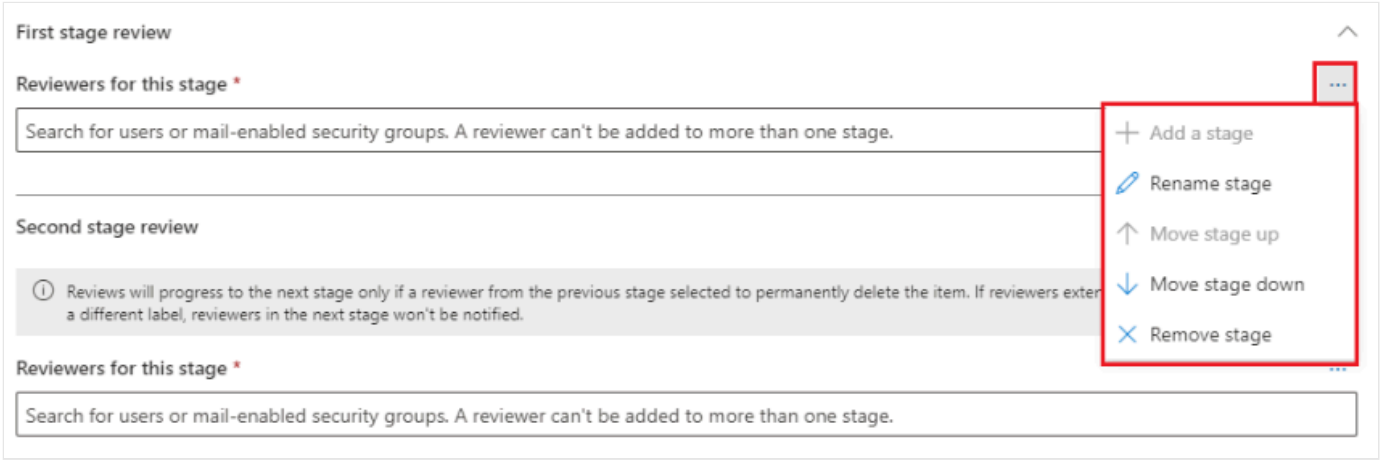
Triggering a disposition review at the end of the retention period is a configuration option that's available only with a retention label. Disposition review isn't available for a retention policy. For more information about these two retention solutions, see Learn about retention policies and retention labels.

From the **Choose what happens after the retention period** page for a retention label:

After you select the **Start a disposition review** option, select **+ Create stages and assign reviewers**. On the next page of the configuration, you'll specify how many consecutive stages of disposition you want and the disposition reviewers for each stage:

Optionally, select whether you want to use automatic-approval. If you use this option, specify the number of days reviewers have to take manual action before the item is automatically moved to the next disposition stage or automatically disposed.

Select **+ Add a stage**, and name your stage for identification purposes. Then specify the reviewers for that stage.



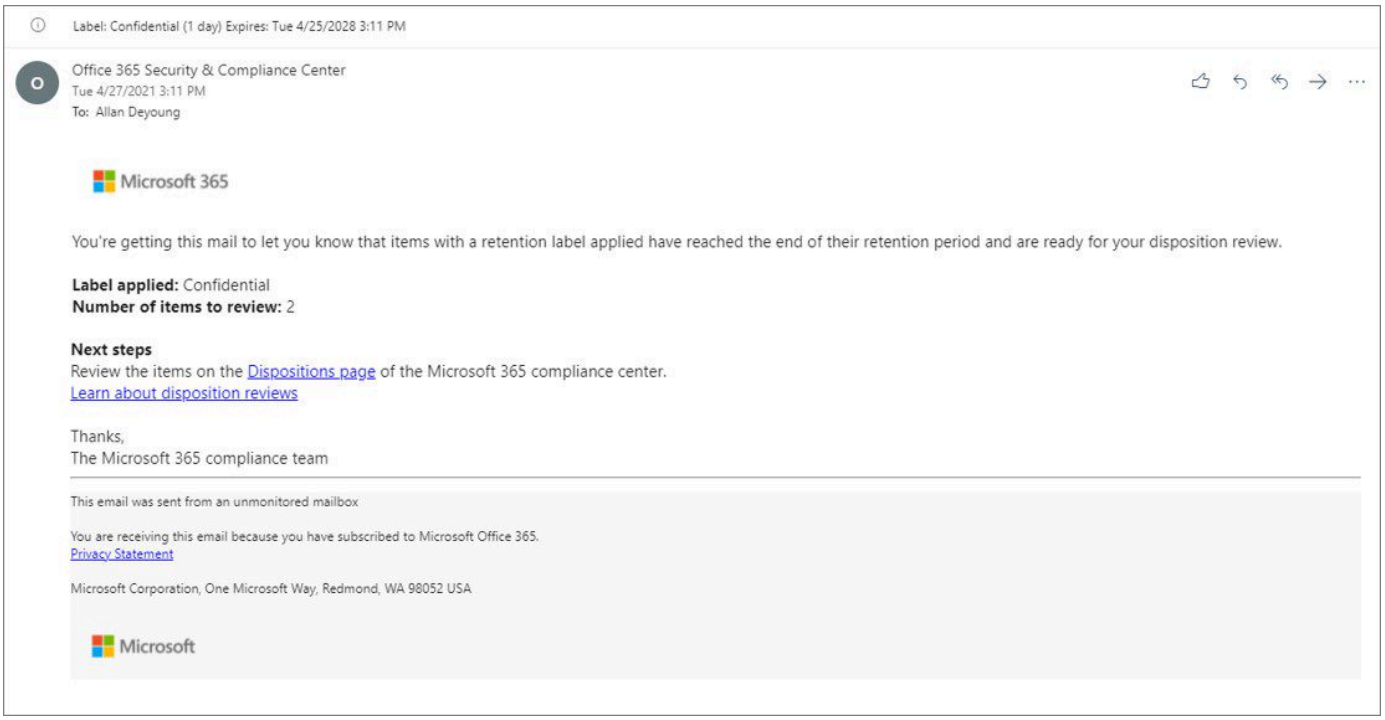
For the reviewers, specify up to 10 individual users or mail-enabled security groups. Microsoft 365 groups aren't supported for this option.

If you need more than one person to review an item at the end of its retention period, select **Add another stage** and repeat the configuration process for the number of stages that you need, with a maximum of five stages.

Within each individual stage of disposition, any of the users you specify for that stage are authorized to take the next action for the item at the end of its retention period. These users can also add other users to their disposition review stage.

> **Note**
>
> If you configured retention labels before multi-staged disposition review was available, you can upgrade your labels to support this feature: Edit the label and select **Edit stages and reviewers** on the **Choose what happens after the retention period** page.

During the configuration phase, for each stage specified, you can rename it, reorder it, or remove it by selecting **Edit stages and reviewers** that now displays for the **Start a disposition review** option. Then for each stage, you can select the Stage actions option (...):



However, you can't reorder or remove a stage after you've created the retention label. You'll see only the **Add a stage** and **Rename a stage** options available. You can still edit the reviewers.

After you've specified your reviewers, remember to grant them the **Disposition Management** role permission. For more information, see the Permissions for disposition section on this page.

How to customize email messages for disposition review

Example default email notification sent to a reviewer:

You can customize the email messages that are sent to disposition reviewers for the initial notification and then reminders.

1. Sign in to the Microsoft Purview portal > **Settings** > **Solutions settings** > **Records Management** > **Disposition**.

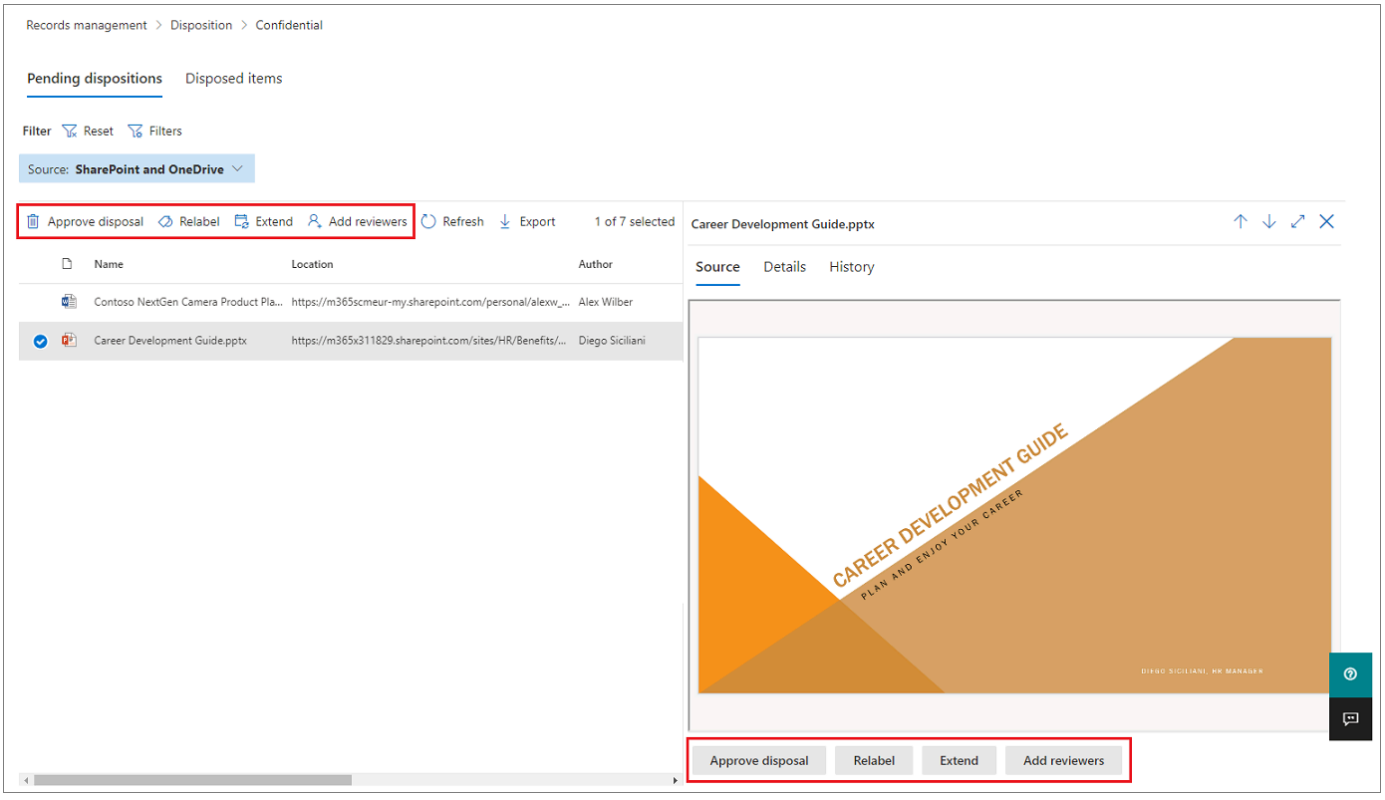
2. From the **Email notifications for disposition reviews** section, select and specify whether you want to use just the default email message, or add your own text to the default message. Your custom text is added to the email instructions after the information about the retention label and before the next steps instructions.

   Text for all languages can be added, but formatting and images are unsupported. URLs and email addresses can be entered as text and depending on the email client, display as hyperlinks or unformatted text in the customized email.

   Example text to add:

   Console

   ```
   If you need additional information, visit the helpdesk website
   (https://support.contoso.com) or send them an email (helpdesk@contoso.com).
   ```



3. Select **Save** to save any changes.

Viewing and disposing of content

When a reviewer is notified by email that content is ready to review, they can click a link in the email that takes them directly to the **Disposition** page from **Records management** in the Microsoft Purview portal. There, the reviewers can see how many items for each retention label are waiting disposition with the **Type** displaying **Pending disposition**. They then select a retention label, and **Open in new window** to see all content with that label:

From the **Pending dispositions** page, they see all pending dispositions for that label. When one or more items are selected, they can use the mini-preview pane and the **Source**, **Details**, and **History** tab to inspect the content before taking action on it:

If you use the horizontal scroll bar, or close the min-review pane, you see more columns that include the expiry date and the name of the disposition review stage.

As you can see from the example shown, the actions supported are:

- **Approve disposal**:

    - When this action is selected for an interim stage of disposition review (you've configured multiple stages): The item moves to the next disposition stage.
    - When this action is selected for the final stage of disposition review, or there's only one stage of disposition: The item is marked as eligible for permanent deletion, which happens within 15 days.

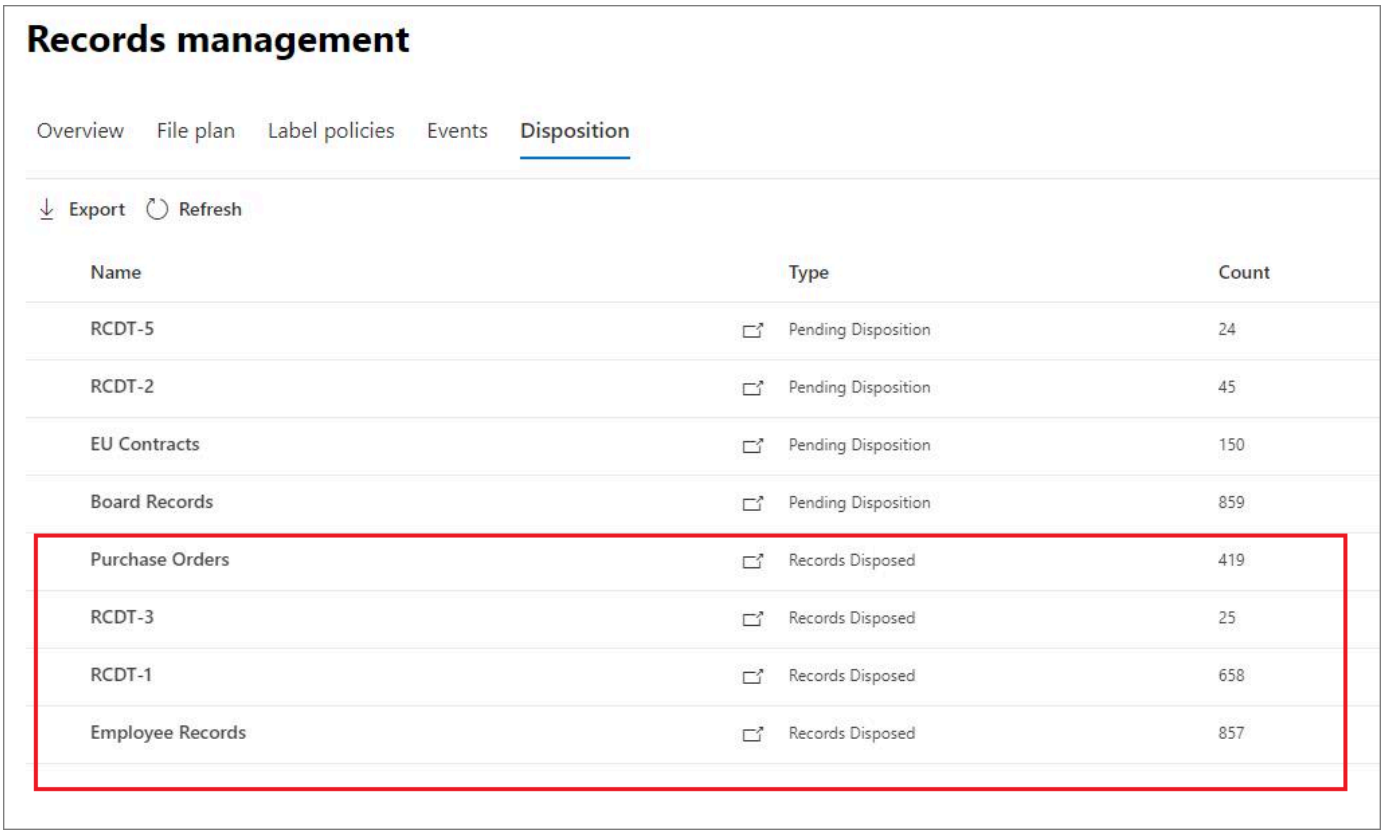
- **Relabel**:
    - When this action is selected, the item exits the disposition review process for the original label. The item is then subject to the retention settings of the newly selected retention label.

- **Extend**:
    - When this action is selected, disposition review is effectively suspended until the end of the extended period and then disposition review is triggered again from the first stage.

- **Add reviewers**:
    - When this action is selected, the user is prompted to specify and add other users for review.

    > ⓘ **Note**
    >
    > This action doesn't automatically grant the required permissions to the users who are added. If they don't have these permissions, they can't participate in the disposition review.

Each action taken has a corresponding audit event in the Disposition review activities auditing activities group.



During the disposition review process, unless you're using the optional setting of an auto-approval timeout period, the content never moves from its original location, and it's not marked for permanent deletion until this action is selected by a reviewer for the final or only disposition stage.

Disposition of records

From the **Records management** main page > **Disposition** tab, you can identify:

- Items deleted as a result of a disposition review.
- Items marked as a record or regulatory record but not marked for disposition review and automatically deleted at the end of their retention period.

These items indicate **Records Disposed** in the **Type** column. For example:

> **Note**
>
> This functionality uses information from the unified audit log and therefore requires auditing to be enabled and searchable so the corresponding events are captured.

For auditing of deleted items that were marked as records or regulatory records, search for **Deleted file marked as a record** in the **File and page activities** category. This audit event is applicable to documents and emails.

Filter and export the views

When you select a retention label from the **Disposition** page, the **Pending disposition** tab (if applicable) and the **Disposed items** tab let you filter the views to help you more easily find items.

For pending dispositions, the time range is based on the expiration date. For disposed items, the time range is based on the deletion date.

You can export information about the items in either view as a .csv file that you can then sort and manage using Excel.

Learn about eDiscovery

Electronic discovery, or eDiscovery, is the process of identifying and delivering electronically stored information (ESI) that you can use as evidence in investigations and legal cases. Use Microsoft Purview eDiscovery to identify, review, and manage content in Microsoft 365 services to support your investigations. Supported Microsoft 365 services include:

- Exchange Online
- Microsoft Teams
- Microsoft 365 Groups
- OneDrive
- SharePoint
- Viva Engage

You can search mailboxes and sites in the same eDiscovery search, and then export the search results. Use eDiscovery cases to identify, hold, and export content found in mailboxes and sites. If your organization has an Office 365 E5 or Microsoft 365 E5 subscription (or related E5 add-on subscriptions), you can further manage cases and analyze content by using premium eDiscovery features.

eDiscovery in the Microsoft Purview portal

Depending on the licensing and subscriptions for your organization, you have access to specific eDiscovery or premium eDiscovery features in the Microsoft Purview portal. All Content Search features are now included within the search experience in eDiscovery, or you can use the Content Search case in eDiscovery to manage all new and existing content searches.

To get the latest information on planned eDiscovery features and capabilities and estimated release dates, see the Microsoft 365 Roadmap.

Notable changes in eDiscovery

If you're familiar with previous versions of eDiscovery, you might notice several differences when using eDiscovery in the Microsoft Purview portal:

- **Advanced indexing**: In previous versions of eDiscovery, when you added a custodian or noncustodial data source to a case, you needed to reindex any content that's partially indexed or has indexing errors. Reindexing determines if the contents are relevant to

defined search conditions. This reindexing process is called *advanced indexing*. As you add more partially and unindexed items to data sources (user's mailbox, OneDrive account, and so on), you need to separately update the index for specific custodian or noncustodial data sources.

In eDiscovery, advanced indexing runs automatically during each search that's scoped for statistics results and when you add results to a review set or export search results, depending on the indexing options you choose for the process. You no longer need to separately reindex data sources before the search process. This just in time indexing process helps avoid issues with stale indices that might result in indexing and search running sequentially and separately in the classic experience. Running (or rerunning) a search automatically updates all indexes.

- **Collections**: In previous versions of eDiscovery, *collections* provided managers with estimates of the content that might be relevant to cases. These estimates allowed managers to make quick, informed decisions about the size and scope of content relevant to cases. Once added to a review set, the collection is immutable.

  In eDiscovery, *Statistics* in searches replace *collections*. Statistics results in searches now allow managers to review important insights about the items included in the results and the relevance to the case. Searches aren't immutable in eDiscovery, even after the results are added to a review set. You can update searches at any time. Adding only a sample of the collection into review set and deleting a search is removed in eDiscovery.

- **Content Search**: Content search in the retired compliance portal was a separate solution from eDiscovery used for basic searches for content. Results from content search were estimated numbers of locations and search results that you could preview or export to a local computer.

  In the Microsoft Purview portal, all Content Search functionality is now included in a system generated eDiscovery case by default for all members of the *eDiscovery manager* and *Administrator* role groups. If you need to limit access to content searches, use *Case settings* to remove or add members to the case to manage access to these searches. You can also select **Content Search** in eDiscovery to create a Content Search case in your organization that contains all new and existing content searches.

  The Content Search case has the same capability as other user-created cases. You can create holds, review sets, and more in the content search case, depending on your subscription.

For more information about the changes to Content Search in eDiscovery, check out the following video:

https://learn-video.azurefd.net/vod/player?id=453b3db7-fd52-4c09-9e9a-03a3e1c4e213&locale=en-us&embedUrl=%2Fpurview%2Fedisc

- **Custodians**: In previous versions of eDiscovery, *custodians* (users) were the primary component of the eDiscovery workflow. Custodians were potential persons of interest in an investigation that you added to cases.

  In eDiscovery, cases are the primary component of the eDiscovery workflow. You still add people, groups, and data sources to cases, but the case is the central organizing unit.

- **Export updates**: The new export flow in eDiscovery supports a unified export structure across premium and nonpremium feature exports, faster export performance, detailed reporting, and flexible export options.

- **Jobs**: In previous versions of eDiscovery, tasks, activities, and reports associated with workflow components were called *jobs*. These events and reports are now referred to as *processes* in eDiscovery.

Features and capabilities

The following table compares key eDiscovery capabilities and features:

Expand table

Capability	eDiscovery feature support	Premium eDiscovery feature support
Search for content	✔	✔
Keyword queries and search conditions	✔	✔
Search statistics and samples	✔	✔
Export search results	✔	✔
Role-based permissions	✔	✔
Case management	✔	✔

Capability	eDiscovery feature support	Premium eDiscovery feature support
Place content locations on hold	✔	✔
Search and delete data	✔	✔
Advanced indexing		✔
Review sets		✔
Import external data to review sets		✔
Support for cloud attachments and SharePoint versions		✔
Optical character recognition		✔
Conversation threading		✔
Decryption		✔
Review set filtering		✔
Review set KQL queries (preview)		✔
Query Report (preview)		✔
Tagging		✔
Analytics		✔
Computed document metadata		✔
Guest user access (preview)		✔
Security Copilot		✔
Transparency of long-running processes		✔
Full reporting for all processes		✔
Enhanced data source mapping		✔

Capability	eDiscovery feature support	Premium eDiscovery feature support
Graph API delegated authentication	✔	✔
Graph API app-only authentication		✔

Here's a description of each eDiscovery capability.

- **Search for content**: Search for content that's stored in Exchange mailboxes, OneDrive accounts, SharePoint sites, Microsoft Teams, Microsoft 365 Groups, and Viva Engage Teams. Searches include content generated by other Microsoft 365 apps that store data in mailboxes and sites.
- **Keyword queries and search conditions**: Create Keyword Query Language (KeyQL) search queries to search for content keywords that match query criteria. You can also include conditions to narrow the scope of your search.
- **Search statistics and samples**: After you run a search, you can view statistics of the estimated search results, such as the number and total size of items matching your search criteria, the content locations that contain the most items, and the number of items returned by the search query. You can also view a representative sample of the items included in the search results.
- **Export search results**: Export search results to a local computer in your organization. When you export search results, items are copied from their original content location and packaged. Then you can download those items in the export package to a local computer.
- **Role-based permissions**: Use role-based access control (RBAC) permissions to control what eDiscovery-related tasks that different users can perform. You can use a built-in eDiscovery-related role group or create custom role groups that assign specific eDiscovery permissions.
- **Case management**: An eDiscovery case contains all searches, holds, and review sets related to a specific investigation. You can also assign members to a case to control who can access the case and view the contents of the case.
- **Place content locations on hold**: Preserve content relevant to your investigation by placing a hold on the content locations in a case. Holds let you secure electronically stored information from inadvertent (or intentional) deletion during your investigation.
- **Search and delete data**: Use eDiscovery to search for and delete email messages, Microsoft Teams chat messages, and Copilot and AI application data across your organization. This capability helps you find and remove content that's potentially harmful or high-risk.
- **Advanced indexing**: When a search, review set, or export process runs, the associated content locations where items are partially indexed are reindexed in a process called

Advanced indexing. Advanced indexing ensures any content deemed as partially indexed is reprocessed to make it fully searchable when you collect data for an investigation.

- **Review sets**: Add relevant data to a review set. A review set is a secure, Microsoft-provided Azure Storage location in the Microsoft cloud. When you add data to a review set, the collected items are copied from their original content location to the review set. Review sets provide a static, known set of content that you can search, filter, tag, analyze, and predict relevancy using predictive coding models. You can also track and report on what content gets added to the review set.
- **Import external data to review sets**: Not all documents that you need to analyze in eDiscovery are in Microsoft 365. By using the external data import feature, you can upload documents that aren't in Microsoft 365 to a review set.
- **Support for cloud attachments and SharePoint versions**: When you add content to a review set, you can include cloud attachments or linked files. The target file of a cloud attachment or linked file is added to the review set. You also can add all versions of a SharePoint document to a review set.
- **Optical character recognition (OCR)**: When content is added to a review set, OCR functionality extracts text from images, and includes the image text with the content that's added to a review set. This feature lets you search for image text when you query the content in the review set.
- **Conversation threading**: When chat messages from Teams and Viva Engage conversations are added to a review set, you can collect the entire conversation thread. The entire chat conversation that contains items that match the search criteria is added to the review set. This feature lets you review chat items in the context of the back-and-forth conversation.
- **Decryption**: eDiscovery supports decryption of content protected with Microsoft encryption technologies. Email messages and attachments encrypted with Microsoft Purview Message Encryption, and documents protected with sensitivity labels or Azure Rights Management, are automatically decrypted when added to search results or review sets.
- **Review set filtering**: After content is added to a review set, you can apply filters to display only the set of items that match your filtering criteria. Then you can save the filter sets as a query, which lets you quickly reapply the saved filters. Review set filtering and saved queries help you quickly select content items that are most relevant to your investigation.
- **Review set KQL queries (preview)**: Use the Advanced review set explorer (preview) to run Kusto Query Language (KQL) queries directly against review set data. Build complex queries with filtering, aggregation, pattern matching, regex, and data visualization to analyze and identify key information in the review set.
- **Query Report (preview)**: Generate and download a consolidated Query Report on multiple queries for a review set. This report lets you quickly see the total count and volume of

filtered items on a particular keyword search or multiple compound KeyQL queries.

- **Tagging**: Tags also help you omit nonrelevant content and identify the most relevant content. When experts, attorneys, or other users review content in a review set, their opinions related to the content can be captured by using tags. For example, if the intent is to exclude unnecessary content, a user can tag documents with a tag such as "nonresponsive". After content is reviewed and tagged, a review set query can be created to exclude any content tagged as "nonresponsive". This process eliminates the nonresponsive content from subsequent steps in the eDiscovery workflow.
- **Analytics**: eDiscovery allows you to analyze review set documents to help you organize the documents in a coherent manner and reduce the volume of documents to be reviewed. *Near duplicate detection* groups textually similar documents together to help you make your review process more efficient. *Email threading* identifies specific email messages that give a complete context of the conversation in an email thread. *Themes* functionality attempts to analyze themes in review set documents and assign a theme to documents so that you can review documents with related theme. These analytics capabilities help make your review process more efficient so that reviewers can review a fraction of collected documents.
- **Computed document metadata**: Many of the eDiscovery premium features, such as conversation threading and analytics, add metadata properties to review set documents. This metadata contains information related to the function performed by a specific feature. When reviewing documents, you can filter on metadata properties to display documents that match your filter criteria. This metadata can be imported into third-party review applications after review set documents are exported.
- **Guest user access (preview)**: Invite guest users to access eDiscovery cases for collaboration with external reviewers. Guest users are assigned the *Reviewer* role group permission and can view and work with case content shared with them.
- **Security Copilot**: Use Microsoft Security Copilot features to draft KeyQL search queries by using natural language and to generate contextual summaries of items in a review set.
- **Transparency of long-running processes**: Processes in eDiscovery typically involve long-running activities that user actions trigger, such as adding custodians to a case, adding content to a review set, running analytics, and creating search queries. You can track the status of these processes and get support information if you need to escalate issues to Microsoft Support.
- **Full reporting for all processes**: Use the Process report to view and manage processes in cases, searches, review sets, and holds.
- **Enhanced data source mapping**: Data sources streamline the process of identifying and managing data. You can search locations based on users, search one site for groups, and

map other locations with groups. You can also explore frequent collaborators as part of data sources.

- **Graph API delegated authentication**: Graph API calls are made on behalf of a signed-in user. The application acquires a token that combines the user's identity with the app's permissions (scopes), so Graph enforces both the user's privileges and the app's consented permissions.
- **Graph API app-only authentication**: Graph API calls are made by the application itself, without a user context. The app authenticates using its own credentials (client secret or certificate) and acquires a token tied solely to its consented application permissions.

Integration with other solutions

Insider risk management

In Microsoft Purview Insider Risk Management, you can quickly escalate cases to new cases in eDiscovery when you need additional legal review for potentially risky user activity. The tight integration between these solutions helps your risk and legal teams work more efficiently and provides a complete end-to-end view of user activities under review.

For more information, see get started with Insider Risk Management and escalate an Insider Risk Management case to an eDiscovery (Premium) case.

Microsoft Security Copilot

In eDiscovery, you can use Microsoft Security Copilot features to draft KeyQL search queries by using natural language. Copilot translates natural language to KeyQL without requiring you to learn how to construct a KeyQL query, know operators, or know supported search metadata fields.

Copilot can also provide a contextual summary of most items in a review set. The summary is in the context of text included in a selected item. This summary saves time for reviewers by quickly identifying information helpful when tagging or exporting items. Security Copilot summarizes the entire item, including any documents, meetings transcripts, or attachments. Most of the common document file types are supported.

For more information about using Security Copilot with review sets, see Summarize an item by using Security Copilot.

Learn about the eDiscovery workflow

The eDiscovery workflow helps you quickly identify, investigate, and take action on electronically stored information (ESI) in your organization. Identifying and taking action on ESI items by using eDiscovery uses the following improved workflow:

Step 1: Escalate from trigger event

Trigger events are activities that escalate in your organization and start the creation of a new case in eDiscovery. These events can be requests from internal or external partners, integrated events associated with alerts in other Microsoft Purview solutions (for example, Insider Risk Management cases), or any other activity that might benefit from the search, investigation, and mitigation actions included with eDiscovery.

Step 2: Create and manage cases

A case in eDiscovery contains all searches, holds, and review sets related to a specific investigation. Cases might include responding to regulatory, investigation, and litigation requests. You can also assign members to a case to control who can access the case and view the contents of the case. eDiscovery also supports new case creation integration with Microsoft Purview Insider Risk Management cases.

Step 3: Search, evaluate results, and refine

After you create a case, use the built-in search tools in eDiscovery to search the content locations in your organization. You can create and run different searches that are associated with the case. Use conditions (such as keywords) to build multiple search queries that return search results with the data that's most likely relevant to the case. You can also:

- View search statistics that might help you refine a search query to narrow the results.
- Preview the search results to quickly verify whether the relevant data is being found.
- Revise queries and rerun searches.

Step 4a: Actions from search results

- **Export search results**: After a search in an eDiscovery case successfully completes, you can export the search results. When you export search results, mailbox items are downloaded in PST files or as individual messages. When you export content from SharePoint and OneDrive sites, copies of native Office documents and other documents are exported. Search exports expire 14 days after creation, so download the export packages before they're automatically deleted.
- **Create review sets**: A review set is a secure, Microsoft-provided Azure Storage location in the Microsoft cloud. When you add data to a review set, the collected items are copied from their original content location to the review set. You can add all search results or configure sampling to add a representative subset. Review sets provide a static, known set of content that you can search, filter, tag, and analyze. You can also track and report on what content gets added to the review set.

Step 4b: Create holds

To preserve and protect data that's relevant to an investigation, place an eDiscovery hold on the data sources associated with a case. After creating a case, you can immediately place a hold on the content locations of the people of interest in your investigation. You can also create query-based holds if needed. Content locations include Exchange mailboxes, SharePoint sites, OneDrive accounts, and mailboxes and sites associated with Microsoft Teams and Microsoft 365 Groups. While placing a hold is optional, creating a hold preserves content that might be relevant to the case during the investigation.

When you create a hold, you can preserve all content in specific content locations or you can create a query-based hold to preserve only the content that matches a hold query. In addition to preserving content, another good reason to create holds is to quickly search the content locations on hold (instead of having to select each location to search) when you create and run

searches in the next step. After you complete your investigation, you can release any hold that you created. For more information, see Manage holds in eDiscovery.

Step 5: Review and take action from review sets

- **Search for content**: In most cases, it's useful to dig deeper into the content in a review set and organize it to facilitate a more efficient review. Using filters and queries in a review set helps you focus on a subset of documents that meet the criteria of your review.
- **Run KQL queries (preview)**: Use the Advanced review set explorer (preview) to run Kusto Query Language (KQL) queries directly against review set data for advanced filtering, aggregation, pattern matching, and data visualization.
- **Run analytics**: eDiscovery provides an integrated analytics tool that helps you further cull data from the review set that you determine isn't relevant to the investigation. In addition to reducing the volume of relevant data, eDiscovery also helps you save legal review costs by letting you organize content to make the review process easier and more efficient. For more information, see Analyze data in a review set in eDiscovery.
- **Tag items**: Organizing content in a review set is important to complete various workflows in the eDiscovery process. This organization often includes identifying relevant content, culling unnecessary content, and identifying content that needs review by an expert or attorney. When experts, attorneys, or other users review content in a review set, they can capture their opinions related to the content by using tags. Tags provide structure and organization to items included in an investigation. For more information, see Tag documents in a review set in eDiscovery.
- **Create a Query report (preview)**: Generate and download a consolidated report on multiple queries for a review set. This report lets you quickly see the total count and volume of filtered items on a particular keyword search or multiple compound KeyQL queries.
- **Add items from the review set to another review set**: In some cases, it might be necessary to select documents from one review set and work with them individually in another review set.
- **Export items**: After you search for and find data that's relevant to your investigation, you can export it out of your Microsoft 365 organization for review by people outside of the investigation team. In addition to the exported data files, the export package contains an export report, a summary report, and an error report. For more information, see Export documents from a review set in eDiscovery.

Throughout the workflow, eDiscovery administrators can use Process reports to track activities that count towards concurrency and daily limits, and Process managers to view process

information scoped to cases, searches, review sets, and holds.

Learn about eDiscovery features and components

This article provides a summary of the key features and components in Microsoft Purview eDiscovery. Use this article to learn about what each feature and component does and to find links to more detailed guidance. For information about the overall eDiscovery workflow, see Learn about the eDiscovery workflow.

Auditing

eDiscovery activities performed by admins, compliance officers, and other users are logged in the audit log. You can search for and review these activities to track actions taken across cases, searches, holds, and review sets. For more information, see Search for eDiscovery activities in the audit log. For a complete list of logged eDiscovery activities, see eDiscovery activities.

Cases

A case contains all searches, holds, and review sets related to a specific investigation. This investigation might include responding to regulatory and litigation requests. You can also assign members to a case to control who can access the case and view the contents of the case. eDiscovery also supports new case creation integration with Microsoft Purview Insider Risk Management cases.

Two general types of cases exist in eDiscovery:

- Cases you create in eDiscovery by using **Create case** on the **Cases** dashboard
- A single Content Search case you create in eDiscovery by using **Create case** on the **Content Search** dashboard.

Content Search case

All content searches are contained in a single eDiscovery case named *Content search*. The **Content Search** option in the eDiscovery (classic) experience in the Microsoft Purview portal is retired.

The new **Content Search** option in the new eDiscovery experience displays a set of all existing content searches in your organization and contains any new content searches that you create in

the Microsoft Purview portal.

Cloud attachments

Cloud attachments are links to documents and files shared in Microsoft Teams messages, Outlook emails, and other Microsoft 365 services. Instead of attaching a traditional copy of a file, users share a link to the file stored in SharePoint or OneDrive. eDiscovery can collect these cloud attachments and include them in search results and review sets, ensuring that shared content is preserved and available for review.

Data sources

In eDiscovery, the concept of *data sources* streamlines the process of identifying and managing data across Microsoft 365 platforms. eDiscovery users select a user, group, or bulk add list of SMTP addresses or URLs, which creates data sources and eDiscovery automatically identifies and organizes relevant data stored across platforms. The data source gathers locations related to the user or group (mailboxes, OneDrive sites, SharePoint sites) and adds the locations in the data source hierarchy. eDiscovery users refine the scope by selecting or excluding specific locations as needed.

SharePoint Embedded container support in eDiscovery (preview) lets data sources include supported user-owned and tenant-owned containers. You can discover relevant containers for a selected user, filter the containers by application, add a known container URL, or bulk import supported container URLs.

Group-owned and app-owned SharePoint Embedded containers aren't currently supported. For details, including the compliance boundary limitation, see Data sources in eDiscovery.

Decryption

eDiscovery supports decryption of content protected with Microsoft encryption technologies. When you add email messages and attachments encrypted with Microsoft Purview Message Encryption, and documents protected with sensitivity labels or Azure Rights Management, to search results or review sets, the system automatically decrypts them. This capability ensures that protected content is available for review and analysis without requiring manual decryption steps.

Exports and downloads

After a search associated with an eDiscovery case runs successfully, you can export the search results. When you export search results, mailbox items are downloaded in PST files or as individual messages. When you export content from SharePoint and OneDrive sites, you export copies of native Office documents and other documents. Search export packages expire 14 days after creation and must be downloaded before they're automatically deleted.

If you add search results to a review set from a case, you can also export review set content to a download package. This package is configurable and includes options to export selected documents only, all filtered documents, or all documents in the review set.

Holds and hold policies

Use an eDiscovery case to create hold policies that preserve content relevant to the investigation by applying an eDiscovery hold. Place a hold on the Exchange mailboxes and OneDrive accounts of people you're investigating in the case. You can also place a hold on the mailboxes and sites associated with Microsoft Teams, Microsoft 365 groups, and Viva Engage Groups. When you place content locations on hold, you preserve content until you remove the content location from the hold or delete the hold. Use the hold management dashboard to view hold status, modify holds, and track hold policies across cases. You can also use the hold report to view information about holds associated with all eDiscovery cases in your organization.

If needed, you can also place a mailbox on Litigation Hold to preserve all mailbox content, including deleted items and original versions of modified items. When you place a mailbox on Litigation Hold, the user's archive mailbox (if it's enabled) is also placed on hold.

Permissions and licensing

To use any of the eDiscovery-related features in the Microsoft Purview portal, assign the appropriate permissions. The easiest way to assign roles is to add the person to the appropriate role group on the **Role groups** page in the Microsoft Purview portal.

Both admins and users working with eDiscovery cases require a Microsoft 365 Enterprise E3 or E5 license. If an admin account doesn't also have a Microsoft SharePoint E3 license, some SharePoint capabilities might be limited. License both admins and users appropriately. Some eDiscovery capabilities also require pay-as-you-go billing configuration. Additionally, if the admin account has any conditional access Entra policy some operations might be restricted, see Troubleshoot sign-in problems with Conditional Access to troubleshoot policy issues.

> **Tip**

You can view your own permissions on the eDiscovery overview page in the Microsoft Purview portal. You must have at least one role assigned for your permissions to be displayed.

Processes

eDiscovery includes a Process report that lists all activities that count towards case concurrency and daily limits in eDiscovery for a defined time period. Processes in eDiscovery (preview) are activities associated with specific tasks that support cases, searches, and review sets. User actions trigger processes when using these components.

eDiscovery administrators and *eDiscovery Managers* (preview) can access this report. Process managers help you view information that is automatically scoped to cases, searches, review sets, and holds.

Review sets

A review set is a secure, Microsoft-provided Azure Storage location in the Microsoft cloud. When you add data to a review set, the collected items are copied from their original content location to the review set. Review sets provide a static, known set of content that you can search, filter, tag, analyze, and predict relevancy using predictive coding models. You can also track and report on what content gets added to the review set.

Key review set capabilities include:

- Search and filter content using the query condition builder to focus on specific subsets of documents.
- Use the Advanced review set explorer (preview) to run Kusto Query Language (KQL) queries directly against review set data for advanced filtering, aggregation, and visualization.
- Group and view items using different grouping options and specialized viewers to examine item details.
- Tag items to organize content, identify relevant documents, and track review progress using customizable tag structures.
- Run analytics to identify near-duplicate documents, email threads, and themes, helping reduce the volume of content to review.
- Export items from a review set to a download package for use outside of eDiscovery.

Searches

Use search to quickly find content relevant to a case. Searches find content across Exchange mailboxes, SharePoint sites and OneDrive locations, Microsoft Teams conversations, and Copilot and AI application data.

Create and run different searches that are associated with the case. Build search queries using the condition builder for a guided experience, or use Keyword Query Language (KQL) for advanced query syntax with autocompletion support.

You can also:

- View search statistics for insights on data volume, content locations, and query hit counts to help you refine your search.
- View search samples to examine a representative set of items returned by the search criteria.
- Preview the search results to quickly verify whether the relevant data is being found.
- Revise a query and rerun the search.
- Export the search results or add the search results to a review set.

Trigger events

Trigger events are activities that escalate in your organization and start the creation of a new case in eDiscovery. These events can be requests from internal or external partners, integrated events associated with alerts in other Microsoft Purview solutions (for example, Insider Risk Management cases), or any other activity that might benefit from the search, investigation, and mitigation actions included with eDiscovery. For more information, see Learn about the eDiscovery workflow.

Last updated on 09/19/2026

Get started with eDiscovery

Use eDiscovery to identify, preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external investigations. Complete the following steps in the eDiscovery workflow to set up prerequisites and configure eDiscovery.

> **Tip**
>
> Do you prefer an interactive configuration guide experience? Check out the **Getting started with Microsoft Purview eDiscovery** guide.

For more information about how eDiscovery can help you with investigations in your organization, see Learn about eDiscovery.

Subscriptions and billing

Before getting started with eDiscovery, review the new billing model for how data storage charges are calculated and what is included with your enterprise subscription. Depending on the types of data included in your eDiscovery cases, different charges might apply.

For more information, see Billing in eDiscovery.

Both admins and users working with eDiscovery cases require a Microsoft 365 Enterprise E3 or E5 license. If an admin account doesn't also have a Microsoft SharePoint E3 license, some SharePoint capabilities might be limited. It is recommended that both admins and users are licensed appropriately. Additionally, if the admin account has any conditional access Entra policy some operations may be restricted, see Troubleshoot sign-in problems with Conditional Access to troubleshoot policy issues.

Step 1: Assign permissions

To use any of the eDiscovery-related tools in the Microsoft Purview portal, you must assign the appropriate permissions to users. The easiest way to assign roles is to add the user to the appropriate role group on the **Role groups** page in the Microsoft Purview portal.

For step-by-step guidance, see Assign permissions in eDiscovery.

> **Tip**
>
> Do you prefer an interactive configuration guide experience? Check out the **Configure permissions and global settings** guide.

Step 2: Verify that required eDiscovery apps are enabled, up to date, and configured correctly

eDiscovery requires the following Enterprise apps to be enabled in your Microsoft 365 or Microsoft Office 365 organization. If you don't enable these apps, you can't access all eDiscovery view, filter, and search features. These apps must be up to date and correctly configured. Make sure that *Enabled for users to sign-in* is selected.

Expand table

App	App ID
Built-in security add-on for on-premises mailboxes (formerly Exchange Online Protection)	00000007-0000-0ff1-ce00-000000000000
ComplianceWorkbenchApp	92876b03-76a3-4da8-ad6a-0511ffdf8647
MicrosoftPurviewEDiscovery	b26e684c-5068-4120-a679-64a5d2c909d9
Office365Zoom	0d38933a-0bbd-41ca-9ebd-28c4b5ba7cb7

To check your app status and configuration, complete the following steps:

1. Go to the Microsoft Azure portal.
2. Go to or search for *Enterprise Applications*.
3. Filter the results for the apps listed in the previous table to review the status and configuration for each app.
4. In each application overview blade, go to **Manage** > **Properties**.
5. Make sure that **Enabled for users to sign-in** property is set to *Yes*.

> **Note**

The *MicrosoftPurviewEDiscovery* app provides support for exporting data through scripts when premium eDiscovery features are enabled. For more information about exporting data through scripts, see Get caseOperation.

Step 3: Configure settings

Depending on the needs of your organization and individual cases, you might need to review and configure global eDiscovery settings:

- **General**: Turn on or off premium eDiscovery features for new cases.
- **Analytics**: Turn on Attorney-client privilege detection within your working sets. If you turn on attorney-client privilege detection, the attorney-client privilege model runs on your data and helps flag documents likely to be privileged. This flag is based on the content and by comparing participants against a user-provided attorney list. This feature doesn't replace the need for privilege review, it's meant to help you get started.
- **Guest users**: Manage guest access to cases in your organization. Invitations to guests are sent after your approval.
- **Tag templates**: Tags help organize content in a review set to complete various workflows. Tags can be reused across multiple review sets and cases with tag templates. You can group tags by sections and allow single or multiple choice tagging.

Step 4: Create a case

To start an investigation, you must create a case and configure case settings. The user who creates the case is automatically added as a member. Members of the case can access the case in the Microsoft Purview portal and perform eDiscovery tasks.

Step 5: Create a search

After creating a new case, you're automatically directed to the **Searches** tab in the case and you're ready to create a search for the case. Searches help you find the items you want to collect for the case.

Step 6: Review and refine search results

After the search query completes, you see the results displayed on the **Statistics** or **Sample** tabs (depending on the initial results type you chose) for the search. To view the results for the

result type not chosen initially, select the applicable tab and you can generate results for the view.

For example, if you choose **Statistics** as the search result type initially, but after the search is completed you'd like to view **Sample** results, you'd select the **Sample** tab and select **Generate sample results** and define sample view settings. Select **Run query** to generate the sample results.

For more information about working with search results, see Review, evaluate, and refine search results in eDiscovery.

Step 7: Take action on search results

After reviewing the items returned in the search query and refining your search as needed, you can take specific actions on selected items included in the search results.

Add search results to a review set

When you're satisfied with the results of a search and you're ready to review and analyze those search results, add them to a review set in the case. Review sets provide a static, known set of content that you can search, filter, tag, analyze, and take other actions on as part of your investigation. To add search result items to a review set, see Add search results to a review set in eDiscovery.

Export or download search results

Exporting and downloading search results helps internal and external partners stay current in your investigations. Download reports provide summary information for selected items in the search results in a .csv file. Exporting search results allows you to customize what items are included in the export, the types of items exported, the export format for item, and more. For more information about exporting search results, see Export search results in eDiscovery.

Download search results

To download the summary information for the search result items, complete the following steps:

1. On the **Statistics** or **Sample** tabs, select **Download reports**.
2. Save the .csv file to your local computer or network share.

Export search results

To export information for items in the search results, select **Export** and complete the details needed for the item export. For step-by-step guidance, see Export search results in eDiscovery.

Create holds

Create holds to preserve content that might be relevant to an eDiscovery case. You can create holds at any time and they're not dependent on searches. For step-by-step guidance, see Create holds in eDiscovery.

Last updated on 04/01/2026

Billing in eDiscovery

eDiscovery uses a billing model based on the combination of your enterprise subscription and pay-as-you-go billing for certain features. This new billing combination includes:

- Your Microsoft 365 subscription and any add-ons. Depending on the licensing and subscriptions for your organization, you have access to specific premium eDiscovery features in the Microsoft Purview portal. For more information about subscriptions and licensing, see the subscription requirements for eDiscovery.
- Pay-as-you-go billing for data storage for non-Microsoft 365 enterprise and cloud AI application data in eDiscovery cases.
- Pay-as-you-go billing for using Microsoft Graph APIs for tenants with E3 eDiscovery licenses.

Configure pay-as-you-go billing

Before you can use features associated with non-Microsoft 365 AI data in eDiscovery in your organization, or use Microsoft Graph APIs with an E3 eDiscovery license, you must configure an Azure subscription for pay-as-you-go billing. For step-by-step guidance, see Enable Microsoft Purview pay-as-you-go features.

Billing details for Microsoft Graph API usage for E3 eDiscovery licensed organizations

Microsoft Graph APIs support tenants with E3 eDiscovery licenses, enabling automation and integration of eDiscovery workflows. These APIs support case management, search, hold, and export operations, offering a secure and consistent experience aligned with the Microsoft Purview portal.

These APIs replicate the portal experience and include:

- **Case management:** Create, Get, List, Update, Close, Reopen, Delete
- **Search management:** Create, List, Get, Update, Delete, Estimate Statistics
- **Hold management:** List, Create, Get, Update, Delete
- **Data source management:** Add, List
- **Export:** Export results, Export report only

For more details on how to use the APIs, see Use the Microsoft Purview eDiscovery API v1.0

Billing calculation for API usage

To use any of the APIs, you need to activate the pay-as-you-go subscription.

Currently, usage of all APIs except Export APIs doesn't contribute towards billing. Usage of Export API is billed based on the volume of data exported. Each organization receives an included amount of free storage per month, with additional usage billed at a set price per GB. The monthly billing details are available in the billing section on the Azure portal.

For more information about API storage and pricing, see Microsoft Purview pricing.

For example, the following table outlines the Graph API billing for a sample month of eDiscovery activity and uses a hypothetical billing rate of $10 USD per GB:

Expand table

Day	Case	API used	Volume	Monthly cumulative volume	Charges	Cumulative charges
Day 1	Case 1	Create case, Create Search 1	N/A	0	0	0
Day 2	Case 1	Create Search 2, Create Hold, Add data sources	N/A	0	0	0
Day 3	Case 1	Export report	1 GB	1 GB	0	0
Day 6	Case 1	Export results	24 GB	25 GB	0	0
Day 10	Case 2	Create case, Create Search	0	25 GB	0	0
Day 11	Case 2	Export results and reports	20 GB	45 GB	0	0
Day 14	Case 1	Create Search 3	0	45 GB	0	0
Day 17	Case 1	Export results from Search 3	15 GB	60 GB	$100	$100
Day 21	Case 2	Create search and export results	12 GB	72 GB	$120	$220

Billing details for non-Microsoft 365 enterprise and cloud AI application data

Data types

Depending on the type of data included in eDiscovery cases in your organization, subscription or pay-as-you-go billing applies:

- **Microsoft 365 data**: Non-AI data from Microsoft 365 services and applications. This data type includes data from Microsoft services like Exchange, SharePoint, OneDrive, and others.

  This data storage is included in your enterprise subscription and isn't subject to pay-as-you-go billing.

- **Microsoft 365 AI data**: AI data from Microsoft 365 services and applications. This data type includes AI data from Microsoft services like Microsoft 365 Copilot and AI data from Microsoft Office applications like Microsoft Word, Microsoft Excel, Microsoft PowerPoint, and others.

  This data storage is included in your enterprise subscription and isn't subject to pay-as-you-go billing.

- **Non-Microsoft 365 AI data**: Data from other generative AI applications from Microsoft and other connected external AI applications. This data type includes Copilot in Microsoft Fabric, Microsoft Security Copilot, and any connected or cloud AI application.

  This data storage isn't included in your enterprise subscription and is subject to pay-as-you-go billing. Data for non-Microsoft 365 services and applications is identified by *ItemClass*.

  The following ItemClasses are applicable to pay-as-you-go billing:
  - IPM.SkypeTeams.Message.Copilot.Fabric.*
  - IPM.SkypeTeams.Message.Copilot.Security.SecurityCopilot
  - IPM.SkypeTeams.Message.Copilot.BAP*
  - IPM.Skypeteams.Message.Copilot.Sql.*
  - IPM.SkypeTeams.Message.ConnectedAIApp.*
  - IPM.SkypeTeams.Message.CloudAIApp.SaaS.*

Non-Microsoft 365 AI data scope

You can add and export non-Microsoft 365 AI data to an eDiscovery case in several ways. Your organization retains this data as long as a case is active or closed. Depending on the data type and the type of process taken in eDiscovery, the application of data storage costs varies.

The following eDiscovery processes use pay-as-you-go billing for non-Microsoft 365 AI data:

- Direct export of this data from cases by using the Microsoft Purview portal
- Adding this data to a review set
- Exporting this data by using Microsoft Graph API

> **Important**
>
> If you use the classic eDiscovery (Premium) experience in the Microsoft Purview portal, importing non-Microsoft 365 or non-Office 365 data to a review set is excluded from pay-as-you-go billing and isn't charged.

The following eDiscovery processes don't use pay-as-you-go billing for non-Microsoft 365 AI data and are included in your enterprise subscription:

- All search processes
- All hold processes
- All case management processes

> **Tip**
>
> A breakdown of the total size of Microsoft 365 data and non-Microsoft 365 AI data is included in the ***summary.csv report*** for exports from search and exports from review sets. This report includes details for metadata when exporting from a review set and can help you estimate data storage charges.

Billing calculation for non-Microsoft 365 AI data

Every 24 hours, the system calculates the total amount of data storage for non-Microsoft 365 AI data for all active and closed eDiscovery cases. Deleted cases don't incur data storage charges after they're deleted. The system multiplies the total amount of data by the daily storage rate to determine the total data storage cost for the day.

At the end of each month, the system adds together the daily charges for the total eDiscovery data storage costs. These costs are part of the all-up data meter storage costs in your Azure account. The system itemizes details for each eDiscovery process and the costs. Use the

Summary.csv report to review a breakdown of the volume of Microsoft 365 and non-Microsoft 365 AI data for processes in scope for pay-as-you-go billing.

For example, the following table outlines the non-Microsoft 365 AI data storage amounts for a sample month of eDiscovery activity:

Expand table

Day	Case	Action	Daily data volume	Running daily total
Day 1	Case 1	Direct export in active case	1 GB	1 GB
Day 2	All cases	No actions	0 GB	1 GB
Day 3	Case 2	Add to review set in active case	5 GB	6 GB
Day 4	All cases	No actions	0 GB	6 GB
Day 5	Case 3	Direct API export in active case	2 GB	8 GB
Day 6	All cases	No actions	0 GB	8 GB
Day 7	All cases	No actions	0 GB	8 GB
Day 8	All cases	No actions	0 GB	8 GB
Day 9	Case 1	Apply holds in active case (not billable)	2 GB	8 GB
Day 10	All cases	No actions	0 GB	8 GB
Day 11	Case 1	Closed case	0 GB	8 GB
Day 12	All cases	No actions	0 GB	8 GB
Day 13	Case 2	Add to review set in active case	2 GB	10 GB
Day 14	All cases	No actions	0 GB	10 GB
Day 15	All cases	No actions	0 GB	10 GB

Day	Case	Action	Daily data volume	Running daily total
Day 16	All cases	No actions	0 GB	10 GB
Day 17	Case 1	Reopened as active case and export	1 GB	11 GB
Day 18	All cases	No actions	0 GB	11 GB
Day 19	All cases	No actions	0 GB	11 GB
Day 20	All cases	No actions	0 GB	11 GB
Day 21	Case 1	Direct export in active case	1 GB	12 GB
Day 22	All cases	No actions	0 GB	12 GB
Day 23	All cases	No actions	0 GB	12 GB
Day 24	All cases	No actions	0 GB	12 GB
Day 25	Case 1	Deleted case (removes data storage)	3 GB	9 GB
Day 26	All cases	No actions	0 GB	9 GB
Day 27	Case 2	Export from review set in active case (not billable)	2 GB	9 GB
Day 28	All cases	No actions	0 GB	9 GB

In this example, the total amount of non-Microsoft 365 AI data storage that is subject to pay-as-you-go-billing rates for the month is 246 GB. Data associated with processes that aren't applicable to data storage billing and data that you remove from your organization don't appear on your monthly bill. You can view billing details in the Azure portal.

Excluding non-Microsoft 365 AI data

To exclude non-Microsoft 365 AI data from processes subject to pay-as-you-go billing, use search conditions and filters to exclude this data type.

KeyQL condition

Use the following KeyQL statement with the *Equals* operator to exclude non-Microsoft 365 AI data from a search query:

```
(NOT((ItemClass:IPM.SkypeTeams.Message.Copilot.Fabric.*) OR
(ItemClass:IPM.SkypeTeams.Message.Copilot.Security.SecurityCopilot) OR
(ItemClass:IPM.SkypeTeams.Message.Copilot.BAP*) OR
(ItemClass:IPM.SkypeTeams.Message.ConnectedAIApp.*) OR
(ItemClass:IPM.SkypeTeams.Message.CloudAIApp.SaaS.*) OR
(ItemClass:ipm.skypeteams.message.copilot.sql.*)))
```

Filter

Use the *Contains none of* operator for the **Non M365 AI activity** type filter to exclude non-Microsoft 365 AI data.

Last updated on 12/01/2025

Assign permissions in eDiscovery

To use eDiscovery capabilities and features in the Microsoft Purview portal, assign the appropriate permissions to users. The easiest way to assign roles is to add users to the appropriate role group on the **Role groups** page in the Microsoft Purview portal. This article describes the permissions required to perform eDiscovery tasks.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

eDiscovery roles and role groups

The primary eDiscovery-related role group in Microsoft Purview portal is called **eDiscovery Manager**. This role group contains two subgroups:

- **eDiscovery Manager**: An *eDiscovery Manager* can search content locations in the organization and perform various search-related actions such as preview and export search results in eDiscovery. Members can also create and manage cases, add, and remove users for a case, create case holds, run searches associated with a case, and access case data. eDiscovery Managers can only access and manage the cases they create. They can't access or manage cases created by other eDiscovery Managers.
  - You can add a mail-enabled security group as a member of the eDiscovery Managers subgroup in the *eDiscovery Manager* role group by using the **Add-RoleGroupMember** cmdlet in Security & Compliance PowerShell. For example, you can run the following command to add a mail-enabled security group to the *eDiscovery Manager* role group.

    PowerShell

    ```
    Add-RoleGroupMember "eDiscoveryManager" -Member <name of security group>
    ```

  - Exchange distribution groups and Microsoft 365 Groups aren't supported. You must use a mail-enabled security group, which you can create in Exchange Online PowerShell by running `New-DistributionGroup -Type Security`. You can also create a mail-enabled security group (and add members) in the Exchange admin center or in the Microsoft

365 admin center. It might take up to 60 minutes after you create it for a new mail-enabled security group to be available to add to the eDiscovery Managers role group.

  - You can't make a mail-enabled security group an eDiscovery Administrator by using the **Add-eDiscoveryCaseAdmin** cmdlet in Security & Compliance PowerShell. You can only add individual users as eDiscovery Administrators.

  - You also can't add a mail-enabled security group as a member of a case.

- **eDiscovery Administrator**: An *eDiscovery Administrator* is a member of the *eDiscovery Manager* role group, and can perform the same content search and case management-related tasks that an eDiscovery Manager can perform. Additionally, an eDiscovery Administrator can:
  - Access all cases that are listed on the **eDiscovery** area in the Microsoft Purview portal.
  - Configure eDiscovery solution settings.
  - Access process and hold reports scoped to all cases.
  - Access case data for any case in the organization.
  - Manage any eDiscovery case after they add themselves as a member of the case.
  - Remove members from an eDiscovery case. Only an eDiscovery Administrator can remove members from a case. Users who are members of the eDiscovery Manager subgroup can't remove members from a case, even if the user created the case.
  - If a person who is the only member of an eDiscovery case leaves your organization, no one (including members of the *Organization Management* role group or another member of the *eDiscovery Manager* role group) can access that eDiscovery case because they aren't a member of a case. In this situation, there's no way to access the data in the case. But because an eDiscovery Administrator can access all eDiscovery cases in the organization, they can view the case and add themselves or another eDiscovery manager as a member of the case.
  - An eDiscovery Administrator can view and access all eDiscovery cases, they can audit and oversee all cases and associated compliance searches. This functionality can help to prevent any misuse of compliance searches or eDiscovery cases. And because eDiscovery Administrators can access potentially sensitive information in the results of a compliance search, you should limit the number of people who are eDiscovery Administrators.

    > **Note**
    >
    > To analyze a user's data when premium eDiscovery features are enabled, the user must be assigned an Office 365 E5 or Microsoft 365 E5 license. Alternatively, users with an Office 365 E1 or an Office 365 or Microsoft 365 E3 license can be assigned a Microsoft

Purview Suite (formerly known as Microsoft 365 E5 Compliance) or Microsoft 365 eDiscovery and Audit add-on license. Administrators, compliance officers, or legal personnel who are assigned to cases as members and use premium eDiscovery features to collect, view, and analyze data don't need an E5 license. For more information about subscriptions and licensing, see the subscription requirements for eDiscovery.

Before you assign permissions

- You need to be a member of the *Organization Management* role group or be assigned the *Role Management* role to assign eDiscovery permissions in the Microsoft Purview portal.
- You can use the Add-RoleGroupMember cmdlet in Security & Compliance PowerShell to add a mail-enabled security group as a member of the *eDiscovery Managers* subgroup in the *eDiscovery Manager* role group. However, you can't add a mail-enabled security group to the *eDiscovery Administrators* subgroup.

Configure app-only authentication for eDiscovery PowerShell

Important

App-only authentication for eDiscovery cmdlets in Security & Compliance PowerShell is unsupported. Transition automations to Microsoft Graph APIs where available. The following steps are best-effort guidance for existing automations that continue to use this unsupported configuration and don't change its support status.

Certificate-based authentication (CBA), also known as app-only authentication, requires both Microsoft Entra authorization and eDiscovery role-based access control (RBAC). The API permission allows the application to authenticate, while service principal registration and role group membership authorize eDiscovery cmdlets.

1. Follow App-only authentication for unattended scripts in Exchange Online PowerShell and Security & Compliance PowerShell to create the Microsoft Entra application and configure its certificate.

2. On the application, select **Add a permission** > **APIs my organization uses** > **Microsoft Exchange Online Protection** > **Application permissions** > **Exchange** >

Exchange.ManageAsApp, and then grant tenant-wide admin consent. The similarly named **Office 365 Exchange Online** permission isn't required for this Security & Compliance PowerShell connection. If the application also runs other Exchange Online automations, keep any permissions that those separate workflows require.

3. Connect to Security & Compliance PowerShell with an account that can manage role groups. Register the enterprise application's service principal in Exchange and Microsoft Purview:

   PowerShell

   ```
   New-ServicePrincipal -AppId <application-client-id> -ObjectId <enterprise-application-object-id> -DisplayName "<display-name>"
   ```

   The *AppId* value is the application (client) ID. The *ObjectId* value is the Object ID from **Enterprise applications**, not the Object ID from **App registrations**. Use a descriptive *DisplayName* value to make the service principal easy to identify.

4. In the Microsoft Purview portal, the *eDiscovery Manager* role group appears under **Settings** > **Role groups**. Assign the registered service principal to this role group by using Security & Compliance PowerShell and the same enterprise application Object ID:

   PowerShell

   ```
   Add-RoleGroupMember -Identity "eDiscoveryManager" -Member <enterprise-application-object-id>
   ```

   The *eDiscovery Manager* role group is the validated least-privileged assignment for app-only eDiscovery. Don't use *eDiscovery Administrator* as an interchangeable service principal assignment.

5. Verify the role group membership:

   PowerShell

   ```
   Get-RoleGroupMember -Identity "eDiscoveryManager"
   ```

6. Use ExchangeOnlineManagement 3.10.1 or later, and include the *EnableSearchOnlySession* switch when you connect:

   PowerShell

```
Connect-IPPSSession -CertificateThumbprint "<certificate-thumbprint>" -AppId "
<application-client-id>" -Organization "<tenant>.onmicrosoft.com" -
EnableSearchOnlySession
```

If the connection returns HTTP 401, verify that **Microsoft Exchange Online Protection** > **Exchange.ManageAsApp** is configured as an Application permission and has tenant-wide admin consent. If the connection succeeds but eDiscovery cmdlets aren't recognized, verify the service principal registration and its membership in the *eDiscovery Manager* role group.

Assign eDiscovery permissions

1. Go to the Microsoft Purview portal and sign in with an account that can assign permissions.
2. Go to **Settings** > **Role groups**.
3. On **Role groups for Microsoft Purview solutions**, select **eDiscovery Manager**.
4. On the **eDiscovery Manager** pane, do one of the following actions based on the eDiscovery permissions that you want to assign.
    - Select **Edit**.
    - On **Manage eDiscovery Manager**, select **Choose users** or **Choose groups**.
    - Search and select the users you want to add as an *eDiscovery Manager*, then select **Select**.
    - Select **Next**.
    - To assign users to the *eDiscovery Administrator* role group, select **Choose users** or **Choose groups**.
    - Search and select the users you want to add as an *eDiscovery Administrator*, then select **Select**.
    - Select **Next**.
5. If the selected users or groups need organization-wide access as part of this role group assignment, go to Step 8.
6. If the selected users or groups need to be assigned to administrative units, select the users or groups and select **Assign admin units**.
7. On **Assign admin units**, select the checkbox for all the administrative units you want to assign to the users or groups. Select **Select**.

8. Select **Next** and **Save** to add the users or groups to the role group. Select **Done** to complete the steps.

> **Note**
>
> You can also use the **Add-eDiscoveryCaseAdmin** cmdlet to make a user an eDiscovery Administrator. However, you must assign the *Case Management* role to the user before you can use this cmdlet to make them an eDiscovery Administrator. For more information, see Add-eDiscoveryCaseAdmin.

On the **Role groups** page in the Microsoft Purview portal, you can also assign users eDiscovery-related permissions by adding them to the *Compliance Administrator*, *Organization Management*, and *Reviewer* role groups. For a description of the eDiscovery-related role-based access control roles assigned to each of these role groups, see Role-based access control roles related to eDiscovery.

RBAC roles related to eDiscovery

The following table lists the eDiscovery-related role-based access control roles in the Microsoft Purview portal, and shows the built-in role groups that each role belongs to by default.

Expand table

Role	Compliance Administrator	eDiscovery Manager & Administrator	Organization Management	Reviewer
Case Management	✓	✓	✓	
Communication		✓		
Compliance Search	✓	✓	✓	
Custodian (Data Sources)		✓		
Export		✓		
Hold	✓	✓	✓	
Manage review set tags		✓		
Preview		✓		

Role	Compliance Administrator	eDiscovery Manager & Administrator	Organization Management	Reviewer
Review		✓		✓
RMS Decrypt		✓		
Search And Purge			✓	

> **Note**
>
> To view the list of eDiscovery cases, a user must have at least one of the roles listed in the preceding table. For users who aren't eDiscovery Administrators, the cases shown are limited to those where the user is a member. The Custodian role provides access to the **Data Sources** tab in eDiscovery to manage data sources related to specific cases.

Run the following diagnostic test to check if the *Export*, *Preview*, or *Search* roles are assigned to the designated admin account.

1. Select the **Help** control in the top right of the Microsoft Purview portal. Enter *Diag:edisRBACdiag* in search (or select this link) to run the **eDiscovery RBAC Check** test.
2. In the **Run diagnostics** section, enter the UPN or email address of the user trying to run an export, preview, or search task.
3. Select **Run Tests**. If the user doesn't have the necessary eDiscovery roles, assign the roles to perform the desired task.

Custom role combinations

If you need to provide custom access to specific feature components of eDiscovery for specific users, use custom role combinations for specific users. For example, you might need to allow a user to manage data sources, but without access to search features. For another user, you might need to allow to manage searches, but without access to data sources.

Consider using the following role combinations as needed:

- *Case Management* and *Search* roles for access to only search features.
- *Case Management* and *Custodian* roles for access to only data source features.
- *Case Management*, *Review*, and *Manage Tags* roles for access to only review features.
- *Case Management* and *Hold* roles for access to only hold features.
- *Case Management* and *Export* roles for access to only export features.

- *Case Management*, *Search*, and *Purge* roles for access to only purge features.

eDiscovery roles

The following sections describe each of the eDiscovery-related RBAC roles listed in the RBAC roles related to eDiscovery table.

Case Management

This role lets users create, edit, delete, and control access to eDiscovery cases in the Microsoft Purview portal. You must assign the *Case Management* role before you can use the **Add-eDiscoveryCaseAdmin** cmdlet to make a user an eDiscovery Administrator. For more information, see Get started with eDiscovery.

Compliance Search

This role lets users search mailboxes and public folders, SharePoint sites, OneDrive sites, Skype for Business conversations, Microsoft 365 groups, Microsoft Teams, and Viva Engage groups. This role allows a user to get an estimate of the search results and create export reports, but other roles are needed to initiate search actions such as previewing, exporting, or deleting search results.

In eDiscovery, users who are assigned the *Compliance Search* role but don't have the *Preview* role can preview the results of a search when a user assigned the *Preview* role initiates the preview action. The user without the *Preview* role can preview results for up to two weeks after the initial preview action was created.

Similarly, users in eDiscovery who are assigned the *Compliance Search* role but don't have the *Export* role can download the results of a search when a user assigned the *Export* role initiates the export action. The user without the *Export* role can download the results of a search for up to two weeks after the initial export action was created. After that, they can't download the results unless someone with the *Export* role restarts the export.

The two-week grace period for previewing and exporting search results (without the corresponding search and export roles) doesn't apply when premium features are enabled in eDiscovery. Users must be assigned the *Preview* and *Export* roles to preview and export content when premium eDiscovery features are enabled.

Custodian

This role lets users identify and manage custodians for eDiscovery cases managed in the retired Microsoft Purview compliance portal and use the information from Microsoft Entra ID and other sources to find data sources associated with custodians. The user can associate other data sources such as mailboxes, SharePoint sites, and Teams with custodians in a case. The user can also place a legal hold on the data sources associated with custodians to preserve content in the context of a case.

Export

This role lets users export search results to a local computer. It also lets them prepare search results for analysis when premium eDiscovery features are enabled. For more information about exporting search results, see Export search results in eDiscovery.

Hold

This role lets users place content on hold in mailboxes, public folders, sites, Skype for Business conversations, and Microsoft 365 groups. When content is on hold, content owners can still modify or delete the original content, but the content is preserved until the hold is removed or until the hold duration expires. For more information about holds, see Create a hold in eDiscovery.

Manage review set tags

This role lets users create, edit, and delete review set tags for cases they can access. Users need to at least have the *Review* role and this role to manage tags during reviews.

> **Note**
>
> eDiscovery guest users are limited to the *Reviewer* role group and can't be assigned the *Manage review set tags* role. Therefore, guest users can't perform review set tagging. For more information about guest-user permissions, see **Configure guest user settings in eDiscovery**.

Preview

This role lets users view a list of items that a search returns. They can also open and view each item from the list to view its contents.

Review

This role lets users access review sets in eDiscovery. Users who are assigned this role can see and open the list of cases that they're members of. After the user accesses an eDiscovery case, they can select **Review sets** to access case data. This role doesn't allow the user to preview the results of a search that's associated with the case or do other search or case management tasks. Users with this role can only access the data in a review set.

RMS Decrypt

This role lets users view rights-protected email messages when previewing search results and export decrypted rights-protected email messages. This role also lets users view (and export) a file that's encrypted with a Microsoft encryption technology when the encrypted file is attached to an email message that's included in the results of an eDiscovery search. Additionally, this role lets users review and query encrypted email attachments that are added to a review set in eDiscovery. For more information about decryption in eDiscovery, see Decryption in Microsoft 365 eDiscovery tools.

Search And Purge

This role lets users perform bulk removal of data matching the criteria of a search. For more information, see Find and delete email messages in eDiscovery.

Add role groups as members of eDiscovery cases

You can add role groups as members of eDiscovery cases so that members of the role groups can access and perform tasks in the assigned cases. The roles assigned to the role group define what members of the role group can do. When you add a role group as a member of the case, members can access and perform those tasks in a specific case.

With this requirement in mind, if you add or remove a role from a role group, the role group is automatically removed as a member of any case it belongs to. This behavior protects your organization from inadvertently providing extra permissions to members of a case. Similarly, if you delete a role group, you remove it from all cases it was a member of.

Before you add or remove roles to a role group that might be a member of an eDiscovery case, run the following commands in Security & Compliance PowerShell to get a list of cases the role group is a member of. After you update the role group, add the role group back as a member of those cases.

Configure general settings in eDiscovery

General settings in eDiscovery let you set the default license level for all cases you create in eDiscovery.

Only users assigned to the eDiscovery *Administrators* role can access this setting. When enabled, the Microsoft 365 Enterprise E5 subscription is the default level for all new eDiscovery cases. You can override this setting on a per-case basis after creating a new case in the settings for a case. This setting isn't available for organizations with Microsoft 365 Enterprise E3 subscription.

Enable or disable premium eDiscovery features

> **Note**
>
> Enabling premium eDiscovery features only affects new cases and doesn't affect the license state of any existing cases.

To enable or disable premium features for your organization:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery *Administrator* permissions.
2. Select the **eDiscovery** solution card, then go to **Settings** > **eDiscovery** > **General**.
3. Select or clear the toggle for **eDiscovery (Premium)**.

Configure analytics settings in eDiscovery

This article explains how to configure organization-level analytics settings for eDiscovery in the Microsoft Purview portal. eDiscovery administrators can use these settings to enable machine learning-based detection of privileged content across all eDiscovery cases in the organization.

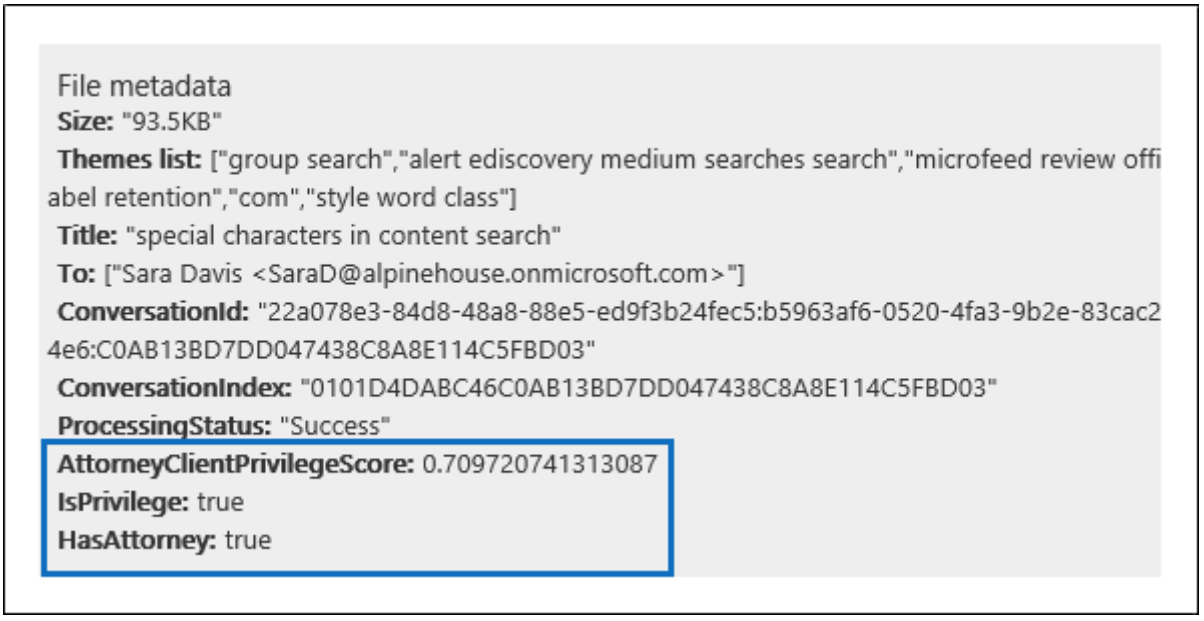
> **Note**
>
> The **Attorney-client privilege detection** feature is the only analytics setting currently available in eDiscovery organization settings. You configure additional case level search and analytics settings in the case settings for individual cases.

Configure attorney-client privilege detection

A major and costly aspect of the review phase of any eDiscovery process is reviewing documents for privileged content. eDiscovery provides machine learning-based detection of privileged content to make this process more efficient. This feature is called *attorney-client privilege detection*.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

How attorney-client privilege detection works



When you enable attorney-client privilege detection, the model processes all documents in a review set when you analyze the data in the review set. The model looks for two things:

- **Privileged content**: The model uses machine learning to determine the likelihood that the document contains content that is legal in nature.
- **Participants**: As part of setting up attorney-client privilege detection, you submit a list of attorneys for your organization. The model then compares the participants of the document with the attorney list to determine if a document has at least one attorney participant.

The model produces the following three properties for every document:

- **AttorneyClientPrivilegeScore**: The likelihood the document is legal in nature; the values for the score are between *0* and *1*.
- **HasAttorney**: This property is set to *true* if one of the document participants is listed in the attorney list; otherwise the value is *false*. The value is also set to *false* if your organization didn't upload an attorney list.
- **IsPrivilege**: This property is set to *true* if the value for **AttorneyClientPrivilegeScore** is over the threshold *or* if the document has an attorney participant; otherwise the value is set to *false*.

These properties (and their corresponding values) are added to the file metadata of the documents in a review set and are searchable within a review set:

Set up the attorney-client privilege detection model

To enable the attorney-client privilege detection model, your organization needs to turn it on and (optionally) upload an attorney list.

Step 1: Turn on attorney-client privilege detection

An eDiscovery Administrator in your organization (a member of the eDiscovery Administrator subgroup in the eDiscovery Manager role group) must make the model available in your eDiscovery cases.

1. In the Microsoft Purview portal, go to **Settings** > **eDiscovery** > **Analytics**.
2. Toggle **Attorney-client privilege detection** to *On*.
3. Select **Save** to save the change.

Step 2: Upload a list of attorneys (optional)

To take full advantage of the attorney-client privilege detection model and use the results of the **Has Attorney** or **Potentially Privileged** detection, upload a list of email addresses for the lawyers and legal personnel who work for your organization.

To upload an attorney list for the attorney-client privilege detection model:

1. Create a .csv file (without a header row) and add the email address for each appropriate person on a separate line. Save this file to your local computer.
2. In the Microsoft Purview portal, go to **Settings** > **eDiscovery** > **Analytics**.
3. Select **Choose file**, then find and select the .csv file that you created in step 1.
4. Select **Save** to upload the attorney list.

Use the attorney-client privilege detection model

Complete the following steps to use attorney-client privilege detection for documents in a review set.

Step 1: Create a smart tag group with attorney-client privilege detection model

One of the primary ways to see the results of attorney-client privilege detection in your review process is by using a smart tag group. A smart tag group shows the results of the attorney-client privilege detection in-line next to the tags. This setup lets you quickly identify potentially privileged documents during document review. You can also use the tags in the smart tag group to tag documents as privileged or nonprivileged. For more information about smart tags, see Set up smart tags.

1. In the review set that contains documents you previously analyzed, select **Manage review set** and then select **Manage tags**.

2. Under **Tags**, select the pull-down next to **Add group** and then select **Add smart tag group**.

3. On the **Choose a model for your smart tag** page, select **Select** next to **Attorney-client privilege**.

   A tag group named **Attorney-client privilege** appears. It contains two child tags named **Positive** and **Negative**, which correspond to the possible results produced by the model.

4. Rename the tag group and tags as appropriate for your review. For example, you can rename **Positive** to **Privileged** and **Negative** to **Not privileged**.

Step 2: Analyze a review set

When you analyze the documents in a review set, the attorney-client privilege detection model also runs and adds the **AttorneyClientPrivilegeScore**, **HasAttorney**, and **IsPrivilege** properties (described in How attorney-client privilege detection works) to every document in the review set. For more information about analyzing data in review set, see Analyze data in a review set in eDiscovery.

Step 3: Use the smart tag group for review of privileged content

After analyzing the review set and setting up smart tags, the next step is to review the documents. If the model determines the document is potentially privileged, the corresponding smart tag in the **Tagging panel** indicates the following results produced by the attorney-client privilege detection:

- If the document has content that might be legal in nature, the label **Legal content** appears next to the corresponding smart tag (which in this case is the default **Positive** tag).
- If the document has a participant who is found in your organization's attorney list, the label **Attorney** appears next to the corresponding smart tag (which in this case is also the default **Positive** tag).
- If the document has content that might be legal in nature *and* has a participant found in the attorney list, both the **Legal content** and **Attorney** labels appear.

If the model determines that a document doesn't contain content that is legal in nature or doesn't contain a participant from the attorney list, then neither label appears in the tagging panel.

After you review a document to see if it contains privileged content, you can tag the document with the appropriate tag.

Configure guest user settings in eDiscovery (preview)

With guest access, you can provide access to eDiscovery cases to people outside your organization. You can invite guest users to eDiscovery cases just like you can invite guests into your Teams environment.

A guest is someone who doesn't have a work or school account with your organization. For example, guests can include external partners, vendors, suppliers, or consultants. Anyone who isn't part of your organization can be added as a guest for an eDiscovery case. This access means that anyone with a Microsoft Entra account or personal email account (Outlook, Gmail, or others) can participate as a guest in eDiscovery and have access to specific eDiscovery cases.

Guest access in eDiscovery uses Azure B2B technology, which depends on an organization-wide Azure collaboration setting. When you invite a guest to eDiscovery, a guest account is created for them in Microsoft Entra ID. They're covered by the same compliance and auditing protection as other Microsoft 365 users. Guest access is subject to Microsoft Entra ID and Microsoft 365 service limits.

> **Note**
>
> eDiscovery guests are currently limited to *Reviewer* role group permission only. The *Reviewer* role allows guests to access review sets and review case data, but it doesn't include the *Manage review set tags* role. As a result, guest users can't create, edit, delete, or apply review set tags. Review set tagging requires both the *Review* and *Manage review set tags* roles. For more information about the reviewer role, see **Assign eDiscovery permissions in the Microsoft Purview portal**.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Set up guest access

Setting up guest access in eDiscovery requires configuring other settings in Microsoft Entra ID. To enable access to invite guests to eDiscovery cases, complete the following steps:

1. Check the B2B external collaboration settings to ensure that collaboration with guests isn't blocked. If the **Guest invite settings** is set to *No one in the organization can invite guests including admins* then inviting guests into eDiscovery is disabled. Contact your system administrator to ensure the B2B external collaboration settings are properly configured. You can view and update the collaboration setting using the Microsoft Graph authorizationPolicy resource.

2. Depending on the specific configuration in Step 1, eDiscovery administrators might or might not need additional roles to approve a guest access request submitted from the eDiscovery user.

    - If the *Anyone in the organization can invite guest including guests and nonadmins (most inclusive)* or *Member users and users assigned to specific admin roles can invite guests including guests with member permission* options are selected, then eDiscovery administrators can approve invitation requests without extra roles.
    - If *Only users assigned to specific admin roles can invite guests* is selected, then the eDiscovery administrator who approves the invitation request requires the *Invite guest* role to approve and trigger the invitation email to the guest. See the Assign Microsoft Entra roles to users article for guidance on how to add the *Guest Inviter* role to users. If you prefer to use PowerShell to add this role, see Assign the Guest Inviter role to a user.

3. To enable collaboration with guest reviewers from other Microsoft 365 cloud environments, including if you're a Microsoft Azure Government organization, both your organization and the guest's organization must enable specific connection settings. For detailed configuration guidance, see Collaborate with guests from other Microsoft 365 cloud environments.

Enable guest access in eDiscovery

eDiscovery admins must enable guest access in eDiscovery before they can invite users as guests.

To enable guest access for guests, complete the following steps:

1. In the Microsoft Purview portal, go to **Settings** > **eDiscovery** > **Guest users**.
2. Set **Guest access** to *On*.

Now eDiscovery managers and admins can start the guest invitation process within any eDiscovery case. To configure guest access to specific cases, see Learn about access and permission settings in eDiscovery cases.

Configure tag templates in eDiscovery

Use tag templates to define and standardize tags and the review workflow across all cases and review sets in your organization. Each tag template contains tag groups where you can create a grouping structure for individual tags.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Create tag templates

To create a new tag template, complete the following steps:

1. In the Microsoft Purview portal, select **Settings** > **eDiscovery** and then select **Tag templates**.
2. Select **Create**.
3. On **New tag template**, enter a name and description for the tag template.
4. In the initial tag group, enter a tag group name and use the dropdown to define this group as a **Multi-select** or **Single-select** tag group.
5. Enter at least one tag name in the tag group. Select **Add tag** to add more tags to the tag group.
6. If needed, select **Add tag group** to add more tag groups and tags to the tag template.
7. Preview the tag template group and tag structure in the **Preview** pane on the right side of **New tag template**.
8. When complete, select **Save**.

The tag template is now available for use in all cases and review sets in your organization.

Manage tag templates

After you create a tag template, you can edit or delete it. You can also view information about the tag template, including the dates when you created or last modified it.

1. In the Microsoft Purview portal, select **Settings** > **eDiscovery** and then select **Tag templates**.

    - To edit a tag template, select the tag template name on **Manage tag templates** and select **Edit**. On **Edit tag template**, you can edit the tag template name, description, and tag groups and tags. When done, select **Save**.
    - To delete a tag template, select the tag template name on **Manage tag templates** and select **Delete**. Select **Yes** to confirm the deletion or **No** to cancel the deletion.

Apply tag templates to a case and review sets

After you create a tag template, you can apply it to a review set. You can apply a tag template when you create a new review set or when you edit an existing review set.

To apply a tag template to a new review set, complete the following steps:

1. In the Microsoft Purview portal, select **eDiscovery** > **Cases** and select a case.
2. In the case, select **Review sets**, select a review set, then select the **All items** tab.
3. On the review set command bar, select **Manage** > **Tags**.
4. On **Manage tags**, delete the blank tag group, then select **Import tag templates**.
5. On **Import tag templates**, select the tag template that you want to apply to the review set, then select **Import**.
6. If needed, edit the tag template as it applies to the case and review set.
7. Select **Save** to apply the tag templates to the case and review set.

The applied tag template is now available for use in the case and all included review sets.

ⓘ **Note:** The author created this article with assistance from AI. Learn more

Last updated on 04/02/2026

Configure export settings in eDiscovery

> **Note**
>
> This setting isn't available in DoD cloud organizations.

Export settings let you manage download links for all exports in eDiscovery. When exporting large eDiscovery results, network interruptions and browser limitations might affect the download experience. Whether you enable the **Enable export download via pre-authorized link** option depends on your environment, security requirements, network bandwidth, and the tools you plan to use.

> **Note**
>
> For export download best practices, see Best practices for downloading export packages.

Use a pre-authorized link when downloading large export packages or when your network connection might be limited. Large exports take longer to download, which naturally increases the chances of a network interruption during the process. Pre-authorized links are designed for this scenario. By using a pre-authorized link, the download can resume when interrupted. Using a pre-authorized link works with tools that support parallel or chunked downloads, such as third-party download accelerators or browser extensions. When you initiate the download, the pre-authorized download link is generated. The link acts like an access token, so tools can download data without repeated sign-ins.

These links grant direct access to your export. If shared, anyone with the link can access the data. To reduce risk, set the shortest possible expiration time based on the size of your export. You can configure export package download link availability for the following durations:

- 1 hour
- 6 hours
- 12 hours
- 24 hours (default)
- 48 hours
- 72 hours
- 168 hours

Disable pre-authorized link for high bandwidth environments. The standard signed-in download method without pre-authorized links is ideal when you have an ExpressRoute connection with high bandwidth to Microsoft. The standard signed-in download method doesn't generate a pre-authorized token, reducing the risk of link misuse. Each session requires sign-in. If the download is interrupted, you need to re-authenticate and restart. Browser resume behavior varies and isn't guaranteed.

Enable preauthorized export download links

> **Important**
>
> Don't share export download links with anyone. Treat these links as secrets.

Changing this setting to turn preauthorized links on or off only applies to future export downloads. It doesn't affect existing links. For example, if you enable preauthorized links with a one-day expiration, any links you created before you disable the setting remain valid until they expire. Turning off the pre-authorized export download link setting doesn't retroactively change the behavior of existing links.

To enable preauthorized export download links for your organization:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery *Administrator* permissions.
2. Select the **eDiscovery** solution card, then go to **Settings** > **eDiscovery** > **Export**.
3. Select the toggle for **Enable export download via pre-authorized link**.
4. Select a duration in **Export Link Settings**.
5. Select **Save**.

Create and manage cases in eDiscovery

After setting up Microsoft Purview eDiscovery and assigning permissions to eDiscovery managers in your organization who manage cases, create and manage a case for escalation activities or investigation requests.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Cases dashboard

The **Cases** dashboard in the Microsoft Purview portal displays all eDiscovery cases in your organization. You can quickly see the cases in your organization, the status of each case, and important information associated with each case.

- **Name**: The name of the case. The case name must be unique in your organization.
- **Case status**: The current status of the case.
- **Case type**: The type of case.
- **Created on**: The date and time in Coordinated Universal Time (UTC) when the case was created.
- **Last modified**: The date and time in Coordinated Universal Time (UTC) when the case was last modified.
- **Last modified by**: The name of the user that last modified the case.
- **Number**: The optional docket number or other custom numeric identifier for the case.
- **Description**: The description of the case entered when the case was created.

Select **Customize columns** to customize the displayed columns and the order of the columns in the **Cases** dashboard. Choose the columns to display or drag and drop columns to reorder.

Filter cases

To filter cases on the **Cases** dashboard, enter a keyword to filter by case names that contain the keyword or select **Filter** on the command bar. Select one or more of the following filters and select **Apply** to help you organize cases for review on the dashboard.

Case status options:

- **Active**: The case is active.
- **Pending delete**: The case likely has a hold in the pending deletion state. Check the hold policy and redistribute to resolve the error. Afterward, cases without any holds should be deleted successfully.
- **Closing**: The case is being closed. This status is seen only for case with active holds. Cases without holds are immediately closed.
- **Closed**: The case is closed without errors and the case can be reopened.
- **Closed with errors**: The case is closed, but there are errors. Errors are most likely associated with holds that weren't released during closing. To resolve, check policies with errors, resolve the errors, and redistribute the policies.

Case type options:

- **Premium**: eDiscovery (Premium) cases.
- **Standard**: eDiscovery (Standard) cases.
- **User data search**: Legacy user data search cases.
- **Content search**: Content searches in your organization.

> **Important**
>
> Case type is used only to map cases to the Microsoft Purview compliance portal during the preview of eDiscovery in the Microsoft Purview portal. This mapping helps you find cases in the compliance portal (if needed). All cases created in the Microsoft Purview portal are the *Premium* type, regardless of your license or subscription. Access to premium features isn't governed by the case settings toggle.

To clear **Case** dashboard filters, select **Filter** > **Clear filters** > **Apply**.

Grouping cases

To group cases on the **Cases** dashboard, select **Group** on the command bar. Select one of the following groupings to help you organize cases for review on the dashboard.

- **None**: Clears grouping for cases.
- **Status**: Groups cases by the status of the case.
- **Last modified by**: Groups cases by the user that last modified the case.
- **Case type**: Groups cases by the case type.

Download a list of cases

To download a list of all cases displayed in the **Cases** dashboard, select **Download list**. A .csv file is generated that contains the case name and all of the **Cases** dashboard column properties for each case.

Create a case

> **Tip**
>
> Do you prefer an interactive configuration guide experience? Check out the **Create and configure a case** guide.

Complete the following steps to create a case and configure case properties. The user who creates the case is automatically added as a member. Members of the case can access the case in the Microsoft Purview portal and perform eDiscovery tasks.

1. Go to the Microsoft Purview portal and sign in using the credentials for a user account assigned eDiscovery permissions. Members of the *Organization Management* role group can also create eDiscovery cases.
2. Select the **eDiscovery** solution card and then select **Cases** in the left navigation.
3. Select **Create case**.
4. On **Enter details to get started**, complete the following fields:
    - **Case name**: give the case a name (required). The case name must be unique in your organization.
    - **Case description**: Add an optional description to help others understand this case.
5. Select **Create** to create the new case and start your investigation.

Add data sources to a case

> **Tip**
>
> Want to try premium eDiscovery features? See the **subscription requirements** for Microsoft 365 Enterprise E5 licensing.

Data sources define the locations that you can quickly include in all case searches and holds. Add data sources to a case with premium eDiscovery features enabled to quickly use data sources across multiple case activities. When you add a data source at the case level, you include all associated resources (mailboxes, sites, and more) for the data source.

SharePoint Embedded container support in eDiscovery (preview) lets you add supported container URLs individually or through bulk import as case data sources.

To discover supported containers relevant to a selected user or filter containers by application, manage the data source in an individual search or hold. Group-owned and app-owned SharePoint Embedded containers aren't currently supported.

For step-by-step guidance on adding data sources to a case, see Data sources in eDiscovery.

Summarize a case with Copilot (preview)

When you summarize cases with Copilot, you can quickly access a comprehensive summary of eDiscovery cases. Copilot consolidates case information into a single, easy-to-understand summary. Copilot analyzes content within the case and generates natural language summaries, giving you a clear, actionable overview of key details in real-time. It eliminates the need to navigate through multiple case tabs by consolidating status updates, completed actions, pending tasks, and ongoing jobs into a single, easy-to-read summary. To use Copilot to summarize a case, Security Copilot must be enabled and the user must be assigned the *eDiscovery Administrator* or *eDiscovery Manager* role.

Whenever you view a case, Copilot automatically reviews the case and displays summary information in the Copilot pane. You can also select **Summarize this case** to run Copilot and display or refresh this summary and pane. When Copilot completes the summary, it displays details about the case in the following areas:

- **Case information**: A high level summary information about the case, including information about the case type, when the case was created, when the case was modified, who the last user was that modified the case, and more.
- **Data sources**: A summary of data sources associated with the case.
- **Exports**: A summary of search and review set exports associated with the case, including details about export items, file sizes, and item counts.
- **Holds**: A summary of hold policies associated with the case, including hold policy, query, and location details.
- **Jobs**: A summary of all the processes associated with the case.

- **Review sets**: A summary of the review sets associated with the case, when they were created, modified, and who edited.
- **Searches**: A summary of searches associated with the case, including query conditions, sources, options, and settings.
- **Settings**: A summary of the case settings, such as OCR, near-duplicate detection, search, document processing, and review set settings.

If the case doesn't have activity for an area, the Copilot summary indicates that the area doesn't have any activities to summarize. For example, if the case doesn't have associated exports, the Copilot summary in **Exports** section confirms that the case doesn't have any exports.

You can also enter customized prompts directly in Copilot to further refine and narrow the scope to specific areas about the case.

To change the data source used for the Copilot summary, select **Microsoft Learn documentation** at the end of the summary. This scopes the Copilot summary to support guidance that can help you learn more about working with cases and can provide step by step guidance or details about eDiscovery features and capabilities.

Mark a case as a favorite

You can mark an eDiscovery case as a favorite for quicker access to cases you want to prioritize. You can quickly access cases marked as favorites through the **Cases** dashboard. To mark a case as a favorite, select the star icon to the left of a case in the case list on the **Cases** dashboard.

Limited format cases

Some cases you previously created in the eDiscovery classic experience might have the *Limited format* status applied. If applicable to a case, this tag appears next to the case title when on any of the action tabs within a case (**Searches**, **Hold policies**, etc.). These cases have some limitations from the features and functionality available in cases created in the Microsoft Purview portal and with the new eDiscovery experience. Advanced indexing isn't available for searches, exporting items from a search, and when adding a search results to a review set.

Manage case settings

Case settings include case information, case license level control, access permissions, and settings that control search and analytics behavior for the case. You can access settings for a specific case by selecting **Case settings** after selecting a case. You can define specific parameters for feature

capabilities based on eDiscovery licenses in your organization, which users, role groups, and guests have access and permissions for the case, and which additional locations are included during organization-wide searches for the case.

For more information about case settings, see:

- Learn about case settings in eDiscovery cases
- Learn about access and permission settings in eDiscovery cases
- Learn about data sources settings in eDiscovery cases
- Learn about search and analytics settings in eDiscovery cases
- Learn about review set settings in eDiscovery cases

Manage case status

> ⚠ **Warning**
>
> Closing or deleting a case turns off all holds. Any content that was on hold is released, which might result in data loss.

To close or delete a case, select **Actions** for an individual case and choose **Close case** or **Delete case**.

For more information about managing case actions, see:

- Closing a case
- Reopening a case
- Deleting a case

Related content

Learn about case settings in eDiscovery

Case settings in eDiscovery let you view and update case information and take action on specific cases in eDiscovery.

The following information displays for the selected case:

- **Premium features**: Shows the status of premium eDiscovery features enabled in the case. To use premium eDiscovery features for the selected case, turn on the **eDiscovery (Premium)** toggle.

> **Note**
>
> Premium features are enabled by default for tenants with premium feature access. To turn off, toggle the setting after a case is created.

- **License**: Shows the current licensing subscription for the case. Values are *eDiscovery (Premium)* or *eDiscovery (Standard)*.
- **ID**: Shows the case identification number. You can review this number, but you can't change it once the case is created.
- **Case name**: Shows the case name. This field is required. To change the case name, enter the new case name and select **Actions** > **Save**.
- **Case number**: Shows an optional docket number or other numeric identifier for the case. To change the case number, enter the new case number and select **Actions** > **Save**.
- **Case description**: Shows an optional description to help others understand this case. To change the case description, enter the new case description and select **Actions** > **Save**.
- **Case status**: Shows the current case status.
- **Case created**: Shows the date and time when the case was created.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Close a case

When you complete the legal case or investigation supported by eDiscovery, you can close the case. Here's what happens when you close an eDiscovery case:

> **Note**
>
> You need to either disable or delete all active hold policies in the case before you can close the case.

- Delete any active hold policies. After you delete the hold, a 30-day grace period (called a *delay hold*) is applied to content locations that were on hold. This delay hold helps prevent content from being immediately deleted and gives you an opportunity to search for or recover content that is permanently deleted after the delay hold period expires.
- The case is still listed on the **Cases** page in the Microsoft Purview portal. The details, holds, searches, and members of a closed case are retained.
- You can edit a closed case. For example, you can add or remove members, create searches, export search results, and prepare search results for analysis in eDiscovery.

To close a case, complete the following steps:

1. Go to the Microsoft Purview portal and sign in using the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card and then select **Cases**.
3. Select a case, then navigate to the *Hold policies* tab.
4. Delete all hold policies in the case.
5. Once the hold policies are deleted, select **Case settings**.
6. On **Case settings**, select **Actions**, then select **Close case**. It might take up to 60 minutes for the closing process to complete.

When you close a case, you see the status of the case changing as the case is processed for closing.

Reopen a closed case

When you reopen an eDiscovery case, the process doesn't automatically reinstate any holds that were in place when the case was closed. After you reopen the case, go to the **Holds** tab and turn on the previous holds. To turn on a hold, select it to display the flyout page, then set the **Status** toggle to **On**.

To reopen a closed case, complete the following steps:

1. Go to the Microsoft Purview portal and sign in using the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left nav.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Actions**, then select **Reopen case**. It might take up to 60 minutes for the reopening process to complete.

Delete a case

You can delete both active and closed eDiscovery cases. When you delete a case, you also delete all components associated with the case, such as the list of communications, searches, review sets, and exports. You can't recover or reopen a deleted case.

> **Note**
>
> In data spillage scenarios, the only way to remove items in a review set is to delete the eDiscovery case. Other search and purge methods don't remove items from a review set.

Before you can delete a case, you must delete *all* hold policies listed on the **Hold policies** tab of the case. This requirement includes deleting holds with a status of **Off**.

To delete hold policies associated with a case, complete the following steps:

1. Go the **Hold policies** tab in the eDiscovery case that you want to delete.
2. Select the hold policy that you want to delete.
3. On the hold policy page, select **Policy actions** > **Delete policy**.

To delete a case, complete the following steps:

1. Go to the Microsoft Purview portal and sign in using the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left nav.
3. Select a case, then select **Case settings**.
4. On the **Case settings** page, select **Actions**, then select **Delete case**.

Learn about access and permission settings in eDiscovery cases

Access and permission settings in eDiscovery let you add or remove users to a case, manage role group membership for a case, and add people outside your organization as guest users for a case.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Add or remove users from an eDiscovery case

You can add or remove users to manage who can access the case. However, before a user can access an eDiscovery case (and perform tasks in the case), you must add the user to the eDiscovery Manager role group in the Microsoft Purview portal. For more information, see Assign eDiscovery permissions.

Add users to a case

Complete the following steps to add users to a case:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card and then select **Cases** in the left navigation.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Access and permissions**.
5. Under **Users**, select **Add** to add users to the case. You can also choose to add a role group to the case by selecting **Add** under **Role groups**.
6. In the list of users or role groups that you can add to the case, select the check box next to the names of the users or role groups that you want to add.

> **Note**
>
> When adding a role group to a case, you can only add the role groups that you're a member of.

7. After you select the people or role groups to add as members of the case, select **Add**. The selected users are added to the case.

> **Important**
>
> If you add or remove a role from a role group that you added as a member of a case, the role group is automatically removed as a member of the case (or any case the role group is a member of). This behavior protects your organization from inadvertently providing extra permissions to members of a case. Similarly, if you delete a role group, it's removed from all cases it was a member of. For more information, see Assign eDiscovery permissions.

Remove users from a case

Only an eDiscovery Administrator can remove users from a case. Even if you're assigned to the *eDiscovery Manager* role group or initially created the case, you can't remove yourself or other members from a case unless you're also an eDiscovery Administrator. To remove yourself or other members from a case, contact an eDiscovery Administrator in your organization.

Complete the following steps to remove users from a case:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card and then select **Cases** in the left navigation.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Access and permissions**.
5. Under **Users**, select **Remove** to remove users from the case. You can also remove users from a role group for the case by selecting **Remove** under **Role groups**.
6. In the list of users or role groups that you can remove from the case, select the check box next to the names of the users or role groups that you want to remove.
7. After you select the people or role groups to add as members of the case, select **Remove**. The selected users are removed from the case.

Guest access in eDiscovery

With guest access, you can provide access to an eDiscovery case to people outside your organization. You can invite guest users to eDiscovery cases just like you can invite guests into your Teams environment. eDiscovery admins must enable guest access in eDiscovery before they can invite users as guests.

Invite guests to an eDiscovery case

After you enable guest access for eDiscovery, complete the following steps to invite guests to an eDiscovery case:

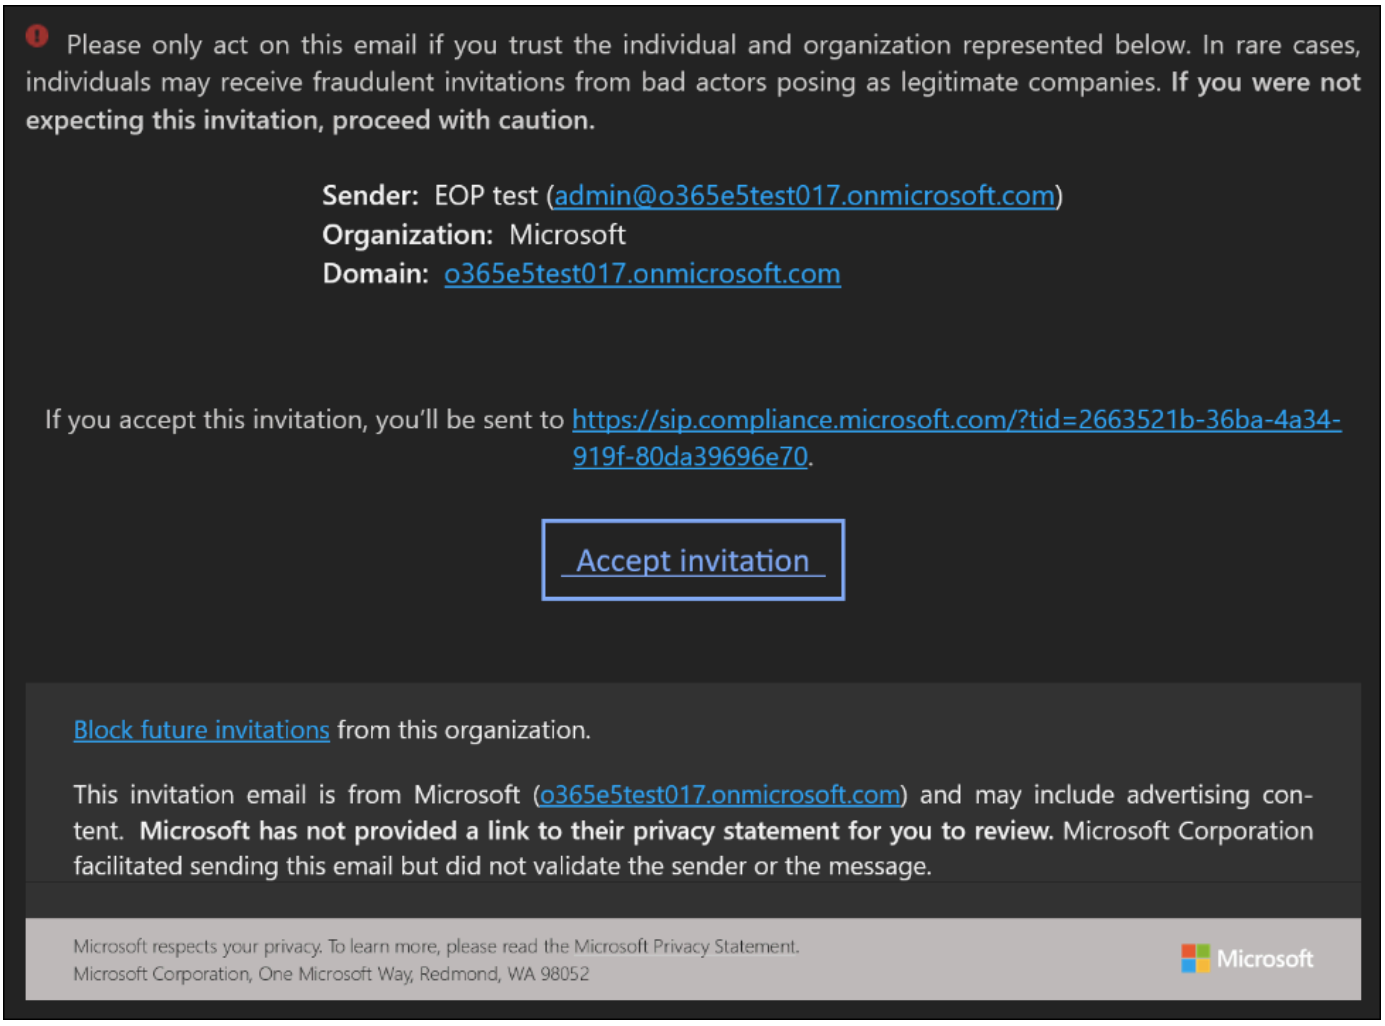
1. In the Microsoft Purview portal, go to **eDiscovery** > **Cases** and select the case you want to invite guests to.
2. In the selected case, select the **Case settings** tab.
3. Select **Access and permissions**.
4. In the **Guest users** section on the **Access and permissions** page, select **Invite**.
5. On the **Invite guest** flyout pane, complete the following fields:
    - **Full name**: Enter the full name of the guest you want to invite.
    - **Email address**: Enter the email address of the guest you want to invite.
    - **Organization**: Enter the organization of the guest you want to invite.
    - **Guest role**: Select the role you want to assign to the guest. The guest is currently limited to *Reviewer* role group permission only. The *Reviewer* role doesn't include the *Manage review set tags* role, so guest users can't perform review set tagging.
    - **Justification**: Explain why this person needs access to the case.
6. Select **Invite** to submit the invitation request for review and approval by an eDiscovery admin.

Approve guest access requests

After submitting guest invitations, eDiscovery admins must approve the requests before the guest can access the case. eDiscovery managers receive notifications of pending invitation requests on the **Guest users** page in eDiscovery settings in the Microsoft Purview portal. To approve guest access requests, eDiscovery administrators must have the *Role Management* role assigned.

To review and approve guest access requests, eDiscovery managers complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Go to **Settings** > **eDiscovery** > **Guest users**.
3. Select the guest request and select **Approve** or **Deny** from the flyout pane.



If the guest is being added to the tenant for the first time, eDiscovery admins need to perform a two-step approval process. They first need to approve creation of an account, which might take up to 24 hours. After 24 hours, eDiscovery admins can approve guest access to the case. For future access requests for access to other cases for the same guest, only one-step approval is required.

If you encounter an error when approving the guest access to a case, check the following points:

- The guest's email isn't disabled, blocked, or deleted by the tenant admin.
- If there are any members in the *Reviewer* role group whose Microsoft Entra account is deleted. Currently, an error occurs when adding a new member to a role group that has any deleted users. If the *Reviewer* role group has any deleted users, remove them from the role group and retry the guest approval.

Accepting guest invitations

After the eDiscovery admin approves the request, the guest receives a welcome email from *Microsoft Invitations*. This email contains information about the eDiscovery invitation and a link where the guest can accept the invite and sign in. The guest must select the unique link provided in the email or copy and paste the link in a browser to sign in to the specific eDiscovery organization.

Guests with a work or school account in Microsoft Entra ID can accept the invitation and authenticate immediately. Other users receive a one-time passcode to validate their identity. You must ensure that the one-time passcode setting is enabled in your organization.

> **Note**
>
> If the guest is signed in to another eDiscovery organization in their browser, they need to sign out from the organization and clear their browser cache before selecting the link in the invitation email.

After accepting the invitation and authenticating, the guest can participate in the eDiscovery case like an internal reviewer of the case and perform review activities such as querying, filtering, redaction, downloading single items for review, and more. Guest users can't perform review set tagging because tagging requires the *Manage review set tags* role, which isn't included in the *Reviewer* role group available to guest users.

Remove guest access

An eDiscovery admin can remove a guest's access to a case from the eDiscovery settings page. To remove guest access for a user, eDiscovery admins must complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Go to **Settings** > **eDiscovery** > **Guest users**.
3. Select the guest and select **Remove** from the flyout pane.

The guest keeps access to other cases they were added to. When you remove a guest from the last case they have access to, you remove them from the *Reviewer* role group and they lose access to all cases in eDiscovery.

The guest keeps their Microsoft Entra guest account in the organization. Regularly review and clean up guest accounts from Microsoft Entra ID.

Learn about search and analytics settings in eDiscovery cases

You can configure settings for each eDiscovery case to control the following functionality:

- Near duplicates and email threading
- Themes
- Autogenerated review set query
- Ignore text
- Optical character recognition

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Configure analytics settings for a case

To configure search and analytics settings for a case:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left nav.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Search & analytics**.
5. The case **Search & analytics** page appears. These settings apply to all review sets in a case.
6. After selecting the applicable search and analytics options, select **Save**.

The following sections describe the analytics settings that you can configure for a case.

Near duplicates and email threading

In this section, set parameters for duplicate detection, near duplicate detection, and email threading.

- **Near duplicates/email threading:** When you turn on this setting, the workflow includes duplicate detection, near duplicate detection, and email threading when you run analytics on the data in a review set.
- **Document and email similarity threshold:** If the similarity level for two documents is over the threshold, both documents are in the same near duplicate set.
- **Minimum/maximum number of words:** These settings specify that near duplicates and email threading analysis are performed only on documents that have at least the minimum number of words and at most the maximum number of words.

Near duplicate detection

Consider a set of documents to review where a subset of documents uses the same template and mostly the same boilerplate language, with a few differences. If a reviewer can identify this subset, review one of the documents thoroughly, and review the differences for the rest, they don't miss any unique information while taking only a fraction of the time it would take to read all documents cover to cover. Near duplicate detection groups textually similar documents together to help you make your review process more efficient.

When you run near duplicate detection, the system parses every document with text. Then, it compares every document against each other to determine whether their similarity is greater than the set threshold. If it is, the system groups the documents together. Once all documents are compared and grouped, the system marks a document from each group as the "pivot." In reviewing your documents, you can review a pivot first and review the other documents in the same near duplicate set, focusing on the difference between the pivot and the document that is in review.

Email threading

Consider an email conversation that goes on for a while. In most cases, the last message in the email thread includes the contents of all the preceding messages. Therefore, reviewing the last message gives a complete context of the conversation that happened in the thread. Email threading identifies such messages so that reviewers can review a fraction of collected documents without losing any context.

Email threading in eDiscovery is the process of organizing a sequence of related emails that are part of the same conversation. This sequence includes the initial email and all subsequent replies and forwards linked to the original email. By grouping these emails into threads, reviewers see the entire context of a conversation, making it easier to understand the flow of communication. This approach helps reviewers identify relevant information more efficiently

and eliminates the need to review each email individually. Email messages included in the analytics process have the following metadata populated:

- **Is Inclusive**: This field identifies whether an email contains all the unique content from a thread, including all previous replies. It ensures that only the most comprehensive email in a thread is reviewed, which is essential for understanding the full context of the conversation without having to review each individual reply.
- **Has Unique Attachments**: This field marks emails that contain attachments not found in other emails within the same thread. Even if the email content is duplicated, unique attachments are flagged to ensure that all relevant documents are reviewed. This aspect is important in the legal review process to ensure that no unique evidence is overlooked, even if the email body itself is not unique.

How is it different from conversations in Outlook?

At a glance, this process sounds similar to conversation groupings in Outlook. However, there are some important distinctions. Consider an email conversation that forks into two conversations. For instance, someone responds to an email that isn't the latest in the conversation so the last two emails in the conversation both have unique content.

Outlook still groups the emails into a single conversation. Reading only the last email might miss the context of the second-to-last email, which also contains unique content. Because email threading parses out each email into individual components and compares them, email threading marks both of the last two emails as inclusive, ensuring that you don't miss any context as long as you read all emails marked as inclusive.

Let's also consider an email thread with multiple replies, where some replies include inline responses that modify the quoted content. If an inline reply alters part of the previous email, the latest reply doesn't fully encompass the content of the earlier email. Both the latest reply and the earlier email with unique content are marked as inclusive. This approach ensures that any unique information from the inline reply is preserved and not overlooked.

Themes

In this section, set the following parameters for themes:

- **Themes:** When turned on, the workflow performs themes clustering when you run analytics on the data in a review set.
- **Maximum number of themes:** Specifies the maximum number of themes that the workflow can generate when you run analytics on the data in a review set.

- **Include numbers in themes:** When turned on, the workflow includes numbers that identify a theme when generating themes.
- **Adjust maximum number of themes dynamically:** In certain situations, there might not be enough documents in a review set to produce the desired number of themes. When you enable this setting, eDiscovery adjusts the maximum number of themes dynamically rather than attempting to enforce the maximum number of themes.

When you create a new document, you generally start with one or more ideas that you want to convey in the document. Then you compose the document using words that align with these ideas. The more prevalent an idea is, the more frequent the words that are related to that idea tend to be. This method also aligns with how readers consume documents. The important things to understand from reading a document are the main ideas that the document is trying to convey. This understanding also includes which ideas appear where and what the relationships between the ideas are.

You can extend this process to how an eDiscovery reviewer wants to consume a set of documents in a case. They want to see which ideas are present in the review sets and which documents discuss those ideas. If they find a particular document of interest, they want to be able to see documents that discuss similar ideas.

The **Themes** functionality in eDiscovery attempts to mimic how humans reason about documents. It analyzes the *themes* that are discussed in a review set and assigns a theme to documents in the review set. In eDiscovery, Themes goes one step further and identifies the *dominant theme* in each review set and document. The *dominant theme* is the one that appears the most often in a document.

How do themes work?

The **Themes** functionality analyzes documents with text in a review set to parse out common themes that appear across all the documents in the review set. eDiscovery assigns those themes to the documents in which they appear. It also labels each theme with the words used in the documents that are representative of the theme. Because a document can contain various types of subject matter, eDiscovery often assigns multiple themes to review sets and documents. This assignment is referred to as the *Themes list*. The theme that appears most prominently in a review set or document is designated as its *dominant theme*.

Configuring Themes

Cases support themes, and they apply to all the review sets within them. You can configure the settings for themes when you create a new case or you can update the theme settings for an

existing case.

To configure themes in a case, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card and then select **Cases** in the left nav.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Search & analytics**.
5. Select the following theme options as applicable:

    - **Max number of themes:** Specifies the maximum number of themes that the workflow can generate when you run analytics on the data in review sets included in a case. For more information on limits, see Limits in eDiscovery.
    - **Include numbers in themes:** Numbers that identify a theme are included when generating themes.
    - **Adjust maximum number of themes dynamically:** In certain situations, there might not be enough documents in a review set to produce the desired number of themes for the case. When you enable this setting, the maximum number of themes is adjusted dynamically rather than attempting to enforce the maximum number of themes.

6. If you need to exclude keywords associated with themes, enter the text or regular expression needed in the **Ignore text** field. In the **Apply to** field, select **Themes** to apply the text or regular expression to all themes.
7. Select **Save**.

After you create a new case, the workflow automatically runs analytics on the data when you add the review sets to the case. The workflow generates themes for the review sets as part of the analytics processing.

Review set query

If you select the **Automatically create a For Review saved search after analytics** checkbox, eDiscovery autogenerates a review set query named **For Review.**

This query filters out duplicate items from the review set, so you can quickly review the unique items in the review set. You create this query only when you run analytics for a review set in the case. For more information about review set queries, see Query the data in a review set.

Ignore text

Certain text can diminish the quality of analytics, such as lengthy disclaimers that get added to email messages regardless of the content of the email. If you know of text that should be ignored, you can exclude it from analytics by specifying the text string and the analytics functionality (near-duplicates, email threading, themes, and relevance) that the text should be excluded for. The system also supports using regular expressions (RegEx) for ignored text.

Optical Character Recognition (OCR)

When you turn on this setting, OCR processing runs on image files when they're advanced indexed and added to a review set. When OCR is applied to image files, text in these files is available in review sets. This extracted text is then searchable within the review set. OCR runs only on items processed during Advanced indexing (if you select this option in the search query).

For example, if a large PDF file that is partially indexed or had other indexing errors is processed during Advanced indexing, OCR is applied. OCR processing only occurs on files that are reindexed during the Advanced indexing process. This condition means there might be situations where content is added to a review set, but some email attachments aren't processed for OCR because these files aren't processed during Advanced indexing.

After you add data to a review set, you can review, search, tag, and analyze image text. You can view the extracted text in the Text viewer of the selected image file in the review set. For more information, see:

- Add search results to a review set
- Supported image file types

The Purview eDiscovery OCR doesn't make images searchable during initial search. The case level setting for OCR is distinct from the tenant level OCR setting and doesn't incur the charges associated to that setting. To learn more about tenant level OCR, see https://learn.microsoft.com/en-us/purview/ocr-learn-about.

Learn about review set settings in eDiscovery cases

You can configure grouping settings for each Microsoft Purview eDiscovery case to control how the data in a review set is grouped and displayed. You can turn on the **Enable group** setting only for review sets in cases created in your organization after March 15, 2023.

Depending on when the case is created, items in a review set can be grouped in two ways:

- **Group review set items by Group ID and Thread ID**: When enabled, review set items are grouped by *Group ID* and *Thread ID*. This setting is the default for all cases created after March 15, 2023.
- **Group review set items by Family ID and Conversation ID**: When disabled, review set items are grouped by *Family ID* and *Conversation ID*. This setting is the default for all cases created before March 15, 2023.

For more information about review set grouping, see Group and view documents in a review set.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Enable review set grouping settings for a case

To enable review set grouping settings for a case:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left nav.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Review sets**.
5. Select the **Enable group** toggle to enable grouping review set items by *Group ID* and *Thread ID*.

> **Note**
>
> For cases created before March 15, 2023, the **Enable group** toggle is disabled. Item grouping in review sets for these cases is based on *Family ID* and *Conversation ID*.

Disable review set grouping settings for a case

To disable review set grouping settings for a case:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, then select **Cases** in the left nav.
3. Select a case, then select **Case settings**.
4. On **Case settings**, select **Review sets**.
5. Select the **Enable group** toggle to disable grouping review set items by *Group ID* and *Thread ID*. Item grouping in review sets for cases is now based on *Family ID* and *Conversation ID*.

Create a search for a case in eDiscovery

Use search in eDiscovery to find in-place content such as email, documents, and instant messaging conversations in your organization that are relevant to a case. Use search to find content in these cloud-based Microsoft 365 data sources:

- Exchange Online mailboxes
- SharePoint sites
- OneDrive accounts
- Microsoft Teams
- Microsoft 365 Groups
- Viva Engage

You can create and run different searches that are associated with the case. Use conditions, such as keywords, to build search queries that return search results with the data that's most likely relevant to the case. You can also:

- View search statistics that might help you refine a search query to narrow the results.
- Preview the search results to quickly verify whether the relevant data is being found.
- Revise a query and rerun the search.

After you search for and find data that's relevant to your investigation, you can send the results to a review set for further investigation or export it for review by people outside of the investigation team.

> **Note**
>
> For organizations that have EU General Data Protection Regulation (GDPR) requirements to protect and enable individuals' privacy rights inside the European Union (EU), you can also manage investigations in response to Data Subject Requests (DSRs) submitted by a person in your organization. The User Data Search case tool is retired, and its functionality is merged with eDiscovery. You can now use search to find content to support DSRs in all locations supported by eDiscovery searches.

> **Tip**

Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Search query tips for eDiscovery cases

Use the following tips when creating and running searches in eDiscovery.

- The time zone for all searches is Coordinated Universal Time (UTC). You can't change the time zone for your organization. Time zone display settings in the search view only apply to values in the *Data* column and don't affect time stamps on collected items.

- Keyword searches are **always case-insensitive**, with no per-query or per-term opt-out. For example, **cat** and **CAT** return the same results, and `subject:"Apple"` matches both **Apple** and **apple**. This rule applies to keyword text and `property:value` syntax across all eDiscovery search surfaces (search, query-based holds, and review set search). The only case-sensitive tokens in KeyQL are the Boolean operators themselves - **AND**, **OR**, **NOT**, and **NEAR** must be uppercase to be parsed as operators.

  > ⓘ Note
  >
  > **Case-sensitive matching isn't supported in eDiscovery search.** If your scenario requires distinguishing **Apple** (the company) from **apple** (the fruit), or differentiating identifiers like **ID** from **id**, use the following pattern: (1) run a deliberately broad case-insensitive collection, (2) add the items to a review set, (3) export the review set or its text and metadata, and (4) apply case-sensitive filtering post-export by using external tooling (for example, PowerShell `Select-String -CaseSensitive`, regular expressions, or a third-party review platform).

- **An empty keyword condition returns all content in the selected data sources, not no content.** If you don't enter any keywords or conditions, the search returns every item in every selected mailbox, site, and group across the entire date range.

  > ⓘ Important
  >
  > For broad-scope cases, an empty keyword condition can return millions of items, exceed result limits, and significantly delay the search. To preserve a defined search scope, enter at least one keyword or condition before you run the search. To

intentionally collect all content in a scope (for example, for a custodial preservation snapshot), confirm the scope size by running **Generate statistics** first.

- The Boolean operators **AND**, **OR**, **NOT**, and **NEAR** must be uppercase.

  > **Important**
  >
  > Use these operators in the *KeyQL* condition field. The search doesn't support these operators in the *Keyword* condition field. The search treats these operators as literal keywords.

- Using quotes stops wild cards and any operations inside the quotes.
- A space between two keywords or two `property:value` expressions is the same as using **OR**. For example, `from:"Sara Davis" subject:reorganization` returns all messages sent by Sara Davis or messages that contain the word reorganization in the subject line. However, using a mix of spaces and **OR** conditionals in a single query might lead to unexpected results. Use either spaces or **OR** in a single query.
- Use syntax that matches the `property:value` format. Values aren't case-sensitive, and they can't have a space after the operator. If there's a space, your intended value is a full-text search. For example `to: pilarp` searches for "pilarp" as a keyword, rather than for messages sent to pilarp.
- When searching a recipient property, such as To, From, Cc, or Recipients, you can use an SMTP address, alias, or display name to denote a recipient. For example, you can use pilarp@contoso.com, pilarp, or "Pilar Pinilla."
- You can use only prefix searches; for example, **cat*** or **set***. Suffix searches (***cat**), infix searches (**c*t**), and substring searches (***cat***) aren't supported.
- When searching a property, use double quotation marks (" ") if the search value consists of multiple words. For example, `subject:budget Q1` returns messages that contain **budget** in the subject line and that contain **Q1** anywhere in the message or in any of the message properties. Using `subject:"budget Q1"` returns all messages that contain **budget Q1** anywhere in the subject line.
- To exclude content marked with a certain property value from your search results, place a minus sign (-) before the name of the property. For example, `-from:"Sara Davis"` excludes

any messages sent by Sara Davis.

- You can export items based on message type. For example, to export Skype conversations and chats in Microsoft Teams, use the syntax `kind:im`. To return only email messages, use `kind:email`. To return chats, meetings, and calls in Microsoft Teams, use `kind:microsoftteams`.

- When searching sites, you have to add the trailing `/` to the end of the URL when using the `path` property to return only items in a specified site. If you don't include the trailing `/`, items from a site with a similar path name are also returned. For example, if you use `path:sites/HelloWorld` then items from sites named `sites/HelloWorld_East` or `sites/HelloWorld_West` are also returned. To return items only from the HelloWorld site, you have to use `path:sites/HelloWorld/`.

- You can define the **Query language-country/region** in your search query before collecting content. Query language that is Chinese, Japanese, or Korean might require special treatment such as breaking a phrase or sentence into individual words or characters for more accurate test results. For more information, see Double-byte character language support in eDiscovery.

- When searching the **Sent** folders for emails, the search doesn't support using the SMTP address for the sender. Items in the **Sent** folder contain only display names.

- When searching data sources for content, optical character recognition (OCR) capabilities use tenant-level OCR scanning. Once data is collected in an eDiscovery review set, the OCR capability uses eDiscovery OCR scanning.

- The search-time *Include partially indexed items* choice affects statistics and preview only. Whether partially indexed items appear in a later export is set independently at export time. If you need them in the export, select the partial-index option on the export dialog as well. For details, see Search-time and export-time settings are independent.

Create a search query

> **Tip**
>
> Do you prefer an interactive configuration guide experience? Check out the **Design a search** guide.

When you create a new case, you're automatically directed to the **Searches** tab in the case and you're ready to create a search for the case. You can also create a new search in the Content Search case in your organization. Searches help you find the items you want to collect for the case.

SharePoint Embedded container support in eDiscovery (preview) includes container discovery and application filtering when you add a user as a data source. You can also add a supported container directly by using its URL.

1. Select **Create a search** in a case or Content Search case. If this new case doesn't have any previous searches, you can also select **Create a search** in the main pane under **Start searching for relevant data**.

2. On the **Enter details to get started** page, complete the following fields:

   - **Search name**: give the search a name (required). The search name must be unique in your organization.
   - **Search description**: Add an optional description to help others understand this search.

3. Select **Create** to create the new search and start your queries to find relevant data for the case.

4. On the **Query** tab, add data sources for the search. For complete guidance and limitations, see Data sources in eDiscovery.

   For SharePoint Embedded container support in eDiscovery (preview), select a user to discover relevant supported user-owned and tenant-owned containers, or enter a known supported container URL as a site location.

5. Select **Manage** to review the mailbox and site locations associated with the selected sources. Otherwise, select **Save and close**.

   If you added a user as a data source, use **Filter by app** as needed, and then select or clear the supported SharePoint Embedded containers relevant to the investigation.

6. Review your selections and confirm the included resources for each data source. Select **Save**. You scoped the data sources that your search queries examine.

7. In the **Data sources** section, select the ellipse menu for any data source for management options for the data source.

   For management options, select from the following options:

- **Manage data source**: Manage data sources for the selected user or site.
- **Disable mailboxes**: Disable mailboxes for the selected user or site. Select this option again to enable the mailbox for the user or site.
- **Disable sites**: Disable the site for the selected user or site. Select this option again to enable the site for the user or site.
- **Frequent collaborators**: Select associated mailboxes and sites for users that frequently collaborate with the selected user.
- **Manager**: Select associated mailboxes and sites of the user's manager.
- **Direct reports**: Select associated mailboxes and sites of the user's direct reports.
- **Groups the user owns**: Select associated mailboxes and sites of groups the user is an owner of.
- **Groups the user is in**: Select associated mailboxes and sites of groups the user is a member of.

For group sources, select from the following options:

- **Members**: Select associated mailboxes and sites of people who are members of the group.

8. Use the **Data sources** command bar controls to add, update, sync, and search for other data sources for the search as needed.

   - **Search and add**: Select the + icon to add data sources.
   - **Manage**: Select the pencil icon to manage assigned data sources.
   - **Sync**: Select the sync icon to synchronize data sources and update the data sources with the most recent data sources in your organization.
   - **Search**: Select the search icon to search the data sources currently included in the search query.

9. To define the parameters of your search query, choose from the following options on the **Query** tab:

   - **Condition builder**: The condition builder option in search provides an easy-to-user search experience when you build search queries in eDiscovery. Use keywords or custom conditions to focus the scope of your search queries. Additionally, you can use the Keyword Query Language (KeyQL) query condition option in search that provides guidance and lets you quickly paste long, complex queries directly into the editor. It also helps you build search queries from scratch and identifies potential errors and displays hints about how to resolve issues.

You can also quickly build KeyQL queries for your search using Microsoft Security Copilot. For guidance, see Create a KeyQL search query with Microsoft Copilot (preview).

10. Select **Run query**. If you want to save the query parameters you defined and run the query later, select **Save as draft**.

Create a KeyQL search query with Microsoft Copilot (preview)

The Natural Language Query (preview) KeyQL builder option in search lets you use natural language and Microsoft Security Copilot to quickly generate a Keyword Query Language (KeyQL) statement. Use the builder to construct complex queries with extra functionality, including AND, OR, and grouping of conditions, all while using natural language prompts.

This feature helps you build queries more easily by using predefined prompts for example scenarios. It also lets you refine and enhance custom prompts for more accurate search queries. You can also choose to use prompt suggestions as a starting point to create and refine KeyQL queries for common or custom search scenarios.

To create a search query with Copilot, complete the following steps:

1. After you select data sources for your query, select **Draft a query with Copilot**.
2. In the **Natural language prompt** pane, choose one of the following options:

    - Enter your search query question. You can include user, data source, and other content details as applicable.
    - Select **View prompts** to select one of the following prompt suggestions:
        - *Find all emails containing the words budget and finance and have attachments*
        - *Search all chats in the month of January 2020 that contain the word 'financial year'*
        - *Search for files of type .docx that contain the words confidential and budget*

3. Review the natural language prompt. To refine the prompt with Copilot, select **Refine**.
4. When the prompt is finalized, select **Generate KeyQL**.
5. Review the KeyQL query in the **Keyword Query Language (KeyQL) result** pane. If you need to refine the KeyQL query results, you can update the prompt in the **Natural language prompt** pane and select **Generate KeyQL** again. 1. When the KeyQL results are finalized, select **Copy KeyQL**.
6. Paste the KeyQL results in the query field on the **Keyword query language (KeyQL)** tab. You can close **Draft a query with Copilot**.

7. Select **Run query**. If you want to save the query parameters you defined and run the query later, select **Save as draft**.

Run a search query

After you create a search query manually or by using Security Copilot, run the query to generate search results.

To run a search query, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned eDiscovery permissions.
2. Select the **eDiscovery** solution card, and then select **Cases** in the left navigation.
3. Select a case. On the **Searches** tab, select a saved search.
4. Select **Run query**.
5. After you select **Run query**, you see the **Choose search results** flyout pane. Choose the view you want to generate for the query and its settings. You can choose either the **Statistics** or **Sample** view:

    - **Statistics**: This view generates a summary of collected data estimates arranged by top indicators. Choose one or more of the following options:
    - **Include categories**: Refine your view to include people, sensitive information types, item types, and errors.
    - **Include query keywords report**: Assess keyword relevance for different parts of your search query.
    - **Investigate partially indexed items**: Partially indexed items typically account for approximately 1% of content in data sources by count. Selecting this option (and only this option) generates summary information (item count and location) about partially indexed items included in the selected data sources for the search. No partially indexed items are reindexed or processed. For more information about how to calculate the ratio of partially indexed items in your organization, see Assess partially indexed items in your organization. To further process partially indexed items in scoped data sources, consider the following advanced indexing options:

- **Exclude partially indexed items in locations without search hits**: Choosing this option reduces the scope of partially indexed items (or advanced indexing if that option is selected) by limiting the inclusion of partially indexed items to only the data sources that include items relevant to your search. This exclusion removes partially indexed items from data sources that don't include any items relevant to your search.

  For example, you select multiple mailboxes, SharePoint sites, and OneDrive sites as data sources for your search. When the search runs, only a few of the mailboxes and sites have indexed items relevant to the search conditions. The rest of the mailboxes and sites don't contain any indexed items relevant to your search conditions. If you select this option, the partially indexed items in the mailboxes and sites that contain indexed items relevant to the search are included in the search statistics results. The partially indexed items in the mailboxes and sites that don't contain any indexed items relevant to the search are ignored and not reported in the search statistics results.

- **Perform advanced indexing on partially indexed items**: The scope of where advanced indexing runs depends on if you select the **Exclude partially indexed items in locations without search hits** option. The advanced indexing process runs a statistical sample of partially indexed items in scope and determines if these items match the query or not:
  - Selected *with* the **Exclude partially indexed items in locations without search hits** option: This setting applies to partially indexed items only to data sources with fully indexed items matching the search query. These items are sampled, indexed, and the items matching the search query are displayed in search statistics (as applicable).
  - Selected *without* the **Exclude partially indexed items in locations without search hits** option: This setting applies to all partially indexed items in all data sources included in the search. All items are sampled, indexed, and the items matching the search query are displayed in search statistics (as applicable).

  > **Important**
  >
  > This feature isn't available for limited format cases.

- **Sample**: This view generates a representative selection of the full search results. Define the parameters for the following options:

- **Select the number of sample items to generate per location**: Choose either *1*, *10*, or *100*.
- **Select the number of locations to get samples from**: Choose *10*, *100*, *1000*, or *10000*.

6. **Tenant-wide source configuration** options in eDiscovery let you include additional data sources during organization-wide searches. Adding more data sources might cause searches to take longer than usual.

   Configure the organization-wide source "All people and groups" to include one or more user or content types:

   - **"All people and groups" should include unlicensed and on-premises users**
   - **"All people and groups" should include guest users**
   - **"All people and groups" should include shared Teams channels**
   - **"All people and groups" should include departed users**

   > **ⓘ Important**
   >
   > For large organizations, tenant-wide searches across all Exchange mailboxes and SharePoint sites are long-running processes. Service throttling can affect the number of mailboxes and sites to search. Before running these tenant-wide searches, review scale limits and throughput guidance in **Limits in eDiscovery** and plan to conduct searches in batches as applicable. To improve performance and operability, break the search into scoped runs using **compliance boundaries** (for example, by region, business unit, or department) so each search targets a subset of mailboxes and sites.

7. Select **Run query** to immediately run the query.

Depending on the query view options you selected, you're automatically directed to the **Statistics** or **Sample** tab. The search query assessment starts and the time remaining to process the query is calculated. For more information about evaluating and fine-tuning your search results, see Review and evaluate search results.

Create a new search from an existing search

In some scenarios, it might be helpful to create a new search based on an existing search. This approach maintains the original data sources and search while making modifications to get new search statistics without changing the original search. When you create a duplicate search, you

keep all the data sources and the search from the original search in the new search. This approach preserves the integrity of the original search and enables you to explore new insights.

To create a new search from an existing search, complete the following steps:

1. Select a case. On the **Searches** tab, open a search.
2. Select **Duplicate**.
3. A new search is automatically created in the same case.

The new search name includes the source search title with *Copy of* prefixed to the title and the timestamp appended. For example, if the source search title is *Search for budget emails*, the new search title is *Copy of Search for budget emails + the timestamp*. To edit the new search title, select the edit control next to the title text.

Create a new search from an existing hold

In some scenarios, it might be helpful to create a new search based on an existing hold. This approach allows you to use the original data sources and search used for the hold to run a new search. When you create a search from an existing hold, you keep all the data sources and the search from the hold in the new search.

> ⓘ **Note**
>
> To create a search from an existing hold, you must be assigned the *Compliance Search* role. For information about adding users to a role group, see Assign eDiscovery permissions.

To create a new search from an existing hold, complete the following steps:

1. Select a case. On the **Hold policies** tab, select and open a hold policy.
2. Select **Create search**.
3. A new search is automatically created and you're automatically redirected to the new search.

The new search name includes the source hold policy name with *Copy of* prefixed to the title and timestamp. For example, if the source hold policy title is *Hold to preserve Contoso project*, the new search title is *Copy of Hold to preserve Contoso project + the timestamp*. To edit the new search title, select the edit control next to the title text.

Delete a search

To reduce the number of previous searches associated with a case, delete specific searches in eDiscovery. If the search has associated exports and review sets, the history of these exports and review sets remains available in the Process Manager and audit logs.

To delete an existing search in a case, complete the following steps:

1. Select a case and select the search to delete.
2. Select the ellipsis (...) in the upper right of the search page, and then select **Delete search**.
3. Select **Yes** on the **Delete search** dialog to delete the search from the case.

> **Note**
>
> You can't delete a search while processes are in progress. Wait for all processes to finish before deleting a search.

Use the condition builder to create search queries in eDiscovery

The condition builder provides an easy-to-use search experience when you build search queries in eDiscovery. Use the condition builder in search and review sets to construct simple and complex keyword queries, queries with operators (AND, OR), or both to help identify items in your organization.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Use the condition builder

To create a query and custom conditional filtering for your search, use the following controls:

- The **Keywords** condition is always available as the first condition in your query, making it easy to get started with search tasks. This condition only supports the **Equal** operator and is removed from your query using **Delete**. In the **Value** field of the Keywords condition, apply logical operators such as **AND**, **OR**, and **NEAR**. For example, entering `red AND blue` treats **AND** as a logical operator rather than a literal keyword. To search for an exact phrase like `"red and blue"`, enclose the text in quotation marks. This tells the search engine to treat the text as a single string. You can also select **Enter** on your keyboard to create a new grid for the next keyword. If you paste a list of keywords separated by line breaks (carriage returns), the system automatically generates a separate grid for each keyword.

  When multiple keyword segments are entered using the condition builder, the query can be converted to KeyQL and each keyword segment is separated by c:s. If your query includes multiple keyword conditions, the resulting KeyQL includes c:s to ensure keyword segmenting so you see hits per segment. This behavior is automatic and doesn't require manual entry of c:s in the KeyQL builder.

  > **Note**

To generate a keyword report in the **statistics** view, you must populate at least two or more keyword grids. If you enter only a single keyword, the total hit count shown reflects the results for that one keyword, and a keyword report isn't generated.

- **Add conditions**: Add a condition for the specific data sources for the search. To add extra conditions to your query, select **Add conditions** to display the list of available conditions. Each condition value selection adds a new condition to your query. Select the **AND/OR** operator as appropriate.
- **AND/OR**: These conditional logical operators let you select the query operation that applies to a specific condition. These operators let you use multiple conditions connected to your query. The operator following the *keyword* condition must be **AND**.
- **Selecting an operator**: Depending on the selected condition, the operators compatible for the condition are available to select. For example, if you select the *Date* condition, the available operators are *Before*, *After*, and *Between*. If you select the *Size (in bytes)* condition, the available operators are *Greater than*, *Greater or equal*, *Less than*, *Less or equal*, *Between*, and *Equal*.
- **Value**: Depending on the selected condition, the values compatible for the condition appear in the value details pane or you can add inline. Depending on the condition type associated with the value, you see options to define, filter, or search for values associated with the selected condition. For example, if you select *Sender* as the condition, you can search for and add specific users in your organization or external users. If you select *Size (in bytes)* as the condition, you see the option to enter a number for the size as the value. If the value is blank, the value field border appears in red to help notify you that a value is needed.
- **Delete a filter condition**: To remove an individual condition, select the delete icon to the right of each filter line.
- **Clear a filter value:** To clear the value for a specific condition, select the remove icon to the right of each filter line.
- **Save as draft**: To save the current set of conditions as a draft, select **Save as draft** above the condition builder area.
- **Discard**: To discard any changes made to the search, including conditions, and data source, select **Discard** above the condition builder area.

Guidelines for using conditions

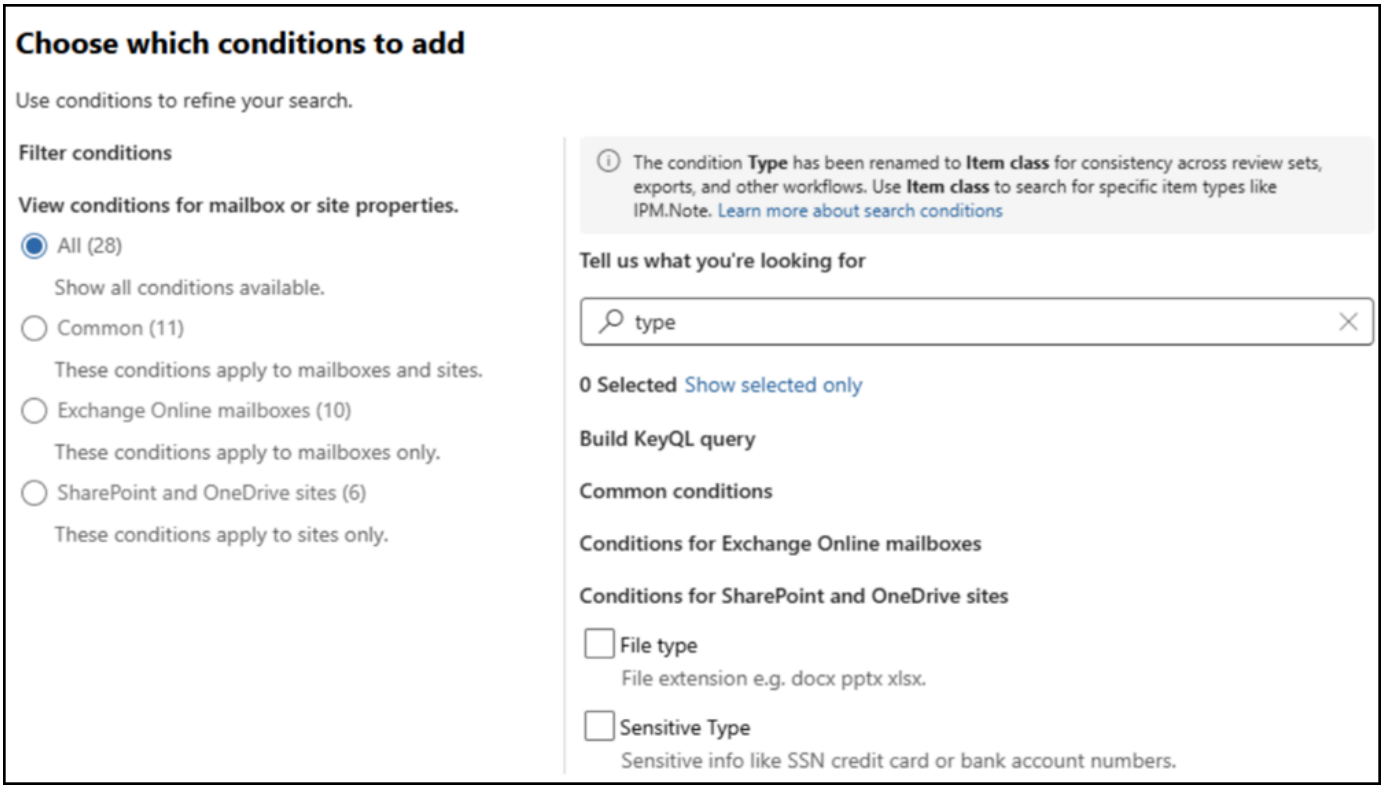
Keep the following guidelines in mind when using search conditions:

- A condition connects logically to the keyword query (specified in the keyword condition) by the **AND** operator. That connection means that items need to satisfy both the keyword query and the condition to be included in the results.
- All conditions that follow the *keyword* condition are grouped together.
- If you add two or more unique conditions to a search query (conditions that specify different properties), those conditions connect logically by the **AND** and **OR** operators. That connection means the search returns only items that satisfy all the conditions (in addition to any keyword query).
- If you add multiple values (separated by commas or semicolons) to a single condition, those values connect by the **OR** operator. That connection means the search returns items if they contain any of the specified values for the property in the condition.
- Any condition that uses an operator with **Contains** and **Equals** logic returns similar search results for simple string searches. A simple string search is a string in the condition that doesn't include a wildcard. For example, a condition that uses **Equals any of** returns the same items as a condition that uses **Contains any of**.
- The search query that you create by using the keywords box and conditions appears on the **Search** page, in the details pane for the selected search. In a query, everything to the right of the notation `(c:c)` indicates conditions that you add to the query. Don't use `(c:c)` in manually entered queries. `(c:c)` isn't equal to **AND** or **OR**.
- If you are searching using *Compliance Tag* or *Retention Label* and the name of the label includes special characters that aren't supported (listed in the Special characters section, they are ignored as a condition of the search.

Find and select conditions

When you select **Add conditions** in the condition builder, you get quick access to some commonly used conditions such as *Date*, *Subject/Title*, and *Participants* along with conditions you used most recently. Select **Show more** and the **Choose which conditions to add** flyout pane appears to help you refine your search query with specific conditions. Use the options in the following sections to help you choose applicable conditions.

Filter conditions by area



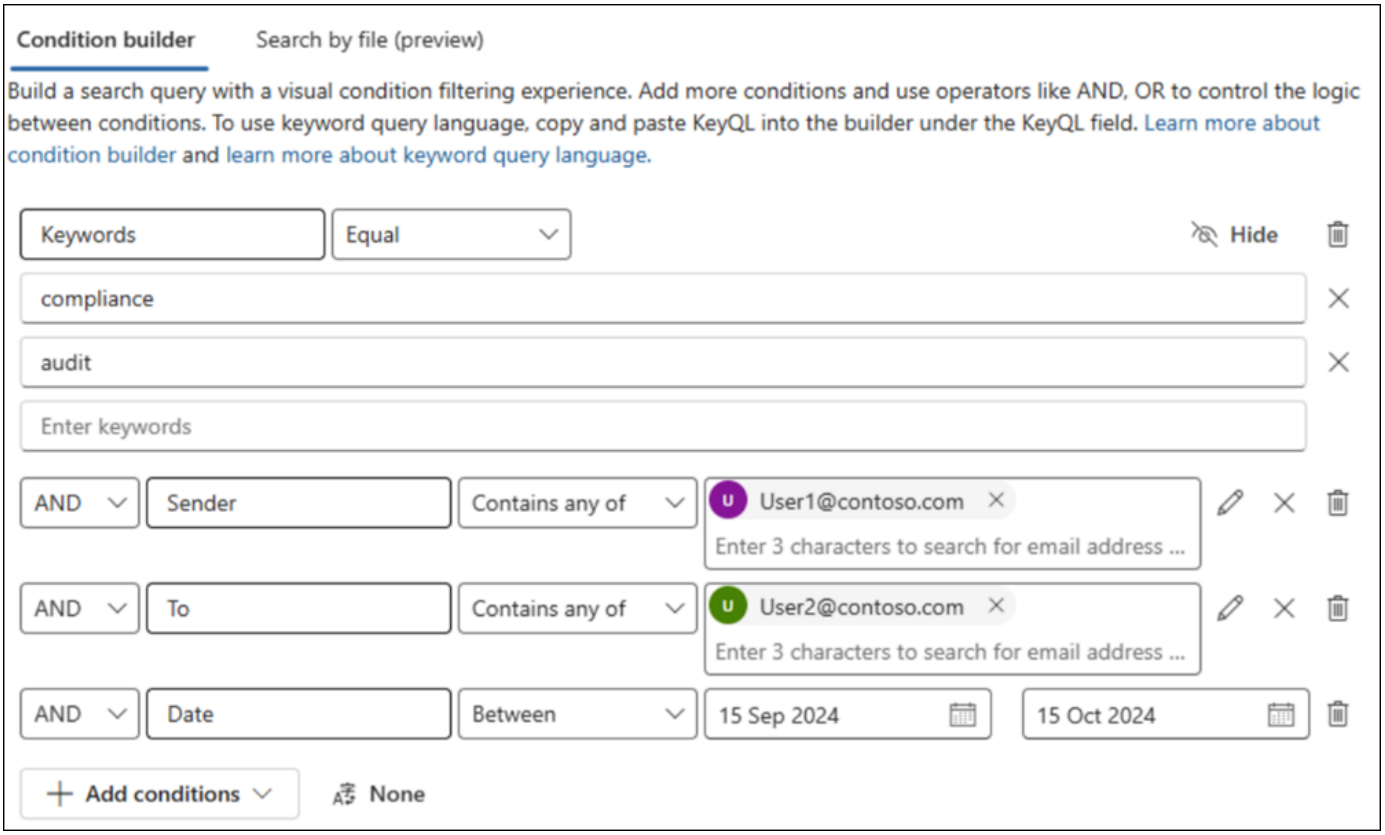
Quickly filter the condition view for mailboxes and site properties to help locate a specific condition for your search query. Filter available conditions in the following global groups:

- **All**: Shows all conditions and condition groups.

- **Common**: Filters and displays only the conditions that apply to both mailboxes and sites.
- **Exchange mailboxes**: Filters and displays only the conditions that apply to mailboxes.
- **SharePoint and OneDrive sites**: Filters and displays only the conditions that apply to SharePoint and OneDrive sites.

Condition picker

To quickly search for a specific condition, use the **Tell us what you're looking for** field to enter the name of the condition. The results automatically scope to the filter for global groups. For example, to search for any condition named *Type* (or one that contains the term *type* in the condition name), select **All** as the global filter, then enter *type* in the **Tell us what you're looking for** field. The condition view returns all conditions in all condition groups that contain the term *type*. Select the applicable condition to add to your search query.



> **Important**
>
> You can only use the *Keyword* and *KeyQL* conditions once each in the condition builder.

Scenario example

The eDiscovery administrator needs to create a query to find emails sent from User1 to User2 that were sent between September 15, 2024 and October 15, 2024 that contains the keywords

compliance and *audit*. For this example, the administrator creates the following query using the new query builder:

1. For the first filter, the administrator uses the *Keywords* condition, the *Equal* operator, and *compliance, audit* as the keyword *Value*.
2. Next, the administrator selects **Add conditions**, selects *Sender*, then selects the *Contains any of* operator, then enter *User1@contoso.com* in the **Value** field. This can include external users.
3. Next, the administrator selects **Add conditions**, selects the *To* filter, then selects the *Contains any of* operator, then selects *User2@contoso.com* in the **Value** field. This can include external users.
4. To define the date range, the administrator selects **Add conditions**, selects *Date*, then selects the *Between* operator, and then selects the starting and ending dates for the *Value*.
5. Finally, the administrator selects **Run query** to return results matching the conditions and their values.

Use search conditions

You can add conditions to a search query to narrow a search and return a more refined set of results. Each condition adds a clause to the KeyQL search query that is created and run when you start the search.

- Special characters

- Conditions for common properties
- Conditions for mail properties
- Conditions for document properties
- Operators used with conditions

Special characters

Some special characters aren't included in the search index and therefore aren't searchable. This limitation also applies to the special characters that represent search operators in the search query. Here's a list of special characters that are either replaced by a blank space in the actual search query or cause a search error.

```
+ - = : ! @ # % ^ & , ; _ / ? ( ) [ ] { }
```

Conditions for common properties

Create a condition using common properties when searching mailboxes and sites in the same search. The following table lists the available properties to use when adding a condition.

Expand table

Condition	Description
Content kind[1]	Applied to both Exchange and SharePoint items, it refers to the type or category of the content. For example, *ContentKind:SharePointDocument*, *ContentKind:Copilot*, etc.
Content source application[1]	Identifies the application or service where the content originated. For example, *ContentSourceApplication:OneDriveForBusiness*, *ContentSourceApplication:SharePoint*, etc.
Date	For email, the date a message was created or imported from a PST file. For documents, the date a document was last modified. For Teams messages, the original message date. Item reports and review set metadata might display different timestamps (such as ingestion or modification dates) for the same Teams message. The date condition filters on the original event date. If you're searching for email messages for a specific time period, use the message *Received* and *Sent* conditions if you're unsure if the email messages might be imported instead of natively created in Exchange.
Identifier[1]	For email, the ID for a specific message. *Message IDs* are included in the audit record, data loss prevention (DLP) alerts, or review set metadata and allow you build a specific search for an individual message.

Condition	Description
	For Microsoft Teams messages, the ID of the chat or reaction. The *ChatThreadID* is included in the audit record, data loss prevention (DLP) alerts, or review set metadata and allow you build a specific search for an individual chat or reaction.
